The immediate problem now is how to fix the boundary condition on $T(q,q')$ such that (41) yields a solution satisfying the quantum-classical-correspondence boundary condition (35), and at the same time satisfying the boundary condition (42). Moreover, it is appropriate to require that the solution to (41) is unique. Again we appeal to our transfer principle. We find the set of boundary conditions satisfied by the free particle kernel that ensures that the corresponding solution to the time kernel equation is unique for the free particle. For this case the time kernel equation reduces to

$$-\frac{\hbar^2}{2\mu}\frac{\partial^2 T(q,q')}{\partial q^2}+\frac{\hbar^2}{2\mu}\frac{\partial^2 T(q,q')}{\partial q'^2}=0. \tag{43}$$

The general solution to this equation is

$$T(q,q')=f(q+q')+g(q-q'). \tag{44}$$

For the free particle, we already have $T(q,q')=\frac{1}{4}(q+q')$. Now we have to identify the set of boundary conditions that isolates this known solution from the general solution.

By inspection $T(q,q')$ satisfies both (41) and (42), and it satisfies the conditions

$$T(q,q)=\frac{q}{2}, \quad T(q,-q)=0. \tag{45}$$

We now show that these two conditions, when imposed on (44) uniquely identifies the free particle solution. Note that these conditions impose that $T(q,q')$ is analytic in the neighborhood of the origin. Imposing the second condition of (45) on (44) gives $T(q,-q)=f(0)+g(2q)=0$; since this must hold for all $q\in\Re$, it must be that $g(2q)=\text{constant}=-f(0)$. On the other hand, imposing the first of (45) gives $T(q,q)=f(2q)-f(0)=\frac{1}{4}(2q)$. Since $T(q,q')$ satisfies Eq. (43), f is at least twice continuously differentiable. We can then write $f(2q)=f(0)+f'(0)(2q)+R_2$, where R_2 is the remainder in the expansion. Thus $T(q,q)=f'(0)(2q)+R_2=\frac{1}{4}(2q)$, which implies that $f'(0)=\frac{1}{4}$ and $R_2=0$. This finally implies that $T(q,q')=\frac{1}{4}(q+q')$, reproducing the solution we know for the free particle.

By our assumed transfer principle, we impose the same boundary conditions (45) on the solution to the time kernel equation (41). That the boundary conditions (45) guarantee that boundary condition (42) is satisfied and that they impose symmetry on $T(q,q')$ under the interchange of its arguments will be shown below for entire analytic potentials.

We claim that Eqs. (41) and (45) constitute the supraquantization of the local time of arrival consistent with the correspondence principle. We will explicitly demonstrate this claim in Sec. VI for the harmonic and anharmonic oscillators, and separately demonstrate in Sec. VII for entire analytic potentials.

C. Canonical form of the time kernel equation

In what follows, we will find it convenient to prove our above assertion by solving the time kernel Eq. (41) in canonical form. This is accomplished by performing a change in variable from (q,q') to $(u=q+q',\ v=q-q')$. The differential Eq. (41) and its accompanying boundary condition (45) then assume the form

$$-2\frac{\hbar^2}{\mu}\frac{\partial^2 T}{\partial u\partial v}+\left(V\left(\frac{u+v}{2}\right)-V\left(\frac{u-v}{2}\right)\right)T(u,v)=0, \tag{46}$$

$$T(u,0)=\frac{u}{4}, \quad T(0,v)=0. \tag{47}$$

The boundary conditions (47) impose that the solution to Eq. (46) is analytic in u and v. In solving for Eq. (46), we will then seek an analytic solution in powers of u and v,

$$T(u,v)=\sum_{m,n\geqslant 0}\alpha_{m,n}u^m v^n, \tag{48}$$

where the $\alpha_{m,n}$'s are constants determined by Eqs. (46) and (47) for a given potential.

Assuming a solution of the form (48), translates the boundary conditions (47) to the boundary condition on the expansion coefficients $\alpha_{m,n}$:

$$\alpha_{m,0}=\tfrac{1}{4}\delta_{m,1} \quad \alpha_{0,n}=0 \tag{49}$$

for all m and n. We arrive at them as follows. The first boundary condition gives $T(u,0)=\Sigma_m \alpha_{m0}u^m=\frac{1}{4}u$, which implies the first of Eqs. (49). And the second boundary condition gives $T(0,v)=\Sigma_n \alpha_{0n}v^n=0$, which implies the second of Eqs. (49). However, in our proof below, we will find it convenient to extend the summation in (48) to negative values of m and n; the analycity of the solution is then imposed by adjoining to (49) the condition that $\alpha_{m,n}=0$ when either m or n is negative or when both are negative.

To show the uniqueness of the solution to (46) for a given potential, we will assume the existence of two distinct solutions, say, $T_1(u,v)$ and $T_2(u,v)$. Then the function $S(u,v)=T_1(u,v)-T_2(u,v)$ satisfies the time kernel equation. $S(u,v)$ then satisfies the boundary conditions $S(u,0)=0$ and $S(0,v)=0$. Since $T_1(u,v)$ and $T_2(u,v)$ are both analytic, $S(u,v)$ must itself be analytic. Then $S(u,v)$ can be expanded in u and v in the same way that T_1 and T_2 can be expanded,

$$S(u,v)=\sum_{m,n\geqslant 0} \eta_{m,n}u^m v^n. \tag{50}$$

Now the boundary condition satisfied by the expansion coefficients are $\eta_{m,0}=0$ and $\eta_{0,n}=0$ for all m and n. The solution is unique if all the expansion coefficients are identically zero or $S(u,v)$ identically vanishes. We will show below that the solutions for entire analytic potentials are unique.

Now we can address the concern raised earlier whether the assumed properties of $T(q,q')$ are sufficient to ensure that the original boundary condition (42) is satisfied. With the assumed form of the solution (48), the solution in the original coordinates will be in the form

$$T(q,q')=\sum_{m\geqslant 1,n\geqslant 0} \alpha_{mn}(q+q')^m(q-q')^n. \tag{51}$$

Evaluating this at $q=q'$, we have $T(q,q)=2\alpha_{1,0}q$, and arrive at $T'(q,q)=\frac{1}{2}$, because of the boundary condition $\alpha_{1,0}=\frac{1}{4}$. On the other hand, we arrive at the following:

$$\left.\frac{\partial T(q,q')}{\partial q}\right|_{q=q'}=\alpha_{1,0}+\sum_{m\geqslant 1} \alpha_{m,1}2q',$$

$$\left.\frac{\partial T(q,q')}{\partial q'}\right|_{q'=q}=\alpha_{1,0}-\sum_{m\geqslant 1} \alpha_{m,1}2q.$$

However, $T(q,q')$ is symmetric, i.e., $T(q,q')=T(q',q)$, so that $\alpha_{m,n}=0$ for odd n. The second terms of the above equations then vanish and they only take contribution from the first terms. With $\alpha_{1,0}=\frac{1}{4}$ the boundary condition (42) is then satisfied. We note that we have appealed to the assumed symmetry of $T(q,q')$, but this is not totally necessary, because, as what will be shown below, the boundary conditions (45) are sufficient to impose the symmetry of $T(q,q')$.

VI. EXPLICIT EXAMPLES

Before we prove our above assertion, we will explicitly demonstrate in this section our claim for two specific systems: the harmonic and the anharmonic oscillators. We will first solve for the local time of arrival in the neighborhood of the origin using

$$t_0(q,p)=\sum_{k=0}^{\infty} (-1)^k T_k(q,p), \tag{52}$$

where the iterates T_k's are generated through the following recurrence relation:

$$T_0(q,p) = -\mu \frac{q}{p}, \tag{53}$$

$$T_k(q,p) = -\frac{\mu}{p} \int_0^q \frac{\partial V}{\partial q'} \frac{\partial T_{k-1}}{\partial p} dq', \tag{54}$$

obtained from the general expressions (23) and (24) by setting $x=0$.

We will then compare the local time of arrival with the Wigner–Weyl transform of the time kernel,

$$\mathcal{T}_\hbar(q,p) = 2\pi \int_{-\infty}^{\infty} \left\langle q + \frac{v}{2} \middle| \mathcal{T} \middle| q - \frac{v}{2} \right\rangle \exp\left(-i \frac{vp}{\hbar} \right) dv. \tag{55}$$

($\mathcal{T}_\hbar(q,p)$ is real valued and odd with respect to p.) For the harmonic oscillator we will find that the local time of arrival and $\mathcal{T}_\hbar$ coincide; and for the anharmonic oscillator it is only in the limit of vanishing or infinitesimal $\hbar$ that $\mathcal{T}_\hbar$ reproduces the local time of arrival at the origin.

A. The harmonic oscillator

1. Global and local time of arrivals

The potential for the harmonic oscillator is $V(q) = \frac{1}{2}\mu\omega^2 q^2$. Substituting the potential back into the general expression for the global time of arrival (12) yields

$$T_0(q,p) = -\frac{1}{\omega} \tan^{-1}\left(\frac{\mu\omega q}{p} \right). \tag{56}$$

We will show below that this can be derived via the local time of arrival.

Substituting the potential in Eq. (54), we generate the first two iterates of the local time of arrival,

$$T_1 = -\frac{1}{3}\mu^3\omega^2 \frac{q^3}{p^3}, \quad T_2 = -\frac{1}{5}\mu^5\omega^4 \frac{q^5}{p^5}.$$

From these iterates, we infer that for every k, the kth iterate is given by

$$T_k = -\alpha_k \mu^{2k+1} \omega^{2k} \frac{q^{2k+1}}{p^{2k+1}}, \tag{57}$$

where the α_k's are constants to be determined. These constants are determined as follows. We shift index $k \to (k-1)$ in T_k to get the expression for α_{k-1}. We then substitute T_{k-1} and the potential back in the right-hand side of Eq. (54) to yield

$$-\frac{\mu}{p} \int_0^q \frac{\partial V}{\partial q'} \frac{\partial T_{k-1}}{\partial p} dq' = -\alpha_{k-1} \frac{(2k-1)}{(2k+1)} \mu^{2k+1} \omega^{2k} \frac{q^{2k+1}}{p^{2k+1}}. \tag{58}$$

If expression (57) holds for all k, then the right-hand sides of Eqs. (57) and (58) must be equal for all k. Strict equality is then satisfied if and only if the α_k's satisfy the following recurrence relation among themselves:

$$\alpha_k = \frac{(2k-1)}{(2k+1)} \alpha_{k-1}, \tag{59}$$

subject to the initial value $\alpha_0=1$. This can in turn be solved to give $\alpha_k=(2k+1)^{-1}$. The local time of arrival is then given by

$$t_0(q,p)=-\sum_{k=0}^{\infty}\frac{(-1)^k}{2k+1}\mu^{2k+1}\omega^{2k}\frac{q^{2k+1}}{p^{2k+1}}. \tag{60}$$

$t_0(q,p)$ can be summed within its region of convergence in the phase space, and the result coincides with the global one in the same region.

In the following we will show that $\mathcal{T}_\hbar(q,p)=t_0(q,p)$, and this is just a special case of our general result on the equality of $\mathcal{T}_\hbar(q,p)$ and $t_0(q,p)$ for linear systems, i.e., systems with linear classical equations of motion.

2. Supraquantization of the local time of arrival

Substituting the potential in Eq. (46) gives the corresponding time kernel equation to solve for the harmonic oscillator,

$$-2\frac{\hbar^2}{\mu}\frac{\partial^2 T}{\partial u\partial v}(u,v)+\frac{\mu\omega^2}{2}uvT(u,v)=0, \tag{61}$$

subject to the boundary conditions (45). We assume a solution of the form

$$T(u,v)=\sum_{m,n}\alpha_{m,n}u^m v^n,$$

where the α's are constants to be determined, subject to the boundary conditions $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$, $\alpha_{0,m}=0$ for all m, and $\alpha_{m,n}=0$ for $m,n<0$. Substituting the assumed solution back into Eq. (61), we arrive at

$$-2\frac{\hbar^2}{\mu}\sum_{m,n}\alpha_{m,n}mnu^{m-1}v^{n-1}+\frac{\mu\omega^2}{2}\sum_{m,n}\alpha_{m,n}u^{m+1}v^{n+1}=0.$$

Shifting indices in the second term, $m\to(m-1)$ and $n\to(n-1)$, and collecting like terms, we get

$$\sum_{m,n}\left(-2\frac{\hbar^2}{\mu}mn\alpha_{m,n}+\frac{\mu\omega^2}{2}\alpha_{m-2,n-2}\right)u^{m-1}v^{n-1}=0.$$

Since u and v are arbitrary, the quantity in the bracket must vanish for all values of u and v, dictating the coefficients to satisfy the recurrence relation

$$\alpha_{m,n}=\left(\frac{\mu^2\omega^2}{4\hbar^2}\right)\frac{1}{m\cdot n}\alpha_{m-2,n-2}. \tag{62}$$

Solving the time kernel then reduces to solving this recurrence relation among the coefficients of the assumed solution.

First for odd n. Since $\alpha_{m,n}=0$ for negative n, let us start from $n=1$. For $n=1$ we get the proportionality $\alpha_{m,2}\propto\alpha_{m-1,-1}$; but the coefficients vanish for negative n for all m; thus the right-hand side of the proportionality vanishes and consequently $\alpha_{m,1}=0$ for all m. Now if for some fixed odd n', $\alpha_{m,n'}=0$ for all m, then for the next odd $n'+2$, $\alpha_{m,n'+2}\propto\alpha_{m-1,n'}=0$ for all m. Since we have already shown that $\alpha_{m,1}=0$ for all m, it follows that $\alpha_{m,n}=0$ for all odd n, for all m. The odd powers of v then do not contribute.

We remark that the vanishing of the contributions for odd n is significant. We recall that the solution $T(q,q')$ to the time kernel equation in the original form must satisfy the boundary condition (42). And we have noted earlier in Sec. V C that if $T(q,q')=T(q',q)$ or $T(u,v)$

$=T(u,-v)$, the condition (42) is automatically satisfied as long as the boundary conditions (45) are satisfied as well. But the condition $T(u,v)=T(u,-v)$ is equivalent to the vanishing of the odd powers of v. Consequently $T(q,q')$ will automatically satisfy (42). $T(q,q')$ will then satisfy the original boundary condition (42). This will be shown to be true for the rest of the potentials considered, particularly for entire analytic potentials.

Now for even n. Since $\alpha_{m,n}=0$ for negative n and $\alpha_{m,0}$ is specified, we start with $n=2$. For $n=2$ we get the proportionality $\alpha_{m,2}\propto\alpha_{m-2,0}$; but $\alpha_{m',0}\propto\delta_{m',1}$, thus only $m=3$ contribute or $\alpha_{3,2}$ is the only nonvanishing coefficient for $n=2$. For $n=4$ we get $\alpha_{m,4}\propto\alpha_{m-2,2}$, which dictates that only $m=5$ contributes or $\alpha_{5,4}$ is the only nonvanishing coefficient for $n=4$. We see that n and m are not independent from each other, i.e., they can be index by the same letter, say k. From the first two coefficients we infer that $m=2k+1$ and $n=2k$, $k=1$, $k=2,\ldots$. We can prove this by induction. Let for some fixed k that $\alpha_{m=2k+1,n=2k}$ is the only nonvanishing coefficient for $n=2k$. Then for $k+1$, we have $\alpha_{m,2(k+1)}\propto\alpha_{m-2,2k}$; but the only nonvanishing contributions come from $m-2=2k+1$ or $m=2k+3$. Thus for $n=2(k+1)$, only $\alpha_{2k+3,2(k+1)}$ is nonzero. Thus indeed only the coefficients $\alpha_{2k+1,2k}$ are nonvanishing for all $k=1,2,\ldots$. Then the double index recurrence relation (62) reduces to the single index recurrence relation,

$$\alpha_k=\left(\frac{\mu^2\omega^2}{4\hbar^2}\right)\frac{1}{(2k+1)2k}\,\alpha_{k-1}, \tag{63}$$

subject to the initial value $\alpha_0=\alpha_{1,0}=\frac{1}{4}$. The solution to Eq. (63) is

$$\alpha_k=\frac{1}{4}\left(\frac{\mu\omega}{2\hbar}\right)^2\frac{1}{(2k+1)!}. \tag{64}$$

Substituting the nonvanishing coefficients back in the assumed solution yields the solution to time kernel equation for the harmonic oscillator,

$$T(u,v)=\frac{\hbar}{2\mu\omega}\sum_{k=0}^{\infty}\frac{1}{(2k+1)!}\left(\frac{\mu\omega}{2\hbar}\right)^{2k+1}u^{2k+1}v^{2k}. \tag{65}$$

Evidently $T(u,v)$ converges everywhere in the uv-plane. Moreover, the solution (65) is unique. This follows from the fact that $S(u,v)$ [see Eq. (50)] satisfies the time kernel equation, and it satisfies the boundary conditions $\eta_{0,n}=0$, $\eta_{m,0}=0$ for all m, n on its coefficients. The recurrence relation on the coefficients $\eta_{m,n}$ will be the same as those of the $\alpha_{m,n}$'s. Since the nonvanishing contributions in $T(u,v)$ come only from the boundary condition $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$, $S(u,v)$ will be identically zero because $\eta_{m,0}=0$ for all m. The analytic solution $T(u,v)$ is then unique. This observation holds for the rest of the potentials considered here.

Transforming back to (q,q') and substituting $T(q,q')$ back into Eq. (39) yields the time kernel for the harmonic oscillator,

$$\langle q|\mathcal{T}|q'\rangle=\frac{1}{2i\omega}\,\mathrm{sgn}(q-q')\sum_{k=0}^{\infty}\frac{1}{(2k+1)!}\left(\frac{\mu\omega}{2\hbar}\right)^{2k+1}(q+q')^{2k+1}(q-q')^{2k}. \tag{66}$$

This likewise converges everywhere in the qq'-plane. Because $T(q,q')$ is everywhere absolutely convergent, $\mathcal{T}$ is a generalized observable in Φ (see Appendix). Now we can finally show that the generalized time of arrival operator reduces to the local time of arrival in the classical limit, as prescribed by Eq. (35). Using the identity[20]

$$\int_{-\infty}^{\infty}\sigma^{m-1}\,\mathrm{sgn}(\sigma)\exp(-ix\sigma)d\sigma=\frac{(m-1)!}{i^m\pi}x^{-m}, \tag{67}$$

we can perform the indicated transformation to give

$$\mathcal{T}_\hbar(q,p)=2\pi\int_{-\infty}^{\infty}\left\langle q+\frac{v}{2}\middle|\mathcal{T}\middle|q-\frac{v}{2}\right\rangle\exp\left(-i\frac{vp}{\hbar}\right)dv$$

$$=2\pi\frac{1}{2i\omega}\sum_{k=0}^{\infty}\frac{1}{(2k+1)!}\left(\frac{\mu\omega}{2\hbar}\right)^{2k+1}(2q)^{2k+1}\int_{-\infty}^{\infty}v^{2k}\,\mathrm{sgn}(v)\exp\left(-i\frac{vp}{\hbar}\right)dv$$

$$=-\frac{1}{\omega}\sum_{k=0}^{\infty}\frac{(-1)^k}{2k+1}\left(\frac{\mu\omega q}{p}\right).$$

We find that $\mathcal{T}_\hbar$ coincides exactly with the local time of arrival in the neighborhood of the origin for the harmonic oscillator given by Eq. (60).

B. The anharmonic oscillator

1. Global and local time of arrivals

In the previous section the Weyl–Wigner transform of the time kernel exactly reproduces the local time of arrival at the origin. But for nonlinear systems, systems with nonlinear equations of motions, we demonstrate that only in the limit of vanishing or infinitesimal $\hbar$ that the local time of arrival (at the origin) is recovered. Let us consider the anharmonic oscillator with the potential $V=\lambda q^4$. The global time of arrival is symbolically given by

$$T_0(q,p)=-\mathrm{sgn}(p)\sqrt{\frac{\mu}{2}}\int_0^q\frac{dq'}{\sqrt{H(q,p)-\lambda q'^4}}. \tag{68}$$

The above expression can be integrated explicitly, but its exact closed integral is not important to our present purposes.

What is important to us is the local time of arrival in the neighborhood of the origin. Following the same procedure we have employed above in determining for the iterates of the harmonic oscillator, we find that the kth iterate of the local time of arrival is given by

$$T_k=\frac{1}{4}\frac{2^k\sqrt{\pi}\Gamma\left(-k-\frac{1}{4}\right)}{\Gamma\left(\frac{3}{4}\right)\Gamma\left(-k+\frac{1}{2}\right)}\alpha_k\mu^{k+1}\lambda^k\frac{q^{4k+1}}{p^{2k+1}}. \tag{69}$$

One can prove this by induction using Eq. (54). Substituting T_k back in Eq. (18) yields the local time of arrival at the origin,

$$t_0(q,p)=\frac{1}{4}\frac{\sqrt{\pi}}{\Gamma\left(\frac{3}{4}\right)}\sum_{k=0}^{\infty}\frac{(-2)^k\Gamma\left(-k-\frac{1}{4}\right)}{\Gamma\left(\frac{1}{2}-k\right)}\mu^{k+1}\lambda^k\frac{q^{4k+1}}{p^{2k+1}}. \tag{70}$$

In the following we will show that $\mathcal{T}_\hbar(q,p)=t_0(q,p)+\mathcal{O}(\hbar^2)$. And this is just a special case of our general result on the equality of $\mathcal{T}_\hbar(q,p)$ and $t_0(q,p)$ only in the limit of vanishing or infinitesimal $\hbar$ for nonlinear systems, i.e., systems with nonlinear classical equations of motion.

2. Supraquantization of the local time of arrival

Substituting the potential equation in Eq. (46) gives the corresponding time kernel equation for the anharmonic oscillator,

$$-2\frac{\hbar^2}{\mu}\frac{\partial^2 T}{\partial v\,\partial u}+\frac{\lambda}{2}(u^3v+uv^3)T(u,v)=0, \tag{71}$$

subject to the same boundary conditions. Again we assume the most general form of the solution to the time kernel Eq. (71),

$$T(u,v)=\sum_{m,n}\alpha_{m,n}u^m v^n,$$

where the $\alpha_{m,n}$'s satisfy the boundary conditions $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$ and $\alpha_{0,n}=0$ for all m and n, and $\alpha_{m,n}=0$ for negative m and n to identify the particular solution we seek.

Substituting the assumed solution back to Eq. (71) gives the following recurrence relation for the coefficients:

$$\alpha_{m,n}=\left(\frac{\mu\lambda}{4\hbar^2}\right)\frac{1}{mn}(\alpha_{m-4,n-2}+\alpha_{m-2,n-4}). \tag{72}$$

First let us consider the coefficients for odd powers of v or for odd n. Since the coefficients vanish for negative m and n, we start from $n=1$. For $n=1$ we get the proportionality $\alpha_{m,1}\propto(\alpha_{m-4,-1}+\alpha_{m-2,-3})$. But $\alpha_{m,n}=0$ for $n<0$ for all m, so that $\alpha_{m,1}=0$ for all m. For $n=3$ we get the proportionality $\alpha_{m,3}\propto(\alpha_{m-4,1}+\alpha_{m-2,-1})$. Since $\alpha_{m,1}=0$ for all m and $\alpha_{m,n}=0$ for $n<0$, $\alpha_{m,3}=0$ for all m as well. Now if for some odd n, $\alpha_{m,n}=0$ for all m, it follows from (72) that for the next odd number $n+2$, $\alpha_{m,n+2}=0$ for all m. Thus odd powers of v vanish. This assures us that $T(q,q')$ satisfies the boundary condition (42).

Let us now consider the even powers of v. For $n=2$ we get the proportionality $\alpha_{m,2}\propto(\alpha_{m-4,0}+\alpha_{m-2,-2})$. Only $m=5$ contributes because $\alpha_{m,n}=0$ for negative n and $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$; thus for $n=2$ only $\alpha_{5,2}$ contributes. For $n=4$ we get the proportionality $\alpha_{m,4}\propto(\alpha_{m-4,2}+\alpha_{m-2,0})$. There are only two contributions: $m=3$, corresponding to $\alpha_{1,0}$, and $m=9$, corresponding to $\alpha_{5,2}$; thus for $n=4$ only $\alpha_{3,2}$ and $\alpha_{9,2}$ contribute. Continuing in this manner, we arrive at the following first few sequences of nonvanishing contributions:

$$n=0:\quad \alpha_{1,0},$$

$$n=2:\quad \alpha_{5,2},$$

$$n=4:\quad \alpha_{9,4},\ \alpha_{3,4},$$

$$n=6:\quad \alpha_{13,6},\ \alpha_{7,6},$$

$$n=8:\quad \alpha_{17,8},\ \alpha_{11,8},\ \alpha_{5,8},$$

$$n=10:\quad \alpha_{21,10},\ \alpha_{15,10},\ \alpha_{9,10}.$$

By inspection the nonvanishing coefficients can be grouped in two groups. Let $n=2j$ for $j=0,1,2,\ldots$. The contributing coefficients can then be written in the form $\alpha_{m(j),2j}$, where for

$$j=\text{odd},\quad m(j)=(j+4),\ (j+4)+6,\ (j+4)+12,\ldots,2j+1,$$

$$j=\text{even},\quad m(j)=(j+1),\ (j+1)+6,\ (j+1)+12,\ldots,2j+1.$$

Evidently for a given j there are $\{j\}$ contributing m's, in which $\{j\}=\frac{1}{2}(j-1)+1$ for $j=$odd, and $\{j\}=(\frac{1}{2}j-1)+1$ for $j=$even. This can be proved by induction.

With the arrangement above for the coefficients, we can sum along the vertical. The above results suggest that the solution can be written in the following form:

$$T(u,v)=\frac{1}{4}\sum_{k=0}^{\infty}\sum_{j=2k}^{\infty}\beta_{k,j}u^{4j+1-6k}v^{2j}, \tag{73}$$

where $\beta_{k,j}$'s are proportional to the nonvanishing coefficients, i.e., $\beta_{k,j}=4\alpha_{4j+1-6k,2j}$, $\beta_{0,0}=1$, for $k\geqslant 0$ and $j\geqslant 2k$. Substituting Eq. (73) back into Eq. (71), we get the following recurrence relation for the $\beta_{k,j}$'s:

$$\beta_{k,j}=\left(\frac{\mu\lambda}{4\hbar^2}\right)\frac{1}{(4j+1-6k)\cdot 2j}(\beta_{k,j-1}+\beta_{k-1,j-2}). \tag{74}$$

This recurrence relation (74) holds for all values of k and j restricted in the assumed solution as long as we agree to set $\beta_{k,j}=0$ when both or either of k and j is negative, or when $j<2k$.

First let us solve for $\beta_{0,j}$ for all $j\geqslant 1$ given $\beta_{0,0}=1$. Setting $k=0$ in Eq. (74) we arrive at the recurrence relation

$$\beta_{0,j}=\left(\frac{\mu\lambda}{4\hbar^2}\right)\frac{1}{(4j+1)\cdot 2j}\beta_{0,j-1}, \tag{75}$$

the $\beta_{k,j}$'s being zero for $k<0$. Let us define

$$\lambda_r^{(j,k)}=\prod_{l=0}^{r}\frac{1}{(4(j-l)+1-6k)}, \tag{76}$$

where the value $r=-1$ is allowed. Equation (75) can be solved recursively to give

$$\beta_{0,j}=\frac{1}{j!}\left(\frac{\mu\lambda}{8\hbar^2}\right)^j\frac{1}{(-4)^{j+1}}\frac{\Gamma\left(-j-\frac{1}{4}\right)}{\Gamma\left(\frac{3}{4}\right)} \tag{77}$$

valid for all $j\geqslant 0$. Given $\beta_{0,j}$ we can proceed in determining of the coefficients.

To solve for $\beta_{k,j}$ for arbitrary k and j, we assume that we know the solution for $(j-1)$ for all j in Eq. (74). This reduces the problem of solving the recurrence relation for some fix j. We shift index $k\rightarrow(k-1)$ in Eq. (74) and substitute it back to Eq. (74). We do this repeatedly until we arrive at the following result:

$$\beta_{k,j}=\sum_{r=0}^{j-2k}\left(\frac{\mu\lambda}{4\hbar^2}\right)^{r+1}\frac{\beta_{k-1,j-2-r}}{2^{r+1}}\frac{(j-1-r)!}{j!}\lambda_r^{(j,k)}. \tag{78}$$

This can be proven by induction. So for $k=1$, Eq. (78) yields

$$\beta_{1,j}=\frac{1}{j!}\left(\frac{\mu\lambda}{8\hbar^2}\right)^{j-1}\sum_{r=0}^{j-2}(j-r-1)\lambda_{j-r-3}^{(j-2-r,0)}\lambda_r^{(j,1)}=\frac{1}{j!}\left(\frac{\mu\lambda}{8\hbar^2}\right)^{j-1}\left[\frac{1}{2}\frac{\Gamma\left(\frac{3}{4}\right)(-1)^j\sqrt{2}\Gamma\left(-j+\frac{5}{4}\right)}{4^j\pi}\right.$$

$$\left.+\frac{1}{192}\frac{(4j-5)(2j+1)(-1)^{j-2}\Gamma\left(-j+\frac{7}{4}\right)\Gamma\left(-j+\frac{5}{4}\right)}{4^{j-2}\Gamma\left(\frac{3}{4}\right)\Gamma\left(\frac{9}{4}-j\right)}\right]. \tag{79}$$

The rest of the contributing coefficients for other k's can be determined similarly.

However, the explicit forms for $\beta_{0,j}$ and $\beta_{1,j}$ suggest a simplification for $\beta_{k,j}$. These coefficients can be explicitly written in the form

$$\beta_{k,j}=\frac{1}{j!}\left(\frac{\mu\lambda}{8\hbar^2}\right)^{j-k}\rho_{k,j} \tag{80}$$

for some constants $\rho_{k,j}$. These constants are found by substituting (80) back in both sides of Eq. (78), with the appropriate shifting of indices in the right-hand side. Doing so leads to the following recurrence relation:

$$\rho_{k,j}=\sum_{r=0}^{j-2k}(j-r-1)\lambda_r^{(j,k)}\rho_{k-1,j-2-r} \tag{81}$$

for all $k\geqslant 1$ and $j\geqslant 2k$. The initial value that determines all the constants $\rho_{k,j}$ is defined by (77). Comparing Eq. (77) and Eq. (80) for $k=0$ gives

$$\rho_{0,j}=\frac{1}{(-4)^{j+1}}\frac{\Gamma\left(-j-\frac{1}{4}\right)}{\Gamma\left(\frac{3}{4}\right)}, \tag{82}$$

valid for all $j\geqslant 0$. Equation (81) can be solved explicitly given the initial value. We do not need to write its explicit solution.

Substituting $\beta_{k,j}$ back in Eq. (73), the solution to the time kernel equation for the anharmonic oscillator assumes the form

$$T(u,v)=\frac{1}{4}\sum_{k=0}^{\infty}\sum_{j=2k}^{\infty}\frac{\rho_{k,j}}{j!}\left(\frac{\mu\lambda}{8\hbar^2}\right)^{j-k}u^{4j+1-6k}v^{2j}. \tag{83}$$

In arriving at this solution we have assumed above that the solution absolutely converges in the neighborhood of the origin in the uv-plane, so that the contributing terms can be rearranged at will. However, we can only assert at this moment absolute convergence in the entire uv-plane of the first two leading terms in the solution. Equation (83) can be written in the form

$$T(u,v)=T_0(u,v)+T_1(u,v)+\cdots, \tag{84}$$

where the subscripts denote the corresponding term for a given k. For $k=0$ and $k=1$, we have the following explicit closed forms:

$$T_0(u,v)=\frac{1}{4}u\,{}_0F_1\left(\frac{5}{4};\frac{\mu\lambda}{32\hbar^2}u^4v^2\right), \tag{85}$$

$$\begin{aligned}T_1(u,v)=&-\frac{1}{96}\left(\frac{\mu\lambda}{8\hbar^2}\right)u^3v^4\,{}_1F_2\left(1;3,\frac{7}{4};\frac{\mu\lambda}{32\hbar^2}u^4v^2\right)+\frac{5}{96}\left(\frac{\mu\lambda}{8\hbar^2}\right)u^3v^4\,{}_1F_2\left(1;3,\frac{5}{4};\frac{\mu\lambda}{32\hbar^2}u^4v^2\right)\\&+\frac{1}{720}\left(\frac{\mu\lambda}{8\hbar^2}\right)^2u^7v^6\,{}_1F_2\left(2;4,\frac{9}{4};\frac{\mu\lambda}{32\hbar^2}u^4v^2\right),\end{aligned} \tag{86}$$

where ${}_pF_q$ is the generalized hypergeometric function. ${}_pF_q$ converges everywhere if $p\leqslant q$. The first two leading terms then converge everywhere in the uv-plane.

Transforming back to (q,q'), the time kernel for the anharmonic oscillator assumes the form

$$\langle q|\mathcal{T}|q'\rangle = \frac{\mu}{4i\hbar}\,\mathrm{sgn}(q-q')\sum_{k=0}^{\infty}\sum_{j=2m}^{\infty}\frac{\rho_{k,j}}{j!}\left(\frac{\mu\lambda}{8\hbar^2}\right)^{j-k}(q+q')^{4j+1-6k}(q-q')^{2j}. \tag{87}$$

The first two groups of terms, corresponding to $k=0$ and $k=1$, converge everywhere in the qq'-plane so that they are functionals in the $\Phi^{\times}$ and define a generalized operator in Φ. We have not been able to make a conclusion on the convergence of the rest of the group of terms. We note though that, since $\langle q|\mathcal{T}|q'\rangle$ must be a functional in $\Phi^{\times}$, it is not necessary that the sum converges in the usual sense; it is sufficient that it converges in the distributional sense in $\Phi^{\times}$ (see Gel'fand and Shilov (1964), p. 368 for a discussion on the convergence of functionals in Φ). Performing the indicated transformation, we have

$$\begin{aligned}\mathcal{T}_{\hbar}(q,p) &= 2\pi\int_{-\infty}^{\infty}\left\langle q+\frac{v}{2}\middle|\mathcal{T}\middle|q-\frac{v}{2}\right\rangle\exp\left(-i\frac{vp}{\hbar}\right)dv\\ &= -\frac{\mu}{2}\sum_{k=0}^{\infty}\hbar^{2k}\sum_{j=2k}^{\infty}(-1)^j\frac{\rho_{k,j}}{j!}(2j)!\left(\frac{\mu\lambda}{8}\right)^{j-k}\frac{(2q)^{4j+1-6k}}{p^{2j+1}}\\ &= \frac{1}{4}\frac{\sqrt{\pi}}{\Gamma\left(\frac{3}{4}\right)}\sum_{j=0}^{\infty}\frac{(-2)^j\Gamma\left(-\frac{1}{4}-j\right)}{\Gamma\left(\frac{1}{2}-j\right)}\mu^{j+1}\lambda^j\frac{q^{4j+1}}{p^{2j+1}}+\mathcal{O}(\hbar^2)=t_0(q,p)+\mathcal{O}(\hbar^2),\end{aligned}$$

where t_0 is the local time of arrival of the anharmonic oscillator as given by Eq. (70). Thus $\mathcal{T}_{\hbar}(q,p)$ reduces to $t_0(q,p)$ in the limit of vanishing $\hbar$ or infinitesimal $\hbar$.

VII. ENTIRE ANALYTIC POTENTIALS

In this section we prove that the local time of arrival is completely derivable from the generalized time of arrival operator for systems subject to entire analytic potentials, e.g., potentials in polynomials of q. We divide our proof for the linear (systems with linear classical equations of motions) and nonlinear (systems with nonlinear classical equations of motions) cases. In particular we will show that

$$\text{Linear Systems:}\quad \mathcal{T}_{\hbar}(q,p)=t_0(q,p), \tag{88}$$

$$\text{Nonlinear Systems:}\quad \mathcal{T}_{\hbar}(q,p)=t_0(q,p)+\mathcal{O}(\hbar^2). \tag{89}$$

Our method of proof will not follow the line used in the previous section. It will be sufficient to show that the leading term in $\mathcal{T}_{\hbar}(q,p)$, $\mathcal{T}_k^0(q,p)$, the term of order $\mathcal{O}(\hbar^0)$, can be written in the form

$$\mathcal{T}_{\hbar}^0(q,p)=\sum_{k=0}^{\infty}(-1)^k\mathcal{T}_k(q,p), \tag{90}$$

where the $\mathcal{T}_k$'s satisfy the initial value and the recurrence relation

$$\mathcal{T}_0(q,p)=-\mu\frac{q}{p}, \tag{91}$$

$$\mathcal{T}_k(q,p)=-\frac{\mu}{p}\int_0^q\frac{\partial V}{\partial q'}\frac{\partial\mathcal{T}_{k-1}}{\partial p}dq', \tag{92}$$

for all k. If they do, then, according to our result in Sec. IV, $\mathcal{T}^0_\hbar(q,p)$ converges to the local time of arrival in the neighborhood of the origin.

A. Linear systems

Now we consider the most general case for linear systems. The most general potential is given by

$$V(q)=aq+\tfrac{1}{2}bq^2, \tag{93}$$

for some constants a and b. A constant can be added to $V(q)$, but it does not change the result. Here we prove that for systems subject to the potential (93) the local time of arrival in the neighborhood of the origin is given by Eq. (88).

We first solve for the time kernel of the generalized time of arrival operator. Substituting the potential in the time kernel equations lead to solve the following partial differential equation:

$$-\frac{2\hbar^2}{\mu}\frac{\partial^2 T}{\partial u\,\partial v}+\left(av+\frac{1}{2}buv\right)T(u,v)=0, \tag{94}$$

subject to the boundary conditions $T(u,0)=\frac{1}{4}u$ and $T(0,v)=0$. We assume the most general solution of the form

$$T(u,v)=\sum_{m,n}\alpha_{m,n}u^m v^n, \tag{95}$$

where the coefficients now satisfy the conditions $\alpha_{m,n}=0$ when both or either m and n are negative, and $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$, $\alpha_{0,n}=0$ for all n. Substituting the assumed solution back into Eq. (94) yields the recurrence relation among the coefficients

$$\alpha_{m,n}=\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{mn}\left(a\alpha_{m-1,n-2}+\frac{1}{2}b\alpha_{m-2,n-2}\right). \tag{96}$$

First let us show that odd powers of v do not contribute in the solution, i.e., $\alpha_{m,n}=0$ for all odd n for all m. For $n=1$ we have the proportionality $\alpha_{m,1}\propto(a\alpha_{m-1,-1}+\frac{1}{2}b\alpha_{m-2,-1})$. But $\alpha_{m,n}=0$ for all negative n, thus $\alpha_{m,1}=0$ for all m. Now let us assume that for some fixed odd n, $\alpha_{m,n}=0$ for all m. Then for the next odd $n'=n+2$, $\alpha_{m,n+2}\propto(a\alpha_{m-1,n}+\frac{1}{2}b\alpha_{m-2,n})$. But $\alpha_{m,n}=0$ for all m, thus $\alpha_{m,n+2}=0$ for all m. Since we have shown that $\alpha_{m,1}=0$ for all m, it then follows that $\alpha_{m,n}=0$ for all m for all odd n. The vanishing of the odd powers of v is significant because it assures us that the boundary condition (42), necessary to impose canonicality, is satisfied.

Now let us determine the coefficients for even n. For $n=2$ we have the proportionality $\alpha_{m,2}\propto(a\alpha_{m-1,0}+\frac{1}{2}b\alpha_{m-2,0})$. Since $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$, only $m=2$ contributes in the first term, and $m=3$ for the second term. For $n=4$, $\alpha_{m,4}\propto(a\alpha_{m-1,2}+\frac{1}{2}b\alpha_{m-2,2})$. Only $m=3$, 4 contribute for the first term; while $m=4$, 5 for the second term. Continuing the process, we arrive at the following first few nonvanishing coefficients,

$$n=0:\quad \alpha_{1,0},$$

$$n=2:\quad \alpha_{2,2},\ \alpha_{3,2},$$

$$n=4:\quad \alpha_{3,4},\ \alpha_{4,4},\ \alpha_{5,4}.$$

We find that for every $n=2j$, for integer j, there are $j+1$ nonvanishing contributions. In particular, for a given j, we can write $\alpha_{m,n}$ in the form $\alpha_{m(j),2j}$, where $m(j)$ takes on one of the following values:

$$m(j)=(j+1),(j+2),\ldots,(2j+1).$$

This can be proven by induction.

The solution to the time kernel equation (94) can then be written in the following form:

$$T(u,v)=\sum_{j=0}^{\infty}\sum_{k=0}^{j}\alpha_{2j+1-k,2j}u^{2j+1-k}v^{2j}=\frac{1}{4}\sum_{k=0}^{\infty}\sum_{j=0}^{k}\eta_{k,j}u^{2j+1-k}v^{2j}, \tag{97}$$

where the $\eta_{k,j}$'s are constants proportional to the nonvanishing $\alpha_{m,n}$'s, with $\eta_{0,0}=1$. Substituting back the second form of the solution to the time kernel equation yields the recurrence relation

$$\eta_{k,j}=\left(\frac{\mu}{2\hbar^2}\right)\frac{\left(a\,\eta_{k-1,j-1}+\frac{1}{2}b\,\eta_{k-1,j}\right)}{2k(2k+1-j)}, \tag{98}$$

valid for all k and j as long as we set $\eta_{j,k}=0$ for all $0>j>k$. Solving this recursively yields the following form:

$$\eta_{k,j}=\left(\frac{\mu}{2\hbar^2}\right)^k\frac{1}{2^k k!}\sigma_{k,j}b^{k-j}a^j, \tag{99}$$

for some constants $\sigma_{k,j}$. Substituting Eq. (99) back into (98) gives the recurrence relation for the constants $\sigma_{k,j}$,

$$\sigma_{k,j}=\frac{1}{(2k+1-j)}\left(\sigma_{k-1,j-1}+\frac{1}{2}\sigma_{k-1,j}\right). \tag{100}$$

This can be solved recursively to give

$$\sigma_{k,j}=\sum_{r=1}^{k-j+1}\frac{\sigma_{k-r,j-1}}{2^{r-1}}\prod_{s=0}^{r-1}\frac{1}{(2(k-s)+1-j)} \tag{101}$$

with $\sigma_{0,0}=1$. We don't need to evaluate this explicitly. We will just need this recurrence relation in proving Eq. (88). The solution to the time kernel equation can now be written in the form

$$T(u,v)=\frac{1}{4}\sum_{k=0}^{\infty}\sum_{j=0}^{k}\left(\frac{\mu}{2\hbar^2}\right)^k\frac{1}{2^k k!}\sigma_{k,j}b^{k-j}a^j u^{2k+1-j}v^{2k}. \tag{102}$$

It can be shown that $T(u,v)$ is everywhere defined in the uv-plane. From the expression for $T(u,v)$, we have

$$T(q,q')=\frac{1}{4}\sum_{k=0}^{\infty}\left(\frac{\mu}{2\hbar^2}\right)^k\frac{1}{2^k k!}(q-q')^{2k}\sum_{j=0}^{k}\sigma_{k,j}b^{k-j}a^j(q+q')^{2k+1-j} \tag{103}$$

in the original coordinate.

Equation (103) allows us to finally write the functional of the generalized time of arrival operator in the neighborhood of the origin,

$$\langle q|\mathcal{T}|q'\rangle=\frac{\mu}{4i\hbar}\,\mathrm{sgn}(q-q')\sum_{k=0}^{\infty}\sum_{j=0}^{k}\left(\frac{\mu}{2\hbar^2}\right)^k\frac{1}{2^k k!}\sigma_{k,j}b^{k-j}a^j(q+q')^{2k+1-j}(q-q')^{2k}. \tag{104}$$

This is a functional for fixed q in Φ. Performing the indicated transformation to go back in the classical regime, we get

$$\mathcal{T}_\hbar(q,p)=2\pi\int_{-\infty}^{\infty}\left\langle q+\frac{v}{2}\right|\mathcal{T}\left|q-\frac{v}{2}\right\rangle\exp\left(-i\frac{vp}{\hbar}\right)dv$$
$$=\sum_{k=0}^{\infty}\sum_{j=0}^{k}(-1)^{k+1}\mu^{k+1}\frac{(2k)!}{k!}\frac{\sigma_{k,j}}{2^j}b^{k-j}a^j\frac{q^{2k+1-j}}{p^{2k+1}}. \tag{105}$$

We note that $\mathcal{T}_\hbar$ is to the order $\mathcal{O}(\hbar^0)$. Now to complete our proof, we write

$$\mathcal{T}_\hbar(q,p)=\sum_{k=0}^{\infty}(-1)^k\mathcal{T}_k, \tag{106}$$

where

$$\mathcal{T}_k=-\frac{(2k)!}{k!}\mu^{k+1}\sum_{j=0}^{k}\frac{\sigma_{k,j}}{2^j}b^{k-j}a^j\frac{q^{2k+1-j}}{p^{2k+1}}. \tag{107}$$

To prove our assertion that $t_0(q,p)=\mathcal{T}_\hbar(q,p)$, we need only to show that $\mathcal{T}_k$ satisfies the initial value condition $t_0(q,p)$ and the recurrence relation is satisfied by the iterates of the local time of arrival at the origin. It is straightforward to show that $\mathcal{T}_0(q,p)=t_0(q,p)$ by setting $k=0$ in Eq. (107). It only remains to show that the $\mathcal{T}_k$'s satisfy the recurrence relation (92). Shifting index $k\to k-1$ in (107) and substituting it back, together with the potential, in right-hand side of Eq. (92) yields

$$-\frac{\mu}{p}\int_0^q\frac{\partial V}{\partial q}\frac{\partial\mathcal{T}_{k-1}}{\partial p}dq=-\frac{(2(k-1))!(2k-1)}{(k-1)!}\mu^{k+1}$$
$$\times\sum_{j=0}^{k}\frac{1}{2^j}\frac{(2\sigma_{k-1,j-1}+\sigma_{k-1,j})}{(2k+1-j)}b^{k-j}a^j\frac{q^{2k+1-j}}{p^{2k+1}}, \tag{108}$$

where $\sigma_{k,j}=0$ for $0>j>k$. Equation (105) converges to the local time of arrival at the origin if and only if Eq. (108) is equal to (107) for all $k\geqslant 1$. Equating $\mathcal{T}_k$ with Eq. (108), we find that $\sigma_{k,j}$ must the satisfy the following recurrence relation if strict equality is required:

$$\sigma_{k,j}=\frac{1}{(2k+1-j)}\left(\sigma_{k-1,j-1}+\frac{1}{2}\sigma_{k-1,j}\right). \tag{109}$$

But this recurrence relation is already satisfied by the $\sigma_{k,j}$'s, as shown by Eq. (100). Thus Eq. (105) converges to the local time of arrival at the origin for the potential given.

We have thus proved what we have sought to prove that for linear systems, $\mathcal{T}_\hbar(q,p)=t_0(q,p)$.

B. Nonlinear systems

In this section we show that for entire analytic potentials of the form

$$V(q)=\sum_{s=1}^{\infty}a_sq^s, \tag{110}$$

with at least a_3 is nonvanishing, the proposed supraquantization of the time of arrival at the origin reduces only to the classical local time of arrival in the limit of vanishing or infinitesimal $\hbar$. Substituting the potential back into the time kernel equation and after some simplification, we arrive at the partial differential equation to solve

$$-2\frac{\hbar^2}{\mu}\frac{\partial^2 T}{\partial u\,\partial v}+\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\sum_{k=0}^{[s]}\binom{2}{2k+1}u^{s-2k-1}v^{2k+1}T(u,v)=0, \tag{111}$$

where $[s]=(s-1)/2$ for $s=$odd and $[s]=(s/2)-1$ for $s=$even, subject to the same boundary conditions.

Now let us assume an analytic solution of the form

$$T(u,v)=\sum_{m,n}\alpha_{m,n}u^m v^n, \tag{112}$$

subject to the boundary conditions $\alpha_{m,n}=0$ for $m,n<0$, $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$, and $\alpha_{0,n}=0$ for all n. Substituting the assumed solution back into (111) and collecting terms of equal powers of u and v yield the following recurrence relation among the coefficients:

$$\alpha_{m,n}=\frac{\mu}{2\hbar^2}\frac{1}{mn}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\sum_{k=0}^{[s]}\binom{s}{2k+1}\alpha_{m-s+2k,n-2k-2}. \tag{113}$$

Imposing the boundary condition, we have the following conditions imposed upon the coefficients: $\alpha_{1,0}=\frac{1}{4}$, $\alpha_{m,n}=0$ for all $n<0$ and $m\leqslant 1$, $\alpha_{m,0}=0$ for all $m\geqslant 2$, and $\alpha_{m,1}=0$ for all m.

1. Odd powers of v

The boundary conditions impose that the $\alpha_{m,n}$'s vanish for odd n for all m. The coefficients already vanish for negative n, so we start with $n=1$. For $n=1$ Eq. (113) gives

$$\alpha_{m,1}=\frac{\mu}{2\hbar^2}\frac{1}{m\cdot 1}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\sum_{k=0}^{[s]}\binom{s}{2k+1}\alpha_{m-s+2k,-2k-1}.$$

Since $\alpha_{m,n}$ vanish for all negative n, $\alpha_{m,1}=0$ for all m. For $n=3$ we have

$$\alpha_{m,3}=\frac{\mu}{2\hbar^2}\frac{1}{m\cdot 3}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\sum_{k=0}^{[s]}\binom{s}{2k+1}\alpha_{m-s+2k,1-2k}.$$

Since $\alpha_{m,1}=0$ for all m and $\alpha_{m,n}=0$ for all negative n, it follows that $\alpha_{m,3}=0$ for all m as well. Now let $n=2j+1$, for $j=0,1,2,...$, and let $\alpha_{m,2j+1}=0$ for all m for all $j\leqslant J$. Then for $n=2(J+1)+1$,

$$\alpha_{m,2(J+1)+1}=\frac{\mu}{2\hbar^2}\frac{1}{m(2(J+1)+1)}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\sum_{k=0}^{[s]}\binom{s}{2k+1}\alpha_{m-s+2k,2J+1-2k}.$$

The $k=0$ term in the inner sum contains the factors $\alpha_{m-s+2k,2J+1}$, which are all vanishing because $\alpha_{m,2J+1}=0$ for all m; the $k=0$ term then does not contribute. The $k=1$ term contains the factors $\alpha_{m-s+2k,2(J-1)+1}$, which are all also vanishing because $\alpha_{m,2j+1}=0$ for all m for all $j\leqslant J$; the $k=1$ term then does not contribute.

Now for all $k\leqslant J$, the coefficients $\alpha_{m-s+2k,2J+1-2k}=\alpha_{m-s+2k,2(J-k)+1}$ vanish, again, because $\alpha_{m,2j+1}=0$ for all m for all $j\leqslant J$; and no contribution comes from them. On the other hand, for all $k>J$, the coefficients $\alpha_{m-s+2k,2(J-k)+1}$ must vanish because of the condition that $\alpha_{m,n}=0$ for all negative n. Thus $\alpha_{m,2(J+1)+1}=0$ for all m as well. We have already shown that $\alpha_{m,1}$

$=0$ and $\alpha_{m,3}=0$ for all m, and it follows that $\alpha_{m,5}=0$ for all m from what we have already shown, and so on. Thus it must be that $\alpha_{m,n}=0$ for all m for every odd n. Odd powers of v then do not contribute in the solution to the time kernel equation.

2. Even powers of v

Now we proceed in determining the nonvanishing coefficients corresponding to even powers of v or to even n. First, for $n=2$, the recurrence relation (113) reduces to

$$\alpha_{m,2}=\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{m\cdot 2}\sum_{s=1}^{\infty}\frac{a_s}{2^{2-1}}\sum_{k=0}^{[s]}\binom{s}{2k+1}\alpha_{m-2+2k,-2k}. \tag{114}$$

Since the $\alpha_{m,n}$'s vanish for all negative n, only the $k=0$ term contributes in (114). Thus

$$\alpha_{m,2}=\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{m\cdot 2}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\binom{s}{1}\alpha_{m-s,0}.$$

But $\alpha_{m',0}=\frac{1}{4}\delta_{m',1}$, so that only the $s=m-1$ term contributes in the preceding relation. Since the power of u is at least to the first order and $s\geqslant 1$, only those coefficients with $m\geqslant 2$ contribute above. Thus

$$\alpha_{m,2}=\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{m\cdot 2}\frac{a_{m-1}}{2^{m-2}}\binom{m-1}{1}\frac{1}{4}. \tag{115}$$

The nonvanishing contributions from those with $m\geqslant 2$.

For $n=4$ the recurrence relation reduces to

$$\alpha_{m,4}=\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{m\cdot 4}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\sum_{k=0}^{[s]}\binom{2}{2k+1}\alpha_{m-s+2k,2-2k}. \tag{116}$$

For all s only the $k=0,1$ contribute to $\alpha_{m,4}$. All of the $s\geqslant 1$ terms contribute to the $k=0$ term. However, only those for $s\geqslant 3$ contribute to the $k=1$ term. Thus

$$\alpha_{m,4}=\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{m\cdot 4}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\binom{s}{1}\alpha_{m-s,2}+\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{m\cdot 4}\sum_{s=3}^{\infty}\frac{a_s}{2^{s-1}}\binom{s}{3}\alpha_{m-s+2,0}.$$

Since $\alpha_{m',2}$ is nonvanishing only for $m'\geqslant 2$, it has to be that $(m-s)\geqslant 2$ in the first term; thus only those $1\leqslant s\leqslant(m-2)$ contribute in the sum. Since $s\geqslant 1$ only those with $m\geqslant 3$ contribute. On the other hand, only $s=m+1$ contributes in the second term. Thus, upon substituting $\alpha_{m',2}$ and $\alpha_{m',0}$,

$$\alpha_{m,4}=\left(\frac{\mu}{2\hbar^2}\right)^2\frac{1}{m\cdot 4}\sum_{s=1}^{m-2}\frac{a_s a_{m-s-1}}{2^{m-2}}\binom{s}{1}\binom{m-s-1}{1}\frac{1}{4}+\left(\frac{\mu}{2\hbar^2}\right)\frac{1}{m\cdot 4}\frac{a_{m+1}}{2^m}\binom{m+1}{3}\frac{1}{4},$$

with the first term having contribution only for $m\geqslant 3$ and the second term for all $m\geqslant 2$.

We would like now to generalize our results for arbitrary j. The explicit forms of $\alpha_{m,0}$, $\alpha_{m,2}$ and $\alpha_{m,4}$ suggest that, for some fixed j, we have

$$\alpha_{m,2j}=\sum_{s=0}^{j-1}\alpha_{m,j}^{(s)}\left(\frac{\mu}{2\hbar^2}\right)^{j-s}, \tag{117}$$

for some constants $\alpha^{(0)}_{m,j}$ independent of $\hbar$ and μ. We prove (117) by induction and consequently determine the recurrence relation satisfied by these constants that determines them uniquely. Now for $n=2j$ for some $j\geqslant 1$, the recurrence relation (113) can be written in the form

$$\alpha_{m,2j}=\frac{\mu}{2\hbar^2}\frac{1}{m\cdot 2j}\sum_{s=1}^{\infty}\frac{a_s}{2^{s-1}}\sum_{k=0}^{j-1}\binom{s}{2k+1}\alpha_{m-s+2k,2(j-k-1)}. \tag{118}$$

We have replaced $[s]$ with $j-1$ in the inner summation limit because whatever extra terms are introduced they are taken care of by the binomial factor. The order of summation can be reordered to yield

$$\begin{aligned}\alpha_{m,2j}&=\frac{\mu}{2\hbar^2}\frac{1}{m\cdot 2j}\sum_{k=0}^{j-1}\sum_{s=2k+1}^{\infty}\frac{a_s}{2^{s-1}}\binom{s}{2k+1}\alpha_{m-s+2k,2(j-k-1)}\\&=\frac{\mu}{2\hbar^2}\frac{1}{m\cdot 2j}\sum_{k=0}^{j-1}\sum_{s=2k+1}^{m+2k-1}\frac{a_s}{2^{s-1}}\binom{s}{2k+1}\alpha_{m-s+2k,2(j-k-1)}.\end{aligned} \tag{119}$$

The second line follows from the fact that $\alpha_{m-s+2k,2(j-k-1)}$ is nonvanishing only when $m-s+2k\geqslant 1$ or $m+2k-1\geqslant s$.

Now we substitute Eq. (117) back into the right-hand side of Eq. (119). This yields

$$\alpha_{m,2j}=\frac{1}{m\cdot 2j}\sum_{k=0}^{j-1}\sum_{r=0}^{j-k-1}\left(\sum_{s=2k+1}^{m+2k-1}\frac{a_s}{2^{s-1}}\binom{s}{2k+1}\alpha^{(r)}_{m-s+2k,j-k-1}\right)\left(\frac{\mu}{2\hbar^2}\right)^{j-k-r}. \tag{120}$$

We can rearrange Eq. (120) to obtain the following simplification:

$$\alpha_{m,2j}=\frac{1}{m\cdot 2j}\sum_{s=0}^{j-1}\left(\sum_{r=0}^{s}\sum_{l=2r+1}^{m+2r-1}\frac{a_l}{2^{l-1}}\binom{l}{2r+1}\alpha^{(s-r)}_{m-l+2r,j-r-1}\right)\left(\frac{\mu}{2\hbar^2}\right)^{j-s}. \tag{121}$$

Expression (117) holds if and only if it equals the right-hand side of (121) for all j. Strict equality holds if and only if the constants $\alpha^{(s)}_{m,j}$ satisfy the recurrence relation

$$\alpha^{(s)}_{m,j}=\frac{1}{m\cdot 2j}\sum_{r=0}^{s}\sum_{l=2r+1}^{m+2r-1}\frac{a_l}{2^{l-1}}\binom{l}{2r+1}\alpha^{(s-r)}_{m-l+2r,j-r-1}, \tag{122}$$

for all $0\leqslant s\leqslant(j-1)$, subject to the initial value $\alpha^{(0)}_{m,0}=\frac{1}{4}\delta_{m,1}$. Equations (120) and (122) now define the nonvanishing coefficients for even powers of v. They can be solved explicitly. In the following we are only interested in the classical limit.

C. The classical coefficients

We now identify the contributing coefficients and determine the leading order of $\hbar$ correction in the classical limit. For a fixed even $n=2j$, $j=0,1,2,...$, we have seen above that the contributing coefficients $\alpha_{m,2j}$'s are of the form

$$\alpha_{m,2j}=\sum_{s=0}^{j-1}\left(\frac{\mu}{2}\right)^{j-s}\frac{\alpha^{(s)}_{m,j}}{\hbar^{2(j-s)}}.$$

The contribution of each term is $\alpha_{m,2j}v^{2j}$ (the u^m factor is left out because it is not relevant in determining the $\hbar$-order of contribution in the classical limit). The classical contribution of this term is proportional to

$$\frac{1}{\hbar}\alpha_{m,n}\int_{-\infty}^{\infty}\mathrm{sgn}(v)v^{2j}\exp\left(-i\frac{vp}{\hbar}\right)dv\propto\sum_{s=0}^{j-1}\left(\frac{\mu}{2}\right)^{j-s}\alpha_{m,j}^{(s)}\hbar^{2s}, \tag{123}$$

where we have arrived at the left-hand side of the first line by using the prescribed classical transition and with the right-hand side using identity (67). We see immediately that the only contributing term in the classical limit corresponds to $s=0$. Moreover, we can already see that the leading $\hbar$ correction in the classical limit is $\mathcal{O}(\hbar^2)$; this corresponds to $s=1$ in Eq. (123).

Thus the coefficients contributing only in the classical limit corresponds to those for $s=0$ for a given j. And these coefficients satisfy the recurrence relation,

$$\alpha_{m,2j}^{(0)}=\frac{1}{m\cdot 2j}\sum_{s=1}^{\infty}\frac{sa_s}{2^{s-1}}\alpha_{m-s,j-1}^{(0)}. \tag{124}$$

With $\alpha_{m,0}=\frac{1}{4}\delta_{m,1}$, we can generate the following first few coefficients

$$\alpha_{m,0}^{(0)}=\tfrac{1}{4}\delta_{m,1},$$

$$\alpha_{m,1}^{(0)}=\frac{1}{2m}\sum_{s=1}^{\infty}\frac{sa_s}{2^{s-1}}\alpha_{m-s,0}^{(0)}=\frac{1}{1\cdot m}\frac{(m-1)a_{m-1}}{2^{m+1}}\quad\text{for all } m\geqslant 2,$$

$$\alpha_{m,2}^{(0)}=\frac{1}{2m}\sum_{s=1}^{\infty}\frac{sa_s}{2^{s-1}}\alpha_{m-s,1}=\frac{1}{1\cdot 2m2^{m+1}}\sum_{s=1}^{m-2}\frac{sa_s}{(m-s)}(m-s-1)a_{m-s-1}\quad\text{for all } m\geqslant 3.$$

From these few iterations, we infer that the coefficients are given by

$$\alpha_{m,j}^{(0)}=\frac{C_{m,j}}{j!\cdot 2^{m+1}m}, \tag{125}$$

where the $C_{m,j}$'s are constants, for all $m\geqslant(j+1)$. Substituting this expression back into the recurrence relation (124), yields the recurrence relation satisfied by the $C_{m,j}$'s,

$$C_{m,j}=\sum_{s=1}^{m-j}\frac{sa_s}{(m-s)}C_{m-s,j-1}. \tag{126}$$

This is uniquely solved by specifying the initial value. Setting $j=0$ in Eq. (125) and comparing it with the known value of $\alpha_{m,0}^{(0)}$ yields the initial value $C_{m,0}=\delta_{m,1}$. The recurrence relation can be solved explicitly, but we do not need to write it down.

D. The solution

The coefficients $\alpha_{m,j}^{(0)}$ give the group of contributions with the order $\mathcal{O}(\hbar^0)$ in the classical limit. For every $j\geqslant 0$, there is a contribution $T_j(u,v)$'s in the solution $T(u,v)$, which is given by

$$T_j(u,v)=\left(\frac{\mu}{2\hbar^2}\right)^j\sum_{m=j+1}^{\infty}\alpha_{m,2j}^{(0)}u^m v^{2j}=\left(\frac{\mu}{2\hbar^2}\right)^j\frac{1}{j!}\sum_{m=j+1}^{\infty}\frac{C_{[m,j]}}{m\cdot 2^{m+1}}u^m v^{2j}.$$

The solution to (46) can then be written in the form

$$T(u,v)=\sum_{j=0}^{\infty}T_j(u,v)+S(u,v), \tag{127}$$

where the second term is responsible for order $\mathcal{O}(\hbar^2)$ in the classical limit. The solution to the time kernel equation in the (q,q') coordinate then assumes the form

$$T(q,q')=\sum_{j=0}^{\infty} T_j(q,q')+S(q,q'), \tag{128}$$

in which $T_j(q,q')$ derives from $T_j(u,v)$ with the substitutions $u=(q+q')$ and $v=(q-q')$.

The functional kernel of the generalized time of arrival operator then splits in two parts

$$\langle q|\mathcal{T}|q'\rangle=\sum_{j=0}^{\infty}\langle q|\mathsf{T}_j|q'\rangle+\langle q|\Delta\mathcal{T}|q'\rangle,$$

where $\langle q|\mathsf{T}_j|q'\rangle=(\mu/i\hbar)T_j(q,q')\mathrm{sgn}(q-q')$. Each of this $\langle q|\mathsf{T}_j|q'\rangle$ contributes in the classical limit,

$$T_j(q,p)=2\pi\int_{-\infty}^{\infty}\left\langle q+\frac{v}{2}\middle|T_j\middle|q-\frac{v}{2}\right\rangle e^{(-(ipv/\hbar))}dv=-(2j-1)!!(-1)^j\frac{\mu^{j+1}}{p^{2j+1}}\sum_{m=j+1}^{\infty}\frac{C_{m,j}}{m}q^m,$$

where a simplification has been made in the second line.

To prove that $\Sigma_{j=0}^{\infty}T_j(q,p)$ converges to the local time of arrival, we write the term with leading order $\mathcal{O}(\hbar^0)$ in the form

$$\mathcal{T}_{\hbar}^{\theta}(q,p)=\sum_{k=0}^{\infty}(-1)^k\mathcal{T}_k(q,p), \tag{129}$$

$$\mathcal{T}_k=-(2k-1)!!\frac{\mu^{k+1}}{p^{2k+1}}\sum_{m=k+1}^{\infty}\frac{C_{m,k}}{m}q^m. \tag{130}$$

$\mathcal{T}_{\hbar}^{0}$ converges to the local time of arrival in the origin if the $\mathcal{T}_0$ reproduces the initial value and the remaining terms satisfy the recurrence relation for the local time of arrival. Since $C_{m,0}=\delta_{m,1}$, for $k=0$, we have

$$\mathcal{T}_0(q,p)=-\mu\frac{q}{p}, \tag{131}$$

as required.

It remains to show that the rest of the terms satisfy the recurrence relation (92). Shifting index $k\to(k-1)$ in $\mathcal{T}_k$, we have

$$\frac{\partial V}{\partial q}\frac{\partial\mathcal{T}_{k-1}}{\partial p}=(2k-1)!!\frac{\mu^k}{p^{2k}}\sum_{s=1}^{\infty}sa_sq^{s-1}\cdot\sum_{m=k}^{\infty}\frac{C_{m,k-1}}{m}q^m=(2k-1)!!\sum_{k+1}^{\infty}\sum_{r=1}^{s-r}\frac{ra_rC_{s-r,k-1}}{(s-r)}q^{s-1}, \tag{132}$$

where we have used the identity

$$\sum_{s=1}^{\infty}a_sx^s\cdot\sum_{k=m}^{\infty}b_kx^k=\sum_{l=m+1}^{\infty}\sum_{n=1}^{l-m}a_nb_{l-n}x^l$$

to arrive at the second line. Now we have

$$-\frac{\mu}{p}\int_0^q dq\frac{\partial V}{\partial q}\frac{\partial\mathcal{T}_{k-1}}{\partial p}=(2k-1)!!\sum_{k+1}^{\infty}\sum_{r=1}^{s-r}\frac{ra_rC_{s-r,k-1}}{(s-r)}\frac{q^s}{s}. \tag{133}$$

$\mathcal{T}_\hbar$ converges to the local time of arrival at the origin if and only if Eqs. (130) and (133) are strictly equal for all k. Equating them, we find that strict equality for all k holds if and only if the $C_{m,k}$'s satisfy the recurrence relation

$$C_{m,k}=\sum_{r=1}^{m-k}\frac{ra_r}{(m-r)}C_{m-r,k-1}. \tag{134}$$

But this is just the recurrence relation we have arrived at above. Thus the $\mathcal{T}_k$'s satisfy the initial value condition and the required recurrence relation. The leading term $\mathcal{T}_\hbar^0$ then converges to the local time of arrival at the origin, as what we have sought to prove.

E. Integral form of the classical term

In the above discussion, we did not bother to consider the convergence of the group of terms contributing in the classical limit, the terms with $\mathcal{O}(\hbar^0)$ when Weyl–Wigner transformed; we denote this group of terms by $\langle q|\mathcal{T}_0|q'\rangle$, and call it the classical term. Here we show that $\langle q|\mathcal{T}_0|q'\rangle$ converges everywhere in the qq'-plane. We do this by showing that it has an integral representation which is defined everywhere.

It will be sufficient for us to derive the integral form of the time kernel for the linear case, because the nonlinear case can be derived similarly. Our goal is to rewrite Eq. (103) such that it is explicitly everywhere convergent in the qq'-plane. We do this as follows. In Eq. (107), we have the following expression for $\mathcal{T}_k$:

$$\mathcal{T}_k=-\frac{(2k)!}{k!}\frac{\mu^{k+1}}{p^{2k+1}}\sum_{j=0}^{k}\frac{\sigma_{k,j}}{2^j}b^{k-j}a^jq^{2k+1-j}. \tag{135}$$

We compare this with Eq. (25) for $x=0$,

$$T_k=-\frac{(2k-1)!!}{k!}\frac{\mu^{k+1}}{p^{2k+1}}\int_0^q(V(q)-V(q'))^kdq'. \tag{136}$$

Since we already know that Eq. (106) converges absolutely to the local time of arrival at the origin, it must be that Eqs. (135) and (136) are equal for all k. Equating them and changing variables $q\to\frac{1}{2}(q+q')$ in the resulting equality gives us the following identity:

$$\sum_{j=0}^{k}\sigma_{k,j}b^{k-j}a^j(q+q')^{2k+1-j}=2^{2k+1}\frac{(2k-1)!}{(2k)!}\int_0^s(V(s)-V(q''))^kdq''|_{s=1/2(q+q')}, \tag{137}$$

which is the simplification we need in Eq. (103). Substituting Eq. (137) into Eq. (103) yields

$$\begin{aligned}T(q,q')&=\frac{1}{2}\sum_{k=0}^{\infty}\left(\frac{\mu}{\hbar^2}\right)^k\frac{(2k-1)!!}{(2k)!k!}(q-q')^{2k}\int_0^s(V(s)-V(q''))^kdq''|_{s=1/2(q+q')}\\&=\frac{1}{2}\int_0^s dq'\,{}_0F_1\left(1;\left(\frac{\mu}{2\hbar^2}\right)(q-q')^2(V(s)-V(q''))\right)|_{s=1/2(q+q')},\end{aligned} \tag{138}$$

where ${}_pF_q$ is the generalized hypergeometric function. The integration can be pulled out of the summation because of the continuity of the potential and the absolute everywhere convergence of the hypergeometric function for $p<q$. $T(q,q')$ is consequently defined everywhere. Finally the time kernel is explicitly given by

$$\langle q|\mathcal{T}_0|q'\rangle = \frac{\mathrm{sgn}(q-q')}{2i\hbar}\int_0^{1/2(a+q')} dq''\,{}_0F_1\left(1;\frac{\mu}{2\hbar^2}(q-q')^2\left\{V\left(\frac{1}{2}(q+q')\right)-V(q'')\right\}\right). \tag{139}$$

We have arrived at Eq. (139) for linear systems, but similar working on the classical term of the solution for the nonlinear case yields the same expression (139), in which $V(q)$ is now the appropriate potential for nonlinear systems.

Since the time kernel and the classical term coincide for linear systems, the time kernel is defined everywhere, and thus a functional in $\Phi^{\times}$, and it defines a generalized observable relative to the rigging provided by Φ (see Appendix). For nonlinear systems, the leading term is likewise defined everywhere, and it defines a generalized observable relative to Φ. We have not been able to investigate the functional structure of the remaining terms for nonlinear systems. Generally the time kernels for entire analytic potentials can then be written in the form

$$\text{Linear Systems:} \quad \langle q|\mathcal{T}|q'\rangle = \langle q|\mathcal{T}_0|q'\rangle, \tag{140}$$

$$\text{Nonlinear Systems:} \quad \langle q|\mathcal{T}|q'\rangle = \langle q|\mathcal{T}_0|q'\rangle + \langle q|\Delta\mathcal{T}|q'\rangle. \tag{141}$$

Comparison of $\langle q|\mathcal{T}_0|q'\rangle$ with the Weyl quantization of the local time of arrival in the origin shows that they are equal. One can check this for himself by applying Weyl's quantization prescription (9) to the local time of arrival. Weyl quantization then agrees only with the result of supraquantization for linear systems and it fails to satisfy the required commutator value for nonlinear systems. By our results for the nonlinear system the second term in Eq. (141) is to the $\mathcal{O}(\hbar^2)$ in the classical limit.

VIII. SUPRAQUANTIZATION FOR ARBITRARY POINTS OF ARRIVAL *x*

Having solved the time of arrival supraquantization problem at the origin, now we show that our results above can be imported to solve the supraquantization at an arbitrary point *x*. Generally the classical time of arrival at a point *x* is given by Eq. (12). Changing variables in Eq. (12) to $(\tilde{q}=q-x,\ \tilde{p}=p)$, the expression for the time of arrival reduces to

$$T_x(\tilde{q},\tilde{p}) = -\,\mathrm{sgn}(\tilde{p})\sqrt{\frac{\mu}{2}}\int_0^{\tilde{q}}\frac{d\tilde{q}'}{\sqrt{H(\tilde{q}+x,\tilde{p})-V(\tilde{q}'+x)}}. \tag{142}$$

Comparing Eq. (142) with the classical time of arrival at the origin, we find that the expression is equivalent to the time of arrival at the origin under the potential $\tilde{V}(\tilde{q})=V(\tilde{q}+x)$.

The surpraquantization for arbitrary arrival points *x* then can be solved by solving the time kernel equation at the origin subject to the potential $\acute{V}(\acute{q})=V(\acute{q}+x)$. For this case the time kernel equation assumes the form

$$-\frac{\hbar^2}{2\mu}\frac{\partial^2 T_x(\tilde{q},\tilde{q}')}{\partial q^2}+\frac{\hbar^2}{2\mu}\frac{\partial^2 T_x(\tilde{q},\tilde{q}')}{\partial \tilde{q}'^2}+(V(\tilde{q}+x)-V(\tilde{q}'+x))T_x(\tilde{q},\tilde{q}')=0$$

and the solution is still subject to the same boundary conditions

$$T_x(\tilde{q},\tilde{q})=\frac{\tilde{q}}{2},\quad T_x(\tilde{q},-\tilde{q})=0. \tag{143}$$

After solving for $T_x(\overline{q},\overline{q'})$, we can transform back to the original coordinate to get the kernel for the original problem. And that completes the supraquantization of the classical time of arrival for arbitrary *x*. Note that our earlier result in the neighborhood of the origin is subsumed in the above solution by simply setting $x=0$.

IX. DISCUSSION AND CONCLUSION

In this paper we have demonstrated that the classical time of arrival can be derived quantum mechanically without solving for and inverting the classical equations of motion. Our results, albeit still needing more clarifications (especially in the nonlinear case), undoubtedly forces us to reconsider our ideas on quantization, and consider supraquantization in places where quantization fails. Generally it is known that obstruction to quantization exists, so that no quantization is possible to consistently satisfy the required commutation relations. For example, Weyl quantization cannot consistently quantize all classical observables as we have demonstrated for the class of time of arrival observables. What is generally done is to choose an elite class of the classical observable that can be consistently quantized and derive the rest of the quantum observables by expressing them in terms of this elite class. In Euclidean space, the choice is usually the Heisenberg class, the position and momentum operators, together with the identity operator. The rest of the quantum observables are then derived by expressing them in terms of this class of operators. This, however, is not wholly satisfactory because the resulting operators do not necessarily satisfy the required algebra.

Now if we strongly require consistency with the required algebra of observables in spaces where obstruction to quantization exists, then we must leave quantization and find an alternative platform. It is here that the idea of supraquantization may come in. However, its implementation may not be straightforward. As what we have discussed earlier, supraquantization may necessarily require some classification of observables, as opposed to quantization which does not classify observables. The classification is necessary, at least for the class of time of arrival observables, in identifying the characteristic properties of the class that can be used in implementing the transfer principle. The natural questions are: "*How do we get the appropriate classification and how do we identify the characteristic properties of the class?*" These may not be easily answered, but they will eventually require us to go back to the basic definition of the elements of the class and the appropriate axioms of quantum mechanics to impose on them.

Assuming that we have settled the first question, we may use quantization itself as a tool in addressing the second question. What we can do is the following: Given a class $\mathcal{C}$ of classical observables, divide $\mathcal{C}$ in two parts $\mathcal{C}_N$ and $\mathcal{C}_O$. The subclass $\mathcal{C}_N$, which we may call the nonobstructed class, consists of those observables that can be consistently quantized; and the subclass $\mathcal{C}_O$, which we may call the obstructed class, consists of those observables that cannot be consistently quantized. We can work on the $\mathcal{C}_N$ using quantization and determine the properties that can be extended to the rest of the class. Once the common property of all those in $\mathcal{C}_N$ has been determined, one can use the transfer principle in treating the obstructed class $\mathcal{C}_O$. For the class of (classical) time of arrival observables, we find that the nonobstructed class with respect to Weyl quantization consists of all linear systems, while the obstructed class consists of all nonlinear systems. Following the above suggestion, we could have arrived at the same solution by working directly with the linear system and extending the result to nonlinear systems via the appropriate transfer principle. The example of the classical time of arrival demonstrates how obstruction to quantization can be formally circumvented with the idea of supraquantization.

ACKNOWLEDGMENTS

The author acknowledges the many fruitful discussions with H. Domingo which led to numerous refinements of the original manuscript, and acknowledges R. de la Madrid for his insightful remarks on rigged Hilbert space theory; and likewise thanks I. Tagaca for her careful reading and suggestions to improve the textual presentation of the entire manuscript.

APPENDIX A

To establish and to avoid possible confusion with our notation for the RHS-extensions and RHS-reductions, in particular the use of the notation $\mathsf{A}_\times\varphi=\langle F_\mathsf{A}|\varphi\rangle=\mathsf{A}\varphi$, we give an example.

Consider the momentum operator P in the Hilbert space $\mathcal{H}=L^2(\mathfrak{R},dq)$. The domain of P, $\mathcal{D}(\mathsf{P})$, consists of all vectors in $\mathcal{H}$ that are almost differentiable everywhere in the real line, and

whose first derivatives are Lesbegue square integrable. For every vector $\varphi(q)$ in $\mathcal{D}(\mathsf{P})$, the momentom operator acts as $(\mathsf{P}\varphi)(q)=-i\hbar\varphi'(q)$. By definition P is self-adjoint so that $\mathsf{P}=\mathsf{P}^\dagger$. Now we choose the rigging $\Phi^\times\supset\mathcal{H}\supset\Phi$, where Φ is the space of infinitely differentiable complex valued functions with compact support in the real line, and $\Phi^\times$ its corresponding functional space. Since Φ is contained in $\mathcal{D}(\mathsf{P})$, we can define its rigged Hilbert space extension and reduction. For every vector φ in Φ and functional ϕ in $\Phi^\times$, we can write $\langle\phi|\varphi\rangle=\int_{\mathfrak{R}}\phi^*(q)\varphi(q)dq$, where the integration is understood in the distributional sense when singular ϕ is involved, say, the Dirac delta.

Now the RHS-extension of P is found as follows: For every φ in Φ and ϕ in $\Phi^\times$, we have

$$\langle\phi|\mathsf{P}^\dagger\varphi\rangle=\int_{\mathfrak{R}}\phi^*(q)(-i\hbar\varphi'(q))dq=\int_{\mathfrak{R}}i\hbar\phi'^*(q)\varphi(q)dq$$

$$=\int_{\mathfrak{R}}(-i\hbar\phi'(q))^*\varphi(q)dq=\int_{\mathfrak{R}}(\mathsf{P}^\times\phi)(q)\varphi(q)dq,$$

where the second line follows from the definition of the derivatives of functionals. The RHS-extension of P is then given by the operator $\mathsf{P}^\times$ which acts everywhere in $\Phi^\times$ as $\mathsf{P}^\times\phi=-i\hbar\phi'$.

On the other hand, the RHS-reduction of P is found as follows: First, we have to indicate the reduction of P in Φ. Its reduction is simply the operator P_Φ, which acts only on vectors φ in Φ according to $(\mathsf{P}_\Phi\varphi)(q)=-i\hbar\varphi'(q)$. Second, we have to find the functional $F_\mathsf{P}(q)$ in $\Phi^\times$ for every q in the real line, such that $\langle F_\mathsf{P}(q)|\varphi\rangle=-i\hbar\varphi'(q)$, for all φ in Φ. By inspection, this functional is given by $F_\mathsf{P}(q)=-i\hbar\delta'(q-q')$. It is so because

$$\langle F_\mathsf{P}(q)|\varphi\rangle=\int_{\mathfrak{R}}F_\mathsf{P}(q)^*\varphi(q')dq'=\int_{\mathfrak{R}}i\hbar\delta'(q-q')\varphi(q')dq'$$

$$=\int_{\mathfrak{R}}\delta(q-q')(-i\hbar\varphi'(q'))dq'=-i\hbar\varphi'(q)=(\mathsf{P}_\Phi)(q).$$

Thus, by our definition, the uniquely associated functional to P is the functional $-i\hbar\delta'(q-q')$. The RHS-reduction of P is now symbolically given by

$$\mathsf{P}_\times=\langle F_\mathsf{P}|\cdot\rangle=\int_{\mathfrak{R}}dq'\,i\hbar\delta'(q-q'),$$

with $F_\mathsf{P}^*=i\hbar\delta(q-q')$ as the functional kernel of $\mathsf{P}_\times$.

Note that possible confusion may arise when the above notation is used, for example, in expressions like $\langle F(\varphi)|\varphi\rangle=\langle\langle F|\varphi\rangle|\varphi\rangle$, such as in the definition of generalized observables. The confusion may creep in when one interprets $\langle F|\varphi\rangle$ as a constant scalar number. While $\langle F|\varphi\rangle$ is indeed a scalar number, it may be understood to range in the complex plane, such as $\langle F_\mathsf{P}(q)|\varphi\rangle$ in the above example, so that $\langle F|\varphi\rangle$ can be understood as a vector in Φ or $\Phi^\times$, whichever the case maybe.

APPENDIX B

Let us consider the function

$$F(q,q')=\mathrm{sgn}(q-q')\sum_{k=0}^{\infty}T_k(q,q'),\tag{B1}$$

where the summation is everywhere absolutely convergent or entire analytic in the qq'-plane. Now for a fixed q, is $F(q,q')$ a functional belonging to $\Phi^\times$?

First it has to be that for all φ in Φ, $|\langle F|\varphi\rangle|<\infty$. Let us denote the sum in Eq. (B1) by $S(q,q')$. Then for all φ in Φ

$$\left|\int_{\Sigma} F(q,q')\varphi(q')dq'\right| \leqslant \sup_{\Sigma}|S(q,q')|\left|\int_{\Sigma}\varphi(q)dq\right|, \tag{B2}$$

where Σ is the support of $\varphi(q)$. The right-hand side of the above inequality is finite because $S(q,q')$ is bounded in any finite region of the qq'-plane. Second, it has to be that for every sequence φ_n in Φ converging to zero in Φ, $\langle F|\varphi_n\rangle$ converges to 0. This follows immediately because $F(q,q')$ is locally integrable. Thus $\langle q|\mathcal{T}|q'\rangle$ is a functional belonging to $\Phi^{\times}$ for a fixed q.

Now for arbitrary φ in Φ, is $G(q)=\int F(q,q')\varphi(q')dq'$ a functional belonging to $\Phi^{\times}$? For all $\phi(q)\in\Phi$,

$$\left|\int_{\Sigma'}\int_{\Sigma} F(q,q')\phi(q)^*\varphi(q')dq'dq\right| \leqslant \sup_{\Sigma\times\Sigma'}|S(q,q')|\left|\int_{\Sigma\times\Sigma'}\phi^*(q)\varphi(q')dqdq'\right|. \tag{B3}$$

The right-hand side of the inequality is finite because $S(q,q')$ is bounded in every bounded region of the qq'-plane. Now it is sufficient to show that for every sequence ϕ_n converging to zero in Φ, $\langle G|\phi_n\rangle\to 0$. This follows immediately by substituting ϕ_n in inequality (B3) for ϕ.

Thus $F(q,q')$ is the functional kernel of an operator $\mathcal{F}$: $\Phi\mapsto\Phi^{\times}$ and thus $\langle F|\varphi\rangle$ is itself a functional in $\Phi^{\times}$.

(Received 4 March 2003; accepted 4 May 2004;
published online 8 July 2004)

We minimize the functional $f\mapsto\int a f d\mu$ under the entropy condition $E(f)=-\int f\log f d\mu\geqslant E$, $\int f d\mu=1$ and $f\geqslant 0$, where $E\in\mathbf{R}$ is fixed. We prove that the minimum is attained for $f=e^{-sa}/\int e^{-sa}d\mu$, where $s\in\mathbf{R}$ is chosen such that $E(f)=E$. We apply the result on minimizing problems in pseudodifferential calculus, where we minimize the harmonic oscillator. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1767623]

I. INTRODUCTION

The aim of the article is to establish and prove basic results for a technique of minimization under entropy conditions which was used by von Neumann already in Ref. 9. We also give applications on minimizing pseudodifferential operators and Toeplitz operators. The entropy occurs frequently in mathematic-related topics. In statistic mechanics and quantum theory, the entropy appears as a functional acting on squares of wave functions. In statistics, such functions are interpreted as probability density functions (PDFs), and then the entropy is defined in a similar way as in quantum physics and statistic mechanics.

Roughly speaking, the entropy measures the concentration for a PDF, in the sense that the entropy is large when the PDF is not concentrated. The entropy therefore has a somewhat similar role as the variance. However, in contrast to the variance, the entropy is completely independent of the expected value and of any norm structure on the sample space.

The applications on pseudodifferential and Toeplitz operators, mentioned above, are based on the fact that Toeplitz operators may be considered as functionals acting on Wigner distributions (or coherent state transformed functions), which satisfy certain entropy conditions. The minimization result therefore applies immediately on Toeplitz operators, which in turn leads to lower bound results for pseudodifferential operators which may be approximated by Toeplitz operators.

In order to describe our results in more details, we recall the definition of the entropy. For a positive measure μ and an appropriate non-negative function $f\in L^1(d\mu)$, the entropy $E_\mu(f)$ is defined by

$$E_\mu(f)=-\int f\log f d\mu+\|f\|_{L^1(d\mu)}\log\|f\|_{L^1(d\mu)}. \tag{1.1}$$

(Cf. Ref. 7 or 8.) Here and in what follows, we let $0\log 0=0$. (We use the usual notation for function and distribution spaces, e.g., Ref. 5). It follows easily that $E_\mu(f)$ becomes large when f is not concentrated.

For an appropriate function a and real number E, we are then going to minimize the functional $f\mapsto\int a f d\mu$, when $0\leqslant f\in L^1(d\mu)$ satisfies

$$\|f\|_{L^1(d\mu)}=1,\quad E_\mu(f)\geqslant E, \tag{1.2}$$

and we prove that the minimum is attained when $f=f_s=e^{-sa}/\|e^{-sa}\|_{L^1(d\mu)}$, where s is chosen such that $E_\mu(f_s)=E$.

a)Electronic mail: joachim.toft@msi.vxu.se

It is not difficult to obtain an intuitive (but imperfect) proof of the result above. In fact, the Frechét derivatives of the left-hand sides of (1.2) are given by

$$h\mapsto\int h\,d\mu \quad \text{and} \quad h\mapsto-\int h(\log f+1)\,d\mu.$$

The Frechét derivative of the functional $f\mapsto\int af\,d\mu$ is given by $h\mapsto\int ah\,d\mu$, and it is intuitively clear that if f minimize $\int af\,d\mu$ under the conditions in (1.2) (with equality in the last condition), then the Frechét derivatives above should be linearly dependent, i.e.,

$$\int ah\,d\mu=C_1\int h\,d\mu+C_2\int h\log f\,d\mu$$

for every appropriate function h. This means that $a=C_1+C_2\log f$, and we obtain that $f=ce^{-sa}$, for some constants c and s, which are determined by (1.2).

Since the minimization result appears by such elementary computations, the method above has been used before. In fact, von Neumann used the technique already in Sec. 5.3 in Ref. 9, in order to solve certain problems in quantum mechanics. The arguments were thereafter used for example in thermodynamics. However, a strict proof that the minimum really exists and attains for $f=f_s$ seems to the author not to be well-known, hence, these missing links are presented here.

In order to describe our applications to Weyl operators and Toeplitz operators, we recall the definitions of such operators. Assume that $g\in\mathcal{S}(\mathbf{R}^n)$ is a unit vector with respect to L^2 and that $a\in\mathcal{S}(\mathbf{R}^{2n})$. Then, the Weyl and Toeplitz operators for a, $a^\omega(x,D)$ and $\mathrm{Tp}(a)=\mathrm{Tp}_g(a)$ respectively, are the continuous operators on $\mathcal{S}(\mathbf{R}^n)$, given by the formulas

$$\begin{aligned}a^\omega(x,D)f(x)&=(2\pi)^{-n}\int\int a((x+y)/2,\xi)f(y)e^{i\langle x-y,\xi\rangle}dy\,d\xi,\\(\mathrm{Tp}_g(a)f_1,f_2)&=\int a(-2X)(V_gf_1)(X)\overline{(V_gf_2)(X)}dX.\end{aligned}\tag{1.3}$$

Here, f, f_1, $f_2\in\mathcal{S}(\mathbf{R}^n)$ and $V_g:\mathcal{S}(\mathbf{R}^n)\to\mathcal{S}(\mathbf{R}^{2n})$ is the coherent state transform or the short time Fourier transform with respect to g which is defined as

$$(V_gf)(X)=(2\pi)^{-n/2}\int f(y/2-x)\overline{g(y/2+x)}e^{i\langle y,\xi\rangle}dy,\quad X=(x,\xi)\in\mathbf{R}^{2n},$$

and $(\cdot,\cdot)$ denotes the usual scalar product on $L^2(\mathbf{R}^n)$ (Ref. 1, 4, 8, 10, or 11). The definitions of $a^\omega(x,D)$ and $\mathrm{Tp}(a)$ extend to any $a\in\mathcal{S}'(\mathbf{R}^{2n})$, in which linear continuous operators from $\mathcal{S}(\mathbf{R}^n)$ to $\mathcal{S}'(\mathbf{R}^n)$ are obtained (Ref. 5, 11, or 12).

The relation which we use when approximating Weyl operators with Toeplitz operators is

$$\mathrm{Tp}_g(a)=(a*u_g)^\omega(x,D),\tag{1.4}$$

where $u_g=(2\pi)^{-n/2}V_g\check{g}$ and $\check{g}(x)=g(-x)$ (see Refs. 11 and 12). When discussing minimization for $a^\omega(x,D)$, we first use (1.4) in order to approximate $a^\omega(x,D)$ by $\mathrm{Tp}(a)$. Then, we apply the minimization properties under the entropy condition above on $\mathrm{Tp}(a)$ in (1.3) with $f=f_1=f_2$, using that $\nu=V_gf$ satisfies the entropy condition

$$\|\nu\|_{L^2}=\|f\|_{L^2},\quad \text{and}\quad E(|\nu|^2)\geqslant n(1+\log(\pi/2))\|f\|_{L^2}^2\tag{1.5}$$

(cf. Refs. 8 and 11). Here and in what follows, we use the notation E instead of E_μ when μ is the Lebesgue measure.

II. L^2-ESTIMATES FOR THE COHERENT STATE TRANSFORM

In this section, we give a review of some basic properties for the coherent state transform V_g, and sum up the results in the form of entropy inequalities. This material is included in order to make the presentation more self-contained, but all the results given here can be found in Ref. 8, for example.

We start to consider the map V_g in (1.1). We note that the map $(f,g)\mapsto V_g f$ is continuous from $\mathcal{S}(\mathbf{R}^n)\times\mathcal{S}(\mathbf{R}^n)$ to $\mathcal{S}(\mathbf{R}^{2n})$ which extends to a continuous map from $\mathcal{S}'(\mathbf{R}^n)\times\mathcal{S}'(\mathbf{R}^n)$ to $\mathcal{S}'(\mathbf{R}^{2n})$ (cf. Ref. 4 or 12). In particular, the following definition makes sense.

Definition 2.1 (see Ref. 8): Assume that $g\in L^2(\mathbf{R}^n)\backslash 0$. Then, $V_g:\mathcal{S}'(\mathbf{R}^n)\to\mathcal{S}'(\mathbf{R}^{2n})$ is called the *coherent state transform* associated with g.

In order to establish entropy conditions on functions of the type $V_g f$, we recall the following result by Lieb, which is based on sharp versions of Hausdorff–Young's inequality and Young's inequality (Ref. 2 or 3)

Theorem 2.2 (*see* Ref. 8): *Assume that $g\in L^2(\mathbf{R}^n)$, and that $q\in[2,\infty]$. Then V_g is continuous from $L^2(\mathbf{R}^n)$ to $L^q(\mathbf{R}^{2n})$, and*

$$\|V_g\|_{L^2\to L^q}\leqslant(2^{1/2}q^{-1/q}\pi^{1/q-1/2})^n. \tag{2.1}$$

Corollary 2.3: If $\nu=V_g f$ where $f,g\in L^2(\mathbf{R}^n)$ such that $\|g\|_{L^2}=1$, then the entropy $E(|\nu|^2)$ is positively homogeneous in ν of degree 2 and (1.5) *holds.*

A proof of Corollary 2.3 was essentially presented in Ref. 8. Since our choices of constants are different, here we recall the arguments.

Proof: The homogenous assertions are obvious. Since ν is bounded, by Theorem 2.2, it follows that $E(|\nu|^2)$ is defined, possibly equal to $+\infty$. Since $\epsilon\log|\nu|\leqslant|\nu|^\epsilon-1$ when $\epsilon>0$, it follows from (2.1) that

$$\int|\nu(x)|^2\log|\nu(x)|dx\leqslant\epsilon^{-1}\int(|\nu(x)|^{2+\epsilon}-|\nu(x)|^2)dx\leqslant\epsilon^{-1}((\pi/2)^{-n(1+\epsilon/2)}(\pi/(2+\epsilon))^n-1).$$

The result follows now if we let $\epsilon\to 0$.

III. MINIMIZATION UNDER ENTROPY CONDITIONS

In this section, we sum up some elementary properties of the entropy functional (see also Ref. 6), and then we discuss some minimization problems for linear functionals under entropy conditions.

Let $0\neq\mu$ be a positive σ-finite measure on the measure space $\mathcal{M}$. Then the entropy E_μ from

$$L^1_{\mu,+}=L^1_+(\mathcal{M},\mu)=\left\{0\leqslant f\in L^1(\mathcal{M},\mu);\int f\log_+ f\,d\mu<\infty\right\}$$

to $(-\infty,\infty]$ is defined by (1.1). Here, $\log_+(t)=\max(\log t,0)$. (Recall that $0\log 0=0$.) Let $\|\mu\|$ be the total mass of μ and denote by $I_\mu\subset(-\infty,\infty]$ the smallest interval which contains

$$\{\log(\mu(\Omega));\Omega\ \text{ is }\ \mu\text{-measurable and }\ \mu(\Omega)>0\}.$$

Proposition 3.1: $L^1_{\mu,+}$ is a convex cone and E_μ is positively homogeneous of degree 1 *on that set. It is concave in the sense that*

$$E_\mu(f+g)\geqslant E_\mu(f)+E_\mu(g),\quad f,g\in L^1_{\mu,+}. \tag{3.1}$$

The image under E_μ of $\{f\in L^1_{\mu,+};\|f\|=1\}$ equals I_μ.

Here and in what follows, we let $\|f\|=\|f\|_{L^1(d\mu)}$.

Proof: First, we observe that $E_\mu(tf)=tE_\mu(f)$ when $t\geqslant 0$ and $f\in L^1_{\mu,+}$. Since $t\log_+ t$ is a convex function on $\mathbf{R}_+$, it is easily seen that $L^1_{\mu,+}$ is a convex cone.

Let $f,g\in L^1_{\mu,+}$ with $\|f\|>0$, $\|g\|>0$. Jensen's inequality gives

$$\int \log(1+g/f) f d\mu/\|f\| \leqslant \log\left(\int (f+g) d\mu/\|f\| \right).$$

Hence,

$$\int f \log(f+g) d\mu - \|f\| \log\|f+g\| \leqslant \int f \log f d\mu - \|f\| \log\|f\|.$$

A similar inequality holds with the roles of f and g interchanged, and summing these inequalities and using that $\|f+g\| = \|f\| + \|g\|$, we get (3.1).

Next, we examine the values of $E_\mu(f)$ when $\|f\| = 1$. Since, by Jensen's inequality,

$$\exp\left(\int f \log(1/f) d\mu \right) \leqslant \int 1 d\mu = \|\mu\|,$$

when $\|f\| = 1$, it follows for such f that $E_\mu(f) \leqslant \log\|\mu\|$. If μ has a finite mass, then equality is obtained when f is constant. If μ has an infinite mass, then we may write $\mathcal{M}$ as a disjoint union of μ-measurable sets Ω_j, $j \geqslant 1$, of mass $\mu_j > 1$. Let $0 \leqslant t_j$ be a sequence with $\Sigma t_j = 1$ and define $f \in L^1_\mu$ by $f = t_j/\mu_j$ on Ω_j. Then $\|f\|_{L^1_\mu} = 1$ and $f \in L^1_{\mu,+}$, since $f \leqslant 1$. In order to prove that the entropy can take the value $+\infty$ we choose t_j such that $\Sigma t_j \log(\mu_j/t_j) = +\infty$. Since $\Sigma t_j \log \mu_j$ is positive this equality is fulfilled if, for example, $t_j = C/(j(\log(j+1))^2)$, where C is chosen such that $\Sigma t_j = 1$.

We now have proven that the right endpoint of I_μ is the maximal value of the entropy restricted to the set where $\|f\| = 1$. When considering lower bounds for the entropy, we first assume that $\mathcal{M}$ contains sets with arbitrarily small and positive μ-measures, such that $\inf I_\mu = -\infty$. Then, by choosing f equal to the characteristic function for sets Ω with $0 < \mu(\Omega)$ approaching 0, one finds that $\inf\{E_\mu(f)/\|f\|\}$ is also equal to $-\infty$.

If $\tau = \inf I_\mu > -\infty$, then there is a family $\{\omega_j\}$ of measurable sets in $\mathcal{M}$ such that

(1) $\mathcal{M} = \cup \omega_j$;
(2) $0 < \mu(\omega_j) < \infty$ for every j; and
(3) if $\omega_j = \omega_j^1 \cup \omega_j^2$, where ω_j^1 and ω_j^2 are μ-measurable sets, then $\mu(\omega_j^1) = \mu(\omega_j)$ or $\mu(\omega_j^2) = \mu(\omega_j)$.

In fact, if Ω is a set with finite μ-mass and Ω_j, $j = 1,...,N$, is any sequence of disjoint μ-measurable subsets of Ω with $\mu(\Omega_j) > 0$, then $\mu(\Omega) \geqslant \Sigma \mu(\Omega_j) \geqslant e^\tau N$, and the assertion follows.

Set $\mu_j = \mu(\omega_j)$ and let t_j be a sequence of nonnegative numbers with $\Sigma t_j = 1$. If $f \in L^1_{\mu,+}$ equals t_j/μ_j at x^j, then $\|f\| = 1$ and $E_\mu(f) = \Sigma t_j \log(\mu_j/t_j) \geqslant \tau$. If we choose f such that it is supported at a single set ω_j with μ-measure arbitrarily close to e^τ, we find that $\inf\{E_\mu(f)/\|f\|\} = \tau$. It is also clear that $E_\mu(f) = \tau$ for some f with $\|f\| = 1$ if and only if there is some point with μ-measure equal to e^τ.

In order to complete the proof, we observe that

$$L^1_{\mu,0} = \{f \in L^1_{\mu,+}; E_\mu(f) < \infty\}$$

is also a convex cone. This is obvious from the inequality

$$(f+g)\log(1/(f+g)) \leqslant f \log(1/f) + g \log(1/g).$$

Since $\{f \in L^1_{\mu,0}; \|f\| = 1\}$ is convex and E_μ is concave on that set, it follows that $\{E_\mu(f); \|f\| = 1\} \cap \mathbf{R}$ is connected, and the proof is complete.

In order to establish further properties for the entropy, it is convenient to use the notation

$$W_a = \{x \in \mathcal{M}; a(x) = \operatorname{ess\,inf}_\mu(a)\}, \tag{3.2}$$

where $\operatorname{ess\,inf}_\mu(a)$ is the essential infimum of a with respect to the measure μ.

Definition 3.2: $\mathcal{A}_\mu$ is the set of all real-valued and μ-measurable functions a such that $e^{-sa} \in L^1_\mu(\mathcal{M})$ for every $s>0$, and we set

$$F(s;a,\mu)=E_\mu(e^{-sa})/\|e^{-sa}\|_{L^1_\mu}, \quad s>0. \tag{3.3}$$

Note that F in Definition 3.2 makes sense since $e^{-sa}\in L^1_{\mu,+}$ when $a\in\mathcal{A}_\mu$ and $s>0$. It is easily seen that this function is smooth in s. It also follows from Proposition 2.1 that

$$F(s;a,\mu)\leqslant\log(\|\mu\|). \tag{3.4}$$

Lemma 3.3: Let $a\in\mathcal{A}_\mu$ and set $F(s)=F(s;a,\mu)$. If $\mu(W_a)=\|\mu\|$, then $F(s)\equiv\log(\|\mu\|)$. If $\mu(W_a)<\|\mu\|$ then $F(s)$ strictly decreases on $\mathbf{R}_+$ and

$$F(s)\to\log(\|\mu\|) \quad \textit{when} \quad s\to 0, \tag{3.5}$$

$$F(s)\to\log\mu(W_a) \quad \textit{when} \quad s\to+\infty. \tag{3.6}$$

Proof: We may assume that $\mu(W_a)<\|\mu\|$ since the assertion is trivial in the first case. Set $I(s)=\int e^{-sa}d\mu$ and $\vartheta(s)=\log(I(s))$ when $s>0$. Then g is smooth, convex, and

$$F(s)=\log(I(s))+\int sae^{-sa}d\mu/I(s)=\vartheta(s)-s\vartheta'(s). \tag{3.7}$$

Hence $F'(s)=-s\vartheta''(s)\leqslant 0$. Suppose that $F(s)$ is not strictly decreasing, then there are $0<s_1<s_2$ such that $F'=0$ on $[s_1,s_2]$. Hence, g is affine on this interval, and this implies that there is a constant β such that

$$\int e^{-s(a-\beta)}d\mu \text{ is constant when } s_1<s<s_2.$$

Since the second derivative of the left-hand side equals $\int(a-\beta)^2e^{-s(a-\beta)}d\mu$, it follows that $a=\beta$ a.e. with respect to μ, which contradicts the hypothesis. Hence, $F(s)$ is strictly decreasing.

Applying Lebesgue's theorem to the integral of e^{-sa} over the set where $a<0$ and the theorem of Beppo–Levi to the integral over the complement of that set, we find that $I(s)\to\|\mu\|$ as $s\to 0$. Since, by (3.7), $F(s)\geqslant\log(I(s))-\int_{a<0}e^{-2sa}d\mu/I(s)$ this gives (3.5) when $\|\mu\|=+\infty$. If instead $\|\mu\|<\infty$, then $\int sae^{-sa}d\mu\to 0$ as $s\to 0$, and this proves (3.5) again.

When proving (3.6) we set $\rho=\operatorname{ess\,inf}_\mu(a)$ and assume first that $\rho>-\infty$. Since $F(s;a,\mu)=F(s;a+C,\mu)$ for every constant C, we may assume that $\rho=0$. If $\mu(W_a)>0$, then $g(s)$ must be a bounded convex function on $(1,\infty)$, which implies that $F(s)-\vartheta(s)=-s\vartheta'(s)\to 0$ as $s\to\infty$. Since $\int e^{-sa}d\mu\to\mu(W_a)$ when $s\to+\infty$, we obtain (3.6).

If instead $\rho=\mu(W_a)=0$, then it follows from Lebesgue's theorem that $I(s)\to 0$, hence $\vartheta(s)\to-\infty$, when $s\to\infty$. Since $\mu(\{x;a(x)<\epsilon\})>0$ for every $\epsilon>0$ it follows that there are constants C_ϵ such that $\vartheta(s)\geqslant-\epsilon s-C_\epsilon$. This shows that $\vartheta(s)/s\to 0$ as $s\to\infty$. Let r be an arbitrary positive number. Then $(r+\vartheta(s))/s\to 0$ when $s\to\infty$ and $(r+\vartheta(s))/s$ is negative for large s. The derivative $(s\vartheta'(s)-\vartheta(s)-r)/s^2$ must therefore be positive for arbitrarily large values of s, and therefore for all large s since $s\vartheta'-\vartheta$ increases. Since r was arbitrary this proves that $s\vartheta'(s)-\vartheta(s)\to+\infty$ as $s\to+\infty$. Hence $F(s)\to-\infty$ as $s\to+\infty$.

It remains to consider the case when $\operatorname{ess\,inf}_\mu(a)=-\infty$. Then $\mu(W_a)=0$, and we have to prove that $F(s)\to-\infty$ as $s\to+\infty$. Assume that this is not true. Then there is a positive constant C such that $\vartheta(s)-s\vartheta'(s)\geqslant-C$, or, equivalently, $(\vartheta/s)'\leqslant C/s^2$. Hence, there is a positive constant ρ such that $\vartheta(s)\leqslant\rho s$, $s\geqslant 1$.

On the other hand, for every positive integer N we may find a constant C_N such that $\int e^{-sa}d\mu\geqslant e^{Ns}/C_N$. Hence,

$$Ns-\log(C_N)\leqslant g(s)\leqslant \rho s,\quad s\geqslant 1.$$

This gives a contradiction for large N, and the proof is complete.

Lemma 3.4: Assume that $a\in\mathcal{A}_\mu$ *and that* $f\in L^1_{\mu,+}$. *Then it is true that* $\max(-af,0)\in L^1_\mu$ *(which implies that* $\int af\,d\mu$ *is a well-defined element of* $\mathbf{R}\cup\{+\infty\}$*), and*

$$\int af\,d\mu\geqslant\frac{1}{s}\left(E_\mu(f)+\left(1-\int e^{-sa}d\mu\right)\int f\,d\mu\right),\quad s>0.$$

Proof: We may assume that $\int f\,d\mu=1$ for reasons of homogeneity. If $s>0$, then

$$af\geqslant\frac{1}{s}(f-f\log f-e^{-as}). \tag{3.8}$$

In fact, if $b=-as$ this inequality may be written $e^b-fb\geqslant f-f\log f$. The left-hand side is a convex function of b. When $f=f(x)>0$, it is stationary and equal to $f-f\log f$ when $b=\log f$. The first assertion follows now since f, $f\log_+ f$, $e^{-as}\in L^1_\mu$, and the second statement follows by integrating (3.8).

Definition 3.5: Assume that $E\in\mathbf{R}$ and $a\in\mathcal{A}_\mu$. Then, we let

$$H(E;\mu)\equiv\left\{f\in L^1_{\mu,+};\int f\,d\mu=1,E_\mu(f)\geqslant E\right\}, \tag{3.9}$$

$$m(E)=m(E;a,\mu)\equiv\inf_{f\in H(E;\mu)}\int af\,d\mu. \tag{3.10}$$

We are now ready to state the main result.

Theorem 3.6: *Let* μ *be a positive measure on* $\mathcal{M}$ *and* $a\in\mathcal{A}_\mu$. *Let* $m(E)=m(E;a,\mu)$ *be as in* (3.10) *when* $E\in\mathbf{R}$ *and set* $W_a=\{x;a(x)=\operatorname{ess\,inf}_\mu(a)\}$. *Then, the following is true*:

(i) *if* $E\leqslant\log(\mu(W_a))$ *then* $m(E)=\operatorname{ess\,inf}_\mu(a)$;

(ii) *if* $\log(\mu(W_a))<E<\log(\|\mu\|)$, *then*

$$m(E)=\int a\phi_s d\mu,$$

where $\phi_s=e^{-sa}/\int e^{-sa}d\mu$ *and* $s\in\mathbf{R}_+$ *is the unique solution to the equation* $E_\mu(\phi_s)=E$ *(cf. Lemma 3.3);*

(iii) *if* $\|\mu\|<\infty$ *and* $E=\log(\|\mu\|)$ *then*

$$m(E)=\int ad\mu/\|\mu\|,$$

and $m(E)=+\infty$ *when* $E>\log(\|\mu\|)$; and

(iv) *if* $\|\mu\|=+\infty$, *then* $m(E)$ *increases to* $+\infty$ *as* $E\to+\infty$.

The following lemmas are important for the proof of Theorem 3.6.

Lemma 3.7: If $E>\log(\|\mu\|)$, *then* $H(E;\mu)=\emptyset$, *and when* $E\leqslant\log(\|\mu\|)$ *then* $H(E;\mu)$ *is a nonempty convex set in* $L^1_{\mu,+}$.

Proof: This is an immediate consequence of Proposition 3.1.

Lemma 3.8: Let $a\in\mathcal{A}_\mu$, $s\in\mathbf{R}_+$ *and* ϕ_s *be the same as in Theorem 3.7. Assume that* E *is a real number such that* $E_\mu(\phi_s)<E$. *Then,*

$$\int a\phi_s d\mu\leqslant\int af\,d\mu\quad\forall f\in H(E;\mu). \tag{3.11}$$

We first prove Theorem 3.6, assuming that Lemma 3.8 holds, and postpone the proof of Lemma 3.8.

Proof of Theorem 3.6: (i) The condition implies that $\mu(W_a)>0$. Since this number must be less than infinity, it follows that $f\in H(E;\mu)$ if f is equal to the characteristic function of W_a divided by $\mu(W_a)$. Hence $m(E)\leqslant \int f d\mu = \operatorname{ess\,inf}_\mu(a)$. Since the opposite inequality is also fulfilled, this proves our assertion.

(ii) It follows from Lemma 3.3 that there is a unique s such that $E_\mu(\phi_s)=E$. If $t>s$ then $E_\mu(\phi_t)<E$ in view of that lemma, and it follows from Lemma 3.8 that

$$\int a\phi_t d\mu \leqslant \int af d\mu \quad \text{when} \quad f\in H(E;\mu).$$

Since $\phi_s\in H(E;\mu)$ we have proven that

$$\int a\phi_t d\mu \leqslant m(E) \leqslant \int a\phi_s d\mu,$$

and when $t\searrow s$ it follows that $m(E)=\int a\phi_s d\mu$.

(iii) It follows from Lemma 3.3 that $E_\mu(\phi_t)\nearrow \log(\|\mu\|)$ when $t\searrow 0$. Hence, by Lemma 3.8

$$\int a\phi_t d\mu \leqslant \int af d\mu$$

when $f\in H(E;\mu)$. If $f=1/\|\mu\|$ then $f\in H(E;\mu)$ and the right-hand side equals $\int a d\mu/\|\mu\|$, which is the limit of the left-hand side as $t\to 0$. Hence, $m(E)=\int a d\mu/\|\mu\|$. The second part of (iii) follows since $H(E;\mu)$ is empty when $E>\log(\|\mu\|)$ in view of Proposition 3.1.

(iv) The assertion is an immediate consequence of Lemma 3.4 with $s=1$, which shows that there is a constant $C=C_{a,\mu}$ such that $m(E)\geqslant E-C$.

Proof of Lemma 3.8: Let W_a be as in (3.2). If $\mu(W_a)=\|\mu\|$ then $\|\mu\|<\infty$, a is constant and (3.11) holds. It therefore follows from Lemma 3.3 that we may assume that $F(s)=E_\mu(\phi_s)$ is strictly decreasing. By replacing E by a smaller number if necessary, we may assume that E is an interior point of I_μ. After a change of notation we may also assume that $s=1$ and for simplicity we denote ϕ_1 by ϕ.

We first consider the case when $\mathcal{M}=\cup_1^N \omega_j$, where $N<\infty$, $\mu_j\equiv\mu(\omega_j)<\infty$ for every $j=1,...,N$, and a and f should be constant on each ω_j. For notational convenience, we will consider the numbers μ_j as the positive point masses of a measure μ on the set $\{1,...,N\}$, and we treat a and f as functions on $\{1,...,N\}$. Since the assertion of the lemma is invariant under renumbering and addition of a constant to a, we may assume that $0=a(1)\leqslant a(2)\leqslant\cdots\leqslant a(N)$.

Assume that (3.11) is not fulfilled. Then, we have for some value on E and some $f\geqslant 0$ that

$$\int af d\mu < \int a\phi d\mu, \quad \int f d\mu = 1, \quad E_\mu(\phi)<E\leqslant E_\mu(f). \tag{3.12}$$

We want to prove that (3.12) leads to a contradiction. By perturbing the $a(j)$ and μ slightly we may assume that $a(j)<a(k)$, when $j<k$. We may also assume that $\int af d\mu$ is minimal among all integrals of functions satisfying (3.12).

We shall first prove that

$$f(j)>0 \quad \text{when} \quad 1\leqslant j\leqslant N. \tag{3.13}$$

Assume that this is not true so that the set J of j with $f(j)=0$ is not empty. We claim that there is a function κ with

$$\int \kappa d\mu = 0, \quad \kappa(j)>0 \quad \text{if } j\in J \quad \text{and} \quad \int a\kappa d\mu<0. \tag{3.14}$$

Assume that such a function does not exist. Then,

$$\sum t_j = 0, \quad t_j > 0 \quad \text{when } j \in J \Rightarrow \sum a(j)t_j \geqslant 0.$$

Hence, there is a real number α and $\epsilon_j \geqslant 0$ with $\epsilon_j = 0$ when $j \notin J$ such that $a(j) = \alpha + \epsilon_j$. The condition that $0 = a(1) < a(2) \cdots < a(N)$ implies $\alpha = 0$, $\epsilon_j = a(j)$, and $J = \{2,...,N\}$. Hence $f(j) = 0$ when $j > 1$ and it follows from (3.12) that $f(1) = 1/\mu_1$. If $b = \int e^{-a} d\mu$ then

$$\int \phi(a + \log b) d\mu = E_\mu(\phi) < E \leqslant E_\mu(f) = \log \mu_1.$$

Since the left-hand side is greater than or equal to $\log b \int \phi d\mu = \log b \geqslant \log \mu_1$ we arrive at a contradiction. This proves that (3.14) has a solution.

Let κ be any solution to (3.14), ϵ be a small positive number and set

$$f_\epsilon(j) = f(j) + \epsilon\kappa(j).$$

Then, $\int f_\epsilon d\mu = 1$ and $f_\epsilon > 0$ when ϵ is small. We have $\int a f_\epsilon d\mu = \int a f d\mu + \epsilon \int a\kappa d\mu < \int a f d\mu$, which by our assumption that $\int a f d\mu$ is minimal implies that

$$E_\mu(f_\epsilon) < E \leqslant E_\mu(f). \tag{3.15}$$

On the other hand, a simple computation allows us to conclude that there are positive constants C and C' such that

$$E_\mu(f_\epsilon) - E_\mu(f) \geqslant -\sum_{j \in J} \epsilon\kappa_j \log(\epsilon\kappa_j)\mu_j - C\epsilon \geqslant \left(\sum_{j \in J} \kappa_j \mu_j \right) \epsilon \log(1/\epsilon) - C'\epsilon.$$

Since the right-hand side is positive when ϵ is sufficiently small, we again obtain a contradiction, and may assume from now on that (3.13) holds.

Let h be an arbitrary function satisfying $\int h d\mu = 0$ and set $f_\epsilon = f + \epsilon h$ when $|\epsilon|$ is sufficiently small. Then, $\int f_\epsilon d\mu = 1$. The assumptions on f allow us to conclude that

$$\frac{d}{d\epsilon} E_\mu(f_\epsilon) > 0 \quad \text{when } \epsilon = 0 \Rightarrow \frac{d}{d\epsilon} \int a f_\epsilon d\mu \geqslant 0 \quad \text{when } \epsilon = 0.$$

Computing derivatives and setting $g(j) = 1 + \log f(j)$, we may write this as

$$\sum h(j)\mu_j = 0, \quad \sum g(j)h(j)\mu_j < 0 \Rightarrow \sum a(j)h(j)\mu_j \geqslant 0.$$

This implies that there are constants λ and ρ with $\lambda \leqslant 0$ such that $a(j) = \lambda g(j) + \rho$. Since the $a(j)$ do not form a constant sequence it follows that $\lambda = -1/\sigma$ for some positive σ. This allows us to conclude that $f = \phi_\sigma$, where $\phi_\sigma = e^{-\sigma a}/I(\sigma)$ and $I(\sigma) = \int e^{-\sigma a} d\mu$.

It is now easy to complete the proof in this case. Let $F(t) = E_\mu(\phi_t)$. It follows from (3.12) that

$$I'(1)/I(1) < I'(\sigma)/I(\sigma), \quad F(1) < F(\sigma).$$

Since $I'(t)/I(t)$ increases with t in view of the convexity of $\log(I(t))$ the first inequality implies that $1 < \sigma$. This contradicts the second inequality since $F(t)$ decreases in view of Lemma 3.3. This proves the lemma in this case.

When proving the lemma in the general case, we shall reduce the proof to the discrete case, considered above. Assume that (3.11) is not fulfilled. Then, we may find $\epsilon > 0$ and $f \in H(E;\mu)$ such that

$$E_\mu(\phi)<E-\epsilon, \quad \int a f d\mu \leqslant \int a\phi d\mu - \epsilon. \tag{3.16}$$

In a first step, we want to reduce the proof to the case when μ is a bounded measure and f is a bounded function. To that end, we let Ω_j, $j=1,2,...$, be an increasing family of μ-measurable sets with characteristic functions χ_j such that $\mu(\Omega_j)<\infty$, and $\int f\chi_j d\mu \to \int f d\mu$ and $\sup \int e^{-sa}|\chi_j - 1|d\mu \to 0$ as $j\to\infty$, where the supremum is taken over all $1/2\leqslant s\leqslant 3/2$. Set (for j large)

$$\mu_j = \chi_j \mu, \quad g_j = \frac{f}{1+f/j}, \quad f_j = \frac{g_j}{\int g_j d\mu_j}, \quad \phi^j = \frac{e^{-a}}{\int e^{-a} d\mu_j}.$$

Then, $\int f_j d\mu_j = 1$ and $f_j \to f$ point wise as $j\to\infty$. We claim that

$$\liminf_{j\to\infty} E_{\mu_j}(f_j) \geqslant E, \quad \limsup_{j\to\infty} \int a f_j d\mu_j \leqslant \int a f d\mu, \tag{3.17}$$

$$\limsup_{j\to\infty} E_{\mu_j}(\phi^j) \leqslant E_\mu(\phi), \quad \liminf_{j\to\infty} \int a\phi^j d\mu_j \geqslant \int a\phi d\mu. \tag{3.18}$$

Assume that these assertions are proven. Then, $f_j \in H(E-\epsilon/2;\mu_j)$ when j is large. The inequalities in (3.16) hold then with f, μ, ϕ replaced by f_j, μ_j, ϕ^j, after ϵ and E have been replaced by some smaller numbers. Thus, when proving that (3.16) leads to a contradiction, we may assume from the beginning that f is bounded and that $\int d\mu < \infty$.

When proving the first inequality in (3.17), we consider $\int g_j(\log g_j)\chi_j d\mu$. Let $\Omega = \{x \in \mathcal{M}; f(x)>1\}$. Then, $g_j(\log g_j)\chi_j$ increases in Ω with j to $f\log f$. Hence, by Beppo–Levi's theorem,

$$\int_\Omega g_j \log g_j d\mu_j \to \int_\Omega f\log f d\mu = \int f \log_+ f d\mu.$$

In Ω^c, one has for large j

$$g_j \log g_j = \frac{f}{1+f/j}\log f + O(1/j)f,$$

which implies that $\int_{\Omega^c} g_j \log g_j d\mu_j \to \int_{\Omega^c} f\log f d\mu$. Since $f_j = g_j/c_j$, where $c_j\to 1$, the first inequality in (3.17) follows.

When proving the second inequality in (3.17), we may replace f_j by g_j, and then it suffices to prove

$$\int_{a\geqslant 0} a g_j d\mu_j \to \int_{a\geqslant 0} a f d\mu, \quad \int_{a<0} a g_j d\mu_j \to \int_{a<0} a f d\mu. \tag{3.19}$$

In the set where $a\geqslant 0$, it is true that $a g_j \chi_j$ increases to af as $j\to\infty$. The first limit in (3.19) is therefore a consequence of Beppo–Levi's theorem. If χ is the characteristic function for the set where $a<0$, then $\chi a f \in L^1_\mu$ by Lemma 3.4. Since $|\chi a g_j \chi_j| \leqslant |\chi a f|$, the second limit in (3.19) is a consequence of Lebesgue's theorem. This proves (3.17).

The assertion (3.18) follows from Lebesgue's theorem since $\phi\log\phi$ and $a\phi$ are μ-integrable.

Now we go back to (3.16), assuming as we may that $\int d\mu<\infty$ and that f is bounded. Let $a_j = a$ when $|a|<j$ and $a_j = 0$ if $|a|\geqslant j$. Set $\phi^j = e^{-a_j}/\int e^{-a_j} d\mu$. Some elementary applications of the theorems of Lebesgue and Beppo–Levi together with Lemma 3.4 show that

$$E_\mu(\phi^j)\to E_\mu(\phi) \quad \text{when } j\to\infty$$

and that $\int a_j f d\mu \leqslant \int a_j \phi^j d\mu - \epsilon/2$ for j large. After replacing ϵ by a smaller number, we may therefore assume in (3.16) that a is bounded. By another argument of approximation, we may also assume that f and a are simple functions. Then, we may also replace μ in (3.16) by a measure supported in a finite set. The first part of the proof now gives us a contradiction. Hence, (3.11) must hold, and the proof is complete.

IV. SOME APPLICATIONS OF ENTROPY ESTIMATES

In this section, we shall use the results from the previous sections and give examples of entropy estimates. We show for example that the lowest eigenvalue of the harmonic oscillator may be computed by considering entropy estimates.

As a preparation, we minimize the functional

$$L^1_+(\mathbf{R}^m)=L^1_+(\mathbf{R}^m,dx)\ni f\mapsto \int |x|^p f(x)dx, \quad p>0,$$

under the condition (1.2), with $E_\mu(f)=E(f)$. Here, we recall that $E(f)$ is the entropy with respect to the Lebesgue measure. By Theorem 3.6, the minimum is attained when

$$f(x)=\phi_s(x)=e^{-s|x|^p}/\|e^{-s|\cdot|^p}\|_{L^1},$$

and s is chosen such that $E(\phi_s)=E$. We notice that $I(s)=\int e^{-s|x|^p}dx$ is homogeneous of degree $-m/p$ in s when $s>0$. Therefore,

$$\int |x|^p \phi_s(x)dx=-I'(s)/I(s)=-\vartheta'(s)=m/sp, \tag{4.1}$$

where $\vartheta(s)=\log(I(s))$. The condition that $E(\phi_s)=E$ means that $\vartheta(s)-s\vartheta'(s)=E$. Since $\vartheta'(s)=I'(s)/I(s)=-m/sp$ this is equivalent to $\int e^{-s|x|^p}dx=e^{E-m/p}$. We may solve the last equation in s, and by straightforward computations it follows that

$$s^{-1}=(\omega_m p^{-1}\Gamma(m/p))^{-m/p}e^{Ep/m-1},$$

where ω_m is the area of the sphere S^{m-1}. By inserting this into (4.1), Theorem 3.6 gives

$$\inf_{E(f)\geqslant E}\int |x|^p f(x)dx=\int |x|^p\phi_s(x)dx=m/sp=(\omega_m p^{-1}\Gamma(m/p))^{-p/m}mp^{-1}e^{Ep/m-1}. \tag{4.2}$$

We shall now apply this result to the Toeplitz operator $\mathrm{Tp}(a)$ when $a(X)=|X|^{2p}$ and $X=(x,\xi)\in\mathbf{R}^{2n}$. We recall from the introduction that $\mathrm{Tp}(a)=\mathrm{Tp}_g(a)$ makes sense as a continuous operator from $\mathcal{S}(\mathbf{R}^n)$ to $\mathcal{S}'(\mathbf{R}^n)$ for any $a\in\mathcal{S}'(\mathbf{R}^{2n})$ and $g\in\mathcal{S}(\mathbf{R}^n)\backslash 0$.

Lemma 4.1: Assume that $f, g\in\mathcal{S}(\mathbf{R}^n)$ such that $\|f\|_{L^2}=\|g\|_{L^2}=1$, and set $a(X)=|X|^{2p}$, where $p>0$, and $X\in\mathbf{R}^{2n}$. Then,

$$\begin{aligned}(\mathrm{Tp}_g(a)f,f)&\geqslant 4^p\pi^{-p}(n/p)p^{p/n}\{\Gamma(n)/\Gamma(n/p)\}^{p/n}e^{E(|V_g f|^2)p/n-1}\\&\geqslant 2^p p^{p/n-1}\{\Gamma(n)/\Gamma(n/p)\}^{p/n}e^{p-1}n.\end{aligned} \tag{4.3}$$

Proof: We apply (4.2) when $m=2n$ and p is replaced by $2p$, observing that $a(-2X)=2^{2p}|X|^{2p}$. Since $\omega_{2n}=2\pi^n/(n-1)!$, the first inequality in (4.3) follows immediately from (1.3), (1.5), and (4.2). The second inequality follows from Corollary 2.3.

Next, we shall apply Lemma 4.1 in order to minimize the harmonic oscillator $H=\Sigma_{j=1}^n(x_j^2+D_j^2)$. We note that the Weyl symbol for H is the function $h(x,\xi)=\Sigma_{j=1}^n(x_j^2+\xi_j^2)$.

Proposition 4.2: Let $u=V_g g$, where $g\in\mathcal{S}(\mathbf{R}^n)$ is even or odd and satisfies $\|g\|_{L^2}=1$. Then,

$$(Hf,f)\geqslant 4n\pi^{-1}e^{E(|V_g f|^2)/n-1}+4^{-1}(\pi/2)^{n/2}(\Delta u)(0)\geqslant 2n+4^{-1}(\pi/2)^{n/2}(\Delta u)(0),$$

for every unit vector $f\in\mathcal{S}(\mathbf{R}^n)$. Here, $\Delta=\Delta_{(x,\xi)}=\Sigma(\partial_{x_j}^2+\partial_{\xi_j}^2)$ is the Laplace operator in the (x,ξ)-coordinates.

In the proof of Proposition 4.2, we shall use some properties for Fourier transformations. In what follows, we let $\hat{f}$ be the Fourier transform for $f\in\mathcal{S}(\mathbf{R}^n)$, given by

$$\hat{f}(\xi)=(\mathcal{F}f)(\xi)=(2\pi)^{-n/2}\int f(x)e^{-i\langle x,\xi\rangle}dx.$$

Proof: Let $\nu=(2\pi)^{-n/2}V_g\check{g}$, and let $X=(x,\xi)\in\mathbf{R}^{2n}$. Since g is even or odd, it follows easily that u and ν are even. This implies that $h*\nu=c_1h+c_2$, where

$$c_1=\int \nu(X)dX \quad\text{and}\quad c_2=\int \nu(X)|X|^2dX.$$

In order to evaluate c_1, we recall the definition of V_g. Then, an application of Fourier's inversion formula gives

$$c_1=(2\pi)^{-n}\int\int\int g(x-y/2)\overline{g(x+y/2)}e^{i\langle y,\xi\rangle}dydxd\xi=\|g\|_{L^2}^2=1.$$

In order to evaluate c_2, we note that $u(x,\xi)=(8\pi)^{n/2}\hat{\nu}(-2\xi,2x)$. It follows now by another application of Fourier's inversion formula that $c_2=-4^{-1}(\pi/2)^{n/2}(\Delta u)(0)$. Hence $h*\nu=h-4^{-1}(\pi/2)^{n/2}(\Delta u)(0)$, and we obtain the result if we combine this equality with Lemma 4.1 and (1.4). The proof is complete.

If we let $u(x,\xi)=(2/\pi)^{n/2}e^{-(|x|^2+|\xi|^2)}$ in Proposition 4.2, then it follows that $\Delta u(0)=-4n(2/\pi)^{n/2}$, which gives us the inequality $(Hf,f)\geqslant n\|f\|_2^2$, as it should.

We shall finish this section by giving a bound from below for the sum of the entropies of a function and its Fourier transform.

Proposition 4.3: Assume that $f\in\mathcal{S}(\mathbf{R}^n)$. Then

$$E(|f|^2)+E(|\hat{f}|^2)\geqslant n(1+\log\pi)\|f\|_2^2. \tag{4.4}$$

Remark 4.4: The entropy $E(g)$ is not invariant under changes of coordinates. In fact, if $0\leqslant g\in\mathcal{S}(\mathbf{R}^n)$, $\|g\|_1=1$ and $g_T(x)=\det(T)g(Tx)$, where T is an invertible linear transformation on $\mathbf{R}^n$, then

$$\int |g_T(x)|\log(|g_T(x)|)dx=\int |g(x)|\log(|g(x)|)dx+\log(|\det T|). \tag{4.5}$$

Since the Fourier transform of f_T is given by $\hat{f}_{\hat{T}}$, where $\hat{T}$ is the adjoint of T^{-1}, it follows however that the left-hand side of (4.4) is invariant under changes of coordinates.

Proof of Proposition 4.3: We may assume that $\|f\|_2=1$. Set $D_p=(2\pi)^{1/p-1/2}p^{-1/2p}p'^{1/2p'}$, where $2<p$ and $1/p+1/p'=1$. Then the sharp Hausdorff–Young's inequality gives

$$\int |\hat{f}|^p d\xi\leqslant D_p^{np}\left(\int |f|^{p'}dx\right)^{p/p'} \tag{4.6}$$

(Ref. 2 or 3). Taylor expansions give

$$D_p = 1-(1+\log\pi)(p-2)/4+O((p-2)^2),$$

$$\int |\hat{f}|^p d\xi = 1-(p-2)(E(|\hat{f}|^2)/2+O((p-2)^2),$$

$$\int |f|^{p'} dx = 1+(p-2)(E(|f|^2)/2+O((p-2)^2).$$

The proposition follows if these expansions are inserted into (4.6).

ACKNOWLEDGMENTS

This article is a review of some parts of the author's Ph.D. thesis (see Ref. 11). The author is very grateful to his supervisor Professor Anders Melin for introducing him to this subject, for his support and encouragement, as well as constructive criticism. The author is also grateful to Professor Lars Hörmander at Lund University for a careful reading and giving valuable advices. Finally, he thanks Mikael Signahl and his father, Rolf Toft, for an enthusiastic reading of the paper, and giving valuable advice concerning the language.

Yang–Mills instantons with Lorentz violation

Don Colladay[a] and Patrick McDonald[b]
Division of Natural Sciences, New College of Florida, 5700 N. Tamiami Trail, Sarasota, Florida 34243

(Received 31 October 2003; accepted 6 May 2004;
published online 8 July 2004)

An analysis is performed of instanton configurations in pure Euclidean Yang–Mills theory containing small Lorentz-violating perturbations that maintain gauge invariance. Conventional topological arguments are used to show that the general classification of instanton solutions involving the topological charge is the same as in the standard case. Explicit solutions are constructed for general gauge invariant corrections to the action that are quadratic in the curvature. The value of the action is found to be unperturbed to lowest order in the Lorentz-violating parameters. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1767624]

I. INTRODUCTION

As is well known, solving pure Yang–Mills theory involves a complicated set of nonlinear partial differential equations. Using a series of clever arguments, some exact solutions to the pure Yang–Mills field equations formulated in four-dimensional Euclidean space were first constructed in the mid 1970s.[1] The complete set of finite action solutions was eventually classified using what is now known as the ADHM construction.[2] Subsequently, instanton physics has stimulated much research in both physics and mathematics.[3]

In pure four-dimensional Yang–Mills theory, Lorentz symmetry and renormalizability coupled with gauge invariance implies that the Lagrange density naturally takes the form of the trace of the square of the curvature tensor. If pure Yang–Mills theory arises as the low-energy limit of some more fundamental theory, it is possible that real physical fields obey a slightly modified version of the conventional equations in which some of the underlying symmetries are spontaneously broken. Specifically, Lorentz and *CPT* invariance, as well as gauge invariance can be affected.[4]

The original motivation for this possibility arose in string theory,[5] and more recently has been analyzed within the context of noncommutative geometry.[6] A framework called the standard model extension (SME) incorporates general fundamental symmetry violations that are consistent with coordinate reparametrization invariance[7] within the context of quantum field theory.[8] Usually, it is convenient to restrict the full range of possible violations to maintain certain subgroups of the original symmetry group. For instance, translational invariance, gauge invariance, and power-counting renormalizability are typically assumed to avoid many of the potential inconsistencies that may arise without these assumptions. This restriction produces a minimal version of the full SME.

The aim of this article is to analyze the instanton solutions for a Yang–Mills action in the presence of Lorentz violation. The main result is that the general classification of the instanton solutions involving the topological charge still applies when Lorentz violation is present. In addition, the value of the Euclidean action is found to be invariant to lowest order in the Lorentz-violating perturbations. Specific calculations are performed within the framework of the minimal SME, but some of the results are in fact more general. In Sec. II, the notation and conventions are described. The existence of static solutions in arbitrary dimensions is examined in Sec. III. Section IV contains the general theory of instantons with Lorentz violation, while Sec. V restricts to the specific example of SU(2) instantons with unit winding number. Section VI summarizes the

[a]Electronic mail: colladay@ncf.edu
[b]Electronic mail: ptm@virtu.sar.usf.edu

results. The Appendix contains an exact solution for the perturbed instantons in the presence of a spatially isotropic Lorentz-violating background tensor.

II. NOTATION AND CONVENTIONS

The conventions used for the Yang–Mills gauge theory are presented in this section. Let G be a compact Lie group with Lie algebra $L(G)$. The base manifold is taken to be $M=\mathbf{R}^4$ and the gauge potential components for the principle G-bundle $P\rightarrow M$ are denoted

$$A_\mu(x)\equiv A_\mu^a(x)L_a\,, \tag{1}$$

where the L_a are hermitian generators of a Lie algebra defined by

$$[L_a\,,L_b]=iC_{abc}L_c\,, \tag{2}$$

with structure constants C_{abc} antisymmetric in all indices. The normalization of the generators is fixed by imposing

$$Tr(L_aL_b)=\tfrac{1}{2}\,\delta_{ab}\,. \tag{3}$$

The associated unitary Lie group elements that generate gauge transformations are denoted by

$$U(x)=e^{-i\omega^a(x)L_a}. \tag{4}$$

These act on the gauge fields via the transformation rule

$$A^\mu(x)\rightarrow U(x)A^\mu(x)U^{-1}(x)-\frac{i}{g}U(x)\partial^\mu U^{-1}(x). \tag{5}$$

The field strength tensor is defined as

$$F^{\mu\nu}=-\frac{i}{g}[D^\mu,D^\nu], \tag{6}$$

where the covariant derivative is taken as $D^\mu=\partial^\mu+igA^\mu$. The field strength transforms under gauge transformations as

$$F^{\mu\nu}\rightarrow U(x)F^{\mu\nu}U^{-1}(x). \tag{7}$$

The dual of F is defined as

$$\tilde{F}_{\mu\nu}\equiv\tfrac{1}{2}\epsilon_{\mu\nu\alpha\beta}F^{\alpha\beta}, \tag{8}$$

where the Levi–Civita tensor is defined such that $\epsilon^{0123}=+1$.

In four-dimensional Minkowski space, with metric $g=\mathrm{diag}(1,-1,-1,-1)$, the most general gauge invariant[9] and power counting renormalizable action is[8]

$$S_M(A)=-\frac{1}{2}\int d^4xTr\left[F^{\mu\nu}F_{\mu\nu}+(k_F)_{\mu\nu\alpha\beta}F^{\mu\nu}F^{\alpha\beta}+(k_{AF})_\kappa\epsilon_{\kappa\lambda\mu\nu}\left(A^\lambda F^{\mu\nu}-\frac{2}{3}igA^\lambda A^\mu A^\nu\right)\right], \tag{9}$$

where the k_F and k_{AF} terms are small constant background parameters. Gauge invariance fixes these parameters to be singlets under the action of the gauge group. The k_{AF} terms present theoretical difficulties associated with negative contributions to the energy[10] even in the Abelian case, and are therefore not considered further in this work. On the other hand, the k_F terms do not cause similar problems provided a concordant frame,[11] in which the parameters are small enough,

is used. The parameters k_F satisfy the symmetries of the Riemann curvature tensor[12] with vanishing total trace. This means that there are 19 independent coefficients that parameterize the violation.

III. STATIC SOLUTIONS

In the conventional case, finite-action static solutions are ruled out in all but four spatial dimensions by considering various integrals of the field strength products motivated by the form of the energy momentum tensor.[13] This result also holds in the Lorentz-violating case due to an analogous argument that will now be presented.

The partially symmetrized energy momentum tensor arising from the action in Eq. (9) generalized to n spatial dimensions is given by the expression

$$\Theta^{\mu\nu}=2Tr[-F^{\nu}{}_{\gamma}(F^{\mu\gamma}+k_F^{\mu\gamma\alpha\beta}F_{\alpha\beta})+\tfrac{1}{4}\eta^{\mu\nu}F_{\alpha\beta}(F^{\alpha\beta}+k_F^{\alpha\beta\lambda\kappa}F_{\lambda\kappa})], \tag{10}$$

and explicitly satisfies $\partial_\mu\Theta^{\mu\nu}=0$. Choosing the static gauge in which A^k is independent of time, the following constraints on finite energy solutions can be derived using the field equations

$$\int dx^n TrF_{0k}(F^{0k}+k_F^{0k\alpha\beta}F_{\alpha\beta})=0, \tag{11}$$

and

$$(n-4)\int dx^n TrF_{ij}(F^{ij}+k_F^{ij\alpha\beta}F_{\alpha\beta})=0. \tag{12}$$

Methods analogous to the ones presented in Ref. 13. have been applied to obtain the above results. These relations imply that no static solutions with nonvanishing action[14] exist when $n\neq 4$. This result is the same as the conventional situation.

IV. INSTANTON SOLUTIONS

To study the instanton solutions, the action is analytically continued to Euclidean space using imaginary time, and a new Euclidean action $S_E\equiv -iS_M$ is defined. The conventions used in this article are obtained using the replacements $x^0\rightarrow -ix_E^0$, $x^k\rightarrow x_E^k$, while the gauge field components are altered to $A^0\rightarrow iA_E^0$, and $A^k\rightarrow A_E^k$. Each time component of k_F also gets multiplied by a factor of i to define its Euclidean counterpart. The Euclidean action becomes (dropping all E subscripts)

$$S(A)=+\frac{1}{2}\int d^4xTr[(F^{\mu\nu}F^{\mu\nu})+(k_F)^{\mu\nu\alpha\beta}F^{\mu\nu}F^{\alpha\beta}], \tag{13}$$

with metric $\delta^{\mu\nu}$. The Euler–Lagrange equations of motion (for this Euclidean action) are

$$[D^\mu,F^{\mu\nu}+k_F^{\mu\nu\alpha\beta}F^{\alpha\beta}]=0, \tag{14}$$

while the Bianchi identity

$$[D^\mu,\tilde{F}^{\mu\nu}]=0, \tag{15}$$

follows from the definition of F in terms of the gauge potential.

The topological charge q is defined as in the usual case

$$q=\frac{g^2}{16\pi^2}\int d^4xTr\tilde{F}^{\mu\nu}F^{\mu\nu}, \tag{16}$$

and conventional arguments indicate that q remains an integer, even in the presence of Lorentz violation. Specifically, the identity

$$\tfrac{1}{4} Tr \tilde{F}^{\mu\nu} F^{\mu\nu} = \partial^{\mu} X^{\mu}, \tag{17}$$

where

$$X^{\mu} \equiv \frac{1}{4} \epsilon^{\mu\nu\lambda\kappa} Tr(A^{\nu} F^{\lambda\kappa} - \tfrac{2}{3} i g A^{\nu} A^{\lambda} A^{\kappa}), \tag{18}$$

ensures that the topological charge depends only on the pure-gauge boundary conditions satisfied by the potential far away from the nonvanishing curvature of the instantons. The quantity q is therefore the first Pontryagin number that corresponds to the winding number of the map from the gauge group to the three sphere at large $|x|$. The specific form of the action does not matter, provided that it is in fact gauge invariant, and that finiteness of the action restricts the curvature from contributing to the topological charge at the boundary. This means that the properties of the topological charge should be preserved, even in the more general case of the SME that includes nonrenormalizable, but gauge invariant corrections to the pure Yang–Mills sector. In particular, since any physical theory of noncommutative gauge fields is argued to be equivalent to a standard gauge theory in the context of the SME,[6] the topological charge should remain integral in realistic noncommutative Yang–Mills theories.

To make further progress, only lowest-order terms in k_F are retained. This approximation has the advantage of retaining terms that are likely to be relevant for future experiments while neglecting the theoretical complications of the nonlinearities introduced by higher-order k_F contributions. An approach that allows explicit calculation to all orders in k_F would be interesting because there is the potential of discovering novel nonperturbative features, but this is beyond the scope of the current article.

For calculational purposes, it is convenient to introduce the quantity[15]

$$F'^{\mu\nu} = F^{\mu\nu} + \tfrac{1}{2} k_F^{\mu\nu\alpha\beta} F^{\alpha\beta}. \tag{19}$$

The action then takes the conventional form in terms of F' to lowest order in k_F. Consider the inequality

$$\frac{1}{2} \int d^4x Tr(F' \mp \tilde{F}')^2 \geqslant 0. \tag{20}$$

This implies that

$$S \geqslant \pm \frac{1}{2} \int d^4x Tr\left[F^{\mu\nu} \tilde{F}^{\mu\nu} + \frac{1}{2} (k_F^{\mu\nu\alpha\beta} + \tilde{k}_F^{\mu\nu\alpha\beta}) F^{\mu\nu} \tilde{F}^{\alpha\beta} \right], \tag{21}$$

where $\tilde{k}_F^{\mu\nu\alpha\beta} \equiv \frac{1}{4} \epsilon^{\mu\nu\lambda\kappa} k_F^{\lambda\kappa\rho\sigma} \epsilon^{\rho\sigma\alpha\beta}$ is defined as the dual to k_F. The upper sign is chosen for $q > 0$ and the lower sign for $q < 0$.

The first term is proportional to the topological charge while the second term generates a correction to the lower bound on S. Provided k_F is small, the correction term will be much smaller than the topological charge term and the perturbed instantons will be close to the conventional ones. This implies that the general classification of the instanton solutions in terms of the winding number will remain unaltered.

It is evident from the form of the correction to the lower bound that splitting the coefficients k_F according to their duality properties will be useful. This decomposition is analogous to the separation of the Riemann tensor of general relativity into a Ricci tensor and a trace-free Weyl conformal tensor. The anti-self-dual k_F components correspond to the Ricci tensor components while the self-dual k_F terms correspond to the Weyl conformal tensor. For the case $k_F = -\tilde{k}_F$, the

lower bound on the action is independent of continuous perturbations of F that do not change the topological charge by an integer, and the minimum is attained for the modified duality condition

$$F' \simeq \pm \tilde{F}', \tag{22}$$

where the symbol $\simeq$ is used to denote an equality to lowest order in k_F. To construct the perturbed solutions, the potential can be expanded about the conventional ($k_F=0$) self-dual and anti-self-dual potentials, denoted by $A_{\rm SD}$ and $A_{\rm ASD}$. The corresponding field tensors are written similarly as $F_{\rm SD}$ and $F_{\rm ASD}$. It remains to show that solutions to the modified duality condition that are consistent with the Bianchi identity exist. The anti-self-duality condition on k_F implies that it must be of the form

$$k_F^{\mu\nu\alpha\beta} = \Lambda_k^{[\mu[\alpha}\delta^{\nu]\beta]}, \tag{23}$$

where $\Lambda_k^{\mu\nu} = \frac{1}{2}k_F^{\alpha\mu\alpha\nu}$ is a traceless symmetric matrix that depends on the trace components of k_F. In fact, the explicit solution can be guessed since the form of the correction to the action is related to the conventional action as described in the skewed coordinate system $\tilde{x}^\mu \equiv x^\mu + \Lambda_k^{\mu\nu}x^\nu$. These terms are exactly the ones that may be transferred to other sectors using an appropriate field redefinition,[16] so it is not surprising that they yield a conventional version of pure Yang–Mills theory when described in skewed coordinates. Note that this does not imply the absence of physical effects arising from an anti-self-dual k_F term in the action. Redefining coordinates effects all fields, not just the Yang–Mills gauge potential, so if the instantons are expressed in terms of new coordinates, the Lorentz violation will show up in the Lagrangian for other particle species that are coupled to the instantons.

The explicit form for the perturbed self-dual instanton gauge potentials are given by

$$A_+^\mu(x) \simeq A_{\rm SD}^\mu(\tilde{x}) + \Lambda_k^{\mu\nu}A_{\rm SD}^\nu(x), \tag{24}$$

yielding a perturbed field tensor

$$F_+^{\mu\nu} \simeq F_{\rm SD}^{\mu\nu}(\tilde{x}) - \Lambda_k^{[\mu\alpha}\delta^{\nu]\beta}F_{\rm SD}^{\alpha\beta}(x) \simeq F_{\rm SD}^{\mu\nu}(\tilde{x}) - \tfrac{1}{2}k_f^{\mu\nu\alpha\beta}F_{\rm SD}^{\alpha\beta}(x), \tag{25}$$

that satisfies the modified duality condition (22). Note that the approximation is in fact not necessary in this case, but the notation becomes rather cumbersome for general k_F. The exact solution for the O(3) rotationally invariant component of k_F (which is in fact anti-self-dual) is presented in the Appendix.

Next, the case $k_F = \tilde{k}_F$ is considered. This condition implies that k_F has the symmetries of the Weyl conformal tensor with vanishing single traces. In this case, the simple argument given above for anti-self-dual k_F fails because the lower bound on the action in Eq. (21) is not a topological invariant, and is therefore sensitive to small perturbations in the field strengths. In this case, there is no obvious duality condition and the equations of motion must be solved directly for the perturbed instanton solutions. A solution to lowest order in k_F always exists, since the equations reduce to a set of linear second-order elliptic partial differential equations for the gauge fields. The propagators for spin-1 particles in instanton background fields have been previously constructed[19] and are exactly what is needed to formally solve the equations. An explicit example is presented in the next section.

For general k_F, the perturbed field strength may be written as a small perturbation of either the $F_{\rm SD}$ or the $F_{\rm ASD}$ solutions. Remarkably, the approximate value of the action is the same as the conventional case. For example, an instanton that is close to self-dual yields an action of

$$S \simeq \frac{1}{2}\int d^4x Tr(F^2 + k_F^{\mu\nu\alpha\beta}F_{\rm SD}^{\mu\nu}F_{\rm SD}^{\alpha\beta}). \tag{26}$$

The first term is the conventional action and is invariant to lowest order in any perturbation of the fields due to the fact that the action is at an extremum for the self dual solutions. The O(4) symmetry of the conventional self-dual solutions imply that the second term must vanish, since only observer Lorentz-invariant components of k_F can contribute after the trace is performed. These terms are zero due to the Lorentz-violating nature of k_F. The same arguments apply to the instantons that are close to the anti-self-dual solutions. The numerical value of the action to leading order in k_F is therefore given by the conventional formula

$$S \simeq (8\pi^2/g^2)|q|, \tag{27}$$

for the general case involving arbitrary k_F values. This argument can also be generalized to nonrenormalizable corrections to the pure Yang–Mills sector involving powers of the curvature tensor. This works because any higher-order Lorentz-violating corrections must vanish when the O(4) symmetric solutions are substituted into the action. As mentioned previously, any realistic theory of noncommutative gauge fields is argued to be equivalent to a subset of the SME,[6] therefore it can be inferred that any realistic theory of noncommutative Yang–Mills fields should not affect the value of the Euclidean action for the instantons to lowest order in the noncommutative Lorentz-violating $\theta^{\mu\nu}$ parameters.

V. INSTANTONS IN SU(2)

To analyze instanton structure, an explicit map is constructed from the asymptotic three-sphere S^3 of Euclidean space into the Yang–Mills gauge group G. The winding number of this map determines the topological charge and therefore the general instanton structure according to the lower bound of the action in Eq. (21). For any simple Lie group G, a theorem by Bott[17] proves that any mapping of S^3 into G can be continuously deformed into a mapping into an SU(2) subgroup of G. It is therefore sufficient to fix SU(2) as the gauge group to construct explicit solutions that will exhibit the generic effect of Lorentz violation on the instanton structure.

Here, we work with the explicit solutions for $q=1$, or unit topological charge. The conventional solutions are denoted using the self-dual, antisymmetric tensor $\tau^{\mu\nu}$, where $\tau^{0i} \equiv \sigma^i$ and $\tau^{ij} \equiv \epsilon^{ijk}\sigma^k$, in terms of the conventional Pauli matrices σ^i. This definition provides an explicit embedding of $\mathrm{SU}(2) \rightarrow \mathrm{SU}(2) \times \mathrm{SU}(2)$ which is isomorphic to O(4). The commutation relations

$$[\tau^{\mu\nu}, \tau^{\alpha\beta}] = 2i(\delta^{\mu\alpha}\tau^{\nu\beta} - \delta^{\mu\beta}\tau^{\nu\alpha} - \delta^{\nu\alpha}\tau^{\mu\beta} + \delta^{\nu\beta}\tau^{\mu\alpha}), \tag{28}$$

and trace relations

$$Tr(\tau^{\mu\nu}\tau^{\alpha\beta}) = 2(\delta^{\mu\alpha}\delta^{\nu\beta} - \delta^{\mu\beta}\delta^{\nu\alpha} + \epsilon^{\mu\nu\alpha\beta}), \tag{29}$$

follow from the above definition. These quantities may also be expressed using the relation $\tau^{\mu\nu} = i(\tau^{\nu}\tau^{\mu\dagger} - \delta^{\mu\nu})$, where $\tau^{\mu} \equiv (i, \boldsymbol{\sigma})$. The self-dual gauge field corresponding to $q=1$ can be expressed as

$$A^{\mu}_{\mathrm{SD}} = -\frac{\tau^{\mu\nu}x^{\nu}}{g(\rho^2 + x^2)}, \tag{30}$$

and the associated field strength is

$$F^{\mu\nu}_{\mathrm{SD}} = \frac{2\rho^2}{g(\rho^2 + x^2)^2}\tau^{\mu\nu}. \tag{31}$$

The parameter ρ determines the instanton size, while the center of the instanton is taken to be at the origin for simplicity. The anti-self-dual solutions are the parity transform of the above fields. These can be expressed using $\tilde{x} = (x^0, -\mathbf{x})$ as $A^0_{\mathrm{ASD}}(x) = A^0_{\mathrm{SD}}(\tilde{x})$, $A^i_{\mathrm{ASD}}(x) = -A^i_{\mathrm{SD}}(\tilde{x})$, $F^{0i}_{\mathrm{ASD}}(x)$

$=-F^{0i}_{\rm SD}(\tilde{x})$, and $F^{ij}_{\rm ASD}(x)=F^{ij}_{\rm SD}(\tilde{x})$. This transformation may also be implemented by the transformation $\tau^{\mu\nu}\to\overline{\tau}^{\mu\nu}$ defined by $\tau^{0i}\to\overline{\tau}^{0i}=-\tau^{0i}$, and $\tau^{ij}\to\overline{\tau}^{ij}=\tau^{ij}$. A useful expression for this quantity is $\overline{\tau}^{\mu\nu}=i(\tau^{\nu\dagger}\tau^{\mu}-\delta^{\mu\nu})$.

For the case $k_F=-\tilde{k}_F$, the modified solutions have already been expressed using Eq. (24) and do not require more explicit computation. For the case $k_F=\tilde{k}_F$, the field equations (14) and (15) must be solved directly since no obvious duality condition can be determined from Eq. (21) due to the noninvariant lower bound. To accomplish this, the vector potential is expanded as a perturbation of the self-dual[18] solution $A=A_{\rm SD}+A_k$ and the linear terms in A_k are retained in the equation of motion. The Bianchi identity (15) is automatically satisfied and the equations of motion (14) become (in the Lorentz gauge $\partial^\mu A^\mu=0$)

$$[D^\nu_{\rm SD},[D^\nu_{\rm SD},A^\mu_k]]+2ig[F^{\mu\nu}_{\rm SD},A^\nu_k]-ig[D^\mu_{\rm SD},[A^\nu_{\rm SD},A^\nu_k]]=j^\mu_k, \tag{32}$$

where

$$j^\mu_k\equiv k_F^{\mu\nu\alpha\beta}[D^\nu_{\rm SD},F^{\alpha\beta}_{\rm SD}], \tag{33}$$

and $D^\mu_{\rm SD}\equiv\partial^\mu+igA^\mu_{\rm SD}$ is the covariant derivative in the conventional self-dual instanton background.

This equation can be solved by performing a convolution of j_k with the corresponding propagator for spin-1 particles in an external instanton field. This propagator has been formally constructed,[19] but the explicit form is rather unwieldy and cannot be easily expressed analytically. An alternative approach is adopted here that uses a combination of the propagator approach and a direct substitution technique. First, the solution is studied to lowest order in ρ^2/x^2, corresponding to the asymptotic region far from the self-dual instanton curvature density. This provides the general tensorial structure of the instanton correction that serves as an ansatz for general values of x^2, generating a simple form for the solution to the problem.

It is convenient to perform a gauge transformation to the singular gauge using $U(x)=-ix\cdot\tau^\dagger/x$ so that the potential is better behaved for large x. The transformed potential becomes

$$\overline{A}^\mu_{\rm SD}=-\frac{\rho^2\overline{\tau}^{\mu\nu}x^\nu}{gx^2(\rho^2+x^2)}, \tag{34}$$

with associated field strength

$$\overline{F}^{\mu\nu}_{\rm SD}=\frac{4\rho^2}{g(\rho^2+x^2)^2}\overline{\tau}^{[\mu\alpha}(1/4\,\delta^{\nu]\alpha}-x^{\nu]}x^\alpha/x^2). \tag{35}$$

In this gauge, the transformed $\overline{j_k}$ is

$$\overline{j}^\mu_k=\frac{48\rho^2}{gx^2(\rho^2+x^2)^3}k_F^{\mu\nu\alpha\beta}\overline{\tau}^{\alpha\gamma}I^{\gamma\nu\beta}(x), \tag{36}$$

where

$$I^{\gamma\nu\beta}\equiv x^\gamma x^\nu x^\beta-\tfrac{1}{6}x^2(\delta^{\nu\gamma}x^\beta+\delta^{\gamma\beta}x^\nu+\delta^{\beta\nu}x^\gamma), \tag{37}$$

is a totally symmetric tensor.

The advantage of working in the singular gauge is that the above expressions are all quadratic in ρ. This means that to lowest order in ρ^2/x^2, the propagator may be approximated by the free field Green's function

$$G_0(x,y)=\frac{1}{4\pi^2(x-y)^2}, \tag{38}$$

satisfying $\partial^\mu\partial^\mu G_0 = -\delta^{(4)}(x-y)$. The perturbed potential to lowest order in ρ^2/x^2 (in the singular gauge) is then given by

$$\overline{A}_k^\mu \simeq -\int d^4y G_0(x,y)\overline{j}_k^\mu(y). \tag{39}$$

This integral can be performed using standard field theoretic integration techniques. The result of the computation is

$$\overline{A}_k^\mu \simeq -\frac{4\rho^2}{gx^6} k_F^{\mu\nu\alpha\beta}\overline{\tau}^{\alpha\gamma} I^{\gamma\nu\beta}(x). \tag{40}$$

It can be seen that the tensorial structure of $\overline{j_k}$ has been preserved by the convolution with G_0. Some complications arise due to divergent logarithms that cancel out in the computation, but these do not cause theoretical difficulties because the validity of the solution can be verified by direct substitution into the equation of motion. It remains to check that the Lorentz gauge condition is satisfied by this solution. Direct calculation shows that this is the case provided k_F is self-dual, the current case of interest. This indicates that this solution method works for the terms that cannot be removed using a reparametrization of the coordinates.

For general values of x^2, an unknown scalar function is included in the expression (40) to produce an ansatz of the form

$$\overline{A}_k^\mu = -\frac{4\rho^2}{g} f(x^2) k_F^{\mu\nu\alpha\beta}\overline{\tau}^{\alpha\gamma} I^{\gamma\nu\beta}(x). \tag{41}$$

Remarkably, upon substitution into the equation of motion (32), the tensorial structure factors out and the following second-order linear differential equation is found for f

$$x^4(\rho^2+x^2)f'' + 5x^2(\rho^2+x^2)f' + 3\rho^2 f = -\frac{3}{(\rho^2+x^2)^2}. \tag{42}$$

This equation has a regular singular point at $x=0$, causing the homogeneous solutions to be badly behaved at the origin. Moreover, any contribution to the homogeneous equation of motion would correspond to a solution to the conventional equations of motion in an instanton background and is therefore not of interest in the present context. On the other hand, the particular solution is well behaved at the origin as can be verified using the following series expansion for f about $x=0$

$$f(x^2) = \frac{1}{\rho^6}\sum_{n=0}^{\infty} a_n \left(\frac{x^2}{\rho^2}\right)^n, \tag{43}$$

and expanding the right-hand side of Eq. (42) as

$$-\frac{3}{(\rho^2+x^2)^2} = -\frac{3}{\rho^4}\sum_{n=0}^{\infty}(-1)^n(n+1)\left(\frac{x^2}{\rho^2}\right)^n, \tag{44}$$

valid for $x^2/\rho^2<1$. The resulting recursion relation for the a_n coefficients is

$$a_{n+1} = \frac{3(-1)^n}{n+4} - \frac{n}{n+2}a_n, \tag{45}$$

with $a_0=-1$. The first few terms give

$$f(x^2)\approx 1/\rho^6\left(-1+\frac{3}{4}\left(\frac{x^2}{\rho^2}\right)-\frac{17}{20}\left(\frac{x^2}{\rho^2}\right)^2+\frac{37}{40}\left(\frac{x^2}{\rho^2}\right)^3-\cdots\right), \tag{46}$$

demonstrating the finite behavior near the origin. For large x^2, a similar expansion in ρ^2/x^2 shows that the function approaches $f(x^2)\to 1/x^6$ as expected.

Transforming the perturbed potential back to the regular gauge yields

$$A_k^\mu \simeq \frac{2\rho^2 x^2}{3g} f(x^2) k_F^{\mu\nu\alpha\beta}\tau^{\alpha\gamma}(\delta^{\gamma\nu}x^\beta+\delta^{\beta\gamma}x^\nu-\delta^{\nu\beta}x^\gamma)], \tag{47}$$

verifying that A_k is zero at the origin in the regular gauge as is required by continuity of the gauge field. The perturbation term behaves asymptotically as $\sim 1/x^3$, and therefore explicitly does not contribute to the topological charge as expected. The resulting correction to the curvature can be computed; however, the specific form is not particularly illuminating. Specifically, there seems to be no obvious generalized duality condition satisfied by F analogous to the situation for $k_F = -\tilde{k}_F$.

VI. SUMMARY

Instantons have long been studied for systems obeying strict Lorentz invariance. In this article, the structure of Yang–Mills instantons in the presence of small Lorentz-violating background fields that maintain gauge invariance is studied for the first time. No new nonzero action static solutions are present in $n\neq 4$ spatial dimensions as is apparent from Eq. (12). The gauge invariance ensures that the conventional pure-gauge asymptotic behavior maintains the same general structure as in the conventional case. This means that conventional arguments can be applied to deduce the quantization of the topological charge. The generality of the SME can then be exploited to infer similar results regarding realistic noncommutative gauge theories.

Specific perturbed instanton solutions for the action considered in this article are split into two categories that depend on the duality properties of the Lorentz-violating background tensor. For the anti-self-dual k_F case, a reparametrization of the coordinates can be used to construct deformed instantons that satisfy a modified duality condition. The perturbed theory is isomorphic to the conventional Yang–Mills theory in this case so the instanton structure is also isomorphic. The O(3) rotationally invariant term of this class is worked out exactly in the Appendix.

When k_F is self-dual, the conventional lower bound argument involving the action fails and the equations of motion must be solved directly. To lowest order in k_F, the resulting equations are linear in the correction to the vector potential and can be formally solved using the Euclidean propagator for a spin-1 particle in an instanton background. For explicit calculation, it turns out to be more practical to first deduce the general tensorial structure in the asymptotic region, then generalize the solution to arbitrary position. General arguments imply that the action is unaltered to lowest order in k_F, but it can be seen from the exact solution given in the Appendix that higher-order corrections are, in general, nonzero.

APPENDIX: EXACT SOLUTION FOR O(3) SYMMETRIC CASE

In this appendix, an exact solution (all orders in k_F) for the case of spatial rotationally invariant k_F is presented. In this case, the tensor k_F can be expressed in terms of one independent parameter $\tilde{\kappa}$ as

$$k_F^{0i0j}=-k_F^{i00j}=-k_F^{0ij0}=k_F^{i0j0}=-\frac{\tilde{\kappa}}{2}\delta^{ij}, \tag{A1}$$

and

$$k_F^{ijkl}=\tilde{\kappa}(\delta^{ik}\delta^{jl}-\delta^{il}\delta^{jk}). \tag{A2}$$

It is convenient to introduce the notation $\tilde{\kappa}=\sin 2\theta$ and the action takes the form

$$S=\frac{1}{2}\int d^4x Tr[F^{\mu\nu}F^{\mu\nu}+\sin 2\theta(F^{ij}F^{ij}-2F^{0i}F^{0i})]. \tag{A3}$$

To construct the analog of the conventional self-dual solution, consider the following inequality

$$\frac{1}{2}\int d^4x Tr\{2[\cos\theta F_{-}^{0i}-\sin\theta F_{+}^{0i}]^2+[\cos\theta F_{-}^{ij}+\sin\theta F_{+}^{ij}]^2\}\geqslant 0, \tag{A4}$$

with $F_{\pm}^{\mu\nu}\equiv F^{\mu\nu}\pm\tilde{F}^{\mu\nu}$. This can be rearranged to give the relation

$$S\geqslant\frac{8\pi^2}{g^2}q\cos 2\theta. \tag{A5}$$

The inequality is saturated when

$$\tilde{F}^{0i}=\frac{1-\tan\theta}{1+\tan\theta}F^{0i}, \tag{A6}$$

and

$$\tilde{F}^{ij}=\frac{1+\tan\theta}{1-\tan\theta}F^{ij}. \tag{A7}$$

A solution to these equations with $q=1$ is provided by the gauge potential

$$A^0=(1+\tan\theta)A^0_{\mathrm{SD}}(\tilde{x}),\quad A^i=(1-\tan\theta)A^i_{\mathrm{SD}}(\tilde{x}), \tag{A8}$$

where $\tilde{x}^\mu\equiv((1+\tan\theta)x^0,(1-\tan\theta)x^i)$. The resulting field strength is

$$F^{0i}=(1-\tan^2\theta)F^{0i}_{\mathrm{SD}}(\tilde{x}),\quad F^{ij}=(1-\tan\theta)^2F^{ij}_{\mathrm{SD}}(\tilde{x}). \tag{A9}$$

The value of the resulting action can be computed directly from the curvature, yielding the expected value

$$S=\frac{8\pi^2}{g^2}q\cos 2\theta. \tag{A10}$$

In fact, this construction applies to any conventional instanton solution, since the spatially rotational invariant k_F term corresponds to a shift in the speed of light for the gauge fields. It is therefore possible to construct the above solutions by rescaling the time and spatial coordinates appropriately. Note that this does not mean that observable effects are absent, since interactions between the instantons and other particles with conventional Lorentz properties may lead to physical effects. The action is reduced relative to the conventional case by a factor of $\cos\theta$ which is, in fact, second order in the k_F coefficients. This result is in agreement with general arguments stating that the numerical value of the action is stable to a lowest-order perturbation in k_F.

(Received 20 April 2004; accepted 4 May 2004; published online 8 July 2004)

The concept of partially invariant solutions is discussed in the framework of the group analysis of models derived from the Nambu–Goto action. In particular, we consider the nonrelativistic Chaplygin gas and the relativistic Born–Infeld theory for a scalar field. Using a general systematic approach based on subgroup classification methods, nontrivial partially invariant solutions with defect structure $\delta=1$ are constructed. For this purpose, a classification of the subgroups of the Lie point symmetry group, which have generic orbits of dimension 2, has been performed. These subgroups allow us to introduce the corresponding symmetry variables and next to reduce the initial equations to different nonequivalent classes of partial differential equations and ordinary differential equations. The latter can be transformed to standard form and, in some cases, solved in terms of elementary and Jacobi elliptic functions. This results in a large number of new partially invariant solutions, which are determined to be either reducible or irreducible with respect to the symmetry group. Some physical interpretation of the results in the area of fluid dynamics and field theory are discussed. The solutions represent traveling and centered waves, algebraic solitons, kinks, bumps, cnoidal and snoidal waves. [DOI: 10.1063/1.1767625]

I. INTRODUCTION: MODELS DERIVED FROM THE NAMBU–GOTO ACTION

A few years ago, Jackiw[1] thoroughly analyzed and reviewed the subject of the motion of a d-brane in $(d+1)$ spatial dimensions moving in $(d+1,1)$-dimensional space–time, and showed that it is described by the Nambu–Goto action. This has generated quite a lot of interest (see, e.g., Refs. 2–4, and has led to the investigation of symmetry properties of relativistic and nonrelativistic models in field theory.[5] Exploiting this connection, we will extend the analysis in Ref. 5 to the case when these models admit partially invariant solutions. According to Ref. 1, we start by introducing the variables of the target space-time $X^{\mu}=(X^0,X^1,\ldots,X^d,X^{d+1})$ in which the d-brane moves, and the world-volume variables $\phi^{\alpha}=(\phi^0,\phi^1,\ldots,\phi^d)$ which parametrize the d-dimensional extended object evolving in ϕ^0. Then the motion of the d-brane is governed by the Nambu–Goto action

$$I_{\mathrm{NG}}=\int d\phi^0\, d\phi^1\cdots d\phi^d\, \sqrt{(-1)^d \det\left(\frac{\partial X^{\mu}}{\partial \phi^{\alpha}}\frac{\partial X_{\mu}}{\partial \phi^{\beta}}\right)}. \tag{1}$$

The action (1) is parametrization invariant, and different choices of parametrization lead to various

a)Electronic mail: grundlan@crm.umontreal.ca
b)Electronic mail: hariton@dms.umontreal.ca

field theory models. Recently, this concept has been applied to the theory of strings and superstrings.[6,7] In particular, it has been established that for strings moving in flat space–time, the Nambu–Goto action (1) reduces to the Polyakov action

$$S_P = -\frac{T}{2}\int d^2\xi \sqrt{-\det(g)}\, g^{\alpha\beta}\partial_\alpha X^\mu \partial_\beta X^\nu \eta_{\mu\nu}, \tag{2}$$

where $g_{\alpha\beta}$ is the world-sheet metric $g_{\alpha\beta}=\partial_\alpha X \partial_\beta X$. Varying the action with respect to the metric leads to the stress tensor

$$T_{\alpha\beta}=\partial_\alpha X \partial_\beta X - \tfrac{1}{2} g_{\alpha\beta} g^{\gamma\delta}\partial_\gamma X \partial_\delta X. \tag{3}$$

Classically, both actions are equivalent.

In particular, we are interested in the two specific cases represented by the light-cone parametrization, which leads to a nonrelativistic fluid dynamical system (Chaplygin gas), and the Cartesian parametrization, which leads to a relativistic Born–Infeld model. In both cases, we choose $(X^1,X^2,\ldots,X^d)$ to coincide with $(\phi^1,\phi^2,\ldots,\phi^d)$ and rename them for physical interpretation as the spatial position vector $\mathbf{r}$ in d dimensions. The remaining variables X^0, X^{d+1}, and ϕ^0 are treated separately for each of the two parametrizations.

A. Chaplygin gas

For the light-cone parametrization, we define

$$X^+=\frac{1}{\sqrt{2}}(X^0+X^{d+1})=t, \quad X^-=\frac{1}{\sqrt{2}}(X^0-X^{d+1})=\theta(\mathbf{r},t), \tag{4}$$

and then identify t with $\sqrt{2\lambda}\,\phi^0$, where $\lambda>0$ is a constant. The Nambu–Goto action (1) then reduces to the action[1]

$$I_\lambda = -2\sqrt{\lambda}\int dt\, d\mathbf{r}\, \sqrt{\theta_t+\tfrac{1}{2}(\nabla\theta)^2}, \tag{5}$$

which in turn leads to an Euler–Lagrange equation of the form

$$\frac{\partial}{\partial t}\left(\frac{1}{\sqrt{\theta_t+\frac{1}{2}(\nabla\theta)^2}}\right)+\nabla\cdot\left(\frac{\nabla\theta}{\sqrt{\theta_t+\frac{1}{2}(\nabla\theta)^2}}\right)=0. \tag{6}$$

Equation (6) is equivalent to the system of differential equations governing the Chaplygin gas[8]

$$\rho_t+(\nabla\rho)\cdot(\nabla\theta)+\rho\,(\nabla^2\theta)=0, \tag{7a}$$

$$\theta_t+\frac{1}{2}(\nabla\theta)^2=\frac{\lambda}{\rho^2}, \tag{7b}$$

where $\lambda>0$ is a constant. Here, $\rho(\mathbf{r},t)$ is the density and $\theta(\mathbf{r},t)$ the velocity potential of an ideal nonrelativistic fluid of zero vorticity in which the pressure P is related to the density by the polytropic relation[1]

$$P=\frac{-2\lambda}{\rho}. \tag{8}$$

The vanishing vorticity allows us to write the velocity $\mathbf{v}$ of the fluids as the gradient of the potential: $\mathbf{v}=\nabla\theta$. Here, Eqs. (7a) and (7b) correspond, respectively, to the equation of continuity

and Euler's force equation, where the current is given by $j=\rho\nabla\theta$. In the case where $\lambda\neq 0$, it is possible to eliminate the variable ρ by using Eq. (7b) to express it in terms of θ. In this way, system (7) reduces to Eq. (6).

Equations (7a) and (7b) can also be considered in the case where $\lambda=0$. In this case, the variable ρ becomes completely independent, and the Eqs. (7a) and (7b) are decoupled. The force equation (7b) can be solved for θ, and then the continuity equation (7a) solved for ρ. A detailed discussion of the symmetry group in one spatial dimension can be found in Ref. 9. This case is not derived from the Nambu–Goto d-brane. Subsequently, in this article, we will consider only the interactive case $(\lambda\neq 0)$.

B. Born–Infeld model

For the Cartesian parametrization, the variable X^0 is renamed ct, where c is the speed of light, and is also identified with $c\phi^0$. The remaining target space variable X^{d+1} is renamed $\theta(\mathbf{r},t)/c$, which is a function of $\mathbf{r}$ and t. The Nambu–Goto action (1) then reduces to the action[1]

$$I_a=-a\int dt\,d\mathbf{r}\,\sqrt{c^2-(\partial_\mu\theta)^2}, \tag{9}$$

and the corresponding Euler-Lagrange equation is found to be

$$\partial^\nu\left(\frac{1}{\sqrt{c^2-(\partial_\mu\theta)^2}}\,\partial_\nu\theta\right)=0. \tag{10}$$

Equation (10) corresponds to the equations

$$\rho_t+\nabla\cdot\left(\nabla\theta\,\sqrt{\frac{\rho^2c^2+a^2}{c^2+(\nabla\theta)^2}}\right)=0, \tag{11a}$$

$$\theta_t+\rho c^2\,\sqrt{\frac{c^2+(\nabla\theta)^2}{\rho^2c^2+a^2}}=0. \tag{11b}$$

This is the Born–Infeld theory for a scalar field θ discussed in Ref. 1. This theory is related to the nonlinear electrodynamics approach of Born and Infeld,[10,11] where the equations of motion were derived from the Lagrangian

$$L_{\mathrm{BI}}=b^2[1-\sqrt{1-(\mathbf{E}^2-\mathbf{B}^2)/b^2-(\mathbf{E}\cdot\mathbf{B})^2/b^4}]. \tag{12}$$

Here, $\mathbf{E}$ and $\mathbf{B}$ are the spatial components of the electric and magnetic fields, respectively. The connection between Lagrangians (9) and (12), in the case where $b^2=-a$, is described by the following relation:

$$\frac{\mathbf{E}^2-\mathbf{B}^2}{b^2}+\frac{(\mathbf{E}\cdot\mathbf{B})^2}{b^4}=-(c^2-(\partial_\mu\theta)^2)\pm 2\sqrt{c^2-(\partial_\mu\theta)^2}. \tag{13}$$

It should be noted that at the limit where $c\to\infty$ the relativistic Born–Infeld Lagrangian and equations reduce to the nonrelativistic Chaplygin Lagrangian and equations discussed previously, where λ is identified with $a^2/2$. A solution $\theta_{\mathrm{NR}}(\mathbf{r},t)$ of the Chaplygin equation (6) is thus related to its relativistic counterpart $\theta_R(\mathbf{r},t)$ for the Born–Infeld equation (10). This will be discussed in further detail in Sec. IV E.

The majority of known solutions in the literature for the Chaplygin and Born–Infeld equations are simple Riemann waves and their superpositions.[12] In those cases, the equations were generally solved only in the hyperbolic region

TABLE I. Commutation table for the Lie algebra L spanned by the vector fields (15).

$X\backslash Y$	$\mathbf{D_1}$	$\mathbf{D_2}$	$\mathbf{B}$	$\mathbf{Z}$	$\mathbf{P_1}$	$\mathbf{P_0}$
$\mathbf{D_1}$	0	0	B	0	$-P_1$	$-2P_0$
$\mathbf{D_2}$	0	0	$-B$	$-2Z$	$-P_1$	0
$\mathbf{B}$	$-B$	B	0	0	$-Z$	$-P_1$
$\mathbf{Z}$	0	$2Z$	0	0	0	0
$\mathbf{P_1}$	P_1	P_1	Z	0	0	0
$\mathbf{P_0}$	$2P_0$	0	P_1	0	0	0

$$c^2+(\theta_x)^2-\frac{(\theta_t)^2}{c^2}>0. \tag{14}$$

Solutions of these equations obtained from the symmetry reduction method are not necessarily required to obey differential inequality (14), as can be seen in Ref. 5.

C. Objectives and organization

Our objective in this article is to study the partially invariant solutions of the Chaplygin and Born–Infeld systems of equations based on the Lie algebra L of the group of symmetries G of the Chaplygin system. We look for new classes of solutions which are not necessarily G-invariant. Partially invariant solutions are of interest for the following reasons. They can be constructed from a simple algorithm similar to the one employed for the G-invariant case. Also, partially invariant solutions may be used to solve larger classes of initial value problems than the G-invariant solutions. Finally, once a partially invariant solution is found under a subgroup G_0, it is possible to verify whether or not it is invariant under some subgroup of the full group G. Such invariant solutions would be considerably more difficult to obtain directly from the standard symmetry reduction method, since in some cases it requires us to solve nonlinear partial differential equations (PDEs) instead of ordinary differential equations (ODEs).

This article is organized as follows. Section II is devoted to a description of the symmetry group structure of the Chalygin and Born–Infeld systems. The properties of the Chaplygin symmetry Lie algebra L are discussed, and we perform a classification of L into conjugate classes of subalgebras, having generic orbits of dimension 2. A complete list of the two-dimensional subalgebras of L is given. In Sec. III, we give a brief theoretical background needed to understand the theory of partially invariant solutions, which includes an algorithm for constructing such classes of solutions. In Sec. IV, we describe and discuss certain classes of partially invariant solutions of the Chaplygin and Born–Infeld equations. All obtained solutions are computed from two-dimensional subalgebras, and have defect structure $\delta=1$. Finally, Sec. V contains observations and a discussion of further applications of our results.

II. STRUCTURE OF THE SYMMETRY LIE ALGEBRA

A. Symmetry properties of the Chaplygin and Born–Infeld equations

The Lie algebra L of Chaplygin gas Eqs. (7a) and (7b) in one spatial dimension is spanned by the six independent vector fields:[5,9]

$$\begin{gathered} P_1=\partial_x, \quad P_0=\partial_t, \quad B=t\partial_x+x\partial_\theta, \quad Z=\partial_\theta, \\ D_1=x\partial_x+2t\partial_t+\rho\partial_\rho, \quad D_2=x\partial_x+2\theta\partial_\theta-\rho\partial_\rho. \end{gathered} \tag{15}$$

Here, P_0 and P_1 represent translations in the independent variables t and x, respectively, B consists of a Galilean boost, Z corresponds to a shift in the potential θ, and D_1 and D_2 are dilations in the dependent and independent variables. The commutation relations between the generators of the Lie algebra L are summarized in Table I.

Using the transformations of the Nambu–Goto parametrizations, we may transform the generators of the Chaplygin Lie algebra L into infinitesimal symmetries of the Born–Infeld Eqs. (11a) and (11b). We first transform the variables x, t, and θ of the Chaplygin gas equations back into the Nambu–Goto target space variables X^0, X^1, X^2:

$$X^0=\frac{1}{\sqrt{2}}(t+\theta), \quad X^1=x, \quad X^2=\frac{1}{\sqrt{2}}(t-\theta). \tag{16}$$

Thus, the derivatives may be transformed to

$$\partial_t=\frac{1}{\sqrt{2}}(\partial_{X^0}+\partial_{X^2}), \quad \partial_x=\partial_{X^1}, \quad \partial_\theta=\frac{1}{\sqrt{2}}(\partial_{X^0}-\partial_{X^2}). \tag{17}$$

Note that under this transformation, $\rho \to \infty$, so that in order to keep the transformations finite it is necessary to set $\partial_\rho=0$. We therefore obtain the generators

$$P_1=\partial_{X^1}, \quad P_0=\frac{1}{\sqrt{2}}(\partial_{X^0}+\partial_{X^2}), \quad B=\frac{1}{\sqrt{2}}(X^0+X^2)\partial_{X^1}+\frac{X^1}{\sqrt{2}}(\partial_{X^0}-\partial_{X^2}),$$

$$Z=\frac{1}{\sqrt{2}}(\partial_{X^0}-\partial_{X^2}), \quad D_1=X^1\partial_{X^1}+(X^0+X^2)(\partial_{X^0}+\partial_{X^2}), \tag{18}$$

$$D_2=X^1\partial_{X^1}+(X^0-X^2)(\partial_{X^0}-\partial_{X^2}),$$

and the commutation relations for the transformed generators (18) are identical to those given in Table I. Thus, it is possible to pass from one system of generators to another through the transformations (16). We then proceed to transform the Nambu–Goto target space variables into the equivalent Born–Infeld variables

$$t=\frac{1}{c}X^0, \quad x=X^1, \quad \theta=cX^2, \tag{19}$$

which leads to the generators

$$\widehat{P_1}=\partial_x, \quad \widehat{P_0}=\frac{1}{\sqrt{2}}\left(\frac{1}{c}\partial_t+c\partial_\theta\right), \quad \hat{B}=\frac{1}{\sqrt{2}}\left(ct+\frac{1}{c}\theta\right)\partial_x+\frac{x}{\sqrt{2}}\left(\frac{1}{c}\partial_t-c\partial_\theta\right),$$

$$\hat{Z}=\frac{1}{\sqrt{2}}\left(\frac{1}{c}\partial_t-c\partial_\theta\right), \quad \widehat{D_1}=x\partial_x+\left(ct+\frac{1}{c}\theta\right)\left(\frac{1}{c}\partial_t+c\partial_\theta\right), \tag{20}$$

$$\widehat{D_2}=x\partial_x+\left(ct-\frac{1}{c}\theta\right)\left(\frac{1}{c}\partial_t-c\partial_\theta\right).$$

As in the previous case, the commutation relations between the generators (20) are identical to those relations given in Table I.

Finally, we note that, for the Chaplygin equations, there exists an infinite number of preserved quantities[1]

$$I_n^{\pm}=\int dx\rho\left(\theta_x\pm\frac{\sqrt{2\lambda}}{\rho}\right)^n. \tag{21}$$

Consequently, we can use the transformations (16) and (19) to derive the corresponding quantities of the Born–Infeld equations

$$J_n^{\pm}=\sqrt{2\lambda}\int dx((\theta_x)^2-\theta_t)^{-1/2}\left(-\theta_x\pm\frac{1}{\sqrt{2}}((\theta_x)^2-\theta_t)^{1/2}\right)^n. \tag{22}$$

This suggests that both models are completely integrable.

B. Classification of the two-dimensional subalgebras

Here, we summarize the results obtained from the classification of the two-dimensional subalgebras of L, the Lie algebra of the Chaplygin Eqs. (7a) and (7b). This result can be extended to include the Born–Infeld equations through the reparametrizations (16) and (19). We focus exclusively on two-dimensional subalgebras because its symmetry reduction leads us mainly to solve ODEs. In order to classify the subalgebras, we can decompose the structure of L into the following solvable semidirect sum

$$L=\{\{D_1,D_2\}\supset\{B\}\} \quad \supset \quad \{Z,P_1,P_0\}. \tag{23}$$

We perform the classification in three steps, using the procedures described in Ref. 13. The full details are presented in Ref. 14.

(i) Consider first the abelian algebra $A=\{D_1,D_2\}$. Its subspaces are

$$A_1=\{0\},\quad A_2=\{D_1\},\quad A_3=\{D_2\},\quad A_4=\{D_1+aD_2,a\neq 0\},$$
$$A_5=\{D_1,D_2\}. \tag{24}$$

Since A is an abelian algebra, all of its subspaces are subalgebras, and each of them is conjugate only to itself under action by the group

$$G_A=\mathbf{e}^{\{D_1,D_2\}}=\{g=e^{\lambda Y}\ :\ Y\in\{D_1,D_2\}\}, \tag{25}$$

generated by A. For each subalgebra A_i of A, its normalizer in G_A

$$Nor(A_i,G_A)=\{g\in G_A\ :\ gXg^{-1}\in A_i,\forall X\in A_i\}, \tag{26}$$

is simply G_A.

(ii) As a next step, let us now consider the algebra

$$F=\{D_1,D_2,B\}=\{\{D_1,D_2\}\supset\{B\}\}=A\supset B. \tag{27}$$

The splitting subalgebras of F are

$$F_1=\{0\},\quad F_2=\{B\},\quad F_3=\{D_1\},\quad F_4=\{D_1,B\},$$
$$F_5=\{D_2\},\quad F_6=\{D_2,B\},\quad F_7=\{D_1+aD_2,a\neq 0\}, \tag{28}$$
$$F_8=\{D_1+aD_2,B\}_{a\neq 0},\quad F_9=\{D_1,D_2\},\quad F_{10}=\{D_1,D_2,B\}=F.$$

In addition, by considering the case of F_7 where $a=1$, we obtain the following nonsplitting subalgebra of F

$$F_{11}=\{D_1+D_2+\varepsilon B,\varepsilon=\pm 1\}. \tag{29}$$

The normalizers of these subalgebras in the group $G_F=\mathbf{e}^{\{D_1,D_2,B\}}$ are presented in Table II.

(iii) Finally, the complete Lie algebra L can be decomposed as a semidirect sum of the previouly considered algebra F and the abelian algebra N:

$$L=\{D_1,D_2,B,Z,P_1,P_0\}=F\supset N, \tag{30}$$

where $F=\{D_1,D_2,B\}$, and $N=\{Z,P_1,P_0\}$ is abelian. The two-dimensional splitting and nonsplitting subalgebras of L are summarized in Tables III and IV, respectively.

The usefulness of the classification is demonstrated in the fact that it allows us to find all corresponding reductions of the Chaplygin equations under the classified nonequivalent two-dimensional subalgebras of the symmetry algebra L. For each conjugacy class given in Tables III

$F_{11}=\{D_1+D_2+\varepsilon B,\varepsilon=\pm 1\}$	$\mathbf{e}^{\{D_1+D_2,B\}}$

and IV, we evaluate the invariants of the corresponding Lie subgroup, and also the corresponding reduced differential equations. We summarize the results in Tables V, and VI. Solutions of these equations will be analyzed in detail in Sec. IV.

III. PARTIALLY INVARIANT SOLUTIONS OF A SYSTEM OF PDEs

The concept of partially invariant solutions originates from the work of Ovsiannikov[15] and since then has been extensively developed by many authors (see, e.g., Refs. 16–22). These types of solutions can be understood as an extension of the group invariant solutions. In the case of

partially invariant solutions, the graph of the solution Γ_f is no longer a G-invariant set (i.e., $G(\Gamma_f)\neq\Gamma_f$) but the difference between the dimensions of the manifolds $G(\Gamma_f)$ and Γ_f has to satisfy the condition

$$0<\delta=\dim G(\Gamma_f)-\dim\Gamma_f<\min(s,q), \tag{31}$$

where δ is called the defect structure of a solution with respect to the group G. Here, we assume that the transformed graph Γ_f under the action of G has a submanifold structure. We denote by s the dimension of the orbit of G and by q the number of dependent variables appearing in the considered system of m PDEs in p independent variables

$$\Delta^l(x,u^{(k)})=0,\quad l=1,\ldots,m. \tag{32}$$

For the computational purpose of constructing partially invariant solutions, it is convenient to evaluate the defect structure δ of a solution of system (32) based on the $q\times s$ characteristic matrix

$$Q_k^\alpha(x,u^{(1)})=\left(\phi_k^\alpha(x,u)-\xi_k^i(x,u)\frac{\partial u^\alpha}{\partial x^i}\right),\quad \alpha=1,\ldots,q,\quad k=1,\ldots,s, \tag{33}$$

of the infinitesimal symmetry generators

$$v_k=\xi_k^i(x,u)\partial_{x^i}+\phi_k^\alpha(x,u)\partial_{u^\alpha},\quad k=1,\ldots,s, \tag{34}$$

of s-dimensional subgroup G_0. We will assume throughout the rest of this article that each subgroup G_0 acts regularly and transversally on the space of independent and dependent variables $M=X\times U$. That is, the rank condition

$$\operatorname{rank}\{\xi_a^i(x,u)\}=\operatorname{rank}\{\xi_a^i(x,u),\phi_a^\alpha(x,u)\}=s, \tag{35}$$

is satisfied.[19] According to Ref. 20, the function $u=f(x)$ is a partially invariant solution of system (32) with defect δ if and only if

$$\operatorname{rank}Q(x,u^{(1)})=\delta. \tag{36}$$

Now, we present the algorithm for constructing partially invariant solutions with defect structure δ. The procedure involves the following steps:

(1) Construct a complete set of functionally independent invariants for a subgroup G_i of G. If the set $\{v_1,\ldots,v_r\}$ is a basis of fiber preserving infinitesimal generators of the Lie algebra $L_i=\exp(G_i)$, where

$$v_b=\xi_b^i(x)\partial_{x^i}+\phi_b^\alpha(x,u)\partial_{u^\alpha},\quad b=1,\ldots,r, \tag{37}$$

then I is an invariant of G_i if and only if $v_b(I)=0$ for all $b=1,\ldots,r$. We obtain a set of

$\mathcal{L}_{8,1}$	$$\rho_{xx}+\left(\frac{1}{2\rho}+\left(\varepsilon x-\frac{1}{2}t^2\right)^{1/2}\frac{F''}{F'}\right)(\rho_x)^2+\left(4\varepsilon\left(\varepsilon x-\frac{1}{2}t^2\right)^{-1}+\varepsilon\left(\varepsilon x-\frac{1}{2}t^2\right)^{-1/2}\frac{F''}{F'}\rho\right)(\rho_x)$$ $$+\left(\frac{\lambda}{\left(\varepsilon x-\frac{1}{2}t^2\right)^4\rho^3(F')^2}+\frac{9}{8}\left(\varepsilon x-\frac{1}{2}t^2\right)^{-2}\rho+\frac{1}{4}\left(\varepsilon x-\frac{1}{2}t^2\right)^{-3/2}\frac{F''}{F'}\rho^2\right)$$ $$-\left(\left(\varepsilon x-\frac{1}{2}t^2\right)^{-3}\frac{1}{(F')^2\rho}+\frac{9}{8}\left(\varepsilon x-\frac{1}{2}t^2\right)^{-3}\frac{F^2}{(F')^2\rho}\right)=0$$

functionally independent invariants of the form

$$\{\eta^k(x), I^j(x,u)\}, \tag{38}$$

where $k=1,\ldots,p+\delta-s$ and $j=1,\ldots,q-\delta$. Then the rank of the Jacobian matrix J is given by

$$\operatorname{rank}(J)=\operatorname{rank}\left(\frac{\partial(I^1(x,u),\ldots,I^{q-\delta}(x,u))}{\partial(u^1,\ldots,u^q)}\right)=q-\delta. \tag{39}$$

(2) Express the $(p+\delta)$-dimensional manifold $G_i\Gamma_f$ in terms of the invariants (38). Note that $G_i\Gamma_f$ is the smallest invariant manifold containing Γ_f, with respect to the action of the group G_i. This manifold is determined by equations of the form

$$I^j(x,u)=f^j(\eta^1(x),\ldots,\eta^{p+\delta-s}(x)), \quad j=1,\ldots,q-\delta. \tag{40}$$

where f^j are arbitrary functions of their arguments.

(3) From Eq. (39) and by applying the implicit function theorem to Eq. (40), we can express $(q-\delta)$ dependent variables u^a as functions of $l\leqslant p$ independent variables x^i, of $(q-\delta)$ arbitrary functions ψ^a and of δ remaining dependent variables u^j

$$u^a=\psi^a(f^j(\eta^1(x),\ldots,\eta^{p+\delta-s}(x)),x^l,u^i), \quad a=1,\ldots,q-\delta. \tag{41}$$

(4) Substitute these $(q-\delta)$ dependent variables u^a into the original system of equations (32) and reduce the problem to a differential system of equations (so called system Δ') for δ dependent variables.

(5) Find leading derivatives among the δ dependent variables and next compute all possible compatibility conditions (modulo these leading derivatives). These conditions imply some constraints on arbitrary functions ψ^a (appearing in (41)) which form differential equations (so called system Δ/G_i) involving $(q-\delta)$ dependent variables u^a and $p+\delta-r$ independent variables.

(6) Solve the system Δ/G_i.

(7) From each solution of Δ/G_i integrate the initial system Δ. This procedure generates different classes of partially invariant solutions with given defect δ to the basic system Δ.

There is no longer a one-to-one correspondence between partially invariant solutions of the initial system Δ and solutions of the system Δ/G_i. For any solution of the system Δ/G_i we obtain, using the above procedure, a family of solutions of the original system Δ.

Note that once these computations are completed, we could check whether the obtained solutions are invariant with respect to some subgroups of the symmetry group G. A partially invariant solution $u=f(x)$, with respect to a subgroup G_i is called reducible with respect to the full group G if

(i) There exists a subgroup $G_a\subset G$ for which $u=f(x)$ is G_a-invariant, and

(ii) The dimension of the orbit of the graph Γ_f under action by G_a satisfies the inequality

$$s_1=\dim(G_a\Gamma_f)\geqslant s-\delta. \tag{42}$$

We are interested in the case of reducible partially invariant solutions, since reducible solutions can be computed from reduced systems involving $p-s_1$ independent variables, where $p-s_1\leqslant p+\delta-s$. Therefore, these reduced systems are easier to solve than the systems Δ/G_i and Δ' which we have to solve to obtain partially invariant solutions.

In order to check whether a partially invariant solution is reducible under any subalgebra of the full symmetry algebra L, one can examine the kernal K of the characteristic matrix Q of L. If a nonzero subspace of K can be generated by constant vectors, then the solution will be invariant with respect to the subalgebra identified by these vectors. In the case of the Chaplygin Eqs. (7a) and (7b), the characteristic matrix Q is

$$Q=\begin{pmatrix} -\theta_x & -\theta_t & 1 & (x-t\theta_x) & (-x\theta_x-2t\theta_t) & (2\theta-x\theta_x) \\ -\rho_x & -\rho_t & 0 & (-t\rho_x) & (\rho-x\rho_x-2t\rho_t) & (-\rho-x\rho_x) \end{pmatrix}. \tag{43}$$

Here, each constant vector $\mathbf{a}=(a_1,\ldots,a_6)$ in the kernal K corresponds to reducibility by the subalgebra

$$\mathcal{S}=\{a_1P_1+a_2P_0+a_3Z+a_4B+a_5D_1+a_6D_2\}. \tag{44}$$

In the nonreducible case, the only constant vector in the kernal K is the zero vector $\mathbf{a}=0$.

IV. PARTIALLY INVARIANT SOLUTIONS OF THE CHAPLYGIN AND BORN–INFELD EQUATIONS

In this section, we discuss the reduced PDEs and ODEs obtained in Table VI, providing partially invariant solutions of the Chaplygin Eqs. (7a) and (7b) and Born–Infeld Eqs. (11a) and (11b) where it is possible. All of these solutions have the defect $\delta=1$ and are computed from two-dimensional symmetry subalgebras of the algebra L. Here, we operate under the hypothesis that the subgroups $G_i\subset G$ are acting regularly and transversally with two-dimensional orbits. We identify the following five types of solutions.

A. Static solutions

Let us discuss some classes of static (time-independent) solutions of the Chaplygin Eqs. (7a) and (7b) which can be obtained directly from PDEs and ODEs associated to the subalgebras listed in Table VI. We discuss the results obtained individually for each subalgebra.

For the subalgebra $L_{1,8}$, the differential equation to be solved is

$$\rho_{xx}+\left(\frac{1}{2\rho}+\frac{F''}{F'}\right)(\rho_x)^2+\frac{\lambda}{\rho^3(F')^2}=0, \tag{45}$$

where F is some function of ρ. We may solve this equation as an ordinary differential equation for ρ in terms of x, provided that we remember to set all constants of integration to be functions of t. We compare Eq. (45) to equation C 6.54 in Ref. 23

$$y''+f(y)y'^2+g(y)y'+h(y)=0. \tag{46}$$

Here, we identify the following functions: $f(y)=1/2y+F''/F'$, $g(y)=0$, and $h(y)=\lambda/y^3(F')^2$. We introduce the quantity $p(y)=y'(x)$, so that Eq. (46) becomes

$$pp'+\left(\frac{1}{2y}+\frac{F''}{F'}\right)p^2+\frac{\lambda}{y^3(F')^2}=0. \tag{47}$$

Setting $q=p^2$, we transform the equation again to

$$\frac{1}{2}q'+\left(\frac{1}{2y}+\frac{F''}{F'}\right)q+\frac{\lambda}{y^3(F')^2}=0. \tag{48}$$

The general solution of Eq. (48) is given by the following quadrature:

$$q(y)=\frac{1}{y}\mathbf{e}^{-2\int F''/F'\,dy}\left[K_0-2\lambda\int\frac{1}{y^2(F')^2}\mathbf{e}^{2\int F''/F'\,dy}dy\right]. \tag{49}$$

Thus, since $y'=q(y)^{1/2}$, the solution $y=y(x)$ is found implicitly through the following relation

$$\int\frac{dy}{q(y)^{1/2}}=x+c_0, \tag{50}$$

so that $\rho(x,t)$ is found by setting the constants of $y(x)$ to be functions of t, and θ is found by setting $\theta=F(\rho)$. This method can be used in general for all differential equations of the form

$$\rho_{xx}+f(\rho)(\rho_x)^2+g(\rho)=0, \tag{51}$$

which include the reduced equations corresponding to the splitting subalgebras $L_{1,9}$, $L_{3,3}$, $L_{4,1}$, $L_{5,3}$, $L_{6,1}$, $L_{7,3}$ (for all values of a), $L_{8,1}$, and the nonsplitting subalgebras $\mathcal{L}_{3,3}$, $\mathcal{L}_{4,1}$, $\mathcal{L}_{5,3}$.

To find a particular solution of Eq. (45), we set the condition $1/2\rho+F''F'=0$, so that $F(\rho)=2K_0\rho^{1/2}+K_1$. Having fixed the function $F(\rho)$, Eq. (45) reduces to

$$\rho_{xx}+\frac{\lambda}{K_0^2\rho^2}=0, \tag{52}$$

which yields the explicit solution

$$\theta(x,t)=2K_0\left(\frac{3}{2}\sqrt{\frac{2\lambda}{K_0^2}}x+K_2\right)^{1/3}+K_1,$$
$$\rho(x,t)=\left(\frac{3}{2}\sqrt{\frac{2\lambda}{K_0^2}}x+K_2\right)^{2/3}. \tag{53}$$

This is a static algebraic solution, with no singularities, and is unbounded at large values of x. It admits the gradient catastrophe since the velocity is unbounded at $x=-2/3\sqrt{K_0^2/2\lambda}K_2$.

Another class of solutions is provided from the subalgebra $L_{3,2}$. In this case, we have to solve a set of two partial differential equations for θ, in variables ξ and η, which are listed in Table VI:

$$8\xi\eta\theta_\eta\theta_{\xi\xi}+4\eta\theta_\xi\theta_\eta+4\xi(\theta_\xi)^2-2\xi\theta_\xi-\xi^2\theta_{\xi\xi}+\eta\theta_\eta-4\xi\eta\theta_\xi\theta_{\xi\eta}+\xi\eta\theta_{\xi\eta}=0, \tag{54}$$

$$4\xi\theta_\xi\theta_{\xi\eta}-\xi\theta_{\xi\eta}+\theta_\eta+\eta\theta_{\eta\eta}=0. \tag{55}$$

The second Eq. (55) corresponds to the fact that $F_\eta=0$ since $F(\xi)$ is a function of ξ only. The function F is related to θ through the formula

$$F(\xi)=\sqrt{\lambda}(2\xi^2(\theta_\xi)^2-\xi^2\theta_\xi+\xi\eta\theta_\eta)^{-1/2}. \tag{56}$$

A number of solutions $\theta(\xi,\eta)$ can be found to the system of Eqs. (54) and (55) by setting certain conditions on the derivatives of θ. By setting $\theta_{\xi\xi}=f(\eta)$, we obtain the solution of the reduced equations

$$\theta=\frac{\xi\eta}{2\eta+C_0}+C_1. \tag{57}$$

This solution however leads to an infinite value for the function F (and therefore an infinite density ρ). On the other hand, if we make the assumption that $\theta_{\xi\eta}=0$, that is $\theta=f(\xi)+g(\eta)$, then one possible solution of the reduced equations is

$$\theta=K_0\ln(\xi\eta)+K_1. \tag{58}$$

The formula (56) gives the finite value $F=\lambda/(2K_0^2)$ and so we obtain the static solution

$$\theta(x,t)=K_0\ln(x^2)+K_1,\quad \rho(x,t)=\frac{\lambda}{2K_0^2}x. \tag{59}$$

This solution is a singular solution which admits a branch point at $x=0$. Consequently, the velocity $\mathbf{v}$ of the fluid is singular there. Since the density ρ vanishes at that point, the entire line $x=0$ must be physically excluded from the domain of the fluid.

Consider the subalgebra $L_{3,4}$. In this case, the reduced differential equation to be solved is

$$\rho_{xx}+\left(\frac{1}{2\rho}+\frac{1}{x}\frac{F''}{F'}\right)(\rho_x)^2-\left(\frac{2}{x}+\frac{2}{x^2}\rho\frac{F''}{F'}\right)(\rho_x)+\left(\frac{\lambda x^2}{\rho^3(F')^2}+\frac{3}{2x^2}\rho+\frac{1}{x^3}\rho^2\frac{F''}{F'}\right)=0, \quad (60)$$

where F is a function of ρ/x. This equation is different from the one considered previously for $L_{1,8}$ in the sense that there exists a nonzero coefficient of ρ_x, in both x and ρ. Thus, Eq. (46) can no longer be used. However, in the case when $F(\xi)=K_0\xi^{1/2}+K_1$, Eq. (60) is a special case of equation C 6.70 discussed in Ref. 23:

$$y''=x^{a-2}f\left(\frac{y}{x^a},\frac{xy'}{x^a}\right), \quad (61)$$

where $a=1$ and

$$f\left(\frac{y}{x},y'\right)=y'-\frac{y}{x}-\frac{4\lambda}{K_0^2}\left(\frac{y}{x}\right)^{-2}. \quad (62)$$

Making the substitution $y(x)=x\,\eta(\xi)$, where $\xi=\ln x$, we obtain the equation

$$\eta''+\frac{4\lambda}{K_0^2\eta^2}=0, \quad (63)$$

which leads to the first integral

$$\frac{d\eta}{d\xi}=\sqrt{\frac{8\lambda}{K_0^2\eta}+K_3}. \quad (64)$$

For the special case where $K_3=0$, we obtain

$$y(x)=x\left(\frac{3}{K_0}\sqrt{2\lambda}\ln|x|+K_4\right)^{2/3}, \quad (65)$$

which leads to the static solution

$$\theta=K_0\left(\frac{3}{K_0}\sqrt{2\lambda}\ln|x|+K_4\right)^{1/3}+K_1, \quad \rho=x\left(\frac{3}{K_0}\sqrt{2\lambda}\ln|x|+K_4\right)^{2/3}. \quad (66)$$

This solution is singular with a branch point at $x=0$. Therefore, we have a situation similar to that of solution (59) above, since the entire line $x=0$ must be excluded from the domain of the solution.

For the subalgebra $L_{5,3}$, the differential equation to be solved is

$$\rho_{xx}-\frac{5}{2\rho}(\rho_x)^2-\frac{1}{4}\rho^3\frac{F'}{F^2}+\frac{\lambda\rho^3}{4F^2}=0, \quad (67)$$

where F is an arbitrary function of t. In the case where $\rho_{xx}=(2/\rho)\,(\rho_x)^2$ and $F=K_0$ is chosen to be a constant, Eq. (67) is satisfied by the static solution

$$\theta=K_0\left(K_2-\sqrt{\frac{\lambda}{2K_0^2}}x\right)^2, \quad \rho=\frac{1}{K_2-\sqrt{\frac{\lambda}{2K_0^2}}x}. \quad (68)$$

This solution has a simple pole at $x=K_2\sqrt{2K_0^2/\lambda}$. Asymptotically, it is unbounded when $x\to\pm\infty$. In general, Eq. (67) can be solved by the quadrature

$$x=\int \frac{d\rho}{\rho^2(\ln\rho)\left(\dfrac{\lambda-F'}{2F^2}-C_0\rho\right)^{1/2}}, \tag{69}$$

leading to a singular solution.

A class of solutions of (7) corresponding to the subalgebra $L_{7,2}$, $a\neq 1$, can be constructed by solving the set of two partial differential equations for θ, in the two independent variables of ξ and η, as listed in Table VI. The function F is related to θ through the relation

$$F(\xi)=\sqrt{\lambda}((a+1)\xi\eta^{-a}\theta_\xi+\eta^{(1-a)}\theta_\eta+2\xi^3\eta^{-2a}(\theta_\xi)^2)^{-1/2}. \tag{70}$$

For the case $a=-1/2$, the assumption $\theta_{\xi\xi}=0$ yields the solution of the reduced equations

$$\theta=K_0\eta^{-1/2}\xi+K_1, \quad F=\sqrt{\frac{\lambda}{2K_0^2}}\xi^{-3/2}, \tag{71}$$

which leads to the algebraic solution

$$\theta=\frac{K_0}{x^2}+K_1, \quad \rho=\sqrt{\frac{\lambda}{2K_0^2}}x^3. \tag{72}$$

This solution admits a double pole at $x=0$. Asymptotically, the velocity of the fluid flow is bounded, but the density is not.

In the case of the nonsplitting subalgebra $\mathcal{L}_{5,2}$, the function F is related to θ through the relation

$$F(\xi)=\sqrt{\lambda}\left(-\frac{\varepsilon\eta^2}{\xi}\theta_\xi-\frac{\varepsilon\eta^3}{\xi^2}\theta_\eta+\frac{1}{2}\frac{\eta^4}{\xi^2}(\theta_\xi)^2\right)^{-1/2}. \tag{73}$$

By setting $\theta_{\xi\xi}=f(\eta)$, we obtain the solution of the reduced equations

$$\theta=\frac{K_0\xi^2}{2\eta^2}+K_1, \tag{74}$$

from where we obtain the algebraic solution of the initial equations

$$\theta=\frac{1}{2}K_0x^2+K_1, \quad \rho=\frac{\sqrt{2\lambda}}{K_0x}, \tag{75}$$

admitting a simple pole at $x=0$. This solution is unbounded, but the velocity does not admit the gradient catastrophe. Note that we also obtain this solution for the subalgebra $L_{5,4}$, in the case where the function F is a constant. All of the static solutions given above are expressed in terms of elementary functions and are reducible with respect to the one-dimensional subalgebra $\{P_0\}$. The structure of the singularities consists of poles and branch points only.

B. Explicit nonstatic solutions

Let us now discuss certain classes of nonstatic solutions of the Chaplygin Eqs. (7a) and (7b) which can be obtained directly by applying the procedure presented in Sec. III to the reduced equations listed in Table VI. Here, we present only the results.

For the subalgebra $L_{1,6}$, we obtain the algebraic solution

$$\theta(x,t)=\frac{1}{2(t-t_0)}x^2+\frac{K_1}{t-t_0}x+\frac{\lambda}{3K_2^2}(t-t_0)^3+\frac{K_1^2}{2(t-t_0)}+K_3,$$
$$\rho(x,t)=\frac{K_2}{t-t_0}, \tag{76}$$

which admits a simple pole at $t=t_0$. Evaluating the characteristic matrix (43) for solution (76), we find that the only constant vectors in the kernal are multiples of the vector

$$\mathbf{a}=(t_0,0,-1,-1,0,0). \tag{77}$$

Therefore, this solution is reducible with respect to the full group G by the one-dimensional subalgebra $S_{1,6}=\{t_0P_1-K_1Z-B\}$.

Similarly, for the subalgebra $L_{2,2}$, we obtain the solution

$$\theta(x,t)=\frac{a_1x^2}{2(a_1t+a_0)}+\frac{a_2x}{(a_1t+a_0)}+\frac{1}{3}\lambda a_1^2t^3+\lambda a_1a_0t^2+\lambda a_0^2t+\frac{a_2^2}{2a_1(a_1t+a_0)}+a_3,$$
$$\rho(x,t)=\frac{1}{a_1t+a_0}. \tag{78}$$

We note that solution (78) is identical to the solution (76) found in the previous case for subalgebra $L_{1,6}$. Here, the simple pole is at $t=a_0/a_1$. We note that both solutions (76) and (78) represent centered wave-type solutions.

A similar situation to that of $L_{1,6}$ and $L_{2,2}$ occurs for the two subalgebras $L_{1,7}$ and $L_{5,2}$. In the case of $L_{1,7}$, we obtain the exponential-type solution

$$\theta(x,t)=-\frac{1}{2}\sqrt{2\lambda}K_1(x-x_0)^2\left(\frac{1+\mathbf{e}^{2\sqrt{2\lambda}K_1(t-t_0)}}{1-\mathbf{e}^{2\sqrt{2\lambda}K_1(t-t_0)}}\right)+K_2,$$
$$\mathbf{v}(x,t)=-\sqrt{2\lambda}K_1(x-x_0)\left(\frac{1+\mathbf{e}^{2\sqrt{2\lambda}K_1(t-t_0)}}{1-\mathbf{e}^{2\sqrt{2\lambda}K_1(t-t_0)}}\right),\quad \rho(x,t)=-\frac{1}{K_1(x-x_0)}. \tag{79}$$

This solution has simple poles at $x=x_0$ and $t=t_0$, and is reducible by the one-dimensional subalgebra $S_{1,7}=\{D_2-x_0P_1\}$.

In the case of subalgebra $L_{5,2}$, the solution is given by

$$\theta(x,t)=\frac{\sqrt{2\lambda}}{2C_0}x^2\left(\frac{\mathbf{e}^{2\sqrt{2\lambda}/C_0(t-t_0)}+1}{\mathbf{e}^{2\sqrt{2\lambda}/C_0(t-t_0)}-1}\right),$$
$$\mathbf{v}(x,t)=\frac{\sqrt{2\lambda}}{C_0}x\left(\frac{\mathbf{e}^{2\sqrt{2\lambda}/C_0(t-t_0)}+1}{\mathbf{e}^{2\sqrt{2\lambda}/C_0(t-t_0)}-1}\right),\quad \rho(x,t)=\frac{C_0}{x}. \tag{80}$$

Indeed, up to a translational shift in x and t, solution (80) is identical to solution (79). The pole in x is now at $x=0$. Both solutions (79) and (80) have a singularity at line $t=t_0$, as well as at line $x=x_0$ (for (79)) or $x=0$ (for (80)). When $K_1>0$, the asymptotic behavior is as follows. As $t\to\infty$, the quantity θ approaches the function $f_+(x)=a(x-x_0)^2$, and as $t\to-\infty$, it approaches the function $f_-(x)=-a(x-x_0)^2$. The density has a simple pole at $x=x_0$, and is constant in time. Both solutions correspond to kinks, and since the current for solution (79)

$$j=\rho\frac{\partial\theta}{\partial x}=\sqrt{2\lambda}\left(\frac{1+\mathbf{e}^{2\sqrt{2\lambda}K_1(t-t_0)}}{1-\mathbf{e}^{2\sqrt{2\lambda}K_1(t-t_0)}}\right), \tag{81}$$

is preserved in x, this suggests the complete integrability of system (7).

For the nonsplitting subalgebra $\mathcal{L}_{2,2}$, the density ρ is related to θ through the relation

$$\rho(\xi)=\sqrt{\lambda}(\theta_\eta-\eta\theta_\xi+\tfrac{1}{2}(\theta_\xi)^2)^{-1/2}. \tag{82}$$

The assumption $\theta_{\xi\xi}=0$ yields the polynomial solution of the reduced equations

$$\theta=\xi\eta+\tfrac{1}{6}\eta^3+K_1\eta+K_0, \tag{83}$$

which leads to the partially invariant solution

$$\theta=\varepsilon xt-\tfrac{1}{3}t^3+K_1t+K_0,\quad \mathbf{v}(x,t)=\varepsilon t,\quad \rho=\sqrt{\lambda}(\varepsilon x-\tfrac{1}{2}t^2+K_1)^{-1/2}. \tag{84}$$

This solution is reducible by the two-dimensional subalgebra $\mathcal{S}_{2,2}=\{\varepsilon P_0+\varepsilon K_1Z+B,4\varepsilon K_1P_1-6K_0Z+D_1\}$. Consequently, solution (84) can be obtained either as a partially invariant solution with $\delta=1$ with respect to the subalgebra $\mathcal{L}_{2,2}$, or as a G-invariant solution ($\delta=0$) with respect to the subalgebra $\mathcal{S}_{2,2}$.

For the subalgebra $L_{7,2}$, $a=1$, we have a set of two partial differential equations for θ listed in Table VI. The density ρ is linked to θ through the relation

$$\rho(\xi)=\sqrt{\lambda}\left(-\frac{\xi}{\eta}\theta_\xi+\theta_\eta+\frac{1}{2\eta^2}(\theta_\xi)^2\right)^{-1/2}. \tag{85}$$

We obtain two different solutions to the reduced system. First, we have

$$\theta=\tfrac{1}{2}\eta\xi^2+C_0, \tag{86}$$

which leads to an infinite density. Also, we have

$$\theta=K_0\eta+K_1, \tag{87}$$

from where we obtain the trivial constant-density solution

$$\theta=K_0t+K_1,\quad \rho=\sqrt{\frac{\lambda}{K_0}}. \tag{88}$$

Solution (88), nevertheless, has a characteristic matrix of rank 1, and is therefore partially invariant. In this case, the solution is reducible by the subalgebra $S_{7,2}=\{P_1,P_0+K_0Z,-2K_1Z+D_1+D_2\}$.

For the subalgebra $L_{11,2}$, the density ρ is related to θ through the relation

$$\rho(\xi)=\sqrt{\lambda}\left(\theta_\eta-\frac{1}{\eta}(\xi+\varepsilon+\varepsilon\ln\eta)\theta_\xi+\frac{2}{\eta^2}(\theta_\xi)^2\right)^{-1/2}. \tag{89}$$

The assumption $\theta_{\xi\eta}=K_0$ yields the solution of the reduced equations

$$\theta=K_0\xi\eta+K_0\varepsilon\eta\ln\eta+(K_1-K_0\varepsilon)\eta+K_2,\quad K_0,K_1,K_2\in\mathfrak{R}, \tag{90}$$

which leads to the constant-density solution

$$\theta(x,t)=2K_0x+(K_1-K_0\varepsilon)t+K_2,$$
$$\rho=\sqrt{\lambda}(K_1+2K_0^2-K_0\varepsilon)^{-1/2}. \tag{91}$$

This solution is reducible by the subalgebra $\mathcal{S}_{11,2}=\{P_1+2K_0Z,P_0+(K_1-K_0\varepsilon)Z,D_1+D_2-2K_2Z\}$, and represents a traveling wave.

Finally, it is interesting to note that the subalgebra $L_{7,4}$, where $a=-1$, leads to a bump-type solution. The reduced equation of the subalgebra has the form

$$\rho_{xx}-\frac{3}{2\rho}(\rho_x)^2+\frac{2F'}{F}\rho_x+\left(\frac{\lambda\rho}{F^2}-\frac{(F')^2\rho}{2F^2}-\frac{F''}{F}\rho\right)=0, \tag{92}$$

where F is a function of x. For the special case where $F=K_0$, the equation becomes

$$\rho_{xx}-\frac{3}{2\rho}(\rho_x)^2+\frac{\lambda}{F^2}\rho=0. \tag{93}$$

We can integrate Eq. (93) twice and obtain the explicit form of the bump solution

$$\rho(x,t)=-\frac{\lambda(t-t_0)}{\cosh^2(\frac{1}{2}\sqrt{2\lambda}(x+C))},$$
$$\theta(x,t)=-\frac{\cosh^2(\frac{1}{2}\sqrt{2\lambda}(x+C))}{\lambda(t-t_0)}, \tag{94}$$

which is reducible by the subalgebra $S_{7,4}=\{D_1-D_2-2t_0P_0\}$. The velocity potential θ admits a simple pole at $t=t_0$. For large values of x, the density ρ is bounded and tends to zero, but the velocity potential is unbounded. It should be noted that θ decreases with time provided that we exclude the region around the pole at t_0. Also, since the current

$$j=\sqrt{2\lambda}\tanh(\tfrac{1}{2}\sqrt{2\lambda}(x+C)), \tag{95}$$

is preserved in time t, and since there exists an infinite number of preserved quantities, the complete integrability of the Chaplygin Eqs. (7a) and (7b) is established.

C. Implicit solutions expressed in terms of elementary functions

A localized solution of (7a) and (7b) can be obtained from the subalgebra $L_{6,1}$. The reduced differential equation from Table VI takes the form

$$\rho_{xx}-\frac{5}{2\rho}(\rho_x)^2-\frac{1}{2tF}\rho^3-\frac{F'}{4F^2}\rho^3+\frac{\lambda\rho^3}{4F^2}=0, \tag{96}$$

where F is a function of t. In the case where $F(t)=1$ we can integrate Eq. (96), and this results in the solution given in implicit form

$$-\frac{1}{2K_0\rho}\sqrt{K_1\rho+2K_0}+\varepsilon\frac{K_1}{(2\varepsilon K_0)^{3/2}}\tanh^{-1}\left(\sqrt{\frac{K_1\rho+2K_0}{2\varepsilon K_0}}\right)=x+C_0, \tag{97}$$

where $K_0(t)=\lambda/4-1/(2t)$, and $\varepsilon=|K_0(t)|/K_0(t)$. This solution represents a kink in the regions where the derivatives of ρ and θ are finite and the gradient catastrophe does not occur. An analysis of the characteristic matrix (43) indicates that the only constant vector in the kernal is the zero vector. Therefore, solution (97) is irreducible with respect to the full group G.

D. Solutions in terms of Jacobi elliptic functions

We now discuss solutions which can be expressed in terms of Jacobi elliptic functions. For the subalgebra $L_{1,9}$, the basic Chaplygin system (7a) and (7b) is reduced to the following differential equation

$$\rho_{xx}+\left(\frac{1}{2\rho}+\frac{F''}{F'}\right)(\rho_x)^2+\left(\frac{\lambda}{\rho^3(F')^2}-\frac{\varepsilon}{\rho(F')^2}\right)=0. \tag{98}$$

Equation (98) has the Painlevé property (no movable singularities other than poles) if and only if

$$F(\rho)=2K_0\rho^{1/2}+K_1, \tag{99}$$

where K_0 and K_1 are functions of t. So, Eq. (98) becomes

$$\rho_{xx}+\frac{\lambda}{K_0^2\rho^2}-\frac{\varepsilon}{K_0^2}=0, \tag{100}$$

the solution of which can be expressed by quadrature

$$\int \frac{\rho d\rho}{\sqrt{\frac{2\varepsilon}{K_0^2}\rho^3+K_2\rho^2+\frac{2\lambda}{K_0^2}\rho}}=x+K_3. \tag{101}$$

Equation (101) can be solved in terms of elliptic functions[24] or degenerate cases thereof (i.e., elementary functions). We can integrate ODE (100) once and write the obtained first-order equation

$$\left(\frac{d\rho}{dx}\right)^2=\frac{1}{\rho^2}(\rho-\rho_1)(\rho-\rho_2)(\rho-\rho_3), \tag{102}$$

where the constants ρ_1, ρ_2, ρ_3 satisfy the relations

$$\begin{aligned}&\rho_1+\rho_2+\rho_3=-\tfrac{1}{2}\varepsilon K_2K_0^2,\\ &\rho_1\rho_2+\rho_2\rho_3+\rho_1\rho_3=\varepsilon\lambda,\\ &\rho_1\rho_2\rho_3=0.\end{aligned} \tag{103}$$

When all three roots ρ_i of the polynomial in Eq. (102) are different, then the solution can be expressed in terms of Jacobi elliptic functions. The results for different ordering of the roots $\rho_1<\rho_2<\rho_3$ are summarized in Table VII.

The moduli k of the Jacobi elliptic functions can be chosen in such a way that $0<k^2<1$. This ensures that the elliptic solutions possess one real and one purely imaginary period and that for real arguments x we have

$$-1\leqslant sn(x,k)\leqslant 1,\quad -1\leqslant cn(x,k)\leqslant 1,\quad \sqrt{1-k^2}\leqslant dn(x,k)\leqslant 1. \tag{104}$$

Note that nonsingular periodic solutions can be physically interpreted as kinks, bumps, cnoidal and snoidal waves, depending on the asymptotic behavior of the modulus k. Singular solutions represent static structures which develop from a point or a line into a growing sphere or cylinder.

Elementary solutions take place when two of the roots are identical, $\rho_1=\rho_2=-(1/4)\varepsilon K_2K_0^2$ and $\rho_3=0$. Then we obtain $\lambda=(1/16)\varepsilon K_2^2K_0^4$, and Eq. (102) becomes

TABLE VII. Jacobi elliptic solutions corresponding to the subalgebra $L_{1,9}$ (splitting) of the Chaplygin equation. Reduction to the ODE $\varepsilon y''+\alpha y^{-2}+\beta$, $\varepsilon=\pm 1$, where $\alpha=\lambda K_0^{-2}$, $\beta=-\varepsilon K_0^{-2}$. The function $U(\rho)$ is such that $U(\rho)=x+c_0$. Here, the constants m, n, $p_\pm$, and $q_\pm$ are defined to be $m=\frac{1}{4}K_2K_0^2+(\frac{1}{16}K_2^2K_0^4+\lambda)^{1/2}$, $n=-\lambda(\frac{1}{4}K_2K_0^2+(\frac{1}{16}K_2^2K_0^4+\lambda)^{1/2})^{-1}$, $p_\pm=-\frac{1}{4}K_2K_0^2\pm(\frac{1}{16}K_2^2K_0^4-\lambda)^{1/2}$, and $q_\pm=\lambda(-\frac{1}{4}K_2K_0^2\pm(\frac{1}{16}K_2^2K_0^4-\lambda)^{1/2})^{-1}$.

	$c=\bar{b}$		
10	$0<\rho<\infty$, and $b,c\in\mathcal{C}$	$\lambda^{1/4}\left(\frac{K_0^2}{2}\right)^{1/2}\left[u_1-2E(u_1)-2\frac{sn(u_1)dn(u_1)}{1-cn(u_1)}\right]$	$-1<k=\left(\frac{\lambda^{1/2}-\frac{1}{16}K_0^2K_2}{2\lambda^{1/2}}\right)^{1/2}<1$
	$\varepsilon=1$		$cn(u_1)=\frac{\rho-\lambda^{1/2}}{\rho+\lambda^{1/2}}$
	$b=-\frac{K_0^2K_2}{4}\pm i\left(\lambda-\frac{K_0^4K_2^2}{16}\right)^{1/2}$		$\phi=\cos^{-1}\left(\frac{\rho-\lambda^{1/2}}{\rho+\lambda^{1/2}}\right)$
	$c=\bar{b}$		

$$\left(\frac{d\rho}{dx}\right)^2=\frac{1}{\rho}\left(\rho+\frac{1}{4}\varepsilon K_2K_0^2\right)^2. \tag{105}$$

The general integral is given in implicit form

$$2\rho^{1/2}-\left(-\frac{1}{4}\varepsilon K_2K_0^2\right)^{1/2}\ln\left(\frac{\left(-\frac{1}{4}\varepsilon K_2K_0^2\right)^{1/2}+(\rho)^{1/2}}{\left(-\frac{1}{4}\varepsilon K_2K_0^2\right)^{1/2}-(\rho)^{1/2}}\right)=\pm x+C_0, \tag{106}$$

which is a singular solution admitting a branch point at $\rho=-(1/4)\varepsilon K_2K_0^2$.

By means of the nonsplitting subalgebra $\mathcal{L}_{3,4}$, the reduced equation from Table VI obtained when we set $F(\xi)=K_0\xi^{1/2}+K_1$, as in the previous cases, is

$$\rho_{xx}-\frac{1}{x}\rho_x+\frac{1}{x^2}\rho+\frac{4\lambda x}{K_0^2\rho^2}-\frac{2}{K_0^2 x}=0. \tag{107}$$

This is once again a special case of Eq. (61), except that the coefficient function is now given by

$$f\left(\frac{y}{x},y'\right)=y'-\frac{y}{x}-\frac{4\lambda}{K_0^2}\left(\frac{y}{x}\right)^{-2}+\frac{2}{K_0^2}, \tag{108}$$

where $a=1$. Making the change of variable $\rho(x)=x\,\eta(\xi)$ where $\xi=\ln x$ into (107), we obtain the first integral

$$\left(\frac{d\eta}{d\xi}\right)=\frac{8\lambda}{K_0^2\eta}+\frac{4\eta}{K_0^2}+K_3. \tag{109}$$

This leads to the quadrature

$$\int \frac{d\eta}{\sqrt{\dfrac{8\lambda}{K_0^2\eta}+\dfrac{4\eta}{K_0^2}+K_3}}=\xi+c_0, \tag{110}$$

which can be solved in terms of elliptic functions.[24] The solutions $\eta=\eta(\xi)$ are found in exactly the same manner as for the previous case $(\rho=\rho(x))$ for subalgebra $L_{1,9}$, except that the coefficients are now different. The right-hand sides of Eq. (103) in terms of η become $-(1/4)K_3K_0^2$, 2λ and 0, respectively. The coefficient ε which previously appeared for the subalgebra $L_{1,9}$ is always set to 1, which means that only those root orderings previously corresponding to the positive branch of ε are included. All implicit partially invariant solutions obtained in Sec. IV D are irreducible with respect to the full group G. This is due to the fact that the kernal of the characteristic matrix (43), built from the derivatives of ρ and θ, does not contain any nonzero constant vectors.

It should be noted that Chaplygin solutions have been found for the two-dimensional subalgebras which have not been discussed above. In order to be concise, we have omitted them from this article, and limit ourselves to a few general comments. The full details can be found in Ref. 14. In the cases of subalgebras $L_{3,3}$, $\mathcal{L}_{3,3}$, $L_{4,1}$, $\mathcal{L}_{4,1}$, $\mathcal{L}_{5,3}$, $L_{7,3}(a=1)$, $L_{7,3}(a\neq 1)$ and $L_{8,1}$, solutions of the reduced equations in Table VI were found implicitly by quadrature. As an example, we present the solution for subalgebra $L_{3,3}$:

$$\int \left(\frac{2\lambda\sqrt{t}}{K_0^2\rho}-\frac{2\rho^{3/2}}{3t^{3/4}K_0}+K_2\right)^{-1/2} d\rho=x+C_0. \tag{111}$$

For the subalgebras $L_{7,4},(a=1)$, $L_{7,5},(a=1)$, $L_{7,4},(a\neq 1)$, $L_{9,1}$, $\mathcal{L}_{7,4},(a\neq 1)$ and $\mathcal{L}_{8,1}$, G-invariant solutions have been constructed. Finally, for subalgebra $\mathcal{L}_{7,2}(a\neq 1)$, a Chaplygin solution has been determined which has infinite density. However, its equivalent Born–Infeld solution has a finite density, as will be shown in the next subsection.

E. Solutions of the Born–Infeld equations

Each solution of the nonrelativistic Chaplygin Eqs. (7a) and (7b) can where possible be used to obtain a corresponding solution of the relativistic Born–Infeld Eqs. (11a) and (11b) in one spatial dimension. Since the Chaplygin and Born–Infeld models involve two distinct parametrizations of the Nambu–Goto target space variables X^0 and X^{d+1}, we equate these variables to both their relativistic and nonrelativistic representations:

$$X^0 = ct_R = \frac{1}{\sqrt{2}}(t_{\mathrm{NR}} + \theta_{\mathrm{NR}}(t_{\mathrm{NR}}, \mathbf{r})),$$
$$X^{d+1} = \frac{1}{c}\theta(t_R, \mathbf{r}) = \frac{1}{\sqrt{2}}(t_{\mathrm{NR}} - \theta_{\mathrm{NR}}(t_{\mathrm{NR}}, \mathbf{r})). \tag{112}$$

Renaming the time variables $T = (1/c)\, t_{\mathrm{NR}}$ and $t = t_R$, we obtain the following method of solution transformation described by Jackiw.[1] If $\theta_{\mathrm{NR}}(\mathbf{r}, t)$ is a solution of the Chaplygin Eq. (6), then a solution $\theta_R(\mathbf{r}, t)$ of the Born–Infeld equation can be determined as follows. First, we determine the function $T(\mathbf{r}, t)$ from the equation

$$T + \frac{1}{c^2}\theta_{\mathrm{NR}}(\mathbf{r}, T) = \sqrt{2}t, \tag{113}$$

then, we obtain the relativistic Born–Infeld solution

$$\theta_R(\mathbf{r}, T) = \frac{1}{\sqrt{2}}c^2 T - \frac{1}{\sqrt{2}}\theta_{\mathrm{NR}}(\mathbf{r}, T) = c^2(\sqrt{2}T - t), \tag{114}$$

which is associated to the Chaplygin solution θ_{NR}. Since Eq. (113) cannot always be solved explicitly for $T(\mathbf{r}, t)$ it follows that explicit Born–Infeld solutions cannot always be found in this manner. However, the following classes of solutions of the Born–Infeld Eq. (10) can be constructed. We summarize the results as follows.

For each static solution $\theta_{\mathrm{NR}}(x)$ given in Sec. IV A, we can find the equivalent Born–Infeld solution

$$\theta_R(x, t) = c^2 t - \sqrt{2}\theta_{\mathrm{NR}}(x), \quad \rho_R(x) = \frac{a}{\sqrt{2}\left(\dfrac{d}{dx}\theta_{\mathrm{NR}}(x)\right)}, \tag{115}$$

where a is related to λ through the relation $\lambda = a^2/2$. Thus, for example, we obtain for the subalgebra $L_{1,8}$ the solution of the Born–Infeld Eq. (11) of the form

$$\theta(x, t) = c^2 t - 2\sqrt{2}K_0\left(\frac{3}{2}\sqrt{\frac{2\lambda}{K_0^2}}x + K_2\right)^{1/3} - \sqrt{2}K_1,$$
$$\rho(x, t) = \frac{1}{\sqrt{2}}\left(\frac{3}{2}\sqrt{\frac{2\lambda}{K_0^2}}x + K_2\right)^{2/3}. \tag{116}$$

For the other static solutions, the full details are given in Ref. 14. Since the coordinate transformation (112) is nonsingular, solution (116) is reducible by the subalgebra $\{\widehat{P_0}\}$ given in (20). It is to be noted that the static Chaplygin solutions are transformed to nonstationary solutions of the Born–Infeld equations.

For the subalgebras $L_{1,6}$ and $L_{2,2}$, Eq. (113) takes the following polynomial form:

$$\lambda T^4 - 4\lambda t_0 T^3 + (2c^2K_2^2 - 2\sqrt{2}c^2K_2^2 + 6\lambda t_0^2)T^2 + (2\sqrt{2}c^2K_2^2 t_0 - 2c^2K_2^2 t_0 + 2K_3K_2^2 - 4\lambda t_0^3)T$$
$$+ (\lambda t_0^4 + K_1^2K_2^2 + K_2^2x^2 + 2K_1K_2^2x - 2K_3K_2^2t_0)$$
$$= 0. \tag{117}$$

This is a quartic equation which can be solved explicitly through the method of Ferrari, by solving the resolvent cubic equation.[25] The quantity T can be expressed as a function of x and t. Since the solution has a complicated form, we will not present it here.

In the case of subalgebras $L_{1,7}$ and $L_{5,2}$, Eq. (113) has the transcendental form for T

$$T-\frac{1}{2c^2}\sqrt{2\lambda}K_1(x-x_0)^2\left(\frac{1+\mathbf{e}^{2\sqrt{2\lambda}K_1(T-t_0)}}{1-\mathbf{e}^{2\sqrt{2\lambda}K_1(T-t_0)}}\right)+\frac{K_2}{c^2}=\sqrt{2}t, \tag{118}$$

which cannot be solved explicitly as a function of x and t.

The associated Eq. (113) for the subalgebra $\mathcal{L}_{2,2}$ reduces to the cubic form

$$T^3-3(c^2+\varepsilon x+K_1)T-3(K_0-\sqrt{2}c^2t)=0. \tag{119}$$

The solution of this equation is given by Cardan's formula for the roots of a cubic

$$\begin{aligned}T(x,t)=&\left(\tfrac{3}{2}(K_0-\sqrt{2}c^2t)+\left(\tfrac{9}{4}(K_0-\sqrt{2}c^2t)^2+(c^2+\varepsilon x+K_1)^3\right)^{1/2}\right)^{1/3}\\&+\left(\tfrac{3}{2}(K_0-\sqrt{2}c^2t)-\left(\tfrac{9}{4}(K_0-\sqrt{2}c^2t)^2+(c^2+\varepsilon x+K_1)^3\right)^{1/2}\right)^{1/3},\end{aligned} \tag{120}$$

and the solution can be expressed simply as $\theta_R(x,t)=c^2(\sqrt{2}T-t)$.

For the subalgebra $L_{7,2}$,$(a=1)$, solution (88) leads to a rather trivial solution, namely,

$$\theta(x,t)=\frac{c^2((c^2+K_0)t-\sqrt{2}K_1)}{c^2-K_0},\quad \rho(x,t)=\frac{a(c^2+K_0)}{c^2\sqrt{-4K_0}}. \tag{121}$$

The associated Born–Infeld solution for the subalgebra $L_{11,2}$ takes the form

$$\theta(x,t)=\frac{c^2}{c^2-K_1+K_0\varepsilon}((c^2+K_1-K_0\varepsilon)t-2\sqrt{2}K_0x-\sqrt{2}K_2),$$

$$\rho(x,t)=\frac{a(c^2+K_1-K_0\varepsilon)}{\sqrt{c^2(c^4-(K_1-K_0\varepsilon)^2)+8c^4K_0^2}}. \tag{122}$$

Finally, for the Chaplygin bump solution (94) corresponding to the subalgebra $L_{7,4}(a=-1)$, the associated Born–Infeld solution is given by

$$\theta(x,t)=\frac{c^2t_0}{\sqrt{2}}\pm\sqrt{2}c^2\left(\frac{(t_0-\sqrt{2}t)^2}{4}+\frac{\cosh^2(\frac{1}{2}\sqrt{2\lambda}(x+C))}{c^2\lambda}\right)^{1/2}, \tag{123}$$

which is nonsingular and asymptotically unbounded. Since they correspond, respectively, to the reducible Chaplygin solutions (88), (91), and (94), the Born–Infeld solutions (121), (122), and (123) are reducible by the transformed subalgebras corresponding to $\mathcal{S}_{7,2}$, $\mathcal{S}_{11,2}$, and $\mathcal{S}_{7,4}$ respectively.

We note that the Jacobi elliptic solutions described in Sec. IV D can be transformed to hyperelliptic solutions of the Born–Infeld equations. Due to the complexity of the expressions involved, we will not include them here.

In addition to the solutions discussed above, it should be noted that certain solutions to the reduced equations in Table VI lead to Chaplygin solutions with infinite density which were not discussed previously due to physical considerations. However, these ''solutions'' can be used to determine finite-density Born–Infeld solutions. As an example, we consider the subalgebra $\mathcal{L}_{7,2}(a\neq 1)$. A solution to the reduced equations in Table VI is

$$\theta_{\mathrm{NR}}=K_0\xi+\frac{\varepsilon K_0}{2}\ln\eta-\frac{K_0^2}{2}\eta+K_1 \tag{124}$$

$$=K_0x-\frac{K_0^2}{2}t+K_1. \tag{125}$$

Since the function F is related to θ by the relation

$$F(\xi)=\sqrt{\lambda}\left(-\frac{\varepsilon\eta}{2}\theta_\xi+\eta^2\theta_\eta+\frac{1}{2}\eta^2(\theta_\xi)^2\right)^{-1/2}, \tag{126}$$

the nonrelativistic density ρ_{NR} becomes infinite. However, if we transform the nonrelativistic θ-function (125) into its relativistic (Born–Infeld) equivalent

$$\theta(x,t)=\frac{c^2}{c^2-\frac{K_0^2}{2}}\left(\left(c^2+\frac{K_0^2}{2}\right)t-\sqrt{2}K_0^2x-\sqrt{2}K_1\right), \tag{127}$$

then, we obtain a finite (though constant) density

$$\rho(x,t)=\varepsilon\left(\frac{a^2c^4\left(c^2+\frac{K_0^2}{2}\right)^2}{2K_0^2c^8(K_0^2-1)}\right)^{1/2},\quad \varepsilon=\pm1, \tag{128}$$

which represents a traveling wave similar to that of solution (122). The negative branch ($\varepsilon=-1$) could be interpreted as an antiparticle density.

V. SUMMARY AND CONCLUDING REMARKS

The main purpose of this article has been to provide a great variety of exact analytic solutions through the systematic use of the subgroup structure of the Chaplygin and Born–Infeld equations in $(1+1)$ dimensions. We concentrate exclusively on partially invariant solutions. Under the hypothesis that the subgroups $G_i\subset G$ are acting regularly with two-dimensional orbits and that the transformed graphs $G_i(\Gamma_f)$ are submanifolds, we construct and investigate partially invariant solutions with defect structure $\delta=1$. We can summarize the results which were obtained using the proposed algorithm in Sec. III, with the following cases.

(1) Elementary solutions, that is, algebraic with one or two simple poles, trigonometric, hyperbolic and logarithmic,
(2) Implicit solutions in terms of elementary functions, and
(3) Doubly periodic solutions which can be expressed in terms of Jacobi elliptic functions sn, cn, and dn.

The explicit partially invariant solutions were found to be reducible, in most cases, by one-dimensional subalgebras of L. It should be noted that these types of solutions are difficult to obtain using the standard symmetry reduction method. All implicit solutions are irreducible with respect to the full group G.

The analysis described in this article could be extended in several directions. Firstly, it should be remembered that the elimination of ρ in the equations of motion (7a), (7b), (11a) and (11b) was only made possible when the constants λ and a, respectively, do not vanish. These quantities correspond to a d-brane ''tension'' which must not vanish if the Nambu–Goto action (1) is to generate dynamics.[1] Consequently, it is reasonable to suppose that an action for a ''tensionless''

d-brane could lead to the noninteractive (free) Chaplygin and Born–Infeld theories, where $\lambda = 0$ and $a = 0$, respectively. More generally, it may be interesting to investigate partially invariant solutions of the more general form of the Nambu–Goto action.

Second, the question also arises as to whether our approach can be extended to a supersymmetric version of the Chaplygin model. Recently, such a generalization has been achieved by Jackiw and Polychronakos[26] where, in particular, the explicit representation has been derived from a supermembrane. A group analysis of this supersymmetric planar model can, through the use of Grassmann variables and the Legendre transformation, provide us with new classes of generalized solutions of this model. This work is currently undertaken.[27]

Finally, using group theoretical techniques, the authors plan to generate, in a systematic way, invariant, and partially invariant solutions of the Born–Infeld equations in $(3+1)$ dimensions. The concept of weak transversality for these types of solutions could also be investigated. This task will be undertaken in a future work.

ACKNOWLEDGMENTS

One of the authors (A.M.G.) would like to thank Professor R. Jackiw, Massachusetts Institute of Technology, for helpful discussions on this topic. The authors' research was partially supported by research grants from NSERC of Canada and FQRNT du Québec.

published online 8 July 2004)

The concept of biperfect (noncocommutative) weak Hopf algebras is introduced and their properties are discussed. A new type of quasi-bicrossed products is constructed by means of weak Hopf skew-pairs of the weak Hopf algebras which are generalizations of the Hopf pairs introduced by Takeuchi. As a special case, the quantum double of a finite dimensional biperfect (noncocommutative) weak Hopf algebra is built. Examples of quantum doubles from a Clifford monoid as well as a noncommutative and noncocommutative weak Hopf algebra are given, generalizing quantum doubles from a group and a noncommutative and noncocommutative Hopf algebra, respectively. Moreover, some characterizations of quantum doubles of finite dimensional biperfect weak Hopf algebras are obtained. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1767989]

I. INTRODUCTION

In a recent work,[1] quantum doubles of finite dimensional Hopf algebras and finite groups are generalized by one of the authors to those of certain finite dimensional weak Hopf algebras and finite Clifford monoids so as to obtain singular solutions of the quantum Yang–Baxter equation. However, the procedure in Ref. 1 is not suitable for noncocommutative weak Hopf algebras. So, it is interesting to construct quantum doubles of noncocommutative weak Hopf algebras. The aim of this paper is to give one class of noncocommutative weak Hopf algebras from which their quantum doubles can be obtained.

As is known,[2] bicrossed product is a fundamental tool to construct the quantum double of a Hopf algebra. Quasi-bicrossed product plays a similar role in Ref. 1 for the construction of quantum doubles of certain weak Hopf algebras (in particular, finite Clifford monoids). In Ref. 3, the concept of weak Hopf pairs was introduced as a generalization of the Hopf pairs of Takeuchi.[4] Using the weak Hopf skew pairs, one type of quasi-bicrossed products, which lie between general quasi-bicrossed products and quantum quasidoubles, were constructed when one of the two weak Hopf algebras in the product is cocommutative. In Sec. III of this paper, we will generalize the results and construct quasi-bicrossed products of the weak Hopf skew pairs corresponding to the case where both weak Hopf algebras in the product are noncocommutative (see Theorem III.6 below).

A bialgebra H over a field k is called a *weak Hopf algebra*[1] if there exists $T \in \mathrm{Hom}_k(H,H)$ such that $\mathrm{id}*T*\mathrm{id}=\mathrm{id}$ and $T*\mathrm{id}*T=T$ where $*$ is the covolution product in $\mathrm{Hom}_k(H,H)$; T is called a *weak antipode* of H. Weak Hopf algebras lie between left (respectively, right) Hopf algebras and bialgebras. So far, two types of such weak Hopf algebras have been found, which are the monoid algebra kS of a regular monoid S (Ref. 1) and the almost quantum algebra $wsl_q(2)$ (Ref. 5) (see also Ref. 6 for weak Hopf algebras corresponding to $U_q[sl_n]$).

An application of weak Hopf algebras was found in the construction of noninvertible solutions

[a)]Electronic mail: fangli@zju.edu.cn
[b)]Electronic mail: yzz@maths.uq.edu.au

of the (quantum) Yang–Baxter equation in Refs. 1 and 5. It was found that for a finite dimensional cocommutative perfect weak Hopf algebra H with an invertible weak antipode T, the quasi-bicrossed product $H^{op}{}^{*}\infty H$ [which is called the *quantum double* of H, denoted by $D(H)$], is a quasibraided almost bialgebra equipped with the quasi-R-matrix $R=\Sigma_{i=1}^{n}(1\infty e_i)\otimes(e^i\infty 1)\in D(H)\otimes D(H)$ where $\{e_i\}_{i=1}^{n}$ is a basis of H as a vector space and $\{e^i\}_{i=1}^{n}$ is its dual basis in $H^{op}{}^{*}$. Then, R is a solution of the quantum Yang–Baxter equation. In Ref. 7, it was shown that this solution R is von Neumann regular but not invertible in general. An example of this solution was constructed from the cocommutative perfect weak Hopf algebra $H=kS$ for any finite Clifford monoid S.

Although the quantum double of a finite Clifford monoid is indeed a generalization of the quantum double of a finite group, the quantum doubles in Ref. 1 cannot usually be regarded as generalizations of quantum doubles of Hopf algebras due to the cocommutativity of the weak Hopf algebras considered in Ref. 1. The goal of this paper is to overcome this so as to construct quantum doubles of noncocommutative weak Hopf algebras. We will give one class of noncocommutative weak Hopf algebras from which their quantum doubles can be obtained. First, we introduce the concept of biperfect weak Hopf algebras and discuss their properties. Then we construct a new type of quasi-bicrossed products by means of the weak Hopf skew pairs of the weak Hopf algebras which are generalizations of the Hopf pairs introduced by Takeuchi.[3] As a special case, the quantum double of a finite dimensional biperfect (noncocommutative) weak Hopf algebra is built. Examples of quantum doubles from a Clifford monoid and a noncommutative and noncocommutative weak Hopf algebra are given as generalizations of those from a group and a noncommutative and noncocommutative Hopf algebra, respectively. Moreover, we discuss some characterizations of quantum doubles of finite dimensional biperfect weak Hopf algebras.

II. PRELIMINARIES

Throughout the paper, k stands for a field. Some notations and definitions unexplained here can be found in Refs. 8, 2, 1, and 9. The word ''quantum quasidouble'' of a weak Hopf algebra in Ref. 1 will always be replaced with ''quantum double.''

We recall[1] that a linear space H is a *k-almost bialgebra* if (H,μ,η) is a k-algebra and (H,Δ,ε) is a k-coalgebra with $\Delta(xy)=\Delta(x)\Delta(y)$ for $x, y\in H$. If K is a subalgebra and also a subcoalgebra of H, then K itself is an almost bialgebra, called as an *almost sub-bialgebra* of H.

Combining formally with the definition of the weak Hopf algebras, we say in Ref. 7 that an almost bialgebra H is an *almost weak Hopf algebra* if there exists $T\in \mathrm{Hom}_k(H,H)$ such that $\mathrm{id}*T*\mathrm{id}=\mathrm{id}$ and $T*\mathrm{id}*T=T$, where T is called an *almost weak antipode* of H.

Let H be an almost bialgebra. If there exists an $R\in H\otimes H$ such that for all $x\in H$, $\Delta^{op}(x)R=R\Delta(x)$, then R is called a *universal quasi-R-matrix*; if simultaneously, $(\Delta\otimes\mathrm{id})(R)=R_{13}R_{23}$ and $(\mathrm{id}\otimes\Delta)(R)=R_{13}R_{12}$ are satisfied, then we call H a *quasibraided almost bialgebra* with a *quasi-R-matrix* R (see Ref. 1). Moreover, if H is a bialgebra and R is invertible, then H is called a *braided bialgebra*.

Let H be a bialgebra and C a coalgebra. If C is a left H-module and $\Delta(hc)=\Delta(h)\Delta(c)$ for every $h\in H$ and $c\in C$, then we call the coalgebra C a *left quasi-module-coalgebra* over H. Moreover, if $\varepsilon(hc)=\varepsilon(h)\varepsilon(c)$, then C is called a *left module-coalgebra* over H. Right quasi-module-coalgebra and right module-coalgebra can be defined similarly.

A pair (X,A) of bialgebras over a field k is called *quasimatched* (respectively, *matched*) if there exist linear maps $\alpha: A\otimes X\to X$ and $\beta: A\otimes X\to A$ which turn X into a left A-quasi-module-coalgebra (respectively, a left A-module-coalgebra) and A into a right X-quasi-module-coalgebra (respectively, a right X-module-coalgebra), such that if one sets $\alpha(a\otimes x)=a\triangleright x$, $\beta(a\otimes x)=a\triangleleft x$ then the following conditions are satisfied:

$$a\triangleright(xy)=\sum_{(a)(x)}(a'\triangleright x')((a''\triangleleft x'')\triangleright y), \tag{2.1}$$

$$a \triangleright 1 = \varepsilon(a)1, \tag{2.2}$$

$$(ab) \triangleleft x = \sum_{(b)(x)} (a \triangleleft (b' \triangleright x'))(b'' \triangleleft x''), \tag{2.3}$$

$$1 \triangleleft x = \varepsilon(x)1, \tag{2.4}$$

$$\sum_{(a)(x)} (a' \triangleleft x') \otimes (a'' \triangleright x'') = \sum_{(a)(x)} (a'' \triangleleft x'') \otimes (a' \triangleright x'), \tag{2.5}$$

for all $a, b \in A$ and $x, y \in X$, where 1 is the identity of X and of A, respectively, in (2.2) and (2.4).

For a quasimatched (respectively, matched) pair of bialgebras (X,A), we know from Refs. 1 and 2 that there exists an almost bialgebra (respectively, a bialgebra) structure on the vector space $X \otimes A$ with identity equal to $1 \otimes 1$ such that its product is given by

$$(x \otimes a)(y \otimes b) = \sum_{(a)(y)} x(a' \triangleright y') \otimes (a'' \triangleleft y'')b, \tag{2.6}$$

its coproduct by

$$\Delta(x \otimes a) = \sum_{(a)(x)} (x' \otimes a') \otimes (x'' \otimes a''), \tag{2.7}$$

and its counit by

$$\varepsilon(x \otimes a) = \varepsilon_X(x)\varepsilon_A(a) \tag{2.8}$$

for all $x, y \in X$, $a, b \in A$. Equipped with this almost bialgebra (respectively, bialgebra) structure, $X \otimes A$ is called the *quasi-bicrossed product* (respectively, *bicrossed product*) of X and A, and denoted as $X \infty A$. Furthermore, the injective maps $i_X(x) = x \otimes 1$ and $i_A(a) = 1 \otimes a$ from X and A, respectively, into $X \infty A$ are bialgebra morphisms. Also, $x \infty a = (x \infty 1)(1 \infty a)$ for $a \in A$ and $x \in X$.

III. BIPERFECT WEAK HOPF ALGEBRAS AND QUASI-BICROSSED PRODUCTS

Definition III.1: A weak Hopf algebra H is called (i) a perfect weak Hopf algebra[7] *if its weak antipode T is an anti-bialgebra morphism satisfying* $(\mathrm{id} * T)(H) \subseteq C(H)$ (*the center of H*); (ii) a coperfect weak Hopf algebra *if its weak antipode T is an anti-bialgebra morphism satisfying* $\Sigma_{(x)} x' T(x'') \otimes x''' = \Sigma_{(x)} x'' T(x''') \otimes x'$ *for any* $x \in H$; (iii) a biperfect weak Hopf algebra *if it is perfect and also coperfect.*

From Proposition 1.2 in Ref. 1, we know that if the weak antipode T of a weak Hopf algebra $H = (H, m, u, \Delta, \varepsilon, T)$ is an invertible antialgebra morphism, then $H^{op} = (H, m^{op}, u, \Delta, \varepsilon)$ and $H^{cop} = (H, m, u, \Delta^{op}, \varepsilon)$ are both weak Hopf algebras with weak antipode T^{-1}.

Lemma III.1: Suppose that $H = (H, m, u, \Delta, \varepsilon, T)$ *is a weak Hopf algebra with T invertible, then H is perfect (respectively, coperfect) if and only if* H^{op} (*respectively,* H^{cop}) *is also perfect (respectively, coperfect).*

Proof: When H is coperfect, then $\Sigma_{(x)} x' T(x'') \otimes x''' = \Sigma_{(x)} x'' T(x''') \otimes x'$ for any $x \in H$. Thus,

$$(T \otimes 1) \sum_{(x)} (x'' T^{-1}(x') \otimes x''') = (T \otimes 1) \sum_{(x)} (x''' T^{-1}(x'') \otimes x').$$

It follows that $\Sigma_{(x)}(x'' T^{-1}(x') \otimes x''') = \Sigma_{(x)}(x''' T^{-1}(x'') \otimes x')$ since T is invertible. This means that H^{cop} is coperfect on the weak antipode T^{-1}. It is similar to prove the result in the case that H is perfect.

For a finite dimensional weak Hopf algebra $H=(H,m,u,\Delta,\varepsilon,T)$, we know[1] that $H^*=(H^*,\Delta^*,\varepsilon^*,m^*,u^*,T^*)$ is a weak Hopf algebra with weak antipode T^*.

Lemma III.2: A finite dimensional weak Hopf algebra H is perfect (respectively, coperfect) if and only if its duality H is coperfect (respectively, perfect).*

Proof: "only if": When H is perfect, we need to prove that for $f\in H^*$,

$$\sum_{(f)} f'T^*(f'')\otimes f'''=\sum_{(f)} f''T^*(f''')\otimes f'.$$

In fact, for $a,\ b\in H$,

$$\begin{aligned}\left(\sum_{(f)} f'T^*(f'')\otimes f'''\right)(a\otimes b)&=\sum_{(f)} (f'T^*(f''))(a)f'''(b)\\&=\sum_{(f)(a)} f'(a')T^*(f'')(a'')f'''(b)\\&=\sum_{(f)(a)} f'(a')f''(T(a''))f'''(b)=\sum_{(a)} f(a'T(a'')b)\\&=\sum_{(a)} f(ba'T(a''))=\sum_{(f)(a)} f'(b)f''(a')f'''(T(a''))\\&=\sum_{(f)(a)} f'(b)f''(a')T^*(f''')(a'')=\sum_{(f)} f'(b)(f''T^*(f'''))(a)\\&=\sum_{(f)} (f''T^*(f''')\otimes f')(a\otimes b).\end{aligned}$$

When H is coperfect, we need to prove that $(\mathrm{id}_{H^*}*T^*)(H^*)\subseteq C(H^*)$.

In fact, for $f,\ g\in H^*,\ x\in H$,

$$\begin{aligned}(g(\mathrm{id}_{H^*}*T^*)(f))(x)&=\sum_{(x)} (g(x')(\mathrm{id}_{H^*}*T^*)(f))(x'')\\&=\sum_{(x)} g(x')\Delta^*(\mathrm{id}_{H^*}\otimes T^*)m^*(f)(x'')\\&=\sum_{(x)} g(x')(\mathrm{id}_{H^*}\otimes T^*)m^*(f)(x''\otimes x''')=\sum_{(x)} g(x')m^*(f)(x''\otimes T(x'''))\\&=\sum_{(x)} g(x')f(x''T(x'''))=\sum_{(x)} f(x'T(x''))g(x''')=((\mathrm{id}_{H^*}*T^*)(f)g)(x).\end{aligned}$$

It is easy to see that T^* is an anti-bialgebra morphism from the same fact of T.

"if": It follows from $H\cong H^{**}$.

Corollary III.3: A finite dimensional weak Hopf algebra H is biperfect if and only if its duality H is biperfect.*

Lemma III.4: Suppose that $H=(H,m,u,\Delta,\varepsilon,T)$ is a finite dimensional weak Hopf algebra and its weak antipode T is an invertible anti-bialgebra morphism. Then (i) H is perfect if and only if $(T*\mathrm{id})(H)\subseteq C(H)$; (ii) H is coperfect if and only if $\Sigma_{(x)}T(x')x''\otimes x'''=\Sigma_{(x)}T(x'')x'''\otimes x'$ for any $x\in H$.

Proof: (i) follows from Lemma 1.1 in Ref. 1.

(ii) Similar to the proof of Lemma III.2, we can prove that H satisfies $(T*\mathrm{id})(H)\subseteq C(H)$ if and only if H^* satisfies $\Sigma_{(f)}T^*(f')f''\otimes f'''=\Sigma_{(f)}T^*(f'')f'''\otimes f'$ for $f\in H^*$.

Then H is coperfect if and only if H^* is perfect, if and only if $(T^**\mathrm{id})(H^*)\subseteq C(H^*)$. But $H\cong(H^*)^*$. So, if and only if $\Sigma_{(x)}T(x')x''\otimes x'''=\Sigma_{(x)}T(x'')x'''\otimes x'$ for $x\in H$.

The concept of a Hopf pair of Hopf algebras was introduced by Takeuchi in Ref. 4, which plays a valid role in the study of the theory of quantum groups. Now, we generalize this and introduce some similar concepts corresponding to the weak Hopf algebras.

Definition III.2: (i) Suppose that A and X are weak Hopf algebras with weak antipodes S_A and S_X, respectively. We call (X,A) a weak Hopf pair, if there exists a nonsingular bilinear form $\langle,\rangle$ from $X\otimes A$ to k satisfying

$$\langle x,ab\rangle=\sum_{(x)}\langle x',a\rangle\langle x'',b\rangle, \tag{3.1}$$

$$\langle x,1_A\rangle=\varepsilon(x), \tag{3.2}$$

$$\langle xy,a\rangle=\sum_{(a)}\langle x,a'\rangle\langle y,a''\rangle, \tag{3.3}$$

$$\langle 1_X,a\rangle=\varepsilon(a), \tag{3.4}$$

$$\langle S_X(x),a\rangle=\langle x,S_A(a)\rangle, \tag{3.5}$$

where $x,\ y\in X,\ a,\ b\in A$.

(ii) In (i), moreover, if S_A is invertible and (3.1) and (3.5) are replaced with the following (3.6) and (3.7):

$$\langle x,ab\rangle=\sum_{(x)}\langle x'',a\rangle\langle x',b\rangle, \tag{3.6}$$

$$\langle S_X(x),a\rangle=\langle x,S_A^{-1}(a)\rangle, \tag{3.7}$$

respectively, we call (X,A) a weak Hopf skew-pair.

From Ref. 1, $A^{op}=(A,\mu^{op},\eta,\Delta,\varepsilon,S_A^{-1})$ is a weak Hopf algebra when S_A is invertible. Therefore (X,A) is a weak Hopf skew-pair if and only if (X,A^{op}) is a weak Hopf pair in the case where S_A is invertible.

We know from Ref. 3 that for two perfect weak Hopf algebras A and X with weak antipodes S_A and S_X, respectively, suppose that A is cocommutative, S_A is invertible and (X,A) is a weak Hopf skew-pair, then (X,A) is a quasimatched pair of bialgebra. We want to generalize this result to the case that A is noncocommutative. In fact, we have the following lemma:

Lemma III.5: For two perfect weak Hopf algebras A and X with weak antipodes S_A and S_X, respectively, suppose that S_A is invertible and (X,A) is a weak Hopf skew-pair. Then A and X are both biperfect.

Proof: For $x\in X,\ a,\ b\in A,$ since A is perfect, we have

$$\begin{aligned}\sum_{(x)}\langle x'S_X(x''),a\rangle\langle x''',b\rangle&=\sum_{(x)(a)}\langle x',a'\rangle\langle S(x''),a''\rangle\langle x''',b\rangle\\&=\sum_{(x)(a)}\langle x',a'\rangle\langle x'',S_A^{-1}(a'')\rangle\langle x''',b\rangle=\sum_{(a)}\langle x,bS_A^{-1}(a'')a'\rangle\\&=\sum_{(a)}\langle x,S_A^{-1}(a'')a'b\rangle=\sum_{(x)(a)}\langle x',b\rangle\langle x'',a'\rangle\langle x''',S_A^{-1}(a'')\rangle\\&=\sum_{(x)(a)}\langle x',b\rangle\langle x'',a'\rangle\langle S_X(x'''),a''\rangle=\sum_{(x)}\langle x''S_X(x'''),a\rangle\langle x',b\rangle,\end{aligned}$$

and hence $\Sigma_{(x)}(x'S_X(x'')\otimes x''')=\Sigma_{(x)}(x''S_X(x''')\otimes x')$. It means that X is coperfect.

Similarly, for $x,\ y\in X,\ a\in A,$ since X is perfect, we can prove

$$\sum_{(a)}\langle x,a''S_A^{-1}(a')\rangle\langle y,a'''\rangle=\sum_{(a)}\langle x,a'''S_A^{-1}(a'')\rangle\langle y,a'\rangle.$$

Hence $\Sigma_{(a)}(a''S_A^{-1}(a')\otimes a''')=\Sigma_{(a)}(a'''S_A^{-1}(a'')\otimes a')$. Thus $\Sigma_{(a)}(a'S_A(a'')\otimes a''')=\Sigma_{(a)}\times(a''S_A(a''')\otimes a')$. It follows that A is coperfect.

Theorem III.6: For two perfect weak Hopf algebras A and X with weak antipodes S_A and S_X, respectively, suppose that S_A is invertible and (X,A) is a weak Hopf skew-pair. Then (X,A) is a quasimatched pair of bialgebras with

$$a\triangleright x=\sum_{(x)}\langle x'S_X(x'''),\ a\rangle x'',$$

$$a\triangleleft x=\sum_{(a)}\langle x,\ S_A^{-1}(a''')a'\rangle a''$$

so as to get a quasi-bicrossed product $X\infty A$, denoted as $D(X,A)$.

Proof: First, we can verify easily the following:

$$\langle a\triangleright x,b\rangle=\sum_{(a)}\langle x,S_A^{-1}(a'')ba'\rangle, \tag{3.8}$$

$$\langle y,a\triangleleft x\rangle=\sum_{(x)}\langle x'yS_X(x''),a\rangle \tag{3.9}$$

for $a,\ b\in A,\ x,\ y\in X$.

Now we prove that A and X are a right X-quasi-module coalgebra and a left A-quasi-module coalgebra with the action $\triangleleft$ and $\triangleright$, respectively. In fact, for any $a\in A,\ x,\ y,\ z\in X,$ we have

$$\langle z,a\triangleleft(xy)\rangle=\sum_{(xy)}\langle(xy)''zS_X((xy)'),a\rangle=\sum_{(x)(y)}\langle x''y''zS_X(y')S_X(x'),a\rangle=\langle z,(a\triangleleft x)\triangleleft y\rangle,$$

then $a\triangleleft(xy)=(a\triangleleft x)\triangleleft y$; $\langle z,a\triangleleft 1\rangle=\langle 1zS_X(1),a\rangle=\langle z,a\rangle$, then $a\triangleleft 1=a$. Thus A is a right X-module. On the other hand,

$$\begin{aligned}\left\langle y\otimes z,\sum_{(a)(x)}(a'\triangleleft x')\otimes(a''\triangleleft x'')\right\rangle&=\sum_{(a)(x)}\langle y,a'\triangleleft x'\rangle\langle z,a''\triangleleft x''\rangle\\&=\sum_{(a)(x)}\langle x'yS_X(x''),a'\rangle\langle x'''zS_X(x^{(4)}),a''\rangle\\&=\sum_{(x)}\langle x'yS_X(x'')x'''zS_X(x^{(4)}),a\rangle\\&=\sum_{(x)}\langle x'yzS_X(x''),a\rangle=\langle yz,a\triangleleft x\rangle=\langle y\otimes z,\Delta(a\triangleleft x)\rangle,\end{aligned}$$

then $\Delta(a\triangleleft x)=\Sigma_{(a)(x)}(a'\triangleleft x')\otimes(a''\triangleleft x'')$. It means that A is a right X-quasi-module-coalgebra. Similarly, we get that X is a left A-quasi-module-coalgebra.

Moreover, we can see that (2.2) and (2.4) are trivial according to (3.4) and (3.2) and the definition of $\triangleright$ and $\triangleleft$. And, using Lemma III.5, we have

$$\left\langle \sum_{(a)(x)} (a'\triangleright x')((a''\triangleleft x'')\triangleright y), b \right\rangle = \left\langle \sum_{(a)(x)} (a'\triangleright x')(\langle x'', S_A^{-1}(a^{(4)})a''\rangle a'''\triangleright y), b \right\rangle$$

$$= \sum_{(a)(b)(x)} \langle x'', S_A^{-1}(a^{(4)})a''\rangle\langle (a'\triangleright x'), b'\rangle\langle (a'''\triangleright y), b''\rangle$$

$$= \sum_{(a)(b)(x)} \langle x'', S_A^{-1}(a^{(5)})a'''\rangle\langle x', S_A^{-1}(a'')b'a'\rangle\langle (a^{(4)}\triangleright y), b''\rangle$$

$$= \sum_{(a)(b)} \langle x, S_A^{-1}(a^{(5)})a'''S_A^{-1}(a'')b'a'\rangle\langle (a^{(4)}\triangleright y), b''\rangle$$

$$= \sum_{(a)(b)} \langle x, S_{(A)}^{-1}(a''')b'a'\rangle\langle (a''\triangleright y), b''\rangle$$

$$= \sum_{(a)(b)} \langle x, S_A^{-1}(a^{(4)})b'a'\rangle\langle y, S_A^{-1}(a''')b''a''\rangle$$

$$= \sum_{(a)} \langle xy, S_A^{-1}(a'')ba'\rangle = \langle a\triangleright(xy), b\rangle,$$

then $a\triangleright(xy)=\Sigma_{(a)(x)}(a'\triangleright x')((a''\triangleleft x'')\triangleright y)$, i.e., Eq. (2.1) holds. Similarly, we get that $(ab)\triangleleft x=\Sigma_{(b)(x)}(a\triangleleft(b'\triangleright x'))(b''\triangleleft x'')$, i.e., Eq. (2.3) holds. Moreover,

$$\sum_{(a)(x)} (a'\triangleleft x')\otimes(a''\triangleright x'') = \sum_{(a)(x)} \langle x', S_A^{-1}(a''')a'\rangle a''\otimes\langle x''S_X(x^{(4)}), a^{(4)}\rangle x'''$$

$$= \sum_{(a)(x)} \langle x', S_A^{-1}(a''')a'\rangle\langle x'', a^{(4)}\rangle\langle S_X(x^{(4)}), a^{(5)}\rangle a''\otimes x'''$$

$$= \sum_{(a)(x)} \langle x', a^{(4)}S_A^{-1}(a''')a'\rangle\langle S_X(x'''), a^{(5)}\rangle a''\otimes x''$$

$$= \sum_{(a)(x)} \langle x', a'''S_A^{-1}(a'')a'\rangle\langle S_X(x'''), a^{(5)}\rangle a^{(4)}\otimes x''$$

$$= \sum_{(a)(x)} \langle x', a'\rangle\langle S_X(x'''), a'''\rangle a''\otimes x''$$

$$= \sum_{(a)(x)} \langle x', a'\rangle\langle x''', S_A^{-1}(a''')\rangle a''\otimes x''$$

$$= \sum_{(a)(x)} \langle x', a'\rangle\langle x''', S_A^{-1}(a^{(5)})a^{(4)}S_A^{-1}(a''')\rangle a''\otimes x''$$

$$= \sum_{(a)(x)} \langle x', a'\rangle\langle x''', S_A^{-1}(a^{(5)})a'''S_A^{-1}(a'')\rangle a^{(4)}\otimes x''$$

$$= \sum_{(a)(x)} \langle x', a'\rangle\langle x''', S_A^{-1}(a'')\rangle\langle x^{(4)}, S_A^{-1}(a^{(5)})a'''\rangle a^{(4)}\otimes x''$$

$$= \sum_{(a)(x)} \langle x', a'\rangle\langle S_X(x'''), a''\rangle\langle x^{(4)}, S_A^{-1}(a^{(5)})a'''\rangle a^{(4)}\otimes x''$$

$$= \sum_{(a)(x)} \langle x' S_X(x'''), a' \rangle \langle x^{(4)}, S_A^{-1}(a^{(4)}) a'' \rangle a''' \otimes x''$$

$$= \sum_{(a)(x)} (a'' \triangleleft x'') \otimes (a' \triangleright x'),$$

then Eq. (2.5) holds. In a word, (X,A) is a quasimatched pair of bialgebras. Hence we get a quasi-bicrossed product $X \infty A$, denoted also as $D(X,A)$.

Note that in this theorem, A is not required to be cocommutative. So, this theorem is a big improvement on the result obtained in Ref. 3.

IV. QUANTUM DOUBLES OF BIPERFECT WEAK HOPF ALGEBRAS

In Theorem III.6, when $A=H$ is a finite dimensional biperfect weak Hopf algebra with invertible weak antipode T, we set $X=H^{*cop}$ and suppose that $\langle , \rangle$ is the bilinear form of H and its dual H^* as linear spaces. It was known in Ref. 1 that $H^{*cop} = (H^*, \Delta^*, \varepsilon^*, (m^*)^{op}, u^*, (T^{*-1}))$. It is easy to see that (H^{*cop}, H) is a weak Hopf skew-pair. Then (H^{*cop}, H) is a quasimatched pair of bialgebras with $a \triangleright f = \Sigma_{(f)} \langle f' T^{*-1}(f'''), a \rangle f''$ and $a \triangleleft f = \Sigma_{(a)} \langle f, T^{-1}(a''') a' \rangle a''$ for $a \in H$ and $f \in H^{*cop}$ so as to get a quasi-bicrossed product $D(H^{*cop}, H) = H^{*cop} \infty H$, denoted briefly as $D(H)$ and called the *quantum double* of H.

Proposition IV.1: Let $H=(H,m,u,\Delta,\varepsilon,T)$ be a finite dimensional biperfect weak Hopf algebra with invertible T. Then the multiplication in $D(H)=H^{*cop} \infty H$ is given by

$$(f \infty a)(g \infty b) = \sum_{(a)} fg(T^{-1}(a''') ? a') \infty a'' b$$

for $f, g \in H^{*cop}$, $a, b \in H$.

Proof:

$$(f \infty a)(g \infty b) = \sum_{(a)(g)} f(a' \triangleright g') \infty (a'' \triangleleft g'') b$$

$$= \sum_{(a)(g)} fg'(T^{-1}(a'') ? a') \infty g''(T^{-1}(a^{(5)}) a''') a^{(4)} b$$

$$= \sum_{(a)} fg(T^{-1}(a^{(5)}) a''' T^{-1}(a'') ? a') \infty a^{(4)} b$$

$$= \sum_{(a)} fg(T^{-1}(a^{(5)}) ? a''' T^{-1}(a'') a') \infty a^{(4)} b = \sum_{(a)} fg(T^{-1}(a''') ? a') \infty a'' b.$$

Now we have the following main result.

Theorem IV.2: *Let $H=(H,m,u,\Delta,\varepsilon,T)$ be a finite dimensional biperfect weak Hopf algebra with invertible T. Then the quantum double $D(H)$ of H is quasibraided equipped with a quasi-R-matrix $R=\Sigma_{i \in I}(1 \infty e_i) \otimes (e^i \infty 1) \in D(H) \otimes D(H)$ where $\{e_i\}_{i \in I}$ is a basis of the k-vector space H together with its dual basis $\{e^i\}_{i \in I}$ in H^{*cop}. Hence R is a solution of the quantum Yang–Baxter equation.*

Proof: For $f \in H^{*cop}$, $a \in H$,

$$\Delta^{op}(f\infty a)R=\sum_{i\in I}\sum_{(f)(a)}(f''\infty a'')(1\infty e_i)\otimes(f'\infty a')(e^i\infty 1)$$

$$=\sum_{i\in I}\sum_{(f)(a)}(f''\varepsilon(T^{-1}(a^{(6)})?a^{(4)})\infty a^{(5)}e_i)\otimes(f'e^i(T^{-1}(a''')?a')\infty a'')$$

$$=\sum_{i\in I}\sum_{(f)(a)}(f''\varepsilon(T^{-1}(a^{(6)}))\varepsilon(a^{(4)})\varepsilon\infty a^{(5)}e_i)\otimes(f'e^i(T^{-1}(a''')?a')\infty a'')$$

$$=\sum_{i\in I}\sum_{(f)(a)}(f''\infty a^{(4)}e_i)\otimes(f'e^i(T^{-1}(a''')?a')\infty a''),$$

$$R\Delta(f\infty a)=\sum_{i\in I}\sum_{(f)(a)}(\varepsilon\infty e_i)(f'\infty a')\otimes(e^i\infty 1)(f''\infty a'')$$

$$=\sum_{i\in I}\sum_{(f)(a)(e_i)}(\varepsilon f'(T^{-1}(e_i''')?e_i')\infty e_i''a')\otimes(e^if''(T^{-1}(1)?1)\infty 1a'')$$

$$=\sum_{i\in I}\sum_{(f)(a)(e_i)}(f'(T^{-1}(e_i''')?e_i')\infty e_i''a')\otimes(e^if''\infty a'').$$

For every $b,\ c\in H,\ u,\ v\in H^{op*}$, let $\xi=b\otimes u\otimes c\otimes v$. Then

$$\langle\Delta^{op}(f\infty a)R,\xi\rangle=\sum_{i\in I}\sum_{(f)(a)}f''(b)u(a^{(4)}e_i)(f'e^i(T^{-1}(a''')?a'))(c)v(a'')$$

$$=\sum_{i\in I}\sum_{(f)(a)(c)}f''(b)u(a^{(4)}e_i)f'(c')e^i(T^{-1}(a''')c''a')v(a'')$$

$$=\sum_{i\in I}\sum_{(f)(a)(c)}f''(b)u(a^{(4)}e^i(T^{-1}(a''')c''a')e_i)f'(c')v(a'')$$

$$=\sum_{(a)(c)}f(bc')u(a^{(4)}T^{-1}(a''')c''a')v(a'')$$

$$=\sum_{(a)(c)}f(bc')u(c''a^{(4)}T^{-1}(a''')a')v(a'')$$

$$=\sum_{(a)(c)}f(bc')u(c''a'''T^{-1}(a'')a')v(a^{(4)})=\sum_{(a)(c)}f(bc')u(c''a')v(a''),$$

$$\langle R\Delta(f\infty a),\xi\rangle=\sum_{i\in I}\sum_{(f)(a)(e_i)}f'(T^{-1}(e_i''')be_i')u(e_i''a')(e^if'')(c)v(a'')$$

$$=\sum_{i\in I}\sum_{(f)(a)(e_i)(c)}f'(T^{-1}(e_i''')be_i')u(e_i''a')e^i(c')f''(c'')v(a'')$$

$$=\sum_{i\in I}\sum_{(a)(e_i)(c)}f(c''T^{-1}(e_i''')be_i')u(e_i''a')e^i(c')v(a'')$$

$$=\sum_{(a)(c)}f(c^{(4)}T^{-1}(c''')bc')u(c''a')v(a'')$$

$$\left(\text{since } \sum_{i\in I}\sum_{(e_i)} e^i(c)e_i'\otimes e_i''\otimes e_i'''=\sum_{(c)} c'\otimes c''\otimes c'''\right)$$

$$=\sum_{(a)(c)} f(c'''T^{-1}(c'')bc')u(c^{(4)}a')v(a'')=\sum_{(a)(c)} f(bc'''T^{-1}(c'')c')u(c^{(4)}a')v(a'')$$

$$=\sum_{(a)(c)} f(bc')u(c''a')v(a'')=\langle\Delta^{op}(f\infty a)R,\xi\rangle.$$

Therefore $\Delta^{op}(f\infty a)R=R\Delta(f\infty a)$. Then $H^{*cop}\infty H$ is an almost quasi-cocommutative almost bialgebra with a universal quasi-R-matrix R.

We can prove in a way similar to the proof of Theorem 2.11 in Ref. 1 that

$$(\Delta\otimes \mathrm{id}_H)(R)=R_{13}R_{23};(\mathrm{id}_H\otimes\Delta)(R)=R_{13}R_{12}.$$

It means that $H^{op*}\infty H$ is quasibraided. Thus, by Proposition 2.8 in Ref. 1, R is a quasi-R-matrix.

Note that since a cocommutative weak Hopf algebra must be coperfect, it means that Theorem IV.2 is a generalization of the one in Ref. 1 on the quantum double of a finite dimensional cocommutative perfect weak Hopf algebra.

It is easy to see that for a finite Clifford monoid $S=\{s_1,\ldots,s_n\}$ (see Refs. 8 and 1), kS is a finite dimensional biperfect weak Hopf algebra with invertible weak antipode T_S satisfying $T_S(s)=s^{-1}$ for $s\in S$. Then by Theorem IV.2, the quantum double $D(kS)$ is quasibraided equipped with a quasi-R-matrix $R=\Sigma_{i=1}^n(1\infty s_i)\otimes(s_i^*\infty 1)\in D(kS)\otimes D(kS)$ where s_i^* is the duality of s_i in $(kS)^{*cop}$. Thus, R is a solution of the quantum Yang–Baxter equation. But, this is also an example of a quantum quasidouble in Theorem 2.11 of Ref. 1 constructed from a finite dimensional cocommutative perfect weak Hopf algebra. So, it is very necessary to find an example of the quantum double from a finite dimensional biperfect weak Hopf algebra with invertible weak antipode which is not cocommutative.

For two biperfect weak Hopf algebras H and K, it is easy to prove that the tensor product $H\otimes K$ is also a biperfect weak Hopf algebra with the comultiplication $\Delta=(I\otimes T\otimes I)(\Delta_H\otimes\Delta_K)$, the multiplication $m=(m_H\otimes m_K)(I\otimes T\otimes I)$, the unit $1=1_H\otimes 1_K$, the counit $\varepsilon=\varepsilon_H\otimes\varepsilon_K$ and the weak antipode $T=T_H\otimes T_K$. $H\otimes K$ is commutative (respectively, cocommutative) if and only if H and K are so.

For a finite noncommutative Clifford monoid S, let $H=kS$ with the weak antipode T_S, then $K=(kS)^*$ is also a finite dimensional biperfect weak Hopf algebra with invertible weak antipode T_S^*. Thus, we get a finite dimensional biperfect weak Hopf algebra $A=kS\otimes(kS)^*$ with invertible weak antipode $T=T_S\otimes T_S^*$, which is indeed not a Hopf algebra unless S is a group. Since kS is noncommutative, $(kS)^*$ is noncocommutative. Hence A is noncommutative and noncocommutative. By Theorem IV.2, the quantum double $D(A)$ of A is quasibraided equipped with a quasi-R-matrix as a solution of the quantum Yang–Baxter equation. This construction is different from that of Theorem 2.11 in Ref. 1. It implies that in Theorem IV.2, the quantum double of a finite dimensional biperfect weak Hopf algebra is indeed a generalization of that of a finite dimensional Hopf algebra.

We know in Ref. 2 that the R-matrix of quantum double of a finite dimensional Hopf algebra is invertible. But, for the quasi-R-matrix in Theorem IV.2, we can only get the regularity as follows.

Proposition IV.3: For a finite dimensional biperfect weak Hopf algebra H with invertible weak antipode T, the quasi-R-matrix $R=\Sigma_{i=1}^n(\varepsilon\infty e_i)\otimes(e_i^*\infty 1)$ of its quantum quasidouble $D(H)$ is a von Neumann regular element in $D(H)\otimes D(H)$ with its inverse $\overline{R}=\Sigma_{i=1}^n(\varepsilon\infty e_i)\otimes(e_i^*T\infty 1)$ where $\{e_1,\ldots,e_n\}$ is a basis of H and $\{e_1^*,\ldots,e_n^*\}$ is the dual basis in H^*.

Proof: For any $\xi=b\otimes u\otimes c\otimes v\in H\otimes H^*\otimes H\otimes H^*$, we have

$$\langle R\overline{R}R,\xi\rangle=\sum_{i,j,l}\varepsilon(b)u(e_ie_je_l)(e_i^*(e_j^*T)e_l^*)(c)v(1)$$

$$=\varepsilon(b)v(1)\sum_{(c)}u\left(\sum_{i=1}^{n}e_ie_i^*(c')\sum_{j=1}^{n}e_je_j^*(T(c''))\sum_{l=1}^{n}e_le_l^*(c''')\right)$$

$$=\varepsilon(b)v(1)u\left(\sum_{(c)}c'T(c'')c'''\right)=\varepsilon(b)v(1)u(c)=\varepsilon(b)v(1)\sum_{i=1}^{n}u(e_i)e_i^*(c)=\langle R,\xi\rangle,$$

then $R\overline{R}R=R$. Similarly, $\langle\overline{R}R\overline{R},\xi\rangle=\langle\overline{R},\xi\rangle$, then $\overline{R}R\overline{R}=\overline{R}$.

For a left $D(H)$-module V, define $C_{V,V}^R$ satisfying $C_{V,V}^R(v\otimes w)=\tau(R(v\otimes w))$ for $v,\ w\in V$, then $C_{V,V}^R$ is a solution of the classical Yang–Baxter equation (see Ref. 7) where τ is the flip map defined as $\tau(v_1\otimes v_2)=v_2\otimes v_1$. From Propositon IV.3, it is easy to prove the following.

Corollary IV.4: For a finite dimensional biperfect weak Hopf algebra H with invertible weak antipode T, let V be a left $D(H)$-module. Then $C_{V,V}^R$ is regular in the endomorphism monoid of $V\otimes V$, with its inverse $C_{V,V}^R$ satisfying $C_{V,V}^R(v\otimes w)=\tau(\overline{R}(v\otimes w))$ for $v,\ w\in V$.

Now we discuss the representation-theoretic interpretation of $D(H)$.

Definition IV.1 (see Ref. 2): For a bialgebra H over k, a crossed H-bimodule V *is a vector space together with linear maps $\mu_V:H\otimes V\to V$ and $\Delta_V:V\to V\otimes H$ such that*

(i) *the map μ_V and Δ_V turn V into a left H-module and a right H-comodule, respectively,*
(ii) $\Sigma_{(a)(\beta)}a'\beta_V\otimes a''\beta_H=\Sigma_{(a)(a''\beta)}(a''\beta)_V\otimes(a''\beta)_Ha'$ *for all $a\in H$ and $\beta\in V$ where we set $\mu_V(a\otimes\beta)=a\beta$ and $\Delta_V(\beta)=\Sigma_{(\beta)}\beta_V\otimes\beta_H$.*

Theorem IV.5: *Suppose H is a finite dimensional biperfect weak Hopf algebra with invertible weak antipode T. Then for a k-linear space V, the following statements are equivalent*:

(i) *V is a left $D(H)$-module*;
(ii) *V is a crossed H-bimodule V and satisfies*

$$\sum_{(a)(\beta)}T^{-1}(a''')a''\beta_H\otimes a'\beta_V=\sum_{(\beta)}\beta_H\otimes a\beta_V \tag{4.1}$$

for all $a\in H$ and $\beta\in V$.

Proof: "(i)⇒(ii)": Let V be a left $D(H)$-module. Since $H^{*cop}\cong H^{*cop}\infty 1$ and $H\cong\varepsilon\infty H$ are subalgebras of $D(H)$, V is a left H-module and also a left H^*-module with $a\beta=(1\infty a)\beta$ and $x\beta=(x\infty 1)\beta$ for $a\in H$, $x\in H^*$, $\beta\in V$. Then, $(ax)(\beta)=a(x\beta)$. But, by Proposition IV.1, we get

$$ax=(1\infty a)(x\infty 1)=\sum_{(a)(x)}\langle x,T^{-1}(a''')?a'\rangle\infty a''=\sum_{(a)(x)}(\langle x,T^{-1}(a''')?a'\rangle\infty 1)(1\infty a'').$$

Hence, $a(x\beta)=\Sigma_{(a)(x)}\langle x,T^{-1}(a''')?a'\rangle(a''\beta)$.

One must show that V can be endowed with a crossed H-bimodule structure. For μ_V, we define $\mu_V(a\otimes\beta)=a\beta$.

Given a basis $\{e_1,\ldots,e_n\}$ of H and the dual basis $\{e_1^*,\ldots,e_n^*\}$ of H^*, note that $x=\Sigma_{i=1}^n x(e_i)e_i^*$ and $a=\Sigma_{i=1}^n e_i^*(a)e_i$ for $x\in H^*$, $a\in H$.

Define $\Delta_V:V\to V\otimes H$ satisfying $\Delta_V(\beta)=\Sigma_i e_i^*\beta\otimes e_i$ for any $\beta\in V$. Consider the dual Δ_V^* of Δ_V, we have that for any $\alpha\in V^*$, $\beta\in V$, $x\in H^*$,

$$\langle\Delta_V^*(\alpha\otimes x),\beta\rangle=\langle\alpha\otimes x,\Delta_V(\beta)\rangle=\sum_{i=1}^{n}\langle\alpha,e_i^*\beta\rangle\langle x,e_i\rangle=\left\langle\alpha,\left(\sum_{i=1}^{n}\langle x,e_i\rangle e_i^*\right)\beta\right\rangle=\langle\alpha,x\beta\rangle;$$

in particular, for $x=\varepsilon$ (the identity of H^*) and any $\beta\in V$,

$$\langle \Delta_V^*(\alpha\otimes\varepsilon),\beta\rangle=\langle \alpha,\beta\rangle.$$

Then $\Delta_V^*(\alpha\otimes\varepsilon)=\alpha$. It follows that, for any $y\in H^*$,

$$\langle \Delta_V^*(\Delta_V^*(\alpha\otimes x)\otimes y),\beta\rangle=\langle \Delta_V^*(\alpha\otimes x),y\beta\rangle=\langle \alpha,x(y\beta)\rangle=\langle \Delta_V^*(\alpha\otimes xy),\beta\rangle,$$

then $\Delta_V^*(\Delta_V^*(\alpha\otimes x)\otimes y)=\Delta_V^*(\alpha\otimes xy)$. Hence V^* is a right H^*-module under the action Δ_V^*. Therefore, dually, V becomes a right H-comodule under the coaction Δ_V.

For $a\in H$, $\beta\in V$, $x\in H^{*cop}$, we have

$$\begin{aligned}(\mathrm{id}\otimes x)\Big(\sum_{(a)(\beta)} a'\beta_V\otimes a''\beta_H\Big)&=\sum_{(a)}\sum_{i=1}^{n} a'(e_i^*\beta)x(a''e_i)=\sum_{(a)(x)}\sum_{i=1}^{n} a'(e_i^*\beta)x'(e_i)x''(a'')\\&=\sum_{(a)(x)} a'(x'\beta)x''(a'')=\sum_{(a)(x)} x''(a^{(4)})x'(T^{-1}(a''')?a')(a''\beta)\\&=\sum_{(a)} x(a^{(4)}T^{-1}(a''')?a')(a''\beta)=\sum_{(a)} x(?a'''T^{-1}(a'')a')(a^{(4)}\beta)\\&=\sum_{(a)} x(?a')(a''\beta)=\sum_{(a)(x)} x'(a')x''(a''\beta)\\&=\sum_{(a)(x)}\sum_{i=1}^{n} x'(a')x''(e_i)e_i^*(a''\beta)\\&=\sum_{(a)}\sum_{i=1}^{n} x(e_ia')e_i^*(a''\beta)=(\mathrm{id}\otimes x)\Big(\sum_{(a)}\sum_{i=1}^{n} e_i^*(a''\beta)\otimes e_ia'\Big)\\&=(\mathrm{id}\otimes x)\Big(\sum_{(a''\beta)(a)}(a''\beta)_V\otimes(a''\beta)_Ha'\Big).\end{aligned}$$

It follows that

$$\sum_{(a)(\beta)} a'\beta_V\otimes a''\beta_H=\sum_{(a''\beta)(a)}(a''\beta)_V\otimes(a''\beta)_Ha'. \tag{4.2}$$

Hence by Definition IV.1, V is a crossed H-bimodule.

