A_4: Bonsais B obtained as follows: suppose that T_2 is constructed by attaching the roots of corollas X_1 and X_2 so that X_1 is on the left and X_2 is on the right. Then B is obtained by attaching the roots of $\bar{\partial} X_1$, V, and X_2 from the left or X_1, V, and $\bar{\partial} X_2$ from the left, where V is obtained by attaching the root of T_1 to the lower vertex of the one-edge clear-edged bonsai, illustrated in Fig. 67. In Fig. 67, the first term of A_4 is constructed by $\bar{\partial} X_1$, V, and X_2, and the second term is constructed by X_1, V, and $\bar{\partial} X_2$.

A_5: Bonsais B obtained as follows: Suppose T_2 is constructed by attaching the roots of bonsais Y_1, E, and Y_2 from the left, where Y_1 and Y_2 are corollas and E is the one-edge bonsai. Then B is

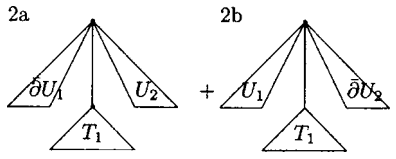

FIG. 72.

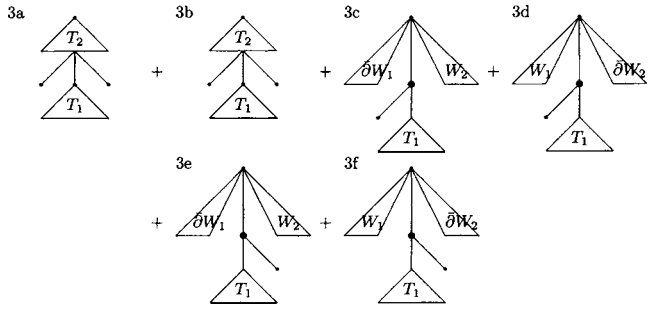

FIG. 73.

constructed by attaching the roots of $\bar{\partial}Y_1$, V, and Y_2 from the left or Y_1, V, and $\bar{\partial}Y_2$ from the left, where V is obtained by connecting the root of T_1 to the lower vertex of E with one edge. This is illustrated in Fig. 68.

If T_1 is the one-vertex bonsai, A_2 becomes 0, since it is equal to $\partial\partial T_2$. And $A_3=0$, since it is twice a multiple of the bonsais obtained by attaching the root of the two-edge corolla to a tip of T_2 (note that we are working mod 2). Also, $A_4=\partial\partial T_2=0$. So $T_1*_1T_2=A_1+A_5$.

12.2.2. When $\partial T_2\neq 0$ and $deg(T_2)=m-1$: When T_1 is not the one-vertex bonsai. This is almost the same as the previous case, but we cannot add more than one edge to the root of T_2. So $T_1*_1T_2$ is the sum of the terms A_1, A_3, and A_5.

When T_1 is the one-vertex bonsai, $A_3=0$, since it is twice a multiple of the bonsais obtained by attaching the root of the two-edge corolla to a tip of T_2 (note that we are working mod 2). So $T_1*_1T_2=A_1+A_5$.

12.2.3. When $\partial T_2=0$ and $deg(T_2)\leqslant m-2$: When T_1 is not the one-vertex bonsai. As in the first case, $T_1*_1T_2=(\partial T_1)*T_2+T_1*(\partial T_2)-\partial(T_1*T_2)$ is

$$T_1*(\partial T_2)$$

$+\Sigma$ [a term in $\partial(T_1*T_2)$ that is obtained by attaching an edge to a vertex of T_1*T_2 not in T_1 so that (i) and (ii) of Definition 11.1 is satisfied]

Here $\partial T_2=0$. So we just have the latter summand in $T_1*_1T_2$. As in the first case again, we have $T_1*_1T_2=A_3+A_4+A_5$.

When T_1 is the one-vertex bonsai: $A_3=0$, since it is a twice multiple of the bonsais obtained by attaching the root of the two-edge corolla to a tip of T_2 (note that we are working mod 2). Also, $A_4=\partial\partial T_2=0$. Hence, $T_1*_1T_2=A_5$.

12.2.4. When $\partial T_2=0$ and $deg(T_2)=m-1$: When T_1 is not the one-vertex bonsai. This is almost the same as the previous case, but we cannot add more than one edge to the root of T_2. So $T_1*_1T_2$ is the sum of the terms A_3 and A_5.

When T_1 is the one-vertex bonsai, $A_3=0$, since it is a twice multiple of the bonsais obtained by attaching the root of the two-edge corolla to a tip of T_2 (note that we are working mod 2). Hence, $T_1*_1T_2=A_5$.

12.2.5. When $deg(T_2)=m$: When T_1 is not the one-vertex bonsai. This is almost the same as the previous case, but we cannot add any more edges to the root of T_2. So $T_1*_1T_2$ is A_3.

When T_1 is the one-vertex bonsai, $A_3=0$, since it is twice a multiple of the bonsais obtained by attaching the root of the two-edge corolla to a tip of T_2 (note that we are working in mod 2). Hence, $T_1*_1T_2=0$.

12.3. $T_1*_2T_2$ when T_2 is a corolla: For each case in the preceding section, let us show that $T_1*_2T_2=0$.

12.3.1. When $\partial T_2\neq 0$ and $deg(T_2)\leqslant m-3$: In this case, we have $deg(\partial T_2\leqslant m-2)$ and $\partial(\partial T_2)=0$. And as in the first case of the preceding section, $T_1*_2T_2$ is

$$T_1*_1(\partial T_2)$$

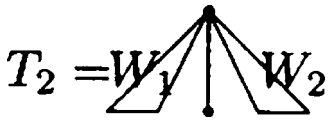

FIG. 74.

$+\Sigma$ [a term in $\partial(T_1 *_1 T_2)$ obtained by attaching an edge to a vertex of $T_1 * T_2$ not in T_1, so that (i) and (ii) of Definition 11.1 are satisfied].

When T_1 is not the one-vertex bonsai, by the third case of the preceding section, $T_1 *_1 (\partial T_2)$ is $A_3+A_4+A_5$, and by the first case of the preceding section, the sum of the terms in $\partial(T_1 *_1 T_2)$ obtained by attaching an edge to a vertex not in T_1 is $\hat{\partial}(T_1 *_1 T_2)=\hat{\partial}A_1+\hat{\partial}A_2+\hat{\partial}A_3+\hat{\partial}A_4+\hat{\partial}A_5$, where $\hat{\partial}X$, when X is a sum of terms in $T_1 *_1 T_2$, is the sum of the bonsais in ∂X obtained by attaching an edge to a vertex which is not originally in T_1.

In order to show that $T_1 *_2 T_2 = T_1 *_1 \partial T_2 + \hat{\partial}(T_1 *_1 T_2)=0$ pictorially, let us introduce a picture convention. In Fig. 69, where T_2 is a corolla with 4 edges, each triangle represents a corolla (including the one-vertex bonsai).

With this pictorial convention, we can draw $T_1 *_1 \partial T_2 = A_3+A_4+A_5$ as in Fig. 70, like A+B+C+D+E+F.

In $\hat{\partial}(T_1 *_1 T_2)$, $\hat{\partial}A_1$ can be drawn as in Fig. 71.

$\hat{\partial}A_2$ is as in Fig. 72.

$\hat{\partial}A_3$ is as in Fig. 73, where W_1 and W_2 are as in Fig. 74.

$\hat{\partial}A_4$ can be drawn as in Fig. 75.

And $\hat{\partial}A_5$ can be drawn as in Fig. 76.

Then we can get the pairs which are canceled as follows; A and 1c, B and 1d, C and 2a, D and 2b, E and 1a, F and 1b, 3a and 3b, 3c and 5e, 3d and 5f, 3e and 5g, 3f and 5h, 4b and 4c, 5b and 5c. 4a, 4d, 5a, and 5d are 0, because they have $\overline{\partial}^2$ in it. (Since 4b and 4c cancel each other, $\hat{\partial}A_4 = 0$.)

And every bonsai in Figs. 70–76 is in one of those pairs. So $T_1 *_2 T_2 = 0$.

When T_1 is the one-vertex bonsai: Since $T_1 *_1 T_2 = A_3+A_5$, it is the sum of A, B, E, and F. And since $T_1 *_1 T_2 = A_1+A_5$, we have $\hat{\partial}(T_1 *_1 T_2)=\hat{\partial}A_1+\hat{\partial}A_5$, and it is the sum of the bonsais in Fig. 71 and Fig. 76. So as above, we have $T_1 *_1 T_2 = 0$.

12.3.2. When $\partial T_2 \neq 0$ and $deg(T_2)=m-2$: When T_1 is not the one-vertex bonsai. We have $\partial(\partial T_2)=0$ and $\deg(\partial T_2)=m-1$. So we have $T_1 *_1 \partial T_2 = A_3+A_5$ and $\hat{\partial}(T_1 *_1 T_2)=\hat{\partial}(A_1+A_2+A_3+A_4+A_5)$. So the $T_1 *_2 T_2$ is the sum of the bonsais A, B, E, and F of Fig. 70 and the bonsais in Figs. 71–73 and Figs. 75 and 76 (2a and 2b are 0, since the valences at the roots are $m+1$). So as in the above case, $T_1 *_2 T_2 = 0$.

When T_1 is not the one-vertex bonsai, $T_1 *_1 \partial T_2 = A_5$ and $\hat{\partial}(T_1 *_1 T_2)=\hat{\partial}(A_1+A_5)$. So $T_1 *_2 T_2$ is the sum of the bonsais E and F of Fig. 70 and the bonsais in Figs. 71 and 76.

12.3.3. When $\partial T_2 \neq 0$ and $deg(T_2)=m-1$: In this case and others, we will just write down what $T_1 *_1 \partial T_2$ and $\hat{\partial}(T_1 *_1 T_2)$ are. In each case, as above, the bonsais in $T_1 *_2 T_2$ all cancel out.

In this case, $\partial(\partial T_2)=0$ and $\deg(\partial T_2)=m$.

When T_1 is not the one-vertex bonsai: $T_1 *_1 \partial T_2 = A_3+A_5$ and $\hat{\partial}(T_1 *_1 T_2)=\hat{\partial}(A_1+A_3+A_5)$.

When T_1 is the one-vertex bonsai, $T_1 *_1 \partial T_2 = A_5$ and $\hat{\partial}(T_1 *_1 T_2)=\hat{\partial}(A_1+A_5)$.

12.3.4. When $\partial T_2 = 0$ and $deg(T_2) \leqslant m-2$: In this case, $\partial T_2 = 0$ and $\deg(T_2) \leqslant m-2$.

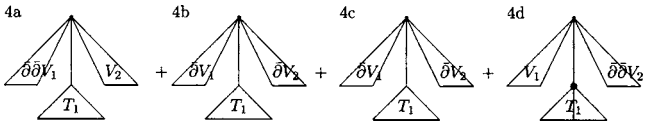

FIG. 75.

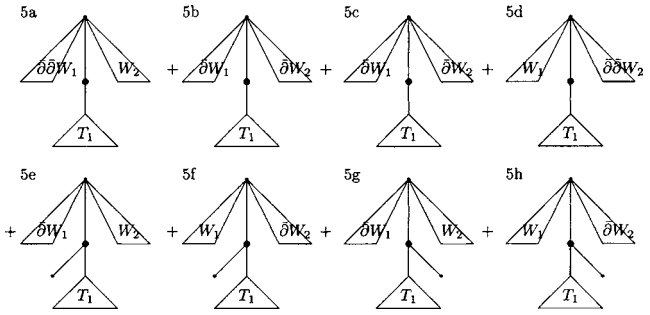

FIG. 76.

When T_1 is not the one-vertex bonsai, $T_1 *_1 \partial T_2 = 0$ and $\hat{\partial}(T_1 *_1 T_2) = \hat{\partial}(A_3 + A_4 + A_5)$.

When T_1 is the one-vertex bonsai, $T_1 *_1 \partial T_2 = 0$ and $\hat{\partial}(T_1 *_1 T_2) = \hat{\partial}(A_5)$.

12.3.5. When $\partial T_2 = 0$ and $deg(T_2) = m-1$: In this case, $\partial T_2 = 0$ and $\deg(T_2) = m-1$.

When T_1 is not the one-vertex bonsai, $T_1 *_1 \partial T_2 = A_3 + A_5$ and $\hat{\partial}(T_1 *_1 T_2) = \hat{\partial}(A_3 + A_5)$.

When T_1 is the one-vertex bonsai, $T_1 *_1 \partial T_2 = 0$ and $\hat{\partial}(T_1 *_1 T_2) = \hat{\partial}(A_5)$.

12.3.6. When $deg(T_2) = m$: In this case, $\partial T_2 = 0$ and $\deg(T_2) = m$.

When T_1 is not the one-vertex bonsai, $T_1 *_1 \partial T_2 = 0$ and $\hat{\partial}(T_1 *_1 T_2) = \hat{\partial}(A_3 + A_5)$.

When T_1 is the one-vertex bonsai, $T_1 *_1 \partial T_2 = 0$ and $\hat{\partial}(T_1 *_1 T_2) = 0$.

12.4. $T_1 *_2 T_2$ for general T_2: Now let us consider the case where T_2 is a general m-bonsai, not only a corolla. First, let us give an expression of a general m-bonsai as a concatenation of corollas. When we have a general clear-edged m-bonsai T as in Fig. 77, we first enumerate the nontip vertices of T in traversing order (cf. Sec. VII), as in Fig. 78, and for each nontip vertex numbered i, denote the corollas attached to that vertex as $T_{i1}, T_{i2}, \ldots, T_{im_i}$ from the left, and denote the given bonsai as $T(T_{11}, \ldots, T_{1m_1}; \ldots; T_{k1}, \ldots, T_{km_k})$, where k is the number of nontip vertices of T.

In Fig. 78, the given bonsai T is

$$T(T_{11}, T_{12}, T_{13}, T_{14}; T_{21}; T_{31}; T_{41}, T_{42}, T_{43}; T_{51}; T_{61}). \tag{72}$$

Now let $T = T(T_{11}, \ldots, T_{1m_1}; \ldots; T_{k1}, \ldots, T_{km_k})$ and just for convenience of algebra, let us denote T as $T(T_1, T_2, \ldots, T_m)$, where $T_1 = T_{11}, T_2 = T_{12}, \ldots, T_k = T_{km_k}$. Then we have $\partial T = \Sigma_i T(T_1, \ldots, \bar{\partial} T_i, \ldots, T_m)$ and $S * T = \Sigma_i T(T_1, \ldots, S * T_i, \ldots, T_m)$. So we have, by the definitions of $\hat{\partial}$, $\bar{\partial}$, and $*$,

$$\begin{aligned} S *_1 T &= S * \partial T + \hat{\partial}(S * T) = \sum_i T(T_1, \ldots, S * \bar{\partial} T_i, \ldots, T_m) + \sum_{i \neq j} T(T_1, \ldots, \bar{\partial} T_i, \ldots, S * T_j, \ldots, T_m) \\ &\quad + \sum_i T(T_1, \ldots, \hat{\partial}(S * T_i), \ldots, T - m) + \sum_{i \neq j} T(T_1, \ldots, \bar{\partial} T_i, \ldots, S * T_j, \ldots, T_m) \\ &= \sum_i T(T_1, \ldots, S * \bar{\partial} T_i, \ldots, T_m) + \sum_i T(T_1, \ldots, \hat{\partial}(S * T_i), \ldots, T - m) = \sum_i T(T_1, \ldots, S *_1 T_i, \ldots, T_m). \end{aligned} \tag{73}$$

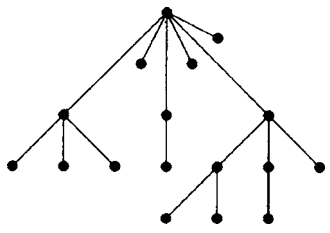

FIG. 77.

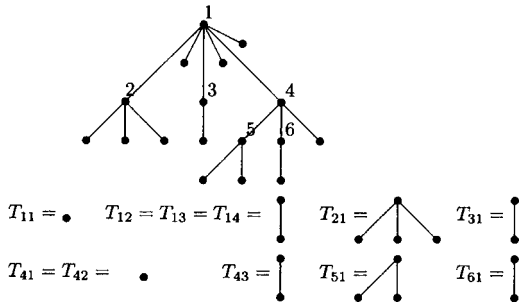

FIG. 78.

Similarly, we have

$$S*_2T = S*_1 \partial T + \hat{\partial}(S*_1T) = \sum_i T(T_1,\ldots,S*_1\bar{\partial}T_i,\ldots,T_m) + \sum_{i\neq j} T(T_1,\ldots,\bar{\partial}T_i,\ldots,S*_1T_j,\ldots,T_m)$$

$$+ \sum_i T(T_1,\ldots,\hat{\partial}(S*_1T_i),\ldots,T-m) + \sum_{i\neq j} T(T_1,\ldots,\bar{\partial}T_i,\ldots,S*_1T_j,\ldots,T_m) \tag{74}$$

$$= \sum_i T(T_1,\ldots,S*_1\bar{\partial}T_i,\ldots,T_m) + \sum_i T(T_1,\ldots,\hat{\partial}(S*_1T_i),\ldots,T-m) = \sum_i T(T_1,\ldots,S*_2T_i,\ldots,T_m) = 0. \tag{75}$$

So we have

Theorem 12.1:: *Mod2, for any clear-edged m-bonsai* T_1 *and* T_2, *we have* $T_1*_2T_2=0$.

XIII. FURTHER DIRECTION

In the next paper of the author, we will investigate a generalization of the *m*-bonsai Hopf algebra, its differentials and cohomology groups. Also we will investigate some possibility of generalization of the appending operation $*$.

Bosonic color-flavor transformation for the special unitary group

(Received 2 February 2005; accepted 23 May 2005; published online 11 July 2005)

We extend Zirnbauer's color-flavor transformation in the bosonic sector to the color group $\mathrm{SU}(N_c)$. Because the flavor group $\mathrm{U}(N_b,N_b)$ is noncompact, the algebraic method by which the original color-flavor transformation was derived leads to a useful result only for $2N_b \leqslant N_c$. Using the character expansion method, we obtain a different form of the transformation in the extended range $N_b \leqslant N_c$. This result can also be used for the color group $\mathrm{U}(N_c)$. The integrals to which the transformation can be applied are of relevance for the recently proposed boson-induced lattice gauge theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1951627]

I. INTRODUCTION

In 1996, Zirnbauer[1] invented a generalized Hubbard-Stratonovitch transformation which trades an integration over a "color" gauge group for an integration over a certain supersymmetric coset space, or "flavor" space. Although the transformation was originally derived to study disordered systems in condensed matter physics, the terminology comes from lattice gauge theory because the integral over the gauge group to which the color-flavor transformation is applied is precisely of the form of a one-link integral in lattice gauge theory at infinite coupling.

The fields that appear in the transformation carry two types of indices that will be referred to as color and flavor indices. The number of colors is denoted by N_c, and the numbers of bosonic and fermionic flavors are denoted by N_b and N_f, respectively. Zirnbauer derived versions of the color-flavor transformation for the three color groups $\mathrm{U}(N_c)$, $\mathrm{O}(N_c)$, and $\mathrm{Sp}(2N_c)$.[1] In his original work, the flavor space contained an equal number of bosonic and fermionic degrees of freedom, but it is possible to relax this constraint.[2] Convergence requirements then place an upper bound on the difference between the number of bosons and fermions. For the case of $\mathrm{U}(N_c)$, this bound is given by $2(N_b-N_f) \leqslant N_c$.

The color-flavor transformation has been used in a number of physical applications, e.g., in the derivation of a field theory for the random flux model by Altland and Simons[3] and in the construction of chiral Lagrangians for lattice gauge theories by Nagao and Nishigaki.[4] In the latter paper, the calculations were done for the above-mentioned color groups. However, in quantum chromodynamics (QCD) the color group is SU(3). To be able to apply the color-flavor transformation to this very important physical case, a variant of the transformation for the special unitary group needed to be derived. Following earlier work by Budczies and Shnir,[5,6] this was done in Refs. 7 and 8 in the fermionic sector, i.e., for $N_b=0$. The result was then applied to lattice QCD in Refs. 8 and 9.

As mentioned above, the color-flavor transformation can only be applied to the one-link integral of lattice gauge theory if the gauge coupling is infinite. Fortunately, it is possible to go beyond the infinite-coupling limit. A gauge action (Yang-Mills action in the continuum or Wilson action on the lattice) can be induced by coupling auxiliary fields to the gauge field (still at infinite coupling) and integrating out these extra fields. This idea, which is known as "induced QCD," has been considered in various forms in the literature.[10–15] For example, the job can be done by a

number N_h of heavy auxiliary fermions with common mass m_h in the combined limit $N_h \to \infty$, $m_h \to \infty$ such that the ratio N_h/m_h^4 is constant, and this constant can then be related to the strength of the induced gauge coupling.

So far, the color-flavor transformation for SU(N_c) has only been derived in the fermionic sector, for three reasons, (a) physical quarks are fermions, (b) a gauge action can be induced by auxiliary fermions alone, and (c) the calculation is somewhat easier for fermions than for bosons. There seemed to be no special need for a bosonic variant of the transformation until Budczies and Zirnbauer suggested a new method to induce the gauge action using auxiliary bosons.[16] Their approach has the advantage of requiring only a small number (essentially equal to N_c) of auxiliary fields. However, to be able to use their method in lattice QCD, one requires an SU(N_c) variant of the color-flavor transformation that accommodates both fermions (the physical quarks) and bosons (to induce the gauge action).

As a first step towards this goal, we found it useful to consider the purely bosonic case with $N_f=0$ for which we will present results in this paper. Our results can be applied to study a boson-induced gauge theory without physical quarks. Focusing on the bosonic sector allows us to separate the complications due to the fact that the fields are bosonic from those due to the supersymmetric framework. This is the main motivation for the present paper. The supersymmetric case will be addressed in a separate paper.

The convergence requirement mentioned above is irrelevant for the purely fermionic case in which $N_b=0$ since the inequality is always satisfied. However, it becomes relevant for the purely bosonic case. We obtain a "standard" form of the color-flavor transformation if the condition $2N_b \leqslant N_c$ is satisfied. In the extended range $N_b \leqslant N_c$ we derive a different form of the transformation. Interestingly, for $N_b < N_c$ our results for SU(N_c) are identical to those for gauge group U(N_c), and we therefore obtain new results for U(N_c) in the range $N_b < N_c < 2N_b$. [The physical reason behind this is the observation that one cannot make baryons out of bosonic quarks if $N_b < N_c$. Such "bosonic baryons" must contain at least as many flavors as colors, see, e.g., Eq. (22) below.] For $N_b > N_c$ we have not been able to simplify our formal result to be useful in applications.

This paper is organized as follows. We first state our results in Sec. II. In Sec. III, we use the algebraic method of Refs. 1 and 7 to derive our general result for the bosonic color-flavor transformation. In Sec. IV, we use a different approach, the character expansion method, to derive an alternative form of the bosonic color-flavor transformation. We close with a brief discussion of possible applications and open problems. The appendix contains derivations of several intermediate results as well as a number of examples for the results from both approaches.

II. STATEMENT OF RESULTS

Let ψ_a^i, $\bar{\psi}_a^i$, φ_a^i, and $\bar{\varphi}_a^i$ be complex bosonic variables that carry a color index (superscript i running from 1 to N_c) and a flavor index (subscript a running from 1 to N_b). The bar denotes complex conjugation. Summation over repeated indices is implied here and throughout the paper unless indicated otherwise. Using the algebraic method of Refs. 1 and 7, we obtain

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}_a^i U^{ij} \psi_a^j + \bar{\varphi}_a^i U^{\dagger ij} \varphi_a^j) = \int_{|ZZ^\dagger| \leqslant 1} \frac{\mathrm{d}Z\, \mathrm{d}Z^\dagger}{\det^{2N_b - N_c}(1 - ZZ^\dagger)} \times \exp(\bar{\psi}_a^i Z_{ab} \varphi_b^i + \bar{\varphi}_a^i Z_{ab}^\dagger \psi_b^i) \sum_{Q=0}^{\infty} \chi_Q, \tag{1}$$

where

$$\chi_0 = \mathcal{C}_0, \quad \chi_{Q>0} = \mathcal{C}_Q(\det{}^Q \mathcal{M} + \det{}^Q \mathcal{N}), \tag{2}$$

the $N_c \times N_c$ matrices $\mathcal{M}$ and $\mathcal{N}$ are defined by $\mathcal{M}^{ij} = \bar{\psi}_a^i (1 - ZZ^\dagger)_{ab} \psi_b^j$ and $\mathcal{N}^{ij} = \bar{\varphi}_a^i (1 - Z^\dagger Z)_{ab} \varphi_b^j$, and the coefficients $\mathcal{C}_Q$ are computed in Appendix B.

The integration on the left-hand side (LHS) of Eq. (1) is over $\mathrm{SU}(N_c)$ matrices U distributed according to the Haar measure $\mathrm{d}U$, normalized such that the group volume is unity. The integration on the right-hand side (RHS) of that equation is over complex $N_b \times N_b$ matrices Z, with the restriction that all eigenvalues of $ZZ^\dagger$ are less than or equal to 1. These matrices parametrize the noncompact coset space $\mathrm{U}(N_b,N_b)/[\mathrm{U}(N_b)\times\mathrm{U}(N_b)]$ (the reason to choose this particular parametrization is given at the end of Sec. III E). The corresponding invariant integration measure is given by[17]

$$\mathrm{d}\mu(Z,Z^\dagger) = \frac{\mathrm{d}Z\,\mathrm{d}Z^\dagger}{\det(1-ZZ^\dagger)^{2N_b}} \quad \text{with } \mathrm{d}Z\,\mathrm{d}Z^\dagger = \prod_{a,b=1}^{N_b} \mathrm{d}\,\mathrm{Re}\,Z_{ab}\mathrm{d}\,\mathrm{Im}\,Z_{ab}. \tag{3}$$

Note that the $N_c \times N_c$ matrices $\mathcal{M}$ and $\mathcal{N}$ can be thought of as products of three matrices of dimension $N_c \times N_b$, $N_b \times N_b$, and $N_b \times N_c$, respectively. The resulting matrix is of full rank only if $N_b \geqslant N_c$. For $N_b < N_c$, we therefore have $\det \mathcal{M} = \det \mathcal{N} = 0$,[18] and the transformation simplifies to

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}^i_a U^{ij} \psi^j_a + \bar{\varphi}^i_a U^{\dagger ij} \varphi^j_a) = \mathcal{C}_0 \int_{|ZZ^\dagger|\leqslant 1} \frac{\mathrm{d}Z\,\mathrm{d}Z^\dagger}{\det^{2N_b-N_c}(1-ZZ^\dagger)} \exp(\bar{\psi}^i_a Z_{ab} \varphi^i_b + \bar{\varphi}^i_a Z^\dagger_{ab} \psi^i_b) \tag{4}$$

with a constant $\mathcal{C}_0$ given in Eq. (B5). This agrees with the result for the color group $\mathrm{U}(N_c)$ in Ref. 2.

Equation (1) looks similar to the result for the fermionic sector presented in Ref. 7. There are two major differences, however. First, due to the nilpotency of Grassmann variables the sum over Q in Eq. (1) only went up to N_f in the fermionic case, whereas it extends to infinity now. Second, the invariant measure of the coset space $\mathrm{U}(N_b,N_b)/[\mathrm{U}(N_b)\times\mathrm{U}(N_b)]$ in Eq. (3) diverges at the boundary, giving rise to convergence issues which we discuss now.

For $2N_b \leqslant N_c$, the divergence of the measure is canceled by the factor of $\det^{N_c}(1-ZZ^\dagger)$ in the integrand of Eq. (1). In this case the result (4) applies and is free from divergences. For $N_b < N_c < 2N_b$, the integral over Z in Eq. (4) diverges. For $N_b = N_c$, the integral over Z in Eq. (1) diverges for $Q < N_b$, whereas for $N_b > N_c$, it diverges for all Q. Of course, the final result for the RHS of Eqs. (1) and (4) must be finite, so whatever divergence arises from the integration over Z will be canceled by a similar divergence in the integral for the corresponding (inverse) constant $\mathcal{C}_Q^{-1}$, see Eq. (56). A finite ratio could in principle be obtained by a suitable regularization and limiting procedure, but it is not clear to us whether this would lead to a simple final result (an explicit example for such a limiting procedure is given in Appendix D 3).

Instead, we have used the character expansion method[19–21] to derive a different form of the color-flavor transformation and obtain for $N_b < N_c$

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}^i_a U^{ij} \psi^j_a + \bar{\varphi}^i_a U^{\dagger ij} \varphi^j_a) = \prod_{n=0}^{N_c-N_b-1} \frac{(N_b+n)!}{n!} \int_{\mathrm{U}(N_b)} \mathrm{d}V \det{}^{N_b-N_c}(VB) \times \exp(\bar{\psi}^i_a V_{ab} \varphi^i_b + \bar{\varphi}^i_a V^\dagger_{ab} \psi^i_b), \tag{5}$$

where the $N_b \times N_b$ matrix B is defined by $B_{ab} = \varphi^i_a \bar{\psi}^i_b$. Note that the integration on the RHS is over the unitary group with the normalized Haar measure $\mathrm{d}V$. Equation (5) is also valid if the integration on the LHS is over the color group $\mathrm{U}(N_c)$ and, to the best of our knowledge, represents a new result for this case.

The corresponding result for $N_b = N_c$ reads

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}_a^i U^{ij} \psi_a^j + \bar{\varphi}_a^i U^{\dagger ij} \varphi_a^j) = \sum_{Q=0}^{\infty} \tilde{\chi}_Q \int_{\mathrm{U}(N_b)} \mathrm{d}V \det{}^{-Q}(VB) \exp(\bar{\psi}_a^i V_{ab} \varphi_b^i + \bar{\varphi}_a^i V_{ab}^\dagger \psi_b^i) \tag{6}$$

with

$$\tilde{\chi}_0 = 1, \quad \tilde{\chi}_{Q>0} = \det{}^Q M + \det{}^Q N, \tag{7}$$

the matrix B as defined above, and $N_c \times N_c$ matrices M and N defined by $M^{ij} = \psi_a^i \bar{\psi}_a^j$ and $N^{ij} = \varphi_a^i \bar{\varphi}_a^j$. Note that we are not allowed to change the order of summation and integration in Eq. (6), see Sec. IV C. If the integration on the LHS of Eq. (6) is over $\mathrm{U}(N_c)$, only the $Q=0$ term contributes on the RHS, see Eq. (77). The integral over $\mathrm{U}(N_b)$ in Eqs. (5) and (6) can be done analytically,[22–24] resulting in a determinant involving modified Bessel functions, but we do not display this result here because Eqs. (5) and (6) are to be viewed as transformations.

As mentioned in the introduction, for $N_b > N_c$ we have not been able to obtain a simple form of the color-flavor transformation in which the divergences have been eliminated.

III. BOSONIC COLOR-FLAVOR TRANSFORMATION: ALGEBRAIC METHOD

The basic idea of the algebraic approach to the color-flavor transformation is to construct two projection operators onto the subspace of Fock space (to be defined below) which is invariant under the action of the color group $\mathrm{SU}(N_c)$. One such projector is implemented by integrating over the color group. The other one is obtained by integrating over a certain coset of the flavor group $\mathrm{U}(N_b, N_b)$. Identification of the two projection operations then leads to Eq. (1). In this section, we shall use this algebraic approach to derive the bosonic color-flavor transformation. We closely follow Refs. 1, 7, and 8 whenever possible.

A. Fock space, Lie algebras, and Lie groups

We introduce two sets of bosonic creation and annihilation operators $\{\bar{c}_a^i, c_a^i\}$ and $\{\bar{d}_a^i, d_a^i\}$, where $i = 1, \ldots, N_c$ and $a = 1, \ldots, N_b$. As mentioned above, we shall refer to the upper index as "color" and to the lower index as "flavor." The Fock vacuum $|0\rangle$ is defined by the requirement that $c_a^i|0\rangle = d_a^i|0\rangle = 0$ for all combinations of i and a, and the Fock space is generated by acting on $|0\rangle$ with the $\bar{c}_a^i$ and $\bar{d}_a^i$. In the following, the two sets of particles created by the $\bar{c}_a^i$ and $\bar{d}_a^i$ will be referred to as particles and antiparticles, respectively.

For simplicity of notation, we also introduce the unified operators $\{\bar{c}_A^i, c_A^i\}$ defined by

$$c_A^i = \begin{cases} c_A^i & \text{for } 1 \leqslant A \leqslant N_b, \\ \bar{d}_{A-N_b}^i & \text{for } N_b < A \leqslant 2N_b, \end{cases}$$

$$\bar{c}_A^i = \begin{cases} \bar{c}_A^i & \text{for } 1 \leqslant A \leqslant N_b, \\ -d_{A-N_b}^i & \text{for } N_b < A \leqslant 2N_b. \end{cases} \tag{8}$$

They satisfy the usual commutation relations for bosonic operators,

$$[c_A^i, \bar{c}_B^j] = \delta^{ij} \delta_{AB}. \tag{9}$$

Next we define operators $E_{AB}^{ij} = \bar{c}_A^i c_B^j$. Simple algebra reveals that they satisfy the commutation relations

$$[E_{AB}^{ij}, E_{CD}^{k\ell}] = \delta_{BC} \delta^{kj} E_{AD}^{i\ell} - \delta_{AD} \delta^{i\ell} E_{CB}^{kj}, \tag{10}$$

and hence they are generators of the Lie algebra $\mathrm{gl}(2N_c N_b)$.

The Lie algebra $\mathrm{gl}(2N_cN_b)$ has two commuting subalgebras that are important for our proof, namely $\mathrm{gl}(2N_b)$, which is generated by the color-singlet operators

$$\left\{ \mathcal{G}_{AB} \equiv \sum_{i=1}^{N_c} E_{AB}^{ii} \right\}, \tag{11}$$

and $\mathrm{sl}(N_c)$, which is generated by the flavor-singlet operators

$$\left\{ \mathcal{E}^{ij} \equiv \sum_{A=1}^{2N_b} E_{AA}^{ij}; i \neq j \right\},$$

$$\left\{ \mathcal{H}^i \equiv \sum_{A=1}^{2N_b} E_{AA}^{ii} - \frac{1}{N_c} \sum_{j=1}^{N_c} \sum_{A=1}^{2N_b} E_{AA}^{jj}; i = 1, \ldots, N_c \right\}. \tag{12}$$

Note that only $N_c - 1$ of the generators $\mathcal{H}^i$ are linearly independent.

The action of the group $\mathrm{GL}(2N_cN_b)$ and its subgroups on the Fock space is defined by exponential mapping, i.e., for all $g \in \mathrm{GL}(2N_cN_b)$ we define a map $g \mapsto T_g$ from group elements to operators by[1,8]

$$T_g = \exp[\bar{c}_A^i (\ln g)_{AB}^{ij} c_B^j]. \tag{13}$$

Following Zirnbauer,[1] one can show that the map $g \mapsto T_g$ is well-defined and a homomorphism of $\mathrm{GL}(2N_cN_b)$,

$$T_g T_h = T_{gh}. \tag{14}$$

Therefore it furnishes a (reducible) representation of $\mathrm{GL}(2N_cN_b)$.

In the following, we will consider the action of the subgroups $\mathrm{SU}(N_c)$ (the color group) and $\mathrm{U}(N_b,N_b)$ (the flavor group) of $\mathrm{GL}(2N_cN_b)$ on the Fock space. The corresponding subalgebras $\mathrm{sl}(N_c)$ and $\mathrm{gl}(2N_b)$ have been given above. What are the reasons to single out these two subgroups? For the color group the reason is simple. The integration on the LHS of Eq. (1) is over $\mathrm{SU}(N_c)$. For the flavor group, the choice of the noncompact subgroup $\mathrm{U}(N_b,N_b)$ is not immediately obvious at this point but will become clear as we proceed. We shall see below that the color-neutral sector of Fock space is noncompact in the bosonic case, as opposed to the fermionic case in which it was compact. Attempts to work with the compact subgroup $\mathrm{U}(2N_b)$ do not lead to useful results. Also, when Eq. (1) is used in applications, one wants the resulting integrals over the bosonic variables to converge, and this requirement necessitates a noncompact integration domain on the RHS of that equation.[1,25–27]

Under the action of the subgroups $\mathrm{SU}(N_c)$ and $\mathrm{U}(N_b,N_b)$, the operators c_A^i and $\bar{c}_A^i$ transform as follows:

$$g \in \mathrm{SU}(N_c): \quad T_g c_A^i T_g^{-1} = (g^{-1})^{ij} c_A^j, \quad T_g \bar{c}_A^i T_g^{-1} = \bar{c}_A^j g^{ji}, \tag{15}$$

$$g \in \mathrm{U}(N_b,N_b): \quad T_g c_A^i T_g^{-1} = g_{AB}^{-1} c_B^i, \quad T_g \bar{c}_A^i T_g^{-1} = \bar{c}_B^i g_{BA}, \tag{16}$$

which can be shown using the Baker-Campbell-Hausdorff formula.

B. Bose coherent states and projection onto the color-neutral sector

We call a vector $|\mathcal{N}\rangle$ in the Fock space color neutral if it is invariant under $\mathrm{SU}(N_c)$ transformations, i.e., $T_U|\mathcal{N}\rangle = |\mathcal{N}\rangle$ for all $U \in \mathrm{SU}(N_c)$. The subspace of Fock space spanned by these invariant vectors is called the color-neutral subspace or sector.

The following argument closely parallels Ref. 8. With the complex bosonic variables ψ_a^i, $\bar{\psi}_a^i$, φ_a^i, and $\bar{\varphi}_a^i$ introduced in Sec. II Bose coherent states are defined as

$$|\Psi\rangle = \exp(\bar{c}^i_a \psi^i_a + \bar{d}^i_a \bar{\varphi}^i_a)|0\rangle, \quad \langle\Psi| = \langle 0|\exp(\bar{\psi}^i_a c^i_a + \varphi^i_a d^i_a). \tag{17}$$

They span the entire Fock space (or its dual). Using Eq. (15) we find

$$\langle\Psi|T_U|\Psi\rangle = \exp(\bar{\psi}^i_a U^{ij} \psi^j_a + \bar{\varphi}^i_a U^{\dagger ij} \varphi^j_a). \tag{18}$$

The LHS of Eq. (1) can therefore be written as

$$\mathcal{Z} = \int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}^i_a U^{ij} \psi^j_a + \bar{\varphi}^i_a U^{\dagger ij} \varphi^j_a) = \langle\Psi|P|\Psi\rangle, \tag{19}$$

where we have introduced the operator P defined by

$$P = \int_{\mathrm{SU}(N_c)} \mathrm{d}U \, T_U. \tag{20}$$

This operator annihilates all states that are not color neutral, while leaving color-neutral states invariant [recall that the volume of $\mathrm{SU}(N_c)$ is unity]. Therefore, it is a projector onto the color-neutral sector. As advertised above, it is one possible representation of such a projector, and we will now derive an alternative form.

C. Action of the flavor group in the color-neutral sector

By definition, color-neutral vectors $|\mathcal{N}\rangle$ are annihilated by all generators of $\mathrm{sl}(N_c)$, i.e., $\mathcal{E}^{ij}|\mathcal{N}\rangle = 0$ and $\mathcal{H}^i|\mathcal{N}\rangle = 0$. Using Eq. (12) and the commutation relations (9), this requirement leads to

$$\left(\sum_{a=1}^{N_b} \bar{c}^i_a c^j_a - \sum_{a=1}^{N_b} \bar{d}^j_a d^i_a \right) |\mathcal{N}\rangle = \delta^{ij} Q |\mathcal{N}\rangle, \tag{21}$$

where Q is an integer. Clearly, the color-neutral sector contains the vacuum. For $i=j$, the operator on the LHS of Eq. (21) counts the difference in the number of particles and antiparticles for each color, the difference being equal to Q.

The color-neutral sector can be generated by acting on the vacuum state with three types of operators,

$$\text{type-1a}, \quad \bar{c}^i_a \bar{d}^i_b,$$

$$\text{type-2a}, \quad \epsilon_{i_1 \cdots i_{N_c}} \bar{c}^{i_1}_{a_1} \bar{c}^{i_2}_{a_2} \cdots \bar{c}^{i_{N_c}}_{a_{N_c}},$$

$$\text{type-2b}, \quad \epsilon_{i_1 \cdots i_{N_c}} \bar{d}^{i_1}_{b_1} \bar{d}^{i_2}_{b_2} \cdots \bar{d}^{i_{N_c}}_{b_{N_c}}, \tag{22}$$

where ϵ denotes the totally antisymmetric Levi-Civita symbol which ensures that the resulting state is invariant under $\mathrm{SU}(N_c)$ transformations. In addition, the following types of operators make transformations in the color-neutral sector:

$$\text{type-1b}, \quad c^i_a d^i_b,$$

$$\text{type-1c}, \quad \bar{c}^i_a c^i_b,$$

$$\text{type-1d}, \quad d_a^i \bar{d}_b^i. \tag{23}$$

When acting on a color-neutral state, type-1 operators do not change the Q value of that state, whereas type-2a (type-2b) operators increase (decrease) the Q value by one. Note, however, that for $N_b < N_c$ the type-2 operators do not exist, which makes it impossible to generate a vector in a nonzero Q sector. The range of Q is therefore given by

$$Q = \begin{cases} -\infty, \ldots, \infty & \text{for } N_b \geqslant N_c, \\ 0 & \text{for } N_b < N_c. \end{cases} \tag{24}$$

[In the case of $N_b < N_c$, we are back to the bosonic color-flavor transformation for the group $\mathrm{U}(N_c)$.[2] The Lie algebra of $\mathrm{U}(N_c)$ has an extra U(1) generator, and by requiring invariance under $\mathrm{U}(N_c)$, this U(1) generator eliminates all nonzero Q sectors.]

The action of the flavor group on the Fock space is defined by Eq. (13) with $g \in \mathrm{U}(N_b, N_b)$. We now choose the color-neutral sector to be the carrier space of this representation. The type-1 operators are the generators of the flavor group and do not change the Q value of a given state. Therefore, under the action of the flavor group, the color-neutral sector decomposes into invariant subspaces labeled by Q, which we shall call "Q sectors." As mentioned above, a Q sector contains Q more particles than antiparticles for each color.

We now prove that the flavor group acts irreducibly in a given Q sector.[1] For this we need to show that from any given state in the Q sector we can reach any other state by the action of the flavor group. Equivalently, we can single out a particular state $|\psi_Q\rangle$, defined by

$$|\psi_{Q>0}\rangle = (\epsilon_{i_1 \cdots i_{N_c}} \bar{c}_1^{i_1} \bar{c}_2^{i_2} \cdots \bar{c}_{N_c}^{i_{N_c}})^Q |0\rangle,$$

$$|\psi_{Q=0}\rangle = |0\rangle,$$

$$|\psi_{Q<0}\rangle = (\epsilon_{i_1 \cdots i_{N_c}} \bar{d}_1^{i_1} \bar{d}_2^{i_2} \cdots \bar{d}_{N_c}^{i_{N_c}})^Q |0\rangle, \tag{25}$$

and show that (i) starting from this state, we can reach any other state, and (ii) from that state we can return to $|\psi_Q\rangle$, using type-1 operators only.

An arbitrary vector in a given Q sector, which we should be able to reach from $|\psi_Q\rangle$, is obtained by acting on the vacuum with the appropriate number of type-1a operators and Q more type-2a than type-2b operators. There are already Q ($-Q$) unpaired type-2a (type-2b) operators associated with $|\psi_Q\rangle$, so what remains are pairs consisting of a type-2a and a type-2b operator. Such a pair can be expanded in terms of type-1a operators as

$$\epsilon_{i_1 \cdots i_{N_c}} \bar{c}_{a_1}^{i_1} \bar{c}_{a_2}^{i_2} \cdots \bar{c}_{a_{N_c}}^{i_{N_c}} \epsilon_{j_1 \cdots j_{N_c}} \bar{d}_{b_1}^{j_1} \bar{d}_{b_2}^{j_2} \cdots \bar{d}_{b_{N_c}}^{j_{N_c}} = \sum_{\sigma \in S_{N_c}} \mathrm{sgn}(\sigma) \bar{c}_{a_1}^{i_1} \bar{d}_{\sigma(b_1)}^{i_1} \cdots \bar{c}_{a_{N_c}}^{i_{N_c}} \bar{d}_{\sigma(b_{N_c})}^{i_{N_c}} \tag{26}$$

and is therefore in the algebra of the flavor group. The type-1c and type-1d operators obey the commutation relations

$$[\bar{c}_a^i c_{b_1}^i, \epsilon_{i_1 \cdots i_{N_c}} \bar{c}_{b_1}^{i_1} \bar{c}_{b_2}^{i_2} \cdots \bar{c}_{b_{N_c}}^{i_{N_c}}] = \epsilon_{i_1 \cdots i_{N_c}} \bar{c}_a^{i_1} \bar{c}_{b_2}^{i_2} \cdots \bar{c}_{b_{N_c}}^{i_{N_c}},$$

$$[d_{b_1}^i \bar{d}_a^i, \epsilon_{i_1 \cdots i_{N_c}} \bar{d}_{b_1}^{i_1} \bar{d}_{b_2}^{i_2} \cdots \bar{d}_{b_{N_c}}^{i_{N_c}}] = \epsilon_{i_1 \cdots i_{N_c}} \bar{d}_a^{i_1} \bar{d}_{b_2}^{i_2} \cdots \bar{d}_{b_{N_c}}^{i_{N_c}}. \tag{27}$$

Thus, they enable us to change the flavor indices of the type-2 operators. We can thus reach any state in a given Q-sector by acting with the corresponding number and subtypes of type-1 operators on $|\psi_Q\rangle$. Furthermore, type-1a operators can be undone by type-1b operators, while type-1c and type-1d operators can undo themselves. We can therefore go from an arbitrary state in the Q

sector back to $|\psi_Q\rangle$. In other words, $|\psi_Q\rangle$ is a cyclic vector in the Q sector under the action of the flavor group, which implies irreducibility.

D. Generalized coherent states and projection onto the color-neutral sector

Generalized coherent states are described in detail in Ref. 28. They are useful for our purposes because they allow a resolution of the identity operator. For a Lie group G and an irreducible representation T_g, a set of generalized coherent states is obtained by acting on a state $|\psi_T\rangle$ in the carrier space of T_g with all elements of T_g. This results in the set $\{T_g|\psi_T\rangle\}$ which, in general, is overcomplete. If H is the maximal subgroup of G such that $T_h|\psi_T\rangle \propto |\psi_T\rangle$ for all $h \in H$, the subgroup H is called the isotropy subgroup of $|\psi_T\rangle$, and the set of generalized coherent states can be parametrized without overcounting by the elements of the coset space G/H. (If the subgroup H is not maximal, some overcounting remains.)

We now set $G=\mathrm{U}(N_b,N_b)$ and consider the representation T_g of Eq. (13) (with $g \in G$) which acts irreducibly in a given Q sector. For the starting vector we choose the vector $|\psi_Q\rangle$ defined in Eq. (25), resulting in the (overcomplete) set of generalized coherent states $\{T_g|\psi_Q\rangle\}$. The identity operator in this Q sector is then given by[28]

$$\mathbb{1}_Q = C_Q \int_G \mathrm{d}g\, T_g|\psi_Q\rangle\langle\psi_Q|T_g^{-1}, \tag{28}$$

where $\mathrm{d}g$ is the invariant measure of $\mathrm{U}(N_b,N_b)$ and C_Q is a normalization factor defined by

$$C_Q^{-1} = \frac{1}{N_Q}\int_G \mathrm{d}g\langle\psi_Q|T_g|\psi_Q\rangle\langle\psi_Q|T_g^{-1}|\psi_Q\rangle. \tag{29}$$

Here, N_Q is the norm of $|\psi_Q\rangle$,

$$N_Q = \langle\psi_Q|\psi_Q\rangle = \prod_{n=0}^{N_c-1}\frac{(|Q|+n)!}{n!}. \tag{30}$$

A detailed calculation of N_Q is given in Appendix A.

Note that the integrals in Eqs. (28) and (29) are divergent for $2N_b > N_c$ as discussed in Sec. II. A regularization procedure is necessary to show that their ratio is finite, see, e.g., Appendix D 3. We return to this issue at the end of Sec. III F.

The operator in Eq. (28) annihilates all states that are not color neutral, as well as color-neutral states corresponding to a different value of Q. Thus, it is a projector onto the Q sector. We can therefore write the projector onto the color-neutral sector as

$$P = \bigoplus_Q \mathbb{1}_Q, \tag{31}$$

where the sum runs over the values of Q given in Eq. (24). Identifying this projection operator with the one in Eq. (20) yields

$$\mathcal{Z} = \sum_Q \mathcal{Z}_Q$$

with

$$\mathcal{Z}_Q = \langle\Psi|\mathbb{1}_Q|\Psi\rangle = \langle 0|\exp(\bar{\psi}^i_a c^i_a + \varphi^i_a d^i_a)\mathbb{1}_Q \exp(\bar{c}^i_a \psi^i_a + \bar{d}^i_a \bar{\varphi}^i_a)|0\rangle. \tag{32}$$

E. Parametrization of the coherent states

The maximal compact subgroup of the flavor group $G=\mathrm{U}(N_b,N_b)$ is $H=H_+\times H_-=\mathrm{U}(N_b)\times\mathrm{U}(N_b)$ with elements $h=\mathrm{diag}(h_+,h_-)$, where $h_\pm \in \mathrm{U}(N_b)$. The corresponding Fock operators are

$$T_h = \exp[\bar{c}^i_a (\ln h_+)_{ab} c^i_b - d^i_a (\ln h_-)_{ab} \bar{d}^i_b]. \tag{33}$$

For $Q=0$, these operators stabilize the vacuum,

$$T_h|0\rangle = \exp(-N_c \operatorname{tr} \ln h_-)|0\rangle = (\det{}^{-N_c} h_-)|0\rangle, \tag{34}$$

and therefore the set of coherent states for $Q=0$ can be parametrized without overcounting by the elements of the noncompact coset space $S=G/H=\mathrm{U}(N_b,N_b)/[\mathrm{U}(N_b)\times U(N_b)]$. (We will use the same coset space also for $Q\neq 0$, see Sec. III G.)

To arrive at this parametrization, we first use the canonical projection $\pi: G \mapsto G/H$ which assigns to each $g \in G$ the corresponding equivalence class gH. We then choose a representative group element $s(\pi(g))$ from each equivalence class and write an arbitrary group element g as the product $g=s(\pi(g))h(g)$. The coset element $s(\pi(g))$ can be parametrized using projective coordinates Z, see Eqs. (5.8n) and (5.28) in Chap. 9 of Ref. 29,

$$s(\pi(g)) \equiv s(Z,Z^\dagger) = \begin{pmatrix} (1-ZZ^\dagger)^{-1/2} & Z(1-Z^\dagger Z)^{-1/2} \\ Z^\dagger(1-ZZ^\dagger)^{-1/2} & (1-Z^\dagger Z)^{-1/2} \end{pmatrix} = \begin{pmatrix} 1 & Z \\ 0 & 1 \end{pmatrix} \begin{pmatrix} (1-ZZ^\dagger)^{1/2} & 0 \\ 0 & (1-Z^\dagger Z)^{-1/2} \end{pmatrix} \times \begin{pmatrix} 1 & 0 \\ Z^\dagger & 1 \end{pmatrix}. \tag{35}$$

Here, Z is an $N_b \times N_b$ complex matrix with the constraint $|ZZ^\dagger| \leqslant 1$. We have $s=s^\dagger$ and $s^{-1}=s(-Z,-Z^\dagger)$. Also, $s(Z,Z^\dagger)$ satisfies the pseudounitarity condition $s\,\mathrm{diag}(\mathbb{1}_{N_b},-\mathbb{1}_{N_b})s^\dagger=\mathrm{diag}(\mathbb{1}_{N_b},-\mathbb{1}_{N_b})$. Using the decomposition (35), the Fock space operator corresponding to $s(Z,Z^\dagger)$ becomes

$$T_{s(Z,Z^\dagger)} = \exp(\bar{c}^i_a Z_{ab} \bar{d}^i_b) \exp\left[\tfrac{1}{2}\bar{c}^i_a \ln(1-ZZ^\dagger)_{ab} c^i_b + \tfrac{1}{2} d^i_a \ln(1-Z^\dagger Z)_{ab} \bar{d}^i_b\right] \exp(-d^i_a Z^\dagger_{ab} c^i_b). \tag{36}$$

The coset space G/H has a G-invariant measure[17] that has already been given in Eq. (3). We can therefore use Eq. (14) to rewrite the integral (28) over G as an integral over H and $S=G/H$,

$$\mathbb{1}_Q = C_Q \int_G \mathrm{d}g\, T_g |\psi_Q\rangle\langle\psi_Q| T_g^{-1} = C_Q \int_{G/H} \mathrm{d}\mu(Z,Z^\dagger) \int_H \mathrm{d}h\, T_s T_h |\psi_Q\rangle\langle\psi_Q| T_h^{-1} T_s^{-1}. \tag{37}$$

The Haar measure $\mathrm{d}h$ of H is normalized to unity.

We pause briefly to explain the reason behind the choice of the coset-space parametrization (35).[1] In the language of lattice gauge theory, the left-hand side of Eq. (1) is a one-link integral with fields $\bar{\psi}$, φ at one end of the link and fields $\bar{\varphi}$, ψ at the other end (the notation is a bit misleading but in line with Refs. 1 and 7). Note that the gauge fields U and $U^\dagger$ couple bosonic fields that live on opposite ends of the link. On the right-hand side of Eq. (1), the matrices Z and $Z^\dagger$ couple bosonic fields that live on the same end of the link. This is a highly desirable feature since, when Eq. (1) is applied to a lattice with many links, the ensuing integral over the bosonic fields has a simpler structure. Other parametrizations of the coset space do not lead to this feature.

F. Calculation of $\mathcal{Z}_0$

For $Q=0$, Eq. (34) tells us that the integration over H in Eq. (37) is trivial, and we are left with

$$\mathcal{Z}_0 = C_0 \int_{G/H} \mathrm{d}\mu(Z,Z^\dagger) \langle 0|\exp(\bar{\psi}^i_a c^i_a + \varphi^i_a d^i_a) T_s|0\rangle\langle 0|T_s^{-1} \exp(\bar{c}^i_a \psi^i_a + \bar{d}^i_a \bar{\varphi}^i_a)|0\rangle. \tag{38}$$

Defining the notation $|Z\rangle = \exp(\bar{c}^i_a Z_{ab} \bar{d}^i_b)|0\rangle$ and $\langle Z| = \langle 0|\exp(d^i_a Z^\dagger_{ab} c^i_b)$, we find

$$T_s|0\rangle = \det{}^{N_c/2}(1-ZZ^\dagger)|Z\rangle \tag{39}$$

and

$$\langle 0|\exp(\bar{\psi}^i_a c^i_a + \varphi^i_a d^i_a)T_s|0\rangle\langle 0|T_s^{-1}\exp(\bar{c}^i_a\psi^i_a + \bar{d}^i_a\bar{\varphi}^i_a)|0\rangle = \det{}^{N_c}(1-ZZ^\dagger)\langle 0|\exp(\bar{\psi}^i_a c^i_a + \varphi^i_a d^i_a)|Z\rangle$$
$$\times\langle Z|\exp(\bar{c}^i_a\psi^i_a + \bar{d}^i_a\bar{\varphi}^i_a)|0\rangle = \det{}^{N_c}(1-ZZ^\dagger)\exp(\bar{\psi}^i_a Z_{ab}\varphi^i_b + \bar{\varphi}^i_a Z^\dagger_{ab}\psi^i_b). \tag{40}$$

Thus

$$\mathcal{Z}_0 = C_0\int_{|ZZ^\dagger|\leqslant 1} D(Z,Z^\dagger)\exp(\bar{\psi}^i_a Z_{ab}\varphi^i_b + \bar{\varphi}^i_a Z^\dagger_{ab}\psi^i_b) \tag{41}$$

with

$$D(Z,Z^\dagger) = \frac{\mathrm{d}Z\,\mathrm{d}Z^\dagger}{\det{}^{2N_b-N_c}(1-ZZ^\dagger)}. \tag{42}$$

Not surprisingly, this is the same result as in Ref. 2 for the color group $\mathrm{U}(N_c)$. From Eq. (29) we have

$$C_0^{-1} = \frac{1}{N_0}\int_G \mathrm{d}g\langle 0|T_g|0\rangle\langle 0|T_g^{-1}|0\rangle = \int_{|Z^\dagger Z|\leqslant 1} D(Z,Z^\dagger). \tag{43}$$

An explicit calculation of C_0 is given in Appendix B.

Note that for $2N_b > N_c$, $D(Z,Z^\dagger)$ becomes divergent at the boundary of the integration domain. This divergence is due to the noncompactness of the symmetric space $\mathrm{U}(N_b,N_b)/[\mathrm{U}(N_b)\times\mathrm{U}(N_b)]$ and is a feature of the bosonic color-flavor transformation. In Ref. 1, this divergence is canceled by the measure of the fermionic degrees of freedom, and the noncompact supersymmetric coset space has a flat measure if there is an equal number of bosons and fermions. In the fermionic case,[7] the integral on the RHS is over the compact symmetric space $\mathrm{U}(2N_f)/[\mathrm{U}(N_f)\times\mathrm{U}(N_f)]$, and there is no divergence problem.

Note also that for $2N_b > N_c$, there are divergences in both numerator and denominator of the above formula. Apart from $D(Z,Z^\dagger)$, the integrands are analytic on the entire coset space, therefore the divergences in numerator and denominator are of the same degree and the ratio must be finite. We will show this for a simple example in Appendix D 3. However, in the general case it is not obvious how to cancel the divergences, and even if it were possible, the resulting expressions might not be simple enough to be useful in applications. That is why in Sec. IV we will use another method to extend the range of N_b in which all terms in the transformation are finite.

G. Calculation of $\mathcal{Z}_Q$ for $Q \neq 0$

Let us start with the case of $Q > 0$; the case of $Q < 0$ follows analogously. Similar to Ref. 7, the idea is to relate the state $|\psi_Q\rangle$ to $|0\rangle$ by the action of the creation operators. Starting from the integrand of Eq. (32), we perform the following manipulations:

$$\begin{aligned}
&\langle 0|\exp(\bar{\psi}^i_a c^i_a + \varphi^i_a d^i_a)T_g|\psi_Q\rangle\langle\psi_Q|T_g^{-1}\exp(\bar{c}^i_a\psi^i_a + \bar{d}^i_a\bar{\varphi}^i_a)|0\rangle = \langle 0|\exp(\bar{\psi}^i_a c^i_a + \varphi^i_a d^i_a)\\
&\quad\times(\epsilon_{i_1\cdots i_{N_c}}T_g\bar{c}^{i_1}_1 T_g^{-1}T_g\bar{c}^{i_2}_2 T_g^{-1}\cdots T_g\bar{c}^{i_{N_c}}_{N_c}T_g^{-1})^Q T_g|0\rangle\\
&\quad\times\langle 0|T_g^{-1}(\epsilon_{i_1\cdots i_{N_c}}T_g c^{i_1}_1 T_g^{-1}T_g c^{i_2}_2 T_g^{-1}\cdots T_g c^{i_{N_c}}_{N_c}T_g^{-1})^Q\exp(\bar{c}^i_a\psi^i_a + \bar{d}^i_a\bar{\varphi}^i_a)|0\rangle\\
&= \det{}^{N_c}(1-ZZ^\dagger)\exp(\bar{\psi}^i_a Z_{ab}\varphi^i_b + \bar{\varphi}^i_a Z^\dagger_{ab}\psi^i_b)\\
&\quad\times[(\epsilon_{i_1\cdots i_{N_c}}\hat{\bar{\psi}}^{i_1}_{a^1_1}\cdots\hat{\bar{\psi}}^{i_{N_c}}_{a^1_{N_c}})\cdots(\epsilon_{j_1\cdots j_{N_c}}\hat{\bar{\psi}}^{j_1}_{a^Q_1}\cdots\hat{\bar{\psi}}^{j_{N_c}}_{a^Q_{N_c}})]\Gamma^{(a^1_1\cdots a^1_{N_c})\cdots(a^Q_1\cdots a^Q_{N_c})}_{(1\cdots N_c)\cdots(1\cdots N_c)}\\
&\quad\times[(\epsilon_{i'_1\cdots i'_{N_c}}\hat{\psi}^{i'_1}_{b^1_1}\cdots\hat{\psi}^{i'_{N_c}}_{b^1_{N_c}})\cdots(\epsilon_{j'_1\cdots j'_{N_c}}\hat{\psi}^{j'_1}_{b^Q_1}\cdots\hat{\psi}^{j'_{N_c}}_{b^Q_{N_c}})]\bar{\Gamma}^{(b^1_1\cdots b^1_{N_c})\cdots(b^Q_1\cdots b^Q_{N_c})}_{(1\cdots N_c)\cdots(1\cdots N_c)}.
\end{aligned} \tag{44}$$

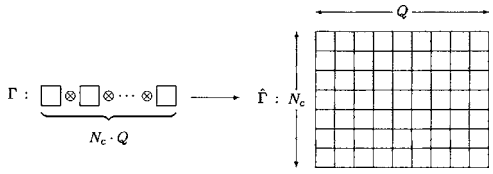

FIG. 1. The (reducible) product of fundamental representations of $\mathrm{U}(N_b)$ contains an irreducible representation of $\mathrm{U}(N_b)$ with symmetric color indices and antisymmetric flavor indices. Here $Q>0$.

In the first step, we have used Eq. (25) and inserted $T_g^{-1}T_g$ between each pair of creation and annihilation operators. In the second step, which involves a tedious but straightforward calculation, we have used the transformation properties of the Fock space operators given in Eq. (16), the Baker-Campbell-Hausdorff formula, and the coset decomposition of the group elements, $g=s(Z,Z^\dagger)h(g)$. We have also defined

$$\hat{\bar{\psi}}^i_a=\bar{\psi}^i_b(1-ZZ^\dagger)^{1/2}_{ba},\quad \hat{\psi}^i_a=(1-ZZ^\dagger)^{1/2}_{ab}\psi^i_b \tag{45}$$

and

$$\Gamma^{(a_1^1\cdots a_{N_c}^1)\cdots(a_1^Q\cdots a_{N_c}^Q)}_{(b_1^1\cdots b_{N_c}^1)\cdots(b_1^Q\cdots b_{N_c}^Q)}=(h_{+a_1^1b_1^1}\cdots h_{+a_{N_c}^1b_{N_c}^1})\cdots(h_{+a_1^Qb_1^Q}\cdots h_{+a_{N_c}^Qb_{N_c}^Q}). \tag{46}$$

The hypermatrix Γ represents the direct product of $N_c\cdot Q$ fundamental representations of $H_+=\mathrm{U}(N_b)$, see Fig. 1. Note that H_- does not appear here. Inserting Eq. (44) into Eq. (32), we obtain

$$\begin{aligned}\mathcal{Z}_Q=C_Q\int_{G/H}\mathrm{d}\mu(Z,Z^\dagger)\int_H\mathrm{d}h\langle 0|\exp(\bar{\psi}^i_ac^i_a+\varphi^i_ad^i_a)T_{s(Z,Z^\dagger)}T_h|\psi_Q\rangle\langle\psi_Q|T_h^{-1}T^{-1}_{s(Z,Z^\dagger)}\\ \times\exp(\bar{c}^i_a\psi^i_a+\bar{d}^i_a\bar{\varphi}^i_a)|0\rangle=\int_{|ZZ^\dagger|\leqslant 1}D(Z,Z^\dagger)\exp(\bar{\psi}^i_aZ_{ab}\varphi^i_b+\bar{\varphi}^i_aZ^\dagger_{ab}\psi^i_b)\chi_Q,\end{aligned} \tag{47}$$

where we have defined

$$\begin{aligned}\chi_Q=C_Q\{(\epsilon_{i_1\cdots i_{N_c}}\hat{\bar{\psi}}^i_{a_1^1}\cdots\hat{\bar{\psi}}^{i_{N_c}}_{a_{N_c}^1})\cdots(\epsilon_{j_1\cdots j_{N_c}}\hat{\bar{\psi}}^{j_1}_{a_1^Q}\cdots\hat{\bar{\psi}}^{j_{N_c}}_{a_{N_c}^Q})\}\\ \times\{(\epsilon_{i'_1\cdots i'_{N_c}}\hat{\psi}^{i'_1}_{b_1^1}\cdots\hat{\psi}^{i'_{N_c}}_{b_{N_c}^1})\cdots(\epsilon_{j'_1\cdots j'_{N_c}}\hat{\psi}^{j'_1}_{b_1^Q}\cdots\hat{\psi}^{j'_{N_c}}_{b_{N_c}^Q})\}\\ \times\int_{\mathrm{U}(N_b)}\mathrm{d}h_+[\Gamma^{(a_1^1\cdots a_{N_c}^1)\cdots(a_1^Q\cdots a_{N_c}^Q)}_{(1\cdots N_c)\cdots(1\cdots N_c)}\bar{\Gamma}^{(b_1^1\cdots b_{N_c}^1)\cdots(b_1^Q\cdots b_{N_c}^Q)}_{(1\cdots N_c)\cdots(1\cdots N_c)}].\end{aligned} \tag{48}$$

It follows from the definition of Γ that the term in square brackets is totally symmetric under the exchange of a^i_a with $a^{i'}_a$ and of b^i_a with $b^{i'}_a$. Because of the contraction with the totally antisymmetric tensor ϵ, the terms in curly brackets are totally antisymmetric under the exchange of a^i_a with $a^i_{a'}$ and of b^i_a with $b^i_{a'}$. Therefore, after the contractions of the a^i_a's and b^i_a's, only terms with the correct symmetry properties survive, i.e., symmetric in color and antisymmetric in flavor. In other words, when the (reducible) direct-product representation Γ is decomposed into irreducible representations, only the irreducible representation $\hat{\Gamma}$ shown in Fig. 1 contributes to χ_Q.

This observation enables us to perform the integration over H_+ in the same way as in Ref. 7. We use the group theoretic result that for irreducible unitary representations Γ^r and $\Gamma^{r'}$ of a compact Lie group G,

$$\int_G \mathrm{d}g\, \bar{\Gamma}^r_{ab}\Gamma^{r'}_{a'b'} = \frac{1}{d_r}\delta_{aa'}\delta_{bb'}\delta^{rr'}\int_G \mathrm{d}g, \tag{49}$$

where d_r is the dimension of Γ^r. The group volume of $\mathrm{U}(N_b)$ is normalized to unity as mentioned above.

Comparing Eq. (48) with Eq. (41) of Ref. 7, we realize that we can use (a slightly modified version of) the result in Eq. (46) of that reference and thus obtain

$$\chi_Q = \frac{(N_c!)^Q}{d^{N_b}_{N_c,Q}(Q!)^{N_c}} C_Q \det{}^Q \mathcal{M}, \tag{50}$$

where we have defined the $N_c \times N_c$ matrix $\mathcal{M}$ by $\mathcal{M}^{ij} = \bar{\psi}^i_a(1-ZZ^\dagger)_{ab}\psi^j_b$. The symbol $d^{N_b}_{N_c,Q}$ denotes the dimension of the irreducible representation of $\mathrm{U}(N_b)$ specified by a Young diagram with N_c rows and Q columns, i.e., of the representation $\hat{\Gamma}$ in Fig. 1. (For $N_b \leqslant N_c$, this dimension is equal to 1.) We will see in a moment that the prefactor of $C_Q \det{}^Q \mathcal{M}$ in Eq. (50) is in fact irrelevant.

We now use Eq. (29) to calculate the normalization factor C_Q. Using similar methods as in the calculation of χ_Q, we obtain

$$\begin{aligned}
\langle\psi_Q|T_g|\psi_Q\rangle &= \det{}^{N_c/2}(1-ZZ^\dagger)\langle\psi_Q|\{(\epsilon_{i_1\cdots i_{N_c}}\bar{c}^{\,i_1}_{c^1_1}\cdots\bar{c}^{\,i_{N_c}}_{c^1_{N_c}})\cdots(\epsilon_{j_1\cdots j_{N_c}}\bar{c}^{\,j_1}_{c^Q_1}\cdots\bar{c}^{\,j_{N_c}}_{c^Q_{N_c}})\}|0\rangle \\
&\quad\times[(1-ZZ^\dagger)^{1/2}_{c^1_1 a^1_1}\cdots(1-ZZ^\dagger)^{1/2}_{c^1_{N_c}a^1_{N_c}}]\cdots[(1-ZZ^\dagger)^{1/2}_{c^Q_1 a^Q_1}\cdots(1-ZZ^\dagger)^{1/2}_{c^Q_{N_c}a^Q_{N_c}}] \\
&\quad\times[h_{+_{a^1_1 1}}\cdots h_{+_{a^1_{N_c}N_c}}]\cdots[h_{+_{a^Q_1 1}}\cdots h_{+_{a^Q_{N_c}N_c}}] = N_Q \det{}^{N_c/2}(1-ZZ^\dagger)\Gamma^{(a^1_1\cdots a^1_{N_c})\cdots(a^Q_1\cdots a^Q_{N_c})}_{(1\cdots N_c)\cdots(1\cdots N_c)} \\
&\quad\times\sum_{\sigma_1\cdots\sigma_Q}[\mathrm{sgn}(\sigma_1)(1-ZZ^\dagger)^{1/2}_{\sigma_1(1)a^1_1}\cdots(1-ZZ^\dagger)^{1/2}_{\sigma_1(N_c)a^1_{N_c}}] \\
&\quad\times\cdots[\mathrm{sgn}(\sigma_Q)(1-ZZ^\dagger)^{1/2}_{\sigma_Q(1)a^Q_1}\cdots(1-ZZ^\dagger)^{1/2}_{\sigma_Q(N_c)a^Q_{N_c}}],
\end{aligned} \tag{51}$$

where we have used $N_Q = \langle\psi_Q|\psi_Q\rangle$. The symbol σ and the symbol ρ in the equation below denote elements of the permutation group S_{N_c}. Analogously, we find

$$\begin{aligned}
\langle\psi_Q|T_g^{-1}|\psi_Q\rangle &= N_Q \det{}^{N_c/2}(1-ZZ^\dagger)\bar{\Gamma}^{(b^1_1\cdots b^1_{N_c})\cdots(b^Q_1\cdots b^Q_{N_c})}_{(1\cdots N_c)\cdots(1\cdots N_c)}\sum_{\rho_1\cdots\rho_Q}[\mathrm{sgn}(\rho_1)(1-ZZ^\dagger)^{1/2}_{b^1_1\rho_1(1)} \\
&\quad\times\cdots(1-ZZ^\dagger)^{1/2}_{b^1_{N_c}\rho_1(N_c)}]\cdots[\mathrm{sgn}(\rho_Q)(1-ZZ^\dagger)^{1/2}_{b^Q_1\rho_Q(1)}\cdots(1-ZZ^\dagger)^{1/2}_{b^Q_{N_c}\rho_Q(N_c)}].
\end{aligned} \tag{52}$$

Combining these two results, we have from Eq. (29),

$$\begin{aligned}
C_Q^{-1} &= \frac{1}{N_Q}\int_{\mathrm{U}(N_b,N_b)}\mathrm{d}g\langle\psi_Q|T_g|\psi_Q\rangle\langle\psi_Q|T_g^{-1}|\psi_Q\rangle = N_Q\int_{|ZZ^\dagger|\leqslant 1}\mathrm{d}\mu(Z,Z^\dagger)\det{}^{N_c}(1-ZZ^\dagger) \\
&\quad\times\sum_{\sigma_1\cdots\sigma_Q}[\mathrm{sgn}(\sigma_1)(1-ZZ^\dagger)^{1/2}_{\sigma_1(1)a^1_1}\cdots(1-ZZ^\dagger)^{1/2}_{\sigma_1(N_c)a^1_{N_c}}]\cdots[\mathrm{sgn}(\sigma_Q)(1-ZZ^\dagger)^{1/2}_{\sigma_Q(1)a^Q_1} \\
&\quad\times\cdots(1-ZZ^\dagger)^{1/2}_{\sigma_Q(N_c)a^Q_{N_c}}]\sum_{\rho_1\cdots\rho_Q}[\mathrm{sgn}(\rho_1)(1-ZZ^\dagger)^{1/2}_{b^1_1\rho_1(1)}\cdots(1-ZZ^\dagger)^{1/2}_{b^1_{N_c}\rho_1(N_c)}] \\
&\quad\times\cdots[\mathrm{sgn}(\rho_Q)(1-ZZ^\dagger)^{1/2}_{b^Q_1\rho_Q(1)}\cdots(1-ZZ^\dagger)^{1/2}_{b^Q_{N_c}\rho_Q(N_c)}] \\
&\quad\times\int_{\mathrm{U}(N_b)}\mathrm{d}h_+\Gamma^{(a^1_1\cdots a^1_{N_c})\cdots(a^Q_1\cdots a^Q_{N_c})}_{(1\cdots N_c)\cdots(1\cdots N_c)}\bar{\Gamma}^{(b^1_1\cdots b^1_{N_c})\cdots(b^Q_1\cdots b^Q_{N_c})}_{(1\cdots N_c)\cdots(1\cdots N_c)}.
\end{aligned} \tag{53}$$

The integration over $\mathrm{U}(N_b)$ is of the same type as in the calculation of χ_Q, and using the same method we obtain

$$C_Q^{-1} = \frac{N_Q (N_c!)^Q}{d_{N_c,Q}^{N_b} (Q!)^{N_c}} \int_{|ZZ^\dagger| \leqslant 1} D(Z,Z^\dagger) \det{}^Q (1 - ZZ^\dagger)_{[N_c]}, \tag{54}$$

where $(1-ZZ^\dagger)_{[N_c]}$ denotes the upper left $N_c \times N_c$ block of the $N_b \times N_b$ matrix $(1-ZZ^\dagger)$. Recall that nonzero Q sectors only exist for $N_b \geqslant N_c$, so this notation always makes sense.

We now combine Eqs. (47), (50), and (54) to obtain for $Q>0$,

$$\mathcal{Z}_Q = \mathcal{C}_Q \int_{|ZZ^\dagger| \leqslant 1} D(Z,Z^\dagger) \exp(\bar{\psi}_a^i Z_{ab} \varphi_b^i + \bar{\varphi}_a^i Z_{ab}^\dagger \psi_b^i) \det{}^Q \mathcal{M}, \tag{55}$$

where we have defined

$$\mathcal{C}_Q^{-1} = N_Q \int_{|ZZ^\dagger| \leqslant 1} D(Z,Z^\dagger) \det{}^Q (1 - ZZ^\dagger)_{[N_c]}. \tag{56}$$

The explicit calculation of this integral is performed in Appendix B. As anticipated, the nontrivial prefactors in Eqs. (50) and (54) have dropped out.

For $Q<0$, the calculation proceeds in exact analogy, and we obtain

$$\mathcal{Z}_Q = \mathcal{C}_{|Q|} \int_{|ZZ^\dagger| \leqslant 1} D(Z,Z^\dagger) \exp(\bar{\psi}_a^i Z_{ab} \varphi_b^i + \bar{\varphi}_a^i Z_{ab}^\dagger \psi_b^i) \det{}^{|Q|} \mathcal{N}, \tag{57}$$

where the $N_c \times N_c$ matrix $\mathcal{N}$ is defined by $\mathcal{N}^{ij} = \bar{\varphi}_a^i (1 - Z^\dagger Z)_{ab} \varphi_b^j$. This completes the derivation of Eq. (1).

A number of concrete examples illustrating the transformation are given in Appendix D 1. In particular, in Appendix D 3 we consider an example where the integration measure diverges, and show how this problem can be solved in a simple case.

H. Generalization to unequal flavor numbers

So far we only considered the case in which particles and antiparticles have equal flavor numbers, i.e., $N_{b+}=N_{b-}=N_b$, where N_{b+} (N_{b-}) denotes the number of flavors of the particles (antiparticles). In practice this constraint may not be present. It is not difficult to see how our method can be extended to the general case in which $N_{b+} \neq N_{b-}$. The flavor group is then $\mathrm{U}(N_{b+},N_{b-})$, and the integral on the RHS of Eq. (1) is over the noncompact symmetric space $\mathrm{U}(N_{b+},N_{b-})/[\mathrm{U}(N_{b+}) \times \mathrm{U}(N_{b-})]$. All results derived in earlier parts of this section are still valid with some minor changes, (1) the complex matrix Z has dimension $N_{b+} \times N_{b-}$, (2) replace $2N_b$ by $N_{b+}+N_{b-}$ in the integration measure, and (3) choose the range of Q accordingly. For example, if $N_{b-} < N_c$ and $N_{b+} \geqslant N_c$, there are no Q_- sectors, and we sum over $Q \geqslant 0$ and set $\mathcal{N}=0$ in our results. We give a concrete example with $N_{b+} \neq N_{b-}$ in Appendix D 2.

IV. BOSONIC COLOR-FLAVOR TRANSFORMATION: CHARACTER EXPANSION METHOD

In this section, we use the character expansion method[19] to derive an alternative form of the bosonic color-flavor transformation which is free from divergences in the range $N_b \leqslant N_c$. We will also make use of the results of Refs. 20 and 21.

A. Setup of the calculation

In the last section, we have traded the integral over the compact color group for an integral over a noncompact manifold parametrized by an $N_b \times N_b$ complex matrix Z. Employing a singular value decomposition, this matrix can be written as

$$Z = U\Lambda V, \tag{58}$$

where $U \in \mathrm{U}(N_b)$, $V \in \mathrm{U}(N_b)/\mathrm{U}^{N_b}(1)$, and Λ is a diagonal matrix with real entries, the so-called radial coordinates, satisfying $0 \leqslant \Lambda_a \leqslant 1$. The divergence problem we met in the last section is caused by the integration over the submanifold spanned by the radial coordinates. Specifically, the divergence of highest degree occurs at the boundary, $\Lambda_a = 1$ for all a, and the entire information that is needed to complete the color-flavor transformation resides in the boundary. A natural question to ask at this point is whether the integration over the radial coordinates can be avoided. To answer this question, we integrate over the two compact unitary groups first. At the same time, we relax the constraints on the radial coordinates by replacing Λ with an arbitrary complex matrix.

Our strategy is as follows. We first perform the integration over the color group on the LHS of the transformation explicitly using the character expansion method. Next we compute an integral over a compact subgroup of the flavor group with a manifestly color-invariant integrand. We then complete the transformation by observing that the two integrals are equal.

We define two rectangular $N_c \times N_b$ matrices Ψ and Φ by

$$\Psi = (\psi_a^i), \quad \Phi = (\varphi_a^i). \tag{59}$$

The integrand on the LHS of Eq. (1) can then be rewritten as

$$\exp(\bar{\psi}_a^i U^{ij} \psi_a^j + \bar{\varphi}_a^i U^{\dagger ij} \varphi_a^j) = \exp(\mathrm{tr}\, UM + \mathrm{tr}\, U^\dagger N), \tag{60}$$

where we have defined two $N_c \times N_c$ matrices M and N by

$$M = (M^{ij}) = (\psi_a^i \bar{\psi}_a^j) = \Psi\Psi^\dagger, \quad N = (N^{ij}) = (\varphi_a^i \bar{\varphi}_a^j) = \Phi\Phi^\dagger. \tag{61}$$

In the following, we consider irreducible representations of $\mathrm{GL}(m)$ (for various values of m) labeled by

$$r = (r_1, r_2, \ldots, r_m) \quad \text{with integers} \quad r_1 \geqslant r_2 \geqslant \cdots \geqslant r_m \geqslant 0, \tag{62}$$

where r_j is the number of boxes in row j of the corresponding Young diagram. Using Eq. (3.5) of Ref. 20, we have

$$\exp(\mathrm{tr}\, UM) = \sum_r \alpha_r^{(0)} \chi_r(UM), \quad \exp(\mathrm{tr}\, U^\dagger N) = \sum_{r'} \alpha_{r'}^{(0)} \chi_{r'}(U^\dagger N), \tag{63}$$

where the sums are over all irreducible representations of $\mathrm{GL}(N_c)$ of the form (62). For a given representation r, we have[20]

$$\alpha_r^{(\nu)} = \det\left[\frac{1}{(r_j - \nu + i - j)!}\right] = \left[\prod_{i=1}^{N_c} \frac{(N_c - i)!}{(k_i - \nu)!}\right] d_r \quad \text{with } k_i = N_c + r_i - i, \tag{64}$$

where i and j run from 1 to N_c, ν is an additional integer which we shall need later on, d_r is the dimension of the representation r, given by Weyl's formula

$$d_r = \left[\prod_{n=1}^{N_c - 1} n!\right]^{-1} \Delta(k_1, \ldots, k_{N_c}), \tag{65}$$

and $\Delta(k_1, \ldots, k_{N_c}) = \prod_{i<j}(k_i - k_j)$ is the Vandermonde determinant. We then obtain

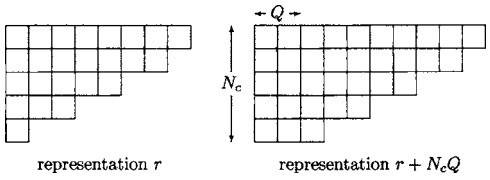

FIG. 2. Irreducible representations r and $r+N_cQ$.

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\mathrm{tr}\, UM + \mathrm{tr}\, U^\dagger N) = \sum_{rr'} \alpha_r^{(0)} \alpha_{r'}^{(0)} \int_{\mathrm{SU}(N_c)} \mathrm{d}U\, \chi_r(UM)\chi_{r'}(U^\dagger N)$$
$$= \sum_{rr'} \alpha_r^{(0)} \alpha_{r'}^{(0)} \int_{\mathrm{SU}(N_c)} \mathrm{d}U\, U_r^{ij} M_r^{ji} \bar{U}_{r'}^{kl} N_{r'}^{kl}, \tag{66}$$

where we use the notation U_r for the matrix corresponding to the representation r specified by a given Young diagram, an example of which is shown on the left-hand part of Fig. 2. On the right-hand part of Fig. 2, we show a Young diagram that has Q more columns, each containing N_c boxes, than the Young diagram for r. (Here we assume $Q \geqslant 0$.) We denote the corresponding representation by $r+N_cQ$. Note that for $\mathrm{SU}(N_c)$, these two representations are identical. We have the orthogonality relation

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U\, U_r^{ij} \bar{U}_{r'}^{kl} = \frac{1}{d_r} \delta^{ik} \delta^{jl} \delta_{r',r+N_cQ}. \tag{67}$$

From Eq. (64) it is clear that

$$\alpha_{r+N_cQ}^{(0)} = \alpha_r^{(-Q)}. \tag{68}$$

Furthermore, for all $g \in \mathrm{GL}(N_c)$ we have[30]

$$g_{r+N_cQ}^{ij} = g_r^{ij} \det{}^Q g. \tag{69}$$

Rewriting the sum over r and r' in Eq. (66) as a sum over r and Q, we obtain

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}_a^i U^{ij} \psi_a^j + \bar{\varphi}_a^i U^{\dagger ij} \varphi_a^j) = \sum_r \frac{\alpha_r^{(0)} \alpha_r^{(0)}}{d_r} \chi_r(MN) + \sum_{Q=1}^{\infty} (\det{}^Q M$$
$$+ \det{}^Q N) \sum_r \frac{\alpha_r^{(0)} \alpha_r^{(-Q)}}{d_r} \chi_r(MN). \tag{70}$$

The sums over r can be done analytically, resulting in an expression involving determinants of modified Bessel functions,[21] but we shall not need this explicit result and therefore do not quote it here.

Note that in the case of color group $\mathrm{U}(N_c)$ only the $Q=0$ term is nonzero in Eq. (67), and therefore only the first term contributes on the RHS of Eq. (70). This observation will allow us to read off results for $\mathrm{U}(N_c)$ from those for $\mathrm{SU}(N_c)$ in Secs. IV B and IV C.

We now turn to the RHS of Eq. (1) and first define two $N_b \times N_b$ matrices

$$B = (B_{ab}) = (\varphi_a^i \bar{\psi}_b^i) = [\Psi^\dagger \Phi]^T, \quad C = (C_{ab}) = (\psi_a^i \bar{\varphi}_b^i) = [\Phi^\dagger \Psi]^T. \tag{71}$$

We then consider the integral

$$\int_{U(N_b)} dU \int_{U(N_b)} dV \det{}^{-Q}(UAVB)\exp[\bar{\psi}^i_a (UAV)_{ab}\varphi^i_b + \bar{\varphi}^i_a (V^\dagger D U^\dagger)_{ab}\psi^i_b]$$

$$= \int_{U(N_b)} dU \int_{U(N_b)} dV \det{}^{-Q}(UAVB)\exp[\mathrm{tr}(UAVB) + \mathrm{tr}(CV^\dagger D U^\dagger)], \tag{72}$$

where A and D are two arbitrary $N_b \times N_b$ matrices. Using Ref. 21, we have for $AD=I$, i.e., A is the inverse of D,

$$(72) = \sum_s \frac{\alpha_s^{(0)}\alpha_s^{(-Q)}}{d_s^2}\chi_s(AD)\chi_s(BC) = \sum_s \frac{\alpha_s^{(0)}\alpha_s^{(-Q)}}{d_s}\chi_s(BC), \tag{73}$$

where the sum is over all irreducible representations s of $\mathrm{GL}(N_b)$ of the form (62), and we have used $d_s=\chi_s(I)$.

In Appendix C we prove the following identity for $\delta=N_c-N_b\geqslant 0$,

$$\sum_r \frac{\alpha_r^{(0)}\alpha_r^{(-Q)}}{d_r}\chi_r(MN) = \prod_{n=0}^{\delta-1}\frac{(N_b+n)!}{(Q+n)!}\sum_s \frac{\alpha_s^{(0)}\alpha_s^{(-Q-\delta)}}{d_s}\chi_s(BC), \tag{74}$$

where the sums on the LHS and the RHS are over all irreducible representations of $\mathrm{GL}(N_c)$ and $\mathrm{GL}(N_b)$, respectively, that are of the form (62). Using this identity, we can now relate Eqs. (70) and (73). We consider separately the cases $N_b<N_c$, $N_b=N_c$, and $N_b>N_c$.

B. $N_b<N_c$

For $N_b<N_c$, the matrices M and N are not of full rank, i.e., we have $\det M=\det N=0$. The terms multiplied by $\det M$ and $\det N$ in Eq. (70) are finite.[21] Thus, only the $Q=0$ term in Eq. (70) survives, and we obtain

$$(70) = \sum_r \frac{\alpha_r^{(0)}\alpha_r^{(0)}}{d_r}\chi_r(MN) = \prod_{n=0}^{\delta-1}\frac{(N_b+n)!}{n!}\sum_s \frac{\alpha_s^{(0)}\alpha_s^{(-\delta)}}{d_s}\chi_s(BC), \tag{75}$$

where we have used Eq. (74). This is already in the form of Eq. (73) with $Q=\delta=N_c-N_b$. We can further simplify the integral in Eq. (72) by choosing $A=D=I$ and using the invariance of the Haar measure to eliminate U from the integrand. This yields

$$\int_{\mathrm{SU}(N_c)} dU \exp(\bar{\psi}^i_a U^{ij}\psi^j_a + \bar{\varphi}^i_a U^{\dagger ij}\varphi^j_a) = \prod_{n=0}^{N_c-N_b-1}\frac{(N_b+n)!}{n!}\int_{U(N_b)} dV \det{}^{N_b-N_c}(VB)$$
$$\times\exp(\bar{\psi}^i_a V_{ab}\varphi^i_b + \bar{\varphi}^i_a V^\dagger_{ab}\psi^i_b) \tag{5}$$

as stated in Sec. II. If in the above expression one wants to take the limit of $\det B\to 0$, the integral over V needs to be done first. This procedure yields a finite result, see the example in Appendix E 3.

The result (5) is also valid if the integration on the LHS is over the color group $\mathrm{U}(N_c)$. This follows immediately from the remarks made after Eq. (70) and from the fact that the terms with $Q>0$ do not contribute on the RHS of Eq. (70).

C. $N_b=N_c$

For $N_b=N_c$ the matrices M and N are of full rank, and all terms in Eq. (70) contribute. Equation (74) now becomes trivial,

$$\sum_r \frac{\alpha_r^{(0)}\alpha_r^{(-Q)}}{d_r}\chi_r(MN) = \sum_s \frac{\alpha_s^{(0)}\alpha_s^{(-Q)}}{d_s}\chi_s(BC). \tag{76}$$

We again simplify the integral in Eq. (72) by choosing $A=D=I$ and using the invariance of the Haar measure to arrive at

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}_a^i U^{ij}\psi_a^j + \bar{\varphi}_a^i U^{\dagger ij}\varphi_a^j) = \sum_{Q=0}^{\infty} \tilde{\chi}_Q \int_{U(N_b)} \mathrm{d}V \det{}^{-Q}(VB)\exp(\bar{\psi}_a^i V_{ab}\varphi_b^i + \bar{\varphi}_a^i V_{ab}^\dagger \psi_b^i) \tag{6}$$

with $\tilde{\chi}_0=1$ and $\tilde{\chi}_{Q>0}=\det{}^Q M+\det{}^Q N$ as stated in Sec. II. If the $\det B\to 0$ limit is desired, the integral over V needs to be done first as mentioned at the end of the preceding section. If $\det{}^{-Q}(VB)$ is combined with the terms in $\tilde{\chi}_{Q>0}$, we obtain $\beta^Q+1/\bar{\beta}^Q$ with $\beta=\det\Psi/\det(\Phi V)$. This shows that we are not allowed to change the order of summation and integration in Eq. (6), since the resulting geometric series would diverge for one of the two terms.

If the integration on the LHS of Eq. (6) is over the color group $\mathrm{U}(N_c)$, only the $Q=0$ term contributes on the RHS as explained after Eq. (70), and we obtain for $N_b=N_c$,

$$\int_{U(N_c)} \mathrm{d}U \exp(\bar{\psi}_a^i U^{ij}\psi_a^j + \bar{\varphi}_a^i U^{\dagger ij}\varphi_a^j) = \int_{U(N_b)} \mathrm{d}V \exp(\bar{\psi}_a^i V_{ab}\varphi_b^i + \bar{\varphi}_a^i V_{ab}^\dagger \psi_b^i), \tag{77}$$

see also Sec. 6 of Ref. 16.

D. $N_b>N_c$

In this case the $N_c\times N_c$ matrices M and N are of full rank, whereas the $N_b\times N_b$ matrices B and C are of rank N_c with N_b-N_c eigenvalues equal to zero so that $\det B=\det C=0$. We now have $\delta=N_c-N_b<0$. Using similar arguments as in Appendix C but in the reverse direction, we obtain instead of Eq. (74),

$$\begin{aligned}\sum_r \frac{\alpha_r^{(0)}\alpha_r^{(-Q)}}{d_r}\chi_r(MN) &= C_{|\delta|}\sum_s \frac{\alpha_s^{(0)}\alpha_s^{(|\delta|-Q)}}{d_s}\chi_s(BC)\\ &= C_{|\delta|}\int_{U(N_b)} \mathrm{d}U \int_{U(N_b)} \mathrm{d}V \det{}^{|\delta|-Q}(UAVB)\exp[\mathrm{tr}(UAVB)+\mathrm{tr}(CV^\dagger DU^\dagger)]\\ &= C_{|\delta|}\int_{U(N_b)} \mathrm{d}V \det{}^{|\delta|-Q}(VB)\exp[\mathrm{tr}(VB)+\mathrm{tr}(CV^\dagger)]\end{aligned} \tag{78}$$

with

$$C_{|\delta|} = \prod_{n=1}^{|\delta|}\frac{(Q-n)!}{(N_b-n)!}, \tag{79}$$

where in the last step in Eq. (78) we have again set $A=D=I$ and used the invariance of the Haar measure to eliminate U from the integrand. Note that this expression is only valid for $Q\geqslant|\delta|=N_b-N_c$. Although $\det B=0$ appears with a nonpositive power, the RHS of Eq. (78) must be finite because the LHS is. This fact can be established explicitly by a suitable limiting procedure.

For $0\leqslant Q<|\delta|$, the integral over $\mathrm{U}(N_b)$ in Eq. (78) is zero because $\det B=0$ appears with a positive power. For this range of Q, we cannot replace the corresponding terms in Eq. (70) by integrals over $\mathrm{U}(N_b)$ and therefore cannot complete the transformation. Thus, it seems that the character expansion method does not yield a useful result for $N_b>N_c$.

V. CONCLUSIONS AND OUTLOOK

We have generalized Zirnbauer's color-flavor transformation in the bosonic sector to the special unitary group $\mathrm{SU}(N_c)$. Because the flavor group $\mathrm{U}(N_b,N_b)$ is noncompact, divergences arise if the number of bosonic flavors is too large. This has already been noted in Refs. 2 and 16 where the gauge group was $\mathrm{U}(N_c)$ and results were given for $2N_b \leqslant N_c$. We have found a "standard" result for the color-flavor transformation in the same range, and an alternative form of the transformation in the extended range $N_b \leqslant N_c$. [A special case of this result for $N_b=N_c$ and color group $\mathrm{U}(N_c)$ has already been given in Ref. 16.] For $N_b<N_c$, the results for $\mathrm{SU}(N_c)$ are identical to those for $\mathrm{U}(N_c)$ because only the sector with $Q=0$ contributes.

The results of the present paper can be applied to study a boson-induced $\mathrm{SU}(N_c)$ lattice gauge theory analogous to the $\mathrm{U}(N_c)$ gauge theory discussed in Ref. 16. We hope that other applications will arise, e.g., in the field of disordered and/or chaotic systems.

One obvious open problem is to obtain a manifestly convergent result for $N_b>N_c$. While the divergences that appear in numerator and denominator of our formal result (1) can always be canceled in special cases, see Appendix D 3, the general case is difficult to deal with. The character expansion method, which led to a convergent result in the extended range $N_b \leqslant N_c$, fails for $N_b>N_c$ since it cannot generate the terms with $0 \leqslant Q<N_b-N_c$ on the RHS of Eq. (70) in terms of integrals over (a subgroup of) the flavor group. However, as stated earlier and in Ref. 16, all necessary information resides in the boundary of the coset space $\mathrm{U}(N_b,N_b)/[\mathrm{U}(N_b)\times\mathrm{U}(N_b)]$, so it is conceivable that an explicit result in terms of an integration over this boundary might yet be obtained.

The other open problem is the extension of the present results to the supersymmetric case in which both fermionic and bosonic flavors are present. In this case the divergence of the integration measure due to the bosonic degrees of freedom can be canceled by the contribution of the fermions to the measure, as long as sufficiently many fermions are included. The physically interesting case is $N_c=3$ (the gauge group of QCD), $N_f \geqslant 2$ (the number of physical quark flavors), and $N_b=N_c$ (the lower bound for N_b so that the bosons induce the correct gauge action[16]). In this case, the convergence requirement $2(N_b-N_f) \leqslant N_c$ is satisfied. However, the supersymmetric case raises other issues which will be addressed in a separate paper.

The authors would like to thank B. Schlittgen for many helpful conversations and M.R. Zirnbauer for a stimulating discussion.

APPENDIX A: NORMALIZATION OF GENERALIZED SLATER STATES

In this section, we calculate the norm, $N_Q=\langle\psi_Q|\psi_Q\rangle$, of the state $|\psi_Q\rangle$ defined in Eq. (25). We first assume $Q \geqslant 0$ and discuss the case of $Q<0$ at the end of this section. The vacuum is normalized by definition so that $N_0=1$. For $Q=1$, $|\psi_Q\rangle$ is the Slater state with the well-known norm $N_1=N_c!$.

Let us mention in passing that N_Q corresponds to the complete contraction of all permutations of totally antisymmetric tensors of the form

$$N_Q=\sum_{\{\sigma_s\}} \epsilon^{i_1^1 i_2^1 \cdots i_{N_c}^1} \cdots \epsilon^{i_1^Q i_2^Q \cdots i_{N_c}^Q} \epsilon_{i_1^{\sigma_1(1)} i_2^{\sigma_2(1)} \cdots i_{N_c}^{\sigma_{N_c}(1)}} \cdots \epsilon_{i_1^{\sigma_1(Q)} i_2^{\sigma_2(Q)} \cdots i_{N_c}^{\sigma_{N_c}(Q)}}, \tag{A1}$$

where the sum is over N_c copies of the permutation group S_Q, i.e., $\sigma_s \in S_Q$, $s=1,\ldots,N_c$. To the best of our knowledge, N_Q was not known previously for $Q>1$.

To prove Eq. (30), we study a different version of the color-flavor transformation in which the flavor group is $\mathrm{U}(N_b)$ with $N_b=N_c$. Note that the flavor group is compact now. We follow the same

method as in Sec. III but keep only the particles created by the $\bar{c}^i_a$ and discard the antiparticles created by the $\bar{d}^i_a$. The flavor group $\mathrm{U}(N_b)$ is then generated by $\{\widetilde{\mathcal{G}}_{ab}=\bar{c}^i_a c^i_b\}$. The state $|\psi_Q\rangle$ is still defined as in Eq. (25). The projector onto the Q-sector is now

$$\mathbb{1}_Q = \widetilde{C}_Q \int_{U(N_b)} \mathrm{d}g\, \widetilde{T}_g |\psi_Q\rangle\langle\psi_Q| \widetilde{T}_g^{-1} \tag{A2}$$

with the normalized Haar measure $\mathrm{d}g$ of $\mathrm{U}(N_b)$ and $\widetilde{T}_g=\exp(\bar{c}^i_a(\ln g)_{ab}c^i_b)$. For $N_b=N_c$, we have by explicit calculation

$$\widetilde{T}_g|\psi_Q\rangle = (\det{}^Q g)|\psi_Q\rangle. \tag{A3}$$

Using this equation, the normalization constant $\widetilde{C}_Q$, see also Eq. (29), simplifies to

$$\widetilde{C}_Q = N_Q\left[\int_{U(N_b)} \mathrm{d}g \langle\psi_Q|\widetilde{T}_g|\psi_Q\rangle\langle\psi_Q|\widetilde{T}_g^{-1}|\psi_Q\rangle\right]^{-1} = N_Q[N_Q^2]^{-1} = \frac{1}{N_Q}. \tag{A4}$$

Next we consider the following integral and perform manipulations similar to those in Sec. III:

$$\begin{aligned}
\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}^i_a U^{ij}\psi^j_a) &= \int_{\mathrm{SU}(N_c)} \mathrm{d}U \langle 0|\exp(\bar{\psi}^i_a c^i_a)\exp(\bar{c}^i_a U^{ij}\psi^j_a)|0\rangle \\
&= \sum_{Q=0}^{\infty} \langle 0|\exp(\bar{\psi}^i_a c^i_a)\mathbb{1}_Q \exp(\bar{c}^i_a\psi^i_a)|0\rangle \\
&= \sum_{Q=0}^{\infty} \widetilde{C}_Q \int_{U(N_b)} \mathrm{d}g \langle 0|\exp(\bar{\psi}^i_a c^i_a)\widetilde{T}_g|\psi_Q\rangle\langle\psi_Q|\widetilde{T}_g^{-1}\exp(\bar{c}^i_a\psi^i_a)|0\rangle \\
&= \sum_{Q=0}^{\infty} \frac{1}{N_Q}\langle 0|\exp(\bar{\psi}^i_a c^i_a)|\psi_Q\rangle\langle\psi_Q|\exp(\bar{c}^i_a\psi^i_a)|0\rangle = \sum_{Q=0}^{\infty}\frac{1}{N_Q}\det{}^Q M,
\end{aligned} \tag{A5}$$

where M is an $N_c\times N_c$ matrix, $M^{ij}=\psi^i_a\bar{\psi}^j_a$, and we have again used Eq. (A3). However, we can also use the character expansion method[19,20] to do this integral. Using the same notation as in Sec. IV, we obtain

$$\begin{aligned}
\int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\bar{\psi}^i_a U^{ij}\psi^j_a) &= \int_{\mathrm{SU}(N_c)} \mathrm{d}U \exp(\mathrm{tr}\, UM) = \int_{\mathrm{SU}(N_c)} \mathrm{d}U \sum_r \alpha^{(0)}_r \chi_r(UM) \\
&= \sum_r \alpha^{(0)}_r M^{ji}_r \int_{\mathrm{SU}(N_c)} \mathrm{d}U\, U^{ij}_r = \sum_{Q=0}^{\infty} \alpha^{(0)}_{r=N_cQ} \det{}^Q M.
\end{aligned} \tag{A6}$$

In the last step, we have used the facts that

$$\int_{\mathrm{SU}(N_c)} \mathrm{d}U\, U^{ij}_r = \begin{cases} 1, & r = N_cQ, \\ 0, & \text{else}, \end{cases} \tag{A7}$$

where $r=N_cQ$ denotes the (one-dimensional) irreducible representation of $\mathrm{GL}(N_c)$ specified by a Young diagram with N_c rows and Q columns, and that for all $M\in\mathrm{GL}(N_c)$ we have $M^{ij}_{r=N_cQ}=\det{}^Q M$, see Eq. (69). (Note that in the one-dimensional representation $r=N_cQ$ the indices i and j only take the value 1.) From Eq. (64) we obtain with $d_{r=N_cQ}=1$,

$$\alpha^{(0)}_{r=N_cQ} = \prod_{n=0}^{N_c-1} \frac{n!}{(Q+n)!}. \tag{A8}$$

Comparing Eqs. (A5) and (A6) we arrive at Eq. (30), valid for $Q \geqslant 0$. The calculation for $Q<0$ proceeds in complete analogy by working with the antiparticles instead of the particles, and the result for this case can be obtained by the replacement $Q \to -Q$ in the expression for N_Q.

APPENDIX B: CALCULATION OF THE $\mathcal{C}_Q$

In this section, we do the integral in Eq. (56). This is an example of so-called Hua-type integrals that were studied by Hua a long time ago[17] and recently extended by Neretin.[31] Here, we follow the method introduced in Ref. 17. We first consider the case of $N_b \geqslant N_c$ and $Q \geqslant 0$, and then give a result for $N_b < N_c$ and $Q=0$.

Using Eq. (42), Eq. (56) becomes

$$\mathcal{C}_Q^{-1} = N_Q \int_{|ZZ^\dagger|\leqslant 1} \frac{\mathrm{d}Z\, \mathrm{d}Z^\dagger}{\det^{2N_b-N_c}(1-ZZ^\dagger)} \det{}^Q(1-ZZ^\dagger)_{[N_c]}. \tag{B1}$$

We now write the matrix Z as $Z=(Z_{N_b,N_b-1}, q)$, where Z_{N_b,N_b-1} is an $N_b \times (N_b-1)$ matrix and q is a single column. We then have

$$1-ZZ^\dagger = 1 - Z_{N_b,N_b-1} Z^\dagger_{N_b,N_b-1} - qq^\dagger. \tag{B2}$$

Since $|1-Z_{N_b,N_b-1}Z^\dagger_{N_b,N_b-1}| \geqslant 0$, i.e., the matrix has real and non-negative eigenvalues, we write $1-Z_{N_b,N_b-1}Z^\dagger_{N_b,N_b-1}=\Gamma\Gamma^\dagger$ and define $q=\Gamma w$. Then

$$\mathrm{d}q\, \mathrm{d}q^\dagger = |\det \Gamma|^2\, \mathrm{d}w\, \mathrm{d}w^\dagger = \det(1 - Z_{N_b,N_b-1}Z^\dagger_{N_b,N_b-1})\mathrm{d}w\, \mathrm{d}w^\dagger. \tag{B3}$$

On the other hand,

$$\det(1-ZZ^\dagger) = \det[\Gamma(1-ww^\dagger)\Gamma^\dagger] = (1-w^\dagger w)\det(1 - Z_{N_b,N_b-1}Z^\dagger_{N_b,N_b-1}),$$

where we have used $\det(1-ww^\dagger)=(1-w^\dagger w)$. Applying the same procedure to Z_{N_b,N_b-1} and so on, we obtain

$$\begin{aligned}
[\mathcal{C}_Q N_Q]^{-1} &= \int_{|ZZ^\dagger|\leqslant 1} \frac{\mathrm{d}Z\, \mathrm{d}Z^\dagger}{\det^{2N_b-N_c}(1-ZZ^\dagger)} \det{}^Q(1-ZZ^\dagger)_{[N_c]} = \prod_{i=1}^{N_c} \int_{w_i^\dagger w_i \leqslant 1} \mathrm{d}w_i\, \mathrm{d}w_i^\dagger (1 \\
&\quad - w_i^\dagger w_i)^{N_c-N_b+Q-i} \prod_{j=N_c+1}^{N_b} \int_{w_j^\dagger w_j \leqslant 1} \mathrm{d}w_j\, \mathrm{d}w_j^\dagger (1-w_j^\dagger w_j)^{N_c-N_b-j} \\
&= \prod_{i=1}^{N_c} \pi^{N_b} \frac{(N_c-N_b+Q-i)!}{(N_c+Q-i)!} \prod_{j=N_c+1}^{N_b} \pi^{N_b} \frac{(N_c-N_b-j)!}{(N_c-j)!}.
\end{aligned} \tag{B4}$$

From this equation, which was derived for $N_b \geqslant N_c$, we see that for $N_b > N_c$, the above integral diverges for all $Q \geqslant 0$, whereas for $N_b=N_c$, it diverges for $Q<N_b$.

For $N_b<N_c$, only the $Q=0$ sector exists, and we obtain from a very similar and even simpler calculation

$$\mathcal{C}_0^{-1} = C_0^{-1} = \pi^{N_b^2} \prod_{n=1}^{N_b} \frac{(N_c-N_b-n)!}{(N_c-n)!}, \tag{B5}$$

which is finite for $2N_b \leqslant N_c$ but diverges for $N_b < N_c < 2N_b$.

APPENDIX C: PROOF OF IDENTITY (74)

We have $\mathrm{tr}(MN)=\mathrm{tr}(\Psi\Psi^\dagger\Phi\Phi^\dagger)=\mathrm{tr}(\Phi^\dagger\Psi\Psi^\dagger\Phi)=\mathrm{tr}(\Phi^\dagger\Psi\Psi^\dagger\Phi)^T=\mathrm{tr}(BC)$, which proves the identity immediately for $N_b=N_c$. In the following, we assume $\delta=N_c-N_b>0$ and prove the identity by an iterative procedure.

The semipositive definite $N_b\times N_b$ matrix $BC=(\Phi^\dagger\Psi\Psi^\dagger\Phi)^T$ has N_b eigenvalues that we denote by λ_a^2 with $a=1,\ldots,N_b$. From linear algebra[18] we know that the $N_c\times N_c$ matrix $MN=\Psi\Psi^\dagger\Phi\Phi^\dagger$ has N_b eigenvalues equal to those of BC and $\delta=N_c-N_b$ eigenvalues equal to zero. We denote the eigenvalues of MN by μ_i^2, with $\mu_i=\lambda_i$ for $1\leqslant i\leqslant N_b$. For the purpose of this proof, we start with nonzero values μ_i for $N_b<i\leqslant N_c$ and let them go to zero one by one, starting with μ_{N_c}. Weyl's character formula is[17]

$$\chi_{(r_1,r_2,\ldots,r_{N_c})}(MN)=\frac{\det(\mu_i^{2(N_c+r_j-j)})}{\Delta(\mu^2)}=\frac{\det(\mu_i^{2k_j})}{\Delta(\mu^2)}, \tag{C1}$$

where the k_j have been defined in Eq. (64) and Δ again denotes the Vandermonde determinant. We have

$$\lim_{\mu_{N_c}\to 0}\Delta_{N_c}(\mu^2)=\lim_{\mu_{N_c}\to 0}\prod_{i<j}^{N_c}(\mu_i^2-\mu_j^2)=\Delta_{N_c-1}(\mu^2)\prod_{i=1}^{N_c-1}\mu_i^2, \tag{C2}$$

where the index on Δ denotes the number of eigenvalues involved. Similarly, we introduce the notation $\det_m(\mu_i^{2k_j})$ to denote the determinant of the $m\times m$ upper-left submatrix of the matrix $(\mu_i^{2k_j})$, i.e., i and j run from 1 to m instead of from 1 to N_c. Note that for $\mu_{N_c}\to 0$, $\det_{N_c}(\mu_i^{2k_j})$ is nonvanishing only if $k_{N_c}=0$ or, equivalently, $r_{N_c}=0$, in which case we have

$$\lim_{\mu_{N_c}\to 0}\det_{N_c}(\mu_i^{2k_j})=\det_{N_c-1}(\mu_i^{2k_j'})\prod_{i=1}^{N_c-1}\mu_i^2, \tag{C3}$$

where

$$k_j'=r_j+(N_c-1)-j\quad\text{with } j=1,\ldots,N_c-1. \tag{C4}$$

We conclude that for $\mu_{N_c}=0$, $\chi_r(MN)$ is nonzero only for representations of $\mathrm{GL}(N_c)$ with Young diagram $r=(r_1\geqslant\cdots\geqslant r_{N_c}=0)$. We thus obtain

$$\begin{aligned}\lim_{\mu_{N_c}\to 0}\sum_r\frac{\alpha_r^{(0)}\alpha_r^{(-Q)}}{d_r}\chi_r(MN)&=\sum_{r_1\geqslant\cdots\geqslant r_{N_c}=0}\frac{\alpha_r^{(0)}\alpha_r^{(-Q)}}{d_r}\frac{\det_{N_c-1}(\mu_i^{2k_j'})}{\Delta_{N_c-1}(\mu^2)}\\&=\prod_{n=1}^{N_c-1}n!\sum_{k_1>\cdots>k_{N_c}=0}\det_{N_c}\left(\frac{1}{k_j!(k_j-N_c+Q+i)!}\right)\frac{\det_{N_c-1}(\mu_i^{2k_j'})}{\Delta_{N_c-1}(\mu^2)},\end{aligned} \tag{C5}$$

where we have used Eqs. (64) and (65). From Eq. (64) with $k_{N_c}=0$ we have

$$\det_{N_c}\left(\frac{1}{k_j!(k_j-N_c+Q+i)!}\right)=\frac{d^{\mathrm{GL}(N_c)}_{(r_1,\ldots,r_{N_c-1},0)}}{\prod_{j=1}^{N_c-1}k_j!}\prod_{i=1}^{N_c}\frac{(N_c-i)!}{(k_i+Q)!}. \tag{C6}$$

From Eq. (65) we find that

$$d^{\mathrm{GL}(N_c)}_{(r_1,\ldots,r_{N_c-1},0)} = \frac{\prod_{j=1}^{N_c-1} k_j}{(N_c-1)!} d^{\mathrm{GL}(N_c-1)}_{(r_1+1,\ldots,r_{N_c-1}+1)}. \tag{C7}$$

Hence, for $\mu_{N_c}=0$, and thus $k_{N_c}=0$, we obtain from (C6), (C7), and (64),

$$\det_{N_c}\left(\frac{1}{k_j!(k_j-N_c+Q+i)!}\right) = \frac{1}{Q!}\det_{N_c-1}\left(\frac{1}{k_j'!(k_j'-(N_c-1)+(Q+1)+i)!}\right). \tag{C8}$$

Putting everything together, we arrive at

$$\lim_{\mu_{N_c}\to 0}\sum_r \frac{\alpha_r^{(0)}\alpha_r^{(-Q)}}{d_r}\chi_r(MN) = \frac{(N_c-1)!}{Q!}\sum_{r'}\frac{\alpha_{r'}^{(0)}\alpha_{r'}^{(-Q-1)}}{d_{r'}}\chi_{r'}(MN), \tag{C9}$$

where the sum on the RHS is over all irreducible representations $r'=(r_1\geqslant\cdots\geqslant r_{N_c-1}\geqslant 0)$ of $\mathrm{GL}(N_c-1)$. Repeating this procedure $\delta=N_c-N_b$ times, we obtain our identity

$$\sum_r \frac{\alpha_r^{(0)}\alpha_r^{(-Q)}}{d_r}\chi_r(MN) = \prod_{n=0}^{\delta-1}\frac{(N_b+n)!}{(Q+n)!}\sum_s \frac{\alpha_s^{(0)}\alpha_s^{(-Q-\delta)}}{d_s}\chi_s(BC), \tag{74}$$

where the sum on the RHS is over all irreducible representations s of $\mathrm{GL}(N_b)$ of the form (62), and where we have again used $\mathrm{tr}(MN)=\mathrm{tr}(BC)$.

APPENDIX D: EXAMPLES FOR THE ALGEBRAIC RESULT

1. $N_c=2$, $N_b=1$

We parametrize elements of SU(2) as

$$U=\begin{pmatrix} e^{i\lambda}\cos\theta & -e^{i\eta}\sin\theta \\ e^{-i\eta}\sin\theta & e^{-i\lambda}\cos\theta \end{pmatrix} \quad \text{with } 0\leqslant\theta\leqslant\frac{\pi}{2},\quad 0\leqslant\lambda,\eta<2\pi. \tag{D1}$$

The corresponding normalized Haar measure is $\mathrm{d}U=(1/2\pi^2)\sin\theta\cos\theta\,\mathrm{d}\theta\,\mathrm{d}\lambda\,\mathrm{d}\eta$. Performing the integral on the LHS of Eq. (4), we obtain

$$\int_{\mathrm{SU}(2)}\mathrm{d}U\exp(\bar\psi^i U^{ij}\psi^j+\bar\varphi^i U^{\dagger ij}\varphi^j) = \sum_{n=0}^{\infty}\frac{1}{n!(n+1)!}(\bar\psi^1\psi^1\bar\varphi^1\varphi^1+\bar\psi^2\psi^2\bar\varphi^2\varphi^2+\bar\psi^1\psi^2\bar\varphi^2\varphi^1 + \bar\psi^2\psi^1\bar\varphi^1\varphi^2)^n. \tag{D2}$$

For the RHS of Eq. (4), we have with $\mathcal{C}_0=1/\pi$,

$$\frac{1}{\pi}\int_{|z|\leqslant 1}\mathrm{d}z\,\mathrm{d}\bar z\exp[(\bar\psi^1\varphi^1+\bar\psi^2\varphi^2)z+(\bar\varphi^1\psi^1+\bar\varphi^2\psi^2)\bar z] = \frac{1}{\pi}\int_0^1 r\,\mathrm{d}r\int_0^{2\pi}\mathrm{d}\theta\exp[(\bar\psi^1\varphi^1+\bar\psi^2\varphi^2)re^{i\theta} + (\bar\varphi^1\psi^1+\bar\varphi^2\psi^2)re^{-i\theta}] = \sum_{n=0}^{\infty}\frac{1}{n!(n+1)!}(\bar\psi^1\psi^1\bar\varphi^1\varphi^1+\bar\psi^2\psi^2\bar\varphi^2\varphi^2+\bar\psi^1\psi^2\bar\varphi^2\varphi^1+\bar\psi^2\psi^1\bar\varphi^1\varphi^2)^n \tag{D3}$$

in agreement with Eq. (D2).

2. $N_c=N_{b+}=2$, $N_{b-}=0$

In this example we check the argument we made in Sec. III H for $N_{b+}\neq N_{b-}$. To have $N_{b-}=0$ we simply set $\bar\varphi_a^i=\varphi_a^i=0$. Using the same parametrization for SU(2) as in Appendix D 1, we calculate the integral on the LHS of Eq. (1),

$$\int_{\mathrm{SU}(2)} \mathrm{d}U \exp(\bar{\psi}_a^i U^{ij} \psi_a^j) = \sum_{n=0}^{\infty} \frac{1}{n!(n+1)!} (\bar{\psi}_1^1 \psi_1^1 \bar{\psi}_2^2 \psi_2^2 + \bar{\psi}_1^2 \psi_1^2 \bar{\psi}_2^1 \psi_2^1 - \bar{\psi}_1^1 \psi_1^2 \bar{\psi}_2^2 \psi_2^1 - \psi_1^1 \bar{\psi}_1^2 \bar{\psi}_2^1 \psi_2^2)^n. \tag{D4}$$

In this case we must sum over Q from zero to infinity on the RHS. The integral over the coset space U(2)/U(2) amounts to evaluating the integrand at the single point $Z=0$. From Eqs. (56) and (30), we have $\mathcal{C}_Q = 1/N_Q = 1/[Q!(Q+1)!]$ and thus obtain

$$\mathrm{RHS} = \sum_{Q=0}^{\infty} \frac{1}{Q!(Q+1)!} \det{}^Q \mathcal{M} = \sum_{Q=0}^{\infty} \frac{1}{Q!(Q+1)!} (\bar{\psi}_1^1 \psi_1^1 \bar{\psi}_2^2 \psi_2^2 + \bar{\psi}_1^2 \psi_1^2 \bar{\psi}_2^1 \psi_2^1 - \bar{\psi}_1^1 \psi_1^2 \bar{\psi}_2^2 \psi_2^1 - \psi_1^1 \bar{\psi}_1^2 \bar{\psi}_2^1 \psi_2^2)^Q \tag{D5}$$

in agreement with Eq. (D4), where we have used $\mathcal{M}^{ij} = \bar{\psi}_a^i \psi_a^j$.

3. $N_c = N_b = 1$

In this example, we run into the divergence problem discussed in Secs. II and III. The LHS of Eq. (1) is simple because the integral over SU(1) reduces to evaluating the integrand at unity,

$$\int_{\mathrm{SU}(1)} \mathrm{d}U \exp(\bar{\psi}^i U^{ij} \psi^j + \bar{\varphi}^i U^{\dagger ij} \varphi^j) = \exp(\bar{\psi}\psi + \bar{\varphi}\varphi). \tag{D6}$$

The RHS of Eq. (1) is a sum over Q. For $Q=0$ we have

$$\mathcal{C}_0^{-1} = \int_{|z|\leqslant 1} \frac{\mathrm{d}z\, \mathrm{d}\bar{z}}{1 - z\bar{z}} = 2\pi \int_0^1 \frac{r\, \mathrm{d}r}{1 - r^2} \tag{D7}$$

and

$$\int_{|z|\leqslant 1} \frac{\mathrm{d}z\, \mathrm{d}\bar{z}}{1 - z\bar{z}} \exp(\bar{\psi} z \varphi + \bar{\varphi} \bar{z} \psi) = 2\pi \sum_{n=0}^{\infty} \frac{(\bar{\psi}\psi\bar{\varphi}\varphi)^n}{(n!)^2} \int_0^1 \frac{r^{2n+1}\, \mathrm{d}r}{1 - r^2}. \tag{D8}$$

We now change the upper limit in the integral to $1-\epsilon$ and let $\epsilon \to 0$ to obtain

$$\mathcal{C}_0 \int_{|z|\leqslant 1} \frac{\mathrm{d}z\, \mathrm{d}\bar{z}}{1 - z\bar{z}} \exp(\bar{\psi} z \varphi + \bar{\varphi} \bar{z} \psi) = \sum_{n=0}^{\infty} \frac{(\bar{\psi}\psi\bar{\varphi}\varphi)^n}{(n!)^2}. \tag{D9}$$

For $Q \geqslant 1$, there are no divergences, and we have

$$\int_{|z|\leqslant 1} \frac{\mathrm{d}z\, \mathrm{d}\bar{z}}{(1 - z\bar{z})^{2N_b - N_c - Q}} \exp(\bar{\psi} z \varphi + \bar{\varphi} \bar{z} \psi) = \pi \sum_{n=0}^{\infty} \frac{(Q-1)!}{n!(n+Q)!} (\bar{\psi}\psi\bar{\varphi}\varphi)^n. \tag{D10}$$

Collecting all terms and using $\mathcal{C}_Q = 1/[\pi(Q-1)!]$, we find for the RHS of Eq. (1),

$$\int_{|ZZ^\dagger|\leqslant 1} D(Z, Z^\dagger) \exp(\bar{\psi}_a^i Z_{ab} \varphi_b^i + \bar{\varphi}_a^i Z_{ab}^\dagger \psi_b^i) \sum_{Q=0}^{\infty} \chi_Q = \sum_{n=0}^{\infty} \sum_{Q=0}^{\infty} \frac{1}{n!(n+Q)!} [(\bar{\psi}\psi)^Q + (\bar{\varphi}\varphi)^Q - \delta_{Q0}] \times (\bar{\psi}\psi\bar{\varphi}\varphi)^n = \exp(\bar{\psi}\psi + \bar{\varphi}\varphi), \tag{D11}$$

where the last step requires some rearrangements of the terms in the sums. We see that the transformation works although for $Q=0$ the normalization factor and the integral on the RHS of the transformation are divergent. After those infinities have been canceled, the finite ratio gives the

correct result. However, as mentioned at the end of Sec. III F, it is not trivial to obtain a simple result for the general case.

APPENDIX E: EXAMPLES FOR THE CHARACTER EXPANSION RESULT

1. $N_c=N_b=1$

Although this example was already considered in Appendix D 3, we revisit it here to check our result obtained using the character expansion method. Again, the LHS equals $\exp(\bar{\psi}\psi+\bar{\varphi}\varphi)$. From Eq. (6) we have

$$\sum_{Q=0}^{\infty}\tilde{\chi}_Q\int_0^{2\pi}\frac{\mathrm{d}\theta}{2\pi}(Be^{i\theta})^{-Q}\exp(\bar{\psi}e^{i\theta}\varphi+\bar{\varphi}e^{-i\theta}\psi)=\sum_{Q=0}^{\infty}[(\bar{\psi}\psi)^Q+(\bar{\varphi}\varphi)^Q-\delta_{Q0}]\sum_{n=0}^{\infty}\frac{1}{n!(n+Q)!}(\bar{\psi}\psi\bar{\varphi}\varphi)^n$$
$$=\exp(\bar{\psi}\psi+\bar{\varphi}\varphi) \tag{E1}$$

as in Eq. (D11), where we have used $M=\psi\bar{\psi}$, $N=\varphi\bar{\varphi}$, and $B=\varphi\bar{\psi}$. We see that the transformation (6) works and that, unlike in Appendix D 3, we do not have any divergence problem.

2. $N_c=N_b=2$

In this case we also have $2N_b>N_c$, and therefore divergences would arise in Eq. (1). We now check our result (6) in which no divergence appears. Using the parametrization of SU(2) in Appendix D 1, we perform the integral on the LHS,

$$\int_{\mathrm{SU}(2)}\mathrm{d}U\exp(\bar{\psi}^i_aU^{ij}\psi^j_a+\bar{\varphi}^i_aU^{\dagger ij}\varphi^j_a)=\sum_{n=0}^{\infty}\frac{1}{n!(n+1)!}(\det M+\det N+\mathrm{tr}\,MN)^n \tag{E2}$$

with M and N given by Eq. (61) and B and C given by Eq. (71). To do the integral on the RHS, we parametrize U(2) by multiplying the matrix in Eq. (D1), which we now call V, by a phase $e^{i\phi}$, with $0\leqslant\phi<2\pi$. The corresponding normalized Haar measure is $\mathrm{d}V=(1/4\pi^3)\sin\theta\cos\theta\,\mathrm{d}\theta\,\mathrm{d}\lambda\,\mathrm{d}\eta\,\mathrm{d}\phi$. We then obtain

$$\sum_{Q=0}^{\infty}\tilde{\chi}_Q\int_{\mathrm{U}(2)}\mathrm{d}V\det{}^{-Q}(VB)\exp(\bar{\psi}^i_aV_{ab}\varphi^i_b+\bar{\varphi}^i_aV^{\dagger}_{ab}\psi^i_b)=\sum_{n=0}^{\infty}\frac{1}{n!(n+1)!}(\det M+\det N+\mathrm{tr}\,BC)^n \tag{E3}$$

with $\tilde{\chi}_Q$ defined in Eq. (7). The two results agree. In the derivation of Eqs. (E2) and (E3) we have used $\det(BC)=\det(MN)$ and $\mathrm{tr}(BC)=\mathrm{tr}(MN)$.

3. $N_c=2$, $N_b=1$

Let us check our result (5). The LHS is given by Eq. (D2). On the RHS we have

$$\prod_{n=0}^{N_c-N_b-1}\frac{(N_b+n)!}{n!}\int_{\mathrm{U}(N_b)}\mathrm{d}V\det{}^{N_b-N_c}(VB)\exp(\bar{\psi}^i_aV_{ab}\varphi^i_b+\bar{\varphi}^i_aV^{\dagger}_{ab}\psi^i_b)=\int_0^{2\pi}\frac{\mathrm{d}\theta}{2\pi}(Be^{i\theta})^{-1}\exp(Be^{i\theta}$$
$$+Ce^{-i\theta})=\sum_{n=0}^{\infty}\frac{1}{n!(n+1)!}(\bar{\psi}^1\psi^1\bar{\varphi}^1\varphi^1+\bar{\psi}^2\psi^2\bar{\varphi}^2\varphi^2+\bar{\psi}^1\psi^2\bar{\varphi}^2\varphi^1+\bar{\psi}^2\psi^1\bar{\varphi}^1\varphi^2)^n, \tag{E4}$$

where we have used $B=\varphi^1\bar{\psi}^1+\varphi^2\bar{\psi}^2$ and $C=\psi^1\bar{\varphi}^1+\psi^2\bar{\varphi}^2$. Thus, the RHS agrees with the result in Eq. (D2).

(Received 13 April 2005; accepted 24 May 2005; published online 14 July 2005)

We consider the contraction of some nonlinear σ models which appear in effective supergravity theories. In particular we consider the contractions of maximally symmetric spaces corresponding to $N=1$ and $N=2$ theories, as they appear in certain low energy effective supergravity actions with mass deformations. The contraction procedure is shown to describe the *integrating out* of massive modes in the presence of interactions, as it happens in many supergravity models after spontaneous supersymmetry breaking. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1960719]

I. INTRODUCTION

Supergravity theories with mass deformations have recently received some attention because of their relation to flux compactifications (for a review see, e.g., Ref. 1) or Scherk–Schwarz generalized dimensional reduction.[2]

For $N \geqslant 2$ local supersymmetry, the supergravity theories admit mass deformations that always correspond to gauged supergravities.[3,4] The mass parameters may be chosen in such a way that a low energy effective Lagrangian for the massless sector can be singled out by deleting the massive modes.

This procedure is usually discussed in the framework of consistent truncations of field theories,[5] but here we want to show that the same phenomenon may arise as well as a *contraction*. The basic argument is that the limiting situation of a mass scale asymptotically large is equivalent to the contraction of some group structure.

Suppose the group structure is a nonlinear σ model related to a maximally symmetric space G/H where G is noncompact and H its maximally compact subgroup.[6,7] One can make an Inönü-Wigner contraction[8] of the group G with respect to a subgroup G'. Let $H'=H\cap G'$. We can induce a contraction G/H to a manifold which will have G'/H' embedded in it. The contracted manifold has the same dimension as the original one (as it happens for contractions of algebras and groups), but with a metric that will be essentially different. An example of this are the contractions of the hyperboloid SU(1, 1)/U(1). If the contraction is made with respect to the subgroup U(1) one

[a)]Electronic mail: Laura.Andrianopoli@cern.ch
[b)]Electronic mail: Sergio.Ferrara@cern.ch
[c)]Electronic mail: Maria.Lledo@ific.uv.es
[d)]Electronic mail: Oscar.Macia@ific.uv.es

obtains the flat metric, whereas if the contraction is made with respect to SO(1, 1) one obtains an hyperbolic sheet, with one translational isometry. We will see in detail how to compute the metrics in these and other cases.

There are other types of contractions that do not fit in the scheme described previously, but that may have physical interest. If G/H is a symmetric space of the noncompact type, it inherits a group structure through the Iwasawa decomposition of G

$$G = G_S \times H.$$

Then $G/H \approx G_S$ is the solvable Lie group associated to G.[6,7,9] Note that G_S depends on the real (noncompact) form of G. We can then consider contractions in which G/H goes to $G'/H' \ltimes \mathbb{R}^n$ (where $\ltimes$ stands for the semidirect product of groups) with $\dim(G/H)=\dim(G'/H')+n$, independently of the fact that G' is a subgroup of G or not. The physical interpretation of these contractions is as a (super)-Higgs mechanism,[10] where the massive modes are described by $\mathbb{R}^n$ degrees of freedom while the fields which remain massless are in G'/H'.[11] Indeed, because of the semidirect product structure, it is always consistent to set to zero (which, in this case, would correspond to integrate out) the elements of $\mathbb{R}^n$, since $\mathbb{R}^n$ is an invariant subalgebra of $G'/H' \ltimes \mathbb{R}^n$.[12] We will consider several examples and discuss their physical applications.

The paper is organized as follows.

In Sec. II we describe the solvable algebras related to symmetric spaces

$$\frac{\mathrm{SO}(1,1+n)}{\mathrm{SO}(1+n)}, \quad \frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1)\times\mathrm{SU}(1+n)}, \quad \frac{\mathrm{SO}(2,2+n)}{\mathrm{SO}(2)\times\mathrm{SO}(2+n)}, \quad \frac{\mathrm{U}(2,2+n)}{\mathrm{U}(2)\times\mathrm{U}(2+n)}, \tag{1}$$

and how these algebras are embedded one into the other. We also compute the metric of these spaces in the solvable parametrization. We show a couple of examples where these spaces are related to one another by gauging some isometries in the corresponding supergravity models followed by an integration of the massive modes.

In Sec. III we study some contractions of the solvable algebras introduced and we show how they are related among themselves. We compute the contracted metric by first giving a *deformation* of it in terms of a parameter ϵ. The limits $\epsilon \to 1$ and $\epsilon \to 0$ correspond to the original and the contracted spaces, respectively. For an arbitrary $\epsilon \neq 0$, the groups are isomorphic but we will see that it is not possible, in general, to reabsorb the parameter into a redefinition of the coordinates of the coset space. This means that the spaces at $\epsilon \neq 0$ are not isometric. We will show this phenomenon in detail. We will see how it is possible to interpret the gauging and integrating procedure of the examples treated in Sec. II as a contraction followed by a quotienting by a submanifold.

In Sec. IV we describe the super Higgs phenomenon associated to an effective $N=2$ supergravity theory with scalar manifold

$$\frac{\mathrm{SU}(1,1+n)}{(\mathrm{U}(1)\times\mathrm{SU}(1+n))}\times\frac{\mathrm{U}(2,2+n)}{(\mathrm{U}(2)\times\mathrm{U}(2+n))},$$

relating it to the contraction procedure described in previous sections.

In the Appendix we explain in more detail the parametrization chosen to study these sigma models.

II. SYMMETRIC SPACES, SOLVABLE PARAMETRIZATIONS AND EMBEDDINGS

We first illustrate the calculation of the solvable Lie algebra associated to a symmetric space of the noncompact type with the simplest example in (1). Essentially one has to diagonalize simultaneously the elements of the maximal abelian subalgebra in the space $\mathfrak{p}$ of the Cartan decomposition

$$\mathfrak{g} = \mathfrak{h} + \mathfrak{p}, \quad \mathfrak{g} = \mathrm{Lie}(G), \quad \mathfrak{h} = \mathrm{Lie}(H).$$

A. Solvable parametrization of SO(1,1+*n*)/SO(1+*n*)

We consider the Lie algebra of $\mathrm{SO}(1,1+n)$, $\mathfrak{so}(1,1+n)$. In the fundamental representation, an element of it is given by

$$X=\begin{pmatrix} & & b_1 \\ & A & \vdots \\ & & b_{n+1} \\ b_1 \cdots b_{n+1} & & 0 \end{pmatrix}, \quad A=-A^T,$$

where A is an antisymmetric $(n+1)\times(n+1)$ matrix. The Cartan decomposition of $\mathfrak{g}=\mathfrak{so}(1,1+n)$ is

$$\mathfrak{g}=\mathfrak{k}+\mathfrak{p}, \quad \mathfrak{k}=\mathfrak{so}(1+n)=\left\{\begin{pmatrix} A & 0 \\ 0 & 0 \end{pmatrix}\right\}, \quad \mathfrak{p}=\left\{\begin{pmatrix} 0 & b \\ b^T & 0 \end{pmatrix}\right\}.$$

It is easy to see that the coset has rank one. We choose the element

$$H=\begin{pmatrix} & & 0 & 0 \\ & 0 & \vdots & \vdots \\ & & 0 & 0 \\ 0\cdots 0 & & 0 & 1 \\ 0\cdots 0 & & 1 & 0 \end{pmatrix}$$

as the generator of the maximal abelian subalgebra in $\mathfrak{p}$. We must diagonalize h to obtain the reduced root pattern. This is easier by noting the following decomposition

$$\mathfrak{so}(1,n+1)\rightarrow\mathfrak{so}(1,1)+\mathfrak{so}(n)+\mathbf{n}^+ +\mathbf{n}^-,$$

where

$$\mathfrak{so}(1,1)=\mathrm{span}\{H\}, \quad \mathbf{n}^{\pm}=\left\{\begin{pmatrix} & & & b_1 & \mp b_1 \\ & & 0 & \vdots & \vdots \\ & & & b_n & \mp b_n \\ -b_1 & \cdots & -b_n & 0 & 0 \\ \mp b_1 & \cdots & \mp b_n & 0 & 0 \end{pmatrix}\right\},$$

and a vector in $\mathbf{n}^{\pm}$ has charge ± 1 with respect to H. In this decomposition the algebra shows a $\mathfrak{so}(1,1)$ grading ($\mathfrak{so}(n)$ has degree 0), and $\mathbf{n}^{\pm}$ are nilpotent (in particular, abelian) subalgebras. The solvable Lie algebra associated to the coset $\mathrm{SO}(1,1+n)/\mathrm{SO}(1+n)$ is then

$$\mathfrak{solv}\left(\frac{\mathrm{SO}(1,1+n)}{\mathrm{SO}(1+n)}\right)=\mathrm{span}\{H\}\ltimes\mathbf{n}^+, \tag{2}$$

with commutation rules

$$[H,X_i]=X_i, \quad i=1,\ldots,n \quad \text{(the rest zero)}.$$

Finally, the Iwasawa decomposition of the Lie algebra is

$$\mathfrak{so}(1,1+n)=\mathfrak{so}(1+n)+\mathfrak{solv}\left(\frac{\mathrm{SO}(1,1+n)}{\mathrm{SO}(1+n)}\right).$$

We choose a coset representative of the following form:

$$L = e^{u_i X_i} e^{\varphi H}, \quad L^{-1} = e^{-\varphi H} e^{-u_i X_i}.$$

We will see that this kind of splitting of the generators is specially useful. The pull back of the Maurer-Cartan form on the group to the coset space, $L^{-1}\mathrm{d}L$, decomposes as

$$L^{-1}\mathrm{d}L = (L^{-1}\mathrm{d}L)_{\mathfrak{k}} + (L^{-1}\mathrm{d}L)_{\mathfrak{p}}.$$

The first term is the connection on the K bundle $G \to G/K$, with $K=\mathrm{SO}(1+n)$ (spin bundle and spin connection) and the second term is the vielbein of G/K.

The metric is then computed as

$$\mathrm{d}s^2 = \langle (L^{-1}\mathrm{d}L)_{\mathfrak{p}}, (L^{-1}\mathrm{d}L)_{\mathfrak{p}} \rangle$$

where $\langle , \rangle$ is the Cartan-Killing form on $\mathfrak{g}$. Using the relation

$$e^{\alpha X} Y e^{-\alpha X} = Y e^{\alpha \beta}, \quad \text{provided } [X,Y] = \beta Y,$$

it is easy to see that the metric becomes

$$\mathrm{d}s^2 = \mathrm{d}\varphi^2 + e^{-2\varphi} \sum_i \mathrm{d}u_i^{\,2}. \tag{3}$$

This metric has the translational isometries $u_i \to u_i + c_i$ which are a maximal abelian ideal of the solvable Lie algebra (see the Appendix). In this case the ideal is $\mathcal{I}=\mathrm{span}\{X_i\}$.

It is now easy to go to the largest space in (1). It has only rank two and the rest of the solvable algebras can be seen as subalgebras of this. In fact we have a chain of embeddings of the solvable Lie algebras which implies a chain of embeddings of the corresponding symmetric spaces.

B. Solvable parametrization of U(2,2+*n*)/U(2)×U(2+*n*)

An element of the Lie algebra $\mathfrak{su}(2,2+n)$ can be written as

$$X = \begin{pmatrix} A_{2\times 2} & B_{2\times(2+n)} \\ B^{\dagger}_{(2+n)\times 2} & D_{(2+n)\times(2+n)} \end{pmatrix}, \quad A^{\dagger} = -A, \quad D^{\dagger} = -D,$$

and the Cartan decomposition of $\mathfrak{su}(2,2+n)=\mathfrak{h}+\mathfrak{p}$ is

$$\mathfrak{h} = \left\{ \begin{pmatrix} A_{2\times 2} & 0 \\ 0 & D_{(2+n)\times(2+n)} \end{pmatrix} \right\}, \quad \mathfrak{p} = \left\{ \begin{pmatrix} 0 & B_{2\times(2+n)} \\ B^{\dagger}_{(2+n)\times 2} & 0 \end{pmatrix} \right\}.$$

A maximal abelian subalgebra of $\mathfrak{p}$ has dimension 2, and so the coset has rank two. We can choose for example, as maximal abelian subalgebra, the one generated by the matrices

$$H_+ = \begin{pmatrix} 0 & 0 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 1 & 0 & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \cdots & \vdots & & & & \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 \end{pmatrix}, \quad H_- = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & i & 0 & 0 & \cdots & 0 \\ 0 & -i & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \cdots & \vdots & & & & \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 \end{pmatrix}$$

The solvable algebra can be shown to be generated by

$$\mathfrak{s}_4 = \mathfrak{solv}\left(\frac{\mathrm{U}(2,2+n)}{\mathrm{U}(2)\times \mathrm{U}(2+n)} \right) = \mathrm{span}\{H_+, H_-\} + \mathrm{span}\{Z^{ia}, Y^{ia}, T^{2,0}, T^{0,2}, S_{\alpha}^{(1,1)}, S_{\alpha}^{(1,-1)}\}, \tag{4}$$

where $i=1,2$, $a=1,\ldots n$, $\alpha=1,2$, with commutation rules

$$[Z^{ia},Z^{jb}]=\epsilon^{ij}\delta^{ab}T^{(2,0)},$$

$$[Y^{ia},Y^{jb}]=\epsilon^{ij}\delta^{ab}T^{(0,2)},$$

$$[Z^{ia},Y^{jb}]=\delta^{ab}(\delta^{ij}S_2^{(1,1)}+\epsilon^{ij}S_1^{(1,1)}),$$

$$[Y^{ia},S_1^{(1,-1)}]=Z^{ia},$$

$$[Y^{ia},S_2^{(1,-1)}]=\epsilon^{ij}Z^{ja},$$

$$[T^{(0,2)},S_\alpha^{(1,-1)}]=2S_\alpha^{(1,1)},$$

$$[S_\alpha^{(1,1)},S_\beta^{(1,-1)}]=\delta_{\alpha\beta}T^{(2,0)},$$

$$[H_+,Z^{ia}]=Z^{ia},$$

$$[H_-,Y^{ia}]=Y^{ia}. \tag{5}$$

The rest of the commutators with the Cartan generators H_+ and H_- are indicated by the upper indices (h_+,h_-). All the other commutators are zero.

Based on this solvable algebra, we choose the following parametrization for the coset representative of $\mathrm{U}(2,2+n)/(\mathrm{U}(2)\times\mathrm{U}(2+n))$ (In the appendix we show that the generators $T^{(2,0)}$, $T^{(0,2)}$, $S_\alpha^{(1,1)}$, and Z^{1a} correspond to true global *translational isometries*.):

$$L(t,\tilde{t},\tilde{s}_\alpha,s_\alpha,z_{ia},y_{ia},\psi,\phi)=A(t,\tilde{t},\tilde{s}_\alpha,z_{1a})B(s_\alpha,z_{2a},y_{ia})C(\psi,\phi), \tag{6}$$

where

$$A=\exp(tT^{(2,0)}+\tilde{t}\,T^{(0,2)}+\tilde{s}_\alpha S_\alpha^{(1,1)}+z_{1a}Z^{1a}),$$

$$B=\exp(s_1S_1^{(1,-1)})\exp(s_2S_2^{(1,-1)})\exp(z_{2a}Z^{2a})\exp(y_{2a}Y^{2a})\exp(y_{1a}Y^{1a}),$$

$$C=\exp(\psi H_+ +\phi H_-).$$

The Maurer Cartan form is

$$\begin{aligned}L^{-1}\mathrm{d}L=&\,e^{-2\psi}(s_\alpha\mathrm{d}\tilde{s}_\alpha+(s_1^2+s_2^2)\mathrm{d}\tilde{t}+\mathrm{d}t+z_{2a}\mathrm{d}z_{1a})T^{(2,0)}+e^{-2\phi}(\mathrm{d}\tilde{t}-y_{1a}\mathrm{d}y_{2a})T^{(0,2)}\\&+e^{-(\phi+\psi)}\big(y_{1a}y_{2a}\mathrm{d}s_1+\tfrac{1}{2}(y_1^2+y_2^2)\mathrm{d}s_2+\mathrm{d}\tilde{s}_1+2s_1\mathrm{d}\tilde{t}-\epsilon_{ij}y_{ia}\mathrm{d}z_{ja}\big)S_1^{(1,1)}\\&+e^{-(\phi+\psi)}\big(y_{1a}y_{2a}\mathrm{d}s_2-\tfrac{1}{2}(y_1^2+y_2^2)\mathrm{d}s_1+\mathrm{d}\tilde{s}_2+2s_2\mathrm{d}\tilde{t}+\delta_{ij}y_{ia}\mathrm{d}z_{ja}\big)S_2^{(1,1)}\\&+e^{-\psi}(-y_{1a}\mathrm{d}s_1+y_{2a}\mathrm{d}s_2+\mathrm{d}z_{1a})Z^{1a}+e^{-\psi}(-y_{2a}\mathrm{d}s_1-y_{1a}\mathrm{d}s_2+\mathrm{d}z_{2a})Z^{2a}+e^{\phi-\psi}\mathrm{d}s_\alpha S_\alpha^{(1,-1)}\\&+e^{-\phi}\mathrm{d}y_{ia}Y^{ia}+\mathrm{d}\psi H_+ +\mathrm{d}\phi H_-.\end{aligned} \tag{7}$$

The metric of the coset is computed now as $\langle(L^{-1}\mathrm{d}L)_\mathfrak{p},(L^{-1}\mathrm{d}L)_\mathfrak{p}\rangle$. On the tangent space to the identity, this gives the following inner product:

$$\langle X,X\rangle=\begin{cases}1 & \text{for } X=H_\pm,T^{(2,0)},T^{(0,2)}\\ \dfrac{1}{2} & \text{for } X=S_1^{(1,1)},S_2^{(1,1)},S_1^{(1,-1)},S_2^{(1,-1)},Y^{1a},Y^{2a},Z^{1a},Z^{2a},\end{cases}$$

and the rest zero.

For $n=0$ we obtain the reduced expression

$$\begin{aligned}
ds^2 &= d\phi^2 + d\psi^2 + e^{-4\psi} dt dt + 2e^{-4\psi} s_1 dt d\tilde{s}_1 + 2e^{-4\psi} s_2 dt d\tilde{s}_2 + 2e^{-4\psi}(s_2^2 + s_1^2) dt d\tilde{t} \\
&+ \frac{1}{2}(e^{-2(\psi+\phi)} + 2e^{-4\psi} s_1^2) d\tilde{s}_1 d\tilde{s}_1 + 2e^{-4\psi} s_2 s_1 d\tilde{s}_1 d\tilde{s}_2 + 2e^{-4\psi} s_1 (e^{2(\psi-\phi)} + s_2^2 + s_1^2) d\tilde{s}_1 d\tilde{t} \\
&+ \frac{1}{2}(e^{-2(\psi+\phi)} + 2e^{-4\psi} s_2^2) d\tilde{s}_2 d\tilde{s}_2 + 2e^{-4\psi} s_2 (e^{2(\psi-\phi)} + s_2^2 + s_1^2) d\tilde{s}_2 d\tilde{t} + \frac{1}{2} e^{2(\phi-\psi)} ds_2 ds_2 \\
&+ \frac{1}{2} e^{2(\phi-\psi)} ds_1 ds_1 + e^{-4(\psi+\phi)}(e^{2\psi} + e^{2\phi}(s_1^2 + s_2^2))^2 d\tilde{t} d\tilde{t}. \qquad (8)
\end{aligned}$$

For arbitrary n we obtain (for this and the rest of the calculations of different metrics we have used the program MATHEMATICA, Version 5.1, Wolfram Research, Inc., Champaign, IL, 2004.) (sum over repeated indices is understood, and we have used the short-hand notation $y_1^2 = y_{1a} y_{1a}$):

$$\begin{aligned}
ds^2 &= d\phi^2 + d\psi^2 + e^{-4\psi} dt dt + 2e^{-4\psi} s_1 dt d\tilde{s}_1 + 2e^{-4\psi} s_2 dt d\tilde{s}_2 + 2e^{-4\psi} z_{2a} dt dz_{1a} + 2e^{-4\psi}(s_2^2 \\
&+ s_1^2) dt d\tilde{t} \\
&+ \frac{1}{2}(e^{-2(\psi+\phi)} + 2e^{-4\psi} s_1^2) d\tilde{s}_1 d\tilde{s}_1 + 2e^{-4\psi} s_2 s_1 d\tilde{s}_1 d\tilde{s}_2 + \frac{1}{2} e^{-2(\psi+\phi)}(y_1^2 + y_2^2) d\tilde{s}_1 ds_2 \\
&+ e^{-2(\psi+\phi)} y_{1a} y_{2a} d\tilde{s}_1 ds_1 - e^{-2(\psi+\phi)} y_{1a} d\tilde{s}_1 dz_{2a} + (2e^{-4\psi} s_1 z_{2a} + e^{-2(\psi+\phi)} y_{2a}) d\tilde{s}_1 dz_{1a} \\
&+ 2e^{-4\psi} s_1 (e^{2(\psi-\phi)} + s_2^2 + s_1^2) d\tilde{s}_1 d\tilde{t} + \frac{1}{2}(e^{-2(\psi+\phi)} + 2e^{-4\psi} s_2^2) d\tilde{s}_2 d\tilde{s}_2 + e^{-2(\psi+\phi)} y_{1a} y_{2a} d\tilde{s}_2 ds_2 \\
&- \frac{1}{2} e^{-2(\psi+\phi)}(y_1^2 + y_2^2) d\tilde{s}_2 ds_1 + e^{-2(\psi+\phi)} y_{2a} d\tilde{s}_2 dz_{2a} + (2e^{-4\psi} s_2 z_{2a} + e^{-2(\psi+\phi)} y_{1a}) d\tilde{s}_2 dz_{1a} \\
&+ 2e^{-4\psi} s_2 (e^{2(\psi-\phi)} + s_2^2 + s_1^2) d\tilde{s}_2 d\tilde{t} + \frac{1}{8} e^{-2(\psi+\phi)}(4e^{4\phi} + 4e^{2\phi}(y_1^2 + y_2^2) + 4(y_{1a} y_{2a})^2 + (y_1^2 + y_2^2) \\
&\times (y_1^2 + y_2^2)) ds_\alpha ds_\alpha - \frac{1}{2} e^{-2(\psi+\phi)}(2e^{2\phi} y_{1b} + (-2(y_{1a} y_{2a}) y_{2b} + (y_1^2 + y_2^2) y_{1b})) ds_2 dz_{2b} \\
&+ \frac{1}{2} e^{-2(\psi+\phi)}(2e^{2\phi} y_{2b} + (2(y_{1a} y_{2a}) y_{1b} + (y_1^2 + y_2^2) y_{2b})) ds_2 dz_{1b} \\
&+ e^{-2(\psi+\phi)}(y_2^2 s_1 + 2y_{2a} s_2 y_{1a} + s_1 y_1^2) ds_2 d\tilde{t} - \frac{1}{2} e^{-2(\psi+\phi)}(2e^{2\phi} y_{2b} + (2(y_{1a} y_{2a}) y_{1b} \\
&+ (y_1^2 + y_2^2) y_{2b})) ds_1 dz_{2b} - \frac{1}{2} e^{-2(\psi+\phi)}(2e^{2\phi} y_{1b} + (-2(y_{1a} y_{2a}) y_{2b} + (y_1^2 + y_2^2) y_{1b})) ds_1 dz_{1b} \\
&- e^{-2(\psi+\phi)}(y_1^2 s_2 - 2y_{1a} s_1 y_{2a} + s_2 y_2^2) ds_1 d\tilde{t} - \frac{1}{2} e^{-2(\phi+\psi)} \epsilon_{ij} \epsilon_{mn} (y_{ia} y_{jb}) dz_{ma} dz_{nb} \\
&+ \frac{1}{2} e^{-2(\psi+\phi)}(e^{2\phi} \delta_{ab} + (y_{1a} y_{1b} + y_{2a} y_{2b})) dz_{2a} dz_{2b} - e^{-2(\psi+\phi)}(2y_1 s_1 - 2s_2 y_2) dz_2 d\tilde{t} \\
&+ \frac{1}{2} e^{-4\psi}(e^{2\psi} \delta_{ab} + 2z_{2a} z_{2b} + e^{2(\psi-\phi)}(y_{1a} y_{1b} + y_{2a} y_{2b})) dz_{1a} dz_{1b} + (2e^{-4\psi}(s_2^2 + s_1^2) z_{2a} \\
&+ 2e^{-2(\psi+\phi)}(y_{1a} s_2 + s_1 y_{2a})) dz_{1a} d\tilde{t} + e^{-4(\psi+\phi)}(e^{2\psi} + e^{2\phi}(s_1^2 + s_2^2))^2 d\tilde{t} d\tilde{t} - 2e^{-4\phi} y_{1a} d\tilde{t} dy_{2a} \\
&+ \frac{1}{2} e^{-4\phi}(e^{2\phi} \delta_{ab} + 2y_{1a} y_{1b}) dy_{2a} dy_{2b} + \frac{1}{2} e^{-2\phi} dy_{1a} dy_{1a}. \qquad (9)
\end{aligned}$$

C. Chain of embeddings

We have the following chain of solvable Lie algebras

$$\mathfrak{s}_4 = \mathfrak{solv}\left(\frac{\mathrm{U}(2,2+n)}{\mathrm{U}(2)\times\mathrm{U}(2+n)}\right) \quad (\text{see}(3)),$$

$$\mathfrak{s}_3 = \mathfrak{solv}\left(\frac{\mathrm{SO}(2,2+n)}{\mathrm{SO}(2)\times\mathrm{SO}(2+n)}\right) = \mathrm{span}\{H_+,H_-\} + \mathrm{span}\{Z^{1a},Y^{1a},S_2^{(1,1)},S_2^{(1,-1)}\},$$

$$\mathfrak{s}_2 = \mathfrak{solv}\left(\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}\right) = \mathrm{span}\{H_+ + H_-\} + \mathrm{span}\{Z^{1a},Y^{1a},S_2^{(1,1)}\},$$

$$\mathfrak{s}_1 = \mathfrak{solv}\left(\frac{\mathrm{SO}(1,1+n)}{\mathrm{SO}(1+n)}\right) = \mathrm{span}\{H_+ + H_-\} + \mathrm{span}\{Y^{1a}\}, \tag{10}$$

with $\mathfrak{s}_i \subset_{\mathrm{sub}} \mathfrak{s}_{i+1}$. Following the same procedure than in the previous examples, one can show that these solvable Lie algebras correspond to the following chain of symmetric spaces:

$$\frac{\mathrm{SO}(1,1+n)}{\mathrm{SO}(1+n)} \subset \frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)} \subset \frac{\mathrm{SO}(2,2+n)}{\mathrm{SO}(2)\times\mathrm{SO}(2+n)} \subset \frac{\mathrm{U}(2,2+n)}{\mathrm{U}(2)\times\mathrm{U}(2+n)}. \tag{11}$$

Notice that in this chain we have

$$\frac{G_i}{H_i} \subset \frac{G_{i+1}}{H_{i+1}}$$

with

$$G_1 \subset G_2, \quad H_1 \subset H_2,$$

$$G_3 \subset G_4, \quad H_3 \subset H_4,$$

$$G_1 \subset G_3, \quad H_1 \subset H_3,$$

$$G_2 \subset G_4, \quad H_2 \subset H_4,$$

but G_2 is not in G_3 nor H_2 in H_3 for generic n.

The solvable parametrization (6) allows us to compute the metric of the spaces in (11) by imposing different restrictions on (9).

For the coset $\mathrm{SO}(2,2+n)/(\mathrm{SO}(2)\times\mathrm{SO}(2+n))$, we have

$$z_{2a} = y_{2a} = t = \tilde{t} = \tilde{s}_1 = s_2 = 0,$$

so the metric is

$$\begin{aligned} \mathrm{d}s^2 = {} & \mathrm{d}\phi^2 + \mathrm{d}\psi^2 + \tfrac{1}{2}e^{-2(\psi+\phi)}\mathrm{d}\tilde{s}_2\mathrm{d}\tilde{s}_2 - \tfrac{1}{2}e^{-2(\psi+\phi)}y_1^2\mathrm{d}\tilde{s}_2\mathrm{d}s_1 + e^{-2(\psi+\phi)}y_{1a}\mathrm{d}\tilde{s}_2\mathrm{d}z_{1a} + \tfrac{1}{8}e^{-2(\psi+\phi)}(4e^{4\phi}+(y_1^2)^2 \\ & + 4e^{2\phi}y_1^2)\mathrm{d}s_1\mathrm{d}s_1 - \tfrac{1}{2}e^{-2(\psi+\phi)}y_{1a}(2e^{2\phi}+y_1^2)\mathrm{d}s_1\mathrm{d}z_{1a} + \tfrac{1}{2}e^{-4\psi}(e^{2\psi}\delta_{ab} + e^{2(\psi-\phi)}y_{1a}y_{1b})\mathrm{d}z_{1a}\mathrm{d}z_{1b} \\ & + \tfrac{1}{2}e^{-2\phi}\mathrm{d}y_{1a}\mathrm{d}y_{1a}. \end{aligned} \tag{12}$$

Imposing the constraints $s_1 = \phi - \psi = 0$, we obtain the metric on $\mathrm{SU}(1,1+n)/\mathrm{U}(1+n)$,

$$ds^2 = 2d\phi^2 + \tfrac{1}{2}e^{-4\phi}d\tilde{s}_2 d\tilde{s}_2 + e^{-4\phi}y_{1a}d\tilde{s}_2 dz_{1a} + \tfrac{1}{2}e^{-4\phi}(e^{2\phi}\delta_{ab} + y_{1a}y_{1b})dz_{1a}dz_{1b} + \tfrac{1}{2}e^{-2\phi}dy_{1a}dy_{1a}, \tag{13}$$

and imposing $z_{1a}=\tilde{s}_2=0$, we obtain the metric for $SO(1,1+n)/SO(1+n)$:

$$ds^2 = 2d\phi^2 + \tfrac{1}{2}e^{-2\phi}dy_{1a}dy_{1a} \tag{14}$$

which, up to a rescaling of the coordinates, corresponds to (3).

We can further impose $y_{1n}=0$ to obtain the same form than (14) but with $a=1,\ldots,n-1$. It is the metric of $SO(1,n)/SO(n)$.

D. Truncations and integration of massive modes

Let us consider a sigma model described by the metric (14). As we have seen, this model has n translational isometries corresponding to the coordinates y_{1a}. We may consider gauging one of these isometries, say y_{1n}. We introduce a gauge field $A=A_\mu dx^\mu$ and substitute dy_{1n} by the covariant differential

$$Dy_{1n} = dy_{1n} + gA.$$

We redefine the connection by a gauge transformation

$$\hat{A} = A + \frac{1}{g}dy_{1n},$$

which will not change the kinetic term for A. Substituting this definition in the metric we obtain

$$ds^2 = 2d\phi^2 + \frac{1}{2}e^{-2\phi}\sum_{a=1}^{n-1} dy_{1a}dy_{1a} + \frac{1}{2}e^{-2\phi}g^2\hat{A}^2.$$

We see that the effect of the gauging is absorbing the field y_{1n} to give mass to the gauge vector. Moreover, in this model $\hat{A}$ is decoupled from the rest of fields (except for the warping factor $e^{-2\phi}$), so setting $\hat{A}=0$ is consistent with the equations of motion. After the truncation the sigma model becomes $SO(1,n)/SO(n)$. This is explained by the mathematical identity

$$\mathfrak{solv}\left(\frac{SO(1,1+n)}{SO(1+n)}\right) = \mathfrak{solv}\left(\frac{SO(1,1+n-k)}{SO(1+n-k)}\right) \ltimes \mathbb{R}^k$$

which is a consequence of (2).

We want to consider now the model SU(1, 2)/U(2), with metric (13) for $n=1$. Note that $\tilde{s}_2$ and z_1 are translational isometries. As before, we can gauge them by introducing abelian connections A^1, A^2 with covariant differentials

$$d\tilde{s}_2 \to D\tilde{s}_2 = d\tilde{s}_2 + k_1 A^1,$$

$$dz_1 \to Dz_1 = dz_1 + k_2 A^2.$$

We define the gauge-transformed connections

$$\hat{A}^1 = A^1 + \frac{1}{k_1}d\tilde{s}_2,$$

$$\hat{A}^2 = A^2 + \frac{1}{k_2}dz_1.$$

By substituting this definition, we can see that in the metric there will appear the terms

$$ds^2 = \cdots + \tfrac{1}{2}e^{-4\phi}(k_1)^2(\hat{A}^1)^2 + \cdots + \tfrac{1}{2}e^{-2\phi}(k_2)^2(\hat{A}^2)^2 + \cdots \ .$$

So, as before, the effect of the gauging has been to give mass to the vectors by absorbing the modes associated to the translational isometries.

Nevertheless, in this case other interactions are present. By assuming that the mass of the vectors is big enough we can take their kinetic terms to zero, and then we obtain algebraic equations for $\hat{A}^1$, $\hat{A}^2$. A straightforward calculation shows that, after the elimination of these fields the metric that remains is SO(1, 2)/SO(2), that is Eq. (14) with $n=1$.

The difference between the two models here described is that in the first case the integration of the massive modes is exact (that is, it is a consistent truncation of the theory), while in the second case a limiting process is involved (masses $\to\infty$).

In the next section we will see that these integrations can be modeled by a *contraction* of the metric of the initial manifold, followed by a *quotienting* of the manifold by a submanifold.

III. CONTRACTIONS OF GROUPS AND COSET SPACES

A. Contraction of a Lie algebra with respect to a subalgebra

We describe the Inönü-Wigner contraction of an algebra with respect to a subalgebra. Let $\mathfrak{g}$ be an arbitrary, finite dimensional Lie algebra with commutator $[,]$ and let $\mathfrak{g}=\mathfrak{g}_1+\mathfrak{g}_2$, with $\mathfrak{g}_1$ a subalgebra. We define the following family of linear maps

$$\phi_\epsilon : \mathfrak{g} \to \mathfrak{g},$$

$$x = x_1 \oplus x_2 \to x = x_1 \oplus \epsilon x_2,$$

labeled by a real parameter ϵ, In matrix form, the map and its inverse ($\epsilon \neq 0$) are block diagonal

$$\phi_\epsilon = \begin{pmatrix} \mathbb{1} & 0 \\ 0 & \epsilon\mathbb{1} \end{pmatrix}, \quad \phi_\epsilon^{-1} = \begin{pmatrix} \mathbb{1} & 0 \\ 0 & \frac{1}{\epsilon}\mathbb{1} \end{pmatrix}.$$

We can define a new commutator

$$[X,Y]_\epsilon = \phi_\epsilon^{-1}([\phi_\epsilon(X), \phi_\epsilon(Y)]), \quad X,Y \in \mathfrak{g}.$$

$[,]_\epsilon$ is a *deformed bracket*, but of a simple form, since for $\epsilon \neq 0$ is, by construction, isomorphic to the bracket with $\epsilon=1$. We define the *contraction* of $\mathfrak{g}$ with respect to the subalgebra $\mathfrak{g}_1$ as a Lie algebra with the same supporting vector space $\mathfrak{g}_c \approx \mathfrak{g}$ and with commutator

$$[X,Y]_c = \lim_{\epsilon\to 0} \phi_\epsilon^{-1}([\phi_\epsilon(X), \phi_\epsilon(Y)]), \quad X,Y \in \mathfrak{g}. \tag{15}$$

This bracket is well defined but, since ϕ_0 is not invertible, $[,]_c$ will not be, in general, isomorphic to the original bracket.

B. Representations of the contracted algebra

We consider now a representation of $\mathfrak{g}$ on a finite dimensional vector space W

$$R(X): W \to W, \quad X \in \mathfrak{g}$$

and assume that $W=W_1 \oplus W_2$ with W_1 an invariant subspace under the action of the subalgebra $\mathfrak{g}_1$. As before, we define a one parameter family of linear maps

$$\psi_\epsilon : W \to W,$$

$$w = w_1 \oplus w_2 \rightarrow w = w_1 \oplus \epsilon w_2,$$

so

$$\psi_\epsilon = \begin{pmatrix} \mathbb{1} & 0 \\ 0 & \epsilon\mathbb{1} \end{pmatrix}, \quad \psi_\epsilon^{-1} = \begin{pmatrix} \mathbb{1} & 0 \\ 0 & \frac{1}{\epsilon}\mathbb{1} \end{pmatrix}.$$

Let us denote

$$R_\epsilon(X) = \psi_\epsilon^{-1} \circ R(\phi_\epsilon(X)) \circ \psi_\epsilon, \quad X \in \mathfrak{g}.$$

R_ϵ is a representation of the deformed algebra. It is easy to check that the map R_c

$$R_c(X) = \lim_{\epsilon \to 0} R_\epsilon(X)$$

is a representation of $\mathfrak{g}_c$ on W.

Notice that $\psi_\epsilon = \phi_\epsilon$ for the adjoint representation.

C. Generalized contractions

The map ϕ_ϵ can in fact be more general than the one considered before, the only constraint being that the bracket in (15) is well defined. The conditions for this to happen were studied in Ref. 13 and are called *generalized Inönü-Wigner contractions*. They are also a particular example of *algebra expansions*.[14]

We will use particular examples of generalized contractions where the brackets can be seen explicitly to have a well defined limit. We will not describe the general theory of these contractions, for which we refer to the original paper, Ref. 13.

D. Deformations and contractions of the metric: Some examples

As we have seen, we can always contract an algebra $\mathfrak{g}$ with respect to a subalgebra $\mathfrak{g}'$. The contracted algebra, $\mathfrak{g}_c$ will have always the structure of a semidirect product

$$\mathfrak{g}_c = \mathfrak{g}' \ltimes \mathbb{R}^n.$$

In chain (10) we have described subalgebras of $\mathfrak{s}_4$, so we can contract each algebra $\mathfrak{s}_i$ with respect to $\mathfrak{s}_j$ with $j < i$

Since the solvable Lie algebras are related to the corresponding symmetric spaces, we are going to define a procedure to contract the symmetric spaces. We will start with a representation R_ϵ of the deformed Lie algebra, and compute the coset representative as in (6) with this new representation. From this, one can compute a deformed vielbein and a deformed metric. This procedure will introduce the parameter ϵ in the metric, so we will have a uniparametric family of metrics. Then, we can take the limit $\epsilon \rightarrow 0$.

We are interested in the simple examples presented in Sec. II D. The first one is trivial, since the contraction of $\mathfrak{s}_1$ for arbitrary n by the subalgebra $\mathfrak{s}_1$ for $n-1$ has no effect, giving again $\mathfrak{s}_1$ for n.

Let us see how this works with the next example. We start with the algebra $\mathfrak{so}\mathfrak{l}\mathfrak{v}(\mathrm{SU}(1,2)/\mathrm{U}(2))$ (which is $\mathfrak{s}_2$ for $n=1$) and we will work out the contraction with respect to $\mathfrak{so}\mathfrak{l}\mathfrak{v}(\mathrm{SO}(1,2)/\mathrm{SO}(2))$ which is ($\mathfrak{s}_1$ for $n=1$).

$$\mathfrak{s}_2(n=1) = \mathrm{span}\{H_1 = H_+ + H_-\} + \mathrm{span}\{Z^1, Y^1, S_1^{(1,1)}\}, \tag{16}$$

$$\mathfrak{s}_1(n=1) = \mathrm{span}\{H_1\} + \mathrm{span}\{Y^1\}. \tag{17}$$

It is convenient to write explicitly the commutation rules

$$[H_1,Z^1]=Z^1,\quad [H_1,Y^1]=Y^1,\quad [H_1,S_1^{(1,1)}]=2S_1^{(1,1)},\quad [Z^1,Y^1]=S_1^{(1,1)}.$$

The deformed algebra is

$$[H_1,Z^1]_\epsilon=Z^1,\quad [H,Y^1]_\epsilon=Y^1,\quad [H_1,S_1^{(1,1)}]_\epsilon=2S_1^{(1,1)},\quad [Z^1,Y^1]_\epsilon=\epsilon S_1^{(1,1)}\to 0.$$

The contracted algebra has the property that the only elements in $\mathfrak{g}'$ that act on the abelian factor $\mathbb{R}^n$ are the elements of the commuting subalgebra of $\mathfrak{p}$. In our case this subalgebra is $H_1=H_+ +H_-$. This property will translate in a particularly simple form of the metric.

We consider the three-dimensional representation (induced from the fundamental of $\mathfrak{su}(1,2)$). We decompose the representation space as

$$\mathbb{C}^3=V_1\oplus V_2,\quad V_1=\left\{\begin{pmatrix} v_1\\ 0\\ v_3\end{pmatrix}\right\},\quad V_2=\left\{\begin{pmatrix} 0\\ v_2\\ 0\end{pmatrix}\right\},$$

being V_1 an invariant subspace under the subalgebra (17) and consider the linear map $\psi_\epsilon(e_1\oplus e_2)=e_1\oplus\epsilon e_2$. Then we have a three dimensional representation of the deformed algebra,

$$R_\epsilon(H_1)=\begin{pmatrix} 0 & 0 & 1\\ 0 & 0 & 0\\ 1 & 0 & 0\end{pmatrix},$$

$$R_\epsilon(Z^1)=\begin{pmatrix} 0 & i & 0\\ i\epsilon^2 & 0 & -i\epsilon^2\\ 0 & i & 0\end{pmatrix}\to\begin{pmatrix} 0 & i & 0\\ 0 & 0 & 0\\ 0 & i & 0\end{pmatrix},$$

$$R_\epsilon(Y^1)=\begin{pmatrix} 0 & 1 & 0\\ -\epsilon^2 & 0 & \epsilon^2\\ 0 & 1 & 0\end{pmatrix}\to\begin{pmatrix} 0 & 1 & 0\\ 0 & 0 & 0\\ 0 & 1 & 0\end{pmatrix},$$

$$R_\epsilon(S_1^{(1,1)})=-\epsilon\begin{pmatrix} i & 0 & 0\\ 0 & i & 0\\ 0 & 0 & -2i\end{pmatrix}\to 0.$$

We compute now the vielbein and the metric in the way that we indicated in Sec. II. Notice that the Euclidean metric that we put on the solvable Lie algebra with the deformed bracket is *the same* as the one for $\epsilon=1$. In this way the normal metric Lie algebras (in the terminology of Ref. 9) are not isomorphic, nor are isometric the corresponding Riemannian spaces. We obtain then a true deformation of the metric.

The result is

$$ds^2=2d\phi^2+\tfrac{1}{2}e^{-4\phi}d\tilde{s}_2d\tilde{s}_2+\epsilon^2e^{-4\phi}y_1d\tilde{s}_2dz_1+\tfrac{1}{2}e^{-4\phi}(e^{2\phi}+\epsilon^4y_1^2)dz_1dz_1+\tfrac{1}{2}e^{-2\phi}dy_1dy_1,\quad (18)$$

which can be compared with (13) for $\epsilon=1$.

For $\epsilon\to 0$ we get

$$ds^2=\left(2d\phi^2+\tfrac{1}{2}e^{-2\phi}dy_1dy_1\right)+\tfrac{1}{2}e^{-2\phi}dz_1dz_1+\tfrac{1}{2}e^{-4\phi}d\tilde{s}_2d\tilde{s}_2.\quad (19)$$

The first two factors correspond to (14). The remaining modes appear decoupled except for warping factors of type $e^{a\phi}/2$. Then, imposing the constraints $z_1=0=\tilde{s}_2$ is always a consistent truncation of the contracted sigma model (19). We see with this simple example that integrating

out massive modes can be geometrically modeled by a contraction of the sigma model, followed by a quotienting by the decoupled modes.

It is instructive to compute Ricci tensor of the deformed metric (18). We obtain (in the ordered basis $\phi, y_1, z_1, \tilde{s}_2$)

$$R^a_b(\epsilon) = \begin{pmatrix} -6 & 0 & 0 & 0 \\ 0 & -2(2+\epsilon^4) & 0 & 0 \\ 0 & 0 & -2(2+\epsilon^4) & 0 \\ 0 & 0 & 8y_1\epsilon^2(\epsilon^4-1) & 2(-4+\epsilon^4) \end{pmatrix}. \tag{20}$$

We see that for arbitrary ϵ it is not an Einstein space. In the relevant limits

$$R^a_b(1) = \begin{pmatrix} -6 & 0 & 0 & 0 \\ 0 & -6 & 0 & 0 \\ 0 & 0 & -6 & 0 \\ 0 & 0 & 0 & -6 \end{pmatrix}, \quad R^a_b(0) = \begin{pmatrix} -6 & 0 & 0 & 0 \\ 0 & -4 & 0 & 0 \\ 0 & 0 & -4 & 0 \\ 0 & 0 & 0 & -8 \end{pmatrix}.$$

For $\epsilon=1$ we have an Einstein space, but not for arbitrary ϵ. It becomes clear from this simple example that the deformation cannot be reabsorbed by a change of coordinates.

We consider now the Inönu-Wigner contraction of $\mathfrak{s}_4$ with respect to $\mathfrak{s}_3$. For simplicity, we take $n=1$, so we have $\mathfrak{s}_4=\mathfrak{s}_3+\mathfrak{g}$ where

$$\mathfrak{s}_3 = \mathrm{span}\{H_+, H_-, S_2^{(1,1)}, S_1^{(1,-1)}, Y^1, Z^1\},$$

$$\mathfrak{g} = \mathrm{span}\{T^{(2,0)}, T^{(0,2)}, S_1^{(1,1)}, S_2^{(1,-1)}, Y^2, Z^2\}.$$

Differently from the first example, we use the adjoint representation to introduce the parameter ϵ. The result for the metric is

$$\begin{aligned}
\mathrm{d}s^2 = {} & \mathrm{d}\phi^2 + \mathrm{d}\psi^2 + e^{-4\psi}\mathrm{d}t\mathrm{d}t + 2e^{-4\psi}s_1\mathrm{d}t\mathrm{d}\tilde{s}_1 + 2e^{-4\psi}s_2\mathrm{d}t\mathrm{d}\tilde{s}_2 + 2e^{-4\psi}z_2\mathrm{d}t\mathrm{d}z_1 + 2e^{-4\psi}(s_2^2\epsilon^2 \\

&- e^{-2(\phi+\psi)}y_1y_2\mathrm{d}z_1\mathrm{d}z_2
\end{aligned} \tag{22}$$

We can compare the first five lines of (22) with (12). They are different, but the extra terms are zero when imposing the constraints

$$z_2 = y_2 = t = \tilde{t} = \tilde{s}_1 = s_2 = 0.$$

This means that there is an isometric embedding of $\mathrm{SO}(2,3)/(\mathrm{SO}(2)\times\mathrm{SO}(3))$ in the manifold with the metric (22). We can improve this result by making use of a generalized contraction, that gives a simpler contracted metric. We will do that in the next section.

E. Generalized contractions: Some examples

1. Generalized contraction of $\mathbf{U(2,3)/(U(2)\times U(3))}$

We consider the following decomposition of s_4,

$$\mathfrak{s}_4 = \mathfrak{g}_0 + \mathfrak{g}_1 + \mathfrak{g}_2 + \mathfrak{g}_3,$$

where

$$\mathfrak{g}_0 = \mathrm{span}\{H_+, H_-, S_2^{(1,1)}, S_1^{(1,-1)}, Y^1, Z^1, T^{(2,0)}\},$$

$$\mathfrak{g}_1 = \mathrm{span}\{S_1^{(1,1)}\}, \quad \mathfrak{g}_2 = \mathrm{span}\{T^{(0,2)}, Z^2\}, \quad \mathfrak{g}_3 = \mathrm{span}\{S_2^{(1,-1)}, Y^2\}$$

and the linear map

$$\begin{array}{ccc} \mathfrak{s}_4 & \xrightarrow{\phi_\epsilon} & \mathfrak{s}_4 \\ e_0 + e_1 + e_2 + e_3 & \longrightarrow & e_0 + \epsilon e_1 + \epsilon^2 e_2 + \epsilon^3 e_3 \end{array} \quad \text{with } e_i \in \mathfrak{g}_i.$$

Equation (15) gives a deformed bracket that has a well defined limit when $\epsilon\to 0$. We write here the contracted bracket. The only surviving commutators from (5) when $\epsilon\to 0$ are

$$[Z^1, Y^1] = S_2^{(1,1)},$$

$$[Y^1, S_1^{(1,-1)}] = Z^1,$$

$$[H_+, Z^i] = Z^i,$$

$$[H_-, Y^i] = Y^i,$$

so the contracted algebra has as a subalgebra

$$\mathfrak{solo}\left(\frac{\mathrm{SO}(2,3)}{\mathrm{SO}(2)\times\mathrm{SO}(3)}\right) = \mathrm{span}\{H_+, H_-\} + \mathrm{span}\{Z^1, Y^1, S_2^{(1,1)}, S_1^{(1,-1)}\}$$

in semidirect product with $\mathbb{R}^6 = \mathrm{span}\{Z^2, Y^2, T^{(0,2)}, T^{2,0}, S_1^{(1,1)}, S_2^{(1,-1)}\}$, where the only generators that act on $\mathbb{R}^6$ are H_+ and H_-.

We use the adjoint representation of the deformed algebra to compute the deformed metric. The result is

$$\begin{aligned}
\mathrm{d}s^2 &= \mathrm{d}\phi^2 + \mathrm{d}\psi^2 + e^{-4\psi}\mathrm{d}t\mathrm{d}t + 2e^{-4\psi}s_1\epsilon\mathrm{d}t\mathrm{d}\tilde{s}_1 + 2e^{-4\psi}s_2\epsilon^3\mathrm{d}t\mathrm{d}\tilde{s}_2 + 2e^{-4\psi}z_2\epsilon^2\mathrm{d}t\mathrm{d}z_1 \\
&+ 2e^{-4\psi}(s_2^2\epsilon^2 + s_1^2\epsilon^8)\mathrm{d}t\mathrm{d}\tilde{t} + \tfrac{1}{2}(e^{-2(\psi+\phi)} + 2e^{-4\psi}s_1^2\epsilon^2)\mathrm{d}\tilde{s}_1\mathrm{d}\tilde{s}_1 + 2e^{-4\psi}s_2s_1\epsilon^4\mathrm{d}\tilde{s}_1\mathrm{d}\tilde{s}_2 \\
&+ \tfrac{1}{2}e^{-2(\psi+\phi)}(y_1^2\epsilon^2 + y_2^2\epsilon^8)\mathrm{d}\tilde{s}_1\mathrm{d}s_2 + e^{-2(\psi+\phi)}y_1y_2\epsilon^2\mathrm{d}\tilde{s}_1\mathrm{d}s_1 - e^{-2(\psi+\phi)}y_1\epsilon\mathrm{d}\tilde{s}_1\mathrm{d}z_2 \\

&\times\mathrm{d}s_1\mathrm{d}z_1 - e^{-2(\psi+\phi)}(y_1^2s_2\epsilon^5 - 2y_1s_1y_2\epsilon^3 + s_2y_2^2\epsilon^{11})\mathrm{d}s_1\mathrm{d}\tilde{t} + \tfrac{1}{2}e^{-2(\psi+\phi)}(e^{2\phi} + y_1^2\epsilon^2 + y_2^2\epsilon^{10}) \\
&\times\mathrm{d}z_2\mathrm{d}z_2 - e^{-2(\psi+\phi)}(2y_1s_1\epsilon^2 - 2s_2y_2\epsilon^{10})\mathrm{d}z_2\mathrm{d}\tilde{t} + \tfrac{1}{2}e^{-4\psi}(e^{2\psi} + 2z_2^2\epsilon^4 + e^{2(\psi-\phi)}(y_1^2 + y_2^2\epsilon^2)) \\
&\times\mathrm{d}z_1\mathrm{d}z_1 + (2e^{-4\psi}(s_2^2\epsilon^{10} + s_1^2\epsilon^4)z_2 + 2e^{-2(\psi+\phi)}(y_1s_2\epsilon^3 + s_1y_2\epsilon^5))\mathrm{d}z_1\mathrm{d}\tilde{t} \\
&+ (e^{4\psi} + e^{4\phi}(s_1^4\epsilon^4 + 2s_1^2s_2^2\epsilon^{10} + s_2^4\epsilon^{16}) + 2e^{2(\phi+\psi)}(s_1^2\epsilon^2 + s_2^2\epsilon^{10}))\mathrm{d}\tilde{t}\mathrm{d}\tilde{t} - 2e^{-4\phi}y_1\epsilon\mathrm{d}\tilde{t}\mathrm{d}y_2 \\
&+ \tfrac{1}{2}e^{-4\phi}(e^{2\phi} + 2y_1^2\epsilon^2)\mathrm{d}y_2\mathrm{d}y_2 + \tfrac{1}{2}e^{-2\phi}\mathrm{d}y_1\mathrm{d}y_1 + e^{-2(\phi+\psi)}y_1y_2(\epsilon^5 - \epsilon^3)\mathrm{d}z_1\mathrm{d}z_2 \\
&+ \tfrac{1}{2}e^{-2\psi}y_1y_2(2(\epsilon^2 - \epsilon^6) + (\epsilon^4 - \epsilon^6)(y_1^2 + y_2^2\epsilon^6))\mathrm{d}s_1\mathrm{d}s_2. \qquad (23)
\end{aligned}$$

And for $\epsilon = 0$ it becomes

$$\begin{aligned}
\mathrm{d}s^2 &= \mathrm{d}\phi^2 + \mathrm{d}\psi^2 + \tfrac{1}{2}e^{-2(\psi+\phi)}\mathrm{d}\tilde{s}_2^2 - \tfrac{1}{2}e^{-2(\psi+\phi)}y_1^2\mathrm{d}\tilde{s}_2\mathrm{d}s_1 + e^{-2(\psi+\phi)}y_1\mathrm{d}\tilde{s}_2\mathrm{d}z_1 \\
&+ \tfrac{1}{8}e^{-2(\psi+\phi)}(4e^{4\phi} + y_1^4 + 4e^{2\phi}y_1^2)\mathrm{d}s_1^2 - \tfrac{1}{2}e^{-2(\psi+\phi)}y_1(2e^{2\phi} + y_1^2)\mathrm{d}s_1\mathrm{d}z_1 \\
&+ \tfrac{1}{2}e^{-4\psi}(e^{2\psi} + e^{2(\psi-\phi)}y_1^2)\mathrm{d}z_1^2 + \tfrac{1}{2}e^{-2\phi}\mathrm{d}y_1^2 + e^{-4\psi}\mathrm{d}t^2 + e^{-4\phi}\mathrm{d}\tilde{t}^2 + \tfrac{1}{2}e^{-2(\phi+\psi)}\mathrm{d}\tilde{s}_1^2 + \tfrac{1}{2}e^{2(\phi-\psi)}\mathrm{d}s_2^2 \\
&+ \tfrac{1}{2}e^{-2\phi}\mathrm{d}y_2^2 + \tfrac{1}{2}e^{-2\psi}\mathrm{d}z_2^2.
\end{aligned}$$

The first three lines reproduce (12) for $n=1$, and the rest of the terms are flat up to factors $e^{(a\phi+b\psi)}$. The physical meaning of this limit remains unclear at this moment, but it relates two different sigma models in what can be a generalized procedure of integrating out some modes.

2. Generalized contraction of $\mathbf{U(2,1+n)/(U(2)\times U(1+n))}$

We show here another example of generalized contraction that has an application in a physically interesting theory.

Let us denote $H_1=H_+ + H_-$. Then the commutation rules of $\mathfrak{s}_2$ are

$$[H_1, Z^{1a}] = Z^{1a}, \quad [H_1, Y^{1a}] = Y^{1a}, \quad [H_1, S_2^{(1,1)}] = 2S_2^{(1,1)}, \quad [Z^{1a}, Y^{1b}] = S_2^{(1,1)}.$$

Consider the subalgebras of $\mathfrak{s}_4$

$$\mathfrak{s}_2' = \mathrm{span}\{H_+, Z^{ia}, T^{(2,0)}\}, \quad s_2'' = \mathrm{span}\{H_-, Y^{ia}, T^{(0,2)}\},$$

with commutation rules

$$[H_+, Z^{ia}] = Z^{ia}, \quad [H_+, T^{(2,0)}] = 2T^{(2,0)}, \quad [Z^{ia}, Z^{jb}] = \delta^{ab}\epsilon^{ij}T^{(2,0)} \quad \text{for } \mathfrak{s}_2',$$

$$[H_-, Y^{ia}] = Y^{ia}, \quad [H_-, T^{(0,2)}] = 2T^{(0,2)}, \quad [Y^{ia}, Y^{jb}] = \delta^{ab}\epsilon^{ij}T^{(0,2)} \quad \text{for } s_2''.$$

We have that $\mathfrak{s}_2 \simeq \mathfrak{s}_2' \simeq \mathfrak{s}_2''$ but $[\mathfrak{s}_2', \mathfrak{s}_2''] \neq 0$, so $\mathfrak{s}_2' \oplus \mathfrak{s}_2''$ is not a subalgebra of $\mathfrak{s}_4$. Nevertheless, one can find a generalized contraction of $\mathfrak{s}_4$ which has $\mathfrak{s}_2' \oplus \mathfrak{s}_2''$ as a subalgebra. We consider the decomposition,

$$\mathfrak{s}_4 = \mathfrak{g}_0 + \mathfrak{g}_1 + \mathfrak{g}_2,$$

where

$$\mathfrak{g}_0 = \mathrm{span}\{H_+, H_-\}, \quad \mathfrak{g}_1 = \mathrm{span}\{Y^{ia}, Z^{ia}, S_\alpha^{(1,1)}\}, \quad \mathfrak{g}_2 = \{T^{(0,2)}, T^{(2,0)}, S_\alpha^{(1,-1)}\},$$

and the linear map

$$\begin{array}{ccc} \mathfrak{s}_4 & \xrightarrow{\phi_\epsilon} & \mathfrak{s}_4 \\ e_0 + e_1 + e_2 & \longrightarrow & e_0 + \epsilon e_1 + \epsilon^2 e_2 \end{array} \qquad e_i \in \mathfrak{g}_i. \tag{24}$$

The contracted Lie algebra, with commutator given by (15) is well defined. It is worthy to see the commutators of the contracted algebra:

$$[Z^{ia}, Z^{jb}]_\epsilon = \epsilon^{ij}\delta^{ab}T^{(2,0)},$$

$$[Y^{ia}, Y^{jb}]_\epsilon = \epsilon^{ij}\delta^{ab}T^{(0,2)},$$

$$[Z^{ia}, Y^{jb}]_\epsilon = \epsilon\delta^{ab}(\delta^{ij}S_2^{(1,1)} + \epsilon^{ij}S_1^{(1,1)}),$$

$$[Y^{ia}, S_1^{(1,-1)}]_\epsilon = \epsilon^2 Z^{ia},$$

$$[Y^{ia}, S_2^{(1,-1)}]_\epsilon = \epsilon^2\epsilon^{ij}Z^{ja},$$

$$[T^{(0,2)}, S_\alpha^{(1,-1)}]_\epsilon = \epsilon^3 2S_\alpha^{(1,1)},$$

$$[S_\alpha^{(1,1)}, S_\beta^{(1,-1)}]_\epsilon = \epsilon\delta_{\alpha\beta}T^{(2,0)},$$

$$[H_+, Z^{ia}]_\epsilon = Z^{ia},$$

$$[H_-, Y^{ia}]_\epsilon = Y^{ia}. \tag{25}$$

showing explicitly $\mathfrak{s}_2' \oplus \mathfrak{s}_2''$ as a subalgebra when $\epsilon \to 0$. We use the adjoint representation to compute the metric, as in the previous examples. The result is

$$\begin{aligned}
ds^2 = {} & d\phi^2 + d\psi^2 + e^{-4\psi} dt dt + 2e^{-4\psi} \epsilon s_1 dt d\tilde{s}_1 + 2e^{-4\psi} \epsilon s_2 dt d\tilde{s}_2 + 2e^{-4\psi} z_{2a} dt dz_{1a} \\
& + 2e^{-4\psi} \epsilon^4 (s_2^2 + s_1^2) dt d\tilde{t} + \tfrac{1}{2}(e^{-2(\psi+\phi)} + 2e^{-4\psi} \epsilon^2 s_1^2) d\tilde{s}_1 d\tilde{s}_1 + 2e^{-4\psi} \epsilon^2 s_2 s_1 d\tilde{s}_1 d\tilde{s}_2 + \tfrac{1}{2} e^{-2(\psi+\phi)} \\
& \times \epsilon^3 (y_1^2 + y_2^2) d\tilde{s}_1 ds_2 + e^{-2(\psi+\phi)} \epsilon^3 y_{1a} y_{2a} d\tilde{s}_1 ds_1 - e^{-2(\psi+\phi)} \epsilon y_{1a} d\tilde{s}_1 dz_{2a} \\
& + \epsilon (2e^{-4\psi} s_1 z_{2a} + e^{-2(\psi+\phi)} y_{2a}) d\tilde{s}_1 dz_{1a} + 2e^{-4\psi} \epsilon^3 s_1 (e^{2(\psi-\phi)} + \epsilon^2 (s_2^2 + s_1^2)) d\tilde{s}_1 d\tilde{t} \\
& + \tfrac{1}{2}(e^{-2(\psi+\phi)} + 2e^{-4\psi} \epsilon^2 s_2^2) d\tilde{s}_2 d\tilde{s}_2 + e^{-2(\psi+\phi)} \epsilon^3 y_{1a} y_{2a} d\tilde{s}_2 ds_2 - \tfrac{1}{2} e^{-2(\psi+\phi)} \epsilon^3 (y_1^2 + y_2^2) d\tilde{s}_2 ds_1 \\
& + e^{-2(\psi+\phi)} \epsilon y_{2a} d\tilde{s}_2 dz_{2a} + \epsilon (2e^{-4\psi} s_2 z_{2a} + e^{-2(\psi+\phi)} y_{1a}) d\tilde{s}_2 dz_{1a} + 2e^{-4\psi} \epsilon^3 s_2 (e^{2(\psi-\phi)} + \epsilon^2 (s_2^2 + s_1^2)) \\
& \times d\tilde{s}_2 d\tilde{t} + \tfrac{1}{8} e^{-2(\psi+\phi)} (4e^{4\phi} + 4e^{2\phi} \epsilon^4 (y_1^2 + y_2^2) + 4\epsilon^6 (y_{1a} y_{2a})^2 + \epsilon^6 (y_1^2 + y_2^2)(y_{1b}^2 + y_{2b}^2)) ds_\alpha ds_\alpha \\
& - \tfrac{1}{2} e^{-2(\psi+\phi)} \epsilon^2 (2e^{2\phi} y_{1b} + \epsilon^2 (-2(y_{1a} y_{2a}) y_{2b} + (y_1^2 + y_2^2) y_{1b})) ds_2 dz_{2b} + \tfrac{1}{2} e^{-2(\psi+\phi)} \epsilon^2 \\
& \times (2e^{2\phi} y_{2b} + \epsilon^2 (2(y_{1a} y_{2a}) y_{1b} + (y_1^2 + y_2^2) y_{2b})) ds_2 dz_{1b} + e^{-2(\psi+\phi)} \epsilon^6 (y_2^2 s_1 + 2 y_{2a} s_2 y_{1a} \\
& + s_1 y_1^2) ds_2 d\tilde{t} \\
& - \tfrac{1}{2} e^{-2(\psi+\phi)} \epsilon^2 (2e^{2\phi} y_{2b} + \epsilon^2 (2(y_{1a} y_{2a}) y_{1b} + (y_1^2 + y_2^2) y_{2b})) ds_1 dz_{2b} - \tfrac{1}{2} e^{-2(\psi+\phi)} \\
& \times \epsilon^2 (2e^{2\phi} y_{1b} + \epsilon^2 (-2(y_{1a} y_{2a}) y_{2b} + (y_{1a}^2 + y_{2a}^2) y_{1b})) ds_1 dz_{1b} \\
& - e^{-2(\psi+\phi)} \epsilon^6 (y_{1a}^2 s_2 - 2 y_{1a} s_1 y_{2a} + s_2 y_{2a}^2) ds_1 d\tilde{t} - \tfrac{1}{2} e^{-2(\phi+\psi)} \epsilon_{ij} \epsilon_{mn} \epsilon^2 (y_{ia} y_{jb}) dz_{ma} dz_{nb} + \tfrac{1}{2} e^{-2(\psi+\phi)} \\
& \times (e^{2\phi} \delta_{ab} + \epsilon^2 (y_{1a} y_{1b} + y_{2a} y_{2b})) dz_{2a} dz_{2b} - e^{-2(\psi+\phi)} \epsilon^4 (2y_1 s_1 - 2s_2 y_2) dz_2 d\tilde{t} \\
& + \tfrac{1}{2} e^{-4\psi} (e^{2\psi} \delta_{ab} + 2 z_{2a} z_{2b} + e^{2(\psi-\phi)} \epsilon^2 (y_{1a} y_{1b} + y_{2a} y_{2b})) dz_{1a} dz_{1b} + \epsilon^4 (2e^{-4\psi} (s_2^2 + s_1^2) z_{2a} \\
& + 2e^{-2(\psi+\phi)} (y_{1a} s_2 + s_1 y_{2a})) dz_{1a} d\tilde{t} + e^{-4(\psi+\phi)} (e^{4\psi} + e^{2(\phi+\psi)} \epsilon^6 (s_1^2 + s_2^2) + e^{4\phi} \epsilon^8 (s_1^2 + s_2^2)^2) d\tilde{t} d\tilde{t} \\
& - 2e^{-4\phi} y_{1a} d\tilde{t} dy_{2a} + \tfrac{1}{2} e^{-4\phi} (e^{2\phi} \delta_{ab} + 2 y_{1a} y_{1b}) dy_{2a} dy_{2b} + \tfrac{1}{2} e^{-2\phi} dy_{1a} dy_{1a}.
\end{aligned} \tag{26}$$

In the contraction limit $\epsilon \to 0$ the metric reduces to

$$\begin{aligned}
ds^2 = {} & \left(d\phi^2 + e^{-4\phi} d\tilde{t} d\tilde{t} - 2e^{-4\phi} y_{1a} d\tilde{t} dy_{2a} + \tfrac{1}{2} e^{-4\phi} (e^{2\phi} \delta_{ab} + 2 y_{1a} y_{1b}) dy_{2a} dy_{2b} + \tfrac{1}{2} e^{-2\phi} dy_{1a} dy_{1a} \right) \\
& + \left(d\psi^2 + e^{-4\psi} dt dt + 2e^{-4\psi} z_{2a} dt dz_{1a} + \tfrac{1}{2} e^{-4\psi} (e^{2\psi} \delta_{ab} + 2 z_{2a} z_{2b}) dz_{1a} dz_{1b} + \tfrac{1}{2} e^{-2\psi} dz_{2a} dz_{2a} \right) \\
& + \tfrac{1}{2} e^{-2(\psi+\phi)} d\tilde{s}_\alpha d\tilde{s}_\alpha + \tfrac{1}{2} e^{-2(\psi+\phi)} ds_\alpha ds_\alpha.
\end{aligned}$$

By comparison with (13) we can see, after a suitable renaming of the coordinates and a rescaling by a global constant factor, that this is the metric on

$$\left(\frac{\mathrm{SU}(1,1+N)}{\mathrm{U}(1+N)} \times \frac{\mathrm{SU}(1,1+N)}{\mathrm{U}(1+N)} \right) \ltimes \mathbb{R}^4.$$

IV. SUPER HIGGS MECHANISM IN SUPERGRAVITY: GEOMETRIC INTERPRETATION

We consider an $N=2$ supergravity model coupled to $n+2$ hypermultiplets and $n+1$ vector multiplets. This model can be obtained as an $N=2$ phase of the compactification of type IIB supergravity on the $N=4$ orientifold $T^6/\mathbb{Z}_2$.[15,16] Indeed, when certain fluxes are turned on, has an $N=3$ phase obtained after the integration of the massive gravitino multiplet. The theory describing

the $N=3$ massless modes can be further Higgsed to an $N=2$ phase by turning on other suitable fluxes and further integration.[17] The scalar manifold for the $N=2$ theory is[11]

$$\mathcal{M}_Q \times \mathcal{M}_{SK} = \frac{\mathrm{U}(2,2+n)}{\mathrm{U}(2)\times \mathrm{U}(2+n)} \times \frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}.$$

Here n refers to the brane degrees of freedom. The special geometry and symplectic basis that describe this model have been discussed in Ref. 18.

The $N=2$ model can also be Higgsed to $N=1,0$ phases by still turning on fluxes. This corresponds in the supergravity language to gauge two translational isometries of the quaternionic manifold. In the parametrization that we have used before (26) it is manifest that the coordinates $\tilde{s}_\alpha$ correspond to two translational isometries, generated by $S_\alpha^{(1,1)}$, and we used the two bulk vector fields to gauge them.

When the gauge interactions are switched on, the σ-model Lagrangian gets modified by the minimal coupling prescription, with

$$\mathrm{d}\tilde{s}_\alpha \to D\tilde{s}_\alpha = \mathrm{d}\tilde{s}_\alpha + k_{\alpha,\Lambda} A^\Lambda, \quad \Lambda = 0,1,\ldots,n+1$$

and we may choose the constants $k_{1,0}\neq 0$, $k_{2,1}\neq 0$ and the rest zero. Then the Higgs mechanism takes place, as we described in Sec. II D, with the $\tilde{s}_\alpha$ contributing to the longitudinal components of the massive vectors

$$\hat{A}^0_\mu = A^0_\mu + \frac{1}{k_{1,0}}\partial_\mu \tilde{s}_1, \quad \hat{A}^1_\mu = A^1_\mu + \frac{1}{k_{2,1}}\partial_\mu \tilde{s}_2.$$

From Eq. (7) we can see that the kinetic term of these modes is

$$\begin{aligned}\mathrm{ds}^2 = \cdots + e^{-4\psi}(s_\alpha D\tilde{s}_\alpha + (s_1^2+s_2^2)\mathrm{d}\tilde{t} + \mathrm{d}t + z_{2a}\mathrm{d}z_{1a})^2 + \tfrac{1}{2}e^{-2(\psi+\phi)}\big(D\tilde{s}_1 + y_{1a}y_{2a}\mathrm{d}s_1 + \tfrac{1}{2}(y_1^2+y_2^2)\mathrm{d}s_2 \\ + 2s_1\mathrm{d}\tilde{t} - \epsilon_{ij}y_{ia}\mathrm{d}z_{ja}\big)^2 + \tfrac{1}{2}e^{-2(\psi+\phi)}\big(D\tilde{s}_2 + y_{1a}y_{2a}\mathrm{d}s_2 - \tfrac{1}{2}(y_1^2+y_2^2)\mathrm{d}s_1 + 2s_2\mathrm{d}\tilde{t} + \delta_{ij}y_{ia}\mathrm{d}z_{ja}\big)^2 + \cdots .\end{aligned}$$

After the substitution

$$D\tilde{s}_\alpha \to k_{\alpha,\Lambda}\hat{A}^\Lambda = B^\Lambda$$

the kinetic term for the vectors remains unchanged, whereas mass terms appear for the vectors $\hat{A}^\Lambda$, with masses $k_{0,1}$ and $k_{1,2}$. The modes $\tilde{s}_\alpha$ disappear from the Lagrangian.

In the large mass limit, the massive fields $B^\Lambda_\mu = m\hat{A}^\Lambda_\mu$ appear in the Lagrangian through expressions of the type

$$(B_\mu + f_\mu)^2,$$

where f_μ is some interaction of the massless modes.[11] The B's are Lagrange multipliers and their equations of motions make these terms to vanish.

The $N=2$ gauged theory has a scalar potential stabilizing two additional scalars which in our parametrization correspond to the coordinates s_α.[19] These fields acquire also a mass through the potential. In the large mass limit, these fields become Lagrange multipliers and the potential is such that their field equations set them to zero.

After performing these integrations, the metric becomes the one of the symmetric space

$$\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)} \times \frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}.$$

Now we see that this example fits with the contraction performed in Sec. III E. We can see that the terms set to zero in the metric by taking the limit $\epsilon \to 0$ are precisely the terms eliminated by the integration procedure. The modes that have become massive are the modes in $\mathbb{R}^4$ in the decomposition

$$\mathfrak{so}[\mathfrak{v}]\left(\frac{\mathrm{U}(2,2+n)}{\mathrm{U}(2)\times\mathrm{U}(2+n)}\right)\to\mathfrak{so}[\mathfrak{v}]\left(\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}\times\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}\right)\ltimes\mathbb{R}^4.$$

Since $\mathbb{R}^4$ is an invariant subgroup of the contracted group, the quotient

$$\mathfrak{so}[\mathfrak{v}]\left(\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}\times\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}\right)\ltimes\mathbb{R}^4/\mathbb{R}^4\approx\mathfrak{so}[\mathfrak{v}]\left(\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}\times\frac{\mathrm{SU}(1,1+n)}{\mathrm{U}(1+n)}\right),$$

is a (solvable) group, associated to the symmetric space. So in the geometrical picture the integration of the massive modes is again modeled by a contraction and a quotient by an invariant subgroup.

APPENDIX: ABOUT SOLVABLE LIE ALGEBRAS AND TRANSLATIONAL ISOMETRIES

A Lie algebra $\mathfrak{s}$ is solvable if the chain of ideals

$$\mathfrak{s}^{(0)}=\mathfrak{s},\quad \mathfrak{s}^{(1)}=[\mathfrak{s},\mathfrak{s}],\ldots,\mathfrak{s}^{(p)}=[\mathfrak{s}^{(p-1)},\mathfrak{s}^{(p-1)}],\ldots$$

has $\mathfrak{s}^{(p+1)}=0$ for some integer p. It is possible to prove[7] that a Lie algebra $\mathfrak{s}$ is solvable if and only if there is a chain of ideals $\mathfrak{i}_{i+1}\subset\mathfrak{i}_i$ with $\mathfrak{i}_i/\mathfrak{i}_{i+1}$ an abelian algebra, $\mathfrak{i}_0=\mathfrak{s}$ and $\mathfrak{i}_{p+1}=0$ for some p. It is clear that $\mathfrak{i}_p=0$ is an abelian ideal.

Example A.1

As an example, let us consider $\mathfrak{s}=\mathfrak{s}_4$ so

$$\mathfrak{i}_0=\mathfrak{s}_4,$$

$$\mathfrak{i}_1=[\mathfrak{i}_0,\mathfrak{i}_0]=\mathrm{span}\{Z^{ia},Y^{ia},T^{2,0},T^{0,2},S_\alpha^{(1,1)},S_\alpha^{(1,-1)}\},$$

$$\mathfrak{i}_2=[\mathfrak{i}_1,\mathfrak{i}_1]=\mathrm{span}\{Z^{ia},T^{2,0},T^{0,2},S_\alpha^{(1,1)}\},$$

$$\mathfrak{i}_3=[\mathfrak{i}_2,\mathfrak{i}_2]=\mathrm{span}\{T^{2,0}\}.$$

Notice that it is possible to substitute $\mathfrak{i}_3$ in the chain by the maximal abelian ideal

$$\mathfrak{i}_3'=\mathrm{span}\{T^{2,0},T^{0,2},S_\alpha^{(1,1)},Z^{1a}\},$$

or by this other one (with the same dimension)

$$\mathfrak{i}''_3 = \mathrm{span}\{T^{2,0}, T^{0,2}, S_\alpha^{(1,1)}, Z^{2a}\},$$

so the chain is not unique. ■

One can also show that $\mathfrak{s}^{(1)}$ is a nilpotent Lie algebra. The unique simply connected group associated to a nilpotent Lie algebra is exponential (the exp map is a diffeomorphism of the Lie algebra into the Lie group).[7]

Let $\mathfrak{g}$ be a Lie algebra and $\mathfrak{t}$ an abelian subalgebra. Let $\{X_i\}$ be a basis of $\mathfrak{t}$ and $\{Y_\alpha\}$ a basis of a complementary space to $\mathfrak{t}$. In a neighborhood of the identity, we have the exponential map

$$L(u^i, v^\alpha) = e^{u^i X_i} e^{v^\alpha Y_\alpha}. \tag{A1}$$

The Maurer-Cartan form is

$$L^{-1}\mathrm{d}L = e^{-v^\alpha Y_\alpha} X_i e^{v^\alpha Y_\alpha} \mathrm{d}u^i + e^{-v^\alpha Y_\alpha} \mathrm{d}(e^{v^\alpha Y_\alpha}).$$

From this expression, one can see that the local expression of the Maurer-Cartan form does not depend on the coordinates u^i. Whenever the group G with Lie algebra $\mathfrak{g}$ is diffeomorphic to $\mathbb{R}^n \times M$, with $\mathbb{R}^n$ parametrized by u^i (in other words, the coordinates u^i are global), we will say that the generators X_i are *translational isometries*.

We consider now the solvable algebras associated to the non compact symmetric spaces by the Iwasawa decomposition and explore the translational isometries in the corresponding symmetric spaces. The solvable Lie algebras are always a semidirect product

$$\mathfrak{s} = \mathfrak{a} \ltimes \mathfrak{n},$$

where $\mathfrak{a}$ is abelian (it contains the non compact Cartan elements) and $\mathfrak{s}^{(1)} = \mathfrak{n}$ is the nilpotent part. The non compact symmetric spaces are simply connected, so they are, in each case, the unique simply connected group associated to the corresponding solvable algebra. We denote it by

$$S = A \ltimes N, \quad \text{with } \mathrm{Lie}(A) = \mathfrak{a} \text{ and } \mathrm{Lie}(N) = \mathfrak{n},$$

and A and N being simply connected as well[6] (and hence, exponential). As a manifold,

$$S = A \times N = \exp(\mathfrak{a}) \times \exp(\mathfrak{n}). \tag{A2}$$

Let us now consider the factor N in (A2). We want to prove that the generators in the abelian ideal are translational isometries. Let $\mathfrak{n} = \mathfrak{n}_1 + \mathfrak{n}_2$, with $\mathfrak{n}_1$ an abelian ideal and $\mathfrak{n}_2$ any complementary subspace. We have that the map

$$\mathfrak{n} \to N,$$

$$(X_1, X_2) \to \exp(X_1 + X_2)$$

is a diffeomorphism. We want to show that, equally, the map

$$\mathfrak{n} \to N,$$

$$(X_1, X_2) \to \exp X_1 \exp X_2$$

is a diffeomorphism. It is enough to prove that any element $\exp(Y_1 + Y_2)$ can be written as $\exp X_1 \exp X_2$ for some $X_i \in \mathfrak{n}_i$. We notice that

$$\exp X_1 \exp X_2 = \exp\left(X_1 + X_2 + \tfrac{1}{2}[X_1, X_2] + \cdots\right) = \exp(X_2 + X_1'), \quad \text{with } X_1' \in \mathfrak{n}_1.$$

We take $Y_2 = X_2$, and the equation $Y_1 = X_1'$ can be solved for some $X_1 \in \mathfrak{n}_1$.

Near threshold expansion of Feynman diagrams

E. Mendels[a)]
Schenkkade 221, The Hague, 2595 AT Den Haag, The Netherlands

(Received 2 February 2005; accepted 13 May 2005; published online 18 July 2005)

The near threshold expansion of Feynman diagrams is derived from their configuration space representation, by performing all x integrations. The general scalar Feynman diagram is considered, with an arbitrary number of external momenta, an arbitrary number of internal lines and an arbitrary number of loops, in n dimensions and all masses may be different. The expansions are considered both below and above threshold. Rules, giving real and imaginary part, are derived. Unitarity of a sunset diagram with I internal lines is checked in a direct way by showing that its imaginary part is equal to the phase space integral of I particles. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1947119]

I. INTRODUCTION

In the usual approach of quantum field theory,[1–4] the successive terms in perturbation theory are represented by diagrams that are given by Feynman rules in momentum space. The most simple Feynman diagram is the zero loop diagram of Fig. 1. Several particles may come in and out, only the sum $\mathbf{p}$ of their momenta is of interest. The momentum space expression of Fig. 1 is

$$\frac{1}{\mathbf{p}^2 - m^2 + i\varepsilon}. \tag{1.1}$$

The one loop diagram (Fig. 2) is given by the momentum space expression

$$\int \mathrm{d}\mathbf{k} \frac{i}{(\mathbf{k}^2 - m_1^2 + i\varepsilon)\{(\mathbf{p}-\mathbf{k})^2 - m_2^2 + i\varepsilon\}}, \tag{1.2}$$

which is logarithmic divergent in four dimensions. The $i\varepsilon$'s may be transformed away by a Wick rotation, dimensional regularization may be introduced and the internal momentum may be integrated away. Integration over one Feynman parameter is left. In this way, (1.2) becomes[5]

$$(1.2) = \pi^{\nu}\Gamma(\nu-2)\int_0^1 \mathrm{d}y\{-y(1-y)\mathbf{p}^2 + ym_1^2 + (1-y)m_2^2\}^{\nu-2}. \tag{1.3}$$

The minus sign in the integrand comes from the inverse Wick rotation at the end of the calculations, which transforms p into ip.

The ν is a continuous variable and (1.3) must be considered in the limit

$$\varepsilon = \nu - \tfrac{1}{2}n \to 0, \tag{1.4}$$

where n is the number of dimensions. The logarithmic divergence of (1.2) in four dimensions is visible through the Γ-function in front,

[a)]Electronic mail: emendels@zonnet.nl

FIG. 1. Zero loop diagram.

$$(1.3) = \frac{\pi^2}{\varepsilon} + \pi^2 \int_0^1 \mathrm{d}y \, \ln\{-y(1-y)p^2 + ym_1^2 + (1-y)m_2^2\}. \tag{1.5}$$

Finally, the integration over y may be done,

$$(1.5) = \frac{\pi^2}{\varepsilon} + \pi^2\left(\frac{p^2 + m_1^2 - m_2^2}{2p^2}\right)\ln m_1^2 + \pi^2\left(\frac{p^2 + m_2^2 - m_1^2}{p^2}\right)\ln m_2^2 - 2\pi^2 + 2\pi^2\frac{a}{p^2}\mathrm{arctg}\left(\frac{p^2 + m_1^2 - m_2^2}{a}\right) + 2\pi^2\frac{a}{p^2}\mathrm{arctg}\left(\frac{p^2 + m_2^2 - m_1^2}{a}\right), \tag{1.6}$$

with

$$a = \sqrt{-(p + m_1 + m_2)(p - m_1 + m_2)(p + m_1 - m_2)(p - m_1 - m_2)}. \tag{1.7}$$

If the absolute value of the argument of the arctangents in (1.6) is smaller than 1, their series expansion is given by

$$\mathrm{arctg}\left(\frac{p^2 + m_1^2 - m_2^2}{a}\right) = \left(\frac{p^2 + m_1^2 - m_2^2}{a}\right) - \frac{1}{3}\left(\frac{p^2 + m_1^2 - m_2^2}{a}\right)^3 + \cdots . \tag{1.8a}$$

If it is larger than 1, the series expansion is given by

$$\mathrm{arctg}\left(\frac{p^2 + m_1^2 - m_2^2}{a}\right) = \frac{\pi}{4} - \left(\frac{a}{p^2 + m_1^2 - m_2^2}\right) + \frac{1}{3}\left(\frac{a}{p^2 + m_1^2 - m_2^2}\right)^3 - \cdots . \tag{1.8b}$$

The two-loop diagram (Fig. 3) is represented in momentum space by

$$\int \mathrm{d}\mathbf{k}_1 \, \mathrm{d}\mathbf{k}_2 \frac{i^2}{(\mathbf{k}_1^2 - m_1^2 + i\varepsilon)(\mathbf{k}_2^2 - m_2^2 + i\varepsilon)\{(\mathbf{p} - \mathbf{k}_1 - \mathbf{k}_2)^2 - m_3^2 + i\varepsilon\}}. \tag{1.9}$$

In four dimensions, it is quadratic divergent and contains subintegrals that are logarithmic divergent. The expression becomes after regularization and integration over the internal momenta,

$$(1.9) = \pi^{2\nu}\Gamma(3 - 2\nu) \int \mathrm{d}y_1 \, \mathrm{d}y_2 \{y_1y_2 + y_1y_3 + y_2y_3\}^{-\nu} \times\left(-\frac{y_1y_2y_3p^2}{y_1y_2 + y_1y_3 + y_2y_3} + y_1m_1^2 + y_2m_2^2 + y_3m_3^2\right)^{2\nu-3} \tag{1.10}$$

with

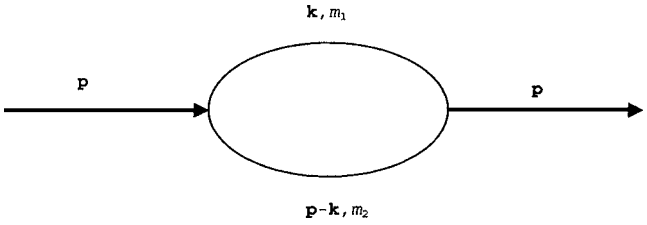

FIG. 2. One loop diagram.

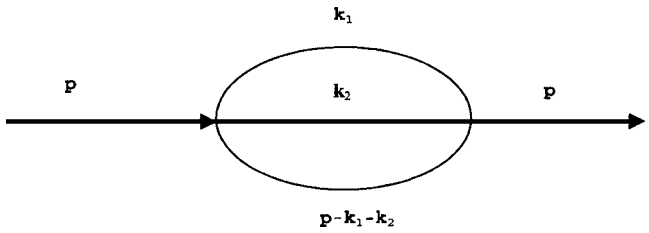

FIG. 3. Two loop diagram.

$$y_3 = 1 - y_1 - y_2. \tag{1.11}$$

One of the infinities is visible through the Γ-function in front. Other infinities become visible only after cumbersome partial integrations over the Feynman parameters y_1 and y_2 and introduction of master integrals to which they are reduced.[6,7]

The cut in the complex $(\Sigma m - p)$ plane, causing an imaginary part above threshold, is not clearly visible in (1.2), nor in (1.5). It becomes manifest in (1.6), after having done the y integration. In the two loop case, it is not visible at all, neither in (1.9), nor in (1.10).

Unitarity implies that the imaginary part of diagrams with two vertices and I internal lines should be equal to the phase space integral of I particles. This relation is valid in the zero loop case of Fig. 1,

$$\frac{1}{\mathbf{p}^2 - m^2 + i\varepsilon} = PP\frac{1}{\mathbf{p}^2 - m^2} - i\pi\delta(\mathbf{p}^2 - m^2). \tag{1.12}$$

On the right-hand side (rhs), both a real and an imaginary part is seen. The latter is given by

$$2\Im\left(\frac{1}{\mathbf{p}^2 - m^2 + i\varepsilon}\right) = -2\pi\int \mathrm{d}\mathbf{k}\ \delta(\mathbf{p} - \mathbf{k})\,\theta(k_0)\,\delta(\mathbf{k}^2 - m^2). \tag{1.13}$$

Indeed, the rhs is the one-particle phase space integral, up to a factor 2π.

In the one loop case of Fig. 2, unitarity is not clear from (1.2) or (1.3). It is seen from (1.8a), which is real if $p < m_1 + m_2$, but if $p > m_1 + m_2$, an imaginary part appears, coming from the $\pi/4$ term in (1.8b),

$$\Im(1.6) = -\frac{\pi^3\theta(p - m_1 - m_2)\sqrt{(p + m_1 + m_2)(p - m_1 + m_2)(p + m_1 - m_2)(p - m_1 - m_2)}}{p^2}. \tag{1.14}$$

On the other hand, the two-particle phase space integral in four dimensions is given by[8]

$$\int \mathrm{d}\mathbf{k}_1\,\mathrm{d}\mathbf{k}_2\ \delta(\mathbf{p} - \mathbf{k}_1 - \mathbf{k}_2)\,\delta(\mathbf{k}_1^2 - m_1)\,\delta(\mathbf{k}_2^2 - m_2^2)\,\theta(k_1^0)\,\theta(k_2^0)$$
$$= \frac{\pi\theta(p - m_1 - m_2)\sqrt{(p + m_1 + m_2)(p - m_1 + m_2)(p + m_1 - m_2)(p - m_1 - m_2)}}{2p^2}. \tag{1.15}$$

Indeed,

$$2(1.14) = -(2\pi)^2(1.15) \tag{1.16}$$

which means unitarity of the one loop diagram in four dimensions.

In the two loop case, the imaginary part of (1.10) is not easily found and if there are near threshold expansions from which it possibly may be derived,[9] it is not clear that it is equal to the three particle phase space integral. On the other hand, if the three particle phase space integral is computed,[10] it is not clear that it equals the imaginary part of (1.10).

To our opinion, it is an unsatisfactory situation that zero loop Feynman rules are given in momentum space, that must be replaced by one loop rules in terms of Feynman parameters that must be replaced once again by rules that work in the case of more loops. Moreover, it is an unsatisfactory situation that real and imaginary parts are not clearly visible in the usual expressions of Feynman diagrams. Finally, it is an unsatisfactory situation that unitarity is not obviously seen in the usual expressions of Feynman diagrams.

It would be more satisfactory if final rules could be derived, that do not have to be redefined twice. For this reason, it has been proposed[11] to describe Feynman diagrams in terms of configuration space parameters, which are structure conserving and, therefore, do not mix different kinds of infinities.

In the configuration space formalism, internal and external lines of a diagram correspond to Bessel functions with a pure imaginary argument. In the case of sunset diagrams, only one integration variable x is needed. On the other hand, these same Bessel functions appear in the configuration space expression of phase space integrals.[12,13] The *integrands* of sunset diagrams and phase space integrals are equal, only the *ranges* of the x integration are different. By this fact, unitarity is built into the formalism in a natural way.

The **x** space formalism has been extended from sunset diagrams to general Feynman diagrams, which implies integration over several configuration space parameters $\mathbf{x}^j$ and over the angles between them.[14]

The purpose of the present paper is to complete the work and to perform all integrations. Rules are derived that immediately give the final result, including cuts, disentangled poles, real and imaginary parts.

The formulas are complicated in the case of a general diagram, summation variables with three and sometimes four indices must be used. To our opinion, this situation is preferable above a formalism, where infinities, cuts and unitarity are hidden in the integration variables and which too is complicated.

The formalism is general, i.e., it is applicable on diagrams with any number of internal lines, any number of vertices, any number of loops in any dimension and all internal and external masses may be different. Scalar fields are considered, but introduction of spin does not give complications since spin leads to matrices and derivatives that do not affect the essential structure of the formulas.