Now, we prove the formula (4.1). With the μ_V and Δ_V as defined above, we have proved that for any $\alpha\in V^*$, $\beta\in V$, $x\in H^*$, $\langle \Delta_V^*(\alpha\otimes x),\beta\rangle=\langle \alpha,x\beta\rangle$. But,

$$\langle \Delta_V^*(\alpha\otimes x),\beta\rangle=\langle \alpha\otimes x,\beta_V\otimes\beta_H\rangle=\langle \alpha,\beta_V\rangle\langle x,\beta_H\rangle=\langle \alpha,\langle x,\beta_H\rangle\beta_V\rangle.$$

So, it follows

$$x\beta=\langle x,\beta_H\rangle\beta_V. \tag{4.3}$$

And, since V is a $D(H)$-module, we have $a(x\beta)=(ax)\beta$. However, by the formula (4.3), $a(x\beta)=\Sigma_{(\beta)}\langle x,\beta_H\rangle a\beta_V$; and by the formulas (4.3) and (4.2),

$$(ax)\beta=\left(\sum_{(a)}\langle x,T^{-1}(a''')?a'\rangle\infty a''\right)\beta=\left(\sum_{(a)}\langle x,T^{-1}(a''')?a'\rangle a''\right)\beta$$

$$=\sum_{(a)}\langle x,T^{-1}(a''')?a'\rangle(a''\beta)=\sum_{(a)(x)}\langle x''',T^{-1}(a''')\rangle\langle x',a'\rangle x''(a''\beta)$$

$$=\sum_{(a)(x)(a''\beta)}\langle x''',T^{-1}(a''')\rangle\langle x'',(a''\beta)_H\rangle\langle x',a'\rangle(a''\beta)_V$$

$$=\sum_{(a)(a''\beta)}\langle x,T^{-1}(a''')(a''\beta)_Ha'\rangle(a''\beta)_V=\sum_{(a)(\beta)}\langle x,T^{-1}(a''')a''\beta_H\rangle a'\beta_V.$$

Hence, for any $x\in H^{*cop}$, $\Sigma_{(\beta)}\langle x,\beta_H\rangle a\beta_V=\Sigma_{(a)(\beta)}\langle x,T^{-1}(a''')a''\beta_H\rangle a'\beta_V$. Then the formula (4.1) follows.

"(ii)⇒(i)": Say that V is a crossed H-bimodule about μ_V and Δ_V. Then, V is a left H-module about μ_V and a right H-comodule about Δ_V. Write $\mu_V(a\otimes\beta)=a\beta$ for $a\in H$, $\beta\in V$. For $x\in H^*$, $\beta\in V$, let $x\beta=\Sigma_{(\beta)}\langle x,\beta_H\rangle\beta_V$, where $\Delta_V(\beta)=\Sigma_{(\beta)}\beta_V\otimes\beta_H$. Since Δ_V is a right coaction, it is easy to show that $(xy)\beta=x(y\beta)$ for $y\in H^*$. Then it follows that V is a left H^{*cop}-module.

Set $(xa)\beta=x(a\beta)$ for $x\in H^{*cop}$, $a\in H$, $\beta\in V$. Then, by (4.1),

$$a(x\beta)=\sum_{(\beta)}\langle x,\beta_H\rangle a\beta_V=\sum_{(a)(\beta)}\langle x,T^{-1}(a''')a''\beta_H\rangle a'\beta_V=(ax)\beta,$$

where the first equality follows from (4.3), the second from (4.1) and the third from (4.3) and (4.2) as proved in "(i)⇒(ii)."

Therefore, V becomes a left $D(H)$-module since H and H^{*cop} are subalgebras of $D(H)$ and the multiplication of $D(H)$ is determined by the interaction of H and H^{*cop}.

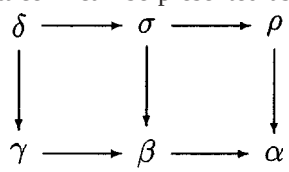
V. EXAMPLES FROM MATRIX GROUPS

Now, we give some examples from a concrete Clifford monoid. The definition of a Clifford semigroup/monoid can be found in Refs. 8 and 1.

Let $Y=\{\alpha,\beta,\gamma,\rho,\sigma,\delta\}$ be the semilattice with multiplication "$\cdot$" given by the following table:

$\cdot$	α	β	γ	ρ	σ	δ
α	α	α	α	α	α	α
β	α	β	β	α	β	β
γ	α	β	γ	α	β	γ
ρ	α	α	α	ρ	ρ	ρ
σ	α	β	β	ρ	σ	σ
δ	α	β	γ	ρ	σ	δ

The partial order in the semilattice Y can be presented as the diagram below:



Obviously, δ is the identity of Y.

For a ring R with identity, $R^{2\times 2}$ denotes the 2×2 full matrix ring over R, $U(R)$ the group consisting of all units in R. Let Z be the integer number ring. For a prime number p, Z_p is a field and $U(Z_p^{2\times 2})$ is just the 2×2 general linear group $GL_2(Z_p)$ over Z_p. Assume that $G_\alpha=\{e_\alpha\}$ and $G_\delta=\{e_\delta\}$ are the trivial groups, $G_\beta=GL_2(Z_2)$, $G_\gamma=U(Z_4^{2\times 2})$, $G_\rho=GL_2(Z_3)$, $G_\sigma=U(Z_6^{2\times 2})$. Then $G_u\cap G_v=\varnothing$ for any $u,v\in Y$, $u\neq v$. Set $S=\cup_{u\in Y}G_u$. We will define a multiplication on S such that $S=\cup_{u\in Y}G_u$ becomes a Clifford monoid related to the semilattice Y.

First, we mention the fact that over a commutative ring R with identity, an $m\times m$ matrix X is invertible if and only if $\det X$ is a unit in R.

Then, for $n=2,3,4,6$, $X=\left[\begin{smallmatrix} x & y \\ a & b\end{smallmatrix}\right]\in U(Z_n^{2\times 2})$ if and only if $\det X=xb-ay\in U(Z_n)$. It is easy to see $U(Z_6)=\{\overline{1},\overline{5}\}$, $U(Z_4)=\{\overline{1},\overline{3}\}$, $U(Z_3)=\{\overline{1},\overline{2}\}$, $U(Z_2)=\{\overline{1}\}$.

A ring homomorphism $\pi_{\sigma,\rho}:Z_6\to Z_3$ can be defined which satisfies $\pi_{\sigma,\rho}(\overline{0})=\overline{0}$, $\pi_{\sigma,\rho}(\overline{1})=\overline{1}$, $\pi_{\sigma,\rho}(\overline{2})=\overline{2}$, $\pi_{\sigma,\rho}(\overline{3})=\overline{0}$, $\pi_{\sigma,\rho}(\overline{4})=\overline{1}$, and $\pi_{\sigma,\rho}(\overline{5})=\overline{2}$.

For $X=\left[\begin{smallmatrix} x & y \\ a & b\end{smallmatrix}\right]\in U(Z_6^{2\times 2})=G_\sigma$, we have $\det X=xb-ay=\overline{1}$, or $\overline{5}$, then

$$\pi_{\sigma,\rho}(x)\pi_{\sigma,\rho}(b)-\pi_{\sigma,\rho}(a)\pi_{\sigma,\rho}(y)=\overline{1},\ \text{or}\ \overline{2}.$$

It follows

$$\begin{bmatrix} \pi_{\sigma,\rho}(x) & \pi_{\sigma,\rho}(y) \\ \pi_{\sigma,\rho}(a) & \pi_{\sigma,\rho}(b)\end{bmatrix}\in GL_2(Z_3)=G_\rho.$$

Thus, we can expand $\pi_{\sigma,\rho}$ to make it a group homomorphism from G_σ to G_ρ. For this, it is enough to define $\pi_{\sigma,\rho}:G_\sigma\to G_\rho$ satisfying

$$\pi_{\sigma,\rho}\begin{bmatrix} x & y \\ a & b\end{bmatrix}=\begin{bmatrix} \pi_{\sigma,\rho}(x) & \pi_{\sigma,\rho}(y) \\ \pi_{\sigma,\rho}(a) & \pi_{\sigma,\rho}(b)\end{bmatrix}$$

since

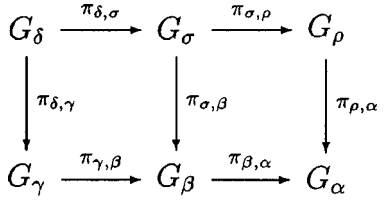
$$\pi_{\sigma,\rho}\left(\begin{bmatrix} x_1 & y_1 \\ a_1 & b_1\end{bmatrix}\begin{bmatrix} x_2 & y_2 \\ a_2 & b_2\end{bmatrix}\right)=\pi_{\sigma,\rho}\begin{bmatrix} x_1 & y_1 \\ a_1 & b_1\end{bmatrix}\pi_{\sigma,\rho}\begin{bmatrix} x_2 & y_2 \\ a_2 & b_2\end{bmatrix}$$

can be shown easily using the fact that $\pi_{\sigma,\rho}$ is a ring homomorphism from Z_6 to Z_3.

Note that $\pi_{\sigma,\rho}(\overline{5})=\overline{2}\in U(Z_3)$, so $\pi_{\sigma,\rho}$ is an epimorphism from G_σ to G_ρ.

Similarly, the ring homomorphisms $\pi_{\sigma,\beta}:Z_6\to Z_2$ and $\pi_{\gamma,\beta}:Z_4\to Z_2$ can be defined respectively satisfying $\pi_{\sigma,\beta}(\overline{0})=\overline{0}$, $\pi_{\sigma,\beta}(\overline{1})=\overline{1}$, $\pi_{\sigma,\beta}(\overline{2})=\overline{0}$, $\pi_{\sigma,\beta}(\overline{3})=\overline{1}$, $\pi_{\sigma,\beta}(\overline{4})=\overline{0}$, $\pi_{\sigma,\beta}(\overline{5})=\overline{1}$ and $\pi_{\gamma,\beta}(\overline{0})=\overline{0}$, $\pi_{\gamma,\beta}(\overline{1})=\overline{1}$, $\pi_{\gamma,\beta}(\overline{2})=\overline{0}$, $\pi_{\gamma,\beta}(\overline{3})=\overline{1}$. Moreover, the group homomorphisms $\pi_{\sigma,\beta}:G_\sigma\to G_\beta$ and $\pi_{\gamma,\beta}:G_\gamma\to G_\beta$ can be constructed in a similar way.

Finally, we define $\pi_{\beta,\alpha}:G_\beta\to G_\alpha$, $\pi_{\rho,\alpha}:G_\rho\to G_\alpha$, $\pi_{\delta,\sigma}:G_\delta\to G_\sigma$, $\pi_{\delta,\gamma}:G_\delta\to G_\gamma$ as the trivial group homomorphisms. Then one has the following diagram:



Now, we introduce the multiplication "$\cdot$" in S by $XW=\pi_{u,uv}(X)\pi_{v,uv}(W)$ if $X\in G_u$ and $W\in G_v$ for $u,v\in Y$. Then, with this multiplication, $S=\cup_{u\in Y}G_u$ becomes a Clifford monoid related to the semilattice Y, and the only element e_δ of G_δ is the identity of S.

Obviously, S is a finite and noncommutative Clifford monoid. Then for the cocommutative weak Hopf algebra kS we may obtain the quantum double $D(S)$ and its quasi-R-matrix R by using the result in Ref. 1. We have the decomposition of linear spaces as follows:

$$D(S)=(kS)^{op*}\infty(kS)=(\oplus_{u\in Y}kG_u)^{op*}\infty(\oplus_{u\in Y}kG_u)=\oplus_{u,v\in Y}((kG_u)^{op*}\infty(kG_v)),$$

where $(kG_u)^{op*}\infty(kG_v)$ means a direct summand of $D(S)$ and ∞ is the same in $D(S)$ since $(kS)^{op*}=\oplus_{u\in Y}(kG_u)^{op*}$ and $kS=\oplus_{u\in Y}kG_u$ such that for each $u\in Y$, $(kG_u)^{op*}$ is embedded into $(kS)^{op*}$ and kG_u is embedded into kS.

Any $\varphi\in(kG_u)^{op*}$ can be expanded to $\overline{\varphi}\in(kS)^{op*}$ satisfying $\overline{\varphi}(U+V)=\varphi(U)$ for any element $U+V$ of $kS=\oplus_{v\in Y}kG_v$ where $U\in kG_u$ and $V\in\oplus_{v\neq u}kG_v$.

Let $u_1, u_2, v_1, v_2\in Y$, $X\in G_{v_1}$, $W\in G_{v_2}$, $A\in G_{u_1}$, $B\in G_{u_2}$. Then their dual elements ϕ_A and ϕ_B of A and B are in $(kG_{u_1})^{op*}$ and $(kG_{u_2})^{op*}$, respectively, where

$$\phi_A(C)=\begin{cases}0 & \text{if } C\in G_{u_1},\quad C\neq A\\ 1 & \text{if } C=A\end{cases}$$

and ϕ_B is given similarly.

The multiplication of $D(S)$ can be presented by

$$(\phi_A\infty X)(\phi_B\infty W)=(\overline{\phi_A}\infty X)(\overline{\phi_B}\infty W)=\overline{\phi_A}\ \overline{\phi_B}(X^{-1}?X)\infty XW,$$

where

$$\overline{\phi_A}\ \overline{\phi_B}(X^{-1}?X)=\begin{cases}0 & \text{if } X^{-1}AX\neq B,\\ \overline{\phi_A}=\phi_A & \text{if } X^{-1}AX=B.\end{cases}$$

By Ref. 1, the quasi-R-matrix of $D(S)$ is

$$R=\sum_{s\in S}(1\infty s)\otimes_k(\overline{\phi_s}\infty 1)=\sum_{u\in Y}\sum_{g_u\in G_u}(1\infty g_u)\otimes_k(\phi_{g_u}\infty 1)\in D(S)\otimes D(S).$$

From $U(Z_6)=\{\overline{1},\overline{5}\}$, $U(Z_4)=\{\overline{1},\overline{3}\}$, $U(Z_3)=\{\overline{1},\overline{2}\}$, $U(Z_2)=\{\overline{1}\}$ and the fact that $X=\left[\begin{smallmatrix}x & y\\ a & b\end{smallmatrix}\right]\in U(Z_n^{2\times 2})$ if and only if $\det X=xb-ay\in U(Z_n)$, it is easy to compute $|G_u|$ for each $u\in Y$. We have $|G_\delta|=1,|G_\alpha|=1,|G_\beta|=6,|G_\gamma|=96,|G_\rho|=48,|G_\sigma|=288$. It follows that the number of monomials of R of $D(S)$ is $|S|=|G_\delta|+|G_\alpha|+|G_\beta|+|G_\gamma|+|G_\rho|+|G_\sigma|=440$. Therefore, from the Clifford monoid $S=\cup_{u\in Y}G_u$ we have constructed an example of the quantum doubles of cocommutative weak Hopf algebras in Ref. 1.

In the following we give an example of the quantum doubles of perfect (noncocommutative) weak Hopf algebras.

For the Clifford monoid S above, $H=kS\otimes(kS)^*$ is a finite dimensional noncommutative and noncocommutative biperfect weak Hopf algebra with invertible weak antipode $T=T_S\otimes T_S^*$ satisfying $T_S(X)=X^{-1}$ and $T_S^*(f)(X)=f(T_S(X))$ for any matrix $X\in S$ and $f\in(kS)^*$. The dimension of H is $\dim H=\dim(kS\otimes(kS)^*)=|S|^2=193\,600$. The quantum double is given by

$$D(H)=H^{op*}\infty H=(kS\otimes(kS)^*)^{op*}\infty(kS\otimes(kS)^*)=((kS)^{op*}\otimes(kS)^{cop})\infty(kS\otimes(kS)^*)$$

$$=((kS)^{op*}\otimes kS)\infty(kS\otimes(kS)^*)=\sum_{u,v,p,q\in Y}((kG_u)^{op*}\otimes kG_v)\infty(kG_p\otimes(kG_q)^*),$$

where $kG_p\otimes(kG_q)^*$ and $(kG_u)^{op*}\otimes kG_v$ are as subspaces of $kS\otimes(kS)^*$ and $(kS)^{op*}\otimes kS$. The multiplication of $D(S)$ obeys the formula in Proposition IV.1.

The quasi-R-matrix of $D(H)$ is

$$R=\sum_{p,q\in Y}\ \sum_{g_p\in G_p,g_q\in G_q}((1\otimes 1)\infty(g_p\otimes\phi_{g_q}))\otimes((\phi_{g_p}\otimes g_q)\infty(1\otimes 1)),$$

whose number of monomials is $|S|^2=193\,600$.

published online 8 July 2004)

We consider the ''thermodynamic limit'' of a d-dimensional lattice of hyperbolic dynamical systems on the 2-torus, interacting via weak and nearest neighbor coupling. We prove that the SRB measure is analytic in the strength of the coupling. The proof is based on symbolic dynamics techniques that allow us to map the SRB measure into a Gibbs measure for a spin system on a $(d+1)$-dimensional lattice. This Gibbs measure can be studied by an extension (decimation) of the usual ''cluster expansion'' techniques. © *2004 American Institute of Physics.*

I. INTRODUCTION AND MAIN RESULTS

In recent years a lot of attention has been devoted to the relation between nonequilibrium statistical mechanics and dynamical systems theory. According to the point of view of Ruelle, Cohen, and Gallavotti,[21,11] a mechanical system evolving in a steady state can be described by a hyperbolic dynamical system and its properties can be deduced from the ''natural'' or SRB distribution (see below for a precise definition) associated with this dynamical system. This line of investigation has already produced several interesting results both analytical, like the ''Fluctuation Theorem'' (see Ref. 11), or numerical, like the works of Evans and Morris (see Ref. 8) and Moran and Hoover (see Ref. 18). Nonetheless, most of the work has been devoted to low dimensional dynamical system, due to their accessibility both to analytical and to numerical study. In this paper we want to study the properties of the SRB distribution for a class of simple systems in very high dimension. For more references on this kind of systems see Ref. 17. The precise model we study here is taken from Ref. 2.

We start considering a linear hyperbolic automorphism of the two-torus $\mathbb{T}^2$. To be definite, we will always consider the so called *Arnold cat map* s_0: $\mathbb{T}^2 \to \mathbb{T}^2$ defined by the action modulus 2π of the matrix

$$A = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}. \tag{1.1}$$

Note that the matrix A admits two orthogonal eigenvectors $v_\pm$ whose respective eigenvalues $\lambda_\pm$ are such that $\lambda_+ > 1 > \lambda_-$ and $\lambda_+ \lambda_- = 1$. For this reason the dynamical system s_0 is uniformly hyperbolic and the stable and unstable manifolds at any point $\phi \in \mathbb{T}^2$ are given by $W^\pm_\phi(t) = \phi + v_\pm t \bmod 2\pi$.

From s_0 we can construct the *uncoupled* lattice dynamics by considering as phase space the Cartesian product $\mathcal{T}=(\mathbb{T}^2)^{\mathbb{Z}^d}$ (namely any point $\psi\in\mathcal{T}$ has Cartesian components $\{\psi_\xi\}_{\xi\in\mathbb{Z}^d}$), equipped with the metric $d(\psi,\psi')=\Sigma_\xi 2^{-|\xi|}\hat{d}(\psi_\xi,\psi'_\xi)$ where $\hat{d}(\psi_\xi,\psi'_\xi)$ is the usual metric on $\mathbb{T}^2$ and $|\xi|=\Sigma_{i=1}^d|\xi_i|$ for $\xi\in\mathbb{Z}^d$. On $\mathcal{T}$ the map S_0 acts simply as

$$S_0^\xi(\psi)=(S_0(\psi))_\xi=s_0(\psi_\xi). \tag{1.2}$$

Note that the stable and unstable manifold of S_0 at a point ψ are the Cartesian product of the stable and unstable manifold of s_0 for the points $\psi_\xi\in\mathbb{T}^2$, i.e., $W^\pm_{0,\psi}(\zeta)=\psi+\Sigma_\xi w^{(\xi)}_{0,\pm}\zeta_\xi \bmod 2\pi$, where $w^{(\xi)}_{0,\pm}$ is the tangent vector to $\mathcal{T}$ that has null component on the tangent space to every $\mathbb{T}^2_\eta$ but for $\mathbb{T}^2_\xi$ where it coincides with $v_\pm$. The action of S_0 on $W^\pm(\psi)$ is naturally given by a diagonal linear transformation.

We observe that the special choice of the matrix A plays no role in the following. Indeed we will show in Appendix A that our results stay true if we replace s_0 with any uniformly hyperbolic analytic automorphism of $\mathbb{T}^2$, not necessarily linear.

To add a coupling to this system we consider an analytic function g: $\mathcal{T}\to\mathbb{T}^2$ and define

$$S^\xi_\epsilon(\psi)\overset{def}{=}s_0(\psi_\xi)+\epsilon g(\rho^\xi\psi)\overset{def}{=}s_0(\psi_\xi)+\epsilon f^\xi(\psi), \tag{1.3}$$

where $(\rho^\xi\psi)_\eta=\psi_{\eta+\xi}$, i.e., ρ is the group of the translations on $\mathbb{Z}^d$. This means that the function f: $\mathcal{T}\to\mathcal{T}$, whose ξ component is $f^\xi=g\circ\rho^\xi$, is translation invariant. We want f to be short ranged: let the nearest neighbor sites of the site ξ be $nn(\xi)=\{\eta:|\xi-\eta|\leqslant 1\}$; we will assume that g depended only on $\psi_{nn(0)}$, where we have used the notation $\psi_V=\{\psi_\xi|\xi\in V\}$ for $V\subset\mathbb{Z}^d$. This implies that $S^\xi_\epsilon(\psi)$ depends only on $\psi_{nn(\xi)}$. More generally we could have assumed that g depends only on ψ_V where V is any finite subset of $\mathbb{Z}^d$ containing 0 but this would not have changed the substance of the following arguments. Moreover, we will take g analytic in all its arguments.

The dynamical system S_ϵ admits many invariant measures. Among them is the "natural" or SRB measure defined as the weak limit of the volume measure on $\mathcal{T}$ under the evolution defined by S_ϵ, when such a limit exists and is ergodic. Being that $\mathcal{T}$ is infinite dimensional, to properly define this concept we will consider finite dimensional approximations. Let $\mathcal{T}_N=(\mathbb{T}^2)^{V_N}$ where V_N is the cube of side $2N+1$ in $\mathbb{Z}^d$ centered at the origin. To define the restriction of S_ϵ to $\mathcal{T}_N$ we have to fix the boundary conditions: we choose periodic ones. To this extent note that $\mathcal{T}_N$ can be naturally identified with the submanifold of $\mathcal{T}$ formed by the points periodic of period $2N+1$. Moreover S_ϵ leaves such a manifold invariant so that we can define $S_{\epsilon,N}\overset{def}{=}S_\epsilon|_{\mathcal{T}_N}$. If no confusion can arise, we will suppress the index N.

We can now define the SRB measure for $S_{\epsilon,N}$ as $\mu_N^{\mathrm{SRB}}=\lim_{T\to\infty}(1/T)\Sigma_{t=0}^{T-1}(S^*_{\epsilon,N})^t\mu_N^0$ where the limit must be understood as a weak limit and $\mu_N^0=\Pi_{\xi\in V_N}d\psi_\xi/(2\pi)^2$ is the Lebesgue measure on $\mathcal{T}_N$. The existence of such a measure follows from rather general theorem on hyperbolic dynamical systems, if ϵ is sufficiently small (see, for example, Ref. 10 and references there). Moreover, μ_N^{SRB} is ergodic, always for small ϵ, and we have that $\mu_N^{\mathrm{SRB}}(\mathcal{O})=\lim_{T\to\infty}(1/T)\Sigma_{t=0}^{T-1}\mathcal{O}(S^t_\epsilon(\psi))$ for μ_N^0 almost every ψ, where $\mathcal{O}$ is an *observable*, i.e., a Holdër continuous function from $\mathcal{T}_N$ to $\mathbb{R}$. This means that μ_N^{SRB} is the *statistic* of S_ϵ. It is well known that the SRB measure is still well defined in the limit $N\to\infty$, for ϵ small enough. This was first proved by Bunimovich and Sinai in Ref. 6. Starting from this work, the model Eq. (1.3) (or similar models of coupled expanding automorphisms of the circle) has been widely studied in the literature (see for instance Refs. 19, 3–5, 16, 17, 1, and 15). Many properties of such systems are well known, mainly uniqueness of the SRB state in the thermodynamic limit and exponential decay of correlations (see Refs. 3–5 for a proof of these properties).

We further investigate the regularity properties of the limiting measure. We show that μ_N^{SRB} depends analytically on ϵ. This means that if we consider an analytic observable $\mathcal{O}$, i.e., an analytic function from $\mathcal{T}_N$ to $\mathbb{R}$, we have that $\mu_N^{\mathrm{SRB}}(\mathcal{O})$ is an analytic function in a domain that depends on the analyticity properties of $\mathcal{O}$.

The main point of this work is to show that such a property remains true when $N\to\infty$, i.e., we want to show that the domain of analyticity of μ_N^{SRB} does not shrink to 0 when $N\to\infty$. More precisely we say that $\mathcal{O}$: $\mathcal{T}\to\mathbb{R}$ is a *local observable* if it depends only on ψ_V for some finite $V\subset\mathbb{Z}^d$. We can summarize our main results as follows

Theorem: *Given S_ϵ as above and a local observable $\mathcal{O}$ we have*

(1) $\mu^{\mathrm{SRB}}(\mathcal{O})=\lim_{N\to\infty}\mu_N^{\mathrm{SRB}}(\mathcal{O})$ exists uniformly in ϵ for $\epsilon<\epsilon_0$ independent on $\mathcal{O}$, and

(2) if $\mathcal{O}$ is local and analytic, then $\mu^{\mathrm{SRB}}(\mathcal{O})$ is analytic in ϵ for $\epsilon<\epsilon_0(\mathcal{O})$.

The proof is mainly based on the possibility of mapping the SRB distribution into the Gibbs state of a suitable spin system on $\mathbb{Z}^{d+1}$ and on the extension of classical techniques used to study such Gibbs states (i.e., cluster expansion) to the particular ones that occur in our system. The key point in order to get analyticity of the measure is proving that the SRB potentials (i.e., the potentials of the Gibbs state the SRB measure is mapped into) are rapidly decaying. Once this decay is proved, analyticity follows via standard techniques. Analyticity of the measure and convergence of cluster expansion imply in particular uniqueness of the Gibbs measure and exponential decay in space and time of the correlations of Hölder continuous observables (see for instance Ref. 10). Our proof can also be adapted to the case of coupled analytic expanding circle map: in fact, also, these models can be mapped into spin systems, and proceeding as below one can prove that the SRB potentials satisfy the same decaying properties.

The rest of the paper is organized as follows. In Sec. II we give a brief review of the main properties of smooth uniformly hyperbolic systems and we briefly describe the construction that allows the above quoted mapping. The detailed proofs of this properties are postponed to Secs. III–V. Finally, in Sec. VI, we complete the proof of the main theorem. Appendix A contain a direct extension of our results to the case in which the uncoupled dynamics is not linear. Appendix B deals with an application. In the contest of the physical application of dynamical systems (see the beginning of this Introduction) a special status has been given to a particular observable, the *phase space contraction rate* defined as $\eta_+(\psi)=\log|\det(DS_\epsilon(\psi))|$ where DS_ϵ is the differential of S_ϵ. Being that our system is infinite, it is more interesting to study the *local* phase space contraction rate $\eta_V(\psi)$ defined by taking the determinant of a (large) minor of DS_ϵ. We show, for a large class of couplings f, that η_V has a positive average and that it obeys a large deviation principle, i.e., its large deviations are asymptotically described by a free energy functional.

II. ANOSOV SYSTEMS

A. Geometric properties

A dynamical system on a smooth compact manifold, whose dynamics is given by a uniformly hyperbolic invertible map, is called an *Anosov system*. From the general theory we know that Anosov systems are structurally stable, namely, given two Anosov diffeomorphisms S, S' on a manifold Ω that are sufficiently close in the C^2 topology, there exist a *conjugation H:* $\Omega\leftrightarrow\Omega$ such that $S\circ H=H\circ S'$.

In our situation this implies the existence of a map h_ϵ: $\mathcal{T}_N\leftrightarrow\mathcal{T}_N$ such that

$$S_\epsilon\circ h_\epsilon=h_\epsilon\circ S_0, \tag{2.1}$$

at least if ϵ is small enough (*a priori* not uniformly in N). The first step of our proof consists in showing that h_ϵ is analytic in ϵ uniformly in N. More precisely, we will construct h_ϵ directly for $N=\infty$. Its finite N version can be obtained by restricting it to $\mathcal{T}_N$. We note that h_ϵ is, in general, only Holdër continuous in the variable ψ. By this we mean that there exist constant c and β such that $d(h_\epsilon(\psi),h_\epsilon(\psi'))\leq c\,d(\psi,\psi')^\beta$. For this reason we cannot say that the SRB measure of S_ϵ is just the image under the map h_ϵ of the SRB measure for S_0, i.e., of the Lebesgue measure on $\mathbb{T}^2$. Notwithstanding, h_ϵ will play a crucial role in the construction on μ_N^{SRB}.

As we saw in the Introduction the tangent space $T_\psi\mathcal{T}$ to $\mathcal{T}$ on a point ψ can be split in two subspaces E^+_ψ and E^-_ψ such that $T_\psi\mathcal{T}=E^+_\psi\oplus E^-_\psi$. Moreover, the distributions $E^\pm$ are continuous and invariant under S_0, i.e., $(DS_0E^\pm_\psi)=E^+_{S_0\psi}$ and we have

$$\begin{aligned}\|DS_0^n w\|&\leqslant C\lambda_-^n\|w\| \quad \text{for } w\in E^-_\psi,\\ \|DS_0^{-n} w\|&\leqslant C\lambda_+^{-n}\|w\| \quad \text{for } w\in E^+_\psi.\end{aligned} \tag{2.2}$$

E^+_ψ and E^-_ψ are called the *stable* and *unstable* subspaces, respectively. In the case of S_0 all these properties are trivially true. In particular we can consider on $E^\pm_\psi$ the basis formed by the vectors $\{w^{(\xi)}_{0,\pm}\}_{\xi\in\mathbb{Z}^d}$.

We will show in Sec. IV that such a splitting can be constructed also for S_ϵ, again uniformly in N, i.e., we will prove the existence of the stable and unstable subspaces $E^\pm_{\epsilon,\psi}$ for S_ϵ. Moreover, we will show that $E^\pm_{\epsilon,h_\epsilon(\psi)}$ is an analytic function of ϵ, although it is only Holdër continuous in ψ. This will turn out to be the right regularity to study the SRB measure. To do this we will directly construct the vectors of the basis $\{w^{(\xi)}_{\epsilon,\pm}(\psi)\}_{\xi\in\mathbb{Z}^d}$ that coincide with $\{w^{(\xi)}_{0,\pm}\}_{\xi\in\mathbb{Z}^d}$ for $\epsilon=0$.

B. Symbolic dynamics

The main property that allows us to study analytically the SRB measure for an Anosov map S acting on a manifold $\mathcal{M}$ is the existence of Markov partitions. We call a collection $\mathcal{Q}_i$, $i=1,...,n$, of closed subsets of $\mathcal{M}$ a *partition* if $\cup_i\mathcal{Q}_i=\mathcal{M}$ and $\mathcal{Q}_i\cap\mathcal{Q}_j=\partial\mathcal{Q}_i\cap\partial\mathcal{Q}_j$ for every $i\neq j$. For every sequence $\sigma=\{\sigma_t\}_{t\in\mathbb{Z}}\in\{1,...,n\}^{\mathbb{Z}}$ we can define the set $\mathcal{X}(\sigma)=\cap_{t=-\infty}^{\infty}S^t(\mathcal{Q}_{\sigma_t})$. Due to the hyperbolicity properties of S, if $\mathcal{Q}_i$ are small enough, $\mathcal{X}(\sigma)$ contains at most one point. This allows us to construct a *symbolic dynamics*, i.e., a map from a subset Σ of $\{1,...,n\}^{\mathbb{Z}}$ to $\mathcal{M}$. In general, the structure of the subset Σ is very complex but for Anosov systems it is possible to construct particular partitions for which the set Σ can be described easily. Given a partition $\mathcal{Q}$ we call the $n\times n$ matrix C given by $C_{ij}=1$ if $\mathrm{int}(S\mathcal{Q}_i)\cap\mathrm{int}(\mathcal{Q}_j)\neq 0$ and 0 otherwise the compatibility matrix. We say that $\mathcal{Q}$ is a *Markov partition* if the set Σ is formed by the sequences σ such that $C_{\sigma_i,\sigma_{i+1}}=1$ for every $i\in\mathbb{Z}$. This means that the sequences that satisfy the above nearest neighbor condition code all the points of $\mathcal{M}$. In such a case we will denote $\Sigma=\{1,...,n\}^{\mathbb{Z}}_C$.

We now show how to construct a Markov partition for our model. We start with s_0. A Markov partition $Q=\{Q_i, i=1,...,n\}$ for s_0 acting on $\mathbb{T}^2$ can be easily constructed starting from its stable and unstable manifolds. Such a construction is standard and can be found, e.g., in Ref. 10. Let C be its compatibility matrix and $\hat{c}_0$ the associated symbolic dynamics.

It is important to note that $\hat{c}_0$ is Holdër continuous in the sense that there exist constants c and β such that, for any two sequences σ, $\sigma'\in\{1,...,n\}^{\mathbb{Z}}_C$, $d(\hat{c}_0(\sigma),\hat{c}_0(\sigma'))\leqslant c\tilde{d}(\sigma,\sigma')^\beta$, with $\tilde{d}(\sigma,\sigma')=e^{-\#(\sigma,\sigma')}$ where $\#(\sigma,\sigma')$ the biggest integer such that $\sigma_j=\sigma'_j$, $\forall|j|\leqslant\#(\sigma,\sigma')$. In this case we can take $\beta=\ln(\lambda_+)$. Another key property is that C is a mixing matrix; this means that there exists a *decorrelation time* $a\in\mathbb{N}$ such that C^a has all entries strictly positive. This means that we can connect any two elements of the Markov partition in a time steps.

For every point $s=\{s_\xi\}_{\xi\in\mathbb{Z}^d}\in\{1,...,n\}^{\mathbb{Z}^d}$ we can consider the Cartesian product $\mathcal{Q}_s=\times_{\xi\in\mathbb{Z}^d}Q_{s_\xi}\subset\mathcal{T}_N$. It is clear that the collection of $\mathcal{Q}_s$ with $s\in\{1,...,n\}^{\mathbb{Z}^d}$ forms a Markov partition for S_0. Note that it is natural to index the element of this partition with the element of $\{1,...,n\}^{\mathbb{Z}^d}$ so that we can associate to this partition the symbolic dynamics $c_0\colon\mathbb{Z}^d\times\mathbb{Z}=\mathbb{Z}^{d+1}\to\mathcal{T}_N$ naturally defined from $\hat{c}_0$. We can still call C the compatibility matrix and $\{1,...,n\}^{\mathbb{Z}^{d+1}}_C$ the set of possible sequences (namely $\sigma=\{\sigma_{\xi,i}\}_{\xi\in\mathbb{Z}^d,i\in\mathbb{Z}}$ is in $\{1,...,n\}^{\mathbb{Z}^{d+1}}_C$ if and only if $C_{\sigma_{\xi,i}\sigma_{\xi,i+1}}=1$ for every $\xi\in\mathbb{Z}^d$ and $i\in\mathbb{Z}$). Given any point $(\xi,i)\in\mathbb{Z}^{d+1}$ we will call ξ its *space component* and i its *time component*.

The key observation is that now the sets $h_\epsilon(\mathcal{Q}_s)$ form a Markov partition for S_ϵ. This implies that the space of symbolic sequences for S_ϵ is the same as that for S_0 and that the symbolic dynamics c_ϵ for S_ϵ is given by $c_\epsilon(\sigma)=h_\epsilon(c_0(\sigma))$. Clearly c_ϵ is still Hölder continuous. This

completes the construction of the Markov partition for S_ϵ. We thus obtained that the manifold $\mathcal{T}$ can be mapped to $\{1,...,n\}_C^{\mathbb{Z}^{d+1}}$ where d directions of the lattice $\mathbb{Z}^{d+1}$ represent the d directions of $\mathcal{T}=(\mathbb{T}^2)^{\mathbb{Z}^d}$ and the last represents the time evolution. Indeed the map S_ϵ on the space $\{1,...,n\}_C^{\mathbb{Z}^{d+1}}$ becomes the shift on the time direction, to be called τ.

C. SRB measure

Let now consider the SRB measure μ_N^{SRB} as defined in Sec. I. In this case we need to keep N finite because it is not easy to give a meaning or construct directly the SRB measure for $N=\infty$.

Let m_N^{SRB} be the measure on $\{1,...,n\}_C^{V_N\times\mathbb{Z}}$ defined as $m_N^{\mathrm{SRB}}(A)=\mu_N^{\mathrm{SRB}}(c_\epsilon^{-1}(A))$, i.e., m_N^{SRB} is the image of μ_N^{SRB} via symbolic dynamics c_ϵ. The measure m_N^{SRB} can be described efficiently through its restrictions to finite subsets of $V_N\times\mathbb{Z}$.

Given $\Lambda\subset V_N\times\mathbb{Z}$, $m_N^{\mathrm{SRB}}(\sigma_\Lambda|\sigma_{\Lambda^c})$ will denote the probability of the event $\{\sigma'|\sigma'_\Lambda=\sigma_\Lambda\}$ conditional to the event $\{\sigma'|\sigma'_{\Lambda^c}=\sigma_{\Lambda^c}\}$ w.r.t. the probability measure m_N^{SRB}, where $\Lambda^c=(V_N\times\mathbb{Z})\backslash\Lambda$ and σ_Λ is the collection of the $\sigma_{\xi,i}$ for $(\xi,i)\in\Lambda$.

From the theory of SRB measures (see Refs. 22 and 10), it follows that m_N^{SRB} is a Gibbs measure and its conditional probabilities satisfy

$$\frac{m_N^{\mathrm{SRB}}(\sigma'_\Lambda|\sigma_{\Lambda^c})}{m_N^{\mathrm{SRB}}(\sigma''_\Lambda|\sigma_{\Lambda^c})}=\lim_{K\to\infty}\left[\frac{\mathcal{D}_\epsilon^{u(2K)}(c_\epsilon(\tau^{-K}\sigma'))}{\mathcal{D}_\epsilon^{u(2K)}(c_\epsilon(\tau^{-K}\sigma''))}\right]^{-1}, \tag{2.3}$$

where σ' (resp. σ'') is the configuration coinciding with σ'_Λ (resp. σ''_Λ) on Λ and with σ_{Λ^c} on Λ^c; τ is the image of S_ϵ through c_ϵ (i.e., it is the one step shift in time direction); $\mathcal{D}_\epsilon^{u(n)}(\psi)$ measures the expansion of the volume on the unstable manifold at the point ψ. To be more precise let $\{w_{\epsilon,+}^{(\xi)}(\psi)\}_{\xi\in V_N}$ be a basis on $E_{\epsilon,\psi}^+$. We will construct one such a basis in Sec. IV. Then we have

$$\mathcal{D}_\epsilon^{u(n)}(\psi)\overset{def}{=}\sqrt{\frac{\det_{\xi\eta}[(DS_\epsilon^n w_{\epsilon,+}^{(\xi)})\cdot(DS_\epsilon^n w_{\epsilon,+}^{(\eta)})]}{\det_{\xi\eta}[w_{\epsilon,+}^{(\xi)}\cdot w_{\epsilon,+}^{(\eta)}]}}(\psi), \tag{2.4}$$

where $u\cdot v$ represent the usual scalar product in $\mathbb{R}^{V_N}$ and $\det_{\xi\eta}$ is the determinant of the expression in square brackets thought as a matrix indexed by ξ and η.

Using the invariance of E_ϵ^+ under S_ϵ and introducing the *unstable Lyapunov matrix* $\mathcal{L}(\psi)$ satisfying the equation

$$DS_\epsilon(\psi)w_{\epsilon,+}^{(\xi)}(\psi)=\sum_\eta w_{\epsilon,+}^{(\eta)}(S_\epsilon(\psi))\mathcal{L}^{\eta\xi}(\psi),$$

we can rewrite the above expression as

$$\mathcal{D}_\epsilon^{u(2K)}(S_\epsilon^{-K}(\psi))=\frac{\sqrt{\det_{\xi\eta}(w_{\epsilon,+}^{(\xi)}\cdot w_{\epsilon,+}^{(\eta)})}(S_\epsilon^K(\psi))}{\sqrt{\det_{\xi\eta}(w_{\epsilon,+}^{(\xi)}\cdot w_{\epsilon,+}^{(\eta)})}(S_\epsilon^{-K}(\psi))}\prod_{j=-K}^{K-1}|\det_{\xi\eta}[\mathcal{L}^{\xi\eta}(S_\epsilon^j\psi)]|. \tag{2.5}$$

Now the first ratio in Eq. (2.5), when inserted in Eq. (2.4), is vanishing; indeed the uniform Hölder continuity of $w_{\epsilon,+}^{(\xi)}(h_\epsilon(\psi))$ and the fact that σ' and σ'' are asymptotically identical in the past and in the future imply that

$$\lim_{K\to\pm\infty}(\ln\sqrt{\det_{\xi\eta}(w_{\epsilon,+}^{(\xi)}\cdot w_{\epsilon,+}^{(\eta)})})(c_\epsilon(\tau^K\sigma'))-(\ln\sqrt{\det_{\xi\eta}(w_{\epsilon,+}^{(\xi)}\cdot w_{\epsilon,+}^{(\eta)})})(c_\epsilon(\tau^K\sigma''))=0; \tag{2.6}$$

thus the choice of the basis in E^+ does not change the result, namely the SRB measure does not depend on the choice of the metric as is to be expected from its definition. Calling $\Lambda^{\xi}(\psi) \overset{def}{=} (\ln \mathcal{L}(h_\epsilon(\psi)))^{\xi\xi}$, we finally get

$$\frac{m_N^{\mathrm{SRB}}(\sigma'_\Lambda|\sigma_{\Lambda^c})}{m_N^{\mathrm{SRB}}(\sigma''_\Lambda|\sigma_{\Lambda^c})} = \exp\left\{ -\sum_{j=-\infty}^{+\infty} \sum_{\xi \in V_N} [\Lambda^{\xi}(c_0(\tau^j \sigma')) - \Lambda^{\xi}(c_0(\tau^j \sigma''))] \right\}. \tag{2.7}$$

Here we used the fact that $c_\epsilon = h_\epsilon \circ c_0$. Furthermore, the Hölder continuity of $\Lambda^{\xi}(c_0(\sigma'))$ implies absolute convergence of the sum in Eq. (2.7) because only points asymptotically equal both in the past and in the future are compared.

The crucial point of this construction is that the matrix $L(\psi) \overset{def}{=} \mathcal{L}(h_\epsilon(\psi))$ is analytic in ϵ due to the fact that it depends only on $w^{(\xi)}_{\epsilon,+}(h_\epsilon(\psi))$. As we already noted $w^{(\xi)}_{\epsilon,+}(h_\epsilon(\psi))$ are analytic in ϵ. We will prove this fact in Sec. IV.

In Sec. VI we will apply to Eq. (2.7) the standard methods developed in the study of Gibbs measure in statistical mechanics. To do this we will need to decompose the ''interaction'' $\Lambda^{\xi}(c_0(\sigma))$ as the sum of potentials depending only on $\sigma_X \overset{def}{=} \{\sigma_j\}_{j \in X}$ where X is a finite subset of $\mathbb{Z}^{d+1}$. More precisely, we will decompose

$$\sum_{(\xi,i) \in V_N \times \mathbb{Z}} \Lambda^{\xi}(c_0(\tau^i \sigma)) = \sum_{X \subset V_N \times \mathbb{Z}} \phi_X(\sigma_X). \tag{2.8}$$

(These two series are not convergent: they represent the formal expression for the ''Hamiltonian'' of a Gibbs measure. See Sec. V B for a more precise statement.) We shall show that we can choose ϕ_X analytic in ϵ, translationally invariant in space and time directions and decaying exponentially in the *tree distance* of the set X, namely the length of the shortest tree connecting all the lattice points in X. In this way (2.7) can be written as

$$\frac{m_N^{\mathrm{SRB}}(\sigma'_\Lambda|\sigma_{\Lambda^c})}{m_N^{\mathrm{SRB}}(\sigma''_\Lambda|\sigma_{\Lambda^c})} = \exp\left\{ -\sum_{X \cap \Lambda \neq 0} [\phi_X(\sigma'_X) - \phi_X(\sigma''_X)] \right\}, \tag{2.9}$$

so that one can finally write

$$m_N^{\mathrm{SRB}}(\sigma_\Lambda|\sigma_{\Lambda^c}) = \frac{\exp\left\{ -\sum_{X \cap \Lambda \neq \emptyset} \phi_X(\sigma_X) \right\}}{\sum_{\sigma_\Lambda} \exp\left\{ -\sum_{X \cap \Lambda \emptyset} \phi_X(\sigma_X) \right\}}. \tag{2.10}$$

This will allow us to show our analyticity claim uniformly in N.

III. PERTURBATIVE CONSTRUCTION OF THE SRB MEASURE

In this section we construct the conjugation h_ϵ and prove that it is analytic in ϵ. The technique we use consists in expanding h_ϵ as a power series in ϵ and writing a recursive relation linking the nth order coefficient to the coefficients of order i with $i<n$. This naturally leads to a tree expansion of the usual form in perturbation theory for quantum field theory, i.e., the trees we will introduce are the ''Feynmann graphs'' of our theory. See also Ref. 10 and reference therein for similar application to KAM theory.

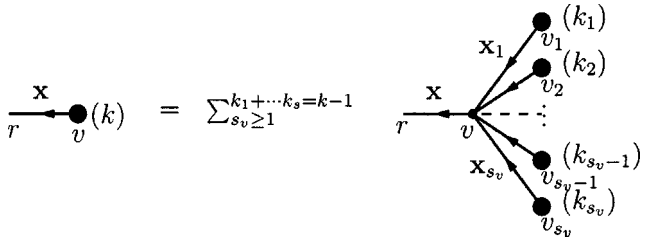

FIG. 1. Graphical interpretation of (3.6).

A. The conjugation

From now on we will identify functions from $\mathcal{T}_N$ to $\mathcal{T}_N$ with their lifts as functions from $\mathbb{R}^{2V_N}$ to $\mathbb{R}^{2V_N}$. Using the definition (2.1) and looking for h_ϵ of the form $h_\epsilon(\psi)=\psi+\delta h_\epsilon(\psi)$, we find

$$\delta h_\epsilon \circ S_0 - S_0 \circ \delta h_\epsilon = \epsilon f \circ (\mathrm{Id}+\delta h_\epsilon), \tag{3.1}$$

where Id is the identity map.

Setting $\lambda \overset{def}{=} \lambda_- = \lambda_+^{-1}$ and writing $f(\psi) \overset{def}{=} \Sigma_{\xi,\alpha} f^{\xi\alpha}(\psi) w_{0,\alpha}^{(\xi)}$ and similarly for $\delta h_\epsilon^{\xi^\pm}$, we get

$$\begin{aligned} \delta h_\epsilon^{\xi^+}(S_0\psi) - \lambda^{-1}\delta h_\epsilon^{\xi^+}(\psi) &= \epsilon f^{\xi^+}(\psi+\delta h_\epsilon(\psi)), \\ \delta h_\epsilon^{\xi^-}(S_0\psi) - \lambda\,\delta h_\epsilon^{\xi^-}(\psi) &= \epsilon f^{\xi^-}(\psi+\delta h_\epsilon(\psi)). \end{aligned} \tag{3.2}$$

Both equations can be implicitly solved by iteration:

$$\delta h_\epsilon^{\xi\alpha}(\psi) = -\alpha\epsilon \sum_{p\geq 0} \lambda^{p+\rho_\alpha} f^{\xi\alpha}(S_0^{\alpha(p+1-\rho_\alpha)}\psi + \delta h_\epsilon(S_0^{\alpha(p+1-\rho_\alpha)}\psi)), \tag{3.3}$$

where $\rho_\alpha=(1+\alpha)/2$.

It is easy to see that the series in Eq. (3.3) is absolutely convergent, since $\lambda<1$ and f is bounded. Expanding $f^{\xi^\alpha}(\psi+\delta h_\epsilon(\psi))$ in power of its argument we find

$$f^{\mathbf{x}}(\psi+\delta h_\epsilon(\psi)) = f^{\mathbf{x}}(\psi) + \sum_{k\geq 1} \epsilon^k \sum_{s=1}^{k} \sum_{\substack{k_1+\cdots+k_s=k \\ k_1,\ldots,k_s \\ k_j\geq 1}} \left(\frac{f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} \delta h_{(k_1)}^{\mathbf{x}_1} \cdots \delta h_{(k_s)}^{\mathbf{x}_s} \right)(\psi), \tag{3.4}$$

where we have introduced the index $\mathbf{x}=(\xi,\alpha)$, with $\alpha=\pm$, and $f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}=\partial_{\mathbf{x}_1}\cdots\partial_{\mathbf{x}_s} f^{\mathbf{x}}$ with $\partial_{(\xi^\alpha)}$ the partial derivative in the direction of $w_{0,\alpha}^{(\xi)}$. Moreover, we use the convention of summing on twice repeated indexes. The first order coefficient of the expansion of the conjugation is then

$$\delta h_{(1)}^{\mathbf{x}}(\psi) = (-\alpha) \sum_{p\geq 0} \lambda^{p+\rho_\alpha} f^{\mathbf{x}}(S_0^{\alpha(p+1-\rho_\alpha)}\psi), \tag{3.5}$$

while the kth, $k>1$, coefficient turns out to be

$$\delta h_{(k)}^{\mathbf{x}}(\psi) = \sum_{s=1}^{k} \sum_{\substack{k_1+\cdots+k_s=k-1 \\ k_1,\ldots,k_s \\ k_j\geq 1}} (-\alpha) \sum_{p\geq 0} \lambda^{p+\rho_\alpha} \left(\frac{f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} \delta h_{(k_1)}^{\mathbf{x}_1} \cdots \delta h_{(k_s)}^{\mathbf{x}_s} \right)(S_0^{\alpha(p+1-\rho_\alpha)}\psi). \tag{3.6}$$

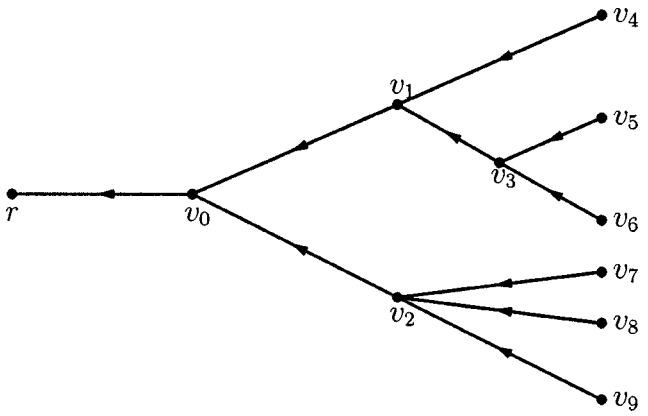

FIG. 2. A tree θ of order $k=10$ appearing in the expansion for δh_ϵ. Labels $\xi(v_i)$, $\alpha(v_i)$ and p_{v_i} are associated to all vertices v_i.

From Eq. (3.5) we see that δh_ϵ is in general nondifferentiable with respect to ψ. Indeed already differentiating $\delta h^{\xi^+}_{(1)}(\psi)$ with respect to ψ we find a nonconverging series. On the contrary, it is clear that Eq. (3.5) is Hölder continuous in ψ for every exponent $\beta<1$.

We can interpret Eq. (3.6) graphically as shown in Fig. 1.

The l.h.s. of the graphical equation in Fig. 1 represents $\delta h^{\mathbf{x}}_{(k)}(\psi)$ while the r.h.s., representing the sum in Eq. (3.6), is a "simple tree" consisting of a "root" r, a "root branch" $\lambda_v \equiv (r,v)$ coming from the "node" (or "vertex") v, and s_v branches "entering v," to be called $\lambda_{v_i} \equiv (v,v_i)$, $i=1,...,s_v$.

Even if the drawing in the figure does not carry them explicitly, we imagine that some labels are affixed to the node v: more precisely $\mathbf{x}(v)=(\xi(v),\alpha(v)) \in V_N \times \{\pm\}$ and $p_v \in \mathbb{Z}_+$. Furthermore, a label $\mathbf{x}_\lambda = (\xi_\lambda, \alpha_\lambda) \in V_N \times \{\pm\}$ is associated to each branch λ. In the figure above $\mathbf{x}_{\lambda_v} \equiv \mathbf{x}$ and $\mathbf{x}_{\lambda_{v_i}} \equiv \mathbf{x}_i$, $i=1,...,s$.

The node v symbolizes the tensor with entries

$$N_{v;\mathbf{x},\mathbf{x}_1,...,\mathbf{x}_s} \overset{def}{=} (-\alpha(v))\lambda^{p_v+\rho_{\alpha(v)}} \frac{f^{\mathbf{x},\mathbf{x}_1,...,\mathbf{x}_{s_v}}}{s_v!} (S_0^{p(v)}\psi), \tag{3.7}$$

where $p(v)=\alpha(v)(p_v+1-\rho_{\alpha(v)})$. Observe that, in order for Eqs. (3.7) and (3.6) to be nonzero, we must have $|\xi_{\lambda_{v_i}} - \xi(v)| \leq 1$, due to our definition of the coupling f.

The line λ_v exiting vertex v symbolizes the *propagator*, that is simply $\delta_{\mathbf{x}_{\lambda_v},\mathbf{x}(v)}$.

The line with label $\mathbf{x}$ exiting from the bullet of the l.h.s. with label (k) represents $\delta h^{\mathbf{x}}_{(k)}(\psi)$; the branches with labels $\mathbf{x}_i$ exiting from the bullets of the r.h.s. with label (k_i) represent $\delta h^{\mathbf{x}_i}_{(k_i)}(S_0^{p(v)}\psi)$.

Even if it is not explicitly written in the figure above, a summation over the free indices $\mathbf{x}(v)$, $\mathbf{x}_{\lambda_{v_i}}$ has to be performed [note that the summation over $\mathbf{x}(v)$ simply fixes $\mathbf{x}(v)=\mathbf{x}$, because of the presence of the propagator $\delta_{\mathbf{x}(v),\mathbf{x}}$].

Since Eq. (3.6) is multilinear in $\delta h^{\mathbf{x}_i}_{k_i}$, we can just replace each of the branches exiting from a bullet with the same graphical expression in the r.h.s. of the above figure, and so on, until the labels (k_i) on the bullets (*top nodes*) become equal to 1. In this case the end-points represent $\delta h_{(1)}$, that is a known expression, see Eq. (3.5), and we will draw these known end-points as small dots.

Thus we have represented our $\delta h^{\mathbf{x}}_{(k)}$ as a "sum over trees" with k branches and k nodes (we shall not regard the root as a node) of suitable *tree values*. In Fig. 2 we draw a typical tree θ we

get via such a procedure.

Note that a tree induces a partial ordering among its nodes: a node w precedes v (and it will be written $w<v$) if there is a path of branches connecting w and v with the arrows pointing from w to v.

Let us now summarize the discussion above. Let $\hat{\mathcal{T}}_k(\mathbf{x})$ be the set of rooted trees with k branches and k nodes, with labels $\mathbf{x}(v)$, p_v attached to their vertices and $\mathbf{x}(v_0)\equiv\mathbf{x}$, where v_0 is the last vertex preceding the root. Given $\theta\in\hat{\mathcal{T}}_k(\mathbf{x})$, let the value of θ be defined as

$$\widehat{\mathrm{Val}}(\theta,\psi)=\prod_{v\in\theta}(-\alpha(v))\lambda^{p_v+\rho_{\alpha(v)}}\frac{f^{\mathbf{x}(v),\mathbf{x}(v_1),\ldots,\mathbf{x}(v_{s_v})}}{s_v!}(S_0^{p(v)}\psi), \tag{3.8}$$

where $v_1,\ldots,v_{s_v}$ are the nodes immediately preceding v and $p(v)=\Sigma_{w\geqslant v}\alpha(v)(p_v+1-\rho_{\alpha(v)})$. With these definitions $\delta h^{\mathbf{x}}_{(k)}(\psi)$ can be calculated as $\delta h^{\mathbf{x}}_{(k)}(\psi)=\Sigma_{\theta\in\hat{\mathcal{T}}_k(\mathbf{x})}\widehat{\mathrm{Val}}(\theta,\psi)$.

B. Convergence and regularity of the perturbative expansion of the conjugation

By definition $g(\psi)$ depends only on $\psi_{nn(0)}$ so that it is analytic in $\mathcal{D}\overset{def}{=}\{\psi^i_\xi\in\mathbb{C}\,|\,|\mathrm{Im}\,\psi^j_\xi|\leqslant r_0, i=1,2,\xi\in nn(0)\}$ for some $r_0>0$. Calling G the maximum of g on $\mathcal{D}$, from Cauchy's formula we get

$$|f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}(\psi)|\leqslant G\frac{m_1!\cdots m_D!}{r_0^s}\leqslant G\frac{s!}{r_0^s}, \tag{3.9}$$

where $m_1,\ldots,m_D$ are the multiplicities of the partial derivatives with respect to the $D\overset{def}{=}2(2d+1)=2|nn(0)|$ possible variables (thus $m_1+\cdots+m_D=s$).

In the same way, if ψ and ψ' are identical on each site but $\xi'\in nn(\xi)$ and if $0<\beta\leqslant 1$, we get

$$|f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}(S_0^p\psi)-f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}(S_0^p\psi')|\leqslant G\frac{(s+1)!}{r_0^{s+1}}(2\pi^2)^{(1-\beta)/2}\lambda^{-\beta p}|\psi_{\xi'}-\psi'_{\xi'}|^\beta, \tag{3.10}$$

where we have used the periodicity of f. Next we bound the value of a tree $\theta\in\hat{\mathcal{T}}_k(\mathbf{x})$. Using Eq. (3.9), for $\theta\in\hat{\mathcal{T}}_k(\mathbf{x})$, we find

$$\|\widehat{\mathrm{Val}}(\theta,\cdot)\|_\infty\leqslant\prod_{v\in\theta}\lambda^{p_v}\frac{G}{r_0^{s_v}}=\frac{G^k}{r_0^{k-1}}\prod_{v\in\theta}\lambda^{p_v}, \tag{3.11}$$

where we used that, if $\theta\in\hat{\mathcal{T}}_k(\mathbf{x})$, $\Sigma_{v\in\theta}s_v=k-1$.

The sum over the trees can be interpreted as a sum over the topological trees and a sum over the labels attached to the trees. If Θ_k is the set of topological trees of order k, we get

$$\begin{aligned}\|\delta h^{\mathbf{x}}_{(k)}\|_\infty&\leqslant\sum_{\theta\in\Theta_k}\sum_{\substack{\mathbf{x}(v),\alpha(v)\\ v\in\theta}}\frac{G^k}{r_0^{k-1}}\sum_{\substack{p_v\\ v\in\theta}}\prod_{v\in\theta}\lambda^{p_v}=\sum_{\theta\in\Theta_k}\sum_{\substack{\xi(v),\alpha(v)\\ v\in\theta}}\frac{G^k}{r_0^{k-1}}\left(\frac{1}{1-\lambda}\right)^k\\&\leqslant\sum_{\theta\in\Theta_k}2^k(2d+1)^k\frac{G^k}{r_0^{k-1}}\left(\frac{1}{1-\lambda}\right)^k\leqslant 2^{2k}2^k(2d+1)^k\frac{G^k}{r_0^{k-1}}\left(\frac{1}{1-\lambda}\right)^k,\end{aligned} \tag{3.12}$$

where we used that:

(1) 2^k is the number of terms in the sum over the $\alpha(v)$ indices;

(2) $(2d+1)^k$ is a bound on the number of terms in the sum over the values of the $\xi(v)$ indices not making $\widehat{\mathrm{Val}}(\theta,\psi)$ vanish [observe that, given a tree θ, its value $\widehat{\mathrm{Val}}(\theta,\psi)$ is vanishing unless $|\xi(v')-\xi(v)|\leqslant 1$, where v' is the node immediately preceding v]; and
(3) 2^{2k} is a bound on the number of unlabeled rooted trees with k nodes.

In the same way we find that, if ψ and ψ' are identical on each site but ξ' and if $0<\beta<1$,

$$\frac{|\delta h^{\mathbf{x}}_{(k)}(\psi)-\delta h^{\mathbf{x}}_{(k)}(\psi')|}{|\psi_{\xi'}-\psi'_{\xi'}|^{\beta}} \leqslant \sum_{\theta\in\Theta}\left(\frac{1}{1-\lambda^{1-\beta}}\right)^k (2\pi^2)^{(1-\beta)/2}\frac{G^k}{r_0^k}2^k(2d+1)^k\sum_{v\in\theta}(s_v+1)$$
$$\leqslant 2^{2k}\left(\frac{1}{1-\lambda^{1-\beta}}\right)^k (2\pi^2)^{(1-\beta)/2}\frac{G^k}{r_0^k}2^k(2d+1)^k(2k-1). \tag{3.13}$$

So the map $h_\epsilon: \mathcal{T}_N\to\mathcal{T}_N$ exists; it is Hölder continuous w.r.t. ψ and analytic w.r.t. ϵ in the complex disc $|\epsilon|\leqslant\epsilon_\beta$, with

$$\epsilon_\beta=\left[\frac{1}{1-\lambda^{1-\beta}}2^3\frac{G}{r_0}(2d+1)\right]^{-1}. \tag{3.14}$$

In order to prove that $h_\epsilon(\psi)$ is an *homeomorphism*, we have to show that it is invertible. The proof is easy and standard. Regarding injectivity, note that two *distinct* points ψ_1, ψ_2, are necessarily far order one in the "future" or in the "past," namely there exists an integer $n\in\mathbb{Z}$ such that $|S_0^n\psi_1-S_0^n\psi_2|=O(1)$. Then $S^n_\epsilon(h_\epsilon(\psi_1))-S^n_\epsilon(h_\epsilon(\psi_2))=S^n_0(\psi_1-\psi_2)+\delta h_\epsilon(S^n_0\psi_1)-\delta h_\epsilon(S^n_0\psi_2)$ cannot vanish as the first term is order one, the other two of order ϵ; thus it cannot be but $h_\epsilon(\psi_1)\neq h_\epsilon(\psi_2)$. Regarding surjectivity, since f is a continuous injective mapping on a torus, f is necessarily surjective (the proof is trivial on $\mathbb{T}^1$ and it can be easily extended by induction to $\mathcal{T}_N$).

IV. THE UNSTABLE DIRECTION

In order to explicitly compute the SRB measure, we have to construct a basis for the unstable subspace E^+_ψ, and the expansion coefficient $\mathcal{D}^{(n)}_\epsilon$ associated to it, as explained in Sec. II B above. Note that we cannot use h_ϵ to find a basis for E^+_ψ because it is only Hölder continuous.

To find the unstable base $\{w^{(\xi)}_{\epsilon,+}(\psi)\}_{\xi\in V}$ and the *Lyapunov matrix* $\mathcal{L}(\psi)$ we have to solve the following equation:

$$(DS_\epsilon w^{(\eta)}_{\epsilon,+})(\psi)=w^{(\xi)}_{\epsilon,+}(S_\epsilon(\psi))\mathcal{L}^{\xi\eta}(\psi). \tag{4.1}$$

In general this equation cannot have solutions analytic in ϵ. In fact, from the general theory we know that the unstable vectors $\{w^{(\xi)}_{\epsilon,+}(\psi)\}_{\xi\in V}$ are not differentiable with respect to ψ. But, as we previously pointed out, to compute the SRB measure we need only to know the expansion coefficient at the point $h_\epsilon(\psi)$, i.e., $\mathcal{D}^{(n)}_\epsilon(h_\epsilon(\psi))$. Let us define $w^{(\xi)}_{\epsilon,+}(h_\epsilon(\psi))\overset{def}{=}v^{(\xi)}_\epsilon(\psi)$ for $\xi\in V$ and note that $v^{(\xi)}_\epsilon(\psi)$ satisfies the equation

$$(DS_\epsilon)(h_\epsilon(\psi))v^{(\eta)}_\epsilon(\psi)=v^{(\xi)}_\epsilon(S_0\psi)L^{\xi\eta}(\psi),\quad L(\psi)=\mathcal{L}(h_\epsilon(\psi)). \tag{4.2}$$

We will show that this equation admits a solution analytic in ϵ. Moreover, the determinant of $L(\psi)$ is all what we need to compute the SRB measure.

At this point, it is convenient to write Eq. (4.2) in components. Denoting by $\mathbf{y}$ the double index η^β (again $\mathbf{x}\overset{def}{=}\xi^\alpha$), defining $v^{(\xi)}_\epsilon(\psi)\overset{def}{=}\Sigma_\eta V^{(\xi)}_{\epsilon,\mathbf{y}}(\psi)w^{(\eta)}_{0,\beta}$ and $(DS_\epsilon w^{(\eta)}_{0,\beta})(\psi)\overset{def}{=}\Sigma_{\mathbf{x}}S^{\mathbf{x},\mathbf{y}}_\epsilon(\psi)w^{(\xi)}_{0,\alpha}$, we get

$$S_{\epsilon}^{\mathbf{x},\mathbf{y}}(h_{\epsilon}(\psi))V_{\epsilon,\mathbf{y}}^{(\rho)}(\psi)=V_{\epsilon,\mathbf{x}}^{(\zeta)}(S_0\psi)L^{\zeta\rho}(\psi). \tag{4.3}$$

Now, defining the corrections δL and δV as follows,

$$L^{\xi\eta}(\psi)\overset{def}{=}\lambda^{-1}\delta_{\xi\eta}+\delta L^{\xi\eta}(\psi),\quad V_{\epsilon,\mathbf{x}}^{(\xi)}(\psi)\overset{def}{=}V_{0,\mathbf{x}}^{(\xi)}+\delta V_{\mathbf{x}}^{(\xi)}(\psi)\quad\text{with } V_{0,\eta^+}^{(\xi)}=\delta_{\xi,\eta},\quad V_{0,\eta^-}^{(\xi)}=0, \tag{4.4}$$

we find that (4.3) is equivalent to

$$\begin{aligned}\delta L^{\xi\rho}(\psi)&=\lambda^{-1}[\delta V_{\xi^+}^{(\rho)}(\psi)-\delta V_{\xi^+}^{(\rho)}(S_0\psi)]+\epsilon f^{\xi^+,\rho^+}(h_{\epsilon}(\psi))+\epsilon f^{\xi^+,\mathbf{y}}(h_{\epsilon}(\psi))\,\delta V_{\mathbf{y}}^{(\rho)}(\psi)\\&\quad-\delta V_{\xi^+}^{(\zeta)}(S_0\psi)\,\delta L^{\zeta\rho}(\psi),\\ \lambda\,\delta V_{\xi^-}^{(\rho)}(\psi)-\lambda^{-1}\delta V_{\xi^-}^{(\rho)}(S_0\psi)&=-\epsilon f^{\xi^-,\rho^+}(h_{\epsilon}(\psi))-\epsilon f^{\xi^-,\mathbf{y}}(h_{\epsilon}(\psi))\,\delta V_{\mathbf{y}}^{(\rho)}(\psi)\\&\quad+\delta V_{\xi^-}^{(\zeta)}(S_0\psi)\,\delta L^{\zeta\rho}(\psi).\end{aligned} \tag{4.5}$$

Of course the above equations cannot determine completely the basis and its associated matrix: indeed, given a solution $\{V_{\mathbf{y}}^{(\rho)}(\psi)\}$, $\{L^{\zeta\rho}(\psi)\}$ of Eq. (4.2) and a generic invertible Hölder continuous matrix $R^{\gamma\rho}(\psi)$, also $\{V_{\mathbf{y}}^{(\gamma)}(\psi)R^{\gamma\rho}(\psi)\}$, $\{R^{-1,\zeta\delta}(S_0\psi)L^{\delta\gamma}(\psi)R^{\gamma\rho}(\psi)\}$ solve (4.2). Thus it is possible to add a constraint to $\delta V_{\mathbf{y}}^{(\rho)}(\psi)$: a possible choice, which greatly simplifies the expressions above, consists in taking $\delta V_{\rho^+}^{(\xi)}(\psi)=0$, so that (4.5) becomes

$$\begin{aligned}\delta L^{\xi\rho}(\psi)&=\epsilon f^{\xi^+,\rho^+}(h_{\epsilon}(\psi))+\epsilon f^{\xi^+,\eta^-}(h_{\epsilon}(\psi))\,\delta V_{\eta^-}^{(\rho)}(\psi),\\ \lambda\,\delta V_{\xi^-}^{(\rho)}(\psi)-\lambda^{-1}\delta V_{\xi^-}^{(\rho)}(S_0\psi)&=-\epsilon f^{\xi^-,\rho^+}(h_{\epsilon}(\psi))-\epsilon f^{\xi^-,\eta^-}(h_{\epsilon}(\psi))\,\delta V_{\eta^-}^{(\rho)}(\psi)\\&\quad+\delta V_{\xi^-}^{(\zeta)}(S_0\psi)\,\delta L^{\zeta\rho}(\psi).\end{aligned} \tag{4.6}$$

An implicit solution of (4.6) (to be inverted iteratively by a new tree expansion, see below) is

$$\begin{aligned}\delta L^{\xi\rho}(\psi)&=\epsilon f^{\xi^+,\rho^+}(h_{\epsilon}(\psi))+\epsilon f^{\xi^+,\eta^-}(h_{\epsilon}(\psi))\,\delta V_{\eta^-}^{(\rho)}(\psi),\\ \delta V_{\xi^-}^{(\rho)}(\psi)&=\sum_{j\geqslant 0}\lambda^{2j+1}[\epsilon f^{\xi^-,\rho^+}(h_{\epsilon}(S_0^{-j}\psi))+\epsilon f^{\xi^-,\eta^-}(h_{\epsilon}(S_0^{-j}\psi))\,\delta V_{\eta^-}^{(\rho)}(S_0^{-j}\psi)\\&\quad-\delta V_{\xi^-}^{(\zeta)}(S_0^{-j+1}\psi)\,\delta L^{\zeta\rho}(S_0^{-j}\psi)].\end{aligned} \tag{4.7}$$

As for the construction of the conjugation, we can expand in power series of ϵ both sides of Eq. (4.7) and equate the coefficients of the same order, thus finding an iterative solution of $\delta L_{(k)}$ and $\delta V_{(k)}$. The first order coefficients are given by

$$\begin{aligned}\delta L_{(1)}^{\xi\rho}(\psi)&=f^{\xi^+,\rho^+}(\psi),\\ \delta V_{\xi^-(1)}^{(\rho)}(\psi)&=\sum_{j\geqslant 0}\lambda^{2j+1}f^{\xi^-,\rho^+}(S_0^{-j}\psi),\end{aligned} \tag{4.8}$$

while, for $k+1\geqslant 2$,

$$\delta L^{\xi\rho}_{(k+1)}(\psi)=\sum_{s\geqslant 1,k_i\geqslant 1}^{k_1+\cdots+k_s=k}\left(\frac{f^{\xi^+,\rho^+\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!}\,\delta h^{\mathbf{x}_1}_{(k_1)}\cdots\delta h^{\mathbf{x}_s}_{(k_s)}\right)(\psi)$$
$$+\sum_{s\geqslant 1,k_i\geqslant 1}^{k_1+\cdots+k_s=k}\left(\frac{f^{\xi^+,\eta^-\mathbf{x}_2,\ldots,\mathbf{x}_s}}{(s-1)!}\,\delta V^{(\rho)}_{\eta^-(k_1)}\delta h^{\mathbf{x}_2}_{(k_2)}\cdots\delta h^{\mathbf{x}_s}_{(k_s)}\right)(\psi) \tag{4.9}$$

and

$$\delta V^{(\rho)}_{\xi^-(k+1)}(\psi)=\sum_{s\geqslant 1,k_i\geqslant 1}^{k_1+\cdots+k_s=k}\sum_{j\geqslant 0}\lambda^{2j+1}\left(\frac{f^{\xi^-,\rho^+\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!}\,\delta h^{\mathbf{x}_1}_{(k_1)}\cdots\delta h^{\mathbf{x}_s}_{(k_s)}\right)(S_0^{-j}\psi)$$
$$+\sum_{s\geqslant 1,\ k_i\geqslant 1}^{k_1+\cdots+k_s=k}\sum_{j\geqslant 0}\lambda^{2j+1}\left(\frac{f^{\xi^-,\eta^-\mathbf{x}_2,\ldots,\mathbf{x}_s}}{(s-1)!}\,\delta V^{(\rho)}_{\eta^-(k_1)}\delta h^{\mathbf{x}_2}_{(k_2)}\cdots\delta h^{\mathbf{x}_s}_{(k_s)}\right)(S_0^{-j}\psi)$$
$$-\sum_{s\geqslant 1,k_i\geqslant 1}^{k_1+\cdots+k_s=k}\sum_{j\geqslant 0}\lambda^{2j+1}\left(\frac{f^{\zeta^+,\rho^+\mathbf{x}_2,\ldots,\mathbf{x}_s}}{(s-1)!}\,(\delta V^{(\zeta)}_{\xi^-(k_1)}\circ S_0)\,\delta h^{\mathbf{x}_2}_{(k_2)}\cdots\delta h^{\mathbf{x}_s}_{(k_s)}\right)(S_0^{-j}\psi)$$
$$-\sum_{s\geqslant 2,k_i\geqslant 1}^{k_1+\cdots+k_s=k}\sum_{j\geqslant 0}\lambda^{2j+1}\left(\frac{f^{\zeta^+,\eta^-\mathbf{x}_3,\ldots,\mathbf{x}_s}}{(s-2)!}\,(\delta V^{(\zeta)}_{\xi^-(k_1)}\circ S_0)\,\delta V^{(\rho)}_{\eta^-(k_2)}\delta h^{\mathbf{x}_3}_{(k_3)}\cdots\delta h^{\mathbf{x}_s}_{(k_s)}\right)$$
$$\times(S_0^{-j}\psi). \tag{4.10}$$

These two relations, together with (3.6), allow a recursive construction of δL and δV. Obviously, repeating the discussion of Sec. III A, one finds that δL and δV can be expressed as sums over trees, obtained by suitably modifying the construction of previous section. It can be easily realized that the estimates for the tree values are qualitatively the same as before [see Eqs. (3.11)–(3.13)]. We point out the differences appearing in the tree expansion for δV:

(1) The nodes can be of four different types [corresponding to the four lines in Eq. (4.10)], so that the number of possible labels for a tree of order k is larger than a factor 4^k.
(2) The number D_v of derivatives acting on a node function can be either s_v or s_v+1 [see Eqs. (4.9) and (4.10)], so that $D_v!$ differs from the combinatorial factor $s_v!$ by at most s_v+1. Then the final estimate contains a factor that can be bounded by $(1/r_0)\Pi_v(s_v+1)\leqslant e^k/r_0$.

A similar discussion can be made for the tree expansion of δL.

The result is that L and V are analytic in ϵ and Hölder continuous in ψ with exponent $0<\beta<1$ in a disc $|\epsilon|\leqslant\epsilon'_\beta$, with ϵ'_β smaller than the convergence radius ϵ_β of h_ϵ [see Eq. (3.14)]. Note that also in this case ϵ'_β is independent of N.

As already explained (see Sec. II B and in particular Eq. (2.7)], in order to compute the SRB measure we need $\Lambda^\xi=(\log L)^{\xi\xi}\overset{def}{=}-\log\lambda+\delta\Lambda^\xi$, where

$$\delta\Lambda^\xi(\psi)=[\log(I+\lambda\,\delta L)]^{\xi\xi}=\sum_{s\geqslant 1}\frac{(-1)^{s+1}}{s}\lambda^s\,\delta L^{\xi\eta_1}(\psi)\cdots\delta L^{\eta_{s-1}\xi}(\psi) \tag{4.11}$$

(no summation on ξ is intended). Expanding Eq. (4.11) in series of ϵ, we get

$$\delta\Lambda^\xi_{(k)}(\psi)=\sum_{s\geqslant 1,k_i\geqslant 1}^{k_1+\cdots+k_s=k}\frac{(-1)^{s+1}}{s}\lambda^s\,\delta L^{\xi\eta_1}_{(k_1)}(\psi)\cdots\delta L^{\eta_{s-1}\xi}_{(k_s)}(\psi). \tag{4.12}$$

Again, the last equation, together with (4.10) and (3.6), allows a recursive construction of the coefficients $\delta\Lambda^{\xi}_{(k)}$ and the result is that Λ^{ξ} is a sum over (suitably modified) trees. The bounds are still qualitatively the same, so that Λ^{ξ} is analytic w.r.t. ϵ in a suitably small complex disc (independent of N) and Hölder continuous w.r.t. ψ.

V. SRB POTENTIALS

The next step towards the construction of the SRB measure and the proof of its analyticity consists in the expansion of Λ^{ξ} in potentials ϕ_X. From the analysis of previous sections it follows that Λ^{ξ}, as well as $h^{\mathbf{x}}_{\epsilon}$, $V^{(\rho)}_{\xi^-}$ and $L^{\xi\eta}$, can be expanded in convergent sums over tree values. We will discuss here how to expand h in potentials, since the analogous expansion for V, L and Λ is conceptually similar, just more involved due to the more complex structure of the trees.

We will proceed as follows. We first write the values of the trees in terms of the symbolic variables σ. We then decompose each of these values as a sum of terms only depending on the σ's on finite but arbitrary large sets. Finally, we define the associated potentials by collecting together the contributions which depend on the same σ's. Our goal is to obtain potentials defined over sets with rather arbitrary shape but decaying exponentially with the *tree distance* [see after Eq. (2.8) for a precise definition] of their support.

To begin with we expand the derivatives of the perturbation function f via a telescopic sum. Given the digits s and $s' \in \{1,...,n\}$ we can always find a sequence of digits $\Sigma(s,s') = s_1 s_2 \cdots s_{a-1}$ such that the sequence $s\Sigma(s,s')s'$ is compatible, i.e., such that $C_{s_i,s_{i+1}}=1$ for $i=0,...,a-1$, where $s_0=s$ and $s_a=s'$. Choosing a sequence $\hat{\sigma} \in \{1,...,n\}^{\mathbb{Z}}_C$ once and for all, given $\sigma \in \{1,...,n\}^{\mathbb{Z}}_C$ we can define its restriction to time j, σ^j as follows: $\sigma^j_{\xi,t}=\sigma_{\xi,t}$ if $|t|\leqslant j$, $\sigma^j_{\xi,t}=\hat{\sigma}_{\xi,t}$ if $|t|>j+a$ and the gap is filled with the sequence constructed above for $s=\sigma_{\xi,\pm j}$ and $s'=\hat{\sigma}_{\xi,\pm(j+a)}$. We can now define

$$f^{\mathbf{x},\mathbf{x}_1,\dots,\mathbf{x}_s}(c_0(\sigma)) = f^{\mathbf{x},\mathbf{x}_1,\dots,\mathbf{x}_s}(c_0(\sigma^0)) + \sum_{j\geqslant 1}\left[f^{\mathbf{x},\mathbf{x}_1,\dots,\mathbf{x}_s}(c_0(\sigma^j)) - f^{\mathbf{x},\mathbf{x}_1,\dots,\mathbf{x}_s}(c_0(\sigma^{j-1}))\right]$$

$$\stackrel{def}{=} \sum_{j\geqslant 0} f^{\mathbf{x},\mathbf{x}_1,\dots,\mathbf{x}_s}_{(j)}(\sigma_{nn^{(j)}(\xi)}), \tag{5.1}$$

where ξ is the spatial coordinate associated to $\mathbf{x}$ and $nn^{(j)}(\xi)=nn(\xi)\times I_j$, $I_j=[-j,j]\cap\mathbb{Z}$. Since $|c_0(\sigma^j)-c_0(\sigma^{j-1})|\leqslant c\lambda^j$ for some $c>0$, $f^{\mathbf{x},\mathbf{x}_1,\dots,\mathbf{x}_s}_{(j)}$ is bounded by

$$\|f^{\mathbf{x},\mathbf{x}_1,\dots,\mathbf{x}_s}_{(j)}\|_{\infty} \leqslant G\frac{(s+1)!}{r_0^{s+1}} c\lambda^j. \tag{5.2}$$

A. Decay of the potentials for the conjugation

Inserting expansion (5.1) in the definition of the value of a tree Eq. (3.8), we find

$$\widehat{\mathrm{Val}}(\theta,c_0(\sigma)) = \prod_{v\in\theta}\sum_{j_v\geqslant 0}(-\alpha(v))\lambda^{p_v+\rho_{\alpha(v)}}\frac{f^{\mathbf{x}(v),\mathbf{x}(v_1),\dots,\mathbf{x}(v_{s_v})}_{(j_v)}}{s_v!}(\tau^{p(v)}\sigma_{nn^{(j_v)}(\xi(v))}), \tag{5.3}$$

where we recall that $\rho_{\alpha(v)}=(1+\alpha(v))/2$, $p(v)=\Sigma_{w\geqslant v}\alpha(v)(p_v+1-\rho_{\alpha(v)})$ and $nn^{(j)}(\xi)=nn(\xi)\times I_j$, $I_j=[-j,j]\cap\mathbb{Z}$. The above expression can be seen as a sum over the values of a new kind of trees, identical to the ones described in Sec. III A, but with a new label $j_v\in\mathbb{N}$ attached to each node. Let $\mathcal{T}_k(\mathbf{x})$ be the set of these new trees of order k contributing to $\delta h^{\mathbf{x}}_{(k)}$, i.e., $\theta\in\mathcal{T}_k(\mathbf{x})$ is a tree with k branches and k nodes (the root is not a node) with the following labels attached to the nodes $v\in\theta$: $\xi(v)\in V$, $p_v\in\mathbb{N}$, $j_v\in\mathbb{N}$ and $\alpha(v)\in\{-1,+1\}$.

Given $\theta\in\mathcal{T}_k(\mathbf{x})$, its value is given by

$$\text{Val}\ \ \theta(\sigma)=\prod_{v\in\theta}(-\alpha(v))\lambda^{p_v+\rho_{\alpha(v)}}\frac{f_{(j_v)}^{\mathbf{x}(v),\mathbf{x}(v_1),\ldots,\mathbf{x}(v_{s_v})}}{s_v!}(\tau^{p(v)}\sigma_{nn^{(j_v)}(\xi(v))}), \tag{5.4}$$

so that we have

$$\delta h^{\mathbf{x}}_{(k)}(c_0(\sigma))=\sum_{\theta\in\mathcal{T}_k(\mathbf{x})}\text{Val}\ \ \theta(\sigma)\quad\text{with}\ \|\text{Val}\ \ \theta\|_\infty\leqslant\left(\frac{ceG}{\lambda r_0^2}\right)^k\prod_{v\in\theta}\lambda^{j_v+p_v+1}, \tag{5.5}$$

where we have used Eq. (5.2). We can now define the support $X(\theta)\subset V\times\mathbb{Z}$ of a tree $\theta\in\mathcal{T}_k(\mathbf{x})$, as the support of the spin variables on which Val θ depends in a nontrivial way, plus a *center* $(\xi,0)$. More precisely,

$$X(\theta)\overset{def}{=}\{(\xi,0)\}\cup\bigcup_{v\in 0}\mathcal{C}(\xi(v),p(v),j_v),$$

where

$$\mathcal{C}(\xi(v),p(v),j_v)\overset{def}{=}\bigcup_{\eta\in nn(\xi(v))}\ \bigcup_{|i|\leqslant j_v}(\eta,p(v)+i). \tag{5.6}$$

namely $\mathcal{C}(\xi,p,j)$ is a cylinder centered in (ξ,p), with the spatial base equal to the set of nearest neighbors of ξ and with height equal to $2j$. Then $X(\theta)$ is the union of $(\xi,0)$ and of cylinders of this kind, one for each node v of the tree. The point $(\xi,0)$ has the role of center of $X(\theta)$ and is added to $X(\theta)$ for later convenience [note in fact that Val $\theta(\sigma)$ could not depend on $\sigma_{(\xi,0)}$].

Given a set $X\subset\mathbb{Z}^{d+1}$ we can partition it in a natural way as a union of timelike segments. More precisely, given $\xi\in\mathbb{Z}^d$, let $T_\xi=\{(\xi,i)\in\mathbb{Z}^{d+1}|i\in\mathbb{Z}\}$. The intersection between T_ξ and X can be uniquely partitioned as a union of n_ξ maximal connected segments. The collection of all these segments forms a partition of X in n_X timelike segments $\{R_i(X)\}_{i=1,\ldots,n_X}$. Let now r_i be the center of $R_i(X)$. If Y is a subset of $\mathbb{Z}^{d+1}$, we call tree distance of Y, $d_t(Y)$, the length of the minimal tree connection of all the points of Y. Finally, let $d_c(X)$ be the tree distance of the set $\{r_i\}_{i=1,\ldots,n_X}$.

From the previous bound on the value of a tree $\theta\in\mathcal{T}_k(\mathbf{x})$, Eq. (5.5) can be interpreted as the tree distance decay of the contribution of order k to δh. Indeed,

$$|\epsilon|^k\|\text{Val}\ \ \theta\|_\infty\leqslant\left(\frac{ceG|\epsilon|^{1/2}}{\lambda r_0^2}\right)^k\left[\lambda^{d_c(X(\theta))}|\epsilon|^{n_{X(\theta)}/2}\prod_{i=1}^{n_{X(\theta)}}\lambda^{|R_i(X(\theta))|}\right]^{1/(2d+1)}, \tag{5.7}$$

where we have the following.

(1) The factor $\lambda^{d_c(X(\theta))}$ comes from $\Pi_{v\in\theta}\lambda^{1+p_v}$; in fact p_v is the displacement in the time direction of the cylinder associated to the node v w.r.t. the one associated to the node v' immediately following v, and 1 is their maximum displacement in spatial direction, so that $\Sigma_v(1+p_v)\geqslant d_c(X(\theta))$.
(2) We used that $n_X\leqslant(2d+1)k$ in order to bound $|\epsilon|^{k/2}$ with $|\epsilon|^{n_X/2(2d+1)}$.
(3) The factor $\Pi_{i=1}^{n_{X(\theta)}}\lambda^{|R_i(X(\theta))|}$ comes from $\Pi_{v\in\theta}\lambda^{j_v}$.
(4) The global power $1/(2d+1)$ in (5.7) comes from the size of the base of each cylinder, namely we used the fact that the number n_X of segments is less than $2d+1$ times the number of cylinders in $X(\theta)$.

Collecting together all the trees θ which have support $X(\theta)=X$ for a given X, we get

$$\delta h^{\mathbf{x}}_{\epsilon}(c_0(\sigma)) = \sum_{X \ni (\xi,0)} \delta h^{\mathbf{x}}_X(\sigma_X) \quad \text{with} \quad \delta h^{\mathbf{x}}_X(\sigma_X) \stackrel{def}{=} \sum_{k \geq 1} \epsilon^k \sum_{\theta \in \mathcal{T}_k(\mathbf{x})} \sum^{X(\theta)\equiv X} \text{Val} \quad \theta(\sigma). \tag{5.8}$$

So, using the bound (5.7) for $|\epsilon|$ small enough, $\gamma_0 = 1/2(2d+1)$, $\kappa_0 = -2\gamma_0 \log \lambda$, $\nu_0 = |\epsilon|^{\gamma_0}$ and a suitable $c > 0$, we get

$$\| \delta h^{\mathbf{x}}_X \|_\infty \leq c e^{-\kappa_0 d_c(X)} \nu_0^{n_X} \prod_{i=1}^{n_X} e^{-\kappa_0 |R_i(X)|}, \tag{5.9}$$

namely $\delta h^{\mathbf{x}}_X$ decays exponentially with the tree distance of X.

B. SRB potentials and their decay

Proceeding as above for the function $\Lambda^{\xi}(c_0(\sigma))$ we obtain that we can write it as

$$\Lambda^{\xi}(c_0(\sigma)) \stackrel{def}{=} \sum_{X \subset (V_N \times \mathbb{Z})} \phi^{(\xi,0)}_X(\sigma_X),$$

where by construction $\phi^{(\xi,0)}_X$ is different from 0 only if $(\xi,0) \in X$. The function $\phi^{(\xi,0)}_X$ is again given by a tree expansion analogous to that in Eq. (5.8). Moreover, we will set

$$\phi^{(\xi,j)}_X(\sigma_X) \stackrel{def}{=} \phi^{(\xi,0)}_{\tau^{-j}X}(\sigma_X).$$

We can define

$$\phi_X(\sigma_X) \stackrel{def}{=} \sum_{(\xi,j) \in X} \phi^{(\xi,j)}_X(\sigma_X),$$

so that we formally obtain Eq. (2.8), namely, given $I_T = [-T/2, T/2] \cap \mathbb{Z}$ (T even) and calling $\Lambda = V_N \times I_T$,

$$\sum_{(\xi,i) \in \Lambda} \Lambda^{\xi}(c_0(\tau^i \sigma)) - \sum_{X \cap \Lambda \neq \emptyset} \phi_X(\sigma_X) = O(\partial \Lambda),$$

where $\partial\Lambda$ is the boundary of Λ and the correction can be exactly computed from the definitions above.

Note the potential $\phi_X(\sigma_X)$ is invariant under time and space translations (respectively for the definition of $\phi^{(\xi,i)}_X$ and for the periodic boundary conditions), namely,

$$\phi_X(\sigma_X) = \phi_{\rho^{\xi} \tau^j X}(\sigma_X) \quad \text{for any} \quad (\xi,j) \in V_N \times \mathbb{Z}. \tag{5.10}$$

Moreover, it can be bounded by

$$\| \phi_X \|_\infty \leq c e^{-\kappa_1 d_c(X)} \nu_1^{n_X} \prod_{i=1}^{n_X} e^{-\kappa_1 |R_i(X)|}, \tag{5.11}$$

for suitable c, γ_1, $\kappa_1 > 0$ and $\nu_1 = |\epsilon|^{\gamma_1}$.

VI. ANALYTICITY OF SRB MEASURE

In the previous sections, we wrote the SRB measure as a Gibbs measure with translationally invariant potentials ϕ_X, decaying as in (5.11), and with hard core interaction in time direction.

Moreover, the potential ϕ_X is analytic in ϵ in a small disc in $\mathbb{C}$ around the origin (independent of N). A well known technique to show analyticity of the Gibbs measure w.r.t. ϵ is the so called *cluster expansion*.

If $\Lambda = V_N \times I_T$, with $I_T \overset{def}{=} [-T/2, T/2] \cap \mathbb{Z}$ for some even $T \in \mathbb{N}$, we call $\Lambda_a = V_N \times I_{T+2a}$. Given a *boundary condition* $\overline{\sigma} \in \{1,...,n\}_C^{\mathbb{Z}^{d+1}}$, we define the *pressure* P_Λ as

$$P_\Lambda \overset{def}{=} |\Lambda|^{-1} \log \sum_\sigma e^{-\Sigma_{X \cap \Lambda \neq \emptyset} \phi_X(\sigma_X)}, \tag{6.1}$$

where the sum is over all the σ that coincide with σ_Λ on Λ, to $\overline{\sigma}$ on Λ_a^c and with $\Sigma(\sigma_{\xi,T/2}, \overline{\sigma}_{\xi,T/2+a})$ in the space remaining. It is well known that the pressure P_Λ can be considered as the generating functional for the Gibbs states. From its analyticity our main theorem will follow easily, as we will see in Sec. VI D.

A. Decimation

In the presence of hard cores we cannot proceed in the standard way (Mayer's expansion), since the standard proof (see Ref. 13) requires weakness of the original interactions. We can overcome this obstacle by a *decimation* (see Ref. 7), namely considering the statistical system on scales larger than the length of decorrelation of the hard core.

1. Decimated lattice Λ_D

For each $\xi \in V_N$, we divide the time interval $I_T^\xi \overset{def}{=} \{\xi\} \times I_T$ into an alternating sequence of blocks, called "*B*-type" and "*H*-type," $B_\xi^{(0)}$, $H_\xi^{(0)}$, $B_\xi^{(1)}$, $H_\xi^{(1)}$,..., $B_\xi^{(\ell-1)}$, $H_\xi^{(\ell-1)}$, $B_\xi^{(\ell)}$, containing a number of spins respectively equal to $b=1$ and $h = h_0 a - 1$, with $h_0 \in \mathbb{N}$ to be chosen later. For this reason we choose the number of points in I_T^ξ to be $|I_T^\xi| = \ell h_0 a + 1$, namely $T = \ell h_0 a$.

Remark: The choice $b=1$ is special for the present case, in which the unperturbed potential is vanishing. In general one could treat with the same technique the case in which the unperturbed potential is order one, with a sufficiently fast decay of the tails, and in that case b should be chosen suitably large (see Ref. 7). Such a case arises, for instance, when the unperturbed system is the product of nonlinear Anosov maps on $\mathbb{T}^2$, namely in the case treated in Appendix A. The present discussion could be easily adapted to cover that case.

Let $\beta_\xi^{(i)} \overset{def}{=} \sigma_{(\xi, -T/2 + i h_0 a)}$, $\xi \in V_N$, $i = 0,...,\ell$, be the spin in the block $B_\xi^{(i)}$ and $\eta_\xi^{(i)} \overset{def}{=} \{\sigma_{(\xi,p)}\}_{(\xi,p) \in H_\xi^{(i)}}$, $\xi \in V_N$, $i = 0,...,\ell-1$, be the collection of spins belonging to the block $H_\xi^{(i)}$; it will be regarded as a sequence of h β spins: $\eta_\xi^{(i)} = (\beta_1(\eta_\xi^{(i)}), \ldots, \beta_h(\eta_\xi^{(i)}))$. The lattice obtained considering the H and B blocks as points:

$$\Lambda_D \overset{def}{=} \{B_\xi^{(p)}, H_\xi^{(q)}\}_{\xi \in V_N, p=0,...,\ell}^{q=0,...,\ell-1} \tag{6.2}$$

will be called the *decimated lattice*; on Λ_D the distances will be computed by thinking of it as having its sites spaced by 1 also in the time direction.

If $X \subset \Lambda$, $Y(X)$ will denote the corresponding subset in Λ_D, namely the smaller subset $Y \subset \Lambda_D$ such that the union of the *B*- and *H*-blocks in Y contains the set X. Defining $\Phi_Y(\beta_Y, \eta_Y) \overset{def}{=} \Sigma_{X: Y(X) = Y} \phi_X(\sigma_x)$ Eq. (6.1) can be rewritten as

$$P_\Lambda = \frac{1}{|\Lambda|} \log \sum_{\beta_\Lambda} \sum_{\eta_\Lambda} e^{-\Sigma_{Y\subset\Lambda_D} \Phi_Y(\beta_Y,\eta_Y)} \prod_{\xi\in V} \prod_{i=0}^{\ell-1} Z(\beta_\xi^{(i)}, \eta_\xi^{(i)}, \beta_\xi^{(i+1)}),$$

where

$$Z(\beta,\eta,\beta') = C_{\beta\beta_1(\eta)} C_{\beta_1(\eta)\beta_2(\eta)} \cdots C_{\beta_{h-1}(\eta)\beta_h(\eta)} C_{\beta_h(\eta)\beta'}. \tag{6.3}$$

Observe that, from Eq. (5.11), if Y does not coincide with a single H-block, Φ_Y satisfies a qualitatively equivalent bound:

$$\|\Phi_Y\|_\infty \leqslant c e^{-\tilde{\kappa} d_c(Y)} \tilde{\nu}^{n_Y} \prod_{i=1}^{n_Y} e^{-\tilde{\kappa}|R_i(Y)|}, \quad Y \neq H_\xi^{(i)}, \tag{6.4}$$

for some c, $\tilde{\kappa}$, $\tilde{\gamma}>0$ and $\tilde{\nu}=|\epsilon|^{\tilde{\gamma}}$. Whereas if $Y=H_\xi^{(i)}$ for some $\xi\in V$ and some $i=0,\ldots,\ell-1$, we have $\|\Phi_Y\|_\infty \leqslant h\tilde{\nu}$.

2. Averaging over many degrees of freedom: The Perron–Frobenius theorem

Decimation is a *renormalization group* technique, consisting in summing first on the H-type spins, thus getting an effective statistical system for the B-blocks: the idea is that if the B-blocks are sufficiently far apart, after the averaging of the η's, the β's should be *almost independent*, as if there were only small interactions among them. The technical tool we shall use to prove rigorously that the effective interactions between the β's are small is the Perron–Frobenius theorem.

Let $Z(\beta,\beta')$ be defined, with a little abuse of notation, as

$$Z(\beta,\beta') \stackrel{def}{=} \sum_\eta Z(\beta,\eta,\beta') = C^{ah_0}_{\beta\beta'}. \tag{6.5}$$

Observe that $1 \leqslant C^a_{\sigma\sigma'} \leqslant q^a$. Since C^a has strictly positive entries, we can apply the Perron–Frobenius theorem and obtain that C^a and its transpose $C^{a,T}$ admit a nondegenerate eigenvalue $l>0$ with eigenvectors π and π^*, respectively, such that π_σ, $\pi^*_\sigma>0$ for any $\sigma=1,\ldots,q$, and $\Sigma_\sigma \pi^*_\sigma \pi_\sigma = 1$. The eigenvalue l is maximal in the spectrum of C^a; namely, if we define P as the projection matrix $P_{\sigma\sigma'} = \delta_{\sigma\sigma'} - \pi_\sigma \pi^*_{\sigma'}$, we have

$$\|(l^{-1}C^a)^k P \omega\|_\infty \leqslant c_\alpha e^{-\alpha k} \|\omega\|_\infty, \tag{6.6}$$

for any $\omega \in \mathbb{R}^q$ and with

$$\alpha \stackrel{def}{=} -\log(1-[\min(C^a_{\sigma\sigma''}/C^a_{\sigma\sigma'})]^2) \geqslant q^{-2a}. \tag{6.7}$$

As a consequence,

$$Z(\beta,\beta') = C^{ah_0}_{\beta\beta'} = \sum_\sigma C^{ah_0}_{\beta\sigma}(\pi_\sigma \pi^*_{\beta'} + P_{\sigma\beta'}) = l^{h_0} \pi_\beta \pi^*_{\beta'} \left[1 + \frac{(l^{-h_0} C^{ah_0} P)_{\beta\beta'}}{\pi_\beta \pi^*_{\beta'}}\right]$$

$$\stackrel{def}{=} l^{h_0} \pi_\beta \pi^*_{\beta'} e^{-I(\beta,\beta')}, \tag{6.8}$$

with $I(\beta,\beta') = O(e^{-h_0 q^{-2a}})$. It is now clear that taking h_0 big enough we can make the two body potential $I(\beta,\beta')$ as small as needed.

Using Eq. (6.8), introducing a new effective potential W including the contributions from Φ and I, defining

$$\prod_{i=0}^{\ell} e^{-U^{(i)}(\beta_\xi^{(i)})} \overset{def}{=} \prod_{i=0}^{\ell-1} \pi_{\beta_\xi^{(i)}} \pi^*_{\beta_\xi^{(i+1)}} \tag{6.9}$$

and using $\lim_{\Lambda\to\infty}|\Lambda|^{-1}\log\Pi_{\xi,i}\Sigma_{\beta_\xi^{(i)}}e^{-U^{(i)}(\beta_\xi^{(i)})}=0$ (as it follows from the normalization condition $\Sigma_\sigma \pi^*_\sigma \pi_\sigma = 1$), we can rewrite P_Λ as

$$P_\Lambda = \frac{1}{a}\log l + \frac{1}{|\Lambda|}\log \sum_{\beta_\Lambda} \sum_{\eta_\Lambda} m(\beta_\Lambda, \eta_\Lambda) \prod_{Y\subset\Lambda} e^{-W_Y(\beta_Y,\eta_Y)}$$

with

$$m(\beta_\Lambda,\eta_\Lambda) \overset{def}{=} \prod_{\xi\in V}\prod_{i=0}^{\ell} \frac{e^{-U^{(i)}(\beta_\xi^{(i)})}}{\Sigma_{\beta_\xi} e^{-U^{(i)}(\beta_\xi)}} \prod_{i=0}^{\ell-1} \frac{Z(\beta_\xi^{(i)},\eta_\xi^{(i)},\beta_\xi^{(i+1)})}{Z(\beta_\xi^{(i)},\beta_\xi^{(i+1)})}, \tag{6.10}$$

where $m(\beta_\Lambda,\eta_\Lambda)$ is a probability density. Observe that, if one chooses $h_0 \simeq -\log\tilde{\nu}$ [so that both $h\tilde{\nu}$ and $I(\beta,\beta')$ are small], the new interaction W satisfies a bound similar to the one of Φ:

$$\|W_Y\|_\infty \leqslant c e^{-\bar{\kappa} d_c(Y)} \bar{\nu}^{n_Y} \prod_{i=1}^{n_Y} e^{-\bar{\kappa}|R_i(Y)|}, \quad \forall Y\subset\Lambda_D, \tag{6.11}$$

for some c, $\bar{\kappa}$, $\bar{\gamma}>0$, $\bar{\nu}=|\epsilon|^{\bar{\gamma}}$.

B. Mayer's expansion and polymer lattice gas

We shall now expand the small potential appearing in the expression for P_Λ, via a *Mayer's expansion*, obtaining the pressure for $\epsilon=0$ plus a correction.

It will be convenient to collect together the contributions of the potentials whose supports have the same *closure*, in the following sense: for a set formed by a unique point $H_\xi^{(i)}\in\Lambda_D$ we define its *closure* as $\overline{(H_\xi^{(i)})} \overset{def}{=} (B_\xi^{(i)}, H_\xi^{(i)}, B_\xi^{(i+1)})$ while for a set formed by a unique point $B_\xi^{(i)} \in \Lambda_D$ we define $\overline{(B_\xi^{(i)})} \overset{def}{=} (B_\xi^{(i)})$; finally for $Y\subset\Lambda_D$ we define its closure as $\bar{Y} \overset{def}{=} \cup_{G\in Y}\overline{(G)}$.

We say that a collection $\mathcal{C}=\{Y_m\}_{m=1}^n$ of sets $Y_i\subset\mathbb{Z}^{d+1}$ (think of them as *molecules*) is *connected* if, given a couple $(Y_{\rm in}, Y_{\rm fin})\in\mathcal{C}\times\mathcal{C}$, it is possible to find $\{Y_{m_j}\}_{j=1}^p$, such that $\bar{Y}_{\rm in}\cap\bar{Y}_{m_1}\neq\emptyset$, $\bar{Y}_{m_i}\cap\bar{Y}_{m_{i+1}}\neq\emptyset$ and $\bar{Y}_{m_p}\cap\bar{Y}_{\rm fin}\neq\emptyset$.

Writing $e^{-W_Y(\beta_Y,\eta_Y)}$ as the value for $\epsilon=0$ plus the correction, namely $1+(e^{-W_Y(\beta_Y,\eta_Y)}-1)$, expanding the product over $Y\subset\Lambda_D$ and collecting together the connected components, we can rewrite Eq. (6.10) as

$$P_\Lambda - \frac{1}{a}\log l = \frac{1}{|\Lambda|}\log \sum_{\beta_\Lambda}\sum_{\eta_\Lambda} m(\beta_\Lambda,\eta_\Lambda) \sum_{\Gamma\subset\Lambda_D} \Upsilon(\Gamma) \prod_{\gamma\in\Gamma} \rho(\gamma|\beta_\gamma,\eta_\gamma), \tag{6.12}$$

where

(1) γ is a subset of Λ_D, to be called in the following *polymer* (they are, indeed, the union of a connected collection of molecules);
(2) Γ is a collection of polymers: $\Gamma=(\gamma_1,\ldots,\gamma_n)$, $n\geqslant 1$ and $\Gamma\subset\Lambda_D$ means that $\gamma\subset\Lambda_D$, $\forall\gamma\in\Gamma$;
(3) $\Upsilon(\Gamma)$ is the function equal to 1 if $\gamma\cap\gamma'=\emptyset$ for every γ, $\gamma'\in X$ with $\gamma\neq\gamma'$ and 0 otherwise;

(4) $\rho(\gamma|\beta_\gamma,\eta_\gamma)$, $\gamma\subset\Lambda_D$ is defined as

$$\rho(\gamma|\beta_\gamma,\eta_\gamma)\overset{def}{=}\sum_{q\geqslant 1}\frac{1}{q!}\sum_{\substack{Y_1,\dots,Y_q\\ \cup_i Y_i=\gamma}}^{*}\prod_{i=1}^{q}(e^{-W_{Y_i}(\beta_{Y_i},\eta_{Y_i})}-1), \tag{6.13}$$

where the $*$ on the sum means that $Y_1\dots,Y_q$ is a connected collection of subsets of Λ_D; (5) the term corresponding to $\Gamma=\emptyset$ must be interpreted as equal to 1.

The key observation is that, thanks to the above definition of closure, in (6.12) we can sum over η spins before summing over the β spins. After doing this the measure $m(\beta_\Lambda,\eta_\Lambda)$ factorizes, i.e.,

$$\begin{aligned}P_\Lambda-\frac{1}{a}\log l&=\frac{1}{|\Lambda|}\log\sum_{\Gamma\subset\Lambda_D}\Upsilon(\Gamma)\prod_{\gamma\in\Gamma}\left[\sum_{\beta_\gamma}\sum_{\eta_\gamma}m(\beta_\gamma,\eta_\gamma)\rho(\gamma|\beta_\gamma,\eta_\gamma)\right]\\&\overset{def}{=}\frac{1}{|\Lambda|}\log\sum_{\Gamma\subset\Lambda_D}\Upsilon(\Gamma)\prod_{\gamma\in\Gamma}\rho(\gamma).\end{aligned} \tag{6.14}$$

Namely, we have rewritten P_Λ as the pressure for $\epsilon=0$ plus a correction having the form of the pressure of a "polymer lattice gas," with activities $\rho(\gamma)$ and hard core potentials $\Upsilon(\Gamma)$.

C. Cluster expansion and its convergence

A standard argument, exposed for instance in Ref. 13, 20, or 10, leads to

$$P_\Lambda-\frac{1}{a}\log l=\frac{1}{|\Lambda|}\log\sum_{\Gamma\subset\Lambda_D}\Upsilon(\Gamma)\rho(\Gamma)=\frac{1}{|\Lambda|}\sum_{\Gamma\subset\Lambda_D}\Upsilon^T(\Gamma)\rho(\Gamma), \tag{6.15}$$

where Υ^T is the Mayer function, defined as

$$\Upsilon^T(\gamma_1,\dots,\gamma_n)\overset{def}{=}\begin{cases}\displaystyle\sum_{g\in\mathcal{G}(n)}\prod_{(i,j)\in g}f(\gamma_i,\gamma_j) & \text{if } n>1,\\ 1 & \text{if } n=1,\end{cases} \tag{6.16}$$

where $\mathcal{G}(n)$ is the set of connected graphs which can be drawn on n vertices labeled 1,...,n by connecting with links couples of distinct vertices; the function $f(\gamma_i,\gamma_j)$ is equal to 1 if $\gamma_i\cap\gamma_j\neq\emptyset$ and 0 otherwise. By construction, $\Upsilon^T(\Gamma)$ is different from zero only if Γ is a connected collection of polymers. Observe that Γ could contain many copies of the same γ. More precisely, here Γ represents a function from the subsets of Λ_D to $\mathbb{N}$ [and we can think $\Gamma(\gamma)$ as representing the number of copies of γ] such that $\Sigma_{\gamma\subset\Lambda_D}\Gamma(\gamma)\leqslant\infty$.

A bound for $\rho(\gamma)$ can be obtained as follows:

$$|\rho(\gamma)|\leqslant\|\rho(\gamma|\cdot,\cdot)\|_\infty\leqslant\sum_{p\geqslant 1}\frac{1}{p!}\sum_{Y_i,\cup_i Y_i=\gamma}^{*}\prod_{i=1}^{p}\|W_{Y_i}\|_\infty e^{\|W_{Y_i}\|_\infty}. \tag{6.17}$$

Using the bound (6.11) (and that, if $\cup_{i=1}^p\overline{Y}_i=\gamma$, one has $\Sigma_{i=1}^p\|W_{Y_i}\|\leqslant c\overline{\nu}|\gamma|$), we find

$$|\rho(\gamma)|\leqslant e^{c\overline{\nu}|\gamma|}\sum_{p\geqslant 1}\frac{1}{p!}\sum_{Y_i,\cup_i Y_i=\gamma}^{*}\prod_{i=1}^{p}ce^{-\overline{\kappa}d_c(Y_i)}\overline{\nu}^{n_{Y_i}}\prod_{j=1}^{n_{Y_i}}e^{-\overline{\kappa}|R_j(Y_i)|}. \tag{6.18}$$

We can now use the connectedness constraint on the sum in order to extract a factor exponentially small in the size of γ. Indeed, if $\cup_{i=1}^{p}\overline{Y}_i=\gamma$, one has both $\Sigma_{i=1}^{p}d_c(Y_i)\geqslant d_c(Y_i)$ and $\Sigma_{i=1}^{p}n_{Y_i}\geqslant n_\gamma$. After extracting such a factor we can relax the constraints on the sum, so that

$$|\rho(\gamma)|\leqslant ce^{c\overline{\nu}|\gamma|}\left[e^{-(\overline{\kappa}/2)d_c(\gamma)}\overline{\nu}^{n_\gamma/2}\prod_{i=1}^{n_\gamma}e^{-(\overline{\kappa}/2)|R_i(\gamma)|}\right]\times\sum_{p\geqslant 1}\frac{1}{p!}\left(\sum_{Y\subset\gamma}e^{-(\overline{\kappa}/2)d_c(Y)}\overline{\nu}^{n_Y/2}\prod_{j=1}^{n_Y}e^{-(\overline{\kappa}/2)|R(Y)|}\right)^p. \tag{6.19}$$

It is easy to see that the last sum is bounded by $c|\gamma|\overline{\nu}^{1/4}$, so that

$$|\rho(\gamma)|\leqslant ce^{c\overline{\nu}|\gamma|}\left[e^{-(\overline{\kappa}/2)d_c(\gamma)}\overline{\nu}^{n_\gamma/2}\prod_{i=1}^{n_\gamma}e^{-(\overline{\kappa}/2)|R_i(\gamma)|}\right]\sum_{p\geqslant 1}\frac{1}{p!}(c|\gamma|\overline{\nu}^{1/4})^p$$

$$\leqslant ce^{-\kappa' d_c(\gamma)}(\nu')^{n_\gamma}\prod_{i=1}^{n_\gamma}e^{-\kappa'|R_i(\gamma)|}, \tag{6.20}$$

for some c, κ', $\gamma'>0$ and $\nu'=|\epsilon|^{\gamma'}$. Using the preceding bound we can easily prove that

$$\sup_{x\in\mathbb{Z}^{d+1}}\sum_{\delta(\gamma)\geqslant r}^{\gamma\ni x}|\rho(\gamma)|\leqslant c(\nu')^{1/2}e^{-(\kappa'/2)r}, \tag{6.21}$$

where $\delta(\gamma)$ is the diameter of the polymer γ. A standard theorem, proved for instance in Refs. 13 and 10, states that, if $\rho(\gamma)$ satisfies (6.21), then

$$\sup_{x\in\Lambda_D}\sum_{\delta(\Gamma)\geqslant r}^{\Gamma\ni x}\Upsilon^T(\Gamma)|\rho(\Gamma)|\leqslant c(\nu')^{1/4}e^{-(\kappa'/4)r}. \tag{6.22}$$

This implies that, varying Λ, P_Λ is a uniformly convergent sequence of analytic functions in a domain independent from Λ. The limit, still analytic in the same domain (thanks to Vitali's convergence theorem), is independent of the way the thermodynamic limit is performed (i.e., one can send the time side of Λ to ∞ either before the spatial side is sent to ∞ or together with it), thanks to the exponentially fast convergence of the sequence, implied by (6.22). For the same reason, the limit is also independent of the choice of boundary conditions and, because of translational invariance, it is equal to

$$P\overset{def}{=}\lim_{|\Lambda|\to\infty}P_\Lambda=\frac{1}{a}\log l+\frac{2}{h_0 a}\sum_{\Gamma\subset\mathbb{Z}^{d+1}}^{\Gamma\ni(0,0)}\frac{\Upsilon^T(\Gamma)\rho(\Gamma)}{|\Gamma|}, \tag{6.23}$$

where $|\Gamma|\overset{def}{=}|\cup_{\gamma\in\Gamma}\gamma|$ and $2/(h_0 a)=\lim_{|\Lambda|\to\infty}|\Lambda_D|/|\Lambda|$.

D. Analyticity of the mean values

The analyticity for the mean value of an analytic local observable $\mathcal{O}(\psi_V)$ (depending on the variables in the finite set $V\subset\mathbb{Z}^d$) is an easy corollary of the previous result.

We first observe that $\mu^{\mathrm{SRB}}(\mathcal{O})=\lim_{N,T\to\infty}(1/|V_N||I_T|)\Sigma_{(\xi,i)\in(V_N\times I_T)}\mu^{\mathrm{SRB}}(\mathcal{O}\circ\rho^{\xi}\circ S_\epsilon^i)$. This is true thanks to the time and space translation invariance of μ^{SRB}. Moreover, it is possible to decompose $\mathcal{O}$ as

$$\mathcal{O}(h_\epsilon(c_0(\sigma))_V)=\sum_{X\cap(V\times\{0\})=\emptyset}\mathcal{O}_X^{(0,0)}(\sigma_X).$$

This can be done expanding $\mathcal{O}(h_\epsilon)$ in power of ψ, using the representation of h_ϵ given in Secs. III and V and collecting the terms with the same support. Moreover, we will set

$$\mathcal{O}_X^{(\xi,j)}(\sigma_X)\overset{def}{=}\mathcal{O}^{(0,0)}_{\rho^{-\xi}\tau^{-j}X}(\sigma_X)$$

and

$$\mathcal{O}_X(\sigma_X)\overset{def}{=}\sum_{\substack{(\xi,j)\\ \rho^\xi V\times\{j\}\cap X\neq\emptyset}}\mathcal{O}_X^{(\xi,j)}(\sigma_X).$$

It is easy to realize that $\mathcal{O}_X$ is invariant under space and time translations, and satisfies

$$\|\mathcal{O}_X\|_\infty\leqslant c_V\nu^{n_X}e^{-\kappa d_c(X)}\prod_{i=1}^{n_X}e^{-\kappa|R_i(X)|},\tag{6.24}$$

for some κ, $\gamma>0$, $\nu=|\epsilon|^\gamma$ and some constant $c_V>0$ which depends on the size of V. Setting $\Lambda=V_N\times I_T$, the thermodynamic limit of the mean value of $\mathcal{O}(\psi_V)$ can be written as

$$\mu^{\mathrm{SRB}}(\mathcal{O})=\lim_{\Lambda\to\infty}\frac{1}{|\Lambda|}\partial_\zeta\log\frac{\Sigma_{\sigma_\Lambda}e^{-\Sigma_{X\cap\Lambda\neq\emptyset}[\phi_X(\sigma_X)-\zeta\mathcal{O}_X(\sigma_X)]}}{\Sigma_{\sigma_\Lambda}e^{-\Sigma_{X\cap\Lambda\neq\emptyset}\phi_X(\sigma_X)}}\Bigg|_{\zeta=0}\overset{def}{=}\partial_\zeta P_{\mathcal{O}}(\zeta).\tag{6.25}$$

Via a new cluster expansion we find

$$\mu^{\mathrm{SRB}}(\mathcal{O})=\lim_{\Lambda\to\infty}\frac{1}{|\Lambda|}\partial_\zeta\sum_{\Gamma\cap\Lambda_D\neq\emptyset}\Upsilon^T(\Gamma)(\rho^\zeta(\Gamma)-\rho(\Gamma))|_{\zeta=0},\tag{6.26}$$

where $\rho^\zeta(\gamma)$ are the activities corresponding to the potential $\phi_X-\zeta\mathcal{O}_X$. For $|\zeta|$ small enough, the potential $\phi_X-\zeta\mathcal{O}_X$ satisfies the same bounds of ϕ_X so that $\Sigma_{\Gamma\cap\Lambda_D\neq\emptyset}\Upsilon^T(\Gamma)(\rho^\zeta(\Gamma)-\rho(\Gamma))$ is a uniformly convergent sequence of functions, analytic in ϵ and ζ in the product of two small discs. This implies that $\mu^{\mathrm{SRB}}(\mathcal{O})$ is analytic in ϵ and given by

$$\mu^{\mathrm{SRB}}(\mathcal{O})=\frac{2}{h_0a}\sum_{\Gamma\subset\mathbb{Z}^{d+1}}^{\Gamma\ni(0,0)}\frac{\Upsilon^T(\Gamma)}{|\Gamma|}\partial_\zeta(\rho^\zeta(\Gamma)-\rho(\Gamma))|_{\zeta=0}.\tag{6.27}$$

ACKNOWLEDGMENTS

P.F. thanks Benedetto Scoppola for his help in understanding the techniques related to the cluster expansion. The authors are indebted to Giovanni Gallavotti for many suggestions and discussions during the preparation of this work.

APPENDIX A: UNPERTURBED NONLINEAR DYNAMICS

The result about analyticity can be extended to the case in which the unperturbed dynamic is made up of independent *nonlinear* analytic Anosov systems $s_0\colon\mathbb{T}^2\to\mathbb{T}^2$. We suppose that there exist $v_\pm(\psi)$ and $\lambda_\pm(\psi)$ such that

$$(Ds_0v_+)(\phi)=\lambda_+(\phi)v_+(s_0(\phi)),\quad (Ds_0v_-)(\phi)=\lambda_-(\phi)v_-(s_0(\phi)),\tag{A1}$$

with $\phi \in \mathbb{T}^2$, $v_\pm(\phi)$ and $\lambda_\pm(\phi)$ are Hölder continuous and $|\lambda_+(\phi)|^{-1}$, $|\lambda_-(\phi)| \leqslant \lambda < 1$. Then we consider again a perturbation $f(\psi)$ on $\mathcal{T}_N$ analytic in ψ. Observe, however, that in this case the most naive example of perturbation, $f(\psi) \overset{def}{=} f^+(\psi) v_+(\psi)$, with $f^+(\psi)$ analytic, is *no longer* an analytic perturbation.

1. Conjugation

The constitutive equation for δh_ϵ, lifted on $\mathbb{R}^{2V_N}$, is

$$S_0(h_\epsilon(\psi)) + \epsilon f(h_\epsilon(\psi)) = S_0(\psi) + \delta h_\epsilon(S_0(\psi)). \tag{A2}$$

In order to exploit the hyperbolicity, it is convenient to arrange the terms as follows:

$$(DS_0 \delta h_\epsilon)(\psi) - \delta h_\epsilon(S_0(\psi)) = -\epsilon f(\psi + \delta h_\epsilon(\psi)) - [S_0(h_\epsilon(\psi)) - S_0(\psi) - (DS_0 \delta h_\epsilon)(\psi)]. \tag{A3}$$

Define

$$f^{,\mathbf{x}_1,\ldots,\mathbf{x}_s}(\psi) \overset{def}{=} \frac{\partial^s}{\partial\zeta_1,\ldots,\partial\zeta_s} f(\psi + \zeta_1 w_{0,\alpha_1}^{(\xi_1)}(\psi) + \cdots + \zeta_s w_{0,\alpha_s}^{(\xi_s)}(\psi))\big|_{\zeta_1=\cdots=\zeta_s=0},$$

whereas

$$f^{\mathbf{x}_1,\ldots,\mathbf{x}_s}(\psi) \overset{def}{=} \sum_{\mathbf{x}} f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}(\psi) w_{0,\alpha}^{(\xi)}(S_0(\psi)) \quad \text{and} \quad S_0^{\mathbf{x}_1,\ldots,\mathbf{x}_s}(\psi) \overset{def}{=} \sum_{\mathbf{x}} S_0^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}(\psi) w_{0,\alpha}^{(\xi)}(S_0(\psi)).$$

Writing $\delta h_\epsilon(\psi) \overset{def}{=} \Sigma_{\mathbf{x}} \delta h_\epsilon^{\mathbf{x}}(\psi) w_{0,\alpha}^{(\xi)}(\psi)$, and $(DS_0 w_{0,\alpha}^{(\xi)})(\psi) \overset{def}{=} \Sigma_{\mathbf{y}} S_0^{\mathbf{y},\mathbf{x}}(\psi) w_{0,\beta}^{(\eta)}(S_0(\psi))$, with $S_0^{\mathbf{y},\mathbf{x}}(\psi) = \lambda_\alpha(\psi_\xi)\delta_{\mathbf{x},\mathbf{y}}$, we get

$$\lambda_\alpha \delta h_\epsilon^{\mathbf{x}}(\psi) - \delta h_\epsilon^{\mathbf{x}}(S_0(\psi)) = -\epsilon \sum_{s\geqslant 0} \left(\frac{f^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} \delta h_\epsilon^{\mathbf{x}_1} \cdots \delta h_\epsilon^{\mathbf{x}_s} \right)(\psi) - \sum_{s\geqslant 2} \left(\frac{S_0^{\mathbf{x},\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} \delta h_\epsilon^{\mathbf{x}_1} \cdots \delta h_\epsilon^{\mathbf{x}_s} \right)(\psi). \tag{A4}$$

Finally, the recursive equation for the Taylor coefficients of $\delta h_\epsilon^{\xi^+}(\psi)$ is

$$\begin{aligned}
\delta h_{(k+1)}^{\xi^+}(\psi) = &- \sum_{p\geqslant 0} \left(\prod_{m=0}^{p} \lambda_+^{-1}(s_0^m(\psi_\xi)) \right) \sum_{s\geqslant 0} \sum_{\substack{k_1+\cdots+k_s=k \\ k_i\geqslant 1}} \left(\frac{f^{\xi^+,\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} \delta h_{(k_1)}^{\mathbf{x}_1} \cdots \delta h_{(k_s)}^{\mathbf{x}_s} \right)(S_0^p(\psi)) \\
&+ \sum_{p\geqslant 0} \left(\prod_{m=0}^{p} \lambda_+^{-1}(s_0^m(\psi_\xi)) \right) \sum_{s\geqslant 2} \sum_{\substack{k_1+\cdots+k_s=k+1 \\ k_i\geqslant 1}} \left(\frac{S_0^{\xi^+,\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} \delta h_{(k_1)}^{\mathbf{x}_1} \cdots \delta h_{(k_s)}^{\mathbf{x}_s} \right) \\
&\times (S_0^p(\psi)).
\end{aligned} \tag{A5}$$

A similar equation holds for $\mathbf{x} = \xi^-$.

From now on, the construction of the conjugation function goes on as in the linear case with similar considerations. We have only to take in account the fact that a tree of order k (w.r.t. ϵ) does not necessarily have k branches, because of the term on the last line of (1.5) (to be called a vertex of type 0). Since the number of lines entering a vertex of type 0 is $\geqslant 2$, one can easily prove that the number b_k of branches of a tree of order k is bounded by $k \leqslant b_k \leqslant 2k-1$, so that nothing qualitatively changes in the bounds and the proof of analyticity of δh_ϵ proceed as in Secs. III and VI.

2. Unstable direction

The perturbed unstable direction in the point $h_\epsilon(\psi)$ is given by the equation

$$(DS_\epsilon w^{(\xi)}_{\epsilon,+})(h_\epsilon(\psi)) = w^{(\eta)}_{\epsilon,+}(h_\epsilon(S_0(\psi)))L^{\eta\xi}(\psi). \tag{A6}$$

Setting $w^{(\xi)}_{\epsilon,+}(h_\epsilon(\psi)) \overset{def}{=} v^{(\xi)}_\epsilon(\psi)$, it is convenient to rearrange the terms of the equation in the following way:

$$\begin{aligned}(DS_0 v^{(\xi)}_\epsilon)(\psi) - \lambda_+(\psi_\xi) v^{(\xi)}_\epsilon(S_0(\psi)) = \delta L^{\eta\xi}(\psi) v^{(\eta)}_\epsilon(S_0(\psi)) - \epsilon(Df)(h_\epsilon(\psi)) v^{(\xi)}_\epsilon(\psi) \\ - [DS_0(h_\epsilon(\psi)) - DS_0(\psi)] v^{(\xi)}_\epsilon(\psi).\end{aligned} \tag{A7}$$

Defining $v^{(\eta)}_\epsilon(\psi) = \Sigma_{\mathbf{x}} V^{(\eta)}_{\epsilon,\mathbf{x}}(\psi) w^{(\xi)}_{0,\alpha}(\psi)$, and using again the considerations of Sec. IV, we finally get

$$\begin{aligned}\lambda_\alpha(\psi_\rho) V^{(\rho)}_{\epsilon,\mathbf{x}}(\psi) - \lambda_+(\psi_\rho) V^{(\rho)}_{\epsilon,\mathbf{x}}(S_0(\psi)) = &+ \delta L^{\zeta\rho}(\psi) V^{(\zeta)}_{\epsilon,\mathbf{x}}(S_0(\psi)) \\ &- \epsilon \sum_{s\geqslant 0} \left(\frac{f^{\mathbf{x},\mathbf{y}\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} V^{(\rho)}_{\epsilon,\mathbf{y}} \delta h^{\mathbf{x}_1}_\epsilon \cdots \delta h^{\mathbf{x}_s}_\epsilon \right)(\psi) \\ &- \sum_{s\geqslant 1} \left(\frac{S_0^{\mathbf{x}\mathbf{y},\mathbf{x}_1,\ldots,\mathbf{x}_s}}{s!} V^{(\rho)}_{\epsilon,\mathbf{y}} \delta h^{\mathbf{x}_1}_\epsilon \cdots \delta h^{\mathbf{x}_s}_\epsilon \right)(\psi)\end{aligned}$$

[with $(DS_0^{\mathbf{x}_1\ldots\mathbf{x}_s} w^{(\xi)}_a)(\psi) \overset{def}{=} S_0^{\mathbf{x}\mathbf{y},\mathbf{x}_1,\ldots,\mathbf{x}_s}(\psi) w^{(\eta)}_b(S_0\psi)$]. Again, because of the third term on the r.h.s. of Eq. (A7), the number of branches of a tree appearing in the construction of δV and δL is greater (in general) than the order of the tree itself. This is not a problem, since one can easily realize that, again, the number b_k of branches of a tree of order k is such that $k \leqslant b_k \leqslant 2k$.

3. SRB interactions

Following the proof in Sec. IV and, proceeding as in Secs. V and VI, one proves analyticity of the SRB distribution. In fact, the only (slight) difference in the construction of SRB potentials is in the telescopic cutting necessary to represent h, L, V and Λ as sums of local functions of spin variables. Notice that now each tree node is associated to the product of a node function $f_v(\psi)$ [e.g., in the case of a tree contributing to δh, f_v can be a derivative of f or a derivative of S_0, see (A5)] times a product of local Lyapunov exponents, like the factor $\Pi^p_{m=0}\lambda_+^{-1}(s_0^m(\psi_\xi)) \overset{def}{=} \Theta_+(p, s_0^{p(v)}(\psi_\xi))$ in (A5); the analogous expression appearing in a vertex with $\alpha(v) = -$ will be denoted by $\Theta_-(p, s_0^{p(v)}\psi_\xi)$. So the total node function associated to a vertex v will now be of the form

$$F^v(p(v), S_0^{p(v)}(\psi)) \overset{def}{=} \Theta_{\alpha(v)}(p(v), s_0^{p(v)}(\psi_{\xi_v})) f_v(S_0^{p(v)}(\psi)), \tag{A8}$$

where v' is the vertex immediately following v. The telescopic expansion (5.1) has to be done *separately* for each of the factors in the above equation [$\lambda(\psi)$ is Hölder continuous], getting in the end potentials with the same kind of decay rate. The bounds are not qualitatively changed and the subsequent analysis of Sec. V follows so that, by suitably modifying the decimation procedure, analyticity of SRB measure can be proved. We point out that a main difference in the proof of convergence of the cluster expansion is that now the unperturbed potentials are not vanishing, but have support only on timelike segments $I \subset \mathbb{Z}$, and are exponentially decaying with the diameter of I. For this reason one cannot proceed exactly as in Sec. VI. The standard way to treat this problem (see Ref. 7), is to choose a length r such that the unperturbed interactions on sets I, diam(I)

$>r$, are small enough for the cluster expansion. Then one fixes the size of the *B*-blocks $b=r$, and the size of the *H*-blocks, h, such that the Perron–Frobenius theorem is true for the *reduced partition function* $Z_r(\beta_\xi^{(p)},\eta_\xi^{(p)},\beta_\xi^{(p+1)})$, in which only the interaction on sets $I\subset(B_\xi^{(p)}\cup H_\xi^{(p)}\cup B_\xi^{(p+1)})$, $\mathrm{diam}(I)\leqslant r$, are taken in account.

APPENDIX B: GREEN–KUBO FORMULA AND LARGE DEVIATION

In this section we deal with an application. We introduce the *local phase space contraction rate*[9] on a volume $V_0\subset V_N$ averaged on a time T_0, given by

$$\eta_{\Lambda_0}(\psi)\overset{def}{=}\frac{1}{|\Lambda_0|}\sum_{j\in I_{T_0}}\log|\det(DS_\epsilon)_{V_0}(S_\epsilon^j(\psi))|, \tag{B1}$$

with $\Lambda_0=V_0\times I_0$ and $I_0\overset{def}{=}[-T_0/2,T_0/2]\cap\mathbb{Z}$. We prove a Green–Kubo formula for η_{Λ_0}, from which it will come out that generically its mean value η_+ is strictly negative. Furthermore, we can show the large fluctuations of η_{Λ_0} around η_+ satisfy a large deviation principle, namely they are asymptotically described by a strictly convex *free energy functional* $F(\eta)$: it can be obtained as the Legendre transform of the generating functional $P(\zeta)=P_{\eta_{\Lambda_0}}(\zeta)$ [see Eq. (6.25)].

For the rest of the Appendix the SRB interaction will be called $\{\phi_X^+\}_{X\subset\mathbb{Z}^{d+1}}$, to remind that they are derived from the unstable restriction of DS_ϵ.

Theorem B1: *Given S_ϵ such that $\eta_+<0$,*

(1) $P(\zeta)$ is analytic and strictly convex in ζ, for $|\epsilon|<\epsilon_0$, $|\zeta|\leqslant 1$, with ϵ_0 small enough; and
(2) the Green–Kubo formula is valid:

$$\partial_\epsilon^2 P'(0)|_{\epsilon=0}=-\tfrac{1}{2}\partial_\epsilon^2 P''(0)|_{\epsilon=0}. \tag{B2}$$

Theorem B2: *Given S_ϵ such that $\eta_+<0$,*

(1) the free energy $F(\eta)$ is analytic in η, for $|\epsilon|<\epsilon_0$, and $\eta\in[P'(-1),P'(1)]$;
(2) if $[a,b]\subset[P'(-1),P'(1)]$, then

$$\lim_{|\Lambda_0|\to\infty}\frac{1}{|\Lambda_0|}\log\mu^{\mathrm{SRB}}(\eta_{\Lambda_0}\in[a,b])=\max_{\eta\in[a,b]}-\Delta F(\eta,\eta_+), \tag{B3}$$

with $\Delta F(\eta,\eta_+)\overset{def}{=}F(\eta)-F(\eta_+)$.

1. Local phase space contraction rate

Repeating the construction of SRB potentials leading to (B8), we set

$$\eta_{\Lambda_0}(h_\epsilon(c_0(\sigma)))\overset{def}{=}\frac{1}{|\Lambda_0|}\sum_{X\subset\mathbb{Z}^{d+1}}^{X\cap\Lambda_0\neq 0}\phi_X(\sigma_X), \tag{B4}$$

for a suitable potential ϕ_X, satisfying

$$\|\phi_X\|_\infty\leqslant ce^{-\kappa d_c(X)}\nu^{n_X}\prod_{i=1}^{n_X}e^{-\kappa|R_i(X)|}, \tag{B5}$$

for some c, κ, $\gamma>0$ and $\nu=|\epsilon|^\gamma$. From the invariance under time translations of the SRB measure, we have

$$\eta_+ \overset{def}{=} \lim_{|V_0|\to\infty} \frac{1}{|V_0|}\mu^{\mathrm{SRB}}(\log|\det(DS_\epsilon)_{V_0}|) = \lim_{|\Lambda_0|\to\infty} \mu^{\mathrm{SRB}}(\eta_{\Lambda_0}) = \lim_{|\Lambda_0|\to\infty} \frac{1}{|\Lambda_0|} \sum_{X\cap\Lambda_0\neq 0} \mu^{\mathrm{SRB}}(\phi_X)$$

$$= \lim_{|\Lambda_0|\to\infty} \lim_{|\Lambda|\to\infty} \frac{1}{|\Lambda_0|}\partial_\zeta \log \frac{\Sigma_{\sigma_\Lambda} e^{-\Sigma_{X\cap\Lambda\neq\emptyset}\phi_X^+(\sigma_X)+\zeta\Sigma_{X\cap\Lambda_0\neq\emptyset}\phi_X(\sigma_X)}}{\Sigma_{\sigma_\Lambda} e^{-\Sigma_{X\cap\Lambda\neq\emptyset}\phi_X^+(\sigma_X)}}\Bigg|_{\zeta=0}. \tag{B6}$$

It is easy to show the last expression is equal to the one with the summations over $X\cap\Lambda\neq\emptyset$ and $X\cap\Lambda_0\neq\emptyset$ replaced by $X\subset\Lambda_0$ and without the limit in Λ (since the correction is only a border effect; or simply using again the cluster expansion developed in Sec. VI D). In this way, defining the *generating function* $P(\zeta)$ as

$$P(\zeta) \overset{def}{=} \lim_{|\Lambda|\to\infty} \frac{1}{|\Lambda|}\log \frac{\Sigma_{\sigma_\Lambda} e^{-\Sigma_{X\subset\Lambda}(\phi_X^+ - \zeta\phi_X)(\sigma_X)}}{\Sigma_{\sigma_\Lambda} e^{-\Sigma_{X\subset\Lambda}\phi_X^+(\sigma_X)}}, \tag{B7}$$

we finally get

$$\eta_+ = P'(0). \tag{B8}$$

Analyticity is achieved by cluster expansion [we do not need ζ small, but we can take, say, $|\zeta|\leqslant 1$, since $\{\phi_X\}_X$ are $O(\epsilon)$].

2. Green–Kubo formula

Consider the case in which s_0 is the Arnold's cat map defined by (A1).

Using the definition of pressure (B7) and the fast convergence properties of the cluster expansion of $P(\zeta)$, we find

$$P(\zeta) = \lim_{|\Lambda|\to\infty} \frac{1}{|\Lambda|}\log \frac{\mu_{N,0}^{\mathrm{SRB}}(e^{-\Sigma_{j\in I_T}\log|\det L\circ S_0^j| + \zeta\Sigma_{j\in I_T}\log|\det DS_\epsilon\circ h_\epsilon\circ S_0^j|})}{\mu_{N,0}^{\mathrm{SRB}}(e^{-\Sigma_{j\in I_T}\log|\det L\circ S_0^j|})}, \tag{B9}$$

where

(1) the matrix $L=\mathcal{L}\circ h_\epsilon$ was introduced in Sec. II B above;

(2) $\mu_{N,0}^{\mathrm{SRB}}$ is the unperturbed SRB measure: if $\mathcal{O}(\psi)$ is a local Hölder continuous observable, it is defined as

$$\mu_{N,0}^{\mathrm{SRB}}(\mathcal{O}) = \lim_{|\Lambda|\to\infty} \frac{\Sigma_{\sigma_\Lambda}\mathcal{O}(c_0(\sigma_\Lambda|\hat\sigma_{\Lambda^c}))}{\Sigma_{\sigma_\Lambda} 1}, \tag{B10}$$

and, independently of the boundary conditions, it is equal to the Lebesgue measure.

Defining U_ζ as

$$U_\zeta = \log|\det L| - \zeta\log|\det S_0^{-1}\circ DS_\epsilon\circ h_\epsilon|, \tag{B11}$$

and using that $\mu_{N,0}^{\mathrm{SRB}}$ is the Lebesgue measure on $\mathcal{T}_N$, we find

$$P(\zeta) = \lim_{|\Lambda|\to\infty} \frac{1}{|\Lambda|}\log \frac{\int d\psi e^{-\Sigma_{j\in I_T} U_\zeta(S_0^j\psi)}}{\int d\psi e^{-\Sigma_{j\in I_T} U_0(S_0^j\psi)}}, \tag{B12}$$

so that $P'(0)$ is equal to

$$P'(0)=\lim_{|\Lambda|\to\infty}\frac{1}{|\Lambda|}\sum_{j\in I_T}\frac{\int \mathrm{d}\psi \log|\det S_0^{-1}DS_\epsilon(h_\epsilon(S_0^j\psi))|e^{-\Sigma_{j\in I_T}U_0(S_0^j\psi)}}{\int \mathrm{d}\psi e^{-\Sigma_{j\in I_T}U_0(S_0^j\psi)}}. \tag{B13}$$

Since $P'(0)|_{\epsilon=0}$ is trivially=0, we can try to see if $\partial_\epsilon P'(0)|_{\epsilon=0}$ is different from zero [if it were, $P'(0)$ would be different from zero for $\epsilon\neq 0$ small enough]. Recalling that $f(\psi)$ is the perturbing function and $f^\xi(\psi)$ is its projection on the ξth site, we get

$$\begin{aligned}\partial_\epsilon P'(0)|_{\epsilon=0}&=\lim_{|\Lambda|\to\infty}\frac{1}{|\Lambda|}\sum_{j\in I_T}\int\frac{\mathrm{d}\psi}{(2\pi)^{2|V_N|}}\mathrm{Tr}[S_0^{-1}Df(S_0^j\psi)]\\&=\lim_{|\Lambda|\to\infty}\frac{1}{|\Lambda|}\sum_{j\in I_T}\sum_{\substack{\alpha=\pm\\ \xi\in V_N}}\int\frac{\mathrm{d}\psi}{(2\pi)^{2|V_N|}}\lambda^\alpha f^{\xi^\alpha,\xi^\alpha}(S_0^j\psi).\end{aligned} \tag{B14}$$

Since f is periodic we have $\partial_\epsilon P'(0)|_{\epsilon=0}=0$.

A straightforward calculation shows that

$$\begin{aligned}\frac{1}{2}\partial_\epsilon^2 P'(0)|_{\epsilon=0}=\lim_{|\Lambda|\to\infty}\frac{1}{|\Lambda|}\sum_{j\in I_T}\int\frac{\mathrm{d}\psi}{(2\pi)^{2|V_N|}}\Bigg\{&\mathrm{Tr}[S_0^{-1}D^2f(S_0^j\psi)\,\delta h_{(1)}(S_0^j\psi)]\\&-\frac{1}{2}\mathrm{Tr}[(S_0^{-1}Df(S_0^j\psi))^2]-\sum_{j'\in I_T}\mathrm{Tr}(S_0^{-1}Df(S_0^j\psi))\mathrm{Tr}^{(u)}(S_0^{-1}Df(S_0^{j'}\psi))\Bigg\},\end{aligned} \tag{B15}$$

where $\mathrm{Tr}^{(u)}$ is the trace restricted to the (unperturbed) unstable manifold. The preceding expression can be rewritten in a more convenient way. Using the explicit expression of $\delta h_{(1)}$, Eq. (3.5), and defining $A_0=\cup_{\xi\in nn(0)}nn(\xi)$, we find that the first term in Eq. (2.15) is equal to

$$\begin{aligned}&\sum_{\substack{\alpha_i=\pm\\ |\xi|\leqslant 1}}\sum_{p\geqslant 0}\int\frac{\mathrm{d}\psi_{A_0}}{(2\pi)^{2|A_0|}}\lambda^{\alpha_1}f^{0^{\alpha_1},0^{\alpha_1}\xi^{\alpha_2}}(\psi)(-\alpha_2)\lambda^{p+\rho_{\alpha_2}}f^{\xi^{\alpha_2}}(S_0^{\alpha_2(p+1-\rho_{\alpha_2})}\psi)\\&=\sum_{\substack{\alpha_i=\pm\\ |\xi|\leqslant 1}}\sum_{p\geqslant 0}\int\frac{\mathrm{d}\psi_{A_0}}{(2\pi)^{2|A_0|}}\lambda^{\alpha_1}f^{0^{\alpha_1},0^{\alpha_1}}(\psi)\alpha_2\lambda^{\alpha_2}f^{\xi^{\alpha_2},\xi^{\alpha_2}}(S_0^{\alpha_2(p+1-\rho_{\alpha_2})}\psi).\end{aligned} \tag{B16}$$

Integrating by parts, we see that the sum of the second and third terms in Eq. (2.15) is equal to

$$-\frac{1}{2}\sum_{\substack{\alpha_i=\pm\\ |\xi|\leqslant 1}}\int\frac{\mathrm{d}\psi_{A_0}}{(2\pi)^{2|A_0|}}\lambda^{\alpha_1}f^{0^{\alpha_1},0^{\alpha_1}}(\psi)\left[\lambda^{\alpha_2}f^{\xi^{\alpha_2},\xi^{\alpha_2}}(\psi)+\lambda\sum_{p\in\mathbb{Z}}f^{\xi^+,\xi^+}(S_0^p\psi)\right]. \tag{B17}$$

Combining the three contributions, we finally find

$$\partial_\epsilon^2 P'(0)|_{\epsilon=0} = -\sum_{\substack{\alpha_i=\pm \\ |\xi|\leqslant 1}} \sum_{p\in\mathbb{Z}} \int \frac{d\psi_{A_0}}{(2\pi)^{2|A_0|}} \lambda^{\alpha_1} f^{0^{\alpha_1},0^{\alpha_1}}(\psi) \lambda^{\alpha_2} f^{\xi^{\alpha_2},\xi^{\alpha_2}}(S_0^p \psi)$$

$$= -\lim_{|\Lambda|\to\infty} \frac{1}{|\Lambda|} \int \frac{d\psi}{(2\pi)^{2|V_N|}} \left(\sum_{j\in I_T} \mathrm{Tr}[S_0^{-1} Df(S_0^j \psi)] \right)^2 = -\frac{1}{2} \partial_\epsilon^2 P''(0)|_{\epsilon=0}, \tag{B18}$$

that is the expected Green–Kubo relation (see Ref. 14).

From Eqs. (2.18) and (2.8), we see that, for ϵ small enough, η_+ is negative and, generically, strictly negative [the condition for f to be *generic* is just that the first line in Eq. (2.18) is different from 0].

Let us now compute Eq. (2.18) in a special case, essentially the simplest possible. Let

$$f^{\xi^+}(\psi) = \sum_{\eta\in nn(\xi)} \sin(\psi_\xi^1 - \psi_\eta^1), \quad f^{\xi^-}(\psi) = 0. \tag{B19}$$

Substituting such choice in Eq. (2.18), we find

$$\partial_\epsilon^2 P'(0)|_{\epsilon=0} = -2 \sum_{|\xi|=1} \int \frac{d\psi_0}{(2\pi)^2} \frac{d\psi_\xi}{(2\pi)^2} \lambda^2 \cos^2(\psi_0^1 - \psi_\xi^1)(v_+ \cdot \hat{e}_1)^2 = -\frac{2d}{1+\lambda^{-2}}, \tag{B20}$$

where $\hat{e}_1 = (1,0)$ and we used that $v_+ = (1/\sqrt{1+\lambda^2}, -\lambda/\sqrt{1+\lambda^2})$.

So, choosing $\epsilon \in \mathbb{R}$ small enough and different from zero, $\eta_+ = P'(0) = -[d/(1+\lambda^{-2})]\epsilon^2 + O(\epsilon^3) < 0$. Furthermore, if $\zeta \in \mathbb{R}$ has modulus smaller than 1, $P(\zeta)$ is strictly convex [since $1/2P''(0) = -P'(0) > 0$ and $P(\zeta)$ is analytic for $|\zeta| \leqslant 1$ and ϵ small enough].

3. Large deviations

In the present section we shall prove a large deviations property for η_{Λ_0}. We will follow the classical strategy set up in Refs. 22 and 12 (in particular we will refer to the formulas in Sec. 5 of the latter). The proof below will hold in the case $\eta_+ < 0$, namely in the generic case or, to be definite, in the case the perturbation is chosen as in Eq. (B19).

Thanks to the convexity of $P(\zeta)$, given $\eta \in [P'(-1), P'(1)]$, there exists a unique point $Z(\eta) \in [-1,1]$ such that $P'(Z(\eta)) \equiv \eta$; considering such a point η and its neighbor of radius δ, $I_\delta(\eta)$, such that $I_\delta(\eta) \subset [P'(-1), P'(1)]$, from the "large deviation property III", Sec. 5 of Ref. 12, we get

$$\mu^{\mathrm{SRB}}(\eta_+ \in I_\delta(\eta)) = O(1) e^{O(\delta|\Lambda_0|)} e^{O(|\partial\Lambda_0|)} \exp\{[P(Z(\eta)) - P(0) - Z(\eta)\eta]|\Lambda_0|\}. \tag{B21}$$

In our case $P(0) = 0$. Still for $\eta \in [P'(-1), P'(1)]$, we define the free energy $F(\eta)$ as the Laplace transform of the generating function $P(\zeta)$:

$$F(\eta) \overset{def}{=} \max_\zeta \{\zeta\eta - P(\zeta)\} = Z(\eta)\eta - P(Z(\eta)); \tag{B22}$$

therefore, for $I_\delta(\eta) \subset [P'(-1), P'(1)]$,

$$\mu^{\mathrm{SRB}}(\eta_+ \in I_\delta(\eta)) = O(1) e^{O(\delta|\Lambda_0|)} e^{O(|\partial\Lambda_0|)} \exp\{-|\Lambda_0| \Delta F(\eta, \eta_+)\}; \tag{B23}$$

where $\Delta F(\eta, \eta_+) \overset{def}{=} F(\eta) - F(\eta_+)$ [indeed $F(\eta_+) = -P(0) = 0$].

Finally, if $[a,b]\subset[P'(-1),P'(1)]$, it is suitable to take $\delta_{\Lambda_0}=|\Lambda_0|^{-\beta}$, $0<\beta<1$, and divide the interval $[a,b]$ in $|b-a||\Lambda_0|^{\beta}$ identical disjoint subintervals centered in $\eta_n \overset{def}{=} a+(n-1/2)\delta_{\Lambda_0}$. We find

$$\mu^{\mathrm{SRB}}(\eta_{\Lambda_0}\in[a,b])=\sum_{n=1}^{|b-a||\Lambda_0|^{\beta}}\mu^{\mathrm{SRB}}(\eta_+\in I_{\delta_{\Lambda_0}}(\eta_n))$$

$$=O(1)|\Lambda_0|^{\beta}e^{O(|\Lambda_0|^{1-\beta})}e^{O(|\partial\Lambda_0|)}\exp\{|\Lambda_0|\max_{\eta\in[a,b]}[-\Delta F(\eta,\eta_+)]\},\tag{B24}$$

namely the result in the second theorem.

(Received 16 December 2003; accepted 12 May 2004; published online 9 July 2004)

We study a (quenched) random-field quantum model of an anharmonic crystal for displacive structural phase transitions in spherical approximation: the random-field quantum spherical (ferroelectric) model. For stationary ergodic random fields its behavior depends on the quantum parameter of the model and on the expectation and covariance of the field. If quantum fluctuations are small enough not to destroy the phase transition, then it can be suppressed when the field fluctuations are large. For the field of independent identically distributed random variables and the short-range interaction we obtain that the *lower* critical dimensionality $d_l=4$ ($d_l=2$ for the zero-field) and that it decreases for long-range interactions. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1769103]

I. INTRODUCTION

References 19 and 20 started a rigorous study of quantum critical fluctuations in the quantum spherical ferroelectric model, known also as the quantum anharmonic crystal model in spherical approximation, see, e.g., Ref. 6. Further examination of the displacive structural (or the ferroelectric) phase transition and the critical behavior of this model shows that the quantum fluctuations are dependent not only on details of the interaction but also on small perturbations (such as an external field) breaking the symmetry of the model.[21,9]

The aim of the present note is to consider the quantum spherical ferroelectric model in quenched external random fields conjugate to particles displacements from equilibria. Since the paper of Ref. 11, it is known that the presence of randomness leads to some new features of the phase transition in the classical spherical model.

In this paper we show that the simultaneous presence of quantum and external random-field fluctuations makes the critical behavior of the random field quantum spherical ferroelectric model rather nontrivial.

In Sec. II we formulate our model and the main Theorem 2.1. There we also discuss the properties of the displacive phase transition as a function of the model parameters. We show that the randomness acts in the same direction as quantum fluctuations, i.e., it has a tendency to suppress the order parameter and the phase transition. For example, in the simplest case of the random field of independent identically distributed variables and of a short-range harmonic interaction the lower critical dimensionality is $d=4$, instead of $d=3$ for the model without the random field. The proof of the main Theorem 2.1 is given in Sec. III. Some concluding remarks are collected in Sec. IV.

II. MODEL AND MAIN THEOREM

Let $\mathbb{Z}^d$ be a d-dimensional hypercubic lattice. With each lattice site $l\in\mathbb{Z}^d$ occupied by a particle of mass m, we associate a position and momentum operators $Q_l\in\mathbb{R}^1$ and $P_l=(\hbar/i)$

[a)]Electronic mail: Christin.Gruber@epfl.ch
[b)]Electronic mail: Valentin.Zagrebnov@cpt.univ-mrs.fr

$\times(\partial/\partial Q_l)$ corresponding (for simplicity) to one-dimensional particle displacements at this site. The case of $Q_l \in \mathbb{R}^\nu, \nu \geqslant 1$, involves more symmetry, but essentially it is very similar to $\nu = 1$, see, e.g., Refs. 4, 5, or 6.

Let $\Lambda \subset \mathbb{Z}^d$ be a finite rectangular subset wrapped according to the periodic boundary conditions:

$$\Lambda := \{l \in \mathbb{Z}^d : -N_\alpha/2 < l_\alpha \leqslant N_\alpha/2\,,\ \alpha = 1,2,\ldots,d\}, \tag{2.1}$$

where we suppose $\{N_\alpha\}_{\alpha=1}^d$ to be even. Then $V := |\Lambda| = N_1 N_2 \cdots N_d$, and Λ^* be the lattice dual to Λ:

$$\Lambda^* := \{k \in \mathbb{R}^d : k_\alpha = 2\pi n_\alpha / N_\alpha, \alpha = 1,2,\ldots,d, \text{ and } \{n_\alpha\}_{\alpha=1}^d \in \Lambda\}. \tag{2.2}$$

The local Hamiltonian of the quantum spherical model in the external random field that we study in this paper is given by the operator

$$H_\Lambda(h^\omega) = \sum_{l\in\Lambda} \frac{P_l^2}{2m} + \frac{1}{4}\sum_{l,l'\in\Lambda} \phi_{l,l'}^\Lambda (Q_l - Q_{l'})^2 + \frac{a}{2}\sum_{l\in\Lambda} Q_l^2 + VW\left(\frac{1}{V}\sum_{l\in\Lambda} Q_l^2\right) - \sum_{l\in\Lambda} h_l^\omega Q_l\,, \tag{2.3}$$

with domain in the Hilbert space $L^2(\mathbb{R}^\Lambda)$. The first term in (2.3) corresponds to the kinetic-energy operator of displacements. The second term represents a harmonic interaction between particles, which are in turn confined by the local harmonic potential with $a \geqslant 0$ described by the third term.

We suppose that the harmonic interaction matrix $\{\phi_{l,l'} = \phi_{l-l'}\}_{l,l'\in\mathbb{Z}^d}$ is positive-definite and translation-invariant. Then for any Λ the matrix $\{\phi_{l,l'}^\Lambda\}_{l,l'\in\Lambda} := \{\phi_{l-l'}^{per}\}_{l,l'\in\Lambda}$ is a restriction to Λ of periodically extended [according to the boundary conditions (2.1)] matrix $\{\phi_{l-l'}\}_{l,l'\in\mathbb{Z}^d}$, which we denoted by $\{\phi_{l-l'}^{per}\}_{l,l'\in\mathbb{Z}^d}$. Therefore, by construction the matrix $\{\phi_{l,l'}^\Lambda\}_{l,l'\in\Lambda}$ is positive-definite and translation-invariant.

The first two terms of the Hamiltonian (2.3) correspond to the one-component Debye phonons, whereas the third term creates a gap in the phonon spectrum, if $a > 0$. The fourth term in (2.3) represents a one-site lattice nonpolynomial anharmonic potential in the (mean) spherical approximation,[18,19] known also as the choquard self-consistent phonons approximation.[2,6–8] One can model this anharmonicity by $W: \mathbb{R}_+^1 \to \mathbb{R}_+^1$, monotonous decreasing to a zero function with a bounded positive second derivative $W'' > 0$, see Refs. 18–20. The last term in (2.3) describes the interaction between particles in positions $\{Q_l\}_{l\in\mathbb{Z}^d}$ and the external random field $\{h_l^\omega\}_{l\in\mathbb{Z}^d} \in \mathbb{R}^{\mathbb{Z}^d}$, where $\omega \in \Omega$, and $(\Omega, \mathcal{F}, \mathbb{P})$ is a corresponding probability space.

We denote by

$$f_\Lambda[H_\Lambda(h^\omega)] := -(\beta V)^{-1} \ln \mathrm{Tr}_{L^2(\mathbb{R}^\Lambda)} \exp\{-\beta H_\Lambda(h^\omega)\}, \tag{2.4}$$

the free-energy density associated with the Hamiltonian (2.3), where $\beta = (k_B T)^{-1}$ and T is the temperature. The main result of the present paper is the following statement:

Theorem 2.1: *Let $W: \mathbb{R}_+^1 \to \mathbb{R}_+^1$, be a monotonous decreasing to zero function with a bounded positive second derivative $W'' > 0$. If the stationary random field $h^\omega := \{h_l^\omega\}_{l\in\mathbb{Z}^d} \in \mathbb{R}^{\mathbb{Z}^d}$ on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ is metrically transitive (ergodic), then the thermodynamic limit (here $\lim_\Lambda$ stays for $\Lambda \uparrow \mathbb{Z}^d$):*

$$f(\beta, h^\omega) := \lim_\Lambda f_\Lambda[H_\Lambda(h^\omega)] \tag{2.5}$$

of the free-energy (2.4) exists for $\mathbb{P}$-almost all $\omega \in \Omega$ and it has the following properties:

(a) *The limit $f(\beta, h^\omega) =: f(\beta, h)$ is $\mathbb{P}$-almost surely* (a.s.) *nonrandom;*

(b) *It coincides with the limiting free-energy density for the approximating Hamiltonian:*

$$H_\Lambda(c,h^\omega) := \sum_{l\in\Lambda}\frac{P_l^2}{2m} + \frac{1}{4}\sum_{l,l'\in\Lambda}\phi_{l,l'}(Q_l - Q_{l'})^2 + \frac{a}{2}\sum_{l\in\Lambda}Q_l^2 + W'(c)\sum_{l\in\Lambda}Q_l^2 - \sum_{l\in\Lambda}h_l^\omega Q_l + V[W(c) - cW'(c)], \tag{2.6}$$

in the sense that

$$f(\beta,h^\omega) = \text{a.s.} - \sup_{c\geqslant c^*}\lim_{\Lambda}\mathbb{E}(f_\Lambda[H_\Lambda(c,h^\omega)]). \tag{2.7}$$

Here $\mathbb{E}(\cdot)$ *is the expectation with respect to the probability* $\mathbb{P}$ *and* c^* *is defined by*

$$c^* := \inf_{c\geqslant 0}\{c : a + 2W'(c) \geqslant 0\}. \tag{2.8}$$

Remark 2.2: Since the approximating Hamiltonian (2.6) is harmonic, the corresponding free-energy density is known explicitly for any Λ *and* $c\geqslant c^*$*:*

$$f_\Lambda[H_\Lambda(c,h^\omega)] = \frac{1}{\beta V}\sum_{q\in\Lambda^*}\ln\left[2\sinh\frac{\beta\lambda\Omega_q(c)}{2}\right] - \frac{1}{2V}\sum_{q\in\Lambda^*}\frac{|h_\Lambda^\omega(q)|^2}{\Omega_q^2(c)} + [W(c) - cW'(c)]. \tag{2.9}$$

Here

$$\Omega_q(c) = (\Delta(c) + \omega_q^2)^{1/2}, \quad q\in\Lambda^* \tag{2.10}$$

is the q-mode frequency of the harmonic (self-consistent) phonons of Hamiltonian (2.6), with the non-negative gap:

$$\Delta(c) := a + 2W'(c) \geqslant 0, \tag{2.11}$$

for $c\geqslant c^*$*. The Debye phonons frequencies are defined by*

$$\omega_q^2 = \tilde{\phi}(0) - \tilde{\phi}(q), \quad q\in\Lambda^*, \tag{2.12}$$

where

$$\tilde{\phi}(q) = \sum_{l\in\mathbb{Z}^d}\phi_{l,0}\exp(-iql), \tag{2.13}$$

and similarly

$$h_\Lambda^\omega(q) := \frac{1}{V^{1/2}}\sum_{l\in\Lambda}h_l^\omega\exp(-iql). \tag{2.14}$$

The quantum parameter of the model λ *is*

$$\lambda = \frac{\hbar}{\sqrt{m}}. \tag{2.15}$$

The Proof of Theorem 2.1 is given in the next section. We conclude this section by some additional remarks concerning the properties of our model (2.3).

Remark 2.3: The simplest stationary ergodic random field $\{h_l^\omega\}_{l\in\mathbb{Z}^d}\in\mathbb{R}^{\mathbb{Z}^d}$ *corresponds to independent identically distributed random variables (i.i.d.r.v.) on the lattice* $\mathbb{Z}^d$*. Since this ran-*

dom field enters in Hamiltonians (2.3), (2.6) as an additive term, the standard self-averaging arguments (see, e.g., Refs. 10–12) for the thermodynamic limit of the free-energy density give

$$\text{a.s.}-\lim_{\Lambda} f_\Lambda[H_\Lambda(h^\omega)]=\lim_{\Lambda}\mathbb{E}f_\Lambda[H_\Lambda(h^\omega)] \tag{2.16}$$

and similarly

$$\text{a.s.}-\lim_{\Lambda} f_\Lambda[H_\Lambda(c,h^\omega)]=\lim_{\Lambda}\mathbb{E}f_\Lambda[H_\Lambda(c,h^\omega)]. \tag{2.17}$$

Corollary 2.4: Let $\{h_l^\omega\}_{l\in\mathbb{Z}^d}$ *be i.i.d.r.v. with expectation* $\mathbb{E}(h_l^\omega)=h$ *and with variance* $var(h_l^\omega)=\sigma^2$. *Then the covariance* $\mathrm{cov}(h_l^\omega,h_{l'}^\omega):=\mathbb{E}((h_l^\omega-h)(h_{l'}^\omega-h))=\sigma^2\delta_{l,l'}$ *and for any* $k\in\Lambda^*$ *one gets*

$$\mathbb{E}(|h_\Lambda^\omega(k)|^2)=\frac{1}{V}\sum_{l,l'\in\Lambda}\mathbb{E}(h_l^\omega h_{l'}^\omega)e^{-ikl}e^{ikl'}=\sigma^2+Vh^2\delta_{k,0}. \tag{2.18}$$

Then by Theorem 2.1 and by the explicit expressions (2.9), (2.18) we obtain

$$f(\beta,h)=\sup_{c\geqslant c^*} f(\beta,h,\sigma^2;c), \tag{2.19}$$

where

$$f(\beta,h,\sigma^2;c):=\frac{1}{(2\pi)^d\beta}\int_{\mathcal{B}_d}d^dq\,\ln\left[2\sinh\frac{\beta\lambda\Omega_q(c)}{2}\right]-\frac{h^2}{2\Delta(c)}-\frac{1}{(2\pi)^d}\int_{\mathcal{B}_d}d^dq\,\frac{\sigma^2}{2\Omega_q(c)^2}$$
$$+[W(c)-cW'(c)], \tag{2.20}$$

and $\mathcal{B}_d:=(-\pi,\pi]^d$ *denotes the first Brillouin zone.*

Therefore, if $h\neq 0$, then by virtue of (2.7) and (2.19), (2.20) the value of the trial parameter c is given by the equation

$$c=\frac{h^2}{\Delta(c)^2}+\frac{1}{(2\pi)^d}\int_{\mathcal{B}_d}d^dq\,\frac{\sigma^2}{\Omega_q(c)^4}+I_d(c,\beta,\lambda), \tag{2.21}$$

where

$$I_d(c,\beta,\lambda):=\frac{\lambda}{(2\pi)^d}\int_{\mathcal{B}_d}d^dq\,\frac{1}{2\Omega_q(c)}\coth\frac{\beta\lambda\Omega_q(c)}{2}. \tag{2.22}$$

Corollary 2.5: Our conditions on the monotone convex function $W(c)\geqslant 0$ *(see Theorem 2.1) imply that derivative* $W'(c)\leqslant 0$ *is a monotone increasing function bounded by zero. If (a priori) phonon spectrum has a gap* $a>0$ *[see (2.3), (2.6), (2.8)], we distinguish two cases:*
(**A**) $\Delta(c=0)\geqslant 0$, *i.e.*, $c^*=0$;
(**B**) $\Delta(c=0)<0$, *i.e.*, $c^*>0$.
In the case (**A**) *for any values of the parameters* β, h, σ, λ *the right-hand side of Eq. (2.21) is strictly positive and decreasing in* $c\in(0,+\infty)$. *Hence, this equation always has a unique positive solution* $\hat{c}(\beta,h,\sigma,\lambda)>0$, *which is a smooth function of those parameters. Therefore, thermodynamic properties of the system are regular, and there are no phase transitions.*

In the case (**B**) *we may have a displacive phase transition. Denote by* $c^*:=c^*(a)$ *a unique root of equation* $a+2W'(c)=0$, *cf. (2.8). By monotonicity of* $W'(c)$ *it exists and we have*: $c^*>0$ *with* $a+2W'(c)\geqslant 0$ *for* $c\geqslant c^*$. *Notice that for* $h\neq 0$ *the solution of Eq. (2.21)*: $\hat{c}(\beta,h$

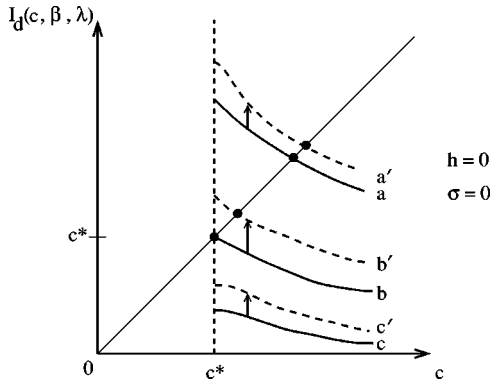

FIG. 1. (a) $\lambda>\lambda_c$, $\beta=\infty$; (a′) $\lambda>\lambda_c$, $\beta<\infty$. (b) $\lambda=\lambda_c$, $\beta=\infty$; (b′) $\lambda=\lambda_c$, $\beta<\infty$. (c) $\lambda<\lambda_c$, $\beta=\infty$; (c′) $\lambda<\lambda_c$, $\beta<\infty$.

$\neq 0,\sigma,\lambda)>c^*$, *and it is still a smooth function of the rest of parameters. This rules out phase transitions if the external field has a nonzero expectation. Thus, we may have a phase transition in the case* (***B***) *only when* $h=0$.

Notice that in the case (**B**) with $h=0$ one has to distinguish two possibilities: $\sigma=0$ and $\sigma\neq 0$. The first one means that the external field is simply absent, whereas the second one corresponds to a random field with nondegenerate distribution.

(**B1**) *Let* $h=0$ *and* $\sigma=0$. Since $c^*>0$, there exists a critical value $\lambda_c:=\lambda_c(c^*)$, of the quantum parameter, defined by Eq. (2.21) at zero temperature:

$$c^*=\lim_{\beta\to\infty} I_d(c^*,\beta,\lambda_c), \tag{2.23}$$

see Fig. 1. By monotonicity of $I_d(c^*,\beta,\lambda)$ in β and λ one gets that $I_d(c^*,\beta,\lambda)\geqslant c^*$ for all $\beta\leqslant\infty$ and $\lambda\geqslant\lambda_c$. Since $I_d(c,\beta,\lambda)$ is monotonous decreasing function of $c\geqslant c^*$, Eq. (2.21) for $h=0$, $\sigma=0$:

$$c=I_d(c,\beta,\lambda), \tag{2.24}$$

has a unique solution $\hat{c}(\beta,h=0,\sigma=0,\lambda)>c^*$ for any $\lambda\geqslant\lambda_c$, Figs. 1(a), 1(a′) and 1(b), 1(b′). The solution is a smooth function of β and λ, including the zero temperature. This phenomenon is well-known as the suppression of the displacive phase transition by large quantum fluctuations, see e.g., Refs. 13, 14, 18, 19, or the recent book (Ref. 6).

If $\lambda<\lambda_c$, then by monotonicity of the integral $I_d(c^*,\beta,\lambda)$ in β, there is $\beta_c(\lambda)$, such that

$$c^*=I_d(c^*,\beta_c(\lambda),\lambda). \tag{2.25}$$

Then for $\beta\leqslant\beta_c(\lambda)$ Eq. (2.24) has again only a unique smooth solution $\hat{c}(\beta,h=0,\sigma=0,\lambda)>c^*$. Whereas for $\beta>\beta_c(\lambda)$ one gets $c^*>I_d(c^*,\beta,\lambda>\lambda_c)$, i.e., formally Eq. (2.24) has no solution, see Figs. 1(c), 1(c′). The value $\beta_c(\lambda)^{-1}$ is the critical temperature of the model. It corresponds to the phase transition breaking the symmetry $\{Q_l\to -Q_l\}_{l\in\mathbb{Z}^d}$. To find the corresponding order parameter one has to return to Eq. (2.24) before taking the thermodynamic limit, i.e., before the corresponding finite-volume Darboux–Riemann sums give us in the limit the integral $I_d(c,\beta,\lambda)$. Another possibility is to add to the Hamiltonian a constant-field term breaking the symmetry, i.e., to put $h\neq 0$, see Refs. 18, 19, 21, 9, and Fig. 2. Using the latter trick one obtains for the displacive order parameter $M(\beta)$:

$$\pm M(\beta):=\lim_{h\to\pm 0}\lim_{\Lambda\uparrow\mathbb{Z}^d}\langle Q_l\rangle_{H_\Lambda(h)}(\beta,h,\sigma=0)=\pm\sqrt{c^*-I_d(c^*,\beta,\lambda<\lambda_c)}, \tag{2.26}$$

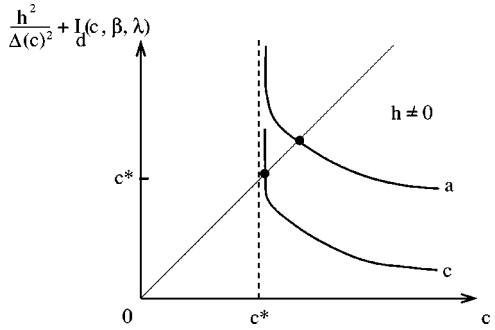

FIG. 2. (a) $\lambda>\lambda_c$, $\beta=\infty$, $h\neq 0$. (c) $\lambda<\lambda_c$, $\beta=\infty$, $h\neq 0$.

when $\beta>\beta_c(\lambda)$, and $M(\beta)=0$ for $\beta\leqslant\beta_c(\lambda)$, Fig. 3. Here $\langle\cdot\rangle_{H_\Lambda(h)}$ is the Gibbs state with Hamiltonian (2.3), for constant external field $h_l^\omega=h$.

Remark 2.6: Notice that the definition of the critical temperature given by Eq. (2.25) demands the convergence of the integral $I_d(c^*,\beta,\lambda<\lambda_c)$. *For the short-range harmonic interaction, i.e., for*

$$\phi_{l-l'}\leqslant A\|l-l'\|^{-(d+\alpha)},\quad \|l-l'\|\to\infty\,, \tag{2.27}$$

with $\alpha\geqslant 2$, *we have*

$$\tilde{\phi}(q)=\tilde{\phi}(0)+s^2\|q\|^2+o(\|q\|^2),\quad \|q\|\to 0\,, \tag{2.28}$$

for some $s>0$. *Therefore, the integral in (2.25) converges only for* $d>2$.

If we suppose that $0<\alpha<2$ *in (2.27) (long-range harmonic interaction), then*

$$\tilde{\phi}(q)=\tilde{\phi}(0)+s^\alpha\|q\|^\alpha+o(\|q\|^\alpha),\quad \|q\|\to 0. \tag{2.29}$$

Hence, the integral in (2.25) converges for $d>\alpha$.

(**B2**) *Let* $h=0$ *and* $\sigma\neq 0$. Then Eq. (2.21) takes the form

$$c=\frac{1}{(2\pi)^d}\int_{\mathcal{B}_d} d^dq\,\frac{\sigma^2}{\Omega_q(c)^4}+I_d(c,\beta,\lambda). \tag{2.30}$$

Now besides (2.25) we need the convergence of the integral

$$J_d(c^*,\sigma):=\frac{1}{(2\pi)^d}\int_{\mathcal{B}_d} d^dq\,\frac{\sigma^2}{\Omega_q(c^*)^4}. \tag{2.31}$$

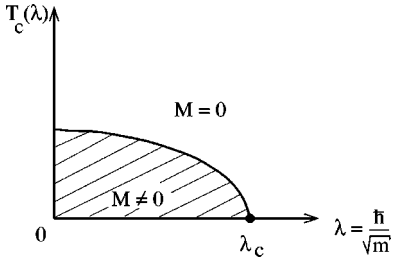

FIG. 3. Phase diagram for $\sigma=0$ $(h=0)$.

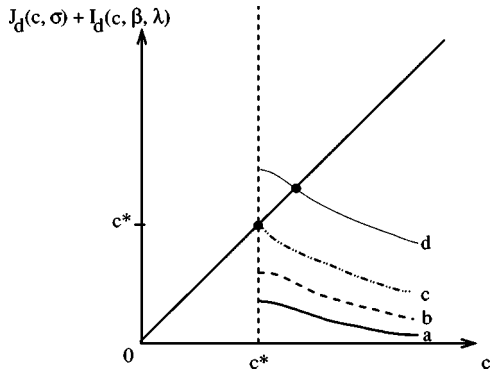

FIG. 4. (a) $\lambda<\lambda_c$, $\beta=\infty$, $\sigma=0$. (b) $\lambda<\lambda_c$, $\beta=\infty$, $\sigma>0$. (c) $\lambda<\lambda_c$, $\beta=\infty$, $\sigma=\sigma_c(\lambda)$. (d) $\lambda<\lambda_c$, $\beta=\infty$, $\sigma>\sigma_c(\lambda)$.

Indeed, if $\lim_{c\downarrow c^*} J_d(c,\sigma)=+\infty$, then Eq. (2.30) has a unique smooth solution $\hat{c}(\beta,h=0,\sigma,\lambda)>c^*$. Notice that even if the integral (2.31) converges, but

$$J_d(c^*,\sigma)+I_d(c^*,\beta=\infty,\lambda)>c^*, \tag{2.32}$$

we arrive to the same conclusion, since

$$\frac{\lambda}{(2\pi)^d}\int_{\mathcal{B}_d} d^dq\,\frac{1}{2\Omega_q(c^*)}=I_d(c^*,\beta=\infty,\lambda)\leqslant I_d(c^*,\beta,\lambda)\leqslant I_d(c^*,\beta=0,\lambda), \tag{2.33}$$

see Fig. 4. Therefore, the stationary random field with zero expectation, $\mathbb{E}(h_l^\omega)=0$, rules out the phase transition if its variance verifies the following estimate from below:

$$\sigma^2>\left\{c^*-\frac{\lambda}{(2\pi)^d}\int_{\mathcal{B}_d} d^dq\,\frac{1}{2\Omega_q(c^*)}\right\}\left\{\frac{1}{(2\pi)^d}\int_{\mathcal{B}_d} d^dq\,\frac{1}{\Omega_q(c^*)^4}\right\}^{-1}=:\sigma_c^2(\lambda). \tag{2.34}$$

Here we supposed that $\lambda<\lambda_c(c^*)$, i.e.,

$$c^*>\frac{\lambda}{(2\pi)^d}\int_{\mathcal{B}_d} d^dq\,\frac{1}{2\Omega_q(c^*)}, \tag{2.35}$$

to avoid the suppression of the phase transition by the quantum fluctuations, see (**B1**).

If the quantum fluctuations are small enough, see (2.35), and $\sigma^2<\sigma_c^2(\lambda)$, then by Eq. (2.30) we find a nontrivial critical temperature $0<\beta_c(\lambda,\sigma)<\infty$ verifying the equation:

$$c^*=J_d(c^*,\sigma)+I_d(c^*,\beta_c(\lambda,\sigma),\lambda), \tag{2.36}$$

for the symmetry breaking phase transition. Following the same method as in (2.26) we obtain for the displacive order parameter:

$$\pm M(\beta):=\lim_{h\to\pm 0}\lim_{\Lambda\uparrow\mathbb{Z}^d}\langle Q_l\rangle_{H_\Lambda(h^\omega+h)}(\beta,h,\sigma)=\pm\sqrt{c^*-J_d(c^*,\sigma)-I_d(c^*,\beta,\lambda)}, \tag{2.37}$$

when $\beta>\beta_c(\lambda,\sigma)$ and $M(\beta)=0$ for $\beta\leqslant\beta_c(\lambda,\sigma)$, see Fig. 5. Here $H_\Lambda(h^\omega+h)$ is the Hamiltonian (2.3) with shifted external field: $\{h_l^\omega+h\}_{l\in\mathbb{Z}^d}$, i.e., with $\mathbb{E}(h_l^\omega+h)=h$.

Remark 2.7: Notice that for the short-range harmonic interaction (2.27) the integral (2.31) converges only for $d>4$. This means that the external field fluctuations of i.i.d.r.v. with $\mathbb{E}(h_l^\omega)$

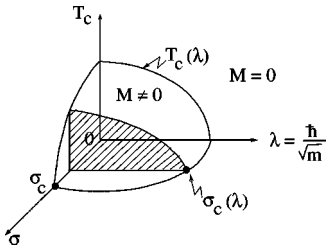

FIG. 5. Phase diagram for $\sigma \neq 0$ $(h=0)$.

$=0$, *suppress the phase transition for all lower dimensions* $d \leqslant 4$. *On the other hand, the estimates (2.32), (2.33) show that for* $d>4$ *there is a competition between external field fluctuations and quantum fluctuations to rule out the phase transition.*

For the long-range harmonic interaction (2.29) the integral (2.31) converges if $d>2\alpha$. *By virtue of Remark 2.6 and (2.33) the integral (2.25) also converges. Now, to ensure phase transition for* $d=3$ *one has to choose* $\alpha<3/2$ *and the quantum parameter* λ *verifying (2.35), together with i.i.d.r. external field variance* $\sigma^2<\sigma_c^2(\lambda)$.

III. PROOFS

The next statement generalizes one of the results from Ref. 19 to the case of random external fields.

Lemma 3.1: Let W verify conditions of the Theorem 2.1 with $b:=\sup_{c\geqslant 0} W''(c)$. *Suppose that* $\{h_l^{\omega}=h\}_{l\in\mathbb{Z}^d}$ *is a nonrandom (constant) field. Then*

$$f(\beta,h)=\lim_{\Lambda} f_{\Lambda}[H_{\Lambda}(h)]=\sup_{c\geqslant c^*}\lim_{\Lambda} f_{\Lambda}[H_{\Lambda}(c,h)]. \tag{3.1}$$

Proof: By virtue of the Bogoliubov convexity inequality (see e.g., Ref. 16 or 17) one gets

$$\frac{1}{V}\langle \delta H_{\Lambda}(c,h)\rangle_{H_{\Lambda}(h)} \leqslant f_{\Lambda}[H_{\Lambda}(h)]-f_{\Lambda}[H_{\Lambda}(c,h)] \leqslant \frac{1}{V}\langle \delta H_{\Lambda}(c,h)\rangle_{H_{\Lambda}(c,h)}, \tag{3.2}$$

where $\delta H_{\Lambda}(c,h):=H_{\Lambda}(h)-H_{\Lambda}(c,h)$, and $c>c^*$, $h\in\mathbb{R}^1$. By (2.3), (2.6) and the condition $b:=\sup_{c\geqslant 0} W''(c)>0$ we have for $\delta H_{\Lambda}(c,h)$ the following operator inequalities:

$$0\leqslant H_{\Lambda}(h)-H_{\Lambda}(c,h)\leqslant V\frac{b}{2}\left(\frac{1}{V}\sum_{l\in\Lambda} Q_l^2-c\right)^2. \tag{3.3}$$

Together with (3.2) these inequalities imply the estimate

$$0\leqslant f_{\Lambda}[H_{\Lambda}(h)]-f_{\Lambda}[H_{\Lambda}(c,h)]\leqslant \frac{b}{2}\left\langle\left(\frac{1}{V}\sum_{l\in\Lambda} Q_l^2-c\right)^2\right\rangle_{H_{\Lambda}(c,h)}. \tag{3.4}$$

Since we still have a freedom to choose the parameter $c>c^*$, we fix it in the right-hand side of (3.3) by the equation:

$$c=\left\langle\frac{1}{V}\sum_{l\in\Lambda} Q_l^2\right\rangle_{H_{\Lambda}(c,h)}. \tag{3.5}$$

Then the following estimate is true:

$$0 \leqslant f_\Lambda[H_\Lambda(h)] - \sup_{c>c^*} f_\Lambda[H_\Lambda(c,h)] \leqslant \frac{b}{2} \left\langle \left(\frac{1}{V} \sum_{l \in \Lambda} Q_l^2 - \left\langle \frac{1}{V} \sum_{l \in \Lambda} Q_l^2 \right\rangle_{H_\Lambda(\hat{c}_\Lambda,h)} \right)^2 \right\rangle_{H_\Lambda(\hat{c}_\Lambda,h)}, \tag{3.6}$$

where $\hat{c}_\Lambda := \hat{c}_\Lambda(\beta,h)$ is the solution of Eq. (3.5). Notice that the approximating Hamiltonian $H_\Lambda(c,h)$ is harmonic. Therefore, we can calculate the expectation in the right-hand side of (3.6) explicitly:

$$\left\langle \left(\frac{1}{V} \sum_{l \in \Lambda} Q_l^2 - \left\langle \frac{1}{V} \sum_{l \in \Lambda} Q_l^2 \right\rangle_{H_\Lambda(c,h)} \right)^2 \right\rangle_{H_\Lambda(c,h)} = \frac{2}{V^2} \sum_{q \in \Lambda^*} \left\{ \frac{\lambda}{2\Omega_q(c)} \coth\left(\frac{1}{2} \beta \lambda \Omega_q(c) \right) \right\}^2 + \frac{2}{V} \left(\frac{h}{\Delta(c)} \right)^4. \tag{3.7}$$

Similarly one gets for the self-consistency equation (3.5),

$$c = \frac{h^2}{\Delta(c)^2} + \frac{1}{V} \sum_{q \in \Lambda^*} \frac{\lambda}{2\Omega_q(c)} \coth\left(\frac{1}{2} \beta \lambda \Omega_q(c) \right). \tag{3.8}$$

Due to the first term in the right-hand side of (3.8) we obtain that solution of this equation for $h \neq 0$ is strictly greater than c^*: $\hat{c}_\Lambda(\beta,h) > c^*$, or $\Delta(\hat{c}_\Lambda(\beta,h)) > 0$. Since the value of the fluctuation (3.7) in the estimate (3.6) should be calculated for $c = \hat{c}_\Lambda(\beta,h)$, the right-hand side of (3.6) tends to zero, when $V \to \infty$, i.e., we get

$$\lim_\Lambda f_\Lambda[H_\Lambda(h \neq 0)] = \lim_\Lambda \sup_{c>c^*} f_\Lambda[H_\Lambda(c,h \neq 0)] = \sup_{c>c^*} \lim_\Lambda f_\Lambda[H_\Lambda(c,h \neq 0)]. \tag{3.9}$$

Here the last equality is due to concavity of the trial free-energy density $f_\Lambda[H_\Lambda(c,h \neq 0)]$ in c. Finely, the pointwise convergence (3.9) for $h \neq 0$ implies the convergence at $h = 0$ by convexity of $\sup_{c>c^*} f_\Lambda[H_\Lambda(c,h)]$ in h. □

Corollary 3.2: Using the explicit form of the trial free-energy density $f_\Lambda[H_\Lambda(c,h \neq 0)]$ (see (2.9) for $h_\Lambda^\omega(q) = \sqrt{V} h \delta_{q,0}$), we obtain that solution of the variational problem $\sup_{c>c^*} f_\Lambda[H_\Lambda(c,h)]$ coincides with solution $\hat{c}_\Lambda(\beta,h)$ of the self-consistency equation (3.8).

Corollary 3.3: Let $\{h_l^\omega\}_{l \in \mathbb{Z}^d}$ be a stationary ergodic random field with expectation $\mathbb{E}(h_l^\omega) = h$. Then similar to (3.6) and (3.7) we get the estimate

$$0 \leqslant f_\Lambda[H_\Lambda(h^\omega)] - \sup_{c>c^*} f_\Lambda[H_\Lambda(c,h^\omega)] \leqslant \frac{b}{2} D_\Lambda(\hat{c}_\Lambda^\omega, \beta, h^\omega). \tag{3.10}$$

Here fluctuations (3.7) for the case of random field have the form

$$D_\Lambda(c,\beta,h^\omega) := \left\langle \left(\frac{1}{V} \sum_{l \in \Lambda} Q_l^2 - \left\langle \frac{1}{V} \sum_{l \in \Lambda} Q_l^2 \right\rangle_{H_\Lambda(c,h^\omega)} \right)^2 \right\rangle_{H_\Lambda(c,h^\omega)}$$
$$= \frac{2}{V^2} \sum_{q \in \Lambda^*} \left\{ \frac{\lambda}{2\Omega_q(c)} \coth\left(\frac{1}{2} \beta \lambda \Omega_q(c) \right) \right\}^2 + \frac{2}{V} \left(\frac{h^2}{\Delta(c)^2} \right)^2 + \frac{2}{V^2} \sum_{q \in \Lambda^* \setminus \{0\}} \left(\frac{|\tilde{h}_\Lambda^\omega(q)|^2}{\Omega_q(c)^4} \right)^2, \tag{3.11}$$

and $\hat{c}_\Lambda^\omega := \hat{c}_\Lambda^\omega(\beta,h^\omega)$ is a solution of the self-consistency equation:

$$c=\frac{h^2}{\Delta(c)^2}+\frac{1}{V}\sum_{q\in\Lambda^*\setminus\{0\}}\frac{|\tilde{h}^{\omega}_{\Lambda}(q)|^2}{\Omega_q(c)^4}+\frac{1}{V}\sum_{q\in\Lambda^*}\frac{\lambda}{2\Omega_q(c)}\coth\left(\frac{1}{2}\beta\lambda\Omega_q(c)\right), \tag{3.12}$$

where $\tilde{h}^{\omega}_{\Lambda}(q)$ *is the lattice Fourier transformation (2.14) of the shifted random field* $\{\tilde{h}^{\omega}_l=h^{\omega}_l-h\}_{l\in\mathbb{Z}^d}$.

Proof (of Theorem 2.1): If $h\neq 0$, then (3.12) implies that for any configuration $\omega\in\Omega$ and uniformly in Λ the solution $\hat{c}^{\omega}_{\Lambda}\geqslant c^*+\epsilon(h)$, where $\epsilon(h)>0$ and $\lim_{h\to 0}\epsilon(h)=0$. Since in this case $\lim_{\Lambda} D_{\Lambda}(c,\beta,h^{\omega})=0$ uniformly in $c\geqslant c^*+\epsilon(h)$, the thermodynamic limit of (3.11) gives $\lim_{\Lambda} D_{\Lambda}(\hat{c}^{\omega}_{\Lambda},\beta,h^{\omega})=0$, i.e.,

$$\lim_{\Lambda} f_{\Lambda}[H_{\Lambda}(h^{\omega})]=\lim_{\Lambda}\sup_{c>c^*} f_{\Lambda}[H_{\Lambda}(c,h^{\omega})]=\sup_{c>c^*}\lim_{\Lambda} f_{\Lambda}[H_{\Lambda}(c,h^{\omega})]. \tag{3.13}$$

Since $\{\Omega^2_q(c)\}_{q\in\Lambda^*}$ are eigenvalues of the matrix $\{\phi_{l,l'}/2+\Delta(c)\delta_{l,l'}\}_{l,l'\in\Lambda}$ with eigenvectors $\{\psi_l(q):=\exp(-iql)\}_{q\in\Lambda^*}$, we can construct a nondecreasing (random) function of the real variable E:

$$\mu^{\omega}_{\Lambda}(E):=\frac{1}{V}\sum_{q\in\Lambda^*:\Omega^2_q(c)\leqslant E}\left|\sum_{l\in\Lambda}\psi_l(q)h^{\omega}_l\right|^2. \tag{3.14}$$

If the random field $\{h^{\omega}_l\}_{l\in\mathbb{Z}^d}$ is stationary and ergodic, then there exists a nonrandom nondecreasing spectral function $\mu(E)$ such that

$$\mu(E)=\text{a.s.}-\lim_{\Lambda}\mu^{\omega}_{\Lambda}(E) \tag{3.15}$$

at all their points of continuity, see e.g., Refs. 12 or 10. This means that the measure $\mu^{\omega}_{\Lambda}(dE)$ converges weakly with $\mathbb{P}$-probability 1 to the measure $\mu(dE)$, or

$$\text{a.s.}-\lim_{\Lambda}\frac{1}{V}\sum_{q\in\Lambda^*}\frac{|h^{\omega}_{\Lambda}(q)|^2}{\Omega_q(c)^4}=\text{a.s.}-\lim_{\Lambda}\int_{\Delta(c^*+\epsilon(h))}^{+\infty}\frac{\mu^{\omega}_{\Lambda}(dE)}{E^2}=\int_{\Delta(c^*+\epsilon(h))}^{+\infty}\frac{\mu(dE)}{E^2}, \tag{3.16}$$

since by virtue of $h\neq 0$ the integration in (3.16) runs over strictly positive E's. Therefore, (3.16) implies the self-averaging of the free-energy limit:

$$\text{a.s.}-\lim_{\Lambda} f_{\Lambda}[H_{\Lambda}(c,h^{\omega})]=\lim_{\Lambda}\mathbb{E}(f_{\Lambda}[H_{\Lambda}(c,h^{\omega})]). \tag{3.17}$$

This, together with (3.13), proves Theorem 2.1 for the random field when $h\neq 0$.

Now let $h=0$. Then one can use the convexity arguments for the free-energy density (as a function of h) to reach the same conclusion as in (3.17) when $h\to 0$, which by continuity coincides with the case $h=0$. □

IV. CONCLUDING REMARKS

We presented here a quenched random quantum model to study the impact of different type of fluctuations (thermal, quantum and random-field) on the second-order phase transition. Here we compare this for quantum and random-field fluctuations. Our main conclusion is that the random-field fluctuations may lift the lower critical dimensionality up to $d_l=4$ to screen the impact of quantum fluctuations for which the lower critical dimensionality is $d_l=2$, and even $d_l=1$ in the pure quantum limit $T=0$, see (2.35).

Notice that our results about suppression of the quantum phase transition by the random external fields with zero mean in some aspects are similar to those for the classical spherical model. For example, we obtain for the critical value of the variance (2.34) of the i.i.d.r. field:

$$\sigma_c^2(\lambda)=\left\{c^*-\frac{\lambda}{(2\pi)^d}\int_{\mathcal{B}_d}d^dq\,\frac{1}{2\Omega_q(c^*)}\right\}\sigma_{c,\mathrm{class}}^2, \tag{4.1}$$

where

$$\sigma_{c,\mathrm{class}}^2=\left\{\frac{1}{(2\pi)^d}\int_{\mathcal{B}_d}d^dq\,\frac{1}{\Omega_q(c^*)^4}\right\}^{-1} \tag{4.2}$$

is the corresponding threshold for the classical spherical model.[10,11] The supplementary factor in front of $\sigma_{c,\mathrm{class}}^2$, see (4.1), is due to quantum fluctuations, $\lambda\neq 0$, and due to a specific choice of the potential function W. We recover the classical result (4.2), if we put $\hbar=0$ and $c^*=1$ in (2.34). The relation (2.34) implies that the lower critical dimensionality $d_l=4$ is identical for classical and quantum random spherical models. Notice that the random field classical n-vector model also has the same lower critical dimensionality $d_l=4$, see Ref. 1. This similarity is not accidental, since the classical spherical random model can be obtained as the $n\to\infty$ limit from the corresponding random n-vector model.[10] Notice that in Refs. 4 and 5 it is shown that the $n\to\infty$ limit of a quantum n-vector crystal model with a one-site anharmonic potential, gives for the free-energy density the same result as the corresponding spherical (or Hartree–Fock) approximation, but it gives different results for fluctuations. Since the critical properties of this quantum n-vector anharmonic crystal in random fields are unknown, we have no quantum analog of the statements.[1,10]

Another open problem concerns the impact of the random field on the displacive (ferroelectric) phase transition in the anharmonic quantum crystal without spherical approximation. It is known that for a rather general class of double-well one-site anharmonic potentials the large quantum fluctuations (large parameter λ) suppress the displacive phase transition in this model,[22] and even make the Gibbs state unique.[3,15] Our conjecture is that the presence of random field will produce the same scenario as we obtained in the spherical approximation.

We consider the Lie-algebra of the group of diffeomorphisms of a d-dimensional torus which is also known to be the algebra of derivations on a Laurent polynomial ring A in d commuting variables denoted by $\mathrm{Der}\,A$. The universal central extension of $\mathrm{Der}\,A$ for $d=1$ is the so-called Virasoro algebra. The connection between Virasoro algebra and physics is well known. See, for example, the book on Conformal Field Theory by Di Francesco, Mathieu, and Senechal. In this paper we classify (A, $\mathrm{Der}\,A$) modules which are irreducible and have finite dimensional weight spaces. Earlier Larsson constructed a large class of modules, the so-called tensor fields, based on $g\ell_d$ modules which are also A modules. We prove that they exhaust all (A, $\mathrm{Der}\,A$) irreducible modules. © *2004 American Institute of Physics.*

I. INTRODUCTION

It is well known that the group of diffeomorphisms on a manifold is very important and shows up directly in many branches of physics (see, for example, Ref. 22). We are particularly interested in d-dimensional torus. The case $d=1$ is well studied by both mathematicians and physicists. The one-dimensional central extension of the Lie-algebra of diffeomorphisms of the circle is a well-known object called Virasoro algebra. The representation theory of Virasoro algebra is studied in great detail. See Ref. 14.

The Virasoro algebra acts on any (except when the level is negative of dual Coxeter number) highest weight module of the affine Lie algebra through the use of the famous Sugawara operators. It is well known that affine Lie algebras admit representation on the Fock space (see Ref. 13) and hence admits a representation of the Virasoro algebra. This classical theory is what we originally want to generalize to d-dimensional torus.

The relation to physics is well established in the book on Conformal Field Theory by Di Francesco, Mathieu, and Senechal, Ref. 5. In particular, Chaps. 13–18 explain the connection between physics and the representation theory of Virasoro and affine Kac–Moody Lie-algebras. Several important papers on these aspects have been put in one volume by Goddard and Olive in Ref. 11. The most fundamental paper in this direction is due to Belavin, Polyakov, and Zamolodchikov in Ref. 1.

The generalization of affine Lie algebra is the so-called toroidal Lie-algebra. For the first time a large class of representations are constructed in Refs. 9 and 21 through the use of vertex operators generalizing the Fock space construction to the toroidal Lie-algebras. One significant difference for the toroidal Lie-algebra is that the universal center is infinite dimensional unlike in the affine case where it is one dimensional.

So the next natural issue is to generalize Virasoro algebra and see whether the algebra acts on the Fock space. For that we first denote the Lie algebra of diffeomorphisms of d-dimensional torus by $\mathrm{Der}\,A$ (it is known that $\mathrm{Der}\,A$ is isomorphic to the derivations of Laurent polynomial ring A in d-variables). Here one should mention that several attempts have been made by physicists to give

a)Electronic mail: senapati@math.tifr.res.in

a Fock space representation to Der A or to its extension (see Ref. 10). They all failed to produce any interesting results due to lack of proper definition of ''normal ordering'' among other things. At this juncture an interesting result has come out from Ref. 23 which says that Der A has no nontrivial central extension for $d \geqslant 2$.

Let us go back to the vertex construction of toroidal Lie-algebra of Ref. 9. Here operators are constructed for Der A generalizing the Sugawara construction. But the corresponding extension for Der A is very wild (certainly noncentral) and not tractable (see Ref. 7). In the process an interesting Abelian extension for Der A has been created in Ref. 9 and the Abelian part is exactly the center of the toroidal Lie algebra. So the semi-direct sum of the toroidal Lie algebra and Der A with common extension has emerged as an interesting object which we will now define.

We will first define toroidal Lie algebra. Let $\mathcal{G}$ be simple finite dimensional Lie algebra and let $\langle , \rangle$ be a nondegenerate symmetric bilinear form on $\mathcal{G}$. Fix a positive integer d and let $A = \mathbb{C}[t_1^{\pm 1}, \ldots, t_d^{\pm 1}]$ be a Laurent polynomial ring in d-commuting variables.

Let Ω_A be the module of differentials which can be defined as vector space spanned by $t^r K_i$, $i = 1, \ldots, d$ and $r \in \mathbb{Z}^n$. Let d_A be the subspace spanned by $\Sigma r_i t^r K_i$ and consider the toroidal Lie algebra $\mathcal{G} \otimes A \oplus \Omega_A / d_A$ with Lie-bracket.

$$[X \otimes t^r, Y \otimes t^s] = [X, Y] \otimes t^{r+s} + \langle X, Y \rangle \Sigma r_i t^{r+s} K_i$$

Ω_A / d_A is central.

Let Der A be the derivation on A. For $u \in \mathbb{C}^d$ and $r \in \mathbb{Z}^d$ let $D(u,r) = \Sigma u_i t^r t_i (\mathrm{d}/\mathrm{d}t_i)$ where $u = (u_1, \ldots, u_d)$ and $r = (r_1, \ldots, r_d), t^r = t_1^{r_1} t_2^{r_2} \cdots t_d^{r_d} \in A$. Let $K(u,r) = \Sigma u_i t^r K_i$. Consider the Lie-algebra

$$\tau = \mathcal{G} \otimes A \oplus \Omega_A / d_A \oplus \mathrm{Der}\, A,$$

$$[D(u,r), D(v,s)] = D(w, r+s) - (u,s)(v,r) K(r, r+s),$$

where $w = (u,s)v - (v,r)u$ and $(,)$ is the standard inner product in $\mathbb{C}^d$,

$$[D(u,r), K(v,s)] = (u,s) K(v, r+s) + (u,v) K(r, r+s),$$

$$[K(u,r), K(v,s)] = 0.$$

The first issue is that can we construct a representation for τ from known methods. Several attempts have been made (Refs. 2, 3, and 9). Eventually in a remarkable paper, Billig (Ref. 4) succeeded in constructing a class of modules for τ through the use of Vertex operator algebras (VOA). In the process Billig has used the Der A modules constructed in Ref. 17 and studied in Ref. 6. One natural question is, do more modules exist for Der A so that we get a much larger class of models of τ.

In an interesting paper by Jiang and Meng (Ref. 12) it is proved that classification of irreducible integrable modules of τ can be reduced to the classification of irreducible (A, Der A) modules which the current paper settles. See also Ref. 8 for more precise results.

Let me explain the results of this paper in more detail. In Ref. 17, Larsson constructed a large class of Der A modules and some of them with finite dimensional weight spaces. In fact he constructed a functor from gl_d-modules to Der A-modules. In Ref. 6 the author proves that the image of an irreducible finite dimensional module is most often irreducible.

Further Larsson's Der A modules are A modules too and they are always irreducible as (A, Der A)-modules. Thus the purpose of the paper is to prove the converse. So we prove in Theorem 2.9 that any (A, Der A) module which is irreducible and has finite dimensional weight spaces has to come from Larsson's construction.

It will certainly be interesting to classify all irreducible Der A modules with finite dimensional weight spaces. Now some kind of highest weight modules are constructed in Refs. 2 and 3 (they are not A modules). We will also note that $GL(d, \mathbb{Z})$ acts as automorphisms on Der A and so we

can twist a Der$A$ module by $GL(d,\mathbb{Z})$. [Larsson's modules are closed under $GL(d,\mathbb{Z})$ action.] So it will be interesting to prove that any irreducible Der$A$ module with finite dimensional weight spaces is either a highest weight module or a Larsson's module up to a twist of $GL(d,\mathbb{Z})$ action. The problem is completely solved for $d=1$ by Mathieu in Ref. 20.

Our results in Ref. 9 have been reinterpreted in the language of physics by Larsson in Refs. 18 and 19. Larsson is also the first to talk about noncentral extensions in Refs. 15 and 16. Der$A$ has also been studied in Ref. 24.

II. CONSTRUCTION OF Der$A$ MODULES

(2.1) Throughout this paper we fix a positive integer $d\geqslant 2$ and a Laurent polynomial ring $A=\mathbb{C}[t_1^{\pm 1},\ldots,t_d^{\pm 1}]$ in d commuting variables. Let $\mathbb{C}^d$ be d copies of complex field $\mathbb{C}$. Let $e_1,\ldots,e_d$ be the standard basis of $\mathbb{C}^d$, and let $(,)$ be the standard form on $\mathbb{C}^d$ such that $(e_i,e_j)=\delta_{ij}$.

(2.2) Let $\Gamma=\mathbb{Z}e_1\oplus\cdots\oplus\mathbb{Z}e_d$. Throughout this paper we use m,n,r, and s to denote elements of Γ. For $r=\Sigma r_i e_i\in\Gamma$ let $t^r=t_1^{r_1}t_2^{r_2}\cdots t_d^{r_d}\in A$ and let $D^i(r)=t^r t_i(\mathrm{d}/\mathrm{d}t_i)$ be a derivation on A. Let Der$A$ be the Lie-algebra of derivations of A. It is easy to verify that $D^i(r),1\leqslant i\leqslant d,r\in\Gamma$ is a basis of Der$A$. For $u=\Sigma u_i e_i\in\mathbb{C}^d$ let $D(u,r)=\Sigma u_i D^i(r)$. Then Der$A$ has the following Lie structure:

(2.3)

$$[D(u,r),D(v,s)]=D(w,r+s),$$

where $w=(u,s)v-(v,r)u$, $r,s\in\Gamma$ and $u,v\in\mathbb{C}^d$. Let h be the subspace spanned by $D^i(0),1\leqslant i\leqslant d$, which is a maximal Abelian subalgebra of Der$A$.

(2.4) Note that $D(u,r)t^s=(u,s)t^{r+s}$. Thus $A\oplus\mathrm{Der}A$ is a Lie-algebra by extending the Lie structure in the following way:

$$[t^r,t^s]=0,$$

$$[D(u,r),t^m]=(u,m)t^{r+m}.$$

Let $\tilde{h}=\mathbb{C}\oplus h$, which is an Abelian subalgebra of $A\oplus\mathrm{Der}A$.

The purpose of this paper is to study $A\oplus\mathrm{Der}A$ modules which are weight modules for $\tilde{h}$ with finite dimensional weight spaces and to classify such modules with some natural conditions.

We first recall Der$A$ modules which are constructed and studied in Refs. 17 and 6.

(2.5) Let $g\ell_d$ be the Lie-algebra of $d\times d$ matrices with entries in $\mathbb{C}$. Let E_{ij} be the elementary matrix with (i,j)th entry 1 and zero elsewhere. Then it is well known that $g\ell_d$ is spanned by $E_{ij},1\leqslant i,j\leqslant d$ with the following Lie-bracket:

$$[E_{ij},E_{k\ell}]=\delta_{jk}e_{i\ell}-\delta_{i\ell}E_{kj}.$$

Let $g\ell_d=s\ell_d\oplus\mathbb{C}I$ where $s\ell_d$ is a Lie-subalgebra of trace zero matrices and I is the identity matrix. Let $V(\psi)$ be the irreducible finite dimensional module for $s\ell_d$ where ψ is a dominant integral weight. Let I act by scalar b on $V(\psi)$ and denote the resultant $g\ell_d$ module by $V(\psi,b)$. Let $\alpha\in\mathbb{C}^d$ and we will make $F^\alpha(\psi,b):=V(\psi,b)\otimes A$ a Der$A$ module. First denote $v\otimes t^m$ by $v(m)$ for v in $V(\psi,b)$ and m in Γ.

(2.6) *Definition* (Ref. 17):

$$D(u,r)\cdot v(m)=(u,m+\alpha)v(m+r)+\left(\sum_{i,j}u_i r_j E_{ji}v\right)(m+r),$$

where $m,r\in\Gamma,u\in\mathbb{C}^d,v\in V(\psi,b)$. We will now recall the following:

(2.7) *Theorem* (Theorem (1.9) and Proposition (5.1) of Ref. 6):
(1) $F^{\alpha}(\psi,b)$ is irreducible as $\mathrm{Der}\,A$ module if $(\psi,b)\neq(\delta_k,k),(0,b),1\leqslant k\leqslant d-1$ where δ_k is the kth fundamental weight of $s\ell_d$.
(2) $F^{\alpha}(0,b)$ is irreducible as $\mathrm{Der}\,A$ module unless $\alpha\in\Gamma$ and $b\in\{0,d\}$.

In all other cases $F^{\alpha}(\psi,b)$ is reducible and the submodule structure has been worked out in Proposition (5.1) and Theorem (5.5) of Ref. 6.

Recall that A is associative algebra with unit and $F^{\alpha}(\psi,b)$ is an A module by defining

$$t^m\cdot v(r)=v(m+r)$$

for $m,r\in\Gamma$ and $v\in V(\psi,b)$. Further it is easy to see that $F^{\alpha}(\psi,b)$ is a $A\oplus\mathrm{Der}\,A$ module.

(2.8) *Proposition:* $F^{\alpha}(\psi,b)$ is irreducible as $A\oplus\mathrm{Der}\,A$ module.

Proof: First note that $F^{\alpha}(\psi,b)$ is a weight module with respect to $\tilde{h}$ and the weight spaces are $V(\psi)\otimes t^m$. Suppose W is a nonzero $A\oplus\mathrm{Der}\,A$ submodule of $F^{\alpha}(\psi,b)$. As submodule of a weight module is a weight module, W is a weight module. From the action of A it is clear that $v(m)\in W$ implies $v(s)\in W$ for all $s\in\Gamma$. Thus $W=W_1\otimes A$ for some $W_1\subseteq V(\psi,b)$. Now choose $u=e_i,r=e_j$ and consider

$$D(u,r)v(m)=(u,m+\alpha)v(m+r)+(E_{ji}v)(m+r).$$

It now follows from the above-presented remarks that W_1 is $g\ell_d$-invariant. Since $V(\psi)$ is irreducible and W_1 is nonzero, it follows that $W_1=V(\psi)$ and hence $W=F^{\alpha}(\psi,b)$.

The purpose of this paper is to prove the converse of the above proposition. In other words we classify $A\oplus\mathrm{Der}\,A$ modules with certain natural properties.

(2.9) *Theorem:* Let V be irreducible module for $A\oplus\mathrm{Der}\,A$ which is also a weight module for $\tilde{h}$ with finite dimensional weight spaces. We further assume the following:

(1) V is an A-module as associative algebra and the Lie-module structure of A comes from associative algebra.
(2) $1.v=v,\forall v$ in V.

Then $V\cong F^{\alpha}(\psi,b)$ (for some α,ψ,b) as $A\oplus\mathrm{Der}\,A$-module.

We need to develop several lemmas to prove the theorem which will be done in Sec. III. The final proof will be given in Sec. IV.

III. FILTERATION OF CO-FINITE IDEALS

First we need to change some notation. We treat A as group algebra over Γ. For that let $k(r)$ be a symbol for $r\in\Gamma$. Let A be the linear span of $k(r),r\in\Gamma$ with multiplication defined as $k(r)\cdot k(s)=k(r+s)$.

Let U be the universal enveloping algebra of $A\oplus\mathrm{Der}\,A$. Let L be the two sided ideal of U generated by $k(r)k(s)-k(r+s)$ and $k(0)-1$.

Throughout this section the module V is as in Theorem (2.9). Since V is an A module, L acts trivially and hence V is a U/L-module. Let $V=\oplus_{r\in\Gamma}V_r$ be the weight space decomposition and $V_r=\{v\in V|D(u,0)v=(u,r+\alpha)v,\forall u \text{ in } \mathbb{C}^d\}$. Such a uniform α in $\mathbb{C}^d$ exists as V is irreducible. In fact take any weight space where h acts as linear function which can be taken as $u\mapsto(u,\alpha)$ for some $\alpha\in\mathbb{C}^d$. Because of irreducibility the action of h on the rest of the spaces is easily computed. Further each V_r is an $\tilde{h}$-module as 1 in A acts as one on the entire module.

(3.1) Let $U_1=U/L$ and let $T(u,r)=k(-r)D(u,r)-D(u,0)$ as an element of U_1 for $u\in\mathbb{C}^d$ and $r\in\Gamma$. Let T be the subspace spanned by $T(u,r)$ for all u and r.

(3.2) *Proposition:*

(1) $[T(v,s),T(u,r)]=(u,s)T(v,s)-(v,r)T(u,r)+T(w,r+s)$ where $w=(v,r)u-(u,s)v$ and hence T is a Lie-subalgebra.
(2) $[D(v,0),T(u,r)]=0$.

(3) Let $V=\oplus V_r$ be weight space decomposition. Then each V_r is T-invariant.
(4) Each V_r is T-irreducible.
(5) $V_r\cong V_s$ as T-module.

Proof: (2)

$$\begin{aligned}&[D(v,0),k(-r)D(u,r)-D(u,0)]\\&\quad=[D(v,0),k(-r)D(u,r)]=[D(v,0),k(-r)]D(u,r)+k(-r)[D(v,0),D(u,r)]\\&\quad=-(v,r)k(-r)D(u,r)+(v,r)k(-r)D(u,r)=0.\end{aligned}$$

(1) From (2) it follows that

$$\begin{aligned}[T(v,s),T(u,r)]&=[k(-s)D(v,s),k(-r)D(u,r)]\\&=[k(-s),k(-r)D(u,r)]D(v,s)+k(-s)[D(v,s),k(-r)D(u,r)]\\&=[k(-s),k(-r)]D(u,r)D(v,s)+k(-r)[k(-s),D(u,r)]D(v,s)\\&\quad+k(-s)[D(v,s),k(-r)]D(u,r)+k(-s)k(-r)[D(v,s),D(u,r)]\\&=(u,s)k(-s)D(v,s)-(v,r)k(-r)D(u,r)\\&\quad+k(-s-r)D(w,r+s)\ \text{ where }\ w=(v,r)u-(u,s)v\\&=(u,s)T(v,s)-(v,r)T(u,r)+T(w,r+s)\ \text{ where }\ w=(v,r)u-(u,s)v.\end{aligned}$$

(3) From (2) it follows that T commutes with h and hence V_r is a T-module.

(4) Let $U=\oplus_{r\in\Gamma}U_r$ where $U_r=\{v\in U|[D(u,0),v]=(u,r)v$ for $u\in\mathbb{C}^d\}$. Since V is $A\oplus\mathrm{Der}\,A$ irreducible for v,w in V_r there exists X in U_0 such that $Xv=w$. This is due to weight reasons. Now $X=\Sigma a_iX_i$ where each X_i is of the form $k(-r)D(u_0,r_1)\cdots D(u_k,r_k)$ where $\Sigma r_i=r$. We are using the fact that L acts trivially on V. Now using the fact that $k(-s)D(u,r)=D(u,r)k(s)-(u,s)D(u,r)$ and the fact that $k(r)k(s)=k(r+s)$ we see that each X_i is linear combination of elements of the form

$$k(-r_1)D(u_1,r_1)k(-r_2)D(u_2,r_2)\cdots k(-r_k)D(u_k,r_k).$$

This proves $X\in U(T)$, the universal enveloping algebra of T. Hence V_r is T irreducible.

(5) First note that $k(s-r)V_r\subseteq V_s$. Repeating the same we see that

$$V_r=k(r-s)k(s-r)V_r\subseteq k(r-s)V_s\subseteq V_r.$$

Thus $V_r=k(r-s)V_s$. Define $f:V_r\to V_s$ by $f(v)=k(s-r)v$ which is clearly injective and surjective. Now

$$f(T(u,k)v)=k(s-r)T(u,k)v=T(u,k)k(s-r)v=T(u,k)f(v).$$

Thus f is a T-homomorphism. This proves (5).

(3.3) *Notation:* For any integer $k>0,r,m_1,\ldots,m_k\in\Gamma$ define

$$T_k(u,r,m_1,\ldots,m_k)=T(u,r)-\sum_i T(u,r+m_i)+\sum_{i<j} T(u,r+m_i+m_j)\cdots(-1)^j$$

$$+\sum_{1\leqslant i_1<i_2<\cdots<i_j\leqslant k} T(u,r+m_{i_1}+\cdots+m_{i_j})\cdots(-1)^k T(u,r+m_1+m_2$$

$$+\cdots+m_k).$$

Let I_k be the linear span of $T_k(u,r,m_1,\ldots,m_k), u\in\mathbb{C}^d$ for all $r,m_1,m_2,\ldots,m_k\in\Gamma$.

(3.4) *Lemma:* (1) $T_k(u,r,m_1,\ldots,m_k)=T_k(u,r,m_{\sigma(1)},\ldots,m_{\sigma(k)})$ for any permutation σ on k-letters.
(2) $T_k(u,r,m_1,\ldots,m_k)=T_{k-1}(u,r,m_1,\ldots,m_{k-1})-T_{k-1}(u,r+m_k,m_1,\ldots,m_{k-1})$
(3) I_k is an ideal of T.
(4) $I_k\subseteq I_{k-1}$ for $k\geqslant 2$.
(5) $[I_k,I_\ell]\subseteq I_{k+\ell-1}$ for $k,\ell\geqslant 1$.

Proof: (1) Follows from definition.

(2) Collect all terms where m_k does not occur in the sum of T_k and that can be seen to be equal to $T_{k-1}(u,r,m_1,\ldots,m_{k-1})$. Sum of the rest of the terms can be seen to be equal to $-T_{k-1}(u,r+m_k,m_1,\ldots,m_{k-1})$. This is because every term contains m_k

$$(3)\ [T(v,s),T_k(u,r,m_1,\ldots,m_k)]=(u,s)\sum_{\ell=0}^{k}\binom{k}{\ell}(-1)^\ell k(-s)D(v,s)-(v,r)T_k(u,r,m_1,\ldots,m_k)$$

$$+\sum (v,m_i)T_{k-1}(u,r+m_i,m_1,\ldots,\widehat{m_i},\ldots,m_k)+(v,r)T_k(u,r$$

$$+s,m_1,\ldots,m_k)-\sum (v,m_i)T_{k-1}(u,r+s$$

$$+m_i,m_1,\ldots,\widehat{m_i},\ldots,m_k)-(u,s)T_k(v,r+s,m_1,\ldots,m_k).$$

By applying Proposition 3.2 (1) write $[T(v,s),T_k(u,r,m_1,\ldots,m_k)]=A_1+A_2+A_3$. It is easy to see that A_1 is the first term of the above-given formula. Now in A_2 look for the terms where (v,m_i) occurs and that can be seen as a component of the third term of the above-given formula. Now in A_2 the terms where no m_i occurs is equal to the second term of the above-given formula. The rest of the formula can be seen in a similar way. This proves the claim. Now note that the first term in the claim is zero. Clearly the second, fourth, and sixth terms are in I_k. Now the third and fifth terms are equal to

$$\sum (v,m_i)T_{k-1}(u,r+m_i,m_1,\ldots,\widehat{m_i},\ldots,m_k)-\sum (v,m_i)T_{k-1}(u,r+m_i+s,m_1\ldots,\widehat{m_i},\ldots,m_k)$$

$$=\sum (v,m_i)T_k(u,r+m_i,m_1,\ldots,\widehat{m_i}\ldots,m_k,s)$$

(by Lemma 3.4 (2)).
(4) Follows from (2).
(5)

$$[T_\ell(v,s,n_1,\ldots,n_\ell),T_k(u,r,m_1,\ldots,m_k)]=\sum_{t=0}^{\ell}\sum_{i_1<i_2<\cdots<i_t}(u,s+n_{i_1}+\cdots+n_{i_t}).$$

$$\sum_{b=0}^{k}\binom{k}{b}(-1)^b T(v,s+n_{i_1}+\cdots+n_{i_t})-\sum_{t=0}^{k}\sum_{j_1<\cdots<j_t}(v,r+m_{j_1}+\cdots+m_{j_t}).$$

$$\sum_{b=0}^{\ell}\binom{\ell}{b}(-1)^b T(u,r+m_{i_1}+\cdots+m_{i_t})+(v,r)T_{k+\ell}(u,r+s,m_1,\ldots,m_k,n_1,\ldots,n_\ell)$$

$$-(u,s)T_{k+\ell}(v,r+s,m_1,\ldots,m_k,n_1,\ldots,n_\ell)-\sum\ (v,m_i)T_{k+\ell-1}(u,r+s$$

$$+m_i,m_1,\ldots,\widehat{m_i},\ldots,m_k,n_1,\ldots,n_\ell)+\sum\ (u,n_j)T_{k+\ell-1}(v,r+s+n_j,m_1,\ldots,m_k,n_1,\ldots,\widehat{n_j},\ldots,n_\ell).$$

The above-presented formula can be deduced as in (3) from Proposition 2.2 (1). Now note that the first two terms are zero as

$$\sum_{b=0}^{k}\binom{k}{b}(-1)^b=0=\sum_{b=0}^{\ell}\binom{\ell}{b}(-1)^b.$$

The rest of the four terms are in $I_{k+\ell-1}$ and this proves (5).

(3.5) *Lemma:* For $u\in\mathbb{C}^d$, $0\neq m_i\in\Gamma$, $s\in\Gamma$.

(1) $T_k(u,s,m_1,\ldots,m_k)\notin I_{k+1}$ for $k\geqslant 1$.

(2) $T_k(u,s,m_1,\ldots,m_k)+T_k(u,s,n,m_2,\ldots,m_k)=T_k(u,s,m_1+n,m_2,\ldots,m_k)+I_{k+1}$.

(3) $T_k(u,s,-m_1,m_2,\ldots,m_k)=-T_k(u,s-m_1,m_1,m_2,\ldots,m_k)$

Proof: To prove the Lemma, we first interpret T_k's as certain polynomials in $A=\mathbb{C}[t_1^{\pm 1},\ldots,t_d^{\pm 1}]$. We fix a nonzero u in $\mathbb{C}^d$. Let k be a positive integer and let $m_1,m_2,\ldots,m_k\in\Gamma$. Let $P_k(m_1,\ldots,m_k)=\Pi_{1\leqslant i\leqslant k}(1-t^{m_i})$. Recall $t^{m_i}=t_1^{(m_i)_1}\cdots t_d^{(m_i)_d}$. Let J_k be the ideal in A generated by $P_k(m_1,\ldots,m_k)$ for all nonzero m_i's $\in\Gamma$. Then clearly $J_{k+1}\subseteq J_k$. It is easy to see that $T_k(u,r,m_1,\ldots,m_k)$ can be identified with polynomial $t^rP_k(m_1,\ldots,m_k)$. Recall that u is fixed.

Thus it is sufficient to prove that

Claim 1: $P_k(m_1,\ldots,m_k)\notin J_{k+1}$. Suppose

$$(*)\qquad P_k(m_1,\ldots,m_k)=\sum\ f_\ell P_{k+1}(n_{\ell_1},n_{\ell_2},\ldots,n_{\ell_{k+1}})$$

where $f_\ell\in A$. Let $Dt_i=t_i(\mathrm{d}/\mathrm{d}t_i)$. Now consider $D_{t_{i_1}}\cdots D_{t_{i_k}}P_{k+1}(n_1,\ldots,n_{k+1})$ and evaluate at $(t_1,\ldots,t_d)=(1,\ldots,1)$. This can be seen to be zero as after differentiating P_{k+1},k times, each component has at least one factor $(t^{n_i}-1)$. We will now prove that there exists $i_1,\ldots,i_k$ such that

Claim 2: $D_{t_{i_1}}\cdots D_{t_{i_k}}P_k(m_1,\ldots,m_k)|_{t=(1,\ldots,1)}$ is nonzero. Thus $*$ cannot hold. This proves claim 1. Now choose $\ell,1\leqslant\ell\leqslant d$ such that $S=\{i|(m_i)_\ell\neq 0\}$ is nonempty. Let $\#S=p$ and let $i_1,\ldots,i_p\in S$. Consider

$$(D_{t_\ell})^pP_k(m_1,\ldots,m_k)=\mu\prod_{i\in S}\ (m_i)_\ell\prod_{j\notin S}\ (1-t^{m_j})t^{m_{i_1}+m_{i_2}+\cdots+m_{i_p}}+J_{k-s+1},$$

which is not too difficult to see—where μ is a non-negative integer. Repeating the process finitely many times (choosing different index $\ell^1\neq\ell$). We see that there exists $i_1,\ldots,i_k$ such that $D_{t_{i_1}}D_{t_{i_2}}\cdots D_{t_{i_k}}.\ P_k(m_1,\cdots,m_k)=\lambda t^{m_1+\cdots+m_k}+J_1$ where λ is nonzero integer. Now evaluating at $t=(1,\ldots,1)$ we see that claim 2 is true.

To see (2) first note that

$$(1-t^m)(1-t^n)+(1-t^{m+n})=(1-t^m)+(1-t^n).$$

Thus

$$t^s\prod_{i=2}^{k}(1-t^{m_i})(1-t^{m_1})+t^s\prod_{i=2}^{k}(1-t^{m_i})(1-t^n)=t^s\prod_{i=2}^{k}(1-t^{m_i})(1-t^n)(1-t^{m_1})+t^s\prod_{i=2}^{k}(1-t^{m_i})\times(1-t^{m_1+n}).$$

This proves (2).

(3) is easy to check.

(3.6) *Lemma:*

$$(1)\quad \mathrm{Dim}(I_k/I_{k+1})\leqslant d^{k+1}, k\geqslant 1.$$

$$(2)\quad T=I_1.$$

In particular I_k is a co-finite ideal in T.

Proof: First note that from Lemma 3.4(2) we have

$$T_k(u,r,m_1,\ldots,m_k)=T_k(u,s,m_1,\ldots,m_k)\ \mod I_{k+1}$$

for all $r,s\in\Gamma$. Further

$$-T_k(u,0,m_1,\ldots,m_k)=T_k(u,0,-m_1,m_2,\ldots,m_k)\ \mod I_{k+1},$$

which follows from above and Lemma 3.5 (3). Now from additive property of Lemma 3.5(2) it follows that I_k/I_{k+1} is spanned by $T_k(u,0,e_{i_1},\ldots,e_{i_k})$ where $e_1,\ldots,e_d$ is the standard basis. Thus (1) follows. (2) follows from definitions. Now it is easy to conclude that I_k is a co-finite ideal for each k.

IV. PROOF OF THE CLASSIFICATION THEOREM

We will explain the plan of the proof of Theorem (2.9). First we will prove that $T/I_2\cong g\ell_d(\mathbb{C})$. Then we will prove that if $I_k, k\geqslant 2$ is zero on a finite dimensional irreducible module V of T then I_2 is zero on V. Thus V is a module for $T/I_2\cong g\ell_d(\mathbb{C})$. Further we prove that any co-finite ideal J of T contains I_k for large k. Thus any irreducible finite dimensional module V of T is actually a module for T/I_2. From this it will be easy to conclude Theorem 2.9 which will be explained at the end of the section.

(4.1) *Proposition:* $T/I_2\cong g\ell_d(\mathbb{C})$.

Proof: First recall that $F^\alpha(\psi,b)$ is an $A\oplus \mathrm{Der}\,A$-module and each weight space $V(\psi)\otimes t^m$ is a T-module. It is easy to verify that I_2 acts trivially on $V(\psi)\otimes t^m$. Now note that $T(e_i,e_j)v(m)=E_{ji}v(m)\neq 0$ for some ψ. From this we conclude that $T(e_i,e_j)$ is nonzero in T/I_2. Now it is easy to see that $T(u,s)+T(u,r)=T(u,r+s)\ \mathrm{mod}\, I_2$ and hence $T(e_i,e_j)$ spans T/I_2. Define $\pi: T/I_2\to g\ell_d(\mathbb{C})$,

$$\pi(T(e_i,e_j))=E_{ji}.$$

Consider

$$\begin{aligned}X=[T(e_i,e_j),T(e_k,e_\ell)]&=[k(-e_j)D(e_i,e_j),k(-e_\ell)D(e_k,e_\ell)]\\&=-\delta_{i\ell}k(-e_\ell)D(e_k,e_\ell)+\delta_{kj}k(-e_j)D(e_i,e_j)\\&\quad-\delta_{kj}k(-e_\ell-e_j)D(e_i,e_\ell+e_j)\\&\quad+\delta_{i\ell}k(-e_\ell-e_j)D(e_k,e_\ell+e_j).\end{aligned}$$

Follows from Proposition (3.2). Note that the following is true in T/I_2:

$$k(-e_\ell-e_j)D(e_s,e_\ell+e_j)=k(-e_\ell)D(e_s,e_\ell)+k(-e_j)D(e_s,e_j)-D(e_s,0)$$

for $s=i,k$. Thus $X=-\delta_{kj}(k(-e_\ell)D(e_i,e_\ell)-D(e_i,0))$

$$+\delta_{i\ell}(k(-e_j)D(e_k,e_j)-D(e_k,0))=-\delta_{kj}T(e_i,e_\ell)+\delta_{i\ell}T(e_k,e_j).$$

Thus π defines a surjective homomorphism. As $T(u,0)$ is zero it follows that $T(e_i,e_j)$ span T/I_2 which proves dim $(T/I_2)\leqslant d^2$. Thus π defines an isomorphism.

(4.2) *Lemma (Billig):* Suppose $\mathcal{G}$ is a Lie-algebra over $\mathbb{C}$ and J is an ideal with spanning set $J_\alpha, \alpha\in B$. Suppose there exists an element I in $\mathcal{G}$ such that $[I,J_\alpha]=\lambda J_\alpha$, $\lambda\neq 0$ for all $\alpha\in B$. then J acts trivially on any irreducible finite dimensional module V of $\mathcal{G}$.

Proof: Since the base field is complex numbers and V is finite dimensional, I has eigen vectors. Let $\lambda_1,\ldots,\lambda_k$ be all the eigenvalues of I on V. Choose λ_i such that $\lambda+\lambda_i$ is not an eigenvalue. Let v be eigenvector with eigenvalue λ_i for I. Consider $IJ_\alpha v=J_\alpha Iv+[I,J_\alpha]v=(\lambda_i+\lambda)J_\alpha v$. This proves $J_\alpha v=0\ \forall\alpha\in B$. Let $W=\{w\in V|J_\alpha w=0\ \forall\alpha\in B\}$. Since J is an ideal, it is easy to see that W is a $\mathcal{G}$-module. But $W\neq 0$. Since V is irreducible $W=V$ which proves that J acts trivially on V.

(4.3) *Proposition:* Suppose V is irreducible finite dimensional module for T such that I_{k+1} acts trivially on V. Then I_2 acts trivially on V.

Proof: From the proof of Lemma 3.4(3) we have

$$[T(v,s),T_k(u,r,m_1,\ldots,m_k)]=-(v,r)T_{k+1}(u,r,m_1,\ldots,m_k,s)-(u,s)T_k(v,r+s,m_1,\ldots,m_k)$$
$$+\sum(v,m_i)T_k(u,r+m_i,m_1,\ldots,\widehat{m_i},\ldots,m_k,s).$$

Let $I=\Sigma T(e_i,e_i)$ and note that I is actually identity element in $T/I_2\cong g\ell_d(\mathbb{C})$. Thus I is nonzero on T/I_{k+1} for $k\geqslant 1$.

Claim:

$$[I,T_k(u,r,m_1,\ldots,m_k)=(k-1)T_k(u,r,m_1,\ldots,m_k).$$

Consider

$$\left[\sum_j T(e_j,e_j),T_k(u,r,m_1,\ldots,m_k)\right]=-\sum u_jT_k(e_j,r+e_j,m_1,\ldots,m_k)+\sum_{i,j}(m_i)_jT_k(u,r$$
$$+m_i,m_1,\ldots,\widehat{m_i},\ldots,m_k,e_j).$$

Now we use Lemma 3.5(2) and the following facts.

(1) T_k is linear in u
(2) $T_k(u,r+m,m_1,\ldots,m_k)=T_k(u,r,m_1,\ldots,m_k)$ mod I_{k+1} (by Lemma 3.4(2)).
(3) I_{k+1} is zero on V.

From that we conclude that

$$[I,T_k(u,r,m_1,\ldots,m_k)]=-T_k(u,r,m_1,\ldots,m_k)+kT_k(u,r,m_1,\ldots,m_k),$$

which proves the claim. Now we can use Lemma (4.2) for the ideal I_k. Thus I_k is zero on V. Repeating this argument we conclude that I_2 acts trivially on V. This argument breaks down for $k=1$ as we cannot apply the Lemma 3.2.

(4.4) *Proposition:* Any co-finite ideal J of T contains I_k for large k.

Proof: Claim $J\cap I_k$ is co-finite in T for all k. For that consider $\varphi: T\mapsto T/J\oplus T/I_k$,

$$v\mapsto(v,v).$$

Clearly ker $\varphi=J\cap I_k$ and $T/J\cap I_k$ is a subalgebra of finite dimensional Lie-algebra $T/J\oplus T/I_k$. This proves the claim.

Consider $I_k/J\cap I_k \overset{\varphi_1}{\hookrightarrow} I_{k-1}/J\cap I_k \overset{\varphi_2}{\hookrightarrow} I_{k-1}/J\cap I_{k-1}$ where φ_1 is injective and φ_2 is surjective. Let $\rho_k=\varphi_2\circ\varphi_1$. Thus $\rho_k: I_k/I_k\cap J\to I_{k-1}/J\cap I_{k-1}$. Clearly ρ_k is injective. Let $t_n=\dim I_n/I_n\cap J$ and note that $t_{n+1}\leqslant t_n$. Thus $\{t_n\}_{n\in\mathbb{Z}^+}$ is a decreasing sequence of non-negative integers. Therefore $t_k=s$ for some s and for large $k>N$.

First we note the following two statements for a fixed i.

(1) For $\ell\neq i$,
$$[T(e_\ell,-e_\ell),T_k(e_i,0,e_{j_1},\ldots,e_{j_k})]=-k_\ell T_k(e_i,0,e_{j_1},\ldots,e_{j_k})$$
where k_ℓ is the number of e_ℓ that occur in $T_k(e_i,0,e_{j_1},\ldots,e_{j_k})$.

(2) Suppose the ideal J contains $\Sigma a_{m,I}T_m(e_i,0,e_{j_1},\ldots,e_{j_m})$ where the number of e_i's that occur in $T_m(e_i,0,e_{j_1},\ldots,e_{j_m})$ is the same for all m where $I=\{j_1,\ldots,j_k\}$. Then J contains $T_m(e_i,0,e_{j_1},\ldots,e_{j_m})$ for $m\ni a_{m,I}\neq 0$.

(1) Follows from the proof of Lemma 3.4(3). (2) follows from (1). We will prove the Proposition assuming $d\geqslant 3$ to avoid some computations. For a fixed i, consider the following set

$$S=\{T_k(e_i,0,e_{j_1},\ldots,e_{j_k})|j_\ell\neq i \text{ for all } \ell\}.$$

Now choose $k\ni \#S>s$ and $k>N$. Thus S is linearly dependent mod $I_k\cap J$. Thus there exist nonzero scalars $a_I(I=\{j_1,\ldots j_k\})$ such that

$$X=\sum a_I T_k(e_i,0,e_{j_1},\ldots,e_{j_k})\in J.$$

Now using (2) we conclude that

$$T_k(e_i,0,e_{j_1},\ldots,e_{j_k})\in J \text{ for some } I.$$

For $m,n\neq i$ consider

$$[T(e_m,e_n),T_k(e_i,0,e_{j_1},\ldots,e_{j_k})]=\ell\,\delta_{j_i m}T_k(e_i,e_m,e_{j_1},\ldots,\hat{e}_{j_i},\ldots,e_{j_k},e_n)\in J.$$

Now

$$T_k(e_i,e_m,e_{j_1},\ldots,\hat{e}_{j_i},\ldots,e_{j_k},e_n)=T_k(e_i,0,e_{j_1},\ldots,\hat{e}_{j_i},\ldots,e_{j_k},e_n)-T_{k+1}(e_i,0,e_{j_1},\ldots,e_{j_i},\ldots,e_{j_k},e_n).$$

Now by (2) it follows that

$$T_k(e_i,0,e_{j_1},\ldots,\hat{e}_{j_i},\ldots,e_{j_k},e_n)\in J.$$

Now repeating this process we see that

$$(*)\qquad T_k(e_i,0,e_{j_1},\ldots,e_{j_k})\in J$$

for all possible indices $j_1,\ldots,j_k$ which are all different from i. Applying $T(e_i,e_i)$ to the above vector to conclude

$$T_k(e_i,e_i,e_{j_1},\ldots,e_{j_k})\in J,$$

$$(**)\qquad T_k(e_i,0,e_{j_1},\ldots,e_{j_k})-T_k(e_i,e_i,e_{j_1},\ldots,e_{j_k})=-T_{k+1}(e_i,0,e_{j_1},\ldots,e_{j_k},e_i)\in J.$$

Fix $j\neq i$. Replacing k by $k+1$, consider the following vector which is in J by $(*)$.

$$[T(e_j,e_i),T_{k+1}(e_i,0,e_{j_1},\ldots,e_{j_{k+1}})]=P\delta_{jj_\ell}T_{k+1}(e_i,e_j,e_{j_1},\ldots,\hat{e}_{j_\ell},\ldots,e_{j_{k+1}},e_i)$$
$$-T_{k+1}(e_j,e_i,e_{j_1},\ldots,e_{j_{k+1}}).$$

Now

$$T_{k+1}(e_i,e_j,e_{j_1},\ldots,\hat{e}_{j_\ell},\ldots,e_{j_{k+1}},e_i)=T_{k+1}(e_i,0,e_{j_1},\ldots,\hat{e}_{j_\ell},\ldots,e_{j_{k+1}},e_i)$$
$$-T_{k+2}(e_i,0,e_{j_1},\ldots,e_j,\ldots,e_{j_{k+1}},e_i).$$

Now by $(**)$ both vectors are in J. Thus we conclude that

$$T_{k+1}(e_j,e_i,e_{j_1},\ldots,e_{j_{k+1}})\in J.$$

Now by (2) we see that

$$T_{k+1}(e_j,0,e_{j_1},\ldots,e_{j_{k+1}})\in J.$$

This is true for all possible indices $j_1,\ldots,j_{k+1}$ which are all different from i.

Now applying $T(e_{j_\ell},e_i)$ for $j_\ell\neq j$ we see that

$$T_{k+1}(e_j,e_{j_\ell},e_{j_1},\ldots,\hat{e}_{j_\ell},\ldots,e_{j_{k+1}},e_i)\in J.$$

Now by (2) we see that

$$T_{k+1}(e_j,0,e_{j_1},\ldots,\hat{e}_{j_\ell},\ldots,e_{j_{k+1}},e_i)\in J.$$

Repeating this process we see that $T_{k+1}(e_j,0,e_{\ell_1},\ldots,e_{\ell_{k+1}})\in J$ for all possible $\ell_1,\ldots,\ell_{k+1}$.

Now using the technique in the proof of Lemma 3.5 we see that

$$T_{k+1}(e_j,0,m_1,\ldots,m_{k+1})\in J \quad \text{for all } m_i\in\Gamma.$$

Now replacing $k+1$ by $k+2$ we see that

$$T_{k+2}(e_j,0,m_1,\ldots,m_{k+2})=T_{k+1}(e_j,0,m_1,\ldots,m_{k+1})-T_{k+1}(e_j,m_{k+2},m_1,\ldots,m_{k+1})\in J.$$

Then it follows that

$$T_{k+1}(e_j,m_{k+2},m_1,\ldots,m_{k+1})\in J.$$

Strictly speaking we have it for non-negative coefficients. But the other cases can be handled similarly. This proves $I_{k+1}\subseteq J$ and the Proposition. Further $s=0$.

Proof of Theorem (2.9): Let V be a module as in Theorem. Let $V=\oplus_{r\in\Gamma}V_r$ be the weight space decomposition where

$$V_r=\{v\in V|D(u,0)v=(u,r+\alpha)v,\ \ \forall u\in\mathbb{C}^d\}.$$

We know that $V_r\cong V_s$ as T-modules from Proposition 3.2(5). This with Proposition (4.3), Proposition (4.4) combined with the fact that some co-finite ideal of T acts trivially on V_r tells us that all V_r's are isomorphic to some $V(\psi,b)$ as $g\ell_d$-modules. Note that the isomorphism between V_r''s is given by $k(r)$ (from proof of proposition 3.2(5)). Thus if we let $V_r=V(\psi,b)\otimes t^r$ we see that $k(r)v(s)=v(s+r)$ for v in $V(\psi,b)$.

Now consider $T(u,r)$ in T/I_2 and note that it is linear in both variables.

Thus

$$T(u,r)v(s)=\sum_{i,j} u_i r_j T(e_i,e_j)v(s)=\sum_{i,j} u_i r_j E_{ji}v(s)$$

Therefore

$$k(-r)D(u,r)v(s)=D(u,0)v(s)+(\Sigma u_i v_j E_{ji}v)(s)=(u,s+\alpha)v(s)+\left(\sum u_i r_j E_{ji}v\right)(s).$$

Multiply both sides by $k(r)$ we get

$$D(u,r)v(s)=(u,s+\alpha)v(s+r)+\left(\sum_{ij} u_i r_j E_{ji}v\right)(s+r).$$

This completes the proof of the theorem.

By means of complex representation and companion vector, this paper studies the problems of eigenvalues and eigenvectors of quaternion matrices, and gives a technique of computing the eigenvalues and eigenvectors of the quaternion matrices in quaternionic quantum mechanics. © *2004 American Institute of Physics*.
[DOI: 10.1063/1.1769106]

I. INTRODUCTION

In quaternionic quantum mechanics (Adler and co-workers, 1995, 1996, 1997; Finkelstein *et al.*, 1962), one of the most important tasks is to solve the Schrödinger equation

$$\frac{\partial}{\partial t}|f\rangle = -\hat{H}|f\rangle, \tag{1.1}$$

with $\hat{H}$ an anti-self-adjoint real quaternion matrix, and $|f\rangle$ an eigenstate to $\hat{H}$. The quaternionic Schrödinger Eq. (1.1) plays an important role in quaternionic quantum mechanics, it is known that the study of the quaternionic Schrödinger Eq. (1.1) is reduced to the study of quaternionic eigenequation

$$\hat{H}\alpha = \alpha\lambda, \tag{1.2}$$

with $\hat{H}$ an anti-self-adjoint real quaternion matrix (time-independent). But because of the noncommutation of quaternions, the studies of the equations are more difficult. In order to solve Eqs. (1.1) and (1.2), the author (Adler, 1995) changed the quaternionic Schrödinger equations into a two-component complex Schrödinger equations, and turned the problem of quaternionic Schrödinger equation into that of complex Schrödinger equation. In this paper, by means of complex representation and companion vector, we study the problems of eigenvalues and eigenvectors of general quaternion matrices, and give a technique of computing eigenvalues and eigenvectors of the quaternion matrices in quaternionic quantum mechanics.

Let $\mathbf{R}$ denote the real number field, $\mathbf{C}=\{a+b\sqrt{-1}|a,b\in\mathbf{R}\}$ the complex number field, $\mathbf{Q}$ the quaternion number field. For any quaternion

$$x = x_0 + x_1 i + x_2 j + x_3 k, \tag{1.3}$$

$$i^2 = j^2 = k^2 = -1, \quad ij = -ji = k, \tag{1.4}$$

in which $x_i \in \mathbf{R}$, the conjugate of quaternion x is $\overline{x} = x_0 - x_1 i - x_2 j - x_3 k$. It is clear that x can be uniquely expressed as $x = y + zj$, in which y, $z \in \mathbf{C}$, and $x = y + zj$ if and only if $\overline{x} = \overline{y} - zj$. Let $\mathbf{F}^{m\times n}$ denote the set of $m\times n$ matrices on the field $\mathbf{F}$. For any $A=(a_{ij})\in\mathbf{Q}^{n\times n}$, $A^T=(a_{ji})$ and $A^H=(\overline{a}_{ji})$ denote the transpose and the conjugate transpose of the quaternion matrix A, respectively, and A is an anti-self-adjoint quaternion matrix if $A^H=-A$. Two quaternions x and y are

a)Electronic mail: tsjemail@163.com

said to be similar if there exists a nonzero quaternion p such that $p^{-1}xp=y$, and this is written as $x\sim y$. It is routine to check that $\sim$ is an equivalence relation on the quaternions. We denote by $[x]$ the equivalence class containing x.

II. COMPLEX REPRESENTATION AND COMPANION VECTOR

For any quaternion $x=x_0+x_1i+x_2j+x_3k=y+zj\in\mathbf{Q}$, and quaternion matrix $A=(a_{ij})\in\mathbf{Q}^{m\times n}$, the complex representation of quaternion x and A are, respectively, defined to be

$$x^f=\begin{pmatrix} x_0+x_1\sqrt{-1} & x_2+x_3\sqrt{-1} \\ -x_2+x_3\sqrt{-1} & x_0-x_1\sqrt{-1} \end{pmatrix}=\begin{pmatrix} y & z \\ -\overline{z} & \overline{y} \end{pmatrix}\in\mathbf{C}^{2\times 2}, \tag{2.1}$$

and

$$A^f=((a_{ij})^f)=\left(\begin{pmatrix} y_{ij} & z_{ij} \\ -\overline{z}_{ij} & \overline{y}_{ij} \end{pmatrix}\right)\in\mathbf{C}^{2m\times 2n}. \tag{2.2}$$

It is easy to verify the following Eqs. (2.3) and (2.4) by the definition of complex representation of quaternion matrices. That is if $A, B\in\mathbf{Q}^{m\times n}$, $r\in\mathbf{R}$, then

$$(A+B)^f=A^f+B^f,\quad (rA)^f=rA^f, \tag{2.3}$$

and if $A\in\mathbf{Q}^{m\times n}$, $B\in\mathbf{Q}^{n\times s}$, then

$$(AB)^f=A^fB^f, \tag{2.4}$$

and A is nonsingular if and only if A^f is nonsingular if $A\in\mathbf{Q}^{n\times n}$, and $(A^f)^{-1}=(A^{-1})^f$.

Next we introduce the concept of companion vector.

If $\alpha=(x_1,x_2,\ldots,x_{2n})^T\in\mathbf{C}^{2n\times 1}$, then the companion vector α^c of vector α is defined to be

$$\alpha^c=(-\overline{x}_2,\overline{x}_1,-\overline{x}_4,\overline{x}_3,\ldots,-\overline{x}_{2n},\overline{x}_{2n-1})^T\in\mathbf{C}^{2n\times 1}.$$

Let $\alpha, \beta\in\mathbf{C}^{2n\times 1}$, $\lambda\in\mathbf{C}$, $A\in\mathbf{Q}^{n\times n}$. Then we can easily get the following Eqs. (2.5) and (2.6) by the definition of companion vector and complex representation,

$$(\alpha\pm\beta)^c=\alpha^c\pm\beta^c,\quad (\alpha^c)^c=-\alpha, \tag{2.5}$$

$$(A^f\alpha)^c=A^f\alpha^c,\quad (\alpha\lambda)^c=\alpha^c\overline{\lambda}, \tag{2.6}$$

and if $\alpha\neq 0$, then α and α^c are linearly independent.

From (2.6) we have following result:

Proposition 2.1: Let $A\in\mathbf{Q}^{n\times n}$. Then the real eigenvalues of complex representation A^f appear in pairs, and the complex eigenvalues of complex representation A^f appear in conjugate pairs.

III. EIGENVALUES AND EIGENVECTORS OF A QUATERNION MATRIX

In this section, by means of complex representation and companion vector, we study the eigenvalues and eigenvectors of quaternion matrices, and give a technique of computing the eigenvalues and eigenvectors of the quaternion matrices in quaternionic quantum mechanics.

Since right and left scalar multiplications of quaternions are different, we need to define right and left eigenvalues for a quaternion matrix. Let $A\in\mathbf{Q}^{n\times n}$, a quaternion λ is said to be a right (left) eigenvalue provided that $A\alpha=\alpha\lambda(A\alpha=\lambda\alpha)$, and α is said to be an eigenvector to corresponding eigenvalue λ. In this paper we mainly focus on the right eigenvalues and eigenvectors of quaternion matrices.

Lemma 3.1 (Fuzhen, 1997): Let $x=x_0+x_1i+x_2j+x_3k$ be a real quaternion. Then there exists a quaternion p such that

$$p^{-1}\lambda p = x_0 + hi, \quad h = \sqrt{x_1^2 + x_2^2 + x_3^2} \geqslant 0, \tag{3.1}$$

namely, $x \in [x_0 + \sqrt{x_1^2 + x_2^2 + x_3^2} i]$. The complex number $\overset{a}{x} = x_0 + hi$ in (3.1) is called principal number of the class $[x]$.

Since $A\alpha = \alpha\lambda$ if and only if $A(\alpha p) = (\alpha p)(p^{-1}\lambda p)$ for any nonzero quaternion p, so λ is an eigenvalue of quaternion matrix A if and only if $p^{-1}\lambda p$ is an eigenvalue of quaternion matrix A, and α is an eigenvector to the eigenvalue λ if and only if αp is an eigenvector to the eigenvalue $p^{-1}\lambda p$ for any nonzero quaternion p.

If $A \in \mathbf{Q}^{n\times n}$, λ is an eigenvalue of quaternion matrix A and let $\overset{a}{\lambda} = p^{-1}\lambda p$ be the principal number of $[\lambda]$ for quaternion p, then

$$A\alpha = \alpha\lambda \Leftrightarrow A(\alpha p) = (\alpha p)(p^{-1}\lambda p) \Leftrightarrow A\beta = \beta\overset{a}{\lambda}, \tag{3.2}$$

where $\beta = \alpha p$ and $\overset{a}{\lambda} = p^{-1}\lambda p$ is the principal eigenvalue. By (2.4) we know that (3.2) is equivalent to

$$A^f\alpha^f = \alpha^f\lambda^f \Leftrightarrow A^f\beta^f = \beta^f\overset{a}{\lambda}^f, \tag{3.3}$$

and if we let $\beta^f = (\gamma, \gamma^c)$, then

$$A^f\beta^f = \beta^f\overset{af}{\lambda} \Leftrightarrow A^f(\gamma, \gamma^c) = (\gamma, \gamma^c)\begin{pmatrix} \overset{a}{\lambda} & 0 \\ 0 & \overline{\overset{a}{\lambda}} \end{pmatrix}, \tag{3.4}$$

i.e., $A^f\gamma = \gamma\overset{a}{\lambda}$ and $A^f\gamma^c = \gamma^c\overline{\overset{a}{\lambda}}$.

From the statement above we obtain the following result:

Theorem 3.2: Let $A \in \mathbf{Q}^{n\times n}$. Then

(1) A quaternion λ is an eigenvalue of quaternion matrix A if and only if $p^{-1}\lambda p$ (for any nonzero quaternion p) is an eigenvalue of quaternion matrix A; a quaternion vector α is an eigenvector corresponding to the eigenvalue λ if and only if αp is an eigenvector corresponding to the eigenvalue $p^{-1}\lambda p$ for any nonzero quaternion p;

(2) A quaternion λ is an eigenvalue of quaternion matrix A if and only if $\overset{a}{\lambda}$ is an eigenvalue of complex representation A^f; and α is an eigenvector corresponding to the eigenvalue λ (i.e., $A\alpha = \alpha\lambda$) if and only if γ is an eigenvector corresponding to the principal eigenvalue $\overset{a}{\lambda}$ (i.e., $A^f\gamma = \gamma\overset{a}{\lambda}$) with $(\alpha p)^f = (\gamma, \gamma^c)$, $\overset{a}{\lambda} = p^{-1}\lambda p$.

Remark: Theorem 3.2 gives a relationship between the eigenvalues and eigenvectors of a quaternion matrix and that of corresponding complex representation matrix by means of complex representation and companion vector, and turns the eigenvalues and eigenvectors of a quaternion matrix into that of a complex matrix.

IV. ALGORITHM

Now we list an algorithm for computing eigenvalues and eigenvectors of a quaternion matrix by means of complex representation and companion vector.

Algorithm: Let $A \in \mathbf{Q}^{n\times n}$.

Step 1: Find the complex representation matrix A^f and all complex eigenvalues and eigenvectors of the complex matrix A^f.

By Proposition 2.1 and (2.6), we may let the eigenvalues and corresponding eigenvectors of the complex matrix A^f be

$$\lambda_1, \overline{\lambda_1}, \lambda_2, \overline{\lambda_2}, \ldots, \lambda_n, \overline{\lambda_n},$$

$$\gamma_1, \gamma_1^c, \gamma_2, \gamma_2^c, \ldots, \gamma_n, \gamma_n^c,$$

with $A^f\gamma_i = \gamma_i\lambda_i$ and $A^f\gamma_i^c = \gamma_i^c\overline{\lambda_i}$, and $\mathrm{Im}\,\lambda_i \geqslant 0$, $i=1,2,...,n$;

Step 2: Find all principal eigenvalues and corresponding eigenvectors of the A.

By step 1, we know that $\lambda_1, \lambda_2, \ldots, \lambda_n$ are all the principal eigenvalues of the quaternion matrix A, let $\alpha_i^f = (\gamma_i, \gamma_i^c)$, since

$$A^f(\gamma_i, \gamma_i^c) = (\gamma_i, \gamma_i^c)\begin{pmatrix} \lambda_i & 0 \\ 0 & \overline{\lambda_i} \end{pmatrix} \Leftrightarrow A^f\alpha_i^f = \alpha_i^f\lambda_i^f \Leftrightarrow A\alpha_i = \alpha_i\lambda_i,$$

so vector $\alpha_i = (\gamma_i, \gamma_i^c)^{f^{-1}}$ is an eigenvector of the A corresponding to the principal eigenvalue λ_i;

Step 3: Find all eigenvalues and corresponding eigenvectors of the A.

For any nonzero quaternion p, by Theorem 3.2 we know that $p^{-1}\lambda_i p$ are all eigenvalues of the A, and $\alpha_i p$ are all eigenvectors of the A corresponding to eigenvalue $p^{-1}\lambda_i p$, $i=1,2,...,n$.

Example: Let

$$A = \begin{pmatrix} i & 1+j \\ -1+j & -k \end{pmatrix}.$$

Find all eigenvalues and corresponding eigenvectors of the quaternion matrix A (an anti-self-adjoint matrix).

It is easy to find the A^f by the definition of complex representation of the A, and

$$A^f = \begin{pmatrix} i & 0 & 1 & 1 \\ 0 & -i & -1 & 1 \\ -1 & 1 & 0 & -i \\ -1 & -1 & -i & 0 \end{pmatrix},$$

and $|\lambda I_{2n} - A^f| = (\lambda^2 + 3)^2$. Therefore eigenvalues of the complex representation matrix A^f are $\lambda_1 = \sqrt{3}i$, $\lambda_2 = -\sqrt{3}i = \overline{\lambda_1}$, and

$$\gamma_1^T = (2i, 0, 1-\sqrt{3}, 1-\sqrt{3}), \quad \gamma_2^T = (0, -2i, -1-\sqrt{3}, 1+\sqrt{3})$$

are two eigenvectors of A^f corresponding to eigenvalues λ_1, namely, $A^f\gamma_1 = \gamma_1\lambda_1$, $A^f\gamma_2 = \gamma_2\lambda_1$, and by (2.6) we also have $A^f\gamma_1^c = \gamma_1^c\overline{\lambda_1}$ and $A^f\gamma_2^c = \gamma_2^c\overline{\lambda_1}$. Let $\alpha_1^T = (\gamma_1, \gamma_1^c)^{f^{-1}} = (2i, (1-\sqrt{3})(1-j))^T$, $\alpha_2^T = (\gamma_1, \gamma_1^c)^{f^{-1}} = (-2k, -(1+\sqrt{3})(1+j))^T$. Then $A\alpha_1 = \alpha_1\lambda_1$, $A\alpha_2 = \alpha_2\lambda_1$, and all eigenvalues of the quaternion matrix A are $p^{-1}\lambda_1 p$, and $\alpha_i p$, $i=1,2$, are the corresponding eigenvectors to $p^{-1}\lambda_1 p$, where p is an arbitrary quaternion.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 8 AUGUST 2004

Time fractional Schrödinger equation

Mark Naber[a)]
Department of Mathematics, Monroe County Community College, Monroe, Michigan 48161-9746

(Received 4 February 2004; accepted 12 May 2004; published online 9 July 2004)

The Schrödinger equation is considered with the first order time derivative changed to a Caputo fractional derivative, the time fractional Schrödinger equation. The resulting Hamiltonian is found to be non-Hermitian and nonlocal in time. The resulting wave functions are thus not invariant under time reversal. The time fractional Schrödinger equation is solved for a free particle and for a potential well. Probability and the resulting energy levels are found to increase over time to a limiting value depending on the order of the time derivative. New identities for the Mittag–Leffler function are also found and presented in an Appendix. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1769611]

I. INTRODUCTION

A Gaussian distribution for random walk problems, in the continuum limit, can be used to generate the ordinary diffusion equation (ignoring boundary conditions and sources)[1]

$$\frac{\partial}{\partial t}\mathrm{U}=c\frac{\partial^2}{\partial x^2}\mathrm{U}, \tag{1}$$

U represents the concentration of the diffusing material. c is the diffusion coefficient which is positive and whose magnitude helps determine the speed at which the diffusion takes place, and, t and x are the temporal and spatial coordinates. The diffusion coefficient may depend on the coordinates and/or the concentration. When non-Gaussian distributions are used fractional diffusion equations are produced. Diffusion that is generated by non-Gaussian distributions is typically referred to as anomalous diffusion. There is a growing body of examples of phenomena that lie outside of what is predicted by the ordinary diffusion equation (see, for example, Refs. 2–7).

Three types of fractional diffusion equations can be produced when considering non-Gaussian distributions. The first is the space fractional diffusion equation

$$\frac{\partial}{\partial t}\mathrm{U}=c\frac{\partial^\beta}{\partial x^\beta}\mathrm{U}. \tag{2}$$

Here $0<\beta\leqslant 2$ (in this paper Caputo fractional derivatives will be used, the reader is directed to Appendix A for definitions and notation conventions). In this case, the diffusion is still Markovian but only exhibits Brownian motion for $\beta=2$.

The second type is the time fractional diffusion equation

$$\frac{\partial^\alpha}{\partial t^\alpha}\mathrm{U}=c\frac{\partial^2}{\partial x^2}\mathrm{U}. \tag{3}$$

a)Electronic mail: mnaber@monroeccc.edu

In this case the diffusion is non-Markovian and can further be divided into sub-($0<\alpha<1$) and super-($1<\alpha<2$) diffusive behavior. Additionally, the mixed case can be considered with both space and time fractional derivatives

$$\frac{\partial^{\alpha}}{\partial t^{\alpha}}\mathrm{U}=c\,\frac{\partial^{\beta}}{\partial x^{\beta}}\mathrm{U}. \tag{4}$$

The Schrödinger equation has the mathematical appearance of a diffusion equation and can be derived by considering probability distributions. Feynman and Hibbs used a Gaussian probability distribution in the space of all possible paths, for a quantum mechanical particle, to derive the Schrödinger equation.[8] Therefore, it is reasonable to consider the different types of Schrödinger equations that are obtainable for non-Gaussian distributions. In an earlier sequence of papers (see Refs. 9–11) Laskin constructed space fractional quantum mechanics. This was done using Feynman's path integral approach, the difference being the use of Levy distributions instead of Gaussian distributions for the set of possible paths. The Schrödinger equation that was obtained had space fractional derivatives. This is the same result that one obtains when studying diffusion processes based on Levy distributions instead of Gaussian distributions. Similarly, a time fractional Schrödinger equation would be obtained if one considered non-Markovian evolution. Laskin was able to show that the fractional Hamiltonian was Hermitian and that parity is conserved. Energy levels were also computed for the hydrogen atom and the harmonic oscillator.

In this paper, properties of the time fractional Schrödinger equation are examined. The time fractional Schrödinger equation will be constructed by rewriting the Schrödinger equation so that all derivative operators appear as dimensionless objects, the time derivative is then fractionalized, and the imaginary unit is raised to the order of the fractional time derivative. This last step is important because it ensures the same physical character of the time fractional Schrödinger equation no matter what the order.

For the time fractional Schrödinger equation there are two cases: One for the order of the time derivative being between zero and one, and another case for the order being between one and two. For the later case the resulting equation has the same draw backs as the Klein–Gordon equation, in that the initial value of the first derivative and the wave function itself must be specified.

In the following section the time fractional Schrödinger equation is constructed. Section III will show that the time fractional Schrödinger equation is equivalent to the usual Schrödinger equation but with a time dependent Hamiltonian. The solutions will not be invariant under time reversal nor will probability be conserved. In Sec. IV solutions are obtained for a free particle. In Sec. V a solution for a potential well is found. In both cases it will be shown that probability increases over time to a limiting value that depends on the order of the time derivative. Section VI presents some properties for the case of the order of the time derivative being between one and two. Concluding remarks are given in Sec. VII. There are also two Appendixes. The first is a primer on Caputo fractional calculus and a rationale of why it should be used to study physical systems instead of Riemann–Liouville fractional calculus. A second appendix presents some properties of the Mittag–Leffler function along with a new identity.

II. TIME FRACTIONAL SCHRÖDINGER EQUATION

To fractionalize the time derivative of the Schrödinger equation care must be taken to preserve the units of the wave function. To begin with, note the definitions and the relationships of the Plank units given below (Plank length, time, mass, and energy):[12]

$$L_p=\sqrt{\frac{G\hbar}{c^3}},\quad T_p=\sqrt{\frac{G\hbar}{c^5}},\quad M_p=\sqrt{\frac{\hbar c}{G}},\quad E_p=M_pc^2. \tag{5}$$

The standard form of the Schrödinger equation in one space and one time dimension is[13]

$$i\hbar\partial_t\psi = -\frac{\hbar^2}{2m}\partial_x^2\psi + V\psi. \tag{6}$$

This can be expressed in Plank units as follows:

$$iT_p\partial_t\psi = -\frac{L_p^2 M_p}{2m}\partial_x^2\psi + \frac{V}{E_p}\psi. \tag{7}$$

Define two dimensionless parameters; $N_m = m/M_p$ the number of Plank masses in m and $N_V = V/E_p$ the number of Plank energies in V

$$iT_p\partial_t\psi = -\frac{L_p^2}{2N_m}\partial_x^2\psi + N_V\psi. \tag{8}$$

When the time derivative is fractionalized there are two options,

$$(iT_p)^\nu \mathrm{D}_t^\nu\psi = -\frac{L_p^2}{2N_m}\partial_x^2\psi + N_V\psi, \tag{9}$$

$$i(T_p)^\nu \mathrm{D}_t^\nu\psi = -\frac{L_p^2}{2N_m}\partial_x^2\psi + N_V\psi. \tag{10}$$

In this paper, D_t^ν shall denote the Caputo fractional derivative of order ν. T_p must be raised to the same order as the fractional derivative to preserve the units of ψ.

The question of whether or not to raise i to the order of the time derivative needs more investigation. There are two reasons to choose Eq. (9) over Eq. (10), one superficial and one physical. When performing a Wick rotation the imaginary unit is raised to the same power as the time coordinate. The second reason involves the temporal behavior of the solution. When solving for the time component of Eq. (9) or Eq. (10) the Laplace transform is the preferred method. For Eq. (9), changing the order of the derivative moves the pole (from the inverse Laplace transform) up or down the negative imaginary axis. Hence, the temporal behavior of the solution will not change. For Eq. (10), changing the order of the derivative moves the pole to almost any desired location in the complex plane. Physically, this would mean that a small change in the order of the time derivative, in Eq. (10), could change the temporal behavior from sinusoidal to growth or to decay. Due to the simpler physical behavior of Eq. (9) and the role of "i" in a Wick rotation, Eq. (9) is the best candidate for a time fractional Schrödinger equation.

III. TIME DEPENDENT HAMILTONIAN AND PROBABILITY CURRENT

The order of the time derivative on the left hand side Eq. (9) is not one, therefore, the operator on the right hand side is not a Hermitian Hamiltonian. Equation (5) can be rearranged to expose a time dependent Hamiltonian. To do so, the order of the time derivative on the left hand side of Eq. (9) must be raised to order one. First note an identity for Caputo derivatives for $0<\nu<1$,

$$\mathrm{D}_t^{1-\nu}\mathrm{D}_t^\nu y(t) = \frac{\mathrm{d}}{\mathrm{d}t}y(t) - \frac{[\mathrm{D}_t^\nu y(t)]_{t=0}}{t^{1-\nu}\Gamma(\nu)}. \tag{11}$$

Now define two parameters:

$$\alpha = \frac{N_V}{T_p^\nu}, \tag{12}$$

$$\beta = \frac{(L_p)^2}{2N_m(T_p)^\nu}, \tag{13}$$

then Eq. (9) can be written as

$$\mathrm{D}_t^\nu \psi = -\frac{\beta}{i^\nu}\partial_x^2 \psi + \frac{\alpha}{i^\nu}\psi. \tag{14}$$

Using the identity for Caputo derivatives, Eq. (11), the time dependent Hamiltonian appears

$$\partial_t \psi = -\frac{\beta}{i^\nu}\partial_x^2(\mathrm{D}_t^{1-\nu}\psi) + \frac{\alpha}{i^\nu}(\mathrm{D}_t^{1-\nu}\psi) + \frac{[\mathrm{D}^\nu \psi(t)]_{t=0}}{t^{1-\nu}\Gamma(\nu)}. \tag{15}$$

Since the Hamiltonian is time dependent we should not expect probability to be conserved. Note also that the Hamiltonian is nonlocal in time, due to the integral in the formulation of the fractional derivative (see the Appendix). This nonlocal character tells us that the solutions will not be invariant under time reversal. The third term in the Hamiltonian goes to zero as time goes to infinity (recall that the order of the original fractional time derivative is less than one).

Consider the nonlocal object in Eq. (15)

$$\mathrm{D}_t^{1-\nu}\psi(t,x) = \frac{1}{\Gamma(1-\nu)}\int_0^t \left(\frac{\mathrm{d}}{\mathrm{d}\tau}\psi(\tau,x)\right)\frac{\mathrm{d}\tau}{(t-\tau)^\nu}. \tag{16}$$

For a possible interpretation of this object recall the interpretation of the first order time derivative in standard quantum mechanics,[13]

$$\frac{\partial}{\partial t} = \frac{E}{i\hbar}, \tag{17}$$

where E is viewed as the energy operator (Hamiltonian). Then the inner product (* denotes complex conjugation),

$$\int_{-\infty}^{\infty} \psi(t,x)^* \mathrm{D}_t^{1-\nu}\psi(t,x)\mathrm{d}x, \tag{18}$$

can be interpreted as being proportional to the weighted time average of the energy of the wave function, the weighting factor being $(t-\tau)^{-\nu}$. For the remainder of the paper denote $\tilde{\psi} = \mathrm{D}_t^{1-\nu}\psi$.

The probability current equation (for a free particle) can be constructed just as for the non-fractional Schrödinger equation.

$$probability\ \ density = P = \psi\psi^*, \tag{19}$$

$$\partial_t P = \partial_t \psi \psi^* + \psi \partial_t \psi^*, \tag{20}$$

$$\partial_t P = \left(-\frac{\beta}{i^\nu}\partial_x^2\tilde{\psi} + \frac{[\mathrm{D}_t^\nu \psi(t,x)]_{t=0}}{t^{1-\nu}\Gamma(\nu)}\right)\psi^* + \psi\left(-\frac{\beta}{(-i)^\nu}\partial_x^2\tilde{\psi}^* + \frac{[\mathrm{D}_t^\nu \psi(t,x)^*]_{t=0}}{t^{1-\nu}\Gamma(\nu)}\right). \tag{21}$$

This can be rearranged

$$\partial_t P+\beta\partial_x\left(\frac{\partial_x\tilde{\psi}\psi^*}{i^\nu}+\frac{\partial_x\tilde{\psi}^*\psi}{(-i)^\nu}\right)=\beta\left(\frac{\partial_x\tilde{\psi}\partial_x\psi^*}{i^\nu}+\frac{\partial_x\tilde{\psi}^*\partial_x\psi}{(-i)^\nu}\right)$$
$$+\frac{\psi^*[\mathrm{D}_t^\nu\psi(t,x)]_{t=0}+\psi[\mathrm{D}_t^\nu\psi(t,x)^*]_{t=0}}{t^{1-\nu}\Gamma(\nu)}. \tag{22}$$

If the Hamiltonian were not time dependent (i.e., if $\nu\to 1$) then the right hand side of Eq. (22) would be zero. The probability current can be identified as

$$J=\frac{\beta}{i^\nu}(\partial_x\tilde{\psi})\psi^*+\frac{\beta}{(-i)^\nu}\psi(\partial_x\tilde{\psi}^*). \tag{23}$$

The right hand side of Eq. (22) can be viewed as a source in the probability current equation. The nonzero source term in Eq. (22) confirms that probability will not be preserved for solutions of the time fractional Schrödinger equation.

$$S(x,t)=\frac{\beta}{i^\nu}\partial_x\tilde{\psi}\partial_x\psi^*+\frac{\beta}{(-i)^\nu}\partial_x\tilde{\psi}^*\partial_x\psi+\frac{\psi^*[\mathrm{D}_t^\nu\psi(t,x)]_{t=0}+\psi[\mathrm{D}^\nu\psi(t,x)^*]_{t=0}}{t^{1-\nu}\Gamma(\nu)}, \tag{24}$$

$$\partial_t P+\partial_x J=S. \tag{25}$$

Integrating Eq. (25) over all space and requiring the wave function and its first derivative go to zero at spatial infinity gives

$$\partial_t\int_{-\infty}^{\infty}P\,\mathrm{d}x=\int_{-\infty}^{\infty}S\mathrm{d}x. \tag{26}$$

IV. FREE PARTICLE SOLUTION

The time fractional Schrödinger equation for a free particle is given by

$$(iT_p)^\nu\mathrm{D}_t^\nu\psi=-\frac{L_p^2}{2N_m}\partial_x^2\psi. \tag{27}$$

To solve this equation, apply a Fourier transform on the spatial coordinate, $\mathcal{F}(\psi(x,t))=\Psi(\lambda,t)$

$$(iT_p)^\nu\mathrm{D}_t^\nu\Psi=\frac{(L_p\lambda)^2}{2N_m}\Psi. \tag{28}$$

The resulting equation can be rearranged and the results of Appendix B can be used. Namely, the identity for the Mittag–Leffler function with a complex argument

$$\mathrm{D}_t^\nu\Psi=\frac{(L_p\lambda)^2}{2N_mT_p^\nu i^\nu}\Psi, \tag{29}$$

$$\Psi=\Psi_0E_\nu(\omega(-it)^\nu), \tag{30}$$

or

$$\Psi=\frac{\Psi_0}{\nu}\{e^{-i\omega^{1/\nu}t}-\nu F_\nu(\omega(-i)^\nu,t)\}, \tag{31}$$

where $\omega=(L_p\lambda)^2/2N_mT_p^{\nu}$. In Eq. (31) the first term is oscillatory, and the second is decay in the time variable. The function, F_{ν}, is defined in Appendix B. Inverse Fourier transforming gives the final solution

$$\psi(x,t)=\mathcal{F}^{-1}\Psi(\lambda,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}e^{i\lambda x}\frac{\Psi_0}{\nu}\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}(\omega(-i)^{\nu},t)\}\mathrm{d}\lambda. \tag{32}$$

This can be broken into two parts, a Schrödinger like piece divided by ν, and a decay term that goes to zero as time goes to infinity

$$\psi_S(x,t)=\frac{1}{2\pi\nu}\int_{-\infty}^{\infty}e^{i\lambda x}\Psi_0 e^{-i\omega^{1/\nu}t}\mathrm{d}\lambda, \tag{33}$$

$$\psi_D(x,t)=\frac{-1}{2\pi}\int_{-\infty}^{\infty}e^{i\lambda x}\Psi_0 F_{\nu}(\omega(-i)^{\nu},t)\mathrm{d}\lambda, \tag{34}$$

$$\psi(x,t)=\psi_S(x,t)+\psi_D(x,t). \tag{35}$$

Note that as ν goes to one the decay term goes to zero and the Schrödinger like term becomes the nonfractional Schrödinger term.

Ψ_0 may be chosen so that the initial probability is one

$$\int_{-\infty}^{\infty}\psi(x,0)\psi^*(x,0)\mathrm{d}x=1. \tag{36}$$

Due to the decay term in the solution one may ask what happens to the total probability as time goes to infinity. Consider the following limit

$$\lim_{t\to\infty}\int_{-\infty}^{\infty}\psi(x,t)\psi^*(x,t)\mathrm{d}x \tag{37}$$

$$=\lim_{t\to\infty}\int_{-\infty}^{\infty}\mathcal{F}^{-1}\left(\frac{\Psi_0}{\nu}\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}(\omega(-i)^{\nu},t)\}\right)\mathcal{F}^{-1}\left(\frac{\Psi_0}{\nu}\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}(\omega(-i)^{\nu},t)\}\right)^*\mathrm{d}x. \tag{38}$$

Now use Parseval's identity

$$=\frac{2\pi}{\nu^2}\lim_{t\to\infty}\int_{-\infty}^{\infty}\Psi_0\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}(\omega(-i)^{\nu},t)\}(\Psi_0\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}(\omega(-i)^{\nu},t)\})^*\mathrm{d}\lambda. \tag{39}$$

In the limit that time goes to infinity F_{ν} goes to zero, this leaves

$$=\frac{2\pi}{\nu^2}\lim_{t\to\infty}\int_{-\infty}^{\infty}\Psi_0 e^{-i\omega^{1/\nu}t}\Psi_0^* e^{i\omega^{1/\nu}t}\mathrm{d}\lambda, \tag{40}$$

$$=\frac{2\pi}{\nu^2}\lim_{t\to\infty}\int_{-\infty}^{\infty}\Psi_0\Psi_0^*\mathrm{d}\lambda. \tag{41}$$

Now use Parseval's identity again

$$=\frac{1}{\nu^2}\lim_{t\to\infty}\int_{-\infty}^{\infty}\psi_0\psi_0^*\,\mathrm{d}x. \tag{42}$$

The remaining integral is unity. Hence,

$$\lim_{t\to\infty}\int_{-\infty}^{\infty}\psi(x,t)\overline{\psi}(x,t)\,\mathrm{d}x=\frac{1}{\nu^2}. \tag{43}$$

Since ν is less than one, the total probability increases over time to the limiting value of Eq. (43).

V. POTENTIAL WELL SOLUTION

Now consider a particle in a potential well

$$V(x)=\begin{cases}0, & 0<x<a\\ \infty & \text{elsewhere,}\end{cases} \tag{44}$$

$$(iT_p)^{\nu}\mathrm{D}_t^{\nu}\psi=-\frac{L_p^2}{2N_m}\partial_x^2\psi, \tag{45}$$

$$\begin{aligned}\psi(0,t)&=0,\\ \psi(a,t)&=0.\end{aligned} \tag{46}$$

This can be solved by separation of variables, $\psi=A(t)B(x)$

$$(iT_p)^{\nu}\frac{\mathrm{D}_t^{\nu}A}{A}=-\frac{L_p^2}{2N_m}\frac{\partial_x^2 B}{B}=\lambda. \tag{47}$$

Solve the spatial component first

$$B''+\lambda\frac{2N_m}{L_p^2}B=0. \tag{48}$$

The boundary conditions give

$$B_n=c_n\sin\left(\frac{n\pi}{a}x\right), \tag{49}$$

$$\lambda_n=\left(\frac{n\pi L_p}{a}\right)^2\frac{1}{2N_m}. \tag{50}$$

The time equation is

$$D_t^{\nu}A=\frac{\lambda_n}{(iT_p)^{\nu}}A. \tag{51}$$

This can be solved in terms of the Mittag–Leffler function (see Appendix B). Let $A(t=0)=1$ so that we can specify an initial wave function.

$$A=E_{\nu}(\omega_n(-it)^{\nu}), \tag{52}$$

$$A=\frac{1}{\nu}\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}((-i\omega)^{\nu},t)\}, \tag{53}$$

where, $\omega_n=\lambda_n/T_p^{\nu}$.

Note also that

$$\lim_{t\to\infty}|A(t)|=\frac{1}{\nu}. \tag{54}$$

The normalized spatial eigenfunctions are

$$\psi_n(x,0)=\sqrt{\frac{2}{a}}\sin(n\pi x/a), \tag{55}$$

$$\int_0^a \psi_n(x,0)\cdot\psi_n(x,0)\mathrm{d}x=1. \tag{56}$$

The solutions for all times can be written as

$$\psi_n(x,t)=\sqrt{\frac{2}{a}}\sin(n\pi x/a)\,\frac{1}{\nu}\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}((-i\omega)^{\nu},t)\}. \tag{57}$$

As in the free particle case it is interesting to compute the limit of the total probability as time goes to infinity

$$\lim_{t\to\infty}\int_0^a \psi_n(x,t)\cdot\overline{\psi}_n(x,t)\mathrm{d}x=\frac{1}{\nu^2}. \tag{58}$$

This is the same result as for the free particle. As ν is less than one, the total probability is greater than one as time goes to infinity. In fact as long as $t_1<t_2$ we have

$$\int_0^a \psi(x,t_1)\cdot\overline{\psi}(x,t_1)\mathrm{d}x<\int_0^a \psi(x,t_2)\cdot\overline{\psi}(x,t_2)\mathrm{d}x. \tag{59}$$

Probability is created as time progresses. This can also be viewed as particles are created (extracted from the potential) as time progresses.

The energy levels for the potential well can be computed. Since the Hamiltonian is time dependent the energy levels will also be time dependent.

$$\mathrm{E}_n(t)=\int_0^a \psi^* i\hbar\,\partial_t\psi\mathrm{d}x, \tag{60}$$

$$\mathrm{E}_n(t)=\frac{2i\hbar}{a\nu^2}\{e^{i\omega^{1/\nu}t}-\nu F_{\nu}((i\omega)^{\nu},t)\}\partial_t\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}((-i\omega)^{\nu},t)\}\int_0^a \sin^2\left(\frac{n\pi x}{a}\right)\mathrm{d}x, \tag{61}$$

$$\mathrm{E}_n(t)=\frac{i\hbar}{\nu^2}\{e^{i\omega^{1/\nu}t}-\nu F_{\nu}((i\omega)^{\nu},t)\}\partial_t\{e^{-i\omega^{1/\nu}t}-\nu F_{\nu}((-i\omega)^{\nu},t)\}. \tag{62}$$

The interesting result is when time goes to infinity

$$\mathrm{E}_n(\infty)=\frac{\hbar(\lambda_n)^{1/\nu}}{\nu^2 T_p}=\frac{\hbar(n\pi L_p)^{2/\nu}}{\nu^2 T_p(2a^2N_m)^{1/\nu}}. \tag{63}$$

This is the same energy spectrum that is obtained for the nonfractional Schrödinger equation except for the factor of $1/\nu^2$ and the exponent of $1/\nu$. The difference between two energy levels, say m and n, is given by

$$\mathrm{E}_m(\infty)-\mathrm{E}_n(\infty)=\frac{\hbar(\pi L_p)^{2/\nu}}{\nu^2 T_p(2a^2N_m)^{1/\nu}}(m^{2/\nu}-n^{2/\nu}). \tag{64}$$

Since ν is less than one the spacing between energy levels is greater than that given by the nonfractional Schrödinger equation. In fact the smaller the value of ν the greater the difference between energy levels. Note also that at $t=0$ the spacing between the energy levels is that same as that of the nonfractional Schrödinger equation. As time progresses the spacing between the energy levels increases to the limiting value given by Eq. (64). Hence, radiation that is emitted, say from state n to state m, at an early time will have a longer wavelength than radiation emitted at a later time.

VI. SOME PROPERTIES FOR $1<\nu\leqslant 2$

In this section the case of $1<\nu\leqslant 2$ is briefly considered. Notice that at the upper limit we have a special case of the Klein–Gordon equation. Like the Klein–Gordon equation, the initial value of the first derivative must also be specified to obtain a solution. Just as in the previous case, Eq. (14) can be recast to expose a time dependent Hamiltonian. First note an identity for Caputo fractional derivatives and integrals for $1<\nu\leqslant 2$

$$I_t^{\nu-1}\mathrm{D}_t^{\nu}f(t)=\mathrm{D}_t^1 f(t)-\mathrm{D}_t^1 f(t)\big|_{t=0}. \tag{65}$$

Applying $I_t^{\nu-1}$ to Eq. (14) yields

$$\partial_t\psi=-\frac{\beta}{i^{\nu}}\partial_x^2(I_t^{1-\nu}\psi)+\frac{\alpha}{i^{\nu}}(I_t^{1-\nu}\psi)+\partial_t\psi(t)\big|_{t=0}. \tag{66}$$

This is very similar to Eq. (15) except that the fractional derivatives are replaced with fractional integrals and the initial value term is for the first derivative.

The solution can also be written down for a free particle just like the previous case

$$\begin{aligned}(iT_p)^{\nu}\mathrm{D}_t^{\nu}\psi&=-\frac{L_p^2}{2N_m}\partial_x^2\psi,\\ \psi(x,0)&=\psi_0,\\ \frac{\mathrm{d}}{\mathrm{d}t}\psi(x,t)\bigg|_{t=0}&=\psi_1.\end{aligned} \tag{67}$$

Denote the Fourier transform (on the spatial coordinate) of the wave function and the initial conditions as

$$\begin{aligned}\Psi(\lambda,t)&=\mathcal{F}(\psi(x,t)),\\ \Psi_0&=\mathcal{F}(\psi_0),\\ \Psi_1&=\mathcal{F}(\psi_1).\end{aligned} \tag{68}$$

The solution, in Fourier space, can then be expressed as

$$\Psi=\Psi_0\left(\frac{e^{i\omega^{1/\nu}t}}{\nu}+F_\nu(\omega(-i)^\nu,t)\right)+\Psi_1\left(\frac{e^{i\omega^{1/\nu}t}}{\omega^{1/\nu}\nu}-F_{\nu-1}(\omega(-i)^\nu,t)\right), \tag{69}$$

where, $\omega=(L_p\lambda)^2/2N_mT_p^\nu$. This solution behaves just like the case of $0<\nu\leqslant 1$ in that there is an oscillatory term and a decay term. The presence of a decay term will again cause probability to increase over time.

VII. CONCLUSION

In this paper the time fractional Schrödinger equation was constructed. It was found to be equivalent to the usual Schrödinger equation but with a Hamiltonian that was time dependent and nonlocal in time. In contrast to the space fractional Schrödinger equation, probability was not conserved but found to increase over time to a limiting value depending on the order of the time derivative. Consequently, the energy of the eigenstates for the potential well were also found to increase over time to a limiting value (for $0<\nu<1$). In the limit that $t\to\infty$ the energy of the eigenstates was found to be similar to that given by the usual Schrödinger equation but divided by the order of the time derivative squared and having an exponent depending on the order of the time derivative. Initially the energy of the eigenstates is the same as for the nonfractional Schrödinger equation. As time progresses the energy of each level increases as does the spacing between the energy levels. Hence, if the spectrum of emitted radiation was monitored over time, for such a fractional well, it would be seen to blue shift and, the space between the spectral lines would also increase. In finding a solution to the time fractional Schrödinger equation a new identity for the Mittag–Leffler function was found. This identity generalizes the Euler identity for the exponential function with complex arguments.

ACKNOWLEDGMENT

The author would like to thank Jean Krisch, Ed Glass, and David Garfinkle for many useful and stimulating discussions. The author would also like to thank P. Dorcey for critically reading an early version of the paper.

APPENDIX A: CAPUTO FRACTIONAL CALCULUS

The bulk of this appendix is taken from Ref. 14. The two most commonly used definitions of fractional derivatives are the Riemann–Liouville and Caputo (there are many definitions, the reader is encouraged to consult Ref. 15 for a more complete discussion). Each definition uses Riemann–Liouville fractional integration and derivatives of whole order. The difference between the two definitions is in the order of evaluation. Riemann–Liouville fractional integration of order μ is defined as

$$\mathrm{I}^\mu(f(t))=\frac{1}{\Gamma(\mu)}\int_0^t\frac{f(\tau)\mathrm{d}\tau}{(t-\tau)^{1-\mu}}. \tag{A1}$$

The next two equations define Riemann–Liouville (RL) and Caputo fractional derivatives of order ν, respectively,

$${}^{\mathrm{RL}}\mathrm{D}_t^\nu f(t)=\frac{\mathrm{d}^k}{\mathrm{d}t^k}(\mathrm{I}^{k-\nu}f(t)), \tag{A2}$$

$${}^{C}\mathrm{D}_t^\nu f(t)=\mathrm{I}^{k-\nu}\left(\frac{\mathrm{d}^k}{\mathrm{d}t^k}f(t)\right), \tag{A3}$$

where $k-1 \leqslant \nu < k$. For now, the Caputo fractional derivative will be denoted by ${}^{C}\mathrm{D}_t^{\nu}$ to maintain a clear distinction with the Riemann–Liouville fractional derivative. The Caputo fractional derivative first computes an ordinary derivative followed by a fractional integral to achieve the desired order of fractional derivative. The Riemann–Liouville fractional derivative is computed in the reverse order.

The desire to formulate initial value problems for physical systems leads to the use of Caputo fractional derivatives rather than Riemann–Liouville fractional derivatives. Consider the Laplace transform of the Riemann–Liouville fractional derivative,

$$\mathcal{L}_t\{{}^{\mathrm{RL}}\mathrm{D}_t^{\nu} f(t)\} = s^{\nu} F(s) - \sum_{k=0}^{n-1} s^k ({}^{\mathrm{RL}}\mathrm{D}_t^{\nu-k-1} f(t))\big|_{t=0}. \tag{A4}$$

The initial conditions, $({}^{\mathrm{RL}}\mathrm{D}_t^{\nu-k-1} f(t))\big|_{t=0}$ for $k=0,\ldots,n-1$, are fractional order derivatives (see Ref. 15 for a detailed discussion of these objects). When studying a physical system, initial conditions are typically conditions that can be measured or imposed on the system. As yet there is no physical interpretation for $({}^{\mathrm{RL}}\mathrm{D}_t^{\nu-k-1} f(t))\big|_{t=0}$ (see Refs. 16 and 17 for a fractal interpretation of the fractional order integral). Some authors using equations with Riemann–Liouville fractional derivatives to model physical systems have added terms to the diffusion equation to eliminate these unphysical terms (see, e.g., Ref. 18).

The Laplace transform of the Caputo fractional derivative is

$$\mathcal{L}_t\{{}^{C}\mathrm{D}_t^{\nu} f(t)\} = s^{\nu} \mathrm{F}(s) - \sum_{k=0}^{n-1} s^{\nu-k-1} (\mathrm{D}_t^k f(t))\big|_{t=0}. \tag{A5}$$

In this case the initial conditions are well understood from a physical point of view. For example if $f(t)$ represents position then $(\mathrm{D}_t^0 f(t))\big|_{t=0}$ is the initial position, $(\mathrm{D}_t^1 f(t))\big|_{t=0}$ is the initial velocity, etc. (see Podlubny Ref. 15, Sec. 2.4 for a more detailed discussion of this point).