II. SERIES EXPANSION OF SUNSET DIAGRAMS

In order to understand the way of working of the formalism, we consider first dimensionally regularized diagrams with two vertices and I internal lines (so-called sunset, sunrise or water melon diagrams). They are represented in x space by the expression

$$F_2^I \prod \frac{(m^j)^{2b^j}}{\Gamma(\alpha^j)} \int_0^\infty \mathrm{d}x\, x^{2\nu-1} i_b(px) k_{bj}(m^j x), \tag{2.1}$$

with notation

$$\prod = \prod_{1 \leqslant j \leqslant I} \tag{2.2}$$

and front factor

$$F_2^I = \frac{(2\pi^{\frac{1}{2}n})^{I+1}}{(2\pi)^n}. \tag{2.3}$$

Equation (2.1) is obtained from the corresponding momentum space expression after a Wick transformation and n dimensional Fourier transformations of the propagators according to

$$\int \mathrm{d}\mathbf{k}^j \frac{e^{-i\mathbf{k}^j\cdot\mathbf{x}}}{(\mathbf{k}^{j^2} + m^{j^2})^{\alpha^j}} = \frac{2\pi^{\frac{1}{2}n} m^{2b^j}}{\Gamma(\alpha^j)} k_{b^j}(m^j x), \tag{2.4}$$

with

$$b^j = \tfrac{1}{2}n - \alpha^j. \tag{2.5}$$

Thereupon, one inverse n dimensional Fourier transformation has been performed. After integration of an exponential over its angles and an inverse Wick transformation according to

$$\int \mathrm{d}\hat{\mathbf{x}}\, e^{i\mathbf{p}\cdot\mathbf{x}} = 2\pi^{\frac{1}{2}n} \mathrm{j}_b(px) \overset{p\to ip}{\longrightarrow} 2\pi^{\frac{1}{2}n} i_b(px), \tag{2.6}$$

with

$$b = \tfrac{1}{2}n - 1, \tag{2.7}$$

the result (2.1) is obtained.[11] The various factors 2 and π in (2.3) are remnants of all these actions.

The functions $i_b(px)$ and $k_{b^j}(m^j x)$ are, up to a factor, modified Bessel functions of the first and third kind,[15] respectively. Details are summarized in Appendix A. In the case of integer b and b^j, the near zero expansions are given by

$$i_b(z) = j_b(iz) = \sum_{k=0}^{\infty} \frac{1}{k\,!\,(b+k)!} \left(\frac{z}{2}\right)^{2k}, \tag{2.8a}$$

$$k_{b^j}(z) = \sum_{0\leqslant k^j\leqslant\infty} K^j \left(\frac{z}{2}\right)^{2k^j} + \sum_{0\leqslant k^j\leqslant\infty} L^j \left(\frac{z}{2}\right)^{2k^j} \ln\left(\frac{z}{2}\right) + \sum_{0\leqslant k^j\leqslant b^j-1} M^j \left(\frac{z}{2}\right)^{-2b^j+2k^j}. \tag{2.8b}$$

K^j, L^j, and M^j are building stones of the functions $k_{b^j}(z)$; they depend on the summation variable k^j and, according to Appendix A, they are given by

$$K^j \equiv K_{b^j}(k^j) = \frac{(-)^{b^j+1}}{k^j\,!\,(b^j+k^j)!} \left\{ \left(\gamma - \frac{1}{1} - \frac{1}{2} - \cdots - \frac{1}{k^j}\right) + \left(\gamma - \frac{1}{1} - \frac{1}{2} - \cdots - \frac{1}{k^j+b^j}\right) \right\},$$
$$(\gamma = 0.577\,215\,664\,9), \tag{2.9a}$$

$$L^j \equiv L_{b^j}(k^j) = \frac{(-)^{b^j+1}}{k^j\,!\,(b^j+k^j)!}, \tag{2.9b}$$

$$M^j \equiv M_{b^j}(k^j) = \frac{(-)^{k^j}(b^j-k^j-1)!}{2k^j!}. \tag{2.9c}$$

As indicated in (2.8b), the summation over k^j is from 0 to ∞ if it concerns K^j or L^j and from 0 to b^j-1 if it concerns M^j.

To compute the integral (2.1), it must be split according to

$$\int_0^\infty \mathrm{d}x = \int_0^X \mathrm{d}x + \int_X^\infty \mathrm{d}x, \tag{2.10}$$

where X is arbitrary. In the $\int_X^\infty \mathrm{d}x$ integral, the asymptotic expansions (A6a) for $k_{bj}(m^j x)$ and (A6f) for $i_b(px)$ are inserted,

$$\begin{aligned}\prod \int_X^\infty \mathrm{d}x\, x^{2\nu-1} i_b(px) k_{bj}(m^j x) = &\sum_{\substack{0\leqslant k^j<H^j \\ 0\leqslant k<H}} \prod \frac{\pi^{(I-1)/2} 2^{2b+2\Sigma b^c}(b,k)(b^j,k^j) e^{-i\pi\left(b+\frac{1}{2}\right)}}{(2p)^{b+k+\frac{1}{2}}(2m^j)^{b^j+k^j+\frac{1}{2}}} \\ &\times \int_X^\infty \mathrm{d}x\, e^{-\left(\Sigma m^c+p\right)x} x^{2\nu-\left(b+k+\frac{1}{2}\right)-\Sigma\left(b^c+k^c+\frac{1}{2}\right)-1} \\ &+ \sum_{\substack{0\leqslant k^j<H^j \\ 0\leqslant k<H}} \prod \frac{\pi^{(I-1)/2} 2^{2b+2\Sigma b^c}(b,k)(b^j,k^j)}{(2p)^{b+k+\frac{1}{2}}(2m^j)^{b^j+k^j+\frac{1}{2}}} \\ &\times \int_X^\infty \mathrm{d}x\, e^{-\left(\Sigma m^c-p\right)x} x^{2\nu-\left(b+k+\frac{1}{2}\right)-\Sigma\left(b^c+k^c+\frac{1}{2}\right)-1} + \text{rest term},\end{aligned} \tag{2.11}$$

with notation

$$\sum = \sum_{1\leqslant c\leqslant I}, \tag{2.12a}$$

$$(b,k) = \frac{\Gamma\left(b+k+\frac{1}{2}\right)}{k!\,\Gamma\left(b-k+\frac{1}{2}\right)}. \tag{2.12b}$$

Though asymptotic expansions of Bessel functions are used,[16–18] it should be remembered that they do not converge in even dimensional spaces[15] (the asymptotic series do converge and even are finite in odd dimensional spaces). Nonetheless, these expansions make sense if their meaning is realized,[19] for a given H and H^j in (2.11), X may be chosen sufficiently large to make the rest term arbitrary small and to make the $X\to\infty$ integrals arbitrary accurate. For this reason, near ∞ integrals over the asymptotic series must be combined with near 0 integrals over expansions that are convergent in the neighborhood of 0.

The integrals of (2.11) make sense only if the exponentials in the integrand are decreasing, i.e., if

$$\sum m^c - p > 0. \tag{2.13}$$

By introducing the parameter

$$\Lambda = \left(\sum m^c - p\right)X \tag{2.14}$$

and choosing Λ large with respect to the asymptotic coefficients (b,H) and (b^j,H^j) of (2.12b), both integrals of (2.11) are small and (2.1) can be computed by doing the integration from 0 to Λ only,

$$F_2^I \prod (m^j)^{2b^j} \int_0^\infty \mathrm{d}x\, x^{2\nu-1} i_b(px) k_{bj}(m^j x) \cong F_2^I \prod \frac{(\mu^j)^{2b^j}}{\left(\sum m^c - p\right)^{2\left(\nu-\Sigma b^c\right)}} \int_0^\Lambda \mathrm{d}\xi\, \xi^{2\nu-1} i_b(\rho\xi) k_{bj}(\mu^j \xi), \tag{2.15}$$

with

$$\rho = \frac{p}{\sum m^c - p}, \tag{2.16a}$$

$$\mu^j = \frac{m^j}{\sum m^c - p}. \tag{2.16b}$$

III. BELOW THRESHOLD

The Bessel function expansions (2.8) must be inserted into the rhs of (2.15) and integration is performed with use of Appendix D.

In the case of the one loop diagram of Fig. 2, the result is

$$\begin{aligned}
&\frac{F_2^2(\mu^1)^{2b^1}(\mu^2)^{2b^2}}{(m^1+m^2-p)^{2(\nu-b^1-b^2)}} \int_0^\Lambda \mathrm{d}\xi\, \xi^{2\nu-1} i_b(\rho\xi) k_{b^1}(\mu^1\xi) k_{b^2}(\mu^2\xi) \\
&\quad = \sum_{k,k^1,k^2} \frac{2^{2\nu} F_2^2 \rho^{2k} (\mu^1)^{2(b^1+k^1)} (\mu^2)^{2(b^2+k^2)}}{(m^1+m^2-p)^{2(\nu-b^1-b^2)} k!\,(b+k)!} \\
&\qquad \times \left\{ F^{11} \ln\left(\frac{\mu^1\Lambda}{2}\right) \ln\left(\frac{\mu^2\Lambda}{2}\right) + F^{10} \ln\left(\frac{\mu^1\Lambda}{2}\right) + F^{01} \ln\left(\frac{\mu^2\Lambda}{2}\right) + F^{00} \right\}.
\end{aligned} \tag{3.1}$$

The coefficients F^{11}, F^{10}, F^{01}, and F^{00} depend on the summation variables k^j and are expressed in terms of the functions K^j, L^j, and M^j of (2.9),

$$F^{11} = \frac{L^1 L^2 (\Lambda/2)^N}{N}, \tag{3.2a}$$

$$F^{10} = -\frac{L^1 L^2 (\Lambda/2)^N}{(N)^2} + \frac{L^1 K^2 (\Lambda/2)^N}{N} + \frac{L^1 M^2 (\Lambda/2)^{(N-2b^2)}}{(N-2b^2)}, \tag{3.2b}$$

$$F^{01} = -\frac{L^1 L^2 (\Lambda/2)^N}{(N)^2} + \frac{K^1 L^2 (\Lambda/2)^N}{N} + \frac{M^1 L^2 (\Lambda/2)^{(N-2b^1)}}{(N-2b^1)}, \tag{3.2c}$$

$$\begin{aligned}
F^{00} = {} & \frac{L^1 L^2 (\Lambda/2)^N}{(N)^3} - \frac{K^1 L^2 (\Lambda/2)^N}{(N)^2} - \frac{M^1 L^2 (\Lambda/2)^{N-2b^1}}{(N-2b^1)^2} - \frac{L^1 K^2 (\Lambda/2)^N}{(N)^2} - \frac{L^1 M^2 (\Lambda/2)^{(N-2b^2)}}{(N-2b^2)} \\
& - \frac{K^1 L^2 (\Lambda/2)^N}{(N)^2} - \frac{M^1 L^2 (\Lambda/2)^{(N-2b^1)}}{(N-2b^1)^2} + \frac{K^1 K^2 (\Lambda/2)^N}{N} + \frac{K^1 M^2 (\Lambda/2)^{(N-2b^2)}}{(N-2b^2)} + \frac{M^1 K^2 (\Lambda/2)^{N-2b_1}}{(N-2b^1)} \\
& + \frac{M^1 M^2 (\Lambda/2)^{N-2b^1-2b^2}}{(N-2b^1-2b^2)},
\end{aligned} \tag{3.2d}$$

with

$$N = 2(\nu + k + k^1 + k^2). \tag{3.3}$$

In the case of four dimensions ($\nu=2$) and propagator exponent 1 ($\nu - b^j = 1$), an infinity appears in (3.2d) through the denominator factor $(N - 2b^1 - 2b^2)$. It corresponds to the infinity in (1.5).

The formula's (3.1), (3.2), and (3.3) may be generalized to sunset diagrams with I internal lines,

$$\prod \frac{F_2^I (\mu^j)^{2b^j}}{\left(\sum m^c - p\right)^{2(\nu - \Sigma b^c)}} \int_0^\Lambda \mathrm{d}\xi\, \xi^{2\nu-1} i_b(\rho\xi) k_{bj}(\mu^j \xi)$$

$$= \sum_{k,k^j} \prod \frac{2^{2\nu} F_2^I \rho^{2k} (\mu^j)^{2(b^j + k^j)}}{\left(\sum m^c - p\right)^{2(\nu - \Sigma b^c)} k!\,(b+k)!} \sum_{0 \leqslant f^j \leqslant 1} F^{f^1 \cdots f^j} \left\{ \ln\left(\frac{\mu^j \Lambda}{2}\right) \right\}^{f^j}, \tag{3.4}$$

with

$$F^{f^1 \cdots f^j} = \sum_{f^j \leqslant g^j \leqslant h^j \leqslant 1} \prod \frac{(-)^G G!\,(K^j)^{(1-h^j)(1-g^j)} (L^j)^{g^j} (M^j)^{(1-g^j)h^j}}{\left\{N - 2\sum (1-g^c) h^c b^c\right\}^{1+G}} \left(\frac{\Lambda}{2}\right)^{N - 2\Sigma(1-g^c)h^c b^c}, \tag{3.5}$$

where

$$G = \sum (g^c - f^c), \tag{3.6a}$$

$$N = 2\left(\nu + k + \sum_{1 \leqslant c \leqslant I} k^c\right). \tag{3.6b}$$

To (3.4) must be added the $\Lambda \to \infty$ integrals (2.11) which may help convergence and may be computed by means of the formulas of Appendix C. The latter integrals are arbitrary small for sufficiently large Λ.

IV. ABOVE THRESHOLD

The threshold at $p = \Sigma m^c$ appears through the logarithmic factors in (3.1) and (3.4). It is a direct consequence of the requirement (2.13) that the asymptotic integrands (2.11) should decrease exponentially.

Analytical continuation to above threshold, i.e., to

$$p > \sum m, \tag{4.1}$$

is obtained after replacement of $(\Sigma m - p)$ by $(p - \Sigma m)$ in (3.1) and (3.4). Terms that are even in $(\Sigma m - p)$ remain unchanged by this replacement, odd terms transform into their opposite and a term $i\pi$ is added to a logarithmic factor,

$$\left(\sum m - p\right)^{2k} \to \left(p - \sum m\right)^{2k}, \tag{4.2a}$$

$$\left(\sum m - p\right)^{2k+1} \to -\left(p - \sum m\right)^{2k+1}, \tag{4.2b}$$

$$\ln\left(\sum m - p\right) \to \ln\left(p - \sum m\right) + i\pi. \tag{4.2c}$$

Imaginary terms appear by these transformations through the factor

$$\sum_{0\leqslant f^i\leqslant 1} F^{f^1,f^2}\left\{\ln\left(\frac{\mu^1\Lambda}{2}\right)\right\}^{f^1}\left\{\ln\left(\frac{\mu^2\Lambda}{2}\right)\right\}^{f^2}.$$

In the one loop case,

$$\begin{aligned}
&F^{11}\ln\left(\frac{\mu^1\Lambda}{2}\right)\ln\left(\frac{\mu^2\Lambda}{2}\right)+F^{10}\ln\left(\frac{\mu^1\Lambda}{2}\right)+F^{01}\ln\left(\frac{\mu^2\Lambda}{2}\right)+F^{00}\\
&\quad=F^{1,1}\ln\left(\frac{\mu^1\Lambda}{2}\right)\ln\left(\frac{\mu^2\Lambda}{2}\right)-\pi^2F^{1,1}+F^{1,0}\ln\left(\frac{\mu^1\Lambda}{2}\right)+F^{0,1}\ln\left(\frac{\mu^2\Lambda}{2}\right)\\
&\quad+i\pi\left\{F^{1,1}\ln\left(\frac{\mu^1\Lambda}{2}\right)+F^{1,1}\ln\left(\frac{\mu^2\Lambda}{2}\right)+F^{1,0}+F^{0,1}\right\}.
\end{aligned}\tag{4.3}$$

V. THE GENERAL FEYNMAN DIAGRAM

A general Feynman diagram, with V vertices and I internal lines, is written in terms of configuration space parameters as[14]

$$\frac{(2\pi^{\frac{1}{2}n})^I}{(2\pi)^{n(V-1)}}\prod\frac{(m_i^j)^{2b_i^j}(m_{i',i}^j)^{2b_{i',i}^j}}{\Gamma(\alpha_i^j)\Gamma(\alpha_{i',i}^j)}\int \mathrm{d}\mathbf{x}_i\, e^{i\mathbf{p}_i\cdot\mathbf{x}_i}k_{b_i^j}(m_i^jx_i)k_{b_{i',i}^j}(m_{i',i}^j|\mathbf{x}_i-\mathbf{x}_{i'}|)\tag{5.1}$$

with notation

$$\prod=\prod_{\substack{1\leqslant i\leqslant V-1\\ 1\leqslant i'<i\\ j}}.\tag{5.2}$$

Internal lines and their corresponding masses wear three indices, the two subscripts i', i indicate the vertices that they are connecting, the superscript j counts the lines between these vertices.

The number of integration vectors $\mathbf{x}_i$ is $V-1$, one less than the number of vertices. The external momenta are given by $V-1$ vectors $\mathbf{p}_i$, the momentum $\mathbf{p}_V$ is given by momentum conservation,

$$\sum_{1\leqslant i\leqslant V}\mathbf{p}_i=0.\tag{5.3}$$

The elaboration of (5.1) goes along the same lines as in the case of Sec. II. It will turn out that the final result is a generalization of the result (3.4) for sunset diagrams.

The integrand of (5.1) contains both functions like $k_{b_i}(m_ix_i)$, with a simple argument, and functions like $k_{b_{i',i}}(m_{i',i}|\mathbf{x}_i-\mathbf{x}_{i'}|)$, with a composed argument. Because of the latter functions, the integration range of (5.1) must be divided into $V!$ subregions. $(V-1)!$ of them are of the kind

$$0<x_1<x_2<\cdots<x_{V-1}<X+\text{permutations},\tag{5.4a}$$

with arbitrary X, and $V!-(V-1)!$ subregions are of the kind

$$0<x_1<x_2<\cdots<X<\cdots<x_{V-1}<\infty.\tag{5.4b}$$

In the subregions of (5.4b), the functions $k_{b_{i',i}}$ with a composed argument are split according to (A8) and the integral (5.1) contains a sum of products of three factors,

$$(5.1) = F_V^I \sum \prod \frac{(m_i^j)^{2b_i^j}(m_{i',i}^j)^{2b_{i',i}^j}}{\Gamma(\alpha_i^j)\Gamma(\alpha_{i',i}^j)} A(r_{i',i}^j) R_1(r_{i',i}^j) R_2(r_{i',i}^j), \tag{5.5}$$

with front factor

$$F_V^I = \frac{(2\pi^{\frac{1}{2}n})^{I+V-1}}{(2\pi)^{n(V-1)}}. \tag{5.6}$$

$A(r_{i',i}^j)$ is an angular factor given in (B8b), $R_1(r_{i',i}^j)$ and $R_2(r_{i',i}^j)$ are radial factors given by (C1a) and (C1b).

The radial integrals are meaningful only if the integrands are decreasing exponentials. From the formulas of Appendix C, it is seen that the latter condition is satisfied below all thresholds, i.e., if

$$\sum m - \sum p \equiv \min_V \left\{ \sum_{a \in V, b \notin V} \left(\sum_c m_{a,b}^c - p_b \right) \right\} > 0, \tag{5.7}$$

where V is a set of vertices and $\min_V$ is the minimum over all possible sets. Under the condition (5.7), integrals in the subregions (5.4b) can be made arbitrary small if

$$\Lambda \equiv \left(\sum m - \sum p \right) X \tag{5.8}$$

is chosen sufficiently large.

The nondisappearing integrals in the subregions (5.4a) are computed by splitting the composed functions $\mathrm{k}_{b_{i',i}}(m_{i',i}|\mathbf{x}_i - \mathbf{x}_{i'}|)$ according to (A11), which leads to a simpler formula than (A8). Integral (5.1) is written in these subregions as the sum over products of an angular and a radial factor according to

$$(5.1) \cong F_V^I \sum \prod \frac{r_{i',i}!}{\Gamma(\alpha_i^j)\Gamma(\alpha_{i',i}^j) r_{i',i}^j!} A(q_i; r_{i',i}) R(q^i; r_{i',i}), \tag{5.9}$$

with

$$r_{i',i} = \sum_c r_{i',i}^c, \tag{5.10a}$$

$$(2\pi^{\frac{1}{2}n})^{V-1} A(q_i, r_{i',i}) = \prod \int \mathrm{d}\hat{\mathbf{x}}_i \frac{(2\hat{\mathbf{p}}_i \cdot \hat{\mathbf{x}}_i)^{q_i}}{q_i!} \frac{(2\hat{\mathbf{x}}_{i'} \cdot \hat{\mathbf{x}}_i)^{r_{i',i}}}{r_{i',i}!} \tag{5.10b}$$

and

$$\begin{aligned} R(q_i; r_{i',i}^j) \equiv & \sum_{l_{i',i}^j=0}^{\infty} \prod \frac{2^{2\nu(V-1)}(-)^{l_{i',i}^j}}{l_{i',i}^j!} p_i^{q_i} (m_i^j)^{2b_i^j} (m_{i',i}^j)^{2(b_{i',i}^j + l_{i',i}^j + r_{i',i}^j)} \\ & \times \int_{0<x_1<\cdots<x_{V-1}<X} d\frac{x_i}{2} \left(\frac{x_i}{2} \right)^{2\nu-1+q_i+2\Sigma l_{i,a}^c + \Sigma r_{a,i} + \Sigma r_{i,a}} k_{b_i^j}(m_i^j x_i) k_{b_{i',i}^j + l_{i',i}^j + r_{i',i}^j}(m_{i',i}^j x_i) \\ & + \text{permutations}. \end{aligned} \tag{5.10c}$$

Summation Σ in the exponent is defined in (B5).

Integral (5.10b) is computed in (B4b) and (5.10c) is computed by insertion of (A3c). The final result is a generalization of the result (3.4) for sunset diagrams,

$$(5.1) \cong \frac{2^{2\nu(V-1)}F_V^I}{\left(\sum m-\sum p\right)^{2\{\nu(V-1)-\Sigma b_a^c-\Sigma b_{a,b}^c\}}}\sum_{k,l,q,r}\prod\frac{r_{i',i}!}{\Gamma(\alpha_i^j)\Gamma(\alpha_{i',i}^j)r_{i',i}^j}A(q_i;r_{i',i})\rho_i^{q_i}\frac{(-)^{l_{i',i}^j}}{l_{i',i}^j}(\mu_i^j)^{2(b_i^j+k_i^j)}$$

$$\times(\mu_{i',i}^j)^{2(b_{i',i}^j+l_{i',i}^j+r_{i',i}^j+k_{i',i}^j)}\sum_{f=0}^{1}F^{f_i^j,f_{i',i}^j}\left\{\ln\left(\frac{\mu_i^j\Lambda}{2}\right)\right\}^{f_i^j}\left\{\ln\left(\frac{\mu_{i',i}^j\Lambda}{2}\right)\right\}^{f_{i',i}^j}, \tag{5.11}$$

with

$$\rho_i=\frac{p_i}{\left(\sum m-\sum p\right)},\quad \mu_i^j=\frac{m_i^j}{\left(\sum m-\sum p\right)},\quad \mu_{i',i}^j=\frac{m_{i',i}^j}{\left(\sum m-\sum p\right)}, \tag{5.12a}$$

and

$$F^{f_i^j,f_{i',i}^j}=\sum_{f\leqslant g_{;V-2}\cdots\leqslant g_{;1}\leqslant g\leqslant h\leqslant 1}\prod\frac{(-)^{G_i}G_i!}{\left(\sum\limits_{1\leqslant a\leqslant i}N_a\right)^{1+G_i}}(K_i^j)^{(1-g_i^j)(1-h_i^j)}(L_i^j)^{g_i^j}(M_i^j)^{(1-g_i^j)h_i^j}(K_{i',i}^j)^{(1-g_{i',i}^j)(1-h_{i',i}^j)}$$

$$\times(L_{i',i}^j)^{g_{i',i}^j}(M_{i',i}^j)^{(1-g_{i',i}^j)h_{i',i}^j}\left(\frac{\Lambda}{2}\right)^{\sum\limits_{1\leqslant a\leqslant V-1}N_a}+\text{permutations}. \tag{5.12b}$$

$F^{f_i^j,f_{i',i}^j}$ depends on the summation variables k,l,q,r through the factors K_i^j, L_i^j, M_i^j, through the factors

$$K_{i',i}^j\equiv K_{b_{i',i}^j+l_{i',i}^j+r_{i',i}^j}(k_{i',i}^j),\quad L_{i',i}^j\equiv L_{b_{i',i}^j+l_{i',i}^j+r_{i',i}^j}(k_{i',i}^j),\quad M_{i',i}^j\equiv M_{b_{i',i}^j+l_{i',i}^j+r_{i',i}^j}(k_{i',i}^j), \tag{5.13}$$

all defined according to (2.9), and through the factors $\Sigma_{1\leqslant a\leqslant i}N_a$ with

$$N_i=2\nu+q_i+2\sum k_i^c+2\sum k_{a,i}^c+2\sum l_{i,a}^c+\sum r_{a,i}^c+\sum r_{i,a}^c$$
$$-2\sum h_i^c(1-g_i^c)b_i^c-\sum h_{a,i}^c(1-g_{a,i}^c)(b_{a,i}^c+l_{a,i}^c+r_{a,i}^c), \tag{5.14}$$

where summation Σ is according to the convention of (B5). G_i is computed in Appendix D,

$$G_i=\sum_{\substack{1\leqslant a\leqslant i\\ c}}(g_{a;i-1}^c-g_{a;i}^c)+\sum_{\substack{1\leqslant a'<a\leqslant i\\ c}}(g_{a',a;i-1}^c-g_{a',a;i}^c), \tag{5.15}$$

where g_i^j, $g_{i',i}^j$, $g_{i;i''}^j$, $g_{i',i;i''}^j$, f_i^j, and $f_{i',i}^j(i'<i\leqslant i''<V-1)$ are summation variables running from 0 to 1 and

$$g_{i;i-1}^j\equiv g_i^j, \tag{5.16a}$$

$$g_{i',i;i-1}^j\equiv g_{i',i}^j, \tag{5.16b}$$

$$g_{i;V-1}^j\equiv f_i^j, \tag{5.16c}$$

$$g_{i',i;V-1}^j\equiv f_{i',i}^j. \tag{5.16d}$$

$\Sigma_{f\leqslant g_{;V-2}\cdots\leqslant g_{;1}\leqslant g\leqslant h\leqslant 1}$ in (5.12b) means summation under the conditions

$$f_i^j\leqslant g_{i;V-2}^j\leqslant\cdots\leqslant g_{i;i}^j\leqslant g_i^j\leqslant h_i^j\leqslant 1, \tag{5.17a}$$

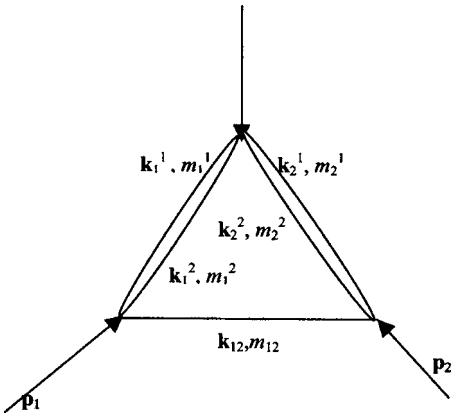

FIG. 4. A diagram with three vertices and five internal lines.

$$f^j_{i',i} \leqslant g^j_{i',i;V-2} \leqslant \cdots \leqslant g^j_{i',i;i} \leqslant g^j_{i',i} \leqslant h^j_{i',i} \leqslant 1, \tag{5.17b}$$

Σ_k means summation over all k^j_i and $k^j_{i',i}$ from 0 to ∞, if they are appearing through factors K and L, the summation is from 0 to b^j_i-1 and $b^j_i+l^j_i+r^j_i-1$, respectively, if they are appearing through a factor M.

Equation (5.11) is a generalization of formula (3.4) for sunset diagrams. It is a sum of terms that have factors K, L, and M, defined in (2.8) and (2.9), in the numerator. Instead of a power of one denominator factor N in (3.4), (5.10c) leads to $V-1$ denominator factors $\Sigma^i_{a=1}N_a(i=1,2,\ldots,V-1)$, which all, in turn, may have higher powers, caused by integration over logarithms. The various terms of (5.12b) may be described by the following features:

(i) The first term consists of I factors L in the numerator. The exponent of x_i in (5.10c) becomes, after integration, a factor $\Sigma^i_{a=1}N_a$, in the denominator. The factor in front is 0! .
(ii) Integration of terms with factors L gives, because of the logarithm of (2.8b), both a term with a logarithm and a term without logarithm.
(iii) In the latter case, the power of the corresponding factors $\Sigma^i_{a=1}N_a$ increases by 1, as well as the argument of the faculty in front, and the sign of the term changes.
(iv) Further terms are obtained after replacement of factors L by K, M or combinations in terms with an increased power of $\Sigma^i_{a=1}N_a$. Each replacement lowers the power of $\Sigma^i_{a=1}N_a$ by 1 as well as the argument of the faculty in front, and changes the sign of the term.
(v) A factor M in the numerator implies addition of a term $-2b$ or $-2(b+l+r)$ to the corresponding N_a in the denominator. If two or more of these terms are added, poles in the complex ν plane may appear.

The integrals in the regions (5.4b), which may be computed by means of the formulas of Appendix C, must be added to (5.11) to help convergence. The latter integrals are arbitrary small for sufficiently large Λ.

Analytical continuation from the region (5.7) to other regions of the complex $(\Sigma m-\Sigma p)$ plane is obtained according to the rules of (4.2).

As an example, we demonstrate a diagram with three vertices and five internal lines according to Fig. 4.

The expression is

$$\frac{(2\pi^{1/2n})^5}{(2\pi)^{2n}} \frac{(m_1^1)^{2b_1^1}(m_1^2)^{2b_1^2}(m_2^1)^{2b_2^1}(m_2^2)^{2b_2^2}(m_{1,2})^{2b_{1,2}}}{\Gamma(\alpha_1^1)\Gamma(\alpha_1^2)\Gamma(\alpha_2^1)\Gamma(\alpha_2^2)\Gamma(\alpha_{1,2})}$$

$$\times \int d\mathbf{x}_1\, d\mathbf{x}_2\, e^{i\mathbf{p}_1\cdot\mathbf{x}_1} e^{i\mathbf{p}_2\cdot\mathbf{x}_2} k_{b_1^1}(m_1^1 x_1) k_{b_1^2}(m_1^2 x_1) k_{b_2^1}(m_2^1 x_2) k_{b_2^2}(m_2^2 x_2) k_{b_{1,2}}(m_{1,2}|\mathbf{x}_1-\mathbf{x}_2|) \tag{5.18}$$

and the region of the radial integrations is divided into subregions $0<x_1<x_2<X$, $0<x_1<X$

$<x_2$, $0<X<x_1<x_2$, and permutations of x_1 and x_2. $(\Sigma m-\Sigma p)$ is given by

$$\left(\sum m-\sum p\right)\equiv \min\begin{cases}(m_1^1+m_1^2+m_{1,2}-p_1),\\ (m_2^1+m_2^2+m_{12}-p_2),(m_1^1+m_1^2+m_2^1+m_2^2-p_1-p_2).\end{cases} \tag{5.19}$$

The contribution of the subregions $0<x_1<X<x_2$, $0<X<x_1<x_2$, and permutations can be made arbitrary small by choosing

$$\Lambda=\left(\sum m-\sum p\right)X \tag{5.20}$$

sufficiently large. In this case, only the two regions $0<x_1<x_2<X$ and $0<x_2<x_1<X$ contribute. In the latter subregions, (5.18) is factorized into an angular and a radial part,

$$(5.18)\cong \frac{(2\pi^{1/2n})^7}{(2\pi)^{2n}\Gamma(\alpha_1^1)\Gamma(\alpha_1^2)\Gamma(\alpha_2^1)\Gamma(\alpha_2^2)\Gamma(\alpha_{12})}A(q_1,q_2,r_{12})R(q_1,q_2,r_{12}) \tag{5.21}$$

with

$$A(q_1,q_2,r_{12})=\frac{1}{(2\pi^{\frac{1}{2}n})^2}\int \mathrm{d}\hat{\mathbf{x}}_1\,\mathrm{d}\hat{\mathbf{x}}_2\frac{(2\hat{\mathbf{p}}_1\cdot\hat{\mathbf{x}}_1)^{q_1}}{q_1!}\frac{(2\hat{\mathbf{p}}_2\cdot\hat{\mathbf{x}}_2)^{q_2}}{q_2!}\frac{(2\hat{\mathbf{x}}_1\cdot\hat{\mathbf{x}}_2)^{r_{1,2}}}{r_{1,2}!}$$

$$=\sum_{q_{1,2},p_{1,2}}{}'\frac{(2\hat{\mathbf{p}}_1\cdot\hat{\mathbf{p}}_2)^{p_{1,2}}}{\frac{1}{2}(n+q_1+r_{1,2})!\,\frac{1}{2}(n+q_2+q_{1,2})!\,\frac{1}{2}(q_1-q_{1,2})!\,\frac{1}{2}(q_2-p_{1,2})!\,\frac{1}{2}(r_{1,2}-q_{1,2})!\,\frac{1}{2}(q_{1,2}-p_{1,2})!\,p_{1,2}!} \tag{5.22a}$$

(Σ' means summation over $q_{1,2}$ and $p_{1,2}$ under the condition that the arguments of the faculties in the denominator are integers) and

$$\begin{aligned}R(q_1,q_2,r_{12})=&\sum_{l_{1,2}}\frac{2^{4\nu}p_1^{q_1}p_2^{q_2}(m_1^1)^{2b_1^1}(m_1^2)^{2b_1^2}(m_2^1)^{2b_2^1}(m_2^2)^{2b_2^2}(-)^{l_{1,2}}(m_{1,2})^{2(b_{1,2}+l_{1,2}+r_{1,2})}}{l_{1,2}!}\\ &\times\int_{0<x_1<x_2<X}d\frac{x_1}{2}d\frac{x_2}{2}\left(\frac{x_1}{2}\right)^{2\nu+q_1+2l_{1,2}+r_{1,2}-1}\left(\frac{x_2}{2}\right)^{2\nu+q_2+r_{1,2}-1}\\ &\times k_{b_1^1}(m_1^1x_1)k_{b_1^2}(m_1^2x_1)k_{b_2^1}(m_2^1x_2)k_{b_1^2}(m_2^2x_2)k_{b_{1,2}+l_{1,2}+r_{1,2}}(m_{1,2}x_2)+\text{permutation}.\end{aligned} \tag{5.22b}$$

The rhs of (5.22b) is computed with use of Appendix D. The final result is

$$(5.18) \cong \sum \frac{2^{4\nu} F_3^5 A(q_1,q_2,r_{1,2}) \rho_1^{q_1} \rho_2^{q_2} (\mu_1^1)^{2(b_1^1+k_1^1)} (\mu_1^2)^{2(b_1^2+k_1^2)} (\mu_2^1)^{2(b_2^1+k_2^1)} (\mu_2^2)^{2(b_2^2+k_2^2)} (-)^{l_{1,2}} (\mu_{1,2})^{2(b_{1,2}+l_{1,2}+r_{1,2}+k_{1,2})}}{\left(\sum m - \sum p\right)^{4\nu-2(b_1^1+b_1^2+b_2^1+b_2^2+b_{1,2})} l_{1,2}!}$$

$$\times \left\{ \begin{array}{l} \left\{ \frac{L_1^1 L_1^2 L_2^1 L_2^2 L_{1,2}}{N_1(N_1+N_2)} \right\} \ln\left(\frac{\mu_1^1\Lambda}{2}\right) \ln\left(\frac{\mu_1^2\Lambda}{2}\right) \ln\left(\frac{\mu_2^1\Lambda}{2}\right) \ln\left(\frac{\mu_2^2\Lambda}{2}\right) \ln\left(\frac{\mu_{1,2}\Lambda}{2}\right) \left(\frac{\Lambda}{2}\right)^{N_1+N_2} \\ + \left\{ \begin{array}{l} -\frac{L_1^1 L_1^2 L_2^1 L_2^2 L_{1,2}}{N_1^2(N_1+N_2)} - \frac{L_1^1 L_1^2 L_2^1 L_2^2 L_{1,2}}{N_1(N_1+N_2)^2} \\ + \frac{K_1^1 L_1^2 L_2^1 L_2^2 L_{1,2}}{N_1(N_1+N_2)} + \frac{M_1^1 L_1^2 L_2^1 L_2^2 L_{1,2}}{(N_1-2b_1^1)(N_1+N_2)} + \cdots \end{array} \right\} \ln\left(\frac{\mu_1^2\Lambda}{2}\right) \ln\left(\frac{\mu_2^1\Lambda}{2}\right) \ln\left(\frac{\mu_2^2\Lambda}{2}\right) \ln\left(\frac{\mu_{1,2}\Lambda}{2}\right) \left(\frac{\Lambda}{2}\right)^{N_1+N_2} \\ + \left\{ -\frac{L_1^1 L_1^2 L_2^1 L_2^2 L_{1,2}}{N_1(N_1+N_2)^2} + \frac{L_1^1 L_1^2 K_2^1 L_2^2 L_{1,2}}{N_1(N_1+N_2)} + \cdots \right\} \ln\left(\frac{\mu_1^1\Lambda}{2}\right) \ln\left(\frac{\mu_1^2\Lambda}{2}\right) \ln\left(\frac{\mu_2^2\Lambda}{2}\right) \ln\left(\frac{\mu_{1,2}\Lambda}{2}\right) \left(\frac{\Lambda}{2}\right)^{N_1+N_2} \\ + \left\{ \frac{L_1^1 L_1^2 M_2^1 L_2^2 L_{1,2}}{N_1(N_1+N_2-2b_2^1)} + \cdots \right\} \ln\left(\frac{\mu_1^1\Lambda}{2}\right) \ln\left(\frac{\mu_1^2\Lambda}{2}\right) \ln\left(\frac{\mu_2^2\Lambda}{2}\right) \ln\left(\frac{\mu_{1,2}\Lambda}{2}\right) \left(\frac{\Lambda}{2}\right)^{N_1+N_2-2b_2^1} \\ + \left\{ \frac{2!\, L_1^1 L_1^2 L_2^1 L_2^2 L_{1,2}}{N_1(N_1+N_2)^3} - \frac{L_1^1 L_1^2 L_2^1 K_2^2 L_{1,2}}{N_1(N_1+N_2)^2} + \cdots \right\} \ln\left(\frac{\mu_1^1\Lambda}{2}\right) \ln\left(\frac{\mu_1^2\Lambda}{2}\right) \ln\left(\frac{\mu_2^1\Lambda}{2}\right) \left(\frac{\Lambda}{2}\right)^{N_1+N_2} \\ + \left\{ -\frac{L_1^1 L_1^2 L_2^1 K_2^2 M_{1,2}}{N_1\{N_1+N_2-2(b_{1,2}+l_{1,2}+r_{1,2})\}^2} + \cdots \right\} \ln\left(\frac{\mu_1^1\Lambda}{2}\right) \ln\left(\frac{\mu_1^2\Lambda}{2}\right) \ln\left(\frac{\mu_2^1\Lambda}{2}\right) \left(\frac{\Lambda}{2}\right)^{N_1+N_2-2(b_{1,2}+l_{1,2}+r_{1,2})} \\ + \left\{ -\frac{L_1^1 L_1^2 L_2^1 M_2^2 M_{1,2}}{N_1\{N_1+N_2-2(b_2^2+b_{1,2}+l_{1,2}+r_{1,2})\}^2} + \cdots \right\} \ln\left(\frac{\mu_1^1\Lambda}{2}\right) \ln\left(\frac{\mu_1^2\Lambda}{2}\right) \ln\left(\frac{\mu_2^1\Lambda}{2}\right) \left(\frac{\Lambda}{2}\right)^{N_1+N_2-2(b_2^2+b_{1,2}+l_{1,2}+r_{1,2})} \end{array} \right\}$$

$$+ \text{many similar terms} + \text{permutations}, \tag{5.23}$$

with

$$N_1 = 2\nu + q_1 + 2k_1^1 + 2k_1^2 + 2l_{1,2} + r_{1,2}, \tag{5.24a}$$

$$N_2 = 2\nu + q_2 + 2k_2^1 + 2k_2^2 + 2k_{1,2} + r_{1,2}. \tag{5.24b}$$

VI. UNITARITY

The S matrix must satisfy the unitarity relation

$$S^\dagger S = I. \tag{6.1}$$

In terms of the T-matrix, which is defined by

$$S = I - i\delta\left(\sum p\right) T, \tag{6.2}$$

(6.1) is written as

$$2\Im(T) \equiv i(T^\dagger - T) = -\delta\left(\sum p\right) T^\dagger T. \tag{6.3}$$

In the case of sunset diagrams, their imaginary part must be equal to the integral over positive energy states with momenta that are on the mass shell, which is the phase space integral.

The n dimensional Laplace transform of $\theta(k^0)\delta(\mathbf{k}^2 - m^2)$ is found by using the integral representation (A14),[13]

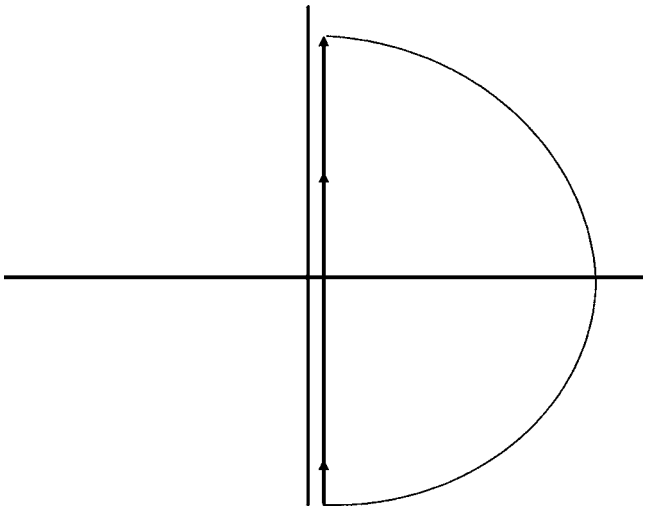

FIG. 5. Integration path to the right.

$$\int_0^\infty \mathrm{d}\mathbf{k}\, e^{-\mathbf{x}\cdot\mathbf{k}}\theta(k^0)\,\delta(\mathbf{k}^2-m^2) = \frac{\pi^{(n-1)/2}}{\Gamma\left(\frac{n-1}{2}\right)}\int_m^\infty \mathrm{d}k^0\, e^{-xk^0}(k^{0^2}-m^2)^{(n-3)/2}$$

$$= \frac{\pi^{(n-1)/2}(m^2)^{(n/2)-1}}{\Gamma\left(\frac{n-1}{2}\right)}\int_1^\infty \mathrm{d}t\, e^{-mxt}(t^2-1)^{(n-3)/2}$$

$$= \pi^{(n/2)-1}(m^2)^{(n/2)-1}k_{(n/2)-1}(mx). \tag{6.4}$$

Applying (6.4) on a product of factors $\theta(k^0)\delta(\mathbf{k}^2-m^2)$ and taking afterwards the inverse n dimensional Laplace transformation, which is an inverse K transform according to (A15), it follows that[12,13]

$$(2\pi)^I \prod \int \mathrm{d}\mathbf{k}^j\ \delta\Big(\mathbf{p}-\sum \mathbf{k}^c\Big)\theta(k_0^j)\,\delta(\mathbf{k}^{j^2}-m^{j^2}) = \frac{F_2^I}{i}\prod (m^j)^{2b^j}\int_{c-i\infty}^{c+i\infty}\mathrm{d}x\, x^{n-1}i_b(px)k_{bj}(m^jx), \tag{6.5}$$

with

$$b = b^j = \tfrac{1}{2}n - 1, \tag{6.6a}$$

$$c > 0, \tag{6.6b}$$

and F_2^I is given in (2.3). The left-hand side (lhs) of (6.5) is, up to a factor $(2\pi)^I$, the I particle phase space integral.

We remark that (6.5) is obtained by Laplace transformations followed by an n dimensional inverse Laplace transformation in the same way as (2.1) is obtained from the momentum space representation by Fourier transformations followed by an n dimensional inverse Fourier transformation. The integrands of (6.5) and (2.1) are equal, the integrals differ by the path of integration.

In the case $p<\Sigma m$, it is seen that (6.5) is 0, by closing the contour to the right of the complex $(\Sigma m-p)$ plane and by remarking that the integrand vanishes towards ∞ (Fig. 5).

In the case $p>\Sigma m$, the integral does not vanish near infinity towards the left-hand side of the complex plane, since the decreasing asymptotic behavior of the integrand is restricted by the

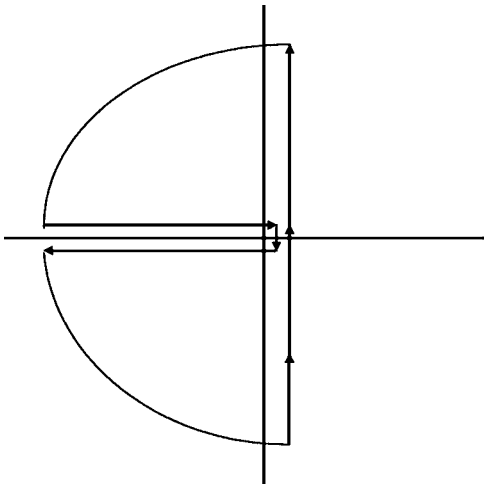

FIG. 6. Integration path to the left.

values of the argument of the integration variable, as indicated in (A6). The integrand vanishes near ∞ only if crossing the negative axis is avoided. Hence, the path of integration must be closed according to Fig. 6. The contribution from the near zero part and that of the near infinity circle are both 0. The contribution along the negative real axis from $-\infty \rightarrow -0$ is equal to the complex conjugate of the $-0 \rightarrow -\infty$ integration.

Hence, we conclude that

$$(6.5) = -F_2^I \prod (m^j)^{2b^j} \int_0^\infty \mathrm{d}x\, x^{n-1} 2\Im\left\{\prod i_{(n/2)-1}(px) k_{(n/2)-1}(m^j x)\right\}. \tag{6.7}$$

After interchanging integral and $\Im$ operation, the unitarity relation

$$2\Im(2.1) = -(2\pi)^I \prod \int \mathrm{d}\mathbf{k}^j\, \delta\left(\mathbf{p} - \sum \mathbf{k}^j\right) \theta(k_0^j)\, \delta(\mathbf{k}^{j^2} - m^{j^2}) \tag{6.8}$$

of a sunset diagram is obtained. It is in agreement with (1.13) and (1.16).

VII. CONVERGENCE

Expansions with many summation variables occurred in the preceding sections and convergence of these series must be discussed.

In the used formulas, faculties of summation variables appear in the denominator, which helps convergence. Also factors like $(-)^k$ and $(-)^l$ may promote convergence.

A point of concern is a Γ function of summation variables in the numerator, like in the factor

$$\frac{(-)^{l^j_{i',i}} M^j_{i',i}}{l^j_{i',i}!} = \frac{(-)^{k^j_{i',i}+l^j_{i',i}} \Gamma(b^j_{i',i} + l^j_{i',i} + r^j_{i',i} - k^j_{i',i})}{2k^j_{i',i}!\, l^j_{i',i}!}. \tag{7.1}$$

Its origin is (A11) where the function $k_b(m|x_i - x_{i'}|)$ with a composed argument is split. Since this Bessel function is analytical, it is not dangerous in itself. Only integration in a region where the argument is zero may cause divergences. These correspond to the ultraviolet divergences in momentum space.

In the case of functions $k_b(mx)$ with simple argument, divergences were appearing through factors of the kind

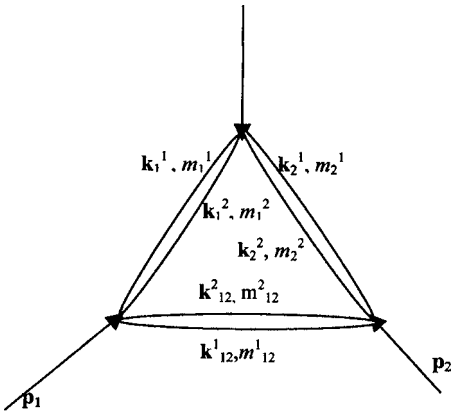

FIG. 7. A diagram with three vertices and six internal lines.

$$\frac{1}{N} = \frac{1}{2\nu - 2\sum b + 2\sum k + \cdots}. \tag{7.2}$$

In the case of functions with a composed argument, the divergences come from integration in the region where $|\mathbf{x}_i - \mathbf{x}_{i'}| = 0$. These manifest by divergence of the summation over the variable $l_{i',i}$. For this reason, the method of Sec. V is applicable only on diagrams like Fig. 4, where composed k-functions correspond to single connected vertices, which add only one term $-2b$ to the denominator of (7.2).

There is a freedom of choice of the configuration space parameters. Transformations like

$$\mathbf{x}_i \rightarrow \mathbf{x}_i + \mathbf{x}_{i'} \tag{7.3}$$

are possible. By such transformations, it may be tried to manage that all multiple connected vertices correspond to simple k functions. This has been done in the case of Fig. 4. However, there are cases where such transformations cannot be found, like the diagram of Fig. 7.

A division of the integral range, finer than in (5.4a), is needed, $(V+1)!$ subregions of the kind

$$x_1 < x_2 < |\mathbf{x}_1 - \mathbf{x}_2| < X \text{ and permutations} \tag{7.4}$$

must be considered and more complicated angle integrations must be performed. This procedure has been discussed in Ref. 14. Fortunately, diagrams like Fig. 7 are not used in today's physics.

A second source of divergences are integrations in the neighborhood of ∞. They correspond to infrared divergences in momentum space. By caring that the asymptotic behavior of the integrand is exponential decreasing, this kind of infinity is avoided.

In the preceding sections, the above-mentioned restrictions have been treated by separating out the corresponding divergences. Hence, the general expression (5.1) is convergent up to the divergences that have been separated out, and so is its expansion (5.11).

The working of the splitting procedure of (2.10) may be elucidated in the case of $\int_0^\infty \mathrm{d}x\, x^{2\nu-1} k_\beta(x)$ with $\nu=2$ and $\beta=1$. The integral is known exactly,[15]

$$\int_0^\infty \mathrm{d}x\, x^{2\nu-1} k_\beta(x) = 2^{2\nu-2}\Gamma(\nu)\Gamma(\nu-\beta). \tag{7.5}$$

On the other hand, we may work out

$$\int_0^\infty \mathrm{d}x\, x^3 k_1(x) = \int_0^\Lambda \mathrm{d}x\, x^3 k_1(x) + \int_\Lambda^\infty \mathrm{d}x\, x^3 k_1(x). \tag{7.6}$$

Insertion of the expansion (A3) into the first term of the rhs and application of (D1) yields

$$\int_0^\Lambda \mathrm{d}x\, x^{2\nu-1} k_1(x) = \sum_{k=0}^{\infty} \frac{2^{2\nu}\left\{\left(\gamma - \frac{1}{1} - \frac{1}{2} - \frac{1}{3} \cdots - \frac{1}{k}\right) + \left(\gamma - \frac{1}{1} - \frac{1}{2} - \frac{1}{3} \cdots - \frac{1}{k} - \frac{1}{k+1}\right)\right\}\left(\frac{\Lambda}{2}\right)^{2\nu+2k}}{k\,!\,(k+1)\,!\,(2\nu+2k)}$$
$$+ \sum_{k=0}^{\infty} \frac{2^{2\nu}\left(\frac{\Lambda}{2}\right)^{2\nu+2k} \ln\left(\frac{\Lambda}{2}\right)}{k\,!\,(k+1)\,!\,(2\nu+2k)} - \sum_{k=0}^{\infty} \frac{2^{2\nu}\left(\frac{\Lambda}{2}\right)^{2\nu+2k} \ln\left(\frac{\Lambda}{2}\right)}{k\,!\,(k+1)\,!\,(2\nu+2k)^2} + \frac{1}{2(2\nu-2)}\left(\frac{\Lambda}{2}\right)^{2\nu-2}. \tag{7.7}$$

Insertion of the asymptotic expansion (A6a) into the second term of the rhs of (7.6) yields

$$\int_\Lambda^\infty \mathrm{d}x\, x^{2\nu-1} k_1(x) \cong \left\{\sqrt{\pi} \sum_{k=0}^{H-1} 2^{\frac{1}{2}-k}(1,k)\right\} \int_\Lambda^\infty \mathrm{d}x\, x^{2\nu-k-\frac{5}{2}} e^{-x}, \tag{7.8}$$

on which (C7) may be applied.

We take the number of terms of the asymptotic series 15 $(H=15)$, $\gamma=0.577\,215\,664\,9$, and find

Λ	$\int_0^\Lambda \mathrm{d}x\, x^3 k_1(x)$	$\int_\Lambda^\infty \mathrm{d}x\, x^3 k_1(x)$	$\int_0^\Lambda \mathrm{d}x\, x^3 k_1(x) + \int_\Lambda^\infty \mathrm{d}x\, x^3 k_1(x)$
2	1.969921963	1.204499139	3.174421102
5	3.734552813	0.26544653	3.999999343
10	3.995697337	0.004301964	3.99999301
15	3.999745608	0.0000503234	3.999795931
20	3.951797003	−0.0000460393	3.951750964
23	2.799347994	−0.008824087	2.781523907

It is seen that for $10<\Lambda<15$ the first integral alone approaches the exact answer 4 of (7.5). For smaller Λ's, the asymptotic integral may help convergence. Apparently, the calculations are not sufficiently accurate for $\Lambda<3$ and $\Lambda>20$.

ACKNOWLEDGMENT

The author thanks Professor J. Smit for a useful discussion.

APPENDIX A: BESSEL FUNCTIONS

Most of the formulas of this appendix are found in the textbook by Watson[15] for the functions $J_\beta(z)$, $I_\beta(z)$, $K_\beta(z)$, $H_\beta^{(1)}(z)$, and $H_\beta^{(2)}(z)$. In this paper, use has been made of functions $j_\beta(z)$, $i_\beta(z)$, $k_\beta(z)$, $h_\beta^+(z)$, and $h_\beta^-(z)$ that differ from them by a factor $(z/2)^\beta$ according to

$$j_\beta(z) = \left(\frac{z}{2}\right)^{-\beta} J_\beta(z) = \sum_{k=0}^{\infty} \frac{(-)^k}{k\,!\,\Gamma(1+\beta+k)}\left(\frac{z}{2}\right)^{2k}, \tag{A1a}$$

$$i_\beta(z) = \left(\frac{z}{2}\right)^{-\beta} I_\beta(z) = \sum_{k=0}^{\infty} \frac{1}{k\,!\,\Gamma(1+\beta+k)}\left(\frac{z}{2}\right)^{2k}, \tag{A1b}$$

$$k_\beta(z)=\left(\frac{z}{2}\right)^{-\beta}K_\beta(z)=\frac{\pi}{2\sin\pi\beta}\sum_{k=0}^{\infty}\left\{\frac{1}{k!\,\Gamma(1-\beta+k)}\left(\frac{z}{2}\right)^{-2\beta+2k}-\frac{1}{k!\,\Gamma(1+\beta+k)}\left(\frac{z}{2}\right)^{2k}\right\}, \tag{A1c}$$

$$h_\beta^{+}(z)=\left(\frac{z}{2}\right)^{-\beta}H_\beta^{(1)}(z)=\frac{-i}{\sin\pi\beta}\sum_{k=0}^{\infty}(-)^k\left\{\frac{1}{k!\,\Gamma(1-\beta+k)}\left(\frac{z}{2}\right)^{-2\beta+2k}-\frac{e^{-i\pi\beta}}{k!\,\Gamma(1+\beta+k)}\left(\frac{z}{2}\right)^{2k}\right\}, \tag{A1d}$$

$$h_\beta^{-}(z)=\left(\frac{z}{2}\right)^{-\beta}H_\beta^{(2)}(z)=\frac{i}{\sin\pi\beta}\sum_{k=0}^{\infty}(-)^k\left\{\frac{1}{k!\,\Gamma(1-\beta+k)}\left(\frac{z}{2}\right)^{-2\beta+2k}-\frac{e^{i\pi\beta}}{k!\,\Gamma(1+\beta+k)}\left(\frac{z}{2}\right)^{2k}\right\}. \tag{A1e}$$

If it is supposed that

$$\beta=b+\varepsilon, \tag{A2}$$

where b is integer, (A1) becomes in the limit $\varepsilon\to 0$,

$$j_b(z)=\sum_{k=0}^{\infty}\frac{(-)^k}{k!\,(b+k)!}\left(\frac{z}{2}\right)^{2k}, \tag{A3a}$$

$$i_b(z)=j_b(iz)=\sum_{k=0}^{\infty}\frac{1}{k!\,(b+k)!}\left(\frac{z}{2}\right)^{2k}, \tag{A3b}$$

$$k_b(z)=K_b(k)\left(\frac{z}{2}\right)^{2k}+L_b\left(\frac{z}{2}\right)^{2k}\ln\left(\frac{z}{2}\right)+M_b(k)\left(\frac{z}{2}\right)^{-2b+2k}, \tag{A3c}$$

$$h_b^{+}(z)=j_b(z)+iy_b(z), \tag{A3d}$$

$$h_b^{-}(z)=j_b(z)-iy_b(z), \tag{A3e}$$

with the notation

$$y_b(z)=\frac{-(-)^k 2}{\pi}\left\{(-)^bK_b(k)\left(\frac{z}{2}\right)^{2k}+(-)^bL_b\left(\frac{z}{2}\right)^{2k}\ln\left(\frac{z}{2}\right)+M_b(k)\left(\frac{z}{2}\right)^{-2b+2k}\right\}, \tag{A4a}$$

$$K_b(k)=\frac{(-)^{b+1}}{k!\,(b+k)!}\left\{\left(\gamma-\frac{1}{1}-\frac{1}{2}-\cdots-\frac{1}{k}\right)+\left(\gamma-\frac{1}{1}-\frac{1}{2}-\cdots-\frac{1}{k+b}\right)\right\},$$
$$(\gamma=0.577\,215\,664\,9), \tag{A4b}$$

$$L_b(k)=\frac{(-)^{b+1}}{k!\,(b+k)!}, \tag{A4c}$$

$$M_b(k)=\frac{(-)^k(b-k-1)!}{2\,.\,k!}. \tag{A4d}$$

From here, we see that

$$h_b^+(iz) = \frac{2i(-)^{b+1}}{\pi} k_b(z), \tag{A5a}$$

$$h_b^-(iz) = 2i_b(z) - \frac{2i(-)^{b+1}}{\pi} k_b(z). \tag{A5b}$$

The asymptotic behavior of the functions $k_\beta(z)$, $h_\beta^+(z)$, $h_\beta^-(z)$, $h_\beta^+(iz)$, and $h_\beta^-(iz)$ is given by

$$k_\beta(z) = e^{-z}\left\{\sum_{k=0}^{H-1} \frac{\sqrt{\pi}2^{2\beta}(\beta,k)}{(2z)^{\beta+k+\frac{1}{2}}} + O(z^{-H})\right\} \quad \left(-\frac{3}{2}\pi < \arg z < \frac{3}{2}\pi\right), \tag{A6a}$$

$$h_\beta^+(z) = \frac{2^{2\beta+1}e^{-\frac{1}{2}i\pi\left(\beta+\frac{1}{2}\right)}e^{iz}}{\sqrt{\pi}}\left\{\sum_{k=0}^{H-1} \frac{i^k(\beta,k)}{(2z)^{\beta+k+\frac{1}{2}}} + O(z^{-H})\right\} \quad (-\pi < \arg z < 2\pi), \tag{A6b}$$

$$h_\beta^-(z) = \frac{2^{2\beta+1}e^{\frac{1}{2}i\pi\left(\beta+\frac{1}{2}\right)}e^{-iz}}{\sqrt{\pi}}\left\{\sum_{k=0}^{H-1} \frac{(-i)^k(\beta,k)}{(2z)^{\beta+k+\frac{1}{2}}} + O(z^{-H})\right\} \quad (-2\pi < \arg z < \pi), \tag{A6c}$$

$$h_\beta^+(iz) = \frac{2^{2\beta+1}e^{-i\pi\left(\beta+\frac{1}{2}\right)}e^{-z}}{\sqrt{\pi}}\left\{\sum_{k=0}^{H-1} \frac{(\beta,k)}{(2z)^{\beta+k+\frac{1}{2}}} + O(z^{-H})\right\} \quad \left(-\frac{3}{2}\pi < \arg z < \frac{3}{2}\pi\right), \tag{A6d}$$

$$h_\beta^-(iz) = \frac{2^{2\beta+1}e^{z}}{\sqrt{\pi}}\left\{\sum_{k=0}^{H-1} \frac{(-)^k(\beta,k)}{(2z)^{\beta+k+\frac{1}{2}}} + O(z^{-H})\right\} \quad \left(-\frac{5}{2}\pi < \arg z < \frac{1}{2}\pi\right), \tag{A6e}$$

$$i_\beta(z) = \frac{2^{2\beta}}{\sqrt{\pi}}\left\{\sum_{k=0}^{H-1} \frac{(-)^k(\beta,k)e^{z}}{(2z)^{\beta+k+\frac{1}{2}}} + \sum_{k=0}^{H-1} \frac{(\beta,k)e^{-i\pi\left(\beta+\frac{1}{2}\right)}e^{-z}}{(2z)^{\beta+k+\frac{1}{2}}} + O(z^{-H})\right\} \quad \left(-\frac{3}{2}\pi < \arg z < \frac{1}{2}\pi\right), \tag{A6f}$$

where $(\beta,0)=1$ and

$$(\beta,k) = \frac{\Gamma\left(\beta+k+\frac{1}{2}\right)}{k!\,\Gamma\left(\beta-k+\frac{1}{2}\right)} = \frac{\left\{\beta^2-\left(\frac{1}{2}\right)^2\right\}\left\{\beta^2-\left(\frac{3}{2}\right)^2\right\}\cdots\left\{\beta^2-\left(\frac{2k-1}{2}\right)^2\right\}}{k!}, \tag{A7}$$

if $k>0$.

The function $k_b(m|\mathbf{x}-\mathbf{y}|)$ may be split according to

$$k_\beta(m|\mathbf{x}-\mathbf{y}|) = \Gamma(\beta)\sum_{l=0}^{\infty}(\beta+l)C_l^\beta(\hat{\mathbf{x}}\cdot\hat{\mathbf{y}})\left(\frac{m^2xy}{4}\right)^l i_{\beta+l}(mx)k_{\beta+l}(my) \tag{A8}$$

if

$$x < y, \tag{A9}$$

where $\hat{\mathbf{x}}\cdot\hat{\mathbf{y}}$ is the cosine of the angle between $\mathbf{x}$ and $\mathbf{y}$ and $C_k^\beta(\hat{\mathbf{x}}\cdot\hat{\mathbf{y}})$ are Gegenbauer polynomials, defined by

$$C_l^\beta(\hat{\mathbf{x}}\cdot\hat{\mathbf{y}}) \equiv \sum_r{}' \frac{(-)^{(l-r)/2}\Gamma\left(\beta+\frac{l+r}{2}\right)(2\hat{\mathbf{x}}\cdot\hat{\mathbf{y}})^r}{\Gamma(\beta)\frac{l-r}{2}!\,r!}. \tag{A10}$$

Σ' means summation under the condition that $(l-r)/2$ is integer. A direct splitting into Bessel functions and cosines is[11]

$$k_\beta(m|\mathbf{x}-\mathbf{y}|) = \sum_{l,r=0}^{\infty} \frac{(-)^l}{l!}\left(\frac{mx}{2}\right)^{r+2l}\left(\frac{my}{2}\right)^r \frac{(2\hat{\mathbf{x}}\cdot\hat{\mathbf{y}})^r}{r!} k_{\beta+l+r}(my) \tag{A11}$$

if

$$x < y. \tag{A12}$$

An integral representation is

$$k_\beta(z) = \frac{1}{2}\int_0^\infty \mathrm{d}\rho\, \rho^{-\beta} e^{-\rho} e^{-z^2/4\rho}, \tag{A13}$$

which establishes the connection between configuration space and Feynman parameters.[14]

Another integral representation is

$$k_\beta(z) = \frac{\sqrt{\pi}}{\Gamma\left(\beta+\frac{1}{2}\right)}\int_1^\infty \mathrm{d}t\, e^{-zt}(t^2-1)^{\beta-\frac{1}{2}}. \tag{A14}$$

If the k_β transform of a function $R(p)$ is defined by

$$S(x) = 2\pi^{\frac{1}{2}n-1}\int_0^\infty \mathrm{d}p\, p^{n-1} k_{\frac{1}{2}n-1}(px) R(p), \tag{A15a}$$

then $R(p)$ is found by the inverse transformation[20]

$$R(p) = \frac{1}{i\pi^{\frac{1}{2}n}2^{n-2}}\int_{c-i\infty}^{c+i\infty} \mathrm{d}x\, x^{n-1} i_{\frac{1}{2}n-1}(px) S(x). \tag{A15b}$$

APPENDIX B: ANGULAR INTEGRATIONS

Integration over n dimensional Euclidean space of a product of cosines is done by using the formula[21,22]

$$\int \mathrm{d}\hat{\mathbf{x}}(\hat{\mathbf{x}}\cdot\mathbf{q}_1)^{q_1}(\hat{\mathbf{x}}\cdot\mathbf{q}_2)^{q_2}\cdots(\hat{\mathbf{x}}\cdot\mathbf{q}_{V-1})^{q_{V-1}} = \sum_{q_i}\frac{q_1!\,q_2!\cdots q_{V-1}!}{(q_1+q_2+\cdots q_{V-1})!}\int \mathrm{d}\hat{\mathbf{x}}\,\hat{\mathbf{x}}\cdot(\mathbf{q}_1+\mathbf{q}_2+\cdots + \mathbf{q}_{V-1})^{q_1+q_2+\cdots q_{V-1}}. \tag{B1}$$

Integration of the rhs yields

$$\prod_{1<i\leqslant V-1}\int \mathrm{d}\hat{\mathbf{x}}_1 \frac{(2\hat{\mathbf{p}}_\mathbf{1}\cdot\hat{\mathbf{x}}_1)^{q_1}}{q_1!}\frac{(2\hat{\mathbf{x}}_1\cdot\hat{\mathbf{x}}_i)^{r_{1,i}}}{r_{1,i}!} = \sum{}' \frac{2\pi^{\frac{1}{2}n}}{\Gamma\left(\frac{n+q_1+r_{1,2}+\cdots+r_{1,V-1}}{2}\right)\frac{q_1-\sum_{1<a\leqslant V-1} q_{1,a}}{2}!}$$
$$\prod_{1<i\leqslant V-1}\frac{(2\hat{\mathbf{p}}_\mathbf{1}\cdot\hat{\mathbf{x}}_i)^{q_{1,i}}}{\frac{r_{1,i}-q_{1,i}-\sum_{1<a<i} q^1_{a,i}-\sum_{i<a\leqslant V-1} q^1_{i,a}}{2}!\, q_{1,i}!}$$
$$\prod_{1\leqslant i'<i\leqslant V-1}\frac{(2\hat{\mathbf{x}}_{i'}\cdot\hat{\mathbf{x}}_i)^{q^1_{i',i}}}{q^1_{i',i}!}, \tag{B2}$$

where Σ' means summation over the variables $q_{1,i}$ and $q^1_{i,i''}$ $(1<i<i''\leqslant V-1)$ from 0 to ∞ in such a way that the arguments of the faculties in the denominator are integers.

Multiple application of (B2) yields

$$\prod\int \mathrm{d}\hat{\mathbf{x}}_i \frac{(2\hat{\mathbf{p}}_i\cdot\hat{\mathbf{x}}_i)^{q_i}}{q_i!}\frac{(2\hat{\mathbf{x}}_{i'}\cdot\hat{\mathbf{x}}_i)^{r^j_{i',i}}}{r^j_{i',i}!} = \frac{(2\pi^{\frac{1}{2}n})^{V-1}r_{i',i}!}{\prod_j r^j_{i',i}!}A(q_i,r_{i',i}), \tag{B3}$$

with notation of Π according to (5.2) and

$$r_{i',i} = \sum_c r^c_{i',i}. \tag{B4a}$$

The angular factor in (B3) is given by

$$A(q_i,r_{i',i}) = \sum{}' \prod$$
$$\frac{\left(r_{i',i}+\sum q^c{}_{i',i}\right)!\left(q_{i',i}+\sum q_{i'}{}^c{}_i\right)!\,(2\hat{\mathbf{p}}_{i'}\cdot\hat{\mathbf{p}}_i)^{p_{i',i}+\Sigma q_{i',i}{}^c}}{\Gamma\left(\frac{n+q_i+\sum r_{i,a}+\sum q^c{}_{i,b}+\sum q_{a,i}+\sum q_a{}^c{}_i}{2}\right)\overline{q_i}!\,\overline{r_{i',i}}!\,\overline{q_{i',i}}!\,r_{i',i}!\,q_{i',i}!\,p_{i',i}!\,q^{i'}{}_{i,i''}!\,q_{i'}{}^i{}_{i''}!\,q_{i',i}{}^{i''}!} \tag{B4b}$$

where we used summation variables $q^{i'}{}_{i,i''}$, $q_{i'}{}^i{}_{i''}$, and $q_{i',i}{}^{i''}$ $(1\leqslant i'<i<i''\leqslant V-1)$ with three indices and summation notation

$$\sum r_{i,a} = \sum_{a=i+1}^{V-1} r_{i,a},\quad \sum q_{a,i} = \sum_{a=1}^{i-1} q_{a,i},\quad \sum q^c{}_{i,b} = \sum_{c=1}^{i-1}\sum_{b=i+1}^{V-1} q^c{}_{i,b},$$

$$\sum q_a{}^c{}_i = \sum_{a=1}^{c-1}\sum_{c=2}^{i-1} q_a{}^c{}_i,\quad \sum q_{i',i}{}^c = \sum_{c=i+1}^{V-1} q_{i',i}{}^c,\quad \text{etc.} \tag{B5}$$

Furthermore,

$$\overline{q_i} = \frac{q_i-\sum q_{i,a}-\sum p_{a,i}}{2}, \tag{B6a}$$

$$\overline{r}_{i',i} = \frac{r_{i',i} + \sum q^{a}{}_{i',i} - q_{i',i} - \sum q^{i'}{}_{a,i} - \sum q^{i'}{}_{i,a}}{2}, \tag{B6b}$$

$$\overline{q}_{i',i} = \frac{q_{i',i} + \sum q_{i'}{}^{a}{}_{i} - p_{i',i} - \sum q_{a,i'}{}^{i} - \sum q_{i',a}{}^{i}}{2}. \tag{B6c}$$

Σ' means summation over the variables $p_{i',i}$, $q_{i',i}$, $q^{i'}{}_{i,i''}$, $q_{i'}{}^{i}{}_{i''}$, and $q_{i',i}{}^{i''}$ from 0 to ∞ in such a way that $\overline{q}_i$, $\overline{q}_{i',i}$, and $\overline{r}_{i',i}$ are integers. Summation over $\overline{q}_i$ yields Bessel functions,

$$\prod \int \mathrm{d}\hat{\mathbf{x}}_i \, e^{i\mathbf{p}_i\cdot\mathbf{x}_i} \frac{(2\hat{\mathbf{x}}_{i'}\cdot\hat{\mathbf{x}}_i)^{r^j_{i',i}}}{r^j_{i',i}!} = \frac{(2\pi^{\frac{1}{2}n})^{V-1} r_{i',i}!}{\prod_j r^j_{i',i}!} \sum{}' A(r_{i',i}) \left(\frac{ip_ix_i}{2}\right)^{s_i - \Sigma\overline{r}_{i,a} - \Sigma\overline{q}_{a,i} - \Sigma q^{i}{}_{a,b} - \Sigma q_{a,b}{}^{i}} j_{(n/2)-1+s_i}(p_ix_i) \tag{B7}$$

with

$$\begin{aligned} s_i &= \frac{\sum q_{i,a} + \sum p_{a,i} + \sum r_{i,a} + \sum q^{c}{}_{i,a} + \sum q_{a,i} + \sum q_{a}{}^{c}{}_{i}}{2} \\ &= \overline{r}_{i,a} + 2\overline{q}_{i,a} + \overline{q}_{a,i} + p_{i,a} + p_{a,i} + q^{i}{}_{a,b} - q_{i}{}^{a}{}_{b} + q_{a,i}{}^{c} + q_{i,a}{}^{c} + q_{a,b}{}^{i} \end{aligned} \tag{B8a}$$

and

$$A(r^j_{i',i}) = \prod \frac{\left(r_{i',i} + \sum q^{c}{}_{i',i}\right)! \left(q_{i',i} + \sum q_{i'}{}^{c}{}_{i}\right)! (2\hat{\mathbf{p}}_{i'}\cdot\hat{\mathbf{p}}_i)^{p_{i',i} + \Sigma q_{i',i}{}^{c}}}{\overline{r}_{i',i}!\, \overline{q}_{i',i}!\, r_{i',i}!\, q_{i',i}!\, p_{i',i}!\, q^{i'}{}_{i,i''}!\, q_{i'}{}^{i}{}_{i''}!\, q_{i',i}{}^{i''}!}. \tag{B8b}$$

APPENDIX C: RADIAL $\Lambda \to \infty$ INTEGRATIONS

The radial factors $R_1(r^j_{i',i})$ and $R_2(r^j_{i',i})$, appearing in (5.5) as result of integrations in the subregions (5.4b), may be expressed, using (A8) and (B7), in terms of Bessel functions. They become

$$R_1(r^j_{i',i}) = \sum{}' \prod \frac{2^{2\nu}(-)^{\frac{l^j_{i',a} - r^j_{i',a} + l^j_{i,i''} - r^j_{i,i''}}{2}} (m^j_{i',i})^{2l^j_{i',i}} \left(b^j_{i',i} + l^j_{i',i}\right)\left(b^j_{i,i''} + l^j_{i,i''}\right) \Gamma\left(b^j_{i',i} + \frac{l^j_{i',i} + r^j_{i',i}}{2}\right) \Gamma\left(b^j_{i,i''} + \frac{l^j_{i,i''} + r^j_{i,i''}}{2}\right)}{\left(\frac{l^j_{i',i} - r^j_{i',i}}{2}\right)! \left(\frac{l^j_{i,i''} - r^j_{i,i''}}{2}\right)!}$$

$$\times \int_{0<x_1<\ldots<x_f<X} d\frac{x_i}{2} \left(\frac{ip_ix_i}{2}\right)^{s_i - \sum\overline{r}_{i,a} - \sum\overline{q}_{a,i} - \sum q^{i}{}_{a,b} - \sum q_{a,b}{}^{i}} \left(\frac{x_i}{2}\right)^{2\nu - 1 + \sum l^{c}_{i,a} + \sum l^{c}_{a,i}}$$

$$\times i_{\frac{n}{2}-1+s_i}(p_ix_i) k_{b^j_i}(m^j_i x_i) k_{b^j_{i',i} + l^j_{i',i}}(m^j_{i',i}x_i) i_{b^j_{i,i''} + l^j_{i,i''}}(m^j_{i,i''}x_i) + \texttt{permutations}, \tag{C1a}$$

which may be computed after insertion of the near zero expansions (A3b) and (A3c), and

$$R_2(r^j_{i',i}) = \sum{}' \prod \frac{2^{2\nu}(-)^{\frac{l^j_{i',i}-r^j_{i',i}+l^j_{i,i''}-r^j_{i,i''}}{2}}(m^j_{i',i})^{2l^j_{i',i}}\left(b^j_{i',i}+l^j_{i',i}\right)\left(b^j_{i,i''}+l^j_{i,i''}\right)\Gamma\left(b^j_{i',i}+\frac{l^j_{i',i}+r^j_{i',i}}{2}\right)\Gamma\left(b^j_{i,i''}+\frac{l^j_{i,i''}+r^j_{i,i''}}{2}\right)}{\left(\frac{l^j_{i',i}-r^j_{i',i}}{2}\right)!\left(\frac{l^j_{i,i''}-r^j_{i,i''}}{2}\right)!}$$

$$\times \int_{X<x_{f+1}<\ldots<x_{F-1}<\infty} d\frac{x_i}{2}\left(\frac{ip_ix_i}{2}\right)^{s_i-\sum\bar{r}_{i,a}-\sum\bar{q}_{a,i}-\sum q^j{}_{a,b}-\sum q_{a,b}{}^i}\left(\frac{x_i}{2}\right)^{2\nu-1+\sum l^i_{i,a}+\sum l^i_{a,i}}$$

$$\times i_{\frac{n}{2}-1+s_i}(p_ix_i)k_{b^j_i}(m^j_ix_i)k_{b^j_{i',i}+l^j_{i',i}}(m^j_{i',i}x_i)i_{b^j_{i,i''}+l^j_{i,i''}}(m^j_{i,i''}x_i)+\texttt{permutations}. \tag{C1b}$$

Insertion of the asymptotic expansions (A6) into (C1b) yields incomplete Γ functions. The power of x_i is restricted since terms s_i and $l^j_{i',i}$ in the exponent are cancelled by terms s_i and $l^j_{i',i}$ in the order of the Bessel functions.

The rhs of (C1b) is computed by use of the following formulas:

$$\int_X^\infty \mathrm{d}x_1\, e^{-M_1x}x_1^{\rho_1-1} = M^{-\rho_1}\sum_{0\leqslant k_1\leqslant H_1-1}\frac{\Gamma(\rho_1)}{\Gamma(\rho_1-k_1)}e^{-M_1X}(M_1X)^{-k_1-1} + M^{-H_1-1}\frac{\Gamma(\rho_1)}{\Gamma(\rho_1-H_1)}\int_X^\infty \mathrm{d}x_1\, e^{-M_1x}x_1^{\rho_1-H_1-1}. \tag{C2}$$

If ρ_1 is positive integer, the series on the rhs is finite. If ρ_1 is positive noninteger, H_1 is chosen $\geqslant\rho_1$ so that the exponent of x_1 in the integrand is negative.

In both cases and also in the case $\rho_1\leqslant 0$ the rhs is restricted according to

$$\int_X^\infty \mathrm{d}x_1\, e^{-M_1x}x_1^{\rho_1-1} \leqslant M_1^{-\rho_1}\sum_{0\leqslant k_1\leqslant H_1}\frac{\Gamma(\rho_1)}{\Gamma(\rho_1-k_1)}\Lambda^{\rho_1-k_1-1}e^{-\Lambda}, \tag{C3}$$

where

$$\Lambda = M_1X. \tag{C4}$$

Multiple application of this formula yields

$$\prod_{1\leqslant i\leqslant g}\int_{X<x_1\cdots<x_g<\infty}\mathrm{d}x_i\, e^{-M_ix}x_i^{\rho_i-1}$$

$$\leqslant\left(\sum_{1\leqslant a\leqslant g}M_a\right)^{-\Sigma_{1\leqslant a\leqslant g}\rho_a}\sum_{0\leqslant k_i\leqslant H_i}\frac{\Gamma\left(\sum_{i\leqslant a\leqslant g}\rho_a-\sum_{i<a\leqslant g}k_a-g+i\right)}{\Gamma\left(\sum_{i\leqslant a\leqslant g}(\rho_a-k_a)-g+i\right)} \times\left(\frac{\sum_{1\leqslant a\leqslant g}M_a}{\sum_{i\leqslant a\leqslant g}M_a}\right)^{-1-k_i}\Lambda^{\Sigma_{1\leqslant a\leqslant g}\rho_a-k_a-g}e^{-\Lambda}. \tag{C5}$$

It is seen that (C3) and (C5) can be made arbitrary small by choosing Λ sufficiently large.

By application of

$$\int_X^\infty dx_1\, e^{-M_1 x_1} x_1^{\rho_1 - 1} = M_1^{\rho_1}\Gamma(\rho_1) - \int_0^X dx_1\, e^{-M_1 x_1} x_1^{\rho_1 - 1}, \tag{C6}$$

the incomplete Γ functions with integer or half-integer arguments may be computed by the following expansions:

$$\int_X^\infty dx_1\, e^{-M_1 x} x_1^{\rho_1 - 1} = \mathsf{P}_{\rho_1} + \mathsf{Q}_{\rho_1} \sum_{\substack{l=0 \\ l \neq -\rho_1}}^{\infty} \frac{(-)^l \Lambda^{\rho_1 + l}}{l\,!\,(\rho_1 + l)}, \tag{C7}$$

where

$$\mathsf{P}_{\rho_1} = (\rho_1 - 1)\,! \quad \text{and } \mathsf{Q}_{\rho_1} = -1 \quad \text{if } \rho_1 \text{ positive integer}, \tag{C8a}$$

$$\mathsf{P}_{\rho_1} = 0 \quad \text{and } \mathsf{Q}_{\rho_1} = 1 \quad \text{if } \rho_1 \text{ nonpositive integer}, \tag{C8b}$$

$$\mathsf{P}_{\rho_1} = \frac{\sqrt{\pi}(2\rho_1 - 1)!}{\left(\rho_1 - \frac{1}{2}\right)!\, 2^{2\rho_1 - 1}} \quad \text{and } \mathsf{Q}_{\rho_1} = -1 \quad \text{if } \rho_1 \text{ positive half-integer}, \tag{C8c}$$

$$\mathsf{P}_{\rho_1} = \frac{\sqrt{\pi}(-)^{\frac{1}{2} - r}\left(\frac{1}{2} - \rho_1\right)!\, 2^{1 - 2\rho_1}}{(1 - 2\rho_1)!} \quad \text{and } \mathsf{Q}_{\rho_1} = -1 \quad \text{if } \rho_1 \text{ negative half-integer}. \tag{C8d}$$

Multiple application of (C7) and (C8) yields

$$\begin{aligned} \prod_{1 \leqslant i \leqslant g} \int_{X < x_1 < \cdots < x_g}^\infty dx_i\, e^{-M_i x} x_i^{\rho_i - 1} &= \mathsf{P}_{\rho_1} \cdots \mathsf{P}_{\rho_g} M_1^{-\rho_1} \cdots M_g^{-\rho_g} \\ &+ \mathsf{P}_{\rho_1} \cdots \mathsf{P}_{\rho_{g-1} + \rho_g + l_g} \mathsf{Q}_{\rho_g} M_1^{-\rho_1} \cdots M_{g-1}^{-\rho_{g-1} - \rho_g} \frac{\left(-\frac{M_g}{M_{g-1}}\right)^{l_g}}{l_g\,!\,(\rho_g + l_g)} \\ &+ 2^g - 1 \quad \text{terms where factors } \mathsf{P}_{\rho_i} \text{ have been replaced by factors } \mathsf{Q}_{\rho_i}. \end{aligned} \tag{C9}$$

Equation (C9) may be inserted into (C1b).

APPENDIX D: RADIAL $0 \to \Lambda$ INTEGRATIONS

Multiple application of

$$\prod_j \int_0^\Lambda d\xi_1\, \xi_1^{N_1 - 1} \{\ln(\mu_1^j \xi_1)\}^{g_1^j} = \sum_{0 \leqslant g_{1;1}^j \leqslant g_1^j} \prod_j \frac{g_1^j\,!\,(-)^{\sum_c (g_1^c - g_{1;1}^c)} \sum_c (g_1^c - g_{1;1}^c)!}{g_{1;1}^j\,!\,(g_1^j - g_{1;1}^j)\,!\, N_1^{1 + \sum_c (g_1^c - g_{1;1}^c)}} \{\ln(\mu_1^j \Lambda)\}^{g_{1;1}^j} \Lambda^{N_1} \tag{D1}$$

gives

$$\prod \int_{0 < \xi_1 < \xi_2 < \cdots < \xi_{V-1} < \Lambda} d\xi_i\, \xi_i^{N_i - 1} (\ln \mu_i^j \xi_i)^{g_i^j}$$

$$= \sum_{0\leqslant f_i^j\leqslant g_{i;V-2}^j\cdots\leqslant g_{i,i}^j\leqslant g_i^j} \prod_{1\leqslant i\leqslant i''\leqslant V-1} \frac{(-)^{G_i} G_i\,!\, g_i^j!}{(g_{i;i''-1}^j - g_{i;i''}^j)\,!\left(\sum_{1\leqslant a\leqslant i} N_a\right)^{1+G_i}} (\ln \mu_i^j \Lambda)^{f_i^j} \Lambda^{\sum_{1\leqslant a\leqslant V-1} N_a}, \tag{D2}$$

with

$$G_i = \sum_{\substack{1\leqslant a\leqslant i \\ c}} (g_{a;i-1}^c - g_{a;i}^c), \tag{D3}$$

where $g_{i;i''}^j$ are summation variables if $i\leqslant i''\leqslant V-1$ and

$$g_{i;i-1}^j \equiv g_i^j, \tag{D4a}$$

$$g_{i;V-1}^j \equiv f_i^j. \tag{D4b}$$

In the case

$$0 \leqslant g_i^j \leqslant 1, \tag{D5}$$

all summation variables are 0 or 1 and (D2) takes the form

$$\prod \int_{0<\xi_1<\xi_2<\cdots<\xi_{V-1}<\Lambda} \mathrm{d}\xi_i\, \xi_i^{N_i-1} (\ln \mu_i^j \xi_i)^{g_i^j}$$

$$= \sum_{0\leqslant f_i^j\leqslant g_{i;V-2}^j\cdots\leqslant g_{i;i}^j\leqslant g_i^j} \prod_{\substack{1\leqslant i\leqslant V-1 \\ j}} \frac{(-)^{G_i} G_i!}{\left(\sum_{1\leqslant a\leqslant i} N_a\right)^{1+G_i}} (\ln \mu_i^j \Lambda)^{f_i^j} \Lambda^{(\Sigma_{1\leqslant a\leqslant V-1} N_a)}. \tag{D6}$$

Laplacian in the hyperbolic space H_n and linearization stability of the Einstein equation for Robertson-Walker models

Lluís Bruna and Joan Girbau
Universitat Autónoma de Barcelona, Edificí C, Bellasterra (Barcelona), 08193, Spain

(Received 1 December 2004; accepted 27 April 2005; published online 23 June 2005)

We prove that some operators related to the rough Laplacian in the hyperbolic space give isomorphisms between Sobolev spaces of 1-forms. By using these results we prove that the Einstein equation of the hyperbolic Robertson-Walker cosmological model is linearization stable. We also study the linearization stability for Robertson-Walker models, $V=S\times I$, with S compact, complete, having either constant negative or zero curvature. © *2005 American Institute of Physics.*

I. INTRODUCTION

Let $\tilde{g}$ be a Lorentz metric. Denote by $\mathrm{Ric}(\tilde{g})$ the Ricci tensor of $\tilde{g}$, by $R(\tilde{g})$ the scalar curvature of $\tilde{g}$, and by $G(\tilde{g})=\mathrm{Ric}(\tilde{g})-(1/2)R(\tilde{g})\tilde{g}$ the Einstein tensor. The Einstein equation with this notation takes the following form:

$$G(\tilde{g})=\chi\tilde{T}, \tag{1}$$

where $\tilde{T}$ is the stress-energy tensor and χ is a constant. We set tildes over Lorentz metrics and over stress-energy tensors in order to indicate that we deal with a four-dimensional manifold. The letters without tildes will be used for three-dimensional manifolds. One often begins with an initial stress-energy tensor, $\tilde{T}_0$, and an initial Lorentz metric, $\tilde{g}_0$, satisfying $\tilde{G}(\tilde{g}_0)=\chi\tilde{T}_0$ and is interested in finding metrics $\tilde{g}$ close to $\tilde{g}_0$ which are solutions of (1) for a given $\tilde{T}$ close to $\tilde{T}_0$. In order to solve this problem, it can sometimes be useful to linearize the equation (1) at the initial metric $\tilde{g}_0$. When the solutions of the linearized equation do really approximate exact solutions of the true equation, we will say that the Einstein equation is linearization stable at the initial metric $\tilde{g}_0$. An exact version of this concept will be given in what follows.

This paper deals with the problem of linearization stability of the Einstein equation in the case where the initial pair $(\tilde{g}_0,\tilde{T}_0)$ consists of the metric and the stress-energy tensor of a Robertson-Walker cosmological model. The Lorentz manifold corresponding to this model is the product $V=S\times I$, where I is an interval in $\mathbb{R}$, $(S,\hat{g}_0)$ is a Riemannian manifold of constant curvature, and $\tilde{g}_0$ is a Lorentz metric of the form $\tilde{g}_0=-\mathrm{d}t^2+\zeta^2(t)\hat{g}_0$ (t is the coordinate of I). The tensor $\tilde{T}_0$ takes the form $\tilde{T}_0=(\rho+p)\mathrm{d}t\otimes\mathrm{d}t+p\tilde{g}_0$. Generally, it is assumed that S is complete and simply connected. Then S should necessarily be either the Euclidean space $\mathbb{R}^3$, the hyperbolic space $\mathbb{H}_3$, or the sphere S^3.

In our papers, Refs. 7 and 8, we have shown that the Euclidean Robertson-Walker model is linearization stable for the Einstein equation and that the spherical model of positive curvature is not. The remaining case to be studied is that of a hyperbolic Robertson-Walker model. In this paper, we will show (Theorem 1) that such a model is linearization stable. For this purpose, we will use a result (Theorem 2) on the Laplace operator in a hyperbolic space proved in the Appendix. Theorem 1 combined with the results in our earlier papers, Refs. 7 and 8, may suggest that the fact whether or not a Robertson-Walker model is linearization stable can be related to the fact

whether or not the Riemannian manifold S is compact. In fact, when the curvature is negative or zero then S is not compact and the model is linearly stable, while when the curvature is positive then S is compact and the model is not linearly stable. This is the case when S is simply connected, but if we drop this condition, Theorem 3 makes it clear that the fact that the Einstein equation of the model is linearization stable has nothing to do with S being compact.

It is quite well known that any complete n-dimensional Riemannian manifold S of constant curvature is always a quotient X/Γ, where X is either the Euclidean space $\mathbb{R}^n$, or the hyperbolic space $\mathbb{H}_n$, or the sphrere S^n, and Γ is a discrete subgroup of the group of isometries of X acting in a free and properly discontinuous manner. In our case, S has dimension 3. In Theorem 3, we will study Robertson-Walker cosmological models, $V=S\times I$, where S is compact, complete, having either constant negative curvature ($S=\mathbb{H}_3/\Gamma$) or curvature zero ($S=\mathbb{R}^3/\Gamma$). We will show that there is stability when the curvature is negative, and there is not when the curvature is zero. This will make it clear that stability has nothing to do with compactness since the manifolds are compact in either of these cases. In fact, when S is compact the existence of Killing vectors is the first reason of instability.

II. WHAT TYPES OF DEFORMATIONS OF THE INITIAL MODEL WE WILL CONSIDER

Let $(V,\tilde{g}_0,\tilde{T}_0)$ be an initial Robertson-Walker model. The aim of the paper is to consider small deformations $\tilde{T}=\tilde{T}_0+\delta\tilde{T}$ of the initial tensor $\tilde{T}_0$ and metrics $\tilde{g}$ close to $\tilde{g}_0$ such that $G(\tilde{g})=\chi\tilde{T}$, and establish what conditions should be satisfied by the initial model for the equation $G(\tilde{g})=\tilde{T}_0+\delta\tilde{T}$ to be linearly stable at the point $\tilde{g}_0$. For this purpose, we must first specify to what class of tensors the deformations $\tilde{T}=\tilde{T}_0+\delta\tilde{T}$ of $\tilde{T}_0$ should belong.

First we introduce some notation and recall a few topics on this subject. From now on V will always stand for the manifold $V=S\times I$, where both the initial metric $\tilde{g}_0$ and the initial tensor $\tilde{T}_0$ are defined. t will denote the coordinate of I. For a fix $t_0\in I$ consider the hypersurface M of V given by $M=S\times\{t_0\}$. Let now $\tilde{g}$ be a Lorentz metric on V close to $\tilde{g}_0$. Denote by g the Riemannian metric on M obtained by restricting $\tilde{g}$ to M and write k for twice the second fundamental quadratic form of M with respect to the metric $\tilde{g}$. Indicate by n the vector field of V with support on M, orthogonal to M at each point, satisfying $\tilde{g}(n,n)=-1$ and $\tilde{g}(n,\partial_t)<0$. Define the function F and the 1-form X on M as follows:

$$F=-\frac{1}{\chi}G(\tilde{g})(n,n)$$
$$X=\frac{1}{\chi}\,i(n)G(\tilde{g})\big|_M, \tag{2}$$

where $i(n)G(\tilde{g})|_M$ means the inner contraction of $G(\tilde{g})$ by n, acting over tangent vectors to M. If $\tilde{T}$ is a stress-energy tensor related to $\tilde{g}$ through the Einstein equation (1), then $F=-\tilde{T}(n,n)$, $X=i(n)\tilde{T}|_M$. Finally, let $\mathcal{H}(g,k)$ and $\mathcal{V}(g,k)$ be the function and the 1-form on M defined as follows:

$$\mathcal{H}(g,k)=\tfrac{1}{8}(k\cdot k-\mathrm{tr}_g^2\,k-4R),$$
$$\mathcal{V}(g,k)_i=\tfrac{1}{2}\nabla^r(k_{ir}-(\mathrm{tr}_g k)g_{ir}).$$

Then it is well known that the following formulas hold:

$$\mathcal{H}(g,k)=\chi F,$$
$$\mathcal{V}(g,k)=\chi X. \tag{3}$$

The type of stress-energy tensors is normally fixed in advance depending on the type of matter considered. For example, the class of stress-energy tensors for perfect fluids is of the form $\tilde{T}=(\rho+p)u^*\otimes u^*+p\tilde{g}$, where p and ρ are functions and u^* is the 1-form associated with a vector field u by means of the metric $\tilde{g}$, satisfying $\tilde{g}(u,u)=-1$. Here, p is a known function of ρ, $p=p(\rho)$ (state equation). We do not fix any concrete value for the variables u, ρ, and $\tilde{g}$ (we do fix the form of the tensor). In general, we can assume that $\tilde{T}$ is a known function of the metric $\tilde{g}$ and of m scalar or vector fields $\Omega_1,\ldots,\Omega_m$, called *matter fields*. In the case of perfect fluids, these variables $\Omega_1,\ldots,\Omega_m$ would be ρ and the vector field u [the latter with the constraint $\tilde{g}(u,u)=-1$]. Since by (1) $\tilde{T}$ is proportional to G, the stress-energy tensor must satisfy $\mathrm{div}_{\tilde{g}}\,\tilde{T}=0$.

Let us focus briefly on the Cauchy problem for the Einstein equation. Consider the manifold $V=S\times I$ without any metric. Let us give a function $\tilde{T}=\tilde{T}(\tilde{g},\Omega_1,\ldots,\Omega_m)$, where $\Omega_1,\ldots,\Omega_m$ are scalar or vector fields on V called *matter fields*, whose concrete values are unknown for us (they are variables). Moreover, let us give a vector field n of V with support in M, transversal to M. Let us give on M a pair (g,k) of symmetric tensor fields of order 2 such that g is positive definite. Let us also give on M values $\omega_1,\ldots,\omega_m$ of the variables $\Omega_1,\ldots,\Omega_m$. Suppose that F and X are the function and the 1-form on M given by $F=-\tilde{T}(n,n)$, $X=i(n)\tilde{T}|_M$. Assume that the data $g,k,\omega_1,\ldots,\omega_m$ on M are such that the two pairs (g,k) and (F,X) satisfy the constraints (3). We ask (Cauchy problem) whether we can find with these data a neighborhood U of M on V, unique values $\Omega_1,\ldots,\Omega_m$ of the matter fields on U and a unique Lorentz metric $\tilde{g}$ on U in such a way that the following conditions be satisfied:

(i) $\tilde{g}$ and $\tilde{T}$ satisfy $G(\tilde{g})=\chi\tilde{T}$ and $\mathrm{div}_{\tilde{g}}\,\tilde{T}=0$,
(ii) n is normal to M with respect to the metric $\tilde{g}$ and $\tilde{g}(n,n)=-1$,
(iii) $\tilde{g}$ restricted to M is g,
(iv) k is twice the second quadratic form of M with respect to the metric $\tilde{g}$,
(v) we have $\Omega_i=\omega_i$ for $i=1,\ldots,m$ over M.

If this happens, that is, if the initial data over M enable us to uniquely retrieve the metric $\tilde{g}$ and the matter fields $\Omega_1,\ldots,\Omega_m$ in a neighborhood of M in V and the solution $(\tilde{g},\Omega_i)$ depends continuously on the initial data (g,k,ω_i), we will say that the Cauchy problem *is well-posed*.

The Cauchy problem for the Einstein equation is a very wide and difficult field of research. It is clear that the above Cauchy problem will not be well posed if no additional assumptions are made. For example, in the case of perfect fluids where $\tilde{T}$ has the form $\tilde{T}=(\rho+p)u^*\otimes u^*+p\tilde{g}$ the Cauchy problem would be well posed if the following additional assumptions were made (see, e.g., Refs. 5,20 or 14):

(1) there exists a positive constant C satisfying $\rho\geqslant C>0$,
(2) p is a known function of ρ (state equation) which can never be negative on the interval $[C,+\infty)$,
(3) $p(\rho)$ belongs to the class C^1 and the derivative $p'(\rho)$ satisfies $0<p'(\rho)<1$.

Since we are going to work with Cauchy data throughout this paper, we will need the Cauchy problem to be well posed. Therefore the tensors $\tilde{T}=\tilde{T}_0+\delta\tilde{T}$ close to $\tilde{T}_0$ we will consider in what follows will be the tensors for perfect fluids satisfying the above-mentioned conditions (1)–(3). These tensors are parametrized by ρ and u, with the condition $\tilde{g}(u,u)=-1$. The initial tensor $\tilde{T}_0$ (which will correspond to the parameters ρ_0, u_0, and $\tilde{g}_0$) should be that of a Robertson-Walker model.

Since (for the Cauchy problem) the transversal field n over M should be defined in advance, we will always take $n=\partial_t$ on M for any set of Cauchy data (g,k,ρ,u). This means that for the Lorentz metrics $\tilde{g}$ we are going to consider (solutions of the Cauchy problem) the vector n will always coincide with ∂_t over M. This is by no means restrictive since if $\tilde{g}$ is an arbitrary metric and n is its unitary normal field over M, we can always find a diffeomorphism $\varphi:U\to U$, where U is

a neighborhood of M in V, such that φ is the identity over M and transforms n into ∂_t at each point of M. Then $\varphi^*\tilde{g}$ is a metric isometric to $\tilde{g}$ and satisfying the required condition (its n is ∂_t).

If u is a velocity field of a stress-energy tensor $\tilde{T}$ of the type we consider then u restricted to M will be of the form $u=q\partial_t+v$, where q is a scalar $\geqslant 0$ and v is a vector field tangent to M. The condition $\tilde{g}(u,u)=-1$ over M is written as $q=\sqrt{1+g(v,v)}$. Therefore (g,ρ,v) determine the tensor $\tilde{T}$ over M. The pair (F,X) is given as a function of (g,ρ,v) by the following formulas:

$$F = -\tilde{T}(\partial_t,\partial_t) = -(\rho + p(\rho))(1 + g(v,v)) + p(\rho),$$

$$X_i = X(\partial/\partial x^i) = \tilde{T}(\partial_t,\partial/\partial x^i) = -(\rho + p(\rho))\sqrt{1 + g(v,v)}v_i. \tag{4}$$

We will take the Cauchy data belonging to appropriate Sobolev spaces we now describe. Denote by $\mathcal{F}_s(M)$, $\Omega_s(M)$, and $\mathcal{S}_s(M)$, respectively, the Sobolev spaces of functions, of 1-forms and of covariant symmetric tensors of order 2 whose degree of regularity is s. For example, $\mathcal{F}_s(M)$ will be the space of all functions belonging $L^2(M)$ whose weak derivatives up to order s belong to $L^2(M)$. Given an initial function f_0 on M belonging to C^∞, we will denote by $\mathcal{F}_s(f_0)$ the set of functions of the form $f=f_0+h$ with $h\in\mathcal{F}_s(M)$. The set $\mathcal{F}_s(f_0)$ is topologized by imposing the condition that the map $f\to h=f-f_0$ from $\mathcal{F}_s(f_0)$ to $\mathcal{F}_s(M)$ should be a homeomorphism. In a similar way, given a 1-form ω_0 on M belonging to C^∞, the set $\Omega_s(\omega_0)$ is defined as the set of 1-forms ω satisfying $\omega-\omega_0\in\Omega_s(M)$. Given a covariant symmetric 2-tensor α_0 belonging to C^∞, we define $\mathcal{S}_s(\alpha_0)$ in an analogous way. The Cauchy data (g,k,ρ,v) will be taken in the Sobolev space $\mathcal{S}_s(g_0)\times\mathcal{S}_s(k_0)\times\mathcal{F}_{s-2}(\rho_0)\times\Omega_{s-1}(v_0)$, where s is a positive integer to be chosen below and (g_0,k_0,ρ_0,v_0) are the Cauchy data corresponding to the Robertson-Walker's initial metric $\tilde{g}_0$ and the initial tensor $\tilde{T}_0$. To be precise, $g_0=\zeta^2(t_0)\hat{g}_0$, $k_0=2\{\dot{\zeta}(t_0)/\zeta(t_0)\}g_0$, ρ_0 is the initial density, and $v_0=0$.

Let F and X be functions of g, ρ, and v defined by (4). Let

$$\begin{gathered} H:\mathcal{S}_s(g_0)\times\mathcal{F}_{s-2}(\rho_0)\times\Omega_{s-1}(v_0) \longrightarrow \mathcal{S}_s(g_0)\times\mathcal{F}_{s-2}(F_0)\times\Omega_{s-1}(X_0), \\ (g,\rho,v) \longrightarrow (g,F,X). \end{gathered} \tag{5}$$

It follows from formula (4) that the linear tangent map to H at the point (g_0,ρ_0,v_0) is

$$(DH)_{(g_0,\rho_0,v_0)}:\mathcal{S}_s(M)\times\mathcal{F}_{s-2}(M)\times\Omega_{s-1}(M) \longrightarrow \mathcal{S}_s(M)\times\mathcal{F}_{s-2}(M)\times\Omega_{s-1}(M),$$

$$(h,f,v) \longrightarrow (h,-f,-(\rho_0+p_0)v).$$

Since ρ_0+p_0 is positive, the above map is an isomorphism. By the inverse function theorem in Banach spaces, the map H can be inverted in a neighborhood of the initial data. Consider the map Ψ obtained by composition of the following maps:

$$(g,k) \longrightarrow (g,(1/\chi)\mathcal{H}(g,k),(1/\chi)\gamma(g,k)) \xrightarrow{H^{-1}} (g,\rho,v) \xrightarrow{\pi} (\rho,v) \tag{6}$$

(where π is the canonical projection). The map Ψ maps $\mathcal{S}_s(g_0)\times\mathcal{S}_s(k_0)$ to $\mathcal{F}_{s-2}(\rho_0)\times\Omega_{s-1}(v_0)$ and is defined in a neighborhood of (g_0,k_0) only. It assigns to any pair (g,k) [close to (g_0,k_0)] the unique pair (ρ,v) satisfying the constrains conditions

$$\begin{aligned} \mathcal{H}(g,k) &= \chi F(g,\rho,v), \\ \gamma(g,k) &= \chi X(g,\rho,v). \end{aligned} \tag{7}$$

We have mentioned in the introduction that we are interested in those metrics $\tilde{g}$ close to $\tilde{g}_0$ which are solutions of (1) for a given $\tilde{T}$ close to $\tilde{T}_0$. However, this cannot be formulated in such

a way. We cannot take an arbitrary $\tilde{T}$ close to $\tilde{T}_0$ and look for the metrics $\tilde{g}$ satisfying $G(\tilde{g})=\chi\tilde{T}$ since, on one hand, the expression for $\tilde{T}$ contains the metric and, on the other hand, $\tilde{T}$ should anyway satisfy the extra condition $\mathrm{div}_{\tilde{g}}\tilde{T}=0$. A correct way of expressing the initial idea (for perfect fluids) is to give a pair (ρ,v) on M (corresponding to the distribution of the matter at $t=t_0$) and acquire about the pairs (g,k) satisfying $\Psi(g,k)=(\rho,v)$. Then the data (g,k,ρ,v) over M completely define $\tilde{g}$ and $\tilde{T}$ satisfying $G(\tilde{g})=\chi\tilde{T}$. The Einstein equation is then replaced by (7).

Remark 1: In our setting, we have demanded that all deformations $\tilde{T}_0+\delta T$ of the initial tensor correspond to perfect fluids. We do this for the sake of clarity in our exposition; however, this is not crucial. What is crucial indeed is that we work with a class of tensors containing the perfect fluids and for which the Cauchy problem would be well posed. For example, Lichnerowicz introduced,[15] a class of fluids he called *holonomous media* whose stress-energy tensor has the form $\tilde{T}=ru^*\otimes u^*+\theta$, where u^* is the 1-form associated to a unitary field u $[\tilde{g}(u,u)=-1]$, r is a positive scalar called *pseudodensity* and where θ is a covariant symmetric 2-tensor whose divergence is the gradient of a function K. Perfect fluids are a particular case of holonomous media with $r=\rho+p$ and $\theta=p\tilde{g}$. If we consider holonomous media whose pseudodensity r and whose function K are both functions of some variable τ (parametrizing both functions), then one can prove that if the function $r(\tau)$ is positive over the whole domain, if $r(\tau)$ and $K(\tau)$ belong to C^1, if the derivative K' is positive and $r'/K'>2$, then the Cauchy problem is well posed for the Cauchy data (g,k,τ,v). In these holonomous media one can work with Cauchy data. Therefore one could consider deformations $\tilde{T}_0+\delta T$ of the initial tensor corresponding to holonomous media, for example.

III. THE NOTION OF LINEAR STABILITY OF THE EINSTEIN EQUATION WITH MATTER

Linear stability of the Einstein equation in the vacuum has been considered in detail in the literature (Refs. 10–13, 1, and 17–19). An interesting bibliography on the subject can be found in Ref. 16. In this case, one begins with an initial Lorentz metric $\tilde{g}_0$ satisfying $G(\tilde{g}_0)=0$ and is interested in metrics $\tilde{g}$ close to $\tilde{g}_0$ which are also solutions of the equation $G(\tilde{g})=0$. Formulated in terms of Cauchy data in appropriate Sobolev spaces, this leads to the following situation: One has a differentiable map $f:X\to Y$ between two Banach spaces, a particular solution $x=x_0$ of the equation $f(x)=0$ is known, and the problem is to find solutions x close to x_0. The classical definition of linearization stability in this case looks as follows: The equation $f(x)=0$ is linearization stable at the point x_0 if for any solution h of the linearized equation $D_{x_0}f(h)=0$ there exists a curve $\lambda\to x(\lambda)$ of solutions of $f(x)=0$ which is tangent to h at x_0. However, the situation in the case of the Einstein equation with matter is not the same. Here, for some $y_0\in Y$, we know $x_0\in X$ such that $f(x_0)=y_0$ and for y close to y_0 we are interested in finding solutions x (close to x_0) of the equation $f(x)=y$. If we take $q=y-y_0$, we would like that for any solution h of the linearized equation $D_{x_0}f(h)=q$, x_0+h would be always close to an exact solution of the equation $f(x)=y$. If this is the case, we will say that the equation $f(x)=y$ is linearization stable at the point x_0. We will make this definition more precise in what follows. Let us observe by now that the difference with the case of vacuum is that we are interested in obtaining not only solutions of $f(x)=y_0$ through linearization for a fixed y_0 (which will be $y_0=0$ in the case of vacuum), but also the solutions of $f(x)=y$ for any y close to y_0. Although we have already given in Ref. 7 a correct definition of linearization stability for this case we shall give here a more simple and clear version.