APPENDIX B: THE MITTAG–LEFFLER FUNCTION

The Mittag–Leffler function, $E_{\nu}(t)$, is a generalization of the exponential function (see Refs. 15 and 19 for additional properties and a history)

$$e^t = \sum_{n=0}^{\infty} \frac{t^n}{n!} = \sum_{n=0}^{\infty} \frac{t^n}{\Gamma(n+1)}, \tag{B1}$$

$$E_{\nu}(t) = \sum_{n=0}^{\infty} \frac{t^n}{\Gamma(\nu n+1)}. \tag{B2}$$

One very useful formula concerning the exponential function is with a complex argument, the Euler identity

$$e^{it} = \cos(t) + i \sin(t). \tag{B3}$$

A similar identity occurs for the Mittag–Leffler function. The derivation is given below. Consider the initial value fractional differential equation

$$\begin{aligned} {}_0\mathrm{D}_t^{\nu} A &= \sigma A, \\ A(t=0) &= A_0. \end{aligned} \tag{B4}$$

The solution of this can be found by Laplace transform in two different ways

$$s^{\nu} \tilde{A} - s^{\nu-1} A_0 = \sigma \tilde{A}, \tag{B5}$$

$$\tilde{A}=\frac{s^{\nu-1}A_0}{s^{\nu}-\sigma}. \tag{B6}$$

Equation (B6) can be expressed as a power series

$$\tilde{A}=A_0\sum_{n=0}^{\infty}\frac{\sigma^n}{s^{1+\nu n}}. \tag{B7}$$

Inverting this series yields a series representation for the Mittag–Leffler function

$$A=A_0\sum_{n=0}^{\infty}\frac{\sigma^n t^{\nu n}}{\Gamma(\nu n+1)}=A_0E_{\nu}(\sigma t^{\nu}). \tag{B8}$$

The solution to

$$\begin{aligned} {}_0\mathrm{D}_t^{\nu}A&=\sigma i^{\nu}A,\\ A(t=0)&=A_0, \end{aligned} \tag{B9}$$

is then given by

$$A=A_0E_{\nu}(\sigma i^{\nu}t^{\nu}). \tag{B10}$$

To see how this breaks up into an oscillatory piece and a decay piece consider the Laplace transform of Eq. (B9)

$$\tilde{A}=\frac{s^{\nu-1}A_0}{s^{\nu}-\sigma i^{\nu}}. \tag{B11}$$

The inverse Laplace transform is given by

$$A(t)=\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty}\frac{e^{st}s^{\nu-1}A_0}{s^{\nu}-\sigma i^{\nu}}\mathrm{d}s. \tag{B12}$$

The inverse Laplace transform can be evaluated using residues. This integral has a branch point at $s=0$ due to $s^{\nu-1}$ in the numerator and s^{μ} in the denominator, and a pole at $s_0=\sigma^{1/\nu}i$. Due to the branch point at the origin the usual Bromwich contour cannot be used. A branch cut along the negative Real(s) axis must be made. That is, a cut from $-\infty$ into and then around the origin in a clockwise sense and then back out to $-\infty$. The usual Bromwich contour is continued after the cut. This is referred to as a Hankel contour. The solution will then be given by the residue minus the contribution along the partial path

$$A(t)=\text{Residue}-\frac{A_0}{2\pi i}\int_{\text{Hankel}}. \tag{B13}$$

The residue is given by

$$\frac{\text{Residue}}{A_0}=\lim_{s\to s_0}\frac{(s-s_0)e^{st}s^{\nu-1}}{s^{\nu}-s_0^{\nu}}=\frac{e^{i\sigma^{1/\nu}t}}{\nu}. \tag{B14}$$

The integral along the Hankel contour only makes contributions along the branch cut. This contribution is given by

$$-\frac{A_0\sigma i^{\nu}}{\pi}\int_0^{\infty}\frac{\sin(\nu\pi)e^{-rt}r^{\nu-1}dr}{r^{2\nu}-2\sigma i^{\nu}\cos(\nu\pi)r^{\nu}+(\sigma i^{\nu})^2}. \tag{B15}$$

Combining the path and residue contributions, and doing some algebra gives

$$\frac{A}{A_0}=\frac{e^{i\sigma^{1/\nu}t}}{\nu}-\frac{\sigma i^{\nu}\sin(\nu\pi)}{\pi}\int_0^{\infty}\frac{e^{-rt}r^{\nu-1}dr}{r^{2\nu}-2\sigma i^{\nu}\cos(\nu\pi)r^{\nu}+(\sigma i^{\nu})^2}. \tag{B16}$$

The first term is oscillatory, and the second decays monotonically in the time variable. Hence, the Mittage–Leffler function, with a complex argument, can be expressed as

$$E_{\nu}(\sigma i^{\nu}t^{\nu})=\frac{e^{i\sigma^{1/\nu}t}}{\nu}-\frac{\sigma i^{\nu}\sin(\nu\pi)}{\pi}\int_0^{\infty}\frac{e^{-rt}r^{\nu-1}dr}{r^{2\nu}-2\sigma i^{\nu}\cos(\nu\pi)r^{\nu}+(\sigma i^{\nu})^2}. \tag{B17}$$

Note that as $\nu\rightarrow 1$ the above equation becomes the Euler identity.

To make this result appear more compact define a new function

$$F_{\nu}(\rho,t)=\frac{\rho\sin(\nu\pi)}{\pi}\int_0^{\infty}\frac{e^{-rt}r^{\nu-1}dr}{r^{2\nu}-2\rho\cos(\nu\pi)r^{\nu}+\rho^2}. \tag{B18}$$

This function decays monotonically in time. The following results are special cases:

$$F_{\nu}(0,t)=0, \tag{B19}$$

$$F_1(\rho,t)=0, \tag{B20}$$

$$F_{\nu}(\rho,0)=\frac{1-\nu}{\nu}, \tag{B21}$$

$$0\leqslant F_{\nu}(\rho,t)\leqslant\frac{1-\nu}{\nu}. \tag{B22}$$

Hence, a solution to ${}_0\mathrm{D}_t^{\nu}A=\sigma i^{\nu}A$, $A(t=0)=A_0$ can be written as

$$\frac{A}{A_0}=\frac{e^{i\sigma^{1/\nu}t}}{\nu}-F_{\nu}(\sigma i^{\nu},t). \tag{B23}$$

Additionally, the solution to ${}_0\mathrm{D}_t^{\nu}A=\sigma(-i)^{\nu}A$, $A(t=0)=A_0$ is given by

$$\frac{A}{A_0}=\frac{e^{-i\sigma^{1/\nu}t}}{\nu}-F_{\nu}\left(\frac{\sigma}{i^{\nu}},t\right). \tag{B24}$$

To recap, the ''Euler identity'' for the Mittag–Leffler function is

$$E_{\nu}(\sigma i^{\nu}t^{\nu})=\frac{e^{i\sigma^{1/\nu}t}}{\nu}-F_{\nu}(\sigma i^{\nu},t). \tag{B25}$$

In a similar fashion, a solution can be worked out for $1<\nu<2$

$${}_0\mathrm{D}_t^{\nu}A=\sigma i^{\nu}A,$$

$$A(t=0)=A_0, \tag{B26}$$

$$
{}_0\mathrm{D}_t^1 A(t=0)=A_1,
$$

$$
A=A_0\left(\frac{e^{i\sigma^{1/\nu}t}}{\nu}+F_\nu(\sigma i^\nu,t)\right)+A_1\left(\frac{e^{i\sigma^{1/\nu}t}}{\sigma^{1/\nu}\nu}-F_{\nu-1}(\sigma i^\nu,t)\right). \tag{B27}

The Lerch function and the thermodynamical functions of the ideal quantum gases

Salvino Ciccariello[a)]
Dipartimento di Fisica "G. Galilei" e unità INFM, via F. Marzolo 8, I-35131 Padova, Italy

(Received 10 January 2004; accepted 17 May 2004;
published online 9 July 2004)

The unified description of the main thermodynamical functions of the Bose and Fermi ideal gases, obtained by Lee [J. Math. Phys. **36**, 1217 (1995)] in terms of the polylogarithmic functions, can also be obtained by analytic continuation in the chemical potential owing to the analytic properties of the Lerch function that is simply related to the polylogarithmic ones. By this procedure we also show that the Fourier coefficients of the thermal Green function of the ideal Bose gas convert into those of the Fermi one. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1771481]

I. INTRODUCTION

The ideal quantum gases of Fermi and Bose[1] are two basic issues of modern physics. They yield a first rough description of the behavior of condensed matter as well as the hints for understanding superfluidity and superconductivity phenomena, the knowledge of which is actively progressing.[2,3] Even though the subject of ideal quantum gases is very old, some new interesting results were obtained in the past decade. These results point to a sort of unified description of the two systems. In fact, Lee[4] showed that the particle number density (PND) $\rho = N/V$, the pressure P, the internal energy U and the entropy S of the two ideal quantum gases can be expressed in terms of the so-called polylogarithm function[5] $\mathrm{Li}_s(z)$ [for its definition, see Eq. (17)], as follows:

$$\frac{(\lambda^D)\rho}{g} = \mathrm{sign}(\zeta)\mathrm{Li}_{D/2}(\zeta), \tag{1}$$

$$\beta P/\rho = \mathrm{Li}_{D/2+1}(\zeta)/\mathrm{Li}_{D/2}(\zeta), \tag{2}$$

$$\beta U/N = (D/2)\mathrm{Li}_{D/2+1}(\zeta)/\mathrm{Li}_{D/2}(\zeta), \tag{3}$$

$$S/Nk_{\mathrm{B}} = (D/2+1)\mathrm{Li}_{D/2+1}(\zeta)/\mathrm{Li}_{D/2}(\zeta) - \ln|\zeta|. \tag{4}$$

Here D denotes the space dimensions, $\lambda = (2\pi\beta/m)^{1/2}$ (with $\hbar = 1$) is the thermal wave-length, $\beta \equiv 1/k_{\mathrm{B}}T$ and $g = (2s+1)$, while k_{B}, T, m and s denote the Boltzman constant, the temperature, the mass and the spin of the particles, respectively. Finally, ζ is equal to z or to $-z$ depending on whether the system is respectively made up of bosons or of fermions, the fugacity z being related to the chemical potential μ of the two systems as $z \equiv e^{\beta\mu}$. The noticeable property of Eqs. (1)–(4) is that the thermodynamical quantities, scaled as reported on the left hand side (lhs) of (1)–(4), only depend on the fugacity of the system and, more importantly, that their values are given by the same analytic functions, respectively evaluated in the ranges $-\infty < \zeta \leqslant 0$ and $0 \leqslant \zeta < 1$ in the cases of the Fermi and Bose gas. A further interesting consequence of (1)–(4), valid in only the two-dimensional case, is the property that the entropy and, consequently, the specific heat at constant

a)Electronic mail: ciccariello@pd.infn.it

volume of the Bose gas, when expressed in terms of ρ and T, coincide with those of the fermion gas.[6–9] As recently shown by Anghel,[10] these properties generalize to 2-D systems obeying fractional exclusion statistics[11] related to the bosonization technique.[12]

The aim of this note is to present an alternative derivation of results (1)–(4) based on the mathematical trick of considering the chemical potential as a complex variable. The plan of the paper is as follows. In Sec. II we show that the product of grand-partition functions of the Bose and Fermi gases, respectively evaluated at $-z$ and z, is equal to one and that the analytic continuation of the grand-potential Ω_B of the Bose gas, with respect to the chemical potential, yields the grand-potential Ω_F of the Fermi gas with the reversed sign. This conclusion is made possible by the fact that the grand-potentials are expressed in terms of the Lerch function[13] that simply reduces to the polylogarithmic function for the samples under analysis. In Sec. III, we show that the same analytic continuation converts the Fourier coefficients of the thermal Green function of the Bose gas into those of the Fermi gas. By this result we show that the same property of analytic continuation, found for the grand-potentials, applies to the internal energy and the mean particle number. Finally, in Sec. IV we report our conclusive remarks.

II. ANALYTIC CONTINUATION OF THE GRAND-POTENTIAL

Throughout the paper we shall adopt the mathematical notation of Ref. 1. The grand-Hamiltonian of a quantum system of noninteracting particles of mass m and spin s is

$$\hat{K}=\hat{H}-\mu\hat{N}, \tag{5}$$

with

$$\hat{H}=\sum_{k,\sigma}\epsilon_k a^{\dagger}_{k,\sigma}a_{k,\sigma}, \quad \hat{N}=\sum_{k,\sigma}a^{\dagger}_{k,\sigma}a_{k,\sigma}$$

and the operator algebras

$$[a_{k,\sigma},a_{k',\sigma'}]_{\pm}=0, \quad [a_{k,\sigma},a^{\dagger}_{k',\sigma'}]_{\pm}=\delta_{k,k'}\delta_{\sigma,\sigma'}, \tag{6}$$

where $\epsilon_k=k^2/2m$ and σ denotes the spin index ranging from $-s$ to s. The case of fermions or bosons corresponds to taking the anticommutator or the commutator in (6). In contrast to standard definition, we assume now that μ can also take complex values in which the physical (or observable) chemical potential is recovered when μ is real. By so doing, $\hat{K}$ is no longer Hermitian, but we can still define the complex valued grand-canonical partition function $\mathcal{Z}_B$ and the complex valued grand-potential Ω_B of the ideal Bose gas by the relations

$$\mathcal{Z}_B(V,T,\mu)\equiv e^{-\beta\Omega_B(V,T,\mu)}\equiv \mathrm{Tr}[e^{-\beta\hat{K}}] \tag{7}$$

that coincide with the physical ones when μ is real. The explicit evaluation of the trace yields

$$\mathcal{Z}_B(V,T,\mu)=\prod_{j=0}^{\infty}\sum_{n=0}^{\infty}e^{-n\beta(\epsilon_j-\mu)},$$

where j labels the couple of indices $(\mathbf{k},\sigma)$. The series can be explicitly summed up under the condition that

$$\Re\mu<\min(\epsilon_0,\ldots,\epsilon_\infty)=\epsilon_0=0. \tag{8}$$

In this way, one gets

$$\mathcal{Z}_{\mathrm{B}}(V,T,\mu)=\tilde{\mathcal{Z}}_{\mathrm{B}}(V,T,z)\equiv\prod_{j=0}^{\infty}\frac{1}{1-ze^{-\beta\epsilon_j}}. \tag{9}$$

Equation (9) makes it evident that $\mathcal{Z}_{\mathrm{B}}(V,T,\mu)$ depends on μ through the fugacity. It will become clear later that $\tilde{\mathcal{Z}}_{\mathrm{B}}(V,T,z)$ is analytic throughout the complex z plane cut along the real half-axis from $z=1$ to $z=\infty$ [see (14)]. In the fermion case one finds that

$$\mathcal{Z}_{\mathrm{F}}(V,T,\mu)\equiv e^{-\beta\Omega_{\mathrm{F}}(V,T,\mu)}=\mathrm{Tr}[e^{-\beta\hat{K}}]=\tilde{\mathcal{Z}}_{\mathrm{F}}(V,T,z)\equiv\prod_{j=0}^{\infty}[1+ze^{-\beta\epsilon_j}] \tag{10}$$

with μ obeying the constraints $-\infty<\Re\mu<\infty$. Taking now $\mu=\mu'+i\pi/\beta$ in Eq. (9) [with $\mu'<0$ as required by (8)] and setting $z'=e^{\beta\mu'}$, one gets

$$\mathcal{Z}_{\mathrm{B}}(V,T,\mu'+i\pi/\beta)=\tilde{\mathcal{Z}}_{\mathrm{B}}(V,T,-z')=\prod_{j=0}^{\infty}\frac{1}{1+e^{\beta(\mu'-\epsilon_j)}}=\frac{1}{\mathcal{Z}_{\mathrm{F}}(V,T,\mu')}=\frac{1}{\tilde{\mathcal{Z}}_{\mathrm{F}}(V,T,z')}.$$

From this relation it follows that

$$\tilde{\mathcal{Z}}_{\mathrm{B}}(V,T,-z')\tilde{\mathcal{Z}}_{\mathrm{F}}(T,V,z')=1 \quad \text{if } 0\leqslant z'<1, \tag{11}$$

a relation already reported in Ref. 14 [see their Eq. (27)] and Ref. 15 [see their Eq. (23), where a minus sign is missed in the argument of one of the two functions]. Equation (11) shows that the grand-partition function of the Bose gas is functionally dependent on that of the Fermi gas and vice versa. Taking the logarithm of Eq. (9) and performing the sum over the spin states one finds

$$-\beta\Omega_{\mathrm{B}}(V,T,\mu)=-g\sum_{\mathbf{k}}\ln(1-ze^{-\beta\epsilon_{\mathbf{k}}}),$$

where $g=2s+1$. In the continuum limit one uses the property

$$\sum_{\mathbf{k}}\rightarrow\frac{V}{(2\pi)^D}\int k^{D-1}dkd\omega^D,$$

where $V=L^D$ is the box volume, $d\omega^D$ is the infinitesimal "surface" element of the unit radius hypersphere of R^D and k is the modulus of $\mathbf{k}$. The resulting integrand only depends on the modulus of $\mathbf{k}$ and the angular integration yields the area of the unit hypersphere, equal to[16] $2\pi^{D/2}/\Gamma(D/2)$. After converting to the new integration variable $x=\beta k^2/2m$ one gets

$$\frac{\lambda^D\beta\Omega_{\mathrm{B}}(V,T,\mu)}{gV}=\frac{1}{\Gamma(D/2)}\int_0^{\infty}x^{D/2-1}\ln(1-ze^{-x})dx. \tag{12}$$

We recall now the definition of the Lerch function $\Phi(z,s,v)$:[13]

$$\Phi(z,s,v)\equiv\sum_{n=0}^{\infty}\frac{z^n}{(v+n)^s}=\frac{1}{\Gamma(s)}\int_0^{\infty}\frac{x^{s-1}e^{-vx}}{1-ze^{-x}}dx, \quad |z|<1, \quad v=0,-1,..., \tag{13}$$

where the integral expression applies if $\Re v>0$ and either $|z|\leqslant 1$, $z\neq 1$, $\Re s>0$ or with $z=1$, $\Re s>1$. By this integral expression, Eq. (12) can be written as

$$\frac{\lambda^D\beta\Omega_{\mathrm{B}}(V,T,\mu)}{gV}=-\frac{1}{\Gamma(D/2)}\int_0^{\infty}dx\int_0^{z}\frac{x^{D/2-1}e^{-x}}{1-te^{-x}}dt=-\int_0^{z}\Phi(t,D/2,1)dt.$$

Assuming that $|z|<1$, we can use the reported power expansion of the Lerch function to evaluate the last integral. We find that

$$\frac{\lambda^D \beta \tilde{\Omega}_B(V,T,z)}{gV} = -z\Phi(z,D/2+1,1),$$

where $\tilde{\Omega}_B(V,T,z) \equiv \Omega_B(V,T,\mu)$. In the continuum limit the evaluation of the grand-potential of the fermion gas can be performed by the same procedure applied to Eq. (10). One finds that

$$-\frac{\lambda^D \beta \Omega_F(V,T,\mu)}{gV} = \frac{1}{\Gamma(D/2)} \int_0^\infty x^{D/2-1} \ln(1+ze^{-x})dx = \frac{1}{\Gamma(D/2)} \int_0^\infty dx \int_0^z \frac{x^{D/2-1}e^{-x}}{1+te^{-x}} dt$$

$$= \int_0^z \Phi(-t,D/2,1)dt$$

$$= z\Phi(-z,D/2+1,1).$$

Collecting the last results we obtain

$$\Omega_B(V,T,\mu) = \tilde{\Omega}_B(V,T,z) = -\left[\frac{gV}{\lambda^D \beta}\right] z\Phi(z,D/2+1,1), \tag{14}$$

$$\Omega_F(V,T,\mu) = \tilde{\Omega}_F(V,T,z) = -\left[\frac{gV}{\lambda^D \beta}\right] z\Phi(-z,D/2+1,1). \tag{15}$$

These relations deserve some comments. They show that the grand-potentials of the Bose and Fermi ideal gases depend on the chemical potential via the fugacity z and that their dependence on z is determined by a single function, i.e., the Lerch function $\Phi(z,s,v)$ with $v=1$ and $s=(D/2+1)$. The further dependence on V, m and the spin s (not to be confused with parameter s present in the Lerch and in the polylogarithmic functions) is fully specified by the factor within square brackets, while the dependence on T is partly determined by the aforesaid factor and partly contained in the fugacity definition. It is recalled now that the Lerch function is analytic throughout the z-plane cut along the real half-axis from $z=1$ to $z=\infty$ as it appears evident from the integral expression reported in (13) (see, also, Sec. 1.11 of Ref. 13). This property implies that $\Omega_B(V,T,\mu)$ is an analytic function of $\mu=\mu'+i\mu''$ within the strip delimited by $\mu''=0^+$ and $\mu''=2\pi/\beta$. Thus, setting $\mu=\mu'+i\pi/\beta$ with $-\infty<\mu'<\infty$ in (14) so as to have $0<\arg(1-z)<2\pi$, we find that

$$\Omega_B(V,T,\mu'+i\pi/\beta) = \tilde{\Omega}_B(V,T,-z') = \left[\frac{gV}{\lambda^D \beta}\right] z'\Phi(-z',D/2+1,1)$$

$$= -\tilde{\Omega}_F(V,T,z') = -\Omega_F(V,T,\mu'). \tag{16}$$

The knowledge of the quantity on the lhs of this relation is made possible by the analytic continuation, ensured by (14), of $\Omega_B(V,T,\mu)$ with respect to μ. At the same time, (16) shows that this analytic continuation yields the grand-potential (with the reversed sign) of the corresponding Fermi gas with chemical potential μ'. Thus, $\Omega_B(V,T,\mu)$ and $-\Omega_F(V,T,\mu)$ are the boundary values of the function $\Omega(V,T,w)=[gV/\lambda^D\beta]e^{\beta w}\Phi(e^{\beta w},D/2+1,1)$, analytic in the complex variable w, as $w\to\mu+i0$ with $\mu<0$ and as $w\to\mu+i\pi/\beta$ with $-\infty<\mu<\infty$, respectively. It should be noted that this property holds only true for $-\Omega_F(V,T,\mu)$ and that it does not apply to $\Omega_F(V,T,\mu)$. This property reflects the fact that the Bose and the Fermi ideal gases are physically different so that the grand-potential of the second cannot be obtained by a simple analytical continuation of the first,[17] but we must also add, so to say "by hand," a further change of sign. Before proceeding to evaluate further thermodynamical functions we add now two remarks. First,

it is simple to verify that results (14) and (15) make (11) fulfilled. Second, Eqs. (14) and (15) can be written in terms of the polylogarithm functions. These being defined as[5]

$$\mathrm{Li}_s(z) \equiv \sum_{n=0}^{\infty} \frac{z^{n+1}}{(n+1)^s}, \quad |z|<1, \tag{17}$$

it is evident that

$$\mathrm{Li}_s(z) = F(z,s) \equiv z\Phi(z,s,1), \tag{18}$$

where $F(z,s)$ is the notation adopted by Erdeley[13] (Sec. 1.11). Thus, Eqs. (14) and (15) also read

$$\frac{\lambda^D \beta \tilde{\Omega}_{\mathrm{B}}(V,T,z)}{gV} = -\mathrm{Li}_{D/2+1}(z), \tag{19}$$

$$\frac{\lambda^D \beta \tilde{\Omega}_{\mathrm{F}}(V,T,z)}{gV} = \mathrm{Li}_{D/2+1}(-z). \tag{20}$$

The entropies $S_{\mathrm{B}}(V,T,\mu)$ and $S_{\mathrm{F}}(V,T,\mu)$ of the two gases can easily be calculated by the thermodynamical relation $S=-\partial\Omega(V,T,\mu)/\partial T$, applied to (14) and (15). By the relation

$$\frac{\partial\Phi(z,s,v)}{\partial z} = \frac{1}{z}[\Phi(z,s-1,v) - v\Phi(z,s,v)],$$

one finds

$$S_{\mathrm{B}}(V,T,\mu) = \frac{gVk_{\mathrm{B}}}{\lambda^D}[(D/2+1)z\Phi(z,D/2+1,1) - \mu\beta z\Phi(z,D/2,1)] \tag{21}$$

for $\mu<0$ and

$$S_{\mathrm{F}}(V,T,\mu) = \frac{gVk_{\mathrm{B}}}{\lambda^D}[(D/2+1)z\Phi(-z,D/2+1,1) - \mu\beta z\Phi(-z,D/2,1)] \tag{22}$$

for $-\infty<\mu<\infty$. The mean numbers of bosons and fermions $N_{\mathrm{B}}(V,T,\mu)$ and $N_{\mathrm{F}}(V,T,\mu)$ and the relevant internal energies could be evaluated by the thermodynamical relations $N=-\partial\Omega/\partial\mu$ and $U=\Omega+TS+\mu N$. It looks, however, more interesting to determine these quantities by the thermal Green function $\mathcal{G}_{\alpha,\beta}(x,x')$.

III. ANALYTIC CONTINUATION OF THE THERMAL GREEN FUNCTION

Even in the presence of a complex chemical potential, it is formally possible to define the statistical operator as in Ref. 1, i.e., $\hat{\rho}_G = e^{\beta(\Omega-\hat{K})}$. In terms of the Schrödinger field operators $\hat{\psi}_\alpha(\mathbf{x},0)$ and $\hat{\psi}^\dagger_\alpha(\mathbf{x},0)$ the modified Heisenberg operators assume the form

$$\hat{\psi}_\alpha(\mathbf{x}\tau) = e^{\hat{K}\tau}\hat{\psi}_\alpha(\mathbf{x},0)e^{-\hat{K}\tau},$$

$$\hat{\psi}^\dagger_\alpha(\mathbf{x}\tau) = e^{\hat{K}\tau}\hat{\psi}^\dagger_\alpha(\mathbf{x},0)e^{-\hat{K}\tau}.$$

They clearly depend on μ (though this dependence is not explicitly reported) because $\hat{K}$ depends on μ [see Eq. (5)]. After denoting the set of variables $(\mathbf{x},\tau)$ by x, the thermal Green function is defined as

$$\mathcal{G}_{\alpha,\beta}(x,x')=-\mathrm{Tr}\{\hat{\rho}_G \mathrm{T}_\tau(\hat{\psi}_\alpha(x)\hat{\psi}^\dagger_\beta(x'))\}, \tag{23}$$

where the meaning of T_τ is reported in Sec. 23 of Ref. 1. One of the most important properties of the thermal Green function is the fact that its knowledge determines the mean value of any single particle operator $\hat{J}=\int \psi^\dagger_\alpha(\mathbf{x})J_{\alpha,\beta}(\mathbf{x})\psi_\beta(\mathbf{x})d^Dx$ through the relation

$$\langle\hat{J}\rangle=\mathrm{Tr}(\hat{\rho}_G\hat{J})=\pm\int \lim_{\mathbf{x}'\to\mathbf{x}} \lim_{\tau'\to\tau^+} (J_{\beta,\alpha}(\mathbf{x})\mathcal{G}_{\alpha,\beta}(\mathbf{x}\tau,\mathbf{x}'\tau'))d^Dx,$$

where the $+$ sign applies to fermions and the $-$ sign to bosons. It is straightforward to verify that, even in presence of a complex μ, the thermal Green function obeys the periodicity or the antiperiodicity condition for bosons and fermions, respectively. Therefore, by the same analysis reported in Ref. 1, one finds that the Fourier coefficients of the thermal Green function are

$$\mathcal{G}^0{}_{B,\alpha,\beta}(\mathbf{k},\omega_n,\mu)=\begin{cases}\dfrac{\delta_{\alpha,\beta}}{i\omega_n-(\epsilon^0{}_{\mathbf{k}}-\mu)} & \text{with even } n\\ 0 & \text{with odd } n,\end{cases} \tag{24}$$

for the ideal Bose gas and

$$\mathcal{G}^0{}_{F,\alpha,\beta}(\mathbf{k},\omega_n,\mu)=\begin{cases}\dfrac{\delta_{\alpha,\beta}}{i\omega_n-(\epsilon^0{}_{\mathbf{k}}-\mu)} & \text{with odd } n\\ 0 & \text{with even } n,\end{cases} \tag{25}$$

for the fermion one. In both equations, we have $\omega_n=n\pi/\beta$. Setting now $\mu=\mu'+i\pi/\beta$ in the denominator of (24), we find that

$$i\omega_n-(\epsilon^0{}_{\mathbf{k}}-\mu'-i\pi/\beta)=i(\omega_n+\pi/\beta)-(\epsilon^0{}_{\mathbf{k}}-\mu')=i\omega_{n+1}-(\epsilon^0{}_{\mathbf{k}}-\mu').$$

Thus, we find the interesting property that the Fourier coefficients of the bosonic thermal Green function, evaluated at $\mu=\mu'+i\pi/\beta$, convert into those of the fermionic Green function evaluated at $\mu=\mu'$, namely

$$\mathcal{G}^0{}_{B,\alpha,\beta}(\mathbf{k},\omega_n,\mu'+i\pi/\beta)=\mathcal{G}^0{}_{F,\alpha,\beta}(\mathbf{k},\omega_{n+1},\mu') \quad \forall n\in\mathcal{Z}. \tag{26}$$

We can now use Eqs. (26.6) and (26.7) of Ref. 1, adapted to the case of the free gases contained in a D-dimensional box, in order to evaluate the mean number of particle and the internal energy of the two ideal quantum gases. In the boson case, we find

$$N_{\mathrm{B}}(V,T,\mu)=-\frac{V_g}{\beta(2\pi)^D}\int d^Dk \sum_{n\ \mathrm{even}} \frac{e^{i\omega_n\eta}}{i\omega_n-(\epsilon^0{}_{\mathbf{k}}-\mu)},$$

which, by the identity (25.38) of Ref. 1, becomes

$$N_{\mathrm{B}}(V,T,\mu)=\frac{Vg}{(2\pi)^D}\int \frac{1}{e^{\beta(\epsilon^0{}_{\mathbf{k}}-\mu)}-1}d^Dk. \tag{27}$$

Setting $\mu=\mu'+i\pi/\beta$ in (27) and using (26) we obtain

$$N_{\mathrm{B}}(V,T,\mu'+i\pi/\beta)=-\frac{Vg}{\beta(2\pi)^D}\int d^Dk \sum_{n\ \mathrm{odd}} \frac{e^{i\omega_n\eta}}{i\omega_n-(\epsilon^0{}_{\mathbf{k}}-\mu')}$$

that, by identity (25.38) of Ref. 1, yields

$$N_{\mathrm{B}}(V,T,\mu'+i\pi/\beta)=-\frac{Vg}{(2\pi)^D}\int\frac{1}{e^{\beta(\epsilon^0_{\mathbf{k}}-\mu')}+1}d^Dk=-N_{\mathrm{F}}(V,T,\mu'). \tag{28}$$

In a similar way, we find that the internal energy of the Bose gas is [see Eq. (26.7) of Ref. 1]

$$\begin{aligned}U_{\mathrm{B}}(V,T,\mu)&=-\frac{Vg}{\beta(2\pi)^D}\int d^Dk\sum_{n\ \mathrm{even}}\frac{e^{i\omega_n\eta}}{2}\left[1+\frac{2\epsilon^0_{\mathbf{k}}}{i\omega_n-(\epsilon^0_{\mathbf{k}}-\mu)}\right]\\&=\frac{Vg}{(2\pi)^D}\int\frac{\epsilon^0_{\mathbf{k}}}{e^{\beta(\epsilon^0_{\mathbf{k}}-\mu)}-1}d^Dk,\end{aligned} \tag{29}$$

and that

$$\begin{aligned}U_{\mathrm{B}}(V,T,\mu'+i\pi/\beta)&=-\frac{Vg}{\beta(2\pi)^D}\int d^Dk\sum_{n\ \mathrm{odd}}\frac{e^{i\omega_n\eta}}{2}\left[1+\frac{2\epsilon^0_{\mathbf{k}}}{i\omega_n-(\epsilon^0_{\mathbf{k}}-\mu')}\right]\\&=-\frac{Vg}{(2\pi)^D}\int\frac{\epsilon^0_{\mathbf{k}}}{e^{\beta(\epsilon^0_{\mathbf{k}}-\mu')}+1}d^Dk=-U_{\mathrm{F}}(V,T,\mu').\end{aligned} \tag{30}$$

The integrals appearing in Eqs. (27)–(30) can be expressed in terms of the appropriate Lerch functions by the procedure reported in the previous section. In particular, from (27) it follows that

$$\frac{\lambda^D N_{\mathrm{B}}(V,T,\mu)}{gV}=\frac{\lambda^D\rho_{\mathrm{B}}(T,\mu)}{g}=z\Phi(z,D/2,1), \tag{31}$$

and from (28) that

$$\frac{\lambda^D\rho_{\mathrm{B}}(T,\mu'+i\pi/\beta)}{g}=-z'\Phi(-z',D/2,1)=-\frac{\lambda^D\rho_{\mathrm{F}}(T,\mu')}{g}. \tag{32}$$

Finally, Eqs. (29) and (30) convert into

$$\frac{\beta\lambda^D U_{\mathrm{B}}(V,T,\mu)}{gV}=(D/2)z\Phi(z,D/2+1,1) \tag{33}$$

and

$$\frac{\beta\lambda^D U_{\mathrm{B}}(V,T,\mu'+i\pi/\beta)}{gV}=-(D/2)z'\Phi(-z',D/2+1,1)=-\frac{\beta\lambda^D U_{\mathrm{F}}(V,T,\mu')}{gV}. \tag{34}$$

The comparison of these relations with Eqs. (14) and (15) shows that, as in the case of the classical ideal gas, the grand-potential and the internal energy of the ideal quantum gases are linearly related,[17] i.e.,

$$\Omega_{\mathrm{B}}(V,T,\mu)=-\frac{2U_{\mathrm{B}}(V,T,\mu)}{D}\quad\text{and}\quad\Omega_{\mathrm{F}}(V,T,\mu)=-\frac{2U_{\mathrm{F}}(V,T,\mu)}{D}, \tag{35}$$

which for both gases imply that

$$(1+D/2)PV=TS+\mu N. \tag{36}$$

[In passing, it is also noted that in the two-dimensional case Eqs. (35) and (36) were shown[10] to hold true for any fractional exclusion statistics.] Similarly to Eq. (16), from Eqs. (31) and (32) one concludes that $\lambda^D\rho_B(T,\mu)/g$ and $-\lambda^D\rho_F(T,\mu)/g$ are the boundary values of the analytic function $z\Phi(z,D/2,1)=e^{\beta w}\Phi(e^{\beta w},D/2,1)$ as $w\to\mu+i0$ with $\mu<0$ and $w\to\mu+i\pi/\beta$ with $-\infty<\mu<\infty$. The same property applies to $\beta\lambda^D U_B(V,T,\mu)/gV$ and to $-\beta\lambda^D U_F(V,T,\mu)/gV$ owing to (33) and (34). [The property is also proven by recalling that it is true for the grand-potentials and then using (35).] We now note that Eq. (1) immediately follows from (31) and (32) using (17) and (18). In a similar way, Eq. (2) is obtained by combining the two expressions obtained by dividing the left hand sides of (19) and (20) by $\lambda^D\rho_B/g$ and $\lambda^D\rho_F/g$, respectively. By the same procedure, starting from (33), (34), (21) and (22) one respectively recovers Eqs. (3) and (4). Since the right hand sides of (2) and (3) are analytic in the complex z-plane cut from $z=1$ to $z=\infty$ along the real axis, it follows that $\beta P/\rho$ for the Bose and the Fermi gases are the boundary values of the same analytic function $\mathrm{Li}_{D/2+1}(e^{\beta w})/\mathrm{Li}_{D/2}(e^{\beta w})=\Phi(e^{\beta w},D/2+1,1)/\Phi(e^{\beta w},D/2,1)$ as $w\to\mu'+i0$ with $-\infty<\mu'<0$ and $w\to(\mu'+i\pi/\beta)$ with $-\infty<\mu'<\infty$. In other words, $\beta P/\rho$ of the ideal Bose gas by analytic continuation in the chemical potential converts into $\beta P/\rho$ of the ideal Fermi gas. On the contrary, this property is neither true for the particle density (because the analytic continuation yields the opposite value of the density) nor for the entropy due to presence of the nonanalytic contribution $\log|\zeta|$. For the entropy, it should also be stressed that (21) and (22) only apply with real values of μ. In fact, the analytic continuation of (21) would yield $S_B(V,T,\mu+i\pi/\beta)=-S_F(V,T,\mu)+i\pi([gVk_B/\lambda^D]e^{\beta\mu}\Phi(-e^{\beta\mu},D/2,1)$ that does not coincide with the entropy (with the reversed sign) of the fermion system for the presence of the imaginary term. On the contrary, starting from (14) with $-\infty<\mu<\infty$, one rightly finds that $-(\partial\Omega_B(V,T,\mu+i\pi/\beta))/(\partial T)=-S_F(V,T,\mu)$ because the temperature derivative also acts on the imaginary part of the chemical potential.

A further advantage of having related the thermodynamical functions of the ideal quantum gases to the Lerch function is the possibility of determining analytically their behaviors as μ approaches the limiting points $-\infty$ and 0^- for the Bose gas and $-\infty$ and ∞ for the Fermi gas. This analysis can be found in Refs. 4 and 17 where the particle number fluctuations are also discussed.

IV. CONCLUSIONS

We have shown that the results obtained by Lee[4] can also be recast in the following way: the particle number density $\rho(T,\mu)$, the internal energy $U(V,T,\mu)$ or the grand-potential $\Omega(V,T,\mu)$ of the Bose and Fermi ideal gases confined to a D-dimensional box, aside from the trivial factors reported in Eqs. (31)–(34), (14) and (15), are the boundary values of the analytic functions $F(e^{\beta w},D/2)=e^{\beta w}\Phi(e^{\beta w},D/2,1)$ and $F(e^{\beta w},D/2+1)=e^{\beta w}\Phi(e^{\beta w},D/2+1,1)$, as $w\to\mu+i0$ with $\mu<0$ and $w\to\mu+i\pi/\beta$ with $-\infty<\mu<\infty$. Since the mentioned trivial factors depend on the bosonic or fermionic nature of the particle, the PND of the Fermi gas cannot be considered as the analytic continuation in the chemical potential of the PND of the Bose gas. The same happens for U_B and U_F. On the contrary, the analytic continuation in μ of U_B/N and P_B/ρ_B respectively yield U_F/N and P_F/ρ_F but these two functions do not fully determine the thermodynamics of the two systems since they are not expressed in terms of their natural variables. An interesting result, which to our knowledge does not seem to have been noted before, is the fact that the analytic continuation from μ to $\mu+i\pi/\beta$ of the Fourier coefficients of the bosonic thermal Green function exactly reproduces the Fourier coefficients of the fermionic function. If we recall that the general expression of the Fourier coefficients, in presence of a spin-independent interaction, is

$$\mathcal{G}_{\alpha,\beta}(\mathbf{k},\omega_n,\mu)=\frac{\delta_{\alpha,\beta}}{i\omega_n-(\epsilon^0_{\mathbf{k}}-\mu)-\Sigma^*(\mathbf{k},\omega_n,\mu)},$$

where $\Sigma^*(\mathbf{k},\omega_n,\mu)$ is the proper self-energy contribution, we realize that the aforesaid analytic continuation does not convert the boson proper self-energy into the fermion one. In fact, even though the Feynman graphs are the same and the substitution $\mu\to\mu+i\pi/\beta$ converts the free

boson propagator into the fermion one, this substitution does not reproduce the factor $(-1)^F$ related to possible fermion loops. Hence, the results illustrated in the paper are only valid in the noninteracting case. They look, however, interesting both for extracting the asymptotic behaviors of the thermodynamical functions and for the resulting unified picture of the boson and fermion free gases.

(Received 5 February 2004; accepted 8 April 2004; published online 12 July 2004)

In this work, the Balian–Low theorem is extended to Gabor (also called Weyl–Heisenberg) frames for subspaces and, more particularly, its relationship with the unique Gabor dual property for subspace Gabor frames is pointed out. To achieve this goal, the subspace Gabor frames which have a unique Gabor dual of type I (resp. type II) are defined and characterized in terms of the Zak transform for the rational parameter case. This characterization is then used to prove the Balian–Low theorem for subspace Gabor frames. Along the same line, the same characterization is used to prove a duality theorem for the unique Gabor dual property which is an analogue of the Ron and Shen duality theorem. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1768621]

I. INTRODUCTION

A Gabor system is a collection of functions generated by a window function $g \in L^2(\mathbb{R})$ and by translations and modulations:

$$\mathbf{G}(\alpha,\beta,g) := \{e^{2\pi i m\alpha} g(x-n\beta) : m,n \in \mathbb{Z}\},$$

where α and β are two positive parameters. Gabor systems were first proposed by Gabor (1946) for the purpose of applications in signal processing. To ensure stable reconstruction of signals, the Gabor system needs to be a frame, a concept introduced by Duffin and Schaeffer (1952) as a generalization of Riesz bases. It is well known that the condition $\alpha\beta \leqslant 1$ is both necessary and sufficient for the existence of a window function $g \in L^2(\mathbb{R})$ such that the Gabor system $\mathbf{G}(\alpha,\beta,g)$ forms a frame for $L^2(\mathbb{R})$ (cf. Daubechies, 1990 and Rieffel, 1981). Moreover, if $\alpha\beta = 1$, then every Gabor frame $\mathbf{G}(\alpha,\beta,g)$ for $L^2(\mathbb{R})$ is Riesz basis while $\mathbf{G}(\alpha,\beta,g)$ cannot be a Riesz basis for $L^2(\mathbb{R})$ when $\alpha\beta < 1$. The following is one of the fundamental results for Gabor systems. It shows that if the system $\mathbf{G}(\alpha,\beta,g)$ forms a frame for $L^2(\mathbb{R})$, the generating function g cannot be at the same time well localized in time and frequency.

Theorem 1.1 (Balian–Low Theorem): *Assume that* $\alpha\beta = 1$ *and suppose that* $g \in L^2(\mathbb{R})$ *is such that* $\mathbf{G}(\alpha,\beta,g)$ *is a frame for* $L^2(\mathbb{R})$. *Then,*

$$\left(\int_{\mathbb{R}} |xg(x)|^2 dx \right) \left(\int_{\mathbb{R}} |\omega \hat{g}(\omega)|^2 d\omega \right) = \infty. \tag{1.1}$$

Note that the Fourier transform defined by

$$\hat{g}(\omega) = \int_{\mathbb{R}} g(x) e^{-2\pi i x\omega} dx, \quad g \in L^1(\mathbb{R}) \cap L^2(\mathbb{R}) \tag{1.2}$$

[a)]Electronic mail: gabardo@mcmaster.ca
[b)]Electronic mail: dhan@pegasus.cc.ucf.edu

can be extended to all of $L^2(\mathbb{R})$ by using the isometry of the transform. The Balian–Low theorem (abbr. BLT) was first proved by Balian (1981) and Low (1985) for orthonormal bases with a gap in their proofs. The gap was later corrected and this result was generalized to Riesz bases (cf. Battle, 1988 and Daubechies, 1990). There have been, since then, some interest in generalizing the BLT to more general frameworks. For some recent progress related to different generalizations of the BLT, we refer to Benedetto *et al.* (2003a); Benedetto *et al.* (2003b); Benedetto and Powell (2004); Gröchenig *et al.* (2002), etc. In this paper we are interested in studying the BLT in the context of Gabor frames for subspaces of $L^2(\mathbb{R})$. Subspace Gabor frames have some interesting properties and, also, certain advantages. For example, the restriction $\alpha\beta\leqslant 1$ is no longer needed when working in the setting of subspace Gabor frames. To simplify the notations, we will denote by $\mathcal{M}(\alpha,\beta,g)$ the closed linear subspace generated by the Gabor system $\mathbf{G}(\alpha,\beta,g)$. We refer to Casazza and Christensen (2001); Gabardo and Han (2003a, 2001, 2003b, 2004) for some recent work on this topic. One of our goals in this paper is to prove the following generalization of the BLT:

Theorem 1.2: *Let* $\mathbf{G}(\alpha,\beta,g)$ *be a frame for* $\mathcal{M}(\alpha,\beta,g)$. *Then*

(i) *If* $\alpha\beta=1$, *then* (1.1) *always holds*.

(ii) *If* $\alpha\beta$ *is an integer larger than 1, then* (1.1) *holds whenever* $\mathbf{G}(\alpha,\beta,g)$ *is not a Riesz sequence*.

(iii) *If* $1/\alpha\beta$ *is an integer larger than 1, then* (1.1) *holds whenever the subspace* $\mathcal{M}(\alpha,\beta,g)\neq L^2(\mathbb{R})$.

We remark that the condition that $\mathbf{G}(\alpha,\beta,g)$ is not a Riesz sequence in (ii) and the condition that $\mathcal{M}(\alpha,\beta,g)\neq L^2(\mathbb{R})$ in (iii) cannot be dropped. In fact, let $g(x)=e^{-x^2}$. Then $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence when $\alpha\beta$ is an integer larger than one and $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbb{R})$ if $1/(\alpha\beta)$ is an integer larger than 1 (see Example 4.8 for details). However, it is clear that

$$\left(\int_{\mathbb{R}}|xg(x)|^2dx\right)\left(\int_{\mathbb{R}}|\omega\hat{g}(\omega)|^2d\omega\right)<\infty. \tag{1.3}$$

For Theorem 1.2, we will, in fact, obtain a more general result which shows that the Balian–Low phenomenon for subspace Gabor frames is, somewhat surprisingly, related to the unique Gabor dual property, a topic that has been investigated in Gabardo and Han (2004). One of our goals, in this paper, is to further investigate the unique Gabor dual property for subspace Gabor frames. In particular, we will give a concrete characterization for those subspace Gabor frames which have the unique Gabor dual property and we will use this result to prove Theorem 1.2. This paper is organized as follows: In Sec. II, we introduce the unique Gabor dual property and discuss the main results. Since the techniques to deal with unique Gabor dual property for the rational (i.e., the case where $\alpha\beta$ is a rational number) and the irrational cases are quite different, we will first treat the rational case in Sec. III and use the Zak-transform in that case to characterize all the functions $g\in L^2(\mathbb{R})$ such that $\mathbf{G}(\alpha,\beta,g)$ has unique Gabor dual of type I or type II. In Sec. IV, we prove our main results including Theorem 1.1, the duality theorem, and the characterization theorem for the unique Gabor dual property in the case of arbitrary parameters α and β.

II. THE UNIQUE GABOR DUAL PROPERTY AND THE MAIN RESULTS

Let us first introduce some terminology and notation that will be used throughout this paper.

A family of vectors $\{x_k\}_{k\in\mathbb{N}}$ is called a *frame* for a Hilbert space H if there exist two positive constants A and B such that

$$A\|x\|^2\leqslant\sum_{k\in\mathbb{N}}|\langle x,x_k\rangle|^2\leqslant B\|x\|^2 \tag{2.1}$$

holds for all $x\in H$. The two optimal constants in (2.1) are called the *frame bounds*. When $A=B=1$, the frame is called a *normalized tight* frame. A family $\{x_k\}$ is called *Bessel* when the second inequality in (2.1) hold. A Bessel sequence $\{y_n\}$ is called a *dual* for a frame $\{x_n\}$ if

$$x=\sum_{n\in\mathbb{N}}\langle x,y_n\rangle x_n \tag{2.2}$$

holds for all $x\in H$, where the convergence of the series in (2.2) is unconditional in the Hilbert space norm.

For a frame $\{x_k\}$, we define the associated *analysis operator* T by

$$Tx=\sum_{k\in\mathbb{N}}\langle x,x_k\rangle e_k,\quad x\in H,$$

where $\{e_k\}$ is the standard orthonormal basis for $\ell^2(\mathbb{N})$. Since $\{x_k\}$ is a frame, Range(T) is a closed linear subspace of $\ell^2(\mathbb{N})$. The associated *frame operator* S is defined to be T^*T. It is a bounded, positive and invertible operator from H onto itself. By the definition of S, it is clear that $\{S^{-1}x_n\}$ is a dual of $\{x_n\}$. It is also called the *standard dual* of the frame $\{x_n\}$.

Given two positive parameter α and β, we define the collection of unitary operators on $L^2(\mathbb{R})$, $\mathcal{U}_{\alpha,\beta}$, by

$$\mathcal{U}_{\alpha,\beta}=\{\mathcal{E}_{m\alpha}\mathcal{T}_{n\beta}:m,n\in\mathbb{Z}\},$$

where the two unitary operators $\mathcal{E}_{m\alpha}$ and $\mathcal{T}_{n\beta}$ are defined by

$$(\mathcal{E}_{m\alpha}f)(x)=e^{2\pi im\alpha x}f(x)\ \text{ and }\ (\mathcal{T}_{n\beta}f)(x)=f(x-n\beta),\quad f\in L^2(\mathbb{R}).$$

For convenience, we also write $g_{m\alpha,n\beta}=\mathcal{E}_{m\alpha}\mathcal{T}_{n\beta}g$, when $g\in L^2(\mathbb{R})$.

If $\mathbf{G}(\alpha,\beta,g)$ is a frame for $\mathcal{M}(\alpha,\beta,g)$, then we say that $\mathbf{G}(\alpha,\beta,g)$ is a *subspace Gabor frame*. We also use T_g to denote the analysis operator associated with $\mathbf{G}(\alpha,\beta,g)$. Let $S=T_g^*T_g$ be the frame operator associated with a subspace Gabor frame $\mathbf{G}(\alpha,\beta,g)$. Then $S^{-1}g\in\mathcal{M}(\alpha,\beta,g)$, and $(S^{-1}g)_{m\alpha,n\beta}=S^{-1}(g_{m\alpha,n\beta})$. Therefore, $\mathbf{G}(\alpha,\beta,S^{-1}g)$ is the standard dual of $\mathbf{G}(\alpha,\beta,g)$. Since we are dealing with Gabor frames for subspaces, we can have several ways of choosing a dual frame which also has the ''Gabor form.'' In particular, we will now introduce two different type of duals, which we call type I and type II duals.

Definition 2.1: Let $\mathbf{G}(\alpha,\beta,g)$ *be a subspace Gabor frame for* $\mathcal{M}(\alpha,\beta,g)$.

(i) *If* $\mathbf{G}(\alpha,\beta,h)$ *is a Bessel sequence such that* $h\in\mathcal{M}(\alpha,\beta,g)$ *and*

$$f=\sum_{m,n}\langle f,h_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta},\ f\in\mathcal{M}(\alpha,\beta,g),$$

then $\mathbf{G}(\alpha,\beta,h)$ *is called a Gabor dual of type I for* $\mathbf{G}(\alpha,\beta,g)$

(ii) *If* $h\in L^2(\mathbb{R})$ (*not necessarily in* $\mathcal{M}(\alpha,\beta,g)$) *is such that* $\mathbf{G}(\alpha,\beta,h)$ *is a Bessel sequence,* $Range(T_h)$ *is contained in* $Range(T_g)$ *and*

$$f=\sum_{m,n}\langle f,h_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta}$$

holds for every $f\in\mathcal{M}(\alpha,\beta,g)$, *then* $\mathbf{G}(\alpha,\beta,h)$ *is called a Gabor dual of type II for* $\mathbf{G}(\alpha,\beta,g)$.

Roughly speaking, for Gabor duals of type I, we are interested in the existence of a dual window function which belongs to the subspace generated by the original frame, while for Gabor dual of type II, the dual window function is not required to be in that subspace, but we require the coefficient sequence $\{\langle f,h_{m\alpha,n\beta}\rangle\}$ to be in the ''analyzing space'' Range(T_g) of the frame $\mathbf{G}(\alpha,\beta,g)$. It is obvious that there is only one Gabor dual of type I if $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence. However, this is not the only case where there could be a unique Gabor dual of type I. A similar situation occurs for the Gabor dual of type II whose uniqueness is guaranteed by the

density in $L^2(\mathbb{R})$ of the subspace generated by the original frame, even though that condition is not always necessary. In this paper, we are interested in finding conditions on g under which there is only one window function generating a Gabor dual of type I (resp. type II) for the frame $\mathbf{G}(\alpha,\beta,g)$.

For type I Gabor duals, we obtained the following characterization theorem in Gabardo and Han (2004; see also Gabardo, 2003):

Theorem 2.2: *Let $\mathbf{G}(\alpha,\beta,g)$ be a normalized Gabor tight frame for $\mathcal{M}(\alpha,\beta,g)$. Then, the following are equivalent:*

(i) *$\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type I.*

(ii) *$\langle g,UVg\rangle=\langle g,VUg\rangle$ holds for all $U,V\in\mathcal{U}_{\alpha,\beta}$.*

(iii) *$e^{2\pi i(nk-m\ell)\alpha\beta}\langle g,g_{m\alpha,n\beta}\rangle=\langle g,g_{m\alpha,n\beta}\rangle$ for all m, n, k, $\ell\in\mathbb{Z}$.*

To prove Theorem 1.2, we need the following more concrete characterization for the unique Gabor dual property. Note that the assumption that $\mathbf{G}(\alpha,\beta,g)$ be a normalized tight frame is not needed here.

Theorem 2.3: *Let $\mathbf{G}(\alpha,\beta,g)$ be a subspace Gabor frame for $\mathcal{M}(\alpha,\beta,g)$.*

A. *If $\alpha\beta$ is irrational, then*

(A_1) *$\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type I if and only if $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence.*

(A_2) *$\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type II if and only if $\mathbf{G}(\alpha,\beta,g)$ is a frame for the whole space $L^2(\mathbb{R})$.*

B. *Suppose that $\alpha\beta$ is rational. Let $\alpha\beta=p/q$ where p, q are positive integers with $gcd(p,q)=1$, and let $\mathcal{G}$ be the corresponding Zak-matrix associated with g (as in* (3.1)*). Then,*

(B_1) *$\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type I if and only if $rank(\mathcal{G})\in\{0,q\}$.*

(B_2) *$\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type II if and only if $rank(\mathcal{G})\in\{0,p\}$.*

The well-known Ron–Shen duality principle (Ron and Shen, 1997) tells us that $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence (hence, $\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type I) if and only if $\mathbf{G}(1/\beta,1/\alpha,g)$ is a frame for $L^2(\mathbb{R})$ (hence, $\mathbf{G}(1/\beta,1/\alpha,g)$ has a unique Gabor dual of type II). Theorem 2.3 allows us to get the following *duality theorem* which is consistent with the Ron–Shen principle:

Theorem 2.4 (Duality Theorem): *Let $\{g_{m\alpha,n\beta}\}$ be a subspace Gabor frame. Then, $\{g_{m\alpha,n\beta}\}$ has a unique Gabor dual of type I if and only if $\{g_{m/\beta,n/\alpha}\}$ has a unique Gabor dual of type II.*

As a consequence of Theorem 2.3, we have:

Corollary 2.5: Let $\{g_{m\alpha,n\beta}\}$ be a subspace Gabor frame.

(i) *If $\alpha\beta$ is an integer, then $\{g_{m\alpha,n\beta}\}$ has a unique Gabor dual of type I.*

(ii) *If $\alpha\beta=1/q$ for some integer q, then $\{g_{m\alpha,n\beta}\}$ has a unique Gabor dual of type II.*

(iii) *If $\alpha\beta=1$, then $\{g_{m\alpha,n\beta}\}$ has a unique Gabor dual of both type I and type II.*

Proof: Statement (*i*) follows from (B_1) of Theorem 2.3 since $\mathcal{G}$ is a $1\times p$ matrix function and thus its rank can only be 0 or 1. Statement (ii) follows from (B_2) of Theorem 2.3 in a similar way and statement (iii) is deduced immediately from (i) and (ii). Note that (i) can also be obtained from Theorem 2.2, since the unitary operators in $\mathcal{U}_{\alpha,\beta}$ commute when $\alpha\beta$ is an integer, and that (ii) follows from (i) and Theorem 2.4. □

It is known that $\{g_{m\alpha,n\beta}\}$ can be a Riesz basis for all of $L^2(\mathbb{R})$ only when $\alpha\beta=1$. In this case, $\{g_{m\alpha,n\beta}\}$ has unique Gabor dual of both types. Therefore, it is natural to ask whether the unique Gabor dual property is related to the Balian–Low phenomenon. We shall prove the following:

Theorem 2.6: *Let $\{g_{m\alpha,n\beta}\}$ be a subspace Gabor frame which has a unique Gabor dual of type I. Then, one of the following must holds:*

(i) *$\{g_{m\alpha,n\beta}\}$ is a Riesz sequence.*

(ii) $(\int_{\mathbb{R}}|xg(x)|^2dx)(\int_{\mathbb{R}}|\omega\hat{g}(\omega)|^2d\omega)=\infty$.

Combining this result together with Theorem 2.4, we get

Corollary 2.7: Let $\{g_{m\alpha,n\beta}\}$ *be a subspace Gabor frame which has a unique Gabor dual of type II. Then, one of the following must hold:*

(i) $\{g_{m\alpha,n\beta}\}$ *is a frame for the whole space* $L^2(\mathbb{R})$.
(ii) $(\int_{\mathbb{R}}|xg(x)|^2dx)(\int_{\mathbb{R}}|\omega\hat{g}(\omega)|^2d\omega)=\infty$.

III. THE ZAK-TRANSFORM CHARACTERIZATION

As we mentioned in the Introduction, in order to prove our main results, different techniques are needed depending on whether $\alpha\beta$ is rational or irrational. In this section, we first deal with the rational case.

Suppose $\alpha\beta=p/q$, where p,q are positive integers with $\gcd(p,q)=1$. We will denote by $\mathcal{M}_{m,n}$ the set of $m\times n$ matrices with complex entries. If $g\in L^2(\mathbb{R})$, we denote by $\mathcal{Z}_\alpha g$ the Zak transform of g defined by

$$\mathcal{Z}_\alpha g(t,\nu)=\alpha^{-1/2}\sum_{k\in\mathbb{Z}} g\left(\frac{t-k}{\alpha}\right)e^{2\pi ik\nu},$$

and associate with g the matrix function $\mathcal{G}(t,\nu)$, taking value in $\mathcal{M}_{q,p}$, defined by

$$\mathcal{G}_{r,s}(t,\nu)=\mathcal{Z}_\alpha g\left(t-r\frac{p}{q},\nu+\frac{s}{p}\right),\quad 0\leqslant r\leqslant q-1,\ 0\leqslant s\leqslant p-1, \tag{3.1}$$

for a. e. (t,ν) in $[0,1)\times[0,1/p)$.

The following result will be needed. It was proved in Gabardo and Han, 2003 in the case $\alpha=1$, although the general case can be handled in a very similar way.

Proposition 3.1: Let g *and* α, β *as above. Then, the following are equivalent.*

(a) $\mathbf{G}(\alpha,\beta,g)$ *is a subspace Gabor frame for* $\mathcal{M}(\alpha,\beta,g)$.
(b) *There exist two constants* C_1, $C_2>0$ *such that*
$$C_1\mathcal{G}\mathcal{G}^*\leqslant(\mathcal{G}\mathcal{G}^*)^2\leqslant C_2\mathcal{G}\mathcal{G}^*,$$
a. e. on $[0,1)\times[0,1/p)$.
(c) *There exist two constants* C_1, $C_2>0$ *such that*
$$C_1\mathcal{G}^*\mathcal{G}\leqslant(\mathcal{G}^*\mathcal{G})^2\leqslant C_2\mathcal{G}^*\mathcal{G},$$
a. e. on $[0,1)\times[0,1/p)$.

Lemma 3.2: Let g *and* α, β *as above and let* $f\in L^2(\mathbb{R})$ *have a Zak transform denoted by* $\mathcal{Z}_\alpha f=F$. *Then, for each* m, $n\in\mathbb{Z}$ *and each* $r=0,\ldots,q-1$, *we have*

$$\langle f,g_{m\alpha,(nq+r)\beta}\rangle=\int_0^1\int_0^{1/p}e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\overline{\mathcal{G}_{r,l}(t,\nu)}F(t,\nu+l/p)d\nu dt.$$

Proof: First note that

$$\begin{aligned}(\mathcal{Z}_\alpha g_{m\alpha,(nq+r)\beta})(t,\nu)&=\alpha^{-1/2}\sum_{k\in\mathbb{Z}}e^{2\pi im\alpha(t-k/\alpha)}g\left(\frac{t-k}{\alpha}-(nq+r)\beta\right)e^{2\pi ik\nu}\\&=\alpha^{-1/2}\sum_{k\in\mathbb{Z}}e^{2\pi imt}g\left(\frac{t-k-(nq+r)\frac{p}{q}}{\alpha}\right)e^{2\pi ik\nu}\\&=\alpha^{-1/2}e^{2\pi imt}\sum_{k\in\mathbb{Z}}g\left(\frac{t-k-np-r\frac{p}{q}}{\alpha}\right)e^{2\pi ik\nu}\end{aligned}$$

$$= \alpha^{-1/2} e^{2\pi imt} \sum_{k\in\mathbb{Z}} g\left(\frac{t-k-r\frac{p}{q}}{\alpha}\right) e^{2\pi i(k-np)\nu}$$

$$= e^{2\pi imt} e^{-2\pi inp\nu} \mathcal{Z}_\alpha g\left(t-r\frac{p}{q},\nu\right).$$

Using the unitarity of the Zak transform as a mapping from $L^2(\mathbb{R})$ to $L^2(I\times I)$, where $I=[0,1)$, we have, for $0\leqslant r\leqslant q-1$ and for $m,n\in\mathbb{Z}$,

$$\langle f, g_{m\alpha,(nq+r)\beta}\rangle = \int_{\mathbb{R}} f(x)\overline{g_{m\alpha,(nq+r)\beta}(x)}dx = \int_I\int_I F(t,\nu)e^{-2\pi imt}e^{2\pi inp\nu}\overline{\mathcal{Z}_\alpha g\left(t-r\frac{p}{q},\nu\right)}d\nu dt$$

$$= \int_0^1\int_0^{1/p} e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\overline{\mathcal{Z}_\alpha g\left(t-r\frac{p}{q},\nu+l/p\right)}F(t,\nu+l/p)d\nu dt$$

$$= \int_0^1\int_0^{1/p} e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\overline{\mathcal{G}_{r,l}(t,\nu)}F(t,\nu+l/p)d\nu dt,$$

which proves the lemma. □

The following result is known (Zibulski and Zeevi, 1997) and will be needed later.

Proposition 3.3: Let g and α, β as above. Then, the following are equivalent.

(a) $\mathbf{G}(\alpha,\beta,g)$ *is a Bessel system in* $L^2(\mathbb{R})$.

(b) *There exists* $C>0$ *such that*

$$\|\mathcal{G}(t,\nu)\|\leqslant C, \quad \text{a. e. on } [0,1)\times\left[0,\frac{1}{p}\right),$$

where $\|.\|$ *denotes the matrix-norm of a matrix in* $\mathcal{M}_{q,p}$.

(c) $\mathcal{Z}_\alpha g$ *belongs to* $L^\infty([0,1)\times[0,1))$.

We will make use of the following fact which is intuitively clear.

Lemma 3.4: If Ω *is a measure space and* $\mathcal{G}:\Omega\to\mathcal{M}_{m,n}$, *where m and n are positive integers, is measurable, then the function* $rank(G):\Omega\to\mathbb{R}$ *is also measurable.*

Proof: The measurability of rank(G) can easily be deduced from the fact that the rank of a matrix $A\neq 1$ is the unique integer $n\geqslant 0$ such that any submatrix of A of size $n+1\times n+1$ has zero determinant and such that there exists a least one submatrix of A of size $n\times n$ with a nonzero determinant. □

The following result is well known and provides a proof of the incompleteness of $\mathcal{M}(\alpha,\beta,g)$ in $L^2(\mathbf{R})$ when $\alpha\beta>1$, in the rational case (Daubechies, 1990 and Zibulski and Zeevi, 1997). We provide a proof here for the reader's comvenience.

Proposition 3.5: Let g be in $L^2(\mathbb{R})$ *and let* $\alpha\beta=p/q$ *as above. Then, the identity* $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbf{R})$ *holds if and only if*

$$rank(\mathcal{G})=p \quad a.\ e.\ on\ [0,1)\times\left[0,\frac{1}{p}\right).$$

Proof: Let f be a function in $L^2(\mathbb{R})$ with Zak transform $\mathcal{Z}_\alpha f=F\in L^2(I\times I)$. Using Lemma 3.2, we can write, for $0\leqslant r\leqslant q-1$ and for m, $n\in\mathbb{Z}$, that

$$\langle f, g_{m\alpha,(nq+r)\beta}\rangle = \int_0^1\int_0^{1/p} e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\overline{\mathcal{G}_{r,l}(t,\nu)}F(t,\nu+l/p)d\nu dt.$$

Since the function defined by the sum inside this last integral belongs to $L^1(I\times I)$, a function $f \in L^2(\mathbb{R})$ is orthogonal to $\mathcal{M}(\alpha,\beta,g)$ if and only if

$$\sum_{l=0}^{p-1} \overline{\mathcal{G}_{r,l}(t,\nu)}F(t,\nu+l/p)=0, \quad \text{for a. e. } (t,\nu)\in[0,1)\times[0,1/p), \tag{3.2}$$

for each $r=0,...,q-1$. Now, if $\operatorname{rank}(\mathcal{G})=p$ for a. e. $(t,\nu)\in[0,1)\times[0,1/p)$, it follows that $F(t,\nu+l/p)=0$ for a. e. $(t,\nu)\in[0,1)\times[0,1/p)$ and thus that $F=0$ as a function in $L^2(I\times I)$. Hence $f=0$ and $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbb{R})$. On the other hand, if $\operatorname{rank}(\mathcal{G})<p$ on a subset of $[0,1)\times[0,1/p)$ with positive measure, then it is easy to construct a nonzero function $F\in L^2(I\times I)$ satisfying (3.2). The function $f:=\mathcal{Z}_\alpha^{-1}F$ is thus a nonzero function in $L^2(\mathbb{R})$ orthogonal to $\mathcal{M}(\alpha,\beta,g)$ which, then, must be a proper subspace of $L^2(\mathbb{R})$. □

Definition 3.6: Let $g\in L^2(\mathbb{R})$ and let α and β be positive numbers. Then we say that the system $\mathbf{G}(\alpha,\beta,g)$ has the *Riesz Property* if, whenever

$$\sum_{m,m\in\mathbb{Z}} c_{m,n}g_{m\alpha,n\beta}=0,$$

where the series converges unconditionally in $L^2(\mathbb{R})$ and $\{c_{m,n}\}\in\ell^2(\mathbb{Z}^2)$, we must have that $c_{m,n}=0$, for all $(m,n)\in\mathbb{Z}^2$.

Remark 3.7: Clearly, if the system $\mathbf{G}(\alpha,\beta,g)$ is a Riesz basis for its span, then it must have the Riesz property.

The following result is essentially known Balan *et al.* (2000). We state it in a slightly more general form that does not require the system to form a frame for its closed linear span.

Proposition 3.8: Let g be in $L^2(\mathbb{R})$ and let $\alpha\beta=p/q$ as above. Then, the system $\mathbf{G}(\alpha,\beta,g)$ has the Riesz property if and only if

$$rank(\mathcal{G})=q \quad a.\ e.\ on\ [0,1)\times\left[0,\frac{1}{p}\right).$$

Proof: Suppose that

$$\sum_{\substack{m,n\in\mathbb{Z}\\ 0\leqslant r\leqslant q-1}} c_{m,nq+r}g_{m,nq+r}=0,$$

where the series converges unconditionally in $L^2(\mathbb{R})$ and $\{c_{m,n}\}\in\ell^2(\mathbb{Z}^2)$. Then, if $f\in L^2(\mathbb{R})$ and $\mathcal{Z}_\alpha f=F$, we have

$$\begin{aligned}
0&=\sum_{\substack{m,n\in\mathbb{Z}\\ 0\leqslant r\leqslant q-1}} c_{m,nq+r}\int_{\mathbb{R}} f(x)\overline{g_{m,nq+r}(x)}dx\\
&=\sum_{\substack{m,n\in\mathbb{Z}\\ 0\leqslant r\leqslant q-1}} c_{m,nq+r}\int_0^1\int_0^1 F(t,\nu)e^{-2\pi imt}e^{2\pi inp\nu}\overline{\mathcal{Z}_\alpha g\left(t-r\frac{p}{q},\nu\right)}d\nu dt\\
&=\int_0^1\int_0^{1/p}\sum_{\substack{m,n\in\mathbb{Z}\\ 0\leqslant r\leqslant q-1}} c_{m,nq+r}e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\mathcal{G}_{r,l}(t,\nu)F(t,\nu+l/p)d\nu dt.
\end{aligned}$$

For $r=0,...,q-1$, let H_r be the functions in $L^2([0,1)\times[0,1/p))$ defined by the series

$$H_r(t,\nu)=\sum_{m,n\in\mathbb{Z}} c_{m,nq+r}e^{-2\pi imt}e^{2\pi inp\nu}, \quad \text{for } r=0,...,q-1,$$

and, for $0\leqslant l\leqslant p-1$, define the functions $F_l(t,\nu)=F(t,\nu+l/p)$, for $(t,\nu)\in[0,1)\times[0,1/p)$. We have thus

$$\int_0^1\int_0^{1/p}\sum_{0\leqslant r\leqslant q-1}H_r(t,\nu)\sum_{l=0}^{p-1}\mathcal{G}_{r,l}(t,\nu)F_l(t,\nu)d\nu dt=0,$$

and, since the functions F_l can be arbitrary functions in $L^2([0,1)\times[0,1/p))$, it follows that, for each $l=0,...,p-1$,

$$\sum_{0\leqslant r\leqslant q-1}H_r(t,\nu)\mathcal{G}_{r,l}(t,\nu)=0 \quad \text{a. e. on } [0,1)\times[0,1/p). \tag{3.3}$$

Therefore, the system $\mathbf{G}(\alpha,\beta,g)$ has the Riesz property if, whenever the functions $H_r\in L^2([0,1)\times[0,1/p))$, for $r=0,...q-1$, and (3.3) holds for each $l=0,...,p-1$, then $H_r=0$, for each $r=0,...,q-1$. This is clearly equivalent to $\operatorname{rank}(\mathcal{G})=q$ for a. e. $(t,\nu)\in[0,1)\times[0,1/p)$. □

Our next goal is to provides a characterization through the Zak transform for systems admitting a unique dual of type I. We note that the standard dual, $S^{-1}g$, where S is the frame operator, is always a dual of type I. Before stating the result, we need the following intermediary steps.

Lemma 3.9: Let $g,h\in L^2(\mathbb{R})$, let $\alpha\beta=p/q$ as above and consider the associated measurable functions $\mathcal{G}$ and $\mathcal{H}$ with values in $\mathcal{M}_{q,p}$ defined as in (3.1). Then, the function $h\in L^2(\mathbb{R})$ belongs to $\mathcal{M}(\alpha,\beta,g)$ if and only if there exists a measurable function $\mathcal{A}$ with values in $\mathcal{M}_{q,q}$ such that

$$\mathcal{H}(t,\nu)=\mathcal{A}(t,\nu)\mathcal{G}(t,\nu), \quad \text{for a. e. } (t,\nu)\in[0,1)\times\left[0,\frac{1}{p}\right).$$

Proof: First note that, if $h\in\mathcal{M}(\alpha,\beta,g)$, then $h_{m\alpha,n\beta}\in\mathcal{M}(\alpha,\beta,g)$ for each $m,n\in\mathbb{Z}$. Thus, $h\in\mathcal{M}(\alpha,\beta,g)$ if and only if, for any $f\in L^2(\mathbb{R})$, the fact that f is orthogonal to $\mathcal{M}(\alpha,\beta,g)$ implies that f is also orthogonal to $\mathcal{M}(\alpha,\beta,h)$. Denoting by F the Zak transform of the function $f\in L^2(\mathbb{R})$, we have, as before, that

$$\langle f,g_{m\alpha,(nq+r)\beta}\rangle=\int_0^1\int_0^{1/p}e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\overline{\mathcal{G}_{r,l}(t,\nu)}F(t,\nu+l/p)d\nu dt,$$

for $m,n\in\mathbb{Z}$ and $0\leqslant r\leqslant q-1$. Thus, letting for $l=0,...,p-1$, $F_l(t,\nu)=F(t,\nu+l/p)$, where $(t,\nu)\in[0,1)\times[0,1/p)$, we see that the fact that f is orthogonal to $\mathcal{M}(\alpha,\beta,g)$ is equivalent to

$$\sum_{l=0}^{p-1}\mathcal{G}_{r,l}(t,\nu)\overline{F_l(t,\nu)}=0, \quad \text{for a. e. } (t,\nu)\in[0,1)\times\left[0,\frac{1}{p}\right). \tag{3.4}$$

Similarly, f is orthogonal to $\mathcal{M}(\alpha,\beta,h)$ if and only if

$$\sum_{l=0}^{p-1}\mathcal{H}_{r,l}(t,\nu)\overline{F_l(t,\nu)}=0, \quad \text{for a. e. } (t,\nu)\in[0,1)\times\left[0,\frac{1}{p}\right). \tag{3.5}$$

Clearly, the implication (3.4)⇒(3.5) holds if and only if, for a. e. $(t,\nu)\in[0,1)\times[0,1/p)$, the rows of the matrix $\mathcal{H}(t,\nu)$ can be expressed as linear combination of those of the matrix $\mathcal{G}(t,\nu)$. This is equivalent to the existence, for a. e. such (t,ν) of a matrix $\mathcal{A}(t,\nu)$ in $\mathcal{M}_{q,q}$ such that $\mathcal{H}(t,\nu)=\mathcal{A}(t,\nu)\mathcal{G}(t,\nu)$. Since $\mathcal{A}$ must clearly be measurable, this proves the lemma. □

Lemma 3.10: Let G belong to $\mathcal{M}_{q,p}$. Then, G has the property that, whenever A belongs to $\mathcal{M}_{q,q}$, the identity $G^*AG=0$ implies that $AG=0$ if and only if $rank(G)\in\{0,q\}$.

Proof: It is clear that the property $G^*AG=0$ implies that $AG=0$ holds if $\operatorname{rank}(G)=0$, i.e., if $G=0$ and if $\operatorname{rank}(G)=q$, i.e., if the range of G is all of C^q, where we view G has a linear mapping from $\mathbf{C}^p$ to $\mathbf{C}^q$. Conversely, if $\operatorname{rank}(G)\notin\{0,q\}$, consider the subspace N of $\mathbf{C}^q$ defined by

$N=G(\mathbf{C}^p)$. Then, by assumption $N\neq\{0\}$ and $N\neq\mathbf{C}^q$. Hence, there exists a nonzero linear mapping from N to $N^{\perp}$. We can extend this mapping to a linear mapping A from C^q to itself by defining A to be 0 on $N^{\perp}$. Let **u.v** denote the standard inner product between two vectors **u** and **v** in $\mathbf{C}^p$. If **x** and **y** belong to $\mathbf{C}^p$, we have

$$G^*AG\mathbf{x}.y=AG\mathbf{x}.Gy=0,$$

so $G^*\,AG=0$, but $AG\mathbf{x}\neq 0$, for some $\mathbf{x}\in\mathbf{C}^p$ by construction, which shows that the property mentioned above cannot hold. □

Remark: The lemma above also holds for measurable matrix-valued functions G and A of the corresponding size if the equalities in the lemma are replaced by a. e. equalities, since, as can be easily shown, all the operations involved in the construction of A, in the case where $\text{rank}(G)\notin\{0,q\}$, can be made to be measurable. The same remark holds, with the obvious changes, for the analoguous Lemma 3.13.

Now we are ready to prove (B_1) of Theorem 2.3:

Theorem 3.11: *Let $\alpha\beta=p/q$ as above and suppose that the system $\mathbf{G}(\alpha,\beta,g)$ is a frame for $\mathcal{M}(\alpha,\beta,g)$. Then, the system $\mathbf{G}(\alpha,\beta,g)$ admits a unique dual of type I (which is thus given by the standard dual) if and only if*

$$rank\ \ (\mathcal{G})\in\{0,q\}\quad \text{a. e. } on\ \ [0,1)\times\left[0,\frac{1}{p}\right).$$

Proof: The existence of two different duals of type I for the system $\mathbf{G}(\alpha,\beta,g)$ is easily seen to be equivalent to the existence of a nonzero function $h\in M$ such that the system $\mathbf{G}(\alpha,\beta,g)$ is Bessel and which satisfies

$$\sum_{m,n\in\mathbb{Z}}\langle f,g_{m\alpha,n\beta}\rangle h_{m\alpha,n\beta}=0,\quad \forall f\in L^2(\mathbb{R}),$$

or, equivalently,

$$\sum_{m,n\in\mathbb{Z}}\langle f_1,g_{m\alpha,n\beta}\rangle\overline{\langle f_2,h_{m\alpha,n\beta}\rangle}=0,\quad \forall f_1,f_2\in L^2(\mathbb{R}). \tag{3.6}$$

Let F_1 and F_2 denote the Zak transform of f_1 and f_2, respectively, and let $\mathcal{G}$ and $\mathcal{H}$ be the functions with valued in $\mathcal{M}_{q,p}$ associated with g and h, respectively, defined as in (3.1). We have

$$\begin{aligned}\sum_{m,n\in\mathbb{Z}}\langle f_1,g_{m\alpha,n\beta}\rangle\overline{\langle f_2,h_{m\alpha,n\beta}\rangle}&=\sum_{\substack{m,n\in\mathbb{Z}\\0\le r\le q-1}}\int_0^1\int_0^1 F_1(t,\nu)e^{-2\pi imt}e^{2\pi inp\nu}\overline{\mathcal{Z}_\alpha g\left(t-r\frac{p}{q},\nu\right)}\,d\nu dt\\&\quad\times\int_0^1\int_0^1\overline{F_2(t,\nu)}e^{2\pi imt}e^{-2\pi inp\nu}\mathcal{Z}_\alpha h\left(t-r\frac{p}{q},\nu\right)d\nu dt\\&=\sum_{\substack{m,n\in\mathbb{Z}\\0\le r\le q-1}}\int_0^1\int_0^{1/p}e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\overline{\mathcal{G}_{r,l}(t,\nu)}F_1(t,\nu+l/p)\,d\nu dt\\&\quad\times\int_0^1\int_0^{1/p}e^{2\pi imt}e^{-2\pi inp\nu}\sum_{l=0}^{p-1}\mathcal{H}_{r,l}(t,\nu)\overline{F_2(t,\nu+l/p)}\,d\nu dt.\end{aligned}$$

Letting $F_l^1(t,\nu)=F_1(t,\nu+l/p)$ and $F_l^2(t,\nu)=F_2(t,\nu+l/p)$ for $(t,\nu)\in[0,1)\times[0,1/p)$, we can write this last expression, using Parseval's identity as

$$\sum_{r=0}^{q-1}\int_0^1\int_0^{1/p}\sum_{l,m=0}^{p-1} F_l^1(t,\nu)\mathcal{G}_{l,r}^*(t,\nu)\mathcal{H}_{r,m}(t,\nu)\overline{F_m^2(t,\nu)}\,d\nu dt$$

$$=\int_0^1\int_0^{1/p}\sum_{l,m=0}^{p-1}(\mathcal{G}^*\mathcal{H})_{l,m}(t,\nu)F_l^1(t,\nu)\overline{F_m^2(t,\nu)}\,d\nu dt$$

Since the functions $F_l^1, F_m^2, l,m=0,\ldots,p-1$, can be arbitrary in $L^2([0,1)\times[0,1/p))$, the identity (3.6) is equivalent to $\mathcal{G}^*\mathcal{H}=0$ a.e. on $[0,1)\times[0,1/p)$. Since $h\in M$, Lemma 3.9 shows the existence of a measurable function $\mathcal{A}$ defined on $[0,1)\times[0,1/p)$ and with values in $\mathcal{M}_{q,q}$ such that $\mathcal{H}=\mathcal{A}\mathcal{G}$. Hence, it follows that $\mathcal{G}^*\mathcal{A}\mathcal{G}=0$ a.e. on $[0,1)\times[0,1/p)$. If $\operatorname{rank}(\mathcal{G})\in\{0,q\}$, Lemma 3.10 shows that $\mathcal{A}\mathcal{G}=\mathcal{H}=0$ a.e. on $[0,1)\times[0,1/p)$ and thus that $h=0$, so the dual of type I must be unique in this case. On the other hand, if $\operatorname{rank}(\mathcal{G})\notin\{0,q\}$ on a subset of $[0,1)\times[0,1/p)$ having positive measure, we can easily construct a $\mathcal{M}_{q,p}$-valued matrix function $\mathcal{A}$ such that $\mathcal{G}^*\mathcal{A}\mathcal{G}=0$ and $\mathcal{A}\mathcal{G}\neq 0$ on a set of positive measure. The function $h\in L^2(\mathbb{R})$ corresponding to $\mathcal{H}=\mathcal{A}\mathcal{G}$ is then a nonzero function in M satisfying (3.6), and adding a nonzero multiple of that function to any dual of type I produces a dual of type I different than the original one. □

Our next goal is to prove (B_2) of Theorem 2.3. We need the following two lemmas.

Lemma 3.12: Let $\alpha\beta=p/q$ as above and assume that the Gabor systems $\mathbf{G}(\alpha,\beta,g)$ and $\mathbf{G}(\alpha,\beta,h)$ are both Bessel. Consider the associated measurable functions $\mathcal{G}$ and $\mathcal{H}$ with values in $\mathcal{M}_{q,p}$ defined as in (3.1). Let $T_g:L^2(\mathbb{R})\to\ell^2(\mathbb{Z}^2)$ and $T_h:L^2(\mathbb{R})\to\ell^2(\mathbb{Z}^2)$ be the analyzing operators associated with the systems $\mathbf{G}(\alpha,\beta,g)$ and $\mathbf{G}(\alpha,\beta,h)$, respectively. Then, $\overline{Range(T_h)}$ is contained in $\overline{Range(T_g)}$ if and only if there exists a measurable $\mathcal{M}_{q,p}$-valued function $\mathcal{B}$ such that

$$\mathcal{H}(t,\nu)=\mathcal{G}(t,\nu)\mathcal{B}(t,\nu)\quad for\ a.\ e.\ (t,\nu)\in[0,1)n\left[0,\frac{1}{p}\right).$$

Proof: First note that, using Proposition 3.1, the entries of both $\mathcal{G}$ and $\mathcal{H}$ belong to $L^\infty([0,1)\times[0,1/p))$ since the systems $\mathbf{G}(\alpha,\beta,g)$ and $\mathbf{G}(\alpha,\beta,h)$ are both assumed to be Bessel. We will first give a description through the Zak transform of the sequences which are orthogonal to $\overline{\operatorname{Range}(T_g)}$. A sequence $\{a_{m,n}\}$ is orthogonal to $\overline{\operatorname{Range}(T_g)}$ if and only if

$$\sum_{\substack{m,n\in\mathbb{Z}\\0\leqslant r\leqslant q-1}} a_{m,nq+r}\langle f,g_{m\alpha,(nq+r)\beta}\rangle=0,\quad \forall f\in L^2(\mathbb{R}).$$

Letting $F=\mathcal{Z}_\alpha f$ and defining $F_l(t,\nu)=\mathcal{Z}_\alpha f(t,\nu+l/p)$, where $(t,\nu)\in[0,1)\times[0,1/p)$, for each $l=0,\ldots,p-1$, this identity can also be written, using Lemma 3.2, as

$$\int_0^1\int_0^{1/p}\sum_{0\leqslant r\leqslant q-1}\sum_{m,n\in\mathbb{Z}} a_{m,nq+r}e^{-2\pi imt}e^{2\pi inp\nu}\sum_{l=0}^{p-1}\overline{\mathcal{G}_{r,l}(t,\nu)}F_l(t,\nu)\,d\nu dt=0,$$

for each function $F_0,\ldots,F_{l-1}\in L^2([0,1)\times[0,1/p))$. If we denote by K_r the functions in $L^2([0,1)\times[0,1/p))$ defined by the series

$$K_r(t,\nu)=\sum_{m,n\in\mathbb{Z}} a_{m,nq+r}e^{-2\pi imt}e^{2\pi inp\nu},$$

for $0\leqslant r\leqslant q-1$, we can simply express the previous identity as

$$\sum_{0\leqslant r\leqslant q-1} K_r(t,\nu)\overline{\mathcal{G}_{r,l}(t,\nu)}=0\quad \text{a. e. on } [0,1)\times\left[0,\frac{1}{p}\right),\tag{3.7}$$

for each $l=0,...,p-1$. Similarly, the fact that the sequence $\{a_{m,n}\}$ is orthogonal to $\overline{\text{Range}(T_h)}$ is equivalent to

$$\sum_{0\leq r\leq q-1} K_r(t,\nu)\overline{\mathcal{H}_{r,l}(t,\nu)}=0 \quad \text{a. e. on } [0,1)\times\left[0,\frac{1}{p}\right), \tag{3.8}$$

for each $l=0,...,p-1$. Thus the inclusion $\overline{\text{Range}(T_h)}\subset\overline{\text{Range}(T_g)}$ can be rephrased by stating that, whenever functions $K_0,\ldots,K_{q-1}\in L^2([0,1)\times[0,1/p))$ exist such that (3.7) holds, then so does (3.8). This last statement is equivalent to the fact that, for a. e. (t,ν), the rows of $\mathcal{H}(t,\nu)$ are linear combinations of those of $\mathcal{G}(t,\nu)$, i.e., to the existence of a measurable $\mathcal{M}_{p,p}$-valued function $\mathcal{B}$ defined on $[0,1)\times[0,1/p)$ such that $\mathcal{H}=\mathcal{G}\mathcal{B}$ almost everywhere. □

Lemma 3.13: Let G belong to $\mathcal{M}_{q,p}$. Then, G has the property that, whenever B belongs to $\mathcal{M}_{p,p}$, the identity $GBG^*=0$ implies that $GB=0$ if and only if $rank(G)\in\{0,p\}$.

Proof: Viewing G as a linear mapping from $\mathbf{C}^p$ to $\mathbf{C}^q$ and G^* as a linear mapping from $\mathbf{C}^q$ to $\mathbf{C}^p$ and using the fact that $\text{rank}(G)=\text{rank}(G^*)$, it is clear that, if $\text{rank}(G)=p$, then $G^*(\mathbf{C}^q)=\mathbf{C}^p$, and thus $GBG^*=0$ implies $GB=0$. The same implication obviously holds if $\text{rank}(G)=0$, i.e., if $G=0$. Conversely, if $0<\text{rank}(G)<p$, then $N=G^*(\mathbf{C}^q)$ is a subspace of $\mathbf{C}^p$ different than $\{0\}$ and $\mathbf{C}^p$. There exists thus a nonzero linear mapping from N to $N^\perp$. Extending this linear mapping to all of $\mathbf{C}^p$ by defining it to be 0 on $N^\perp$, we obtain in this way a linear mapping $B:\mathbf{C}^p\to\mathbf{C}^p$ such that $GBG^*=0$ but $GB\neq 0$. This proves the lemma. □

We can now state state our Zak transform characterization for the unique dual of type II, which complete the proof of (B_2) of Theorem 2.3.

Theorem 3.14: *Let $g\in L^2(\mathbb{R})$, let $\alpha\beta=p/q$ as above and suppose that the system $\mathbf{G}(\alpha,\beta,g)$ is a frame for $\mathcal{M}(\alpha,\beta,g)$. Then, the system $\mathbf{G}(\alpha,\beta,g)$ admits a unique dual of type II (which is thus given by the standard dual) if and only if*

$$rank\ (\mathcal{G})\in\{0,p\} \quad a.\ e.\ on\ [0,1)\times\left[0,\frac{1}{p}\right).$$

Proof: The existence of two different duals of type II for the system $\mathbf{G}(\alpha,\beta,g)$ is easily seen to be equivalent to the existence of a nonzero function $h\in L^2(\mathbb{R})$ such that the system $\mathbf{G}(\alpha,\beta,h)$ is Bessel, which satisfies $\overline{\text{Range}(T_h)}\subset\overline{\text{Range}(T_g)}$ and

$$\sum_{m,n\in\mathbb{Z}}\langle f,h_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta}=0, \quad \forall f\in M,$$

or, equivalently,

$$\sum_{m,n\in\mathbb{Z}}\langle f_1,g_{m\alpha,n\beta}\rangle\overline{\langle f_2,h_{m\alpha,n\beta}\rangle}=0, \quad \forall f_1\in L^2(\mathbb{R}),\ \forall f_2\in M. \tag{3.9}$$

As in the proof of Theorem 3.11, we can write the left side of the equality (3.9) as

$$\int_0^1\int_0^{1/p}\sum_{i,j=0}^{p-1}(\mathcal{G}^*\mathcal{H})_{i,j}(t,\nu)F_i^1(t,\nu)\overline{F_j^2(t,\nu)}\,d\nu dt,$$

where $F_i^1(t,\nu)=\mathcal{Z}_\alpha f_1(t,\nu+i/p)$, $F_j^2(t,\nu)=\mathcal{Z}_\alpha f_2(t,\nu+j/p)$ for $(t,\nu)\in[0,1)\times[0,1/p)$. Furthermore, letting $f_2=g_{m,nq+r}\in M$, where $m,n\in\mathbb{Z}$, and, using the fact that

$$\mathcal{Z}_\alpha g_{m,nq+r}(t,\nu)=e^{2\pi imt}e^{-2\pi inp\nu}\mathcal{Z}_\alpha g\left(t-r\frac{p}{q},\nu\right),$$

we deduce from (3.9) that

$$\int_0^1 \int_0^{1/p} \sum_{i,j=0}^{p-1} (\mathcal{G}^*\mathcal{H})_{i,j}(t,\nu) F_i^1(t,\nu) e^{-2\pi i m t} e^{2\pi i n p \nu} \overline{\mathcal{G}_{r,j}(t,\nu)} d\nu dt = 0,$$

for every $F_0^1,\ldots,F_{p-1}^1 \in L^2([0,1)\times[0,1/p)$, for every m, $n \in \mathbb{Z}$ and for every integer r from 0 to $q-1$, which is equivalent to $\mathcal{G}^*\mathcal{H}\mathcal{G}^* = 0$ a. e. on $[0,1)\times[0,1/p)$. Since $\overline{\text{Range}(T_h)} \subset \overline{\text{Range}(T_g)}$, Lemma 3.12 shows the existence of a $\mathcal{M}_{q,p}$-valued measurable function $\mathcal{B}$ defined on $[0,1)\times[0,1/p)$ such that $\mathcal{H} = \mathcal{G}\mathcal{B}$. Hence, it follows that $\mathcal{G}^*\mathcal{G}\mathcal{B}\mathcal{G}^* = 0$ a.e. on $[0,1)\times[0,1/p)$ which is equivalent to $\mathcal{G}\mathcal{B}\mathcal{G}^* = 0$ a.e. on $[0,1)\times[0,1/p)$. If $\text{rank}(\mathcal{G}) \in \{0,p\}$, Lemma 13 shows that $\mathcal{G}\mathcal{B} = \mathcal{H} = 0$ a. e. on $[0,1)\times[0,1/p)$ and thus that $h = 0$, so the dual of type II must be unique in this case. On the other hand, if $\text{rank}(\mathcal{G}) \notin \{0,p\}$ on a subset of $[0,1)\times[0,1/p)$ having positive measure, we can easily construct a $\mathcal{M}_{p,p}$-valued function $\mathcal{B}$ such that $\mathcal{G}\mathcal{B}\mathcal{G}^* = 0$ and $\mathcal{G}\mathcal{B} \neq 0$ on a set of positive measure. The function $h \in L^2(\mathbb{R})$ corresponding to $\mathcal{H} = \mathcal{G}\mathcal{B}$ is then a nonzero function in M satisfying (3.9), and adding a nonzero multiple of that function to any dual of type II produces a dual of type II different than the original one. □

IV. PROOFS OF THE MAIN RESULTS

Proof of Theorem 2.3

Part *B* of Theorem 2.3 is proved in Theorems 3.11 and 3.14. Therefore, all that is left to prove is part *A*.

We can assume that $\mathbf{G}(\alpha,\beta,g)$ is a normalized tight Gabor frame for $\mathcal{M}(\alpha,\beta,g)$, since the system $\mathbf{G}(\alpha,\beta,g_1)$, (where $g_1 = S^{-1/2}g$ and S is the associated frame operator), is a normalized tight frame for $\mathcal{M}(\alpha,\beta,g)$ and it is easy to check that this system admits a unique dual of type I (resp. type II) if and only if the original one does.

(i) Since $\alpha\beta$ is irrational, it follows that identity (iii) of Theorem 2.2 holds for all m, n, k, $\ell \in \mathbb{Z}$ if and only if $\{g_{m\alpha,n\beta}\}$ is orthogonal. Hence, (A_1) holds.

To prove (A_2), we first assume that $\mathbf{G}(\alpha,\beta,g)$ is a frame for the whole space $L^2(\mathbb{R})$. Let $\mathbf{G}(\alpha,\beta,h)$ be a dual of type II for $\mathbf{G}(\alpha,\beta,g)$. We need to show that $g = h$. Since $\text{Range}(T_h) \subset \text{Range}(T_g)$, there exists a function $f \in L^2(\mathbb{R})$ such that $T_h(g) = T_g(f)$ which implies that $\langle g, h_{m\alpha,n\beta}\rangle = \langle f, g_{m\alpha,n\beta}\rangle$ holds for all m, $n \in \mathbb{Z}$. Also note that

$$g = \sum_{m,n\in\mathbb{Z}} \langle g, h_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta}$$

and

$$f = \sum_{m,n\in\mathbb{Z}} \langle f, g_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta}.$$

Thus $f = g$, which implies that

$$\langle g, h_{m\alpha,n\beta}\rangle = \langle g, g_{m\alpha,n\beta}\rangle, \quad m,n \in \mathbb{Z},$$

and so,

$$\langle g_{-m\alpha,-n\beta}, h\rangle = \langle g_{-m\alpha,-n\beta}, g\rangle, \quad m,n \in \mathbb{Z}.$$

Therefore $h = g$ since $\mathbf{G}(\alpha,\beta,g)$ is a frame for the whole space $L^2(\mathbb{R})$.

Now assume that $\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type II. Let us show that $\mathcal{M}(\alpha,\beta,g) = L^2(\mathbb{R})$. Suppose, to the contrary, that $\mathcal{M}(\alpha,\beta,g) \neq L^2(\mathbb{R})$. Let P be the orthogonal projection onto M. Then $P \in \mathcal{A}'_{\alpha,\beta}$. Since $\mathcal{A}'_{\alpha,\beta}$ is a factor von Neumann algebra, and $0 \neq P \neq I$, by a standard result about in von Neumann algebra theory (cf. Takesaki, 1979), there exists a nonzero partial isometry $V \in \mathcal{A}'_{\alpha,\beta}$ with initial space contained in M and final space contained in $M^\perp$. Let $h = g + Vg$. Then $h \neq g$ since $Vg \neq 0$ (In fact, if $Vg = 0$, then $Vg_{m\alpha,n\beta} = 0$ for all m, $n \in \mathbb{Z}$, which

implies $V=0$). We claim that $\mathbf{G}(\alpha,\beta,h)$ is a type II Gabor dual of $\mathbf{G}(\alpha,\beta,g)$ which will yield a contradiction. Indeed, clearly $\mathbf{G}(\alpha,\beta,h)$ is Bessel since $V\in\mathcal{A}'_{\alpha,\beta}$. Secondly, for any $f\in L^2(\mathbb{R})$, we have

$$T_h(f)=\{\langle f,h_{m\alpha,n\beta}\rangle\}=\{\langle f,g_{m\alpha,n\beta}+(Vg)_{m\alpha,n\beta}\rangle\}=\{\langle f,(I+V)g_{m\alpha,n\beta}\rangle\}=T_g((I+V^*)f).$$

Thus, Range$(T_h)\subset$Range(T_g). Finally, note that M is orthogonal to Range(V). So

$$\sum_{m,n}\langle f,h_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta}=\sum_{m,n}\langle f,g_{m\alpha,n\beta}+Vg_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta}=\sum_{m,n}\langle f,g_{m\alpha,n\beta}\rangle g_{m\alpha,n\beta}=f$$

holds for every $f\in M$. Therefore, $\mathbf{G}(\alpha,\beta,h)$ is a type II Gabor dual of $\mathbf{G}(\alpha,\beta,g)$ as claimed. □

In order to prove our duality theorem (Theorem 2.4), we need a few more lemmas. The first lemma follows from the identity

$$\mathcal{F}(g_{m\alpha,n\beta})=e^{2\pi imn\alpha\beta}(\mathcal{F}g)_{-n\beta,m\alpha},\quad m,n\in\mathbb{Z}$$

(where $\mathcal{F}(h)$ denotes the Fourier transform of h) and the definition of type I and II Gabor dual property. The second one is elementary and well-known.

Lemma 4.1: Let $\mathbf{G}(\alpha,\beta,g)$ be a subspace Gabor frame for $\mathcal{M}(\alpha,\beta,g)$. Then $\mathbf{G}(\alpha,\beta,g)$ has unique Gabor dual of type I (resp. type II) if and only if $\mathbf{G}(\beta,\alpha,\hat{g})$ has unique Gabor dual of type I (resp. type II).

Lemma 4.2: Let p and q be relatively prime positive integer. For $k\in\{0,...,q-1\}$, define $\sigma(k)$ to be the unique integer in $\{0,...,q-1\}$ such that

$$kp=\sigma(k)+r(k)q,$$

where $r(k)$ in an integer. Then $\sigma:\{0,...,q-1\}\to\{0,...,q-1\}$ is a bijection.

Lemma 4.3: Let $A=(A_{k,l})_{q\times p}$, where $0\leq k\leq q-1$ and $0\leq l\leq p-1$ be a $q\times p$ matrix and let α_k, $0\leq k\leq q-1$, and β_l, $0\leq l\leq p-1$, be nonzero complex numbers. Then the rank of the matrix $B=B_{k,l}$ defined by

$$B_{k,l}=A_{k,l}\alpha_k\beta_l,\quad k=0,...,q-1,\ l=0,...p-1,$$

is the same as that of A.

Proof: This follows easily from the fact that if L is a subset of $\{0,...,p-1\}$ and c_l, $l\in L$, are complex numbers, then the implication

$$\sum_{l\in L}A_{k,l}c_l=0,\ k=0,...q-1\Rightarrow c_l=0,\ l\in L$$

is equivalent to

$$\sum_{l\in L}B_{k,l}c_l=0,\ k=0,...q-1\Rightarrow c_l=0,\ l\in L$$

□

Lemma 4.4: Let $A=(A_{k,l})_{q\times p}$, where $0\leq k\leq q-1$ and $0\leq l\leq p-1$ be a $q\times p$ matrix, let σ be a permutation of the set $\{0,...,q-1\}$ and let τ be a permutation of the set $\{0,...,p-1\}$. Then the rank of the matrix $C=C_{k,l}$ defined by

$$C_{k,l}=A_{\sigma(k),\tau(l)}\quad k=0,...,q-1,\ l=0,...p-1,$$

is the same as that of A.

Proof: This, again, follows easily from the fact that, if m is a positive integer, the implication

$$\sum_{l\in L} A_{k,l}c_l=0,\ \ k=0,...\Rightarrow c_l=0,\ \ l\in L,$$

for any subset L of $\{0,...,p-1\}$ of cardinality m is equivalent to

$$\sum_{l\in L} B_{k,l}c_l=0,\ \ k=0,...\Rightarrow c_l=0,\ \ l\in L,$$

for any subset L of $\{0,...,p-1\}$ of cardinality m. □

Now we are ready to prove Theorem 2.4.

Proof of Theorem 2.4

Case 1: $\alpha\beta$ is irrational

From Theorem 2.3, $\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type I if and only if $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence. Thus, using the Ron and Shen duality theorem, $\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type I is in turn equivalent to $\mathbf{G}(1/\beta,1/\alpha,g)$ is a Gabor frame for the whole space $L^2(\mathbb{R})$. Therefore, again by Theorem 2.3, this is equivalent to the condition that $\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type II.

Case 2: $\alpha\beta=p/q$ with $\gcd(p,q)=1$ is rational

In the computations above, we use the fact that

$$\mathcal{Z}_\alpha g(t+m,\nu)=e^{2\pi im\nu}\mathcal{Z}_\alpha g(t,\nu),\quad \mathcal{Z}_\alpha g(t,\nu+m)=\mathcal{Z}_\alpha g(t,\nu),$$

and

$$\mathcal{Z}_\alpha \hat{g}(t,\nu)=e^{2\pi it\nu}\mathcal{Z}_{1/\alpha}g(-\nu,t) \tag{4.1}$$

for any $g\in L^2(\mathbb{R})$ and an integer m.

By Lemma 4.1 and Theorem 2.3 (B) we have that $G(1/\beta,1/\alpha,g)$ has a unique dual of type II if and only $G(1/\alpha,1/\beta,\hat{g})$ has a unique dual of type II, which is in turn equivalent to the condition that $\widetilde{\mathcal{G}}=(\widetilde{\mathcal{G}}_{k,l})_{p\times q}$ has a rank in $\{0,q\}$ (a.e.), where $\widetilde{\mathcal{G}}_{k,l}=\mathcal{Z}_{1/\alpha}\hat{g}(t-kq/p,\nu+l/q)$ has a rank in $\{0,q\}$ $(0\leqslant k\leqslant p-1$ and $0\leqslant l\leqslant q-1)$

From (4.1), we have that $\widetilde{\mathcal{G}}_{k,l}=e^{2\pi i(t-kq/p)(\nu+l/q)}\mathcal{Z}_\alpha g(-\nu-l/q,t-kq/p)$.

Now let σ be the permutation of $\{0,...,q-1\}$ defined by

$$l=\sigma(l)p+r(l)q,\quad l=0,....,q-1,$$

where $\sigma(l)\in\{0,...,q-1\}$ and $r(l)\in\mathbb{Z}$ (Lemma 4.2). Therefore, we have

$$\begin{aligned}
\widetilde{\mathcal{G}}_{k,l}&=e^{2\pi i(t-kq/p)(\nu+l/q)}\mathcal{Z}_\alpha g\left(-\nu-\frac{l}{q},t-k\frac{q}{p}\right)\\
&=e^{2\pi i(t-kq/p)(\nu+\sigma(l)p/q+r(l))}\mathcal{Z}_\alpha g\left(-\nu-\sigma(l)\frac{p}{q}-r(l),t-k\frac{q}{p}\right)\\
&=e^{2\pi i(t-kq/k)(\nu+\sigma(l)p/q+r(l))}e^{2\pi i(t-kq/p)(-r(l))}\mathcal{Z}_\alpha g\left(-\nu-\sigma(l)\frac{p}{q},t-k\frac{q}{p}\right)\\
&=e^{2\pi i(t-kq/p)(\nu+\sigma(l)p/q)}\mathcal{Z}_\alpha g\left(-\nu-\sigma(l)\frac{p}{q},t-k\frac{q}{p}\right)\\
&=e^{2\pi it\nu}e^{2\pi it(\sigma(l)p/q)}e^{2\pi i(-kq/p)\nu}\mathcal{Z}_\alpha g\left(-\nu-\sigma(l)\frac{p}{q},t-k\frac{q}{p}\right).
\end{aligned}$$

Now, letting τ be the permutation of $\{0,...,p-1\}$ defined by

$$-kq=\tau(k)+s(k)p, \quad k=0,...,p-1,$$

where $\tau(k)\in\{0,...,p-1\}$ and $s(k)\in\mathbb{Z}$ (Lemma 4.2), we can rewrite the matrix entry above as

$$e^{2\pi it\nu}e^{2\pi it(\sigma(l)p/q)}e^{2\pi i(\tau(k)/p+s(k))\nu}\mathcal{Z}_\alpha g\left(-\nu-\sigma(l)\frac{p}{q},t+\frac{\tau(k)}{p}+s(k)\right),$$

which is equal to

$$e^{2\pi it\nu}e^{2\pi it(\sigma(l)p/q)}e^{2\pi i(\tau(k)/p+s(k))\nu}\mathcal{Z}_\alpha g\left(-\nu-\sigma(l)\frac{p}{q},t+\frac{\tau(k)}{p}\right).$$

Using Lemmas 4.3 and 4.4, the rank of that last matrix is the same as that of the matrix with (k, l) entries:

$$\mathcal{Z}_\alpha g\left(-\nu-l\frac{p}{q},t+\frac{k}{p}\right)$$

Finally, by (B_1) of Theorem 2.3, this matrix has a rank in $\{0,q\}$ if and only if $G(\alpha,\beta,g)$ has a unique dual of type I, which proves the result. □

Our next goal is to prove Theorem 2.6 and Corollary 2.7 which state that if g is a nonzero smooth and well localized window function such that the system $\mathbf{G}(\alpha,\beta,g)$ is a frame for its closed linear span, then this system admits a unique dual of type I if and only if it is a Riesz basis for its closed linear span and the system $\mathbf{G}(\alpha,\beta,g)$ admits a unique dual of type II if and only if its closed linear span is $L^2(\mathbb{R})$. We first need the following lemma.

Lemma 4.5: Let $g\in L^2(\mathbb{R})$ satisfy

$$\int_{\mathbf{R}}x^2|g(x)|^2dx<\infty \quad and \quad \int_{\mathbb{R}}\xi^2|\hat{g}(\xi)|^2d\xi<\infty.$$

Then, for a. e. $t\in[0,1)$, $\mathcal{Z}_\alpha g(t,.)$ is a continuous function of the second variable and for a. e. $\nu\in[0,1)$, $\mathcal{Z}_\alpha g(.,\nu)$ is a continuous function of the first variable.

Proof: To show that, for a. e. $t\in[0,1)$, $\mathcal{Z}_\alpha g(t,\nu)$ is a continuous function of ν, it is enough to show, that, as a function of ν, the series defining the Zak transform of g is an absolutely convergent Fourier series for a. e. $t\in[0,1)$. This last fact follows easily from Cauchy–Schwartz inequality since,

$$\int_{[0,1)}\sum_{k\neq 0,1}\left|g\left(\frac{t-k}{\alpha}\right)\right|=\alpha\int_{|u|\geqslant 1}|g(u)|du\leqslant\alpha\left[\int_{|u|\geqslant 1}u^2|g(u)|^2du\right]^{1/2}\left[\int_{|u|\geqslant 1}\frac{1}{u^2}du\right]^{1/2}<\infty.$$

To prove the second part of our assertion, we use the first part and the fact that

$$\mathcal{Z}_\alpha\hat{g}(t,\nu)=e^{2\pi it\nu}\mathcal{Z}_{1/\alpha}g(-\nu,t),$$

for any $g\in L^2(\mathbb{R})$. □

Remark 4.6: The previous lemma can also be proved by using well known properties of Sobolev spaces, since our assumptions on g are equivalent to the fact that $\mathcal{Z}_\alpha g$, $(\partial/\partial t)\mathcal{Z}_\alpha g$ and $(\partial/\partial\nu)\mathcal{Z}_\alpha g$ are in $L^2_{\mathrm{loc}}(\mathbb{R}^2)$ (see Daubechies, 1992).

We complete the proofs of Theorem 2.6 and Corollary 2.7 by proving the following result.

Theorem 4.7: *Let $\alpha\beta=p/q$ and let $g\in L^2(\mathbb{R})$ with $g\neq 0$. Suppose, furthermore, that the system $\mathbf{G}(\alpha,\beta,g)$ is a frame for $\mathcal{M}(\alpha,\beta,g)$ and that*

$$\int_{\mathbf{R}} |xg(x)|^2 dx < \infty \quad \text{and} \quad \int_{\mathbb{R}} |\omega \hat{g}(\omega)|^2 d\omega < \infty.$$

Then,

(a) *The system* $\mathbf{G}(\alpha,\beta,g)$ *admits a unique dual of type I if and only if it forms a Riesz basis for* $\mathcal{M}(\alpha,\beta,g)$.
(b) *The system* $\mathbf{G}(\alpha,\beta,g)$ *admits a unique dual of type II if and only if the identity* $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbb{R})$ *holds.*

Proof: It is clear that if the system $\mathbf{G}(\alpha,\beta,g)$ forms a Riesz basis for M, then the standard dual is the unique dual of type I (see the statements of Proposition 3.8 and Theorem 3.11), and that, if $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbb{R})$, then the standard dual is the unique dual of type II (see the statements of Proposition 3.5 and Theorem 3.14). Conversely, if g satisfies the conditions of the theorem and the system $\mathbf{G}(\alpha,\beta,g)$ admits a unique dual of type I, let $\mathcal{G}$ be the measurable $\mathcal{M}_{q,p}$-valued function defined by (3.1) on the set $[0,1)\times[0,1/p)$. Since the system $\mathbf{G}(\alpha,\beta,g)$ is a frame for $\mathcal{M}(\alpha,\beta,g)$, the equivalence of (a) and (b) in Proposition 3.1 shows the existence of two positive constants C_1 and C_2 such that

$$C_1\mathcal{G}\mathcal{G}^* \leqslant (\mathcal{G}\mathcal{G}^*)^2 \leqslant C_2\mathcal{G}\mathcal{G}^*, \tag{4.2}$$

a. e. on $[0,1)\times[0,1/p)$. By Theorem 3.11, the system $\mathbf{G}(\alpha,\beta,g)$ admits a unique dual of type I if and only if $\operatorname{rank}(\mathcal{G})=0$ or q a. e. on $[0,1)\times[0,1/p)$. Since the rank of $\mathcal{G}\mathcal{G}^*$ is the same as that of $\mathcal{G}$, it follows that, for a.e. $(t,\nu)\in[0,1)\times[0,1/p)$, the $q\times q$ matrix $(\mathcal{G}\mathcal{G}^*)(t,\nu)$ is either identically zero or invertible. On the set where $(\mathcal{G}\mathcal{G}^*)(t,\nu)$ is invertible, (4.1) reduces to the inequalities

$$C_1 I \leqslant \mathcal{G}\mathcal{G}^* \leqslant C_2 I, \tag{4.3}$$

where I denote the $q\times q$ identity matrix. Let $h(t,\nu)$ denote the first entry of $(\mathcal{G}\mathcal{G}^*)(t,\nu)$, i.e., $(\mathcal{G}\mathcal{G}^*)_{0,0}(t,\nu)$. Then, $\mathcal{G}\mathcal{G}^*$ is the zero $q\times q$ matrix on the set where $h=0$ and $\mathcal{G}\mathcal{G}^*$ is invertible on the set where $h\geqslant C_1$. By Lemma 4.5, $h(t,.)$ is continuous for a. e. $t\in[0,1)$. Hence, for a. e. $t\in[0,1)$, the function $\nu\mapsto h(t,\nu)$ is either identically zero or larger than C_1 for all $\nu\in[0,1/p)$. Therefore, if E is the subset of $[0,1)\times[0,1/p)$ where $\mathcal{G}\mathcal{G}^*$ is invertible, then E must thus be a Cartesian product of the form $E=E_1\times[0,1/p)$, where E_1 is a measurable subset of $[0, 1)$, modulo a set of zero measure. Similarly, since, by Lemma 4.5, the function $t\mapsto h(t,\nu)$ is continuous for a. e. $\nu\in[0,1/p)$, E must also have the form $E=[0,1)\times E_2$, where E_2 is a measurable subset of $[0,1/p)$, modulo a set of zero measure. Since $g\neq 0$, E must have positive measure and thus $E=[0,1)\times[0,1/p)$, modulo a set of zero measure, i.e., the rank of $\mathcal{G}\mathcal{G}^*$ is equal to q a. e. on $[0,1)\times[0,1/p)$. Proposition 3.5 shows then that the system $\mathbf{G}(\alpha,\beta,g)$ is a Riesz basis for $\mathcal{M}(\alpha,\beta,g)$. To prove that, under the conditions of the theorem, if the system $\mathbf{G}(\alpha,\beta,g)$ admits a unique dual of type II, then $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbb{R})$, we use similar arguments and, in particular, the equivalence of (a) and (c) in Proposition (3.1) as well as Proposition 3.8. □

Proof of Theorem 1.2

By Theorem 2.3, the subspace Gabor frame $\mathbf{G}(\alpha,\beta,g)$ has a unique Gabor dual of type I whenever $\alpha\beta$ is an integer. Therefore, we can apply Theorem 2.6.

First assume that $\alpha\beta=1$. If $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbb{R})$, then it is well-known that $\mathbf{G}(\alpha,\beta,g)$ is a Riesz basis for $L^2(\mathbb{R})$. Thus (1.1) holds by the Balian–Low theorem (Theorem 1.1). Otherwise, it is known that $\mathbf{G}(\alpha,\beta,g)$ cannot be a Riesz sequence (cf. Gabardo, 20xx). Therefore, we also have (1.1) by Theorem 2.5. Similarly, (ii) follows immediately from Theorem 2.6 and (iii) from Corollary 2.7 □

Finally we give an example showing that the condition in Theorem 1.2 cannot be dropped.

Example 4.8: Let $g(x)=e^{-x^2}$. Then

$$\left(\int_{\mathbb{R}} |xg(x)|^2 dx \right) \left(\int_{\mathbb{R}} |\omega \hat{g}(\omega)|^2 d\omega \right) < \infty$$

and $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence when $\alpha\beta$ is an integer larger than 1. We only need to check that $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence. We can assume that $\alpha=1$ and $\beta=n>1$. Since g is Gaussian, the Zak-transform of g has a single zero on the unit square $[0,1]\times[0,1]$ (Janssen, 1981; see also Janssen, 2003). Also, the associated Zak-transform matrix for $\mathbf{G}(\alpha,\beta,g)$ is the row matrix:

$$\mathcal{G}(t,\nu)=[Zg(t,\mu),Zg(t,\nu+1/n),\ldots,Zg(t,\nu+(n-1)/n)].$$

Hence, $\mathcal{G}\mathcal{G}^*(t,\nu)=\Sigma_{j=0}^{n-1}|Zg(t,\nu+j/n)|^2$ is a continuous function with no zeros on $[0,1]\times[0,1/n]$ (because $n>1$) and is, therefore, bounded from below. It is also true that $\mathcal{G}\mathcal{G}^*(t,\nu)$ is bounded. Thus, by Propositions 3.1 and 3.8, $\mathbf{G}(\alpha,\beta,g)$ is a Riesz sequence. Similar arguments using Propositions 3.1 and 3.5 show that, when $1/(\alpha\beta)$ is an integer larger than 1, then $\mathcal{M}(\alpha,\beta,g)=L^2(\mathbb{R})$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 8 AUGUST 2004

Bounds on the dragging rate of slowly and differentially rotating relativistic stars

M. J. Pareja
Departamento de Física Teórica II, Facultad de Ciencias Físicas, Universidad Complutense de Madrid, E–28040 Madrid, Spain

(Received 16 May 2003; accepted 20 March 2004; published online 12 July 2004)

For relativistic stars rotating slowly and differentially with a positive angular velocity, some properties in relation to the positiveness of the rate of rotational dragging and of the angular momentum density are derived. Moreover, the proof for the bounds on the rotational mass-energy, which we have generalized (outside the slow rotation limit) in a previous paper, is briefly exposed. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1767987]

I. INTRODUCTION

In a previously published paper[1] we have given general bounds on the dragging rate (angular velocity of locally nonrotating observers, or angular velocity of cumulative dragging) of a differentially rotating relativistic stellar configuration; however, the validity of these bounds depends heavily on the underlying *rotation law*, which must be compatible with the field equations.

In the prescription for calculating a *slowly* and differentially rotating relativistic stellar configuration the field equations are expanded in powers of a *fluid angular velocity parameter*, and the perturbations (around a nonrotating configuration) are calculated by retaining only first and second order terms. Hartle[2] has derived these equations of structure in the rigidly rotating case. It is remarkable that at first order the only effect of the rotation is to drag the inertial frames; at second order it also deforms the star. An expansion of the dragging rate potential in powers of the angular velocity parameter only contains odd powers. Hence, if one is interested in calculating all effects up to second order, it is then sufficient to include only the linear (first order) corrections in the dragging rate. And it turns out that up to first order there are no restrictions on the rotation profile by the field equations, more exactly, by the Euler equation, through a rotation law. Hence, the result on bounds on the dragging rate in the general (differentially) rotating case, mentioned above (Proposition 3 in Ref. 1), does not apply any more in the slow rotation limit. In the present paper the bounds on the dragging rate (including positivity of the angular momentum density) are refined for the slowly and differentially rotating case.

The first order equations of structure reduce to the time-angle field equation component (to first order), which is a partial differential equation, linear in the dragging rate potential. This linearity in the dragging rate persuades us to rewrite that equation in appropriate coordinates—in order to avoid the coordinate singularity occurring on the axis of rotation in spherical polar coordinates, generally used in the slow rotation approximation—so that in the new coordinates the equation writes in a ''regular'' form as an elliptic equation with measurable and bounded coefficients. This allows us to apply a minimum principle for generalized supersolutions in the whole domain (interior and exterior of the star). Making use of the asymptotic flatness condition, this will lead us directly to the positivity of the dragging rate, provided that the distribution of angular velocity of the fluid is non-negative everywhere (and nontrivial) and that we start from a reasonable unperturbed (nonrotating) stellar model satisfying the weak energy condition. In this case, the linearity (in the rotation) of the considered equation will guarantee a positive angular momentum density, provided that the amplitude of the rotation profile is bounded in a certain way.

The *rotational mass-energy*, derived by Hartle in Ref. 3, although accurate to second order in the angular velocity, involves only quantities which can be calculated from the first order structure equation (time-angle component of the Einstein field equations) as well. A proof of the positivity

and an upper bound on this rotational energy was given in the same paper,[3] however using an expansion in eigenfunctions (and leaving open the nontrivial mathematical problems which may arise on the existence of these eigenfunctions). We found a much simpler proof of that result, avoiding expansions in eigenfunctions (in the present paper briefly exposed) which, remarkably, was possible to generalize to the general differentially rotating case, i.e., outside the slow rotation limit (cf. Sec. V of Ref. 1).

The paper is organized as follows. After a description of the relativistic rotating stellar model in Sec. II, and a brief revision of the concepts of angular momentum density and rate of rotational dragging in Sec. III, in Sec. IV we concentrate on the slow rotation approximation, particularly on the first order perturbations of the metric (linear correction of the dragging rate, with description of the unperturbed, i.e., zero order, configuration), and explicit expressions for the expansions of the angular momentum density and of the rotational mass-energy are derived. In the same section the null contribution (at first order in the angular velocity) of the integrability condition of the Euler equation is discussed, and the time-angle component of the Einstein equations (to first order) is written in appropriate coordinates, as a background allowing to apply a minimum principle and obtain the first of the properties mentioned above and proved in Sec. V, and consequences of that one. Apart from this, we sketch here the alternative proof of the bounds on the rotational energy. Finally, in Sec. VI, concluding remarks are briefly stated.

II. THE RELATIVISTIC ROTATING STELLAR MODEL

The space–time of a rotating relativistic star is represented by a Lorentzian 4-manifold $(\mathcal{M}, \mathbf{g})$ which satisfies the following.

A. Assumptions

(i) The space–time is stationary in time and axially symmetric, which means that $\mathbf{g}$ admits two global Killing vector fields, a timelike future-directed one, $\boldsymbol{\xi}$, and a spacelike one, with closed trajectories, $\boldsymbol{\eta}$, except on a timelike 2-surface (defining the axis of rotation) where $\boldsymbol{\eta}$ vanishes;

(ii) the space–time is asymptotically flat; in particular, $\mathbf{g}(\boldsymbol{\xi},\boldsymbol{\xi})\to -1$, $\mathbf{g}(\boldsymbol{\eta},\boldsymbol{\eta})\to +\infty$, and $\mathbf{g}(\boldsymbol{\xi},\boldsymbol{\eta})\to 0$ at spatial infinity [the signature of the metric $\mathbf{g}$ being $(-+++)$];

(iii) the matter—confined in a compact region in the space (interior), with vacuum on the outside, so that (ii) holds—is perfect fluid, and therefore the energy-momentum tensor (source of the Einstein equations) is written as

$$\mathbf{T}=(\varepsilon+p)\mathbf{u}^\flat\otimes\mathbf{u}^\flat+p\,\mathbf{g}\,,$$

where ε and p denote the energy density and the pressure of the fluid, respectively; and $\mathbf{u}^\flat$ denotes the 1-form equivalent to the 4-velocity of the fluid $\mathbf{u}$ (in the exterior $\mathbf{T}\equiv 0$; hence, $\varepsilon+p=p=0$ there);

(iv) the fluid velocity is azimuthal (nonconvective) (*circularity condition*), i.e.,

$$\mathbf{u}^\flat\wedge\boldsymbol{\xi}^\flat\wedge\boldsymbol{\eta}^\flat=0\,;$$

(v) $(\mathcal{M}, \mathbf{g})$ satisfies Einstein's field equations $\mathbf{G}=8\pi\mathbf{T}$ for the energy-momentum tensor $\mathbf{T}$ of a perfect fluid (iii), where $\mathbf{G}\equiv\mathbf{Ric}-1/2\,R\,\mathbf{g}$ denotes the Einstein tensor—equations which can also be written in the form

$$\mathbf{Ric}=8\pi(\mathbf{T}-\tfrac{1}{2}tr(\mathbf{T})\,\mathbf{g})\,; \tag{1}$$

(vi) ε and p satisfy a barotropic (one-parameter) equation of state, $\varepsilon=\varepsilon(p)$;

(vii) $\varepsilon+p\geqslant 0$ (*weak energy condition* for perfect fluid, assuming $\varepsilon\geqslant 0$);[4]

(viii) the metric functions are essentially bounded.

B. Form of the metric

Assumptions (i) and (ii) imply that the two Killing fields commute, $[\boldsymbol{\xi},\boldsymbol{\eta}]=0$,[5] which is equivalent to the existence of coordinates $x^0\equiv t$ and $x^1\equiv\phi$ such that $\boldsymbol{\xi}\equiv\partial_t$ and $\boldsymbol{\eta}\equiv\partial_\phi$; moreover, by the circularity condition (iv), the space–time $\mathbf{g}$ admits 2-surfaces orthogonal to the group orbits of the Killing fields (orthogonal transitivity).[6] We may then choose the two remaining coordinates (x^2,x^3) in one of these 2-surfaces and carry them to the whole space–time along the integral curves of $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$; accordingly, the metric can be written in the form

$$\mathrm{d}s^2\equiv g_{\alpha\beta}\,\mathrm{d}x^\alpha\,\mathrm{d}x^\beta=g_{tt}\,\mathrm{d}t^2+2g_{t\phi}\,\mathrm{d}t\,\mathrm{d}\phi+g_{\phi\phi}\,\mathrm{d}\phi^2+g_{22}(\mathrm{d}x^2)^2+2g_{23}\,\mathrm{d}x^2\,\mathrm{d}x^3+g_{33}(\mathrm{d}x^3)^2\,,$$

where the metric coefficients are independent of the time $x^0\equiv t$ and azimuthal $x^1\equiv\phi$ coordinates corresponding to the two Killing fields; that is, $g_{\alpha\beta}=g_{\alpha\beta}(x^2,x^3)$.

When solving Einstein's field equations it is convenient to specify the coordinates x^2 and x^3 in such a way as to simplify the task; a particular choice, usually made when studying slowly rotating configurations,[2] is the one which makes $g_{23}=0$ and $g_{33}=g_{\phi\phi}\sin^{-2}x^3$. Hence x^2 and x^3 are chosen so that at large spatial distances the asymptotically flat metric is expressed in terms of spherical polar coordinates in the usual way. In the resulting coordinate system, with the notation $x^2\equiv r$, $x^3\equiv\theta$, and with new symbols for the metric functions, the line element reads

$$\mathrm{d}s^2=-H^2\,\mathrm{d}t^2+Q^2\,\mathrm{d}r^2+r^2K^2[\mathrm{d}\theta^2+\sin^2\theta\,(\mathrm{d}\phi-A\,\mathrm{d}t)^2]\,, \tag{2}$$

where H, Q, K, and A are functions of r and θ alone. In these coordinates ($r\geqslant 0$, $0\leqslant\theta\leqslant\pi$) the spatial infinity is given by $r\to\infty$, and the axis of rotation ($\partial_\phi\equiv\boldsymbol{\eta}=0$) is described by $\theta\to 0$ or π ($r\geqslant 0$).

Notice that the function A appears in the metric (2) as the nonvanishing of the $(t\phi)$ metric component of a rotating configuration. A is actually the *dragging rate* potential (cf. Sec. III).

C. Differential rotation

According to assumption (iv) of Sec. II A—circularity condition—the fluid 4-velocity $\mathbf{u}$ has the form

$$\mathbf{u}=u^t\partial_t+u^\phi\partial_\phi=u^t(\partial_t+\Omega\,\partial_\phi),\quad \text{where}\ \ \Omega\equiv\frac{u^\phi}{u^t}=\frac{\mathrm{d}\phi}{\mathrm{d}t}$$

is the angular velocity of the fluid measured in units of t, i.e., as seen by an inertial observer at infinity whose proper time is the same as the coordinate t (observer ∂_t), and u^t is the normalization factor, such that $\mathbf{g}(\mathbf{u},\mathbf{u})=-1$, i.e., $(u^t)^{-2}=-(g_{tt}+2\Omega g_{t\phi}+\Omega^2 g_{\phi\phi})$. The star's matter rotates then in the azimuthal direction ϕ.

We consider a star rotating differentially, with a prescribed distribution of angular velocity

$$\Omega\equiv\Omega(x^2,x^3)\equiv\Omega(r,\theta)\,,$$

an essentially bounded function. However, with the assumptions made (Sec. II A), the rotation profile of the fluid cannot be freely chosen, this shows up in the following. We consider the equation of hydrostatic equilibrium, $T^{\alpha\beta}{}_{;\beta}=0$ (integrability conditions of the field equations), particularly, its part orthogonal to the fluid 4-velocity $\mathbf{u}$, i.e., the Euler equation,

$$\mathrm{d}p=-(\varepsilon+p)\,\mathbf{a}\,, \tag{3}$$

where $\mathbf{a}$ is the 4-acceleration of the fluid, $\mathbf{a}^\sharp=\nabla_{\mathbf{u}}\mathbf{u}$, specifically,

$$\mathbf{a}=-\,\mathrm{d}\ln u^t+u^t u_\phi\,\mathrm{d}\Omega\,. \tag{4}$$

And the integrability condition of Eq. (3), taking into account (vi) of Sec. II A, $\varepsilon=\varepsilon(p)$, is d**a** $=0$; following, from (4), $\mathrm{d}(u^t u_\phi)\wedge \mathrm{d}\Omega=0$; in other words, the fluid angular velocity, Ω, is functionally related to the specific angular momentum times u^t,

$$u^t u_\phi=\mathcal{F}(\Omega)\,. \tag{5}$$

Nevertheless, as will be seen in Sec. IV B, in the slow rotation approximation, at first order in the angular velocity, Eq. (5) is no restriction on the rotation profile $\Omega(r,\theta)$.

III. ANGULAR MOMENTUM DENSITY AND DRAGGING RATE

The total angular momentum of a rotating relativistic star can be defined[7] from the variational principle for general relativity—for an isolated system which is not radiating gravitational waves—but this is shown[7] to coincide with the *geometrical* definition—from the asymptotic form of the metric at large spacelike distances from the rotating fluid—(analog to the ADM mass), which for stationary and axisymmetric (asymptotically flat) space–times is given by the Komar integral for the angular momentum,[8] a surface integral, which, when reformulated using the Gauss theorem and the Einstein equations, converts into the volume integral over the interior

$$J=\int_{\mathcal{I}} T_\alpha{}^\beta \eta^\alpha n_\beta \,\mathrm{d}v \tag{6}$$

$$=\int_{\mathcal{I}} T_\phi{}^t n_t \,\mathrm{d}v=\int_{\mathcal{I}} T_\phi{}^t(-\mathrm{g})^{1/2}\,\mathrm{d}^3x\,, \tag{7}$$

where **T** is the energy-momentum tensor of perfect fluid, $\boldsymbol{\eta}$ is the Killing field corresponding to the axial symmetry, $\mathbf{n}^\sharp$ is the unit timelike and future pointing normal to the hypersurface of constant t, i.e., $\mathbf{n}=n_t\,\mathrm{d}t$, with $n_t>0$, and $\mathrm{d}v$ is the proper volume element of the surface $t=$const, i.e., $\int_{\mathcal{I}}\mathrm{d}v=\mathrm{Vol}$, the volume of the body of the star, $\mathcal{I}\equiv$interior of the star ($t=$const). Here $g\equiv\det(\mathbf{g})$. The invariantly defined integrand of this volume integral (6), $T_\alpha{}^\beta\eta^\alpha n_\beta$, is what one would naturally define as *angular momentum density*—coinciding with the standard form in special relativity—and can be calculated as

$$\begin{aligned} T_\alpha{}^\beta\eta^\alpha n_\beta &= n_t T_\phi{}^t = n_t(\varepsilon+p)u^t u_\phi \quad [u_\phi=u^t(g_{t\phi}+\Omega g_{\phi\phi})]= n_t(\varepsilon+p)(u^t)^2(g_{t\phi}+\Omega g_{\phi\phi}) \\ &= n_t(\varepsilon+p)(u^t)^2 g_{\phi\phi}(\Omega-A), \quad \text{with } n_t=H=\left(\frac{-g_{tt}g_{\phi\phi}+g_{t\phi}^2}{g_{\phi\phi}}\right)^{1/2}, \end{aligned} \tag{8}$$

where A is the metric function [cf. (2)] such that

$$g_{t\phi}=-A\ g_{\phi\phi}\,. \tag{9}$$

It is remarkable that, since $n_t>0$, $g_{\phi\phi}\geqslant 0$, and we are assuming the energy condition $\varepsilon+p\geqslant 0$ [(vii) in Sec. II A], the sign of the angular momentum density (8) is determined by the sign of the difference $\Omega-A$.

The metric function A is indeed the angular velocity of a particle which is dragged along in the gravitational field of the star, as seen from a nonrotating observer at spatial infinity (∂_t), so that it has zero angular momentum relative to the axis, $p_\phi=0$,

$$\frac{\mathrm{d}\phi}{\mathrm{d}t}=\frac{p^\phi}{p^t}=\frac{g^{t\phi}p_t}{g^{tt}p_t}=\frac{g^{t\phi}}{g^{tt}}=\frac{-g_{t\phi}}{g_{\phi\phi}}, \quad g_{t\phi}+\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)g_{\phi\phi}=0, \quad \frac{\mathrm{d}\phi}{\mathrm{d}t}=A\,.$$

A is called *angular velocity of cumulative dragging* (shortly called *dragging rate*).[9,10] One of the purposes of this work is precisely to find appropriate bounds on the uniformly non-negative

distribution of angular velocity, $\Omega \equiv \Omega(x^2,x^3) \geqslant 0$, of a slowly differentially rotating star, so that $\Omega - A \geqslant 0$ holds; from where the positivity of the angular momentum density (8) follows [property (c) in Sec. V].

Observe, in the special relativistic limit [$g_{t\phi} \to 0$, using coordinates (x^2,x^3) which go at spatial infinity to the usual flat coordinates, cf. Sec. II B], if the fluid rotates uniformly with angular velocity Ω positive (negative), then the angular momentum density, Eq. (8), is uniformly positive (negative).

IV. SLOWLY DIFFERENTIALLY ROTATING STARS: FIRST ORDER PERTURBATIONS

By slow rotation we mean that the absolute value of the angular velocity is much smaller than the critical value $\Omega_{\text{crit}} \equiv (M/R^3)^{1/2}$ (taking units $c=G=1$), where M is the total mass of the unperturbed (nonrotating) configuration, and R, its radius; $|\Omega(x^2,x^3)|/\Omega_{\text{crit}} \ll 1$. Thus, stars which rotate slowly can be studied by expanding the Einstein field equations for a fully relativistic differentially rotating star in powers of the dimensionless ratio

$$\frac{|\Omega_{\max}|}{\Omega_{\text{crit}}} =: \mu \,, \tag{10}$$

where $|\Omega_{\max}|$ is the maximum value of $|\Omega(x^2,x^3)|$ (at the interior of the star).

A. The metric and the energy density and pressure of the fluid

We assume that the star is slowly rotating, with angular velocity

$$\Omega(r,\theta) \equiv \Omega(x^2,x^3) = O(\mu) \,,$$

parameter μ given, e.g., by (10). Because the star (stationary in time and axially symmetric) rotates in the ϕ direction [(iv) of Sec. II A], a time reversal ($t \to -t$) would change the sense of rotation, as well as an inversion in the ϕ direction ($\phi \to -\phi$) would do. As a result, the metric coefficients H, Q, and K [in (2)] and the energy density will not change sign under *one of* these inversions, whereas A will do. Therefore, an expansion of H, Q, and K, as well as of the energy density, ε, and, hence, of the pressure, p, in powers of the angular velocity parameter μ will contain only even powers, while an expansion of the dragging rate, A, will have only odd ones. Hence, considering effects up to second order only the linear corrections in the dragging rate count. Indeed, the only first order $O(\mu)$ perturbation brought about by the rotation is the dragging of the inertial frames; the star is still spherical, because the ''potential functions'' which deform the shape of the star are $O(\mu^2)$. We shall keep here only the effects linear in the angular velocity. At first order, $O(\mu)$, the metric coefficients, and fluid energy density and pressure, are

$$\begin{aligned} H &= H_0 + O(\mu^2), \\ Q &= Q_0 + O(\mu^2), \\ K &= K_0 + O(\mu^2), \\ \varepsilon &= \varepsilon_0 + O(\mu^2), \\ p &= p_0 + O(\mu^2), \\ \text{but } A &= \omega + O(\mu^3), \end{aligned} \tag{11}$$

where H_0, Q_0, and K_0 are the coefficients of the unperturbed (nonrotating) configuration, and ω denotes the linear (first order) correction in μ of the dragging rate A, so that, from Eq. (9),

$$g_{t\phi} = -\omega \ (g_{\phi\phi})_0 + O(\mu^3) \,. \tag{12}$$

The (unperturbed) nonrotating configuration: The starting nonrotating equilibrium configuration is described by the spherically symmetric metric in the Schwarzschild form

$$\begin{aligned} ds^2 &= -e^{\nu(r)}\,dt^2 + e^{\lambda(r)}\,dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\phi^2) \\ &\equiv -H_0{}^2\,dt^2 + Q_0{}^2\,dr^2 + r^2K_0{}^2\,(d\theta^2 + \sin^2\theta\, d\phi^2) \quad (A_0 = 0)\,, \end{aligned} \tag{13}$$

with $\lambda(r)$, or equivalently, the mass $m(r)$ interior to a given radial coordinate r, given by

$$1 - \frac{2m(r)}{r} = e^{-\lambda(r)}\,, \tag{14}$$

and $\nu(r)$, together with the pressure $p_0(r)$, and the energy density $\varepsilon_0(r)$, solutions of the system of equations of general relativistic hydrostatics, which for a nonrotating configuration are the equation of hydrostatic equilibrium (Tolman–Oppenheimer–Volkoff equation),

$$\frac{dp_0}{dr}(r) = -\frac{[\varepsilon_0(r) + p_0(r)][m(r) + 4\pi r^3 p_0(r)]}{r^2[1 - 2m(r)/r]}\,, \tag{15}$$

the mass equation,

$$\frac{dm}{dr}(r) = 4\pi r^2 \varepsilon_0(r)\,, \tag{16}$$

and the source equation for ν,

$$\frac{d\nu}{dr}(r) = -\frac{2}{\varepsilon_0(r) + p_0(r)}\,\frac{dp_0}{dr}(r)\,, \tag{17}$$

with the initial boundary conditions

$$0 < p_0(0) = p_{0c} < \infty \quad \text{(central pressure)},$$

$$m(0) = 0\,, \quad \text{and}$$

$$\nu(0) = \nu_c \quad \text{(constant fixed by the asymptotic condition at infinity)},$$

this being the prescription for the interior of the star, that is, inside the fluid, $r \leqslant R$, $R \equiv$ radius of the surface of the star, determined by $p_0(R) = 0$. Furthermore, we assume p_0 and ε_0 related to each other by a barotropic equation of state,

$$\varepsilon_0 = \varepsilon_0(p_0)\,, \tag{18}$$

$p_0 \mapsto \varepsilon_0(p_0)$ a bounded function on any closed interval, and satisfying the weak energy condition

$$\varepsilon_0 + p_0 \geqslant 0\,. \tag{19}$$

Observe, from Eqs. (15) and (19), p_0 is a decreasing function from the center, $r = 0$, to the star's surface, $r = R$; in particular, $p_0 \geqslant 0$ and attains its maximum value p_{0c} at the center.

In the exterior (vacuum) the geometry is described by the same line element (13), but with the metric function ν specified and related to λ by

$$e^{\nu(r)} = e^{-\lambda(r)} = 1 - \frac{2M}{r}, \quad \forall r > R\,, \tag{20}$$

where $M \equiv m(R)$ is the star's total mass.

Notice that this standard form of the nonrotating metric, (13), is the limit of zero rotation of the general rotating metric in spherical polar coordinates (2),

$$H\to H_0\equiv e^{\nu/2},\quad Q\to Q_0\equiv e^{\lambda/2},\quad K\to K_0\equiv 1,\quad A\to A_0\equiv 0\,,$$

from where the effect of the rotation can be seen as given by the term $\mathrm{d}\phi - A\,\mathrm{d}t$ in the place of $\mathrm{d}\phi$.

Note, since at first order in the angular velocity there is still no effect on the pressure and on the energy density [cf. (11)], conditions (18) and (19) for the starting nonrotating configuration guarantee (vi) and (vii) of Sec. II A at first order.

B. Euler equation

It will be important to note that at first order the Ω-profile is not restricted by the field equations (through the Euler equation). That shows up in the following. Consider the first integral of the Euler equation (3), namely,

$$\int_0^{p(r,\theta)} \frac{\mathrm{d}\overline{p}}{\varepsilon(\overline{p})+\overline{p}} + \frac{1}{2}\ln[(u^t)^{-2}]\Big|_{(r,\theta)} + \int_{\Omega_0}^{\Omega(r,\theta)} \mathcal{F}(\Omega)\,\mathrm{d}\Omega = \mathrm{const}\,, \tag{21}$$

where Eqs. (4) and (5) have been used, and Ω_0 is a given constant (changing the value of Ω_0 simply modifies the value of the constant on the right-hand side). The first term in Eq. (21) is a function of the pressure, which is, to this approximation, a function of r, i.e., $O(1)$ with respect to the angular velocity; on the other hand,

$$(u^t)^{-2} = -(g_{tt}+2\Omega g_{t\phi}+\Omega^2 g_{\phi\phi}) = H^2 - K^2 r^2 \sin^2\theta\,(\Omega-A)^2 = O(1-(\Omega-A)^2)\,,$$

so the second term is $O((\Omega-A)^2)$ and, hence, $O(\mu^2)$; also, since

$$u^t u_\phi = (u^t)^2 g_{\phi\phi}(\Omega-A) = \frac{K^2 r^2 \sin^2\theta\,(\Omega-A)}{H^2 - K^2 r^2 \sin^2\theta\,(\Omega-A)^2} = O(\Omega-A)\,,$$

$\mathcal{F}(\Omega) = u^t u_\phi = O(\Omega-A)$, thus, the third term is $O((\Omega-A)^2)$ as well, and, hence, $O(\mu^2)$. Consequently, to $O(\mu)$, the Euler equation reduces to its static (nonrotating) case, and indeed we have presumably already used it to get the starting unperturbed solution. Therefore, at this order in the angular velocity, Eq. (5) is no restriction on $\Omega(r,\theta)$.

C. The angular momentum density

Using the definition of ω, linear correction of the dragging rate, via the expansion of the metric coefficient $g_{t\phi}$, Eq. (12), and the metric coefficients of the nonrotating configuration [cf. (13)], we obtain the expansion for the angular momentum density (8),

$$\begin{aligned} T_\alpha{}^\beta \eta^\alpha n_\beta = n_t T_\phi{}^t &= n_t(\varepsilon+p)(u^t)^2(g_{t\phi}+\Omega g_{\phi\phi}) \\ &= (n_t)_0(\varepsilon_0+p_0)[(-g_{tt})_0]^{-1}[-\omega\ (g_{\phi\phi})_0+\Omega\ (g_{\phi\phi})_0]+O(\mu^3) \\ &= e^{\nu/2}(\varepsilon_0+p_0)e^{-\nu}r^2\sin^2\theta(\Omega-\omega)+O(\mu^3) \\ &= (\varepsilon_0+p_0)\,e^{-\nu/2}r^2\sin^2\theta\ (\Omega-\omega)+O(\mu^3)\,. \end{aligned} \tag{22}$$

Thus showing also for the first order rotational perturbation that, since we are assuming the energy condition $\varepsilon_0+p_0\geqslant 0$, the sign of the angular momentum density (22) to $O(\mu)$ is determined by the sign of $\Omega-\omega$.

D. The rotational mass-energy

In Ref. 3 Hartle has derived the difference in total mass-energy, $M_{\rm rot}$, between a slowly and differentially rotating relativistic star and a nonrotating star with the same number of baryons and the same distribution of entropy, namely,

$$M_{\rm rot}=\frac{1}{2}\int_{\mathcal{I}}\Omega\,\mathrm{d}J+O(\mu^4)\,,$$

where $\mathrm{d}J$ is the angular momentum of a fluid element in the star (to first order in the angular velocity), i.e., from (7),

$$\mathrm{d}J=T_{\phi}{}^{t}(-\mathrm{g})^{1/2}\,\mathrm{d}^3x|_{O(\mu)}\,;$$

taking into account (22) and (13), we obtain an explicit expression for the expansion of $M_{\rm rot}$ in powers of the angular velocity parameter μ,

$$M_{\rm rot}=\frac{1}{2}\int_0^R\mathrm{d}r\int_0^{\pi}\,\mathrm{d}\theta\,2\pi(\varepsilon_0+p_0)\,r^4\,e^{(\lambda-\nu)/2}\sin^3\theta\,\Omega(\Omega-\omega)+O(\mu^4)\,. \tag{23}$$

E. The time-angle component of the Einstein equation

The $(t\phi)$ field equation component retaining only first order terms in the angular velocity (second order terms vanish), i.e., from Eq. (1),

$$R_{\phi}{}^{t}=8\pi T_{\phi}{}^{t}+O(\mu^3)\,,$$

takes the form

$$\partial_r[r^4j(r)\,\partial_r\omega]+\frac{r^2\,k(r)}{\sin^3\theta}\,\partial_\theta[\sin^3\theta\,\partial_\theta\omega]-16\pi\,r^4k(r)[\varepsilon_0(r)+p_0(r)][\omega-\Omega]=0\,, \tag{24}$$

where we have introduced the abbreviations

$$j(r)\equiv e^{-[\lambda(r)+\nu(r)]/2}\quad\text{and}\quad k(r)\equiv e^{[\lambda(r)-\nu(r)]/2}\,. \tag{25}$$

As outlined in Ref. 2, using the 0-order field equations, (14)–(17), it follows

$$4\pi\,r\,[\varepsilon_0(r)+p_0(r)]\,k(r)=-j'(r) \tag{26}$$

(where $'\equiv\mathrm{d}/\mathrm{d}r$), which, substituted into Eq. (24), yields

$$\partial_r[r^4j(r)\,\partial_r\omega]+\frac{r^2\,k(r)}{\sin^3\theta}\,\partial_\theta[\sin^3\theta\,\partial_\theta\omega]+4\,r^3j'(r)\,\omega=4\,r^3j'(r)\,\Omega(r,\theta)\,. \tag{27}$$

We write this differential equation for the dragging rate in the abbreviated form

$$\overline{L}\,\omega=-\Psi^2\Omega\,, \tag{28}$$

with the linear second order partial differential operator $\overline{L}\equiv\overline{L}_0-\Psi^2$, where

$$\overline{L}_0\omega:=\frac{1}{r^4j(r)}\,\partial_r[r^4j(r)\,\partial_r\omega]+\frac{k(r)}{r^2j(r)\sin^3\theta}\,\partial_\theta[\sin^3\theta\,\partial_\theta\omega] \tag{29}$$

and

$$\Psi^2(r) := -\frac{4}{r}\frac{j'(r)}{j(r)} = 16\pi[\varepsilon_0(r)+p_0(r)]\frac{k(r)}{j(r)} \geqslant 0 \quad \forall r \geqslant 0\,. \tag{30}$$

Equation (26) has been used in (30), and the sign follows from the assumed energy condition (19), the functions j and k [cf. (25)] are always positive. Notice, $\Psi^2 \equiv 0$ in the exterior ($\forall r \in [R,\infty[$), where vacuum [$\varepsilon_0 = p_0 = 0$, cf. (iii) in Sec. II A] is considered.

Specifically, we are only interested in solutions $\omega \equiv \omega(r,\theta)$ of Eq. (28) in $[0,\infty[\times[0,\pi]$, which satisfy the *boundary conditions*

$$\omega \quad \text{asymptotically flat} \quad \left(\lim_{r\to\infty}\omega = 0\right), \tag{31}$$

$$\omega \quad C^1 \text{ regular on the axis of rotation}, \tag{32}$$

and a *matching condition*, namely, to be at least a class C^1 function on the surface of the star—which is spherical at first order rotational perturbations—

$$\omega(.,\theta) \text{class } C^1 \text{ across } r = R\,. \tag{33}$$

Notice, (31) follows from our star model [condition (ii) in Sec. II A], and it can be easily seen that (33) follows from the equation itself, provided that $\omega(.,\theta)$ and $\Omega(.,\theta)$ are at least essentially bounded ($\in L^\infty$)—as has been assumed—i.e., even if they have a jump discontinuity.

At the star's surface, $r = R$, higher regularity of $\omega(.,\theta)$ is not guaranteed by the equation, due to a jump discontinuity of the function Ψ^2 at this point. For this reason, we shall be considering (in the following section) *generalized* ($\in W^{1,2}$) solutions ω of Eq. (28) in the whole domain (interior and exterior).

"*Coordinate change*": In order to avoid the coordinate singularity occurring on the axis in polar coordinates (r,θ), and wishing instead to have in the differential operator (29) a Lapacian in some higher dimension, we consider the following "change of coordinates." First, we introduce *isotropic* cylindrical coordinates in the meridian plane,

$$(r,\theta) \mapsto (\rho := h(r)\sin\theta,\ \ z := h(r)\cos\theta) \in \mathbb{R}_0^+ \times \mathbb{R}\,, \tag{34}$$

with the function h satisfying the following ordinary differential equation of first order with separated coefficients:

$$\frac{h'(r)}{h(r)} = \frac{e^{\lambda(r)/2}}{r} \tag{35}$$

[which makes the coefficient of the crossed derivatives in the operator (29) after the change (34) to vanish], and the *boundary condition*

$$\lim_{r\to\infty}\frac{h(r)}{r} = 1\,, \tag{36}$$

i.e., so that the *isotropic* radius $h(r) \equiv \overline{r}$ approaches r at spatial infinity, because far away from the source we assume to have Euclidean geometry. This leads us to the definition of the function [having $\omega(r,\theta)$]

$$w(\rho,z) := \omega(h^{-1}(\sqrt{\rho^2+z^2}),\ \arctan(\rho/z))\,, \tag{37}$$

or inversely, w such that

$$\omega(r,\theta) = w(h(r)\sin\theta,\ h(r)\cos\theta)\,.$$

Second (in the spirit of Ref. 11), we define [with $w(\rho,z)$] the 5-*lift of* $w:\mathbb{R}_0^+\times\mathbb{R}\to\mathbb{R}$ in flat $\mathbb{R}^5$, axisymmetric around the x_5 axis, by

$$w\mapsto\tilde{\omega}\ \text{ such that }\ \tilde{\omega}(\mathbf{x})\equiv\tilde{\omega}(x_1,x_2,x_3,x_4,x_5):=w\left(\ \rho=\left(\sum_{i=1}^{4}x_i^{\,2}\right)^{1/2},\ z=x_5\ \right), \tag{38}$$

and, for every function $\tilde{\omega}:\mathbb{R}^5\to\mathbb{R}$, the *meridional cut (in direction* x_1*) of* $\tilde{\omega}$,

$$\tilde{\omega}\mapsto w\ \text{ such that }\ w(\rho,z):=\tilde{\omega}(\rho,0,0,0,z)\,.$$

For axisymmetric functions these are isometric operations inverse to each other.[11] After considering the change of variable (34) with (37) in the differential operator $\overline{L_0}$ (29), we get [remember (25), $e^{\lambda}=k/j$]

$$\overline{L_0}\,w=\frac{e^{\lambda(r)}h(r)^2}{r^2}\left\{\partial_{\rho\rho}w+\partial_{zz}w+\frac{3}{\rho}\partial_\rho w+H(r)\,\frac{\rho\,\partial_\rho w+z\,\partial_z w}{h(r)}\right\}, \tag{39}$$

where

$$H(r):=\frac{-e^{[-\lambda(r)/2]}[-6+6\,e^{[\lambda(r)/2]}+r\,\nu'(r)]}{2\,h(r)}. \tag{40}$$

But, through the 5-lift (38), the flat Laplacian in five dimensions of the "lifted" function $\tilde{\omega}$ gives exactly

$$\Delta\tilde{\omega}\equiv\sum_{i=1}^{5}\partial_{ii}\tilde{\omega}=\partial_{\rho\rho}w+\partial_{zz}w+\frac{3}{\rho}\partial_\rho w\,, \tag{41}$$

the first three terms in the curly brackets of (39). Furthermore, as outlined in Ref. 11, n-lift and meridional cut (of *axisymmetric functions*) leave the regularity properties and the norm invariant; and *axisymmetric* operations, like multiplication, $\partial_{\overline{r}}$ [$\overline{r}\equiv h(r)=(\rho^2+z^2)^{1/2}=(\Sigma_{i=1}^5 x_i^{\,2})^{1/2}$], and scalar product, commute with n-lift and meridional cut. In particular, in the fourth term in the curly brackets of (39) the factor

$$\rho\,\partial_\rho w+z\,\partial_z w=\partial_{\overline{r}}\tilde{\omega}=\sum_{i=1}^{5}x_i\,\partial_i\tilde{\omega}\,. \tag{42}$$

Therefore, substituting (41) and (42) into (39), Eq. (28) in the form $\overline{L_0}\tilde{\omega}=-\Psi^2(\tilde{\Omega}-\tilde{\omega})$ (with $\tilde{\Omega}$ defined from Ω as it was $\tilde{\omega}$ from ω, and $\Psi^2=e^{\lambda}16\pi[\varepsilon_0+p_0]$) now writes

$$\overline{L_0}\,\tilde{\omega}\equiv\frac{e^{\lambda(r)}h(r)^2}{r^2}\left\{\Delta\tilde{\omega}+H(r)\,\frac{\Sigma_{i=1}^5 x_i\,\partial_i\tilde{\omega}}{h(r)}\right\}=e^{\lambda(r)}\{-16\pi[\varepsilon_0(r)+p_0(r)][\tilde{\Omega}-\tilde{\omega}]\}\,,$$

or, equivalently,[12]

$$\Delta\tilde{\omega}+H(r)\,\frac{\Sigma_{i=1}^5 x_i\,\partial_i\tilde{\omega}}{h(r)}=-16\pi\,\frac{r^2}{h(r)^2}[\varepsilon_0(r)+p_0(r)][\tilde{\Omega}-\tilde{\omega}]\,. \tag{43}$$

V. PROPERTIES

With the assumptions made in Sec. II A for this slowly rotating configuration [starting from a nonrotating one as described in Sec. IV A; particularly, satisfying the energy condition $\varepsilon_0+p_0\geqslant 0$], and considering only solutions of Eq. (28) satisfying the boundary and matching conditions (31), (32), and (33), the following results hold.

Property (a) (positiveness of the dragging rate): If the distribution of angular velocity of the fluid is non-negative (and nontrivial), then the dragging rate *(to first order in the fluid angular velocity) is positive everywhere,*

$$\Omega \geqslant 0, \quad \Omega \not\equiv 0 \Rightarrow \ \omega > 0 \, .$$

Proof: We have seen in the former section that, using the coordinate change (34) and the 5-lift (38), Eq. (28) for ω is equivalent to Eq. (43) for $\tilde{\omega}$, which reads

$$L\tilde{\omega} \coloneqq \Delta\tilde{\omega} + \sum_{i=1}^{5} H(r)\frac{x_i}{h(r)}\partial_i\tilde{\omega} - 16\pi[\varepsilon_0 + p_0]\frac{r^2}{h(r)^2}\tilde{\omega} = -16\pi[\varepsilon_0 + p_0]\frac{r^2}{h(r)^2}\tilde{\Omega} \, . \tag{44}$$

This equation may be obviously written *in divergence form*

$$L\tilde{\omega} \equiv \partial_i[a^{ij}(\mathbf{x})\partial_j\tilde{\omega} + a^i(\mathbf{x})\,\tilde{\omega}] + b^i(\mathbf{x})\,\partial_i\tilde{\omega} + c(\mathbf{x})\,\tilde{\omega} = g(\mathbf{x})$$

(where repeated indices denote summation over the index), with the coefficients

$$\begin{gathered} a^{ij}(\mathbf{x}) \equiv \delta_{ij} \quad (=1 \ \text{ if } \ i=j, \ \text{ and } \ =0 \ \text{ otherwise}) \, , \\ a^i(\mathbf{x}) \equiv 0 \, , \\ b^i(\mathbf{x}) = H(r)\frac{x_i}{h(r)} \quad (\forall\, i,j \in \{1,\ldots,5\}), \\ c(\mathbf{x}) = -16\pi[\varepsilon_0(r) + p_0(r)]\frac{r^2}{h(r)^2} \quad (\leqslant 0) \, , \end{gathered} \tag{45}$$

and

$$g(\mathbf{x}) = c(\mathbf{x})\,\tilde{\Omega}(\mathbf{x}) \, . \tag{46}$$

The isotropic radius $\overline{r} \equiv h(r)$ is Gaussian coordinate with respect to the star's surface, $\overline{r} = h(R)$, and, thus, $\tilde{\omega}$ is at least class C^1 across this surface; therefore, $\tilde{\omega} \in C^1(\mathbb{R}^5)$. Thus, considering the domain G defined by a ball in $\mathbb{R}^5$ centered at the origin of coordinates $\mathbf{x} = \mathbf{0}$ ($\overline{r} = 0$) and of arbitrary large radius σ,

$$G \coloneqq \mathcal{B}_\sigma(\mathbf{0}) \subset \mathbb{R}^5 \, , \tag{47}$$

the function $\tilde{\omega}$ and its (first) derivatives (continuous in $\mathbb{R}^5$) are 2-integrable in G, i.e., $\tilde{\omega} \in W^{1,2}(G) \cap C^1(G)$, and Eq. (43) is satisfied in G in a generalized sense (cf. Appendix B).

Notice, whenever $\tilde{\Omega} \geqslant 0$, we have, by (46), $g \leqslant 0$ (because $c \leqslant 0$), and, hence, $L\tilde{\omega} \leqslant 0$, specifically $\tilde{\omega}$ is a generalized supersolution relative to the operator L, in (44), and the domain G (47). We look at the requirements for a minimum principle to be applied (Appendix B). The Laplacian operator is obviously strictly elliptic, and the coefficients (45) are measurable and bounded functions on G, this shows up in the following: the mapping $r \mapsto r/h(r)$ is bounded from above and below everywhere in $[0,\infty[$ (Appendix A); $\varepsilon_0 + p_0$ is also bounded, since p_0 is bounded and $p_0 \mapsto \varepsilon_0(p_0)$ is bounded in any closed interval (Sec. IV A); consequently, the coefficient c is bounded (from above and below); the coefficients of the first derivatives, b^i, are also bounded (from above and below), because the function H is bounded everywhere (Appendix A) and since $(\forall i = 1,\ldots,5)$ ${x_i}^2 \leqslant \Sigma_{j=1}^5 {x_j}^2 = h(r)^2$, we have $[x_i/h(r)]^2 \leqslant 1$. Thus, all conditions of a minimum principle for generalized supersolutions relative to the differential operator L and the domain G hold, and, as a result of the *weak* minimum principle (Theorem 1 in Appendix B), we have

$$\inf_G \tilde{\omega} \geqslant \inf_{\partial G} \tilde{\omega}^- \quad [\tilde{\omega}^- \equiv \min(\tilde{\omega},0)]. \tag{48}$$

But, since the radius of the ball G is arbitrary, we can make it sufficiently large ($\sigma \to \infty$) so that, by asymptotic flatness [$\lim_{h(r)\to\infty} \tilde{\omega}=0$, from condition (31) and $\lim_{r\to\infty}[h(r)/r]=1$], $\tilde{\omega}$ is arbitrary small at ∂G, following, from (48), $\tilde{\omega} \geqslant 0$. Actually, the positivity is strict, because if $\tilde{\omega}(\mathbf{x}_0)=0$ for some $\mathbf{x}_0 \in G$ (interior point), then $\tilde{\omega}(\mathbf{x}_0)=\min \tilde{\omega}$ (since $\tilde{\omega} \geqslant 0$), and, by the *strong* minimum principle (Theorem 2 in Appendix B), $\tilde{\omega}$ would be constant in G; in this case, $\tilde{\omega} \equiv \text{const}=0$ in G (i.e., everywhere); but $\tilde{\omega} \equiv 0$ yields, by Eq. (44), $\tilde{\Omega} \equiv 0$, or, equivalently, $\Omega \equiv 0$, and we are assuming that Ω is nontrivial. We conclude then $\omega > 0$ everywhere. □

Property (b): Suppose we perturb the nonrotating configuration (in particular, with a given equation of state) with two (small) different distributions of angular velocity, Ω_1 and Ω_2, and integrate Eq. (28) to obtain their respective solutions for the dragging rate, ω_1 and ω_2, then

$$\Omega_1 \geqslant \Omega_2, \quad \Omega_1 \neq \Omega_2 \Rightarrow \ \omega_1 > \omega_2.$$

Proof: This follows from the linearity of Eq. (28) and Property (a). □

We are already in position to get a result about the positiveness of the difference $\Omega - \omega$, and, hence, of the *angular momentum density* (22). However, in order to first do this more specific and concrete, we shall make use of a property for the particular case of rigid rotation (RR), which can be found in Ref. 2, Sec. IV.

Property RR: For the slowly rotating configuration, if $\Omega(r,\theta) \equiv \text{const} \equiv \hat{\Omega} > 0$ ($in\ [0,R] \times [0,\pi]$) then

$$\omega(r,\theta) = \omega(r),$$

$$0 < \omega(r) < \hat{\Omega} \ \ in \ \ [0,R]$$

$$\omega > 0 \ in \ \ [0,\infty[\,, \ \ \omega' < 0 \ \ in \ \ ]0,\infty[\,, \ \ \omega'(0)=0.$$

Property (c) (positiveness of the angular momentum density): For the slowly rotating configuration, with a given equation of state, its dragging rate ω will satisfy

$$\omega(r,\theta) < \Omega(r,\theta)$$

if $\Omega \equiv \Omega(r,\theta)$ ($\geqslant 0$) is bounded in the form

$$\underline{\Omega}(\overline{\Omega}) \equiv \underline{\Omega} \ \leqslant \ \Omega(r,\theta) \ \leqslant \ \overline{\Omega}$$

(in $[0,R]\times[0,\pi]$), where $\overline{\Omega}$ is an arbitrary positive constant $0 < \overline{\Omega}$ ($\ll \Omega_{\text{crit}}$) (Sec. IV), and $\underline{\Omega} = \overline{\omega}(0)$, $\overline{\omega}$ solution of Eq. (28) with $\overline{\Omega}(r,\theta) = \text{const} = \overline{\Omega}$, and with the same 0-order coefficients (same starting nonrotating configuration) as the ones considered for our slowly rotating configuration, in particular with the same equation of state; or, more generally, if (with that notation)

$$\overline{\omega}(r) \ \leqslant \ \Omega(r,\theta) \ \leqslant \ \overline{\Omega}.$$

Notice, $\omega < \Omega$ means that the angular momentum density *to first order in the fluid angular velocity, (22), of this configuration [with the energy condition (19)] is $\geqslant 0$, vanishing on the axis.*

[Remarkably, the upper bound required on Ω is not restrictive, because for Ω continuous, Ω is essentially bounded ($\in L^\infty$) there, and $\Omega/\|\Omega\|_\infty \leqslant 1$.]

Proof: We give a practical method of construction in two steps.

First step: Consider $\overline{\Omega}(r,\theta) := \overline{\Omega} = \text{const} > 0$, and solve the corresponding Eq. (28) for $\overline{\omega}$. Then, by Property RR, the solution satisfies

$$\overline{\omega}(r,\theta) = \overline{\omega}(r), \tag{49}$$

$$0<\overline{\omega}(r)<\overline{\Omega} \text{ in } [0,R], \tag{50}$$

$$\text{and } \overline{\omega}>0 \text{ in } [0,\infty[\,, \overline{\omega}'<0 \text{ in }]0,\infty[\,, \overline{\omega}'(0)=0. \tag{51}$$

Second step: Consider a slowly rotating configuration starting from the same nonrotating configuration (as in the first step) with a fluid angular velocity distribution $\Omega(r,\theta)$ such that

$$\overline{\omega}(0)=:\underline{\Omega} \leqslant \Omega(r,\theta) \leqslant \overline{\Omega}. \tag{52}$$

Observe, we are always allowed to do this because of (50). Or, more generally, such that $\overline{\omega}(r) \leqslant \Omega(r,\theta) \leqslant \overline{\Omega}$; notice, from (51), $\overline{\omega}$ is a (positive) decreasing function; in particular, $\overline{\omega}(0) \geqslant \overline{\omega}(r)>0, \ \forall r \in [0,\infty[$.

From the second inequality in (52), i.e., from $\Omega(r,\theta) \leqslant \overline{\Omega}$, and, since we have the same starting unperturbed configuration (same 0-order coefficients) for these both slowly rotating configurations, it follows, by Property (b), that their corresponding solutions [of Eq. (28)] satisfy

$$\omega(r,\theta)<\overline{\omega}(r), \tag{53}$$

where we have used (49). On the other hand, the first inequality in (52), and (51) yield

$$\overline{\omega}(r) \leqslant \overline{\omega}(0) =: \underline{\Omega} \leqslant \Omega(r,\theta), \tag{54}$$

and consequently, from (53) and (54),

$$\omega(r,\theta) < \Omega(r,\theta).$$

□

Remark: Notice, the same argument also assures that, given a slowly rotating configuration with $\overline{\Omega}(r,\theta)$ such that the corresponding dragging rate $\overline{\omega}(r,\theta)<\overline{\Omega}(r,\theta)$, we shall have the same positivity result [property (c)] for any slowly rotating configuration, starting from the same unperturbed configuration (in particular, with the same equation of state), with an angular velocity distribution $\Omega(r,\theta)$ such that

$$\underline{\Omega}(r,\theta) =: \overline{\omega}(r,\theta) \leqslant \Omega(r,\theta) \leqslant \overline{\Omega}(r,\theta),$$

because we obtain, from the last inequality and property (b), $\omega(r,\theta)<\overline{\omega}(r,\theta)$, and hence, $\omega(r,\theta)<\Omega(r,\theta)$.

Series expansion: M_{rot}. Before we prove the next property, we first stress that, since Ω and ω transform like vectors under rotation, Eq. (27) may be separated by expanding them as

$$\Omega(r,\theta) \equiv \Omega(r,x) \sim \sum_{l=1}^{\infty} \Omega_l(r)\, y_l(x) \tag{55}$$

and

$$\omega(r,\theta) \equiv \omega(r,x) \sim \sum_{l=1}^{\infty} \omega_l(r)\, y_l(x), \tag{56}$$

with the change of variable $\theta \mapsto x := \cos\theta$, and

$$y_l(x) := \frac{d\mathcal{P}_l}{dx} \qquad \forall x \in [-1,1] (\theta \in [0,\pi]), \quad \mathcal{P}_l \equiv \text{Legendre polynomial of degree } l. \tag{57}$$

Then the equation for ω_l takes the form

$$\frac{\mathrm{d}}{\mathrm{d}r}[r^4 j(r)\ \ \omega_l']+[4\,r^3 j'(r)-r^2\,k(r)\,\lambda_l]\ \ \omega_l=4\,r^3 j'(r)\ \ \Omega_l(r)\,, \tag{58}$$

with $\lambda_l := l(l+1)-2$, $l\in\mathbb{N}$, $l\neq 0$, and j and k defined in (25).

From conditions (31) and (32) on ω, we have the respective boundary conditions on ω_l,

$$\lim_{r\to\infty}\omega_l(r)=0\,, \tag{59}$$

$$\omega_l \quad C^1 \ \text{regular at the origin}, \tag{60}$$

and, from (33), the matching condition

$$\omega_l \ \text{class}\ C^1\ \text{across}\ r=R\,. \tag{61}$$

In Sec. IV D an explicit expression for the expansion of the rotational mass-energy M_{rot} in powers or the angular velocity parameter was obtained (23), or, using Eq. (26),

$$M_{\mathrm{rot}}=-\frac{1}{4}\int_0^R \mathrm{d}r\, r^3 j'\int_0^\pi \mathrm{d}\theta \sin^3\theta\,\Omega(\Omega-\omega)+O(\mu^4)\,. \tag{62}$$

Using the series expansions of Ω and ω, (55) and (56), and the fact that the system $\{y_l\}_{l=1}^\infty$ is orthogonal in the Hilbert space $L^2_\rho([-1,1])$, with respect to the weight function $\rho(x):=1-x^2$, $x\in[-1,1]$, and have norm $\|y_l\|_\rho{}^2=2l(l+1)/(2l+1)$, the integral over θ in (62) may be expressed as the sum

$$\int_0^\pi \mathrm{d}\theta\sin^3\theta\,\Omega(r,\theta)[\Omega(r,\theta)-\omega(r,\theta)]=\sum_{l=1}^\infty \frac{2l(l+1)}{2l+1}\Omega_l(r)[\Omega_l(r)-\omega_l(r)]\,, \tag{63}$$

and, consequently, the rotational mass-energy (62) can be expressed as a sum of integrals (over r)

$$M_{\mathrm{rot}}=\sum_{l=1}^\infty \frac{l(l+1)}{2(2l+1)}M_l+O(\mu^4)\,, \tag{64}$$

with

$$M_l := \int_0^R f^2(r)\,\Omega_l(r)[\Omega_l(r)-\omega_l(r)]\,\mathrm{d}r\,,\quad f^2(r):=-r^3 j'(r)\geqslant 0\,. \tag{65}$$

Property (d) (positivity and upper bound on the rotational energy M_{rot}): We consider Eq. (58), which can be written

$$\frac{\mathrm{d}}{\mathrm{d}r}(r^4 j\,\omega_l')-r^2 k\,\lambda_l\,\omega_l=-4\,f^2\,(\Omega_l-\omega_l)\,. \tag{66}$$

The main observation is that, multiplying both sides of Eq. (66) by ω_l, integrating from $r=0$ to $r=\infty$, and taking into account that $f^2=-r^3 j'=4\pi r^4(\varepsilon_0+p_0)\,k\equiv 0\,\forall\, r>R$,

$$\int_0^\infty\left[\frac{\mathrm{d}}{\mathrm{d}r}(r^4 j\,\omega_l')\,\omega_l-r^2 k\,\lambda_l\,\omega_l{}^2\right]\mathrm{d}r=-4\int_0^R f^2\,\omega_l\,(\Omega_l-\omega_l)\,\mathrm{d}r$$

[note, the integral on the left-hand side converges, because an asymptotically flat (59) solution of Eq. (58) must behave, for $r\to\infty$, as $\omega_l=O(r^{-l-2})$, and $\omega_l'=O(r^{-l-3})$, $l\geqslant 1$]; and, after integrating once by parts the first term on the left-hand side,

$$r^4\, j\, \omega_l'\, \omega_l|_0^\infty - \int_0^\infty [r^4\, j\, (\omega_l')^2 + r^2\, k\, \lambda_l\, \omega_l{}^2]\mathrm{d}r = -4\int_0^R f^2\, \omega_l\, (\Omega_l - \omega_l)\, \mathrm{d}r\,.$$

The first term vanishes because ω_l falls off rapidly enough at $r\to\infty$, and the second term (minus the integral on the left-hand side) is nonpositive (since j and k are always positive), therefore

$$\int_0^R f^2\, \omega_l\, (\Omega_l - \omega_l)\, \mathrm{d}r \geqslant 0\,. \tag{67}$$

Using a few simple linear algebra calculations [including the Cauchy-Schwarz inequality for the bilinear form $\langle u,v\rangle_f := \int_0^R f^2(r)\, u(r)\, v(r)\, \mathrm{d}r u,v \in C^0([0,R])$], the former inequality (67) yields (see Ref. 1, Sec. V) $0 \leqslant M_l \leqslant \int_0^R f^2\, \Omega_l{}^2\, \mathrm{d}r$, which gives respective bounds on M_{rot} [cf. (64)],

$$0 \leqslant M_{\mathrm{rot}} \leqslant \sum_{l=1}^{\infty} \frac{l(l+1)}{2(2l+1)} \int_0^R f^2(r)\, \Omega_l{}^2(r)\, \mathrm{d}r + O(\mu^4)\,,$$

or, writing the sum as integral over θ [as in (63)],

$$0 \leqslant M_{\mathrm{rot}} \leqslant \frac{1}{4}\int_0^R \mathrm{d}r\, f^2(r) \int_0^\pi \mathrm{d}\theta \sin^3\theta\, [\Omega(r,\theta)]^2 + O(\mu^4)\,, \tag{68}$$

where $f^2 := -r^3\, j' = 4\pi\, r^4\, (\varepsilon_0 + p_0) e^{(\lambda-\nu)/2}$. Additionally, $\int_0^R f^2\, \omega_l{}^2\, \mathrm{d}r \leqslant \int_0^R f^2\, \Omega_l{}^2\, \mathrm{d}r$ also follows from (67), yielding the "mean values" inequality (in full general)

$$\int_0^R \mathrm{d}r\, f^2(r) \int_0^\pi \mathrm{d}\theta \sin^3\theta\, [\omega(r,\theta)]^2 \leqslant \int_0^R \mathrm{d}r\, f^2(r) \int_0^\pi \mathrm{d}\theta \sin^3\theta\, [\Omega(r,\theta)]^2 + O(\mu^4)\,. \tag{69}$$

□

VI. CONCLUDING REMARKS

Summing up, it has been seen that relativistic stars rotating slowly and differentially, with a non-negative (and nontrivial) angular velocity distribution, $\Omega(x_2,x_3) \geqslant 0\ (\not\equiv 0)$, and satisfying the energy condition $\varepsilon + p \geqslant 0$, have positive *rate of rotational dragging* $\omega > 0$ [property (a) in Sec. V]; and a restriction on the amplitude of the Ω-profile assures also the positivity of the difference $\Omega - \omega$ and, hence, of the *angular momentum density*, this later vanishes on the axis [property (c)]. We also observe that the *rotational mass-energy*, [from property (d)] non-negative and (as expected) "increased" by a (slow) angular velocity of the fluid, Ω, is "decreased" by the dragging effect (over what it would be if this effect were neglected), i.e., is decreasing with respect to dragging rate, ω, despite of [as shown in property (b)] ω being an "increasing function" of Ω. Property (b) and, hence, also property (c) are based on the linearity of the time-angle field equation component to first order in the fluid angular velocity. In the general differentially rotating case, i.e., outside the slow rotation limit, the rotation profile Ω cannot be freely chosen, but is restricted by the integrability condition of the Euler equation, i.e., by Eq. (5). This makes unlikely a generalization of Property (c) outside the slow rotation limit, other than in the form given in Ref. 1, Sec. IV B.

APPENDIX A: BOUNDEDNESS OF SOME FUNCTIONS IN $[0,\infty[\ \ni r$

1. The ratio radius-isotropic radius $\chi(r):=r/h(r)$

We have

$$\frac{h'(r)}{h(r)}=\frac{e^{\lambda(r)/2}}{r}, \tag{A1}$$

with

$$e^{-\lambda(r)}=1-\frac{2\,m(r)}{r}, \tag{A2}$$

where

$$m(r):=\begin{cases} 4\pi\int_0^r \varepsilon_0(s)s^2\,\mathrm{d}s & :\ r\in[0,R], \\ M\equiv 4\pi\int_0^R \varepsilon_0(s)s^2\,\mathrm{d}s & :\ r\in\,]R,\infty[, \end{cases} \tag{A3}$$

if we denote the stellar radius of the static model by $R>0$. As we start with a (physically) regular (i.e., noncollapsed) static solution, we assume that $2m(r)<r$ (for all $r\in\,]0,R[$), and $2M<R$.

Integrating Eq. (A1) and using Eq. (A2) we get

$$h(r)=h(R)\exp\left(\int_R^r \frac{\mathrm{d}s}{\sqrt{s(s-2m(s))}}\right). \tag{A4}$$

[Note, the constant $h(R)$ is determined by the asymptotic condition

$$\lim_{r\to\infty}\frac{h(r)}{r}=1\,;$$

see below.] Let

$$g(r):=\int_R^r \frac{\mathrm{d}s}{\sqrt{s(s-2m(s))}} \quad \forall r>0\,. \tag{A5}$$

With this definition, the solution (A4) now writes

$$h(r)=h(R)\exp(g(r))\,. \tag{A6}$$

Due to the assumptions made for m, g is obviously a continuous function in the open interval $]0,\infty[$; consequently, by (A6), h is also a continuous function there, and, in particular, $h(r)$ cannot be zero in $]0,\infty[$ [unless $h(R)=0$, however this would contradict asymptotic flatness]; therefore $\chi: r\mapsto\chi(r):=r/h(r)$ is continuous in $]0,\infty[$ as well. Choose an $\epsilon\in\,]0,R[$ and an $\epsilon'\in\,]R,\infty[$, then χ is bounded below and above in the interval $[\epsilon,\epsilon']$ (where the upper and lower bound depend on the selected ϵ and ϵ', of course). Let us now consider the intervals $[0,\epsilon]$ and $[\epsilon',\infty[$ separately.

On $[\epsilon',\infty[$: We have

$$0\leqslant m(r)\equiv M\,.$$

Then

$$\frac{1}{s}\leqslant\frac{1}{\sqrt{s(s-2m(s))}}\equiv\frac{1}{\sqrt{s(s-2M)}}\quad\forall r\in[\epsilon',\infty].$$

As in this interval $r\geqslant R$, we find, with Eq. (A5),

$$\ln\left(\frac{r}{R}\right)=\int_R^r\frac{\mathrm{d}s}{s}\leqslant g(r)\equiv\int_R^r\frac{\mathrm{d}s}{\sqrt{s(s-2M)}}=2\ln\left(\frac{\sqrt{r}+\sqrt{r-2M}}{\sqrt{R}+\sqrt{R-2M}}\right).$$

Inserting it into Eq. (A6), yields (since exp is a monotonically increasing function)

$$\frac{h(R)}{R}r\leqslant h(r)\equiv h(R)\left(\frac{\sqrt{r}+\sqrt{r-2M}}{\sqrt{R}+\sqrt{R-2M}}\right)^2\leqslant\frac{4h(R)}{(\sqrt{R}+\sqrt{R-2M})^2}r. \tag{A7}$$

Note especially that

$$\lim_{r\to\infty}\frac{h(r)}{r}=\frac{4h(R)}{(\sqrt{R}+\sqrt{R-2M})^2},$$

but, by asymptotic flatness, $\lim_{r\to\infty}[h(r)/r]=1$; therefore $h(R)=\frac{1}{4}(\sqrt{R}+\sqrt{R-2M})^2>0$. Thus, $h(R)>0$, and, from Eq. (A7),

$$0<\frac{(\sqrt{R}+\sqrt{R-2M})^2}{4h(R)}\leqslant\chi(r)\leqslant\frac{R}{h(R)}<\infty\quad\forall r\in[\epsilon',\infty[. \tag{A8}$$

On $[0,\epsilon]$: We have

$$0\leqslant m(r)=4\pi\int_0^r\varepsilon_0(s)s^2\,\mathrm{d}s\leqslant\frac{4\pi}{3}\hat{\varepsilon}_0r^3=:\frac{c_0}{2}r^3,$$

where $\hat{\varepsilon}_0:=\sup_{r\in[0,R]}\varepsilon_0(r)>0$. Next choose $\epsilon>0$, such that $1-c_0r^2>0$ on $[0,\epsilon]$ [e.g., $\epsilon:=(2\sqrt{c_0})^{-1}$]. Then

$$\frac{1}{s}\leqslant\frac{1}{\sqrt{s(s-2m(s))}}\leqslant\frac{1}{s\sqrt{1-c_0s^2}}\quad\forall r\in[0,\epsilon],$$

and, since in this interval $r\leqslant R$, we find, with Eq. (A5),

$$\ln\left(\frac{R}{r}\right)=\int_r^R\frac{\mathrm{d}s}{s}\leqslant-g(r)\leqslant\int_r^R\frac{\mathrm{d}s}{s\sqrt{1-c_0s^2}}=\ln\left(\frac{R}{r}\right)+\ln\left(\frac{1+\sqrt{1-c_0r^2}}{1+\sqrt{1-c_0R^2}}\right).$$

Again, inserting it into Eq. (A6), yields

$$\frac{h(R)}{R}r\geqslant h(r)\geqslant\frac{h(R)}{R}\frac{1+\sqrt{1-c_0R^2}}{1+\sqrt{1-c_0r^2}}r\geqslant\frac{h(R)(1+\sqrt{1-c_0R^2})}{2R}r,$$

and, hence,

$$0<\frac{R}{h(R)}\leqslant\chi(r)\leqslant\frac{2R}{h(R)(1+\sqrt{1-c_0R^2})}<\infty\quad\forall r\in[0,\epsilon]. \tag{A9}$$

We can therefore conclude that, since $\mathbb{R}_0^+=[0,\epsilon]\cup[\epsilon,\epsilon']\cup[\epsilon',\infty[$ and χ is bounded (from above and below) in each of these subintervals, χ is bounded (from above and below) in $\mathbb{R}_0^+$. □

2. The function *H*

We have

$$H(r):=\frac{-e^{[-\lambda(r)/2]}[-6+6\,e^{[\lambda(r)/2]}+r\,\nu'(r)]}{2\,h(r)},$$

and

$$e^{-\lambda(r)/2}=\sqrt{1-\frac{2m(r)}{r}},$$

$$r\,\nu'(r)=\frac{2m(r)+8\,\pi r^3 p_0(r)}{r-2m(r)}=\frac{\dfrac{2m(r)}{r}+8\,\pi r^2 p_0(r)}{1-\dfrac{2m(r)}{r}}.$$

Thus,

$$H(r)=\frac{1}{2h(r)}\left\{6\left[\sqrt{1-\frac{2m(r)}{r}}-1\right]-\left[\frac{2m(r)}{r}+8\,\pi r^2 p_0(r)\right]\left(\sqrt{1-\frac{2m(r)}{r}}\right)^{-1}\right\}. \tag{A10}$$

Using the Cauchy–Schwarz inequality in (A10), and the following estimates in $r\in[0,\epsilon]$, for some $\epsilon\in\,]0,R[$ small (see former section in Appendix A)

$$0\leqslant m(r)\leqslant\frac{c_0}{2}r^3, \tag{A11}$$

$$0\leqslant\sqrt{1-x}\leqslant 1-\frac{x}{2}\quad\forall x\in[0,1], \tag{A12}$$

$$0\leqslant c_1 r\leqslant h(r)\leqslant c_2 r, \tag{A13}$$

$$0\leqslant p_0(r)\leqslant\hat{p}_0:=\sup_{r\in[0,R]}p_0(r)\quad\forall r\geqslant 0\,, \tag{A14}$$

where the constants $c_{i\ (i=0,\ldots,2)}$ are all strictly positive (and finite), we get

$$\begin{aligned}|H(r)|&\leqslant\frac{1}{2h(r)}\left\{6\left|\sqrt{1-\frac{2m(r)}{r}}-1\right|+\left|\frac{2m(r)}{r}+8\,\pi r^2 p_0(r)\right|\left(\sqrt{1-\frac{2m(r)}{r}}\right)^{-1}\right\}\\&\leqslant\frac{1}{2c_1 r}\left\{6\left[\frac{c_0}{2}r^2\right]+[c_0 r^2+8\,\pi\hat{p}_0 r^2](\sqrt{1-c_0\epsilon^2})^{-1}\right\}=:\frac{c_3 r^2}{c_1 r}=:c_4 r\,,\end{aligned} \tag{A15}$$

with $0<c_3\,,c_4<\infty$. Therefore H is bounded in $[0,\epsilon]$. [Especially, due to Eq. (A15), $H(0)=0$.] And, since, by Eq. (A10), H is also continuous in the open interval $]0,\infty[$ and $\lim_{r\to\infty}H(r)=0$ (because $\lim_{r\to\infty}[h(r)/r]=1$), H is bounded everywhere in $[0,\infty[$. □

APPENDIX B: THE MINIMUM PRINCIPLE FOR GENERALIZED SUPERSOLUTIONS

Consider in a domain (open and connected set) $G\subset\mathbb{R}^n$ $(n\geqslant 2)$ the differential operator with principal part of divergence form, defined by

$$Lu=\partial_i[a_{ij}(x)\partial_j u+a_i(x)\,u]+b_i(x)\,\partial_i u+c(x)\,u\,,$$

with $a_{ij}=a_{ji}$. Notice, an operator L of the general form $Lu=\tilde{a}_{ij}(x)\partial_{ij}u+\tilde{b}_i(x)\partial_i u+\tilde{c}(x)u$ may be written in divergence form provided its principal coefficients $\tilde{a}_{ij}$ are differentiable. If furthermore the $\tilde{a}_{ij}$ are constants, then even with coinciding coefficients ($a_{ij}=\tilde{a}_{ij}$, $b_i=\tilde{b}_i$, $c=\tilde{c}$) and $a_i\equiv 0$. Let us assume that

(1) L is strictly elliptic in G, i.e., $\exists$ a constant $\lambda>0$ such that $\lambda\leqslant$the minimum eigenvalue of the principal coefficient matrix $[a_{ij}(x)]$,

$$\lambda\,|y|^2\leqslant a_{ij}(x)\,y_i y_j \quad \forall y\in\mathbb{R}^n, \quad \forall x\in G\,; \tag{B1}$$

(2) a_{ij}, a_i, b_i, and c are measurable and bounded functions in G,

$$|a_{ij}|<\infty, \quad |a_i|<\infty, \quad |b_i|<\infty, \quad |c|<\infty \text{ in } G \quad (i,j\in\{1,\ldots,n\})\,. \tag{B2}$$

By definition, for a function u which is only assumed to be *weakly differentiable* and such that the functions $a_{ij}\partial_j u+a_i u$ and $b_i\partial_i u+cu$, $i=1,\ldots,n$ are locally integrable [in particular, for u belonging to the Sobolev space $W^{1,2}(G)$], u is said to satisfy $Lu=g$ in G *in a generalized (or weak) sense* (g also a locally integrable function in G) if it satisfies

$$\mathcal{L}(u,\varphi;G):=\int_G\{(a_{ij}\partial_j u+a_i u)\partial_i\varphi-(b_i\partial_i u+cu)\varphi\}\mathrm{d}x=-\int_G g\,\varphi\,\mathrm{d}x, \quad \forall\varphi\geqslant 0, \quad \varphi\in C_c^1(G)$$

[where $C_c^1(G)$ is the set of functions in $C^1(G)$ with compact support in G].

Notice, u is *generalized supersolution* relative to a differential operator L and the domain G (i.e., satisfies $Lu\leqslant 0$ in G in a generalized sense) if it satisfies $\mathcal{L}(u,\varphi;G)\geqslant 0$, $\forall\varphi\geqslant 0$, $\varphi\in C_c^1(G)$.

Theorem 1 (weak minimum principle): *Let $u\in W^{1,2}(G)$, G a bounded domain, satisfy $Lu\leqslant 0$ in G in a generalized sense with*

$$\int_G(c\varphi-a^i\partial_i\varphi)\,\mathrm{d}x\leqslant 0, \quad \forall\varphi\geqslant 0, \quad \varphi\in C_c^1(G) \tag{B3}$$

and conditions (B1) *and* (B2) *above, then*

$$\min_{\bar{G}}\,u\geqslant\min_{\partial G}u^- \quad [\,u^-\equiv\min(u,0)\,]\,.$$

(A proof of this theorem can be found in Ref. 13, Theorem 8.1.)

Theorem 2 (strong minimum principle): *Let $u\in W^{1,2}(G)\cap C^0(G)$ satisfy $Lu\leqslant 0$ in G in a generalized sense, with the operator L satisfying conditions* (B1), (B2), *and* (B3), *then u cannot achieve a nonpositive minimum in the interior of G, unless $u\equiv$*const.

(A proof of this theorem can be found in Ref. 13, Theorem 8.19.) Note that the weak minimum principle, Theorem 1, for $C^0(G)$ supersolutions is a direct consequence.

[12] Indeed, the first order terms (in the fluid angular velocity) of the general metric, as given in Ref. 1, yield (omitting here the tilde symbol for all 5-*lifted* functions) $H(r)=(3\partial_{\bar{r}}B-4\partial_{\bar{r}}U)|_{h(r)}$, where $\bar{r}=h(r)$, given by Eq. (35). [This can be seen by a straightforward calculation, using $e^{2U(h(r))}=e^{\nu(r)}$, $h(r)^2e^{2[B(h(r))-U(h(r))]}=r^2$, and their differentiations with respect to r.] And since [from $h(r)=(\Sigma_{i=1}^{5}x_i^2)^{1/2}$] $\partial_i h(r)=x_i h(r)^{-1}$, we have $H(r)x_i h(r)^{-1}=(3\partial_i B-4\partial_i U)|_{O(\Omega)}$, and, hence, $\langle 3\nabla B-4\nabla U,\nabla\omega\rangle|_{O(\Omega)}$ as the second term in Eq. (43). Also, since to first order (spherical; $K=B$) $e^{2K}N^{-1}=e^{2(B-U)}=r^2h^{-2}$, the coefficient of the right-hand side of Eq. (43) is actually $-\Psi(r)^2e^{-\lambda(r)}r^2h(r)^{-2}=-\psi^2|_{O(\Omega)}$, in the notation of Ref. 1.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 8 AUGUST 2004

Dirac theory within the Standard-Model Extension

Ralf Lehnert[a)]
CENTRA, Departamento de Física, Universidade do Algarve, 8000-117 Faro, Portugal

(Received 12 January 2004; accepted 14 May 2004; published online 12 July 2004)

The modified Dirac equation in the Lorentz-violating Standard-Model Extension (SME) is considered. Within this framework, the construction of a Hermitian Hamiltonian to all orders in the Lorentz-breaking parameters is investigated, discrete symmetries and the first-order roots of the dispersion relation are determined, and various properties of the eigenspinors are discussed. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1769105]

I. INTRODUCTION

Perhaps the most intriguing open question in present-day fundamental physics concerns a quantum theory of all fundamental interactions including gravitation. Experimental research in this field is challenging because quantum-gravitational effects are expected to be suppressed by the Planck scale $M_{\mathrm{Pl}} \simeq 10^{19}$ GeV. However, Lorentz violation is a promising candidate signature of fundamental physics that lies within the sensitivity range of experiments with current or near-future technology.[1]

At presently attainable energy scales, the effects of Lorentz violation can be described within an effective-field-theory framework called the Standard-Model Extension (SME).[2–4] At the classical level, the action of the SME incorporates, e.g., all leading-order contributions to the Lagrangian that are formed by combining Standard-Model and gravitational fields with Lorentz-breaking parameters such that coordinate independence is maintained. Nonzero parameters for Lorentz violation can arise in a variety of approaches to underlying physics including strings,[5] various nonstring models of quantum gravity,[6] noncommutative field theories,[7] varying couplings,[8,9] random dynamics,[10] multiverses,[11] and brane-world scenarios.[12] The flat-space–time limit of the SME has provided the basis for numerous investigations of Lorentz violation involving mesons,[13–15] baryons,[16–19] electrons,[20–23] photons,[24–27] muons,[28] and neutrinos.[2,29,30]

The extraction of the physical content of the SME requires an initial investigation of the quadratic sectors of its Lagrangian paralleling the conventional case. More specifically, the source-free equations of motion, the associated Hamiltonians, the dispersion relations, and, in the fermion case, the eigenspinors form a cornerstone on which further theoretical studies and comparisons with experiment rest. For example, the majority of the aforementioned analyses of Lorentz tests involve the theory of free massive fermions of the SME. Some basics of this theory have been made plausible or have been derived in certain limits as needed, but a comprehensive treatment has been lacking. The present work is intended to fill this gap.[31] More specifically, we give a more rigorous and detailed study of the general free Dirac equation and its solutions in the context of the SME. These results provide important tools for further studies of the physical implications of Lorentz violation.

The paper is organized as follows. Section II sets up the notation, reviews the basics of the modified Dirac equation, and comments on its structure. The construction of a Hermitian Hamiltonian to arbitrary order in the Lorentz-violating parameters is discussed in Sec. III. In Sec. IV, we perform a systematic analysis of discrete dispersion-relation symmetries. Explicit leading-order approximations of the fermion eigenenergies are obtained in Sec. V. Sections VI and VII contain an investigation of the eigenspinors including a discussion of their symmetries and a derivation of

a)Electronic mail: rlehnert@ualg.pt

the generalized spinor projectors. A brief summary is presented in Sec. VIII.

II. BASICS

The general Lorentz-violating Lagrangian for a single spin-1/2 fermion[2] can be cast into a variety of forms. One such form reminiscent of the ordinary Dirac Lagrangian and emphasizing the derivative structure is[17]

$$\mathcal{L}=\frac{1}{2}i\overline{\psi}\Gamma^{\nu}\overleftrightarrow{\partial}_{\nu}\psi-\overline{\psi}M\psi\,, \tag{1}$$

where

$$\begin{aligned}\Gamma^{\nu}&\equiv\gamma^{\nu}+c^{\mu\nu}\gamma_{\mu}+d^{\mu\nu}\gamma_5\gamma_{\mu}+e^{\nu}+if^{\nu}\gamma_5+\frac{1}{2}g^{\lambda\mu\nu}\sigma_{\lambda\mu}\,,\\ M&\equiv m+a_{\mu}\gamma^{\mu}+b_{\mu}\gamma_5\gamma^{\mu}+\frac{1}{2}H^{\mu\nu}\sigma_{\mu\nu}\,.\end{aligned} \tag{2}$$

The gamma matrices $\{I,\gamma_5,\gamma^{\mu},\gamma_5\gamma^{\mu},\sigma^{\mu\nu}\}$ have conventional properties, and the signature of the Minkowski metric $\eta_{\mu\nu}$ is -2. The Lorentz-violating parameters a_{μ}, b_{μ}, $c_{\mu\nu}$, $d_{\mu\nu}$, e_{μ}, f_{μ}, $g_{\mu\nu\lambda}$, and $H_{\mu\nu}$ are taken as real with $c_{\mu\nu}$ and $d_{\mu\nu}$ traceless, $g_{\mu\nu\lambda}$ antisymmetric in its first two indices, and $H_{\mu\nu}$ antisymmetric. Note that a_{μ}, b_{μ}, e_{μ}, f_{μ}, and $g_{\mu\nu\lambda}$ break CPT symmetry as well. For definiteness, we assume $m>0$. However, many of our results also hold in the massless case. On phenomenological grounds, all Lorentz-violating coefficients must be minute in a certain class of inertial frames called *concordant frames*, in which the Earth moves nonrelativistically. Then, paralleling the usual Dirac case, a Hermitian Hamiltonian with two positive and two negative eigenvalues exists.[3]

For future reference, we provide an equivalent form of Lagrangian (1) emphasizing its gamma-matrix structure:[3]

$$\mathcal{L}=\overline{\psi}(S+iP\gamma_5+V^{\mu}\gamma_{\mu}+A^{\mu}\gamma_5\gamma_{\mu}+T^{\mu\nu}\sigma_{\mu\nu})\psi\,. \tag{3}$$

Here, we have defined

$$\begin{aligned}&S[i\partial]\equiv e^{\mu}i\partial_{\mu}-m\,,\quad P[i\partial]\equiv f^{\mu}i\partial_{\mu}\,,\quad V^{\mu}[i\partial]\equiv i\partial^{\mu}+c^{\mu\nu}i\partial_{\nu}-a^{\mu}\,,\quad A^{\mu}[i\partial]\equiv d^{\mu\nu}i\partial_{\nu}-b^{\mu}\,,\\ &T^{\mu\nu}[i\partial]\equiv\frac{1}{2}(g^{\mu\nu\rho}i\partial_{\rho}-H^{\mu\nu})\,,\end{aligned} \tag{4}$$

where the dependence of the introduced quantities on the quantum-mechanical four-momentum operator has been displayed for clarity. The Lagrangians (1) and (3) differ only by a total divergence, so that they are physically equivalent. Note that the replacement $i\partial\rightarrow 1/2\,i\overleftrightarrow{\partial}$ in Def. (4) renders both Lagrangians identical.

The associated modified Dirac equation is given by

$$(i\Gamma^{\mu}\partial_{\mu}-M)\psi(x)=0\,. \tag{5}$$

A Klein–Gordon-type equation can be obtained employing the following squaring procedure. Consider the modified Dirac operator $(i\Gamma^{\mu}\partial_{\mu}-M)$ and change the signs of the parameters b^{μ}, $d^{\mu\nu}$, $g^{\mu\nu\rho}$, and $H^{\mu\nu}$. Application of the resulting operator to Eq. (5) yields the desired second-order equation

$$(\check{S}+\check{P}\gamma^5+\check{V}^{\mu}\gamma_{\mu})\psi(x)=0\,, \tag{6}$$

where we have defined

$$\check{S}\equiv S^2-P^2+V^2+A^2-2T^2\ ,\quad \check{P}\equiv 2(iPS-V\cdot A-iT\tilde{T})\ ,$$

$$\check{V}^\mu\equiv 2(SV^\mu+iPA^\mu-2iT^{\mu\nu}V_\nu+2\tilde{T}^{\mu\nu}A_\nu)\ . \tag{7}$$

In the above expressions, the dependence of the various quantities on $i\partial$ is understood. The tensor $\tilde{T}^{\mu\nu}=1/2\epsilon^{\mu\nu\alpha\beta}T_{\alpha\beta}$ denotes the dual and $\epsilon^{\mu\nu\alpha\beta}$ is the totally antisymmetric symbol with $\epsilon^{0123}=+1$, as usual. The unconventional off-diagonal pieces in Eq. (6) can be eliminated with a second squaring procedure involving the application of $(\check{S}-\check{P}\gamma^5-\check{V}^\mu\gamma_\mu)$ to the Klein–Gordon-type equation (6). As expected, the resulting fourth-order operator can be expressed as the determinant of the modified Dirac operator, paralleling the conventional case:

$$\det(i\Gamma^\mu\partial_\mu-M)\psi(x)=0\ . \tag{8}$$

Thus, each individual component of a spinor solving the modified Dirac equation (5) satisfies Eq. (8).

A plane-wave ansatz $\psi(x)=\exp(-i\lambda^\mu x_\mu)W(\vec{\lambda})$ for solutions to the modified Dirac equation (5) yields

$$(\Gamma^\mu\lambda_\mu-M)W(\vec{\lambda})=0 \tag{9}$$

determining the four-component spinor $W(\vec{\lambda})$, where the four-momentum λ^μ must solve the dispersion relation

$$\det(\Gamma^\mu\lambda_\mu-M)=0\ . \tag{10}$$

With our earlier assumption, dispersion relation (10) has two positive-valued roots $\lambda^0_{+(1,2)}(\vec{\lambda})$ and two negative-valued ones $\lambda^0_{-(1,2)}(\vec{\lambda})$. The corresponding four-momenta and eigenspinors are $\lambda^\mu_{\pm(\alpha)}$ and $W^{(\alpha)}_\pm(\vec{\lambda})$, respectively. Throughout this work, indices in parentheses can take the values 1 and 2. After the usual reinterpretation of the negative-energy solutions, the four-momenta are denoted by

$$p^{(\alpha)}_u\equiv\lambda_{+(\alpha)}\ ,\quad p^{(\alpha)}_v\equiv-\lambda_{-(\alpha)}\ , \tag{11}$$

where we have omitted the Minkowski indices for brevity. The notation for the reinterpreted eigenspinors is

$$U^{(\alpha)}(\vec{p})\equiv W^{(\alpha)}_+(\vec{\lambda})\ ,\quad V^{(\alpha)}(\vec{p})\equiv W^{(\alpha)}_-(-\vec{\lambda})\ . \tag{12}$$

The spinors and the dispersion relation are discussed in more detail in subsequent sections.

For a four-momentum λ_μ that fails to satisfy dispersion relation (10), the cofactor matrix of the modified Dirac operator $(\Gamma^\mu\lambda_\mu-M)$ in λ-momentum space is given by

$$\mathrm{cof}(\Gamma^\mu\lambda_\mu-M)=\det(\Gamma^\mu\lambda_\mu-M)(\Gamma^\mu\lambda_\mu-M)^{-1}\ . \tag{13}$$

This matrix appears in many applications of our model (1), such as the anticommutator function.[3] A more explicit expression is therefore desirable. As a corollary of the above discussion of the equations of motion, we obtain

$$\mathrm{cof}(\Gamma^\mu\lambda_\mu-M)=(\check{S}-\check{P}\gamma^5-\check{V}^\mu\gamma_\mu)(S+iP\gamma_5+V^\mu\gamma_\mu-A^\mu\gamma_5\gamma_\mu-T^{\mu\nu}\sigma_{\mu\nu})\ . \tag{14}$$

As we are now working in momentum space, the according change from $i\partial$ to λ in Defs. (4) and (7) is implied. Replacing $\lambda \to i\partial$ everywhere in (14), yields the associated relation in position space, as usual.

III. HAMILTONIAN

In concordant frames, Γ^0 is invertible,[3] so that the modified Dirac equation (5) can be cast into Schrödinger form:

$$i\partial_0\psi(x) = (\Gamma^0)^{-1}(i\vec{\Gamma}\cdot\vec{\nabla} + M)\psi(x) \ . \tag{15}$$

Although the operator $\tilde{H}[i\vec{\nabla}] \equiv (\Gamma^0)^{-1}(i\vec{\Gamma}\cdot\vec{\nabla} + M)$ appearing above is reminiscent of a Hamiltonian, it fails to be Hermitian in general. This results in such undesirable features like a nonunitary time evolution. This issue can be resolved by a spinor redefinition $A\chi \equiv \psi$ chosen to eliminate the unconventional time-derivative couplings.[21] Here, A is a nonsingular space–time-independent 4×4 matrix, which exists in concordant frames.[3] This field redefinition leaves the physics unaffected because it is a canonical transformation. It amounts to a change of basis in spinor space.

The existence of A is equivalent[3] to the positive definiteness of $\gamma^0\Gamma^0$. One can then define[32] the "square root" of $\gamma^0\Gamma^0$ as the unique, positive-definite, invertible matrix $(\gamma^0\Gamma^0)^{1/2}$ that obeys $(\gamma^0\Gamma^0)^{1/2}(\gamma^0\Gamma^0)^{1/2} = \gamma^0\Gamma^0$. The matrix A can now be expressed as

$$A = (\gamma^0\Gamma^0)^{-1/2} \ . \tag{16}$$

Note that the hermiticity of $\gamma^0\Gamma^0$ yields $A = A^\dagger$. It can now be verified that the Hamiltonian H given by

$$H[i\vec{\nabla}] = (\gamma^0\Gamma^0)^{-1/2}\gamma^0(i\vec{\Gamma}\cdot\vec{\nabla} + M)(\gamma^0\Gamma^0)^{-1/2} \ , \tag{17}$$

which governs the time evolution of the redefined field χ, is Hermitian, as desired. We also point out that H and $\tilde{H}$ are related by the similarity transformation

$$H = (\gamma^0\Gamma^0)^{1/2}\tilde{H}(\gamma^0\Gamma^0)^{-1/2} \ . \tag{18}$$

The determination of the explicit form of the matrix A is challenging in general. In practice, however, it usually suffices to determine A up to a given order in the Lorentz-violating coefficients. Notice that $\gamma^0\Gamma^0$ can be split into the 4×4 identity I plus a Lorentz-breaking correction: $\gamma^0\Gamma^0 = I + \gamma^0(\Gamma^0 - \gamma^0)$. This suggests the following expansion:

$$A = I + \sum_{n=1}^{\infty} \frac{(2n-1)!!}{(2n)!!}(I - \gamma^0\Gamma^0)^n \ . \tag{19}$$

In a basis in which $\gamma^0\Gamma^0$ is diagonal, it is straightforward to verify that the expansion (19) indeed converges and is consistent with the "square root" definition. It can therefore be used to determine A to arbitrary order.

IV. SYMMETRIES OF THE DISPERSION RELATION

An explicit expression for the single-particle dispersion relation (10) can be found by expanding the determinant:[3]

$$\begin{aligned}\det(\Gamma^\mu\lambda_\mu - M) = {} & 4(V_{[\mu}A_{\nu]} - V_\mu V_\nu + A_\mu A_\nu + PT_{\mu\nu} - S\tilde{T}_{\mu\nu} + T_{\mu\alpha}T^\alpha{}_\nu + \tilde{T}_{\mu\alpha}\tilde{T}^\alpha{}_\nu)^2 \\ & + (V^2 - A^2 - S^2 - P^2)^2 - 4(V^2 - A^2)^2 + 6(\epsilon_{\mu\nu\alpha\beta}A^\alpha V^\beta)^2 \ . \end{aligned} \tag{20}$$

Here, S, P, V^μ, A^μ, and $T^{\mu\nu}$ are given in λ-momentum space, and $V_{[\mu}A_{\nu]}=V_\mu A_\nu - A_\mu V_\nu$ denotes the antisymmetric part. Relation (20) also follows directly from Eqs. (13) and (14). The position-space version of Eq. (20) can be used to cast Eq. (8) into a more explicit form.

Further insight about the structure of dispersion relation (10) can be gained by analyzing its properties under charge conjugation C, parity inversion P, and time reversal T. For example, in the absence of explicit expressions for the eigenenergies, these investigations can be used to obtain information about their degeneracy. One such transformation, charge conjugation C, has been considered previously.[3] It was shown that the two sets of roots

$$\{\lambda^0_{-(\alpha)}(\vec{\lambda},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})\}=\{-\lambda^0_{+(\beta)}(-\vec{\lambda},m,-a^\mu,b^\mu,c^{\mu\nu},-d^{\mu\nu},-e^\mu,-f^\mu,g^{\mu\nu\rho},-H^{\mu\nu})\} \tag{21}$$

are identical. In this section, we employ the same methodology to find additional symmetries of the dispersion relation (10) and point out some subtleties regarding the labeling of the roots.

The idea is as follows. Multiplication of the modified Dirac operator $(\Gamma^\mu\lambda_\mu - M)$ with a nonsingular, λ-independent matrix contributes only a nonzero multiplicative factor to the determinant in Eq. (10) leaving this equation, and thus its roots, unchanged. The determinant remains also invariant under transposition or complex conjugation of the modified Dirac operator. The latter is true because $\det(\Gamma^\mu\lambda_\mu - M)$ is real, which follows from Eq. (20) and Def. (4).

We first consider

$$(\Gamma^\mu\lambda_\mu - M)\to\gamma^0(\Gamma^\mu\lambda_\mu - M)\gamma^0\ , \tag{22}$$

which corresponds to parity inversion P in spinor space. We remark in passing that $\det(\Gamma^\mu\lambda_\mu - M)$ remains unchanged, since the overall factor induced is $\det(\gamma^0\gamma^0)=1$. It follows that the dispersion relation (10) is invariant under

$$\{\lambda^\mu,m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu}\}\to\{\lambda_\mu,m,a_\mu,-b_\mu,c_{\mu\nu},-d_{\mu\nu},e_\mu,-f_\mu,g_{\mu\nu\rho},H_{\mu\nu}\}\ . \tag{23}$$

Hence, the two sets

$$\{\lambda^0_{+(\alpha)}(\vec{\lambda},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})\}=\{\lambda^0_{+(\beta)}(-\vec{\lambda},m,a_\mu,-b_\mu,c_{\mu\nu},-d_{\mu\nu},e_\mu,-f_\mu,g_{\mu\nu\rho},H_{\mu\nu})\}\ , \tag{24}$$

each containing the two positive-valued solutions of Eq. (10), must be identical. The result for the remaining sets of the two negative-valued roots is obtained by replacing the subscript $+$ by $-$ in Eq. (24).

Next, we investigate spinor-space time reversal given by

$$(\Gamma^\mu\lambda_\mu - M)\to i\gamma^5 C(\Gamma^\mu\lambda_\mu - M)^* iC\gamma^5\ , \tag{25}$$

where $*$ denotes complex conjugation and C is the usual charge-conjugation matrix. Again, $\det(\Gamma^\mu\lambda_\mu - M)$ is left unchanged. The resulting symmetry between the positive-valued roots of the dispersion relation (10) takes the form

$$\{\lambda^0_{+(\alpha)}(\vec{\lambda},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})\}=\{\lambda^0_{+(\beta)}(-\vec{\lambda},m,a_\mu,b_\mu,c_{\mu\nu},d_{\mu\nu},e_\mu,-f_\mu,-g_{\mu\nu\rho},-H_{\mu\nu})\}\ . \tag{26}$$

For the corresponding expression involving the negative-valued solutions, the subscript $+$ must be changed to $-$.

Note that the above arguments, which generated (21), (24), and (26), provide only equalities between *sets* of roots. In order to find relations between the individual roots, additional considerations are needed. Charge conjugation, on one hand, and parity inversion and time reversal, on the other hand, have to be treated separately.

We begin by discussing charge conjugation. Equality (21) relates positive- and negative-valued eigenenergies. It therefore follows already at this point that in principle relation (21) and the knowledge of one root suffices to construct another solution. The remaining less important question is how the subscript (α) behaves under C. If an additional conserved quantity commuting with H is known (such as a spin component or helicity in the conventional case), the subscript (α) may be used to label its eigenvalues. A definite correspondence can then be determined by investigating the behavior of this conserved quantity under C. In the present case without knowledge of such an additional conserved quantity, the label (α) becomes essentially arbitrary and can therefore be chosen freely.[33] Our conventions agree with the conventional ones in the following sense:[34] the labels of eigenvalues and eigenspinors match and change under charge conjugation. This produces after reinterpretation

$$E_v^{(1,2)}(\vec{p},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})=E_u^{(2,1)}(\vec{p},m,-a^\mu,b^\mu,c^{\mu\nu},-d^{\mu\nu},-e^\mu,-f^\mu, g^{\mu\nu\rho},-H^{\mu\nu}) , \tag{27}$$

where $E_{u,v}^{(1,2)}$ denotes the zero-components of $p_{u,v}^{(1,2)}$ defined by (11). We remark that this labeling agrees with our previous choice.[3]

We now turn to parity inversion and time reversal. The equalities (24) and (26) provide a correspondence between roots of the same sign. As opposed to the previous case for C, it is therefore unclear *a priori* whether P and T individually can be used to construct additional eigenvalues from a known one. However, the combined transformation PT should give a different root: it connects different eigenspinors,[35] and according to our above conventions, this fact should be reflected in the labels of the eigenenergies. The invariance of the dispersion relation (10) under the transformation PT yields with this choice of labeling after reinterpretation

$$E_{u,v}^{(1,2)}(\vec{p},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})=E_{u,v}^{(2,1)}(\vec{p},m,a^\mu,-b^\mu,c^{\mu\nu},-d^{\mu\nu},e^\mu,f^\mu, -g^{\mu\nu\rho},-H^{\mu\nu}) . \tag{28}$$

To determine equalities between the individual roots in (24) and (26), a definite labeling scheme is needed. Without knowledge of an additional conserved operator this becomes a matter of choice constrained only by Eq. (28). Contrary to the charge-conjugation case, there is more freedom even at the conventional level: the two customary labels, spin projection onto a fixed direction or helicity, behave differently under both P and T. For definiteness, we choose the label (α) to change under P, but not under T. This agrees with the behavior of the conventional helicity labeling.

We mention that from any other combination of C, P, and T additional correspondences can be constructed straightforwardly. However, if one eigenenergy (with functional dependence agreeing with our choice of labeling) is known explicitly, the symmetries (27) and (28) suffice to determine the remaining three. As an illustrative example, consider the following case: all Lorentz-violating parameters except a_μ and b_0 are zero. The eigenenergies are then given by[2]

$$E_u^{(\alpha)}=\sqrt{m^2+(|\vec{p}-\vec{a}|+(-1)^\alpha b_0)^2}+a_0 , \quad E_v^{(\alpha)}=\sqrt{m^2+(|\vec{p}+\vec{a}|-(-1)^\alpha b_0)^2}-a_0 . \tag{29}$$

Suppose only one of the above energies, say $E_u^{(1)}=[m^2+(|\vec{p}-\vec{a}|-b_0)^2]^{1/2}+a_0$, is known. According to Eq. (28), the eigenvalue $E_u^{(2)}$ for the other positive-energy solution can then be obtained by keeping the sign of a_μ the same, but reversing the sign of b_0 in complete agreement with Eq. (29). Similarly, the symmetry (27) permits the determination of the antiparticle energy $E_v^{(2)}$ by

keeping all signs unchanged except for the one of a_μ, which has to be reversed. Again, the result is identical to the one given by (29). The remaining antiparticle energy $E_v^{(1)}$ can be found in the same way as $E_v^{(2)}$, but starting from $E_u^{(2)}$ instead of $E_u^{(1)}$.

The above method for the construction of additional eigenvalues from a known root has to be taken with a grain of salt. It is required that the functional dependence of the given eigenenergy on the Lorentz-violating parameters is consistent with our above choice of labeling. The following example illustrates this issue. Consider a model in which Lorentz breaking can be described by a^μ and $\vec{b}$ only. The following expressions for the reinterpreted eigenenergies satisfy its dispersion relation:[2]

$$\begin{aligned} E_u^{\pm} &= [m^2+(\vec{p}-\vec{a})^2 \pm 2\sqrt{m^2\vec{b}^2+(\vec{b}\cdot(\vec{p}-\vec{a}))^2}+\vec{b}^2]^{1/2}+a_0\ , \\ E_v^{\pm} &= [m^2+(\vec{p}+\vec{a})^2 \pm 2\sqrt{m^2\vec{b}^2+(\vec{b}\cdot(\vec{p}+\vec{a}))^2}+\vec{b}^2]^{1/2}-a_0\ . \end{aligned} \tag{30}$$

Suppose again that only one of these eigenenergies, say E_u^+, were known. Employing symmetry (28), i.e., reversing the sign of $\vec{b}$, does not yield any of the other eigenenergies. This can be traced to the fact that the functional dependence in Eq. (30) does not agree with our convention that the labels should change under PT. In Eq. (30), the labels reflect the sign of a square root in the expression rather than being related to the PT transformation. We remark that a suitable labeling can be obtained by multiplying the inner square roots in Eq. (30) by a quantity D that can take the values $+1$ and -1 and changes sign when $\vec{b}$ is reversed (i.e., a possible choice would be $D=\vec{b}\cdot\vec{B}/|\vec{b}\cdot\vec{B}|$, where $\vec{B}$ is arbitrary but fixed and satisfies $\vec{b}\cdot\vec{B}\neq 0$).

The symmetries (27) and (28) can also be used to find parameter combinations yielding degenerate roots. It follows from Eq. (28) that for

$$b^\mu = d^{\mu\nu} = g^{\mu\nu\rho} = H^{\mu\nu} = 0\ , \tag{31}$$

roots of the same sign are equal. Thus, Eq. (31) provides a sufficient condition for energy equality of two (distinct) particle states of a given three-momentum. The same holds true for the antiparticles. Suppose the Lorentz-violating parameters obey

$$a^\mu = d^{\mu\nu} = e^\mu = f^\mu = H^{\mu\nu} = 0\ , \tag{32}$$

or

$$a^\mu = b^\mu = e^\mu = f^\mu = g^{\mu\nu\rho} = 0\ . \tag{33}$$

Either one of the conditions (32) and (33) is sufficient for an energy degeneracy such that for each particle there exists an antiparticle of equal four-momentum. This can be verified by using the symmetries (27) and (28). As a corollary of the above discussion we remark that if $c^{\mu\nu}$ is the only nonvanishing Lorentz-violating parameter, then all four eigenenergies become degenerate after reinterpretation.

V. FIRST-ORDER APPROXIMATION OF THE EIGENENERGIES

In principle, the dispersion relation (20) and Eq. (4) allow the determination of the exact eigenenergies at a given three-momentum in the presence of Lorentz violation. In many circumstances, however, only leading-order corrections to the conventional eigenenergies are of interest. They can be obtained with the method described below.

With the aid of generalized Foldy–Wouthuysen techniques one can find a (momentum-dependent) unitary matrix U transforming the Hamiltonian (17) into the following block-diagonal form:[17]

$$U^{\dagger}HU=\begin{pmatrix} h_{\rm rel} & 0 \\ 0 & \overline{h}_{\rm rel} \end{pmatrix}, \tag{34}$$

where the two 2×2 matrices $h_{\rm rel}$ and $\overline{h}_{\rm rel}$ are the respective Hamiltonians for the fermion and the antifermion. From the procedure it is obvious that the eigenvalues of the matrices $h_{\rm rel}$ and $\overline{h}_{\rm rel}$ are the respective particle and antiparticle energies. To make further progress, consider the expansion

$$h_{\rm rel}=h_0+\sum_{j=1}^{3} h_j\sigma_j \tag{35}$$

of $h_{\rm rel}$ with respect to the basis $\{I,\sigma_j\}$. Here, I is the 2×2 identity and σ_j are the usual Pauli matrices. The components $h_0,\ldots,h_3$ depend on the three-momentum, the mass, and the parameters for Lorentz breaking as determined by the Foldy–Wouthuysen transformation. They yield the fermion eigenenergies by means of

$$E_u^{(\alpha)}=h_0\pm\sqrt{\sum_{j=1}^{3} h_j h_j}\,. \tag{36}$$

Note that the correspondence between the energy superscript (α), $\alpha\in\{1,2\}$ and the sign of the square root in (36) is only constrained by the symmetry (28).

This method is suitable for extracting the leading-order approximation of the eigenenergies because the components $h_0,\ldots,h_3$ are known to first order in the Lorentz-violating parameters:[17]

$$\begin{aligned}
h_0&=\gamma m+\left(a_0-\frac{mc_{00}}{\gamma}-me_0\right)+[a_j-\gamma m(c_{0j}+c_{j0})-me_j]\frac{p^j}{\gamma m}-(c_{jk}-\eta_{jk}c_{00})\frac{p^jp^k}{\gamma m}\,,\\
h_j&=-\frac{1}{\gamma}b_j+md_{j0}+\frac{1}{2}\varepsilon^{kl}{}_jH_{kl}-\frac{1}{2\gamma}m\varepsilon^{kl}{}_jg_{kl0}+\Bigg[\eta_{jk}b_0+m(d_{jk}-\eta_{jk}d_{00})+\varepsilon^{l}{}_{kj}H_{0l}\\
&\quad-\gamma m\varepsilon^{lm}{}_j\left(\frac{1}{2}g_{lmk}-\eta_{km}g_{l00}\right)\Bigg]\frac{p^k}{\gamma m}+\Bigg[\frac{(\gamma-1)m}{\vec{p}^{\,2}}\left(b_k+md_{k0}+\frac{1}{2}\varepsilon^{mn}{}_kH_{mn}+\frac{1}{2}m\varepsilon^{mn}{}_kg_{mn0}\right)\eta_{jl}\\
&\quad-(d_{0k}+d_{k0})\eta_{jl}+\varepsilon^{m}{}_{lj}(g_{m0k}+g_{mk0})\Bigg]\frac{p^kp^l}{\gamma m}+\frac{(\gamma-1)}{\vec{p}^{\,2}}\Bigg[-(d_{kl}-\eta_{kl}d_{00})-\frac{1}{2}\varepsilon^{nq}{}_lg_{nqk}\Bigg]\\
&\quad\times\eta_{jm}\frac{p^kp^lp^m}{\gamma}\,,
\end{aligned} \tag{37}$$

where $\gamma\equiv\sqrt{1+\vec{p}^{\,2}/m^2}$ is the usual relativistic gamma factor, and the totally antisymmetric rotation tensor ε^{jkl} satisfies $\varepsilon_{123}=+1$ and $\varepsilon^{jkl}=-\varepsilon_{jkl}$. Note that the parameter f^{μ} does not contribute to the eigenenergies at leading order. We remark that the symmetries (27) and (28) permit the construction of the antifermion energies.

As an illustration, consider the previously considered (a_{μ},b_0) model with the eigenenergies (29). For this model, we have $h_0=\gamma m+a_0-\vec{p}\cdot\vec{a}/\gamma m$ and $h_j=b_0p_j/\gamma m$. For this case, Eq. (36) yields

$$E_u^{(1,2)}=\sqrt{m^2+\vec{p}^{\,2}}+a_0-\frac{\vec{p}\cdot\vec{a}\pm b_0|\vec{p}|}{\sqrt{m^2+\vec{p}^{\,2}}}\,. \tag{38}$$

One can verify that Eqs. (29) and (38) agree to leading order in the Lorentz-violating coefficients provided the upper and lower signs in Eq. (38) are identified with the labels $\alpha=1$ and $\alpha=2$, respectively. The corresponding antiparticle energies to first order can now be obtained with the aid of symmetry (27), as discussed previously.

VI. SYMMETRIES OF THE EIGENSPINORS

It is necessary to begin this section by introducing our conventions and some more notation. The four eigenspinors $w_{\pm}^{(\alpha)}(\vec{\lambda})$ of $H(\vec{\lambda})$ are determined by

$$(H(\vec{\lambda})-\lambda^{0}_{\pm(\alpha)})w_{\pm}^{(\alpha)}(\vec{\lambda})=0\,. \tag{39}$$

We have used that the dispersion relation (10), and thus its roots $\lambda^{0}_{\pm(\alpha)}$, remain unchanged under the field redefinition. The eigenspinors $w_{\pm}^{(\alpha)}(\vec{\lambda})$ are related to the observer-covariant momentum-space spinors $W_{\pm}^{(\alpha)}(\vec{\lambda})$ obeying Eq. (9) by

$$W_{\pm}^{(\alpha)}(\vec{\lambda})=Aw_{\pm}^{(\alpha)}(\vec{\lambda})\,, \tag{40}$$

where A is the field-redefinition matrix discussed earlier. After reinterpretation of the negative-energy solutions we denote the eigenspinors of H by $u^{(\alpha)}(\vec{p})$ and $v^{(\alpha)}(\vec{p})$ in complete analogy to Def. (12). Thus, the transformation (40) remains valid even after the reinterpretation. The four eigenspinors for a given momentum, which can be taken as orthogonal, span spinor space. Our choice of normalization is

$$u^{(\alpha)\dagger}(\vec{p})u^{(\alpha')}(\vec{p})=\delta^{\alpha\alpha'}\frac{E_u^{(\alpha)}}{m}\,,\quad v^{(\alpha)\dagger}(\vec{p})v^{(\alpha')}(\vec{p})=\delta^{\alpha\alpha'}\frac{E_v^{(\alpha)}}{m}\,,\quad u^{(\alpha)\dagger}(\vec{p})v^{(\alpha')}(-\vec{p})=0\,. \tag{41}$$

Note that the physical spinors $w_{\pm}^{(\alpha)}$, and thus $u^{(\alpha)}$ and $v^{(\alpha)}$, fail to be observer Lorentz covariant due to the frame dependence of A.

The discrete transformations C, P, and T determine correspondences between sets of spinors, paralleling the eigenenergy case. For the charge-conjugation transformation our previous result[3]

$$\{W_{-}^{(\alpha)}(\vec{\lambda},m,a^{\mu},b^{\mu},c^{\mu\nu},d^{\mu\nu},e^{\mu},f^{\mu},g^{\mu\nu\rho},H^{\mu\nu})\}\propto\{W_{+}^{(\beta)c}(-\vec{\lambda},m,-a^{\mu},b^{\mu},c^{\mu\nu},-d^{\mu\nu},-e^{\mu},-f^{\mu},g^{\mu\nu\rho},-H^{\mu\nu})\} \tag{42}$$

holds, which we provide here for completeness. The charge-conjugated spinor $W^{c}\equiv C\overline{W}^{T}$ is defined with the conventional charge-conjugation matrix C. A $\propto$ sign, such as the one in relation (42), is to be understood as follows. For each spinor in one set there exists a spinor in the other set such that the two spinors are linearly dependent.

The parity transformation (22) induces the following relation:

$$\{W_{+}^{(\alpha)}(\vec{\lambda},m,a^{\mu},b^{\mu},c^{\mu\nu},d^{\mu\nu},e^{\mu},f^{\mu},g^{\mu\nu\rho},H^{\mu\nu})\}\propto\{W_{+}^{(\beta)p}(-\vec{\lambda},m,a_{\mu},-b_{\mu},c_{\mu\nu},-d_{\mu\nu},e_{\mu},-f_{\mu},g_{\mu\nu\rho},H_{\mu\nu})\}\,, \tag{43}$$

where $W^{p}\equiv\gamma^{0}W$ denotes the parity-inverted spinor as usual. The relation for the negative-eigenvalue spinors is obtained by replacing the subscripts $+$ with $-$. The result for time reversal (25) is given by

$$\{W_{+}^{(\alpha)}(\vec{\lambda},m,a^{\mu},b^{\mu},c^{\mu\nu},d^{\mu\nu},e^{\mu},f^{\mu},g^{\mu\nu\rho},H^{\mu\nu})\}\propto\{W_{+}^{(\beta)t}(-\vec{\lambda},m,a_{\mu},b_{\mu},c_{\mu\nu},d_{\mu\nu},e_{\mu},-f_{\mu},-g_{\mu\nu\rho},-H_{\mu\nu})\}\,. \tag{44}$$

Here, $W^{t}\equiv-i\gamma^{5}CW^{*}$ is the conventional time-reversed spinor. Again, changing the subscripts from $+$ to $-$ yields the corresponding relation for the remaining eigenspinors.

To find correspondences between individual eigenspinors, a definite labeling scheme for the spinors must be selected. The associated subtleties are analogous to the eigenenergy case and do not require additional discussion. Our previous convention that the labeling of the roots and eigenspinors matches leads after reinterpretation to the symmetries

$$V^{(1,2)}(\vec{p},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})=\zeta U^{(2,1)c}(\vec{p},m,-a^\mu,b^\mu,c^{\mu\nu},-d^{\mu\nu},-e^\mu,-f^\mu,g^{\mu\nu\rho},-H^{\mu\nu}) \tag{45}$$

and

$$U^{(1)}(\vec{p},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})=\eta U^{(2)pt}(\vec{p},m,a^\mu,-b^\mu,c^{\mu\nu},-d^{\mu\nu},e^\mu,f^\mu,-g^{\mu\nu\rho},-H^{\mu\nu}) \tag{46}$$

resulting from C and PT, respectively. Here, ζ and η are (possibly spinor-dependent) proportionality factors, and the superscript pt stands for the combined spinor transformations P and T defined above. The relation arising from PT, but involving the spinors $V^{(1,2)}$ can be obtained by replacing U with V in Eq. (46). If one eigenspinor is known explicitly (with functional dependence agreeing with our choice of labeling), the symmetries (45) and (46) can in principle be used to construct the remaining three.

As an illustration, we again consider the (a_μ,b_0) model. Its eigenspinors in Pauli–Dirac representation are[2]

$$\begin{aligned} U^{(\alpha)}(\vec{p},m,a^\mu,b^0)&=\left(\frac{E_u^{(\alpha)}(E_u^{(\alpha)}-a_0+m)}{2m(E_u^{(\alpha)}-a_0)}\right)^{1/2}\begin{pmatrix}\phi^{(\alpha)}(\vec{p}-\vec{a})\\ \dfrac{-(-1)^\alpha|\vec{p}-\vec{a}|-b_0}{E_u^{(\alpha)}-a_0+m}\phi^{(\alpha)}(\vec{p}-\vec{a})\end{pmatrix},\\ V^{(\alpha)}(\vec{p},m,a^\mu,b^0)&=\left(\frac{E_v^{(\alpha)}(E_v^{(\alpha)}+a_0+m)}{2m(E_v^{(\alpha)}+a_0)}\right)^{1/2}\begin{pmatrix}\dfrac{-(-1)^\alpha|\vec{p}+\vec{a}|+b_0}{E_v^{(\alpha)}+a_0+m}\phi^{(\alpha)}(\vec{p}+\vec{a})\\ \phi^{(\alpha)}(\vec{p}+\vec{a})\end{pmatrix}, \end{aligned} \tag{47}$$

where the two-component spinors $\phi^{(\alpha)}(\vec{k})$ are given by

$$\phi^{(1)}(\vec{k})=\begin{pmatrix}\cos(\theta/2)\\ e^{i\varphi}\sin(\theta/2)\end{pmatrix},\quad \phi^{(2)}(\vec{k})=\begin{pmatrix}-e^{-i\varphi}\sin(\theta/2)\\ \cos(\theta/2)\end{pmatrix}. \tag{48}$$

Here, θ and φ are the spherical-polar angles subtended by $\vec{k}$. Suppose that only one of the spinors in Eq. (47), say $U^{(1)}(\vec{p},m,a^\mu,b^0)$, is known. With the symmetry (46) one can now construct $U^{(2)}(\vec{p},m,a^\mu,b^0)$ up to a constant: in $U^{(1)}(\vec{p},m,a^\mu,b^0)$, the sign of b^0 has to be reversed. Note that this entails changing $E_u^{(1)}$ to $E_u^{(2)}$ by virtue of Eq. (28). Complex conjugation resulting from time reversal affects only $\phi^{(1)}(\vec{p}-\vec{a})$ because all other quantities in the expression are real for this specific model. The final step is multiplication with the matrix $-i\gamma^3\gamma^1\gamma^0=\left(\begin{smallmatrix}-\sigma^2 & 0\\ 0 & \sigma^2\end{smallmatrix}\right)$, where σ^2 denotes the usual Pauli matrix associated with the two-direction. This is somewhat simplified by observing that $\sigma^2\phi^{(1)*}(\vec{k})=i\phi^{(2)}(\vec{k})$. Comparison with Eq. (47) shows that the resulting spinor is indeed $U^{(2)}(\vec{p},m,a^\mu,b^0)$ up to a factor of $-i$. The symmetry (45) determines (up to constants) the remaining two spinors $V^{(1)}(\vec{p},m,a^\mu,b^0)$ and $V^{(2)}(\vec{p},m,a^\mu,b^0)$ from $U^{(2)}(\vec{p},m,a^\mu,b^0)$ and $U^{(1)}(\vec{p},m,a^\mu,b^0)$, respectively: reverse the sign of a^μ, complex conjugate and multiply by $i\gamma^2$. This procedure yields $V^{(2)}(\vec{p},m,a^\mu,b^0)$ exactly and $V^{(1)}(\vec{p},m,a^\mu,b^0)$ up to a relative minus sign.

With an explicit labeling scheme like that selected for the eigenenergies, additional relations between the spinors can be determined using other combinations of Eqs. (42), (43), and (44). The corresponding symmetries for the physical spinors defined earlier can be obtained by replacing $U^{(1,2)}$ and $V^{(1,2)}$ in Eqs. (45) and (46) by $u^{(1,2)}$ and $v^{(1,2)}$, respectively. Note that the field-

redefinition matrix A depends on the Lorentz-violating parameters. For example, to construct $u^{(\alpha)}(\vec{p},m,-a^\mu,b^\mu,c^{\mu\nu},-d^{\mu\nu},-e^\mu,-f^\mu,g^{\mu\nu\rho},-H^{\mu\nu})$ from $U^{(\alpha)}(\vec{p},m,a^\mu,b^\mu,c^{\mu\nu},d^{\mu\nu},e^\mu,f^\mu,g^{\mu\nu\rho},H^{\mu\nu})$ and $A(c^{\mu 0},d^{\mu 0},e^0,f^0,g^{\mu\nu 0})$, the appropriate sign changes have to be implemented *both* in $U^{(\alpha)}$ and in A.

VII. GENERALIZATION OF THE CONVENTIONAL SPINOR PROJECTORS

In the ordinary Dirac case, the spinor matrices that project on the positive- and negative-energy eigenspaces

$$\pm\sum_{\alpha=1}^{2} w_{\pm}^{(\alpha)}\otimes\overline{w}_{\pm}^{(\alpha)}=\frac{\not{\lambda}_{\pm}+m}{2m} \tag{49}$$

are an indispensable tool in numerous calculations. To obtain the Lorentz-violating analog, we fix an arbitrary three-momentum $\vec{\lambda}$ and express the left-hand side of Eq. (13) in terms of the Hamiltonian (17):

$$\mathrm{cof}(\Gamma_\mu\lambda^\mu-M)=\det(\Gamma^0)\prod_{[j]}(\lambda^0-\lambda^0_{[j]})(\gamma^0\Gamma^0)^{-1/2}(\lambda^0-H)^{-1}(\gamma^0\Gamma^0)^{-1/2}\gamma^0\ . \tag{50}$$

Here and in what follows, the dependence of the eigenvalues, the eigenspinors, and the Hamiltonian on the fixed $\vec{\lambda}$ is omitted for brevity. The two positive and two negative eigenvalues $\lambda^0_{+(1,2)}$ and $\lambda^0_{-(1,2)}$ of H are denoted collectively by $\lambda^0_{[j]}$, where $[j]\in\{-(2),-(1),+(1),+(2)\}$. The product in Eq. (50) runs over all four of these eigenvalues. Since the Hamiltonian (17) is Hermitian, there exists a spinor basis in which H is diagonal. In this basis, we have explicitly

$$\mathrm{cof}(\Gamma_\mu\lambda^\mu-M)=\det(\Gamma^0)(\gamma^0\Gamma^0)^{-1/2}P_{\lambda^0}(\gamma^0\Gamma^0)^{-1/2}\gamma^0\ , \tag{51}$$

where the diagonal matrix P_{λ^0} is given by

$$P_{\lambda^0}\equiv\begin{pmatrix}(\lambda^0-\lambda^0_{+(2)})(\lambda^0-\lambda^0_{-(1)})(\lambda^0-\lambda^0_{-(2)}) & & & \cdots & 0\\ & (\lambda^0-\lambda^0_{+(1)})(\lambda^0-\lambda^0_{-(1)})(\lambda^0-\lambda^0_{-(2)}) & & & \vdots\\ \vdots & & (\lambda^0-\lambda^0_{+(1)})(\lambda^0-\lambda^0_{+(2)})(\lambda^0-\lambda^0_{-(2)}) & & \\ 0 & \cdots & & (\lambda^0-\lambda^0_{+(1)})(\lambda^0-\lambda^0_{+(2)})(\lambda^0-\lambda^0_{-(1)})\end{pmatrix}. \tag{52}$$

For $\lambda^0\to\lambda^0_{+(1)}$, the nondegenerate case $\lambda^0_{+(1)}\neq\lambda^0_{+(2)}$ and the degenerate case $\lambda^0_{+(1)}=\lambda^0_{+(2)}$ have to be distinguished.

In the nondegenerate case, the matrix P_{λ^0} simplifies to

$$P_{\lambda^0_{+(1)}}=\begin{pmatrix}(\lambda^0_{+(1)}-\lambda^0_{+(2)})(\lambda^0_{+(1)}-\lambda^0_{-(1)})(\lambda^0_{+(1)}-\lambda^0_{-(2)}) & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\end{pmatrix}, \tag{53}$$

which can be written $P_{\lambda^0_{+(1)}}=(H-\lambda^0_{+(2)})(H-\lambda^0_{-(1)})(H-\lambda^0_{-(2)})$. Thus, $P_{\lambda^0_{+(1)}}$ is proportional to the projector on the $\lambda^0_{+(1)}$ eigenspace. The above argument applied to an arbitrary nondegenerate eigenvalue $\lambda^0_{[r]}$ yields

$$\mathrm{cof}(\Gamma_\mu\lambda^\mu_{[r]}-M)=\det(\Gamma^0)(\gamma^0\Gamma^0)^{-1/2}\prod_{[j]\neq[r]}(H-\lambda^0_{[j]})(\gamma^0\Gamma^0)^{-1/2}\gamma^0\ . \tag{54}$$

The $P_{\lambda^0_{[r]}}$ can be expressed in terms of the eigenspinors in the usual way. Our normalization (41) gives explicitly

$$\prod_{[j]\neq[r]}(H-\lambda^0_{[j]})=\frac{m}{|\lambda^0_{[r]}|}w_{[r]}\otimes w^\dagger_{[r]}\prod_{[j]\neq[r]}(\lambda^0_{[r]}-\lambda^0_{[j]})\ , \tag{55}$$

where $w_{[r]}\in\{w^{(2)}_-,w^{(1)}_-,w^{(1)}_+,w^{(2)}_+\}$ is a shorthand notation for the $\lambda^0_{[r]}$ eigenspinor. One can now determine the desired projectors for the observer-invariant eigenspinors. We obtain for nondegenerate eigenvalues $\lambda^0_{[r]}$:

$$\frac{m}{|\lambda^0_{[r]}|}W_{[r]}\otimes\overline{W}_{[r]}=\frac{\mathrm{cof}(\Gamma_\mu\lambda^\mu_{[r]}-M)}{\det(\Gamma^0)\prod_{[j]\neq[r]}(\lambda^0_{[r]}-\lambda^0_{[j]})}\ . \tag{56}$$

For degenerate eigenvalues $\lambda^0_{[q]}=\lambda^0_{[r]}$, $([q]\neq[r])$, the matrix $P_{\lambda^0_{[r]}}$ vanishes. However, Eq. (51) can be modified to

$$\widehat{\mathrm{cof}}(\Gamma_\mu\lambda^\mu-M)=\det(\Gamma^0)(\gamma^0\Gamma^0)^{-1/2}\hat{P}_{\lambda^0}(\gamma^0\Gamma^0)^{-1/2}\gamma^0\ , \tag{57}$$

where a caret denotes division by the appropriate $(\lambda^0-\lambda^0_{[r]})$ factor. The existence of $\hat{P}_{\lambda^0}$ in the limit $\lambda^0\to\lambda^0_{[r]}$ is immediate from Def. (52). Note that the resulting matrix $\hat{P}_{\lambda^0_{[r]}}$ is again, up to normalization, the projector on the $\lambda^0_{[r]}$ eigenspace. By virtue of Eq. (57), $\widehat{\mathrm{cof}}(\Gamma_\mu\lambda^\mu-M)$ is also well defined for all λ^0. Considerations similar to the ones for a nondegenerate eigenvalue yield the following intermediate expression involving the eigenspinors of H:

$$\prod_{[j]\neq[q],[r]}(H-\lambda^0_{[j]})=\frac{m}{|\lambda^0_{[r]}|}\sum_{[k]=[q],[r]}w_{[k]}\otimes w^\dagger_{[k]}\prod_{[j]\neq[q],[r]}(\lambda^0_{[r]}-\lambda^0_{[j]})\ . \tag{58}$$

The final result for the case of two degenerate eigenvalues $\lambda^0_{[q]}=\lambda^0_{[r]}$, $([q]\neq[r])$ is given by

$$\frac{m}{|\lambda^0_{[r]}|}\sum_{[k]=[q],[r]}W_{[k]}\otimes\overline{W}_{[k]}=\frac{\widehat{\mathrm{cof}}(\Gamma_\mu\lambda^\mu_{[r]}-M)}{\det(\Gamma^0)\prod_{[j]\neq[q],[r]}(\lambda^0_{[r]}-\lambda^0_{[j]})}\ . \tag{59}$$

For any square matrix B, the relation $U^\dagger\mathrm{cof}(B)U=\mathrm{cof}(U^\dagger BU)$ holds, where U is unitary. Thus expressions (56) and (59) for the generalized projectors are independent of the spinor-space basis. We also remark that the projectors (49) for the ordinary Dirac case can be recovered from these results, as expected. In this case, the eigenenergies are degenerate so that Eq. (59) must be employed. Moreover, no field redefinition is necessary, so that the covariant and physical spinors are identical. The matrix of cofactors is given by $(\lambda^2-m^2)(\not{\lambda}+m)$, which can be verified directly or can be obtained from Eq. (14). Assembling everything yields Eq. (49).

As an immediate application, the generalized projector (56) permits the construction of a more explicit form of the eigenspinor in the case when there is a nondegenerate eigenvalue $\lambda^0_{[r]}$:

$$W_{[r]}(\vec{\lambda})=N_{[r]}(\vec{\lambda})\mathrm{cof}(\Gamma_\mu\lambda^\mu_{[r]}-M)W^0_{[r]}(\vec{\lambda})\ , \tag{60}$$

where $N_{[r]}(\vec{\lambda})$ is a normalization factor and $W^0_{[r]}(\vec{\lambda})$ any spinor only constrained by $W^0_{[r]}(\vec{\lambda})\notin\mathrm{Ker}[\mathrm{cof}(\Gamma_\mu\lambda^\mu_{[r]}-M)]$. The remaining spinors can be determined, e.g., with the symmetries discussed earlier. If both the negative- and the positive-valued roots are degenerate and an additional conserved quantity commuting with the Hamiltonian is unknown, no orthonormal

spinor basis spanning the eigenspaces is preferred. One can then replace cof$\rightarrow\widehat{\text{cof}}$ in Eq. (60) and in the associated requirement on $W^0_{[r]}(\check{\lambda})$. It is now possible to proceed as in the nondegenerate case.

VIII. SUMMARY

This work has discussed the theory of the Lorentz-violating Dirac equation in the Standard-Model Extension (SME). The main results include various symmetry properties of the solutions and generalizations of conventional relations. In particular, Eq. (19) permits the construction of a Hermitian Hamiltonian to arbitrary order in the Lorentz-violating parameters. Symmetries of the eigenenergies and the eigenspinors arising from the discrete C, P, and T transformations are given by Eqs. (27) and (28), and by Eqs. (45) and (46), respectively. The analog of the conventional spinor projectors is provided by Eq. (56) in the nondegenerate case or Eq. (59) in the degenerate case. These latter two equations involve the matrix of cofactors of the modified Dirac operator, which is given explicitly by Eq. (14).

[33] Note, however, that the labeling should reflect in a consistent way the functional dependence of the roots on the three-momentum, the mass, and Lorentz-violating parameters. To illustrate this issue, consider a b_0 model with dispersion-relation roots labeled $\lambda^0_{+(\alpha)}(\vec{\lambda},m,b_0)=\sqrt{m^2+(|\vec{\lambda}|+(-1)^\alpha b_0)^2}$ and $\lambda^0_{-(\alpha)}(\vec{\lambda},m,b_0)=-\sqrt{m^2+(|\vec{\lambda}|+(-1)^\alpha|b_0|)^2}$. This labeling entails the undesirable feature that the behavior of (α) under C depends on the sign of b_0. A different choice of labels, such as $|b_0|\to b_0$ in $\lambda^0_{-(\alpha)}$, would be more natural. This issue is particularly important for the PT transformation.
[34] In the ordinary Dirac case, either helicity or spin projection with respect to a given direction in the rest frame of the particle is usually employed to characterize the degeneracy of the eigenergies. Note that under charge conjugation both of these operators change sign (Ref. 36). For the present purpose it is therefore irrelevant whether helicity or spin-projection labels are taken as the conventional ones.
[35] Suppose this were not true. In the conventional case, the arguments of the spinors, $\vec{p}$ and m, remain unchanged under the combined transformation of parity inversion and time reversal. This implies that there exist spinors W that are proportional to their PT image $-iC\gamma^5\gamma^0 W$. That this is impossible can be verified by an explicit calculation in Pauli–Dirac representation. Thus the claim holds true in the conventional case for any labeling. Assuming that in the present context the spinors depend smoothly on the Lorentz-breaking parameters as they approach zero, the result can be extended to the case of small Lorentz violation.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 8 AUGUST 2004

Nonlinear canonical transformations in classical and quantum mechanics

Alastair Brodlie[a)]
School of Mathematics, University of Leeds, Leeds LS2 9JT, United Kingdom

(Received 11 January 2004; accepted 14 May 2004; published online 12 July 2004)

p-mechanics is a consistent physical theory which describes both classical and quantum mechanics simultaneously through the representation theory of the Heisenberg group. In this paper we describe how nonlinear canonical transformations affect *p*-mechanical observables and states. Using this we show how canonical transformations change a quantum mechanical system. We seek an operator on the set of *p*-mechanical observables which corresponds to the classical canonical transformation. In order to do this we derive a set of integral equations which when solved will give us the coherent state expansion of this operator. The motivation for these integral equations comes from the work of Moshinsky and a variety of collaborators. We consider a number of examples and discuss the use of these equations for non-bijective transformations. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1771482]

I. INTRODUCTION

Canonical transformations are at the center of classical mechanics.[5,14,18] A canonical transformation in classical mechanics is a map A defined on phase space (throughout this paper we take phase space to be $\mathbb{R}^{2n}$) which preserves the Poisson bracket. That is A: $\mathbb{R}^{2n}\rightarrow\mathbb{R}^{2n}$ such that for any two classical mechanical observables f, g

$$\{f\circ A,g\circ A\}=\{f,g\}\circ A. \tag{1}$$

It is important to note that the map A may well be non-bijective and nonlinear. A condition which is equivalent to (1) is that the map A must also preserve the symplectic form on $\mathbb{R}^{2n}$,

$$\omega(A(q,p),A(q',p'))=\omega((q,p),(q',p')), \tag{2}$$

where ω is defined as $\omega((q,p),(q',p'))=qp'-q'p$. The most advanced applications of canonical transformations in classical mechanics are the Hamilton–Jacobi theory (Ref. 14, Chap. 10, and Ref. 5, Chap. 9) and action angle variables (Ref. 18, Sec. 6.2, and Ref. 5, Chap. 9).

The passage of canonical transformations from classical mechanics to quantum mechanics has been a long journey which is still incomplete. The first person to give a clear formulation of quantum canonical transformations was Dirac; this is presented in his book.[9] Mario Moshinsky along with a variety of collaborators has published a great number of enlightening papers on the subject.[27,29,30,13,10] In these papers the aim is to find an operator, U, defined on a Hilbert space which corresponds to the canonical transformation. Moshinsky and his collaborators developed a system of differential equations which when solved gave the matrix elements—with respect to the eigenfunctions of the position or momentum operator—of U. More recently Arlen Anderson[2,3] has published some results on modeling canonical transformations in quantum mechanics using nonunitary operators.

In this paper we use *p*-mechanics to exhibit relations between classical and quantum canonical transformations. *p*-mechanics[8] describes both classical and quantum mechanics using the Heisen-

a)Electronic mail: abrodlie@maths.leeds.ac.uk

berg group (denoted $\mathbb{H}^n$). The theory contains both observables and states which can both be realized as functions/distributions on $\mathbb{H}^n$. *p*-mechanical observables can be transformed into both quantum and classical observables using different representations of $\mathbb{H}^n$.

We derive a system of integral equations using *p*-mechanics which when solved give the coherent state expansion of an operator on the set of *p*-mechanical observables corresponding to the canonical transformation. Under representations of $\mathbb{H}^n$ this will give us the representation of canonical transformations in both classical and quantum mechanics. Our approach, unlike Moshinsky's, does not need observables to be members of the algebra generated by the position and momentum operators.

In Sec. II we give an outline of *p*-mechanics and extend it to fit the needs of this paper. In Sec. III we derive systems of integral equations for canonical transformations which when solved will give the corresponding operator on *p*-mechanical states in terms of coherent state expansions. For Hilbert space states this is presented in Sec. III A while for states realized as integration kernels these equations are derived in Sec. III B. We consider applications of these equations to nonbijective transformations in Sec. III D. Finally, we summarize the paper and suggest some interesting extensions in Sec. IV.

II. *p*-MECHANICS

The theory of *p*-mechanics has been presented in a number of papers[7,24,23]—a recent review article is Ref. 8. In this section we extend these concepts to fit the purposes of our paper. In particular we give a new definition of *p*-mechanical observables and show how the kernel states can be expanded out using coherent states.

At the heart of *p*-mechanics is the Heisenberg group.[12,34] The Heisenberg group (denoted $\mathbb{H}^n$) is the set of all triples in $\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^n$ under the law of multiplication

$$(s,x,y)\cdot(s',x',y')=(s+s'+\tfrac{1}{2}(x\cdot y'-x'\cdot y),x+x',y+y'). \tag{3}$$

The noncommutative convolution of two functions $B_1,\ B_2\in L^1(\mathbb{H}^n)$ is

$$(B_1*B_2)(g)=\int_{\mathbb{H}^n}B_1(h)B_2(h^{-1}g)dh=\int_{\mathbb{H}^n}B_1(gh^{-1})B_2(h)dh, \tag{4}$$

where dh is Haar measure on $\mathbb{H}^n$ which is Lebesgue measure $ds\,dx\,dy$ on $\mathbb{R}^{2n+1}$. In this paper the convolution algebra $L^1(\mathbb{H}^n)$ is too restrictive so we extend convolution to spaces of distributions. Spaces of interest in this paper are

(i) $\mathcal{E}'(\mathbb{H}^n)$ of distributions with compact support (Ref. 35, Thm. 24.2) on $\mathbb{H}^n$;
(ii) $\mathcal{S}'(\mathbb{H}^n)$ of tempered distributions (also known as the Schwartz space) (Ref. 35, Defn. 25.2) on $\mathbb{H}^n$; and
(iii) $\mathcal{D}'(\mathbb{H}^n)$ of all distributions (Ref. 35, and Chap. 21) on $\mathbb{H}^n$.

The convolution of two distributions is defined in a natural way (Ref. 34, Chap. 0). The spaces $\mathcal{E}'(\mathbb{H}^n)$ and $\mathcal{D}'(\mathbb{H}^n)$ are closed under convolution.

The Lie algebra of $\mathbb{H}^n$ is denoted by $\mathfrak{h}_n$ and can be realized by the left invariant vector fields

$$S=\frac{\partial}{\partial s},\quad X_j=\frac{\partial}{\partial x_j}-\frac{y_j}{2}\frac{\partial}{\partial s},\quad Y_j=\frac{\partial}{\partial y_j}+\frac{x_j}{2}\frac{\partial}{\partial s},$$

with the Heisenberg commutator relations

$$[X_i,Y_j]=\delta_{ij}S.$$

The most common representation of the Heisenberg group is the Schrödinger representation (Ref. 12, Sec. 1.3, and Ref. 34, Eq. 2.23) on $L^2(\mathbb{R}^n)$:

$$(\rho_h^S(s,x,y)\psi)(\xi)=e^{-2\pi ihs-2\pi ix\xi-\pi ihxy}\psi(\xi+hy). \tag{5}$$

Throughout this paper we do not use (5); instead we show how a representation unitarily equivalent to this can at times be advantageous. We now introduce this representation and the space on which it is defined.

Definition 2.1: We define the space $F^2(\mathcal{O}_h)$ *as*

$$F^2(\mathcal{O}_h)=\{f_h(q,p)\in L^2(\mathbb{R}^{2n}):D_h^j f_h=0,\quad \text{for } 1\leqslant j\leqslant n\}, \tag{6}$$

where the operator D_h^j *on* $L^2(\mathbb{R}^{2n})$ *is defined as* $(h/2)(\partial/\partial p_j+i\partial/\partial q_j)+2\pi(p_j+iq_j)$.

The inner product on $F^2(\mathcal{O}_h)$ is given by

$$\langle v_1,v_2\rangle_{F^2(\mathcal{O}_h)}=\left(\frac{4}{h}\right)^n\int_{\mathbb{R}^{2n}}v_1(q,p)\overline{v_2(q,p)}dqdp. \tag{7}$$

$F^2(\mathcal{O}_h)$ is a Hilbert space with this inner product (Ref. 21, Sec. 4.1). The motivation for using this space in p-mechanics originates from Kirillov's method of orbits[19,20]—this relation is discussed in Refs. 8 and 24. $F^2(\mathcal{O}_h)$ is similar to the Fock–Segal–Bargmann [Refs. 6, 12 (Sec. 1.6), and 34 (Chap. 1)] space of analytic functions on $\mathbb{C}^n$ which are square integrable with respect to the measure $e^{-2|z|^2/h}dz$. It is shown in Ref. 24, Prop. 2.6, that $f_h(q,p)$ is in $F^2(\mathcal{O}_h)$ if and only if $f_h(z)e^{|z|^2/h}$ is in the Fock–Segal–Bargmann space with $z=p+iq$. The integral kernel

$$K_I(q,p,x)=e^{2\pi iqx-\pi ipq}e^{-\pi(x-p)^2}$$

provides an isometry W: $L^2(\mathbb{R}^n)\to F^2(\mathcal{O}_h)$ by

$$\psi(x)\mapsto f(q,p)=\int_{\mathbb{R}^n}\psi(x)K_I(q,p,x)dx. \tag{8}$$

This is proved in Ref. 21, Sec. 4.2. It is also shown in Ref. 21, Sec. 4.2, that $F^2(\mathcal{O}_h)$ is a reproducing kernel Hilbert space with reproducing kernel

$$K_R(q,p,q',p')=\exp\left(-\frac{2\pi}{h}(q^2+p^2+q'^2+p'^2-2qq'-2pp'-2iq'p+2iqp')\right).$$

The representation ρ_h (Refs. 24 and 8) of $\mathbb{H}^n$ on $F^2(\mathcal{O}_h)$ is defined by

$$\rho_h(s,x,y):f_h(q,p)\mapsto e^{-2\pi i(hs+qx+py)}f_h\left(q-\frac{h}{2}y,p+\frac{h}{2}x\right), \tag{9a}$$

which is unitary with respect to the inner product defined in (7). This representation is intertwined with the Schrödinger representation by the unitary map (8)[21] and so is unitarily equivalent to the Schrödinger representation.

The crucial theorem which motivates the whole of p-mechanics is the following.

Theorem 2.1 *(The Stone–von Neumann Theorem): All unitary irreducible representations of the Heisenberg group,* $\mathbb{H}^n$*, up to unitary equivalence, are either*

(i) *of the form* ρ_h *on* $F^2(\mathcal{O}_h)$ *from Eq. (9) or*
(ii) *for* $(q,p)\in\mathbb{R}^{2n}$ *the commutative one-dimensional representations on* $\mathbb{C}=L^2(\mathcal{O}_{(q,p)})$

$$\rho_{(q,p)}(s,x,y)u=e^{-2\pi i(q\cdot x+p\cdot y)}u. \tag{9b}$$

Proof: In Ref. 12 or 34 it is shown that this holds for the Schrödinger representation. Our result follows since ρ_h is intertwined with the Schrödinger representation by the isometry W given in (8). □

We can extend both ρ_h and $\rho_{(q,p)}$ to the representation of an infinitely differentiable compactly supported function, $B \in C_0^\infty(\mathbb{H}^n)$, on $\mathbb{H}^n$ by

$$\rho(B) = \int_{\mathbb{H}^n} B(g)\rho(g)dg.$$

The representation of distributions is done in the natural way (Ref. 34, Chap 0, Eq 3.4).

The basic idea of *p*-mechanics is to choose particular functions or distributions on $\mathbb{H}^n$ which under the infinite dimensional representation will give quantum mechanical observables, while under the one dimensional representation will give classical mechanical observables. In doing this it is shown that both mechanics are derived from the same source. *p*-mechanical observables can be realized as operators (some of which are unbounded) on a subset of $L^2(\mathbb{H}^n)$ generated by convolutions of the chosen functions or distributions. To define *p*-mechanical observables properly we need to introduce a map from the set of classical observables to the set of *p*-mechanical observables. In Refs. 8 and 24 a map of *p*-mechanization, $\mathcal{P}$, from the set of classical observables to the set of *p*-mechanical observables is defined as

$$(\mathcal{P}f)(s,x,y) = \delta(s)\check{f}(x,y), \tag{10}$$

where f is any classical observable and $\check{f}$ is the inverse Fourier transform of f [that is, $\check{f}(x,y) = \int_{\mathbb{R}^{2n}} f(q,p)e^{2\pi i(qx+py)}dqdp$].

Definition 2.2 (*p*-Mechanical Observables): *The set of p-mechanical observables is the image of the set of classical observables under the map $\mathcal{P}$ from Eq. (10).*

Clearly this definition depends on how the set of classical observables is defined. Any physically reasonable classical mechanical observable can be realized as an element of $\mathcal{S}'(\mathbb{R}^{2n})$. Since the Fourier transform maps $\mathcal{S}'(\mathbb{R}^{2n})$ into itself, $\mathcal{S}'(\mathbb{H}^n)$ is a natural choice for the set of *p*-mechanical observables. It includes the image of all classical observables which are polynomials or exponentials of the variables q and p.

If we take the ρ_h representation (9) of many of the distributions described above, we would get unbounded operators. For example, the distribution $\delta(s)\delta^{(1)}(x)\delta(y)$ under the ρ_h representation will generate the unbounded operator $(h/2)(\partial/\partial p) - 2\pi iqI$. This operator is clearly not defined on the whole of $F^2(\mathcal{O}_h)$. This technical problem can be solved by the usual method of rigged Hilbert spaces (also known as Gelfand triples)[36,32,33] which uses the theory of distributions. Another approach to dealing with unbounded operators is given by using the Gårding space as explained in Ref. 34, Chap. 0.

The dynamics of a *p*-mechanical system is described in Refs. 8, 23, and 24 using the universal brackets. The universal brackets (also known as *p*-mechanical brackets) are

$$\{[B_1, B_2]\} = \mathcal{A}(B_1 * B_2 - B_2 * B_1), \tag{11}$$

where $\mathcal{A}$ is the right inverse to the vector field $S = \partial/\partial s$. It is shown in Ref. 23, Prop. 3.5, that under the one and infinite dimensional representations the universal brackets become the Poisson brackets and the quantum commutator, respectively. Hence, for a system with Hamiltonian B_H (the *p*-mechanization of the classical Hamiltonian H) solving the *p*-dynamic equation,

$$\frac{dB}{dt} = \{[B, B_H]\} \tag{12}$$

will give the quantum and classical dynamics under the infinite and one dimensional representations, respectively.

In Refs. 7 and 8, states in *p*-mechanics were introduced. They were defined as functionals on the set of *p*-mechanical observables and came in two forms—elements of a Hilbert space and integration kernels.

Definition 2.3: The Hilbert space $\mathcal{H}_h$, $h \in \mathbb{R}\backslash\{0\}$, is defined as the set of functions on $\mathbb{H}^n$,

$$\mathcal{H}_h=\{e^{-2\pi ihs}f(x,y):E_h^j f=0 \quad 1\leqslant j\leqslant n \quad \text{and} \quad f\in L^2(\mathbb{R}^{2n})\}, \tag{13}$$

where the operator $E_h^j=\pi h(y-ix)+i\partial/\partial x-\partial/\partial y$ *[this is the Fourier transform of* D_h^j *from (6)].*

The inner product on $\mathcal{H}_h$ is defined as

$$\langle v_1,v_2\rangle_{\mathcal{H}_h}=\left(\frac{4}{h}\right)^n\int_{\mathbb{R}^{2n}}v_1(s,x,y)\overline{v_2}(s,x,y)dxdy. \tag{14}$$

The set of *p*-mechanical observables acts on $\mathcal{H}_h$ by convolution. For many observables this will give rise to unbounded operators which are not defined on the whole of $\mathcal{H}_h$. This problem is solved as before by the use of rigged Hilbert spaces. It is shown in Ref. 7, Eq. 3.4, that any element $v\in\mathcal{H}_h$ is of the form $v(s,x,y)=e^{-2\pi ihs}\hat{f}(x,y)$ for some $f\in F^2(\mathcal{O}_h)$ ($\hat{f}$ denotes the Fourier transform of f).

The state corresponding to $v\in\mathcal{H}_h$ can be realized by an integration kernel

$$l(s,x,y)=\left(\frac{4}{h}\right)^n\int_{\mathbb{R}^{2n}}v((s,x,y)^{-1}(s',x',y'))\overline{v((s',x',y'))}dx'dy'. \tag{15}$$

For any *p*-mechanical observable B the following relation is proved in Ref. 7, Thm. 3.1 and Thm. 3.2:

$$\langle\rho_h(B)f,f\rangle=\langle B*v,v\rangle=\int_{\mathbb{H}^n}B(g)l(g)dg, \tag{16}$$

where f is the element of $F^2(\mathcal{O}_h)$ such that $v(s,x,y)=e^{-2\pi ihs}\hat{f}(x,y)$ and l is the kernel corresponding to v through relation (15). Equation (16) gives the expectation value of the observable B in the state corresponding to f, v and l.

In Ref. 7 an overcomplete system of coherent states in $\mathcal{H}_h$ is derived using representations of the Heisenberg group:

$$v_{(h,q,p)}(s,x,y)=\left(\frac{h}{2}\right)^n\exp\left(-2\pi ihs+\pi i(xq+yp)-\frac{\pi h}{2}\left(\left(x+\frac{p}{h}\right)^2+\left(y-\frac{q}{h}\right)^2\right)\right). \tag{17}$$

The corresponding kernel coherent states are

$$l_{(h,q,p)}=\exp\left(-2\pi i(qx+py)+2\pi ihs-\frac{\pi h}{2}(x^2+y^2)\right). \tag{18}$$

It is shown in Ref. 7 that if we choose $B=\mathcal{P}(f)$, then

$$\lim_{h\to 0}\langle B*v_{(h,q,p)},v_{(h,q,p)}\rangle=\int_{\mathbb{H}^n}Bl_{(h,q,p)}dg=f(q,p).$$

By the usual theory of coherent states (that is, wavelets),[1] in a Hilbert space any element $v\in\mathcal{H}_h$ can be written as

$$v=\int_{\mathbb{R}^{2n}}\langle v,v_{(h,q,p)}\rangle v_{(h,q,p)}dqdp. \tag{19}$$

If we define an inner product on the set of kernels as

$$\langle l_1,l_2\rangle=\int_{\mathbb{R}^{2n}}l_1(s,x,y)\overline{l_2(s,x,y)}dxdy, \tag{20}$$

this inner product will be well defined for any two kernel coherent states from (18) since the integral on the right hand side of (20) will be finite. Then we can define our space of kernels, $\mathcal{L}_h$, as the completion of the set of linear combinations of the coherent states (18). Clearly $\mathcal{L}_h$ is a Hilbert space so we can expand any kernel in $\mathcal{L}_h$ by the formula

$$l(s,x,y)=\int_{\mathbb{R}^{2n}}\int_{\mathbb{R}^{2n}} l(s,x',y')\overline{l_{(h,q,p)}(s,x',y')}dx'dy'l_{(h,q,p)}(s,x,y)dqdp.$$

We now show that the $\mathcal{H}_h$ coherent states are eigenfunctions of the creation and annihilation operators. The creation and annihilation distributions are defined as

$$a^+=\frac{1}{2\pi i}(\delta(s)\delta^{(1)}(x)\delta(y)-i\delta(s)\delta(x)\delta^{(1)}(y)), \tag{21}$$

$$a^-=\frac{1}{2\pi i}(\delta(s)\delta^{(1)}(x)\delta(y)+i\delta(s)\delta(x)\delta^{(1)}(y)). \tag{22}$$

The creation and annihilation operators are convolution by the above distributions. It should be noted that a^+ and a^- are the p-mechanization of the classical observables $q-ip$ and $q+ip$, respectively. By a direct calculation it can be shown that

$$a^-*v_{(h,q,p)}=(q+ip)v_{(h,q,p)},$$

so $v_{(h,q,p)}$ is an eigenfunction for a^- with eigenvalue $(q+ip)$. By another direct calculation using (24) we have

$$\langle v_{(h,q,p)},v_{(h,q',p')}\rangle_{\mathcal{H}_h}=\exp\left(-\frac{\pi}{2h}((p-p')^2+(q-q')^2+2i(qp'-q'p))\right). \tag{23}$$

Finally, by another direct calculation we have that a^- and a^+ are adjoints of each other.

A well known equation which will be used throughout this paper is

$$\int_{\mathbb{R}}\exp(-ax^2+2bx)dx=\left(\frac{\pi}{a}\right)^{1/2}\exp\left(\frac{b^2}{a}\right), \tag{24}$$

where $a>0$. A similar equation (Ref. 15, p. 337) which we repeatedly use is

$$\int_{\mathbb{R}}x^n\exp(-ax^2+2bx)dx=\frac{1}{2^{n-1}a}\left(\frac{\pi}{a}\right)^{1/2}\frac{d^{n-1}}{db^{n-1}}\left(b\exp\left(\frac{b^2}{a}\right)\right), \tag{25}$$

providing $a>0$ and n is an integer greater than or equal to 1. This equation for the particular value of $n=1$ is well known:

$$\int_{\mathbb{R}}x\exp(-ax^2+2bx)dx=\left(\frac{\pi}{a}\right)^{1/2}\left(\frac{b}{a}\right)\exp\left(\frac{b^2}{a}\right). \tag{26}$$

III. NONLINEAR CANONICAL TRANSFORMATIONS

In Refs. 7 and 8 the p-dynamic equation (12) for the forced and harmonic oscillators are solved in p-mechanics. In doing so it was made evident that the quantum and classical pictures of the problems were generated from the same source. To solve the p-dynamic equation for more complicated problems, such as the Kepler problem, technical problems are encountered. In classical mechanics, when these problems arise the solution often lies in finding a canonical transformation to a set of coordinates in which Hamilton's equations have a more manageable form. For

example, the transformation to action-angle variables completely solves the Kepler problem (Ref. 14, Sec. 10.8). By studying canonical transformations in *p*-mechanics we have a tool which will transform the *p*-dynamic equation (12) into a more desirable form.

In studying *p*-mechanical canonical transformations we show how canonical transformations can be represented in the mathematical framework of both quantum and classical mechanics. It is stated in Ref. 3 that canonical transformations have three important roles in both quantum and classical mechanics:

(i) time evolution
(ii) physical equivalence of two theories, and
(iii) solving a system.

Taking the one and infinite dimensional representation of the *p*-mechanical system will show how these properties are exhibited in classical and quantum mechanics respectively.

There are further benefits of considering canonical transformations in *p*-mechanics. Canonical transformations can represent the symmetries of a classical mechanical system. In looking at the image of canonical transformations in quantum mechanics we can see how these symmetries are represented in quantum mechanics. In Ref. 2 Anderson shows how quantum integrability can be defined in terms of canonical transformations. In Ref. 4 it is shown that quantum canonical transformations can also help in the study of partial differential equations.

In this section we consider nonlinear canonical transformations. The role of linear canonical transformations in *p*-mechanics is straightforward and is described in Refs. 8, 24, and 22. Unfortunately, some of the most fundamental canonical transformations are nonlinear—for example, the passage to action angle variables for the harmonic and the repulsive oscillator.

For nonlinear transformations we follow an approach which is an enhancement of a method pioneered by Mario Moshinsky and a variety of collaborators.[27,29,30,13,10] In this paper we are looking at general *p*-mechanical observables as opposed to just quantum mechanical observables. We also make use of the *p*-mechanical coherent states (17) and (18).

A. Equations for nonlinear transformations involving $\mathcal{H}_h$ states

This method starts with the observation that a canonical transformation in classical mechanics described by $2n$ independent relations

$$q_i \to Q_i(q,p), \tag{27}$$

$$p_i \to P_i(q,p), \tag{28}$$

$i=1,...,n$, where $\{Q_i,P_j\}_{q,p}=\delta_{ij}$ can be realized by $2n$ functional relations

$$f_i(q,p)=F_i(Q,P), \tag{29}$$

$$g_i(q,p)=G_i(Q,P), \tag{30}$$

for $i=1,...,n$ where $\{f_i,g_i\}_{q,p}=\{F_i,G_i\}_{Q,P}$. The advantage of this approach is that the *p*-mechanization (10) of the functions in (29) and (30) may be easier to derive than the functions on the right hand side of Eqs. (27) and (28). We assume throughout the paper that the above functions of q and p are C^∞ with isolated singularities and when integrated next to an element of $\mathcal{S}(\mathbb{R}^{2n})$ will be finite. This means they can always be realized as elements of $\mathcal{S}'(\mathbb{R}^{2n})$. The isolated singularity condition means the equality in system (29) and (30) holds everywhere except at a finite number of isolated points.

We now derive an equation which will give us a clear form of an operator U on $\mathcal{H}_h$ corresponding to a canonical transformation. This equation will supply us with the matrix elements of the operator U with respect to the overcomplete set of coherent states, that is, it will give us $\langle Uv_{(h,q,p)},v_{(h,q',p')}\rangle$ for all $q, p, q', p' \in \mathbb{R}^n$.

In Dirac's original treatment of quantum canonical transformations (Ref. 9, Chap. 27) he proposed that the canonical transformation from Eqs. (27) and (28) should be represented in quantum mechanics by a unitary operator U on a Hilbert space such that

$$\tilde{Q}_i = U\tilde{q}_i U^{-1} \quad \text{and} \quad \tilde{P}_i = U\tilde{p}_i U^{-1},$$

$i=1,...,n$. Here $\tilde{Q}_i$, $\tilde{P}_i$, $\tilde{q}_i$, $\tilde{p}_i$ are the quantum mechanical observables corresponding to the classical mechanical observables Q_i, P_i, q_i, p_i, respectively.

In Ref. 27 Mello and Moshinsky suggested that in some circumstances it is easier to define the operator U by the equations

$$\tilde{F}U = U\tilde{f} \quad \text{and} \quad \tilde{G}U = U\tilde{g},$$

where $\tilde{F}$, $\tilde{G}$, $\tilde{f}$, $\tilde{g}$ are the quantum mechanical observables (that is operators on a Hilbert space) corresponding to the classical observables F, G, f, g from Eqs. (29) and (30).

We proceed to transfer this approach into p-mechnaics. We want to understand the operator U which is defined by the equations

$$\mathcal{P}(f_i(q,p)) * Uv = U\mathcal{P}(F_i(Q,P)) * v, \tag{31}$$

$$\mathcal{P}(g_i(q,p)) * Uv = U\mathcal{P}(G_i(Q,P)) * v, \tag{32}$$

where $\mathcal{P}$ is the map of p-mechanization (10) and v is any element of $\mathcal{H}_h$.

We will now divert from deriving the general equation by giving an example to illuminate these ideas. (The example we give is a linear transformation, but it must be stressed that this work holds for nonlinear transformations, too.)

Example 3.1: Consider the linear canonical transformation

$$q \to -P, \quad p \to Q.$$

This can be realized by the two equations

$$q + ip = -P + iQ, \tag{33}$$

$$q - ip = -P - iQ, \tag{34}$$

the p-mechanizations of which are

$$a^- = iA^-, \tag{35}$$

$$a^+ = iA^+, \tag{36}$$

where a^- and a^+ are defined in Eqs. (21) and (22).

We now continue to derive the equation which will help us understand the operator U. For the rest of this section we just write the equations out using f_i and F_i, but all these will still hold if they are replaced by g_i and G_i. We begin by taking the matrix elements of Eq. (31) with respect to the coherent states defined in Eq. (17); we get

$$\langle \mathcal{P}(f_i) * Uv_{(h,q,p)}, v_{(h,q',p')} \rangle = \langle U\mathcal{P}(F_i) * v_{(h,q,p)}, v_{(h,q',p')} \rangle. \tag{37}$$

We can expand $Uv_{(h,q,p)}$ using our system of coherent states

$$Uv_{(h,q,p)} = \int_{\mathbb{R}^{2n}} \langle Uv_{(h,q,p)}, v_{(h,q'',p'')} \rangle v_{(h,q'',p'')} dq'' dp''.$$

The left hand side of Eq. (37) now becomes

$$\int_{\mathbb{R}^{2n}} \langle U v_{(h,q,p)}, v_{(h,q'',p'')} \rangle \langle \mathcal{P}(f_i) * v_{(h,q'',p'')}, v_{(h,q',p')} \rangle dq'' dp''.$$

Similarly, we expand out $\mathcal{P}(F_i) * v_{(h,q,p)}$ out as

$$\mathcal{P}(F_i) * v_{(h,q,p)} = \int_{\mathbb{R}^{2n}} \langle \mathcal{P}(F_i) * v_{(h,q,p)}, v_{(h,q'',p'')} \rangle v_{(h,q'',p'')} dq'' dp'',$$

so the right hand side of (37) becomes

$$\int_{\mathbb{R}^{2n}} \langle U v_{(h,q'',p'')}, v_{(h,q',p')} \rangle \langle \mathcal{P}(F_i) * v_{(h,q,p)}, v_{(h,q'',p'')} \rangle dq'' dp''.$$

Hence, if we set $m(a,b,c,d) = \langle U v_{(h,a,b)}, v_{(h,c,d)} \rangle$, Eq. (37) becomes

$$\int_{\mathbb{R}^{2n}} m(q,p,q'',p'') \langle \mathcal{P}(f_i) * v_{(h,q'',p'')}, v_{(h,q',p')} \rangle dq'' dp''$$

$$= \int_{\mathbb{R}^{2n}} m(q'',p'',q',p') \langle \mathcal{P}(F_i) * v_{(h,q,p)}, v_{(h,q'',p'')} \rangle dq'' dp''. \tag{38}$$

Note that to get the full system of equations we need a further n equations which we get by replacing f_i and F_i with g_i and G_i. If we can solve this integral equation for m, then we can understand the effect of U on any element v of $\mathcal{H}_h$ through coherent state expansions. Even if we cannot solve the integral equation (38), we can still gain some useful insights into the nature of the canonical transformation in question.

By (19) the unitarity of U is equivalent to the following two equations holding:

$$\int_{\mathbb{R}^{2n}} \langle v_{(h,q',p')}, U v_{(h,q''',p''')} \rangle \langle U^T v_{(h,q'',p'')}, v_{(h,q''',p''')} \rangle dq''' dp''' = \langle v_{(h,q',p')}, v_{(h,q'',p'')} \rangle,$$

$$\int_{\mathbb{R}^{2n}} \langle v_{(h,q',p')}, U^T v_{(h,q''',p''')} \rangle \langle U v_{(h,q'',p'')}, v_{(h,q''',p''')} \rangle dq''' dp''' = \langle v_{(h,q',p')}, v_{(h,q'',p'')} \rangle,$$

where U^T stands for Hermitian conjugate. Since for many functions f, $\langle \mathcal{P}(f) * v_{(h,q,p)}, v_{(h,q',p')} \rangle$ is a manageable function of q, p, q', p', Eq. (38) will take a simple form for a variety of examples. For example, consider the distributions involved in Eqs. (35) and (36). Since $v_{(h,q,p)}$ is an eigenfunction of the annihilation operator a^- with eigenvalue $(q+ip)$ we have

$$\langle a^- * v_{(h,q,p)}, v_{(h,q',p')} \rangle = (q+ip) \langle v_{(h,q,p)}, v_{(h,q',p')} \rangle,$$

and hence

$$\langle \mathcal{P}(q+ip) * v_{(h,q,p)}, v_{(h,q',p')} \rangle = (q+ip) \langle v_{(h,q,p)}, v_{(h,q',p')} \rangle$$

$$= (q+ip) \exp\left(-\frac{\pi}{2h} ((p-p')^2 + (q-q')^2 + 2i(qp' - q'p)) \right). \tag{39}$$

Here we have used (23). Furthermore, since a^- is the adjoint of a^+ we have

$$\langle a^+ * v_{(h,q,p)}, v_{(h,q',p')} \rangle = \langle v_{(h,q,p)}, a^- * v_{(h,q',p')} \rangle = (q'-ip') \langle v_{(h,q,p)}, v_{(h,q',p')} \rangle,$$

hence

$$\langle \mathcal{P}(q-ip)*v_{(h,q,p)}, v_{(h,q',p')}\rangle = (q'-ip')\langle v_{(h,q,p)}, v_{(h,q',p')}\rangle$$
$$= (q'-ip')\exp\left(-\frac{\pi}{2h}((p-p')^2+(q-q')^2+2i(qp'-q'p))\right). \tag{40}$$

We are now in a position to present Eqs. (38) for the canonical transformation

$$q \to -P, \quad p \to Q.$$

Using Eqs. (33), (34), (39) and (40) we can see that Eqs. (38) must take the form

$$\int_{\mathbb{R}^{2n}} m(q,p,q'',p'')(q''+ip'')\exp\left(-\frac{\pi}{2h}[(p''-p')^2+(q''-q')^2+2i(q''p'-q'p'')]\right)dq''dp''$$
$$= \int_{\mathbb{R}^{2n}} m(q'',p'',q',p')i(q+ip)\exp\left(-\frac{\pi}{2h}[(p-p'')^2+(q-q'')^2+2i(qp''-q''p)]\right)dq''dp''$$

and

$$\int_{\mathbb{R}^{2n}} m(q,p,q'',p'')(q'-ip')\exp\left(-\frac{\pi}{2h}[(p''-p')^2+(q''-q')^2+2i(q''p'-q'p'')]\right)dq''dp''$$
$$= \int_{\mathbb{R}^{2n}} m(q'',p'',q',p')(-i(q''-ip''))\exp\left(-\frac{\pi}{2h}[(p-p'')^2+(q-q'')^2 + 2i(qp''-q''p)]\right)dq''dp''$$

for this canonical transformation. The function

$$m(q,p,q',p') = \exp\left(-\frac{\pi}{2h}(q^2+p^2+q'^2+p'^2-2iqp-2iqq'+2iqp')\right)$$

can be shown to satisfy these equations through the repeated use of formulas (26) and (24). Even though we have only looked at this equation for a linear example, it must be stressed that it holds for nonlinear examples also. We do not give any examples of this here as in the next section we derive some more manageable equations using the kernel states.

B. Equations for nonlinear transformations for states realized as kernels

In Ref. 7 we showed that *p*-mechanical states could be realized as integration kernels. In this section we derive an equation similar to (38) for the kernel states. It is shown that this equation in many circumstances is easier to solve than (38).

Let $\mathcal{U}$ denote the operator on the algebra of *p*-mechanical observables corresponding to a canonical transformation

$$\mathcal{U}B = U^{-1}BU.$$

The adjoint operator $\mathcal{U}^*$ action on a kernel l is defined by

$$\langle \mathcal{U}B, l\rangle = \langle B, \mathcal{U}^* l\rangle. \tag{41}$$

Note here that this is not an inner product, instead a functional on the right acting on a *p*-observable which is on the left. In Sec. II we showed that any kernel l can be expanded using the coherent state kernels, that is,

$$l(s,x,y)=\int_{\mathbb{R}^{2n}}\int_{\mathbb{R}^{2n}} l(s,x',y')\overline{l_{(h,q,p)}(s,x',y')}dx'dy'l_{(h,q,p)}(s,x,y)dqdp.$$

We now derive an integral equation which when solved will give us $\langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')}\rangle$. Initially we present a lemma which will give an exact formula for the *p*-mechanization of a classical observable evaluated by a kernel coherent state.

Lemma 3.1: If f is a classical observable and $\mathcal{P}$ is the map of p-mechanization as defined in Eq. (10), then

$$\langle \mathcal{P}(f), l_{(h,q,p)}\rangle=\left(\frac{2}{h}\right)^n \exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)$$
$$\times\int_{\mathbb{R}^{2n}} f(a,b)\exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb.$$

Proof: By a direct calculation

$$\langle \mathcal{P}(f), l_{(h,q,p)}\rangle=\int_{\mathbb{R}^{2n+1}}\delta(s)\int_{\mathbb{R}^{2n}} f(a,b)\exp(2\pi i(ax+by))dadb$$
$$\times\exp\left(2\pi ihs-2\pi i(qx+py)-\frac{\pi h}{2}(x^2+y^2)\right)dsdxdy,$$

which implies that

$$\langle \mathcal{P}(f), l_{(h,q,p)}\rangle=\int_{\mathbb{R}}\delta(s)\exp(2\pi ihs)ds\int_{\mathbb{R}^{4n}} f(a,b)\exp(x(2\pi i(a-q)))\exp(y(2\pi i(b-p)))$$
$$\times\exp\left(-\frac{\pi h}{2}(x^2+y^2)\right)dadbdxdy.$$

Using (24) the right hand side of the above equation becomes

$$\left(\frac{2}{h}\right)^n\int_{\mathbb{R}^{2n}} f(a,b)\exp\left(\frac{(\pi i(a-q))^2}{\pi h/2}\right)\exp\left(\frac{(\pi i(b-p))^2}{\pi h/2}\right)dadb$$
$$=\left(\frac{2}{h}\right)^n\int_{\mathbb{R}^{2n}} f(a,b)\exp\left(-\frac{2\pi}{h}[(a-q)^2+(b-p)^2]\right)dadb.$$

The result follows from a trivial rearrangement of the above equation. □

So now if we have $2n$ relations as in (29) and (30) we can define the operator $\mathcal{U}$ by the relation

$$\mathcal{U}\mathcal{P}(F_i)=\mathcal{P}(f_i).$$

Applying the kernel $l_{(h,q,p)}$ to both sides of this equation we get

$$\langle \mathcal{U}\mathcal{P}(F_i), l_{(h,q,p)}\rangle=\langle \mathcal{P}(f_i), l_{(h,q,p)}\rangle.$$

This is equivalent to

$$\langle \mathcal{P}(F_i), \mathcal{U}^* l_{(h,q,p)}\rangle=\langle \mathcal{P}(f_i), l_{(h,q,p)}\rangle. \tag{42}$$

However,

$$\mathcal{U}^* l_{(h,q,p)}=\int_{\mathbb{R}^{2n}}\langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')}\rangle l_{(h,q',p')}dq'dp', \tag{43}$$

where the $\langle , \rangle$ for two kernels is just $\langle l, l' \rangle = \int_{\mathbb{R}^{2n}} l\overline{l'} dxdy$. (However, if they contain an observable and a kernel, it is still the evaluation of the observable by the functional.) Substituting (43) into (42) gives us

$$\left\langle \mathcal{P}(F_i), \int_{\mathbb{R}^{2n}} \langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')} \rangle l_{(h,q',p')} dq' dp' \right\rangle = \langle \mathcal{P}(f_i), l_{(h,q,p)} \rangle,$$

which is equivalent to

$$\int_{\mathbb{R}^{2n}} \langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')} \rangle \langle \mathcal{P}(F_i), l_{(h,q',p')} \rangle dq' dp' = \langle \mathcal{P}(f_i), l_{(h,q,p)} \rangle.$$

Using Lemma 3.1 this equation becomes

$$\begin{aligned} &\int_{\mathbb{R}^{2n}} \langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')} \rangle \left(\frac{2}{h}\right)^n \exp\left(-\frac{2\pi}{h}(q'^2+p'^2)\right) \int_{\mathbb{R}^{2n}} F_i(a,b) \exp\Bigg(-\frac{2\pi}{h}(a^2+b^2) \\ &\quad + \frac{4\pi}{h}(aq'+bp')\Bigg) dadbdq'dp' \\ &= \left(\frac{2}{h}\right)^n \exp\left(-\frac{2\pi}{h}(q^2+p^2)\right) \int_{\mathbb{R}^{2n}} f_i(a,b) \exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right) dadb, \end{aligned}$$

which can be simplified to

$$\begin{aligned} &\int_{\mathbb{R}^{2n}} \langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')} \rangle \exp\left(-\frac{2\pi}{h}(q'^2+p'^2)\right) \int_{\mathbb{R}^{2n}} F_i(a,b) \\ &\quad \times \exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq'+bp')\right) dadbdq'dp' \\ &= \exp\left(-\frac{2\pi}{h}(q^2+p^2)\right) \int_{\mathbb{R}^{2n}} f_i(a,b) \exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right) dadb. \end{aligned} \tag{44}$$

We will now go on to show that for a number of canonical transformations this integral equation takes a clear form which is easy to solve.

C. The Hamilton transformation from the forced oscillator

We now demonstrate how Eqs. (44) can deal with a nonlinear transformation. We do this through applying it to the Hamilton transformation for the forced oscillator. This is the canonical transformation which is generated by the time evolution of phase space due to the forced oscillator. The *p*-mechanical forced oscillator is discussed in Ref. 7, for simplicity we consider the oscillator to be of unit mass and unit frequency, but forced by an arbitary function $z(t)$. The classical canonical transformation (this is for the time evolution from time 0 to time t) is defined by

$$Q = q\cos(t) + p\sin(t) + \int_0^t z(\tau)\sin(\tau)d\tau,$$

$$P = -q\sin(t) + p\cos(t) + \int_0^t z(\tau)\cos(\tau)d\tau.$$

Using Eqs. (26) and (24) we get the relations

$$\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\int_{\mathbb{R}^{2n}} a\exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb=\frac{h}{2}q,$$

$$\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\int_{\mathbb{R}^{2n}} b\exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb=\frac{h}{2}p,$$

$$\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\int_{\mathbb{R}^{2n}} \exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb=\frac{h}{2}.$$

These relations imply that Eqs. (44) for this transformation take the form

$$\int_{\mathbb{R}^{2n}}\langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')}\rangle q'dq'dp' = q\cos(t)+p\sin(t)+\int_0^t z(\tau)\sin(\tau)d\tau, \tag{45}$$

$$\int_{\mathbb{R}^{2n}}\langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')}\rangle q'dq'dp' = -q\sin(t)+p\cos(t)+\int_0^t z(\tau)\cos(\tau)d\tau. \tag{46}$$

By observing Eqs. (26) and (24), a potential solution of Eqs. (45) and (46) is

$$\langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')}\rangle = \frac{1}{h}\exp\left(-\frac{\pi}{h}\left[\left(q\cos(t)+p\sin(t)+\int_0^t z(\tau)\sin(\tau)d\tau-q'\right)^2 + \left(\int_0^t z(\tau)\cos(\tau)d\tau-q\sin(t)+p\cos(t)-p'\right)^2\right]\right). \tag{47}$$

We now show that this satisfies (45):

$$\begin{aligned}
&\int_{\mathbb{R}^{2n}}\langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')}\rangle q'dq'dp' \\
&\quad=\int_{\mathbb{R}^{2n}}\frac{1}{h}\exp\left(-\frac{\pi}{h}\left[\left(q\cos(t)+p\sin(t)+\int_0^t z(\tau)\sin(\tau)d\tau-q'\right)^2\right.\right. \\
&\qquad\left.\left.+\left(\int_0^t z(\tau)\cos(\tau)d\tau-q\sin(t)+p\cos(t)-p'\right)^2\right]\right)q'dq'dp' \\
&\quad=\frac{1}{h}\exp\left(-\frac{\pi}{h}\left[\left(q\cos(t)+p\sin(t)+\int_0^t z(\tau)\sin(\tau)d\tau\right)^2\right.\right. \\
&\qquad\left.\left.+\left(\int_0^t z(\tau)\cos(\tau)d\tau-q\sin(t)+p\cos(t)\right)^2\right]\right)\int_{\mathbb{R}^{2n}}\exp\left(\frac{2\pi}{h}\left[q'\left(q\cos(t)+p\sin(t)\right.\right.\right. \\
&\qquad\left.\left.\left.+\int_0^t z(\tau)\sin(\tau)d\tau\right)+p'\left(\int_0^t z(\tau)\cos(\tau)d\tau-q\sin(t)+p\cos(t)\right)\right]\right) \\
&\qquad\times\exp\left(-\frac{\pi}{h}(q'^2+p'^2)\right)q'dq'dp'.
\end{aligned} \tag{48}$$

Using (26) and (24) this becomes

$$\int_{\mathbb{R}^{2n}} \langle \mathcal{U}^* l_{(h,q,p)}, l_{(h,q',p')} \rangle q' dq' dp'$$

$$= \frac{1}{h} \exp\left(-\frac{\pi}{h} \left[\left(q\cos(t) + p\sin(t) + \int_0^t z(\tau)\sin(\tau) d\tau \right)^2 \right.\right.$$

$$\left.\left. + \left(\int_0^t z(\tau)\cos(\tau) d\tau - q\sin(t) + p\cos(t) \right)^2 \right] \right)$$

$$\times h\left(q\cos(t) + p\sin(t) + \int_0^t z(\tau)\sin(\tau) d\tau \right) \exp\left(\frac{\pi}{h} \left[\left(q\cos(t) + p\sin(t) \right.\right.\right.$$

$$\left.\left.\left. + \int_0^t z(\tau)\sin(\tau) d\tau \right)^2 + \left(\int_0^t z(\tau)\cos(\tau) d\tau - q\sin(t) + p\cos(t) \right)^2 \right] \right)$$

$$= q\cos(t) + p\sin(t) + \int_0^t z(\tau)\sin(\tau) d\tau.$$

By a similar calculation we can show that (47) satisfies (45).

D. A note on non-bijective transformations

In Ref. 29 the problem of representing non-bijective canonical transformations in quantum mechanics is considered. The majority of canonical transformations in classical mechanics are non-bijective—one example is the action angle variables for the Kepler problem. If we can represent non-bijective canonical transformations in *p*-mechanics, we can use the infinite dimensional representations to get their representation in quantum mechanics. The physical importance of non-bijective canonical transformations in quantum mechanics is discussed in Ref. 29, Sec. 7. It is claimed that some nonlinear canonical transformations can be used to show that some elements of quantum mechanics are already contained in classical mechanics.