Definition 1: Let $f:U\to Y$ be a continuously differentiable map of an open set U in a Banach space X to a Banach space Y. Let $x_0\in U$ and $y_0=f(x_0)$. For any $q\in Y$ consider

$$H_q=\{x\in U \text{ solution of } f(x)=y_0+q\},$$

$$L_q=\{x\in U: x=x_0+h,\quad h \text{ solution of } D_{x_0}f(h)=q\}.$$

Let $\mathcal{K}$ be a closed vector subspace of Y. We will say that the equation $f(x)=y_0+q$ is linearization stable at x_0 in the direction of the subspace $\mathcal{K}$ if there exist a neighborhood V of the origin in $\mathcal{K}$,

a neighborhood W of the origin in $L=\ker D_{x_0}f$, a neighborhood U' of x_0, $U'\subset U$, and continuously differentiable maps φ and ψ,

$$\begin{array}{cccc} \mathcal{K}\times L & U & \mathcal{K}\times L & U \\ \cup & \cup & \cup & \cup \end{array}$$

$$\varphi: V\times W \longrightarrow U' \quad \varphi: V\times W \longrightarrow U'$$

such that for any $q\in V$ the maps

$$\varphi_q: W \longrightarrow H_q\cap U', \quad \psi_q: W \longrightarrow L_q\cap U',$$

$$z \longrightarrow \varphi(q,z), \quad z \longrightarrow \psi(q,z)$$

are differentiable bijections having differentiable inverses (that is, they are respective parametrizations of $H_q\cap U'$ and $L_q\cap U'$) satisfying $\varphi_0(0)=x_0$ and $\psi_0(0)=x_0$. Moreover, for any $q\in V$ and any $z\in W$ the error $E_q(z)=\varphi_q(z)-\psi_q(z)$ committed in considering $\psi_q(z)$ instead of $\varphi_q(z)$ satisfies

$$\lim_{(z,q)\to(0,0)} \frac{E_q(z)}{\sqrt{\|z\|^2+\|q\|^2}}=0. \tag{8}$$

Intuitively, this definition consists in demanding that for any $q\in\mathcal{K}$ close to zero the set H_q of solutions of the equation $f(x)=y_0+q$ and the set L_q of solutions of the linearized equation be parametrizable by the same vector space of parameters L in such a way that the error $E_q(z)$ committed in considering the solution of the linearized equation corresponding to the parameter z instead of the true solution corresponding to the same parameter satisfies condition (8). Observe that if the subspace $\mathcal{K}$ of Y is $\mathcal{K}=\{0\}$, Definition 1 coincides with the classical definition for the vacuum.

Definition 2: With the same notations as those in Definition 1, if $f(x)=y$ is linearization stable at the initial point x_0 in the direction of $\mathcal{K}=Y$, we will simply say that it is linearization stable at this point.

In Ref. 7, the following sufficient condition for linearization stability was proved. *If $L=\ker D_{x_0}$ has a topologic supplement and if the map $D_{x_0}f: X\to Y$ is surjective, then f is linearization stable at the point x_0.*

We will have to apply these tools to the particular case where the space X is $X=\mathcal{S}_s(g_0)\times\mathcal{S}_s(k_0)$, the space Y is $Y=\mathcal{F}_{s-2}(\rho_0)\times\Omega_{s-1}(v_0)$, and f is the map Ψ defined in (6). We will take as the degree of regularity s of Sobolev spaces any integer $s>4$. Then all the elements of the Sobolev spaces appearing in our study will be differentiable elements of the class C^1.

IV. STABILITY IN THE CASE OF A HYPERBOLIC RW MODEL

Theorem 1: *Suppose that the initial pair $(\tilde{g}_0,\tilde{T}_0)$ consists of the metric and the stress-energy tensor of a Robertson-Walker (RW) cosmological model, $V=S\times I$, where S is the hyperbolic space $\mathbb{H}_3$. In this case, the Einstein equation is linearization stable.*

Proof: We need only show that the map $D_{(g_0,k_0)}\Psi$ is surjective and has a splitting kernel. Let Φ be the map

$$\Phi: \mathcal{S}_s(g_0)\times\mathcal{S}_s(k_0) \longrightarrow \mathcal{F}_{s-2}(\rho_0)\times\omega_{s-1}(v_0),$$

$$(g,k) \longrightarrow (\mathcal{H}(g,k),\gamma(g,k)).$$

Let J be the map of the space $\mathcal{F}_{s-2}(M)\times\Omega_{s-1}(M)$ into the same space defined by $J=(\mathrm{id},1/(\rho_0+p_0)\mathrm{id})$. By definition (6) of Ψ, we deduce that $D_{(g_0,k_0)}\Psi=-(1/\chi)J\circ D_{(g_0,k_0)}\Phi$. Therefore we need only see that

$$D_{(g_0,k_0)}\Phi:\mathcal{S}_s(M)\times\mathcal{S}_s(M)\to\mathcal{F}_{s-2}(M)\times\Omega_{s-1}(M)$$

is surjective and has a splitting kernel. For simplicity of our notation, we denote the initial pair (g_0,k_0) by (g,k). The map $D_{(g,k)}\Phi$ is calculated in Ref. 7. It is clear that $D_{(g,k)}\Phi=D_{(g,k)}\mathcal{H}\times D_{(g,k)}\gamma$. If we set $g'=g+h$, $k'=k+K$ and take the linear part in (h,K) of the expressions $\mathcal{H}(g',k')$ and $\gamma(g',k')$, we obtain the formulas for $D_{(g,k)}\mathcal{H}$ and $D_{(g,k)}\gamma$ as functions of the variables (h,K) appearing at the end of p. 5128 in Ref. 7. Since the k corresponding to the initial model is $k=2Cg$, where $C=\dot{\zeta}(t_0)/\zeta(t_0)$, and the Ricci tensor of g is $2cg/\zeta(t_0)^2$, where c is the constant curvature of the model (-1 for the hyperbolic space, but we make no assumptions over c by the moment), these expressions are

$$D_{(g,k)}\mathcal{H}(h,K)=\frac{1}{8}\left[\left(16C^2+\frac{8c}{\zeta(t_0)^2}\right)\mathrm{tr}(h)-8C\,\mathrm{tr}(K)-4\nabla^i\nabla^j h_{ij}+4\nabla^i\nabla_i\,\mathrm{tr}(h)\right],$$

$$D_{(g,k)}\gamma(h,K)_i=\tfrac{1}{2}[\nabla^j K_{ij}-\partial_i\,\mathrm{tr}(K)+2C\partial_i\,\mathrm{tr}(h)-2C\nabla^j h_{ji}]. \tag{9}$$

We are now interested in those pairs (h,K) having the form $h=g\tau$, $K=-2L_Yg+2(\mathrm{div}\,Y)g+2C\tau g$, where τ and Y are a function and a vector field on M. By substituting in (9) these expressions for h and K, we will have the following expressions for $D_{(g,k)}\mathcal{H}$ and for $D_{(g,k)}\gamma$ as functions of the variables τ, Y:

$$D_{(g,k)}\mathcal{H}(Y,\tau)=\left(\frac{3c}{\zeta^2(0)}\tau-2C\,\mathrm{div}\,Y-\Delta\tau\right),$$

$$D_{(g,k)}\gamma(Y,\tau)=(\delta L_Yg), \tag{10}$$

where as usual $\Delta\tau$ denotes $-\nabla^i\nabla_i\tau$ (the Laplace operator of τ) and δL_Yg denotes the 1-form whose components are $(\delta L_Yg)_i=-\nabla^j(L_Yg)_{ij}$ (the operator δ is the Hodge operator, applied here to a symmetric 2-tensor). In order to prove surjectivity of $D_{(g,k)}\Phi$, we use the following result whose proof can be found in the Appendix.

Theorem 2: *For any real number $q\geqslant 0$, the following two maps,*

$$\mathcal{F}_s(\mathbb{H}_3)\to\mathcal{F}_{s-2}(\mathbb{H}_3),\quad \mathcal{X}_s(\mathbb{H}_3)\to\Omega_{s-2}(\mathbb{H}_3),$$

$$\tau\to\Delta\tau+q\tau,\quad Y\to\delta L_Yg,$$

are isomorphisms [$\mathcal{X}_s(\mathbb{H}_3)$ *denotes here the Sobolev space of degree of regularity s of vector fields over the hyperbolic space* $\mathbb{H}_3$].

We will use this theorem for proving surjectivity of $D_{(g,k)}\Phi$. Given $(f,\omega)\in\mathcal{F}_{s-2}(M)\times\Omega_{s-2}(M)$, there exists, by Theorem 2, $Y\in\mathcal{X}_s(M)$ such that $\delta L_Yg=\omega$. By the same theorem, there exists $\tau\in\mathcal{F}_s(M)$ such that

$$\Delta\tau+\frac{3}{\zeta(t_0)^2}\tau=-2C\,\mathrm{div}\,Y-f.$$

By (10), we will then have (taking into account that now $c=-1$)

$$(D_{(g,k)}\Phi)(\tau,Y)=((D_{(g,k)}\mathcal{H})(\tau,Y),(D_{(g,k)}\gamma)(\tau,Y))=(f,\omega).$$

We need only see that the kernel of $D_{(g,k)}\Phi$ has a topological supplement. For any pair (h,K), consider the only pair (h',K') satisfying $h'=2g\tau$, $K'=-2L_Yg+2\,\mathrm{div}(Y)g+2C\tau g$ such that $(D_{(g,k)}\Phi)(h,K)=(D_{(g,k)}\Phi)(h',K')$ [it is unique since $D_{(g,k)}\Phi$ is an isomorphism over the pairs (h',K')]. Then

$$(h,K) = (h - h', K - K') + (h', K')$$

gives the required splitting. □

V. NOT SIMPLY CONNECTED RW MODELS

In this section, we will assume that the initial pair $(\tilde{g}_0, \tilde{T}_0)$ consists of the metric and the stress-energy tensor of a Robertson-Walker model, $V = S \times I$, where $(S, \hat{g})$ is a complete Riemannian manifold of constant sectional curvature. We will restrict here to the case where S is compact of curvature $\leqslant 0$ (since the compact case of curvature >0 is the sphere already studied). If the curvature is zero, S will be a plate torus, $S = \mathbb{R}^3/\Gamma$, where Γ is a group of translations. If the curvature is negative, we have $S = \mathbb{H}_3/\Gamma$, where Γ is a certain discrete subgroup of isometries of $\mathbb{H}_3$. For these models, we have the following.

Theorem 3: *If the initial pair $(\tilde{g}_0, \tilde{T}_0)$ corresponds to a RW model, $V = S \times I$, where S is a plate torus, then there exists no closed vector subspace $\mathcal{K}$ of $\mathcal{F}_{s-2}(\rho_0) \times \Omega_{s-1}(0)$ such that the map*

$$\Psi : \mathcal{S}_s(g_0) \times \mathcal{S}_s(k_0) \to \mathcal{F}_{s-2}(\rho_0) \times \Omega_{s-1}(0)$$

defined in (6) is linearization stable at the initial pair (g_0, k_0) in the direction of $\mathcal{K}$ (observe that in RW models we have $v_0 = 0$). However, if the initial pair corresponds to a RW model, $V = S \times I$, where S is a compact, complete, orientable Riemannian manifold of negative constant curvature, then Ψ is linearization stable at the initial pair.

Proof: By Definition 1, if $f : U \to Y$ is linearization stable at a point $x_0 \in U$ in the direction of a certain closed vector subspace of Y, the set $\{x \in U$: solving $f(x) = y_0 + q\}$ is a differentiable manifold whose parametrization is given by Definition 1. In particular, taking $q = 0$, the set $\{x \in U$: solving $f(x) = y_0\}$ is a differentiable manifold. We will apply this to the map Ψ when y_0 is the initial pair $(\rho_0, 0)$. In order to prove instability, it will be sufficient to prove that the set $\{(g,k)$ fulfilling $\Psi(g,k) = (\rho_0, 0)\}$ is not a differentiable manifold. Since, by (5) and (4), we have $H(g_0, \rho_0, 0) = (g_0, -\rho_0, 0)$, it follows from the definition of Ψ given in (6) that the above set is the set of pairs (g,k) such that $F(g,k) = -\rho_0$, $X(g,k) = 0$. Therefore the instability will be proved if we check that the set $\{(g,k)$ such that $\Phi(g,k) = (-\chi\rho_0, 0)\}$ is not a differentiable manifold.

Let us change variables according to $(g,k) \to (g,p)$, where $p = k - (\mathrm{tr}_g k)g$ and let us express Φ using variables (g,p),

$$\Phi : (g,p) \to (\mathcal{H}(g,p), \gamma(g,p)).$$

Let $D_{(g_0,p_0)}\Phi$ be the linear map tangent to Φ at the initial pair (g_0, p_0). As we have already done in the preceding section, we denote for brevity the initial pair (g_0, p_0) by (g,p) and by (g', p') the pairs close to (g,p). Set $g' = g + h$, $p' = p + P$. This is the same notation as that on pp. 5134 and 5135 of Ref. 8. The linear map $D_{(g,p)}\Phi$ induces a map

$$D_{(g,p)}\Phi : \mathcal{S}_\infty(M) \times \mathcal{S}_\infty(M) \to \mathcal{F}_\infty(M) \times \Omega_\infty(M). \tag{11}$$

If M is compact (which is the case we consider now), following Ref. 8 we introduce a scalar product $\langle\ ,\ \rangle$ on $\mathcal{S}_\infty(M) \times \mathcal{S}_\infty(M)$ defined by

$$\langle (h,P), (h',P') \rangle = \int_M (h,P)_x \cdot (h',P')_x \, \mathrm{d}v,$$

where $\mathrm{d}v$ is the volume element in M and $(h,P)_x . (h',P')_x$ is the inner product defined for each $x \in M$ by the formula

$$(h,P)_x \cdot (h',P')_x = g^{ir}(x) g^{js}(x) [h_{ir}(x) h'_{js}(x) + P_{ir}(x) + P'_{js}(x)].$$

In a similar way, $\mathcal{F}_\infty(M) \times \Omega_\infty(M)$ is endowed with the scalar product

$$\langle (f,Y),(f',Y')\rangle = 4\int_M f(x)f'(x)\mathrm{d}v + 4\int_M g^*(Y,Y')_x\,\mathrm{d}v,$$

where g^* is the scalar product induced by g over 1-forms. The map (11) has an adjoint with respect to these scalar products

$$(D_{(g,p)}\Phi)^*:\mathcal{F}_\infty(M)\times\Omega_\infty(M)\longrightarrow \mathcal{S}_\infty(M)\times\mathcal{S}_\infty(M),$$

$$(f,Y)\longrightarrow (A(f,Y),B(f,Y))$$

which induces a map between the corresponding Sobolev spaces. The expressions for $D_{(g,p)}\Phi$, $D^2_{(g,p)}\Phi$, and $(D_{(g,p)}\Phi)^*$ are given by formulas (3), (4), and (6) in Ref. 8, p. 5133. In order to apply these formulas, one should recall that in a RW model one has $k=2Cg$ with $C=\dot{\zeta}(t_0)/\zeta(t_0)$, $p=k-\mathrm{tr}_g(k)g=-4Cg$, $\mathcal{R}(g)=2cg/\zeta(t_0)^2$, where $c=0,1,-1$ is the constant curvature of the model. One should also take into account that $\gamma(g,p)=\chi X(\rho_0,0)=0$. Then formula (6) in Ref. 8 giving $(A,B)=(D_{(g,p)}\Phi)^*(f,Y)$ yields

$$A(f,Y)=\left(8C^2+\frac{4c}{\zeta^2(0)}\right)fg-4CL_Yg-2\,\mathrm{Hess}(f)-2(\Delta f)g,$$

$$B(f,Y)=2Cfg-L_Yg. \tag{12}$$

It is proved in Ref. 8, p. 5133, that if $\mathcal{C}=\{(g',k')$ satisfying $\Phi(g',k')=-(\chi\rho_0,0)\}$ is a differentiable manifold, then

$$\langle (D^2_{(g,p)}\Phi)(h,P),(f,Y)\rangle = 0, \tag{13}$$

for all $(f,Y)\in\mathcal{F}_\infty(M)\times\Omega_\infty(M)$ belonging to $\mathrm{Ker}(D_{(g,p)}\Phi)^*$ and all (h,P) belonging to $\mathrm{Ker}\,D_{(g,p)}\Phi$. Therefore in order to see that $\mathcal{C}$ is not a differentiable manifold, it will suffice to find $(h,P)\in\mathrm{Ker}\,D_{(g,p)}\Phi$ and $(f,Y)\in\mathrm{Ker}(D_{(g,p)}\Phi)^*$ which fail to satisfy (13). For this purpose, we take a pair (f,Y) having $f=0$ and Y to be a Killing vector field. Then (12) implies that $(0,Y)\in\mathrm{Ker}(D_{(g,p)}\Phi)^*$. By the same argument as that in Ref. 8, p. 5135, one can readily obtain

$$\langle (D^2_{(g,p)}\Phi)(h,P),(0,Y)\rangle = -\int_M(\nabla_Y h\cdot P)\mathrm{d}v - 2\int_M Y^i\nabla_r(h^{rs}P_{is})\mathrm{d}v. \tag{14}$$

Take an atlas on the torus $\mathbb{T}_3=\mathbb{R}^3/\Gamma$ where the coordinates of any local chart are induced by the canonical coordinates of $\mathbb{R}^3$ (coordinate changes will be given by translations). In these coordinates, $\hat{g}_{ij}=\delta_{ij}$ and $\partial_i=\partial/\partial x^i$ are Killing fields. Denote by x, y, z the three coordinates x^1, x^2, x^3 and take $Y=\partial_x$, $h=\partial_x\otimes\partial_y+\partial_y\otimes\partial_x$, $P=x(\partial_x\otimes\partial_y+\partial_y\otimes\partial_x)-z(\partial_y\otimes\partial_z+\partial_z\otimes\partial_y)$. Then h and P have zero trace and divergence. This makes (h,P) belong to $\mathrm{Ker}\,D_{(g,p)}\Phi$, as one can see by applying formula (13) in Ref. 8, p. 5136, to this concrete pair (h,P) and taking into account that $\nabla_i\nabla_j h^{ij}=0$. In fact,

$$\nabla_i\nabla_j h^{ij}=\partial_i(\nabla_j h^{ij})-\Gamma^m_{ij}\nabla_m h^{ij}+\Gamma^i_{im}\nabla_j h^{mj}+\Gamma^j_{im}\nabla_j h^{mi}.$$

The second and fourth terms are opposed. Thus $\nabla_i\nabla_j h^{ij}=0$ because $\mathrm{div}(h)=0$.

On the other hand, one has $\nabla_Y h=0$. Therefore the first integral in (14) equals zero. Calculating the second term in (14) we have

$$Y^i\nabla_r(h^{rs}P_{is})=Y^i\nabla_1(h^{12}P_{i2})+Y^i\nabla_2(h^{21}P_{i1})=Y^1\nabla_1(h^{12}P_{12})=\nabla_1P_{12}=\partial_x(x)=1.$$

Then

$$\int_{\mathbb{T}_3} Y^i \nabla_r (h^{rs} P_{is}) \mathrm{d}v = \mathrm{vol}(\mathbb{T}_3) \neq 0.$$

This proves the first part of the theorem.

Let us now consider the case of a RW model, $V = S \times I$, where S is a compact complete orientable Riemannian manifold of constant negative curvature. By the Berger-Ebin theorem,[3] if one of the two operators $D_{(g,p)}\Phi$ or $(D_{(g,p)}\Phi)^*$ has injective symbol, then the following splitting holds:

$$\Omega_{s-1} \times \mathcal{F}_{s-2} = \mathrm{Image}(D_{(g,p)}\Phi) \oplus \ker(D_{(g,p)}\Phi)^*.$$

Then the fact that $D_{(g,p)}\Phi$ is surjective is equivalent to the fact that $(D_{(g,p)}\Phi)^*$ is injective. For each $x \in M$ and $\xi \in T_x(M)^*$, we calculate the symbol of $(D_{(g,p)}\Phi)^*$,

$$\sigma_L(x,\xi): T_x(M) \times \mathbb{R} \longrightarrow (S_2 \times S_2),$$

$$(X, f) \longrightarrow (\alpha, \beta).$$

In order to find expressions for α and β we apply formulas (12) recalling that $(L_X g)_{ij} = \nabla_i X_j + \nabla_j X_i$, $(\mathrm{Hess}\, f)_{ij} = \nabla_i \nabla_j f$ i $\Delta f = -\nabla^i \nabla_i f$. Then we have

$$\alpha_{rs} = -2\xi_r \xi_s f - 2\xi \cdot \xi f g_{rs},$$

$$\beta_{rs} = -\xi_r X_s - \xi_s X_r.$$

This implies that $\mathrm{tr}(\alpha) = g^{rs}\alpha_{rs} = -8(\xi.\xi)f$. If we assume that $\alpha = 0$, then $\mathrm{tr}(\alpha) = 0$. Since $\xi.\xi \neq 0$, this implies $f = 0$. Since $\xi \neq 0$, we can take a basis $\{\omega^1, \omega^2, \omega^3\}$ in $T_x(M)^*$ such that $\omega^1 = \xi$. The components of ξ in this basis are $\xi = (1,0,0)$. If we assume that $\beta = 0$, then $\xi_r X_s = -\xi_s X_r$. By applying this to $r = 1$ and $s = 2,3$ we obtain $X_2 = X_3 = 0$. Finally, $0 = \beta_{11} = -2\xi_1 X_1 = -2X_1$. Therefore the symbol $\sigma_L(x,\xi)$ is injective. Let us now prove that $(D_{(g,p)}\Phi)^*$ is also injective. If we take $B = 0$ in (12), we obtain $L_X g = 2Cfg$. Substitute this into the expression of $A(f,X)$ to obtain

$$A(f,X) = -\frac{4}{\zeta(t_0)^2} fg - 2\,\mathrm{Hess}(f) - 2(\Delta f) g.$$

If $A = 0$, then $\mathrm{tr}(A) = 0$ and the above expression implies that $\Delta f + (3/\zeta(t_0)^2) f = 0$. Then perform scalar multiplication of this equality by f to obtain

$$\langle \mathrm{d}f, \mathrm{d}f \rangle + \frac{3}{\zeta(t_0)^2} \langle f, f \rangle = 0.$$

This implies that $f = 0$. Coming back to (12) we obtain $L_X g = 0$. This means that the kernel of $(D_{(g,p)}\Phi)^*$ is formed by those pairs which are written as $(0,X)$, where X is a Killing field. On the other hand, any compact Riemannian manifold whose Ricci tensor is negative definite does not have Killing vectors.[4] This means that our operator $(D_{(g,p)}\Phi)^*$ is injective. □

APPENDIX: OPERATORS RELATED TO THE LAPLACIAN OF THE HYPERBOLIC SPACE

In this Appendix, we prove two theorems (Theorem 4 and Theorem 5) which enable us to obtain the two isomorphisms in Theorem 2. The proofs rely heavily on the results and the techniques in Ref. 9 (see also Ref. 6).

1. Notations

The manifold M we will work with will be the n-dimensional hyperbolic space $\mathbb{H}_n$. We will always denote by g the Riemannian metric on M of constant curvature -1. We will denote the components of the covariant differential $\nabla\alpha$ of a p-tensor α by $\nabla_i\alpha_{i_1\cdots i_p}$. The notation $\nabla^{(k)}$ is used for the kth iterate of ∇.

If α and β are two covariant tensors of order p indicate by (α,β) the function defined coordinatewise by $\alpha^{i_1\cdots i_p}\beta_{i_1\cdots i_p}$. This definition does not depend on the coordinates chosen. Write $\langle\alpha,\beta\rangle=\int_M(\alpha,\beta)\mathrm{d}v$, where $\mathrm{d}v$ is the volume element. Naturally, $\langle\alpha,\beta\rangle$ is only defined when the above integral is finite. Denote $|\alpha|=\sqrt{(\alpha,\alpha)}$ and $\|\alpha\|=\sqrt{\langle\alpha,\alpha\rangle}$.

The metric adjoint ∇^* of ∇ is defined by $\langle\nabla\alpha,\beta\rangle=\langle\alpha,\nabla^*\beta\rangle$ for any p-tensor α and any $(p+1)$-tensor β belonging to the class C^∞ and having compact support. The operator $\Delta_R=\nabla^*\nabla$ is called the rough Laplacian and is defined over all covariant p-tensors. It follows from the definition that Δ_R is self-adjoint and positive. The coordinatewise expressions of ∇^* and Δ_R are the following:

$$(\nabla^*\alpha)_{i_1\cdots i_{p-1}}=-\nabla^j\alpha_{ji_1\cdots i_{p-1}},\quad (\Delta_R\alpha)_{i_1\cdots i_p}=-\nabla^j\nabla_j\alpha_{i_1\cdots i_p}.$$

Observe that the expression of ∇^* coincides with that of the Hodge operator δ (the metric adjoint of the exterior differential d). The latter, however, is defined only over p-forms (antisymmetrics), while ∇^* is defined over all covariant p-tensors. Observe also that the operator denoted by δ in Theorem 2 is in fact the operator ∇^* since it operates over a 2-tensor (not antisymmetric).

We will say that a p-covariant tensor α over M is of L^2 type if its coefficients in any local chart are measurable functions with respect to the measure $\mathrm{d}v$ and, moreover, the function $|\alpha|$ belongs to $L^2(\mathrm{d}v)$, that is, $\|\alpha\|<+\infty$. Denote by $L^2_p(M)$ the space of p-forms belonging to L^2.

Given $\omega\in L^2_p(M)$, we will say that ω has a generalized or weak kth order covariant derivative $\nabla^{(k)}\omega$ in L^2 if for any covariant tensor β of order $p+k$ belonging to the class C^∞ and having compact support we have

$$|\langle\omega,(\nabla^*)^{(k)}\beta\rangle|\leqslant C\|\beta\|$$

for some positive constant C. Then the map $\beta\to\langle\omega,(\nabla^*)^{(k)}\beta\rangle$ is continuous and therefore there exists a unique element $f\in L^2_{p+k}(M)$ such that $\langle\omega,(\nabla^*)^{(k)}\beta\rangle=\langle f,\beta\rangle$. This f is taken to be $\nabla^{(k)}\omega$.

Let $L^2_{p,s}(M)$ be the space of L^2 p-forms ω such that $\nabla^{(k)}\omega$ belongs to L^2 for $k\leqslant s$. We will assume that this space is endowed with the norm

$$\|\omega\|_s=\left(\sum_{k=0}^{s}\|\nabla^{(k)}\omega\|^2\right)^{1/2}.$$

Denote by $\mathcal{D}_p(M)$ the space of C^∞ p-forms on M having compact support. It is clear that $\mathcal{D}_p(M)\subset L^2_{p,s}(M)$. Denote by $H^s_p(M)$ the closure of $\mathcal{D}_p(M)$ in $L^2_{p,s}(M)$. Aubin proved,[2] under certain assumptions, including the case we are interested in (curvature -1 and complete manifold) that one has $H^s_p(M)=L^2_{p,s}(M)$, that is, the density of $\mathcal{D}_p(M)$ in $L^2_{p,s}(M)$. An explicit proof of this fact can be found for our case in Ref. 9.

2. Proof of the first isomorphism in Theorem 2

Given $q\in\mathbb{R}$, $q\geqslant 0$ and $p\in\mathbb{Z}$, $0\leqslant p\leqslant n$, consider the operator $T=\Delta_R+qI$ (where I is the identity operator) acting on p-forms in $M=\mathbb{H}_n$. For any integer $s\geqslant 0$, T yields a continuous operator $T:H^{s+2}_p(M)\to H^s_p(M)$. If $\alpha\in H^{s+2}_p$, $T\alpha$ should be interpreted in the sense of weak derivatives. That is, $T\alpha$ is the unique element in L^2 such that

$$\langle T\alpha,\beta\rangle=\langle\alpha,T^*\beta\rangle=\langle\alpha,T\beta\rangle$$

for any $\beta\in\mathcal{D}_p$ (T is self-adjoint and $T^*=T$). The fact that $\alpha\in H^{s+2}_p$ implies that $T\alpha\in H^s_p$. We shall prove the following.

Theorem 4: *The linear map*

$$T{:}H_p^{s+2} \to H_p^s, \tag{A1}$$

where $T=\Delta_R+qI$, *is a topological isomorphism.*

If we take into account that the rough Laplacian Δ_R coincides with the De Rham Laplacian $\Delta=\delta d$ on functions, the first isomorphism in Theorem 2 appears to be a particular case of Theorem 4 with $p=0$ and $n=3$. The proof of Theorem 4 we will carry out in the sequel (for any p, not only for $p=0$) will give us a hint on the proof of the second isomorphism in Theorem 2.

Proof: As we have already said, (A1) is continuous. The fact that (A1) is injective follows from the fact that $T\alpha$ belongs to $H_p^0=L_p^2$ for $\alpha \in H_p^{s+2} \subset H_p^2$ and we have

$$\langle T\alpha, \alpha\rangle = \langle \Delta_R\alpha, \alpha\rangle + q\langle \alpha, \alpha\rangle. \tag{A2}$$

Since $\langle \Delta_R\alpha, \alpha\rangle > 0$ if $\alpha \neq 0$ and since $q \geqslant 0$, $T\alpha=0$ implies $\alpha=0$. Therefore we should check that (A1) is surjective and has a continuous inverse. The latter is written as $\|\alpha\|_{s+2} \leqslant \text{const}\|T\alpha\|_s \,\forall\, \alpha \in H_p^{s+2}$. We will prove both statements by induction on s. Let us begin with $s=0$.

Consider the scalar product B in H_p^1 defined by the formula

$$B[\alpha,\beta] = \langle \nabla\alpha, \nabla\beta\rangle + q\langle \alpha, \beta\rangle.$$

Denote by $\|\ \|_B$ the norm induced by this scalar product. If $q>0$, this norm coincides with the Sobolev norm $\|\ \|_1$, if $q=0$, this, however, is not the case. Let us see that $T{:}H_p^2 \to H_p^0$ is surjective. Given $f \in H_p^0$, we would like to find $\omega \in H_p^2$ such that $T\omega=f$. Consider the liner map $L{:}H_p^1 \to \mathbb{R}$ defined by $L(\beta)=\langle f, \beta\rangle$. It is well known that we have $\|\beta\| \leqslant \text{const}\|\nabla\beta\|$ in the hyperbolic space (see Ref. 9, p. 155). Therefore

$$|L(\beta)| = |\langle f, \beta\rangle| \leqslant \|f\|\,\|\beta\| \leqslant \text{const}\,\|f\|\,\|\nabla\beta\| \leqslant \text{const}\,\|f\|\,\|\beta\|_B.$$

This means that L is continuous with respect to the topology in H_p^1 induced by $\|\ \|_B$. Therefore there exists a unique $\omega \in H_p^1$ such that $L(\beta)=B[\omega,\beta] \,\forall\, \beta$. That is,

$$\langle \nabla\omega, \nabla\beta\rangle + q\langle \omega, \beta\rangle = \langle f, \beta\rangle.$$

If $\beta \in \mathcal{D}_p$, this is equivalent to

$$\langle \omega, (\Delta_R + qI)\beta\rangle = \langle f, \beta\rangle$$

which is the same as saying that $T\omega=f$ (T operates over L^2 elements in the sense of weak derivatives). It remains to see that $\omega \in H_p^2$. Since ω and $\Delta_R\omega$ belong to $L_p^2=H_p^0$, Lemma 3.3 in Ref. 9 implies that $\omega \in H_p^2$. We should still check that $\|\alpha\|_2 \leqslant \text{const}\,\|T\alpha\| \,\forall\, \alpha \in H_p^2$. Proposition 2.3 in Ref. 9 gives $\|\alpha\|_2 \leqslant \text{const}\,\|\Delta_R\alpha\|$. Then

$$\|\alpha\|_2 \leqslant \text{const}\,\|\Delta_R\alpha\| = \text{const}\,\|T\alpha - q\alpha\| \leqslant \text{const}\,\|T\alpha\| + \text{const}\,\|\alpha\|. \tag{A3}$$

Now (A2) implies that $\|\alpha\|^2 \leqslant \text{const}\langle T\alpha, \alpha\rangle \leqslant \text{const}\|T\alpha\|\,\|\alpha\|$. Therefore $\|\alpha\| \leqslant \text{const}\,\|T\alpha\|$. Substitute this into (A2) to obtain $\|\alpha\|_2 \leqslant \text{const}\,\|T\alpha\|$ as is required.

Take any $s>0$ and let us prove that (A1) is surjective. Given $f \in H_p^s \subset H_p^{s-1}$, the induction assumption implies that there exists a unique $\omega \in H_p^{s+1} \subset H_p^s$ satisfying $T\omega=f$. We would like to see that $\omega \in H_p^{s+2}$. Since $f=T\omega=\Delta_R\omega+q\omega$, we have $\Delta_R\omega \in H_p^s$, because ω and f belong to H_p^s, and Lemma 3.3 in Ref. 9 gives $\omega \in H_p^{s+2}$. It remains to prove the inequality $\|\alpha\|_{s+2} \leqslant \text{const}\,\|T\alpha\|_s \,\forall\, \alpha \in H_p^{s+2}$. By Proposition 2.3 in Ref. 9, we have $\|\alpha\|_{s+2} \leqslant \text{const}\,\|\Delta_R\alpha\|_s$. Therefore it will suffice to check that $\|\Delta_R\alpha\|_s \leqslant \text{const}\,\|T\alpha\|_s$. We will also prove this fact by induction on s. We have

$$\begin{aligned}\|\Delta_R\alpha\|_s = \|T\alpha - q\alpha\|_s \leqslant \|T\alpha\|_s + q\|\alpha\|_s \leqslant \|T\alpha\|_s + q\|\alpha\|_{s+1} \leqslant \|T\alpha\|_s + \text{const}\,\|\Delta_R\alpha\|_{s-1}\\ \leqslant (\text{by induction hyp.}) \leqslant \|T\alpha\|_s + \text{const}\,\|T\alpha\|_{s-1} \leqslant \text{const}\,\|T\alpha\|_s.\end{aligned}$$

□

3. A sketch of the proof of the second isomorphism in Theorem 2

Denote by F the operator defined on vector fields X by $F(X)=\nabla^* L_X g$, where $L_X g$ denotes the Lie derivative of g with respect to the vector field X. If we identify vector fields with 1-forms through the metric, F is an operator transforming 1-forms into 1-forms. In a local chart, $L_X g$ is expressed as follows:

$$(L_X g)_{ij} = \nabla_i X_j + \nabla_j X_i.$$

Then

$$F(X)_j = (\nabla^* L_X g)_j = -\nabla^i \nabla_i X_j - \nabla^i \nabla_j X_i = (\Delta_R X)_j - (\nabla^i \nabla_j - \nabla_j \nabla^i) X_i - \nabla_j \nabla^i X_i.$$

Since the curvature of the hyperbolic space is constant and equals -1, the Ricci identity reads $(\nabla^i \nabla_j - \nabla_j \nabla^i) X_i = -(n-1) X_j$. On the other hand, the term $-\nabla_j \nabla^i X_i$ is $(\mathrm{d}\delta X)_j$. Therefore

$$F = \Delta_R + (n-1)I + \mathrm{d}\delta.$$

This formula shows that F is a self-adjoint and positive operator. For any integer $s \geqslant 0$, F yields a continuous operator $F: H_1^{s+2}(M) \to H_1^s(M)$.

Theorem 5: *For any $s \in \mathbb{Z}$, $s \geqslant 0$, the map*

$$F: H_1^{s+2}(M) \to H_1^s(M). \tag{A4}$$

is a topological isomorphism.

The second isomorphism in Theorem 2 is a particular case of this theorem when the dimension n of the hyperbolic space is 3. If the expression of F did not contain the term $\mathrm{d}\delta$, Theorem 5 would be a particular case of Theorem 4 (with $p=1$). The term $\mathrm{d}\delta$ appearing in the expression of F is an order 2 operator and therefore makes the situation a bit more complex. We will prove Theorem 5 following the same method as that used in the proof of Theorem 4. In order to adapt that method to the present situation, we need a result similar to Lemma 3.3 in Ref. 9 for the operator $G = \Delta_R + \mathrm{d}\delta$. To be exact, we need the following proposition.

Proposition 1: If $\alpha \in H_1^s(M)$ and $G(\alpha) = \Delta_R \alpha + \mathrm{d}\delta\alpha \in H_1^s(M)$, then $\alpha \in H_1^{s+2}(M)$ and there exist positive constants such that for all α under the above assumptions the following inequalities hold:

(a) $\|\Delta_R \alpha\|_s \leqslant \mathrm{const}\, \|G(\alpha)\|_s$,
(b) $\|\alpha\|_{s+2} \leqslant \mathrm{const}\, \|G(\alpha)\|_s$.

With this proposition, the proof of Theorem 5 simply follows the lines of that of Theorem 4. Indeed we have the following.

Proof of Theorem 5: Since

$$\langle F(\alpha), \alpha \rangle = \langle \nabla \alpha, \nabla \alpha \rangle + \langle \delta\alpha, \delta\alpha \rangle + (n-1)\langle \alpha, \alpha \rangle, \tag{A5}$$

for all $\alpha \in H_1^{s+2}$, it is clear that $F(\alpha)=0$ implies $\alpha=0$. In order to see that (A4) is surjective and has a continuous inverse, the induction on s is used. Let us check the case of $s=0$. Consider the scalar product B in H_1^1 defined by

$$B[\alpha, \beta] = \langle \nabla \alpha, \nabla \beta \rangle + \langle \delta\alpha, \delta\beta \rangle + (n-1)\langle \alpha, \beta \rangle.$$

Given $f \in H_1^0$, in order to find $\omega \in H_1^2$ satisfying $F(\omega) = f$, we consider the map $L: H_1^1 \to \mathbb{R}$ defined by $L(\beta) = \langle f, \beta \rangle$. Here, we have $|L(\beta)| \leqslant \mathrm{const}\, \|f\|\, \|\beta\|_B$ as has already happened in Theorem 4 proving that L is continuous with respect to the norm $\|\ \|_B$. Therefore there exists a unique $\omega \in H_1^1$ such that $L(\beta) = B[\omega, \beta]$. Then

$$\langle \nabla \omega, \nabla \beta \rangle + \langle \delta\omega, \delta\beta \rangle + (n-1)\langle \alpha, \beta \rangle = \langle f, \beta \rangle.$$

If $\beta \in \mathcal{D}_1$, this is written as $\langle \omega, F(\beta) \rangle = \langle f, \beta \rangle$ meaning that $F(\omega) = f$ (since F is self-adjoint and operates on L^2 elements in the sense of weak derivatives). Since ω and $G(\omega)$ belong to $L_1^2 = H_1^0$,

Proposition 1 implies that $\omega \in H_1^2$ as is required. The inequality $\|\alpha\|_2 \leqslant \text{const}\,\|F(\alpha)\|$ for all $\alpha \in H_1^2$ is then proved in the following way:

$$\|\alpha\|_2 \leqslant (\text{by (b) in Proposition 1}) \leqslant \text{const}\,\|G(\alpha)\| = \text{const}\,\|F(\alpha) - (n-1)\alpha\| \leqslant \text{const}\,(\|F(\alpha)\| + \|\alpha\|). \tag{A6}$$

By (A5), we have $\|\alpha\|^2 \leqslant \text{const}\,\langle F(\alpha), \alpha\rangle \leqslant \text{const}\,\|F(\alpha)\|\,\|\alpha\|$. Then one has $\|\alpha\| \leqslant \text{const}\,\|F(\alpha)\|$. Substitute this into (A6) to obtain the required inequality. The proof by induction corresponding to any $s>0$ is also carried out following the lines of the proof of Theorem 4. ■

Observe that we have used only inequality (b) among inequalities (a) and (b) in Proposition 1. In fact, (a) is only required to prove (b).

The only thing we need to complete the proof of Theorem 5 is to prove Proposition 1.

4. Preliminary material for the proof of Proposition 1

Before proceeding to the proof of Proposition 1 we will need the following lemma.

Lemma 1: For any integer $s \geqslant 0$ there exists a constant such that

$$\|\Delta_R \omega\|_s \leqslant \text{const}\,\|G(\omega)\|_s$$

for any $\omega \in H_1^{s+2}(M)$.

In order to prove this lemma, we will need the following two lemmas.

Lemma 2: Let (M,g) be an n-dimensional Riemannian manifold of constant curvature K. If α is a covariant p-tensor and σ is a permutation of the indices $\{1,\ldots,s\}$, let $\sigma(\nabla^{(s)}\alpha)$ be the covariant $(p+s)$-tensor defined as follows:

$$\sigma(\nabla^{(s)}\alpha)(X_1,\ldots,X_s,Y_1,\ldots,Y_p) = (\nabla^{(s)}\alpha)(X_{\sigma(1)},\ldots,X_{\sigma(s)},Y_1,\ldots,Y_p).$$

Then, given an integer $s \geqslant 2$ and a permutation σ of the indices $\{1,\ldots,s\}$, there exists a constant such that the formula

$$\|\sigma(\nabla^{(s)}\alpha) - \nabla^{(s)}\alpha\| \leqslant \text{const}\,\|\alpha\|_{s-2},$$

holds for any covariant p-tensor α having compact support and belonging to the class C^∞.

Proof: Let τ be the transposition of the two successive indices k and $k+1$,

$$\tau:\{1,\ldots,k,k+1,\ldots,s\} \to \{1,\ldots,k+1,k,\ldots,s\}$$

(any permutation can be expressed as a product of transpositions). In a local chart, the components of $\tau(\nabla^{(s)}\alpha)$ will be

$$\tau(\nabla^{(s)}\alpha)_{i_1\cdots i_s j_1\cdots j_p} = \nabla_{i_1}\cdots\nabla_{i_{k+1}}\nabla_{i_k}\cdots\nabla_{i_s}\alpha_{j_1\cdots j_p}.$$

Since the curvature K is constant, the Ricci identity implies that for any r-tensor β

$$(\nabla_i\nabla_j - \nabla_j\nabla_i)\beta_{i_1\cdots i_r} = K(g_{ii_1}\beta_{ji_2\cdots i_r} - g_{ji_1}\beta_{ii_2\cdots i_r}) + \cdots + K(g_{ii_r}\beta_{i_1\cdots i_{r-1}j} - g_{ji_r}\beta_{i_1\cdots i_{r-1}i}).$$

Set

$$\beta_{i_{k+2}\cdots i_s j_1\cdots j_p} = \nabla_{i_{k+2}}\cdots\nabla_{i_s}\alpha_{j_1\cdots j_p}.$$

Taking into account that the covariant differential of the metric tensor g equals zero one obtains that $(\tau(\nabla^{(s)}\alpha) - \nabla^{(s)}\alpha)_{i_1\cdots i_s j_1\cdots j_p}$ will be the sum of $2((s-k-1)+p)$ terms having the form

$$\pm K g_{\sigma(i_1)\sigma(i_2)}\nabla_{\sigma(i_3)}\cdots\nabla_{\sigma(i_s)}\alpha_{j_1\cdots j_p},$$

where σ is a certain permutation of the indices $\{1,\ldots,s\}$. Since all of these terms contain $s-2$ derivatives, the norm $\|\sigma(\nabla^{(s)}\alpha) - \nabla^{(s)}\alpha\|$ will be controlled by $\|\alpha\|_{s-2}$. □

Lemma 3: Let (M,g) be a Riemannian manifold of constant curvature K. Given an integer

$s \geqslant 0$, there exists a constant such that the formula

$$\|(\nabla^{(s)}\Delta_R - \Delta_R\nabla^{(s)})\alpha\| \leqslant \text{const}\,\|\alpha\|_s$$

holds for any covariant p-tensor α having compact support and belonging to the class C^∞.

This lemma is readily obtained from the previous lemma.

Proof of Lemma 1: Since $\mathcal{D}_1(M)$ is dense in $H_1^{s+2}(M)$ and the operators Δ_R and G are continuous in the Sobolev norm, it is enough to prove the inequality for $\omega \in \mathcal{D}_1(M)$. We proceed by induction on s. In order to obtain the required result for $s=0$, we must prove that $\|\Delta_R\omega\| \leqslant \text{const}\,\|(\Delta_R + \mathrm{d}\delta)\omega\|$. We have

$$\langle(\Delta_R + \mathrm{d}\delta)\omega, (\Delta_R + \mathrm{d}\delta)\omega\rangle \geqslant \langle\Delta_R\omega, \Delta_R\omega\rangle + 2\langle\mathrm{d}\delta\omega, \Delta_R\omega\rangle. \tag{A7}$$

In hyperbolic spaces of constant curvature $=-1$ the rough Laplacian is related to the De Rham Laplacian $\Delta = \mathrm{d}\delta + \delta\mathrm{d}$ by $\Delta_R = \Delta + (n-1)I$. Then

$$\langle\mathrm{d}\delta\,\omega, \Delta_R\omega\rangle = \langle\mathrm{d}\delta\,\omega, \mathrm{d}\delta\,\omega + \delta\,\mathrm{d}\omega + (n-1)\omega\rangle = \langle\mathrm{d}\delta\,\omega, \mathrm{d}\delta\,\omega\rangle + \langle\mathrm{d}\delta\,\omega, \delta\,\mathrm{d}\omega\rangle + (n-1)\langle\mathrm{d}\delta\,\omega, \omega\rangle.$$

Among the three terms on the right-hand side, the first term and the third term are $\geqslant 0$ while the second equals zero since

$$\langle\mathrm{d}\delta\,\omega, \delta\,\mathrm{d}\omega\rangle = \langle\mathrm{d}\,\mathrm{d}\delta\omega, \mathrm{d}\omega\rangle = 0.$$

So $<\mathrm{d}\delta\omega, \Delta_R\omega>$ is $\geqslant 0$. Then (A7) implies

$$\|(\Delta_R + \mathrm{d}\delta)\omega\|^2 = \langle(\Delta_R + \mathrm{d}\delta)\omega, (\Delta_R + \mathrm{d}\delta)\omega\rangle \geqslant \langle\Delta_R\omega, \Delta_R\omega\rangle = \|\Delta_R\omega\|^2,$$

which is the required result.

Assume that the result is proved for $s-1$ and let us prove it for s. We have

$$\langle\nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega, \nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega\rangle \geqslant \langle\nabla^{(s)}\Delta_R\omega, \nabla^{(s)}\Delta_R\omega\rangle + 2\langle\nabla^{(s)}\,\mathrm{d}\delta\omega, \nabla^{(s)}\Delta_R\omega\rangle. \tag{A8}$$

In order to complete the proof, we need the following lemma describing the last term in the above inequality.

Lemma 4: $<\nabla^{(s)}\mathrm{d}\delta\,\omega, \nabla^{(s)}\Delta_R\omega>$ can be expressed as the sum of two terms $T_1 + T_2$, where $T_1 \geqslant 0$ and T_2 satisfy the inequality

$$|T_2| \leqslant \text{const}\,\|\omega\|_{s+1}^2.$$

Assume that Lemma 4 is proved and let us see how the proof of Lemma 1 is completed. Inequality (A8) implies

$$\langle\nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega, \nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega\rangle \geqslant \langle\nabla^{(s)}\Delta_R\omega, \nabla^{(s)}\Delta_R\omega\rangle + 2T_2.$$

Then we obtain

$$\begin{aligned}\langle\nabla^{(s)}\Delta_R\omega, \nabla^{(s)}\Delta_R\omega\rangle &\leqslant \langle\nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega, \nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega\rangle + 2|T_2| \\ &\leqslant \|\nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega\|^2 + \text{const}\,\|\omega\|_{s+1}^2.\end{aligned}$$

By Proposition 2.3 in Ref. 9, we have $\|\omega\|_{s+1} \leqslant \text{const}\,\|\Delta_R\omega\|_{s-1}$ and, by the induction assumption, $\|\Delta_R\omega\|_{s-1} \leqslant \|(\Delta_R + \mathrm{d}\delta)\omega\|_{s-1}$. Hence

$$\|\nabla^{(s)}\Delta_R\omega\|^2 \leqslant \|\nabla^{(s)}(\Delta_R + \mathrm{d}\delta)\omega\|^2 + \text{const}\,\|(\Delta_R + \mathrm{d}\delta)\omega\|_{s-1}^2 \leqslant \text{const}\,\|(\Delta_R + \mathrm{d}\delta)\omega\|_s^2$$

which proves Lemma 1. □

It remains to prove Lemma 4.

Proof of Lemma 4: The local scalar product of $\nabla^{(s)}\,\mathrm{d}\delta\,\omega$ by $\nabla^{(s)}\Delta_R\omega$ is

$$(\nabla^{(s)}\,\mathrm{d}\delta\,\omega,\nabla^{(s)}\Delta_R\omega)=(\nabla_{i_1}\cdots\nabla_{i_s}\nabla_i\nabla^k\omega_k)(\nabla^{i_1}\cdots\nabla^{i_s}\nabla^r\nabla_r\omega^i). \tag{A9}$$

Permute the derivatives $\nabla_{i_1}\cdots\nabla_{i_s}\nabla_i$ in the first factor in order to place ∇_i first. We obtain

$$\nabla_{i_1}\cdots\nabla_{i_s}\nabla_i\nabla^k\omega_k=\nabla_i\nabla_{i_1}\cdots\nabla_{i_s}\nabla^k\omega_k+A(\omega)_{ii_1\cdots i_s},$$

where $A(\omega)$ is a globally defined $(s+1)$-tensor. By substituting into (A9), we have

$$(\nabla^{(s)}\,\mathrm{d}\delta\,\omega,\nabla^{(s)}\Delta_R\omega)=(\nabla_i\nabla_{i_1}\cdots\nabla_{i_s}\nabla^k\omega_k)(\nabla^{i_1}\cdots\nabla^{i_s}\nabla^r\nabla_r\omega^i)+(A(\omega),\nabla^{(s)}\Delta_R\omega).$$

Adding a divergence we pass the derivation ∇_i from the first factor to the second factor,

$$(\nabla^{(s)}\,\mathrm{d}\delta\,\omega,\nabla^{(s)}\Delta_R\omega)=-(\nabla_{i_1}\cdots\nabla_{i_s}\nabla^k\omega_k)(\nabla_i\nabla^{i_1}\cdots\nabla^{i_s}\nabla^r\nabla_r\omega^i)+\mathrm{div}+(A(\omega),\nabla^{(s)}\Delta_R\omega). \tag{A10}$$

As before

$$\nabla_i\nabla_{i_1}\cdots\nabla_{i_s}\nabla^r\nabla_r\omega^i=\nabla_{i_1}\cdots\nabla_{i_s}\nabla_i\nabla^r\nabla_r\omega^i+B(\omega)_{i_1\cdots i_s},$$

where $B(\omega)$ is a globally defined s-tensor. Substitute this result into (A10) to obtain

$$\begin{aligned}(\nabla^{(s)}\,\mathrm{d}\delta\,\omega,\nabla^{(s)}\Delta_R\omega)=&-(\nabla_{i_1}\cdots\nabla_{i_s}\nabla^k\omega_k)(\nabla^{i_1}\cdots\nabla^{i_s}\nabla_i\nabla^r\nabla_r\omega^i)+(\nabla^{(s)}\delta\omega,B(\omega))\\&+\mathrm{div}+(A(\omega),\nabla^{(s)}\Delta_R\omega).\end{aligned} \tag{A11}$$

Finally, passing the Laplacian $\Delta_R=-\nabla^r\nabla_r$ in front of all,

$$\nabla^{i_1}\cdots\nabla^{i_s}\nabla_i\nabla^r\nabla_r\omega^i=\nabla^r\nabla_r\nabla^{i_1}\cdots\nabla^{i_s}\nabla_i\omega^i+C(\omega)_{i_1\cdots i_s},$$

where $C(\omega)$ is a globally defined s-tensor. By (25), we obtain

$$\begin{aligned}(\nabla^{(s)}\,\mathrm{d}\delta\,\omega,\nabla^{(s)}\Delta_R\omega)=&-(\nabla_{i_1}\cdots\nabla_{i_s}\nabla^k\omega_k)(\nabla^r\nabla_r\nabla^{i_1}\cdots\nabla^{i_s}\nabla_i\omega^i)+(\nabla^{(s)}\delta\omega,C(\omega))+(\nabla^{(s)}\delta\omega,B(\omega))\\&+\mathrm{div}+(A(\omega),\nabla^{(s)}\Delta_R\omega).\end{aligned}$$

Integrating over the whole manifold,

$$\langle\nabla^{(s)}\,\mathrm{d}\delta\,\omega,\nabla^{(s)}\Delta_R\omega\rangle=\langle\nabla^{(s)}\delta\omega,\Delta_R\nabla^{(s)}\delta\omega\rangle+\langle\nabla^{(s)}\delta\omega,C(\omega)+B(\omega)\rangle+\langle A(\omega),\nabla^{(s)}\Delta_R\omega\rangle.$$

Define now

$$T_1=\langle\nabla^{(s)}\delta\omega,\Delta_R\nabla^{(s)}\delta\omega\rangle,\quad T_2=\langle\nabla^{(s)}\delta\omega,C(\omega)+B(\omega)\rangle+\langle A(\omega),\nabla^{(s)}\Delta_R\omega\rangle.$$

It is clear that $T_1\geqslant 0$. It remains to see that T_2 satisfies the inequality in the lemma. It is not difficult to check, using Lemmas 2 and 3, that every term appearing in the definition of T_2 satisfies this inequality. □

5. Proof of Proposition 1

We first give a naive and simple proof of Proposition 1.

A naive proof: Lemma 1 assures that for any integer $s\geqslant 0$ there exists a constant such that

$$\|\Delta_R\omega\|_s\leqslant\mathrm{const}\,\|G(\omega)\|_s \tag{A12}$$

for any $\omega\in\mathcal{D}_1$. Since the space $\mathcal{D}_1$ is dense in H_1^s, one should expect that inequality (A12) also holds for $\alpha\in H_1^s$. Therefore, since $G(\alpha)\in H_1^s$ means that $\|G(\alpha)\|_s$ is finite, (A12) implies that $\|\Delta_R\alpha\|_s$ is finite and then $\Delta_R\alpha\in H_1^s$. Now Lemma 3.3 in Ref. 9 states that $\alpha\in H_1^{s+2}$ and $\|\alpha\|_{s+2}\leqslant\mathrm{const}\,\|\Delta_R\alpha\|_s$. Then inequality (A12) enables us to write $\|\alpha\|_{s+2}\leqslant\mathrm{const}\,\|G(\alpha)\|_s$. □

Nevertheless, the fact that (A12) holds for $\omega\in\mathcal{D}_1$ does not imply in a simple way that it will also hold for $\alpha\in H_1^s$. In fact, Lemma 1 assures only that (A12) holds for $\alpha\in H_1^{s+2}$. The more

difficult task is to show that $\nabla^{s+1}\alpha$ and $\nabla^{s+2}\alpha$ belong to L^2. For this purpose a delicate regularization argument in hyperbolic space is needed. In order to obtain a rigorous proof of Proposition 1, we first deal with a particular case of it.

A particular case of Proposition 1. Proposition 1 holds for 1-forms α belonging to the class C^∞.

Proof of the particular case: We start with a sequence $\{\chi_m\}$ of C^∞-functions on M with compact support, $\chi_m \in \mathcal{D}(M)$, (an *exhausting sequence*) such that $\chi_m \nearrow 1$ and $|\nabla^{(k)}\chi_m(x)| \leqslant c_k$ for all m and all $x \in M$. In Ref. 9 is verified that such a sequence really exists when $M=\mathbb{H}_n$. Also it is proved that given a C^∞ form $\alpha \in H_1^s(M)$ then $\chi_m\alpha \to \alpha$ in $H_1^s(M)$.

As usual we use induction on s. Let us begin with the case $s=0$. Let $\alpha_m=\chi_m\alpha$. We have $\alpha_m \in \mathcal{D}_1(M)$. Since $G=\Delta_R+\mathrm{d}\delta=\nabla^*\nabla+\mathrm{d}\delta$,

$$\langle G(\alpha_m), \alpha_m\rangle = \langle \nabla\alpha_m, \nabla\alpha_m\rangle + \langle \delta\alpha_m, \delta\alpha_m\rangle.$$

This implies

$$\langle \nabla\alpha_m, \nabla\alpha_m\rangle \leqslant \langle G(\alpha_m), \alpha_m\rangle.$$

Develop each member of the previous inequality. Since $\nabla\alpha_m=\nabla(\chi_m\alpha)=(\nabla\chi_m)\otimes\alpha+\chi_m\nabla\alpha$, the pointwise inner product $(\nabla\alpha_m, \nabla\alpha_m)$ is

$$\begin{aligned}(\nabla\alpha_m, \nabla\alpha_m) &= (\nabla\chi_m\otimes\alpha, \nabla\chi_m\otimes\alpha) + (\chi_m\nabla\alpha, \chi_m\nabla\alpha) + 2(\nabla\chi_m\otimes\alpha, \chi_m\nabla\alpha)\\ &= |\mathrm{d}\chi_m|^2|\alpha|^2 + \chi_m^2|\nabla\alpha|^2 + 2(\mathrm{d}\chi_m\otimes\alpha, \chi_m\nabla\alpha),\end{aligned}$$

On the other hand, we have

$$\begin{aligned}G(\chi_m\alpha) = \chi_m G(\alpha) + (\Delta_R\chi_m)\alpha - C_{23}(\nabla^{(2)}\chi_m\otimes\alpha) - 2C_{12}(\mathrm{d}\chi_m\otimes\nabla\alpha)\\ - C_{13}(\mathrm{d}\chi_m\otimes\nabla\alpha) + (\delta\alpha)\mathrm{d}\chi_m,\end{aligned} \tag{A13}$$

where, for example, C_{12} means the operator obtained at each point $x \in M$ by contraction through the metric between the first and second factor of $\otimes^3 T_x(M)^*$. The above formula can be proved by making a trivial coordinatewise calculation. Then

$$\begin{aligned}(G(\alpha_m), \alpha_m) = (G(\chi_m\alpha), \chi_m\alpha) = \chi_m^2(G(\alpha), \alpha) + \chi_m\Delta_R\chi_m(\alpha, \alpha) - \chi_m(\nabla^{(2)}\chi_m, \alpha\otimes\alpha)\\ - 2\chi_m(\nabla\alpha, \mathrm{d}\chi_m\otimes\alpha) - \chi_m(\nabla\alpha, \alpha\otimes\mathrm{d}\chi_m) - \chi_m\delta\alpha(\mathrm{d}\chi_m, \alpha).\end{aligned}$$

The inequality $\langle\nabla\alpha_m, \nabla\alpha_m\rangle \leqslant \langle G(\alpha_m), \alpha_m\rangle$ writes

$$\begin{aligned}\int \{|\mathrm{d}\chi_m|^2|\alpha|^2 + |\chi_m|^2|\nabla\alpha|^2 + 4\chi_m(\mathrm{d}\chi_m\otimes\alpha, \nabla\alpha)\}\mathrm{d}v\\ \leqslant \int \{|\chi_m|^2(G(\alpha), \alpha) + \chi_m\Delta_R\chi_m|\alpha|^2 - \chi_m(\nabla^{(2)}\chi_m, \alpha\otimes\alpha)\\ - \chi_m(\nabla\alpha, \alpha\otimes\mathrm{d}\chi_m) - \chi_m\delta\alpha(\mathrm{d}\chi_m, \alpha)\}\mathrm{d}v.\end{aligned}$$

We know that χ_m, $|\mathrm{d}\chi_m|$, $|\nabla^{(2)}\chi_m|$, and $|\Delta_R\chi_m|$ are bounded (for all $x \in M$) by a constant independent of m, hence

$$|(\mathrm{d}\chi_m\otimes\alpha, \nabla\alpha)| \leqslant \text{const}\,|\alpha||\nabla\alpha|, \quad |(\nabla^{(2)}\chi_m, \alpha\otimes\alpha)| \leqslant \text{const}\,|\alpha|^2,$$

$$|\delta\alpha||(\mathrm{d}\chi_m, \alpha)| \leqslant \text{const}\,|\alpha||\nabla\alpha|.$$

Let I_m be the integral $\int_M |\chi_m|^2|\nabla\alpha|^2\,\mathrm{d}v$, (finite because $\chi_m \in \mathcal{D}$). Since $\alpha, G(\alpha) \in H_p^0(M)$ the global products $\langle G\alpha, \alpha\rangle$ and $\langle\alpha, \alpha\rangle$ are finite, and hence one deduces from the previous inequality that

$$I_m \leqslant \text{const}\left(\langle G(\alpha),\alpha\rangle + \langle \alpha,\alpha\rangle + \int |\chi_m||\alpha||\nabla\,\alpha|\mathrm{d}v\right). \tag{A14}$$

The Schwarz inequality asserts that

$$\int |\chi_m||\alpha|\,|\nabla\,\alpha|\mathrm{d}v \leqslant \left\{\int |\chi_m|^2|\nabla\,\alpha|^2\mathrm{d}v\right\}^{1/2}\left\{\int |\alpha|^2\mathrm{d}v\right\}^{1/2} = I_m^{1/2}\|\alpha\|.$$

If x, y, and ε are real numbers, we have

$$(y-2\varepsilon x)^2 = y^2 + 4\varepsilon^2x^2 - 4\varepsilon xy \geqslant 0,$$

whence

$$xy \leqslant \varepsilon x^2 + \frac{y^2}{4\varepsilon}.$$

For a fixed ε, this inequality holds for all x, y. This means that

$$I_m^{1/2}\|\alpha\| \leqslant \varepsilon I_m + \frac{\|\alpha\|^2}{4\varepsilon}.$$

For a fixed ε, this holds for all I_m and $\|\alpha\|$. Then we obtain

$$\int_M \chi_m|\alpha||\nabla\,\alpha|\mathrm{d}v \leqslant \varepsilon I_m + \frac{\|\alpha\|^2}{4\varepsilon}.$$

Take ε such that $0<\varepsilon<1$. Then expression (A14) yields (by collecting in the first member all the terms containing I_m)

$$I_m = \int |\chi_m|^2|\nabla\,\alpha|^2\,\mathrm{d}v \leqslant \text{const}\,(\langle G(\alpha),\alpha\rangle + \|\alpha\|^2).$$

But $\langle G(\alpha),\alpha\rangle \leqslant \|G(\alpha)\|\,\|\alpha\| \leqslant (1/2)(\|G(\alpha)\|^2+\|\alpha\|^2)$. Therefore

$$I_m = \int |\chi_m|^2|\nabla\,\alpha|^2\,\mathrm{d}v \leqslant \text{const}\,(\|\alpha\|^2 + \|G(\alpha)\|^2).$$

By the dominated convergence theorem [which can be applied since both $\|\alpha\|$ and $\|G(\alpha)\|$ are finite because α and $G(\alpha)$ belong to $H_1^0(M)=L_1^2(M)$], we have that $\int|\nabla\alpha|^2\,\mathrm{d}v$ is finite. That is, $\nabla\alpha \in L_1^2(M)$. Then $\alpha\in H_1^1(M)$. Therefore we know that the sequence $\{\alpha_m\}$ converges to α in the norm of $H_1^1(M)$. In particular, $\{\nabla\alpha_m\}$ converges to $\nabla\alpha$ in $L_1^2(M)$. Since, on the other hand, $G(\alpha)\in L_1^2(M)$, $\{G(\alpha_m)\}$ converges to $G(\alpha)$ in $L_1^2(M)$. We can then pass to the limit in inequality $\langle\nabla\alpha_m,\nabla\alpha_m\rangle \leqslant \langle G(\alpha_m),\alpha_m\rangle$ to obtain

$$\langle\nabla\alpha,\nabla\,\alpha\rangle \leqslant \langle G(\alpha),\alpha\rangle.$$

This implies that

$$\|\nabla\,\alpha\|^2 \leqslant \|G(\alpha)\|\,\|\alpha\| \leqslant (1/2)(\|G(\alpha)\|^2+\|\alpha\|^2).$$

From expression (A13) one obtains

$$\|G(\alpha_m)\|^2 \leqslant \text{const}\,(\|G(\alpha)\|^2+\|\alpha\|^2).$$

This inequality will enable us to establish that $\Delta_R\alpha\in L_1^2(M)$. The inequality in Lemma 1 gives

$$\|\Delta_R\alpha_m\|^2 \leqslant \text{const}\,\|G\alpha_m\|^2 \leqslant \text{const}\,(\|G\alpha\|^2 + \|\alpha\|^2).$$

As one can easily check

$$\Delta_R\alpha_m = \Delta_R(\chi_m\alpha) = (\Delta_R\chi_m)\alpha + \chi_m\Delta_R\alpha - 2C_{12}(d\chi_m \otimes \nabla\,\alpha), \tag{A15}$$

and therefore

$$\|\chi_m\Delta_R\alpha\| \leqslant \|\Delta_R\alpha_m\| + \|\alpha\Delta_R\chi_m\| + 2\|d\chi_m \otimes \nabla\,\alpha\|.$$

Since $\{\chi_m\}$ is an exhausting sequence and $(\|G(\alpha)\|^2+\|\alpha\|^2)$ controls the norm $\|\nabla\alpha\|$ as well as $\|\Delta_R\alpha_m\|$, we have

$$\int \chi_m^2|\Delta_R\alpha|^2\,\mathrm{d}v \leqslant \text{const}\,(\|G(\alpha)\|^2 + \|\alpha\|^2).$$

Then, by the dominated convergence theorem, the integral $\int|\Delta_R\alpha|^2\,\mathrm{d}v$ is finite. That is, $\Delta_R\alpha \in L_1^2(M)$. Therefore we can apply Lemma 3.3 in Ref. 9 giving $\alpha\in H_1^2(M)$ and $\|\alpha\|_2 \leqslant \text{const}\,\|\Delta_R\alpha\|$. Once we know that $\Delta_R\alpha\in L_1^2(M)$, we can take limits in the inequality $\|\Delta_R\alpha_m\| \leqslant \text{const}\,\|G(\alpha_m)\|$ and obtain $\|\Delta_R\alpha\|\leqslant\text{const}\,\|G(\alpha)\|$. Combining this results with earlier ones, we have

$$\|\alpha\|_2 \leqslant \text{const}\,\|\Delta_R\alpha\| \leqslant \text{const}\,\|G(\alpha)\|,$$

completing the proof of the lemma for $s=0$.

Let us suppose that the particular case of Proposition 1 holds for $s-1$. Since α and $G(\alpha)$ belong to $H_1^s(M)\subset H_1^{s-1}(M)$ then by the induction assumption, $\alpha\in H_1^{s+1}(M)$, $\|\alpha\|_{s+1} \leqslant \text{const}\,\|G(\alpha)\|_{s-1}$, and $\|\Delta_R\alpha\|_{s-1}\leqslant\text{const}\,\|G(\alpha)\|_{s-1}$. Next we try to control $\|\Delta_R\alpha_m\|_s$ by the finite quantities $\|G(\alpha)\|_s$ and $\|\alpha\|_{s+1}$. Write (A13) ordering the terms by the order of derivatives of α they contain,

$$G(\chi_m\alpha)_i = \chi_m G(\alpha)_i - 2(\nabla_k\chi_m)(\nabla^k\alpha_i) - (\nabla_k\chi_m)(\nabla_i\alpha^k) - (\nabla^k\alpha_k)(\nabla_i\chi_m) + (\Delta_R\chi_m)\alpha_i - (\nabla_i\nabla_k\chi_m)\alpha^k.$$

Then

$$\nabla^{(s)}G(\alpha_m) = \nabla^{(s)}G(\chi_m\alpha) = \chi_m\nabla^{(s)}G(\alpha) + T,$$

where T denotes the sum of terms containing less than s derivatives of $G(\alpha)$ and of terms containing less than $s+2$ derivatives of α. The local inner product of $\nabla^{(s)}G(\alpha_m)$ by itself will be

$$(\nabla^{(s)}G(\alpha_m),\nabla^{(s)}G(\alpha_m)) = \chi_m^2(\nabla^{(s)}G(\alpha),\nabla^{(s)}G(\alpha)) + (T,T) + 2\chi_m(\nabla^{(s)}G(\alpha),T).$$

Integrate this expression over M to obtain

$$\begin{aligned}\|\nabla^{(s)}G(\alpha_m)\|^2 &= \int_M |\chi_m|^2|\nabla^{(s)}G(\alpha)|^2\,\mathrm{d}v + \|T\|^2 + 2\int_M |\chi_m|(\nabla^{(s)}G(\alpha),T)\mathrm{d}v \\ &\leqslant \text{const}\,\|\nabla^{(s)}G(\alpha)\|^2 + \|T\|^2 + \text{const}\,|\langle\nabla^{(s)}G(\alpha),T\rangle|.\end{aligned}$$

Since

$$|\langle\nabla^{(s)}G(\alpha),T\rangle| \leqslant \|\nabla^{(s)}G(\alpha)\|\,\|T\| \leqslant \tfrac{1}{2}(\|\nabla^{(s)}G(\alpha)\|^2 + \|T\|^2)$$

and $\|T\|^2\leqslant\text{const}\,(\|\alpha\|_{s+1}^2+\|G(\alpha)\|_{s-1}^2)$ we get

$$\|G(\alpha_m)\|_s^2 = \|\nabla^{(s)}G(\alpha_m)\|^2 + \|G(\alpha_m)\|_{s-1}^2 \leqslant \text{const}\,(\|G(\alpha)\|_s^2 + \|\alpha\|_{s+1}^2).$$

Lemma 1 gives $\|\Delta_R\alpha_m\|_s\leqslant\text{const}\,\|G(\alpha_m)\|_s$. Then

$$\|\Delta_R \alpha_m\|_s^2 \leqslant \text{const}\,(\|G(\alpha)\|_s^2 + \|\alpha\|_{s+1}^2). \tag{A16}$$

Using formula (A13) and applying to $\nabla^{(s)}\Delta_R\alpha_m$ the same argument as that applied to I_m, we conclude that

$$\int |\chi_m|^2 |\nabla^{(s)}\Delta_R\alpha|^2 \, dv \leqslant \text{const}\,(\|\Delta_R\alpha\|_{s-1}^2 + \|G(\alpha)\|_s^2 + \|\alpha\|_{s+1}^2).$$

By the induction assumption, $\|\Delta_R\alpha\|_{s-1}^2 \leqslant \text{const}\,\|G(\alpha)\|_{s-1}^2 \leqslant \text{const}\,\|G(\alpha)\|_s^2$ and $\|\alpha\|_{s+1}^2 \leqslant \text{const}\,\|G(\alpha)\|_{s-1}^2 \leqslant \text{const}\,\|G(\alpha)\|_s^2$. Then

$$\int \chi_m^2 |\nabla^{(s)}\Delta_R\alpha|^2 \, dv \leqslant \text{const}\,\|G(\alpha)\|_s.$$

This proves that $\int |\nabla^{(s)}\Delta_R\alpha|^2 \, dv$ is finite and

$$\int |\nabla^{(s)}\Delta_R\alpha|^2 \, dv \leqslant \text{const}\,\|G(\alpha)\|_s.$$

Hence

$$\|\Delta_R\alpha\|_s^2 = \int |\nabla^{(s)}\Delta_R\alpha|^2 \, dv + \|\Delta_R\alpha\|_{s-1}^2 \leqslant \text{const}\,\|G(\alpha)\|_s^2.$$

Lemma 3.3 in Ref. 9 then gives $\alpha \in H_1^{s+2}(M)$ and

$$\|\alpha\|_{s+2} \leqslant \text{const}\,\|\Delta_R\alpha\|_s \leqslant \text{const}\,\|G(\alpha)\|_s$$

completing the proof. □

Final part of the proof of Proposition 1: We have to approximate forms α in $H_1^s(\mathbb{H}_n)$ with $G(\alpha) \in H_1^s(\mathbb{H}_n)$ by C^∞ forms with the same properties. This is achieved via the hyperbolic regularization (see Ref. 9). There one defines for any $\varepsilon > 0$ the hyperbolic convolution $C_\varepsilon\alpha$ of a form α by

$$(C_\varepsilon\alpha)(x) = \int_{\mathbb{H}^n} \alpha(y) \wedge \star\,\delta_\varepsilon(x,y).$$

Here $\star$ stands for Hodge operator. Each $C_\varepsilon\alpha$ is a C^∞ 1-form on $\mathbb{H}^n$ invariant for all isometries, that is, $C_\varepsilon(\varphi\alpha) = \varphi(C_\varepsilon\alpha)\,\forall\,\varphi \in \text{Iso}(\mathbb{H}_n)$. It is proved that $C_\varepsilon\alpha \in H_1^s(\mathbb{H}_n)$, that

$$\|C_\varepsilon\alpha\|_s \leqslant \text{const}\,\|\alpha\|_s \tag{A17}$$

and that $C_\varepsilon\alpha$ tends to α in $H_1^s(\mathbb{H}_n)$ as $\varepsilon \to 0$.

The operator $G = \Delta_R + d\delta$ in $\mathbb{H}^n$ commutes with all isometries, that is, if φ is an isometry then $G(\varphi^*(\alpha)) = \varphi^*(G(\alpha))$, because all the operators involved are defined in terms of the metric. Then one can show that C_ε commutes with G. Since $\alpha \in H_1^s(\mathbb{H}_n)$, the inequality (A17) gives $C_\varepsilon\alpha \in H_1^s(\mathbb{H}_n)$ for all ε. Since, on the other hand, $G(\alpha) \in H_1^s(\mathbb{H}_n)$, we have in a similar manner that $C_\varepsilon(G(\alpha)) \in H_1^s(\mathbb{H}_n)$. The particular case of Proposition 1 applied to $C_\varepsilon\alpha$ and to $G(C_\varepsilon\alpha) = C_\varepsilon(G(\alpha))$ gives $C_\varepsilon\alpha \in H_1^{s+2}(\mathbb{H}_n)$. Let us prove that (by varying ε) $\{C_\varepsilon\alpha\}$ is a Cauchy sequence in the space $H_1^{s+2}(\mathbb{H}_n)$. For this purpose, we apply the particular case of Proposition 1 to the difference $C_\varepsilon\alpha - C_{\varepsilon'\alpha}$. We have

$$\|C_\varepsilon\alpha - C_{\varepsilon'}\alpha\|_{s+2} \leqslant \text{const}\,\|G(C_\varepsilon\alpha - C_{\varepsilon'}\alpha)\|_s \leqslant \text{const}\,\|C_\varepsilon G(\alpha) - C_{\varepsilon'}G(\alpha)\|_s. \tag{A18}$$

Since $G(\alpha)$ and $C_\varepsilon G(\alpha)$ belong to $H_1^s(\mathbb{H}_n)$ and $C_\varepsilon G(\alpha)$ converges in this space to $G(\alpha)$ as $\varepsilon \to 0$, we have that $\{C_\varepsilon G(\alpha)\}$ is a Cauchy sequence in $H_1^s(\mathbb{H}_n)$ and then (A18) implies that $\{C_\varepsilon\alpha\}$ is also a Cauchy sequence in $H_1^{s+2}(\mathbb{H}_n)$. Since this space is complete, this Cauchy sequence has a

limit $\beta \in H_1^{s+2}(\mathbb{H}_n) \subset H_1^s(\mathbb{H}_n)$. Let us see that this limit coincides with α. Since the convergence in the norm $\| \|_{s+2}$ is stronger than that in the norm $\| \|_s$, β will also be the limit of $\{C_\varepsilon \alpha\}$ in the norm $\| \|_s$. This limit, however, was α. Therefore $\alpha = \beta$ and $\alpha \in H_1^{s+2}(\mathbb{H}_n)$. Finally, by taking limits in the inequalities

$$\|C_\varepsilon \alpha\|_{s+2} \leqslant \text{const} \, \|G(C_\varepsilon \alpha)\|_s = \text{const} \, \|C_\varepsilon G(\alpha)\|_s,$$

$$\|\Delta_R C_\varepsilon \alpha\|_s \leqslant \text{const} \, \|G(C_\varepsilon \alpha)\|_s = \text{const} \, \|C_\varepsilon G(\alpha)\|_s,$$

we obtain

$$\|\alpha\|_{s+2} \leqslant \text{const} \, \|G(\alpha)\|_s,$$

$$\|\Delta_R \alpha\|_s \leqslant \text{const} \, \|G(\alpha)\|_s.$$

(Received 16 May 2005; accepted 27 May 2005; published online 15 July 2005)

We show that the solutions of the Lovelock equations with spherical, planar, or hyperbolic symmetry are locally isometric to the corresponding static Lovelock black hole. As a consequence, these solutions are locally static: they admit an additional Killing vector that can either be space-like or time-like, depending on the position. This result also holds in the presence of an abelian gauge field, in which case the solutions are locally isometric to a charged static black hole. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1960798]

In four-dimensional general relativity, it is well known that the spherically symmetric solutions of Einstein's field equations in the vacuum are locally isometric to the Schwarzschild solution—this is Birkhoff's theorem, see e.g., Ref. 1. As a consequence, these solutions are locally static outside the horizon and a spherically symmetric source does not radiate gravitational waves. In this letter, we extend Birkhoff's theorem to Lovelock gravity.

Lovelock theory is the most general classical theory of gravity leading to second order field equations and conserved energy momentum, in D dimensions. The corresponding field equations without matter sources read[2]

$$\sum_{k=0}^{[(D-1)/2]} \alpha_k \mathcal{E}_{(k)a} = 0, \tag{1}$$

where the brackets stand for the integer part, the α_k are real constants and the $\mathcal{E}_{(k)a}$ (with $a=1,\ldots,D$) are given by

$$\mathcal{E}_{(k)a} = \left(\bigwedge_{l=1}^{k} \Omega^{a_{2l-1}a_{2l}} \right) \wedge \theta^{*}_{aa_1\cdots a_{2k}}, \tag{2}$$

which is of order k in the curvature 2 form $\Omega^a{}_b = \frac{1}{2} R^a{}_{bcd} \theta^c \wedge \theta^d$. Finally, $\theta^{*}_{a_1\cdots a_k}$ is the Hodge dual of $\theta^{a_1} \wedge \cdots \wedge \theta^{a_k}$, the basis of the space of k forms $\Omega^{(k)}(TM)$, and we thus have

$$\theta^{*}_{a_1\cdots a_k} = \frac{1}{(D-k)!} \epsilon_{a_1\cdots a_k a_{k+1}\cdots a_D} \theta^{a_{k+1}} \wedge \cdots \wedge \theta^{a_D}. \tag{3}$$

When $D=4$, Eq. (1) reduces to Einstein equations ($k=1$) with a cosmological constant α_0, whilst for $D=5$, the Gauss–Bonnet term ($k=2$) must be added. For arbitrary D, the static spherically symmetric solutions of (1) were found in Ref. 3 and their extension to planar and hyperbolic symmetry is given in Ref. 4. All these solutions belong to a one parameter family and read

[a)]Electronic mail: robin.zegers@th.u-psud.fr
[b)]UMR 7164 (CNRS, Université Paris 7, CEA, Observatoire de Paris).

$$g = -h(r)dt^2 + \frac{dr^2}{h(r)} + r^2\bar{g}_{(D-2,K)}, \tag{4}$$

where h is given as a root of a polynomial that depends on the Lovelock coupling constants α_k and on the mass parameter μ, and $\bar{g}_{(D-2,K)}$ is the $(D-2)$-dimensional metric with spherical $(K=1)$, planar $(K=0)$ or hyperbolic $(K=-1)$ symmetry and hence with isometry groups $SO(D-1)$, E_{D-2} or $SO(1,D-2)$ respectively. Notice that, in addition to these isometries, the solutions (4) also admit ∂_t as a Killing vector and this can either be space-like when $h<0$ or time-like when $h>0$, so that g is locally static. This family contains static black holes, with one or more horizons.[5] These horizons can be spherical as in the Schwarzschild case, but also planar or hyperbolic, yielding a much richer topology as for topological black holes.[6] Though solutions of the form (4) do not only describe static black holes, we shall refer to them as static Lovelock black hole solutions. Now, we shall prove the following.

Theorem: *The $\mathcal{C}^2$ solutions of the Lovelock field equations without matter (1), with spherical, planar or hyperbolic symmetry are locally isometric to the corresponding static Lovelock black hole solutions (4).*

Before proceeding with the proof, note that this theorem implies that the solutions of (1), with spherical, planar or hyperbolic symmetry are also locally static; by which we mean that they have an additional Killing vector that is locally time-like. In the specific case of Einstein–Gauss–Bonnet gravity, this theorem was already proven in Refs. 7–9.

Proof: We begin with a D-dimensional space-time with spherical, planar or hyperbolic symmetry. We thus consider a Lorentzian manifold (M,g) admitting, respectively, $SO(D-1)$, E_{D-2}, or $SO(1,D-2)$ as an isometry group with $(D-2)$-dimensional space-like orbits Σ. For all point $P \in M$, if Σ_P is the orbit of P, the tangent space T_PM can be decomposed into $T_PM = T_P\Sigma_P \oplus (T_P\Sigma_P)^\perp$. Then, let $\Sigma_P^\perp$ be the set of all the geodesics passing through P that are tangent to $(T_P\Sigma_P)^\perp$. Locally, $\Sigma_P^\perp$ is a two-dimensional submanifold of M that is perpendicular to the orbit Σ_P. Thus, on taking (∂_t, ∂_z) as a coordinate basis of $T\Sigma^\perp$ and making use of the conformal flatness of the two-dimensional submanifold $\Sigma^\perp$, one can write

$$g = A^2(t,z)(-dt^2 + dz^2) + R^2(t,z)\bar{g}_{(D-2,K)}, \tag{5}$$

where $\bar{g}_{(D-2,K)}$ is the metric over the orbits of the corresponding isometry group. Since these orbits are invariant under their isometry group, they are homogeneous and have constant induced curvature

$$\bar{\Omega}^i{}_j = K\bar{\theta}^i \wedge \bar{\theta}_j, \tag{6}$$

where $i,j=1,\ldots,D-2$, $\bar{\theta}^i$ is the orthonormal frame adapted to $\bar{g}_{(D-2,K)}$,

$$\bar{g}_{(D-2,K)} = \delta_{ij}\bar{\theta}^i \otimes \bar{\theta}^j, \tag{7}$$

and $\bar{\theta}^i \wedge \bar{\theta}^j$ is the resulting basis of the space of 2 forms on the orbits, $\Omega^{(2)}(T\Sigma)$. It will be useful to introduce the conformal coordinates

$$u = \frac{z+t}{2} \quad \text{and} \quad v = \frac{z-t}{2}, \tag{8}$$

together with the following parametrization of the metric:

$$g = e^{2\nu(u,v)}(du \otimes dv + dv \otimes du) + B^2(u,v)\bar{g}_{(D-2,K)}. \tag{9}$$

We define the associated orthonormal frame

$$\theta^\mu = e^{\nu(u,v)}du, \tag{10}$$

$$\theta^v = e^{\nu(u,v)}dv, \tag{11}$$

$$\theta^i = B(u,v)\bar{\theta}^i, \tag{12}$$

so that

$$g = 2\theta^{(u} \otimes \theta^{v)} + \delta_{ij}\theta^i \otimes \theta^j. \tag{13}$$

In this basis, indices are raised and lowered using

$$\eta_{ab} = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & \delta_{ij} \end{pmatrix}. \tag{14}$$

Given a torsion-free metric connection ∇, one can define a connection 1 form $\omega^a{}_b$, such that $\omega_{ab}=-\omega_{ba}$ and $d\theta^a=-\omega^a{}_b\wedge\theta^b$. From the latter, it is straightforward to derive the components of the connection 1 form. The curvature 2 form then follows from

$$\Omega^a{}_b = d\omega^a{}_b + \omega^a{}_c \wedge \omega^c{}_b, \tag{15}$$

yielding

$$\Omega^u{}_u = -\Omega^v{}_v = \frac{2\nu_{uv}}{e^{2\nu}}\theta^v \wedge \theta^u, \tag{16}$$

$$\Omega^i{}_u = \frac{1}{Be^{2\nu}}[(B_{uu} - 2B_u\nu_u)\theta^u \wedge \theta^i + B_{uv}\theta^v \wedge \theta^i], \tag{17}$$

$$\Omega^i{}_v = \frac{1}{Be^{2\nu}}[B_{uv}\theta^u \wedge \theta^i + (B_{vv} - 2B_v\nu_v)\theta^v \wedge \theta^i], \tag{18}$$

$$\Omega^i{}_j = \bar{\Omega}^i{}_j - \frac{2B_uB_v}{B^2e^{2\nu}}\theta^i \wedge \theta^j = \frac{K - 2B_uB_ve^{-2\nu}}{B^2}\theta^i \wedge \theta^j, \tag{19}$$

where $f_{u(v)}=\partial_{u(v)}f$. Now, the projection of the u (respectively, v) components of (1) onto θ^*_v (respectively, θ^*_u) yields the integrability conditions

$$P'\left[\frac{K - 2B_uB_ve^{-2\nu}}{B^2}\right](B_{uu} - 2B_u\nu_u) = 0 \tag{20}$$

$$P'\left[\frac{K - 2B_uB_ve^{-2\nu}}{B^2}\right](B_{vv} - 2B_v\nu_v) = 0, \tag{21}$$

where

$$P[X] \equiv \sum_{k=0}^{[(D-1)/2]} \frac{\alpha_k}{(D-2k-1)!}X^k \tag{22}$$

and a prime stands for a derivative with respect to the unique argument of a function. Notice how (20) and (21) factorize as a product of a polynomial, times the integrability conditions one gets from pure Einstein gravity.[10] Up to the possible vanishing of P', Einstein and Lovelock gravities thus obey the same integrability conditions and the theorem will hold. The projection of the u (respectively v) component of (1) onto θ^*_u (respectively θ^*_v) then yields a further equation

$$P\left[\frac{K-2B_uB_ve^{-2\nu}}{B^2}\right]-\frac{2}{(D-1)}P'\left[\frac{K-2B_uB_ve^{-2\nu}}{B^2}\right]\left(\frac{1}{Be^{2\nu}}\left(B_{uv}-2\frac{B_uB_v}{B}\right)+\frac{K}{B^2}\right)=0. \quad (23)$$

Finally, the i component of (1) only projects onto θ_i^* giving

$$(D-1)(D-2)P\left[\frac{K-2B_uB_ve^{-2\nu}}{B^2}\right]-\frac{2}{Be^{2\nu}}P'\left[\frac{K-2B_uB_ve^{-2\nu}}{B^2}\right]\left(\frac{(2D-5)}{B}(Ke^{2\nu}-2B_uB_v)\right.$$
$$\left.+(2D-6)B_{uv}+2B\nu_{uv}\right)+\frac{4}{B^2e^{4\nu}}P''\left[\frac{K-2B_uB_ve^{-2\nu}}{B^2}\right]\left(\left(B_{uv}-2\frac{B_uB_v}{B}+\frac{Ke^{2\nu}}{B}\right)^2\right.$$
$$\left.-(B_{uu}-2B_u\nu_u)(B_{vv}-2B_v\nu_v)\right)=0. \quad (24)$$

Equations (20), (21), (23), and (24) form the full set of Lovelock equations. From the integrability conditions (20) and (21), we distinguish two classes of solutions

- class I for which $P'[(K-2B_uB_ve^{-2\nu})/B^2]=0$ and
- class II for which $P'[(K-2B_uB_ve^{-2\nu})/B^2]\neq 0$.

For class I,

$$K-2B_uB_ve^{-2\nu}=\lambda B^2, \quad (25)$$

where λ is one of the real roots of P' and is thus a function of the α_k. On using Eq. (23), it follows that $P[\lambda]=0$, whilst Eq. (24) is trivially satisfied since (25) implies that

$$\left(B_{uv}-2\frac{B_uB_v}{B}+\frac{Ke^{2\nu}}{B}\right)^2=(B_{uu}-2B_u\nu_u)(B_{vv}-2B_v\nu_v). \quad (26)$$

The solutions thus read

$$g=\frac{2B_uB_v}{K-\lambda B^2}(du\otimes dv+dv\otimes du)+B^2\bar{g}_{(D-2,K)}, \quad (27)$$

where B is an arbitrary function of its two arguments u and v. For all harmonic B, a couple of new coordinates (t,r) can be defined on $\Sigma^\perp$, so that $r=B$ and $dt=(B_u\,du-B_v\,dv)/(K-\lambda B^2)$. In these coordinates, the solutions actually reduce to

$$g=-(K-\lambda r^2)dt^2+\frac{dr^2}{K-\lambda r^2}+r^2\bar{g}_{(D-2,K)}, \quad (28)$$

which is just a spherical, planar or hyperbolic slicing of dS_D or adS_D.[11] The fine-tuning condition $P[\lambda]=0$ must hold, so that a space-time of constant curvature λ is an acceptable solution of the Lovelock equations (1). Birkhoff's theorem thus holds for class I solutions.

For class II, the integrability conditions (20) and (21) yield

$$B(u,v)=H(F(u)+G(v)) \quad \text{and} \quad e^{2\nu(u,v)}=H'F'G', \quad (29)$$

where H, F, and G are three functions that depend only on one argument and a prime denotes the derivative of a function with respect to its single argument. To all functions F and G, one can associate a new set of coordinates $\tilde{u}=F(u)$ and $\tilde{v}=G(v)$ on $\Sigma^\perp$. Further, trading the $(\tilde{u},\tilde{v})$ conformal coordinates for time-like $\tilde{t}=\tilde{u}+\tilde{v}$ and space-like $\tilde{z}=\tilde{u}-\tilde{v}$, the metric can be rewritten as

$$g=2H'(\tilde{z})(-d\tilde{t}^2+d\tilde{z}^2)+H^2(\tilde{z})\bar{g}_{(D-2,K)}, \quad (30)$$

which has a time-like Killing vector $\partial_{\tilde{t}}$ in all neighborhood where $H'(\tilde{z})>0$ and is thus locally static. In particular, setting $r=H(\tilde{z})$, we can put it into the following form:

$$g = -h(r)dt^2 + \frac{dr^2}{h(r)} + r^2 \bar{g}_{(D-2,K)}, \tag{31}$$

where $h(r)=2H'(\tilde{z})$ solves Eq. (23),

$$P\left[\frac{K-h}{r^2}\right] - \frac{1}{D-1}P'\left[\frac{K-h}{r^2}\right]\left(\frac{h'}{r} + \frac{2(K-h)}{r^2}\right) = 0. \tag{32}$$

The latter can be integrated, yielding

$$P\left[\frac{K-h}{r^2}\right] = \frac{\mu}{r^{D-1}}, \tag{33}$$

where μ is a real constant. Let $\Lambda(\alpha_0, \ldots, \alpha_{[(D-1)/2]})$ denote a real root of $P[X]$, as a function of the Lovelock couplings, so that we can write

$$h(r) = K - r^2\Lambda\left(\alpha_0 - \frac{\mu}{r^{D-1}}, \alpha_1, \ldots, \alpha_{[(D-1)/2]}\right). \tag{34}$$

The metric (31), with h given by (34), is the static Lovelock black hole found in Refs. 3 and 4. Birkhoff's theorem thus holds for class II solutions. ■

As we shall now see, this result still holds in the presence of an abelian gauge field that is invariant under the chosen isometry group. Such a gauge field has a 1 form potential $A(u,v) = L(u,v)du + M(u,v)dv$ and therefore

$$F = dA = \frac{M_u - L_v}{e^{2\nu}}\theta^u \wedge \theta^v. \tag{35}$$

This of course implies that $dF=0$. From $d*F=0$, on the other hand, it follows that

$$F = \frac{Q}{B^{(D-2)}}\theta^u \wedge \theta^v, \tag{36}$$

where Q is a real constant. The integrability conditions (20) and (21) are unchanged, but there is no class I solution if $Q \neq 0$. We are thus left with class II, which is still free of any fine-tuning, and for which Eq. (32) becomes

$$P\left[\frac{K-h}{r^2}\right] = \frac{\mu}{r^{D-1}} - \frac{Q^2}{r^{2D-4}} \tag{37}$$

as it is now sourced by the stress-energy of the gauge field. In the end, the metric is still of the form (31), but now, h is given by

$$h(r) = K - r^2\Lambda\left(\alpha_0 - \frac{\mu}{r^{D-1}} + \frac{Q^2}{r^{2D-4}}, \alpha_1, \ldots, \alpha_{[(D-1)/2]}\right). \tag{38}$$

This is the Lovelock analog of the Reissner–Nordstrøm black hole of general relativity.[3,5] Class II solutions are the only solutions of the Lovelock equations, coupled to a non-vanishing abelian gauge field, with spherical, planar, or hyperbolic symmetry and they are locally static.

Though the set of Killing vectors of space times with spherical, planar, or hyperbolic symmetry, *a priori* reduces to the generators of their respective isometry groups $SO(D-1)$, E_{D-2}, or $SO(1,D-2)$, we have shown that the solutions of the Lovelock equations with these symmetries admit an additional Killing vector that enlarges their isometry group, so that they reduce to locally static space times. The static Lovelock black holes therefore span the whole set of solutions of the Lovelock equations without matter or in the presence of an abelian gauge field, with spherical, planar or hyperbolic symmetry.

ACKNOWLEDGMENTS

It is a pleasure to thank Christos Charmousis and Danièle Steer for helpful suggestions and comments. I also thank Stanley Deser for pointing out that the class I solutions also obey Birkhoff's theorem.[11]

We study a two-body problem given by the sum of the Newtonian potential and an anisotropic perturbation that is a homogeneous function of degree $-\beta$, $\beta \geqslant 2$. For $\beta > 2$, the sets of initial conditions leading to collisions/ejections and the one leading to escapes/captures have positive measure. For $\beta > 2$ and $\beta \neq 3$, the flow on the zero-energy manifold is chaotic. For $\beta = 2$, a case we prove integrable, the infinity manifold of the zero-energy level has heteroclinic connections with the collision manifold. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1952580]

I. INTRODUCTION

In the past three centuries, celestial mechanics has stimulated the development of many branches of mathematics.[11,13] This trend continues, and even its most basic question, known as the *two-body problem* or the *Kepler problem*, still attracts the vivid interest of mathematicians and physicists, both in its classical form[1] and in more recent versions.

Among the latter are the problems raised by *quasihomogeneous* potentials, given by the sum of homogeneous functions, and problems set in *anisotropic* spaces, for which the interaction law is different in each direction of the space. For quasihomogeneous problems the terminology and the first qualitative results were introduced in the mid-1990s;[9,12,21] this potential unifies several dynamical laws, including those of Newton, Coulomb, Manev, Schwarzschild, Lennard-Jones, Birkhoff and others. The anisotropic case is more related to physics, and was initiated by Gutzwiller in the 1970s[17,18] for the quantization of classical ergodic systems. Among Gutzwiller's goals was also that of finding connections between classical and quantum mechanics. A combination of the quasihomogeneous and anisotropic aspects shows up in the anisotropic Manev problem, whose dynamics contains classical, quantum and relativistic features.[6,10,14,15]

In the present paper we consider a version of the Kepler problem, which combines two of the above characteristics, isotropy and anisotropy. The potential [see formula (3)] is the sum of the classical Keplerian potential and an anisotropic perturbation, the latter being a homogeneous function of degree $-\beta$, $\beta \geqslant 2$ that depends on a parameter $\mu > 1$ measuring the strength of the anisotropy. This is the first analysis of a *quasihomogeneous* potential that mixes isotropic and anisotropic components. For previously studied problems, all terms have been either isotropic or anisotropic. As we will see, this case has some surprising dynamical properties, often very different from the ones that characterize potentials whose terms are not mixed.

[a)]Electronic mail: diacu@math.uvic.ca
[b)]Electronic mail: epc@xanum.uam.mx
[c)]Electronic mail: msantopr@math.uci.edu

Such mixed potentials can be used to understand the dynamics of satellites around oblate planets or the motion of stars around black holes. Here, however, we are not interested in applications. Our endeavours are restricted to mathematical results.

In Sec. II we introduce the basic notations, the equations of motion, and set into evidence the symmetries of the problem. In Sec. III we begin the study of the case $\beta>2$, define the collision manifold, which is an essential qualitative tool, and perform a geometric study of the flow in the neighborhood of collisions. We classify all collision-ejection orbits and prove that the set of initial conditions leading to them has positive measure. We achieve this while studying the flow on and near the collision manifold in terms of McGehee-type coordinates.

In Sec. IV we investigate the existence of heteroclinic orbits on the collision manifold for potentials with $\mu>1$ and $\beta=2+[2/(1+2k)]$ or $\beta=2+[1/(1+k)]$. The main result of this section is that for an open and dense set of μ values, saddle-saddle connections do not exist on the collision manifold. Section V deals with capture and escape orbits in the zero-energy case. We show that the infinity manifold has two circles of normally hyperbolic equilibria, one attractive and one repelling. This proves the existence of infinitely many capture and escape orbits.

In Sec. VI we consider the case $\beta=2$, which we show to be integrable. Apparently this is quite surprising since the anisotropic Manev problem, which resembles this case except for the anisotropy of the Newtonian term, is nonintegrable.[3,15] But as we will show, the surprise element vanishes once we look at the problem in the larger context of the Hamilton-Jacobi theory. In Sec. VII we study the flow on and near the collision manifold and see that its qualitative behavior is similar to that of the anisotropic Manev problem.

In Sec. VIII we prove the existence of heteroclinic orbits connecting the collision and infinity manifolds in the zero-energy case for $\beta=2$.

In Sec. IX we consider a perturbative approach of the problem. The perturbation function of the Hamiltonian is a homogeneous function of degree $-\beta$ with $\beta>3/2$. We end the paper with Sec. X, in which we apply the Melnikov method to show that for every $\beta\neq 2,3$, the flow on the zero-energy manifold is chaotic.

II. EQUATIONS OF MOTION AND SYMMETRIES

Consider the Hamiltonian

$$H_\beta(\mathbf{q},\mathbf{p}) = \tfrac{1}{2}\mathbf{p}^2 + U_\beta(\mathbf{q}), \tag{1}$$

where $\mathbf{q}=(x,y)$ and $\mathbf{p}=(p_x,p_y)$. The equations of motion are

$$\dot{\mathbf{q}} = \mathbf{p},$$

$$\dot{\mathbf{p}} = -\nabla U_\beta(\mathbf{q}), \tag{2}$$

where U_β is a potential of the form

$$U_\beta(x,y) = -\frac{1}{\sqrt{x^2+y^2}} - \frac{b}{(\mu x^2+y^2)^{\beta/2}}, \tag{3}$$

with the constants $\beta\geqslant 2$, $\mu\geqslant 1$, and $b>0$. The symmetries of (2) are given by the following analytic diffeomorphisms in the extended phase space:

$$\text{Id:}\quad (x,y,p_x,p_y,t)\to(x,y,p_x,p_y,t),$$

$$S_0\text{:}\quad (x,y,p_x,p_y,t)\to(x,y,-p_x,-p_y,-t),$$

$$S_1\text{:}\quad (x,y,p_x,p_y,t)\to(x,-y,-p_x,p_y,-t),$$

$$
\begin{aligned}
S_2&: \quad (x,y,p_x,p_y,t) \to (-x,y,p_x,-p_y,-t),\\
S_3&: \quad (x,y,p_x,p_y,t) \to (-x,-y,-p_x,-p_y,t),\\
S_4&: \quad (x,y,p_x,p_y,t) \to (-x,y,-p_x,p_y,t),\\
S_5&: \quad (x,y,p_x,p_y,t) \to (x,-y,p_x,-p_y,t),\\
S_6&: \quad (x,y,p_x,p_y,t) \to (-x,-y,p_x,p_y,-t),
\end{aligned}
\tag{4}
$$

where Id is the identity. These diffeomorphisms form a group that is isomorphic to $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$.[14,22] Invariance under these symmetries implies that if $\gamma(t)$ is a solution of (2), then also $S_i(\gamma(t))$ is a solution for $i\in\{0,1,2,3,4,5,6\}$.

III. THE COLLISION MANIFOLD FOR $\beta>2$

We will further express the equations of motion in McGehee-type coordinates,[8,20] which are suitable for understanding the motion near collision. The transformations are given step by step as follows. Take

$$
\begin{aligned}
r &= \sqrt{x^2+y^2},\\
\theta &= \arctan\frac{y}{x},\\
\tilde{v} &= r\dot{r} = (xp_x + yp_y),\\
\tilde{u} &= r^2\dot{\theta} = (xp_y - yp_x),
\end{aligned}
\tag{5}
$$

rescale $\tilde{v}$ and $\tilde{u}$ by

$$
v = r^{(\beta-2)/2}\tilde{v}, \quad u = r^{(\beta-2)/2}\tilde{u},
$$

and then rescale the time variable using the transformation

$$
\frac{\mathrm{d}t}{\mathrm{d}\tau} = r^{\beta/2+1}.
$$

The equations of motion take the form

$$
\begin{aligned}
r' &= rv,\\
v' &= \frac{\beta-2}{2}v^2 + r^{\beta-1} + 2hr^{\beta} - \frac{b(\beta-2)}{\Delta^{\beta/2}},\\
\theta' &= u,\\
u' &= \frac{\beta-2}{2}uv + \frac{b\beta(\mu-1)\sin 2\theta}{2\Delta^{(\beta+2)/2}},
\end{aligned}
\tag{6}
$$

where $\Delta=\mu\cos^2\theta+\sin^2\theta$ and the prime denotes differentiation with respect to the independent time variable τ. For simplicity, we keep the same notation for the dependent variables.

In these coordinates, the energy integral $H_\beta=h$ [see Eq. (1)], takes the form

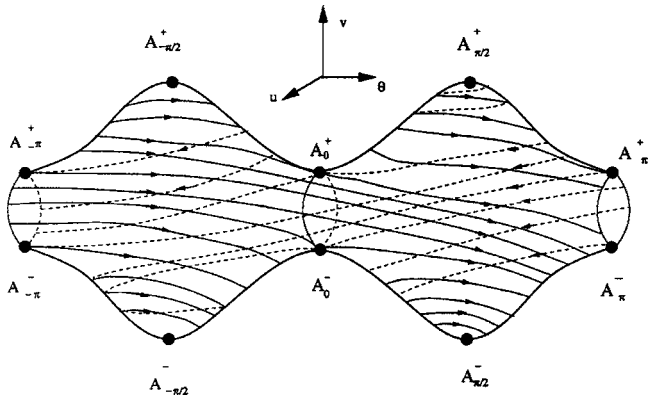

FIG. 1. The collision manifold C for $\beta>2$.

$$u^2+v^2-2r^{\beta-1}-\frac{2b}{\Delta^{\beta/2}}=2hr^{\beta}. \tag{7}$$

We define the collision manifold (see Fig. 1) as

$$C=\left\{ (r,v,\theta,u)\middle|\ r=0,\ u^2+v^2=\frac{2b}{\Delta^{\beta/2}}\right\}. \tag{8}$$

Notice that C is homeomorphic to a torus. The flow on this manifold is given by the system

$$v'=\frac{\beta-2}{2}(-u^2),$$

$$\theta'=u,$$

$$u'=\frac{\beta-2}{2}uv+\frac{b\beta(\mu-1)\sin 2\theta}{2\Delta^{(\beta+2)/2}}. \tag{9}$$

We can now prove the following results.

Proposition 3.1: All the equilibrium points of system (6) lie on the collision manifold C and are given by

$$r=0,\quad v=\pm\sqrt{\frac{2b}{\Delta^{\beta/2}}},\quad \theta=0,\ \pi/2,\ 3\pi/2,\quad u=0.$$

Proof: It is obvious that the above points are equilibria for the flow defined by (6). To check that there are no equilibria outside the collision manifold, from the first equation in (6) with $r\neq 0$ we see that $v=0$ and from the third equation in (6) that $u=0$. So, if there are equilibrium points with $r\neq 0$, they must be on the zero velocity curve (ZVC); substituting these values in (7), we obtain that the ZVC exists just for $h<0$, it is given by

$$r^{\beta-1}+\frac{b}{\Delta^{\beta/2}}=-hr^{\beta}. \tag{10}$$

Solving the equation $v'=0$ in (6), we are led to

$$r^{\beta-1} - \frac{b(\beta-2)}{\Delta^{\beta/2}} = -2hr^{\beta}. \tag{11}$$

But (10) and (11) have no common solutions for $h<0$, therefore there are no equilibria outside the collision manifold. □

Proposition 3.2: The flow on the collision manifold C is gradientlike (i.e., increasing) with respect to the $(-v)$*-coordinate*.

Proof: Since $\beta>2$, we see from the first equation in (9) that $v'<0$ except at equilibria, therefore the flow on C increases with respect to $-v$, so is gradientlike relative to it. □

To match the sign of v and the value of θ, we denote the equilibria on C by $A_0^{\pm}$, $A_{\pi/2}^{\pm}$, $A_{\pi}^{\pm}$, and $A_{3\pi/2}^{\pm}$, respectively. Observe that $\Delta(0)=\Delta(\pi)=\mu$ and $\Delta(\pi/2)=\Delta(3\pi/2)=1$. With this notation, we can describe the following properties of the flow.

Theorem 3.1: *On the collision manifold C, the equilibria* $A_0^{\pm}$ *and* $A_{\pi}^{\pm}$ *are saddles,* $A_{\pi/2}^{+}$ *and* $A_{3\pi/2}^{+}$ *are sources and* $A_{\pi/2}^{-}$ *and* $A_{3\pi/2}^{-}$ *are sinks. Outside C, the equilibria* A_0^{+}, A_{π}^{+}, $A_{\pi/2}^{+}$, *and* $A_{3\pi/2}^{+}$ *have a local one-dimensional unstable analytic manifold, whereas* A_0^{-}, A_{π}^{-}, $A_{\pi/2}^{-}$, *and* $A_{3\pi/2}^{-}$ *have a local one-dimensional stable analytic manifold. All these equilibrium points are hyperbolic*.

Proof: Consider the function

$$F(r,v,\theta,u) = u^2 + v^2 - 2r^{\beta-1} - \frac{2b}{\Delta^{\beta/2}} - 2hr^{\beta} = 0.$$

According to Eq. (7), the surface of constant energy M_h defined by the equation

$$F(r,\theta,v,u) = 0$$

is a three-dimensional manifold. At every point B of M_h, the tangent space is given by

$$T_B F = \{\,(r,v,\theta,u) \,|\, \nabla F(B)\cdot(r,v,\theta,u) = 0\}.$$

At any equilibrium point A, the tangent space is defined by

$$T_A F = \{\,(r,\theta,v,u) | v = 0\}.$$

A straightforward computation shows that at the equilibria $A_0^{\pm}$ and $A_{\pi}^{\pm}$ the linearized system corresponding to (6) has the matrix

$$\begin{bmatrix} \pm\sqrt{\dfrac{2b}{\mu^{\beta/2}}} & 0 & 0 & 0 \\ 0 & (\beta-2)\pm\left(\sqrt{\dfrac{2b}{\mu^{\beta/2}}}\right) & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & \dfrac{b\beta(\mu-1)}{\mu^{\beta+2/2}} & \pm\dfrac{(\beta-2)}{2}\left(\sqrt{\dfrac{2b}{\mu^{\beta/2}}}\right) \end{bmatrix},$$

therefore the linear part of the vector field (6) restricted to $T_{A_{0,\pi}}^{+,-}$ is given by

$$L = \begin{pmatrix} \pm\sqrt{\dfrac{2b}{\mu^{\beta/2}}}r \\ 0 \\ u \\ \dfrac{b\beta(\mu-1)}{\mu^{\beta+2/2}}\theta + \pm\dfrac{(\beta-2)}{2}\left(\sqrt{\dfrac{2b}{\mu^{\beta/2}}}\right)u \end{pmatrix}.$$

As a basis for the tangent space $T_{A_{0,\pi}}^{+,-}$, we take the vectors

$$\xi_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad \xi_2 = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \quad \xi_3 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}. \tag{12}$$

The representation of the linear part L relative to this basis is given by the matrix

$$J^* = \begin{pmatrix} \pm\sqrt{\dfrac{2b}{\mu^{\beta/2}}} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & \dfrac{b\beta(\mu-1)}{\mu^{\beta+2/2}} & \pm\dfrac{(\beta-2)}{2}\left(\sqrt{\dfrac{2b}{\mu^{\beta/2}}}\right) \end{pmatrix}.$$

The characteristic polynomial shows that all eigenvalues are real and that the equilibrium is a saddle in each case.

At the equilibria $A^{\pm}_{\pi/2}$ and $A^{\pm}_{3\pi/2}$, the same linearized system has the matrix

$$\begin{bmatrix} \pm\sqrt{2b} & 0 & 0 & 0 \\ 0 & (\beta-2)\pm(\sqrt{2b}) & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -b\beta(\mu-1) & \pm\dfrac{(\beta-2)}{2}(\sqrt{2b}) \end{bmatrix}.$$

Using the vectors given in (12) as a basis for the tangent space $T^{+,-}_{A_{\pi/2,3\pi/2}}$, the linear part is given by the matrix

$$J^* = \begin{pmatrix} \pm\sqrt{2b} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & b\beta(\mu-1) & \pm\dfrac{(\beta-2)}{2}(\sqrt{2b}) \end{pmatrix}.$$

The eigenvalues at $A^{+}_{\pi/2}$ and at $A^{+}_{3\pi/2}$ are

$$\sqrt{2b}, \quad \frac{(\beta-2)}{2}(\sqrt{2b}) + \sqrt{\frac{b}{2}[(\beta-2)^2 - 8\beta(\mu-1)]},$$

and

$$\frac{(\beta-2)}{2}(\sqrt{2b}) - \sqrt{\frac{b}{2}[(\beta-2)^2 - 8\beta(\mu-1)]}.$$

This means that all of them are positive or have positive real part. At $A^{-}_{\pi/2}$ and $A^{-}_{3\pi/2}$ the eigenvalues are all negative or have negative real part. □

Corollary 3.1: The set of initial conditions leading to collisions or ejections has positive measure.

Proof: The equilibrium points $A^{-}_{\pi/2}$ ($A^{+}_{\pi/2}$) and $A^{-}_{3\pi/2}$ ($A^{+}_{3\pi/2}$) are sinks (sources) for the global flow, therefore their basin of attraction (repulsion) is a three-dimensional set of collision (ejection) orbits. □

Remark 3.1. If $0<\mu<(\beta+2)^2/8\beta$, all the eigenvalues are real and positive. If $\mu>(\beta+2)^2/8\beta$, there are two complex eigenvalues with positive real part, so some orbits have the spiraling property, i.e., engage into an infinite spin. For example, to have spiraling orbits in the

case $\beta=3$, it is necessary that $\mu>\frac{25}{24}$. Therefore when μ is sufficiently close to 1, no spiraling orbits exist.

Remark 3.2: The inequalities in Remark 3.1 do not depend on the parameter b.

Remark 3.3: For μ close enough to 1, though the set of collision orbits has positive measure, there are no spiralling orbits.

IV. SADDLE-SADDLE CONNECTIONS ON C

Using ideas similar to those found in Ref. 7, we will further study the existence of saddle-saddle connections on C for $\mu>1$ and β of the form

$$\beta=2+\frac{2}{1+2k} \quad \text{and} \quad \beta=2+\frac{1}{1+k},$$

k integer, $k\neq-1$. The reason for choosing these values of β will be clarified below. In the proof we restrict ourselves to the cases $\beta=3,4$. This is because the method requires the computation of an integral for each value of k, and each integral must be computed separately. But the principle is the same for every such k.

To show that there are no heteroclinic connections is sufficient to prove that the stable and unstable manifolds of corresponding fixed points miss each other. We will show that this holds true for most values of $\mu>1$.

It is now convenient to introduce different coordinates on C. Since C is homeomorphic to a torus, we can describe the flow using angle variables. With the transformations

$$u=\frac{\sqrt{2b}}{\Delta^{\beta/4}}\sin\psi,$$

$$v=\frac{\sqrt{2b}}{\Delta^{\beta/4}}\cos\psi, \tag{13}$$

we can rewrite the flow on the equations of motion (9) on C as

$$\begin{aligned}\theta'&=\frac{\sqrt{2b}}{\Delta^{\beta/4}}\sin\psi,\\ \psi'&=\frac{\beta-2}{2}\frac{\sqrt{2b}}{\Delta^{\beta/4}}\sin\psi+\frac{d}{d\tau}\left(\frac{\sqrt{2b}}{\Delta^{\beta/4}}\right)\frac{\Delta^{\beta/4}}{\sqrt{2b}}\cot\psi,\end{aligned} \tag{14}$$

where

$$\frac{d}{d\tau}\left(\frac{\sqrt{2b}}{\Delta^{\beta/4}}\right)=\frac{\beta(\mu-1)\sqrt{2b}}{4\Delta^{(\beta+4)/4}}\sin 2\theta. \tag{15}$$

The equilibrium points in the variables (θ,ψ) are $A^-_{\pm\pi/2}=(\pm\pi/2,0)$, $A^+_{\pm\pi/2}=(\pm\pi/2,\pi)$, $A^-_0=(0,0)$, $A^+_0=(0,\pi)$, $A^-_\pi=(\pi,0)$, and $A^+_\pi=(\pi,\pi)$.

Notice that if $\mu=1$ (the isotropic case), the collision manifold is a torus for which the upper and lower circles C^+ and C^- consist of fixed points. The equations (14) take the form

$$\theta'=\sqrt{2b}\sin\psi,$$

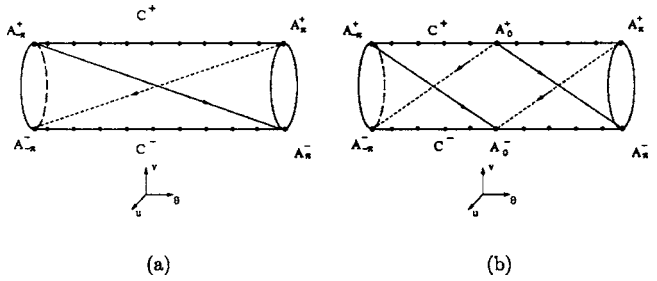

FIG. 2. The collision manifold and the heteroclinic connections for (a) $\mu=1$, $\beta=3$ and for (b) $\mu=1$, $\beta=4$.

$$\psi' = \frac{\beta-2}{2}\sqrt{2b}\sin\psi. \tag{16}$$

It is easy to see that in this case there are heteroclinic orbits that connect the critical points A_0^+ to A_π^- and A_π^+ to A_0^- when

$$\beta = 2 + \frac{2}{1+2k},$$

k integer, $k\neq -1$, and connect the critical points $A_{-\pi}^+$ to A_π^- and A_π^+ to $A_{-\pi}^-$ when

$$\beta = 2 + \frac{1}{1+k},$$

k integer, $k\neq -1$.

Figure 2(a) depicts the collision manifold for $\mu=1$ and $\beta=3$ and the heteroclinic connections on it, while Fig. 2(b) does the same for $\mu=1$ and $\beta=4$.

In the following we will show that if $\mu-1=\epsilon>0$ and small, such saddle-saddle connections are broken and the same result holds for an open dense set of $\mu-1=\epsilon>0$.

Theorem 4.2: *For $\beta=3$ and for an open and dense set of real numbers $\mu>1$, the unstable manifolds at $A_{-\pi}^-$ and A_π^- miss the stable manifolds at A_π^+ and $A_{-\pi}^+$. For $\beta=4$ and for an open and dense set of real numbers $\mu>1$, the unstable manifolds at A_0^+ and $A_{-\pi}^+$ miss the stable manifolds at A_π^- and A_0^-.*

Proof: Dividing the first of equations (14) by the second one we have

$$\frac{\mathrm{d}\psi}{\mathrm{d}\theta} = \frac{d}{\mathrm{d}\tau}\left(\frac{\sqrt{2b}}{\Delta^{\beta/4}}\right)\frac{\Delta^{\beta/2}}{2b}\frac{\cos\psi}{\sin^2\psi} + \left(\frac{\beta-2}{2}\right) = F_\beta(\theta,\psi,\epsilon), \tag{17}$$

where $\epsilon=\mu-1$ and $\Delta=1+\epsilon\cos^2\theta$.

First consider $\beta=3$, and the unstable manifolds $W_3^u(-\pi,0)=W_3^u(\pi,0)$. When $\epsilon=0$, $W_3^s(\pi,\pi)$ matches $W_3^u(-\pi,0)$. Consider the branch of $W_3^u(-\pi,0)$ which contains $(0,\pi/2)$. This curve lies along the line

$$-2\psi+\theta=-\pi. \tag{18}$$

When ϵ varies, this branch of the unstable manifold $W_3^u(-\pi,0)$ varies smoothly on C. Let $\zeta^3(\theta,\epsilon)$ denote the ψ-coordinate of this curve, satisfying $\zeta^3(-\pi,\epsilon)=0$.

Now let $\beta=4$ and $W_4^u(-\pi,0)=W_4^u(\pi,0)$. When $\epsilon=0$, $W_4^s(-\pi,0)$ matches $W_4^u(0,\pi)$. Consider the branch of $W_4^u(-\pi,0)$ that contains $(-\pi/2,\pi/2)$. This curve lies along the line

$$-2\psi+2\theta=-2\pi. \tag{19}$$

As ϵ varies, this branch of $W_4^u(-\pi,0)$ varies smoothly on C. Let $\zeta^4(\theta,\epsilon)$ denote the ψ-coordinate of this curve, satisfying $\zeta^4(-\pi,\epsilon)=0$. Now we need the following result, which we will prove at the end of this demonstration.

Lemma 4.1: With the above notations, $(\partial/\partial\epsilon)\zeta^3(0,0)=3/4\pi>0$ *and* $(\partial/\partial\epsilon)\zeta^4(-\pi/2,0)=\pi/2>0$.

From this lemma it follows that $\zeta^3(0,\epsilon)>0$ and $\zeta^4(0,\epsilon)>0$ for $\epsilon>0$ small. Thus, it is easy to show that $v_{1+\epsilon}(0,\zeta^l(0,\epsilon))>0$, where $l=3,4$. Equations (17) are reversed by the transformation

$$(\theta,\psi)\to(-\theta,\pi-\psi). \tag{20}$$

If $\beta=3$, the unstable manifold through $(-\pi,0)$ is mapped onto the stable manifold through (π,π). Hence the stable manifold intersects the line $\theta=0$ at some point $(0,\psi_0)$ such that $v_{1+\epsilon}(0,\psi_0)<0$. Consequently the stable manifold misses the unstable one for $\epsilon>0$ small.

Moreover the stable and unstable manifolds intersect only for a discrete set of ϵ, since they vary analytically with ϵ.

Furthermore equations (17) are reversed by the transformation

$$(\theta,\psi)\to(-\theta-\pi,\pi-\psi). \tag{21}$$

If $\beta=4$, the unstable manifold through $(-\pi,0)$ is mapped onto the stable manifold through $(0,\pi)$. Hence the stable manifold intersects the line $\theta=0$ at some point $(0,\psi_0)$ such that $v_{1+\epsilon}(0,\psi_0)<0$ and the stable manifold misses the unstable one for $\epsilon>0$ small.

Moreover the stable and unstable manifolds intersect only for a discrete set of ϵ, since they vary analytically with ϵ.

Similar arguments can be applied to the remaining stable and unstable manifolds. This concludes the proof of Proposition 4.1. □

Proof of Lemma 4.1: Observe that ζ^β satisfies the equation

$$\zeta^\beta(\theta,\epsilon)=\int_{-\pi}^{\theta}F_\beta(\eta,\zeta^\beta(\eta),\epsilon)\mathrm{d}\eta, \tag{22}$$

where F_β is given by (17). For ϵ small we can write

$$\zeta^\beta=\zeta_0^\beta(\theta)+\epsilon\zeta_1^\beta(\theta)+O(\epsilon^2). \tag{23}$$

We also have

$$\begin{aligned}\zeta_0^3(\theta)&=(1/2)\theta+\pi/2,\\ \zeta_0^4(\theta)&=\theta+\pi.\end{aligned} \tag{24}$$

To compute $\zeta_1(\theta)$, we can use the Taylor expansion of (22) with respect to ϵ and find

$$\zeta_1^\beta(\theta)=\int_{-\pi}^{\theta}\left(\frac{\partial}{\partial\epsilon}F_\beta(\eta,\zeta_0^\theta(\eta),0)+\frac{\partial}{\partial\psi}F_\beta(\eta,\zeta_0^\beta(\eta),0)\zeta_1^\beta(\eta)\right)\mathrm{d}\eta. \tag{25}$$

Standard computations show that

$$\frac{\partial}{\partial\epsilon}F_\beta(\eta,\zeta_0^\beta(\eta),\epsilon)=\frac{\beta}{2}\frac{\cos(\eta)\sin(\eta)\cos(\zeta_0^\beta(\eta))}{\sin(\zeta_0^\beta(\eta))}+O(\epsilon) \tag{26}$$

and that

$$\frac{\partial}{\partial \psi} F_\beta(\eta, \zeta_0^\beta(\eta), \epsilon) = O(\epsilon). \tag{27}$$

We can now compute $\zeta_1^\beta(\theta)$ as follows:

$$\zeta_1^\beta(\theta) = \int_{-\pi}^{\theta} \left(\frac{\partial}{\partial \epsilon} F_\beta + \frac{\partial}{\partial \psi} F_\beta \zeta_1 \right) \mathrm{d}\eta = \frac{\beta}{2} \int_{-\pi}^{\theta} \frac{\cos(\eta)\sin(\eta)\cos(\zeta_0^\beta(\eta))}{\sin(\zeta_0^\beta(\eta))} \mathrm{d}\eta. \tag{28}$$

When $\beta=3$,

$$\zeta_1^3(\theta) = \frac{3}{2} \int_{-\pi}^{\theta} \frac{\cos(\eta)\sin(\eta)\cos(\eta/2+\pi/2)}{\sin(\eta/2+\pi/2)} \mathrm{d}\eta = -\frac{9}{2} \cos\left(\frac{1}{2}\theta\right) \sin\left(\frac{1}{2}\theta\right) + \frac{3}{4}\theta + 3\left(\cos\left(\frac{1}{2}\theta\right)\right)^3 \sin\left(\frac{1}{2}\theta\right) + \frac{3}{4}\pi \tag{29}$$

and, in particular, for $\theta=0$, we have

$$\zeta_1^3(0) = \frac{3}{4}\pi = \frac{\partial}{\partial \epsilon} \zeta^3(0,0). \tag{30}$$

When $\beta=4$,

$$\zeta_1^4(\theta) = \frac{3}{2} \int_{-\pi}^{\theta} \frac{\cos(\eta)\sin(\eta)\cos(\eta+\pi)}{\sin(\eta+\pi)} \mathrm{d}\eta = \cos(\theta)\sin(\theta) + \theta + \pi \tag{31}$$

and, in particular, for $\theta=-\pi/2$, we have

$$\zeta_1^4\left(-\frac{\pi}{2}\right) = \frac{\pi}{2} = \frac{\partial}{\partial \epsilon} \zeta^4\left(-\frac{\pi}{2}, 0\right). \tag{32}$$

This concludes the proof of Lemma 4.1. □

V. ESCAPE AND CAPTURE SOLUTIONS FOR $h=0$

We will further study escape (capture) solutions, i.e., the ones for which $r \to \infty$ when $t \to \infty$ ($t \to -\infty$). From the energy relation (7), we can see that for $h<0$, the radial coordinate r is bounded by the zero velocity curve ($u=0, v=0$), so escapes exist only for $h \geqslant 0$. We restrict our analysis to the case $h=0$, in which the energy relation (7) takes the form

$$u^2 + v^2 = 2r^{\beta-1} + \frac{2b}{\Delta^{\beta/2}}. \tag{33}$$

With the transformations

$$\rho = r^{-1}, \quad \bar{v} = \rho^{(\beta-1)/2} v, \quad \bar{u} = {}^{(\beta-1)/2} u,$$

the energy relation becomes

$$\bar{u}^2 + \bar{v}^2 = 2 + \frac{2b}{\Delta^{\beta/2}} \rho^{\beta-1}. \tag{34}$$

We define the *infinity manifold* I_0 as

$$I_0 = \{ (\rho, \bar{v}, \theta, \bar{u}) \mid \rho = 0,\ \bar{u}^2 + \bar{v}^2 = 2 \}. \tag{35}$$

Since the variable $\theta \in S^1$, the infinity manifold I_0 is a torus.

Remark 5.4: The infinity manifold I_0 is independent of the parameter β.

After rescaling the time τ with the transformation $\mathrm{d}\tau=\rho^{(\beta-1)/2}\,\mathrm{d}s$, the equations (6) take the form

$$\frac{\mathrm{d}\rho}{\mathrm{d}s}=-\rho\bar{v},$$

$$\frac{\mathrm{d}\bar{v}}{\mathrm{d}s}=-\frac{1}{2}\bar{v}^2=\frac{b(\beta-2)}{\Delta^{\beta/2}}\rho^{\beta-1}+1,$$

$$\frac{\mathrm{d}\theta}{\mathrm{d}s}=\bar{u},$$

$$\frac{\mathrm{d}\bar{u}}{\mathrm{d}s}=-\frac{1}{2}\bar{u}\bar{v}+\frac{b\beta(\mu-1)\sin 2\theta}{2\Delta^{\beta+2/2}}\rho^{\beta-1}. \tag{36}$$

Equations (34) and (36) are well defined on the boundary $\rho=0$. Consequently, the phase space of the coordinates $(\rho,\bar{v},\theta,\bar{u})$ can be analytically extended to contain the manifold I_0. Since $\mathrm{d}\rho/\mathrm{d}s=0$ for $\rho=0$, this manifold is invariant under the flow.

Proposition 5.3: All the equilibrium solutions of the flow given by (36) lie on the infinity manifold I_0 and they form two circles of equilibria given by

$$\rho=0,\quad \bar{v}=\pm\sqrt{2},\quad \theta\in S^1,\quad \bar{u}=0.$$

Proof: It is obvious that any point of the above circles is an equilibrium orbit. If $\bar{v}=0$ in (36), by the third equation we have that $\bar{u}=0$, but this is a contradiction with the energy relation given by (34). This proves the result. □

On the infinity manifold I_0, the equations of motion take the form

$$\frac{\mathrm{d}\bar{v}}{\mathrm{d}s}=-\tfrac{1}{2}\bar{v}^2+1=\bar{u}^2/2,$$

$$\frac{\mathrm{d}\theta}{\mathrm{d}s}=\bar{u},$$

$$\frac{\mathrm{d}\bar{u}}{\mathrm{d}s}=-\tfrac{1}{2}\bar{u}\bar{v}. \tag{37}$$

We can now prove the following properties.

Proposition 5.4: The flow on I_0 is gradientlike with respect to the $\bar{v}$-coordinate.

Proof: From the first equation in (37), we obtain that $\bar{v}'>0$ except at equilibria, which proves the gradientlike property. □

In agreement with the sign of $\bar{v}$, and by similarity with the collision manifold for $\mu=1$ studied in Sec. IV, we also denote the equilibria on I_0 as $C^{\pm}$, respectively.

Theorem 5.3: *On the infinity manifold I_0, the two circles of equilibria C^+ and C^- are normally hyperbolic. C^+ corresponds to a sink, whereas C^- corresponds to a source. The escape orbits are the ones having C^+ as an ω-limit, whereas capture orbits are the ones having C^- as an α-limit.*

Proof: The proof is similar to the one of Theorem 3.1, so we will only sketch the main steps. From Eq. (34), we define

$$G(\rho,\bar{v},\theta,\bar{u}) = \bar{u}^2 + \bar{v}^2 - 2 - \frac{2b}{\Delta^{\beta/2}}\rho^{\beta-1} = 0.$$

Then I_∞ is the three-dimensional manifold given by $G^{-1}(0)$. To study the tangent spaces to this manifold at the equilibria, we use as a basis the same vectors (12). Then the linear representation of the vector field (36) at any equilibrium C^+ and C^- is given by the matrix

$$\begin{pmatrix} -v_0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & \dfrac{-v_0}{2} \end{pmatrix}.$$

Notice that for C^+, $v_0=\sqrt{2}$ and for C^-, $v_0=-\sqrt{2}$. In the former case two eigenvalues are negative and one is zero, whereas in the latter case two eigenvalues are positive and one is zero. This completes the proof of the normal hyperbolicty and shows the existence of infinitely many escape orbits and capture orbits. □

The next result, which is a direct consequence of Theorem 5.3, characterizes the flow on the infinity manifold.

Corollary 5.2: For $h=0$, the infinity manifold I_0 is foliated by heteroclinic orbits between C^- to C^+.

The flow on I_0 given by Eqs. (37) is easy to draw. Because on I_0, $\bar{u}^2+\bar{v}^2=2$, we can introduce the angular variable ψ with the transformation

$$\bar{u} = \sqrt{2}\cos\psi, \quad \bar{v} = \sqrt{2}\sin\psi.$$

On I_0, the equations of motion take the form

$$\dot{\psi} = -2\sqrt{2}\cos\psi, \quad \dot{\theta} = \sqrt{2}\cos\psi.$$

From here we obtain that

$$\frac{d\psi}{d\theta} = -2.$$

On I_0 we can also study the projection of the flow on the $v-\theta$ plane, which is given by

$$\frac{dv}{d\theta} = \frac{\sqrt{2-v^2}}{2},$$

whose solution is $v(\theta)=\sqrt{2}\sin[(\theta+k)/2]$, where k is a constant determined by the initial condition.

VI. INTEGRABILITY FOR $\beta=2$

We will further study the problem for $\beta=2$ and deal with a Hamiltonian (1) of the form

$$H_2 = \frac{1}{2}\mathbf{p}^2 - \frac{1}{\sqrt{x^2+y^2}} - \frac{b}{\mu x^2+y^2}. \tag{38}$$

With the notation $\epsilon=\mu-1$, the Hamiltonian expressed in polar coordinates becomes

$$H_2 = \frac{p_r^2}{2} + \frac{p_\theta^2}{2r^2} - \frac{1}{r} - \frac{b}{r^2(1+\epsilon\cos^2(\theta))}. \tag{39}$$

The corresponding system is integrable since it admits another first integral independent of the Hamiltonian, namely

$$G = \frac{p_\theta^2}{2} - \frac{b}{1 + \epsilon \cos^2(\theta)}. \tag{40}$$

Indeed,

$$\{H_2, G\} = \frac{\partial H_2}{\partial \theta}\frac{\partial G}{\partial p_\theta} - \frac{\partial H_2}{\partial p_\theta}\frac{\partial G}{\partial \theta}, \tag{41}$$

and since

$$\frac{\partial H_2}{\partial \theta} = -\frac{\epsilon b \sin(2\theta)}{r^2(1 + \epsilon \cos^2(\theta))^2}, \quad \frac{\partial H_2}{\partial p_\theta} = \frac{p_\theta}{r^2} \tag{42}$$

and

$$\frac{\partial G}{\partial \theta} = -\frac{\epsilon b \sin(2\theta)}{(1 + \epsilon \cos^2(\theta))^2}, \quad \frac{\partial G}{\partial p_\theta} = p_\theta \tag{43}$$

the Poisson's bracket is $\{H_2, G\}=0$, also G and H_2 are linearly independent.

The existence of the integral G is not surprising. Indeed it is well known[19] that given the Hamiltonian

$$\bar{H} = \frac{p_r^2}{2} + \frac{p_\theta^2}{2r^2} + U(r, \theta), \tag{44}$$

the corresponding Hamilton-Jacobi equation

$$\frac{\partial S}{\partial t} + \bar{H}\left(r, \theta; \frac{\partial S}{\partial r}, \frac{\partial S}{\partial \theta}\right) = 0 \tag{45}$$

[where $S=S(r, \theta, t)$ is the action expressed as function of the coordinates and time, $\partial S/\partial r=p_r$ and $\partial S/\partial \theta=p_\theta$] can be solved by separation of variables if the potential energy is of the form

$$U = a(r) + \frac{b(\theta)}{r^2}. \tag{46}$$

Since the Hamiltonian is time independent we take $S(r, \theta, t)=S_0(r, \theta)-Et$ (where E is a constant), and the Hamilton-Jacobi equation for S_0 becomes

$$\frac{1}{2}\left(\frac{\partial S}{\partial r}\right)^2 + a(r) + \frac{1}{2r^2}\left[\left(\frac{\partial S}{\partial \theta}\right)^2 + 2b(\theta)\right] = E. \tag{47}$$

Looking for a solution of the form

$$S_0 = S_1(r) + S_2(\theta), \tag{48}$$

we find for S_1 and S_2 the equations

$$\left(\frac{dS_2}{d\theta}\right)^2 + 2b(\theta) = 2G,$$

$$\frac{1}{2}\left(\frac{dS_1}{dr}\right)^2 + a(r) + \frac{2G}{2r^2} = E, \tag{49}$$

which define two independent integrals. Solving these equations leads to a solution of the Hamilton-Jacobi equations and thus to a general solution of the equations of motion. The above technique applies to the Hamiltonian H_2 and to the additional integral G.

This approach also shows that the Hamiltonian system given by H_2 is integrable by quadratures. The same conclusion can be reached by directly applying the Liouville-Arnold theorem.[2]

VII. THE COLLISION MANIFOLD FOR $\beta=2$

For $\beta=2$ the equation of motion (6) in McGehee coordinates can be written as

$$r' = rv,$$

$$v' = 2r^2h + r,$$

$$\theta' = u,$$

$$u' = \epsilon b \sin(2\theta)\Delta^{-2}, \tag{50}$$

where the prime denotes differentiation with respect to τ and $\Delta=1+\epsilon\cos^2(\theta)$. In McGehee coordinates, the energy relation takes the form

$$u^2 + v^2 - 2r - 2b\Delta^{-1} = 2r^2h, \tag{51}$$

where h is the energy constant. The first integral G can be written as

$$g = \tfrac{1}{2}(u^2 - 2b\Delta^{-1}), \tag{52}$$

where g is also constant along orbits.

The vector field (50) is analytic on the boundary $r=0$, since r no longer occurs in the denominators of the vector field. The collision manifold reduces to

$$C = \{(r,\theta,v,u): r = 0,\ u^2 + v^2 = 2b\Delta^{-1}\}. \tag{53}$$

This shows that C is homeomorphic to a torus. The restriction of equations (50) to C yields the system

$$v' = 0,$$

$$\theta' = u,$$

$$u' = \epsilon b\Delta^{-2}\sin 2\theta. \tag{54}$$

All nonequilibrium orbits on C are periodic. Comparing the collision manifold and vector field above with the corresponding ones in Ref. 6, we see that the collision manifold and the flow for $\beta=2$ are identical to the ones of the anisotropic Manev problem.

VIII. HETEROCLINIC ORBITS FOR $\beta=2$ AND $h=0$

The main goal of this section is to study the infinity manifold for $h=0$ and the heteroclinic orbits that connect the collision and infinity manifold. First notice that for $h<0$ the motion is bounded and therefore there is no infinity manifold. More precisely, we have the following result.

Proposition 8.5: If $h<0$ the motion is bounded by the zero velocity curve

$$r_0 = \frac{-1+\sqrt{1-4hb\Delta^{-1}}}{2h}, \quad v=0,\ \theta,\ u=0. \tag{55}$$

Proof: Obviously $u=0$ and $v=0$ if and only if $u^2+v^2=0$. Also $v=0$ implies $r'=0$. Using the energy relation we can draw the conclusion that $u^2+v^2=0$ if and only if $2r^2h+2r+2b\Delta^{-1}=0$. This quadratic equation has the solutions

$$r = \frac{-1 \pm \sqrt{1 - 4hb\Delta^{-1}}}{2h}. \tag{56}$$

Since $r \geqslant 0$ and $h < 0$ the only valid solution r_0 is the one with the minus sign. This shows that (55) is the zero velocity curve. The fact that the motion is bounded by this curve follows from the fact that if $r > r_0$ then $u^2 + v^2 < 0$. □

To describe the behavior of the solution at infinity we need to study the equations (36) with $\beta = 2$ and $h = 0$, that is

$$\dot{\rho} = -\rho\bar{v},$$

$$\dot{\bar{v}} = -\tfrac{1}{2}\bar{v}^2 + 1,$$

$$\dot{\theta} = \bar{u},$$

$$\dot{\bar{u}} = -\tfrac{1}{2}\bar{v}\bar{u} + \epsilon b\rho \sin 2\theta\Delta^{-2}, \tag{57}$$

where the dot denotes differentiation with respect to the time variable s. The energy relation is

$$\bar{u}^2 + \bar{v}^2 - 2 - 2b\rho\Delta^{-1} = 0 \tag{58}$$

and the other first integral can be written as

$$\bar{u}^2 - 2b\rho\Delta^{-1} = 2\rho g. \tag{59}$$

The infinity manifold is a two-manifold embedded in $\mathbb{R}^3 \times S^1$ given by the equations

$$I_0 = \{ (\rho, \bar{v}, \theta, \bar{u}) | \rho = 0,\ \bar{u}^2 + \bar{v}^2 = 2 \}, \tag{60}$$

i.e., the points in phase space that satisfy the condition $\rho = 0$ and the energy relation. This shows that I_0 is a torus $S^1 \times S^1$.

The first two equations of the system (57) are independent from the others, and we would like to determine ρ and $\bar{v}$. If we set $\bar{v} = \pm\sqrt{2}$, then $\rho = \exp(\mp\sqrt{2}(s - s_0))$ is a solution of the two equations mentioned above. If $\bar{v} = \pm\sqrt{2}$ the energy integral (58) gives the condition

$$\bar{u} = \pm\sqrt{2b\rho\Delta^{-1}}. \tag{61}$$

Moreover the previous condition and Eq. (59) impose $g = 0$. Differentiating (61) with respect to s we obtain

$$\dot{\bar{u}} = \pm\sqrt{2b}\left(\frac{\Delta^{-1/2}}{2\rho^{1/2}}\dot{\rho} + \frac{\epsilon}{2}\bar{u}\sqrt{\rho\Delta}\frac{\sin 2\theta}{\Delta^2}\dot{\theta}\right) \tag{62}$$

and using the first equation in (57) and Eq. (61) it follows that

$$\dot{\bar{u}} = -\tfrac{1}{2}\bar{v}\bar{u} + \epsilon b\rho \sin 2\theta\Delta^{-2}. \tag{63}$$

This shows that system (57) admits solutions with $\bar{v} = \pm\sqrt{2}$.

The other solutions of the first two equations of the system (57) can be found by dividing the second equation by the first. This leads to the equation

$$\frac{\dot{\bar{v}}}{\dot{\rho}} = \frac{1}{2}\frac{\bar{v}}{\rho} - \frac{1}{\rho\bar{v}}, \tag{64}$$

which can be solved by separating the variables. This leads to

$$\int_{\rho_0}^{\rho} \frac{\mathrm{d}\xi}{\xi} = \int_{\bar{v}_0}^{z} \frac{z\,\mathrm{d}z}{\frac{1}{2}z^2 - 1} \tag{65}$$

and consequently yields

$$\rho = \left(\frac{\rho_0}{\bar{v}_0^2 - 2}\right)(\bar{v}^2 - 2), \tag{66}$$

where ρ_0 and v_0 are initial conditions and $\rho \geqslant 0$, since $\rho < 0$ has no physical meaning. Now we can prove the following result relative to the heteroclinic solutions connecting the infinity and the collision manifolds.

Theorem 8.4: *The solutions whose ω-limit set belongs to the infinity manifold have the α-limit set contained in the collision manifold. In particular, the following properties take place:*

(1) *If* $\bar{v} = \sqrt{2}$ $(\bar{v} = -\sqrt{2})$, *the above solutions belong to the unstable (stable) manifold of one of the periodic orbits on the equator of the collision manifold.*

(2) *If* $0 < \sqrt{1/k} < \sqrt{2b}$ *and* $\sqrt{1/k} \neq \sqrt{2b/\mu}$ *with* $k = \rho_0/(\bar{v}_0^2 - 2)$, *the above solutions belong to the unstable (stable) manifold of the periodic orbits on the collision manifold with* $v = \sqrt{1/k}$ $(v = -\sqrt{1/k})$.

(3) *If* $\sqrt{1/k} = \sqrt{2b/\mu}$ $(-\sqrt{1/k} = \sqrt{2b/\mu})$, *then the above solutions belong to the unstable (stable) manifold of one of the fixed points* A_0^+, A_π^+ (A_0^-, A_π^-).

(4) *If* $\sqrt{1/k} = \sqrt{2b}$ $(-\sqrt{1/k} = \sqrt{2b})$, *then the above solutions belong to the unstable (stable) manifold of one of the fixed points* $A_{-\pi/2}^+$, $A_{\pi/2}^+$ $(A_{-\pi/2}^-, A_{\pi/2}^+)$.

Proof: To prove (1) observe that $v = \bar{v}/\rho^{1/2} = \pm\sqrt{2}/\rho^{1/2}$. Thus $\lim_{s\to\infty} v = \lim_{s\to\infty} \pm\sqrt{2}/\rho^{1/2} = \lim_{\tau\to\infty} \pm\sqrt{2}/\rho^{1/2} = \lim_{\tau\to\infty} v = 0$, since $\lim_{s\to\infty} \tau = \infty$. To prove (2), (3), and (4) we consider the limit $\lim_{\tau\to\infty} v$, which with the help of Eq. (66) becomes

$$\lim_{\tau\to\infty} v = \lim_{\tau\to\infty} \frac{\bar{v}}{\rho^{1/2}} = \pm \lim_{\tau\to\infty} \sqrt{\frac{\rho + 2k}{k}}\rho^{-1/2} = \pm\sqrt{\frac{1}{k}}.$$

Moreover from the energy relation $\bar{u}^2 + \bar{v}^2 - 2 - 2b\rho/\Delta = 0$ and the fact that $\bar{v}^2 = (\rho + 2k)/k$ it is easy to see that

$$\bar{u}^2 = -\rho\left(\frac{1}{k} - \frac{2b}{\Delta}\right),$$

and since $\rho > 0$ and $\bar{u}^2 \geqslant 0$, we have

$$\frac{1}{k} \leqslant \frac{2b}{\Delta} \leqslant 2b.$$

Consequently we have shown that

$$0 < \sqrt{\frac{1}{k}} \leqslant \sqrt{2b}. \tag{67}$$

In particular it is clear that when $\sqrt{1/k} = \sqrt{2b/\mu}$ $(-\sqrt{1/k} = \sqrt{2b/\mu})$ the solutions lie on the unstable (stable) manifold of one of the fixed points A_0^+, A_π^+ (A_0^-, A_π^-). Similarly when $\sqrt{1/k} = \sqrt{2b}$ $(-\sqrt{1/k} = \sqrt{2b})$, the solutions lie on the unstable (stable) manifold of one of the fixed points $A_{-\pi/2}^+$, $A_{\pi/2}^+$ $(A_{-\pi/2}^-, A_{\pi/2}^-)$. In the remaining cases the solutions lie on the unstable (stable) manifold of the periodic orbits on the collision manifold with $v = \sqrt{1/k}$ $(v = -\sqrt{1/k})$. □

IX. A PERTURBATIVE APPROACH

In this and the next section we study the appearance of chaos on the zero-energy manifold for the system of Hamiltonian H_β given by Eq. (1). In order to do that we study the problem for small values of ϵ and b and we use an extension of the Melnikov method that is briefly illustrated in the following section. Consider the Hamiltonian

$$\mathcal{H}_\beta = \frac{1}{2}\mathbf{p}^2 - \frac{1}{r} - \frac{b}{r^\beta} + \epsilon b \frac{\beta \cos^2 \theta}{2r^\beta} \equiv \mathcal{H}^0 + b\mathcal{W}^1_\beta(r,\theta) + \epsilon b \mathcal{W}^2_\beta(r,\theta), \tag{68}$$

where $\beta > 3/2$, $b \ll 1$, $\epsilon \ll 1$. This is the original Hamiltonian H_β [defined in (1)] truncated to the second order in ϵ and b. Consider, as in Ref. 5, the parabolic solutions of the unperturbed ($\epsilon = 0, b = 0$) problem (68), defined by the Hamiltonian $\mathcal{H}^0$ of the classical Kepler problem that are on the zero-energy manifold and play the role of homoclinic solutions corresponding to the critical point at infinity, i.e., $r = \infty$, $\dot{r} = 0$. These solutions satisfy the equations

$$\dot{r} = \pm \frac{\sqrt{2r - k^2}}{r}, \quad \dot{\theta} = \frac{k}{r^2}, \tag{69}$$

where $k \neq 0$ is the (constant) angular momentum and the sign $-$ (respectively, $+$) holds for $t < 0$ (respectively, $t > 0$). From (69) we get

$$\pm t = \frac{k^2 + r}{3}\sqrt{2r - k^2} + \text{const},$$

$$\theta = \pm 2 \arctan \frac{\sqrt{2r - k^2}}{\sqrt{k^2}} + \text{const}. \tag{70}$$

We denote by

$$R = R(t) \quad \text{and } \Theta = \Theta(t) \tag{71}$$

the expressions giving the dependence of r and of θ on the time t. These are obtained by "inverting" the equations (70) with the conditions $R(0) = r_{\min} = k^2/2$ and $\Theta(0) = 0$. Let us emphasize that, as in Ref. 5, it is not necessary to have the explicit form of these functions. But it is important to remark that $R(t)$ is even and $\Theta(t)$ is odd, both in the time variable. The choice $\Theta(0) = 0$ correspond to selecting the solution describing the parabola with axis coinciding with the x axis and going to infinity when $x \to -\infty$.

The parabolic orbits can also be described in parametric form.[19] If $p = k^2 \neq 0$, we can write

$$r = \frac{p}{2}(1 + \eta^2), \quad t = \frac{p^{3/2}}{2}\eta\left(1 + \frac{\eta^2}{3}\right), \quad \eta = \tan\frac{\theta}{2}. \tag{72}$$

We also have

$$\cos 2\theta = 2\frac{(1 - \eta^2)^2}{(1 + \eta^2)^2} - 1. \tag{73}$$

We will further use these remarks to apply the Melnikov method.

X. THE MELNIKOV METHOD

Consider the problem defined in (68). The homoclinic manifold, i.e., the set of solution of the unperturbed equation which are doubly asymptotic to $r = \infty$, $\dot{r} = 0$, is given for each value $k \neq 0$ of the angular momentum by the two-dimensional manifold described by the family of solutions $r = R(t - t_0)$, $\vartheta = \Theta(t - t_0) + \theta_0$, where $R(t)$ and $\Theta(t)$ have been defined in (71), with arbitrary t_0, θ_0.

It is clear from Eq. (68) that the first order in b of the perturbation (i.e., the term $b\mathcal{W}_\beta^1$) does not contribute to the Melnikov integrals. This is because the perturbed Hamiltonian truncated at the first order, i.e., $\mathcal{H}_0+b\mathcal{W}_\beta^1$, is integrable and, at this order, the positively and negatively asymptotic sets coincide. Furthermore, for the same reason, the terms in b^n for $n\geqslant 2$ do not contribute to the Melnikov integral. Consequently the first nonvanishing terms of the Melnikov integrals are of order ϵb.

The perturbation resulting from a small anisotropy vanishes as $r\to\infty$ since $\mathcal{W}_\beta^2(r,\theta)\sim 1/r^\beta$ with $\beta>3/2$. This guarantees, among other things, the integrability of the Melnikov integrals and the applicability of the aforementioned method.[5] This allows us to write the first nonvanishing effect on the Melnikov integral in the same form as in Ref. 5, with the difference that here we can drop the dependence on time,

$$M_1(\theta_0)=\int_{-\infty}^{+\infty}\left[\dot{R}(t)\frac{\partial\mathcal{W}_\beta^2(R(t),\Theta(t)+\theta_0)}{\partial r}+\dot{\Theta}(t)\frac{\partial\mathcal{W}_\beta^2(R(t),\Theta(t)+\theta_0)}{\partial\theta}\right]\mathrm{d}t=0, \tag{74}$$

$$M_2(\theta_0)=\int_{-\infty}^{+\infty}\frac{\partial\mathcal{W}_\beta^2(R(t),\Theta(t)+\theta_0)}{\partial\theta}\mathrm{d}t=0. \tag{75}$$

Since the perturbation $\mathcal{W}_\beta^2$ vanishes as $t\to\pm\infty$, the first Melnikov condition can be written as

$$M_1(\theta_0)=\int_{-\infty}^{+\infty}\frac{\partial\mathcal{W}_\beta^2(R(t),\Theta(t)+\theta_0)}{\partial t}\mathrm{d}t\equiv 0. \tag{76}$$

The above integral is identically zero because the perturbation $\mathcal{W}_\beta^2$ is not time dependent. This simplifies our discussion since we must only find the solutions of (75). Such solutions correspond, at the order ϵb, to intersections of the positively and negatively asymptotic sets of the critical point at infinity. If one such solution exists then there are infinitely many. Moreover, if the solutions correspond to simple zeroes of $M_2(\theta_0)$, the intersection is transversal and, for ϵ and b sufficiently small, higher order terms are not going to destroy the intersection.

It is significant to remark, and easy to verify, that these conditions can be written also in terms of the first integrals of the unperturbed problem as

$$M_1(\theta_0)=\int_{-\infty}^{+\infty}\{H_0,\mathcal{W}_\beta^2\}(\cdots)\mathrm{d}t=0 \tag{77}$$

and

$$M_2(\theta_0)=\int_{-\infty}^{+\infty}\{K,\mathcal{W}_\beta^2\}(\cdots)\mathrm{d}t=0, \tag{78}$$

where $(\cdots)$ represents the homoclinic orbit.

This resembles some properties obtained for the Gyldén problem[5,16] and is related to the symmetries of the problem. In the Gyldén problem there is a perturbation that does not depend on the angle θ, but depends on time. This means that the perturbation destroys the time homogeneity, so the Hamiltonian is not an integral of motion anymore, but does not destroy the rotational invariance, so the angular momentum is still conserved. Therefore the only one condition is given by (74). However, the anisotropy destroys the rotational symmetry but not the homogeneity of time, so we are left with the condition (75).

Here the Melnikov condition for M_2 becomes

$$M_2(\theta_0) = \frac{\beta}{2}\int_{-\infty}^{+\infty} \frac{\sin[2(\Theta(t)+\theta_0)]}{R(t)^\beta} \mathrm{d}t = 0. \tag{79}$$

Using some trigonometry the integral can be written as

$$M_2(\theta_0) = I_1 \cos 2\theta_0 + I_2 \sin 2\theta_0, \tag{80}$$

where I_1 and I_2 are defined by

$$I_1 = \frac{\beta}{2}\int_{-\infty}^{+\infty} \frac{\sin 2\Theta(t)}{R(t)^\beta} \mathrm{d}t,$$

$$I_2 = \frac{\beta}{2}\int_{-\infty}^{+\infty} \frac{\cos 2\Theta(t)}{R(t)^\beta} \mathrm{d}t. \tag{81}$$

Recall that $R(t)$ is an even function of time and $\Theta(t)$ is an odd function. This implies that the integrand of I_1 is an odd function. Therefore $I_1 \equiv 0$, and M_2 can be rewritten as

$$M_2(\theta_0) = I_2 \sin 2\theta_0. \tag{82}$$

Thus $M_2(\theta_0)$ has infinitely many simple zeroes, provided that $I_2 \neq 0$. To complete the proof we must verify that $I_2 \neq 0$. We compute I_2 using the parametric form of the parabolic orbits defined in Eqs. (72). Since $\mathrm{d}t = (p^{3/2}/2)(1+\eta^2)\mathrm{d}\eta$, we can write

$$I_2 = 2^{\beta-1} p^{3/2-\beta} \frac{\beta}{2}\int_{-\infty}^{+\infty} \frac{1}{(1+\eta^2)^{\beta-1}} \left(\frac{2(1-\eta^2)^2}{(1+\eta)^2} - 1 \right) \mathrm{d}\eta. \tag{83}$$

Computing the integral, we find that

$$I_2 = \frac{2^{\beta-1} p^{3/2-\beta}}{2\Gamma(\beta-1)} \sqrt{\pi} \left[\Gamma\left(\beta - \frac{3}{2}\right) \left(\frac{3}{2(\beta-1)\beta} - 1 \right) + 2\frac{\Gamma\left(\beta+\frac{1}{2}\right) - \Gamma\left(\beta-\frac{1}{2}\right)}{(\beta-1)\beta} \right], \tag{84}$$

where $\Gamma(z)$ is Euler's gamma function. Thus $I_2(\beta)$ is an analytic function in β for $\beta > 3/2$, since $\Gamma(z)$ is analytic for $z > 0$. Recall that the gamma function can be expressed as

$$\Gamma(z) = \lim_{n\to\infty} \frac{n!\, n^z}{z(z+1)\cdots(z+n)} \tag{85}$$

if $z \neq 0, -1, -2, -3, \ldots$. Using this form of the gamma function, and letting $A = 2^{\beta-2} p^{3/2-\beta}$, we find that

$$\begin{aligned} I_2 &= A \lim_{n\to\infty} n^{3/2} \sqrt{\pi} \frac{\beta(\beta+1)(\beta+2)\cdots(\beta-1+n)}{\left(\beta-\frac{3}{2}\right)\left(\beta-\frac{1}{2}\right)\cdots\left(\beta-\frac{1}{2}+n\right)} (\beta^2 - 5\beta + 6) \\ &= \frac{A\sqrt{\pi}\,\Gamma\left(\beta+\frac{1}{2}\right)}{(\beta-1)\left(\beta-\frac{3}{2}\right)\left(\beta-\frac{1}{2}\right)\Gamma(\beta-1)} (\beta^2 - 5\beta + 6), \end{aligned} \tag{86}$$

which is zero if and only if $\beta^2 - 5\beta + 6 = 0$, since the gamma function $\Gamma(z)$ is always positive for $z > 0$ and therefore the first factor never vanishes. Consequently I_2 vanishes if and only if $\beta^2 - 5\beta + 6 = 0$, namely for $\beta = 2$ or $\beta = 3$, see Fig. 3.

This proves that for every $\beta > 3/2$, $\beta \neq 2, 3$, and ϵ small, the system given by the Hamiltonian $\mathcal{H}_\beta$ of Eq. (68) exhibits chaotic dynamics on the zero energy manifold induced by an infinite sequence of intersections on the Poincaré section of the positively and negatively asymptotic sets of the critical point at infinity. Moreover, if ϵ and b are sufficiently small, one can consider the

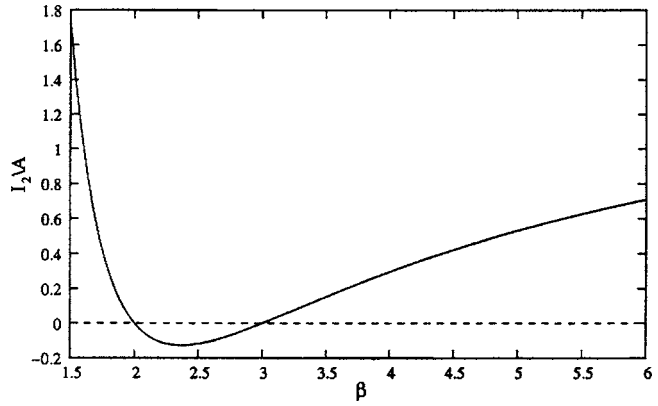

FIG. 3. I_2/A as a function of β.

Hamiltonian H_β of Eq. (1) and the simple zeroes of the Melnikov function cannot be destroyed by the higher-order terms of the perturbation. Therefore chaos persists for the Hamiltonian system of Hamiltonian (1). This proves the following.

Theorem 10.5: For every $\beta > 3/2$, $\beta \neq 2, 3$, *and* ϵ *small, the system given by the Hamiltonian* H_β *defined by Eq. (1) exhibits chaotic dynamics on the zero energy manifold.*

This type of chaotic behavior is induced by a chain of infinitely many intersections of the positively and negatively asymptotic sets to the critical point at infinity. The Smale-Birkhoff theorem does not directly apply to this situation, which is degenerate. But it is well known that the existence of Smale horseshoes and positive topological entropy can arise in the case of nonhyperbolic equilibria.[4]

(Received 14 December 2004; accepted 23 May 2005; published online 8 July 2005)

We consider a three-dimensional quadratic system S in $\mathbb{R}^3$ with six parameters which appears in geophysical fluid dynamics (atmospheric blocking). In this paper we start its systematic study from the point of view of dynamical systems. First, we reduce the number of its parameters from six to three. Thus, we must study a three-dimensional quadratic system with three parameters, which recalls us the famous Lorenz-63 system. Traditionally, system S has been studied by considering two subcases, called the conservative and the dissipative case, as the parameter responsible for dissipation is zero or not. In the conservative case, we reduce system S to systems without parameters. Among these there are two interesting systems: one is homeomorphic to the simple pendulum, and the other is a perturbation of it. In the latter system the saddle point corresponding to topographic instability is connected to two homoclinic orbits to it. In the dissipative case we prove that all trajectories of system S enter in an ellipsoid for any values of the parameters. We characterize their invariant algebraic surfaces of degree 2, and for those systems having such invariant algebraic surfaces we describe their global phase portraits. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1955448]

I. INTRODUCTION

In this paper we consider the following quadratic system in $\mathbb{R}^3$

$$\dot{x} = az - b(x - c),$$

$$\dot{y} = -(dx - e)z - by,$$

$$\dot{z} = (dx - e)y - fx - bz, \tag{1}$$

where a, b, c, d, e, and f are arbitrary real parameters and the overdot denotes differentiation with respect to time t. We start the systematic study of its flow from the point of view of dynamical systems. System (1) with positive parameters is a subsystem of Charney DeVore (CdV) model, well known in geophysical fluid dynamics, and describes topographically driven disturbances of an atmospheric zonal flow. The CdV model is a quadratic system in $\mathbb{R}^6$ introduced by Charney and DeVore in 1979 as a truncation of the equations describing barotropic atmospheric flow over topography. They found that more than one stable equilibrium state may occur for a given external

[a)]Electronic mail: danidbrv@yahoo.com
[b)]Electronic mail: jllibre@mat.uab.es

force, and that these equilibrium states are analogues of the observed large-scale preferent states of the atmospheric circulation. For more details, see Ref. 2. This work has been considered by many researchers in geophysical fluid dynamics (see Refs. 24, 15–17, 32, 6, 7, 13, 14, and 4). The CdV model in $\mathbb{R}^6$ or its extensions up to $\mathbb{R}^{25}$ have been studied by numerical methods.

Another quadratic system which models the general atmospheric circulation is the famous Lorenz-84 model:[22]

$$\dot{x} = -y^2 - z^2 - ax + aF, \quad \dot{y} = xy - bxz - y + G, \quad \dot{z} = bxy + xz - z, \tag{2}$$

where F and G are forcing terms due to the average north-south temperature contrast and the earth-sea temperature contrast, respectively. For more details on physical interpretation of the variables x, y, z and of suitable choices of parameters a and b, see e.g., Ref. 22. Both systems (1) and (2) are spectrally truncated versions of Navier-Stokes equations. However, system (1) is a barotropic quasigeostrophic model, whereas system (2) is a geostrophic baroclinic model, i.e., a more general one. Values of parameters F and G for which system (2) is chaotic are known. For instance, if $a=1/4$, $b=4$, $F=8$ and $G=1$, i.e., winter conditions for the forcing terms, then the behavior of system (2) is chaotic.[29] Thus, the study of bifurcations and strange attractors for system (2) is more advanced than for system (1). For example, a comprehensive bifurcation analysis of system (2) is presented in Ref. 26. It is shown that the system admits a codimension-two saddle-node Hopf bifurcation. Nontrivial limit sets in the form of a chaotic attractor or repeller are found in some parameter ranges. Their presence implies an increased unpredictability of the system of parameter values corresponding to the winter season. In Ref. 1 system (2) is studied by using a three-dimensional Poincaré mapping, depending on the forcing parameters F and G of the system and on the relative amplitude of the oscillating part of the forcing. In order to simulate seasonal effects, F and G are subject to periodic forcing where the period is one year. It is showed that system (2) displays periodicity, quasiperiodicity, and strange attractors. The transitions of the attractors are explained in terms of codimension one bifurcations (saddle-node and Hopf). In Ref. 29 van Veen investigated the atmosphere-ocean interaction at midlatitudes in a low-order climate model (van Veen model, hereafter). This model combines the Lorenz-84 model for the atmosphere on a fast time scale and a box model for the ocean on a slow time scale; the ocean is forced strongly by the atmosphere and the feedback to the atmosphere is weak, but capable of producing decadal variability in atmospheric observables. The physical focus of Ref. 29 is on the interplay of the short time scale variability of the atmospheric component and the long time scale of the oceanic component. The mathematical focus is on periodic and chaotic solutions of the Lorenz-84 model and on intermittency in van Veen model. The most recent paper on six-component CdV model is Ref. 4. Its authors provide support for the hypothesis that regime transitions are related to heteroclinic connections. By parameter tuning, the Hopf bifurcation corresponding to barotropic instability can be made to coincide with one of the saddle-node bifurcations that are due to the topography in the model. Heteroclinic connections and homoclinic orbits connected to equilibria are related to such a bifurcation. In this paper we have not performed a bifurcation analysis of system (1) as our approach logically precedes such a study.

In this paper we begin the systematic analytic study of the subsystem (1) in $\mathbb{R}^3$ of the CdV model. Our first step is to reduce system (1) to a system whose dynamics is either easy to analyze, or has at most three parameters instead of six. This is done in Sec. II. In Sec. III we describe the phase portraits of the systems to which system (1) is reduced excepting system (18), whose dynamics is difficult to describe exhaustively. However, in Sec. IV we prove that all solutions of system (18) enter in an ellipsoid for any values of its three parameters. In Sec. V we characterize the invariant algebraic surfaces of degree 2 for system (18). In Sec. VI, we describe the phase portraits of system (18) having these invariant algebraic surfaces. To this end, we use that the existence of invariant algebraic surfaces implies the existence of semipermeable surfaces; i.e., the trajectories cross these surfaces always in the same direction. Finally in Sec. VII we compare our results with the previous ones.

II. REDUCED FORMS OF SYSTEM (1)

In this section we transform system (1) by rescalings and changes of variables to one of the following 12 systems: (3)–(7), (9)–(12), and (16)–(18). The advantage is that the transformed system, either has an easy dynamics to analyze, or has at most three parameters instead of the initial six parameters. We prove this in Lemmas 1–4.

When specifying the change of variables, we always denote new variables in uppercase X,Y,Z and old variables in lowercase x,y,z. For brevity, and when no confusion is possible, we rewrite the new system using lowercase letters as well.

Lemma 1: We consider system (1). If $b=0$ *and* $d=0$, *then system (1) is equivalent to the linear system* $\dot{\mathbf{x}}=L\mathbf{x}$ *where*

(a) *if* $e^2+af<0$, *then*

$$L=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \tag{3}$$

(b) *if* $e^2+af>0$, *then*

$$L=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \tag{4}$$

(c) *if* $e^2+af=0$ *and* $e\neq 0$, *then*

$$L=\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \tag{5}$$

(d) *if* $e=0$, $af=0$ *and* $a^2+f^2\neq 0$, *then*

$$L=\begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \tag{6}$$

(e) *if* $e=a=f=0$, *then*

$$L=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}=O_3. \tag{7}$$

Proof: If $b=d=0$ then system (1) becomes $\dot{\mathbf{x}}=A\mathbf{x}$ with

$$A=\begin{pmatrix} 0 & 0 & a \\ 0 & 0 & e \\ -f & -e & 0 \end{pmatrix}.$$

Its real Jordan normal form J_A depends on the sign of e^2+af. If $e^2+af<0$, then

$$J_A=\begin{pmatrix} 0 & 0 & 0 \\ 0 & \sqrt{r} & 0 \\ 0 & 0 & -\sqrt{r} \end{pmatrix},$$

where $r=-(e^2+af)>0$. After a time rescaling, we obtain (3). If $e^2+af>0$, then

$$J_A = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -\sqrt{r} \\ 0 & \sqrt{r} & 0 \end{pmatrix},$$

where now $r=e^2+af$. Using again a time rescaling, we get (4). If $e^2+af=0$ then we have three cases: (i) $e\neq 0$, (ii) $e=0$ and $a^2+f^2\neq 0$, and (iii) $e=a=f=0$.

Case (i): Since $e\neq 0$ and $e^2+af=0$, the parameters a and f are also nonzero. In particular, $f=-e^2/a$, and the matrix A becomes

$$B = \begin{pmatrix} 0 & 0 & a \\ 0 & 0 & e \\ e^2/a & -e & 0 \end{pmatrix}.$$

The matrix B has the zero as an eigenvalue of algebraic multiplicity three, and geometric multiplicity one. By standard procedure,

$$B = P^{-1}AP = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \tag{8}$$

where P is the matrix whose columns are generalized eigenvectors of A. Now we put the last matrix of (8) in the form (5) doing the change of variables $X=z, Y=y, Z=x$.

Case (ii): If $e=f=0$ and $a\neq 0$, then by a rescaling we get (6). If $e=a=0$ and $f\neq 0$, then after the change of variables $X=-z, Y=y, Z=x$, we obtain (6).

Case (iii): If $e=a=f=0$, then obviously $L=A=O_3$, and we have (7). ■

Lemma 2: We consider system (1). Assume $b=0$ and $d\neq 0$. Then system (1) reduces to system S where

(a) *if $ef=0$ and $a\neq 0$, then S is*

$$\dot{x}=z, \quad \dot{y}=-xz, \quad \dot{z}=xy; \tag{9}$$

(b) *if $ef=0$ and $a=0$, then S is*

$$\dot{x}=0, \quad \dot{y}=-xz, \quad \dot{z}=xy; \tag{10}$$

(c) *if $ef\neq 0$ and $a\neq 0$, then S is*

$$\dot{x}=z, \quad \dot{y}=-xz, \quad \dot{z}=xy-1; \tag{11}$$

(d) *if $ef\neq 0$ and $a=0$, then S is*

$$\dot{x}=0, \quad \dot{y}=-xz, \quad \dot{z}=xy-1. \tag{12}$$

Proof: Since $b=0$ and $d\neq 0$, after rescaling the time parameter $T=dt$, system (1) becomes

$$\dot{x}=a_1z, \quad \dot{y}=-(x-e_1)z, \quad \dot{z}=(x-e_1)y-f_1x, \tag{13}$$

where $a_1=a/d$, $e_1=e/d$, $f_1=f/d$. The change of variables $X=x-e_1$, $Y=y-f_1$ transforms system (13) into

$$\dot{x}=a_1z, \quad \dot{y}=-xz, \quad \dot{z}=xy-e_1f_1. \tag{14}$$

Assume $ef=0$. Then $e_1f_1=0$. If $a=0$ then $a_1=0$, and system (14) is system (10). If $a\neq 0$ then $a_1\neq 0$, and system (14) becomes system (9) after the rescaling $Y=a_1y$, $Z=a_1z$. If $ef\neq 0$ and $a=0$, then also $e_1f_1\neq 0$ and $a_1=0$. By the rescaling $Y=hy$, $Z=hz$, where $h=1/(e_1f_1)$, we get system (12) from system (14). If $ef\neq 0$ and $a\neq 0$ then also $e_1f_1\neq 0$ and $a_1\neq 0$. System (14) becomes system (11) after the rescaling $X=\alpha x$, $Y=\beta y$, $Z=\gamma z$, $T=\delta t$ where $\alpha=1/\delta$, $\beta=\gamma=\delta/(e_1f_1)$, and δ is

a fixed nonzero real number such that $\delta^3=a_1e_1f_1$. ■

For the remaining of this section we assume $b\neq 0$, and we denote

$$a_1=a/b,\quad d_1=d/b,\quad e_1=e/b,\quad f_1=f/b. \tag{15}$$

Lemma 3: We consider system (1). *If* $b\neq 0$ *and* $d=0$, *then system* (1) *is becomes*

$$\dot{x}=-x+a_1z+c,\quad \dot{y}=-y+e_1z,\quad \dot{z}=-z-f_1x-e_1y, \tag{16}$$

where a_1, e_1, f_1 *are given in* (15).

Proof: Since $b\neq 0$ and $d=0$, system (1) becomes system (16) after rescaling the time ($T=bt$). ■

Lemma 4: We consider system (1). *Assume* $bd\neq 0$. *We recall the notation introduced in* (15) *for* a_1, d_1, e_1 *and* f_1. *We denote* $c_1=cd_1-e_1$, $f_2=f_1/d_1$, $r=-a_1f_1$, $c_2=re_1$.

(a) *If* $a=0$, *then system* (1) *reduces to*

$$\dot{x}=-x,\quad \dot{y}=-y-(x+c_1)z,\quad \dot{z}=-z+(x+c_1)y-f_2x-cf_1, \tag{17}$$

(b) *If* $a\neq 0$, *then system* (1) *becomes*

$$\dot{x}=-x+y+c_1,\quad \dot{y}=-y+rx-xz+c_2,\quad \dot{z}=-z+xy. \tag{18}$$

Proof: After rescaling the time ($T=bt$) system (1) becomes

$$\dot{x}=a_1z-x+c,\quad \dot{y}=-(d_1x-e_1)z-y,\quad \dot{z}=(d_1x-e_1)y-f_1x-z. \tag{19}$$

(a) If $a=0$ then $a_1=0$. After the changes of variables $X=d_1x-e_1$ and $X=x-c_1$, system (19) becomes system (17). (b) If $a\neq 0$ then $a_1\neq 0$. System (19) is transformed into system (18) after the following four changes of variables: $X=d_1x-e_1$; $Y=a_1d_1y$, $Z=a_1d_1z$; $Y=z$, $Z=y$; and $Z=-z$. ■

III. PHASE PORTRAITS OF SYSTEM (1)

In this section we describe all the phase portraits of the systems to which system (1) is reduced with the exception of system (18); i.e., systems (3)–(7), (9)–(12), (16), and (17). First of all, we introduce a definition and some notations. Consider the differential system $\dot{\mathbf{x}}=f(\mathbf{x})$ with $\mathbf{x}=(x,y,z)$ in $\mathbb{R}^3$, $f:\mathbb{R}^3\to\mathbb{R}^3$, and suppose that it has two first integrals, H_1 and H_2. If the set $\{\mathbf{x}\in\mathbb{R}^3$: rank $M<2\}$, where

$$M=\begin{pmatrix} \dfrac{\partial H_1}{\partial x} & \dfrac{\partial H_1}{\partial y} & \dfrac{\partial H_1}{\partial z} \\ \dfrac{\partial H_2}{\partial x} & \dfrac{\partial H_2}{\partial y} & \dfrac{\partial H_2}{\partial z} \end{pmatrix},$$

has zero Lebesgue measure in $\mathbb{R}^3$, then we say that H_1 and H_2 are *linearly independent*.

We denote by I_{h_i} the h_i-level sets of the first integrals H_i (i=1,2); i.e.

$$I_{h_i}:=\{(x,y,z)\in\mathbb{R}^3: H_i(x,y,z)=h_i\}\quad (i=1,2)$$

where h_i (i=1,2) are arbitrary real numbers. We also denote $I_{h_1,h_2}=I_{h_1}\cap I_{h_2}$.

System (3): The set of singular points is the x axis. In the yz plane, the orbits are the axes and hyperbolas, because system (3) restricted to this plane is a linear saddle. All the planes $x=$constant are copies of the flow in the plane $x=0$.

System (4): As before, the set of singular points is the x axis. In the yz plane, the phase portrait is given by concentric circles, because system (4) restricted to this plane is a linear center. All the planes $x=$constant are copies of the flow in the plane $x=0$.

System (5): The set of singular points is the x axis. Clearly, the function z is a first integral. So, the planes $z=C$, with $C\in\mathbb{R}$, are invariant by the flow. System $\dot{x}=y$, $\dot{y}=C$ with $C\neq 0$ is equivalent

to $\dot{x}=y$, $\dot{y}=1$. This system has the first integral $y^2/2-x=$constant. Consequently, each plane $z=C$, with $C\neq 0$, is filled with these parabolas. The plane $z=0$ is filled with straight lines parallel to the x axis.

System (6): The set of singular points is the xy plane. Clearly, y is a first integral. Thus, all the planes $y=$constant are copies of the flow in the plane $y=0$. In this plane the flow is given by the system $\dot{x}=z$, $\dot{z}=0$. Therefore, the plane $y=0$ is filled with straight lines parallel to the x-axis, which is formed by singular points.

System (7): The whole space $\mathbb{R}^3$ is filled with singular points.

System (9): It is easy to see that $H_1(x,y,z)=y^2+z^2$ and $H_2(x,y,z)=x^2+2y$ are linearly independent first integrals.

The set I_{h_1} is empty if $h_1<0$, I_{h_1} is the x axis filled with singular points if $h_1=0$, and I_{h_1} is a cylinder of radius $\sqrt{h_1}$ around the x axis if $h_1>0$.

The set of finite singular points of system (9) is the union of the x and y axes.

The set I_{h_1,h_2} is empty if $h_1=0$ and $h_2<0$, it is a singular point (the origin (0, 0, 0)) if $h_1=h_2=0$, and it is formed by two singular points $((-\sqrt{h_2},0,0)$ and $(\sqrt{h_2},0,0))$ if $h_1=0$ and $h_2>0$.

We note that the sets I_{h_2} and $\mathcal{P}_{h_2}\times\mathbb{R}$, where $\mathcal{P}_{h_2}=\{(x,y,0)\in\mathbb{R}^3: x^2+2y=h_2\}$, are homeomorphic.

Proposition 5: For $h_1>0$ the flow on the cylinder I_{h_1} is as follows: I_{h_1,h_2} is empty if $h_2<-2\sqrt{h_1}$; it is the center $\{(0,-\sqrt{h_1},0)\}$ if $h_2=-2\sqrt{h_1}$; it is a periodic orbit if $-2\sqrt{h_1}<h_2<2\sqrt{h_1}$; it is formed by the saddle $\{(0,\sqrt{h_1},0)\}$ and two homoclinic orbits to this saddle if $h_2=2\sqrt{h_1}$; and finally, it is formed by two periodic orbits if $h_2>2\sqrt{h_1}$.

Proof: In the xy plane, the parabola $\mathcal{P}_{h_2}$ intersects the y-axis at the point $(0,h_2/2)$. For $h_1>0$ the cylinder I_{h_1} intersects the xy plane into the pair of parallel lines $y^2=h_1$. For $h_2=-2\sqrt{h_1}$, the intersection $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is the point $(0,-\sqrt{h_1},0)$. For $-2\sqrt{h_1}<h_2<2\sqrt{h_1}$, the intersection of the cylinder I_{h_1} with the topological plane $\mathcal{P}_{h_2}\times\mathbb{R}$ is a topological circle. For $h_2=2\sqrt{h_1}$, $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is a union of two topological circles, both of them containing the singular point $\{(0,\sqrt{h_1},0)\}$. For $h_2>2\sqrt{h_1}I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is a union of two disjoint topological circles. ■

We note that, when we fix $h_1>0$, the phase portraits of system (9) and of the simple pendulum are exactly the same. Since both systems have the same separatrix configuration, by a theorem of Neumann,[23] it follows that both phase portraits are topologically equivalent.

Note that system (9) also appears in Refs. 18 and 25 in the context of a dynamo problem under the form

$$\dot{x}=y,\quad \dot{y}=x-xz,\quad \dot{z}=xy.$$

However, this is system (9), after two changes of variables ($Z=z-1$, and $Y=-z$, $Z=y$).

System (10): We can check that $H_1(x,y,z)=y^2+z^2$ and $H_2(x,y,z)=x$ are linearly independent first integrals. The set I_{h_1} is empty if $h_1<0$, I_{h_1} is the x axis filled with singular points if $h_1=0$, and I_{h_1} is a cylinder of radius $\sqrt{h_1}$ around the x axis if $h_1>0$. The set I_{h_2} is the plane $\{x=h_2\}$.

The set of finite singular points of system (10) is the union of the yz plane with the x axis. The set I_{0,h_2} is the singular point $(h_2,0,0)$ for all h_2.

Proposition 6: For $h_1>0$ the flow on the cylinder I_{h_1} is as follows: I_{h_1,h_2} is a periodic orbit if $h_2\neq 0$ and it is a circle filled with singular points if $h_2=0$.

Proof: For any h_2, I_{h_1,h_2} is the circle $y^2+z^2=h_1, x=h_2$. When $h_2=0$ the circle is contained in the plane $x=0$, which is entirely formed by singular points. ■

System (11): Two linearly independent first integrals of system (11) are $H_1(x,y,z)=(x+1)^2+(y+1)^2+z^2$ and $H_2(x,y,z)=x^2+2y$. The description of the topology of I_{h_1} is the following: I_{h_1} is empty if $h_1<0$, I_{h_1} is the singular point $(-1,-1,0)$ if $h_1=0$, and I_{h_1} is the sphere of center $(-1,-1,0)$ and radius $\sqrt{h_1}$ if $h_1>0$.

The set of finite singular points of system (11) is the hyperbola $\mathcal{H}:=\{(x,y,z)\in\mathbb{R}^3: xy=1, z$

$=0\}$. We denote by $\mathcal{C}_{h_1}:=\{(x,y,z)\in\mathbb{R}^3:(x+1)^2+(y+1)^2=h_1,z=0\}$ the circle of center $(-1,-1,0)$ and radius $\sqrt{h_1}$ contained in the plane $z=0$, and by $\mathcal{P}_{h_2}:=\{(x,y,z)\in\mathbb{R}^3:x^2+2y=h_2,z=0\}$ a parabola in the plane $z=0$.

We note that $I_{h_1}\cap\{z=0\}=\mathcal{C}_{h_1}$ and $I_{h_2}\cap\{z=0\}=\mathcal{P}_{h_2}$. Moreover, since $I_{h_2}=\{(x,y,z)\in\mathbb{R}^3:(x,y)\in\mathcal{P}_{h_2}\}$, we can denote I_{h_2} by $\mathcal{P}_{h_2}\times\mathbb{R}$.

We provide the phase portrait of system (11) in $\mathbb{R}^3$, describing it on every sphere of center $(-1,-1,0)$. We distinguish three cases according to the values of $h_1>0$.

For $0<h_1<8$, the circle $\mathcal{C}_{h_1}$ intersects the hyperbola $\mathcal{H}$ in two points, which are singular points of system (11). They are situated in the quadrant $\{x<0,y<0\}$, and we denote them by $P_1=(x_1,y_1,0)$, and $P_4=(x_4,y_4,0)$ where $x_4<x_1<0$. We also denote $h_{21}:=H_2(x_1,y_1,0)$, and $h_{24}:=H_2(x_4,y_4,0)$. We claim that $h_{21}<h_{24}$. Indeed, a direct computation yields $h_{24}-h_{21}=(x_4-x_1)(x_1+x_4-2/x_1x_4)$. Since both factors are strictly negative, we get that $h_{24}-h_{21}>0$.

Proposition 7: For $0<h_1<8$ *the phase portrait on the sphere* I_{h_1} *consists of two singular points,* $I_{h_1,h_{21}}=\{P_1\}$, *and* $I_{h_1,h_{24}}=\{P_4\}$, *which are centers, and of periodic orbits* $I_{h_1h_2}$ *for* $h_{21}<h_2<h_{24}$.

Proof: For $h_2=h_{21}$ the set $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is the point P_1 (in other words, the parabola $\mathcal{P}_{h_2}$ is tangent to the circle $\mathcal{C}_{h_1}$ at P_1). For $h_{21}<h_2<h_{24}$ the intersection of the sphere I_{h_1} with the topological plane $\mathcal{P}_{h_2}\times\mathbb{R}$ is a topological circle. For $h_2=h_{24}$, the set $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is the point P_2 (in other words, $\mathcal{P}_{h_2}$ is tangent to $\mathcal{C}_{h_1}$ at P_4). ■

For $h_1=8$, the circle $\mathcal{C}_8$ intersects the hyperbola $\mathcal{H}$ in three points, which are singular points of system (11). Two of them are situated in the quadrant $\{x<0,y<0\}$, denoted by $P_1=(x_1,y_1,0)$, and $P_4=(x_4,y_4,0)$ with $x_4<x_1<0$, and one is situated in the quadrant $\{x>0,y>0\}$, denoted by $P_2=(x_2,y_2,0)$ where $x_2>0$. We also denote $h_{2i}:=H_2(x_i,y_i,0)$, for $i=1,2,4$.

We claim that $h_{21}<h_{22}<h_{24}$. We prove these inequalities by using the equation $h_{2i}-h_{2j}=(x_i-x_j)(x_i+x_j-2/x_ix_j)$, for $i\neq j$ equal to 1,2,4, and by computing the abscissas x_1, and x_2.

Both abscissas are solutions of the same equation, $(x+1/x+1)^2=9$, but $x_1<0$ while $x_2>0$. Thus, x_1 is the greatest negative solution of the equation $x+1/x+1=-3$, while x_2 is the unique positive solution of the equation $x+1/x+1=3$. Direct computation yields $x_1=-2+\sqrt{3}$, and $x_2=1$.

Therefore, the first inequality is true, because

$$h_{22}-h_{21}=\frac{(x_1-1)^2}{-x_1}(x_1+2)$$

is strictly positive, as all its factors.

The second inequality also holds, because

$$h_{24}-h_{22}=(x_4-1)^2\frac{x_4+2}{x_4}$$

and the ratio is strictly positive (by direct computation it is equal to $2\sqrt{3}-3$, because $x_4=-2-\sqrt{3}$).

Proposition 8: For $h_1=8$ *the phase portrait over the sphere* I_{h_1} *consists of three singular equilibrium points* P_1,P_2,P_4 *and of periodic orbits. The singular points* $P_1(x_1,y_{1,0})=I_{h_1,h_{21}}$ *and* $P_4(x_4,y_{4,0})=I_{h_1,h_{24}}$ *are centers and the singular point* $P_2(x_2,y_{2,0})=I_{h_1,h_{22}}$ *with* $x_4<x_1<0<x_2<1$ *has a homoclinic orbit to it. The local phase portrait of* P_2 *is formed by the union of two hyperbolic sectors. The periodic orbits are obtained for* $h_{21}<h_2<h_{22}$ *and* $h_{22}<h_2<h_{24}$.

Proof: It follows from the statements below: (i) for $h_2=h_{21}$ or h_{24}, the set $I_8\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is formed by the point P_1 or P_4, respectively, (in other words, for $h_2=h_{21}$ or h_{24} the parabola $\mathcal{P}_{h_2}$ is tangent to the circle $\mathcal{C}_8$ at P_1, respectively at P_4); (ii) for $h_{21}<h_2<h_{22}$, and $h_{22}<h_2<h_{24}$, the intersection of the sphere I_8 with the topological plane $\mathcal{P}_{h_2}\times\mathbb{R}$ is a topological circle; (iii) for $h_2=h_{22}$, $I_8\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is a topological circle containing the singular point P_2.

With respect to the statement on the local phase portrait of P_2, in addition to (ii) and (iii), we note that for $h_2=h_{22}$, $\mathcal{P}_{h_2}$ and $\mathcal{C}_8$ share the same tangent at the common point P_2, namely $x+y$

$-2=0$. We also note that $\mathcal{P}_{h_{22}}$ intersects the y-axis at the point of coordinates $(0,3/2)$ and the x-axis at the point of coordinates $(\sqrt{3},0)$, while $\mathcal{C}_8$ intersects the y-axis at the point of coordinates $(0,\sqrt{7}-1)$ and the x-axis at the point of coordinates $(\sqrt{8}-1,0)$. Note that $\sqrt{7}-1>3/2$ and $\sqrt{7}-1<\sqrt{3}$. We now prove that $\mathcal{P}_{h_{22}}$ is below the circle $\mathcal{C}_8$ in the first quadrant for $0<x<1$, and above it for $x>1$. This fact reduces to show that $\sqrt{8-(1+x)^2}-(5-x^2)/2\geqslant 0$ for $0<x<1$, and that the opposite inequality holds for $1<x<\sqrt{7}-1$. Therefore, it suffices to prove $(x-1)^3(x+3)\leqslant 0$ for $0<x<1$, and the opposite inequality for $1<x<\sqrt{7}-1$, which is evident. ■

For $h_1>8$, the circle $\mathcal{C}_{h_1}$ intersects the hyperbola $\mathcal{H}$ in four points, which are singular points of system (11). Two of them are situated in the quadrant $\{x<0,y<0\}$, denoted by $P_1=(x_1,y_1,0)$, and $P_4=(x_4,y_4,0)$ where $x_4<x_1<0$, and the other two are in the quadrant $\{x>0,y>0\}$, denoted by $P_2=(x_2,y_2,0)$, and $P_3=(x_3,y_3,0)$ where $0<x_2<x_3$. We also denote $h_{2i}:=H_2(x_i,y_i,0)$, for $i=1,2,3,4$. We claim that $h_{21}<h_{22}<h_{23}<h_{24}$.

We prove these inequalities by using the equation $h_{2i}-h_{2j}=(x_i-x_j)(x_i+x_j-2/x_ix_j)$, for $i\neq j$ equal to 1,2,3,4 and by computing the abscissas $x_i, i=1,2,3,4$.

The abscissas are obtained by elementary computations: $2x_4=-1-r-\sqrt{(r+3)(r-1)}$, $2x_1=-1-r+\sqrt{(r+3)(r-1)}$, $2x_2=-1+r-\sqrt{(r-3)(r+1)}$, $2x_3=-1+r+\sqrt{(r-3)(r+1)}$, where $r:=\sqrt{1+h_1}>3$ because $h_1>8$.

The inequality $h_{21}<h_{22}$ holds because $x_2-x_1>0$ and $x_1+x_2-2/x_1x_2>0$. Indeed, $x_2>0>x_1$ implies the first inequality, and the fact that $-2/x_1x_2>0$. Thus, it is sufficient to prove that $x_1+x_2>0$. By using the above expressions of x_1 and x_2 as a function of r, we have $x_1+x_2>0$ if and only if $12(1+h_1)+13>0$, which holds because $h_1>8$.

The inequality $h_{22}<h_{23}$ holds because x_2 and x_3 are the roots of the quadratic equation $x^2+(1-r)x+1=0$, and by Viète equations we have $x_2+x_3=r-1$ and $x_2x_3=1$, hence $h_{23}-h_{22}=(x_3-x_2)(x_2+x_3-2/x_2x_3)=(x_3-x_2)(r-3)>0$, because $x_3>x_2$ and $r>3$.

The inequality $h_{23}<h_{24}$ holds because both factors of $h_{24}-h_{23}$, (i.e. x_4-x_3 and x_3+x_4-2/x_3x_4), are strictly negative. The first one is strictly negative because $x_3>0>x_4$. In order to prove that the second one is also strictly negative we use the following three statements:

(a) $r>3$ implies that $x_3>1$;
(b) $r>3$ implies that $-x_4>x_3+1$;
(c) If a and b are real numbers such that $b>a+1$ and $a>1$, then $a-b+2/ab<0$.

Since $r>3$ implies $\sqrt{(r-3)(r+1)}>0>-r+3$, i.e. $2x_3>2$, and (a) follows.

From $r>3>0$ we get that $r^2+2r-3>r^2-2r-3>0$, which implies that $\sqrt{r^2+2r-3}>\sqrt{r^2-2r-3}$, hence $-2x_4>2x_3+2$. So (b) is proved.

On one hand, $b>a+1$ and $a>1$ implies $ab>a(a+1)>2$. On the other hand, $b>a+1$ implies $2>2/(b-a)$. Thus, $ab>2/(b-a)$. The last inequality is equivalent to the desired one, because $b-a>1>0$. Hence, (c) follows.

Now $x_3+x_4-2/x_3x_4<0$ follows from (c) for $a=x_3$ and $b=-x_4$. The proof of $h_{23}<h_{24}$ is complete.

Proposition 9: For $h_1>8$ the phase portrait over the sphere I_{h_1} is as follows: $I_{h_1,h_{21}}=\{P_1\}$ is a center; for $h_{21}<h_2<h_{22}$, I_{h_1,h_2} is a periodic orbit; $I_{h_1,h_{22}}$ is formed by the saddle P_2 and two homoclinic orbits to this saddle; for $h_{22}<h_2<h_{23}$, I_{h_1,h_2} is formed by two periodic orbits; $I_{h_1h_{23}}$ is formed by the center P_3 and a periodic orbit; for $h_{23}<h_2<h_{24}$, I_{h_1,h_2} is a periodic orbit; and finally, $I_{h_1,h_{24}}=\{P_4\}$ is a center.

Proof: For $h_2=h_{21}$ (respectively, h_{24}) the set $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is the point P_1 (respectively, P_4). In other words, for $h_2=h_{21}$ (respectively h_{24}) the parabola $\mathcal{P}_{h_2}$ is tangent to the circle $\mathcal{C}_{h_1}$ at P_1 (respectively, at P_4). For $h_{21}<h_2<h_{22}$ the intersection of the sphere I_{h_1} with the topological plane $\mathcal{P}_{h_2}\times\mathbb{R}$ is a topological circle. For $h_2=h_{22}$, the set $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is a union of two topological circles, both of them containing the singular point P_2. For $h_{22}<h_2<h_{23}$ the set $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is union of two disjoint topological circles. For $h_2=h_{23}$ the set $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is the union of the point P_3 with a topological circle which does not contain P_3. For $h_{23}<h_2<h_{24}$ the set $I_{h_1}\cap\mathcal{P}_{h_2}\times\mathbb{R}$ is a topological circle. ■

System (12): Clearly, x is a first integral. The flow of system (12) has the same pattern in every plane $x=x_0$ with $x_0\neq 0$. It suffices to analyze the two-dimensional system: $\dot{y}=-x_0z$, $\dot{z}=x_0y-1$. There are two cases: $x_0=0$ and $x_0\neq 0$. If $x_0=0$ then the system becomes $\dot{y}=0$, $\dot{z}=-1$. Its flow on the yz plane consists of the straight lines $y=y_0$, on which the orientation of the flow is opposite to the z axis. If $x_0\neq 0$ then, since the linear part at its singular point is given by the matrix

$$\begin{pmatrix} 0 & -x_0 \\ x_0 & 0 \end{pmatrix},$$

we have a global center.

System (16): Denote $\Delta=a_1f_1+e_1^2$ and $f_4=f_1/(1+e_1^2)$. The following statements hold:

(a) If $\Delta<-1$, then its singular point has a two-dimensional stable manifold and a one-dimensional unstable one.
(b) If $\Delta>-1$, then its singular point is a global attractor.
(c) If $\Delta=-1$ and $c\neq 0$, then there are no singular points.
(d) If $\Delta=-1$ and $c=0$, then the set of singular points is the straight line (a_1z,e_1z,z) with arbitrary z. Every one of these singular points is contained in an invariant plane $f_1x+e_1y+z=h$, for a convenient constant h. In each of these planes the corresponding singular point is a global attractor.

Now we prove the above statements. The singular points of system (16) are given by the equations

$$(1+\Delta)/(1+e_1^2)x=c, \quad y=-e_1f_4x, \quad z=-f_1f_4x. \tag{20}$$

If $\Delta\neq -1$, then clearly system (16) has a unique singular point S. Now we prove statements (a) and (b). To this purpose, we consider the linear part A of the vector field of system (16) at the singular point S

$$A=\begin{pmatrix} -1 & 0 & a_1 \\ 0 & -1 & e_1 \\ -f_1 & -e_1 & -1 \end{pmatrix},$$

and we study its eigenvalues. The characteristic equation is $(1+\lambda)((1+\lambda)^2+\Delta)=0$. It is therefore sufficient to prove that if $\Delta\neq -1$, then the roots of the equation in λ $(1+\lambda)^2=-\Delta$ have the real parts strictly negative. If $\Delta<-1$, then the eigenvalues of matrix A are -1, $-1-\sqrt{-\Delta}$ and $-1+\sqrt{-\Delta}$. Thus, all of them are real, two of them being strictly negative and one strictly positive. Statement (a) is proved by the Hartman–Grobman Theorem. If $-1<\Delta\leqslant 0$, then the eigenvalues of the matrix A are given by the same formulas as before but now they are all strictly negative. If $\Delta>0$ then the eigenvalues of A are -1, and $-1\pm i\sqrt{\Delta}$. All of them have strictly negative real part. Statement (b) is proved. If $\Delta=-1$ and $c\neq 0$, then equations (20) have no solution. Statement (c) follows. If $\Delta=-1$ and $c=0$, then equations (20) have the solution $(x,-e_1f_4x,-f_4x)$ with arbitrary x. At each singular point, the associated eigenvalues are $0,-1,-2$. The linear center eigenspace (i.e., corresponding to the zero eigenvalue) is the straight line (a_1z,e_1z,z) with z arbitrary in $\mathbb{R}$. The linear stable eigenspace corresponding to eigenvalues -1 and -2 is $f_1x+e_1y-z=0$. Clearly, in our case, $H=f_1x+e_1y-z$ is a first integral of system (16). The planes $f_1x+e_1y+z=h$, where h is an arbitrary constant, are parallel and on each of these planes the corresponding singular point is a global attractor.

System (17): This system has only one finite singular point, namely $(0,-c_1f_3,f_3)$ where $f_3=-cf_1/(1+c_1^2)$. Now we prove that $(0,-c_1f_3,f_3)$ is a global attractor of system (17) in $\mathbb{R}^3$. Since $\dot{x}=-x$, it follows that if $(x(t),y(t),z(t))$ is an orbit passing through the point (x_0,y_0,z_0) at $t=0$, then $x(t)=e^{-t}x_0$. Thus, all trajectories of system (17) tends towards the plane $x=0$ when $t\to\infty$; and if $x_0=0$, then $x(t)=0$ for all t. On the other hand, in the plane $x=0$ the singular point $(0,-c_1f_3,f_3)$ is a global attractor, because on the plane $x=0$ the system is $\dot{y}=-y-c_1z$, $\dot{z}=-z+c_1y-cf_1$, and the

eigenvalues of the singular point $(c_1 f_3, -f_3)$ are $-1 \pm i|c_1|$. Consequently, the singular point $(0, -c_1 f_3, f_3)$ is a global attractor of $\mathbb{R}^3$.

IV. BOUNDEDNESS OF SOLUTIONS FOR SYSTEM (18)

The goal of this section is to prove that all trajectories of system (18) enter in an ellipsoid, i.e., all ω-limit sets of the orbits of (18) are contained in that ellipsoid.

We first introduce some notation. If $\mathcal{E}$ is the ellipsoid $\mathcal{E}: x^2/a^2+y^2/b^2+z^2/c^2=1$ then its *exterior* is the set $\text{Ext}\,\mathcal{E}: x^2/a^2+y^2/b^2+z^2/c^2>1$, its *interior* is the set $\text{Int}\,\mathcal{E}: x^2/a^2+y^2/b^2+z^2/c^2<1$. We also denote $\mathcal{E}^- = \text{Int}\,\mathcal{E} \cup \mathcal{E}$. Consider now the differential equation

$$\dot{\mathbf{x}} = d\mathbf{x}/dt = f(\mathbf{x}), \quad \mathrm{x} \text{ in } \mathbb{R}^n. \tag{21}$$

The *orbital derivative* of a differentiable function $V: \mathbb{R}^n \mapsto \mathbb{R}$ along the vector field f parameterized by t is the scalar product $L_t V(\mathbf{x}) = \text{grad}\, V(\mathbf{x}) \cdot f(\mathbf{x})$. The *orbit* of (21) starting from the point $\mathbf{x}$ is denoted by $\varphi_t(\mathbf{x})$ where φ_t is the *flow* of (21). A point $\mathbf{y}$ is an *ω-limit point* of the orbit $\varphi_t(\mathbf{x})$ through the point $\mathbf{x}$ if there exists a sequence of numbers $t_1 < t_2 < t_3 < \cdots$ such that $\lim_{n\to\infty} t_n = \infty$ and $\lim_{n\to\infty} \varphi_{t_n}(\mathbf{x}) = \mathbf{y}$. The *$\omega$-limit set* of the orbit $\varphi_t(\mathbf{x})$, denoted $\omega(\varphi_t(\mathbf{x}))$, is the set of its all ω-limit points.

Theorem 10: *We consider the differential equation $\dot{\mathbf{x}} = f(\mathbf{x})$, where $f: \mathbb{R}^3 \mapsto \mathbb{R}^3$ is a C^1 function, a differentiable function $V: \mathbb{R}^3 \mapsto \mathbb{R}$, and an ellipsoid $\mathcal{E}$ in $\mathbb{R}^3$ such that $L_t V(\mathbf{x}) < 0$ for $\mathbf{x}$ in $\text{Ext}\,\mathcal{E}$. Then $\omega(\varphi_t(\mathbf{x})) \subseteq \mathcal{E}^-$ for any $\mathbf{x}$ in $\mathbb{R}^3$.*

Remark: This result is similar and more general than the well-known Lyapunov's Stability Theorem, the role of the singular point being played by the ellipsoid. Our proof follows the Chicone's one[3] for the mentioned theorem.

Proof of Theorem 10: Let $\mathbf{x} \in \mathbb{R}^3$ and $\xi \in \omega(\varphi_t(\mathbf{x}))$. We want to prove that $\xi \in \mathcal{E}^-$. Assume the contrary. Then $\xi \in \text{Ext}\,\mathcal{E}$. Since $\xi \in \omega(\varphi_t(\mathbf{x}))$, there is a monotone increasing sequence of numbers $\{t_n\} \to \infty$ such that $\varphi_{t_n}(\mathbf{x}) \to \xi \in \text{Ext}\,\mathcal{E}$. Therefore, there is some natural number N such that $\varphi_{t_n}(\mathbf{x}) \in \text{Ext}\,\mathcal{E}$ for any $n \geqslant N$. By the continuity of function V, $V(\varphi_{t_n}(\mathbf{x})) \to V(\xi)$. By hypothesis, the function $t \mapsto V(\varphi_t(\mathbf{x}))$ is strictly decreasing for $\varphi_t(\mathbf{x}) \in \text{Ext}\,\mathcal{E}$. Thus, $V(\varphi_{t_n}(\mathbf{x})) \geqslant V(\xi)$ for any $n \geqslant N$. On the other hand, $\lim V(\varphi_{t_N+t_n}(\mathbf{x})) = \lim V(\varphi_{t_N}(\varphi_{t_n}(\mathbf{x}))) = V(\varphi_{t_N}(\xi)) < V(\xi)$. Consequently, there is some natural number $q \geqslant N$ such that $V(\varphi_{t_N+t_q}(\mathbf{x})) < V(\xi)$. There is also a natural number $m > N$ such that $t_m > t_N + t_q$. For this number we get $V(\varphi_{t_m}(\mathbf{x})) < V(\varphi_{t_N+t_q}((x))) < V(\xi) \leqslant V(\varphi_{t_m}((x)))$, i.e., a contradiction. The assumption that $\xi \notin \mathcal{E}^-$ is false. The proof is completed.■

Lemma 11: Consider system (18). Then for any $\alpha > 0$ and $\beta > 0$ there is a differentiable function $V_{\alpha,\beta}: \mathbb{R}^3 \mapsto \mathbb{R}$ and an ellipsoid $\mathcal{E}_{\alpha,\beta}$ in $\mathbb{R}^3$ such that

$$L_t V_{\alpha,\beta}(x,y,z) < 0 \quad \textit{for } (x,y,z) \textit{ in } \textit{Ext}\,\mathcal{E}_{\alpha,\beta}. \tag{22}$$

Proof: Let $\alpha > 0$ and $\beta > 0$ be fixed, and take

$$V_{\alpha,\beta}(x,y,z) = \alpha x^2 + \beta y^2 + \beta(z - (r + \alpha/\beta))^2 - R_V, \tag{23}$$

where

$$R_V = (\alpha + \beta r)^2/\beta. \tag{24}$$

Clearly, the function $V_{\alpha,\beta}(x,y,z)$ is differentiable. It follows that

$$\frac{1}{2} L_t V_{\alpha,\beta}(x,y,z) = -\alpha(x - c_1/2)^2 - \beta(y - c_2/2)^2 - \beta\left(z - \frac{\alpha + \beta r}{2\beta}\right)^2 + R_L, \tag{25}$$

where

$$R_L = \alpha c_1^2/4 + \beta c_2^2/4 + R_V/4. \tag{26}$$

Now it is easy to see that $L_t V_{\alpha,\beta}(x,y,z) < 0$ for any $(x,y,z) \in \text{Ext}\,\mathcal{E}_{\alpha,\beta}$ where $\mathcal{E}_{\alpha,\beta}$ is the ellipsoid

$$\mathcal{E}_{\alpha,\beta}: \alpha(x-c_1/2)^2+\beta(y-c_2/2)^2+\beta\left(z-\frac{\alpha+\beta r}{2\beta}\right)^2=R_L. \tag{27}$$

In short, we found the function $V_{\alpha,\beta}(x,y,z)$ and the ellipsoid $\mathcal{E}_{\alpha,\beta}$ satisfying (22). ■

The main result of this section follows directly from Lemma 11 and Theorem 10.

Theorem 12. *Let φ_t be the flow of system* (18). *Then, there exists an ellipsoid $\mathcal{E}$ in $\mathbb{R}^3$ such that $\omega(\varphi_t(\mathbf{x}))\subseteq\mathcal{E}^-$ for any $\mathbf{x}$ in $\mathbb{R}^3$.*

Remark: In fact, for any $\alpha>0$ and $\beta>0$ fixed there exists such an ellipsoid.

V. QUADRATIC INVARIANT ALGEBRAIC SURFACES FOR SYSTEM (18)

This section has two parts. In the first part we prove the proposition below. In the second part of this section we discuss the nature of the surface f obtained in Proposition 13(d). We also prove some general results in Lemma 17 about limit sets of quadratic systems with constant cofactor and apply them to our case.

Proposition 13: Let χ be the vector field associated to system (18); *i.e.*,

$$\mathcal{X}=(-x+y+c_1)\frac{\partial}{\partial x}+(-y+rx-xz+c_2)\frac{\partial}{\partial y}+(-z+xy)\frac{\partial}{\partial z}.$$

If

$$f=\sum_{d=0}^{2}\sum_{\substack{i+j+k=d,\\ 0\leqslant i,j,k\leqslant 2}} a_{ijk}x^iy^jz^k \tag{28}$$

in $\mathbb{R}[x,y,z]$ is such that

$$\mathcal{X}f=Kf, \tag{29}$$

for some polynomial K in $\mathbb{R}[x,y,z]$, then

(a) $K=k_0\in\mathbb{R}$;
(b) *if* $k_0\neq -2$, *then* $f=0$;
(c) *if* $k_0=-2$ *and* $c_2\neq -rc_1$, *then* $f=0$;
(d) *if* $k_0=-2$ *and* $c_2=-rc_1$, *then* $f=a(-r(x-c_1)^2+y^2+z^2)$, *where a is an arbitrary real constant.*

Let $f\in\mathbb{R}[x,y,z]\backslash\mathbb{R}$. The algebraic surface $f(x,y,z)=0$ is called an *invariant algebraic surface* of system (18) if equation (29) holds for some real polynomial $K(x,y,z)$, which is called the *cofactor* of the surface $f=0$. For simplicity, we will refer to the surface $f=0$ only by f.

We separate the main parts of the proof of Proposition 13 into two steps.

Step 1: We prove that each cofactor for system (18) is constant. First, we recall the definition of the weight of a polynomial as introduced in Ref. 28. Next, we prove the properties we need in Lemma 14. Finally, in Lemma 15 we prove that each cofactor for system (18) is constant.

The *weight of a monomial* $Cx^ay^bz^c$ is $a+2b+2c$, and the *weight of a nonzero polynomial* is the largest of the weights of its constituent monomials. For any polynomial f of degree d, and any integer $n\geqslant 0$ we denote by W_nf, and by G_df, the sum of those monomials of f which have weight exactly n, and degree exactly d, respectively. We say that a polynomial is *weight homogeneous of weight w* if it is the sum of monomials of weight w. By $w(f)$, and by $\deg(f)$, we denote the weight, and the degree of polynomial f, respectively.

Lemma 14: The following statements hold

(a) $w(\chi f)\leqslant w(f)+1$ *for any polynomial f*
(b) $w(fg)=w(f)+w(g)$ *for any two polynomials f and g.*
If f is a polynomial of degree d_0 and $w_0=w(G_{d_0}f)$ then
(c) $W_{w_0+1}G_{d_0+1}\chi f=W_{w_0+1}G_{d_0+1}\chi(W_{w_0}G_{d_0}f)$;

(d) $W_{w_0}G_{d_0}f=x^n\phi(y,z)$ *where* $n=2d_0-w_0$ *and* ϕ *is a homogeneous polynomial of degree* $m=w_0-d_0$.

Proof: Statements (*a*) and (*b*) follow from the fact that they hold for mononomials, and from the definition of the weight of a polynomial.

(*c*) Denote by $S_{w<w_0}f$, and by $S_{d<d_0}f$, the sum of the monomials in f which have weight strictly less than w_0, and degree strictly less than d_0, respectively. Then, $G_{d_0}f=W_{w_0}G_{d_0}f+S_{w<w_0}f$, since $w_0=w(G_{d_0}f)$, and $f=G_{d_0}f+S_{d<d_0}f$. Consequently, $\chi f=\chi(W_{w_0}G_{d_0}f+S_{w<w_0}f+S_{d<d_0}f)$. Any term of $\chi(S_{w<w_0}f)$ is of weight at most w_0, and any term of $\chi(S_{d<d_0}f)$ is of degree at most d_0, because the vector field χ increases weight and degree by at most one (as proved in (a)). Therefore, the third statement is proved.

(d) Clearly, $W_{w_0}G_{d_0}f$ is a finite sum of terms of the form $C_ix^{a_i}y^{b_i}z^{c_i}$ with $a_i+b_i+c_i=d_0$ and $a_i+2b_i+2c_i=w_0$ for any i. Therefore, we have $a_i=2d_0-w_0=n$ and $b_i+c_i=w_0-d_0=m$ for any i. The proof is completed. ■

Lemma 15: If f and K are polynomials such that (29) *holds, then K is constant.*

Proof: The idea is to use the fact that if $\mathcal{X}f=Kf$, then

$$w(\mathcal{X}f)=w(Kf) \tag{30}$$

and

$$W_{w_0+1}G_{d_0+1}\mathcal{X}f=W_{w_0+1}G_{d_0+1}(Kf), \tag{31}$$

where we denote $\deg(f)=d_0$ and $w(G_{d_0}f)=w_0$. Clearly, from (30) and Lemma 14 (*a*) and (*b*) we get $w(K)\leqslant 1$, i.e., $K=k_{100}x+k_0$. It suffices now to show that (31) implies $k_{100}=0$. To this purpose, we look more carefully at the terms of Eq. (31). By Lemma 14 (*c*) and (*d*), the left term is $W_{w_0+1}G_{d_0+1}\mathcal{X}f=W_{w_0+1}G_{d_0+1}\mathcal{X}(W_{w_0}G_{d_0})f=W_{w_0+1}G_{d_0+1}\mathcal{X}(x^n\phi)=x^{n+1}(y(\partial\phi/\partial z)-z(\partial\phi/\partial y))$. The right term of (31) is $W_{w_0+1}G_{d_0+1}(Kf)=W_{w_0+1}G_{d_0+1}(k_{100}xf)=W_{w_0+1}(k_{100}xG_{d_0}f)=k_{100}xW_{w_0}(G_{d_0}f)=k_{100}x^{n+1}\phi$. Therefore, Eq. (31) reduces to

$$y\frac{\partial\phi}{\partial z}-z\frac{\partial\phi}{\partial y}=k_{100}\phi, \tag{32}$$

where $\phi(y,z)$ is a homogeneous polynomial of degree m. The change of variables $\eta=y+iz$, $\zeta=y-iz$ transforms (32) into

$$i\left(\eta\frac{\partial\psi}{\partial\eta}-\zeta\frac{\partial\psi}{\partial\zeta}\right)=k_{100}\psi, \tag{33}$$

with $\phi(\eta,\zeta)$ a homogeneous polynomial of degree m. Then, the solutions of Eq. (33) are of the from $\phi=C\eta^{m-\mu}\zeta^{\mu}$ for some integer μ with $0\leqslant\mu\leqslant m$ and $k_{100}=i(m-2\mu)$. Since k_{100} must be real, $m=2\mu$. So, $k_{100}=0$. ■

Remark: The method of proof is taken from Ref. 28, where the same result was proved for Lorenz system. Note that the result holds not merely for quadratic but for arbitrary polynomials f.

Remark: We remark that from Eq. (33) we can get additional information interesting in itself about the degree of its solutions. More precisely, m is even. Hence the polynomial ϕ in Lemma 14(*d*) is of even degree.

Step 2: If f is a quadratic polynomial (28), K is constant and both satisfy (29), now we shall prove that statements (*b*)–(*d*) of Proposition 13 hold.

Let f be a quadratic polynomial (28), $K=k_0$ constant and both satisfying (29). Clearly, (29) is a polynomial equation in $\mathbb{R}[x,y,z]$. The coefficients a_{ijk} of the polynomial f will be determined by comparing the coefficients of equal degree of the polynomials $\mathcal{X}f$ and Kf. In order to write the corresponding equations, it is more convenient to write each polynomial of Eq. (29) as a sum of its homogeneous parts. Given a polynomial $A\in\mathbb{R}[x,y,z]$ of degree m, we denote by H_lA its homogeneous part of degree l, for any $0\leqslant l\leqslant m$. Before computing the homogeneous parts of

polynomials $\mathcal{X}f$ and Kf we need to compute the partial derivatives of f. Here and after, we denote by f_x, f_y and f_z the derivatives of f with respect to x, y and z, respectively,

$$f_x = 2a_{200}x + a_{110}y + a_{101}z + a_{100},$$

$$f_y = a_{110}x + 2a_{020}y + a_{011}z + a_{010},$$

$$f_z = a_{101}x + a_{011}y + 2a_{002}z + a_{001}.$$

Therefore, $\mathcal{X}f=\Sigma_{l=0}^{3}H_l\mathcal{X}f$ where

$$H_3\mathcal{X}f = -xz(a_{110}x + 2a_{020}y + a_{011}z) + xy(a_{101}x + a_{011}y + 2a_{002}z),$$

$$H_2\mathcal{X}f = (-x+y)(2a_{200}x + a_{110}y + a_{101}z) + (rx-y)(a_{110}x + 2a_{020}y + a_{011}z) - z(a_{101}x + a_{011}y + 2a_{002}z),$$

$$H_1\mathcal{X}f = a_{100}(-x+y) + c_1(2a_{200}x + a_{110}y + a_{101}z) + a_{010}(rx-y) + c_2(a_{110}x + 2a_{020}y + a_{011}z) - a_{001}z,$$

$$H_0\mathcal{X}f = c_1a_{100} + c_2a_{010},$$

and $Kf=\Sigma_{l=0}^{3}H_lKf$ where

$$H_3Kf = 0,$$

$$H_2Kf = k_0H_2f,$$

$$H_1Kf = k_0H_1f,$$

$$H_0Kf = a_0k_0.$$

Writing that $H_l\mathcal{X}f=H_lKf$ for each $l=0,\ldots,3$, we get, respectively, for $l=3$

$$a_{110} = a_{101} = a_{011} = 0, \tag{34}$$

$$a_{002} = a_{020}; \tag{35}$$

for $l=2$

$$(k_0+2)a_{200} = 0, \tag{36}$$

$$(k_0+2)a_{020} = 0, \tag{37}$$

$$2a_{200} + 2ra_{020} = -a_{001}, \tag{38}$$

$$a_{010} = 0; \tag{39}$$

for $l=1$

$$2c_1a_{200} = (k_0+1)a_{100}, \tag{40}$$

$$2c_2a_{020} = -a_{100}, \tag{41}$$

$$(k_0+1)a_{001}=0; \tag{42}$$

for $l=0$

$$c_1a_{100}=k_0a_0. \tag{43}$$

Proof of Proposition 13: Statement (*a*) follows from Lemma 15. Statement (*b*) is obtained directly from Eqs. (34)–(43). Statements (*c*) and (*d*) can be proved simultaneously. Indeed, $k_0=-2$ by hypothesis. From Eqs. (34)–(43) we get

$$a_{001}=0, \tag{44}$$

$$a_{200}=-ra_{020}, \tag{45}$$

$$2c_1a_{200}=-a_{100}, \tag{46}$$

$$2c_2a_{020}=-a_{100}, \tag{47}$$

$$c_1a_{100}=-2a_0. \tag{48}$$

Now we combine (45) and (46) and get

$$-2rc_1a_{020}=-a_{100}. \tag{49}$$

By using (49) and (48) we deduce $a_0=-rc_1^2a_{020}$. From (49) and (47) we obtain $(rc_1+c_2)a_{020}=0$. Now statements (*c*) and (*d*) easily follow. This concludes the proof of Proposition 13. ■

From Proposition 13 follows immediately.

Corollary 16: Consider system (18).

(a) *If* $c_2=-rc_1$, *then* $f=-r(x-c_1)^2+y^2+z^2$ *is the only quadratic invariant algebraic surface for system* (18). *Moreover, its cofactor is* $K=-2$.
(b) *If* $c_2\neq -rc_1$ *then there are no quadratic invariant algebraic surfaces for system* (18).

Remark: The nature of the invariant algebraic surface is as follows. If $r<0$ then $\mathcal{S}$ reduces to the point $(c_1,0,0)$. If $r=0$ then $\mathcal{S}$ becomes the x-axis. If $r>0$ then $\mathcal{S}$ is a cone.

Remark: We consider a general quadratic system on $\mathbb{R}^3$

$$\dot{\mathbf{x}}=F(\mathbf{x}), \tag{50}$$

and $U\subset\mathbb{R}^3$ an open set. We say that an analytic function $I(x,y,z,t):U\times\mathbb{R}\mapsto\mathbb{R}$ is an *invariant* of system (50) if $I(x,y,z,t)=$constant for all values of t for which the solution $(x(t),y(t),z(t))$ is defined and contained in U.

Lemma 17: We consider the quadratic system (50) *on* $\mathbb{R}^3$ *and assume that the system has an invariant algebraic surface* f *of constant cofactor* K. *If* γ *is an orbit, we denote by* $\omega(\gamma)$ *its* ω*-limit set. We also denote by* $\mathcal{F}$ *the surface* $f=0$ *in* $\mathbb{R}^3$. *Then*

(a) $I=fe^{-Kt}$ *is an invariant of system* (50),
(b) *If* $K<0$ *then* $\omega(\gamma)\subset\mathcal{F}$ *for any orbit* γ, and
(c) *If* $K>0$ *then* $\alpha(\gamma)\subset\mathcal{F}$ *for any orbit* γ.

Proof: (a) We denote the vector field associated to (50) by $\mathcal{X}=X(\partial/\partial x)+Y(\partial/\partial y)+Z(\partial/\partial z)$. For $I=I(\mathbf{x}(t),t)$ we denote $\mathrm{d}I/\mathrm{d}t=X(\partial I/\partial x)+Y(\partial I/\partial y)+Z(\partial I/\partial z)+\partial I/\partial t$. Clearly, $\mathrm{d}I/\mathrm{d}t=e^{-Kt}(\mathrm{d}f/\mathrm{d}t-Kf)=0$.

(b) Let γ be an orbit of system (50). By (a) we have $fe^{-Kt}=$constant. In particular, $\lim_{t\to+\infty}fe^{-Kt}$ is finite. But $\lim_{t\to+\infty}e^{-Kt}=+\infty$. Therefore, we must have $\lim_{t\to+\infty}f(\mathbf{x}(t))=0$. Let P

$\in \omega(\gamma)$. Then there exists a sequence $\{t_n\} \to +\infty$ such that $\{\mathbf{x}(t_n)\} \to P$. It follows that $\{f(\mathbf{x}(t_n))\} \to f(P)$, because the function f is continuous. Consequently, $f(P)=0$. Thus, $P \in \mathcal{F}$.

(c) The proof is similar to that of (b). ■

In our case, if $c_2=-rc_1$ then $I=fe^{2t}$ is an invariant of system (18) and the ω-limit set of any orbit is the surface $-r(x-c_1)^2+y^2+z^2=0$.

VI. SYSTEM (18) WITH $c_1=c_2=0$

We note that if $c_1=c_2=0$, then system (18) is the particular case $s=b=1$ of the famous Lorenz system (63):

$$\dot{x}=-x+y, \quad \dot{y}=-y+rx-xz, \quad \dot{z}=-z+xy. \tag{51}$$

Although the Lorenz system has been intensively studied, most of the papers are concerned with the parameter values $s=10$, $b=8/3$, and r fixed to 28 or varying from 0 to ∞. We will study the Lorenz system for $s=b=1$ and $r \in \mathbb{R}$ arbitrary. More precisely, in this section we determine the phase portrait of system (51) in Theorems 18, 19, and 20.