We now outline a method of how to deal with non-bijective canonical transformations in *p*-mechanics. Our method is best illustrated through an example—we look at the transformation into the action angle coordinates for the repulsive oscillator. This is a nonlinear, non-bijective transformation which is discussed in great detail in Ref. 29. The canonical transformation is

$$Q = \ln|p+q|, \tag{49}$$

$$P = \tfrac{1}{2}(p^2 - q^2). \tag{50}$$

The non-bijectiveness of this transformation is manifested by the points (q,p) and $(-q,-p)$ in the original phase space being mapped into the same point. Also the entire line $q+p=0$ is mapped to the single point $Q=-\infty$, $P=0$. To derive an equation for the states realized as kernels we put Eqs. (49) and (50) into the form

$$\exp(2Q) = (p+q)^2,$$

$$P = \tfrac{1}{2}(p^2 - q^2).$$

To derive Eqs. (44) for this example we need the following lemma.

Lemma 3.2: We have the following relations:

$$\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\int_{\mathbb{R}^{2n}}\exp(2a)\exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb$$
$$=\left(\frac{h}{2}\right)\exp\left(2q+\frac{h}{2\pi}\right), \tag{51}$$

$$\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\int_{\mathbb{R}^{2n}}a^2\exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb=\frac{h}{2}\left(\frac{h}{4\pi}+q^2\right). \tag{52}$$

Clearly analogous relations to these hold if we replace a by b on the left hand side and q by p on the right hand side. Furthermore, we have that

$$\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\int_{\mathbb{R}^{2n}}ab\exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb=\frac{h}{2}qp. \tag{53}$$

Proof: Equation (51) follows from a direct calculation using (24):

$$\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\int_{\mathbb{R}^{2n}}\exp(2a)\exp\left(-\frac{2\pi}{h}(a^2+b^2)+\frac{4\pi}{h}(aq+bp)\right)dadb$$
$$=\exp\left(-\frac{2\pi}{h}(q^2+p^2)\right)\left(\frac{h}{2}\right)\exp\left(\frac{2\pi p^2}{h}\right)\exp\left(\frac{((2\pi/h)q+1)^2}{2\pi/h}\right)=\left(\frac{h}{2}\right)\exp\left(2q+\frac{h}{2\pi}\right).$$

Similarly (52) can be verified by a direct calculation using (25) with $n=2$. Likewise (53) can be verified by using (26) twice. □

Using Lemma 3.2, Eqs. (44) for this example take the form

$$\int_{\mathbb{R}^{2n}}\langle\mathcal{U}^*l_{(h,q,p)},l_{(h,q',p')}\rangle\exp\left(2q'+\frac{h}{2\pi}\right)dq'dp'=(p+q)^2+\frac{h}{2\pi}, \tag{54}$$

$$\int_{\mathbb{R}^{2n}}\langle\mathcal{U}^*l_{(h,q,p)},l_{(h,q',p')}\rangle p'dq'dp'=(p^2-q^2). \tag{55}$$

The non-bijectiveness is apparent in Eqs. (54) and (55) since they are invariant under the translation $(q,p)\mapsto(-q,-p)$. Any solution of (54) and (55) will be such that

$$\langle\mathcal{U}^*l_{(h,q,p)},l_{(h,q',p')}\rangle=\langle\mathcal{U}^*l_{(h,-q,-p)},l_{(h,q',p')}\rangle. \tag{56}$$

Since

$$\mathcal{U}^*l_{(h,q,p)}=\int_{\mathbb{R}^{2n}}\langle\mathcal{U}^*l_{(h,q,p)},l_{(h,q',p')}\rangle l_{(h,q',p')}dq'dp'$$

it is clear that $\mathcal{U}^*l_{(h,q,p)}=\mathcal{U}^*l_{(h,-q,-p)}$. Now we show that this map $\mathcal{U}^*$: $\mathcal{L}_h\to\mathcal{L}_h$ is not a bijection. We have the formula for any kernel l

$$\mathcal{U}^*l=\int_{\mathbb{R}^{2n}}\int_{\mathbb{R}^{2n}}\langle\mathcal{U}^*l_{(h,q,p)},l_{(h,q',p')}\rangle\langle l,l_{(h,q,p)}\rangle l_{(h,q',p')}dqdpdq'dp'.$$

So $\mathcal{U}^*l=\mathcal{U}^*l'$ if and only if

$$\int_{\mathbb{R}^{2n}}\langle\mathcal{U}^*l_{(h,q,p)},l_{(h,q',p')}\rangle\langle l,l_{(h,q,p)}\rangle dqdp=\int_{\mathbb{R}^{2n}}\langle\mathcal{U}^*l_{(h,q,p)},l_{(h,q',p')}\rangle\langle l',l_{(h,q,p)}\rangle dqdp$$

holds for almost all q', p'. (Almost every and almost everywhere are measure theoretic terms, see Refs. 31 and 25.) By (56) this is equivalent to

$$\int_{q+p>0}(\langle l,l_{(h,q,p)}\rangle+\langle l,l_{(h,-q,-p)}\rangle)\langle \mathcal{U}^* l_{(h,q,p)},l_{(h,q',p')}\rangle dqdp$$

$$=\int_{q+p>0}(\langle l',l_{(h,q,p)}\rangle+\langle l',l_{(h,-q,-p)}\rangle)\langle \mathcal{U}^* l_{(h,q,p)},l_{(h,q',p')}\rangle dqdp.$$

This holds if and only if

$$\langle l,l_{(h,q,p)}\rangle+\langle l,l_{(h,-q,-p)}\rangle=\langle l',l_{(h,q,p)}\rangle+\langle l',l_{(h,-q,-p)}\rangle \tag{57}$$

holds for almost every q, p such that $q+p>0$. So one way of restoring bijectiveness would be to reduce the size of the original set of kernels by factoring out by the equivalence relation, $l\sim l'$, if and only if (57) holds. In the obvious way we would have a bijection from $\mathcal{L}_h/\sim$ to $\mathcal{L}_h$.

Instead of taking this approach we take the simpler approach of increasing the size of the set of kernels to which we map. In doing so we derive a bijection from $\mathcal{L}_h$ to $\mathcal{L}_h\times\mathcal{L}_h$. We do this through introducing two new operators $\mathcal{U}^{*+}$, $\mathcal{U}^{*-}$: $\mathcal{L}_h\to\mathcal{L}_h$ which are defined as

$$\mathcal{U}^{*+}l_{(h,q,p)}=\begin{cases}\mathcal{U}^* l_{(h,q,p)}, & \text{if } q+p>0\\ 0, & \text{if } q+p<0;\end{cases}$$

and

$$\mathcal{U}^{*-}l_{(h,q,p)}=\begin{cases}0, & \text{if } q+p>0\\ \mathcal{U}^* l_{(h,q,p)}, & \text{if } q+p<0.\end{cases}$$

These operators can be extended to the entire space by coherent state (i.e., wavelet) expansions. Furthermore, we define the mapping: $\tilde{\mathcal{U}}^*$: $\mathcal{L}_h\to\mathcal{L}_h\times\mathcal{L}_h$ by

$$\tilde{\mathcal{U}}^* l=[\mathcal{U}^{*+}l,\mathcal{U}^{*-}l].$$

So for any kernel l,

$$\tilde{\mathcal{U}}^* l=\int_{\mathbb{R}^{2n}}\langle l,l_{(h,q,p)}\rangle\tilde{\mathcal{U}}^* l_{(h,q,p)}dqdp$$

$$=\int_{\mathbb{R}^{2n}}\langle l,l_{(h,q,p)}\rangle[\mathcal{U}^{*+}l_{(h,q,p)},\mathcal{U}^{*-}l_{(h,q,p)}]dqdp$$

$$=\left[\int_{q+p>0}\langle l,l_{(h,q,p)}\rangle\mathcal{U}^* l_{(h,q,p)}dqdp,\int_{q+p<0}\langle l,l_{(h,q,p)}\rangle\mathcal{U}^* l_{(h,q,p)}dqdp\right].$$

Hence $\tilde{\mathcal{U}}^* l=\tilde{\mathcal{U}}^* l'$ if and only if

$$\int_{q+p>0}\langle l,l_{(h,q,p)}\rangle\mathcal{U}^* l_{(h,q,p)}dqdp=\int_{q+p>0}\langle l',l_{(h,q,p)}\rangle\mathcal{U}^* l_{(h,q,p)}dqdp$$

and

$$\int_{q+p<0}\langle l,l_{(h,q,p)}\rangle\mathcal{U}^* l_{(h,q,p)}dqdp=\int_{q+p<0}\langle l',l_{(h,q,p)}\rangle\mathcal{U}^* l_{(h,q,p)}dqdp.$$

These two equations hold if and only if

$$\langle l, l_{(h,q,p)}\rangle = \langle l', l_{(h,q,p)}\rangle$$

holds for almost every q, p such that $q+p>0$ and almost every q, p such that $q+p<0$. This is equivalent to l and l' being equal. Hence we have restored bijectiveness.

The implications to quantum mechanics of this are as follows. We now have a map $\tilde{\mathcal{U}}$ (the adjoint of $\mathcal{U}^*$) which transforms p-mechanical observables corresponding to this non-bijective canonical transformation. If we take the ρ_h representation of this, we get a map for quantum observables.

This work also has classical implications. Initially looking at nonstatistical mechanics we have if the canonical transformation changes a classical observable $f(q,p)$ into $\tilde{f}(q,p)$ and the p-mechanization of f is $B(s,x,y)$, then

$$\tilde{f}(q,p) = \langle B, \mathcal{U}^* l_{(0,q,p)}\rangle = \langle B, \mathcal{U}^* l_{(0,-q,-p)}\rangle = \tilde{f}(-q,-p).$$

Hence we have a demonstration of the classical non-bijectiveness directly from p-mechanics. If we let A denote the set of classical observables, we have shown that the mapping from A→A by $f \mapsto \tilde{f}$ is non-bijective. However, we can restore bijectiveness in the classical mapping through p-mechanics. If we introduce the operator $\widetilde{\mathcal{U}^{class}}$: A→A×A by

$$\widetilde{\mathcal{U}^{class}} f(q,p) = \langle B, \widetilde{\mathcal{U}^*} l_{(0,q,p)}\rangle,$$

where B is the p-mechanization of f, then

$$\widetilde{\mathcal{U}^{class}} f(q,p) = \langle B, \tilde{\mathcal{U}}^* l_{(0,q,p)}\rangle = [\langle B, \mathcal{U}^{*+} l_{(0,q,p)}\rangle, \langle B, \mathcal{U}^{*-} l_{(0,q,p)}\rangle] = \begin{cases} [\tilde{f}(q,p),0] & \text{if } q+p>0 \\ [0,\tilde{f}(q,p)] & \text{if } q+p<0. \end{cases}$$

Now we have a map A→A×A representing this canonical transformation which is bijective. We can extend all of this to statistical mechanics[16] by using linear combinations of these coherent states.

IV. SUMMARY AND POSSIBLE EXTENSIONS

One of the main features of this work is demonstrating how using coherent states in a Segal–Bargmann–Fock-type space can sometimes be advantageous over using the matrix elements of position and momentum in $L^2(\mathbb{R}^n)$. Another feature of our equations is that they do not rely on the property that observables are elements of the algebra generated by the position and momentum operators. In Refs. 29 and 27 all the quantum mechanical operators are derived using this algebra condition—in this paper we use an integral transform instead. This integral transform at first makes our equations look less desirable, but it is shown that for many examples they take a simple form. This work has also demonstrated the advantages of representing states as integration kernels—this complements the work in Ref. 7.

The most immediate extension of this work would be to look at more complex examples, especially some more nonlinear, non-bijective examples. One possible and interesting extension would be to extend these ideas to phase spaces other than $\mathbb{R}^{2n}$. This would be to extend these ideas to a phase space which is a general symplectic manifold (Ref. 26, Chap. 5), for example T^*M for some general manifold M (Ref. 5, Chaps. 7–10, and Ref. 18, Chap. 5). Another interesting extension would be to look at the role of Egorov's theorem[22] in infinitesimal canonical transformations for p-mechanics. Egorov's theorem[11] has always been posed in the language of pseudodifferential and Fourier integral operators on $L^2(\mathbb{R}^n)$; this idea could be extended to our space $F^2(\mathcal{O}_h)$ with pseudodifferential operators being replaced by Toeplitz operators as in Ref. 17.

All these equations could be defined outside the world of p-mechanics. If the usual coherent states in $L^2(\mathbb{R}^n)$ (Ref. 28, Sec. 10.7) were used instead of the eigenfunctions of position and momentum, Moshinsky's equations would be immediately transformed into integral equations.

Analytic representations based on su(3) coherent states and Robertson intelligent states

M. Daoud[a)]
Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

(Received 9 April 2004; accepted 7 June 2004; published 26 July 2004)

Robertson intelligent states which minimize the Schrödinger–Robertson uncertainty relation are constructed as eigenstates of a linear combination of Weyl generators of the su(3) algebra. The construction is based on the analytic representations of su(3) coherent states. New classes of coherent and squeezed states are explicitly derived. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1777794]

I. INTRODUCTION

The coherent states introduced as displacement of the ground state of harmonic oscillator by Schrödinger,[1] have found revived interest when it was realized that they are eigenfunctions of the annihilation operator and minimize the Heisenberg uncertainty relation. The generalization of the usual coherent states from the Weyl–Heisenberg to the other Lie algebras and from harmonic oscillator to other potentials, followed these three approaches, namely, (i) eigenstates of lowering group generator for Lie algebras or annihilation operator of exactly solvable system, (ii) as orbits of the extremal weight state, or (iii) as states minimizing the uncertainty relation. These different approaches lead to distinct sets of coherent states and coincide only in the special case of the harmonic oscillator (see Refs. 2–4 for review). Concerning the optimization of the uncertainty principle, it was observed that a relation more accurate than the Heisenberg one may be used to construct generalized coherent states and squeezed states. Indeed this relation known as Schrödinger–Robertson uncertainty inequality[5] can be minimized and gives rise to new sets of coherent and squeezed states (see the pioneering works[6–8]). The states resulting from this minimization have different names in the literature such as correlated states[6–8] or Robertson intelligent states.[9]

More recently, there has been much interest in such states for Lie algebras[9–13] as well as for quantum systems evolving in various potentials.[14–17] Robertson intelligent states for the quadrature components of Weyl generators of the algebras su(1,1) and su(2) were constructed.[9–13] They were also defined for exactly solvable quantum systems as the eigenstates of complex combination of creation and annihilation operators.[14–17]

The purpose of this paper is to further extend the classes of Robertson intelligent states for higher symmetries. In this sense, the main idea of this note is to construct the intelligent states for the quadrature components of Weyl operators of the algebra su(3). For this end, it may be useful to start by giving the explicit computation of the associated coherent states and their analytic representations. Hence, one can introduce the differential realizations for the su(3) generators. As we will see, the analytic realization enables us to convert the eigenvalue equations arising from the minimization of Schrödinger–Robertson inequality into quasilinear differential equations which provide the Robertson intelligent states.

The paper is organized as follows. In Sec. II we review the derivation of su(3) coherent states. We compute explicitly the action of unitary displacement operator on the highest weight vector of the finite dimension representation space of the algebra su(3). We give the analytic representations of the su(3) coherent states. We construct also the differential operators corresponding to the actions of the generators of su(3) on the Fock–Bargmann space. In Sec. III, we show how the

[a)]Permanent address: LPMC, Faculty of Sciences, University Ibn Zohr, Agadir, Morocco.

analytic representation based on the coherent states provides us with the tool to solve the eigenvalue equations resulting from the minimization of the Schrödinger–Robertson relation and to obtain intelligent states for the quadrature components of su(3) Weyl generators. We conclude in Sec. IV after pointing out a number of interesting open problems.

II. ANALYTIC REPRESENTATIONS OF su(3)-COHERENT STATES

A. Reconstructing su(3)-coherent states

We shall begin by re-examining the construction of the coherent states associated with a quantum system of dynamical symmetry su(3). Although this subject has been considered previously in Refs. 18 and 19 (see also Refs. 20 and 21), we thought that it is always interesting to give another method based on the explicit computation of the action of the displacement operator on the highest weight state (fudicial vector) of the finite dimensional representation space of the algebra su(3). The explicit forms of such states are needed to perform their analytic representations and to give the realization of the generators of the algebra under consideration.

The algebra su(3) is defined by the generators e_i, f_i, h_i $(i=1,2)$ and the relations

$$[e_i,f_i]=\delta_{ij}h_j, \tag{1}$$

$$[h_i,e_j]=a_{ij}e_j, \quad [h_i,f_j]=-a_{ij}f_j, \tag{2}$$

$$[e_i,e_j]=0 \quad \text{for} \quad |i-j|>1, \tag{3}$$

$$e_i^2e_{i\pm1}-2e_ie_{i\pm1}e_i+e_{i\pm1}e_i^2=0, \tag{4}$$

$$f_i^2f_{i\pm1}-2f_if_{i\pm1}f_i+f_{i\pm1}f_i^2=0, \tag{5}$$

where $(a_{ij})_{i,j=1,2}$ is the Cartan matrix of su(3), i.e., $a_{ii}=2$, $a_{i,i\pm1}=-1$ and $a_{ij}=0$ for $|i-j|>1$. Many aspects of Lie algebras are best considered after choosing a special type of representation basis. Since one would write down the su(3) coherent states, the most convenient choice, in this case, is the bosonic realization. Indeed, an adapted basis is given in term of three bosonic pairs of creation and annihilation operators; they satisfy the commutation relations

$$[a_k^-,a_l^+]=\delta_{kl}, \tag{6}$$

where $k,l=1,2,3$. The operator numbers are $N_k=a_k^+a_k^-$. The Fock space is generated by the eigenstates $|n_1,n_2,n_3\rangle$ of a number of operators, namely,

$$|n_1,n_2,n_3\rangle=\frac{(a_1^+)^{n_1}}{\sqrt{n_1!}}\frac{(a_2^+)^{n_2}}{\sqrt{n_2!}}\frac{(a_3^+)^{n_3}}{\sqrt{n_3!}}|0,0,0\rangle. \tag{7}$$

In this bosonic representation, we define the generators of su(3) as

$$e_i=a_i^+a_{i+1}^-, \quad f_i=a_i^-a_{i+1}^+, \quad h_i=N_i-N_{i+1}. \tag{8}$$

The generators e_i, f_i are called step, ladder or Weyl operators. The Cartan subalgebra is generated by the elements h_i. They act on the representation space of dimension $\frac{1}{2}(j_1+1)(j_1+2)$ that is obtained from the Fock space of three harmonic oscillators by restricting the total number of quantas to $j_1=n_1+n_2+n_3$. In the present representation the state of highest weight is $|j_1,0,0\rangle$. The generators of su(3) having a nontrivial action (nonvanishing and nondiagonal) on the fudicial vector $|j_1,0,0\rangle$ are $f_1=a_1^-a_2^+$ and $f_3=[f_2,f_1]=a_1^-a_3^+$. At this stage, one can define the coherent state as

$$|z_1,z_2\rangle = D(z_1,z_2)|j_1,0,0\rangle = \exp(z_1 f_1 + z_2 f_3 - \overline{z_1}e_1 - \overline{z_2}e_3)|j_1,0,0\rangle, \tag{9}$$

where $e_3=[e_1,e_2]=a_1^+a_3^-$. Expanding the displacement operator $D(z_1,z_2)$ and using the action of creation and annihilation operators on the restricted Fock space,

$$\mathcal{F} = \{|n_1,n_2,n_3\rangle; n_1+n_2+n_3 = j_1\},$$

one obtains

$$|z_1,z_2\rangle = \sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2} z_1^{j_2} z_2^{j_3} I_{j_2}^{j_1}(|z_1|) I_{j_3}^{j_2}(|z_2|)|j_1-j_2, j_2-j_3, j_3\rangle, \tag{10}$$

where

$$I_{j_{s+1}}^{j_s}(|z_s|) = \sum_{k=0}^{\infty} \frac{(-)^k(|z_s|^2)^k}{(j_{s+1}+2k)!} P(j_{s+1}+1,k), \tag{11}$$

for $s=1,2$. The quantities P occuring in (11) are given by

$$P(j_{s+1}+1,k) = P(j_{s+1}+1,0)\sum_{l_1=1}^{j_{s+1}+1} E_s(l_1)\sum_{l_2=1}^{l_1+1} E_s(l_2)\cdots\sum_{l_k=1}^{l_{k-1}+1} E_s(l_k) \tag{12}$$

with $P(j_{s+1}+1,0)=j_s!\,j_{s+1}!/(j_s-j_{s-1})!$ and $E_s(l)=(j_s-l+1)l$. They satisfy the following recursion relation:

$$P(j_{s+1}+1,k) = \sqrt{E_s(j_{s+1})}P(j_{s+1},k) + \sqrt{E_s(j_{s+1}+1)}P(j_{s+1}+2,k-1). \tag{13}$$

Setting

$$J_{j_{s+1}}^{j_s}(|z_s|) = |z_s|^{j_s} P(j_{s+1}+1,0) I_{j_{s+1}}^{j_s}(|z_s|), \tag{14}$$

we get the first order differential equation

$$\frac{\mathrm{d}J_{j_{s+1}}^{j_s}(|z_s|)}{d|z_s|} = J_{j_{s+1}-1}^{j_s}(|z_s|) - (E_s(j_{s+1}+1))^2 J_{j_{s+1}+1}^{j_s}(|z_s|). \tag{15}$$

The solution of this equation takes the simple form

$$J_{j_{s+1}}^{j_s}(|z_s|) = \frac{1}{j_{s+1}!}(\cos(|z_s|))^{j_{s+1}-1}(\mathrm{tg}(|z_s|))^{j_{s+1}}, \tag{16}$$

and the su(3) coherent states rewrite as

$$|\zeta_1,\zeta_2\rangle = (1+|\zeta_1|^2+|\zeta_1|^2|\zeta_2|^2)^{-(j_1/2)}\sum_{j_2=0}^{j_1}\sqrt{\frac{j_1!}{j_2!\,(j_1-j_2)!}}\zeta_1^{j_2} \times\sum_{j_3=0}^{j_2}\sqrt{\frac{j_2!}{j_3!\,(j_2-j_3)!}}\zeta_2^{j_3}|j_1-j_2,j_2-j_3,j_3\rangle, \tag{17}$$

where $\zeta_s=(z_s/|z_s|)\mathrm{tg}(|z_s|)\cos(|z_{s+1}|)^{2-s}$ for $s=1,2$. They have the property of strong continuity in the label space and overcompletion in the sense that there exists a positive measure such that they solve the resolution to identity. The appropriate form of this resolution is

$$\int \mathrm{d}\mu(\zeta_1,\overline{\zeta_1},\zeta_2,\overline{\zeta_2})|\zeta_1,\zeta_2\rangle\langle\zeta_1,\zeta_2| = \sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2}|j_1-j_2,j_2-j_3,j_3\rangle\langle j_1-j_2,j_2-j_3,j_3|. \tag{18}$$

Assuming the isotropy of the measure $\mathrm{d}\mu(\zeta,\overline{\zeta})$, we set

$$\mathrm{d}\mu(\zeta_1,\overline{\zeta_1},\zeta_2,\overline{\zeta_2}) = \pi^2(1+|\zeta_1|^2+|\zeta_1|^2|\zeta_2|^2)^{j_1/2}h(|\zeta_1|^2)h(|\zeta_2|^2)|\zeta_1|d|\zeta_1||\zeta_2|d|\zeta_2|\mathrm{d}\theta_1\mathrm{d}\theta_2 \tag{19}$$

with $\zeta_s=|\zeta_s|e^{i\theta_s}$. Substituting (19) in Eq.(18), we obtain the following sum:

$$\int_0^\infty x_s^{j_{s+1}}h(x_s)\mathrm{d}x_s = \frac{j_{s+1}!\,(j_s-j_{s+1})!}{j_s!}, \tag{20}$$

which should be satisfied by the function $h(x_s=|\zeta_s|^2)$. One obtains

$$h(x_s) = \frac{j_s+1}{(1+x_s^2)^{j_s+2}}. \tag{21}$$

This result can be obtained by using the definition of Meijer's G-function and the Mellin inversion theorem.[22] The resolution to identity is necessary to build up the Fock–Bargmann space based on the set of su(3) coherent states.

B. Differential realization of the su(3) generators

It is well established that the use of the Fock–Bargmann representation is a powerful method for obtaining closed analytic expressions for various properties of coherent states. Calculation for some quantum exception values and solutions for some eigenvalue equations are simlpified by exploiting the theory of analytical entire functions. Here, we give the Fock–Bargmann representation of a su(3) quantum mechanical system. We define the Fock–Bargmann space as a space of functions which are holomorphic. The scalar product is written with an integral of the form

$$\langle f|g\rangle = \int \overline{f}(\zeta_1,\zeta_2)g(\zeta_1,\zeta_2)\mathrm{d}\mu(\zeta_1,\overline{\zeta_1},\zeta_2,\overline{\zeta_2}), \tag{22}$$

where the measure is defined above [see Eq. (19)]. Due to overcompletion of the coherent states, it is induced by the scalar product in $\mathcal{F}$. Let

$$|\psi\rangle = \sum_{n_1,n_2,n_3} a_{n_1,n_2,n_3}|n_1,n_2,n_3\rangle \tag{23}$$

be an arbitrary quantum state of $\mathcal{F}$, it can be represented as a function of the complex variables ζ_1,ζ_2 as

$$\psi(\zeta_1,\zeta_2) = (1+|\zeta_1|^2+|\zeta_1|^2|\zeta_2|^2)^{j_1/2}\langle\overline{\zeta_1},\overline{\zeta_2}|\psi\rangle. \tag{24}$$

In particular, the analytic functions associated to elements of the basis of $\mathcal{F}$ are defined as

$$\psi_{j_1,j_2,j_3}(\zeta_1,\zeta_2) = (1+|\zeta_1|^2+|\zeta_1|^2|\zeta_2|^2)^{j_1/2}\langle\overline{\zeta_1},\overline{\zeta_2}|j_1-j_2,j_2-j_3,j_3\rangle. \tag{25}$$

We now investigate the form of the action of the operators e_i, f_i, and h_i on Fock–Bargmann space. Indeed, any operator O of the algebra su(3) is represented in the space of the entire analytical functions by some differential operator $\mathcal{O}$, defined by

$$\langle\overline{\zeta_1},\overline{\zeta_2}|O|\psi\rangle = \mathcal{O}\psi(\zeta_1,\zeta_2) \tag{26}$$

for any state $|\psi\rangle$ of $\mathcal{F}$.

According to this definition, we obtain

$$e_1 = \frac{\partial}{\partial \zeta_1}, \quad e_3 = \frac{\partial}{\partial \zeta_2}, \tag{27}$$

$$f_1 = j_1\zeta_1 - \zeta_1^2\frac{\partial}{\partial \zeta_1} - \zeta_1\zeta_2\frac{\partial}{\partial \zeta_2}, \tag{28}$$

$$f_3 = j_1\zeta_2 - \zeta_2^2\frac{\partial}{\partial \zeta_2} - \zeta_1\zeta_2\frac{\partial}{\partial \zeta_1}, \tag{29}$$

$$e_2 = \zeta_1\frac{\partial}{\partial \zeta_2}, \quad f_2 = \zeta_2\frac{\partial}{\partial \zeta_1}, \tag{30}$$

$$h_1 = j_1 - 2\zeta_1\frac{\partial}{\partial \zeta_1} - \zeta_2\frac{\partial}{\partial \zeta_2}, \tag{31}$$

$$h_2 = \zeta_1\frac{\partial}{\partial \zeta_1} - \zeta_2\frac{\partial}{\partial \zeta_2}. \tag{32}$$

To obtain the above differential realization:

(i) we remark that the coherent states (17) can be also written as

$$|\zeta_1,\zeta_2\rangle = (1 + |\zeta_1|^2 + |\zeta_1|^2|\zeta_2|^2)^{-j_1/2}D(\zeta_1,\zeta_2)|j_1,0,0\rangle, \tag{33}$$

where $D(\zeta_1,\zeta_2)=\exp(\zeta_1 f_1+\zeta_2 f_3)$;

(ii) we observe that

$$\frac{\partial}{\partial \zeta_1}D(\zeta_1,\zeta_2) = f_1D(\zeta_1,\zeta_2), \quad \frac{\partial}{\partial \zeta_2}D(\zeta_1,\zeta_2) = f_3D(\zeta_1,\zeta_2); \tag{34}$$

(iii) we use the Hausdorff formula

$$e^{-B}Ae^{B} = \sum_{n\geqslant 0}\frac{1}{n!}(-\,a\mathrm{d}B)^nA, \tag{35}$$

where $(a\mathrm{d}B)A=[B,A]$;

(iv) we use also the actions of the elements of su(3) on the basis of Fock space $\mathcal{F}$, in particular the fudicial vector $|j_1,0,0\rangle$, and the structure relations (1)–(5) of the algebra su(3).

From the previous considerations, it follows that the su(3) generators act as first-order holomorphic differential operators on the space of the analytic functions generated by the elements (25). One can verify that the commutation relations (1)–(5) are preserved. This result combined with eigenvalue equations ensuring the minimization of Schrödinger–Robertson inequality provides the intelligent states as will be explained in the next section.

III. su(3) ROBERTSON STATES

As we have already mentioned, in this section, we will study the fluctuations of the quadrature components of the Weyl generators which represent creation and annihilation of states for a quantum mechanical system of su(3) symmetry. In this order, to construct the intelligent states of any pair of ladder operators e_i, f_i $(i=1,2,3)$, it is natural to introduce the quantum observables $\sqrt{2}p_i=e_i+f_i$ and $\mathbf{i}\sqrt{2}q_i=e_i-f_i$ where $\mathbf{i}^2=-1$. These observables obey

$$[p_i, q_i] = \mathbf{i}h_i. \tag{36}$$

We known that p_i and q_i satisfy, in a given state, the Robertson–Shrödinger uncertainty relation

$$(\Delta p_i)^2(\Delta q_i)^2 \geqslant \tfrac{1}{4}(\langle h_i\rangle^2 + \langle c_i\rangle^2), \tag{37}$$

where Δp_i and Δq_i are the dispersions and the Hermitian operator $c_i = \{p_i - \langle p_i\rangle, q_i - \langle q_i\rangle\}$ gives the covariance (correlation) of the observables p_i and q_i. The symbol $\{,\}$ stands for the standard definition of the anticommutator. A state $|\Phi\rangle$ providing the equality in (37) is the so-called Robertson intelligent state. It was proven that such state satisfies the following eigenvalue equation:

$$((1+\alpha)e_i + (1-\alpha)f_i)|\Phi\rangle = \lambda|\Phi\rangle, \tag{38}$$

where $\alpha \neq 0$ and $\lambda = (1+\alpha)\langle e_i\rangle + (1-\alpha)\langle f_i\rangle$ are complex parameters. Furthermore, the variances and covariance, in the intelligent state $|\Phi\rangle$, are related by

$$(\Delta p_i)^2 = |\alpha|\Delta_i, \quad (\Delta q_i)^2 = \frac{1}{|\alpha|}\Delta_i, \tag{39}$$

where $\Delta_i = \frac{1}{2}\sqrt{\langle h_i\rangle^2 + \langle c_i\rangle^2}$. Remark that they can be also expressed as

$$(\Delta p_i)^2 = \frac{|\alpha|^2}{u}\langle h_i\rangle, \quad (\Delta q_i)^2 = \frac{1}{u}\langle h_i\rangle, \quad \langle c_i\rangle = \frac{v}{u}\langle h_i\rangle, \tag{40}$$

where the real parameters u and v are such that $u^2 + v^2 = 4|\alpha|^2$. (As example, one can take $u = 2$ Re α and $v = 2$ Im α.) It is clear that the dispersions and the correlation can be obtained from the mean value of the observable h_i. The state $|\Phi\rangle$ satisfying (38) with $|\alpha| = 1$ are coherent because they satisfy $(\Delta p_i)^2 = (\Delta q_i)^2 = \Delta_i$. The fluctuations are equal and minimized in the sense of the Schrödinger–Robertson uncertainty relation. The state satisfying (38) with $|\alpha| \neq 1$ are squeezed because if $|\alpha| < 1$, we have $(\Delta p_i)^2 < \Delta_i < (\Delta q_i)^2$ and if $|\alpha| > 1$, we have $(\Delta q_i)^2 < \Delta_i < (\Delta p_i)^2$.

To solve the eigenvalues equation (38), we will use the analytic representations of coherent states as well as the differential realizations of the generators e_i and f_i given by Eqs. (27)–(30). So, let us start by deriving the eigenfunctions of Eq. (38) for the first pair e_1, f_1. By introducing the analytic function

$$\Phi_1 \equiv \Phi_1(\zeta_1, \zeta_2, \alpha, \lambda, j_1) = (1 + |\zeta_1|^2 + |\zeta_1|^2|\zeta_2|^2)^{j_1/2}\langle\overline{\zeta_1}, \overline{\zeta_2}|\Phi_1\rangle, \tag{41}$$

it can be easily checked that the eigenvalue equation (38) can be converted in the following first order differential equation:

$$(j_1\eta_1 - \lambda')\Phi_1 + (1 - \eta_1^2)\frac{\partial\Phi_1}{\partial\eta_1} - \eta_1\eta_2\frac{\partial\Phi_1}{\partial\eta_2} = 0, \tag{42}$$

where $\eta_1 = \sqrt{(1-\alpha)/(1+\alpha)}\zeta_1$, $\eta_2 = \zeta_2$ and $\lambda' = \lambda/\sqrt{1-\alpha^2}$ for $\alpha \neq \pm 1$. The function $\Phi_1(\zeta_1, \zeta_2, \alpha, \lambda, j_1)$ can be expanded as

$$\Phi_1 = \sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2} a_{j_1,j_2,j_3}\eta_1^{j_2}\eta_2^{j_3}. \tag{43}$$

Substitution of (43) in (42) yields the recursion formula

$$(j_1 - j_2 - j_3 + 1)a_{j_1,j_2-1,j_3} - \lambda' a_{j_1,j_2,j_3} + (j_2+1)a_{j_1,j_2+1,j_3} = 0, \tag{44}$$

which can be solved by the Laplace method. Indeed, we set

$$a_{j_1,j_2,j_3} = \int_{-1}^{+1} x^{j_2} f(x)\mathrm{d}x \tag{45}$$

that we introduce in (44) to obtain, after partial integration, the simple first order differential equation satisfied by the function $f(x)$,

$$(x - x^3)\frac{\mathrm{d}f}{\mathrm{d}x} + (j_1 - j_3 + 1 - \lambda' x - x^2) = 0. \tag{46}$$

The last equation is easily solvable. Replacing in (45), one obtains

$$a_{j_1,j_2,j_3} = \int_{-1}^{+1} x^{j_2 - j_1 + j_3 - 1}(1 - x)^{(-\lambda' + j_1 - j_3)/2}(1 + x)^{(\lambda' + j_1 - j_3)/2}\mathrm{d}x, \tag{47}$$

or

$$a_{j_1,j_2,j_3} = (-)^{j_2}\frac{\Gamma\left(\frac{\lambda' + j_1 - j_3}{2} + 1\right)\Gamma\left(\frac{-\lambda' + j_1 - j_3}{2} + 1\right)}{\Gamma(j_1 - j_3 + 2)} \times {}_2F_1\left(j_1 - j_3 - j_2 + 1, \frac{\lambda' + j_1 - j_3}{2} + 1, j_1 - j_3 + 2, 2\right) \tag{48}$$

using the integral representation for the hypergeometric function ${}_2F_1$.[20] Comparing the expansion (43) with the general formula (41), we have the decomposition of Robertson intelligent states over the basis of Fock space $\mathcal{F}$,

$$|\Phi_1\rangle = \sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2} a_{j_1,j_2,j_3}\left(\frac{1-\alpha}{1+\alpha}\right)^{j_2/2}\sqrt{\frac{(j_1 - j_2)\,!\,j_3\,!\,(j_2 - j_3)!}{j_1!}}|j_1 - j_2, j_2 - j_3, j_3\rangle, \tag{49}$$

where the coefficients a_{j_1,j_2,j_3} are given by Eq. (48).

Now we consider the construction of intelligent states for the second pair e_2, f_2. The eigenvalues equation (38) gives, in this case, the following quasilinear differential equation:

$$\xi_1\frac{\partial \Phi_2}{\partial \xi_2} + \xi_2\frac{\partial \Phi_2}{\partial \xi_1} - \lambda'\Phi_2 = 0, \tag{50}$$

where $\xi_1 = \sqrt{(1+\alpha)/(1-\alpha)}\zeta_1$, $\xi_2 = \zeta_2$, and $\lambda' = \lambda/\sqrt{1-\alpha^2}$. Here also, we expand the eigenfunction $\Phi_2 \equiv \Phi_2(\xi_1, \xi_2, \alpha, \lambda, j_1)$ as

$$\Phi_2 = \sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2} b_{j_1,j_2,j_3}\xi_1^{j_2}\xi_2^{j_3} \tag{51}$$

that we insert in Eq. (50) to obtain the recursion relation linking the coefficients b's,

$$(j_3 + 1)b_{j_1,j_2-1,j_3+1} - \lambda' b_{j_1,j_2,j_3} + (j_2 + 1)b_{j_1,j_2+1,j_3-1} = 0. \tag{52}$$

Setting $b_{j_1,j_2,j_3} \equiv b_{j_1,j_2-j,j}$ where $2j = j_2 + j_3$, the previous relation can be transformed to

$$(j_2 + 1)b_{j_1,j_2-j+1,j} - \lambda' b_{j_1,j_2-j,j} + (j_3 + 1)b_{j_1,j_2-j-1,j} = 0, \tag{53}$$

solvable in a similar manner as that given by the solution of the recursion formula (44), and one has

$$b_{j_1,j_2,j_3}=(-)^{j_2}\frac{\Gamma\left(\frac{\lambda'+j_2+j_3}{2}+1\right)\Gamma\left(\frac{-\lambda'+j_2+j_3}{2}+1\right)}{\Gamma(j_2+j_3+2)}$$
$$\times{}_2F_1\left(j_3+1,\frac{\lambda'+j_2+j_3}{2}+1,j_2+j_3+2,2\right). \tag{54}$$

Finally, one obtains

$$|\Phi_2\rangle=\sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2}b_{j_1,j_2,j_3}\left(\frac{1+\alpha}{1-\alpha}\right)^{j_2/2}\sqrt{\frac{(j_1-j_2)\,!\,j_3\,!\,(j_2-j_3)!}{j_1!}}|j_1-j_2,j_2-j_3,j_3\rangle. \tag{55}$$

It remains to determine the e_3, f_3 intelligent states. In this case, the Robertson states should satisfy the following equation:

$$(j_1\vartheta_2-\lambda')\Phi_3+(1-\vartheta_2^2)\frac{\partial\Phi_3}{\partial\vartheta_2}-\vartheta_1\vartheta_2\frac{\partial\Phi_3}{\partial\vartheta_1}=0, \tag{56}$$

where $\vartheta_1=\zeta_1$, $\vartheta_2=\sqrt{(1-\alpha)/(1+\alpha)}\zeta_2$ and λ' is defined above. In a similar way as that presented above, one obtains the intelligent states

$$\Phi_3=\sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2}c_{j_1,j_2,j_3}\vartheta_1^{j_2}\vartheta_2^{j_3}, \tag{57}$$

where $\Phi_3\equiv\Phi_3(\zeta_1,\zeta_2,\alpha,\lambda,j_1)$ and the constants c's are given by

$$c_{j_1,j_2,j_3}=(-)^{j_3}\frac{\Gamma\left(\frac{\lambda'+j_1-j_2}{2}+1\right)\Gamma\left(\frac{-\lambda'+j_1-j_2}{2}+1\right)}{\Gamma(j_1-j_2+2)}$$
$$\times{}_2F_1\left(j_1-j_2-j_3+1,\frac{\lambda'+j_1-j_2}{2}+1,j_1-j_2+2,2\right). \tag{58}$$

Analogously to the above cases, the intelligent states Φ_3 can be converted as follows:

$$|\Phi_3\rangle=\sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2}c_{j_1,j_2,j_3}\left(\frac{1+\alpha}{1-\alpha}\right)^{j_3/2}\sqrt{\frac{(j_1-j_2)\,!\,j_3\,!\,(j_2-j_3)!}{j_1!}}|j_1-j_2,j_2-j_3,j_3\rangle. \tag{59}$$

To close this section, let us note that it is clear that the Fock–Bargmann representation of the coherent states provide a simplification and a "minimization" in the problem of finding intelligent states of su(3) Weyl generators. It is evident that the procedure described here can be relevant in the derivation of intelligent states for other quadrature components of type, for instance, e_i, e_j and f_i, f_j $(i\neq j)$.

IV. DISCUSSION AND OUTLOOK

In conclusion, we have developed a method for finding the Robertson intelligent states for linear combination of the Weyl operators e_i and f_i for $i=1,2,3$, corresponding to the Lie algebra su(3). The use of the analytic representation enables us to write the eigenvalue equations, satisfied by states minimizing the Schrödinger–Robertson uncertainty relation, as quasilinear first order differential equation. Interestingly, new types of coherent states for su(3) emerge for $|\alpha|=1$. Also when $|\alpha|\neq 1$, the solutions give squeezed states. As it is noted in the end of the preceding section, the approach used through this work can be applied to derive Robertson intelligent states associ-

ated to the other quadratures of the su(3) generators. In a unified scheme, they can be obtained by considering the eigenvalue problem for an operator which is a complex linear combination of all elements of su(3),

$$\sum_{i=1,2} (\alpha_i^+ e_i + \alpha_i^- f_i + \alpha_i^0 h_i)|\Phi\rangle = \lambda|\Phi\rangle. \tag{60}$$

The solutions of such a general problem give the so-called algebra eigenstates or algebraic coherent states (Ref. 13 and references therein). Taking specific constraints on the complex parameters occurring in this general eigenvalue equation, one can get various kinds of coherent and squeezed states, in particular ones that are not discussed in this paper. This constitutes the first possible prolongation of our results. Also, as a continuation, it would be interesting to apply the approach presented here to other Lie algebras like su(n) or su(p,q).

(Received 6 October 2003; accepted 5 May 2004; published online 28 July 2004)

We analyze a generalized diffusion equation which extends some known equations such as the fractional diffusion equation and the porous medium equation. We start our investigation by considering the linear case and the nonlinear case afterward. The linear case is discussed taking fractional time and spatial derivatives into account in a unified approach. We also discuss the modifications that emerge by employing simple drifts and the diffusion coefficient given by $\mathcal{D}(x,t)=\mathcal{D}(t)|x|^{-\theta}$. For the nonlinear case, we study scaling behavior of the time in connection with the asymptotic behavior for the solution of the nonlinear fractional diffusion equation. © *2004 American Institute of Physics.*

I. INTRODUCTION

Nowadays, fractional diffusion equations (e.g., $\partial_t^\gamma \rho = \mathcal{D}\partial_x^2 \rho$) and nonlinear diffusion equations (e.g., $\partial_t \rho = \mathcal{D}\partial_x^2 \rho^\nu$) play important roles in describing anomalous diffusion due to their broadness of the physical applications. In fact, they have been applied to several physical situations such as percolation of gases through porous media,[1] thin saturated regions in porous media,[2] diffusion of dissolved solutes into immobile water zones of various sizes, a standard solid-on-solid model for surface growth, thin liquid films spreading under gravity,[3] modeling of non-Markovian dynamical processes in protein folding,[4] relaxation to equilibrium in a system (such as polymer chains and membranes) with long temporal memory,[5] and anomalous transport in disordered systems.[6] Some properties concerning the nonlinear fractional diffusion have also been investigated in Ref. 7. In this scenario, a high order diffusion-like equation such as the thin film equation,[8] which contains a fourth order derivative, has been used to describe the lubrication models for thin viscous films, spreading droplets and Hele-Shaw cells.[9] Note that the physical situations mentioned above essentially concern anomalous diffusion of the correlated type (both sub- and superdiffusion; see Ref. 10 and references therein) or of the Lévy type (superdiffusion; see Ref. 11 and references therein). The anomalous correlated diffusion usually has a finite second moment $\langle x^2\rangle \propto t^\sigma$ ($\sigma>1$, $\sigma=1$ and $0<\sigma<1$ correspond to superdiffusion, normal diffusion and subdiffusion, respectively; $\sigma=0$ corresponds basically to localization). The second type is essentially characterized by Lévy distributions and, consequently, it has no finite second moment, i.e., $\langle x^2\rangle$ diverges.

Now, let us accomplish the above situations in a unified approach based on the generalized diffusion equation

$$\frac{\partial^\gamma}{\partial t^\gamma}\rho(x,t)=\int_0^t dt' \frac{\partial}{\partial|x|}\left\{\mathcal{D}(x,t-t')\frac{\partial^{\mu-1}}{\partial|x|^{\mu-1}}[\rho(x,t')]^\nu\right\}-\frac{\partial}{\partial x}\{F(x)\rho(x,t)\}\ , \tag{1}$$

[a]Electronic mail: eklenzi@dfi.uem.br

where $\nu,\gamma,\mu\in\mathcal{R}$, $\mathcal{D}(x,t)=\mathcal{D}(t)|x|^{-\theta}$ is a diffusion coefficient, and $F(x)\equiv -dV(x)/dx$ is an external force (*drift*) associated with the potential $V(x)$. We use the Caputo[12] operator for the time derivative. For the spatial fractional derivative we consider the Riesz–Weyl operator.[13–15] Also, we employ, in general, the initial condition $\rho(x,0)=\delta(x)$ or $\rho(x,0)=\tilde{\rho}(x)$ and the boundary condition $\rho(x\to\pm\infty,t)\to 0$ or $\rho(x\to 0,t)=\rho(x\to\infty,t)\to 0$ depend on the situation analyzed. For Eq. (1), one can prove that $\int_{-\infty}^{\infty}dx\ \rho(x,t)$ is time independent (hence, if ρ is normalized at $t=0$, it will remain so forever). Indeed, if we write Eq. (1) as $\partial_t^{\gamma}\rho=-\partial_x\mathcal{J}$ and, for simplicity, assume the boundary conditions $\mathcal{J}(\pm\infty,t)\to 0$, it can be shown that $\int_{-\infty}^{\infty}dx\ \rho(x,t)$ is a constant of motion. Note that Eq. (1) recovers, for $(\mu,\gamma,\nu)=(2,1,1)$, the standard Fokker–Planck equation in the presence of a drift taking memory effects into account. The particular case $F(x)=0$ (no drift) and $\mathcal{D}(x,t)=\mathcal{D}\delta(t)$ with $(\mu,\gamma,\theta)=(2,1,0)$ has been considered by Spohn,[16] and the case $(\mu,\gamma)=(2,1)$ has been investigated in Refs. 17 and 18. Our present investigation involves extensions of these cases by considering a wide variety of situations: Employing fractional derivatives, nonlinearity and the mixing of them. Note that Eq. (1) has also a kernel which takes a memory effect into account. In this way, we expect to bring new aspects of physical phenomena to be explored, for example, when a mixing between the fractional diffusion equations and the nonlinear diffusion equations are present. In addition, by using Eq. (1), a well-known limitation of the description of diffusion processes with the diffusion equation, i.e., the infinite velocity of information propagation inherent to a parabolic equation caused by the model assumption that the collision frequency is infinite, can be avoided.

From the previous discussion, we verify that the diffusion equations investigated in the manuscript may be useful to model several physical situations. On the other hand, exact solutions play an important role in analyzing physical situations, since they contain, in principle, precise information about the system. In particular, they can be used as a useful guide to control the accuracy of numerical solutions. For these reasons, we dedicated this work to investigate some solutions of these equations in order to give support to possible investigations of physical systems modeling by the diffusion equations studied here. The reminder of this paper goes as follows. In Sec. II, we investigate several situations for Eq. (1) by considering the linear case ($\nu=1$). In Sec. III, we discuss the nonlinear ($\nu\neq 1$) fractional diffusion equation and connect the asymptotic behavior with the distributions which emerge from the nonextensive statistics.[19,20] In Sec. IV, we present our conclusions.

II. LINEAR CASE

We start our discussion by considering the linear case, i.e., $\nu=1$, with $\mathcal{D}(x,t)=\mathcal{D}(t)$ and $\mu=2$ without external force. Thus, Eq. (1) reads

$$\frac{\partial^{\gamma}}{\partial t^{\gamma}}\rho(x,t)=\int_0^t dt'\left\{\mathcal{D}(t-t')\frac{\partial^2}{\partial x^2}\rho(x,t')\right\}. \tag{2}$$

Notice that for $\gamma=1$ Eq. (2) reduces to the one obtained from a dichotomous random process.[21] In fact, by identifying the diffusion coefficient with the normalized correlation function

$$\Phi_{\xi}(t)=\frac{\langle\xi\xi(t)\rangle}{\langle\xi^2\rangle}, \tag{3}$$

we formally recover the evolution equation for the density probability present in Refs. 14 and 21. It is also interesting to note that we can also use Eq. (2) by considering an appropriate $\mathcal{D}(t)$ as a model for the diffusion that takes a finite collision time into account. Indeed, the usual diffusion equation is an approximation only valid on time scales which are large compared to the time scale at which the diffusion-causing collisions take place. One of the most striking unphysical properties of the diffusion equation is an infinite velocity of information propagation. However, the inclusion of the finite collision frequency in the system may create additional difficulties to treat the prob-

lem; an approximation which makes the problem more tractable is discussed by Bourret,[22] and it leads to an integral equation with a correlation function in the kernel-like equation Eq. (2).

Before analyzing the solutions of Eq. (2), we obtain formal results for the time behavior of the moments, in particular, of the second moment. In this direction, by simple calculation, we obtain a dynamic equation for the nth moment:

$$\frac{d^{\gamma}}{dt^{\gamma}}\langle x^{2n}\rangle(t)=2n(2n-1)\int_0^t dt'\,\mathcal{D}(t-t')\langle x^{2n-2}\rangle(t')\ , \tag{4}$$

for $n=1,2,\ldots$. To find the nth moment related to this equation, a coupled system of equations needs to be solved. For simplicity, we consider $0<\gamma<1$. Thus, we start by evaluating the second moment and then we use this result to obtain the nth moment. By choosing $n=1$ in Eq. (4) we have an equation for the second moment whose solution is

$$\langle x^2\rangle=\frac{2}{\Gamma(\gamma+1)}\int_0^t dt'\ \ (t-t')^{\gamma}\mathcal{D}(t')\ . \tag{5}$$

Using the above result we can show that the nth moment is given by

$$\langle x^{2n}\rangle=\frac{(2n)!}{\Gamma(n\gamma+1)}\int_0^t dt^{(1)}(t-t^{(1)})^{n\gamma}\int_0^{t^{(1)}}dt^{(2)}\mathcal{D}(t^{(1)}-t^{(2)})\cdots\int_0^{t^{(n-1)}}dt^{(n)}$$
$$\times\mathcal{D}(t^{(n-1)}-t^{(n)})\mathcal{D}(t^{(n)})\ . \tag{6}$$

Now, let us investigate the solutions for Eq. (2). By employing the Laplace transform in Eq. (2), we obtain that

$$s^{\gamma}\hat{\rho}(x,s)-s^{\gamma-1}\rho(x,0)=\mathcal{D}(s)\frac{d^2}{dx^2}\hat{\rho}(x,s), \tag{7}$$

($\hat{\rho}(x,s)=\mathcal{L}\{\rho(x,t)\}$ where $\mathcal{L}\{\cdots\}=\int_0^{\infty}dte^{-st}\cdots$), whose solution, for $\rho(x,0)=\delta(x)$, is given by

$$\hat{\rho}(x,s)=\frac{1}{2s}\left(\frac{s^{\gamma}}{\mathcal{D}(s)}\right)^{1/2}\exp\left[-\left(\frac{s^{\gamma}}{\mathcal{D}(s)}\right)^{1/2}|x|\right]\ . \tag{8}$$

Note that, if we take a general diffusion coefficient into account in the above equation, the inversion of the Laplace transform becomes a hard task. However, for some cases it is possible to calculate the inverse of Laplace transform. For instance, $\mathcal{D}(s)=constant$ ($\mathcal{D}(t)=\mathcal{D}\delta(t)$), which recovers the result presented in Ref. 14, Cattaneo's case,[23] i.e., $\mathcal{D}(s)=\mathcal{D}/(1+\tau_c s)$ ($\mathcal{D}(t)=\mathcal{D}/\tau_c e^{-t/\tau_c}$), and $\mathcal{D}(s)=\mathcal{D}s^{-\alpha}$ ($\mathcal{D}(t)=\mathcal{D}t^{\alpha-1}/\Gamma(\alpha)$) which lead us to

$$\rho(x,t)=\frac{1}{\sqrt{4\mathcal{D}t^{\gamma+\alpha}}}\ \mathrm{H}_1^{\,1\ 0}_{\,1\ 1}\left[\frac{|x|}{\sqrt{\mathcal{D}t^{\gamma+\alpha}}}\middle|\begin{matrix}(1-(\gamma+\alpha)/2\,,(\gamma+\alpha)/2)\\(0,1)\end{matrix}\right]\ , \tag{9}$$

where $\mathrm{H}_p^{\,m\ n}_{\,q}[x|^{(a_1,A_1),\ldots,(a_p,A_p)}_{(b_1,B_1),\ldots,(b_q,B_q)}]$ is the FOX function.[24] In Fig. 1, we show the behavior of the above equation by considering typical values of $\gamma+\alpha$ with $0<\gamma<1$. It is interesting to note that for $\gamma+\alpha<1$ we have a unimodal distribution, similar result is reported in Ref. 14, and for $1<\gamma+\alpha<2$ we have a bimodal distribution, in according to the results present in Ref. 21. The asymptotic behavior of Eq. (9) is

$$\rho(x,t)\sim\frac{1}{\sqrt{4\pi\mathcal{D}t^{\gamma+\alpha}}}\left(\frac{|x|}{\sqrt{\mathcal{D}t^{\gamma+\alpha}}}\right)^{(-1-\gamma-\alpha)/(2-\gamma-\alpha)}\exp\left[-\mathcal{C}_{\gamma,\alpha}\left(\frac{|x|}{\sqrt{\mathcal{D}t^{\gamma+\alpha}}}\right)^{2/(2-\gamma-\alpha)}\right], \tag{10}$$

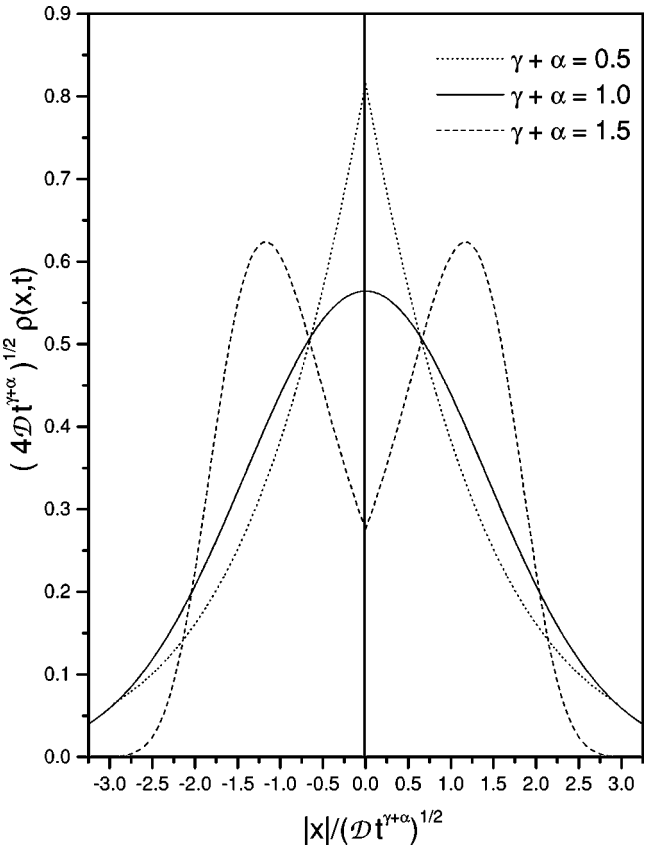

FIG. 1. In this figure, we illustrate the behavior of Eq. (9) by plotting $(4\mathcal{D}t^{\gamma+\alpha})^{1/2}\rho(x,t)$ vs $|x|/(\mathcal{D}t^{\gamma+\alpha})^{1/2}$, for typical values of for $\gamma+\alpha$ with $0<\gamma<1$.

where $\mathcal{C}_{\gamma,\alpha}=[(2-\gamma-\alpha)/2][(\gamma+\alpha)/2]^{(\gamma+\alpha)/(2-\gamma-\alpha)}$. Similar asymptotic behavior is found in homogeneous and isotropic random walk models.[25,26] Notice that Eq. (9) recovers the Gaussian distribution for $\gamma+\alpha=1$. In particular, for a general initial condition, i.e., $\rho(x,0)=\tilde{\rho}(x)$, we have that

$$\rho(x,t)=\frac{1}{\sqrt{4\mathcal{D}t^{\gamma+\alpha}}}\int_{-\infty}^{\infty}dx'\,\tilde{\rho}(x')\;\mathrm{H}_{1\;1}^{1\;0}\left[\frac{|x-x'|}{\sqrt{\mathcal{D}t^{\gamma+\alpha}}}\middle|\begin{matrix}(1-(\gamma+\alpha)/2,(\gamma+\alpha)/2)\\ \\ (0,1)\end{matrix}\right]. \tag{11}$$

In order to extend the above results, we incorporate a linear drift force, i.e., $F(x)=-\mathcal{K}x$. In this case, by employing the Fourier and Laplace transforms we can show that

$$\rho(k,s)=s^{\gamma-1}\int_0^{\infty}du\,e^{-us^{\gamma}}e^{-\mathcal{D}(s)/2\mathcal{K}|k|^2(1-e^{-2u\mathcal{K}})}\,. \tag{12}$$

The second moment obtained from the above equation is given by

$$\langle x^2\rangle=2\int_0^t dt'\mathcal{D}(t-t')t'^{\;\gamma}\mathrm{E}_{\gamma,\gamma+1}(-2\mathcal{K}t'^{\;\gamma})\,, \tag{13}$$

where $\mathrm{E}_{\alpha,\beta}(x)$ is the generalized Mittag–Leffler function

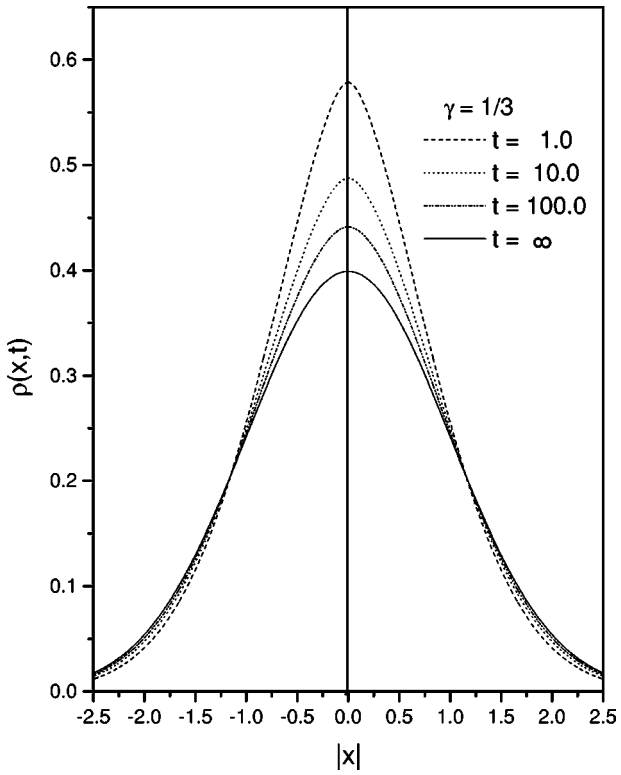

FIG. 2. In this figure, we illustrate the behavior of Eq. (15), by considering $\rho(x,t)$ vs $|x|$ for several times, with $\gamma=1/3$, $\mathcal{K}=1$, and $\mathcal{D}=1$. Note that for long times we have the Gaussian behavior for the stationary solution.

$$\mathrm{E}_{\alpha,\beta}(x)=\sum_{n=0}^{\infty}\frac{x^n}{\Gamma(n\alpha+\beta)}\,. \tag{14}$$

We notice that for $\mathcal{K}=0$ in Eq. (12) we recover Eq. (8). For simplicity, by choosing $\mathcal{D}(s)=\mathcal{D}$ in (12) we can reduce it to

$$\rho(x,t)=\sqrt{\frac{\mathcal{K}}{2\pi\mathcal{D}}}\int_0^{\infty}du\,\frac{\mathcal{W}(1-\gamma,-\gamma;-u)}{(1-e^{-2ut^{\gamma}\mathcal{K}})^{1/2}}\exp\left[-\frac{\mathcal{K}x^2}{2\mathcal{D}(1-e^{-2ut^{\gamma}\mathcal{K}})}\right], \tag{15}$$

where $\mathcal{W}(\beta,\alpha;x)$ is the Wright function[27]

$$\mathcal{W}(\beta,\alpha;u)=\frac{1}{2\pi i}\int_{Ha}d\tau\tau^{-\beta}e^{\tau+u\tau^{-\alpha}}\,, \tag{16}$$

and Ha denotes the Hankel contour and $0<\gamma<1$. In particular, $\mathcal{W}(1-\gamma,-\gamma;-u)=\mathcal{M}(\gamma,u)$, where $\mathcal{M}(\gamma,u)$ is the Mainardi function (for detail, see Ref. 28). In Fig. 2, we show the time behavior of Eq. (15) by considering $\gamma=1/3$. We verify that the time behavior is unimodal. Further, for small times Eq. (15) has a similar behavior like the one present in Fig. 1 for the case $\gamma+\alpha<1$ $(0<\gamma<1)$, and for long times the solution recovers the usual stationary solution. This behavior obtained for Eq. (15) is in accordance to the results reported in Ref. 14. Note that the solution (15) is valid for $0<\gamma<1$ (subdiffusive case). If we had considered the range $1<\gamma<2$, it would be convenient to use an extension of Eq. (15) such as presented in Ref. 14. Thus, for $1<\gamma<2$, we verify for small times a bimodal behavior, similar to the case $\alpha+\gamma>1$ $(0<\gamma<1)$ obtained in Fig. 1. Further, the bimodal behavior present for small times evolves to a unimodal

distribution in such way that for long times the unimodal Gaussian distribution is recovered. In particular, Eq. (15) always recovers the usual stationary solution $\rho(x)\sim e^{-(\mathcal{K}/2\mathcal{D})x^2}$ for long times. For the case $\mu\neq 1$ with a generic initial condition, Eq. (15) is modified to

$$\rho(x,t)=\int_0^\infty du\,\mathcal{W}(1-\gamma,-\gamma;-u)\int_{-\infty}^{\infty}dx'\,\tilde{\rho}(x-x')\mathcal{G}(x',u;t)\ ,$$

$$\mathcal{G}(x,u;t)=\frac{1}{\mu|x|}\,\mathrm{H}_{2\ 2}^{1\ 1}\left[\left(\frac{\mu\mathcal{K}}{\mathcal{D}}\right)^{1/\mu}\frac{|x|}{(1-e^{-\mu u t^{\gamma}\mathcal{K}})^{1/\mu}}\middle|\begin{matrix}(1,1/\mu) & , & (1,1/2)\\ (1,1) & , & (1,1/2)\end{matrix}\right]. \tag{17}$$

Note that the above equation, in contrast with Eq. (15), has a Lévy distribution as a stationary solution for long times.

Interesting features can be incorporated in the above scenario when we consider a spatial dependence on the diffusion coefficient, i.e., $\mathcal{D}(x,t)=\mathcal{D}(t)|x|^{-\theta}$. In particular, this kind of diffusion coefficient may be related to several physical situations, for example, diffusion on fractals,[29] turbulence[30] and fast electrons in a hot plasma in the presence of a dc electric field.[31] In this direction, the mean first passage time has also been analyzed in Ref. 32. Thus, Eq. (1) is given by

$$\frac{\partial^{\gamma}}{\partial t^{\gamma}}\rho(x,t)=\int_0^t dt'\frac{\partial}{\partial|x|}\left\{\mathcal{D}(t-t')|x|^{-\theta}\frac{\partial}{\partial|x|}\rho(x,t')\right\}, \tag{18}$$

in the absence of external force for $\mu=2$. To investigate solutions for the above equation we consider, for simplicity, x nonnegative, the boundary conditions $\rho(0,t)=\rho(\infty,t)=0$ and use the following integral transform:

$$\rho(k,t)=\int_0^\infty dx\ \ x^{1/2(1+\theta)}\mathrm{J}_{(1+\theta)/(2+\theta)}\left(\frac{2kx^{1/2(2+\theta)}}{2+\theta}\right)\rho(x,t),$$

$$\rho(x,t)=\frac{2}{2+\theta}\int_0^\infty dk\ \ kx^{1/2(1+\theta)}\mathrm{J}_{(1+\theta)/(2+\theta)}\left(\frac{2kx^{1/2(2+\theta)}}{2+\theta}\right)\rho(k,t)\ , \tag{19}$$

obtained from the Sturm–Liouville problem related to the differential equation for the spatial variable of Eq. (1) with $(\nu,\mu)=(1,2)$ and $\mathcal{D}(x,t)=\mathcal{D}|x|^{-\theta}$. By using Eq. (19), we can simplify Eq. (18) and obtain

$$\frac{d^{\gamma}}{dt^{\gamma}}\rho(k,t)=-k^2\int_0^t dt'\ \mathcal{D}(t-t')\rho(k,t')\ , \tag{20}$$

whose Laplace transform is given by

$$\rho(k,s)=\frac{s^{\gamma-1}}{s^{\gamma}+\mathcal{D}(s)k^2}\rho(k,0)\ . \tag{21}$$

By substituting the above equation in Eq. (19), we obtain that

$$\rho(x,s)=\frac{2x^{1/2(1+\theta)}}{2+\theta}\int_0^\infty dk\,\frac{s^{\gamma-1}k}{s^{\gamma}+\mathcal{D}(s)k^2}\mathrm{J}_{(1+\theta)/(2+\theta)}\left(\frac{2kx^{1/2(2+\theta)}}{2+\theta}\right)\rho(k,0)\ . \tag{22}$$

In order to invert the Laplace transform, for simplicity, we employ $\mathcal{D}(s)=\mathcal{D}s^{\alpha}$ $(\alpha<\gamma)$ and the condition $\rho(x,0)=\tilde{\rho}(x)$. Then, after some calculations, we can show that

$$\rho(x,t)=\frac{2x^{1/2(1+\theta)}}{2+\theta}\int_0^\infty du\,\mathcal{W}(1+\alpha-\gamma,\alpha-\gamma;-u)\int_0^\infty dx'\;\; x'^{1/2(1+\theta)}\tilde{\rho}(x')$$
$$\times\int_0^\infty dk\;\; k\;\; \mathrm{J}_{(1+\theta)/(2+\theta)}\left(\frac{2kx^{1/2(2+\theta)}}{2+\theta}\right)\mathrm{J}_{(1+\theta)/(2+\theta)}\left(\frac{2kx'^{1/2(2+\theta)}}{2+\theta}\right)e^{-ut^{\gamma-\alpha}\mathcal{D}k^2}\;. \quad (23)$$

By using the identity

$$\int_0^\infty dk\;\; k\;\; \mathrm{J}_\nu(\alpha k)\mathrm{J}_\nu(\beta k)e^{-a^2k^2}=\frac{1}{2a^2}e^{-\beta^2+\alpha^2/4a^2}\mathrm{I}_\nu\left(\frac{\alpha\beta}{2a^2}\right)\;, \quad (24)$$

present in Ref. 33, we may simplify Eq. (23) and obtain

$$\rho(x,t)=\frac{x^{1/2(1+\theta)}}{(2+\theta)\mathcal{D}t^{\gamma-\alpha}}\int_0^\infty\frac{du}{u}\,\mathcal{W}(1+\alpha-\gamma,\alpha-\gamma;-u)\int_0^\infty dx'\;\; x'^{1/2(1+\theta)}\tilde{\rho}(x')$$
$$\times\mathrm{I}_{(1+\theta)/(2+\theta)}\left(\frac{2x^{1/2(2+\theta)}x'^{1/2(2+\theta)}}{(2+\theta)^2\mathcal{D}ut^{\gamma-\alpha}}\right)\exp\left[-\frac{x^{2+\theta}+x'^{2+\theta}}{(2+\theta)^2\mathcal{D}ut^{\gamma-\alpha}}\right]\;, \quad (25)$$

where $\mathrm{I}_\nu(x)$ is a modified Bessel function.

III. NONLINEAR CASE

The scaling relation is remarkable in physics due to the broadness that may arise in diverse situations, for instance, the systems of the water transport in soil are related to the dependence of the concentration on distance and time,[34] and the asymptotic form of the propagator on fractals, in Sierpinski gasket.[14] In this sense, it is interesting to analyze the time scaling behavior and the asymptotic solutions for nonlinear diffusion equations taking time fractional derivative into account. Thus, we focus our attention on the following equation:

$$\frac{\partial^\gamma}{\partial t^\gamma}\rho(x,t)=\int_0^t dt'\frac{\partial}{\partial|x|}\left\{\mathcal{D}(x,t-t')\frac{\partial}{\partial|x|}[\rho(x,t')]^\nu\right\}\;, \quad (26)$$

where $\mathcal{D}(x,t)=\mathcal{D}|x|^{-\theta}t^\alpha$. In order to investigate the scaling behavior of the above equation we assume that the solution can be written as follows:

$$\rho(x,t)=\frac{1}{\Phi(t)}\overline{\rho}\left(\frac{x}{\Phi(t)}\right)\;. \quad (27)$$

Note that this kind of solution has been considered in several situations to analyze the nonlinear diffusion equation.[7] With these considerations we proceed to obtain the time evolution equation for the second moment related to Eq. (26) and it is given by

$$\frac{d^\gamma}{dt^\gamma}\langle x^2\rangle=2(1-\theta)\mathcal{D}\int_0^t dt'\,(t-t')^\alpha\int_{-\infty}^\infty dx|x|^{-\theta}[\rho(x,t')]^\nu\;. \quad (28)$$

By substituting Eq. (27) into Eq. (28), we can obtain a nonlinear fractional differential equation for $\Phi(t)$,

$$\frac{d^\gamma}{dt^\gamma}[\Phi(t)]^2=2(1-\theta)\mathcal{D}\frac{\mathcal{I}_1}{\mathcal{I}}\int_0^t dt'\,(t-t')^\alpha[\Phi(t')]^{1-\nu-\theta}\;, \quad (29)$$

with $\mathcal{I}=\int_{-\infty}^\infty d\overline{x}\,\overline{x}^2\overline{\rho}(\overline{x})$ and $\mathcal{I}_1=\int_{-\infty}^\infty d\overline{x}\,|\overline{x}|^{-\theta}[\overline{\rho}(\overline{x})]^\nu$. In addition, we supposed $\mathcal{I}$ and $\mathcal{I}_1$ are defined. Note that our investigation about the time scaling behavior is based on the second

moment which is finite when we consider a fractional time derivative applied to the diffusion equation, in contrast to the fractional spatial derivatives. For this reason, we only consider a fractional time derivative. The solution is given by

$$\Phi(t)=\mathcal{C}t^{(1+\gamma+\alpha)/(1+\nu+\theta)}\,, \tag{30}$$

where

$$\mathcal{C}=\left[\frac{(1-\theta)\alpha\mathcal{D}\mathcal{I}_1\Gamma(\alpha)}{\overline{\alpha}\mathcal{I}\ \Gamma(2\overline{\alpha})}\,\frac{\Gamma(1+2\overline{\alpha}-\gamma)\Gamma(1+\overline{\alpha}(1-\nu-\theta))}{\Gamma(2+\alpha+\overline{\alpha}(1-\nu-\theta))}\right]^{1/(1+\nu+\theta)}\,, \tag{31}$$

with

$$\overline{\alpha}=\frac{1+\gamma+\alpha}{1+\nu+\theta}\,. \tag{32}$$

From Eq. (30), we have $\langle x^2\rangle\propto t^{2((1+\gamma+\alpha)/(1+\nu+\theta))}$, so, for $(1+\gamma+\alpha)/(1+\nu+\theta)<1/2$, $(\gamma+\alpha)/(1+\nu+\theta)=1/2$ or $(1+\gamma+\alpha)/(1+\nu+\theta)>1/2$, which characterizes the sub, normal or superdiffusive behavior. In order to investigate the asymptotic behavior of Eq. (26), we consider

$$\rho(x,t)\sim\frac{1}{\Phi(t)}\left(\frac{|x|}{\Phi(t)}\right)^{-\eta}\,. \tag{33}$$

Note that Eq. (33) is Eq. (27) with $\overline{\rho}(x)\sim|x|^{-\eta}$. By substituting the above equation into (26), we find that $\eta=(2+\theta)/(1-\nu)$. It is possible to establish a connection between the asymptotic solution obtained here and the one obtained from the nonextensive statistics. In this sense, we compare Eq. (33) with the expression $1/|x|^{2/(q-1)}$ that appears in Ref. 20 for the entropic problem in this asymptotic behavior. Thus, we have that

$$q=\frac{4-2\nu+\theta}{2+\theta}\,. \tag{34}$$

Note that for $\theta=0$ the above result recovers the usual relation $q=2-\nu$ employed in Ref. 18.

IV. SUMMARY AND CONCLUSION

In summary, we have worked on a one-dimensional generalized diffusion equation [Eq. (1)] in several situations by considering the space and time fractional derivatives in the absence or presence of an external drift. We have also employed a time and spatial dependent diffusion coefficient. In this context, we have obtained a general expression for nth moment. Further, for some cases of $\mathcal{D}(x,t)$, we have obtained the exact solution for the probability density. Some peculiar aspects related to fractional approach have been shown along the text. It is interesting to note that the fractional derivative can deal with a bimodal distribution (see Fig. 1) which is absent in the ordinary case. For the nonlinear case we have analyzed the scaling behavior of the time and employed the scaling argument, on the space and time, to obtain an asymptotic solution for the probability density. In particular, we have related our asymptotic solution to the one obtained from nonextensive statistics. Finally, we hope that the results present in this work may be applied to physical systems exhibiting nontrivial forms of anomalous diffusion.

(Received 6 April 2004; accepted 24 May 2004; published 29 July 2004)

We consider the three-dimensional Schrödinger operators H_0 and H where $H_0=(i\nabla+A)^2-b$, A is a magnetic potential generating a constant magnetic field of strength $b>0$, and $H=H_0+V$ where $V\in L^1(\mathbb{R}^3;\mathbb{R})$ satisfies certain regularity conditions. Then the spectral shift function $\xi(E;H,H_0)$ for the pair of operators H, H_0 is well-defined for energies $E\neq 2qb$, $q\in\mathbb{Z}_+$. We study the asymptotic behavior of $\xi(E;H,H_0)$ as $E\to\infty$, $E\in\mathcal{O}_r$, $r\in(0,b)$, where $\mathcal{O}r:=\{E\in(0,\infty)|\mathrm{dist}(E,2b\mathbb{Z}+)>r\}$. We obtain a Weyl-type formula $\lim_{E\to\infty,E\in\mathcal{O}_r}E^{-1/2}\xi(E;H,H_0)=(1/4\pi^2)\int_{\mathbb{R}^3}V(x)dx$. © *2004 American Institute of Physics.*

I. INTRODUCTION

In this note we study the high energy asymptotics of the spectral shift function (SSF) for the three-dimensional Schrödinger operator with constant magnetic field, perturbed by an electric potential which decays fast enough at infinity. The note could be regarded as a supplement to the articles in Ref. 5 where the asymptotic behavior of the SSF in the strong magnetic field regime was considered, and Ref. 6 where the singularities of the SSF at the Landau levels were investigated.

Let $H_0:=(i\nabla+A)^2-b$ be the unperturbed three-dimensional magnetic Schrödinger operator, essentially self-adjoint on $C_0^\infty(\mathbb{R}^3)$. Here the magnetic potential $A=(-bx_2/2,bx_1/2,0)$ generates the constant magnetic field $B=\mathrm{curl}\,A=(0,0,b)$, $b>0$. It is well-known that $\sigma(H_0)=\sigma_{\mathrm{ac}}(H_0)=[0,\infty)$ (see Ref. 1), where $\sigma(H_0)$ denotes the spectrum of H_0, and $\sigma_{\mathrm{ac}}(H_0)$ its absolutely continuous spectrum. Moreover, the so-called Landau levels $2bq$, $q\in\mathbb{Z}_+:=\{0,1,\ldots\}$, play the role of thresholds in $\sigma(H_0)$.

For $\mathbf{x}=(x_1,x_2,x_3)\in\mathbb{R}^3$ we denote by $X_\perp=(x_1,x_2)$ the variables on the plane perpendicular to the magnetic field. We assume that V satisfies

$$V\not\equiv 0,\quad V\in C(\mathbb{R}^3),\quad |V(\mathbf{x})|\leqslant C_0\langle X_\perp\rangle^{-m_\perp}\langle x_3\rangle^{-m_3},\quad \mathbf{x}=(X_\perp,x_3)\in\mathbb{R}^3, \tag{1.1}$$

with $C_0>0$, $m_\perp>2$, $m_3>1$, and $\langle x\rangle:=(1+|x|^2)^{1/2}$, $x\in\mathbb{R}^d$, $d\geqslant 1$. By (1.1) and the diamagnetic inequality (see, e.g., Ref. 1), for each $E_0<0$ we have

$$|V|^{1/2}(H_0-E_0)^{-1}\in S_2, \tag{1.2}$$

a)Electronic mail: vincent.bruneau@math.u-bordeaux1.fr
b)Author to whom correspondence should be addressed. Electronic mail: graykov@uchile.cl

$$|V|^{1/2}(H_0 - E_0)^{-1/2} \in S_\infty, \tag{1.3}$$

where S_2 denotes the Hilbert–Schmidt class, while S_∞ denotes the class of linear compact operators. The resolvent identity combined with (1.2) implies that for each $E_0 < \inf \sigma(H) \leqslant \inf \sigma(H_0)$ we have

$$(H - E_0)^{-1} - (H_0 - E_0)^{-1} \in S_1, \tag{1.4}$$

where S_1 denotes the trace class. Then there exists a unique function $\xi(.;H,H_0) \in L^1(\mathbb{R};(1+E^2)^{-1}dE)$ which vanishes identically on $(-\infty, \inf \sigma(H))$, and satisfies the Lifshits–Krein trace formula

$$\mathrm{Tr}(\phi(H) - \phi(H_0)) = \int_{\mathbb{R}} \xi(E;H,H_0)\phi'(E)dE, \quad \phi \in C_0^\infty(\mathbb{R})$$

(see Ref. 14, Theorem 8.9.1). The function $\xi(.;H,H_0)$ is called the SSF for the pair of the operators H and H_0. For almost every $E > 0$ the SSF $\xi(E;H,H_0)$ is related to the scattering determinant $\det S(E;H,H_0)$ for the pair H, H_0 by the Birman–Krein formula

$$\det S(E;H,H_0) = e^{-2\pi i \xi(E;H,H_0)}$$

(see Ref. 3, 4, or 14, Sec. 8.4).

A priori, the SSF $\xi(E;H,H_0)$ is defined only for almost every $E \in \mathbb{R}$. In Sec. III C below we introduce a representative of the equivalence class determined by $\xi(.;H,H_0)$, defined on $\mathbb{R}\backslash 2b\mathbb{Z}_+$, which is bounded on each compact subset of the complement of the Landau levels, and is continuous on $\mathbb{R}\backslash\{2b\mathbb{Z}_+ \cup \sigma_p(H)\}$ where $\sigma_p(H)$ denotes the set of the eigenvalues of the operator H. In this note we will identify the SSF with this particular representative of its equivalence class.

The main goal of the paper is the study of the asymptotics of $\xi(E;H,H_0)$ as $E \to \infty$, $E \in \mathcal{O}_r$, where

$$\mathcal{O}_r := \{E \in (0,\infty) | \mathrm{dist}\,(E, 2b\mathbb{Z}_+) > r\}, \quad r \in (0,b). \tag{1.5}$$

The paper is organized as follows. In Sec. II we formulate our main result. In Sec. III we obtain some preliminary estimates, while the proof of our main result can be found in Sec. IV.

II. FORMULATION OF THE MAIN RESULT

Theorem 2.1: *Assume that V satisfies (1.1). Then we have*

$$\lim_{E \to \infty, E \in \mathcal{O}_r} E^{-1/2}\xi(E;H,H_0) = \frac{1}{4\pi^2}\int_{\mathbb{R}^3} V(\mathbf{x})d\mathbf{x}, \quad r \in (0,b). \tag{2.1}$$

Remarks: (i) It is essential to avoid the Landau levels in (2.1), i.e., to suppose that $E \in \mathcal{O}_r$, $r \in (0,b)$, as $E \to \infty$, since the SSF has singularities at the Landau levels, at least in the case where V has a fixed sign (see Ref. 6).

(ii) For $E \in \mathbb{R}$ set

$$\xi_{\mathrm{cl}}(E) := \int_{T^*\mathbb{R}^3} (\theta(E - |\mathbf{p} + A(\mathbf{x})|^2) - \theta(E - |\mathbf{p} + A(\mathbf{x})|^2 - V(\mathbf{x})))d\mathbf{x}d\mathbf{p}$$

$$= \frac{4\pi}{3}\int_{\mathbb{R}^3} (E_+^{3/2} - (E - V(\mathbf{x}))_+^{3/2})d\mathbf{x}$$

where

$$\theta(t) := \begin{cases} 0 & \text{if} \quad t \leqslant 0, \\ 1 & \text{if} \quad t > 0 \end{cases}$$

is the Heaviside function. Note that $\xi_{\mathrm{cl}}(E)$ is independent of the magnetic field $b \geqslant 0$. Evidently, under the assumptions of Theorem 2.1 we have

$$\lim_{E\to\infty} E^{-1/2}\xi_{\mathrm{cl}}(E) = 2\pi \int_{\mathbb{R}^3} V(\mathbf{x})d\mathbf{x}.$$

Hence, in the case $\int_{\mathbb{R}^3} V(\mathbf{x})d\mathbf{x} \neq 0$, relation (2.1) is equivalent to

$$\xi(E;H,H_0) = (2\pi)^{-3}\xi_{\mathrm{cl}}(E)(1+o(1)), \quad E\to\infty, \quad E\in\mathcal{O}_r, \quad r\in(0,b). \tag{2.2}$$

Asymptotic relations of the type (2.2) are known in the case of decaying magnetic potentials A (see, e.g., Ref. 13). However, in the last case the magnetic part $iA.\nabla + i\,\mathrm{div}\,A + |A|^2$ of the operator H_0 is a relatively compact perturbation of the Laplacian $-\Delta$, so that the resemblance with the case of a constant magnetic field, and, hence, of a linear magnetic potential, considered in the present note, is only formal. In particular, the methods of Ref. 13 are not directly applicable.

(iii) As far as the authors are informed, the high energy asymptotics of the SSF for three-dimensional Schrödinger operators with constant magnetic fields is investigated for the first time in the present note. However, we would like to mention a result contained in Ref. 9 where an axisymmetric $V=V(|X_\perp|,x_3)$ is considered. It is well-known (see, e.g., Ref. 1) that in this case the operators H and H_0 are unitarily equivalent to the orthogonal sums $\Sigma_{m\in\mathbb{Z}}\oplus H^{(m)}$ and $\Sigma_{m\in\mathbb{Z}}\oplus H_0^{(m)}$, respectively, where the operators

$$H_0^{(m)} := -\frac{1}{\varrho}\frac{\partial}{\partial\varrho}\varrho\frac{\partial}{\partial\varrho} - \frac{\partial^2}{\partial x_3^2} + \left(\frac{b\varrho}{2}+\frac{m}{\varrho}\right)^2, \quad H^{(m)} := H_0^{(m)} + V(\varrho,x_3), \quad m\in Z,$$

are self-adjoint in $L^2(\mathbb{R}_+\times\mathbb{R};\varrho d\varrho dx_3)$. For an arbitrary fixed $m\in\mathbb{Z}$ the authors of Ref. 9 studied the asymptotics as $E\to\infty$, $E\in\mathcal{O}_r$, of the SSF $\xi(E;H^{(m)},H_0^{(m)})$. Note that (2.1) cannot be deduced from the results of Ref. 9 even in the case of axial symmetry of V.

III. AUXILIARY RESULTS

A. Classes of compact operators

In this subsection we introduce some basic notations used throughout the paper. As above, we denote by S_∞ the class of linear compact operators acting in a fixed Hilbert space. Let $T=T^*\in S_\infty$. Denote by $\mathbb{P}_I(T)$ the spectral projection of T associated with the interval $I\subset\mathbb{R}$. For $s>0$ set

$$n_\pm(s;T) := \mathrm{rank}\ \mathbb{P}_{(s,\infty)}(\pm T).$$

For an arbitrary (not necessarily self-adjoint) operator $T\in S_\infty$ put

$$n_*(s;T) := n_+(s^2;T^*T), \quad s>0. \tag{3.1}$$

If $T=T^*$, then evidently

$$n_*(s;T) = n_+(s,T) + n_-(s;T), \quad s>0. \tag{3.2}$$

Further, we denote by S_p, $p\in[1,\infty)$, the Schatten–von Neumann class of compact operators for which the norm $\|T\|_p := (p\int_0^\infty s^{p-1}n_*(s;T)ds)^{1/p}$ is finite. In particular, as already indicated, S_1 stands for the trace class, and S_2 for the Hilbert–Schmidt class. If $T\in S_p$, $p\in[1,\infty)$, then the following elementary inequality,

$$n_*(s;T) \leqslant s^{-p}\|T\|_p^p, \tag{3.3}$$

holds for every $s>0$. If $T=T^* \in S_p$, $p \in [1,\infty)$, then (3.2) and (3.3) imply

$$n_\pm(s;T) \leqslant s^{-p}\|T\|_p^p, \quad s>0. \tag{3.4}$$

Finally, we define the self-adjoint operators $\mathrm{Re}\, T := \frac{1}{2}(T+T^*)$ and $\mathrm{Im}\, T := \frac{1}{2i}(T-T^*)$.

B. Index for a pair of projections

In this subsection we introduce the concepts of index of a Fredholm pair of orthogonal projections, and index for a pair of self-adjoint operators, and describe some basic properties related to these concepts which will be often used in the sequel. More details can be found in Ref. 2.

A pair of orthogonal projections P, Q is said to be Fredholm if

$$\{-1,1\} \cap \sigma_{\mathrm{ess}}(P-Q) = \emptyset\,.$$

In particular, if $P-Q \in S_\infty$, then the pair P, Q is Fredholm.

Assume that the pair of orthogonal projections P, Q is Fredholm. Set

$$\mathrm{index}(P,Q) := \dim \mathrm{Ker}\,(P-Q-I) - \dim \mathrm{Ker}\,(P-Q+I).$$

Let $\widetilde{M}$, M, be bounded self-adjoint operators. If the spectral projections $\mathbb{P}_{(-\infty,0)}(\widetilde{M})$ and $\mathbb{P}_{(-\infty,0)}(M)$ form a Fredholm pair, we shall use the short-hand notation

$$\mathrm{ind}(\widetilde{M},M) := \mathrm{index}(\mathbb{P}_{(-\infty,0)}(\widetilde{M}),\mathbb{P}_{(-\infty,0)}(M)).$$

A sufficient condition that the pair $\mathbb{P}_{(-\infty,0)}(\widetilde{M})$, $\mathbb{P}_{(-\infty,0)}(M)$ be Fredholm is $\widetilde{M}=M+A$, where M is a bounded self-adjoint operator such that $0 \notin \sigma_{\mathrm{ess}}(M)$, and $A=A^* \in S_\infty$.

Lemma 3.1 (see Ref. 12, Lemma 5.2): Let $M=M^*$, $0 \notin \sigma(M)$, $0 \leqslant A=A^* \in S_\infty$. Then for $t \in (0,\infty)$ we have

$$\mathrm{ind}(M+tA,M) = -\lim_{\varepsilon \downarrow 0} n_-(1-\varepsilon;tA^{1/2}M^{-1}A^{1/2}), \tag{3.5}$$

$$\mathrm{ind}(M-tA,M) = n_+(1;tA^{1/2}M^{-1}A^{1/2}). \tag{3.6}$$

Lemma 3.2 [see Ref. 5, Sec. 3.2, Property (g)]: Let M be a bounded self-adjoint operator such that $0 \notin \sigma(M)$. Let A and B be compact self-adjoint operators. Then for $s \in (0,\infty)$ such that $[-s,s] \cap \sigma(M)=\emptyset$ we have

$$\mathrm{ind}(M+s+B,M+s) - n_+(s;A) \leqslant \mathrm{ind}(M+A+B,M) \leqslant \mathrm{ind}(M-s+B,M-s) + n_-(s;A). \tag{3.7}$$

Lemma 3.3 (see Ref. 11, Lemma 2.1, or Ref. 5, Sec. 3.3): Let M be a bounded self-adjoint operator such that $0 \notin \sigma(M)$. Let $T_1=T_1^* \in S_\infty$ and $T_2=T_2^* \in S_1$. Then for each $s_1>0$, $s_2>0$ such that $[-s,s] \cap \sigma(M)=\emptyset$ with $s=s_1+s_2$ we have

$$\int_{\mathbb{R}} |\mathrm{ind}(M+T_1+t\,T_2,M)|\,d\mu(t) \leqslant n_*(s_1;T_1) + \frac{1}{\pi s_2}\|T_2\|_1, \tag{3.8}$$

where $d\mu(t) := (1/\pi)[dt/(1+t^2)]$.

C. Representation of the SSF

In this subsection we describe a representation of the SSF $\xi(E;H,H_0)$ which is a special case of the general representation of the SSF for a pair of lower-bounded self-adjoint operators, obtained by Gesztesy, Makarov, and Pushnitski (see Refs. 11, 8, and 12).

For $z\in\mathbb{C}$, $\operatorname{Im} z>0$, set $T(z):=|V|^{1/2}(H_0-z)^{-1}|V|^{1/2}$.

Lemma 3.4 (see Ref. 5, Lemma 3.1): Let (1.1) hold. Then for every $E\in\mathbb{R}\setminus 2b\mathbb{Z}_+$, the operator-norm limit

$$T(E):=\mathrm{n}-\lim_{\delta\downarrow 0} T(E+i\delta) \tag{3.9}$$

exists, and by (1.3) we have $T(E)\in S_\infty$. Moreover, $\operatorname{Im} T(E)\in S_1$.

Lemma 3.4 follows easily from Propositions 3.2 and 3.3 below (see Corollary 3.2).

Denote by J the multiplier by the function

$$\operatorname{sign} V(\mathbf{x})=\begin{cases}1 & \text{if } V(\mathbf{x})\geqslant 0,\\ -1 & \text{if } V(\mathbf{x})<0.\end{cases}$$

Introduce the function

$$\widetilde{\xi}(E;H,H_0)=\int_{\mathbb{R}}\operatorname{ind}(J+\operatorname{Re}T(E)+t\operatorname{Im}T(E),J)\,d\mu(t),\quad E\in\mathbb{R}\setminus 2b\mathbb{Z}_+, \tag{3.10}$$

which is well-defined by Lemmas 3.3 and 3.4.

Proposition 3.1 (see Ref. 5, Proposition 2.5): The function $\widetilde{\xi}(E;H,H_0)$ is continuous on $\mathbb{R}\setminus\{2b\mathbb{Z}_+\cup\sigma_p(H)\}$, and is bounded on every compact subset of $\mathbb{R}\setminus 2b\mathbb{Z}_+$.

Remark: Note that, in contrast to the case $b=0$, we cannot rule out the possibility of existence of embedded eigenvalues, by imposing short-range assumptions of the type of (1.1): Theorem 5.1 of Ref. 1 shows that there are axisymmetric potentials V of compact support such that below each Landau level $2bq$, $q\in\mathbb{Z}_+$, there exists an infinite sequence of eigenvalues of H which converges to $2bq$. On the other hand, generically, the only possible accumulation points of the eigenvalues of the operators H are the Landau levels [see Ref. 1, Theorem 4.7, and Ref. 7, Theorem 3.5.3 (iii)]. Further information of the location of these eigenvalues can be found in Ref. 5.

Theorem 3.1 (see Refs. 11, 8, 12, or 5, Sec. 3.3): *Let (1.1) hold. Then for almost every $E\in\mathbb{R}$ we have*

$$\xi(E;H,H_0)=\widetilde{\xi}(E;H,H_0). \tag{3.11}$$

Remark: As explained in the Introduction, we identify $\xi(E;H,H_0)$ with $\widetilde{\xi}(E;H,H_0)$. The identification on the set $\mathbb{R}\setminus\{2b\mathbb{Z}_+\cup\sigma_p(H)\}$ where $\widetilde{\xi}$ is continuous, is natural. On the other hand, the values prescribed to the SSF at the eigenvalues $E\in\sigma_p(H)$ may seem somewhat arbitrary; in any case, as Theorem 2.1 shows, these values are consistent with the asymptotics of $\xi(E;H,H_0)$ as $E\to\infty$, $E\in\mathcal{O}_r$, $r\in(0,b)$, *and* $E\notin\sigma_p(H)$.

D. Preliminary estimates

Introduce the Landau Hamiltonian

$$h(b):=\left(i\frac{\partial}{\partial x_1}-\frac{bx_2}{2}\right)^2+\left(i\frac{\partial}{\partial x_2}+\frac{bx_1}{2}\right)^2-b, \tag{3.12}$$

i.e., the two-dimensional Schrödinger operator with constant scalar magnetic field $b>0$, essentially self-adjoint on $C_0^\infty(\mathbb{R}^2)$. It is well-known that $\sigma(h(b))=\cup_{q=0}^\infty\{2bq\}$, and each eigenvalue $2bq$, $q\in\mathbb{Z}_+$, has infinite multiplicity (see, e.g., Ref. 1).

For $\mathbf{x},\mathbf{x}' \in \mathbb{R}^2$ denote by $\mathcal{P}_{q,b}(\mathbf{x},\mathbf{x}')$ the integral kernel of the orthogonal projection $p_q(b)$ onto the subspace $\mathrm{Ker}(h(b)-2bq)$, $q \in \mathbb{Z}_+$. It is well-known that

$$\mathcal{P}_{q,b}(\mathbf{x},\mathbf{x}') = \frac{b}{2\pi} L_q\left(\frac{b|\mathbf{x}-\mathbf{x}'|^2}{2}\right)\exp\left(-\frac{b}{4}(|\mathbf{x}-\mathbf{x}'|^2 + 2i(x_1x_2' - x_1'x_2))\right) \tag{3.13}$$

(see Ref. 10) where $L_q(t) := \sum_{k=0}^{q}\binom{q}{k}(-t)^k/k!$, $t \in \mathbb{R}$, $q \in \mathbb{Z}_+$, are the Laguerre polynomials. Note that

$$\mathcal{P}_{q,b}(\mathbf{x},\mathbf{x}) = \frac{b}{2\pi} \tag{3.14}$$

for each $q \in \mathbb{Z}_+$ and $\mathbf{x} \in \mathbb{R}^2$. Introduce the orthogonal projections $P_q : L^2(\mathbb{R}^3) \to L^2(\mathbb{R}^3)$, $q \in \mathbb{Z}_+$, by $P_q := p_q \otimes I$ where I denotes the identity operator in $L^2(\mathbb{R}_{x_3})$. For $z \in \mathbb{C}$ with $\mathrm{Im}\, z > 0$, define the operator $R(z) := (-d^2/dx_3^2 - z)^{-1}$ bounded in $L^2(\mathbb{R})$, as well as the operators

$$T_q(z) := |V|^{1/2} P_q (H_0 - z)^{-1} |V|^{1/2}, \quad q \in \mathbb{Z}_+,$$

bounded in $L^2(\mathbb{R}^3)$. The operator $R(z)$ admits the integral kernel $\mathcal{R}_z(x_3 - x_3')$ where $\mathcal{R}_z(x) = ie^{i\sqrt{z}|x|}/(2\sqrt{z})$, $x \in \mathbb{R}$, the branch of $\sqrt{z}$ being chosen so that $\mathrm{Im}\,\sqrt{z} > 0$. Moreover, $T_q(z) = |V|^{1/2}(p_q(b) \otimes R(z-2bq))|V|^{1/2}$.

For $\lambda \in \mathbb{R}$, $\lambda \neq 0$, define $R(\lambda)$ as the operator with integral kernel $\mathcal{R}_\lambda(x_3 - x_3')$ where

$$\mathcal{R}_\lambda(x) := \lim_{\delta \downarrow 0} \mathcal{R}_{\lambda + i\delta}(x) = \begin{cases} \dfrac{e^{-\sqrt{-\lambda}|x|}}{2\sqrt{-\lambda}} & \text{if} \quad \lambda < 0, \\ \dfrac{ie^{i\sqrt{\lambda}|x|}}{2\sqrt{\lambda}} & \text{if} \quad \lambda > 0, \end{cases} \qquad x \in \mathbb{R}. \tag{3.15}$$

Evidently, if $w \in L^2(\mathbb{R})$ and $\lambda \neq 0$, then $wR(\lambda)\overline{w} \in S_2$. For $E \in \mathbb{R}$, $E \neq 2bq$, $q \in \mathbb{Z}_+$, set

$$T_q(E) := |V|^{1/2}(p_q(b) \otimes R(E - 2bq))|V|^{1/2}.$$

Proposition 3.2 (Ref. 6, Proposition 4.1 and Corollaries 4.1, 4.2): Let $E \in \mathbb{R}$, $q \in \mathbb{Z}_+$, $E \neq 2bq$. *Assume that (1.1) holds.*

(i) *We have* $T_q(E) \in S_2$, *and* $\lim_{\delta \downarrow 0} \|T_q(E + i\delta) - T_q(E)\|_2 = 0$.
(ii) *We have* $\mathrm{Im}\, T_q(E) \geqslant 0$, *and if* $E < 2bq$, *then* $\mathrm{Im}\, T_q(E) = 0$. *Moreover,* $\mathrm{Im}\, T_q(E) \in S_1$.

Proposition 3.3 (see Ref. 6, Proposition 4.2): Let $b > 0$, $E \notin 2b\mathbb{Z}_+$. *Assume that V satisfies (1.1). Then the operator series* $T_+(E + i\delta) := \sum_{l=[E/2b]+1}^{\infty} T_l(E + i\delta)$, $\delta > 0$, *and* $T_+(E) := \sum_{l=[E/2b]+1}^{\infty} T_l(E)$, *where* $[x]$ *denotes the integer part of the real number x, are convergent in* S_2. *Moreover,*

$$\|T_+(E)\|_2^2 \leqslant \frac{C_0 b}{8\pi} \sum_{l=[E/2b]+1}^{\infty} (2bl - E)^{-3/2} \int_{R^3} |V(\mathbf{x})| d\mathbf{x}. \tag{3.16}$$

Finally, $\lim_{\delta \downarrow 0} \|T_+(E + i\delta) - T_+(E)\|_2 = 0$.

Corollary 3.1: Let $r \in (0, b)$. *Then we have*

$$\|\mathrm{Re}\, T_+(E)\|_2^2 = O(1), \quad E \to \infty, \quad E \in \mathcal{O}_r. \tag{3.17}$$

Proof: Estimate (3.17) follows immediately from (3.16) since we have

$$\sum_{l=[E/2b]+1}^{\infty}(2bl-E)^{-3/2}\leqslant\sum_{p=1}^{\infty}(2bp)^{-3/2}+r^{-3/2}.$$

For sufficiently large $E\in\mathcal{O}_r$ with $r\in(0,b)$, set $T_-(E):=\Sigma_{l=0}^{[E/2b]}T_l(E)$. Propositions (3.2) and (3.3) imply the following.

Corollary 3.2: For $E\in\mathcal{O}_r$ *with* $r\in(0,b)$ *the operator-norm limit* (3.9) *exists, and* $T(E)=T_-(E)+T_+(E)$. *Moreover,* $\mathrm{Re}\,T(E)=\mathrm{Re}\,T_-(E)+T_+(E)$, *and* $\mathrm{Im}\,T(E)=\mathrm{Im}\,T_-(E)\in S_1$.

For $n=0,1$ and $E\in\mathcal{O}_r$, $r\in(0,b)$, set $\varphi_n(E):=\Sigma_{q=0}^{[E/2b]}(E-2bq)^{-1+n/2}$.

Lemma 3.5: Let $r>0$. *Then the asymptotic relations*

$$\varphi_0(E)=O(\ln E),\tag{3.18}$$

$$\varphi_1(E)=E^{1/2}\frac{1}{b}(1+o(1)),\tag{3.19}$$

hold as $E\to\infty$, $E\in\mathcal{O}_r$.

Proof: Evidently, for $E>0$ large enough,

$$\varphi_n(E)=E^{-1+n/2}\sum_{q=0}^{[E/2b]-1}\left(1-\frac{2bq}{E}\right)^{-1+n/2}+(E-2b[E/2b])^{-1+n/2},\quad n=0,1.\tag{3.20}$$

Since the functions $(0,E/2b)\ni x\mapsto(1-2bx/E)^{-1+n/2}$, $n=0,1$, are increasing, and $E\in\mathcal{O}_r$, we have

$$\begin{aligned}\sum_{q=0}^{[E/2b]-1}\left(1-\frac{2bq}{E}\right)^{-1+n/2}&\leqslant\int_0^{[E/2b]}\left(1-\frac{2bx}{E}\right)^{-1+n/2}dx\leqslant\int_0^{(E-r)/(2b)}\left(1-\frac{2bx}{E}\right)^{-1+n/2}dx\\&=\frac{E}{2b}\int_0^{1-r/E}(1-t)^{-1+n/2}dt,\quad n=0,1.\end{aligned}\tag{3.21}$$

Further,

$$\int_0^{1-r/E}(1-t)^{-1+n/2}dt=\begin{cases}\ln(E/r) & \text{if}\quad n=0,\\ 2(1-(r/E)^{1/2}) & \text{if}\quad n=1.\end{cases}\tag{3.22}$$

Finally, we estimate the second term on the r.h.s. of (3.20):

$$(E-2b[E/2b])^{-1+n/2}\leqslant r^{-1+n/2},\quad n=0,1.\tag{3.23}$$

Putting together (3.20)–(3.23), we obtain (3.18), as well as $\limsup_{E\to\infty,E\in\mathcal{O}_r}E^{-1/2}\varphi_1(E)\leqslant 1/b$. In order to prove (3.19), it remains to show that $\liminf_{E\to\infty,E\in\mathcal{O}_r}E^{-1/2}\varphi_1(E)\geqslant 1/b$, which follows immediately from

$$\begin{aligned}\varphi_1(E)&\geqslant E^{-1/2}\int_{-1}^{[E/2b]}\left(1-\frac{2bx}{E}\right)^{-1/2}dx\geqslant E^{-1/2}\int_0^{E/2b-1}\left(1-\frac{2bx}{E}\right)^{-1/2}dx=\frac{E^{1/2}}{2b}\int_0^{1-2b/E}(1-t)^{-1/2}dt\\&=\frac{E^{1/2}}{b}\left(1-\left(\frac{2b}{E}\right)^{1/2}\right).\end{aligned}$$

Corollary 3.3: Let $r\in(0,b)$. *Then the asymptotic estimate*

$$\|T_-(E)\|_2^2=O(\ln E)\tag{3.24}$$

holds as $E\to\infty$, $E\in\mathcal{O}_r$.

Proof: We have

$$\begin{aligned}\|T_-(E)\|_2^2 &= \left\| |V|^{1/2} \sum_{q=0}^{[E/2b]} (p_q \otimes R(E-2bq))|V|^{1/2} \right\|_2^2 \\ &\leqslant C_0^2 \left\| \sum_{q=0}^{[E/2b]} (p_q \langle X_\perp\rangle^{-m_\perp/2}) \otimes (\langle x_3\rangle^{-m_3/2} R(E-2bq)\langle x_3\rangle^{-m_3/2}) \right\|_2^2 \\ &= C_0^2 \sum_{q=0}^{[E/2b]} \|p_q\langle X_\perp\rangle^{-m_\perp/2}\|_2^2 \|\langle x_3\rangle^{-m_3/2} R(E-2bq)\langle x_3\rangle^{-m_3/2}\|_2^2 \\ &= C_0^2 \frac{b}{8\pi} \int_{\mathbb{R}^2} \langle X_\perp\rangle^{-m_\perp} dX_\perp \left(\int_{\mathbb{R}} \langle x_3\rangle^{-m_3} dx_3 \right)^2 \varphi_0(E) \end{aligned} \tag{3.25}$$

[see (3.13) for the definition of the integral kernel of p_q, (3.14) for its value on the diagonal, and (3.15) for the definition of the integral kernel of $R(E-2bq)$]. Bearing in mind (3.18), we find that (3.25) implies (3.24). □

Proposition 3.4: Let $r \in (0,b)$. Then we have

$$\|\mathrm{Im}\, T(E)\| = O(1), \quad E \to \infty, \quad E \in \mathcal{O}_r. \tag{3.26}$$

Proof: Estimate (3.26) follows immediately from Ref. 5, Lemma 4.2, according to which we have $\|T(E)\| \leqslant r^{-1/2}(C_0/2)\int_{\mathbb{R}}\langle x_3\rangle^{-m_3} dx_3$. □

IV. PROOF OF THE MAIN RESULT

Fix an arbitrary $\varepsilon \in (0,1)$. Applying (3.5)–(3.7), and arguing as in the proof of Ref. 5, Lemma 5.1, we easily get

$$\begin{aligned} &\frac{1}{\pi}\mathrm{Tr}\arctan((\mathrm{Im}\, T(E))^{1/2}(J+\varepsilon)^{-1}(\mathrm{Im}\, T(E))^{1/2}) - n_+(\varepsilon;\mathrm{Re}\, T(E)) \\ &\quad \leqslant \int_{\mathbb{R}} \mathrm{ind}(J + \mathrm{Re}\ T(E) + t\ \mathrm{Im}\ T(E); J) d\mu(t) \\ &\quad \leqslant \frac{1}{\pi}\mathrm{Tr}\arctan((\mathrm{Im}\, T(E))^{1/2}(J-\varepsilon)^{-1}(\mathrm{Im}\, T(E))^{1/2}) + n_-(\varepsilon;\mathrm{Re}\, T(E)). \end{aligned} \tag{4.1}$$

Set

$$G_s = G_s(E) := (\mathrm{Im}\, T(E))^{1/2}(J+s)^{-1}(\mathrm{Im}\, T(E))^{1/2}, \quad s \in (-1,1).$$

Evidently, for each $s \in (-1,1)$ we have

$$\begin{aligned} |\mathrm{Tr}\arctan G_s(E) - \mathrm{Tr}\, G_s(E)| &\leqslant \tfrac{1}{3}\|G_s(E)\|_3^3 \leqslant \tfrac{1}{3}\|G_s(E)\|_2^2\|G_s(E)\| \leqslant \tfrac{1}{3}\|(J+s)^{-1}\|^3\|\mathrm{Im}\, T(E)\|_2^2\|\mathrm{Im}\, T(E)\| \\ &\leqslant \tfrac{1}{3}(1-|s|)^{-3}\|\mathrm{Im}\, T(E)\|_2^2\|\mathrm{Im}\, T(E)\|. \end{aligned} \tag{4.2}$$

The operator $(J+s)^{-1}\,\mathrm{Im}T(E)$ admits an explicit kernel

$$\begin{aligned} &\frac{1}{2}\sum_{q=0}^{[E/2b]} (E-2bq)^{-1/2}\mathcal{P}_q(X_\perp, X'_\perp)\cos(\sqrt{E-2bq}(x_3-x'_3)) \\ &\quad \times (\mathrm{sign}(V(X_\perp,x_3)) + s)^{-1}|V(X_\perp,x_3)|^{1/2}|V(X'_\perp,x'_3)|^{1/2}, \quad (X_\perp,x_3) \in \mathbb{R}^3, \quad (X'_\perp,x'_3) \in \mathbb{R}^3 \end{aligned}$$

[see (3.13) for the definition of $\mathcal{P}_q$]. Therefore,

$$\mathrm{Tr}G_s(E) = \mathrm{Tr}((J+s)^{-1}\mathrm{Im}\,T(E)) = \frac{b}{4\pi}\sum_{q=0}^{[E/2b]}(E-2bq)^{-1/2}\int_{\mathbb{R}^3}(\mathrm{sign}(V(\mathbf{x}))+s)^{-1}|V(\mathbf{x})|d\mathbf{x}$$

$$= \frac{b}{4\pi}\varphi_1(E)\int_{\mathbb{R}^3}(\mathrm{sign}(V(\mathbf{x}))+s)^{-1}|V(\mathbf{x})|d\mathbf{x} \tag{4.3}$$

[see (3.14)]. Finally, we estimate the second terms in the first and third lines in (4.1):

$$n_{\pm}(\varepsilon;\mathrm{Re}\,T(E)) \leqslant \varepsilon^{-2}\|\mathrm{Re}\,T(E)\|_2^2 \leqslant 2\varepsilon^{-2}(\|\mathrm{Re}\,T_-(E)\|_2^2 + \|\mathrm{Re}\,T_+(E)\|_2^2), \tag{4.4}$$

using (3.4) with $p=2$. Combining (4.1)–(4.4) with (3.10), making use of (3.19), (3.24), (3.17), and (3.26), and applying our convention to identify $\tilde{\xi}(E;H,H_0)$ with $\xi(E;H,H_0)$ we find that for each $\varepsilon\in(0,1)$ we have

$$\limsup_{E\to\infty,E\in\mathcal{O}_r} E^{-1/2}\xi(E;H,H_0) \leqslant \frac{1}{4\pi^2}\int_{\mathbb{R}^3}(\mathrm{sign}(V(\mathbf{x}))-\varepsilon)^{-1}|V(\mathbf{x})|d\mathbf{x},$$

$$\liminf_{E\to\infty,E\in\mathcal{O}_r} E^{-1/2}\xi(E;H,H_0) \geqslant \frac{1}{4\pi^2}\int_{\mathbb{R}^3}(\mathrm{sign}(V(\mathbf{x}))+\varepsilon)^{-1}|V(x)|d\mathbf{x}.$$

Letting $\varepsilon\downarrow 0$, we obtain (2.1).

Global periodic attractor for strongly damped wave equations with time-periodic driving force

Hongyan Li, Shengfan Zhou,[a] and Fuqi Yin
Department of Mathematics, Shanghai University, Shanghai 200436, People's Republic of China

(Received 23 October 2003; accepted 21 May 2004; published 30 July 2004)

In this paper, we consider the existence of a global periodic attractor for a strongly damped nonlinear wave equation with time-periodic driving force under homogeneous Dirichlet boundary condition. It is proved that in certain parameter region, for arbitrary time-periodic driving force, the system has a unique periodic solution attracting any bounded set exponentially. This implies that the system behaves exactly as a one-dimensional system. We mention, in particular, that the obtained result can be used to prove the existence of global periodic attractor of the usual damped and driven wave equations. © *2004 American Institute of Physics.*

I. INTRODUCTION

In this paper, we study the following strongly damped nonlinear wave equation:

$$\frac{\partial^2 u}{\partial t^2} - \alpha\Delta\frac{\partial u}{\partial t} - \Delta u + h\left(\frac{\partial u}{\partial t}\right) + f(u) = g(x,t), \quad (x,t) \in \Omega \times R_+, \tag{1}$$

with the homogeneous Dirichlet boundary condition,

$$u(x,t)_{x\in\partial\Omega} = 0, \quad t > 0, \tag{2}$$

and the initial value conditions,

$$u(x,0) = u_0(x), \quad \frac{\partial u}{\partial t}(x,0) = u_1(x), \quad x \in \Omega, \tag{3}$$

where $u=u(x,t)$ is a real-valued function on $\Omega\times[0,+\infty)$, Ω is an open bounded set of $R^n(n \in N)$ with a smooth boundary $\partial\Omega$, $\alpha>0$, h, $f\in C^1(R,R)$, $u_0(x)\in H_0^1(\Omega)$, $u_1(x)\in L^2(\Omega)$, $D(-\Delta) = H_0^1(\Omega)\cap H^2(\Omega)$, $g(\cdot,t)$ is a continuous T-periodic function in t, that is,

$$g(\cdot,t+T) = g(\cdot,t), \quad t \in R, \tag{4}$$

where T is a positive constant.

Wave equations, describing a great variety of wave phenomena, occur in the extensive applications of mathematical physics. Equation (1) can be regarded as a perturbed equation of continuous Josephson junction $[f(u)=\sin u]$.[1]

Strongly damped nonlinear wave equations have been studied widely in a different context by various methods. A large part of literature is devoted to the study of the asymptotic behavior of solutions (see Refs. 2–6). For the autonomous damped and driven sine-Gordon equation (f and g are independent of t), where $\alpha=0$, $h(u_t)=\gamma u_t$, $f(u)=\beta\sin u$, Zhao and Li proved that in Ref. 8 if

[a]Author to whom correspondence should be addressed. Electronic mail: sfzhou@mail.shu.edu.cn

$$|\beta| < \lambda_1^{1/2} \min\left(\frac{\gamma}{4}, \frac{\lambda_1}{2\gamma}, \sqrt{\frac{\lambda_1}{2}}\right),$$

where λ_1 is the first positive eigenvalue of operator $-\Delta$, when $g(x,t)=g(x)$, the global attractor is exactly an equilibrium point, which suggests that $|\beta|$ decreases as the damping γ grows and $\lim_{\gamma\to\infty}|\beta|=0$. This implies that the system behaves as a linear one as the damping γ tends to infinity. It is difficult to comprehend from physical intuition. For the non autonomous equations, Zhou and Fan[6] considered the existence of kernel sections and obtained an upper bound of its Hausdorff dimension. The existence of global periodic attractor, under a certain parameter region, was derived by Zhu and Zhou in Ref. 7 for the damped sine-Gordon equation with time-periodic force. In this paper, our goal is to find a parameter region under which there exists a continuous periodic solution attracting exponentially any bounded sets for the equation (1), hence, the problem behaves as a one-dimensional system. According to our result, in the particular case considered by Zhao and Li,[8] it reads that the nonlinear term $\beta \sin u$ is not necessary to become zero as $\gamma\to\infty$, which conforms to the physical intuition.

We arrange this paper as follows. First we present the existence and uniqueness of solutions. Then following the idea of Ref. 6, by introducing a new norm in the phase space E which is equivalent to the usual norm in E, we obtain a parameter region under which system (1)–(3) possesses a global periodic attractor. Finally, for the special case $\alpha=0$, we discuss the existence of a global periodic attractor.

II. PRELIMINARIES

It is known that the linear operator $A=-\Delta: D(A)=H_0^1(\Omega)\cap H^2(\Omega)\to L^2(\Omega)$ is self-adjoint positive and linear, and eigenvalues $\{\lambda_i\}_{i\in N}$ of A satisfy

$$0<\lambda_1\leqslant\lambda_2\leqslant\cdots\leqslant\lambda_m\leqslant\cdots, \quad \lambda_m\to+\infty (m\to+\infty).$$

Set $E=H_0^1(\Omega)\times L^2(\Omega)$, and let

$$(u,v)=\int_\Omega uv\ \mathrm{d}x, \quad |u|=(u,u)^{1/2}, \quad \forall\, u,v\in L^2(\Omega),$$

$$((u,v))=\int_\Omega \nabla u\cdot\nabla v\ \mathrm{d}x, \quad \|u\|=((u,v))^{1/2}, \quad \forall\, u,v\in H_0^1(\Omega),$$

and

$$(Y_1,Y_2)_{H_0^1\times L^2}=((u_1,u_2))+(v_1,v_2), \quad |Y|_{H_0^1\times L^2}=(Y,Y)^{1/2}_{H_0^1\times L^2},$$

$$\forall Y_i=(u_i,v_i)^T, \quad Y=(u,v)^T\in H_0^1(\Omega)\times L^2(\Omega), \quad i=1,2,$$

denote the usual inner products and norms in $L^2(\Omega), H_0^1(\Omega)$, and E, respectively.

In what follows, we consider the system (1)–(3) and present the existence and uniqueness of its solutions. It is convenient to reduce system (1)–(3) to an evolution equation of the first order in time. Let $u_t=v$, then (1)–(3) are equivalent to the following initial value problem in the Hilbert space E:

$$\begin{aligned}&\dot{Y}=CY+F(Y,t), \quad x\in\Omega, t>0,\\ &Y(0)=Y_0=(u_0,v_0)^T\in E,\end{aligned} \tag{5}$$

where $Y=(u,v)^T$, $F(Y,t)=(0,-h(v)-f(u)+g(x,t))^T$, and

$$C = \begin{pmatrix} 0 & I \\ -A & -\alpha A \end{pmatrix}. \tag{6}$$

Massatt in Ref. 2 proved that C in (6) is a sectorial operator and generates an analytic semigroup e^{Ct} on E for $t>0$.

Let $f,h \in C^1(R,R)$, we make the following assumptions:

(i) There exists a non-negative constant $c_0 \geqslant 0$ such that

$$f(0)=0, \quad |f(u_1)-f(u_2)| \leqslant c_0|u_1-u_2|, \quad \forall\, u_1,u_2 \in R, \tag{7}$$

where $|\cdot|$ denotes the absolute value of number in R.

(ii) There exist two constants β_1,β_2 such that

$$h(0)=0, \quad -\alpha\lambda_1 < \beta_1 \leqslant h'(s) \leqslant \beta_2 < +\infty, \quad \forall\, s \in R, \tag{8}$$

where λ_1 is the first eigenvalue of the operator A on Ω under the boundary condition (2).

By the assumptions (7) and (8), it is easy to check that the function $F(Y,t):E\to E$ is continuous differentiable and globally Lipschitz continuous with respect to Y. By the classical theory concerning the existence and uniqueness of the solutions of evolution differential equations,[9] we have the following lemma (see Ref. 6 for the proof detail).

Lemma 1: If (7) and (8) hold, then, for any $Y_0 \in E$, there exists a unique continuous function $Y(\cdot)=Y(\cdot,Y_0) \in C(R_+;E)$ such that $Y(0,Y_0)=Y_0$ and $Y(t)$ satisfies the integral equation

$$Y(t,Y_0) = e^{Ct}Y_0 + \int_0^t e^{C(t-s)}F(Y(s),s)\mathrm{d}s.$$

$Y(t)$ is called a (mild) solution of (5), and $Y(t,Y_0)$ is jointly continuous in t and Y_0.

Therefore, for $u_0 \in H_0^1(\Omega)$, $u_1 \in L^2(\Omega)$, there exists unique function $u(t)$ such that

$$(u,u_t) \in C(R_+;H_0^1(\Omega)) \times [C(R_+;L^2(\Omega)) \cap L^2(0,T^*;H_0^1(\Omega))], \quad \forall\, T^*>0, \tag{9}$$

satisfies (1)–(3). From (9), we can define a map

$$S(t):Y_0=(u_0,u_1) \to (u,u_t)=Y(t,Y_0), \quad E\to E, \quad \forall\, t \geqslant 0,$$

where $Y(t,Y_0)$ is the (mild) solution of (5), then $\{S(t),t\geqslant 0\}$ is a continuous process on E. Again since $g(x,t)$ is a T-periodic function with respect to $t \in R$, $\{S(nT)|n \in N\}$ is a discrete semidynamical system in E.

III. MAIN RESULT

In this section, we will study the existence of a global periodic attractor for system (5) in E. For this purpose, we define a new weighted inner product and norm in $E=H_0^1(\Omega)\times L^2(\Omega)$ as

$$(\varphi,\psi)_E = r((u_1,u_2)) + (v_1,v_2), |\varphi|_E = (\varphi,\varphi)_E^{1/2}, \tag{10}$$

for any $\varphi=(u_1,v_1)^T$, $\psi=(u_2,v_2)^T \in E$, where r is chosen as

$$r = \frac{4+(\alpha\lambda_1+\beta_1)\alpha+\beta_2^2/\lambda_1}{4+2(\alpha\lambda_1+\beta_1)\alpha+\beta_2^2/\lambda_1} \in \left(\frac{1}{2},1\right). \tag{11}$$

Obviously, the norm $|\cdot|_E$ in (10) is equivalent to the usual norm $|\cdot|_{H_0^1\times L^2}$ in E.

Let $\varphi=(u,v)^T$, $v=u_t+\varepsilon u$, where ε is chosen as

$$\varepsilon = \frac{\alpha\lambda_1 + \beta_1}{4 + 2(\alpha\lambda_1 + \beta_1)\alpha + \beta_2^2/\lambda_1}, \tag{12}$$

and then the system (1)–(3) can be written as

$$\varphi_t + H(\varphi) = F_1(\varphi,t), \quad \varphi(0) = (u_0, u_1 + \varepsilon u_0)^T, \quad t \geqslant 0, \tag{13}$$

where

$$\begin{aligned} F_1(\varphi,t) &= \begin{pmatrix} 0 \\ -f(u) + g(x,t) \end{pmatrix}, \\ H(\varphi) &= \begin{pmatrix} \varepsilon u - v \\ Au - \varepsilon(\alpha A - \varepsilon)u + (\alpha A - \varepsilon)v \end{pmatrix} + \begin{pmatrix} 0 \\ h(v - \varepsilon u) \end{pmatrix}. \end{aligned} \tag{14}$$

Our main result in this paper is as follows.

Theorem 1: *If (4), (7), and (8) and* $\beta_2 \geqslant |\beta_1| + \min\{1/\alpha, (\alpha\lambda_1 + \beta_1)/2\}$ *hold and* c_0 *in (7) satisfies*

$$0 \leqslant c_0 \leqslant \sqrt{\lambda_1 r \sigma(\sigma + \alpha\lambda_1 + \beta_1)}, \tag{15}$$

where

$$\sigma = \frac{\lambda_1\alpha + \beta_1}{\gamma_1 + \sqrt{\gamma_1\gamma_2}}, \quad \gamma_1 = 4 + (\alpha\lambda_1 + \beta_1)\alpha + \frac{\beta_2^2}{\lambda_1}, \quad \gamma_2 = (\alpha\lambda_1 + \beta_1)\alpha + \frac{\beta_2^2}{\lambda_1}. \tag{16}$$

Then system (5) [*or (1)–(3)*] *has a unique T-periodic solution which attracts any bounded set exponentially.*

Proof: Let $\varphi_1(t), \varphi_2(t)$ be two solutions of (5) with the initial values $\varphi_{01}, \varphi_{02} \in E$ and $\varphi(t) = \varphi_1(t) - \varphi_2(t)$. We obtain from (13) that

$$\frac{\partial \varphi(t)}{\partial t} + H(\varphi_1(t)) - H(\varphi_2(t)) = F_1(\varphi_1(t),t) - F_1(\varphi_2(t),t). \tag{17}$$

Taking the scalar product of two sides of (17) with $\varphi(t) = (u,v)^T$ in E, we find

$$\frac{1}{2}\frac{d}{dt}|\varphi|_E^2 + (H(\varphi_1(t)) - H(\varphi_2(t)), \varphi)_E = (F_1(\varphi_1(t),t) - F_1(\varphi_2(t),t), \varphi)_E. \tag{18}$$

For the second term on the left-hand side of (18), according to (8), $\beta_2 \geqslant |\beta_1| + \min\{1/\alpha, (\alpha\lambda_1 + \beta_1)/2\}$ and $r = 1 - \varepsilon\alpha$, we have

$$\begin{aligned} (H(\varphi_1(t)) - H(\varphi_2(t)), \varphi)_E - \sigma|\varphi|_E^2 - \frac{\alpha\lambda_1 + \beta_1}{2}|v|^2 &\geqslant (\varepsilon - \sigma)r\|u\|^2 + \left(\frac{\alpha\lambda_1 + \beta_1}{2} - \varepsilon - \sigma\right)|v|^2 \\ &\quad - \frac{\varepsilon\beta_2}{\sqrt{\lambda_1 r}} \cdot \sqrt{r}\|u\| \cdot |v|. \end{aligned} \tag{19}$$

By (12) and (16), simple computation shows

$$4(\varepsilon - \sigma)\left(\frac{\alpha\lambda_1 + \beta_1}{2} - \varepsilon - \sigma\right) \geqslant \frac{\varepsilon^2\beta_2^2}{r\lambda_1}.$$

By (19),

$$(H(\varphi_1(t)) - H(\varphi_2(t)), \varphi)_E \geqslant \sigma|\varphi|_E^2 + \frac{\alpha\lambda_1 + \beta_1}{2}|v|^2, \tag{20}$$

where σ is as in (16). From (7), (18), and (20), we have

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}|\varphi|_E^2 &\leqslant -2\sigma|\varphi|_E^2 - \alpha\lambda_1|v|^2 - \beta_1|v|^2 + 2|f(u_1) - f(u_2)| \cdot |v| \\ &\leqslant -\sigma|\varphi|_E^2 - \sigma r\|u\|^2 - (\sigma + \alpha\lambda_1 + \beta_1)|v|^2 + \frac{2c_0}{\sqrt{\lambda_1 r}}\sqrt{r}\|u\| \cdot |v| \\ &\leqslant -\sigma|\varphi|_E^2 - \left(2\sqrt{\sigma(\sigma + \alpha\lambda_1 + \beta_1)} - \frac{2c_0}{\sqrt{\lambda_1 r}}\right)\sqrt{r}\|u\| \cdot |v| \leqslant -\sigma|\varphi|_E^2,\end{aligned}$$

which implies

$$|\varphi(t)|_E \leqslant e^{-(\sigma/2)t}|\varphi(0)|_E, \quad \forall\, t \geqslant 0. \tag{21}$$

Now considering T-mapping $S(T): E \to E$, $S(T)\varphi_0 = \varphi(T, \varphi_0)$, where $\varphi(t, \varphi_0)$ is the solution of (5), $\varphi(0, \varphi_0) = \varphi_0$. From (21), $\forall \varphi_1, \varphi_2 \in E$, we obtain

$$|S(T)\varphi_1 - S(T)\varphi_2|_E \leqslant e^{-(\sigma/2)T}|\varphi_1 - \varphi_2|_E.$$

Thus $S(T)$ is a contraction mapping. By Banach's fixed point theorem, there exists a unique fixed point φ^* for $S(T)$ in E such that $S(T)\varphi^* = \varphi^*$. At the same time, since $\{S(nT)|n \in N\}$ is a discrete semidynamical system in E, we can deduce

$$S(nT)\varphi^* = S(T)^n\varphi^*, \quad \forall\, n \in N$$

and

$$\varphi^*(t + T) = S(t)\varphi^*(T) = S(t)\varphi^* = \varphi^*(t),$$

where $\varphi^*(t)$ is the solution passing $\varphi^* \in E$. Thus $\varphi^*(t) = \varphi(t, \varphi^*)$ is a T-periodic solution of system (1)–(3). By (21), $\varphi^*(t)$ attracts any bounded set exponentially. The proof is completed.

Remark: If $g(x,t) = g(x)$ is independent of t, then the T-periodic solution in Theorem 1 is an equilibrium point.

IV. SPECIAL CASE $\alpha = 0$

When $\alpha = 0$, Eq. (1) reduces to the following damped and driven wave equation with time-periodic driving force:

$$\frac{\partial^2 u}{\partial t^2} + h\left(\frac{\partial u}{\partial t}\right) - \Delta u + f(u) = g(x,t), \quad (x,t) \in \Omega \times R_+, \tag{22}$$

endowed with the homogeneous Dirichlet boundary condition (2) and the initial value condition (3), where Ω is an open bounded domain of $R^n (n \in N)$ with a smooth boundary $\partial\Omega$. We assume that the functions $g(\cdot, t)$ and $h, f \in C^1(R, R)$ satisfy (4), (7), and (8). From Theorem 1, we have the following result.

Theorem 2: *Suppose* $0 \leqslant c_0 \leqslant \sqrt{\sigma\lambda_1(\sigma + \beta_1)}$, *where*

$$\sigma = \frac{\beta_1\lambda_1}{\sqrt{\beta_2^2 + 4\lambda_1}(\beta_2 + \sqrt{\beta_2^2 + 4\lambda_1})}.$$

Then system (22) with conditions (2) and (3) possesses a global T-periodic attractor which attracts any bounded set exponentially.

In particular, when $h(u_t)=\gamma u_t$, $f(u)=\beta \sin u$, $\gamma>0$, $\beta>0$, Eq. (22) reduces to the damped and driven sine-Gordon equation modeling the Josephson junction in superconduction,

$$\frac{\partial^2 u}{\partial t^2}+\gamma\frac{\partial u}{\partial t}-\Delta u+\beta \sin u=g(x,t), \quad u(x,t)\in R, \quad x\in R, \tag{23}$$

which was studied by many authors (see Refs. 7, 8, and 10). When $g(x,t)=I(x)+f(x)\sin \omega t$, Zhu and Zhou[7] proved the existence of global periodic solution in a certain parameter region. As a corollary of Theorem 2, we have

Corollary: Assume that $|\beta|\leqslant\sqrt{\sigma\lambda_1(\sigma+\gamma)}$, where $\sigma=\gamma\lambda_1\big/\sqrt{\gamma^2+4\lambda_1}(\gamma+\sqrt{\gamma^2+4\lambda_1})$, *then system (23) with conditions (2) and (3) has a global T-periodic attractor which attracts any bounded set exponentially*.

Remark: The main point of the present paper is to show the existence of a global periodic attractor of the system (1)–(3). Our method here is different from that in Ref. 7. Zhao and Li proved that in Ref. 8 if $|\beta|<\lambda_1^{1/2}\min(\gamma/4,\lambda_1/2\gamma,\sqrt{\lambda_1}/2)$, *when* $g(x,t)=g(x)$, *the global attractor for system (23) with conditions (2) and (3) is exactly an equilibrium point, which suggests that* $|\beta|$ *decreases as the damping* γ *grows and* $\lim_{\gamma\to\infty}|\beta|=0$. *It implies that the system behaves as a linear one as the damping* γ *tends to infinity. However, from our result, if* $|\beta|\leqslant\sqrt{\sigma\lambda_1(\sigma+\gamma)}$, *then system (23), (2), and (3) possesses a T-periodic solution for* $t\in R$, *which attracts any bounded set exponentially. In particular, we point out that* $\sqrt{\sigma\lambda_1(\sigma+\gamma)}$ *increases as the damping* γ *grows, and* $\lim_{\gamma\to+\infty}\sqrt{\sigma\lambda_1(\sigma+\gamma)}=\lambda_1/\sqrt{2}$, *thus the nonlinear term* $\beta \sin u$ *is not necessary to become zero as* $\gamma\to\infty$, *which conforms to the physical intuition*.

(Received 25 August 2003; accepted 31 May 2004; published 30 July 2004)

We consider the Euler's variational equations deriving from a general Lagrangian $L(\partial_\alpha q^r, q^s)$. Under the assumption of convexity of energy, we write down some inequalities for the energy-momentum tensor including Hawking–Ellis energy conditions. We show that there exists the same number of positive and negative wave velocities and no velocity can change sign. Finally, we study the structure of the characteristic shocks with particular attention to the generalized Born–Infeld Lagrangian describing the electron with spin. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1780611]

I. INTRODUCTION

It is well known that a system of balance laws with a convex extension can be symmetrized in the sense of Friedrichs.[1] In Physics this additional equation corresponds to an entropy or energy law. The convexity requirement is satisfied in many physical situations and, for instance, corresponds in thermomechanics to restrictions on the constitutive functions and on the field such that stability holds: the pressure of a fluid increases with the material density, the specific heat at constant volume must be positive together with the density and the temperature. This entropy principle was used in the construction of the Extended Thermodynamics for non-equilibrium fluids.[2,3] As we shall see in nonlinear electrodynamics it imposes an upper bound for the electric field.

In a privileged set of field variables (main field) the original system is symmetric hyperbolic and is generated by a potential four-vector[4–6] (see also Ref. 7) ensuring, in particular, the local well-posedness of the Cauchy problem.[8,9]

More specifically in various physical situations there exists a variational principle. Instead of a four-vector, a *single* function, the Lagrangian, suffices to determine the corresponding Euler's system which admits *four* (instead of one) supplementary laws representing the conservation of the energy-momentum tensor.[10]

Nonlinear electrodynamics, regarded with a new interest and connected to string theory[11,12] was introduced by Born and Infeld in their 1934 celebrated paper[13] with the Lagrangian

$$L = \sqrt{-R^2 + k(2Q + k)}, \tag{1}$$

where Q and R are the electromagnetic invariants and the constant $\sqrt{k}$ (absolute field) is an upper limit for the electric field thus eliminating the Maxwell singularity at the point charge through the *BIon* (to quote Gibbons[14]) solution

$$E = \frac{\sqrt{k}}{\sqrt{1 + (r/r_0)^4}}, \tag{2}$$

where r_0 is the radius of the electron. (See also Ref. 15.)

More generally considering a Lagrangian $L(Q,R)$ depending on Q and R, several interesting properties of nonlinear wave propagation appear. In particular by requiring that the two families of discontinuity waves never evolve into shocks (exceptionality conditions) the Lagrangian assumes the form stated in Sec. VII (exceptional Lagrangian) which includes spin and reduces to (1) in the case of a null Planck constant.[16] However, if the shock does exist at some initial time it propagates on characteristic surfaces.[7,17]

From the convexity of the energy density of a general Lagrangian some results concerning the energy-momentum tensor and the characteristic velocities are derived. In particular in Sec. III we show that the assumption $T^{0i}=T^{i0}$ implies the complete symmetry of the energy momentum tensor $T^{\alpha\beta}$ and we obtain several inequalities for its components including Hawking–Ellis energy condition.[18–20,11,21] In Sec. IV we can verify that there always exists the same number of positive and negative wave velocities and no velocity can change sign. As a consequence it is immediately seen, for instance, that the equations of fluid dynamics cannot derive from a variational principle for this very last reason.

In Sec. V we give the structure of the characteristic shocks and in particular we discuss their boundedness. Then we apply the results to the Born–Infeld model and its generalization. We verify that the characteristic shocks of the proper Born–Infeld model are unbounded while for the generalized Lagrangian several possibilities can occur.

II. EULER'S VARIATIONAL EQUATIONS

Let $q^r(x^\alpha)$, $r=1,\ldots,M$ be functions of the space-time coordinates $x^\alpha(\alpha=0,i;\ i=1,2,3;\ x^0=t)$, $q^r_\alpha \doteqdot \partial_\alpha q^r$ be the derivative of q^r with respect to x^α and $L(q^r_\alpha,q^r)$ a general Lagrangian function. Let us agree that summation occurs only for repeated indices in up and down positions. Then a classical solution of Euler's equations

$$\partial_\alpha\left(\frac{\partial L}{\partial q^s_\alpha}\right) = \frac{\partial L}{\partial q^s} \tag{3}$$

also satisfies the four additional conservation laws

$$\partial_\alpha T^\alpha_\beta = 0,$$

where T^α_β is defined by

$$T^\alpha_\beta = q^r_\beta \frac{\partial L}{\partial q^r_\alpha} - L\,\delta^\alpha_\beta. \tag{4}$$

With the field

$$\breve{\mathbf{u}} \equiv \left(\frac{\partial L}{\partial q^s_0}, q^s_i, q^s\right) \tag{5}$$

(the breve denotes the transpose) (3) can be written as a first order partial differential system of $5M$ balance laws,

$$\partial_t \mathbf{u} + \partial_i \mathbf{f}^i(\mathbf{u}) = \mathbf{f}(\mathbf{u}),$$

i.e.,

$$\partial_t\left(\frac{\partial L}{\partial q^s_0}\right) + \partial_i\left(\frac{\partial L}{\partial q^s_i}\right) = \frac{\partial L}{\partial q^s},$$

$$\partial_t q_i^s - \partial_i q_0^s = 0, \quad s = 1, \ldots, M,$$

$$\partial_t q^s = q_0^s. \tag{6}$$

Instead, if we introduce the main field[4,5]

$$\check{\mathbf{u}}' = \frac{\partial T^0{}_0}{\partial \mathbf{u}} \equiv \left(q_0^s, -\frac{\partial L}{\partial q_i^s}, -\frac{\partial L}{\partial q^s} \right),$$

(6) appears as a Friedrichs–Lax–Godunov symmetric hyperbolic system

$$\mathbf{H}'(\mathbf{u}')\partial_t \mathbf{u}' + \mathbf{A}'^i \partial_i \mathbf{u}' = \mathbf{B}'\mathbf{u}', \tag{7}$$

where the constant symmetric matrices $\mathbf{A}'^i$, satisfy a Duffin–Kemmer–Petiau relation

$$\mathbf{A}'^i\mathbf{A}'^k\mathbf{A}'^j + \mathbf{A}'^j\mathbf{A}'^k\mathbf{A}'^i = \delta^{ik}\mathbf{A}'^j + \delta^{jk}\mathbf{A}'^i \tag{8}$$

while $\mathbf{B}'$ is skew-symmetric and the Hessian matrix $\mathbf{H}' \doteq \partial \mathbf{u}/\partial \mathbf{u}'$ is positive definite provided that the energy density T_0^0 is a convex function of the field variables $\mathbf{u}$,[7] which means that

$$\delta\check{\mathbf{u}}' \cdot \delta\mathbf{u} = \delta q_0^s \delta\left(\frac{\partial L}{\partial q_0^s} \right) - \delta q_i^s \delta\left(\frac{\partial L}{\partial q_i^s} \right) - \delta q^s \delta\left(\frac{\partial L}{\partial q^s} \right) > 0. \tag{9}$$

This property (which is supposed to hold in the following) also insures a global one to one correspondence between $\mathbf{u}$ and $\mathbf{u}'$. If, as usual, the Lagrangian does not depend explicitly on q^s the last equation in (6) and the last component of the main field can be dropped and (7) becomes a system of $4M$ conservation laws without second member. It is interesting to observe that this last system is a principal subsystem of the former one following the definitions and the properties stated in Ref. 22. Similarly the Euler–Lagrange equations of analytical mechanics are another principal subsystem of (6).

III. THE SYMMETRIC ENERGY-MOMENTUM TENSOR

In terms of the $\mathbf{u}$ and $\mathbf{u}'$ fields the components of T_β^α take the form[10]

$$T_0^i = \tfrac{1}{2}\check{\mathbf{u}}'\mathbf{A}'^i\mathbf{u}', \quad T_i^0 = -\tfrac{1}{2}\check{\mathbf{u}}\mathbf{A}'^i\mathbf{u}, \quad T_j^i = T^0{}_0\delta_j^i - \check{\mathbf{u}}\mathbf{A}'^j\mathbf{A}'^i\mathbf{u}'.$$

While Physics usually requires T to be a symmetric tensor in general T is not a tensor and is not symmetric. Suppose nevertheless that we raise the lower indices with the Minkowski metric, $\eta^{\alpha\beta} = \mathrm{diag}(1,-1,-1,-1)$,

$$T^{\alpha\beta} = \eta^{\beta\gamma}T_\gamma^\alpha.$$

Then the mere condition $T^{0i} \equiv T^{i0}$ implies that $T^{ij} \equiv T^{ji}$, i.e., complete symmetry.

To see this we differentiate

$$\check{\mathbf{u}}'\mathbf{A}'^i\mathbf{u}' = \check{\mathbf{u}}\mathbf{A}'^i\mathbf{u}$$

with respect to $\mathbf{u}'$ to get

$$\check{\mathbf{u}}'\mathbf{A}'^i = \check{\mathbf{u}}\mathbf{A}'^i\mathbf{H}' \tag{10}$$

so that

$$T^{ij} \equiv T^{ji} = \check{\mathbf{u}}\mathbf{A}'^i\mathbf{H}'\mathbf{A}'^j\mathbf{u} - T^{00}\delta^{ij}. \tag{11}$$

Now for any unit vector $\vec{n}$ since

$$T^{i0} = \tfrac{1}{2}\breve{\mathbf{u}}\mathbf{A}'^{i}\mathbf{H}'\mathbf{u}'$$

and thanks to Schwarz inequality

$$(T^{i0}n_i)^2 \leqslant \tfrac{1}{2}\breve{\mathbf{u}}'\mathbf{H}'\mathbf{u}'\left(\frac{T^{ij}n_in_j + T^{00}}{2}\right),$$

$$(T^{ij})^2 \leqslant (T^{ii} + T^{00})(T^{jj} + T^{00}), \quad i \neq j.$$

From (11),

$$T^{00} + T^{ij}n_in_j \geqslant 0, \quad \vec{n}^2 = 1 \Rightarrow T^{ii} + T^{00} \geqslant 0.$$

Provided that the absolute values of the wave velocities, i.e., the eigenvalues of $\mathbf{A}'_n/\mathbf{H}'$ ($\mathbf{A}'_n \doteq \mathbf{A}'^{i}n_i$, see below), do not exceed 1, the matrices $\mathbf{H}' \pm \mathbf{A}'_n$ are semidefinite positive. Thus

$$-T^{i0}n_i = \tfrac{1}{2}\breve{\mathbf{u}}'(\mathbf{H}' - \mathbf{A}'_n)\mathbf{u}' - \tfrac{1}{2}\breve{\mathbf{u}}'\mathbf{H}'\mathbf{u}' \Rightarrow T^{i0}n_i \leqslant \tfrac{1}{2}\breve{\mathbf{u}}'\mathbf{H}'\mathbf{u}'. \tag{12}$$

With the same subluminal restriction a (weak) energy condition holds true.[18–20,11,21] Let l_α be a null vector ($l_0^2 = \vec{l}^2$)). From the Duffin–Kemmer–Petiau relation (8) we first obtain

$$\mathbf{A}'^{i}\mathbf{A}'_n\mathbf{A}'^{j}l_il_j = l_0l_i\mathbf{A}'^{i}, \quad n_k = l_k/l_0$$

from which follows

$$T^{\alpha\beta}l_\alpha l_\beta = l_il_j\breve{\mathbf{u}}\mathbf{A}'^{i}(\mathbf{H}' + \mathbf{A}'_n)\mathbf{A}'^{j}\mathbf{u} \geqslant 0.$$

Now assume T is a (symmetric) tensor. *Hawking–Ellis "dominant energy condition,"*

$$T^{\mu\nu}t_\mu s_\nu \geqslant 0 \tag{13}$$

for all pairs of future-directed timelike vectors follows with the additional restriction

$$T^{00} \geqslant \tfrac{1}{2}\breve{\mathbf{u}}'\mathbf{H}'\mathbf{u}'.$$

The invariant inequality (13) is verified in the rest frame $s_0 = 1$, $s_i = 0$,

$$T^{00}t_0 + T^{0i}t_i = t_0\{T^{00} - \tfrac{1}{2}\breve{\mathbf{u}}'\mathbf{H}'\mathbf{u}' + \tfrac{1}{2}\breve{\mathbf{u}}'(\mathbf{H}' + \mathbf{A}'^{i}t_i/t_0)\mathbf{u}'\} \geqslant 0,$$

and so in any frame. Alternatively $T^{\lambda\nu}s_\lambda$ is not a spacelike vector

$$T_{\mu\nu}s^\mu T^{\lambda\nu}s_\lambda \geqslant 0$$

for

$$T^{0\mu}T_{0\mu} = (T^{00})^2 - \sum (T^{0i})^2 \geqslant 0$$

by (12).

All these conditions are easily checked for the linear Maxwell equations where $\breve{\mathbf{u}}' = \breve{\mathbf{u}} = (\vec{E}, \vec{B})$, i.e., $\mathbf{H}' = \mathbf{I}$. As an illustration with many interesting features consider the scalar field.[7,23] The Lagrangian depends on the derivatives q_α of a single function $q(x^\alpha)$ and the condition for symmetry reads

$$T^{0i} = T^{i0} \Rightarrow q_0\frac{\partial L}{\partial q_i} + q_i\frac{\partial L}{\partial q_0} = 0$$

that implies

$$q_0\left(dL-\frac{\partial L}{\partial q_0}dq_0\right)+\frac{\partial L}{\partial q_0}d\left(\frac{1}{2}\vec{q}^2\right)=0$$

from which follows

$$L=L(Q),\quad Q=\tfrac{1}{2}(q_0^2-\vec{q}^2)=\tfrac{1}{2}\eta^{\alpha\beta}q_\alpha q_\beta,\quad T_{\alpha\beta}=L'(Q)q_\alpha q_\beta-L\,\eta_{\alpha\beta}.$$

As for convexity (9) gives

$$\delta\breve{\mathbf{u}}'\,\delta\mathbf{u}=(L'+q_0^2L'')\,\delta q_0^2+L'\,\delta\vec{q}^2-L''(\vec{q}\,.\,\delta\vec{q})^2>0,$$

which requires

$$L'>0,\quad L'+q_0^2L''>0,\quad L'-\vec{q}^2L''>0\Rightarrow(QL')'>0.$$

IV. CHARACTERISTIC VELOCITIES

Across a wave front $\varphi(x^\alpha)=0$ the second order derivatives of the functions q^r may suffer discontinuities so that by Hadamard condition $[\partial_\beta q^r_\alpha]=\partial_\alpha\varphi\partial_\beta\varphi\delta^2q^r$ and (3) yields

$$\frac{\partial^2L}{\partial q^r_\alpha\partial q^s_\beta}\partial_\alpha\varphi\partial_\beta\varphi\,\delta^2q^r=0 \tag{14}$$

giving the characteristic equation of the wave front

$$\det\left(\frac{\partial^2L}{\partial q^r_\alpha\partial q^s_\beta}\partial_\alpha\varphi\partial_\beta\varphi\right)=0. \tag{15}$$

If we define the normal (to the wave surface) velocity $\lambda(\mathbf{u},\vec{n})\vec{n}$ by $\lambda=-\partial_t\varphi/|\nabla\varphi|$, $n_i=\partial_i\varphi/|\nabla\varphi|$ and substitute in (14) we have

$$\left\{\lambda^2\frac{\partial^2L}{\partial q^r_0\partial q^s_0}-\lambda\left(\frac{\partial^2L}{\partial q^r_i\partial q^s_0}+\frac{\partial^2L}{\partial q^r_0\partial q^s_i}\right)n_i+\frac{\partial^2L}{\partial q^r_i\partial q^s_j}n_in_j\right\}\delta^2q^r=0. \tag{16}$$

The inequality (9) shows that the first matrix, coefficient of λ^2, is positive definite, and the last $(M\times M)$ matrix is negative definite. *Therefore M wave velocities are positive and M are negative and no one can change sign* [$\lambda=0$ *is not solution of* (16)] (for instance D'Alembert equation has velocities $\pm c$). As a consequence translational waves of the form $\lambda=\vec{\Lambda}(\mathbf{u})\cdot\vec{n}$, i.e., with a ray velocity $\vec{\Lambda}$ independent of $\vec{n}$ cannot be found because λ would change sign when the normal varies. It is important to remark that if such a wave exists the system cannot derive from a variational principle (in the sense of this paper). This occurs, for example, in the classical Euler's fluid dynamics where a ray velocity coincides with the fluid velocity (known as contact discontinuity or entropy wave).

Consider now the interesting case of a second order polynomial solution of (15),

$$G^{\alpha\beta}(\mathbf{u})\partial_\alpha\varphi\partial_\beta\varphi=0$$

with $G^{00}>0$. The convexity of $T^0{}_0$ implies that

$$G^{ij}n_in_j<0 \tag{17}$$

since both roots λ must be real and different from zero for every $\vec{n}$.

V. RIEMANN INVARIANTS. EXCEPTIONAL WAVES AND CHARACTERISTIC SHOCKS

In the reduction (7) the first order derivatives of the field may be discontinuous across the wave front. Making the substitution

$$\partial_t \to -\lambda\delta, \quad \partial_i \to n_i\delta$$

shows that $\delta\mathbf{u}'$ is an eigenvector and the normal velocities λ are eigenvalues of $\mathbf{A}'_n/\mathbf{H}'$. Associated with them a complete set of eigenvectors forms a basis in the field space. However zero eigenvalues (with no physical meaning) appear with a $3M$ multiplicity in the first order reduction; the associated disturbances are canceled by the differential constraints

$$\partial_i q^r_j - \partial_j q^r_i = 0, \quad \partial_i q^r = q^r_i.$$

Taking account of a possible multiplicity m^a of λ^a,

$$\begin{gathered}(\mathbf{A}'_n - \lambda^a\mathbf{H}')\mathbf{d}'_A = 0, \quad \lambda^a \neq 0, \quad A = 1,2,3,\ldots,m^a,\\ \mathbf{A}'_n\mathbf{d}'_\omega = 0, \quad \lambda = 0, \quad \omega = 1,2,3,\ldots,3M.\end{gathered} \tag{18}$$

A function $w^a(\mathbf{u}',\vec{n})$ is a Riemann invariant corresponding to a (possibly multiple) λ^a if its gradient with respect to the field $\mathbf{u}'$ is orthogonal to all corresponding eigenvectors,

$$\delta w^a = 0 \Leftrightarrow \boldsymbol{\nabla}' w^a \mathbf{d}'_A \equiv 0, \quad A = 1,2,3,\ldots,m^a.$$

In particular if this is true for λ^a itself,

$$\delta\lambda^a = 0, \tag{19}$$

the wave is said to be *exceptional* or *linearly degenerated* a concept due to Lax.[24] If all the waves are *exceptional* the field is *completely exceptional*.[17] A number of fields in Physics share this property (including, of course, the linear fields) but also in Mathematics: the Monge–Ampère equation,[25,7] the Cayley–Darboux equation.[26]

A shock is a discontinuity $[\mathbf{u}]\equiv\mathbf{u}_1-\mathbf{u}_0$ in the field itself, $\mathbf{u}_0$ is the field ahead of the shock and $\mathbf{u}_1$ the field behind the shock. It satisfies the Rankine–Hugoniot relations

$$[\mathbf{f}^i]n_i - s[\mathbf{u}] = 0.$$

In general the shock speed s differs from the wave velocities. However when a wave is exceptional a shock may exist that moves with this velocity: it is called a *characteristic shock*. Across such a shock a Riemann invariant ($\delta w=0$) is continuous $[w]=0$ so that $s=\lambda^a(\mathbf{u}_0)=\lambda^a(\mathbf{u}_1)$.

If we define the vector $\mathbf{g}^a$ by

$$\mathbf{g}^a(\mathbf{A}'_n - \lambda^a\mathbf{H}') = -\boldsymbol{\nabla}'\lambda^a, \quad \mathbf{g}^a\mathbf{H}'\mathbf{d}'_A = 0, \ A = 1,2,\ldots,m^a \tag{20}$$

we can write the jump of the main field in the explicit form

$$[\mathbf{u}'] = u^A\mathbf{d}'_A(\mathbf{u}'_0,\vec{n}) + w(u^A,\mathbf{u}'_0,\vec{n})\breve{\mathbf{g}}^a(\mathbf{u}'_0,\vec{n}),$$

where the u^A's are m^a parameters corresponding to the multiplicity of λ^a and w is a nonlinear function of the u^A. More precisely for Euler's equations

$$\alpha_0 w^2 - 2w + |u|^2 = 0,$$

where $|u|^2=\Sigma(u^A)^2$ if the eigenvectors are normalized with $\mathbf{H}'$ and α_0 is the value of

$$\alpha = \mathbf{g}^a\mathbf{A}'_n\breve{\mathbf{g}}^a/\lambda^a \tag{21}$$

for $\mathbf{u}'=\mathbf{u}'_0$. Here the jumps of $\mathbf{u}$ and $\mathbf{u}'$ are linearly related. From (7) follows

$$[\mathbf{u}] = \mathbf{A}'_n[\mathbf{u}']/\lambda^a_0 = u^A\mathbf{H}'(\mathbf{u}'_0)\mathbf{d}'_A(\mathbf{u}'_0,\vec{n}) + w\mathbf{A}'_n\breve{\mathbf{g}}^a(\mathbf{u}'_0,\vec{n})/\lambda^a_0$$

and the product of the nonlinear parts (in u^A) of $[\mathbf{u}]$ and $[\mathbf{u}']$ is just $\alpha_0 w^2$. The jump is bounded if $\alpha_0>0$.

If there are only two velocities $\lambda^+>0$, $\lambda^-<0$ of multiplicity M and therefore two shocks each function of M parameters $\mathbf{g}$ can be expanded on the basis of the eigenvectors by (20)

$$\check{\mathbf{g}}^+ = \mathbf{d}'^- + \mathbf{d}'^0,$$

where $\mathbf{d}'^-$, $\mathbf{d}'^0$ are eigenvectors for the eigenvalues λ^- and 0, respectively. As a result (21)

$$\alpha^+ = \mathbf{g}^+ \mathbf{A}'_n \check{\mathbf{g}}^+ / \lambda^+ = (\lambda^-/\lambda^+) \check{\mathbf{d}}'^- \mathbf{H}' \mathbf{d}'^- < 0.$$

The aim of Sec. VII is to evaluate the explicit expression of the characteristic shock and in particular to find the sign of α in nonlinear electrodynamics.

VI. NONLINEAR ELECTRODYNAMICS. BORN–INFELD LAGRANGIAN

After the scalar field we consider the (four-dimensional) vector field where

$$q^r \to \phi_\beta, \quad q^r_\alpha \to \phi_{\beta,\alpha}, \quad L = L(\phi_{\beta,\alpha}).$$

The field equations thus obtained

$$\partial_\alpha L^{\alpha\beta} = 0, \quad L^{\alpha\beta} = \partial L / \partial \phi_{\beta,\alpha}$$

have no tensorial character unless L only depends on the curl

$$F_{\alpha\beta} \doteqdot \phi_{\beta,\alpha} - \phi_{\alpha,\beta}$$

through its invariants

$$Q = \tfrac{1}{4} F_{\alpha\beta} F^{\alpha\beta}, \quad R = \tfrac{1}{4} F_{\alpha\beta} F^{*\alpha\beta},$$

where $F_{\alpha\beta} = \partial_\alpha \phi_\beta - \partial_\beta \phi_\alpha$ is the electromagnetic tensor and $F^{*\alpha\beta} = \eta^{\mu\nu\alpha\beta} F_{\mu\nu}/2$ its dual. This is the starting point of nonlinear electrodynamics a natural generalization of Maxwell theory [where $L(Q,R)$ is a linear function of Q and R]. Because of the electromagnetic tensor skew symmetry the field equations

$$\partial_\alpha L^{\alpha\beta} \equiv \partial_\alpha (L_Q F^{\alpha\beta} + L_R F^{*\alpha\beta}) = 0, \quad \partial_\alpha F^{*\alpha\beta} = 0$$

corresponding to $\beta = 0$ do not contain the time derivative and are called *involutive constraints* in the sense that they are true at any instant if they are satisfied at some time. It is also well known that the divergence free quantity

$$\phi_{\beta,\gamma} L^{\alpha\gamma}$$

is added to transform $-T^\alpha_\beta$ as defined by (4) into the conserved symmetric tensor

$$T^\alpha_\beta = L \delta^\alpha_\beta - L^{\alpha\gamma} F_{\beta\gamma}.$$

The two families of wave surfaces associated with the field equations are given by[11,16]

$$G^{\alpha\beta} \partial_\alpha \varphi \partial_\beta \varphi = 0, \quad G^{\alpha\beta} = \tau^{\alpha\beta} + (\zeta + Q) g^{\alpha\beta},$$

where $\tau^{\alpha\beta} = Q g^{\alpha\beta} - F^{\alpha\rho} F^\beta{}_\rho$ is the usual Maxwell tensor and $\zeta(Q,R)$ takes on two positive values $\zeta_{(1)}, \zeta_{(2)}$.

From (17) one sees that in terms of the electromagnetic field vectors

$$G^{00} = \zeta + B^2 > 0, \quad G^{ij} n_i n_j = E^2 - \zeta - E_n^2 - B_n^2 < 0,$$

which means that

$$E^2 < \min(\zeta_{(1)}, \zeta_{(2)}) \tag{22}$$

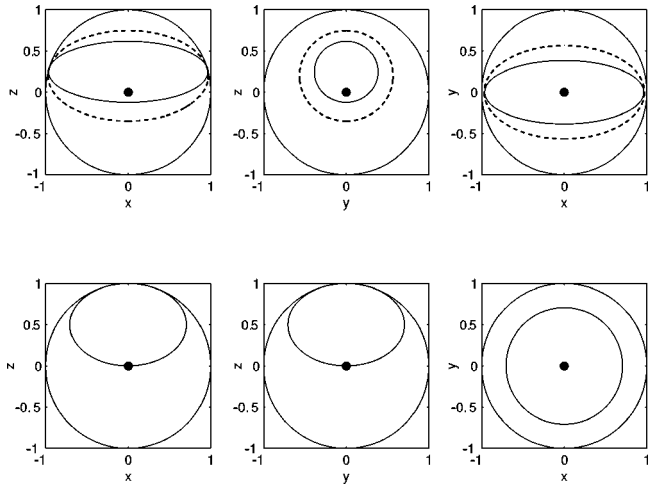

FIG. 1. Sections of the wave surface by the coordinate planes. The ellipsoids corresponding to different values $\zeta_{(1)}$, $\zeta_{(2)}$ of the absolute field are drifted along the z axis, are tangent to each other and to the light sphere in two points (upper left). Below, the limit case ($E^2=\zeta$, $Q=R=0$) of a drift velocity equals to $1/2$. See also Gibbons and Herdeiro (Ref. 11).

is a necessary condition (which turns out to be sufficient) for the *convexity of energy*.[27] The wave front issuing from the origin is no longer a sphere as in Maxwell theory but an ellipsoid drifted along its smallest axis in the direction of the Poynting vector.[16,28] This limitation of the electric field also expresses the fact that the origin stays inside the ellipsoid. Further it ensures the subluminal character of the wave and shock velocities. See Fig. 1 which also shows the limiting case (independent of the nonlinear Lagrangian) corresponding to the ellipsoid

$$x^2 + y^2 + 2(z - \tfrac{1}{2})^2 = \tfrac{1}{2}.$$

Only in the case of the Born–Infeld Lagrangian[13] do both values of ζ coincide with a positive constant k called the *absolute field*, which by (22) is an upper limit to the electric field as in (2),

$$E^2 < k.$$

Thus the Born–Infeld Lagrangian appears as the fundamental one. We consider it as the approximation of a null Planck constant as we shall see in the next section. The wave velocities being double are *exceptional* and both α's are *negative* according to the preceding section.

VII. EXCEPTIONAL LAGRANGIAN WITH SPIN

Here the covariant formulation of (19) that both wave fronts must satisfy is simply[16]

$$\partial_\alpha\varphi\partial_\beta\varphi\delta G^{\alpha\beta} = 0 \Leftrightarrow \delta\zeta = 0,$$

which is obviously true in the case of Born–Infeld since both ζ's are equal to the same constant k. All the Lagrangians yielding field equations that are *completely exceptional* have been determined. The most general one (nonconstant ζ's) has the form

$$L = F(\zeta)f + RG(\zeta) + H(\zeta), \quad f = \sqrt{-R^2 + \zeta(2Q + \zeta)}$$

with $\zeta(Q,R)$ implicitly determined by

$$\partial L/\partial\zeta = O \Rightarrow F' f^2 + (RG' + H')f + (Q + \zeta)F = 0. \tag{23}$$

This function which turns out to be a direct generalization of the Born–Infeld Lagrangian (although it is obtained in a completely different way) must be independent on the choice of $\zeta_{(1)}$ or

$\zeta_{(2)}$ to replace ζ. This condition allows for the determination of the three functions F, G, H. With (say) $\zeta_{(1)}=\zeta$ they read[16]

$$F^2=\frac{1}{s(1+\gamma^2)\zeta^2}\{\gamma^2(k^2-h^2)+2K\gamma\zeta-\zeta^2\}, \tag{24}$$

$$G\zeta=-\gamma H, \quad H^2=\frac{1}{s(1+\gamma^2)}\{h^2-(\zeta-k)^2\}, \tag{25}$$

where

$$2K=k\left(\frac{s+1}{\gamma}+\gamma(s-1)\right).$$

Four constants appear: h may be proportional to the Planck constant since $\zeta\to k$ when $h\to 0$ as can be seen from the expression of H thus giving the Born–Infeld field equations; γ is set equal to $\tan(\theta/2)$ and in the study of the electron field s appears to be equal to $1/2$ and may be associated with the spin.[29] Having solved these equations for $\zeta_{(1)}=\zeta(Q,R;k,h,s,\theta)$ the other value $\zeta_{(2)}$ (and the functions $F_{(2)}$, $G_{(2)}$, $H_{(2)}$ of this variable) immediately follow by the simple change of constants $s\to -s$, $\theta\to\theta+\pi$. For instance $\zeta_{(2)}=\zeta(Q,R;k,h,-s,\theta+\pi)$, $G_{(2)}\zeta_{(2)}=H_{(2)}/\gamma$.

VIII. JUMP OF THE ELECTROMAGNETIC TENSOR

Now let us study the characteristic shocks. Several quantities (Riemann invariants) are continuous across the shock and have already been determined: the scalar ζ and a set of four vectors

$$V^\alpha_{(\gamma)}{:}u^\alpha,\ \frac{e^\alpha}{\sqrt{\zeta}},\ \frac{(Re^\alpha+\zeta b^\alpha)}{f\sqrt{\zeta}},\ \frac{S^\alpha}{f},\ V_{(\mu)\alpha}V^\alpha_{(\nu)}=\eta_{\mu\nu}$$

containing the electric, magnetic fields, and the Poynting vector

$$e_\alpha=F_{\rho\alpha}u^\rho, \quad b_\alpha=F^*_{\rho\alpha}u^\rho, \quad S^\alpha=\eta^{\alpha\beta\gamma\delta}e_\beta b_\gamma u_\delta$$

in the frame of the ray velocity $u^\alpha\propto\{\tau^{\alpha\beta}+(\zeta+Q)g^{\alpha\beta}\}\partial_\beta\varphi$.[16] In terms of these vectors we can write

$$F_{\alpha\beta}=\sqrt{\zeta}a_{\alpha\beta}-\frac{fb^*_{\alpha\beta}}{\sqrt{\zeta}}+\frac{Ra^*_{\alpha\beta}}{\sqrt{\zeta}}, \quad F^*_{\alpha\beta}=\sqrt{\zeta}a^*_{\alpha\beta}+\frac{fb_{\alpha\beta}}{\sqrt{\zeta}}-\frac{Ra_{\alpha\beta}}{\sqrt{\zeta}},$$

where

$$a^{\alpha\beta}=V^\alpha_{(0)}V^\beta_{(1)}-V^\beta_{(0)}V^\alpha_{(1)}, \quad b^{\alpha\beta}=V^\alpha_{(0)}V^\beta_{(2)}-V^\beta_{(0)}V^\alpha_{(2)},$$

$$a^{*\alpha\beta}=V^\alpha_{(2)}V^\beta_{(3)}-V^\beta_{(2)}V^\alpha_{(3)}, \quad b^{*\alpha\beta}=V^\alpha_{(3)}V^\beta_{(1)}-V^\beta_{(3)}V^\alpha_{(1)},$$

$a^{**}_{\alpha\beta}=-a_{\alpha\beta}$, etc.

The jump follows easily

$$\sqrt{\zeta}[F_{\alpha\beta}]=[R]a^*_{\alpha\beta}-[f]b^*_{\alpha\beta}. \tag{26}$$

It can be observed that a jump of the electromagnetic field is generated by a first order discontinuity of the potential vector so that

$$[F_{\alpha\beta}]=\Phi_\beta\partial_\alpha\varphi-\Phi_\alpha\partial_\beta\varphi,$$

which is just the structure of the preceding expression since $\partial_\alpha\varphi\propto S_\alpha\propto V_{(3)\alpha}$.[16]

Since each shock velocity is single the jump must depend on a single parameter. To find the link between $[R]$ and $[f]$ we eliminate $Q+\zeta$ between

$$2\zeta(Q+\zeta) = f^2 + R^2 + \zeta^2$$

and (23) obtaining

$$\left(\frac{F\zeta}{f} + H'\right)^2 + \left(\frac{FR}{f} + G'\zeta\right)^2 = \rho^2(\zeta)$$

with

$$\rho^2(\zeta) = \zeta^2 G'^2 + H'^2 - F(F + 2\zeta F').$$

From (24) and (25) we get

$$\zeta(G^2 + F^2) = -\frac{\zeta}{s} + k\frac{1+s}{s}$$

and substituting

$$(\zeta F^2)' = -\frac{1}{s} - (\zeta G^2)'$$

in the preceding equation we obtain

$$\rho^2 = \frac{1}{s} + (\zeta G)'^2 + H'^2 = \frac{1}{s} + (1+\gamma^2)H'^2 = \frac{h^2}{s^2(1+\gamma^2)H^2}.$$

We introduce the shock parameter ω through

$$\frac{F\zeta}{f} + H' = \rho \sin\omega, \quad \frac{FR}{f} + G'\zeta = \rho\cos\omega.$$

But ζ is continuous across the shock $(\zeta_1 = \zeta_0)$ and therefore the values of f and R behind the shock front

$$f_1 = \frac{F_0\zeta_0}{\rho_0 \sin\omega - H_0'}, \quad R_1 = \zeta_0\frac{\rho_0\cos\omega - G_0'\zeta_0}{\rho_0\sin\omega - H_0'},$$

determine by (26) the jump $[F_{\alpha\beta}]$ of the electromagnetic field which is certainly bounded if $|H_0'/\rho_0| > 1$. To each value of ζ correspond two shocks with different ray velocities. From (25) we have

$$\left(\frac{H_{(1)}'}{\rho_{(1)}}\right)^2 = \frac{(\zeta_{(1)} - k)^2}{h^2(1+\gamma^2)} < 1$$

for $\zeta = \zeta_{(1)}$ which shows that the jump of the field can reach large values. For the other family of shocks, i.e., for $\zeta_{(2)}$ the different functions F, G, H are obtained with the mentioned substitution $s \to -s$, $\gamma \to -1/\gamma$ which gives

$$\left(\frac{H_{(2)}'}{\rho_{(2)}}\right)^2 = \frac{(\zeta_{(2)} - k)^2\gamma^2}{h^2(1+\gamma^2)},$$

a quantity that may or may not be smaller than 1. In fact for the spherically symmetric solution[29]

$$\zeta_{(2)} = k + h\frac{\phi + s}{\sqrt{s^2 + \phi^2 + 2s\phi\cos\theta}}, \qquad \phi = \frac{r^4}{r_0^4 + r^4},$$

$$\left|\frac{H'_{(2)}}{\rho_{(2)}}\right| = \frac{\sin\dfrac{\theta}{2}}{\sqrt{1 - \dfrac{4s\phi}{(\phi + s)^2}\sin^2\dfrac{\theta}{2}}},$$

where $s = 1/2$. When r varies from 0 to infinity this quantity has a minimum, $\sin(\theta/2)$, for $r = 0$ and a maximum, $\tan(\theta/2)$, for $r = r_o$. Hence it is less than 1 for all r only if $\theta < \pi/2$.

On the initial boundary value problem for a shallow water equation

Shixiang Ma[a] and Shijin Ding[b]
Department of Mathematics, South-China Normal University, Guangzhou, 510631, China

(Received 19 March 2004; accepted 26 April 2004;
published online 5 August 2004)

In this paper, we obtain the existence and uniqueness of the local strong solutions to the initial boundary problem for a one-dimensional shallow-water equation (Camassa–Holm equation) on the half-space $\{x>0\}$ with initial data $u_o \in H^2(R^+)\cap H_0^1(R^+)$. The solution is obtained as a limit of the solutions for a class of approximation problems. We also establish the global result of the corresponding solution, provided that the initial data u_0 satisfies certain positivity condition. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1765216]

I. INTRODUCTION

In this paper we consider the existence and uniqueness of strong solutions to the initial boundary value problem for the following one-dimensional shallow-water equation on the half-space $\{x>0\}$:

$$\begin{cases} \partial_t u + u\partial_x u + \partial_x p = 0, & t>0, x>0, \\ p(t,x) = \displaystyle\int_0^\infty h(x,y)\left(u^2 + \frac{1}{2}(\partial_x u)^2\right)(t,y)\,dy, & t>0, x>0, \end{cases} \tag{1.1}$$

where

$$h(x,y) = \begin{cases} e^{-x}shy, & y\leqslant x, \\ e^{-y}shx, & y>x, \end{cases}$$

with the initial data

$$u(0,x) = u_0(x), \quad x>0, \tag{1.2}$$

and boundary value

$$u(t,0) = 0, \quad t>0, \tag{1.3}$$

which is formally equivalent to the initial boundary value problem for the Camassa–Holm equation[1] (simply denoted by C–H equation),

$$\partial_t u - \partial_t \partial_{xx} u + 3u\partial_x u = 2\partial_x u \partial_{xx} u + u\partial_{xxx} u. \tag{1.1'}$$

Here u denotes the fluid velocity at time t in the x direction (or, equivalently, the height of the water's free surface above a flat bottom).

[a]Electronic mail: wanghg@scnu.edu.cn
[b]Electronic mail: dingsj@scnu.edu.cn

Equation (1.1) is derived physically by Camassa and Holm who used an asymptotic expansion directly in the Hamiltonian for Euler's equations in the shallow-water regime.[2] Equation (1.1) also proved to be formally integrable by Fuchssteiner and Fokas as a bi-Hamiltonian generalization of KDV.[3]

Many special features make (1.1) an important equation in the shallow-water regime. Besides the bi-Hamiltonian structure and the formal integrability, Camassa and Holm discovered that the solitary waves have a discontinuity in the first derivative at their peak and that soliton interactions occur for (1.1). In fact, physical water waves often break down, which cannot be predicted by the solutions for the KDV equation.[4] So Eq. (1.1) is the first model that is completely integrable and yet exhibits the remarkable finite-time breakdown phenomena as commented upon by Constantin and Escher.[5] Equation (1.1) possesses an infinite number of conservation laws due to its bi-Hamiltonian structure, but, unlike KDV, the global existence of regular solutions is guaranteed for only a special class of initial data, and the $H^k(R)$ norm is preserved for smooth solutions to (1.1) only for $k=1$. Indeed, it has been observed that finite-time breakdown of smooth solutions always occurs for a large class of initial data.[2,5,10]

Recently, after Camassa and Holm established that Eq. (1.1) also has physical meaning, numerous papers were devoted to its study. For example, Hongjun Gao *et al.* proved the local existence and property of blow-up to the initial boundary value problem of (1.1′) with initial data $u_0 \in \mathcal{B}=\{u \in H^4(0,1): u(0)=u_{xx}(0)=u(1)=u_{xx}(1)=0\}$;[17] Constantin *et al.* made sequential researches on the C–H equation, such as the well posedness, spectral problem, and inverse spectral problem, etc. (Refs. 5–9 and 11–14); Blanco established the well posedness to the Cauchy problem associated with (1.1′) with the initial data $u_0 \in H^s(R), s>\frac{3}{2}$;[22] and Zhouping Xin *et al.* obtained the existence and uniqueness of the weak solution to the Cauchy problem of (1.1′) with initial $u_0 \in H^1(R)$.[15,16] But, it is worthwhile to note that despite an abundance of literature on the C–H equation, the initial boundary value problem on the half-space $\{x>0\}$ hardly seems to have been treated except for Yang Ling'e and Guo Boling who proved the well-posedness of classical solutions to (1.1)–(1.3) with the intial data $u_0 \in H^3(R^+) \cap H_0^1(R^+)$.[23] Natural questions arise: Can a strong solution to the initial boundary value problem on the half-space $\{x>0\}$ exist? Is it local or global in time if it does? Is it unique? How about a weak solution? The aim of this paper is to prove the existence and uniqueness of the local solutions for (1.1)–(1.3) with initial data $u_0 \in H^2(R^+) \cap H_0^1(R^+)$, and to analyze the global existence and blow-up phenomena.

Before giving the precise statements of the main results, we first introduce the definition of a strong solution to the initial boundary value problem (1.1)–(1.3).

Definition: A function $u=u(t,x)$ is said to be a strong solution to the initial boundary value problem (1.1)–(1.3) if $u \in L^\infty(0,T;H^2(R^+) \cap H_0^1(R^+))$, $\partial_t u \in L^\infty(0,T;H_0^1(R^+))$, and

$$\partial_t u + u\partial_x u + \partial_x p = 0 \quad a.e.[0,T)\times R^+, \quad u(0,x)=u_0(x) \quad a.e.R^+.$$

If T is an arbitrarily given positive constant, u is said to exist globally in time.

The main results of this paper can be stated as follows:

(1) Local existence and uniqueness: Given $u_0 \in H^2(R^+) \cap H_0^1(R^+)$, there exists a $T^*>0$ depending only on $\|u_0\|_{H^2(R^+)}$ and a unique strong solution to problems (1.1)–(1.3)
$$u=u(t,x) \in C([0,T^*];H^2(R^+) \cap H_0^1(R^+)) \cap C^1([0,T^*];H_0^1(R^+)).$$
(2) Global existence and uniqueness: Suppose that $u_0 \in H^2(R^+) \cap H_0^1(R^+)$, with $V_0=(1-\partial_{xx})u_0 \geqslant 0$. Then the unique strong solution $u(t,x)$ to problems (1.1)–(1.3) exist globally in time.
(3) Blow-up: Let $u_0 \in H^2(R^+) \cap H_0^1(R^+)$, with $\partial_x u(\overline{x}) \leqslant -\sqrt{2}\|u_0\|_{H^1(R^+)}$ for some $\overline{x} \in R^+$. Then the strong solution to problems (1.1)–(1.3) blows-up in finite time.

Remark 1: The major difficulty of this work is that the domain of the problem we considered is $\{(t,x): x \in R^+\}$ and the regularity of the initial data is not good enough so that we cannot directly apply Kato's Theorem to prove the existence of the strong solution to problems (1.1)–(1.3) as in Refs. 22, 23. We prove the main results by an approximation method. We expect that

the strong solution to problems (1.1)–(1.3) can be obtained as a strong limit in $C([0,T^*];H^2(R^+)\cap H_0^1(R^+))$ of the approximations, $u^n=u^n(t,x)$, which solves the following approximation problem:

$$\begin{cases} \partial_t u^n + u^n \partial_x u^n + \partial_x p^n = 0, & t>0, x>0, \\ p^n(t,x) = \displaystyle\int_0^\infty h(x,y)\left((u^n)^2 + \frac{1}{2}(\partial_x u^n)^2 \right)(t,y)\,dy, & t>0, x>0, \\ u^n(0,x) = u_0^n(x), & x>0, \\ u^n(t,0) = 0, & t>0, \end{cases} \tag{1.4}$$

where $u_0^n \in \mathcal{B}=\{u\in H^4(R^+)\,|\,u(0)=\partial_{xx}u(0)=0\}$ is an approximation of u_0, i.e.,

$$u_0^n \to u_0, \quad \text{as} \quad n\to\infty \quad \text{in} \quad H^2(R^+)\cap H_0^1(R^+).$$

II. THE LOCAL SOLUTION FOR AN APPROXIMATION PROBLEM

In this section, we construct the approximate solution sequence $u^n=u^n(t,x)$ as solutions to the problem (1.4). The existence and uniqueness on this approximate solution sequence are given in the following theorem. For convenience we will omit the supscript n in $u^n(t,x)$ in this section.

Theorem 1: *Given $u_0\in\mathcal{B}$, there exists a maximal $T>0$ depending only on $\|u_0\|_{H^4(R^+)}$ and a unique strong solution to (1.4) such that*

$$u=u(t,x)\in C([0,T);\mathcal{B})\cap C^1([0,T);H^2(R^+)\cap H_0^1(R^+)).$$

We reformulate (1.4) as the following initial boundary value problem:

$$\begin{cases} m=(1-\partial_{xx})u, & x>0, t>0, \\ \partial_t m + u\partial_x m = -2m\partial_x u, & t>0, x>0, \\ m(0,x)=m_0(x)=(1-\partial_{xx})u_0, & x>0, \end{cases} \tag{2.1}$$

where $u_0\in\mathcal{B}$, and $m_0\in H^2(R^+)\cap H_0^1(R^+)$.

The new form is suitable to be analyzed with Kato's method for abstract quasilinear evolution equations of the hyperbolic type. For complement we state here Kato's Theorem[18] in the form appropriate for our purposes.

Consider the Cauchy problem for the abstract quasilinear evolution equation

$$\begin{cases} \dfrac{dv}{dt} + A(v)v = f(v), & t>0, \\ v(0)=v_0. \end{cases} \tag{Q}$$

Assume that:

(X) X,Y are reflexive Banach spaces, where $Y\hookrightarrow X$ continuously and densely, and there is an isomorphism S from Y onto X such that $\|\phi\|_Y=\|S\phi\|_X$, for all $\phi\in Y$. Let $W\subset Y$ be an open ball centered at 0 and with radius r.

(i) For each $y\in W$, the linear operator $A(y)$ belongs to $G(X,1,\beta)$ where β is a real number, i.e., $-A(y)$ generates a C_0 semigroup such that
$$\|e^{-tA(y)}\|\leqslant e^{\beta t}, \quad t\geqslant 0.$$

(ii) $Y\subset D(A(y))$ for each $y\in W$ (so that $A(y)|_Y\in\mathcal{B}(Y,X)$) satisfies the following Lipschitz condition:
$$\|A(y)-A(z)\|_{\mathcal{B}(Y,X)}\leqslant \mu_1\|y-z\|_X,$$
for all $y,z\in Y$.

(iii) For each $y \in W$, one has

$$SA(y)S^{-1}=A(y)+B(y),$$
$$B(y)\in\mathcal{B}(X), \quad \|B(y)\|_X\leqslant\lambda_1.$$

(iv) The function $f:W\to Y$ is bounded, i.e., there is a constant $\lambda_2>0$ such that

$$\|f(y)\|_Y\leqslant\lambda_2,$$

for all $y\in W$. The function $y\in X\to f(y)$ is Lipschitz-continuous in X, i.e.,

$$\|f(y)-f(z)\|_X\leqslant\mu_2\|y-z\|_X,$$

for all $y,z\in X$.

Here λ_1,λ_2 depend only on r; and, μ_1 and μ_2 depend only on $\max\{\|y\|_Y,\|z\|_Y\}$ and $\max\{\|y\|_X,\|z\|_X\}$, respectively.

Kato's Theorem: *Assume that* (X) *and* (i)–(iv) *hold. Given* $v_0\in Y$, *there exists a maximal* $T>0$ *depending only on* $\|v_0\|_Y$ *and a unique solution to* (Q) *such that*

$$v=v(t,x)\in C([0,T);Y)\cap C^1([0,T);X).$$

We apply Kato's Theorem to prove the following lemma.

Lemma 1: For $m_0\in H^2(R^+)\cap H_0^1(R^+)$, *there exists a maximal* $T>0$ *depending only on* $\|m_0\|_{H^2(R^+)}$ *and a unique solution to (2.1) such that*

$$m=m(t,x)\in C([0,T);H^2(R^+)\cap H_0^1(R^+))\cap C^1([0,T),L^2(R^+)).$$

Proof: Let $X=L^2(R^+), Y=H^2(R^+)\cap H_0^1(R^+), W=\{y\in Y:\|y\|_Y\leqslant r\}$ and $S=1-\partial_{xx}$. Clearly the embedding $Y\hookrightarrow X$ is continuous and dense. Moreover, $S:Y\to X$ is an isometric isomorphism. In fact, $\forall f\in L^2(R^+)$, the well-known existence theorem of weak solution and regularity for boundary problem of elliptic equation implies that the boundary value problem

$$\begin{cases} v-\partial_{xx}v=f, \\ v(0)=v(+\infty)=0, \end{cases}$$

has a unique solution

$$v(t,x)=\int_0^{+\infty}h(x,y)f(t,y)dy$$

in $H^2(R^+)\cap H_0^+(R^+)$, where $h(x,y)=\begin{cases} e^{-x}shy, & y\leqslant x, \\ e^{-y}shx, & y>x. \end{cases}$

Rewrite problem (2.1) into an abstract form

$$\begin{cases} \dfrac{dm}{dt}+A(m)m=f(m), \quad t>0 \\ m(0)=m_0, \end{cases}$$

where $A(m)=(S^{-1}m)\partial_x$, $f(m)=-2m\partial_x(S^{-1}m)$.

To prove Lemma 1, it suffices to verify conditions (i)–(iv) of Kato's Theorem.

Step 1: Let $v=S^{-1}m\in H^2(R^+)\cap H_0^1(R^+)$, $\overline{A}=v\partial_x=A(m)$, and $A_0=\overline{A}+\frac{1}{2}\partial_x vI$. We show that the operator iA_0 is self-adjoint, i.e., $A_0^*=-A_0$. In fact,

$$D(A(m))=\{u\in X:(S^{-1}m)\partial_x u\in X\},$$

$$D(A_0)=D(\overline{A})=\{u\in X:v\partial_x u\in X\},$$

$$D(A_0^*)=\{w\in X: A_0^*w\in X\}$$
$$=\{w\in X: \text{there exists a } M_w>0,$$
$$\text{such that } |(w,A_0u)_X|\leqslant M_w\|u\|_X, \text{ for all } u\in D(A_0)\}.$$

Fix $w\in D(A_0^*)$ $\forall\phi\in\mathcal{D}(R^+)$, we deduce that $v\partial_x w\in X$:

$$(\phi,A_0^*w)_X=(A_0\phi,w)_X=\int_0^\infty (v\partial_x\phi+\tfrac{1}{2}\phi\partial_x v)w\,dx$$
$$=-\int_0^\infty (\phi\partial_x(vw)-\tfrac{1}{2}\phi w\partial_x v)dx$$
$$=-\int_0^\infty \phi(v\partial_x w+\tfrac{1}{2}w\partial_x v)dx$$
$$=-(\phi,v\partial_x w+\tfrac{1}{2}w\partial_x v)_X.$$

Since $\mathcal{D}(R^+)$ is dense in $D(A_o)$, the above formula holds for all $\phi\in D(A_0)$. Hence $-(v\partial_x w+\frac{1}{2}w\partial_x v)=A_0^*w\in X$. This implies $v\partial_x w\in X$. Thus $w\in D(A_0)$ and $A_0w=-A_0^*w$. This proves that $A_0^*\subset -A_0$.

Conversely, fix $u\in D(A_0)$ and let $u^n=\rho_n * u$, where ρ_n is the usual mollifiers on R^+. It follows from the proof of (2.3) in Ref. 6 that

$$\lim_{n\to\infty}\overline{A}(u_n)=\overline{A}(u) \text{ in } L^2(R^+).$$

Then

$$(A_0z,u)_X=\lim_{n\to\infty}(A_0z,u_n)_X=\lim_{n\to\infty}\int_0^\infty (v\partial_x z+\tfrac{1}{2}z\partial_x v)u_n=-\lim_{n\to\infty}\int_0^\infty (z\partial_x(vu_n)-\tfrac{1}{2}u_nz\partial_x v)$$
$$=-\int_0^\infty z(v\partial_x u+\tfrac{1}{2}u\partial_x v)$$
$$=-(z,A_0u).$$

Thus $u\in D(A_0^*)$ and $A_0^*u=-A_0u$. This proves that $-A_0\subset A_0^*$.

Hence $A_0^*=-A_0$, that is, iA_0 is self-adjoint in X. Stone theorem[19] implies that A_0 is the infinitesimal generator of a C_0 group unitary operators on X, and so $-A_0$ is the infinitesimal generator of a C_0 semigroup of contraction on X. In addition, $\|(A_0-A(m))w\|_X=\|\frac{1}{2}w\partial_x(S^{-1}m)\|_X\leqslant\frac{1}{2}\sup_{x\in R^+}|\partial_x(S^{-1}m)|\|w\|_X=\omega\|w\|_X$. If $\omega<\infty$, it follows from the theorem 3.1.1 in Ref. 19 that $-A(m)=(A_0-A(m))+(-A_0)$ is the infinitesimal generator of a C_0 semigroup and $\|e^{-tA(m)}\|\leqslant e^{\omega t}$.

Next, we need to estimate $\sup_{x\in R^+}|\partial_x(S^{-1}m)|$. Since $v=S^{-1}m\in H^2(R^+)\cap H_0^1(R^+)$ solves the equation $v-v_{xx}v=m$, we have

$$\int_0^\infty (v^2-2v\partial_{xx}v+(\partial_{xx}v)^2)dx=\int_0^\infty m^2(x)dx,$$

$$2\int_0^\infty v\partial_{xx}v\,dx=-\int_0^\infty (\partial_x v)^2dx.$$

Hence

$$\int_0^\infty (v^2+2(\partial_x v)^2+(\partial_{xx}v)^2)dx=\int_0^\infty m^2(x)dx,$$

and so

$$\|v\|^2_{H^2(R^+)}+\|\partial_x v\|^2_{L^2(R^+)}=\|m\|^2_{L^2(R^+)},$$

that is,

$$\|S^{-1}m\|^2_{H^2(R^+)}+\|\partial_x(S^{-1}m)\|^2_{L^2(R^+)}=\|m\|^2_{L^2(R^+)}, \tag{2.2}$$

it follows that

$$(\partial_x(S^{-1}m))^2(x)-(\partial_x(S^{-1}m)(0))^2=2\int_0^x \partial_x(S^{-1}m)\partial_{xx}(S^{-1}m)dx\leqslant\|S^{-1}m\|^2_{H^2(R^+)}\leqslant\|m\|^2_{L^2(R^+)},$$

$$|\partial_x(S^{-1}m)(0)|=\left|\int_0^\infty e^{-y}m(y)dy\right|\leqslant\|m\|_{L^2(R^+)}\|e^{-y}\|_{L^2(R^+)}=\frac{1}{\sqrt{2}}\|m\|_{L^2(R^+)},$$

and so $\forall x\in R^+$, $(\partial_x(S^{-1}m))^2(x)\leqslant\frac{3}{2}\|m\|^2_{L^2(R^+)}$,

$$\sup_{x\in R^+}|\partial_x(S^{-1}m|\leqslant\sqrt{3/2}\|m\|_{L^2(R^+)}. \tag{2.3}$$

Consequently,

$$\omega=\frac{1}{2}\sup_{x\in R^+}|\partial_x(S^{-1}m)|\leqslant\|m\|_{L^2(R^+)}\leqslant\|m\|_Y\leqslant r.$$

So the condition (i) of Kato's Theorem is verified with constant $\beta=r$.

Step 2: To check condition (ii) of Kato's Theorem.

$\forall m_1,m_2,w\in Y$,

$$\|(A(m_1)-A(m_2))w\|_X=\|(S^{-1}m_1-S^{-1}m_2)\partial_x w\|_X\leqslant\|S^{-1}(m_1-m_2)\|_{L^\infty(R^+)}\|\partial_x w\|_X$$
$$\leqslant\|m_1-m_2\|_X\|w\|_Y, \tag{2.4}$$

due to the fact that

$$(S^{-1}m)^2(x)=2\int_0^x S^{-1}m\partial_x(S^{-1}m)dy\leqslant\|S^{-1}m\|^2_{H^1(R^+)}\leqslant\|S^{-1}m\|^2_{H^2(R^+)}\leqslant\|m\|^2_{L^2(R^+)}.$$

So $\|A(m_1)-A(m_2)\|_{\mathcal{B}(Y,X)}\leqslant\|m_1-m_2\|_X$.

$\forall m\in W\subset Y$, let $m_1=m,m_2=0$ in (2.4), we have

$$\|A(m)w\|_X\leqslant\|m\|_X\|w\|_Y\leqslant r\|w\|_Y.$$

Thus $A(m)|_Y\in\mathcal{B}(Y,X)$.

Step 3: Now we check condition (iii) of Kato's Theorem.

$\forall m\in W,w\in Y$, by direct computation we obtain

$$
\begin{aligned}
SA(m)S^{-1}w &= S(S^{-1}m\partial_x(S^{-1}w)) \\
&= S^{-1}m\partial_x(S^{-1}w) - \partial_{xx}(S^{-1}m\partial_x(S^{-1}w)) \\
&= S^{-1}m\partial_x(S^{-1}w) - [\partial_{xx}(S^{-1}m)\partial_x(S^{-1}w) \\
&\quad + 2\partial_x(S^{-1}m)\partial_{xx}(S^{-1}w) + S^{-1}m\partial_{xxx}(S^{-1}w)] \\
&= S^{-1}m\partial_x(S^{-1}w) - [(S^{-1}m - m)\partial_x(S^{-1}w) \\
&\quad + 2\partial_x(S^{-1}m)(S^{-1}w - w) + S^{-1}m(\partial_x(S^{-1}w) - \partial_x w)] \\
&= m\partial_x(S^{-1}w) - 2\partial_x(S^{-1}m)(S^{-1}w - w) - S^{-1}m\partial_x(S^{-1}w) + (S^{-1}m)\partial_x w \\
&= (m - S^{-1}m)\partial_x(S^{-1}w) + 2\partial_x(S^{-1}m)(w - S^{-1}w) + A(m)w.
\end{aligned}
$$

Hence

$$
SA(m)S^{-1} = (m - S^{-1}m)\partial_x S^{-1} + 2\partial_x(S^{-1}m)(1 - S^{-1}) + A(m).
$$

Let $B(m) = (m - S^{-1}m)\partial_x S^{-1} + 2\partial_x(S^{-1}m)(1 - S^{-1})$, so that

$$
SA(m)S^{-1} = A(m) + B(m),
$$

and $B(m)$ can be extended to an operator in X. Next we show that $B(m) \in \mathcal{B}(X)$.

$\forall w \in X$,

$$
\begin{aligned}
\|B(m)w\|_X &= \|(m - S^{-1}m)\partial_x(S^{-1}w) + 2\partial_x(S^{-1}m)(w - S^{-1}w)\|_X \\
&\leqslant \|m - S^{-1}m\|_X \|\partial_x(S^{-1}w)\|_{L^\infty(R^+)} + 2\|\partial_x(S^{-1}m)\|_{L^\infty(R^+)} \|w - S^{-1}w\|_X \\
&\leqslant \sqrt{3/2}\|m\|_X \|w\|_X + 2\sqrt{3/2}\|m\|_X \|w\|_X \\
&\leqslant 6\|m\|_X \|w\|_X \\
&\leqslant 6\|m\|_Y \|w\|_X \\
&\leqslant \lambda_1 \|w\|_X,
\end{aligned}
$$

due to (2.2)–(2.3) and the fact that $m - S^{-1}m = -\partial_{xx}(S^{-1}m)$, where $\lambda_1 = 6r$. So $B(m) \in \mathcal{B}(X)$ and $\|B(m)\|_{\mathcal{B}(X)} \leqslant \lambda_1$.

Step 4: Finally we check condition (iv) of Kato's Theorem.

$\forall m \in W$, it follows from (2.3) that

$$
\begin{aligned}
\|f(m)\|_Y = 2\|m\partial_x(S^{-1}m)\|_Y &\leqslant 2\|\partial_x(S^{-1}m)\|_{L^\infty(R^+)} \|m\|_Y \\
&\leqslant 2\sqrt{3/2}\|m\|_X \|m\|_Y \leqslant 4\|m\|_Y^2 \leqslant \lambda_2,
\end{aligned}
$$

where $\lambda_2 = 4r^2$,

$\forall m_1, m_2 \in X$,

$$
\begin{aligned}
\|f(m_1) - f(m_2)\|_X &= 2\|m_1\partial_x(S^{-1}m_1) - m_2\partial_x(S^{-1}m_2)\|_X \\
&\leqslant 2\|\partial_x(S^{-1}m_1)\|_{L^\infty(R^+)} \|m_1 - m_2\|_X + 2\|m_2\|_X \|\partial_x(S^{-1}(m_1 - m_2))\|_{L^\infty(R^+)} \\
&\leqslant 2\sqrt{3/2}\|m_1\|_X \|m_1 - m_2\|_X + 2\sqrt{3/2}\|m_2\|_X \|m_1 - m_2\|_X \\
&\leqslant 4(\|m_1\|_X + \|m_2\|_X)\|m_1 - m_2\|_X \\
&\leqslant \mu_2 \|m_1 - m_2\|_X,
\end{aligned}
$$

where $\mu_2 = 8\max\{\|m_1\|_X, \|m_2\|_X\}$.

By Kato's Theorem, the proof of Lemma 1 is completed.

The proof of Theorem 1: Since $S:\mathcal{B}\to Y$ is bijective, $\forall m(t,\cdot)\in Y=H^2(R^+)\cap H_0^1(R^+)$, we can solve $u\in\mathcal{B}$ from $Su=m$ uniquely

$$u(t,x)=\int_0^\infty h(x,y)m(t,y)dy$$

$$=e^{-x}/2\int_0^x e^y m(t,y)dy+e^x/2\int_x^\infty e^{-y}m(t,y)dy-e^{-x}/2\int_0^\infty e^{-y}m(t,y)dy.$$

Consequently the result follows from this and Lemma 1.

III. THE EXISTENCE AND UNIQUENESS OF LOCAL SOLUTIONS TO PROBLEMS (1.1)–(1.3)

In this section, we consider the existence and uniqueness of the local solution to problems (1.1)–(1.3), i.e.,

$$\begin{cases} \partial_t u+u\partial_x u+\partial_x p=0, & t>0,x>0,\\ p(t,x)=\displaystyle\int_0^\infty h(x,y)\left(u^2+\frac{1}{2}(\partial_x u)\right)^2(t,y)dy, & t>0,x>0,\\ u(0,x)=u_0(x), & x>0,\\ u(t,0)=0, & t>0, \end{cases} \tag{3.1}$$

where

$$h(x,y)=\begin{cases} e^{-x}shy, & y\leqslant x,\\ e^{-y}shx, & y>x, \end{cases}$$

with $u_0\in H^2(R^+)\cap H_0^1(R^+)$. First we introduce some lemmas as follows.

Lemma 2 (Ref. 20, Lemma 4(ii)): Let $X\subset E\subset Y$ be Banach spaces, the imbedding $X\hookrightarrow E$ being compact. Then the following imbedding is compact:

$$L^\infty(0,T;X)\cap\left\{\phi:\frac{\partial\phi}{\partial t}\in L^r(0,T;Y)\right\}\hookrightarrow C([0,T];E),1<r\leqslant\infty.$$

Lemma 3 (Ref. 21, Lemma 1.4): Let X and Y be two Banach spaces such that $X\hookrightarrow Y$ with a continuous injection. If a function ϕ belongs to $L^\infty(0,T;X)$ and is weakly continuous with values in Y, then ϕ is weakly continuous with values in X.

Lemma 4 (Ref. 20, Lemma 6): Let $g\in W^{1,1}(0,T)$ and $k\in L^1(0,T)$ satisfy

$$\frac{dg}{dt}\leqslant F(g)+k,\quad \forall t\in(0,T),$$

$$g(0)\leqslant g_0,$$

where F is bounded on bounded sets from R into R, that is

$$\forall a>0,\exists A>0\quad \text{such that } |x|\leqslant a\Rightarrow|F(x)|\leqslant A.$$

Then for every $\epsilon>0$, there exists $T_\epsilon>0$ independent of g such that

$$g(t)\leqslant g_0+\epsilon,\quad \forall t\leqslant T_\epsilon.$$

Theorem 2: *Given* $u_0 \in H^2(R^+) \cap H_0^1(R^+)$, *there exists a* $T^* > 0$ *depending only on* $\|u_0\|_{H^2(R^+)}$ *and a unique solution to (3.1)*

$$u = u(t,x) \in C([0,T^*];H^2(R^+) \cap H_0^1(R^+)) \cap C^1([0,T^*];H_0^1(R^+)).$$

Proof: We begin with the proof of existence.

Since $\mathcal{B} = \{u \in H^4(R^+) | u(0) = \partial_{xx} u(0) = 0\}$ is dense in $H^2(R^+) \cap H_0^1(R^+)$, there exists a sequence $\{u_0^n\} \subset \mathcal{B}$ such that

$$u_0^n \to u_0 \quad \text{in} \quad H^2(R^+) \cap H_0^1(R^+) \quad \text{and} \quad \|u_0^n\|_{H^2(R^+)} \leqslant \|u_0\|_{H^2(R^+)}. \tag{3.2}$$

It follows from Theorem 1 that there exists a unique solution $u^n(t,x) \in C([0,T^n);\mathcal{B}) \cap C^1([0,T^n);H^2(R^+) \cap H_0^1(R^+))$ to problem (1.4), i.e.,

$$\begin{cases} \partial_t u^n + u^n \partial_x u^n + \partial_x p^n = 0, & t > 0, x > 0, \quad (3.3) \\ p^n(t,x) = \displaystyle\int_0^\infty h(x,y) \left((u^n)^2 + \frac{1}{2} (\partial_x u^n)^2 \right)(t,y)\, dy, & t > 0, x > 0, \quad (3.4) \\ u^n(0,x) = u_0^n(x), & x > 0, \quad (3.5) \\ u^n(t,0) = 0, & t > 0, \quad (3.6) \end{cases}$$

where T^n is the life span of the solution $u^n(t,x)$ in $C([0,T^n);\mathcal{B})$, then

$$\lim_{t \to T^n} \|u^n(t,\cdot)\|_{H^4(R^+)} = +\infty.$$

It follows from the proof of (2.4) in Ref. 15 that this holds if and only if

$$\lim_{t \to T^n} (\|u^n(t,\cdot)\|_{L^\infty(R^+)} + \|\partial_x u^n(t,\cdot)\|_{L^\infty(R^+)}) = +\infty.$$

Suppose that there exists a time $T^* > 0$ and a constant $C > 0$ independent of n such that $\sup_{[0,T^*)} \|u^n(t,\cdot)\|_{H^2(R^+)} \leqslant C$. This implies that $T^n \geqslant T^*$. Indeed, if this is not true one has

$$\sup_{[0,T^*)} \|u^n(t,\cdot)\|_{H^2(R^+)} \geqslant \sup_{[0,T^n)} \|u^n(t,\cdot)|_{H^2(R^+)} \geqslant \sup_{[0,T^n)} (\|u^n(t,\cdot)\|_{L^\infty(R^+)} + \|\partial_x u^n(t,\cdot)\|_{L^\infty(R^+)}) = +\infty,$$

which is a contradiction.

Next, we prove that T^* and C do exist.

Indeed, since $u^n(t,x) \in C([0,T^n);\mathcal{B})$ and satisfies Eq. (3.3):

$$\partial_t u^n + u^n \partial_x u^n + \partial_x p^n = 0,$$

then

$$\partial_t \partial_x u^n = -(\partial_x u^n)^2 - u^n \partial_{xx} u^n - \partial_{xx} p^n = -\tfrac{1}{2}(\partial_x u^n)^2 - u^n \partial_{xx} u^n + (u^n)^2 - p^n, \tag{3.7}$$

$$\partial_t \partial_{xx} u^n = -\partial_x (u^n \partial_{xx} u^n) - \partial_x p^n + 2 u^n \partial_x u^n - \partial_x u^n \partial_{xx} u^n, \tag{3.8}$$

it follows that

$$\frac{1}{2} \frac{d}{dt} \|u^n(t,\cdot)\|_{L^2(R^+)}^2 = \int_{R^+} (p^n - (u^n)^2) \partial_x u^n \, dx, \tag{3.9}$$

$$\frac{1}{2}\frac{d}{dt}\|\partial_x u^n(t,\cdot)\|^2_{L^2(R^+)} = -\frac{1}{2}\int_{R^+}(\partial_x u^n)^3 dx - \int_{R^+} u^n \partial_{xx} u^n \partial_x u^n dx + \int_{R^+}((u^n)^2 - p^n)\partial_x u^n dx$$

$$= \int_{R^+}((u^n)^2 - p^n)\partial_x u^n dx, \tag{3.10}$$

$$\frac{1}{2}\frac{d}{dt}\|\partial_{xx} u^n(t,\cdot)\|^2_{L^2(R^+)} = \int_{R^+} u^n \partial_{xx} u^n \partial_{xxx} u^n dx - \int_{R^+} \partial_x p^n \partial_{xx} u^n dx$$

$$+2\int_{R^+} u^n \partial_x u^n \partial_{xx} u^n dx - \int_{R^+} \partial_x u^n (\partial_{xx} u^n)^2 dx$$

$$= -\frac{3}{2}\int_{R^+} \partial_x u^n (\partial_{xx} u^n)^2 dx - \int_{R^+} \partial_x p^n \partial_{xx} u^n dx + 2\int_{R^+} u^n \partial_x u^n \partial_{xx} u^n dx. \tag{3.11}$$

Due to (3.9) and (3.10), we obtain

$$\frac{1}{2}\frac{d}{dt}\|u^n(t,\cdot)\|^2_{H^1(R^+)} = 0, \tag{3.12}$$

then,

$$\|u^n(t,\cdot)\|_{H^1(R^+)} = \|u_0^n\|_{H^1(R^+)} \leqslant \|u_0^n\|_{H^2(R^+)} \leqslant \|u_0\|_{H^2(R^+)}. \tag{3.13}$$

Due to (3.11) and (3.12), we obtain

$$\frac{1}{2}\frac{d}{dt}\|u^n(t,\cdot)\|^2_{H^2(R^+)} = -\frac{3}{2}\int_{R^+} \partial_x u^n (\partial_{xx} u^n)^2 dx - \int_{R^+} \partial_x p^n \partial_{xx} u^n dx + 2\int_{R^+} u^n \partial_x u^n \partial_{xx} u^n dx$$

$$\leqslant \frac{3}{2}\|\partial_x u^n(t,\cdot)\|_{L^\infty(R^+)}\|\partial_{xx} u^n(t,\cdot)\|^2_{L^2(R^+)}$$

$$+\|\partial_x p^n(t,\cdot)\|_{L^2(R^+)}\|\partial_{xx} u^n(t,\cdot)\|_{L^2(R^+)}$$

$$+\|u^n(t,\cdot)\|_{L^\infty(R^+)}\|\partial_x u^n(t,\cdot)\|^2_{H^1(R^+)}$$

$$\leqslant C\|u^n(t,\cdot)\|^3_{H^2(R^+)}, \tag{3.14}$$

where C is a constant depending on nothing, and, the imbedding $H^2(R^+) \hookrightarrow W^{1,\infty}(R^+)$ and the following facts are used:

$$\|p^n(t,\cdot)\|^2_{L^2(R^+)} \leqslant \int_0^\infty \left\{ \int_0^\infty h(x,y)|((u^n)^2 + \tfrac{1}{2}(\partial_x u^n)^2)(t,y)|^2 dy \int_0^\infty h(x,y)dy \right\} dx$$

$$\leqslant \int_0^\infty \int_0^\infty h(x,y)|((u^n)^2 + \tfrac{1}{2}(\partial_x u^n)^2)(t,y)|^2 dy dx$$

$$= \int_0^\infty |((u^n)^2 + \tfrac{1}{2}(\partial_x u^n)^2)(t,y)|^2 \left(\int_0^\infty h(x,y)dx \right) dy$$

$$\leqslant \int_0^\infty |(u^n)^2 + \tfrac{1}{2}(\partial_x u^n)^2(t,y)|^2 dy \leqslant 2\|u^n(t,\cdot)\|^4_{L^4(R^+)} + 2\|\partial_x u^n(t,\cdot)\|^4_{L^4(R^+)}$$

$$\leqslant 2\|u^n(t,\cdot)\|^2_{L^\infty(R^+)}\|u^n(t,\cdot)\|^2_{L^2(R^+)} + 2\|\partial_x u^n(t,\cdot)\|^2_{L^\infty(R^+)}\|\partial_x u^n(t,\cdot)\|^2_{L^2(R^+)}$$

$$\leqslant 4\|u^n(t,\cdot)\|^4_{H^2(R^+)}, \tag{3.15}$$

and

$$\begin{aligned}\|\partial_x p^n(t,\cdot)\|^2_{L^2(R^+)} &= \int_0^\infty |\partial_x p^n|^2 dx \\ &= -\int_0^\infty p^n \partial_{xx} p^n dx \\ &= \int_0^\infty p^n \left((u^n)^2 + \frac{1}{2}(\partial_x u^n)^2 - p^n \right) dx \\ &\leqslant \|p^n(t,\cdot)\|_{L^2(R^+)} (\|u^n(t,\cdot)\|^2_{L^4(R^+)} + \|\partial_x u^n(t,\cdot)\|^2_{L^4(R^+)} + \|p^n(t,\cdot)\|_{L^2(R^+)}) \\ &\leqslant C\|u^n(t,\cdot)\|^4_{H^2(R^+)}, \end{aligned} \tag{3.16}$$

where C is a constant depending on nothing.

It follows from (3.14) and Lemma 4 that there exists a time $T^*>0$ and a constant $C_1>0$ depending only on $\|u_0\|_{H^2(R^+)}$ such that

$$\|u^n(t,\cdot)\|_{H^2(R^+)} \leqslant C_1, \tag{3.17}$$

and so $T^n \geqslant T^*, \forall n$.

On the other hand,

$$\begin{aligned}\|\partial_t u^n\|_{L^\infty(0,T^*;L^2(R^+))} &\leqslant \|u^n \partial_x u^n\|_{L^\infty(0,T^*;L^2(R^+))} + \|\partial_x p^n\|_{L^\infty(0,T^*;L^2(R^+))} \\ &\leqslant \sup_{0<t<T^*} \|u^n(t,\cdot)\|_{L^\infty(R^+))} \|\partial_x u^n(t,\cdot)\|_{L^2(R^+)} + \sup_{0<t<T^*} \sqrt{C}\|u^n(t,\cdot)\|^2_{H^2(R^+)} \\ &\leqslant (1+\sqrt{C})C_1^2 \triangleq C_2, \end{aligned} \tag{3.18}$$

due to (3.3) and (3.16)–(3.17), where C_2 is constant depending only on $\|u_0\|_{H^2(R^+)}$.

It follows from (3.17)–(3.18) and Lemma 2 that there exist a subsequence of $\{u^n\}$, still denoted by $\{u^n\}$, and some function $u \in L^\infty(0,T^*;H^2(R^+)\cap H_0^1(R^+)) \cap C([0,T^*];C^1_{\text{loc}}(R^+)), \partial_t u \in L^\infty(0,T^*;L^2(R^+))$ such that

$$u^n \overset{*}{\rightharpoonup} u, \text{ as } n\to\infty \text{ in } L^\infty(0,T^*;H^2(R^+)\cap H_0^1(R^+)), \tag{3.19}$$

$$\partial_t u^n \overset{*}{\rightharpoonup} \partial_t u, \text{ as } n\to\infty \text{ in } L^\infty(0,T^*;L^2(R^+)), \tag{3.20}$$

$$u^n \to u, \text{ as } n\to\infty \text{ in } C([0,T^*];C^1_{\text{loc}}(R^+)), \text{ uniformly on each compact subset of } [0,T^*]\times R^+. \tag{3.21}$$

It follows from Lemma 3 that $u \in C([0,T^*];H^2(R^+)\cap H_0^1(R^+))$.

Now, $\{p^n\}$ is uniformly bounded in $L^\infty(0,T^*;H^2(R^+)\cap H_0^1(R^+))$ due to (3.15)–(3.17) and the fact $\partial_{xx} p^n = p^n - (u^n)^2 - \frac{1}{2}(\partial_x u^n)^2$. On the other hand,

$$(1-\partial_{xx})\frac{\partial}{\partial t} p^n = \partial_t((u^n)^2) + \frac{1}{2}\partial_t((\partial_x u^n)^2),$$

$\partial_t((u^n)^2) = 2u^n \partial_t u^n$ is uniformly bounded in $L^\infty(0,T^*;L^2(R^+))$, and

$$\tfrac{1}{2}\partial_t((\partial_x u^n)^2)=\partial_x u^n \partial_{xt} u^n=-\tfrac{1}{2}(\partial_x u^n)^3-u^n\partial_x u^n \partial_{xx} u^n+((u^n)^2-p^n)\partial_x u^n,$$

which is uniformly bounded in $L^\infty(0,T^*;L^2(R^+))$, consequently $\{\partial_t p^n\}$ is uniformly bounded in $L^\infty(0,T^*;L^2(R^+))$. It follows from Lemma 2 that there exists a subsequence of $\{p^n\}$, still denoted by $\{p^n\}$, and some function $p\in L^\infty(0,T^*;H^2(R^+)\cap H_0^1(R^+))\cap C([0,T^*];C^1_{\mathrm{loc}}(R^+))$ such that

$$p^n \overset{*}{\rightharpoonup} p, \quad \text{as} \quad n\to\infty \quad \text{in} \quad L^\infty(0,T^*;H^2(R^+)\cap H_0^1(R^+)), \tag{3.22}$$

$$p^n \to p, \quad \text{as} \quad n\to\infty \quad \text{in} \quad C([0,T^*];C^1_{\mathrm{loc}}(R^+)), \tag{3.23}$$

then $p\in C([0,T^*];H^2(R^+)\cap H_0^1(R^+))$ and

$$\partial_{xx}p^n=p^n-(u^n)^2-\tfrac{1}{2}(\partial_x u^n)^2\to p-u^2-\tfrac{1}{2}(\partial_x u)^2 \quad \text{as} \quad n\to\infty \quad \text{in} \quad C([0,T^*],C_{\mathrm{loc}}(R^+)).$$

Consequently,

$$\begin{cases}(1-\partial_{xx})p=u^2+\tfrac{1}{2}(\partial_x u)^2,\\ p(t,0)=p(t,\infty)=0,\end{cases}$$

and so $p(t,x)=\int_0^\infty h(x,y)(u^2+\frac{1}{2}(\partial_x u)^2)(t,y)dy$.

For any $v\in L^2(0,T^*;\mathcal{D}(R^+))$, by multiplying v to both sides of (3.3) and integrating over $[0,T^*]\times R^+$, we find

$$\int_0^{T^*}\int_0^\infty(\partial_t u^n+u^n\partial_x u^n+\partial_x p^n)v\,dx\,dt=0,$$

passing to the limit, due to (3.19) and (3.20) and (3.22), we obtain

$$\int_0^{T^*}\int_0^\infty(\partial_t u+u\partial_x u+\partial_x p)v\,dx\,dt=0,$$

that is, $\partial_t u+u\partial_x u+\partial_x p=0$ in the weak sense. Note that $u\in C([0,T^*];H^2(R^+)\cap H_0^1(R^+))$, which implies

$$\partial_t u=-u\partial_x u-\partial_x p\in C([0,T^*];H_0^1(R^+)),$$

and so

$$u\in C([0,T^*];H^2(R^+)\cap H_0^1(R^+))\cap C^1([0,T^*];H_0^1(R^+)),$$

consequently $\partial_t u+u\partial_x u+\partial_x p=0$ a. e. $[0,T^*]\times R^+$.

It follows from $u^n(0,x)=u_0^n(x)$, (3.2) and (3.20), we obtain

$$u(0,x)=u_0(x).$$

The proof of existence is completed.

Before proving the uniqueness, we introduce the following Lemma.

Lemma 5: Let $u_0\in H^2(R^+)\cap H_0^1(R^+)$, *and* $u\in C([0,T];H^2(R^+)\cap H_0^1(R^+))\cap C^1([0,T];H_0^1(R^+))$ *be a solution to (3.1). Then the following problem:*

$$\begin{cases} \dfrac{d\Phi^x(t)}{dt} = u(t,\Phi^x(t)), & t>0, \\ \Phi^x(0) = x, & x\geqslant 0, \end{cases}$$

has a unique solution $\Phi^x(t)\in C^1([0,T])$ *and* $x\in R^+\to\Phi^x(t)\in R^+$ *is an isomorphism.*

Proof: Let $\tilde{u}(t,x)=\begin{cases} u(t,x), & x\geqslant 0, \\ -u(t,-x), & x<0. \end{cases}$

We consider the ordinary differential equation

$$\begin{cases} \dfrac{d\Phi^x(t)}{dt} = \tilde{u}(t,\Phi^x(t)), & t>0, \\ \Phi^x(0) = x, & x\geqslant 0. \end{cases} \tag{3.24}$$

Note that $u(t,x)\in C([0,T];H^2(R^+)\cap H_0^1(R^+))$. It follows from the definition of $\tilde{u}$ and Sobolev Embedding Theorem that $\tilde{u}(t,q)$ is Lipschitz continuous with respect to q. Then for any $x\geqslant 0$, there exists a unique solution $\Phi^x(t)\in C^1([0,T])$ to (3.24). Let $q(t,x)=\Phi^x(t)$, then $q(t,x)$ solves the following problem:

$$\begin{cases} q_t = \tilde{u}(t,q), & t>0, \\ q(0,x) = x, & x\geqslant 0. \end{cases} \tag{3.25}$$

Applying ∂_x to (3.25), we have

$$\begin{cases} q_{xt} = \tilde{u}_q(t,q)q_x, & t>0, \\ q_x(0,x) = 1, & x\geqslant 0, \end{cases} \tag{3.26}$$

and so $q_x(t,x)=e^{\int_0^t \tilde{u}_q(\tau,q(\tau,x))q_x(\tau,x)d\tau}>0$. From the facts that $q(t,x)$ is continuous with respect to x and that

$$|q(t,x)-x|\leqslant \int_0^t |\tilde{u}(\tau,q(\tau,x))|d\tau \leqslant 2\|u_0\|_{H^2}t,$$

we know

(1) $q(t,x)>q(t,0)=0, t\in[0,T]$,

(2) $\lim_{x\to+\infty} q(t,x)=+\infty, t\in[0,T]$,

(3) $q(t,x)$ is a homeomorphism.

Consequently $x\in R^+\to\Phi^x(t)\in R^+$ is an isomorphism. The proof of Lemma 5 is completed.

Now, we turn to the proof of the uniqueness. Let $u_1(t,x)$ and $u_2(t,x)$ be any two solutions of (3.1). Set $W=u_1-u_2$. Then W solves

$$\begin{cases} \partial_t W + u_1\partial_x W = -\partial_x(p_1-p_2) - W\partial_x u_2, \\ W(0,x)=0, \\ W(t,0)=0. \end{cases} \tag{3.27}$$

Thus by (3.27), Lemma 5, and the characteristic method, we get

$$W(t,x) = -\int_0^t (\partial_x(p_1-p_2) + W\partial_x u_2)(s,x)ds,$$

and so

$$\|W(t,\cdot)\|_{L^\infty(R^+)} \leqslant \int_0^t \|(\partial_x(p_1-p_2) + W\partial_x u_2)(s,\cdot)\|_{L^\infty(R^+)}ds, \forall t\in[0,T]. \tag{3.28}$$

On the other hand, by the definition of P_i $(i=1,2)$, we have

$$\begin{aligned}\partial_x(p_1-p_2)&=\partial_x(1-\partial_{xx})^{-1}\{(u_1^2-u_2^2)+\tfrac{1}{2}[(\partial_x u_1)^2-(\partial_x u_2)^2]\}\\&=\partial_x(1-\partial_{xx})^{-1}\{(u_1+u_2)W+\tfrac{1}{2}\partial_x W\partial_x(u_1+u_2)\}.\end{aligned}\tag{3.29}$$

The second term on the right-hand side of (3.29) can be rewritten as

$$\begin{aligned}\partial_x(1-\partial_{xx})^{-1}(\partial_x W\partial_x(u_1+u_2))&=\partial_{xx}(1-\partial_{xx})^{-1}(W\partial_x(u_1+u_2))-\partial_x(1-\partial_{xx})^{-1}(W\partial_{xx}(u_1+u_2))\\&=-W\partial_x(u_1+u_2)+(1-\partial_{xx})^{-1}(W\partial_x(u_1+u_2))\\&\quad-\partial_x(1-\partial_{xx})^{-1}(W\partial_{xx}(u_1+u_2)).\end{aligned}$$

Hence

$$\begin{aligned}\partial_x(p_1-p_2)=&\tfrac{1}{2}\partial_x(1-\partial_{xx})^{-1}\{(u_1+u_2)W+(v_1+v_2)W\}+\tfrac{1}{2}(1-\partial_{xx})^{-1}(W\partial_x(u_1+u_2))\\&-\tfrac{1}{2}W\partial_x(u_1+u_2),\end{aligned}$$

where $v_i=(1-\partial_{xx})u_i$, $i=1,2$.

And so

$$\begin{aligned}\partial_x(p_1-p_2)+W\partial_x u_2=&\tfrac{1}{2}\partial_x(1-\partial_{xx})^{-1}\{(u_1+u_2)W+(v_1+v_2)W\}\\&+\tfrac{1}{2}(1-\partial_{xx})^{-1}(W\partial_x(u_1+u_2))-\tfrac{1}{2}W\partial_x W.\end{aligned}\tag{3.30}$$

Using the definition of $(1-\partial_{xx})^{-1}$, we have

$$\begin{aligned}&\|\partial_x(1-\partial_{xx})^{-1}((u_1+u_2)W)(t,\cdot)\|_{L^\infty(R^+)}\\&=\sup_{x\in R^+}\left|\int_0^x e^{-x}shy((u_1+u_2)W)(t,y)dy+\int_x^\infty e^{-y}chx((u_1+u_2)W)(t,y)dy\right|\\&\leqslant\sup_{x\in R^+}\left(\left(\int_0^x|e^{-x}shy|^2dy\right)^{1/2}+\left(\int_x^\infty|e^{-y}chx|^2dy\right)^{1/2}\right)\\&\quad\times\|(u_1+u_2)(t,\cdot)\|_{L^2(R^+)}\|W(t,\cdot)\|_{L^\infty(R^+)}\\&\leqslant\frac{3\sqrt{2}}{4}\|(u_1+u_2)(t,\cdot)\|_{L^2(R^+)}\|W(t,\cdot)\|_{L^\infty(R^+)}\\&\leqslant\frac{3\sqrt{2}}{4}(\|u_1(t,\cdot)\|_{L^2(R^+)}+\|u_2(t,\cdot)\|_{L^2(R^+)})\|W(t,\cdot)\|_{L^\infty(R^+)},\end{aligned}\tag{3.31}$$

$$\begin{aligned}&\|\partial_x(1-\partial_{xx})^{-1}((v_1+v_2)W)(t,\cdot)\|_{L^\infty(R^+)}\\&\leqslant\frac{3\sqrt{2}}{4}\|(v_1+v_2)(t,\cdot)\|_{L^2(R^+)}\|W(t,\cdot)\|_{L^\infty(R^+)}\\&\leqslant\frac{3\sqrt{2}}{4}\|(u_1+u_2)(t,\cdot)\|_{H^2(R^+)}\|W(t,\cdot)\|_{L^\infty(R^+)}\\&\leqslant\frac{3\sqrt{2}}{4}(\|u_1(t,\cdot)\|_{H^2(R^+)}+\|u_2(t,\cdot)\|_{H^2(R^+)})\|W(t,\cdot)\|_{L^\infty(R^+)},\end{aligned}\tag{3.32}$$

$$\|(1-\partial_{xx})^{-1}(W\partial_x(u_1+u_2))(t,\cdot)\|_{L^\infty(R^+)}$$
$$\leqslant \sup_{x\in R^+}\left(\int_0^\infty |h(x,y)|^2 dy\right)^{1/2}\|\partial_x(u_1+u_2)(t,\cdot)\|_{L^2(R^+)}\|W(t,\cdot)\|_{L^\infty(R^+)}$$
$$\leqslant\left(\frac{\sqrt{2}}{4}+\frac{1}{2}\right)(\|u_1(t,\cdot)\|_{H^2(R^+)}+\|u_2(t,\cdot)\|_{H^2(R^+)})\|W(t,\cdot)\|_{L^\infty(R^+)}, \tag{3.33}$$

$$\|(W\partial_x W)(t,\cdot)\|_{L^\infty(R^+)}\leqslant\|W(t,\cdot)\|_{L^\infty(R^+)}\|(\partial_x W)(t,\cdot)\|_{L^\infty(R^+)}$$
$$\leqslant\|W(t,\cdot)\|_{L^\infty(R^+)}\|W(t,\cdot)\|_{H^2(R^+)}\leqslant\|W(t,\cdot)\|_{L^\infty(R^+)}(\|u_1(t,\cdot)\|_{H^2(R^+)}+\|u_2(t,\cdot)\|_{H^2(R^+)}). \tag{3.34}$$

Putting all the estimates (3.28) and (3.30)–(3.34) together, we can find some constant C which depends only on $\|u_i\|_{L^\infty(0,T;H^2(R^+))}$ $(i=1,2)$, such that

$$\|W(t,\cdot)\|_{L^\infty(R^+)}\leqslant C\int_0^t\|W(s,\cdot)\|_{L^\infty(R^+)}ds,\forall t\in[0,T].$$

This yields, by Gronwall's inequality, that

$$\|W(t,\cdot)\|_{L^\infty(R^+)}=0,\forall t\in[0,T],$$

and so $W=0$, which completes the proof of the uniqueness.

Remark 2: The proof of uniqueness implies that for any $T>0$, if there exists a solution to (3.1) in $C([0,T];H^2(R^+)\cap H_0^1(R^+))\cap C^1([0,T];H_0^1(R^+))$, then the solution must be unique.

IV. THE EXISTENCE AND UNIQUENESS OF THE GLOBAL SOLUTION TO PROBLEMS (1.1)–(1.3)

In this section we will show that the solution to (1.1)–(1.3) is global in-time provided u_0 satisfies a certain positivity condition.

Theorem 3: *Suppose that $u_0\in H^2(R^+)\cap H_0^1(R^+)$ and $V_0=(1-\partial_{xx})u_0\geqslant 0$. Then the unique strong solution to (1.1)–(1.3) exists globally in time.*

Proof: We proceed in four steps.

Step 1: First we mollify the initial data u_0.

Let $\rho(x)\in C_0^\infty(R^+):\rho(x)\geqslant 0,\int_{R^+}\rho(x)dx=1$, and $\rho_n(x)=n\rho(nx)$ be the usual mollifiers on R^+, $u_0^n=\rho_n^* u_0$, where $*$ denote the convolution. Then

$$u_0^n\to u_0 \text{ in } H^2(R^+)\cap H_0^1(R^+) \text{ and } \|u_0^n\|_{H^2(R^+)}\leqslant\|u_0\|_{H^2(R^+)}. \tag{4.1}$$

Note that $u_0\in H_0^1(R^+)$. We get $u_0^n\in\mathcal{B}$ and

$$V_0^n=(1-\partial_{xx})u_0^n=\rho_n*(1-\partial_{xx})u_0\geqslant 0.$$

For this $u_0^n\in\mathcal{B}$, it follows from Theorem 1 that there exists a unique solution to (1.4) such that

$$u^n(t,x)\in C([0,T^n);\mathcal{B})\cap C^1([0,T^n);H^2(R^+)\cap H_0^1(R^+)).$$

Let $V^n(t,x)=(1-\partial_{xx})u^n(t,x)$, then

$$u^n(t,x)=(1-\partial_{xx})^{-1}V^n(t,x)=\int_0^\infty h(x,y)V^n(t,y)dy.$$

Step 2: To prove that $V^n(t,x)\geqslant 0$.

Since $V^n(t,x)=(1-\partial_{xx})u^n(t,x)$, Eq. (3.3) can be rewritten as

$$\partial_t V^n + u^n \partial_x V^n = -2V^n \partial_x u^n. \tag{4.2}$$

It follows from Lemma 5 that the following problem:

$$\begin{cases} \dfrac{d\Phi^x(t)}{dt} = u^n(t,\Phi^x(t)), & t>0, \\ \Phi^x(0) = x, & x \geqslant 0, \end{cases}$$

has a unique solution $\Phi^x(t) \in C^1(0,T^n)$ and $x \in R^+ \to \Phi^x(t) \in R^+$ is an isomorphism. Set $S(t) = V^n(t,\Phi^x(t))$. Then $S(0) = V^n(0,x) = V_0^n(x)$ and

$$\begin{aligned} \frac{dS}{dt} = \partial_t V^n(t,\Phi^x(t)) + \partial_x V^n(t,\Phi^x(t)) \frac{d\Phi^x(t)}{dt} &= \partial_t V^n(t,\Phi^x(t)) + u^n(t,\Phi^x(t)) \partial_x V^n(t,\Phi^x(t)) \\ &= -2V^n(t,\Phi^x(t)) \partial_x u^n(t,\Phi^x(t)) \\ &= -2S \partial_x u^n(t,\Phi^x(t)), \end{aligned}$$

due to (4.2). From this and (3.26), we get

$$\partial_t \{S(t)[\partial_x \Phi^x(t)]^2\} = 0,$$

and so

$$S(t)[\partial_x \Phi^x(t)]^2 = S(0)[\partial_x \Phi^x(0)]^2 = S(0), \tag{4.3}$$

consequently $S(t) \geqslant 0$. Since $x \in R^+ \to \Phi^x(t) \in R^+$ is an isomorphism, we get that

$$V^n(t,x) \geqslant 0.$$

Step 3: To get some *a priori* estimates.
Since

$$\begin{aligned} u^n(t,x) &= \int_0^\infty h(x,y) V^n(t,y)\, dy \\ &= e^{-x}/2 \int_0^x e^y V^n(t,y)\, dy + e^x/2 \int_x^\infty e^{-y} V^n(t,y)\, dy - e^{-x}/2 \int_0^\infty e^{-y} V^n(t,y)\, dy, \end{aligned}$$

$$\partial_x u^n(t,x) = -e^{-x}/2 \int_0^x e^y V^n(t,y)\, dy + e^x/2 \int_x^\infty e^{-y} V^n(t,y)\, dy + e^{-x}/2 \int_0^\infty e^{-y} V^n(t,y)\, dy,$$

we get

$$u^n(t,x) + \partial_x u^n(t,x) = e^x \int_x^\infty e^{-y} V^n(t,y)\, dy \geqslant 0,$$

and so

$$\begin{aligned} -\partial_x u^n(t,x) \leqslant u^n(t,x) \leqslant \|u^n(t,x)\|_{L^\infty} &\leqslant \|u^n(t,x)\|_{H^1(R^+)} \\ &= \|u_0^n\|_{H^1(R^+)} \leqslant \|u_0^n\|_{H^2(R^+)} \leqslant \|u_0\|_{H^2(R^+)}. \end{aligned}$$

Then by multiplying $2V^n$ to (4.2), integrating the resulting identity over R^+ associated with x and performing integration by parts, we obtain

$$\frac{d}{dt}\|V^n(t,\cdot)\|^2_{L^2(R^+)}=-3\int_{R^+}(V^n(t,x))^2\partial_x u^n(t,x)dx\leqslant 3\|u_0\|_{H^2(R^+)}\|V^n(t,\cdot)\|^2_{L^2(R^+)}.$$

It follows from Gronwall's inequality that

$$\|V^n(t,\cdot)\|_{L^2(R^+)}\leqslant\|V_0^n\|_{L^2(R^+)}e^{3/2\|u_0\|_{H^2(R^+)}t}\leqslant\|u_0^n\|_{H^2(R^+)}e^{3/2\|u_0\|_{H^2(R^+)}t}\leqslant\|u_0\|_{H^2(R^+)}e^{3/2\|u_0\|_{H^2(R^+)}t},$$

and so

$$\|u^n(t,\cdot)\|_{H^2(R^+)}\leqslant\|V^n(t,\cdot)\|_{L^2(R^+)}\leqslant\|u_0\|_{H^2(R^+)}e^{3/2\|u_0\|_{H^2(R^+)}t}.$$

Consequently, $\forall T>0,\{u^n\}$ is uniformly bounded in $L^\infty(0,T;H^2(R^+)\cap H_0^1(R^+))$.

On the other hand,

$$\begin{aligned}\|\partial_t u^n\|_{L^\infty(0,T;L^2(R^+))}&\leqslant\|u^n\partial_x u^n\|_{L^\infty(0,T;L^2(R^+))}+\|\partial_x p^n\|_{L^\infty(0,T;L^2(R^+))}\\&\leqslant 2\sup_{0<t<T}\|u^n(t,\cdot)\|^2_{H^2(R^+)}\\&\leqslant 2\|u_0\|^2_{H^2(R^+)}e^{3\|u_0\|_{H^2(R^+)}T},\end{aligned}$$

that is, $\{\partial_t u^n\}$ is uniformly bounded in $L^\infty(0,T;L^2(R^+))$.

Step 4: Passing to the limit.

Since $\forall T>0$, $\{u^n\}$ and $\{\partial_t u^n\}$ are uniformly bounded in $L^\infty(0,T;H^2(R^+)\cap H_0^1(R^+))$ and $L^\infty(0,T;L^2(R^+))$, respectively, there exists a subsequence of $\{u^n\}$, still denoted by $\{u^n\}$, and some function $u\in L^\infty(R^+;H^2(R^+)\cap H_0^1(R^+))\cap C(R^+;C^1_{\mathrm{loc}}(R^+))$, $\partial_t u\in L^\infty(R^+,L^2(R^+))$ by the diagonal process of choice to $\{u^n\}$, such that

$$u^n\overset{*}{\rightharpoonup}u,\ \text{as}\ \ n\to\infty\ \ \text{in}\ \ L^\infty(0,T;H^2(R^+)\cap H_0^1(R^+)),\tag{4.4}$$

$$\partial_t u^n\overset{*}{\rightharpoonup}\partial_t u,\ \text{as}\ \ n\to\infty\ \ \text{in}\ \ L^\infty(0,T;L^2(R^+)),\tag{4.5}$$

$$u^n\to u,\ \text{as}\ \ n\to\infty\ \ \text{in}\ \ C([0,T];C^1_{\mathrm{loc}}(R^+)),\tag{4.6}$$

for any $T>0$. Then by the same method of passing to the limit in the proof of the existence of the local solution, we obtain $u\in C([0,T];H^2(R^+)\cap H_0^1(R^+))\cap C^1([0,T];H_0^1(R^+))$, and

$$\partial_t u+u\partial_x u+\partial_x p=0,\ \text{a. e.}\ \ [0,T]\times R^+.$$

Since T is arbitrary, we get that $u\in C([0,\infty);H^2(R^+)\cap H_0^1(R^+))\cap C^1([0,\infty);H_0^1(R^+))$, and

$$\partial_t u+u\partial_x u+\partial_x p=0,\ \text{a. e.}\ \ [0,\infty)\times R^+,$$

which proves that the solution exists globally in time. Finally the solution must be unique due to Remark 2.

We complete the proof of Theorem 3.

Remark 3: The relation (4.3) is not accidental. It actually represents something fundamental in the periodic case, when the Camassa–Holm equation is a re-expression of geodesic flow on the diffeomorphism group of the circle endowed with the H^1-right-invariant metric; this geometric interpretation was first described by Misioek.[24] Within the geometric framework it turns out that this relation represents conservation of momentum and is a consequence of Noether's theorem.[25]

V. BLOW-UP

Theorem 4: *Let* $u_0 \in H^2(R^+) \cap H_0^1(R^+)$ *with* $\partial_x u_0(\overline{x}) \leqslant -\sqrt{2}\|u_0\|_{H^2(R^+)}$ *for some* $\overline{x} \in R^+$. *Then the strong solution to (1.1)–(1.3) blows-up in finite time.*

Proof: Let $S(t) = \partial_x u(t, x(t))$ with $x(0) = \overline{x}$. It follows from Lemma 5 that

$$\frac{dx(t)}{dt} = u(t, x(t)),$$

then

$$\frac{dS}{dt} = \partial_{xt} u + \partial_{xx} u \frac{dx(t)}{dt} = \partial_{xt} u + u \partial_{xx} u.$$

On the other hand, applying ∂_x to (1.1) we have

$$\partial_{xt} u = -(\partial_x u)^2 - u \partial_x u - \partial_{xx} p = -\tfrac{1}{2}(\partial_x u)^2 - u \partial_{xx} u - p + u^2.$$

Thus

$$\frac{dS}{dt} = -\frac{1}{2} S^2 + u^2 - p. \tag{5.1}$$

Observing that $p \geqslant 0$, expression (5.1) can be transformed in

$$\frac{dS}{dt} + \frac{1}{2} S^2 \leqslant u^2 \leqslant \|u(t, \cdot)\|^2_{L^\infty(R^+)} \leqslant \|u_0\|^2_{H^2(R^+)},$$

that is

$$\frac{dS}{dt} \leqslant \|u_0\|^2_{H^2(R^+)} - S^2/2.$$

Solving this inequality, we obtain

$$\frac{S_0 + k}{S_0 - k} e^{kt} - 1 \leqslant \frac{2k}{S - k},$$

where $k = \sqrt{2}\|u_0\|_{H^2(R^+)}$ and $S_0 = S(0) = \partial_x u(0, x(0)) = \partial_x u_0(\overline{x})$, and so

$$S \leqslant \frac{2k}{\dfrac{S_0 + k}{S_0 - k} e^{kt} - 1} + k.$$

Taking $T_0 = 1/k \ln (S_0 - k)/(S_0 + k) > 0$, we get

$$\lim_{t \to T_0^-} S(t) \leqslant \lim_{t \to T_0^-} \frac{2k}{\dfrac{S_0 + k}{S_0 - k} e^{kt} - 1} + k = -\infty,$$

which implies

$$\lim_{t \to T_0^-} \|u(t, \cdot)\|_{H^2(R^+)} = \infty,$$

since $|\partial_x u(t,x)| \leqslant \|\partial_x u(t,\cdot)\|_{L^\infty(R^+)} \leqslant \|u(t,\cdot)\|_{H^2(R^+)}$.

published online 5 August 2004)

We give a detailed study of the asymptotic behavior of field commutators for linearly polarized, cylindrically symmetric gravitational waves in different physically relevant regimes. We also discuss the necessary mathematical tools to carry out our analysis. Field commutators are used here to analyze microcausality, in particular the smearing of light cones owing to quantum effects. We discuss in detail several issues related to the semiclassical limit of quantum gravity, in the simplified setting of the cylindrical symmetry reduction considered here. We show, for example, that the small G behavior is not uniform in the sense that its functional form depends on the causal relationship between space–time points. We consider several physical issues relevant for this type of models such as the emergence of large gravitational effects. © *2004 American Institute of Physics.*

I. INTRODUCTION

Among the many symmetry reductions of general relativity that have been considered in the past, linearly polarized cylindrical waves (also known as Einstein–Rosen waves[1,2]) have been the focus of intensive study. They provide a model with an infinite number of degrees of freedom that can be exactly solved in spite of the fact that it is nonlinear. This is not only true classically but also quantum mechanically, and hence this system is a valuable tool to explore the physics that may be found if a successful quantization of full general relativity is ever achieved.[3–6]

One of the main reasons behind this success is the fact that the physical Hamiltonian is a function of the free Hamiltonian of a $2+1$ dimensional, axially symmetric, massless scalar field evolving in an auxiliary Minkowskian background.[4,5,7] In a previous paper[6] we took advantage of this fact to study the quantum corrections to the space–time structure by considering the commutator of this scalar field at different space–time points. As is well known, microcausality in quantum field theories can be discussed by looking at the commutator of quantum fields (or anticommutator in the case of fermions). In the standard examples the microcausality requirement means that this (anti)commutator must vanish for spatially separated space–time points. A similar argument can be made for vector fields, though issues of gauge invariance change some of the conclusions; in particular if one computes the commutator of the four-vector potential A_μ at two spatially separated points, it may be different from zero in some gauges, even though it is always true that the commutator of gauge invariant objects is zero for such points.

The issue of gauge invariance in the context of cylindrical gravitational waves has been discussed at length by Bičák and collaborators.[8] These authors show that is is legitimate to use the Ashtekar–Pierri gauge fixed action[3] written in terms of the scalar field that encodes the physical

information in this model to obtain gauge invariant structures such as Dirac observables or the S matrix. This justifies the computation of the type of objects—field commutators—that we will be considering here to extract conclusions about the quantum structure of space–time.

The particular problem that we will be concerned with in this paper is the detailed study of the field commutator (given as a certain integral) and, in particular, its limiting behavior when the time and length separations are much larger than the natural length scale of the problem—the Planck length. In order to do this the procedure of expanding the integrand of the field commutator as a power series in the gravitational constant and other asymptotic parameters is not useful. In fact it will be necessary to adapt some methods developed for the asymptotic analysis of integrals and get a consistent procedure to expand the relevant objects as asymptotic series. It is possible to understand this *a posteriori* as a consequence of the fact that some limiting behaviors (i.e., in G) of the field commutator change in a nontrivial way as the space–time intervals go from spacelike to timelike or when one of the space–time points lies in the symmetry axis. Also the functional dependence in some of these parameters is highly nonpolynomial. This is not what one would expect to obtain in the familiar perturbative treatment of quantum field theories (QFT's).

The paper is divided in two main sections: A physical discussion of the behavior of the field commutator followed by a detailed description of the asymptotic methods necessary to study the different physically relevant regimes. Specifically, after this introduction we will give the different asymptotic expansions for all the relevant parameters (involving the $G\rightarrow 0$ limit and also the limits in which the difference in the time coordinates or the radial coordinates go to infinity). Using them we will discuss the main physical consequences of the quantization of this model as far as microcausality is concerned. In this respect it is particulary interesting to point out the existence of a certain type of large quantum mechanical effects (in a sense that will be made precise later) when one of the space–time points in the field commutator lies in the symmetry axis.

A technical issue that should be considered is the role of regulators in the final physical results. As is well known regulators are necessary to give sense to otherwise ill-defined objects. They must be introduced, for example, to obtain a finite norm vector by acting with the field operator on the vacuum state. Cutoffs are a simple way to regulate amplitudes. It is conceivable that physical regulators exist that restrict, for example, the integration intervals for some physical objects (such as the field commutators considered here) to finite real intervals. However, it is also possible that they are just a convenient way to render some physical objects finite in such a way that no footprint is left in the final results. This is the philosophy that one has in mind in the usual renormalization scheme where cutoffs are taken to infinity and disappear from physical quantities.

The point of view of this paper is that the un-regulated objects (integrals), when defined, are a good approximation to the regulated ones. The asymptotic analysis of regulated commutators and their relation with the un-regulated ones will be discussed elsewhere.

In the usual perturbative QFT computations Green functions, matrix elements, and similar objects are expanded as power series in the coupling constants of the model with coefficients that are usually written as regulated integrals. This is a necessary step because it is usually not possible to write them in closed form. Here the situation is different because it is possible to write down expressions for the objects of interest (field commutators in the present example) that depend on the coupling constants in a nontrivial way. This has the advantage of allowing us to use approximation techniques specially adapted to their specific form and much better suited to its study. It also permits to consider some problems that may be difficult to tackle for the usual QFT's; for example, one can try to figure out if the asymptotic behavior of some regulated object coincides with its asymptotic behavior after the regulator is removed.

A detailed technical discussion of the techniques needed to explore the relevant asymptotic regimes is presented in Sec. III. These techniques will be useful tools in order to analyze other types of physical objects (such as S-matrix elements) so they provide the necessary background for a perturbative framework properly adapted to this model; this is why we invest some time to study them here. We end the paper with a summary of the main results, comments, perspectives for future work, and several appendices. Numerical and algebraic computations have been performed with the aid of MATHEMATICA®.

II. THE FIELD COMMUTATOR

We start with a brief description of the model and introduce our conventions and notation. As is well known[1,2,9] Einstein–Rosen waves correspond to topologically trivial space–times with two linearly independent, commuting, spacelike, and hypersurface orthogonal Killing vector fields. The metric in this case can be writen as

$$ds^2 = e^{\gamma-\psi}(-dT^2+dR^2)+e^{-\psi}R^2 d\theta^2+e^{\psi}dZ^2, \tag{1}$$

where we are using coordinates (T,R,θ,Z), $T\in\mathbb{R}$, $R\in[0,\infty)$, $\theta\in[0,2\pi)$, $Z\in\mathbb{R}$, and ψ and γ are functions only of R and T. The Einstein field equations for this metric are very simple: The scalar field ψ must satisfy the wave equation for a massless, axially symmetric scalar field in three dimensions

$$\partial_T^2\psi-\partial_R^2\psi-\frac{1}{R}\partial_R\psi=0,$$

and the function γ can be expressed in terms of this field on the classical solutions[3,5] as

$$\gamma(R)=\frac{1}{2}\int_0^R d\overline{R\,R}\,[(\partial_T\psi)^2+(\partial_{\overline{R}}\psi)^2].$$

Throughout the paper we will use a system of units such that $c=\hbar=1$ and define $G\equiv\hbar G_3$, where G_3 denotes the gravitational constant per unit length in the direction of the symmetry axis.[16] The metric function $\gamma(R)$ admits a simple physical interpretation: Apart from a factor of $8G$ it is the energy of the scalar field in a ball of radius R, and $\gamma_\infty\equiv\lim_{R\to\infty}\gamma(R)$ the energy of the whole two-dimensional flat space. Furthermore, $\gamma_\infty/(8G)$ coincides with the Hamiltonian H_0 of the system obtained by linearizing the metric (1).[3,6]

In order to arrive at a unit asymptotic timelike Killing vector that allows us to introduce a physical notion of energy (per unit length) it is convenient to use coordinates (t,R,θ,Z) defined by $T=e^{-\gamma_\infty/2}t$. In these coordinates the metric takes the form[2,9]

$$ds^2=e^{\gamma-\psi}(-e^{-\gamma_\infty}dt^2+dR^2)+e^{-\psi}R^2d\theta^2+e^{\psi}dZ^2.$$

By choosing a metric function ψ with a sufficiently fast fall-off as $R\to\infty$, this metric describes asymptotically flat space–times with a certain (nonzero) deficit angle and such that ∂_t is a unit timelike Killing vector in the asymptotic region.

The Einstein field equations can be obtained from a Hamiltonian action principle[9–11] where the Hamiltonian H is a function of that corresponding to the free scalar field, H_0:

$$H=E(H_0)=\frac{1}{4G}(1-e^{-4GH_0}).$$

In the following we will refer to t as the physical time and to H as the physical Hamiltonian.

In terms of the T-time and imposing that ψ be regular at $R=0$,[3] the classical solutions for the field ψ can be written as

$$\psi(R,T)=\sqrt{4G}\int_0^\infty dk\,J_0(Rk)[A(k)e^{-ikT}+A^\dagger(k)e^{ikT}],$$

where $A(k)$ [and its complex conjugate $A^\dagger(k)$] are determined by the initial conditions.[17] The free Hamiltonian H_0 can be written now as

$$\gamma_\infty=H_0=\int_0^\infty dk\,kA^\dagger(k)A(k).$$

Using this expression, we can obtain the t-evolution of the field

$$\psi_E(R,t)=\sqrt{4G}\int_0^\infty dk\, J_0(Rk)[A(k)e^{-ikte^{-\gamma_\infty/2}}+A^\dagger(k)e^{ikte^{-\gamma_\infty/2}}].$$

The quantization can be carried out by following the usual steps. We introduce a Fock space in which $\hat{\psi}(R,0)$, the quantum counterpart of $\psi(R,0)$, is an operator-valued distribution.[12] Its action is determined by those of $\hat{A}(k)$ and $\hat{A}^\dagger(k)$, the annihilation and creation operators with nonvanishing commutators given by

$$[\hat{A}(k_1),\hat{A}^\dagger(k_2)]=\delta(k_1,k_2).$$

Explicitly,

$$\hat{\psi}(R,0)=\hat{\psi}_E(R,0)=\sqrt{4G}\int_0^\infty dk\, J_0(Rk)[\hat{A}(k)+\hat{A}^\dagger(k)].$$

Evolution in T is given by the unitary operator $\hat{U}_0(T)=\exp(-iT\hat{H}_0)$ where

$$\hat{H}_0=\int_0^\infty dk\, k\,\hat{A}^\dagger(k)\hat{A}(k)$$

is the quantum Hamiltonian operator of a three-dimensional, axially symmetric scalar field. The quantum scalar field in the Heisenberg picture is hence given by

$$\hat{\psi}(R,T)=\hat{U}_0^\dagger(T)\,\hat{\psi}(R,0)\hat{U}_0(T)=\sqrt{4G}\int_0^\infty dk\, J_0(Rk)[\hat{A}(k)e^{-ikT}+\hat{A}^\dagger(k)e^{ikT}].$$

If we choose the physical time t to define the evolution in our model, the quantum Hamiltonian is $\hat{H}=E(\hat{H}_0)=(1-e^{-4G\hat{H}_0})/(4G)$ and unitary evolution is given by $\hat{U}(t)=\exp(-it\hat{H})$. With this time evolution the annihilation and creation operators in the Heisenberg picture are

$$\hat{A}_E(k,t)\equiv\hat{U}^\dagger(t)\hat{A}(k)\hat{U}(t)=\exp[-itE(k)e^{-4G\hat{H}_0}]\hat{A}(k),$$

$$\hat{A}_E^\dagger(k,t)=\hat{A}^\dagger(k)\exp[itE(k)e^{-4G\hat{H}_0}],$$

where $E(k)=(1-e^{-4Gk})/(4G)$, and the field operator evolved with the physical Hamiltonian [that we denote as $\hat{\psi}_E(R,t)$] is given by

$$\hat{\psi}_E(R,t)=\sqrt{4G}\int_0^\infty dk\, J_0(Rk)[\hat{A}_E(k,t)+\hat{A}_E^\dagger(k,t)].$$

The field commutator $[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]$ can be computed from these expressions.[6] One of its interesting features is the fact that it is not proportional to the identity as in the case of free theories (or if we consider the quantum evolution defined by the Hamiltonian H_0 of the linearized model) but is a nondiagonal operator in the chosen basis. We are hence led to consider its matrix elements. We will concentrate here on the most relevant of these elements (at least from the perspective of the microcausality of the classical background of the model), namely the vacuum expectation value, which is explicitly given by

$$\frac{1}{8iG}\langle 0|\,[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]\,|0\rangle=\int_0^\infty dk\, J_0(R_1k)J_0(R_2k)\sin\left[\frac{t_2-t_1}{4G}(1-e^{-4Gk})\right]. \quad (2)$$

As we can see it depends on the time coordinates through their difference t_2-t_1 (which we will assume to be, e.g., positive) and depends symmetrically on R_1 and R_2. The functional dependence in G is less trivial, a fact that will require special attention when studying the limit in which the relevant lengths and time differences are much larger than the Planck length. For comparison purposes we remember that

$$\frac{1}{8iG}\langle 0|\,[\hat{\psi}(R_1,T_1),\hat{\psi}(R_2,T_2)]\,|0\rangle=\int_0^\infty dk\,J_0(R_1k)J_0(R_2k)\sin[k(T_2-T_1)]. \tag{3}$$

In the following it will be convenient to refer the dimensional parameters of the integral to another length scale that we choose as R_1. We hence define $R_2=\rho R_1$, $t_2-t_1=\tau R_1$, $\lambda=R_1/(4G)$ and rewrite (2) as

$$\frac{1}{8iG}\langle 0|\,[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]\,|0\rangle=\frac{\lambda}{R_1}\Im\left\{\int_0^\infty dq J_0(\lambda q)J_0(\rho\lambda q)e^{i\tau\lambda(1-e^{-q})}\right\}, \tag{4}$$

after introducing the new variable $k=q/(4G)$. Here $\Im$ denotes the imaginary part.

A. Asymptotic behavior in ρ: Smearing of light cones

The integral (4) can be written as a standard h-transform,[14] with asymptotic parameter ρ, by the change of variables $t=q\lambda$,

$$\frac{1}{R_1}\Im\left\{\int_0^\infty dt\,J_0(\rho t)J_0(t)e^{i\tau\lambda(1-e^{-t/\lambda})}\right\}. \tag{5}$$

In this case a straightforward Mellin transform analysis[14] (discussed in Sec. III) gives the following asymptotic behavior in the $\rho\to\infty$ limit

$$\begin{aligned}&\frac{1}{R_1}\Im\left\{\frac{1}{\rho}+\frac{1}{\rho^3}\left(\frac{1}{4}+\frac{\tau^2}{2}+\frac{i\tau}{2\lambda}\right)+\frac{9}{\rho^5}\left(\frac{1}{64}-\frac{i\tau}{24\lambda^3}+\frac{i\tau}{8\lambda}+\frac{\tau^2}{8}+\frac{i\tau^2}{4\lambda}-\frac{7\tau^2}{24\lambda^2}+\frac{\tau^4}{24}\right)+O\left[\frac{1}{\rho^7}\right]\right\}\\&\quad=\frac{1}{R_1}\left\{\frac{\tau}{2\lambda\rho^3}+\frac{1}{\rho^5}\left(\frac{9\tau}{8\lambda}-\frac{3\tau}{8\lambda^3}+\frac{9\tau^2}{4\lambda}\right)+O\left[\frac{1}{\rho^7}\right]\right\}.\end{aligned} \tag{6}$$

The asymptotic behavior in the $\rho\to\infty$ limit gives a precise and quantitative description of the smearing of (cylindrically symmetric) light cones because it shows, for example, that for fixed values of R_1 and t_2-t_1 the expectation value of the commutator (over $8iG$) falls off for large values of R_2 as

$$\frac{2G(t_2-t_1)}{R_2^3}+O\left[\frac{1}{R_2^5}\right].$$

This means that even for large spatial separations the scalar field that encodes the gravitational field does not commute with itself.

In the $\rho\to 0^+$ limit, on the other hand, we get

$$\frac{1}{R_1}\Im\left\{\int_0^\infty dt J_0(t)e^{i\tau\lambda(1-e^{-t/\lambda})}\right\}+O(\rho). \tag{7}$$

This shows that the commutator is a continuous function of ρ in $\rho=0$, a fact that will be important in the analysis of the semiclassical limit.

B. Asymptotic behavior in τ: Large quantum gravity effects

The integral in (5) has the convenient form of a h-transform if the asymptotic parameter is chosen to be ρ; however, this is no longer true if the asymptotic parameter is τ (which corresponds to considering large separations in the time coordinates). This introduces some mathematical difficulties in the asymptotic analysis that will be discussed later.

In this case one has to perform separate analyses for $\rho=0$ and $\rho\neq 0$. In $\rho=0$ one finds that the asymptotic behavior when $\tau\to\infty$ is given by

$$\frac{1}{R_1}\left[\frac{\lambda}{2\pi\log\tau}\right]^{1/2}\Im\{e^{i[\pi/4+\tau\lambda-\lambda\log(\tau\lambda)]}e^{(\pi/2)\lambda}\Gamma(i\lambda)+e^{-i[\pi/4-\tau\lambda-\lambda\log(\tau\lambda)]}e^{-(\pi/2)\lambda}\Gamma(-i\lambda)\}$$
$$+O\left[\frac{1}{(\log\tau)^{3/2}}\right], \tag{8}$$

whereas for $\rho\neq 0$ we find

$$\frac{1}{2\pi R_1\sqrt{\rho}\log\tau}\Im\{e^{i[\pi/2+\tau\lambda-\lambda(1+\rho)\log(\tau\lambda)]}e^{(\pi/2)\lambda(1+\rho)}\Gamma[i\lambda(1+\rho)]$$
$$+e^{-i[\pi/2-\tau\lambda-\lambda(1+\rho)\log(\tau\lambda)]}e^{-(\pi/2)\lambda(1+\rho)}\Gamma[-i\lambda(1+\rho)]$$
$$+e^{i[\tau\lambda-\lambda(1-\rho)\log(\tau\lambda)]}e^{(\pi/2)\lambda(1-\rho)}\Gamma[i\lambda(1-\rho)]$$
$$+e^{i[\tau\lambda-\lambda(\rho-1)\log(\tau\lambda)]}e^{(\pi/2)\lambda(\rho-1)}\Gamma[i\lambda(\rho-1)]\}+O\left[\frac{1}{(\log\tau)^2}\right]. \tag{9}$$

The most striking feature of these expressions is the unusual dependence on the asymptotic parameter τ; in fact the dependence on inverse powers of logarithms (especially on the inverse square root of $\log\tau$) cannot be obtained by direct application of the usual asymptotic expressions derived by Mellin transform techniques. It is also remarkable how slowly the commutator decays in τ—in particular in the axis $\rho=0$—a fact that is suggestive of the large quantum gravity effects discussed by Ashtekar in Ref. 4. Outside the axis the decay is quicker but still rather slow. A consequence of the different asymptotic behaviors in τ for $\rho=0$ and $\rho\neq 0$ is the impossibility to recover (8) as the limit when $\rho\to 0$ of (9). It is interesting to point out that the frequency of the oscillations of the commutator in the τ parameter is controlled by the value of λ (proportional to the inverse of G) in such a way that although the amplitude of the oscillations decays very slowly they will average to the value of the free commutator on scales much larger than the Planck length.

The $\tau\to 0$ limit is simpler to analyze. Actually we find that the series obtained by expanding $e^{i\tau\lambda(1-e^{-t/\lambda})}$ as a power series in $e^{-t/\lambda}$, exchanging integration and infinite sum, and computing the resulting integrals gives an expansion that converges to the value of the commutator.

C. Asymptotic behavior in λ: The semiclassical limit

The possibility of studying the asymptotic behaviors in ρ and τ by using the powerful mathematical tools provided by the theory of Mellin transforms relies on the fact that these integrals can be written as h-transforms of the type mentioned above. However, this is no longer possible if one wants to study the limit $\lambda\to\infty$ (corresponding to the situation when R_1 is much larger than the Planck length) because of the particular dependence of these integrals on λ. There is, however, a way out of this if one is willing to abandon Mellin transforms: writing the integral in (4) as a multiple integral by introducing the integral representation of the Bessel functions J_n $(n=0,1,\ldots)$,

$$J_n(z)=\frac{1}{2\pi i}\oint_\gamma \frac{dt}{t^{n+1}}e^{(z/2)(t-1/t)},$$

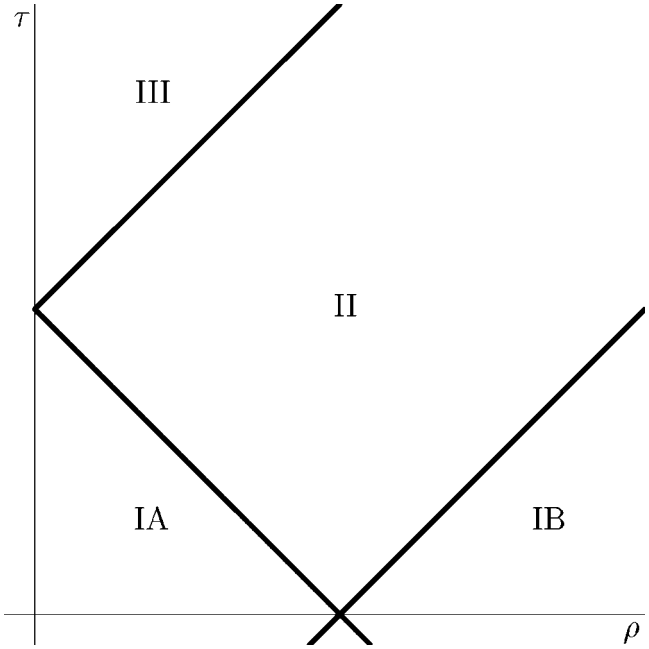

FIG. 1. Regions in the (ρ, τ) plane used in the discussion of the λ asymptotics. Region I corresponds to $0<\tau<|\rho-1|$, region II to $|\rho-1|<\tau<\rho+1$, and region III to $\rho+1<\tau$.

where γ is a closed, positively oriented, simple path in the complex plane surrounding the origin. By doing this the right hand side (r.h.s.) of (4) can be rewritten in the following form:

$$-\frac{1}{R_1}\Im\left\{\frac{\lambda e^{i\tau\lambda}}{4\pi^2}\int_0^\infty dq\oint_{\gamma_1}dt_1\oint_{\gamma_2}dt_2\frac{1}{t_1t_2}e^{\lambda[(q/2)(t_1-1/t_1)+(\rho q/2)(t_2-1/t_2)-i\tau e^{-q}]}\right\}. \tag{10}$$

Although the contours γ_1 and γ_2 may be different in principle we will take them equal in practice. Besides, we will see in the next section that it is convenient to choose them in a specific way.

As in the τ case one has to perform separate asymptotic analyses for $\rho=0$ and $\rho\neq 0$. In order to proceed it is necessary to divide the (ρ, τ) plane into the same regions that appear in the discussion of the ''free'' commutator[6] (3) which corresponds to the evolution dictated by the Hamiltonian H_0 (see Fig. 1).

In $\rho=0$ one finds that the asymptotic behavior when $\lambda\to\infty$ is given by

$$\frac{1}{R_1}\Im\left\{\frac{i}{\sqrt{\tau^2-1}}+\frac{e^{i\lambda[\tau-\log\tau-1]}}{\sqrt{\log\tau}}\right\}+O\left[\frac{1}{\lambda}\right]\quad \tau>1, \tag{11}$$

$$\frac{1}{R_1}\frac{\tau(1+2\tau^2)}{2\lambda(1-\tau^2)^{5/2}}+O\left[\frac{1}{\lambda^2}\right]\qquad \tau<1. \tag{12}$$

If $\rho\neq 0$ the asymptotic behavior in the different regions shown in Fig. 1 is the following: Regions IA and IB

$$\frac{\tau}{2\pi R_1\lambda}\left\{\frac{2[1+\rho^4+2\tau^2-3\tau^4+2\rho^2(\tau^2-1)]\sqrt{(1+\rho)^2-\tau^2}}{(1+\rho-\tau)^2(1-\rho+\tau)^2(-1+\rho+\tau)^2(1+\rho+\tau)^2}E\left(\sqrt{\frac{4\rho}{(1+\rho)^2-\tau^2}}\right)\right.$$

$$\left.-\frac{2\tau^2}{[\rho^4+(\tau^2-1)^2-2(1+\tau^2)\rho^2]\sqrt{(1+\rho)^2-\tau^2}}K\left(\sqrt{\frac{4\rho}{(1+\rho)^2-\tau^2}}\right)\right\}+O\left[\frac{1}{\lambda^2}\right]. \tag{13}$$

Region II

$$\frac{1}{\pi R_1\sqrt{\rho}}K\left(\sqrt{\frac{\tau^2-(\rho-1)^2}{4\rho}}\right)+\frac{1}{R_1}\Im\left\{\frac{e^{-i\,\pi/4}e^{i\lambda[\tau+|\rho-1|(1+\log\tau/|\rho-1|)]}}{\sqrt{2\pi\lambda\rho|1-\rho|}\log\dfrac{\tau}{|1-\rho|}}\right\}+O\left[\frac{1}{\lambda^{3/2}}\right]. \quad (14)$$

Region III

$$\frac{2}{\pi R_1}\frac{1}{\sqrt{\tau^2-(1-\rho)^2}}K\left(\sqrt{\frac{4\rho}{\tau^2-(1-\rho)^2}}\right)+\frac{1}{R_1}\Im\left\{\frac{e^{-i\,\pi/4}e^{i\lambda[\tau-|\rho-1|(1+\log\tau/|\rho-1|)]}}{\sqrt{2\pi\lambda\rho|1-\rho|}\log\dfrac{\tau}{|1-\rho|}}\right.$$
$$\left.+\frac{e^{i\pi/4}e^{i\lambda[\tau+(\rho+1)(\log(1+\rho/\tau)-1)]}}{\sqrt{2\pi\lambda\rho(1+\rho)}\log\dfrac{\tau}{1+\rho}}\right\}+O\left[\frac{1}{\lambda^{3/2}}\right]. \quad (15)$$

Here $K(k)$ and $E(k)$ denote the complete elliptic integrals of the first and second kind, respectively, defined by

$$K(k)\equiv\int_0^{\pi/2}\frac{d\theta}{\sqrt{1-k^2\sin^2\theta}},\qquad E(k)\equiv\int_0^{\pi/2}d\theta\sqrt{1-k^2\sin^2\theta}.$$

Some comments are in order now. The first is that the λ independent terms in the above expressions correspond to the commutator obtained from the free Hamiltonian H_0 both in the axis and outside the axis. The remaining terms (except when $\rho=0$ and $\tau>1$) are corrections to this free commutator that fall off to zero as $\lambda\to\infty$, and have an additional, non-polynomial dependence in $1/\lambda$. Since the free commutator defines a characteristic light cone structure these terms are responsible for the smearing of the light cones in this model. It is worthwhile pointing out that the asymptotic behavior in λ is different in regions I, II, III, and in the axis—this is the reason that explains the appearance of singularities in the borders between adjacent regions[18]—and it has a nonpolynomial dependence on $1/\lambda$. This kind of behavior cannot possibly appear in an ordinary perturbative QFT where the relevant objects (propagators, Green's functions, and so on) are expanded as power series in the coupling constants. One of the novel features of the approach that we follow in this paper is that by using more sophisticated approximation techniques, and taking advantage of the fact that we have closed explicit expressions for the objects of interest, we are able to extract such nontrivial behaviors. In the axis we notice that for $\tau>1$ there is a λ-independent contribution that corresponds to the free commutator and an oscillating contribution with a frequency that depends on λ (this term is similar to the one obtained in the asymptotic analysis for τ). For large values of λ this term oscillates very fast and averages to zero. For $\tau<1$ we get a correction to the free commutator (which is zero in region I) that goes to zero as $1/\lambda$. Outside the axis we see that the corrections to the free commutator fall-off as $1/\lambda$ in region I—outside the light cone—but only as $1/\sqrt{\lambda}$ (with the additional non-polynomial terms) in regions II and III. The presence of two oscillating terms in region III produces some interference effects that manifest themselves as a checkered pattern in plots of the commutator—especially close to the axis—which suggests a division of space–time into cells of a size governed by the value of the gravitational constant (through λ). These are shown in Fig. 2 where we plot the free commutator over $8iG$ plus the first asymptotic correction, given by the above expressions in each of the regions. For comparison we also display a plot constructed with the power series representation obtained in Ref. 6:

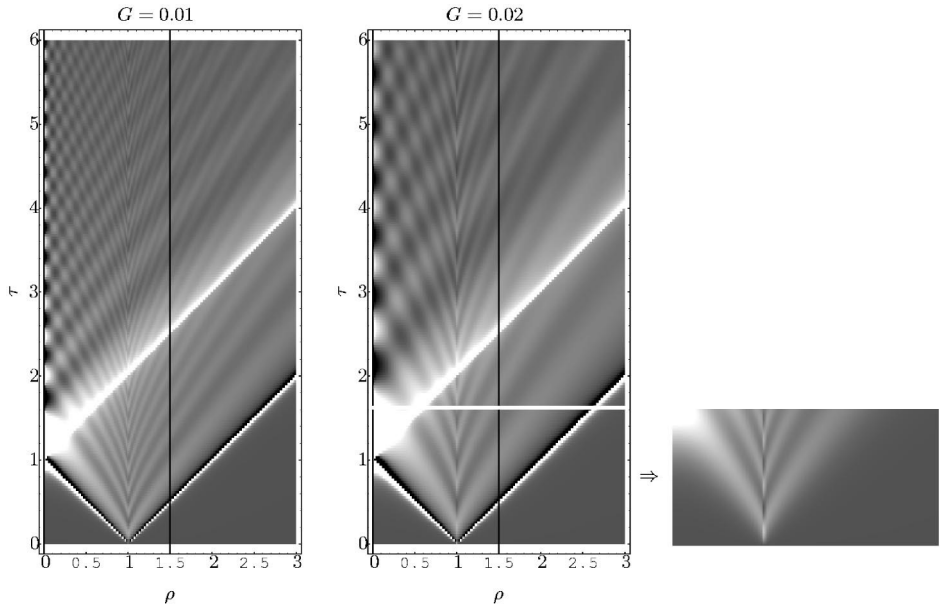

FIG. 2. Density plot of the asymptotic approximation in λ for the field commutator (over $8iG$) as a function of (ρ, τ) for $G=0.01$ and $G=0.02$. Notice the singular behavior of the approximation in the boundaries between the regions I, II, and III, and on the axis. For comparison we show part of the plot for $G=0.02$ obtained with the series expansion (16). Sections of these plots for $\rho=0$ and $\rho=1.5$ with $G=0.02$ are shown in Figs. 3 and 4.

$$\frac{1}{\pi R_1\sqrt{\rho}}\left\{\sin(\lambda\tau)\sum_{n=0}^{\infty}\frac{(-1)^n(\lambda\tau)^{2n}}{(2n)!}Q_{-1/2}[\sigma_{2n}(\rho)]\right.$$
$$\left.-\cos(\lambda\tau)\sum_{n=0}^{\infty}\frac{(-1)^n(\lambda\tau)^{2n+1}}{(2n+1)!}Q_{-1/2}[\sigma_{2n+1}(\rho)]\right\}, \tag{16}$$

where

$$\sigma_n(\rho)=\frac{n^2+\lambda^2(1+\rho^2)}{2\rho\lambda^2},$$

and $Q_{-1/2}(x)=\pi F(3/4,1/4;1;1/x^2)/\sqrt{2x}$ [for $x>1$] is the associated Legendre function of the second kind.[13] As can be seen, the result of the asymptotic approximation matches that obtained with the power series expansion (16).[19] In Figs. 3 and 4 we also plot the commutator as a function of τ for $\rho=0$ and a value of ρ different from zero. It is interesting to point out that, as τ grows, a distinctive beating pattern appears due to the interference of terms in the asymptotic expressions for region III mentioned above.

Comparison with the results of numerical integration confirm the accuracy of the approximation provided by the asymptotic expressions, as long as one is far enough from the boundary between regions. This is shown in Figs. 3 and 4, where we compare the asymptotic approximation with the result obtained by numerically computing the field commutator at $\rho=0$ and $\rho=1.5$.

The limit $\lambda\to 0$ is directly obtained by truncating (16) to the desired number of terms.

III. ASYMPTOTIC ANALYSIS: MATHEMATICAL DETAILS

We discuss in detail here the techniques used to obtain the asymptotic expansions discussed in the previous section. Even though we will be mostly employing standard techniques it is nonetheless necessary to adapt them to the different parameters that appear in the problem, (ρ, τ, λ).

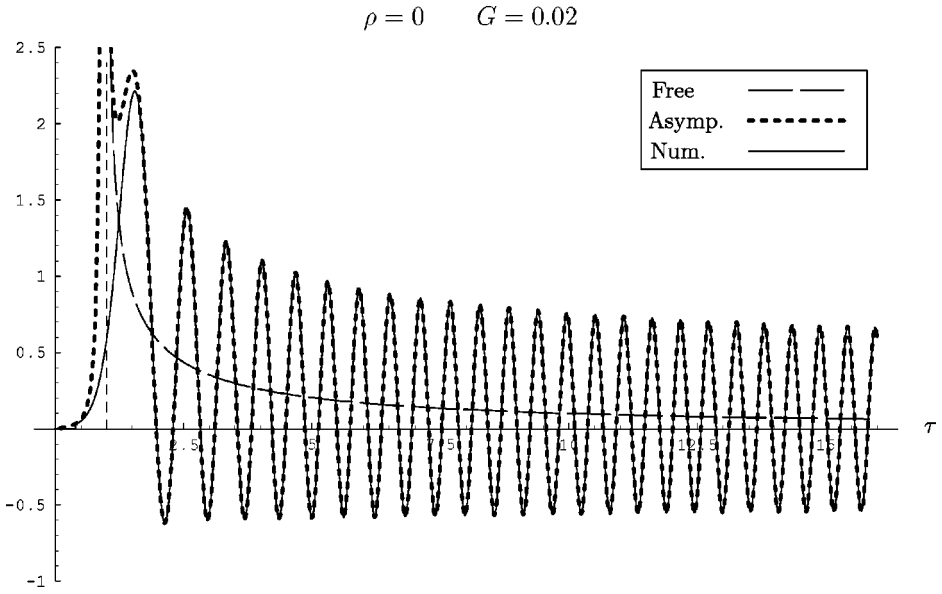

FIG. 3. Asymptotic approximation in λ for the field commutator (over $8iG$) as a function of τ for $\rho=0$ and $G=0.02$. We plot, for comparison, the commutator corresponding to the free Hamiltonian discussed in Ref. 6. The solid line corresponds to a numerical computation of (4). As can be seen the asymptotic approximation is very good for most of the values of τ.

Before studying the asymptotic expansions we present some results on Mellin transforms and explain the basics of their use to obtain the asymptotic behavior of integrals.

Whenever possible it will prove useful to write the integrals under consideration as h-transforms, i.e., objects of the type

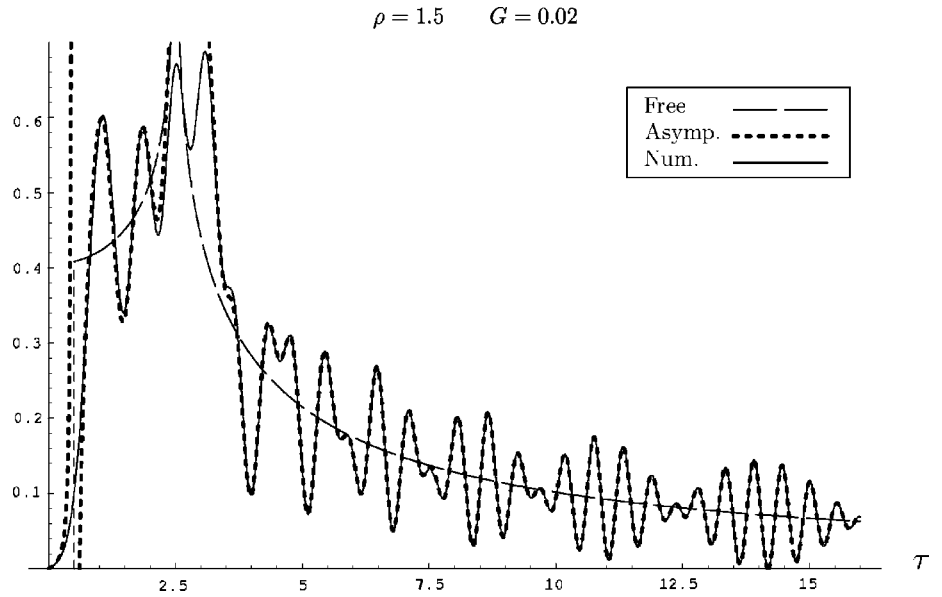

FIG. 4. Asymptotic approximation in λ for the field commutator (over $8iG$) as a function of τ for $\rho=1.5$ and $G=0.02$. We plot, as before, the contribution corresponding to the free Hamiltonian and a numerical computation of the commutator.

$$H[f;\zeta] := \int_0^\infty h(\zeta t) f(t) dt,$$

where ζ is the asymptotic parameter (that in practice approaches either 0 or ∞) and f and h are locally integrable functions in $(0,\infty)$ [functions that are integrable in every closed interval in $(0,\infty)$]. This will allow us, in many cases, to employ standard asymptotic techniques (see, e.g. Ref. 14) based on Mellin transforms[20] that can be summarized in the following.

Theorem: *Let $h:(0,\infty)\mapsto\mathbb{C}$ and $f:(0,\infty)\mapsto\mathbb{C}$ be locally integrable functions. Let us assume that they, respectively, have the following asymptotic expansions when $t\to\infty$ and $t\to 0^+$:*

$$h(t) \sim e^{-dt^\nu} \sum_{m=0}^{\infty} \sum_{n=0}^{N(m)} c_{mn} t^{-r_m} (\log t)^n \tag{17}$$

[$\Re(d)\geqslant 0$, $\nu>0$, $\Re(r_m)$ grows monotonically to ∞, and $N(m)>0$ is a finite integer for each value of m] and

$$f(t) \sim e^{-qt^\mu} \sum_{m=0}^{\infty} \sum_{n=0}^{\bar{N}(m)} p_{mn} t^{a_m} (\log t)^n \tag{18}$$

[$\Re(q)\geqslant 0$, $\mu>0$, $\Re(a_m)$ grows monotonically to ∞ and $\bar{N}(m)>0$ is a finite integer for each value of m].

Let $M[h;z]$ and $M[f;z]$ be the Mellin transforms of h and f (in the generalized sense, see Ref. 14 for details), holomorphic in the strips $\alpha<\Re(z)<\beta$ and $\gamma<\Re(z)<\delta$ that we assume overlapping. Let us suppose also that the Parseval identity holds:[21]

$$H[f;\zeta] = \frac{1}{2\pi i} \int_{r-i\infty}^{r+i\infty} dz\, \zeta^{-z} M[h;z] M[f;1-z] \equiv \frac{1}{2\pi i} \int_{r-i\infty}^{r+i\infty} dz\, \zeta^{-z} G(z), \tag{19}$$

with r in the intersection of the holomorphicity strips. If $\lim_{|y|\to\infty} G(x+iy)=0$ for each $x\in[r,R]$, $(R\in\mathbb{R})$ and $\int_{-\infty}^{\infty} dy |G(R+iy)|$ is finite then

$$H[f;\zeta] \sim -\sum_{r<\Re(z)<R} \operatorname{res}(\zeta^{-z} M[h;z] M[f;1-z]),$$

is a finite asymptotic expansion of $H[f;\zeta]$ as $\zeta\to\infty$ with respect to the asymptotic sequence $\Phi_{j,m}(\zeta)=\{\zeta^{-\alpha_j}(\log\zeta)^{n_j-m}\}$, $m=0,1,\ldots,n$, $j=0,1,\ldots$ with error $O(\zeta^{-R})$. If the previous hypotheses hold for arbitrary values of R we get an asymptotic expansion with an infinite number of terms.

In the following we will only need to consider the case when $d\neq 0$ and $q=0$. The result of the previous theorem can be written as

$$H[f;\zeta] \sim \sum_{m=0}^{\infty} \zeta^{-1-a_m} \sum_{n=0}^{\bar{N}(m)} p_{mn} \sum_{j=0}^{n} \binom{n}{j} (-\log\zeta)^j M^{(n-j)}[h;z]\big|_{z=1+a_m}, \tag{20}$$

with $M^{(k)}[h;z]$ denoting the kth derivative of the Mellin transform with respect to to z.

A. Asymptotic behavior in ρ

We write the integral that gives the field commutator in the form (5) and choose ρ as the asymptotic parameter. In order to apply the previous theorem we need the asymptotic expansion of $f(t)=J_0(t)e^{i\tau\lambda(1-e^{-t/\lambda})}$ as $t\to 0^+$ and the Mellin transform of $h(t)=J_0(t)$. From the first we get $a_k=k$ $(k=0,1,\ldots)$, $p_{00}=1, p_{10}=i\tau$, etc. The Mellin transform of h is given by

$$M[h;z]=\frac{2^{z-1}\Gamma(z/2)}{\Gamma(1-z/2)}.$$

Since $M[h;k]=0$ for even values of k, we get the asymptotic expansion in odd powers of $1/\rho$ given in (6).

In order to obtain the asymptotic expansion of the commutator when $\rho\to 0^+$ we change variables in (5) according to $s=\rho t$,

$$\frac{1}{\rho R_1}\Im\left\{\int_0^\infty ds\, J_0(s)J_0\left(\frac{s}{\rho}\right)e^{i\tau\lambda(1-e^{-s/\rho\lambda})}\right\},$$

take $1/\rho$ as the asymptotic parameter, and switch the roles[14] of f and h [$f(s)=J_0(s)$, $h(s)=J_0(s)e^{i\tau\lambda(1-e^{-s/\lambda})}$]. The Mellin transform of h is given now by

$$M[h;z]=\int_0^\infty dt\, t^{z-1}J_0(t)e^{i\tau\lambda(1-e^{-t/\lambda})},$$

which converges in the strip $0<\Re(z)<3/2$. We do not know any closed expression for this integral but it suffices to obtain the first term of the asymptotic expansion of the commutator when $\rho\to 0^+$. The asymptotic expansion of f gives now $a_k=2k$ $(k=0,1,\ldots)$, $p_{00}=1, p_{10}=-1/4$, etc. and using the theorem we obtain the expansion (7). Under mild restrictions[14] it can be shown that $M[h;z]$ admits an analytic continuation for $\Re(z)\to\infty$ which is meromorphic, at worst, in the complex plane, and that can be used to get further terms of the analytic expansion as $\rho\to 0^+$. Notice, however, that beyond the first term we cannot use the integral representation of the Mellin transform of h given above because the integral becomes divergent for $z=2k$; $k\geqslant 1$. This prevents us from getting further terms in the asymptotic expansion as $\rho\to 0^+$ by using this method.

B. Asymptotic behavior in τ

The integral in (4) is not an h-transform when τ is chosen as the asymptotic parameter but can be written as such by using the change of variables $u=\lambda e^{-t/\lambda}$. This gives

$$\frac{\lambda}{R_1}\Im\left\{e^{i\tau\lambda}\int_0^\lambda du\,\frac{e^{-i\tau u}}{u}J_0\left(\lambda\log\frac{u}{\lambda}\right)J_0\left(\rho\lambda\log\frac{u}{\lambda}\right)\right\}. \tag{21}$$

Even though this integral has now the appropriate form with $f(u)=(1/u)\,\chi_{[0,\lambda]}(u)J_0[\lambda\log(u/\lambda)]J_0[\rho\lambda\log(u/\lambda)]$ and $h(u)=e^{-iu}$, the asymptotic behavior of $f(u)$ as $u\to 0^+$ is not of the type considered in the theorem. This has some unpleasant consequences, the Mellin transform of f cannot be analytically continued as a meromorphic function on $\mathbb{C}$, and we cannot use the expressions given in the theorem for the asymptotic behavior of h-transforms. This forces us to follow a more complicated approach. We will consider the cases $\rho=0$ and $\rho\neq 0$ separately.

1. $\rho=0$

We have to study the integral

$$\frac{\lambda}{R_1}\Im\left\{e^{i\tau\lambda}\int_0^\lambda du\,\frac{e^{-i\tau u}}{u}J_0\left(\lambda\log\frac{u}{\lambda}\right)\right\}, \tag{22}$$

when $\tau\to\infty$. Let us set $h(u)=e^{-i\tau u}$ and $f(u)=\chi_{[0,\lambda]}(u)\,(1/u)\,J_0[\lambda\log(u/\lambda)]$ [remember that h-transforms are defined as integrals over $(0,\infty)$]. The Mellin transforms of these functions are

$$M[h;z]=\tau^{-z}\Gamma(z)e^{-i\pi z/2},$$

convergent in the strip $0<\Re(z)<1$, and

$$M[f;z]=\frac{\lambda^{z-1}}{\sqrt{\lambda^2+(z-1)^2}},$$

which converges in $1<\Re(z)$. Several comments are in order. First we see that the Mellin transform of f cannot be analytically continued as a meromorphic function over the complex plane because of the cuts coming from the square root. If we choose the branch[22] given by $\log(z)=\log|z|+i\arg(z)$ with $\arg(z)\in(-\pi,\pi]$ the cuts are those parts of the imaginary axis with $|z|\geqslant\lambda$. Another comment is that the regions where the Mellin transforms converge do not overlap; this fact precludes us from directly employing the Mellin–Parseval formula (19). The reason can be traced back to the behavior of $h(t)$ as $t\to 0^+$; fortunately this problem can be fixed in a straightforward way. First we rewrite (22) as

$$\frac{\lambda}{R_1}\Im\left\{e^{i\tau\lambda}\int_0^\lambda du\,\frac{(e^{-i\tau u}-1)}{u}J_0\left(\lambda\log\frac{u}{\lambda}\right)\right\}+\frac{i\lambda}{R_1}\Im\left\{e^{i\tau\lambda}\int_0^\lambda du\,\frac{1}{u}J_0\left(\lambda\log\frac{u}{\lambda}\right)\right\}$$
$$=\frac{1}{R_1}\Im\left\{e^{i\tau\lambda}\left[1+\lambda\int_0^\lambda du\,\frac{(e^{-i\tau u}-1)}{u}J_0\left(\lambda\log\frac{u}{\lambda}\right)\right]\right\}.$$

In order to study the last integral, we choose $f(u)$ as above and $h(u)=\chi_{[0,\lambda]}(u)[e^{-i\tau u}-1]$. The Mellin transform of h can be written in terms of confluent hypergeometric functions but one can work with a simpler expression by realizing that, since $f(u)$ is zero if $u>\lambda$, one can replace h with a new function $\tilde{h}$ that differs from it only for $u>\lambda$:

$$\tilde{h}:\mathbb{R}^+\to\mathbb{R}:s\mapsto\begin{cases}e^{-i\tau s}-1 & s\in(0,\lambda)\\ e^{-i\tau s} & s\in[\lambda,\infty).\end{cases}$$

The result is easily seen to be independent of this extension of h. The integral giving the Mellin transform of $\tilde{h}$ converges in the strip $-1<\Re(z)<1$ with $M[\tilde{h};z]=\tau^{-z}\Gamma(z)e^{-i\pi z/2}-\lambda^z/z$. Since we now have overlapping convergence strips we can use the Mellin–Parseval formula and obtain a Mellin–Barnes representation of our integral as

$$\frac{1}{R_1}\Im\left\{e^{i\tau\lambda}\left[1+\frac{\lambda}{2\pi i}\int_{c-i\infty}^{c+i\infty}dz\,\frac{\tau^{-z}\lambda^{-z}\Gamma(z)e^{-i\pi z/2}-1/z}{\sqrt{\lambda^2+z^2}}\right]\right\}$$
$$=\frac{1}{R_1}\Im\left\{e^{i\tau\lambda}\left[1+\frac{\lambda}{2\pi i}\int_{c-i\infty}^{c+i\infty}dz\,\frac{\tau^{-z}\lambda^{-z}\Gamma(z)e^{-i\pi z/2}}{\sqrt{\lambda^2+z^2}}\right]\right\},\qquad(23)$$

with $\Re(c)\in(-1,0)$. We have employed the fact that

$$\int_{c-i\infty}^{c+i\infty}dz\,\frac{dz}{z\sqrt{\lambda^2+z^2}}=0.$$

The analytic continuation of the integrand in the r.h.s. of (23) is immediate. It has algebraic singularities at $z=\pm i\lambda$ (see Fig. 5) with cuts in those points of the imaginary axis where $|z|>\lambda$, and simple poles on $-z\in\mathbb{N}\cup\{0\}$.

In order to study the limit $\tau\to 0^+$ we can displace the integration contour in (23) leftwards parallel to the imaginary axis.[23] A simple analysis using the asymptotics of $\Gamma(z)$ for large values of $\Im(z)$ shows that the series given by the residues of the integrand at the poles $-z\in\mathbb{N}$, namely

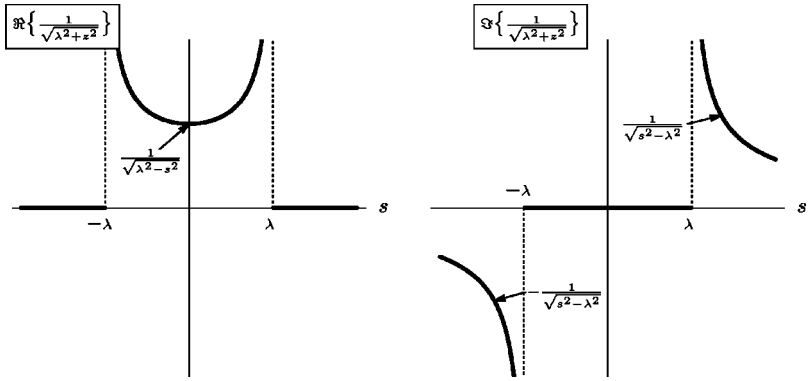

FIG. 5. Real and imaginary parts of $1/\sqrt{\lambda^2+z^2}$ on the curve $z=-0^+ + is$ (corresponding to $\rho=0$). In the vicinity of the singularities at $is=\pm i\lambda$ the real and imaginary parts of this function behave as $1/\sqrt{2\lambda(\lambda\mp s)}$ ($|s|<\lambda$) and $\pm 1/\sqrt{2\lambda(\pm s-\lambda)}$ ($|s|>\lambda$).

$$\frac{\lambda}{R_1}\mathfrak{I}\left\{ e^{i\tau\lambda}\sum_{k=0}^{\infty}\frac{(-i\lambda\tau)^k}{k!\sqrt{\lambda^2+k^2}}\right\},$$

converges to the value of the integral. This is precisely what one would get by expanding the exponential in (22), exchanging sum and integration, and computing the integrals that appear. This was the procedure used in Ref. 6.