Since $c_2=-rc_1=0$, from Corollary 16 system (51) possesses the algebraic invariant surface $f=-rx^2+y^2+z^2$ with cofactor -2. Let $\mathcal{X}$ be the vector field associated to system (51), and let φ_t be its flow. Then

$$\mathcal{X}f=-2rx\dot{x}+2y\dot{y}+2z\dot{z}=(-2rx,2y,2z)\cdot(\dot{x},\dot{y},\dot{z}) \tag{52}$$

is precisely the scalar product $\pi(x,y,z)$ between the normal vector to the surface $S_k:-rx^2+y^2+z^2=k$ (k is an arbitrary constant) at a given point $\mathbf{x}=(x,y,z)$ and the tangent to the trajectory $\varphi_t(\mathbf{x})$. Therefore, for a given surface S_k, this scalar product is constant and equal to $-2k$, having the same sign for every point of S_k. In other words, each surface S_k is crossed by the flow φ_t in the same direction. This direction depends on the sign of the constant k. Such surfaces are called *semipermeable*, and for instance in the Lorenz system has been used in Refs. 10 and 11.

Theorem 18: If $r<1$ then the origin is a global attractor of system (51).

Proof: If $r<0$ then take $k>0$. The surface $S_k:-rx^2+y^2+z^2=k$ is an ellipsoid such that the scalar product (52) is strictly negative at any point of S_k. Therefore, for any $k>0$, all trajectories of system (51) enter into the ellipsoid S_k. When $k \to 0$ the ellipsoid S_k shrinks to the origin, therefore it is a global attractor. If $0 \leqslant r<1$ then, following Ref. 25, we consider the function $W(x,y,z)=x^2+y^2+z^2$. Clearly, $L_tW=-2(x^2-(r+1)xy+y^2+z^2)=-2((x-(r+1)y/2)^2+(r+3)(1-r)y^2/4+z^2)<0$ for $-3<r<1$. Also $W(0,0,0)=0$. Therefore W is a global Lyapunov function for the singular point (0,0,0), consequently it is a global attractor. ■

Theorem 19: If $r=1$ then the origin is a global attractor of system (51).

Proof: If $r=1$ then system (51) becomes:

$$\dot{x}=y-x, \quad \dot{y}=-y+x-xz, \quad \dot{z}=-z+xy. \tag{53}$$

The origin is its only finite singular point. Consider the family of surfaces $S_k:-x^2+y^2+z^2=k$. When $k=0$, S_0 is a cone surrounding the x axis. When $k>0$, S_k is a hyperboloid of one sheet also surrounding the x axis, and S_0 is in the interior of S_k for all $k>0$. When $k<0$, S_k is a hyperboloid of two sheets whose line joining the foci is the x axis, and S_k is inside the cone S_0. We prove the theorem in two steps.

Step 1: Now we prove that any trajectory starting at a point which is not on the cone S_0 tends to this cone as time $t \to \infty$. We take $k>0$ arbitrary and fixed, and consider a point P on S_k. Then the scalar product

$$(-2x,2y,2z)\cdot(-x+y,-y+x-xz,-z+xy)=-2k$$

is strictly negative. The normal to S_k is directed outward S_k, so the tangent to the trajectory which passes through the point P must be directed inward the hyperboloid S_k with $k>0$. Similarly, when $k<0$, the tangent to the trajectory is directed outward the hyperboloid of two sheets S_k. So, Step

1 is proved. Another way to show it is using the invariant $H(x,y,z,t)=(x^2-y^2-z^2)\exp 2t$ of system (53), see the definition for Eq. (50). From Lemma 17(b) we conclude Step 1.

Step 2: Here, we prove that any trajectory starting on the cone S_0 tends to the origin of $\mathbb{R}^3$. Now we study the flow on the cone $x^2=y^2+z^2$. Clearly, this cone is invariant. On it, the system becomes

$$\dot{y}=-y+(1-z)\sqrt{y^2+z^2}, \quad \dot{z}=-z+y\sqrt{y^2+z^2}.$$

Passing to polar coordinates $y=r\cos\theta$, $z=r\sin\theta$, we get $\dot{r}=r(\cos\theta-1)$, $\dot{\theta}=r-\sin\theta$, if we are on the half-cone $x>0$; and $\dot{r}=r(-\cos\theta-1)$, $\dot{\theta}=-(r-\sin\theta)$, if we are on the half-cone $x<0$. Note that always $\dot{r}<0$ (it is 0 when $\theta=0$, but then $\dot{\theta}$ is not zero), so over the cone r always decreases with the time. In other words, the flow over the cone tends to the origin when time $t\to\infty$. In short, for this system we have proved that the origin is a global attractor. ■

Theorem 20: *If $r>1$ then we consider the cone $S_0: rx^2=y^2+z^2$, and denote S_0^+ (S_0^-) the positive (negative) half-cone S_0 with $x>0$ ($x<0$). On S_0^+ the system has two singular points, the origin O and $C_+=(\sqrt{r-1},\sqrt{r-1},r-1)$. The global flow of system* (51) *on the half-cone S_0^+ is as follows. Let γ^s and γ^u be the two separatrices of O, the stable and the unstable, respectively. Then, if we denote by $\alpha(\gamma)$ and $\omega(\gamma)$ the α- and ω-limit sets of the orbit γ, we have*

$$\alpha(O)=\omega(O)=O, \quad \alpha(C_+)=\omega(C_+)=C_+,$$

$$\alpha(\gamma^s)=\infty, \quad \omega(\gamma^s)=O, \quad \alpha(\gamma^u)=O, \quad \omega(\gamma^u)=C_+,$$

$$\alpha(\gamma)=\infty, \quad \omega(\gamma)=C_+,$$

for any orbit γ on the half-cone S_0^+ different from O, C_+, γ^s, and γ^u. The flow on the negative half-cone S_0^- is obtained by using the symmetry $(x,y,z)\to(-x,-y,z)$.

Proof: The origin is locally unstable because one of its eigenvalues is positive whereas the other two are negative. Indeed, its eigenvalues are the roots of the equation $(a+1)((a+1)^2-r)=0$, i.e. $-1<0, -1-\sqrt{r}<0$, and $-1+\sqrt{r})>0$. However, $C_\pm$ are locally stable for any $r>1$. Clearly, their eigenvalues are the roots of the equation $(a+2)(a^2+a+r-1=0)$, and their real part is always negative.

As in the case $r=1$, there is a family of semipermeable surfaces, $S_k: -rx^2+y^2+z^2=k$. For every $k>0$ ($k<0$) the tangent to the trajectory through a point on the surface S_k is directed inwardly (outwardly). Consequently, trajectories which start at a point which is not on the cone S_0 tend to it.

The cone $S_0: rx^2=y^2+z^2$ is invariant. Now we study the flow on this cone. Passing to polar coordinates, $y=\rho\cos\theta$, $z=\rho\sin\theta$, for $x>0$ we obtain the system

$$\dot{\rho}=\rho(\sqrt{r}\cos\theta-1), \quad \dot{\theta}=\frac{1}{\sqrt{r}}(\rho-r\sin\theta), \tag{54}$$

with $\rho\geqslant 0$ and $\theta\in\mathbb{S}^1$. We denote by S_0^+ the positive half-cone S_0 with $x>0$.

Step 1: We study the finite singular points of system (54). They are given by the equations (i) $\rho=0$, $\sin\theta=0$; and (ii) $\cos\theta=1/\sqrt{r}$, $\rho=r\sin\theta$. Equation (i) gives the following pairs (ρ,θ): (0, 0) and $(0,\pi)$; both of them correspond to the origin. Equation (ii) gives only the point $(\sqrt{r(r-1)},\theta)$ with $\cos\theta=1/\sqrt{r}$, $\sin\theta=\sqrt{(r-1)/r}>0$. The value of θ corresponding to $\sin\theta<0$ is not acceptable since it would give $\rho=r\sin\theta<0$.

The eigenvalues of the third point are given by the equation $a^2+a+r-1=0$, i.e. they are $(-1\pm\sqrt{5-4r})/2$ for $1<r\leqslant 5/4$ and $(-1\pm i\sqrt{-(5-4r)})/2$ for $r>5/4$. Therefore this point is a local attractor: a stable node if $1<r\leqslant 5/4$, and a stable focus if $r>5/4$.

Step 2: Now we determine the local phase portrait at the origin of system (54). When passing to polar coordinates (ρ,θ), the origin blows up to the circle $\rho=0$ ($\theta\in[0,2\pi[$). On this circle there

are two singular points: (0, 0) and $(0,\pi)$. The topological type of each of them can be determined using the Hartman-Grobman Theorem.

For the point (0, 0) the linearized flow has the associated matrix

$$\begin{pmatrix} \sqrt{r}-1 & 0 \\ \dfrac{1}{\sqrt{r}} & -\sqrt{r} \end{pmatrix},$$

with eigenvalues $-\sqrt{r}$ and $\sqrt{r}-1$ and corresponding eigenvectors $u_1=(0,1)$ and $u_2=(2r-\sqrt{r},1)$. Thus, the point (0, 0) is a saddle with stable manifold tangent to the direction u_1, and unstable manifold tangent to the direction u_2.

Similarly, the point $(0,\pi)$ is a saddle with stable manifold tangent to the direction $v_1=(-2r-\sqrt{r},1)$, and unstable manifold tangent to the direction $v_2=(0,1)$.

Finally, we can contract the circle $\rho=0$ to the origin to obtain the local phase portrait. The origin has two separatrices (one stable and one unstable) and two hyperbolic sectors.

Step 3: Now we study system (54) at infinity. Doing the change of variables $u=1/\rho$, system (54) becomes

$$\mathrm{d}u/\mathrm{d}t=-u(\sqrt{r}\cos\theta-1),\quad \mathrm{d}\theta/\mathrm{d}t=(1/u-r\sin\theta)/\sqrt{r}. \tag{55}$$

where $u>0$, $\theta\in\mathbb{S}^1$. After the time reparameterization $\mathrm{d}t=u\mathrm{d}s$, system (55) becomes

$$\mathrm{d}u/\mathrm{d}s=-u^2(\sqrt{r}\cos\theta-1),\quad \mathrm{d}\theta/\mathrm{d}s=(1-ru\sin\theta)/\sqrt{r}. \tag{56}$$

where $u\in\mathbb{R}$, $\theta\in\mathbb{S}^1$. The study of system (54) at infinity is now reduced to the study of system (56) at $u=0$. (We need system (56) instead of system (55) because the circle $u=0$ is invariant for system (56), whereas system (55) is not defined at $u=0$).

Note that the circle $u=0$ is an invariant curve of system (56). Moreover, it is a closed curve and it does not contain any singular points. Therefore, $u=0$ is a periodic orbit of system (56). We shall prove that $u=0$ is an unstable periodic orbit for system (56). System (56) can be written as

$$\mathrm{d}u/\mathrm{d}\theta=-u^2\sqrt{r}(\sqrt{r}\cos\theta-1)/(1-ru\sin\theta), \tag{57}$$

where $u\in\mathbb{R}$, $\theta\in\mathbb{S}^1$. Instead of studying the stability of the periodic orbit $u=0$ for system (57), which is hard to integrate, we note that if $u(t)$ is a solution of system (57) such that $\sup|u(t)|$ is sufficiently small, then $|u(t)r\sin\theta|<1$ for all t. Consequently, by using that $1/(1-x)=1+x+O(x^2)$ for $|x|<1$, we have that if $u(t)$ is a solution of system (57) such that $\sup|u(t)|$ is sufficiently small, then $u(t)$ satisfies

$$\mathrm{d}u/\mathrm{d}\theta=-\sqrt{r}u^2(\sqrt{r}\cos\theta-1)+O(u^3). \tag{58}$$

Solving Eq. (58) after omitting the terms of $O(u^3)$, we get the solution $u(\theta)=1/(r\sin\theta-\sqrt{r}\theta+1/u(0))$. Here $u(0)>0$ has to be small enough in order to insure that $u(t)\geqslant 0$ for all $\theta\in[0,2\pi]$. Since $u(2\pi)=1/-2\pi\sqrt{r}+1/u(0)>u(0)$, $u=0$ is an unstable periodic orbit for system (58), and consequently also unstable for systems (57) and (56). In short, the infinity of system (54) is unstable.

Step 4: Now we prove that system (54) has no periodic orbits. This follows from Bendixson's criterion (see Ref. 31), because the vector field of system (54) has constant divergence, equal to -1 in the whole plane $(\rho,\theta)\in\mathbb{R}_+\times\mathbb{S}^1$.

Step 5: Now if we summarize the results obtained for the global flow on the half-cone S_0^+, we get the conclusions of the statement of the theorem. ■

VII. DISCUSSION OF RESULTS

(1) System (1) belongs to a special class of quadratic systems which we describe now. It is known[9,6] that by spectral expansion and truncation, the governing equations of most fluid dynamical problems can be reduced to a quadratic system of N ordinary differential equations

$$\dot{x}_i = \sum_{j,k=1}^{N} a_{ijk} x_j x_k - \sum_{j=1}^{N} b_{ij} x_j + c_i \quad (i = 1, \ldots, N). \tag{59}$$

Hereafter, N is the truncation number. The indices i,j,k are ranging between 1 and N. The *quadratic coefficients* a_{ijk}, the *linear coefficients* b_{ij}, and the *forcing coefficients* c_i are real numbers. The overdot denotes differentiation with respect to time t. We denote $X=(x_1,x_2,\ldots,x_N)$. As usual, when $N=3$ we write x,y,z instead of x_1,x_2,x_3, respectively. Following the terminology of Ref. 9, we call the quadratic coefficients a_{ijk} *conservative* if

$$\sum_{i,j,k=1}^{N} a_{ijk} x_i x_j x_k = 0 \tag{60}$$

and not all of them are zero. System (59) is called a *forced system* if not all of its forcing coefficients c_i are zero. System (59) is called *dissipative* if its linear coefficients are such that

$$\sum_{i,j=1}^{N} b_{ij} x_i x_j > 0 \tag{61}$$

for any $X \neq 0$. Finally, system (59) is a *forced dissipative* system if it is forced and dissipative at the same time. It is known[9] that all trajectories of such a system eventually enter a ball and never leave it again.

An example of a forced dissipative system is the following one:

$$\dot{x} = s(y-x), \quad \dot{y} = -y - sx - xz, \quad \dot{z} = -bz + xy - b(r+s), \tag{62}$$

which is obtained from the famous Lorenz system[21]

$$\dot{x} = s(y-x), \quad \dot{y} = -y + rx - xz, \quad \dot{z} = -bz + xy. \tag{63}$$

by the change of variables $X=x, Y=y, Z=z-r-s$ (here, the parameters s,b,r are strictly positive).

According to the above definition, system (1) is also forced dissipative after imposing some restrictions on the parameters. For instance, condition (61) holds for system (1) if $b>0$ and $b^2+e^2+af>0$. If $r<1$ then system (18) is forced dissipative and therefore all its trajectories eventually enter an ellipsoid. However, in Theorem 12 we prove that system (18) has this property for any r.

Regarding the relation between system (1) and Lorenz system, we note that both of them are spectrally truncated versions of some partial differential equations. More precisely, system (63) originates in the coupled Navier-Stokes and heat equations, modeling the Rayleigh-Bénard convection problem, i.e., Eq. (5.31a,b) of Ref. 9, whereas system (1) arises from the nonlinear barotropic quasigeostrophic potential vorticity equation, i.e., Eq. (6.14) of Ref. 9. However, unlike system (63), system (1) includes the effects of topography and of Earth's rotation.

(2) If $b=0$ and parameters a,d,e,f are all strictly positive, then we reduced system (1) to system (11). This case is also considered in Refs. 2, 6, 7, and 9. However our approach leads to a complete description of the phase portrait. We also considered the cases when a,d,e,f are nonpositive. We proved that if $b=ef=0$ and $d\neq 0$, then system (1) is reduced to (9); i.e., to the simple pendulum.

(3) If $b\neq 0$ then we reduce system (1) to systems (16)–(18). If the other parameters are nonnegative, then systems (16) and (17) have only one singular point. It is a global attractor, in accordance with known results.[2,6,7,9] Also, system (18) has at most three singular points. It remains

to characterize first, if system (18) has only one singular point when it is a global attractor; and second if system (18) has three singular points, when two of them are stable and one is unstable. It was stated in Ref. 6 that this second question holds for system (1) when all its parameters are strictly positive. We have obtained this result in Theorem 20 in the case $c_1=c_2=0$ for any $r>1$.

(4) We proved that system (18) possesses the quadratic invariant algebraic surface $f=-r(x-c_1)^2+y^2+z^2=0$ if and only if $c_2=-rc_1$. A similar result holds for Lorenz system.[20]

(5) Knowing the invariant algebraic surface helps to determine the phase portrait of the system. As an application, we describe the phase portrait of system (18) when $c_1=c_2=0$ in Sec. VI.

(6) 1—In Ref. 6 DeSwart found that the singular points of system (1) for $b=c=0$ are of the form $(\bar{x},f\bar{x}/(\mathrm{d}\bar{x}-e),0)$ where $\bar{x}$ is an arbitrary real number. Moreover, if

$$e/d<\bar{x}<(aef)^{1/3}/d+e/d, \tag{64}$$

then the equilibrium point $(\bar{x},f\bar{x}/(\mathrm{d}\bar{x}-e),0)$ is unstable, because one of the eigenvalues of the Jacobian matrix of the system at this equilibrium point becomes positive. The number aef in (64) is nonzero only if a parameter related to amplitude topography is nonzero. Thus, the occurence of unstable equilibrium points of this type is physically interpreted as topographic instability.

In our approach we obtain that the singular points of system (11), which is the physically interesting reduced form of the above-mentioned system in the conservative case $b=c=0$, are of the form $(\bar{x},1/\bar{x},0)$ where $\bar{x}$ is an arbitrary real (nonzero) number. The eigenvalues of the Jacobian matrix of the system at $(\bar{x},1/\bar{x},0)$ are given by the equation $\Lambda(\Lambda^2-a)=0$ where $a=(1-\bar{x}^3)/\bar{x}$. Thus, if $0<\bar{x}<1$ then one of these eigenvalues is positive, and the equilibrium point $(\bar{x},1/\bar{x},0)$ is unstable. Condition $0<\bar{x}<1$ corresponds to Eq. (64) found in Ref. 6.

From Propositions 7, 8, and 9 we see that system (11) has singular points $(\bar{x},1/\bar{x},0)$ with $0<\bar{x}<1$ only when $h_1>8$; in this case, the equilibrium point P_2, which is a saddle point with two homoclinic orbits to it, is unstable and corresponds to topographic instability. This is a nice and new connection between topographic instability and homoclinic orbits. Such homoclinic orbits could be remnants of heteroclinic orbits of the six-component CdV model, in accordance with Ref. 4.

2—In Ref. 2 Charney and DeVore suggested that flow regimes should be identified with equilibrium solutions of the equations describing the evolution of large-scale atmospheric flow. In Ref. 4 it is suggested that regime transitions in deterministic atmosphere models are related to the existence of heteroclinic connections between these regimes. A characteristic property of the atmosphere is its *vacillation* behavior, i.e., the irregular fluctuation of atmospheric circulation between different preferent flow regimes which are also called weather regimes.[7]

Recall the dynamics of system (11) on the sphere I_{h_1}: for $0<h_1<8$ there are only two equilibria (flow regimes) which are centers, i.e., stable but not asymptotically stable, and all other orbits are periodic. As h_1 increases, new equilibria appear. When $h_1=8$, a third equilibrium occurs, and it is unstable, with a homoclinic orbit to it and with two hyperbolic sectors in a neighborhood of it. The point which are now on the homoclinic orbit where previously situated on a periodic orbit. When $h_1>8$, a fourth equilibrium point appears; it is a center, whereas the third equilibrium point is still unstable (a saddle with two homoclinic orbits to it).

Since system (11) has only periodic and homoclinic orbits, there are no transitions between equilibria. Thus, system (11) cannot model vacillation behavior. However, not any equilibrium point of an atmospheric model can be identified with a weather regime.[5] For instance, some conditions such as the presence of forcing and dissipation, are necessary.[8] Future work is necessary to clarify the role of homoclinic and heteroclinic orbits in transitions between weather regimes (when an equilibrium of a given model of atmospheric circulation (59) represents a weather regime? when a heteroclinic orbit between such equilibria represents a transition between weather regimes?).

3—We note that when $b=c=0$, system (1) can be interpreted as a Volterra gyrostat with two pairs of gyrostatic terms corresponding to rotation and topography effects (see Ref. 12).

(7) The problem of finding the values of parameters of a given quadratic system for which the system is chaotic, if such values do exist, is still open. Such values, but not all of them are known for Lorenz-63 model,[21] and for Lorenz-84 model,[29] but not for system (1).

ACKNOWLEDGMENTS

One of the authors (D.D.) wishes to thank Professor Yoden and Dr. DeSwart for providing their papers. The supervision and hospitality of the Dynamical System Group of the Universitat Autònoma de Barcelona are gratefully ackowledged. In this paper we apply the Darboux theory of integrability to the classical Bianchi IX system. Thus, we provide a complete description of the Darboux polynomials, exponential factors, rational first integrals, and Darboux first integrals, for the classical Bianchi IX system. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1955453]

I. INTRODUCTION TO THE PROBLEM

The Bianchi IX model can be written as the Hamiltonian system (see Ref. 8):

$$\dot{q}_1 = 12q_1(p_1q_1 - p_2q_2 - p_3q_3),$$

$$\dot{q}_2 = 12q_2(-p_1q_1 + p_2q_2 - p_3q_3),$$

$$\dot{q}_3 = 12q_3(-p_1q_1 - p_2q_2 + p_3q_3),$$

$$\dot{p}_1 = -12p_1(p_1q_1 - p_2q_2 - p_3q_3) - \tfrac{1}{3}(q_1 - q_2 - q_3),$$

$$\dot{p}_2 = -12p_2(-p_1q_1 + p_2q_2 - p_3q_3) - \tfrac{1}{3}(-q_1 + q_2 - q_3),$$

$$\dot{p}_3 = -12p_3(-p_1q_1 - p_2q_2 + p_3q_3) - \tfrac{1}{3}(-q_1 - q_2 + q_3), \tag{1}$$

in $\mathbb{R}^6$ with the Hamiltonian

$$G = 6(p_1^2q_1^2 + p_2^2q_2^2 + p_3^2q_3^2 - 2p_1q_1p_2q_2 - 2p_1q_1p_3q_3 - 2p_2q_2p_3q_3) + \frac{1}{6}(q_1^2 + q_2^2 + q_3^2 - 2q_1q_2 - 2q_1q_3 - 2q_2q_3).$$

This system has been throughly investigated from the point of view of integrability by using different methods for studying the existence of first integrals. One of these methods is the Painlevé test (see, for instance, Refs. 10, 5, and 6) where the authors prove that the solutions of the equation of motion do not have movable critical points and conjecture that system (1) is integrable. Later on, in Ref. 7 the same authors of Ref. 6 find new arguments, this time against the integrability. Another method is the numerical computation of the Lyapunov exponents (see Ref. 1), where the authors also conjecture the integrability of system (1). In Ref. 8 the authors, by means of sym-

[a)]Electronic mail: jllibre@mat.uab.es
[b)]Electronic mail: cvalls@math.ist.utl.pt

plectic geometrical techniques, prove that system (1) is locally integrable. In Ref. 12 it is shown that system (1) is not completely integrable in the Birkhoff sense. We also want to mention the work of Ref. 13, where the author proves that the Hamiltonian system (1) is not completely integrable with rational first integrals (see Theorem 2 in the following) using techniques from the differential Galois theory.

We say that the functions $F_1,\dots,F_n$ are in *involution* if $\{F_i,F_j\}=0$ for all $i\neq j$, where $\{\cdot,\cdot\}$ denotes the Poisson bracket. Moreover, they are *independent* if the one forms $dF_1,\dots,dF_n$ are linearly independent over a full Lebesgue measure subset of the common definition domain of F_j for $j=1,\dots,n$. By definition, a Hamiltonian system with n degrees of freedom having n independent first integrals in involution is *(completely) integrable*.

A *rational first integral* of system (1) is a rational function f which is constant over the trajectories of system (1), where it is defined.

The aim of this paper is to study the integrability of system (1) by using the Darboux theory of integrability (see Refs. 9 and 11). The main results of this paper are the following Theorems 1 and 3.

Theorem 1: *All rational first integrals of system* (1) *are rational functions in the variable G*.

As a corollary of Theorem 1 we obtain the following result given in Ref. 13.

Theorem 2: *The Hamiltonian system* (1) *is not completely integrable with rational first integrals*.

Note that Theorem 1 is stronger than Theorem 2.

Writing system (1) as

$$\dot{x}_j = X_j(x_1,\dots,x_6), \quad j=1,\dots,6, \tag{2}$$

we have the following three definitions.

A *Darboux polynomial* of system (1) is a polynomial $f\in\mathbb{C}[x_1,\dots,x_6]\backslash\mathbb{C}$ such that

$$\frac{\mathrm{d}f}{\mathrm{d}t}=\sum_{j=1}^{6}X_j\frac{\partial f}{\partial x_j}=Kf,$$

for some polynomial $K\in\mathbb{C}[x_1,\dots,x_6]$ called the *cofactor*. Taking into account the degrees of the polynomials which appear in the previous equation, it follows easily that the degree of the cofactor is at most 2. Note that $f=0$ is an invariant algebraic hypersurface for the flow of system (2).

Note that a *polynomial first integral* of system (1) is a Darboux polynomial with cofactor zero.

An *exponential factor* F of the polynomial differential system (1) is a function $F=\exp(f/g)\notin\mathbb{C}$ with $f,g\in\mathbb{C}[x_1,\dots,x_6]$ satisfying that

$$\frac{\mathrm{d}F}{\mathrm{d}t}=\sum_{j=1}^{6}X_j\frac{\partial F}{\partial x_j}=LF,$$

for some polynomial $L\in\mathbb{C}[x_1,\dots,x_6]$ of degree at most 2. See Proposition 7 for more details about the exponential factors.

A first integral G of system (1) is called *Darboux* if G is of the form

$$G=f_1^{\lambda_1}\dots f_p^{\lambda_p}F_1^{\mu_1}\dots F_q^{\mu_q},$$

where $f_1,\dots,f_p$ are Darboux polynomials, $F_1,\dots,F_q$ are exponential factors and $\lambda_j,\mu_k\in\mathbb{C}$, for $j=1,\dots,p$, $k=1,\dots,q$.

We note that for real polynomial differential systems, as system (1), when we look for their Darboux first integrals we use in general complex Darboux polynomials and complex exponential factors. This is due to the fact that these objects appear in pairs (one and its conjugate), and this forces that the Darboux first integral becomes real. For more details see Ref. 3.

The second main result of this paper is the following.

Theorem 3: *All Darboux first integrals of system (1) are of the form*

$$P_1^{\lambda_1} \cdots P_r^{\lambda_r} \exp(Q/R),$$

where P_i, Q, *and* R *are polynomials in* $\mathbb{C}[G]$ *and* $\lambda_i \in \mathbb{C}$ *for* $i=1,\ldots,r$.

This paper is organized as follows. In Sec. II we state some preliminary and basic results on the Darboux theory of integrability that will be used through the paper. In Sec. III we reduce the study of the Bianchi IX system to a homogeneous differential system. In Sec. IV we see that it is sufficient to study the homogeneous Darboux polynomials. In Secs. V and VI we analyze the homogeneous polynomial first integrals and the homogeneous Darboux polynomials with nonzero cofactor, respectively. Finally, in Sec. VII, we prove the main results of this paper.

II. PRELIMINARIES

We consider a differential system with polynomial right–hand sides

$$\dot{x}_j = X_j(x_1, \ldots, x_n), \quad j = 1, \ldots, n. \tag{3}$$

of degree m, i.e., $m=\max\{\deg X_j : j=1,\ldots,n\}$, defined in an open subset of $\mathbb{R}^n$. The proof of the next results can be found in Refs. 2–4, with the exception of Proposition 6 which can be proved easily.

Proposition 4: Let f *be a polynomial and* $f=\Pi_{j=1}^{s} f_j^{\alpha_j}$ *its decomposition into irreducible factors in* $\mathbb{C}[x_1,\ldots,x_n]$. *Then,* f *is a Darboux polynomial if and only if all the* f_j *are Darboux polynomials. Moreover, if* K *and* K_j *are the cofactors of* f *and* f_j, *then* $K=\Sigma_{j=1}^{s}\alpha_j K_j$.

Theorem 5: *Suppose that the differential polynomial system (3) defined in* $\mathbb{R}^n$ *of degree* m *admits* p *invariant algebraic hypersurfaces* $f_i=0$ *with cofactors* K_i *for* $i=1,\ldots,p$ *and* q *exponential factors* $F_j=\exp(g_j/h_j)$ *with cofactors* L_j *for* $j=1,\ldots,q$. *Then, there exist* λ_j, $\mu_j \in \mathbb{C}$ *not all zero such that* $\Sigma_{i=1}^{p}\lambda_i K_i + \Sigma_{j=1}^{q}\mu_j L_j = 0$ *if and only if the following real (multivalued) function of Darboux type*

$$f_1^{\lambda_1} \ldots f_p^{\lambda_p} F_1^{\mu_1} \ldots F_q^{\mu_q},$$

substituting $f_i^{\lambda_i}$ *by* $|f_i|^{\lambda_i}$ *if* $\lambda_i \in \mathbb{R}$, *is a first integral of system (3).*

Proposition 6: The existence of a rational first integral for a polynomial differential system (3) implies either the existence of a polynomial first integral, or the existence of two Darboux polynomials having the same nonzero cofactor.

Proposition 7: If $F=\exp(h/g)$ *is an exponential factor for the polynomial differential system (3) and* g *is not a constant polynomial, then* $g=0$ *is an invariant algebraic hypersurface of system (3) with multiplicity higher than 1.*

III. REDUCTION TO A HOMOGENEOUS DIFFERENTIAL SYSTEM

We do two changes of variables, the change $(q_1,q_2,q_3,p_1,p_2,p_3) \to (y_1,y_2,y_3,z_1,z_2,z_3)$ given by

$$y_i = q_i, \quad z_i = p_i q_i, \quad i = 1,2,3; \tag{4}$$

and the change $(y_1,y_2,y_3,z_1,z_2,z_3,t) \to (6y_1,6y_2,6y_3,z_1,z_2,z_3,t/12)$. In these last variables system (1) becomes

$$\begin{aligned}
\dot{y}_1 &= y_1(z_1 - z_2 - z_3),\\
\dot{y}_2 &= y_2(-z_1 + z_2 - z_3),\\
\dot{y}_3 &= y_3(-z_1 - z_2 + z_3),\\
\dot{z}_1 &= -y_1(y_1 - y_2 - y_3),
\end{aligned} \tag{5}$$

$$\dot{z}_2 = -y_2(-y_1 + y_2 - y_3),$$

$$\dot{z}_3 = -y_3(-y_1 - y_2 + y_3).$$

System (5) has the first integral:

$$H = \tfrac{1}{2}(z_1^2 + z_2^2 + z_3^2 - 2z_1z_2 - 2z_1z_3 - 2z_2z_3) + \tfrac{1}{2}(y_1^2 + y_2^2 + y_3^2 - 2y_1y_2 - 2y_1y_3 - 2y_2y_3).$$

Of course, H is the first integral G in the new variables.

Lemma 8: The following statements hold.

(a) *If* $f(y_1,y_2,y_3,z_1,z_2,z_3)$ *is a rational first integral of system (5), then* $f(q_1,q_2,q_3,p_1q_1,p_2q_2,p_3q_3)$ *is a rational first integral of system (1).*
(b) *If* $f(q_1,q_2,q_3,p_1,p_2,p_3)$ *is a rational first integral of system (1), then* $f(y_1,y_2,y_3,z_1/y_1,z_2/y_2,z_3/y_3)$ *is a rational first integral of system (5).*

Proof: (a) is immediate. Now we prove (b). If $f(q_1,q_2,q_3,p_1,p_2,p_3)$ is a rational first integral of system (1), this means that $f(q_1,q_2,q_3,p_1,p_2,p_3) = f_1(q_1,q_2,q_3,p_1,p_2,p_3)/f_2(q_1,q_2,q_3,p_1,p_2,p_3)$, with f_1 and f_2 polynomials. From (4), we define

$$\bar{f}(y_1,y_2,y_3,z_1,z_2,z_3) = f_1\left(y_1,y_2,y_3,\frac{z_1}{y_1},\frac{z_2}{y_2},\frac{z_3}{y_3}\right)/f_2\left(y_1,y_2,y_3,\frac{z_1}{y_1},\frac{z_2}{y_2},\frac{z_3}{y_3}\right).$$

Therefore, multiplying f_1 and f_2 by $y_1^{N_1}y_2^{N_2}y_3^{N_3}$ where, for $i=1,2,3$, $N_i=\max\{N_i^1,N_i^2\}$ with N_i^1 the maximum degree of f_1 in the variable p_i, and N_i^2 the maximum degree of f_2 in the variable p_i, we have that $\bar{f}(y_1,y_2,y_3,z_1,z_2,z_3)$ is also a rational first integral of system (5). ■

By Lemma 8, if we prove that the unique rational first integrals of system (5) are functions of H, Theorem 1 will be proved. Therefore, to prove Theorem 1, it is enough to prove the following result.

Theorem 9: *For system (5) the unique rational first integrals are rational functions in the variable* H.

For proving Theorem 9, we need previously to study the Darboux polynomials of system (5) with zero cofactor (i.e., the polynomial first integrals) and with nonzero cofactor. We will do that in the next three sections. In the first one we will see that it is sufficient to study the homogeneous Darboux polynomials. Finally, in Sec. VII we prove Theorem 9.

IV. REDUCTION TO HOMOGENEOUS DARBOUX POLYNOMIALS

The equation defining a Darboux polynomial f for system (5) is

$$\dot{y}_1\frac{\partial f}{\partial y_1} + \dot{y}_2\frac{\partial f}{\partial y_2} + \dot{y}_3\frac{\partial f}{\partial y_3} + \dot{z}_1\frac{\partial f}{\partial z_1} + \dot{z}_2\frac{\partial f}{\partial z_2} + \dot{z}_3\frac{\partial f}{\partial z_3} = Kf,$$

where the cofactor $K=a_0+a_1y_1+a_2y_2+a_3y_3+a_4z_1+a_5z_2+a_6z_3$.

Lemma 10: Any Darboux polynomial f *of system* (5) *has a cofactor of the form*

$$K = a_1y_1 + a_2y_2 + a_3y_3 + a_4z_1 + a_5z_2 + a_6z_3. \tag{6}$$

Proof: See Ref. 14 where the authors prove Lemma 10 in a more general context of arbitrary homogeneous polynomial systems. ■

Proposition 11: We write f *in sum of its homogeneous parts as* $f=f_1+\cdots+f_n$. *Then,* f *is a Darboux polynomial of system* (5) *with cofactor* K *if and only if for all* $j=1,\ldots,n$, f_j *is a Darboux polynomial of system* (5) *with cofactor* K.

Proof: See Ref. 14 where the authors prove Proposition 11 in a more general context of arbitrary homogeneous polynomial systems. ■

Proposition 12: System (5) *has exactly three irreducible Darboux polynomials of degree* 1,

namely y_1, y_2, *and* y_3.

Proof: It follows easily from the definition of Darboux polynomial. ■

Let $\tau:\mathbb{C}[y_1,y_2,y_3,z_1,z_2,z_3]\to\mathbb{C}[y_1,y_2,y_3,z_1,z_2,z_3]$ be the automorphism

$$\tau(y_i)=-y_i,\quad \tau(z_i)=z_i,\quad i=1,2,3;$$

and let $\sigma:\mathbb{C}[y_1,y_2,y_3,z_1,z_2,z_3]\to\mathbb{C}[y_1,y_2,y_3,z_1,z_2,z_3]$ be the automorphism

$$\sigma(y_1)=y_2,\quad \sigma(y_2)=y_3,\quad \sigma(y_3)=y_1,\quad \sigma(z_1)=z_2,\quad \sigma(z_2)=z_3,\quad \sigma(z_3)=z_1.$$

Proposition 13: If g is an irreducible (homogeneous) Darboux polynomial of degree >1 *for system* (5) *with cofactor K given by* (6), *then* $f=(g\cdot\sigma g\cdot\sigma^2 g)\cdot\tau(g\cdot\sigma g\cdot\sigma^2 g)$ *is a (homogeneous) Darboux polynomial invariant by* τ *and* σ *with a cofactor of the form* $2(a_4+a_5+a_6)(z_1+z_2+z_3)$. *If the cofactor of g is zero, then the cofactor of f is also zero. Moreover,* y_i *is not a factor f for i* $=1,2,3$.

Proof: Since system (5) is invariant under τ, σ, and σ^2, τg is a Darboux polynomial of system (5) with cofactor $\tau(K)$. Moreover, by Proposition 4, $g\cdot\sigma g\cdot\sigma^2 g$ is also a Darboux polynomial of (5) with cofactor $K+\sigma(K)+\sigma^2(K)$. Therefore, again by Proposition 4, the cofactor of f is $2(a_4+a_5+a_6)(z_1+z_2+z_3)$.

Finally, y_i is not a factor f for $i=1,2,3$, otherwise some y_i would be a factor of g, and g is irreducible of degree >1. ■

In Proposition 13 the parenthesis in the word homogeneous means that the statement of the proposition holds if g is homogeneous, as if it is not.

V. HOMOGENEOUS POLYNOMIAL FIRST INTEGRALS

In this section we study the homogeneous polynomial first integrals of system (5), or equivalently its homogeneous Darboux polynomials with zero cofactor.

Proposition 14: If f is a homogeneous polynomial first integral of degree n even for system (5) restricted to $y_1=0$, $z_1=0$, *then* $f=\sum_{k=0}^{n/2}a_k H_1^k H_2^{n/2-k}$ *with*

$$H_1=\tfrac{1}{2}(z_2-z_3)^2+\tfrac{1}{2}(y_2-y_3)^2,\quad H_2=y_2y_3. \tag{7}$$

Proof: Let f be a homogeneous polynomial first integral of degree n even of system (5) restricted to $y_1=0$, $z_1=0$. Then f satisfies

$$(z_2-z_3)\left(y_2\frac{\partial f}{\partial y_2}-y_3\frac{\partial f}{\partial y_3}\right)-(z_2-z_3)\left(y_2\frac{\partial f}{\partial z_2}-y_3\frac{\partial f}{\partial z_3}\right)=0. \tag{8}$$

By direct computation, it is straightforward to prove that H_1, H_2, and linear combinations of them are the unique polynomial first integrals of system (5) restricted to $y_1=0$, $z_1=0$ of degree $n=2$. So, the proposition is proved if $n=2$. Assume, by induction, that it is proved until degree $n-2$ and we shall prove it for degree n. We denote by $\bar{f}_2=f(0,y_3,z_2,z_3)$. Then, restricting (8) to $y_2=0$, we get that $\bar{f}_2$ is a first integral of the system

$$\dot{z}_2=0,\quad \dot{y}_3=y_3(z_3-z_2),\quad \dot{z}_3=-y_3^2. \tag{9}$$

Now, we do the linear change of variables $x_1=z_2$, $x_2=z_2-z_3+iy_3$ and $x_3=z_2-z_3-iy_3$. In these new variables system (9) becomes

$$\dot{x}_1=0,\quad \dot{x}_2=-\tfrac{1}{2}(x_2-x_3)x_2,\quad \dot{x}_3=\tfrac{1}{2}(x_2-x_3)x_3. \tag{10}$$

Since the change of variables is linear, if we have a polynomial first integral of system (10) we have a polynomial first integral of system (9) and vice versa.

Let $g=g(x_1,x_2,x_3)$ be a polynomial first integral of system (10). Then, after dividing by $(x_2-x_3)/2$, g satisfies

$$-x_2\frac{\partial g}{\partial x_2}+x_3\frac{\partial g}{\partial x_3}=0. \tag{11}$$

The general solution of this linear partial differential equation is an arbitrary function of x_2x_3. Since we are only interested in the homogeneous polynomial solutions of degree n of (11) in the variables x_1, x_2, x_3, g must be a polynomial in x_2x_3 with coefficients polynomials in the variable x_1. Thus, we have

$$\bar{f}_2=\sum_{l+2k=n} a_{l,k}z_2^l((z_2-z_3)^2+y_3^2)^k.$$

Now, taking the notation $\bar{f}_3=f(y_2,0,z_2,z_3)$, restricting (8) to $y_3=0$ and proceeding as for $\bar{f}_2$, we get that $\bar{f}_3$ has the form

$$\bar{f}_3=\sum_{l+2k=n} b_{l,k}z_3^l((z_2-z_3)^2+y_2^2)^k.$$

We note that for $y_2=y_3=0$, $\bar{f}_2$ restricted to $y_3=0$ and $\bar{f}_3$ restricted to $y_2=0$ must coincide. Thus, we get the relation

$$\sum_{l+2k=n} a_{l,k}z_2^l(z_2-z_3)^{2k}=\sum_{l+2k=n} b_{l,k}z_3^l(z_2-z_3)^{2k}. \tag{12}$$

We claim that

$$a_{l,k}=b_{l,k}=0, \quad \text{for all } l>0 \text{ and } a_{0,n/2}=b_{0,n/2}. \tag{13}$$

First, we prove the claim for $l=n$ ($n\geqslant 2$). To do it, we restrict (12) to $z_2=z_3$. Then, we get $a_{n,0}z_2^n=b_{n,0}z_3^n$, which obviously implies $a_{n,0}=b_{n,0}=0$. Suppose that the claim is true for $l=n,\ldots,n-2m$ with $0\leqslant m<(n-2)/2$. Then, we want to prove it for $l=n-2(m+1)$. Clearly, by induction hypothesis, (12) is equal to

$$\sum_{l+2k=n,l\leqslant n-2m} a_{l,k}z_2^l(z_2-z_3)^{2k}=\sum_{l+2k=n,l\leqslant n-2m} b_{l,k}z_3^l(z_2-z_3)^{2k}. \tag{14}$$

In the equality (12), we substitute the equality (14), so it remains as the terms with $k>m$. Therefore, we can remove the common factor $(z_2-z_3)^{2m+2}$, and (12) becomes

$$\sum_{l+2k=n,k>m} a_{l,k}z_2^l(z_2-z_3)^{2(k-m-1)}=\sum_{l+2k=n,k>m} b_{l,k}z_3^l(z_2-z_3)^{2(k-m-1)}.$$

So, $a_{l,k}=b_{l,k}=0$ for $l=n-2(m+1)$. Thus, by induction hypothesis, (12) reduces to $a_{0,n/2}(z_2-z_3)^n=b_{0,n/2}(z_2-z_3)^n$, which obviously implies $a_{0,n/2}=b_{0,n/2}$ and finishes the proof of the claim. Therefore, from (13) we get $\bar{f}_2=a_{0,n/2}((z_2-z_3)^2+y_3^2)^{n/2}$ and $\bar{f}_3=b_{0,n/2}((z_2-z_3)^2+y_2^2)^{n/2}$.

Now, by the Newton's binomial formula, we get

$$((z_2-z_3)^2+y_2^2+y_3^2)^{n/2}=((z_2-z_3)^2+y_3^2)^{n/2}+y_2^2g_1,$$

$$((z_2-z_3)^2+y_2^2+y_3^2)^{n/2}=((z_2-z_3)^2+y_2^2)^{n/2}+y_3^2g_2,$$

where g_1 and g_2 are of homogeneous polynomial of degree $n-2$. Then, using this and the fact that $\bar{f}_2$ is the restriction of f to $y_2=0$, we can write

$$f=\bar{f}_2+y_2g_3=a_{0,n/2}((z_2-z_3)^2+y_2^2+y_3^2)^{n/2}+y_2g_4+y_2y_3g_5,$$

where g_4,g_5 are polynomials, and g_4 does not depend on y_3. In an analogous way, since $\bar{f}_3$ is the restriction of f to $y_3=0$, we can write

$$f = a_{0,n/2}((z_2 - z_3)^2 + y_2^2 + y_3^2)^{n/2} + y_3 g_6 + y_2 y_3 g_7,$$

where g_6 and g_7 are polynomials, and g_6 does not depend on y_2. Then, equating these two expressions for f we obtain $y_2 g_4 - y_3 g_6 = y_2 y_3 (g_5 - g_7)$, which obviously yields $g_4 = g_6 = 0$ and $g_7 = g_5$. Thus, since $(z_2 - z_3)^2 + y_2^2 + y_3^2 = 2(H_1 + H_2)$, also by the Newton's binomial formula, we obtain

$$f = a_{0,n/2}((z_2 - z_3)^2 + y_2^2 + y_3^2)^{n/2} + y_2 y_3 g_5 = 2^{n/2} a_{0,n/2} H_1^{n/2} + y_2 y_3 g_8,$$

for some homogeneous polynomial g_8. Then, since f, $y_2 y_3$ and H_1 are first integrals of system (5) restricted to $y_1 = 0$, $z_1 = 0$, we have that g_8 is also a first integral of system (5) restricted to $y_1 = 0$, $z_1 = 0$ of degree $n-2$. Hence, by induction assumption, g_8 can be written as in the statement of the proposition, with n replaced by $n-2$. Therefore, the proposition follows for f. ■

Proposition 15: If f is a homogeneous polynomial first integral of degree n even for system (5) *restricted to* $y_1 = 0$, *then* $f = \Sigma_{l+2k=n} a_{l,k} z_1^l H_3^k$ *with*

$$H_3 = \frac{1}{2}(z_1^2 + z_2^2 + z_3^2 - 2z_1 z_2 - 2z_1 z_3 - 2z_2 z_3) + \frac{1}{2}(y_2 - y_3)^2.$$

Proof: Let f be a homogeneous polynomial first integral of degree n even of system (5) restricted to $y_1 = 0$, then f satisfies

$$y_2(-z_1 + z_2 - z_3)\frac{\partial f}{\partial y_2} + y_3(-z_1 + z_3 - z_2)\frac{\partial f}{\partial y_3} - (y_2 - y_3)\left(y_2 \frac{\partial f}{\partial z_2} - y_3 \frac{\partial f}{\partial z_3}\right) = 0.$$

By direct computation, it is straightforward to prove that the unique first integrals of degree 2 of system (5) restricted to $y_1 = 0$, are z_1^2, H_3 and linear combinations of them. So, the proposition is proved if $n = 2$ and we can assume that $n \geqslant 4$. Moreover, we assume, by induction, that it is proved until degree $n-2$ and we shall prove it for degree n.

We first consider the restriction of system (5) to $y_1 = 0$, $z_1 = 0$. Any homogeneous polynomial first integral f of system (5) of degree n even restricted to $y_1 = 0$, $z_1 = 0$ satisfies (8) with f replaced by $\bar{f}$, where $\bar{f} = \bar{f}(y_2, y_3, z_2, z_3) = f(y_2, y_3, 0, z_2, z_3)$.

By Proposition 14, we have that $\bar{f} = \Sigma_{2k+2m=n} a_{k,m} H_1^k H_2^m$, where H_1 was introduced in (7), and $a_{k,m} \in \mathbb{C}$. Since $\bar{f}$ is the restriction of f to $z_1 = 0$, is also a homogeneous polynomial of degree n, and $H_3 = H_1 + \frac{1}{2} z_1 (z_1 - 2z_2 - 2z_3)$, we get that

$$f = \sum_{2k+2m=n} a_{k,m} H_3^k H_2^m + z_1 g_3, \tag{15}$$

with $g_3 = g_1 + g_2$ a homogeneous polynomial of degree $n-1$.

Now, since f, z_1, and H_3 are first integrals of system (5) restricted to $y_1 = 0$, we obtain, after simplifying by z_1, that

$$\frac{\mathrm{d}g_3}{\mathrm{d}t} = 2 \sum_{2k+2m=n} a_{k,m} m H_3^k H_2^m, \tag{16}$$

where this expression is evaluated along a solution of system (5) restricted to $y_1 = 0$. We write $g_3 = \bar{g}_3 + z_1 g_4$, where $\bar{g}_3$ is a homogeneous polynomial of degree $n-1$ and g_4 is a homogeneous polynomial of degree $n-2$. Further, $\bar{g}_3$ satisfies (16) restricted to $z_1 = 0$, that is

$$\frac{d\bar{g}_3}{dt} = 2 \sum_{2k+2m=n} a_{k,m} m H_1^k H_2^m, \tag{17}$$

where this expression is evaluated along a solution of system (5) restricted to $y_1 = 0$, $z_1 = 0$. Now, we claim that

$$\bar{g}_3 = y_2 y_3 h_1 \quad \text{for some polynomial } h_1 = h_1(z_2, z_3, y_2, y_3). \tag{18}$$

To prove (18), we restrict (17) to $y_2=0$ and denote by $\tilde{g}_3$ the restriction of $\bar{g}_3$ to $y_2=0$. Then, if we introduce the variables $x_1=z_2$, $x_2=z_2-z_3+iy_3$, $x_3=z_2-z_3-iy_3$, and denote $\tilde{g}_3(z_2,z_3,y_3)=G(x_1,x_2,x_3)$, we get, after dividing by $(x_2-x_3)/2$, that G satisfies (11) with g replaced by G. Thus, the same arguments used in the proof of Proposition 14 imply that $\tilde{g}_3=\Sigma_{l+2k=n-1}c_{l,k}z_2^l((z_2-z_3)^2+y_3^2)^k$. Further, if we denote by $\hat{g}_3$ the restriction of $\bar{g}_3$ to $y_3=0$, then proceeding as for $\tilde{g}_3$ we get that $\hat{g}_3=\Sigma_{l+2k=n-1}d_{l,k}z_3^l((z_2-z_3)^2+y_2^2)^k$. We note that for $y_2=y_3=0$, $\tilde{g}_3$ restricted to $y_3=0$ and $\hat{g}_3$ restricted to $y_2=0$ must coincide. Thus we get the relation

$$\sum_{l+2k=n-1} c_{l,k} z_2^l (z_2 - z_3)^{2k} = \sum_{l+2k=n-1} d_{l,k} z_3^l (z_2 - z_3)^{2k}. \tag{19}$$

We claim that

$$c_{l,k} = d_{l,k} = 0 \quad \text{for all } l \geqslant 1. \tag{20}$$

Proceeding exactly in the same way as in the proof of claim (13) we can prove by induction that $c_{l,k}=d_{l,k}=0$ for $l\geqslant 3$. Then, (19) reduces to $c_{1,(n-2)/2}z_2(z_2-z_3)^{n-2}=d_{1,(n-2)/2}z_3(z_2-z_3)^{n-2}$ which clearly implies $c_{1,(n-2)/2}=d_{1,(n-2)/2}=0$ and finishes the proof of the claim. Therefore from (20), we get that $\tilde{g}_3=\hat{g}_3=0$. Now, using that $\tilde{g}_3$ is the restriction of $\bar{g}_3$ to $y_2=0$ and $\hat{g}_3$ is the restriction of $\bar{g}_3$ to $y_3=0$, we can write $\bar{g}_3$ in the two following forms $\bar{g}_3=y_2G_0$ and $\bar{g}_3=y_3G_1$, where G_0, G_1 are polynomials. Then, equating the two expressions for $\bar{g}_3$ we readly obtain $\bar{g}_3=y_2y_3h_1$ for some polynomial h_1. Thus, the claim (18) is proved.

Now, from (18) and (16), and after dividing by $H_2=y_2y_3$ we get

$$\frac{\mathrm{d}h_1}{\mathrm{d}t} = 2 \sum_{2k+2m=n, m\geqslant 1} a_{k,m} m H_1^k H_2^{m-1}. \tag{21}$$

We claim that

$$a_{k,m} = 0,\ h_1 = (y_2 y_3)^m h_{m+1} \quad \text{for } m = 1, \ldots, n/2 \tag{22}$$

where h_{m+1} are polynomials.

First, we prove the claim (22) for $m=1$. To do it, we restrict (21) to $y_2=0$. Then, taking the notation $\tilde{h}_1$ for the restriction of h_1 to $y_2=0$, using the variables x_1,x_2,x_3 introduced previously, and denoting $F(x_1,x_2,x_3)=\tilde{h}_1(z_2,z_3,y_3)$ we get

$$\frac{x_2 - x_3}{2}\left(-x_2\frac{\partial F}{\partial x_2} + x_3\frac{\partial F}{\partial x_3}\right) = a_{(n-2)/2,1}\left(\frac{1}{2}x_2x_3\right)^{(n-2)/2} \tag{23}$$

Evaluating (23) on $x_2=x_3$, we get $a_{(n-2)/2,1}=0$. Since (21) is of the same type as (17) replacing $\bar{g}_3$ by h_1, the same arguments used for $\bar{g}_3$ imply that $h_1=y_2y_3h_2$ for some polynomial h_2. This proves the claim for $m=1$.

Now, assume the claim is true for $1\leqslant m\leqslant j$ with $0<j<n/2$. Then, we want to prove it for $m=j+1$. Clearly, by induction hypotheses $h_1=(y_2y_3)^jh_{j+1}$ and since y_2y_3 is a first integral of system (5) restricted to $y_1=0$, $z_1=0$, after simplifying by $(y_2y_3)^j$, (21) is equal to

$$\frac{dh_{j+1}}{dt} = 2 \sum_{2k+2m=n, m\geqslant j+1} a_{k,m} m H_1^k H_2^{m-j-1} = 2 \sum_{2k+2m=n, k\leqslant n/2-(j+1)} a_{k,m} m H_1^k H_2^{m-j-1}.$$

Now, repeating for h_{j+1} the arguments we did for h_1 in the case $m=1$, we get that $a_{n/2-j-1,j+1}=0$ and $h_{j+1}=y_2y_3h_{j+2}$ for some polynomial h_{j+2}. Hence, the claim is proved.

In short, using the claim (22) we have, $\bar{g}_3=(y_2y_3)^{n/2+1}h_{n/2+1}$, which due to the fact that the degree of $\bar{g}_3$ is $n-1$ we get that $h_{n/2+1}=0$ and thus $\bar{g}_3=0$. Further, applying the claim (22) to (15), we obtain $f=a_{n/2,0}H_3^{n/2}+z_1^2g_4$. Then, since f, H_3, and z_1 are first integrals of system (5) restricted to

$y_1=0$, we have that g_4 is also a first integral of system (5) restricted to $y_1=0$ of degree $n-2$. Hence, by induction assumption g_4 can be written as in the statement of the proposition with n replaced by $n-2$. Therefore, the proposition follows for f. ■

VI. HOMOGENEOUS DARBOUX POLYNOMIALS WITH NONZERO COFACTOR

The objective of this section is to study the homogeneous Darboux polynomials of system (5) with nonzero cofactor.

Proposition 16. System (5) has no homogeneous Darboux polynomials invariant by τ and σ with cofactor $K=a(z_1+z_2+z_3)$, $a\in\mathbb{C}\backslash\{0\}$ that are coprime with y_1, y_2, and y_3.

Proof: Let f be a homogeneous Darboux polynomial invariant by τ and σ with cofactor $K=a(z_1+z_2+z_3)$, $a\in\mathbb{C}\backslash\{0\}$ that is coprime with y_1, y_2, and y_3. By Proposition 12, the degree n of f satisfies that $n>1$, and by assumptions, y_i is not a factor f for $i=1,2,3$. Now, the proof of the proposition will be completed if we reach a contradiction. We write $f_0=f_0(y_2,y_3,z_1,z_2,z_3)=f(0,y_2,y_3,z_1,z_2,z_3)$. Since y_1 is not a factor f, then $f_0\neq 0$. We separate the proof in two different cases.

Case 1: f_0 is not divisible by y_2. In this case, we can write $f_{0,0}=f_0(0,y_3,z_1,z_2,z_3)$. Then, the polynomial $f_{0,0}$ is a Darboux polynomial of system (5) restricted to $y_1=y_2=0$ and thus, it satisfies the equation

$$y_3(-z_1-z_2+z_3)\frac{\partial f_{0,0}}{\partial y_3}-y_3^2\frac{\partial f_{0,0}}{\partial z_3}=a(z_1+z_2+z_3)f_{0,0}. \tag{24}$$

Hence, from (24) and since $a\neq 0$, $f_{0,0}$ is divisible by y_3. We write $f_{0,0}=y_3^m g$ where $1\leqslant m\leqslant n$, $\deg(g)=n-m$, $g\neq 0$ and g is not divisible by y_3. We have that $m<n$; otherwise, $f_{0,0}=by_3^n$ with $b\in\mathbb{C}\backslash\{0\}$, and from (24) we get a contradiction. From (24) and Proposition 4, we obtain that g is a Darboux polynomial of system (5) restricted to $y_1=y_2=0$ satisfying

$$y_3(-z_1-z_2+z_3)\frac{\partial g}{\partial y_3}-y_3^2\frac{\partial g}{\partial z_3}=[a(z_1+z_2+z_3)+m(z_1+z_2-z_3)]g.$$

Hence, if $m<n$ then g is divisible by y_3, a contradiction. Thus, Case 1 is not possible.

Case 2: f_0 is divisible by y_2. In this case, we write $f_0=y_2^m g$ where $1\leqslant m\leqslant n$, $\deg(g)=n-m$, $g\neq 0$ and g is not divisible by y_2. We have that $m<n$; otherwise, $f_0=by_2^m$ with $b\in\mathbb{C}\backslash\{0\}$ and $y_2(-z_1+z_2-z_3)\partial f_0/\partial y_2=a(z_1+z_2+z_3)f_0$, a contradiction. Since f_0 and y_2 are Darboux polynomials of system (5) restricted to $y_1=0$, from Proposition 4, g is also a Darboux polynomial of system (5) restricted to $y_1=0$ satisfying

$$\begin{aligned}&y_2(-z_1+z_2-z_3)\frac{\partial g}{\partial y_2}+y_3(-z_1-z_2+z_3)\frac{\partial g}{\partial y_3}-y_2(y_2-y_3)\frac{\partial g}{\partial z_2}-y_3(-y_2+y_3)\frac{\partial g}{\partial z_3}\\&\quad=[a(z_1+z_2+z_3)-m(-z_1+z_2-z_3)]g.\end{aligned}$$

We write $g_0=g(0,y_3,z_1,z_2,z_3)$. Since g is not divisible by y_2 we have that $g_0\neq 0$. Moreover, g_0 is a Darboux polynomial of system (5) restricted to $y_1=y_2=0$, and g_0 satisfies

$$y_3(-z_1-z_2+z_3)\frac{\partial g_0}{\partial y_3}-y_3^2\frac{\partial g_0}{\partial z_3}=[a(z_1+z_2+z_3)-m(-z_1+z_2-z_3)]g_0. \tag{25}$$

Hence, g_0 is divisible by y_3 and we can write $g_0=y_3^l h$, where $1\leqslant l\leqslant n-m$, $h\neq 0$ and h is not divisible by y_3. We have that $l<n-m$; otherwise, $g_0=by_3^{n-m}$ with $b\in\mathbb{C}\backslash\{0\}$, and we get a contradiction using (25). Again from (25) and Proposition 4, we have that

$$y_3(-z_1-z_2+z_3)\frac{\partial h}{\partial y_3}-y_3^2\frac{\partial h}{\partial z_3}=[(a+m+l)z_1+(a-m+l)z_2+(a+m-l)z_3]h. \tag{26}$$

Note that since $m\neq 0$ and $l\neq 0$, then $(a+m+l)z_1+(a-m+l)z_2+(a+m-l)z_3\neq 0$. Hence, from (26), we get that h must be divisible by y_3, a contradiction. Thus, Case 2 is not possible. ■

VII. PROOF OF THE MAIN RESULTS

The next two results will play a main role in the proofs of Theorems 1 and 3, our main results.

Theorem 17. *All homogeneous Darboux polynomials of degree n with zero cofactor (i.e., homogeneous polynomial first integrals of degree n) for system (5) are of the form* $aH^{n/2}$ *with n even and* $a\in\mathbb{C}\backslash\{0\}$.

Proof: Let g be a homogeneous polynomial first integral of system (5) of degree n. By Proposition 13, $f=(g\cdot\sigma g\cdot\sigma^2 g)\cdot\tau(g\cdot\sigma g\cdot\sigma^2 g)$ is a homogeneous polynomial first integral invariant by τ and σ of degree equal to $6n$. We claim that there exists a polynomial h such that

$$f=a_{3n}H^{3n}+y_1y_2y_3h. \tag{27}$$

From Proposition 15 (with n replaced by $6n$) and since f is invariant by σ, we have that there exist a homogeneous polynomial g_3 such that

$$f=\sum_{l+k=3n}a_{l,k}z_1^{2l}H_3^k+y_1g_3=\sum_{l+k=3n}a_{l,k}z_2^{2l}H_4^k+y_2\cdot\sigma g_3=\sum_{l+k=3n}a_{l,k}z_3^{2l}H_5^k+y_3\cdot\sigma^2 g_3, \tag{28}$$

where $H_4=\sigma H_3$ and $H_5=\sigma^2 H_3$.

Restricting (28) to $y_1=y_2=y_3=0$, we get the

$$\sum_{l+k=3n}a_{l,k}z_1^{2l}\bar{H}^k=\sum_{l+k=3n}a_{l,k}z_2^{2l}\bar{H}^k=\sum_{l+k=3n}a_{l,k}z_3^{2l}\bar{H}^k,$$

where $\bar{H}=\frac{1}{2}(z_1^2+z_2^2+z_3^2-2z_1z_2-2z_1z_3-2z_2z_3)$. These equalities between polynomials in the variables $\bar{H}$, z_1, z_2 and z_3 imply that $a_{l,k}=0$ for $l>0$. Therefore, from the first equation of (28) we have

$$f=a_{0,3n}H_3^{3n}+y_1g_3. \tag{29}$$

Since $H=H_3+\frac{1}{2}y_1(y_1-2y_2-2y_3)=H_3+y_1h$, we obtain that $H_3^{3n}=H^{3n}+y_1T_1$, where T_1 is a homogeneous polynomial of degree $n-1$. Therefore, taking into account that H is invariant by σ, (29) can be written in the three equivalent forms,

$$f=a_{0,3n}H^{3n}+y_1f^3=a_{0,3n}H^{3n}+y_2\cdot\sigma f^3=a_{0,3n}H^{3n}+y_3\cdot\sigma^2 f^3, \tag{30}$$

where f^3 is a homogeneous polynomial of degree $6n-1$. Now, equating the three identities of (30), it follows that the claim (27) is proved.

From (27) and since f and H are invariant by σ and τ, it follows that $h=\sigma h=-\tau h$. Moreover, since f and H are first integrals of system (5), we have

$$0=\frac{d}{dt}(y_1y_2y_3h)=y_1y_2y_3\left(-(z_1+z_2+z_3)h+\frac{dh}{dt}\right),$$

on the solutions of system (5). Therefore, h is either 0, or a Darboux polynomial of system (5) with cofactor $K=z_1+z_2+z_3$. Therefore, the polynomial $h^2=-h\cdot\tau h$ is a Darboux polynomial of system (5) with cofactor $2K$ (see Proposition 4) invariant by σ and by τ.

From Proposition 16, if $h\neq 0$, then $h^2=Py_1^{n_1}y_2^{n_2}y_3^{n_3}$ with P a Darboux polynomial of system (5) with zero cofactor and n_1,n_2,n_3 nonnegative integers satisfying $n_1+n_2+n_3\geqslant 1$, because $2K$ is nonzero. Since h^2 is a Darboux polynomial of cofactor $2K$, using Proposition 4 we get

$$\frac{dh^2}{dt} = [z_1(n_1 - n_2 - n_3) + z_2(-n_1 + n_2 - n_3) + z_3(-n_1 - n_2 + n_3)]h^2 = 2(z_1 + z_2 + z_3)h^2.$$

Therefore, $n_1 = n_2 = n_3 = -2$, a contradiction with the fact that $n_1 + n_2 + n_3 \geqslant 1$. Thus, $h^2 = 0$, that is, $h = 0$ and consequently from (27), $f = a_{3n}H^{3n}$. Hence, since H is irreducible, by the definition of f, it follows that $3n$ must be even, i.e., n must be even and g is of the form $aH^{n/2}$. So, the theorem is proved. ■

Theorem 18. *For system (5) the unique irreducible homogeneous Darboux polynomials with nonzero cofactor are* y_1, y_2, and y_3.

Proof: By Proposition 12, if g is an irreducible homogeneous Darboux polynomial of degree 1, it must be y_1, y_2, or y_3. Now, assume that g is an irreducible homogeneous Darboux polynomial of degree $n > 1$ for system (5) with nonzero cofactor K of the form (6). Then, from Proposition 13, we can assume that $f = (g \cdot \sigma g \cdot \sigma^2 g) \cdot \tau(g \cdot \sigma g \cdot \sigma^2 g)$ is a homogeneous Darboux polynomial invariant by τ and σ, with degree $6n$ and nonzero cofactor of the form $2(a_4 + a_5 + a_6)(z_1 + z_2 + z_3)$ and such that y_i is not a factor f for $i = 1, 2, 3$. From Proposition 16, we get that $a_4 + a_5 + a_6 = 0$, otherwise we have a contradiction. Hence, f is a homogeneous polynomial first integral of system (5). By Theorem 17, f is of the form aH^{3n} with n even and $a \in \mathbb{C}\backslash\{0\}$. Therefore, from the definition of f and since H and g are irreducible and invariant for σ and τ, it follows that $g = bH^{n/2}$, in contradiction with the fact that the cofactor of g is not zero. ■

Now we prove Theorem 9, that as it was shown in Sec. III is equivalent to prove Theorem 5.

Proof of Theorem 9: By Theorems 17 and 18, it follows that every Darboux polynomial of system (5) is of the form $y_1^m y_2^n y_3^l P_H$ with cofactor

$$K = (m - n - l)z_1 + (n - m - l)z_2 + (l - m - n)z_3, \tag{31}$$

where m, n, and l are nonnegative integers, and P_H is some polynomial of the variable H.

From Proposition 6 and Theorem 17, the existence of a rational first integral which is not a function of H, implies the existence of two coprime Darboux polynomials with the same nonzero cofactor. So, the first integral must be of the form $R/S = y_1^{m_1} y_2^{n_1} y_3^{l_1} P_H / (y_1^{m_2} y_2^{n_2} y_3^{l_2} Q_H)$ with at most one m_i, n_i, and l_i nonzero, and the cofactors of R and S must be equal.

Suppose that m_1, n_1, and l_2 are the possible nonzero exponents. Then, according to Eq. (31), the equality of the cofactors of R and S imply that

$$(m_1 - n_1 + l_2)z_1 + (n_1 - m_1 + l_2)z_2 - (l_2 + m_1 + n_1)z_3 = 0.$$

Hence, $m_1 = n_1 = l_2 = 0$. All the other combinations with the possible non-zero exponents, also end showing that the six exponents are zero. In short, the only rational first integrals are rational functions in the variable H. ■

The equation defining the exponential factor $F = \exp(h/g)$ with cofactor L is

$$\dot{y}_1 \frac{d}{dy_1}\frac{h}{g} + \dot{y}_2 \frac{d}{dy_2}\frac{h}{g} + \dot{y}_3 \frac{d}{dy_3}\frac{h}{g} + \dot{z}_1 \frac{d}{dz_1}\frac{h}{g} + \dot{z}_2 \frac{d}{dz_2}\frac{h}{g} + \dot{z}_3 \frac{d}{dz_3}\frac{h}{g} = L, \tag{32}$$

where we have simplified the common factor F, and

$$L = b_0 + b_1 y_1 + b_2 y_2 + b_3 y_3 + b_4 z_1 + b_5 z_2 + b_6 z_3. \tag{33}$$

According to Proposition 7 and Theorems 17 and 18, if system (5) has exponential factors, they must be of the form $\exp(h/(y_1^{n_1} y_2^{n_2} y_3^{n_3}))$, $\exp(h/(y_1^{n_1} y_2^{n_2} y_3^{n_3} P_H))$, where h and P_H are polynomials in $\mathbb{C}[y_1, y_2, y_3, z_1, z_2, z_3]$ and $\mathbb{C}[H]$, respectively; and n_1, n_2, and n_3 are nonnegative integers.

We shall need the following auxiliary result.

Proposition 19: The unique irreducible homogeneous Darboux polynomials with non-zero cofactor of system (5) restricted to $y_1 = z_1 = 0$ *are* y_2 *and* y_3.

Proof: It follows by direct computations that if g is an irreducible homogeneous Darboux polynomial of degree 1 for system (5) restricted to $y_1 = z_1 = 0$, it must be y_2 or y_3. Now, assume that g is an irreducible homogeneous Darboux polynomial of degree $n > 1$ for system (5) restricted to

$y_1=z_1=0$ with nonzero cofactor K of the form (6) restricted to $y_1=z_1=0$. Then, we can assume that $f=(g\cdot\sigma g)\cdot\tau(g\cdot\sigma g)$ is a homogeneous Darboux polynomial invariant by τ and σ, with degree $4n$, nonzero cofactor of the form $2(a_5+a_6)(z_2+z_3)$ and such that y_2 and y_3 are not factors f. Repeating the arguments used in the proof of Proposition 16 with $y_1=z_1=0$, we get that $a_5+a_6=0$, otherwise we have a contradiction. Hence, f is a homogeneous polynomial first integral of system (5) restricted to $y_1=z_1=0$. By Proposition 14 (with n replaced by $4n$), f is of the form $f=\sum_{k=0}^{2n}a_kH_1^kH_2^{n/2-k}$, with n even and $a_k\in\mathbb{C}\backslash\{0\}$. Therefore, from the definition of f it follows that $g=g(H_1,H_2)$, in contradiction with the fact that the cofactor of g is not zero. ■

Proposition 20: The unique exponential factors of system (5) are of the form $\exp(P)$ *and* $\exp(P/Q)$, *where P and Q are polynomials in $\mathbb{C}[H]$. Moreover, such exponential factors have cofactor zero.*

Proof: We start showing that if system (5) has an exponential factor of the form $\exp(h/Q^\lambda)$, with $\lambda\in\{0,1\}$, then h is a polynomial in H. Since Q is a Darboux polynomial with cofactor zero (by Proposition 7), applying (32) with $h/g=h/Q$ we get

$$\dot{y}_1\frac{\mathrm{d}h}{\mathrm{d}y_1}+\dot{y}_2\frac{\mathrm{d}h}{\mathrm{d}y_2}+\dot{y}_3\frac{\mathrm{d}h}{\mathrm{d}y_3}+\dot{z}_1\frac{\mathrm{d}h}{\mathrm{d}z_1}+\dot{z}_2\frac{\mathrm{d}h}{\mathrm{d}z_2}+\dot{z}_3\frac{\mathrm{d}h}{\mathrm{d}z_3}=LQ^\lambda, \tag{34}$$

with L given by (33). Taking $y_1=y_2=y_3=0$ in (34), since $H_{|y_1=y_2=y_3=0}\neq 0$, it holds that $b_0=b_4=b_5=b_6=0$. Restricting (34) to $y_1=y_2=0$ and $z_3=z_1+z_2$, we get

$$-y_3^2\frac{\partial h}{\partial z_3}_{|y_1=y_2=0,z_3=z_1+z_2}=y_3b_3Q(\bar{H})^\lambda, \tag{35}$$

where $\bar{H}=-2z_1z_2+\frac{1}{2}y_3^2$. From (35) we obtain that either $b_3=0$ or $Q(\bar{H})$ must be divisible by y_3. This last case is impossible and then $b_3=0$. In a similar way, restricting (34) to $y_1=y_3=0$, $z_2=z_1+z_3$ we get $b_2=0$, and restricting (34) to $y_2=y_3=0$ and $z_1=z_2+z_3$ we get $b_1=0$. Thus we have $L=0$. Therefore, from (34), h is a polynomial first integral. From Proposition 11, we can assume h is a homogeneous polynomial first integral and then, from Theorem 17, h is a polynomial function of H.

Suppose that $\exp(h/(y_1^{n_1}y_2^{n_2}y_3^{n_3}P^\lambda))$ is an exponential factor of system (5), where n_1,n_2,n_3 are nonnegative integers with at least one of them positive, $\lambda\in\{0,1\}$ and h is coprime with y_1, y_2, y_3 and P. Of course, P is a polynomial in the variable H. Then, h satisfies

$$\dot{y}_1\frac{\partial h}{dy_1}+\dot{y}_2\frac{\partial h}{dy_2}+\dot{y}_3\frac{\partial h}{dy_3}-\left(\frac{\dot{y}_1}{y_1}n_1+\frac{\dot{y}_2}{y_2}n_2+\frac{\dot{y}_3}{y_3}n_3\right)h+\dot{z}_1\frac{\partial h}{dz_1}+\dot{z}_2\frac{\partial h}{dz_2}+\dot{z}_3\frac{\partial h}{dz_3}=Ly_1^{n_1}y_2^{n_2}y_3^{n_3}P^\lambda, \tag{36}$$

where we have simplified the common factor $\exp(h/(y_1^{n_1}y_2^{n_2}y_3^{n_3}P^\lambda))$ and multiplied by $y_1^{n_1}y_2^{n_2}y_3^{n_3}P^\lambda$.

Without loss of generality, we can assume that $n_1>0$. Taking $y_1=0$ in (36) and denoting by $\bar{h}$ the restriction of h to $y_1=0$, we conclude that $\bar{h}$ satisfies

$$\dot{y}_2\frac{\partial\bar{h}}{dy_2}+\dot{y}_3\frac{\partial\bar{h}}{dy_3}+\dot{z}_2\frac{\partial\bar{h}}{dz_2}+\dot{z}_3\frac{\partial\bar{h}}{dz_3}=(z_1(n_1-n_2-n_3)+z_2(-n_1+n_2-n_3)+z_3(-n_1-n_2+n_3))\bar{h}. \tag{37}$$

Since by hypothesis h is coprime with y_1, we have that $\bar{h}\neq 0$. We consider two different cases:

Case 1: $\bar{h}$ is not divisible by z_1. In this case, we write $\bar{h}_0=\bar{h}(y_2,y_3,0,z_2,z_3)$. Then, $\bar{h}_0\neq 0$ and $\bar{h}_0$ satisfies (37) restricted to $z_1=0$, that is

$$\dot{y}_2\frac{\partial \bar{h}_0}{dy_2}+\dot{y}_3\frac{\partial \bar{h}_0}{dy_3}+\dot{z}_2\frac{\partial \bar{h}_0}{dz_2}+\dot{z}_3\frac{\partial \bar{h}_0}{dz_3}=(z_2(-n_1+n_2-n_3)+z_3(-n_1-n_2+n_3))\bar{h}_0. \tag{38}$$

Since $n_1>0$, $z_2(-n_1+n_2-n_3)+z_3(-n_1-n_2+n_3)\neq 0$. Thus, since $\bar{h}_0\neq 0$, Eq. (38) implies that $\bar{h}_0$ is a Darboux polynomial of system (5) restricted to $y_1=z_1=0$. From Proposition 19, we obtain that $\bar{h}_0=Ry_2^{m_2}y_3^{m_3}$, with R a Darboux polynomial with zero cofactor of system (5) restricted to $y_1=z_1=0$, and m_2 and m_3 are nonnegative integers such that $m_2+m_3>0$. Substituting $\bar{h}_0=Py_2^{m_2}y_3^{m_3}$ in (38), we get that $(m_2-m_3)(z_2-z_3)=z_2(-n_1+n_2-n_3)+z_3(-n_1-n_2+n_3)$ which implies $n_1=0$, in contradiction with the fact that $n_1>0$.

Case 2: $\bar{h}$ is divisible by z_1. In this case, we write $\bar{h}=z_1^n g$ where $\deg(g)=\deg(\bar{h})-n$ and $0\leqslant n\leqslant \deg(\bar{h})$. Further, $g\neq 0$ and g is not divisible by z_1. Then, since z_1 is a first integral of system (5) restricted to $y_1=0$, then g satisfies (37). Thus, if we set $g_0=g(y_2,y_3,0,z_2,z_3)$, then $g_0\neq 0$ and g_0 satisfies (38). Hence, applying to g_0 the arguments we used for $\bar{h}$ in Case 1, we get a contradiction. This completes the proof of the proposition. ■

Proof of Theorem 3: From Theorems 5, 17, and 18 and Proposition 20, if system (5) has a Darboux first integral G, then

$$G=y_1^{\lambda_1}y_2^{\lambda_2}y_3^{\lambda_3}P_1^{\mu_1}\cdots P_r^{\mu_r}\exp(Q/R)\quad \text{with } \lambda_1,\lambda_2,\lambda_3,\mu_i\in\mathbb{C},$$

where P, Q, and R are polynomials in the variable H, and $i=1,\ldots,r$. Since G and H are first integrals and the cofactors of P_i and $\exp(P/R)$ are zero, using Theorem 5, it must hold $(\lambda_1-\lambda_2-\lambda_3)z_1+(\lambda_2-\lambda_1-\lambda_3)z_2+(\lambda_3-(\lambda_1-\lambda_2)z_3=0$. This implies $\lambda_1=\lambda_2=\lambda_3=0$, and completes the proof of the theorem. ■

(Received 13 February 2005; accepted 25 April 2005; published online 12 July 2005)

For type I superconductors with penetration parameter λ below a certain critical value, the existence of multiple local minimizers of the energy functional is shown. The behavior of these minimizers is examined when the Ginzburg–Landau parameter is small, and a hysteresis phenomenon is demonstrated. In contrast to the case investigated by X. B. Pan [J. Math. Phys. **44**, 2639 (2003)] where λ is above the critical value, the results presented in this paper show that type I superconductors with λ below the critical value have higher critical magnetic field H_c, and exhibit more complicated superconducting behavior. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1938747]

I. INTRODUCTION

The following functional:

$$\mathcal{G}[\psi,\mathcal{A}] := \int_\Omega \left\{ |\nabla \psi - i\mathcal{A}\psi|^2 + \frac{\kappa^2}{2\lambda^2}(1-|\psi|^2)^2 \right\} dx + \lambda^2 \int_{\mathbb{R}^3} |\mathrm{curl}\, \mathcal{A} - \mathcal{H}|^2 dx$$

is a rescaled version of the Gibbs free energy in the Ginzberg–Landau theory (see for instance Refs. 1 and 2), which can be derived from the original Ginzburg–Landau energy functional by performing a series of changes of variables. It can also be obtained from the functional given in Ref. 3 [Eq. (1.3)] by letting $\kappa=\lambda\sqrt{\mu}$. According to the Ginzburg–Landau theory[4] (also see Refs. 5–11), the critical points $(\psi,\mathcal{A})$ of this functional (in a space to be specified in Sec. III), namely the solutions of the Euler equations associated with this functional, describe the superconducting behavior of a superconductor occupying a bounded domain $\Omega\subset\mathbb{R}^3$ with penetration parameter λ and Ginzburg–Landau parameter κ, subjected to an applied magnetic field $\mathcal{H}$. Here ψ is a complex-valued function known as the order parameter, and $\mathcal{A}$ is a real-valued vector field called the magnetic potential. Superconductors with $\kappa<1/\sqrt{2}$ are called type I superconductors and those with $\kappa>1/\sqrt{2}$ are termed type II. It is well known that for type I superconductors there is a critical magnetic field H_c, below which the material will be in the so-called superconducting Meissner state, but above which it will be in the normal state where no superconductivity is observed. In the Ginzburg–Landau theory, a critical point $(\psi,\mathcal{A})$ with $\psi(x)\equiv 0$ indicates that the sample is in the normal state, and *a critical point* $(\psi,\mathcal{A})$ *where* $|\psi(x)|$ *is close to a positive constant everywhere on the whole domain corresponds with the Meissner state*.

We consider in this paper a type I superconductor with small κ, and subjected to an applied magnetic field of the form $\mathcal{H}=\sigma\mathbf{h}$, where $\mathbf{h}$ is a fixed unit vector in $\mathbb{R}^3$, and σ is a real parameter representing the strength of the applied field. One tends to believe that minimizers with a small

[a)]Electronic mail: ydu@turing.une.edu.au
[b)]Electronic mail: xbpan@math.ecnu.edu.cn

value of κ have simpler behavior, and may expect a simple transition from the Meissner state to the normal state as the applied field varies. The results in Ref. 3 show that the phase transition is simple if λ is greater than a critical value $\lambda(\mathbf{h})$. In this paper we shall show that the phase transition is not simple if $\lambda<\lambda(\mathbf{h})$; we will provide estimates for the critical value H_c, examine the change of state of the superconductor as the applied field crosses H_c, and discuss a hysteresis phenomenon.

We assume throughout this paper that Ω is a simply connected and bounded domain in $\mathbb{R}^3$ and has smooth boundary $\partial\Omega$. For the given applied field $\mathcal{H}=\sigma\mathbf{h}$, letting $\mathcal{A}=\sigma\mathbf{A}$, we have

$$\mathcal{G}[\psi,\mathcal{A}]=\mathcal{G}_\sigma[\psi,\mathbf{A}],$$

where

$$\mathcal{G}_\sigma[\psi,\mathbf{A}]:=\int_\Omega\left\{|\nabla_{\sigma\mathbf{A}}\psi|^2+\frac{\kappa^2}{2\lambda^2}(1-|\psi|^2)^2\right\}\mathrm{d}x+\lambda^2\sigma^2\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbf{A}-\mathbf{h}|^2\mathrm{d}x. \tag{1.1}$$

Here and in the following, we will let ν denote the outward unit normal of $\partial\Omega$, and we shall use the usual notations

$$\nabla_{\mathcal{A}}\psi=\nabla\psi-i\psi\mathcal{A},$$

$$\nabla_{\mathcal{A}}^2\psi=(\nabla-i\mathcal{A})^2\psi=\Delta\psi-i(2\mathcal{A}\cdot\nabla\psi+\psi\,\mathrm{div}\,\mathcal{A})-|\mathcal{A}|^2\psi.$$

Let $\mathbf{F_h}$ be a smooth vector field associated with the above-mentioned given unit vector $\mathbf{h}$ such that

$$\mathrm{curl}\,\mathbf{F_h}=\mathbf{h},\quad \mathrm{div}\,\mathbf{F_h}=0\quad \text{in } \mathbb{R}^3. \tag{1.2}$$

It is easily seen that such $\mathbf{F_h}$ is uniquely determined up to a harmonic gradient (namely, the gradient field of a real-valued harmonic function). For convenience of later discussions, we fix such an $\mathbf{F_h}$ so that

$$\int_\Omega\mathbf{F_h}\mathrm{d}x=\mathbf{0}.$$

It is known that for large σ, the only minimizers of $\mathcal{G}_\sigma$ are

$$(\psi,\mathbf{A})=(0,\mathbf{F_h}+\nabla\phi),$$

where ϕ is an arbitrary real-valued smooth function (see Refs. 3, 12, and 13). We will henceforth call $(0,\mathbf{F_h})$ the trivial solution or trivial critical point of $\mathcal{G}_\sigma$; it corresponds to the normal state of the superconductor. Let us define the critical field H_c by

$$H_c=H_c(\mathbf{h};\kappa,\lambda)=\inf\{\sigma>0:(0,\mathbf{F_h})\text{ is a global minimizer of }\mathcal{G}_\sigma\}. \tag{1.3}$$

[In Ref. 3 a definition of the critical field $H_c(\mathbf{h},\kappa,\mu)$ regarding the functional considered there was given. In the present paper we fix λ and examine the value of H_c for $\kappa=\lambda\varepsilon$, $\varepsilon\to0$. Therefore it is more convenient to treat H_c as a function of $\mathbf{h}$, λ, and κ. The critical field $H_c(\mathbf{h},\kappa,\mu)$ defined in Ref. 3 and the critical field $H_c(\mathbf{h};\kappa,\lambda)$ defined in the present paper are related by the equality $H_c(\mathbf{h};\kappa,\lambda)=H_c(\mathbf{h},\kappa,(\kappa/\lambda)^2)$.]

Clearly for any $0<\sigma<H_c$, $\mathcal{G}_\sigma$ has a nontrivial global minimizer, indicating that the sample is in the superconducting state.

The value of $H_c(\mathbf{h};\kappa,\lambda)$ was estimated in Ref. 3 (Theorem 1). Two positive numbers $a(\mathbf{h})$ and $\lambda(\mathbf{h})$, both depending only on $\mathbf{h}$ and Ω, were introduced there in order to describe the estimates [see also Eqs. (2.3) and (2.8) in Sec. II for the definition]. In particular, it has been shown that, for small $\kappa>0$,

$$H_c(\mathbf{h};\kappa,\lambda) = a(\mathbf{h})\frac{\kappa}{\lambda} + o(\kappa) \quad \text{for fixed } \lambda \geqslant \lambda(\mathbf{h}). \tag{1.4}$$

In fact, for the case $\lambda > \lambda(\mathbf{h})$, the following better estimate has been established in Ref. 3 (Theorem 4.1):

$$H_c(\mathbf{h};\kappa,\lambda) = a(\mathbf{h})\frac{\kappa}{\lambda} + O(\kappa^3) \quad \text{as } \kappa \to 0.$$

Moreover, the asymptotic behavior of the global minimizers of $\mathcal{G}_\sigma$ with $\sigma = a\kappa/\lambda$ with $0 < a < a(\mathbf{h})$ and $\kappa \to 0$ has also been established in Ref. 3 (see Theorem 2 there for details), which, together with Theorem 5.3 in this paper, have the following physical explanation. (We should mention that the actual mathematical results in Theorem 5.3 are more complicated, but their physical meaning is well described by the statement given in Conclusion A.)

Conclusion A: For type I superconductors with small Ginzburg–Landau parameter κ *and penetration parameter* $\lambda \geqslant \lambda(\mathbf{h})$, *and subjected to the applied magnetic field* $\mathcal{H} = \sigma\mathbf{h}$, *there exists a critical field* H_c *such that*,

(i) *as the applied field increases, the Meissner state is a global minimizer of the Ginzburg–Landau energy for* $0 < \sigma < H_c$, *and disappears for* $\sigma > H_c$;
(ii) *as the applied field decreases, the normal state is a global minimizer for* $\sigma > H_c$, *and becomes unstable when* $0 < \sigma < H_c$.

The case where $0 < \lambda < \lambda(\mathbf{h})$ and κ being small is not covered by the above results in Ref. 3, and it will be examined in this paper. To state our results we need two positive constants $C(\lambda)$ and $a^*(\lambda)$ with the property

$$a(\mathbf{h}) < a^*(\lambda) < C(\lambda), \tag{1.5}$$

which depend only on λ, $\mathbf{h}$, and Ω; see Lemmas 2.2 and 2.3 for the definitions. We shall see that, in contrast to (1.4), the value of $H_c(\mathbf{h};\kappa,\lambda)$ is significantly larger when $0 < \lambda < \lambda(\mathbf{h})$.

Theorem 1: *Let* $\mathbf{h}$ *be a unit vector and* $0 < \lambda < \lambda(\mathbf{h})$. *For small* $\kappa > 0$ *we have*

$$H_c(\mathbf{h};\kappa,\lambda) = a^*(\lambda)\frac{\kappa}{\lambda} + o(\kappa). \tag{1.6}$$

Here for fixed $\mathbf{h}$ *and* λ, $\lim_{\kappa\to 0} o(\kappa)/\kappa = 0$.

We shall also show that the sample exhibits rather different and interesting superconducting behavior when $0 < \lambda < \lambda(\mathbf{h})$, see Theorems 5.2 and 6.1. The physical explanation of these results can be stated as follows.

Conclusion B: For type I superconductors with small Ginzburg–Landau parameter κ *and penetration parameter* $\lambda < \lambda(\mathbf{h})$, *and subjected to the applied magnetic field* $\mathcal{H} = \sigma\mathbf{h}$, *there exist three critical fields* H_{sc}, H_c, *and* H_{sh} *satisfying*

$$H_{sc} < H_c < H_{sh} \tag{1.7}$$

such that

(i) *as the applied field increases, the Meissner state is a global minimizer of the Ginzburg–Landau energy for* $0 < \sigma < H_c$, *remains stable (a local minimizer) for* $H_c \leqslant \sigma < H_{sh}$, *and disappears for* $\sigma > H_{sh}$;
(ii) *as the applied field decreases, the normal state is a global minimizer for* $\sigma > H_c$, *remains stable (a local minimizer) for* $H_{sc} < \sigma \leqslant H_c$, *and becomes unstable when* $0 < \sigma < H_{sc}$.

Moreover,

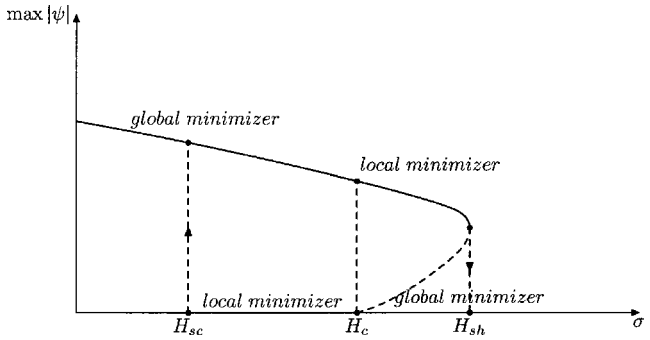

FIG. 1. Bifurcation and hysteresis for $0<\lambda<\lambda(\mathbf{h})$.

$$H_{sc} \sim a(\mathbf{h})\frac{\kappa}{\lambda}, \quad H_c \sim a^*(\lambda)\frac{\kappa}{\lambda}, \quad H_{sh} \sim C(\lambda)\frac{\kappa}{\lambda} \quad \text{for small } \kappa. \tag{1.8}$$

Remark 1.2. We believe that Conclusion B suggests a hysteresis phenomenon for type I superconductors with small penetration length $\lambda<\lambda(\mathbf{h})$: As the applied field increases from below H_c, the superconductor remains in the Meissner state until the field reaches H_{sh}, then it jumps to the normal state once the applied field increases past H_{sh}. On the other hand, as the applied field is lowered from above H_c, the superconductor is in normal state until the field reaches H_{sc}, then it jumps to the Meissner state once the magnetic field decreases past H_{sc}. These are sometimes called *superheating* and *subcooling*, respectively. We illustrate this in Fig. 1 (see Remark 5.4 for further details).

We should point out that the hysteresis phenomena described in Remark 1.2 are only natural physical explanations of our mathematical results. The actual mathematical results in Theorems 5.2 and 6.1 are more complicated. We would like to mention that an interesting hysteresis phenomenon for type II superconductors under an applied field near H_{C_1} has been analyzed by Lin and Du;[14] see also Ref. 15 for discussions related to the super-heating phenomenon for a similar situation to Ref. 14.

Remark 1.3: Comparing our results in the present paper for the case $0<\lambda<\lambda(\mathbf{h})$ with the results obtained in Ref. 3 for $\lambda\geqslant\lambda(\mathbf{h})$, we see that $\lambda(\mathbf{h})$ is a critical value for the penetration parameter λ. The superconducting behavior makes an important change between the cases $\lambda>\lambda(\mathbf{h})$ and $\lambda<\lambda(\mathbf{h})$, with more complicated behavior occurring when $0<\lambda<\lambda(\mathbf{h})$.

Remark 1.4: It is customary to perform the rescaling of the Ginzburg–Landau energy functional in a way that the parameter λ is reduced to 1. In that setting, the change in the value of λ in the present paper is translated into the change of the domain size of the sample, and our results can be roughly described as follows: Conclusion A applies when the sample is below a certain critical size, and Conclusion B applies if the sample is above that critical size. For a more accurate statement see the Appendix (Conclusion C). We would like to mention that A. Geim *et al.*[16] discovered numerous phase transitions of superconductors whose character changes rapidly with size and temperature. In particular, a sample can be either type I or type II depending on its size. Superconductivity for samples with small size has been studied by Aftalion and Dancer[17] and Aftalion and Du.[18] We should mention that Ginzburg–Landau equations in one-dimensional domains have been studied by many authors, and many interesting phenomena have been discovered; see for instance Bolley and Helffer,[19] Hastings and Troy,[20] and Aftalion and Troy.[21] We should also mention that the vortices of the minimizers of Ginzburg–Landau functional for large κ have been extensively studied; see for instance Bethuel *et al.*,[22] Lin,[23] and Sandier and Serfaty.[24]

Now we sketch the general scheme of the proof of our main results. The main part of the proof is to classify all critical points of the functional $\mathcal{G}_\sigma$ with $\sigma=a\varepsilon$ and $\kappa=\lambda\varepsilon$, and study their minimality, where $a>0$ is fixed, and $\varepsilon>0$ is small. We prove that when ε is small, all nontrivial critical points $(\psi_\varepsilon,\mathbf{A}_\varepsilon)$ have expansions

$$\psi_\varepsilon \sim e^{ic_\varepsilon}\rho^{1/2}(1+ia\varepsilon w^\rho), \quad \mathbf{A}_\varepsilon \sim \mathbf{A}^\rho + O(\varepsilon),$$
$$\mathcal{G}_{a\varepsilon}[\psi_\varepsilon, \mathbf{A}_\varepsilon] = \varepsilon^2 F(a,\rho) + O(\varepsilon^3), \tag{1.9}$$

where $(w^\rho, \mathbf{A}^\rho)$ satisfies Eq. (2.11), and ρ is a root of the equation

$$f(a,\rho) = 1, \tag{1.10}$$

where $f(a,\rho)$ and $F(a,\rho)$ are functions defined by the integrals involving w^ρ and $\nabla\mathbf{A}^\rho$, see (2.13). Note that $(w^\rho, \mathbf{A}^\rho)$ depends also on λ, and hence $f(a,\rho)$ depends on λ through w^ρ and $\mathbf{A}^\rho$. The detailed information about the roots of (1.10) has been given in Ref. 3, which is useful to classify all the critical points of $\mathcal{G}_{a\varepsilon}$. If $\lambda \geqslant \lambda(\mathbf{h})$, then (1.10) has exactly one root $\rho(a)$ for all $0 < a < C(\lambda)$. If $0 < \lambda < \lambda(\mathbf{h})$, then (1.10) has exactly one root when $0 < a < a(\mathbf{h})$ and has exactly two roots $\rho_*(a)$ and $\rho(a)$ when $a(\mathbf{h}) < a < C(\lambda)$. Moreover, we shall show that $\rho(a)$ is a minimizer of the function $F(a,\cdot)$ and $\rho_*(a)$ is a maximizer of $F(a,\cdot)$. Using this fact and the expansions in (1.9) we are able to prove the local minimality of the critical points with $\rho = \rho(a)$. These local minimizers describe the Meissner state of type I superconductors, and their existence is proved by minimizing a new functional

$$g_{a,\varepsilon}[\rho, w, \mathbf{A}] = \frac{1}{\varepsilon^2}\mathcal{G}_{a\varepsilon}[\rho^{1/2}(1+ia\varepsilon w), \mathbf{A}].$$

The existence of unstable critical points corresponding to $\rho_*(a)$ can be proved by using the well-known Mountain Pass Lemma,[25] but the details will be omitted. To examine the minimality of the normal state $(0, \mathbf{F_h})$, we need uniform estimates of the lowest eigenvalue of the operator $-\nabla^2_{\varepsilon_n \mathbf{A}_n}$, where $\mathbf{A}_n \to \mathbf{F_h}$ in $W^{1,2}(\Omega, \mathbb{R}^3)$.

The rest of the paper is organized as follows. In Sec. II, we collect some notations and results from Ref. 3, which clarify the results previously mentioned, and more importantly, play an essential role in our discussions to follow. In Sec. III, we collect some elliptic estimates for weak solutions of the Ginzburg–Landau equations. These estimates are already known for global minimizers. In Sec. IV we obtain a family of nontrivial local minimizers and also determine the local minimality and uniqueness in a chosen gauge of the normal state $(0, \mathbf{F_h})$. In Sec. V, we obtain a classification of all possible critical points of the energy functional, and this helps us to determine, in Sec. VI, the region of the parameters where the local minimizers are global minimizers, which in turn leads to a description for the critical value H_c and an explanation of the hysteresis phenomenon around H_c. Theorem 1.1 will be obtained in Sec. VI as a corollary of Theorem 6.1. In the Appendix we give a brief discussion about the effect of the size of a sample on its superconducting behavior.

II. PRELIMINARIES

In this section we introduce the various constants that have been used in stating our results in the introduction, namely, $\omega(\mathbf{h})$, $a(\mathbf{h})$, $\lambda(\mathbf{h})$, $a^*(\lambda)$, and $C(\lambda)$. We shall also introduce the constants $\rho(a)$ and $\rho_*(a)$ that depend on a parameter a. The numbers $\rho(a)$ and $\rho_*(a)$ will play an important role in our study.

Recall that $\mathbf{h}$ is a unit vector in $\mathbb{R}^3$ and $\mathbf{F_h}$ is a fixed vector field satisfying (1.2) and $\int_\Omega \mathbf{F_h} dx = \mathbf{0}$. Let

$$\omega(\mathbf{h}) = \inf_{\phi \in W^{1,2}(\Omega)} \fint_\Omega |\nabla \phi - \mathbf{F_h}|^2 dx, \tag{2.1}$$

where $\fint_\Omega = |\Omega|^{-1}\int_\Omega$ and $|\Omega|$ denotes the volume of Ω. It is well known that $\omega(\mathbf{h})$ is achieved by a real-valued function $w_\mathbf{h}$ which satisfies

$$\Delta w_{\mathbf{h}} = 0 \quad \text{in } \Omega, \quad \frac{\partial w_{\mathbf{h}}}{\partial \nu} = \mathbf{F}_{\mathbf{h}} \cdot \nu \quad \text{on } \partial\Omega. \tag{2.2}$$

Such $w_{\mathbf{h}}$ is unique if we further require $\int_\Omega w_{\mathbf{h}} dx = 0$. We define

$$a(\mathbf{h}) = \omega(\mathbf{h})^{-1/2}. \tag{2.3}$$

Lemma 2.1: (Ref. 3, Lemma 2.1) Let $\mu(\varepsilon \mathbf{F}_{\mathbf{h}})$ denote the lowest eigenvalue of the problem

$$-\nabla^2_{\varepsilon \mathbf{F}_{\mathbf{h}}} \phi = \mu\phi \quad \text{in } \Omega, \quad (\nabla_{\varepsilon \mathbf{F}_{\mathbf{h}}} \phi) \cdot \nu = 0 \quad \text{on } \partial\Omega.$$

Then

$$\mu(\varepsilon \mathbf{F}_{\mathbf{h}}) = \omega(\mathbf{h})\varepsilon^2 + O(\varepsilon^3) \quad \text{as } \varepsilon \to 0. \tag{2.4}$$

A simple application of Lemma 2.1 yields the following result (see Ref. 3, Theorem 3.2):

$$\liminf_{\varepsilon \to 0^+} \frac{H_c(\mathbf{h}, \lambda\varepsilon, \lambda)}{\varepsilon} \geqslant a(\mathbf{h}) \quad \text{uniformly for } \lambda \in (0, \infty). \tag{2.5}$$

Let

$$D^{1,2}(\mathbb{R}^3) = \{\phi \in L^1_{\text{loc}}(\mathbb{R}^3) : |\nabla \phi| \in L^2(\mathbb{R}^3)\},$$

and for $\phi \in D^{1,2}(\mathbb{R}^3)$ define $\|\phi\|_{1,2} = \|\nabla \phi\|_{L^2(\mathbb{R}^3)}$. It is well known that, after identifying functions that differ by a constant, $D^{1,2}(\mathbb{R}^3)$ is a Hilbert space under the norm $\|\cdot\|_{1,2}$. We denote by $\mathbf{D}^{1,2}(\mathbb{R}^3)$ the corresponding space of vector fields in $\mathbb{R}^3$. Let us recall the following well-known formula

$$\|\mathbf{B}\|^2_{1,2} = \int_{\mathbb{R}^3} |\nabla \mathbf{B}|^2 dx = \int_{\mathbb{R}^3} \{|\text{curl } \mathbf{B}|^2 + |\text{div } \mathbf{B}|^2\} dx, \quad \mathbf{B} \in \mathbf{D}^{1,2}(\mathbb{R}^3). \tag{2.6}$$

The definition of $\lambda(\mathbf{h})$ involves the following problem:

$$\text{curl}^2 \mathbf{U} = (\nabla w_{\mathbf{h}} - \mathbf{F}_{\mathbf{h}})\chi_\Omega, \quad \text{div } \mathbf{U} = 0 \quad \text{in } \mathbb{R}^3, \quad \mathbf{U} \in \mathbf{D}^{1,2}(\mathbb{R}^3). \tag{2.7}$$

It has been proved in Ref. 3 (Lemma 3.4) that (2.7) has a solution and it belongs to $C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3, \mathbb{R}^3)$ for any $\alpha \in (0,1)$. Moreover, it is unique up to an additive constant vector. Let $\mathbf{U}_{\mathbf{h}}$ be the solution of (2.7) such that $\int_\Omega \mathbf{U}_{\mathbf{h}} dx = \mathbf{0}$. For convenience we introduce the notation

$$\mathbf{D}^{1,2}(\mathbb{R}^3, \text{div}, \Omega) = \left\{ \mathbf{A} \in \mathbf{D}^{1,2}(\mathbb{R}^3) : \text{div } \mathbf{A} = 0 \text{ in } \mathbb{R}^3, \quad \int_\Omega \mathbf{A} dx = \mathbf{0} \right\}.$$

Therefore $\mathbf{F}_{\mathbf{h}}, \mathbf{U}_{\mathbf{h}} \in \mathbf{D}^{1,2}(\mathbb{R}^3, \text{div}, \Omega)$. We define

$$\lambda(\mathbf{h}) = \frac{\sqrt{2}a(\mathbf{h})}{\sqrt{|\Omega|}} \|\text{curl } \mathbf{U}_{\mathbf{h}}\|_{L^2(\mathbb{R}^3)}. \tag{2.8}$$

To define $a^*(\lambda)$ and $C(\lambda)$, we need to introduce the following functional for given constants $\lambda > 0$ and $\rho \geqslant 0$:

$$J_\rho[w, \mathbf{A}] = \lambda^2 \int_{\mathbb{R}^3} |\text{curl } \mathbf{A} - \mathbf{h}|^2 dx + \rho \int_\Omega |\nabla w - \mathbf{A}|^2 dx, \quad (w, \mathbf{A}) \in Y, \tag{2.9}$$

where

$$Y = \left\{ (w,\mathbf{A}) : w \in W^{1,2}(\Omega,\mathbb{C}), \int_\Omega w \mathrm{d}x = 0;\ \mathbf{A} - \mathbf{F_h} \in \mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div},\Omega) \right\}. \tag{2.10}$$

Let

$$\widetilde{Y} := \{(w,\widetilde{\mathbf{A}}) : \widetilde{\mathbf{A}} = \mathbf{A} - \mathbf{F_h}, (w,\mathbf{A}) \in Y\}.$$

We observe that $\widetilde{Y}$ is a Hilbert space with norm

$$\|(w,\widetilde{\mathbf{A}})\|_{\widetilde{Y}} := (\|w\|^2_{W^{1,2}(\Omega,\mathbb{C})} + \|\widetilde{\mathbf{A}}\|^2_{1,2})^{1/2}.$$

In what follows, we write

$$(w_n,\mathbf{A}_n) \to (w^*,\mathbf{A}^*) \quad \text{in } Y$$

if and only if $(w_n - w^*, \mathbf{A}_n - \mathbf{A}^*)$ converges to $(0,\mathbf{0})$ in the Hilbert space $\widetilde{Y}$.

It was shown in Ref. 3 (Sec. III) that, for any $\rho > 0$, the following problem has a unique solution $(w^\rho,\mathbf{A}^\rho) \in Y$:

$$\begin{gathered} \Delta w = 0 \quad \text{in } \Omega; \\ \lambda^2 \operatorname{curl}^2 \mathbf{A} = \rho(\nabla w - \mathbf{A})\chi_\Omega \quad \text{in } \mathbb{R}^3; \\ \frac{\partial w}{\partial \nu} = \mathbf{A}\cdot\nu \quad \text{on } \partial\Omega, \\ \mathbf{A} - \mathbf{F_h} \in \mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div}), \end{gathered} \tag{2.11}$$

and it is the unique global minimizer of $J_\rho[w,\mathbf{A}]$ over the set Y defined previously [note that any solution of (2.11) in Y necessarily has w real valued; therefore the result in Ref. 3, which is stated for real-valued w only, applies to our more general setting here.] When $\rho=0$, clearly the global minimum of J_0 is achieved by $(w,\mathbf{F_h})$ with $w \in W^{1,2}(\Omega,\mathbb{C})$ arbitrary. However, $(w_\mathbf{h},\mathbf{F_h})$ is the unique solution of (2.11) in Y when $\rho=0$. We define, for $\rho=0$, $(w^0,\mathbf{A}^0)=(w_\mathbf{h},\mathbf{F_h})$. It is easily seen that

$$(w^\rho,\mathbf{A}^\rho) \to (w^0,\mathbf{A}^0) \quad \text{as } \rho \to 0.$$

For given $a>0$, the solutions $\rho \in [0,1]$ of

$$a^2 \int_\Omega |\nabla w^\rho - \mathbf{A}^\rho|^2 \mathrm{d}x + \rho = 1 \tag{2.12}$$

will be useful in proving our main results of this paper. Write

$$f(a,\rho) = a^2 \int_\Omega |\nabla w^\rho - \mathbf{A}^\rho|^2 \mathrm{d}x + \rho. \tag{2.13}$$

It is proved in Ref. 3 (Sec. III) that f is C^2 for $a>0$ and $\rho>0$, and

$$\frac{\partial f}{\partial \rho}(a,0^+) = 1 - \left(\frac{a}{a(\mathbf{h})}\right)^2 \left(\frac{\lambda(\mathbf{h})}{\lambda}\right)^2, \quad \frac{\partial^2 f}{\partial \rho^2}(a,\rho) > 0. \tag{2.14}$$

Clearly for $a>0$,

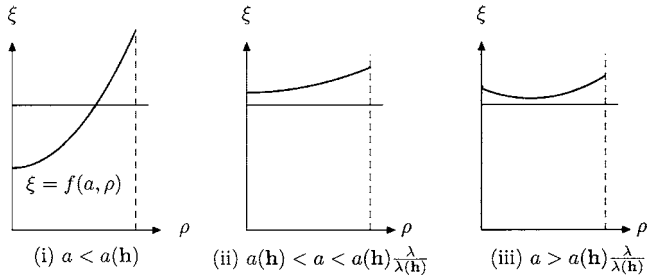

FIG. 2. Graph of $f(a,\rho)$ with $\lambda>\lambda(\mathbf{h})$.

$$f(a,0)=\left(\frac{a}{a(\mathbf{h})}\right)^2, \quad f(a,1)>1. \tag{2.15}$$

Using (2.14) and (2.15), the following result was proved in Ref. 3, Lemma 3.5.

Lemma 2.2: Suppose $0<\lambda<\lambda(\mathbf{h})$. *Then the following conclusions hold.*

(i) *There exists a constant* $C(\lambda)>a(\mathbf{h})$ *such that (2.12) has no solution if* $a>C(\lambda)$; *it has a unique solution* $\rho_0\in(0,1)$ *if* $a=C(\lambda)$.

(ii) *If* $0<a<C(\lambda)$, *(2.12) has a maximal solution* $\rho(a)\in(0,1)$, *and*

$$\lim_{a\to 0^+}\rho(a)=1, \qquad \lim_{a\to C(\lambda)^-}\rho(a)=\rho_0.$$

(iii) *If* $a(\mathbf{h})\leqslant a<C(\lambda)$, *(2.12) has exactly one more solution* $\rho_*(a)$,

$$0<\rho_*(a)<\rho(a) \quad \text{for all } a\in(a(\mathbf{h}),C(\lambda)),$$

$$\rho_*(a(\mathbf{h}))=0, \qquad \lim_{a\to C(\lambda)^-}\rho_*(a)=\rho_0.$$

(iv) *If* $0<a<a(\mathbf{h})$, $\rho(a)$ *is the only solution of (2.12).*

The results of Lemma 3.5 in Ref. 3 also discuss the case $\lambda>\lambda(\mathbf{h})$. Since this part is not used in this paper, we will not recall its full details, but only illustrate it in Fig. 2 above, which provides an interesting comparison to the conclusions in Lemma 2.2 (illustrated by Fig. 3).