It is not possible to directly get the asymptotic behavior in the $\tau\to\infty$ limit by displacing the integration contour rightwards because of the presence of the cut and, even worse, the absence of poles with $\Re(z)\geqslant 0$. One could consider choosing a value for c and write (23) as a real integral in the variable $y\in\mathbb{R}$ after the change $z=c+iy$. In fact, by doing that one obtains the sum of two h-transforms with asymptotic parameter $\log\tau$ that can be studied with the standard formulas. Unfortunately, proceeding in this way one gets a trivial *zero* asymptotic expansion. The reason, as we will find out later on, is that $\log\tau$ is *almost*, but not quite, the right asymptotic parameter.[24]

The solution to our problem is displacing the integration contour all the way to the cut (choosing $c\to 0^-$) as shown in Fig. 6.

The contribution of the arcs Γ_2 and Γ_4 to the integral in the r.h.s. of (23) goes to zero as $-c=\epsilon\to 0^+$. The remaining three contributions to the integral (without prefactors) are

$$\Gamma_1 \qquad -\int_{\lambda}^{\infty} dy\,\frac{e^{-iy\log(\lambda\tau)}e^{\pi y/2}\Gamma(iy)}{\sqrt{y^2-\lambda^2}},$$

$$\Gamma_3 \qquad -\frac{\pi i}{\lambda}+i\,\mathrm{P.V.}\int_{-\lambda}^{\lambda} dy\,\frac{e^{-iy\log(\lambda\tau)}e^{\pi y/2}\Gamma(iy)}{\sqrt{\lambda^2-y^2}},$$

$$\Gamma_5 \qquad \int_{-\infty}^{-\lambda} dy\,\frac{e^{-iy\log(\lambda\tau)}e^{\pi y/2}\Gamma(iy)}{\sqrt{y^2-\lambda^2}}.$$

The asymptotic expansions of these integrals can be obtained by a variety of methods, for example by steepest descents. Nonetheless, it is now possible to employ formula (20) and obtain, in principle, the asymptotics to any order.

The integral over Γ_1 can be written as the following standard h-transform by the change of variables $y=\lambda(1+s)$ with $s\in[0,\infty)$:

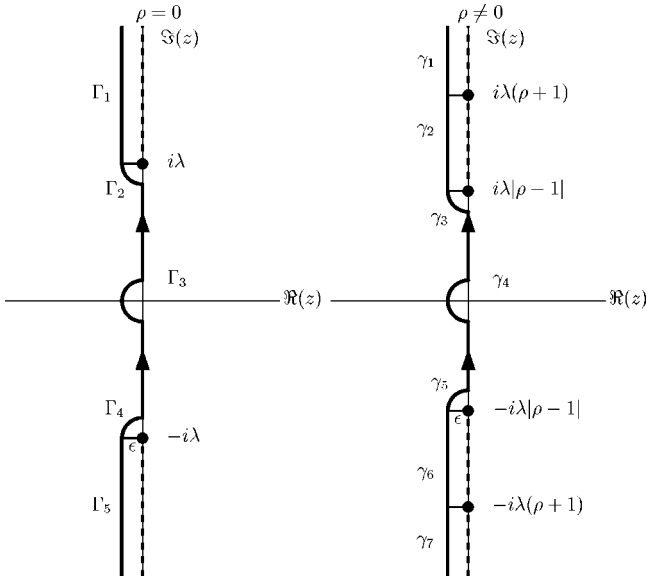

FIG. 6. Cuts and singularities of the integrand and integration contours in the complex plane for the Mellin–Barnes representation used in the asymptotic analysis for $\tau\to\infty$ in the cases $\rho=0$ and $\rho\neq 0$.

$$-e^{-i\lambda\,\log(\lambda\tau)}e^{\pi\lambda/2}\int_0^\infty ds\, e^{-i\lambda s\,\log\tau}\frac{e^{-i\lambda s\,\log\lambda}e^{\pi\lambda s/2}\Gamma[i\lambda(1+s)]}{\sqrt{s(s+2)}}.$$

Taking $h(z)=e^{-i\lambda z}$, $f(z)=e^{-i\lambda z\,\log\lambda}e^{\pi\lambda z/2}\Gamma[i\lambda(1+z)]/\sqrt{z(z+2)}$, and the asymptotic parameter $\log\tau$ we can use formulas (19) and (20). Since the asymptotic behavior of f when $z\to 0^+$ is

$$f(z)\sim\frac{\Gamma(i\lambda)}{\sqrt{2z}}+O(z^{1/2}),$$

and $M[h;z]=\lambda^{-z}e^{-\pi iz/2}\Gamma(z)$, we get for the integral over Γ_1 an asymptotic expansion in powers of $1/\sqrt{\log\tau}$ with a τ oscillating factor $e^{-i\lambda\,\log(\lambda\tau)}$, namely

$$-e^{-i\lambda\,\log(\lambda\tau)+\,\pi\lambda/2\,-\,\pi i/4}\Gamma(i\lambda)\left\{\sqrt{\frac{\pi}{2\lambda\,\log\tau}}+O\left[\frac{1}{(\log\tau)^{3/2}}\right]\right\}.$$

A similar argument can be used to calculate the asymptotic expansion of the integral over Γ_5,

$$e^{i\lambda\,\log(\lambda\tau)-\,\pi\lambda/2\,+\,\pi i/4}\Gamma(-i\lambda)\left\{\sqrt{\frac{\pi}{2\lambda\,\log\tau}}+O\left[\frac{1}{(\log\tau)^{3/2}}\right]\right\}.$$

Finally, to get the asymptotics of the integral over Γ_3 we express it in the form

$$-\frac{\pi i}{\lambda}+i\int_0^\lambda dy\,\cos[y\,\log\tau]\frac{e^{-iy\,\log\lambda}e^{\pi y/2}\Gamma(iy)+e^{iy\,\log\lambda}e^{-\pi y/2}\Gamma(-iy)}{\sqrt{\lambda^2-y^2}}$$

$$-i\int_0^\lambda dy\,\sin[y\,\log\tau]\frac{e^{iy\,\log\lambda}e^{-\pi y/2}\Gamma(-iy)-e^{-iy\,\log\lambda}e^{\pi y/2}\Gamma(iy)}{\sqrt{\lambda^2-y^2}}.$$

By introducing neutralizers, as in Ref. 14, it is possible to show that the critical points for the previous two integrals are 0 and λ. The contributions to the asymptotic expansion from both points

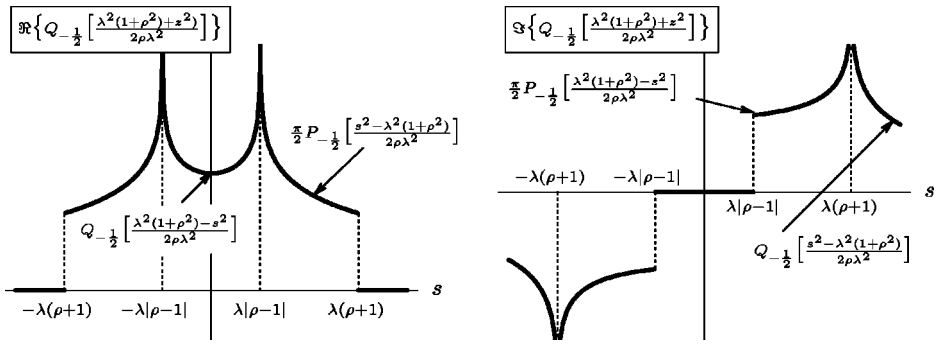

FIG. 7. Real and imaginary parts of $Q_{-1/2}[(\lambda^2(1+\rho^2)+z^2)/(2\rho\lambda^2)]$ on the curve $z=-0^+ +is$ for $\rho\neq 0$.

can be obtained in a straightforward way using formula (20). The contribution from zero is $-\pi i/\lambda$ whereas the one from λ coincides precisely with the sum of the contributions obtained before for Γ_1 and Γ_5. Summing all the terms and substituting the result in (23) we finally get the behavior in τ presented in Sec. II.

It is worth remarking that the asymptotic expansions discussed can be written as an oscillating factor that depends on $\log\tau$ multiplying an expansion in terms of inverse powers of $\sqrt{\log\tau}$. Moreover, note that the frequency of these oscillations is *exactly* that of the oscillating factor that we have already obtained.

2. $\rho\neq 0$

Consider now the integral (21). We set $h(u)=e^{-i\tau u}$ and $f(u)=\chi_{[0,\lambda]}(u)\,(1/u)\,J_0[\lambda\log(u/\lambda)]J_0[\rho\lambda\log(u/\lambda)]$. The Mellin transform of f is

$$M[f;z]=\frac{\lambda^{z-2}}{\pi\sqrt{\rho}}Q_{-1/2}\left[\frac{\lambda^2(1+\rho^2)+(z-1)^2}{2\rho\lambda^2}\right].$$

Proceeding as in the $\rho=0$ case we get the following Mellin–Barnes representation:

$$\frac{1}{\pi R_1\sqrt{\rho}}\Im\left\{e^{i\tau\lambda}\left[Q_{-1/2}\left(\frac{1+\rho^2}{2\rho}\right)+\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}dz\left(\tau^{-z}\lambda^{-z}\Gamma(z)e^{-i\pi z/2}-\frac{1}{z}\right)\right.\right.$$
$$\left.\left.\times Q_{-1/2}\left(\frac{\lambda^2(1+\rho^2)+z^2}{2\rho\lambda^2}\right)\right]\right\}=\frac{1}{\pi R_1\sqrt{\rho}}\Im\left\{e^{i\tau\lambda}\left[Q_{-1/2}\left(\frac{1+\rho^2}{2\rho}\right)\right.\right.$$
$$\left.\left.+\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}dz\;\tau^{-z}\lambda^{-z}e^{-i\pi z/2}\Gamma(z)Q_{-1/2}\left(\frac{\lambda^2(1+\rho^2)+z^2}{2\rho\lambda^2}\right)\right]\right\}. \tag{24}$$

The main difference with the previous case is the appearance of the associated Legendre function $Q_{-1/2}$. This function has cuts on the imaginary axis for $|\Im(z)|\geqslant\lambda|\rho-1|$. On the left of the cut the real and imaginary parts behave as shown in Fig. 7. They become singular in the neighborhood of the four points $z=\pm i\lambda|\rho-1|$ and $z=\pm i\lambda(\rho+1)$. The real functions that describe each of the continuous pieces are shown in the plots. Some of them are given by $Q_{-1/2}(x)$ evaluated on $x>1$. Quite surprisingly, the others can be written in terms of the associated Legendre function $P_{-1/2}$ [$P_{-1/2}(x)=F(1/2,1/2;1;(1-x)/2)$] with argument $x>-1$. The fundamental consequence of this is a change in the singularity structure of the integrand of (24).

The limit $\tau\to 0^+$ can be obtained as we did for $\rho=0$. The result is given by (16).

By displacing the integration contour rightwards to the cut as in the $\rho=0$ case (see Fig. 6) we can split the last integral in (24) into seven different contributions corresponding to the integration curves $\gamma_1,\ldots,\gamma_7$. It is straightforward to show that the contributions from γ_3 and γ_5 go to zero as the contour gets closer to the imaginary axis. We are then left with

$$\gamma_1 \qquad -\int_{\lambda(\rho+1)}^{\infty} dy e^{-iy\log(\lambda\tau)} e^{\pi y/2}\Gamma(iy) Q_{-1/2}\left(\frac{y^2-\lambda^2(1+\rho^2)}{2\rho\lambda^2}\right),$$

$$\gamma_2 \qquad \frac{\pi}{2} i \int_{\lambda|\rho-1|}^{\lambda(\rho+1)} dy e^{-iy\log(\lambda\tau)} e^{\pi y/2}\Gamma(iy)\left[P_{-1/2}\left(\frac{y^2-\lambda^2(1+\rho^2)}{2\rho\lambda^2}\right)+iP_{-1/2}\left(\frac{\lambda^2(1+\rho^2)-y^2}{2\rho\lambda^2}\right)\right],$$

$$\gamma_4 \qquad -i\pi Q_{-1/2}\left(\frac{1+\rho^2}{2\rho}\right)+i\,\mathrm{P.V.}\int_{-\lambda|\rho-1|}^{\lambda|\rho-1|} dy e^{-iy\log(\lambda\tau)} e^{\pi y/2}\Gamma(iy) Q_{-1/2}\left(\frac{\lambda^2(1+\rho^2)-y^2}{2\rho\lambda^2}\right),$$

$$\gamma_6 \qquad \frac{\pi}{2} i \int_{-\lambda(\rho+1)}^{-\lambda|\rho-1|} dy e^{-iy\log(\lambda\tau)} e^{\pi y/2}\Gamma(iy)\left[P_{-1/2}\left(\frac{y^2-\lambda^2(1+\rho^2)}{2\rho\lambda^2}\right)\right.$$
$$\left.-iP_{-1/2}\left(\frac{\lambda^2(1+\rho^2)-y^2}{2\rho\lambda^2}\right)\right],$$

$$\gamma_7 \qquad \int_{-\infty}^{-\lambda(\rho+1)} dy e^{-iy\log(\lambda\tau)} e^{\pi y/2}\Gamma(iy) Q_{-1/2}\left(\frac{y^2-\lambda^2(1+\rho^2)}{2\rho\lambda^2}\right).$$

All these integrals can be written as Fourier transforms whose only critical points are the integration limits. These can be isolated by using the appropriate neutralizers[14] and the integrals so obtained can be written as h-transforms by straightforward changes of variables. An interesting feature of some of the integrals that arise is the fact that the asymptotic expansion of the corresponding f functions involve logarithms precisely in the form assumed in (18). This means that in addition to the p_{m0} coefficients that appeared in the $\rho=0$ case we will have also contributions coming from the p_{mn}'s with $n\neq 0$.

In order to get the asymptotic behavior of the different f functions close to their singularities it is useful to remember the asymptotic expansions of $P_{-1/2}(x)$ and $Q_{-1/2}(x)$ at $x=-1^+$ and $x=1^+$, respectively:

$$P_{-1/2}(x)\sim \frac{5}{\pi}\log 2-\frac{1}{\pi}\log(x+1)+\cdots,$$

$$Q_{-1/2}(x)\sim \frac{5}{2}\log 2-\frac{1}{2}\log(x-1)+\cdots.$$

With the previous guidelines, and following the same steps as in the $\rho=0$ case, it is easy (albeit lengthy) to deduce (9). It is possible to arrive at the same result by different methods that are somewhat simpler (i.e., steepest descents) but they only allow to compute the first contribution to the asymptotic behavior of the field commutator. The advantage of the method employed here is that one can calculate as many terms as desired for the asymptotic expansion just by taking more terms in the asymptotic series of the function f.

C. Asymptotic behavior in λ

We will consider now integrals of the form

$$\int_B^A dq \oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2\, f_{(0)}(q;t_1,t_2) e^{\lambda\Phi(q;t_1,t_2)}, \tag{25}$$

$(0\leqslant B<A)$ where q is a real variable, t_1 and t_2 are complex variables and $\gamma_{1,2}$ are closed paths (possibly different) in the complex plane. The functions $f_{(0)}$ and Φ are supposed to be holomorphic in the two complex arguments and C^n in q (with n possibly infinite) in an open neighborhood of the integration region. In the following we will use the notation $\partial_i \equiv \partial_{t_i}$, $i=1,2$, $\nabla \equiv (\partial_q, \partial_1, \partial_2)$, and $\|\nabla\Phi\|^2 \equiv \eta_q(\partial_q\Phi)^2 + \eta_{t_1}(\partial_1\Phi)^2 + \eta_{t_2}(\partial_2\Phi)^2$, where η_q, η_{t_1}, and η_{t_2} are some functions of q, t_1, and t_2 that will be chosen later in the discussion. This freedom will prove to be useful when we parametrize the curves $\gamma_{1,2}$ because it will allow us to have denominators in the integrand that are real positive functions, facilitating the analysis of the $A\to\infty$ limit. If $\|\nabla\Phi\|^2$ differs from zero for all $q\in[B,A]$, $t_1\in\gamma_1$, and $t_2\in\gamma_2$, it is possible to devise an ''integration by parts'' procedure for this type of integrals by writing them as

$$\frac{1}{\lambda}\int_B^A dq \oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \left[\frac{f_{(0)}\eta_q \partial_q\Phi\,\partial_q e^{\lambda\Phi}}{\|\nabla\Phi\|^2} + \frac{f_{(0)}\eta_{t_1}\partial_1\Phi\,\partial_1 e^{\lambda\Phi}}{\|\nabla\Phi\|^2} + \frac{f_{(0)}\eta_{t_2}\partial_2\Phi\,\partial_2 e^{\lambda\Phi}}{\|\nabla\Phi\|^2} \right].$$

The contribution of the first term can be written, after integrating by parts in q, as

$$\frac{1}{\lambda}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{f_{(0)}\eta_q\partial_q\Phi e^{\lambda\Phi}}{\|\nabla\Phi\|^2}\bigg|_B^A - \frac{1}{\lambda}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \int_B^A dq e^{\lambda\Phi}\partial_q \frac{f_{(0)}\eta_q\partial_q\Phi}{\|\nabla\Phi\|^2}$$

(notice that the integration region is compact and the function integrable so that we can apply Fubini's theorem and freely exchange orders of integration). Integration by parts in t_1 gives

$$\frac{1}{\lambda}\int_B^A dq \oint_{\gamma_2} dt_2 \oint_{\gamma_1} dt_1 \partial_1 \frac{f_{(0)}\eta_{t_1}\partial_1\Phi e^{\lambda\Phi}}{\|\nabla\Phi\|^2} - \frac{1}{\lambda}\int_B^A dq \oint_{\gamma_2} dt_2 \oint_{\gamma_1} dt_1 e^{\lambda\Phi}\partial_1 \frac{f_{(0)}\eta_{t_1}\partial_1\Phi}{\|\nabla\Phi\|^2}.$$

If $(f_{(0)}\eta_{t_1}\partial_1\Phi e^{\lambda\Phi})\|\nabla\Phi\|^{-2}$ is a holomorphic function of t_1 in an open set containing the *closed* curve γ_1 (for all $q\in[B,A]$ and $t_2\in\gamma_2$) the first integral is zero and we are left only with the second term. The same argument applies to the integration in t_2. We finally get that (25) can be written as

$$\frac{1}{\lambda}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{f_{(0)}\eta_q\partial_q\Phi e^{\lambda\Phi}}{\|\nabla\Phi\|^2}\bigg|_B^A - \frac{1}{\lambda}\int_B^A dq \oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2\, f_{(1)}(q;t_1,t_2) e^{\lambda\Phi(q;t_1,t_2)}, \quad (26)$$

here we have introduced the notation

$$f_{(k+1)} \equiv \partial_q \frac{f_{(k)}\eta_q\partial_q\Phi}{\|\nabla\Phi\|^2} + \partial_1 \frac{f_{(k)}\eta_{t_1}\partial_1\Phi}{\|\nabla\Phi\|^2} + \partial_2 \frac{f_{(k)}\eta_{t_2}\partial_2\Phi}{\|\nabla\Phi\|^2}, \quad k=0,1,\ldots .$$

The second integral in (26) has the same structure as the original integral, so the same procedure can be applied as long as the appropriate regularity conditions are satisfied for expressions involving the successive $f_{(k)}$, $k=1,\ldots$ The strategy to obtain asymptotic expansions for the original integral consists in getting expansions for the lower dimensional boundary integrals that arise in this way, provided that the remaining nonboundary integral behaves nicely in the $\lambda\to\infty$ limit. Particularizing this argument to the case of a single complex variable t is straightforward.

In our case [see Eq. (10)] we actually want to obtain an asymptotic expansion of an improper integral. So we will also have to study the asymptotics of the limit $A\to\infty$,

$$-\frac{1}{\lambda}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{f_{(0)}\eta_q\partial_q\Phi e^{\lambda\Phi}}{\|\nabla\Phi\|^2}\bigg|_B + \lim_{A\to\infty}\left\{ \frac{1}{\lambda}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{f_{(0)}\eta_q\partial_q\Phi e^{\lambda\Phi}}{\|\nabla\Phi\|^2}\bigg|_A - \frac{1}{\lambda}\int_B^A dq \oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2\, f_{(1)}(q;t_1,t_2) e^{\lambda\Phi(q;t_1,t_2)} \right\}. \quad (27)$$

In order to derive useful asymptotic expansions from the previous formulas it is desirable that $e^{\lambda\Phi(q;t_1,t_2)}$ be bounded by a λ-independent function.[25] This happens, for example, if $\Re[\Phi(q;t_1,t_2)]\leqslant 0$ in the integration region $[B,A]\times\gamma_1\times\gamma_2$. In fact, we will take advantage of the freedom in the choice of the integration contours $\gamma_{1,2}$ to impose this condition.

If there are points in the integration region (referred to in the following as singular points) where $\|\nabla\Phi\|^2=0$ the argument presented above to derive (26) is no longer true. In such a situation the way to proceed[14,15] is to isolate them by introducing neutralizers.[26] This allows us to divide the integration region into several pieces and study the resulting integrals by choosing the most suitable techniques. This is facilitated by the fact that neutralizers force most of the boundary integrals to be zero. In the process of obtaining asymptotic expansions from (27) it may be useful to further divide the integration region of the last integral in several pieces, by introducing additional neutralizers, in order to localize the singular points in a region that does not contain the boundary $q=A$; this simplifies the analysis of the $A\to\infty$ limit.

The freedom to choose the integration contours in (25) may be useful for other purposes. One can, for example, avoid singularities of the boundary integrals over $\{B\}\times\gamma_1\times\gamma_2$ and $\{A\}\times\gamma_1\times\gamma_2$; it may be possible to write the integrals involving the singular points as (multidimensional) Laplace or Fourier transforms for which the analysis of singular points can be carried out by standard procedures (see Ref. 14) or to improve the behavior for large values of q if one intends to study the asymptotics of the improper integral when $A\to\infty$.[27] Finally in some cases this freedom may allow us to simplify the analysis of the contribution of some of the singular points.

As in the study of the τ asymptotics, we will consider the cases $\rho=0$ and $\rho\neq 0$ separately.

1. $\rho=0$

We study the integral (10) for $\rho=0$:

$$-\frac{1}{R_1}\lim_{A\to\infty}\Im\left\{\frac{i\lambda e^{i\tau\lambda}}{2\pi}\int_0^A dq\oint_\gamma dt\,\frac{1}{t}e^{\lambda[(q/2)(t-1/t)-i\tau e^{-q}]}\right\}. \tag{28}$$

Let us discuss first the possible choices of integration contour γ. As commented above it is convenient to impose that the real part of the exponent in the integrand be less or equal to zero, i.e., $\Re(t-1/t)\leqslant 0$. It is straightforward to show that this happens when $u(u^2+v^2-1)\geqslant 0$ $(t=u+iv)$. This complex region (see Fig. 8) is given by the points inside the unit circle centered at the origin with positive real part, those outside this circle with negative real part, and the boundary of these two regions (i.e., the imaginary axis and the unit circumference centered at the origin). The integration contour can be any closed, positively oriented, simple curve contained in this region that surrounds the origin. Notice that all these contours contain the points $t=\pm i$.

If we choose $\eta_q=-1$ and $\eta_t=t^2$ we have

$$\|\nabla\Phi\|^2=\frac{1}{4}\left[q^2\left(t+\frac{1}{t}\right)^2-\left(t-\frac{1}{t}+2i\tau e^{-q}\right)^2\right].$$

At the left boundary $(q=0)$ this is zero when $t=-i\tau\pm\sqrt{1-\tau^2}$. Depending on the value of τ these points may be on the unit circumference; it is, hence, convenient to choose integration contours in the allowed part of $\mathbb{C}$ that avoid them (see Fig. 8). This will always be possible except for $\tau=1$. When $q\neq 0$ the condition $\|\nabla\Phi\|^2=0$ gives, generically, four possible solutions (depending on q and τ) that may or may not be in the integration region. If $\tau>1$, there is one of these, $(t=-i,\ q=\log\tau)$ that will be in the integration region for every possible choice of the integration contour γ. The remaining ones will or will not belong to the integration region depending on γ. In principle one would proceed by picking a certain contour, determine the values of q corresponding to these points, introduce suitable neutralizers, and study the neutralized integrals one at a time. There is, however, a simple argument that shows that it is not necessary to discuss them in detail (we assume $q\neq 0$ in the following discussion unless otherwise specified).

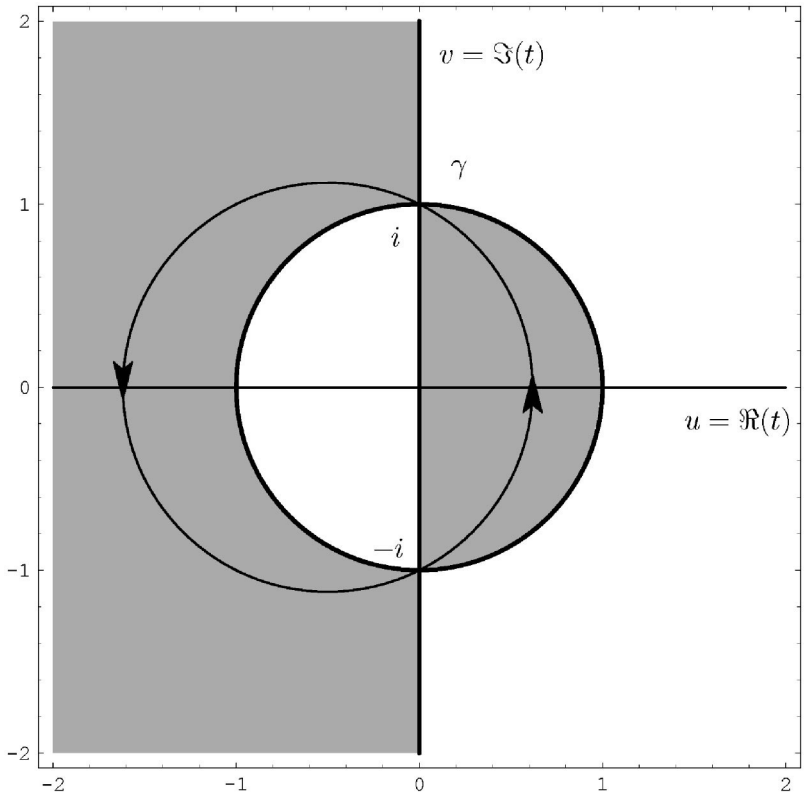

FIG. 8. The region $\Re(t-1/t)\leqslant 0$ consists of the shadowed area and its boundary. A possible choice of the integration contour γ is also shown.

The idea is to write the integral in (28) as the sum of three integrals I_j, $j=1,2,3$ and choose *different*[28] contours for each of them. These integrals are

$$I_j \equiv -\frac{1}{R_1}\Im\left\{\frac{i\lambda e^{i\tau\lambda}}{2\pi}\int_0^A dq \oint_\gamma dt\, \nu_j(q)\frac{1}{t}e^{\lambda[(q/2)(t-1/t)-i\tau e^{-q}]}\right\},$$

where we have introduced three neutralizer functions $\nu_j(q)$, $j=1,2,3$ satisfying $\nu_1+\nu_2+\nu_3=1$ in $[0, A]$ and

$$\nu_1(q)=1 \quad \text{if} \quad q\in[0,\alpha_1],$$

$$\nu_1(q)=0 \quad \text{if} \quad q\in[\alpha_2,A],$$

$$\nu_2(q)=0 \quad \text{if} \quad q\in[0,\alpha_1]\cup[\beta_2,A],$$

$$\nu_2(q)=1 \quad \text{if} \quad q\in[\alpha_2,\beta_1],$$

$$\nu_3(q)=0 \quad \text{if} \quad q\in[0,\beta_1],$$

$$\nu_3(q)=1 \quad \text{if} \quad q\in[\beta_2,A],$$

with $0<\alpha_1<\alpha_2<\beta_1<\beta_2<A$ (the specific choices for these parameters will be explained later). By doing this the effective integration regions in q are $[0,\alpha_2]$, $[\alpha_1,\beta_2]$, and $[\beta_1,A]$, respectively; notice that the boundary $q=0$ appears only in the first.

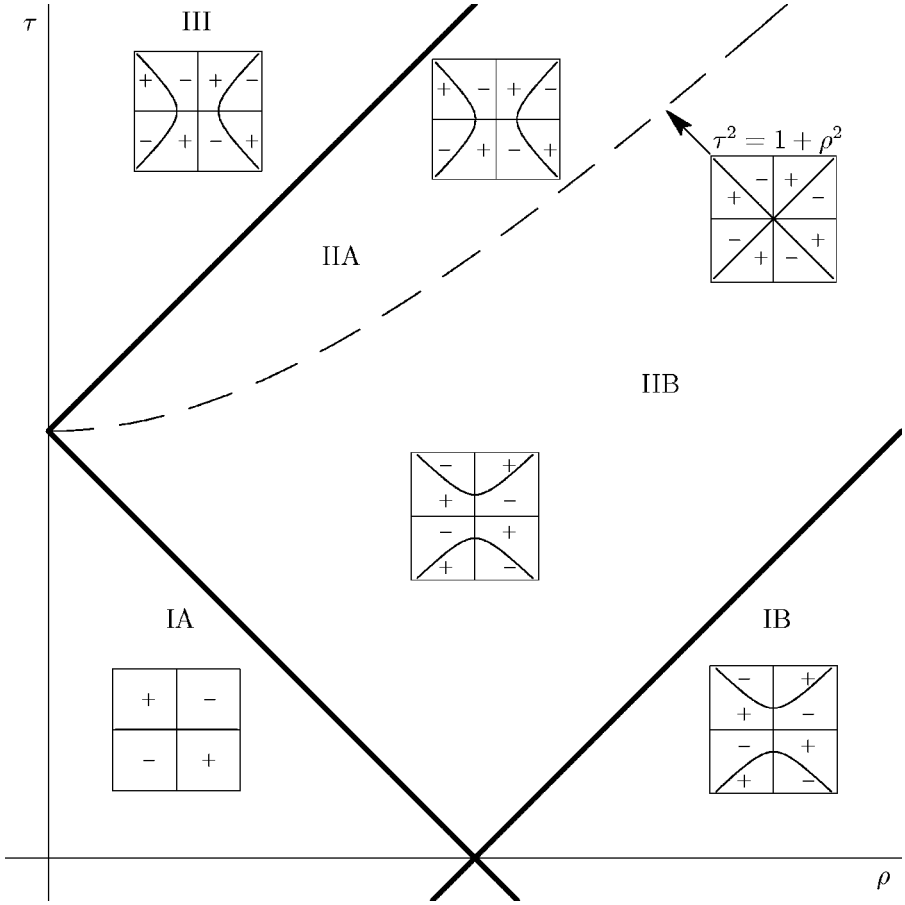

FIG. 9. Sign of $\Re[\sqrt{Q_1(s)Q_2(s)}/(is^2-i)]$ for every choice of ρ and τ. Each inset shows this sign for $s=x+iy\in\mathbb{C}$. The hyperbolas that separate some of the regions in these insets have the equation $x^2-y^2=(1+\rho^2-\tau^2)/[1-(\rho+\tau)^2]$.

Let us consider first I_1. In this case it is convenient to choose an integration contour γ that avoids the unit circumference (except at $t=\pm i$) because, if $\tau<1$, the integration by parts procedure introduced above could, otherwise, give a boundary contribution at $q=0$ involving a singular function. We pick the contour depicted in Fig. 8. In order to use integration by parts it is also necessary to show that it is possible to find α_2 such that $\|\nabla\Phi\|^2\neq 0$ in the integration region. The solutions to $\|\nabla\Phi\|^2=0$ are those satisfying the following quadratic equations

$$(1+q)t^2+2i\tau e^{-q}t-1+q=0,$$

$$(1-q)t^2+2i\tau e^{-q}t-1-q=0.$$

It can easily be shown (by using the implicit function theorem or the explicit solution of these equations in t) that the solutions are continuous at $q=0$ (if $\tau\neq 1$), i.e., the solutions for small enough q are close to $t=-i\tau\pm\sqrt{1-\tau^2}$. If $\tau\neq 1$ it is then possible to choose α_2 and γ in such a way that $\|\nabla\Phi\|^2\neq 0$ in the integration region $\gamma\times[0,\alpha_2]$.

We can use formula (27) to get an asymptotic expansion for I_1. We first note that the term corresponding to the second integral in (26) is $O(1/\lambda)$ because our choice of contour allows us to bound the absolute value of the integrand by a regular function independent of λ. The integral I_1 is then given at leading order by the contribution of the boundary terms which can be written as

$$I_1=\frac{1}{\pi R_1}\Im\left\{ i \oint_\gamma \frac{dt}{t^2+2i\tau t-1}\right\}$$

[the function $\nu_1(q)$ kills the contribution coming from the $q=\alpha_2$ boundary]. If $\tau<1$ the poles of the integrand $t=-i\tau\pm\sqrt{1-\tau^2}$ are on the unit circumference but only that with the negative real part is inside γ. The value of the residue of the integrand at this point is $-1/(2\sqrt{1-\tau^2})$ and hence

$$I_1=\frac{1}{R_1}\Im\left\{\frac{1}{\sqrt{1-\tau^2}}\right\}=0.$$

If $\tau>1$ the poles of the integrand are on the imaginary axis $t=-i\tau\pm i\sqrt{\tau^2-1}$; now only that with the positive sign in the square root is inside γ. The residue is $1/(2i\sqrt{\tau^2-1})$ and hence

$$I_1=\frac{1}{R_1}\Im\left\{\frac{i}{\sqrt{\tau^2-1}}\right\}=\frac{1}{R_1\sqrt{\tau^2-1}}. \tag{29}$$

Consider next I_2. In this case it is convenient to choose the unit circumference for γ because, parametrizing it by an angle ($t(\theta)=e^{i\theta}$, $\theta\in(-\pi,\pi]$), the exponent $\lambda\Phi(q;t)$ becomes a purely imaginary function of the two real variables q and θ,

$$i\lambda\phi(q;\theta)\equiv\lambda\Phi[q;t(\theta)]=i\lambda(q\sin\theta-\tau e^{-q}),$$

and the integral becomes a Fourier transform on a rectangular region determined by the support of the neutralizer. As is well known the critical points for Fourier transforms are given by the boundaries of the integration region and those interior points where the gradient of the *real* function ϕ is zero. In our case the $q=\alpha_1$ and $q=\beta_2$ boundaries give no contribution for this integral owing to the presence of the neutralizer. Let us then find the interior critical points. Since $\|\nabla\Phi\|^2[q;t(\theta)]$ is a sum of squares of real numbers[29] these points are precisely those where our procedure of integration by parts fails. We have to solve the following equations:

$$q\cos\theta=0,$$

$$\sin\theta+\tau e^{-q}=0.$$

The solution is $q=0$, $\theta=-\arcsin\tau$ if $\tau<1$ (these are outside the effective integration region for I_2) and $q=\log\tau$, $\theta=-\pi/2$ if $\tau>1$. The choices of $\alpha_{1,2}$ can be made in such a way that the critical point with $q>0$ (present only when $\tau>1$) always corresponds to I_2 (we also choose β_1 such that $\log\tau<\beta_1$ to avoid having critical points in I_3). The asymptotic expansion of I_2 can be now obtained by using the standard formulas[14] for the contribution of critical points. In our case this is simply

$$\frac{1}{R_1}\Im\left\{\frac{e^{i\lambda(\tau-\log\tau-1)}}{\sqrt{\log\tau}}\right\}+O\left[\frac{1}{\lambda}\right], \tag{30}$$

for $\tau>1$ and 0 if $\tau<1$. We do not need to discuss the limit $A\to\infty$ of I_1 and I_2 because the integrand has compact support independent of A; we have only assumed that $\log\tau<A$. However this is no longer true for I_3.

Let us analyze, finally, $\lim_{A\to\infty} I_3$. We choose again the unit circumference for γ (with the same parametrization) and write

$$\lim_{A\to\infty} I_3 = \Im\left\{ \frac{\lambda e^{i\tau\lambda}}{2\pi R_1} \lim_{A\to\infty} \int_{\beta_1}^{A} dq \int_{-\pi}^{\pi} d\theta\, \nu_3(q) e^{i\lambda\phi(q;\theta)} \right\}.$$

Using formula (27) with $\eta_q = -1$, $\eta_t = t^2$, and taking into account that $\nu_3(\beta_1) = 0$, this expression becomes

$$\Im\left\{ \frac{\lambda e^{i\tau\lambda}}{2\pi R_1} \lim_{A\to\infty}\left[\frac{-i}{\lambda} \int_{-\pi}^{\pi} d\theta \frac{(\tau e^{-A} + \sin\theta) e^{i\lambda\phi(A;\theta)}}{A^2\cos^2\theta + (\tau e^{-A} + \sin\theta)^2} + \frac{i}{\lambda}\int_{\beta_1}^{A} dq \int_{-\pi}^{\pi} d\theta\, \nu_3(q) e^{i\lambda\phi(q;\theta)} g_1(q;\theta) \right] \right\}. \tag{31}$$

Here[30]

$$g_1(q;\theta) \equiv i e^{i\theta} f_{(1)}[q; t(\theta)] = \frac{(\tau e^{-q} + \sin\theta)^2 (\tau e^{-q} - q\sin\theta) + q\cos^2\theta[(q^2-4)\sin\theta - \tau(q+4)e^{-q}]}{[q^2\cos^2\theta + (\tau e^{-q} + \sin\theta)^2]^2}.$$

We have disregarded in Eq. (31) a term containing derivatives of $\nu_3(q)$ because it can be shown to be $O(1/\lambda^R)$ for every $R>0$. We want to show that (31) does not contribute to the asymptotic expansion at the order in λ considered. Note that it is difficult to prove that the limit of the last integral is zero when $\lambda\to\infty$ by using an argument inspired in the Riemann–Lebesgue lemma, because changing variables to write it as a Fourier transform introduces singularities in the integrand that are not easy to deal with. To study the asymptotics of (31) we will follow instead several steps:

(i) Use integration by parts to further decompose the second integral in (31) as a surface term and a double integral in q and θ;
(ii) split each of the integrands obtained in this way in two pieces; one with a simpler denominator and another whose limit $A\to\infty$ vanishes. After this step we will be left with two integrals in q and a double integral;
(iii) split in two the double integral by writing the exponential term as

$$e^{i\lambda\phi(q;\theta)} = e^{i\lambda[q\sin\theta - \tau e^{-q}]} = e^{i\lambda q\sin\theta}(e^{-i\lambda\tau e^{-q}} - 1) + e^{i\lambda q\sin\theta},$$

(iv) show that the contribution coming from $e^{i\lambda q\sin\theta}(e^{-i\lambda\tau e^{-q}} - 1)$ vanishes sufficiently fast when $\lambda\to\infty$ by using the Hölder inequality;
(v) finally, show that the remaining terms have a simple asymptotic behavior.

Step (i): After an additional integration by parts (31) becomes

$$\Im\left\{ \frac{\lambda e^{i\tau\lambda}}{2\pi R_1} \lim_{A\to\infty}\left[-\frac{i e^{-i\lambda\tau e^{-A}}}{\lambda} \int_{-\pi}^{\pi} d\theta \frac{(\tau e^{-A} + \sin\theta) e^{i\lambda A\sin\theta}}{A^2\cos^2\theta + (\tau e^{-A} + \sin\theta)^2} + \frac{e^{-i\lambda\tau e^{-A}}}{\lambda^2} \int_{-\pi}^{\pi} d\theta \frac{(\sin\theta - \tau e^{-A}) e^{i\lambda A\sin\theta}}{A^2\cos^2\theta + (\tau e^{-A} + \sin\theta)^2} g_1(A;\theta) - \frac{1}{\lambda^2}\int_{\beta_1}^{A} dq \int_{-\pi}^{\pi} d\theta \nu_3(q) e^{i\lambda\phi(q;\theta)} g_2(q;\theta) \right] \right\}.$$

Step (ii): All the integrands that appear in the first step have factors of the type

$$\frac{1}{[q^2\cos^2\theta+(\tau e^{-q}+\sin\theta)^2]^N} \quad N=1,2,\ldots$$

that can be written as

$$\frac{1}{[q^2\cos^2\theta+\sin^2\theta]^N}+\frac{\Sigma_{j=1}^{2N}\tau^j e^{-jq}P_j(q,\sin\theta,\cos\theta)}{[q^2\cos^2\theta+(\tau e^{-q}+\sin\theta)^2]^N[q^2\cos^2\theta+\sin^2\theta]^N} \quad N=1,2,\ldots$$

with $P_j(q,\sin\theta,\cos\theta)$ a polynomial of degrees $2(N-1)$, $2(N-1)$, and $2N-1$ in q, $\cos\theta$, and $\sin\theta$ respectively. For fixed values of q larger than a certain $Q>\log\tau$ the maximum of the function $y(\theta)=[q^2\cos^2\theta+(\tau e^{-q}+\sin\theta)^2]^{-1}$ is $(1-\tau e^{-q})^{-2}$, so we have,[31] for $N=1,2,...$,

$$\left|\frac{\Sigma_{j=1}^{2N}\tau^j e^{-jq}P_j(q,\sin\theta,\cos\theta)}{[q^2\cos^2\theta+(\tau e^{-q}+\sin\theta)^2]^N[q^2\cos^2\theta+\sin^2\theta]^N}\right|\leqslant\frac{\Sigma_{j=1}^{2N}\tau^j e^{-jq}\tilde{P}_j(q)}{(1-\tau e^{-q})^{2N}(q^2\cos^2\theta+\sin^2\theta)^N},$$

where $\tilde{P}_j(q)$ is the polynomial in q obtained from $P_j(q,\sin\theta,\cos\theta)$ by taking the absolute value of the coefficients and substituting $\sin\theta=1$, $\cos\theta=1$. This formula, and the fact that

$$\int_{-\pi}^{\pi}d\theta\frac{1}{[A^2\cos^2\theta+\sin^2\theta]^N}\sim 2\frac{\sqrt{\pi}}{A}\frac{\Gamma(N-1/2)}{\Gamma(N)} \quad \text{as } A\to\infty,$$

allows us to show that the first two integrals obtained in step (i) can be substituted by

$$-\frac{i}{\lambda}\int_{-\pi}^{\pi}d\theta\frac{\sin\theta}{A^2\cos^2\theta+\sin^2\theta}e^{i\lambda A\sin\theta}+\frac{1}{\lambda^2}\int_{-\pi}^{\pi}d\theta\frac{A(A^2-4)\sin^2\theta\cos^2\theta-A\sin^4\theta}{[A^2\cos^2\theta+\sin^2\theta]^3}e^{i\lambda A\sin\theta}.$$

Let us consider now the double integral appearing in step (i). The function $g_2(q;\theta)$ can be written as the sum of two pieces $h_2(q;\theta)$ and $G_2(q;\theta)$. The first one is

$$h_2(q;\theta)=\frac{q^4(q^2-4)\cos^6\theta+q^2(40-23q^2+3q^4)\cos^4\theta\sin^2\theta-(4-23q^2+8q^4)\cos^2\theta\sin^4\theta+(q^2-1)\sin^6\theta}{(q^2\cos^2\theta+\sin^2\theta)^4},$$

and $G_2(q;\theta)$ is a sum of factors $(\tau e^{-q})^N$ $(N=1,2,\ldots)$ times quotients of polynomials in q, $\sin\theta$, and $\cos\theta$ divided by products of powers of $[q^2\cos^2\theta+\sin^2\theta]$ and $[q^2\cos^2\theta+(\tau e^{-q}\sin\theta)^2]$ (notice that these functions never vanish in the integration region). The integral becomes

$$-\frac{1}{\lambda^2}\int_{\beta_1}^{A}dq\int_{-\pi}^{\pi}d\theta\,\nu_3(q)e^{i\lambda\phi(q;\theta)}[h_2(q;\theta)+G_2(q;\theta)].$$

The absolute value of the integrand involving $G_2(q;\theta)$ is an integrable function owing to the decreasing exponential factors and the fact that they multiply terms that grow polynomially at worst in q. Hence its contribution to the total integral is $O(1/\lambda^2)$ even after taking the limit $A\to\infty$. We thus conclude that (31) behaves asymptotically as

$$\Im\Bigg\{\frac{\lambda e^{i\tau\lambda}}{2\pi R_1}\lim_{A\to\infty}\Bigg[-\frac{i}{\lambda}\int_{-\pi}^{\pi}d\theta\frac{\sin\theta}{A^2\cos^2\theta+\sin^2\theta}e^{i\lambda A\sin\theta}$$
$$+\frac{1}{\lambda^2}\int_{-\pi}^{\pi}d\theta\frac{A(A^2-4)\sin^2\theta\cos^2\theta-A\sin^4\theta}{[A^2\cos^2\theta+\sin^2\theta]^3}e^{i\lambda A\sin\theta}$$
$$-\frac{1}{\lambda^2}\int_{\beta_1}^{A}dq\int_{-\pi}^{\pi}d\theta e^{i\lambda\phi(q;\theta)}\nu_3(q)h_2(q;\theta)\Bigg]\Bigg\}+O\left[\frac{1}{\lambda}\right]. \tag{32}$$

Step (iii): Note that we have already managed to substitute the exponential factor $e^{i\lambda\phi(A;\theta)}$ by $e^{i\lambda\sin\theta}$ within the integrals over θ. However, it is not possible to remove the function $\phi(q,\theta)$ from the double integral. We instead proceed to rewrite it as

$$-\frac{1}{\lambda^2}\int_{\beta_1}^{A}dq\int_{-\pi}^{\pi}d\theta e^{i\lambda q\sin\theta}[e^{-i\lambda\tau e^{-q}}-1]\nu_3(q)h_2(q;\theta)$$
$$-\frac{1}{\lambda^2}\int_{\beta_1}^{A}dq\int_{-\pi}^{\pi}d\theta e^{i\lambda q\sin\theta}\nu_3(q)h_2(q;\theta).$$

Step (iv): Consider the first of these integrals in the limit $A\to\infty$,

$$-\frac{1}{\lambda^2}\int_{\beta_1}^{\infty}dq\int_{-\pi}^{\pi}d\theta e^{i\lambda q\sin\theta}[e^{-i\lambda\tau e^{-q}}-1]\nu_3(q)h_2(q;\theta). \tag{33}$$

This integral converges because $(e^{-i\lambda\tau e^{-q}}-1)$ falls off exponentially as $q\to\infty$. Let us define now the functions $f(q,\theta)=q^{\sigma}(e^{-i\lambda\tau e^{-q}}-1)$ and $g(q,\theta)=q^{-\sigma}e^{i\lambda q\sin\theta}\nu_3(q)h_2(q;\theta)$ with σ chosen so that $f,g\in L^2([\beta_1,\infty)\times[-\pi,\pi))$. For example, we set $\sigma=3$. The Hölder inequality gives

$$\left|\frac{1}{\lambda^2}\int_{\beta_1}^{\infty}dq\int_{-\pi}^{\pi}d\theta e^{i\lambda q\sin\theta}[e^{-i\lambda\tau e^{-q}}-1]\nu_3(q)h_2(q;\theta)\right|$$
$$\leqslant\frac{1}{\lambda^2}\int_{\beta_1}^{\infty}dq\int_{-\pi}^{\pi}d\theta|f(q,\theta)g(q,\theta)|$$
$$\leqslant\frac{1}{\lambda^2}\left\{\int_{\beta_1}^{\infty}dq\int_{-\pi}^{\pi}d\theta|f(q,\theta)|^2\right\}^{1/2}\left\{\int_{\beta_1}^{\infty}dq\int_{-\pi}^{\pi}d\theta|g(q,\theta)|^2\right\}^{1/2}.$$

The integral involving $|g(q,\theta)|^2$ is convergent and independent of λ and the one involving $|f(q,\theta)|^2$ satisfies

$$\left\{\int_{\beta_1}^{\infty}dq\int_{-\pi}^{\pi}d\theta\left|f(q,\theta)\right|^2\right\}^{1/2}\leqslant 2\sqrt{2\pi}\left\{\int_0^{\infty}dqq^6\sin^2\left(\frac{\tau\lambda}{2}e^{-q}\right)\right\}^{1/2}$$
$$=2\sqrt{2\pi}\left\{\int_0^1 dt\frac{1}{t}(\log t)^6\sin^2(\Lambda t)\right\}^{1/2},$$

after changing variables ($t=e^{-q}$) and defining $\Lambda=\tau\lambda/2$. As we show in Appendix A this last integral is $O(\log^7\lambda)$ and, hence, the term (33) is $O(\log^{7/2}\lambda/\lambda^2)$. So in expression (32) we obtain

$$\Im\Bigg\{\frac{\lambda e^{i\tau\lambda}}{2\pi R_1}\lim_{A\to\infty}\Bigg[-\frac{i}{\lambda}\int_{-\pi}^{\pi}d\theta\frac{\sin\theta}{A^2\cos^2\theta+\sin^2\theta}e^{i\lambda A\sin\theta}$$
$$+\frac{1}{\lambda^2}\int_{-\pi}^{\pi}d\theta\frac{A(A^2-4)\sin^2\theta\cos^2\theta-A\sin^4\theta}{[A^2\cos^2\theta+\sin^2\theta]^3}e^{i\lambda A\sin\theta}$$
$$-\frac{1}{\lambda^2}\int_{\beta_1}^{A}dq\int_{-\pi}^{\pi}d\theta e^{i\lambda q\sin\theta}\nu_3(q)h_2(q;\theta)\Bigg]\Bigg\}+O\left[\frac{1}{\lambda}\right]+O\left[\frac{\log^{7/2}\lambda}{\lambda}\right]. \tag{34}$$

The reason why we had to integrate by parts in the first step is to get an additional factor of λ dividing the powers of $\log\lambda$.

Step (v): Using integration by parts twice one can check that the terms in the square brackets in (34) can be written when $A\to\infty$ as

$$2\pi\lim_{A\to\infty}\int_{\beta_1}^{A}dq\,\nu_3(q)J_0(\lambda q)=\lim_{A\to\infty}\int_{\beta_1}^{A}dq\int_{-\pi}^{\pi}d\theta\,\nu_3(q)e^{i\lambda q\sin\theta}, \tag{35}$$

plus an extra contribution coming from derivatives of $\nu_3(q)$ that does not contribute at this asymptotic order. In Appendix B we show that (35) is $O(1/\lambda^R)$ for all $R>0$. We, therefore, conclude that (31) is $O(\log^{7/2}\lambda/\lambda)$. In our proof we have used integration by parts twice to arrive at (34). Actually by using it repeatedly and applying the five-steps procedure explained above it is possible to argue that $\lim_{A\to\infty}I_3$ is, in fact, $O(1/\lambda^R)$ for all $R>0$.

We hence conclude that the first terms in the asymptotic expansion of (28) are given by the contributions (29) and (30), and therefore, by (11) when $\tau>1$. In order to get the first nonzero term in the asymptotics for $\tau<1$ it is necessary to perform integration by parts twice and follow the steps detailed above. This leads to the contribution for $\tau<1$ shown in (12),

$$-\frac{1}{2\pi R_1}\Im\left\{\frac{i}{\lambda}\oint_{\gamma}dt\frac{8i\tau t^2}{(t^2+2i\tau t-1)^3}\right\}=\frac{1}{R_1}\frac{\tau(1+2\tau^2)}{2\lambda(1-\tau^2)^{5/2}}.$$

The $\lambda\to0^+$ limit, on the other hand, can be obtained by using Taylor's theorem to write

$$e^{-i\tau\lambda e^{-t/\lambda}}=\sum_{k=0}^{N}\frac{(-i\tau\lambda)^k}{k!}e^{-kt/\lambda}+\frac{(-i\tau\lambda)^{(N+1)}}{(N+1)!}e^{-i\xi(t)}e^{-(N+1/\lambda)t},$$

with $0<\xi(t)<\tau\lambda e^{-t/\lambda}$. Substituting this in (5) (with $\rho=0$) we get

$$\frac{1}{R_1}\Im\left\{e^{i\tau\lambda}\int_0^{\infty}dtJ_0(t)\left[\sum_{k=0}^{N}\frac{(-i\tau\lambda)^k}{k!}e^{-kt/\lambda}+\frac{(-i\tau\lambda)^{(N+1)}}{(N+1)!}e^{-i\xi(t)}e^{-(N+1/\lambda)t}\right]\right\}.$$

The contribution of the last term can be easily bounded

$$\left|\frac{e^{i\tau\lambda}(-i\tau\lambda)^{N+1}}{(N+1)!}\int_0^{\infty}dt\,J_0(t)e^{-i\xi(t)}e^{-(N+1/\lambda)t}\right|\leqslant\frac{(\tau\lambda)^{N+1}}{(N+1)!}\int_0^{\infty}dt\,e^{-(N+1/\lambda)t}=\frac{\tau^{N+1}\lambda^{N+2}}{(N+1)(N+1)!}$$
$$=O(\lambda^{N+2}).$$

So we find that the asymptotics of (5) in this limit is given by

$$\frac{\lambda}{R_1}\Im\left\{e^{i\tau\lambda}\sum_{k=0}^{N}\frac{(-i\tau\lambda)^k}{k!\sqrt{k^2+\lambda^2}}\right\}+O(\lambda^{N+2}).$$

2. $\rho \neq 0$

We study now the integral (10) for $\rho \neq 0$. We will basically follow the same steps of the $\rho = 0$ case so we will skip some details. We choose $\eta_q = -1$, $\eta_{t_1} = t_1^2$, and $\eta_{t_2} = t_2^2$, obtaining

$$\|\nabla\Phi\|^2 = \frac{1}{4}\left\{ q^2\left[\left(t_1 + \frac{1}{t_2}\right)^2 + \rho^2\left(t_2 + \frac{1}{t_2}\right)^2\right] - \left[t_1 - \frac{1}{t_1} + \rho\left(t_2 - \frac{1}{t_2}\right) + 2i\tau e^{-q}\right]^2\right\}.$$

As we did above we introduce neutralizers ν_j, $j = 1, 2, 3$ and write (10) as a sum of the tree integrals

$$I_j \equiv -\frac{1}{R_1}\Im\left\{ \frac{\lambda e^{i\tau\lambda}}{4\pi^2}\int_0^\infty dq \oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{\nu_j(q)}{t_1 t_2} e^{\lambda[(q/2)(t_1 - 1/t_1) + (\rho q/2)(t_2 - 1/t_2) - i\tau e^{-q}]}\right\}.$$

Starting with I_1 we fix $\gamma_{1,2}$ as in Fig. 8. Integrating by parts we find that only the boundary term contributes at leading order. This contribution can be written as

$$\frac{1}{R_1}\Im\left\{ \frac{1}{2\pi^2} \oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{1}{\rho t_1(t_2^2 - 1) + t_2(t_1^2 + 2i\tau t_1 - 1)}\right\}. \tag{36}$$

This integral can be computed exactly (see Appendix C) and, in fact, it is equal to the free commutator given in Ref. 6; in particular it is zero in the regions IA and IB of Fig. 1. This means that we will have to use integration by parts again, as in the $\rho = 0$ case, to get the first significant asymptotic term when $\lambda \to \infty$ for these regions. After doing this we get the double integral

$$-\frac{1}{R_1}\Im\left\{ \frac{2i\tau}{\pi^2\lambda} \oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{t_1^2 t_2^2}{[\rho t_1(t_2^2 - 1) + t_2(t_1^2 + 2i\tau t_1 - 1)]^3}\right\}. \tag{37}$$

It can be easily checked that this reproduces the result obtained above for $\rho = 0$. This integral, in the considered regions outside the light cone, can be written in terms of complete elliptic integrals of the first and second kind, as shown in Appendix D. The result is just the $1/\lambda$ contribution appearing in Eq. (13).

Though it is also possible to compute the integral I_1 in the remaining regions, we will not do so because their contributions are subdominant with respect to those coming from the critical points of I_2.

Consider then I_2 and take as before the unit circumference as the integration path $\gamma_{1,2}$. We parametrize this curve according to $t_1(\theta_1) = e^{i\theta_1}$, $t_2(\theta_2) = e^{i\theta_2}$, $\theta_{1,2} \in (-\pi, \pi]$. Now we have

$$i\lambda\phi(q; \theta_1, \theta_2) \equiv \lambda\Phi[q; t_1(\theta_1), t_2(\theta_2)] = i\lambda[q(\sin\theta_1 + \rho\sin\theta_2) - \tau e^{-q}],$$

so that the critical points are given by the solutions to the equations

$$\sin\theta_1 + \rho\sin\theta_2 + \tau e^{-q} = 0,$$

$$q\cos\theta_1 = 0,$$

$$q\rho\cos\theta_2 = 0.$$

Since we are computing I_2 we are only interested in solutions with $q \neq 0$. Therefore, we must have $\cos\theta_1 = 0$ and $\cos\theta_2 = 0$, i.e. $\theta_1 = \pm\pi/2$ and $\theta_2 = \pm\pi/2$. For $\theta_1 = \theta_2 = \pi/2$, the remaining equation implies $1 + \rho + \tau e^{-q} = 0$, which has no solutions for $q \in \mathbb{R}$. If $\theta_1 = -\theta_2 = \pi/2$ we get $1 - \rho + \tau e^{-q} = 0$; this equation has solutions $q = \log\tau/(\rho - 1)$ in the integration region $q > 0$ only if $\tau > \rho - 1 > 0$. If $\theta_1 = -\theta_2 = -\pi/2$, we must have $-1 + \rho + \tau e^{-q} = 0$, and there exists a critical point $q = \log\tau/(1 - \rho)$ in the integration region only if $\tau > 1 - \rho > 0$. Finally if $\theta_1 = \theta_2 = -\pi/2$ we obtain $-1 - \rho + \tau e^{-q} = 0$, which is solved by $q = \log\tau/(1 + \rho)$; in this case $q > 0$ only when $\tau > 1 + \rho$. As

we see when (τ, ρ) are in the regions IA and IB of Fig. 1 there are no critical points for I_2, if (τ, ρ) is in region II there is only one critical point, and if (τ, ρ) is in region III there are two critical points. The contribution of these critical points to the asymptotics of I_2, that can be obtained with the standard formulas,[14] are the following in regions II and III, respectively:

$$\frac{1}{R_1}\Im\left\{\frac{e^{-i\,\pi/4}e^{i\lambda[\tau+|\rho-1|(1+\log\tau/|\rho-1|)]}}{\sqrt{2\pi\lambda\rho|1-\rho|}\log\dfrac{\tau}{|1-\rho|}}\right\}+O\left[\frac{1}{\lambda^{3/2}}\right],$$

$$\frac{1}{R_1}\Im\left\{\frac{e^{-i\,\pi/4}e^{i\lambda[\tau-|\rho-1|(1+\log\tau/|\rho-1|)]}}{\sqrt{2\pi\lambda\rho|1-\rho|}\log\dfrac{\tau}{|1-\rho|}}+\frac{e^{i\,\pi/4}e^{i\lambda[\tau+(\rho+1)(\log(1+\rho/\tau)-1)]}}{\sqrt{2\pi\lambda\rho(1+\rho)}\log\dfrac{\tau}{1+\rho}}\right\}+O\left[\frac{1}{\lambda^{3/2}}\right].$$

These, together with the contribution of the boundary term, provide (14) and (15).

Finally it is possible to prove that $\lim_{A\to\infty} I_3$ gives no contribution by essentially following the same steps as when $\rho=0$.

It is interesting to comment on the singularities that appear in the borders between the different regions I–III, and the axis $\rho=0$. Their presence is a manifestation of the fact that the asymptotic behavior in λ changes abruptly between adjacent regions. Notice, nonetheless, that the behavior is continuous in the border between the portion of the axis with $\tau<1$ and region IA, where the leading terms of the asymptotic expansion in λ are both $O(1/\lambda)$.

To conclude let us point out that the limit $\lambda\to 0^+$ can be obtained as in the $\rho=0$ case. The result is

$$\frac{1}{\pi R_1\sqrt{\rho}}\Im\left\{e^{i\tau\lambda}\sum_{k=0}^{N}\frac{(-i\tau\lambda)^k}{k!}Q_{-1/2}\left[\frac{\lambda^2(1+\rho^2)+k^2}{2\rho\lambda^2}\right]\right\}+O(\lambda^{N+2}).$$

IV. CONCLUSIONS AND COMMENTS

We have analyzed in detail the issue of microcausality for linearly polarized cylindrical waves by looking at the commutator of the axially symmetric scalar field that encodes the physical degrees of freedom of the system. We have been able to show several interesting effects that appear in the model. The first is a smearing of the cylindrical light cones. This is especially obvious if one studies the behavior of the commutator (divided by $8iG$) at two points with coordinates (t_1,R_1) and (t_2,R_2) when λ (the quotient of R_1 and the Planck length) is large. If R_2 is not too close to the axis one gets, in this limit, the discontinuous, cylindrical light cone structure defined by the free commutator. In particular, outside the region defined by this light cone the commutator is zero and, hence, observables would commute as in ordinary perturbative QFT. If, instead, one looks at the behavior when $R_2=0$ one finds a peculiar behavior as $\lambda\to\infty$; now superimposed to the free contribution, the commutator shows a characteristic oscillating behavior when the variable $\tau=(t_2-t_1)/(4G)$ grows. The frequency of this oscillation is controlled by the value of λ but the amplitude is *independent* of it, and turns out to decrease very slowly with τ in such a way that one recovers the value given by the free commutator only for very large values of τ. Nonetheless, there is a sense in which the free propagator is recovered if one averages over time intervals sufficiently larger than $4G$.

In our study we have had to find the most efficient methods to obtain the relevant asymptotic behaviors. Though this has not required the introduction of completely novel techniques it has been necessary to extend to our situation the usual Mellin transform methods and those employed for the analysis of multiple integrals. We have needed also to take into account that the integrals that define the commutator are, actually, improper.

Several issues are worth discussing in more detail. One is the problem of introducing regulators in the field operators and compare the results with those derived here. Though it is clear that

the approximation provided by the improper integrals considered in this work must be good in certain regimes, at some point the existence of a physical cutoff might manifest itself in the behavior of the field commutator, especially in the asymptotic regimes that we have explored. Another task that can be confronted with the techniques that we have developed here is the computation of other matrix elements for the commutator. It would also be interesting to consider other Green functions and some related objects, such as S matrix elements. We plan to do that in the future.

APPENDIX A: ASYMPTOTICS OF THE INTEGRAL IN STEP (iv)

We want to investigate the asymptotic behavior of $\int_0^1 dt\,[(\log t)^m/t]\sin^2\Lambda t$, $m\in\mathbb{N}$, when $\Lambda\to\infty$. This can be found by a straightforward use of the Mellin–Parseval formula (19) in order to get a Mellin–Barnes representation for the integral. Defining $h(t)=\sin^2 t$ and $f(t)=(\log t)^m/t$ we get the Mellin transforms

$$M[h;z]=-\frac{\Gamma(z)\cos\frac{\pi z}{2}}{2^{1+z}},\quad -2<\Re(z)<0,$$

$$M[f;1-z]=-\frac{\Gamma(m+1)}{z^{m+1}},\quad 1<\Re(z),$$

so that

$$\int_0^1 dt\,\frac{(\log t)^m}{t}\sin^2\Lambda t=\frac{m!}{2\pi i}\int_{c-i\infty}^{c+i\infty}dz\,\Lambda^{-z}\frac{\Gamma(z)\cos\frac{\pi z}{2}}{2^{1+z}z^{m+1}},\qquad c\in(-2,0).$$

The integrand in this last expression can be analytically extended as a meromorphic function to $\mathbb{C}$ with poles in $z=-2n$, $n=0,1,\ldots$. By displacing the integration contour to the right of the pole at $z=0$, we get

$$\int_0^1 dt\,\frac{(\log t)^m}{t}\sin^2\Lambda t=-\operatorname{res}\left[\Lambda^{-z}\frac{m!\Gamma(z)\cos\frac{\pi z}{2}}{2^{1+z}z^{m+1}},z=0\right]+\frac{m!}{2\pi i}\int_{x_0-i\infty}^{x_0+i\infty}dz\,\Lambda^{-z}\frac{\Gamma(z)\cos\frac{\pi z}{2}}{2^{1+z}z^{m+1}}\tag{A1}$$

($x_0>0$) whenever the integral converges and provided we can neglect the contributions from the segments needed to close the integration contour at large values of $\Im(z)$. Writing $z=x_0+iy$ we have

$$\left|\frac{m!}{2\pi i}\int_{x_0-i\infty}^{x_0+i\infty}dz\,\Lambda^{-z}\frac{\Gamma(z)\cos\frac{\pi z}{2}}{2^{1+z}z^{m+1}}\right|\leqslant\frac{m!}{4\pi(2\Lambda)^{x_0}}\int_{-\infty}^{\infty}dy\left|\frac{\Gamma(x_0+iy)\cos\frac{\pi}{2}(x_0+iy)}{(x_0+iy)^{m+1}}\right|,$$

and using $\lim_{|y|\to\infty}(1/\sqrt{2\pi})\,|\Gamma(x+iy)|e^{\pi|y|/2}|y|^{-x+1/2}=1$ we find that

$$\left|\frac{\Gamma(x_0+iy)\cos\frac{\pi}{2}(x_0+iy)}{(x_0+iy)^{m+1}}\right| \sim \sqrt{\frac{\pi}{2}}|y|^{x_0-m-3/2}.$$

Hence, the integral in (38) is absolutely convergent if $x_0<m+1/2$ and its contribution is $O[1/\Lambda^{x_0}]$. It is straightforward to show that the residue at the pole $z=0$ is an $m+1$ degree polynomial in $\log\Lambda$ with the higher degree term given by $[(-1)^{m+1}/(2m+2)](\log\Lambda)^{m+1}$. This proves that, for $m\in\mathbb{N}$,

$$\int_0^1 dt\,\frac{(\log t)^m}{t}\sin^2\Lambda t = O[(\log\Lambda)^{(m+1)}].$$

APPENDIX B: ASYMPTOTICS OF THE INTEGRAL IN STEP (v)

Let us analyze the asymptotic behavior of $2\pi\int_{\beta_1}^{\infty}dq\;\nu_3(q)J_0(\lambda q)$ when $\lambda\to\infty$. After changing variables according to $k=\lambda q$ this integral becomes

$$\frac{2\pi}{\lambda}\int_{\lambda\beta_1}^{\infty}dk\;\nu_3\left(\frac{k}{\lambda}\right)J_0(k).$$

Taking into account that $J_0(k)=[-(1/k)(d\ /dk)-d^2/dk^2]J_0(k)$, this can be written as

$$\frac{2\pi}{\lambda}\int_{\lambda\beta_1}^{\infty}dk\;\nu_3\left(\frac{k}{\lambda}\right)\left[-\frac{1}{k}\frac{d}{dk}-\frac{d^2}{dk^2}\right]^N J_0(k),$$

with $N\in\mathbb{N}$. It is straightforward to prove by induction that

$$\left[-\frac{1}{k}\frac{d}{dk}-\frac{d^2}{dk^2}\right]^N=\sum_{j=1}^{2N}\frac{a_j}{k^{2N-j}}\frac{d^j}{dk^j},$$

for certain coefficients $a_j\in\mathbb{Z}$. Since all the derivatives of $(1/k^{2N-j})\,\nu_3(k/\lambda)$ at $k=\lambda\beta_1$ cancel, by integrating by parts j times and changing variables according to $k=q\lambda$ we obtain for our integral the following expression:

$$\frac{2\pi}{\lambda}\sum_{j=1}^{2N}(-1)^j a_j\int_{\lambda\beta_1}^{\infty}dk\,\frac{d^j}{dk^j}\left[\frac{1}{k^{2N-j}}\nu_3\left(\frac{k}{\lambda}\right)\right]J_0(k)=\frac{2\pi}{\lambda^{2N}}\sum_{j=1}^{2N}(-1)^j a_j\int_{\beta_1}^{\infty}dq\,\frac{d^j}{dq^j}\left[\frac{\nu_3(q)}{q^{2N-j}}\right]J_0(\lambda q).$$

Using that $J_0(x)\leqslant 1$ for all $x\in\mathbb{R}$, we hence get

$$\left|\frac{2\pi}{\lambda}\int_{\lambda\beta_1}^{\infty}dk\;\nu_3\left(\frac{k}{\lambda}\right)J_0(k)\right|\leqslant\frac{2\pi}{\lambda^{2N}}\sum_{j=1}^{2N}|a_j|\int_{\beta_1}^{\infty}dq\left|\frac{d^j}{dq^j}\left[\frac{\nu_3(q)}{q^{2N-j}}\right]\right|,$$

with all the integrals in the last sum being convergent. We conclude that, for all $N\in\mathbb{N}$,

$$\frac{2\pi}{\lambda}\int_{\lambda\beta_1}^{\infty}dk\;\nu_3\left(\frac{k}{\lambda}\right)J_0(k)=O\left[\frac{1}{\lambda^{2N}}\right].$$

APPENDIX C: COMPUTATION OF (36)

It is possible to show that choosing $\gamma_{1,2}$ as in Fig. 8 its denominator is always different from zero except for those exceptional values of ρ and τ corresponding to the borders between regions I and II, and II and III. We can use Fubini's theorem and exchange orders of integration. To integrate in t_1 we fix a value of t_2 on γ. The poles of the integrand are

$$t_1^{\pm}=\frac{1}{2t_2}[\rho-\rho t_2^2-2i\pi t_2\pm\sqrt{4t_2^2+(-\rho+\rho t_2^2+2i\pi t_2)^2}].$$

One of them is always inside γ and the other outside. For a fixed value of t_2 we find that t_1^- is inside γ when

$$\Re\left[\frac{1}{t_2}\sqrt{4t_2^2+(-\rho+\rho t_2^2+2i\pi t_2)^2}\right]>0,$$

or in certain exceptional cases when $\Re(t_1^-)=0$. Analogously t_1^+ is inside γ when

$$\Re\left[\frac{1}{t_2}\sqrt{4t_2^2+(-\rho+\rho t_2^2+2i\pi t_2)^2}\right]<0,$$

or, again, in certain exceptional occasions with $\Re(t_1^+)=0$ (in this last case t_1^- is outside γ). The residues at these poles are

$$t_1^+\to\frac{1}{\sqrt{4t_2^2+(-\rho+\rho t_2^2+2i\pi t_2)^2}},$$

$$t_1^-\to\frac{-1}{\sqrt{4t_2^2+(-\rho+\rho t_2^2+2i\pi t_2)^2}},$$

and integrating in t_1, (36) becomes

$$\Im\left\{-\frac{i}{\pi R_1}\oint_\gamma dt\,\frac{\operatorname{sgn}\Re[\sqrt{4t^2+(-\rho+\rho t^2+2i\pi t)^2}/t]}{\sqrt{4t^2+(-\rho+\rho t^2+2i\pi t)^2}}\right\}. \tag{C1}$$

Let us define $A=-1+\rho-\tau$, $B=1+\rho+\tau$, $C=1+\rho-\tau$, and $D=-1+\rho+\tau$. It is not difficult to check that

$$4t^2+(-\rho+\rho t^2+2i\pi t)^2=\tfrac{1}{4}[A(t-i)^2+B(t+i)^2][C(t-i)^2+D(t+i)^2],$$

and, hence, the integral (C1) is

$$\Im\left\{-\frac{2i}{\pi R_1}\oint_\gamma dt\,\frac{\operatorname{sgn}\Re[\sqrt{[A(t-i)^2+B(t+i)^2][C(t-i)^2+D(t+i)^2]}/t]}{\sqrt{[A(t-i)^2+B(t+i)^2][C(t-i)^2+D(t+i)^2]}}\right\}. \tag{C2}$$

In the following we restrict γ to be a positively oriented circumference going through $\pm i$ and parametrize it as $z(\theta)=-a+\sqrt{1+a^2}e^{i\theta}$, with $\theta\in[0,2\pi)$ and $a>0$ a constant. Changing variables according to the Möbius transformation $s(t)=(t+i)/(t-i)$ and denoting $Q_1(s)=A+Bs^2$, $Q_2(s)=C+Ds^2$ we can write (C2) in the form

$$\Im\left\{ -\frac{1}{\pi R_1}\int_{s(\gamma)} ds\, \frac{\operatorname{sgn}\Re\left[\dfrac{s-1}{i(s+1)}\sqrt{\dfrac{Q_1(s)Q_2(s)}{(s-1)^4}}\right]}{(s-1)^2\sqrt{\dfrac{Q_1(s)Q_2(s)}{(s-1)^4}}}\right\}$$

$$=\Im\left\{ -\frac{1}{\pi R_1}\int_{s(\gamma)} ds\, \frac{\operatorname{sgn}\Re\left[\dfrac{\sqrt{Q_1(s)Q_2(s)}}{i(s^2-1)}\right]}{\sqrt{Q_1(s)Q_2(s)}}\right\}\equiv \Im(I), \tag{C3}$$

where $s(\gamma)$–the image of the circumference γ–is a straight line through the origin with slope $-1/a<0$. The sign in the numerator in the last integral, for each $s\in\mathbb{C}$, is shown in Fig. 9 in the different regions in the (ρ,τ) parameter space.

We now proceed to compute the integral I appearing in (C3) for the regions IA, IB, IIA, IIB, and III, and for the hyperbola $\tau^2=\rho^2+1$.

Region IA: Here $A<0$, $B>0$, $C>0$, $D<0$, and the sign in the integrand is positive. We choose $a\to 0$ and parametrize $s(\gamma)$ as $s=\sigma(i-\epsilon)$ $[\sigma\in\mathbb{R},\epsilon\to 0^+]$. We have

$$I=-\frac{i}{\pi R_1}\int_{\mathbb{R}}\frac{d\sigma}{\sqrt{(A-B\sigma^2)(C-D\sigma^2)-i\varepsilon}},$$

with $\varepsilon\to 0^+$. Recalling our choice of branch for the square root, changing variables according to $u=\sqrt{-(B/A)}\sigma$, and noticing that $0<AD/(BC)<1$, this integral can be written as

$$I=\frac{1}{\pi R_1}\frac{1}{\sqrt{BC}}\int_{\mathbb{R}}\frac{du}{\sqrt{(1+u^2)\left(1+\dfrac{AD}{BC}u^2\right)}}=\frac{2}{\pi R_1}\frac{1}{\sqrt{(1+\rho)^2-\tau^2}}K\left(\sqrt{\frac{4\rho}{(1+\rho)^2-\tau^2}}\right). \tag{C4}$$

Region IB: Here $A>0$, $B>0$, $C>0$, $D>0$, and the sign in the integrand is positive. We choose $a\to\infty$ and parametrize $s(\gamma)$ as $s=\sigma(-1+i\epsilon)$ $[\sigma\in\mathbb{R},\epsilon\to 0^+]$. Then

$$I=\frac{i}{\pi R_1}\int_{\mathbb{R}}\frac{d\sigma}{\sqrt{(A+B\sigma^2)(C+D\sigma^2)-i\varepsilon}},$$

with $\varepsilon\to 0^+$. After the change of variables $u=\sqrt{(B/A)}\sigma$ (and since $0<AD/(BC)<1$) this integral becomes exactly (C4).

Region IIA: Here $A<0$, $B>0$, $C>0$, $D>0$, and the sign in the integrand is negative. Letting $a\to 0$ and parametrizing $s(\gamma)$ as $s=\sigma(i-\epsilon)$ $[\sigma\in\mathbb{R},\epsilon\to 0^+]$ we obtain (with $\varepsilon\to 0^+$)

$$I=\frac{i}{\pi R_1}\int_{\mathbb{R}}\frac{d\sigma}{\sqrt{(A-B\sigma^2)(C-D\sigma^2)+i\varepsilon}}.$$

This last integral can be split in two pieces:

$$I=\frac{2}{\pi R_1}\int_0^{\sqrt{C/D}}\frac{d\sigma}{\sqrt{(-A+B\sigma^2)(C-D\sigma^2)}}+\frac{2i}{\pi R_1}\int_{\sqrt{C/D}}^{\infty}\frac{d\sigma}{\sqrt{(A-B\sigma^2)(C-D\sigma^2)}}.$$

We find then [see formulas (3.152-3) and (3.152-6) of Ref. 13]

$$I=\frac{1}{\pi R_1\sqrt{\rho}}K\left(\sqrt{\frac{(1+\rho)^2-\tau^2}{4\rho}}\right)+\frac{i}{\pi R_1\sqrt{\rho}}K\left(\sqrt{\frac{\tau^2-(\rho-1)^2}{4\rho}}\right). \tag{C5}$$

Region IIB: Here $A<0$, $B>0$, $C>0$, $D>0$, and the sign in the integrand is positive. With the choice $a\to\infty$ and the parametrization $s=\sigma(-1+i\epsilon)$ $[\sigma\in\mathbb{R}]$ for $s(\gamma)$ we arrive at

$$I=\frac{1}{\pi R_1}\int_{\mathbb{R}}\frac{d\sigma}{\sqrt{(A+B\sigma^2)(C+D\sigma^2)-i\varepsilon}},$$

with $\varepsilon\to 0^+$. This can be written as

$$I=\frac{2i}{\pi R_1}\int_0^{\sqrt{-A/B}}\frac{d\sigma}{\sqrt{-(A+B\sigma^2)(C+D\sigma^2)}}+\frac{2}{\pi R_1}\int_{\sqrt{-A/B}}^{\infty}\frac{d\sigma}{\sqrt{(A+B\sigma^2)(C+D\sigma^2)}},$$

which gives again (C5).

Boundary between regions IIA and IIB: This is the hyperbola $\tau^2=1+\rho^2$. Parametrizing $s(\gamma)$ as $s=\sigma(i-\epsilon)$ $[\sigma\in\mathbb{R},\epsilon\to 0^+]$ we get

$$I=\frac{i}{\pi R_1}\int_{\mathbb{R}}\frac{d\sigma}{\sqrt{(A-B\sigma^2)(C-D\sigma^2)+i\varepsilon}}$$

(with $\varepsilon\to 0^+$) which reduces to the previous two cases. Substituting $\tau^2=1+\rho^2$ we thus obtain

$$I=\frac{1+i}{\pi R_1\sqrt{\rho}}K\left(\frac{1}{\sqrt{2}}\right)=\frac{1+i}{4\pi R_1\sqrt{\pi\rho}}\left[\Gamma\left(\frac{1}{4}\right)\right]^2.$$

Region III: Here $A<0$, $B>0$, $C<0$, $D>0$, and the sign in the integrand is negative. Letting $a\to 0$ and parametrizing $s(\gamma)$ as $s=\sigma(i-\epsilon)$ $[\sigma\in\mathbb{R},\epsilon\to 0^+]$ we obtain (with $\varepsilon\to 0^+$)

$$I=\frac{i}{\pi R_1}\int_{\mathbb{R}}\frac{d\sigma}{\sqrt{(A-B\sigma^2)(C-D\sigma^2)-i\varepsilon}}.$$

With the change of variables $u=\sqrt{-(D/C)}\sigma$ and noticing that $0<BC/(AD)<1$, this becomes

$$I=\frac{i}{\pi R_1}\frac{1}{\sqrt{-AD}}\int_{\mathbb{R}}\frac{du}{\sqrt{(1+u^2)\left(1+\dfrac{BC}{AD}u^2\right)}}=\frac{2i}{\pi R_1}\frac{1}{\sqrt{\tau^2-(1-\rho)^2}}K\left(\sqrt{\frac{4\rho}{\tau^2-(1-\rho)^2}}\right).$$

APPENDIX D: COMPUTATIONS OF THE DOUBLE INTEGRAL (37)

In order to do this we first integrate in t_1. Fixing t_2 we find that the poles coincide with those of (36). The arguments showing whether they are inside or outside γ are the same as in Appendix C. The residues are now

$$t_1^+\to\frac{t_2^2[\rho^2(t_2^2-1)^2+4i\rho\tau t_2(t_2^2-1)-2(1+2\tau^2)t_2^2]}{[4t_2^2+(-\rho+\rho t_2^2+2i\tau t_2)^2]\sqrt{4t_2^2+(-\rho+\rho t_2^2+2i\tau t_2)^2}},$$

$$t_1^-\to-\frac{t_2^2[\rho^2(t_2^2-1)^2+4i\rho\tau t_2(t_2^2-1)-2(1+2\tau^2)t_2^2]}{[4t_2^2+(-\rho+\rho t_2^2+2i\tau t_2)^2]\sqrt{4t_2^2+(-\rho+\rho t_2^2+2i\tau t_2)^2}}.$$

Integrating in t_1, (37) becomes then

$$\Im\Bigg\{-\frac{4\tau}{\pi R_1\lambda}\times\oint_\gamma dt\,\frac{\operatorname{sgn}\Re\Big[\frac{1}{t}\sqrt{4t^2+(-\rho+\rho t^2+2i\tau t)^2}\Big]\big[\rho^2(t^2-1)^2+4i\rho\tau t(t^2-1)-2(1+2\tau^2)t^2\big]t^2}{\big[4t^2+(-\rho+\rho t^2+2i\tau t)^2\big]^2\sqrt{4t^2+(-\rho+\rho t^2+2i\tau t)^2}}\Bigg\}. \tag{D1}$$

The same Möbius transformation used above allows us to write (D1) as

$$\Im\Bigg\{-\frac{i\tau}{2\pi R_1\lambda}\int_{s(\gamma)}ds\,\operatorname{sgn}\Re\Big[\frac{\sqrt{Q_1(s)Q_2(s)}}{i(s^2-1)}\Big]\times\frac{(s^2-1)^2[2\rho^2(1+s^2)^2+4\rho\tau(s^4-1)+(1+2\tau^2)(s^2-1)^2]}{Q_1^2(s)Q_2^2(s)\sqrt{Q_1(s)Q_2(s)}}\Bigg\}.$$

We compute it only in regions IA and IB, remembering that the sign in the integrand is that shown in Fig. 9.

Region IA: Here $A<0$, $B>0$, $C>0$, $D<0$, and the sign is positive. We choose $a\to 0$ and parametrize $s(\gamma)$ as $s=\sigma(i-\epsilon)$ $[\sigma\in\mathbb{R},\epsilon\to 0^+]$ getting

$$\Im\Bigg\{\frac{i\tau}{2\pi R_1\lambda}\int_{\mathbb{R}}d\sigma\,\frac{(1+\sigma^2)^2[2\rho^2(1-\sigma^2)^2+4\rho\tau(\sigma^4-1)+(1+2\tau^2)(\sigma^2+1)^2]}{(A-B\sigma^2)^2(C-D\sigma^2)^2\sqrt{-(A-B\sigma^2)(C-D\sigma^2)}}\Bigg\}.$$

The integrand consists of a rational function of σ divided by the square root of a fourth degree polynomial and the integration extends over the real axis; hence, it can be written in terms of complete elliptic integrals. The way to proceed now is to perform a partial fraction decomposition of the rational part and write it as a sum of integrals of the four following types

$$\int_{\mathbb{R}}\frac{dx}{\sqrt{(a^2+x^2)(b^2+x^2)^3}},\quad\int_{\mathbb{R}}\frac{dx}{\sqrt{(a^2+x^2)^3(b^2+x^2)}},$$

$$\int_{\mathbb{R}}\frac{dx}{\sqrt{(a^2+x^2)(b^2+x^2)^5}},\quad\int_{\mathbb{R}}\frac{dx}{\sqrt{(a^2+x^2)^5(b^2+x^2)}}.$$

These integrals can be found in Ref. 13 [see Eqs. (3.158-2), (3.158-4), (3.162-4), and (3.162-2) in that reference]. The result is the $1/\lambda$ contribution appearing in Eq. (13).

Region IB: Here $A>0$, $B>0$, $C>0$, $D>0$, and the sign in the integrand is positive. With the choice $a\to 0$ and the parametrization $s=\sigma(-1+i\epsilon)$ $[\sigma\in\mathbb{R},\epsilon\to 0^+]$ we obtain

$$\Im\Bigg\{\frac{i\tau}{2\pi R_1\lambda}\int_{\mathbb{R}}d\sigma\,\frac{(\sigma^2-1)^2[2\rho^2(1+\sigma^2)^2+4\rho\tau(\sigma^4-1)+(1+2\tau^2)(\sigma^2-1)^2]}{(A+B\sigma^2)^2(C+D\sigma^2)^2\sqrt{(A+B\sigma^2)(C+D\sigma^2)}}\Bigg\}.$$

It can be shown that this integral gives again the result found in region IA.

[16] Notice that in this system of units G has dimensions of length.
[17] Throughout the paper improper integrals are understood in the Riemann sense $\int_a^\infty = \lim_{A\to\infty} \int_a^A$.
[18] As shown in Ref. 6 the only real singularity that appears now corresponds to $\rho = 1$.
[19] The very slow convergence of this oscillating series for large values of τ or large values of λ makes it impractical for numerical computations. This is the reason why we only give the lower portion of the plot in Fig. 2.
[20] The Mellin transform of a locally integrable function f in $(0, \infty)$ is given by $\int_0^\infty dt t^{z-1} f(t)$. It is a holomorphic function defined on the strip $\alpha < \Re(z) < \beta$ of the complex plane where the integral is absolutely convergent.
[21] Conditions for this identity to hold can be found in Ref. 14.
[22] We will use this choice throughout the paper.
[23] Formula (20) is obtained, precisely, by displacing the integration contour parallel to the imaginary axis. For functions with the asymptotic behaviors considered in the theorem the only singularities are poles whose residues give the asymptotic expansion.
[24] More precisely, an asymptotic sequence given by inverse powers of $\log \tau$ is appropriate to capture the behavior of our integral in τ.
[25] The asymptotic analysis of multiple integrals is greatly simplified by the identification of the *critical points*, those points that give the dominant contributions. For Laplace or Fourier types of integrals these are easy to identify and, in practice, they are just a finite number of isolated points that can be singled out and studied by using neutralizers.
[26] These are real, positive, $C^\infty(\mathbb{R})$ functions $\nu(q;\alpha_1,\alpha_2;\beta_1,\beta_2)$ satisfying $\nu(q;\alpha_1,\alpha_2;\beta_1,\beta_2) = 0$ if $q \in (-\infty,\alpha_1] \cup [\alpha_2,\infty)$ and $\nu(q;\alpha_1,\alpha_2;\beta_1,\beta_2) = 1$ if $q \in [\beta_1,\beta_2]$ (some of the parameters $\alpha_1,\alpha_2,\beta_1,\beta_2$ may be taken to be infinite). In several variables $q_1,\ldots,q_n$ it is sometimes useful to consider neutralizers that depend only on $\|q\|$.
[27] It is important to point out that the asymptotic behavior of an improper integral over $[0,\infty)$ may be very different from the limit of the asymptotic expansion of the integral over $[0, A]$ when $A \to \infty$.
[28] The reason why we use neutralizers depending only on q is, precisely, to exploit this freedom.
[29] This is no longer true for other choices of γ for which $\|\nabla\Phi\|^2$ is, in general, complex. In these cases $\|\nabla\Phi\|^2$ may be zero even though the partial derivatives of Φ are different from zero.
[30] In the following we will denote $g_k(q;\theta) \equiv i e^{i\theta} f_{(k)}[q;t(\theta)]$, the $i e^{i\theta}$ factor comes from the measure in the integral.
[31] We choose $\beta_1 > Q > \log \tau$ in the neutralizers introduced before.

(Received 11 March 2004; accepted 8 April 2004;
published online 5 August 2004)

The Schrödinger equation, in hyperspherical coordinates, is solved in closed form for a system of three particles on a line, interacting via pair delta functions. This is for the case of equal masses and potential strengths. The interactions are replaced by appropriate boundary conditions. This leads then to requiring the solution of a free-particle Schrödinger equation subject to these boundary conditions. A generalized Kontorovich–Lebedev transformation is used to write this solution as an integral involving a product of Bessel functions and pseudo-Sturmian functions. The coefficient of the product is obtained from a three-term recurrence relation, derived from the boundary condition. The contours of the Kontorovich–Lebedev representation are fixed by the asymptotic conditions. The scattering matrix is then derived from the exact solution of the recurrence relation. The wavefunctions that are obtained are shown to be equivalent to those derived by McGuire. The method can clearly be applied to a larger number of particles and hopefully might be useful for unequal masses and potentials.
[DOI: 10.1063/1.1769613]

I. INTRODUCTION

Three-body systems and processes are of fundamental interest in physics.[1] One of these, with which a number of us have been concerned, is the recombination of three-particles to a dimer plus a free particle, in a many body system forming a Bose–Einstein condensate.[2] The condensate is not the lowest state of the system, but a metastable state. The three-body recombination is the dominant mechanism for cooling and lowering the overall energy of the system.

Experimental and theoretical studies have shown that this recombination rate depends mainly on the two-body scattering length a,[2–6] as the collision energy is low and the interaction is weak—owing to large interparticle distances, and on the bound state energies.

This would suggest that zero-range potentials (ZRP), defined in terms of the scattering length[7]

$$\lim_{r\to 0}\left[\frac{1}{r\psi}\frac{\partial(r\psi)}{\partial r}\right]=-1/a. \tag{1}$$

can be applied to model the interaction between the particles of the condensate. It has been shown by Nielsen and Macek using the hidden crossing technique that the ZRP describes properly the recombination transition in a system of three ^{4}He atoms.[2] Also, Gasaneo and Macek showed that the ZRP gives a quite good representation for the adiabatic potential of the same system.[8] A closed form solution for a system of three-particles interacting via a ZRP has been recently presented by Gasaneo *et al.*[9] The fragmentation process $^4\mathrm{He}_2+{}^4\mathrm{He}\rightarrow{}^4\mathrm{He}+{}^4\mathrm{He}+{}^4\mathrm{He}$ was studied and relatively good agreement was found when compared with the hidden crossing calculations. In the nuclear physics area we just want to mention the study of the $1+2$ elastic scattering of nnp and Λnp systems,[10] in which, besides the scattering length, it is included the effective range and the shape parameter in the boundary conditions. Recently, there has been several applications of the ZRP model in one dimension. The study of ion–atom collision have been done by Burgdörfer[11] and the photo-double ionization processes has been studied by Le Rouzo.[12] The use of one dimensional model to bosons has been considered by Muda and Snider using periodic boundary conditions and to the dynamics of fermions systems by McGuire.[13]

In this paper, we seek to apply our techniques to a famous model: Three particles in one dimension, subject to pair delta–function interactions. For this model, introduced by McGuire,[14] one can obtain exact solutions for the wave functions, the scattering matrix and the binding energies, in the case of particles of identical masses and equally weighted interactions. As such it has been extended to a larger number of particles,[15] using Bethe's Ansatz,[16] and also found to be exceedingly useful when used as a test-bed for the development of a number of different methods (pertubative, Faddeev, hyperspherical adiabatic, etc.).[17]

Here, we note that using ZRP and (1), in three-dimensions, leads to the Thomas effect and the collapse of the three-body ground state.[18] However, in one dimension, an equation similar to (1)—with a not the scattering length—provides boundary conditions which correctly characterizes the wave functions and replace the use of the δ-function interactions, and should, therefore, again give us exact results. One of these, though, is that the recombination rate, for this model, is exactly zero.

In Sec. II we propose a solution, written in integral form, for the free particle Schrödinger equation, written in hyperspherical coordinates. A linear combination of free particle solutions can then be found to satisfy the boundary condition that we alluded to earlier, and thus provide us with the solution of the problem with interaction. The requirement that the wave function satisfy the boundary conditions leads us to one of the important results of this paper, namely that the weight of the free particle solutions, in the integral form, satisfies a recurrence relation similar to that obtained in Refs. 19 and 9.

In Sec. III the method is applied to a particular case in which two of the particles are bound. It is shown that the recurrence relation, defining the coefficient of the free-particle expansion, can be solved in closed form and, thus, the scattering matrix is also obtained in a closed form. This allows us to have a detailed test of our method. In this section it is also shown that the wave function obtained is equivalent to the McGuire plane wave solution, and that our expression for the $\mathcal{S}$ matrix is the matrix obtained by McGuire, in the particular case discussed in this paper. In Sec. IV the relation between the hyperspherical adiabatic approach and the present one is discussed.

In Appendix A, the pseudo-Sturmian functions are derived. In Appendix B, the wave function is written as the symmetric wave plane in cartesian coordinates.

II. EXACT INTEGRAL REPRESENTATION

To begin the study of the three identical–particle system (therefore, with equal masses), consider the center of mass and Jacobi coordinates

$$r=\tfrac{1}{3}(x_1+x_2+x_3),$$

$$\eta=\sqrt{\tfrac{1}{2}}(x_1-x_2), \tag{2}$$

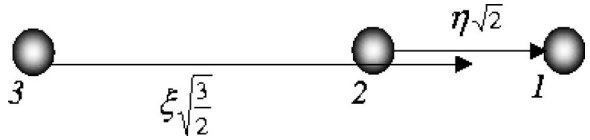

FIG. 1. One of three sets of Jacobi coordinates for the three particles.

$$\xi = \sqrt{\frac{2}{3}}\left(\frac{x_1 + x_2}{2} - x_3\right),$$

the x_i give us the locations of the 3 particles along the line, see Fig. 1. Using polar coordinates, the 2 Jacobi variables allow us to define, in turn, a hyper radius R and an angle θ as

$$\eta = R\cos\theta, \qquad \xi = R\sin\theta, \tag{3}$$

where $-\pi < \theta \leqslant \pi$ and $0 \leqslant R < \infty$. In terms of these coordinates the Schrödinger equation for the "relative" system can be written as

$$H\Psi(R,\theta) = \left(\frac{2m}{\hbar^2}\right) E\Psi(R,\theta), \tag{4}$$

where

$$H = -\left(\frac{1}{R}\frac{\partial}{\partial R}R\frac{\partial}{\partial R} + \frac{1}{R^2}\frac{\partial^2}{\partial\theta^2}\right) + \frac{1}{R}C(\theta). \tag{5}$$

The function $C(\theta)$ is defined by

$$C(\theta) = \frac{\pi}{3}c\sum_{j=0}^{5}\delta(\theta - \theta_j), \tag{6}$$

where the coefficient c equals $(3/\pi\sqrt{2})(2m/\hbar^2)g$, g being the strength of the interactions. This c is negative for attractive interactions and positive for repulsive ones. The angles θ_j equal $(2j+1)\pi/6$. The lines $\theta = \theta_j$ divide the (ρ,θ) plane in six regions. In each region the order of particles is fixed, so that between θ_4 and θ_5, $x_1 < x_2 < x_3$, etc. A different permutation of particles is associated to each region. From now on, we will choose the units such that $2m = 1$ and $\hbar = 1$. In each sector, we now seek a free particle solution that satisfies the boundary condition that will replace the effect of the potential, i.e.,

$$\lim_{\theta^- \to \theta_j}\left[\frac{1}{R\Psi(R,\theta)}\frac{\partial\Psi(R,\theta)}{\partial\theta}\right] = -\frac{1}{a}, \tag{7}$$

where $\theta^- = \theta < \theta_j$, $j = 0,1,\ldots,5$. In Eq. (7) $a = (6/\pi c)$ does not depend on j because all the strengths of the interactions and all the masses are equal. Writing a solution for the free particle system as the product $\psi_{\text{free}}(R,\theta) = \Theta(\nu,\theta)R^{1/2}\mathcal{R}_\nu(\mathrm{K}R)$, where $\mathrm{K}^2 = E$, leads to the set of free particle equations

$$\frac{R^2}{R^{-1/2}Z_\nu(\mathrm{K}R)}\left[\frac{\partial^2}{\partial R^2} + \mathrm{K}^2\right]R^{-1/2}Z_\nu(\mathrm{K}R) = \frac{-1}{\Theta(\nu,\theta)}\left(\frac{\partial^2}{\partial\theta^2} + \frac{1}{4}\right)\Theta(\nu,\theta) = \nu^2 - \frac{1}{4}, \tag{8}$$

where $Z_\nu(\mathrm{K}R) = R^{1/2}\mathcal{R}_\nu(\mathrm{K}R)$ is a Bessel function and ν a separation constant. If for the $\Theta(\nu,\theta)$ functions we choose the pseudo-Sturmian functions $S(\nu,\theta)$, defined, for fixed ν, as the solutions of

$$-\left[\frac{\partial^2}{\partial\theta^2}+\frac{1}{4}-\rho(\nu)C(\theta)\right]S(\nu,\theta)=\left(\nu^2-\frac{1}{4}\right)S(\nu,\theta), \tag{9}$$

then the functions $\psi_{\text{free}}(\theta,R)=S(\nu,\theta)Z_\nu(\mathrm{K}R)$ are solutions of the Schrödinger equation Eq. (4) for values of $\rho(\nu)=R$. Note that Eq. (9) may be replaced by the relation

$$\left[\frac{\partial^2}{\partial\theta^2}+\nu^2\right]S(\nu,\theta)=0, \tag{10}$$

subject to the boundary conditions

$$\lim_{\theta^-\to\theta_j}\left[\frac{1}{\rho(\nu)}\,\frac{1}{S(\nu,\theta)}\,\frac{\partial S}{\partial\theta}(\nu,\theta)\right]=-\frac{1}{a},\quad j=0,1,\ldots,5. \tag{11}$$

In the last equation, we assumed that $S(\nu,\theta)$ is symmetric about each line $\theta=\theta_j$.

We now propose to write the general wave function of the system as a Kontorovich–Lebedev transform, in terms of the base functions just discussed, that is, as

$$\Psi(R,\theta)=\int_{\mathrm{s}} d\nu A(\nu)S(\nu,\theta)Z_\nu(\mathrm{K}R), \tag{12}$$

provided that its derivative satisfies the boundary conditions, i.e., Eq. (7). The contour of integration must be chosen so that the wave function has the correct asymptotic behavior.

Following the reasoning of Gasaneo *et al.*,[8] we will now show that the boundary conditions, Eq. (7), can be transformed into a recurrence relation for $A(\nu)$. First, we substitute Eq. (12) into Eq. (7), and then interchange the order in which the integral and the derivative are taken, to obtain for each j

$$\lim_{\theta^-\to\theta_j}\int_{\mathrm{s}} d\nu A(\nu)\left[\frac{1}{R}Z_\nu(\mathrm{K}R)\,\frac{\partial S(\nu,\theta)}{\partial\theta}+\frac{1}{a}S(\nu,\theta)Z_\nu(\mathrm{K}R)\right]=0. \tag{13}$$

Second, we use Eq. (11) and the identity $(2\nu/z)Z_\nu(z)=Z_{\nu+1}(z)-Z_{\nu-1}(z)$ to transform the equation to

$$\lim_{\theta^-\to\theta_j}\left\{\int_{\mathrm{s}} d\nu A(\nu)\frac{1}{\nu}[-\rho(\nu)/a]S(\nu,\theta)\times[Z_{\nu+1}(KR)-Z_{\nu-1}(KR)]\right.$$
$$\left.+\frac{2}{Ka}\int_{\mathrm{s}} d\nu A(\nu)S(\nu,\theta)Z_\nu(KR)\right\}=0. \tag{14}$$

We assumed in the previous equation that $\mathrm{K}=iK$ and $K\geqslant 0$, because we are mainly interested in negative energies. By selecting the appropriate contours we can now transform the last equation to

$$\lim_{\theta^-\to\theta_j}\int_{\mathrm{s}} d\nu\left[A(\nu-1)\frac{1}{\nu-1}\rho(\nu-1)S(\nu-1,\theta)-A(\nu+1)\frac{1}{\nu+1}\rho(\nu+1)S(\nu+1,\theta)\right.$$
$$\left.-\frac{2}{K}A(\nu)S(\nu,\theta)\right]Z_\nu(KR)=0. \tag{15}$$

Since the set of Bessel functions forms a complete set of basis functions, the function within the square brackets should be zero at the limit. We arrive, finally, at the recurrence relation that we are looking for

$$B(\nu-1)\rho(\nu-1)S(\nu-1,\theta_j)-B(\nu+1)\rho(\nu+1)S(\nu+1,\theta_j)=\frac{2\nu}{K}B(\nu)S(\nu,\theta_j), \tag{16}$$

where $B(\nu)=A(\nu)/\nu$. In the following section, we will apply this approach to a particular case of this three body system and show that we can obtain the wave function and the $\mathcal{S}$-matrix.

III. 2+1 SYSTEM

Consider now the case where two of the particles are bound. The wave function $\psi(R,\theta)$ can still be written in terms of the Kontorovich–Lebedev representation, Eq. (12). The unnormalized angle pseudo-Sturmian function $S(\nu,\theta)$, a six-fold symmetric function, is defined by the Eqs. (10) and (11). As can be seen in Appendix A, the function $S(\nu,\theta)$ may be written as

$$S(\nu,\theta)=\cos\left[\left(\theta-j\frac{\pi}{3}\right)\nu\right], \quad \left|\theta-j\frac{\pi}{3}\right|<\frac{\pi}{6}, \tag{17}$$

with $j=0,1,\ldots,5$, where $\rho(\nu)$ satisfies the relation

$$\nu\tan\left(\nu\frac{\pi}{6}\right)=\frac{1}{(6/\pi c)}\rho(\nu). \tag{18}$$

From the previous section, we can immediately conclude that $A(\nu)$ satisfies the recurrence relation

$$A(\nu+1)\sin\left[(\nu+1)\frac{\pi}{6}\right]-A(\nu-1)\sin\left[(\nu-1)\frac{\pi}{6}\right]=-\frac{\pi c}{3K}A(\nu)\cos\left[\nu\frac{\pi}{6}\right]. \tag{19}$$

A. Solution of the recurrence relation

The recurrence relation, displayed in Eq. (19), can be written as

$$e^{i(\pi/6)\nu}\left[A(\nu+1)e^{i(\pi/6)}-A(\nu-1)e^{-i(\pi/6)}+\frac{i\pi c}{3K}A(\nu)\right]+e^{-i(\pi/6)\nu}\left[-A(\nu+1)e^{-i(\pi/6)}\right.$$
$$\left.+A(\nu-1)e^{i(\pi/6)}+\frac{i\pi c}{3K}A(\nu)\right]=0. \tag{20}$$

An inspection, of the solution of the recurrence relation—Eq. (25) in Ref. 8, leads us to propose a coefficient in the form of the series

$$A(\nu)=e^{-\beta\nu}[e^{-i(\pi/3)\nu}+\mathcal{S}e^{i(\pi/3)\nu}+\mathcal{S}_1e^{-i(\pi/6)\nu}+\mathcal{S}_2e^{i(\pi/6)\nu}+\mathcal{S}_3]. \tag{21}$$

Substituting this expression in Eq. (20), and equating to zero the coefficients of exponentials, with different arguments that depend on ν, we obtain the following values for the parameters:

$$\mathcal{S}=\tan\left(\frac{\pi}{6}-i\beta\right)\cot\left(\frac{\pi}{6}+i\beta\right),$$

$$\mathcal{S}_3=-\cot\frac{\pi}{6}\cot\left(\frac{\pi}{6}+i\beta\right), \tag{22}$$

$$\cos(i\beta)=-\frac{\pi c}{6K},$$

$$\sin(i\beta)=i\frac{k}{K}. \tag{23}$$

Consequently, the solution for the coefficient can be written as

$$A(\nu)=e^{-\beta\nu}(e^{(-i\pi/3)\nu}+\mathcal{S}e^{(i\pi/3)\nu}+\mathcal{S}_3), \tag{24}$$

or

$$A(\nu)=2\,e^{-\beta\nu}\left[\cos\left(\frac{\pi}{3}\nu+\delta\right)+\alpha\right], \tag{25}$$

where

$$\mathcal{S}=e^{2i\delta} \tag{26}$$

and

$$\alpha=-\frac{1}{2}\cot\frac{\pi}{6}\sqrt{\cot\left(\frac{\pi}{6}-i\beta\right)\cot\left(\frac{\pi}{6}+i\beta\right)}. \tag{27}$$

In the next section, we demonstrate that $\mathcal{S}$ represents the scattering matrix and, accordingly, δ the phase shift. We should stress the remarkable fact that the S-matrix appears explicitly in the solution of the recurrence relation. In the next subsection it is shown that the expression obtained for $\mathcal{S}$ in this work is equivalent to the formula for the exact symmetric $\mathcal{S}$-matrix for the $2+1$ process, given in Ref. 21.

B. Asymptotic wave function

To be specific we will restrict the following discussion to the case of total negative energies, and will write $K=\sqrt{(\pi c)^2/36-k^2}\geqslant 0$, in which $-(\pi c)^2/36$ is the two-body bound energy and k^2 is the effective energy. Next, we will show that the imaginary axis is the appropriate contour to obtain the correct asymptotic behavior of the wave function. Substituting the coefficients $A(\nu)$ defined in Eqs. (22) and (24), the pseudo-Sturmian functions given in Eq. (17) and the modified Bessel functions $K_\nu(KR)$, into Eq. (12), as well as choosing the imaginary axis as the contour of integration, we find

$$\begin{aligned}\Psi=&\int_\varsigma d\nu(\cosh[(i\pi/3+\beta)\nu]-\sinh[(i\pi/3+\beta)\nu])\times\cos\left[\left(\theta-j\frac{\pi}{3}\right)\nu\right]K_\nu(KR)\\&+\mathcal{S}\int_\varsigma d\nu(\cosh[(i\pi/3-\beta)\nu]+\sinh[(i\pi/3-\beta)\nu])\cos\left[\left(\theta-j\frac{\pi}{3}\right)\nu\right]K_\nu(KR)\\&+\mathcal{S}_3\int_\varsigma d\nu(\cosh[\beta\nu]-\sinh[\beta\nu])\cos\left[\left(\theta-j\frac{\pi}{3}\right)\nu\right]K_\nu(KR).\end{aligned} \tag{28}$$

Note that in the above expression the exponentials in the coefficients have been written in terms of hyperbolic functions. The integral over the odd terms vanishes, leaving only the even terms in the integrand. After a trigonometric identity, this leads to

$$\Psi=\frac{1}{2}\Bigg\{\int_{\varsigma}d\nu\cosh\Bigg(\Bigg[\beta+i\Bigg(\theta-[j-1]\frac{\pi}{3}\Bigg)\Bigg]\nu\Bigg)K_{\nu}(KR)+\int_{\varsigma}d\nu\cosh\Bigg(\Bigg[-\beta$$
$$+i\Bigg(\theta-[j+1]\frac{\pi}{3}\Bigg)\Bigg]\nu\Bigg)K_{\nu}(KR)+\mathcal{S}\Bigg[\int_{\varsigma}d\nu\cosh\Bigg(\Bigg[-\beta+i\Bigg(\theta-[j-1]\frac{\pi}{3}\Bigg)\Bigg]\nu\Bigg)K_{\nu}(KR)$$
$$+\int_{\varsigma}d\nu\cosh\Bigg(\Bigg[\beta+i\Bigg(\theta-[j+1]\frac{\pi}{3}\Bigg)\Bigg]\nu\Bigg)K_{\nu}(KR)\Bigg]+\mathcal{S}_3\Bigg[\int_{\varsigma}d\nu\cosh\Bigg(\Bigg[-\beta+i\Bigg(\theta-j\frac{\pi}{3}\Bigg)\Bigg]\nu\Bigg)$$
$$\times K_{\nu}(KR)+\int_{\varsigma}d\nu\cosh\Bigg(\Bigg[\beta+i\Bigg(\theta-j\frac{\pi}{3}\Bigg)\Bigg]\nu\Bigg)K_{\nu}(KR)\Bigg]. \tag{29}$$

Using the Kontorovich–Lebedev Transforms,[20] we obtain

$$\Psi=\frac{i\pi}{2}\Bigg(\exp\Bigg\{-KR\cosh\Bigg(\beta+i\Bigg[\theta-(j-1)\frac{\pi}{3}\Bigg]\Bigg)\Bigg\}+\exp\Bigg\{-KR\cosh\Bigg(-\beta+i\Bigg[\theta-(j+1)\frac{\pi}{3}\Bigg]\Bigg)\Bigg\}$$
$$+\mathcal{S}\Bigg[\exp\Bigg\{-KR\cosh\Bigg(\beta+i\Bigg[\theta-(j+1)\frac{\pi}{3}\Bigg]\Bigg)\Bigg\}+\exp\Bigg\{-KR\cosh\Bigg(-\beta+i\Bigg[\theta-(j-1)\frac{\pi}{3}\Bigg]\Bigg)\Bigg\}\Bigg]$$
$$+\mathcal{S}_3\Bigg[\exp\Bigg\{-KR\cosh\Bigg(-\beta+i\Bigg[\theta-j\frac{\pi}{3}\Bigg]\Bigg)\Bigg\}+\exp\Bigg\{-KR\cosh\Bigg(\beta+i\Bigg[\theta-j\frac{\pi}{3}\Bigg]\Bigg)\Bigg\}\Bigg]. \tag{30}$$

Introducing β from Eq. (23) into this expression, yields

$$\Psi=\frac{i\pi}{2}\Bigg(\exp\Bigg\{\frac{\pi c}{6}R\cos\Bigg[\theta-(j-1)\frac{\pi}{3}\Bigg]-ikR\sin\Bigg[\theta-(j-1)\frac{\pi}{3}\Bigg]\Bigg\}$$
$$+\exp\Bigg\{\frac{\pi c}{6}R\cos\Bigg[\theta-(j+1)\frac{\pi}{3}\Bigg]+ikR\sin\Bigg[\theta-(j+1)\frac{\pi}{3}\Bigg]\Bigg\}+\mathcal{S}\Bigg[\exp\Bigg\{\frac{\pi c}{6}R\cos\Bigg[\theta-(j+1)\frac{\pi}{3}\Bigg]$$
$$-ikR\sin\Bigg[\theta-(j+1)\frac{\pi}{3}\Bigg]\Bigg\}+\exp\Bigg\{\frac{\pi c}{6}R\cos\Bigg[\theta-(j-1)\frac{\pi}{3}\Bigg]+ikR\sin\Bigg[\theta-(j-1)\frac{\pi}{3}\Bigg]\Bigg\}\Bigg]$$
$$+\mathcal{S}_3\Bigg[\exp\Bigg\{\frac{\pi c}{6}R\cos\Bigg[\theta-j\frac{\pi}{3}\Bigg]+ikR\sin\Bigg[\theta-j\frac{\pi}{3}\Bigg]\Bigg\}+\exp\Bigg\{\frac{\pi c}{6}R\cos\Bigg[\theta-j\frac{\pi}{3}\Bigg]$$
$$-ikR\sin\Bigg[\theta-j\frac{\pi}{3}\Bigg]\Bigg\}\Bigg]\Bigg),\quad j=0,1,\ldots,5. \tag{31}$$

From Eq. (17) it is easily seen that this wave function is fully symmetric under the interchange of particles. The function is invariant under the addition of $\pi/3$ to θ, together with the addition of one unit to j, which is what should be done to move from one region in the (ρ,θ) plane to its next counterclockwise neighbor. Remember that for each region there is a specific order of the particles.

We can also see that the real part of each of the exponential arguments is negative, except when $\theta-(j\mp1)\pi/3=\pm\pi/2$, that is on the lines $\theta=\theta_j$, where its value is zero. Thus, when R is large, the wave function is negligible except near the lines $\theta=\theta_j$. Note that only the first four terms give a significant contribution in the asymptotic region. We can conclude that the form of the wave function is that of products of bound state functions, associated with two particles, with oscillatory functions, which describe the location of the third particle with respect to the 2 bound ones. Evaluating, then, the wave function for large values of R, its asymptotic form can be written as

$$\Psi(R,\theta') \sim e^{\{\pi c/6\, R\cos\theta'\}}(e^{\{-ikR\sin\theta'\}} + \mathcal{S}\, e^{\{ikR\sin\theta'\}}) \tag{32}$$

where $\pi/6 < \theta' = \theta - (j-1)\,\pi/3 < \pi/2$, $j = 0,1,\ldots,5$. This asymptotic expression consists of a wave representing a two particles bound state multiplied by an incoming wave, together with an outgoing wave multiplied by $\mathcal{S}$.

From the expression in Eq. (22) the matrix $\mathcal{S}$ can be written as

$$S = \frac{\sin\left(\frac{\pi}{6}+i\beta\right)\cos\left(\frac{\pi}{6}-i\beta\right)}{\cos\left(\frac{\pi}{6}+i\beta\right)\sin\left(\frac{\pi}{6}-i\beta\right)} = \frac{\sin\frac{\pi}{3}-\sin(-2i\beta)}{\sin\frac{\pi}{3}+\sin(-2i\beta)} = \frac{\sin\frac{\pi}{3}+2\sin(i\beta)\cos(i\beta)}{\sin\frac{\pi}{3}-2\sin(i\beta)\cos(i\beta)}. \tag{33}$$

In terms of K

$$\cos(i\beta)\sin(i\beta) = -\frac{\pi c}{6K}\frac{ik}{K} = \frac{-i\pi ck}{6(\pi^2c^2/36-k^2)}. \tag{34}$$

Therefore

$$\mathcal{S} = \frac{1-36(k/\pi c)^2 - i(24/\sqrt{3})(k/\pi c)}{1-36(k/\pi c)^2 + i(24/\sqrt{3})(k/\pi c)}. \tag{35}$$

This is, precisely, the scattering matrix

$$S = \frac{[-1-i(6\sqrt{3}/\pi c)k][3+i(6\sqrt{3}/\pi c)k]}{[3+i(6\sqrt{3}/\pi c)k][-1+i(6\sqrt{3}/\pi c)k]}, \tag{36}$$

given as Eq. (61) in Ref. 21. It corresponds to the symmetric S matrix calculated for the specific process $2+1$.

The matrix $\mathcal{S}_3$, see again (22), has the following form as a function of k

$$\mathcal{S}_3 = \frac{3+i(6\sqrt{3}/\pi c)k}{-1+i(6\sqrt{3}/\pi c)k}. \tag{37}$$

$\mathcal{S}_3$ multiplies the shorter ranged part of the exact wave function, that goes to zero when R goes to ∞.

Additional insight can be gained, by following the reasoning of McGuire.[14] The scattering of 3 asymptotically free particles, to 3 also asymptotically free particles, requires 3 (successive) collisions, and yields the part of the wave function associated with the calculation of the S-matrix. Intermediate stages, associated with fewer collisions, give rise to the shorter ranged part of the wave functions. A similar reasoning holds for the $2+1$ processes.

In conclusion, we have shown that this integration contour, and the choice of Bessel functions, have imparted the correct asymptotic behavior. Furthermore, we can deduce from the asymptotic expression that the coefficient $\mathcal{S}$ represents the S-matrix.

IV. RELATION TO ADIABATIC THEORY

The eigenfunctions of the following eigenvalue equation[21] form a complete set of orthogonal hyperspherical adiabatic basis functions. Changing, a bit, the usual notation:

$$\left[\frac{1}{R'^2}\left(\frac{\partial^2}{\partial\theta^2}+\frac{1}{4}\right) - \frac{1}{R'}C(\theta) + \Lambda_\kappa(R')\right]B_\kappa(\theta;R') = 0, \tag{38}$$

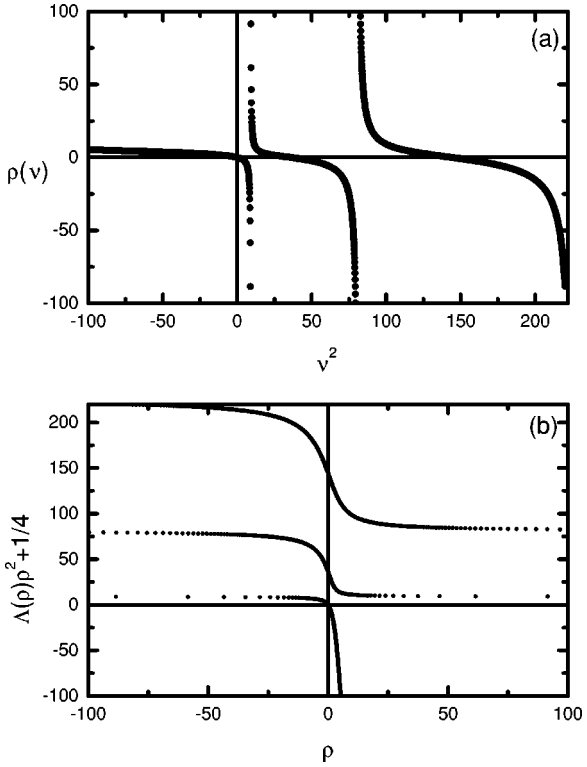

FIG. 2. Plot of the pseudo-Sturmian eigenvalue $\rho(\nu)$. In (a) we plot $\rho(\nu)$ as a function of ν^2. In (b) the plot of (a) is rotated and flipped to give ν^2 as a function of ρ. For ρ positive, $\nu^2=\Lambda(\rho)\rho^2+\frac{1}{4}$.

where R', a real parameter in this equation, is held fixed; $\kappa=0,6,12,\ldots$ and $\Lambda_\kappa(R')\rightarrow(\kappa^2-1/4)/R'^2$ as the interaction is turned off. The unnormalized eigenfunctions

$$B_\kappa(\theta;R')=\cos\left[q_\kappa\left(\theta-\frac{j\pi}{3}\right)\right], \tag{39}$$

where j is an integer such that $|\theta-j(\pi/3)|<\pi/6$ and q_κ satisfies

$$q_\kappa\tan\left(\frac{\pi}{6}q_\kappa\right)=\frac{\pi R'c}{6}. \tag{40}$$

In the adiabatic approach the parameter R' is identified with the hyper radius R. For $E<0$ there is only one open channel, labeled by $\kappa=0$. For large R, the channel function is concentrated along the lines defined by $\theta=\theta_j$. Accordingly it can represent the two-body bound state. For $E>0$, there is an infinite number of open channels, labeled by the successive numbers κ, equal and greater than zero. They describe, asymptotically, three free particles or a two-body bound state, together with a free particle.

Note that the function $\rho(\nu)$, Eq. (18), is a real function if, and only if, ν takes on values along the imaginary or the real axis, see Fig. 2. It can be seen that the pseudo-Sturmian function defined in Eq. (9) coincides, apart from normalization constants, with the lowest adiabatic function $B_0(\theta;R')$ when $\nu=q_0$ is an imaginary number and $\rho(\nu)=R'(q_0)$. Also, if $\nu=q_\kappa$ are in the real intervals $(3+[\kappa-6],9+[\kappa-6])$ with $\kappa=6,12,\ldots$, then $\rho(\nu)=R'(q_\kappa)$ and the pseudo-Sturmian functions become equal, except for the normalization constants, to the adiabatic eigenfunctions $B_\kappa(\theta;R')$.

Thus, in the case of the example considered in this paper, that is $E<0$ and the $2+1$ system, the integral Eq. (12), along the imaginary axis in the complex ν plane, can be written in terms of the lowest adiabatic function as

$$\Psi(R,\theta)=\int_{\varsigma} d\nu A(\nu)B_0(\theta;R'(\nu))Z_\nu(KR), \tag{41}$$

where ν runs from $-i\infty$ to $i\infty$. The most important contribution of the adiabatic functions to the integral, at large R, comes from the lines $\theta=\theta_j$, where two of the particles are joined. When these adiabatic functions are multiplied by the appropriate Bessels functions, their linear combination [Eq. (41)] should have the correct asymptotic behavior, and will represent a two-body bound system in the colliding with a third particle.

V. CONCLUSIONS AND OUTLOOK

We have shown that the integral representation approach within the hyperspherical context, when applied to McGuire's model, offers a reliable tool to study the collisional dynamics of the three-body system. We have obtained several interesting results, namely:

(i) an exact solution to the corresponding Schrödinger equation;
(ii) a closed form for the angular basis for this system, the pseudo-Sturmian functions;
(iii) a recurrence relation for the coefficients, in the expansion of the wave function in terms of the free-particle basis;
(iv) the S-matrix, obtained directly from the solution of the recurrence relation;
(v) the relation of the present approach to the traditional adiabatic approach;
(vi) the relation of the present solution to the known plane wave exact solution.

The simplicity of the approach as compared with the adiabatic one, promises to be very useful in extending it to more complicated situations, like the system with different masses and systems with more particles, currently under research, or systems in three dimensions modeled by ZRP potentials. In the last case, the method can be applied to a wide kind of systems to obtain asymptotic solutions which can be matched to solutions obtained with methods like the R-matrix one, simplifying substantially the calculations.

APPENDIX A: PSEUDO-STURMIAN FUNCTIONS

Fixing ν, the general solution for the eigenvalue equation

$$\left[\frac{\partial^2}{\partial\theta^2}+\nu^2\right]\varphi(\theta)=\left[\rho(\nu)\frac{\pi c}{3}\sum_{j=0}^{5}\delta(\theta-\theta_j)\right]\varphi(\theta), \tag{A1}$$

with $\theta_j=(2j+1)\pi/6$, can be written as the free angular wave solution $\varphi(\theta)=D_\nu\cos[\nu(\theta-\gamma_j)]$, $j=0,1,\ldots,5$, provided that it be continuous through the boundary lines $\theta=\theta_j$, that is,

$$\cos[\nu(\theta_j-\gamma_{j+1})]=\cos[\nu(\theta_j-\gamma_j)], \tag{A2}$$

and satisfies the boundary conditions

$$\lim_{\zeta\to 0}\ \int_{\theta_j-\zeta}^{\theta_j+\zeta}\left\{ d\theta\left[\frac{\partial^2}{\partial\theta^2}+\nu^2\right]\varphi(\theta)-\left[\rho(\nu)\frac{\pi c}{3}\sum_{l=0}^{5}\ \delta(\theta-\theta_l)\right]\varphi(\theta)\right\}=0, \tag{A3}$$

with $j=0,1,\ldots,5$. D_ν, which does not depend on j for the symmetric solution, determined by normalizing the wave function.[22] The requirement of continuity leads to the conditions $\gamma_j+\gamma_{j+1}=2\theta_j=(j+[j+1])\pi/3$ or to $\gamma_{j-1}=\gamma_j$. The second condition does not satisfy (A3) so we shall use the first one, which can be written as $\gamma_j=j\ \ \pi/3$. Now to focus on Eq. (A3). Continuity implies that the integral of the second term gives zero. For each j, the first and the third terms give

$$\lim_{\zeta\to 0}\left(\frac{\partial}{\partial\theta}(\cos\nu[\theta-\gamma_{j+1}])_{\theta=\theta_j+\varsigma}-\frac{\partial}{\partial\theta}(\cos\nu[\theta-\gamma_j])_{\theta=\theta_j-\varsigma}\right)-\rho(\nu)\frac{\pi c}{3}\cos\nu[\theta_j-\gamma_j]=0. \tag{A4}$$

If we select a symmetric solution, then

$$-\frac{\partial}{\partial\theta}\ \cos(\nu[\theta_j+\varsigma-\gamma_{j+1}])=\frac{\partial}{\partial\theta}\ \cos(\nu[\theta_j-\varsigma-\gamma_j]), \tag{A5}$$

and taking the limit in Eq. (A4), we obtain the desired form of the boundary condition

$$\lim_{\theta^-\to\theta_j}\ \frac{1}{\rho(\nu)\cos(\nu[\theta-\gamma_j])}\frac{\partial}{\partial\theta}\ \cos(\nu[\theta-\gamma_j])=-\frac{\pi c}{6}, \tag{A6}$$

where $j=0,1,\ldots,5$. Calculating the derivative and the limit in Eq. (A6) yields

$$\frac{6}{\pi c}v\tan\nu\pi/6=\rho(\nu). \tag{A7}$$

We conclude that $\cos[\nu(\theta-j\pi/3)]$, $j=0,1,\ldots,5$, satisfies Eq. (A1), provided that $\rho(\nu)$ satisfies Eq. (A7).

APPENDIX B: DERIVATION OF THE PLANE WAVE REPRESENTATION IN TERMS OF CARTESIAN COORDINATES

For the $2+1$ system, and aside from an ultimate normalization, the incoming wave function from Eq. (31) can be written in terms of Cartesian coordinates, as

$$\begin{aligned}\psi^i=\exp\Bigg\{&\frac{\pi c}{6}\left(\frac{x_1-x_2}{\sqrt{2}}\cos\left[(j-1)\frac{\pi}{3}\right]+\frac{x_1+x_2-2x_3}{\sqrt{6}}\sin\left[(j-1)\frac{\pi}{3}\right]\right)\\&-ik\left(\frac{x_1+x_2-2x_3}{\sqrt{6}}\cos\left[(j-1)\frac{\pi}{3}\right]-\frac{x_1-x_2}{\sqrt{2}}\sin\left[(j-1)\frac{\pi}{3}\right]\right)\Bigg\}\\&+\exp\Bigg\{\frac{\pi c}{6}\left(\frac{x_1-x_2}{\sqrt{2}}\cos\left[(j+1)\frac{\pi}{3}\right]+\frac{x_1+x_2-2x_3}{\sqrt{6}}\sin\left[(j+1)\frac{\pi}{3}\right]\right)\\&+ik\left(\frac{x_1+x_2-2x_3}{\sqrt{6}}\cos\left[(j+1)\frac{\pi}{3}\right]-\frac{x_1-x_2}{\sqrt{2}}\sin\left[(j+1)\frac{\pi}{3}\right]\right)\Bigg\}.\end{aligned} \tag{B1}$$

Evaluating the trigonometric functions for $j=0$ in the above expression, the argument of the first exponential function takes the form

$$i\left[-\frac{2}{\sqrt{6}}kx_1+\left(i\frac{\pi c}{6\sqrt{2}}+\frac{k}{\sqrt{6}}\right)x_2+\left(-i\frac{\pi c}{6\sqrt{2}}+\frac{k}{\sqrt{6}}\right)x_3\right]. \tag{B2}$$

By labeling the particle wave numbers as in Ref. 21,

$$k_1=i\frac{\pi c}{6\sqrt{2}}-\frac{1}{\sqrt{6}}k,$$

$$k_2=-i\frac{\pi c}{6\sqrt{2}}-\frac{1}{\sqrt{6}}k, \tag{B3}$$

$$k_3=\sqrt{\frac{2}{3}}k,$$

the incoming wave takes the form

$$\psi^i=\exp\{-i(k_3x_1+k_2x_2+k_1x_3)\}_{j=0}+\exp\{i(k_2x_1+k_3x_2+k_1x_3)\}_{j=0}.$$

The outgoing wave for $j=0$ can be obtained from the incoming one by substituting k by $-k$, which in turns means interchanging $k_1\leftrightarrow k_2$ and inverting the sign of the whole argument within all exponentials, that is,

$$\mathcal{S}[\exp\{-i(k_1x_1+k_3x_2+k_2x_3)\}_{j=0}+\exp\{i(k_3x_1+k_1x_2+k_2x_3)\}_{j=0}].$$

The wave associated to the factor $\mathcal{S}_3$ can be written as

$$\exp\{-i(k_1x_1+k_2x_2+k_3x_3)\}_{j=0}+\exp\{i(k_2x_1+k_1x_2+k_3x_3)\}_{j=0}].$$

The above results correspond to the sector $j=0$ in the (ρ,θ) plane, in which the order of particles is given by $x_2<x_3<x_1$. The waves in different sectors can be obtained by the appropriate permutation of the set of coordinates $\{x_1,x_2,x_3\}$. The completely symmetric wave plane may then be written as

$$\begin{aligned}\psi=\Sigma_p[&\{\exp[-i(k_3x_1+k_2x_2+k_1x_3)]_{j=j_p}+\exp[i(k_2x_1+k_3x_2+k_1x_3)]_{j=j_p}\}\\&+\mathcal{S}(p)\{\exp[-i(k_1x_1+k_3x_2+k_2x_3)]_{j=j_p}+\exp[i(k_3x_1+k_1x_2+k_2x_3)]_{j=j_p}\}\\&+\mathcal{S}_3(p)\{\exp[-i(k_1x_1+k_2x_2+k_3x_3)]_{j=j_p}+\exp[i(k_2x_1+k_1x_2+k_3x_3)]_{j=j_p}\}],\end{aligned} \tag{B4}$$

where the sum runs over all permutations of the set $\{x_1,x_2,x_3\}$.

A complete study of the structure of Ricci collineations for type B warped space–times is carried out. This study can be used as a method to obtain these symmetries in such space–times. Special cases as 2+2 reducible space–times, and plane and spherical symmetric space–times are considered specifically. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1775875]

I. INTRODUCTION

In the last years, symmetries in general relativity have been studied in depth because of their interest from both a mathematical and a physical viewpoint. In fact, symmetries are important not only because of their classical physical significance, but also because they simplify Einstein equations and provide a classification of the space–times according to the structure of the corresponding Lie algebra. They are described by vector fields X on the space–time which satisfy a relation of the form

$$\pounds_X \Phi = \Lambda,$$

where Φ is any of the quantities g_{ab}, R_{ab}, R^a_{bcd}, etc, Λ is a tensor with the same index symmetries as Φ, and $\pounds$ represents the Lie derivative. Depending on Φ and Λ, there are different classes of symmetries (the relation between them was studied in Ref. 9). For example, if $\Phi = g_{ab}$ and $\Lambda = \psi g_{ab}$, with ψ a function, then X is a Killing vector field if $\psi = 0$, a homothetic vector field if $\psi_{,a} = 0$, a special conformal vector field if $\psi_{;ab} = 0$, and a conformal vector field if ψ is arbitrary. A symmetry will be called proper if it does not belong to any of its subtypes, otherwise it will be said improper.

In this paper we will concentrate on Ricci collineations, that is, the case when $\Phi = R_{ab}$ and $\Lambda = 0$. These symmetries are interesting because, among other things, they provide information about the energy-momentum tensor via the Einstein equations (although Ricci collineations are not usually matter collineations). In order to ensure that Ricci collineations form a Lie algebra with the usual bracket operation, we shall assume that they are smooth vector fields. Recall that this algebra naturally contains all the special conformal vector fields (and thus, all the homothetic and Killing vector fields). Regarding the Ricci tensor, we shall consider (up to Sec. V) that it is nondegenerate,

a)Electronic mail: floresj@math.sunysb.edu
b)Electronic mail: jparra@ula.ve
c)Electronic mail: upercoco@ula.ve

i.e., rank 4; in particular, this ensures that the corresponding Lie algebra is finite dimensional, with maximal dimension being 10. Further information on dimensionality and degenerate Ricci tensors can be found, for example, in Refs. 5 and 8.

In Ref. 3 the general form and classification of Ricci collineations of Robertson–Walker space–times is provided in detail. Afterwards, in Ref. 2 the authors compute Ricci collineations of metrics g_{ab} which are conformal to $1+(n-1)$ decomposable metrics by using an interesting technique. Roughly speaking, they construct the generic metric G_{ab} defined from the symmetry group of g_{ab}. Then, proper Ricci collineations are the Killing vector fields of G_{ab} which are not Killing vector fields of g_{ab}. This method provides the Ricci collineations of Robertson–Walker space–times without any further calculations.

A few years ago, the problem of determining all Ricci collineations of type B warped space–times was considered in Ref. 6. This class of space–times is important because its structure is satisfied by multiple examples of interest in Physics as Schwarzschild, Robertson–Walker, etc. Unfortunately, the conclusion obtained there cannot be considered the solution of the problem, because it does not give *all* Ricci collineations of such space–times. In fact, two simple counterexamples to the main result in Ref. 6 were given in Ref. 1. On the other hand, the technique introduced in Ref. 2 does not seem to be applicable directly to these space–times. In conclusion, this problem remains still open.

Our aim in this paper is to describe in a general context the structure of all Ricci collineations of type B warped space–times. In fact, after a study of the equations which define these symmetries in such space–times, we classify them according to their structure. This classification can be considered a method to obtain all Ricci collineations. In particular, the counterexamples given in Ref. 1 are clearly contained in our results, Remark 4.3 (1). This paper is organized as follows.

After some preliminaries on type B warped space–times, in Sec. II we obtain two conclusions (Propositions 2.1 and 2.3) on the structure of Killing vector fields and Ricci collineations of such space–times. In Sec. III, these results are applied systematically. Ricci collineations are classified according to having or not having mixed variables and, in each case, according to their vertical component. As consequence, an exhaustive description of the structure of these symmetries is obtained. In Sec. IV, $2+2$ reducible space–times (Sec. IV A) and plane and spherical symmetric space–times (Sec. IV B) are studied specifically. Finally, the case when Ricci tensor is degenerate is briefly considered in Sec. V.

II. PRELIMINARIES

Let (M_1,g_1) and (M_2,g_2) be semi-Riemannian manifolds, and $\phi>0$ a smooth function on M_1. A warped product with base (M_1,g_1), fiber (M_2,g_2), and warping function $\phi>0$ is the product manifold $M=M_1\times M_2$ endowed with the metric tensor:

$$g^{\phi}=\pi_1^{*}g_1+(\phi\circ\pi_1)^2\pi_2^{*}g_2\equiv g_1+\phi^2 g_2,$$

where π_1 and π_2 are the natural projections of $M_1\times M_2$ onto M_1 and M_2, respectively. If, additionally, (M,g^{ϕ}) is a connected time-oriented four-dimensional Lorentzian manifold, then we say that (M,g^{ϕ}) is a warped space–time. In this case, a classification can be made according to the respective dimensions of M_1 and M_2 (see Ref. 4 and references therein for a general discussion).

In this paper we will concentrate on the study of type B warped space–times, that is, the case when M_1 and M_2 are both of dimension 2. In this case, and whenever we work locally, we can assume

$$g^{\phi}=g_{AB}(x^C)\mathrm{d}x^A\mathrm{d}x^B+\phi^2(x^C)g_{\alpha\beta}(x^{\gamma})\mathrm{d}x^{\alpha}\mathrm{d}x^{\beta},\quad \begin{matrix}A,B,C=0,1,\\ \alpha,\beta,\gamma=2,3,\end{matrix}$$

where g_{AB} and $g_{\alpha\beta}$ are the components of g_1 and g_2 in certain charts $(U_1\subseteq M_1,x^0,x^1)$, $(U_2\subseteq M_2,x^2,x^3)$, respectively.

Let X be a vector field on M and consider its horizontal and vertical components X_1, X_2; that is,

$$X_1(x^A,x^\alpha) = \mathrm{d}\pi_1(X)(x^A,x^\alpha), \quad X_2(x^A,x^\alpha) = \mathrm{d}\pi_2(X)(x^A,x^\alpha).$$

Then, the Lie derivative of g^ϕ with respect to X is

$$(\pounds_X g^\phi)_{AB} = (\pounds_{X_1} g_1)_{AB}, \tag{2.1}$$

$$(\pounds_X g^\phi)_{A\alpha} = g_{AC} X^C_{1,\alpha} + \phi^2 g_{\alpha\beta} X^\beta_{2,A}, \tag{2.2}$$

$$(\pounds_X g^\phi)_{\alpha\beta} = \phi^2 (\pounds_{X_2} g_2)_{\alpha\beta} + \phi^2_{,C} X^C_1 g_{\alpha\beta}. \tag{2.3}$$

In order to find the Killing vector fields of (M,g^ϕ), (2.1)–(2.3) must be set equal to zero. Condition (2.1) equal to zero is equivalent to the following: for every $p_2 \in M_2$ the restriction of X_1 to $M_1 \times p_2$ is a Killing vector field (perhaps zero) of $(M_1 \times p_2, g_1)$. On the other hand, (2.3) equal to zero is equivalent to the following: for every $p_1 \in M_1$ the restriction of X_2 to $p_1 \times M_2$ is a conformal vector field (perhaps zero) of $(p_1 \times M_2, g_2)$ with conformal factor

$$\psi = -\frac{1}{2}\frac{\phi^2_{,C} X^C_1}{\phi^2}.$$

These simple facts are summarized in the following way.

Proposition 2.1: Let (M,g^ϕ) be a type B warped space–time with base (M_1,g_1), fiber (M_2,g_2) and warping function $\phi>0$. A vector field $X \not\equiv 0$ on M is Killing of (M,g^ϕ) if and only if the following statements hold:

(i) *for every $p_1 \in M_1$, X_2 is a conformal vector field (perhaps zero) of $(p_1 \times M_2, g_2)$ with conformal factor ψ,*

(ii) *for every $p_2 \in M_2$, X_1 is a Killing vector field (perhaps zero) of $(M_1 \times p_2, g_1)$, which satisfies*

$$\phi^2_{,C} X^C_1 = -2\psi\phi^2, \tag{2.4}$$

(iii) *components (2.2) are equal to zero.*

A direct computation provides the following components R_{ab} of the Ricci tensor $\mathbf{R}$ of a type B warped space–time:

$$R_{AB} = \tfrac{1}{2} R_1 g_{AB} - \frac{2}{\phi}\phi_{A;B},$$

$$R_{A\alpha} = 0,$$

$$R_{\alpha\beta} = \tfrac{1}{2}(R_2 - (\phi^2)^A_{;A}) g_{\alpha\beta} \equiv F g_{\alpha\beta}, \tag{2.5}$$

where, obviously, $F := \frac{1}{2}(R_2 - (\phi^2)^A_{;A})$, R_1 and R_2 are the scalar curvatures of g_1 and g_2, respectively, and the semicolon indicates the covariant derivative with respect to g^ϕ.

Remark 2.2: Although the terms $\phi_{A;B}$ and $(\phi^2)^A_{;A}$ in (2.5) include covariant derivatives with respect to all the metric g^ϕ, a direct computation shows that they are independent of the variables x^γ of M_2. In fact,

$$\phi_{A;B} = \phi_{,AB} - \frac{g^{CD}}{2}(g_{DB,A} + g_{DA,B} - g_{AB,D})\phi_{,C},$$

$$(\phi^2)^A_{;A} = g^{AB}\phi^2_{,AB} - \frac{g^{AB}g^{CD}}{2}(g_{DB,A} + g_{DA,B} - g_{AB,D})\phi^2_{,C}.$$

The Lie derivative of $\mathbf{R}$ with respect to X is

$$(\pounds_X \mathbf{R})_{AB} = R_{AB,C}X^C_1 + R_{AC}X^C_{1,B} + R_{CB}X^C_{1,A}, \tag{2.6}$$

$$(\pounds_X \mathbf{R})_{A\alpha} = R_{AC}X^C_{1,\alpha} + R_{\alpha\beta}X^\beta_{2,A}, \tag{2.7}$$

$$(\pounds_X \mathbf{R})_{\alpha\beta} = F(\pounds_{X_2} g_2)_{\alpha\beta} + F_{,C}X^C_1 g_{\alpha\beta} + F_{,\gamma}X^\gamma_2 g_{\alpha\beta}. \tag{2.8}$$

In the following, our aim will be to find the Ricci collineations of (M, g^ϕ); that is, the vector fields $X \not\equiv 0$ on M such that (2.6)–(2.8) are equal to zero.

As commented in the Introduction, we will assume that $\mathbf{R}$ is nondegenerate. Therefore, $F \neq 0$ everywhere. Moreover, from (2.5) and Remark 2.2, R_{AB} can be seen as the components of a metric tensor g_R defined on M_1. Then, reasoning as in Proposition 2.1, condition (2.6) equal to zero is equivalent to the following: for every $p_2 \in M_2$ the restriction of X_1 to $M_1 \times p_2$ is a Killing vector field (perhaps zero) of $(M_1 \times p_2, g_R)$. On the other hand, (2.8) equal to zero is equivalent to the following: for every $p_1 \in M_1$ the restriction of X_2 to $p_1 \times M_2$ is a conformal vector field (perhaps zero) of $(p_1 \times M_2, g_2)$ with conformal factor

$$\psi = -\frac{1}{2}\frac{F_{,C}X^C_1 + F_{,\gamma}X^\gamma_2}{F}. \tag{2.9}$$

Equation (2.9) can be simplified by using the classical expression of the Lie derivative of the Ricci $\mathbf{R}_h$ of a semi-Riemannian manifold (N, h) with respect to a conformal vector field Y of conformal factor ξ (see Ref. 7); that is,

$$(\pounds_Y \mathbf{R}_h)_{ab} = -(n-2)\xi_{|ab} - (\Delta_h \xi)h_{ab}, \tag{2.10}$$

where $n = \dim N$ and $\Delta_h \xi = \xi_{|cd}h^{cd}$ is the Laplacian of ξ with respect to h (obviously, the stroke denotes the covariant derivative with respect to h). In fact, assume that X_2 is a conformal vector field of $(p_1 \times M_2, g_2)$ with conformal factor ψ. Then, from (2.10) we obtain

$$(\pounds_{X_2} \mathbf{R}_{g_2})_{\alpha\beta} = -(\Delta_{g_2}\psi)g_{\alpha\beta}.$$

But, obviously,

$$\pounds_{X_2}(\mathbf{R}_{g_2})_{\alpha\beta} = \pounds_{X_2}(\tfrac{1}{2}R_2 g_2)_{\alpha\beta} = \tfrac{1}{2}(R_{2,\gamma}X^\gamma_2 + 2\psi R_2)g_{\alpha\beta};$$

thus

$$R_{2,\gamma}X^\gamma_2 + 2\psi R_2 = -2\Delta_{g_2}\psi. \tag{2.11}$$

On the other hand, by replacing in (2.9) the expression of F we have

$$2\psi(R_2 - (\phi^2)^A_{;A}) = (\phi^2)^A_{;A,C}X^C_1 - R_{2,\gamma}X^\gamma_2. \tag{2.12}$$

Therefore, from (2.11) and (2.12) we obtain

$$(\phi^2)^A_{;A,C}X^C_1 = -2\psi(\phi^2)^A_{;A} - 2\Delta_{g_2}\psi. \tag{2.13}$$

These facts are summarized in the following result.

Proposition 2.3: Let (M,g^{ϕ}) *be a type B warped space–time with base* (M_1,g_1)*, fiber* (M_2,g_2) *and warping function* $\phi>0$*. A vector field* $X\not\equiv 0$ *on* M *is a Ricci collineation of* (M,g^{ϕ}) *if and only if the following statements hold:*

(i) *for every* $p_1\in M_1$*,* X_2 *is a conformal vector field (perhaps zero) of* $(p_1\times M_2,g_2)$ *with conformal factor* ψ*,*
(ii) *for every* $p_2\in M_2$*,* X_1 *is a Killing vector field (perhaps zero) of* $(M_1\times p_2,g_R)$*, which satisfies (2.13), and*
(iii) *components (2.7) are equal to zero.*

In the next section, Propositions 2.1 and 2.3 will be exploited in order to describe the general structure of Ricci collineations of (M,g^{ϕ}).

III. RICCI COLLINEATIONS OF TYPE B WARPED SPACE–TIMES

For simplicity, first we will classify these symmetries in two families. In the first family, we will include Ricci collineations whose variables are not mixed, that is, when the corresponding vector field X can be written as

$$X(x^A,x^{\alpha})=X_1(x^A)+X_2(x^{\alpha}).$$

Our study is completed by including in a second family Ricci collineations such that either $\partial X_1/\partial x^{\alpha}\neq 0$ or $\partial X_2/\partial x^A\neq 0$.

Family 1: Ricci collineations with nonmixed variables.

Notice that, in this case, statements (iii) in Propositions 2.1 and 2.3 always hold. On the other hand, from Proposition 2.3, we can distinguish four types in this family attending to the vertical component X_2 of X.

Type 1.1: X_2 is a Killing vector field (perhaps zero) of (M_2,g_2).

From Proposition 2.3 (ii), $X\not\equiv 0$ will be a Ricci collineation if, additionally, X_1 is a Killing vector field (perhaps zero) of (M_1,g_R) with $(\phi^2)^A_{;A,C}X_1^C=0$. Therefore, Ricci collineations $X\not\equiv 0$ of type 1.1 are

$$X=X_1+X_2=\sum_{i=1}^{k_R}a_i^1X_1^i+\sum_{j=1}^{k_2}a_j^2X_2^j,$$

where

(i) $\{X_1^i\}_{i=1}^{k_R}$ is the algebra of Killing vector fields of (M_1,g_R),
(ii) $\{X_2^j\}_{j=1}^{k_2}$ is the algebra of Killing vector fields of (M_2,g_2), and
(iii) coefficients $\{a_i^1\}_{i=1}^{k_R}$ satisfy

$$\sum_{i=1}^{k_R}a_i^1(\phi^2)^A_{;A,C}X_1^{i\ C}=0. \tag{3.1}$$

Additionally, from Proposition 2.1 X is not a Killing vector field of (M,g^{ϕ}) if,
(iv) either $\phi^2_{,C}X_1^C\neq 0$ or X_1 is not a Killing vector field of (M_1,g_1) (in particular, $X_1\not\equiv 0$).

Remark 3.1: As dim $M_i=2$, $i=1,2$, necessarily $k_R,k_2=0,1,3$. But, from (iv), (M,g^{ϕ}) admits proper Ricci collineations of type 1.1 only if $k_R=1,3$. Therefore, in this case, if the curvature of (M_1,g_R) is not constant, necessarily $k_R=1$, and thus, Eq. (3.1) reduces to $(\phi^2)^A_{;A,C}X_1^{1\ C}=0$.

Type 1.2: X_2 is a proper homothetic vector field of (M_2,g_2).

Obviously, this type of collineations only exists if the curvature of (M_2,g_2) is not a constant different from zero. In this case, X will be a Ricci collineation if, additionally, X_1 is a Killing vector field (perhaps zero) of (M_1,g_R) with

$$(\phi^2)^A_{;A,C}X_1^C = -2\lambda(\phi^2)^A_{;A}, \tag{3.2}$$

where $\lambda \neq 0$ is the homothetic factor of X_2. From (3.2), recall that if $X_1=0$ then, necessarily $(\phi^2)^A_{;A}=0$.

In conclusion, Ricci collineations $X \not\equiv 0$ of type 1.2 are

$$X = X_1 + X_2 = \sum_{i=1}^{k_R} a_i^1 X_1^i + \sum_{j=1}^{k_2} a_j^2 X_2^j + \lambda Y,$$

where

(i) as before, $\{X_1^i\}_{i=1}^{k_R}$, $\{X_2^j\}_{j=1}^{k_2}$ are the algebras of Killing vector fields of (M_1,g_R), (M_2,g_2), respectively,
(ii) Y is the homothetic vector field of (M_2,g_2) with homothetic factor 1, and
(iii) coefficients $\{a_i^1\}_{i=1}^{k_R}$ and $\lambda \neq 0$ satisfy

$$\sum_{i=1}^{k_R} a_i^1 (\phi^2)^A_{;A,C} X_1^{i\ C} = -2\lambda(\phi^2)^A_{;A}.$$

Additionally, X is not a Killing vector field of (M,g^ϕ) if,
(iv) either $\phi^2_{,C}X_1^C \neq -2\lambda\phi^2$ or X_1 is not a Killing vector field of (M_1,g_1).

Type 1.3: X_2 is a proper special conformal vector field of (M_2,g_2).

This type of collineations only exists if $(\phi^2)^A_{;A}=0$. In fact, now the conformal factor ψ associated to X_2 is a nonconstant function of x^α with $\Delta_{g_2}\psi=0$. Therefore, if we assume that (2.13) holds, and derive it with respect to x^γ, we deduce that $(\phi^2)^A_{;A}=0$.

Under this restriction, all Ricci collineations $X \not\equiv 0$ of type 1.3 are given by

$$X = X_1 + X_2 = \sum_{i=1}^{k_R} a_i^1 X_1^i + \sum_{j=1}^{s_2} a_j^2 X_2^j,$$

where

(i) $\{X_1^i\}_{i=1}^{k_R}$ is the algebra of Killing vector fields of (M_1,g_R),
(ii) $\{X_2^j\}_{j=1}^{s_2}$ is the algebra of special conformal vector fields of (M_2,g_2) and,
(iii) some of the coefficients $\{a_j^2\}_{j=h_2+1}^{s_2}$ are different from zero, being h_2 the dimension of the algebra of homothetic vector fields of (M_2,g_2).

Moreover, these collineations are not Killing vector fields of (M,g^ϕ) because they do not satisfy (2.4).

Remark 3.2: Notice that condition $(\phi^2)^A_{;A}=0$ implies that proper homothetic and special conformal vector fields of (M_2,g_2) are also Ricci collineations of (M,g^ϕ) of types 1.2 and 1.3, respectively. Moreover, they are not Killing vector fields of (M,g^ϕ) [since they do not satisfy (2.4)].

Type 1.4: X_2 is a proper conformal vector field of (M_2,g_2).

This type of collineations only exists if $(\phi^2)^A_{;A}$ remains constant wherever ψ is not constant. In fact, if we assume that (2.13) holds, and derive it with respect to x^γ, we deduce that

$$\Delta_{g_2}\psi = -(\phi^2)^A_{;A}\cdot\psi = -\text{const}\cdot\psi \tag{3.3}$$

on such a domain.

In conclusion, Ricci collineations $X \not\equiv 0$ of type 1.4 satisfy the expression

$$X = X_1 + X_2 = \sum_{i=1}^{k_R} a_i^1 X_1^i + \sum_{j=1}^{c_2} a_j^2 X_2^j,$$

where

(i) $\{X_1^i\}_{i=1}^{k_R}$ is the algebra of Killing vector fields of (M_1, g_R),
(ii) $\{X_2^j\}_{j=1}^{c_2}$ is the conformal algebra of (M_2, g_2) and,
(iii) coefficients $\{a_j^2\}_{j=k_2+1}^{c_2}$ are such that the conformal factor of X_2,

$$\psi = \sum_{j=k_2+1}^{c_2} a_j^2 \psi_2^j,$$

satisfies (2.13) [in particular, satisfies (3.3) wherever ψ is not constant], where $\{\psi_2^j\}_{j=k_2+1}^{c_2}$ are the corresponding conformal factors of $\{X_2^j\}_{j=k_2+1}^{c_2}$, and some of the coefficients $\{a_j^2\}_{j=s_2+1}^{c_2}$ must be different from zero.

Again, these collineations are not Killing vector fields of (M, g^ϕ) because they do not satisfy (2.4).

Family 2: Ricci collineations with mixed variables.

In this family, the dependence of X_1 and X_2 is not restricted to x^A and x^α, respectively. Therefore, (iii) in Propositions 2.1 and 2.3 must be also taken into account in order to find these symmetries. Summarizing, Ricci collineations $X \not\equiv 0$ are given now by

$$X = X_1 + X_2 = \sum_{i=1}^{k_R} a_i^1(x^\alpha) X_1^i + \sum_{j=1}^{c_2} a_j^2(x^A) X_2^j,$$

where

(i) $\{X_1^i\}_{i=1}^{k_R}$ is the algebra of Killing vector fields of (M_1, g_R),
(ii) $\{X_2^j\}_{j=1}^{c_2}$ is the conformal algebra of (M_2, g_2), and
(iii) functions $\{a_i^1(x^\alpha)\}_{i=1}^{k_R}$, $\{a_j^2(x^A)\}_{j=1}^{c_2}$ satisfy

$$\sum_{i=1}^{k_R} a_i^1(x^\alpha)(\phi^2)^A_{;A,C} X_1^{i\,C} = -2\left(\sum_{j=k_2+1}^{c_2} a_j^2(x^A)\psi_2^j\right)(\phi^2)^A_{;A} - 2\sum_{j=s_2+1}^{c_2} a_j^2(x^A)\Delta_{g_2}\psi_2^j, \tag{3.4}$$

$$\sum_{i=1}^{k_R} \frac{da_i^1(x^\gamma)}{dx^\alpha} R_{AC} X_1^{iC} + \sum_{j=1}^{c_2} \frac{da_j^2(x^C)}{dx^A} R_{\alpha\beta} X_2^{j\beta} = 0, \quad A = 0,1, \quad \alpha = 2,3 \tag{3.5}$$

(the indexes k_2, s_2 are again the dimensions of the homothetic and special conformal algebras). Additionally, X is not a Killing vector field of (M, g^ϕ) if
(iv) any of the statements of Proposition 2.1 do not hold.

Analogously to Family 1, we classify these collineations in four types.

Type 2.1: For every $p_1 \in M_1$, X_2 is a Killing vector field (perhaps zero) of $(p_1 \times M_2, g_2)$.

In this case the only functions which can be different from zero are $\{a_i^1(x^\alpha)\}_{i=1}^{k_R}$, $\{a_j^2(x^A)\}_{j=1}^{k_2}$. As a consequence, Eq. (3.4) reduces to

$$\sum_{i=1}^{k_R} a_i^1(x^\alpha)(\phi^2)^A_{;A,C} X_1^{i\,C} = 0.$$

Type 2.2: For every $p_1 \in M_1$, X_2 is a homothetic vector field (perhaps zero) of $(p_1 \times M_2, g_2)$ which is not always Killing.

This type of collineations only exists if the curvature of (M_2, g_2) is not a constant different from zero. In this case, only the functions $\{a_i^1(x^\alpha)\}_{i=1}^{k_R}$, $\{a_j^2(x^A)\}_{j=1}^{k_2}$, $a_{k_2+1}^2(x^A) \equiv \lambda(x^A)$ can be different from zero, and they must satisfy

$$\sum_{i=1}^{k_R} a_i^1(x^\alpha)(\phi^2)^A_{;A,C} X_1^{i\ C} = -2\lambda(x^A)(\phi^2)^A_{;A},$$

where we have assumed the homothetic factor $\psi_2^{k_2+1}$ normalized to 1.

Type 2.3: For every $p_1 \in M_1$, X_2 is a special conformal vector field (perhaps zero) of $(p_1 \times M_2, g_2)$ which is not always homothetic.

In this case, only the functions $\{a_i^1(x^\alpha)\}_{i=1}^{k_R}$, $\{a_j^2(x^A)\}_{j=1}^{s_2}$ can be different from zero. As a consequence, Eq. (3.4) reduces now to

$$\sum_{i=1}^{k_R} a_i^1(x^\alpha)(\phi^2)^A_{;A,C} X_1^{i\ C} = -2\left(\sum_{j=k_2+1}^{s_2} a_j^2(x^A)\psi_2^j\right)(\phi^2)^A_{;A}.$$

Type 2.4: For every $p_1 \in M_1$, X_2 is a conformal vector field (perhaps zero) of $(p_1 \times M_2, g_2)$ which is not always special. In general, we cannot simplify the structure of these Ricci collineations.

In the following section a brief application of our study to some examples of type B warped space–times is carried out. Without any further calculations, we obtain interesting information about the particular structure of their symmetries.

IV. EXAMPLES

In this section we will apply our point of view to the following families of type B warped space–times: 2+2 reducible space–times, and plane and spherical symmetric space–times.

A. 2+2 reducible space–times

In this case the product manifold $M = M_1 \times M_2$ is endowed with the metric tensor

$$g = \pi_1^* g_1 + \pi_2^* g_2 \equiv g_1 + g_2.$$

Therefore, these space–times are type B warped space–times with $\phi^2 = 1$ and, thus, we can apply our previous study. First, take into account that now $g_R = 1/2R_1 g_1 = \mathbf{R}_{g_1}$. Thus, Killing vector fields X_1 of (M_1, g_R) are just the conformal vector fields of (M_1, g_1) with conformal factors satisfying $\Delta_{g_1}\psi_1 = 0$ [recall (2.10)]. Therefore, if we apply Proposition 2.3 to these space–times, we obtain the following consequences.

Corollary 4.1: Ricci collineations $X \not\equiv 0$, with nonmixed variables, of a 2+2 reducible space–time (M, g) are the vector fields $X = X_1 + X_2$ such that, X_l are conformal vector fields of (M_l, g_l) with conformal factors ψ_l satisfying

$$\Delta_{g_l}\psi_l = 0, \quad l = 1,2.$$

Corollary 4.2: Ricci collineations $X \not\equiv 0$, with mixed variables, of a 2+2 reducible space–time (M, g) are the vector fields

$$X = X_1 + X_2 = \sum_{i=1}^{c_1} a_i^1(x^\alpha) X_1^i + \sum_{j=1}^{c_2} a_j^2(x^A) X_2^j,$$

where $\{X_1^i\}_{i=1}^{c_1}$, $\{X_2^j\}_{j=1}^{c_2}$ are the conformal algebras of (M_1, g_1), (M_2, g_2), respectively, and functions $\{a_i^1(x^\alpha)\}_{i=1}^{c_1}$, $\{a_j^2(x^A)\}_{j=1}^{c_2}$ satisfy

$$\sum_{i=s_1+1}^{c_1} a_i^1(x^\alpha)\Delta_{g_1}\psi_1^i = \sum_{j=s_2+1}^{c_2} a_j^2(x^A)\Delta_{g_2}\psi_2^j = 0,$$

$$\sum_{i=1}^{c_1} \frac{\mathrm{d}a_i^1(x^\gamma)}{\mathrm{d}x^\alpha} R_{AC} X_1^{iC} + \sum_{j=1}^{c_2} \frac{\mathrm{d}a_j^2(x^C)}{\mathrm{d}x^A} R_{\alpha\beta} X_2^{j\beta} = 0, \quad A = 0,1, \quad \alpha = 2,3,$$

being $\{\psi_1^i\}_{i=1}^{c_1}$, $\{\psi_2^j\}_{j=1}^{c_2}$ *the corresponding conformal factors.*

Remark 4.3: (1) Counterexamples given in Ref. 1 are clearly contained in these results. In fact, $M=\mathbb{R}^2\times\mathbb{R}^2$ endowed with

$$g = e^{t^2/2}(-\mathrm{d}t^2 + \mathrm{d}x^2) + e^{-y^2/2}(\mathrm{d}y^2 + \mathrm{d}z^2)$$

is a 2+2 reducible space–time and, both, $X=\partial_t+\partial_y$, $Y=z\partial_t+\partial_y+t\partial_z$ are Ricci collineations which satisfy hypotheses of corollaries 4.1 and 4.2, respectively.

(2) From Eqs. (2.5), it is clear that both corollaries also hold for space–times not necessarily 2+2 reducible, but satisfying $\phi_{A;B}=(\phi^2)^A_{;A}\equiv 0$.

B. Plane and spherical symmetric space–times

Consider now the family of space–times $M=\mathbb{R}^2\times M_2$ endowed with the metric tensor

$$g^\phi = -e^{2v}\mathrm{d}t^2 + e^{2w}\mathrm{d}x^2 + \phi^2 g_2,$$

where v, w, and ϕ are each functions of t and x, and

$$(M_2,g_2) = \begin{cases} \mathbb{R}^2 \\ \mathbb{S}^2 \end{cases}$$

endowed with their corresponding usual metrics (if we also include the hyperbolic space, g^ϕ can be characterized by admitting a group G_3 acting multiply-transitively on spacelike orbits V_2, see Ref. 10). To avoid the vanishing of F, and thus, the degeneracy of Ricci tensor **R** [recall (2.5)], we will also assume

$$(\phi^2)^A_{;A} \neq R_2 \quad \text{for all} \quad (t,x) \in \mathbb{R}^2. \tag{4.1}$$

From Sec. III, the component X_1 of a Ricci collineation $X\not\equiv 0$ of these space–times is different from zero only if (M_1,g_R) admits some Killing vector fields. In this case, the dimension k_R of the corresponding algebra must be 3 or 1, depending on if v, w, and ϕ makes (R^2,g_R) being maximally symmetric or not. To study the structure of X_2, we must consider the two cases separately.

1. Plane symmetry

The conformal algebra of the plane $(\mathrm{R}^2,\mathrm{d}y^2+\mathrm{d}z^2)$ is the (infinite-dimensional) *Virasoro algebra*, which has the following special conformal vector fields:

$$X_2^1 = \partial_y, \quad \psi_2^1 = 0,$$

$$X_2^2 = \partial_z, \quad \psi_2^2 = 0,$$

$$X_2^3 = z\partial_y - y\partial_z, \quad \psi_2^3 = 0,$$

$$X_2^4 = y\partial_y + z\partial_z, \quad \psi_2^4 = 1,$$

$$X_2^5 = (y^2 - z^2)\partial_y + 2yz\partial_z, \quad \psi_2^5 = 2y,$$

$$X_2^6 = 2yz\partial_y + (z^2 - y^2)\partial_z, \quad \psi_2^6 = 2z.$$

Therefore, $k_2=3$, $h_2=4$, $s_2=6$ (and $c_2=\infty$). In this case, we can establish the following:

(i) The vertical component X_2 of a Ricci collineation $X \not\equiv 0$ of type 1.1 is a linear combination of the $k_2=3$ Killing vector fields of the plane. On the other hand, the horizontal component X_1 satisfies the equation in k_R variables (3.1).

(ii) The component X_2 of a Ricci collineation of type 1.2 is a linear combination of the $h_2=4$ homothetic vector fields of the plane. On the other hand, the horizontal component X_1 satisfies Eq. (3.2). If $k_R=0$, there are not Ricci collineations of this type since, in this case, (3.2) reduces to $(\phi^2)^A_{;A}=0$, which contradicts (4.1).

(iii) There are not Ricci collineations of type 1.3. Moreover, there are collineations of type 1.4 only if $(\phi^2)^A_{;A}=\text{const}\neq 0$.

(iv) Ricci collineations in Family 2 must satisfy Eqs. (3.4) and (3.5), which are in general complicated. If $k_R=0$ and we consider collineations of type 2.3, these equations reduce to

$$a_4^2 + 2y\ a_5^2 + 2z\ a_6^2 = 0$$

and

$$a_{1,t}^2 + z\ a_{3,t}^2 + y\ a_{4,t}^2 + (y^2 - z^2)a_{5,t}^2 + 2yz\ a_{6,t}^2 = 0,$$

$$a_{2,t}^2 - y\ a_{3,t}^2 + z\ a_{4,t}^2 + 2yz\ a_{5,t}^2 + (z^2 - y^2)a_{6,t}^2 = 0,$$

$$a_{1,x}^2 + z\ a_{3,x}^2 + y\ a_{4,x}^2 + (y^2 - z^2)a_{5,x}^2 + 2yz\ a_{6,x}^2 = 0,$$

$$a_{2,x}^2 - y\ a_{3,x}^2 + z\ a_{4,x}^2 + 2yz\ a_{5,x}^2 + (z^2 - y^2)a_{6,x}^2 = 0.$$

2. Spherical symmetry

In this case, the second space (M_2, g_2) is the unitary bidimensional sphere $\mathbb{S}^2$. The *local* conformal algebra of $\mathbb{S}^2$, like that of the plane, is the Virasoro algebra. In order to single out a finite-dimensional subalgebra from it, we will impose that conformal vectors must be *globally* defined on $\mathbb{S}^2$. Then, a well-known computation shows that the only *global* conformal vector fields of $\mathbb{S}^2$ expressed in spherical coordinates are

$$X_2^1 = \cos\ \varphi\partial_\theta - \sin\ \varphi\ \cot\ \theta\partial_\varphi, \quad \psi_2^1 = 0,$$

$$X_2^2 = \sin\ \varphi\partial_\theta + \cos\ \varphi\ \cot\ \theta\partial_\varphi, \quad \psi_2^2 = 0,$$

$$X_2^3 = \partial_\varphi, \quad \psi_2^3 = 0,$$

$$X_2^4 = \sin\ \theta\partial_\theta, \quad \psi_2^4 = \cos\ \theta,$$

$$X_2^5 = \cos\theta\ \cos\varphi\partial_\theta - \frac{\sin\ \varphi}{\sin\ \theta}\partial_\varphi, \quad \psi_2^5 = -\sin\ \theta\ \cos\varphi,$$

$$X_2^6 = \cos\ \theta\ \sin\ \varphi\partial_\theta - \frac{\cos\ \varphi}{\sin\ \theta}\partial_\varphi, \quad \psi_2^6 = -\sin\ \theta\ \sin\ \varphi.$$

(Nevertheless, recall that other conformal vectors—necessarily *locally* defined—can appear as vertical components of a Ricci collineation of a spherically symmetric space–time.)

In conclusion, $k_2=h_2=s_2=3$ and $c_2=6$. Therefore, we obtain the following:

(i) The vertical component X_2 of a Ricci collineation $X \not\equiv 0$ of type 1.1 is a linear combination of the $k_2=3$ Killing vector fields of $\mathbb{S}^2$. On the other hand, the horizontal component X_1 satisfies the equation in k_R variables (3.1).

(ii) As the curvature of $\mathbb{S}^2$ is a constant different from zero, there are not Ricci collineations of types 1.2, 2.2. Even more, as $s_2-h_2=0$, there are not Ricci collineations of types 1.3, 2.3 either.

(iii) A simple computation shows that $\Delta_{g_2}\psi_2^j=-2\psi_2^j$, $j=4,5,6$. But then, (3.3) implies $(\phi^2)^A_{;A}=R_2=2$, which contradicts (4.1). Therefore, there are not Ricci collineations of type 1.4.

(iv) Ricci collineations in Family 2 must satisfy Eqs. (3.4) and (3.5), which are in general complicated. If $k_R=0$, there are not Ricci collineations in this family. In fact, in this case (3.4); [or, equivalently, (2.13)] implies again $(\phi^2)^A_{;A}=R_2=2$, in contradiction with (4.1).

V. THE DEGENERATE CASE

For completeness, we briefly analyse here the cases when Ricci tensor is degenerate. From (2.5), the Ricci tensor of a type B warped space–time is degenerate if $F\equiv 0$ or $\phi_{A;B}\equiv(\phi/4)R_1 g_{AB}$ (if both identities hold, the Ricci tensor is zero and any vector field is a Ricci collineation).

Consider the case $F\equiv 0$ [or, equivalently, $(\phi^2)^A_{;A}\equiv R_2=0$]. Then, Eqs. (2.6)–(2.8) show that a vector field $X=X_1+X_2\not\equiv 0$ is a Ricci collineation of the space–time if and only if X_1 is a Killing vector field (perhaps zero) of $(M_1\times p_2, g_R)$ satisfying $R_{AC}X^C_{1,\alpha}=0$ for every $p_2\in M_2$. In particular, any Killing vector field of (M_1,g_R) is always a Ricci collineation of the space–time. Moreover, the group of Ricci collineations becomes infinity, since every vector field $X\not\equiv 0$ with horizontal component $X_1\equiv 0$ generates a Ricci collineation. That is, the vertical component (which is just the component where Ricci tensor degenerates) of these Ricci collineations is largely arbitrary (see Ref. 3 Sec. II, for a similar property in Robertson–Walker space–times).

The situation is more complicated when the source of degeneracy is the identity $\phi_{A;B}\equiv(\phi/4)R_1 g_{AB}$. In this case, Proposition 2.3 shows that a vector field $X=X_1+X_2\not\equiv 0$ is a Ricci collineation of the space–time if and only if X_2 is a conformal vector field (perhaps zero) of $(p_1\times M_2, g_2)$ satisfying $R_{\alpha\beta}X^\beta_{2,A}=0$ for every $p_1\in M_1$ and, additionally, X_1 satisfies (2.13) for every $p_2\in M_2$. So, in this case we have restrictions on both, the vertical and horizontal components of X. This is due to the dependence of F on both components, and breaks the similarities with respect to the Robertson–Walker case.

VI. CONCLUSION

By analyzing the equations which characterize Ricci collineations of type B warped space–times, we have determined the structure of these symmetries. They have been classified in eight types according to having or not mixed variables, and according to their vertical component. As a consequence, several examples of interest have been considered, and new information about their collineations has been provided. This study must be understood as an initial point to begin a systematic computation of Ricci collineations for a wide family of space–times of this class.

As a final remark we would like to point out that it would be very useful to use computer algebra packages to automate the search of symmetries. Nevertheless, as far as we know, the available algorithms can only check if a given vector field is a symmetry or not (at least this is the case of GRTensor with which we have some familiarity).

(Received 6 May 2004; accepted 4 June 2004; published 6 August 2004)

According to a theorem by Treves [Duke Math. J. **108**, 251 (2001)], the conserved functionals of the KdV equation vanish on each formal Laurent series $1/x^2+u_0+\Sigma_{k=2}^{+\infty}u_k x^k$. We propose a new, very simple geometrical proof for this statement. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1777795]

I. INTRODUCTION

In 2001, Treves obtained a new characterization for the conserved quantities of the Korteweg–de Vries (KdV) equation. Roughly speaking, his result concerns functionals which are integrals of differential polynomials, and their evaluation on formal Laurent series with complex coefficients in one variable x (defining the integral as the residue in x). For each functional h of this kind on the Laurent series, Treves[1] proved the equivalence between (a) and (b):

(a) *h is a conserved functional for the KdV equation;*
(b) *$h(u)=0$ for each Laurent series of the form* $u=1/x^2+u_0+\Sigma_{k=2}^{+\infty}u_k x^k$ $(u_0,u_2,u_3,\ldots\in\mathbb{C})$.

Subsequently, Treves obtained a similar result for the modified KdV equation and derived the analogue of (a)⇒(b) for the conserved functionals of the nonlinear Schrödinger equation.[2]

In all cases analyzed by Treves, the proof of either (a)⇒(b) or (b)⇒(a) is very long. A simple, alternative derivation of (a)⇒(b) for the KdV case was given by Dickey,[3] using the dressing method for the Lax operator; this author also derived an analogue of this implication for the Boussinesq theory.

We became aware of the above results very recently, due to a talk given in Milano by Professor Treves,[4] and we soon developed an interest in a further simplification of the proofs. We investigated in particular the implication (a)⇒(b), concentrating for brevity on the KdV case and trying to isolate a *single geometrical property* of the conserved functionals, sufficient to derive the thesis. The conclusion of our analysis is described in this paper: here we propose a proof of (a)⇒(b) for the KdV, different from the ones of Treves and Dickey and possessing in our opinion the previously asked feature; the same approach could be probably used for other integrable systems.

Our argument can be described in very few lines, in the following way.

(I) The conserved KdV functionals are known to be invariant under the Bäcklund transformation (often called auto-Bäcklund) $M\circ R\circ M^{-1}$, where M and R are the Miura and reflection transformations, respectively. This is the geometrical property from which everything follows.
(II) Any Laurent series $u=1/x^2+u_0+\Sigma_{k=2}^{+\infty}u_k x^k$ is the Bäcklund transform of a series $w=w_0+\Sigma_{k=2}^{\infty}w_k x^k$.

a)Electronic mail: carmor@mate.polimi.it
b)Electronic mail: livio.pizzocchero@mat.unimi.it

(III) If h is a conserved KdV functional and u, w are as before, we have $h(u)=h(w)$; on the other hand, $h(w)=0$ for a trivial reason: in fact, this is the integral of a series with no negative powers of x and thus with zero residue. The conclusion is $h(u)=0$.

The rest of the paper is simply a rigorous formulation of items (I)–(III). In Sec. II, to fix the language we give some background on differential polynomials, functionals, KdV theory and state precisely the Treves theorem; in Sec. III, we review the Bäcklund transformation and formalize statement (I) in the framework of the Laurent series. Expert readers can skip most of the preliminaries in these two sections, and concentrate on Eqs. (2.14) and (2.15) describing the space of Laurent series; Eqs. (3.3)–(3.6) on the Bäcklund transformation and the invariance of KdV functionals. In Sec. IV, we prove (II) and show (a)$\Rightarrow$(b) along the lines of (III).

Let us point out how the idea (I)–(III) could be employed in relation to other integrable equations. First of all, one needs a Bäcklund transformation leaving invariant the conserved functionals. Trivially, all functionals of the theory vanish on the subspace of formal series with no negative powers of x. One should start from this subspace or a subset of it, and characterize its image under the Bäcklund transformation; the latter is made of nontrivial Laurent series, on which the conserved functionals are again zero. In the KdV case, the starting set and its Bäcklund image consist, respectively, of the series w, u mentioned in (II).

Some terminology: All vector spaces considered in this paper are over $\mathbb{C}$. By a differential algebra, we mean an associative and *commutative* algebra equipped with a derivation, i.e., with a linear map of the algebra into itself having the Leibnitz property with respect to the product. A morphism of differential algebras is an algebraic morphism respecting the derivations.

II. FORMAL VARIATIONAL CALCULUS, KdV AND THE TREVES THEOREM

In all concrete manipulations, the KdV equation $(d/dt)q=q_{xxx}-12qq_x$ is understood as a vector field on some "space" $\mathcal{Q}$, whose elements q are "functions of one variable x." The analysis of this vector field is greatly simplified if one assumes $\mathcal{Q}$ to be closed under pointwise sums and products, and under the operation $q\mapsto q_x$ of derivation with respect to x; in this case, $\mathcal{Q}$ is a differential algebra.

Investigations in this area soon made clear that the striking features of KdV are largely independent of the choice of the differential algebra $\mathcal{Q}$; the same can be said for other integrable PDEs, discovered shortly after it. To take this fact into account, Gelfand and Dickey (see Ref. 5 and the bibliography therein) invented a *formal variational calculus*, allowing to describe the KdV and similar systems within a very pure algebraic setting. Hereafter we illustrate some facts about this calculus, in a fashion convenient for our purposes (and partly inspired by the setting of Ref. 1).

Formal variational calculus for KdV theory can be based on the commutative algebra

$$\mathfrak{F} := \mathbb{C}[\boldsymbol{\xi}, \boldsymbol{\xi}_x, \boldsymbol{\xi}_{xx}, \dots]_0, \tag{2.1}$$

made of complex polynomials in infinitely many indeterminates $\boldsymbol{\xi}, \boldsymbol{\xi}_x, \boldsymbol{\xi}_{xx}, \dots$ without a constant term. $\mathfrak{F}$ becomes a differential algebra, when equipped with the unique derivation $\boldsymbol{\partial}$ such that[6]

$$\boldsymbol{\partial}\boldsymbol{\xi} = \boldsymbol{\xi}_x, \quad \boldsymbol{\partial}\boldsymbol{\xi}_x = \boldsymbol{\xi}_{xx}, \quad \dots . \tag{2.2}$$

We write $\boldsymbol{F}, \boldsymbol{G}$, etc. for the elements of $\mathfrak{F}$, and $\boldsymbol{FG}$ for their product as polynomials. The *composition product* $\boldsymbol{F}\circ\boldsymbol{G}\in\mathfrak{F}$ is the polynomial obtained from the expression of $\boldsymbol{F}$ replacing $\boldsymbol{\xi}, \boldsymbol{\xi}_x, \dots$ with $\boldsymbol{G}$, $\boldsymbol{\partial G}, \dots$.[7] For each fixed $\boldsymbol{G}$, the mapping $\boldsymbol{F}\mapsto\boldsymbol{F}\circ\boldsymbol{G}$ is the unique automorphism of the differential algebra $\mathfrak{F}$ sending $\boldsymbol{\xi}$ into $\boldsymbol{G}$. The operation $\circ$ is associative, so $(\mathfrak{F}, \circ)$ is a monoid with unit $\boldsymbol{\xi}$.

Let us consider any differential algebra $(\mathcal{Q}, \cdot_x)$ (of elements $q, p, \dots$, with a derivation $q \in \mathcal{Q}\mapsto q_x\in\mathcal{Q}$; this notation for the derivation is purely conventional). Then, we can represent the elements of $\mathfrak{F}$ as *transformations of* $\mathcal{Q}$ into itself. More precisely, if $\boldsymbol{F}\in\mathfrak{F}$ and $q\in\mathcal{Q}$, let us denote with $F(q)\in\mathcal{Q}$ the element obtained from the expression of $\boldsymbol{F}$ substituting the symbols

$\boldsymbol{\xi}, \boldsymbol{\xi}_x, \ldots$ with q, q_x, etc. In this way, $\boldsymbol{F}$ induces a map of polynomial type[8]

$$F: \mathcal{Q} \to \mathcal{Q}, \quad q \mapsto F(q). \tag{2.3}$$

We point out the remotion of bold typeface to distinguish this map from $\boldsymbol{F}$; in particular, the transformation $\xi: \mathcal{Q} \to \mathcal{Q}$ induced by $\boldsymbol{\xi}$ is just the identity map $q \mapsto q$. As $\boldsymbol{F}$ ranges over the whole $\boldsymbol{\mathfrak{F}}$, we get a correspondence

$$\boldsymbol{F} \to \mathrm{Pol}(\mathcal{Q}, \mathcal{Q}), \quad \boldsymbol{F} \mapsto F. \tag{2.4}$$

Now, the set $\mathrm{Pol}(\mathcal{Q}, \mathcal{Q})$ of polynomial maps $\mathcal{Q} \to \mathcal{Q}$ is itself a commutative algebra, with all the operations defined pointwisely: for $K, L: \mathcal{Q} \to \mathcal{Q}$ and $\lambda \in \mathbb{C}$, $K+L$, λK, $KL: \mathcal{Q} \to \mathcal{Q}$ are the maps $q \mapsto K(q)+L(q)$, $q \mapsto \lambda K(q)$, $q \mapsto K(q)L(q)$. Furthermore, $\mathrm{Pol}(\mathcal{Q}, \mathcal{Q})$ becomes a differential algebra with the derivation $\partial: K \mapsto \partial K$ such that $(\partial K)(q) := K(q)_x$ for all $q \in \mathcal{Q}$. One easily recognizes that (2.4) is a morphism of differential algebras: for all $\boldsymbol{F}, \boldsymbol{G} \in \boldsymbol{\mathfrak{F}}$ and $\lambda \in \mathbb{C}$, the transformations corresponding to $\boldsymbol{F}+\boldsymbol{G}$, $\lambda \boldsymbol{F}$, $\boldsymbol{FG}$, $\boldsymbol{\partial F}$ are $F+G$, λF, FG, ∂F.

$\mathrm{Pol}(\mathcal{Q}, \mathcal{Q})$ is also a monoid with the usual composition of maps $F \circ G: q \mapsto F(G(q))$ and the identity map as unit; it turns out that (2.4) is a monoid morphism between $(\boldsymbol{\mathfrak{F}}, \circ)$ and $(\mathrm{Pol}(\mathcal{Q}, \mathcal{Q}), \circ)$.

Due to the previous facts, it is helpful for intuition *to think the elements of* $\boldsymbol{\mathfrak{F}}$ *as transformations, even when no differential algebra* $(\mathcal{Q}, \cdot_x)$ *is specified.*

The next step in formal variational calculus is the introduction of *functionals*, which are "integrals" of transformations. The only property needed for the integral is to vanish on a derivative; for this reason Gelfand and Dickey defined this operation as the quotient map

$$\int : \boldsymbol{\mathfrak{F}} \to \boldsymbol{\mathfrak{F}} / \mathrm{Im}\ \boldsymbol{\partial}, \tag{2.5}$$

and called functionals the elements of $\boldsymbol{\mathfrak{F}} / \mathrm{Im}\ \boldsymbol{\partial}$; each of them has the form

$$\boldsymbol{f} = \int \boldsymbol{F}\ (\boldsymbol{F} \in \boldsymbol{\mathfrak{F}}). \tag{2.6}$$

For any "transformation" $\boldsymbol{G} \in \boldsymbol{\mathfrak{F}}$, the functional

$$\boldsymbol{f} \circ \boldsymbol{G} := \int (\boldsymbol{F} \circ \boldsymbol{G}) \in \boldsymbol{\mathfrak{F}} / \mathrm{Im}\ \boldsymbol{\partial} \tag{2.7}$$

is well defined (i.e., independent on the choice of $\boldsymbol{F}$ within the equivalence class $\boldsymbol{f}$); we call this the *composition* between $\boldsymbol{f}$ and $\boldsymbol{G}$. One easily checks the linearity of the map $\boldsymbol{f} \mapsto \boldsymbol{f} \circ \boldsymbol{G}$, and the associative property $(\boldsymbol{f} \circ \boldsymbol{G}) \circ \boldsymbol{G}' = \boldsymbol{f} \circ (\boldsymbol{G} \circ \boldsymbol{G}')$ for $\boldsymbol{f}, \boldsymbol{G}$ as before and $\boldsymbol{G}' \in \boldsymbol{\mathfrak{F}}$.

To get concrete counterparts of functionals, consider any differential algebra $(\mathcal{Q}, \cdot_x)$, and define an *integration* for it to be any linear map

$$\int : \mathcal{Q} \to \mathbb{C} \quad \text{such that} \quad \int q_x = 0\ \forall\ q \in \mathcal{Q}; \tag{2.8}$$

the triple $(\mathcal{Q}, \cdot_x, \int)$ will then be called an *integral-differential algebra*. If $\boldsymbol{f} = \int \boldsymbol{F} \in \boldsymbol{\mathfrak{F}} / \mathrm{Im}\ \boldsymbol{\partial}$, define

$$f: \mathcal{Q} \to \mathbb{C}, \quad q \mapsto f(q) := \int F(q); \tag{2.9}$$

this definition is well posed, and gives a linear correspondence

$$\mathfrak{F}/\mathrm{Im}\ \boldsymbol{\partial} \to \mathrm{Pol}(\mathcal{Q},\mathbb{C}), \quad \boldsymbol{f} \mapsto f; \tag{2.10}$$

for all $\boldsymbol{f}$ as above and $\boldsymbol{G} \in \mathfrak{F}$, the map $\mathcal{Q} \to \mathbb{C}$ induced by $\boldsymbol{f} \circ \boldsymbol{G}$ is the usual composition $f \circ G: q \mapsto f(G(q))$.

One can then go on at the level of $\mathfrak{F}$, defining notions such as *vector fields* (identifiable with elements of $\mathfrak{F}$), and the (Lie) *derivative* of a functional $\boldsymbol{h}$ along a vector field $\boldsymbol{X}$; if the latter vanishes, we say that $\boldsymbol{h}$ is *conserved by* $\boldsymbol{X}$ (see Ref. 5 and the bibliography therein).

All this machinery is designed to discuss topics such as the *KdV vector field* and its conserved functionals, i.e.,

$$\boldsymbol{X}_{\mathrm{KdV}} := \boldsymbol{\xi}_{xxx} - 12\boldsymbol{\xi}\boldsymbol{\xi}_x, \tag{2.11}$$

$$\mathfrak{Z}_{\mathrm{KdV}} := \{\boldsymbol{h} \in \mathfrak{F}/\mathrm{Im}\boldsymbol{\partial} | \boldsymbol{h} \text{ is a conserved by } \boldsymbol{X}_{\mathrm{KdV}}\}. \tag{2.12}$$

An outstanding feature of KdV theory is that $\mathfrak{Z}_{\mathrm{KdV}}$ is *infinite dimensional* (as a vector space over $\mathbb{C}$). A basis for it is well known and consists of countably many functionals $(\boldsymbol{h}_k)_{k=1,2,\ldots}$, for which several equivalent constructions are available: for example, one can use the Magri–Lenard recursion scheme,[9] or the method of fractional powers.[5] The first elements are

$$\boldsymbol{h}_1 := -\tfrac{1}{4}\int \boldsymbol{\xi}, \quad \boldsymbol{h}_2 := \tfrac{1}{2}\int \boldsymbol{\xi}^2, \quad \boldsymbol{h}_3 := -\int (2\boldsymbol{\xi}^3 + \tfrac{1}{2}\boldsymbol{\xi}_x^2), \quad \boldsymbol{h}_4 := \int (10\boldsymbol{\xi}^4 + 10\boldsymbol{\xi}\boldsymbol{\xi}_x^2 + \tfrac{1}{2}\boldsymbol{\xi}_{xx}^2). \tag{2.13}$$

We finally come to the Treves theorem, concerning the KdV conserved functionals and their representation on a particular integral-differential algebra $(Q, \cdot_x, \int)$. By definition, this is made of formal Laurent series in one indeterminate x and complex coefficients, i.e.,

$$\mathcal{Q} := \left\{ q = \sum_k q_k x^k \,\middle|\, k \in \mathbb{Z}, q_k \in \mathbb{C}\ \forall\, k, q_k = 0 \text{ for } k \leqslant k_* = k_*(q) \right\}; \tag{2.14}$$

$\mathcal{Q}$ is a commutative algebra with the usual Cauchy product; it carries the derivation and integration

$$\cdot_x: \mathcal{Q} \to \mathcal{Q}, \quad q \mapsto q_x := \sum_k k q_k x^{k-1}; \qquad \int: \mathcal{Q} \to \mathbb{C}, \quad q \mapsto \int q := q_{-1}. \tag{2.15}$$

Clearly, $\int q = 0$ iff $q = p_x$ for some $p \in \mathcal{Q}$; of course, the definition of $\int q$ as the "residue" q_{-1} suggests to interpret it as a loop integral about zero.

With the previous notations, the Treves theorem reads as follows.

Proposition 2.1 (see Ref. 1): For any $\boldsymbol{h} \in \mathfrak{F}/\mathrm{Im}\ \boldsymbol{\partial}$, *statements (a) and (b) are equivalent*:

(a) $\boldsymbol{h} \in \mathfrak{Z}_{\mathrm{KdV}}$;
(b) $h(u) = 0$ *for each* $u \in Q$ *of the form* $u = 1/x^2 + u_0 + \sum_{k=2}^{+\infty} u_k x^k$.

As anticipated, the rest of the paper is a new geometrical proof of the implication (a) $\Rightarrow$ (b).

III. A REVIEW OF THE MIURA AND BÄCKLUND TRANSFORMATIONS

The basic facts on these transformations can be stated in the language of formal variational calculus; so, we consider the algebra $\mathfrak{F}$ of the preceding section, and state the following.

Definition 3.1: The Miura and reflection transformations are

$$\boldsymbol{M} := \boldsymbol{\xi}_x + 2\boldsymbol{\xi}^2; \quad \boldsymbol{R} := -\boldsymbol{\xi}. \tag{3.1}$$

Both $\boldsymbol{M}, \boldsymbol{R}$ are elements of $\mathfrak{F}$, so they can be composed as explained previously; of course $\boldsymbol{M} \circ \boldsymbol{R} = -\boldsymbol{\xi}_x + 2\boldsymbol{\xi}^2$. We can as well compose functionals $\in \mathfrak{F}/\mathrm{Im}\boldsymbol{\partial}$ with these transformations; for

example, composing the first KdV conserved functionals (2.13) with the Miura transformation we obtain

$$\boldsymbol{h}_1 \circ \boldsymbol{M} = -\tfrac{1}{2}\int \boldsymbol{\xi}^2, \quad \boldsymbol{h}_2 \circ \boldsymbol{M} = \int (2\boldsymbol{\xi}^4 + \tfrac{1}{2}\boldsymbol{\xi}_x^2), \quad \boldsymbol{h}_3 \circ \boldsymbol{M} = -\int (16\boldsymbol{\xi}^6 + 20\boldsymbol{\xi}^2\boldsymbol{\xi}_x^2 + \tfrac{1}{2}\boldsymbol{\xi}_{xx}^2),$$

$$\boldsymbol{h}_4 \circ \boldsymbol{M} = \int (160\boldsymbol{\xi}^8 + 560\boldsymbol{\xi}^4\boldsymbol{\xi}_x^2 + 18\boldsymbol{\xi}_x^4 + 96\boldsymbol{\xi}\boldsymbol{\xi}_x^2\boldsymbol{\xi}_{xx} + 28\boldsymbol{\xi}^2\boldsymbol{\xi}_{xx}^2 + \tfrac{1}{2}\boldsymbol{\xi}_{xxx}^2). \tag{3.2}$$

The following facts are known from the very beginning of KdV history.

Proposition 3.2: For each $\boldsymbol{h} \in \mathfrak{Z}_{\mathrm{KdV}}$:

(i) $\boldsymbol{h}\circ\boldsymbol{M}$ *is a conserved functional for the modified KdV vector field* $\boldsymbol{X}_{\mathrm{mKdV}} := \boldsymbol{\xi}_{xxx} - 24\boldsymbol{\xi}^2\boldsymbol{\xi}_x$.

(ii) $\boldsymbol{h}\circ\boldsymbol{M}$ *is invariant under reflection*: $(\boldsymbol{h}\circ\boldsymbol{M})\circ\boldsymbol{R} = \boldsymbol{h}\circ\boldsymbol{M}$.

References for the proof: For (i), see the original papers by Miura *et al.*[10] (ii) is proved recursively for all elements $(\boldsymbol{h}_k)_{k=1,2,\ldots}$ in the basis of $\mathfrak{Z}_{\mathrm{KdV}}$, using the Magri–Lenard recursion relations[9] connecting $\boldsymbol{h}_k\circ\boldsymbol{M}$ to $\boldsymbol{h}_{k+1}\circ\boldsymbol{M}$: these relations are reflection invariant. ■

For our purposes, (ii) is the essential feature of $\boldsymbol{M}$ and $\boldsymbol{R}$; now we represent this result on any integral-differential algebra $(\mathcal{Q}, \cdot_x, \int)$. Let us consider the maps of Q into itself induced by $\boldsymbol{M}, \boldsymbol{R}$ according to the framework of the preceding section; these are

$$M: \mathcal{Q} \to \mathcal{Q}, \quad p \mapsto M(p) = p_x + 2p^2; \quad R: \mathcal{Q} \to \mathcal{Q}, \quad p \mapsto R(p) = -p \tag{3.3}$$

(the letter p for elements of $\mathcal{Q}$ is used here for future convenience). The above maps will be called the *Miura and reflexion transformations* on $\mathcal{Q}$. Let us also recall that any functional $\boldsymbol{f} \in \mathfrak{F}/\mathrm{Im}\boldsymbol{\partial}$ induces a map $f: \mathcal{Q} \to \mathbb{C}$; in particular, considering the KdV conserved functionals we infer from Proposition 3.2 (ii) that

$$(h \circ M) \circ R = h \circ M \quad \text{for each } \boldsymbol{h} \in \mathfrak{Z}_{\mathrm{KdV}}, \tag{3.4}$$

with $\circ$ the usual composition of maps.

We go on and introduce the Bäcklund transformation on $\mathcal{Q}$; essentially, this is the composition of maps $M\circ R\circ M^{-1}$, leaving invariant any conserved KdV functional due to Eq. (3.4). However, M is typically noninvertible on the full space $\mathcal{Q}$: to overcome this difficulty, we use the following.

Definition 3.3: Consider the set $2^{\mathcal{Q}}$ *of the parts of* $\mathcal{Q}$ (*i.e., the collection of all subsets of* $\mathcal{Q}$). *The Bäcklund transformation on* $\mathcal{Q}$ *is the set-valued map*

$$B: \mathcal{Q} \to 2^{\mathcal{Q}}, \quad q \mapsto B(q) := \{(M \circ R)(p) | p \in \mathcal{Q}, M(p) = q\}. \tag{3.5}$$

With this definition, Eq. (3.4) implies the following.

Proposition 3.4: Let $\boldsymbol{h} \in \mathfrak{Z}_{\mathrm{KdV}}$; *then the map* $h: \mathcal{Q} \to \mathbb{R}$ *is Bäcklund invariant, in the following sense: for all* $q, r \in \mathcal{Q}$,

$$r \in B(q) \quad \Rightarrow \quad h(r) = h(q). \tag{3.6}$$

IV. THE IMPLICATION (a)⇒(b) IN PROPOSITION 2.1: A NEW PROOF

The simple geometrical proof we propose is based on the scheme (I)–(III) of the Introduction. Item (I) has been treated in the preceding section; here we formalize (II) and (III). From now on, $(Q, \cdot_x, \int)$ is the integral-differential algebra (2.14) and (2.15) of the formal Laurent series.

Definition 4.1: We set

$$\mathcal{W}:=\left\{ w\in\mathcal{Q}\,\middle|\, w=w_0+\sum_{k=2}^{+\infty} w_k x^k\right\};\quad \mathcal{V}:=\left\{ v\in\mathcal{Q}\,\middle|\, v=\frac{1}{2x}+v_1x+\sum_{k=3}^{+\infty} v_k x^k\right\};$$

$$\mathcal{U}:=\left\{ u\in\mathcal{Q}\,\middle|\, u=\frac{1}{x^2}+u_0+\sum_{k=2}^{+\infty} u_k x^k\right\}. \tag{4.1}$$

Lemma 4.2: Consider the Miura and reflections transformations M,R of Eq. (3.3). *Then*

(i) *M is one to one between $\mathcal{V}$ and $\mathcal{W}$;*
(ii) *$M\circ R$ is one to one between $\mathcal{V}$ and $\mathcal{U}$.*

Proof: (i) For all $v\in\mathcal{V}$, an elementary computation gives

$$M(v)=v_x+2v^2=3v_1+(5v_3+2v_1^2)x^2+6v_4x^3+(7v_5+4v_1v_3)x^4+(8v_6+4v_1v_4)x^5$$
$$+\sum_{k=6}^{\infty}\left((k+3)v_{k+1}+4v_1v_{k-1}+2\sum_{j=3}^{k-3}v_jv_{k-j}\right)x^k; \tag{4.2}$$

from here, we see that $M(v)\in\mathcal{W}$. Now, let us consider any $w\in\mathcal{W}$ and show that the equation $M(v)=w$ has a unique solution $v\in\mathcal{V}$. In fact, $M(v)=w$ is equivalent to $3v_1=w_0$, $5v_3+2v_1^2=w_2$, etc., giving

$$v_1=\tfrac{1}{3}w_0,\quad v_3=-\tfrac{2}{5}v_1^2+\tfrac{1}{5}w_2=-\tfrac{2}{45}w_0^2+\tfrac{1}{5}w_2,\quad v_4=\tfrac{1}{6}w_3,$$

$$v_5=\tfrac{8}{945}w_0^3-\tfrac{4}{105}w_0w_2+\tfrac{1}{7}w_4,\quad v_6=-\tfrac{1}{36}w_0w_3+\tfrac{1}{8}w_5,$$

$$v_{k+1}=-\frac{2}{k+3}\left(2v_1v_{k-1}+\sum_{j=3}^{k-3}v_jv_{k-j}\right)+\frac{w_k}{k+3}\quad\text{for all } k\geqslant 6; \tag{4.3}$$

the equation in the last line is a recursion formula, determining uniquely v_k for all $k\geqslant 7$.

(ii) For all $v\in\mathcal{V}$, we find

$$(M\circ R)(v)=-v_x+2v^2=\frac{1}{x^2}+v_1+(-v_3+2v_1^2)x^2-2v_4x^3+(-3v_5+4v_1v_3)x^4+(-4v_6+4v_1v_4)x^5$$
$$+\sum_{k=6}^{\infty}\left((1-k)v_{k+1}+4v_1v_{k-1}+2\sum_{j=3}^{k-3}v_jv_{k-j}\right)x^k; \tag{4.4}$$

this shows that $(M\circ R)(v)\in\mathcal{U}$. For all $u\in\mathcal{U}$, the equation $(M\circ R)(v)=u$ has a unique solution $v\in\mathcal{V}$, given by

$$v_1=u_0,\quad v_3=2u_0^2-u_2,\quad v_4=-\tfrac{1}{2}u_3,$$

$$v_5=\tfrac{8}{3}u_0^3-\tfrac{4}{3}u_0u_2-\tfrac{1}{3}u_4,\quad v_6=-\tfrac{1}{2}u_0u_3-\tfrac{1}{4}u_5,$$

$$v_{k+1}=\frac{2}{k-1}\left(2v_1v_{k-1}+\sum_{j=3}^{k-3}v_jv_{k-j}\right)-\frac{u_k}{k-1}\quad\text{for all } k\geqslant 6. \tag{4.5}$$

■

Of course, the previous Lemma implies the following.

Corollary 4.3: Define a restricted Bäcklund transformation

$$B_0:\mathcal{W}\to\mathcal{U},\quad B_0:=((M\circ R)\restriction\mathcal{V})\circ(M\restriction\mathcal{V})^{-1};\tag{4.6}$$

then, B_0 is one to one between $\mathcal{W}$ and $\mathcal{U}$.

The final step in our argument is trivial.

Lemma 4.4: Consider any functional $\boldsymbol{f}\in\mathfrak{F}/\mathrm{Im}\,\boldsymbol{\partial}$; then f vanishes on the "holomorphic subspace,"

$$\mathcal{Z}:=\left\{z\in\mathcal{Q}\;\middle|\;z=\sum_{k=0}^{\infty}z_k x^k\right\}.\tag{4.7}$$

Proof: $\mathcal{Z}$ is a differential subalgebra of $\mathcal{Q}$, and $\int$ clearly vanishes on $\mathcal{Z}$. Consider any functional $\boldsymbol{f}=\int\boldsymbol{F}$. For all $z\in\mathcal{Z}$ we have $F(z)\in\mathcal{Z}$ and $f(z)=\int F(z)=0$. ■

We are finally ready to prove the following.

Proof of the implication $(a)\Rightarrow(b)$ in the Treves theorem: Consider a functional $\boldsymbol{h}\in\mathfrak{Z}_{\mathrm{KdV}}$, and any Laurent series $u\in\mathcal{U}$. By the previous Corollary, there is a unique $w\in\mathcal{W}$ such that $u=B_0(w)$; of course this implies $u\in B(w)$, with B the (set-valued) Bäcklund transformation (3.5). These facts give

$$h(u)=h(w)=0.\tag{4.8}$$

The first equality above is ensured by the Bäcklund invariance of h (Proposition 3.4); the second one follows from Lemma (4.4) and the evident inclusion $\mathcal{W}\subset\mathcal{Z}$. ■

[6] One occasionally needs the full algebra $\mathbb{C}[\boldsymbol{\xi},\boldsymbol{\xi}_x,\boldsymbol{\xi}_{xx},\ldots]$, including polynomials with constant term. This is an algebra with unity, containing $\mathfrak{F}$ as an ideal and identifiable with $\mathfrak{F}\oplus\mathbb{C}$ as a vector space; the derivation $\boldsymbol{\partial}$ is extended to this larger algebra setting $\boldsymbol{\partial}1:=0$. However, this enlargement plays no role in our construction.
[7] For example, if $\boldsymbol{F}=\boldsymbol{\xi}+\boldsymbol{\xi}_x^2$ and $\boldsymbol{G}=\boldsymbol{\xi}^4+\boldsymbol{\xi}_{xx}$, we have $\boldsymbol{FG}=\boldsymbol{\xi}^5+\boldsymbol{\xi}^4\boldsymbol{\xi}_x^2+\boldsymbol{\xi}\boldsymbol{\xi}_{xx}+\boldsymbol{\xi}_x^2\boldsymbol{\xi}_{xx}$; $\boldsymbol{F}\circ\boldsymbol{G}=\boldsymbol{G}+(\boldsymbol{\partial G})^2=(\boldsymbol{\xi}^4+\boldsymbol{\xi}_{xx})+(4\boldsymbol{\xi}^3\boldsymbol{\xi}_x+\boldsymbol{\xi}_{xxx})^2=\boldsymbol{\xi}^4+16\boldsymbol{\xi}^6\boldsymbol{\xi}_x^2+\boldsymbol{\xi}_{xx}+8\boldsymbol{\xi}^3\boldsymbol{\xi}_x\boldsymbol{\xi}_{xxx}+\boldsymbol{\xi}_{xxx}^2$.
[8] A map $K:\mathcal{S}\to\mathcal{T}$, where $\mathcal{S}$ and $\mathcal{T}$ are vector spaces, is said to be of polynomial type if there are m-linear maps $K_m:\times^m\mathcal{S}\to\mathcal{T}$ $(m=0,\ldots,n)$ such that $K(s)=\sum_{m=0}^n K_m(s,\ldots,s)$ for all $s\in\mathcal{S}$. We will write $\mathrm{Pol}(\mathcal{S},\mathcal{T})$ for the maps of polynomial type between $\mathcal{S}$ and $\mathcal{T}$.

We study the problem of Bose–Einstein condensation in the perfect Bose gas in the canonical ensemble, in anisotropically dilated rectangular parallelepipeds (Casimir boxes). We prove that in the canonical ensemble for these anisotropic boxes there is the same type of generalized Bose–Einstein condensation as in the grand-canonical ensemble for the equivalent geometry. However the amount of condensate in the individual states is different in some cases and so are the fluctuations. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1777402]

I. INTRODUCTION

Many calculations in the grand-canonical ensemble (GCE) show a dependence of Bose–Einstein condensation (BEC) on the way the infinite volume limit is taken. For example, in Refs. 14 and 16 the authors study the perfect boson gas (PBG) in the GCE in rectangular parallelepipeds whose edges go to infinity at different rates (*Casimir boxes*, see Ref. 4). They showed that this *anisotropic dilation* can modify the standard ground-state BEC, converting it into a *generalized* BEC of type II or III. For a short history of the notion of *generalized* BEC we refer the reader to Refs. 14 and 16.

On the other hand, due to the lack of (*strong*) equivalence of ensembles, the PBG in the canonical ensemble (CE) and in the GCE gives different expectations and fluctuations for many observables. For example, it was shown in Ref. 3 that for the *isotropic dilation* of the *canonical* PBG the distribution of ground-state occupation number is *different* from the one in the GCE. The same is true for the fluctuations of the occupation numbers, which are shape dependent and are not normal or Gaussian. Therefore this lack of equivalence of ensembles does not allow us to deduce the same shape dependence for BEC in the CE as for its grand-canonical counterpart and so far the question of whether it is true in the CE has not been considered except in a special case.[2]

Our aim in the present paper is to fill this gap. We study the problem of BEC in the PBG in the CE, in anisotropically dilated rectangular boxes. We shall prove that in the CE for these anisotropic boxes there is the same type of generalized BEC as in the GCE for the equivalent geometry. However the amount of condensate in the individual states is different in some cases and so are the fluctuations.

We would like to note that there is a renewed interest in *generalized* BEC both from the theoretical[9,11,18] and experimental[5,13] points of view. This due to recent experiments which produce "fragmentation" of BEC (see, e.g., Refs. 6 and 10), that is, the single state condensation can be "smeared out" over two or more quantum states. We return to this point in Sec. IV.

The structure of the present paper is as follows. In the rest of this section we give the mathematical setting. In Sec. II we collect together the results about PBG in the GCE that we shall

[a)]Research Associate, School of Theoretical Physics, Dublin Institute for Advanced Studies. Electronic mail: Joe.Pule@ucd.ie
[b)]Electronic mail: zagrebnov@cpt.univ-mrs.fr

need. In Sec. III we study the PBG in the CE for the system of anisotropic parallelepipeds. We start by giving some results which are common to the three cases corresponding to the three characteristic ways of taking the thermodynamic limit. These are determined by how fast the longest edge grows: (a) faster than the square root of the volume, (b) like the square root of the volume and (c) slower than the square root of the volume. In the three subsections of Sec. III we study these cases separately. In Sec. IV we discuss the results.

We finish this section by establishing the general setting and notation.

Let Λ_V be a rectangular parallelepiped of volume V:

$$\Lambda_V := \{x \in \mathbb{R}^3 : 0 \leqslant x_j \leqslant V^{\alpha_j}, j = 1,2,3\}, \tag{1.1}$$

where

$$\alpha_1 \geqslant \alpha_2 \geqslant \alpha_3 > 0, \quad \text{and} \quad \alpha_1 + \alpha_2 + \alpha_3 = 1. \tag{1.2}$$

The space of one-particle wave-functions is $\mathcal{H}_V = L^2(\Lambda_V)$ and the one-particle Hamiltonian t_V is the self-adjoint extension of the operator $-\Delta/2$ determined by the Dirichlet boundary conditions on $\partial\Lambda_V$. We denote by $\{E_k(V)\}_{k=1}^{\infty}$ the ordered eigenvalues of t_V:

$$0 < E_1(V) < E_2(V) \leqslant E_3(V) \leqslant \cdots.$$

We also introduce the boson Fock space on $\mathcal{H}_V$ defined by $\mathcal{F}(\mathcal{H}_V) := \oplus_{n=0}^{\infty} \mathcal{H}_{V,\mathrm{symm}}^n$, where $\mathcal{H}_{V,\mathrm{symm}}^n := (\otimes_{j=1}^n \mathcal{H}_V)_{\mathrm{symm}}$ stands for the space of n-particle symmetric functions. Then $T_V^{(n)}$ denotes the n-particle free Hamiltonian determined by $t_V \equiv T_V^{(1)}$ on $\mathcal{H}_{V,\mathrm{symm}}^n$, and T_V the corresponding Hamiltonian in the Fock space.

Now the expectations for the PBG in the canonical ensemble at temperature β^{-1} and density $\rho = n/V$ are defined by the Gibbs state,

$$\langle - \rangle_V^{\mathcal{C}}(\rho) := (Z_V(n))^{-1} \mathrm{Tr}_{\mathcal{H}_{V,\mathrm{symm}}^n} (-) e^{-\beta T_V^{(n)}}, \tag{1.3}$$

where

$$Z_V(n) := \mathrm{Tr}_{\mathcal{H}_{V,\mathrm{symm}}^n} e^{-\beta T_V^{(n)}} \tag{1.4}$$

is the n-particle canonical partition function. As usual we put $Z_V(0) = 1$. The grand-canonical Gibbs state is defined by

$$\langle - \rangle_V^{\mathcal{GC}}(\mu) := (\Xi_V(\mu))^{-1} \mathrm{Tr}_{\mathcal{F}(\mathcal{H}_V)} (-) e^{-\beta(T_V - \mu N_V)}, \tag{1.5}$$

where μ is the corresponding chemical potential. Here N_V is the particle number operator, that is, $N_V := \Sigma_{k \geqslant 1} N_k$ where N_k denotes the operator for the number of particles in the k-th one-particle state. The grand-canonical partition function at chemical potential $\mu < E_1(V)$ is

$$\Xi_V(\mu) := \mathrm{Tr}_{\mathcal{F}(\mathcal{H}_V)} e^{-\beta(T_V - \mu N_V)}. \tag{1.6}$$

Because of their commutative nature it is useful to think of N_V and $\{N_k\}_{k \geqslant 1}$ as random variables rather than operators.

Notice that the one-particle Hamiltonian spectrum $\sigma(t_V) = \{E_k(V)\}_{k=1}^{\infty}$ coincides with the set

$$\left\{ \epsilon_{\mathbf{n},V} = \frac{\pi^2}{2} \sum_{j=1}^{3} \frac{n_j^2}{V^{2\alpha_j}} : n_j = 1,2,3, \ldots, \ j = 1,2,3 \right\}, \tag{1.7}$$

described by the multi-index $\mathbf{n} = (n_1, n_2, n_3)$. Then and the ground-state eigenvalue $E_1(V) = \epsilon_{(1,1,1),V}$.

Let $\{\eta_k(V) := E_k(V) - E_1(V)\}_{k \geqslant 1}$. For a given V we define $F_V : \mathbb{R} \to \mathbb{R}_+$ by

$$F_V(\eta) := \frac{1}{V}\#\{k: \eta_k(V) \leqslant \eta\}. \tag{1.8}$$

Note that F_V is a nondecreasing function on $\mathbb{R}$ with $F_V(\eta)=0$ for $\eta<0$. $F_V(\eta-E_1(V))$ is the distribution of the eigenvalues (*integrated density of states*) of the one-particle Hamiltonian t_V. One can prove in many ways, for example, by using Lemma 3.1 or by taking the Laplace transform, that

$$F(\eta) := \lim_{V\to\infty} F_V(\eta) = (\sqrt{2}/3\pi^2)\eta^{3/2}, \quad \eta \geqslant 0. \tag{1.9}$$

We shall show (see Lemma 3.1) that $F_V(\eta)\leqslant(\sqrt{2}/3\pi^2)\eta^{3/2}$ if $\eta>C/V^{2\alpha_3}$ for some $C>0$. This bound and (1.9) imply that the *critical* density of the PBG,

$$\rho_c := \lim_{\varepsilon\downarrow 0}\lim_{V\to\infty}\int_{(\varepsilon,\infty)}\frac{1}{e^{\beta\eta}-1}F_V(d\eta) = \int_0^\infty \frac{1}{e^{\beta\eta}-1}F(d\eta) < \infty, \tag{1.10}$$

is finite for any nonzero temperature.

By (1.5) the mean occupation number of the PBG in the grand-canonical ensemble in the state k is given by

$$\langle N_k\rangle_V^{\mathcal{G}C}(\mu) = \frac{1}{e^{\beta(E_k(V)-\mu)}-1}. \tag{1.11}$$

Let $\mu_V(\rho)<E_1(V)$ be the unique root of the equation

$$\rho = \frac{1}{V}\langle N_V\rangle_V^{\mathcal{G}C}(\mu), \tag{1.12}$$

for a given V. Then a standard result[16] shows that the boundedness of the critical density (1.10) implies the existence of *generalized* BEC with condensate density, ρ_0, given by

$$\rho_0 := \lim_{\varepsilon\downarrow 0}\lim_{V\to\infty}\frac{1}{V}\sum_{\{k:E_k(V)<\varepsilon\}}\langle N_k\rangle_V^{\mathcal{G}C}(\mu_V(\rho)) = \rho-\rho_c, \quad \text{for } \rho>\rho_c. \tag{1.13}$$

Following the van den Berg–Lewis–Pulé classification, Refs. 14 and 16, it is useful to identify three categories of generalized BEC.

(I) The condensation is of type I when a *finite* number of single-particle states are macroscopically occupied.
(II) It is of type II when an *infinite* number of states are macroscopically occupied.
(III) It is of type III when *none* of the states is macroscopically occupied.

For a specific geometry we have more detailed information at our disposal. In the next section we collect the results from Ref. 14 that we shall need later about the GCE in the case of the anisotropically dilated parallelepipeds (1.1).

Remark 1.1: Though we have chosen here to work with Dirichlet boundary conditions, the proofs in this paper can be adapted without difficulty to periodic or Neumann boundary conditions.

Remark 1.2: Note that according to the classification presented above the condensate "fragmentation" is nothing but a generalized BEC of type I or II.

II. GENERALIZED BOSE–EINSTEIN CONDENSATION OF THE PERFECT BOSE GAS IN THE GRAND-CANONICAL ENSEMBLE

Proposition 2.1 (Ref. 14, Theorem 1): *Let* $\overline{\mu_V}(\rho)=\mu_V(\rho)-E_1(V)$. *Then the behavior of* $\overline{\mu_V}(\rho)$ *is as follows.*

(1) *For* $\rho \leqslant \rho_c$, $\lim_{V\to\infty}\overline{\mu}_V(\rho)=\overline{\mu}(\rho)$ *where* $\overline{\mu}(\rho)<0$ *is the unique root* $\overline{\mu}(\rho)<0$ *of the equation*

$$\rho = \lim_{V\to\infty}\frac{1}{V}\langle N_V\rangle_V^{\mathcal{GC}}(\mu) = \int_0^\infty \frac{1}{e^{\beta(\eta-\mu)}-1}F(d\eta). \tag{2.1}$$

(2) *For* $\rho>\rho_c$, $\lim_{V\to\infty}\overline{\mu}_V(\rho)=0$ *and for* $V\to\infty$,

$$\overline{\mu}_V(\rho) = -\{\beta V(\rho-\rho_c)\}^{-1} + \mathrm{O}(1/V), \text{ if } \alpha_1 < 1/2; \tag{2.2}$$

$$\overline{\mu}_V(\rho) = -\{\beta V A(\rho)\}^{-1} + \mathrm{O}(1/V), \text{ if } \alpha_1 = 1/2; \tag{2.3}$$

$$\overline{\mu}_V(\rho) = -\{2\beta V^{2(1-\alpha_1)}(\rho-\rho_c)^2\}^{-1} + \mathrm{O}(1/V), \text{ if } \alpha_1 > 1/2, \tag{2.4}$$

where $A(\rho)$ *is the unique root of the equation*

$$(\rho-\rho_c) = \sum_{j=1}^{\infty}\left[\frac{\pi^2}{2}(j^2-1)+A^{-1}\right]^{-1}. \tag{2.5}$$

The next statement by the same authors shows that there are different *types* of generalized BEC corresponding to different asymptotics (2.2)–(2.4).

Proposition 2.2 (Ref. 14): *For* $\rho\leqslant\rho_c$ *there is no generalized BEC and therefore no BEC of any type.*

For $\rho>\rho_c$ *there is generalized BEC and all three types of BEC occur.*

(1) *For* $\alpha_1<1/2$ *only the ground-state is macroscopically occupied (BEC of type I):*

$$\lim_{V\to\infty}\frac{1}{V}\langle N_{\mathbf{n}}\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \begin{cases}\rho-\rho_c, & \text{for } \mathbf{n}=(1,1,1),\\ 0, & \text{for } \mathbf{n}\neq(1,1,1).\end{cases} \tag{2.6}$$

(2) *For* $\alpha_1=1/2$ *there is macroscopic occupation of an infinite number of low-lying levels (BEC of type II):*

$$\lim_{V\to\infty}\frac{1}{V}\langle N_{\mathbf{n}}\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \begin{cases}\{(n_1^2-1)\pi^2/2+A^{-1}\}^{-1}, & \text{for } \mathbf{n}=(n_1,1,1),\\ 0, & \text{for } \mathbf{n}\neq(n_1,1,1).\end{cases} \tag{2.7}$$

(3) *Finally, for* $\alpha_1>1/2$ *no single-particle state is macroscopically occupied (BEC of type III):*

$$\lim_{V\to\infty} V^{-1}\langle N_{\mathbf{n}}\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = 0, \tag{2.8}$$

$$\lim_{V\to\infty} V^{2(\alpha_1-1)}\langle N_{\mathbf{n}}\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \begin{cases}2(\rho-\rho_c)^2, & \text{for } \mathbf{n}=(n_1,1,1),\\ 0, & \text{for } \mathbf{n}\neq(n_1,1,1).\end{cases} \tag{2.9}$$

We shall need an easy generalization of the foregoing proposition to obtain the distribution of the random variables N_k through their Laplace transform.

Theorem 2.1: *Let* $\rho>\rho_c$. *Then we have the following.*

(1) *For* $\alpha_1<1/2$,

$$\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_{\mathbf{n}}}{V}\right)\right\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \begin{cases}\dfrac{1}{1+\lambda(\rho-\rho_c)}, & \text{for } \mathbf{n}=(1,1,1),\\ 0, & \text{for } \mathbf{n}\neq(1,1,1).\end{cases} \tag{2.10}$$

(2) *For* $\alpha_1=1/2$,

$$\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_{\mathbf{n}}}{V}\right)\right\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \begin{cases} \dfrac{(n_1^2-1)\pi^2/2 + A^{-1}}{(n_1^2-1)\pi^2/2 + A^{-1} + \lambda}, & \text{for } \mathbf{n} = (n_1,1,1), \\ 0, & \text{for } \mathbf{n} \neq (n_1,1,1). \end{cases} \tag{2.11}$$

(3) *For* $\alpha_1 > 1/2$,

$$\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_{\mathbf{n}}}{V}\right)\right\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = 1, \tag{2.12}$$

$$\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_{\mathbf{n}}}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \begin{cases} \dfrac{1}{1+2\lambda(\rho-\rho_c)^2}, & \text{for } \mathbf{n} = (n_1,1,1), \\ 0, & \text{for } \mathbf{n} \neq (n_1,1,1). \end{cases} \tag{2.13}$$

Proof: This follows easily from Proposition 2.1 and the identity

$$\langle \exp(-\lambda N_k)\rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \frac{1-e^{-\beta(\eta_k(V)-\bar{\mu}_V(\rho))}}{1-e^{-\beta(\eta_k(V)-\bar{\mu}_V(\rho)+\lambda/\beta)}}. \tag{2.14}$$

□

We shall require some properties of the *Kac distribution* $\mathbb{K}_\Lambda(\mu;d\rho)$, see, e.g., Refs. 7, 14, 16, and 19. The Kac distribution relates the canonical (1.3) and grand-canonical (1.5) expectations in a finite volume:

$$\langle - \rangle_V^{\mathcal{GC}}(\mu) = \int_{[0,\infty)} \langle - \rangle_V^{\mathcal{C}}(x)\mathbb{K}_V(\mu;dx). \tag{2.15}$$

The *limiting* Kac distribution gives the decomposition of the limiting grand-canonical state $\langle - \rangle^{\mathcal{GC}}(\mu)$ into limiting canonical states $\langle - \rangle^{\mathcal{C}}(\rho)$. In the particular case of the PBG it is more convenient to define the Kac distribution in terms of the mean particle density, rather then the chemical potential. Therefore we define

$$\tilde{\mathbb{K}}_V(\rho;dx) := \mathbb{K}_V(\mu_V(\rho);dx), \tag{2.16}$$

so that

$$\langle - \rangle_V^{\mathcal{GC}}(\mu_V(\rho)) = \int_{[0,\infty)} \langle - \rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho;dx). \tag{2.17}$$

The next proposition proved in Ref. 14 gives the limiting Kac density for anisotropically dilated parallelepipeds.

Proposition 2.3: Let

$$\tilde{\mathbb{K}}(\rho;dx) := \lim_{V\to\infty} \tilde{\mathbb{K}}_V(\rho;dx). \tag{2.18}$$

If $\rho \leqslant \rho_c$, *then the PBG limiting Kac distribution has the one-point support:*

$$\tilde{\mathbb{K}}(\rho;dx) = \delta_\rho(dx). \tag{2.19}$$

If $\rho > \rho_c$, *then we have the following.*

(1) *For* $\alpha_1 < 1/2$,

$$\tilde{\mathbb{K}}(\rho;dx)=\begin{cases}0, & \text{for } x<\rho_c,\\ \dfrac{1}{\rho-\rho_c}\exp\left(-\dfrac{x-\rho_c}{\rho-\rho_c}\right)dx, & \text{for } x>\rho_c.\end{cases} \tag{2.20}$$

(2) *For* $\alpha_1=1/2$,

$$\tilde{\mathbb{K}}(\rho;dx)=\begin{cases}0, & \text{for } x<\rho_c,\\ \dfrac{\pi^2\sinh(2/A-\pi)^{1/2}}{(2/A-\pi)^{1/2}}\displaystyle\sum_{n=1}^{\infty}(-1)^{n-1}n^2\exp\left(-(x-\rho_c)\frac{\pi^2}{2}\left(n^2+\frac{2}{A\pi^2}-1\right)\right)dx, & \text{for } x>\rho_c.\end{cases} \tag{2.21}$$

(3) *For* $\alpha_1>1/2$,

$$\tilde{\mathbb{K}}(\rho;dx)=\delta_\rho(dx). \tag{2.22}$$

III. GENERALIZED BOSE–EINSTEIN CONDENSATION AND FLUCTUATIONS OF THE PERFECT BOSE GAS IN THE CANONICAL ENSEMBLE

In this section we prove results for the CE analogous to those for the GCE. We are forced to use different methods for the three regimes, so we treat them in separate subsections. But first we give some results which will be useful in all three cases. The basic identity for the canonical expectations at density $\rho=n/V$ of the occupation numbers is [see Ref. 3, Eq. (10)]:

$$\langle\exp(-\lambda N_k)\rangle_V^{\mathcal{C}}(\rho)=e^{\lambda}-(e^{\lambda}-1)Z_V(n)^{-1}\sum_{m=0}^{n}e^{-(\beta E_k+\lambda)(n-m)}Z_V(m). \tag{3.1}$$

The canonical expectations are notoriously difficult to calculate and are only accessible through the grand-canonical expectations. In the two cases $\alpha_1<1$ and $\alpha_1=1$ we shall exploit the fact that the sum on the right-hand side of Eq. (3.1) is very similar to the grand-canonical partition function.

The next theorem shows that the canonical expectations are monotonic increasing in the density. Note that this theorem holds for the PBG with any one-particle spectrum.

Theorem 3.1: *For fixed* $k\geqslant 1$ *and fixed,* V*, the canonical expectations for the PBG,* $\langle\exp(-\lambda N_k)\rangle_V^{\mathcal{C}}(\rho)$*, are monotonic decreasing functions of the density* ρ *for* $\lambda>0$ *while the moments* $\langle N_k^r\rangle_V^{\mathcal{C}}(\rho)$*,* $r\geqslant 1$ *are monotonic increasing functions of the density.*

Proof: From (3.1) we get

$$\langle\exp(-\lambda N_k)\rangle_V^{\mathcal{C}}((n+1)/V)-\langle\exp(-\lambda N_k)\rangle_V^{\mathcal{C}}(n/V)=-(e^{\lambda}-1)\left\{e^{-(\beta E_k+\lambda)(n+1)}Z_V(n+1)^{-1}+\sum_{m=0}^{n}e^{-(\beta E_k+\lambda)(n-m)}\left(\frac{Z_V(m+1)}{Z_V(n+1)}-\frac{Z_V(m)}{Z_V(n)}\right)\right\}. \tag{3.2}$$

Since

$$\left(\frac{Z_V(m+1)}{Z_V(n+1)}-\frac{Z_V(m)}{Z_V(n)}\right)=\frac{Z_V(m)}{Z_V(n+1)}\left(\frac{Z_V(m+1)}{Z_V(m)}-\frac{Z_V(n+1)}{Z_V(N)}\right),$$

by the inequalities (see Ref. 7)

$$\frac{Z_V(m+1)}{Z_V(m)} \geqslant \frac{Z_V(m+2)}{Z_V(m+1)} \geqslant \cdots \geqslant \frac{Z_V(n+1)}{Z_V(n)},$$

and by (3.2) we get the monotonicity

$$\langle \exp(-\lambda N_k)\rangle_V^{\mathcal{C}}((n+1)/V) - \langle \exp(-\lambda N_k)\rangle_V^{\mathcal{C}}(n/V) \leqslant 0. \tag{3.3}$$

By differentiating (3.2) r times with respect to λ at $\lambda=0$,

$$\langle N_k^r\rangle_V^{\mathcal{C}}((n+1)/V) - \langle N_k^r\rangle_V^{\mathcal{C}}(n/V) = \{n^r-(n-1)^r\}e^{-\beta E_k(n+1)}Z_V(n+1)^{-1} + \sum_{m=0}^{n}\{(n-m)^r-(n-m-1)^r\}e^{-\beta E_k(n-m)}\left(\frac{Z_V(m+1)}{Z_V(n+1)}-\frac{Z_V(m)}{Z_V(n)}\right), \tag{3.4}$$

which is positive by the same argument. □

Remark: In this paper whenever we take the limit

$$\lim_{V\to\infty}\langle - \rangle_V^{\mathcal{C}}(\rho); \tag{3.5}$$

we shall mean that we take the system with n particles in a container of volume $V_n = n\rho$ and then let $n\to\infty$, that is,

$$\lim_{n\to\infty}\langle - \rangle_{np}^{\mathcal{C}}(\rho). \tag{3.6}$$

The next theorem is valid for containers of any geometry and not just for rectangular boxes.

Theorem 3.2: *For $\rho \geqslant \rho_c$ the generalized condensate in the CE at density ρ is equal to $\rho - \rho_c$, that is*

$$\lim_{\varepsilon\downarrow 0}\lim_{V\to\infty}\sum_{\eta_k<\varepsilon}\langle N_k/V\rangle_V^{\mathcal{C}}(\rho) = \rho - \rho_c. \tag{3.7}$$

Proof: The statement is true for the imperfect (mean-field) Bose gas in the GCE; see Ref. 15. Since the mean-field term in the CE is irrelevant, the theorem follows from monotonicity and the fact that the Kac density for the imperfect Bose gas has one-point support. □

In the next theorem we shall make certain assumptions that are clearly satisfied for the parallelepipeds we are considering. We believe that in fact they hold much more generally.

Theorem 3.3: *Suppose that* $\lim_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{GC}}(\mu_\Lambda(\rho'))$ and $\tilde{\mathbb{K}}(\rho';[\rho,\infty))$ *are continuous in ρ' at ρ and that* $\tilde{\mathbb{K}}(\rho;[\rho,\infty)) \neq 0$. *Then* $\lim_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{GC}}(\mu_V(\rho))=0$ *implies that* $\lim_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{C}}(\rho)=0$.

Proof: Using the decomposition (2.17) and monotonicity we get for any $\varepsilon>0$:

$$\begin{aligned}\lim_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{GC}}(\mu_\Lambda(\rho+\varepsilon)) &= \lim_{V\to\infty}\int_{[0,\infty)}\langle N_k/V\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho+\varepsilon;dx)\\ &\geqslant \lim_{V\to\infty}\int_{[\rho,\infty)}\langle N_k/V\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho+\varepsilon;dx)\\ &\geqslant \limsup_{V\to\infty}\{\langle N_k/V\rangle_V^{\mathcal{C}}(\rho)\tilde{\mathbb{K}}_V(\rho+\varepsilon;[\rho,\infty))\}\\ &= \limsup_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{C}}(\rho)\tilde{\mathbb{K}}(\rho+\varepsilon;[\rho,\infty)).\end{aligned}$$

Since $\lim_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{GC}}(\mu_\Lambda(\rho'))$ and $\tilde{\mathbb{K}}(\rho';[\rho,\infty))$ are continuous in ρ', letting ε tend to zero, we get

$$\lim_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{G}C}(\mu_\Lambda(\rho)) \geqslant \limsup_{V\to\infty}\langle N_k/V\rangle_V^{\mathcal{C}}(\rho)\widetilde{\mathbb{K}}(\rho;[\rho,\infty)),$$

and because $\widetilde{\mathbb{K}}(\rho;[\rho,\infty))$ does not vanish the result follows. □

Remark: Note that this lemma implies that for $\rho \leqslant \rho_c$, there is never BEC in the CE.

Before looking at the three cases $\alpha_1 < 1/2$, $\alpha_1 = 1/2$ and $\alpha_1 > 1/2$ we first obtain lower and upper bounds on the density of states.

Lemma 3.1:

$$\frac{\sqrt{2}}{3\pi^2}(\eta^{1/2} - CV^{-\alpha_3})^3 < F_V(\eta) < \frac{\sqrt{2}}{3\pi^2}(\eta + E_1(V))^{3/2}, \tag{3.8}$$

for some C.

Proof:

$$VF_V(\eta - E_1(V)) = \#\left\{\mathbf{n}|\mathbf{n}\in\mathbb{N}^3, \frac{\pi^2}{2}\sum_{j=1}^{d=3}\frac{n_j^2}{V^{2\alpha_j}} < \eta\right\}, \tag{3.9}$$

that is, $VF_V(\eta - E_1(V))$ is the number of points of $\mathbb{N}^3$ inside the ellipsoid,

$$\frac{x^2}{2V^{2\alpha_1}\eta/\pi^2} + \frac{y^2}{2V^{2\alpha_2}\eta/\pi^2} + \frac{z^2}{2V^{2\alpha_3}\eta/\pi^2} = 1. \tag{3.10}$$

If we associate the point $\mathbf{n}$ with the volume of the unit cube centered at $\mathbf{n} - \left(\frac{1}{2},\frac{1}{2},\frac{1}{2}\right)$ we see that this number is less the volume of the ellipsoid in the first octant which is equal to $\pi(2V^{2\alpha_1}\eta/\pi^2)^{1/2}(2V^{2\alpha_2}\eta/\pi^2)^{1/2}(2V^{2\alpha_3}\eta/\pi^2)^{1/2}/6 = \sqrt{2}\eta^{3/2}V/3\pi^2$. Thus

$$VF_V(\eta - E_1(V)) < \frac{\sqrt{2}}{3\pi^2}\eta^{3/2}V, \tag{3.11}$$

and so

$$F_V(\eta) < \frac{\sqrt{2}}{3\pi^2}(\eta + E_1(V))^{3/2}. \tag{3.12}$$

Let $a > b > c > 0$, let $\lambda = 1 - 3/c$ and $a' = \lambda a$, $b' = \lambda b$, and $c' = \lambda c$. If the point in the first quadrant (x,y,z) satisfies $x^2/a'^2 + y^2/b'^2 + z^2/c'^2 \leqslant 1$, then it satisfies $(x+1)^2/a^2 + (y+1)^2/b^2 + (z+1)^2/c^2 \leqslant 1$. That is, each point inside the first quadrant of the ellipsoid $x^2/a'^2 + y^2/b'^2 + z^2/c'^2 = 1$ lies in a unit cube with the corner $\mathbf{n} \in \mathbb{N}^3$ (with $n_1 > x$, $n_2 > y$ and $n_3 > y$) inside the ellipsoid $x^2/a^2 + y^2/b^2 + z^2/c^2 = 1$. Therefore

$$VF_V(\eta - E_1(V)) > \frac{\sqrt{2}}{3\pi^2}V\left(\eta^{1/2} - \frac{3\pi}{\sqrt{2}V^{\alpha_3}}\right)^3, \tag{3.13}$$

yielding

$$F_V(\eta) > \frac{\sqrt{2}}{3\pi^2}\left((\eta + E_1(V))^{1/2} - \frac{3\pi}{\sqrt{2}V^{\alpha_3}}\right)^3 > \frac{\sqrt{2}}{3\pi^2}V\left(\eta^{1/2} - \frac{3\pi}{\sqrt{2}V^{\alpha_3}}\right)^3. \tag{3.14}$$

□

A. Case $\alpha_1 > 1/2$

We study this case first because it is the simplest since the limiting Kac distribution is a delta measure concentrated at ρ and we have strong equivalence of ensembles (see Proposition 2.3). We

shall use this fact together with the monotonicity properties of Theorem 3.1 to show that in this case the limiting canonical and grand-canonical expectations are identical.

Lemma 3.2: For $\alpha_1 > 1/2$ *and* $\lambda > 0$ *the following inequalities hold:*

$$\begin{aligned}\liminf_{\varepsilon\downarrow 0}\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{G}C}(\mu_V(\rho-\varepsilon)) &\geqslant \limsup_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(\rho)\\ &\geqslant \liminf_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(\rho)\\ &\geqslant \limsup_{\epsilon\downarrow 0}\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{G}C}(\mu_\Lambda(\rho+\varepsilon)).\end{aligned} \tag{3.15}$$

Proof: We start with the first inequality. Using the decomposition (2.17) we get for any $\varepsilon > 0$:

$$\begin{aligned}\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{G}C}(\mu_V(\rho-\varepsilon)) &= \lim_{V\to\infty}\int_{[0,\infty)}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho-\varepsilon;dx)\\ &\geqslant \lim_{V\to\infty}\int_{[0,\rho)}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho-\varepsilon;dx)\\ &\geqslant \limsup_{V\to\infty}\left\{\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(\rho)\tilde{\mathbb{K}}_V(\rho-\varepsilon;[0,\rho))\right\}\\ &= \limsup_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(\rho).\end{aligned} \tag{3.16}$$

In the penultimate inequality we have used the monotonicity established in Theorem 3.1 and in the last one we have used (2.19) and (2.22). The last inequality in (3.15) is proved similarly:

$$\begin{aligned}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{G}C}(\mu_V(\rho+\varepsilon)) &= \int_{[0,\infty)}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho+\varepsilon;dx)\\ &= \int_{[0,\rho)}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho+\varepsilon;dx)\\ &\quad+\int_{[\rho,\infty)}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho+\varepsilon;dx)\\ &\leqslant \tilde{\mathbb{K}}_V(\rho+\varepsilon;[0,\rho))\\ &\quad+\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(\rho)\tilde{\mathbb{K}}_V(\rho-\varepsilon;[\rho,\infty)).\end{aligned} \tag{3.17}$$

Therefore

$$\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{G}C}(\mu_V(\rho+\varepsilon)) \leqslant \liminf_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(\rho). \tag{3.18}$$

□

The following theorem and corollary give the distribution and the mean of $N_{\mathbf{n}}/V^{2(1-\alpha_1)}$ and therefore they give the fluctuations about the mean.

Theorem 3.4: *If* $\alpha_1 > 1/2$ *and* $\rho > \rho_c$ *then the limiting distribution in the canonical ensemble of* $N_{\mathbf{n}}/V^{2(1-\alpha_1)}$ *has Laplace transform for* $\lambda > 0$ *given by*

$$\lim_{V\to\infty}\left\langle \exp\left(-\lambda\frac{N_k}{V^{2(1-\alpha_1)}}\right)\right\rangle_V^{\mathcal{C}}(\rho)=\begin{cases}\dfrac{1}{1+2\lambda(\rho-\rho_c)^2}, & \text{for } \mathbf{n}=(n_1,1,1),\\ 0, & \text{for } \mathbf{n}\neq(n_1,1,1).\end{cases} \tag{3.19}$$

Proof: This follows from the preceding lemma and Theorem 2.1. □

Corollary 3.1: If $\alpha_1>1/2$ *and* $\rho>\rho_c$ *then*

$$\lim_{V\to\infty}\left\langle \frac{N_{\mathbf{n}}}{V^{2(1-\alpha_1)}}\right\rangle_V^{\mathcal{C}}(\rho)=\begin{cases}2\lambda(\rho-\rho_c)^2, & \text{for } \mathbf{n}=(n_1,1,1),\\ 0, & \text{for } \mathbf{n}\neq(n_1,1,1).\end{cases} \tag{3.20}$$

Proof: We have to check that there exists $K<\infty$ such that for all V,

$$\left\langle\left(\frac{N_k}{V^{2(1-\alpha_1)}}\right)^2\right\rangle_V^{\mathcal{C}}(\rho)<K. \tag{3.21}$$

Then the corollary follows from the preceding theorem. We have again for any $\varepsilon>0$,

$$\begin{aligned}\left\langle\left(\frac{N_k}{V^{2(1-\alpha_1)}}\right)^2\right\rangle_V^{\mathcal{GC}}(\mu_V(\rho+\epsilon))&=\int_{[0,\infty)}\left\langle\left(\frac{N_k}{V^{2(1-\alpha_1)}}\right)^2\right\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho+\epsilon;dx)\\ &\geqslant\int_{[\rho,\infty)}\left\langle\left(\frac{N_k}{V^{2(1-\alpha_1)}}\right)^2\right\rangle_V^{\mathcal{C}}(x)\tilde{\mathbb{K}}_V(\rho+\epsilon;dx)\\ &\geqslant\left\langle\left(\frac{N_k}{V^{2(1-\alpha_1)}}\right)^2\right\rangle_V^{\mathcal{C}}(\rho)\tilde{\mathbb{K}}_V(\rho+\epsilon;[\rho,\infty))\geqslant\frac{1}{2}\left\langle\left(\frac{N_k}{V^{2(1-\alpha_1)}}\right)^2\right\rangle_V^{\mathcal{C}}(\rho),\end{aligned} \tag{3.22}$$

if V is large enough. This implies the existence of K as above since

$$\left\langle\left(\frac{N_k}{V^{2(1-\alpha_1)}}\right)^2\right\rangle_V^{\mathcal{GC}}(\mu_V(\rho+\epsilon)), \tag{3.23}$$

converges as $V\to\infty$. □

Corollary 3.2: When $\alpha_1>1/2$, *there is type III BEC in the canonical ensemble.*

Proof: From the preceding corollary or from Theorem 3.3 we can deduce immediately that

$$\lim_{V\to\infty}\left\langle\frac{N_k}{V}\right\rangle_V^{\mathcal{C}}(\rho)=0, \tag{3.24}$$

for any $\rho>\rho_c$. □

B. Case $\alpha_1=1/2$

For this case BEC into the ground state is treated in Ref. 2. Here we extend the result to higher levels.

Because for $\alpha_1=1/2$ the spectral series (1.7) corresponding to $n_1=1,2,3,\ldots$, has the *smallest* energy spacing $\pi^2/2V$, it plays a specific role in calculations of the limiting occupation densities. Let

$$\epsilon_n:=\pi^2n^2/2,\quad \eta_{m,n}:=\beta(\epsilon_m-\epsilon_n),\quad b_{m,n}:=\eta_{m,n}^{-1}\prod_{\{m'\neq n,m'\neq m\}}(1-\eta_{m,n}/\eta_{m',n})^{-1}, \tag{3.25}$$

for $m\neq n$.

In Ref. 2 the following result was proved.

Let $\alpha_1=1/2$. *Then for* $\rho>\rho_c$,

$$\lim_{V\to\infty}\left\langle \frac{N_1}{V}\right\rangle_V^{\mathcal{C}}(\rho)=\frac{\sum_{m=2}^{\infty} b_{m,1}\{\eta_{m,1}(\rho-\rho_c)-1+\exp[-\eta_{m,1}(\rho-\rho_c)]\}}{\sum_{m=2}^{\infty} b_{m,1}\eta_{m,1}\{1-\exp[-\eta_{m,1}(\rho-\rho_c)]\}}. \tag{3.26}$$

Here we give an extension of (3.26) to other k's. Note that by Theorem 3.3 and a comparison with the GCE, in this case there can only be condensation in states corresponding to $\mathbf{n}=(n_1,1,1)$. The main tool in the technique developed in Refs. 2 and 3 is the following identity.

Let $\{K_{k,V}(dx)\}_{k\geqslant 1}$ be (non-normalized) measures whose distributions are the functions

$$K_{k,V}(x)=\begin{cases} Z_V(r)\exp\{-\beta(V_{pk}-rE_k(V))\}, & \text{for } r/V<x\leqslant (r+1)/V,\\ 0, & \text{for } x\leqslant 0,\end{cases} \tag{3.27}$$

for $r=0,1,2,\ldots$, and some $\{p_k\}_{k\geqslant 1}$. Then we can re-write Eq. (3.1) as follows:

$$\begin{aligned}\langle\exp\{-\lambda N_k/V\}\rangle_V^{\mathcal{C}}(\rho)&=e^{-\lambda\rho}\int_{[0,\rho+1/V]} e^{\lambda x}K_{k,V}(dx)/K_{k,V}(\rho+1/V)\\ &=e^{-\lambda/V}-\lambda e^{-\lambda\rho}\int_0^{\rho+1/V} K_{k,V}(x)e^{\lambda x}dx/K_{k,V}(\rho+1/V).\end{aligned} \tag{3.28}$$

We shall use this identity to calculate the thermodynamic limit of its left-hand side for a given density and $k\geqslant 1$. From (3.27) we can calculate the Laplace transformation of the measure $K_{k,V}(dx)$:

$$\int_{\mathbb{R}} e^{-\lambda x}K_{k,V}(dx)=(1-e^{-\lambda/V})e^{-V\beta_{pk}}\Xi_V(E_k(V)-\lambda/\beta V), \tag{3.29}$$

where for the PBG the grand-canonical partition function (1.6) has the explicit form

$$\Xi_V(\mu)=\prod_{k=1}^{\infty}\{1-e^{-\beta(E_k(V)-\mu)}\}^{-1}.$$

Now we fix the p_k's which are still arbitrary by defining

$$p_k:=-\frac{1}{\beta V}\sum_{j\neq k}\ln|1-e^{-\beta(E_j(V)-E_k(V))}| \tag{3.30}$$

and prove the following lemma. We put

$$\tilde{K}_{n,V}:=K_{(n,1,1),V}. \tag{3.31}$$

Lemma 3.3: Let $\alpha_1=1/2$. *Then*

$$\tilde{K}_n(x):=\lim_{V\to\infty}\tilde{K}_{n,V}(x)=\begin{cases}0, & \text{for } x\leqslant\rho_c,\\ (-1)^{(n-1)}\sum_{m=1,m\neq n}^{\infty} b_{m,n}\eta_{m,n}\{1-\exp[-\eta_{m,n}(x-\rho_c)]\}, & \text{for } x>\rho_c.\end{cases} \tag{3.32}$$

Proof: Let $\lambda>V(E_k-E_1)$. From the definitions (3.29) and (3.30) we get

$$\int_{\mathbb{R}} e^{-\lambda x}K_{k,V}(dx)=\prod_{j\neq k}\frac{|1-e^{-\beta(E_j(V)-E_k(V))}|}{1-e^{-\beta(E_j(V)-E_k(V)+\lambda/\beta V)}}=\exp\left\{-\sum_{j\neq k}\ln\left|1+\frac{1-e^{-\lambda/V}}{e^{\beta(E_j(V)-E_k(V))}-1}\right|\right\}.$$

For $k \geqslant 1$ and $\eta \geqslant \eta_1(V) - \eta_k(V)$ we define the *shifted* integrated density of states; cf. (1.8):

$$F_{k,V}(\eta \geqslant 0) := \frac{1}{V} \#\{j : \eta_j(V) \leqslant \eta + \eta_k(V), j \neq k\} = F_V(\eta + \eta_k(V)) - \frac{1}{V}\mathbf{1}_{[0,\infty)}(\eta). \tag{3.33}$$

For $b > a$, let

$$I_{k,V}(a,b) := V \int_{[a,b)} \ln \left| 1 + \frac{1 - e^{-\lambda/V}}{e^{\beta\eta} - 1} \right| F_{k,V}(d\eta). \tag{3.34}$$

Then

$$\sum_{j \neq k} \ln \left| 1 + \frac{1 - e^{-\lambda/V}}{e^{\beta(E_j(V) - E_k(V))} - 1} \right| = V \int_{[\eta_1(V) - \eta_k(V), \infty)} \ln \left| 1 + \frac{1 - e^{-\lambda/V}}{e^{\beta\eta} - 1} \right| F_{k,V}(d\eta) = I_{k,V}(\eta_1(V) - \eta_k(V), \infty). \tag{3.35}$$

We can write

$$I_{k,V}(\eta_1(V) - \eta_k(V), \infty) = I_{k,V}(\eta_1(V) - \eta_k(V), 1/V^{2\alpha_3}) + I_{k,V}(1/V^{2\alpha_3}, \infty). \tag{3.36}$$

Since $\lim_{V \to \infty} \eta_k(V) = 0$, by Lemma 3.1 we have

$$\lim_{V \to \infty} F_{k,V}(\eta) = \lim_{V \to \infty} F_V(\eta + \eta_k(V)) = F(\eta) \tag{3.37}$$

and

$$F_{k,V}(\eta) \leqslant C' \eta^{3/2}, \tag{3.38}$$

for $\eta > 1/V^{2\alpha_3}$; using the estimate $x - x^2/2 \leqslant \ln(1+x) \leqslant x$ we get

$$\lim_{V \to \infty} I_{k,V}(1/V^{2\alpha_3}, \infty) = \lambda \rho_c. \tag{3.39}$$

On the lower part of the spectrum we need to scale $F_{k,V}$. Let

$$G_{k,V}(\xi) := V F_{k,V}(\xi/V). \tag{3.40}$$

Then

$$I_{k,V}(\eta_1(V) - \eta_k(V), 1/V^{2\alpha_3}) = \int_{[V(\eta_1(V) - \eta_k(V)), V^{1-2\alpha_3}]} \ln \left| 1 + \frac{1 - e^{-\lambda/V}}{e^{\beta\xi/V} - 1} \right| G_{k,V}(d\xi). \tag{3.41}$$

Now let $E_k(V)$ correspond to $\epsilon_{(n,1,1),V}$. Then in the limit, $G_{k,V}$ gives a nontrivial point measure concentrated on the set $\{\beta^{-1}\eta_{m,n}, m \neq n\}$:

$$\lim_{V \to \infty} G_{k,V}(\xi > 0) = \#\{m : \beta^{-1}\eta_{m,n} \leqslant \xi, m \neq n\}. \tag{3.42}$$

Therefore, by (3.41) and (3.42) we get

$$\lim_{V \to \infty} \{I_{k,V}(V(\eta_1(V) - \eta_k(V)), 1/V^{2\alpha_3}\} = \sum_{m \neq n} \ln \left| 1 + \frac{\lambda}{\eta_{m,n}} \right|. \tag{3.43}$$

Thus for $\lambda > |\eta_{1,n}|$,

$$\lim_{V \to \infty} \int_0^\infty K_{k,V}(dx) e^{-\lambda x} = \exp\{-\lambda \rho_c\} \exp\left\{ - \sum_{m \neq n} \ln \left| 1 + \frac{\lambda}{\eta_{m,n}} \right| \right\}, \tag{3.44}$$

and the lemma follows by inverting the Laplace transform. □

Theorem 3.5: *Let $\rho>\rho_c$ and $\alpha_1=1/2$. Let $E_k(V)$ correspond to $\epsilon_{(n,1,1),V}$. Then*

$$\lim_{V\to\infty}\langle\exp\{-\lambda N_k/V\}\rangle_V^{\mathcal{C}}(\rho)=\frac{\sum_{m=1,m\neq n}^{\infty}b_{m,n}\frac{\eta_{m,n}^2}{\eta_{m,n}-\lambda}\{\exp[\lambda(\rho-\rho_c)]-\exp[-\eta_{m,n}(\rho-\rho_c)]\}}{\sum_{m=1,m\neq n}^{\infty}b_{m,n}\eta_{m,n}\{1-\exp[-\eta_{m,n}(\rho-\rho_c)]\}}. \tag{3.45}$$

Proof: The identity (3.28) gives

$$\lim_{V\to\infty}\langle\exp\{-\lambda N_k/V\}\rangle_V^{\mathcal{C}}(\rho)=1-\frac{\lambda e^{-\lambda\rho}\int_0^{\rho}K_k(x)e^{\lambda x}dx}{K_k(\rho)}. \tag{3.46}$$

From the preceding lemma and for $\lambda>0$,

$$\begin{aligned}&\frac{\lambda e^{-\lambda\rho}\int_0^{\rho}K_k(x)e^{\lambda x}dx}{K_k(\rho)}\\&=\frac{\sum_{m\neq n}^{\infty}b_{m,n}\eta_{m,n}\lambda e^{-\lambda\rho}\int_{\rho_c}^{\rho}e^{\lambda x}\{1-\exp[-\eta_{m,n}(x-\rho_c)]\}dx}{\sum_{m\neq n}b_{m,n}\eta_{m,n}\{1-\exp[-\eta_{m,n}(\rho-\rho_c)]\}}\\&=-\frac{\sum_{m\neq n}b_{m,n}\frac{\eta_{m,n}}{\eta_{m,n}-\lambda}\{\eta_{m,n}\exp[-\lambda(\rho-\rho_c)]-\lambda\exp[-\eta_{m,n}(\rho-\rho_c)]-(\eta_{m,n}-\lambda)\}}{\sum_{m\neq n}b_{m,n}\eta_{m,n}\{1-\exp[-\eta_{m,n}(\rho-\rho_c)]\}}.\end{aligned} \tag{3.47}$$

This gives (3.45). □

We are now in a position to prove that in this case there is BEC of type II for $\rho>\rho_c$.

Theorem 3.6: *For $\rho>\rho_c$ and for $\alpha_1=1/2$ all states with $\mathbf{n}=(n,1,1)$ are macroscopically occupied (BEC of type II) while all the other states are not. The occupation density is given by*

$$\lim_{V\to\infty}\left\langle\frac{N_{(n,1,1)}}{V}\right\rangle_V^{\mathcal{C}}(\rho)=\frac{\sum_{m=1,\neq n}^{\infty}b_{m,n}\{\eta_{m,n}(\rho-\rho_c)-1+\exp[-\eta_{m,n}(\rho-\rho_c)]\}}{\sum_{m=1,m\neq n}^{\infty}b_{m,n}\eta_{m,n}\{1-\exp[-\eta_{m,n}(\rho-\rho_c)]\}}.$$

Proof: It is sufficient to check that there exists $K<\infty$ such that for all V,

$$\langle(N_k/V)^2\rangle_V^{\mathcal{C}}(\rho)<K. \tag{3.48}$$

Then the theorem follows from the preceding one. We have

$$\langle (N_k/V)^2\rangle_V^{\mathcal{G}C}(\mu_V(\rho)) = \int_{[0,\infty)} \langle (N_k/V)^2\rangle_V^{\mathcal{C}}(x)\widetilde{\mathbb{K}}_V(\rho;dx) \geqslant \int_{[0,\infty)} \langle (N_k/V)^2\rangle_V^{\mathcal{C}}(x)\widetilde{\mathbb{K}}_V(\rho;dx)$$

$$\geqslant \langle (N_k/V)^2\rangle_V^{\mathcal{C}}(\rho)\widetilde{\mathbb{K}}_V(\rho;[\rho,\infty)). \quad (3.49)$$

This implies the existence of K as above since $\langle (N_k/V)^2\rangle_V^{\mathcal{G}C}(\mu_V(\rho))$ converges as $V\to\infty$ and $\widetilde{\mathbb{K}}_V(\rho;[\rho,\infty))$ converges to a nonzero limit. □

C. Case $\alpha_1 < 1/2$

In Ref. 3 the canonical PBG in parallelepipeds,

$$\Lambda_V := \{x\in\mathbb{R}^3 : 0\leqslant x_j\leqslant a_j V^{1/3}, j=1,2,3\}, \quad a_1a_2a_3 = 1, \quad (3.50)$$

was considered. It was proved that for this system there is BEC of *type I*. In particular the following was proved.

Proposition 3.1 (Ref. 3, Theorem 1): *For the PBG in parallelepipeds (3.50), the following limits hold when* $\lambda\in\mathbb{R}$:

$$\lim_{V\to\infty}\langle \exp\{-\lambda N_k/V\}\rangle_V^{\mathcal{C}}(\rho) = \begin{cases} \exp\{-\lambda(\rho-\rho_c)\}, & \text{for } k=1,\\ 1, & \text{for } k>1, \end{cases} \quad (3.51)$$

if $\rho>\rho_c$, *and*

$$\lim_{V\to\infty}\langle \exp\{-\lambda V^{\gamma}N_k/V\}\rangle_V^{\mathcal{C}}(\rho) = 1, \quad (3.52)$$

for any $0\leqslant\gamma<1$ *and* $k\geqslant 1$, *if* $\rho\leqslant\rho_c$.

Note that in Ref. 3, Theorem 1, $\lambda\leqslant 0$, but this is not necessary.

In this section we shall prove a similar result to Proposition 3.1 for the case of the rectangular parallelepipeds (1.1) with $\alpha_1<1/2$, that is, we shall show that in this case there is also *type I* BEC. It is sufficient to show that there is condensation in the ground state since by Theorem 3.3 no other state can be macroscopically occupied.

Let $K_{1,V}(dx)$ be as in (3.27) in Sec. III B.

Lemma 3.4: Let $\alpha_1<1/2$. *Then*

$$\lim_{V\to\infty} K_{1,V}(dx) = \delta_{\rho_c}(dx). \quad (3.53)$$

Proof: The proof is almost identical to that of Lemma 3.3. The only difference is that since $\eta_j(V)-\eta_1(V)\geqslant a_{j,k}/V^{2\alpha_1}$, (3.40) implies that

$$G_{1,V}(\xi>0) = \#\{j : \eta_j(V)-\eta_1(V)\leqslant \xi/V\}\to 0, \quad \text{when } V\to\infty, \quad (3.54)$$

for $\alpha_1<1/2$, and the lemma follows. □

We can now prove that in this case there is BEC of type I for $\rho>\rho_c$.

Theorem 3.7: *For* $\rho>\rho_c$ *and for* $\alpha_1<1/2$ *only the ground-state is macroscopically occupied (BEC of type I):*

$$\lim_{V\to\infty}\frac{1}{V}\langle N_{\mathbf{n}}\rangle_V^{\mathcal{C}}(\rho) = \begin{cases} \rho-\rho_c & \text{for } \mathbf{n}=(1,1,1),\\ 0, & \text{for } \mathbf{n}\neq(1,1,1). \end{cases} \quad (3.55)$$

Proof: From the preceding lemma and the identity (3.28) we have for $\lambda>0$,

$$\lim_{V\to\infty}\langle\exp(-\lambda N_{\mathbf{n}}/V)\rangle_V^{\mathcal{G}C}(\rho)=\exp(-\lambda(\rho-\rho_c)). \tag{3.56}$$

It is sufficient to show the second moment is bounded, that is, there exists $K<\infty$ such that for all V,

$$\langle(N_k/V)^2\rangle_V^{\mathcal{C}}(\rho)<K. \tag{3.57}$$

The bound can be obtained by the same argument as in Theorem 3.6. □

In the rest of this subsection we study the fluctuations of N_1/V. We need the shifted integrated density of states in d dimensions $F_1^{(d)}$, $d=1,2,3$, in the unit boxes $[0,1]^d$:

$$F_1^{(d)}(\eta):=\#\left\{\mathbf{n}|\mathbf{n}\in\mathbb{N}^d,\frac{\pi^2}{2}\sum_{j=1}^{d}(n_j-1)^2\leqslant\eta\right\}. \tag{3.58}$$

Theorem 3.8: *Suppose* $\alpha_1<1/2$ *and let* $\gamma=1-2\alpha_1>0$. *Then for* $\rho>\rho_c$,

$$\lim_{V\to\infty}\langle\exp\{\lambda V^{\gamma}(N_1/V-\langle N_1/V\rangle_V^{\mathcal{C}}(\rho))\}\rangle_V^{\mathcal{C}}(\rho)$$
$$=\begin{cases}\exp(g_1(\lambda)), & \text{if } \alpha_3<\alpha_2<\alpha_1<1/2,\\ \exp(2g_1(\lambda)+g_2(\lambda)), & \text{if } \alpha_3<\alpha_2=\alpha_1<1/2,\\ \exp(3g_1(\lambda)+3g_2(\lambda)+g_3(\lambda)), & \text{if } \alpha_3=\alpha_2=\alpha_1=1/3,\end{cases} \tag{3.59}$$

where

$$g_1(\lambda)=\int_{(0,\infty)}\left[-\ln\left(1+\frac{\lambda}{\beta\eta}\right)+\frac{\lambda}{\beta\eta}\right]F_1^{(1)}(d\eta),$$

$$g_2(\lambda)=\int_{(0,\infty)^2}\left[-\ln\left(1+\frac{\lambda}{\beta(\eta_1+\eta_2)}\right)+\frac{\lambda}{\beta(\eta_1+\eta_2)}\right]F_1^{(2)}(d\eta_1,d\eta_2),$$

$$g_3(\lambda)=\int_{(0,\infty)^3}\left[-\ln\left(1+\frac{\lambda}{\beta(\eta_1+\eta_2+\eta_3)}\right)+\frac{\lambda}{\beta(\eta_1+\eta_2+\eta_3)}\right]F_1^{(3)}(d\eta_1,d\eta_2,d\eta_3). \tag{3.60}$$

Remark: Note that $3g_1(\lambda)+3g_2(\lambda)+g_3(\lambda)$ is the same as $g(\lambda)$ in Ref. 3.

Proof: Let

$$L_V(x):=\begin{cases}Z_V(r)\exp\{-\beta(Vp_1-rE_k(V))\}, & \text{for } V^{\gamma}(r/V-\rho_c^V)<x\leqslant V^{\gamma}((r+1)/V-\rho_c^V),\\ 0, & \text{for } x\leqslant -V^{\gamma}\rho_c^V,\end{cases}$$

for $r=0,1,2,\ldots$, where p_1 is as in (3.30),

$$\rho_c^V:=\int_{(0,\infty)}\frac{1}{e^{\beta\eta}-1}F_V(d\eta), \tag{3.61}$$

and where we put $Z_V(0)=1$. Then

$$\langle\exp\{\lambda V^{\lambda}(N_1/V-(\rho-\rho_c^V))\}\rangle_V^{\mathcal{C}}(\rho)=\int_{(-\infty,\delta_V)}e^{-\lambda x}L_V(dx)/K_{1,V}(\rho+1/V), \tag{3.62}$$

where $\delta_V=V^{\gamma}(\rho-\rho_c^V)+V^{-2\alpha_1}$. By Lemma 3.4 for $\rho>\rho_c$, $\lim_{V\to\infty}K_{1,V}(\rho+1/V)=1$ and therefore

$$\langle \exp\{\lambda V^{\lambda}(N_1/V-(\rho-\rho_c^V))\}\rangle_V^{\mathcal{C}}(\rho)=\lim_{V\to\infty}\int_{(-\infty,\infty)}e^{-\lambda x}L_V(dx). \tag{3.63}$$

Now

$$\begin{aligned}\ln\int_{(-\infty,\infty)}e^{-\lambda x}L_V(dx)&=V\int_{(0,\infty)}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta\eta}-1}\right)+\frac{\lambda V^{-2\alpha_1}}{e^{\beta\eta}-1}\right]F_V(d\eta)\\&=\sum_{\mathbf{n}\neq(1,1,1)}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{\mathbf{n},V}-\epsilon_{(1,1,1),V})}-1}\right)+\frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{\mathbf{n},V}-\epsilon_{(1,1,1),V})}-1}\right].\end{aligned} \tag{3.64}$$

Consider first the case $\alpha_3<\alpha_2<\alpha_1<1/2$. We split up the last sum into two parts, the first corresponds to the eigenvalues that go to zero like $V^{-2\alpha_1}$ and the second to the rest:

$$\ln\int_{(-\infty,\infty)}e^{-\lambda x}L_V(dx)=A_V+B_V, \tag{3.65}$$

where

$$A_V=\sum_{n_1\neq 1}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{(n_1,1,1),V}-\epsilon_{(1,1,1),V})}-1}\right)+\frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{(n_1,1,1),V}-\epsilon_{(1,1,1),V})}-1}\right] \tag{3.66}$$

and

$$B_V=\sum_{(n_2,n_3)\neq(1,1)}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{\mathbf{n},V}-\epsilon_{(1,1,1),V})}-1}\right)+\frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{\mathbf{n},V}-\epsilon_{(1,1,1),V})}-1}\right]. \tag{3.67}$$

Note that by definition (3.58),

$$A_V=\int_{(0,\infty)}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta V^{-2\alpha_1}\eta}-1}\right)+\frac{\lambda V^{-2\alpha_1}}{e^{\beta V^{-2\alpha_1}\eta}-1}\right]F_1^{(1)}(d\eta). \tag{3.68}$$

Using the bounds [obtained from the inequality $-x<-\ln(1+x)<\frac{1}{2}x^2-x$]:

$$0<\frac{\lambda-1+e^{-\lambda}}{e^x-1}<-\ln\left(1+\frac{1-e^{-\lambda}}{e^x-1}\right)+\frac{\lambda}{e^x-1}<\frac{1}{2}\left(\frac{1-e^{-\lambda}}{e^x-1}\right)^2+\frac{\lambda-1+e^{-\lambda}}{e^x-1}<\frac{c\lambda^2}{x^2}, \tag{3.69}$$

we get using the Dominated Convergence Theorem,

$$\lim_{V\to\infty}A_V=g_1(\lambda). \tag{3.70}$$

Using the same inequality,

$$\begin{aligned}0<B_V&\leqslant\frac{\lambda^2}{\beta^2V^{4\alpha_1}}\sum_{(n_2,n_3)\neq(1,1)}\frac{1}{(\epsilon_{\mathbf{n},V}-\epsilon_{(1,1,1),V})^2}\\&=\frac{4\lambda^2}{\pi^4\beta^2V^{4\alpha_1}}\sum_{(n_2,n_3)\neq(1,1)}\frac{1}{\left(\frac{(n_1^2-1)}{V^{2\alpha_1}}+\frac{(n_2^2-1)}{V^{2\alpha_2}}+\frac{(n_3^2-1)}{V^{2\alpha_3}}\right)^2}\\&=\frac{4\lambda^2}{\pi^4\beta^2}\sum_{(n_2,n_3)\neq(1,1)}\frac{1}{((n_1^2-1)+(n_2^2-1)V^{2(\alpha_1-\alpha_2)}+(n_3^2-1)V^{2(\alpha_1-\alpha_2)})^2}.\end{aligned} \tag{3.71}$$

Now the summand in the last sum tends to zero as $V\to\infty$ and it is bounded above by

$$\frac{1}{((n_1^2-1)+(n_2^2-1)+(n_3^2-1))^2}. \tag{3.72}$$

Since

$$\sum_{(n_2,n_3)\neq(1,1)} \frac{1}{((n_1^2-1)+(n_2^2-1)+(n_3^2-1))^2} < \infty, \tag{3.73}$$

$B_V\to 0$ as $V\to\infty$ by the same theorem.

Next we consider the case $\alpha_3<\alpha_2=\alpha_1<1/2$. Now we take

$$A_V = \sum_{(n_1,n_2)\neq(1,1)} \left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{(n_1,n_2,1),V}-\epsilon_{(1,1,1),V})}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{(n_1,n_2,1),V}-\epsilon_{(1,1,1),V})}-1}\right] \tag{3.74}$$

and

$$B_V = \sum_{n_3\neq 1} \left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{\mathbf{n},V}-\epsilon_{(1,1,1),V})}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{\mathbf{n},V}-\epsilon_{(1,1,1),V})}-1}\right]. \tag{3.75}$$

In this case by definition (3.58),

$$\begin{aligned} A_V &= 2\sum_{n_1\neq 1}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{(n_1,1,1),V}-\epsilon_{(1,1,1),V})}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{(n_1,1,1),V}-\epsilon_{(1,1,1),V})}-1}\right] \\ &\quad + \sum_{n_1\neq 1,n_2\neq 1}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{(n_1,n_2,1),V}-\epsilon_{(1,1,1),V})}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{(n_1,n_2,1),V}-\epsilon_{(1,1,1),V})}-1}\right] \\ &= 2\int_{(0,\infty)}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta V^{-2\alpha_1}\eta}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta V^{-2\alpha_1}\eta}-1}\right] F_1^{(1)}(d\eta) \\ &\quad + \int_{(0,\infty)^2}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta V^{-2\alpha_1}(\eta_1+\eta_2)}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta V^{-2\alpha_1}(\eta_1+\eta_2)}-1}\right] F_1^{(2)}(d\eta_1,d\eta_2). \end{aligned} \tag{3.76}$$

By the same argument as above,

$$\lim_{V\to\infty} A_V = 2g_1(\lambda)+g_2(\lambda), \tag{3.77}$$

and

$$\lim_{V\to\infty} B_V = 0. \tag{3.78}$$

Finally, for $\alpha_3=\alpha_2=\alpha_1=1/3$,

$$\begin{aligned} \int_{(-\infty,\infty)} L_V(dx)e^{-\lambda x} &= 3\sum_{n_1\neq 1}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{(n_1,1,1),V}-\epsilon_{(1,1,1),V})}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{(n_1,1,1),V}-\epsilon_{(1,1,1),V})}-1}\right] \\ &\quad + 3\sum_{n_1\neq 1,n_2\neq 1}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta(\epsilon_{(n_1,n_2,1),V}-\epsilon_{(1,1,1),V})}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta(\epsilon_{(n_1,n_2,1),V}-\epsilon_{(1,1,1),V})}-1}\right] \\ &= 3\int_{(0,\infty)}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta V^{-2\alpha_1}\eta}-1}\right) + \frac{\lambda V^{-2\alpha_1}}{e^{\beta V^{-2\alpha_1}\eta}-1}\right] F_1^{(1)}(d\eta) \end{aligned}$$

$$+3\int_{(0,\infty)^2}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta V^{-2\alpha_1}(\eta_1+\eta_2)}-1}\right)+\frac{\lambda V^{-2\alpha_1}}{e^{\beta V^{-2\alpha_1}(\eta_1+\eta_2)}-1}\right]F_1^{(2)}(d\eta_1,d\eta_2)$$
$$+\int_{(0,\infty)^3}\left[-\ln\left(1+\frac{1-e^{-\lambda V^{-2\alpha_1}}}{e^{\beta V^{-2\alpha_1}(\eta_1+\eta_2+\eta_3)}-1}\right)+\frac{\lambda V^{-2\alpha_1}}{e^{\beta V^{-2\alpha_1}(\eta_1+\eta_2+\eta_3)}-1}\right]$$
$$\times F_1^{(3)}(d\eta_1,d\eta_2,d\eta_3). \tag{3.79}$$

Thus

$$\lim_{V\to\infty}\ln\int_{(-\infty,\infty)}e^{-\lambda x}L_V(dx)=3g_1(\lambda)+3g_2(\lambda)+g_3(\lambda). \tag{3.80}$$

We have therefore proved that

$$\lim_{V\to\infty}\langle\exp\{\lambda V^{\gamma}(N_1/V-(\rho-\rho_c^V))\}\rangle_V^{\mathcal{C}}(\rho)=\begin{cases}\exp(g_1(\lambda)), & \text{if } \alpha_3<\alpha_2<\alpha_1<1/2,\\ \exp(2g_1(\lambda)+g_2(\lambda)), & \text{if } \alpha_3<\alpha_2=\alpha_1<1/2,\\ \exp(3g_1(\lambda)+3g_2(\lambda)+g_3(\lambda)), & \text{if } \alpha_3=\alpha_2=\alpha_1=1/3.\end{cases}$$

To finish the proof we center the distribution about $\langle N_1/V\rangle_V^{\mathcal{C}}(\rho)$. From (3.62) we get

$$\langle\{\lambda V^{\gamma}(N_1/V-(\rho-\rho_c^V))\}^2\rangle_V^{\mathcal{C}}(\rho)=\int_{(-\infty,\alpha_V)}x^2L_V(dx)/K_{1,V}(\rho+1/V)\leqslant 2\int_{(-\infty,\infty)}x^2L_V(dx).$$

Using (3.64) this gives

$$\langle[V^{\gamma}(N_1/V-(\rho-\rho_c^V))]^2\rangle_V^{\mathcal{C}}(\rho)\leqslant V^{1-4\alpha_1}\int_{(-\infty,\infty)}\left\{\frac{1}{2(e^{\beta\eta}-1)}+\frac{1}{(e^{\beta\eta}-1)^2}\right\}F_V(d\eta)$$
$$\leqslant\frac{3V^{1-4\alpha_1}}{2}\int_{(-\infty,\infty)}\frac{1}{\eta^2}F_V(d\eta). \tag{3.81}$$

Thus by the same arguments as we used above for dealing with the expression in (3.64), this second moment is bounded. Since $g_1'(0)=g_2'(0)=g_3'(0)$ we then have

$$\lim_{V\to\infty}V^{\gamma}(\langle N_1/V\rangle_V^{\mathcal{C}}(\rho)-(\rho-\rho_c^V))=\lim_{V\to\infty}\langle V^{\gamma}(N_1/V-(\rho-\rho_c^V))\rangle_V^{\mathcal{C}}(\rho)=0, \tag{3.82}$$

completing the proof. □

IV. CONCLUSION

(a) Since the paper by Buffet and Pulé,[3] it has been known that there are differences in the fluctuations of the PBG condensate in the canonical and grand-canonical ensembles. We have shown that the picture becomes even more complicated if one passes to the case of Casimir boxes where there is already generalized BEC in the GCE.

We have shown in general that there is a kind of *stability principle* relating the two ensembles: condensation in the GCE is more stable than in the CE. In fact we proved (Theorem 3.3) that the absence of the macroscopically occupied single-particle states in GCE implies the same in the CE, whereas the converse is not necessarily true. However in the case of the Casimir boxes considered here the two ensembles exhibit the same types of BEC for the same geometry. What varies in some cases is the fluctuations and the amount of condensate in the individual levels.

(b) As we have mentioned in Sec. I, BEC of *types* I and II is also known in the literature describing the experiments with trapped bosons as "fragmentation" of the condensate.[5,6,13] In these papers the authors relate this phenomenon to the interaction properties of the Bose gas, arguing that it is the exchange interaction that causes bosons with repulsive interaction to condense into a

single one-particle state whereas for attractive interactions the condensate may be "fragmented" into a number of degenerate or nearly degenerate single particle states; see Refs. 11 and 17. Here we have shown that BEC of type II occurs in the *noninteracting* Bose gas and that this is due simply to a geometric anisotropy of the boxes known since Casimir.[4] On the other hand, there are exactly soluble models (in cubic boxes) showing that some truncated repulsive interactions are able to convert BEC in the ground state into a generalized condensation of type III (see Refs. 1 and 8). In Ref. 12 an even simpler repulsive interaction than in Refs. 1 and 8 is proposed that produces type I condensation in a few degenerate single-particle states.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 9 SEPTEMBER 2004

Evaluation of phase-modulated lattice sums

Mark A. Stremler[a)]
Department of Mechanical Engineering, Vanderbilt University, Nashville, Tennessee 37235-1592

(Received 20 May 2004; accepted 2 June 2004; published 9 August 2004)

An exact evaluation of two-dimensional phase-modulated lattice sums of the form $\Sigma' \exp(i\mathbf{G}\cdot x)|\mathbf{G}|^{-2}$ is presented in terms of the Jacobian theta functions. The result generalizes the identity derived by M. L. Glasser [J. Math. Phys. **15**, 188 (1974)] to allow for evaluation on nonrectangular lattices. The generalized identity is also applied to a problem in vortex dynamics. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1777403]

I. INTRODUCTION

A number of problems in mechanics and mathematical physics involve evaluation of two-dimensional phase-modulated lattice sums of the form

$$\Phi = \sum_{\mathbf{G}\neq 0} \frac{e^{i\mathbf{G}\cdot \mathrm{x}}}{|\mathbf{G}|^2}, \tag{1}$$

where $\mathbf{G}$ is a (nonzero) lattice vector. Problems of interest come from various fields, including electrostatics,[1] superconductivity,[2] fluid turbulence,[3] and vortex dynamics.[4] This sum is slowly and conditionally convergent, and numerous formulations have been presented to facilitate its rapid computation.[5]

When the lattice defined by $\mathbf{G}$ is square or rectangular, the evaluation of these sums can be accomplished very elegantly using an identity derived by Glasser.[6] This identity provides an exact representation of the sum in terms of the Jacobian theta functions, which allows for rapid computation and enables mathematical analysis. However, the application of Glasser's identity is somewhat limited by the restriction to square or rectangular lattices, as many physical situations require consideration of a more general lattice structure. For example, a triangular lattice of identical point vortices is more energetically favorable than a square lattice.[7] The analysis presented in Sec. II generalizes the identity derived by Glasser to include all possible two-dimensional lattices that can be generated by two (unique) vectors $\mathbf{e}_1$ and $\mathbf{e}_2$. A brief look at how the generalized identity can be used is shown in Sec. III with an example from vortex dynamics.

II. THE IDENTITY

Consider a general two-dimensional lattice generated by the vectors $\mathbf{e}_1$ and $\mathbf{e}_2$ as shown in Fig. 1. The magnitudes of these vectors are a and b, respectively, and the angle between the vectors is φ. Without any loss of generality, $\mathbf{e}_1$ can be restricted to lie along the x axis and the angle can be restricted to $0<\varphi\leqslant\pi$. Any point in the basic parallelogram spanned by $\mathbf{e}_1$ and $\mathbf{e}_2$ can be represented as $\mathbf{x}=\xi\,\mathbf{e}_1+\eta\mathbf{e}_2$ for $0\leqslant\xi,\eta<1$, where

[a)]Electronic mail: mark.stremler@vanderbilt.edu

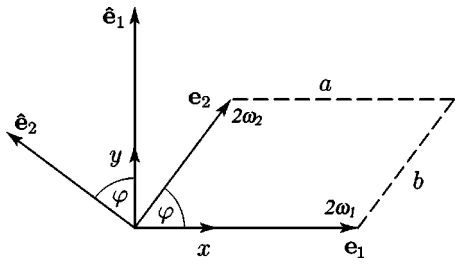

FIG. 1. Lattice vectors $\mathbf{e}_1$, $\mathbf{e}_2$ and reciprocal lattice vectors $\hat{\mathbf{e}}_1$, $\hat{\mathbf{e}}_2$ defining the basic periodic parallelogram with sides of length a and b. In the complex plane the basic parallelogram is defined by the half-periods ω_1 and ω_2.

$$\xi = \frac{x \sin\varphi - y\cos\varphi}{a \sin\varphi} \quad \text{and} \quad \eta = \frac{y}{b \sin\varphi}. \tag{2}$$

The vector $\mathbf{G}$ from Eq. (1) can then be given in terms of the reciprocal lattice vectors $\hat{\mathbf{e}}_1$ and $\hat{\mathbf{e}}_2$ as

$$\mathbf{G} = \frac{2\pi}{\Delta}(n\hat{\mathbf{e}}_1 - m\hat{\mathbf{e}}_2), \quad m,n = 0, \pm 1, \pm 2, \ldots, \tag{3}$$

where $\Delta = ab \sin\varphi$ is the area of the basic parallelogram spanned by $\mathbf{e}_1$ and $\mathbf{e}_2$.

The evaluation of phase-modulated lattice sums presented here for general two-dimensional lattices parallels, in large part, the analysis of Glasser.[6] The details of the analysis are included here for completeness.

Rewriting the sum in Eq. (1) using the notation introduced above gives

$$\Phi = \left(\frac{a \sin\varphi}{2\pi}\right)^2 \sum_{(m,n)\neq(0,0)} \frac{\exp[2\pi i(m\xi + n\eta)]}{m^2 + (a/b)^2 n^2 - 2(a/b)mn\cos\varphi}, \tag{4}$$

which can be evaluated by first applying the identity

$$x\int_0^\infty e^{-xt}\mathrm{d}t = 1 \tag{5}$$

and then separating out the term $n=0$ from the double sum to obtain

$$\Phi = \left(\frac{a \sin\varphi}{2\pi}\right)^2 \int_0^\infty \mathrm{d}t \left\{ \sum_{m\neq 0} \exp(-tm^2 + 2\pi i m\xi) + \sum_{\substack{m \\ n\neq 0}} \exp\left[-t\left(\frac{a}{b}\right)^2 n^2 + 2\pi i n\eta\right] \exp\left[-tm^2 + 2\pi i m\left(\xi - itn\frac{a\cos\varphi}{\pi b}\right)\right]\right\}. \tag{6}$$

By Jacobi's imaginary transformation, namely[8,9]

$$\sum_u \exp(-tu^2 + 2\pi i u x) = \sqrt{\frac{\pi}{t}} \sum_u \exp\left[\frac{-\pi^2(x-u)^2}{t}\right], \tag{7}$$

the lattice sum in (6) becomes

$$\Phi = \left(\frac{a\sin\varphi}{2\pi}\right)^2 \left\{ \sum_{m\neq 0} \exp(2\pi i m\xi) \int_0^\infty \mathrm{d}t \, \exp(-tm^2) \right.$$
$$+ \sqrt{\pi} \sum_{\substack{m \\ n\neq 0}} \exp\left[2\pi i\left(n\eta + (\xi - m)\frac{an\cos\varphi}{b}\right)\right]$$
$$\left. \times \int_0^\infty \mathrm{d}t \, \sqrt{t} \exp\left[-t\left(\frac{an\sin\varphi}{b}\right)^2\right] \exp\left[\frac{-\pi^2(\xi-m)^2}{t}\right] \right\}. \tag{8}$$

This form of the lattice sum can be rewritten using the identity[10]

$$\int_0^\infty \mathrm{d}t \, t^{-1/2} e^{-pt} e^{-q/t} = 2\left(\frac{q}{p}\right)^{1/4} \mathrm{K}_{1/2}(2\sqrt{pq}), \tag{9a}$$

where K_s is the modified Bessel function. By the definition of the Basset function[11] this identity becomes

$$\int_0^\infty \mathrm{d}t \, t^{-1/2} e^{-pt} e^{-q/t} = \sqrt{\pi/p} \exp(-2\sqrt{pq}). \tag{9b}$$

Using Eq. (9) and the identity in Eq. (5), the sum Φ can now be written as

$$\Phi = \frac{a^2\sin^2\varphi}{2\pi^2} \sum_{m=1}^\infty \frac{\cos(2\pi m\xi)}{m^2} + \frac{ab\sin\varphi}{4\pi} \sum_{n=1}^\infty \frac{1}{n} \left\{ \exp\left[2\pi n\left((-\sin\varphi + i\cos\varphi)\frac{a}{b}\xi + i\eta\right)\right] + \text{c.c.} \right\}$$
$$+ \frac{ab\sin\varphi}{4\pi} \sum_{m=1}^\infty \sum_{n=1}^\infty \frac{1}{n} \left\{ \exp\left[-2\pi mn\frac{a}{b}(\sin\varphi + i\cos\varphi)\right] \right.$$
$$\times \left\{ \exp\left[2\pi n\left((\sin\varphi + i\cos\varphi)\frac{a}{b}\xi - i\eta\right)\right] \right.$$
$$\left. \left. + \exp\left[2\pi n\left((-\sin\varphi - i\cos\varphi)\frac{a}{b}\xi + i\eta\right)\right] \right\} + \text{c.c.} \right\}, \tag{10}$$

where c.c. denotes the complex conjugate.

At this point in his analysis, Glasser changes variables to[12]

$$q = \exp\left[-\pi\frac{a}{b}(\sin\varphi - i\cos\varphi)\right], \quad \alpha = \eta + \frac{a}{b}(\cos\varphi + i\sin\varphi)\xi. \tag{11}$$

Alternatively, choose

$$q = e^{-\pi i/\tau} \text{ and } \alpha = \frac{ibz}{a\tau}, \tag{12}$$

where $\tau = (b/a)(\cos\varphi + i\sin\varphi)$ and $z = x + iy$. Then, Eq. (10) can be expressed as

$$\Phi = \frac{a^2\sin^2\varphi}{2\pi^2} \sum_{m=1}^\infty \frac{\cos(2\pi m\xi)}{m^2} + \frac{ab\sin\varphi}{4\pi} \sum_{n=1}^\infty \frac{1}{n}[e^{-2\pi n\alpha/b} + \text{c.c.}]$$
$$+ \frac{ab\sin\varphi}{4\pi} \sum_{m=1}^\infty \sum_{n=1}^\infty \frac{1}{n}[q^{2mn}(e^{2\pi n\alpha/b} + e^{-2\pi n\alpha/b}) + \text{c.c.}]. \tag{13}$$

This form of the sum allows the analysis to continue to parallel that of Glasser[6] despite the

alternative change of variables. The sums over n are evaluated with the identity[13]

$$\sum_{n=1}^{\infty} \frac{x^n}{n} = -\ln(1-x), \tag{14}$$

giving

$$\Phi = \frac{a^2 \sin^2 \varphi}{2\pi^2} \sum_{m=1}^{\infty} \frac{\cos(2\pi m\xi)}{m^2} - \frac{ab \sin \varphi}{2\pi} \ln\left|1 - e^{-2\pi\alpha/b}\right| - \frac{ab \sin \varphi}{2\pi} \sum_{m=1}^{\infty} \ln\left|\left(1 - q^{2m} e^{2\pi\alpha/b}\right)\left(1 - q^{2m} e^{-2\pi\alpha/b}\right)\right|. \tag{15}$$

The first term in Eq. (15) is the well-know Fourier series[14]

$$\frac{a^2 \sin^2 \varphi}{2\pi^2} \sum_{m=1}^{\infty} \frac{\cos(2\pi m\xi)}{m^2} = \frac{a^2 \sin^2 \varphi}{2} \left(\xi^2 - \xi + \tfrac{1}{6}\right). \tag{16}$$

After a few manipulations the second term in Eq. (15) can be written as

$$\frac{-ab \sin \varphi}{2\pi} \ln\left|1 - e^{-2\pi\alpha/b}\right| = \frac{a^2 \sin^2 \varphi}{2} \xi - \frac{ab \sin \varphi}{2\pi} [\ln 2 + \ln|\sin(\pi i\alpha/b)|]. \tag{17}$$

The third term in Eq. (15) can be simplified by introducing the Jacobi ϑ_1-function[15]

$$\vartheta_1(z;q) = 2\mathcal{G} q^{1/4} \sin \pi z \prod_{u=1}^{\infty} (1 - 2q^{2u} \cos 2\pi z + q^{4u}), \tag{18a}$$

where[16]

$$\mathcal{G} = \prod_{u=1}^{\infty} (1 - q^{2u}), \quad \vartheta_1'(0;q) = 2\mathcal{G} q^{1/4} \prod_{u=1}^{\infty} (1 - q^{2u})^2, \tag{18b}$$

so that

$$\prod_{u=1}^{\infty} (1 - 2q^{2u} \cos 2\pi z + q^{4u}) = \frac{2^{-2/3} q^{-1/6}}{\sin \pi z} \frac{\vartheta_1(z;q)}{[\vartheta_1'(0;q)]^{1/3}}. \tag{19}$$

Note that the result on the right-hand side of Eq. (19) disagrees with Glasser's result by a factor of 2.[17] Using the identity in Eq. (19), the third term in Eq. (15) can be written as

$$\frac{-ab \sin \varphi}{2\pi} \sum_{m=1}^{\infty} \ln\left|(1 - q^{2m} e^{2\pi\alpha/b})(1 - q^{2m} e^{-2\pi\alpha/b})\right| = \frac{-a^2 \sin^2 \varphi}{12} + \frac{ab \sin \varphi}{2\pi} \left\{ \frac{2 \ln 2}{3} + \ln\left|\sin\left(\frac{\pi i\alpha}{b}\right)\right| - \ln\left|\frac{\vartheta_1(i\alpha/b;q)}{[\vartheta_1'(0;q)]^{1/3}}\right| \right\}. \tag{20}$$

By Jacobi's imaginary transformation[8,9]

$$\vartheta_1(z;q) \equiv \vartheta_1\left(z; -\frac{1}{\tau}\right) = -i \sqrt{\frac{\tau}{i}}\, e^{i\tau z^2/\pi} \vartheta_1(z\tau;\tau), \tag{21a}$$

$$\vartheta_1'(0;q) \equiv \vartheta_1'\left(0;-\frac{1}{\tau}\right) = \left(\frac{\tau}{i}\right)^{3/2}\vartheta_1'(0;\tau), \tag{21b}$$

so that

$$\frac{\vartheta_1(i\alpha/b;q)}{[\vartheta_1'(0;q)]^{1/3}} = -i\exp\left[(\sin\varphi - i\cos\varphi)\frac{\pi\alpha^2}{ab}\right]\frac{\vartheta_1(i\alpha\tau/b;\tau)}{\left[\vartheta_1'(0;\tau)\right]^{1/3}}. \tag{22}$$

Applying Eq. (22) to Eq. (20), the third term in Eq. (15) becomes

$$\begin{aligned}&\frac{-ab\sin\varphi}{2\pi}\sum_{m=1}^{\infty}\ln\left|(1-q^{2m}e^{2\pi\alpha/b})(1-q^{2m}e^{-2\pi\alpha/b})\right| \\ &\quad = \frac{a^2\sin^2\varphi}{2}\left[\left(\frac{b}{a}\right)^2\eta^2 - \xi^2 - \tfrac{1}{6}\right] + \frac{ab\sin\varphi}{2\pi}\left[\frac{2\ln 2}{3} + \ln\left|\sin\left(\frac{\pi i\alpha}{b}\right)\right| - \ln\left|\frac{\vartheta_1(i\alpha\tau/b;\tau)}{[\vartheta_1'(0;\tau)]^{1/3}}\right|\right].\end{aligned} \tag{23}$$

Thus, combining Eqs. (16), (17), and (23) with the notation from Eqs. (2) and (12) gives the result

$$\Phi = \sum_{\mathbf{G}\neq 0}\frac{e^{i\mathbf{G}\cdot\mathbf{x}}}{|\mathbf{G}|^2} = \frac{y^2}{2} - \frac{\Delta}{6\pi}\ln 2 - \frac{\Delta}{2\pi}\ln\left|\frac{\vartheta_1(z/a;\tau)}{[\vartheta_1'(0;\tau)]^{1/3}}\right|. \tag{24}$$

III. AN APPLICATION IN VORTEX DYNAMICS

The generalized identity in Eq. (24) allows for a new, independent derivation of the equations of motion for point vortices arranged in a doubly-periodic lattice. Incidentally, this problem provided the motivation for establishing the generalized result.

Consider a system of N point vortices arranged within the basic parallelogram spanned by the vectors $\mathbf{e}_1$ and $\mathbf{e}_2$. Let vortex α $(=1,2,\ldots,N)$ have strength Γ_α and position $\mathbf{x}_\alpha=(x_\alpha,y_\alpha)$ or $z_\alpha = x_\alpha + iy_\alpha$. The equations of motion for these vortices can be cast in Hamiltonian form[18] by taking

$$\frac{\mathrm{d}x_\alpha}{\mathrm{d}t} = \frac{1}{\Gamma_\alpha}\frac{\mathrm{d}H}{\mathrm{d}y_\alpha}, \quad \Gamma_\alpha\frac{\mathrm{d}y_\alpha}{\mathrm{d}t} = \frac{\mathrm{d}H}{\mathrm{d}x_\alpha}, \tag{25}$$

where x_α are the generalized coordinates and $\Gamma_\alpha y_\alpha$ are the generalized momenta. In a fluid with density ρ, the quantity ρH gives the "interaction energy" of the fluid within the basic parallelogram;[19] that is, it gives the energy of the fluid less the (infinite) contribution to the energy from the fluid in the neighborhood of each point vortex. The Fourier representation of the interaction energy is well known to be[3]

$$E = \frac{\rho}{\Delta}\sum_{\alpha=1}^{N}\sum_{\beta=\alpha+1}^{N}\Gamma_\alpha\Gamma_\beta\sum_{\mathbf{G}\neq 0}\frac{\exp[i\mathbf{G}\cdot(\mathbf{x}_\alpha - \mathbf{x}_\beta)]}{|\mathbf{G}|^2}. \tag{26}$$

By applying Eq. (24) to Eq. (26), the Hamiltonian for this vortex system can be written as

$$\begin{aligned}H &= -\frac{1}{2\pi}\sum_{\alpha=1}^{N}\sum_{\beta=\alpha+1}^{N}\Gamma_\alpha\Gamma_\beta\left\{\ln\left|\frac{\vartheta_1[(z_\alpha - z_\beta)/a;\tau]}{[\vartheta_1'(0;\tau)/2]^{1/3}}\right| - \frac{\pi(y_\alpha - y_\beta)^2}{\Delta}\right\} \\ &= -\frac{1}{2\pi}\sum_{\alpha=1}^{N}\sum_{\beta=\alpha+1}^{N}\Gamma_\alpha\Gamma_\beta\left\{\ln|\sigma(z_\alpha - z_\beta)| - \mathrm{Re}\left[\frac{\eta_1(z_\alpha - z_\beta)^2}{2\omega_1}\right] - \frac{\pi(y_\alpha - y_\beta)^2}{\Delta}\right\} \\ &\quad - \frac{1}{3\pi}\left(\sum_{\alpha=1}^{N}\sum_{\beta=\alpha+1}^{N}\Gamma_\alpha\Gamma_\beta\right)\ln\left|\frac{\vartheta_1'(0;\tau)}{2\omega_1^{3/2}}\right|,\end{aligned} \tag{27}$$

where $\sigma(z;\omega_1,\omega_2)$ is the Weierstrass σ-function defined in terms of the half-periods ω_1 and ω_2 (see Fig. 1), $\eta_1=\zeta(\omega_1;\omega_1,\omega_2)$ is the Weierstrass ζ-function evaluated at the half-period ω_1, and the last term in Eq. (27) is a constant. This Hamiltonian can then be differentiated according to Eq. (25) to give the equations of motion

$$\frac{d\overline{z_\alpha}}{dt}=\frac{1}{2\pi i}\sum_{\beta=1}^{N}{}'\,\Gamma_\beta\left[\zeta(z_\alpha-z_\beta)-\frac{\eta_1}{\omega_1}(z_\alpha-z_\beta)-\frac{2\pi}{\Delta}(y_\alpha-y_\beta)\right], \tag{28}$$

where the overbar denotes complex conjugation and the sum is over all $\beta\neq\alpha$. This result confirms previous derivations[20] that determined the vortex velocities directly in terms of the Weierstrass ζ-function.

It would be interesting to examine the impact of the generalization in Eq. (24) on other results that use Glasser's identity, such as the set of lattice sum identities derived by McPhedran and co-workers.[21,22]

Reduction of the classical MICZ-Kepler problem to a two-dimensional linear isotropic harmonic oscillator

P. G. L. Leach[a] and M. C. Nucci
Dipartimento di Matematica e Informatica, Università di Perugia, 06123 Perugia, Italy

(Received 9 February 2004; accepted 18 June 2004; published 9 August 2004)

The classical MICZ-Kepler problem is shown to be reducible to an isotropic two-dimensional system of linear harmonic oscillators and a conservation law in terms of new variables related to the Ermanno–Bernoulli constants and the components of the Poincaré vector. An algorithmic route to linearization is shown based on Lie symmetry analysis and the reduction method [Nucci, J. Math. Phys. **37**, 1772 (1996)]. First integrals are also obtained by symmetry analysis and the reduction method [Marcelli and Nucci,J. Math. Phys. **44**, 2111 (2002)]. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1781748]

I. INTRODUCTION

The classical MICZ-Kepler problem was introduced and studied by McIntosh and Cizneros[35]—hence the MIC—and independently by Zwanziger[54]—whence the Z. The equation of motion is

$$\ddot{\mathbf{r}} + \frac{\lambda \mathbf{L}}{r^3} + \left(\frac{\mu}{r^2} + \frac{2\nu}{r^3}\right)\hat{\mathbf{r}} = 0, \tag{1}$$

in which $\mathbf{r}$ is the position vector, of magnitude r and unit vector $\hat{\mathbf{r}}$, in $\Re^3$, the overdot denotes differentiation with respect to time, $\mathbf{L}(:=\mathbf{r}\times\dot{\mathbf{r}})$ is the reduced angular momentum, λ, μ, and ν are constants and the three forces are due to a magnetic monopole, the Newtonian gravitational potential and a Newton–Cotes potential, respectively.

In the case of a particle moving in the field of a magnetic monopole, indifferently to the presence or absence of a central force, the angular momentum is not conserved. However, Poincaré,[49] writing on an experiment of Kristian Birkeland, the pioneer investigator of the Aurora Borealis, showed that there does exist a related conserved vector, now known as the Poincaré's vector. In the literature relating to magnetic monopoles Poincaré's vector is termed the *total* angular momentum to distinguish it from the mechanical angular momentum which is called the orbital angular momentum. In this paper we use the notation and terminology to be found in the general literature of Mechanics. If one takes the vector product of $\mathbf{r}$ with (1),

$$0 = \mathbf{r}\times\ddot{\mathbf{r}} + \lambda\frac{\mathbf{r}\times\mathbf{L}}{r^3} = \mathbf{r}\times\ddot{\mathbf{r}} - \lambda\dot{\hat{\mathbf{r}}} \Rightarrow \mathbf{P}: = \mathbf{L} - \lambda\hat{\mathbf{r}}. \tag{2}$$

One notes that both P and L are constants. Specifically they are given by

$$L^2 = r^4(\dot{\theta}^2 + \dot{\phi}^2 \sin^2\theta) \quad \text{and} \quad P^2 = L^2 + \lambda^2. \tag{3}$$

[a]Permanent address: School of Mathematical Sciences, University of KwaZulu-Natal, Howard College Campus, Durban 4041, Republic of South Africa.

In the same spirit as adopted for the calculation of the Laplace–Runge–Lenz vector of the classical Kepler problem[4,5] we take the vector product of (1) with **P** (rather than the **L** as in the case of the Kepler Problem) to obtain

$$\ddot{\mathbf{r}} \times \mathbf{P} + \frac{\lambda}{r^3}\left(\mathbf{L} + \frac{2\nu}{\lambda}\hat{\mathbf{r}}\right) \times \mathbf{P} + \frac{\mu}{r^2}\hat{\mathbf{r}} \times \mathbf{P} = 0. \tag{4}$$

If we restrict 2ν to $-\lambda^2$, (4) becomes

$$\ddot{\mathbf{r}} \times \mathbf{P} + \frac{\lambda}{r^3}\mathbf{P} \times \mathbf{P} + \frac{\mu}{r^2}\hat{\mathbf{r}} \times \mathbf{L} = 0. \tag{5}$$

The middle term of (5) vanishes and the third term reduces to $r^2\dot{\hat{\mathbf{r}}}$ when $\dot{\mathbf{r}}$ is written as $\dot{r}\hat{\mathbf{r}}+r\dot{\hat{\mathbf{r}}}$. We integrate (5) to obtain a conserved vector of Laplace–Runge–Lenz-type, *videlicet*

$$\mathbf{J} = \dot{\mathbf{r}} \times \mathbf{P} - \mu\hat{\mathbf{r}}. \tag{6}$$

This vector can equally be written as

$$\mathbf{J} = \dot{\mathbf{r}} \times \mathbf{L} - \mu\hat{\mathbf{r}} + \frac{\lambda\mathbf{L}}{r}, \tag{7}$$

which emphasizes the add-on effect of the magnetic monopole to the standard form of the Laplace–Runge–Lenz vector.

There is a vast literature devoted to the analysis of (1) and its higher dimensional analogues (see, for example, the original papers of Manton,[33] Gibbons and Manton,[14] Fehér and Horváthy,[12] Gibbons and Ruback,[15] Cordani *et al.*,[6] and Cordani *et al.*,[7] and also those of Iwai and Sunako;[22] Odzijewicz and Świçtochowski;[46] Iwai *et al.*;[23] Pletyulhov and Tolkachov;[47] Pletyulhov and Tolkachov;[48] Lambert and Kibler;[29] Kibler and Winternitz;[26] Mladenov and Tsanov[37]) much of it related to the embedding of the problem in a space of greater dimension in which the nonlinear problem is reduced to an oscillator under constraint. The latter connection in the case of the quantum mechanical problem was reported by Niederer.[39] A more recent extension into the Chern–Simons field theory has been given by Duval *et al.*[9]

In this article we show how (1) (with $2\nu=-\lambda^2$) can be reduced to a two-dimensional linear isotropic oscillator plus a conservation law. The method used is an application of the method of reduction of order developed by Nucci[42] to show how the nonlocal symmetries of the Kepler problem derived by Krause[27,28] could be obtained by local methods. The method has been applied successfully to a variety of problems resembling the Kepler problem, such as the Kepler problem with drag[8,24,30,36] to obtain their nonlocal symmetries and, by accident as it were, to show that these problems are all related by means of generalized transformations.[43,44]

II. LIE SYMMETRIES: FIRST INTEGRALS AND LINEARIZATION

The equation of motion (1) with $2\nu=-\lambda^2$ has the radial, polar, and azimuthal components

$$\ddot{r} - r\dot{\theta}^2 - r\dot{\phi}^2 \sin^2\theta = -\frac{\mu}{r^2} + \frac{\lambda^2}{r^3}, \tag{8a}$$

$$r\ddot{\theta} + 2\dot{r}\dot{\theta} - r\dot{\phi}^2 \sin\theta\cos\theta = \frac{\lambda\dot{\phi}}{r}\sin\theta, \tag{8b}$$

$$(r\ddot{\phi} + 2\dot{r}\dot{\phi})\sin\theta + 2r\dot{\theta}\dot{\phi}\cos\theta = -\frac{\lambda\dot{\theta}}{r}, \tag{8c}$$

respectively.

The Cartesian components of **P** and **J** are

$$P_x = -r^2[\dot{\theta}\sin\phi + \dot{\phi}\sin\theta\cos\theta\cos\phi] - \lambda\sin\theta\cos\phi,$$

$$P_y = r^2[\dot{\theta}\cos\phi - \dot{\phi}\sin\theta\cos\theta\sin\phi] - \lambda\sin\theta\sin\phi, \tag{9}$$

$$P_z = r^2\dot{\phi}\sin^2\theta - \lambda\cos\theta,$$

and

$$J_x = \left(\frac{L^2}{r} - \mu\right)\sin\theta\cos\phi - r^2\dot{r}(\dot{\theta}\cos\theta\cos\phi - \dot{\phi}\sin\theta\sin\phi) - \lambda r(\dot{\theta}\cos\phi - \dot{\phi}\sin\theta\cos\theta\sin\phi),$$

$$J_y = \left(\frac{L^2}{r} - \mu\right)\sin\theta\sin\phi - r^2\dot{r}(\dot{\theta}\cos\theta\sin\phi - \dot{\phi}\sin\theta\cos\phi) - \lambda r(\dot{\theta}\sin\phi - \dot{\phi}\sin\theta\cos\theta\cos\phi), \tag{10}$$

$$J_z = \left(\frac{L^2}{r} - \mu\right)\cos\theta + r^2\dot{r}\dot{\theta}\sin\theta + \lambda r\dot{\phi}\sin^2\theta,$$

respectively.

We examine the system (8) algorithmically in an approach based upon the underlying Lie symmetries of the integrals and equations of motion and hence use the assistance of a suitable symbolic manipulation code. We use the interactive package developed by Nucci.[40,41]

The algorithm is designed to calculate Lie symmetries[42] and first integrals[34] and in the process determining parabolic partial differential equations arise the characteristics of which are "useful variables" and consequently reduce the amount of branching in the algorithm.

A system of first-order equations has an infinite number of Lie point symmetries and the calculation of a subset of them requires the imposition of some constraint on the structure of the symmetries sought. Although there are instances, such as in systems of linear equations,[20,21,45] for which a prescribed structure can be argued to be sensible, such a prescription is not so obvious in the case of systems of nonlinear equations as we have here. The introduction of one or more second-order equations reduces the number of point symmetries and these can then be computed using Lie's algorithm.[42]

We write the system of equations (8), as the set of six first-order equations

$$\dot{w}_1 = w_4, \tag{11a}$$

$$\dot{w}_2 = w_5, \tag{11b}$$

$$\dot{w}_3 = w_6, \tag{11c}$$

$$\dot{w}_4 = w_1 w_5^2 + w_1 w_6^2\sin^2 w_2 - \frac{\mu}{w_1^2} + \frac{\lambda^2}{w_1^3}, \tag{11d}$$

$$\dot{w}_5 = -2\frac{w_4 w_5}{w_1} + w_6^2\sin w_2\cos w_2 + \frac{\lambda w_6}{w_1^2}\sin w_2, \tag{11e}$$

$$\dot{w}_6 = -2\frac{w_4 w_6}{w_1} - 2w_5 w_6 \cot w_2 - \frac{\lambda w_5}{w_1^2 \sin w_2}, \tag{11f}$$

where $w_1 = r$, $w_2 = \theta$, and $w_3 = \phi$. To make the process of the determination of the symmetries of (11) finite we convert the system of six first-order equations to one of four first-order equations plus a second-order equation. We use (11a) to eliminate w_4 and now we have the system

$$\ddot{w}_1 = w_1 w_5^2 + w_1 w_6^2 \sin^2 w_2 - \frac{\mu}{w_1^2} + \frac{\lambda^2}{w_1^3},$$

$$\dot{w}_2 = w_5,$$

$$\dot{w}_3 = w_6,$$

$$\dot{w}_5 = -2\frac{\dot{w}_1 w_5}{w_1} + w_6^2 \sin w_2 \cos w_2 + \frac{\lambda w_6}{w_1^2} \sin w_2,$$

$$\dot{w}_6 = -2\frac{\dot{w}_1 w_6}{w_1} - 2w_5 w_6 \cot w_2 - \frac{\lambda w_5}{w_1^2 \sin w_2}. \tag{12}$$

Note that we have not changed the independent variable which is the standard procedure in the method of reduction of order.[42,43] We are actually trying to find first integrals by using the Lie symmetries in the manner described in Ref. 34. If we apply Lie symmetry analysis to system (13), i.e., we look for a Lie symmetry of the form $\Gamma = V(w_1, w_2, w_3, w_5, w_6, t)\partial_t$, then, as was shown in Ref. 34, the algorithm leads to a parabolic equation in V the characteristics of which, in this case $w_1^2 w_5$ and $w_1^2 w_6$, provide the new set of dependent variables, i.e., u_5 and u_4, respectively. Also, in order to avoid the ill-behavior of the computer algebra system in the presence of trigonometric functions, we introduce the transformation $w_2 = 2\arctan(u_2)$ and thereby render the system of equations in rational form. So we define a new set of dependent variables and list their differential equations, *videlicet*

$$\begin{aligned}
&u_1 = w_1 && \ddot{u}_1 = \frac{\lambda^2(u_2^2+1)^2 - \mu u_1 (u_2^2+1)^2 + 4u_2^2 u_4^2 + u_5^2 (u_2^2+1)^2}{u_1^3 (u_2^2+1)^2},\\
&u_2 = \tan(w_2/2) && \dot{u}_2 = \frac{u_5 (u_2^2+1)}{2u_1^2},\\
&u_3 = w_3 && \dot{u}_3 = u_4 u_1^{-1},\\
&u_4 = w_1^2 w_6 && \dot{u}_4 = \frac{u_5(-\lambda u_2^2 - \lambda + 2u_2^2 u_4 - 2u_4)}{2u_1^2 u_2},\\
&u_5 = w_1^2 w_5 && \dot{u}_5 = \frac{2u_2 u_4 (\lambda u_2^2 + \lambda - u_2^2 u_4 + u_4)}{u_1^2 (u_2^2+1)}.
\end{aligned} \tag{13}$$

If we apply Lie symmetry analysis to system (13), i.e., we again look for a Lie symmetry of the form $\Gamma = V(u_1, u_2, u_3, u_4, u_5, t)\partial_t$, then we obtain the following partial differential equation for V:

$$u_5^2 (u_2^2+1)^3 \frac{\partial V}{\partial u_2} + 2u_2 u_4 (u_2^2+1)^2 \frac{\partial V}{\partial u_3} - u_5((u_2^2+1)\lambda - 2(u_2^2-1)u_4)(u_2^2+1)^2 \frac{\partial V}{\partial u_4} + 4u_2^2 u_4 (\lambda u_2^2 + \lambda - u_2^2 u_4 + u_4)\frac{\partial V}{\partial u_5} = 0 \tag{14}$$

with now $V = V(u_2, u_3, u_4, u_5)$. There are three characteristics to be obtained from (14), each of

which is a first integral.[34] The characteristics are found from the associated Lagrange's system

$$\frac{\mathrm{d}u_2}{u_2u_5(u_2^2+1)^3}=\frac{\mathrm{d}u_3}{2u_2u_4(u_2^2+1)^2}=\frac{\mathrm{d}u_4}{-u_5((u_2^2+1)\lambda-2(u_2^2-1)u_4)(u_2^2+1)^2}$$
$$=\frac{\mathrm{d}u_5}{4u_2^2u_4(\lambda u_2^2+\lambda-u_2^2u_4+u_4)}. \tag{15}$$

We use MAPLE 7 to facilitate the solution of (15). We obtain

$$I_1=\frac{2u_2^2u_4-\lambda u_2^2-\lambda}{2(u_2^2+1)^2}, \tag{16}$$

which evidently comes from the first and third of (15) since u_5 is a common factor of the two denominators,

$$I_2=\frac{u_5^2(u_2^2+1)^4+2\lambda^2u_2^2(u_2^2+1)^2-4\lambda u_2^6u_4+4\lambda u_2^2u_4+4u_2^2u_4^2+4u_2^6u_4^2}{(u_2^2+1)^4} \tag{17}$$

and

$$I_3=u_3+\frac{1}{2}\arctan\left(\frac{u_5^2(u_2^2+1)^3+4u_2^2u_4\lambda(u_2^2+1)-4u_2^4u_4^2+4u_2^2u_4^2}{2u_2u_5(1+u_2^2)(2u_2^2u_4-\lambda u_2^2-\lambda)}\right)$$
$$-\frac{1}{2}\arctan\left(\frac{u_5^2(u_2^2+1)^3-4u_2^2u_4\lambda(u_2^2+1)+4u_2^4u_4^2-4u_2^2u_4^2}{2u_2u_5(\lambda u_2^2+\lambda+2u_4)(1+u_2^2)}\right). \tag{18}$$

It is perhaps of some interest to express the three integrals in terms of the known physical quantities of this problem. After some algebraic simplification we find that

$$I_1=\tfrac{1}{4}(P_z-\lambda),$$

$$I_2=\tfrac{1}{2}(P_x^2+P_y^2+L^2),$$

$$I_3=\frac{1}{2}\arctan\left\{\frac{2P_xP_y}{P_x^2-P_y^2}\right\}. \tag{19}$$

In the case of I_3 we have used the formulas for the addition of arctans to combine the expressions found in (18) which has the nature of a relationship of phases. When we express the three integrals in terms of known physical quantities, as in (19), we see quite clearly the effect of the requirement that a variable be absent from the integral. We recall that the absent variable is $w_4=\dot{r}$. The three integrals are all combinations of components of the Poincaré vector, which are individually conserved, and the magnitude of the angular momentum. (The magnitude of the angular momentum is conserved, but the individual components are not conserved.) These conserved quantities are all free of $\dot{r}$. One also notes that the expressions are not simple. In an arbitrary problem, for which one does not have a preknowledge of the conserved quantities, one can only expect something to be presented as an integral which is not necessarily a "physical" conserved quantity. This means that the algorithm finds first integrals if they exist with the only limitation being the absence of one of the variables, in this case w_4. There is no essential difference in the working of the algorithm if we wish to take one of the other variables absent.

In Ref. 31 we found a transformation which reduced the Kepler Problem to a two-dimensional linear isotropic harmonic oscillator and also found the complete symmetry group of this problem as described by Krause.[27,28] Here we show how to reduce the Kepler problem to a two-dimensional linear isotropic harmonic oscillator using Lie symmetries and the reduction method.

Then we show how to do the same for the MICZ-Kepler problem. Thus the algorithm of Lie point symmetries and the reduction method reveal the physical property underlying the model. As far as we know such a reduction has never been described before.

The Kepler system of equations can be written as the set of six first-order equations,

$$\dot{w}_1 = w_4,$$

$$\dot{w}_2 = w_5,$$

$$\dot{w}_3 = w_6,$$

$$\dot{w}_4 = w_1 w_5^2 + w_1 w_6^2 \sin^2 w_2 - \frac{\mu}{w_1^2},$$

$$\dot{w}_5 = -2\frac{w_4 w_5}{w_1} + w_6^2 \sin w_2 \cos w_2,$$

$$\dot{w}_6 = -2\frac{w_4 w_6}{w_1} - 2 w_5 w_6 \cot w_2, \tag{20}$$

where $w_1 = r$, $w_2 = \theta$, and $w_3 = \phi$. We use the method of reduction of order by choosing $y = w_3$ as the new independent variable to obtain the reduced system

$$w_1' = \frac{w_4}{w_6}, \tag{21a}$$

$$w_2' = \frac{w_5}{w_6}, \tag{21b}$$

$$w_4' = \frac{w_1 w_5^2}{w_6} + w_1 w_6 \sin^2 w_2 - \frac{\mu}{w_1^2 w_6}, \tag{21c}$$

$$w_5' = -2\frac{w_4 w_5}{w_1 w_6} + w_6 \sin w_2 \cos w_2, \tag{21d}$$

$$w_6 = -2\frac{w_4}{w_1} - 2 w_5 \cot w_2. \tag{21e}$$

If we eliminate w_5 from (21b) and search for Lie symmetries we obtain the first integral $\xi = w_6 w_1^2 \sin(w_2)^2$, i.e., the "$z$-component" of the angular momentum, as the characteristic curve of a parabolic determining equation. Finally we convert the system of six first-order equations to two second-order equations, *videlicet*

$$w_4'' = (2\cos(w_2) w_4' w_2' - \sin(w_2)^3 w_4 - \sin(w_2) w_4 w_2'^2)/\sin(w_2),$$

$$w_2'' = (\cos(w_2)(\sin(w_2)^2 + 2 w_2'^2))/\sin(w_2), \tag{22}$$

by eliminating $w_6 = \xi/(\sin^2(w_2) w_1^2)$ from the integral obtained, $w_5 = w_2' \xi/\sin^2(w_2) w_1^2$ from (21b) and $w_1 = \xi^2(w_2'^2 + \sin^2(w_2))/(\sin^2(w_2)(w_4' \xi + \sin^2(w_2)\mu))$ from (21c). Using the interactive REDUCE pro-

grams developed by Nucci[40,41] we obtain a 15-dimensional Lie symmetry algebra, isomorphic to $\mathrm{sl}(4,\mathbb{R})$,[13] generated by the following 15 operators:

$$X_1 = \mathrm{cosec}(w_2)\cos(y)w_4\partial_y + \cos(w_2)\sin(y)\partial_{w_2} - \sin(w_2)\sin(y)w_4^2\partial_{w_4},$$

$$X_2 = \mathrm{cosec}(w_2)\sin(y)w_4\partial_y - \cos(w_2)\cos(y)w_4\partial_{w_2} + \sin(w_2)\cos(y)w_4^2\partial_{w_4},$$

$$X_3 = w_4\sin(w_2)\partial_{w_2} + \cos(w_2)w_4^2\partial_{w_4},$$

$$X_4 = -\cot(w_2)\sin(y)\partial_y + \cos(y)\partial_{w_2},$$

$$X_5 = \cot(w_2)\cos(y)\partial_y + \sin(y)\partial_{w_2},$$

$$X_6 = \cos(w_2)\partial_{w_4},$$

$$X_7 = \sin^2(w_2)\sin(y)\partial_{w_2} + \sin(w_2)\cos(w_2)\sin(y)w_4\partial_{w_4},$$

$$X_8 = \sin^2(w_2)\cos(y)\partial_{w_2} + \sin(w_2)\cos(w_2)\cos(y)w_4\partial_{w_4},$$

$$X_9 = \partial_y,$$

$$X_{10} = \sin(y)\cos(y)\partial_y - \sin(w_2)\cos(w_2)\cos^2(y)\partial_{w_2} + (1-\cos^2(w_2))\cos^2(y)w_4\partial_{w_4},$$

$$X_{11} = \cos^2(y)\partial_y + \sin(w_2)\cos(w_2)\sin(y)\cos(y)\partial_{w_2} - (1-\cos^2(w_2))\sin(y)\cos(y)w_4\partial_{w_4},$$

$$X_{12} = \sin(w_2)\cos(w_2)\partial_{w_2} + \cos^2(w_2)w_4\partial_{w_4},$$

$$X_{13} = w_4\partial_{w_4},$$

$$X_{14} = \sin(w_2)\sin(y)\partial_{w_4},$$

$$X_{15} = \cos(y)\sin(w_2)\partial_{w_4}. \tag{23}$$

In order to find the linearizing transformation we need to find a four-dimensional Abelian subalgebra of rank 2.[50] Following Soh and Mahomed's classification of four-dimensional Lie algebras in the real space,[51] we have to transform this four-dimensional subalgebra into the canonical form

$$\partial_{\tilde{v}_1}, \quad \partial_{\tilde{v}_2}, \quad f(y)\partial_{\tilde{v}_1} + g(y)\partial_{\tilde{v}_2}, \quad h(y)\partial_{\tilde{v}_1} + k(y)\partial_{\tilde{v}_2}, \quad [f'(y)k'(y) \neq g'(y)h'(y)]$$

with $\tilde{v}_1$ and $\tilde{v}_2$ the new dependent variables. We find that one such subalgebra is that generated by X_7, X_8, X_{14}, X_{15} for which we make the mapping $X_{14} \to \partial_{\tilde{v}_1}, X_7 \to \partial_{\tilde{v}_2}, X_{15} \to \cot(y)\partial_{\tilde{v}_1}, X_8 \to -\cot(y)\partial_{\tilde{v}_2}$. Then it is easy to derive that

$$\tilde{v}_1 = \frac{w_4}{\sin(y)\sin(w_2)}, \quad \tilde{v}_2 = \frac{\cot(w_2)}{\sin(y)} \tag{24}$$

and system (22) becomes

$$\tilde{v}_1'' + 2\cot(y)\tilde{v}_1' = 0,$$

$$\tilde{v}_2'' + 2\cot(y)\tilde{v}_2' = 0, \tag{25}$$

which is not the equation of motion of a free particle in two dimensions as was claimed it would be in Ref. 51.

Nevertheless we note that, if we take the y-independent version of transformation (24), i.e.,

$$v_1 = \frac{w_4}{\sin(w_2)}, \quad v_2 = \cot(w_2),$$

then system (22) becomes

$$v_1'' + v_1 = 0,$$

$$v_2'' + v_2 = 0, \tag{26}$$

i.e., the two-dimensional harmonic oscillator.

Now we return to system (11) and mimic the same procedure as used for the Kepler problem by taking $y=w_3$ as the new independent variable. If we again eliminate w_4, then the Lie group analysis yields the substitutions $w_5=u_5/w_1^2$, $w_6=u_4/w_1^2$ from the determining parabolic partial differential equation. Then, after replacing $w_2=2\arctan(u_2)$ for the reason based on the workings of symbolic manipulation in a computer given above, deriving u_4 from I_1, i.e., $u_4=(u_2^2+1)\times(2I_1u_2^2+\lambda+2I_1)/(2u_2^2)$ and eliminating u_5 from the system, i.e., $u_5=-(\lambda u_2^2-\lambda-u_2^2I_1-I_1)u_2'/(2u_2^2)$, we find that the system (11) is reduced to the following three differential equations:

$$u'' = -\frac{(\lambda u^2+\lambda-I_1u^2+I_1)u^2+2(\lambda+I_1)u'^2}{(\lambda u^2-\lambda-I_1u^2-I_1)u}, \tag{27}$$

$$w_1' = -\frac{4u^2w_1^2w_4}{(\lambda u^2-\lambda-I_1u^2-I_1)(u^2+1)}, \tag{28}$$

$$w_4' = -\frac{(u^2+1)^2I_1^2-4\mu u^2w_1+(\lambda u^2+\lambda-2I_1u^2+2I_1)(u^2+1)\lambda}{(\lambda u^2-\lambda-I_1u^2-I_1)(u^2+1)w_1} - \frac{(\lambda u^2-\lambda-I_1u^2-I_1)u'^2}{(u^2+1)u^2w_1}, \tag{29}$$

where prime denotes derivative with respect to y and $u=u_2$. Equation (27) admits an eight-dimensional Lie symmetry algebra of point symmetries and therefore is linearizable by means of a point transformation.[32] The eight symmetries are

$$\Omega_1 = -\cos(y)\frac{u^2}{\lambda+I_1-(\lambda-I_1)u^2}\partial_u,$$

$$\Omega_2 = \sin(y)\frac{u^2}{\lambda+I_1-(\lambda-I_1)u^2}\partial_u,$$

$$\Omega_3 = -\frac{(\lambda u^2+\lambda-I_1u^2+I_1)u}{(\lambda+I_1-(\lambda-I_1)u^2)(\lambda-I_1)}\partial_u,$$

$$\Omega_4 = \partial_y,$$

$$\Omega_5 = \cos(y)\frac{\lambda u^2 + \lambda - I_1 u^2 + I_1}{u}\partial_y + \sin(y)\frac{(\lambda^2 + \lambda I_1 + I_1^2)(u^4+1) - (3u^4-1)\lambda I_1}{\lambda + I_1 - (\lambda - I_1)u^2}\partial_u,$$

$$\Omega_6 = -\sin(y)\frac{\lambda u^2 + \lambda - I_1 u^2 + I_1}{u}\partial_y + \cos(y)\frac{(\lambda^2 + \lambda I_1 + I_1^2)(u^4+1) - (3u^4-1)\lambda I_1}{\lambda + I_1 - (\lambda - I_1)u^2}\partial_u,$$

$$\Omega_7 = \cos(2y)\partial_y + \sin(2y)\frac{(\lambda u^2 + \lambda - I_1 u^2 + I_1)u}{\lambda + I_1 - (\lambda - I_1)u^2}\partial_u,$$

$$\Omega_8 = -\sin(2y)\partial_y + \cos(2y)\frac{(\lambda u^2 + \lambda - I_1 u^2 + I_1)u}{\lambda + I_1 - (\lambda - I_1)u^2}\partial_u. \tag{30}$$

In order to find the linearizing transformation we have to look for a two-dimensional Abelian intransitive subalgebra and, following Lie's classification of two-dimensional algebras in the real plane,[32] we have to transform the subalgebra into the canonical form

$$\partial_{\tilde{u}}, \quad \tilde{y}\partial_{\tilde{u}} \tag{31}$$

with $\tilde{u}$ and $\tilde{y}$ the new dependent and independent variables, respectively. We find that one such subalgebra is that generated by Ω_1 and Ω_2, which yields the following point transformation:

$$\tilde{u} = \frac{\lambda u^2 + \lambda - I_1 u^2 + I_1}{\cos(y)u}, \quad \tilde{y} = -\frac{\sin(y)}{\cos(y)} \tag{32}$$

and Eq. (27) becomes

$$\frac{\mathrm{d}^2\tilde{u}}{\mathrm{d}\tilde{y}^2} = 0. \tag{33}$$

The transformation which takes the free particle equation (33) into a harmonic oscillator, i.e.,

$$\frac{\mathrm{d}^2 x}{\mathrm{d}\tau^2} + x = 0$$

is (see, for example, Whittaker,[53] p. 307)

$$x = \frac{1}{\sqrt{\tilde{u}^2 + \tilde{y}^2}}, \quad \tau = \arctan\left(-\frac{\tilde{u}}{\tilde{y}}\right)$$

and vice versa

$$\tilde{u} = \frac{\sin(\tau)}{x}, \quad \tilde{y} = -\frac{\cos(\tau)}{x}.$$

Therefore we obtain a harmonic oscillator if we make the transformation

$$x = \frac{\cos(y)u}{\sqrt{(\lambda u^2 + \lambda - I_1 u^2 + I_1)^2 + \sin(y)^2 u^2}},$$

$$\tau = \arctan\left(\frac{\lambda u^2 + \lambda - I_1 u^2 + I_1}{\sin(y)u}\right). \tag{34}$$

The reduced system, (27)–(29), is separated into the second-order ordinary differential equation (27) containing the single dependent variable $u(y)$ and the pair of nonlinear first order ordi-

nary differential equations (28) and (29). Given the solution of (27) we may rewrite (28) and (29) as a pair of nonautonomous first-order ordinary differential equations. We eliminate w_4 from (29) using (28) to obtain a nonlinear second-order ordinary differential equation for w_1. The symmetry analysis of this equation shows that it has eight Lie point symmetries. Consequently it is linearizable by means of a point transformation. Thus we have shown how to reduce (21) to a two-dimensional linear isotropic harmonic oscillator plus a conservation law by using Lie symmetries and the reduction method.

III. ALGEBRAIC CONSIDERATIONS

The richness of the Lie algebraic structure of the symmetries suggests the following algebraic approach.

We obtain the Ermanno–Bernoulli constants—so named to give the discoverers[3,11,19] of the Laplace–Runge–Lenz vector at least a footnote in the history of the Kepler problem—as

$$J_{\pm} = J_x \pm iJ_y = \left[\left(\frac{L^2}{r} - \mu \right) \sin\ \theta - r^2 \dot{r} \dot{\theta} \cos\ \theta - \lambda r \dot{\phi} \sin\ \theta \cos\ \theta \pm i(-r^2 \dot{r} \dot{\phi} \sin\ \theta + \lambda r \dot{\theta}) \right] e^{\pm i\phi}, \tag{35}$$

which can be written in the more compact form

$$J_{\pm} = (v_1 \pm iv_1') e^{\pm i\phi}, \tag{36}$$

where

$$v_1 = \left(\frac{L^2}{r} - \mu \right) \sin\ \theta - r^2 \dot{r} \dot{\theta} \cos\ \theta - \lambda r \dot{\phi} \sin\ \theta \cos\ \theta,$$

$$v_1' = -r^2 \dot{r} \dot{\phi} \sin\ \theta + \lambda r \dot{\theta}$$

with the prime denoting differentiation with respect to the azimuthal angle, ϕ. The new variable, v_1, satisfies

$$v_1'' + v_1 = 0. \tag{37}$$

Equation (37), that of a simple harmonic oscillator with independent variable ϕ, replaces the radial equation (8a).

The introduction of the standard integrating factor, $r \sin\ \theta$, makes (8c) exact, *videlicet*

$$\frac{d}{dt}(r^2 \dot{\phi} \sin^2\ \theta - \lambda \cos\ \theta) = 0 \tag{38}$$

and one recognizes that this simply represents the conservation of P_z, the z-component of Poincaré's vector. To maintain a uniformity of notation we define

$$v_3 = r^2 \dot{\phi} \sin^2\ \theta - \lambda \cos\ \theta \tag{39}$$

and replace (8c) with the conservation law

$$v_3' = 0. \tag{40}$$

In a manner analogous to that used to obtain the Ermanno–Bernoulli constants we define

$$P_{\pm} = -[P_x \pm iP_y] = [r^2 \dot{\phi} \sin\ \theta \cos\ \theta + \lambda \sin\ \theta \pm i(-r^2 \dot{\theta})] e^{\pm i\phi} = (v_2 \pm iv_2') e^{\pm i\phi},$$

where

$$v_2 = r^2\dot{\phi}\sin\theta\cos\theta + \lambda\sin\theta \tag{41}$$

satisfies the second order ordinary differential equation for a second simple harmonic oscillator, *videlicet*

$$v_2'' + v_2 = 0. \tag{42}$$

Equally this equation may be obtained directly from the polar and azimuthal equations. One multiplies (8b) and (8c) by r and $r\sin\theta$, respectively, to give

$$\frac{\mathrm{d}}{\mathrm{d}t}(r^2\dot{\theta}) - \dot{\phi}(r^2\dot{\phi}\sin\theta\cos\theta + \lambda\sin\theta) = 0, \tag{43}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}(r^2\dot{\phi}\sin\theta\cos\theta + \lambda\sin\theta) + r^2\dot{\theta}\dot{\phi} = 0,$$

and on replacement of time by the new independent variable, ϕ, (43) is just the system of two first order equations equivalent to (42) since

$$v_2 = r^2\dot{\phi}\sin\theta\cos\theta + \lambda\sin\theta,$$

$$v_2' = -r^2\dot{\theta}. \tag{44}$$

Consequently we have reduced the MICZ-Kepler problem, (1) with $2\nu = -\lambda^2$, from the sixth-order nonlinear system (8) to a fifth-order system comprising a linear isotropic harmonic oscillator plus a conservation law, *videlicet*

$$v_1'' + v_1 = 0, \tag{45a}$$

$$v_2'' + v_2 = 0, \tag{45b}$$

$$v_3' = 0, \tag{45c}$$

by virtue of using the conserved vectors **J** and **P**. We note that the reduced system is still autonomous.

The reduced system is a two-dimensional isotropic linear harmonic oscillator plus a conservation law. The system (45) possesses 16 Lie point symmetries comprising 15 for the pair of oscillators and an additional one for the conservation law. (One should note that the first-order ordinary differential equation for the conservation law has an infinite number of Lie point symmetries. However, we are considering a system of three equations and that infinity has to be reduced somewhat in number to be consistent with the two other equations.) They are[16]

$$\Gamma_1 = \partial_\phi, \quad \Gamma_{7\pm} = \mathrm{e}^{\pm i\phi}\partial_{v_1},$$

$$\Gamma_2 = v_1\partial_{v_1}, \quad \Gamma_{8\pm} = \mathrm{e}^{\pm i\phi}\partial_{v_2},$$

$$\Gamma_3 = v_1\partial_{v_2}, \quad \Gamma_{9\pm} = \mathrm{e}^{\pm 2i\phi}[\partial_\phi \pm i(v_1\partial_{v_1} + v_2\partial_{v_2})],$$

$$\Gamma_4 = v_2\partial_{v_1}, \quad \Gamma_{10\pm} = v_1\mathrm{e}^{\pm i\phi}[\pm i\partial_\phi + v_1\partial_{v_1} + v_2\partial_{v_2}],$$

$$\Gamma_5 = v_2\partial_{v_2}, \quad \Gamma_{11\pm} = v_2\mathrm{e}^{\pm i\phi}[\pm i\partial_\phi + v_1\partial_{v_1} + v_2\partial_{v_2}],$$

$$\Gamma_6 = \partial_{v_3}, \tag{46}$$

which is a representation of the algebra $A_1 \oplus \mathrm{sl}(4,R)$ and Γ_6 is the symmetry associated with the conservation law and the contributor of the A_1 part of the algebra given above. The original system (8) (with $2\nu = -\lambda^2$) possesses just the four Lie point symmetries

$$X_1 = \partial_t, \quad X_2 = \partial_\phi, \quad X_{3\pm} = \mathrm{e}^{\pm i\phi}(\pm i \cot\theta \partial_\phi + \partial_\theta), \tag{47}$$

i.e., a representation of $A_1 \oplus \mathrm{so}(3)$. (In the absence of the Newtonian gravitational potential (1) is an instance of a generalized Ermakov system[10] with so(3) imposed[17] which possesses the six-dimensional algebra $\mathrm{sl}(2,R) \oplus \mathrm{so}(3)$—Mladenov[37] prefers $\mathrm{so}(2,1) \oplus \mathrm{so}(3)$—so that the addition of the Kepler potential has the effect of symmetry-breaking. As is evident from the work reported in this note, the symmetry-breaking is at the level of point symmetries.)

From the set of symmetries (46) one can extract the representation of the complete symmetry group of the MICZ-Kepler problem. In general there are several equivalent representations of the complete symmetry group of systems of oscillators.[2] The generic isotropic oscillator in n dimensions is completely specified by the $(2n+1)$-dimensional algebra $A_1 \oplus_s (2n) A_1$, i.e., a representation of the group of the semidirect product of dilations and translations in $(2n)$-dimensional space. However, there are some anomalies.[2] In the case of dimension four there are two distinct complete symmetry groups. In the cases of dimensions two and three the anomalous group has one element fewer than the generic group and so is the sole representative of the complete symmetry group for the isotropic oscillator. Consequently for (45) we select Γ_1, $\Gamma_{9\pm}$ and $\tilde{\Gamma} = \Gamma_3 - \Gamma_4$—the conservation law, (45c), does not require any additional symmetry—with the algebra $\mathrm{sl}(2,R) \oplus \mathrm{so}(2)$,[31] which is the direct sum of $\mathrm{sl}(2,R)$ with the algebra of rotations in two dimensions.

To this set of symmetries one adds ∂_t to obtain a representation of the complete symmetry group of the MICZ-Kepler problem, *videlicet* $A_1 \oplus \mathrm{sl}(2,R) \oplus \mathrm{so}(2)$.

Of some interest is that the reduction of the MICZ-Kepler problem to the system (45) parallels that of the Kepler problem and its variations.[44] In the case of the latter systems a critical feature for the success of this reduction appears to be the possession of a conserved vector of Laplace–Runge–Lenz-type and in the introduction of Ermanno–Bernoulli constants. We have seen how the method of reduction of order leads to the reduction of the system to that of an isotropic two-dimensional oscillator plus a conservation law. In the case of the MICZ-Kepler problem we had such a vector in (7) and we obtained the results presented above. We emphasize that the algorithmic derivation of the reduction to the system of two oscillators plus a conservation law did not require any preknowledge of the physical problem described by the equations for the MICZ-Kepler problem, but was simply a consequence of the general procedure.

The solution of the system (45) is

$$v_1 = J_+ \mathrm{e}^{-i\phi} + J_- \mathrm{e}^{i\phi},$$

$$v_2 = P_+ \mathrm{e}^{-i\phi} + P_- \mathrm{e}^{i\phi},$$

$$v_3 = P_z, \tag{48}$$

in which the constants of integration are expressed in terms of the Ermanno–Bernoulli constants and the corresponding constants for the Poincaré vector.

IV. CONCLUSION

One recalls that the Poisson bracket relation for the monopole is not standard. The Hamiltonian[38] for the equation of motion (1) is

$$H = \frac{1}{2}\left(\mathbf{p}\cdot\mathbf{p} + \frac{\lambda^2}{r^2}\right) - \frac{\mu}{r}, \tag{49}$$

where the momentum is $\mathbf{p}=\dot{\mathbf{r}}$ and the fundamental Poisson Bracket relations are

$$[x_i,x_j]_{\mathrm{PB}} = 0, \quad [x_i,p_j]_{\mathrm{PB}} = \delta_{ij}, \quad [p_i,p_j]_{\mathrm{PB}} = \lambda\epsilon_{ijk}\frac{x_k}{r^3} \tag{50}$$

with $r=|\mathbf{r}|$, $x_ix_i=r^2$ and δ_{ij} and ϵ_{ijk} are Kronecker's delta and epsilon, respectively. The Poisson bracket relations of the components of the conserved vectors, **P** and **J**, are

$$[P_i,P_j]_{\mathrm{PB}} = \epsilon_{ijk}P_k, \quad [P_i,J_j]_{\mathrm{PB}} = \epsilon_{ijk}J_k, \quad [J_i,J_j]_{\mathrm{PB}} = -2H\epsilon_{ijk}P_k, \tag{51}$$

which provides a representation of the algebras so(4), e(3), and so(3,1) depending upon whether H is negative, zero, or positive which is a result well-known in the literature. These are exactly the same algebras as are found for the Kepler problem. We note that the Poisson bracket algebras of the first integrals and the Lie point symmetries of the underlying systems of ordinary differential equations which model the problems have different provenances. The former is based on the symplectic space of the Hamiltonian system and the latter on the invariance of the differential equations of the system under infinitesimal transformation. The Lie point symmetries of the equations of motion differ for the two problems being $A_1 \oplus \mathrm{so}(3)$ for the MICZ-Kepler problem and $A_2 \oplus \mathrm{so}(3)$ for the Kepler problem. However, the algebras become identical in the reduced system since the reduced systems are identical.

In general the Lie point symmetries of the reduced system (45) are nonlocal symmetries for the source system when expressed in terms of the coordinates of the original system. It is a matter of some curiosity that the majority of elements of the complete symmetry group should be represented by nonlocal symmetries, but not an isolated instance. A classic example is the equation (see Ref. 25, Chap. 6, p. 542ff)

$$y'' = \frac{y'^2}{y} + f'(x)y^{p+1} + pf(x)y'y^p, \tag{52}$$

which has no Lie point symmetries for general $f(x)$ and yet is trivially integrable.[52] By means of the nonpoint transformation

$$X = x \quad Y = \log\left\{-py^p \exp\left[-\int pf(x)y^p\mathrm{d}x\right]\right\}, \tag{53}$$

(52) is transformed to the trivial $\mathrm{d}^2Y/\mathrm{d}X^2=0$ for which three point symmetries with the algebra $A_{3,3}$ ($\Leftrightarrow D\oplus_s T_2$) provide the representation of the complete symmetry group. These point symmetries become horribly nonlocal when expressed in terms of the variables of (52).[1]

Since the elements of the complete symmetry algebra are the minimal set of symmetries required to specify completely the system concerned, the importance of nonlocal symmetries is further highlighted. One has the distinct impression that nonlocal symmetries come in two varieties, useful and nonuseful. (This statement is probably true of all symmetries, but one tends to attach a special value to point and contact symmetries.[18]) A possible definition of utility in this instance is that there is some transformation of dependent and independent variables which renders the nonlocal symmetry into the more comfortable point form. The technique of reduction of order[42,43] provides a systematic algorithmic procedure to identify these desirable transformations and thereby provides greater information and the potential for greater understanding of these systems.

In this paper we have approached the question of the possible linearization of the MICZ-Kepler problem on a purely algorithmic basis using a combination of the method of reduction of order and the Lie point symmetry analysis. We have shown that the MICZ-Kepler problem is essentially the same problem has the well-known Kepler problem, the reduction of which we have

also given. In terms of the natural coordinates for the description of each problem the Lie point symmetries of the equations of motion differ in number so that in terms of these coordinates the problems appear to be algebraically different. Nevertheless we have demonstrated their essential oneness in an appropriate coordinate system. The attraction of the algorithmic procedure we have demonstrated here is that there is no necessity to have a deep knowledge of the system being described. In our provision of an alternate derivation of the reduction through manipulation of the equations of motion we highlighted the approach which one can take if one is very familiar with the way these systems possess conserved quantities. Such systems are rare. We do not deny that elegant treatments are possible for certain problems. Rather our concern is for those systems for which these elementary manipulations are not obvious or perhaps even possible and yet which have a very simple structure in a suitable coordinate system. The method which we have presented here is designed for the nonobvious.

Our considerations here have been confined to the three-dimensional MICZ-Kepler problem since it is susceptible to a very transparent treatment. The extension of the application of the method of reduction of order to the higher-dimensional problems of this type of interest in the literature is intended to be the subject of a future report.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 9 SEPTEMBER 2004

The existence problem for dynamics of dissipative systems in quantum probability

Palle E. T. Jorgensen[a)]
Department of Mathematics, The University of Iowa, Iowa City, Iowa 52242-1419

(Received 25 March 2004; accepted 29 May 2004; published 16 August 2004)

Motivated by existence problems for dissipative systems arising naturally in lattice models from quantum statistical mechanics, we consider the following C^*-algebraic setting: A given Hermitian dissipative mapping δ is densely defined in a unital C^*-algebra $\mathfrak{A}$. The identity element in $\mathfrak{A}$ is also in the domain of δ. Completely dissipative maps δ are defined by the requirement that the induced maps, $(a_{ij}) \to (\delta(a_{ij}))$, are dissipative on the n-by-n complex matrices over $\mathfrak{A}$ for all n. We establish the existence of different types of maximal extensions of completely dissipative maps. If the enveloping von Neumann algebra of $\mathfrak{A}$ is injective, we show the existence of an extension of δ which is the infinitesimal generator of a quantum dynamical semigroup of completely positive maps in the von Neumann algebra. If δ is a given well-behaved $*$-derivation, then we show that each of the maps $\pm\delta$ is completely dissipative. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1777401]

I. INTRODUCTION

Recent applications of the operator-theoretic approach to dissipative quantum systems include Refs. 22 and 37. For a more systematic approach, see Ref. 36. Suppose we are given a one-parameter group of automorphisms $\alpha_t: a \mapsto e^{itH} a e^{-itH}$ which acts on some set of observables a, specified as a dense "local" subalgebra of a completed C^*-algebra. If we then differentiate at $t=0$, we get the derivation $\delta: a \mapsto i[H,a] = i(Ha - aH)$ which takes the form of a formal commutator. The issue is complicated by the fact that the Hamiltonian H is typically an unbounded operator in statistical models, say infinite lattice spin systems. In applications, it is H that is given, and the process must be run in reverse. By analogy to boundary value problems from partial differential equations, we then expect to encounter an existence problem for reconstructing the dynamics of the system from knowing only a formula for H.

We adopt the C^*-W^*-formalism for the dynamics of infinite quantum systems.[10,14,18,20,21,24,31,33] For the special case of quantum spin systems it is believed that the dynamics in the time-reversible case is given by an unbounded derivation of a suitable algebra $\mathfrak{A}$ of observables.[31] Depending on the range of the interaction, and the number of dimensions of the spin lattice, it is possible to exponentiate the infinitesimal derivation to a one-parameter group of automorphisms α_t $(-\infty < t < \infty)$ of $\mathfrak{A}$, or of the enveloping W^*-algebra $\mathfrak{A}''$ (see Ref. 35), or the W^*-algebra generated by a given invariant state.[10,17,26,29,32,33]

It is known that (open) irreversible systems may be obtained as restrictions of time-reversible systems, and it follows[20] that the dynamics of the open system is given mathematically by a semigroup τ_t $(0 \leqslant t < \infty)$ of completely positive mappings of the C^*-algebra $\mathfrak{A}$, or W^*-algebra $\mathfrak{A}''$. The corresponding infinitesimal generator is completely dissipative. Completely positive semigroups also play a role in quantum computing algorithms.[27] The philosophy is that noise in the quantum processes dictates the dissipative systems, as opposed to the conservative ones (which are governed by one-parameter groups of automorphisms).

[a)]Electronic mail: jorgen@math.uiowa.edu; URL: http://www.math.uiowa.edu/~jorgen/

But in high lattice dimensions, or for long-range interaction, there are difficulties in exponentiating the infinitesimal generators. The determination of the time evolutions α_t (respectively, τ_t) seems to require "extra boundary conditions."[7,10,26,32,33] It is therefore a meaningful foundational question, for a given completely dissipative infinitesimal transformation δ in a C^*-algebra $\mathfrak{A}$, to ask if it is always possible to extend δ to a transformation $\tilde{\delta}$ which is the infinitesimal generator for a quantum dynamical semigroup. Under the assumption that δ is Hermitian, and that the W^*-algebra $\mathfrak{A}''$ is injective, we establish the existence of a generator extension $\tilde{\delta}$. Our extension is thus an algebraic parallel to Friederichs's extension for semibounded operators in Hilbert space, or an analogue of Phillips's[30] maximal dissipative extension of the general dissipative operator in Hilbert space.

In earlier articles[7,10,28,31] the uniqueness problem was considered for the generator extension, $\delta \subset \tilde{\delta}$. But, just as the case for operators in Hilbert space (Friedrichs, Phillips), the extension is generally not unique, reflecting the possibility of different "boundary conditions" at infinity.

We refer the reader to Refs. 14, 18, and 33, for details on the mathematical foundations of algebraic quantum theory.

The issues centering around the existence problem for the dynamical one-parameter groups, or semigroups, of quantum statistical mechanics are perhaps best known in the setup of *quantum spin systems*, as they are treated in Refs. 9, 25, and 34.

Example I.1: The mathematical framework is rather general such as to allow a wide variety of applications, including recent ones to nonequilibrium statistical mechanics.[34] A countably infinite set L (say a lattice; it may be $\mathbb{Z}^\nu$ where ν is the lattice rank, or dimension) is specified at the outset. Points $s \in L$ are sites at which quantum spins are located. For each $s \in L$, let $\mathcal{H}_s$ be a finite-dimensional complex Hilbert space, i.e., the spin vectors at site s; and for a finite $\Lambda \subset L$, set

$$\mathcal{H}_\Lambda := \bigotimes_{s \in \Lambda} \mathcal{H}_s.$$

Then let $\mathfrak{A}_\Lambda$ be the $*$-algebra of all (bounded) operators on $\mathcal{H}_\Lambda$. With the natural embedding

$$\mathfrak{A}_{\Lambda_1} \subset \mathfrak{A}_{\Lambda_2} \text{ for } \Lambda_1 \subset \Lambda_2$$

given by

$$\mathfrak{A}_{\Lambda_1} \mapsto \mathfrak{A}_{\Lambda_1} \otimes 1_{\Lambda_2 \setminus \Lambda_1} \subset \mathfrak{A}_{\Lambda_2},$$

we get the usual inductive limit C^*-algebra $\lim_\Lambda \mathfrak{A}_\Lambda =: \mathfrak{A}$. A function $\Lambda \mapsto \Phi(\Lambda) = \Phi(\Lambda)^* \in \mathfrak{A}_\Lambda$ defined on the finite subsets Λ of L is called an *interaction*, and

$$H_\Phi(\Lambda) = \sum_{X \subset \Lambda} \Phi(X) \tag{1.1}$$

is the associated local *Hamiltonian*, where in (1.1), the summation is over all finite subsets X of Λ. Since $\mathfrak{A}_{\Lambda_1}$ and $\mathfrak{A}_{\Lambda_2}$ commute when $\Lambda_1 \cap \Lambda_2 = \emptyset$, it follows that

$$\delta(a) = \lim_\Lambda [H(\Lambda), a] \tag{1.2}$$

is well defined for all local observables a in the dense $*$-subalgebra,

$$\mathfrak{A}_0 = \bigcup_{\Lambda \text{ fin}} \mathfrak{A}_\Lambda \text{ in } \mathfrak{A},$$

where $[\cdot, \cdot]$ in (1.2) denotes the usual commutator $[b, a] := ba - ab$. Ruelle proved that, if Φ is translationally invariant, and if, for some $\lambda > 0$,

$$\sum_{n=0}^{\infty} e^{n\lambda} \sup_{s\in L} \sum_{\substack{s\in X \text{ fin} \\ \text{card } X=n+1}} \|\Phi(X)\| < \infty , \tag{1.3}$$

then the $*$-derivation δ defined in (1.2) is the infinitesimal generator of a one-parameter subgroup of $*$-automorphisms $\{\alpha_t\}_{t\in\mathbb{R}} \subset \mathrm{Aut}(\mathfrak{A})$, which then satisfies

$$\alpha_t(a) = \lim_{\Lambda \nearrow L} e^{itH(\Lambda)} a e^{-itH(\Lambda)} \tag{1.4}$$

for all $a\in\mathfrak{A}$ and $t\in\mathbb{R}$, i.e., it is approximately inner. This means that, if $a\in\mathfrak{A}_0$, then

$$\lim_{\substack{t\to 0 \\ t\neq 0}} t^{-1}(\alpha_t(a) - a) = \delta(a). \tag{1.5}$$

Moreover, δ is, when extended from $\mathfrak{A}_0$, a closed $*$-derivation, in the sense that the graph of δ is closed in $\mathfrak{A}\times\mathfrak{A}$. But if Φ is not translationally invariant, or if (1.3) is not known to hold, then no such conclusion is within reach, and the issue of extensions of δ arises. We then ask if some extension $\tilde{\delta}$ of δ to a generator of a one-parameter group of automorphisms, or a semigroup of dissipations (see details below), exists.

II. DEFINITIONS AND TERMINOLOGY

Let X and Y be Banach spaces. Then the space of bounded linear operators from X to Y is denoted $L(X,Y)$. The *conjugate* (i.e., *dual*) Banach space to X is $L(X,\mathbb{C})$, and is denoted X'. If $\mathcal{H}$ is a Hilbert space, the C^*-algebra of all bounded operators on $\mathcal{H}$ is denoted $B(\mathcal{H})$. Let $\mathcal{L}$ be a linear subspace of $B(\mathcal{H})$ which is self-adjoint and contains the identity operator I. With the order inherited from $B(\mathcal{H})$, the subspace $\mathcal{L}$ gets the structure of an *operator system*, in the terminology of Effros.[11] The full matrix algebra M_n of all complex n-by-n matrices is also an operator system, and so is $\mathcal{L}_n = \mathcal{L}\otimes M_n$. The elements in $\mathcal{L}_n$ may be realized as n-by-n matrices with entries from $\mathcal{L}$, $(a_{ij})_{i,j=1}^n$, $a_{ij}\in\mathcal{L}$. If $\mathcal{L}$ and $\mathcal{R}$ are operator systems and $\varphi:\mathcal{L}\to\mathcal{R}$ is a linear mapping, then the induced map $(a_{ij})\to(\varphi(a_{ij}))$ of $\mathcal{L}_n$ into $\mathcal{R}_n$ is denoted φ_n. It is, in fact, $\varphi\otimes \mathrm{id}_n$. We say[2] that φ is *completely positive* (respectively, *completely contractive*) if φ_n is positive (respectively, contractive) for all n. We say that $\mathcal{R}$ is *injective* if for every pair of operator systems, $\mathcal{L}\subset\mathcal{L}_1$, and every completely positive map $\varphi:\mathcal{L}\to\mathcal{R}$, there is a completely positive extension $\psi:\mathcal{L}_1\to\mathcal{R}$. That is, $\psi(x)=\varphi(x)$ for all $x\in\mathcal{L}$. If $\mathcal{R}$ is a von Neumann algebra in a Hilbert space $\mathcal{H}$, it is known[13,38] that $\mathcal{R}$ is injective iff there is a norm-one projection of $B(\mathcal{H})$ onto $\mathcal{R}$.

If $\mathfrak{A}$ is a C^*-algebra, it is known[12] that $\mathfrak{A}$ is nuclear iff the double conjugate (dual) $\mathfrak{A}''$ is injective as a W^*-algebra. Connes showed[13] that a factor $\mathcal{R}$ on a separable Hilbert space is injective iff it is matricial.

III. DISSIPATIVE TRANSFORMATIONS

An operator δ in a Banach space X is said to be dissipative[29] if one of the following three equivalent conditions is satisfied:

(i) For all x in the domain $D(\delta)$ of δ, there is an element $f\in X'$, depending on x, such that $\|f\|=1$, $f(x)=\|x\|$, and $\mathrm{Re}\, f(\delta(x))\leqslant 0$.

(ii) For all x in $\mathcal{D}(\delta)$, and all $f\in X'$ satisfying $\|f\|=1$, and $f(x)=\|x\|$, the inequality $\mathrm{Re}\, f(\delta(x)) \leqslant 0$ is valid.

(iii) For all x in $\mathcal{D}(\delta)$, and all $\alpha\in\mathbb{R}_+$, the inequality $\|x-\alpha\delta(x)\|\geqslant\|x\|$ holds.

The proof of the equivalence can be found, for example, in Ref. 7, but the equivalence can also be shown to be a consequence of the approximation idea in Sec. IX and Proposition X.2 in the present paper.

If X is an operator system, we say that δ is *completely dissipative* if the induced mapping δ_n

in X_n is dissipative for all $n=1,2,\ldots$. Recall that $X_n = X \otimes M_n$, and $\delta_n:(x_{ij}) \to (\delta(x_{ij}))$, with domain $\mathcal{D}(\delta_n)=\{(x_{ij}) \in X_n : x_{ij} \in \mathcal{D}(\delta)\}$.

Finally we say that the transformation δ is *Hermitian* if the domain $\mathcal{D}(\delta)$, in the operator system X, is invariant under the $*$-involution of X, and if $\delta(x^*)=\delta(x)^*$ for all $x \in \mathcal{D}(\delta)$.

If $\delta: X \to Y$ is merely a linear transformation between Banach spaces X and Y, with domain $\mathcal{D}(\delta)$ dense in X, then the transposed (or conjugate) transformation δ' is well defined as a linear transformation $\delta': Y' \to X'$ with domain $\mathcal{D}(\delta')=\{f \in Y' : \exists g \in X'$ s.t. $f(\delta(x))=g(x)$ for all $x \in \mathcal{D}(\delta)\}$. For $f \in \mathcal{D}(\delta')$, $\delta'(f)=g$. The domain $\mathcal{D}(\delta')$ is weak*-dense in Y' iff δ is closable. It is known[29] that dissipative operators are closable.

IV. COMPLETELY POSITIVE SEMIGROUPS (QUANTUM DYNAMICAL SEMIGROUPS)

Let M be a W^*-algebra with predual M_*. Let τ_t be a family of completely positive mappings of M into itself, indexed by the time parameter $t \in [0,\infty)$. Assume that τ_0 is the identity transformation in M, and that $\tau_t(\mathbb{1})=\mathbb{1}$ for all $t \in [0,\infty)$, where $\mathbb{1}$ denotes the unit element of the W^*-algebra M in question. We assume further that the semigroup law holds, $\tau_{t_1+t_2}=\tau_{t_1}\circ\tau_{t_2}$ for $t_1,t_2 \in [0,\infty)$, and finally that each τ_t is a normal mapping in M. Recall that normality is equivalent to the requirement that the conjugate semigroup τ_t' (Ref. 16) of M' leaves invariant the subspace M_*. Finally we require continuity of each scalar function, $t \to \varphi(\tau_t(a))$, for all $\varphi \in M_*$ and $a \in M$. A semigroup which satisfies all the requirements above is called a *completely positive semigroup*. Because of the relevance to quantum dynamics, we shall also call it a quantum dynamical semigroup.[21]

The *infinitesimal generator* of a given completely positive semigroup (τ_t, M) is a, generally unbounded, transformation, denoted by ζ, in M. The domain of the generator ζ is given by

$$\mathcal{D}(\zeta) = \left\{ a \in M : \exists\, b \in M \text{ s.t. for all } t,\ \tau_t(a) - a = \int_0^t \tau_s(b)\mathrm{d}s \right\}.$$

By definition $\zeta(a)=b$. It is easy to see[16] that $\zeta(a)=(\mathrm{d}/\mathrm{d}t)\tau_t(a)|_{t=0}$, where the derivative is taken in the $\sigma(M,M^*)$-topology. Finally note that infinitesimal generators are completely dissipative.

Example IV.1: It is known that the generator δ of a completely positive semigroup $\{\tau_t\}_{t\in\mathbb{R}_+}$ on a C^*-algebra $\mathfrak{A}$ is completely dissipative on a dense subspace $\mathcal{D}$ in $\mathfrak{A}$; see Ref. 4. The following is a "canonical" example of this: it is built on the C^*-algebra over the canonical commutation relations (CCR); see Ref. 8. Specifically, let $\mathcal{H}$ be a complex Hilbert space. Then there is a C^*-algebra $\mathfrak{A}=\mathfrak{A}(\mathcal{H})$ which is generated by the identity element $\mathbb{1}$ and a family of unitary elements $\{u_\xi | \xi \in \mathcal{H}\setminus\{0\}\}$ such that

$$u_\xi u_\eta = e^{(i/2)\mathrm{Im}\langle\xi|\eta\rangle} u_{\xi+\eta}$$

for all $\xi,\eta \in \mathcal{H}$, with the understanding that $u_0=\mathbb{1}$. Then it follows that there is a unique, completely positive semigroup $\{\tau_t\}_{t\in\mathbb{R}_+}$ in $\mathfrak{A}$, such that

$$\tau_t(u_\xi) = e^{-t\|\xi\|_{\mathcal{H}}^2} u_\xi \text{ for } \xi \in \mathcal{H}.$$

Hence the subalgebra $\mathcal{D} \subset \mathfrak{A}$ spanned by the elements $\{u_\xi | \xi \in \mathcal{H}\}$ is contained in the domain of the generator δ, and

$$\delta(u_\xi) = -\|\xi\|_{\mathcal{H}}^2 u_\xi. \tag{4.1}$$

It follows from the observation in Refs. 3 and 5 that this δ is completely dissipative with dense domain $\mathcal{D}$ in the C^*-algebra $\mathfrak{A}$. That is, δ defined by

$$\delta(a) = \lim_{t\to 0_+} t^{-1}(\tau_t(a) - a) \quad \text{(norm limit)}$$

is well defined for $a = u_\xi \in \mathcal{D}$, and (4.1) holds.

We now turn to the general existence problem.

Theorem IV.2: *Let $\mathfrak{A}$ be a C*-algebra with unit $\mathbb{1}$, and let δ be a completely dissipative transformation in $\mathfrak{A}$ with dense domain $\mathcal{D}(\delta)$. Assume $\mathbb{1} \in \mathcal{D}(\delta)$, $\delta(\mathbb{1}) = 0$, and further that δ is Hermitian. Moreover assume that the double conjugate (dual) $\mathfrak{A}''$ is an injective W*-algebra. Then δ has an extension $\tilde{\delta}$ to an ultraweakly densely defined transformation in $\mathfrak{A}''$ which is at the same time the infinitesimal generator of a completely positive semigroup of normal unital transformations in $\mathfrak{A}''$.*

We have divided the proof of Theorem IV.2 into two main sections: one is concerned with the analysis of the family of extensions of the *partial resolvent operator* $(I-\delta)^{-1}$. This analysis leads to a distinguished set of contractive, and maximal, extensions which is associated with a set of extensions $\tilde{\delta}$ of δ. But $\tilde{\delta}$ turns out to be an operator in the enveloping W*-algebra of $\mathfrak{A}$. The generation properties of $\tilde{\delta}$ are analyzed in the second section of the proof, Sec. VI below.

V. EXTENSIONS OF $(I-\delta)^{-1}$

We may assume that δ is in fact a closed operator in $\mathfrak{A}$. (If not, it would be possible to replace δ by the closure $\tilde{\delta}$, and $\tilde{\delta}$ will have the properties which were listed for δ.)

This means that the linear space $\mathcal{S} = \mathrm{Ran}(I-\delta) = \{x - \delta(x) : x \in \mathcal{D}(\delta)\}$ is closed in $\mathfrak{A}$. In view of the (Hermitian) assumption on δ we note that $\mathcal{S}$ is also self-adjoint, and that $\mathbb{1} \in \mathcal{S}$. The operator $R : \mathcal{S} \to \mathfrak{A}$ defined by $x - \delta(x) \to x$, and denoted by $(I-\delta)^{-1}$, is completely positive (Ref. 2, Prop. 1.2.8). Clearly $R(\mathbb{1}) = \mathbb{1}$.

We now consider the double dual to $\mathfrak{A}$, denoted by $\mathfrak{A}''$, as a W*-algebra M, and make the appropriate identification (via the universal *-representation for $\mathfrak{A}$) such that $\mathfrak{A}$ is regarded as a C*-subalgebra of $\mathfrak{A}''$, and the predual of $\mathfrak{A}''$ is identified with the dual $\mathfrak{A}'$ of $\mathfrak{A}$. (The reader is referred to Ref. 35 Sec. 1.17, p. 42 for details.) Since $M = \mathfrak{A}''$ (with the Arens multiplication) is injective as a W*-algebra, by the assumption, it follows that a completely positive extension mapping $E : M \to M$ exists. If we regard $\mathfrak{A}$ as a subalgebra of M (as we shall), then the extension property is given by the identity

$$R(s) = E(s) \quad \text{for all } s \in \mathcal{S}. \tag{5.1}$$

Note that $\mathcal{S} \subset \mathfrak{A}$, so that $\mathcal{S}$ becomes a subspace of M with the above-mentioned identification.

The completely positive transformations of M into itself will be denoted by $CP(M)$, and the space $L(M)$ of completely bounded linear transformations in M gets an ordering arising from the cone $CP(M)$. Indeed, for $F \in L(M)$ we define $E \leqslant F$ by the requirement that $F - E \in CP(M)$. Among all the particular extensions F of R, $F \in L(M)$, such that $E \leqslant F$, we choose by Zorn a maximal element F_0. [For the basic facts on topologies on $CP(M)$ which are needed, the reader is referred to Ref. 2, Chap. 1.]

This extension F_0, described above, has the special property of being 1–1. We first consider the restriction of F_0 to the positive elements in M, M_+, that is. More precisely, we have the implication

$$x \in M_+, \ F_0(x) = 0 \Rightarrow x = 0. \tag{5.2}$$

Let $\eta : M \to M/\mathcal{S}$ be the canonical linear quotient mapping, and consider the cone $\mathcal{C}$ in the normed quotient space $\mathcal{E} = \mathcal{M}/\mathcal{S}$ given by $\mathcal{C} = \eta(M_+)$.

If the element x in (5.2) belongs to $\mathcal{S}$, then the conditions $R(x) = F_0(x) = 0$ imply $x = 0$, since $R = (I-\delta)^{-1}$. Hence, we shall assume that x is not in $\mathcal{S}$. This means that $\eta(x) \in \mathcal{C}$ defines a one-dimensional subspace $\{k\eta(x) : k \in \mathbb{C}\}$ in $\mathcal{E}$, and the functional $f : k\eta(x) \to k$ is nonzero and positive. By Krein's theorem (Ref. 1, Theorem 1, Chap. 3, p. 157) f extends to a positive functional $\tilde{f}$ on $\mathcal{E}$, and we may define

$$F_1(y) = F_0(y) + \tilde{f}(\eta(y))\mathbb{1} \text{ for } y \in M. \tag{5.3}$$

We claim that F_1 is one of the extensions considered in the Zorn process which was described above. But $F_0 \leqslant F_1$, and $F_0 \neq F_1$, contradicting the maximality of F_0—and so, we must have $x = 0$, concluding the proof of (5.2). [Note that in (5.3), instead of the identity element $\mathbb{1}$ on the right-hand side of the equation, we could have used any nonzero element in M_+. The corresponding F_1-transformation would properly majorize F_0, and have its range contained in M, since the range of F_0 falls in M.]

Since F_0 is completely positive, we have, in particular, $F_0(x^*) = F_0(x)^*$. So, to establish the identity $N(F_0) = \{x \in M : F_0(x) = 0\} = 0$, it is enough to show that the Hermitian part of $N(F_0)$ is zero. Since we have already considered positive elements, it only remains to consider $x = x^* \in N(F_0)$ satisfying $x \notin \mathcal{S}$. Choose a positive real number k such that $x_k = x + k\mathbb{1} \in M_+$. We then have $F_0(x_k) = k$ and $x_k \notin \mathcal{S}$. It is possible, therefore, by Krein's theorem, to choose a positive functional $\tilde{f}$ on $\mathcal{E} = M/\mathcal{S}$ satisfying $\tilde{f}(\eta(x_k)) = l > 0$. Then define $F_2(y) = F_0(y) + \tilde{f}(\eta(y))\mathbb{1}$ for $y \in M$. It is a simple matter to check that F_2 is one of the Zorn extensions. Indeed, $F_0 \leqslant F_2$ since $\tilde{f}$ is chosen positive. Finally $F_2(x_k) = F_0(x_k) + l\mathbb{1} > F_0(x_k)$. This contradiction to the maximality of F_0 concludes the proof. Since $N(F_0) = 0$, the inverse F_0^{-1} is defined on $F_0(M) = \{F_0(x) : x \in M\}$.

We proceed to show that $F_0(M)$ is in fact dense in the $\sigma(M, \mathfrak{A}')$-topology of M: First note that the extension property (5.1) for F_0 translates into

$$F_0(x - \delta(x)) = x \text{ for } x \in \mathcal{D}(\delta), \tag{5.4}$$

and the corresponding transposed mappings in $\mathfrak{A}'$ therefore satisfy

$$(I - \delta')F_0' = I \text{ (the identity operator in } \mathfrak{A}'). \tag{5.5}$$

Hence F_0' is 1–1, and the desired density of $F_0(M)$ follows from the bipolar theorem applied to the $\mathfrak{A}' - M$ duality. Note that in fact every extension of R has dense range, because condition (5.5) is satisfied for the most general such extension.

Since F_0 is an extension of $(I - \delta)^{-1}$ it is clear that $\tilde{\delta} = I - F_0^{-1}$ is therefore an extension of δ.

VI. GENERATION PROPERTIES OF $\tilde{\delta}$

The operator $\tilde{\delta}$ is closed and densely defined in the σ-topology of M. But $(I - \tilde{\delta})^{-1} = F_0$, so we also have $\|x - \tilde{\delta}(x)\| \geqslant \|x\|$ for all $x \in \mathcal{D}(\tilde{\delta})$. We proceed to show that in fact

$$\|kx - \tilde{\delta}(x)\| \geqslant k\|x\| \tag{6.1}$$

for all $k > 0$ and $x \in \mathcal{D}(\tilde{\delta})$. Indeed, let Λ denote the set of $k > 0$ such that the inequality (6.1) is satisfied for all $x \in \mathcal{D}(\tilde{\delta})$. Then we have seen that $k = 1$ belongs to Λ. It turns out that Λ is both open and closed as a subset of $\mathbb{R}_+$, and our result follows by connectedness.

To show openness, suppose first that $k_0 \in \Lambda$, and that $k \in \mathbb{R}_+$ satisfies $|k - k_0| < k_0$. We then use (6.1), for k_0, in estimating the terms in the Neumann expansion for $(kI - \tilde{\delta})^{-1}$, taken around the point k_0. Due to the assumption $|k - k_0| < k_0$, the Neumann series is convergent, and does indeed define a bounded inverse $R(k, \tilde{\delta})$ to $kI - \tilde{\delta}$. Termwise estimation gives $\|R(k, \tilde{\delta})\| \leqslant k^{-1}$, and it follows that (6.1) is satisfied in a neighborhood of k_0.

Consider next a convergent sequence of points $k_n \to k_0$ with $k_n \in \Lambda$ and $k_0 \in \mathbb{R}_+$. By assumption the resolvent operators $R(k_n, \tilde{\delta}) = (k_n I - \tilde{\delta})^{-1}$ exist, and they therefore satisfy the resolvent identity

$$R(k_n,\tilde{\delta}) - R(k_m,\tilde{\delta}) = (k_n - k_m)R(k_n,\tilde{\delta})R(k_m,\tilde{\delta}),$$

as well as the estimate $\|R(k_n,\tilde{\delta})\| \leqslant k_n^{-1}$. It follows that the norm-limit $\tilde{R} = \lim_n R(k_n,\tilde{\delta}) \in L(M)$ exists, and it is trivial to check that $\tilde{R}$ defines a bounded inverse to $k_0 I - \tilde{\delta}$. The estimate (6.1) for k_0 is now implied in the limit by $\|\tilde{R}\| \leqslant k_0^{-1}$. Hence Λ is closed, and the argument is completed.

We have shown that the operator $\tilde{\delta}$ in M is dissipative and closed in the $\sigma(M,\mathfrak{A}')$-topology. It is, of course, also closed in the norm topology, and it can be shown that $\mathcal{D}(\tilde{\delta})$ is norm dense. It follows by semigroup theory[23,29] that $\tilde{\delta}$ is the infinitesimal generator of a strongly continuous semigroup τ_t $(0 \leqslant t < \infty)$ of contraction operators in the Banach space M.

To show that each τ_t is a normal transformation we consider the adjoint semigroup τ_t' (cf. Ref. 16) in the norm-dual M' and show that τ_t' leaves $\mathfrak{A}'$ invariant. Note that $\mathfrak{A}'$ is being identified with the predual of the W^*-algebra M, so that we may regard it as a subspace of M'.

Let $\tilde{\delta}'$ (respectively, F_0') denote the transposed operators to $\tilde{\delta}$ (respectively, F_0) with respect to the $M-M'$ duality. It follows by operator theory that $\tilde{\delta}'$ is the generator of τ_t', and that $(I - \tilde{\delta}')^{-1} = F_0'$. From the construction of F_0 we now deduce that $\mathfrak{A}'$ is invariant under F_0'. Indeed, recall that δ' denotes the transposed transformation to δ with respect to the $\mathfrak{A}-\mathfrak{A}'$ duality. By definition $\mathcal{D}(\delta') = \{a' \in \mathfrak{A}' : \exists\, b' \in \mathfrak{A}', \langle b', x\rangle = \langle a', \delta(x)\rangle \text{ for all } x \in \mathcal{D}(\delta)\}$. But for $a' \in \mathfrak{A}'$ and $x \in \mathcal{D}(\delta)$ we have $\langle F_0'(a'), x - \delta(x)\rangle = \langle a', x\rangle$. Hence, $F_0'(a') \in \mathcal{D}(\delta') \subset \mathfrak{A}'$ by (5.5).

An application of the Neumann expansion to $[I - (t/n)\tilde{\delta}']^{-1}$ shows that $\mathfrak{A}'$ is also invariant under this operator for all $t \geqslant 0$, $n \in \mathbb{Z}_+$. But τ_t' is obtained as a weak*-limit of these operators $(n \to \infty)$, and the desired invariance $\tau_t'(\mathfrak{A}') \subset \mathfrak{A}'$ follows.

A final application of the Neumann series, now to the operators $[I - (t/n)\tilde{\delta}]^{-1}$, shows that τ_t is completely positive in M for all $t \geqslant 0$. Indeed $[I - (t/n)\tilde{\delta}]^{-1}$ may be expanded in a norm-convergent power series in the completely positive operator $F_0 = (I - \tilde{\delta})^{-1}$, and $\tau_t = \lim_{n\to\infty}[I - (t/n)\tilde{\delta}]^{-1}$.

VII. THE INEQUALITY $\delta(x^*x) \geqslant \delta(x)^*x + x^*\delta(x)$

It was shown in Ref. 19 that if δ is a bounded Hermitian linear map in a C^*-algebra $\mathfrak{A}$, then the following two conditions are equivalent:

$$e^{t\delta}(x * x) \geqslant e^{t\delta}(x *)e^{t\delta}(x), \quad \forall\, x \in \mathfrak{A},\ t \in \mathbb{R}_+, \tag{7.1}$$

and

$$\delta(x * x) \geqslant \delta(x *)x + x * \delta(x), \quad \forall\, x \in \mathfrak{A}. \tag{7.2}$$

For unbounded $\mathfrak{A}$ the situation is not as well understood. It is therefore of interest to study the connection between the property (7.2) for δ, and the other conditions which are customarily used in the applications of unbounded dissipative mappings in operator algebras to quantum dynamics.

Theorem VII.1: *Let $\mathfrak{A}$ be a C^*-algebra with unit $\mathbb{1}$, and let δ be a completely dissipative transformation in $\mathfrak{A}$ with dense domain $\mathcal{D}(\delta)$. Assume $\mathbb{1} \in \mathcal{D}(\delta)$, and $\delta(\mathbb{1}) = 0$.*

(a) *Let $x \in \mathcal{D}(\delta)$ and assume that $x^*x \in \mathcal{D}(\delta)$. Then*

$$\delta(x * x) \geqslant \delta(x) * x + x * \delta(x). \tag{7.3}$$

(b) *Suppose both x and x^* belong to $\mathcal{D}(\delta)$. Then $\delta(x^*) = \delta(x)^*$.*

The following results are corollaries to the proofs of Theorems IV.2 and VII.1.

Corollary VII.2: Let $\mathfrak{A}$ be a C^*-algebra with unit $\mathbb{1}$, and let δ be completely dissipative in $\mathfrak{A}$ with dense domain $\mathcal{D}(\delta)$, $\mathbb{1} \in \mathcal{D}(\delta)$, $\delta(\mathbb{1}) = 0$.

(a) *If $\mathfrak{A} \subset B(\mathcal{H})$ for some Hilbert space $\mathcal{H}$, then there is a sequence of completely positive maps $E_n : \mathfrak{A} \to B(\mathcal{H})$, $E_n(\mathbb{1}) = \mathbb{1}$, such that the following norm convergence holds:*

(i)

$$E_n(x) \to x \quad \text{for } x \in \mathfrak{A},$$

and

(ii)

$$n(E_n(x) - x) \to \delta(x) \quad \text{for } x \in \mathcal{D}(\delta).$$

(b) *If $\mathcal{D}(\delta)$ is Hermitian, then δ is Hermitian as well, i.e., $\delta(x^*) = \delta(x)^*$ for all $x \in \mathcal{D}(\delta)$, and it is then possible, for each n, to choose E_n* to be 1–1 *with dense range.*

(c) *Let δ and $\mathfrak{A}$ be as in* (a), *and let $\pi: \mathfrak{A} \to B(\mathcal{K})$ be a representation of $\mathfrak{A}$ in a Hilbert space $\mathcal{K}$. Then there exists a sequence $E_n \in CP(\mathfrak{A}, B(\mathcal{K}))$ such that the following norm convergence holds:*

(i′)

$$E_n(x) \to \pi(x) \quad \text{for } x \in \mathfrak{A},$$

and

(ii′)

$$n(E_n(x) - \pi(x)) \to \pi(\delta(x)) \quad \text{for } x \in \mathcal{D}(\delta).$$

Proofs: We consider again the range subspace $\mathcal{S} = \text{Ran}(I - \delta) = \{x - \delta(x) : x \in \mathcal{D}(\delta)\}$. As in the proof of Theorem IV.2 note that $R = (1 - \delta)^{-1} : \mathcal{S} \to \mathfrak{A}$ is completely contractive, and $R(\mathbb{1}) = \mathbb{1}$. If $\mathfrak{A}$ is considered as a subalgebra of $B(\mathcal{H})$, where $\mathcal{H}$ is the Hilbert space of the universal representation, then there is, by Arveson's extension theorem (Ref. 2, Theorem 1.2.9) a completely positive mapping $E: \mathfrak{A} \to B(\mathcal{H})$ such that

$$R(s) = E(s) \quad \text{for all } s \in \mathcal{S}. \tag{7.4}$$

If for each $n = 1, 2, \ldots$ the operator δ is replaced by $n^{-1}\delta$, then the above argument yields a completely positive map $E_n: \mathfrak{A} \to B(\mathcal{H})$ such that E_n is an extension of the partially defined operator $(I - n^{-1}\delta)^{-1}$.

We claim that the sequence (E_n) satisfies conditions (i) and (ii) which are listed in Corollary VII.2(a). Indeed, for x in dense $\mathcal{D}(\delta)$ we have $E_n(x - n^{-1}\delta(x)) = x$, and therefore

$$E_n(x) = n^{-1}E_n(\delta(x)) + x \tag{7.5}$$

and

$$E_n(\delta(x)) = n(E_n(x) - x). \tag{7.6}$$

Passing to the limit in (7.5), we get (i) for the special case $x \in \mathcal{D}(\delta)$, but then also for all x in $\mathfrak{A}$ by a 3-ε argument since each E_n is contractive. The result (ii) of Corollary VII.2(a) is now an immediate consequence of (7.6).

Returning to the proof of Theorem VII.1, we note that (b) is trivial from (ii). Indeed, for x and x^* in $\mathcal{D}(\delta)$ we have

$$\delta(x^*) = \lim n(E_n(x^*) - x^*) = \lim_n (n(E_n(x) - x))^* = \delta(x)^*.$$

The proof of Theorem VII.1(a) is based on both (i) and (ii), together with the Kadison–Schwarz inequality for E_n: Suppose $x \in \mathcal{D}(\delta)$ and $x^*x \in \mathcal{D}(\delta)$. Then $\delta(x^*x) = \lim n(E_n(x^*x) - x^*x)$. For each term on the right-hand side we have

$$n(E_n(x*x)-x*x) \geqslant n(E_n(x)*E_n(x)-x*x)$$
$$= \tfrac{1}{2}((n(E_n(x)-x))*(E_n(x)+x)+(E_n(x)+x)*n(E_n(x)-x))$$
$$\to \tfrac{1}{2}(\delta(x)*(2x)+(2x)*\delta(x)) = \delta(x)*x+x*\delta(x), \tag{7.7}$$

where the last convergence $\to$ is based on (i) and (ii) from Corollary VII.2(a). Since $\delta(x*x)$ is obtained in the limit on the left, the desired inequality (7.3) in (a) of Theorem VII.1 follows.

Only part (b) of the corollary remains. The technique from the proof of Theorem IV.2 is applied here. We go back to the extension E from (7.4) in the beginning of the present proof. Consider the ordering on all the extensions F of R, $F \in L(\mathfrak{A}, B(\mathcal{H}))$, which is induced by the cone $CP(\mathfrak{A}, B(\mathcal{H}))$, and choose by Zorn a particular extension F, $E \leqslant F$, which is maximal. The argument from the proof of Theorem IV.2 then shows that F is 1–1, and the range $\mathrm{Ran}(F)$ is dense. It follows that the operator $\tilde{\delta} = I - F^{-1}: \mathrm{Ran}(F) \to \mathfrak{A}$ exists and satisfies $\tilde{\delta}(x) = \delta(x)$ for all $x \in \mathcal{D}(\delta)$.

If α is a positive real number, then the same construction may be carried out for the transformation $\alpha\delta$, instead of δ. Hence we get completely positive unital maps F_α such that the inverse F_α^{-1} exists for each α, and the domain of $I - F_\alpha^{-1}$ contains $\mathcal{D}(\delta)$. Moreover $\tilde{\delta}_\alpha = I - F_\alpha^{-1}$ satisfies $\tilde{\delta}_\alpha(x) = \delta(x)$ for $x \in \mathcal{D}(\delta)$. To get a sequence of mappings satisfying the conditions in Corollary VII.2(b), we need only take $E_n = F_{n^{-1}}$ in the special case $\alpha = n^{-1}$.

The proof of part (c) in the corollary is parallel to (a) with the following modification: Arveson's extension theorem is now applied to the mapping $\pi \circ (I - \delta)^{-1}: \mathcal{S} \to B(\mathcal{K})$. □

VIII. THE IMPLEMENTATION PROBLEM

The conclusion (ii′) in Corollary VII.2(c) is of interest when one wants to implement the transformation δ by a dissipative operator in Hilbert space. In particular, one is interested in implementing a completely dissipative δ-operator by a dissipative Hilbert-space operator. We shall establish a clear two-way connection between the dissipative notion for δ, and for the implementing Hilbert-space operator.

Theorem VIII.1: *Let $\mathfrak{A}$ be a C*-algebra with unit $\mathbb{1}$, and let δ be a completely dissipative transformation in $\mathfrak{A}$ with dense domain $\mathcal{D}(\delta)$. Assume $\mathbb{1} \in \mathcal{D}(\delta)$ and $\delta(\mathbb{1}) = 0$. Let ω be a state of $\mathfrak{A}$, and let $(\pi_\omega, \mathcal{K}_\omega, \Omega)$ be the corresponding GNS representation of $\mathfrak{A}$. Let $\tilde{\omega}$ be the vector state on $B(\mathcal{K}_\omega)$ given by the cyclic vector Ω, i.e., $\tilde{\omega}(X) = \langle X\Omega | \Omega \rangle$ for $X \in B(\mathcal{K}_\omega)$, and assume that it is possible to choose the sequence $(E_n) \subset CP(\mathfrak{A}, B(\mathcal{K}_\omega))$ from Corollary VII.2(c) in such a manner that*

$$\tilde{\omega}(E_n(x)) = \omega(x) \quad \textit{for all } x \in \mathfrak{A}. \tag{8.1}$$

Then there is a dissipative operator L_ω in $\mathcal{K}_\omega$ such that

$$\pi_\omega(\delta(x))\Omega = L_\omega(\pi_\omega(x)\Omega) \quad \textit{for all } x \in \mathcal{D}(\delta). \tag{8.2}$$

Proof: Let $\pi = \pi_\omega$, $\mathcal{K} = \mathcal{K}_\omega$, and let $(E_n) \subset CP(\mathfrak{A}, B(\mathcal{K}))$ be a sequence which, along with the conditions listed in Corollary VII.2(c), also fulfills the invariance restriction (8.1) of the present theorem. For each n define an operator C_n in $\mathcal{K}$ as follows:

$$C_n(\pi(x)\Omega) = E_n(x)\Omega, \quad x \in \mathfrak{A}.$$

Then

$$\|C_n\pi(x)\Omega\|^2 = \|E_n(x)\Omega\|^2$$
$$= \tilde{\omega}(E_n(x)*E_n(x)) \leqslant \tilde{\omega}(E_n(x*x)) = \omega(x*x) = \langle \pi(x*x)\Omega | \Omega \rangle = \|\pi(x)\Omega\|^2,$$

where the norm is that of $\mathcal{K}$, and where the Schwarz inequality is applied to E_n. It follows that C_n is well defined, and that it extends by limits (in $\mathcal{K}$) to a contraction operator, $C_n \in B(\mathcal{K})$, $\|C_n\| \leqslant 1$.

By Corollary VII.2(c) (ii′), we then have

$$\pi(\delta(x))\Omega = \lim n(E_n(x)\Omega - \pi(x)\Omega)$$
$$= \lim n(C_n(\pi(x)\Omega) - \pi(x)\Omega) = \lim n(C_n - I)\pi(x)\Omega \quad \text{for } x \in \mathcal{D}(\delta).$$

As a consequence, the following quadratic form on $\mathcal{K}$:

$$\pi(x)\Omega, \pi(y)\Omega \to \lim\langle n(C_n - I)\pi(x)\Omega | \pi(y)\Omega\rangle_{\mathcal{K}}$$

is well defined. Using the contractive property of C_n, it is easy to show that this quadratic form is given by a dissipative operator L; that is to say

$$\lim\langle n(C_n - I)\pi(x)\Omega | \pi(y)\Omega\rangle = \langle L\pi(x)\Omega | \pi(y)\Omega\rangle.$$

Since the limit on the left-hand side is also equal to the inner product

$$\langle \pi(\delta(x))\Omega | \pi(y)\Omega\rangle,$$

the identity (8.2) of the theorem follows. □

IX. A CONDITION FOR COMPLETE DISSIPATIVENESS

In applications[18,24,33] it is often possible to determine the derivation δ in a particular representation. If moreover the derivation is known to be implemented by a dissipative operator in the corresponding Hilbert space, then it follows in special cases that δ itself is completely dissipative.

Theorem IX.1: *Let $\mathfrak{A}$ be a C*-algebra with unit $\mathbb{1}$ and let δ be a densely defined transformation in $\mathfrak{A}$ such that $\mathbb{1} \in \mathcal{D}(\delta)$ and $\delta(\mathbb{1}) = 0$. Let ω be a state on $\mathfrak{A}$ such that δ is implemented by a dissipative Hilbert-space operator L in the representation π_ω. Assume moreover that π_ω is faithful, and that $L\Omega = 0$ where Ω denotes the cyclic vector in the GNS representation. Then δ is completely dissipative on its domain.*

Proof: Let $\mathcal{H} = \mathcal{H}_\omega$ be the Hilbert space of the faithful representation π_ω and let L be the operator in $\mathcal{H}$ which is assumed to exist, satisfying conditions (i) and (ii) below:

(i) The domain of L is $\pi_\omega(\mathcal{D}(\delta))\Omega$, and L is a dissipative operator in the Hilbert space $\mathcal{H}$;
(ii) L implements δ in the representation π_ω, which is equivalent to the requirement that L^* is defined on $\pi_\omega(\mathcal{D}(\delta))\Omega$, and that on this domain the following operator identiy is valid:

$$\pi(\delta(a)) = L\pi(a) + \pi(a)L^* \quad \text{for all } a \in \mathcal{D}(\delta). \tag{9.1}$$

We show first that δ must necessarily be a dissipative operator. Indeed, by Phillips's theorem (Ref. 30, Theorem 1.1.3) an extension $\tilde{L}$ of L exists which is the infinitesimal generator of a strongly continuous semigroup $S(t)$ of contraction operators in the Hilbert space $\mathcal{H}$. We note that $S(t)$ implements a semigroup $\sigma(t)$ of positive mappings in $B(\mathcal{H})$, given by

$$\sigma(t)(A) = S(t)AS(t)^* \tag{9.2}$$

for all $t \in [0, \infty)$ and $A \in B(\mathcal{H})$. By semigroup theory we note that the generator (ζ say) of $\sigma(t)$ is dissipative, so the following estimate holds:

$$\|A - \alpha\zeta(A)\| \geqslant \|A\| \tag{9.3}$$

for all $\alpha \in [0, \infty)$ and $A \in \mathcal{D}(\zeta)$.

If δ_ω denotes the operator $\pi_\omega(a) \to \pi_\omega(\delta(a))$ with domain $\pi_\omega(\mathcal{D}(\delta))$, then we claim (easy proof) that

$$\delta_\omega(A) = \zeta(A) \quad \text{for all } A \in \mathcal{D}(\delta_\omega), \tag{9.4}$$

and the known estimate (9.3) above then implies

$$\|\pi_\omega(a) - \alpha\pi_\omega(\delta(a))\| \geqslant \|\pi_\omega(a)\| \tag{9.5}$$

for $a \in \mathcal{D}(\delta)$ and $\alpha \in [0,\infty)$. But π_ω is faithful (and hence isometric), so (9.5) is in fact equivalent to the dissipation estimate

$$\|a - \alpha\delta(a)\| \geqslant \|a\|$$

for the operator δ itself.

For each $n=1,2,\ldots$, we now consider the tensor-product construction of the C^*-algebra $\mathfrak{A}$ with the n-by-n complex matrices M_n; and we define $\mathfrak{A}_n=\mathfrak{A}\otimes M_n$, $\delta_n=\delta\otimes \mathrm{id}_n$, the operator obtained by application of δ to each entry a_{ij} in the matrix representation of elements in $\mathfrak{A}_n$, $\omega_n=\omega\otimes \mathrm{tr}_n$ where tr_n denotes the normalized trace on M_n, π_{ω_n}: the GNS representation of $\mathfrak{A}_n$ associated to ω_n.

The problem is to show that each of the operators δ_n is dissipative. We show that in fact δ_n is implemented by a dissipative Hilbert-space operator in the representation π_{ω_n}. Hence, the first part of the proof applies and yields the conclusion of the claim since each representation π_{ω_n} is faithful, being the tensor product of faithful representations.

Let $\mathcal{H}_n$ denote the representation Hilbert space of π_{ω_n}. We proceed to find a dissipative operator L_n in $\mathcal{H}_n$ such that δ_n is implemented by L_n. In view of (9.1) this means that

$$\pi_{\omega_n}(\delta_n(a)) = L_n\pi_{\omega_n}(a) + \pi_{\omega_n}(a)L_n^*$$

for all $a \in \mathcal{D}(\delta_n)=\mathcal{D}(\delta_n)\otimes M_n$ (algebraic tensor product) $\subset\mathfrak{A}_n$ as an operator identity on $\pi_{\omega_n}(\mathcal{D}(\delta_n))\Omega_n \subset \mathcal{H}_n$. Here Ω_n denotes the cyclic vector for the representation π_{ω_n}, i.e.,

$$\omega_n(a) = \langle \pi_{\omega_n}(a)\Omega_n|\Omega_n\rangle \text{ for all } a \in \mathfrak{A}_n. \tag{9.6}$$

Our next step is the verification of the following:

$$\mathrm{Re}\ \omega_n(a^*\delta_n(a)) \leqslant 0 \text{ for all } a \in \mathcal{D}(\delta_n), \tag{9.7}$$

$$L_n\Omega_n = 0, \tag{9.8}$$

$$\omega_n(a^*\delta_n(a)) = \langle L_n\pi_{\omega_n}(a)\Omega_n|\pi_{\omega_n}(a)\Omega_n\rangle \text{ for } a \in \mathcal{D}(\delta_n). \tag{9.9}$$

It will follow from (9.7) and (9.9) that an implementing operator L_n satisfying (9.8) must necessarily be dissipative.

Note that (9.8) is verified for $n=1$ by assumption. Hence $\omega(a^*\delta(a))=\langle\pi(\delta(a))\Omega|\pi(a)\Omega\rangle = \langle L\pi(a)\Omega+\pi(a)L^*\Omega|\pi(a\Omega)\rangle$. Substitution of $L^*\Omega=-L\Omega=0$ into this identity yields identity (9.9) for the case $n=1$.

Let T_n denote the trace vector for the trace representative τ_n of M_n. Then $\pi_{\omega_n}=\pi\otimes\tau_n$, and therefore

$$\begin{aligned}\langle \pi_{\omega_n}(a\otimes b)\Omega\otimes T_n|\Omega\otimes T_n\rangle &= \langle \pi(a)\Omega\otimes\tau_n(b)T_n|\Omega\otimes T_n\rangle \\ &= \langle\pi(a)\Omega|\Omega\rangle\langle\tau_n(b)T_n|T_n\rangle = \omega(a)\mathrm{tr}_n(b) = \omega\otimes\mathrm{tr}_n(a\otimes b) = \omega_n(a\otimes b)\end{aligned}$$

for all $a\in\mathfrak{A}$ and $b\in M_n$. Hence $\Omega_n=\Omega\otimes T_n$. If we can show that a simple tensor operator L_n implements δ_n in π_{ω_n}, then identity (9.9), for arbitrary n, follows from the case $n=1$ which was established above.

However, it is easy to see that the operator $L_n=L\otimes I_n$ satisfies the requirements which were listed above. Indeed

$$\begin{aligned}\pi_{\omega_n}(\delta_n(a\otimes b)) &= \pi_\omega(\delta(a))\otimes\tau_n(b)\\ &= (L\pi_\omega(a)+\pi_\omega(a)L^*)\otimes\tau_n(b)\\ &= L_n\pi_\omega(a)\otimes\tau_n(b)+\pi_\omega(a)\otimes\tau_n(b)L_n^* = L_n\pi_{\omega_n}(a\otimes b)+\pi_{\omega_n}(a\otimes b)L_n^*\end{aligned}$$

for all $a\in\mathfrak{A}$ and $b\in M_n$. It follows that L_n implements δ_n in π_{ω_n}.

Only the verification of (9.7) for $n>1$ then remains. Let $a_{ij}\in\mathfrak{A}$ be the matrix entries in some $a\in\mathfrak{A}_n=\mathfrak{A}\otimes M_n$. Then the (i,j)th entry c_{ij} in $a^*\delta_n(a)$ is $\Sigma_{k=1}^n a_{ki}^*\delta(a_{kj})$. Hence

$$\omega_n(a^*\delta_n(a)) = (\omega\otimes\mathrm{tr}_n)(c_{ij}) = \sum_{i=1}^n \omega(c_{ii}) = \sum_i\sum_k \omega(a_{ki}^*\delta(a_{ki})).$$

Since $\mathrm{Re}\,\omega(a_{ki}^*\delta(a_{ki}))\leqslant 0$, (9.7) follows. □

Remark IX.2: In the foundations of irreversible statistical thermodynamics,[14,20,21,24,28] the most conclusive results have been obtained for dynamical semigroups which are described mathematically as strongly continuous, completely positive, contraction semigroups T_t on the Banach space $\mathcal{T}(\mathcal{H})$ of all trace-class operators on a given separable ∞-dimensional Hilbert space $\mathcal{H}$. Lindblad[28] found a formula for the infinitesimal generator

$$W = \left.\frac{\mathrm{d}}{\mathrm{d}t}T_t\right|_{t=0}$$

in the case of norm-continuous semigroups, and Davies[15] extended the results to strongly continuous T_t (i.e., unbounded generator W), satisfying certain side conditions. The condition of relevance to our paper is the invariance assumption of Ref. 15 that

$$T_t'(\mathcal{C}(\mathcal{H}))\subset\mathcal{C}(\mathcal{H})$$

for all $t\in[0,\infty)$, where $\mathcal{C}(\mathcal{H})$ denotes the compact operators, and T_t' the conjugate semigroup on $B(\mathcal{H})$. Our Theorem IV.2 does not apply to the algebra $\mathfrak{A}=B(\mathcal{H})$ since $B(\mathcal{H})''$ is known not to be injective.[11] [Of course, $B(\mathcal{H})$ is injective by Arveson's theorem.]

However, Theorem IV.2 combined with the above results suggests that a W^*-algebra, properly smaller than $B(\mathcal{H})$, is suitable for quantum dynamics. On the one hand, $B(\mathcal{H})$ [or $\mathcal{T}(\mathcal{H})$ in the conjugate (dual) formulation] is too big to accommodate the extensions; and, on the other hand, the requirement that $\mathcal{C}(\mathcal{H})$ contain the domain of the generator also appears to be too restrictive.

X. UNBOUNDED *-DERIVATIONS

Let $\mathfrak{A}$ be a unital C^*-algebra, and let $\mathcal{D}(\delta)$ be a dense $*$-subalgebra containing the identity $\mathbb{1}$. A linear transformation $\delta:\mathcal{D}(\delta)\to\mathfrak{A}$ is said to be a (unbounded) *-derivation if $\delta(ab)=\delta(a)b+a\delta(b)$ for $a,b\in\mathcal{D}(\delta)$, and $\delta(a^*)=\delta(a)^*$ for $a\in\mathcal{D}(\delta)$.

Since, for $*$-derivations, one is primarily interested in extensions which are also $*$-derivations, it is natural to work with a two-sided condition in place of the dissipative notions which were studied in the preceding sections for more general operators. The following such two-sided condition was suggested by Sakai,[36] and adopted by several authors in subsequent research on unbounded $*$-derivations.

Definition X.1: A $*$-derivation $\delta:\mathcal{D}(\delta)\to\mathfrak{A}$ is said to be well behaved if for all positive $a\in\mathcal{D}(\delta)$ there is a state ϕ on $\mathfrak{A}$ such that $\phi(a)=\|a\|$ and $\phi(\delta(a))=0$.

The argument in the preceding section yields the following.

Proposition X.2: Let $\delta:\mathcal{D}(\delta)\to\mathfrak{A}$ be a $*$-derivation. Then the following four conditions are equivalent:

(i) *δ is well behaved.*

(ii) *For all positive $a\in\mathcal{D}(\delta)$, and for all states ϕ on $\mathfrak{A}$ satisfying $\phi(a)=\|a\|$, we have $\phi(\delta(a))=0$.*

(iii) *Each of the operators* $\pm\delta$ *is dissipative.*
(iv) $\|a+\alpha\delta(a)\| \geqslant \|a\|$ *for all* $\alpha \in \mathbb{R}$ *and all* $a \in \mathcal{D}(\delta)$.

Definition X.3: A $*$-derivation $\delta: \mathcal{D}(\delta) \to \mathfrak{A}$ is said to be well behaved in the *matricial sense* if, for each $n=1,2,\ldots$, the $*$-derivation $\delta_n = \delta \otimes \mathrm{id}_n : \mathcal{D}(\delta) \otimes M_n \to \mathfrak{A} \otimes M_n$ is well behaved. Recall that δ_n may be regarded as a transformation on n-by-n matrices with entries in $\mathfrak{A}$. For such a matrix $a=(a_{ij})$, $i, j=1,\ldots,n$, we have $\delta_n(a)=(\delta(a_{ij}))$.

Theorem X.4: *Every well-behaved *-derivation is also well behaved in the matricial sense (i.e., completely well behaved).*

Lemma X.5: Let $\delta: \mathcal{D}(\delta) \to \mathfrak{A}$ *be a well-behaved *-derivation, and let* $a \in \mathcal{D}(\delta)$ *be positive. Then there is a state* ϕ *on* $\mathfrak{A}$ *such that* $\phi(a)=\|a\|$, *and* $\phi(\delta(b))=0$ *for a dense set of elements* $b \in C^*(a) \cap \mathcal{D}(\delta)$. [*Here* $C^*(a)$ *denotes the Abelian C*-subalgebra generated by a; and every element in* $C^*(a)$ *can be approximated in norm by a sequence of elements b satisfying the conclusion of the lemma.*]

Proofs: The implication (i)$\Rightarrow$(ii) in Proposition X.2 is the key to the proof of Lemma X.5. Since functional calculus is also applied, we shall assume in fact that δ is closed. By a result of Kishimoto–Sakai[36] this is no loss of generality. Let a be a positive element in $\mathcal{D}(\delta)$. Note that the Gelfand transform sets up an isomorphism between the C^*-algebras $C^*(a)$ and $C(\mathrm{sp}(a))$, continuous functions on the spectrum of a. Let $\lambda_0 = \mathrm{l.u.b.sp}(a)$. Then the state $c \to c(\lambda_0)$ on $C(\mathrm{sp}(a))$ corresponds to a state on $C^*(a)$ via the Gelfand transform. The latter state is then extended to $\mathfrak{A}$ by Krein's theorem, and the extended state is denoted by ϕ. It has the multiplicative property: $\phi(b_1 b_2)=\phi(b_1)\phi(b_2)$ for $b_1, b_2 \in C^*(a)$.

Now let g be a nondecreasing (monotone) continuous real function defined on $\mathrm{sp}(a)$. Then the Gelfand transform of $g(a)$ achieves its maximum at the point λ_0 since the transform of a does. But it is known that if g is also of class C^2 (two continuous derivatives) then $g(a) \in \mathcal{D}(\delta) \cap C^*(a)$. Hence $\phi(g(a))=\|g(a)\|$. An application of Proposition X.2, (i)$\Rightarrow$(ii), then yields the conclusion

$$\phi(\delta(g(a))) = 0.$$

The restriction of an arbitrary monomial λ^n to $\mathrm{sp}(a)$ satisfies the conditions listed for g. Hence, by Stone–Weierstrass there is a dense set of elements $b \in C^*(a) \cap \mathcal{D}(\delta)$ satisfying the conclusion of the lemma. [Alternatively, every positive function f in C^4 may be written in the form $f=g_1-g_2$, with g_1 and g_2 both having the properties listed above for g, we conclude that $\phi(\delta(f(a))) = \phi(\delta(g_1(a))) - \phi(\delta(g_2(a))) = 0$.]

Now, for each fixed element $a \in \mathcal{D}(\delta)_+$ we choose a state $\phi=\phi_a$ and a dense $*$-subalgebra $\mathfrak{B}=\mathfrak{B}_a$ of $C^*(a)$ according to Lemma X.5; i.e., we require that $\phi_a(\delta(b))=0$ for $b \in \mathfrak{B}_a$, as well as $\phi_a(a)=\|a\|$. Consider the GNS representation of the algebra $\mathfrak{B}$, respectively, $\mathfrak{A}$, with representation space $\mathcal{H}_\phi$, respectively, $\mathcal{K}_\phi$, and define

$$\mathcal{H} = \sum\nolimits^{\otimes} \mathcal{H}_\phi, \text{ respectively, } \mathcal{K} = \sum\nolimits^{\otimes} \mathcal{K}_\phi. \tag{10.1}$$

Then $\mathcal{H}$ is a closed subspace of the Hilbert space $\mathcal{K}$, and we can then define an operator S with dense domain from $\mathcal{H}$ to $\mathcal{K}$ as follows:

$$S\pi_\phi(b)\Omega_\phi = \pi_\phi(\delta(b))\Omega_\phi \text{ for } b \in \mathfrak{B}_\phi. \tag{10.2}$$

For vectors ξ_1 and ξ_2 in the domain of S we have

$$\langle S\xi_1 | \xi_2 \rangle + \langle \xi_1 | S\xi_2 \rangle = 0. \tag{10.3}$$

The verification of (10.3) may be based on the direct-sum decomposition (10.1) above. If $\xi_i = \Sigma_\phi^{\otimes} \pi(b_i)\Omega_\phi$ for $i=1, 2$ and $b_i \in \mathfrak{B}_\phi$, then identity (10.3) reduces to

$$\sum \langle \pi_\phi(\delta(b_1))\Omega_\phi | \pi_\phi(b_2)\Omega_\phi \rangle + \sum \langle \pi_\phi(b_1)\Omega_\phi | \pi_\phi(\delta(b_2))\Omega_\phi \rangle = 0.$$

The individual terms work out to be

$$\phi(b_2^*\delta(b_1)) + \phi(\delta(b_2)^* b_1) = \phi(\delta(b_2^* b_1)) = 0.$$

Hence, the symmetry condition (10.3) is hereby reduced to the conclusion of Lemma X.5 for a given well-behaved derivation δ.

If P denotes the orthogonal projection in $\mathcal{K}$ with range $\mathcal{H}$, identity (10.3) implies that the operator $\xi \to PS\xi$ may in fact be regarded as a skew symmetric operator in the Hilbert space $\mathcal{H}$, with dense domain there. We shall also denote this operator by S. The verification of the identity

$$\pi(\delta(b)) = S\pi(b) - \pi(b)S$$

is left to the reader.

Following the idea of Sec. IX, we now consider the *-derivations $\delta_n = \delta \otimes \mathrm{id}_n$ (for each $n = 1, 2, \ldots$) introduced in Definition X.3. For a given *-algebra $\mathfrak{C}$ we denote by $\mathfrak{C}_n$ the *-algebra $\mathfrak{C} \otimes M_n$. Correspondingly, *-algebras $\mathcal{D}(\delta)_n$, $\mathfrak{A}_n$, and $\mathfrak{B}_n$ are defined for each n. Application of the GNS representation to each $\phi_n = \phi \otimes \mathrm{tr}_n$ yields sequences of Hilbert spaces

$$\mathcal{H}^{(n)} \subset \mathcal{K}^{(n)}$$

as in (10.1) with each $\mathcal{H}^{(n)}$, respectively, $\mathcal{K}^{(n)}$, a direct sum of GNS representation spaces associated to ϕ_n.

The calculations in Sec. IX show that the operator $S_n = S \otimes I_n$ satisfies the nth-order version of (10.2), that is, (10.2) holds with the quadruple S, π, $\mathfrak{B}$, δ replaced by S_n, π_n, $\mathfrak{B}_n$, δ_n. Similarly $\langle S_n \xi_1^{(n)} | \xi_2^{(n)} \rangle + \langle \xi_1^{(n)} | S_n \xi_2^{(n)} \rangle = 0$ for vectors $\xi_i^{(n)}$, $i = 1, 2$, in the respective domains.

Hence Theorem IX.1 in Sec. IX implies that each of the operators $\pm\delta_n$ for $n = 1, 2, \ldots$ is dissipative. By Proposition X.2, (iii) $\Rightarrow$ (i), it follows that δ_n is well behaved, concluding the proof of Theorem X.4. □

As an application of the theorem we get the following existence result for generator extensions of well-behaved $*$-derivations $\delta: \mathcal{D}(\delta) \to \mathfrak{A}$ in *nuclear* C^*-algebras $\mathfrak{A}$. Indeed, if δ is such a $*$-derivation, each of the operators $\pm\delta$ is completely dissipative. Hence, by Theorem IV.2, there are extensions $\widetilde{\delta}_\pm \supset \pm\delta$ to infinitesimal generators of dynamical semigroups $a_t^{(\pm)}$ in the enveloping W^*-algebra $\mathfrak{A}''$.

ACKNOWLEDGMENTS

(Received 19 March 2004; accepted 4 June 2004; published 16 August 2004)

We consider the convex sets of QO's (quantum operations) and POVM's (positive operator valued measures) which are covariant under a general finite-dimensional unitary representation of a group. We derive necessary and sufficient conditions for extremality, and give general bounds for ranks of the extremal POVM's and QO's. Results are illustrated on the basis of simple examples. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1777813]

I. INTRODUCTION

The need for miniaturization and the new quantum information technology[1] has recently motivated a search for new quantum devices with maximum control at the quantum level. Among the many problems posed by the new technology there is the need of engineering quantum devices which perform specific measurements[2–5] or particular state transformations—the so-called *quantum operations*[6–8]—which are optimized with respect to some given criterion. In most cases such optimal quantum measurements/operations are *covariant*[9] with respect to a group of physical transformations. For the case of a quantum measurement, "group-covariant" means that there is an action of the group on the probability space which maps events into events, in such a way that when the quantum system is transformed according to a group transformation, the probability of the given event becomes the probability of the transformed event. This situation is very natural, and occurs in most practical applications. (See Refs. 10 and 11.) For example, the heterodyne measurement[12,13] is covariant under the group of displacements of the complex field, which means that if we displace the state of radiation by an additional complex averaged field, then the output photocurrent will be displaced by the same complex quantity.

In quantum mechanics the probabilities for a given apparatus for all possible states are described by positive operator valued measures (POVM),[3] and we will say that the measurement is covariant when its POVM is covariant under a unitary group representation.[2,10] For quantum operations (QO), on the other hand, covariance means that the output of a group-transformed input state is simply the transformed output state—a situation again quite common in practice. Typically covariance means that the apparatus is required to work equally well on a full set of states which is invariant under a group of transformations. For instance, if one wants to engineer an eavesdropping apparatus for a BB84 cryptographic scheme[14,15] that clones equally well all equatorial qubits, then the optimal cloning operation must be covariant under the group $\mathbf{G}=\mathbb{Z}_4$ of $\pi/2$ rotations of the Bloch sphere around its polar axis, which is a subgroup of the group of all axial rotations $\mathbf{G}=\mathbb{U}(1)$.[16] Similarly, if one wants to engineer a QO which works equally well on all pure states, then the operation must be covariant under the full $\mathbb{SU}(d)$ group, where d is the dimension of the Hilbert space of the quantum system.

It is easy to see that all POVM's covariant under some group representation make a convex set, which describes the complete class of possible covariant apparatuses. The same obviously

a)Electronic mail: dariano@unipv.it; http://www.qubit.it

holds for group-covariant QO's. Typically in most applications the optimization resorts to minimize a concave function on the convex set of covariant machines (in quantum estimation theory[3] actually such function is generally linear), whence the optimal machine will correspond to an extremal element of the convex set. For such purpose it is convenient to classify all extremal covariant POVM's and QO's, and this is precisely the subject of the present paper.

For finite dimensional Hilbert space, a characterization of all noncovariant extremal QO's was given in Ref. 17, whereas a characterization of all extremal POVM's can be found in Refs. 18 and 19 for discrete finite probability space. On the other hand, no classification of the extremal QO's or POVM's is available yet under a covariance constraint, since, as we will see, this constraint makes the classification problem much harder. Coincidentally, in many applications the optimal QO/POVM is restricted to be rank-one from the special form of the optimization function (this is the case, for example, of optimal phase estimation for pure states,[2,3,20] or of phase covariant optimal cloning of pure states[16]), and this has lead to a widespread belief that optimality is synonym of rank-one. However, as we will see in this paper, for sufficiently large dimension the extremal QO's/POVM's can easily have rank larger than one: this can actually happen for optimization with mixed input states, such as in the case of optimal phase estimation with phase-coherent mixed states.[21]

In this paper we provide a classification for finite dimensions of all extremal POVM's and QO's that are covariant under a general unitary group representation. We will generally consider continuous Lie groups, since then all results will also apply to the case of discrete groups as well, with just a little change of notation. We provide necessary and sufficient conditions for extremality, along with simple necessary conditions, which allow to "sieve" the extremal QO's/POVM's. From these conditions general bounds for the rank of the extremal QO's/POVM's easily follow as corollaries.

The paper is organized as follows. In Sec. II we briefly review the concept of POVM and that of covariant POVM based on the Holevo's theorem.[2] In Sec. III we recall the necessary concepts about QO's, including their operator form introduced in Ref. 22, which allows to easily classify the covariant QO's as non-negative operators in the commutant of a suitable representation of the group. Section IV is entirely devoted to some technical lemmas which will be used in the classification of both POVM's and QO's. Finally Secs. V and VI contains the classification theorem of extremal group covariant POVM's and QO's, respectively, with some simple explicit examples, in particular with application to phase-covariant estimation and phase-covariant optimal cloning.

II. POSITIVE OPERATOR VALUED MEASURES

In the following we will denote by $\boldsymbol{B}(\mathcal{K},\mathcal{H})$ the linear space of bounded operators from the Hilbert space $\mathcal{K}$ to the Hilbert space $\mathcal{H}$, and by $\boldsymbol{B}(\mathcal{H}) \doteq \boldsymbol{B}(\mathcal{H},\mathcal{H})$ the algebra of bounded operators on $\mathcal{H}$. By $\boldsymbol{T}_1(\mathcal{H})$ we will denote the trace-class operators on $\mathcal{H}$, and by $\boldsymbol{T}_1^+(\mathcal{H})$ its positive elements.

A general measurement is described by a probability space $\mathfrak{X}$ equipped with a sigma-algebra structure $\sigma(\mathfrak{X})$ of measurable subsets $B \in \sigma(\mathfrak{X})$. The measurement returns a random outcome $x \in \mathfrak{X}$. In quantum mechanics the probability that the outcome belongs to a subset $B \in \sigma(\mathfrak{X})$ depends on the state $\rho \in \boldsymbol{T}_1^+(\mathcal{H})$ of the system in a way which is distinctive of the measuring apparatus according to the Born rule

$$p(B) = \mathrm{Tr}[P(B)\rho], \tag{1}$$

where P is a function on $\sigma(\mathfrak{X})$ which is positive-operator valued in $\boldsymbol{B}(\mathcal{H})$, with the normalization condition

$$P(\mathfrak{X}) = I_{\mathcal{H}}. \tag{2}$$

Positivity of P is needed for positivity of probabilities for every state ρ, whereas Eq. (2) guarantees normalization of probabilities. In synthesis, P is a positive operator valued measure (POVM) on the probability space $\mathfrak{X}$. In a sense the POVM P represents our knowledge of the measuring

apparatus from which we can infer information on the state ρ from probabilities. The linearity of the Born rule (1) in both arguments ρ and P is consistent with the intrinsically statistical nature of the measurement, in which our partial knowledge of both the system and the apparatus reflects in convex structures for both states and POVM's. This means that not only states, but also POVM's can be "mixed," namely there are POVM's that give probability distributions that are equivalent to choose randomly among different apparatuses.

Group covariant POVM's: Let us consider now the general scenario in which a group of physical transformations $\mathbf{G}$ can act on the probability space $\mathcal{X}$. We will write gx for the action of the group element $g \in \mathbf{G}$ on the point $x \in \mathcal{X}$, and gB for the action of g on a whole subset $B \subseteq \mathcal{X}$. We will always consider the case in which $\mathbf{G}$ acts transitively on $\mathcal{X}$, namely for any two points on $\mathcal{X}$ there is always a group element which connects them. A consequence of transitivity is that $\mathcal{X}$ can be always regarded as the homogeneous factor space $\mathcal{X} = \mathbf{G}/\mathbf{G}_x$, $\mathbf{G}_x$ denoting the stability group of any point $x \in \mathcal{X}$.

A POVM P on $\mathcal{H}$ for the probability space $\mathcal{X}$ is covariant under the unitary representation $g \to U_g$ of the group $\mathbf{G}$ when for every set $B \in \sigma(\mathcal{X})$ one has

$$U_g^\dagger P(B) U_g = P(g^{-1}B). \tag{3}$$

The following general theorem by Holevo[2] classifies all group-covariant POVM's.

Theorem 1 (Holevo): *For square-integrable representations, a POVM P on the probability space $\mathcal{X}$ is covariant with respect to the unitary representation $g \to U_g$ on $\mathcal{H}$ of the group $\mathbf{G}$ of transformations of $\mathcal{X}$ if and only if it admits a density of the form*

$$\mathrm{d}P_x = U_{g_x}^\dagger \Xi U_{g_x} \mathrm{d}x, \quad g_x \in \mathbf{G} : g_x x_0 = x, \tag{4}$$

where $\mathrm{d}x$ *is an invariant measure on* $\mathcal{X}$, *with* $\Xi \geqslant 0$ *in the commutant* $\mathbf{G}'_{x_0}$ *of the isotropy group* $\mathbf{G}_{x_0}$ *of* x_0, *satisfying the constraint*

$$\int_{\mathbf{G}} \mathrm{d}g \; U_g^\dagger \Xi U_g = I_{\mathcal{H}}, \tag{5}$$

with $\mathrm{d}g$ *invariant measure on* $\mathbf{G}$.

In the case in which the POVM is designed to estimate the group element itself $g \in \mathbf{G}$ corresponding to an unknown transformation U_g, then the stability group is the identity, whence $\mathcal{X} = \mathbf{G}$ and the POVM P is covariant if and only if it admits a density of the form

$$\mathrm{d}P_g = U_g^\dagger \Xi U_g \, \mathrm{d}g, \quad g \in \mathbf{G} \tag{6}$$

for any $\Xi \geqslant 0$ satisfying the constraint (5). The possible *seed* operators $\Xi \geqslant 0$ satisfying the constraint (5) form a convex set. In Sec. V we will classify all extremal elements Ξ of such convex set.

III. QUANTUM OPERATIONS

The mathematical structure that describes the most general state change in quantum mechanics—such as the evolution of an open system or the state change due to a measurement—is the *quantum operation* (QO) of Kraus.[1,6] Such abstract theoretical evolution has a precise physical counterpart in its implementations as a unitary interaction between the system undergoing the QO and a part of the apparatus—the so-called *ancilla*—which after the interaction is read by means of a conventional quantum measurement. We can consider generally different input and output Hilbert spaces $\mathcal{H}$ and $\mathcal{K}$, respectively, allowing the treatment of very general quantum machines, e.g., of the kind of quantum optimal cloners.[22,23] For example, in the cloning from one to n copies one has input space $\mathcal{H}$ and output space $\mathcal{K} = \mathcal{H}^{\otimes n}$, or its symmetric version $\mathcal{K} = (\mathcal{H}^{\otimes n})_+$ for symmetric cloning. Within the present paper we will only consider finite-dimensional Hilbert spaces. In the Heisenberg picture the QO evolves observables, and will be denoted by a map $\mathcal{M}$ from $\boldsymbol{B}(\mathcal{K})$ to

$\boldsymbol{B}(\mathcal{H})$. In the Schrödinger picture the QO evolves states, and it is given by the dual map $\mathcal{M}^\tau: \boldsymbol{T}_1(\mathcal{H}) \to \boldsymbol{T}_1(\mathcal{K})$, the dualism being determined by the equivalence of the two pictures in terms of the trace inner product, namely $\mathrm{Tr}[\mathcal{M}(X)\rho] = \mathrm{Tr}[\mathcal{M}^\tau(\rho)X]$ for all $\rho \in \boldsymbol{T}_1(\mathcal{H})$ and for all $X \in \boldsymbol{B}(\mathcal{K})$. The maps $\mathcal{M}$ and $\mathcal{M}^\tau$ are linear *completely positive* (CP), namely they preserve positivity of the input operator for any trivial extension $\mathcal{M} \otimes \mathcal{I}$ on a larger Hilbert space that includes any possible additional quantum system, $\mathcal{I}$ denoting the identity map on the additional system. In the Schrödinger picture the CP property physically means that the map $\mathcal{M}^\tau$ from $\boldsymbol{T}_1(\mathcal{H})$ to $\boldsymbol{T}_1(\mathcal{K})$ preserves positivity of any input state of the quantum system (with Hilbert space $\mathcal{H}$) entangled with any possible additional quantum system. The map $\mathcal{M}^\tau$ of a QO must also be trace-not-increasing, with the trace $\mathrm{Tr}[\mathcal{M}^\tau(\rho)] \leqslant 1$ representing the probability that the transformation occurs, and the input and output states being connected as follows:

$$\rho \mapsto \rho' = \frac{\mathcal{M}^\tau(\rho)}{\mathrm{Tr}[\mathcal{M}^\tau(\rho)]}. \tag{7}$$

By denoting with $I_\mathcal{H}$ the identity operator on the Hilbert space $\mathcal{H}$, we see that the trace-not-increasing condition along with positivity of the map are equivalent to the constraint

$$\mathcal{M}(I_\mathcal{K}) = K \in \boldsymbol{B}(\mathcal{H}), \quad 0 \leqslant K \leqslant I_\mathcal{H}. \tag{8}$$

For finite-dimensional Hilbert spaces it is convenient to represent the maps $\mathcal{M}$ from $\boldsymbol{B}(\mathcal{K})$ to $\boldsymbol{B}(\mathcal{H})$ as operators $R_\mathcal{M}$ on $\mathcal{K} \otimes \mathcal{H}$ using the following one-to-one correspondence:

$$R_\mathcal{M} = \mathcal{M}^\tau \otimes \mathcal{I}(|I\rangle\langle I|), \quad \mathcal{M}^\tau(\rho) = \mathrm{Tr}_\mathcal{H}[(I_\mathcal{K} \otimes \rho^\tau)R_\mathcal{M}], \tag{9}$$

where $|I\rangle = \Sigma_n |n\rangle \otimes |n\rangle$ is a fixed vector in $\mathcal{H} \otimes \mathcal{H}$, $\{|n\rangle \otimes |m\rangle\}$ denotes an orthonormal basis for $\mathcal{H} \otimes \mathcal{H}$, and the transposition τ for operators is defined with respect to the orthonormal basis $|n\rangle\langle m|$ for $\boldsymbol{B}(\mathcal{H})$ taken as real. One can easily check the correspondence (9), and injectivity follows from linearity. In addition, the operator $R_\mathcal{M}$ is non-negative if and only if the map $\mathcal{M}$ is CP, and the constraint (8) in terms of the operator K rewrites as follows:

$$\mathrm{Tr}_\mathcal{K}[R_\mathcal{M}] = K, \quad 0 \leqslant K \leqslant I_\mathcal{H}. \tag{10}$$

The positive operators $R_\mathcal{M}$ satisfying the constraint (10) make a convex set, which is the operator counterpart of the convex set of the corresponding QO's $\mathcal{M}$.

Group covariant CP-maps: We call the map $\mathcal{M}$ from $\boldsymbol{B}(\mathcal{K})$ to $\boldsymbol{B}(\mathcal{H})$ **G**-covariant, when

$$\mathcal{M}(V_g^\dagger X V_g) = U_g^\dagger \mathcal{M}(X) U_g, \quad \forall\, g \in \mathbf{G}, \tag{11}$$

$\{U_g\}$ and $\{V_g\}$ denoting unitary representations of **G** over the input and output spaces $\mathcal{H}$ and $\mathcal{K}$, respectively. The Schrödinger picture version of identity (11) is

$$\mathcal{M}^\tau(U_g \rho U_g^\dagger) = V_g \mathcal{M}^\tau(\rho) V_g^\dagger, \quad \forall\, g \in \mathbf{G}, \tag{12}$$

where $\mathcal{M}^\tau$ goes from $\boldsymbol{T}_1(\mathcal{H})$ to $\boldsymbol{T}_1(\mathcal{K})$.

The operator form $R_\mathcal{M}$ for maps $\mathcal{M}$ simplifies the classification of QO's that are covariant under a group **G**, resorting to the Wedderburn's decomposition of the commutant of the representation. It is easy to show that the map $\mathcal{M}$ is **G**-covariant [i.e., it satisfies Eq. (11)] if and only if its corresponding operator $R_\mathcal{M}$ is invariant under the representation $V_g \otimes U_g^*$.[22] In fact, from Eq. (9) using invariance of partial trace under cyclic permutation of operators acting only on the traced space one has

$$0 = \mathcal{M}^\tau(\rho) - V_g^\dagger \mathcal{M}^\tau(U_g \rho U_g^\dagger) V_g = \mathrm{Tr}_\mathcal{H}\{(I_\mathcal{K} \otimes \rho^\tau)[R_\mathcal{M} - (V_g^\dagger \otimes U_g{}^\tau) R_\mathcal{M} (V_g \otimes U_g^*)]\}, \tag{13}$$

and, since Eq. (9) is a one-to-one correspondence between maps and operators, one concludes that

$$[R_{\mathcal{M}}, V_g \otimes U_g^*] = 0, \quad \forall\, g \in \mathbf{G}. \tag{14}$$

Therefore, the problem of classifying covariant CP-maps resorts to that of classifying positive elements of the commutant of the representation $V_g \otimes U_g^*$ on $\mathcal{K} \otimes \mathcal{H}$. By labeling with k the generic equivalence class of the representation, with multiplicity m_k, the Wedderburn's decomposition of the representation space is written as follows:[24]

$$\mathcal{K} \otimes \mathcal{H} = \bigoplus_k (\mathcal{H}_k \otimes \mathbb{C}^{m_k}). \tag{15}$$

Then, since $R_{\mathcal{M}}$ must be a positive operator in the commutant of the representation it must have the general form

$$R_{\mathcal{M}} = \oplus_k (I_{\mathcal{H}_k} \otimes w_k^\dagger w_k) = W^\dagger W, \quad W \doteq \oplus_k (I_{\mathcal{H}_k} \otimes w_k), \tag{16}$$

where w_k is any operator on $\mathbb{C}^{m_k}$, i.e., a $m_k \times m_k$ matrix. Therefore, the classification of covariant trace-not-increasing QO's with $\mathcal{M}(I_{\mathcal{K}}) = \mathcal{K} \leqslant I_{\mathcal{H}}$ is equivalent to classify the operators $R_{\mathcal{M}}$ of the form (16) with the constraint

$$\sum_k \mathrm{Tr}_{\mathcal{K}}[(I_{\mathcal{H}_k} \otimes w_k^\dagger w_k)] = K \leqslant I_{\mathcal{H}}. \tag{17}$$

The constraint (17) is generally quite involved, due to the subspace mismatch between the tensor product $\mathcal{K} \otimes \mathcal{H}$ and the Wedderburn's decomposition: its simplification will be the main task of Sec. VI.

IV. TECHNICAL LEMMAS

This section will be entirely devoted to technical lemmas, which will be used for the classification of both extremal covariant POVM's and QO's. The lemmas connect conditions on the vanishing of partial traces with linear spannings.

In the following we will make use of the following simple fact for any linear space $\mathcal{L}$ and a subspace $\mathcal{S} \subseteq \mathcal{L}$: if the only vector of $\mathcal{L}$ that is orthogonal to the whole subspace $\mathcal{S}$ is the null vector, then one has $\mathcal{S} = \mathcal{L}$. Moreover, since orthogonality to a set s of vector implies orthogonality to its linear span $\mathsf{Span}(\mathsf{s})$, then the previous assertion holds also for subsets $\mathsf{s} \subseteq \mathcal{L}$ (not necessarily subspace), namely if the only vector orthogonal to the subset s is the null vector, than one has $\mathcal{L} \equiv \mathsf{Span}(\mathsf{s})$. From now we will also make use of the following natural notation

$$X(\boldsymbol{B}(\mathcal{A}) \otimes I_B)Y^\dagger \doteq \mathsf{Span}\{X(A \otimes I_B)Y^\dagger, A \in \boldsymbol{B}(\mathcal{A})\}, \tag{18}$$

for X, Y any operators with domain $\mathcal{A} \otimes \mathcal{B}$.

Lemma 1: *Let $B \in \boldsymbol{B}(\mathcal{B}_2 \otimes \mathcal{B}_1, \mathcal{A})$, $\mathcal{A}$ and $\mathcal{B}_{1,2}$ denoting arbitrary finite-dimensional Hilbert spaces. Then, the injectivity of the linear CP map $\mathcal{W}(A) = \mathrm{Tr}_{B_1}[B^\dagger A B]$ on $\boldsymbol{B}(\mathcal{A})$ is equivalent to the spanning condition*

$$\boldsymbol{B}(\mathcal{A}) = B(\boldsymbol{B}(\mathcal{B}_2) \otimes I_{B_1})B^\dagger. \tag{19}$$

Proof: The injectivity of the map $\mathcal{W}(A) = \mathrm{Tr}_{B_1}[B^\dagger A B]$ on $\boldsymbol{B}(\mathcal{A})$ means that

$$\forall A \in \boldsymbol{B}(\mathcal{A}), \quad \mathrm{Tr}_{B_1}[B^\dagger A B] = 0 \Rightarrow A = 0. \tag{20}$$

The condition $\mathrm{Tr}_{\mathcal{B}_1}[B^\dagger A B] = 0$ is equivalent to $\mathrm{Tr}[C\ \mathrm{Tr}_{B_1}[B^\dagger A B]] = 0\ \forall C \in \boldsymbol{B}(\mathcal{B}_2)$. Therefore, since one has

$$\mathrm{Tr}[C\ \mathrm{Tr}_{\mathcal{B}_1}[B^\dagger A B]] = \mathrm{Tr}[(C \otimes I_{B_1})B^\dagger A B] = \mathrm{Tr}[B(C \otimes I_{B_1})B^\dagger A] \tag{21}$$

condition (20) is then equivalent to

$$\forall A \in \boldsymbol{B}(\mathcal{A}), \quad \mathrm{Tr}[B(\boldsymbol{B}(\mathcal{B}_2) \otimes I_{B_1})B^\dagger A] = 0 \Rightarrow A = 0, \tag{22}$$

where we used notation (18). Equation (22) says that the only operator $A \in \boldsymbol{B}(\mathcal{A})$ orthogonal to the operator space $B(\boldsymbol{B}(\mathcal{B}_2) \otimes I_{B_1})B^\dagger \subseteq \boldsymbol{B}(\mathcal{A})$ is the null operator, which means that $B(\boldsymbol{B}(\mathcal{B}_2) \otimes I_{B_1})B^\dagger$ is actually the full linear space $\boldsymbol{B}(\mathcal{A})$, namely condition (22) is equivalent to condition (19). ■

The above theorem leads immediately to the following corollaries.

Corollary 1: A necessary condition for injectivity of the map $\mathcal{W}(A) = \mathrm{Tr}_{B_1}[B^\dagger AB]$ *on* $\boldsymbol{B}(\mathcal{A})$ *is*

$$\dim(\mathcal{A}) \leqslant \min\{\dim(\mathcal{B}_2), \mathrm{rank}(B)\}. \tag{23}$$

Corollary 2: The injectivity of the map $\mathcal{W}(A) = \mathrm{Tr}_{B_1}[B^\dagger AB]$ *on* $\boldsymbol{B}(\mathcal{A})$ *is equivalent to the existence of a linear injective map* $\mathcal{V}$ *from* $\boldsymbol{B}(\mathcal{A})$ *to* $\boldsymbol{B}(\mathcal{B})$ *such that*

$$\forall A \in \boldsymbol{B}(\mathcal{A}), \quad B(\mathcal{V}(A) \otimes I_{\mathcal{B}_1})B^\dagger = A. \tag{24}$$

The relation between the maps $\mathcal{W}$ *and* $\mathcal{V}$ *is given by*

$$\mathcal{W}(A) = \mathrm{Tr}_{\mathcal{B}_1}[B^\dagger B(\mathcal{V}(A) \otimes I_{\mathcal{B}_1})B^\dagger B]. \tag{25}$$

Proof: The spanning condition (19)—equivalent to the injectivity of the map $\mathcal{W}(A) = \mathrm{Tr}_{\mathcal{B}_1}[B^\dagger AB]$ on $\boldsymbol{B}(\mathcal{A})$—guarantees that for each $A \in \boldsymbol{B}(\mathcal{A})$ there exists an element, say V_A, of $\boldsymbol{B}(\mathcal{B})$ such that $B(V_A \otimes I_{\mathcal{B}_1})B^\dagger = A$. Consider now an orthonormal basis A_j for $\boldsymbol{B}(\mathcal{A})$, and denote by V_j any element of $\boldsymbol{B}(\mathcal{B})$ such that $B(V_j \otimes I_{\mathcal{B}_1})B^\dagger = A_j$. It is clear that the $\{V_j\}$ can be chosen as linearly independent. Now, for every element $A \in \boldsymbol{B}(\mathcal{A})$ define $\mathcal{V}(A) = \Sigma_j \mathrm{Tr}[A_j^\dagger A]V_j$. This map is clearly linear and injective. The map $\mathcal{V}(A)$ corresponds to a nonorthogonal change of basis (from $\{A_j\}$ to $\{V_j\}$) which compensates the nonorthogonal change of basis $B(V_j \otimes I_{\mathcal{B}_1})B^\dagger = A_j$. Equation (25) follows by substituting Eq. (24) into the map $\mathcal{W}$. ■

We have also the additional lemma.

Lemma 2: As in Lemma 1, *the injectivity of the map* $\mathcal{W}(A) = \mathrm{Tr}_{\mathcal{B}_1}[B^\dagger AB]$ *on* $\boldsymbol{B}(\mathcal{A})$ *is equivalent to the linear independence of the set of operators* $\{W_i^\dagger W_j\}$, *where* $W_i \in \boldsymbol{B}(\mathcal{B}_1, \mathcal{B}_2)$ *are defined from the singular value decomposition* $B = \Sigma_i |V_i\rangle\langle W_i|$ *through the identity* $|W_i\rangle = (W_i \otimes I_{\mathcal{B}_1})|I\rangle$, $|I\rangle \in \mathcal{B}_1^{\otimes 2}$ *denoting the fixed vector* $|I\rangle = \Sigma_l |l\rangle \otimes |l\rangle$, *for* $\{|l\rangle \otimes |m\rangle\}$ *arbitrary orthonormal basis of* $\mathcal{B}_1^{\otimes 2}$.

Proof: First, notice that the identity $|X\rangle = (X \otimes I_{\mathcal{B}_1})|I\rangle$ sets a bijection between vectors $|X\rangle \in \mathcal{B}_2 \otimes \mathcal{B}_1$ and operators $X \in \boldsymbol{B}(\mathcal{B}_1, \mathcal{B}_2)$. Then, using the singular value decomposition $B = \Sigma_i |V_i\rangle\langle W_i|$, with $|V_i\rangle \in \mathcal{A}$ and $|W_i\rangle \in \mathcal{B}_2 \otimes \mathcal{B}_1$, the partial trace in Eq. (20) becomes

$$\mathrm{Tr}_{\mathcal{B}_1}[B^\dagger AB] = \sum_{ij} \langle V_i|A|V_j\rangle \mathrm{Tr}_{\mathcal{B}_1}[|W_i\rangle\langle W_j|] = \sum_{ij} \langle V_i|A|V_j\rangle W_i^\tau W_j^*, \tag{26}$$

where τ denotes the transposition for which $(X \otimes I_{\mathcal{B}_1})|I\rangle = (I_{\mathcal{B}_1} \otimes X^\tau)|I\rangle$, and * denotes complex conjugation, i.e., $X^\dagger = (X^\tau)^*$. By taking the complex conjugate of the last equation and introducing the matrix $A_{ij} \doteq \langle V_i|A|V_j\rangle^* \in \mathsf{M}_N(\mathbb{C})$ where $N = \mathrm{rank}(B)$ (N^2 is the cardinality of the set $\{W_i^\dagger W_j\}$), the statement (20) is equivalent to

$$\{A_{ij}\} \in \mathsf{M}_N(\mathbb{C}), \quad \sum_{ij} A_{ij} W_i^\dagger W_j = 0 \Rightarrow A_{ij} = 0, \quad \forall\, i,j, \tag{27}$$

namely the operators $\{W_i^\dagger W_j\}$ are linearly independent. ■

In the following we will need the following generalization of Lemma 1.

Lemma 3: Let $B \in \boldsymbol{B}(\oplus_k(\mathcal{B}_2^{(k)} \otimes \mathcal{B}_1^{(k)}), \mathcal{A})$, *and denote by* P_k *the orthogonal projector over* $\mathcal{B}_2^{(k)} \otimes \mathcal{B}_1^{(k)}$, $\mathcal{A}$ *and* $\mathcal{B}_{1,2}^{(k)}$ *being arbitrary finite-dimensional Hilbert spaces*.

The following implication,

$$A \in \boldsymbol{B}(\mathcal{A}), \quad \mathrm{Tr}_{\mathcal{B}_2^{(k)}}[P_k B^\dagger ABP_k] = 0 \ \forall\, k \Rightarrow A = 0, \tag{28}$$

is equivalent to

$$\boldsymbol{B}(\mathcal{A}) = \mathrm{Span}\{B[\oplus_k(\boldsymbol{B}(\mathcal{B}_2^{(k)}) \otimes I_{\mathcal{B}_1^{(k)}})]B^\dagger\}, \tag{29}$$

and necessary conditions are

$$\dim(\mathcal{A})^2 \leqslant \sum_k \dim(\mathcal{B}_2^{(k)})^2, \tag{30}$$

$$\dim(\mathcal{A}) \leqslant \mathrm{rank}(B). \tag{31}$$

Proof: The condition $\mathrm{Tr}_{\mathcal{B}_1^{(k)}}[P_k B^\dagger A B P_k] = 0 \ \forall k$ is equivalent to say that for any $C_k \in \boldsymbol{B}(\mathcal{B}_2^{(k)})$ one has $\mathrm{Tr}[P_k C_k \mathrm{Tr}_{\mathcal{B}_1^{(k)}}[P_k B^\dagger A B P_k]] = 0 \ \forall k$. Since one has

$$\mathrm{Tr}[C_k \mathrm{Tr}_{\mathcal{B}_1^{(k)}}[P_k B^\dagger A B P_k]] = \mathrm{Tr}[(C_k \otimes I_{\mathcal{B}_1^{(k)}}) P_k B^\dagger A B P_k] = \mathrm{Tr}[B P_k (C_k \otimes I_{\mathcal{B}_1^{(k)}}) P_k B^\dagger A], \tag{32}$$

and, therefore, condition (28) is equivalent to

$$A \in \boldsymbol{B}(\mathcal{A}), \quad \mathrm{Tr}[B P_k (\boldsymbol{B}(\mathcal{B}_2^{(k)}) \otimes I_{\mathcal{B}_1^{(k)}}) P_k B^\dagger A] = 0 \ \forall \ k \Rightarrow A = 0. \tag{33}$$

The last condition says that the only operator in $\boldsymbol{B}(\mathcal{A})$ which is orthogonal to the set $B P_k (\boldsymbol{B}(\mathcal{B}_2^{(k)}) \otimes I_{\mathcal{B}_1^{(k)}}) P_k B^\dagger \ \forall k$ is the null operator, or, in other words that the set spans the full operator space $\boldsymbol{B}(\mathcal{A})$, namely Eq. (29). The necessary conditions then follow trivially. ■

We are now ready to classify the extremal group covariant POVM's and QO's in the following sections. In order to classify extremal elements of convex sets, we will use the method of perturbations. We will call a non-null operator B a *perturbation* for an operator A in a convex set if both $A \pm tB$ are still in the convex set for some (sufficiently small) $t > 0$. Then, clearly A is not extremal in the convex set if and only if it has a perturbation.

V. EXTREMAL COVARIANT POVM'S

We have seen that the covariant POVM for the estimation of a group element g of an unknown unitary transformation U_g is of the general form

$$\mathrm{d}P_g = \mathrm{d}g \ U_g^\dagger \Xi U_g^\dagger, \tag{34}$$

with probability space $\mathcal{X} = \mathbf{G}$, and with

$$\int_{\mathbf{G}} \mathrm{d}_g \ U_g^\dagger \Xi U_g = I_{\mathcal{H}}. \tag{35}$$

The Wedderburn's decomposition (15) of the representation space here rewrites as follows:

$$\mathcal{H} = \bigoplus_k (\mathcal{H}_k \otimes \mathbb{C}^{m_k}), \tag{36}$$

where we remind that k labels the equivalence class of irreducible components, and m_k denotes its multiplicity. The integral in the normalization condition (35) belongs to the commutant of the representation, whence it can be rewritten as follows:

$$\int_{\mathbf{G}} \mathrm{d}g \ U_g^\dagger \Xi U_g = \bigoplus_k d_{\mathcal{H}_k}^{-1} [I_{\mathcal{H}_k} \otimes \mathrm{Tr}_{\mathcal{H}_k}(P_k \Xi P_k)] = I_{\mathcal{H}}, \tag{37}$$

P_k denoting the orthogonal projector on the subspace $\mathcal{H}_k \otimes \mathbb{C}^{m_k}$. Equation (37) follows from the simple fact that for an irreducible representation on the space say $\mathcal{L}$, one has $\int_{\mathbf{G}} \mathrm{d}g \ U_g^\dagger Z U_g = d_{\mathcal{L}}^{-1} \mathrm{Tr}[Z] I_{\mathcal{L}}$ for measure $\mathrm{d}g$ normalized to unit on $\mathbf{G}$. Equation (37) allows to split the constraint (35) into the following set of constraints:

$$\mathrm{Tr}_{\mathcal{H}_k}(P_k \Xi P_k) = d_{\mathcal{H}_k} I_{m_k}, \quad \forall\, k, \tag{38}$$

where by I_{m_k} we denote the identity matrix over $\mathbb{C}^{m_k}$. We then conclude that the classification of extremal **G**-covariant POVM's is equivalent to find the extremal Ξ within the convex set of operators $\Xi \geqslant 0$ satisfying the constraints (38). For such purpose we have the following theorem.

Theorem 2: Let Ξ be an element of the convex set of positive operators on $\mathcal{H}$ satisfying the constraints

$$\mathrm{Tr}_{\mathcal{H}_k}(P_k \Xi P_k) = d_{\mathcal{H}_k} I_{m_k}, \quad \forall\, k \in \mathsf{S}, \tag{39}$$

where S *denotes the set of equivalence classes of irreducible components in the representation. Write Ξ in the form $\Xi = X^\dagger A X$ with $A \geqslant 0$, choosing* $\mathsf{Rng}(X) = \mathsf{Supp}(A) \doteq \mathsf{Ker}(A)^\perp$. *Then*

(1) *Θ is a perturbation of Ξ if and only if Θ is Hermitian, with* $\mathrm{Tr}_{\mathcal{H}_k}(P_k \Theta P_k) = 0\ \forall k \in \mathsf{S}$, *and* $\Theta = X^\dagger B X$ *for some nonzero Hermitian B with* $\mathsf{Supp}(B) \subseteq \mathsf{Supp}(A)$.
(2) *For the specific choice of the form of A as* $A = \oplus_k A_k$, *with* $A_k \in B(\mathcal{H}_k \otimes \mathbb{C}^{m_k})$, *one has* $B = \oplus_k B_k$, $B_k \in \boldsymbol{B}(\mathcal{H}_k \otimes \mathbb{C}^{m_k})$ *and* $\mathsf{Supp}(B_k) \subseteq \mathsf{Supp}(A_k)$, $\forall k \in \mathsf{S}$;
(3) *$\Xi = X^\dagger X$ is extremal if and only if*

$$\boldsymbol{B}(\mathsf{Rng}(X)) = \mathsf{Span}\{X[\oplus_k (I_{\mathcal{H}^{(k)}} \otimes \boldsymbol{B}(\mathbb{C}^{m_k}))]X^\dagger\}. \tag{40}$$

Proof:

(1) Let Θ Hermitian, with $\mathrm{Tr}_{\mathcal{H}_k}(P_k \Theta P_k) = 0$, and $\Theta = X^\dagger B X$ for some nonzero Hermitian $B \in \boldsymbol{B}(\mathcal{H})$ and with $\mathsf{Supp}(B) \subseteq \mathsf{Supp}(A)$. Then for $\mathrm{rank}(B) > 0$ Θ is necessarily nonzero, and since $A \geqslant 0$, both constraints $A \pm tB \geqslant 0$ and $\mathrm{Tr}_{\mathcal{H}_k}(P_k(\Xi \pm t\Theta)P_k) = d_{\mathcal{H}_k} I_{m_k}\, \forall k$ are satisfied for some $t > 0$, whence Θ is a perturbation for Ξ. Conversely, suppose $\Theta \in \boldsymbol{B}(\mathcal{H})$ is a perturbation for Ξ. Since we must have $\Xi \pm t\Theta \geqslant 0$ and $Tr_{\mathcal{H}_k}[P_k(\Xi \pm t\Theta)P_k] = d_{\mathcal{H}_k} I_{m_k}$ for some $t > 0$, then Θ is Hermitian with $\mathrm{Tr}_{\mathcal{H}_k}(P_k \Theta P_k) = 0\ \forall k \in \mathsf{S}$. Moreover, if we write Ξ in the form $\Xi = X^\dagger A X$ with nonnegative $A \in \boldsymbol{B}(\mathcal{H})$, and $\mathsf{Rng}(X) = \mathsf{Supp}(A)$, then also Θ can be written in the same form $\Theta = X^\dagger B X$ for some nonzero Hermitian $B \in \boldsymbol{B}(\mathcal{H})$ and $\mathrm{Tr}_{\mathcal{H}_k}[P_k(\Xi \pm t\Theta)P_k] = d_{\mathcal{H}_k} I_{m_k}$. In fact, if X is not invertible, it can be always completed to an invertible operator $Z = X + Y$ by adding an operator Y with $\mathsf{Rng}(Y) = \mathsf{Ker}(A)$, and one can equivalently write $\Xi = Z^\dagger A Z$. Now we can write also the perturbation operator in the form $\Theta = Z^\dagger B Z$. However, since $A \pm tB \geqslant 0$ for some t, then necessarily B must have $\mathsf{Supp}(B) \subseteq \mathsf{Supp}(A) = \mathsf{Rng}(X)$, whence $Z^\dagger B Z = X^\dagger B X$.
(2) First it is obvious that a choice of the form $A = \oplus_k A_k$, with $A_k \in \boldsymbol{B}(\mathcal{H}_k \otimes \mathbb{C}^{m_k})$ is always possible. Then, in order to have $A \pm tB \geqslant 0$ for some $t > 0$, one must have $B = \oplus_k B_k$, each B_k Hermitian, with $\mathsf{Supp}(B_k) \subseteq \mathsf{Supp}(A_k)$, $\forall k \in \mathsf{S}$.
(3) Since $\mathsf{Supp}(A) \subseteq \mathsf{Rng}(X)$ and $A \geqslant 0$, we can always merge $\sqrt{A}$ into X by substituting $X \to \sqrt{A}X$. Then, since Ξ is not extremal iff it has a perturbation, by part (1) one sees that Ξ is extremal iff for Hermitian $B \in \boldsymbol{B}(\mathcal{H})$ with $\mathsf{Supp}(B) \subseteq \mathsf{Rng}(X)$, one has

$$\mathrm{Tr}_{\mathcal{H}_k}(P_k X^\dagger B X P_k) = 0\ \forall\, k \in \mathsf{S} \quad \Rightarrow \quad B = 0, \tag{41}$$

whence via Cartesian decomposition of B we have the equivalent statement

$$B \in \boldsymbol{B}(\mathsf{Rng}(X)), \quad \mathrm{Tr}_{\mathcal{H}_k}(P_k X^\dagger B X P_k) = 0\ \forall\, k \in \mathsf{S} \quad \Rightarrow \quad B = 0. \tag{42}$$

Then, by Lemma 3 this is equivalent to condition (40). ■

Corollary 3: A necessary condition for extremality of the seed Ξ of a group covariant representation as in Theorem 2 is

$$\mathrm{rank}(\Xi)^2 \leqslant \sum_k m_k^2. \tag{43}$$

Proof: Equation (43) is a trivial consequence of the necessary condition (40). ■

Corollary 4: Every rank-one POVM is extremal.

Proof: For $\mathrm{rank}(X)=1$ the iff condition (40) is trivially satisfied. ■

Theorem 3: *For* S *containing only a single equivalence class, say* h*, with multiplicity* $m_h \geqslant 1$*, the extremality of a covariant POVM on the Hilbert space* $\mathcal{H}=\mathcal{H}_h\otimes\mathbb{C}^{m_h}$ *is equivalent to the linear independence of the set of operators* $\{W_i^\dagger W_j\}$*, where* $W_i\in\boldsymbol{B}(\mathbb{C}^{m_h},\mathcal{H}_h)$ *are defined from the spectral decomposition* $\Xi=\sum_i |W_i\rangle\langle W_i|$ *of the seed* Ξ *of the POVM through the identity* $|W_i\rangle = (W_i\otimes I_{m_h})|I\rangle$*,* $|I\rangle\in(\mathbb{C}^{m_h})^{\otimes 2}$ *denoting the fixed vector* $|i\rangle=\sum_l |l\rangle\otimes|l\rangle$*, for* $\{|l\rangle\otimes|m\rangle\}$ *arbitrary orthonormal basis of* $(\mathbb{C}^{m_h})^{\otimes 2}$*. Extremal POVM's with any rank* $\mathrm{rank}(\Xi)\leqslant m_h$ *are admissible.*

Proof: For S containing a single equivalence class h with multiplicity $m_h\geqslant 1$ the seed Ξ of the POVM must satisfy the single constraint

$$\mathrm{Tr}_{\mathcal{H}_h}(\Xi) = d_{\mathcal{H}_h} I_{m_h}. \tag{44}$$

Now, write Ξ in the form $\Xi=X^\dagger AX$ with $X\in\boldsymbol{B}(\mathcal{H}_h\otimes\mathbb{C}^{m_h},\mathcal{A})$, and $\mathsf{Rng}(X)=\mathsf{Supp}(A)$, A being a Hilbert space such that $\mathsf{Supp}(A)\subseteq\mathcal{A}\subseteq\mathcal{H}_h\otimes\mathbb{C}^{m_h}$, and which can be chosen as $\mathcal{A}\simeq\mathsf{Rng}(X)$. Then, according to Theorem 2 Θ is a perturbation for Ξ iff it is of the form $\Theta=X^\dagger BX$, with B Hermitian, $\mathsf{Supp}(B)\subseteq\mathsf{Supp}(A)$, and $\mathrm{Tr}_{\mathcal{H}_h}(X^\dagger BX)=0$. This means that the extremality of Ξ is equivalent to the injectivity of the map $\mathcal{W}(B)=\mathrm{Tr}_{\mathcal{H}_h}(X^\dagger BX)$ over the set of Hermitian operators B with $\mathsf{Supp}(B)\subseteq\mathsf{Supp}(A)$, which is equivalent to injectivity of the same map on $\boldsymbol{B}(\mathsf{Rng}(X))$. We are thus in the situation of Lemma 2, with $\mathcal{A}=\mathsf{Rng}(X)$, $\mathcal{B}_1=\mathbb{C}^{m_h}$ and $\mathcal{B}_2=\mathcal{H}_h$. Therefore, by writing the singular value decomposition of $X=\sum_i |V_i\rangle\langle W_i|$, with $\mathsf{Span}\{||V_i\rangle\}=\mathsf{Rng}(X)=\mathsf{Supp}(A)$ the injectivity of the map $\mathcal{W}(B)=\mathrm{Tr}_{\mathcal{H}_h}[X^\dagger BX]$ on $\boldsymbol{B}(\mathsf{Rng}(\mathcal{X}))$ is equivalent to the linear independence of the set of operators $\{W_i^\dagger W_j\}$, where $W_i\in\boldsymbol{B}(\mathbb{C}^{m_h},\mathcal{H}_h)$ are defined through the identity $|W_i\rangle=(W_i\otimes I_{m_h})|I_i\rangle$, $|I\rangle\in(\mathbb{C}^{m_h})^{\otimes 2}$ denoting the fixed vector $|I\rangle=\sum_l |l\rangle\otimes|l\rangle$, with $\{|l\rangle\otimes|m\rangle\}$ arbitrary orthonormal basis of $(\mathbb{C}^{m_h})^{\otimes 2}$. Now, the maximum rank of the POVM is given by the maximum number of operators W_i such that the set of operators $\{W_i^\dagger W_j\}$ in $\boldsymbol{B}(\mathbb{C}^{m_h})$ is linearly independent. Since we can have at most m_h^2 linearly independent operators in $\boldsymbol{B}(\mathbb{C}^{m_h})$, the maximum cardinality of the set $\{W_i\}$ is m_h. ■

Corollary 5: A POVM which is covariant under an irreducible representation is extremal: *If and only if iff it is rank one.*

Proof: For S containing a single equivalence class h with multiplicity $m_h=1$ the iff condition (40) rewrites

$$\boldsymbol{B}(\mathsf{Rng}(X)) = \mathsf{Span}\{X(I_{\mathcal{H}^{(h)}}\otimes\mathbb{C}^1)X^\dagger\} = \mathsf{Span}\{XX^\dagger\}, \tag{45}$$

which is satisfied iff $\mathrm{rank}(X)=1$. As an alternative proof, the present corollary corresponds to the situation of Theorem 3 for multiplicity $m_h=1$. ■

A. Example

Consider a POVM on $\mathcal{H}$ with $\dim(\mathcal{H})=d$ covariant under $\mathbf{G}=\mathbb{U}(1)$, with

$$U_\phi = \exp(i\phi N), \quad N=\sum_{n=0}^{d-1} n|n\rangle\langle n|. \tag{46}$$

Here we have d one-dimensional irreducible representations with characters $\chi_k(\phi)=\exp(ik\phi)$, $k=0,\ldots,d-1$, namely they are all inequivalent, whence with unit multiplicity. Therefore, the necessary condition (43) bounds the rank of the POVM as follows:

$$\mathrm{rank}(\Xi)^2 \leqslant \dim(\mathcal{H}), \tag{47}$$

and in order to have $\mathrm{rank}(\Xi)=2$ one must have $\dim(\mathcal{H})\geqslant 4$. According to Theorem 2 the extremal POVM's have seed of the form $\Xi=X^\dagger X$ satisfying the identity

$$\boldsymbol{B}(\mathsf{Rng}(X)) = \mathsf{Span}\{|X_k\rangle\langle X_k| : 0 \leqslant k \leqslant \dim(\mathcal{H})\}, \tag{48}$$

where $|X_k\rangle = X|k\rangle$, $\{|k\rangle\}$ denoting any orthonormal basis for $\mathcal{H}$. Notice that in the present example the operator Ξ corresponds to a so-called *correlation matrix*, namely a positive matrix with all ones on the diagonal. This follows from the constraint (38), which in our case is simply $\langle k|\Xi|k\rangle = 1, \forall k$. Therefore, the present classification of extremal POVM's coincides with the classification of extremal correlation matrices given in Ref. 25.

B. Example

Consider a POVM for n qubits on the Hilbert space $\mathcal{H} = (\mathbb{C}^2)^{\otimes n}$ covariant under the tensor representation $U_\phi^{\otimes n}$ of $\mathbf{G} = \mathbb{U}(1)$, with

$$U_\phi = \exp(i\phi|1\rangle\langle 1|), \tag{49}$$

where $\{|0\rangle, |1\rangle\}$ is a orthonormal basis for $\mathbb{C}^2$. Here we have $n+1$ one-dimensional irreducible representations with characters $\chi_k(\phi) = \exp(ik\phi)$, $k = 0, \ldots, n$, and with multiplicity $m_k = \binom{n}{k}$. An orthonormal basis of each subspace $\mathbb{C}^{m_k}$ of $\mathcal{H} = \oplus_k \mathbb{C}^{m_k}$ is given by

$$\{|j\rangle_k\} = \{P_j^{(n,k)}|\underbrace{00\cdots0}_{n-k}\underbrace{11\cdots1}_{k}\rangle\}, \tag{50}$$

where $P_j^{(n,k)}$ denotes the jth permutation of k qubits in the state $|1\rangle$ in the tensor product of n qubits in total, with all other qubits in the state $|0\rangle$. In the present example, the iff condition for extremality (40) requires that $\Xi = X^\dagger X$ satisfies the identity

$$\boldsymbol{B}(\mathsf{Rng}(X)) = \mathsf{Span}\{X|i\rangle_{kk}\langle j|X^\dagger, k \in \mathsf{S}, i, j = 1, \ldots, m_k\}, \tag{51}$$

where now $\{|i\rangle_k\}$ denotes any orthonormal basis for $\mathbb{C}^{m_k}$. The necessary condition (43) bounds the rank of the POVM as follows:

$$\mathrm{rank}(\Xi)^2 \leqslant \sum_{k=0}^{n} \binom{n}{k}^2 = \binom{2n}{n}. \tag{52}$$

Here, in order to have $\mathrm{rank}(\Xi) \geqslant 2$ one needs $n \geqslant 2$ qubits. For $n = 2$ according to the previous example, one necessarily must have at least two inequivalent classes, since each of the irreducible components has less than four dimensions (the same is true also for $n = 3$). The previous example is also recovered by considering the special case in which $\mathsf{Rng}(X) \subseteq ((\mathbb{C}^2)^{\otimes n})_+$, i.e., containing only the subrepresentation of $U_\phi^{\otimes n}$ on the symmetric subspace $((\mathbb{C}^2)^{\otimes n})_+$, with multiplicity 1.

C. Example

Consider a POVM on $\mathcal{H}^{\otimes 2}$ which is covariant under the group representation $U_g \otimes I_{\mathcal{H}}$, where U_g is an irreducible representation of $\mathbf{G}$ on $\mathcal{H}$. Here, we trivially have a single equivalence class, say h, (corresponding to the irreducible representation U_g) with multiplicity $m_h = \dim(\mathcal{H})$, i.e., the Hilbert space $\mathcal{H}$ coincides with the multiplicity space $\mathcal{H} \simeq \mathbb{C}^{m_h}$. This is exactly the case considered in Theorem 3. Therefore, the extremality of the POVM is equivalent to the linear independence of the set of operators $\{W_i^\dagger W_j\}$, where $W_i \in \boldsymbol{B}(\mathcal{H})$ are defined from the spectral decomposition $\Xi = \Sigma_i |W_i\rangle\langle W_i|$ of the seed Ξ of the POVM through the identity $|W_i\rangle = (W_i \otimes I_{\mathcal{H}})|I\rangle$, as in Theorem 3. Therefore, we can have extremal POVM's with any $\mathrm{rank}(\Xi) \leqslant \dim(\mathcal{H})$. Notice that there cannot be more than a single maximally entangled vector $|W_i\rangle$ in the decomposition of Ξ, since, otherwise, at least two operators W_i would be proportional to unitary operators, and then the set $\{W_i^\dagger W_j\}$ would be necessarily linearly dependent (two products would be both proportional to the identity). The rank-one case with a single maximally entangled projector corresponds to a so-called *Bell POVM*.

VI. EXTREMAL COVARIANT QUANTUM OPERATIONS

In the following we will denote shortly by $\boldsymbol{A}_{\mathbf{G}}$ the operator algebra generated by the group representation $V_g \otimes U_g^*$, by $\boldsymbol{A}'_{\mathbf{G}}$ its commutant, and finally by $\boldsymbol{H}'_{\mathbf{G}}$ the Hermitian operators in the commutant. The following theorem classifies all extremal **G**-covariant maps $\mathcal{M}$ in the convex set given by Eq. (17).

Theorem 4: *Let R be an element of the convex set of positive operators in the commutant $\boldsymbol{A}'_{\mathbf{G}}$ of the operator algebra $\boldsymbol{A}_{\mathbf{G}}$ generated by the group representation $V_g \otimes U_g^*$ on $\mathcal{K} \otimes \mathcal{H}$, i.e., of the form*

$$R = \oplus_k (I_{\mathcal{H}_k} \otimes w_k^\dagger w_k) = W^\dagger W, \quad W \doteq \oplus_k (I_{\mathcal{H}_k} \otimes w_k), \tag{53}$$

satisfying the constraint

$$\sum_k \mathrm{Tr}_{\mathcal{K}}[(I_{\mathcal{H}_k} \otimes w_k^\dagger w_k)] = K \leqslant I_{\mathcal{H}}, \tag{54}$$

where

$$\mathcal{H} \otimes \mathcal{K} = \bigoplus_k (\mathcal{H}_k \otimes \mathbb{C}^{m_k}) \tag{55}$$

is the Wedderburn's decomposition of the representation space, k labeling the equivalence class of representations, with multiplicity m_k. Denote by P_k the orthogonal projector over the space $\mathcal{H}_k \otimes \mathbb{C}^{m_k}$ of the equivalence class. Write R in the form $R = X^\dagger Q X$ with $Q, X \in \boldsymbol{A}'_{\mathbf{G}}$ and $\mathsf{Rng}(X) = \mathsf{Supp}(Q)$. Then:

(1) *S is a perturbation of R if and only if $S \in \boldsymbol{H}'_{\mathbf{G}}$, with $\mathrm{Tr}_{\mathcal{K}}[S] = 0$, and $S = X^\dagger O X$ for some nonzero $O \in \boldsymbol{H}'_{\mathbf{G}}$ with $\mathsf{Supp}(O) \subseteq \mathsf{Rng}(X)$. Specifically, writing $Q = \oplus_k (I_{\mathcal{H}_k} \otimes Q_k)$ and $X = \oplus_k (I_{\mathcal{H}_k} \otimes X_k)$, one has $O = \oplus_k (I_{\mathcal{H}_k} \otimes O_k)$ with $\mathsf{Supp}(O_k) \subseteq \mathsf{Rng}(X_k)\ \forall k$.*

(2) *One can always write R in the form $R = X^\dagger X$, with $X \in \boldsymbol{A}'_{\mathbf{G}}$ of the form $X = \oplus_k (I_{\mathcal{H}_k} \otimes X_k)$. Denote by S the set of equivalence classes k for which $X_k \neq 0$. Then, a necessary and sufficient condition for extremality of $R = X^\dagger X$ with $\mathrm{Tr}_{\mathcal{K}}[R] = K$ is the injectivity of the map $\mathcal{T}(O) = \mathrm{Tr}_{\mathcal{K}}[X^\dagger O X]$ on $\boldsymbol{A}'_{\mathbf{G}} \cap \boldsymbol{B}(\mathsf{Rng}(X))$, namely*

$$O \in \boldsymbol{A}'_{\mathbf{G}} \cap \boldsymbol{B}(\mathsf{Rng}(X)), \quad \mathrm{Tr}_{\mathcal{K}}[X^\dagger O X] = 0 \Rightarrow O = 0, \tag{56}$$

which is equivalent to

$$\oplus_{k \in \mathsf{S}} \boldsymbol{B}(\mathsf{Rng}(X_k)) = \oplus_{k \in \mathsf{S}} X_k \mathrm{Tr}_{\mathcal{H}_k}[P_k (I_{\mathcal{K}} \otimes \boldsymbol{B}(\mathcal{H})) P_k] X_k^\dagger. \tag{57}$$

Proof:

(1) Let $S \in \boldsymbol{H}'_{\mathbf{G}}$, with $\mathrm{Tr}_{\mathcal{K}}[S] = 0$, and $S = X^\dagger O X$ for some nonzero Hermitian O with $\mathsf{Supp}(O) \subseteq \mathsf{Supp}(Q)$. Then for $\mathrm{rank}(O) > 0$ $S \in \boldsymbol{H}'_{\mathbf{G}}$ is necessarily nonzero, and since $\boldsymbol{H}'_{\mathbf{G}} \ni Q \geqslant 0$, all constraints: $Q \pm tO \in \boldsymbol{H}'_{\mathbf{G}}$, $Q \pm tO \geqslant 0$, and $\mathrm{Tr}_{\mathcal{K}}[R \pm tS] = K$ are satisfied for some $t > 0$, whence S is a perturbation for R. Conversely, suppose that $S \in \mathcal{K} \otimes \mathcal{H}$ is a perturbation for R. Since we must have $\boldsymbol{H}'_{\mathbf{G}} \ni R \pm tS \geqslant 0$ and $\mathrm{Tr}_{\mathcal{K}}[R \pm tS] = K$ for some $t > 0$, then $S \in \boldsymbol{H}'_{\mathbf{G}}$ with $\mathrm{Tr}_{\mathcal{K}}[S] = 0$. Moreover, if we write R in the form $R = X^\dagger Q X$ with $\mathsf{Rng}(X) = \mathsf{Supp}(Q)$, then also S can be written in the form $S = X^\dagger O X$ for some nonzero Hermitian $O \in \boldsymbol{H}'_{\mathbf{G}}$. In fact, if X is not invertible, it can be always completed to an invertible operator $Z = X + Y$ by adding an operator $Y \in \boldsymbol{A}'_{\mathbf{G}}$ of the form $Y = \oplus_k (I_{\mathcal{H}_k} \otimes Y_k)$ with $\mathsf{Rng}(Y_k) = \mathsf{Ker}(Q_k)$ [where $Q = \oplus_k (I_{\mathcal{H}_k} \otimes Q_k)$], and one can equivalently write $R = Z^\dagger Q Z$ with $Q \in \boldsymbol{H}'_{\mathbf{G}}$ and $Z \in \boldsymbol{A}'_{\mathbf{G}}$. Now we can write also the perturbation operator in the form $S = Z^\dagger O Z$. However, since for some t the operator $Q \pm tO \geqslant 0$ must belong to the commutant $\boldsymbol{A}'_{\mathbf{G}}$, then necessarily $O \in \boldsymbol{H}'_{\mathbf{G}}$ and $\mathsf{Supp}(O) \subseteq \mathsf{Supp}(Q) = \mathsf{Rng}(X)$, with $Z^\dagger O Z = X^\dagger O X$. Specifically, writing $Q = \oplus_k (I_{\mathcal{H}_k} \otimes Q_k)$, one has $O = \oplus_k (I_{\mathcal{H}_k} \otimes O_k)$ with $\mathsf{Supp}(O_k) \subseteq \mathsf{Supp}(Q_k) = \mathsf{Rng}(X_k)\ \forall k$.

(2) As in part (1) we can always take Q as the identity, and redefine $X \to \sqrt{Q}X$, since $Q \geqslant 0$, keeping X of the form $X = \oplus_k (I_{\mathcal{H}_k} \otimes X_k)$, since both operators in the product $\sqrt{Q}X$ belong to the algebra $\boldsymbol{A}'_{\mathbf{G}}$. From part (1) we then see that $R = X^\dagger X$ with $X \in \boldsymbol{A}'_{\mathbf{G}}$ is extremal if and only if

$$O \in \boldsymbol{H}'_{\mathbf{G}} \cap \boldsymbol{B}(\mathsf{Rng}(X)), \quad \mathrm{Tr}_{\mathcal{K}}[X^\dagger O X] = 0 \Rightarrow O = 0, \tag{58}$$

and via Cartesian decomposition this is equivalent to

$$O \in \boldsymbol{A}'_{\mathbf{G}} \cap \boldsymbol{B}(\mathsf{Rng}(X)), \quad \mathrm{Tr}_{\mathcal{K}}[X^\dagger O X] = 0 \Rightarrow O = 0. \tag{59}$$

Since $O \in \boldsymbol{A}'_{\mathbf{G}} \cap \boldsymbol{B}(\mathsf{Rng}(X))$ can be decomposed as $O = \oplus_k (I_{\mathcal{H}_k} \otimes O_k)$ with $O_k \in \boldsymbol{B}(\mathsf{Rng}(X_k))$ $\forall k \in \mathsf{S}$, then the statement (59) is equivalent to

$$\forall k \in \mathsf{S}\ O_k \in \boldsymbol{B}(\mathsf{Rng}(X_k)),$$

$$\sum_{k \in \mathsf{S}} \mathrm{Tr}_{\mathcal{K}}[(I_{\mathcal{H}_k} \otimes X_k)^\dagger (I_{\mathcal{H}_k} \otimes O_k)(I_{\mathcal{H}_k} \otimes X_k)] = 0 \Rightarrow O_k = 0\ \forall\ k \in \mathsf{S}, \tag{60}$$

or else

$$\forall k \in \mathsf{S} \quad O_k \in \boldsymbol{B}(\mathsf{Rng}(X_k)),$$

$$\mathrm{Tr}_{\mathcal{K}}[\oplus_{k \in \mathsf{S}} (I_{\mathcal{H}_k} \otimes X_k)^\dagger (I_{\mathcal{H}_k} \otimes O_k)(I_{\mathcal{H}_k} \otimes X_k)] = 0 \Rightarrow O_k = 0\ \forall\ k \in \mathsf{S}, \tag{61}$$

The vanishing of the partial trace can be written as the vanishing of the trace $\mathrm{Tr}[\oplus_{k \in \mathsf{S}} (I_{\mathcal{H}_k} \otimes X_k)^\dagger (I_{\mathcal{H}_k} \otimes O_k)(I_{\mathcal{H}_k} \otimes X_k)(I_{\mathcal{K}} \otimes C)]$ for any $C \in \boldsymbol{B}(\mathcal{H})$, namely the vanishing of $\mathrm{Tr}\{\oplus_{k \in \mathsf{S}} O_k X_k\, \mathrm{Tr}_{\mathcal{H}_k}[P_k (I_{\mathcal{K}} \otimes C) P_k] X_k^\dagger\}$ for any $C \in \boldsymbol{B}(\mathcal{H})$, and upon defining $S = \oplus_{k \in \mathsf{S}} O_k$, the statement (61) rewrites

$$S \in \oplus_{k \in \mathsf{S}} \boldsymbol{B}(\mathsf{Rng}(X_k)), \quad \mathrm{Tr}\{S \oplus_{k \in \mathsf{S}} X_k\, \mathrm{Tr}_{\mathcal{H}_k}[P_k (I_{\mathcal{K}} \otimes \boldsymbol{B}(\mathcal{H})) P_k] X_k^\dagger\} = 0 \Rightarrow S = 0, \tag{62}$$

namely, since the only operator in the linear space $\oplus_{k \in \mathsf{S}} \boldsymbol{B}(\mathsf{Rng}(X_k))$ orthogonal to the subspace $\oplus_{k \in \mathsf{S}} X_k\, \mathrm{Tr}_{\mathcal{H}_k}[P_k (I_{\mathcal{K}} \otimes \boldsymbol{B}(\mathcal{H})) P_k] X_k^\dagger$ is the null operator, one has

$$\oplus_{k \in \mathsf{S}} \boldsymbol{B}(\mathsf{Rng}(X_k)) = \oplus_{k \in \mathsf{S}} X_k\, \mathrm{Tr}_{\mathcal{H}_k}[P_k (I_{\mathcal{K}} \otimes \boldsymbol{B}(\mathcal{H})) P_k] X_k^\dagger. \tag{63}$$

■

Corollary 6: As in Theorem 4, a necessary condition for extremality is

$$\sum_{k \in \mathsf{S}} \mathrm{rank}(X_k)^2 \leqslant \dim(\mathcal{H})^2. \tag{64}$$

Corollary 7: Any rank-one covariant QO is extremal.

Proof: For $\mathrm{rank}(X) = 1$ the set S must contain only one equivalence class, and the iff condition (57) of Theorem 4 is then trivially satisfied. ■

Corollary 8: For an irreducible representation any extremal covariant QO must be rank-one.

Corollary 9 (Choi): In the noncovariant case, a QO $\mathcal{M}$ from $\boldsymbol{B}(\mathcal{K})$ to $\boldsymbol{B}(\mathcal{H})$ is extremal iff it can be written in the form $\mathcal{M}(O) = \Sigma_i\, W_i^\dagger O W_i$, with $W_i \in \boldsymbol{B}(\mathcal{H}, \mathcal{K})$ and the set of operators $\{W_i^\dagger W_j\}$ linearly independent.

Proof: The noncovariant case corresponds to the trivial covariance group $\mathbf{G} = \mathbf{I}$, i.e., the group containing only the identity element. This corresponds to have just a single equivalence class, with multiplicity equal to $\dim(\mathcal{H} \otimes \mathcal{K})$. Then, as in the proof of point (2) of Theorem 4 the extremality of $R = X^\dagger X \in \boldsymbol{B}(\mathcal{H} \otimes \mathcal{K})$ is equivalent to the injectivity of the map $\mathcal{W}(A) = \mathrm{Tr}_{\mathcal{K}}[X^\dagger A X]$ on $\boldsymbol{B}(\mathsf{Rng}(X))$. According to Lemma 2, using the singular value decomposition $X = \Sigma_i\, |V_i\rangle\langle W_i|$, with $|V_i\rangle$ orthonormal basis for $\mathsf{Rng}(X)$ and $|W_i\rangle \in \mathcal{K} \otimes \mathcal{H}$, one has $\mathcal{M}(O) = \Sigma_i\, W_i^\dagger O W_i$ for $O \in \boldsymbol{B}(\mathcal{K})$, and $\mathcal{W}(A) = \Sigma_{ij}\, \langle V_i | A | V_j \rangle W_i^\tau W_j^*$ for $A \in \boldsymbol{B}(\mathsf{Rng}(X))$, and injectivity of $\mathcal{W}$ is equivalent to linear

TABLE I. Orthonormal bases for the supporting spaces $\mathcal{H}_k \otimes \mathbb{C}^{m_k} \equiv \mathbb{C}^{m_k}$ of the kth equivalence class of irreducible representations for 1 to 2 phase-covariant cloning. The orthonormal basis are chosen as subsets of an orthonormal basis for the tensor product $\mathcal{K} \otimes \mathcal{H}$.

k	$\lvert k_i\rangle \otimes \lvert h_j\rangle$
−1	$\lvert 001\rangle$
0	$\lvert 101\rangle, \lvert 011\rangle, \lvert 000\rangle$
1	$\lvert 100\rangle, \lvert 010\rangle, \lvert 111\rangle$
2	$\lvert 110\rangle$

independence of the set of operators $\{W_i^\dagger W_j\}$. ■

Corollary 9 is the same as Choi theorem.[17] Notice that differently from the case of QO's, for POVM's the noncovariant case cannot be recovered as a special case of the covariant classification, since the group itself (or, more generally, the homogeneous factor space) coincides with the probability space $\mathcal{X}$ of the POVM, whence trivializing **G** also trivializes $\mathcal{X}$.

A. Example

Consider the phase-covariant cloning[16,22] for equatorial qubits from 1 to 2 copies. This corresponds to $\mathbf{G} = \mathbb{U}(1)$, with representations $U_\phi = e^{i\phi |1\rangle\langle 1|_0}$ and $V_\phi = e^{i\phi \Sigma_{s=1}^2 |1\rangle\langle 1|_s}$ where $s=0$ denotes the input qubit and $s=1,2$ the output ones. Here $\mathcal{H} = \mathbb{C}^2$ and $\mathcal{K} = \mathcal{H}^{\otimes 2}$. We first need to decompose the representation $V_\phi \otimes U_\phi^*$. This is made of one-dimensional representations, with characters $e^{ik\phi}$, with $k = -1, 0, 1, 2$ and multiplicities $m_{-1}=1$, $m_0=3$, $m_1=3$, and $m_2=1$. The necessary condition (64) in the present case becomes $\Sigma_{k\in \mathsf{S}} \operatorname{rank}(X_k)^2 \leqslant \dim(\mathcal{H})^2 = 4$, which means that we can have either a single equivalence class with $\operatorname{rank}(X_k) \leqslant 2$, or two equivalence classes with $\operatorname{rank}(X_k) = 1$ each. Orthonormal bases for the supporting spaces $\mathcal{H}_k \otimes \mathbb{C}^{m_k} \equiv \mathbb{C}^{m_k}$ of the kth equivalence class of irreducible representations are reported in Table I as subset of an orthonormal basis for the tensor product $\mathcal{K} \otimes \mathcal{H}$.

The operators $R = \Sigma_{k\in \mathsf{S}} R_k = \Sigma_{k\in \mathsf{S}} \Sigma_l \lvert\psi_l^{(k)}\rangle\langle\psi_l^{(k)}\rvert$ satisfying the necessary conditions and the trace-preserving condition are reported in Table II. It is easy to check that the case of $\operatorname{rank}(X_k) = 2$, which would be possible only for $k=0$ or $k=1$, does not satisfy the iff condition (56). Therefore it is possible to have only rank-one operators X_k.

As a specific optimization problem, let us consider the maximization of the fidelity averaged over the two outputs

TABLE II. Cloning from 1 to 2 copies: classification of operators $R = \Sigma_{k\in \mathsf{S}} R_k = \Sigma_{k\in \mathsf{S}} \Sigma_l \lvert\psi_l^{(k)}\rangle\langle\psi_l^{(k)}\rvert$ satisfying the necessary condition.

TABLE III. Orthonormal bases for the supporting spaces $\mathcal{H}_k \otimes \mathbb{C}^{m_k} \equiv \mathbb{C}^{m_k}$ of the kth equivalence class of irreducible representations for 1 to 3 phase-covariant cloning. The orthonormal basis are chosen as subsets of an orthonormal basis for the tensor product $\mathcal{K} \otimes \mathcal{H}$.

k	$\lvert k_i\rangle \otimes \lvert h_j\rangle$
−1	$\lvert 0001\rangle$
0	$\lvert 1001\rangle, \lvert 0101\rangle, \lvert 0011\rangle, \lvert 0000\rangle$
1	$\lvert 1000\rangle, \lvert 0100\rangle, \lvert 0010\rangle, \lvert 1101\rangle, \lvert 1011\rangle, \lvert 0111\rangle$
2	$\lvert 1100\rangle, \lvert 1010\rangle, \lvert 0110\rangle, \lvert 1111\rangle$
3	$\lvert 1110\rangle$

$$F = \langle\psi|\tfrac{1}{2}\{\mathrm{Tr}_1[\mathcal{M}^\tau(|\psi\rangle\langle\psi|)] + \mathrm{Tr}_2[\mathcal{M}^\tau(|\psi\rangle\langle\psi|)]\}|\psi\rangle = \mathrm{Tr}\left[\tfrac{1}{2}(I \otimes |\psi\rangle\langle\psi| + |\psi\rangle\langle\psi| \otimes I)\mathcal{M}^\tau(|\psi\rangle\langle\psi|)\right] \tag{65}$$

and for equatorial qubits we can choose $|\psi\rangle = |+\rangle$, where $|\pm\rangle \doteq (1/\sqrt{2})(|0\rangle \pm |1\rangle)$. Then the fidelity rewrites as

$$F = \mathrm{Tr}[W R_{\mathcal{M}}], \tag{66}$$

$$W = |+\rangle\langle+|^{\otimes 3} + \tfrac{1}{2}(|-\rangle\langle-| \otimes |+\rangle\langle+| + |+\rangle\langle+| \otimes |-\rangle\langle-|) \otimes |+\rangle\langle+|. \tag{67}$$

One can see that W is invariant for permutations over the output copies, and, by construction, also all vectors in Table II have the same symmetry. Due to the special form of the fidelity, the optimal map [satisfying $\mathcal{M}(I_{\mathcal{K}}) = I_{\mathcal{H}}$] is obtained for $\mathsf{S} = \{0, 1\}$ with corresponding rank-two operator $R_{\mathcal{M}}$ given by

$$R_{\mathcal{M}} = |\psi^{(0)}\rangle\langle\psi^{(0)}| + |\psi^{(1)}\rangle\langle\psi^{(1)}|,$$

$$|\psi^{(0)}\rangle - = \frac{1}{\sqrt{2}}\left(|000\rangle + \frac{1}{\sqrt{2}}|011\rangle + \frac{1}{\sqrt{2}}|101\rangle\right),$$

$$|\psi^{(1)}\rangle - = \frac{1}{\sqrt{2}}\left(|111\rangle + \frac{1}{\sqrt{2}}|100\rangle + \frac{1}{\sqrt{2}}|010\rangle\right), \tag{68}$$

B. Example

Consider the phase-covariant cloning[16,22] for equatorial qubits from 1 to 3 copies. This correspond to $\mathbf{G} = \mathbb{U}(1)$, with representations $U_\phi = e^{i\phi|1\rangle\langle 1|_0}$ and $V_\phi = e^{i\phi\Sigma_{s=1}^3 |1\rangle\langle 1|_k}$ where $s = 0$ denotes the input qubit and $s = 1, 2, 3$ the output ones. Here $\mathcal{H} = \mathbb{C}^2$ and $\mathcal{K} = \mathcal{H}^{\otimes 3}$. We first need to decompose the representation $V_\phi \otimes U_\phi^*$. This is made of one-dimensional representations, with characters $e^{ik\phi}$, with $k = -1, 0, 1, 2, 3$ and multiplicities $m_{-1} = 1$, $m_0 = 4$, $m_1 = 6$, $m_2 = 4$, and $m_3 = 1$. Orthonormal bases for the supporting spaces $\mathcal{H}_k \otimes \mathbb{C}^{m_k} \equiv \mathbb{C}^{m_k}$ of the kth equivalence class of irreducible representations are reported in Table III as subset of an orthonormal basis for the tensor product $\mathcal{K} \otimes \mathcal{H}$. Again, since $\dim(\mathcal{H}) = 2$, the necessary condition (64) says that we can have only one equivalence class k with $\mathrm{rank}(X_k) \leqslant 2$, or two equivalence classes both with $\mathrm{rank}(X_k) = 1$. In Ref. 22 it is shown that the map which optimizes the averaged equatorial fidelity is actually given by the rank-one map for $\mathsf{S} = \{1\}$ with corresponding operator $R_{\mathcal{M}}$ given by

$$R_{\mathcal{M}} = |\psi^{(1)}\rangle\langle\psi^{(1)}|,$$

$$|\psi^{(1)}\rangle = \frac{1}{\sqrt{3}}(|1000\rangle + |0100\rangle + |0010\rangle + |1101\rangle + |1011\rangle + |0111\rangle). \tag{69}$$

Notice that, as a consequence of the specific symmetric form of the chosen fidelity criterion, the cloning maps of the examples in Secs. VI A and VI B are both symmetrical, namely the output Hilbert space is indeed restricted to the symmetric tensor space $(\mathcal{H}^{\otimes n})_+$. Clearly, with the same method also nonsymmetric types of cloning can be analyzed well.

C. Example

Consider a generic covariant QO with $\mathcal{K} \simeq \mathcal{H}$, $V_g = U_g$, and $\mathbf{G} = \mathrm{SU}(d)$, where $d = \dim(\mathcal{H})$. In this case the representation $U_g \otimes U_g^*$ has two irreducible components, one which is one dimensional, corresponding to the invariant vector $|I\rangle \in \mathcal{H}^{\otimes 2}$, and one on the orthogonal complement, and the two components will be denoted by $k=0$ and $k=1$, respectively. Since both the irreducible components of the representation have unit multiplicity, the operator $R = X^\dagger X$ must have $X = \Sigma_{k\in \mathsf{S}}\, c_k P_k$, $c_k \in \mathbb{C}$, P_k denoting the orthogonal projector on the invariant space of the irreducible component k, and the necessary condition (64) is trivially satisfied. On the other hand, one can see that the iff condition (56) is satisfied for the irreducible representations $\mathsf{S} = \{0\}$ and $\mathsf{S} = \{1\}$, whereas for the reducible one $\mathsf{S} = \{0,1\}$ the map $\mathcal{T}(O) = \mathrm{Tr}_{\mathcal{K}}[X^\dagger O X]$ is never injective on $\boldsymbol{A}'_{\mathbf{G}} \cap \boldsymbol{B}(\mathsf{Rng}(X))$ [one has $\mathrm{Tr}_{\mathcal{K}}[X^\dagger O X] = (1/d)[|c_0|^2 a_0 + (d^2-1)|c_1|^2 a_1] I_{\mathcal{H}}$ for $O = a_0 P_0 + a_1 P_1$, $a_0, a_1 \in \mathbb{C}$]. Therefore, the only trace-preserving optimal maps are those corresponding to the operators $R = |I\rangle\langle I|$ and $R = [d/(d^2-1)](I^{\otimes 2} - (1/d)|I\rangle\langle I|)$, corresponding to the trivial map $\mathcal{M} = \mathcal{J}$ and to the so-called isotropic depolarizing channel $\mathcal{M}(O) = [d/(d^2-1)]\mathrm{Tr}[O] I_{\mathcal{H}} - [1/(d^2-1)]\rho$. Finally, notice that in the present example the optimal covariant maps are compatible only with (multiple of) the trace-preserving condition, since both partial traces $\mathrm{Tr}_{\mathcal{K}}[P_k]$ are proportional to the identity.

D. Example

We consider now the same problem as in the previous example, but now with $V_g = U_g^*$. In this case we need to consider the positive operators R which are invariant under $U_g^* \otimes U_g^*$. It will be easier to consider the representation $U_g \otimes U_g$ and then take the complex conjugate of R at the end. Now we have again two irreducible inequivalent components, say $k = \pm$ with invariant spaces $(\mathcal{H}^{\otimes 2})_\pm$, the symmetric and the antisymmetric spaces. As in the previous example, the general form of $R = X^\dagger X$ is $X = \Sigma_{k\in \mathsf{S}}\, c_k P_k$, $c_k \in \mathbb{C}$, and $P_\pm = \frac{1}{2}(I_{\mathcal{H}}^{\otimes 2} \pm E)$, where E is the swap operator on the tensor product. However, the map $\mathcal{T}(O) = \mathrm{Tr}_{\mathcal{K}}[X^\dagger O X]$ is injective on $\boldsymbol{A}'_{\mathbf{G}} \cap \boldsymbol{B}(\mathsf{Rng}(X))$ only for representations with a single irreducible component. One can see that $\mathrm{Tr}_{\mathcal{H}}[P_\pm] = \frac{1}{2}(d \pm 1) I_{\mathcal{H}}$, and only trace-preserving (or multiplying by a constant) QO's are compatible with the present covariance. In conclusion, the only extremal covariant operators are $R_\pm = (d \pm 1)^{-1}(I^{\otimes 2} \pm E)$, corresponding to the channels $\mathcal{M}_\pm(O) = (d \pm 1)^{-1}[\mathrm{Tr}(O) I_{\mathcal{H}} \pm O^\tau]$. The map $\mathcal{M}_+$ is the optimal transposition map of Ref. 26.

[10] It must be noticed that in the present paper we are focusing only on the statistical description of the measurement process—not on the change of state due to the measurement, nor on its realization scheme—and for this reason we identify the measurement covariance with the covariance of the POVM. The state change due to the measurement is described by the so-called "instrument" (Ref. 11), and the measuring scheme is given in terms of a unitary interaction with an ancilla and an orthogonal measurement on it. Clearly, the POVM covariance does not imply the covariance of all of its instruments, and the covarance of an instrument does not imply the covariance of all of the measurement realizations of the instrument.

(Received 15 December 2002; accepted 13 June 2004; published 17 August 2004)

The previous supersymmetric generalization of the unitary Harish-Chandra integral prompted the conjecture that the Harish-Chandra formula should have an extension to superspaces. We prove this conjecture for the unitary orthosymplectic supermanifold UOSp($k_1/2k_2$). To this end, we construct and solve an eigenvalue equation. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1781746]

I. INTRODUCTION

Harish-Chandra[1] gave a closed formula for a class of group integrals. Let $\mathcal{G}$ be a compact semisimple Lie group and let a and b fixed elements in the Cartan subalgebra $\mathcal{H}_0$ of $\mathcal{G}$. Harish-Chandra's formula then reads

$$\int_{U\in\mathcal{G}} \exp(\mathrm{tr}\ U^{-1}aUb)d\mu(U) = \frac{1}{|\mathcal{W}|}\sum_{w\in\mathcal{W}} \frac{\exp(\mathrm{tr}\ w(a)b)}{\Pi(a)\Pi(w(b))}, \tag{1.1}$$

where $d\mu(U)$ stands for the properly normalized invariant measure and $\Pi(a)$ for the product of all positive roots of $\mathcal{H}_0$. Moreover, $\mathcal{W}$ is the Weyl reflection group of $\mathcal{G}$ and $|\mathcal{W}|$ is the number of its elements. We notice that the integrals (1.1) should not be confused with Gelfand's spherical functions.[2–5] They are defined by a group integral which looks at first sight just like the one in Eq. (1.1), however, for Gelfand's spherical functions, a and b are not in the Cartan subalgebra. Thus, Gelfand's spherical functions are very different objects. Only in the case of $\mathcal{G}=\mathrm{SU}(N)$, the Harish-Chandra integral (1.1) coincides with the unitary spherical function of Gelfand. It is known as the Itzykson–Zuber integral.[6] A very handy diffusion equation method was developed in Ref. 6 to derive this unitary case.

A supersymmetric generalization of the Itzykson–Zuber integral, i.e., the extension of the Harish-Chandra integral to the case of the unitary supermanifold U(k_1/k_2), was first obtained in Ref. 7 by generalizing the Itzykson–Zuber diffusion equation method to supersymmetry. In its most general form, this integral was obtained in Ref. 8 as an application of Gelfand–Tzetlin coordinates for U(k_1/k_2) and also in Ref. 9 by employing the methods as given in Ref. 7.

Serganova[10] and Zirnbauer[11] conjectured that Harish-Chandra's formula should not only have a supersymmetric extension in the unitary case, but also generalize to all classical supermanifolds $\mathcal{SG}$ which can be viewes as certain extensions of the ordinary Lie groups. Thus, one would expect a result of the following form to hold,

$$\int_{u\in\mathcal{SG}} \exp(\mathrm{trg}\ u^{-1}sur)d\mu(u) = \frac{1}{|\mathcal{SW}|}\sum_{w\in\mathcal{SW}} \frac{\exp(\mathrm{trg}\ w(s)r)}{\pi(s)\pi(w(r))}, \tag{1.2}$$

where s and r are in the Cartan subalgebra $\mathcal{SH}_0$ of $\mathcal{SG}$. The Weyl reflection group $\mathcal{SW}$ and the root system $\pi(s)$ have to be properly generalized to superspace, $|\mathcal{SW}|$ is the number of elements in $\mathcal{SW}$. The extension of the Harish-Chandra integral to the case of the unitary supermanifold U(k_1/k_2) is certainly of the form (1.2). The most interesting remaining case is the unitary ortho-

symplectic supermanifold $\mathrm{UOSp}(k_1/2k_2)$. For this case, we present a proof of the conjecture (1.2) in this note. In Sec. II, we state and derive the supersymmetric Harish-Chandra integral for $\mathrm{UOSp}(k_1/2k_2)$. We summarize and conclude in Sec. III.

II. THE SUPERMANIFOLD INTEGRAL AND ITS DERIVATION

After briefly summarizing properties of the supermanifold $\mathrm{UOSp}(k_1/2k_2)$ and introducing our notation in Sec. II A, we state the supermanifold integral in Sec. II B. The solution is sketched in the following two sections. In Sec. II C, we formulate an eigenvalue equation for the integral. It is solved by separation in Sec. II D.

A. The supermanifold $\mathrm{UOSp}(k_1/2k_2)$

Kac[12,13] gave a classification of the classical superalgebras similar to Cartan's classification of the Lie algebras in ordinary space. In principle, to each classical superalgebra a supergroup is associated by the exponential mapping. However, the classification pattern of the supergroups is usually somewhat coarser.[14,15] If one omits the supergroup stemming from the exceptional superalgebras, one is left with only four different types of subgroups of the general linear supergroup $\mathrm{GL}(k_1/k_2)$, namely the unitary supergroup $\mathrm{U}(k_1/k_2)$ the orthosymplectic supergroup $\mathrm{OSp}(k_1/2k_2)$ and the supergroups associated with the strange superalgebras $\mathrm{P}(k)$ and $\mathrm{Q}(k)$. The supergroup $\mathrm{OSp}(k_1/2k_2)$ consists of the elements u in $\mathrm{GL}(k_1/2k_2)$ which leave invariant the metric

$$L = \mathrm{diag}(1_{k_1}, J), \tag{2.1}$$

such that $u^T L u = L$. Here, J is the symplectic metric

$$J = \tau^{(1)} \otimes 1_{k_2} = \begin{bmatrix} 0 & 1_{k_2} \\ -1_{k_2} & 0 \end{bmatrix}, \quad \text{with} \quad \tau^{(1)} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}. \tag{2.2}$$

Especially important in physical applications are the supergroup $\mathrm{U}(k_1/k_2)$ and the supermanifold $\mathrm{UOSp}(k_1/2k_2)$, formed by the elements of $\mathrm{OSp}(k_1/2k_2)$ which fulfill the additional condition $u^\dagger u = 1$. It contains the compact ordinary groups $\mathrm{O}(k_1)$ and $\mathrm{USp}(2k_2)$ as subgroups. However, it is strictly speaking not a compact real form of $\mathrm{OSp}(k_1/2k_2)$, see Appendix A and Refs. 16 and 17. While the fermionic dimension $2k_2$ of $\mathrm{UOSp}(k_1/2k_2)$ is always even, the bosonic dimension k_1 can be even or odd, eventually resulting in some slight differences for the supermanifold integral. One can also define the superalgebra $\mathrm{uosp}(k_1/2k_2)$ connected as usual to the supermanifold $\mathrm{UOSp}(k_1/2k_2)$ via the exponential mapping.[15] For $\sigma \in \mathrm{uosp}(k_1/2k_2)$ we have $u = \exp(\sigma) \in \mathrm{UOSp}(k_1/2k_2)$. These generators σ span the superalgebra. An element of this superalgebra can be written as

$$\sigma = \begin{bmatrix} \sigma^{(\mathrm{o})} & \sigma^{(\mathrm{a})\dagger} & & -\sigma^{(\mathrm{a})T} \\ \sigma^{(\mathrm{a})} & & & \\ & & \sigma^{(\mathrm{usp})} & \\ \sigma^{(\mathrm{a})*} & & & \end{bmatrix}. \tag{2.3}$$

The $k_1 \times k_1$ matrix $\sigma^{(\mathrm{o})}$ is antisymmetric, it is in the algebra $\mathrm{o}(k_1)$ and generates the ordinary group $\mathrm{O}(k_1)$. The $2k_2 \times 2k_2$ matrix $\sigma^{(\mathrm{usp})}$ is in the algebra $\mathrm{usp}(2k_2)$ and generates the ordinary group $\mathrm{USp}(2k_2)$, i.e. in the basis defined by Eq. (2.1) it is of the form

$$\sigma^{(\mathrm{usp})} = \begin{bmatrix} \sigma^{(\mathrm{usp},1)} & -\sigma^{(\mathrm{usp},2)} \\ \sigma^{(\mathrm{usp},2)\dagger} & -\sigma^{(\mathrm{usp},1)T} \end{bmatrix}. \tag{2.4}$$

Here $\sigma^{(\mathrm{usp},1)}$ is a skew–Hermitian matrix and $\sigma^{(\mathrm{usp},2)}$ is complex symmetric. The $k_2 \times k_1$ matrix $\sigma^{(\mathrm{a})}$ in Eq. (2.3) contains $k_1 k_2$ independent complex anticommuting variables, it is in the sector $\mathrm{usop}(k_1/2k_2) - \mathrm{o}(k_1) - \mathrm{usp}(2k_2)$. The asterisk denotes the complex conjugate of the second kind for

Grassmann variables. One uses the supertrace denoted by trg to define an invariant bilinear form on the superalgebra. Although the algebra uosp$(k_1/2k_2)$ defined by the matrices σ in Eq. (2.3) is closely related to the algebra of the orthosymplectic group osp$(k_1/2k_2)$ we avoid the notation of a real form of osp$(k_1/2k_2)$ since it cannot be derived from osp$(k_1/2k_2,R)$ by an involutive automorphism.[17]

Particularly important in the present context is the Cartan subalgebra uosp$^{(0)}(k_1/2k_2)$ of uosp$(k_1/2k_2)$. As in the theory of Lie–algebras in ordinary space there is a difference for the orthogonal group in even or odd dimension. We introduce the notation $[k_1/2]$ for the integer part of $k_1/2$. Then, for even bosonic dimension $[k_1/2]=k_1/2$, the elements of uosp$^{(0)}(k_1/2k_2)$ are the matrices

$$\sigma^{(0)} = \mathrm{diag}(s_{11}\tau^{(1)}, \ldots, s_{[k_1/2]1}\tau^{(1)}, is_{12}, \ldots, is_{k_2 2}, -is_{12}, \ldots, -is_{k_2 2}), \tag{2.5}$$

while for odd bosonic dimension $[k_1/2]=(k_1-1)/2$, the Cartan subalgebra uosp$^{(0)}(k_1/2k_2)$ consists of the matrices

$$\sigma^{(0)} = \mathrm{diag}(s_{11}\tau^{(1)}, \ldots, s_{[k_1/2]1}\tau^{(1)}, 0, is_{12}, \ldots, is_{k_2 2}, -is_{12}, \ldots, -is_{k_2 2}). \tag{2.6}$$

Thus, uosp$^{(0)}(k_1/2k_2)$ is the direct sum of the Cartan subalgebras o(k_1) and usp$(2k_2)$. We could now work with the superalgebra as defined above. However, we redefine it by a procedure similar to a Wick rotation. In most of the physics literature, this is done to ensure convergence of the integrals in superspace, see for example Ref. 21. Although the Wick rotation is not necessary in the present context, we decided to redefine the superalgebra to keep with the notation in the physics literature and in previous work on the unitary supergroup.[7–9] Hence, we proceed as follows. The Killing–Cartan form of the supermatrices defined in Eqs. (2.5) and (2.6) is not negative definite. We define another set of diagonal supermatrices by

$$s = \begin{bmatrix} i & 0 \\ 0 & 1 \end{bmatrix} \sigma^{(0)}, \tag{2.7}$$

such that always trg $s^2>0$. In the sequel we use exclusively the set of supermatrices s. We denote it also by uosp$^{(0)}(k_1/2k_2)$. By the same token we refer to its orbits under the group action $\sigma = u^{-1}su$, $u \in \mathrm{UOSp}(k_1/2k_2)$ as the superalgebra uosp$(k_1/2k_2)$. We emphasize once more that this redefinition has no direct impact in the present context.

A remark is in order for the mathematically oriented reader. The object UOSp$(k_1/2k_2)$ defined above is not included in the usual classification of symmetric superspaces. However, it still is a group in the naive, but in the present context crucial, sense that it describes generalized rotations in a superspace. It belongs to a class of supermanifolds which have been termed cs manifolds in Ref. 18. We refer the reader to the literature for further reading on the classification of supermanifolds[12–16,19,20] and to Appendix A. For this reason we refer to UOSp$(k_1/2k_2)$ defined above always as *supermanifold*.

B. Statement of the supermanifold integral

We can now write formula (1.2) for the case of the supermanifold UOSp$(k_1/2k_2)$ more explicitly. For two fixed elements s and r of the Cartan subalgebra uosp$^{(0)}(k_1/2k_2)$, we have

$$\int_{u\in \mathrm{UOSp}(k_1/2k_2)} \exp(i\ \mathrm{trg}\ u^{-1}sur)d\mu(u) = \frac{1}{[k_1/2]!\,k_2!} \frac{(\det[\cos(2s_{p1}r_{q1})] + \det[i\ \sin(2s_{p1}r_{q1})])\det[-2i\ \sin(2s_{p2}r_{q2})]}{B_{k_1 2k_2}(s)B_{k_1 2k_2}(r)} \tag{2.8}$$

for k_1 even and

$$\int_{u\in \mathrm{UOSp}(k_1/2k_2)} \exp(i\ \mathrm{trg}\ u^{-1}sur)d\mu(u) = \frac{1}{[k_1/2]!\,k_2!}\frac{\det[i\ \sin(2s_{p1}r_{q1})]\det[2\ \cos(2s_{p2}r_{q2})]}{B_{k_1 2k_2}(s)B_{k_1 2k_2}(r)} \tag{2.9}$$

for k_1 odd. We introduced the function $B_{k_1 2k_2}(s)$ which is given by

$$B_{k_1 2k_2}(s) = 2^{k_2}\frac{\prod_{p<q}(s_{p1}^2 - s_{q1}^2)\prod_{p<q}(s_{p2}^2 - s_{q2}^2)\prod_{p=1}^{k_2} s_{p2}}{\prod_{p,q}(s_{p1}^2 + s_{q2}^2)} \tag{2.10}$$

for even bosonic dimension k_1 and by

$$B_{k_1 2k_2}(s) = 2^{k_2}\frac{\prod_{p<q}(s_{p1}^2 - s_{q1}^2)\prod_{p<q}(s_{p2}^2 - s_{q2}^2)\prod_{p=1}^{[k_1/2]} s_{p1}}{\prod_{p,q}(s_{p1}^2 + s_{q2}^2)} \tag{2.11}$$

for odd bosonic dimension k_1. These two formulas differ only in the last terms of the numerators.

Formulas (2.8) and (2.9) contain, as special cases, the ordinary orthogonal and unitary symplectic Harish-Chandra integrals for $\mathcal{G}=\mathrm{SO}(k_1)$ and for $\mathcal{G}=\mathrm{USp}(2k_2)$, if we set $k_2=0$ or $k_1=0$, respectively. Thus, the derivation of the supersymmetric integral to follow also includes a rederivation of those ordinary integrals. For equal bosonic and fermionic dimension, formula (2.8) was conjectured in Ref. 11 and used to calculate the correlation functions in a certain circular random matrix ensemble.

We mention in passing that the invariant measure $d\mu(u)$ and its normalization relate to nontrivial questions of certain boundary contributions in superanalysis[22] which are highly important in applications. In the present context, however, we do not need to go into this.

C. Eigenvalue equation

The main idea for the derivation of formulas (2.8) and (2.9) is to properly modify the supersymmetric extension[7] of the Itzykson–Zuber diffusion equation method[6] to the present case. It turns out that it is somewhat more convenient to construct the eigenvalue equation associated with the diffusion equation. The two equations are related by Fourier expansion. Such an eigenvalue equation for the ordinary case of SU(N) as originally discussed by Itzykson and Zuber[6] was constructed by Brézin.[23] Berezin and Karpelevich[24] had studied such an eigenvalue equation to calculate the twofold group integral named after them, see also Ref. 25. To construct the eigenvalue equation needed to derive formulas (2.8) and (2.9), we adjust the steps made in Refs. 26 and 27, where a supersymmetric eigenvalue equation was employed for the extension of the Berezin–Karpelevich integral.

We introduce the Laplace operator over the superalgebra $\mathrm{uosp}(k_1/2k_2)$

$$\Delta = \frac{1}{2}\sum_{p<q}^{k_1}\frac{\partial^2}{\partial\,\sigma_{pq}^{(\mathrm{o})2}} + \sum_{p,q}^{2k_2}\frac{1+\delta_{pq}}{4}\frac{\partial^2}{\partial\,\sigma_{pq}^{(\mathrm{usp})}\,\partial\,\sigma_{pq}^{(\mathrm{usp})*}} + \frac{1}{2}\sum_{p=1}^{k_1}\sum_{q=1}^{k_2}\frac{\partial^2}{\partial\,\sigma_{pq}^{(\mathrm{a})}\,\partial\,\sigma_{pq}^{(\mathrm{a})*}}. \tag{2.12}$$

Its eigenfunctions are the plane waves $\exp(i\ \mathrm{trg}\ \sigma\rho)$ with both matrices $\sigma,\rho\in\mathrm{uosp}(k_1/2k_2)$. Thus, we have

$$\Delta\ \exp(i\ \mathrm{trg}\ \sigma\rho) = -\ \mathrm{trg}\ \rho^2\ \exp(i\ \mathrm{trg}\ \sigma\rho). \tag{2.13}$$

We now diagonalize both matrices according to $\sigma=u^{-1}su$ and $\rho=v^{-1}rv$, where u and v are in the supermanifold $\mathrm{UOSp}(k_1/2k_2)$ and s and r are in the Cartan subalgebra $\mathrm{uosp}^{(0)}(k_1/2k_2)$, i.e., given

by Eq. (2.5) or Eq. (2.6), respectively. Integrating both sides over v and using the invariance of the measure $d\mu(v)$, we arrive at the radial eigenvalue equation

$$\Delta_s \chi_{k_1 2k_2}(s,r) = -\operatorname{trg} r^2 \chi_{k_1 2k_2}(s,r), \tag{2.14}$$

where, now using u instead of v again, the function

$$\chi_{k_1 2k_2}(s,r) = \int_{u \in \mathrm{UOSp}(k_1/2k_2)} \exp(i \operatorname{trg} u^{-1} s u r) d\mu(u) \tag{2.15}$$

is the integral we want to calculate. The operator Δ_s in Eq. (2.14) is the radial part of Δ. The term radial refers to the Cartan subalgebra. This usage which is common in mathematics should not lead to confusions with the radial operators used, for example, in Refs. 28–31 where quite different spaces were studied. To obtain the radial operator Δ_s, we need the Jacobian, or Berezinian, of the variable transformation $\sigma = u^{-1} s u$. This Berezinian is given by the the functions $B^2_{k_1 2k_2}(s)$ of Eqs. (2.10) and (2.11). It was not possible for us to find out where this Berezinian was first obtained, and we do not claim originality for its calculation. In any case, to make the paper self-contained, we sketch the calculation in Appendix B. Hence, the radial part of the Laplacian over $\mathrm{uosp}(k_1/2k_2)$ reads

$$\Delta_s = \frac{1}{2} \sum_{p=1}^{[k_1/2]} \frac{1}{B^2_{k_1 2k_2}(s)} \frac{\partial}{\partial s_{p1}} B^2_{k_1 2k_2}(s) \frac{\partial}{\partial s_{p1}} + \frac{1}{2} \sum_{p=1}^{k_2} \frac{1}{B^2_{k_1 2k_2}(s)} \frac{\partial}{\partial s_{p2}} B^2_{k_1 2k_2}(s) \frac{\partial}{\partial s_{p2}}. \tag{2.16}$$

The number of bosonic eigenvalues is $[k_1/2]$, i.e., identical for the pairs $\mathrm{uosp}(k_1/2k_2)$ and $\mathrm{uosp}(k_1+1/2k_2)$ with k_1 even. However, the operator Δ_s is not the same in these two cases, because the functions (2.10) and (2.11) differ.

D. Solution by separation

The Laplacian (2.16) is separable. We make an ansatz for the supermanifold integral which separates off the square roots of the Berezinians,

$$\chi_{k_1 2k_2}(s,r) = \frac{\omega_{k_1 2k_2}(s,r)}{B_{k_1 2k_2}(s) B_{k_1 2k_2}(r)}. \tag{2.17}$$

A tedious but straightforward calculation then yields the trivial eigenvalue equation

$$\frac{\partial^2}{\partial \vec{s}^2} \omega_{k_1 2k_2}(s,r) = -\operatorname{trg} r^2 \omega_{k_1 2k_2}(s,r) \tag{2.18}$$

for the function $\omega_{k_1 2k_2}(s,r)$. Here we introduced the gradient

$$\frac{\partial}{\partial \vec{s}} = \left(\frac{\partial}{\partial s_{11}}, \ldots, \frac{\partial}{\partial s_{[k_1/2]1}}, \frac{\partial}{\partial s_{12}}, \ldots, \frac{\partial}{\partial s_{k_2 2}} \right), \tag{2.19}$$

which also defines the flat Laplacian $\partial^2/\partial \vec{s}^{\,2}$ appearing in the eigenvalue equation (2.18). A crucial feature of the square root of the Berezinian enters the derivation of Eq. (2.18). It satisfies the harmonic equation

$$\frac{\partial^2}{\partial \vec{s}^{\,2}} B_{k_1 2k_2}(s) = 0, \tag{2.20}$$

which we prove in Appendix C. Any linear combination of products of exponentials solves the eigenvalue equation (2.18). However, as the supermanifold integral and the eigenvalue equations are obviously invariant under permutations of the variables in the $\mathrm{o}(k_1)$ sector

$s_{p1}, p=1,\ldots,[k_1/2]$ or, equivalently, $r_{p1}, p=1,\ldots,[k_1/2]$ and under permutations of the variables in the uosp$(2k_2)$ sector $is_{p2}, p=1,\ldots,k_2$ or, equivalently, $ir_{p2}, p=1,\ldots,k_2$, the desired solution must have the same property. Moreover, there is a symmetry under a parity transformation for the variables $is_{p2}, p=1,\ldots,k_2$ and $ir_{p2}, p=1,\ldots,k_2$. That is, the solution must be invariant under the substitution $s_{p2}\rightarrow -s_{p2}$ and $r_{p2}\rightarrow -r_{p2}$. For k_1 odd, the same symmetry must hold also for $s_{p1}, p=1,\ldots,[k_1/2]$ and $r_{p1}, p=1,\ldots,[k_1/2]$ respectively. By these symmetries the solution of Eq. (2.18) for k_1 odd is up to normalization uniquely determined,

$$\omega_{k_1 2k_2}(s,r)=\frac{1}{[k_1/2]!\,k_2!}\det[i\,\sin(2s_{p1}r_{q1})]\det[2\,\cos(2s_{p2}r_{q2})]. \tag{2.21}$$

For k_1 even, the part antisymmetric under the parity transformation has to be kept and we find

$$\omega_{k_1 2k_2}(s,r)=\frac{1}{[k_1/2]!\,k_2!}(\det[\cos(2s_{p1}r_{q1})]+\det[i\,\sin(2s_{p1}r_{q1})])\det[-2i\,\sin(2s_{p2}r_{q2})]. \tag{2.22}$$

These results give, together with the ansatz (2.17), the desired supermanifold integrals (2.8) and (2.9). As already mentioned, our derivation of the supersymmetric group integral contains as special cases a rederivation of the ordinary orthogonal and unitary symplectic Harish-Chandra integrals for $k_2=0$ or $k_1=0$, respectively.

III. SUMMARY AND CONCLUSIONS

We calculated the supersymmetric Harish-Chandra integral for the unitary orthosymplectic supermanifold, thereby proving a conjecture.[10,11] Our derivation uses a diffusion equation or, equivalentely, eigenvalue equation method. It is based on the separability of the Laplacian. Our present contribution is a further extension of this technique, which, to the best of our knowledge, has previously only been used for group integrals over the unitary group: orginally, it was introduced for the Harish-Chandra integral over the ordinary unitary group,[6,23] then extended for the supersymmetric Harish-Chandra integral over the unitary supermanifold.[7] Already in 1958, Berezin and Karpelevich[24] had developed such a technique for an integral over two unitary groups, see also Ref. 25. This was also extended to the supersymmetric case.[26,27] Here, we considered the unitary orthosymplectic supermanifold and adjusted the eigenvalue equation method to this case. As the unitary orthosymplectic supermanifold contains the ordinary orthogonal and unitary symplectic groups as subgroups and special cases, we automatically also extended the eigenvalue equation method to these two ordinary groups.

We are aware of only two methods which could be an alternative: character expansions and Gelfand–Tzetlin coordinates. Balantekin developed the character expansion method for the unitary ordinary and supermanifold[32,33] and obtained various group integrals. Recently, this method was further extended and employed in Ref. 34. Similar considerations are also of interest if one studies the Itzykson–Zuber integral for matrices of large dimension.[35] Moreover, character expansions could also be developed for the calculation of certain integrals over the ordinary orthogonal and unitary symplectic group,[36] but Harish-Chandra integrals have so far not been tackled with this approach. Gelfand–Tzetlin coordinates[37,38] allow one to compute the ordinary[39] and supersymmetric[8] Itzykson–Zuber integral directly, i.e., without using a diffusion or eigenvalue equation. This method has not been applied yet to work out Harish-Chandra integrals for the ordinary orthogonal or unitary symplectic or the supersymmetric unitary orthosymplectic manifold. However, it has been employed for Gelfand's spherical functions.[28–31]

Considering all the cases, in which nontrivial group integrals could be obtained for the first time or in which known results could be rederived faster, the diffusion or eigenvalue equation method used and further extended here shows a remarkably wide range of applicability.

APPENDIX A: ON THE SUPERMANIFOLD UOSp($k_1/2k_2$)

The real form of a complex supergroup $\mathcal{G}$ is obtained by acting with some involutive antilinear automorphism s onto the group. Then the set $\mathcal{G}_s$ of fixed points of s is a real form of $\mathcal{G}$. Since the number of antilinear involutive automorphisms is limited, so is the number of inequivalent real forms. Indeed, the real forms of all complex superalgebras (and therefore of the supergroups) have been classified in Refs. 16 and 17. In particular, there it has been shown that the complex supergroup $\mathrm{OSp}(k_1/2k_2)$ has only two real forms. They are most conveniently characterized by the restriction of $\mathcal{G}_s$ to its even part $\mathcal{G}_{s0}$. For $\mathrm{OSp}(k_1/2k_2)$ this even part $\mathcal{G}_{s0}$ has to be a product of some real forms of $\mathrm{O}(k_1,C)$ and $\mathrm{Sp}(2k_2,C)$. The only two possibilities for $\mathcal{G}_{s0}$ are $\mathrm{O}(r,k_1-r)\otimes\mathrm{Sp}(k_2,R)$ and in addition, for k_1 even, $\mathrm{O}^*(k_1)\otimes\mathrm{Sp}(r,k_2-r)$. The corresponding automorphisms can also be found in Refs. 16 and 17. That is, both real forms are noncompact supergroups. Since we wish to generalize Harish-Chandra's formula for ordinary compact groups we have to relax the definition above and seek for a class of automorphisms of the algebra that allow for compact manifolds. Therefore we consider automorphisms t which are involutive only on the even elements $t^2g_0=g_0$ and antiinvolutive $t^2g_0=-g_0$ on the odd elements. For $\mathrm{osp}(k_1/2k_2)$ such an automorphism is given by $tg=g^\dagger$ with $g\in\mathrm{osp}(k_1/2k_2)$. Now we can construct a functor from the pair $\mathbf{(}\mathrm{osp}(k_1/2k_2),t\mathbf{)}$ to a supermanifold. The so constructed object is, however not a real supermanifold since the functor is not defined on the set of real supercommutative algebrae. It falls into the class of cs (complex supersymmetric) -manifolds.[18] It is, however a frequently arising object in physics[21,40] and has an intuitive meaning in terms of the matrices as defined in Sec. II A with the usual anticommutator as product.

APPENDIX B: CALCULATION OF THE BEREZINIAN

We use the standard procedure of obtaining the metric tensor g whose superdeterminant is the square of the Berezinian. The variation of the element $\sigma=u^{-1}su\in\mathrm{uosp}(k_1/2k_2)$ reads

$$d\sigma=u^{-1}(ds+[s,\delta\tilde{u}])u,\quad \text{where}\quad \delta\tilde{u}=duu^{-1} \tag{B1}$$

is also in the superalgebra $\mathrm{uosp}(k_1/2k_2)$. Thus, the invariant length element is given by

$$\begin{aligned}\mathrm{trg}\ d\sigma^2=\mathrm{trg}\ (ds+[s,\delta\tilde{u}])^2=\mathrm{trg}\ ds^2+\mathrm{trg}\ [s,\delta\tilde{u}]^2=&\sum_{p=1}^{[k_1/2]}ds_{p1}^2+\sum_{p=1}^{k_2}ds_{p2}^2+\sum_n(\alpha_n^{(\mathrm{o})})^2(\delta\tilde{u}_{(\mathrm{o})}^n)^2\\&+\sum_n(\alpha_n^{(\mathrm{usp})})^2(\delta\tilde{u}_{(\mathrm{usp})}^n)^2+\sum_n(\alpha_n^{(\mathrm{a})})^2(\delta\tilde{u}_{(\mathrm{a})}^n)^2.\end{aligned} \tag{B2}$$

In the last step, we expanded the traces, the metric g can then be read of from the coefficients in front of the squared variation differentials. We split the contribution from the commutator in three terms and introduced a new index n, labelling the roots and the variation differentials stemming from $\delta\tilde{u}$. There are three types of roots, corresponding to the $\mathrm{o}(k_1)$ and the $\mathrm{usp}(2k_2)$ subalgebras and the remaining sector $\mathrm{uosp}(k_1/2k_2)-\mathrm{o}(k_1)-\mathrm{usp}(2k_2)$ containing the anticommuting degrees of freedom. For even bosonic dimension $2k_1$, there are $2k_1(k_1-1)$ roots $\alpha_n^{(\mathrm{o})}$ of $\mathrm{o}(2k_1)$, given by $\pm s_{p1}\pm s_{q1}$ with independent signs and $p<q$. For odd bosonic dimension $2k_1+1$, there are $2k_1$ additional roots $\pm s_{p1}$ which are needed for the complete root system of $\mathrm{o}(2k_1+1)$. The roots $\alpha_n^{(\mathrm{usp})}$ of $\mathrm{usp}(2k_2)$ are $\pm is_{p2}\pm is_{q2}$ with independent signs and $p<q$, and furthermore $\pm 2is_{p2}$, all together $2k_2^2$ roots. Finally, we have the $2k_1k_2$ roots $\alpha_n^{(\mathrm{a})}$ from $\mathrm{uosp}(k_1/2k_2)-\mathrm{o}(k_1)-\mathrm{usp}(2k_2)$, which read

$\pm s_{p1} \pm i s_{q2}$ with independent signs and indices p,q. For odd bosonic dimension we have $2k_1$ additional roots $\alpha_n^{(a)} = \pm i s_{p2}$. Collecting everything, the superdeterminant detg g of the metric g is the product of all roots from $o(k_1)$ and $usp(2k_2)$, divided by the product of all roots from $uosp(k_1/2k_2) - o(k_1) - usp(2k_2)$. The square root of $\det g$ then gives the Berezinians (2.10) and (2.11).

APPENDIX C: SQUARE ROOT OF THE BEREZINIAN AS A HARMONIC FUNCTION

The result (2.20) is crucial for the separation ansatz and for the derivation of the ensuing eigenvalue equations. It is tedious, but elementary to prove it by explicit calculation. We consider even k_1, the case of odd k_1 is treated in the same way. Using relations such as

$$\sum_{p\neq q} \frac{1}{s_{p1}^2 - s_{q1}^2} = 0 \quad \text{and} \quad \sum_{p\neq q\neq t} \frac{s_{p1}^2}{(s_{p1}^2 - s_{q1}^2)(s_{p1}^2 - s_{t1}^2)} = 0, \tag{C1}$$

we find

$$\frac{1}{B_{k_1 2k_2}(s)} \sum_{p=1}^{[k_1/2]} \frac{\partial^2}{\partial s_{p1}^2} B_{k_1 2k_2}(s) = \sum_{p,q,t} \frac{4s_{p1}^2}{(s_{p1}^2 + s_{q2}^2)(s_{p1}^2 + s_{t2}^2)} - \sum_{p\neq q,t} \frac{8s_{p1}^2}{(s_{p1}^2 - s_{q1}^2)(s_{p1}^2 + s_{t2}^2)} - \sum_{p,q} \frac{6}{s_{p1}^2 + s_{q2}^2} + \sum_{p,q} \frac{4s_{p1}^2}{(s_{p1}^2 + s_{q2}^2)^2}. \tag{C2}$$

Similarly, we obtain

$$\frac{1}{B_{k_1 2k_2}(s)} \sum_{p=1}^{k_2} \frac{\partial^2}{\partial s_{p2}^2} B_{k_1 2k_2}(s) = \sum_{p,q,t} \frac{4s_{p2}^2}{(s_{p2}^2 + s_{q1}^2)(s_{p2}^2 + s_{t1}^2)} - \sum_{p\neq q,t} \frac{8s_{p2}^2}{(s_{p2}^2 - s_{q2}^2)(s_{p2}^2 + s_{t1}^2)} - \sum_{p,q} \frac{2}{s_{p1}^2 + s_{q2}^2} + \sum_{p,q} \frac{4s_{q2}^2}{(s_{p1}^2 + s_{q2}^2)^2}. \tag{C3}$$

Combining these two intermediate results, we arrive at

$$\begin{aligned}
\frac{1}{B_{k_1 2k_2}(s)} \frac{\partial^2}{\partial \vec{s}^{\,2}} B_{k_1 2k_2}(s) &= \sum_{p\neq q,t} \left(\frac{4s_{t2}^2}{(s_{p1}^2 + s_{t2}^2)(s_{q1}^2 + s_{t2}^2)} - \frac{8s_{p1}^2}{(s_{p1}^2 - s_{q1}^2)(s_{p1}^2 + s_{t2}^2)} \right) \\
&\quad + \sum_{p\neq q,t} \left(\frac{4s_{t1}^2}{(s_{t1}^2 + s_{p2}^2)(s_{t1}^2 + s_{q2}^2)} - \frac{8s_{p2}^2}{(s_{p2}^2 - s_{q2}^2)(s_{p2}^2 + s_{t1}^2)} \right) + \sum_{p,q} \left(\frac{8s_{p1}^2}{(s_{p1}^2 + s_{q2}^2)^2} \right. \\
&\quad \left. + \frac{8s_{q1}^2}{(s_{q1}^2 + s_{p2}^2)^2} \right) - \sum_{p,q} \frac{8}{s_{p1}^2 + s_{q2}^2} \\
&= \sum_{p\neq q,t} \left(\frac{4s_{t2}^2}{(s_{p1}^2 + s_{t2}^2)(s_{q1}^2 + s_{t2}^2)} - \frac{4s_{p1}^2}{(s_{p1}^2 - s_{q1}^2)(s_{p1}^2 + s_{t2}^2)} - \frac{4s_{q1}^2}{(s_{q1}^2 - s_{p1}^2)(s_{q1}^2 + s_{t2}^2)} \right) \\
&\quad + \sum_{p\neq q,t} \left(\frac{4s_{t1}^2}{(s_{t1}^2 + s_{p2}^2)(s_{t1}^2 + s_{q2}^2)} - \frac{4s_{p2}^2}{(s_{p2}^2 - s_{q2}^2)(s_{p2}^2 + s_{t1}^2)} - \frac{4s_{q2}^2}{(s_{q2}^2 - s_{p2}^2)(s_{q2}^2 + s_{t1}^2)} \right) \\
&= 0,
\end{aligned} \tag{C4}$$

which is Eq. (2.20).

In this paper we consider an Ising model with three competing restricted interactions on the Cayley tree $J^2(J^3)$. The translation invariant and periodic Gibbs measures for these models are investigated and the problem of the phase transition in these classes is solved. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1781747]

I. INTRODUCTION

The Ising model, which was originally regarded as a ferromagnetic model, has found some applications in many other physical, biological, and chemical systems, and even in sociology. The model we considered in (Ref. 6) is a natural generalization of the Ising model, and a model of the similar form has recently been investigated by Monroe[11,12] to understand the physical aspects associated with the Husimi tree or the Kagome lattice. On a similar note, the topic of statistical mechanics on nonamenable graphs is a modern growing field.[2,10] In the same paper,[6] we have presented the exact solution of an Ising model with competing restricted interactions and zero external magnetic field on the Cayley tree for J^2 order 2.

In this paper we consider the Ising model with three competing interactions on the Cayley tree which is defined by the following Hamiltonian:

$$H(\sigma) = -J_3 \sum_{\langle x,y,z\rangle} \sigma(x)\sigma(y)\sigma(z) - J\sum_{\rangle x,y\langle} \sigma(x)\sigma(y) - J_1\sum_{\langle x,y\rangle} \sigma(x)\sigma(y) - h\sum_{x\in V} \sigma(x), \tag{1}$$

where the sum in the first term ranges all triples of neighbors, the second sum ranges all second neighbors, the third sum ranges all nearest neighbors and the spin variables $\sigma(x)$ assume the values ± 1. (See Ref. 7 for models with competing interactions, and see Refs. 2 and 10–12 for the physical motivation underlying the study of these models.)

The various partial cases of this model have been investigated in numerous works, for example, the case $J_3=h=0$ was considered in Refs. 11, 12, and 6. In Ref. 6, the exact solution of an Ising model with competing restricted interactions with zero external field was presented. The case $J=h=0$ was considered in Refs. 12 and 5. In Ref. 5, the exact solution was found for the problem of phase transitions in the Ising model for competing ternary and binary interactions.

Note: Let us connect all pairs vertices (x,y) of J^2 with the same level for which $d(x,y)=2$. Then the Cayley tree J^2 is transformed to a graph $\hat{J}^2$ (see Fig. 1). Assume that the interaction

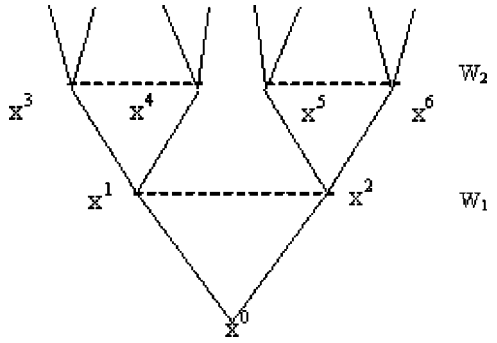

FIG. 1. A semi-infinite Cayley tree J^2 of order 2.

between nearest neighbors $\langle x,y\rangle$ in $\hat{J}^2$ is defined by constant J, if vertices x and y have distinct level and by constant J_1, if vertices x and y have the same level. The Hamiltonian of Ising model on graph $\hat{J}^2$ is the same as a modification to the Hamiltonian (1) with $J_3=0$ which we will define later. Thus the result which is proved for modification to the Hamiltonian (1) will be also valid for Ising model on the graph $\hat{J}^2$. When we let $J_1=J$, we found a critical point, $\beta J=\frac{1}{4}\ln 5$, which is the critical value found by Monroe for the special case $J_3=h=0$.[11]

In this paper we also consider restricted ternary and binary interactions. Exact definitions of such restricted interactions will be given later. The general part of our results were proven in the Cayley tree of order 2, but some parts of the results were proven also in the Cayley tree of order 3.

We end this section by some necessary definitions and preliminary results. The Cayley tree J^q (see Ref. 1) of order $q\geqslant 1$ is an infinite tree, i.e., a graph without cycles, from each vertex of which exactly $q+1$ edges issue. Let $J^q=(V,L,i)$, where V is the set of vertices of J^q, L is the set of edges of J^q, and i is the incidence function associating each edge $l\in L$ with its end points $x,y\in V$. If $i(l)=\{x,y\}$, then x and y are called nearest neighbouring vertices and we write $l=\langle x,y\rangle$. The distance $d(x,y)$, $x,y\in V$ on the Cayley tree is defined by the formula $d(x,y)=\min\{d|x=x_0,x_1,\ldots,x_{d-1},x_d=y\in V$ such that the pairs $\langle x_0,x_1\rangle,\ldots,\langle x_{d-1},x_d\rangle$ are neighboring vertices$\}$.

For the fixed $x^0\in V$ we set

$$W_n=\{x\in V|d(x,x^0)=n\},$$

$$V_n=\cup_{m=0}^{n}W_m=\{x\in V|d(x,x^0)\leqslant n\},$$

$$L_n=\{l=\langle x,y\rangle\in L|x,y\in V_n\}.$$

A collection of the pairs $\langle x,x_1\rangle,\ldots,\langle x_{d-1},y\rangle$ is called a path from x to y. We write $x<y$ if the path from x^0 to y goes through x. We call the vertex y a direct successor of x, if $y>x$ and x,y are nearest neighbors. The set of the direct successors of x is denoted by $S(x)$, i.e.,

$$S(x)=\{y\in W_{n+1}|d(x,y)=1\},\quad x\in W_n.$$

We observe that for any vertex $x\neq x^0$, x has q direct successors and x^0 has $q+1$.

The vertices x and y are called second neighbor which is denoted by $\rangle x,y\langle$, if there exists a vertex $z\in V$ such that x,z and y,z are nearest neighbors. Three vertices x,y and z are called a triple of neighbors and they are denoted by $\langle x,y,z\rangle$, if $\langle x,y\rangle$ and $\langle y,z\rangle$ are nearest neighbors and $x\neq z$. The fixed vertex x^0 is called the 0 th level and the vertices in W_n are called the nth level.

Proposition 1 (Ref. 3): There exists a one-to-one correspondence between the set V of the

vertices of the Cayley tree of order $q \geqslant 1$ *and the group* G_q *of the free products of* $q+1$ *cyclic groups of the second order with generators* $a_1, a_2, \ldots, a_{q+1}$.

Let us define a group structure on the J^q as follows. Vertices which correspond to the "words" $g, h \in G_q$ are called nearest neighbors and are connected by an edge if either $g = ha_i$ or $h = ga_j$ for some i or j. The graph thus defined is a Cayley tree of order q. Consider a left (resp. right) transformation shift on G_q defined as follows: for $g_o \in G_q$ we put

$$T_{g_0} h = g_0 h (\text{resp. } T_{g_0} h = g_0 h) \; \forall \; h \in G_q.$$

Then the set of all left (resp. right) shifts on G_q is isomorphic to the group G_q.

A semi-infinite Cayley tree J^q for order q is a infinite tree that is a graph having no cycles, from each vertex of which, except on vertex x^0, which is the root of the tree, emanates q edges (see Fig. 1). Here, just as before, we will use the same notation which is defined for the Cayley tree.

II. THE RECURRENT EQUATIONS FOR PARTITION FUNCTIONS IN THE ISING MODEL WITH RESTRICTED INTERACTIONS

There are several approaches to derive the equation describing the limiting Gibbs measures for lattice models on the Cayley tree. One approach is based on properties of Markov random fields on the Cayley tree (Refs. 16 and 13). Another approach is based on recurrent equations for partition functions.[8] Naturally both approaches lead to the same equation. However, the latter is more suitable for models with competing interactions. For the sake of completeness, we repeat the necessary notations.

From the beginning, we consider a semi-infinite Cayley tree J^k. Let Λ be a finite subset of V. Assume $\Omega(\Lambda)$ is the set of all configuration on Λ, that is the functions $\{\sigma(x), x \in \Lambda\}$. Let $\overline{\sigma}(V \setminus \Lambda)$ be a fixed boundary configuration. The total energy of configuration $\sigma(\Lambda) \in \Omega(\Lambda)$ under condition $\overline{\sigma}(V \setminus \Lambda)$ is defined as

$$\begin{aligned} H(\sigma(\Lambda)|\overline{\sigma}(V \setminus \Lambda)) = &- J_3 \sum_{\substack{\langle x,y,z \rangle \\ x,y,z \in \Lambda}} \sigma(x)\sigma(y)\sigma(z) - J \sum_{\substack{\rangle x,y \langle \\ x,y \in \Lambda}} \sigma(x)\sigma(y) - J_1 \sum_{\substack{\langle x,y \rangle \\ x,y \in \Lambda}} \sigma(x)\sigma(y) - h \sum_{x \in \Lambda} \sigma(x) \\ &- J_3 \sum_{\substack{\langle x,y,z \rangle \\ x \in \Lambda, y \notin \Lambda, z \notin \Lambda \text{ or} \\ x \in \Lambda, y \in \Lambda, z \notin \Lambda}} \sigma(x)\sigma(y)\sigma(z) - J \sum_{\substack{\rangle x,y \langle \\ x \in \Lambda, y \notin \Lambda}} \sigma(x)\overline{\sigma}(y) - J_1 \sum_{\substack{\langle x,y \rangle \\ x \in \Lambda, y \notin \Lambda}} \sigma(x)\overline{\sigma}(y). \end{aligned}$$

When all boundary points $\{\overline{\sigma}(y), y \in V \setminus \Lambda\}$ are fixed as +1, we have the positive boundary condition and when they are fixed as −1, we have negative boundary condition. The free boundary condition corresponds to the case when the last three sums in the above are absent, that is formally all boundary points are fixed as 0.

The partition function $Z_\Lambda(\overline{\sigma}(V\Lambda))$ in volume Λ under boundary condition $\overline{\sigma}(V \setminus \Lambda))$ is defined as

$$Z_\Lambda = \sum_{\sigma(\Lambda) \in \Omega(\Lambda)} \exp(-\beta H(\sigma(\Lambda))|\overline{\sigma}(V \setminus \Lambda)),$$

where $\beta = 1/kT$ is the inverse temperature. Then the conditional Gibbs measure μ_Λ in volume Λ under boundary condition $\overline{\sigma}(V \setminus \Lambda)$ is defined as

$$\mu_\Lambda(\sigma(\Lambda)) = \frac{\exp(-\beta H(\sigma(\Lambda))|\overline{\sigma}(V \setminus \Lambda))}{Z_\Lambda}.$$

We consider the configurations $\sigma(V_n)$, the partition functions Z_{V_n} and conditional Gibbs measure μ_{Λ_n} in volume V_n where $V_n = \cup_{i=0}^{n} W_i$ and for brevity we denote it as σ_n, $Z^{(n)}$ and μ_n, respectively.

Definition 1: The second neighbors $\rangle x, y \langle$ *will be named one-level neighbors and is denoted by*

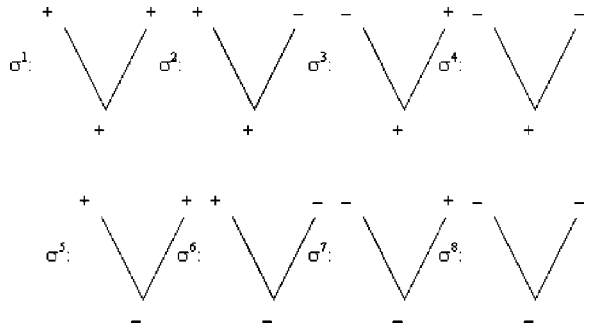

FIG. 2. All possible configurations on $V_1=\{x^0,x^1,x^2\}$.

$\overline{\rangle x,y\langle}$, *if vertices x and y belong to* W_n *for some n, that is if they are situated on the same level.*

Definition 2: The neighbors $\langle x,y,z\rangle$ *will be named two-level neighbors and is denoted by* $\overline{\langle x,y,z\rangle}$, *if vertices x and z belong to* W_n *for some n, that is if they are situated on the same level where as x and y, z, and y are nearest neighbors.*

Definition 3: The Ising model with competing restricted ternary and binary interactions on the Cayley tree is defined by the Hamiltonian

$$H(\sigma) = -J_3 \sum_{\overline{\langle x,y,z\rangle}} \sigma(x)\sigma(y)\sigma(z) - J\sum_{\overline{\rangle x,y\langle}} \sigma(x)\sigma(y) - J_1\sum_{\langle x,y\rangle} \sigma(x)\sigma(y) - h\sum_{x\in V} \sigma(x), \tag{2}$$

where the sum in the first term is taken over two-level triples of neighbors, the second term is taken over one-level second neighbors and the third term is taken over nearest neighbors.

We set

$$\theta_3 = \exp(\beta J_3), \quad \theta = \exp(\beta J), \quad \theta_1 = \exp(2\beta J_1)\,\theta_2 = \exp(\beta h)$$

and

$$u_n(x^0) = \frac{Z_+^{(n)}(x^0)}{Z_-^{(n)}(x^0)},$$

where

$$Z_+^{(n)} = \sum_{\sigma_n\in\Omega(V_n):\sigma_n(x^0)=+1} \exp(-\beta H_n(\sigma_n))$$

and

$$Z_-^{(n)} = Z^{(n)} - Z_+^{(n)}.$$

Proposition 2: For $q=2$, *the sequence* $\{u_n(x^0)\}$ *satisfies the following recurrent equation:*

$$u_n(x^0) = \theta_2^2 \frac{\theta_3^2\theta^2\theta_1^2 u_{n-1}^2(x^0) + 2\theta_1 u_{n-1}(x^0) + \theta^2\theta_3^2}{\theta^2\theta_1^2 + 2\theta_1\theta_3^2 u_{n-1}(x^0) + \theta^2 u_{n-1}^2(x^0)}, \quad n = 2,3,\ldots, \tag{3}$$

where $u_1(x^0)=\theta_1^2\theta_2^2\theta_3^2$ *for the positive boundary,* $u_1(x^0)=\theta_2^2\theta_3^2/\theta_1^2$ for the negative boundary and $u_1(x^0)=\theta_2^2[\theta^2\theta_3^2(1+\theta_1)+2\theta_1]/[\theta^2(1+\theta_1)+2\theta_1\theta_3^2]$ for the free boundary.

Proof: Consider the set of all configurations on $V_1=\{x^0,x^1,x^2\}$ and enumerate them as shown in Fig. 2. We divide the partition function $Z^{(n)}$ into eight sums

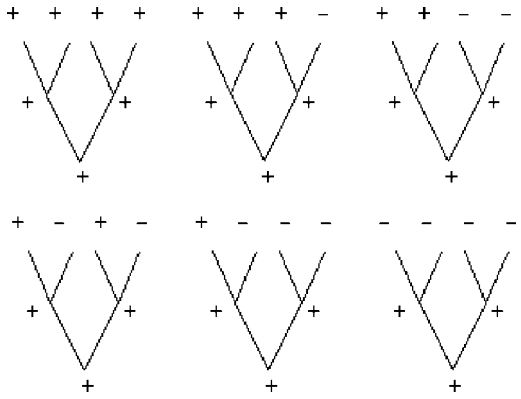

FIG. 3. Six essentially different possibilities at the second level for σ^1.

$$Z^{(n)} = \sum_{i=1}^{8} Z_i^{(n)},$$

where

$$Z_i^{(n)} = \sum_{\sigma_n \in \Omega(V_n):\sigma_n|=\sigma^i} \exp(-\beta H_n(\sigma_n)).$$

Next, we consider all the possibilities for the second level W_2 of our tree J^2 with σ^i on the $V_1, i=1,2,\ldots,8$. For example, there are a total of six different possibilities at the second level for σ^1 as shown in Fig. 3.

It is not hard to deduce the following system

$$Z_1^{(n)} = \theta_3\theta\theta_1\theta_2[Z_1^{(n-1)} + 2Z_2^{(n-1)} + Z_4^{(n-1)}]^2,$$

$$Z_2^{(n)} = Z_3^{(n)} = \theta_3^{-1}\theta^{-1}\theta_2[Z_1^{(n-1)} + 2Z_2^{(n-1)} + Z_4^{(n-1)}] \cdot [Z_5^{(n-1)} + 2Z_6^{(n-1)} + Z_8^{(n-1)}],$$

$$Z_4^{(n)} = \theta_3\theta\theta_1^{-1}\theta_2[Z_5^{(n-1)} + 2Z_6^{(n-1)} + Z_8^{(n-1)}]^2,$$

$$Z_5^{(n)} = \theta_3^{-1}\theta\theta_1^{-1}\theta_2^{-1}[Z_1^{(n-1)} + 2Z_2^{(n-1)} + Z_4^{(n-1)}]^2,$$

$$Z_6^{(n)} = Z_7^{(n)} = \theta_3\theta^{-1}\theta_2^{-1}[Z_1^{(n-1)} + 2Z_2^{(n-1)} + Z_4^{(n-1)}] \cdot [Z_5^{(n-1)} + 2Z_6^{(n-1)} + Z_8^{(n-1)}],$$

$$Z_8^{(n)} = \theta_3^{-1}\theta\theta_1\theta_2^{-1}[Z_5^{(n-1)} + 2Z_6^{(n-1)} + Z_8^{(n-1)}]^2.$$

We briefly describe how the first of the equations is obtained. According to Fig. 3, as $Z_2^{(n)} = Z_3^{(n)}$ and $Z_6^{(n)} = Z_7^{(n)}$, we have

$$Z_1^{(n)} = \theta_3\theta\theta_1\theta_2[(Z_1^{(n-1)})^2 + 4Z_1^{(n-1)}Z_2^{(n-1)} + 2Z_1^{(n-1)}Z_4^{(n-1)} + 4(Z_2^{(n-1)})^2 + 4Z_2^{(n-1)}Z_4^{(n-1)} + (Z_4^{(n)})^2],$$

where the coefficient $\theta_3\theta\theta_1\theta_2$ in front of the square bracket is taken into account for the interactions on σ^1. Here we do not take into account the interactions of the second neighbors $\langle x^0, x^3\rangle$, $\langle x^0, x^4\rangle$, $\langle x^0, x^5\rangle$, and $\langle x^0, x^6\rangle$ and also the interactions of triples of neighbors that are not two-level. The other equations are obtained similarly. Then,

$$u_n(x^0)=\frac{Z_+^{(n)}(x^0)}{Z_-^{(n)}(x^0)}=\frac{\theta_3\theta\theta_1\theta_2[Z_+^{(n-1)}]^2+2\theta_3^{-1}\theta^{-1}\theta_2Z_+^{(n-1)}Z_-^{(n-1)}+\theta_3\theta\theta_1^{-1}\theta_2[Z_-^{(n-1)}]^2}{\theta_3^{-1}\theta\theta_1^{-1}\theta_2^{-1}[Z_+^{(n-1)}]^2+2\theta_3\theta^{-1}\theta_2^{-1}Z_+^{(n-1)}Z_-^{(n-1)}+\theta_3^{-1}\theta\theta_1\theta_2^{-1}[Z_-^{(n-1)}]^2}$$
$$=\theta_2^2\frac{\theta_3^2\theta^2\theta_1^2u_{n-1}^2(x^0)+2\theta_1u_{n-1}(x^0)+\theta^2\theta_3^2}{\theta^2\theta_1^2+2\theta_1\theta_3^2u_{n-1}(x^0)+\theta^2u_{n-1}^2(x^0)},\quad n=2,3,\ldots.$$

Here we have the initial data $u_1=\theta_1^2\theta_2^2\theta_3^2$ for positive boundary and $u_1=\theta_2^2\theta_3^2/\theta_1^2$ for negative boundary. For the free boundary we have $u_1(x^0)=\theta_2^2[\theta^2\theta_3^2(1+\theta_1)+2\theta_1]/[\theta^2(1+\theta_1)+2\theta_1\theta_3^2]$.

Evidently,

$$u_n(x^0)=\frac{\mu_n(\sigma_n(x^0)=1)}{\mu_n(\sigma_n(x^0)=-1)}.$$

If we can find the limit of $u_n(x^0)$ as n tends to infinity, we will find the ratio for probability of a $+1$ to the probability of a (-1) at the root of the limiting Gibbs measure.

Now we give the construction of a special class of limiting Gibbs measures for our model (2). We consider a Cayley tree J^k below.

Let $H_n(\sigma_n)$ be the total energy of σ_n with respect to the free boundary condition.

Let $h:x\to R$ be a real valued function of $x\in V$. Given $n=1,2,\ldots$, consider the probabiity measure $\mu^{(n)}$ on $\{-1,+1\}^{V_n}$ which is defined by

$$\mu^{(n)}(\sigma_n)=Z_n^{-1}\exp\left\{-\beta H(\sigma_n)+\sum_{x\in W_n}h_x\sigma(x)\right\}.$$

Here, as before, $\beta=1/kT$ and $\sigma_n:x\in V_n\to\sigma_n(x)$ and Z_n is the corresponding partition function

$$Z_n=\sum_{\tilde{\sigma}_n\in\Omega(V_n)}\exp\left\{-\beta H(\tilde{\sigma}_n)+\sum_{x\in W_n}h_x\sigma(x)\right\}.$$

The consistency condition for $\mu^{(n)}(\sigma_n)$, $n\geqslant 1$ is

$$\sum_{\sigma^{(n)}}\mu^{(n)}(\sigma_{n-1},\sigma^{(n)})=\mu^{(n-1)}(\sigma_{n-1}),\tag{4}$$

where $\sigma^{(n)}=\{\sigma(x),x\in W_n\}$.

Let $V_1\subset V_2\subset\cdots,\cup_{n=1}^{\infty}V_n=V$ and $\mu_1,\mu_2,\ldots$ be a sequence of the probability measures on $\Phi^{V_1},\Phi^{V_2},\ldots$ satisfying the consistency condition, where $\Phi=\{-1,+1\}$. Then, according to the Kolmogorov theorem (see, e.g., Ref. 14), there is a unique limit Gibbs measure μ_h on Ω such that for every $n=1,2,\ldots$ and $\sigma_n\in\Phi^{V_n}$ the following equality holds:

$$\mu\left(\left\{\sigma\big|_{V_n}=\sigma_n\right\}\right)=\mu^{(n)}(\sigma_n).$$

The following statement describes the conditions on h_x which guarantee the consistency condition of measures $\mu^{(n)}(\sigma_n)$.

Proposition 3: The measure $\mu^{(n)}(\sigma_n)$, $n=1,2,\ldots$ satisfies the consistency condition (4) if and only if for any $x\in V$ the following equation holds:

$$h_x=\frac{1}{2}\log\left(\theta_2^2\frac{\theta_3^2\theta^2\theta_1^2e^{2(h_y+h_z)}+2\theta_1(e^{2h_y+2h_z})+\theta^2\theta_3^2}{\theta^2\theta_1^2+2\theta_1\theta_3^2(e^{2h_y}+e^{2h_z})+\theta^2e^{2(h_y+h_z)}}\right).\tag{5}$$

Here $S(x)=\{y,z\}$ and $\langle y,x,z\rangle$ is a two level ternary neighbor.

Proof: Necessity. According to the consistency condition (4) we have

$$\frac{Z_{n-1}}{Z_n}\sum_{\sigma^{(n)}}\exp\Bigg\{-\beta H_{n-1}(\sigma_{n-1})+\beta J_1\sum_{\substack{x\in W_{n-1},\\ y,z\in S(x)}}\sigma(x)(\sigma(y)+\sigma(z))+\beta J\sum_{\substack{x\in W_{n-1},\\ y,z\in S(x)}}\sigma(y)\sigma(z)$$
$$+\beta J_3\sum_{\substack{x\in W_{n-1},\\ y,z\in S(x)}}\sigma(x)\sigma(y)\sigma(z)+\sum_{x\in W_{n-1}}\beta h\sigma(x)+\sum_{x\in W_{n-1}}h_x(\sigma(x))\Bigg\}$$
$$=\exp\Bigg\{-\beta H_{n-1}(\sigma_{n-1})+\sum_{x\in W_{n-1}}h_x(\sigma(x))\Bigg\}.$$

After simplification we have

$$\frac{Z_{n-1}}{Z_n}\sum_{\sigma^{(n)}}\prod_{x\in W_{n-1}}\exp\{\beta J_1\sigma(x)(\sigma(y)+\sigma(z))+\beta J\sigma(y)\sigma(z)+\beta J_3\sigma(x)\sigma(y)\sigma(z)+\beta h\sigma(x)+h_y\sigma(y)$$
$$+h_z\sigma(z)\}=\prod_{x\in W_{n-1}}\exp\{h_x\sigma(x)\}.$$

Let $x\in W_{n-1}$ and $S(x)=\{y,z\}$, $\sigma_x^{(n)}=\{\sigma(y),\sigma(z)\}$. As $\sigma^{(n)}=\cup_{x\in W_{n-1}}\sigma_x^{(n)}$, then

$$\frac{Z_{n-1}}{Z_n}\prod_{x\in W_{n-1}}\sum_{\sigma_x^{(n)}}\exp\{\beta J_1\sigma(x)(\sigma(y)+\sigma(z))+\beta J\sigma(y)\sigma(z)+\beta J_3\sigma(x)\sigma(y)\sigma(z)+\beta h\sigma(x)+h_y\sigma(y)$$
$$+h_z(z)\}=\prod_{x\in W_n}\exp\{h_x\sigma(x)\}. \tag{6}$$

Now fix $x\in W_{n-1}$ and rewrite (6) for the cases $\sigma(x)=1$ and $\sigma(x)=-1$. If $\sigma(x)=1$, we have

$$N=\sum_{\sigma_x^{(n)}=\{\sigma(y),\sigma(z)\}}\exp\{\beta J_1(\sigma(y)+\sigma(z))+\beta J\sigma(y)\sigma(z)+\beta J_3\sigma(y)\sigma(z)+\beta h\sigma(x)+h_y\sigma(y)+h_z\sigma(z)\}$$
$$=\exp\{h_x\};$$

and if $\sigma(x)=-1$, then

$$D=\sum_{\sigma_x^{(n)}=\{\sigma(y),\sigma(z)\}}\exp\{-\beta J_1(\sigma(y)+\sigma(z))+\beta J\sigma(y)\sigma(z)\}+\beta J_3\sigma(y)\sigma(z)+\beta h\sigma(x)+h_y\sigma(y)+h_z\sigma(z)$$
$$=\exp\{-h_x\}.$$

So that

$$\frac{N}{D}=\exp\{2h_x\}. \tag{7}$$

The numerator N of the left-hand side is equal to

$$N=\exp(2\beta J_1+\beta J+\beta J_3+\beta h+h_y+h_z)+\exp(-\beta J-\beta J_3+\beta h-h_y+h_z)+\exp(-\beta J-\beta J_3+\beta h$$
$$+h_y-h_z)+\exp(-2\beta J_1+\beta J+\beta J_3+\beta h-h_y-h_z)$$

while the denumerator D is equal to

$$D=\exp(-2\beta J_1+\beta J+\beta J_3-\beta h+h_y+h_z)+\exp(-\beta J-\beta J_3-\beta h-h_y+h_z)+\exp(-\beta J-\beta J_3-\beta h$$
$$+h_y-h_z)+\exp(2\beta J_1+\beta J+\beta J_3-\beta h-h_y-h_z).$$

Then the equality $N/D=\exp\{2h_x\}$ implies (5).

Sufficiency. Assume that (5) is valid, then we have (7). From (7) we get

$$\sum_{\sigma_x^{(n)}=\{\sigma(y),\sigma(z)\}} \exp\{\beta J_1\sigma(x)(\sigma(y)+\sigma(z)) + \beta J\sigma(y)\sigma(z) + \beta J_3\sigma(x)\sigma(y)\sigma(z) + \beta h\sigma(x) + h_y\sigma(y) + h_z\sigma(z)\} = a(x)\exp\{\sigma(x)h_x\},$$

where $\sigma(x)=\pm 1$. This equality implies

$$\prod_{x\in W_{n-1}}\sum_{\sigma_x^{(n)}=\{\sigma(y),\sigma(z)\}} \exp\{\beta J_1\sigma(x)(\sigma(y)+\sigma(z)) + \beta J\sigma(y)\sigma(z) + \beta J_3\sigma(x)\sigma(y)\sigma(z) + \beta h\sigma(x) + h_y\sigma(y) + h_z\sigma(z)\} = \prod_{x\in W_{n-1}} a(x)\exp\{\sigma(x)h_x\}. \tag{8}$$

Denoting $A_n(x)=\Pi_{x\in W_{n-1}} a(x)$, we have from (8)

$$Z_{n-1}A_{n-1}\mu^{(n-1)}(\sigma_{n-1}) = Z_n\sum_{\sigma^{(n)}} \mu^{(n)}(\sigma_{n-1},\sigma^{(n)}).$$

As $\mu^{(n)}$, $n\geqslant 1$ is a probability, we have

$$\sum_{\sigma_{n-1}}\sum_{\sigma^{(n)}} \mu^{(n)}(\sigma_{n-1},\sigma^{(n)}) = \sum_{\sigma_{n-1}} \mu^{n-1}(\sigma_{n-1}) = 1.$$

From these equalities we get $Z_{n-1}A_{n-1}=Z_n$, which means that (4) holds.

According to Proposition 3 the problem of describing the Gibbs measures is reduced to the description of the solutions of the functional Eq. (5).

Let $\Omega=\{-1,+1\}^V$. According to Proposition 1 any transformation S of the group G_q induces a shift automorphism $\tilde{S}:\Omega\to\Omega$ by

$$(\tilde{S}\sigma)(h) = \sigma(Sh), h\in G_q, \sigma\in\Omega.$$

By G_q we denote the set of all shifts on Ω. We say that a Gibbs measure μ on Ω is translation-invariant if for any $T\in G_q$ the equality $\mu(T(A))=\mu(A)$ is valid for all $A\in\mathbb{F}$, where $\mathbb{F}$ is a standard σ-algebra of subsets of Ω generated by cylinder subsets.

The analysis of the solution of (5) is rather tricky. It is nartural to begin with the translation-invariant solutions where $h_x=h$ is constant for all $x\in V$. It is evident that a Gibbs measure corresponding to this solution is translation-invariant. In this case from (5), we have

$$u = \theta_2^2\frac{\theta_3^2\theta^2\theta_1^2u^2 + 2\theta_1u + \theta^2\theta_3^2}{\theta^2\theta_1^2 + 2\theta_1\theta_3^2u + \theta^2u^2}, \tag{9}$$

where $u=e^{2h}$.

Note that this equation describes the fixed points of Eq. (4). If there is more than one positive solution for Eq. (9), then there is more than one tranlation-invariant Gibbs measure corresponding to these solutions. We say that a phase transition occurs for model (2), if Eq. (9) has more than one positive solution. The number of the solutions of Eq. (3) naturally depends on the parameter $\beta=1/kT$. The phase transition usually occurs for low temperature. If it is possible to find an exact value of temperature T^* such that a phase transition occurs for all $T<T^*$, where T^* is called a critical value of temperature.

Finding the exact value of the critical temperature for some models means to exactly solve the models.

III. THE PROOF OF EXISTENCE OF PHASE TRANSITIONS FOR ZERO EXTERNAL FIELD

For the case $h=0$, Eq. (9) has the following form:

$$u = \frac{\theta_3^2\theta^2\theta_1^2u^2 + 2\theta_1u + \theta^2\theta_3^2}{\theta^2\theta_1^2 + 2\theta_1\theta_3^2u + \theta^2u^2}, \tag{10}$$

which is equivalent to the cubic equation

$$u^3 + \beta\alpha u^2 - \alpha u - \beta = 0, \tag{11}$$

where $\beta = \theta_3^2$ and $\alpha = (2\theta_1 - \theta_1^2\theta^2)/\theta^2$.

By changing the variable $u = v - (\alpha\beta/3)$, we obtain as cubic equation[9] as follows:

$$v^3 + pv + q = 0,$$

where

$$p = -\frac{\alpha^2\beta^2 + 3\alpha}{3} \quad \text{and} \quad q = \frac{2\alpha^3\beta^3}{27} + \frac{\alpha^2\beta}{3} - \beta.$$

It is well known (see, e.g., Ref. 9) that Eq. (11) has three real roots if $Q < 0$, where

$$Q = -\frac{4\alpha^3\beta^4 + (\alpha^4 + 18\alpha^2 - 27)\beta^2 + 4\alpha^3}{108}.$$

In Ref. 5, it was proven that $Q < 0$ for all $(\theta_1, \theta, \theta_3)$ such that $\theta_1^2 > 3$, $\theta^2 > 2\theta_1/(\theta_1^2 - 3)$ and $\theta_3^* < \theta_3 < \theta_3^{**}$, where

$$\theta_3^* = \sqrt{\frac{27 - 18\alpha^2 - \alpha^4 + (\alpha^2 - 9)\sqrt{\alpha^4 - 10\alpha^2 + 9}}{8\alpha^3}}$$

and

$$\theta_3^{**} = \sqrt{\frac{27 - 18\alpha^2 - \alpha^4 - (\alpha^2 - 9)\sqrt{\alpha^4 - 10\alpha^2 + 9}}{8\alpha^3}}.$$

Proposition 4 (Ref. 5): If $\theta_1^2 > 3$ *and* $\theta^2 > 2\theta_1/(\theta_1^2 - 3)$, *then* Eq. (11) *has three positive roots for all* $\theta, \theta_1, \theta_3$ *such that* $Q < 0$.

We write PR-domain to denote the set of all $(\theta, \theta_1, \theta_3)$ such that $\theta_1^2 > 3$, $\theta^2 > 2\theta_1/(\theta_1^2 - 3)$ and $Q < 0$ (see Fig. 4).

Now, we investigate the function

$$\psi(u) = \frac{\theta_3^2\theta^2\theta_1^2u^2 + 2\theta_1u + \theta^2\theta_3^2}{\theta^2\theta_1^2 + 2\theta_1\theta_3^2u + \theta^2u^2}$$

for $u > 0$. Let $u_1^* < u_2^* < u_3^*$ be the fixed points of Eq. (10). It is not hard to show by simple calculus that for all $(\theta_1, \theta, \theta_3)$ in the PR-domain (see Fig. 5), the function $\psi(u)$ will be increasing and will have a single positive point of inflection in the interval $(1, u_3^*)$, where u_3^* is the largest fixed point.

It is easy to show diagrammatically (see Fig. 5), that if $0 < u_1 < u_1^*$, u_n in Eq. (3) will monotonically increase to u_1^*, the smallest fixed point. For values $u_1^* < u_1 < u_2^*$, u_n will decrease monotonically to u_1^*. For values $u_2^* < u_1 < u_3^*$, u_n will increase monotonically to u_3^*. Finally, if $u_1 > u_3^*$, u_n will decrease monotonically to u_3^*.

As $\theta_1^2 > 3$, then $\theta^2\theta_3^2/\theta_1^2 < \theta^2\theta_1^2\theta_3^2$ so that the smallest fixed point gives the limiting probability ratio for the negative boundary condition and the largest fixed point gives the limiting probability ratio for the positive boundary condition.

We have thus proven the following theorem:

Theorem 1: *For the Ising model with ternary and binary interactions in Hamiltonian (2), and with zero external field, the PR-domain is the region of phase transition.*

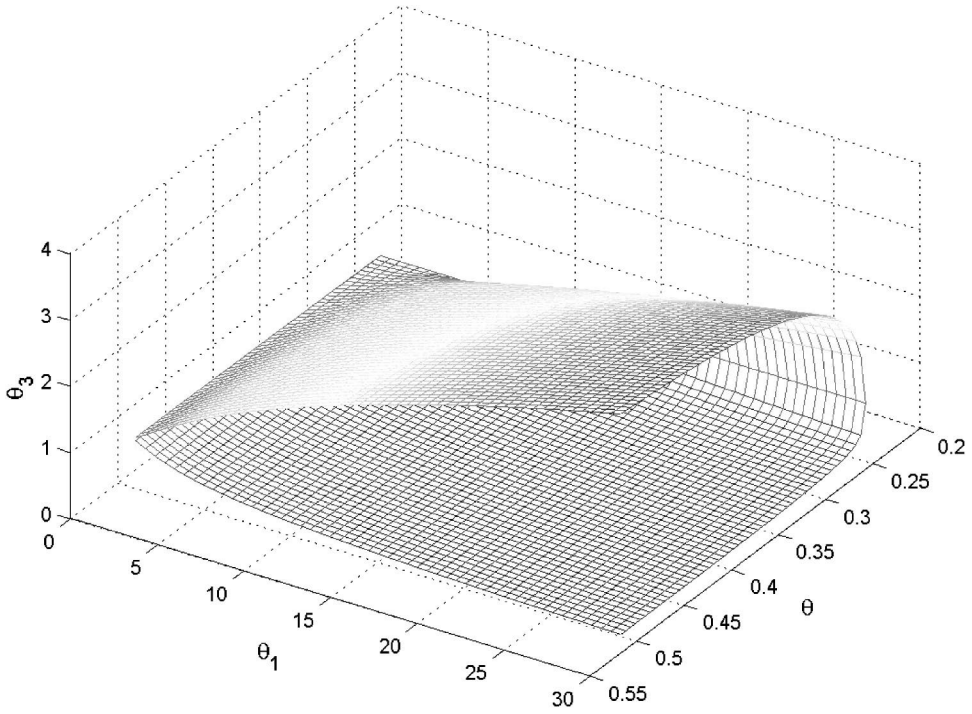

FIG. 4. For all $(\theta_1, \theta, \theta_3)$ inside the surface, a phase transition occurs.

The particular case of this theorem for $J=0$ was proven in Ref. 5 and the theorem for $J_3=0$ was proven in Ref. 6.

For $q=3$, we have the following theorem:

Theorem 2: *For the Ising model (2) with* $J_3=h=0$ *and* $q=3$, *the curve* $\theta^*=3\theta_1/(\theta_1^2-2)$ *in the plane* (θ_1, θ) *is a critical curve for phase transitions, namely, for an arbitrary pair of parameters* (θ_1, θ) *above the critical curve the phase transition takes place and for any pair of parameters on or below the critical curve there occurs a single Gibbs state*.

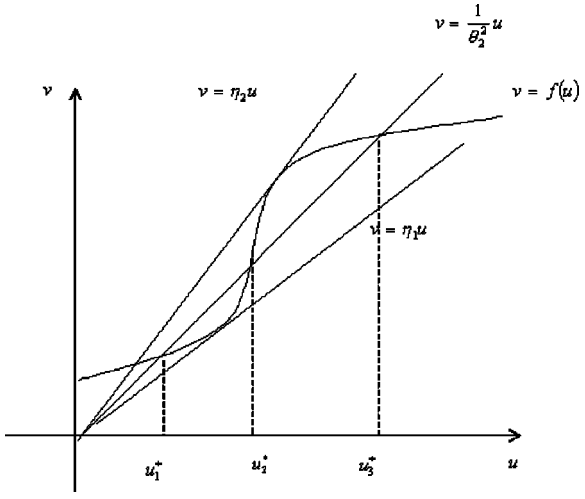

FIG. 5. The largest fixed point u_3^* and the smallest fixed point u_1^*.

IV. THE PERIODIC GIBBS MEASURES

The notions of periodic Gibbs measures, periodic Hamiltonians, and periodic configuration are introduced in Ref. 15. Let G_q be a free product of $q+1$ cyclic groups of order 2. According to Proposition 1 there is a one-to-one correspondence between the set of vertices V of the Cayley tree J^q and the group G_q. Let $\tilde{G}_q \subset G_q$ be a normal subgroup of finite index.

Definition 4: We say that $h=\{h_x : x \in G_q\}$ is $\tilde{G}_q$*-periodic if* $h_{yx}=h_x$ *for all* $x \in G_q$ *and* $y \in \tilde{G}_q$. *A Gibbs measure is called* $\tilde{G}_q$*-periodic if it corresponds to* $\tilde{G}_q$*-periodic function* h.

Observe that a translation-invariant Gibbs measure is G_q-periodic.

Let $\tilde{G}_2$ be the subgroup in G_2 consisting of all words of even length. Clearly, $\tilde{G}_2$ is a normal subgroup of index 2. In this section we consider $\tilde{G}_2$-periodic Gibbs measure, that is periodic measures of period 2 only. The description of periodic extreme Gibbs measures on some lattice models on the Cayley tree was given in Ref. 4. Here we consider a similar problem for our model. To describe the periodic Gibbs measure, we begin by investigating the following equation:

$$\psi(\psi(u)) = u,$$

where

$$\psi(u) = \frac{\theta_3^2\theta^2\theta_1^2u^2 + 2\theta_1 u + \theta^2\theta_3^2}{\theta^2\theta_1^2 + 2\theta_1\theta_3^2 u + \theta^2 u^2}.$$

Evidently the positive roots of the equation

$$\frac{\psi(\psi(u)) - u}{\psi(u) - u} = 0$$

describe the periodic nontranslation-invariant states.

As we are looking for positive roots this equation has a following form:

$$\theta^2\theta_1^2(\theta^2 + \theta^2\theta_1^2\theta_3^4 + 2\theta_1\theta_3^4)u^2 + \theta_3^2(\theta^4\theta_1^4 + 4\theta^2\theta_1^3 + 4\theta_1^2 - \theta^4)u + \theta_1^2\theta^2(\theta^2\theta_3^4 + \theta^2\theta_1^2 + 2\theta_1) = 0. \tag{12}$$

The discriminant Δ of (12) is equal to

$$\Delta = -4\theta^6\theta_1^5(\theta^2\theta_1 + 2)\theta_3^8 + A\theta_3^4 - 4\theta^6\theta_1^5(\theta^2\theta_1 + 2),$$

where

$$A = (-3\theta_1^8 - 6\theta_1^4 + 1)\theta^8 - 8\theta_1^3(\theta_1^4 + 1)\theta^6 - 8\theta_1^2(1 - \theta_1^4)\theta^4 + 32\theta_1^5\theta^2 + 16\theta_1^4.$$

Equation (12) has two positive roots if $\Delta > 0$ and $\theta^4(1-\theta_1^4) - 4\theta_1^3\theta^2 - 4\theta_1^2 > 0$. Evidently the last inequality is valid for $\theta_1 < 1$ and $\theta^2 > (2\theta_1/1-\theta_1^2)$.

The roots of equation $\Delta = 0$ with respect to θ_3, have the same sign. So they are positive when $A > 0$ and $A^2 - 64\theta^{12}\theta_1^{10}(\theta^2\theta_1+2)^2 > 0$, that is $A > 8\theta^6\theta_1^5(\theta^2\theta_1+2)$. After subsituting the value of A, the last inequality has the following form:

$$(1 - 3\theta_1^2)(\theta_1^2 + 1)^3\theta^8 - 8\theta_1^3(\theta_1^2 + 1)^2\theta^6 + 8\theta_1^2(\theta_1^4 - 1)\theta^4 + 32\theta_1^5\theta^2 + 16\theta_1^4 > 0.$$

Factorizing the left hand side, we have

$$(1 - 3\theta_1^2)(\theta_1^2 + 1)\left(\theta^2 - \frac{2\theta_1}{1 - 3\theta_1^2}\right)\left(\theta^2 - \frac{2\theta_1}{1 + \theta_1^2}\right)^2\left(\theta^2 + \frac{2\theta_1}{1 + \theta_1^2}\right) > 0.$$

This inequality has a solution when $1-3\theta_1^2 > 0$ and it follows that $\theta^2 > 2\theta_1/(1-3\theta_1^2)$ is the corresponding solution. Evidently from condition $\theta^2 > 2\theta_1/(1-3\theta_1^2)$ we have condition $\theta^2 > 2\theta_1/(1 - \theta_1^2)$. Thus if $\theta_1 < 1/\sqrt{3}$ and $\theta^2 > 2\theta_1/(1-3\theta_1^2)$, then the equation $\Delta = 0$ with respect to θ_3 has two

positive roots θ_3^* and θ_3^{**} where $\theta_3^* < \theta_3^{**}$. In this case Eq. (12) has 2 positive roots when $\theta_1 < 1/\sqrt{3}$, $\theta^2 > 2\theta_1/(1-3\theta_1^2)$ and $\theta_3^* < \theta_3 < \theta_3^{**}$.

Therefore, the following theorem is proven:

Theorem 3: *For an Ising model (2) with zero external field, a phase transition occurs for arbitrary* $(\theta, \theta_1, \theta_3)$ *such that* $0 < \theta_1 < 1/\sqrt{3}$, $\theta^2 > 2\theta_1/(1-3\theta_1^2)$ *and* $\theta_3^* < \theta_3 < \theta_3^{**}$, where θ_3^* *and* θ_3^{**} *are the positive solutions of the equation* $\Delta = 0$.

Similarly, we have found the following assertion for the same model with $q=3$:

Theorem 4: *For an Ising model (2) with* $J_3 = h = 0$ *and* $q=3$, *for* $\theta_1 < 1/\sqrt{2}$, *the curve* $\theta^* = 3\theta_1/(1-2\theta_1^2)$ *in the plane* (θ_1, θ) *is a critical curve for phase transitions, such that for an arbitrary pair of parameters* (θ_1, θ) *above the critical curve the phase transition takes place.*

V. THE PROOF OF EXISTENCE OF PHASE TRANSITIONS FOR NONZERO EXTERNAL FIELD

Here we solve the problem of phase transition for Ising model (2) for arbitrary external magnetic field h when $J_3 = 0$. Then the Eq. (9) is reduced to the equation

$$u = \theta_2^2 \frac{\theta^2\theta_1^2u^2 + 2\theta_1 u + \theta^2}{\theta^2\theta_1^2 + 2\theta_1 u + \theta^2 u^2}. \tag{13}$$

First of all, we prove the following lemma which is a generalization of Proposition 10.7 in Ref. 13.

Lemma: The equation

$$\frac{1}{\theta_2^2} \cdot u = \frac{\theta^2\theta_1^2u^2 + 2\theta_1 u + \theta^2}{\theta^2\theta_1^2 + 2\theta_1 u + \theta^2 u^2} \tag{14}$$

(*with* $u > 0$) *has a unique solution if* $\theta \leqslant \sqrt[4]{4/(\theta_1^2+1)}$.

If $\theta > \sqrt[4]{4/(\theta_1^2+1)}$, *then there are numbers* $\eta_1(\theta,\theta_1), \eta_2(\theta,\theta_1)$ *with* $0 < \eta_1(\theta,\theta_1) < \eta_2(\theta,\theta_1)$ *such that Eq. (14) has three roots, when* $\eta_1(\theta,\theta_1) < 1/\theta_2^2 < \eta_2(\theta,\theta_1)$; *it has two roots if either* $1/\theta_2^2 = \eta_1(\theta,\theta_1)$ *or* $1/\theta_2^2 = \eta_2(\theta,\theta_1)$ *and a unique solution if* $1/\theta_2^2 \in [\eta_1(\theta,\theta_1), \eta_2(\theta,\theta_1)]$.

The numbers $\eta_i, i = 1,2$ *are defined from the formula below:*

$$\eta_i(\theta,\theta_1) = \frac{1}{u_i} \cdot \frac{\theta^2\theta_1^2u_i^2 + 2\theta_1 u_i + \theta^2}{\theta^2\theta_1^2 + 2\theta_1 u_i + \theta^2 u_i^2},$$

where u_1, u_2 *are the solutions of the following equation:*

$$\theta_1^2\theta^4u^4 + 4\theta_1\theta^2u^3 + (3\theta^4 - \theta^4\theta_1^4 + 4\theta_1^2)u^2 + 4\theta_1\theta^2u + \theta_1^2\theta^4 = 0. \tag{15}$$

Proof: We first define

$$f(u) = \frac{\theta^2\theta_1^2u^2 + 2\theta_1 u + \theta^2}{\theta^2\theta_1^2 + 2\theta_1 u + \theta^2 u^2}.$$

It is easy to check that there is more than one solution to (14) if and only if there is at least one solution to the equation $x \cdot f'(x) = f(x)$ which is the same as

$$\theta_1^2\theta^4u^4 + 4\theta_1\theta^2u^3 + (3\theta^4 - \theta^4\theta_1^4 + 4\theta_1^2)u^2 + 4\theta_1\theta^4u + \theta_1^2\theta^4 = 0.$$

It is a symmetric one. So, after substitution of $u + (1/u) = t$, it reduces to the following:

$$\theta_1^2\theta^4t^2 + 4\theta_1\theta^2t - [(\theta^4(\theta_1^4 + 2\theta_1^2 - 3) - 4\theta_1^2)] = 0.$$

This equation has a positive root larger than 2 and, respectively, Eq. (14) has two positive roots u_1 and u_2, when $\theta_1^2 > 3$ and $\theta^2 > 2\theta_1/(\theta_1^2-3)$. Solving the inequality

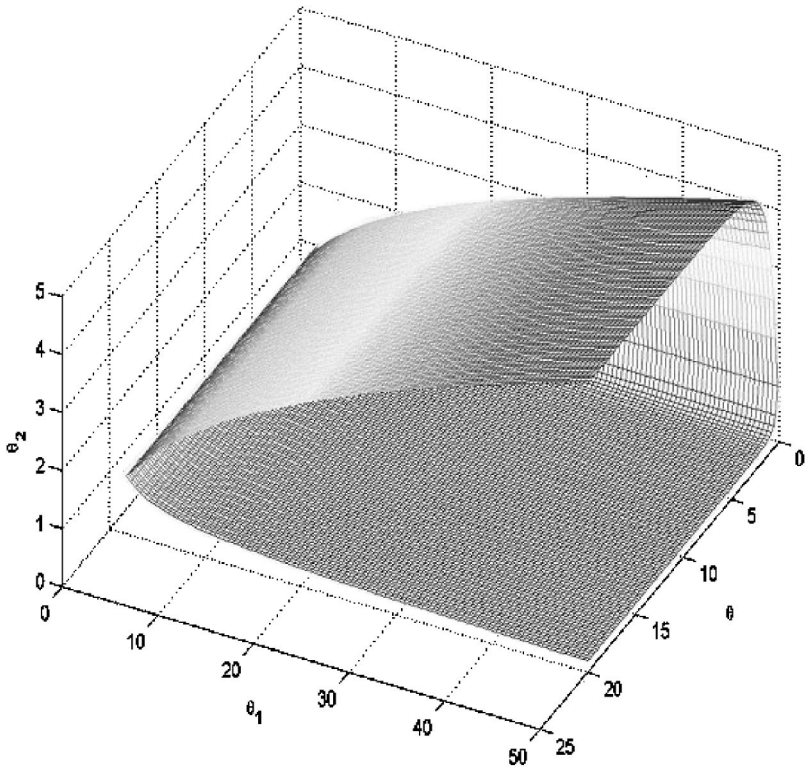

FIG. 6. For all $(\theta_1, \theta, \theta_2)$ inside the surface, a phase transition occurs.

$$\frac{2\theta_1\theta^2 + \sqrt{4\theta_1^2\theta^4 + \theta_1^2\theta^4[\theta^4(\theta_1^4 + 2\theta_1^2 - 3) - 4\theta_1^2]}}{\theta_1^2\theta^4} > 2,$$

we have

$$\theta^4(\theta_1^2 - 3)(\theta_1^2 + 1) - 8\theta^2\theta_1 - 4\theta_1^2 > 0.$$

Evidently $\theta_1^2 > 3$. Now solving this quadratic inequality with respect to θ^2, we have $\theta^2 > 2\theta_1/(\theta_1^2 - 3)$.

Since u_1 and u_2 are solutions of the equation $u^2 - tu + 1 = 0$, so $u_1 \cdot u_2 = 1$ and then $\eta_1(\theta, \theta_1) \cdot \eta_2(\theta, \theta_1) = 1$.

Theorem 5: *For Ising model (2) with $J_3 = 0$ and nonzero external magnetic field, a phase transition occurs when $\theta_1^2 > 3$, $\theta^2 > 2\theta_1/(\theta_1^2 - 3)$ and for θ_2 which satisfies the following inequalities:*

$$\eta_1(\theta, \theta_1) < \theta_2^2 < \eta_2(\theta, \theta_1),$$

where $\eta_1(\theta, \theta_1)$ and $\eta_2(\theta, \theta_1)$ are defined in the Lemma above.

Proof: According to the Lemma, Eq. (14) has three positive different roots u_1^*, u_2^*,and u_3^*. It is easy to show diagramatically (see Fig. 5) that if $0 < u_1 < u_1^*$, u_n in Eq. (3) will monotonically increase to u_1^*, the smallest root of Eq. (14). For value $u_1^* < u_1 < u_2^*$, u_n will decrease monotonically to u_1^*. For value $u_2^* < u_1 < u_3*$, u_n will monotonically increase to u_3^*. Finally if $u_1 > u_3^*$, u_n will decrease monotonically to u_3^*. Therefore, the roots u_1^* and u_3^* of Eq. (14) are two stable fixed points of the recurrent equation (3). The smallest (resp. largest) fixed point gives the limiting probability ratio for the negative (resp. positive) boundary. Hence the theorem is proven.

In Fig. 6, it is shown that the surface such that for all $(\theta_1, \theta, \theta_2)$ inside it, the conditions of Theorem 5 are valid.

VI. CONCLUSIONS

From Theorem 1 and Theorem 5, it follows that in the class of the translation-invariant state, a phase transition occurs when $\theta_1 > 1$, that is, the model (2) is a ferromagnetic one with respect to the binary interaction J_1 of the nearest neighboring vertices, namely $J_1 > 0$. From Theorem 3, it follows that in the case of nontranslation-invariant periodic state with period 2, a phase transition occurs when $\theta_1 < 1$, that is, the model (2) is an antiferromagnetic one with respect to the same binary interactions J_1, namely $J_1 < 0$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 9 SEPTEMBER 2004

Finite size universe or perfect squash problem

Ludwik Turko[a)]
Institute of Theoretical Physics, University of Wrocław, Pl. Maksa Borna 9, 50-204 Wrocław, Poland

(Received 21 October 2003; accepted 21 June 2004; published 17 August 2004)

We give a physical notion to all self-adjoint extensions of the operator id/dx in the finite interval. It appears that these extensions realize different nonunitary equivalent representations of CCR and are related to the momentum operator viewed from different inertial systems. This leads to the generalization of Galilei equivalence principle and gives a new insight into the quantum correspondence rule. It is possible to get transformation laws of the wave function under Galilei transformation for any scalar potential. This generalizes the mass superselection rule. There is also given a new and general interpretation of a momentum representation of the wave function. It appears that consistent treatment of this problem leads to the time-dependent interactions and to the abrupt switching-off of the interaction. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1782671]

I. INTRODUCTION

A square well potential, although this is the simplest analytically solvable quantum model, can be used as a tool to investigate more involved quantum peculiarities. It was used recently for such different phenomena as quantum fractals,[1,2] quantum chaos[3] or wave-function revivals.[4,5] It can also be used as an approximation to experimentally realized semiconductor quantum well lasers or micromaser cavities with atomic rubidium.[6,7]

The Schrödinger equation with a square well potential can also be considered as a model of a quantum squash. An infinite well corresponds to perfectly rigid and perfectly resistant side walls. A finite square well potential corresponds to perfectly rigid but not perfectly resistant side walls—a high energy squash ball breaks through the wall. A physicist is here like a passive player. He or she [=(s)he] can use a racket only as a measurement apparatus—to register the energy or the momentum of the ball.

A simplicity of the model may be misleading. A closer inspection (see, e.g., Refs. 8–10) shows that the infinite potential well has mathematical traps which, when neglected, lead to contradictions or misinterpreted results.

The aim of this paper is to study physical consequences of different self-adjoint extensions of the "momentum" operator for a quantum squash. The "momentum" means here the differential operator $-i\hbar\nabla$. In the case of square integrable functions on $\mathbb{R}^n$ $(n=1,2,3)$ this operator is self-adjoint—so it is interpreted as the momentum operator. A situation is much more involved for a particle in a box. There are infinitely many self-adjoint extensions of the "momentum" operator. Different extensions correspond to different boundary conditions of functions from the domain of the operator and they have different spectra. A question arises which of these extensions is the physical momentum operator and what are physical notions of other self-adjoint extensions of the operator $-i\hbar\boldsymbol{\nabla}$?

It will be shown that all those self-adjoint extensions have physical meanings. They are closely related to the Galilei transformed reference frames moving with different velocities with respect to the primary frame. The primary frame is chosen as the frame with a time-independent

[a)]Electronic mail: turko@ift.uni.wroc.pl

potential. This means that our squash play does not move on the squash field. When (s)he changes this passive strategy and starts to run (with a constant velocity of course) then (s)he observes shifted momenta of the squash ball. This picture is in a perfect agreement with a physical "classical" intuition. It appears also that when (s)he solves corresponding Schrödinger equation then a transformed wave function behaves according to projective representations of the Galilei group.

A role of projective representations of the Galilei group was well established long ago.[11–16] All results were then obtained with Galilei-invariant potentials. For one particle this was equivalent to a free-particle case. It appears that basic results, the Bargmann superselection rule including, can be reproduced for any potential.

Finally, we are going to clarify the momentum representation puzzle. Let us consider a squash player confined to the finite region bounded by perfectly rigid and perfectly resistant side walls. For the player this squash-room is like a finite Universe. The spectrum of the momentum operator is discrete in this Universe. Since according to basic rules of quantum mechanics the only possible results of the momentum measurement are eigenvalues of the corresponding observable the momentum distribution should be a discrete one. However, there is a common procedure (see, e.g., Refs. 17 and 18) to take the Fourier integral transform of the wave function. This Fourier transform is interpreted as the momentum representation. This inconsistency was also observed in Ref. 8 but authors did not push the problem further.

One can show that both momentum representations have well established physical interpretations, although both describe different physical situations. The Fourier integral transformation of the wave function is simply related to the abrupt switch-off of the potential. As the infinite square well potential can be used as a model for the perfect squash so the Fourier integral of the harmonic oscillator wave function can be used for the quantum sling theory.