Let

$$I(a)=\int_0^{\rho(a)}[f(a,\rho)-1]\mathrm{d}\rho. \tag{2.16}$$

Lemma 2.3: Suppose $0<\lambda<\lambda(\mathbf{h})$. *Then* $I(a)$ *is continuous and strictly increasing for* $a\in(0,C(\lambda))$, *and there exists a unique* $a^*=a^*(\lambda)\in(a(\mathbf{h}),C(\lambda))$ *such that* $I(a^*)=0$.

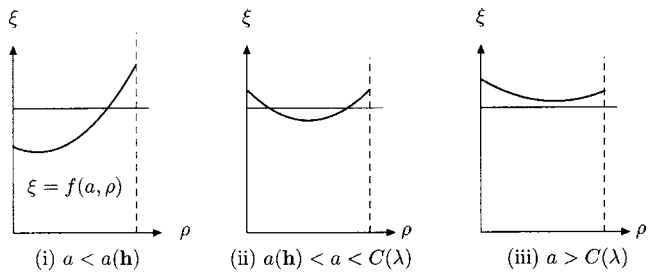

FIG. 3. Graph of $f(a,\rho)$ with $0<\lambda<\lambda(\mathbf{h})$.

Proof: Note that $\rho_*(a)$ and $\rho(a)$ also depend on λ but we regard $\lambda \in (0, \lambda(\mathbf{h}))$ as fixed in the following analysis. Since

$$\frac{\partial f}{\partial a}(a,\rho) > 0, \quad \frac{\partial f}{\partial \rho}(a,\rho_*(a)) < 0, \quad \frac{\partial f}{\partial \rho}(a,\rho(a)) > 0,$$

we apply the implicit function theorem to the solutions $\rho=\rho_*(a)$ and $\rho=\rho(a)$ of the equation

$$f(a,\rho) = 1 \tag{2.17}$$

to find that $\rho_*(a)$ and $\rho(a)$ are C^2 functions for $a \in (a(\mathbf{h}), C(\lambda))$ and $(0, C(\lambda))$, respectively, and

$$\rho_*{}'(a) > 0 \quad \text{for } a(\mathbf{h}) \leqslant a < C(\lambda), \quad \rho'(a) < 0 \quad \text{for } 0 < a < C(\lambda).$$

Note that $I(a)$ is a continuously differentiable function of $a \in (0, C(\lambda))$, and

$$I'(a) = \int_0^{\rho(a)} \frac{\partial f}{\partial a}(a,\rho)\mathrm{d}\rho > 0.$$

When $0<\lambda<\lambda(\mathbf{h})$, it follows from (2.13) (see also Ref. 3, proof of Lemma 3.5) that

$$f(a(\mathbf{h}),0) = f(a(\mathbf{h}),\rho(a(\mathbf{h})) = 1, \quad \text{and } f(a(\mathbf{h}),\rho) < 1 \quad \text{for all} \quad 0 < \rho < \rho(a(\mathbf{h})).$$

Hence $I(a(\mathbf{h}))<0$. On the other hand, we have (see Ref. 3, proof of Lemma 3.5)

$$f(C(\lambda),\rho) > 1 \quad \text{for all } 0 \leqslant \rho < \rho_0,$$

where ρ_0 is the positive number given in Lemma 2.2. So $I(C(\lambda))>0$. Since $I(a)$ is continuous and strictly increasing, there exists a unique $a^*=a^*(\lambda) \in (a(\mathbf{h}), C(\lambda))$ such that $I(a^*)=0$. □

Let us define

$$F(a,\rho) = \frac{|\Omega|}{2}(1-\rho)^2 + a^2 J_\rho[w^\rho, \mathbf{A}^\rho], \tag{2.18}$$

where $(w^\rho, \mathbf{A}^\rho)$ is the unique solution of (2.11) in Y. By Remark 3.8 of Ref. 3,

$$\frac{\partial F}{\partial \rho}(a,\rho) = |\Omega|(f(a,\rho) - 1),$$

where $f(a,\rho)$ is the function given in (2.13). Therefore, for fixed $a \in (a(\mathbf{h}), C(\lambda))$, $F(a,\rho)$ is strictly increasing for $\rho \in (0, \rho_*(a))$, strictly decreasing for $\rho \in (\rho_*(a), \rho(a))$, and strictly increasing for $\rho > \rho(a)$. Hence $\rho_*(a)$ is a local maximizer of $F(a,\cdot)$ and $\rho(a)$ is a local minimizer of $F(a,\cdot)$. By a similar consideration, for fixed $a \in (0, a(\mathbf{h})]$, $\rho(a)$ is a local minimizer of $F(a,\cdot)$. This fact is a key element in our study.

From the previous equality (2.16) and the fact $F(a,0)=|\Omega|/2$, we have

$$F(a,\rho(a)) - F(a,0) = |\Omega| I(a). \tag{2.19}$$

It follows that $F(a,\rho(a))-F(a,0)$ is a strictly increasing function of a in $[0, C(\lambda)]$ and has a unique zero at $a=a^*(\lambda)$.

III. ELLIPTIC ESTIMATES OF CRITICAL POINTS

We first introduce the spaces in which minimizers of $\mathcal{G}_\sigma$ are sought. Let $W^{1,2}(\Omega, \mathbb{C})$ be the Sobolev space of all complex-valued functions defined on Ω, and let

$$\mathcal{W}(\Omega) = \{(\psi, \mathbf{A}) : \psi \in W^{1,2}(\Omega, \mathbb{C}), \mathbf{A} - \mathbf{F}_\mathbf{h} \in \mathbf{D}^{1,2}(\mathbb{R}^3)\}.$$

Our minimization problem for $\mathcal{G}_\sigma[\psi, \mathbf{A}]$ is

$$\inf_{(\psi,\mathbf{A})\in\mathcal{W}(\Omega)} \mathcal{G}_\sigma[\psi,\mathbf{A}]. \tag{3.1}$$

It is standard to show that (3.1) is always achieved by a minimizer $(\psi,\mathbf{A})$ which satisfies (in the weak sense)

$$\begin{gathered} -\nabla_{\sigma\mathbf{A}}^2\psi=\frac{\kappa^2}{\lambda^2}(1-|\psi|^2)\psi \quad \text{in } \Omega,\\ \operatorname{curl}^2\mathbf{A}=\frac{1}{\lambda^2\sigma}\operatorname{Im}(\bar{\psi}\nabla_{\sigma\mathbf{A}}\psi)\chi_\Omega \quad \text{in } \mathbb{R}^3,\\ (\nabla_{\sigma\mathbf{A}}\psi)\cdot\nu=0 \quad \text{on } \partial\Omega,\\ (\psi,\mathbf{A})\in\mathcal{W}(\Omega), \end{gathered} \tag{3.2}$$

where ν denotes the unit outward normal of $\partial\Omega$ and χ_Ω is the characteristic function of Ω. To be more precise, by a weak solution to (3.2) we mean a pair $(w,\mathbf{A})\in\mathcal{W}(\Omega)$ satisfying

$$\int_\Omega \nabla_{\sigma\mathbf{A}}\psi\cdot\overline{\nabla_{\sigma\mathbf{A}}\phi}\,dx=\frac{\kappa^2}{\lambda^2}\int_\Omega(1-|\psi|^2)\psi\bar{\phi}\,dx, \quad \text{for all } \phi\in W^{1,2}(\Omega,\mathbb{C}),$$

$$\int_{\mathbb{R}^3}\operatorname{curl}(\mathbf{A}-\mathbf{F_h})\cdot\operatorname{curl}\mathbf{B}\,dx=\frac{1}{\lambda^2\sigma}\int_\Omega\operatorname{Im}(\bar{\psi}\nabla_{\sigma\mathbf{A}}\psi)\cdot\mathbf{B}\,dx, \quad \text{for all } \mathbf{B}\in\mathbf{C}_0^\infty(\mathbb{R}^3,\mathbb{R}^3).$$

It is well known that $\mathcal{G}_\sigma$ is invariant under the gauge transformation

$$(\psi,\mathbf{A})\to(\tilde{\psi},\tilde{\mathbf{A}}),$$

where $\tilde{\psi}=\psi e^{i\sigma\eta}$, $\tilde{\mathbf{A}}=\mathbf{A}-\sigma\nabla\eta$, and where η is an arbitrary smooth and real-valued function. By replacing $\mathbf{A}$ by $\mathbf{A}+\nabla\eta$, where $\eta=\eta_0-x\cdot(\int_\Omega\mathbf{A}dx)$, and η_0 is the unique solution of

$$-\Delta\eta_0=\operatorname{div}\mathbf{A}\in L^2(\mathbb{R}^3), \quad \eta_0\in W^{1,2}(\mathbb{R}^3),$$

we may require that

$$\operatorname{div}\mathbf{A}=0 \quad \text{and} \quad \int_\Omega\mathbf{A}dx=\mathbf{0}$$

in (3.1). Let

$$\mathcal{W}_0(\Omega,\operatorname{div})=\left\{(\psi,\mathbf{A})\in\mathcal{W}(\Omega):\operatorname{div}\mathbf{A}=0 \text{ in } \mathbb{R}^3,\int_\Omega\mathbf{A}dx=0\right\}.$$

Then (3.1) is equivalent to

$$\inf_{(\psi,\mathbf{A})\in\mathcal{W}_0(\Omega,\operatorname{div})}\mathcal{G}_\sigma[\psi,\mathbf{A}]. \tag{3.3}$$

Lemma 3.1: If $(\psi,\mathbf{A})\in\mathcal{W}_0(\Omega,\operatorname{div})$ *is a weak solution to* (3.2), *then there exists a constant vector* $\mathbf{v}\in\mathbb{R}^3$ *such that* $\mathbf{A}-\mathbf{F_h}-\mathbf{v}\in W^{1,2}(\mathbb{R}^3,\mathbb{R}^3)$.

Proof: Let $\mathbf{f}$ denote the right-hand side of the second equation in (3.2). Then $\mathbf{f}\in L^{3/2}(\mathbb{R}^3)$ and, due to the facts

$$\operatorname{div} \mathbf{A} = \operatorname{div} \mathbf{F_h} = 0, \quad \operatorname{curl}^2 \mathbf{F_h} = \mathbf{0},$$

the second equation in (3.2) can be written as

$$-\Delta(\mathbf{A} - \mathbf{F_h}) = \mathbf{f} \text{ in } \mathbb{R}^3.$$

It is well-known that the problem

$$-\Delta \mathbf{V} = \mathbf{f} \text{ in } \mathbb{R}^3, \quad \mathbf{V} \in W^{2,3/2}(\mathbb{R}^3, \mathbb{R}^3)$$

has a unique solution $\mathbf{V_f}$. Let $\mathbf{v} = (\mathbf{A} - \mathbf{F_h}) - \mathbf{V_f}$. Then $\mathbf{v}$ is a harmonic vector-valued function on $\mathbb{R}^3$ with $|\nabla \mathbf{v}| \in L^2(\mathbb{R}^3)$. It follows that $\mathbf{v}$ is a constant vector. By the Sobolev imbedding theorem we find $\mathbf{A} - \mathbf{F_h} - \mathbf{v} = \mathbf{V_f} \in W^{1,2}(\mathbb{R}^3, \mathbb{R}^3)$. □

Now we give some estimates for the critical points of $\mathcal{G}_\sigma$, which will be used in later sections for $\kappa = \lambda\varepsilon$, where λ is fixed and $\varepsilon > 0$ is small. Similar estimates have already been established for global minimizers, see Ref. 3 (Lemma 3.3) and Ref. 26 (Proposition 4.2 in two-dimensional case).

Lemma 3.2: Let $(\psi, \mathbf{A})$ *be a critical point of* $\mathcal{G}_\sigma$ *in* $\mathcal{W}_0(\Omega, \operatorname{div})$. *Then there exist positive constants* C_0 *and* $C(\lambda, \kappa/\lambda)$, *with* C_0 *depending only on* Ω *and* $\mathbf{h}$, *and* $C(\lambda, \kappa/\lambda)$ *depending only on* Ω, $\mathbf{h}$, λ *and upper bound of* κ/λ, *such that*

(i) $\|\nabla_{\sigma\mathbf{A}}\psi\|_{L^2(\Omega)} \leq \kappa/\lambda \|\psi\|_{L^2(\Omega)}$;

(ii) $\|\nabla_{\sigma\mathbf{A}}\psi\|_{L^\infty(\Omega)} \leq C(\lambda, \kappa/\lambda)(1 + \sqrt{\sigma})\|\psi\|_{L^\infty(\Omega)}$;

(iii) $\|\nabla(\mathbf{A} - \mathbf{F_h})\|_{L^2(\mathbb{R}^3)} \leq C_0 \kappa/\lambda^3 \sigma$;

(iv) $\|\mathbf{A} - \mathbf{F_h}\|_{L^2(\Omega)} \leq C_0 \kappa/\lambda^3 \sigma$.

(v) *For any* $0 < \alpha < 1$, $\psi \in C^{2+\alpha}(\bar{\Omega})$, $\mathbf{A} \in C^{1+\alpha}(\bar{\Omega})$, *and for any* $R > 0$ *such that* $\bar{\Omega} \subset B_R$, *there exists a positive constant* $C_{\alpha,R}$ *depending only on* Ω, $\mathbf{h}$, α *and* R, *such that, for* $q = 3/(1 - \alpha)$,

$$\|\nabla(\mathbf{A} - \mathbf{F_h})\|_{C^\alpha(B_R)} \leq C_{\alpha,R}\left\{\frac{\kappa}{\lambda^3\sigma} + \frac{1}{\lambda^2\sigma}\|\bar{\psi}\nabla_{\sigma\mathbf{A}}\psi\|_{L^q(\Omega)}\right\}. \tag{3.4}$$

Proof: It is well known (see Ref. 9) that $|\psi(x)| \leq 1$ in Ω. Multiplying the first equation in (3.2) by $\bar{\psi}$ and integrating over Ω yields

$$\int_\Omega |\nabla_{\sigma A}\psi|^2 dx = \frac{\kappa^2}{\lambda^2}\int_\Omega (1 - |\psi|^2)|\psi|^2 dx \leq \frac{\kappa^2}{\lambda^2}\int_\Omega |\psi|^2 dx,$$

which gives (i).

To prove (iii), we use Lemma 3.1 to find a constant vector $\mathbf{v}$ such that

$$\mathbf{V} := \mathbf{A} - \mathbf{F_h} - \mathbf{v} \in W^{1,2}(\mathbb{R}^3, \mathbb{R}^3).$$

In particular, $\mathbf{A} - \mathbf{F_h} \in W^{1,2}(\Omega, \mathbb{R}^3)$. Let

$$\mathbf{f} = \frac{1}{\lambda^2\sigma}\operatorname{Im}(\bar{\psi}\nabla_{\sigma\mathbf{A}}\psi)\chi_\Omega.$$

The weak formulation of the second equation in (3.2) gives

$$\int_{\mathbb{R}^3} \operatorname{curl}(\mathbf{A} - \mathbf{F_h}) \cdot \operatorname{curl} \mathbf{B} dx = \int_\Omega \mathbf{f} \cdot \mathbf{B} dx,$$

for all $\mathbf{B} \in C_0^\infty(\mathbb{R}^3, \mathbb{R}^3)$. Since $\mathbf{V} \in W^{1,2}(\mathbb{R}^3, \mathbb{R}^3)$, we can choose $\mathbf{B}_j \in C_0^\infty(\mathbb{R}^3, \mathbb{R}^3)$ such that

$$\|\mathbf{B}_j - \mathbf{V}\|_{W^{1,2}(\mathbb{R}^3,\mathbb{R}^3)} \to 0 \quad \text{as } j \to \infty.$$

It follows that

$$\int_{\mathbb{R}^3} |\text{curl}(\mathbf{A} - \mathbf{F_h})|^2 \mathrm{d}x = \int_\Omega \mathbf{f} \cdot \mathbf{V} \mathrm{d}x.$$

Therefore, for an arbitrary positive constant δ_0 we have

$$\int_{\mathbb{R}^3} |\text{curl}(\mathbf{A} - \mathbf{F_h})|^2 \mathrm{d}x \leqslant \frac{1}{\delta_0} \int_\Omega |\mathbf{f}|^2 \mathrm{d}x + \delta_0 \int_\Omega |\mathbf{V}|^2 \mathrm{d}x.$$

Since $\mathbf{V} \in W^{1,2}(\mathbb{R}^3, \mathbb{R}^3)$, using Hölder's inequality and the Sobolev inequality we deduce

$$\int_\Omega |\mathbf{V}|^2 \mathrm{d}x \leqslant |\Omega|^{2/3} \|\mathbf{V}\|^2_{L^6(\Omega)} \leqslant |\Omega|^{2/3} \|\mathbf{V}\|^2_{L^6(\mathbb{R}^3)} \leqslant C_1 \| \nabla \mathbf{V}\|^2_{L^2(\mathbb{R}^3)} = C_1 \int_{\mathbb{R}^3} |\text{curl}(\mathbf{A} - \mathbf{F_h})|^2 \mathrm{d}x.$$

Hence

$$\int_{\mathbb{R}^3} |\text{curl}(\mathbf{A} - \mathbf{F_h})|^2 \mathrm{d}x \leqslant \frac{1}{\delta_0} \int_\Omega |\mathbf{f}|^2 \mathrm{d}x + C_1 \delta_0 \int_{\mathbb{R}^3} |\text{curl}(\mathbf{A} - \mathbf{F_h})|^2 \mathrm{d}x.$$

Choose $\delta_0 = 1/(2C_1)$, we find

$$\int_{\mathbb{R}^3} | \nabla (\mathbf{A} - \mathbf{F_h})|^2 \mathrm{d}x = \int_{\mathbb{R}^3} |\text{curl}(\mathbf{A} - \mathbf{F_h})|^2 \mathrm{d}x \leqslant 4C_1 \int_\Omega |\mathbf{f}|^2 \mathrm{d}x.$$

In view of (i), we find (iii) is true.

Since $\int_\Omega (\mathbf{A} - \mathbf{F_h}) \mathrm{d}x = \mathbf{0}$, we can apply Poincarè inequality to obtain (iv) from (iii) (replacing C_0 by a larger constant if necessary).

(v) was essentially proved in Ref. 3 (Lemma 3.3). In fact, it was proved in Ref. 3 that, for $\Omega \subset B_r \subset B_R$,

$$\| \nabla (\mathbf{A} - \mathbf{F_h})\|_{C^\alpha(B_r)} \leqslant C(r, R, \alpha) \{ \|\text{curl}(\mathbf{A} - \mathbf{F_h})\|_{L^2(\mathbb{R}^3)} + \|\mathbf{f}\|_{L^q(B_R)} \}.$$

Using this, (i) and (iii) we get (v) immediately.

To prove (ii), we first use (iv) and apply the L^∞ estimate of elliptic equations to prove the conclusion for bounded σ, then apply the blow-up argument used in Ref. 26 (Proposition 4.2) to prove the conclusion for large σ. □

IV. LOCAL MINIMIZERS

Throughout this section we assume $\kappa = \lambda\varepsilon$ and $\sigma = a\varepsilon$, where $\lambda > 0$ and $a > 0$ are fixed, and ε is small. If $0 < a < a(\mathbf{h})$, then by the theory in Ref. 3 [see (2.5) previously displayed], besides the trivial critical point $(0, \mathbf{F_h})$, $\mathcal{G}_{a\varepsilon}$ has a nontrivial global minimizer in $\mathcal{W}_0(\Omega, \text{div})$ for all small $\varepsilon > 0$. In this section, we shall show that if $0 < \lambda < \lambda(\mathbf{h})$, then for each $a \in [a(\mathbf{h}), C(\lambda))$, the functional $\mathcal{G}_{a\varepsilon}$ also has a nontrivial local minimizer when $\varepsilon > 0$ is small. If $a \in (a^*(\lambda), C(\lambda))$, then $\mathcal{G}_{a\varepsilon}$ has a third (unstable) critical point (see Remark 4.4 and Lemma 5.1). We will further give a description of the way of the change of the local minimality and uniqueness, up to an additive constant vector in the vector potential, of the trivial solution $(0, \mathbf{F_h})$, when a changes. The results presented in this Section will be crucial in Sec. VI.

Let us recall from Sec. II that if we fix $\lambda \in (0, \lambda(\mathbf{h}))$, then (2.12) has exactly one positive solution $\rho(a)$ if $0 < a < a(\mathbf{h})$, and has exactly two nonnegative solutions $\rho_*(a) < \rho(a)$ if $a(\mathbf{h}) \leqslant a < C(\lambda)$. For convenience of presentation, we extend the definition of $\rho_*(a)$ and $\rho(a)$ by letting

$$\rho_*(a) = 0 \quad \text{if } 0 < a \leqslant a(\mathbf{h}), \quad \rho(0) = 1;$$
$$\rho_*(C(\lambda)) = \rho(C(\lambda)) = \rho_0, \tag{4.1}$$

where $\rho_0 \in (0,1)$ is the number given in Lemma 2.2. Then $\rho_*(a)$ is continuous on $[0, C(\lambda)]$ and is C^2 and strictly increasing in $(a(\mathbf{h}), C(\lambda))$, and $\rho(a)$ is continuous on $[0, C(\lambda)]$ and is C^2 and strictly decreasing in $(0, C(\lambda))$.

In the following we assume

$$0 < \lambda < \lambda(\mathbf{h}), \quad \kappa = \lambda\varepsilon, \quad \sigma = a\varepsilon, \tag{4.2}$$

where λ is fixed, $\varepsilon > 0$ is small and $a > 0$. We look for a local minimizer of $\mathcal{G}_{a\varepsilon}$ with ψ of the form

$$\psi = \rho^{1/2}(1 + ia\varepsilon w), \tag{4.3}$$

where $0 < \rho \leqslant 1$, $w \in W^{1,2}(\Omega, \mathbb{C})$. Let us define

$$g_{a,\varepsilon}[\rho, w, \mathbf{A}] = \frac{1}{\varepsilon^2}\mathcal{G}_{a\varepsilon}[\rho^{1/2}(1 + ia\varepsilon w), \mathbf{A}], \tag{4.4}$$

and let

$$Y_R = \{(w, \mathbf{A}) \in Y : \|(w, \mathbf{A} - \mathbf{F_h})\|_{\tilde{Y}} < R\},$$

$$\partial Y_R = \{(w, \mathbf{A}) \in Y : \|(w, \mathbf{A} - \mathbf{F_h})\|_{\tilde{Y}} = R\}.$$

Lemma 4.1: We have

$$g_{a,\varepsilon}[\rho, w, \mathbf{A}] = \frac{|\Omega|}{2}(1 - \rho)^2 + a^2 J_\rho[w, \mathbf{A}] + O(\varepsilon), \tag{4.5}$$

where the error term $O(\varepsilon)$ has the following property: For any given $R > 0$, there exists a constant $M(R) > 0$ such that

$$|O(\varepsilon)| \leqslant M(R)\varepsilon \quad \textit{for all } a \in [0, R], \quad \rho \in [0,1], \quad (w, \mathbf{A}) \in Y_R. \tag{4.6}$$

Proof: The conclusion is proved by a direct calculation. In fact for ψ given in (4.3), $\kappa = \lambda\varepsilon$ and $\sigma = a\varepsilon$ we have

$$|\nabla_{a\varepsilon\mathbf{A}}\psi|^2 = a^2\rho\varepsilon^2\{|\nabla w - \mathbf{A}|^2 - 2a\varepsilon\mathfrak{I}(\bar{w}\mathbf{A}(\nabla w - \mathbf{A})) + a^2\varepsilon^2|w\mathbf{A}|^2\},$$

$$\frac{1}{2}(1 - |\psi|^2)^2 = \frac{(1-\rho)^2}{2} + a\rho(1-\rho)\varepsilon[2\mathfrak{I}(w) - a\varepsilon|w|^2] + \frac{a^2\rho^2\varepsilon^2}{2}[2\mathfrak{I}(w) - a\varepsilon|w|^2]^2.$$

So we have

$$\begin{aligned}\frac{1}{\varepsilon^2}\mathcal{G}_{a\varepsilon}[\psi, \mathbf{A}] &= \frac{|\Omega|}{2}(1-\rho)^2 + a^2 J_\rho[w, \mathbf{A}] - 2a\rho\varepsilon\int_\Omega \{a^2\mathfrak{I}(\bar{w}\mathbf{A}(\nabla w - \mathbf{A})) - (1-\rho)\mathfrak{I}(w)\}\mathrm{d}x \\ &\quad + a^2\rho\varepsilon^2\int_\Omega \left\{a^2|w\mathbf{A}|^2 - (1-\rho)|w|^2 + \frac{\rho}{2}[2\mathfrak{I}(w) - a\varepsilon|w|^2]^2\right\}\mathrm{d}x \\ &= \frac{|\Omega|}{2}(1-\rho)^2 + a^2 J_\rho[w, \mathbf{A}] + \varepsilon q_a[\rho, w, \mathbf{A}],\end{aligned}$$

where

$$q_a[\rho,w,\mathbf{A}] = -2a\rho\int_\Omega \{a^2\mathfrak{I}(\bar{w}\mathbf{A}(\nabla w-\mathbf{A}))-(1-\rho)\mathfrak{I}(w)\}\mathrm{d}x$$
$$+a^2\rho\varepsilon\int_\Omega\left\{a^2|w\mathbf{A}|^2-(1-\rho)|w|^2+\frac{\rho}{2}[2\mathfrak{I}(w)-a\varepsilon|w|^2]^2\right\}\mathrm{d}x.$$

Using the Sobolev imbedding theorems and Hölder's inequality we can easily show that

$$M(R)=\sup_{a\in[0,R],\rho\in[0,1],(w,\mathbf{A})\in Y_R}|q_a[\rho,w,\mathbf{A}]|<\infty. \tag{4.7}$$

Hence the conclusion is true. □

Let us introduce the notation

$$I_{a,\varepsilon_0}=(\rho(a)-\varepsilon_0,\rho(a)+\varepsilon_0). \tag{4.8}$$

Lemma 4.2: Assume (4.2) *holds and let* $g_{a,\varepsilon}[\rho,w,\mathbf{A}]$ *be defined by* (4.4). *Given a small constant* $\delta>0$ *and a large constant* $R_0>0$, *there exist positive constants* $R>R_0$, ε_0, *and* ε^*, *all depending on* δ *and* R_0, *such that for each* $\varepsilon\in(0,\varepsilon^*)$ *and each* $a\in[\delta,C(\lambda)-\delta]$, *the infimum*

$$\inf_{I_{a,\varepsilon_0}\times Y_R} g_{a,\varepsilon}[\rho,w,\mathbf{A}]$$

is achieved by some $(\rho_\varepsilon^a,w_\varepsilon^a,\mathbf{A}_\varepsilon^a)\in I_{a,\varepsilon_0}\times Y_R$. *Moreover we have*

$$\lim_{\varepsilon\to0^+}\rho_\varepsilon^a=\rho(a)\quad\text{and}\quad\lim_{\varepsilon\to0^+}\|(w_\varepsilon^a-w^{\rho(a)},\mathbf{A}_\varepsilon^a-\mathbf{A}^{\rho(a)})\|_{\tilde{Y}}=0, \tag{4.9}$$

and they hold uniformly for $a\in[\delta,C(\lambda)-\delta]$.

Proof: It follows from Lemma 2.2 that given a small number $\delta>0$, we can find $\varepsilon_0>0$ depending on δ such that

$$\rho(a)-\varepsilon_0>\rho_*(a)\quad\text{and}\quad\rho(a)+\varepsilon_0<1\quad\text{for all } a\in[\delta,C(\lambda)-\delta].$$

By the properties of $F(a,\rho)$, we can find $\delta_0>0$ such that

$$F(a,\rho(a))+\delta_0\leqslant\min\{F(a,\rho(a)-\varepsilon_0),F(a,\rho(a)+\varepsilon_0)\},\quad\text{for all } a\in[\delta,C(\lambda)-\delta]. \tag{4.10}$$

We now divide our proof into several steps.

Step 1: There exist $\varepsilon_1>0$ *and* $R>R_0$ *such that if* $a\in[\delta,C(\lambda)-\delta]$ *and* $\varepsilon\in(0,\varepsilon_1)$ *are fixed, then for each* $\rho\in[\rho(a)-\varepsilon_0,\rho(a)+\varepsilon_0]$, *the functional* $g_{a,\varepsilon}[\rho,\cdot,\cdot]$ *has a minimizer* $(w_\varepsilon^\rho,\mathbf{A}_\varepsilon^\rho)$ *in* Y_R, *namely*

$$g_{a,\varepsilon}[\rho,w_\varepsilon^\rho,\mathbf{A}_\varepsilon^\rho]=\min_{(w,\mathbf{A})\in Y_R}g_{a,\varepsilon}[\rho,w,\mathbf{A}].$$

We easily see from the definition (2.9) for $J_\rho[w,\mathbf{A}]$ that for a fixed $\rho\in\bar{I}_{a,\varepsilon_0}=[\rho(a)-\varepsilon_0,\rho(a)+\varepsilon_0]$,

$$J_\rho[w,\mathbf{A}]\geqslant J_{\rho(a)-\varepsilon_0}[w,\mathbf{A}]\to\infty\quad\text{as }\|(w,\mathbf{A}-\mathbf{F_h})\|_{\tilde{Y}}\to\infty.$$

On the other hand, for the given $\delta>0$, we have

$$\sup_{a\in[\delta,C(\lambda)-\delta],\rho\in\bar{I}_{a,\varepsilon_0}}F(a,\rho)<\infty.$$

Therefore, we can find $R>R_0$ large enough so that whenever $(w,\mathbf{A})\in Y$ satisfies $\|(w,\mathbf{A}-\mathbf{F_h})\|_{\tilde{Y}}\geqslant R$, we have

$$a^2 J_\rho[w,\mathbf{A}] > \sup_{\rho\in I_{a,\varepsilon_0}} F(a,\rho)+1 \quad \text{for all a} \in [\delta, C(\lambda)-\delta].$$

We may assume that

$$R > 1 + \max_{\rho\in[0,1]} \|(w^\rho, \mathbf{A}^\rho - \mathbf{F_h})\|_{\tilde{Y}}.$$

For this R, we choose $\varepsilon_1 > 0$ small enough so that $O(\varepsilon)$ in (4.5) satisfies

$$|O(\varepsilon)| \leqslant 1/2 \quad \text{for all a} \in [0,R], \quad \rho \in [0,1], \quad \varepsilon \in (0,\varepsilon_1), \quad (w,\mathbf{A}) \in Y_R.$$

Then for any fixed $a \in [\delta, C(\lambda)-\delta]$, $\varepsilon \in (0,\varepsilon_1)$, and $\rho \in [\rho(a)-\varepsilon_0, \rho(a)+\varepsilon_0]$, we have

$$g_{a,\varepsilon}[\rho,w,\mathbf{A}] > \sup_{\rho\in I_{a,\varepsilon_0}} F(a,\rho)+1 > g_{a,\varepsilon}[\rho,w^\rho,\mathbf{A}^\rho] \quad \text{for all } (w,\mathbf{A}) \in \partial Y_R, \tag{4.11}$$

and

$$g_{a,\varepsilon}[\rho,w,\mathbf{A}] > F(a,\rho) - \frac{1}{2} \quad \text{for all } (w,\mathbf{A}) \in Y_R. \tag{4.12}$$

From (4.12) we know that for a, ρ, and ε as chosen previously,

$$\inf_{(w,\mathbf{A})\in Y_R} g_{a,\varepsilon}[\rho,w,\mathbf{A}] \geqslant F(a,\rho) - \frac{1}{2}$$

and hence it is finite. Let $(w_n,\mathbf{A}_n)$ be a minimizing sequence of $g_{a,\varepsilon}[\rho,\cdot,\cdot]$ on Y_R, namely:

$$g_{a,\varepsilon}[\rho,w_n,\mathbf{A}_n] \to \inf_{(w,\mathbf{A})\in Y_R} g_{a,\varepsilon}[\rho,w,\mathbf{A}],$$

and let

$$\psi_n = \rho^{1/2}(1 + ia\varepsilon w_n).$$

Since $\|\mathbf{A}_n - \mathbf{F_h}\|_{\mathbf{D}^{1,2}(\mathbb{R}^3)} \leqslant R$, we may assume that

$$\operatorname{curl} \mathbf{A}_n - \mathbf{h} \to \mathbf{B}_0.$$

weakly in $L^2(\mathbb{R}^3)$ as $n\to\infty$. On the other hand, using the condition $\int_\Omega \mathbf{A}_n dx = \mathbf{0}$ and the Sobolev imbedding theorems on bounded sets, and a standard diagonal argument, and passing to a subsequence if necessary, we may assume that $\mathbf{A}_n$ converges strongly in $L^4(B_r)$ and weakly in $W^{1,2}(B_r,\mathbb{R}^3)$ to some $\mathbf{A}_0$ for all balls $B_r \subset \mathbb{R}^3$. It follows that $\mathbf{B}_0 = \operatorname{curl} \mathbf{A}_0 - \mathbf{h}$ and $\int_\Omega \mathbf{A}_0 dx = \mathbf{0}$. Thus

$$\operatorname{curl} \mathbf{A}_n - \mathbf{h} \to \operatorname{curl} \mathbf{A}_0 - \mathbf{h}$$

weakly in $L^2(\mathbb{R}^3)$ as $n\to\infty$.

Since $\{\psi_n\}$ is bounded in $W^{1,2}(\Omega,\mathbb{C})$, we can apply the Sobolev imbedding theorems to conclude that after passing to a subsequence, $\phi_n \to \phi_0$ weakly in $W^{1,2}(\Omega,\mathbb{C})$ and strongly in $L^4(\Omega)$ as $n\to\infty$, and $\psi_0 = \rho^{1/2}(1+ia\varepsilon w_0)$. It now follows easily that

$$\mathcal{G}_{a\varepsilon}[\psi_0,\mathbf{A}_0] \leqslant \lim_{n\to\infty} \mathcal{G}_{a\varepsilon}[\psi_n,\mathbf{A}_n],$$

and hence

$$g_{a,\varepsilon}[\rho,w_0,\mathbf{A}_0] \leqslant g_{a,\varepsilon}[\rho,w_n,\mathbf{A}_n] = \inf_{(w,\mathbf{A})\in Y_{R_0}} g_{a,\varepsilon}[\rho,w,\mathbf{A}].$$

Clearly we have $(w_0,\mathbf{A}_0) \in \bar{Y}_{R_0}$. From (4.11), $(w_0,\mathbf{A}_0) \in Y_{R_0}$. Therefore we have

$$g_{a,\varepsilon}[\rho, w_0, \mathbf{A}_0] = \inf_{(w,\mathbf{A}) \in Y_{R_0}} g_{a,\varepsilon}[\rho, w, \mathbf{A}].$$

Letting $(w_\varepsilon^\rho, \mathbf{A}_\varepsilon^\rho) = (w_0, \mathbf{A}_0)$, the conclusion in step 1 is proved.

Step 2: We have

$$\lim_{\varepsilon \to 0^+} \|(w_\varepsilon^\rho, \mathbf{A}_\varepsilon^\rho) - (w^\rho, \mathbf{A}^\rho)\|_{\tilde{Y}} = 0,$$

and it holds uniformly for $a \in [\delta, C(\lambda) - \delta]$ *and* $\rho \in \bar{I}_{a,\varepsilon_0}$.

We first prove the convergence for fixed a and ρ. Let ε_n be a sequence converging to 0, and we may assume that each ε_n is small enough so that there is a minimizer $(w_{\varepsilon_n}^\rho, \mathbf{A}_{\varepsilon_n}^\rho)$ as given in step 1. To simplify the notations we let $(w_n, \mathbf{A}_n)$ denote this minimizer. Clearly it suffices to show that there exists a subsequence, still denoted by $(w_n, \mathbf{A}_n)$, such that $\|(w_n, \mathbf{A}_n) - (w^\rho, \mathbf{A}^\rho)\|_{\tilde{Y}} \to 0$ as $n \to \infty$.

By (4.5), we see that $(w_n, \mathbf{A}_n)$ is also a minimizing sequence of $J_\rho[w, \mathbf{A}]$ over Y_R. Then a similar argument as used in step 1 shows that after passing to a subsequence,

$$\operatorname{curl} \mathbf{A}_n - \mathbf{h} \to \operatorname{curl} \mathbf{A}_0 - \mathbf{h} \quad \text{weakly in } L^2(\mathbb{R}^3),$$

$$\mathbf{A}_n \to \mathbf{A}_0 \quad \text{strongly in } L^4(\Omega),$$

$$w_n \to w_0 \quad \text{weakly in } W^{1,2}(\Omega, \mathbb{C}) \text{ and strongly in } L^4(\Omega).$$

It is then standard to obtain

$$J_\rho[w_0, \mathbf{A}_0] \leqslant \lim_{n \to \infty} J_\rho[w_n, \mathbf{A}_n] = \inf_{Y_R} J_\rho[w, \mathbf{A}].$$

Since $(w_0, \mathbf{A}_0) \in \bar{Y}_R$, we necessarily have

$$J_\rho[w_0, \mathbf{A}_0] = \inf_{Y_R} J_\rho[w, \mathbf{A}] = \lim_{n \to \infty} J_\rho[w_n, \mathbf{A}_n]. \tag{4.13}$$

As we know from Sec. II that $(w^\rho, \mathbf{A}^\rho)$ is the unique global minimizer of J_ρ, and by our choice of R, $(w^\rho, \mathbf{A}^\rho) \in Y_R$, so we must have $(w_0, \mathbf{A}_0) = (w^\rho, \mathbf{A}^\rho)$. From (4.13), we find

$$\lim_{n \to \infty} J_\rho[w_n, \mathbf{A}_n] = J_\rho[w^\rho, \mathbf{A}^\rho].$$

It follows that

$$\lim_{n \to \infty} \int_{\mathbb{R}^3} |\operatorname{curl} \mathbf{A}_n - \mathbf{h}|^2 \mathrm{d}x = \int_{\mathbb{R}^3} |\operatorname{curl} \mathbf{A}^\rho - \mathbf{h}|^2 \mathrm{d}x, \tag{4.14}$$

and

$$\lim_{n \to \infty} \int_\Omega |\nabla w_n - \mathbf{A}_n|^2 \mathrm{d}x = \int_\Omega |\nabla w^\rho - \mathbf{A}^\rho|^2 \mathrm{d}x. \tag{4.15}$$

The limit in (4.14) implies that $\operatorname{curl} \mathbf{A}_n - \operatorname{curl} \mathbf{A}_0$ converges to $\mathbf{0}$ strongly in $L^2(\mathbb{R}^3)$. Since $\operatorname{div}(\mathbf{A}_n - \mathbf{A}^\rho) = 0$, we find $\|\mathbf{A}_n - \mathbf{A}^\rho\|_{\mathbf{D}^{1,2}(\mathbb{R}^3)}$ converges to 0. From (4.15) and the fact that ∇w_n converges to ∇w^ρ weakly in $L^2(\Omega)$ and $\mathbf{A}_n - \mathbf{A}^\rho$ converges to $\mathbf{0}$ strongly in $L^2(\Omega)$, we easily deduce

$$\lim_{n\to\infty}\int_\Omega |\nabla w_n|^2 dx = \int_\Omega |\nabla w^\rho|^2 dx.$$

Recalling $\int_\Omega w_n dx = 0$, we deduce $w_n \to w^\rho$ strongly in $W^{1,2}(\Omega)$. This proves the claimed convergence for fixed a and ρ.

To show that the convergence is uniform in a and ρ, we observe that if in the previous argument we replace (a,ρ) by (a_n,ρ_n) with $a_n \to a$ and $\rho_n \to \rho$, then using (4.5) and (4.6) we find that

$$g_{a_n,\varepsilon_n}[\rho_n, w_n, \mathbf{A}_n] = \frac{|\Omega|}{2}(1-\rho_n)^2 + a_n^2 J_{\rho_n}[w_n, \mathbf{A}_n] + o(1) = \frac{|\Omega|}{2}(1-\rho)^2 + a^2 J_\rho[w_n, \mathbf{A}_n] + o(1).$$

Hence $(w_n, \mathbf{A}_n)$ is a minimizing sequence of $J_\rho[w, \mathbf{A}]$ in Y_R, and the proof follows the same line as the previous one. This finishes the proof for step 2.

Step 3: There exists $\varepsilon^* > 0$ such that for each $\varepsilon \in (0, \varepsilon^*)$ and each $a \in [\delta, C(\lambda) - \delta]$,

$$g_{a,\varepsilon}[\rho, w, \mathbf{A}] > g_{a,\varepsilon}[\rho(a), w^{\rho(a)}, \mathbf{A}^{\rho(a)}] \quad \text{for all } (\rho, w, \mathbf{A}) \in \partial(I_{a,\varepsilon_0} \times Y_R). \tag{4.16}$$

By (4.5) and (4.6) we can find $\varepsilon_2 \in (0, \varepsilon_1]$ so that for $a \in [\delta, C(\lambda) - \delta]$, $\varepsilon \in (0, \varepsilon_2)$, and $\rho \in I_{a,\varepsilon_0}$, one has

$$F(a,\rho) - \frac{\delta_0}{3} < g_{a,\varepsilon}[\rho, w^\rho, \mathbf{A}^\rho] < F(a,\rho) + \frac{\delta_0}{3}, \tag{4.17}$$

where δ_0 is given in (4.10). By (4.11), we see that (4.16) holds if $(\rho, w, \mathbf{A}) \in I_{a,\varepsilon_0} \times (\partial Y_R)$ whenever $\varepsilon \in (0, \varepsilon_1)$. Consider now the remaining case $(\rho, w, \mathbf{A}) \in (\partial I_{a,\varepsilon_0}) \times Y_R$. Let ρ^* stand for either $\rho(a) - \varepsilon_0$ or $\rho(a) + \varepsilon_0$. Then for $(w, \mathbf{A}) \in Y_R$,

$$g_{a,\varepsilon}[\rho^*, w, \mathbf{A}] \geqslant g_{a,\varepsilon}[\rho^*, w_\varepsilon^{\rho^*}, \mathbf{A}_\varepsilon^{\rho^*}].$$

By the conclusion in step 2 and (4.5) and (4.6), we have

$$\lim_{\varepsilon \to 0^+} g_{a,\varepsilon}[\rho^*, w_\varepsilon^{\rho^*}, \mathbf{A}_\varepsilon^{\rho^*}] = F(a, \rho^*).$$

Therefore we can find $\varepsilon_3 \in (0, \varepsilon_2]$ such that

$$g_{a,\varepsilon}[\rho^*, w_\varepsilon^{\rho^*}, \mathbf{A}_\varepsilon^{\rho^*}] > F(a,\rho^*) - \frac{\delta_0}{3} \quad \text{for all } \varepsilon \in (0, \varepsilon_3).$$

Therefore,

$$g_{a,\varepsilon}[\rho^*, w, \mathbf{A}] > F(a,\rho^*) - \frac{\delta_0}{3} \quad \text{for all } \varepsilon \in (0, \varepsilon_3), \quad (w, \mathbf{A}) \in Y_R.$$

In view of (4.10) and (4.17), we obtain from the above inequality that for $\varepsilon \in (0, \varepsilon_3)$,

$$g_{a,\varepsilon}[\rho^*, w, \mathbf{A}] > F(a, \rho(a)) + \frac{2\delta_0}{3} > g_{a,\varepsilon}[\rho(a), w^{\rho(a)}, \mathbf{A}^{\rho(a)}] + \frac{\delta_0}{3}.$$

Therefore we can choose $\varepsilon^* = \varepsilon_3$ and the proof for step 3 is complete.

We would like to remark that the conclusion of step 3 also follows from the independent argument in the proof for (4.9) in step 4 below. However, the argument gives a better idea on how ε^* is chosen, and indeed we feel it makes the idea of the entire proof of this lemma more transparent.

Step 4: Completion of the proof.

By (4.12), we know that the infimum

$$\inf_{(\rho,w,\mathbf{A})\in I_{a,\varepsilon_0}\times Y_R} g_{a,\varepsilon}[\rho,w,\mathbf{A}]$$

is finite. Let $(\rho_n,w_n,\mathbf{A}_n)$ be a minimizing sequence. We may assume that $\rho_n\to\rho_\varepsilon$ as $n\to\infty$. Then

$$g_{a,\varepsilon}[\rho_n,w_n,\mathbf{A}_n]=g_{a,\varepsilon}[\rho_\varepsilon,w_n,\mathbf{A}_n]+o(1).$$

Therefore $(w_n,\mathbf{A}_n)$ must be a minimizing sequence of $g_{a,\varepsilon}[\rho_\varepsilon,\cdot,\cdot]$ over Y_R. From the argument in step 1 we know that after passing to a subsequence,

$$\|(w_n,\mathbf{A}_n)-(w_\varepsilon,\mathbf{A}_\varepsilon)\|_{\tilde{Y}}\to 0 \quad \text{as } n\to\infty,$$

where $(w_\varepsilon,\mathbf{A}_\varepsilon)\in Y_R$ and is a minimizer of $g_{a,\varepsilon}[\rho_\varepsilon,\cdot,\cdot]$ in Y_R. It follows that

$$\lim_{n\to\infty} g_{a,\varepsilon}[\rho_n,w_n,\mathbf{A}_n]=g_{a,\varepsilon}[\rho_\varepsilon,w_\varepsilon,\mathbf{A}_\varepsilon].$$

Therefore, $(\rho_\varepsilon,w_\varepsilon,\mathbf{A}_\varepsilon)$ is a minimizer of $g_{a,\varepsilon}$ on $\bar{I}_{a,\varepsilon_0}\times\bar{Y}_R$. It follows from step 3 that this minimizer does not locate on the boundary of $I_{a,\varepsilon_0}\times Y_R$, and hence is a local minimizer of $g_{a,\varepsilon}$ on $I_{a,\varepsilon_0}\times Y_R$.

It remains to prove (4.9). We first prove (4.9) for a fixed a. Let ε_n be a sequence converging to 0 and let $(\rho_n,w_n,\mathbf{A}_n)$ denote $(\rho_{\varepsilon_n},w_{\varepsilon_n},\mathbf{A}_{\varepsilon_n})$. We may assume that $\rho_n\to\rho$ as $n\to\infty$. Using (4.5) and (4.6), we obtain

$$g_{a,\varepsilon_n}[\rho_n,w_n,\mathbf{A}_n]=\frac{|\Omega|}{2}(1-\rho)^2+a^2J_\rho[w_n,\mathbf{A}_n]+o(1). \tag{4.18}$$

Therefore, $(w_n,\mathbf{A}_n)$ is a minimizing sequence of $J_\rho[w,\mathbf{A}]$ over Y_R. Now the argument in the proof of step 2 shows that

$$\|(w_n,\mathbf{A}_n)-(w^\rho,\mathbf{A}^\rho)\|_{\tilde{Y}}\to 0 \quad \text{as } n\to\infty.$$

It follows from (4.18) that

$$\lim_{n\to\infty} g_{a,\varepsilon_n}[\rho_n,w_n,\mathbf{A}_n]=F(a,\rho).$$

Note that $\rho\in\bar{I}_{a,\varepsilon_0}$. If $\rho\neq\rho(a)$, we have $F(a,\rho)>F(a,\rho(a))$; and by (4.5) and (4.6),

$$\lim_{n\to\infty} g_{a,\varepsilon_n}[\rho(a),w^{\rho(a)},\mathbf{A}^{\rho(a)}]=F(a,\rho(a))<F(a,\rho).$$

Hence for all large n,

$$g_{a,\varepsilon_n}[\rho_n,w_n,\mathbf{A}_n]>g_{a,\varepsilon_n}[\rho(a),w^{\rho(a)},\mathbf{A}^{\rho(a)}].$$

But this inequality contradicts the assumption that $(\rho_n,w_n,\mathbf{A}_n)$ is a minimizer of g_{a,ε_n} over $I_{a,\varepsilon_0}\times Y_R$. Therefore we must have $\rho=\rho(a)$. It follows that the entire original sequence $(\rho_n,w_n,\mathbf{A}_n)$ converges to $(\rho(a),w^{\rho(a)},\mathbf{A}^{\rho(a)})$ in the obvious sense.

Finally we can apply the argument used in step 2 to show that (4.9) holds uniformly in a. The details are omitted. □

Let us define

$$Z_{a,\varepsilon}=\{(\psi,\mathbf{A}):\psi=z(1+ia\varepsilon w),\quad z\in\mathbb{C},\quad |z|^2\in I_{a,\varepsilon_0},\quad (w,\mathbf{A})\in Y_R\}.$$

Now we can state the main result in this section.

Proposition 4.3: Under assumption (4.2), *for any small* $\delta>0$ *and large* $R_0>0$, *there exist* $R>R_0$, $\varepsilon_0>0$, *and* $\varepsilon^*>0$ *such that, for each* $a\in[\delta,C(\lambda)-\delta]$ *and* $\varepsilon\in(0,\varepsilon^*)$, *the functional* $\mathcal{G}_{a\varepsilon}$ *has a nontrivial local minimizer* $(\psi_\varepsilon^a,\mathbf{A}_\varepsilon^a)$, *and*

$$\mathcal{G}_{a\varepsilon}[\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a] = \inf_{(\psi,\mathbf{A})\in Z_{a,\varepsilon}} \mathcal{G}_{a\varepsilon}[\psi, \mathbf{A}].$$

Moreover, we have

(i) $\psi_\varepsilon^a = \sqrt{\rho_\varepsilon^a}(1 + ia\varepsilon w_\varepsilon^a)$, *where* $(\rho_\varepsilon^a, w_\varepsilon^a, \mathbf{A}_\varepsilon^a) \in I_{a,\varepsilon_0} \times Y_R$;
(ii) $\lim_{\varepsilon\to 0} \rho_\varepsilon^a = \rho(a)$, $\lim_{\varepsilon\to 0} \|(w_\varepsilon^a, \mathbf{A}_\varepsilon^a) - (w^{\rho(a)}, \mathbf{A}^{\rho(a)})\|_{\tilde{Y}} = 0$ *uniformly in* $a \in [\delta, C(\lambda) - \delta]$.

Proof: Note that the set

$$\{(\psi, \tilde{\mathbf{A}}) : \tilde{\mathbf{A}} = \mathbf{A} - \mathbf{F_h}, \quad (\psi, \mathbf{A}) \in Z_{a,\varepsilon}\}$$

is an open set in the space $W^{1,2}(\Omega, \mathbb{C}) \times \mathbf{D}^{1,2}(\mathbb{R}^3, \mathrm{div}, \Omega)$ with $(\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a - \mathbf{F_h})$ lying in its interior, or speaking loosely, $Z_{a,\varepsilon}$ is an open set in $\mathcal{W}_0(\Omega, \mathrm{div})$ containing $(\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a)$. Also note that

$$\mathcal{G}_\sigma[\psi, \mathbf{A}] = \mathcal{G}_\sigma[z\psi, \mathbf{A}] \quad \text{for all } z \in \mathbb{C} \text{ with } |z| = 1.$$

Thus $(\psi, \mathbf{A}) \in Z_{a,\varepsilon}$ is a local minimizer of $\mathcal{G}_{a\varepsilon}$ with $\psi = \sqrt{\rho}(1 + ia\varepsilon w)$ if and only if $(\rho, w, \mathbf{A})$ is a local minimizer of $g_{a,\varepsilon}$. Therefore Proposition 4.3 follows directly from Lemma 4.2. □

Remark 4.4: From Lemma 4.2 and Proposition 4.3 we find that, under assumption (4.2) we have:

(i) *for any fixed* $a \in (0, C(\lambda))$, *there exists a constant* $\varepsilon_a > 0$ *such that* $\mathcal{G}_{a\varepsilon}$ *has a nontrivial local minimizer* $(\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a)$ *for all* $0 < \varepsilon < \varepsilon_a$.
(ii) *if* $a \in (a^*(\lambda), C(\lambda))$ *is fixed, then for all small* $\varepsilon > 0$, *the energy functional* $\mathcal{G}_{a\varepsilon}(\psi, \mathbf{A})$ *has two local minima:* $(0, \mathbf{F_h})$ *and* $(\psi_\varepsilon, \mathbf{A}_\varepsilon)$. *It is possible to use the well-known mountain pass theorem to show that, in this case,* $\mathcal{G}_{a\varepsilon}$ *has a third critical point* $(\psi_\varepsilon^*, \mathbf{A}_\varepsilon^*)$; *and if we write*

$$\psi_\varepsilon^* = \alpha_\varepsilon^*(1 + ia\varepsilon w_\varepsilon^*),$$

where

$$\alpha_* = \fint_\Omega \psi_\varepsilon^* dx,$$

then as $\varepsilon \to 0$,

$$|\alpha_\varepsilon^*|^2 \to \rho_*(a), \quad \|(w_\varepsilon^*, \mathbf{A}_\varepsilon^*) - (w^{\rho_*(a)}, \mathbf{A}^{\rho_*(a)})\|_{\tilde{Y}} \to 0.$$

We will discuss this point further in the next section (see Lemma 5.1).

We next examine the change of local minimality and uniqueness, up to an additive constant vector in the vector potential, of $(0, \mathbf{F_h})$ as a varies. To this end, we need an estimate of the lowest eigenvalue $\mu(\varepsilon\mathbf{A})$ for small ε which holds uniformly in $\mathbf{A}$, where $\mu(\mathbf{A})$ denotes the lowest eigenvalue of the problem

$$-\nabla_{\mathbf{A}}^2 \phi = \mu\phi \quad \text{in } \Omega, \quad (\nabla_{\mathbf{A}}\phi) \cdot \nu = 0 \quad \text{on } \partial\Omega. \tag{4.19}$$

The following estimate is an extension of Lemma 2.1.

Lemma 4.5. Suppose that $\{\mathbf{A}_n\}$ *is a sequence of vector fields in* $W^{1,2}(\Omega, \mathbb{R}^3)$ *such that*

$$\mathrm{div}\, \mathbf{A}_n = 0, \quad \int_\Omega \mathbf{A}_n dx = \mathbf{0}, \quad \lim_{n\to\infty} \|\mathbf{A}_n - \mathbf{F_h}\|_{W^{1,2}(\Omega,\mathbb{R}^3)} = 0.$$

Then for any positive sequence $\varepsilon_n \to 0$, *we have*

$$\lim_{n\to\infty} \frac{\mu(\varepsilon_n \mathbf{A}_n)}{\varepsilon_n^2} = \omega(\mathbf{h}), \tag{4.20}$$

where $\mu(\varepsilon_n \mathbf{A}_n)$ *is the lowest eigenvalue of* (4.19) *for* $\mathbf{A}=\varepsilon_n \mathbf{A}_n$.

Proof: In the proof C denotes a generic constant which varies from line to line but is independent of n. Let $\mu_n=\mu(\varepsilon_n \mathbf{A}_n)$ and let ϕ_n be a corresponding eigenfunction satisfying $\|\phi_n\|_{W^{1,2}(\Omega,\mathbb{C})}=1$. Let

$$\psi_n = 1 + i\varepsilon_n w_{\mathbf{h}},$$

where $w_{\mathbf{h}}$ is the function given in Sec. II that achieves $\omega(\mathbf{h})$. Using the variational characterization of $\mu(\varepsilon_n \mathbf{A}_n)$, we obtain

$$\frac{\mu_n}{\varepsilon_n^2} \leqslant \frac{\int_\Omega |\nabla_{\varepsilon_n \mathbf{A}_n} \psi_n|^2 \mathrm{d}x}{\varepsilon_n^2 \int_\Omega |\psi_n|^2 \mathrm{d}x} = \frac{\int_\Omega (|\nabla w_{\mathbf{h}} - \mathbf{A}_n|^2 + \varepsilon_n^2 |w_{\mathbf{h}} \mathbf{A}_n|^2)\mathrm{d}x}{\int_\Omega (1+\varepsilon_n^2 |w_{\mathbf{h}}|^2)\mathrm{d}x} \to \omega(\mathbf{h})$$

as $n \to \infty$. Therefore, after passing to a subsequence, we have $\mu_n=\lambda_n \varepsilon_n^2$ with $\lambda_n \to \lambda_0 \in [0, \omega(\mathbf{h})]$.

Since $\operatorname{div} \mathbf{A}_n=0$, the equation for ϕ_n can be written in the form

$$\begin{aligned} -\Delta \phi_n &= \mu_n \phi_n - 2i\varepsilon_n \mathbf{A}_n \cdot \nabla \phi_n - \varepsilon_n^2 |\mathbf{A}_n|^2 \phi_n \quad \text{in } \Omega, \\ \frac{\partial \phi_n}{\partial \nu} &= i\varepsilon_n \phi_n \mathbf{A}_n \cdot \nu \quad \text{on } \partial\Omega. \end{aligned} \tag{4.21}$$

Applying the Agmon–Douglis–Nirenberg L^p theory for elliptic equations (see Ref. 27, Theorem 15.2) to (4.21) we have, for $1<p<\infty$,

$$\|\phi_n\|_{W^{2,p}(\Omega,\mathbb{C})} \leqslant C_1 (\|f_n\|_{L^p(\Omega)} + \|\eta_n\|_{W^{1/2,p}(\partial\Omega)} + \|\phi_n\|_{L^p(\Omega)}), \tag{4.22}$$

where C_1 depends only on Ω,

$$f_n = \mu_n \phi_n - 2i\varepsilon_n \mathbf{A}_n \cdot \nabla \phi_n - \varepsilon_n^2 |\mathbf{A}_n|^2 \phi_n,$$

$$\eta_n = i\varepsilon_n \phi_n \mathbf{A}_n \cdot \nu,$$

and $\|\cdot\|_{W^{1/2,p}(\partial\Omega)}$ is the trace norm defined by

$$\|\eta\|_{W^{1/2,p}(\partial\Omega)} = \inf_{\phi \in W^{1,2}(\Omega), \gamma(\phi)=\eta} \|\phi\|_{W^{1,p}(\Omega)},$$

where γ is the trace operator. Since $\|\mathbf{A}_n\|_{W^{1,2}(\Omega,\mathbb{R}^3)}$ is bounded and $\int_\Omega \mathbf{A}_n \mathrm{d}x=\mathbf{0}$, we deduce from the standard Sobolev imbedding theorems that $\{\mathbf{A}_n\}$ is bounded in $L^6(\Omega)$. Similarly, since $\{\phi_n\}$ is bounded in $W^{1,2}(\Omega,\mathbb{C})$, it is bounded in $L^6(\Omega)$. Using Hölder's inequality we find

$$\|f_n\|_{L^{3/2}(\Omega)} \leqslant C, \quad \|\eta_n\|_{W^{1/2,3/2}(\partial\Omega)} \leqslant C. \tag{4.23}$$

To obtain the second inequality in (4.23) note that

$$\|\eta_n\|_{W^{1/2,3/2}(\partial\Omega)} \leqslant C\varepsilon_n \|\phi_n \mathbf{A}_n\|_{W^{1,3/2}(\Omega,\mathbb{R}^3)},$$

and

$$\begin{aligned} \|\nabla(\phi_n \mathbf{A}_n)\|_{L^{3/2}(\Omega)} &\leqslant \|\phi_n \nabla \mathbf{A}_n\|_{L^{3/2}(\Omega)} + \|\mathbf{A}_n \nabla \phi_n\|_{L^{3/2}(\Omega)} \\ &\leqslant \|\phi_n\|_{L^6(\Omega)} \|\nabla \mathbf{A}_n\|_{L^2(\Omega)} + \|\mathbf{A}_n\|_{L^6(\Omega)} \|\nabla \phi_n\|_{L^2(\Omega)}. \end{aligned}$$

Recall that $\|\phi_n\|_{W^{1,2}(\Omega,\mathbb{C})}=1$. From (4.22) and (4.23) we have

$$\|\phi_n\|_{W^{2,3/2}(\Omega,\mathbb{C})} \leqslant C.$$

This implies, by the Sobolev imbedding theorems again, that $\{\phi_n\}$ is precompact in $W^{1,2}(\Omega,\mathbb{C})$. Hence, after passing to a subsequence, we may assume that

$$\phi_n \to \phi_0 \quad \text{in } W^{1,2}(\Omega,\mathbb{C}) \text{ as } n \to \infty,$$

and $\|\phi_0\|_{W^{1,2}(\Omega,\mathbb{C})}=1$. Using this and (4.21), we find that ϕ_0 satisfies the following equation:

$$-\Delta\phi_0 = 0 \quad \text{in } \Omega, \quad \frac{\partial\phi_0}{\partial\nu} = 0 \quad \text{on } \partial\Omega.$$

It follows that ϕ_0 is a constant c_0, and $|c_0|$ is uniquely determined by $\|\phi_0\|_{W^{1,2}(\Omega,\mathbb{C})}=1$. Without loss of generality we may assume that c_0 is a positive number.

Now we define

$$\alpha_n = \int_\Omega \phi_n \mathrm{d}x, \quad \tilde{\phi}_n = \frac{\phi_n - \alpha_n}{\varepsilon_n}.$$

From (4.21) we obtain the equation for $\tilde{\phi}_n$:

$$\begin{aligned} -\Delta\tilde{\phi}_n &= \varepsilon_n\lambda_n\phi_n - 2i\mathbf{A}_n\cdot\nabla\phi_n - \varepsilon_n|\mathbf{A}_n|^2\phi_n \quad \text{in } \Omega, \\ \frac{\partial\tilde{\phi}_n}{\partial\nu} &= i\phi_n\mathbf{A}_n\cdot\nu \quad \text{on } \partial\Omega. \end{aligned} \tag{4.24}$$

Let

$$\tilde{f}_n = \varepsilon_n\lambda_n\phi_n - 2i\mathbf{A}_n\cdot\nabla\phi_n - \varepsilon_n|\mathbf{A}_n|^2\phi_n,$$

$$\tilde{\eta}_n = i\phi_n\mathbf{A}_n\cdot\nu.$$

Since $\int_\Omega\tilde{\phi}_n\mathrm{d}x=0$, the L^p theory for elliptic equations[27,28] applied to (4.24) implies

$$\|\tilde{\phi}_n\|_{W^{2,3/2}(\Omega,\mathbb{C})} \leqslant C_2(\|\tilde{f}_n\|_{L^2(\Omega)} + \|\tilde{\eta}_n\|_{W^{1/2,3/2}(\partial\Omega)}), \tag{4.25}$$

where C_2 depends only on Ω. Similar to (4.23) we have

$$\|\tilde{f}_n\|_{L^{3/2}(\Omega)} \leqslant C, \quad \|\tilde{\eta}_n\|_{W^{1/2,3/2}(\partial\Omega)} \leqslant C.$$

Thus we have

$$\|\tilde{\phi}_n\|_{W^{2,3/2}(\Omega,\mathbb{C})} \leqslant C.$$

In particular, $\{\tilde{\phi}_n\}$ is precompact in $W^{1,2}(\Omega,\mathbb{C})$. After passing to a subsequence again, we may assume $\tilde{\phi}_n \to \tilde{\phi}_0$ in $W^{1,2}(\Omega,\mathbb{C})$ as $n\to\infty$, and then find from (4.24),

$$-\Delta\tilde{\phi}_0 = 0 \quad \text{in } \Omega, \quad \frac{\partial\tilde{\phi}_0}{\partial\nu} = ic_0\mathbf{F}_\mathbf{h}\cdot\nu \quad \text{on } \partial\Omega.$$

Comparing this with (2.2) we see that $\tilde{\phi}_0/(ic_0)$ satisfies the same equation as $w_\mathbf{h}$. Moreover, since $\int_\Omega\tilde{\phi}_n\mathrm{d}x=0$, we have $\int_\Omega\tilde{\phi}_0\mathrm{d}x=0$. It follows from the uniqueness of $w_\mathbf{h}$ that $\tilde{\phi}_0=ic_0w_\mathbf{h}$, i.e.,

$$\tilde{\phi}_n \to ic_0w_\mathbf{h} \quad \text{in } W^{1,2}(\Omega,\mathbb{C}) \text{ as } n\to\infty.$$

Let us now write

$$\tilde{\phi}_n = i\beta_n w_{\mathbf{h}} + \varepsilon\hat{\phi}_n, \quad \beta_n = -\frac{i\int_\Omega w_{\mathbf{h}}\tilde{\phi}_n \mathrm{d}x}{\int_\Omega |w_{\mathbf{h}}|^2 \mathrm{d}x}.$$

We easily see that $\beta_n \to c_0$ as $n \to \infty$. Moreover, from (4.24) we find that $\hat{\phi}_n$ satisfies

$$\begin{aligned} -\Delta\hat{\phi}_n &= \lambda_n\phi_n - 2i\mathbf{A}_n\cdot\nabla\tilde{\phi}_n - |\mathbf{A}_n|^2\phi_n \quad \text{in } \Omega, \\ \frac{\partial\hat{\phi}_n}{\partial\nu} &= i\tilde{\phi}_n\mathbf{A}_n\cdot\nu + i\varepsilon_n^{-1}[\alpha_n\mathbf{A}_n - \beta_n\mathbf{F}_{\mathbf{h}}]\cdot\nu \quad \text{on } \partial\Omega. \end{aligned} \tag{4.26}$$

Integrating the first equation of (4.26) over Ω, we obtain

$$\lambda_n\int_\Omega \phi_n \mathrm{d}x = \int_\Omega (|\mathbf{A}_n|^2\phi_n + 2i\mathbf{A}_n\cdot\nabla\tilde{\phi}_n - \Delta\hat{\phi}_n)\mathrm{d}x.$$

Since

$$\int_{\partial\Omega}\mathbf{A}_n\cdot\nu \mathrm{d}S = \int_\Omega \operatorname{div}\mathbf{A}_n \mathrm{d}x = 0$$

and

$$\int_{\partial\Omega}\mathbf{F}_{\mathbf{h}}\cdot\nu \mathrm{d}s = \int_\Omega \operatorname{div}\mathbf{F}_{\mathbf{h}}\mathrm{d}x = 0,$$

from the second equality in (4.26) we have

$$\int_\Omega \Delta\hat{\phi}_n \mathrm{d}x = \int_{\partial\Omega}\frac{\partial\hat{\phi}_n}{\partial\nu}\mathrm{d}S = \int_{\partial\Omega} i\tilde{\phi}_n\mathbf{A}_n\cdot\nu \mathrm{d}S + i\varepsilon_n^{-1}\int_{\partial\Omega}[\alpha_n\mathbf{A}_n\cdot\nu - \beta_n\mathbf{F}_{\mathbf{h}}\cdot\nu]\mathrm{d}S = \int_{\partial\Omega} i\tilde{\phi}_n\mathbf{A}_n\cdot\nu \mathrm{d}S.$$

Since $\mathbf{A}_n \to \mathbf{F}_{\mathbf{h}}$ in $W^{1,2}(\Omega,\mathbb{R}^3)$ and $\tilde{\phi}_n \to ic_0 w_{\mathbf{h}}$ as $n\to\infty$, we deduce

$$\int_\Omega \mathbf{A}_n\cdot\nabla\tilde{\phi}_n \mathrm{d}x \to ic_0\int_\Omega \mathbf{F}_{\mathbf{h}}\cdot\nabla w_{\mathbf{h}}\mathrm{d}x = ic_0\int_{\partial\Omega} w_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}\cdot\nu \mathrm{d}S = ic_0\int_{\partial\Omega} w_{\mathbf{h}}\frac{\partial w_{\mathbf{h}}}{\partial\nu}\mathrm{d}S = ic_0\int_\Omega |w_{\mathbf{h}}|^2\mathrm{d}x,$$

$$\int_{\partial\Omega} i\tilde{\phi}_n\mathbf{A}_n\cdot\nu \mathrm{d}S \to -\int_{\partial\Omega} c_0 w_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}\cdot\nu \mathrm{d}S = -c_0\int_\Omega |w_{\mathbf{h}}|^2\mathrm{d}x,$$

$$\int_\Omega |\mathbf{A}_n|^2\phi_n \mathrm{d}x \to \int_\Omega |\mathbf{F}_{\mathbf{h}}|^2 c_0 \mathrm{d}x.$$

We thus obtain

$$\lambda_0 c_0|\Omega| = \lim_{n\to\infty}\lambda_n\int_\Omega \phi_n \mathrm{d}x = c_0\int_\Omega (|\mathbf{F}_{\mathbf{h}}|^2 - |\nabla w_{\mathbf{h}}|^2)\mathrm{d}x = c_0\int_\Omega |\nabla w_{\mathbf{h}} - \mathbf{F}_{\mathbf{h}}|^2\mathrm{d}x = c_0\omega(\mathbf{h})|\Omega|.$$

Therefore,

$$\lambda_0 = \omega(\mathbf{h}).$$

This completes the proof. □

Now we fix a small $\varepsilon > 0$, and examine the minimality of $(0, \mathbf{F_h})$ when a changes. Note that, for any constant vector $\mathbf{c}$, $(0, \mathbf{F_h} + \mathbf{c})$ is a critical point of $\mathcal{G}_{a\varepsilon}$. In the following we consider the uniqueness of local minimizers in the space $\mathcal{W}_0(\Omega, \mathrm{div})$, in which the vector component is normalized so that the integral average over Ω is zero. Let

$$W_r := \{(\psi, \mathbf{A}) \in \mathcal{W}_0(\Omega, \mathrm{div}) : \|\psi\|_{W^{1,2}(R^3,\mathbb{C})} < r, \quad \|\mathbf{A} - \mathbf{F_h}\|_{\mathbf{D}^{1,2}(\mathbb{R}^3)} < r\}. \tag{4.27}$$

Proposition 4.6: Under assumption (4.2), for any small $\delta > 0$, there exist $\varepsilon_* > 0$, $r > 0$, and $L > 0$ such that, for every $\varepsilon \in (0, \varepsilon_*)$ being fixed,

(i) *if $a \in (0, a(\mathbf{h}) - \delta]$, then $(0, \mathbf{F_h})$ is not a local minimizer of $\mathcal{G}_{a\varepsilon}$ in $\mathcal{W}_0(\Omega, \mathrm{div})$;*
(ii) *if $a(\mathbf{h}) + \delta \leqslant a \leqslant L$, then $(0, \mathbf{F_h})$ is a local minimizer of $\mathcal{G}_{a\varepsilon}$ in $\mathcal{W}_0(\Omega, \mathrm{div})$, and it is the only critical point in W_r;*
(iii) *if $a \geqslant L$, then $(0, \mathbf{F_h})$ is the only critical point of $\mathcal{G}_{a\varepsilon}$ in $\mathcal{W}_0(\Omega, \mathrm{div})$, and hence it is the global minimizer.*

Proof: Conclusion (i) has been proved in Ref. 3. In fact, for $0 < a < a(\mathbf{h}) - \delta$, let $\phi_{a\varepsilon}$ be an eigenfunction associated with the lowest eigenvalue $\mu(a\varepsilon \mathbf{F_h})$. For small $\varepsilon > 0$, we can use (2.4) to show that for all small $t > 0$,

$$\mathcal{G}_{a\varepsilon}[t\phi_{a\varepsilon}, \mathbf{F_h}] < \frac{\varepsilon^2}{2}|\Omega| = \mathcal{G}_{a\varepsilon}[0, \mathbf{F_h}].$$

Conclusion (iii) is a consequence of Theorem 4.1 in Ref. 12. In fact it follows from Ref. 12 that there exists $L > 0$ such that, if $a \geqslant L$, then the only critical points are the normal solutions $(0, \mathbf{F_h} + \mathbf{c})$, where $\mathbf{c}$ is a constant vector. Since $(0, \mathbf{F_h} + \mathbf{c}) \in \mathcal{W}_0(\Omega, \mathrm{div})$ we must have $\mathbf{c} = \mathbf{0}$. (Note that the scaling we use in the present paper is different to that used in Ref. 12.)

To prove conclusion (ii) we use Lemma 4.5 to find $\varepsilon_1 > 0$ and $r_1 > 0$ small so that the lowest eigenvalue $\mu(a\varepsilon \mathbf{A})$ of (4.19) for $a\varepsilon \mathbf{A}$ satisfies

$$\mu(a\varepsilon \mathbf{A}) > \left(\frac{a(\mathbf{h})}{a(\mathbf{h}) + \delta/2}\right)^2 \omega(\mathbf{h}) a^2 \varepsilon^2 = \left(\frac{a\varepsilon}{a(\mathbf{h}) + \delta/2}\right)^2 \tag{4.28}$$

whenever $a\varepsilon \in (0, \varepsilon_1)$ and $\|\mathbf{A} - \mathbf{F_h}\|_{W^{1,2}(\Omega,\mathbb{R}^3)} < r_1$. Since $\int_\Omega \mathbf{A} \mathrm{d}x = \int_\Omega \mathbf{F_h} \mathrm{d}x = \mathbf{0}$, there exists a constant C such that

$$\|\mathbf{A} - \mathbf{F_h}\|_{W^{1,2}(\Omega,\mathbb{R}^3)} \leqslant C\|\mathbf{A} - \mathbf{F_h}\|_{\mathbf{D}^{1,2}(\mathbb{R}^3)}.$$

Therefore, if we choose $r = r_1/C$ and $\varepsilon_* = \varepsilon_1/L$, then for $\varepsilon \in (0, \varepsilon_*)$ and $a \in [a(\mathbf{h}) + \delta, L]$, we have, for any $(\psi, \mathbf{A}) \in W_r$ with $\psi \not\equiv 0$,

$$\mathcal{G}_{a\varepsilon}[\psi, \mathbf{A}] - \mathcal{G}_{a\varepsilon}[0, \mathbf{F_h}] \geqslant \mu(a\varepsilon \mathbf{A}) \int_\Omega |\psi|^2 \mathrm{d}x - \varepsilon^2 \int_\Omega |\psi|^2 \mathrm{d}x \geqslant \varepsilon^2 \left[\left(\frac{a(\mathbf{h}) + \delta}{a(\mathbf{h}) + \delta/2}\right)^2 - 1\right] \int_\Omega |\psi|^2 \mathrm{d}x > 0$$

It follows that $(0, \mathbf{F_h})$ is a local minimizer in W_r.

With ε, r, and a chosen as above, we now suppose that (ψ_0, A_0) is an arbitrary critical point of $\mathcal{G}_{a\varepsilon}$ in W_r. We show that $\psi_0 \equiv 0$. Otherwise, from Lemma 3.2 (i) we have $\mu(a\varepsilon \mathbf{A}_0) \leqslant \varepsilon^2$. However, from (4.28) and the choice of a we have

$$\mu(a\varepsilon \mathbf{A}_0) > \left(\frac{a(\mathbf{h}) + \delta}{a(\mathbf{h}) + \delta/2}\right)^2 \varepsilon^2 > \varepsilon^2.$$

Therefore we necessarily have $\psi_0 = 0$. From (3.2) we find

$$\operatorname{curl}^2 \mathbf{A}_0 = \mathbf{0} \text{ in } \mathbb{R}^3, \quad \mathbf{A}_0 - \mathbf{F_h} \in \mathbf{D}^{1,2}(\mathbb{R}^3, \operatorname{div}, \Omega).$$

Thus $\mathbf{B} \equiv \mathbf{A}_0 - \mathbf{F_h}$ satisfies

$$\Delta \mathbf{B} = \mathbf{0} \text{ in } \mathbb{R}^3, \quad \int_{\mathbb{R}^3} |\nabla \mathbf{B}|^2 dx = 0.$$

Hence $\mathbf{B}$ is a constant vector. Since $\int_\Omega \mathbf{B} dx = \int_\Omega (\mathbf{A}_0 - \mathbf{F_h}) dx = \mathbf{0}$, we have $\mathbf{B} = \mathbf{0}$, namely $\mathbf{A}_0 = \mathbf{F_h}$. This completes the proof. □

V. CLASSIFICATION OF NONTRIVIAL SOLUTIONS

We show in this section that, under assumption (4.2), for all small $\varepsilon > 0$, the nontrivial critical points of $\mathcal{G}_{a\varepsilon}$ can be easily classified according to the value of a. To this end, we let $(\psi_n, \mathbf{A}_n) \in \mathcal{W}_0(\Omega, \operatorname{div})$ be an arbitrary nontrivial critical point of $\mathcal{G}_{a_n \varepsilon_n}$, namely, it is a weak solution of the following system

$$\begin{aligned} &-\nabla^2_{a_n \varepsilon_n \mathbf{A}} \psi = \varepsilon^2 (1 - |\psi|^2)\psi \quad \text{in } \Omega, \\ &\operatorname{curl}^2 \mathbf{A} = \frac{1}{\lambda^2 a_n \varepsilon_n} \operatorname{Im}(\bar{\psi} \nabla_{a_n \varepsilon_n \mathbf{A}} \psi) \chi_\Omega \quad \text{in } \mathbb{R}^3, \\ &(\nabla_{a_n \varepsilon_n \mathbf{A}} \psi) \cdot \nu = 0 \quad \text{on } \partial\Omega, \\ &(\psi, \mathbf{A}) \in \mathcal{W}_0(\Omega, \operatorname{div}), \end{aligned} \tag{5.1}$$

and $\psi \equiv 0$. Due to the gauge invariance, for any complex number z_n with $|z_n| = 1$, $(z_n \psi_n, \mathbf{A}_n)$ is also a critical point. We assume that ψ_n is uniquely chosen from this gauge invariant class so that

$$\alpha_n = \int_\Omega \psi_n dx \geqslant 0. \tag{5.2}$$

Lemma 1.5: Assume $\varepsilon_n \to 0$, $a_n \to a$, *where* $0 < a < \infty$. *Let* $(\psi_n, \mathbf{A}_n) \in \mathcal{W}_0(\Omega, \operatorname{div})$ *be a nontrivial critical point of* $\mathcal{G}_{a_n \varepsilon_n}$ *where* ψ_n *satisfies* (5.2). *Then we necessarily have* $a \leqslant C(\lambda)$. *Moreover,* $\alpha_n > 0$ *for all large* n; *and if we write*

$$\psi_n = \alpha_n (1 + i a_n \varepsilon_n w_n),$$

then the following conclusions hold.

(i) *If* $0 < a < a(\mathbf{h})$, *then, as* $n \to \infty$,

$$\alpha_n \to \rho(a)^{1/2}, \quad \|(w_n, \mathbf{A}_n) - (w^{\rho(a)}, \mathbf{A}^{\rho(a)})\|_{\tilde{Y}} \to 0.$$

(ii) *If* $a(\mathbf{h}) \leqslant a < C(\lambda)$, *then, as* $n \to \infty$, *subject to a subsequence, either*

$$\alpha_n \to \rho(a)^{1/2}, \quad \|(w_n, \mathbf{A}_n) - (w^{\rho(a)}, \mathbf{A}^{\rho(a)})\|_{\tilde{Y}} \to 0,$$

or

$$\alpha_n \to \rho_*(a)^{1/2}, \quad \|(w_n, \mathbf{A}_n) - (w^{\rho_*(a)}, \mathbf{A}^{\rho_*(a)})\|_{\tilde{Y}} \to 0.$$

(iii) *If* $a = C(\lambda)$, *then, as* $n \to \infty$,

$$\alpha_n \to \rho_0^{1/2}, \quad \|(w_n, \mathbf{A}_n) - (w^{\rho_0}, \mathbf{A}^{\rho_0})\|_{\tilde{Y}} \to 0.$$

Proof: In the proof C, C_1, C_2, etc., denote generic positive constants which may be dependent

of Ω, $\mathbf{h}$, and λ but are independent of n. Let $(\psi_n, \mathbf{A}_n) \in \mathcal{W}_0(\Omega, \mathrm{div})$ be a critical point of $\mathcal{G}_{a_n\varepsilon_n}$. From Lemma 3.1, there exists a constant vector $\mathbf{v}_n \in \mathbb{R}^3$ such that

$$\mathbf{B}_n := \mathbf{A}_n - \mathbf{F}_\mathbf{h} - \mathbf{v}_n \in W^{1,2}(\mathbb{R}^3, \mathbb{R}^3).$$

In particular, $\mathbf{A}_n - \mathbf{F}_\mathbf{h} \in W^{1,2}(\Omega, \mathbb{R}^3)$.

Step 1. $\{(\psi_n, \mathbf{A}_n - \mathbf{F}_\mathbf{h})\}$ *is bounded in* $W^{1,2}(\Omega, \mathbb{C}) \times \mathbf{D}^{1,2}(\mathbb{R}^3, \mathrm{div}, \Omega)$.

It is well known (see Ref. 9) that $|\psi_n(x)| \leqslant 1$ in Ω. From Lemma 3.2 (with $\kappa = \lambda\varepsilon$ and $\sigma = a\varepsilon$) we see that

$$\int_\Omega |\nabla_{a_n\varepsilon_n \mathbf{A}_n} \psi_n|^2 \mathrm{d}x \leqslant \varepsilon_n^2 |\Omega|, \quad \| \nabla (\mathbf{A}_n - \mathbf{F}_\mathbf{h}) \|_{L^2(\mathbb{R}^3)} \leqslant C_1. \tag{5.3}$$

In particular

$$\|\mathbf{A}_n\|_{W^{1,2}(\Omega, \mathbb{R}^3)} \leqslant C_2. \tag{5.4}$$

From the first and third equations in (5.1) we see that ψ_n is a weak solution of the following equation

$$-\Delta\psi = 2ia_n\varepsilon_n \mathbf{A}_n \cdot \nabla \psi_n + g_n \text{ in } \Omega, \quad \frac{\partial \psi}{\partial \nu} = h_n \text{ on } \partial\Omega, \tag{5.5}$$

where

$$g_n = a_n^2 \varepsilon_n^2 |\mathbf{A}_n|^2 \psi_n + \varepsilon_n^2 (1 - |\psi_n|^2) \psi_n,$$

$$h_n = ia_n\varepsilon_n (\mathbf{A}_n \cdot \nu) \psi_n.$$

Multiplying (5.5) by $\bar{\psi}_n$, integrating over Ω and using the Sobolev imbedding theorems we find

$$\int_\Omega |\nabla \psi_n|^2 \mathrm{d}x = \int_\Omega \{2ia_n\varepsilon_n \mathbf{A}_n \cdot \nabla \psi_n + g_n\} \bar{\psi}_n \mathrm{d}x + \int_{\partial\Omega} h_n \bar{\psi}_n \mathrm{d}S.$$

From (5.4) and using the fact $\|\psi_n\|_{L^\infty(\Omega)} \leqslant 1$, we have

$$\|g_n\|_{L^2(\Omega)} \leqslant C_3\varepsilon_n^2, \quad \|h_n\|_{L^2(\partial\Omega)} \leqslant C_4\varepsilon_n,$$

$$\left| \int_\Omega 2ia_n\varepsilon_n \mathbf{A}_n \cdot \nabla \psi_n \bar{\psi}_n \mathrm{d}x \right| \leqslant C_5\varepsilon_n \int_\Omega |\mathbf{A}_n| |\nabla \psi_n| \mathrm{d}x \leqslant C_5\varepsilon_n \|\mathbf{A}_n\|_{L^2(\Omega)} \|\nabla \psi_n\|_{L^2(\Omega)}$$
$$\leqslant C_6\varepsilon_n \|\nabla \psi_n\|_{L^2(\Omega)}.$$

From these inequalities we have

$$\|\psi_n\|^2_{W^{1,2}(\Omega,\mathbb{C})} = \int_\Omega |\nabla \psi_n|^2 \mathrm{d}x + \int_\Omega |\psi_n|^2 \mathrm{d}x \leqslant C_7\varepsilon_n \|\psi_n\|_{W^{1,2}(\Omega,\mathbb{C})} + |\Omega|.$$

Hence there exists a constant $C_8 > 0$ such that, for all n,

$$\|\psi_n\|_{W^{1,2}(\Omega,\mathbb{C})} \leqslant C_8.$$

The proof for step 1 is complete.

Step 2: The asymptotic limit of $(\psi_n, \mathbf{A}_n)$.

We now use the equations for ψ_n and $\mathbf{A}_n$ to find their limits as $n \to \infty$. Let

$$\delta_n = \|\psi_n\|_{W^{1,2}(\Omega,\mathbb{C})}, \quad \hat{\psi}_n = \frac{\psi_n}{\delta_n}.$$

From Step 1, we may assume

$$\delta_n \to \delta_0 \geqslant 0, \quad \alpha_n \to \alpha \geqslant 0.$$

We obtain from (5.5) the equation for $\hat{\psi}_n$:

$$\begin{aligned} -\Delta\hat{\psi}_n &= 2ia_n\varepsilon_n\mathbf{A}_n\cdot\nabla\hat{\psi}_n + a_n^2\varepsilon_n^2|\mathbf{A}_n|^2\hat{\psi}_n + \varepsilon_n^2(1-\delta_n^2|\hat{\psi}_n|^2)\hat{\psi}_n \quad \text{in } \Omega, \\ \frac{\partial\hat{\psi}_n}{\partial\nu} &= ia_n\varepsilon_n\hat{\psi}_n\mathbf{A}_n\cdot\nu \quad \text{on } \partial\Omega. \end{aligned} \tag{5.6}$$

From the conclusion obtained in step 1 and the fact $\int_\Omega \mathbf{A}_n \mathrm{d}x = \mathbf{0}$ we see that $\{\mathbf{A}_n\}$ is bounded in $W^{1,2}(\Omega,\mathbb{R}^3)$. Also note that $\|\hat{\psi}_n\|_{W^{1,2}(\Omega,\mathbb{C})}=1$. Thus the right-hand side of the first equation in (5.6) is bounded in $L^{3/2}(\Omega)$, and the right side of the second equation in (5.6) is bounded in $W^{1/2,3/2}(\partial\Omega)$. Therefore the L^p estimate used for (4.21) [see (4.22)] can be applied to (5.6) to conclude that $\{\hat{\psi}_n\}$ is bounded in $W^{2,3/2}(\Omega,\mathbb{C})$. After passing to a subsequence, $\hat{\psi}_n$ converges to some $\hat{\psi}_0$ in $W^{1,2}(\Omega,\mathbb{C})$ and

$$-\Delta\hat{\psi}_0 = 0 \quad \text{in } \Omega, \quad \frac{\partial\hat{\psi}_0}{\partial\nu} = 0 \quad \text{on } \partial\Omega.$$

Therefore $\hat{\psi}_0 \equiv c_0$, a nonzero constant satisfying $\|c_0\|_{W^{1,2}(\Omega,\mathbb{C})}=1$. From (5.2) we deduce

$$c_0 = \lim_{n\to\infty}\frac{\alpha_n}{\delta_n} \geqslant 0.$$

Therefore $c_0 = 1/\sqrt{|\Omega|}$. It follows that for all large n, $\alpha_n > 0$. We assume from now on that $\alpha_n > 0$ for all $n \geqslant 1$. Thus we have

$$\hat{\psi}_n \to c_0 \text{ in } W^{1,3/2}(\Omega,\mathbb{C}) \text{ as } n\to\infty, \quad \lim_{n\to\infty}\frac{\alpha_n}{\delta_n} = c_0 = \frac{1}{\sqrt{|\Omega|}}. \tag{5.7}$$

Define

$$\tilde{\psi}_n = \frac{1}{\alpha_n\varepsilon_n}(\psi_n - \alpha_n). \tag{5.8}$$

We find from (5.6) that

$$\begin{aligned} -\Delta\tilde{\psi}_n &= \frac{\delta_n}{\alpha_n}[2ia_n\mathbf{A}_n\cdot\nabla\hat{\psi}_n + a_n^2\varepsilon_n|\mathbf{A}_n|^2\hat{\psi}_n + \varepsilon_n(1-\delta_n^2|\hat{\psi}_n|^2)\hat{\psi}_n] \quad \text{in } \Omega, \\ \frac{\partial\tilde{\psi}_n}{\partial\nu} &= \frac{\delta_n}{\alpha_n}[ia_n\hat{\psi}_n\mathbf{A}_n\cdot\nu] \quad \text{on } \partial\Omega. \end{aligned} \tag{5.9}$$

From $\lim_{n\to\infty}\delta_n/\alpha_n = 1/c_0 > 0$, $\|\hat{\psi}_n\|_{W^{1,2}(\Omega,\mathbb{C})}=1$, and using (5.4), we see that the right-hand side of the first equation in (5.9) is uniformly bounded in $L^{3/2}(\Omega)$, and the right-hand side of the second equation in (5.9) is uniformly bounded in $W^{1/2,3/2}(\partial\Omega)$. Note that $\int_\Omega \tilde{\psi}_n \mathrm{d}x = 0$. So the L^p estimate used for (4.24) [see (4.25)] can now be applied to (5.9) to conclude that $\{\tilde{\psi}_n\}$ is uniformly bounded in $W^{2,3/2}(\Omega,\mathbb{C})$. Therefore, after passing to a subsequence again, we have,

$$\tilde{\psi}_n \to \tilde{\psi}_0 \quad \text{in } W^{1,2}(\Omega,\mathbb{C}) \text{ as } n \to \infty.$$

Now we look at the equation for $\mathbf{A}_n$:

$$-\Delta \mathbf{A}_n = \operatorname{curl}^2 \mathbf{A}_n = \frac{\delta_n^2}{\lambda^2 a_n} \operatorname{Im}\left[\bar{\hat{\psi}}_n\left(\frac{\alpha_n}{\delta_n}\nabla \tilde{\psi}_n - i a_n \mathbf{A}_n \hat{\psi}_n\right)\right]\chi_\Omega. \tag{5.10}$$

From the conclusion obtained in step 1 and the fact $\int_\Omega \mathbf{A}_n dx = \mathbf{0}$, we know that $\{\mathbf{A}_n\}$ is bounded in $W^{1,2}_{\mathrm{loc}}(\mathbb{R}^3,\mathbb{R}^3)$. Using the Hölder inequality we see that the right-hand side of (5.10) is bounded in $L^{3/2}_{\mathrm{loc}}(\mathbb{R}^3)$. Then the standard interior L^p estimates of elliptic equations imply that $\{\mathbf{A}_n\}$ is bounded in $W^{2,3/2}_{\mathrm{loc}}(\mathbb{R}^3,\mathbb{R}^3)$. Using the Sobolev imbedding theorem and a standard diagonal argument we find that, after passing to a subsequence, we have

$$\mathbf{A}_n \to \mathbf{A}_0 \text{ in } W^{1,2}_{\mathrm{loc}}(\mathbb{R}^3,\mathbb{R}^3) \text{ as } n \to \infty.$$

On the other hand, from Lemma 3.1 we know that $\mathbf{B}_n = \mathbf{A}_n - \mathbf{F_h} - \mathbf{v}_n$ is a bounded sequence in $W^{1,2}(\mathbb{R}^3,\mathbb{R}^3)$. Therefore, after passing to a subsequence, it converges to some $\mathbf{B}_0$ weakly in $W^{1,2}(\mathbb{R}^3,\mathbb{R}^3)$. In particular, $\operatorname{curl} \mathbf{B}_n = \operatorname{curl}(\mathbf{A}_n - \mathbf{F_h})$ converges weakly in $L^2(\mathbb{R}^3)$ to $\operatorname{curl} \mathbf{B}_0$. Therefore, we necessarily have

$$\operatorname{curl}(\mathbf{A}_0 - \mathbf{F_h}) = \operatorname{curl} \mathbf{B}_0 \in L^2(\mathbb{R}^3).$$

Recall that we have assumed that $\alpha_n \to \alpha \geqslant 0$. Then we use (5.7), (5.9), and (5.10) to obtain

$$\begin{gathered} -\Delta \tilde{\psi}_0 = 0 \quad \text{in } \Omega, \\ \operatorname{curl}^2 \mathbf{A}_0 = \frac{\alpha^2}{\lambda^2 a} \operatorname{Im}[\nabla \tilde{\psi}_0 - i a \mathbf{A}_0)]\chi_\Omega \quad \text{in } \mathbb{R}^3, \\ \frac{\partial \tilde{\psi}_0}{\partial \nu} = i a \mathbf{A}_0 \cdot \nu \quad \text{on } \partial\Omega, \\ \mathbf{A}_0 - \mathbf{F_h} \in \mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div},\Omega). \end{gathered} \tag{5.11}$$

Let

$$\phi_0 := \frac{\tilde{\psi}_0}{ia}.$$

From (5.11) we see that ϕ_0 satisfies

$$-\Delta \phi_0 = 0 \quad \text{in } \Omega, \quad \frac{\partial \phi_0}{\partial \nu} = \mathbf{A}_0 \cdot \nu \quad \text{on } \partial\Omega. \tag{5.12}$$

Since $\int_\Omega \phi_0 dx = 0$, from (5.12) we see immediately that ϕ_0 is real valued. From (5.11) we see that $\mathbf{A}_0$ satisfies

$$\lambda^2 \operatorname{curl}^2 \mathbf{A}_0 = \alpha^2(\nabla \phi_0 - \mathbf{A}_0)\chi_\Omega \text{ in } \mathbb{R}^3, \quad \mathbf{A}_0 - \mathbf{F_h} \in \mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div},\Omega). \tag{5.13}$$

Comparing (5.12) and (5.13) with (2.11), we realize that

$$(\phi_0,\mathbf{A}_0) = (w^{\alpha^2},\mathbf{A}^{\alpha^2}).$$

Summarizing, we have proved that, subject to a subsequence,

$$\psi_n = \alpha_n(1+\varepsilon_n\tilde{\psi}_n), \quad \alpha_n \to \alpha \geqslant 0, \quad \|(\tilde{\psi}_n, \mathbf{A}_n) - (iaw^{\alpha^2}, \mathbf{A}^{\alpha^2})\|_{\tilde{Y}} \to 0. \tag{5.14}$$

Step 3: The value of α and completion of the proof.

Let $\tilde{\psi}_n$ be defined in (5.8), and for $\rho > 0$ let

$$\psi_n^\rho = \rho(1+\varepsilon_n\tilde{\psi}_n).$$

We know that $(\psi_n^\rho, \mathbf{A}_n)$ is a critical point of $\mathcal{G}_{a_n\varepsilon_n}$ when $\rho = \alpha_n$. It follows that

$$\frac{\partial}{\partial\rho}\mathcal{G}_{a_n\varepsilon_n}[\psi_n^\rho, \mathbf{A}_n]|_{\rho=\alpha_n} = 0 \quad \text{for all } n \geqslant 1.$$

A direct calculation gives

$$\frac{\partial}{\partial\rho}\mathcal{G}_{a_n\varepsilon_n}[\psi_n^\rho, \mathbf{A}_n] = 2\varepsilon_n^2\rho\left\{\int_\Omega |\nabla\tilde{\psi}_n - ia_n\mathbf{A}_n(1+\varepsilon_n\tilde{\psi}_n)|^2 dx - \int_\Omega (1-\rho^2|1+\varepsilon_n\tilde{\psi}_n|^2)|1+\varepsilon_n\tilde{\psi}_n|^2 dx\right\}.$$

It follows by taking $\rho = \alpha_n$ that

$$\int_\Omega |\nabla\tilde{\psi}_n - ia_n\mathbf{A}_n(1+\varepsilon_n\tilde{\psi}_n)|^2 dx = \int_\Omega (1-\alpha_n^2|1+\varepsilon_n\tilde{\psi}_n|^2)|1+\varepsilon_n\tilde{\psi}_n|^2 dx.$$

Letting $n \to \infty$ and using (5.14), we obtain

$$a^2\int_\Omega |\nabla w^{\alpha^2} - \mathbf{A}^{\alpha^2}|^2 dx = (1-\alpha^2)|\Omega|.$$

Therefore $\rho = \alpha^2 \geqslant 0$ is a solution to (2.12). By Lemma 2.2, we must have

$$a \leqslant C(\lambda), \tag{5.15}$$

and

$$\alpha = \begin{cases} \rho(a)^{1/2} & \text{if } a \in (0, a(\mathbf{h})) \\ \rho(a)^{1/2} \text{ or } \rho_*(a)^{1/2} & \text{if } a \in [a(\mathbf{h}), C(\lambda)) \\ \rho_0^{1/2} & \text{if } a = C(\lambda). \end{cases} \tag{5.16}$$

In view of (5.14), we find all the conclusions in our theorem follow from the previous formulas for α. □

Let us define

$$N_r^\rho = \{(\psi, \mathbf{A}) : \psi = z(1+ia\varepsilon w), \quad z \in \mathbb{C}, \quad ||z|^2 - \rho| + \|(w - w^\rho, \mathbf{A} - \mathbf{A}^\rho)\|_{\tilde{Y}} < r\}. \tag{5.17}$$

From Lemma 5.1 and Proposition 4.6 (iii), we immediately obtain the following result.

Theorem 5.2: *Under assumption (4.2), for any given small $\delta > 0$ and $r > 0$, there exists $\varepsilon_* > 0$ so that for every $\varepsilon \in (0, \varepsilon_*)$ being fixed, the following conclusions hold.*

(i) *If $\delta \leqslant a \leqslant a(\mathbf{h}) - \delta$ and if $(\psi, \mathbf{A}) \in \mathcal{W}_0(\Omega, \text{div})$ is a nontrivial critical point of $\mathcal{G}_{a\varepsilon}$, then $(\psi, \mathbf{A}) \in N_r^{\rho(a)}$.*

(ii) *If $a(\mathbf{h}) - \delta \leqslant a \leqslant C(\lambda) - \delta$ and if $(\psi, \mathbf{A}) \in \mathcal{W}_0(\Omega, \text{div})$ is a nontrivial critical point of $\mathcal{G}_{a\varepsilon}$, then either $(\psi, \mathbf{A}) \in N_r^{\rho(a)}$ or $(\psi, \mathbf{A}) \in N_r^{\rho_*(a)}$.*

(iii) *If $C(\lambda) - \delta \leqslant a \leqslant C(\lambda) + \delta$ and if there exists any nontrivial critical point $(\psi, \mathbf{A}) \in \mathcal{W}_0(\Omega, \text{div})$ of $\mathcal{G}_{a\varepsilon}$, then either $(\psi, \mathbf{A}) \in N_r^{\rho(a)}$ or $(\psi, \mathbf{A}) \in N_r^{\rho_*(a)}$. Here if $C(\lambda) \leqslant a \leqslant C(\lambda) + \delta$, we define $\rho(a) = \rho^*(a) = \rho_0$, where ρ_0 is the positive number given in Lemma 2.2.*

(iv) *If $a \geqslant C(\lambda) + \delta$, then $(0, \mathbf{F_h})$ is the only critical point of $\mathcal{G}_{a\varepsilon}$ in $\mathcal{W}_0(\Omega, \text{div})$.*

Recall that the existence of multiple critical points of $\mathcal{G}_{a\varepsilon}$ for $0<\lambda<\lambda(\mathbf{h})$ is essentially due to the existence of multiple positive solutions of Eq. (2.17). When $\lambda\geqslant\lambda(\mathbf{h})$, it has been shown in Ref. 3 (Lemma 3.5) that (2.17) has a unique positive solution $\rho(a)$ if $0<a<a(\mathbf{h})$, a unique non-negative solution $\rho=0$ if $a=a(\mathbf{h})$, and has no non-negative solutions if $a>a(\mathbf{h})$. Also note that it follows from Ref. 12 (Theorem 4.1) that $(0,\mathbf{F_h})$ is the only critical point of $\mathcal{G}_{a\varepsilon}$ in $\mathcal{W}_0(\Omega,\mathrm{div})$ if a is large. Using these facts and applying the arguments used in Lemma 5.1, we have the following.

Theorem 5.3: *Assume that*

$$\lambda\geqslant\lambda(\mathbf{h})\ \textit{is fixed},\quad \kappa=\lambda\varepsilon,\quad \sigma=a\varepsilon,\quad \textit{where } \varepsilon>0\ \textit{is small}. \tag{5.18}$$

For any given small $\delta>0$ and $r>0$, there exists $\varepsilon_*>0$ so that for every $\varepsilon\in(0,\varepsilon_*)$ being fixed, the following conclusions hold.

(i) *If $\delta\leqslant a\leqslant a(\mathbf{h})-\delta$, then the global minimizer of $\mathcal{G}_{a\varepsilon}$ over $\mathcal{W}_0(\Omega,\mathrm{div})$ is nontrivial, and lies in $N_r^{\rho(a)}$.*

(ii) *If $a(\mathbf{h})-\delta\leqslant a\leqslant a(\mathbf{h})+\delta$ and if there exists any nontrivial critical point $(\psi,\mathbf{A})\in\mathcal{W}_0(\Omega,\mathrm{div})$ of $\mathcal{G}_{a\varepsilon}$, then $(\psi,\mathbf{A})\in N_r^{\rho(a)}$. Here if $a(\mathbf{h})\leqslant a\leqslant a(\mathbf{h})+\delta$, we define $\rho(a)=0$.*

(iii) *If $a\geqslant a(\mathbf{h})+\delta$, then $(0,\mathbf{F_h})$ is the only critical point of $\mathcal{G}_{a\varepsilon}$ in $\mathcal{W}_0(\Omega,\mathrm{div})$.*

Remark 5.4: The results in this section and Remark 4.6 suggest that, under assumption (4.2), for fixed small $\varepsilon>0$, the set of nontrivial critical points of $\mathcal{G}_{a\varepsilon}(\psi,\mathbf{A})$ in the space of $(a,\psi,\mathbf{A})$ can be described by a bifurcation diagram (see Fig. 1):

(i) *A branch of nontrivial critical points bifurcates from the trivial solution branch*

$$\{(a,0,\mathbf{F_h}):0<a<+\infty\}$$

at $a=\varepsilon^{-2}\mu(a\varepsilon\mathbf{F_h})$, the value of which is approximately equal to $a(\mathbf{h})$ for small ε.

(ii) *Along this branch of nontrivial solutions the value of a initially increases until it reaches some critical value $C_\varepsilon(\lambda)$, which is approximately equal to $C(\lambda)$ for small ε, then the branch bends back, i.e., the value of a decreases when the branch is further continued, until a reaches 0.*

This bifurcation diagram is very much similar in nature to the curve

$$\{(a,\rho):(a,\rho)\ \textit{satisfies}\ (2.12)\},$$

i.e., the solution curve of $f(a,\rho)=1$, in the (a,ρ) plane.

VI. GLOBAL MINIMIZERS AND HYSTERESIS

In this section, under assumption (4.2), we fix a small $\varepsilon>0$ and determine the global minimizers of $\mathcal{G}_{a\varepsilon}$ according to the value of a. We will also explain how our results suggest a hysteresis phenomenon. We use the notations from previous sections. In particular, $a^*(\lambda)$ denotes the unique zero point of the function $I(a)$, see Lemma 2.3; $Z_{a,\varepsilon}$ denotes the set defined in Sec. IV, and N_r^ρ denotes the set defined in (5.17).

Theorem 6.1: *Under assumption (4.2), for any given small constants $\delta>0$ and $r>0$, there exists $\varepsilon_*>0$ such that for every $\varepsilon\in(0,\varepsilon_*)$ being fixed, we have:*

(i) *if $\delta\leqslant a\leqslant a^*(\lambda)-\delta$, then the local minimizer $(\psi_\varepsilon^a,\mathbf{A}_\varepsilon^a)$ obtained in Proposition 4.3 is a global minimizer of $\mathcal{G}_{a\varepsilon}$ over $\mathcal{W}_0(\Omega,\mathrm{div})$, and any other global minimizer, if it exists, must belong to $N_r^{\rho(a)}$;*

(ii) *if $a\geqslant a^*(\lambda)+\delta$, then $(0,\mathbf{F_h})$ is the only global minimizer of $\mathcal{G}_{a\varepsilon}$ in $\mathcal{W}_0(\Omega,\mathrm{div})$.*

Proof. From (4.5) and (4.6) we have

$$g_{a,\varepsilon}[\rho, w^{\rho}, \mathbf{A}^{\rho}] = F(a,\rho) + O(\varepsilon), \tag{6.1}$$

where $F(a,\rho)$ was defined in (2.18). From Lemma 2.3 and (2.19) we have

$$F(a,\rho(a)) - F(a,0) = I(a)|\Omega| \begin{cases} \leqslant I(a^*(\lambda) - \delta)|\Omega| < 0 & \text{if } 0 < a \leqslant a^*(\lambda) - \delta \\ \geqslant I(a^*(\lambda) + \delta)|\Omega| > 0 & \text{if } a^*(\lambda) + \delta \leqslant a \leqslant C(\lambda). \end{cases}$$

Let us define, for small $\delta > 0$,

$$\sigma_1(\delta) = -I(a^*(\lambda) - \delta)|\Omega|,$$

$$\sigma_2 \delta = I(a^*(\lambda) + \delta)|\Omega|, \tag{6.2}$$

$$\sigma_0(\delta) = \frac{1}{2}\min\{\sigma_1, \sigma_2\}.$$

Then $\sigma_j(\delta) > 0$ for small $\delta > 0$, and we have

$$F(a,\rho(a)) - F(a,0) \begin{cases} \leqslant -\sigma_1 & \text{if } 0 < a \leqslant a^*(\lambda) - \delta \\ \geqslant \sigma_2 & \text{if } a^*(\lambda) + \delta \leqslant a \leqslant C(\lambda). \end{cases} \tag{6.3}$$

Moreover, we have

$$F(a,\rho_*(a)) \geqslant \max\{F(a,0), F(a,\rho(a))\} \quad \text{if } 0 < a \leqslant C(\lambda), \tag{6.4}$$

see the discussion after the proof of Lemma 4.1. Due to (6.1), we can choose $\varepsilon_1 > 0$, $\delta_1 \in (0,\delta]$ and $r_1 \in (0,r]$ small enough so that for every $\varepsilon \in (0,\varepsilon_1)$ and $a \in [\delta, C(\lambda) + \delta_1]$, the conclusions in Theorem 5.2 holds with (δ, r) replaced by (δ_1, r_1), and

$$N_{r_1}^{\rho(a)} \subset Z_{a,\varepsilon}, \tag{6.5}$$

$$|\varepsilon^{-2}\mathcal{G}_{a\varepsilon}[\psi, \mathbf{A}] - F(a,\rho(a))| < \sigma_0 \quad \text{for all } (\psi, \mathbf{A}) \in N_{r_1}^{\rho(a)}, \tag{6.6}$$

$$|\varepsilon^{-2}\mathcal{G}_{a\varepsilon}[\psi, \mathbf{A}] - F(a,\rho_*(a))| < \sigma_0 \quad \text{for all } (\psi, \mathbf{A}) \in N_{r_1}^{\rho_*(a)}. \tag{6.7}$$

Here, as in Theorem 5.2, we understand that $\rho(a) = \rho_*(a) = \rho_0$ for $a \geqslant C(\lambda)$.

Suppose $\delta \leqslant a \leqslant a^*(\lambda) - \delta$. We shall show that the critical point $(\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a)$ obtained in Proposition 4.3 is a global minimizer of $\mathcal{G}_{a\varepsilon}$ over $\mathcal{W}_0(\Omega, \mathrm{div})$. To prove, let $(\psi^*, \mathbf{A}^*)$ be any global minimizer of $\mathcal{G}_{a\varepsilon}$. By Theorem 5.2, we find either $(\psi^*, \mathbf{A}^*) = (0, \mathbf{F_h})$ or $(\psi^*, \mathbf{A}^*) \in N_{r_1}^{\rho(a)}$ or $(\psi^*, \mathbf{A}^*) \in N_{r_1}^{\rho_*(a)}$. To determine which case must occur, we estimate the energy in each case. Clearly

$$\varepsilon^{-2}\mathcal{G}_{a\varepsilon}[0, \mathbf{F_h}] = F(a,0).$$

By (6.2)–(6.7), we obtain

$$\varepsilon^{-2}\mathcal{G}_{a\varepsilon}[\psi^*, \mathbf{A}^*] \begin{cases} > F(a,0) + \sigma_0 & \text{if } (\psi^*, \mathbf{A}^*) \in N_{r_1}^{\rho_*(a)} \\ < F(a,0) - \sigma_0 & \text{if } (\psi^*, \mathbf{A}^*) \in N_{r_1}^{\rho(a)}. \end{cases}$$

Therefore we must have $(\psi^*, \mathbf{A}^*) \in N_{r_1}^{\rho(a)}$. Recall from Proposition 4.3 that $(\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a)$ is a global minimizer of $\mathcal{G}_{a\varepsilon}$ over the set $Z_{a,\varepsilon}$. In view of (6.5), we have the inequality $\mathcal{G}_{a\varepsilon}[\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a] \leqslant \mathcal{G}_{a\varepsilon}[\psi^*, \mathbf{A}^*]$. Since $(\psi^*, \mathbf{A}^*)$. is a global minimizer, the equality must hold, and hence $(\psi_\varepsilon^a, \mathbf{A}_\varepsilon^a)$ is a global minimizer.