We begin by consideration of the notion of momentum distributions. It appears that a momentum distribution of the wave function understood as a Fourier transform is directly related to the solution of Schrödinger equation with a time-dependent interaction. The Fourier transform $\Phi(\vec{p},t)$ of the wave function $\Psi(\vec{r},t)$ is the probability amplitude to measure at time $t>0$ the momentum $\vec{p}$ when an interaction was switch-off at $t=0$. This gives also a new insight into a David–Goliath fight, as is presented in Sec. II B.

In Sec. III some necessary mathematical preliminaries are given. These are related to self-adjoint extensions of differential operators id/dx and d^2/dx^2. This material does not pretend to give a new insight into the problem, but collects some mathematical facts not always known to the physical community. An analysis of stationary solutions of the infinite square well potential is given as an example in Sec. III A.

Section IV deals with a physical interpretation of self-adjoint extensions of the operator $-id/dx$ in the Hilbert space of square integrable functions on a finite interval. First an analysis of the notion of the quantum momentum observable is performed. An operator can be identified with the physical momentum only if it transforms under Galilei transformation similarly to the classical momentum. This assumption allows one to add physics to all self-adjoint extensions of the operator $-id/dx$. These extensions correspond to momenta seen by moving observers from different inertial systems. It will be shown that those different extensions realize different nonunitary equivalent representations of Canonical Commutation Relations.

A natural problem which arises at that moment is to find how different moving observers see quantum mechanics from their systems. It is well known since the papers of Bargmann, Inönu and Wigner[11,12] that the free Schrödinger equation is Galilei invariant provided that wave function transforms under a projective representation of the Galilei group. Section V deals with this problem and generalizes a concept of Galilean covariance to any scalar potential. Now, a problem of the momentum distribution is reexamined. Solutions of the infinite potential well are taken as examples. It appears that momentum distributions are more tricky as it seemed before. In particular, a mathematical identity,

$$\sin x = \frac{1}{2i}(e^{ix} - e^{-ix}),$$

is not so obvious in a quantum word. This is explained in Sec. V C.

Final conclusions are given in Sec. VI.

II. MOMENTUM DISTRIBUTIONS

It is common knowledge that there is the discrete energy spectrum of a quantum particle placed in an infinite square well potential. A one-dimensional potential of the form

$$U(x) = \begin{cases} 0 & \text{for } 0 \leqslant x \leqslant a, \\ \infty & \text{for } x \text{ everywhere else,} \end{cases} \tag{1}$$

with boundary conditions

$$\psi(0) = \psi(a) = 0, \tag{2}$$

leads to the solutions

$$\psi_N(x) = \begin{cases} \sqrt{\frac{2}{a}} \sin \frac{N\pi}{a} x & \text{for } 0 \leqslant x \leqslant a, \\ 0 & \text{for } x \text{ everywhere else,} \end{cases} \tag{3}$$

where N is an arbitrary positive integer.

Corresponding energy levels are

$$E_N = \frac{\pi^2 \hbar^2}{2ma^2} N^2. \tag{4}$$

Let us consider the Fourier integral of the wave function (3),

$$\tilde{\psi}_N(k) = \frac{1}{\sqrt{2\pi}} \int_0^a dx \psi_N(x) e^{-ikx}. \tag{5}$$

One gets

$$\tilde{\psi}_N(k) = -\sqrt{\pi a} \frac{2N}{a^2k^2 - N^2\pi^2} e^{-iak/2} \begin{cases} i \sin \frac{ak}{2} & \text{for } N \text{ even,} \\ \cos \frac{ak}{2} & \text{for } N \text{ odd.} \end{cases} \tag{6}$$

This mathematical expression is usually (see, e.g., Refs. 17 and 18 and a lot of other textbooks) interpreted as the physical momentum (with $p = \hbar k$) representation of the wave function. According to such an interpretation the probability distribution of the measurement of the momentum yielding a result between p and $p+dp$ is

$$\mathcal{P}_N(p) = \frac{4\pi a \hbar^3 N^2}{(a^2p^2 - \hbar^2 N^2 \pi^2)^2} \begin{cases} \sin^2 \frac{ap}{2\hbar} & \text{for } N \text{ even,} \\ \cos^2 \frac{ap}{2\hbar} & \text{for } N \text{ odd.} \end{cases} \tag{7}$$

This gives an average value of the momentum equal to zero, and an average value of the squared momentum is

$$\langle p^2\rangle_N = \int_{-\infty}^{+\infty} dp p^2 \mathcal{P}_N(p) = \frac{N^2\pi^2\hbar^2}{a^2}. \tag{8}$$

This is in agreement (on average) with (4). This is, however, not an answer for the question about the squash ball momentum. Besides that, there is a question about the energy conservation: how is it possible to get any value of the momentum in the state with a given value of the energy (4)?

For the player in h(is)er finite Universe $0 \leqslant x \leqslant a$ the only allowed values of a momentum are those which are eigenvalues of the corresponding self-adjoint observable. Using the trivial identity

$$\psi_N(x) = \sqrt{\frac{2}{a}}\,\sin\frac{N\pi}{a}x = \frac{1}{2i}\sqrt{\frac{2}{a}}(e^{(i\pi N/a)x} - e^{-(i\pi N/a)x}), \tag{9}$$

one gets a simple conclusion that allowed values of momenta are $\pm N\pi\hbar/a$. This is of course in perfect agreement (not only on average) with (4).

Such kinds of contradictions led recently to the conclusion[8] that the Fourier integral "is just a mathematically equivalent version of the same object, *not* the momentum representation wave function."

As we will see later, the use of Eq. (9) as a plane waves superposition is an oversimplification of the problem. There is, however, a surprisingly simple answer to a question about the physical notion of Eq. (6).

A. General momentum distribution

Let us consider a time-dependent Hamiltonian,

$$\hat{H} = \begin{cases} \dfrac{\hbar^2}{2m}\Delta + U(\vec{r}) & \text{for } t \leqslant 0, \\ -\dfrac{\hbar^2}{2m}\Delta & \text{for } t > 0. \end{cases} \tag{10}$$

Let ψ be any solution of the Schrödinger equation,

$$i\hbar\frac{\partial\psi}{\partial t} = -\frac{\hbar^2}{2m}\Delta\psi + U(\vec{r})\psi.$$

A general form of the free Schrödinger equation is a wave packet,

$$\int d^3p g(\vec{p}) e^{-i(p^2/2m\hbar)t} e^{(i/\hbar)\vec{p}\cdot\vec{r}}.$$

A function

$$\Psi(\vec{r},t) = \begin{cases} \psi(\vec{r},t) & \text{for } t \leqslant 0, \\ \displaystyle\int d^3p g(\vec{p}) e^{-i(p^2/2m\hbar)t} e^{(i/\hbar)\vec{p}\cdot\vec{r}} & \text{for } t > 0, \end{cases} \tag{11}$$

is a solution of the Schrödinger equation

$$i\hbar\frac{\partial\Psi}{\partial t} = \hat{H}\Psi,$$

and the wave function $\Psi(\vec{r},t)$ is continuous at $t=0$. This continuity condition gives

$$\psi(\vec{r},0) = \int d^3p g(\vec{p}) e^{(i/\hbar)\vec{p}\cdot\vec{r}}. \tag{12}$$

If a function ψ is a stationary solution then

$$\psi_E(\vec{r},t) = \phi_E(\vec{r}) e^{-(iE/\hbar)t},$$

with ϕ_E satisfying a stationary Schrödinger equation

$$-\frac{\hbar^2}{2m}\Delta\phi_E + U(\vec{r})\phi_E = E\phi_E.$$

Equation (12) now gives

$$\phi_E(\vec{r}) = \int d^3p g(\vec{p}) e^{(i/\hbar)\vec{p}\cdot\vec{r}}. \tag{13}$$

So we have gotten a general interpretation of the Fourier transform of a wave function. This gives the momentum distribution of a particle which was influenced by a potential and at time $t=0$ was suddenly freed. There is no question here about the energy conservation because of the time-dependency of the Hamiltonian (10).

Let us take as an example a well known Biblical story.

B. How Goliath was defeated by David

David's sling can be considered as a two-dimensional quantum rotator with a potential,

$$U(\vec{r}) = \frac{1}{2}m\omega^2(x^2+y^2).$$

Stationary solutions corresponding to the energy

$$E_{n_1,n_2} = \hbar\omega(n_1+n_2+1)$$

are given by

$$\phi_{n_1,n_2}(x,y) = C_{n_1,n_2} e^{-(m\omega/2\hbar)(x^2+y^2)} H_{n_1}\left(x\sqrt{\frac{m\omega}{\hbar}}\right) H_{n_2}\left(y\sqrt{\frac{m\omega}{\hbar}}\right). \tag{14}$$

If Goliath were hit directly by a stone still on a cord then he would absorb an impact energy E_{n_1,n_2}. But if a stone was freed from the sling then its momentum distribution was given by the Fourier transform of the function (14). So the probability distribution to have a stone with a momentum between p and $p+dp$ is proportional to

$$e^{-(p_x^2+p_y^2)/m\omega\hbar} H_{n_1}^2\left(\frac{p_x}{\sqrt{m\omega\hbar}}\right) H_{n_2}^2\left(\frac{p_y}{\sqrt{m\omega\hbar}}\right). \tag{15}$$

The corresponding impact energy is $p^2/2m$, in general, different from E_{n_1,n_2}. It is easy to check that it is more probable to get the impact energy *lower* than E_{n_1,n_2}. However there is a finite, although exponentially decreasing, probability that a high momentum stone would be thrown. One should notice that such an effect is impossible for a classical (i.e., not-quantum) sling. An exponentially small probability was not a problem in the considered case taking into account David's Protector. The crucial point was here a quantum nature of the sling.

III. MATHEMATICAL PRELIMINARIES

A cornerstone of quantum mechanics is a precise mathematical interpretation to the notion of observables. To each observable there corresponds a self-adjoint operator in the Hilbert state.[19] For unbounded symmetric operators there was a nontrivial problem to find all self-adjoint extensions but it was solved long ago.[20–22] To give a careful mathematical definition of operators related to observables is not a matter of a mathematical pedantry. Even in the simplest case of one dimensional infinite square well a lack of precision leads to obvious paradoxes.[9]

Let us consider a differential operator $-id/dx$ in the Hilbert space $L_2(0,a)$. Since

$$\int_0^a dx \bar{f}\frac{dg}{dx} = \bar{f}g|_0^a - \int_0^a dx \frac{d\bar{f}}{dx} g,$$

there are infinitely many self-adjoint extensions of the operator $-id/dx$. These extensions are parametrized by a continuous parameter $\sigma \in [0, 2\pi)$ and are defined on domains

$$\mathcal{D}_\sigma = \{f : f(a) = e^{i\sigma} f(0)\}. \tag{16}$$

The corresponding eigenvalues are

$$\lambda_n^{(\sigma)} = \frac{\sigma}{a} + \frac{2\pi n}{a}, \tag{17}$$

and normalized eigenfunctions,

$$f_n^{(\sigma)}(x) = \begin{cases} \dfrac{1}{\sqrt{a}} e^{i(\sigma/a)x} e^{i(2\pi n/a)x} & \text{for } 0 \leqslant x \leqslant a, \\ 0 \quad \text{for } x \text{ everywhere else}, \end{cases} \tag{18}$$

where $n = 0, \pm 1, \pm 2, \ldots$.

Self-adjoint operators,

$$\hat{p}_{(\sigma)} = -i\hbar \frac{d}{dx},$$

defined on the domains $\mathcal{D}_\sigma$ will henceforth be called the σ-momentum operator. Standard solutions of the infinite potential well take as the "physical momentum" the operator $\hat{p}_{(0)}$ and other extensions are simply rejected. We are going to show that other σ-momenta have an also well established physical meaning.

To consider the energy operator one should look for a self-adjoint extension of the operator d^2/dx^2. Here the situation is more involved. It was shown[23,24] that domains of self-adjoint extensions are given by a set of boundary conditions,

$$\alpha_{11} f(0) + \beta_{11} f(a) - \alpha_{12} f'(0) - \beta_{12} f'(a) = 0, \tag{19a}$$

$$\alpha_{21} f(0) + \beta_{21} f(a) - \alpha_{22} f'(0) - \beta_{22} f'(a) = 0, \tag{19b}$$

with coefficients α_{ij} and β_{kl} satisfying

$$\alpha_{11}\bar{\alpha}_{12} - \alpha_{12}\bar{\alpha}_{11} = \beta_{11}\bar{\beta}_{12} - \beta_{12}\bar{\beta}_{11}, \tag{20a}$$

$$\alpha_{21}\bar{\alpha}_{22} - \alpha_{22}\bar{\alpha}_{21} = \beta_{21}\bar{\beta}_{22} - \beta_{22}\bar{\beta}_{21}. \tag{20b}$$

In the case of the infinite potential well (1) a natural choice is to impose on the wave functions boundary conditions

$$f(0) = f(a) = 0, \tag{21a}$$

which are consistent with the continuity of the wave function. This choice corresponds to coefficients α_{ij} and β_{kl},

$$\alpha_{11} = 1, \quad \beta_{11} = -1, \quad \alpha_{12} = 0, \quad \beta_{12} = 0, \tag{21b}$$

$$\alpha_{21} = 1, \quad \alpha_{22} = 0, \quad \beta_{21} = 0, \quad \beta_{22} = 0. \tag{21c}$$

This means that functions satisfying boundary conditions (21a) form a domain $\mathcal{D}_{\Pi}$ of the self-adjoint extension of the operator d^2/dx^2. In the case of a particle on a circle a natural choice is to impose on the wave functions boundary conditions

$$f(0) = f(a), \quad f'(0) = f'(a). \tag{22a}$$

This choice corresponds to coefficients α_{ij} and β_{kl},

$$\alpha_{11} = 1, \quad \beta_{11} = -1, \quad \alpha_{12} = 0, \quad \beta_{12} = 0, \tag{22b}$$

$$\alpha_{21} = 0, \quad \alpha_{22} = 1, \quad \beta_{21} = 0, \quad \beta_{22} = -1. \tag{22c}$$

It is remarkable that the intersection of all admissible domains of σ-momenta is

$$\bigcap_{\sigma} \mathcal{D}_{\sigma} = \{f : f(a) = f(b) = 0\} = \mathcal{D}_{\Pi}. \tag{23}$$

This property makes the extension (21a) exceptional, at least from the point of view of momentum operators. A kinetic term d^2/dx^2 with this domain is well defined in (not *on*!) domains of all σ-momenta.

$\mathcal{D}_{\Pi}$ is a dense set in the Hilbert space $L_2(0,a)$ as the domain of a self-adjoint operator. This set is too small, however, to define on it a self-adjoint extension of the operator id/dx. But the property (23) together with the general theorem,[25] *any function from the domain of a self-adjoint operator $\mathcal{A}$ can be expanded in a uniformly convergent series of eigenfunctions of this operator*, allows us to write the following corollary.

Corollary 1: *Any energy eigenfunction (3) can be expanded in a uniformly convergent series of eigenfunctions of any σ-momentum.*

We also have the following corollary.

Corollary 2: *σ-momentum eigenfunctions (18) cannot be represented as uniformly convergent series of energy eigenfunctions.*

Both corollaries can be stated as follows.

In the infinite potential well σ-momentum representations of stationary states are always uniformly convergent. Energy representations of σ-momentum eigenfunctions are not uniformly convergent.

Let us make a mathematical exercise to calculate the following.

A. σ-momentum representation of stationary states

We have

$$\sqrt{\frac{2}{a}} \sin\frac{N\pi}{a}x = e^{i(\sigma/a)x}\frac{1}{\sqrt{a}}\sum_{n=-\infty}^{+\infty} c_n(\sigma)e^{i(2\pi n/a)x}. \tag{24}$$

Coefficients $c_n(\sigma)$ are given here as

$$\frac{\sqrt{2}}{a}\int_0^a dx\, e^{-i(\sigma/a+2\pi n/a)x}\sin\frac{\pi N}{a}x=\pi N\sqrt{2}\frac{e^{-i\sigma}(-1)^N-1}{(\sigma+2\pi n)^2-\pi^2N^2}. \tag{25}$$

It is convenient to discuss cases of even and odd N separately.

If $N=2r$ we can write

$$c_n(\sigma)=-4i\pi r\sqrt{2}e^{-i(\sigma/2)}\frac{\sin\frac{\sigma}{2}}{(\sigma+2\pi n)^2-4\pi^2r^2}. \tag{26}$$

A special care is needed when the nominator of this expression is equal to zero. For $\sigma=0$ one gets then

$$c_n(0)=\frac{1}{i\sqrt{2}}\begin{cases}1 & \text{for } n=r,\\ -1 & \text{for } n=-r,\\ 0 & \text{in other cases.}\end{cases} \tag{27}$$

After substitution to Eq. (24) this gives a consistency check,

$$\psi_{2r}(x)=\frac{1}{2i}\sqrt{\frac{2}{a}}(e^{i(2\pi r/a)x}-e^{-i(2\pi r/a)x}). \tag{28}$$

For nonzero σ we have

$$\psi_{2r}(x)=-4\pi ir\sqrt{\frac{2}{a}}e^{-i(\sigma/2)}e^{i(\sigma/a)x}\sin\frac{\sigma}{2}\sum_{n=-\infty}^{+\infty}\frac{e^{i(2\pi r/a)x}}{(\sigma+2\pi n)^2-4\pi^2r^2}. \tag{29}$$

If $N=2r+1$ we can write Eq. (25) as

$$c_n(\sigma)=-2\pi(2r+1)\sqrt{2}e^{-i(\sigma/2)}\frac{\cos\frac{\sigma}{2}}{(\sigma+2\pi n)^2-\pi^2(2r+1)^2}. \tag{30}$$

For $\sigma=\pi$ one gets similarly, like in Eq. (27),

$$c_n(\pi)=\frac{1}{i\sqrt{2}}\begin{cases}1 & \text{for } n=r,\\ -1 & \text{for } n=-r-1,\\ 0 & \text{in other cases.}\end{cases} \tag{31}$$

This gives, similarly like in Eq. (28),

$$\psi_{2r+1}(x)=\frac{1}{2i}\sqrt{\frac{2}{a}}(e^{i[2(r+1)\pi/a]x}-e^{-i[2(r+1)\pi/a]x}). \tag{32}$$

For $\sigma\neq\pi$ we have

$$\psi_{2r+1}(x)=-2\pi(2r+1)\sqrt{\frac{2}{a}}e^{-i(\sigma/2)}e^{i(\sigma/a)x}\cos\frac{\sigma}{2}\sum_{n=-\infty}^{+\infty}\frac{e^{i(2\pi n/a)x}}{(\sigma+2\pi n)^2-\pi^2(2r+1)^2}. \tag{33}$$

All these mathematical expansions from Eqs. (28), (29), (32), and (33), would have a physical meaning with a satisfactory physical interpretation of σ-momenta. This will be done in the next section. It should be now noted that the choice $\sigma=0$ gives expansions of the potential well stationary states into momentum eigenfunctions. The momentum spectrum is given then by Eq. (17) with $\sigma=0$. An elusively simple equation (9) *is not always* a momentum expansion because $N\pi/a$ are allowed momenta only for even N. Only in such cases a stationary state can be visual-

ized as the superposition of two waves with opposite momenta. For odd N the momentum expansion is

$$\psi_{2r+1}(x) = -2\pi(2r+1)\sqrt{\frac{2}{a}}\sum_{n=-\infty}^{+\infty}\frac{e^{i(2\pi n/a)x}}{4\pi^2n^2-\pi^2(2r+1)^2}, \tag{34}$$

with a much richer structure.

A more detailed analysis of this problem will be performed in Sec. V C.

IV. MOMENTUM SEEN FROM THE MOVING REFERENCE FRAME

We are going to find the physical meaning of different self-adjoint extensions of the operator $-id/dx$. It is a standard procedure to identify this operator with the translation generator. It is not enough, however, to relate this to the physical momentum. The same differential operator can be also related to a component of the angular momentum even for the same boundary conditions.

Let us consider as an example the operator $-i\hbar d/dx$ in the Hilbert space $L_2(0,2\pi)$ defined on the domain

$$\mathcal{D}_0 = \{f: f(2\pi) = f(0)\}. \tag{35}$$

A spectrum of this operator,

$$\lambda_n^{(0)} = n\hbar, \tag{36}$$

and normalized eigenfunctions,

$$f_n^{(0)}(x) = \frac{1}{\sqrt{2\pi}}e^{inx}, \tag{37}$$

are the same both for the momentum in the interval $(0,2\pi)$ as for the third component of the angular momentum when the variable $x \in (0,2\pi)$ is interpreted as an angular variable.

To get a momentum operator proper transformation properties are needed, specific for the corresponding classical variable. Let us consider two coordinate systems $\mathcal{O}(x,t)$ and $\mathcal{O}'(\zeta,\tau)$ related by the Galilei transformation

$$x = \zeta + V\tau; \quad t = \tau. \tag{38}$$

The following discussion is based on the "passive point of view" when the same system is observed by different observers A in $\mathcal{O}$ and A' in $\mathcal{O}'$ having different relations to the system.

Let $-i\hbar d/dx$ be a momentum operator in the system $\mathcal{O}$ and let f_λ be an eigenfunction of the momentum operator associated with the eigenvalue λ. The momentum operator should fulfill the following conditions.

(i) A momentum operator has the same structure in all inertial systems, i.e.,

$$-i\hbar d/d\zeta \text{ is a momentum operator in the coordinate system } \mathcal{O}'. \tag{39a}$$

(ii) A physical state with a defined momentum in one inertial system has a definite momentum in any inertial system, i.e.,

$$f_\lambda \text{ is transformed into } \tilde{f}_{\tilde{\lambda}}: -i\hbar\frac{d\tilde{f}_{\tilde{\lambda}}}{d\zeta} = \tilde{\lambda}\tilde{f}_{\tilde{\lambda}}. \tag{39b}$$

(iii) Eigenvalues of the momentum operator transform under the Galilei transformation like their classical counterparts, i.e.,

$$\tilde{\lambda} = \lambda - mV. \tag{39c}$$

We make an ansatz,

$$\tilde{f}_{\lambda}(\zeta,\tau) = e^{ig(\zeta,\tau)} f(\zeta + V\tau). \tag{40}$$

This gives

$$-i\hbar\frac{d\tilde{f}}{d\zeta} = \hbar\frac{dg}{d\zeta}e^{ig}f - i\hbar e^{ig}\frac{df_{\lambda}}{dx} = \hbar\frac{dg}{d\zeta}\tilde{f} + \lambda\tilde{f} = \tilde{\lambda}\tilde{f}. \tag{41}$$

The correspondence rule (39c) gives

$$\hbar\frac{dg}{d\zeta} + \lambda = \lambda - mV. \tag{42}$$

A general solution has a form

$$g(\zeta,\tau) = -\frac{mV}{\hbar}\zeta + T(\tau), \tag{43}$$

where T is an arbitrary function of the variable τ.

Starting from the consistency conditions (39a)–(39c) we have obtained a general transformation rule for momentum eigenfunctions under the Galilei transformation

$$\tilde{f}_{\lambda-mV}(\zeta,\tau) = e^{-i((mV/\hbar)\zeta - T(\tau))} f_{\lambda}(\zeta + V\tau). \tag{44}$$

Because of properties of self-adjoint operators this rule gives transformation rules for any vector from the Hilbert space.

If the momentum operator has a point spectrum, then its eigenfunctions form a base in a Hilbert space. This is a case for the $L_2(0,a)$ space. Any element u of this space can be expanded as

$$u(x) = \sum_{\lambda} c_n \tilde{f}_{\lambda}(x). \tag{45}$$

It follows from this that an observer from the Galilei transformed reference frame (38) sees this vector as

$$\tilde{u}(\zeta,\tau) = e^{-i(mV/\hbar\zeta - T(\tau))}\sum_{\lambda} c_n f_{\lambda}(\zeta + V\tau) = e^{-i(mV/\hbar\zeta - T(\tau))} u(\zeta + V\tau). \tag{46}$$

A function T is fixed by subsidiary conditions fulfilled by the function u. It will be shown in Sec. V that for one particle Schrödinger equation a function $T(\tau)$ has a form $-mV^2\tau/2$.

A result (46) can be easily generalized to the case of a continuous spectrum of the momentum operator. That is a standard mathematical procedure[21,22,26] equivalent to the replacement of the sum in Eq. (45) by the Fourier integral.

For the moment we restrict ourselves to the following.

A. Momentum inside the infinite potential well

The momentum observable "at rest" is $-i\hbar d/dx$ with the domain

$$\mathcal{D}_0 = \{f : f(a) = f(0)\}. \tag{47}$$

Boundary conditions in the moving reference frame $\mathcal{O}'(\zeta,\tau)$ are given at points $\zeta = -V\tau$ and $\zeta = -V\tau + a$. Using transformations rules given by Eqs (41) and (43) one gets the boundary conditions for the function $\tilde{f}$,

$$\tilde{f}(-V\tau + a, \tau) = e^{-i(mV/\hbar)a}\tilde{f}(-V\tau, \tau). \tag{48}$$

This gives us a direct interpretation of σ-momenta: *σ-momentum is the momentum observable measured by the observer moving with a velocity V such that*

$$\sigma = -\frac{mV}{\hbar}a \mod 2\pi. \tag{49}$$

To make the σ-momentum a real quantum mechanical momentum one should check the validity of Canonical Commutation Relations (CCR) of a momentum and a position operator in our system. In general, a problem of CCR on the finite interval is far from being obvious.[27] As opposed to the entire real line case where both position $\hat{X}$ and momentum $\hat{P}$ operators are unbounded, here the operator $\hat{X}$ is bounded in the Hilbert space $L_2(0,a)$ whereas the operator $\hat{P} = -i\hbar\partial$ is unbounded. This leads to technical troubles related to the domain $\mathcal{D}([\hat{X},\hat{P}])$ of the commutator $[\hat{X},\hat{P}]$. The domain where CCR are fulfilled is

$$\mathcal{D}(\hat{P}\hat{X}) \cap \mathcal{D}(\hat{X}\hat{P}), \tag{50}$$

where $\mathcal{D}(\hat{P}\hat{X})$ and $\mathcal{D}(\hat{X}\hat{P})$ are domains of operator products $\hat{P}\hat{X}$ and $\hat{X}\hat{P}$ correspondingly.

The domain $\mathcal{D}(\hat{P}\hat{X})$ is

$$\mathcal{D}(\hat{P}\hat{X}) = \{f : (\hat{X}f) \in \mathcal{D}(\hat{P})\}, \tag{51}$$

and the domain of the product $\hat{X}\hat{P}$ is equal here to the domain of the momentum operator because of the boundedness of the position operator.

For the σ-momentum $\hat{p}_{(\sigma)}$ the domain $\mathcal{D}_\sigma$ is given by (16). Then

$$\mathcal{D}([\hat{X},\hat{p}_{(\sigma)}]) = \{f : (\hat{X}f)(a) = e^{i\sigma}(\hat{X}f)(0)\} \cap \{f : f(a) = e^{i\sigma}f(0)\} = \{f : f(a) = f(b) = 0\}. \tag{52}$$

So CCR are realized on the dense domain in $L_2(0,a)$. This domain does not depend on the σ-realization of the momentum operator and coincides with the domain D_Π (23) of the energy operator.

Different σ-momenta, as corresponding to unitary nonequivalent projective representation of the Galilei group, correspond to different unitary nonequivalent representations of CCR although all are realized on the same dense domain D_Π.

Coming back to our quantum squash model: a player running with the velocity V sees a squash ball having σ-momentum. σ is given here by Eq. (49). H(is)er momentum eigenfunctions take on the form

$$\tilde{f}_n(\zeta,\tau) = e^{-i(mV/\hbar)\zeta}e^{i(2\pi n/a)(\zeta+V\tau)} = e^{(i/\hbar)(2\pi n/a - mV)\zeta}e^{i(2\pi n/a)V\tau}. \tag{53}$$

It is also interesting to look for solutions of the infinite potential well observed by a running player. This will be the subject of the next section.

V. SCHRÖDINGER EQUATION SEEN FROM THE MOVING REFERENCE FRAME

Let us consider a particle subjected to the influence of a time-dependent potential U. In the coordinate system $\mathcal{O}(x,t)$ the Schrödinger equation takes on the form

$$i\hbar\frac{\partial\Psi}{\partial t} = -\frac{\hbar^2}{2m}\frac{d^2\Psi}{\partial x^2} + U(x,t)\Psi. \tag{54}$$

This equation is obviously not Galilei-invariant unless the potential is a trivial constant. A typical procedure is to investigate physical consequences of the symmetry group starting from the symmetry-invariant equations. In the case of the Galilei (or Poincaré) group this leads to a free

particle wave function realizing a unitary representation of the group. For the Galilei group and the Schrödinger equation one gets[11–14] that only nontrivial projective representations are physical realizations of the symmetry.

We are going to consider a more general approach based on the equivalence of all inertial coordinate systems. This Galilean equivalence principle demands that all laws of physics take the same form in different frames connected by the Galilei (or Poincaré for relativistic theory) transformations. We derive from the postulates that "the Galilei transformation is true" and "the Schrödinger equation is true" the transformation law of wave function for any scalar potential. So we do what Galilei would do, "if Galilei had know quantum mechanics."[28]

An observer in the reference frame $\mathcal{O}'(\zeta,\tau)$ sees the potential U as

$$\tilde{U}(\zeta,\tau)=U(\zeta+V\tau,\tau). \tag{55}$$

It is assumed here that the potential is a scalar with respect to the Galilei transformation (38). The equivalence principle demands that a wave function $\tilde{\Psi}(\zeta,\tau)$ viewed by an observer A' in the coordinate system $\mathcal{O}'$ satisfies the Schrödinger equation

$$i\hbar\frac{\partial\tilde{\Psi}}{\partial\tau}=-\frac{\hbar^2}{2m}\frac{d^2\tilde{\Psi}}{\partial\zeta^2}+\tilde{U}(\zeta,\tau)\Psi. \tag{56}$$

An ansatz,

$$\tilde{\Psi}(\zeta,\tau)=e^{iu(\zeta,\tau)}\Psi(\zeta+V\tau,t), \tag{57}$$

gives

$$\frac{\partial\tilde{\Psi}}{\partial\tau}=ie^{iu}\frac{\partial u}{\partial\tau}\Psi+e^{iu}\frac{\partial\Psi}{\partial x}V+e^{iu}\frac{\partial\Psi}{\partial\tau},$$

$$\frac{\partial\tilde{\Psi}}{\partial\zeta}=ie^{iu}\frac{\partial u}{\partial\zeta}\Psi+e^{iu}\frac{\partial\Psi}{\partial x},$$

$$\frac{\partial^2\tilde{\Psi}}{\partial\zeta^2}=ie^{iu}\frac{\partial^2u}{\partial\zeta^2}\Psi-e^{iu}\left(\frac{\partial u}{\partial\zeta}\right)^2\Psi+2ie^{iu}\frac{\partial u}{\partial\zeta}\frac{\partial\Psi}{\partial x}+e^{iu}\frac{\partial^2\Psi}{\partial x^2}.$$

We see that Eq. (56) is fulfilled if

$$i\hbar\frac{\partial\Psi}{\partial x}V=-\frac{\hbar^2}{2m}2i\frac{\partial u}{\partial\zeta}\frac{\partial\Psi}{\partial x}, \tag{58a}$$

and

$$-\hbar\frac{\partial u}{\partial\tau}=\frac{\hbar^2}{2m}\frac{m^2}{\hbar^2}V^2. \tag{58b}$$

A solution of Eqs (58a) and (58b) takes on the form

$$u(\zeta,\tau)=-\frac{m}{\hbar}V\zeta-\frac{mV^2}{2\hbar}\tau+C(V). \tag{59}$$

So wave functions in different inertial reference frames connected by the Galilei transformation (38) are connected (up to the constant phase factor e^{iC}) by the relation

$$\tilde{\Psi}(\zeta,\tau)=e^{-(i/\hbar)(mV\zeta+(mV^2/2)\tau)}\Psi(x,t). \tag{60}$$

We have obtained the same factor as obtained by Bargmann[12] for a free Schrödinger particle subjected to the Galilei transformation. This factor leads to the mass-superselection rule which is mathematically due to the fact that projective (ray) representations of the Galilei group are not unitary equivalent to the usual representations.[13]

A. Stationary states seen from the moving reference frame

Let us consider now a particle in a static potential $U(x)$ described by a stationary wave function,

$$\Psi_n(x,t)=\psi_n(x)e^{-(i/\hbar)E_nt}, \tag{61}$$

$$-\frac{\hbar^2}{2m}\frac{d^2\psi_n}{dx^2}+U(x)\psi_n(x)=E_n\psi_n(x). \tag{62}$$

According to the general rule (60), this state when viewed by a moving observer from the reference frame $\mathcal{O}'(\zeta,\tau)$ is described by a wave function,

$$\tilde{\Psi}_n(\zeta,\tau)=e^{-(i/\hbar)mV\zeta}\psi_n(\zeta+V\tau)e^{-(i/\hbar)(E_n+mV^2/2)\tau}. \tag{63}$$

One should note that this is not an energy eigenstate. This follows, at least formally, from the fact that Galilei transformed potential $\tilde{U}(\zeta,\tau)$ is now time dependent. The energy, however, is still conserved. To check this let us calculate an average value of the energy for the state described by the wave function (63). It is given as

$$\langle E\rangle_n=i\hbar\int d\zeta\tilde{\Psi}_n^*(\zeta,\tau)\frac{\partial}{\partial\tau}\tilde{\Psi}_n(\zeta,\tau). \tag{64}$$

Taking into account that solutions of Eq. (62) are real one obtains then

$$\langle E\rangle_n=E_n+\frac{mV^2}{2}. \tag{65}$$

This result seems to be surprising even in the simplest case of a free particle with the momentum p. Taking into account that the energy $E=p^2/2m$ and the momentum is Galilei transformed to $p-mV$ one should expect in Eq. (65) a subsidiary term of the form $-pV$. However, this not the case. Energy $p^2/2m$ is "produced" by a particle with the momentum $\pm p$. A real stationary state is a superposition of two waves corresponding to opposite momenta $\pm p$. They are Galilei transformed to $p\mp mV$ correspondingly and give contributions to the energy $p^2/2m+mV^2/2\mp pV$. These are additive contributions to the total energy so terms $\pm pv$ cancel each other. This remark gives a perfect agreement of Eq. (65) with our classical intuition although, as we will see later, does not always agree with a quantum reality.

B. Infinite potential well seen from the moving reference frame

When the potential well (1) is observed from the moving reference frame $\mathcal{O}'$ it is seen as

$$U(\zeta+V\tau)=\begin{cases}0 & \text{if } -V\tau\leqslant\zeta\leqslant a-V\tau,\\ \infty & \text{if } \zeta\notin\langle -V\tau,a-V\tau\rangle.\end{cases} \tag{66}$$

The wave function satisfies boundary conditions

$$\tilde{\Psi}(-V\tau,\tau)=\tilde{\Psi}(a-V\tau,\tau)=0. \tag{67}$$

The solution (63) has now a form

$$\tilde{\Psi}_N(\zeta,\tau)=\begin{cases}\sqrt{\dfrac{2}{a}}e^{-(i/\hbar)mV\zeta}\sin\dfrac{N\pi}{a}(\zeta+V\tau)e^{-(i/\hbar)((\pi^2\hbar^2/2ma^2)N^2+mV^2/2)\tau} & \text{if } -V\tau\leqslant\zeta\leqslant a-V\tau,\\ 0 \quad \text{if } \zeta\notin\langle -V\tau, a-V\tau\rangle.\end{cases} \tag{68}$$

where $N=1,2,\ldots$.

This solution can be written in the region $-V\tau\leqslant\zeta\leqslant a-V\tau$ as a superposition of two plain waves:

$$\tilde{\Psi}_N(\zeta,\tau)=\psi_{(+),N}(\zeta,\tau)-\psi_{(-),N}(\zeta,\tau), \tag{69a}$$

where

$$\psi_{(+),N}(\zeta,\tau)=\frac{1}{2i}\sqrt{\frac{2}{a}}e^{\frac{i}{\hbar}(N\pi\hbar/a-mV)\zeta}e^{-(i/2m\hbar)(N\pi\hbar/a-mV)^2\tau}, \tag{69b}$$

$$\psi_{(-),N}(\zeta,\tau)=\frac{1}{2i}\sqrt{\frac{2}{a}}e^{-(i/\hbar)(N\pi\hbar/a+mV)\zeta}e^{-(i/2m\hbar)(N\pi\hbar/a+mV)^2\tau}. \tag{69c}$$

This decomposition confirms our semiclassical understanding of the quantum problem. Alas, our semiclassical understanding does not quite agree with the mathematics behind the scene.

C. Moving observer measures momentum in the well

A measurement of an observable is mathematically equivalent to the spectral decomposition of the wave function into corresponding eigenfunctions. A general mathematical decomposition into momentum eigenfunctions was done in Sec. III A. A physical problem "what are possible momenta measured by a moving observer in the infinite potential well?," will be solved when h(is)er wave function $\tilde{\Psi}_N(\zeta,\tau)$ (68) will be expanded into h(is)er momentum eigenfunctions $\tilde{f}_n(\zeta,\tau)$ (53),

$$\tilde{\Psi}_N(\zeta,\tau)=\sum_{n=-\infty}^{+\infty}c_n^{(N)}(\tau)\tilde{f}_n(\zeta,\tau). \tag{70}$$

Coefficients $c_n^{(N)}$ are calculated as

$$\begin{aligned}c_n^{(N)}(\tau)&=\frac{\sqrt{2}}{a}e^{-\frac{i}{\hbar}((\pi^2\hbar^2/2ma^2)N^2+mV^2/2)\tau}\int_{-V\tau}^{-V\tau+a}d\zeta\,\sin\frac{N\pi}{a}(\zeta+V\tau)e^{-i(2\pi n/a)(\zeta+V\tau)}\\ &=e^{(-i/\hbar)(\pi^2\hbar^2/2ma^2)N^2+mV^2/2\tau}\times\begin{cases}-\dfrac{2N\sqrt{2}}{(4n^2-N^2)\pi} & \text{for odd } N,\\ \pm\dfrac{1}{i\sqrt{2}} & \text{for even } N, n=\pm N/2,\\ 0 \quad \text{for even } N, n\neq N/2.\end{cases}\end{aligned} \tag{71}$$

This gives *for even N* a simple expression, consistent with a semiclassical approach,

$$\tilde{\Psi}_N(\zeta,\tau)=\frac{1}{2i}\sqrt{\frac{2}{a}}[e^{(i/\hbar)(\pi N\hbar/a-mV)\zeta}e^{-(im/2\hbar)(V-\pi\hbar N/ma)^2\tau}-e^{-(i/\hbar)(\pi N\hbar/a+mV)\zeta}e^{-(im/2\hbar)(\pi\hbar N/ma+V)^2\tau}]. \tag{72}$$

The case *for odd N* is more involved and the momentum expansion (70) takes on the form

$$\tilde{\Psi}_N(\zeta,\tau)=\frac{2}{\pi N}\sqrt{\frac{2}{a}}e^{-i(mV/\hbar)\zeta}e^{-(i/\hbar)((\pi^2\hbar^2/2ma^2)N^2+mV^2/2)\tau}$$
$$-\frac{2N}{\pi}\sqrt{\frac{2}{a}}e^{-i(mV/\hbar)\zeta}e^{-(i/\hbar)((\pi^2\hbar^2/2ma^2)N^2+mV^2/2)\tau}\sum_{n=1}^{+\infty}\frac{1}{4n^2-N^2}[e^{i(2\pi n/a)(\zeta+V\tau)}+e^{-i(2\pi n/a)(\zeta+V\tau)}]. \tag{73a}$$

This can be also written as

$$\tilde{\Psi}_N(\zeta,\tau)=\frac{4N}{\pi}\sqrt{\frac{2}{a}}\sum_{n=-\infty}^{+\infty}\frac{e^{-i(\pi^2\hbar/2ma^2)(N^2-4n^2)\tau}}{N^2-4n^2}\,e^{(i/\hbar)(2\pi\hbar n/a-mV)\zeta}e^{-(im/2\hbar)(2\pi\hbar n/ma-V)^2\tau}, \tag{73b}$$

where contributions from stationary plane waves states are explicitly selected. We shall call from this time on a "stationary plane wave state" a plain wave with an explicit time dependence, i.e., a function of the form

$$e^{-i(p^2/2m\hbar)t}e^{(i/\hbar)\vec{p}\cdot\vec{r}}. \tag{74}$$

There is a striking difference in the behavior of odd- and even-N states $\tilde{\Psi}_N$. Any even N state is a superposition of two stationary plane waves states, while an odd-N state cannot be represented as a superposition of stationary plane wave states. An underlying mechanism is the same which made difference between Eqs (28) and (34)—allowed momenta in the infinite well are not always the same as formal arguments of the energy eigenfunctions (3).

This can be changed with a change of boundary conditions (2). If they are replaced by periodic-type conditions (22a),

$$\psi(0)=\psi(a),\quad \psi'(0)=\psi'(a), \tag{75}$$

then eigenfunctions of the Hamiltonian are

$$\sqrt{\frac{2}{a}}\sin\frac{2N\pi}{a}x,\quad \sqrt{\frac{2}{a}}\cos\frac{2N\pi}{a}x. \tag{76}$$

We see that for such boundary conditions allowed momenta in the infinite well are always the same as formal arguments of energy eigenfunctions and any state (76) is a superposition of two plane waves with the definite momenta. So, in a sense, a situation of periodic boundary conditions is "better" than for boundaries (3).

It is easy to create a "worse" situation. To this end it is enough to take antiperiodic-type boundary conditions,

$$\psi(0)=-\psi(a),\quad \psi'(0)=-\psi'(a). \tag{77}$$

Then eigenfunctions of the Hamiltonian are

$$\sqrt{\frac{2}{a}}\sin\frac{(2N+1)\pi}{a}x, \quad \sqrt{\frac{2}{a}}\cos\frac{(2N+1)\pi}{a}x. \tag{78}$$

For such boundary conditions allowed momenta in the infinite well are never the same as formal arguments of energy eigenfunctions and there is no state (78) as a superposition of two plane waves with the definite momenta.

VI. CONCLUSIONS

We performed a careful analysis of the notion of an observable related to the physical momentum. For the beginning one should identify a self-adjoint operator connected to this notion. In quantum mechanics defined on a finite interval a situation is more complicated than in the case of an unrestricted theory on $\mathbb{R}$ because there is a continuum (16) of self-adjoint extensions of the differential operator id/dx.

If you want to go beyond an argument that $-i\hbar d/dx$ is a physical momentum when it is assigned to the letter "p," and it is an angular momentum when assigned to the sign "l_z," then appropriate transformation properties must be taken into account. In a similar manner, three numbers can be a finite three-elements set or components of a three dimensional vector. A choice depends on assumed transformation properties with respect to rotations. In the momentum case, transformation properties are given (in a nonrelativistic approach) by the Galilei group as was done by conditions (39a)–(39c). All this together, supplemented with the equivalence of all inertial coordinate systems, led to different realizations of the momentum operator in the finite volume—in Sec. V C. Those different realizations have different spectra. This is quite obvious from the physical point of view.

Such an approach, based on a generalized correspondence principle (39a)–(39c), gave a physical interpretation of all self-adjoint extensions of the operator $-i\hbar d/dx$. It was also shown that those different extensions realize different nonunitary equivalent representations of CCR on the universal dense domain.

Obtained results can be generalized for a three dimensional rectangular box and the momentum operator $-i\hbar\nabla$.

Results of Sec. V show that important physical properties, related to transformation laws of wave functions, can be obtained under a much weaker assumption than was done in the past. A condition of Galilei invariance, widely used to obtain the mass superselection rule, is replaced by a (generalized) Galilei equivalence principle. This allows us to go beyond a free particle theory and gives results also for an arbitrary scalar potential.

The transformation law (63) can be treated as a realization of different self-adjoint extensions of the Hamiltonian. This is clearly visible in the infinite potential well where Eqs. (19) and (20) give different self-adjoint extensions of the operator d^2/dx^2. However, a situation here is not so simple as in the case of momentum operators. A structure of self-adjoint extensions of the operator d^2/dx^2 is much richer than in the case of the momentum operator. Only a part of those extensions can be related to the Galilei transformations and these are done by Eq. (68).

Results related to the momentum distribution, obtained in Secs. II and V C, need some comments. We have shown that the Fourier integral of the stationary wave function is directly related to the time-dependent dynamics given by Eq. (10). This gives a direct interpretation of that, which is usually called the "momentum representation of the wave function" or the "wave function in momentum space." This interpretation is different from what is usually found in textbooks. A simple statement that a wave function in momentum space,

$$\Phi(\vec{p},t) = \int d^3r \Psi(\vec{r},t) e^{-(i/\hbar)\vec{p}\cdot\vec{r}}, \tag{79}$$

is a probability amplitude to measure the momentum $\vec{p}$ at time t *is simply not true!* It sometimes reasonable, for technical reasons, to use a momentum representation of the wave function but only because of its mathematical equivalence to the wave function.

There is an exception in the "finite Universe" with dynamics defined on a finite interval. Let us introduce here two notions of momentum representation. The first is analogous to the previous one. You take the Fourier integral and you obtain a dynamics as in Eq. (10). This means that at $t=0$ all impenetrable walls vanish and you are left with a free particle. Such a situation is used in the HBT effect,[29] originally invented to determine the dimensions of distant astronomical objects. This method is widely used in high energy hadronic interaction to obtain information about the geometric properties of the source. Multi-pion and photon spectra provide precise information about reaction space time geometry in hadron–hadron and heavy ion collisions.[30,31]

Another concept of momentum representation—let us call it the "momentum distribution"—means to expand a wave function into stationary plane wave states (74). It was shown in Eq. (72) that this was possible for even-N states and impossible for odd-N states.

Such a momentum distribution in the "infinite Universe" would mean that

$$\Psi(\vec{r},t)=\int d^3p\Phi(\vec{p},t)e^{(i/\hbar)\vec{p}\cdot\vec{r}}e^{-i(p^2/2m\hbar)t}, \tag{80}$$

which is in general not possible.

(Received 4 November 2002; accepted 14 June 2004; published 17 August 2004)

By using the method of Helffer and Sjöstrand to construct Moyal projections, we extend the almost invariant subspace theory to the semiclassical context. Applications to the semiclassical limit for two component Klein–Gordon Hamiltonian are given. More precisely, under the conditions that the potential is analytic and its eigenvalues never cross we prove that the scattering matrix is block diagonal up to exponentially small errors. Also, we show how the existence of almost invariant subspaces leads to the existence of quasimodes with exponentially long lifetimes. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1782279]

I. INTRODUCTION

This paper is concerned with the semiclassical limit for matricial Klein–Gordon operators. More precisely we consider the two component Klein–Gordon Hamiltonian, acting in $\mathcal{H}=L^2(\mathbf{R}^n)^{\oplus 2}=L^2(\mathbf{R}^n)\oplus L^2(\mathbf{R}^n)$,

$$H_\epsilon=(\sqrt{\epsilon^2\Delta+1}-1)\mathbf{1}_2+V(x), \tag{1.1}$$

where $V(x)$ is a 2×2 Hermitian matrix valued function. At the heuristic level, under the conditions that $V(x)$ is smooth enough and its eigenvalues never cross, one expects (much like in the Born–Oppenheimer approximation) that the spectral and scattering problems for (1.1) can be reduced, up to some small errors, to the corresponding ones for two "scalar" effective Hamiltonians. Although the semiclassical limit can be viewed as a perturbation theory, it is a highly singular one so perturbed invariant subspaces do not exist and then one has to look for *almost* invariant subspaces as in the case of singular perturbation theory or adiabatic expansions [see Nenciu (2002), Nenciu (1993)]. The aim of this paper is to substantiate the heuristic picture by showing that the almost invariant subspace theory developed in Nenciu (2002) can be extended to the case at hand and in this respect the present paper can be considered as a direct continuation of Nenciu (2002).

The key point of the theory is to construct orthogonal projections,

$$\Pi_\epsilon^{\,2}=\Pi_\epsilon=\Pi_\epsilon^*,$$

satisfying

$$\|[\Pi_\epsilon,H_\epsilon]\|\leqslant s(\epsilon), \tag{1.2}$$

with $s(\epsilon)$ as small as possible so that with respect to the decomposition

$$L^2(\mathbf{R}^n)^{\oplus 2}=\Pi_\epsilon(L^2(\mathbf{R}^n)^{\oplus 2})\oplus(1-\Pi_\epsilon)(L^2(\mathbf{R}^n)^{\oplus 2}),$$

H_ϵ takes an almost diagonal form

$$H_\epsilon = H_\epsilon^D + H_\epsilon^{OD},$$

where

$$H_\epsilon^D = \Pi_\epsilon H_\epsilon \Pi_\epsilon + (1-\Pi_\epsilon) H_\epsilon (1-\Pi_\epsilon),$$

$$H_\epsilon^{OD} = (1-2\Pi_\epsilon)[\Pi_\epsilon, H_\epsilon],$$

with

$$\|H_\epsilon^{OD}\| \leqslant s(\epsilon).$$

As well known, the natural framework for the semiclassical limit is the theory of pseudodifferential operators and indeed our construction of the almost invariant subspaces rely heavily on pseudodifferential operators techniques, more exactly on the construction of Moyal projections, i.e., of orthogonal projections in the algebra of formal symbols which (at the formal symbols level) commutes with the symbol of the Hamiltonian. There are at least two different methods of constructing Moyal projections [Helffer and Sjöstrand (1990), Emmrich and Weinstein (1996), Brummelhuis and Nourrigat (1999)] and we shall follow the method of Helffer and Sjöstrand (1990) which is close in spirit with the Rellich–Kato perturbation theory. Then we follow Nenciu (2002) to construct, out of the formal Moyal projection, a bona fide orthogonal projection which almost commutes with the Hamiltonian.

We use the existence of almost invariant subspaces to prove the following results on scattering and spectral theory for matricial Klein–Gordon Hamiltonian:

(i) Under appropriate analytic and decay conditions on the potential, the scattering operator has, up to exponentially small errors, a block diagonal structure. This means that a state prepared at $t \to -\infty$ to have zero lower component will have as $t \to \infty$ only an exponentially small lower component.

(ii) The *existence* and the control on the (exponentially long) lifetime of metastable states (quasimodes). More precisely, suppose that the diagonal part, H_ϵ^D has discrete spectrum of one of the "channels" embedded into the continuous spectrum of the other channel. Then the (small) off diagonal part H_ϵ^{OD} turns these bound (stable) states into metastable states whose time life is controlled by the size of H_ϵ^{OD}. Let us mention here that in many instances [see, e.g., Stefanov (1999)] one can make the connection with the resonances defined as poles of the resolvent of scattering operator. In the cases when this connection can be made this implies that the imaginary part of the resonances is exponentially small.

The content of the paper is as follows. In Sec. II we give, at a general heuristic level, the construction of almost invariant subspaces. The reason for this is that we expect the methods developed here to be relevant and lead to a systematic theory for a much broader class of problems such as Born–Oppenheimer approximation [see, e.g., Littlejohn and Weigert (1993), Hagedorn and Joye (2000), Hagedorn and Joye (2001)], dynamics of crystal electrons in weak external fields [see, e.g., Blount (1962), Nenciu (1991), Hövermann, Spohn, and Teufel (2001)], dynamics of Pauli–Fierz model [see Teufel and Spohn (2002)], semiclassical limit of the Dirac operator [see, e.g., Littlejohn (1993), Spohn (2000)], etc. [Indeed after this paper appeared in the preprint form the almost invariant subspaces framework of this paper has been used in some recent papers on these subjects: Martinez and Sordoni (2002), Panati, Spohn, and Teufel (2003), Sordoni (2003), Bolte and Glaser (2004). For a comprehensive review of all these new developements we send the interested reader to the recent monograph Teufel (2003).]

Section III contains the technicalities for the case of analytic matricial Klein–Gordon operators as well as the applications to spectral and scattering theory. The technicalities are somewhat heavy for two reasons. First, in order to check the power of the method, we want to push the estimations up to exponential order, i.e., [see (1.2)], $s(\epsilon) \sim e^{-ct/\epsilon}$. The reader interested only in powerlike errors can skip most ot the technicalities and only the elementary pseudodifferential

operators theory is needed [see Teufel (2003) for further discussion]. Second, the application to the scattering theory is somewhat subtle since the perturbed Hamiltonian is almost diagonal with repect to a *ϵ-dependent* decomposition while the free one is diagonal with respect to the *canonical* decomposition given by

$$P_0 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}. \tag{1.3}$$

Accordingly one must rotate the perturbed Hamiltonian so that the rotated one is almost diagonal with respect to the canonical decomposition and to prove that the rotation does not affect the scattering matrix. So besides the fact that one must prove that as $x \to \infty$ the rotated Hamiltonian approaches the free one sufficiently quick one needs also to prove that the rotation is close to the identity for states localized far away (see Remark II.4).

In the Appendix we collect, in an appropriate form, the results we need on pseudodifferential operators with analytic symbols. For a readable account of basic pseudodifferential operators theory we send the reader to Martinez (2002). Further details and references to pseudodifferential operators with matrix valued symbols can be found in Teufel (2003), Bolte and Glaser (2003, 2004).

We end with a few comments on earlier results on spectral and scattering theory for the matricial Klein–Gordon Hamiltonian in the semiclassical limit. Results on almost diagonal structure of the scattering matrix at *fixed* energy were obtained before in Nakamura (1994), Benchaou (1998), Benchaou and Martinez (1999), Martinez, Nakamura, and Sordoni (2002) both for Klein–Gordon and Schrödinger cases, by the method of phase space tunnelling developed by Martinez (1994) [see also Martin and Nenciu (1995) where almost invariant subspaces at fixed energies were constructed in the case of the one-dimensional Schrödinger operator, for energies above the potential barrier]. We would like to stress that aside from more restrictive conditions on the potential the results quoted above were proved *only* for nontrapping energies a condition which implies, in particular, the absence of resonances close to real axis and it is not valid in general at low energies (which are the most interesting from the physical point of view). Without entering the technicalities [we send the interested reader to Jecko (1998), Jecko (2004) for details and extended bibliography] we remind that an energy is nontrapping if *all* the trajectories of the corresponding classical system (i.e., the classical Hamiltonian is the symbol of the quantum Hamiltonian) are not bounded. Notice that at the heuristic level on intervals of trapping energies one expects bound states and/or quasimodes to exist. In some sense our results on the existence of quasimodes are extensions of the shape resonance theory to the matricial case. As for the scattering theory it seems that our result is the first one valid also for the trapping energies. In the same time it is weaker in the sense that involve an averaging over intervals of energies (see Sec. III for precise formulation and a heuristic discussion of its significance).

The results have been announced in Nenciu (2004).

II. GENERALITIES. MOYAL PROJECTIONS, ALMOST INVARIANT SUBSPACES AND BLOCK DIAGONALIZATION

We start by fixing some terminology and notations. In what follows, $x,\ \xi \in \mathbf{R}^n$, $n \geqslant 1$, $\epsilon \in [0, \epsilon_0]$, $\epsilon_0 > 0$, and $h(x,\xi;\epsilon)$ are C^∞, $m \times m$ Hermitian matrix valued functions on $\mathbf{R}^{2n} \times [0, \epsilon_0]$ [actually by adding the necessary technicalities one can consider the case when $h(x,\xi;\epsilon)$ are C^∞ self-adjoint operator valued functions]. If h and its derivatives satisfies suitable estimates (see Appendix), then associated to $h(x,\xi;\epsilon)$ one can consider the (essentially self-adjoint under appropriate conditions) operator H_ϵ obtained as the Weyl quantization of $h(x,\xi;\epsilon)$ (called the symbol of H_ϵ), i.e., for $\phi \in (S(\mathbf{R}^n))^{\oplus m}$,

$$(H_\epsilon \phi)(x) = (\mathrm{Op}^w_\epsilon(h)\phi)(x) = \left(\frac{1}{2\pi\epsilon}\right)^n \int e^{i[(x-y)\xi/\epsilon]} h\left(\frac{x+y}{2}, \xi; \epsilon\right) \phi(y) \mathrm{d}y\, \mathrm{d}\xi.$$

If $h(x,\xi;\epsilon)$ has an asymptotic expansion (as $\epsilon \to 0$)

$$h(x,\xi;\epsilon) \sim \sum_{j=0}^{\infty} h_j(x,\xi)\epsilon^j, \tag{2.1}$$

we say that $\Sigma_{j=0}^{\infty} h_j(x,\xi)\epsilon^j$ is the formal symbol of H_ϵ. Given another symbol b and denoting by $B_\epsilon = \mathrm{Op}_\epsilon^w(b)$, then as is well known [see Martinez (2002)], the operator multiplication corresponds to the Moyal product of symbols

$$H_\epsilon B_\epsilon = \mathrm{Op}_\epsilon^w(h\#b),$$

where $h\#b$ is given by the oscillatory integral

$$(h\#b)(x,\xi;\epsilon) = \frac{1}{2\pi\epsilon}^{2n} \int e^{i\varphi(x,y,v,\xi,\eta,\theta)/\epsilon} h\left(\frac{x+u}{2},\eta;\epsilon\right) b\left(\frac{x+v}{2},\theta;\epsilon\right) \mathrm{d}u\,\mathrm{d}v\,\mathrm{d}\eta\,\mathrm{d}\theta, \tag{2.2}$$

with $\varphi(x,y,v,\xi,\eta,\theta) = (\xi-\eta)(v-x)+(\xi-\theta)(x-v)$. At the level of formal symbols by expanding the oscillatory integral (2.2), one can obtain that $h\#b \sim \Sigma_{j=0}^{\infty}(h\#b)_j\epsilon^j$, where

$$(h\#b)_j(x,\xi) = \sum_{|\alpha|+|\beta|+k+l=j} \Gamma(\alpha,\beta)\partial_\xi^\alpha D_x^\beta h_k(x,\xi)\partial_\xi^\beta D_x^\alpha b_l(x,\xi) \tag{2.3}$$

and

$$\Gamma(\alpha,\beta) := \frac{(-1)^{|\beta|}}{\alpha!\beta!2^{|\alpha|}2^{|\beta|}}.$$

As already mentioned, we are looking for almost invariant subspace for H_ϵ in the semiclassical limit, $\epsilon \to 0$. The basic idea is to construct first Moyal projections, i.e., formal symbols

$$\pi(x,\xi;\epsilon) \sim \sum_{j=0}^{\infty} \pi_j(x,\xi;\epsilon)\epsilon^j \tag{2.4}$$

satisfying (at a formal series level)

$$\pi \sim \pi^* \sim \pi\#\pi, \tag{2.5}$$

$$\pi\#h - h\#\pi \sim 0 \tag{2.6}$$

[here by $\pi^*(x,\xi;\epsilon)$ we mean the adjoint of the matrix $\pi(x,\xi;\epsilon)$]. The proposition below says that one can always construct Moyal projections corresponding to isolated parts of the spectrum of the principal symbol $h_0(x,\xi)$ of $h(x,\xi;\epsilon)$,

$$h(x,\xi;\epsilon) = h_0(x,\xi) + \mathcal{O}(\epsilon). \tag{2.7}$$

Let $\sigma(x,\xi)$ be the spectrum of $h_0(x,\xi)$ and suppose that, for some $(x_0,\xi_0) \in \mathbf{R}^{2n}$,

$$\sigma(x_0,\xi_0) = \sigma_1(x_0,\xi_0) \cup \sigma_2(x_0,\xi_0),$$

$$\mathrm{dist}(\sigma_1(x_0,\xi_0),\sigma_2(x_0,\xi_0)) := \mathrm{d}(x_0,\xi_0) > 0. \tag{2.8}$$

Then by perturbation theory there exists a neighborhood $\mathcal{U}(x_0,\xi_0)$ of (x_0,ξ_0) such that, for $(x,\xi) \in \mathcal{U}(x_0,\xi_0)$ the spectrum of $h_0(x,\xi)$ is well separated, i.e., (2.8) is satisfied on $\mathcal{U}(x_0,\xi_0)$ with $\mathrm{d}(x,\xi) \geqslant \mathrm{d}(x_0,\xi_0)/2$, and there exists a contour Γ_{x_0,ξ_0} [not depending upon $(x,\xi) \in \mathcal{U}(x_0,\xi_0)$] enclosing $\sigma_1(x,\xi)$ and satisfying

$$\mathrm{dist}(\Gamma_{x_0,\xi_0},\sigma(x,\xi)) \geqslant \mathrm{d}(x_0,\xi_0)/2. \tag{2.9}$$

Proposition II.1: Suppose (2.8) holds true. Then, for $(x,\xi) \in \mathcal{U}(x_0,\xi_0)$, *there exist unique*

$\pi_j(x,\xi)$, $j=0,1,\ldots$, such that $\pi_0(x,\xi)$ is the spectral projection of $h_0(x,\xi)$ corresponding to $\sigma_1(x,\xi)$ and the formal symbol $\Sigma_{j=0}^{\infty}\pi_j(x,\xi)\epsilon^j$ satisfies (2.5) and (2.6).

The result in Proposition II.1 was found independently by different authors in different contexts and actually Proposition II.1 appeared many times in the literature, e.g., Helffer and Sjöstrand (1990), Emmrich and Weinstein (1996), Brummelhuis and Nourrigat (1999) [see also Sjöstrand (1993) where the earlier construction in Nenciu (1993) and Joye and Pfister (1993) of adiabatic projections corresponding to the case $h(x,\xi;\epsilon)=\xi+H_\epsilon(x)$ was obtained in the framework of the theory of pseudodifferential operators]. There are essentially two methods of proof. The first one, Nenciu (1993), Emmrich and Weinstein (1996), Brummelhuis and Nourrigat (1999), is a recurrent construction for π_j solving the equations coming from (2.5) and (2.6). The second one, Helffer and Sjostrand (1990), Sjöstrand (1993) is close in spirit to Rellich–Kato perturbation theory [see, e.g., Kato (1980)]: due to (2.9), for all $z\in\Gamma_{x_0,\xi_0}$, one can construct [see Robert (1987), Martinez (2002)] the parametrix

$$q(x,\xi;\epsilon,z)\sim\sum_{j=0}^{\infty}q_j(x,\xi;z)\epsilon^j,$$

satisfying (at a formal series level)

$$q\#(h-z)\sim(h-z)\#q\sim 1, \tag{2.10}$$

and then obtain $\pi_j(x,\xi)$ from Riesz formula for spectral projection,

$$\pi(x,\xi;\epsilon)=\frac{i}{2\pi}\int_{\Gamma_{x_0,\xi_0}}q(x,\xi;\epsilon,z)\mathrm{d}z, \tag{2.11}$$

i.e.,

$$\pi_j(x,\xi)=\frac{i}{2\pi}\int_{\Gamma_{x_0,\xi_0}}q_j(x,\xi;z)\mathrm{d}z. \tag{2.12}$$

In what follows, we shall use the second method since, on the one hand, it gives explicit formulas for π_j and, on the other hand, allows a much easier control on $\pi_j(x,\xi)$ and their derivatives than the recurrent construction [compare for example the estimations in Nenciu (1993) with those in Martinez and Nenciu (1995) in the adiabatic case].

Remarks:

II.1. If $h_0(x,\xi)$ has a part of the spectrum which remains isolated for all $(x,\xi)\in\mathbf{R}^{2n}$, then, from Proposition II.1, one obtains $\pi_j(x,\xi)$ defined on all $\mathbf{R}^{2n}$. Moreover $\pi_j(x,\xi)$ are C^∞ and if $h_j(x,\xi)$ are real analytic $\pi_j(x,\xi)$ are also real analytic.

II.2. It is known [Helffer and Sjöstrand (1990)] that the existence of $\pi(x,\xi)$ satisfying (2.5) and (2.6) is equivalent with the block diagonalization of $h(x,\xi;\epsilon)$ at a formal level [see, e.g., Nirenberg (1973), Taylor (1981)], i.e., with the existence of a formal symbol

$$u(x,\xi;\epsilon)\sim\sum_{j=0}^{\infty}u_j(x,\xi)\epsilon^j,$$

satisfying (at the formal symbol level)

$$u\#u^*\sim u^*\#u\sim 1$$

such that, setting

$$\tilde{h}:\sim u^*\#h\#u,$$

then

$$\pi_0 \# \tilde{h} - \tilde{h} \# \pi_0 \sim 0.$$

It is worth mentioning that the formal block diagonalization appeared also in the physical literature, see e.g., Blount (1962), Littlejohn and Weigert (1993) and references therein. Let us remark that, unlike π_j, u_j (and then u and $\overline{h}$) are not unique. A somewhat canonical choice is the one mimicking the reduction scheme of Rellich–Kato perturbation theory, i.e., writing $u(x,\xi;\epsilon)$ as the Sz–Nagy matrix [see (2.25)] corresponding to the pair $\pi(x,\xi;\epsilon)$, $\pi_0(x,\xi)$,

$$u \sim (\pi \# \pi_0 + (1-\pi) \# (1-\pi_0)) \# \left(1 + \sum_{j=1}^{\infty} \frac{(2j-1)!!}{2^j j!} (\pi - \pi_0)^{\#2j}\right).$$

Let us stress that Proposition II.1 gives $\pi(x,\xi;\epsilon)$ only at the formal symbol level, that is the series $\Sigma_{j=0}^{\infty} \pi_j(x,\xi)\epsilon^j$ is not convergent in general. As a consequence (2.5) and (2.6) do not imply the existence of a corresponding orthogonal projection which commutes with H_ϵ. However, by resummation [Martinez (2002)], there exist symbols $\hat{\pi}(x,\xi;\epsilon)$ [unique modulo $\mathcal{O}(\epsilon^\infty)$] which are asymptotically equivalent with the formal symbol $\Sigma_{j=0}^{\infty} \pi_j \epsilon^j$ and satisfy (2.5) and (2.6) [where now # means the Weyl product in (4.6)] up of errors smaller than any power of ϵ, i.e., (2.5) and (2.6) hold modulo $\mathcal{O}(\epsilon^\infty)$. In addition, the ressumation can be chosen (see Appendix) as to insure that $\hat{\pi}(x,\xi;\epsilon) = \hat{\pi}^*(x,\xi;\epsilon)$.

We turn now to the construction, out of the formal symbol $\Sigma_{j=0}^{\infty} \pi_j \epsilon^j$ of almost invariant subspaces for the H_ϵ. Suppose that $\pi_j(x,\xi)$ are globally defined on $\mathbf{R}^{2n}$ and are uniformly bounded together with their derivatives. Then, by resummation, one can obtain [unique up to $\mathcal{O}(\epsilon^\infty)$] $\hat{\pi}(x,\xi;\epsilon)$ which is also bounded together with its derivatives uniformly on $\mathbf{R}^{2n} \times [0, \epsilon_0]$, for some $\epsilon_0 > 0$. Then, by Calderon–Vaillancourt theorem (see Appendix),

$$\hat{\Pi}_\epsilon = \mathrm{Op}_\epsilon^w(\hat{\pi}(x,\xi;\epsilon)) \tag{2.13}$$

is bounded and satisfies

$$\hat{\Pi}_\epsilon^2 - \hat{\Pi}_\epsilon = \mathcal{O}(\epsilon^\infty), \quad \hat{\Pi}_\epsilon^* = \hat{\Pi}_\epsilon. \tag{2.14}$$

For applications to spectral and scattering theory one would like to construct almost invariant subspaces which amounts to construct out of π_j an orthogonal projection Π_ϵ,

$$\Pi_\epsilon^2 = \Pi_\epsilon = \Pi_\epsilon^*, \tag{2.15}$$

satisfying

$$\|[\Pi_\epsilon, H_\epsilon]\| \leqslant s(\epsilon) \tag{2.16}$$

with $s(\epsilon) \geqslant 0$ as small as possible [if the series in (2.4) is nonconvergent one cannot have in general $s(\epsilon) = 0$ in (2.16)]. Of course, such a construction is not unique and we shall follow the one of Nenciu (1993), Nenciu (2002). Since $\hat{\Pi}_\epsilon^2 - \hat{\Pi}_\epsilon = \mathcal{O}(\epsilon^\infty)$, for ϵ sufficiently small the spectrum of $\hat{\Pi}_\epsilon$ is concentrate near 0 and 1 and then one can define Π_ϵ by

$$\Pi_\epsilon = \frac{i}{2\pi} \int_{|z-1|=1/2} (\hat{\Pi}_\epsilon - z)^{-1} \, dz. \tag{2.17}$$

Obviously Π_ϵ given by (2.17) satisfies (2.15). By a straightforward computation [Nenciu (1993), Nenciu (2002)], it is easy to see that, for ϵ sufficiently small, we have

$$\|[\Pi_\epsilon, H_\epsilon]\| \leqslant 2\|[\hat{\Pi}_\epsilon, H_\epsilon]\|. \tag{2.18}$$

Since it turns out that (2.6) implies that

$$[\hat{\Pi}_\epsilon, H_\epsilon] = \mathcal{O}(\epsilon^\infty), \tag{2.19}$$

we obtain almost invariant subspace modulo $\mathcal{O}(\epsilon^\infty)$. It turns out that

$$\|\hat{\Pi}_\epsilon - \Pi_\epsilon\| = \mathcal{O}(\epsilon^\infty)$$

so Π_ϵ is close to a pseudodifferential operator [actually, the results in Dimassi and Sjöstrand (1999) implies that Π_ϵ is a pseudodifferential operator]. Moreover, under appropriate analyticity properties of $h(x,\xi;\epsilon)$, one can choose a resummation of the analytic formal symbol $\Sigma_{j=0}^\infty \pi_j(x,\xi)\epsilon^j$ (see Appendix) in order to obtain an almost invariant subspace modulo $\mathcal{O}(e^{-c/\epsilon})$ for some positive constant $c>0$ independent of ϵ, i.e., one can take $s(\epsilon)=Ce^{-c/\epsilon}$ in (2.16). With respect to the decomposition

$$L^2(\mathbf{R}^n)^{\oplus m} = \Pi_\epsilon(L^2(\mathbf{R}^n)^{\oplus m}) \oplus (1-\Pi_\epsilon)(L^2(\mathbf{R}^n)^{\oplus m}),$$

H_ϵ takes an almost diagonal form,

$$H_\epsilon = H_\epsilon^{\,D} + H_\epsilon^{\,OD}, \tag{2.20}$$

where

$$H_\epsilon^{\,D} = \Pi_\epsilon H_\epsilon \Pi_\epsilon + (1-\Pi_\epsilon)H_\epsilon(1-\Pi_\epsilon), \tag{2.21}$$

$$H_\epsilon^{\,OD} = (1-2\Pi_\epsilon)[\Pi_\epsilon, H_\epsilon], \tag{2.22}$$

with

$$\|H_\epsilon^{\,OD}\| \leqslant s(\epsilon). \tag{2.23}$$

If $\pi_0(x,\xi)=\pi_0(x)$ does not depend upon ξ (as is the case of the Klein–Gordon or Schrödinger operators) then $\Pi_0=\mathrm{Op}_\epsilon^w(\pi_0)$ is just a multiplication matrix valued operator. Since

$$\lim_{\epsilon\to 0}\|\Pi_\epsilon - \Pi_0\| = 0, \tag{2.24}$$

for sufficiently small ϵ one can write down the Sz–Nagy transformation matrix corresponding to the pair Π_ϵ, Π_0 [see Kato (1980)],

$$U_\epsilon = (1-(\Pi_\epsilon-\Pi_0)^2)^{-1/2}(\Pi_\epsilon\Pi_0 + (1-\Pi_\epsilon)(1-\Pi_0)) \tag{2.25}$$

having the properties

$$U_\epsilon^{\,*}U_\epsilon = U_\epsilon U_\epsilon^{\,*} = 1, \tag{2.26}$$

$$\Pi_\epsilon = U_\epsilon \Pi_0 U_\epsilon^{\,*}. \tag{2.27}$$

From (2.20)–(2.23), (2.26), and (2.27) one gets that

$$\tilde{H}_\epsilon = U_\epsilon^{\,*} H_\epsilon U_\epsilon \tag{2.28}$$

has an almost diagonal form $\tilde{H}_\epsilon=\tilde{H}_\epsilon^{\,D}+\tilde{H}_\epsilon^{\,OD}$ with respect to the ϵ independent decomposition

$$L^2(\mathbf{R}^n)^{\oplus m} = \Pi_0(L^2(\mathbf{R}^n)^{\oplus m}) \oplus (1-\Pi_0)(L^2(\mathbf{R}^n)^{\oplus m})$$

with

$$\|\tilde{H}_\epsilon^{OD}\| \leqslant s(\epsilon). \tag{2.29}$$

Further, since $\mathbf{R}^n$ is contractible, one can find $Q(x)$ (see Lemma III.5 for an explicit construction in our case) unitary in $\mathbf{C}^n$ and satisfying

$$\Pi_0(x) = Q(x)P_0Q^*(x)$$

with $P_0 = \left(\begin{smallmatrix} \mathbf{1}_p & 0 \\ 0 & 0 \end{smallmatrix}\right)$ where $p = \dim \Pi_0(x)$ (which does not depend upon x) and then

$$H_\epsilon^{\text{eff}} = Q\tilde{H}_\epsilon Q^* \tag{2.30}$$

has an almost block diagonal form with respect to the *canonical* decomposition

$$L^2(\mathbf{R}^n)^{\oplus m} = L^2(\mathbf{R}^n)^{\oplus p} \oplus L^2(\mathbf{R}^n)^{\oplus(m-p)}.$$

In this way, up to a unitary transformation and errors of order $s(\epsilon)$ the study of H_ϵ in $L^2(\mathbf{R}^n)^{\oplus m}$ is reduced to the study of two operators in $(L^2(\mathbf{R}^n))^{\oplus p}$ and $(L^2(\mathbf{R}^n))^{\oplus(m-p)}$, respectively. If one assumes that all the m eigenvalues of $h_0(x,\xi)$ remain isolated over all $\mathbf{R}^{2n}$, one can make a complete diagonalization which reduces [up to errors of order $s(\epsilon)$] the study of the m-states Hamiltonian H_ϵ to the study of m scalar operators in $L^2(\mathbf{R}^n)$.

Remarks:

II.4. For the scattering theory the estimates (2.16) or (2.34) have to be improved at $|x| \to \infty$; for example, in the Klein–Gordon case one has to replace (2.16) by (we use the notation $\langle x\rangle = \sqrt{1+x^2}$)

$$\|\langle x\rangle^{t\delta}[\Pi_\epsilon, H_\epsilon]\langle x\rangle^{(1-t)\delta}\| \leqslant s(\epsilon), \quad t \in [0,1] \tag{2.31}$$

for some $\delta > 1$. At the technical level this amounts to show that the decay of $V(x)$ [see (3.3) below] "propagates" through the construction of Π_ϵ.

II.5. The above construction works nicely if $\pi_j(x,\xi)$ are bounded as it is the case for Klein–Gordon or Dirac operators. Unfortunately, this is not the case in the Schrödinger case where $\pi_j(x,\xi)$ behaves like $\langle\xi\rangle^j$ as $|\xi| \to \infty$ irrespective of how nice the potential is. As a consequence a block diagonalization valid on the whole $L^2(\mathbf{R}^n)^{\oplus m}$ seems not to exist (in concordance with the physical arguments saying that the adiabatic decoupling becomes poorer and poorer as energy increases) [see also the remarks in Martin and Nenciu (1995)]. However one can still hope to have it as far as the energy (and then $|\xi|$) remains bounded. One can show [see Sordoni (2003)] that this is indeed the case and the idea is to replace $\hat{\Pi}_\epsilon$ with

$$\hat{\Pi}_\epsilon^\Phi = \Phi(H_\epsilon)\hat{\Pi}_\epsilon + (1-\Phi(H_\epsilon))\hat{\Pi}_\epsilon\Phi(H_\epsilon) + (1-\Phi(H_\epsilon))\Pi_0(1-\Phi(H_\epsilon)), \tag{2.32}$$

where Φ is a smooth cutoff function on $\mathbf{R}$. Then the whole procedure works and, defining

$$\Pi_\epsilon^\Phi := \frac{i}{2\pi}\int_{|z-1|=1/2} (\hat{\Pi}_\epsilon^\Phi - z)^{-1}\,dz, \tag{2.33}$$

gives instead of (2.16),

$$\|\chi(H_\epsilon)[\Pi_\epsilon^\Phi, H_\epsilon]\| \leqslant s(\epsilon), \tag{2.34}$$

for any cutoff function χ such that $\chi^\Phi = \chi$.

III. TWO COMPONENT KLEIN–GORDON SYSTEMS. EXPONENTIAL ESTIMATES

In this section we prove the existence of invariant subspaces up to exponential small errors as $\epsilon \to 0$, for two component Klein–Gordon systems, and apply this to spectral and scattering theory. Consider the two-component Klein–Gordon Hamiltonian,

$$H_\epsilon = a(\epsilon D_x)\mathbf{1}_2 + V(x) \tag{3.1}$$

acting on $\mathcal{H}=L^2(\mathbf{R}^n)^{\oplus 2}:=L^2(\mathbf{R}^n)\oplus L^2(\mathbf{R}^n)$. Here $a(\xi)=(\sqrt{\xi^2+1}-1)$,$\mathbf{1}_2$ is the 2×2 identity matrix and $V(x)$ is a 2×2 Hermitian matrix valued function that admits an analytic extension in some strip

$$\Gamma_a = \{x \in \mathbf{R}^n; |\mathrm{Im}\, x| < a\}, \quad a > 0. \tag{3.2}$$

Moreover, since we have in mind application to scattering theory we assume $V(x)$ to be short range, i.e., there exists a Hermitian 2×2 matrix V_∞ such that

$$\sup_{x\in\Gamma_a} \langle x\rangle^\delta |V(x) - V_\infty| < \infty \tag{3.3}$$

uniformly on Γ_a with $\delta > 1$. Without loss of generality we can assume that

$$V_\infty = \begin{pmatrix} \lambda_{1,\infty} & 0 \\ 0 & \lambda_{2,\infty} \end{pmatrix}. \tag{3.4}$$

Concerning the spectrum of $V(x)$, we assume that the two real eigenvalues $\lambda_i(x)$, satisfy

$$\inf_{x\in\mathbf{R}^n} (\lambda_1(x) - \lambda_2(x)) = 2d > 0. \tag{3.5}$$

By eventually shrinking Γ_a, one can suppose that

$$\inf_{x\in\Gamma_a} |\lambda_1(x) - \lambda_2(x)| \geqslant d. \tag{3.6}$$

It follows that on Γ_a

$$V(x) = \lambda_1(x)\pi_0(x) + \lambda_2(x)(1 - \pi_0(x)),$$

where $\pi_0(x)$ is a bounded projection in $\mathbf{C}^2$, analytic in Γ_a and self-adjoint for $x \in \mathbf{R}^n$. Due to (3.4), $\pi_0(\infty) = \lim_{|x|\to+\infty} \pi(x) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, and from (3.3),

$$\sup_{x\in\Gamma_a} \langle x\rangle^\delta |\pi_0(x) - \pi_0(\infty)| < \infty. \tag{3.7}$$

In what follows, "for ϵ sufficiently small" is short hand for "there exists $\epsilon_0 > 0$ such that for $0 < \epsilon \leqslant \epsilon_0$." A finite number of finite, strictly positive constants independent of ϵ will appear in this section; they are all denoted by c or C. For an operator A and $\eta > 0$ we shall denote

$$\|A\|_\eta = \sup_{t\in[0,1]} \|\langle x\rangle^{t\eta} A \langle x\rangle^{(1-t)\eta}\|.$$

In the following we denote by Π_0 the operator in $\mathcal{H}$ acting as multiplication by the matrix $\pi_0(x)$.

Theorem III.1: *Assume (3.2), (3.3), and (3.5) hold true. Then, for sufficiently small ϵ, there exists an orthogonal projection Π_ϵ in $\mathcal{H}$ satisfying*

$$\|[\Pi_\epsilon, H_\epsilon]\|_\delta = \mathcal{O}(e^{-c/\epsilon}), \tag{3.8}$$

$$\epsilon^{-1}\|\Pi_\epsilon - \Pi_0\|_\delta = \mathcal{O}(1) \tag{3.9}$$

uniformly with respect to $\epsilon \in (0, \epsilon_0]$.

Proof: As already said in Sec. II, the main step in the proof of Theorem III.1 is the construction of Moyal projections for

$$h_0(\xi, x) = a(\xi)\mathbf{1}_2 + V(x). \tag{3.10}$$

Lemma III.2: There exists a formal analytic symbol

$$\pi(x,\xi;\epsilon) = \pi_0(x) + \sum_{j=1}^{\infty} \pi(x,\xi)\epsilon^j, \tag{3.11}$$

that satisfies (2.5) and (2.6), and, in addition, such that $\pi(x,\xi;\epsilon) - \pi_0(x) \in S_A^0(\langle x\rangle^{-\delta})$ *[see Appendix for the definition of* $S_A^0(1)$ *and* $S_A^0(\langle x\rangle^{-\delta})$*].*

Proof: Let $x_0,\ \xi_0 \in \mathbf{R}^n,\ 0<\eta<d/4$ and $\Gamma_{x_0,\xi_0,d,\eta}=\{z\in\mathbf{C}; d/2-\eta<|z-a(\xi_0)-\lambda_1(x_0)|<d/2+\eta\}$. Since $V(x)$ is analytic and uniformly bounded on Γ_a, $a(\xi)$ is analytic on Γ_1 and in addition $\partial_\xi^\alpha a(\xi)$, $|\alpha|=1$ are uniformly bounded on Γ_1, there exists $b>0$, $M>0$ independent on x_0, $\xi_0 \in \mathbf{R}^n$ such that for all $z\in\Gamma_{x_0,\xi_0,d,\eta}$,

$$q_0(x,\xi,z) = (h_0(x,\xi)-z)^{-1}$$

is analytic in $|x-x_0|<b$, $|\xi-\xi_0|<b$ and in addition

$$\operatorname*{Sup}_{|x-x_0|<b,|\xi-\xi_0|<b,z\in\Gamma_{x,\xi,d,\eta}} |q_0(x,\xi,z)| < M. \tag{3.12}$$

Then from Cauchy inequalities there exists $C>0$ such that for any $\alpha,\ \beta\in\mathbf{N}^n$,

$$\operatorname*{Sup}_{x,\xi\in\mathbf{R}^n,z\in\Gamma_{x,\xi,d,\eta}} |\partial_\xi^\alpha\partial_x^\beta q_0(x,\xi,z)| \leqslant C^{|\alpha|+|\beta|+1}\alpha!\beta! \tag{3.13}$$

and in addition [see (3.3)], if $|\beta|\neq 0$,

$$\operatorname*{Sup}_{x,\xi\in\mathbf{R}^n,z\in\Gamma_{x,\xi,d,\eta}} |\langle x\rangle^\delta\partial_\xi^\alpha\partial_x^\beta q_0(x,\xi,z)| \leqslant C^{|\alpha|+|\beta|+1}\alpha!\beta!. \tag{3.14}$$

Define now for $x,\ \xi\in\mathbf{R}^n$, $z\in\Gamma_{x,\xi,d,\eta}$ the formal analytic symbol

$$r = \sum_{j=1}^{\infty} r_j(x,\xi;z)\epsilon^j$$

by

$$(h_0(x,\xi)-z)\,\#\,q_0(x,\xi;z) = 1 - r(x,\xi;\epsilon,z).$$

Notice that $r_0(x,\xi)=0$. Taking into account (3.13) and (3.14) and that, for all $\alpha,\ \beta\in\mathbf{N}^n$, $|\beta|\neq 0$,

$$\operatorname*{Sup}_{(x,\xi)\in\mathbf{R}^n} |\langle x\rangle^\delta\partial_\xi^\alpha\partial_x^\beta h_0(x,\xi)| \leqslant C^{|\alpha|+|\beta|+1}\alpha!\beta!, \tag{3.15}$$

from the composition rule, Leibnitz formula and Lemma IV.4 one obtains that, for all $j=0,1,\ldots$, and $\alpha,\ \beta\in\mathbf{N}^n$,

$$\operatorname*{Sup}_{x,\xi\in\mathbf{R}^n,z\in\Gamma_{x,\xi,d,\eta}} |\langle x\rangle^\delta\partial_\xi^\alpha\partial_x^\beta r_j(x,\xi,z)| \leqslant C^{j+|\alpha|+|\beta|+1}\alpha!\beta!j!. \tag{3.16}$$

If we define the formal symbol $q(x,\xi;\epsilon,z)$ by

$$q = q_0 + q_0\,\#\sum_{j=1}^{\infty} r^{\#j}, \tag{3.17}$$

then q satisfy an estimate like (3.16). More exactly we have the following.

Lemma III. 3: There exists C such that for all $j=1,2,\ldots$, *and* $\alpha,\ \beta\in\mathbf{N}^n$,

$$\operatorname*{Sup}_{x,\xi\in\mathbf{R}^n,z\in\Gamma_{x,\xi,d,\eta}} |\langle x\rangle^\delta\partial_\xi^\alpha\partial_x^\beta q_j(x,\xi,z)| \leqslant C^{j+|\alpha|+|\beta|+1}\alpha!\beta!j!. \tag{3.18}$$

Proof: Replace the supremum over $(x,\xi)\in\Gamma_{a'}\times\Gamma_{b'}$ in (4.5) with the supremum over $x,\ \xi$

$\in \mathbf{R}^n$, $z \in \Gamma_{x,\xi,d,\eta}$ and mimic the proof of Lemmas IV.4 and IV.5 in the Appendix.

From (2.10) it follows that, for x, $\xi \in \mathbf{R}^n$, $z \in \Gamma_{x,\xi,d,\eta}$, $q(x,\xi;\epsilon,z)$ satisfies the resolvent equation

$$q(x,\xi;\epsilon,z) - q(x,\xi;\epsilon,z') = (z - z')q(x,\xi;\epsilon,z) \# q(x,\xi;\epsilon,z'). \tag{3.19}$$

Mimicking the proof of the Riesz formula for the spectral projection [see, e.g., Kato (1980)] one obtains that the formal symbol $\Sigma_{j=0}^{\infty}\pi_j(x,\xi)\epsilon^j$ defined by

$$\pi_j(x,\xi) = \frac{i}{2i\pi}\int_{\Gamma_{x,\xi}} q_j(x,\xi,z)\, dz, \tag{3.20}$$

where $\Gamma_{x,\xi}=\{z \in \mathbf{C}; |z-a(\xi)-\lambda_1(x)|=d/2\}$ satisfies (2.5) and (2.6).

We can now finish the proof of Lemma III.2: plug the estimation (3.18) into (3.20).

End of the proof of Theorem III.1: Let $\hat{\pi}_N$ be a resummation of the formal analytic symbol as given in the Appendix, i.e., $\hat{\pi}_N(x,\xi;\epsilon)=\Sigma_{j=0}^{N}\pi_j(x,\xi)\epsilon^j$. From Lemmas IV.6 and III.2, it follows that

$$\hat{\pi}_N \# \hat{\pi}_N(x,\xi;\epsilon) = \hat{\pi}_N(x,\xi;\epsilon) + r_N(x,\xi;\epsilon) \tag{3.21}$$

with

$$|||r_N|||_{p,\delta} \leqslant (C\epsilon)^{N+1}(N+1)!$$

for a new constant C. Consider now $h_0\#\hat{\pi}_N - \hat{\pi}_N\#h_0$. Since h_0 is unbounded, at the first sight, one cannot use directly Lemmas IV.6 and III.2 to obtain a similar bound. However, due to the fact that *all* the derivatives of h_0 are bounded and that since we consider a commutator so that the term without derivatives vanish one can still apply the stationary phase theorem and obtain the estimation

$$|||h\# \hat{\pi}_N - \hat{\pi}_N\#h|||_{p,\delta} \leqslant (C\epsilon)^{N+1}(N+1)!.$$

Then, taking $N=[1/B\epsilon]$ with B sufficiently large and denoting

$$\hat{\pi}^B := \sum_{j=0}^{[1/B\epsilon]} \pi_j\epsilon_j,$$

by Stirling formula, one has

$$|||\hat{\pi}^B\#\hat{\pi}^B - \hat{\pi}^B|||_{p,\delta} + |||h_0\#\hat{\pi}^B - \hat{\pi}^B\#h_0|||_{p,\delta} \leqslant Ce^{-c/h} \tag{3.22}$$

for some constants c, $C>0$ independent of ϵ. Let now

$$\hat{\Pi}_\epsilon = \mathrm{Op}_\epsilon^w(\hat{\pi}^B). \tag{3.23}$$

Then from (3.22), Lemma IV.6 and Calderon–Vaillancourt theorem (see Theorem IV.7) $\hat{\Pi}_\epsilon$ is bounded uniformly with respect to ϵ, and in addition,

$$\|\hat{\Pi}_\epsilon^2 - \hat{\Pi}_\epsilon\|_\delta = \mathcal{O}(e^{-c/\epsilon}), \tag{3.24}$$

$$\|[\hat{\Pi}_\epsilon, H_\epsilon]\|_\delta = \mathcal{O}(e^{-c/\epsilon}) \tag{3.25}$$

for some constant $c>0$ independent of $\epsilon \in (0,\epsilon_0]$. Then [see Sec. II and Nenciu (1993), Nenciu (2002) for details], if Π_ϵ is given by

$$\Pi_\epsilon = \frac{i}{2\pi}\int_{|z-1|=1/2} (\hat{\Pi}_\epsilon - z)^{-1}\, dz$$

the only thing to be verified is the $\langle x\rangle^{-\delta}$ decay as $|x|\to\infty$. By a simple computation [see Appendix in Nenciu (2002)],

$$(\hat{\Pi}_\epsilon - z)^{-1} = \frac{\hat{\Pi}_\epsilon + z - 1}{z(z-1)}\left[1 + \frac{\Delta_\epsilon}{z(1-z)}\right]^{-1}, \tag{3.26}$$

where

$$\Delta_\epsilon = \hat{\Pi}_\epsilon^2 - \hat{\Pi}_\epsilon. \tag{3.27}$$

Expanding in (3.26) and using (3.24), one has uniformly for sufficiently small ϵ,

$$\|(\hat{\Pi}_\epsilon - z)^{-1}\|_\delta = \mathcal{O}(1). \tag{3.28}$$

Again by a simple computation

$$\Pi_\epsilon - \hat{\Pi}_\epsilon = -\Delta_\epsilon \frac{i}{2\pi}\oint_{|z-1|=1/2} \frac{1}{z(1-z)}\left(\frac{\hat{\Pi}_\epsilon}{z(1-z)} + 1\right)\left(1 + \frac{\Delta_\epsilon}{z(1-z)}\right)^{-1} dz,$$

which together with (3.24) and (3.28) gives

$$\|\Pi_\epsilon - \hat{\Pi}_\epsilon\|_\delta \leqslant Ce^{-c/\epsilon}, \tag{3.29}$$

which implies (3.9). For (3.8) use

$$[H_\epsilon, \Pi_\epsilon] = -\frac{i}{2\pi}\oint_{|z-1|=1/2} (\hat{\Pi}_\epsilon - z)^{-1}[H_\epsilon, \hat{\Pi}_\epsilon](\hat{\Pi}_\epsilon - z)^{-1}\, dz,$$

(3.28) and (3.25).

Remarks:

III.1. From (3.29), Π_ϵ is exponentially close to $\hat{\Pi}_\epsilon$ which is a pseudodifferential operator with an analytic symbol. Actually, by using the results in Dimassi and Sjöstrand (1999) on functional calculus for pseudodifferential operators, one can show that Π_ϵ is a pseudodifferential operator with symbol $\hat{\pi} \in S_A^0(1)$ given by (3.11) and such that $\hat{\pi} - \pi_0 \in S_A^0(\langle x\rangle^{-\delta})$.

We turn now to applications to spectral and scattering theory for H_ϵ. Consider the scattering problem for the pair H_ϵ and

$$H_{\epsilon,0} := a(\epsilon D_x)\mathbf{1}_2 + \begin{pmatrix} \lambda_{1,\infty} & 0 \\ 0 & \lambda_{2,\infty} \end{pmatrix}. \tag{3.30}$$

We need the following elementary propagation estimate.

Lemma III.4: Let $\phi \in \mathcal{H}$, $\hat{\phi}$(= the Fourier transform of ϕ) $\in C_0^\infty(\mathbf{R}^n\setminus\{0\})^{\oplus 2}$. Then there exists $K(\phi) > 0$ such that, uniformly for sufficiently small ϵ,

$$\|\langle x\rangle^{-\delta} e^{-itH_{\epsilon,0}}\phi\| \leqslant K(\phi)\epsilon^{-2\delta}\langle t\rangle^{-\delta}. \tag{3.31}$$

Proof: The proof is standard stationary phase estimates [see, e.g., Appendix to XI.3 in Reed and Simon (1979)] and the only thing to do is to control their ϵ dependence. For this, write

$$\sqrt{\epsilon^2 k^2 + 1} - 1 = \epsilon^2 K_\epsilon(k)$$

and observe that

$$\mathrm{Inf}_{\epsilon\in(0,\epsilon_0]}|\mathbf{grad}\, K_\epsilon(k)| = \frac{|k|}{\sqrt{\epsilon_0^2 k^2+1}}$$

and

$$K_\epsilon(k) = \frac{k^2}{2} + \mathcal{O}(\epsilon^2 k^4).$$

From Lemma III.4, by the standard Cook argument, the wave operators

$$W_\pm(H_\epsilon, H_{\epsilon,0}) = s - \lim_{t\to\pm\infty} e^{itH_\epsilon} e^{-itH_{\epsilon,0}} \tag{3.32}$$

exist for $\delta>1$. As for completeness, if $\delta>n$, it follows by a direct application of Birman's theorem [see Reed and Simon (1979)], Theorem XI.10 [mimic the proof of Theorem XI.30 in Reed and Simon (1979)]. Actually the completeness holds true for $\delta>1$; one can prove it [see Simon (1979)] using Enss method. The same argument applies to all the wave operators appearing in this section so in what follows we shall assume that all of them exist and are complete. Let S be the scattering operator corresponding to the pair H_ϵ, $H_{\epsilon,0}$,

$$S = W_+(H_\epsilon, H_{\epsilon,0})^* W_-(H_\epsilon, H_{\epsilon,0}). \tag{3.33}$$

One expects that (3.8) implies that S has an almost block diagonal structure with respect to the decomposition given by Π_ϵ, and indeed one can prove (see the proof of Theorem III.8 below) that if $\phi_1\in\mathcal{H}$, $\phi_2\in(1-\Pi_\epsilon)(\mathcal{H})$ and $\hat{\phi}_j\in\mathcal{C}_0^\infty(\mathbf{R}^n\backslash\{0\})^{\oplus 2}$ then

$$|(\phi_2, S\phi_1)| \leqslant K(\phi_1,\phi_2)e^{-c/\epsilon}.$$

What we shall prove below [under an additional condition on $V(x)$, see Lemma III.5 below] that S has an almost diagonal form with respect to the *canonical* decomposition of $\mathcal{H}$, i.e., the decomposition given by

$$P_0 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

We start with the following elementary lemma.

Lemma III.5: Suppose that either

$$\mathrm{Sup}_{x\in\Gamma_a}\|\pi_0(x) - P_0\| < 1 \tag{3.34}$$

or, for $x\in\mathbf{R}^n$, *that*

$$V_{ij}(x) = \overline{V_{ij}(x)}, \tag{3.35}$$

i.e., $V(x)$ *has real entries for* $x\in\mathbf{R}^n$. *Then there exists a matrix* $Q(x)$ *bounded with bounded inverse uniformly in* Γ_a, *unitary for* $x\in\mathbf{R}^n$ *and satisfying*

$$\pi_0(x) = Q(x)P_0Q(x)^{-1} \tag{3.36}$$

and

$$\mathrm{Sup}_{x\in\mathbf{R}^n}|(Q(x)-\mathbf{1}_2)\langle x\rangle^\delta| < \infty. \tag{3.37}$$

Proof: If (3.34) holds true, one can take as $Q(x)$ the Sz–Nagy transformation matrix corresponding to the pair $\pi_0(x)$, $\pi_0(\infty)=P_0$.

Suppose now (3.35) holds true. For $x=(x',x_n)\in\Gamma_a$, let us set $x_n=y_n+i\eta$, $y_n\in\mathbf{R}$ and define $Q(x)$ by

$$Q(x) = 1 + \int_{-\infty}^{y_n} (1 - 2\pi_0(x', s + i\eta)) \left(\frac{\mathrm{d}}{\mathrm{d}s} \pi_0(x', s + i\eta) \right) Q(x', s + i\eta) \mathrm{d}s. \tag{3.38}$$

Notice that the integral in (3.38) is convergent since $(\mathrm{d}/\mathrm{d}s)\pi_0(x', s+i\eta) = \mathcal{O}(\langle s \rangle^{-\delta})$. Now [see, e.g., Kato (1980), Reed and Simon (1978)] $Q(x)$ is analytic and uniformly bounded in Γ_a and satisfies (3.36) since

$$\lim_{y_n \to +\infty} \pi_0(x', y_n + i\eta) = \pi(\infty) = P_0. \tag{3.39}$$

Since (3.38) implies that for $x \in \mathbf{R}^n$, $Q(x) = \overline{Q(x)}$, from (3.36) and (3.7) one obtains

$$Q_{1,1}^2(x) - 1 = \mathcal{O}(\langle x \rangle^{-\delta}),\ Q_{1,1}(x) Q_{1,2}(x) = \mathcal{O}(\langle x \rangle^{-\delta}). \tag{3.40}$$

This implies that as $|x| \to +\infty$, $Q_{1,1}(x) \to \pm 1$. By continuity the choice is the same for all directions. Since, for $x_n \to -\infty$, $Q(x) \to \mathbf{1}_2$, it follows that $\lim_{|x| \to +\infty} Q_{1,1}(x) = 1$ which together with (3.40) finishes the proof.

Let now U_ϵ be the Sz–Nagy transformation matrix corresponding to the pair Π_ϵ, Π_0 [see (2.25)] and consider the rotated Hamiltonian [see (2.28) and (2.30)]:

$$H_\epsilon^{\mathrm{eff}} = Q * U_\epsilon^* H U_\epsilon Q, \tag{3.41}$$

where Q is the operator of multiplication with $Q(x)$.

Corollary III.6: Under assumptions (3.2), (3.3), (3.5), and (3.34) or (3.35) we have

$$H_\epsilon^{\mathrm{eff}} = \begin{pmatrix} a(\epsilon D_x) + \lambda_1(x) & 0 \\ 0 & a(\epsilon D_x) + \lambda_2(x) \end{pmatrix} + \epsilon B_\epsilon, \tag{3.42}$$

where $B_{\epsilon,ii}$; $i, j = 1, 2$ are bounded operators satisfying

$$\|B_{\epsilon,ii}\|_\delta = \mathcal{O}(1), \tag{3.43}$$

$$\|B_{\epsilon,12}\|_\delta = \|B_{\epsilon,21}\|_\delta = \mathcal{O}(e^{-c/\epsilon}), \tag{3.44}$$

uniformly with respect to sufficiently small ϵ.

Proof: Write

$$H_\epsilon^{\mathrm{eff}} = Q * (H_\epsilon + U_\epsilon^* [H_\epsilon, U_\epsilon] Q) = \begin{pmatrix} a(\epsilon D_x) + \lambda_1(x) & 0 \\ 0 & a(\epsilon D_x) + \lambda_2(x) \end{pmatrix} + Q * [a(\epsilon D_x)\mathbf{1}_2, Q] + Q * U_\epsilon^* [H_\epsilon, U_\epsilon] Q. \tag{3.45}$$

The fact that, uniformly for ϵ sufficiently small,

$$\epsilon^{-1} \| \mathcal{O} * [a(\epsilon D_x)\mathbf{1}_2, Q] \|_\delta = \mathcal{O}(1) \tag{3.46}$$

follows from the fact that $\langle x \rangle^\delta$ commutes with Q, (3.37) and Lemma IV.6. Analogously

$$\epsilon^{-1} \| [H_\epsilon, \Pi_0] \|_\delta = \mathcal{O}(1). \tag{3.47}$$

Since $\langle x \rangle^\delta$ commutes with Π_0 from (3.9) one has

$$\| \langle x \rangle^\delta \Pi_\epsilon \langle x \rangle^{-\delta} \| = \mathcal{O}(1). \tag{3.48}$$

Hence, from the Sz–Nagy formula for U_ϵ, (3.8), (3.47), and (3.48) one has

$$\epsilon^{-1} \| [H_\epsilon, U_\epsilon] \|_\delta = \mathcal{O}(1), \tag{3.49}$$

$$\epsilon^{-1}\|U_\epsilon - 1\|_\delta = \mathcal{O}(1), \tag{3.50}$$

uniformly for small ϵ. From (3.49) and (3.50),

$$\epsilon^{-1}\|Q^* U_\epsilon^*[H_\epsilon, U_\epsilon]Q\|_\delta, \tag{3.51}$$

which together with (3.46) finishes the proof of (3.43). Now from (3.36) and $\Pi_\epsilon = U_\epsilon \Pi_0 U_\epsilon^*$ it follows that

$$\Pi_\epsilon = U_\epsilon Q P_0 Q^* U_\epsilon^*$$

and then

$$[H_\epsilon^{\text{eff}}, P_0] = Q^* U_\epsilon^*[H_\epsilon, \Pi_\epsilon]U_\epsilon Q, \tag{3.52}$$

which together with (3.8) and (3.50) gives

$$\|[H_\epsilon^{\text{eff}}, P_0]\|_\delta = \mathcal{O}(e^{-c/\epsilon}). \tag{3.53}$$

Taking into account that

$$\epsilon B_{\epsilon,12} + \epsilon B_{\epsilon,21} = (1 - 2P_0)[H_\epsilon^{\text{eff}}, P_0],$$

(3.53) implies (3.44).

Let us stress here that the constructive proof above provides the means to compute effectively the formal symbol of H_ϵ^{eff}.

Remarks:

III.2. As in the case of Π_ϵ, from (3.45) one sees that H_ϵ^{eff} is exponentially close to a pseudodifferential operator and again the results in Dimassi and Sjöstrand (1999) enables to show that in fact H_ϵ^{eff} is a pseudodifferential operator.

The following lemma allows to replace H_ϵ by H_ϵ^{eff} when computing the scattering operator.

Lemma III.7: Let $\tilde{S}$ be the scattering operator corresponding to the pair H_ϵ^{eff} $H_{\epsilon,0}$. Then for sufficiently small ϵ,

$$S = \tilde{S}. \tag{3.54}$$

Proof: Let $\Omega_\epsilon = QU_\epsilon$. From (3.37) and (3.50),

$$\|(\Omega_\epsilon - 1)\langle x\rangle^\delta\| = \mathcal{O}(1). \tag{3.55}$$

Now [see (3.41)]

$$W_\pm(H_\epsilon^{\text{eff}}, H_{\epsilon,0}) = \Omega_\epsilon^*(s - \lim_{t\to\pm\infty} \Omega_\epsilon e^{itH_\epsilon^{\text{eff}}} e^{-itH_{\epsilon,0}}) = \Omega_\epsilon^* W_\pm(H_\epsilon, H_{\epsilon,0}) + (s - \lim_{t\to\pm\infty} \Omega_\epsilon^* e^{itH_\epsilon}(\Omega_\epsilon - 1)e^{-itH_{\epsilon,0}}).$$

Let now $\phi \in \mathcal{H}$, $\hat{\phi} \in \mathcal{C}_0^\infty(\mathbf{R}^n \setminus \{0\})^{\oplus 2}$. Then from Lemma III.4 and (3.55),

$$\|\Omega_\epsilon^* e^{itH_\epsilon}(\Omega_\epsilon - 1)e^{-itH_{\epsilon,0}}\phi\| \leq C(\phi)\epsilon^{-2\delta}\langle t\rangle^{-\delta}.$$

Sending $|t| \to \infty$ (at fixed ϵ!), by density we get

$$s - \lim_{t\to\pm\infty} \Omega_\epsilon^* e^{itH_\epsilon}(\Omega_\epsilon - 1)e^{-itH_{\epsilon,0}} = 0,$$

which gives

$$W_\pm(H_\epsilon^{\text{eff}}, H_{\epsilon,0}) = \Omega_\epsilon^* W_\pm(H_\epsilon, H_{\epsilon,0})$$

and the proof of the lemma is finished.

We are now in position to state one of the main results of the paper.

Theorem III.8: *Let, for* $j=1,2$,

$$H^{\text{eff}}_{\epsilon,j}=a(\epsilon D_x)+\lambda_j(x)+\epsilon B_{\epsilon,ii},\ \ H_{\epsilon,j,0}=a(\epsilon D_x)+\lambda_{j,\infty} \tag{3.56}$$

acting in $L^2(\mathbf{R}^n)$ *and* S_j *the scattering operator corresponding to the pair* $H^{\text{eff}}_{\epsilon,j}$, $H_{\epsilon,j,0}$. *Then, there exists* $c>0$ *independent of* ϵ, *such that, for any* $\phi_k\in\mathcal{H}$, $\hat{\phi}_k\in\mathcal{C}^\infty_0(\mathbf{R}^n\backslash\{0\})^{\oplus 2}$, $k=1,2$ *and* $\epsilon\in(0,\epsilon_0]$ *sufficiently small, we have*

$$\left|\left(\phi_2,\left(S-\begin{pmatrix}S_1&0\\0&S_2\end{pmatrix}\right)\phi_1\right)\right|\leqslant C(\phi_1,\phi_2)e^{-c/\epsilon} \tag{3.57}$$

for some constant $C(\phi_1,\phi_2)>0$ *depending on* ϕ_1,ϕ_2 *but not on* ϵ.

Proof: Write

$$D_\epsilon=\begin{pmatrix}H^{\text{eff}}_{\epsilon,1}&0\\0&H^{\text{eff}}_{\epsilon,2}\end{pmatrix},\ \ R_\epsilon:=H^{\text{eff}}_\epsilon-D_\epsilon$$

and let $\phi\in\mathcal{H}$, $\hat{\phi}\in\mathcal{C}^\infty_0(\mathbf{R}^n\backslash\{0\})^{\oplus 2}$. By the usual Cook argument, for $T>0$, we have

$$\|(W_+(H^{\text{eff}}_\epsilon,H_{\epsilon,0})-e^{iTH^{\text{eff}}_\epsilon}e^{-iTH_{\epsilon,0}}\phi\,\|=\left\|\int_T^\infty e^{itH^{\text{eff}}_\epsilon}(H^{\text{eff}}_\epsilon-H_{\epsilon,0})e^{-itH_{\epsilon,0}}\phi\right\|\leqslant C(\phi)\epsilon^{-2\delta+1}T^{1-\delta} \tag{3.58}$$

and

$$\|(W_+(D_\epsilon,H_{\epsilon,0})-e^{iTD_\epsilon}e^{-iTH_{\epsilon,0}}\phi\,\|=\left\|\int_T^\infty e^{itD_\epsilon}(D_\epsilon-H_{\epsilon,0})e^{-itH_{\epsilon,0}}\phi\right\|\leqslant C(\phi)\epsilon^{-2\delta+1}T^{1-\delta}. \tag{3.59}$$

For the last inequality we used Lemma III.4 and the fact that (see Corollary III.6) $\|H^{\text{eff}}_\epsilon-H_{\epsilon,0}\|_\delta+\|D_\epsilon-H_{\epsilon,0}\|_\delta=\mathcal{O}(\epsilon)$. On the other hand, from Duhamel's formula,

$$e^{iTH^{\text{eff}}_\epsilon}=e^{iTD_\epsilon}+i\int_0^T e^{i(T-s)D}\text{Re}^{isH^{\text{eff}}_\epsilon}\,\text{d}s, \tag{3.60}$$

which together with (3.44) gives

$$\|e^{iTH^{\text{eff}}_\epsilon}e^{-iTD_\epsilon}-\mathbf{1}_2\|\leqslant C'\epsilon Te^{-c/\epsilon}. \tag{3.61}$$

From (3.58), (3.59), and (3.61) one obtains

$$\|(W_+(H^{\text{eff}}_\epsilon,H_{\epsilon,0})-W_+(D_\epsilon,H_{\epsilon,0}))\phi\|\leqslant 2C(\phi)\epsilon^{-2\delta+1}T^{1-\delta}+C'\epsilon Te^{-c/\epsilon}. \tag{3.62}$$

By choosing $T=\epsilon^{-2-1/\delta}e^{c/\delta\epsilon}$ in (3.62) one obtains

$$\|(W_+(H^{\text{eff}}_\epsilon,H_{\epsilon,0})-W_+(D_\epsilon,H_{\epsilon,0}))\phi\|\leqslant C_1(\phi)e^{-c/\epsilon} \tag{3.63}$$

for some c', $0<c'\leqslant c$, and $C=C(\phi)>0$ independent of ϵ. In the same manner

$$\|(W_-(H^{\text{eff}}_\epsilon,H_{\epsilon,0})-W_-(D_\epsilon,H_{\epsilon,0}))\phi\|\leqslant C_2(\phi)e^{-c/\epsilon}. \tag{3.64}$$

Writing

$$\begin{aligned}S(H^{\text{eff}}_\epsilon,H_{\epsilon,0})-S(D_\epsilon,H_{\epsilon,0})&=(W_+(H^{\text{eff}}_\epsilon,H_{\epsilon,0})^*-W_+(D_\epsilon,H_{\epsilon,0})^*)W_+(H^{\text{eff}}_\epsilon,H_{\epsilon,0})\\&\quad+W_+(D_\epsilon,H_{\epsilon,0})^*(W_+(H^{\text{eff}}_\epsilon,H_{\epsilon,0})-W_+(D_\epsilon,H_{\epsilon,0}))\end{aligned}$$

and using (3.63) and (3.64) and Lemma III.7, (3.57) follows.

Since $\tilde{S}$ commutes with $H_{\epsilon,0}$, one can define the scattering matrix at fixed energy $\tilde{S}(\lambda)$. Let us stress that Theorem III.8 does not imply the corresponding result for $\tilde{S}(\lambda)$; when shrinking the supports of ϕ_1 and ϕ_2 the constant $C(\phi_1,\phi_2)$ may blow up. At the heuristic level the reason for this blowing up is clear: Corollary III.6 (via the Duhamel's formula) implies that the transitions *per unit time* between the two levels is exponentially small, but if, at the given energy, there is a resonance very (exponentially) close to the real axis, it has an exponentially long lifetime and during this time considerable transitions can take place. Accordingly, one expects exponentially block diagonalization of $\tilde{S}(\lambda_0)$ only if there are no resonances around λ_0 or in other words if $\tilde{S}(\lambda)$ is smooth in a neighborhood of λ_0 and this is true if λ_0 is nontrapping.

Remarks:

III.3. For nontrapping energies the block diagonal structure (up to exponentially small errors) of $\tilde{S}(\lambda_0)$ has been proved in the papers quoted in the Introduction. Let us point out that one can prove similar results [see Sordoni (2003)] by using Corollary III.6 and resolvent estimates [see, e.g., Jensen and Nakamura (1992), Wang (1988)].

We turn now to some direct applications of Corollary III.6 to spectral theory. We shall discuss H_ϵ^{eff} but all the results apply to H_ϵ also, since they are unitarily equivalent. If

$$\operatorname*{Inf}_{x\in\mathbf{R}^n} \lambda_2(x) = m_2 < \lambda_{2,\infty}$$

then H_ϵ^{eff} has discrete spectrum in the interval $(m_2,\lambda_{2,\infty})$ which, up to exponentially small errors, equals the union of the (discrete) spectra of $H_{\epsilon,j}^{\text{eff}}$ in this interval [see Nenciu (2002) for details]. Suppose now

$$\operatorname*{Inf}_{x\in\mathbf{R}^n} \lambda_1(x) = m_1 < \lambda_{1,\infty}.$$

Then $H_{\epsilon,1}^{\text{eff}}$ has bound states in the interval $(m_1,\lambda_{1,\infty})$ and as a consequence, D_ϵ has bounded states embedded in the continuum spectrum in the interval $(\text{Max}\{m_1,\lambda_{2,\infty}\},\lambda_{1,\infty})$. The small off-diagonal term, R_ϵ, turns (generically) these bound (stable) states into metastable states. Let Ψ be an eigenfunction of such a bound state, i.e.,

$$H_{\epsilon,1}^{\text{eff}}\Psi = E\Psi, \quad E \in (\text{Max}\{m_1,\lambda_{2,\infty}\},\lambda_{1,\infty}).$$

Then from Corollary III.6,

$$\|(H_\epsilon^{\text{eff}} - E)\Psi\| \leqslant Ce^{-c/\epsilon},$$

i.e., Ψ, E, are pseudoeigenvectors and pseudoeigenvalues [see Kato (1980)] of exponential order for H_ϵ^{eff} (the name quasimodes is also used). A more physical picture is given by Duhamel formula (3.60) which together with Corollary III.6 gives the following.

Corollary III.9:

$$|(\Psi, e^{-itH_\epsilon^{\text{eff}}}\Psi)| \geqslant 1 - C|t|e^{-c/\epsilon}. \tag{3.65}$$

As it stands Corollary III.9 gives the *existence* and the control on the (exponentially long) lifetime of metastable states (quasimodes) in the semiclassical limit. However in many instances [see, e.g., Stefanov (1999)] one can make the connection with the resonances (defined as poles of the resolvent of scattering operator). In the cases when this connection can be made Corollary III.9 says that the imaginary part of the resonances is exponentially small. The same argument applies to other bound states and/or resonances of D in the interval $(\lambda_{1,\infty},\infty)$ (as far as they exist).

APPENDIX A: ANALYTIC SYMBOLS

We recall here in an appropriate form, besides some standard facts about pseudodifferential operators, the results we need for analytic symbols. For more details and proofs see Robert (1987), Dimassi and Sjostrand (1999), Martinez (2002), Taylor (1981), Boutet de Monvel and Kree (1967).

We consider matrix valued symbols so the product and the modulus are the standard product and matrix norm, respectively. We employ the standard notations concerning the derivatives, factorial, etc. Also for $y \in \mathbf{C}^n$, $\langle y\rangle = (1+|y|^2)^{1/2}$, and for $a,b>0$

$$\Gamma_a \times \Gamma_b = \{(x,\xi) \in \mathbf{C}^{2n},\ |\mathrm{Im}\, x| < a |\mathrm{Im}\, \xi| < b\}.$$

Symbols $a(x,\xi;\epsilon)$ are smooth matrix valued functions of $(x,\xi) \in \mathbf{R}^{2n}$ or Γ_a, depending on $\epsilon \in (0,\epsilon_0]$, as a parameter.

Definition IV.1: A function $a(x,\xi;\epsilon)$ defined on $\mathbf{R}^{2n}\times(0,\epsilon_0]$, is said to be a symbol in $S^m(\langle x\rangle^{-\delta})$, for some $m,\delta \in \mathbf{R}$ if a is a smooth function of (x,ξ) and, for all $\alpha,\beta \in \mathbf{N}^n$, there exist $C_{\alpha,\beta}>0$ such that

$$\sup_{(x,\xi)\in\mathbf{R}^{2n},\epsilon\in(0,\epsilon_0]} |\langle\xi\rangle^{-m}\langle x\rangle^{\delta}\partial_x^{\alpha}\partial_{\xi}^{\beta}a(x,\xi,\epsilon)| \leqslant C_{\alpha,\beta}.$$

In particular $S^0(1)$ is the set of $a(x,\xi,\epsilon)$ which are uniformly bounded together with all their derivatives. For $a \in \mathcal{S}^0(\langle x\rangle^{-\delta})$ and $p \in \mathbf{N}$ we set

$$|||a|||_{p,\delta} = \sup_{(x,\xi)\in\mathbf{R}^{2n},\epsilon\in(0,\epsilon_0]} \sum_{|\alpha|+|\beta|\leqslant p} |\langle x\rangle^{\delta}\partial_x^{\alpha}\partial_{\xi}^{\beta}a(x,\xi;\epsilon)|. \tag{4.1}$$

Definition IV.2: A function $a(x,\xi,\epsilon)$, $(x,\xi)\in\Gamma_a\times\Gamma_b$, $\epsilon\in(0,\epsilon_0]$ is called an analytic symbol of class $\mathcal{S}_A^m(\langle x\rangle^{-\delta})$ for some m, $\delta\in\mathbf{R}$ if it is analytic in $\Gamma_a\times\Gamma_b$ and, for any $a'<a, b'<b$, there exists $K>0$ such that

$$\sup_{(x,\xi)\in\Gamma_{a'}\times\Gamma_{b'},\epsilon\in(0,\epsilon_0]} |\langle\xi\rangle^{-m}\langle x\rangle^{\delta}a(x,\xi,\epsilon)| \leqslant K. \tag{4.2}$$

Definition IV.3: Given a family $a_j(x,\xi)\in\mathcal{S}_A^m(\langle x\rangle^{-\delta})$, $j\in\mathbf{N}$, analytic on $\Gamma_a\times\Gamma_b$ such that, for any $a'<a, b'<b$, there exists a constant $C>0$ independent of j such that

$$\sup_{(x,\xi)\in\Gamma_{a'}\times\Gamma_{b'}} |\langle\xi\rangle^{m}\langle x\rangle^{\delta}a_j(x,\xi)| \leqslant C^{j+1}j! \tag{4.3}$$

we call $a_f=\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$ a formal analytic symbol of class $\mathcal{S}_A^0(\langle x\rangle^{-\delta})$ on $\Gamma_a\times\Gamma_b$.

We say that a symbol $a(x,\xi;\epsilon)\in\mathcal{S}_A^m(\langle x\rangle^{-\delta})$ is asymptotic equivalent to the formal analytic symbol $\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$ and we write

$$a \sim \sum_{j=0}^{\infty} \epsilon^j a_j(x,\xi)$$

if there exists a constant $C>0$ such that for any $N\in\mathbf{N}$ and any $a'<a, b'<b$,

$$\sup_{(x,\xi)\in\Gamma_{a'}\times\Gamma_{b'},\epsilon\in(0,\epsilon_0]} \left| \langle\xi\rangle^{-m}\langle x\rangle^{\delta}\left(a(x,\xi;\epsilon) - \sum_{j=0}^{N} \epsilon^j a_j(x,\xi)\right)\right| \leqslant C^{N+1}\epsilon^{N+1}(N+1)!. \tag{4.4}$$

If $\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$ *is a formal analytic symbol, and $T>0$ is sufficiently large then one can define $a^T(x,\xi;\epsilon)=\Sigma_{j=0}^{[1/T\epsilon]}\epsilon^j a_j(x,\xi)$ (unique modulo $\mathcal{O}(e^{-c/\epsilon})$) satisfying (4.4). The symbol $a^T(x,\xi;\epsilon)$ is called a resummation of the formal analytic symbol $\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$ and any symbol a that can be written as such a resummation up to error $O(e^{-c/\epsilon})$ is an analytic representation of the formal analytic symbol $\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$.*

Let us notice [see Boutet de Monvel and Kree (1967)] that a formal symbol $a=\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$ belongs to $S_A^{m_1}(\langle x\rangle^{-\delta_1})$ on $\Gamma_a\times\Gamma_b$ if and only if, for any $a',b'>0, a'<a, b'<b$, the series

$$N_{\delta_1}^{m_1}(a,T)=\sum_{j=0}^{\infty}T^j\left(\sum_{|\alpha|+|\beta|+2k=j}c_{k,\alpha}^{\beta}A_{k,\alpha,\delta_1}^{\beta,m_1}\right),$$

where

$$A_{k,\alpha,\delta_1}^{\beta,m_1}:=\sup_{(x,\xi)\in\Gamma_{a'}\times\Gamma_{b'}}\left|\langle x\rangle^{\delta_1}\langle\xi\rangle^{-m_1}\partial_x^{\alpha}\partial_\xi^{\beta}a_k\right|\leqslant C^{k+|\alpha|+|\beta|+1}k!\alpha!\beta! \tag{4.5}$$

and

$$c_{k,\alpha}^{\beta}=\frac{2(2n)^{-k}k!}{(k+|\alpha|)!(k+|\beta|)!}$$

has a nonzero radius of convergence as a series in T.

If $a_f=\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$ and $b_f=\Sigma_{j=0}^{\infty}\epsilon^j b_j(x,\xi)$ are two formal analytic symbols on $\Gamma_a\times\Gamma_b$, we define, as usual, the Weyl product

$$a_f\# b_f\equiv r_f=\sum_{m=0}^{\infty}\epsilon^m r_m, \tag{4.6}$$

where

$$r_m=\sum_{|\gamma|+|\theta|+l+s=m}\Gamma(\gamma,\theta)D_x^{\gamma}\partial_\xi^{\theta}a_l D_x^{\theta}\partial_\xi^{\gamma}b_l \tag{4.7}$$

and $\Gamma(\alpha,\beta)=(1)^{\beta}/\alpha!\beta!2^{|\alpha|}2^{|\beta|}$.

The basic result [Boutet de Monvel and Kree (1967)] about the class of formal analytic symbols is that it is closed under Mpyal multiplication. More precisely, using Lemma 1.2 in Boutet de Monvel and Kree (1967), one can prove that

$$N_{\delta_1^+\delta_2}^{m_1+m_2}(r,T)\lll N_{\delta_1}^{m_1}(p,T)N_{\delta_2}^{m_2}(q,T),$$

where $\lll$ means that the coefficient of T^j in the first member is less than the same in the second member. As a consequence we have the following.

Lemma IV.4: Let $a_f=\Sigma_{j=0}^{\infty}\epsilon^j a_j(x,\xi)$ and $b_f=\Sigma_{j=0}^{\infty}\epsilon^j b_j(x,\xi)$ two formal analytic symbol on $\Gamma_a\times\Gamma_b$, then $a_f\# b_f$ is a formal analytic symbol on $\Gamma_a\times\Gamma_b$ in the class $S_A^{m_1+m_2}(\langle x\rangle^{-\delta_1-\delta_2})$.

Moreover, we have the following.

Lemma IV.5: Let $r_f=\Sigma_{j=1}^{\infty}\epsilon^j r_j$ is a formal analytic symbol in the class $S_A^0(\langle x\rangle^{-\delta_1})$ on $\Gamma_a\times\Gamma_b$. Then $\Sigma_{j=1}^{\infty}r_f^{\#j}$ is a formal analytic symbol in the class $S_A^0(\langle x\rangle^{-\delta_1})$ on $\Gamma_a\times\Gamma_b$.

Proof: It is sufficient to observe that

$$N_\delta^0\left(\sum_{j=1}^{\infty}r^{\#j},T\right)\lll N_\delta^0(r,T)\sum_{j=0}^{\infty}N_0^0(r,T)^j=N_\delta^0(r,T)(1-N_0^0(r,T))^{-1}.$$

[The last series is a convergent for sufficiently small $\langle T\rangle$ since $N_0^0(r,T)$ is, for sufficiently small T, a convergent series and has no constant term.]

We are now in position to state the basic result on composition of pseudodifferential operators [see, e.g., Martinez (2002)]. Given a symbol $a\in S_A^m(\langle x\rangle^{-\delta})$ we denote by $\mathrm{Op}_\epsilon^w(q(x,\xi;\epsilon))$ we denote the ϵ-pseudodifferential operator which, for $\phi\in C_0^{\infty}(\mathbf{R}^n,\mathbf{R}^{\oplus k})$ is defined by the oscillatory integral

$$\mathrm{Op}_\epsilon^w(a(x,\xi;\epsilon))\phi=(2\pi\epsilon)^{-n}\int e^{i(x-y)\xi/\epsilon}a\left(\frac{x+y}{2},\xi;\epsilon\right)\phi(y)\mathrm{d}y\,\mathrm{d}\xi. \tag{4.8}$$

Lemma IV.6: Let $a(x,\xi,\epsilon)\epsilon S^{m_1}(\langle x\rangle^{-\delta_1})$, $b(x,\xi,\epsilon)\in S^{m_2}(\langle x\rangle^{-\delta_2})$, m_i,δ_i, $i=1,2$. *Then* $a\#b$ *given by the oscillatory integral (2.2) belong to* $S^{m_1+m_2}(\langle x\rangle^{-(\delta_1+\delta_2)})$.

Moreover, if $a(x,\xi,\epsilon)\sim\Sigma_{j=0}^{\infty}a_j(x,\xi)\epsilon^j\in S_A^{m_1}(\langle x\rangle^{-\delta_1})$, $b(x,\xi,\epsilon)\sim\Sigma_{j=0}^{\infty}b_j(x,\xi)\epsilon^j\in S_A^{m_2}(\langle x\rangle^{-\delta_2})$ *then* $a\#b\in S_A^{m_1+m_2}(\langle x\rangle^{-(\delta_1+\delta_2)})$ *and*

$$a\#b\sim\left(\sum_{j=0}^{\infty}a_j(x,\xi)\epsilon^j\right)\#\left(\sum_{j=0}^{\infty}b_j(x,\xi)\epsilon^j\right),\tag{4.9}$$

where # is the Weyl composition of formal symbol defined in (4.6) and (4.7).

The last result we collect is the Calderon–Vaillancourt theorem.

Theorem IV.7: *Let* $a(x,\xi;\epsilon)\in S^0(\langle x\rangle^{-\delta})$. *Then, there exists* $M>0$, $p\in\mathbf{N}$ *depending only on* n,m,δ *such that*

$$\|\mathrm{Op}_\epsilon^w(a)\|_\delta\leqslant M|||a|||_{p,\delta}.\tag{4.10}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 10 OCTOBER 2004

INTRODUCTION

Quantum groups are a remarkable generalization of conventional groups using an algebraic language by now quite well-known to mathematical physicists. One replaces the notion of a Lie algebra symmetry by a "quantum enveloping algebra" which generalizes the usual enveloping algebra of a Lie algebra. Or one may replace the coordinate algebra of functions on a conventional group by a more general algebra, typically noncommutative or "quantum." In either case, the natural formulation of the more general object is a "Hopf algebra," a notion that had been proposed in the 1940s by pure mathematicians but without truly representative examples. It is now about 20 years since the subject exploded with the discovery of such quantum groups in mathematical physics, mainly in the theory of quantum inverse scattering (the quantum groups $U_q(g)$ of Drinfeld and Jimbo) but also in Planck-scale physics (the less well-known bicrossproduct quantum groups based on Lie group factorizations). The latter have provided some of the first models of noncommutative space–time with potentially measurable quantum/gravity corrections.

Remarkably, it is also about 20 years since the serious development of "noncommutative geometry" in the form of cyclic cohomology as a means of capturing geometric information about a space in terms of its algebra of functions, while making sense for more general algebras. Here again the roots of the subject go back on the mathematics side to theorems of Gelfand and Naimark in the 1940s and 1950s followed by the development of K-theory and K-homology in the 1970s. From a physicists point of view the "general idea" of replacing classical coordinates such as x, p on a classical phase space by noncommuting operator variables $\mathbf{x}$, $\mathbf{p}$ dates back to the birth of quantum mechanics itself; many authors, starting with Dirac in the 1920s, have asked how far "geometry" could be extended to such operator variables. Again, convincing examples were an issue, with the papers of Connes and of Connes-Rieffel on the differential structure of, and Yang–Mills theory over, a noncommutative torus in the 1980s probably a turning point.

Both fields have matured considerably over the intervening 20 years and two things could be said to be emerging. First of all, noncommutative geometry and quantum groups *should* be intimately related and this is slowly beginning to be explored; the cyclic cohomology of (for example, bicrossproduct) quantum groups has been computed while conversely quantum groups methods such as "Drinfeld cotwisting" are being applied to construct geometry on noncommutative tori and their cousins. The process is still in its infancy; for example the q-deformed quantum groups do not fit well into usual cyclic cohomology, which has to be generalized. Secondly, and more importantly for this volume, 20 years has been long enough for mathematical physicists to absorb the new ideas and algebraic methods and, now finding them routine, begin actually to use them in genuine physical situations. As with supersymmetry before it, it could be considered that the "wave of algebraic methods" encompased by quantum groups and noncommutative geometry has swept through the general mathematical physics community and left it enriched with powerful new tools which were not widely known before.

In this special issue on **Quantum groups and noncommutative geometry** it is certainly not possible to do justice to all the new directions which are opening up in the light of such developments. Rather, the volume aims to provide a partial snapshot of a few of the more exciting aspects looking forward. Most of the articles are research articles but two are major reviews. Bearing in mind that both quantum groups and noncommutative geometry are already covered in existing textbooks (such as my 1995 book from the Hopf algebras perspective and Connes's 1994 book from the cyclic cohomology perspective), the review articles are intended to give more exposure to other important points of view. The review article on the deformation theory view of quantum groups contains much that is accessible to physicists while providing a self-contained clean presentation of results which are otherwise scattered or vaguely formulated as well as some new results. The other review article is part of an approach to noncommutative algebraic geometry and introduces the reader to powerful homological methods which have an emerging role in mirror symmetry, string theory, BRST quantization and other topics.

The research articles meanwhile fall into three groups reflecting a broad interpretation both of noncommutative geometry and of the role of quantum groups and related objects. The first group of papers consists of several articles involving quantum groups or Hopf algebras in their mature form. Two of them are applications to actual physics, to renormalization in quantum field theory and to anyons. Two more are q-deformation papers of the "classical" style in quantum group theory, here relating to noncompact quantum groups which is a topic currently on the cutting edge. The remaining article in the group is about the famous "quantum Yang–Baxter equations," but now on finite sets which is another active frontier. New algebraic structures emerge in connection with these famous equations, linked to finite group bicrossproducts among other things.

The second group of papers is centered on categorical methods and two themes which we consider important for future developments in both physics and mathematics: 2-categories on the one hand and nonassociative algebras such as the octonions on the other. If quantum groups has taught us one thing, it is perhaps that categorical issues impinge directly on what is "natural" in physics and can be used to create and organize correct structures. Quantum group methods enter in the form of quasi-Hopf algebras, monoidal categories, and in the foundations of the theory of 2-categories, for example. While three of the papers are quite mathematical, three others relate to the potential physics of quite a concrete nature in the areas of nonstandard statistics and quarks, parallel transport on surfaces in higher gauge theory, and the possible role of the octonions in the standard model.

The last group of papers contains work on Fedosov quantization, mirror symmetry, and groupoids, all aspects of the broader noncommutative geometry of manifolds. We may stress again that the special issue covers only a small and incomplete sample of the rapidly developing literature.

(Received 11 June 2004; accepted 7 June 2004; published 12 October 2004)

Deformation quantization, which gives a development of quantum mechanics independent of the operator algebra formulation, and quantum groups, which arose from the inverse scattering method and a study of Yang–Baxter equations, share a common idea abstracted earlier in algebraic deformation theory: that algebraic objects have infinitesimal deformations which may point in the direction of certain continuous global deformations, i.e., "quantizations." In deformation quantization the algebraic object is the algebra of "observables" (functions) on symplectic phase space, whose infinitesimal deformation is the Poisson bracket and global deformation a "star product," in quantum groups it is a Hopf algebra, generally either of functions on a Lie group or (often its dual in the topological vector space sense, as we briefly explain) a completed universal enveloping algebra of a Lie algebra with, for infinitesimal, a matrix satisfying the modified classical Yang–Baxter equation (MCYBE). Frequently existence proofs are known but explicit formulas useful for physical applications have been difficult to extract. One success here comes from "universal deformation formulas" (UDFs), expressions built from a Lie algebra which deform any algebra on which the Lie algebra operates as derivations. The most famous of these is the Moyal product, a special case of a class in which the Lie algebra is Abelian. Another comes from recognition that the Belavin–Drinfel'd solutions to the MCYBE are, in fact, infinitesimal deformations for which, in the case of the special linear groups, it is possible to give explicit formulas for the corresponding quantum Yang–Baxter equations. This review paper discusses, necessarily in brief, these and related topics, including "twisting" as a form of UDF and finding formulas for "preferred deformations" of Hopf algebras in which the multiplication or comultiplication is rigid and must be preserved in the course of deformation. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1786681]

I. INTRODUCTION

Mathematics arose as an abstraction of the physical world and thenceforth often became something entirely different. Still, the physical origin of many mathematical notions can be traced and is implicit in many developments. That is what we call physical *mathematics*. On the other hand, mathematics is the main language of theoretical physics, albeit used with a very peculiar accent, and the "mathematics toolbox" is crucial in *mathematical physics*. That mutual interaction appears as a watermark throughout many works, including the present paper.

It can be said that quantum groups arose "experimentally" in the Leningrad LOMI group of Ludwig Faddeev around 1980 [see, e.g., Kulish and Reshetikhin (1981) and Faddeev *et al.* (1988)], during attempts to quantize two-dimensional integrable models by methods coming from inverse scattering and a study of what they called Yang–Baxter equations. *A posteriori* it was discovered that some aspects (e.g., q-special functions in the 19th century) were present much earlier and that the notion is of importance in various areas of physics, including solid state. A recent primer of quantum groups from the physical viewpoint is Majid (2002).

Significant steps forward were made shortly afterwards, in particular when Jimbo (1985) systematized these attempts in his study of quantized enveloping algebras. Even more so when Drinfel'd (1987) made explicit the underlying Hopf algebra structures and, relating the dual aspect to deformation quantization, coined the expression "quantum groups."

Deformation quantization was certainly "in the back of the mind" of many almost since the beginning of quantum mechanics ["wave mechanics" in de Broglie (1928)] and its avatars developed since 1925 by Heisenberg ("matrix mechanics"), Schrödinger (with his celebrated equation) and especially Weyl with his quantization procedure [Weyl (1931) and Wigner (1932)]. But the relation with deformation theory [Gerstenhaber (1964)] and its role in physics [see, e.g., Flato (1982)] was made only in Bayen *et al.* (1978).

Already in the formulation of Drinfel'd (1987), it is clear that quantum groups are an avatar of deformation quantization, when the category of Hopf algebras is taken into account. But one aspect remained imprecise: the duality between the two aspects, deformations of (functions over) Poisson–Lie groups, and quantized enveloping algebras. That was, at least in the compact and semisimple cases, made clear later [Bonneau *et al.* (1994) and Bidegain and Pinczon (1996)], using natural topologies on the corresponding Hopf algebras.

There is another duality which remains largely unexplored. The Gelfand isomorphism theorem, by which commutative algebras can be considered as algebras of functions over some space (their spectrum), expresses a "duality" between a commutative algebra and a topological space. Now, on one hand, commutative algebras are deformed into noncommutative (associative or Hopf) algebras. On the other hand, differentiable manifolds, characterized, e.g., by some algebraic properties, are deformed into noncommutative ones. And manifolds have symmetries that often can be quantized. These related aspects are so far developed separately, to a large extent. A natural question is thus to study their relations. A very abstract attempt can be found in Kontsevich and Rosenberg (2000). In view of the present rapid developments in noncommutative manifolds [see, e.g., Kontsevich and Rosenberg (2000), Connes and Landi (2001), and Connes and Dubois-Violette (2003)] one should probably start with specific examples and see if a pattern arises, hence the need for explicit approaches.

In mathematics an abstract existence proof [such as the one in Etingof and Kazhdan (1998)] is perfectly satisfactory, even more so when an algorithmic construction is given [such as in Fedosov (1994)]. But for physical applications one needs to perform explicit calculations and few realizations are truly explicit. In the compact case, the ideas underlying Bonneau *et al.* (1994) were tested in the basic example of SU(2) where explicit formulas were obtained [Bonneau *et al.* (1992)]. We shall present here that example with this fact in mind. We also present the only known explicit formulas expressing the preferred deformation of a standard quantum algebra. Namely, the preferred *-products for the quantum linear spaces associated with the standard q-deformation of the special linear group $\mathrm{SL}(n)$. These approaches show that deformation quantization is implicit in most aspects of quantum groups theory.

Now, for deformation quantization, the paradigm of the Moyal star product is explicit enough,

and so are a number of related integral formulas in $\mathbb{R}^{2n}$ and a few manifolds. Some examples can be found in Bieliavsky and Maeda (2002). But for general symplectic, even more so Poisson, manifolds one has mainly existence theorems which are not easily made explicit. At its origin 25 years ago and again much more recently [Frønsdal (1979)], some explicit formulas were and are being developed. A somewhat explicit formula for many coadjoint orbits was recently developed (Alekseev and Lachowska) in terms of a pairing for generalized Verma modules. Related formulas can be found in Donin and Mudrov (2002), Enriquez *et al.* (2004), and Karolinsky *et al.* (2003). Part of this paper will be devoted to explicit approaches in that underlying aspect of quantum groups theory. In particular we shall see that quantum groups techniques may produce explicit (strict) deformation quantizations on the basis of what we call universal deformation formulas (UDFs). These come from mathematical entities living within a given algebraic structure S and they produce explicit deformations of any algebra which is also an S-module.

We start this paper (Sec. II) with a short presentation of deformation theory, mostly following Gerstenhaber. That somewhat arid presentation will be balanced by complements and, in Sec. III, by a survey of how quantum mechanics *is* a deformation of classical mechanics, with some explicit examples. Section IV begins with the explicit example [the case of $\mathrm{SU}_q(2)$] that triggered the general theory (presented afterwards) of both approaches to quantum groups (functions on a Poisson–Lie group and quantized enveloping algebras) as dual topological Hopf algebras, at least in the semisimple case. The latter theory being (in the general case) not explicit enough we devote Sec. V to a variety of explicit formulas for deformation quantization (star products), in particular for symmetric spaces and related universal deformation formulas. Section VI discusses the implications of the preceding study for obtaining explicit formulas for quantum groups, via star products or R matrices.

This paper contains only a brief review of some of the rapid developments in deformation quantization since its introduction in Bayen *et al.* (1978). André Weil's prediction near the end of the last century that deformation theory would be a major topic in the 21st so far seems justified.

II. PRELIMINARIES

A. The Gestenhaber theory of deformations of algebras

A concise formulation of a Gerstenhaber deformation of an algebra (associative, Lie, bialgebra, etc.) is [Gerstenhaber (1963, 1964) and Bonneau *et al.* (1994)]:

Definition: A deformation of an algebra A over a field $\mathbb{K}$ with deformation parameter ν is a $\mathbb{K}[[\nu]]$-algebra $\tilde{A}$ such that $\tilde{A}/\nu\tilde{A} \approx A$, where A is here considered as an algebra over $\mathbb{K}[[\nu]]$ by base field extension. Two deformations $\tilde{A}$ and $\tilde{A}'$ are called equivalent if they are isomorphic over $\mathbb{K}[[\nu]]$ (by a deformation which reduces to the identity modulo ν, which will always be tacitly understood). A deformation $\tilde{A}$ is said to be trivial if it is isomorphic to the original algebra A (considered by base field extension as a $\mathbb{K}[[\nu]]$-algebra).

Whenever we consider a topology on A, $\tilde{A}$ is supposed to be topologically free. The above definition can [cf., e.g., Kontsevich (1999) and Kontsevich and Soibelman (2000)] be extended to operads, so as to apply to the Assoc, Lie, Bialg and maybe Gerst operads, and also to the Hopf category (which can not be described by an operad), all possibly with topologies. In the present mathematical physics paper we shall not probe these sophistications, but the reader should keep such powerful possibilities in mind.

For associative (resp. Lie) algebras, the above definition tells us that there exists a new product * (resp. bracket $[\cdot,\cdot]$) such that the new (deformed) algebra is again associative (resp. Lie). Denoting the original composition laws by ordinary product (resp. $\{\cdot,\cdot\}$) this means that, for $u_1, u_2 \in A$ (we can extend this to $A[[\nu]]$ by $\mathbb{K}[[\nu]]$-linearity) we have

$$u_1 * u_2 = u_1 u_2 + \sum_{r=1}^{\infty} \nu^r C_r(u_1, u_2), \tag{1}$$

$$[u_1,u_2]=\{u_1,u_2\}+\sum_{r=1}^{\infty}\nu^r B_r(u_1,u_2), \tag{2}$$

where the C_r are Hochschild 2-cochains and the B_r (skew-symmetric) Chevalley–Eilenberg 2-cochains, such that for $u_1,u_2,u_3\in A$ we have $(u_1*u_2)*u_3=u_1*(u_2*u_3)$ and $\mathcal{S}[[u_1,u_2],u_3]=0$, where $\mathcal{S}$ denotes summation over cyclic permutations.

For a (topological) *bialgebra* (an associative algebra A where we have in addition a coproduct $\Delta:A\to A\otimes A$ and the obvious compatibility relations), denoted by $\otimes_\nu$ the tensor product of $\mathbb{K}[[\nu]]$-modules we can identify $\tilde{A}\hat{\otimes}_\nu\tilde{A}$ with $(A\hat{\otimes}A)[[\nu]]$, where $\hat{\otimes}$ denotes the algebraic tensor product completed with respect to some topology (e.g., projective for Fréchet nuclear topology on A). We similarly have a deformed coproduct $\tilde{\Delta}=\Delta+\Sigma_{r=1}^{\infty}\nu^r D_r$, $D_r\in \mathrm{L}(A,A\hat{\otimes}A)$, satisfying $\tilde{\Delta}(u_1*u_2)=\tilde{\Delta}(u_1)*\tilde{\Delta}(u_2)$. In this context appropriate cohomologies can be introduced [Gerstenhaber and Schack (1990) and Bonneau (1992)]. There are natural additional requirements for Hopf algebras.

Equivalence means that there is an isomorphism $T_\nu=I+\Sigma_{r=1}^{\infty}\nu^r T_r$, $T_r\in \mathrm{L}(A,A)$ so that $T_\nu(u_1*'u_2)=(T_\nu u_1*T_\nu u_2)$ in the associative case, denoting by * (resp. *′) the deformed laws in $\tilde{A}$ (resp. $\tilde{A}'$;) and similarly in the Lie, bialgebra and Hopf cases. In particular we see (for $r=1$) that a deformation is trivial at order 1 if it starts with a 2-cocycle which is a 2-coboundary. More generally, exactly as above, we can show [Bayen *et al.* (1978)] [Gerstenhaber and Schack (1988) and Bonneau (1992) in the Hopf case] that if two deformations are equivalent up to some order t, the condition to extend the equivalence one step further is that a 2-cocycle (defined using the T_k, $k\leqslant t$) is the coboundary of the required T_{t+1} and therefore *the obstructions to equivalence lie in the 2-cohomology*. In particular, if that space is null, all deformations are trivial.

Unit: An important property is that a *deformation of an associative algebra with unit* (what is called a unital algebra) is again unital, and *equivalent to a deformation with the same unit*. This follows from a more general result of Gerstenhaber (for deformations leaving unchanged a subalgebra) and a proof can be found in Gerstenhaber and Schack (1988).

Remark 1: In the case of (topological) *bialgebras* or *Hopf* algebras, *equivalence* of deformations has to be understood as an isomorphism of (topological) $\mathbb{K}[[\nu]]$-algebras, the isomorphism starting with the identity for the degree 0 in ν. A deformation is again said to be *trivial* if it is equivalent to that obtained by base field extension. For Hopf algebras the deformed algebras may be taken (by equivalence) to have the same unit and counit, but in general not the same antipode.

B. Complements

1. A brief historical survey: Contractions and deformations

The discovery, about 2000 years ago, of the nonflat nature of Earth is probably the first empirical introduction of the notion of deformation in our description of the universe. Closer to us, the paradox coming from the Michelson and Morley experiment (1887) was resolved in 1905 by Einstein with the special theory of relativity: in our context, one can express that by saying that the Galilean geometrical symmetry group of Newtonian mechanics is deformed to the Poincaré group, the deformation parameter being c^{-1}, where c is the velocity of light in vacuum.

Curiously, it is the (less precisely defined) inverse notion of contraction of symmetries that was first introduced in mathematical physics [Segal (1951), Inönü and Wigner (1953), Saletan (1961)]. Contractions, "limits of Lie algebras" as they were called in the first examples, can be viewed as an inverse of deformations—but not necessarily of Gerstenhaber-type deformations (see Sec. II B 3 below). We shall not expand here on that "inverse" notion but, for completeness, give its flavor. A (finite dimensional) Lie algebra can be described in a given basis L_i $(i=1,\ldots,n)$ by its structure constants $C_{i,j}^k$. The equations governing the skew symmetry of the Lie bracket and the Jacobi identity insure that the set of all structure constants lies on an algebraic variety in that n^3 dimensional space [Lévy-Nahas (1967)]. A contraction is obtained, e.g., when one makes a simple basis change of the form $L_i'=\varepsilon L_i$ on some of the basis elements, and then lets $\varepsilon\to 0$. Take, for

example, $n=3$ and restrict to the three-dimensional subspace of the algebraic variety of three-dimensional Lie algebras with commutation relations $[L_1,L_2]=c_3L_3$ and cyclic permutations. The semi-simple algebras $\mathfrak{so}(3)$ and $\mathfrak{so}(2,1)$ are obtained in the open set $c_1c_2c_3\neq 0$. A contraction gives the Euclidean algebras, where one c_i is 0. The "coordinate axes" (two of the c_i's are 0) give the Heisenberg algebra and the origin is the Abelian Lie algebra. This is of course a partial picture (e.g., solvable algebras are missing) but it is characteristic. The passage from the Poincaré Lie algebra to the Galilean is a higher dimensional version of it. Dirac constraints [mathematically, a restriction from $\mathbb{R}^{2n}$ to a symplectic or Poisson submanifold, see, e.g., Lichnerowicz (1975)] can give such contractions and be interpreted in terms of star products [Arnal and Cortet (1979)].

An implicit mathematical example of deformations (in a geometric context) was introduced in mid-19th century by Riemann who counted the number of "moduli" or parameters of Riemann surfaces. Teichmüller (1939) ["It does not of necessity follow that, if the work delights you with its grace, the one who wrought it is worthy of your esteem," cf. Lipman Bers (1998) (p. 324, after Plutarch, Pericles 2.1; Lives, Loeb's Classical Library 3, p. 5) who however, with André Weil, despite personal abhorrence of someone who helped drive Jewish mathematicians from Nazi Germany, fully credited his work] made deformations of Riemann surfaces explicit and identified infinitesimal deformations as quadratic differentials. The correct definition, applicable to complex manifolds of arbitrary dimension, is in the short but ground breaking note of Frölicher and Nijenhuis (1957). They showed that if all infinitesimal deformations vanished then the manifold was rigid ("stable" in their terminology), i.e., possessed no global deformations. This was the impetus for the deep and comprehensive work of Kodaira and Spencer (1958). Curiously, however, the possibility of obstructions to infinitesimal deformations (which cannot occur in the case of Riemann surfaces because of the low dimension) was not originally understood, and appeared in the words of Kodaira and Spencer as an "experimental fact."

Now, when one has an action on a geometrical structure, it is natural to try and "linearize" it by inducing from it an action on an algebra of functions on that structure. That is implicitly what Gerstenhaber (1964) did with his definition and thorough study of deformations of rings and algebras. We shall encounter the concept of contraction more explicitly as it relates to quantum groups later in Sec. VI D.

2. Homotopy of deformations

For reasons that are related to the so-called Donald–Flanigan conjecture, two of us considered [see Gerstenhaber and Giaquinto (1998) and Gerstenhaber *et al.* (2001)] the question of (formal) *compatibility* of deformations, a kind of homotopy in the variety of algebras between two deformations (1) with parameters ν and ν' and cochains C_r and C'_r. By this he means a 2-parameter deformation of the form

$$u_1 \tilde{*} u_2 = u_1u_2 + \nu C_1(u_1,u_2) + \nu' C'_1(u_1,u_2) + \sum_{r=2}^{\infty} \Phi_r(u_1,u_2;\nu,\nu'), \tag{3}$$

where each Φ_r is a polynomial of total degree r in ν and ν', which reduces to the first one-parameter deformation when $\nu'=0$ and to the second when $\nu=0$. At the first order the condition for this to hold (e.g., for associative algebras) is that the Gerstenhaber bracket [Gerstenhaber (1964)] $[C_1,C'_1]_G$ is a 3-coboundary, and here also there are higher obstructions. As an example, it follows from Hochschild *et al.* (1962) that the Weyl algebra and the quantum plane are formally **(**but nonanalytically [Giaquinto and Zhang (1995)]**)** compatible nonequivalent deformations of the polynomial algebra $\mathbb{C}[x,y]$. Below we shall see another appearance of such a 2-parameter deformation in a physical context [Basart *et al.* (1984)].

3. More general deformations

Deformations that are more general than the "DrG-deformations" of Gerstenhaber can (and have been) introduced, where, e.g., the deformation "parameter" may act on the algebra.

Nambu (1973) published some calculations which he had made a dozen years before: with quarks in the back of his mind he started with a kind of "Hamilton equations" on $\mathbb{R}^3$ with two "Hamiltonians" g, h functions of r. In this new mechanics the evolution of a function f on $\mathbb{R}^3$ is $df/dt=\partial(f,g,h)/\partial(x,y,z)$, a 3-bracket, where the right-hand side is the Jacobian of the mapping $\mathbb{R}^3\to\mathbb{R}^3$ given by $(x,y,z)\mapsto(f,g,h)$. That expression was easily generalized, e.g., to n functions f_i, $i=1,\ldots,n$.

In order to quantize the Nambu bracket a natural idea is to replace, in the definition of the Jacobian, the pointwise product of functions by a deformed product. For this to make sense, the deformed product should be Abelian, so we are lead to consider commutative DrG-deformations of an associative and commutative product. But the commutative part of Hochschild cohomology (called Harrison cohomology) is trivial, at least in the absence of singularities [see however Frønsdal (2002)]. So in Dito *et al.* (1997) a kind of "second quantization" procedure was used, where the deformation parameter behaves as if it was nilpotent (like Pauli matrices).

This triggered Pinczon (1997) and Nadaud (1998) to generalize the Gerstenhaber theory to the case of a deformation parameter which *does not commute with the algebra*, but acts on it. Though this generalization of deformations does not (yet) give Nambu mechanics quantization, it opens a whole new direction of research for deformation theory. In particular [Pinczon (1997)], while the Weyl algebra W_1 (generated by the Heisenberg Lie algebra h_1) is known to be DrG-rigid, it can be nontrivially deformed in such a *supersymmetric deformation theory* to the supersymmetry enveloping algebra $\mathcal{U}(\mathfrak{osp}(1,2))$. Also [Nadaud (1998)] on the polynomial algebra $\mathbb{C}[x,y]$ in 2 variables, Moyal-type products of a new type were discovered. All these deformations give the original algebra by a contraction, when the parameter goes to 0. So there is life outside the DrG framework, even if that is so far largely unexplored.

III. QUANTUM MECHANICS AS A DEFORMATION

A. The setting

Intuitively, classical mechanics is the limit of quantum mechanics when $\hbar=h/2\pi$ goes to zero. But how can this be realized when in classical mechanics the observables are functions over phase space (a Poisson manifold) and not operators? The deformation philosophy promoted by Flato shows the way: one has to look for deformations of algebras of classical observables, functions over Poisson manifolds, and realize there quantum mechanics in an *autonomous* manner.

What we call "deformation quantization" relates to (and generalizes) what in the conventional (operatorial) formulation are the Heisenberg picture and Weyl's quantization procedure. In the latter [Weyl (1931)], starting with a classical observable $u(p,q)$, some function on phase space $\mathbb{R}^{2\ell}$ (with $p,q\in\mathbb{R}^{\ell}$), one associates an operator (the corresponding quantum observable) $\Omega(u)$ in the Hilbert space $L^2(\mathbb{R}^{\ell})$ by the following general recipe:

$$u\mapsto\Omega_w(u)=\int_{R^{2\ell}}\tilde{u}(\xi,\eta)\exp(i(P\cdot\xi+Q\cdot\eta)/\hbar)w(\xi,\eta)d^{\ell}\xi d^{\ell}\eta, \tag{4}$$

where $\tilde{u}$ is the inverse Fourier transform of u, P_α and Q_α are operators satisfying the canonical commutation relations $[P_\alpha,Q_\beta]=i\hbar\delta_{\alpha\beta}$ $(\alpha,\beta=1,\ldots,\ell)$, w is a weight function and the integral is taken in the weak operator topology. What is called in physics normal (or antinormal) ordering corresponds to choosing for weight $w(\xi,\eta)=\exp\left(-\frac{1}{4}(\xi^2\pm\eta^2)\right)$. Standard ordering (the case of the usual pseudodifferential operators in mathematics) corresponds to $w(\xi,\eta)=\exp(-(i/2)\xi\eta)$ and the original Weyl (symmetric) ordering to $w=1$. An inverse formula was found shortly afterwards by Eugene Wigner (1932) and maps an operator into what mathematicians call its symbol by a kind of trace formula. For example Ω_1 defines an isomorphism of Hilbert spaces between $L^2(\mathbb{R}^{2\ell})$ and Hilbert–Schmidt operators on $L^2(\mathbb{R}^{\ell})$ with inverse given by

$$u = (2\pi\hbar)^{-\ell}\,\mathrm{Tr}[\Omega_1(u)\exp((\xi\cdot P+\eta\cdot Q)/i\hbar)] \tag{5}$$

and if $\Omega_1(u)$ is of trace class one has $\mathrm{Tr}(\Omega_1(u))=(2\pi\hbar)^{-\ell}\int u\omega^{\ell}\equiv \mathrm{Tr}_M(u)$, the "Moyal trace," where ω^{ℓ} is the (symplectic) volume dx on $\mathbb{R}^{2\ell}$. Looking for a direct expression for the symbol of a quantum commutator, Moyal (1949) found what is now called the Moyal bracket:

$$M(u_1,u_2)=\nu^{-1}\sinh(\nu P)(u_1,u_2)=P(u_1,u_2)+\sum_{r=1}^{\infty}\frac{\nu^{2r}}{(2r+1)!}P^{2r+1}(u_1,u_2), \tag{6}$$

where $2\nu=i\hbar$, $P^r(u_1,u_2)=\Lambda^{i_1j_1}\cdots\Lambda^{i_rj_r}(\partial_{i_1\cdots i_r}u_1)(\partial_{j_1\cdots j_r}u_2)$ is the rth power ($r\geqslant 1$) of the Poisson bracket bidifferential operator P, $i_k,j_k=1,\ldots,2\ell$, $k=1,\ldots,r$ and $(\Lambda^{i_kj_k})=\left(\begin{smallmatrix}0 & -I\\ I & 0\end{smallmatrix}\right)$. To fix ideas we may assume here $u_1,u_2\in\mathcal{C}^{\infty}(\mathbb{R}^{2\ell})$ and the sum is taken as a formal series. A corresponding formula for the symbol of a product $\Omega_1(u)\Omega_1(v)$ can be found in Groenewold (1946) and may now be written more clearly as a (Moyal) *star product:*

$$u_1{}^{*}{}_{M}u_2=\exp(\nu P)(u_1,u_2)=u_1u_2+\sum_{r=1}^{\infty}\frac{\nu^{r}}{r!}P^r(u_1,u_2). \tag{7}$$

The formal series may be deduced [see, e.g., Bieliavsky (2002)] from an integral formula of the type

$$(u_1*u_2)(x)=c_{\hbar}\int_{\mathbb{R}^{2\ell}\times\mathbb{R}^{2\ell}}u_1(x+y)u_2(x+z)e^{-(i/\hbar)\Lambda^{-1}(y,z)}dydz. \tag{8}$$

Other integral formulas are known for quite some time [Rieffel (1993) and Maillard (1986) where the Weyl correspondence between bounded operators in $L^2(\mathbb{R}^l)$ and bounded twisted convolution operators of $L^2(\mathbb{R}^{2l})$ is also described]. It was noticed, however after deformation quantization was introduced, that the composition of symbols of pseudodifferential operators (ordered, like differential operators, "first q, then p") is a star product.

One recognizes in (7) a special case of (1), and similarly for the bracket. So, via a Weyl quantization map, the algebra of quantized observables can be viewed as a deformation of that of classical observables.

But the deformation philosophy tells us more. Deformation quantization is not merely "a reformulation of quantizing a mechanical system" [Douglas and Nekrasov (2001)], e.g., in the framework of Weyl quantization: *The process of quantization itself is a deformation*. In order to show that explicitly it was necessary to treat in an *autonomous* manner significant physical examples (in effect, those for which a complete and rigorous spectral theory exists), without recourse to the traditional operatorial formulation of quantum mechanics. That was achieved in Bayen *et al.* (1978) with the paradigm of the harmonic oscillator and more, including the angular momentum and the hydrogen atom.

In particular what plays here the role of the unitary time evolution operator of a quantized system is the "star exponential" of its classical Hamiltonian H (expressed as a usual exponential series but with "star powers" of $tH/i\hbar$, t being the time, and computed as a distribution both in phase space variables and in time); in a very natural manner, the spectrum of the quantum operator corresponding to H is the support of the Fourier-Stieltjes transform (in t) of the star exponential (what Laurent Schwartz had called the spectrum of that distribution). It is worth mentioning that our definition of spectrum permits to define a spectrum even for symbols of nonspectrable operators, such as the derivative on a half-line which has different deficiency indices; this corresponds to an infinite potential barrier. That is one of the many advantages of our autonomous approach to quantization. Further examples were (and are still being) developed, in particular in the direction of field theory.

B. Quantum mechanics without operators: Harmonic oscillator, angular momentum, and hydrogen atom

In quantum mechanics it is preferable to work (for $X=\mathbb{R}^{2\ell}$) with the Moyal product, which has maximal symmetry, i.e., has $\mathfrak{sp}(\mathbb{R}^{2\ell})\cdot\mathfrak{h}_\ell$ as what we call (see Sec. IV C 2 below) algebra of preferred observables. One indeed finds [Bayen *et al.* (1978)] that star powers of these preferred observables H (polynomials of order $\leqslant 2$) are usual polynomials in H (not only in p and q), and as a consequence their star exponential is proportional to the usual exponential and a function of H. More precisely, if $H=\alpha p^2+\beta pq+\gamma q^2\in\mathfrak{sl}(2)$ with $p,q\in\mathbb{R}^\ell$, $\alpha,\beta,\gamma\in\mathbb{R}$, setting $d=\alpha\gamma-\beta^2$ and $\delta=|d|^{1/2}$ one gets by summing the star exponential (with deformation parameter $\nu=i\hbar/2$) and then taking its Fourier (or Fourier–Stieltjes) development, the sums and integrals appearing in the various expressions of the star exponential being convergent as distributions, in phase-space variables and in t or λ:

$$\exp(Ht)=\begin{cases}(\cos\ \delta t)^{-l}\exp((H/i\hbar\delta)\tan(\delta t)) & \text{for } d>01\\ \exp(Ht/i\hbar) & \text{for } d=01\\ (\cosh\ \delta t)^{-l}\exp((H/i\hbar\delta)\tanh(\delta t)) & \text{for } d<0,\end{cases}\tag{9}$$

$$\exp(Ht)=\begin{cases}\displaystyle\sum_{n=0}^{\infty}\Pi_n^{(\ell)}e^{(n+(\ell/2))t} & \text{for } d>0\\ \displaystyle\int_{-\infty}^{\infty}e^{\lambda t/i\hbar}\Pi(\lambda,H)d\lambda & \text{for } d<0.\end{cases}\tag{10}$$

We thus get the discrete spectrum $(n+(\ell/2))\hbar$ of the harmonic *oscillator* and the continuous spectrum $\mathbb{R}$ for the dilation generator pq. The eigenprojectors $\Pi_n^{(\ell)}$ and $\Pi(\lambda,H)$ are given [Bayen *et al.* (1978)] by known special functions on phase-space (generalized Laguerre and hypergeometric, multiplied by some exponential). Formulas (9) and (10) can, by analytic continuation, be given a sense outside singularities and even (as distributions) for values of t for which the expressions are singular.

Other orderings give similar formulas [Maillard (2004)] and other examples can be brought to this case, in particular by functional manipulations [Bayen *et al.* (1978)]. For instance the Casimir element C of $\mathfrak{so}(\ell)$ representing *angular momentum*, which can be written $C=p^2q^2-(pq)^2-\ell(\ell-1)(\hbar^2/4)$, has $n(n+(\ell-2))\hbar^2$ for spectrum. For the *hydrogen atom*, with Hamiltonian $H=\frac{1}{2}p^2-|q|^{-1}$, the Moyal product on $\mathbb{R}^{2\ell+2}$ ($\ell=3$ in the physical case) induces a star product on $X=T^*S^\ell$; the energy levels, solutions of $(H-E)*\phi=0$, are found from (10) and the preceding calculations for angular momentum to be (as they should, with $\ell=3$) $E=\frac{1}{2}(n+1)^{-2}\hbar^{-2}$ for the discrete spectrum, and $E\in\mathbb{R}^+$ for the continuous spectrum.

We thus have recovered, in a completely autonomous manner entirely within deformation quantization, the results of "conventional" quantum mechanics in these typical examples (and many more can be treated similarly). It is worth noting that the term $\ell/2$ in the harmonic oscillator spectrum, obvious source of divergences in the infinite-dimensional case, disappears if the normal star product is used instead of Moyal—which is one of the reasons it is preferred in field theory.

C. Modern developments

Since the original papers in 1976–1978 [Flato *et al.* (1976) and Bayen *et al.* (1978)] deformation quantization has been extended considerably. It now includes general symplectic and Poisson (finite dimensional) manifolds, with further results for infinite dimensional manifolds, for "manifolds with singularities" and for algebraic varieties, and has many far reaching ramifications in both mathematics and physics [see, e.g., a brief overview in Dito and Sternheimer (2002)]. As in quantization itself [Weyl (1931)], symmetries (group theory) play a special role and an autonomous theory of star representations of Lie groups was developed, in the nilpotent and solvable cases of course (due to the importance of the orbit method there), but also in significant other

examples. The presentation that follows can be seen as an extension of the latter, when one makes full use of the Hopf algebra structures and of the "duality" between the group structure and the set of its irreducible representations.

It goes without saying (but mentioning it will not hurt) that deformation theory and Hopf algebras are seminal in a variety of problems ranging from theoretical physics to algebraic geometry, number theory and more. We shall not insist here on the manifold applications of quantum groups, certainly treated in many contributions to this special issue. In theoretical physics one finds now applications (see, e.g., Connes and Kreimer (1999), Dito *et al.* (1997), Tamarkin (2003)] to renormalization and Feynman integrals and diagrams. Noncommutativity is a staple in modern theoretical physics [Douglas and Nekrasov (2001)] (including string theory and its avatars) even at the level of space–time; deformation quantization (in particular Moyal products) is an important tool there, at least at the formal level. But the applications (and by-products therefrom to physics) extend as far as algebraic geometry and number theory [see, e.g., Kontsevich (2001) and Kontsevich and Zagier (2001)] including algebraic curves à la Zagier [cf. Connes and Moscovici (2004), Connes and Marcoli, and Connes's lectures at Collège de France, Winter 2003 and 2004).

IV. QUANTUM GROUPS AS DEFORMATIONS

In this section we explore in detail the concept of viewing quantum groups as Hopf algebra deformations of $\mathcal{U}\mathfrak{g}$ and $\mathcal{C}^\infty(G)$. We restrict to the case where G is a semisimple Lie group with Lie algebra $\mathfrak{g}$.

A. Formal deformations

We begin with a summary of important considerations regarding *formal deformations*: all vector spaces, tensor products, etc. being complete in the ν-adic topology. This is a purely algebraic approach with no consideration to any topological or convergence questions. All of what follows can be extracted from Drinfel'd (1989a, 1989b), Gerstenhaber and Schack (1990a, 1990b).

Recall that a bialgebra is called *rigid* it every deformation is trivial. Neither $\mathcal{U}\mathfrak{g}$ nor $\mathcal{C}^\infty(G)$ is rigid but, as the theorem below asserts, each is *half-rigid* in the following sense: $\mathcal{U}\mathfrak{g}$ is rigid as an algebra and $\mathcal{C}^\infty(G)$ is rigid as a coalgebra. This means that for any deformation $\mathcal{U}_\nu(\mathfrak{g})$, there is an equivalent one in which the original multiplication $\mu_0: \mathcal{U}\mathfrak{g}\otimes\mathcal{U}\mathfrak{g}\to\mathcal{U}\mathfrak{g}$ is preserved and so $\mathcal{U}_\nu(\mathfrak{g}) \cong (\mathcal{U}\mathfrak{g}[[\nu]], \mu_0, \tilde{\Delta})$ for some coassociative $\tilde{\Delta}$. Similarly, any deformation $\mathcal{C}^\infty_\nu(G)$ is equivalent to one in which the comultiplication $\Delta_0: \mathcal{C}^\infty(G)\to\mathcal{C}^\infty(G)$ is preserved on all elements. Thus $\mathcal{C}^\infty_\nu(G) \cong (\mathcal{C}^\infty(G)[[\nu]], *, \Delta_0)$ for some associative *-product. Such deformations in which one of the original structure maps is preserved are called *preferred*.

The structure of the deformed comultiplication of $\mathcal{U}\mathfrak{g}$ and the deformed multiplication $\mathcal{C}^\infty(G)$ are produced via certain elements of $(\mathcal{U}\mathfrak{g}\otimes\mathcal{U}\mathfrak{g})[[\nu]]$. For $F\in(\mathcal{U}\mathfrak{g}\otimes\mathcal{U}\mathfrak{g})[[\nu]]$ and $u\in\mathcal{U}\mathfrak{g}$, define $\Delta_F(u)=F\Delta_0(u)F^{-1}$. In a dual sense, we can define $f*_F g$ for $f,g\in\mathcal{C}^\infty(G)$. To define $*_F$ we need some notation first. For $x\in\mathfrak{g}$, let x_λ and x_ρ be the left invariant and right invariant, respectively, derivations of $\mathcal{C}^\infty(G)$ arising from the corresponding left and right invariant vector fields on G associated with x. Taking the tensor product and extending linearly, we associate to every $F \in (\mathcal{U}\mathfrak{g}\otimes\mathcal{U}\mathfrak{g})[[\nu]]$ two formal sums of bidifferential operators F_λ and F_ρ. With this, we define $f*_F g=\mu_0\circ(F_\lambda\circ F_\rho^{-1})(f\otimes g)$. Note that if $F\cong 1\otimes 1 \bmod \nu$, then $\Delta_F(u)$ and $f*_F g$ are series whose constant terms are the original structure maps $\Delta_0(u)$ and $f\cdot g$. However, Δ_F will not generally be coassociative and $*_F$ will not generally be associative. The appropriate condition for F to satisfy is given by the following important result.

Theorem IV.1 [Drinfel'd (1989a, 1989b), Gerstenhaber and Schack (1992)]: *Let G be a semisimple Lie group with Lie algebra $\mathfrak{g}$, and suppose that $F\in(\mathcal{U}\mathfrak{g}\otimes\mathcal{U}\mathfrak{g})[[\nu]]$ with $F\cong 1\otimes 1 \bmod \nu$.*

Then $(\mathcal{U}\mathfrak{g}[[\nu]], \mu_0, \Delta_F)$ and $(\mathcal{C}^\infty(G)[[\nu]], *_F, \Delta_0)$ are deformations if and only if

$$F_{12}(\Delta_0\otimes 1)F = \Phi F_{23}(1\otimes\Delta_0)F \tag{11}$$

for some $\Phi \in (\mathcal{U}\mathfrak{g} \otimes \mathcal{U}\mathfrak{g} \otimes \mathcal{U}\mathfrak{g})^{\mathfrak{g}}$. *Moreover, every deformation of* $\mathcal{U}\mathfrak{g}$ *and* $\mathcal{C}^{\infty}(G)$ *is equivalent to one defined by such an* F.

Note that (11) is an equation which must hold in the triple tensor product $\mathcal{U}\mathfrak{g} \otimes \mathcal{U}\mathfrak{g} \otimes \mathcal{U}\mathfrak{g}$. (The comultiplication Δ_0 in this equation is that of $\mathcal{U}\mathfrak{g}$.) The half-rigidity of $\mathcal{U}\mathfrak{g}$ was first proved in Drinfel'd (1989a) and it was derived for $\mathcal{C}^{\infty}(G)$ in Gerstenhaber and Schack (1992). The specific form of the deformations can be deduced from Drinfel'd (1989b).

If $\Phi = 1 \otimes 1 \otimes 1$ (a trivial $\mathfrak{g}$-invariant), then F is called a *twisting element* and, if Φ is a nontrivial invariant, then F is a *modified twisting element*. In either case, we say the deformation is given by a "twist."

From the viewpoint of deformation quantization, it may seem that Theorem IV.1 settles the story. In a way it does, but it opens up many more questions which we will address throughout the remainder of this survey. The most basic question is to find elements F which solve Eq. (11). This task is easier said than done. Indeed, no modified twisting elements are explicitly known for any simple Lie algebra $\mathfrak{g}$—even for the rank 1 case of $\mathfrak{sl}(2)$! The situation is different for twisting elements—there is a handful which are explicitly known, and we will exhibit some of them later in Sec. VI B.

There is an interesting irony here concerning the infinitesimals (or first order terms) of the two types of twisting elements. The possible infinitesimals of modified twisting elements are all constructively classified in the famous paper of Belavin and Drinfel'd (1984). In contrast, such a classification for the infinitesimals of the twisting elements is an intractable problem. (It would require, in particular, a constructive classification of all Abelian subalgebras of $\mathfrak{g}$, a question which is known to be too broad to solve as stated.)

B. Topological preliminaries

In the next few sections, we describe a "topological" approach to quantum groups via deformation quantization. Instead of working formally over complete power series rings, we consider other topologies which have more desirable properties, especially in terms of dualization. The theory was initiated in Bonneau (1994) and its generalizations can be found in Bidegain and Pinczon (1996).

1. Example: The SU(2) case

First we will investigate in detail the example that the general theory is based on. It is interesting and merits special attention because apart from giving the main ideas, it differs in two crucial points: it is *explicit* and *convergent*. The main reference is Bonneau *et al.* (1992).

We start with Jimbo's definition of $\mathcal{U}_q\mathfrak{sl}(2)$ [Jimbo (1985)]. As an algebra, $\mathcal{U}_q\mathfrak{sl}(2)$ has generators E, F, $K^{\pm 1}$ and the relations

$$KEK^{-1} = qE, \quad KFK^{-1} = q^{-1}F, \quad EF - FE = \frac{K^2 - K^{-2}}{q - q^{-1}}.$$

The coalgebra structure on $\mathcal{U}_q\mathfrak{sl}(2)$ is given by

$$\Delta(E) = E \otimes K^{-1} + K \otimes E, \quad \Delta(F) = F \otimes K^{-1} + K \otimes F, \quad \Delta(K) = K \otimes K.$$

Remark IV.1:

(1) *One may view* $\mathcal{U}_q\mathfrak{sl}(2)$ *as an algebra over* $\mathbb{K}$ (*with* $q \in \mathbb{K}^*$) *or over the rational function field* $\mathbb{K}(q)$ (*with* q *an indeterminate*). *For what follows it will be convenient to view* $q = e^{i\nu} \in \mathbb{C}$.

(2) *Note that, as presented,* $\mathcal{U}_q\mathfrak{sl}(2)$ *is not a deformation of* $\mathcal{U}\mathfrak{sl}(2)$. *If one formally sets* $K = q^{H/2}$ (*where* $[E,F] = H$ *in* $sl(2)$) *and completes the algebra with respect to the* ν*-adic topology, then one indeed has a genuine deformation of* $\mathcal{U}\mathfrak{sl}(2)$. *This fact, however, is not obvious from looking at just the relations. It is usually proved by analyzing the representation theory of the algebras involved.*

Even though $\mathcal{U}_q\mathfrak{sl}(2)$ is undefined at $q=1$, one may make sense of it as q approaches 1. Specifically, under the linear change of generators,

$$S = \frac{K - K^{-1}}{q - q^{-1}},$$

$$C = \frac{K + K^{-1}}{2},$$

one has the following set of relations:

$$EF - FE = 2SC, \quad SC = CS,$$

$$ES = (S\cos\nu - C)E, \quad EC = (C\cos\nu + S\sin^2\nu)E,$$

$$FS = (S\cos\nu + C)F, \quad FC = (C\cos\nu - S\sin^2\nu)F,$$

$$C^2 + S^2\sin^2\nu = 1. \tag{12}$$

This new system of generators and relations is well-defined for all ν, and it turns out that $\mathcal{U}_1\mathfrak{sl}(2) \cong \mathcal{U}\mathfrak{sl}(2) \otimes \mathbb{K}[X]/(X^2-1)$. The element X is called a *parity*. The Jimbo quantum groups $\mathcal{U}_q\mathfrak{g}$ have, in general, r parities, where r is the rank of $\mathfrak{g}$ and so they are clearly not a formal deformation of $\mathcal{U}\mathfrak{g}$, notwithstanding the aforementioned rigidity result of Theorem IV.1.

The algebra $\mathcal{A}$: Let $\{(\pi_n, V_n)\}_{n\in(1/2)\mathbb{N}}$ be the finite dimensional irreducible representations of $\mathfrak{sl}(2)$ [or SU(2), as they are the same]. Let $\mathcal{A} = \Pi_{n\in(1/2)\mathbb{N}}\mathrm{End}(V_n)$. We consider the product topology on $\mathcal{A}$ (Fréchet). We have embeddings $\mathcal{U}\mathfrak{sl}(2) \hookrightarrow \mathcal{A}$ and $\mathbb{C}G \hookrightarrow \mathcal{A}$ by $u \mapsto (\pi_n(u))$ and $x \mapsto (\pi_n(x))$. These maps are injective because $\{(\pi_n, V_n)\}$ is a complete set of representations for $\mathfrak{sl}(2)$ [or SU(2)].

Let π be the representation of $\mathcal{U}\mathfrak{sl}(2)$ [or SU(2)] defined by $\Sigma_{n\in(1/2)\mathbb{N}}\pi_n$. Then $\mathcal{A}$ coincides with the bicommutant of π and, by semisimplicity of π and the density theorem of Jacobson, we get

$$\overline{\mathcal{U}\mathfrak{sl}(2)} = \mathcal{A} \quad \text{and} \quad \mathbb{C}\overline{G} = \mathcal{A}.$$

Since the set $\{(\pi_n, V_n)\}_{n\in(1/2)\mathbb{N}}$ is also a complete set of representations for $\mathcal{U}_q\mathcal{G}$ we have the following similar results:

$$\mathcal{U}_q\, sl(2) \hookrightarrow \mathcal{A} \quad \text{and} \quad \overline{\mathcal{U}_q\mathfrak{sl}(2)} = \mathcal{A}, \quad \text{for all} \quad \nu \notin 2\pi\mathbb{Q}.$$

Details can be found in Bonneau *et al.* (1992).

Thus, both $\mathcal{U}\mathfrak{sl}(2)$ and $\mathcal{U}_q\mathfrak{sl}(2)$ are dense subalgebras of $\mathcal{A}$. We denote by A_ν the subalgebra of $\mathcal{A}$ isomorphic to $\mathcal{U}_q\mathfrak{sl}(2)$. Since $A_\nu \cong A_{\nu'}$ if and only if $\nu' = \pm\nu + 2k\pi, k \in \mathbb{Z}$, it follows that A_ν is a deformation of A_0.

By a standard density argument, the coproduct Δ_ν of $A_\nu, \nu \notin 2\pi\mathbb{Q}$, can be extended to the whole algebra $\mathcal{A}$; the same holds true for the antipode. Thus we have a preferred deformation of $\mathcal{A}$ as the coalgebra structure varies with a fixed algebra structure. In fact, this deformation of $\mathcal{A}$ has the same form as any preferred deformation of $\mathcal{U}\mathfrak{g}$. Specifically, there is an invertible element $F \in \mathcal{A}\hat{\otimes}\mathcal{A}$ such that $\Delta_\nu = F\Delta_0 F^{-1}$. The element F is constructed component by component using equivalences of representations, see Bonneau *et al.* (1992) for details. A consequence is that all the Hopf structures on $\mathcal{A}$ induced by various A_ν are isomorphic as quasi-Hopf algebras [see Drinfel'd (1989)].

So far we have not used the topology on $\mathcal{A}$, but it will play a crucial role as we now want to consider its dualization. The strong topological dual of $\mathcal{A} = \Pi_{n\in(1/2)\mathbb{N}}\ \mathrm{End}\ (V_n)$ is $\mathcal{A}^* = \mathcal{H}$

$=\oplus_{n\in(1/2)\mathbb{N}}\ \mathrm{End}\ (V_n)$, the coefficient Hopf algebra of polynomial functions on SU(2). Since $(\mathcal{A}\hat{\otimes}\mathcal{A})^*=\mathcal{H}\hat{\otimes}\mathcal{H}$, we obtain a Hopf algebra on $\mathcal{A}^*$, which we denote $\mathcal{H}_\nu$.

Proposition IV.1: $\mathcal{H}_\nu$ coincides precisely with the deformation of the function Hopf algebra $\mathbb{C}[SL_2]$, the quantum group $\mathbb{C}[SL_2]$, given in Faddeev et al. (1988).

Thus we have shown that there is an explicit embedding of the Jimbo quantum group $\mathcal{U}_q\mathfrak{sl}(2), q\in\mathbb{C}$ ($q^n\neq 1$ for all $n\in\mathbb{N}$) in the $\mathbb{C}$-Hopf algebra $\mathcal{A}$.

In the general case that will not be possible. We shall have to use the $\mathbb{C}[[\nu]]$-Hopf algebra $\mathcal{A}[[\nu]]$ and the nonexplicit Drinfel'd isomorphisms.

2. Some topological Hopf algebras (well-behaved Hopf algebras)

We shall now briefly review applications of the deformation theory of algebras in the context of Hopf algebras endowed with appropriate topologies and in the spirit of deformation quantization. That is, we shall consider Hopf algebras of functions on Poisson–Lie groups (or their topological duals) and their deformations, and show how this framework is a powerful tool to understand the standard examples of quantum groups, and more. In order to do so we first recall some notions on topological vector spaces and apply them to our context.

Definition IV.1: A topological vector space (tvs) V is said well-behaved if V is either nuclear and Fréchet, or nuclear and dual of Fréchet [Grothendieck (1955) and Trèves (1967)].

Proposition IV.2: If V is a well-behaved tvs and W a tvs, then

$$(i)V^{**}\simeq V,\quad (ii)(V\hat{\otimes}V)^*\simeq V^*\hat{\otimes}V^*,\quad (iii)\mathrm{Hom}_{\mathbb{K}}(V,W)\simeq V^*\hat{\otimes}W,$$

where V^* denotes the strong topological dual of V, $\hat{\otimes}$ the projective topological tensor product and the base field $\mathbb{K}$ is $\mathbb{R}$ or $\mathbb{C}$.

Definition IV.2: $(A,\mu,\eta,\Delta,\varepsilon,S)$ is a WB (well-behaved) Hopf algebra [Bonneau et al. (1994)] if

(1) A is a well-behaved topological vector space;
(2) The multiplication $\mu:A\hat{\otimes}A\to A$, the coproduct $\Delta:A\to A\hat{\otimes}A$, the unit η, the counit ε, and the antipode S are continuous;
(3) $\mu,\eta,\Delta,\varepsilon$, and S satisfy the usual axioms of a Hopf algebra.

Corollary IV.1: If $(A,\mu,\eta,\Delta,\varepsilon,S)$ is a WB Hopf algebra, then $(A^*,{}^t\Delta,{}^t\varepsilon,{}^t\mu,{}^t\eta,{}^tS)$ is also a WB Hopf algebra.

Examples IV.1: Let G be a semisimple Lie group and $\mathfrak{g}$ its complexified Lie algebra.

(1) $\mathcal{C}^\infty(G)$, the algebra of the smooth functions on G, is a WB Hopf algebra (Fréchet and nuclear).
(2) $\mathcal{D}(G)=\mathcal{C}^\infty(G)^*$, the algebra of the compactly supported distributions on G, is a WB Hopf algebra (dual of Fréchet and nuclear). The product is the transposed map of the coproduct of $\mathcal{C}^\infty(G)$ that is, the convolution of distributions.
(3) $\mathcal{H}(G)$, the algebra of coefficient functions of finite dimensional representations of G (or polynomial functions on G) is a WB Hopf algebra, the Hopf structure being that induced from $\mathcal{C}^\infty(G)$.

A short description of that algebra is as follows: We take a set $\hat{G}$ of irreducible finite dimensional representations of G such that there is *one and only one* element for each equivalence class, and, if $\pi\in\hat{G}$, its contragredient $\check{\pi}$ is also in $\hat{G}$. We define

$$C_\pi=\mathrm{vect}\{\text{coefficient functions of } \pi\}\overset{\text{Burnside}}{\simeq}\mathrm{End}(V_\pi)\ \text{for}\ \pi\in\hat{G}.$$

Then $\mathcal{H}(G)\overset{\text{alg.}}{\simeq}\oplus_{\pi\in\hat{G}}C_\pi\overset{\text{v.s.}}{\simeq}\oplus_{\pi\in\hat{G}}\mathrm{End}\ (V_\pi)$. So we take on $\mathcal{H}(G)$ the "direct sum" topology. Then $\mathcal{H}(G)$ is dual of Fréchet and nuclear and so is WB.

(4) Let $\mathcal{A}(G)$, the algebra of "generalized distributions," be defined by $\mathcal{A}(G)=\mathcal{H}(G)^{*}\overset{\text{alg.}}{\simeq}\Pi_{\pi\in\hat{G}}\,\mathrm{End}\,(V_\pi)$. The (product) topology is Fréchet and nuclear, and therefore $\mathcal{A}(G)$ is WB.

Proposition IV.3 [Bidegain and Pinczon (1996) and Bonneau et al. (1994)]: We denote by $\mathcal{U}\mathfrak{g}$ the universal enveloping algebra of $\mathfrak{g}$ and by $\mathbb{C}G$ the group algebra of G. All the following inclusions are inclusions of Hopf algebras. $\Subset$, $\ni$, $\Cup$, $\Subset$ mean a dense inclusion,

$$\begin{array}{ccccccc} \mathcal{U}\mathfrak{g} & \Subset & \mathcal{A}(G) & \underset{\ni}{\overset{(*)}{}} & \mathbb{C}G & & \mathcal{H}(G) \\ & & \Cup(*) & & & & \Subset(*) \\ \mathcal{U}\mathfrak{g} & \subset & \mathcal{D}(G) & \ni & \mathbb{C}G & & \mathcal{C}^{\infty}(G) \end{array}$$

(*) *is true if and only if G is linear (i.e., with a faithful finite dimensional representation).*

C. Topological quantum groups

We shall now deform the preceding topological Hopf algebras and indicate how this explains various models of quantum groups. For clarity of the exposition, throughout this section and the remainder of the paper, we shall limit to a minimum the details concerning the Hopf algebra structures other than product and coproduct. But whenever we write Hopf algebras and not only bialgebras, the relevant structures are included in the discussion and dealing with them is quite straightforward. Note that the results which pertain only to the formal aspect of the theory were already mentioned in Sec. IV A.

1. Topological quantization

If $\mathcal{U}_\nu\mathfrak{g}$ is a deformation of $\mathcal{U}\mathfrak{g}$, then an isomorphism (it is not unique!) $\varphi:\mathcal{U}_\nu\mathfrak{g}\to\mathcal{U}\mathfrak{g}[[\nu]]$ guaranteed to exist by Theorem IV.1 will be called a *Drinfel'd isomorphism*.

Theorem IV.2 [Bonneau *et al.* (1994) and Bidegain and Pinczon (1996)]: *Let G be a connected semisimple Lie group and $\mathfrak{g}$ be its complexified Lie algebra.*

(1) *If $\mathcal{U}_\nu\mathfrak{g}$ is a deformation of $\mathcal{U}\mathfrak{g}$ (a "quantum group") then there exists $F\in(\mathcal{U}\mathfrak{g}\otimes\mathcal{U}\mathfrak{g})[[\nu]]$ such that $(\mathcal{U}_\nu\mathfrak{g},\mu_\nu,\Delta_\nu)\simeq(\mathcal{U}\mathfrak{g}[[\nu]],\mu_0,F\Delta_0F^{-1})$.*

(2) *$\mathcal{A}_\nu(G):=(\mathcal{A}(G)[[\nu]],\mu_0,F\cdot\Delta_0\cdot F^{-1})$ is a Hopf deformation of $\mathcal{A}(G)$ and $\mathcal{U}_\nu\mathfrak{g}\overset{\text{Hopf}}{\subset}\mathcal{A}_\nu(G)$.*

(3) *$\mathcal{D}_\nu(G):=(\mathcal{D}(G)[[t]],\mu_0,F\cdot\Delta_0\cdot F_\nu^{-1})$ is a Hopf deformation of $\mathcal{D}(G)$ and $\mathcal{U}_\nu\mathfrak{g}\overset{\text{Hopf}}{\subset}\mathcal{D}_\nu(G)$.*

(4) *$\mathcal{C}^{\infty}_\nu(G):=\mathcal{D}_\nu(G)^{*}$ and $\mathcal{H}_\nu(G):=\mathcal{A}_\nu(G)^{*}$ are quantized algebras of functions. They are Hopf deformations of $\mathcal{C}^{\infty}(G)$ and $\mathcal{H}(G)$.*

Similar results hold for other WB Hopf algebras (e.g., constructed with infinite dimensional representations) [Bidegain (1996)].

Proof: Linear case: Item (1) is a direct consequence of Theorem IV.1. To prove item (2), observe that $F\in(\mathcal{U}\mathfrak{g}\otimes\mathcal{U}\mathfrak{g})[[\nu]]\subset(\mathcal{A}(G)\hat{\otimes}\mathcal{A}(G))[[\nu]]$ and coassociativity follows from the dense inclusion $\mathcal{U}\mathfrak{g}\Subset\mathcal{A}(G)$. Item (3) it true by restriction of (2), and item (4) holds by simple dualization from (2) and (3).

Nonlinear case: Here, as $\mathcal{D}(G)\not\subset\mathcal{A}(G)$ we have to treat $\mathcal{D}(G)$ and $\mathcal{A}(G)$ separately.

(a) Since we can prove [see Bidegain and Pinczon (1996)] that "there exists a compact connected Lie group K such that $\mathcal{H}(G)=\mathcal{H}(K)$," we have $\mathcal{A}(G)=\mathcal{A}(K)$ and we can apply the linear case.

(b) To treat $\mathcal{D}(G)$ we use the density of $\mathbb{C}G$ in $\mathcal{D}(G)$ and go from $\mathcal{U}\mathfrak{g}$ to $\mathbb{C}G$ by exponentiating [Bidegain and Pinczon (1996)]. ■

Remark IV.2: "Hidden group structure" in a quantum group. All the deformations constructed here are *preferred*, that is, the product on $\mathcal{D}_\nu(G)$ and on $\mathcal{A}_\nu(G)$ [resp. the coproduct on $\mathcal{C}^{\infty}_\nu(G)$ and

on $\mathcal{H}_\nu(G)$] is not deformed and the basic structure is still the product on the group G. So this approach gives an interpretation of the Tannaka–Krein philosophy in the case of quantum groups: it has often been noticed that, in the generic case, finite dimensional representations of a quantum group are (essentially) representations of its classical limit. So the algebras involved should be the same, which is justified by the above mentioned rigidity result of Drinfel'd. This shows that the initial classical group is still there, acting as a kind of "hidden variables" in this quantum group theory, which is exactly what we see in this quantum group theory. This fact was implicit in Drinfel'd's work. The Tannaka–Krein interpretation of the twisting of quasi-Hopf algebras can be found in Majid [see, e.g., Majid (1992)]. It was made explicit, within the framework exposed here, in Bonneau *et al.* (1994).

Thus, for any connected Lie group G and for any deformation of the universal enveloping algebra of $\mathfrak{g}=\mathrm{Lie}_{\mathbb{C}}(G)$, we obtain a star product * on $\mathcal{C}^\infty(G)$ and $\mathcal{H}(G)$. For noncompact groups see Bidegain and Pinczon (1995). The next result shows that these deformation quantizations induce other ones on some quotients of G:

Proposition IV.4: Let H be a closed normal subgroup of G.

(1) ** induces a star product on $\mathcal{C}^\infty(G/H)$.*
(2) *If G is linear, * induces a star product on $\mathcal{H}(G/H)$.*

2. Unification of models and generalizations

a. Drinfel'd models: We call "Drinfel'd model of quantum group" a deformation of $\mathcal{U}\mathfrak{g}$ for $\mathfrak{g}$ simple, as given in Drinfel'd (1987)). We have seen in the preceding section that from any Drinfel'd model $\mathcal{U}_\nu\mathfrak{g}$ of a quantum group (which can be generalized to any deformation of the Hopf algebra $\mathcal{U}\mathfrak{g}$), we obtain a deformation of $\mathcal{D}(G)$ and $\mathcal{A}(G)$ that contains $\mathcal{U}_\nu\mathfrak{g}$ as a sub-Hopf algebra. So $\mathcal{D}_\nu(G)$ and $\mathcal{A}_\nu(G)$ are quantum group models that describe Drinfel'd models. By duality, $\mathcal{C}^\infty_\nu(G)$ and $\mathcal{H}_\nu(G)$ are "quantum group deformations" of $\mathcal{C}^\infty(G)$ and $\mathcal{H}(G)$. The deformed product on $\mathcal{H}(G)$ is the restriction of that on $\mathcal{C}^\infty(G)$. Furthermore, as we shall see, these deformations coincide with the usual "quantum algebras of functions." Let us look more in detail at $\mathcal{H}_\nu(G)$:

b. Faddeev–Reshetikhin–Takhtajan (FRT) models: In Faddeev *et al.* (1988) quantized algebras of functions are defined in terms of generators and relations, the key relation being given by the star-triangle (Yang–Baxter) equation, $R(T\otimes \mathtt{Id})(\mathtt{Id}\otimes T)=(\mathtt{Id}\otimes T)(T\otimes \mathtt{Id})R$, for a given R-matrix $R\in \mathtt{End}(V\otimes V)$ and for $T\in \mathtt{End}(V)$, V being a finite dimensional vector space.

As our deformations are given by a twist F, it is not surprising, from a structural point of view [Majid (1992)] that, dually, we obtain in each case a Yang–Baxter relation and so a "FRT-type" quantized algebra of functions. Our Fréchet-topological context permits us to write precisely such a construction for the infinite-dimensional Hopf algebras involved.

c. Linear case: If G is semisimple and linear, there exists π a finite dimensional representation of G such that $\mathcal{H}(G)\simeq\mathbb{C}[\pi_{ij};1\leqslant i,j\leqslant N]$ where the π_{ij} are the coefficient functions of π. Denote by $(\mathcal{H}_\nu(G),*)$ the deformation of $\mathcal{H}(G)$ obtained in this way and by T the matrix $[\pi_{ij}]$. Define $T_1:=T\otimes Id$ and $T_2:=Id\otimes T$. Then we have

Proposition IV.5 [Bonneau et al. (1994) and Bidegain and Pinczon (1996)]:

(1) *$\{\pi_{ij};1\leqslant i,j\leqslant N\}$ is a topological generator system of the $\mathbb{C}[[\nu]]$-algebra $\mathcal{H}(G)_\nu$.*
(2) *There exists an invertible $\mathcal{R}\in\mathcal{L}(V_\pi\otimes V_\pi)[[t]]$ such that $\mathcal{R}\cdot T_1 * T_2 = T_2 * T_1\cdot\mathcal{R}$ (so $\mathcal{H}_\nu(G)$ is a "quantum algebra of functions" of type FRT).*
(3) *We recover every quantum group given in [FRT] by this construction.*

Sketch of proof:

(1) Perform a precise study of the deformed tensor product of representations.
(2) Since the deformations $\mathcal{A}_\nu(G)$ are given by a twist F, $\mathcal{A}_\nu(G)$ is quasicocommutative, i.e., there exists $R\in(\mathcal{A}(G)\hat{\otimes}\mathcal{A}(G))[[\nu]]$ such that $\sigma\circ\Delta_\nu(a)=R\Delta_F(a)R^{-1}$ with $\sigma(a\otimes b)=b\otimes a$. Standard computations give the result.

(3) We want to follow the ideas used in Drinfel'd (1987) to link Drinfel'd to FRT models. Since the main point here is that our deformations are obtained through a Drinfel'd isomorphism, we therefore have to show:

(a) There exists a specific Drinfel'd isomorphism deforming the standard representation of $\mathfrak{g}$ into the representation of $\mathcal{U}_\nu\mathfrak{g}$ used in Drinfel'd (1987).
(b) Two Drinfel'd isomorphisms give equivalent deformations. ■

For instance, the FRT quantization of SL(n) can be seen as a Hopf deformation of $\mathcal{H}(\mathrm{SU}(n))$ (with nondeformed coproduct). Moreover, this Hopf deformation extends to $\mathcal{C}^\infty(G)$.

Remark IV.3:

(1) This proposition justifies the terminology "deformation," often employed but never justified in these cases. See, e.g., Gerstenhaber *et al.* (1990), where it is shown that relations of type $\mathcal{R}T_1T_2=T_2T_1\mathcal{R}$ need not define a deformation, even if $\mathcal{R}$ is Yang–Baxter.
(2) Starting from Drinfel'd models, our construction produces FRT models also, e.g., $G=\mathrm{Spin}(n)$ and for exceptional Lie groups. In addition, at least some multiparameter deformations [Reshetikhin (1990)] can be easily treated in this way [Bonneau *et al.* (1994)].

d. Nonlinear case:

Proposition IV.6 [Bidegain and Pinczon (1996)]: If G is semisimple with finite center, there exists a dense subalgebra of $(\mathcal{C}^\infty_\nu(G),*)$ *generated by the coefficient functions of a finite number of (possibly infinite dimensional) representations.*

e. Jimbo-type models: The Jimbo models [Jimbo (1985)] have generators $E_i^\pm$, K_i, and K_i^{-1}. As stated earlier (Sec. IV B 1) these are not deformations in our sense due to the presence of parities.

The $G=\mathrm{SU}(2)$ case was developed in Sec. IV B 1. Similarly, for $G=\mathrm{SL}(2,\mathbb{C})$, Martin and Zouagui (1996) realize $\mathcal{U}_\nu\mathfrak{sl}(2,\mathbb{C})$ as a dense sub-Hopf algebra of $\mathcal{A}(G)$, $\forall t\in\mathbb{C}\backslash 2\pi\mathbb{Q}$ (with $q=\hat{e}^\nu$). Then, for the Lorentz algebra $\mathfrak{sl}(2,\mathbb{C})$, this unifies [Martin and Zouagui (1996)] all the models proposed so far in the literature for a quantum Lorentz group. We obtain here *convergent* deformations as in the above example of the SU(2) case.

For $\mathfrak{sl}(2,\mathbb{C})$, it was first proposed in Podleś and Woronowicz (1990) to consider the quantum double [Drinfel'd (1987)] of $\mathcal{U}_q\,\mathfrak{su}(2)$ as the q-deformed Lorentz group. It was known from Reshetikhin and Semenov-Tian-Shansky (1989) that in such cases the double, as an algebra, is the tensor product of two copies of $\mathcal{U}_\nu\mathfrak{su}(2)$. See also Ogievetsky *et al.* (1991), Schmidke *et al.* (1991), and Majid (1993) for a dual version and another semidirect product form.

f. Deformation quantization: From the main construction, using deformations of $\mathcal{U}\mathfrak{g}$, we deduce the following general theorem:

Theorem IV.3 [Bidegain and Pinczon (1996)]: *Let G be a semisimple connected Lie group with a Poisson–Lie structure. There exists a deformation* $(\mathcal{C}^\infty_\nu(G),*)$ *of* $\mathcal{C}^\infty(G)$ *such that * is a (differential) star product.*

Remark IV.4: Techniques similar to those indicated here can be applied to other q-algebras [more general quantum groups such as those in Frønsdal (1997) and more recent examples, Yangians, etc.]. In particular those used in the case of the Jimbo models should be applicable to q-algebras defined by generators and relations. That direction of research has not yet been developed.

Since from any Drinfel'd quantum group we obtain a star product, and since any FRT quantum group can be seen as a restriction of such a star product, we have showed that the data of a "semisimple" quantum group is equivalent to the data of a star product on $\mathcal{C}^\infty(G)$ satisfying $\Delta(f*g)=\Delta(f)*\Delta(g)$.

Actually the functorial existence results of Etingof and Kazhdan (1996) on the quantization of Lie bialgebras [see also Enriquez (2002)] show that the latter is true also for "nonsemisimple" quantum groups.

In our framework, we obtained a result in this direction about preferred deformations:

Theorem IV.4 [Bidegain and Pinczon (1996)]: *Let G be a simply connected Poisson–Lie group such that its associated Lie bialgebra has a preferred quantization. Then there exists a*

deformation $(\mathcal{C}^\infty_\nu(G),*)$ *of* $\mathcal{C}^\infty(G)$ *such that* * *is a (differential) star product.*

This can be applied, for example, when Lie (G) is the double of some Lie algebra, since there exists a preferred quantization [Etingof and Kazhdan (1996)].

It is important to remark that the proof of this theorem does not use the preceding construction. The main argument is an integrability result concerning formal deformations [Lesimple and Pinczon (1993)].

V. TOWARDS EXPLICIT REALIZATIONS. I

A. Star exponentials and star representations

Let G be a Lie group (connected and simply connected), acting by symplectomorphisms on a symplectic manifold X (e.g., coadjoint orbits in the dual of the Lie algebra $\mathfrak{g}$ of G). The elements $x,y\in\mathfrak{g}$ will be supposed to be realized by functions u_x,u_y in $\mathcal{C}^\infty(X)$ so that their Lie bracket $[x,y]_\mathfrak{g}$ is realized by $\{u_x,u_y\}$.

We define $(g.u.)(\xi)=u(g^{-1}\cdot\xi)$ the induced action of G on $\mathcal{C}^\infty(X)$. A very natural problem is the existence of a star product * on $\mathcal{C}^\infty(X)$ such that $g.u.*g.v.=g.(u*v),\forall u,v\in\mathcal{C}^\infty(X),\forall g\in G$, that is, a G-invariant star product. Explicit examples of such star products will be given later (on some symmetric spaces). But in general, even for a nilpotent G acting on a coadjoint orbit, an invariant star product does not always exists.

This leads to consider a weaker condition: we say that * is *covariant* if there exists a deformation τ of $.(\tau_g(u)=g\cdot u+\nu\cdots)$ such that * is invariant under τ. It can be shown [Arnal and Cortet (1985)] that is equivalent to ask that $\{u_x,u_y\}=[u_x,u_y]\equiv(u*v-v*u)/2\nu$.

Now take a G-covariant star-product *, then the map $\mathfrak{g}\ni x\mapsto(2\nu)^{-1}u_x\in\mathcal{C}^\infty(X)$ is a Lie algebra morphism. The appearance of ν^{-1} here and in the trace (see 2.2.1) cannot be avoided and explains why we have often to take into account both ν and ν^{-1}. We can now define the *star exponential*

$$E(e^x)=\exp(x)\equiv\sum_{n=0}^{\infty}(n)^{-1}(u_x/2\nu)^{*n},\tag{13}$$

where $x\in\mathfrak{g}$, $e^x\in G$ and the power $*n$ denotes the nth star-power of the corresponding function. By the Campbell–Hausdorff formula one can extend E to *a group homomorphism* $E:G\to(\mathcal{C}^\infty(X)\times[[\nu,\nu^{-1}]],*)$ where, in the formal series, ν and ν^{-1} are treated as independent parameters for the time being. Alternatively, the values of E can be taken in the algebra $(\mathcal{P}[[\nu^{-1}]],*)$, where $\mathcal{P}$ is the algebra generated by $\mathfrak{g}$ with the *-product (it is a representation of the enveloping algebra).

A star representation [Bayen *et al.* (1978)] of G is a distribution $\mathcal{E}$ (valued in Im E) on X defined by

$$D\ni f\mapsto\mathcal{E}(f)=\int_G f(g)E(g^{-1})dg,$$

where D is some space of test-functions on G. The corresponding *character* χ is the (scalar-valued) distribution defined by $D\ni f\mapsto\chi(f)=\int_X\mathcal{E}(f)d\mu$, $d\mu$ being a quasi-invariant measure on X.

The character is one of the tools which permit a comparison with usual representation theory. For semisimple groups it is singular at the origin in irreducible representations, which may require caution in computing the star exponential (13). In the case of the harmonic oscillator that difficulty was masked by the fact that the corresponding representation of $\mathfrak{sl}(2)$ generated by (p^2,q^2,pq) is integrable to a double covering of $\mathrm{SL}(2,\mathbb{R})$ and decomposes into a sum $D(\frac{1}{4})\oplus D(\frac{3}{4})$: the singularities at the origin cancel each other for the two components.

This theory is now very developed, and parallels in many ways the usual (operatorial) representation theory. A detailed account of all the results would take us too far, but among the most notable one may quote:

(i) An exhaustive treatment of *nilpotent* or *solvable exponential* [Arnal and Cortet (1985)] and

even general solvable Lie groups [Arnal *et al.* (1995) and Arnal and Cortet (1990)]. The coadjoint orbits are there symplectomorphic to $\mathbb{R}^{2\ell}$ and one can lift the Moyal product to the orbits in a way that is adapted to the Plancherel formula. Polarizations are not required, and "star-polarizations" can always be introduced to compare with usual theory. Wavelets, important in signal analysis, are manifestations of star-products on the (two-dimensional solvable) affine group of $\mathbb{R}$ or on a similar three-dimensional solvable group [Bertrand and Bertrand (1998)].

(ii) For *semisimple* Lie groups an array of results exists. Some explicit and autonomous formulas for star exponentials [Frønsdal (1979)] are available. In [Arnal *et al.* (1988) and Moreno (1986)] a complete treatment of the *holomorphic discrete series* (this includes the case of compact Lie groups) was made, using a kind of Berezin dequantization. Similar techniques have also been used [Cahen *et al.* (1995) and Karabegov (1998)] to find invariant star-products on Kähler and Hermitian symmetric spaces (convergent for an appropriate dense subalgebra). Note however, as shown by recent developments of unitary representations theory [see, e.g., Schmid (1997)], that for semisimple groups the coadjoint orbits alone are no more sufficient for the unitary dual and one needs far more elaborate constructions.

(iii) For semidirect products, and in particular for the Poincaré and Euclidean groups, an autonomous theory has also been developed [see, e.g., Arnal *et al.* (1980)].

Comparison with the usual results of "operatorial" theory of Lie group representations can be performed in several ways, in particular by constructing an invariant Weyl transform generalizing (4), finding "star-polarizations" that always exist, in contradistinction with the geometric quantization approach (where at best one can find complex polarizations), study of spectra (of elements in the center of the enveloping algebra and of compact generators) in the sense of (2.2.3.1), comparison of characters, etc. Note also in this context that the pseudodifferential analysis and (non autonomous) connection with quantization developed extensively by Unterberger, first in the case of $\mathbb{R}^{2\ell}$, has been extended to the above invariant context [Unterberger (1984) and Unterberger and Upmeier (1994)]. But our main insistence is that the theory of star representations is an *autonomous* one that can be formulated completely within this framework, based on coadjoint orbits (and some additional ingredients when required).

B. Universal deformation formulas

For an endomorphism ϕ of an algebra A, write a^{ϕ} for the right action of ϕ on $a \in A$. It was noticed early in deformation theory [see Gerstenhaber (1968)] that if ϕ and ψ are commuting derivations of A, then the product

$$a * b = ab + \nu a^{\phi} b^{\psi} + \frac{\nu^2}{2} a^{\phi^2} b^{\psi^2} + \cdots + \frac{\nu^n}{n!} a^{\phi^n} b^{\psi^n} + \cdots$$

defines an associative multiplication. This deformation can simply be written as

$$a * b = \mu_0((a \otimes b)^{\exp\ \nu(\phi \otimes \psi)})$$

and can be generalized to any sum of commuting derivations. The Moyal product can be realized in this fashion: take $A = \mathcal{C}^{\infty}(\mathbb{R}^{2n})$ and $\Sigma_{i<j} \partial_{x_i} \wedge \partial_{x_j}$ as the infinitesimal.

The first explicit deformation formula involving noncommuting derivations appeared in Coll *et al.* (1989). Suppose that ϕ and ψ are derivations satisfying $[\phi, \psi] = \psi$, and let $\phi^{(n)} = \phi(\phi + 1) \cdots (\phi + n - 1)$. Then,

$$a * b = ab + \nu a^{\phi} b^{\psi} + \frac{\nu^2}{2} a^{\phi^{(2)}} b^{\psi^2} + \cdots + \frac{\nu^n}{n!} a^{\phi^{(n)}} b^{\psi^n} + \cdots \tag{14}$$

is associative. As an exponential, this deformation may be written as

$$a * b = \mu_0((a \otimes b)^{\exp(\phi \otimes \ln(1+\nu\psi))}).$$

As we will see, it is this formula that produces the "Jordanian" quantization of $\mathcal{C}^\infty(\mathrm{SL}_2)$. Related *-products are given in Bieliavsky and Maeda (2002).

These are examples of *universal deformation formulas*, a construction of formal deformations inspired by Drinfel'd's twisting concept of introduced in Drinfel'd (1989a, 1989b). The basic idea is that one has a deformation solely based upon information about the Lie algebra of derivations, and the formula is independent of the actual algebra in question. Such constructions are examples of a mutual feedback between Hopf algebraic techniques in quantum groups and deformation quantization. The following subsections provide further examples.

Definition V.1: An element $F \in B \otimes B$ is a twisting element (based on a bialgebra B with comultiplication Δ_B and counit ε_B) if

(1) $(\varepsilon_B \otimes \mathrm{Id})F = 1 \otimes 1 = (\mathrm{Id} \otimes \varepsilon_B)F$, *and*
(2) $F_{12}[(\Delta_B \otimes \mathrm{Id})(F)] = F_{23}[(\mathrm{Id} \otimes \Delta_B)(F)]$.

The virtue of having such an F is that it can be used to twist the entire category of right B-module algebras and left B-module coalgebras in a uniform way. The following result from Giaquinto and Zhang (1998) is based on the fundamental ideas from Drinfel'd (1989b).

Theorem V.1: *Let $F \in B \otimes B$ be a twisting element:*

(1) *If A is a right B-module algebra, then $A_F = A(\mu_A \circ F_r, 1_A)$ is an associative algebra*;
(2) *If C is a left B-module coalgebra, then $C_F = C(F_l \circ \Delta_C, \varepsilon_C)$ is a coassociative coalgebra*;
(3) *If F is invertible and $\Delta'_B = F_l \circ F_r^{-1} \circ \Delta_B$, then $B_F = B(\mu_B, \Delta'_B, 1_B, \varepsilon_B)$ is a k-bialgebra*;
(4) *If F is invertible A is a right B-module algebra, then A_F is a right B_F-module algebra*;
(5) *If F is invertible and C is a left B-module coalgebra, then C_F is a left B_F-module coalgebra.*

The connection between twisting elements and deformations is the following:

Definition V.2: A universal deformation formula (UDF) based on a bialgebra B is a twisting element F based on $B[[\nu]]$ of the form

$$F = 1 \otimes 1 + \nu F_1 + \nu^2 F_2 + \cdots + \nu^n F_n + \cdots,$$

where each $F_i \in B \otimes B$.

If F is a UDF then it is clear that A_F, C_F, and B_F as constructed in the theorems above are all deformations. It is clear that the twisting elements defined after Theorem (IV.1) are UDFs with $B = \mathcal{U}\mathfrak{g}[[\nu]]$.

Example V.1:

(1) *The most basic UDF is based on the bialgebra $B = \mathcal{U}\mathfrak{a}$ where $\mathfrak{a}$ is an Abelian Lie algebra. The UDF is the classic exponential formula $F = \exp \nu b$, where $b \in \mathfrak{a} \otimes \mathfrak{a}$ is arbitrarily chosen. An example of a deformation arising from this UDF arise is the Moyal deformation of $\mathcal{C}^\infty(\mathbb{R}^{2n})$. Another example is the deformation of the standard quantum group $\mathcal{C}_q^\infty(SL(n))$ to the multi-parameter family first introduced in Reshetikhin (1990).*
(2) *$\mathfrak{s}$ is the two-dimensional solvable Lie algebra with basis $\{\phi, \psi\}$ and relation $[\phi, \psi] = \psi$, and set $B = \mathcal{U}\mathfrak{s}$. Then $F = \exp(\phi \otimes \ln(1 + \nu\psi))$ is a UDF.*
(3) *Other specific examples of UDF's, including ones not based on enveloping algebras, can be found in Bieliavsky et al. (2003), Caldararu et al. (2004), Connes and Moscovici (2004), Kulish et al. (1999), Lyakhovsky and Samsonov (2002), Giaquinto and Zhang (1998).*

Note that, according to Theorems (IV.1) and (V.1), a UDF based on $\mathcal{U}\mathfrak{g}$ produces a preferred deformation $\mathcal{U}\mathfrak{g}$ and matching "covariant" deformations of $\mathcal{C}^\infty(M)$ for every manifold which admits an action of the Lie group G. We shall discuss this topic in more detail later on.

C. Crossed products

The literature on Hopf algebras and quantum groups contains a large collection of what we can call generically semidirect products, or crossed products. These constructions make crucial use of the comultiplication and we will use the standard Sweedler notation for the coproducts [Sweedler (1969)]: in a coalgebra (H,Δ), $\Delta(x)=\Sigma_{(x)}x_{(1)}\otimes x_{(2)}$ and, by coassociativity, $(\mathrm{Id}\otimes\Delta)\Delta(x)=(\Delta\otimes\mathrm{Id})\Delta(x)=\Sigma_{(x)}x_{(1)}\otimes x_{(2)}\otimes x_{(3)}$. See also Abe (1980) for generalities on Hopf algebras.

Considering crossed products gives explicit, concise and workable formulas. The properties of these structures, as well as for semidirect products of groups or Lie algebras, may be deduced from the ones of the two original structures. So we can hope to obtain interesting results on, for example, cohomology or representation theories.

We will investigate two original examples: the topological quantum double and the deformation quantizations of some symmetric spaces.

But first, let us give a general idea of what it is. The simplest example of these crossed products is usually called the smash product [see Sweedler (1968) and Molnar (1977)].

Definition V.3: Let B be a bialgebra and C a B-module algebra. The smash product $C\sharp B$ is the algebra constructed on the vector space $C\otimes B$ where the multiplication is defined by

$$(f\otimes a)\overset{\rightharpoonup}{*}(g\otimes b)=\sum_{(a)}f(a_{(1)}\rightharpoonup g)\otimes a_{(2)}b \tag{15}$$

for $f,g\in C$ and $a,b\in B$.

Remark V.1:

(1) (a) Let H and K be groups and let $\tau:K\to\mathrm{Aut}(H)$ be an action of K on H. This induces a $\mathbb{C}K$-module algebra structure on $\mathbb{C}H$. Then $\mathbb{C}H\sharp\mathbb{C}K\cong\mathbb{C}(H\rtimes K)$, $H\rtimes K$ denoting the semidirect product of H by K.
(b) Similarly, for Lie algebras $\mathfrak{h}$ and $\mathfrak{k}$, a Lie algebra homomorphism $\sigma:\mathfrak{k}\to\mathrm{Der}(\mathfrak{h})$ induces a $\mathcal{U}\mathfrak{k}$-module algebra structure on $\mathcal{U}\mathfrak{h}$. Then $\mathcal{U}\mathfrak{h}\sharp\mathcal{U}\mathfrak{k}\cong\mathcal{U}(\mathfrak{h}\rtimes\mathfrak{k})$.

(2) The smash product can be seen as the algebraic version of what is called "crossed product" in the C^*-algebra literature [Drabant *et al.* (1999) and Pedersen (1979)]. Note that this is an important structure in this context, extensively used, for example, in the works around the Baum-Connes conjecture.

Now let us describe some generalizations:

This product can be seen in the cohomological interpretation of Sweedler (1968) as a representative of the trivial class of a theory of extensions. The formula of the smash product can be "twisted" a little more by some 2-cocycle from $B\otimes B$ to C and is called a crossed product.

If B and C are bialgebras, C a B-module algebra and B a C-module algebra, with some compatibilities between the two actions, one can write some kind of more "symmetric" formula. Majid has called double crossproduct the resulting algebra [Majid (1990)]. This definition leads to a good description of the structure of quantum double introduced by Drinfel'd in 1987 (see below for details).

If C is a bialgebra and B is cocommutative, the natural tensor coproduct on $C\otimes B$ yields a bialgebra structure on $C\sharp B$. If everything is Hopf, $C\sharp B$ can be made Hopf as well [Molnar (1977)].

By dualizing Definition V.3, one gets a coalgebra called the cosmash product. Combining smash and cosmash in order to form a bialgebra leads to the notion of bicrossproduct [Majid (1990)].

Before introducing a new and useful generalization of this kind of definitions let us go back to an application of the double crossproduct to the notion of quantum double in the context of topological Hopf algebras.

1. Topological quantum double

Drinfel'd (1987) defined the quantum double of $\mathcal{U}_\nu\mathfrak{g}$ [see also Semenov-Tian-Shansky (1994)]. This can be adapted to the context of topological Hopf algebras [Bonneau (1994)].

For this subsection A will denote $\mathcal{D}(G), \mathcal{A}(G), \mathcal{D}_\nu(G)$, or $\mathcal{A}_\nu(G)$.

Definitions: If A is described by (A, μ, Δ, S) then $A^* = (A^*, {}^t\Delta, {}^t\mu, {}^tS)$. Define $A^0 = A^{*co-op} = (A^*, {}^t\Delta, {}^t\mu^{op}, {}^tS^{op})$, where $\mu^{op}(x \otimes y) := \mu(y \otimes x)$ and S^{op} is the antipode compatible with μ^{op} and Δ.

If we consider the vector space $A^* \otimes A$, Drinfel'd (1987) defines the quantum double as follows:

(i) $D(A) \simeq A^0 \otimes A$ as coalgebras,
(ii) $(f \otimes Id_A) \cdot (Id_{A^0} \otimes b) = f \otimes b$,
(iii) $(Id_{A^0} \otimes e_s) \cdot (e^t \otimes Id_A) = \Delta_s^{kjn} \mu_{plk}^t S'^p_n (e^l \otimes Id_A)(Id_{A^0} \otimes e_j)$, where $\{e_s\}$ is a basis of A and $\{e^t\}$ the dual basis.

The Drinfel'd double was expressed [Majid (1990)] in a Sweedler form for dually paired Hopf algebras as an example of a theory of 'double smash products.' Adapting that formulation to our topological context we can now define the double as

Definition V.4: The double of A, D(A), is the topological Hopf algebra $(A^* \overline{\otimes} A, \mu_D, {}^t\mu^{op} \otimes \Delta, {}^tS^{op} \otimes S)$ *with*

$$\mu_D((f \otimes a) \otimes (g \otimes b)) = \sum_{(a)} f\langle g, S^{op}(a_{(3)}) \,?\, a_{(1)}\rangle \otimes a_{(2)}b$$

$$= \sum_{(a)(g)} \langle g_{(1)}, a_{(1)}\rangle \langle {}^tS^{op}(g_{(3)}), a_{(3)}\rangle f g_{(2)} \otimes a_{(2)}b,$$

where $\langle , \rangle$ *denotes the pairing* A^*/A, *"?" stands for a variable in A and* $\overline{\otimes}$ *is the completed inductive tensor product.*

As topological vector spaces we have $D(A) = A^* \overline{\otimes} A$. Thus $D(A)^* = A \hat{\otimes} A^*$ and $D(A)^{**} = D(A)$. So $D(A)$ is "almost self-dual" (it is self-dual up to a completion) and is reflexive.

Extension theory:

If A is cocommutative then the product μ_D of $D(A)$ is the smash product $\overline{\mu}^{\rightharpoonup}$ on $A^0 \overline{\otimes} A$

$$\overline{\mu}^{\rightharpoonup}((f \otimes a) \otimes (g \otimes b)) = \sum_{(a)} f(a_{(1)} \rightharpoonup g) \otimes a_{(2)}b$$

where $\rightharpoonup$ denotes the coadjoint action of A on A^0, $\langle a \rightharpoonup f, b\rangle = \Sigma_{(a)} \langle f, S(a_{(1)}) b a_{(2)}\rangle$. This product is the "zero class" of an extension theory, defined by Sweedler (1968), classified by a space of 2-cohomology $H^2_{sw}(A, A^0)$. The products are of the form, for τ a 2-cocycle,

$$\overline{\mu}^{\rightharpoonup}_\tau((f \otimes a) \otimes (g \otimes b)) = \sum_{(a)(b)} f(a_{(1)} \rightharpoonup g) \tau(a_{(2)} \otimes b_{(2)}) \otimes a_{(3)}b_{(2)}.$$

The coproduct of $D(A)$ is a smash coproduct for the trivial co-action. We can dualize the theory and, putting the two things together, we obtain an extension theory for bialgebras which is classified by a cohomology space $H^2_{\text{bisw}}(A^0, A)$.

So we can ask the following question: are there other possible definitions of the double as an extension of A^0 by A?

We get a partial answer:

Proposition V.1 [Bonneau (1994)]: $H^2_{\text{bisw}}(\mathcal{D}(G), \mathcal{C}^\infty(G)) = \{0\}$ *so* $D(\mathcal{D}(G))$ *is the unique extension of* $\mathcal{C}^\infty(G)$ *by* $\mathcal{D}(G)$.

2. L-R smash product

In order to shed light on the general definition which follows, we return to the simplest case of deformation quantization: the Moyal product on $\mathbb{R}^2$. We look at $\mathbb{R}^2$ as $T^*\mathbb{R} \equiv \mathbb{R} \times \mathbb{R}^*$ and therefore can write $\mathcal{C}^\infty(\mathbb{R}^2) \simeq \mathcal{C}^\infty(\mathbb{R}) \hat{\otimes} \mathcal{C}^\infty(\mathbb{R}^*)$. We consider first two functions of a special kind in this algebra: $u(x) = u(x_1, x_2) = f(x_1)P(x_2)$ and $v(x) = v(x_1, x_2) = g(x_1)Q(x_2)$ where $f, g \in \mathcal{C}_0^\infty(\mathbb{R})$ and P, Q are polynomials in $\mathsf{Pol}(\mathbb{R}^*) \simeq \mathsf{S}\mathbb{R}$. We can then write the usual coproduct on the symmetric algebra $\mathsf{S}\mathbb{R}$ as $\Delta(P)(x_2, y_2) = P(x_2 + y_2) \overset{\text{notation}}{=} \Sigma_{(P)} P_{(1)}(x_2) P_{(2)}(y_2))$.

We now look at formula (8) for the Moyal star product on $\mathbb{R}^2$ and perform on it some formal calculations (we do not discuss the convergence of the integrals involved). Up to a constant (depending on ν) we get

$$
\begin{aligned}
(u * v)(x) &= \int_{\mathbb{R}^2 \times \mathbb{R}^2} u(x+y) v(x+z) e^{-(i/\nu)\Lambda^{-1}(y,z)} dy dz \\
&= \int_{\mathbb{R}^2 \times \mathbb{R}^2} f(x_1 + y_1) P(x_2 + y_2) g(x_1 + z_1) Q(x_2 + z_2) e^{-(i/\nu)(y_1 z_2 - y_2 z_1)} dy_1 dy_2 dz_1 dz_2 \\
&= \int_{\mathbb{R}^2} f(x_1 + y_1) Q(x_2 + z_2) e^{-(i/\nu) y_1 z_2} dy_1 dz_2 \cdot \int_{\mathbb{R}^2} g(x_1 + z_1) P(x_2 + y_2) e^{(i/\nu) y_2 z_1} dy_2 dz_1 \\
&= \sum_{(P)(Q)} (\partial^+_{Q_{(1)}} f)(x_1) Q_{(2)}(x_2) \cdot (\partial^-_{P_{(1)}} g)(x_1) P_{(2)}(x_2) \quad \text{(up to a constant)}
\end{aligned}
$$

with $\partial^\pm_{Q_{(1)}} = Q_{(1)}(\mp i\nu \partial_{x_1})$ (the same for P), since $F^\mp_\nu(\alpha F^\pm_\nu(h)(\alpha))(x) = \mp i\nu \partial_x h(x)$ for $h \in \mathcal{C}_0^\infty(\mathbb{R})$ with $F^\pm_\nu(h)(\alpha)$ defined as $\int_{\mathbb{R}} h(x) e^{\mp (i/\nu) x\alpha} dx$. This suggests the following small generalization of the smash product:

Definition V.5: Let B be a cocommutative bialgebra and C a B-bimodule algebra (i.e., a B-module algebra for both, left and right, B-module structures). The **L-R-smash product** *$C \natural B$ is the algebra constructed on the vector space $C \otimes B$ where the multiplication is defined by*

$$
(f \otimes a) * (g \otimes b) = \sum_{(a)(b)} (f \leftharpoonup b_{(1)})(a_{(1)} \rightharpoonup g) \otimes a_{(2)} b_{(2)} \tag{16}
$$

for $f, g \in C$ and $a, b \in B$.

Proposition V.2: The L-R smash product is associative.

In the same spirit, one has

Lemma V.1: If C is a B-bimodule bialgebra, the natural tensor product coalgebra structure on $C \otimes B$ defines a bialgebra structure to $C \natural B$.

If C and B are Hopf algebras, $C \natural B$ is a Hopf algebra as well, defining the antipode by

$$
\begin{aligned}
J_*(f \otimes a) &= \sum_{(a)} J_B(a_{(1)}) \rightharpoonup J_C(f) \leftharpoonup J_B(a_{(2)}) \otimes J_B(a_{(3)}) \\
&= \sum_{(a)} (1_C \otimes J_B(a_{(1)})) * (J_C(f) \otimes 1_B) * (1_C \otimes J_B(a_{(2)})).
\end{aligned} \tag{17}
$$

Now by a careful computation, one proves

Proposition V.3: Let B be a cocommutative bialgebra, C a B-bimodule algebra and $(C \natural B, *)$ their L-R-smash product.

Let S be a linear automorphism of C (as a vector space). We define

(i) *the product $\bullet^S$ on C by*

$$
f \bullet^S g = S^{-1}(S(f) \cdot S(g)); \tag{18}
$$

(ii) *the left and right B-module structures,* $\overset{S}{\rightharpoonup}$ and $\overset{S}{\leftharpoonup}$, by

$$a\overset{S}{\rightharpoonup} f := S^{-1}(a \rightharpoonup S(f)) \quad \text{and} \quad f\overset{S}{\leftharpoonup} a := S^{-1}(S(f) \leftharpoonup a); \tag{19}$$

(iii) *the product,* $*^S$, *on* $C\otimes B$ *by*

$$(f\otimes a)*^S(g\otimes b) = T^{-1}(T(f\otimes a) * T(g\otimes b)), \tag{20}$$

where $T := S\otimes \mathrm{Id}$.

Then $(C, \bullet^S)$ *is a B-bimodule algebra for* $\overset{S}{\rightharpoonup}$ *and* $\overset{S}{\leftharpoonup}$ *and* $*^S$ *is the L-R-smash product defined by these structures.*

Moreover, if $(C, ., \Delta_C, J_C, \rightharpoonup, \leftharpoonup)$ *is a Hopf algebra and a B-bimodule bialgebra, then*

$$C_S := (C, \bullet^S, \Delta_C^S := (S^{-1}\otimes S^{-1})\circ\Delta_C\circ S, J_C^S := S^{-1}\circ J_C\circ S, \overset{S}{\rightharpoonup}, \overset{S}{\leftharpoonup})$$

is also a Hopf algebra and a B-bimodule bialgebra. Therefore, by Lemma V.1,

$$(C_S \sharp B, *^S, \Delta^S = (23)\circ(\Delta_C^S\otimes\Delta_B), J_*^S),$$

is a Hopf algebra for Δ^S *the natural tensor product coalgebra structure on* $C_S \natural B$ (with (23): $C\otimes C\otimes B\otimes B \to C\otimes B\otimes C\otimes B, c_1\otimes c_2\otimes b_1\otimes b_2 \mapsto c_1\otimes b_1\otimes c_2\otimes b_2$) *and* J_*^S *the antipode given on* $C_S \natural B$ *by Lemma V.1. Also, one has*

$$\Delta^S = (T^{-1}\otimes T^{-1})\circ(23)\circ(\Delta_C\otimes\Delta_B)\circ T \quad \textit{and} \quad J_*^S = T^{-1}\circ J_*\circ T$$

with $T = S\otimes \mathrm{Id}$.

3. Examples in deformation quantization on $T^*(G)$

Let G be a Lie group with Lie algebra $\mathfrak{g}$ and $T^*(G)$ its cotangent bundle. We denote by $\mathcal{U}\mathfrak{g}$, $\mathsf{T}\mathfrak{g}$ and $\mathsf{S}\mathfrak{g}$, respectively, the enveloping, tensor, and symmetric algebras of g. Let $\mathsf{Pol}(\mathfrak{g}^*)$ be the algebra of polynomial functions on $\mathfrak{g}^*$. We have the usual identifications:

$$\mathcal{C}^\infty(T^*G) \simeq \mathcal{C}^\infty(G\times\mathfrak{g}^*) \simeq \mathcal{C}^\infty(G)\hat{\otimes}\mathcal{C}^\infty(\mathfrak{g}^*) \supset \mathcal{C}^\infty(G)\otimes\mathsf{Pol}(\mathfrak{g}^*) \simeq \mathcal{C}^\infty(G)\otimes\mathsf{S}\mathfrak{g}.$$

First we deform $\mathsf{S}\mathfrak{g}$ via the "parametrized version," $\mathcal{U}_\nu\mathfrak{g}$, of $\mathcal{U}\mathfrak{g}$ defined by

$$\mathcal{U}_\nu\mathfrak{g} = \frac{\mathsf{T}\mathfrak{g}[[\nu]]}{\langle XY - YX - \nu[X,Y]; X, Y\in\mathfrak{g}\rangle}.$$

$\mathcal{U}_\nu\mathfrak{g}$ is naturally a Hopf algebra with $\Delta(X) = 1\otimes X + X\otimes 1$, $\varepsilon(X) = 0$ and $S(X) = -X$ for $X\in\mathfrak{g}$. For $X\in\mathfrak{g}$, we denote by $\widetilde{X}$ (resp. $\overline{X}$) the left- (resp. right-) invariant vector field on G such that $\widetilde{X}_e = \overline{X}_e = X$. We consider the following $\mathbb{K}[[\nu]]$-bilinear actions of $B = \mathcal{U}_\nu\mathfrak{g}$ on $C = \mathcal{C}^\infty(G)[[\nu]]$, for $f\in C$ and $\lambda\in[0,1]$:

(i) $(X\rightharpoonup f)(x) = \nu(\lambda - 1)(\widetilde{X}\cdot f)(x)$,

(ii) $(f\leftharpoonup X)(x) = \nu\lambda(\overline{X}\cdot f)(x)$.

One then has

Lemma V.2: C is a B-bimodule algebra w.r.t. the above left and right actions (i) and (ii).

Definition V.6: We denote by $*_\lambda$ *the star product on* $(\mathcal{C}^\infty(G)\otimes\mathsf{Pol}(\mathfrak{g}^*))[[\nu]]$ *given by the L-R-smash product on* $\mathcal{C}^\infty(G)[[\nu]]\otimes\mathcal{U}_\nu\mathfrak{g}$ *constructed from the bimodule structure of the preceding lemma.*

Proposition V.4: For $G = \mathbb{R}^n$, $*_{\frac{1}{2}}$ *is the Moyal star product (Weyl ordered),* $*_0$ *is the standard*

ordered star product, and $*_1$ *the antistandard ordered one. In general* $*_\lambda$ *yields the* λ*-ordered quantization, within the notation of M. Pflaum (1999).*

Remark V.2: In the general case, it would be interesting to compare our λ-ordered L-R smash product with classical constructions of star products on $T^*(G)$ with Gutt's product as one example [Gutt (1983)].

4. Hopf structures

We have discussed (see Lemma V.1) the possibility of having a Hopf structure on $C \natural B$. Let us consider the particular case of $\mathcal{C}^\infty(\mathbb{R}^n)[[\nu]] \natural \mathcal{U}_\nu \mathbb{R}^n = \mathcal{C}^\infty(\mathbb{R}^n)[[\nu]] \natural \mathsf{S}\mathbb{R}^n$ ($\mathbb{R}^n$ is commutative). $\mathsf{S}\mathbb{R}^n$ is endowed with its natural Hopf structure but we also need a Hopf structure on $\mathcal{C}^\infty(\mathbb{R}^n) \times[[\nu]] = \mathcal{C}^\infty(\mathbb{R}^n) \otimes \mathbb{R}[[\nu]]$. We will not use the usual one. Our alternative structure is defined as follows:

Definition V.7: We endow $\mathbb{R}[[\nu]]$ *with the usual product, the coproduct* $\Delta(P)(t_1,t_2) := P(t_1 + t_2)$*, the co-unit* $\varepsilon(P) = P(0)$ *and the antipode* $J(\nu) = -\nu$*. We consider the Hopf algebra* $(\mathcal{C}^\infty(\mathbb{R}^n), \cdot, \mathbf{1}, \Delta_C, \varepsilon_C, J_C)$*, with pointwise multiplication, the unit* $\mathbf{1}$ *(the constant function of value* 1*), the coproduct* $\Delta_C(f)(x,y) = f(x+y)$*, the co-unit* $\varepsilon(f) = f(0)$ *and the antipode* $J_C(f)(x) = f(-x)$*. The tensor product of these two Hopf algebras then yields a Hopf algebra denoted by*

$$(\mathcal{C}^\infty(\mathbb{R}^n)[[\nu]], \cdot, \mathbf{1}, \Delta_\nu, \varepsilon_\nu, J_\nu).$$

Note that Δ_ν *and* J_ν *are not linear in* ν*. We then define, on the L-R smash* $\mathcal{C}^\infty(\mathbb{R}^n)[[\nu]] \natural \mathsf{S}\mathbb{R}^n$*,*

$$\Delta_* := (23) \circ (\Delta_\nu \otimes \Delta_B), \varepsilon_* := \varepsilon_\nu \otimes \varepsilon_B \text{ and } J_*$$

as in Lemma V.1.

Proposition V.5: $(\mathcal{C}^\infty(\mathbb{R}^n)[[\nu]] \natural \mathsf{S}\mathbb{R}^n, *_\lambda, \mathbf{1} \otimes 1, \Delta_*, \varepsilon_*, J_*)$ *is a Hopf algebra.*

Remark V.3: The case $\lambda = \frac{1}{2}$ yields the usual Hopf structure on the enveloping algebra of the Heisenberg Lie algebra.

D. UDFs revisited and quantization of symmetric spaces

1. Introduction

The previous discussion of universal deformation formulas was purely formal. However, the ideas can be extended to include geometric considerations, which allows for more flexibility in the applications.

Let G be a group acting on a set M. Denote by $\tau: G \times M \to M: (g,x) \mapsto \tau_g(x)$ the (left) action and by $\alpha: G \times \mathrm{Fun}(M) \to \mathrm{Fun}(M)$ the corresponding action on the space of (complex valued) functions (or formal series) on M ($\alpha_g := \tau^*_{g^{-1}}$). Assume that on a subspace $\mathbb{A} \subset \mathrm{Fun}(G)$, one has an associative $\mathbb{C}$-algebra product $*^G_{\mathbb{A}}: \mathbb{A} \times \mathbb{A} \to \mathbb{A}$ such that

(i) $\mathbb{A}$ is invariant under the (left) regular action of G on $\mathrm{Fun}(G)$;
(ii) the product $*^G_{\mathbb{A}}$ is left-invariant as well, i.e., for all $g \in G; a,b \in \mathbb{A}$, one has

$$(L^*_g a) *^G_{\mathbb{A}} (L^*_g b) = L^*_g (a *^G_{\mathbb{A}} b). \tag{21}$$

(In Hopf algebra language, this means that $(\mathbb{A}, *^G_{\mathbb{A}})$ is a $\mathbb{C}G$-module algebra.)

Given a function on M, $u \in \mathrm{Fun}(M)$, and a point $x \in M$, one denotes by $\alpha^x(u) \in \mathrm{Fun}(G)$ the function on G defined as

$$\alpha^x(u)(g) := \alpha_g(u)(x). \tag{22}$$

Then one readily observes that the subspace $\mathbb{B} \subset \mathrm{Fun}(M)$ defined as

$$\mathbb{B} := \{u \in \mathrm{Fun}(M) \,|\, \forall x \in M: \alpha^x(u) \in \mathbb{A}\} \tag{23}$$

becomes an associative $\mathbb{C}$-algebra when endowed with the product $*^M_{\mathbb{B}}$ given by

$$u *_{\mathbb{B}}^{M} v(x) := (\alpha^x(u) *_{\mathbb{A}}^{G} \alpha^x(v))(e) \tag{24}$$

(e denotes the neutral element of G). Of course, all this can be defined for right actions as well.

Definition V.8: A pair $(\mathbb{A}, *_{\mathbb{A}}^{G})$ *is called a (left) universal deformation of* G*, while formula* (24) *is called the associated* universal deformation formula (*briefly* UDF).

In the present article, we will be concerned with the case where G is a Lie group. The function space $\mathbb{A}$ will be either a functional subspace (or a topological completion) of $\mathcal{C}^\infty(G,\mathbb{C})$ containing the smooth compactly supported functions in which case we will talk about *strict deformation* (following Rieffel (1989); or, the space $\mathbb{A}=\mathcal{C}^\infty(G)[[\nu]]$ of formal power series with coefficients in the smooth functions on G in which case, we will speak about *formal deformation*. In any case, we will assume the product $*_{\mathbb{A}}^{G}$ admits an asymptotic expansion of star-product type:

$$a *_{\mathbb{A}}^{G} b \sim ab + \frac{\nu}{2i}\mathbf{w}(\mathrm{d}u,\mathrm{d}v) + o(\nu^2) \quad (a,b \in \mathcal{C}_c^\infty(G)),$$

where $\mathbf{w}$ denotes some (left-invariant) Poisson bivector on G [Bayen *et al.* (1978) and Drinfel'd (1993)]. In the strict cases considered here, the product will be defined by an integral three-point kernel $K \in \mathcal{C}^\infty(G\times G\times G)$:

$$a *_{\mathbb{A}}^{G} b(g) := \int_{G\times G} a(g_1)b(g_2)K(g,g_1,g_2)\mathrm{d}g_1\mathrm{d}g_2 \quad (a,b \in \mathbb{A}),$$

where dg denotes a normalized left-invariant Haar measure on G. Moreover, our kernels will be of *WKB type* [Weinstein (1994) and Karasev (1994)], i.e.,

$$K = Ae^{(i/\nu)\Phi},$$

with A (the *amplitude*) and Φ (the *phase*) in $\mathcal{C}^\infty(G\times G\times G,\mathbb{R})$ being invariant under the (diagonal) action by left-translations.

Note that in the case where the group G acts smoothly on a smooth manifold M by diffeomorphisms: $\tau: G\times M\to M:(g,x)\mapsto \tau_g(x)$, the first-order expansion term of $u *_{\mathbb{B}}^{M} v$, $u,v \in C^\infty(M)$ defines a Poisson structure $\mathbf{w}^M$ on M which can be expressed in terms of a basis $\{X_i\}$ of the Lie algebra $\mathfrak{g}$ of G as

$$\mathbf{w}^M = [\mathbf{w}_e]^{ij} X_i^* \wedge X_j^*, \tag{25}$$

where X^* denotes the fundamental vector field on M associated to $X \in \mathfrak{g}$.

2. Elementary solvable symplectic symmetric spaces and their strict quantization

a. Symmetric spaces: Definition V.9 [Bieliavsky (1995)]: A symplectic symmetric space is *a triple* (M,ω,s)*, where* (M,ω) *is a smooth connected symplectic manifold and* $s: M\times M\to M$ *is a smooth map such that*

(i) *For all* x *in* M*, the partial map* $s_x: M\to M: y\mapsto s_x(y) := s(x,y)$ *is an involutive symplectic diffeomorphism of* (M,ω) *called the* symmetry *at* x;
(ii) *For all* x *in* M*,* x *is an isolated fixed point of* s_x;
(iii) *For all* x *and* y *in* M*, one has* $s_x s_y s_x = s_{s_x(y)}$.

Two symplectic symmetric spaces (M,ω,s) *and* (M',ω',s') *are* isomorphic *if there exists a symplectic diffeomorphism* $\varphi:(M,\omega)\to(M',\omega')$ *such that* $\varphi s_x = s'_{\varphi(x)}\varphi$.

We denote by G the *transvection group* of (M,s) (i.e., the subgroup of $\mathtt{Aut}(M,\omega,s)$ generated by $\{s_x\circ s_y; x,y\in M\}$).

Definition V.10: Let $(\mathfrak{g},\sigma)$ *be an* involutive algebra*, that is,* $\mathfrak{g}$ *is a finite dimensional real Lie algebra and* σ *is an involutive automorphism of* $\mathfrak{g}$*. Let* Ω *be a skewsymmetric bilinear form on* $\mathfrak{g}$*. Then the triple* $(\mathfrak{g},\sigma,\Omega)$ *is called a symplectic triple if the following properties are satisfied:*

(1) *Let* $\mathfrak{g}=\mathfrak{k}\oplus\mathfrak{p}$, *where* $\mathfrak{k}$ *(resp.* $\mathfrak{p}$*) is the* $+1$ *(resp.* -1*) eigenspace of* σ. *Then* $[\mathfrak{p},\mathfrak{p}]=\mathfrak{k}$ *and the representation of* $\mathfrak{k}$ *on* $\mathfrak{p}$, *given by the adjoint action, is faithful.*

(2) Ω *is a Chevalley 2-cocycle for the trivial representation of* $\mathfrak{g}$ *on* $\mathbb{R}$ *such that* $\forall X\in\mathfrak{k}$, $i(X)\Omega=0$. *Moreover, the restriction of* Ω *to* $\mathfrak{p}\times\mathfrak{p}$ *is nondegenerate.*

The dimension of $\mathfrak{p}$ *defines the dimension of the triple. Two such triples* $(\mathfrak{g}_i,\sigma_i,\Omega_i)$ $(i=1,2)$ *are* isomorphic *if there exists a Lie algebra isomorphism* $\psi:\mathfrak{g}_1\to\mathfrak{g}_2$ *such that* $\psi\circ\sigma_1=\sigma_2\circ\psi$ *and* $\psi^*\Omega_2=\Omega_1$.

Proposition V.6 [Bieliavsky (1995)]: There is a bijective correspondence between the isomorphism classes of simply connected symplectic symmetric spaces (M,ω,s) *and the isomorphism classes of symmetric triples* $(\mathfrak{g},\sigma,\Omega)$.

Proposition V.7: To each symplectic symmetric space (corresponding to a class $[(\mathfrak{g},\sigma,\Omega)]$, *we can associate another triple* $\tau=(\mathfrak{h}(\mathfrak{g}),\sigma,\Omega)$ *such that*

(a) $\mathfrak{h}(\mathfrak{g})$ *is a one-dimensional central extension of* $\mathfrak{g}$;

(b) $(\mathfrak{h}(\mathfrak{g}),\sigma)$ *is an involutive Lie algebra such that if* $\mathfrak{h}(\mathfrak{g})=\mathfrak{l}\oplus\mathfrak{p}$ *is the decomposition w.r.t.* σ *one has* $[\mathfrak{p},\mathfrak{p}]=\mathfrak{l}$;

(c) Ω *is a Chevalley 2-coboundary (i.e.,* $\Omega=\delta\xi,\xi\in\mathfrak{h}(\mathfrak{g})^*$*) such that* $i(\mathfrak{l})\Omega=0$ *and* $\Omega|_{\mathfrak{p}\times\mathfrak{p}}$ *is symplectic.*

Such a triple is called exact triple.

b. Elementary solvable symplectic symmetric spaces: In Definition V.11 below, we define a particular type of solvable symmetric spaces which we call elementary. It has been proven [Bieliavsky (1998), Proposition 3.2] that every solvable symmetric space is realized through a sequence of split extensions by Abelian (flat) factors successively taken over an elementary solvable symmetric space. We therefore consider elementary solvable symmetric spaces as the "first induction step" when studying solvable symmetric spaces.

Definition V.11: A symplectic symmetric space (M,ω,s) *is called an elementary solvable symplectic symmetric space if its associated exact triple* $(\mathfrak{h}(\mathfrak{g}),\sigma,\Omega=\delta\xi)$ *(see Lemma V.7) is of the following type:*

(i) *The Lie algebra* $\mathfrak{h}(\mathfrak{g})$ *is a split extension of Abelian Lie algebras* $\mathfrak{a}$ *and* $\mathfrak{b}$:

$$0\to\mathfrak{b}\to\mathfrak{h}(\mathfrak{g})\to\mathfrak{a}\to 0.$$

(ii) *The automorphism* σ *preserves the splitting* $\mathfrak{h}(\mathfrak{g})=\mathfrak{b}\oplus\mathfrak{a}$.

Such an exact triple (associated to an elementary solvable symplectic symmetric space) is called an elementary solvable exact triple.

Observe that, since $\mathfrak{a}\cap\mathfrak{k}\subset\mathfrak{a}\cap[\mathfrak{h}(\mathfrak{g}),\mathfrak{h}(\mathfrak{g})]=0$, one has $\mathfrak{a}\subset\mathfrak{p}$. Therefore $\mathfrak{b}=\mathfrak{k}\oplus\mathfrak{l}$, with $\mathfrak{l}\subset\mathfrak{p}$. Moreover, since $\mathfrak{l}$ and $\mathfrak{a}$ are Abelian and Ω is nondegenerate, the subspaces $\mathfrak{a}$ and $\mathfrak{l}$ of $\mathfrak{p}$ are dual Lagrangians.

Now let (M,ω,s) be an elementary solvable symplectic symmetric space with associated exact triple $(\mathfrak{h}(\mathfrak{g}),\sigma,\Omega=\delta\xi)$ as above. In a neighborhood U of the origin, the map

$$\mathfrak{p}=\mathfrak{a}\times\mathfrak{l}\to M:(a,l)\mapsto\exp(a)\exp(l)\,.\,o \tag{26}$$

turns out to be a Darboux chart when $U\subset\mathfrak{p}$ has the symplectic structure $\Omega=\delta\xi$. Moreover, there exists a unique immersion $\phi:U\cap\mathfrak{a}\to\mathfrak{a}$ such that in the local coordinate system (26), one has the following linearization property:

$$\xi(\sinh(a)l)=\xi[\phi(a),l], \tag{27}$$

where, for $a\in\mathfrak{a}$ we set $\sinh(a):=\frac{1}{2}((\exp(\rho(a))-\exp(-\rho(a)))\in\mathrm{End}(b)$. This immersion is called the *twisting map*.

Proposition V.8: An elementary solvable symplectic symmetric space is strictly geodesically convex if and only if its associated twisting map extends to $\mathfrak{a}$ *as a global diffeomorphism of* $\mathfrak{a}$. *In*

this case, the Darboux chart (26) extends as a global symplectomorphism $(\mathfrak{p},\Omega)\to(M,\omega)$.

Quantization: Associated to the twisting map one has a three-point function $S\in\mathcal{C}^\infty(M\times M\times M,\mathbb{R})$ called the WKB-phase of the elementary solvable symplectic symmetric space

$$S(x_0,x_1,x_2):=\xi\left(\oint_{0,1,2}\sinh(a_0-a_1)l_2\right), \tag{28}$$

where $\oint_{0,1,2}$ stands for cyclic summation and where $x_i=(a_i,l_i)$ $(i=0,1,2)$. The phase S turns out to be invariant under the (diagonal) action of the symmetries $\{s_x\}_{x\in M}$ on $M\times M\times M$. This will be the essential constituent of the associative oscillatory kernel defining a symmetry-invariant strict quantization on every elementary solvable symplectic symmetric space. We now recall this construction as in [Bieliavsky (2002)].

Definition V.12: For a compactly supported function $u\in C_c^\infty(\mathfrak{p})$, *identifying* $\mathfrak{l}^*$ with $\mathfrak{a}$, *we denote by* $\tilde{u}\in\mathcal{C}^\infty(\mathfrak{a}\times\mathfrak{a})$ *its partial Fourier transform*

$$\tilde{u}(a,\alpha):=\int_{\mathfrak{l}}e^{i\Omega(\alpha,l)}u(a,l)\mathrm{d}l. \tag{29}$$

We also denote by $\phi_\nu:\mathfrak{a}\to a$ *the one-parameter family of twisting maps*

$$\phi_\nu(a):=\frac{2}{\nu}\phi\left(\frac{\nu}{2}a\right). \tag{30}$$

For $u,v\in C_c^\infty(\mathfrak{p})$, *we set*

$$\langle u|v\rangle_\nu:=\int_{\mathfrak{a}\times\mathfrak{a}}\tilde{u}(a,\alpha)\overline{\tilde{v}(a,\alpha)}|Jac_{\phi^{-1}}(\alpha)|\mathrm{d}a\mathrm{d}\alpha. \tag{31}$$

The pair $(\mathcal{C}^\infty(\mathfrak{p}),\langle,\rangle_\nu)$ *is a pre-Hilbert space, and we denote by* $\mathcal{H}_\nu$ *its Hilbert completion.*

The Hilbert product $\langle,\rangle_\nu$ turns out to be symmetry-invariant on $\mathcal{C}_c^\infty(M)$. The action of the transvection group then extends by continuity to an isometric action on $\mathcal{H}_\nu$.

Theorem V.2 [Bieliavsky (2002)]: *Let* (M,ω,s) *be a strictly geodesically convex elementary solvable symplectic symmetric space. Realize it symplectically as* $(\mathfrak{p}=\mathfrak{a}\times\mathfrak{l},\Omega)$, *and define the two-point function* $A\in\mathcal{C}^\infty(M\times M)$ *by*

$$A(x_1,x_2):=|Jac_\phi(a_1-a_2\,.\,)|. \tag{32}$$

This function is called the WKB-amplitude *and turns out to be symmetry-invariant. In this notation, one has the following:*

(i) *For all* $\nu\in\mathbb{R}\setminus\{0\}$ *and* $u,v\in\mathcal{C}_c^\infty(M)$, *the formula*

$$u*_\nu v(x_0):=\int_{M\times M}u(x_1)v(x_2)A(x_1,x_2)e^{\frac{i}{\nu}S(x_0,x_1,x_2)}\mathrm{d}x_1\mathrm{d}x_2 \tag{33}$$

extends as an associative product on $\mathcal{H}_\nu$ ($\mathrm{d}x$ *denotes some normalization of the symplectic volume on* (M,ω)). *Moreover (for suitable* u,v and x_0*) the stationary phase method yields a power series expansion of the form*

$$u*_\nu v(x_0)\sim uv(x_0)+\frac{\nu}{2i}\{u,v\}(x_0)+o(\nu^2), \tag{34}$$

where $\{,\}$ *denotes the symplectic Poisson bracket on* (M,ω).

(ii) *The pair* $(\mathcal{H}_\nu,*_\nu)$ *is a topological Hilbert algebra which the transvection group of* (M,ω,s) *acts on by automorphisms.*

A classical procedure then produces a similar result in the C^*-context, see Bieliavsky (2002) for details.

Remark V.4: Whether a symmetric space is strictly geodesically convex is of course entirely encoded in the spectral content of the splitting endomorphism $\rho:\mathfrak{a}\to\mathrm{End}(\mathfrak{b})$. This is discussed in detail in Bieliavsky (2002).

Before applying these results, let us discuss heuristically the ideas that led to this quantization. Denote by $\tilde{G}$ the group naturally obtained from the Lie algebra $\mathfrak{h}(\mathfrak{g})$. Proposition V.8 gives a global Darboux chart from $\mathfrak{p}\simeq\mathfrak{a}\times\mathfrak{l}\simeq M$ to the coadjoint orbit $\mathcal{O}=Ad^*(\tilde{G}).\xi\subset\mathfrak{h}(g)^*$. Denote by $\lambda_X\in\mathcal{C}^\infty(\mathfrak{p})$ the Hamiltonian function associated with the infinitesimal action of $X\in\mathfrak{h}(\mathfrak{g})$ and by $*_\nu^M$ the standard Moyal star product on $(\mathfrak{p},\Omega)$. So, using ideas coming from star representation theory (see Sec. V A) we remark that $[\lambda_X,\lambda_Y]_{*_\nu^M}=(\nu/i)\{\lambda_X,\lambda_Y\}$, that is, $*_\nu^M$ is $\mathfrak{h}(\mathfrak{g})$-covariant. This covariance allows us to define a representation of $\mathfrak{h}(\mathfrak{g})$ on the space $\mathcal{C}^\infty(\mathcal{O})[[\nu]]$, $\rho_\nu(X)u=(i/\nu)\times[\lambda_X,u]_{*_\nu^M}$.

Through the partial Fourier transform F (29) ($F(u):=\tilde{u}$) we obtain a representation on $\mathcal{C}^\infty(\mathfrak{a}\times\mathfrak{a})[[\nu]]$, $\tilde{\rho}_\nu$ s.t. $\tilde{\rho}_\nu(X)\tilde{u}=X_{\mathfrak{a}}.\tilde{u}+c_\nu(X)\tilde{u}$. The expression of the cocycle c_ν is very similar to the one of the "twisting map" ϕ_ν (30). So now let us consider a deformation of the partial Fourier transform defined by $Z_\nu(u)(a,\alpha)=\tilde{u}(a,\phi_\nu(\alpha))$. Defining the commutative product $\bullet_\nu$ on $\mathcal{C}^\infty(\mathfrak{a}\times\mathfrak{a})[[\nu]]$ by $f\bullet_\nu g=Z_\nu(Z_\nu^{-1}(f)\cdot Z_\nu^{-1}(g))$, calculations show that $\bullet_\nu$ is invariant under $\tilde{\rho}_\nu$.

More, we have $Z_\nu^{-1}\circ\tilde{\rho}_\nu(X)\circ Z_\nu=X^*$, X^* being the vector field induced on M by the action of $\mathfrak{h}(\mathfrak{g})$. That means that the action of $\mathfrak{h}(\mathfrak{g})$ on the "underlying manifold" M_ν of $(\mathcal{C}^\infty(\mathfrak{a}\times\mathfrak{a})[[\nu]],\bullet_\nu)$ is equivalent to the one of $\mathfrak{h}(\mathfrak{g})$ on M. So, "going back" to M by F^{-1} we define $T_\nu=F^{-1}\circ Z_\nu$ and we get a formal product on $\mathcal{C}^\infty(\mathfrak{p})[[\nu]]$ defined by

$$u*_\nu v = T_\nu^{-1}(T_\nu u *_\nu^M T_\nu v) \tag{35}$$

which is invariant under the coadjoint action of $\tilde{G}$ on $\mathcal{O}=\mathfrak{p}$.

3. UDF and Hopf algebra structure

In Bieliavsky *et al.* (2003) we define a specific class of Lie groups called elementary solvable presymplectic Lie groups. Let g be a group in this class. By the quantification of elementary solvable symmetric spaces described above, we get a left G-invariant star product on a G-invariant (under the regular action of G) algebra of functions on G, $\mathbb{A}$. That is, we get a UDF $(\mathbb{A},*_{\mathbb{A}}^G)$ (see definition V.8) for every group G in this class. The formulas are convergent (strict deformation quantization). By asymptotic expansion we obtain also a formal UDF on $\mathcal{C}^\infty(G)[[\nu]]$.

Now, at the formal level, we will obtain compatible coproducts and antipode, seeing the above quantization as a L-R smash product (definition V.5).

To do that let us recall that the obtained star products are of the form

$$u*_\nu v = T_\nu^{-1}(T_\nu u *_\nu^M T_\nu v)$$

with $T=F^{-1}\circ(\mathrm{Id}\otimes\phi_\nu^*)\circ F$. But F does not act on the $\mathfrak{a}$ variable, so we can see it as a map from $\mathcal{C}^\infty(\mathfrak{l})$ to $\mathcal{C}^\infty(\mathfrak{a})$. So we have $T=\mathrm{Id}\otimes S$ with $S=F^{-1}\circ\phi_\nu^*\circ F$. Considering that

$$\mathcal{C}^\infty(M)\simeq\mathcal{C}^\infty(\mathfrak{p})\simeq\mathcal{C}^\infty(\mathfrak{a})\hat{\otimes}\mathcal{C}^\infty(\mathfrak{l})\underset{a\simeq\mathfrak{l}^*}{\simeq}\mathcal{C}^\infty(\mathfrak{l}^*)\hat{\otimes}\mathcal{C}^\infty(\mathfrak{l})\supset Pol(\mathfrak{l}^*)\otimes\mathcal{C}^\infty(\mathfrak{l})\underset{\mathfrak{l}\text{ Abelian}}{\simeq}\mathcal{U}\mathfrak{l}\otimes\mathcal{C}^\infty(\mathfrak{l}),$$

it is easy to show

Proposition V.9: The formal version of the invariant WKB-quantization of an elementary solvable symplectic symmetric spaces defined in Theorem V.2 is a L-R-smash product of the form $*^S$ (*cf. Proposition V.3*).

Corollary V.1: The UDF's for elementary solvable pre-symplectic Lie groups admit compatible coproducts and antipodes.

Then Bieliavsky (2003) gives a UDF and an associated Hopf algebra structure for every three dimensional solvable Lie group. The dressing action of the "book" group on SU(2) is particularly investigated.

VI. TOWARDS EXPLICIT REALIZATIONS. II

In the next sections, we revisit in more detail the ideas that were hinted upon in Sec. IV A. Recall that any formal deformation of $\mathcal{U}\mathfrak{g}$ or $\mathcal{C}^\infty(G)$ is preferred and all are produced by modified twisting elements [solutions of (11) with nontrivial Φ] or twisting elements [solutions of (11) with $\Phi=1\otimes 1\otimes 1$]. In both cases, $F=1\otimes 1+\nu r+O(\nu^2)$. We will be particularly interested in the infinitesimal r.

The deformation of $\mathcal{U}\mathfrak{g}$ or $\mathcal{C}^\infty(G)$ is called "triangular" if F is a twisting element. A standard cohomological equivalence argument can be invoked to ensure that the infinitesimal r lies in $\mathfrak{g}\wedge\mathfrak{g}$ and satisfies the *classical Yang-Baxter equation* (CYBE)

$$[r_{12},r_{13}]+[r_{12},r_{23}]+[r_{13},r_{23}]=0. \tag{36}$$

We will frequently call this type of infinitesimal a *triangular r-matrix*.

The deformation of $\mathcal{U}\mathfrak{g}$ or $\mathcal{C}^\infty(G)$ is called *quasitriangular* if F is a modified twisting element. A deep result of Drinfel'd (1989b) asserts that, in the quasitriangular case, the element Φ is uniquely determined up to a certain natural equivalence. The element Φ is known as the *associator* and it has deep connections to the theory of quasi-Hopf algebras, the Kniznik–Zamolodchikov equations, and a theorem of Kohno regarding certain representations of braid groups. It also enters in a crucial way in the operadic demonstration [Tamarkin (1998), Hinich (2003)] of the Kontsevich formality theorem [Kontsevich (2003)] (which gives the existence of a star-product on every Poisson manifold).

We do not have the time to discuss these matters in this survey. In this case however, the infinitesimal r still satisfies the CYBE but $r\in\mathfrak{g}\otimes\mathfrak{g}$ is no longer skew. Instead, we have $r+r_{21}=\Omega$ where Ω is the Casimir element in $\mathfrak{g}\otimes\mathfrak{g}$ chosen with respect to some fixed invariant bilinear form on $\mathfrak{g}$. In this case, the infinitesimal r is called a *quasitriangular r*-matrix, and it necessarily follows that $\tilde{r}=r-(\Omega/2)\in\mathfrak{g}\wedge\mathfrak{g}$ will satisfy the *modified classical Yang-Baxter equation* (MCYBE)

$$[\tilde{r}_{12},\tilde{r}_{13}]+[\tilde{r}_{12},\tilde{r}_{23}]+[\tilde{r}_{13},\tilde{r}_{23}]\in(\mathfrak{g}\wedge\mathfrak{g}\wedge\mathfrak{g})^{\mathfrak{g}}. \tag{37}$$

Given an r-matrix of either type, it is natural to seek the twisting element F [guaranteed to exist by Drinfel'd (1985, 1989)] whose infinitesimal is r. In the explicit sense, the results are quite scarce. Indeed, as previously mentioned, F is unknown for all quasitriangular r-matrices including, in particular, the "standard" solution which serves as the infinitesimal for the quantum groups $\mathcal{U}_q(\mathfrak{g})$ and $\mathcal{C}_q^\infty(G)$.

A. Preferred *-products for the standard quantum *n*-space

Since the F is unknown, it should be no surprise that the preferred *-products have not been exhibited even for $\mathcal{C}_q^\infty(\mathrm{SL}(n))$. However, we do have the preferred *-products for the covariant quantization, $\mathcal{C}_q^\infty(\mathbb{C}^n)$, of the function algebra $\mathcal{C}^\infty(\mathbb{C}^n)$. If x_i are the coordinate functions on $\mathbb{C}^n$, then $\mathcal{C}_q^\infty(\mathbb{C}^n)$ is characterized by the relations $x_ix_j=qx_jx_i$ for $i<j$. In the classical case, the action of the group SL_n on $\mathbb{C}^n$ makes $\mathcal{C}^\infty(\mathbb{C}^n)$ into an $\mathcal{C}^\infty(\mathrm{SL}(n))$-comodule algebra. This means that $\mathcal{C}^\infty(\mathbb{C}^n)$ is an $\mathcal{C}^\infty(\mathrm{SL}(n))$-comodule with the compatibility condition that the coaction map is an algebra homomorphism. The same is true at the quantized level: $\mathcal{C}_q^\infty(\mathbb{C}^n)$ is an $\mathcal{C}_q^\infty(\mathrm{SL}(n))$-comodule algebra. A preferred covariant deformation in this case is a *-product on $\mathcal{C}^\infty(\mathbb{C}^n)$ which is compatible with both the original unchanged (on all elements) comodule structure map (on all elements) and the preferred quantization of $\mathcal{C}^\infty(\mathrm{SL}(n))$ to $\mathcal{C}_q^\infty(\mathrm{SL}(n))$.

In order to describe the preferred *-products for the quantum linear space, we need some combinatorial notation. Define the q-factorial to be

$$m!_q = \frac{(1-q^m)(1-q^{m-1})\cdots(1-q)}{(1-q)^m}$$

and for $\lambda \in \mathbb{N}^n$ with $|\lambda| = \lambda_1 + \cdots + \lambda_n$ let

$$\langle \lambda \rangle_q = \frac{|\lambda|!_q}{\lambda_1!_q \cdots \lambda_n!_q}$$

be the q-multinomial coefficient. Without the subscript, $\langle \lambda \rangle$ will denote the usual multinomial coefficient. The symbol X^λ will denote the monomial $x_1^{\lambda_1}\cdots x_n^{\lambda_n}$. Note that by linearity, it is only necessary to consider the product of monomials. The ordinary commutative multiplication is simply expressible as $X^\lambda X^\nu = X^{\lambda+\nu}$. Finally, for $\lambda, \nu \in \mathbb{N}^n$ set

$$(\lambda : \nu) = \sum_{i=1}^{n} \sum_{j>i} \lambda_i \nu_j.$$

Theorem VI.1 [Gerstenhaber *et al.* (1990) and Giaquinto (1992)]: *The preferred deformation for the quantum linear space $\mathcal{C}_q(\mathbb{C}^n)$ is given by*

$$X^\lambda * X^\nu = \left(\frac{\langle \lambda \rangle_{q^2} \langle \nu \rangle_{q^2} \langle \lambda + \nu \rangle}{\langle \lambda \rangle \langle \nu \rangle \langle \lambda + \nu \rangle_{q^2}} \right)^{1/2} q^{(\lambda:\nu)} X^{\lambda+\nu}. \tag{38}$$

The presence of the factor $q^{(\lambda:\nu)}$ is clear as it comes directly from the defining relations $x_i x_j = q x_j x_i$ of $\mathcal{C}_q^\infty(\mathbb{C}^n)$. The other numerical factor in the formula may be viewed as a ratio of norms and its necessity is less obvious. Note that some of the products in (38) are undefined when q is a root of unity which helps explain from the deformation quantization viewpoint that the standard quantum groups at roots of unity have different behavior than at generic specializations of q. Upon seeing this formula in 1990, Ludwig Faddeev was startled and claimed that, within a year, we would have the preferred *-products on all of $\mathcal{C}_q^\infty(\mathrm{SL}(n))$. Unfortunately, time has not been kind to his prediction as this problem is unfortunately still open.

Formula (38) of Theorem VI.1 was recently rediscovered by Blohmann (2003) using q-Clebsch–Gordan coefficients.

B. Triangular *r*-matrices and twists

Suppose that r is a triangular r-matrix [a solution of (VI)]. Drinfel'd has given a procedure in Drinfel'd (1985) which, given a triangular r, produces the twisting F. It is generally difficult though to extract the exact form of F since the construction uses, among other things, the Campbell–Baker–Hausdorff formula for the series of $\ln(e^x e^y)$, where $x, y \in \mathfrak{g}$. In the "strong" explicit sense, the twisting F is known only for certain classes of r-matrices including the "Jordanian" solution for $\mathfrak{sl}(2)$ and several of its generalizations.

Let us recall the basic classification scheme [see Belavin and Drinfel'd (1982)] for triangular r-matrices. Our formulation follows that of Stolin (1991). A Lie algebra $\mathfrak{f}$ is quasi-Frobenius if there exists a nondegenerate two-cocycle $\phi : \mathfrak{f} \wedge \mathfrak{f} \to \mathbb{C}$. The connection to triangular r-matrices is that the cocycle condition for the bilinear form ϕ is equivalent to ϕ^{-1} (the element of $\mathfrak{f} \wedge \mathfrak{f}$ whose matrix of coefficients is the inverse of the matrix of ϕ) satisfying the classical Yang–Baxter equation. The problem of finding triangular r-matrices up to equivalence is then reduced to listing the quasi-Frobenius Lie algebras, their normalizers, and calculating the second cohomology group $H^2(\mathfrak{f}, \mathbb{C})$. A simple Lie algebra $\mathfrak{g}$ is never quasi-Frobenius but if $r \in \mathfrak{g} \wedge \mathfrak{g}$ is classical r-matrix, then there is a unique quasi-Frobenius "carrier" subalgebra $\mathfrak{f} \subset \mathfrak{g}$ for which $r \in \mathfrak{f} \wedge \mathfrak{f}$. Note that such an $\mathfrak{f}$ is necessarily even-dimensional. This approach does not give a constructive classification of triangular r-matrices as there is no effective way to find all quasi-Frobenius Lie subalgebras of $\mathfrak{g}$.

The easiest example of the foregoing is when $\mathfrak{f}$ is an Abelian subalgebra of $\mathfrak{g}$. Then any $r \in \mathfrak{f} \wedge \mathfrak{f}$ is a classical r-matrix and it is elementary to check that the corresponding twisting element is $F = \exp(\nu r)$. We have already seen that this twisting element (=UDF) produces, in particular, the Moyal deformation.

Perhaps the most well known example of a triangular r-matrix is based on the Borel subalgebra of $\mathfrak{sl}(2)$ which is generated by h and e with $[h,e]=2e$. The r-matrix $h \wedge e$ is the infinitesimal of the "Jordanian" quantization of $\mathcal{C}^\infty(\mathrm{SL}(2))$, which is its unique (up to equivalence) triangular quantization. The twisting element can be derived using (14) and comes out to be $F = \exp((h/2) \otimes \ln(1+\nu e))$. Note that the infinitesimal is $h \otimes e$ and not $h \wedge e$. These are equivalent r-matrices and the twisting element with infinitesimal $h \wedge e$ is given in Giaquinto and Zhang (1998).

There are various extensions of the Jordanian r-matrix to $\mathfrak{sl}(n)$ with $n > 2$. In particular, the triangular r-matrix

$$r = (e_{11} - e_{nn}) \wedge e_{1n} + 2\sum_{j=2}^{n-1} e_{1j} \wedge e_{jn}$$

was exhibited in Gerstenhaber *et al.* (1990). The element F for this family has been called an *extended Jordanian* twist and was derived independently in Giaquinto and Zhang (1995) and Kulish *et al.* (1999), although the latter reference has the following more compact form of the twisting element

$$F = \exp\left\{ 2\nu \sum_{i=2}^{n-1} e_{1i} \otimes e_{in} e^{-\sigma} \right\} \exp\{(e_{11} - e_{nn}) \otimes \sigma\},$$

where $\sigma = \frac{1}{2} \ln(1+2\nu e_{1n})$. Note that the carriers for this family are contained in the Borel subalgebra of $\mathfrak{sl}(n)$, and are hence solvable.

Another interesting generalization of the Jordanian twist is a family of r-matrices whose carriers, in contrast with the above examples, are nonsolvable subalgebras of $\mathfrak{sl}(n)$. In particular, the carrier algebra is the (Frobenius) Lie algebra $\mathfrak{p}_1$ which denotes the maximal parabolic subalgebra generated by all simple positive root vectors $e_{i,i+1}$, the Cartan subalgebra of traceless matrices, and the simple negative root vectors $e_{i+1,i}$ *except* e_{21}. For example, when $n=3$, this Lie algebra consists of all traceless matrices of the form

$$\begin{pmatrix} * & * & * \\ 0 & * & * \\ 0 & * & * \end{pmatrix}.$$

The r-matrix with carrier $\mathfrak{p}_1 \subset \mathfrak{sl}(n)$ was discovered in Gerstenhaber and Giaquinto (1997). For $n=3$ the explicit form is

$$r = (2e_{11} - e_{22} - e_{33}) \wedge e_{12} + (e_{11} + e_{22} - 2e_{33}) \wedge e_{23} + e_{13} \wedge e_{32}.$$

The twist for this family is only known in the case of $n=3$; it has the form of a product of an extended Jordanian twist (as illustrated above) with a "deformed" Jordan type twist. Details of this interesting twist can be found in Lyakhovsky and Samsonov (2002).

C. Quasitriangular *r*-matrices: The Belavin–Drinfel'd classification

We now turn to the case of quasitriangular r-matrices. First, some good news. There is a complete constructive classification of all such $r \in \mathfrak{g} \otimes \mathfrak{g}$ when $\mathfrak{g}$ is simple. This is the famous Belavin–Drinfel'd classification, see Belavin and Drinfel'd (1984). To describe this classification we need some notation. Let $\mathfrak{h}$ be a Cartan subalgebra of $\mathfrak{g}$. The root system will be denoted by Δ and Γ will be a set of simple roots. Let $\Omega_0 \in \mathfrak{g} \otimes \mathfrak{g}$ be the restriction of the Casimir element Ω to $\mathfrak{h} \otimes \mathfrak{h}$.

Definition VI.1: A Belavin–Drinfel'd triple for $\mathfrak{g}$ *is a triple* (Γ_1, Γ_2, T), *where* Γ_i *are subsets of*

the positive simple roots of $\mathfrak{g}$ *and* $T:\Gamma_1\to\Gamma_2$ *is a bijection which preserves the invariant bilinear form and for all* $\alpha\in\Gamma_1$, *there exists* $k>1$ *such that* $T^k\notin\Gamma_1$.

Given such a triple (henceforth simply denoted T), an element $s\in\mathfrak{h}\otimes\mathfrak{h}$ is called T-admissible if

$$s+s_{21}=\Omega_0 \quad \text{and} \quad (T(\alpha)\otimes 1)s+(1\otimes\alpha)s=\Omega_0$$

for all $\alpha\in\Gamma_1$. A T-admissible s is always of the form $s=\tilde{s}+\Omega_0/2$, where $\tilde{s}\in\mathfrak{h}\wedge\mathfrak{h}$. The set of all admissible $\tilde{s}$ forms a linear subvariety of $\mathfrak{h}\wedge\mathfrak{h}$ whose dimension is $\binom{d}{2}$ where $d=\#(\Gamma-\Gamma_1)$.

The map T can be extended to an isomorphism of Lie subalgebras $T:\mathfrak{g}_1\to\mathfrak{g}_2$ where $\mathfrak{g}_i$ is the Lie subalgebra of $\mathfrak{g}$ generated by the simple roots in Γ_i. Choose $e_\alpha\in\mathfrak{g}_\alpha$ such that $(e_\alpha,e_{-\alpha})=1$ and $T(e_\alpha)=e_{T\alpha}$ and define an ordering on Δ by $\alpha\prec\beta$ if $T^k\alpha=\beta$ for some positive integer k. View $\mathfrak{g}\wedge\mathfrak{g}$ as a subset of $\mathfrak{g}\otimes\mathfrak{g}$ according to the identification $x\wedge y=1/2(x\otimes y-y\otimes x)$. The spectacular result of Belavin and Drinfel'd is the content of the next theorem.

Theorem VI.2 [Belavin and Drinfel'd (1984)]: Let $\mathfrak{g}$ *be a simple complex Lie algebra and suppose that T is a triple. Then for every admissible s, the element*

$$r=s+\sum_{\alpha>0}e_{-\alpha}\otimes e_\alpha+2\sum_{\substack{\alpha,\beta>0\\ \alpha\prec\beta}}e_{-\alpha}\wedge e_\beta$$

is a quasitriangular solution to the Yang–Baxter equation satisfying $r_{12}+r_{21}=\Omega$. *Moreover, every such solution is of this form up to the adjoint action of* $\mathfrak{g}$ *on* $\mathfrak{g}\otimes\mathfrak{g}$.

The standard solution, $r_{st}=\Omega_0+\Sigma_{\alpha>0}\,e_{-\alpha}\otimes e_\alpha$, corresponds to the empty triple (with $\Gamma_i=\emptyset$) and $\tilde{s}=0$. It is the infinitesimal for the quantum groups $\mathcal{U}_q(\mathfrak{g})$ and $\mathcal{C}_q^\infty(G)$. For this triple, any $s=\Omega_0+\tilde{s}$ with $\tilde{s}\in\mathfrak{h}\wedge\mathfrak{h}$ is admissible so the dimension of this family of solutions is $\binom{l}{2}$ where l is the rank of $\mathfrak{g}$.

At the other extreme, there are certain triples for which there is a unique T-admissible element. For $\mathfrak{g}=\mathfrak{sl}_n$, these are the *generalized Cremmer–Gervais* triples, see Gerstenhaber and Giaquinto (1997). If $\{\alpha_1,\ldots,\alpha_{n-1}\}$ are the simple positive roots and i is relatively prime to n, then the triple T_i with

$$\Gamma_1=\Gamma-\{\alpha_{n-i}\},\quad \Gamma_2=\Gamma-\{\alpha_m\},\quad T(\alpha_j)=\alpha_{i+j \mod n} \tag{39}$$

is a generalized Belavin-triple. The r-matrix where $m=1$ serves as the infinitesimal of the Cremmer-Gervais R-matrix, see Cremmer and Gervais (1990). The original approach of Cremmer–Gervais made no mention of the Belavin–Drinfel'd triple; the connection was first made in Gerstenhaber *et al.* (1993).

D. Boundary solutions of the classical Yang–Baxter equation

Suppose $r\in\mathfrak{g}\wedge\mathfrak{g}$ is a solution of the modified classical Yang–Baxter equation (VI) $[r_{12},r_{13}]+[r_{12},r_{23}]+[r_{13},r_{23}]=c\omega$, where ω is a $\mathfrak{g}$-invariant element in $\mathfrak{g}\wedge\mathfrak{g}\wedge\mathfrak{g}$ and c is a scalar. It should be intuitively clear that as c tends to zero, r tends to a solution of the classical Yang–Baxter equation. This theory of this type of "degeneration" was made precise in Gerstenhaber and Giaquinto (1997), and it is essentially the concept of contraction which was elaborated upon earlier in this paper.

Let $\mathcal{M}$ be the set of all solutions to the modified classical Yang–Baxter equation in the projective space $\mathbb{P}(\mathfrak{g}\wedge\mathfrak{g})$ of lines in $\mathfrak{g}\wedge\mathfrak{g}$. Similarly, $\mathcal{C}$ will denote the solutions to the classical Yang-Baxter equation in $\mathbb{P}(\mathfrak{g}\wedge\mathfrak{g})$.

Theorem VI.3 [Gerstenhaber and Giaquinto (1997)]:

(1) *The set* $\mathcal{M}$ *is a quasiprojective variety (i.e., an open subset of* $\overline{\mathcal{M}}$, *its closure);*
(2) *Any element in the closure of* $\mathcal{M}$ *not lying in* $\mathcal{M}$ *is contained in* $\mathcal{C}$;
(3) *There exist elements of* $\mathcal{C}$ *which are not in* $\overline{\mathcal{M}}$.

In light of the theorem, call an r which lies in $\overline{\mathcal{M}}$ but not $\mathcal{M}$ a *boundary solution* of the classical Yang–Baxter equation.

Question VI.1: Is there a reasonable constructive classification of the boundary r-matrices? As stated earlier, no such classification seems likely for all triangular r-matrices. But the relation of the boundary solutions to the constructively known set $\mathcal{M}$ gives plausibility to a positive answer to this question.

An easy way to construct boundary r matrices is the following: Take an ad-nilpotent element $x \in \mathfrak{g}$ and any modified classical r-matrix r. Then $\exp(\xi \mathrm{ad}_x)\cdot r$ is necessarily of the form $r+\xi r_1 + \cdots + \xi^m r_m$. Dividing the result by ξ^m and letting ξ approach zero then shows that r_m must be a boundary solution of the classical Yang–Baxter equation. The extended Jordanian and parabolic triangular r-matrices discussed earlier were first realized with this construction. The extended Jordanian r lies in the boundary of an orbit of the standard solution to the modified classical Yang–Baxter equation, see Gerstenhaber *et al.* (1990). The more interesting example is the parabolic r-matrix. It lies in the closure of an orbit of the Cremmer–Gervais solution to the modified classical Yang–Baxter equation. What is striking here is that both the parabolic solution and the Cremmer–Gervais solution are uniquely determined by the first root of $\mathfrak{sl}(n)$. The parabolic subalgebra is the unique r-matrix with carrier $\mathfrak{p}_1$ (determined by deleting the first negative root), and the Cremmer–Gervais triple is the unique one whose Γ_2 omits only the first root. There should be a parallel situation with the modified Cremmer–Gervais triples, each of which is uniquely determined by an integer relatively prime to n. Elashvili (1982) has proved that the parabolic subalgebra $\mathfrak{p}_i$ of $\mathfrak{sl}(n)$ determined by deleting $\alpha_i = e_{i+1,i}$ is quasi-Frobenius if and only if i and n are relatively prime.

Conjecture VI.1: Suppose i is relatively prime to n. Then the triangular r-matrix whose carrier is the maximal parabolic subalgebra $\mathfrak{p}_i$ lies in the closure of the orbit of the modified Cremmer–Gervais quasitriangular r-matrix determined by the triple T_i [defined in formula (VI.3)].

In unpublished work, the second and third authors have verified this conjecture by direct computation in the case $n=5$ and $i=2$.

E. The GGS "magic" formula

The central aspect of the FRT approach is a quantum Yang–Baxter matrix $R \in \mathrm{End}(V \otimes V)$ where V is the vector representation of G. The matrix R is used to provide commutation relations for the generators which define the quantized Hopf algebra of functions. Given a solution r to the classical Yang–Baxter equation (triangular or quasitriangular), a natural question is quantize it to an R-matrix of the form $R = 1 + \nu r + \nu^2 r_2 + \cdots$ which satisfies the quantum Yang–Baxter equation $R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}$ (QYBE).

If r is triangular and F is its corresponding twisting element, then $\mathcal{R} = FF_{21}^{-1}(\mathcal{U}\mathfrak{g} \otimes \mathcal{U}\mathfrak{g})[[\nu]]$ is a universal solution to the QYBE. Specializing to the vector representation then gives a quantum Yang–Baxter matrix. However, it is hard to be explicit here because the F is unknown in the strong explicit sense, except in some cases previously mentioned. However, if r is quasitriangular, there is the Belavin–Drinfel'd classification and an interesting question is to quantize these r-matrices. For general simple $\mathfrak{g}$ there is no satisfactory answer as of yet, but for $\mathfrak{sl}(n)$ there is a remarkable explicit quantization called the *GGS Formula*, see Gerstenhaber *et al.* (1993). Our esteemed colleague Yvette Kosmann–Schwarzbach calls this the magic formula because of its simplicity and the remarkable fact that such a simple formula can work for all quasitriangular r-matrices.

For the standard solution r_{st} the corresponding R-matrix

$$R_{\mathrm{st}} = q\sum_i e_{ii} \otimes e_{ii} + \sum_{i \neq j} e_{ii} \otimes e_{jj} + (q - q^{-1})\sum_{i>j} e_{ij} \otimes e_{ji} \tag{40}$$

is well-known. In addition to the quantum Yang–Baxter equation, PR_{st} satisfies the Hecke relation $(PR-q)(PR+q^{-1})=0$, where P is the matrix representing the interchange of factors in $V \otimes V$. If $\tilde{s} \in \mathfrak{h} \wedge \mathfrak{h}$ then recall that $r_{\mathrm{st}} + \tilde{s}$ is a quasitriangular r-matrix associated with the empty triple. Its quantization has the elementary form $q^{\tilde{s}} R_{\mathrm{st}} q^{\tilde{s}}$ and was first given in Reshetikhin (1990), a paper

which initiated a flurry of activity in the area of multiparameter quantum groups.

Until 1993, the only other specific R-matrix was that given by Cremmer and Gervais (1990). Then a conjecture was made by Gerstenhaber, Giaquinto, and Schack which gave a formula which was conjectured to produce an R-matrix from each Belavin–Drinfel'd r-matrix for $\mathfrak{sl}(n)$. This became known as the "GGS conjecture." Evidence of the conjecture's validity was confirmed by computer programs for all triples up through $\mathfrak{sl}(5)$ in Giaquinto and Hodges (1998), and for all triples up through $\mathfrak{sl}(12)$ in Schedler (1999). Up to a natural notion of equivalence, there are 210,300 triples for $\mathfrak{sl}(12)$.

To describe the GGS formula, we need some notation. Let $r_{\mathrm{st}}+s+a$ be a Belavin–Drinfel'd quasitriangular r-matrix. Recall that $s=\tilde{s}+\Omega_0/2$ with $\tilde{s}\in\mathfrak{h}\otimes\mathfrak{h}$. Set

$$\varepsilon = ar_{\mathrm{st}} + r_{\mathrm{st}}a + a^2.$$

For $M\in M_n(\mathbb{C})\otimes M_n(\mathbb{C})$ we use the Kronecker notation $M=\Sigma M_{ik}^{jl}e_{ij}\otimes e_{kl}$. Define

$$\tilde{a} = \sum a_{ij}^{kl} q^{a_{ij}^{kl}\varepsilon_{ij}^{kl}} e_{ij}\otimes e_{kl}.$$

Theorem VI.4 [Gerstenhaber *et al.* (1993) and Schedler (2000)]: *Let $r_{\mathrm{st}}+s+a$ be a Belavin–Drinfel'd quasitriangular r-matrix, and define*

$$R_{GGS} = q^{\tilde{s}}(R_{\mathrm{st}} + (q-q^{-1})\tilde{a})q^{\tilde{s}}. \tag{41}$$

Then R_{GGS} satisfies the quantum Yang–Baxter equation which quantizes r, and PR_{GGS} satisfies the Hecke relation.

The proof of the conjecture is due to Schedler (2000) and is rather complicated. In related work, Etingof, Schedler, and Schiffmann gave an (explicit) quantization of the so-called dynamical r-matrices for simple Lie algebras [Etingof *et al.* (2000)]. A special case of their construction gives a universal quantization of any quasi-triangular r-matrix. Even though the construction is "explicit," it is a formidable task to perform computations with the universal quantization in a specific representation. Indeed, Schedler begins his proof of the GGS conjecture with the ESS universal quantization and then he proceeds to evaluate it in the tensor square of the vector representation. After 25 pages of lengthy combinatorial computations, he finds out that the result is exactly the GGS matrix! Something is wanting, however, for a more elementary proof as the statement of the GGS conjecture is just an assertion about specific linear transformation of a finite dimensional vector space.

Question VI. 2:

(1) *Find a similar GGS-type formula which quantizes the quasitriangular r-matrices for the other classical series (B,C,D) of simple Lie algebras. So far, no progress has been made in this direction.*
(2) *Find a "boundary GGS formula." By this, we mean formula which quantizes the boundary r-matrices. For example, it was proved in Gerstenhaber and Giaquinto (1998) that for any triangular r-matrix in $\mathfrak{sl}(n)\wedge\mathfrak{sl}(n)$ which lies in the boundary of the standard solution $\Sigma_{i>j}\, e_{ij}\wedge e_{ji}$ to the MCYBE, then $\exp(\xi r)$ is a boundary solution to the QYBE.*

In a matter related to the second question, Endelman and Hodges (2000) have shown that the Cremmer–Gervais R-matrix degenerates to a QYBE matrix which quantizes the parabolic triangular r-matrix associated to the parabolic subalgebra $\mathfrak{p}_1$ of $\mathfrak{sl}(n)$. This may be seen as the quantum version of the degeneration of the Cremmer–Gervais quasitriangular r-matrix to the triangular parabolic r-matrix.

F. Quantizing in representation space

Let V be the vector representation of a simple complex Lie algebra $\mathfrak{g}$. In the last section, we exhibited a canonical QYBE matrix $R\in\mathrm{End}(V\otimes V)$ associated with each Belavin–Drinfel'd infinitesimal for $\mathfrak{sl}(n)$. The FRT formalism then may be used to produce commutation relations for

the generators of a quantization $\mathbb{C}_R[\mathrm{SL}(n)]$ of the coordinate Hopf algebra of $\mathrm{SL}(n)$. Each R-matrix also enjoys many other nice properties. For example, the operator $\hat{R}=PR$ has eigenvalues q and $-q^{-1}$ with multiplicities $(n^2+n)/2$ and $(n^2-1)/2$, respectively. These numbers coincide with the multiplicities of the eigenspaces corresponding to the eigenvalues ± 1 of the permutation operator P.

What the R-matrix does not do, however, is *quantize* the module $V\otimes V$—that is, transform the $+1$-eigenspace for P to the q-eigenspaces for $\hat{R}$ and the—1-eigenspace for P to the $-q^{-1}$-eigenspace for $\hat{R}$. Some explanation is in order to explain more precisely what we mean here. In the classical $(q=1)$ case the module $V\otimes V$ splits into a direct sum $V^+\oplus V^-$, where V^+ consists of the symmetric vectors (eigenvalue -1 for P) and V^- is the space of skew-symmetric vectors (eigenvalue -1 for P). In the quantized case the same idea holds. Specifically, $V\otimes V\cong V_q^+\oplus V_q^-$, where V_q^+ is the space of q-symmetric vectors (eigenvalue q for $\hat{R}$) and V_q^- is the space of q-skew-symmetric vectors (eigenvalue $-q^{-1}$) for $\hat{R}$. What we seek is a *quantizing transformation* $Q\in \mathsf{End}(V\otimes V)$ which takes V^+ to V_q^+ and V^- to V_q^-. If the Belavin–Drinfel'd infinitesimal of R is r, then it is known that any possible quantizing transformation Q has infinitesimal $\tilde{r}=r-(\Omega/2)$, the solution to the MCYBE associated with r. Ideally we would like to have a canonical (explicit of course!) simple formula for the quantizing transformation Q as a function of $\tilde{r}$.

For the standard solution R_{st}, we do have a pleasant description of Q which we now describe. The solution to the MCYBE associated to r_{st} is $\tilde{r}_{\mathrm{st}}=\Sigma_{i>j}\, e_{ij}\wedge e_{ji}$. Let $e_1,\ldots,e_n$ be the standard basis of $V\cong\mathbb{C}^n$. It will be convenient to use the inner product on V defined by $(e_i,e_j)=\delta_{ij}$. This extends to one on $V\otimes V$ in which the set of all $e_i\otimes e_j$ forms an orthonormal basis. Then an elementary calculation shows that

$$V_q^+=\left\{\{\, e_i\otimes e_i \,|\, 1\leqslant i\leqslant n\}\cup\left\{\left.\frac{qe_i\otimes e_j+e_j\otimes e_i}{\sqrt{1+q^2}}\right|\, i<j\right\}\right\}$$

and

$$V_q^-=\left\{\left\{\left.\frac{e_i\otimes e_j-qe_j\otimes e_i}{\sqrt{1+q^2}}\right|\, i<j\right\}\right\}.$$

Note that these are orthogonal bases and that setting $q=1$ gives orthogonal bases for the eigenspaces $V^{\pm}$ of P.

Theorem VI.5 [Gerstenhaber *et al.* (1990)]: *Let* $Q=\exp(\nu\tilde{r}_{\mathrm{st}})$ *and* $q=\sec\nu-\tan\nu$. *Then* $Q(e_i\otimes e_i)=e_i\otimes e_i$ *for each* i *and for all* $i<j$

$$Q\left[\frac{e_i\otimes e_j+e_j\otimes e_i}{\sqrt{2}}\right]=\frac{qe_i\otimes e_j+e_j\otimes e_i}{\sqrt{1+q^2}},\quad \textit{and}\quad Q\left[\frac{e_i\otimes e_j-e_j\otimes e_i}{\sqrt{2}}\right]=\frac{e_i\otimes e_j-qe_j\otimes e_i}{\sqrt{1+q^2}}$$

and

$$\hat{R}_{\mathrm{st}}=\frac{1}{\cos\,\nu}(Q^{-1}PQ-\sin\,\nu).$$

Thus Q is an orthogonal quantizing transformation and $\hat{R}_{\mathrm{st}}$ (and hence also R_{st}) is easily recoverable from Q. In fact, the transformation Q performs the quantization eigenvector by eigenvector, which is quite desirable. In the simplest case of $n=2$, Q is a rotation in the plane spanned by $e_1\otimes e_2$ and $e_2\otimes e_1$. The striking aspect of this theorem is that Q, being just an exponential, is produced in a very elementary way solely based on infinitesimal data. Thus we recover R_{st} in a particularly simple way. Also note that the choice of $q=\sec\nu-\tan\nu$ is absolutely necessary for the theorem. From the viewpoint of deformation quantization, it turns out that this seems to be the natural choice for the parameter q, and not e^{ν}, or $e^{i\nu}$ as many (including us!) authors tend to use.

It was shown in Gerstenhaber *et al.* (1990) [see also Blohmann (2003)] that if $\mathcal{F} \in \mathcal{U}(\mathfrak{sl}(n)) \otimes U(\mathfrak{sl}(n))[[\nu]]$ is the modified twisting element which gives the preferred deformation of $\mathcal{C}^\infty(\mathrm{SL}(n))$ to $\mathcal{C}_q^\infty(\mathrm{SL}(n))$, then $(\rho \otimes \rho)F = Q^{-1}$ where $\rho : \mathfrak{sl}(n) \to \mathsf{End}(V)$ is the vector representation. Thus, the inverse of the quantizing transformation Q coincides with the image of the modified twisting element in the vector representation.

Optimally, we would like to have such an elementary quantizing transformation as a simple function of the corresponding $\tilde{r}_{\mathrm{st}}$ for the orthogonal and symplectic Lie algebras. Recent work of second and third authors shows that this is indeed possible, but the construction is more subtle. The difficulty lies in the fact that for these Lie algebras, $V \otimes V$ contains a one-dimensional g-module, a vector which represents the defining bilinear form of $\mathfrak{g}$. For the orthogonal Lie algebras, this vector splits off of the symmetric vectors and in the symplectic case it splits off of the skew vectors. A similar decomposition occurs in the quantized cases. This difficulty is paralleled in fact that the operator $\hat{R}_{\mathrm{st}}$ has three eigenvalues. For type B_n, they are q, $-q^{-1}$, and q^{1-N} where $N = 2n+1$, and the remaining types of C_n and D_n have a similarly formed third eigenvalue. Unfortunately, space prohibits a detailed description of the quantizing transformation in these cases. We can just say what it is not: unlike the A_n series, the exponential of $\tilde{r}_{\mathrm{st}}$ does not produce the quantizing transformation. Nevertheless, like many deformation problems, the exponential function plays a substantial role in the construction of the quantizing transformation.

Mirror symmetry and noncommutative geometry of A_∞-categories

Yan Soibelman[a)]
Department of Mathematics, Kansas State University, Manhattan, Kansas 66506

(Received 27 January 2004; accepted 15 June 2004; published 12 October 2004)

Homological mirror symmetry aims to explain the phenomenon of mirror symmetry in the language of A_∞-categories and their deformation theory. In these notes I discuss various aspects of this approach from the point of view of noncommutative algebraic geometry in the tensor category of graded vector spaces. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1789282]

I. INTRODUCTION

This review article is an extended version of my lectures at a workshop at UCLA. My aim was to discuss one aspect of mirror symmetry, namely, the categorical one. It is known as homological mirror symmetry, and was suggested by Maxim Kontsevich in 1993 (see Kontsevich, 1994). Mirror symmetry of course has many other aspects related to string theory, algebraic geometry, differential equations, differential geometry, and symplectic geometry. In order to have a more general picture the interested reader should look at the literature [see, for example, the list of references in Cox and Katz (1999)]. The homological approach is characterized by restating the symplectic and complex geometry of mirror symmetry in terms of so-called A_∞-categories. The latter are homotopy versions of ordinary categories. Thus, for example, A-branes (Lagrangian submanifolds equipped with flat bundles) become objects of the so-called Fukaya category (see Kontsevich, 1994; Fukaya *et al.*, 2000). Interaction between A-branes is interpreted in terms of morphisms in the Fukaya category. In the simplest case the interaction between two A-branes is "measured" by the vector space spanned by their intersection points. On the other hand, B-branes (holomorphic vector bundles) are naturally objects of the derived category of coherent sheaves. The duality between the A and B sides of mirror symmetry then becomes an equivalence of the corresponding A_∞-categories assigned to dual Calabi–Yau manifolds. All numbers (for example, the number of rational curves on a Calabi–Yau manifold) become a part of categorical data. Conversely, one expects that the numbers which appear in mirror symmetry can be recovered from the categorical data intrinsically. This opens a way to generalize mirror symmetry to the world of noncommutative spaces.

It is clear after Kontsevich (1994) that homological mirror symmetry is closely related to the deformation theory of A_∞-categories. Therefore one needs the language which fits well to homological algebra and deformation theory. This language is briefly explained in Secs. III and VI.

Another conceptual point of discussion is the geometric framework of homological mirror symmetry. Currently, the only way to formulate rigorously homological mirror conjecture from Kontsevich (1994) is to consider degenerating *families* of Calabi–Yau manifolds. In this paper we follow the ideas of Kontsevich and Soibelman (2000a) where the relevant geometry was formulated in terms of Gromov–Hausdorff collapse. In the simplest example of such a collapse a complex elliptic curve collapses to its equator circle. In general, various structures inherited by such a limit can be axiomatized. Subsequently the geometric portion of mirror symmetry admits an easy formulation in terms of limiting data (see Sec. II).

[a)]Electronic mail: soibel@math.ksu.edu

The nontrivial part of the story is to formulate instanton corrections (i.e., the structure of A_∞-category on A-branes) in terms of the limiting data. This is done in Sec. V. A_∞-category of B-branes is explained in Sec. IV.

Sections VII and VIII are devoted to the language suitable for generalization to noncommutative Calabi–Yau manifolds (we give the definition of the latter in Sec. VII).

The paper has two appendixes. In the first one we recall the picture of Kontsevich and Soibelman (2000a) of the collapse of conformal field theories. It makes a striking parallel to the purely mathematical picture of Gromov–Hausdorff collapse. Appendix B is devoted to the language of saturated A_∞-categories. It is appropriate for the pure categorical definition of the notion of smooth projective variety, and hence works for noncommutative Calabi–Yau manifolds as well.

I should say that there are many topics within homological mirror symmetry which I do not discuss in this review. Here are few examples of what is missing:

(a) noncommutative periods (Barannikov and Kontsevich, 1997; Barannikov, 1999, 2000),
(b) homological mirror symmetry for Fano and general type varieties (Kontsevich, Kapustin, Katzarkov, Seidel),
(c) homological mirror symmetry for noncommutative spaces (see Bressler and Soibelman, 2002;, Kapustin and Orlov, 2001; Soibelman, 2000), and
(d) moduli space of stability structures (Bridgeland, 2002).

II. COMMUTATIVE CALABI–YAU MANIFOLDS

A. Calabi–Yau manifolds and their moduli spaces

Definition 1: *Let k be a field. A Calabi–Yau manifold over k is a smooth projective variety X having the trivial canonical bundle* $K_X = \wedge^{top} T_X^*$.

Example 1: *An Abelian variety over k is a Calabi–Yau manifold.*

For the purposes of mirror symmetry the most interesting cases are

(a) $k = \mathbf{C}$;
(b) k is a complete non-Archimedean local field, for example, $k = \mathbf{C}((q))$.

In the case (a) of the field of complex numbers one can study Calabi–Yau manifolds by means of differential geometry due to the following theorem of Yau.

Theorem 1: *Let X be a compact complex manifold,* $dim_{\mathbf{C}} X = n$, *with the trivial canonical bundle. Let* g_X *be a Kähler metric on X and* ω_X *the corresponding Kähler form. There exists a unique Kähler metric* g_X^{CY} *with the holonomy in* $SU(n)$ *such that the cohomology classes of the Kähler forms* ω_X *and* ω_X^{CY} *are the same.*

In Yau's theorem X does not have to be algebraic. The metric g_X^{CY} is called *Calabi–Yau metric*. It has vanishing Ricci curvature, i.e., in local coordinates one has $Ricci(g_X^{CY}) = \partial\overline{\partial}(\log(det(g_{ij}^{CY}))) = 0$. One can see that X admits a holomorphic volume form vol_X (trivialization of K_X) such that the wedge product $vol_X \wedge \overline{vol}_X$ coincides (up to a known scalar factor) with the Riemannian volume form given by the Kähler metric. With these properties in mind one can speak even about noncompact Calabi–Yau manifolds (unless we say otherwise, all complex Calabi–Yau manifolds will be assumed compact).

Formal deformations of the complex structure of X are described by the deformation functor $Def_X : Artin_{\mathbf{C}} \to Sets$ from the category of Artinian local algebras to the category of sets. Namely, for an Artinian local algebra A with the maximal ideal m the set $Def_X(A)$ consists of isomorphism classes of families of Calabi–Yau manifolds over $Spec(A)$ such that the fiber over $\mathbf{C} = Spec(A/m) \subset Spec(A)$ is isomorphic to X. It follows from the Bogomolov–Tian–Todorov theorem (see Bogomolov, 1978; Tian, 1987; Todorov, 1989) that this functor is pro-represented by the completed local algebra of a point of a complex manifold. In particular, the formal moduli space is unobstructed and smooth. This is true for nonformal deformations as well. In other words, the deformation functor which describes isomorphism classes of *analytic* families of Calabi–Yau manifolds, such that X is the fiber over a marked point, is represented by the germ of a complex

manifold. The structure of the global moduli space is more complicated. In the case of complex projective Calabi–Yau manifolds the moduli space is an orbifold.

One of the ideas behind homological mirror symmetry is the suggestion to extend this picture to the deformations of X within the class of "noncommutative" Calabi–Yau manifolds. Before discussing the details I would like to make few motivating comments.

(1) With a complex Calabi–Yau manifold X which has " very large volume" physicists suggest to associate two "theories" denoted by $A(X)$ and $B(X)$ (A-model and B-model). The precise meaning of these words is not important for us at this time. Roughly speaking, the theory $A(X)$ depends on the symplectic structure of X, while the theory $B(X)$ depends on the complex structure of X. It is believed that for an algebraic X there is a "dual" (or mirror symmetric) one denoted by $X^\vee$, which satisfies the following property:

The theory $A(X)$ is equivalent to the theory $B(X^\vee)$, and the theory $B(X)$ is equivalent to the theory $A(X^\vee)$.

Construction of the dual Calabi–Yau manifold $X^\vee$ is known for many X, but not in general.

The equivalence of the theories is an incarnation of mirror symmetry. Moreover, according to Witten (1999) the graded tangent space to the moduli space $\mathcal{M}^A(X)$ of formal deformations of $A(X)$ is naturally isomorphic to the cohomology space $H^\bullet(X,\mathbf{C})=\oplus_{n\geqslant 0}H^n(X,\mathbf{C})$, while the graded tangent space to the moduli space $\mathcal{M}^B(X)$ of formal deformations of $B(X)$ is isomorphic to $H^\bullet(X,\mathbf{C})=\oplus_{p,q\geqslant 0}H^p(X,\wedge^q T_X)$. Notice that the former tangent space contains $H^2(X,\mathbf{C})$ (which is the tangent space to the moduli space of deformations of complexified symplectic structure), while the latter one contains $H^1(X,T_X)$ (the tangent space to the moduli space of complex structures). Therefore $\mathcal{M}^A(X)$ and $\mathcal{M}^B(X)$ can be treated as "generalized" moduli spaces of the corresponding structures. "Mirror map" identifies $\mathcal{M}^A(X)$ with $\mathcal{M}^B(X^\vee)$, interchanging "stupid" and Hodge filtrations on the cohomology.

(2) Mathematically these observations can be (roughly) encoded in the following way (see Kontsevich, 1994; Kontsevich and Soibelman, 2000a, 2004a). To a "maximally degenerate" family $\mathcal{X}=(X_q)_{q\to 0}$ of complex Calabi–Yau manifolds one associates two "noncommutative spaces" over a non-Archimedean field k, often $k=\mathbf{C}((q))$. Let us denote these spaces by $F(\mathcal{X})$ and $D(\mathcal{X})$. The former depends on the symplectic structure of the canonically defined (singular) torus fibration, while the latter depends on the structure of rigid analytic space over k on the base of this torus fibration. The mirror dual family $\mathcal{X}^\vee=(X_q^\vee)_{q\to 0}$ defines another pair of noncommutative spaces $F(\mathrm{X}^\vee)$ and $D(\mathrm{X}^\vee)$, which are associated with the dual torus fibration. Then the homological mirror conjecture is a statement about the equivalences of noncommutative spaces

$$F(\mathcal{X})\simeq D(\mathcal{X}^\vee),$$

$$D(\mathcal{X})\simeq F(\mathcal{X}^\vee).$$

As we will see below, the noncommutative spaces $F(\mathcal{X})$ and $D(\mathcal{X})$ are described in terms of the so-called A_∞-categories, and the above statement claims an equivalence of A_∞-categories. More precisely one should take triangulated envelopes of these categories, which are in fact saturated A_∞-categories with Serre functor (see below and Kontsevich and Soibelman, 2004b).

Mirror map identifies the moduli spaces of formal deformations of $F(\mathcal{X})$ and $D(\mathcal{X}^\vee)$ [resp. $D(\mathcal{X})$ and $F(\mathcal{X}^\vee)$], and there is a cohomological description of the tangent spaces to these moduli spaces.

B. Maximal degenerations of Calabi–Yau manifolds: Algebro-geometric description

We start with the geometric side of the story following Kontsevich and Soibelman (2000a).

Let $\mathbf{C}_q^{mer}=\{f=\Sigma_{n\geqslant n_0}a_nq^n\}$ be the field of germs at $q=0$ of meromorphic functions in one complex variable and $\mathcal{X}_{mer}$ be an algebraic n-dimensional Calabi–Yau manifold over $\mathbf{C}_q^{mer}$ (i.e., $\mathcal{X}_{mer}$ is a smooth projective manifold over $\mathbf{C}_q^{mer}$ with the trivial canonical class: $K_{\mathcal{X}_{mer}}=0$). We fix

an algebraic nonvanishing volume element $vol \in \Gamma(\mathcal{X}_{mer}, K_{\mathcal{X}_{mer}})$. The pair $(\mathcal{X}_{mer}, vol)$ defines a one-parameter analytic family of complex Calabi–Yau manifolds $(X_q, vol_q), 0<|q|<r_0$, for some $r_0>0$.

Let $[\omega] \in H^2_{DR}(\mathcal{X}_{mer})$ be the cohomology class in the ample cone. Then for every q, such that $0<|q|<r_0$, it defines a Kähler class ω_q on X_q. By Yau's theorem, there exists a unique Calabi–Yau metric $g^{CY}_{X_q} := g_{X_q}$ on X_q with the Kähler class $[\omega_q]$.

It follows from the resolution of singularities that as $q \to 0$, one has the following formula:

$$\int_{X_q} vol_q \wedge \overline{vol}_q = C(\log|q|^m |q|^{2k}(1 + o(1))$$

for some $C \in \mathbf{C}^*, k \in \mathbf{Z}, 0 \leqslant m \leqslant n = dim\ (\mathcal{X}_{mer})$.

Definition 2: *We say that $\mathcal{X}_{mer}$ has maximal degeneration at $q=0$ if in the above formula we have $m=n$.*

This definition is equivalent to the algebro-geometric one, given in terms of variations of Hodge structures (see, for example, Morrison, 1993). More precisely, the following result holds.

Proposition 1 (Kontsevich and Soibelman, 2000a): The Calabi–Yau manifold $\mathcal{X}_{mer}$ has maximal degeneration iff for all sufficiently small q there exists a vector $v \in H^n(X_q, \mathbf{C})$ such that $(T - Id)^{n+1} v = 0$ and $(T - id)^n v \neq 0$, where T is the monodromy operator.

C. Differential-geometric description

The Gromov–Hausdorff metric ρ_{GH} is a metric on the set of isometry classes of compact metric spaces. We say that two metric spaces M_1 and M_2 are ε-close with respect to ρ_{GH} if there exists a metric space M containing both M_1 and M_2 as metric subspaces, such that M_1 belongs to the ε-neighborhood of M_2 and vice versa. Then $\rho_{GH}(M_1, M_2)$ is given by the infimum of such ε.

Let us rescale the Calabi–Yau metric: $g^{new}_{X_q} = g_{X_q} / diam(X_q, g_{X_q})^2$. Thus we obtain a one-parameter family of Riemannian manifolds $X^{new}_q = (X_q, g^{new}_{X_q})$ of diameter 1. Motivated by Gromov's theory of collapsing Riemannian manifolds (see, for example, Cheeger and Colding, 1997) and some considerations from conformal field theory (see Kontsevich and Soibelman, 2000a) we proposed the following conjecture.

Conjecture 1 (Gross and Wilson, 2000; Kontsevich and Soibelman, 2000a): If $\mathcal{X}_{mer}$ has maximal degeneration at $q=0$, then there exists a limit $(\overline{Y}, g_{\overline{Y}})$ of X^{new}_q in the Gromov–Hausdorff metric such that the following hold.

(a) *$(\overline{Y}, g_{\overline{Y}})$ is a compact metric space, which contains a smooth oriented Riemannian manifold (Y, g_Y) of dimension $n=dim(\mathcal{X}_{mer})$ as a dense open metric subspace. The Hausdorff dimension of $Y^{sing} = \overline{Y} \setminus Y$ is less than or equal to $n-2$.*

(b) *Y carries an integral affine structure, i.e., a torsion-free flat connection ∇ with the holonomy contained in $SL(n, \mathbf{Z})$.*

(c) *The metric g_Y has a potential, i.e., it is locally given in affine coordinates by a symmetric matrix $(g_{ij}) = (\partial^2 K / \partial x_i \partial x_j)$, where K is a smooth function (defined modulo adding an affine function, i.e., the sum of a linear function and a constant).*

(d) *In affine coordinates the metric volume element is constant, i.e., $det(g_{ij}) = det(\partial^2 K / \partial x_i \partial x_j) = const$ (the latter is called real Monge–Ampère equation).*

Example 2: *Let $E_q = \mathbf{C}^*/q^{\mathbf{Z}}, q \to 0$ be a maximally degenerate family of elliptic curves. Then $\overline{Y} = Y = \mathbf{R}/2\pi\mathbf{Z}$. Similarly, in the case of complex Abelian varieties of dimension n one gets $\overline{Y} = Y$ = flat n-dimensional torus. In the case of K3 surfaces $\overline{Y} \simeq S^2$, while Y is obtained from the sphere S^2 by removing 24 points.*

D. Monge–Ampère manifolds and geometric mirror symmetry

In this section we propose mathematical language for the geometric counterpart of mirror symmetry, which is understood as a duality of torus fibrations over the same base. We start with axiomatization of the Gromov–Hausdorff limits of Calabi–Yau manifolds discussed above [more on this "real" analog of Kähler geometry see in Kontsevich and Soibelman (2000a)].

Definition 3: *A Monge–Ampère manifold is a triple* (Y,g,∇), *where* (Y,g) *is a smooth Riemannian manifold with the metric* g, *and* ∇ *is a torsion-free flat connection on* T_Y *such that we have the following*.

(a) ∇ *defines an affine structure on* Y.
(b) *Locally in affine coordinates* $(x_1,\ldots,x_n)$ *the matrix* $((g_{ij}))$ *of* g *is given by* $((g_{ij}))=((\partial^2 K/\partial x_i \partial x_j))$ *for some smooth real-valued function* K.
(c) *The Monge–Ampère equation* $det((\partial^2 K/\partial x_i \partial x_j))=const$ *is satisfied*.

Monge–Ampère manifolds were studied (under a different name) in Cheng and Yau (1982) where it was proved that if Y is *compact*, then it is a finite cover of a torus.

Proposition 2: *For a given Monge–Ampère manifold* (Y,g_Y,∇_Y) *there is a canonically defined dual Monge–Ampère manifold* $(Y^\vee,g_Y^\vee,\nabla_Y^\vee)$ *such that* (Y,g_Y) *is identified with* $(Y^\vee,g_Y^\vee)$ *as Riemannian manifolds, and the local system* $(T_{Y^\vee},\nabla_Y^\vee)$ *is naturally isomorphic to the local system dual to* (T_Y,∇_Y).

Corollary 1: *If* ∇_Y *defines an integral affine structure on* Y *(i.e., the holonomy of* ∇_Y *belongs to* $GL(n,\mathbf{Z})$*), then* $\nabla_Y^\vee$ *defines an integral affine structure on* $Y^\vee$. *As the dual covariant lattice one takes the lattice* $(T_Y^{\mathbf{Z}})^\vee$, *which is dual to* $T_Y^{\mathbf{Z}}$ *with respect to the metric* g_Y.

Let us call *integral* Monge–Ampère manifolds with integral affine structure. Now we can state the geometric counterpart of the mirror symmetry conjecture.

Conjecture 2: *Let* X *and* $\mathrm{X}^\vee$ *be dual families of Calabi–Yau manifolds, which have maximal degeneration at* $q=0$. *Let* $M=(Y,g_Y,\nabla_Y)$ *and* $M'=(Y',g_{Y'},\nabla')$ *be smooth parts of their Gromov–Hausdorff limits (see Conjecture 1). Then* M *and* M' *are dual integral Monge–Ampère manifolds*.

Reversing the logic, one can use our conjectures as a mathematical definition of dual families of Calabi–Yau manifolds.

Remark 1: *If* $M=(Y,g_Y,\nabla_Y,T_Y^{\mathbf{Z}})$ *is an integral Monge–Ampère manifold then the total space of the torus fibration* $p:T_Y/T_Y^{\mathbf{Z}}\to Y$ *carries a canonical structure of the complex Calabi–Yau manifold (noncompact if* Y *is noncompact). It is easy to see that passing from* M *to* $M^\vee$ *amounts to the passing from the torus fibration* p *to the dual torus fibration* $p^\vee:T_Y^*/(T_Y^{\mathbf{Z}})^\vee\to Y$. *The dual potential function* $K^\vee$ *is the Legendre transform (in affine coordinates) of the potential function* K. *This picture should be compared with Strominger et al. (1996), where the special Lagrangian torus fibration structure of Calabi–Yau manifolds near the "large complex structure limit" was suggested. Our point of view is different in the following sense: we suggest to work with the limiting Monge–Ampère manifolds and their singularities. All the quantities appearing in the mirror symmetry story (like the number of rational curves on a Calabi–Yau manifold) should be computed in terms of the limiting data*.

III. A_∞-CATEGORIES AND NONCOMMUTATIVE SCHEMES

Here we only outline the geometric language A_∞-categories. See Kontsevich and Soibelman (2004b) for the details.

Let k be a commutative unital ring and $\mathcal{C}$ be a k-linear Abelian tensor category. The category of (commutative) affine schemes $Aff_{\mathcal{C}}$ is by definition the one opposite to the category $Comm_{\mathcal{C}}$ of commutative unital algebras in $\mathcal{C}$. Similarly, the category of noncommutative affine schemes in $\mathcal{C}$ (notation $NAff_{\mathcal{C}}$) is the category opposite to the category of associative unital algebras $Alg_{\mathcal{C}}$. For an algebra $A\in Ob(Alg_{\mathcal{C}})$ the corresponding noncommutative affine scheme is denoted by $Spec(A)$. Every affine scheme can be considered as a noncommutative affine scheme, so we use the same notation $Spec(A)$ for a commutative algebra A. To save the space we will discuss below mainly noncommutative affine schemes. The reader can make obvious changes for commutative affine

schemes (see also Kontsevich and Soibelman, 2004a, 2004b). Morphisms of noncommutative schemes correspond to homomorphisms of unital algebras. Our main example from now on will be the tensor category $\mathcal{C}=Vect_k^{\mathbf{Z}}$, where k is a field of characteristic zero [here we have the Quillen rule of signs: $a_ib_j=(-1)^{ij}b_ja_i$, where i and j are degrees of a_i and b_j, respectively]. Noncommutative *ind-affine* schemes by definition correspond to projective systems $((A_i)_{i\in I},\phi_{ji})$ of unital algebras in $\mathcal{C}$, such that the morphisms $\phi_{ji}:A_i\to A_j$ are surjective homomorphisms of unital algebras. Equivalently, a noncommutative ind-affine scheme is an inductive system $((X_i)_{i\in I},\psi_{ji})$ of noncommutative affine scheme, such that the morphisms $\psi_{ji}:X_i\to X_j$ are closed embeddings. Since any counital coalgebra B in $Vect_k^{\mathbf{Z}}$ is a union of finite-dimensional counital subcoalgebras, we can assign to B a noncommutative ind-affine scheme X_B.

Example 3: *(a) Let V be a $\mathbf{Z}$-graded k-vector space. Then the formal neighborhood of zero in the noncommutative affine space V_{NC}, by definition, corresponds to the cofree tensor coalgebra $T(V)=\oplus_{n\geqslant 0}V^{\otimes n}$.*

(b) Replacing $T(V)$ by $S(V)=\oplus_{n\geqslant 0}S^n(V)$ (sum of symmetric tensor powers) we arrive at the definition of the formal neighborhood of zero in the (commutative) affine space V.

This example can be generalized further. Indeed the cofree coalgebra $T(V)$ is the coalgebra of the quiver with one vertex and $N=dim_kV$ loops. Let Q be an arbitrary quiver in $Vect_k^{\mathbf{Z}}$ with the set of vertices I. Then the coalgebra B_Q of Q gives rise to a noncommutative ind-affine scheme X_{B_Q}. It contains a noncommutative closed ind-subscheme X_I of disjoint points (vertices of Q), corresponding to the direct sum of trivial coalgebras $\oplus_I k$. If I is finite, then X_{B_Q} is smooth in the sense of Cuntz and Quillen (1995). In general it is an inductive limit of noncommutative smooth affine schemes (we can call them ind-smooth for short). In any case we can speak about vector fields on X_{B_Q}. A vector field of degree n is a derivation of B_Q of degree n. Clearly vector fields on X_{B_Q} form a differential-graded Lie algebra.

Let now $X\simeq X_{B_Q}$ be an ind-affine scheme corresponding to a quiver Q, and let d be a vector field on X_Q of degree +1 which vanishes on the subscheme X_I, commutes with the natural morphisms $X\to X_I$ (projection) and $X_I\to X$ (closed embedding), and satisfies the condition $[d,d]=0$.

Definition 4: *We say that the pair (X,d) defines a noncommutative differential-graded (dg for short) ind-manifold with marked points X_I.*

Equivalently we say that X is a (nonlinear) small A_∞-*category* with the set of objects I. Assume Q has only one vertex i and N loops of various degrees. Then the coalgebra B_Q is generated by a $\mathbf{Z}$-graded N-dimensional vector space $A=\oplus_{m\in Z}A^m$ of loops $i\to i$ (degree of the trivial loop is zero, other degrees are arbitrary). Let $A[-1]$ denote the vector space A with the grading shifted by one: $A[-1]^n=A^{n-1}$. Then we say that $A[-1]$ is an A_∞-*algebra*. It is easy to see that Taylor coefficients of d at the marked point define a sequence of linear maps

$$m_n:A^{\otimes n}\to A[2-n],\quad n\geqslant 1,$$

of degree $n-2$ (higher products) satisfying a system of quadratic equations.

Analogously, a small A_∞-category $\mathcal{A}$ is defined by the set of objects I, $\mathbf{Z}$-graded spaces of morphisms $Hom_{\mathcal{A}}(X,Y)$ and a collection of higher composition maps

$$m_n:Hom_{\mathcal{A}}(X_0,X_1)\otimes\cdots\otimes Hom_{\mathcal{A}}(X_{n-1},X_n)\to Hom_{\mathcal{A}}(X_0,X_n)[2-n]$$

satisfying a system of quadratic equations (see, for example, Kontsevich and Soibelman, 2000a).

Therefore an A_∞-category is a nonlinear A_∞-category with the choice of affine structure (i.e., a quiver Q and an isomorphism $X\simeq X_{B_Q}$).

Remark 2: *For any collection of objects $(X_0,X_1,\ldots,X_r)$ the sequence $m_n, n\geqslant 1$, defines a structure of an A_∞-algebra on $\oplus_{0\leqslant i,j\leqslant r}Hom_{\mathcal{A}}(X_i,X_j)$. This A_∞-structure is compatible with inclusions of collections of objects. Then one can derive many results about A_∞-categories from similar results about A_∞-algebras.*

In the above version of A_∞-categories the space of morphisms $Hom_{\mathcal{A}}(M,N)$ is well-defined for any two objects M and N. Furthermore, for any object M there is an identity morphism $id_M\in Hom_{\mathcal{A}}(M,M)$. There are various versions of A_∞-categories in which these (or other) conditions

are weakened [for example, one can work with the identity morphisms which exist only in cohomology $H^{\bullet}(Hom_{\mathcal{A}}(M,M),m_1)$]. Moreover, there is a version of nonlinear A_∞-categories where I is a (commutative) dg ind-manifold. If we drop the condition that the vector field d vanishes at the marked points, we obtain the notions of *generalized* A_∞-algebra and A_∞-category. In this case one can have a nontrivial element m_0. See Fukaya *et al.* (2000) and Kontsevich and Soibelman (2000a, 2004a, 2004b) for some details. For simplicity of the exposition we will disregard all these difficulties below.

For two noncommutative dg ind-manifolds X and Y which correspond to the A_∞-categories $\mathcal{A}$ and $\mathcal{B}$, respectively, one can define a noncommutative dg ind-manifold $Maps(X,Y)$ of morphisms $X\to Y$. Algebraically it corresponds to the A_∞-category of A_∞-functors $Funct(\mathcal{A},\mathcal{B})$. There are explicit formulas for the A_∞-structure on $Funct(\mathcal{A},\mathcal{B})$ given in terms of the summation over the set of trees (see Kontsevich and Soibelman, 2004b).

In the next two sections we are going outline constructions of $F(\mathcal{X})$ and $D(\mathcal{X})$ (see the Introduction) in the simplest case when $\overline{Y}=Y$ (i.e., the torus fibration is nonsingular). The construction in the general case is not known.

IV. NONCOMMUTATIVE SPACE $D(\mathcal{X})$

Let $(Y,g_Y,\nabla_Y,T_Y^{\mathbf{Z}})$ be an integral Monge–Ampère manifold of dimension n. The construction consists of several steps [see Kontsevich and Soibelman (2000a) for the details].

(1) Using the affine structure on Y one defines a sheaf $\mathcal{O}_Y$ of algebras over the field $\mathbf{C}_\varepsilon$: $=\{\Sigma_{i\geqslant 0}a_i e^{-\lambda_i/\varepsilon}\,|\,a_i\in\mathbf{C},\lambda_i\in\mathbf{R},\lambda_i\to+\infty\}$. For an open chart $U\subset\mathbf{R}^n$ the algebra $\mathcal{O}_{\mathbf{R}^n}(U)$ is a vector space over $\mathbf{C}_\varepsilon$ consisting of formal Laurent series

$$f=\sum_{k_1,\ldots,k_n\in\mathbf{Z}^n} a_{k_1\cdots k_n}z_1^{k_1}\cdots z_n^{k_n},$$

where $z_1,\ldots,z_n$ are formal variables, $a_{k_1\cdots k_n}\in\mathbf{C}_\varepsilon$, and for any $(y_1,\ldots,y_n)\in U$ we have $\lim_{\Sigma_i|k_i|\to\infty}(v(a_{k_1\cdots k_n})+\Sigma_i k_i y_i)=+\infty$. Here we denote by $v:\mathbf{C}_\varepsilon\to\mathbf{R}\cup\{+\infty\}$ a (nondiscrete) valuation such that $v(\Sigma_{\lambda_1<\lambda_2<\ldots}c_i e^{-\lambda_i/\varepsilon})=\lambda_1$ if $c_1\neq 0$ and $v(0)=+\infty$.

(2) The sheaf $\mathcal{O}_Y$ admits a resolution $\hat{\Omega}_Y^*$ by a soft sheaf of dg-algebras. Locally, for a small open $U\subset Y$, sections of $\hat{\Omega}_*^Y$ are given by sums $\alpha=\Sigma_{i_1,\ldots,i_n}c_{i_1\cdots i_n}z_1^{i_1}\cdots z_n^{i_n}$ where $c_{i_1\cdots i_n}=\Sigma_j c_{j,i_1\cdots i_n}e^{-\lambda_{j,i_1\cdots i_n}/\varepsilon}$, $c_{j,i_1\cdots i_n}\in\Omega^*(U)$ (de Rham differential forms), with the same convergence conditions as for the sheaf $\mathcal{O}_Y$. Differential is given by the de Rham differential acting on the coefficients $c_{j,i_1\cdots i_n}$.

(3) We define a dg-category $D(\mathcal{X})$ such as follows. Objects are finite complexes of locally free $\mathcal{O}_Y$-modules of finite rank. For any two such complexes E_1 and E_2 we define the space of morphisms as

$$Hom(E_1,E_2)=\Gamma(Y,Hom_{\mathcal{O}_Y}(E_1,E_2)\hat{\otimes}_{\mathcal{O}_Y}\hat{\Omega}_*^Y),$$

where we use the completed tensor product on the RHS. Differential and grading on the spaces of morphisms are induced by those on $E_1,E_2,\hat{\Omega}_Y^*$.

According to the general philosophy of the previous section we interpret this dg-category as a noncommutative dg ind-manifold. Notice that in general we have to work with the non-Archimedean field $\mathbf{C}_\varepsilon$ rather than with $\mathbf{C}((q))$ (the latter can be used under some integrality conditions on $\mathcal{X}$).

Remark 3: *The above discussion indicates the relevance of non-Archimedean geometry to mirror symmetry. There are too many non-Archimedean aspects of Kähler geometry in general and mirror symmetry in particular to discuss them here. We refer the reader to Kontsevich and Soibelman (2000a, 2004c), and Kontsevich and Tschinkel (2004) for some of them. Foundational facts about non-Archimedean geometry and Berkovich spectra can be found in Berkovich (1990).*

V. NONCOMMUTATIVE SPACE $F(\mathcal{X})$

We will sketch main steps in the definition of the A_∞-category $F(\mathcal{X})$, assuming that the base Y of the torus fibration $p: T_Y/T_Y^{\mathbf{Z}} \to Y$ has dimension greater than one.

The total space V of the torus fibration carries canonical symplectic form ω, canonical metric g_V (it is invariant with respect to the natural torus action on V) and a complex structure J compatible with ω and g_V. Moreover, V carries a Calabi–Yau manifold structure.

Let $L \subset V$ be a Lagrangian submanifold such that $p_{|L}: L \to Y$ is an unramified covering.

(1) Objects of the A_∞-category $F(V)$ (the Fukaya category of V) are pairs (L, ρ) where L is a Lagrangian submanifold as above (let us call it admissible) and ρ is a local system on L. We will call L the support of the object (L, ρ).

(2) For two objects with transversal supports we define the space of morphisms such as follows:

$$Hom_{F(V)}((L_1,\rho_1),(L_2,\rho_2)) := (\oplus_{x \in L_1 \cap L_2} Hom(\rho_{1x}, \rho_{2x})) \otimes \mathbf{C}_\varepsilon.$$

There is a $\mathbf{Z}$-grading of the space of morphisms given in terms of Maslov index $deg: L_1 \cap L_2 \to \mathbf{Z}$.

(3) The A_∞-structure is defined by means of a collection of maps (higher compositions) of graded vector spaces

$$m_k^{F(V)}: \otimes_{0 \leqslant i \leqslant k-1} Hom_{F(V)}((L_i,\rho_i),(L_{i+1},\rho_{i+1})) \to Hom_{F(V)}((L_0,\rho_0),(L_k,\rho_k))[2-k],$$

where $k \geqslant 1$ and the sequence $(L_0, \ldots, L_k)$ corresponds to a "transversal" sequence of objects of $F(V)$.

In the case, when all local systems are trivial of rank one, the map m_k is defined such as follows. Let D be a standard disc $D = \{z \in \mathbf{C} \,|\, |z| \leqslant 1\}$. Let us fix a sequence $(L_0, \ldots, L_k)$ of supports of objects with pairwise transversal intersections, intersection points $x_i \in L_i \cap L_{i+1}, 0 \leqslant i \leqslant k-1$, $x_k \in L_0 \cap L_k$, and $\beta \in \pi_2^{free}(V, \cup_{0 \leqslant i \leqslant k} L_i)$. We denote by $\mathcal{M}(L_0, \ldots, L_k; x_0, \ldots, x_k; \beta)$ the set of collections $(y_0, \ldots, y_k; \psi)$, where $y_i, 0 \leqslant i \leqslant k$ are cyclically ordered pairwise distinct points on the boundary ∂D, and $\psi: D \to (V, J)$ a pseudo-holomorphic map such that $\psi(y_i) = x_i$, $\psi(\overline{y_i y_{i+1}}) \subset L_i, 0 \leqslant i \leqslant k, y_0 = y_k$, $[\psi] = \beta$. Here $\overline{y_i y_{i+1}}$ denotes the arc between y_i and y_{i+1}. There is a natural action of $PSL(2, \mathbf{R})$ on $\mathcal{M}(L_0, \ldots, L_k; x_0, \ldots, x_k; \beta)$ arising from the holomorphic action on D by fractional linear transformations. The action is free except for the case $k=1, x_0 = x_1, \beta = 0$, which is not relevant for our purposes.

Let $x_i \in L_i \cap L_{i+1}, 0 \leqslant i \leqslant k-1, x_k \in L_0 \cap L_k$ satisfy the condition $deg\ x_k = \Sigma_{0 \leqslant i \leqslant k-1} deg\ x_i + 2 - k$. Then the matrix element $(m_k(x_0, x_1, \ldots, x_{k-1}), x_k)$ is given by the formula $(m_k(x_0, x_1, \ldots, x_{k-1}), x_k) = \Sigma \pm q^{(\beta, [\omega])}$, where $q = \exp(-1/\varepsilon)$, and the sum is taken over all $PSL(2, \mathbf{R})$-orbits of points in $\mathcal{M}(L_0, \ldots, L_k; x_0, \ldots, x_k; \beta)$. Signs are derived from orientations of certain cycles in the moduli space

$$\mathcal{M} = \mathcal{M}(L_0, \ldots, L_k; x_0, \ldots, x_k; \beta)/PSL(2, \mathbf{R}).$$

The precise definition depends on some other choices [see Fukaya *et al.* (2000) and Kontsevich and Soibelman (2000a) for more details].

(4) The dilation of the lattice $T_Y^{\mathbf{Z}}$ by a parameter η such that $(y, v) \mapsto (y, \eta v), y \in Y, v \in T_y Y$, gives rise to a family of complex structures J_η on V (and the corresponding family of holomorphic volume forms Ω_η). In this way one obtains a family of A_∞-categories with the same objects and morphisms as $F(V)$, but with varying higher compositions $m_n^\eta, n \geqslant 1$. Moreover, one can prove that there exist limits $m_n^\infty = \lim_{\eta \to 0} m_n^\eta$ and they give rise to an A_∞-category, which we denote by $F(\mathcal{X})$ and call the *Fukaya-Oh category*. See Kontsevich and Soibelman (2000a), where its relation to the Morse theory is discussed and an important conjecture from Fukaya and Oh (1998) was proved. Furthermore, it was used in Kontsevich and Soibelman (2000a) for the proof of a version of homological mirror conjecture for Abelian varieties.

Remark 4: *In the above sketch we skip several important points. In particular, there is an*

obvious problem with identity morphisms and nontransversal Lagrangian supports of objects. Also, it is possible to have a Lagrangian submanifold $L\subset V$ and a pseudo-holomorphic disc D with the boundary $\partial D\subset L$. This creates the so-called "m_0-problem" in the definition of the Fukaya category, and requires a generalization of the notion of A_∞-category we mentioned before. We again refer the reader to Fukaya et al. (2000) and Kontsevich and Soibelman (2000a, 2004a, 2004b) for the discussion on how to overcome these (and some other) difficulties in the definition of the Fukaya category.

VI. DEFORMATION THEORY OF A_∞-CATEGORIES

Deformation theory of $F(\mathcal{X})$ and $D(\mathcal{X})$ is a special case of the deformation theory of A_∞-categories (or, more generally, noncommutative dg ind-manifolds). We are going to illustrate it in the case of the category with one object, since the general case is similar (see Kontsevich, 1994; Kontsevich and Soibelman, 2004a, 2004b).

Let A be a $\mathbf{Z}$-graded vector space over the field k of characteristic zero. We denote by $C^\bullet(A,A)=\Pi_{n\geqslant 0}\, Hom_{Vect_k^{\mathbf{Z}}}(A^{\otimes n},A)$ the graded space of *Hochschild cochains*. Shifting the grading by 1 we can introduce a graded Lie algebra structure on $C^\bullet(A,A)[1]=\Pi_{n\geqslant 0}(C^\bullet(A,A)[1])^n$. The Lie bracket is called the *Gerstenhaber bracket*. It has the following well-known geometric interpretation. Consider the formal neighborhood of zero in the noncommutative affine space $A[1]$. Then $C^\bullet(A,A)[1]$ is the graded Lie algebra of vector fields on this neighborhood. It contains the graded Lie subalgebra $C^\bullet_+(A,A)[1]$ of vector fields preserving zero. Algebraically these graded Lie algebras are interpreted as derivations of the corresponding tensor coalgebras generated by $A[1]$. To have a structure of an $\mathcal{A}_\infty$-algebra on A is the same as to have an element $m\in C^\bullet_+(A,A)[1]$ of degree +1 such that $[m,m]=0$ where $[x,y]$ denotes the Gerstenhaber bracket of x and y. To have a structure of an A_∞-category A with one object X such that $Hom_{\mathcal{A}}(X,X)=A$ means the same thing but this time $m\in C^\bullet(A,A)[1]$. In the latter case we can have a nontrivial $m_0\in Hom_{Vect_k^{\mathbf{Z}}}(k,A)$. In either case m gives rise to a structure of differential-graded Lie algebra (DGLA for short) on $C^\bullet(A,A)[1]$. In the case of the category with one object it is the structure of DGLA on $C^\bullet(A,A)[1]$, with the differential $d=d_m=[m,\bullet]$. The pair $(C^\bullet(A,A)[1],d)$ is called the *Hochschild complex* of the category (the terminology is slightly abused because we care not only about structure of a complex, but also about the Lie bracket). The cohomology of this complex is called the *Hochschild cohomology* and is denoted by $HH^\bullet(A,A)$. The pair $(C^\bullet_+(A,A)[1],d)$ is called the *truncated* Hochschild complex. The same terminology is applied to the A_∞-algebra A.

Definition 5: *The deformation functor associated with the DGLA $(C^\bullet(A,A)[1],d)$ is the functor $Def_A: Artin_k\to Sets$ from the category of Artinian local k-algebras to sets, such that for an Artinian algebra R with the maximal ideal m_R the set $Def_A(R)$ consists of classes of equivalence of solutions $\gamma\in(C(A,A)[1])^1\otimes m_R$ to the Maurer–Cartan equation*

$$d\gamma+\tfrac{1}{2}[\gamma,\gamma]=0,$$

modulo the following action of the group $\exp((C(A,A)[1])^0\otimes m_R)$:

$$\gamma\mapsto g\gamma g^{-1}-dg\cdot g^{-1}.$$

Geometrically, the deformation functor can be interpreted in the following way. Let $g=C^\bullet(A,A)[1]$ be our DGLA. Then the cocommutative cofree coalgebra $C(g[1])=\oplus_{n\geqslant 0}S^n(g[1])$ gives rise to a (commutative) ind-affine scheme (in fact, formal manifold) with the marked point zero. The differential d gives rise to a vector field $d_{g[1]}$ in the formal neighborhood of zero. Higher compositions (products) m_n are Taylor coefficients of the vector field $d_{g[1]}$ at zero. In particular, if $m_0\neq 0$, then the vector field does not vanish at zero. The Maurer–Cartan equation singles out the formal subscheme Z of zeros of the vector field [more precisely it gives R-points $Z(R)$ for every $R\in Artin_k$]. Suppose $0\in Z(R)$. Then for any local Artinian ring R we obtain an A_∞-category $\mathcal{A}(R)$ such that the set of objects $Ob(\mathcal{A}(R))$ is $Z(R)$ and the A_∞-structure defined by $m+\gamma$, where m is the

A_∞-structure on $\mathcal{A}$ and γ is a solution to the Maurer–Cartan equation. Therefore the DGLA $g = C^\bullet(A,A)[1]$ gives rise to the deformation functor describing the formal deformation theory of the A_∞-category with one object.

The ind-affine scheme Z admits a (singular) foliation: two points γ and γ' of $Z(R)$ belong to the same leaf of the foliation iff they can be joined by the curve which is tangent to the distribution $[d_{g[1]}, \bullet]$ (see Kontsevich, 1997; Kontsevich and Soibelman, 2004a, 2000b). This construction gives rise to a functor isomorphic to Def_A.

The same considerations apply to general A_∞-categories. Deformation theory of an A_∞-algebra structure on a fixed graded vector space A is controlled by the DGLA $g_+ = C^\bullet_+(A,A)[1]$.

The notion of *quasi-isomorphism* of noncommutative (or commutative) dg ind-manifolds corresponds to the notion of quasi-isomorphism of the corresponding differential-graded coalgebras. The following result explains the role of this notion.

Theorem 2 (Kontsevich, 1997; Kontsevich and Soibelman, 2004a): *Quasi-isomorphic dg ind-manifolds with marked points give rise to isomorphic deformation functors.*

In other words, the corresponding deformation theories are equivalent. If a dg ind-manifold has an affine structure at the marked point (i.e., if an explicit isomorphism of coalgebras $B \simeq S(V[1])$ is chosen), then V is called an L_∞-algebra (or homotopy Lie algebra). Often the above notion of quasi-isomorphism refers directly to V. If V is quasi-isomorphic to an L_∞-algebra with the trivial structure, then the deformation functor is especially simple (since the Maurer–Cartan equation is empty). In this case the formal moduli space is smooth (example: formal moduli space of deformations of the complex structure on a Calabi–Yau manifold).

The structure of the tangent space to the moduli space of deformations of an A_∞-category is described in the following two results (see Kontsevich and Soibelman, 2004b).

Theorem 3: *Let X be a noncommutative dg ind-manifold corresponding to an A_∞-algebra A, and $CC^\bullet(A,A) := CC^\bullet(X,X)$ be the Hochschild cochain complex. Then one has the following quasi-isomorphism of complexes*

$$CC^\bullet(X,X)[1] \simeq T_{[id_X]}(Maps(X,X)),$$

where $T_{[id_X]}$ denotes the tangent complex at the identity map.

Corollary 2: *Let $\mathcal{A}$ be an A_∞-category with finite-dimensional Hochschild cohomology. Then*

$$HH^\bullet(\mathcal{A},\mathcal{A}) \simeq Ext^\bullet(Id_{\mathcal{A}}, Id_{\mathcal{A}}),$$

where the RHS denotes the cohomology of the tangent complex at the identity functor $Id_{\mathcal{A}}$ [we consider the identity functor as the identity map $id_X \in Maps(X,X)$, where X is the noncommutative dg ind-manifold corresponding to the A_∞-category $Funct(\mathcal{A},\mathcal{A})$].

Let me demonstrate how these results can be applied to homological mirror symmetry. Under the assumption $\overline{Y} = Y$ one can compute the Hochschild cohomology of the A_∞-categories $D(\mathcal{X})$ and $F(\mathcal{X})$ in terms of the torus fibration $p: T_Y/T_Y^{\mathbf{Z}} \to Y$. The total space V of the torus fibration is a symplectic manifold. Then (see Kontsevich, 1994) $HH^\bullet(F(\mathcal{X}),F(\mathcal{X})) \simeq Ext^\bullet_{F(V\times V)}(\Delta,\Delta)$, where $\Delta \subset V \times V$ is the diagonal, considered as a Lagrangian submanifold, equipped with the trivial local system. Similarly $HH^\bullet(D(\mathcal{X}),D(\mathcal{X})) \simeq Ext^\bullet_{D(V\times V)}(\mathcal{O}_\Delta,\mathcal{O}_\Delta)$. In both cases the cohomology groups can be computed (see Kontsevich, 1994) and coincide with the total cohomology of V, graded as in the Introduction. The Fukaya category gives rise to the quantum cohomology product on $H^\bullet(X)$. The equivalence of A_∞-categories $F(\mathcal{X})$ and $D(\mathcal{X}^\vee)$ implies the existence of the mirror map between the moduli spaces of their formal deformations. More explicitly, the equivalence $F(\mathcal{X}) \simeq D(\mathcal{X}^\vee)$ is given by a combination of the Legendre transform along Y with the non-Archimedean analog of the Fourier–Mukai transform along fibers of the torus fibration (see Kontsevich and Soibelman, 2000a).

Remark 5: *The A_∞-category $F(\mathcal{X})$ is a "generic fiber" of the one-parameter deformation of the "trivial" A_∞-category $F_{triv}(\mathcal{X})$. Objects and morphisms of $F_{triv}(\mathcal{X})$ are the same as for $F(\mathcal{X})$. All compositions $m_n^{F_{triv}(X)}, n \geqslant 0$, are equal to zero. This observation follows from the fact that $F(\mathcal{X})$*

can be actually defined over the ring $\mathbf{C}_\varepsilon^+ \subset \mathbf{C}_\varepsilon$ *consisting of formal series with all non-negative* λ_i. *Moreover, all higher compositions* m_n *are given by formal series which start with* $\exp(-\lambda/\varepsilon), \lambda > 0$. *Hence they vanish modulo the ideal J consisting of such series (assuming certain integrality conditions we have a formal family over* $\mathbf{C}[[q]]$, *and all* m_n *vanish modulo* $q\mathbf{C}[[q]]$).

VII. SATURATED A_∞-CATEGORIES AND NONCOMMUTATIVE CALABI–YAU MANIFOLDS

For an A_∞-category $\mathcal{A}$ there exists its *triangulated envelope* $\mathcal{A}^{tr}$, which is a *triangulated* A_∞-category [see Appendix B and Kontsevich and Soibelman (2004b)]. The category of complexes is an A_∞-category, and it is triangulated. The A_∞-category $D(\mathcal{X}) = D(\mathcal{X})^{tr}$ is triangulated, but $F(\mathcal{X})$ is not. Replacing the latter by its triangulated envelope (called the category of twisted complexes) one can formulate the homological mirror conjecture as an equivalence $F(\mathcal{X})^{tr} \simeq D(\mathcal{X}^\vee)^{tr}$. The dg-category $D(\mathcal{X})$ is an A_∞-version of the derived category of coherent sheaves on the rigid analytic space $(Y, \mathcal{O}_Y)$ (remember that we are discussing the case $\overline{Y} = Y$). Both categories $F(\mathcal{X})^{tr}$ and $D(\mathcal{X})$ possess the Serre duality: for any two objects M and N one has a functorial isomorphism $Hom(M,N)^* \simeq Hom(M, N[2dim_{\mathbf{R}} Y])$ (see Kontsevich, 1994). Furthermore, the A_∞-category $D(\mathcal{X})$ is saturated [see Appendix B and Kontsevich and Soibelman (2004b)]. Homological mirror symmetry predicts an equivalence of triangulated A_∞-categories compatible with the dualities. The last observation can be used for the following approach to the proof of homological mirror conjecture.

(1) Construct a collection of objects $(M_i)_{i \in I}$ in $F(\mathcal{X})$ which generate $F(\mathcal{X})^{tr}$.
(2) Construct the mirror functor $\varphi: F(\mathcal{X}) \to D(\mathcal{X}^\vee)$.
(3) Prove that the minimal triangulated subcategory of $D(\mathcal{X}^\vee)$, which contains all $\varphi(M_i)$, contains also the generator of $D(\mathcal{X}^\vee)$. Then φ provides the desire equivalence.

For example, one can take as $(M_y)_{y \in Y}$ the set of Lagrangian tori which are fibers of the torus fibration $p: T_Y / T_Y^{\mathbf{Z}} \to Y$. Then $\varphi(M_y)$ is a torsion sheaf. Such sheaves generate the A_∞-category $D(\mathcal{X})$. This idea can be used even in the case of a singular torus fibration.

Motivated by all that, one can try to extend homological mirror symmetry to the world of noncommutative spaces. In particular, one needs to define a noncommutative analog of Calabi–Yau manifold. Recall [see Appendix B and Kontsevich and Soibelman (2004b)] that if $\mathcal{A}$ is a triangulated A_∞-category, then the *Serre functor* is an A_∞-autoequivalence $S: \mathcal{A} \to \mathcal{A}$ of triangulated A_∞-categories, such that for any two objects M, N one has a functorial isomorphism

$$Hom_{\mathcal{A}}(M,N)^* \simeq Hom_{\mathcal{A}}(N, S(M)).$$

It is well-known that if X is a smooth projective variety over a field k and $\mathcal{A} = D^b(X)$ is the bounded derived category of coherent sheaves (or rather $\mathcal{A}$ is the A_∞-version of $D^b(X)$, constructed via complexes of perfect sheaves), then $S(F^\bullet) = F^\bullet \otimes K_X[dim\ X]$ is a Serre functor. If X is a Calabi–Yau manifold, then the canonical sheaf K_X is trivial, and the Serre functor reduces to the shift by the dimension. This motivates the following definition.

Definition 6: *(a) A noncommutative Calabi–Yau manifold of dimension d (a.k.a. Calabi–Yau category) is a saturated* A_∞*-category* $\mathcal{A}$ *which carries a Serre functor S such that* $S \simeq [d], d \in \mathbf{Z}_+$.

(b) A fractional noncommutative Calabi–Yau manifold of dimension d is defined as in (a) with the last condition being replaced by $S^m \simeq [dm]$ *for* $d \in \mathbf{Z}_+$ *and some integer* $m \geqslant 1$.

The notion of fractional Calabi–Yau manifold can be useful even in the commutative case. Fractional Calabi–Yau manifolds can appear as derived categories of coherent sheaves on orbifolds or derived categories of representations of oriented quivers. Hopefully the homological mirror symmetry is a fact about the (properly defined) moduli space (stack) of noncommutative Calabi–Yau manifolds. The reader can think that "commutative" points of this moduli space (i.e., ordinary Calabi–Yau manifolds) are similar to the commutative algebras as points in the moduli space of all associative (or A_∞ algebras) (see Kontsevich, 1997; Kontsevich and Soibelman,

2000b). This analogy implies that the tangent space to the moduli space of A_∞-deformations of a "commutative" Calabi–Yau manifold should carry a structure of 2-algebra [Deligne's conjecture, see Kontsevich and Soibelman (2000b)].

VIII. DEFORMATION THEORY OF A_∞-CATEGORIES WITH SERRE DUALITY

Let X be a noncommutative complex dg ind-manifold corresponding to a small A_∞-category $\mathcal{A}$. The moduli space of formal deformations of $\mathcal{A}$ is a (commutative) dg ind-manifold $\mathcal{M}_X$ with the marked point $[X] \in \mathcal{M}_X$. The tangent space $T_{[X]}\mathcal{M}_X$ is isomorphic to the Hochschild cohomology (Corollary 2): $HH^\bullet(\mathcal{A},\mathcal{A}) \simeq \oplus_{i\geqslant 0} Ext^i_{Funct}(Id_\mathcal{A}, Id_\mathcal{A})$, where $Funct = Funct(\mathcal{A},\mathcal{A})$ denotes the A_∞-category of A_∞-functors. It turns out that if $\mathcal{A}$ possesses the Serre duality (in particular if X is a noncommutative Calabi–Yau manifold), then one can say more. We are going to sketch the main idea below in the case of an A_∞-algebra A with a nondegenerate trace. We skip the definition of a trace in the A_∞-case. The reader can think of A as an associative algebra. In this case the definition of a trace is obvious. Let $\mathcal{M}_{A,trace}$ denote the moduli space of deformations of A as an A_∞-algebra with a trace, while $\mathcal{M}_A$ denotes the moduli space of its deformations as an A_∞-algebra. There is natural (forgetful) morphism of dg ind-manifolds with marked points, $f: \mathcal{M}_{A,trace} \to \mathcal{M}_A$. It is easy to see that $T_{[A]}\mathcal{M}_{A,trace} \simeq HC_\bullet(A) \simeq HC^\bullet(A)$, where $HC_\bullet$ and $HC^\bullet$ denotes the cyclic homology and cohomology, respectively (they can be identified by means of the trace). It is well-known that $HC^\bullet(A)$ is a module over $HC^\bullet(\mathbf{C}) \simeq H^\bullet(\mathbf{CP}^\infty) \simeq \mathbf{C}[u]$. For the periodic cyclic cohomology $HP^\bullet(A)$ one has $HP^\bullet(A) \simeq HC^\bullet(A) \otimes_{HC^\bullet(\mathbf{C})} \mathbf{C}$. Hence we have a family of vector spaces over the line $\mathbf{C}$. The fiber over $u \neq 0$ is isomorphic to $HP^\bullet(A)$, and the fiber over $u=0$ is isomorphic to the Hochschild cohomology $HH^\bullet(A,A)$. Then for any $u \neq 0$ we have a linear map $HC^\bullet(A) = T_{[A]}\mathcal{M}_{A,trace} \to HP^\bullet(A)$, i.e., to a one-form α on $\mathcal{M}_{A,trace}$ with values in $HP^\bullet(A)$.

Conjecture 3: *The one-form α is closed.*

If the conjecture is true, then locally $\alpha = dg_u$ for some function g_u. This gives us a map $g_u: \mathcal{M}_{A,trace} \to HP^\bullet(A) \simeq HP_\bullet(A)$ which is defined up to a constant.

Conjecture 4: *This map gives rise to an embedding of $\mathcal{M}_{A,trace}$ in the affine space, with the underlying vector space being the space of sections of a vector bundle on* $\mathbf{C}$ *with the fiber over $u \neq 0$ isomorphic to $HP_\bullet(A)$.*

Corollary 3: *There is a family of dg ind-manifolds $(\mathcal{M}_A^u)_{u\in\mathbf{C}}$ such that $\mathcal{M}_A^{u=0} \simeq \mathcal{M}_A$ and $\mathcal{M}_A^{u\neq 0}$ carries an affine structure with the pole of first order at $u=0$.*

The grading on the tangent space $T_{[A]}\mathcal{M}_A \simeq HH^\bullet(A,A)$ arises as the limit of filtrations on the tangent spaces to $\mathcal{M}_A^u, u \neq 0$.

It is natural to expect that the mirror functor extends to an isomorphism of the one-parameter families of dg ind-manifolds $\mathcal{M}_A^u$, constructed for $F(\mathcal{X})$ and $D(\mathcal{X}^\vee)$. It gives not only an isomorphism of moduli spaces at $u=0$ [i.e., equivalences of A_∞-categories $F(\mathcal{X})$ and $D(\mathcal{X}^\vee)$ and the moduli spaces of their formal deformations] but also identifies the corresponding Hodge structures arising from the filtrations on the tangent space to $\mathcal{M}_A^u, u \neq 0$ (see Barannikov, 1999), Sec. V, where the "holomorphic" side of the story was considered).

ACKNOWLEDGMENTS

Since the article derives from lectures at the workshop "Symplectic Geometry and Physics" (Inst. Pure and Appl. Math. at UCLA, 18–21 March 2003), I thank the organizers for the invitation to give a lecture course. The material of this paper is largely based on the joint work and numerous discussions with Maxim Kontsevich. It can be considered as a short review of some parts of several ongoing projects (see Kontsevich and Soibelman, 2000a, 2000b, 2004a, 2004b, 2004c). Needless to say that I am fully responsible for all omissions, mistakes, etc.

APPENDIX A: MODULI SPACE OF CONFORMAL FIELD THEORIES

It was first suggested in Kontsevich and Soibelman (2000a) that mirror symmetry should be treated in the framework of collapsing conformal field theories, thus making yet another link to noncommutative geometry. Here we recall very briefly the data of CFT.

Unitary conformal field theory (abbreviated by CFT below) is well-defined mathematically. It is described by the following data:

(1) A real number $c \geqslant 0$ called central charge.
(2) A bi-graded pre-Hilbert *space of states* $H=\oplus_{p,q\in \mathbf{R}_{\geqslant 0}} H^{p,q}, p-q\in \mathbf{Z}$ such that $dim(\oplus_{p+q\leqslant E} H^{p,q})$ is finite for every $E\in \mathbf{R}_{\geqslant 0}$. Equivalently, there is an action of the Lie group $\mathbf{C}^*$ on H, so that $z\in \mathbf{C}^*$ acts on $H^{p,q}$ as $z^p\overline{z}^q := (z\overline{z})^p \overline{z}^{q-p}$.
(3) An action of the product of Virasoro and anti-Virasoro Lie algebras $Vir\times \overline{Vir}$ (with the same central charge c) on H, so that the space $H^{p,q}$ is an eigenspace of the generator L_0 (resp. $\overline{L_0}$) with the eigenvalue p (resp. q).
(4) The space H carries some additional algebraic structures derived from the operator product expansion (OPE). The OPE is described by a linear map $H\otimes H\to H\hat{\otimes}\mathbf{C}\{z,\overline{z}\}$. Here $\mathbf{C}\{z,\overline{z}\}$ is the topological ring of formal power series $f=\Sigma_{p,q}\, c_{p,q} z^p\overline{z}^q$ where $c_{p,q}\in \mathbf{C}, p,q\to +\infty, p,q \in \mathbf{R}, p-q\in \mathbf{Z}$. The OPE satisfies a list of axioms [see Gawedzki (2000) for the details].

For a given CFT one can consider its group of symmetries (i.e., the group of automorphisms of the space $H=\oplus_{p,q} H^{p,q}$ preserving all the structures). Conjecturally the group of symmetries is a compact Lie group of dimension less than or equal to $dim\ H^{1,0}$.

Let us fix real numbers $c_0\geqslant 0$, $E_{min}>0$, and consider the moduli space $\mathcal{M}_{c\leqslant c_0}^{E_{min}}$ of all irreducible CFTs with the central charge $c\leqslant c_0$ and

$$min\{p+q>0 | H^{p,q}\neq 0\}\geqslant E_{min}.$$

It is expected that $\mathcal{M}_{c\leqslant c_0}^{E_{min}}$ is a compact real analytic stack of finite local dimension. The dimension of the base of the minimal versal deformation of a given CFT is less than or equal to $dim\ H^{1,1}$. We define $\mathcal{M}_{c\leqslant c_0}=\cup_{E_{min}>0}\mathcal{M}_{c\leqslant c_0}^{E_{min}}$. It is natural to compactify this stack by adding boundary components corresponding to certain asymptotic degenerations of the theories with $E_{min}\to 0$. Conjecturally, the compactified space is a compact stack $\overline{\mathcal{M}}_{c\leqslant c_0}$. We will loosely use the word "space" instead of the word "stack."

Remark 6: *Mirror symmetry is related to $N=2$ superconformal field theories (SCFTs). There is a version of the above data and axioms for SCFT. In that case each $H^{p,q}$ is a Hermitian super vector space. There is an action of the super extension of the product of Virasoro and anti-Virasoro algebra on H. We will not distinguish between CFTs and SCFTs, because except for some minor details, main conclusions are true in both cases. The $N=2$ analog of the compactified moduli space will be denoted by $\overline{\mathcal{M}}_{c\leqslant c_0}^{N=2}$.*

Physicists believe that to a Calabi–Yau manifold X of "large volume" one can assign an $N=2$ superconformal field theory, denoted by *SCFT(X)*. The construction assumes some other choices [like the so-called *B*-field, which can be thought of as an element of $H^2(X,\mathbf{R}/\mathbf{Z})$]. Calabi–Yau manifolds X and $X^\vee$ are called dual if $SCFT(X)$ is equivalent to $SCFT(X^\vee)$. One can think of $SCFT(X)$ as the "noncommutative extension" of X. Central charge plays a role of the dimension. Compactified moduli space $\overline{\mathcal{M}}_{c\leqslant c_0}^{N=2}$ contains the moduli space of Calabi–Yau manifolds of the fixed dimension as a boundary stratum. In other words, targets for sigma models can be thought of as "commutative degenerations at infinity" of the noncommutative spaces.

Observation that $SCFT(X)$ does not determine the underlying Calabi–Yau manifold gives a striking parallel to the fact that the derived category of coherent sheaves of a projective variety does not determine it up to an isomorphism if K_X is trivial [see Bondal and Orlov (2002) about the philosophy of replacing a projective variety by the derived category of coherent sheaves on it]. The importance of the derived categories in homological mirror symmetry was recognized by Kontsevich at the early stage of his program (see Kontsevich, 1994).

APPENDIX B: TRIANGULATED AND SATURATED A_∞-CATEGORIES

The material of this section is largely borrowed from Kontsevich and Soibelman (2004b).

First we will define pairs of A_∞-categories (in fact dg-categories) $C_1^{(i)}, C_2^{(i)}, 1 \leqslant i \leqslant 5$.

(1) The category $C_1^{(1)}$ is the empty category with no objects.

The category $C_2^{(1)}$ has one object F such that $Hom(F,F)=0$.

(2) The category $C_1^{(2)}$ is an A_∞-category with two objects E_1, E_2 such that $Hom(E_i,E_j)=0$ for $i \neq j$, and $Hom(E_i,E_i)=k$ for all i,j.

The category $C_2^{(2)}$ has three objects F_1, F_2, F such that $Hom(F_i,F_j) \simeq Hom(E_i,E_j)$ and $Hom(F,F_1)=Hom(F,F_2)=Hom(F_1,F)=Hom(F_2,F)=k, Hom(F,F)=k \oplus k$.

(3) The category $C_1^{(3)}$ has one object E_1 such that $Hom(E_1,E_1)=k$.

The category $C_2^{(3)}$ has three objects F_0, F_1, F_{-1} such that $Hom(F_i,F_j)=k[i-j]$ for all i,j.

The differentials on the morphisms are zero in all cases 1–3.

(4) The category $C_1^{(4)}$ has two objects E_1, E_2 such that $Hom(E_1,E_1)=0$ and all other spaces of morphisms are isomorphic to the ground field k.

Differentials are trivial on the spaces of morphisms.

The category $C_2^{(4)}$ has three objects F_1, F_2, F such that $Hom(F_i,F_j) \simeq Hom(E_i,E_j)$ for all i,j. We set $Hom(F_1,F)=k$ with the trivial differential, and $Hom(F_2,F)=k[1] \oplus k$. Furthermore, $Hom(F,F_1)=k \oplus k[-1], Hom(F,F_2)=k[-1], Hom(F,F)=k \oplus k \oplus k[-1]$.

Differentials on the spaces of morphisms are defined in such a way that $F=F_1[1] \oplus F_2$ with the differential corresponding to the cone of a morphism. For example, $Hom(F_2,F)=k[1] \oplus k$ carries the differential d such that $d(1_{k[1]})=1_k$.

(5) The category $C_1^{(5)}$ has one object E_1 such that $Hom(E_1,E_1)=k[p]/(p^2-p)$, where $deg\ p=0$.

The category $C_2^{(5)}$ has two objects F_1, F such that $Hom(F_1,F_1)=k[p]/(p^2-p), deg\ p=0$ and all other spaces of morphisms are equal to the ground field k.

The differentials are trivial for these categories.

Obviously there are A_∞-functors $\phi_i: C_1^{(i)} \to C_2^{(i)}, 1 \leqslant i \leqslant 5$, such that $\phi_i(E_j)=F_j$ for all j. The functors ϕ_i are faithful (i.e., induce embeddings on the zero cohomologies of the complexes of morphisms).

Definition 7: *We say that an A_∞-category $\mathcal{A}$ satisfies the Axiom i, $1 \leqslant i \leqslant 5$, if the induced A_∞-functor $\phi_i^*: Funct(C_2^{(i)}, \mathcal{A}) \to Funct(C_1^{(i)}, \mathcal{A})$ is an equivalence of A_∞-categories of functors*.

We say that the category $\mathcal{A}$ is triangulated if it satisfies Axioms 1–5.

Axioms 1–5 have special names:

Axiom 1: Existence of a zero object of the category.

Axiom 2: Existence of the direct sum of two objects.

Axiom 3: Existence of shifts of an object.

Axiom 4: Existence of a cone of a morphism.

Axiom 5: Splitting of the image of a projector.

Motivations for these names are self-evident from the definitions [for example, in the case of Axiom 5 one thinks of the object F as of $p(F_1)$].

Similarly to the conventional theory of triangulated and derived categories one can define the notion of a thick subcategory of a triangulated A_∞-category. Then one can embed an A_∞-category $\mathcal{C}$ into the A_∞-category $\hat{\mathcal{C}}=Funct(\mathcal{C}^{op}, \mathbf{K})$, where $\mathbf{K}$ is the category of complexes of k-vector spaces. The embedding A_∞-functor Yo is an A_∞-analog of the Yoneda functor. Finally, an A_∞-category $\mathcal{C}$ is triangulated iff its image $Yo(\mathcal{C})$ is a thick subcategory of $\hat{\mathcal{C}}$ [see Kontsevich and Soibelman (2004b) for the details].

Let $\mathcal{C}$ be a triangulated A_∞-category over k.

Definition 8: *We say that $\mathcal{C}$ is saturated if the following properties are satisfied*:

(1) *For any* $E,F \in Ob(\mathcal{C})$ *and one has* $\Sigma_{n\in\mathbf{Z}} dim(Hom(E,F[n])) < \infty$.
(2) *The identity functor* $Id_{\mathcal{C}}$ *belongs to the smallest triangulated category generated by the image of the natural bifunctor* $\Psi \in Bifunct((\mathcal{C}^{op},\mathcal{C}),Funct(\mathcal{C},\mathcal{C}))$ *such that* $\Psi(X,Y)(Z) = Hom_C(X,Y)\otimes Z$ *for any* $X,Y,Z \in Ob(\mathcal{C})$.

Definition 9: *The triangulated envelope of a set of objects of a triangulated* A_∞*-category is the minimal triangulated subcategory containing this set of objects*.

The triangulated envelope consists of images of projectors of finite extensions of shifts of given objects. Then we can say that the condition (2) above means that the identity functor belongs to the triangulated envelope of the set $\Psi(Ob(\mathcal{C}))$. Let us denote by S^{tr} the triangulated envelope of the set S. If $S=\{F\}$ consists of one object F, we say that F is a *generator* of the category.

Proposition 3: *If* $\mathcal{C}$ *is saturated, then it has a generator*.

Example 4: *Let* A *be an* A_∞*-algebra. The category* $A-mod$ *of* A_∞*-modules over* A *is saturated iff* A *is a perfect* A*-*A*-bimodule, i.e., as an* A_∞*-bimodule* A *is isomorphic to a direct summand of an extension of the sequence* $(A^{op}\otimes A)[n_i], n_i \in \mathbf{Z}$ *(in the category of bimodules)*.

Example 5 (Kontsevich, 1994, 1997; Seidel, 2000): Let X *be a Calabi–Yau manifold,* $f: X \to \mathbf{CP}^1$ *be a holomorphic map which has only isolated singularities. Assume that the generic fiber of* f *is a Calabi–Yau manifold* $Y, dim_{\mathbf{C}} Y > 2$. *Then the triangulated envelope of the Fukaya category* $F(Y)$ *is saturated. [Hint: it is generated by the Lagrangian spheres vanishing at the critical points. Indeed the shift functor* $E \mapsto E[2]$ *(monodromy at infinity) can be represented as a product of reflections at the vanishing spheres. It follows that the identity functor belongs to the triangulated envelope of the set of vanishing Lagrangian spheres.]*

(Received 12 February 2004; accepted 7 June 2004; published 12 October 2004)

In recent years a Hopf algebraic structure underlying the process of renormalization in quantum field theory was found. It led to a Birkhoff factorization for (regularized) Hopf algebra characters, i.e., for Feynman rules. In this work we would like to show that this Birkhoff factorization finds its natural formulation in terms of a classical r-matrix, coming from a Rota–Baxter structure underlying the target space of the regularized Hopf algebra characters. Working in the rooted tree Hopf algebra, the simple case of the Hopf subalgebra of ladder trees is treated in detail. The extension to the general case, i.e., the full Hopf algebra of rooted trees or Feynman graphs, is briefly outlined. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1786680]

I. INTRODUCTION

In 1960 the mathematician Glen Baxter[1] used a simple algebraic identity to solve an analytic problem in probability. Later, in 1963 Atkinson[2] gave a characterization of this relation in terms of Birkhoff's concept of a so-called subdirect (de)composition of algebras. It was Rota who investigated this identity more thoroughly and realized its importance within combinatorics and other fields in mathematics.[3–5] This identity is called the Rota–Baxter relation and will be introduced in the next section. See Refs. 6,7 for reviews and Refs. 8–12 for recent developments relating this identity to other fields in mathematics.

The same relation in its Lie algebraic version was later rediscovered under the name (operator form of the modified) classical Yang–Baxter (here the relation is named after the physicists Yang and Baxter) equation within the field of integrable systems.[13–15] See Ref. 16 for a nice review, especially with respect to double Lie algebras and factorization theorems, i.e., the Riemann–Hilbert problem.

Very recently the Rota–Baxter relation was found to be of crucial importance within the Hopf algebraic approach of Kreimer, and Connes and Kreimer to renormalization theory of perturbative quantum field theory.[17–20] It implies a Birkhoff decomposition of Hopf algebra characters with the target space being a Rota–Baxter algebra. See Ref. 21 for a first introduction.

In this work we aim at a clarification of the link between the last two subjects. We show how the Rota–Baxter relation on the target space of the Hopf algebra characters can be lifted to the Lie algebra of infinitesimal characters. Atkinson's theorem then implies an infinitesimal factorization on this space. This factorization in turn implies the Birkhoff decomposition for the Hopf algebra

[c)]Electronic mail: kreimer@ihes.fr and dkreimer@bu.edu

characters. We derive its twisted antipode form first found by one of us.[17] There it was introduced in a formal way mainly motivated by its ability to reproduce Zimmermann's forest formula. Dimensional regularization together with a minimal subtraction scheme furnishes one special case (distinguished by its convenience in applied particle physics) of our approach in which the target space consists of the algebra of Laurent series with finite pole part. Its Rota–Baxter structure stems from the projection onto the pole part of a Laurent series. Here, we will discuss the algebraic Birkhoff decomposition for general Rota–Baxter maps R, provided by various choices of renormalization schemes. Let us mention here that we will restrict our attention later on to the case of the Hopf subalgebra of rooted ladder trees. In this manner we can avoid lengthy formulas generated by the Baker-Campbell-Hausdorff formula, and can treat this case in full technical detail. In the end it will be outlined though how the general case, i.e., for arbitrary rooted trees or graphs, is derived. Details and also a mathematically more rigorous presentation will be given in a forthcoming paper, emphasizing the link to integrable systems.

The paper is structured as follows. In the next section we introduce the notion of a Rota–Baxter algebra and its main characterization by Atkinson's theorem. Section III contains the main results. We briefly introduce the Hopf algebra of rooted trees and the group of characters and its Lie algebra of infinitesimal characters, with target space of the Rota–Baxter type. The Birkhoff decomposition is then derived. We stress that we obtain Bogoliubov's R-bar operation from scratch, as a natural consequence of Atkinson's theorem. We end this work with a summary and an outline describing the case when the Hopf algebra is not cocommutative.

II. ROTA–BAXTER ALGEBRAS AND THE DOUBLE CONSTRUCTION

Let $\mathbb{K}$ be a field of characteristic 0. By a $\mathbb{K}$-algebra we mean an associative algebra over $\mathbb{K}$ that is not necessarily unital or commutative unless stated otherwise.

Definition 2.1: Let $\mathcal{A}$ be a $\mathbb{K}$-algebra with a $\mathbb{K}$-linear map $R:\mathcal{A}\to\mathcal{A}$. We call $\mathcal{A}$ a Rota–Baxter $\mathbb{K}$-algebra and R a Rota–Baxter map (of weight $\theta\in\mathbb{K}$) if the operator R holds the following Rota–Baxter relation of weight $\theta\in\mathbb{K}$:

$$R(x)R(y)+\theta R(xy)=R\big(R(x)y+xR(y)\big),\qquad \forall\, x,y\in\mathcal{A}. \tag{1}$$

[Some authors denote this relation in the form $R(x)R(y)=R\big(R(x)y+xR(y)+\lambda xy\big)$, so $\lambda=-\theta$.]

We note that a Rota–Baxter relation can be defined on $\mathcal{A}$ even when the multiplication on $\mathcal{A}$ is not associative, e.g., when $\mathcal{A}$ is a Lie or pre-Lie algebra. In the case $\theta=0$, the Rota–Baxter operator is somewhat degenerate (see Atkinson's theorem below). When $\theta\neq 0$, a simple transformation $R\to\theta^{-1}R$ gives the standard form of Eq. (1). For the rest of the paper we will always assume the Rota–Baxter map to be of weight $\theta=1$, i.e., to be in standard form.

Remark 2.2: (1) If R fulfills relation (1) for $\theta=1$ then $\tilde{R}:=id-R$ fulfills the same Rota–Baxter relation.

(2) The images of R and $id-R$ give subalgebras in $\mathcal{A}$.

Example 2.3: (1) An important class of Rota–Baxter maps is given by certain projectors. This is the case for the minimal subtraction map R_{MS} in renormalization theory, which is a Rota–Baxter map of weight $\theta=1$ on the algebra of Laurent series $\mathbb{C}[\![\epsilon,\epsilon^{-1}]$.[18] For $\Sigma_{k\geqslant -m}^{\infty}c_k\epsilon^k\in\mathbb{C}[\![\epsilon,\epsilon^{-1}]$,

$$R_{\mathrm{MS}}\left(\sum_{k\geqslant -m}^{\infty}c_k\epsilon^k\right):=\sum_{k\geqslant -m}^{-1}c_k\epsilon^k. \tag{2}$$

.

(2) Another nice example[10] of a Rota–Baxter map of weight $\theta\in\mathbb{K}$ is the operator $\beta:M_n^{\mathrm{up}}(\mathbb{K})\to M_n^{\mathrm{up}}(\mathbb{K})$ defined on the subalgebra of $n\times n$ upper triangular matrices $M_n^{\mathrm{up}}(\mathbb{K})\subset M_n(\mathbb{K})$, mapping an element x to the diagonal matrices $M_n^{\mathrm{up}}(\mathbb{K})\ni x\mapsto\beta(x)\in M_n^{d}(\mathbb{K})\subset M_n^{\mathrm{up}}(\mathbb{K})$:

$$(\beta(x))_{ij} := \delta_{ij}\theta\sum_{k\geqslant i}^{n} x_{ik}.$$

(3) The Riemann integral,

$$R[f](x) := \int_0^x f(y)dy,$$

provides an example for a Rota–Baxter map of weight zero; (1) for $\theta=0$ gives the rule for integration by parts.

We now introduce the modified Rota–Baxter relation. Its Lie algebraic version can be found in Refs. 13,14.

Definition 2.4: Let $\mathcal{A}$ be a Rota–Baxter algebra, R its Rota–Baxter map. Define the modified Rota–Baxter map to be the operator $B:\mathcal{A}\to\mathcal{A}, B:=id-2R$, and call the corresponding relation fulfilled by B:

$$B(x)B(y) = B(B(x)y + xB(y)) - xy, \quad \forall\, x,y \in \mathcal{A} \tag{3}$$

the modified Rota–Baxter relation.

Proposition 2.5: In the case of the Rota–Baxter algebra $\mathcal{A}$ to be either an associative or pre-Lie $\mathbb{K}$-algebra, the (modified) Rota–Baxter relation naturally extends to the Lie algebra $\mathcal{L}_{\mathcal{A}}$ with bracket $[x,y]:=xy-yx, \forall\, x,y\in\mathcal{A}$:

$$[R(x),R(y)] + R([x,y]) = R([R(x),y] + [x,R(y)]), \tag{4}$$

$$[B(x),B(y)] = B([B(x),y] + [x,B(y)]) - [x,y]. \tag{5}$$

The proof of this follows from a simple calculation. The relations (4) and (5) are well-known as the (operator form of the) classical Yang–Baxter and modified Yang-Baxter equation.

The following Proposition 2.6 and Theorem 2.9 characterize Rota–Baxter algebras.

Proposition 2.6: Let $\mathcal{A}$ be a Rota–Baxter algebra with (modified) Rota–Baxter map $R(B=id-2R)$. Equipped with the new product,

$$a*_R b := R(a)b + aR(b) - ab \tag{6}$$

$$= -\frac{1}{2}(B(a)b + aB(b)), \tag{7}$$

$\mathcal{A}$ is again a Rota–Baxter algebra of the same type, denoted by $\mathcal{A}_R$.

The proof of this proposition is immediate by the definition of $*_R$. We call this new Rota–Baxter algebra $\mathcal{A}_R$ the double of $\mathcal{A}$.

Remark 2.7: (1) It is obvious that Proposition 2.6 implies a whole hierarchy of doubles $\mathcal{A}_R^{(i)}$ (here, $*_R=*_R^{(1)}$):

$$\mathcal{A}_R^{(0)} := \mathcal{A}, \quad \mathcal{A}_R^{(1)} := (\mathcal{A},*_R),\ldots, \quad \mathcal{A}_R^{(i)} := (\mathcal{A},*_R^{(i)}),\ldots,$$

$$a*_R^{(i)}b := \left.\frac{d^i}{dt^i}\right|_{t=0} e^{(-1/2)tB}(a)e^{(-1/2)tB}(b), \quad a,b\in\mathcal{A}.$$

Let us call $\mathcal{A}_R^{(i)}$ the *i-th* double of $\mathcal{A}$ and the double of $\mathcal{A}_R^{(i-1)}$.

(2) The Rota–Baxter map becomes an algebra homomorphism between $\mathcal{A}_R^{(i)}$ and $\mathcal{A}_R^{(i-1)}, i\in\mathbb{N}$:

$$R(a*_R^{(i)}b) = R(a)*_R^{(i-1)}R(b).$$

(3) For the Rota–Baxter map $\tilde{R} := id - R$, we have

$$\tilde{R}(a *_R^{(i)} b) = -\tilde{R}(a) *_R^{(i-1)} \tilde{R}(b).$$

The last equation can be written as $\hat{R} := -\tilde{R}, \hat{R}(a *_R^{(i)} b) = \hat{R}(a) *_R^{(i-1)} \hat{R}(b)$. As a side remark we should mention that the notion of the double of $\mathcal{A}$ for associative and nonassociative algebras may be found in Ref. 14.

A relation closely related to the Rota–Baxter relation (1) is

$$N(x)N(y) + N^2(xy) = N(N(x)y + xN(y)), \quad x,y \in \mathcal{A}. \tag{8}$$

The map N might be called an associative Nijenhuis operator or just Nijenhuis map for short.[28] In this setting "associative" refers to the relation (8) to distinguish it clearly from its Lie algebraic version:[29,30]

$$[N(x),N(y)] + N^2([x,y]) = N([N(x),y] + [x,N(y)]). \tag{9}$$

As in the case of the Rota–Baxter relation, a Nijenhuis map on a $\mathbb{K}$-algebra $\mathcal{A}$ also gives a Nijenhuis map for the associated Lie algebra $\mathcal{L}_{\mathcal{A}} := (\mathcal{A}, [-,-]), [-,-]$ being the commutator. Also, similar to the case of the Rota–Baxter relation the associative Nijenhuis identity implies a hierarchy of algebra products. We will not go further into details with respect to this relation.

Proposition 2.8: Let $\mathcal{A}$ be a commutative, associative Rota–Baxter algebra. For $n \in \mathbb{N}, x \in \mathcal{A}$ we have

$$(-R(x))^n = -R\left(x^n + \sum_{k=1}^{n-1} \binom{n}{k} (-R(x))^{(n-k)} x^k\right), \tag{10}$$

$$\tilde{R}(x)^n = \tilde{R}\left(x^n + \sum_{k=1}^{n-1} \binom{n}{k} (-R(x))^{(n-k)} x^k\right). \tag{11}$$

The proof works inductively. Proposition 2.8 will lead us to the twisted antipode formula.[17–19]

We come now to the important result of Atkinson, reformulating the Rota–Baxter relation in terms of a subdirect (de)composition in the sense of Birkhoff.

Theorem 2.9 (Atkinson[2]): *For a $\mathbb{K}$-algebra $\mathcal{A}$ with a linear map $R: \mathcal{A} \to \mathcal{A}$ to be a Rota–Baxter $\mathbb{K}$-algebra, it is necessary and sufficient that $\mathcal{A}$ has a subdirect Birkhoff decomposition.*

It should be underlined here that this theorem is true quite generally, in the sense that the algebra needs not to be associative, nor commutative.

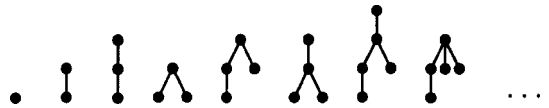
Essentially, the subdirect Birkhoff decomposition in this case means that the Cartesian product $\mathcal{D} := (R(\mathcal{A}), -\tilde{R}(\mathcal{A})) \subset \mathcal{A} \times \mathcal{A}$ is a subalgebra in $\mathcal{A} \times \mathcal{A}$ and that every element $x \in \mathcal{A}$ has a unique decomposition $x = R(x) + \tilde{R}(x)$. The double construction introduced here and Atkinson's theorem should be compared with the results in Refs. 13–16.

III. *R*-MATRIX APPROACH TO RENORMALIZATION: THE ROOTED LADDER TREE CASE

We will now briefly introduce the Connes–Kreimer Hopf algebra of rooted trees.[22–24]

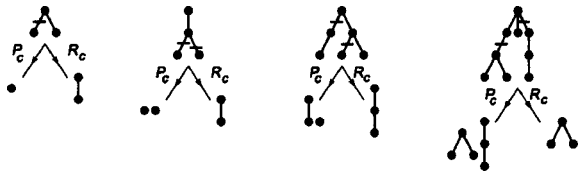
Definition 3.1: A rooted tree is a finite, connected oriented graph without loops in which every vertex has exactly one incoming edge, except one (the root) which has no incoming but only outgoing edges. We denote the set of edges and vertices of a rooted tree T by $E(T), V(T)$, respectively.

Let us denote the set of (isomorphism classes of) rooted trees by $\mathcal{T}_{\mathrm{rt}}$:



Let $\mathcal{H}_{\mathrm{rt}}$ be the commutative algebra generated by these symbols $T \in \mathcal{T}_{\mathrm{rt}}$ (one for each isomorphism class). The commutative product $m_{\mathcal{H}_{\mathrm{rt}}}: \mathcal{H}_{\mathrm{rt}} \otimes \mathcal{H}_{\mathrm{rt}} \to \mathcal{H}_{\mathrm{rt}}$ is written as concatenation $m_{\mathcal{H}_{\mathrm{rt}}}(T', T'') =: T'T''$ and the empty tree is denoted by 1 giving the unit. The algebra may be graded by the number of vertices $\#(T) = |V(T)|$ of the rooted tree T. We equip this algebra with a counit map $\epsilon: \mathcal{H}_{\mathrm{rt}} \to \mathbb{K}, \epsilon(1) := 1$ and $\epsilon(T_1 \cdots T_n) = 0$ for $T_1 \cdots T_n \neq 1$.

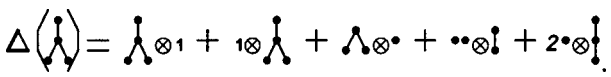
We now define the coproduct $\Delta: \mathcal{H}_{\mathrm{rt}} \to \mathcal{H}_{\mathrm{rt}} \otimes \mathcal{H}_{\mathrm{rt}}$. For this we first introduce the notion of simple cuts on rooted trees. A simple or admissible cut c_T of a tree T is a subset of its edges such that along any path from its root to one of its leaves one meets at most one element of c_T. Deleting the set $c_T \subset E(T)$ of edges in T produces one tree R_{c_T} still containing the original root and a set of pruned rooted trees P_{c_T}, the roots of which are identified with the vertex which had the cut edge in c_T as an incoming edge. The following examples may be helpful in understanding the concept of simple cuts, R_{c_T} and P_{c_T}:



The coproduct may then be defined as follows. Let C_T be the set of all admissible cuts of the rooted tree T. We exclude the empty cut $c_T^{(0)}, P_{c_T^{(0)}} = \emptyset, R_{c_T^{(0)}} = T$ and the full cut $c_T^{(1)}, P_{c_T^{(1)}} = T, R_{c_T^{(1)}} = \emptyset$:

$$\Delta(T) = T \otimes 1 + 1 \otimes T + \sum_{c_T \in C_T} P_{c_T}(T') \otimes R_{c_T}(T''). \tag{12}$$

Here T', respectively, T'' stand for the rooted trees produced when applying c_T. As an example we calculate the coproduct of the rooted tree of weight $\#(\cdot) = 4$:

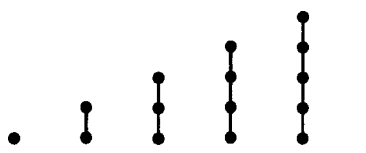


The coproduct (12) is extended by linearity, and we define it to be an algebra homomorphism $\Delta(T_1 \cdots T_n + T_{n+1} \cdots T_m) = \Pi_{i=1}^{n} \Delta(T_i) + \Pi_{i=n+1}^{m} \Delta(T_i), \Delta(1) := 1 \otimes 1$. Obviously, (12) is not cocommutative. So far we have a connected graded bialgebra, hence by general arguments a rooted tree Hopf algebra with antipode $S: \mathcal{H}_{\mathrm{rt}} \to \mathcal{H}_{\mathrm{rt}}$:

$$S(T) := -T - \sum_{c_T \in C_T} S(P_{c_T}(T')) R_{c_T}(T''). \tag{13}$$

Again we exclude the empty and full cut, i.e. $c_T^{(0)}, c_T^{(1)}$, respectively, in the above sum.

The Hopf algebra $\mathcal{H}_{\mathrm{rt}}$ contains a cocommutative Hopf subalgebra denoted by $\mathcal{H}_{l\ \mathrm{rt}}$, generated by rooted ladder graphs:



which we will denote in general by $t_n \in \mathcal{H}_{l\ \mathrm{rt}} \subset \mathcal{H}_{\mathrm{rt}}$, where $n \in \mathbb{N}$ is the number of vertices, having at most one incoming and also at most one outgoing edge. By t_0 we denote the unit, i.e. the empty tree 1. The coproduct then becomes

$$\Delta(t_n) = t_n \otimes 1 + 1 \otimes t_n + \sum_{i=1}^{n-1} t_i \otimes t_{n-i}. \tag{14}$$

The graded dual $\mathcal{H}_{\mathrm{rt}}^*$ equipped with the convolution product $f \star g := m_{\mathbb{K}} \circ f \otimes g \circ \Delta, f, g \in \mathcal{H}_{\mathrm{rt}}^*$ becomes an associative $\mathbb{K}$-algebra. We denote the pairing by brackets, $\langle f, T \rangle := f(T) \in \mathbb{K}$.

Let $\mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}} \subset \mathcal{H}_{\mathrm{rt}}^*$ be the group of characters, i.e. algebra morphisms into $\mathbb{K}$, with inverse $\phi^{-1} := \phi \circ S, \phi \in \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}}$. Let $\partial\, \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}} \subset \mathcal{H}_{\mathrm{rt}}^*$ be the Lie algebra of infinitesimal characters, i.e. derivations into $\mathbb{K}$:

$$Z(T'T'') = Z(T')\epsilon(T'') + \epsilon(T')Z(T''), \quad Z \in \partial\ \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}}, \tag{15}$$

with Lie bracket

$$[Z', Z''] := Z' \star Z'' - Z'' \star Z'. \tag{16}$$

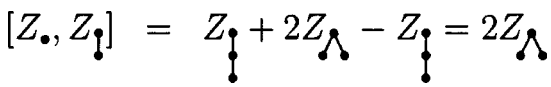
$\partial\, \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}}$ is generated by the infinitesimal characters Z_T indexed by rooted trees $T \in \mathcal{T}_{\mathrm{rt}}$, and defined by

$$\langle Z_T, T' \rangle := \delta_{T,T'}. \tag{17}$$

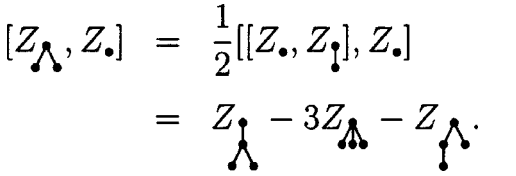
Tree monomials are excluded from the index set due to the Leibniz rule (15). The Lie bracket for these generators is given by Ref. 22:

$$[Z_{T'}, Z_{T''}] = \sum_{T \in \mathcal{T}_{\mathrm{rt}}} (n(T', T''; T) - n(T'', T'; T)) Z_T, \tag{18}$$

where the $n(T', T''; T) \in \mathbb{N}$ denote so-called section coefficients which count the number of single simple cuts, $|c_T| = 1$, such that $P_{c_T} = T'$ and $R_{c_T} = T''$:



(19)



(20)

Remark 3.2: (1) The composition $Z_{T'} \star Z_{T''} = \Sigma_{T \in \mathcal{T}_{\mathrm{rt}}} n(T', T''; T) Z_T$ defines a left pre-Lie algebra structure on $\partial\, \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}}$.

(2) Antisymmetrizing this pre-Lie product gives the above Lie algebra, which lies at the heart of the combinatorics of renormalization theory in pQFT.[25,26]

The exponential map gives the bijection from $\partial\, \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}} \to \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}}$:

$$\exp^{\star}(Z) := \sum_{n=0}^{\infty} \frac{Z^{\star n}}{n!} \in \mathrm{char}_{\mathbb{K}}\, \mathcal{H}_{\mathrm{rt}}. \tag{21}$$

Here Z is given as a series,

$$Z = \sum_{T \in \mathfrak{T}_{rt}} a^T Z_T = a^{\bullet} Z_{\bullet} + a^{\bullet^1} Z_{\bullet^1} + a^{\bullet^2} Z_{\bullet^2} + a^{\bullet^3} Z_{\bullet^3} + \cdots$$

The exponential map (21) is well defined since due to the Leibniz rule (15) we have $Z^{\star n}(T)=0$ for $n>\#(T)$.

Following the Hopf algebraic approach to renormalization in perturbative quantum field theory (pQFT), we introduce the notion of regularized (infinitesimal) characters, mapping $\mathcal{H}_{\mathrm{rt}}$ into a commutative, associative, unital Rota–Baxter algebra $\mathcal{A}$. [$\mathcal{A}=\mathbb{C}[\![\epsilon,\epsilon^{-1}]$ in dimensional regularization together with minimal subtraction in pQFT, where the Rota–Baxter R map is then given by Eq. (2).] We therefore extend $\mathcal{H}_{\mathrm{rt}}^{*}$ to $\mathcal{H}_{\mathrm{rt}}^{*}\otimes\mathcal{A}=L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})$, consisting of $\mathbb{K}$-linear maps from $\mathcal{H}_{\mathrm{rt}}$ into the Rota–Baxter algebra $\mathcal{A}$, i.e. $\langle\phi,T\rangle\in\mathcal{A}, \phi\in L(\mathcal{H}_{\mathrm{rt}},\mathcal{A}), T\in\mathcal{H}_{\mathrm{rt}}$.

We then lift the Rota–Baxter map $R:\mathcal{A}\to\mathcal{A}$ to $L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})$.

Proposition 3.3: Define the linear map $\mathcal{R}:L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})\to L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})$ *by* $f\mapsto\mathcal{R}(f):=R\circ f:\mathcal{H}_{\mathrm{rt}}\to R(\mathcal{A})$. *Then* $L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})$ *becomes an associative, unital Rota–Baxter algebra. The Lie algebra of infinitesimal characters* $\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}}\subset L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})$ *with bracket (16) becomes a Lie Rota–Baxter algebra, i.e. for* $Z',Z''\in\partial\,\mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}$,

$$[\mathcal{R}(Z'),\mathcal{R}(Z'')]=\mathcal{R}([Z',\mathcal{R}(Z'')])+\mathcal{R}([\mathcal{R}(Z'),Z''])-\mathcal{R}([Z',Z'']). \tag{22}$$

Notice that we replaced $\mathbb{K}$ by $\mathcal{A}$ for the target space of the regularized infinitesimal characters. The proof follows from the fact that R is $\mathbb{K}$-linear and

$$\begin{aligned}
\mathcal{R}(f)\star\mathcal{R}(g)(T) &= m_{\mathcal{A}}(\mathcal{R}(f)\otimes\mathcal{R}(g))\circ\Delta(T)\\
&= m_{\mathcal{A}}(R(f(T_{(1)}))\otimes R(g(T_{(2)})))\\
&\overset{(1)}{=} -R\circ m_{\mathcal{A}}(f(T_{(1)})\otimes g(T_{(2)}))+R\circ m_{\mathcal{A}}(f(T_{(1)})\otimes R(g(T_{(2)})))\\
&\quad +R\circ m_{\mathcal{A}}(R(f(T_{(1)}))\otimes g(T_{(2)}))\\
&= -R\circ m_{\mathcal{A}}(f\otimes g)\circ\Delta(T)+R\circ m_{\mathcal{A}}(f\otimes\mathcal{R}(g))\circ\Delta(T)+R\circ m_{\mathcal{A}}(\mathcal{R}(f)\otimes g)\circ\Delta(T)\\
&= \mathcal{R}(f\star\mathcal{R}(g))(T)+\mathcal{R}(\mathcal{R}(f)\star g)(T)-\mathcal{R}(f\star g)(T),
\end{aligned} \tag{23}$$

where we used Sweedler's notation $\Delta(T)=\Sigma T_{(1)}\otimes T_{(2)}$ for the coproduct (12), omitting the summation sign above. For the second assertion, we only have to show that $\mathcal{R}:\partial\,\mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}\to\partial\,\mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}$, but this again follows from the $\mathbb{K}$-linearity of R and $\epsilon(T)\in\mathbb{K}$.

Using the double construction and Atkinson's theorem of Sec. II we have the following.

Lemma 3.4: The Rota–Baxter algebra $L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})$ *equipped with the convolution product,*

$$f\star_{\mathcal{R}}g=f\star\mathcal{R}(g)+\mathcal{R}(f)\star g-f\star g, \tag{24}$$

gives a Rota–Baxter algebra structure on the set of linear functionals into the double $\mathcal{A}_R$ *of* $\mathcal{A}$, *denoted by* $L(\mathcal{H}_{\mathrm{rt}},\mathcal{A}_R)$. *An analog for* $\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}}$ *exists and is denoted by* $\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}\mathcal{R}}$. $\mathcal{R}$ *becomes a (Lie) algebra morphism* $(\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}\mathcal{R}}\to\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}})L(\mathcal{H}_{\mathrm{rt}},\mathcal{A}_R)\to L(\mathcal{H}_{\mathrm{rt}},\mathcal{A})$.

Remark 3.5: The above is also true for $\widetilde{R}:=id-R$, respectively $\widetilde{\mathcal{R}}$ (see Remark 2.7). We will denote $\mathcal{R}(\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}})$ by $\mathcal{L}^{-}_{\mathcal{H}_{\mathrm{rt}}^{*}}$ and $\widetilde{\mathcal{R}}(\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}})$ by $\mathcal{L}^{+}_{\mathcal{H}_{\mathrm{rt}}^{*}}$.

We now apply Atkinson's theorem to the Lie algebra $\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}}$ of infinitesimal characters, the generators of the group of Hopf algebra characters $\mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}$.

Lemma 3.6: Every infinitesimal character $Z\in\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}}$ *has a unique subdirect Birkhoff decomposition* $Z=\mathcal{R}(Z)+\widetilde{\mathcal{R}}(Z)$.

Remark 3.7: (1) In the case of an idempotent Rota–Baxter map R we have a direct decomposition $\mathcal{A}=\mathcal{A}_{-}+\mathcal{A}_{+}$, respectively, $\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}}=\mathcal{L}^{-}_{\mathcal{H}_{\mathrm{rt}}^{*}}+\mathcal{L}^{+}_{\mathcal{H}_{\mathrm{rt}}^{*}}$.

(2) Let $Z \in \mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^*}$ be the infinitesimal character generating the character $\phi = \exp^\star(Z) \in \mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}$. Using the result in Proposition 2.8, easily generalized to the noncommutative case, we then see that $\exp^\star(-\mathcal{R}(Z)) = \mathcal{R}(\exp^{\star_{\mathcal{R}}}(-Z))$.

Let us define

$$b[\phi] := \exp^{\star_{\mathcal{R}}}(-Z),$$

which is a character of $\mathcal{H}_{\mathrm{rt}} \to \mathcal{A}_R$, i.e., $b[\phi] \in \mathrm{char}_{\mathcal{A}_R}\mathcal{H}_{\mathrm{rt}}$ and which we will call Bogoliubov's recursion R-map for reasons which will become clear soon. Therefore

$$\begin{aligned}\exp^\star(-\mathcal{R}(Z))(T'T'') &= \mathcal{R}(\exp^{\star_{\mathcal{R}}}(-Z))(T'T'') = R(b[\phi](T') *_R b[\phi](T'')) \\ &= \exp^\star(-\mathcal{R}(Z))(T')\exp^\star(-\mathcal{R}(Z))(T''). \qquad (25)\end{aligned}$$

We then have the following.

Lemma 3.8: The Lie Rota–Baxter map $\mathcal{R}(\tilde{\mathcal{R}})$ becomes a Lie group (anti-) homomorphism from $\mathrm{char}_{\mathcal{A}_R}\mathcal{H}_{\mathrm{rt}}$ to $\mathrm{char}_{\mathcal{A}}^{-(+)}\mathcal{H}_{\mathrm{rt}}$, *where* $\mathrm{char}_{\mathcal{A}}^{-(+)}\mathcal{H}_{\mathrm{rt}}$ *are the Lie subgroups generated by the Lie subalgebras* $\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^*}^{-(+)}$.

As we already mentioned in the Introduction, here we will only consider in detail the simple case of the cocommutative Hopf subalgebra $\mathcal{H}_{l\ \mathrm{rt}}$, respectively $L(\mathcal{H}_{l\ \mathrm{rt}}, \mathcal{A})$. The latter is generated by the $Z_{t_n} \in \partial\,\mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}, n \in \mathbb{N}$ and necessarily is an Abelian Lie algebra $\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}, [Z_{t_n}, Z_{t_m}] = 0, n, m \in \mathbb{N}$.

The Abelianess of $\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}$ and Atkinson's result imply the following theorem [which extends to the non-Abelian case using the appropriate BCH formulas for the (multi-)commutator of $\mathcal{R}(Z)$ with $\tilde{\mathcal{R}}(Z)$].

Theorem 3.9 (Ladder case of integrable renormalization): *Let $\phi \in \mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{l\ \mathrm{rt}}$ be generated by $Z \in \mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}$, i.e.* $\exp^\star(Z) = \phi$. *We have the following factorization*:

$$\exp^\star(Z) = \phi = \exp^\star(\mathcal{R}(Z) + \tilde{\mathcal{R}}(Z)) = \exp^\star(\mathcal{R}(Z)) \star \exp^\star(\tilde{\mathcal{R}}(Z)). \qquad (26)$$

Proposition 3.10: With the same assumption as in Theorem 3.9 and the definitions $\phi_-^{-1} := \exp^\star(\mathcal{R}(Z))$ and $\phi_+ := \exp^\star(\tilde{\mathcal{R}}(Z))$, we have

$$\phi_-(t_n) = \exp^\star(-\mathcal{R}(Z))(t_n) = \mathcal{R}(\exp^{\star_{\mathcal{R}}}(-Z))(t_n) \qquad (27)$$

$$= -R\left\{\phi(t_n) + \sum_{k=1}^{n-1} \phi_-(t_k)\phi(t_{n-k})\right\}, \qquad (28)$$

$$\phi_+(t_n) = \exp^\star(\tilde{\mathcal{R}}(Z))(t_n) = -\tilde{\mathcal{R}}(\exp^{\star_{\mathcal{R}}}(-Z))(t_n) \qquad (29)$$

$$= \tilde{R}\left\{\phi(t_n) + \sum_{k=1}^{n-1} \phi_-(t_k)\phi(t_{n-k})\right\}. \qquad (30)$$

The proof of this proposition follows immediately by Proposition 2.8 and (10) and (11). It can be generalized to the non-Abelian case using the Hochschild cohomology of the Hopf algebra as in Ref. 27 and the resolution of the non-Abelian Lie algebra in terms of its lower central series.

Remark 3.11: (1) From expressions (25), (27), and (29) it is evident that $\phi_\pm$ are characters. We will see the same for the general case.

(2) For the ladder case we therefore arrive at the following result. Since $\exp^{\star}(-\mathcal{R}(Z)) = \mathcal{R}(\exp^{\star_{\mathcal{R}}}(-Z)) =: \mathcal{R}(b[\phi])$ (Remark 3.7), we have

$$b[\phi](t_n) = \exp^{\star_{\mathcal{R}}}(-Z)(t_n) = -\phi(t_n) - \sum_{k=1}^{n-1} \phi_-(t_k)\phi(t_{n-k}).$$

This justifies the name Bogoliubov's $\overline{R}$-map[19] for $b[\phi]$, which finds its natural algebraic formulation as a character $b[\phi]=\exp^{\star_{\mathcal{R}}}(-Z) \in \mathrm{char}_{\mathcal{A}_R} \mathcal{H}_{l\ \mathrm{rt}}$ and which is mapped by the Rota–Baxter operator $\mathcal{R}$ into $\mathrm{char}_{\mathcal{A}} \mathcal{H}_{l\ \mathrm{rt}}$. As mentioned before this result carries over to the general case, i.e., to the noncocommutative Hopf algebras of Feynman graphs or arbitrary decorated rooted trees. Note that formulas (28) and (30) have been established already in Ref. 17, while to express (27) and (29) in a convenient way using the necessary BCH corrections will be reserved to future work.

Also, we would like to underline the similarity with the factorization theorems in Refs. 14–16. We will dwell on this connection in greater depth in the future.

Let us summarize the result in Proposition 3.10. The (Abelian) Lie algebra $\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}$ naturally extends to a Lie Rota–Baxter algebra due to the Rota–Baxter structure on its target space. Therefore it contains two Lie algebra structures with respect to the original Lie bracket and the double coming from the Rota–Baxter map $\mathcal{R}$. Due to Atkinson's theorem it decomposes into two Lie subalgebras $\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}^{-(+)}$ which generate the Lie subgroups $\mathrm{char}_{\mathcal{A}}^{-(+)} \mathcal{H}_{l\ \mathrm{rt}}$. The infinitesimal decomposition on $\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}$ extends in the ladder case to the global factorization on the Lie group $\mathrm{char}_{\mathcal{A}} \mathcal{H}_{l\ \mathrm{rt}}$. We have the following diagrams on the Lie algebra level, respectively, Lie group level.

Let b denote Bogoliubov's recursion formula, which is defined in terms of the exponential with respect to the double product $\star_{\mathcal{R}}$. We define $\mathcal{G}^l := \mathrm{char}_{\mathcal{A}} \mathcal{H}_{l\ \mathrm{rt}}, \mathcal{G}_{\mathcal{R}}^l := \mathrm{char}_{\mathcal{A}_R} \mathcal{H}_{l\ \mathrm{rt}}$ and $\mathcal{G}^{l\pm} := \mathrm{char}_{\mathcal{A}}^{\pm} \mathcal{H}_{l\ \mathrm{rt}}$:

$$\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^* \mathcal{R}} \overset{(\mathcal{R},\mathcal{R}-id)}{\rightarrow} (\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}^-, \mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}^+) \overset{(id,-id)}{\rightarrow} \mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^*}. \tag{31}$$

Here, $Z=\mathcal{R}(Z)-(\mathcal{R}-id)(Z)=(id,-id)\circ(\mathcal{R},\mathcal{R}-id)(Z)$ gives the infinitesimal factorization, i.e., Atkinson's theorem:

$$\mathcal{G}^l \overset{b}{\rightarrow} \mathcal{G}_{\mathcal{R}}^l \overset{(-\mathcal{R}\otimes\tilde{\mathcal{R}})}{\rightarrow} (\mathcal{G}^{l-}, \mathcal{G}^{l+}) \overset{m_{\mathcal{G}^l}}{\rightarrow} \mathcal{G}^l. \tag{32}$$

The last diagram contains the global factorization, i.e. on the level of the Lie group $\mathcal{G}^l$ coming from the Lie algebra $\mathcal{L}_{\mathcal{H}_{l\ \mathrm{rt}}^*}$.

Remark 3.12: (1) Using the idea of normal coordinates in Ref. 31, we may relate the simple rooted ladder graphs, given by Schur polynomials $P^{(n)}(t_1,\ldots,t_n)$ of order n for each rooted ladder tree t_n and the $\phi_\pm$ character in the following way. [Schur polynomial of order $n, P^{(n)}$: Taylor expansion of $\log(\Sigma_{n\geq 0} t_n x^n) = \Sigma_{n\geq 0} P^{(n)}(t_1,\ldots,t_n)x^n$.[31]] Starting with the regularized character $\phi: \mathcal{H}_{\mathrm{rt}} \rightarrow \mathcal{A}$, we define the series (we omit tensor product signs)

$$Z_\phi := \sum_{n>0} Z_{t_n} \phi(P^{(n)}(t_1,\ldots,t_n)) \in \mathrm{char}_{\mathbb{K}} \mathcal{H}_{\mathrm{rt}} \otimes \mathcal{A}.$$

It then follows from Ref. 31 that $\exp^{\star}(Z_{\phi})(t_n)=\phi(t_n)$, i.e. Z_{ϕ} is the infinitesimal character generating the Lie group element ϕ. As an example we calculate $\phi_{-}(\bullet\!\!\uparrow)$:

$$\begin{aligned} exp^{\star}(-\mathcal{R}(Z_{\phi}))(\bullet\!\!\uparrow) &= \Big\{ -Z_{\bullet\!\!\uparrow}R\big(\phi(P^{(3)}(\bullet,\bullet,\bullet\!\!\uparrow))\big) \\ &\quad +\frac{1}{2}(Z_{\bullet}\star Z_{\bullet\!\!\uparrow}+Z_{\bullet\!\!\uparrow}\star Z_{\bullet})R(\phi(\bullet))R\big(\phi(P^{(2)}(\bullet,\bullet\!\!\uparrow))\big) \\ &\quad +\frac{-1}{3!}Z_{\bullet}\star Z_{\bullet}\star Z_{\bullet}R(\phi(\bullet))^3\Big\}\Big(\bullet\!\!\uparrow\Big) \\ &= -R\Big(\phi\big(P^{(3)}(\bullet,\bullet,\bullet\!\!\uparrow)\big)-R(\phi(\bullet))R\big(\phi(P^{(2)}(\bullet,\bullet\!\!\uparrow))\big) \\ &\qquad +\frac{1}{3!}R(\phi(\bullet))^3\Big). \end{aligned}$$

(2) Let us briefly outline the approach to the general case. The full Lie algebra of infinitesimal characters $\mathcal{L}_{\mathcal{H}_{\mathrm{rt}}^{*}}$ is of course non-Abelian and therefore the factorization has to include contributions in a subtractive manner to eliminate BCH terms. This may be achieved in a systematic way using the Baker–Campbell–Hausdorff (BCH) functional,

$$\mathrm{BCH}(A,B) := \frac{1}{2}[A,B]+\frac{1}{12}([A,[A,B]]-[B,[A,B]])+\cdots,$$

which starts with a commutator, i.e., is of order >1 in the number of infinitesimal characters. Recursively, order by order in the grading on $\mathcal{H}_{\mathrm{rt}}$, the correct contributions may be calculated. The first term of second order essentially takes care of the cherry tree $\curlywedge$ renormalization:

$$\chi^{(2)}=-\frac{1}{2}[\mathcal{R}(Z),Z],$$

for $\phi=\exp^{\star}(Z)\in \mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}$ and which should be compared to (19). Again, the normal coordinates theorem in Ref. 31 provides a convenient way to identify terms from the BCH formula. This way we derive the implicitly given formulas for $\phi_{\pm}$ in Ref. 19, respectively give an explicit formula for them in terms of the exponential map and an element in the image of the Rota–Baxter maps $\mathcal{R}$, respectively $\widetilde{\mathcal{R}}$.

(3) The present setting resembles the loop algebra-group case of integrable systems theory. The generalization takes place by using a general Rota–Baxter algebra as the target space. In a later publication we will dwell more carefully on this point.

(4) Following the recent work by Sakakibara[32] we derive the scattering type formula for $\phi_{\pm}$. We first extend the Lie algebra $\partial\,\mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}$ by an element Z_0 such that $[Z_0,Z_T]=Y(Z_T):=\#(T)Z_T$ where Y is the grading operator $Y(T):=\#(T)$, i.e. a derivation on $\mathcal{H}_{\mathrm{rt}}$ (see Ref. 20 for details). This implies a one parameter group $\theta_t\in\mathrm{Aut}(\mathcal{H}_{\mathrm{rt}})$ acting on $\mathrm{char}_{\mathcal{A}}\,\mathcal{H}_{\mathrm{rt}}$ by

$$\langle\theta_t(\phi),T\rangle := \langle\phi,\theta_t(T)\rangle,$$

i.e. $\theta_t=\mathrm{Ad}_{\exp^{\star}(tZ_0)}$, and such that $(d\theta_t/dt)|_{t=0}=Y$. We then define a so-called β-function:

$$\beta(\phi) := \phi_{\pm}\star Y(\phi_{\pm}^{-1})=\phi_{\pm}\star[Z_0,\phi_{\pm}^{-1}]=\phi_{\pm}\star Z_0\star\phi_{\pm}^{-1}-Z_0,$$

such that[32]

$$\exp^{\star}(t(\beta(\phi)+Z_0))\star\exp^{\star}(-tZ_0)=\phi_{\pm}\star\theta_t(\phi_{\pm}^{-1})\overset{t\to\infty}{\longrightarrow}\phi_{\pm}.$$

This should be compared to the expression we found for $\phi_{\pm}$ in terms of the Rota–Baxter map $\mathcal{R}$.

IV. SUMMARY, CONCLUSION AND OUTLOOK

In an earlier work[19] the combinatorics of renormalization in pQFT was described in terms of a Birkhoff factorization of the regularized Hopf algebra characters. The identification of the singular part ϕ_- as a character relies on the Rota–Baxter structure on the target space of the characters. Emphasizing the latter point and restricting for pedagogical reasons to the simple case of rooted ladder trees we were able to derive the twisted antipode formula for the singular part of the Birkhoff decomposition, solely using the properties of the Rota–Baxter map lifted to the Lie algebra of infinitesimal characters.

Extending this simple exercise to the general case of a noncocommutative Hopf algebra poses no conceptual challenge but becomes technically more demanding and will be presented elsewhere.

In our view it is important to underline that it is the Lie algebra of rooted trees, or more generally the insertion-elimination Feynman Lie algebra, which completely describes the process of renormalization in pQFT. This will become even more apparent when we treat the general case, indicated in the last remark in Sec. III. These results strongly indicate that there is a deeper link between the realm of (classically) integrable systems and the RG-flows. The last point especially demands for a deeper understanding of the Lie algebra of infinitesimal characters, respectively, the Lie Group of regularized characters. We hope that this may be partly achieved by analyzing the link to the well established field of integrable systems.

(Received 19 April 2004; accepted 7 June 2004; published 12 October 2004)

We realize the physical N-anyon Hilbert spaces, introduced previously via unitary representations of the group of diffeomorphisms of the plane, as N-fold braided-symmetric tensor products of the 1-particle Hilbert space. This perspective provides a convenient Fock space construction for nonrelativistic anyon quantum fields along the more usual lines of boson and fermion fields, but in a braided category, and clarifies how discrete (lattice) anyon fields relate to anyon fields in the continuum. We also see how essential physical information is encoded. In particular, we show how the algebraic structure of the anyonic Fock space leads to a natural anyonic exclusion principle related to intermediate occupation number statistics, and obtain the partition function for an idealized gas of fixed anyonic vortices. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1787620]

I. INTRODUCTION

Anyons are particles or excitations in two-dimensional space that obey exchange statistics interpolating those of bosons and fermions. When two identical anyons are exchanged without coincidence along a continuous path in the plane, their relative winding number m (the net number of counterclockwise exchanges) is well-defined, depending only on the homotopy class of the path implementing the exchange. The quantum-mechanical wave function then acquires a relative phase $e^{im\theta}$, where θ is a real fixed parameter between 0 and 2π. When $\theta=0$ we have bosons, and $\theta=\pi$ corresponds to fermions.

The possibility of such intermediate statistics was suggested by Leinaas and Myrheim[1] and confirmed by Goldin, Menikoff, and Sharp,[2] who derived the quantum theory rigorously from representations of local nonrelativistic current algebra and the corresponding diffeomorphism group. They obtained the anyonic shifts in angular momentum and energy spectra, and made connections with configuration space topology and the physics of charged particles circling regions of magnetic flux. The term "anyon" was subsequently introduced by Wilczek,[3] who proposed a model for such objects based on charged-particle/flux-tube composites and suggested their association with fractional spin in two dimensions. The idea found some immediate applications to surface phenomena and related areas of physics.[4,5] Reference 6 clarified that the shift in the angular momentum spectrum associated with anyons is in the kinetic (or orbital) angular momentum, not the canonical (or total) angular momentum.

In Ref. 7 the *braid group* B_N was identified as the group whose one-dimensional representations describe the anyonic wave function symmetry. A more extensive discussion of the braid group and anyon statistics followed in Ref. 8, where it was argued that only the one-dimensional

a)Electronic mail: gagoldin@dimacs.rutgers.edu
b)Electronic mail: s.majid@qmw.ac.uk

representations of B_N should occur in quantum mechanics. However, as noted in Ref. 9, the diffeomorphism group approach allows also the possibility of quantum systems described by higher-dimensional representations of B_N (particles later termed "plektons"). An overview of that approach, which underlies the present article, may be found in Ref. 10.

The extensive development of these ideas that occurred during the 1980s and early 1990s, including their relation to Chern–Simons quantum field theories, their application in describing the integer and fractional quantum Hall effects, and their role in describing possible mechanisms for superconductivity, are reviewed in Refs. 11 and 12.

Anyonic systems can also be associated with quantum groups and q-deformations of classical Lie algebras.[13–17] In Ref. 18 it was shown that creation and annihilation fields for anyons could be constructed so as to intertwine the N-anyon representations of the group of compactly supported diffeomorphisms $\mathrm{Diff}_c(\mathbb{R}^2)$ in the Hilbert space $\mathcal{H}_N$ of N-particle states. The assumption that these fields transform consistently with the diffeomorphism group representations dictates the form they should take; and the fact that they obey q-commutation relations, where q is the anyonic phase shift, emerges as a consequence of this. In this work, the spaces $\mathcal{H}_N$ were constructed (for each N) using "topological configurations" of N points equipped with attached filaments going out to infinity in the plane.

In the present article, we show how to construct such a theory along lines more familiar from bosonic (respectively, fermionic) algebras of canonical commutation (resp. anticommutation) relations—i.e., CCR (resp. CAR) algebras—where the N-particle Fock subspaces are built up by symmetrizing or antisymmetrizing sets of 1-particle states. We shall effectively "q-symmetrize"[19] using braided category techniques coming out of quantum group theory,[20] so that

$$\mathcal{H}_N = \mathcal{H}_1 \underset{s}{\otimes} \mathcal{H}_1 \underset{s}{\otimes} \cdots \underset{s}{\otimes} \mathcal{H}_1$$

(N times), where $\otimes_s$ is the symmetrized tensor product with respect to a certain symmetry Ψ_0. A difficulty in formulating anyonic field theory this way has been the apparent need to work in a *strictly* braided category, with a braiding Ψ defined by q. The fact that the braid group is infinite would then seem to require an infinite sum of powers of q. But it turns out that the associated operator Ψ_0 obeys the condition $\Psi_0^2 = \mathrm{id}$. Thus it generates an action of the symmetric group S_N, rather than the braid group B_N. In effect, the nontrivial braid group representation and its inverse conspire with each other to give us a braided tensor category that is actually *symmetric* (up to sets of measure zero).

Moreover, in our construction the full anyonic Fock space $S_{\Psi_0}(\mathcal{H}_1)$, obtained as the direct sum of the different spaces $\mathcal{H}_1 \otimes_s \cdots \otimes_s \mathcal{H}_1$, is an algebra with product $\otimes_s$. This algebra generalizes the algebra of functions on a linear space or superspace in the Bose or Fermi cases, with its respective commutative or anticommutative product. The annihilation and creation operators in our construction then act by pointwise multiplication and (functional) differentiation on this space, exactly in conformity with the usual functional representation in field theory. The difference is that the anyonic case only makes sense in a braided category, with a braiding Ψ. In this category $S_{\Psi_0}(\mathcal{H}_1)$ is the "coordinate ring" of a braided group, with the braided coproduct $\underline{\Delta}$ expressing addition.[13,20–22] The use here of *two* Yang–Baxter operators Ψ and Ψ_0 is a general feature of the theory of such "braided linear spaces," and the strictness of the braiding Ψ is essential for this.

As an important application, we show how the structure of $S_{\Psi_0}(\mathcal{H}_1)$ as the braided version of the coordinate algebra of a linear space leads to an "anyonic exclusion principle" when q is a root of unity. Specifically, with $q^r = 1$, the creation operator $\psi^*(x)$ cannot occur in a reduced Fock state more than $r-1$ times. This important physical fact means that the relevant occupation number statistics is of the nature of Gentile statistics,[23] and has some similarities to other algebraic approaches to generalized exclusion principles such as that proposed in Ref. 24. The exclusion also applies to states obtained from the smeared field; i.e., $\psi^*(h)^r = 0$ in our Hilbert space representation for any test function h. Earlier articles have approached the fractional exclusion statistics of a one-dimensional gas, or of anyons in two space dimensions, from quite different perspectives;[25–30] see also Ref. 31.

An outline of the present article is as follows: In Sec. II we summarize the topological construction of the spaces $\mathcal{H}_N$ of N-anyon states, and write the corresponding current algebra, diffeomorphism group, and anyon creation and annihilation field representations. In Sec. III we carry out our construction using braided symmetric tensor categories, and in Sec. IV we show that this indeed leads to the same result as the earlier topological construction. In Sec. V we provide some algebraic consequences, including the anyonic exclusion principle when q is a root of unity. Throughout we consider both the physical continuum case and the discrete case, as the latter may be useful for lattice versions of the theory or for anyon fields on a finite number of points. The discrete case turns out to have a number of instructive subtleties. Finally, in Sec. VI we offer some further comments of a conceptual nature.

II. TOPOLOGICAL STATE SPACES $\mathcal{H}_N$

We begin by recalling the set-up for anyon field representations proposed in Ref. 18. For the nonrelativistic quantum theory of identical particles in n space dimensions, we are interested in representations ρ, J of the semidirect sum Lie algebra $C_c^\infty(\mathbb{R}^n) \rtimes \mathrm{vect}_c(\mathbb{R}^n)$, where ρ and J are self-adjoint operator-valued distributions describing the mass and momentum densities, respectively, i.e.,

$$\rho(f) = \int \rho(x) f(x) \mathrm{d}^n x, \quad J(v) = \int J(x) \cdot v(x) \mathrm{d}^n x,$$

where the test function $f \in C_c^\infty(\mathbb{R}^n)$ is a compactly-supported real-valued C^∞ function on $\mathbb{R}^n$, and $v \in \mathrm{vect}_c(\mathbb{R}^n)$ is a compactly-supported (tangent) vector field on $\mathbb{R}^n$. Then the well-known current algebra

$$[\rho(f), \rho(g)] = 0, \quad [\rho(f), J(v)] = i\hbar \rho(\nabla_v f), \quad [J(v), J(w)] = -i\hbar J([v,w]) \tag{1}$$

represents the bracket in the Lie algebra, where $[v,w]$ is the usual Lie bracket of vector fields. The group-level version is based on the natural semidirect product of the group of compactly-supported functions under addition, with the group of compactly-supported diffeomorphisms of $\mathbb{R}^n$ under composition: $G = C_c^\infty(\mathbb{R}^n) \rtimes \mathrm{Diff}_c(\mathbb{R}^n)$, with $(f,\phi)\cdot(g,\psi) = (f + g\circ\phi, \psi\circ\phi)$. Then in a continuous unitary representation of G, we can write the 1-parameter subgroups $U(f)$ and $V(\phi_t)$, where ϕ_t is the flow on $\mathbb{R}^n$ generated by v. Under appropriate conditions, the self-adjoint generators defined from $U(f) = e^{i\rho(f)}$ and $V(\phi_t) = e^{i(t/\hbar)J(v)}$ represent the current algebra. The idea is that different physical systems in quantum mechanics should correspond to different (unitarily inequivalent) irreducible representations of G.

In particular consider a family $\mathcal{H}_N$ of Hilbert spaces, where $N \in \mathbb{N}$, along with annihilation operators $\psi(h)$ and creation operators $\psi^*(h)$, where the test functions h belong to a domain in $\mathcal{H}_1$. Thus

$$\psi(h): \mathcal{H}_{N+1} \to \mathcal{H}_N, \quad \psi^*(h): \mathcal{H}_N \to \mathcal{H}_{N+1}.$$

Suppose we have representations U_N, V_N in $\mathcal{H}_N$ of the group $G = C_c^\infty(\mathbb{R}^n) \rtimes \mathrm{Diff}_c(\mathbb{R}^n)$, for each N, intertwined by ψ and ψ^* in such a way that

$$U_{N+1}(f)\psi^*(h) = \psi^*(U_1(f)h) U_N(f), \quad V_{N+1}(\phi)\psi^*(h) = \psi^*(V_1(\phi)h) V_N(\phi). \tag{2}$$

Then the U_N, V_N $(N = 1,2,3,\ldots)$ are interpreted as a *hierarchy* of representations of G describing systems of N particles (or quantum excitations) of the species created and annihilated by the field operators. At the level of the algebra, the corresponding requirements are

$$[\rho(f), \psi^*(h)] = \psi^*(\rho_1(f)h), \quad [J(v), \psi^*(h)] = \psi^*(J_1(v)h). \tag{3}$$

Here ψ^* is the adjoint of ψ; but we note that later, when we consider the discrete anyonic case, that will be modified.

When $n=2$, one has the possibility in this general framework of anyonic representations of G, and corresponding fields satisfying Eqs. (2) and (3). Then the representation U_N, V_N of G acts in the Hilbert space

$$\mathcal{H}_N = L^2_{B_N}(\tilde{\Delta}_N),$$

defined as follows. The configuration space Δ_N for N identical anyons is the space of (unordered) N-point subsets of $\mathbb{R}^2$; thus $\gamma \in \Delta_N$ is given by $\gamma=\{x_1,\ldots,x_N\}\subset\mathbb{R}^2$. The fundamental group $\pi_1(\Delta_N)$ is B_N, the braid group on N-strands. We denote by $\tilde{\Delta}_N$ the universal covering space of Δ_N, which has infinitely many sheets; for $\tilde{\gamma}\in\tilde{\Delta}_N$, we have the projection map $p:\tilde{\gamma}\to\gamma$. The braid group then acts on $\tilde{\Delta}_N$; writing this action as $\tilde{\gamma}\to\tilde{\gamma}\cdot b$ for $b\in B_N$, we have $p(\tilde{\gamma}\cdot b)=p(\tilde{\gamma})$. The elements of $\mathcal{H}_N$ are now wave functions $\tilde{\Phi}$ on $\tilde{\Delta}_N$, taking values in an inner product space $\mathcal{V}$ that carries a unitary representation $T(b)$ of B_N. We shall consider only the case $\mathcal{V}=\mathbb{C}$ (scalar-valued wave functions), and one-dimensional representations of B_N. Such a representation is specified by choosing a fixed phase $q=\exp i\theta$, and setting $T(b)=q$ when b is the crossing of one strand over another in a forward (left over right) direction. The wave functions are required to be *equivariant* under T, in the sense that for all $b\in B_N$,

$$\tilde{\Phi}(\tilde{\gamma}\cdot b) = T(b)\tilde{\Phi}(\tilde{\gamma}).$$

In other words, $\tilde{\Phi}\in\mathcal{H}_N$ is an equivariant section of a vector bundle over $\tilde{\Delta}_N$. When $\tilde{\Phi}_1$ and $\tilde{\Phi}_2$ satisfy the same such equivariance condition, the product $\overline{\tilde{\Phi}_1(\tilde{\gamma})}\tilde{\Phi}_2(\tilde{\gamma})$ depends only on $\gamma=p(\tilde{\gamma})$, and not on the particular choice of $\tilde{\gamma}$ within $p^{-1}(\gamma)$ at which $\tilde{\Phi}_1$ and $\tilde{\Phi}_2$ are evaluated. Thus we may write the integral of this product with respect to a (local) Lebesgue measure $dx_1\cdots dx_N$ on Δ_N. Finally, we take $\mathcal{H}_N$ to consist of the square-integrable functions, so that for any pair $\tilde{\Phi}_1$, $\tilde{\Phi}_2$,

$$\langle\tilde{\Phi}_1,\tilde{\Phi}_2\rangle = \int_{\Delta_N}\overline{\tilde{\Phi}_1(\tilde{\gamma})}\tilde{\Phi}_2(\tilde{\gamma})dx_1\cdots dx_N<\infty \tag{4}$$

defines the inner product of $\tilde{\Phi}_1$ with $\tilde{\Phi}_2$ in $\mathcal{H}_N$.

Given any diffeomorphism ϕ of $\mathbb{R}^2$, let ϕ act on Δ_N in the obvious way. This action lifts to an action on $\tilde{\Delta}_N$ compatible with the projection map, i.e., if $p(\tilde{\gamma})=\gamma$, then $p(\phi\tilde{\gamma})=\phi\gamma$. The N-anyon representation in $\mathcal{H}_N$ is then defined by

$$U_N(f)\tilde{\Phi}(\tilde{\gamma}) = e^{i\Sigma_{j=1}^N f(x_j)}\tilde{\Phi}(\tilde{\gamma}),\quad V_N(\phi)\tilde{\Phi}(\tilde{\gamma}) = \tilde{\Phi}(\phi\tilde{\gamma})\prod_{j=1}^N\sqrt{\mathcal{J}_\phi(x_j)}, \tag{5}$$

where $\mathcal{J}_\phi$ is the Jacobian of ϕ. The factor of $\Pi_{j=1}^N\sqrt{\mathcal{J}_\phi(x_j)}$ means that V_N transforms $\overline{\tilde{\Phi}_1(\tilde{\gamma})}\tilde{\Phi}_2(\tilde{\gamma})\ \Pi_{j=1}^N dx_j$ to $\overline{\tilde{\Phi}_1(\phi\tilde{\gamma})}\tilde{\Phi}_2(\phi\tilde{\gamma})\ \Pi_{j=1}^N\mathcal{J}_\phi(x_j)dx_j$, and thus does not change the value of the inner product.

One may construct these representations more explicitly as follows. We describe an element of $\tilde{\Delta}_N$ by a set of nonintersecting paths $\Gamma=\{\Gamma_1,\ldots,\Gamma_N\}$ in the plane, extending from infinity in (let us say) the negative y-direction, and terminating in the unordered set γ of N distinct points in $\mathbb{R}^2$. Then $\tilde{\Delta}_N$ is the set of homotopy classes of such Γ, with the projection map given by mapping Γ to the set of its end points. We shall call the homotopy class of Γ a "topological configuration." Moreover, we can lift any configuration $\gamma\in\Delta_N$ (with the exception of a measure zero set) to the element Γ_0^γ belonging to $\tilde{\Delta}_N$, given by taking paths that go vertically downward (in the negative y-direction) from each point in γ. This defines a sheet $\Gamma_0(\Delta_N)\subset\tilde{\Delta}_N$ that we conventionally associate with the identity element of B_N. Now diffeomorphisms in $\mathrm{Diff}_c(\mathbb{R}^2)$ act as the identity at $y=-\infty$ since they are compactly supported, and so they lift from Δ_N to act on the space of topological configurations.

Consider the subgroup $\mathrm{Diff}_c^\gamma(\mathbb{R}^2)$ of diffeomorphisms that take the set of end points γ of a fixed topological configuration Γ into itself. This is the stability subgroup for the point $\gamma \in \Delta_N$. A diffeomorphism $\phi \in \mathrm{Diff}_c^\gamma(\mathbb{R}^2)$ then determines an element of B_N by its action on Γ_0^γ, denoted by $b = h_\gamma(\phi)$. Moreover, given any topological configuration Γ with end points γ, we can obtain it by starting with Γ_0^γ (with the same end points γ), and applying a diffeomorphism $\phi \in \mathrm{Diff}_c^\gamma(\mathbb{R}^2)$, so that $\phi\Gamma_0^\gamma = \Gamma$. Then h_γ is a surjective homomorphism, from $\mathrm{Diff}_c^\gamma(\mathbb{R}^2)$ onto B_N. A topological configuration Γ with end points γ is conventionally identified with the pair (γ, b); when b is the identity element, we have Γ_0^γ. The equivariance condition in this description becomes

$$\tilde{\Phi}(\Gamma) = T(b)\tilde{\Phi}(\Gamma_0^\gamma).$$

Thus it is enough to specify $\tilde{\Phi}$ on the sheet $\Gamma_0(\Delta_N)$; the equivariance condition then defines it almost everywhere in $\tilde{\Delta}_N$.

In this explicit realization, one next defines the creation and annihilation fields intertwining the N-anyon representations (5) in accordance with Eqs. (2) or (3). Given an N-point subset $\gamma \subset \mathbb{R}^2$, and $x \in \mathbb{R}^2$, let us denote by Γ_x^γ the element of $\tilde{\Delta}_{N+1}$ that is obtained by *adjoining* to Γ_0^γ an additional path, terminating at x, that extends toward $y = -\infty$ on the *left* of all the paths in Γ_0^γ (this modifies the convention in Ref. 18). Then we set

$$(\psi(x)\tilde{\Phi})(\Gamma_0^\gamma) = \tilde{\Phi}(\Gamma_x^\gamma).$$

To write the adjoint field, let $\hat{\gamma}_j = \gamma - \{x_j\}$, where j refers to some indexing of the elements of γ. The topological configuration $\Gamma_x^{\hat{\gamma}_j}$ then defines an element of $\tilde{\Delta}_N$, with the set of terminal points $\hat{\gamma}_j \cup \{x\}$. Express $\Gamma_x^{\hat{\gamma}_j}$ as $\phi\Gamma_0^{\hat{\gamma}_j \cup \{x\}}$, and define $b_{x,j} = h_{\hat{\gamma}_j \cup \{x\}}(\phi)$. Then

$$(\psi^*(x)\tilde{\Phi})(\Gamma_0^\gamma) = \sum_{j=1}^{N} \delta(x - x_j)\tilde{\Phi}(\Gamma_0^{\hat{\gamma}_j}) T^*(b_{x,j}).$$

In this realization, one can recover the local current algebra (1) by defining

$$\rho(x) = \psi^*(x)\psi(x), \quad J(x) = \frac{\hbar}{2i}(\psi^*(x)(\nabla\psi)(x) - (\nabla\psi^*)(x)\psi(x)), \tag{6}$$

where ρ is the number density of anyons and J is the momentum density. Then also

$$[\rho(f), \psi^*(h)] = \psi^*(fh), \quad [J(v), \psi^*(h)] = \frac{\hbar}{2i}\psi^*(\nabla_v h + \nabla \cdot (vh)), \tag{7}$$

which are precisely Eqs. (3). Equations (1), (3), and (6) are the same in the anyonic case as in the usual Bose or Fermi cases. But now we have, in place of the CCR or CAR algebras, the following equal-time q-commutation relations:[18] in the half-space $x^1 < y^1$, with $[A, B]_q = AB - qBA$ (where the phase q generates the representations $T(b)$ of B_N),

$$[\psi(x), \psi(y)]_q = [\psi^*(x), \psi^*(y)]_q = 0, \quad [\psi(y), \psi^*(x)]_q = \delta(x - y). \tag{8}$$

In the complementary half-space $x^1 > y^1$, q must be replaced by $\bar{q} = q^{-1}$. The choice of a half-space, like the definition of the sheet $\Gamma_0(\Delta_N)$, is conventional and has no physical consequence.

III. ANYONIC FOCK SPACE CONSTRUCTION

For the usual bosonic or fermionic representations, we have of course a more conventional construction. Let $\mathcal{H} = \mathcal{H}_1 = L^2(\mathbb{R}^n)$ be the space of 1-particle states, and $\mathcal{H}_N = \mathcal{H}^{\otimes_s N}$ be a symmetrized or skew symmetrized tensor product. Then $\psi^*(h) = h\otimes_s$ and $\psi(h)$ is given by the interior product, yielding the usual equal-time commutation or anticommutation relations, respectively. In this section we give such a "Fock space" construction, more in line with the usual Bose or Fermi

cases but now with nontrivial q-statistics. We then show in Sec. IV that in the continuum case it is isomorphic to the topological construction of Ref. 18 described above. We shall use the machinery of braided linear spaces and braided Weyl algebras as described in Refs. 20–22, and elsewhere.

Let us start with a construction that works for any totally ordered space $(X,<)$. We shall initially take X to be discrete. Note that we do *not* assume here that ψ^* is the adjoint of ψ, although this turns out to be true in the continuum case (see Sec. VI); a more complicated relation holds between ψ and ψ^* in the discrete case. Subsequently we consider $X=\mathbb{R}^2$, with $x<y$ if $x^1<y^1$, or if $x^1=y^1$ then $x^2<y^2$.

Let $\mathcal{H}$ denote a space of functions on X, and $\{\delta_x\}$ a basis of δ-functions. We also define the functions

$$\epsilon_0(x,y)=\begin{cases}1 & \text{if } x<y,\\ 0 & x=y,\\ -1 & x>y,\end{cases}$$

$$\epsilon(x,y)=\begin{cases}1 & \text{if } x\leqslant y,\\ -1 & x>y.\end{cases}$$

These are almost, but not quite, the same. Even in the continuum case they are not quite the same, because of the existence of distributions with support on the set $x=y$. In what follows, we derive a version of the equal time q-commutation relations (8) as

$$\psi(x)\psi(y)=q^{\epsilon_0(x,y)}\psi(y)\psi(x),\quad \psi^*(x)\psi^*(y)=q^{\epsilon_0(x,y)}\psi^*(y)\psi^*(x),$$

$$\psi(x)\psi^*(y)-q^{\epsilon(y,x)}\psi^*(y)\psi(x)=\delta(x-y),\quad \forall\, x,y\in X, \tag{9}$$

where as noted ψ^* is not the same as the adjoint operator $\psi^\dagger$. Equations (9) are the refinement of Eqs. (8) that comes out of our Fock space construction, and are consistent with the representations of the fields described using the topological configurations above.

A. Discrete version

Let $(X,<)$ be a discrete totally ordered space, $\mathcal{H}$ a space of functions on X, and δ_x the function that is 1 on x and 0 elsewhere in X. We define the generalized flip (or braiding) operators Ψ, $\Psi_0:\mathcal{H}\otimes\mathcal{H}\to\mathcal{H}\otimes\mathcal{H}$ by

$$\Psi_0(\delta_x\otimes\delta_y)=q^{\epsilon_0(x,y)}\delta_y\otimes\delta_x,\quad \Psi(\delta_x\otimes\delta_y)=q^{\epsilon(x,y)}\delta_y\otimes\delta_x. \tag{10}$$

These both obey the familiar braid or Yang–Baxter relations

$$\Psi_{12}\Psi_{23}\Psi_{12}=\Psi_{23}\Psi_{12}\Psi_{23},$$

where the numerical subscripts refer to the position in $\mathcal{H}^{\otimes 3}$. They also satisfy the cross-compatibility conditions

$$(\Psi+\mathrm{id})(\Psi_0-\mathrm{id})=0,\quad (\Psi_0)_{12}\Psi_{23}\Psi_{12}=\Psi_{23}\Psi_{12}(\Psi_0)_{23},\quad \Psi_{12}\Psi_{23}(\Psi_0)_{12}=(\Psi_0)_{23}\Psi_{12}\Psi_{23}. \tag{11}$$

In addition $\Psi_0^2=\mathrm{id}$, but this fact and the braid relations for Ψ_0 are not essential here.

One can write these operators in an R-matrix form: $\Psi(\delta_x\otimes\delta_y)=\delta_b\otimes\delta_a R^{a\ b}_{\ x\ y}$ (summing over the repeated variables a, b), with $R^{a\ b}_{\ x\ y}=\delta^a_{\ x}\delta^b_{\ y}q^{\epsilon(x,y)}$; and similarly for Ψ_0, in terms of a matrix R'. Associated to any such R, R'-matrices (Ref. 20, Th. 10.2.1) is a "braided linear space" which in our case we denote $S_{\Psi_0}(\mathcal{H})$. It is defined as the quadratic algebra generated by formal products of the $\{\delta_x\}$ generators, modulo the relations

$$\delta_x \underset{s}{\otimes} \delta_y = \underset{s}{\otimes}(\Psi_0(\delta_x \otimes \delta_y)) \equiv \delta_y \underset{s}{\otimes} \delta_x q^{\epsilon_0(x,y)}, \tag{12}$$

where we denote the product in $S_{\Psi_0}(\mathcal{H})$ by $\otimes_s$. The actual braiding Ψ enters in the braided coproduct $\underline{\Delta}: S_{\Psi_0}(\mathcal{H}) \to S_{\Psi_0}(\mathcal{H}) \otimes S_{\Psi_0}(\mathcal{H})$, that makes $S_{\Psi_0}(\mathcal{H})$ a braided group or a Hopf algebra in a braided category. On generators, this is just the linear coproduct given by $\underline{\Delta}\delta_x = \delta_x \otimes 1 + 1 \otimes \delta_x$, but it extends to products under $\otimes_s$ via Ψ; thus

$$\underline{\Delta}(\delta_x \underset{s}{\otimes} \delta_y) = (\delta_x \underset{s}{\otimes} \delta_y) \otimes 1 + \delta_x \otimes \delta_y + q^{\epsilon(x,y)} \delta_y \otimes \delta_x + 1 \otimes (\delta_x \underset{s}{\otimes} \delta_y). \tag{13}$$

As explained in Ref. 20, for the theory of braided spaces one needs not one but *two* operators. One of these operators controls the "internal" noncommutativity of the algebra, and the other controls the "external" noncommutativity or braid statistics with other independent copies. In our case, the physics actually dictates the use of Ψ rather than Ψ_0 in the second role; as only this choice in Eq. (13) correctly reduces to the constant minus sign in the flip for fermions when $q=-1$.

Next, we define the operators ψ_x^* and ψ^x on $S_{\Psi_0}(\mathcal{H})$, by left multiplication and braided differentiation, respectively. Let $[N+1, \Psi] = \mathrm{id} + \Psi_{12} + \Psi_{12}\Psi_{23} + \cdots + \Psi_{12}\cdots\Psi_{N,N+1}$ be the braided integer matrix,[20,22] where, for example, Ψ_{12} denotes Ψ acting in the (1, 2) pair of copies of $\mathcal{H}$. Then,

$$\psi_x^*(\delta_{x_1} \underset{s}{\otimes} \cdots \underset{s}{\otimes} \delta_{x_N}) = \delta_x \underset{s}{\otimes} \delta_{x_1} \underset{s}{\otimes} \cdots \underset{s}{\otimes} \delta_{x_N}, \tag{14}$$

and

$$\begin{aligned}\psi^x(\delta_{x_1} \underset{s}{\otimes} \cdots \underset{s}{\otimes} \delta_{x_{N+1}}) &= \delta_{y_2} \underset{s}{\otimes} \cdots \underset{s}{\otimes} \delta_{y_{N+1}} [N+1, \Psi]^{x y_2 \cdots y_{N+1}}_{x_1 x_2 \cdots x_{N+1}} \\ &= \delta^x_{x_1} \delta_{x_2} \underset{s}{\otimes} \cdots \underset{s}{\otimes} \delta_{x_{N+1}} + q^{\epsilon(x_1,x)} \delta^x_{x_2} \delta_{x_1} \underset{s}{\otimes} \delta_{x_3} \underset{s}{\otimes} \cdots \underset{s}{\otimes} \delta_{x_{N+1}} \\ &\quad + \cdots + q^{\epsilon(x_1,x)+\cdots+\epsilon(x_N x)} \delta^x_{x_{N+1}} \delta_{x_1} \underset{s}{\otimes} \cdots \underset{s}{\otimes} \delta_{x_N}.\end{aligned} \tag{15}$$

Clearly the braided derivative ψ^x (or ∂^x in the notation of Ref. 20) is given by the evaluation or interior product pairing with $\mathcal{H}$, but extended to the whole of $S_{\Psi_0}(\mathcal{H})$ as a braided derivation. This is like a super-derivation, but using Ψ to braid ψ^x past elements of $\mathcal{H}$. These operators of braided differentiation arise as infinitesimal translations on the braided space, as expressed through the linear braided coproduct. From the braided Leibniz rule for these operators, one has easily the following relations:[20]

$$\psi_x^* \psi_y^* = \psi_b^* \psi_a^* R'^{a\ b}_{\ x\ y} = \psi_y^* \hat{\psi}_x^* q^{\epsilon_0(x,y)}, \quad \psi^x \psi^y = R'^{x\ y}_{\ a\ b} \psi^b \psi^a = q^{\epsilon_0(x,y)} \psi^y \psi^x, \tag{16}$$

and

$$\delta^x_y = \psi^x \psi^*_y - \psi^*_a R^{a\ x}_{\ y\ b} \psi^b = \psi^x \psi^*_y - q^{\epsilon(y,x)} \psi^*_y \psi^x, \tag{17}$$

just as in Eqs. (9). Notice that the ψ^x operators again obey the algebra $S_{\Psi_0}(\mathcal{H})$, as do (more obviously) the ψ_x^*, but now we have also the cross relation (17).

To sum up, the space $S_{\Psi_0}(\mathcal{H})$, which should be viewed geometrically as the algebra of Ψ_0-symmetric functions (on the dual space of $\mathcal{H}$), first decomposes as a vector space. We have $S_{\Psi_0}(\mathcal{H}) = \oplus_N \mathcal{H}^{\otimes_s N}$, where the components $\mathcal{H} \otimes_s \cdots \otimes_s \mathcal{H}$ (N copies) consist of Ψ_0-symmetric functions of degree N. We shall study these components more explicitly in the next section. Secondly, the same algebra acts by "pointwise multiplication" and "infinitesimal translation" on itself, generating a braided Weyl algebra and satisfying the relations (9) in our discrete setting. This construction generalizes both the usual CCR and CAR algebras, along with their usual realizations on symmetric or antisymmetric product algebras. All of this is an easy case of the general theory of braided spaces and braided derivatives,[22] for our particular R, R'-matrices.

Note also that although we have carefully distinguished δ_x (the basis of the space $\mathcal{H}$ generating $S_{\Psi_0}(\mathcal{H})$) from the operators ψ_x^* and ψ^x that act on $S_{\Psi_0}(\mathcal{H})$, we can also identify $\mathcal{H}$ with the space generated by the ψ_x^* acting on 1 by multiplication. Thus we can identify the whole "acted-upon" copy of $S_{\Psi_0}(\mathcal{H})$ with the copy of $S_{\Psi_0}(\mathcal{H})$ generated by the ψ_x^*. The vacuum state is $|0\rangle = 1$. From the geometrical point of view, the ψ^x act by braided differentiation. From the "Fock space" point of view, they act via the commutation relations and the condition that $\psi^x|0\rangle = 0$.

Finally, let us specialize X to a finite ordered set, writing $X = \{1, \ldots, n\}$. Then using Eqs. (15), we have the following results for $S_{\Psi_0}(\mathcal{H})$ and the corresponding braided Weyl algebra:

$$\psi_i^* \psi_j^* = q \psi_j^* \psi_i^*, \quad \psi^i \psi^j = q \psi^j \psi^i, \quad \psi^i \psi_j^* = q^{-1} \psi_j^* \psi^i, \quad \psi^j \psi_i^* = q \psi_i^* \psi^j \quad (\forall\, i < j)$$

$$\psi^i \psi_i^* - q \psi_i^* \psi^i = 1 \quad (\forall\, i), \tag{18}$$

where

$$\psi_i^* |m_1, \ldots, m_n\rangle = q^{-\Sigma_{j<i} m_j} |m_1, \ldots, m_i + 1, \ldots, m_n\rangle,$$

$$\psi^i |m_1, \ldots, m_n\rangle = q^{\Sigma_{j<1} m_j} [m_i; q] |m_1, \ldots, m_i - 1, \ldots, m_n\rangle. \tag{19}$$

Here

$$|m_1, \ldots, m_n\rangle = (\psi_1^*)^{m_1} \cdots (\psi_n^*)^{m_n} |0\rangle,$$

while

$$[m; q] = 1 + q + \cdots + q^{m-1} = (1 - q^m)/(1 - q)$$

is a "q-integer." These equations yield, for example, the "density operator" as

$$\rho_i = \psi_i^* \psi^i, \quad \rho_i |m_1, \ldots, m_n\rangle = [m_i; q] |m_1, \ldots, m_n\rangle. \tag{20}$$

We note again that the final equation of (18) implies ψ_i^* cannot be the adjoint of ψ^i unless q is real. In general the q-integers in Eq. (20) are complex, and the operator ρ_i is not self-adjoint.

Although we are taking the above "quantum-mechanical harmonic oscillator" point of view, the same mathematical structures can also be viewed as space–time position and momentum generators. Then we would denote the generators δ_i by X^i, and regard them as the coordinates of a noncommutative spacetime, with the usual "q-plane" relations, $X_i X_j = q X_j X_i$ for $i < j$. Similarly, we would write $\psi_i^* = \hat{X}_i$ for the operation of left-multiplication by X_i, and $\psi^i = \partial^i$ for the braided differentiation

$$\partial^i (X_1^{m_1} \cdots X_n^{m_n}) = q^{\Sigma_{j<i} m_j} [m_i; q] X_1^{m_1} \cdots X_i^{m_i - 1} \cdots X_n^{m_n}.$$

This is the "geometrical" point of view to which we alluded above. Here ∂^i acts on the X_i variable by q-differentiation, with an additional braiding q-factor as ∂^i moves past the X_j, $j < i$, in order to reach the X_i. Note that the q-plane is usually associated with more complicated R-matrices related to quantum groups $\mathrm{SL}_q(n)$ but this is not the case here. Indeed, many different R-matrices can give the same quantum plane.

B. Functional version

We next proceed to a functional version of the above, more suitable for the continuum case. Clearly, on general functions $h, g \in \mathcal{H}$, the braiding is given by

$$\Psi_0(h \otimes g)(x, y) = g(x) h(y) q^{-\epsilon_0(x,y)}, \tag{21}$$

where $\Psi_0(h \otimes g) = \int dx dy \Psi_0(h \otimes g)(x, y) \delta_x \otimes \delta_y$ (the integrals here and below should be interpreted as sums in the discrete case). Next, a basis for $\mathcal{H} \otimes_s \cdots \otimes_s \mathcal{H}$ is given by "normal ordering," i.e., we

choose $\{\delta_{x_1}\otimes_s\cdots\otimes_s\delta_{x_N}|x_1\leqslant x_2\leqslant\cdots\leqslant x_N\}$. We let the coefficients in this basis be partially defined functions $f(x_1,x_2,\ldots,x_N)$ so that

$$f=\int_{x_1\leqslant\cdots\leqslant x_N}dx_1\cdots dx_N f(x_1,x_2,\ldots,x_N)\,\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_{x_N}.$$

Then, defining $\psi^*(h)=\int dx h(x)\hat{\delta}_x$, we compute

$$\begin{aligned}\psi^*(h)f=&\int_{x\leqslant x_1\leqslant\cdots\leqslant x_N}dx dx_1\cdots dx_N h(x)f(x_1,\ldots,x_N)\,\delta_x\underset{s}{\otimes}\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}x_{x_N}\\&+q^{-1}\int_{x_1<x\leqslant x_2\cdots\leqslant x_N}dx_1dx\cdots dx_N h(x)f(x_1,\ldots,x_N)\,\delta_{x_1}\underset{s}{\otimes}\delta_x\underset{s}{\otimes}\delta_{x_2}\underset{s}{\otimes}\cdots\otimes\delta_{x_N}+\cdots\\&+q^{-N}\int_{x_1\leqslant\cdots\leqslant x_N<x}dx_1\cdots dx_N dx h(x)f(x_1,\ldots,x_N)\,\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_{x_N}\underset{s}{\otimes}\delta_x,\end{aligned}\tag{22}$$

where we have used the relations (12). After relabeling, we read off the coefficients as

$$\begin{aligned}(\psi^*(h)f)(x_1,\ldots,x_{N+1})=&\,h(x_1)f(x_2,\ldots,x_{N+1})+q^{-1}h(x_2)f(x_1,x_3,\ldots,x_{N+1})+\cdots\\&+q^{-N}h(x_{N+1})f(x_1,\ldots,x_N),\end{aligned}\tag{23}$$

for distinct "normally ordered" arguments. This is our representation of ψ^* in the continuum case.

Similarly, we linearly extend the definition (15) of ∂^x, doing in each case one of the integrals and relabeling the integration variables $x_1,\ldots,x_N$. This gives

$$\begin{aligned}\psi(x)f=&\int_{x\leqslant x_1\cdots\leqslant x_N}dx_1\cdots dx_N f(x,x_1,\ldots,x_N)\,\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_N\\&+q\int_{x_1\leqslant x\leqslant x_2\leqslant\cdots\leqslant x_N}dx_1\cdots dx_N f(x_1,x,x_2,\ldots,x_N)\,\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_N+\cdots\\&+q^N\int_{x_1\leqslant\cdots\leqslant x_N\leqslant x}dx_1\cdots dx_N f(x_1,\ldots,x_N,x)\,\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_N,\end{aligned}$$

which yields

$$(\psi(x)f)(x_1,\ldots,x_N)=q^m f(x_1,\ldots,x_m,x,x_{m+1},\ldots,x_N)\quad\text{for } x_m<x<x_{m+1},\tag{24}$$

with distinct, "normally ordered" $x_1,\ldots,x_N$ (using the usual conventions for $m=0$ or $m=N$). This is our representation of ψ in the continuum case.

Finally, if the basis elements are taken in a different order, the corresponding coefficients are related through Eq. (12), e.g., we have

$$f(x_2,x_1,\ldots,x_N)=q^{\epsilon_0(x_1,x_2)}f(x_1,x_2,\ldots,x_N),$$

and so forth. In this way, any coefficient function defined on "normally ordered" arguments extends uniquely to an element of $\mathcal{H}^{\otimes N}$ obeying such relations.

Hence, proceeding now in the continuum case, we can characterize $\mathcal{H}\otimes_s\cdots\otimes_s\mathcal{H}$ as the subspace of "Ψ_0-symmetric" functions

$$\mathcal{H}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\mathcal{H}=\{f\in\mathcal{H}^{\otimes N}|f(\sigma(x_1,\ldots,x_N))=q^{\ell(\sigma)}f(x_1,\ldots,x_N),\ \ \forall\,\sigma\in S_N, x_1<\cdots<x_N\},\tag{25}$$

where $\ell(\sigma)$ is the length of the permutation σ. It suffices to impose the symmetrization condition here almost everywhere. For example,

$$\mathcal{H}\underset{s}{\otimes}\mathcal{H}=\{f|f(y,x)=qf(x,y),\ \ \forall\,x<y\},$$

and

$$\mathcal{H}\underset{s}{\otimes}\mathcal{H}\underset{s}{\otimes}\mathcal{H}=\{f|f(y,x,z)=f(x,z,y)=qf(x,y,z), f(z,x,y)=f(y,z,x)=q^2f(x,y,z),$$
$$f(z,y,x)=q^3f(x,y,z),\ \ \forall\,x<y<z\}.$$

Making use of the subspace description (25), there is a corresponding formula for the action of $\psi^*(h)$ that involves factors of q^{ϵ}. For example, letting $\psi^*(h)$ act on a function $f\in\mathcal{H}\otimes_s\mathcal{H}$, we have

$$(\psi^*(h)f)(x,y,z)=h(x)f(y,z)+q^{\epsilon(y,x)}h(y)f(x,z)+q^{\epsilon(z,x)+\epsilon(z,y)}h(z)f(x,y).\tag{26}$$

The general formula for degree N is

$$\psi^*(h)f=(\mathrm{id}+\Psi_{12}+\Psi_{23}\Psi_{12}+\cdots+\Psi_{N,N+1}\cdots\Psi_{23}\Psi_{12})(h\otimes f),\tag{27}$$

which up to a normalization is just $h\otimes f$ followed by total Ψ-symmetrization (given the assumed Ψ-symmetry of f). Similarly, the formula for $\psi(x)$ may be written in the subspace description. It comes out simply as the interior product

$$\psi(x)f=f(x,\ldots),\tag{28}$$

where we evaluate the first argument of f at x. These are the field operators when we work with N-particle wave functions as symmetrized functions in N variables, as in the usual Bose or Fermi Fock spaces.

When there are products of fields, we will typically smear at least some of the variables with test functions to make sense of the distributions. Thus the q-commutation relations can be written as

$$\psi(x)\psi(h)=\psi(\theta_{0x}h)\psi(x),\quad \psi^*(x)\psi^*(h)=\psi^*(\theta_{0x}h)\psi^*(x),$$

$$\psi(h)\psi^*(x)=\psi^*(x)\psi(\theta_x h)+h(x),\tag{29}$$

for $x\in X$ and h in a dense domain of $\mathcal{H}$, where for each fixed x we define

$$\theta_{0x}(y)=q^{\epsilon_0(x,y)},\quad \theta_x(y)=q^{\epsilon(x,y)}$$

as functions of y (having modulus 1 when q is a phase), and where $\theta_{0x}h$ and $\theta_x h$ refer to the action on $\mathcal{H}$ given by pointwise multiplication. The second equation of (29) can also be written

$$\psi(x)\psi^*(h)=\psi^*(\overline{\theta}_x h)\psi(x)+h(x),$$

where $\overline{\theta}_x(y)=q^{\epsilon(y,x)}$.

As before, essentially the same algebra $S_{\Psi_0}(\mathcal{H})$ leads both to the Hilbert space of the system with components $\mathcal{H}^{\otimes_s N}$ as above (ignoring its algebra structure), and to the generalized field algebra of the $\psi^*(h)$ together with another copy for the $\psi(h)$ as an algebra of operator-valued

distributions obeying (9) and represented according to (23) and (24). The Fock space can also be viewed as generated by the operators $\psi^*(h)$ for a sufficient set of test functions h, acting repeatedly on $|0\rangle$.

We also have a geometrical picture as at the end of the last section, with $\psi(h)$ acting now by "braided functional differentiation."

C. Unitarity considerations

Until now we have worked rather generally, and have taken q to be arbitrary. We now work specifically over $\mathbb{C}$, and take q to be a phase. Addressing first the continuum case, we consider the L^2 inner product on $\mathcal{H}$, and verify that all our operator constructions are suitably self-adjoint.

First we see that Ψ_0 is self-adjoint, since

$$(a\otimes b,\Psi_0(h\otimes g))=\int\int dxdy\overline{a}(x)\overline{b}(y)g(x)h(y)q^{-\epsilon_0(x,y)}$$

$$=\int\int dxdy\overline{\Psi_0(a\otimes b)(y,x)}h(y)g(x)=(\Psi_0(a\otimes b),h\otimes g).$$

Next we make use of the fact that the spaces $\mathcal{H}\otimes_s\cdots\otimes_s\mathcal{H}$ have L^2 inner products, when we write their elements as functions f defined on the fundamental domain of "normally ordered" coordinates. We perform the integration over this domain. Thus:

$$(g,\psi^*(h)f)=\int_{x_1\leqslant\cdots\leqslant x_{N+1}}dx_1\cdots dx_{N+1}\overline{g}(x_1,\ldots,x_{N+1})\cdot\sum_{m=0}^{N+1}q^{-m}h(x_{m+1})f(x_1,\ldots,\hat{x}_{m+1},\ldots,x_{N+1})$$

$$=\sum_{m=0}^{N}\int_{x_1\leqslant\cdots\leqslant x_N}dx_1\cdots dx_N\cdot\overline{\int_{x_m}^{x_{m+1}}dxq^m\overline{h}(x)g(x_1,\ldots,x_m,x,x_{m+1},\ldots,x_N)f(x_1,\ldots,x_N)}$$

$$=(\psi(\overline{h})g,f),\tag{30}$$

where we have used the previous results for $\psi^*(h)$ and $\psi(x)$, interpreted $\psi(\overline{h})$ as the integral of $\psi(x)$ times $\overline{h}$, and relabeled the x_i in the calculation. The cases $m=0$ and $m=N$ are understood in the obvious way (the integration is then taken to $\pm\infty$). In the summations for $\psi^*(h)f$ (see Eq. (22)) some of the inequalities in the region of integration are strict, but we are permitted to ignore this distinction in the present continuum case.

Finally, in our subspace description of $\mathcal{H}\otimes_s\cdots\otimes_s\mathcal{H}$ we would like to define the inner product in terms of that on $\mathcal{H}^{\otimes N}$. Indeed, for f, g extended to Ψ_0-symmetric elements of $\mathcal{H}^{\otimes N}$, we have

$$(g,f)_{\mathcal{H}^{\otimes N}}=\sum_{\sigma\in S_N}\int_{x_1\leqslant\cdots\leqslant x_N}dx_1\cdots dx_N\overline{g}(\sigma(x_1,\ldots,x_N))f(\sigma(x_1,\ldots,x_N))=N!\,(g,f).$$

That is, the natural inner product with respect to which ψ and ψ^* are mutually adjoint is $N!^{-1}$ times the usual tensor product inner product. Alternatively, if one wished to use the usual tensor product inner product, then one should work with $(N+1)^{-1}\psi^*(h)$. From Eq. (27) we see that this would then be a true averaging over the symmetric group, and would correspond to the usual normalization in the Bose and Fermi cases.

For the continuum case, we see that ψ^* is the adjoint of ψ as in Ref. 18. The discrete case requires us to perform summations instead of integrations, and to be careful about the domains of summation. Thus, in the second term of Eq. (22), we have $x_1<x\leqslant x_2\leqslant\cdots\leqslant x_N$; and similarly for the other terms. Then, as a correction to Eq. (30), we have the following:

$$(\psi(\overline{h})g,f) = (g,\psi^*(h)f) + \sum_{x_1\leqslant x_2\leqslant\cdots\leqslant x_N} (q^{-1}h(x_1)\overline{g}(x_1,x_1,x_2,\ldots,x_N) + \cdots$$
$$+ q^{-N}h(x_N)\overline{g}(x_1,\ldots,x_{N-1},x_N,x_N))\cdot f(x_1,\ldots,x_N). \tag{31}$$

Writing $\psi(\overline{h})^\dagger = \psi^*(h) + T_h^*$, where $\psi(\overline{h})^\dagger$ is the adjoint of $\psi(\overline{h})$, we find

$$T_h^*(\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_{x_N}) = \sum_{m=1}^{N} q^{-m}h(x_m)\,\delta_{x_1}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_{x_m}\underset{s}{\otimes}\delta_{x_m}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\delta_{x_N}$$

where δ_{x_m} is duplicated on the right-hand side, and where $x_1\leqslant\cdots\leqslant x_N$.

To proceed further, it is convenient (though not essential) to use the simplified notation for the set $X=\{1,\ldots,n\}$. We then find

$$T_i^*((\delta_1)^{m_1}\cdots(\delta_n)^{m_n}) = q^{-\Sigma_{j<i}m_j}(q^{-1}+\cdots+q^{-m_i})(\delta_1^{m_1})\cdots(\delta_i^{m_i+1})\cdots(\delta_n)^{m_n}$$

(where we have omitted the symbols $\otimes_s$ for the symmetrized tensor product). Hence

$$T_i^*|m_1,\ldots,m_n\rangle = q^{-1}q^{-\Sigma_{j<i}m_j}[m_i;q^{-1}]|m_1,\ldots,m_i+1,\ldots,m_n\rangle,$$

and

$$\psi^{i\dagger}|m_1,\ldots,m_n\rangle = (1+q^{-1}[m_i;q^{-1}])\psi_i^*|m_1,\ldots,m_n\rangle = [m_i+1;q^{-1}]\psi_i^*|m_1,\ldots,m_n\rangle.$$

Noting that $\rho_i^\dagger$ has values which are the complex conjugates of the values of the diagonal operator ρ_i in Eq. (20), we see that

$$\psi^{i\dagger} = \rho_i^\dagger\psi_i^*, \quad \psi^i = (\psi_i^*)^\dagger\rho_i. \tag{32}$$

It is worth remarking that

$$\psi^{i\dagger}\psi^i|m_1,\ldots,m_n\rangle = \rho_i^\dagger\rho_i = |[m_i;q]|^2|m_1,\ldots,m_n\rangle = \frac{1-\cos m_i\theta}{1-\cos\theta}|m_1,\ldots,m_n\rangle \tag{33}$$

if $q=e^{i\theta}$.

While the density operators ρ_i are not self-adjoint in the discrete case, they have some nice properties. For example,

$$[\rho_i,\psi_j^*] = 0 = [\rho_i,\psi^j] \quad (\forall\, i\neq j)$$

but

$$\rho_i\psi_i^* - q\psi_i^*\rho_i = \psi_i^*, \quad \psi^i\rho_i - q\rho_i\psi^i = \psi^i, \tag{34}$$

with similar relations for $\rho_i^\dagger$; also $[\rho_i,\rho_i^\dagger]=0$. The results differ from the continuum case, where we already know that Eq. (7) holds with the usual commutator, not the q-commutator of Eq. (34).

The same conclusions apply for any discrete set X. The origin of the differences from the corresponding equations in the continuum case is that in the discrete case, we have treated the δ-function in Eq. (9) as a Kronecker-δ with values 0 and 1. This makes it the "same size" as the δ-functions arising in the combinatorics of the summations. Such a treatment leads to elegant q-deformation formulas, as obtained above. For a $\mathbb{Z}^n$-lattice theory that correctly converges in the zero-spacing limit to the continuum theory, one could use $\delta_{x,y}/\Delta^n$ in the right-hand side of Eq. (9), where Δ is the lattice spacing.

IV. IDENTIFICATION WITH THE TOPOLOGICAL PICTURE

It remains to identify the Hilbert spaces $\mathcal{H}_N$ in the previous section with the braided-symmetrized tensor products we have obtained. Let the map $\pi: B_N\to S_N$ be the natural homomor-

phism defined by identifying a crossing with its inverse crossing. As in Sec. II, we describe a topological configuration $\tilde{\gamma}$ by the pair (γ,b), where $p(\tilde{\gamma})=\gamma\in\Delta_N(\mathbb{R}^2)$, and where $b\in B_N$ (the fundamental group of Δ_N). Then with $\gamma=\{x_1,\ldots,x_N\}$,

$$\mathcal{H}_N\cong\mathcal{H}\underset{s}{\otimes}\cdots\underset{s}{\otimes}\mathcal{H},\quad \tilde{\Phi}(\gamma,b)=f(\pi(b)(x_1,\ldots,x_N)),\quad \forall\, x_1<x_2\cdots<x_N.$$

While γ is unordered, we introduce the conventional lexicographic ordering in indexing its elements.

For example if $x<y<z$ in $\mathbb{R}^2$, then

$$\tilde{\Phi}(\{x,y,z\},e)=f(x,y,z),\quad \tilde{\Phi}(\{x,y,z\},b_{23})=f(x,z,y)=q\tilde{\Phi}(\{x,y,z\},e)=qf(x,y,z)$$

by equivariance, where b_{23} is the braid group generator braiding strand 2 with strand 3. In general, if $x_1<\cdots<x_N$, then

$$f(\sigma(x_1,\ldots,x_N))=\tilde{\Phi}(\{x_1,\ldots,x_N\},i(\sigma))=q^{\ell(\sigma)}\tilde{\Phi}(\{x_1,\ldots,x_N\},e)=q^{\ell(\sigma)}f(x_1,\ldots,x_N),\qquad(35)$$

where $i(\sigma)$ is the braid defined as follows: Let $\sigma=s_{j_1}\cdots s_{j_{\ell(\sigma)}}$ be a reduced expression for σ in terms of simple exchanges $s_j=(j,j+1)$. Let b_j be the braid group generator braiding strands j and $j+1$. Then $i(\sigma)=b_{j_1}\cdots b_{j_{\ell(\sigma)}}$. Note that $i(\sigma)$ does not define a group homomorphism. Equation (35) is just as required; our symmetry condition on f corresponds to the equivariance under B_N of $\tilde{\Phi}$.

Likewise, using the definitions in Sec. II and the diagrammatic notation as in Ref. 18, one obtains

$$(\psi^*(h)\tilde{\Phi})(\{x,y,z\},e)=q^{-\#(y,z<x)}h(x)\tilde{\Phi}(\{y,z\},e)+q^{-\#(x,z<y)}h(y)\tilde{\Phi}(\{x,z\},e)$$
$$+q^{-\#(x,y<z)}h(z)\tilde{\Phi}(\{x,y\},e),$$

as well as

$$(\psi(z)\tilde{\Phi})(\{x,y\},e)=q^{\#(x,y<z)}\tilde{\Phi}(\{x,y,z\},e),$$

where $\#(x,y<z)$ denotes the number of points in the set $\gamma=\{x,y\}$ to the left of z in $\mathbb{R}^2$. These actions are to be compared with (24) and (26). Similarly one proves in general that the two constructions coincide; that is, the representation of the anyon creation and annihilation fields in the spaces $\mathcal{H}_N$ of topological configurations is equivalent to their representation in the braided Fock space by $h\otimes_s$ and the interior product.

V. ROOTS OF UNITY AND THE ANYONIC EXCLUSION PRINCIPLE

In this section we specialize further to the case where $q=e^{2\pi i/r}$ is a primitive rth root of unity. Our main observation is that in the continuum case, the explicit representation (23) on Ψ_0-symmetric tensor products implies that

$$\psi(h)^r=0,\quad \psi^*(h)^r=0\quad(\forall h);\qquad(36)$$

that is, we have an *anyonic exclusion principle*. Here h is any test-function, and the smearing of ψ by h makes sense of the products of distributions. By taking "bump functions" that are increasingly localized at an arbitrary point x, we can also write informally,

$$\psi(x)^r=0,\quad \psi^*(x)^r=0\quad(\forall x),\qquad(37)$$

a condition which we shall justify directly in the discrete case. Before doing so let us note that conversely, the pointwise condition (37) in the discrete case implies (36), since

$$\psi(\lambda\delta_x+\mu\delta_y)^r=(\lambda\psi(x)+\mu\psi(y))^r=\sum_{s=0}^{s=r}\lambda^s\mu^{r-s}\psi(x)^s\psi(y)^{r-s}\begin{bmatrix} r \\ s \end{bmatrix}_{;q^{\epsilon_0(y,x)}}=\lambda^r\psi(x)^r+\mu^r\psi(y)^r, \tag{38}$$

for any constants λ,μ and $x\neq y$. In obtaining (38), we use the q-binomial theorem for q-commuting quantities, with q-binomial coefficients defined in the usual way but with q-integers in place of integers in the factorials. Since $q^r=1$ we have $[r;q^{\pm1}]=0$ and hence only $s=0$ and $s=r$ contribute. So the pointwise and smeared versions are formally equivalent, with the smeared version being more suitable in the continuum case.

To prove (36) in the continuum, we use (23) acting on the vacuum (the identity function with no arguments) to deduce that

$$\psi^*(h)^m(x_1,\ldots,x_m)=[m;q^{-1}]!\,h(x_1)\cdots h(x_m)$$

for all non-negative integers m. This follows by induction on m. It is true for $m=1$; assuming it for m, we have

$$\begin{aligned}\psi^*(h)^{m+1}(x_1,\ldots,x_{m+1})&=h(x_1)\psi^*(h)^m(x_2,\ldots,x_{m+1})+q^{-1}h(x_2)\psi^*(h)^m(x_1,x_3,\ldots,x_{m+1})+\cdots\\&\quad+q^{-m}h(x_{m+1})\psi^*(h)^m(x_1,\ldots,x_m)\\&=(1+q^{-1}+\cdots+q^{-m})[m;q^{-1}]!h(x_1)\cdots h(x_{m+1})\end{aligned}$$

as required. The exclusion principle follows when $q^r=1$, since then $[r;q^{-1}]=0$ as already noted above. Next, letting $\psi^*(h)^r$ act on any Fock state of the form $\psi^*(h_1)\cdots\psi^*(h_N)|0\rangle$, we move $\psi^*(h)^r$ to the right until it arrives to act on the vacuum. In doing so, h will be replaced by a convolution with all the $h_1,\ldots,h_N$ [see Eqs. (29)], giving us a new function h'. But we have already verified that $\psi^*(h')^r|0\rangle$ for all test functions; hence (36) holds in the representation. The result for $\psi(h)^r$ follows, as in the continuum case it is the adjoint.

In fact, in the continuum theory one can formally conclude (36) as a statement about operator-valued distributions. We exhibit the reasoning for $r=3$ (the general case is similar). We have

$$\begin{aligned}\psi^*(h)^3&=\int dxdydzh(x)h(y)h(z)\psi^*(x)\psi^*(y)\psi^*(z)\\&=\sum_{\sigma\in S_3}\int_{\sigma(x)<\sigma(y)<\sigma(z)}dxdydzh(x)h(y)h(z)q^{-\ell(\sigma)}\psi^*(\sigma(x))\psi^*(\sigma(y))\psi^*(\sigma(z))\\&=\sum_{\sigma\in S_3}q^{-\ell(\sigma)}\int_{x<y<z}dxdydz\psi^*(x)\psi^*(y)\psi^*(z)=0,\end{aligned}$$

where we have written $\sigma(x,y,z)=(\sigma(x),\sigma(y),\sigma(z))$, and where $\ell(\sigma)$ is the length of the permutation. In effect we have broken up the threefold integral into 3! permutations of the fundamental domain where $x<y<z$ (not being concerned about coincident points since these form a subset of measure zero); then we have used the q-commutation relations (9), and finally we have changed variables to give many copies of the integral over the fundamental domain. The result is zero since $\Sigma q^{-\ell(\sigma)}=[3;q^{-1}]!=0$ when $q^3=1$. The same argument holds for general r and for $\psi(h)^r=0$.

The arguments for the discrete case are more subtle, and indeed the formulas $\psi(x)^r=0$ and $\psi^*(x)^r=0$ do not hold automatically in our representation. Rather, we argue that in this case it is natural to *impose* these according to the algebraic structure. This is similar to "truncated versions" of quantum groups and other q-algebras in conformal field theory and other settings at roots of unity. Indeed we then have $\Psi^r=\mathrm{id}$ for the braiding, and we are essentially in the setting that has been called "anyonic vector spaces " in Refs. 13 and 20.

From a physical point of view, the key observation is that for q a primitive rth root of unity, the operators

$$\psi(x)^r, \quad \psi^*(x)^r$$

are in any case central. In fact, from (9) we have $\psi(x)^m\psi(y)=q^{m\epsilon_0(x,y)}\psi(y)\psi(x)^m$, and

$$\begin{aligned}\psi(x)^m\psi^*(y) &= \psi(x)^{m-1}q^{\epsilon(y,x)}\psi^*(y)\psi(x) + \psi(x)^{m-1}\delta(x-y)\\ &= q^{m\epsilon(y,x)}\psi^*(y)\psi(x)^m + \delta(x-y)\psi(x)^{m-1}[m;q^{\epsilon(y,x)}].\end{aligned}$$

Hence, when $q^r=1$, we have $[r;q^{\pm1}]=0$ and $\psi(x)^r$ is central. Note that here it is critical that we used ϵ and not ϵ_0 in the calculation involving $\psi^*(y)$. Similarly, we have that $\psi^*(x)^r$ central. Therefore, in an irreducible sector of the theory, these operators should be set to multiples of the identity.

This argument is needed only in the discrete case, but the algebraic structures apply (suitably understood) in both cases; thus we have used a notation applicable to both.

As for which value these operators should be assigned, we have already seen that (37) is suitable for the constraint to be linear (basis independent), in the sense of applying to all h. Clearly zero is the only value with this property. Another way to reach the same conclusion is in terms of the braided coproduct on $S_{\Psi_0}(\mathcal{H})$. On products it extends by Ψ, and one has

$$\underline{\Delta}\psi^*(x)^r = \sum_{s=0}^{s=r}\psi^*(x)^s\otimes\psi^*(x)^{r-s}\begin{bmatrix} r \\ s \end{bmatrix}_{;q} = \psi^*(x)^r\otimes 1 + 1\otimes\psi^*(x)^r.$$

A similar result holds for $\psi(x)^r$. Since $\underline{\Delta}1=1\otimes 1$, only (37) allows the braided coproduct to descend to the reduced algebra; no other constant will do. Moreover, since this $\underline{\Delta}$ underlies the braided-differentiation operation ∂^x in Sec. III A, our representation of ψ^* (and more obviously ψ) then descends to an action of the truncated algebra $S_{\Psi_0}(\mathcal{H})$ (in which (37) is imposed) on itself, by the same formulas as before. This is in subtle contrast to the continuum case, where (36) already holds.

Next we note that because $\psi^*(x)$ and $\psi^*(y)$ commute up to a factor $q^{\epsilon_0(x,y)}$, any state formed by a sequence of creation field operators applied to the vacuum, where r or more occurrences of $\psi^*(x)$ are included, must vanish. That is,

$$\psi^*(x)\psi^*(y)\psi^*(z)\cdots\psi^*(x)\psi^*(w)\cdots\psi^*(x)\cdots|0\rangle = 0$$

if there are r or more instances of $\psi^*(x)$. The distinct $\psi^*(y)$, $\psi^*(z)$ and so forth can equally be annihilation fields $\psi(y)$, $\psi(z)$ and so forth, since these too q-commute with $\psi^*(x)$.

More generally, a state formed from the vacuum will be zero if there are m annihilation $\psi(x)$ operators, and $r+m$ or more $\psi^*(x)$. This can be proved by induction on m, as follows. The case $m=0$ is covered above. Suppose it is true for $m-1$. Given an expression with m annihilation operators, look at the rightmost $\psi(x)$. Applying the q-commutation relation with the ψ^* to its right, we move $\psi(x)$ to the right and pick up a second term with a δ-function and with one fewer $\psi(x)$, and at most one fewer $\psi^*(x)$; by our induction hypothesis, this second term vanishes. Meanwhile, the first term has $\psi(x)$ one step to the right; repeating this eventually brings it to act directly on $|0\rangle$, giving zero. This proof makes sense in the discrete case, or with the assumption that the δ-functions are approximated by bounded functions with the limit taken only at the end (in order to treat $\delta(0)$ as a number). More precisely, in terms of annihilation operators smeared with test functions,

$$\psi^*(x)\cdots\psi(h_1)\cdots\psi^*(x)\cdots\psi(h_m)\cdots\psi^*(x)\cdots|0\rangle = 0$$

if there are m annihilation operators and at least $r+m$ creations $\psi^*(x)$ anywhere in the string. This follows from (29) and a similar proof by induction.

For general $\psi^*(h)$ we always have the exclusion principle (36). But the stronger version, in which some of the $\psi^*(h)$ are not adjacent, is more complicated. The various $\psi^*(h)$ needed are modified by the intervening creation field operators, according to (29). Thus, one has instead exclusion conditions that take the form

$$\psi^*(\theta_{0x_1}\cdots\theta_{0x_m}h)^{n_0}\psi^*(x_1)\psi^*(\theta_{0x_2}\cdots\theta_{0x_m}h)^{n_1}\cdots\psi^*(x_{m-1})\psi^*(\theta_{0x_m}h)^{n_{m-1}}\psi^*(x_m)\psi^*(h)^{n_m}|0\rangle = 0,$$

when $n_0+\cdots+n_m \geqslant r$. In the Bose or Fermi cases, the functions θ_{0x} are constant (± 1), up to a set of measure zero; but otherwise they must be taken into account. The same complication applies when there are annihilation operators present. This would appear to be a feature of the anyonic theory $(r>2)$, that is not present for fermions.

On the other hand, we do not see this complication if all our smeared fields have disjoint support. Thus, from (29) we find that

$$\psi^*(h)\psi^*(g) = \psi^*(g)\psi^*(h)\begin{cases} q & \text{if } \mathrm{supp}(h) < \mathrm{supp}(g) \\ q^{-1} & \text{if } \mathrm{supp}(h) > \mathrm{supp}(g) \end{cases}$$

$$\psi(h)\psi^*(g) = (\overline{g},h) + \psi^*(g)\psi^*(h)\begin{cases} q^{-1} & \text{if } \mathrm{supp}(h) < \mathrm{supp}(g) \\ q & \text{if } \mathrm{supp}(h) > \mathrm{supp}(g) \end{cases}$$

with a similar equation for $\psi(h)\psi(g)$. When they occur, these have a similar form to (9). Hence, as an application, one may take the $\psi^*(x)$ as given more precisely by smearing with "bump functions" of small support around the relevant point. As long as these bumps do not touch, the various smeared $\psi^*(x)$ fields behave as in the discrete case, and may be collected together by similar relations. For such states we have the full exclusion principle again, without any complications when the instances of the smeared field $\psi^*(x)$ are separated from each other in the product of field operators.

With this last observation in mind, let us give a straightforward application of the exclusion principle to a gas of noninteracting anyonic particles (e.g., vortices) localized in disjoint sets around points $x_1,\ldots,x_n$ in $\mathbb{R}^2$. Let us suppose that each particle carries a fixed unit E of energy, which does not depend on the positions; the latter will therefore be considered as fixed (or else, we must factor out the resulting degeneracy). As per the discrete version of the theory, the reduced range of states is then

$$|m_1,\ldots,m_n\rangle = \psi^*(x_1)^{m_1}\cdots\psi^*(x_n)^{m_n}|0\rangle, \quad m_i = 0,\ldots,r-1.$$

Let us decompose this reduced Hilbert space as $\oplus_N \mathcal{H}_N$ according to $N=\Sigma_{i=1}^n m_i$, which is the value of the occupation number operator

$$\mathcal{N} = \int dx\rho(x) = \int dx\psi^*(x)\psi(x).$$

The statistical partition function is then

$$Z_\beta = \mathrm{Trace}(e^{-\beta E\mathcal{N}}) = \sum_N e^{-\beta EN}\dim(\mathcal{H}_N) = \sum_{\{m_i\}} e^{-\beta E\Sigma_i m_i} = [r;e^{-\beta E}]^n. \tag{39}$$

The q-integer again appears, but now at the real value $e^{-\beta E}$. Each mode ψ_i^* may be counted separately, so that the computation here is the same as that for 1 particle, but raised to the nth power. When $r=2$ we recover the usual partition function for fermions, while for $r=\infty$ we recover the usual result for bosons

$$[2;e^{-\beta E}] = e^{-\beta E}+1; \quad [\infty;e^{-\beta E}] = \frac{1}{1-e^{-\beta E}}.$$

The general formula $[r;e^{-\beta E}]$ interpolates the two. From the partition function one may then proceed as usual to obtain the thermodynamic properties of such a gas.[32]

More generally, we may take Hamiltonians with interaction terms, including those that arise from the field theory rather than the harmonic oscillator point of view (i.e., with kinetic and current–current interaction terms). Such applications will be developed elsewhere.

VI. CONCLUDING REMARKS

We have obtained a generalized exclusion principle for anyons—an important physical result—not from analysis of the statistical mechanics of anyons, but from the explicit representation of nonrelativistic creation and annihilation fields in an appropriate braided tensor product space. As one would expect in this context, the principle holds when the anyonic phase shift is a root of unity. It applies both to smeared fields $\psi(h)$, $\psi^*(h)$ and to (unsmeared) operator-valued distributions $\psi(x)$, $\psi^*(x)$ satisfying q-commutation relations; but it takes a rather cleaner form in the latter case (a subtle distinction that disappears for bosons and fermions).

On the other hand, the discrete version in which we work directly with points (rather then with increasingly peaked bump functions) turns out to be different and algebraically more complicated; with ψ^i and ψ_i^* no longer adjoint to each other. The fact that one has a different theory from the continuum limit is an interesting feature of our analysis. We believe this subject, and its relation to Gentile statistics and to generalized harmonic oscillators, deserves some renewed attention.

Let us also mention some related conceptual aspects of interest. Our construction of $S_{\Psi_0}(\mathcal{H})$ in Sec. II is manifestly dependent on an ordering, since this enters in the braiding. This is true for quantum planes (see the remarks at the start of Sec. V), where $X=\{1,2,\ldots,n\}$ is the indexing set; and it remains true when we apply our formalism to the second quantization of nonrelativistic fields (so that X denotes physical space). The Fock space construction might then seem to be strongly dependent on the somewhat artificial lexicographical total ordering on $\mathbb{R}^2$ used in Sec. III. However the isomorphism in Sec. IV, with the spaces $\mathcal{H}_N$ described by means of topological configurations, tells us that in fact the underlying diffeomorphism invariance remains as far as the physics is concerned. The lexicographical ordering places the physical system into an algebraic form described by the symmetric tensor products $\otimes_s$, but this is for mathematical convenience only.

This suggests an answer to a certain puzzle in q-deformed physics—how to physically interpret noncommutative tensor products (as generated by noncocommutative quantum groups). That is, if A and B are two physically equivalent systems, what is the difference between $A\otimes_s B$ and $B\otimes_s A$, and which is the correct description of the joint system? In our anyonic model this is an unphysical distinction that is needed to work algebraically; just as (physically) the points $\gamma=\{x_1,\ldots,x_N\}$ in Δ_N are intrinsically unordered, but it can nevertheless be helpful (mathematically) to order them. This is the difference between diffeomorphisms of the manifold $\mathbb{R}^2$ acting on subsets of $\mathbb{R}^2$, and the coordinate description of their lifting to the universal covering space of N-identical-particle configuration space.

Another interesting feature is the way that the strictness of the braiding Ψ comes about from the structure of the singularities at coincident points (expressed here as Kronecker or Dirac δ-functions). In general one has diagonal singularities when multiplying operator fields, but in some cases (such as in conformal field theory) these can be controlled (e.g., by the operator product expansion). It would be interesting to see how braidings that arise in conformal field theory relate to diffeomorphism group ideas and to q-Fock space ideas along the lines of the present paper. In some situations, such as the Wess–Zumino–Witten model, there is also a topological path picture leading to the quantum group $U_q(su_2)$.

Finally, we note that the basic ideas described here apply also to plektons—particles associated with higher-dimensional (non-Abelian) unitary representations of the braid group. Here $T(b)$ in Sec. II is not simply a phase, but a finite-dimensional unitary operator acting on a multicomponent wave function; and we work with a multiplet of operator fields. Essentially, we then have an R-matrix for the linear braid group representation, in place of q in the formulas above; and we must also be more careful about ordering. Thus the creation and annihilation fields act no longer by multiplication by powers of q representing the number of crossings in the resulting braid, but

by matrix operation on the multiplet. In place of $q^{\epsilon(x,y)}$ and $q^{\epsilon_0(x,y)}$, we define Ψ and Ψ_0, using R or R^{-1} according to the ordering—but with the same conceptual picture that we have used in the anyonic case.

(Received 31 March 2004; accepted 7 June 2004; published 12 October 2004)

We give new solutions of the quantum conformal deformations of the full Maxwell equations in terms of deformations of the plane wave. We study the compatibility of these solutions with the conservation of the current. We also start the study of quantum linear conformal (Weyl) gravity by writing the corresponding *q*-deformed equations. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1790049]

I. INTRODUCTION

One of the purposes of quantum deformations is to provide an alternative of the regularization procedures of quantum field theory. Applied to Minkowski space–time the quantum deformations approach is also an alternative to Connes' noncommutative geometry.[1] The first step in such an approach is to construct a noncommutative quantum deformation of Minkowski space–time. There are several possible such deformations, cf. Refs. 2–6. We shall follow the deformation of Ref. 6 which is different from the others, the most important aspect being that it is related to a deformation of the conformal group.

The first problem to tackle in a noncommutative deformed setting is to study the *q*-deformed analogues of the conformally invariant equations. Here we continue the study of hierarchies of deformed equations derived in Refs. 6–8 with the use of quantum conformal symmetry. We give now a description of our setting starting from the simplest example.

It is well known that the d'Alembert equation,

$$\Box\varphi(x) = 0, \quad \Box = \partial^{\mu}\partial_{\mu} = (\partial_0)^2 - (\vec{\partial})^2, \tag{1.1}$$

is conformally invariant, cf., e.g., Ref. 9. Here φ is a scalar field of fixed conformal weight, $x = (x_0, x_1, x_2, x_3)$ denotes the Minkowski space–time coordinates. Not known was the fact that (1.1) may be interpreted as conditionally conformally invariant equation and thus may be rederived from a subsingular vector of a Verma module of the algebra sl(4), the complexification of the conformal algebra su(2,2).[7]

The same idea was used in Ref. 7 to derive a *q*-d'Alembert equation, namely, as arising from a subsingular vector of a Verma module of the quantum algebra $U_q(\mathrm{sl}(4))$. The resulting equation is a *q*-difference equation and the solution spaces are built on the noncommutative *q*-Minkowski space–time of Ref. 6.

Besides the *q*-d'Alembert equation in Ref. 7 were derived a whole hierarchy of equations corresponding to the massless representations of the conformal group and parametrized by a

[a)]Permanent address.

non-negative integer r.[7] The case $r=0$ corresponds to the q-d'Alembert equation, while for each $r>0$ there are two couples of equations involving fields of conjugated Lorentz representations of dimension $r+1$. For instance, the case $r=1$ corresponds to the massless Dirac equation, one couple of equations describing the neutrino, the other couple of equations describing the antineutrino, while the case $r=2$ corresponds to the Maxwell equations.

The construction of solutions of the q-d'Alembert hierarchy was started in Ref. 10 with the q-d'Alembert equation. One of the solutions given was a deformation of the plane wave as a formal power series in the noncommutative coordinates of q-Minkowski space–time and four-momenta. This q-plane wave has some properties analogous to the classical one but is not an exponent or q-exponent. Thus, it differs conceptually from the classical plane wave and may serve as a regularization of the latter. In the same sense it differs from the q-plane wave in the paper,[11] which is not surprising, since there is used different q-Minkowski space–time (from Refs. 2–4) and different q-d'Alembert equation both based only on a (different) q-Lorentz algebra, and not on q-conformal [or $U_q(\mathrm{sl}(4))$] symmetry as in our case. In fact, it is not clear whether the q-Lorentz algebra of Refs. 2–4 used in Ref. 11 is extendable to a q-conformal algebra.

For the equations labeled by $r>0$ it turned out that one needs a second q-deformation of the plane wave in a conjugated basis.[12] The solutions of the hierarchy in terms of the two q-plane waves were given in Ref. 12 for $r=1$ and in Ref. 13 for $r>1$. Later these two q-plane waves were generalized and correspondingly more general solutions of the hierarchy were given in Ref. 14.

Another hierarchy derived in Ref. 6 is the Maxwell hierarchy. The two hierarchies have only one common member—the Maxwell equations—they are the lowest member of the Maxwell hierarchy and the $r=2$ member of the massless hierarchy. The compatibility of the solutions of the free q-Maxwell equations with the q-potential equations was studied.[15]

In the present paper we study the full q-Maxwell equations and the compatibility of their solutions with the conservation of the current. We give new solutions of the full q-Maxwell equations in two conjugated bases. The solutions of the homogeneous equations are also new (generalizing previously given solutions).

Another family contained in Ref. 8, but not explicated there, is related with the linear conformal (Weyl) gravity which we start to study in this paper. Namely, in the last section we write the quantum conformal deformations of the linear conformal (Weyl) gravity.

II. PRELIMINARIES

First we introduce new Minkowski variables,

$$x_\pm \equiv x_0 \pm x_3,\ \ v \equiv x_1 - ix_2,\ \ \overline{v} \equiv x_1 + ix_2, \tag{2.1}$$

which (unlike the x_μ), have definite group-theoretical interpretation as part of a six-dimensional coset of the conformal group SU(2, 2) (as explained in Ref. 6). In terms of these variables, e.g., the d'Alembert equation (1.1) is

$$\Box\varphi = (\partial_-\partial_+ - \partial_v\partial_{\overline{v}})\varphi = 0. \tag{2.2}$$

In the q-deformed case we use the noncommutative q-Minkowski space–time of Ref. 6 which is given by the following commutation relations (with $\lambda \equiv q - q^{-1}$):

$$x_\pm v = q^{\pm 1} v x_\pm,\ \ x_\pm \overline{v} = q^{\pm 1}\overline{v} x_\pm,\ \ x_+x_- - x_-x_+ = \lambda v\overline{v},\ \ \overline{v}v = v\overline{v}, \tag{2.3}$$

with the deformation parameter being a phase: $|q|=1$. Relations (2.3) are preserved by the anti-linear anti-involution ω:

$$\omega(x_\pm) = x_\pm,\ \ \omega(v) = \overline{v},\ \ \omega(q) = \overline{q} = q^{-1}\ \ (\omega(\lambda) = -\lambda). \tag{2.4}$$

The solution spaces consist of formal power series in the q-Minkowski coordinates (which we give in two conjugate bases):

$$\varphi = \sum_{j,n,\ell,m \in \mathbb{Z}_+} \mu_{jn\ell m} \varphi_{jn\ell m}, \quad \varphi_{jn\ell m} = \hat{\varphi}_{jn\ell m}, \widetilde{\varphi}_{jn\ell m}, \tag{2.5}$$

$$\hat{\varphi}_{jn\ell m} = v^j x_-^n x_+^\ell \overline{v}^m, \tag{2.6}$$

$$\widetilde{\varphi}_{jn\ell m} = \overline{v}^m x_+^\ell x_-^n v^j = \omega(\hat{\varphi}_{jn\ell m}). \tag{2.7}$$

The solution spaces (2.5) are representation spaces of the quantum algebra $U_q(\mathrm{sl}(4))$. For the latter we use the rational basis of Jimbo.[16] The action of $U_q(\mathrm{sl}(4))$ on $\hat{\varphi}_{jn\ell m}$ was given in Ref. 17, and on $\widetilde{\varphi}_{jn\ell m}$ in Ref. 12. Because of the conjugation ω we are actually working with the conformal quantum algebra which is a deformation of $U(\mathrm{su}(2,2))$.

Further we suppose that q is not a nontrivial root of unity.

In order to write our q-deformed equations in compact form it is necessary to introduce some additional operators. We first define the operators

$$\hat{M}_\kappa^\pm \varphi = \Sigma_{j,n,\ell,m \in \mathbb{Z}_+} \mu_{jn\ell m} \hat{M}_\kappa^\pm \varphi_{jn\ell m}, \quad \kappa = \pm, v, \overline{v}, \tag{2.8}$$

$$T_\kappa^\pm \varphi = \Sigma_{j,n,\ell,m \in \mathbb{Z}_+} \mu_{jn\ell m} T_\kappa^\pm \varphi_{jn\ell m}, \quad \kappa = \pm, v, \overline{v}, \tag{2.9}$$

and $\hat{M}_+^\pm$, $\hat{M}_-^\pm$, $\hat{M}_v^\pm$, $\hat{M}_{\overline{v}}^\pm$, respectively, act on $\varphi_{jn\ell m}$ by changing by ± 1 the value of j, n, ℓ, m, respectively, while $T_+^\pm$, $T_-^\pm$, $T_v^\pm$, $T_{\overline{v}}^\pm$, respectively, act on $\varphi_{jn\ell m}$ by multiplication of $q^{\pm j}$, $q^{\pm n}$, $q^{\pm \ell}$, $q^{\pm m}$, respectively. We shall use also the "logs" N_κ such that $T_\kappa = q^{N_\kappa}$. Now we can define the q-difference operators,

$$\hat{\mathcal{D}}_\kappa \varphi = \frac{1}{\lambda} \hat{M}_\kappa^{-1} (T_\kappa - T_\kappa^{-1}) \varphi = \frac{1}{\lambda} \hat{M}_\kappa^{-1} (q^{N_\kappa} - q^{-N_\kappa}) \varphi. \tag{2.10}$$

Note that when $q \to 1$ then $\hat{D}_\kappa \to \partial_k$. Using (2.8) and (2.10) the q-d'Alembert equation may be written as,[7,12] respectively,

$$(q \hat{\mathcal{D}}_- \hat{\mathcal{D}}_+ T_v T_{\overline{v}} - \hat{\mathcal{D}}_v \hat{\mathcal{D}}_{\overline{v}}) T_v T_- T_+ T_{\overline{v}} \hat{\varphi} = 0, \tag{2.11}$$

$$(\hat{\mathcal{D}}_- \hat{\mathcal{D}}_+ - q \hat{\mathcal{D}}_v \hat{\mathcal{D}}_{\overline{v}} T_v T_{\overline{v}}) T_- T_+ \widetilde{\varphi} = 0. \tag{2.12}$$

Note that when $q \to 1$ both Eqs. (2.11) and (2.12) go to (2.2). Note that the operators in (2.8) and (2.10)–(2.12) for different variables commute, i.e., we have passed to commuting variables. However, keeping the normal ordering it is straightforward to pass back to noncommuting variables.

Next we recall that the Maxwell's equations are part also of Maxwell's hierarchy of equations. The quantum conformal deformation of the equations of the hierarchy are[6]

$${}_q I_{nq}^+ F_n^+ = {}_q J^n, \quad {}_q I_n^- {}_q F_n^- = {}_q J^n, \tag{2.13}$$

where in the basis (2.6) the operators are

$$\begin{aligned} {}_q I_n^+ = \tfrac{1}{2}\big((q\hat{\mathcal{D}}_v + \hat{M}_{\overline{z}} \hat{\mathcal{D}}_+ (T_- T_v)^{-1} T_{\overline{v}}) T_- [n + 2 - N_z]_q - q^{-n-2} (\hat{\mathcal{D}}_- T_- + q^{-1} \hat{M}_{\overline{z}} \hat{\mathcal{D}}_{\overline{v}} \\ - \lambda \hat{M}_v \hat{M}_{\overline{z}} \hat{\mathcal{D}}_- \hat{\mathcal{D}}_+ T_{\overline{v}}) T_-^{-1} \hat{\mathcal{D}}_z) T_+ T_v T_z T_{\overline{z}}^{-1}, \end{aligned} \tag{2.14}$$

$${}_q I_n^- = \tfrac{1}{2}(\hat{\mathcal{D}}_{\overline{v}} + q \hat{M}_z \hat{\mathcal{D}}_+ T_{\overline{v}} T_- T_v^{-1} - q\lambda \hat{M}_v \hat{\mathcal{D}}_- \hat{\mathcal{D}}_+ T_{\overline{v}}) T_{\overline{v}} [n + 2 - N_{\overline{z}}]_q - \tfrac{1}{2} q^{n+3} (\hat{\mathcal{D}}_- + q \hat{M}_z \hat{\mathcal{D}}_v T_-) \hat{\mathcal{D}}_{\overline{z}} T_- T_{\overline{v}}, \tag{2.15}$$

while where in the basis (2.7) the operators are

$$
\begin{aligned}
{}_qI_n^+ = {} & \tfrac{1}{2}q(\hat{\mathcal{D}}_v + \hat{M}_{\bar{z}}\hat{\mathcal{D}}_+T_-T_{\bar{v}}^{-1}T_v)T_v[n+2-N_z]_q - \tfrac{1}{2}q^{n+3}(\hat{\mathcal{D}}_- + \hat{M}_z\hat{\mathcal{D}}_{\bar{v}}T_- \\
& + \lambda q^{-1}\hat{M}_v\hat{M}_{\bar{z}}\hat{\mathcal{D}}_-\hat{\mathcal{D}}_+T_{\bar{v}}^{-1}T_-)\hat{\mathcal{D}}_zT_-T_v,
\end{aligned} \tag{2.16}
$$

$$
\begin{aligned}
{}_qI_n^- = {} & \tfrac{1}{2}((\hat{\mathcal{D}}_{\bar{v}}T_{\bar{v}}T_- + \hat{M}_z\hat{\mathcal{D}}_+T_v + q^{-1}\lambda\hat{M}_v\hat{\mathcal{D}}_-\hat{\mathcal{D}}_+T_-)[n+2-N_{\bar{z}}]_q \\
& - q^{-n-2}(\hat{\mathcal{D}}_- + \hat{M}_z\hat{\mathcal{D}}_vT_-^{-1})\hat{\mathcal{D}}_{\bar{z}}T_{\bar{v}})T_+T_{\bar{z}}T_z^{-1}.
\end{aligned} \tag{2.17}
$$

Note that for $q=1$ (2.14) and (2.15) coincide with (2.16) and (2.17), respectively. Maxwell's equations $\partial^\mu F_{\mu\nu}=J_\nu$, $\epsilon_{\mu\nu\rho\sigma}\partial^\mu F^{\rho\sigma}=0$ are obtained from (2.13) for $n=0$, $q=1$, substituting the fixed helicity constituents $F^\pm$ by $F^+=z^2(F_1^+ + iF_2^+) - 2zF_3^+ - (F_1^+ - iF_2^+)$, $F^-=\bar{z}^2(F_1^- - iF_2^-) - 2\bar{z}F_3^- - (F_1^- + iF_2^-)$, $F_k^\pm = F_{k0} \pm (i/2)\varepsilon_{k\ell m}F_{\ell m} = E_k \pm iH_k$, $J^0 = \bar{z}z(J_0+J_3) + z(J_1+iJ_2) + \bar{z}(J_1-iJ_2) + (J_0-J_3)$, and then comparing the coefficients of the resulting first order polynomials in z and $\bar{z}$.

We shall look for solutions of the full q-Maxwell's equations in terms of deformations of the plane wave. Let us first recall these deformations from Ref. 14. The first deformation is given in the basis (2.6):

$$
\widehat{\exp}_q(k,x) = \sum_{s=0}^{\infty} \frac{1}{[s]_q!}\hat{h}_s,
$$

$$
[s]_q! \equiv [s]_q[s-1]_q \cdots [1]_q,\ [0]_q! \equiv 1,\ [n]_q \equiv \frac{q^n - q^{-n}}{q - q^{-1}}, \tag{2.18}
$$

$$
\begin{aligned}
\hat{h}_s = {} & \beta^s \sum_{a,b,n \in \mathbb{Z}_+} \frac{(-1)^{s-a-b}q^{n(s-2a-2b+2n)+a(s-a-1)+b(-s+a+b+1)}q^{P_s(a,b)}}{\Gamma_q(a-n+1)\Gamma_q(b-n+1)\Gamma_q(s-a-b+n+1)[n]_q!} \\
& \times k_v^{s-a-b+n}k_-^{b-n}k_+^{a-n}k_{\bar{v}}^n v^n x_-^{a-n}x_+^{b-n}\bar{v}^{s-a-b+n},
\end{aligned}
$$

$$
(\beta^s)^{-1} = \sum_{p=0}^{s} \frac{q^{(s-p)(p-1)+p}}{[p]_q![s-p]_q!}, \tag{2.19}
$$

where the momentum components $(k_v, k_-, k_+, k_{\bar{v}})$ are supposed to be noncommutative between themselves [obeying the same rules (2.3) as the q-Minkowski coordinates], and commutative with the coordinates. Further, Γ_q is a q-deformation of the Γ-function, of which here we use only the properties $\Gamma_q(p)=[p-1]_q!$ for $p \in \mathbb{N}$, $1/\Gamma_q(p)=0$ for $p \in \mathbb{Z}_-$; $P_s(a,b)$ is a polynomial in a, b. Note that $(\hat{h}_s)|_{q=1}=(k\cdot x)^s$ and thus $(\widehat{\exp}_q(k,x))|_{q=1}=\exp(k\cdot x)$. This q-plane wave has some properties analogous to the classical one but is not an exponent or q-exponent, cf. Ref. 18. This is enabled also by the fact (true also for $q=1$) that solving the equations may be done in terms of the components $\hat{h}_s$. This deformation of the plane wave generalizes the original one from Ref. 10 to obtain which one sets $P_s(a,b)=0$, in which case we shall use the notation f_s for the components from Ref. 10 since

$$
(\hat{h}_s)_{P_s(a,b)=0} = f_s. \tag{2.20}
$$

Each $\hat{h}_s$ satisfies the q-d'Alembert equation (2.11) on the momentum q-cone,

$$
\mathcal{L}_q^k \equiv k_-k_+ - q^{-1}k_vk_{\bar{v}} = k_+k_- - qk_vk_{\bar{v}} = 0. \tag{2.21}
$$

The second deformation is given in the basis (2.7),

$$\widetilde{\exp}_q(k,x)=\sum_{s=0}^{\infty}\frac{1}{[s]_q!}\tilde{h}_s, \tag{2.22}$$

$$\tilde{h}_s=\tilde{\beta}^s\sum_{a,b,n}\frac{(-1)^{s-a-b}q^{n(2a+2b-2n-s)+a(a-s-1)+b(s-a-b+1)}q^{Q_s(a,b)}}{\Gamma_q(a-n+1)\Gamma_q(b-n+1)\Gamma_q(s-a-b+n+1)[n]_q!}$$
$$\times k_v^n k_+^{a-n}k_-^{b-n}k_v^{s-a-b+n}\bar{v}^{s-a-b+n}x_+^{b-n}x_-^{a-n}v^n,$$

$$(\tilde{\beta}^s)^{-1}=\sum_{p=0}^{s}\frac{q^{(p-s)(p-1)+p}}{[p]_q!\,[s-p]_q!}, \tag{2.23}$$

where $Q_s(a,b)$ are arbitrary polynomials. If the latter are zero then $\widetilde{\exp}_q(k,x)$ becomes the q-plane wave deformation found in Ref. 12. The $\tilde{h}_s$ have the same properties as the $\hat{h}_s$ but the conjugated basis is used; in particular, they satisfy the q-d'Alembert equation (2.12) on the momentum q-cone (2.21).

III. SOLUTIONS OF THE *q*-MAXWELL EQUATIONS

First we shall use the basis (2.6). The solutions of (2.13) for $n=0$ in the homogeneous case ($J=0$) are

$$\hat{F}^{h\pm}\doteq({}_qF_0^{\pm})_{J=0}=\sum_{m,s=0}^{\infty}\frac{1}{[s]_q!}\hat{F}_{ms}^{h\pm}(k)f_s, \tag{3.1}$$

$$\hat{F}_{ms}^{h+}(k)=\sum_{i=0}^{m}\left(\sum_{j=0}^{m-i}\hat{p}_{ij}^{ms1}k_v^ik_-^{m-i-j}k_{\bar{v}}^j(k_v-q^{s+6}zk_-)(k_v-q^{s+3}zk_-)+\hat{p}_i^{ms2}k_v^ik_{\bar{v}}^{m-i}(k_v-q^{s+6}zk_-)(k_+-q^{s+3}zk_{\bar{v}})\right.$$
$$\left.+\sum_{j=0}^{m-i}\hat{p}_{ij}^{ms3}k_v^ik_+^{m-i-j}k_{\bar{v}}^j(k_+-q^{s+6}zk_{\bar{v}})(k_+-q^{s+3}zk_{\bar{v}})\right), \tag{3.2}$$

$$\hat{F}_{ms}^{h-}(k)=\sum_{i=0}^{m}\left(\sum_{j=0}^{m-i}\hat{r}_{ij}^{ms1}k_v^ik_-^{m-i-j}k_{\bar{v}}^j(k_{\bar{v}}-q^{-1}\bar{z}k_-)(k_{\bar{v}}-\bar{z}k_-)+\hat{r}_i^{ms2}k_v^ik_{\bar{v}}^{m-i}(k_+-q^{-1}\bar{z}k_v)(k_{\bar{v}}-\bar{z}k_-)\right.$$
$$\left.+\sum_{j=0}^{m-i}\hat{r}_{ij}^{ms3}k_v^ik_+^{m-i-j}k_{\bar{v}}^j(k_+-q^{-1}\bar{z}k_v)(k_+-\bar{z}k_v)\right), \tag{3.3}$$

where $\hat{p}_{i(j)}^{msa},\hat{r}_{i(j)}^{msa}$ are independent constants. The check that these are solutions is done for commutative Minkowski coordinates and noncommutative momenta on the q-cone. The terms with $m=0$ of the solutions (3.1)–(3.3), were obtained earlier[13] (later they were generalized using more general q-plane waves[14]). The solution (3.3) can be written in terms of the deformed plane wave if we suppose that the $\hat{r}_{i(j)}^{msa}$ for different s coincide, $\hat{r}_{i(j)}^{msa}=\hat{r}_{i(j)}^{ma}$. Then we have

$$\hat{F}^{h-}=\sum_{m=0}^{\infty}\hat{F}_m^{h-}(k)\exp_q(k,x),\quad \hat{F}_m^{h-}(k)=\hat{F}_{ms}^{h-}(k). \tag{3.4}$$

In the inhomogeneous case the solutions of (2.13) for $n=0$ are

$${}_qJ^0=\bar{z}z\hat{J}_+ + z\hat{J}_v+\bar{z}\hat{J}_{\bar{v}}+\hat{J}_-, \tag{3.5}$$

$$\hat{J}_\kappa = \sum_{m,s=o}^{\infty} \frac{1}{[s]_q!} \hat{J}_\kappa^{ms}(k) f_{s-1}, \quad \kappa = \pm, v, \bar{v}; \tag{3.6}$$

$$\hat{J}_+^{ms}(k) = -\hat{K}_m^s(k) k_-; \tag{3.7}$$

$$\hat{J}_-^{ms}(k) = -q^{-s-2} \hat{K}_m^s(k) k_+,$$

$$\hat{J}_v^{ms}(k) = \hat{K}_m^s(k) k_{\bar{v}},$$

$$\hat{J}_{\bar{v}}^{ms}(k) = q^{-s-2} \hat{K}_m^s(k) k_v,$$

$$\hat{K}_m^s(k) \doteq \hat{\gamma}_v^s k_v^{m+1} + \hat{\gamma}_-^s k_-^{m+1} + \hat{\gamma}_+^s k_+^{m+1} + \hat{\gamma}_{\bar{v}}^s k_{\bar{v}}^{m+1};$$

$${}_qF_0^{\pm} = \hat{F}^{\pm} + \hat{F}^{h\pm}; \tag{3.8}$$

$$\hat{F}^{\pm} = \sum_{m,s=0}^{\infty} \frac{1}{[s]_q!} \hat{F}_{ms}^{\pm}(k) f_s, \tag{3.9}$$

$$\hat{F}_{ms}^{+}(k) = 2d_s q^{-s}((q^{-s-5}\hat{\gamma}_-^s k_-^m + z\hat{\gamma}_v^s k_v^m)(k_v - q^{s+3} z k_-) + (q^{-s-5}\hat{\gamma}_v^s k_{\bar{v}}^m + z\hat{\gamma}_+^s k_+^m)(k_+ - q^{s+3} z k_{\bar{v}})),$$

$$\hat{F}_{ms}^{-}(k) = 2d_s q^{-2s-2}((\hat{\gamma}_-^s k_-^m + q^{-2}\bar{z}\hat{\gamma}_v^s k_{\bar{v}}^m)(k_{\bar{v}} - \bar{z} k_-) + (\hat{\gamma}_v^s k_v^m + q^{-2}\bar{z}\hat{\gamma}_+^s k_+^m)(k_+ - \bar{z} k_v)),$$

where $d_s = \beta^s / \beta^{s+1}$. As in the homogeneous case we cannot make $\hat{F}_{ms}^{+}(k)$ independent of s. We can make $\hat{F}_{ms}^{-}(k)$ independent of s by choosing $\hat{\gamma}_\kappa^s \sim q^{2s} d_s^{-1}$, but we cannot make $\hat{J}_\kappa^{ms}(k)$ independent of s.

Since we work with the full Maxwell equations we have also to check the q-deformation of the current conservation $\partial^\nu J_\nu = 0$,

$$I_{13} J = 0, \tag{3.10}$$

$$\begin{aligned} I_{13} = {} & q^3 [N_z - 1]_q T_z \hat{\mathcal{D}}_{\bar{z}} \hat{\mathcal{D}}_v T_v T_- T_+ + q \hat{\mathcal{D}}_z T_z \hat{\mathcal{D}}_{\bar{z}} \hat{\mathcal{D}}_- T_v T_+ + q [N_z - 1]_q T_z [N_{\bar{z}} - 1]_q \hat{\mathcal{D}}_+ T_+ T_{\bar{v}} \\ & + q^{-1} [N_{\bar{z}} - 1]_q \hat{\mathcal{D}}_z T_z \hat{\mathcal{D}}_{\bar{v}} T_v T_-^{-1} T_+ - \lambda \hat{M}_v [N_{\bar{z}} - 1]_q \hat{\mathcal{D}}_z T_z \hat{\mathcal{D}}_- \hat{\mathcal{D}}_+ T_v T_-^{-1} T_+ T_{\bar{v}}. \end{aligned} \tag{3.11}$$

Substituting (3.5) and (3.6) in the above we get

$$q J_+^s(k) k_+ + J_v^s(k) k_v + q^{s+2} J_{\bar{v}}^s k_{\bar{v}} + q^{s+1} J_-^s(k) k_- = 0. \tag{3.12}$$

The latter is fulfilled by the explicit expressions in (3.7), but we should note that these expressions fulfill also the following splittings of (3.12):

$$\begin{gathered} q J_+^s(k) k_+ + J_v^s(k) k_v = 0, \quad q J_{\bar{v}}^s(k) k_{\bar{v}} + J_-^s(k) k_- = 0, \\ J_+^s(k) k_+ + q^{s+1} J_{\bar{v}}^s(k) k_{\bar{v}} = 0, \quad J_v^s(k) k_v + q^{s+1} J_-^s(k) k_- = 0. \end{gathered} \tag{3.13}$$

Furthermore the expressions from (3.7) fulfill also

$$qJ^s_+(k)k_{\overline{v}} + J^s_v(k)k_- = 0, \quad qJ^s_{\overline{v}}(k)k_+ + J^s_-(k)k_v = 0,$$
$$J^s_+(k)k_v + q^{s+1}J^s_{\overline{v}}(k)k_- = 0, \quad J^s_v(k)k_+ + q^{s+1}J^s_-(k)k_{\overline{v}} = 0. \tag{3.14}$$

Now we shall use the basis (2.7). Then solutions of (2.13) for $n=0$ in the homogeneous case ($J=0$) are

$$\widetilde{F}^{h\pm} \doteq ({}_qF^{\pm}_0)_{J=0} = \sum_{m,s=0}^{\infty} \frac{1}{[s]_q!}\widetilde{F}^{h\pm}_{ms}(k)\widetilde{h}_s, \tag{3.15}$$

$$\widetilde{F}^{h+}_{ms}(k) = \sum_{i=0}^{m}\left(\sum_{j=0}^{m-i}\widetilde{p}^{ms1}_{ij}k^i_{\overline{v}}k^{m-i-j}_-k^j_v(k_v - zk_-)(k_v - qzk_-) + \widetilde{p}^{ms2}_i k^i_{\overline{v}}k^{m-i}_v(k_+ - zk_{\overline{v}})(k_v - qzk_-)\right.$$
$$\left. + \sum_{j=0}^{m-i}\widetilde{p}^{ms3}_{ij}k^i_{\overline{v}}k^{m-i-j}_+k^j_v(k_+ - zk_{\overline{v}})(k_+ - qzk_{\overline{v}})\right), \tag{3.16}$$

$$\widetilde{F}^{h-}_{ms}(k) = \sum_{i=0}^{m}\left(\sum_{j=0}^{m-i}\widetilde{r}^{ms1}_{ij}k^i_{\overline{v}}k^{m-i-j}_-k^j_v(k_{\overline{v}} - q^{s+1}\overline{z}k_-)(k_{\overline{v}} - q^{s+2}\overline{z}k_-) + \widetilde{r}^{ms2}_i k^i_v k^{m-i}_{\overline{v}}(k_{\overline{v}} - q^{s+1}\overline{z}k_-)(k_+ - q^{s+2}\overline{z}k_v)\right.$$
$$\left. + \sum_{j=0}^{m-i}\widetilde{r}^{ms3}_{ij}k^i_v k^{m-i-j}_+k^i_{\overline{v}}(k_+ - q^{s+1}\overline{z}k_v)(k_+ - q^{s+2}\overline{z}k_v)\right), \tag{3.17}$$

where $\widetilde{p}^{msa}_{i(j)}, \widetilde{r}^{msa}_{i(j)}$ are independent constants, $Q_s(a,b)=0$ in $\widetilde{h}_s$. The terms with $m=0$ of the solutions (3.15)–(3.17) were obtained earlier in Ref. 13 (and using the generalized q-plane wave in Ref. 14). The solution (3.16) can be written in terms of the deformed plane wave if we suppose that the $\widetilde{p}^{msa}_{i(j)}$ for different s coincide, $\widetilde{p}^{msa}_{i(j)} = \widetilde{p}^{ma}_{i(j)}$. Then we have

$$\widetilde{F}^{h+} = \sum_{m=0}^{\infty}\widetilde{F}^{h+}_m(k)\widetilde{\exp}_q(k,x), \quad \widetilde{F}^{h+}_m(k) = \widetilde{F}^{h+}_{ms}(k). \tag{3.18}$$

In the inhomogeneous case the solutions of (2.13) for $n=0$ are

$${}_qJ^0 = \overline{z}z\widetilde{J}_+ + z\widetilde{J}_v + \overline{z}\widetilde{J}_{\overline{v}} + \widetilde{J}_-; \tag{3.19}$$

$$\widetilde{J}_\kappa = \sum_{m,s=o}^{\infty}\frac{1}{[s]_q!}\widetilde{J}^{ms}_\kappa(k)\widetilde{h}_{s-1}, \quad \kappa = \pm, v, \overline{v}; \tag{3.20}$$

$$\widetilde{J}^{ms}_+(k) = -q^{s+1}\widetilde{K}^s_m(k)k_-, \tag{3.21}$$

$$\widetilde{J}^{ms}_-(k) = -q^{-1}\widetilde{K}^s_m(k)k_+,$$

$$\widetilde{J}^{ms}_v(k) = \widetilde{K}^s_m(k)k_{\overline{v}},$$

$$\widetilde{J}^{ms}_{\overline{v}}(k) = q^s\widetilde{K}^s_m(k)k_v,$$

$$\widetilde{K}^s_m(k) \doteq \widetilde{\gamma}^s_v k^{m+1}_v + \widetilde{\gamma}^s_- k^{m+1}_- + \widetilde{\gamma}^s_+ k^{m+1}_+ + \widetilde{\gamma}^s_{\overline{v}}k^{m+1}_{\overline{v}};$$

$$ {}_qF_0^{\pm} = \tilde{F}^{\pm} + \tilde{F}^{h\pm}; \tag{3.22} $$

$$ \tilde{F}^{\pm} = \sum_{m,s=0}^{\infty} \frac{1}{[s]_q!} \tilde{F}^{\pm}_{ms}(k)\tilde{h}_s, \tag{3.23} $$

$$ \tilde{F}^{+}_{ms}(k) = 2\tilde{d}_s q^{s-2}((\tilde{\gamma}^s_{-} k_{-}^m + q^{-1} z \tilde{\gamma}^s_{v} k_{v}^m)(k_v - qzk_{-}) + (\tilde{\gamma}^s_{v} k_{\bar{v}}^m + q^{-1} z \tilde{\gamma}^s_{+} k_{+}^m)(k_{+} - qzk_{\bar{v}})), $$

$$ \tilde{F}^{-}_{ms}(k) = 2\tilde{d}_s((q^{-s-3}\tilde{\gamma}^s_{-} k_{-}^m + q\bar{z}\tilde{\gamma}^s_{v} k_{\bar{v}}^m)(k_{\bar{v}} - q^{s+2}\bar{z}k_{-}) + (q^{-s-3}\tilde{\gamma}^s_{v} k_{v}^m + q\bar{z}\tilde{\gamma}^s_{+} k_{+}^m)(k_{+} - q^{s+2}\bar{z}k_{v})), $$

where $\tilde{d}_s = \tilde{\beta}^s / \tilde{\beta}^{s+1}$, $Q_s(a,b) = 0$ in $\tilde{h}_s$. We cannot make $\tilde{F}^{-}_{ms}(k)$ or $\tilde{J}^{ms}_{\kappa}(k)$ independent of s. We can make $\tilde{F}^{+}_{ms}(k)$ independent of s by choosing $\tilde{\gamma}^s_{\kappa} \sim q^{-s}\tilde{d}_s^{-1}$.

Also here we shall check whether the q-deformation of the current conservation (3.10) is fulfilled. The analog of (3.11) in the basis (2.7) is

$$ \begin{aligned} I_{13} = {} & [N_z - 1]_q \hat{\mathcal{D}}_{\bar{z}} T_{\bar{z}} \hat{\mathcal{D}}_v T_{\bar{v}} T_{+} T_{-}^{-1} + q \hat{\mathcal{D}}_{\bar{z}} T_{\bar{z}} \hat{\mathcal{D}}_z \hat{\mathcal{D}}_{-} T_{\bar{v}} T_{+} + q[N_{\bar{z}} - 1]_q T_{\bar{z}} [N_z - 1]_q \hat{\mathcal{D}}_{+} T_{+} T_v \\ & + q^2 [N_{\bar{z}} - 1]_q \hat{\mathcal{D}}_z T_{\bar{z}} \hat{\mathcal{D}}_{\bar{v}} T_{\bar{v}} T_{-} T_{+} - \lambda q \hat{M}_v [N_{\bar{z}} - 1]_q \hat{\mathcal{D}}_z T_{\bar{z}} \hat{\mathcal{D}}_{-} \hat{\mathcal{D}}_{+} T_{-} T_{+}. \end{aligned} \tag{3.24} $$

Then the analog of (3.12) is

$$ J^s_{+}(k)k_{+} + q^s J^s_{v}(k)k_v + J^s_{\bar{v}} k_{\bar{v}} + q^s J^s_{-}(k)k_{-} = 0. \tag{3.25} $$

The latter is fulfilled by the explicit expressions in (3.21), but we should note that these expressions fulfill also the following splittings of (3.25):

$$ \begin{gathered} J^s_{+}(k)k_{+} + q^s J^s_{v}(k)k_v = 0, \quad J^s_{\bar{v}}(k)k_{\bar{v}} + q^s J^s_{-}(k)k_{-} = 0, \\ J^s_{+}(k)k_{+} + J^s_{\bar{v}}(k)k_{\bar{v}} = 0, \quad J^s_{v}(k)k_v + J^s_{-}(k)k_{-} = 0. \end{gathered} \tag{3.26} $$

Furthermore the expressions from (3.21) fulfill also

$$ \begin{gathered} J^s_{+}(k)k_{\bar{v}} + q^s J^s_{v}(k)k_{-} = 0, \quad J^s_{\bar{v}}(k)k_{+} + q^s J^s_{-}(k)k_v = 0, \\ J^s_{+}(k)k_v + J^s_{\bar{v}}(k)k_{-} = 0, \quad J^s_{v}(k)k_{+} + J^s_{-}(k)k_{\bar{v}} = 0. \end{gathered} \tag{3.27} $$

Summarizing, we have given new solutions of the full q-Maxwell equations in two conjugated bases (2.6) and (2.7). The solutions of the homogeneous equations are also new (the old solutions are special cases). We see that the roles of the solutions F^{+} and F^{-} are exchanged in the two conjugated bases. We note also that the current components are different: $\hat{J}^{ms}_{\kappa} \neq \tilde{J}^{ms}_{\kappa}$ (for $q \neq 1$, $\kappa \neq v$), and in both cases they cannot be made independent of s. Thus, there is no advantage of choosing either of the bases (2.6) or (2.7). It may be also possible to use both in a Connes–Lott type model.[19]

IV. LINEAR CONFORMAL GRAVITY

We consider now the quantum group analogs of linear conformal gravity following the approach of Ref. 8. We start with the $q=1$ situation and we first write the Weyl gravity equations in an indexless formulation, trading the indices for two conjugate variables $z, \bar{z}$, just as for the Maxwell equations.

Weyl gravity is governed by the Weyl tensor,

$$C_{\mu\nu\sigma\tau} = R_{\mu\nu\sigma\tau} - \tfrac{1}{2}(g_{\mu\sigma}R_{\nu\tau} + g_{\nu\tau}R_{\mu\sigma} - g_{\mu\tau}R_{\nu\sigma} - g_{\nu\sigma}R_{\mu\tau}) + \tfrac{1}{6}(g_{\mu\sigma}g_{\nu\tau} - g_{\mu\tau}g_{\nu\sigma})R, \tag{4.1}$$

where $g_{\mu\nu}$ is the metric tensor. Linear conformal gravity is obtained when the metric tensor is written as $g_{\mu\nu}=\eta_{\mu\nu}+h_{\mu\nu}$, where $\eta_{\mu\nu}$ is the flat Minkowski metric, $h_{\mu\nu}$ are small so that all quadratic and higher order terms are neglected. In particular, $R_{\mu\nu\sigma\tau}=\frac{1}{2}(\partial_\mu\partial_\tau h_{\nu\sigma}+\partial_\nu\partial_\sigma h_{\mu\tau} - \partial_\mu\partial_\sigma h_{\nu\tau}-\partial_\nu\partial_\tau h_{\mu\sigma})$. The equations of linear conformal gravity are

$$\partial^\nu\partial^\tau C_{\mu\nu\sigma\tau} = T_{\mu\sigma}, \tag{4.2}$$

where $T_{\mu\nu}$ is the energy-momentum tensor. From the symmetry properties of the Weyl tensor it follows that it has 10 independent components. These may be chosen as follows (introducing notation for future use):

$$C_0 = C_{0123},\ \ C_1 = C_{2121},\ \ C_2 = C_{0202},\ \ C_3 = C_{3012},$$

$$C_4 = C_{2021},\ \ C_5 = C_{1012},\ \ C_6 = C_{2023}, \tag{4.3}$$

$$C_7 = C_{3132},\ \ C_8 = C_{2123},\ \ C_9 = C_{1213}.$$

Furthermore, the Weyl tensor transforms as the direct sum of two conjugate Lorentz irreps, which we shall denote as $C^\pm$. The tensors $T_{\mu\nu}$ and $h_{\mu\nu}$ are symmetric and traceless with nine independent components.

In order to be more precise we recall that the physically relevant representations T^χ of the four-dimensional conformal algebra su(2,2) may be labeled by $\chi=[n_1,n_2;d]$, where n_1,n_2 are non-negative integers fixing finite-dimensional irreducible representations of the Lorentz subalgebra [the dimension being $(n_1+1)(n_2+1)$], and d is the conformal dimension (or energy). [In the literature these Lorentz representations are labeled also by $(j_1,j_2)=(n_1/2,n_2/2)$.] The Weyl tensor transforms as the direct sum,

$$\begin{gathered}\chi^+ \oplus \chi^-, \\ \chi^+ = [4,0;2],\ \ \chi^- = [0,4;2],\end{gathered} \tag{4.4}$$

while the energy-momentum tensor and the metric transform as

$$\chi_T = [2,2;4],\ \ \chi_h = [2,2;0], \tag{4.5}$$

as anticipated. Indeed, $(n_1,n_2)=(2,2)$ is the nine-dimensional Lorentz representation (carried by $T_{\mu\nu}$ or $h_{\mu\nu}$), and $(n_1,n_2)=(4,0),(0,4)$ are the two conjugate five-dimensional Lorentz representations (carried by $C^\pm$), while the conformal dimensions are the canonical dimensions of a energy-momentum tensor ($d=4$), of the metric ($d=0$), and of the Weyl tensor ($d=2$). (For comparison, note that the Maxwell components F^+, F^-, used in the preceding sections, have signatures: [2, 0; 2], [0, 2; 2], respectively, while the current J has signature [1, 1; 3].) Further, we shall use again the fact that a Lorentz irrep (spin-tensor) with signature (n_1,n_2) may be represented by a polynomial $G(z,\bar z)$ in z, $\bar z$ of order n_1,n_2, respectively. More explicitly, for the irreps mentioned above we use

$$C^+(z) = z^4C_4^+ + z^3C_3^+ + z^2C_2^+ + zC_1^+ + C_0^+, \tag{4.6a}$$

$$C^-(\bar z) = \bar z^4C_4^- + \bar z^3C_3^- + \bar z^2C_2^- + \bar zC_1^- + C_0^-, \tag{4.6b}$$

$$T(z,\bar z) = z^2\bar z^2T'_{22} + z^2\bar zT'_{21} + z^2T'_{20} + z\bar z^2T'_{12} + z\bar zT'_{11} + zT'_{10} + \bar z^2T'_{02} + \bar zT'_{01} + T'_{00}, \tag{4.6c}$$

$$h(z,\overline{z}) = z^2\overline{z}^2 h'_{22} + z^2\overline{z}h'_{21} + z^2 h'_{20} + z\overline{z}^2 h'_{12} + z\overline{z}h'_{11} + zh'_{10} + \overline{z}^2 h'_{02} + \overline{z}h'_{01} + h'_{00}, \tag{4.6d}$$

where the indices on the right-hand side are not Lorentz-covariance indices, they just indicate the powers of z, $\overline{z}$. The components $C_k^{\pm}$ are given in terms of the Weyl tensor components as follows:

$$\begin{gathered}
C_0^+ = C_2 - \tfrac{1}{2}C_1 - C_6 + i(C_0 + \tfrac{1}{2}C_3 + C_7),\\
C_1^+ = 2(C_4 - C_8 + i(C_9 - C_5)),\\
C_2^+ = 3(C_1 - iC_3),\\
C_3^+ = 8(C_4 + C_8 + i(C_9 + C_5)),\\
C_4^+ = C_2 - \tfrac{1}{2}C_1 + C_6 + i(C_0 + \tfrac{1}{2}C_3 - C_7),\\
C_0^- = C_2 - \frac{C_1}{2} - C_6 - i(C_0 + \tfrac{1}{2}C_3 + C_7),\\
C_1^- = 2(C_4 - C_8 - i(C_9 - C_5)),\\
C_2^- = 3(C_1 + iC_3),\\
C_3^- = 2(C_4 + C_8 - i(C_9 + C_5)),\\
C_4^- = C_2 - \tfrac{1}{2}C_1 + C_6 - i(C_0 + \tfrac{1}{2}C_3 - C_7),
\end{gathered} \tag{4.7}$$

while the components T'_{ij} are given in terms of $T_{\mu\nu}$ as follows:

$$\begin{gathered}
T'_{22} = T_{00} + 2T_{03} + T_{33},\\
T'_{11} = T_{00} - T_{33},\\
T'_{00} = T_{00} - 2T_{03} + T_{33},\\
T'_{21} = T_{01} + iT_{02} + T_{13} + iT_{23},\\
T'_{12} = T_{01} - iT_{02} + T_{13} - iT_{23},\\
T'_{10} = T_{01} + iT_{02} - T_{13} - iT_{23},\\
T'_{01} = T_{01} - iT_{02} - T_{13} + iT_{23},\\
T'_{20} = T_{11} + 2iT_{12} - T_{22},\\
T'_{02} = T_{11} - 2iT_{12} - T_{22},
\end{gathered} \tag{4.8}$$

and similarly for h'_{ij} in terms of $h_{\mu\nu}$.

In these terms all linear conformal (Weyl) gravity equations (4.2) may be written in compact form as the following pair of equations:

$$\widetilde{I}^{+}C^{+}(z) = T(z,\overline{z}), \tag{4.9a}$$

$$\widetilde{I}^{-}C^{-}(\overline{z}) = T(z,\overline{z}), \tag{4.9b}$$

where the operators $I^{\pm}$ are given as follows:

$$\begin{aligned}\widetilde{I}^{+} = {} & (z^2\overline{z}^2\partial_+^2 + z^2\partial_v^2 + \overline{z}^2\partial_{\overline{v}}^2 + \partial_-^2 + 2z^2\overline{z}\partial_v\partial_+ + 2z\overline{z}^2\partial_+\partial_{\overline{v}} + 2z\overline{z}(\partial_-\partial_+ + \partial_v\partial_{\overline{v}}) + 2\overline{z}\partial_-\partial_{\overline{v}} + 2z\partial_v\partial_-)\partial_z^2 \\ & - 6(z\overline{z}^2\partial_+^2 + z\partial_v^2 + 2z\overline{z}\partial_v\partial_+ + \overline{z}^2\partial_+\partial_{\overline{v}} + \overline{z}(\partial_-\partial_+ + \partial_v\partial_{\overline{v}}) + \partial_v\partial_-)\partial_z 12(\overline{z}^2\partial_+^2 + \partial_v^2 + 2\overline{z}\partial_v\partial_+),\end{aligned} \tag{4.10a}$$

$$\begin{aligned}\widetilde{I}^{-} = {} & (z^2\overline{z}^2\partial_+^2 + z^2\partial_v^2 + \overline{z}^2\partial_{\overline{v}}^2 + \partial_-^2 + 2z^2\overline{z}\partial_v\partial_+ + 2z\overline{z}^2\partial_+\partial_{\overline{v}} + 2z\overline{z}(\partial_-\partial_+ + \partial_v\partial_{\overline{v}}) + 2\overline{z}\partial_-\partial_{\overline{v}} + 2z\partial_v\partial_-)\partial_z^2 \\ & - 6(z^2\overline{z}\partial_+^2 + \overline{z}\partial_{\overline{v}}^2 + 2z\overline{z}\partial_+\partial_{\overline{v}} + z^2\partial_v\partial_+ + z(\partial_-\partial_+ + \partial_v\partial_{\overline{v}}) + \partial_-\partial_{\overline{v}})\partial_z 12(z^2\partial_+^2 + \partial_{\overline{v}}^2 + 2z\partial_+\partial_{\overline{v}}).\end{aligned} \tag{4.10b}$$

To make more transparent the origin of these expressions and in the same time to derive the quantum group deformation of (4.9) and (4.10) we first introduce the following parameter-dependent operators:

$$\widetilde{I}^{+}(n) = \tfrac{1}{2}(n(n-1)I_1^2I_2^2 - 2(n^2-1)I_1I_2^2I_1 + n(n+1)I_2^2I_1^2), \tag{4.11a}$$

$$\widetilde{I}^{-}(n) = \tfrac{1}{2}(n(n-1)I_3^2I_2^2 - 2(n^2-1)I_3I_2^2I_3 + n(n+1)I_2^2I_3^2), \tag{4.11b}$$

where

$$I_1 \equiv \partial_z, \quad I_2 \equiv \overline{z}\overline{z}\partial_+ + z\partial_v + \overline{z}\partial_{\overline{v}} + \partial_-, \quad I_3 \equiv \partial_{\overline{z}}. \tag{4.12}$$

It is easy to check that we have the following relation:

$$\widetilde{I}^{\pm} = \widetilde{I}^{\pm}(4). \tag{4.13}$$

We note in passing that group theoretically the operators I_a correspond to the three simple roots of the root system of sl(4), while the operators $I_n^{\pm}$ correspond to the two nonsimple nonhighest roots.[20]

This is the form that is immediately generalizable to the q-deformed case. Using results from Ref. 8 we have

$${}_q\widetilde{I}^{+}(n) = \tfrac{1}{2}([n]_q[n-1]_{qq}I_{1q}^2I_2^2 - 2[n-1]_q[n+1]_{qq}I_{1q}I_{2q}^2I_1 + [n]_q[n+1]_{qq}I_{2q}^2I_1^2), \tag{4.14a}$$

$${}_q\widetilde{I}^{-}(n) = \tfrac{1}{2}([n]_q[n-1]_{qq}I_{3q}^2I_2^2 - 2[n-1]_q[n+1]_{qq}I_{3q}I_{2q}^2I_3 + [n]_q[n+1]_{qq}I_{2q}^2I_3^2), \tag{4.14b}$$

where the q-deformed versions ${}_qI_a$ of (4.12) in the basis (2.6) are

$${}_qI_1 = \hat{\mathcal{D}}_zT_zT_vT_+(T_-T_{\overline{v}})^{-1}, \tag{4.15a}$$

$$\begin{aligned}{}_qI_2 = {} & (q\hat{M}_z\hat{\mathcal{D}}_vT_-^2 + \hat{M}_z\hat{M}_{\overline{z}}\hat{\mathcal{D}}_+T_-T_{\overline{v}}T_v^{-1} + \hat{\mathcal{D}}_-T_- + q^{-1}\hat{M}_{\overline{z}}\hat{\mathcal{D}}_{\overline{v}} - \lambda\hat{M}_v\hat{M}_{\overline{z}}\hat{\mathcal{D}}_-\hat{\mathcal{D}}_+T_{\overline{v}})T_{\overline{v}}T_{\overline{z}}^{-1},\end{aligned} \tag{4.15b}$$

$$ {}_qI_3 = \hat{\mathcal{D}}_z T_{\bar{z}}. \tag{4.15c} $$

Then the *q*-Weyl equations are

$$ {}_q\tilde{I}^{+}(4)C^{+}(z) = T(z,\bar{z}), \tag{4.16a} $$

$$ {}_q\tilde{I}^{-}(4)C^{-}(\bar{z}) = T(z,\bar{z}). \tag{4.16b} $$

[For comparison, note that for the derivation of the *q*-Maxwell operators (2.13) were used for the following expressions: ${}_qI_n^{+}=\frac{1}{2}([n+2]_{qq}I_{1q}I_2-[n+3]_{qq}I_{2q}I_1)$, ${}_qI_n^{-}=\frac{1}{2}([n+2]_{qq}I_{3q}I_2-[n+3]_{qq}I_{2q}I_3)$.]

Finally, we write down the pair of equations which give the Weyl tensor components in terms of the metric tensor,

$$ {}_q\tilde{I}^{+}(2)h(z,\bar{z}) = C^{+}(z), \tag{4.17a} $$

$$ {}_q\tilde{I}^{-}(2)h(z,\bar{z}) = C^{-}(\bar{z}). \tag{4.17b} $$

We stress the advantage of the indexless formalism due to which two different pairs of equations, (4.16) and (4.17), may be written using the same parameter-dependent operator expressions by just specializing the values of the parameter.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 10 OCTOBER 2004

Degenerate principal series of quantum Harish–Chandra modules

Olga Bershtein[a)]
Institute for Low Temperature Physics and Engineering, 47 Lenin Avenue, 61103 Kharkov, Ukraine

(Received 22 January 2004; accepted 7 June 2004; published 12 October 2004)

In this paper we study a quantum analog of a degenerate principal series of $U_q\mathfrak{su}_{n,n}$-modules $(0<q<1)$ related to the Shilov boundary of the quantum $n\times n$-matrix unit ball. We give necessary and sufficient conditions for the modules to be simple and unitarizable and investigate their equivalence. These results are q-analogs of known classical results on reducibility and unitarizability of $\mathrm{SU}(n,n)$-modules obtained by Johnson, Sahi, Zhang, Howe, and Tan. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1786348]

I. INTRODUCTION

In this paper we investigate a quantum analog of the degenerate principal series of representations of the algebra $U_q\mathfrak{su}_{n,n}$ related to the Shilov boundary of the quantum $n\times n$-matrix unit ball. We give necessary and sufficient conditions for the representations to be irreducible and unitary.

In this work we provide q-analogs of classical results obtained by Johnson, Sahi, Zhang, Howe, and Tan.[1–5] Another degenerate principal series is considered in the Klimyk and Pakuliak paper.[6]

We use Bargman's approach for investigating representations (see Ref. 7, where unitary strongly continuous irreducible representations of the group SU(1,1) were described). Explicit formulas for operators of $\mathfrak{su}_{1,1}$-representations were found in a weight vectors basis in Ref. 7. Results on irreducibility and unitarizability can be obtained from the formulas as corollaries.

In the general case one needs much more effort to obtain similar formulas. Important results in this direction were obtained by Howe in Ref. 1. He received certain results on irreducibility and unitarizability of modules of the simplest degenerate principal series for $\mathrm{U}(m,n)$ and some other classical groups.

The Lee paper[8] directly continues this Howe work. In Ref. 8 the degenerate principal series for $\mathrm{U}(n,n)$ related to the Shilov boundary of the $n\times n$-quantum ball is investigated and answers to the same questions are obtained.

This work generalizes results from Ref. 8 to the quantum case with $0<q<1$. Passing to the limit as $q\mapsto 1$ one can get up to notation the results of the above-mentioned paper.

This paper is organized as follows: In Sec. II we define the representations $\pi_{\alpha,\beta}$ of the degenerate principal series [see (5)]. In Sec. III we investigate the equivalence of $\pi_{\alpha,\beta}$ (see Proposition 3). In Sec. IV we discuss some auxiliary results on $\pi_{\alpha,\beta}$. These results will be used in the sequel. In Sec. V we give necessary and sufficient for $\pi_{\alpha,\beta}$ to be irreducible (see Proposition 11). For the case $\pi_{\alpha,\beta}$ is reducible, we describe all its irreducible subrepresentations. In Sec. VI we find explicit formulas for intertwining operators between $\pi_{\alpha,\beta}$ and $\pi_{-n-\beta,-n-\alpha}$ [see (17)]. In Sec. VII we investigate unitarizability of irreducible representations of the degenerate principal series. Most of the technical details of the proofs are contained in the Appendix.

II. DEFINITION OF THE DEGENERATE PRINCIPAL SERIES OF REPRESENTATIONS

Recall some concepts on geometric realizations for certain series of representations of real semisimple Lie groups and Lie algebras.

Consider the affine algebraic group $G=\mathrm{SL}_{2n}(\mathbb{C})$ and its maximal parabolic subgroup

$$P=\left\{\begin{pmatrix} A & B \\ 0 & D \end{pmatrix} \middle| A,B,D \in Mat_{n,n}(\mathbb{C}), (\det A)(\det D)=1\right\}.$$

Then the projective variety G/P is isomorphic to the space $Gr_n(\mathbb{C}^{2n})$ of n-dimensional subspaces in $\mathbb{C}^{2n}$. The subgroup $K=S(GL_n(\mathbb{C})\times GL_n(\mathbb{C}))$ acts naturally on G/P. Denote by Ω the open K-orbit. It can be easily proved that

$$\Omega=\{L \in Gr_n(\mathbb{C}^{2n}) | \dim L \cap (\mathbb{C}^n)_1 = \dim L \cap (\mathbb{C}^n)_2 = 0\},$$

where $(\mathbb{C}^n)_1$ and $(\mathbb{C}^n)_2$ are the subspaces generated by the elements $\{\varepsilon_1,\ldots,\varepsilon_n\}$, $\{\varepsilon_{n+1},\ldots,\varepsilon_{2n}\}$ of the standard basis for $\mathbb{C}^{2n}$, respectively. It can be verified that Ω is an affine variety.

Set

$$\mathbf{t}=\begin{pmatrix} t_{11} & t_{12} & \cdots & t_{12n} \\ \cdots & \cdots & \cdots & \cdots \\ t_{n1} & t_{n2} & \cdots & t_{n2n} \end{pmatrix}, \quad \mathrm{rk}\mathbf{t}=n,$$

and $\mathbb{C}[\mathrm{Mat}_{n,2n}] \overset{\text{def}}{=} \mathbb{C}[t_{11},\ldots,t_{n2n}]$. Define

$$t_J^{\wedge n} \overset{\text{def}}{=} \sum_{s\in S_n} (-1)^{l(s)} t_{1j_{s(1)}} \cdot t_{2j_{s(2)}} \cdots t_{nj_{s(n)}},$$

where $l(s)$ is the length of permutation s, $J=\{j_1,\ldots,j_n\}$, $1\leqslant j_1<\cdots<j_n\leqslant 2n$, and t_{ij} are the matrix entries of $\mathbf{t}$. The elements $t_J^{\wedge n}$ are called Plucker projective "coordinates" on $Gr_n(\mathbb{C}^{2n})$. Denote by $\mathbb{C}[\mathrm{Pl}_{n,2n}]\subset\mathbb{C}[\mathrm{Mat}_{n,2n}]$ the subalgebra generated by all $t_J^{\wedge n}$.

Consider the algebra $\mathbb{C}[\Omega]$ of regular functions on Ω. Let us introduce some notation. Set $t \overset{\text{def}}{=} t^{\wedge n}_{\{n+1,\ldots,2n\}}$ and

$$z_a^b = t^{-1} t^{\wedge n}_{J_{ab}}, \quad a,b=1,\ldots,n, \quad \text{where } J_{ab}=\{n+1,\ldots,2n\}\setminus\{2n+1-b\}\cup\{a\};$$

$$\mathbf{z}=\begin{pmatrix} z_1^1 & \ldots & z_1^n \\ \ldots & \ldots & \ldots \\ z_n^1 & \ldots & z_n^n \end{pmatrix}, \quad \det\mathbf{z}=\det\begin{pmatrix} z_1^1 & \ldots & z_1^n \\ \ldots & \ldots & \ldots \\ z_n^1 & \ldots & z_n^n \end{pmatrix}.$$

Then the algebra $\mathbb{C}[\Omega]$ is canonically isomorphic to the localization of the algebra $\mathbb{C}[\mathrm{Mat}_n] \overset{\text{def}}{=} \mathbb{C}[z_1^1,\ldots,z_n^n]$ with respect to the multiplicative set $(\det\mathbf{z})^{\mathbb{Z}_+}$. The vector space $\mathbb{C}[\Omega]=\mathbb{C}[\mathrm{Mat}_n]_{\det\mathbf{z}}$ can be naturally equipped with the $\mathfrak{sl}_{2n}$-module structure and the K-module structure, and these structures are compatible (see Ref. 9).

Therefore the action of the universal enveloping algebra $U\mathfrak{sl}_{2n}$ in the vector space $\mathbb{C}[\mathrm{Mat}_n]_{\det\mathbf{z}}$ is well defined. Moreover, the $U\mathfrak{sl}_{2n}$-action in the localization of the algebra $\mathbb{C}[\mathrm{Pl}_{n,2n}]$ with respect to the multiplicative set $t^{\mathbb{Z}_+}$ is well defined. Hence the $U\mathfrak{sl}_{2n}$-action in the space $\mathbb{C}[\mathrm{Mat}_n]_{\det\mathbf{z}}\cdot(\det\mathbf{z})^\alpha t^\beta$ is well defined for each $\alpha,\beta\in\mathbb{Z}$ (they are spaces of sections of homogeneous vector bundles over Ω; we pass from $\alpha,\beta\in\mathbb{Z}$ to $\alpha,\beta\in\mathbb{R}$ standardly).

Now let us pass to the quantum case. Everywhere in the sequel $q\in(0,1)$, $\mathbb{C}$ is the ground field and all algebras are unital and associative.

Denote by $U_q\mathfrak{sl}_{2n}$ the algebra defined by its generators $\{E_i,F_i,K_i,K_i^{-1}\}_{i=1}^{2n-1}$ and the relations

$$K_iK_j = K_jK_i, \quad K_iK_i^{-1} = K_i^{-1}K_i = 1;$$

$$K_iE_i = q^2E_iK_i, \quad K_iF_i = q^{-2}F_iK_i;$$

$$E_iF_j - F_jE_i = \delta_{ij}(K_i - K_i^{-1})/(q - q^{-1});$$

$$K_iE_j = q^{-1}E_jK_i, \quad K_iF_j = qF_jK_i, \quad |i-j| = 1;$$

$$E_i^2E_j - (q + q^{-1})E_iE_jE_i + E_jE_i^2 = 0, \quad |i-j| = 1;$$

$$F_i^2F_j - (q + q^{-1})F_iF_jF_i + F_jF_i^2 = 0, \quad |i-j| = 1;$$

$$K_iE_j - E_jK_i = K_iF_j - F_jK_i, = E_iE_j - E_jE_i = F_iF_j - F_jF_i = 0, \quad |i-j| > 1.$$

We equip $U_q\mathfrak{sl}_{2n}$ with the standard Hopf algebra structure. The comultiplication, the counit and the antipode are defined by their actions on the generators:

$$\triangle E_j = E_j \otimes 1 + K_j \otimes E_j, \quad \varepsilon(E_j) = 0, \quad S(E_j) = -K_j^{-1}E_j,$$

$$\triangle F_j = F_j \otimes K_j^{-1} + 1 \otimes F_j, \quad \varepsilon(F_j) = 0, \quad S(F_j) = -F_jK_j,$$

$$\triangle K_j = K_j \otimes K_j, \quad \varepsilon(K_j) = 1, \quad S(K_j) = K_j^{-1}$$

for all $j = 1, \ldots, 2n-1$.

The algebra $\mathbb{C}[\mathrm{Mat}_{n,2n}]_q$ of polynomials on the quantum $n \times 2n$-matrix space is defined by its generators $\{t_{ij}\}_{i=1,\ldots,n;j=1,\ldots,2n}$ and the relations (cf. Ref. 10)

$$t_{ik}t_{jk} = qt_{jk}t_{ik}, \quad t_{ki}t_{kj} = qt_{kj}t_{ki}, \quad i < j,$$

$$t_{ij}t_{kl} = t_{kl}t_{ij}, \quad i < k \text{ and } j > l,$$

$$t_{ij}t_{kl} - t_{kl}t_{ij} = (q - q^{-1})t_{ik}t_{jl}, \quad i < k \text{ and } j < l. \tag{1}$$

Define q-minors as follows:

$$t_{IJ}^{\wedge k} \overset{\text{def}}{=} \sum_{s \in S_k} (-q)^{l(s)} t_{i_1 j_{s(1)}} \cdots t_{i_k j_{s(k)}}, \tag{2}$$

for any $I = \{i_1, \ldots, i_k\}$, $1 \leqslant i_1 < \cdots < i_k \leqslant n$, $J = \{j_1, \ldots, j_k\}$, $1 \leqslant j_1 < \cdots < j_k \leqslant 2n$; here $l(s)$ denotes the length of permutation s.

Consider the algebra $\mathbb{C}[\mathrm{Pl}_{n,2n}]_q \subset \mathbb{C}[\mathrm{Mat}_{n,2n}]_q$ generated by all q-minors $t_{\{1,\ldots,n\}J}^{\wedge n}$, card $J = n$. It is equipped with the standard $U_q\mathfrak{sl}_n^{op} \otimes U_q\mathfrak{sl}_{2n}$-module algebra structure. ($U_q\mathfrak{sl}_n^{op}$ is a Hopf algebra with the same multiplication and the opposite comultiplication.) It is easy to show that the $U_q\mathfrak{sl}_n^{op}$-structure can be reconstructed from the below equalities:

$$K_l t_{ij} = \begin{cases} q^{-1}t_{ij}, & l = i-1, \\ qt_{ij}, & l = i, \\ 0, & \text{otherwise;} \end{cases}$$

$$E_l t_{ij} = q^{-1/2} \cdot \begin{cases} t_{(i+1)j}, & l = i, \\ 0, & \text{otherwise;} \end{cases} \qquad F_l t_{ij} = q^{1/2} \cdot \begin{cases} t_{(i-1)j}, & l = i-1, \\ 0, & \text{otherwise.} \end{cases}$$

The element $t \overset{\text{def}}{=} t^{\wedge n}_{\{1,2,\ldots,n\}\{n+1,n+2,\ldots,2n\}}$ quasicommutes with t_{ij} for all $i=1,\ldots,n$, $j=1,\ldots,2n$ and is $U_q\mathfrak{sl}_n^{op}$-invariant.

Denote by $\mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t}$ the localization of the algebra $\mathbb{C}[\mathrm{Pl}_{n,2n}]_q$ with respect to the multiplicative system $t^{\mathbb{Z}_+}$. Introduce q-analogs of coordinates on Ω as follows:

$$z_a^b \overset{\text{def}}{=} t^{-1} t^{\wedge n}_{\{1,2,\ldots,n\}J_{ab}}, \tag{3}$$

where $J_{ab}=\{n+1,n+2,\ldots,2n\}\setminus\{2n+1-b\}\cup\{a\}$.

The defining relations for the subalgebra generated by the elements z_a^b are obtained in Ref. 11:

$$z_a^{b_1} z_a^{b_2} = q z_a^{b_2} z_a^{b_1}, \quad b_1 < b_2,$$

$$z_{a_1}^{b} z_{a_2}^{b} = q z_{a_2}^{b} z_{a_1}^{b}, \quad a_1 < a_2,$$

$$z_{a_1}^{b_1} z_{a_2}^{b_2} = z_{a_2}^{b_2} z_{a_1}^{b_1}, \quad b_1 < b_2 \text{ and } a_1 > a_2,$$

$$z_{a_1}^{b_1} z_{a_2}^{b_2} - z_{a_2}^{b_2} z_{a_1}^{b_1} = (q - q^{-1}) z_{a_1}^{b_2} z_{a_2}^{b_1}, \quad b_1 < b_2 \text{ and } a_1 < a_2.$$

(For the special case $n=2$ see the Noumi paper.[12])

It can be checked easily that $zt=qtz$ for any $z \in \{z_a^b \mid a,b=1,\ldots,n\}$.

It can be proved that for any $\xi \in U_q\mathfrak{sl}_{2n}$, $f \in \mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t}$ there is a unique Laurent polynomial $p_{f,\xi}$ of the variable $u=q^k$ with coefficients in $\mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t}$ such that $p_{f,\xi}(q^k)=\xi\cdot(ft^k)t^{-k}$. This allows one to prove the existence of an extension of the $U_q\mathfrak{sl}_{2n}$-module algebra structure onto $\mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t}$ (see Ref. 13).

The subalgebra generated by z_a^b is the algebra $\mathbb{C}[\mathrm{Mat}_n]_q$ of "polynomials on the quantum $n\times n$-matrix space" [cf. (1)]. The algebra $\mathbb{C}[\mathrm{Mat}_n]_q$ is a $U_q\mathfrak{sl}_{2n}$-module subalgebra of the $U_q\mathfrak{sl}_{2n}$-module algebra $\mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t}$ (see Ref. 14).

Proposition 1 (Ref. 14): For all $a,b=1,\ldots,n$

$$K_n^{\pm 1} z_a^b = \begin{cases} q^{\pm 2} z_a^b, & a = n \text{ and } b = n \\ q^{\pm 1} z_a^b, & (a = n \text{ and } b \neq n) \text{ or } (a \neq n \text{ and } b = n) \\ z_a^b, & \text{otherwise,} \end{cases}$$

$$F_n z_a^b = q^{1/2} \cdot \begin{cases} 1, & a = n \text{ and } b = n \\ 0, & \text{otherwise,} \end{cases} \qquad E_n z_a^b = -\, q^{1/2} \cdot \begin{cases} q^{-1} z_a^n z_n^b, & a \neq n \text{ and } b \neq n \\ (z_n^n)^2, & a = n \text{ and } b = n \\ z_n^n z_a^b, & \text{otherwise} \end{cases}$$

and for all $k \neq n$ we have

$$K_k^{\pm 1} z_a^b = \begin{cases} q^{\pm 1} z_a^b, & (k < n \text{ and } a = k) \text{ or } (k > n \text{ and } b = 2n-k), \\ q^{\mp 1} z_a^b, & (k < n \text{ and } a = k+1) \text{ or } (k > n \text{ and } b = 2n-k+1), \\ z_a^b, & \text{otherwise,} \end{cases}$$

$$F_k z_a^b = q^{1/2}\cdot\begin{cases} z_{a+1}^b, & k<n \text{ and } a=k,\\ z_a^{b+1}, & k>n \text{ and } b=2n-k,\\ 0, & \text{otherwise,}\end{cases}\quad E_k z_a^b = q^{-1/2}\cdot\begin{cases} z_{a-1}^b, & k<n \text{ and } a=k+1,\\ z_a^{b-1}, & k>n \text{ and } b=2n-k+1,\\ 0, & \text{otherwise.}\end{cases}$$

□

In the sequel we use the following notation for q-minors:

$$\mathbf{z}^{\wedge k\{b_1,\dots,b_k\}}_{\{a_1,\dots,a_k\}} \overset{\text{def}}{=} \sum_{s\in S_k}(-q)^{l(s)} z^{b_{s(1)}}_{a_1}\cdots z^{b_{s(k)}}_{a_k}, \tag{4}$$

where $a_1<\cdots<a_k$, $b_1<\cdots<b_k$. It is known that the element $\det_q \mathbf{z} \overset{\text{def}}{=} \mathbf{z}^{\wedge n\{1,\dots,n\}}_{\{1,\dots,n\}}$ belongs to the center of $\mathbb{C}[\mathrm{Mat}_n]_q$ and $\mathbb{C}[\mathrm{Mat}_n]_q$ has no zero divisors.

Denote by $\mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}}$ the localization of the algebra $\mathbb{C}[\mathrm{Mat}_n]_q$ with respect to the multiplicative system $(\det_q \mathbf{z})^{\mathbb{Z}_+}$. We consider $\mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}}$ as a q-analog of the space of regular functions on the open orbit Ω. Let $\tilde{t}=t^{\wedge n}_{\{1,\dots,n\}\{1,\dots,n\}}$. Since $\det_q \mathbf{z}=t^{-1}\tilde{t}$, we see that the algebra $\mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}}$ is a $U_q\mathfrak{sl}_{2n}$-module subalgebra of the $U_q\mathfrak{sl}_{2n}$-module algebra $\mathbb{C}[\mathrm{Pl}_{n,2n}]_{q,t\cdot\tilde{t}}$. (As above, to verify that the extension is well defined we use the following fact: for all $\xi\in U_q\mathfrak{sl}_{2n}$, $f\in V$ the vector valued function $\xi\cdot(f(\det_q \mathbf{z})^k)(\det_q \mathbf{z})^{-k}$ is a Laurent polynomial of the variable $u=q^k$.)

Denote by V the vector space $\mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}}$. Assume first that $\alpha,\beta\in\mathbb{Z}$. Define a representation $\pi_{\alpha,\beta}: U_q\mathfrak{sl}_{2n}\to \mathrm{End}\, V$ as follows:

$$\pi_{\alpha,\beta}(\xi)f=(\xi\cdot(f(\tilde{t})^\alpha t^\beta))t^{-\beta}(\tilde{t})^{-\alpha}=(\xi\cdot(f(\det_q \mathbf{z})^\alpha t^{\beta+\alpha}))t^{-\alpha-\beta}(\det_q \mathbf{z})^{-\alpha} \tag{5}$$

for every $\xi\in U_q\mathfrak{sl}_{2n}$, $f\in V$. For each $\lambda\in\mathbb{Z}$ we have

$$E_j t^\lambda=0,\quad F_j t^\lambda=0,\quad K_j t^\lambda=t^\lambda,\quad j=1,\dots,2n-1,\quad j\neq n,$$

$$E_n t^\lambda=q^{-3/2}\frac{1-q^{-2\lambda}}{1-q^{-2}}z_n^n t^\lambda,\quad F_n t^\lambda=0,\quad K_n^{\pm1}t^\lambda=q^{\mp\lambda}t^\lambda,$$

$$E_j(\det_q \mathbf{z})^\lambda=0,\quad F_j(\det_q \mathbf{z})^\lambda=0,\quad K_j(\det_q \mathbf{z})^\lambda=(\det_q \mathbf{z})^\lambda,\quad j=1,\dots,2n-1,\quad j\neq n,$$

$$K_n^{\pm1}((\det_q \mathbf{z})^\lambda)=q^{\pm2\lambda}(\det_q \mathbf{z})^\lambda,\quad E_n((\det_q \mathbf{z})^\lambda)=-q^{1/2}\frac{1-q^{2\lambda}}{1-q^2}z_n^n(\det_q \mathbf{z})^\lambda,$$

$$F_n((\det_q \mathbf{z})^\lambda)=q^{1/2}\frac{1-q^{-2\lambda}}{1-q^{-2}}\mathbf{z}^{\wedge n-1}_{\{1,\dots,n-1\}\{1,\dots,n-1\}}(\det_q \mathbf{z})^{\lambda-1},\quad \lambda\neq0.$$

From these equalities we see that for each $\xi\in U_q\mathfrak{sl}_{2n}$, $f\in V$ the vector valued function $p_{f,\xi}(q^\alpha,q^\beta)\overset{\text{def}}{=}\pi_{\alpha,\beta}(\xi)(f)$ is a Laurent polynomial of the variables q^α, q^β. These Laurent polynomials are defined by their values on the set $\{(q^\alpha,q^\beta)\,|\,\alpha,\beta\in\mathbb{Z}\}$ and deliver the canonical "analytic continuation" for $\pi_{\alpha,\beta}(\xi)(f)$ to $(\alpha,\beta)\in\mathbb{C}^2$.

Let $(\alpha,\beta)\in\mathbb{C}^2$. Define a representation $\pi_{\alpha,\beta}(\xi)(f)\overset{\text{def}}{=}p_{f,\xi}(q^\alpha,q^\beta)$. Indeed, to prove that the representation $\pi_{\alpha,\beta}$ is well defined for $(\alpha,\beta)\in\mathbb{C}^2$ it is sufficient to verify some identities for Laurent polynomials. These identities are correct for $\alpha,\beta\in\mathbb{Z}$.

Introduce a "deformation parameter" h by the equality $q=e^{-h/2}$. Clearly, if $\alpha_1=\alpha_2+i(2\pi/h)$ and $\beta_1=\beta_2+i(2\pi/h)$, then $\pi_{\alpha_1,\beta_1}=\pi_{\alpha_2,\beta_2}$. Then it is enough to consider $(\alpha,\beta)\in D$, where

$$D=\left\{(\alpha,\beta)\in\mathbb{C}^2|0\leqslant \operatorname{Im}\alpha<\frac{2\pi}{h},0\leqslant \operatorname{Im}\beta<\frac{2\pi}{h}\right\}.$$

Recall that a representation $\rho: U_q\mathfrak{sl}_{2n}\to \operatorname{End} W$ is called *weight* if the representation space W decomposes as follows:

$$W=\bigoplus_{\lambda} W_\lambda,\quad \text{where } \lambda=(\lambda_1,\ldots,\lambda_{2n-1})\in\mathbb{Z}^{2n-1},$$

$$W_\lambda=\left\{v\in W|\rho(K_j^{\pm})v=q^{\pm\lambda_j}v, j=1,\ldots,2n-1\right\}.$$

The subspace W_λ is called weight subspace with weight λ. In the sequel we will consider only weight representations. It is clear that $\pi_{\alpha,\beta}$ is a weight representation if and only if $q^{\alpha-\beta}\in q^{\mathbb{Z}}$.

Let W be a weight $U_q\mathfrak{sl}_{2n}$-module. Define operators H_i for $i=1,\ldots,2n-1$ by the formula $H_i|_{W_\lambda}=\lambda_i$.

III. EQUIVALENCE OF THE REPRESENTATIONS

Recall that $q=e^{-h/2}$. For any complex α,β such that $0\leqslant \operatorname{Im}\alpha<2\pi/h$, $0\leqslant \operatorname{Im}\beta<2\pi/h$, the statements $\alpha-\beta\in\mathbb{Z}$ and $q^{\alpha-\beta}\in q^{\mathbb{Z}}$ are equivalent.

Proposition 2: If $\alpha,\beta\notin\mathbb{Z}$, then the representations $\pi_{\alpha,\beta}$ and $\pi_{-n-\beta,-n-\alpha}$ are equivalent.

The proof is reduced to explicit formulas for the intertwining operators. It is given in Sec. VI.

If $\alpha,\beta\in\mathbb{Z}$, then the representations $\pi_{\alpha,\beta}$ and $\pi_{-n-\beta,-n-\alpha}$ are not equivalent. This fact follows from the statement that only one of the representations $\pi_{\alpha,\beta}$ and $\pi_{-n-\beta,-n-\alpha}$ for integral α,β has a finite dimensional subrepresentation. An explanation of this fact is given in the end of Sec. V.

The representations $\pi_{\alpha,\beta}$ and $\pi_{\alpha-1,\beta+1}$ are equivalent for all α,β. The corresponding intertwining operator $T: V\to V$ is defined as follows: for every $f\in V=\mathbb{C}[\operatorname{Mat}_n]_{q,\det_q \mathbf{z}}$ $T(f)=f(\det_q \mathbf{z})^{-1}$. Indeed, since for each $f\in V$, $\xi\in U_q\mathfrak{sl}_{2n}$;

$$\begin{aligned}\pi_{\alpha-1,\beta+1}(\xi)(f)&=(\xi\cdot(f(\det_q \mathbf{z})^{\alpha-1}t^{\beta+\alpha}))t^{-\alpha-\beta}(\det_q \mathbf{z})^{1-\alpha}\\&=(\xi\cdot(f(\det_q \mathbf{z})^{-1}(\det_q \mathbf{z})^{\alpha}t^{\beta+\alpha}))t^{-\alpha-\beta}(\det_q \mathbf{z})^{-\alpha}(\det_q \mathbf{z})=\pi_{\alpha,\beta}(\xi)(f(\det_q \mathbf{z})^{-1})\det_q \mathbf{z},\end{aligned}$$

we see that T intertwines the representations $\pi_{\alpha,\beta}$ and $\pi_{\alpha-1,\beta+1}$. Therefore without loss of generality we can assume that $\alpha,\beta\in\mathcal{D}$, where

$$\mathcal{D}=\left\{(\alpha,\beta)\in\mathbb{C}^2|\alpha-\beta\in\{0,1\},0\leqslant \operatorname{Im}\alpha<\frac{2\pi}{h},0\leqslant \operatorname{Im}\beta<\frac{2\pi}{h}\right\}. \tag{6}$$

Let us introduce an equivalence relation on $\mathcal{D}$. The equivalence class of (α,β) consists of one point for $\alpha,\beta\in\mathbb{Z}$ and from two points for $\alpha,\beta\notin\mathbb{Z}$:

$$(\alpha_1,\beta_1)\sim(\alpha_2,\beta_2),\quad \text{iff}\begin{cases}\alpha_1=-n-\beta_2,\ \beta_1=-n-\alpha_2 & \text{for } \operatorname{Im}\alpha_1=\operatorname{Im}\alpha_2=0,\\ \alpha_1=\dfrac{2\pi i}{h}-n-\beta_2,\ \beta_1=\dfrac{2\pi i}{h}-n-\alpha_2, & \text{otherwise.}\end{cases}$$

Proposition 3: The set of equivalence classes $\mathcal{D}/\sim$ is in the one-to-one correspondence $(\alpha,\beta)\mapsto\pi_{\alpha,\beta}$ with the set of equivalence classes of the representations of the degenerate principal series.

Proof: By the above, each representation of the degenerate principal series is equivalent to the representation $\pi_{\alpha,\beta}$ for some $(\alpha,\beta)\in\mathcal{D}$.

Prove that the representations π_{α_1,β_1} and π_{α_2,β_2}, with (α_1,β_1), $(\alpha_2,\beta_2)\in\mathcal{D}$, are equivalent if and only if $(\alpha_1,\beta_1)\sim(\alpha_2,\beta_2)$. For that we calculate the action of a central element $C\in U_q\mathfrak{sl}_{2n}^{\text{ext}}$ (see Ref. 15 for the definition). It can be proved that $\pi_{\alpha,\beta}(C)$ is a scalar operator for all $\alpha,\beta\in\mathcal{D}$.

From Ref. 16 it follows that there exists a unique central element C which acts on the $U_q\mathfrak{sl}_{2n}$-highest vector v^{high} with weight λ as follows:

$$C(v^{\text{high}}) = \sum_{j=0}^{2n-1} q^{-2(\mu_j,\lambda+\rho)} v^{\text{high}},$$

where $\mu_0=\varpi_1$, $\mu_j=-\varpi_j+\varpi_{j+1}$ for $j=1,\dots,2n-2$, $\mu_{2n-1}=-\varpi_{2n-1}$, ϖ_j are the fundamental weights, 2ρ is the sum of positive roots of the Lie algebra $\mathfrak{sl}_{2n}$, and we choose the invariant scalar product such that $(\alpha,\alpha)=2$ for any simple root α.

First let α,β be integers. It can be proved that

$$\pi_{\alpha,\beta}(C)(\det_q \mathbf{z})^\beta = 4 \operatorname{ch}\frac{h}{2}(\alpha+\beta+n)\left(\sum_{j=0}^{n-1}\operatorname{ch}\frac{h}{2}j\right)(\det_q \mathbf{z})^\beta.$$

Hence $\pi_{\alpha,\beta}(C)=4\operatorname{ch}(h/2)(\alpha+\beta+n)(\Sigma_{j=0}^{n-1}\operatorname{ch}(h/2)j)\cdot \mathrm{Id}$ for all $(\alpha,\beta)\in\mathcal{D}$.

Suppose that π_{α_1,β_1} and π_{α_2,β_2} are equivalent. Equivalent representations have the same weight lattice. Therefore $(\alpha_1-\beta_1)-(\alpha_2-\beta_2)\in 2\mathbb{Z}$. Since $(\alpha_1,\beta_1),(\alpha_2,\beta_2)\in\mathcal{D}$, we see that $(\alpha_1-\beta_1)-(\alpha_2-\beta_2)=0$.

Then the equivalent representations π_{α_1,β_1} and π_{α_2,β_2} have the same values of central characters, which means that

$$\left(\operatorname{ch}\frac{h}{2}(\alpha_1+\beta_1+n)-\operatorname{ch}\frac{h}{2}(\alpha_2+\beta_2+n)\right)\sum_{j=0}^{n-1}\operatorname{ch}\frac{h}{2}j=0.$$

Since $0\leqslant \operatorname{Im}\alpha_1<2\pi/h$, $0\leqslant\operatorname{Im}\beta_1<2\pi/h$, $0\leqslant\operatorname{Im}\alpha_2<2\pi/h$, $0\leqslant\operatorname{Im}\beta_2<2\pi/h$, we have that $\alpha_1+\beta_1=\alpha_2+\beta_2$, or $\alpha_1+\beta_1=-\alpha_2-\beta_2-2n$, or $\alpha_1+\beta_1=-\alpha_2-\beta_2-2n-(4\pi i/h)$. If $\alpha_1+\beta_1=\alpha_2+\beta_2$, then $\alpha_1=\alpha_2$ and $\beta_1=\beta_2$. For any fixed nonintegral α_1,β_1 there is a unique pair $(\alpha_2,\beta_2)\in\mathcal{D}$ such that either $\alpha_1+\beta_1=-\alpha_2-\beta_2-2n$ or $\alpha_1+\beta_1=-\alpha_2-\beta_2-2n-(4\pi i/h)$, and $(\alpha_1,\beta_1)\sim(\alpha_2,\beta_2)$. Although for integral parameters π_{α_1,β_1} and π_{α_2,β_2} are not equivalent, because the only one of them has a finite-dimensional subrepresentation. This can be deduced from Corollary 4. Thus each equivalence class in $\mathcal{D}$ is assigned to a unique equivalence class of the representations of the degenerate principal series $\pi_{\alpha,\beta}$. □

IV. AUXILIARY STATEMENTS ON THE $\pi_{\alpha,\beta}$-STRUCTURE

In this section we describe some necessary technical results, that will be useful in the sequel.

Everywhere in this section we assume that $n>1$. However, Propositions 4, 7, and 10 and Corollaries 1 and 2 are still sensible and correct for $n=1$.

Let $U_q\mathfrak{k}_{ss}\subset U_q\mathfrak{sl}_{2n}$ be the Hopf subalgebra generated by E_j, F_j, $K_j^{\pm1}$, $j=1,\dots,2n-1$, $j\neq n$ and $U_q\mathfrak{k}\subset U_q\mathfrak{sl}_{2n}$ be the Hopf subalgebra generated by $K_n^{\pm1}$ and $U_q\mathfrak{k}_{ss}$.

Note that $\pi_{\alpha,\beta}|_{U_q\mathfrak{k}_{ss}}$ does not depend on α,β. The following preliminary result on reducibility of $\pi_{\alpha,\beta}$ is well known in the classical case. For brevity, set

$$\mathbf{z}^{\wedge k}=\mathbf{z}^{\wedge k\{1,\cdots,k\}}_{\{1,\cdots,k\}}$$

(note that, obviously $\mathbf{z}^{\wedge n}=\det_q\mathbf{z}$). Introduce the following notation: $\hat{K}=\{\overline{\mathbf{k}}=(k_1,\dots,k_n)\in\mathbb{Z}^n \mid k_1\geqslant k_2\geqslant\cdots\geqslant k_n\}$, $\mathbf{e_j}=(0,\dots,\overset{j}{1},\dots,0)\in\mathbb{Z}^n$.

Proposition 4: The representation space V for $\pi_{\alpha,\beta}$ splits into a sum of simple pairwise nonisomorphic $U_q\mathfrak{k}$-modules as follows:

$$V=\bigoplus_{\overline{\mathbf{k}}\in\hat{K}} V_{\overline{\mathbf{k}}},\quad \text{with } V_{\overline{\mathbf{k}}}=\pi_{\alpha,\beta}(U_q\mathfrak{k})\cdot v^{\frac{h}{\mathbf{k}}}_{\overline{\mathbf{k}}} \quad\text{and}\quad v^{\frac{h}{\mathbf{k}}}_{\overline{\mathbf{k}}}=(\mathbf{z}^{\wedge1})^{k_1-k_2}\cdots(\mathbf{z}^{\wedge n-1})^{k_{n-1}-k_n}(\mathbf{z}^{\wedge n})^{k_n}.$$

Proof: Consider the filtration $V=\cup_{k=0}^{\infty}V^{(k)}$ with $V^{(k)}=\mathbb{C}[\mathrm{Mat}_n]_q\cdot(\det_q \mathbf{z})^{-k}$. It is sufficient to prove that

$$V^{(k)}=\bigoplus_{k_n\geqslant -k} V_{\mathbf{k}}^{-}.$$

Equip the vector space $V^{(k)}$ with the natural grading $V^{(k)}=\overset{\infty}{\underset{j=-nk}{\oplus}}(V^{(k)})_j$ as follows: $(V^{(k)})_j=\{v\in V^{(k)}\,|\,K_0 v=q^{2j}v\}$, with $K_0\overset{\text{def}}{=}K_1K_2^2K_3^3\cdots K_n^nK_{n+1}^{n-1}\cdots K_{2n-2}^2K_{2n-1}$. Therefore we must prove that

$$(\mathbb{C}[\mathrm{Mat}_n]_q\cdot(\det_q \mathbf{z})^{-k})_j=\bigoplus_{\substack{k_n\geqslant -k,\\ k_1+\cdots+k_n=j}} V_{\mathbf{k}}^{-}. \tag{7}$$

For $k=0$ statement (7) means that $(\mathbb{C}[\mathrm{Mat}_n]_q)_j=\bigoplus_{k_n\geqslant 0,k_1+\cdots+k_n=j} V_{\mathbf{k}}^{-}$.

First, the dimensions of homogeneous components $\mathbb{C}[\mathrm{Mat}_n]_{q,j}$ of the standardly graded algebra $\mathbb{C}[\mathrm{Mat}_n]_q$ are equal to the dimensions in the classical case,

$$\dim\,\mathbb{C}[\mathrm{Mat}_n]_{q,j}=\binom{n^2+j-1}{j}$$

(it can be easily proved via the Bergman diamond lemma,[15] Sec. 4.1.5). Second, the dimensions of the $U_q\mathfrak{k}$-modules $V_{\mathbf{k}}^{-}$ are equal to the classical ones (this follows from results of quantum groups theory,[17] Chap. 5). Third, there is the well-known Hua result on the coincidence of the dimensions $\mathbb{C}[\mathrm{Mat}_n]_j$ and $\bigoplus_{\substack{k_n\geqslant 0,\\ k_1+k_2+\cdots+k_n=j}} V_{\mathbf{k}}^{-}$ in the classical case.[18] Hence,

$$\dim\,(\mathbb{C}[\mathrm{Mat}_n]_q)_j=\sum_{\substack{k_n\geqslant 0,\\ k_1+\cdots+k_n=j}}\dim V_{\mathbf{k}}^{-},$$

and, finally,

$$(\mathbb{C}[\mathrm{Mat}_n]_q)_j=\bigoplus_{\substack{k_n\geqslant 0,\\ k_1+\cdots+k_n=j}} V_{\mathbf{k}}^{-}.$$

For $k>0$ one has

$$(\mathbb{C}[\mathrm{Mat}_n]_q\cdot(\det_q \mathbf{z})^{-k})_j=\mathbb{C}[\mathrm{Mat}_n]_{q,nk+j}\cdot(\det_q \mathbf{z})^{-k}=\bigoplus_{\substack{k_n\geqslant 0,\\ k_1+\cdots+k_n=nk+j}} V_{\mathbf{k}}^{-}\cdot(\det_q \mathbf{z})^{-k}=\bigoplus_{\substack{k_n\geqslant -k,\\ k_1+\cdots+k_n=j}} V_{\mathbf{k}}^{-}.$$

(Since there are no zero divisors in $\mathbb{C}[\mathrm{Mat}_n]_{q,\det_q \mathbf{z}}$, the proof of statement (7) follows from the last equality.) □

Remark: It can be easily verified that $v_{\mathbf{k}}^{h}$ is a $U_q\mathfrak{k}$-highest vector and with weight $(k_1-k_2,\ldots,k_{n-1}-k_n,2k_n+\alpha-\beta,k_{n-1}-k_n,\ldots,k_1-k_2)$. Then the highest weight of simple $U_q\mathfrak{k}$-module $V_{\mathbf{k}}^{-}$ is equal to $(k_1-k_2,\ldots,k_{n-1}-k_n,2k_n+\alpha-\beta,k_{n-1}-k_n,\ldots,k_1-k_2)$.

In the classical case $\mathfrak{sl}_{2n}=\mathfrak{p}^{-}\oplus\mathfrak{k}\oplus\mathfrak{p}^{+}$ where

$$\mathfrak{p}^{-}=\left\{\begin{pmatrix}0&0\\A&0\end{pmatrix}\middle|\,A\in\mathrm{Mat}_{n,n}(\mathbb{C})\right\},\quad \mathfrak{p}^{+}=\left\{\begin{pmatrix}0&A\\0&0\end{pmatrix}\middle|\,A\in\mathrm{Mat}_{n,n}(\mathbb{C})\right\}.$$

Therefore $U\mathfrak{sl}_{2n}\simeq U\mathfrak{p}^{-}\otimes U\mathfrak{k}\otimes U\mathfrak{p}^{+}$ as $U\mathfrak{k}$-modules ($U\mathfrak{p}^{-}$ and $U\mathfrak{p}^{-}$ are $U\mathfrak{k}$-modules under the adjoint action).

In the quantum case we have an analog of this decomposition obtained by Jakobsen in Ref. 19. A quantum analog $\mathrm{ad}_a, a \in U_q\mathfrak{sl}_{2n}$ of the adjoint action is introduced via the Hopf algebra structure of $U_q\mathfrak{sl}_{2n}$. (The operator ad_a is defined on $b \in U_q\mathfrak{sl}_{2n}$ in the following way: $\mathrm{ad}_a(b) = \Sigma S(a')ba''$, where $\Delta a = \Sigma a' \otimes a''$ is the comultiplication, S is the antipode in $U_q\mathfrak{sl}_{2n}$.) There are n^2-dimensional vector subspaces $\mathfrak{p}_q^+ = U_q\mathfrak{k} \cdot E_n$, $\mathfrak{p}_q^- = U_q\mathfrak{k} \cdot (K_n F_n)$, which are $U_q\mathfrak{k}$-invariant under the adjoint action. Instead of $U\mathfrak{p}^-$, $U\mathfrak{p}^+$, there are the subalgebras $U_q\mathfrak{p}^-$, $U_q\mathfrak{p}^+ \subset U_q\mathfrak{sl}_{2n}$ generated by $\mathfrak{p}_q^-$, $\mathfrak{p}_q^+$, respectively. The algebras $U_q\mathfrak{p}^-$ and $U_q\mathfrak{p}^+$ are $U_q\mathfrak{k}$-modules under the adjoint action. Therefore in the quantum case we get $U_q\mathfrak{sl}_{2n} \simeq U_q\mathfrak{p}^- \otimes U_q\mathfrak{k} \otimes U_q\mathfrak{p}^+$ as $U_q\mathfrak{k}$-modules (see Ref. 19). It is worthwhile to note that $U_q\mathfrak{p}^-$ and $U_q\mathfrak{p}^+$ are not Hopf subalgebras unlike the classical case.

In the last part of this section we describe how each $U_q\mathfrak{k}$-isotypic component $V_{\mathbf{k}}^-$ transforms under the action of $\mathfrak{p}_q^-$ and $\mathfrak{p}_q^+$. This allows one to understand how V transforms under the $U_q\mathfrak{sl}_{2n}$-action. Since

$$U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n) \simeq \mathbb{C}[K_0^{\pm 1}] \otimes (U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n) = \mathbb{C}[K_0^{\pm 1}] \otimes U_q\mathfrak{k}_{ss},$$

where

$$K_0 = K_1 K_2^2 K_3^3 \cdots K_n^n K_{n+1}^{n-1} \cdots K_{2n-2}^2 K_{2n-1}, \tag{8}$$