Next, assume $a \geqslant a^*(\lambda)+\delta$. We shall show that $(0,\mathbf{F_h})$ is the only global minimizer of $\mathcal{G}_{a\varepsilon}$ over $\mathcal{W}_0(\Omega,\mathrm{div})$. Let $(\psi^*,\mathbf{A}^*)$ be a global minimizer. By Theorem 5.2, we find that $(\psi^*,\mathbf{A}^*)=(0,\mathbf{F_h})$ if $\varepsilon \in (0,\varepsilon_1)$ and $a \geqslant C(\lambda)+\delta_1$. In the remaining case $a \in [a^*(\lambda)+\delta, C(\lambda)+\delta_1]$, if $(\psi^*,\mathbf{A}^*) \neq (0,\mathbf{F_h})$, then Theorem 5.2 tells us that either $(\psi^*,\mathbf{A}^*) \in N_{r_1}^{\rho(a)}$ or $(\psi^*,\mathbf{A}^*) \in N_{r_1}^{\rho_*(a)}$. In either case, we can use (6.2)–(6.7) to deduce

$$\varepsilon^{-2}\mathcal{G}_{a\varepsilon}[\psi^*,\mathbf{A}^*] \geqslant F(a,0)+\sigma_0 = \varepsilon^{-2}\mathcal{G}_{a\varepsilon}[0,\mathbf{F_h}]+\sigma_0.$$

This contradiction shows that we must have $(\psi^*,\mathbf{A}^*)=(0,\mathbf{F_h})$. Therefore, if we take $\varepsilon_*=\varepsilon_1$, then both (i) and (ii) hold. □

Proof of Theorem 1.1: It follows from Theorem 6.1 immediately. □

Hysteresis: We are now in a position to explain how our results suggest a hysteresis phenomenon under assumption (4.2), see Fig. 1.

We first consider the change of superconducting behavior of the sample when the applied magnetic field is increased from below H_c.

(i) When $\sigma=a\varepsilon$ with $a<a^*(\lambda)$, $(\psi_\varepsilon^a,\mathbf{A}_\varepsilon^a)$ is a (nontrivial) global minimizer, which indicates that the sample is in a superconducting state.

(ii) As a increases across $a^*(\lambda)$, $(0,\mathbf{F_h})$ becomes a global minimizer but is uniformly away from $(\psi_\varepsilon^a,\mathbf{A}_\varepsilon^a)$ by a positive distance; moreover $(\psi_\varepsilon^a,\mathbf{A}_\varepsilon^a)$ remains to be a local minimizer until a is increased further to $C(\lambda)$, and after which this local minimizer disappears.

Therefore it seems reasonable to believe that the superconducting state of the sample does not jump to the normal state $(0,\mathbf{F_h})$ when a first crosses $a^*(\lambda)$, rather it remains to be represented by the local minimizer until a approaches $C(\lambda)$, then the state of the sample jumps to the normal state. This suggests that there is super-heating at $\sigma=H_{sh}\sim C(\lambda)\varepsilon$.

Next we consider the situation that the superconductor changes from the normal state to a superconducting state when the magnetic field is decreased from above H_c.

(i) Suppose we initially have $\sigma=a\varepsilon$ with $a>a^*(\lambda)$. Then $(0,\mathbf{F_h})$ is the global minimizer, which indicates that the sample is in the normal state.

(ii) As a decreases across $a^*(\lambda)$, $(0,\mathbf{F_h})$ loses its status as a global minimizer but it remains to be a local minimizer until a approaches $a(\mathbf{h})$; and the global minimizer $(\psi_\varepsilon^a,\mathbf{A}_\varepsilon^a)$ is uniformly away from $(0,\mathbf{F_h})$ by a positive distance.

Therefore it is reasonable to believe that the sample remains in the normal state when a decreases across $a^*(\lambda)$ until a approaches $a(\mathbf{h})$, then the state of the sample jumps to a superconducting state represented by the global minimizer $(\psi_\varepsilon^a,\mathbf{A}_\varepsilon^a)$. This suggests that sub-cooling occurs at $\sigma=H_{sc}\sim a(\mathbf{h})\varepsilon$.

APPENDIX

Let us write the functional (1.1) by $\mathcal{G}_\sigma[\psi,\mathbf{A},\lambda,\Omega]$ to indicate the dependence on the domain Ω and the parameter λ. Let us introduce

$$\Omega_\lambda=\lambda^{-1}\Omega, \quad \psi_\lambda(y)=\psi(\lambda y), \quad \mathbf{A}_\lambda(y)=\lambda^{-1}\mathbf{A}(\lambda y), \quad \tau=\lambda^2\sigma. \tag{A1}$$

A simple computation shows

$$\mathcal{G}_\sigma[\psi,\mathbf{A},\lambda,\Omega]=\lambda\mathcal{G}_\tau[\psi_\lambda,\mathbf{A}_\lambda,1,\Omega_\lambda], \tag{A2}$$

where

$$\mathcal{G}_\tau[\phi,\mathbf{B},1,\Omega_\lambda]=\int_{\Omega_\lambda}\left\{|\nabla_{\tau\mathbf{B}}\phi|^2+\frac{\kappa^2}{2}(1-|\phi|^2)^2\right\}\mathrm{d}y+\tau^2\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbf{B}-\mathbf{h}|^2\mathrm{d}y.$$

Given a unit vector $\mathbf{h}$, let $H_c(\mathbf{h};\kappa,\lambda,\Omega)$ denote the critical field for Ω defined in (1.3). From (A2) we see that $\mathcal{G}_\sigma$ has a nontrivial minimizer if and only if $\mathcal{G}_{\lambda^2\sigma}$ has a nontrivial minimizer. Hence

$$H_c(\mathbf{h};\kappa,1,\Omega_\lambda)=\lambda^2H_c(\mathbf{h};\kappa,\lambda,\Omega). \tag{A3}$$

Let $\mathbf{F_h}$ be the vector field defined in (1.2), and let $w_\mathbf{h}$ and $\mathbf{U_h}$ be defined in (2.2) and (2.7) with respect to Ω. Set

$$\mathbf{F}_{\mathbf{h},\lambda}(y)=\frac{1}{\lambda}\mathbf{F_h}(\lambda y),\quad w_{\mathbf{h},\lambda}(y)=\frac{1}{\lambda^2}w_\mathbf{h}(\lambda y),\quad \mathbf{U}_{\mathbf{h},\lambda}(y)=\frac{1}{\lambda^2}\mathbf{U_h}(\lambda y).$$

Then $\mathbf{F}_{\mathbf{h},\lambda}$, $w_{\mathbf{h},\lambda}$, and $\mathbf{U}_{\mathbf{h},\lambda}$ satisfy (1.2), (2.2), and (2.7) for Ω_λ, respectively. Let $\omega(\mathbf{h},\Omega)$, $a(\mathbf{h},\Omega)$, and $\lambda(\mathbf{h},\Omega)$ be the numbers defined for Ω in (2.1), (2.3), and (2.8), respectively. We have

$$\omega(\mathbf{h},\Omega_\lambda)=\frac{1}{\lambda^2}\omega(\mathbf{h},\Omega),\quad a(\mathbf{h},\Omega_\lambda)=\lambda a(\mathbf{h},\Omega). \tag{A4}$$

Thus

$$\lambda(\mathbf{h},\Omega_\lambda)=\lambda(\mathbf{h},\Omega). \tag{A5}$$

Let $(w^\rho,\mathbf{A}^\rho)$ be the unique solution of (2.11) for Ω and define

$$w^\rho_\lambda(y)=\frac{1}{\lambda^2}w^\rho(\lambda y),\quad \mathbf{A}^\rho_\lambda(y)=\frac{1}{\lambda}\mathbf{A}^\rho(\lambda y).$$

Then $(w^\rho_\lambda,\mathbf{A}^\rho_\lambda)$ satisfies

$$\begin{cases}\Delta w^\rho_\lambda=0 & \text{in } \Omega_\lambda,\\ \mathrm{curl}^2\,\mathbf{A}^\rho_\lambda=\rho(\nabla w^\rho_\lambda-\mathbf{A}^\rho_\lambda)\chi_{\Omega_\lambda} & \text{in } \mathbb{R}^3,\\ \dfrac{\partial w^\rho_\lambda}{\partial\nu}=\mathbf{A}^\rho_\lambda\cdot\nu & \text{on } \partial\Omega_\lambda,\\ \mathbf{A}^\rho_\lambda-\mathbf{F}_{\mathbf{h},\lambda}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div}).\end{cases} \tag{A6}$$

Let $f(a,\rho,\Omega)$ denote the function defined in (2.13) for Ω and $\rho(a,\Omega)$ denote the maximal solution of (2.12) for Ω. Using (A5) we find

$$f(a\lambda,\rho,\Omega_\lambda)=f(a,\rho,\Omega),\quad \rho(a\lambda,\Omega_\lambda)=\rho(a,\Omega).$$

Hence

$$I(a\lambda,\Omega_\lambda)=I(a,\Omega),$$

where $I(a,\Omega)$ denotes the function defined in (2.16) for Ω. Therefore, if $a^*(\lambda,\Omega)$ denotes the zero of $I(a,\Omega)$ given in Lemma 2.3, we have

$$a^*(\lambda,\Omega_\lambda)=\lambda a^*(\lambda,\Omega). \tag{A7}$$

Finally, let $C(\lambda,\Omega)$ be the number given in Lemma 2.2 for Ω such that $f(a,\cdot,\Omega)$ has no zero for $a>C(\lambda,\Omega)$. We have

$$C(\lambda,\Omega_\lambda)=\lambda C(\lambda,\Omega). \tag{A8}$$

Moreover,

$$a(\mathbf{h},\Omega_\lambda)<a^*(\lambda,\Omega_\lambda)<C(\lambda,\Omega_\lambda). \tag{A9}$$

From (1.4), (1.6), and the previous discussions we have

Theorem A1: *For small* κ,

$$H_c(\mathbf{h};\kappa,1,\Omega_\lambda)\sim\begin{cases}a(\mathbf{h},\Omega_\lambda)\kappa & \text{if } \lambda\geqslant\lambda(\mathbf{h},\Omega_\lambda)\\ a^*(\lambda,\Omega_\lambda)\kappa & \text{if } 0<\lambda<\lambda(\mathbf{h},\Omega_\lambda).\end{cases} \tag{A10}$$

Now we can state Conclusions A and B as follows.

Conclusion C: Let Ω *be a bounded, smooth and simply-connected domain in* $\mathbb{R}^3$. *For type I superconductors with small Ginzburg–Landau parameter* κ, *occupying* $\Omega_\lambda=\lambda^{-1}\Omega$, *and subjected to the applied magnetic field* $\mathcal{H}=\sigma\mathbf{h}$, *we have the following conclusions.*

(a) *If* $\lambda\geqslant\lambda(\mathbf{h},\Omega_\lambda)$, *there exists a critical field* H_c *such that,*

- (i) *the Meissner state is a global minimizer of the Ginzburg–Landau energy for* $0<\sigma<H_c$, *and disappears for* $\sigma>H_c$;
- (ii) *the normal state is a global minimizer for* $\sigma>H_c$, *and becomes unstable when* $0<\sigma<H_c$.

Moreover, for small κ,

$$H_c\sim a(\mathbf{h},\Omega_\lambda)\kappa.$$

(b) *If* $0<\lambda<\lambda(\mathbf{h},\Omega_\lambda)$, *there exist three critical fields* $H_{sc}<H_c<H_{sh}$, *such that*,

- (i) *the Meissner state is a global minimizer of the Ginzburg–Landau energy for* $0<\sigma<H_c$, *remains stable (a local minimizer) for* $H_c\leqslant\sigma<H_{sh}$, *and disappears for* $\sigma>H_{sh}$;
- (ii) *the normal state is a global minimizer for* $\sigma>H_c$, *remains stable (a local minimizer) for* $H_{sc}<\sigma\leqslant H_c$, *and becomes unstable when* $0<\sigma<H_{sc}$.

Moreover, for small κ,

$$H_{sc}\sim a(\mathbf{h},\Omega_\lambda)\kappa,\quad H_c\sim a^*(\lambda,\Omega_\lambda)\kappa,\quad H_{sh}\sim C(\lambda,\Omega_\lambda)\kappa.$$

Dynamical clusters of infinite particle dynamics

V. A. Malyshev[a)]

(Received 5 January 2005; accepted 25 May 2005; published online 13 July 2005)

For any system $\{i\}$ of particles with the trajectories $x_i(t)$ in R^d on a finite time interval $[0,\tau]$ we define the interaction graph G. Vertices of G are the particles, there is an edge between two particles i and j iff for some $t\in[0,\tau]$ the distance between particles i and j is not greater than some constant. We undertake a detailed study of this graph for infinite particle dynamics and prove exponential estimates for its finite connected components. This also solves continuous percolation problem for complicated geometrical objects—the tubes around particle trajectories. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1955513]

I. INTRODUCTION

We undertake a detailed study of the interaction graph for infinite particle dynamics and prove exponential estimates for its finite clusters. Cluster properties of classical infinite-particle dynamics is a folklor notion now, cluster dynamics was discussed in Ref. 1. In more general sense, weak dependence of far away particle trajectories plays substantial role in many papers, see e.g., Refs. 2–5. For classical (deterministic or stochastic) dynamics, the cluster property reveals a clear geometric picture, where the system of infinite particles is subdivided into random finite subsets (clusters) which do not interact with each other on a fixed time interval. Thus the dynamics is reduced to finite particle dynamics. The new feature of this article is that we describe clusters in detail combinatorially and give combinatorial estimates of their probabilities. This solves continuous percolation problem for complicated geometrical objects—the tubes around particle trajectories.

Note that cluster property can have also different (but related) meaning: decay of correlations, existence of quasiparticles, especially for the quantum case, see Ref. 6, we do not pursue this issue here.

We assume that at time 0, for any cube Λ, Poisson point field with density ρ is given. Thus the number $N(\Lambda)$ of particles in Λ has Poisson distribution with $\langle N(\Lambda)\rangle/|\Lambda|=\rho$. The initial velocities $v_i(0)$ of the particles are assumed to be independently and identically distributed. Random initial configuration of coordinates $x_i(0)$ and velocities $v_i(0)$ is denoted by $\omega=\omega_\Lambda$.

We assume that for any cube Λ and any fixed number of particles $N(\Lambda)$ some finite particle dynamics in Λ is given. Here we mean by this that for (almost) any initial coordinates $x_i(0)$ and velocities $v_i(0)$ the trajectories $x_i(t)=x_i^{(\Lambda)}(t)$ are uniquely defined on the time interval $[0,\tau]$, they are assumed to be piecewise smooth (then the velocities $v_i(t)=\mathrm{d}x_i(t)/\mathrm{d}t$ are defined a.e.).

We further fix on some $r>0$. We call the tube (or r tube) $T_i(\tau)$ of the particle i the r-neighborhood of its trajectory $x_i(t,\omega)$, $0\leqslant t\leqslant\tau$. We say that two particles i, j interact at time t if

$$\mathrm{dist}(x_i(t),x_j(t))\leqslant 2r$$

that is if the closed r neighborhoods of $x_i(t)$ and $x_j(t)$ (the time t slices of the corresponding tubes) intersect. Then

a)Electronic mail: vadim.malyshev@inria.fr

$$s_{ij} = \min\{t:\mathrm{dist}(x_i(t),x_j(t)) \leqslant 2r\}$$

is called the first interaction time of particles i and j.

To define dynamical clusters we consider (for any τ) the following finite random graphs $G^\Lambda = G^\Lambda(\tau) = G^\Lambda(\tau,\omega)$. Vertices of G^Λ are the particles. We can assume that they are labelled by the initial coordinates of the particles. Two vertices are connected by an edge if on the time interval $[0,\tau]$ these two particles interact at least at one time moment. The sets of vertices of connected components of $G^\Lambda = G^\Lambda(\tau)$ are called dynamical clusters in Λ (or simply clusters) if τ and Λ are fixed. Equivalently, the connected components are the same as the topological connected components of the union of all tubes $T = \cup T_i(\tau)$ in $\Lambda \times [0,\tau]$.

Within this general setting, sufficient for our purpose, we have to do three additional assumptions:

(1) For simplicity of presentation we assume translation invariance of the dynamics and periodic boundary conditions and that the particle i moves freely on the time interval $(t,t+s)$

$$x_i(t+s] = x_i(t) + v_i(t+0)s$$

if for any $t' \in (t,t+s)$ this particle does not interact with other particles.

(2) We assume that for any two particles i,j their first interaction times $s_{ij} = s_{ij}(\omega)$ are all different a.s. This holds trivially in many known dynamical models.

(3) Our main assumption is that the velocities are uniformly bounded, that is for some constant $v^0 > 0$ and any i and $t \in [0,\tau]$

$$|v_i(t)| \leqslant v^0.$$

This is a very simplifying assumption. However, even under such condition the combinatorics of clusters is not easy. I hope that the obtained estimates allow to weaken essentially this condition.

Remark 1.1: Note that our dynamics is very general—we do not even assume that the particle trajectories are related for different Λ. We could even take, with some precautions. any metric space instead of R^d with trajectories satisfying Lipschitz condition

$$\mathrm{dist}(x(t),x(t')) \leqslant v^0|t-t'|.$$

At the same time we could consider the infinite particle system directly in R^d with the same existence assumptions (1)–(3).

Physical intuition and percolation theory: If the velocities are uniformly bounded then on the time interval $[0,\tau]$ the tube of a particle belongs to the ball of radius $v^0\tau + r$ with the center in its initial coordinate. The results from continuous percolation theory, see Refs. 7–9, tell us that the infinite system of balls of radius $v^0\tau + r$ around Poisson points in R^d a.s. has no infinite clusters for ρ small. More exactly, simple space scaling shows that if ρ does not exceed $\alpha_0(v^0\tau + r)^{-d}$ for some fixed factor $\alpha_0 > 0$ sufficiently small, then all clusters are finite a.s. Moreover, exponential cluster estimates hold. However this result is too rough for our purpose.

Physics tells us that the correct answer is given by the Boltzman–Grad (BG) scaling. Note that the volume λ swept up by the particle, that is the volume of its tube, is of the order $v^0\tau r^{d-1}$, where $v^0\tau$ is the length of the trajectory and r^{d-1} is of the order of the circular section of the tube. Heuristically, for the densities smaller than $\alpha_0\lambda^{-1}$, the limiting dynamical clusters should be finite a.s. The reason is that $N(\Lambda)$ particles sweep up the volume $v^0\tau r^{d-1}N(\Lambda)$ which should be small compared to Λ.

We give the proof here. As far as I know, this does not follow from the existing results in continuous percolation theory. One of the reasons is that the particle tubes are not independent volumes around the Poisson points.

For obvious reasons we assume that $v^0\tau \gg r$, that is $v^0\tau > C_1 r$ for some C_1 sufficiently large. Otherwise, the percolation properties of the initial configuration of balls of radius r would prevail.

Moreover, exactly under this condition the BG volume $v_0\tau r^{d-1}+r^d$ is much smaller than the volume $(v_0\tau+r)^d$, and our result is stronger than the one obtained from continuous percolation theory.

Result: Denote $P_k^\Lambda(\tau|x)$ the conditional probability that, under the condition that there is a particle at the point x, the cluster, containing this particle, has exactly k particles. Then the following exponential estimate holds.

Theorem 1.2: *There are constants* C, $\alpha_0>0$ *such that for any* τ, v^0, r *and*

$$\rho=\frac{N(\Lambda)}{\Lambda}=\alpha(\tau v^0 r^{d-1})^{-1} \tag{1.1}$$

with $0<\alpha<\alpha_0$ *and any* k *we have, uniformly in* Λ *and in* x,

$$P_k^\Lambda(\tau|x)\leqslant(C\alpha)^{k-1}. \tag{1.2}$$

Corollary: If for any $t\in[0,\tau]$ the thermodynamic limit of the dynamics (that is $\lim_{\Lambda\to\infty}x^{(\Lambda)}\times(t)$ exists, then all clusters in R^d are finite and the exponential estimates (1.2) hold for $P_k(\tau)=\lim_{\Lambda\to\infty}P_k^\Lambda(\tau|x)$.

Under our general dynamics one cannot prove the existence of thermodynamic limit (it may not even exist). However, there are many results, obtained in a different way, concerning the existence of the thermodynamic limit.[2,4,10,11] In the last section we give an example of the (random) dynamics which satisfies our conditions.

To prove the theorem one has to decribe somehow the set of possible clusters. There are combinatorial and geometric aspects in the description of the set of clusters. The idea of the proof is to separate these two aspects. Combinatorial part consists of describing possible "collision schemes," that is the order in which particles interact at the first time. The central difficulty lies in the estimation of the number of such schemes.

II. TREES DESCRIBING THE DYNAMICS OF CLUSTERS

Dynamical clusters grow in time. Here we describe this growth in combinatorial terms.

A. Labeled trees

Assume that $N(\Lambda)$ particles together with their initial coordinates and velocities (that is a point ω in our probability space) are given in the volume Λ. Then by assumption 1 the trajectories of particles are uniquely defined. For given ω, any $t\in[0,\tau]$ and any set A of $N=N(A)\leqslant N(\Lambda)$ particles consider the subgraph $G_A(t)=G_A(t,\omega)$ of $G(t)=G(\tau)$. Then there is a finite number of moments t when the structure of this subgraph changes (the number of edges increases). We will be interested only in the moments when some connected components join together.

Denote $A_{-j}, j=1,2,\ldots,N_1\leqslant N$, the connected components of $G_A(0)$. Assume first, for convenience, that $N_1=N$, that is all these connected components are the one-point subsets of A.

Denote

$$0<t_1<\cdots<t_l<\cdots<t_{N-1}\leqslant\tau$$

all moments when the number of connected components decreases (by assumption 2 it decreases by 1). Denote A_k, $k>0$, the connected component which appeared at time t_k. It is a union of two nonintersecting connected components $A_{i(k)}$ and $A_{j(k)}$ for some $i(k)$, $j(k)<k$. One can say that t_k is the first collision time of the clusters $A_{i(k)}$ and $A_{j(k)}$. For example, $t_1=t_1(\omega)$ is the first moment when a pair of particles from A begin to interact. Thus the cluster A_1 consists of two vertices.

Now define the tree $T(A)=T(A,\omega)$ with $2N-1$ vertices. N vertices of this tree are labeled by the initial coordinates $x_1(0),\ldots,x_N(0)$, that is by clusters of $G_A(0)$. Denote this set of vertices V_0. Let us agree that to all vertices of V_0 time moment 0 is assigned. Other $N-1$ vertices are labeled by time moments t_i (or by the clusters A_i). Denote this set of vertices $V_1=\{1,\ldots,N-1\}$. If A_k is the union of connected components $A_{i(k)}$ and $A_{j(k)}$ then we draw a directed edge from $i(k)$ to k and

directed edge from $j(k)$ to k. Now V_0 can be defined as the set of vertices having no ingoing edges. The level of the vertex w is defined to be the maximal length of the (directed) paths from V_0 to w. Thus the vertices of level 0 are exactly the vertices of V_0.

Define the complete order R on V_1: $w<w'$ iff $t(w)<t(w')$. Note that this complete order is compatible with the natural partial order on the tree defined as: $w<w'$ iff $A_w \subset A_{w'}$.

At time t_k the connected component A_k appears because some particle from $A_{i(k)}$ and some particle from $A_{j(k)}$ interact at time t_k. Denote the pair of vertices from V_0, corresponding to these two particles, as $f(i(k)), f(j(k)) \in V_0$, where $f: V_1 \to V_0$ is the function, which to any $w \in V_1$ assigns an element of A_w.

Thus, each cluster with N points defines a tree T, some complete order relation R, defined by the time moments t_k, on the set V_1, and a function $f(w)$, which assigns to each vertex w a vertex $f(w)$ of level 0, lying under w.

Formally we did not assume that the particles from A do not interact with particles outside A on time interval $[0,\tau]$. However further we will consider the trees only for this case.

B. Unlabeled structured trees

There is a continuum of the labeled trees, introduced previously. Note that all trees $T(A,\omega)$ have the following property: each vertex (except those of level 0) has exactly two adjacent vertices of lower level. Denote the corresponding class of unlabeled trees $\mathcal{T}(N)$, N is thus the number of zero level vertices. Note that the number of trees in $\mathcal{T}(N)$ does not exceed C^N for some absolute constant $C>0$ and that for any (directed) unlabeled tree $T \in \mathcal{T}(N)$ the sets $V_0=V_0(T)$, $V_1=V_1(T)$ are uniquely defined.

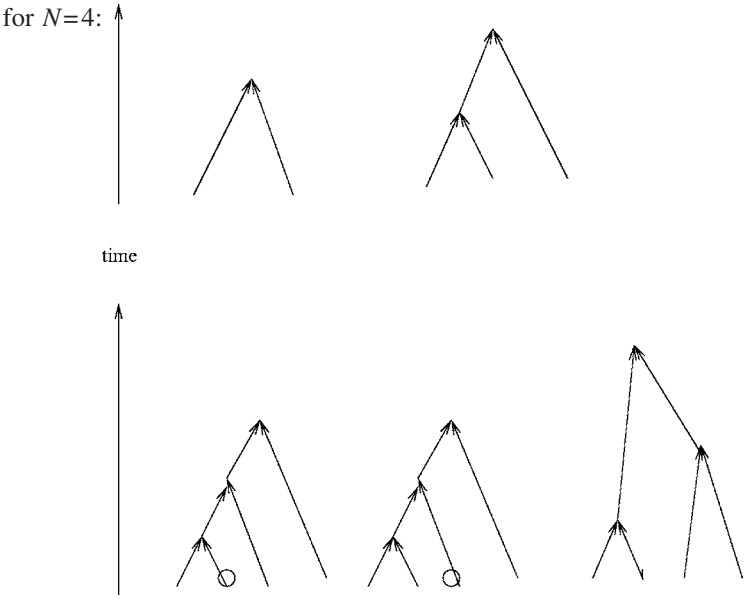
The triple

$$\mathbf{B} = (T,R,f)$$

will be our underlying combinatorial structure. Here $T \in \mathcal{T}(N)$, R is a complete order on $V_1(T)$ and function f on $V_1(T)$, where $f(w)$ is a directed path p from V_0 to w.

Now consider the set $\mathcal{B}(N)$ of equivalence classes of such triples under isomorphisms ψ of trees respecting the complete order R and such that $\psi f = f\psi$. Note that the number of elements in $\mathcal{B}(N)$ is finite for any N. The elements of $\mathcal{B}(N)$ can be called collision schemes (of cluster formation).

The following diagram shows unique collision schemes for $N=2,3$ and all 3 collision schemes for $N=4$:



On the first two isomorphic trees for $N=4$ the small circles show the particle of the left-most cluster which interacts at time t_3 with the right-most particle.

C. Main combinatorial estimate

Note first, that in the following sections one of the vertices of V_0 will be specified. This vertex will correspond to the particle situated in some fixed point x. One could agree that the isomorphisms, introduced previously, respect the specified vertices. Choice of the specified vertex gives factor N in combinatorial estimates. It is neglectable in the foregoing estimates, and we do not consider it in this section.

For any T we shall get an upper bound for $|\mathcal{B}(T,N)|$, the number of triples from $\mathcal{B}(N)$ with given T.

Let $K(T)\leqslant(N-1)!$ be the number of ordering R. For any vertex w let D_w be the number of elements in the subcluster A_w In total this gives the factor

$$D(T)=\prod_{w=1}^{N-1} D_w.$$

The main combinatorial estimate is the following result, which is interesting in its own.

Lemma 2.1: For any tree T

$$|\mathcal{B}(T,N)|\leqslant Q(T,N)=K(T)D(T)<C^N N! \tag{2.1}$$

for some absolute constant $C>0$.

Proof: The first inequality is evident. To prove the second we need the following notation. Let S_k, S_l be two completely ordered sets with k and l elements correspondingly. Denote $R(k,l)$ the number of complete orderings of the set $S_k\cup S_l$ which do not change the order inside S_k and inside S_l. Take, for example, $k\leqslant l$, then

$$R(k,l)=2\sum_{i=1}^{k} C_{k-1}^{i-1}C_{l-1}^{i-1}.$$

In fact, we can split each of S_k and S_l on $i=1,\ldots,k$ consecutive nonempty groups and arrange these groups in a sequence in alternative order. For example, S_k can be split on i consecutive parts by putting $i-1$ walls on $k-1$ empty places between consecutive elements of S_k, that gives the factor C_{k-1}^{i-1}.

For any tree T, $|T|=N$, we have the recurrent relation

$$Q(T,N)=NQ(k,T_1)Q(N-k,T_2)R(k,N-k) \tag{2.2}$$

if under the root vertex of T there are trees T_1 and T_2 with $|T_1|=k$, $|T_2|=N-k$ correspondingly. For $q=\log_2 Q$ we have

$$q(T,N)=\log N+q(k,T_1)+q(N-k,T_2)+\log R(k,N-k). \tag{2.3}$$

One can easily get uniform estimates separately for $K(T)\leqslant N!$ and $D(T)\leqslant N!$, but it is too rough, because there are cases where $K(T)=N!$, $D(T)=C^N$ and vice versa. This is seen from the following two examples. In the first one for the sequence of subclusters

$$\{1,2\},\{1,2,3\},\ldots,\{1,2,\ldots,N-1\}$$

we have $K(T)=1$, $D(T)=(N-1)!$.

From the second example one sees, moreover, that the estimate (2.1) cannot be improved. Put $N=2^n$ and consider the tree T with 2^{n-k} vertices on levels $k=0,\ldots,n$. Denote $Q(n)=K(T)D(T)$. We have the recurrent relation

$$Q(n) = 2^{2n}Q^2(n-1)R(2^{n-1},2^{n-1}).$$

It follows

$$Q(n) \leqslant 2^{2n}Q^2(n-1)a\frac{2^N}{\sqrt{N}}$$

for some constant $a>0$. For $q(n)=\log_2 Q(n)$ this gives for $n \geqslant 2$

$$q(n) \leqslant 2q(n-1) + 2^n + bn, q(1) = 1$$

for some constant $b>0$. The solution of this inequality is

$$q(n) \leqslant \sum_{k=1}^{n} 2^k(2^{n-k} + b(n-k)) = n2^n + b2^n\sum_{k=1}^{n}(n-k)2^{-n+k} = (n+c)2^n$$

for some $c>0$. This gives

$$Q(N) \leqslant 2^{N\log N + cN}.$$

Now we come to the general case. Put $Q(N)=P(N)N!$, then from (2.2) we get

$$P(N) \leqslant NP(k)P(N-k)r(k,N-k),$$

where

$$r(k,N-k) = \frac{2\sum_{i=1}^{k} C_{k-1}^{i-1}C_{N-k-1}^{i-1}}{C_N^k}$$

for some $k \leqslant [N/2]$. For $p(N)=\log P(N)$ we have

$$p(N) = p(k) + p(N-k) + a(v),$$

$$a(v) = a(k,N-k) = \log(Nr(k,N-k)).$$

This equation can be solved explicitely as

$$p(N) = \sum_{v} a(v).$$

To make estimation of this sum we need some notation and results. In the inductive procedure for a given tree T we will distinguish vertices of type A or B, where correspondingly $k \in [\alpha[N/2],[N/2]]$ and $k \in [0,\alpha[N/2]]$ where $\alpha=1-\varepsilon$ for some small $\varepsilon>0$. Denote their numbers N_A and N_B correspondingly. We have $N_A+N_B=N-1$.

Introduce the depth $m(v)$ of the vertex v of the tree—the distance from the root vertex. It is clear that $\log N \leqslant m(v) \leqslant N$. The A-depth $m_A(v)$ of the A-vertex v is the number of A vertices on the path from it to the root. We have

$$m_A(v) < \log_b N, \quad b = \tfrac{1}{2}(1+\epsilon). \tag{2.4}$$

The number

$$\sharp(v{:}m_A(v) = m) < c^m, \quad c = 2(1+\epsilon). \tag{2.5}$$

Denote $N(v)$ the number of level 0 vertices under v. We have

$$c_-^{m(v)} < N(v) < Nc_+^{m(v)}, \tag{2.6}$$

where

$$c_- = \tfrac{1}{2}(1-\epsilon), \quad c_+ = \tfrac{1}{2}(1+\epsilon).$$

We will need some inequalities.

(1) For any k,N

$$\frac{2\sum_{i=1}^{k} C_{k-1}^{i-1} C_{N-k-1}^{i-1}}{C_N^k} \leqslant 1. \tag{2.7}$$

This can be proved by simple combinatorial argument. Take four intervals $1,2,[3,k+1],[k+2;N]$. Then we choose k elements from these two intervals. The number $2C_{k-1}^{i-1}C_{N-k-1}^{i-1}$ gives only restricted choice: we choose one of the first two elements (factor of 2), $i-1$ elements from the last interval (factor C_{N-k-1}^{i-1}) and $k-i$ elements from the third interval (factor C_{k-1}^{i-1}).

(2) (Large deviation estimate) We will use the asymptotics

$$\log C_N^{\alpha N} \sim H(\alpha)N, H(\alpha) = -\alpha \log \alpha - (1-\alpha)\log(1-\alpha).$$

Then for $\gamma \leqslant \beta \leqslant \frac{1}{2}$ the maximum of

$$\log C_{\beta N}^{\gamma N} + \log C_{(1-\beta)N}^{\gamma N}$$

is attained for γ satisfying

$$\frac{1}{\beta}\log\frac{\beta-\gamma}{\gamma} + \frac{1}{1-\beta}\log\frac{1-\beta-\gamma}{\gamma} = 0.$$

In fact,

$$\log C_{\beta N}^{\gamma N} + \log C_{(1-\beta)N}^{\gamma N} \sim N\left(H\left(\frac{\gamma}{\beta}\right)\beta + H\left(\frac{\gamma}{1-\beta}\right)(1-\beta)\right),$$

$$\frac{d}{d\gamma}\left(H\left(\frac{\gamma}{\beta}\right)\beta + H\left(\frac{\gamma}{1-\beta}\right)(1-\beta)\right) = \frac{1}{\beta}\log\frac{\beta-\gamma}{\gamma} + \frac{1}{1-\beta}\log\frac{1-\beta-\gamma}{\gamma}.$$

Then by large deviation principle for any $k \sim \beta N$, $\beta < \frac{1}{2}$

$$\log r(k, N-k) < (1-\delta)^N. \tag{2.8}$$

We estimate $a_v < N$ for B vertices and $a_v < N(v)c_+^{m(v)}$ for A vertices. Using the bounds (2.4)–(2.7) we get the proof. □

III. GEOMETRY AND PROBABILITY OF CLUSTERS

In the previous section we assigned to any ω and any cluster A the triple $\mathbf{B}=\mathbf{B}(\omega,A)$. Here we follow inverse way: for any triple $\mathbf{B} \in \mathcal{B}(\mathbf{N})$ we describe the set of ω and the set of clusters A, containing given point x, such that $\mathbf{B}=\mathbf{B}(\omega,A)$.

Note that in finite volume Λ any cluster is finite, thus for any x

$$\sum_{k=1}^{\infty} P_k^{\Lambda}(\tau|x) = 1.$$

To prove the theorem we will describe the set of initial configurations containing k particles $X = (x_1(0), v_1(0), \ldots, x_k(0), v_k(0))$ which would give a cluster with exactly k particles, if other particles in Λ were not taken into account. We estimate by 1 the conditional probability (given X) that

there are no other particles, which could interact with the particles of the cluster on the time interval $[0,\tau]$. We get these estimates uniformly in Λ and x.

For any $\mathbf{B}=(T,R,f)$ and any sequence $0<t_1<\cdots<t_{N-1}\leqslant\tau$ define the set $I(\mathbf{B},t_1,\ldots,t_{N-1})$ of initial configurations ω of particles such that there exists a set $A,|A|=N$, among them (containing some particle at x) such that A defines a cluster, $N(A)=N$ and $\mathbf{B}(A,\omega)=\mathbf{B}$. The order of t_k, of course, should be compatible with the order R. Denote

$$I(\mathbf{B}) = \cup_{t_1,\ldots,t_{N-1}} I(\mathbf{B},t_1,\ldots,t_{N-1}).$$

We use the estimate

$$P_N^{\Lambda}(\tau|x) \leqslant \sum_{\mathbf{B}} P(I(\mathbf{B})|x).$$

In the previous section we have proved the factorial estimate of the number of terms in the sum $\Sigma_{\mathbf{B}}$. Thus from Lemma 1 and the following Lemma 2 the theorem follows.

Lemma 3.1: The following bound holds uniformly in $\mathbf{B}$

$$P(I(\mathbf{B})|x) \leqslant \frac{(C\alpha)^{N-1}}{N!}$$

for some absolute constant $C>0$.

The proof of this lemma is an easy (but unwieldy) matter and will be given in the next section. It is based on simple geometric considerations with piecewise smooth trajectories and simple facts about Poisson point fields.

IV. PROOF OF LEMMA 2

It is very instructive to understand first the proof for $N=2,3$. Anyway, this is the first step of the inductive procedure below.

A. Two particle cluster

For $N=2$ we have the only tree and the only $\mathbf{B}$. We have to describe geometrically all two particle clusters

Let two particles 1 and 2 have initial velocities v_1 and v_2 correspondingly. Assume that the initial coordinate of particle 1 is $x_1(0)=x$. For any r denote $S_r(x)$ the $(d-1)$-dimensional sphere of radius r and centre $x\in R^d$, let $B_r(x)$ be the corresponding d-dimensional ball. Put $S_r=S_r(0)$ and $B_r=B_r(0)$.

At the first collision time t_1 the particles 1 and 2 should be at the points $x_1(t_1)=x_1(0)+t_1v_1$ and $x_2(t_1)=x_1(0)+t_1v_1+y_1$ correspondingly, where y_1 is any point on the sphere S_{2r}, such that for any $0\leqslant t<t_1$ the spheres $S_r(x_1(0)+tv_1)$ and $S_r(x_2(0)+tv_2)$ do not intersect. This event $G_1(t_1,y_1)$ can also be defined as the event that initially at the point $x_2(0)=x+y_1+t_1(v_1-v_2)$ there is a particle. In other words the relative initial coordinate $x_2(0)-x_1(0)$ of the particle 2 is

$$z_{12}(0) = x_2(0) - x_1(0) = y_1 + t_1(v_1 - v_2).$$

Thus $x_2(0)$, for given $v_1,v_2,t_1,x_1(0)$, should be in a subset of the sphere

$$u_1(t_1) = S_{2r}(x + t_1(v_1 - v_2)) = S_{2r} + x + t_1(v_1 - v_2)$$

in R^d.

Consider the majorizing event

$$G_1(t_1) = \cup_{y_1\in S_{2r}} G_1(t_1,y_1)$$

that there is at least one particle in $u_1(t_1)$. The union

$$G = \cup_{t_1 \in [0,\tau]} G(t_1)$$

is the event that initially there is at least one particle in the union

$$U = \cup_{t_1 \in [0,\tau]} u_1(t_1)$$

which is a closed subset of Λ, parametrized (not one-to-one) by $[0,\tau] \times S_{2r}$. The volume of U does not exceed $C\tau v^0 r^{d-1}$, uniformly in v_1, v_2 (here the boundedness of velocities is used), where C_d is some absolute constant. That is obtained by integration in t_1. Thus the probability that initially there is a particle in this volume does not exceed

$$1 - \exp(-C_d \alpha).$$

This gives the bound $C_d \alpha$ if α is small.

Note that we estimated the conditional probability for given v_1 and v_2, we should now integrate over the velocity distributions

$$\int \int \mathrm{d}\mu(v_1)\mu(v_2),$$

where μ is the initial velocity distribution.

Given the initial coordinates of the two particles, we estimate from above the conditional probability that there are no more particles in their vicinity so that they could interact with them on the time interval $(0,\tau]$, by 1.

B. Three particle cluster

For general N, and in particular for $N=3$, we should only describe the set of relative coordinates of all particles. Then we choose one particle and put its coordinate equal x (this will give a nonessential factor N), thus shifting correspondingly all configuration.

For $N=3$ we also have the unique $\mathbf{B}=(T,R,f)$. Denote velocities of the particles (say 1 and 2) colliding at time t_1 correspondingly v_1, v_2. We can assume that at time t_2 the particle 3, having velocity v_3 collides with particle 1.

Introduce the events $G_1(y_1,t_1), G_1(t_1)$ exactly as in the case of two particles. Let $x_1(s) = x_1(s;y_1)$ be the trajectory of particle 1 for $s \in [t_1,t_2]$, it depends on y_1 (or on $x_2(0)$). Introduce the conditional (given t_1, y_1) event $G_2(t_2,y_2;t_1,y_1)$ that at the moment of collision of the particle 3 with particle 1

$$x_3(t_2) = x_1(t_2) + y_2, y_2 \in S_{2r}.$$

In other words

$$x_3(0) = x_1(t_2) + y_2 - v_3 t_2.$$

Consider the events

$$G_2(t_2;y_1,t_1) = \cup_{y_2 \in S_{2r}} G_2(t_2,y_2;t_1,y_1),$$

$$G_2([s,s'];t_1,y_1) = \cup_{t_2 \in [s,s']} G_2(t_2;t_1,y_1).$$

Using the independence property of Poisson point field, we can estimate, uniformly in y_1, the probability of the event $G_2([t_2,t_2+\mathrm{d}t_2];t_1,y_1)$ as

$$\rho C v^0 r^{d-1} \mathrm{d}t_2.$$

Thus the probability of the event

$$\cup_{s_1\in[t_1,t_1+dt_1]}\cup_{s_2\in[t_2,t_2+dt_2]}(G_1(y_1,s_1)\cap G_2(s_2;t_1,y_1))$$

can be estimated as

$$\rho C v^0 r^{d-1} dt_1 \rho C v^0 r^{d-1} dt_2.$$

Put also

$$G=\cup_{t_1\in[0,\tau]}(G_1(y_1,t_1)\cap G_2(t_1,y_1))=\cup_{t_1\in[0,\tau]}\cup_{t_2\in[t_1,\tau]}(G_1(y_1,t_1)\cap G_2(t_2;t_1,y_1)).$$

Then the probability of the latter event G is estimated by

$$\int_0^\tau C\rho v^0 r^{d-1} dt_1 \int_{t_1}^\tau C\rho v^0 r^{d-1} dt_2 = (C\rho v^0 r^{d-1})^2 \frac{\tau^2}{2!}.$$

C. General case

Assume now for any N that **B** and the velocities $v_1,\dots,v_N$ of the particles are fixed. We should describe the possible initial coordinates $x_1(0),\dots,x_N(0)$ which give rise to a cluster with N particles. The emergence of the cluster occurs as a sequence of $N-1$ conditional events

$$G_1(t_1,y_1),\dots,G_k(t_k,y_k;t_{k-1},y_{k-1};\dots;t_1,y_1),\dots,G_{N-1}(t_{N-1},y_{N-1};t_{N-2},y_{N-2};\dots;t_1,y_1)$$

at the moments $t_1,\dots,t_{N-1}$. We define these events inductively.

Our inductive assumption is that after step k the vectors $y_1,\dots,y_k\in S_{2r}$ and the events $G_1,\dots,G_k$ are defined. Moreover, there are $m(k)=N-k$ maximal (that is not contained in other clusters) clusters $A_{k,1},\dots,A_{k,m(k)}$ at time t_k, as on each step the number of clusters decreases by 1. For each $i=1,\dots,m(k)$, denote a vertex of the tree, corresponding to the cluster $A_{k,i}$, by i. Assume that at time moment t_{k+1} the clusters $A_{k,i(k+1)}$ and $A_{k,j(k+1)}$ (the choice of these clusters is unique as dictated by **B**) collide and the colliding particles be $f(i(k+1))$ and $f(j(k+1))$. Moreover, after k steps the initial relative coordinates inside all maximal clusters are fixed, they enter the definition of the events $G_1,\dots,G_k$.

Thus at time t_{k+1} the particle $f(i(k+1))$ will be at the point $x_{f(i(k+1))}(t_{k+1})$, the trajectory $x_{f(i(k+1))}(s)$ on the time interval $[t_k,t_{k+1}]$ depends in a rather complicated way on the relative coordinates inside the cluster $A_{i(k+1)}$ and in a simple way (translation invariance) on the initial coordinate $x_{f(i(k+1))}(0)$. Then the particle $f(j(k+1))$ will be at the point $x_{f(i(k+1))}(t_{k+1})+y_{k+1}$. Thus the initial coordinate of the particle $f(j(k+1))$ is

$$x_{f(i(k+1))}(t_{k+1})+y_{k+1}-x^{(0)}_{f(j(k+1))}(t_{k+1}),$$

where the upper index 0 means that the initial coordinate of the particle $f(j(k+1))$ is 0, and the relative coordinates inside this cluster were fixed in the inductive process. Here we use the translation invariance of the dynamics. It follows that we know now the initial relative coordinate of the particles $f(i(k+1))$ and $f(j(k+1))$, thus all relative initial coordinates inside the new cluster $A_{k+1}=A_{k,i(k+1)}\cup A_{k,j(k+1)}$.

We have, as in case $N=3$, the inductive estimates

$$\rho C v^0 r^{d-1} dt_k$$

for the probabilites of the events

$$G_k([t_k,t_k+dt_k])=\cup_{y_k\in S_{2r}}\cup_{s_k\in[t_k,t_k+dt_k]}G_k(s_k,y_k;t_{k-1},y_{k-1};\dots;t_1,y_1)$$

uniformly in $t_{k-1},y_{k-1},\dots,t_1,y_1$. Then for the product of events

$$\cap_{k=1}^{N-1} G_k([t_k, t_k + \mathrm{d}t_k])$$

we get the estimate

$$\prod_{k=1}^{N-1} \rho C v^0 r^{d-1} \mathrm{d}t_k.$$

Then, using the known formula

$$\int_0^\tau \cdots \int_{t_{N-3}}^\tau \int_{t_{N-2}}^\tau \mathrm{d}t_{N-1} \cdots \mathrm{d}t_1 = \int_0^\tau \cdots \int_0^{t_3} \int_0^{t_2} \mathrm{d}t_1 \cdots \mathrm{d}t_{N-1} = \frac{\tau^{N-2}}{(N-2)!}$$

we get the estimate of Lemma 2.

We assumed throughout the proof that the graph $G_A(0)$ has no clusters other than one-point clusters. If however there are some clusters at time zero, then the proof proceeds along the same lines. Moreover, it is easy to see, using our assumption $r \ll v^0 \tau$, that the cluster probability will be even smaller.

V. EXAMPLE OF DYNAMICS

Here we give an example of dynamics "with chemical reactions," satisfying the above general conditions. This dynamics however will be a random dynamics. In this dynamics randomness occurs because of random initial conditions and random interaction rules of dynamics.

Define first the finite volume dynamics. There are $N(\Lambda) < \infty$ particles in the cube Λ, each particle is characterized at time $t \in R_+$ by its coordinate $x(t) \in \Lambda \subset R^d$, velocity $v(t) \in R^d$ and type $q(t) \in \{1, \ldots, Q\}$. Initial coordinates $x_i(0)$ are distributed uniformly in Λ. The vectors $(q_i(0), v_i(0))$ are independently distributed with densities $p_q(v)$

$$\sum_q \int p_q(v) \mathrm{d}v = 1.$$

We will define a continuous time Markov process $(x_i(t), v_i(t), q_i(t) : i = 1, 2, \ldots, N)$ together with initial data $(x_i(0), v_i(0), q_i(0) : i = 1, 2, \ldots, N)$. It is a mixture of piecewise linear movement for the coordinates and random jumps for the velocities and types. We will not write down the generator of this process, but rather describe it more intuitively. The coordinates are defined as

$$x_i(t, \omega) = x_i(0, \omega) + \int_0^t v_i(t, \omega) \mathrm{d}t.$$

At the same time, any pair of particles i and j (independently of other pairs) at any time interval $(t, t+dt)$ can change their types and velocities with rates

$$\lambda(q_i(t) \,.\, v_i(t), q_j(t) \,.\, v_j(t), x_i(t) - x_j(t)) \chi_{2r}(x_i(t) - x_j(t)),$$

where $\chi_{2r}(x) = 1$ if $|x| \leqslant 2r$, and 0 otherwise. Functions λ are assumed to be bounded. As a result of this jump coordinates do not change, but types and velocities change

$$(q_i, v_i, q_j, v_j) = (q_i, v_i, q_j, v_j)(t) \to (q_i', v_i', q_j', v_j') = (q_i', v_i', q_j', v_j')(t + 0)$$

via conditional probability densities $P(q_i', v_i', q_j', v_j' \,|\, q_i, v_i, q_j, v_j)$ so that for any q_i, v_i, q_j, v_j we have

$$\sum_{q_i', q_j'} \int P(q_i', v_i', q_j', v_j' | q_i, v_i, q_j, v_j) dv_i' dv_j' = 1.$$

Our main assumption that velocities are uniformly bounded that is

$$P(q_i',v_i',q_j',v_j'|q_i,v_i,q_j,v_j)=0$$

if v_i' or v_j' exceed some constant $v^0>0$.

Thus, the velocities and types are piecewise constant on $[0,\infty]$, jumps occur at discrete time moments

$$0<t_1(\omega)<\cdots<t_k(\omega)<\cdots\ .$$

The process is well defined—$x_i(t,\omega)$ exist for any initial data and are piecewise linear a.s. This means that between the jumps the particles move freely with constant velocities $v_i(t)=\mathrm{d}x_i(t)/\mathrm{d}t$ defined a.e.

All previous results for the deterministic dynamics hold for this random dynamics with piecewise random trajectories as well. In this example, from this one can easily prove, in particular, the existence of the thermodynamic limit for small times. This limit coincides with the directly and similarly defined infinite particle dynamics.

(Received 3 January 2005; accepted 22 April 2005; published online 16 June 2005)

Two dielectric waveguides coupled through small windows are considered. In the case of single coupling window we prove the existence of an eigenvalue below the threshold. It's estimation is obtained. If there is the periodic set of coupling windows a band below the threshold exists. Using variational estimations of the band edges we prove that there exists a gap between the band and the threshold. This result shows that the system has a property of photonic band gap material (photonic crystal). It can be used for construction of optical fiber systems. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1933046]

I. INTRODUCTION

Photonic band gap materials (also called photonic crystals) have attracted a lot of attention lately. The reason of this is a wealth of expected (and partly achieved) applications. Probably the main feature of these materials is the existence of a gap (stopband) in the frequency spectrum of propagating electromagnetic waves.[1] In spite of the fact that there is a great number of experimental and numerical investigations of photonic crystals, theoretical studies are far from being completed (see, e.g., Refs. 2 and 3). That is why it is interesting to analyze the corresponding systems from the point of theoretical investigations. In this paper we will discuss the system of three dielectric layers. The central layer has large permittivity. Electromagnetic waves, which passed along the layers, are considered. Analysis reduces to investigation of two possible polarizations when the electric field or correspondingly, magnetic field is orthogonal to the boundary. In each case the problem reduces to the scalar equation for the electric field (correspondingly, magnetic field). If electric field E is orthogonal to the system plane, one obtains a two-dimensional Helmholtz equation in the orthogonal cross section of the system, $-\Delta E=\lambda\varepsilon(y)E$, where $\lambda=(\omega/c)^2$, ω, wave frequency; c, speed of light; $\varepsilon(y)$, permittivity. Let us take layers of dielectric material with permittivity of $\varepsilon=\varepsilon_1$, separated by a narrow (with width 2δ) central layer with large $\varepsilon=\varepsilon_2\gg\varepsilon_1$. And there is a number of small slots (with width $2a$) in the central layer. In the case of a single narrow window (with width $2a$) in the central strip it was shown in Refs. 2 and 4 that under the assumption that $\varepsilon\delta\to 0$ or $\varepsilon\delta\to$const ($\varepsilon=\varepsilon_2-\varepsilon_1$) (i.e., for high contrast), the spectrum of the Helmholtz operator splits into two parts. One part is related with the transport properties of a narrow dielectric waveguide. The second one is close to the spectrum of the Helmholtz operator for the domain with the narrow strip replaced by a line with the Dirichlet boundary condition. Variational estimation of the bound state close to the threshold for the Dirichlet case was obtained in Refs. 5 and 6. In the case of the periodic system of narrow windows (with width $2a$) in the central strip of zero width, the asymptotics of the band edges was obtained in Ref. 7. Variational estimates of the band were obtained in Ref. 8.

The present paper has the following structure. At first, we describe the idea of the proof of the existence of eigenvalue below the threshold. We use the variational approach and the proof reduces to the obtaining of the corresponding estimations. The second section is devoted to the method of the trial function construction and to the description of the way of the main ratio estimation. The next section contains the proof of the eigenvalue existence for the case of single coupling window (the geometry of the system is shown in Fig. 1). Then we consider the case of the periodic set of coupling windows (see Fig. 2). Here we prove that there exists a band below the

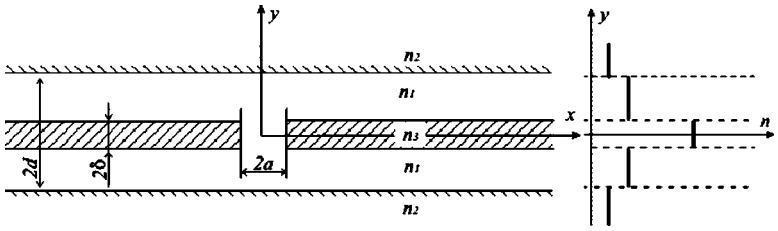

FIG. 1. Three-layer dielectric waveguide with a single coupling window.

threshold and obtain variational estimation of the gap. Note that this band belongs to the part of the spectrum which is close to the spectrum of the corresponding Dirichlet problem (see above). Thus, the described system has the spectral property which is analogous to that of a photonic crystal. The appendix contains some calculations, which are omitted in the main text.

II. THE METHOD OF THE PROOF

It is assumed that in the corresponding three-dimensional problem we deal with polarized monochromatic light (the case of TE modes is considered, i.e., $E_x=0$) passes along x axis. The layers are unbounded in the directions of x and z. Under these assumptions, mode solutions for a one-layer planar waveguide (with the refraction index n) are obtained from the Helmholtz equation for E_z [harmonic dependence on time t ($e^{i\omega t}$) is taken into account],

$$\frac{\partial^2 E_z}{\partial y^2} + \frac{\partial^2 E_z}{\partial x^2} + n^2 k_0^2 E_z = 0, \tag{1}$$

where $k_0=\omega\sqrt{\varepsilon_0\mu_0}$ and $n^2=\varepsilon/\varepsilon_0$. For the harmonic dependence of E_z on x and time t, $e^{i(\omega t-\lambda x)}$, one gets

$$\frac{\partial^2 E_z}{\partial y^2} + (n^2 k_0^2 - \lambda^2) E_z = 0, \tag{2}$$

where λ^2 is an eigenvalue of the corresponding boundary problem. Mode solutions for a multilayer waveguide are obtained by matching together the solutions for each layer. We take

$$E_z = \Psi(x,y).$$

Then for each layer we can write

$$\frac{\partial^2 \Psi_i}{\partial y^2} + (n_i^2 k_0^2 - \lambda^2)\Psi = 0,$$

where $i=1,2,3$—the number of the layer. Eigenfunction Ψ can be constructed using Ψ_1, Ψ_2, and Ψ_3. It satisfies the equation

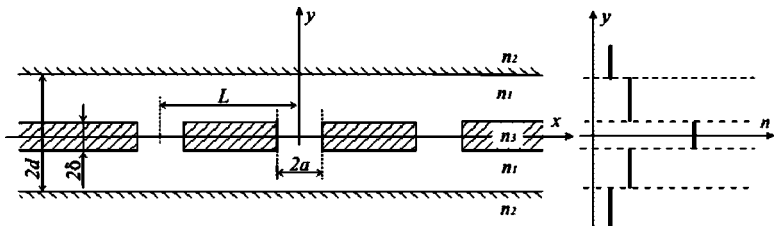

FIG. 2. Three-layer dielectric waveguide with the periodic set of coupling windows.

$$\frac{\partial^2\Psi}{\partial y^2} + (n^2k_0^2 - \lambda^2)\Psi = 0, \tag{3}$$

where

$$n = \begin{cases} n_1, & y \in [-d,-\delta] \cup [\delta,d], \\ n_2, & y \in [-\infty,-d] \cup [d,\infty], \\ n_3, & y \in [-\delta,\delta]. \end{cases} \tag{4}$$

Our system is symmetric. Hence, it is sufficient to analyze the system only for $y \geqslant 0$. The boundary conditions at $y=\delta$ and $y=d$ are

$$\begin{aligned} \Psi_2|_{(y=d)} &= \Psi_1|_{(y=d)}, \quad \left.\frac{\partial\Psi_2}{\partial y}\right|_{(y=d)} = \left.\frac{\partial\Psi_1}{\partial y}\right|_{(y=d)}, \\ \Psi_3|_{(y=\delta)} &= \Psi_1|_{(y=\delta)}, \quad \left.\frac{\partial\Psi_3}{\partial y}\right|_{(y=\delta)} = \left.\frac{\partial\Psi_1}{\partial y}\right|_{(y=\delta)}, \end{aligned} \tag{5}$$

where $\Psi_1 = \Psi|_{(\delta \leqslant y \leqslant d)}$, $\Psi_2 = \Psi|_{(d \leqslant y \leqslant \infty)}$, $\Psi_3 = \Psi|_{(0 \leqslant y \leqslant \delta)}$. We will construct an approximation of the eigenfunction $\hat{\Psi}$ for the case when there exists coupling windows as a perturbation of Ψ. That is in the corresponding two-dimensional problem the function $\hat{\Psi}$ satisfies the equation $H\hat{\Psi} - n^2k_0^2\hat{\Psi} = 0$, where $H = -\Delta$ is the Laplacian with the matching conditions at the interfaces. In accordance with the variational principles if there exists a trial function $\hat{\Psi}$ (satisfying the matching conditions at the interfaces) such that the following ratio is negative:

$$\frac{(H\hat{\Psi},\hat{\Psi}) - \|\hat{\Psi}\sqrt{n^2k_0^2 - \lambda^2}\|^2}{\|\hat{\Psi}\|^2} \leqslant 0, \tag{6}$$

then there exists an eigenvalue Λ^2 less than the threshold, $\Lambda^2 < \lambda^2$. Note that we work in the orthogonal subspace to the subspace corresponding to the first branch of the continuous spectrum (with zero lower bound), i.e., $\hat{\Psi}$ satisfies the orthogonality condition. Thus, the idea is to find a trial function $\hat{\Psi}$ which makes the ratio

$$\frac{M(\hat{\Psi})}{\|\hat{\Psi}\|^2} \tag{7}$$

negative, where

$$M(\hat{\Psi}) = (H\hat{\Psi},\hat{\Psi}) - \|\hat{\Psi}\sqrt{n^2k_0^2 - \lambda^2}\|^2. \tag{8}$$

We take the trial function $\hat{\Psi}$ as

$$\hat{\Psi} = F + G, \tag{9}$$

where

$$F = \alpha v(y) f(x), \tag{10}$$

$$v(y) = \begin{cases} N_3 \sin(\mu y), & y \in [0,\delta], \\ N_1 \cos(\nu y) + M_1 \sin(\nu y), & y \in [\delta,d], \\ N_2 e^{-\gamma(y-d)}, & y \in [d,\infty], \end{cases} \tag{11}$$

$$\gamma = \sqrt{\lambda^2 - n_2^2 k_0^2}, \quad \nu = \sqrt{\lambda^2 - n_1^2 k_0^2}, \quad \mu = \sqrt{n_3^2 k_0{}^2 - \lambda^2}, \tag{12}$$

$$G = \eta r(y) g(x), \tag{13}$$

$$r(y) = \begin{cases} e^{-\pi y/2a} + t_1, & y \in [0, d/2], \\ \dfrac{2t_2}{d}(d - y), & y \in [d/2, d], \\ 0, & y \in [d, \infty], \end{cases} \tag{14}$$

where α, η are free parameters of the trial function, 2δ is the width of the central layer, $2d$ is the width of the three-layered waveguide,

$$t_1 = \frac{2}{\pi d}\left[e^{-\pi d/4a}\left(4a + \frac{\pi d}{2}\right) - 4a \right],$$

$$t_2 = \frac{2}{\pi d}[e^{-\pi d/4a}(4a + \pi d) - 4a].$$

The functions $v(y)$ and $r(y)$ are y symmetrical. t_1 and t_2 are chosen in such a way that the corresponding functions satisfy the orthogonality condition

$$\int_{-d}^{d} v(y)dy = 0, \quad \int_{-d}^{d} r(y)dy = 0.$$

The functions $f(x)$ and $g(x)$ will be defined later. Now it is important that in general the values of $f(x)$ and $g(x)$ are complex. In the case of a single narrow window these functions will meet the requirements

$$f(\infty) = f(-\infty) = 0,$$

$$g(\infty) = g(-\infty) = 0. \tag{15}$$

In the case of the periodic system of narrow windows (with period L), these functions will meet Bloch's condition

$$f(x + L) = e^{i\theta L} f(x),$$

$$g(x + L) = e^{i\theta L} g(x). \tag{16}$$

Lemma 1: The trial function $\hat{\Psi}$ defined in (9)–(16) satisfies the following condition:

$$(H\hat{\Psi}, \hat{\Psi}) = \|\hat{\Psi}_x\|^2 + \|\hat{\Psi}_y\|^2. \tag{17}$$

Proof: Here we mark $\hat{\Psi}$ as Ψ for simplification. We can write

$$(H\Psi, \Psi) = \int\int \frac{\partial^2 \Psi}{\partial^2 x} \overline{\Psi}\, \mathrm{d}x\, \mathrm{d}y + \int\int \frac{\partial^2 \Psi}{\partial^2 y} \overline{\Psi}\, \mathrm{d}x\, \mathrm{d}y. \tag{18}$$

Using integration by parts we can write the first term in (18) as

$$\int\int \frac{\partial^2\Psi}{\partial^2 x}\overline{\Psi}\,dx\,dy = \int\int \frac{\partial^2(F+G)}{\partial^2 x}(\overline{F}+\overline{G})dx\,dy$$
$$= \int_{-\infty}^{\infty} \frac{\partial(F+G)}{\partial x}(\overline{F}+\overline{G})\Big|_{X_{\min}}^{X_{\max}} dy + \int_{-\infty}^{\infty}\int_{X_{\min}}^{X_{\max}} \frac{\partial(F+G)}{\partial x}\frac{\partial(\overline{F}+\overline{G})}{\partial x}dx\,dy$$
$$= \int_{-\infty}^{\infty} \frac{\partial(F+G)}{\partial x}(\overline{F}+\overline{G})\Big|_{X_{\min}}^{X_{\max}} dy + \|\Psi_x\|^2, \tag{19}$$

and the second term in (18) as

$$\int\int \frac{\partial^2\Psi}{\partial^2 y}\overline{\Psi}\,dx\,dy = \int\int \frac{\partial^2(F+G)}{\partial^2 y}(\overline{F}+\overline{G})dx\,dy$$
$$= \int_{X_{\min}}^{X_{\max}} \frac{\partial(F+G)}{\partial y}(\overline{F}+\overline{G})\Big|_{-\infty}^{\infty} dx + \int_{X_{\min}}^{X_{\max}}\int_{-\infty}^{\infty} \frac{\partial(F+G)}{\partial y}\frac{\partial(\overline{F}+\overline{G})}{\partial y}dx\,dy$$
$$= \int_{X_{\min}}^{X_{\max}} \frac{\partial(F+G)}{\partial y}(\overline{F}+\overline{G})\Big|_{-\infty}^{\infty} dx + \|\Psi_y\|^2. \tag{20}$$

It follows from the definitions (10)–(14) that

$$v(\infty) = v(-\infty) = 0, \quad r(\infty) = r(-\infty) = 0.$$

Then the first term on the right-hand side of (20) is equal to zero

$$\frac{\partial(F+G)}{\partial y}(\overline{F}+\overline{G})\Big|_{y=-\infty}^{y=\infty} = 0.$$

At last, we need to calculate the first term on the right-hand side of (19). In the case of a single narrow window we have

$$X_{\min} = -\infty, \quad X_{\max} = \infty,$$

then from conditions (15)

$$\frac{\partial(F+G)}{\partial x}(\overline{F}+\overline{G})\Big|_{X_{\min}}^{X_{\max}} = \frac{\partial(F+G)}{\partial x}(\overline{F}+\overline{G})\Big|_{x=-\infty}^{x=\infty} = 0.$$

In the case of the periodic system of narrow windows we have

$$X_{\min} = -L/2, \quad X_{\max} = L/2,$$

then from the conditions (16)

$$\frac{\partial(F+G)}{\partial x}(\overline{F}+\overline{G})\Big|_{X_{\min}}^{X_{\max}} = \frac{\partial(F+G)}{\partial x}(\overline{F}+\overline{G})\Big|_{x=-L/2}^{x=L/2} = 0.$$

Q.E.D.

It's easy to see, that $\hat{\Psi}$ is symmetrical in y direction, so we will take interval $0 \leqslant y \leqslant \infty$.

Lemma 2: The form $M(\Psi)$ for the trial function $\hat{\Psi}$ defined in (9)–(14) can be represented as follows:

$$M(\hat{\Psi}) = \|F_x\|^2 + \|G_x\|^2 + \|G_y\|^2 + \int_0^d \int_{X_{\min}}^{X_{\max}} (\overline{F}_x \overline{G}_x + F_x G_x)\mathrm{d}x\,\mathrm{d}y - \|G\sqrt{n^2k_0^2 - \lambda^2}\|^2$$
$$- \int_{X_{\min}}^{X_{\max}} [\overline{F}_y(x,0)\overline{G}(x,0) + F_y(x,0)G(x,0)]\mathrm{d}x. \tag{21}$$

Proof: We get from (8), by Lemma 1, after some calculations

$$M(\hat{\Psi}) = \|\hat{\Psi}_x\|^2 + \|\hat{\Psi}_y\|^2 - \|\hat{\Psi}\sqrt{n^2k_0^2 - \lambda^2}\|^2 = \|F_x\|^2 + \|G_x\|^2 + \|G_y\|^2 + \int_0^d \int_{X_{\min}}^{X_{\max}} (\overline{F}_y \overline{G}_y + F_y G_y)\mathrm{d}x\,\mathrm{d}y$$
$$+ \int_0^d \int_{X_{\min}}^{X_{\max}} (\overline{F}_x \overline{G}_x + F_x G_x)\mathrm{d}x\,\mathrm{d}y - \left[\|G\sqrt{n^2k_0^2 - \lambda^2}\|^2 + \int_0^d \int_{X_{\min}}^{X_{\max}} (\overline{FG} + FG)(n^2k_0^2 \right.$$
$$\left. - \lambda^2)\mathrm{d}x\,\mathrm{d}y \right]. \tag{22}$$

Using integration by parts, we reduce the first integral in the previous formula to the following expression:

$$\int_0^d \int_{X_{\min}}^{X_{\max}} (\overline{F}_y \overline{G}_y + F_y G_y)\mathrm{d}x\,\mathrm{d}y = \int_0^d \int_{X_{\min}}^{X_{\max}} \overline{F}_y \overline{G}_y\,\mathrm{d}x\,\mathrm{d}y + \int_0^d \int_{X_{\min}}^{X_{\max}} F_y G_y\,\mathrm{d}x\,\mathrm{d}y$$
$$= - \int_{X_{\min}}^{X_{\max}} [\overline{F}_y(x,0)\overline{G}(x,0) + F_y(x,0)G(x,0)]\mathrm{d}x$$
$$- \int_{X_{\min}}^{X_{\max}} \int_0^d (\overline{F}_{yy}\overline{G} + F_{yy}G)\mathrm{d}y\,\mathrm{d}x, \tag{23}$$

where

$$\int_{X_{\min}}^{X_{\max}} [\overline{F}_y(x,d)\overline{G}(x,d) + F_y(x,d)G(x,d)] = 0,$$

because $G(x,d) = \overline{G}(x,d) = 0$. The absolute value of the last term in (23) is equal to the absolute value of the last term in (22)

$$\int_0^d \int_{X_{\min}}^{X_{\max}} [\overline{F}_{yy}\overline{G} + F_{yy}G]\mathrm{d}y\,\mathrm{d}x = -\alpha\eta \int_0^d r(y)v(y)(n^2k_0^2 - \lambda^2)\mathrm{d}y \int_{X_{\min}}^{X_{\max}} [\overline{f}(x)\overline{g}(x) + f(x)g(x)]\mathrm{d}x, \tag{24}$$

$$\int_0^d \int_{X_{\min}}^{X_{\max}} [\overline{FG} + FG](n^2k_0^2 - \lambda^2)\mathrm{d}x\,\mathrm{d}y = \alpha\eta \int_0^d r(y)v(y)(n^2k_0^2 - \lambda^2)\mathrm{d}y \int_{X_{\min}}^{X_{\max}} [\overline{f}(x)\overline{g}(x) + f(x)g(x)]\mathrm{d}x. \tag{25}$$

To obtain (21) it is necessary to substitute (23)–(25) into (22). Q.E.D.

This lemma will help us to estimate the ratio (7) for two different cases of the system geometry (a single narrow window and the periodic system of narrow windows).

III. THE CASE OF SINGLE NARROW WINDOW

We will analyze here a two-dimensional three-layered dielectric waveguide with one narrow window (width $2a$) in the central layer (Fig. 1). In this case for the full definition of $\hat{\Psi}$ in (9) we choose

$$f(x) = \min\{1, e^{-q(|x|-a)}\}, \tag{26}$$

$$g(x) = \begin{cases} \cos(\pi x/2a), & x \in [-a,a], \\ 0, & x \in [-\infty,-a] \cup [a,\infty]. \end{cases} \tag{27}$$

Theorem 1: The ratio (7) is negative for the trial function $\hat{\Psi}$ described in (9)–(14), (26), and (27), and

$$\frac{M(\hat{\Psi})}{\|\hat{\Psi}\|^2} \leqslant -\frac{a^4 2^9 N_3^4}{\pi^6 \mu^4 (1+\epsilon)^2 N_{vv}^2}, \tag{28}$$

where N_3, N_{vv} are positive constants, $\epsilon \sim e^{-\pi d/2a}$.

Proof: For the proof we need to estimate all terms in (21), Lemma 2. At first, we estimate $\|G_y\|^2$, $\|G_x\|^2$, $\|G\|^2$, and $\|G\sqrt{n^2k_0^2-\lambda^2}\|^2$,

$$\|G_x\|^2 = \int_{-a}^{a}\int_{0}^{\infty} G_x^2 \,\mathrm{d}y\,\mathrm{d}x < \tfrac{1}{2}\pi\eta^2(1+\epsilon),$$

$$\|G\|^2 = \eta^2 \int_0^\infty r(y)^2 \,\mathrm{d}y \int_{-a}^{a} g(x)^2 \,\mathrm{d}x, \tag{29}$$

$$\|G\sqrt{n^2k_0^2-\lambda^2}\|^2 = \eta^2 \int_0^\infty r(y)^2 (n(y)^2k_0^2-\lambda^2)\mathrm{d}y \int_{-a}^{a} g(x)^2 \,\mathrm{d}x < \eta^2\nu^2\frac{a^2}{\pi}\left(1+\frac{32a}{3d\pi}\right),$$

where $\epsilon > 0$ and $\epsilon \sim e^{-\pi d/2a}$. Then we estimate $\|F_x\|^2$,

$$\|F_x\|^2 = \int_{-\infty}^{\infty}\int_{0}^{\infty} \overline{F}_x F_x \,\mathrm{d}y\,\mathrm{d}x = \alpha^2 \int_0^\infty v(y)^2 \,\mathrm{d}y \int_{-\infty}^{\infty} \overline{f}_x(x) f_x(x)\mathrm{d}x = \alpha^2 N_{vv} q,$$

where N_{vv} is some non-negative constant. The calculations of the integrals in (21) (Lemma 2) gives us

$$\begin{aligned}\int_{-a}^{a} G(x,0)[\overline{F}_y(x,0) + F_y(x,0)]\mathrm{d}x &= \alpha\eta \int_{-a}^{a} r(0)v(0)g(x)(\overline{f}(x) + f(x))\mathrm{d}x \\ &= \alpha\eta N_3 \int_{-a}^{a} g(x)(\overline{f}(x) + f(x))\mathrm{d}x = \alpha\eta N_3 \frac{8a}{\pi},\end{aligned} \tag{30}$$

$$\int_0^d \int_{-a}^{a} G_x(\overline{F}_x + F_x)\mathrm{d}x\,\mathrm{d}y = \alpha\eta \int_0^\infty r(y)v(y)\mathrm{d}y \int_{-a}^{a} g_x(x)(\overline{f}_x(x) + f_x(x))\mathrm{d}x = 0, \tag{31}$$

due to the equality $f_x(x) = 0$ on the interval $[-a,a]$. Now we can write the estimation of $M(\hat{\Psi})$. After the substitution of (29)–(31) into (21) we get

$$M(\hat{\Psi}) \leqslant \frac{\pi\eta^2}{2}(1+\epsilon) + \alpha^2 N_{vv} q - \alpha\eta \frac{N_3}{\mu}\frac{8a}{\pi}. \tag{32}$$

α, η, and q are free parameters and one can choose their values by an appropriate way. To get the upper boundary of the ratio (7) we minimize (32) by η (η^* is corresponding minimizing value),

$$\eta^* = \frac{\alpha a 2^3 N_3}{\mu\pi^2(1+\epsilon)},$$

$$M(\hat{\Psi}) \leqslant -\frac{\alpha^2 a^2 2^5 N_3^2}{\pi^3\mu^2(1+\epsilon)} + \alpha^2 N_{vv} q. \tag{33}$$

The estimation of $\|\hat{\Psi}\|^2$ is

$$\|\hat{\Psi}\|^2 \leqslant 2\|F\|^2_{a<x<\infty} + 2\|F\|^2_{-a<x<a} + 2\|G\|^2_{-a<x<a} = 2(\|F\|^2_{a<x<\infty} + \|F\|^2_{-a<x<a}) + 2a\eta^2\|r\|^2, \tag{34}$$

where

$$\|F\|^2_{-a<x<a} = \alpha^2 N_{vv}\int_{-a}^{a} \overline{f(x)} f(x)\mathrm{d}x = \alpha^2 N_{vv} 2a,$$

$$\|F\|^2_{a<x<\infty} = \alpha^2 N_{vv}\int_{a}^{\infty} \overline{f(x)} f(x)\mathrm{d}x = \alpha^2 N_{vv}\frac{1}{2q}.$$

The estimation of the ratio (7) follows from (32) and (34)

$$\frac{M(\Psi)}{\|\Psi\|^2} \leqslant -\frac{a^2 2^6 N_3^2}{\pi^3\mu^2(1+\epsilon)N_{vv}} q + 2q^2. \tag{35}$$

Now we need to choose the parameter q. Therefore we minimize the last ratio estimation by q (q^* is the corresponding minimizing value),

$$q^* = \frac{a^2 2^4 N_3^2}{\pi^3\mu^2(1+\epsilon)N_{vv}},$$

$$\frac{M(\Psi)}{\|\Psi\|^2} \leqslant -\frac{a^4 2^9 N_3^4}{\pi^6\mu^4(1+\epsilon)^2 N_{vv}^2}. \tag{36}$$

Q.E.D.

Thus, we have proved that there exists a bound state below the threshold and simultaneously obtained it's estimation.

IV. THE CASE OF THE PERIODIC SET OF NARROW WINDOWS

In this section we estimate the ratio (7) for three-layer dielectric waveguide with the periodic set of narrow windows (of widths $2a$) in the central layer (Fig. 2). The trial function $\hat{\Psi}$ in this case satisfies the Bloch's condition,

$$\hat{\Psi}(x+nL,y) = e^{i\theta nL}\hat{\Psi}(x,y), \tag{37}$$

where θ is the quasimomentum, L is a period, $-\pi/L \leqslant \theta \leqslant \pi/L$. It is sufficient to describe the trial function $\hat{\Psi}$ on the segment $[-L/2, L/2]$ (one period). According to (9)–(14) and (16), functions $f(x)$ and $g(x)$ satisfies the Bloch's condition. Let

$$f(x) = \sum_{n=-\infty}^{\infty} f_i(x,n)e^{-i\theta nL}, \tag{38}$$

where

$$f_i(x,n) = \begin{cases} e^{q(x+a)-qLn}, & x \in [nL - L/2, nL - a], \\ 1, & x \in [nL - a, nL + a], \\ e^{-q(x-a)+qLn}, & x \in [nL + a, nL + L/2]. \end{cases}$$

The function $f(x)$ on the segment $[-L/2, L/2]$ is described in the following manner:

$$f(x)_{[-L/2,-a]} = e^{q(x+a)} + e^{q(x+a)}A + e^{-q(x-a)}B,$$

$$f(x)_{[-L/2,-a]} = 1 + e^{q(x+a)}A + e^{-q(x-a)}B, \tag{39}$$

$$f(x)_{[-L/2,-a]} = e^{-q(x-a)} + e^{q(x+a)}A + e^{-q(x-a)}B,$$

where

$$A = \sum_{n=1}^{\infty} e^{-qnL-i\theta n} = \frac{e^{-qL-i\theta L}}{1 - e^{-qL-i\theta L}}, \tag{40}$$

$$B = \sum_{n=-1}^{-\infty} e^{qnL-i\theta n} = \frac{e^{-qL+i\theta L}}{1 - e^{-qL+i\theta L}}, \tag{41}$$

and

$$\overline{A} = B, \quad \overline{B} = A, \quad A^2 = B^2 = AB. \tag{42}$$

Let

$$g(x) = \sum_{-\infty}^{\infty} \chi_{[nL-a,nL+a]}e^{-i\theta nL} \cos\left(\frac{\pi(x - nL)}{2a}\right), \tag{43}$$

where $\chi_{[nL-a,nL+a]}$ is the characteristic function of the interval $[nL-a, nL+a]$.

Lemma 3: The functions $f(x)$ and $g(x)$, defined in (38) and (43), satisfy the Bloch's condition.

Proof: For the functions $f(x)$ and $g(x)$ we have

$$f(x+L) = \sum_{n=-\infty}^{\infty} f_i(x + (n+1)L)e^{-i\theta nL} = e^{i\theta L}f(x),$$

$$g(x+L) = \sum_{n=-\infty}^{\infty} \chi_{[nL-a,nL+a]}e^{-i\theta nL} \cos\left(\frac{\pi(x - (n-1)L)}{2a}\right) = e^{-i\theta L}g(x).$$

Q.E.D.

Theorem 2: For the trial function $\hat{\Psi}$, defined in (9)–(14), (38), and (43), the ratio (7) is negative, and

$$\frac{M(\hat{\Psi})}{\|\hat{\Psi}\|^2} \leqslant -ac, \tag{44}$$

where c is some non-negative constant.

Proof: For the proof we need to estimate all terms in (21), Lemma 2. Estimations of $\|G_y\|^2$, $\|G_x\|^2$, $\|G\|^2$, and $\|G\sqrt{n^2k_0^2-\lambda^2}\|^2$ will not change in the case of the periodic system of narrow windows, so we can get them from (29), Theorem 1. We need to calculate other terms in (21). At first, we estimate $\|F_x\|^2$,

$$\|F_x\|^2 = \int_{-L/2}^{L/2}\int_0^\infty \overline{F}_x F_x \,\mathrm{d}y\,\mathrm{d}x = \alpha^2 \int_0^\infty v(y)^2\,\mathrm{d}y \int_{-L/2}^{L/2} \overline{f}_x(x) f_x(x)\mathrm{d}x = \alpha^2 N_{vv} q e^{2qa}\Phi_1(A,B), \tag{45}$$

where

$$\Phi_1(A,B) = 2AB[\sinh(qL) - \sinh(2qa) - qL + 2qa] - (A+B)[qL - 2qa + e^{-qL} - e^{-2qa}] - [e^{-qL} - e^{-2qa}] \geqslant 0,$$

and the constant N_{vv} is non-negative. Then we write the estimations of integral terms in (21),

$$\begin{aligned}\int_{-a}^{a} G(x,0)[\overline{F}_y(x,0) + F_y(x,0)]\mathrm{d}x &= \alpha\eta\int_a^a r(0)v(0)g(x)(\overline{f}(x) + f(x))\mathrm{d}x \\ &= \alpha\eta N_3 \int_{-a}^{a} g(x)(\overline{f}(x) + f(x))\mathrm{d}x = \alpha\eta N_3 \\ &\quad \left[\frac{8a}{\pi} + \frac{8e^{qa}(A+B)a\pi\cosh(qa)}{4q^2a^2+\pi^2}\right],\end{aligned} \tag{46}$$

$$\begin{aligned}\int_0^d\int_{-a}^{a} G_x(\overline{F}_x + F_x)\mathrm{d}x\,\mathrm{d}y &= \alpha\eta\int_0^\infty r(y)v(y)\mathrm{d}y\int_{-a}^{a} g_x(x)(\overline{f}_x(x) + f_x(x))dx \\ &= \alpha\eta a N_{vr}\int_{-a}^{a} g_x(x)(\overline{f}_x(x) + f_x(x))\mathrm{d}x \\ &= \alpha\eta a N_{vr}\left[-\frac{8q^2e^{qa}(A+B)\pi a\cosh(qa)}{4q^2a^2+\pi^2}\right],\end{aligned} \tag{47}$$

where constants N_3, N_{vr} are non-negative. Now we can write the estimation of $M(\hat{\Psi})$. After substitution of (29) and (45)–(47) into (21) we get

$$M(\Psi) \leqslant \frac{\pi\eta^2}{4}(1+2\epsilon) + \alpha^2 N_{vv} q e^{2qa}\Phi_1(A,B) - \alpha\eta\left[N_3\frac{8a}{\pi} + \Phi_2(A,B)(N_3 + aN_{vr}q^2)\right], \tag{48}$$

where

$$\Phi_2(A,B) = \frac{8e^{qa}(A+B)a\pi\cosh(qa)}{4q^2a^2+\pi^2}.$$

Now we need to choose the parameter η. Therefore, we minimize the right-hand part of $M(\hat{\Psi})$ by η (η^* is the minimizing value),

$$\eta^* = 2\frac{\alpha(8N_3a + \Phi_2(A,B)\pi[N_3 + aN_{vr}q^2])}{\pi^2(1+2\epsilon)},$$

$$M(\hat{\Psi}) \leqslant \alpha^2\left(-\frac{(8N_3a + \Phi_2(A,B)\pi[N_3 + aN_{vr}q^2])^2}{\pi^3(1+2\epsilon)} + N_{vv}qe^{2qa}\Phi_1(A,B)\right). \tag{49}$$

The estimation of $\|\hat{\Psi}\|^2$ has the form

$$\|\hat{\Psi}\|^2 \leqslant 2\|F\|^2_{a<x<(L/2)} + 2\|F\|^2_{-a<x<a} + 2\|G\|^2_{-a<x<a} = 2(\|F\|^2_{a<x<(L/2)} + \|F\|^2_{-a<x<a}) + 2a\eta^2\|r\|^2, \tag{50}$$

where

$$\|F\|^2_{-a<x<a} = \alpha^2 N_{vv}\int_{-a}^{a}\overline{f(x)}f(x)\mathrm{d}x = \alpha^2 N_{vv}\Phi_3(A,B),$$

$$\Phi_3(A,B) = 2a + 4e^{qa}(A+B)\frac{\sinh(qa)}{q} + 2e^{2qa}AB\left(2a + \frac{\sinh(2qa)}{q}\right), \tag{51}$$

and

$$\|F\|^2_{a<x<L/2} = \alpha^2 N_{vv}\int_{a}^{L/2}\overline{f(x)}f(x)\mathrm{d}x = \alpha^2 N_{vv}\tfrac{1}{2}e^{2qa}\Phi_4(A,B),$$

$$\Phi_4(A,B) = \frac{(-e^{-qL} + e^{-2qa})}{q} + (A+B)\left[L - 2a + \frac{(-e^{-qL} + e^{-2qa})}{q}\right] + 2AB\left[L - 2a + \frac{(\sinh(qL) - \sinh(2qa))}{q}\right]. \tag{52}$$

The theorem must be proved for all values of the quasimomentum θ. It is easy to see that the parameter θ is in the functions $\Phi_i(A,B)$ only. So we need to calculate the expressions $(A+B)$ and (AB),

$$(A+B) = -\frac{\cosh(Lq) - \sinh(Lq) - \cos(L\theta)}{\cosh(Lq) - \cos(L\theta)}, \tag{53}$$

$$(AB) = \frac{\cosh(Lq) - \sinh(Lq)}{2\cosh(Lq) - 2\cos(L\theta)}. \tag{54}$$

Note, that when $q\to 0$, $\theta\to 0$ the denominator tends to zero. Hence, this case should be treated especially. Let q be sufficiently small (e.g., $q\sim a^2$), but not equal to zero. Then we can expand the right-hand sides of formulas (53) and (54) in series (by q)

$$(A+B) = -\left[1 - \frac{Lq + \frac{1}{6}L^3q^3 + \frac{1}{120}L^5q^5 + O(q^7)}{1 + \frac{1}{2}L^2q^2 + \frac{1}{24}L^4q^4 + O(q^6) - \cos(L\theta)}\right],$$

$$(AB) = \frac{1}{2}\frac{1 - Lq + \frac{1}{2}L^2q^2 - \frac{1}{6}L^3q^3 + \frac{1}{24}L^4q^4 - \frac{1}{120}L^5q^5 + O(q^6)}{1 + \frac{1}{2}L^2q^2 + \frac{1}{24}L^4q^4 + O(q^6) - \cos(L\theta)},$$

where $-\pi\leqslant L\theta\leqslant\pi$. Here we split the proof into two parts, when $L\theta\neq 2\pi n$ and when $L\theta\to 2\pi n$. In the first case $\cos(L\theta)\neq 1$, then

$$(A+B) = -\left(1 - \frac{Lq + O(q^3)}{1 - \cos(L\theta) + \frac{1}{2}L^2q^2 + O(q^4)}\right) \sim -C_1(\theta),$$

$$(AB) = \frac{1}{2}\frac{1 - Lq + O(q^2)}{1 - \cos(L\theta) + \frac{1}{2}L^2q^2 + O(q^4)} \sim C_2(\theta),$$

where $0 < C_1(\theta) < 1$, $0 < C_2(\theta)$. Then

$$\Phi_1 = 2(AB)[\sinh(qL) - \sinh(2qa) - qL + 2qa] - (A+B)[qL - 2qa + e^{-qL} - e^{-2qa}] - [e^{-qL} - e^{-2qa}]$$
$$\sim q(L-2a) + O(q^2), \tag{55}$$

$$\Phi_2 = \frac{8e^{qa}(A+B)a\pi\cosh(qa)}{4q^2a^2 + \pi^2} \sim -8\frac{aC_1(\theta)}{\pi}(1+a), \tag{56}$$

$$\Phi_3 = 2a + 4e^{qa}(A+B)\frac{\sinh(qa)}{q} + 2e^{2qa}AB\left(2a + \frac{\sinh(2qa)}{q}\right)$$
$$\sim a(2 - 4C_1(\theta) + 8C_2(\theta)) + 4a^2q(-C_1(\theta) + 4C_2(\theta)) + O(q^2a^3) > 0, \tag{57}$$

$$\Phi_4 = \frac{(-e^{-qL} + e^{-2qa})}{q} + (A+B)\left[L - 2a + \frac{(-e^{-qL} + e^{-2qa})}{q}\right]$$
$$+ 2AB\left[L - 2a + \frac{(\sinh(qL) - \sinh(2qa))}{q}\right]$$
$$\sim (2L - 4a)[-C_1(\theta) + 2C_2(\theta)] + q[-C_1(\theta)(-1/2L^2 + 2a^2) + L - 2a] + O(q^2) > 0. \tag{58}$$

At last, we have from (49), (55), and (56),

$$M(\hat{\Psi}) \leqslant \alpha^2\left(-\frac{a^2 2^6[N_3 - C_1(\theta)(1+a)(N_3 + aN_v r q^2)]^2}{\pi^3(1+2\epsilon)} + N_{vv}q^2e^{2qa}(L-2a)\right). \tag{59}$$

And the denominator $\|\hat{\Psi}\|^2$ is

$$\|\hat{\Psi}\|^2 \leqslant \alpha^2 2N_{vv}[\Phi_3 + 1/2e^{2qa}\Phi_4] = \alpha^2 2N_{vv}C_\psi(\theta) > 0, \tag{60}$$

where

$$C_\psi(\theta) = a[2 - 4C_1(\theta) + 8C_2(\theta)] + 1/2e^{2qa}(2L - 4a)[-C_1(\theta) + 2C_2(\theta)] + O(q) > 0.$$

From (59) and (60) we get the ratio

$$\frac{M(\hat{\Psi})}{\|\Psi\|^2} \leqslant -\frac{a^2 2^6[N_3 - C_1(\theta)(1+a)(N_3 + aN_{vr}q^2)]^2}{\pi^3(1+2\epsilon)N_{vv}2C_\psi(\theta)} + \frac{q^2e^{2qa}(L-2a)}{2C_\psi(\theta)}. \tag{61}$$

Thus for

$$q^2 < \frac{a^2 2^6[N_3 - C_1(\theta)(1+a)(N_3 + aN_{vr}q^2)]^2}{\pi^3(1+2\epsilon)N_{vv}e^{2qa}(L-2a)} \tag{62}$$

and $L\theta \neq 0$ the theorem is proved. In the case $L\theta \to 0$ we expand $\cos(L\theta)$ in series in expressions $(A+B)$ and (AB),

$$(A+B) \sim -\left[1 - \frac{Lq + O(q^3)}{1/2(L^2q^2 + L^2\theta^2) + O(q^6 + \theta^6)}\right], \tag{63}$$

$$(AB) \sim \frac{1}{2}\frac{1}{1/2(L^2q^2 + L^2\theta^2) + O(q^6 + \theta^6)}, \tag{64}$$

If θ is sufficiently small like q or q^2 (or even if $\theta=0$) we can write

$$(A+B) \sim \frac{1}{Lq}C_1, \tag{65}$$

$$(AB) \sim \frac{1}{L^2q^2}C_2, \tag{66}$$

where C_1, C_2 are non-negative. In this case it is difficult to see the dependencies of θ. Here we calculate an estimation of the ratio (7) as a constant for all $L\theta < q$. Let us see the $\Phi_i(A,B)$ calculations

$$\Phi_1 \leqslant 2(L-2a)q + O(q^2),$$

$$\Phi_2 = \frac{8aC_1}{\pi Lq} + O(1),$$

$$\Phi_3 = \frac{8aC_2}{L^2q^2} + \frac{4a}{Lq}\left(\frac{4aC_2}{L} + C_1\right) + O(1),$$

$$\Phi_4 = 4C_2\frac{L-2a}{L^2q^2} + 2C_1\frac{L-2a}{Lq} + O(1),$$

and then the ratio estimation is

$$\frac{M(\hat{\Psi})}{\|\hat{\Psi}\|^2} \leqslant -\frac{2^4aC_1^2(1+\epsilon_1)}{\pi^2(1+2\epsilon)2N_{vv}(8C_2 + O(q))} + \frac{q^4e^{2qa}(L-2a)}{a(8C_2 + O(q))}, \tag{67}$$

where $\epsilon_1 \sim aq^2$. Then for

$$q^4 < \frac{2^3a^2C_1^2(1+\epsilon_1)}{\pi^2(1+2\epsilon)N_{vv}e^{2qa}(L-2a)}$$

the theorem is proved. The dependence of the ratio

$$\frac{M(\hat{\Psi})}{\|\hat{\Psi}\|^2}$$

for the trial function $\hat{\Psi}$ of the quasimomentum θ and the parameter q is shown in Figs. 3 and 4. One can see that there is a specific behavior near the points $2\pi n$. That is why we consider the ratio in neighborhoods of these points separately. The figures show that the ratio is strongly negative for all values of θ. Theorem 2 gives us a more precise result—an estimation for the gap. Summarizing the results for different θ, we obtain the following estimation of the ratio for the trial function:

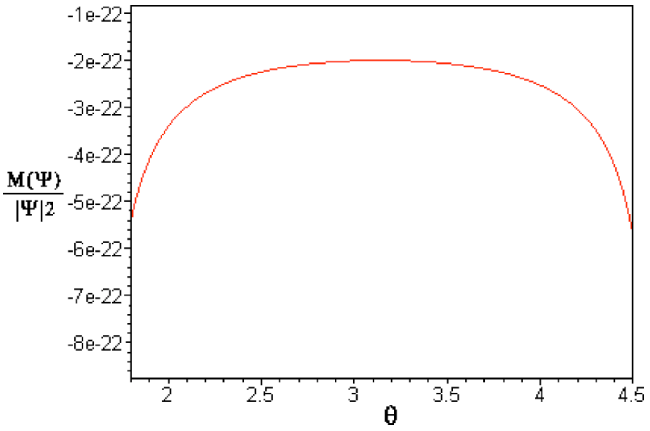

FIG. 3. The dependence of the ratio $M(\hat{\Psi})/\|\hat{\Psi}\|^2$ on the quasimomentum θ for $q=10^{-8}$.

$$\frac{M(\Psi)}{\|\Psi\|^2} \leqslant -ac, \quad c = \frac{2C_1^2(1+\epsilon_1)}{\pi^2(1+2\epsilon)N_{vv}(8C_2+O(q))}. \tag{68}$$

The assumptions which we made are sufficient and not necessary. We assume that the separating layer is strongly narrow, but there is no assumption concerning the very high dielectric contrasts as in the work of Kuchment and co-workers.[2,4]

APPENDIX

Here we place the formulas, that are not in the main text, but which are useful for the reader's understanding of the proofs.

Calculations of $M(\hat{\Psi})$ in Lemma 2 are as follows:

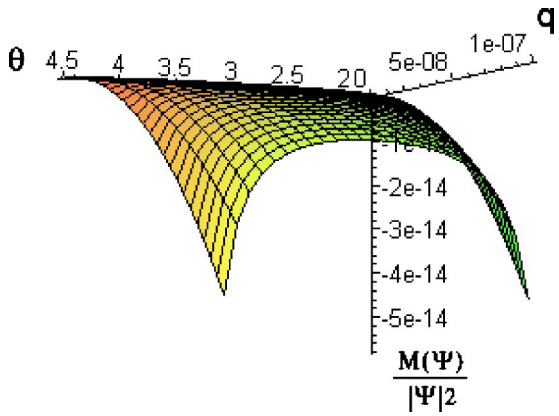

FIG. 4. The dependence of the ratio $M(\hat{\Psi})/\|\hat{\Psi}\|^2$ on the quasimomentum θ and parameter q.

$$M(\hat{\Psi}) = \|\hat{\Psi}_x\|^2 + \|\hat{\Psi}_y\|^2 - \|\hat{\Psi}\sqrt{n^2k_0^2 - \lambda^2}\|^2 = \|F_x\|^2 + \|G_x\|^2 + \int_0^d \int_{-\infty}^{\infty} \overline{F_x}\overline{G_x} + F_xG_x \,\mathrm{d}x\,\mathrm{d}y + \|F_y\|^2$$
$$+ \|G_y\|^2 + \int_0^d \int_{-\infty}^{\infty} \overline{F_y}\overline{G_y} + F_yG_y \,\mathrm{d}x\,\mathrm{d}y - \|F\sqrt{n^2k_0^2 - \lambda^2}\|^2 - \|G\sqrt{n^2k_0^2 - \lambda^2}\|^2$$
$$- \int_0^d \int_{-\infty}^{\infty} (\overline{FG} + FG)\sqrt{n^2k_0^2 - \lambda^2}\mathrm{d}x\,\mathrm{d}y = \|F_x\|^2 + \|G_x\|^2 + \|G_y\|^2 + \int_0^d \int_{-\infty}^{\infty} \overline{F_y}\overline{G_y} + F_yG_y \,\mathrm{d}x\,\mathrm{d}y$$
$$+ \int_0^d \int_{-\infty}^{\infty} \overline{F_x}\overline{G_x} + F_xG_x \,\mathrm{d}x\,\mathrm{d}y - \left[\|G\sqrt{n^2k_0^2 - \lambda^2}\|^2 + \int_0^d \int_{-\infty}^{\infty} (\overline{FG} + FG)(n^2k_0^2 - \lambda^2)\mathrm{d}x\,\mathrm{d}y \right], \tag{A1}$$

where

$$\int_0^d \int_{-\infty}^{\infty} \overline{F_y}\overline{G_y} + F_yG_y \,\mathrm{d}x\,\mathrm{d}y = \int_0^d \int_{-\infty}^{\infty} \overline{F_y}\overline{G_y} \,\mathrm{d}x\,\mathrm{d}y + \int_0^d \int_{-\infty}^{\infty} F_yG_y \,\mathrm{d}x\,\mathrm{d}y$$
$$= \int_{-\infty}^{\infty} \left[F_yG|_0^d - \int_0^d \overline{F_{yy}}\overline{G}\,\mathrm{d}y \right]\mathrm{d}x + \int \left[F_yG|_0^d - \int F_{yy}G\,\mathrm{d}y \right]\mathrm{d}x$$
$$= \int_{-\infty}^{\infty} (\overline{F_y}\overline{G} + F_yG)|_0^d \,\mathrm{d}x - \int_{-\infty}^{\infty} \int_0^d (\overline{F_{yy}}\overline{G} + F_{yy}G)\mathrm{d}y\,\mathrm{d}x$$
$$= -\int_{-\infty}^{\infty} [\overline{F_y}(x,0)\overline{G}(x,0) + F_y(x,0)G(x,0)]\mathrm{d}x$$
$$- \int_{-\infty}^{\infty} \int_0^d (\overline{F_{yy}}\overline{G} + F_{yy}G)\mathrm{d}y\,\mathrm{d}x. \tag{A2}$$

Calculations of $\|G\sqrt{n^2k_0^2-\lambda^2}\|^2$ are as follows:

$$\|G\sqrt{n^2k_0^2 - \lambda^2}\|^2 = \eta^2 \int_0^{\infty} r(y)^2(n(y)^2k_0^2 - \lambda^2)\mathrm{d}y \int_{-a}^{a} g(x)^2 \,\mathrm{d}x < \eta^2\nu^2\frac{a^2}{\pi}\left(1 + \frac{32a}{3d\pi}\right), \tag{A3}$$

where

$$\int_0^{\infty} r(y)^2(n(y)^2k_0^2 - \lambda^2)\mathrm{d}y = \nu^2 \int_0^{\infty} r(y)^2 \,\mathrm{d}y < \nu^2\frac{a}{\pi}\left(1 + \frac{32a}{3d\pi}\right), \tag{A4}$$

and

$$\int_{-a}^{a} g(x)^2 \,\mathrm{d}x = \int_{-a}^{a} \cos\left(\frac{\pi x}{2a}\right)^2 \mathrm{d}x = a. \tag{A5}$$

The integral of $v(y)^2$ is used to calculate the norms $\|F\|^2$ and $\|F_y\|^2$, which are used in Theorem 1 and Theorem 2. In the proofs we mark the value of this integral as N_{vv}. Calculations of the integral are

$$N_{vv} = \int_0^\infty v(y)^2\,\mathrm{d}y = N_3^2\int_0^\delta \sin(\mu y)^2\,\mathrm{d}y + (N_1+M_1)^2\int_\delta^d \cos(\nu y - arg)^2\,\mathrm{d}y + N_2^2\int_d^\infty e^{-2\gamma(y-d)}\,\mathrm{d}y$$
$$= N_3^2\frac{1}{2}\left(\frac{1}{2\mu}\sin(2\mu\delta) + 2\delta\right) + N_2^2\frac{1}{2\gamma} + (N_1+M_1)^2\frac{1}{2}\left(\frac{1}{2\mu}(\sin(2(\mu d - arg)) - \sin(2(\mu\delta - arg))) + (d-\delta)\right), \tag{A6}$$

where $N_{vv} \geqslant 0$. In the case of a single coupling window for the norm $\|f(x)\|^2$ we have

$$\int_{-\infty}^{\infty} \overline{f_x}(x) f_x(x)\mathrm{d}x = \int_{-a}^{a} \overline{f_x}(x) f_x(x)\mathrm{d}x + 2\int_{-\infty}^{-a} \overline{f_x(x)} f_x(x)\mathrm{d}x = q. \tag{A7}$$

And in the case of the periodic set of coupling windows we have

$$\int_{-L/2}^{L/2} \overline{f_x}(x) f_x(x)\mathrm{d}x = \int_{-a}^{a} \overline{f_x}(x) f_x(x)\mathrm{d}x + 2\int_{-L/2}^{-a} \overline{f_x}(x) f_x(x)\mathrm{d}x$$
$$= \int_{-a}^{a} q^2 e^{2qa}(2AB\cosh(2qx) - A^2 - B^2) + 2\int_{-L/2}^{-a} q^2 e^{2qa}(2AB\cosh(2qx) - A^2 - B^2$$
$$- A - B + (A+B+1)e^{2qx})$$
$$= -2qe^{2qa}[-AB\sinh(2qa) + qa(A^2+B^2)] + qe^{2qa}[-2AB(\sinh(2qa) - \sinh(qL))$$
$$+ (2qa - qL)(B^2 + A^2 + A + B)] + qe^{2qa}[(e^{-2qa} - e^{-qL})(A+B+1)]$$
$$= qe^{2qa}[2AB(\sinh(qL) - \sinh(2qa) - qL + 2qa) - (qL - 2qa + e^{-qL} - e^{-2qa})$$
$$\times(A+B)] - qe^{2qa}[e^{-qL} - e^{-2qa}] = qe^{2qa}\Phi_1(A,B), \tag{A8}$$

where $\Phi_1(A,B) \geqslant 0$. The integral of $v(y)r(y)$ is used in both theorems and known as constant N_{vr},

$$\int_0^d v(y)r(y)\mathrm{d}y = \int_0^\delta N_3\sin(\mu y)e^{-\pi y/2a}\,\mathrm{d}y + \int_\delta^{d/2}(N_1\cos(\nu y) + M_1\sin(\nu y))e^{-\pi y/2a}\,\mathrm{d}y$$
$$+ \int_{d/2}^{d}(N_1\cos(\nu y) + M_1\sin(\nu y))2\left(1 - \frac{y}{d}\right)e^{-\pi d/4a}\,\mathrm{d}y$$
$$= \int_0^\delta N_3\sin(\mu y)e^{-\pi y/2a}\,\mathrm{d}y + (N_1+M_1)\int_\delta^{d/2}\cos(\nu y - arg)e^{-\pi y/2a}\,\mathrm{d}y + (N_1+M_1)$$
$$\int_{d/2}^{d}\cos(\nu y - arg)2\left(1 - \frac{y}{d}\right)e^{-\pi d/4a}\,\mathrm{d}y, \tag{A9}$$

where

$$N_3\int_0^\delta \sin(\mu y)e^{-\pi y/2a}\,\mathrm{d}y = N_3\frac{2a}{\pi^2 + 4\mu^2a^2}(2a\mu - e^{-\pi\delta/2a}[\pi\sin(\mu\delta) + 2\mu a\cos(\mu\delta)]), \tag{A10}$$

$$(N_1 + M_1)\int_{\delta}^{d/2} \cos(\nu y - arg)e^{-\pi y/2a}\,dy$$

$$= (N_1 + M_1)\frac{2a}{\pi^2 + 4\nu^2 a^2}(e^{-\pi d/4a}(-\pi\cos(1/2\,\nu d - arg) + 2a\nu\sin(1/2\,\nu d - arg)) - e^{-\pi\delta/2a}(-\pi\cos(\nu\delta - arg) + 2a\nu\sin(\nu\delta - arg)))$$

$$= (N_1 + M_1)\frac{2a}{\pi^2 + 4\nu^2 a^2}\left(e^{-\pi\delta/2a}(\pi\cos(\nu\delta - arg) - 2a\nu\sin(\nu\delta - arg)) + \epsilon_1\right), \tag{A11}$$

$$(N_1 + M_1)\int_{d/2}^{d} \cos(\nu y - arg)2\left(1 - \frac{y}{d}\right)e^{-\pi d/4a}\,dy = (N_1 + M_1)\frac{e^{-\pi d/4a}}{\nu^2 d}(-2\cos(\nu d - arg) - \sin(1/2\,\nu d - arg)\nu d + 2\cos(1/2\,\nu d - arg)) = (N_1 + M_1)\epsilon_1, \tag{A12}$$

where $\epsilon_1 \sim e^{-\pi d/4a}$. So,

$$\int_0^d v(y)r(y)dy = aN_{vr}. \tag{A13}$$

Weak Hopf algebras corresponding to Cartan matrices

Shilin Yang[a)]
College of Applied Sciences, Beijing University of Technology, Beijing 100022, People's Republic of China

(Received 26 March 2005; accepted 22 April 2005; published online 16 June 2005)

We replace the group of grouplike elements of the quantized enveloping algebra $U_q(\mathfrak{g})$ of a finite dimensional semisimple Lie algebra $\mathfrak{g}$ by some regular monoid and get the weak Hopf algebra $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. It is a subclass of weak Hopf algebras but not Hopf algebras. Then we devote to constructing a basis of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ and determine the group of weak Hopf algebra automorphisms of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ when q is not a root of unity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1933063]

I. INTRODUCTION

Recently, many mathematicians are interested in generalizations of Hopf algebras, of which importance has been recognized in both mathematics and physics. One way is to introduce the notion of a weak coproduct, such that $\Delta(1) \neq 1 \otimes 1$, which was motivated by the study of symmetries in low dimensional quantum field theory. This resulted in the definition of weak Hopf algebras, introduced by Böhm, Nill, and Szlachányi (see, for example, Ref. 3). Since they are not bialgebras, but almost bialgebras, there were also axioms required to define a weak antipode, differing slightly from the usual notion of a Hopf algebra. The face algebras[7] and generalized Kac algebras[19] are examples of this class of weak Hopf algebras.

It is possible to define a weak antipode on a given bialgebra. This was introduced by Li in Ref. 11. By definition, a bialgebra $\mathcal{H}=(H,\mu,\eta,\Delta,\varepsilon)$ over a field k together with the identity map id in $\hom_k(H,H)$ is called a *weak Hopf algebra* if there exists $T \in \hom_k(H,H)$ such that $\mathrm{id}*T*\mathrm{id}=\mathrm{id}$ and $T*\mathrm{id}*T=T$ where $*$ is the convolution product. The map T is called a weak antipode. It is noted that the notion of Hopf algebras, and left or right Hopf algebras are included in this class of weak Hopf algebras (see Refs. 17, 16, and 6). Another typical example is the weak quantum algebras $\mathfrak{w}\mathfrak{sl}_q(2)$ and $v\mathfrak{sl}_q(2)$ constructed in Ref. 12. It is the generalization by replacing the set of grouplike elements of $U_q(\mathfrak{sl}_2)$ by the set of some regular monoid, where $U_q(\mathfrak{sl}_2)$ is the quantized enveloping algebra corresponding to three-dimensional semisimple Lie algebra. The basis and some properties of $\mathfrak{w}\mathfrak{sl}_q(2)$ [respectively, $v\mathfrak{sl}_q(2)$] were studied in Ref. 12. Recently, Aizawa and Isaac[1] gave a description of weak Hopf algebra $\mathfrak{w}\mathfrak{sl}_q^d(n)$ in general, which is corresponding to the known Hopf algebra $U_q(\mathfrak{sl}_n)$.

Our aim is to give more nontrivial examples for weak Hopf algebras in the sense of Li. Following the idea,[1,12] we would like to extend this construction to the more general one $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ corresponding to arbitrary finite dimensional semisimple Lie algebra $\mathfrak{g}$.

Thanks to the definition of quantum group $U_q(\mathfrak{g})$ defined by Refs. 13 and 9, we can also replace the group $G(U_q(\mathfrak{g}))$ of grouplike elements by some regular monoid and get the weak Hopf algebra $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$, which is resulted from quantum group $U_q(\mathfrak{g})$.[12,9,13] This successful construction provides us with a subclass of weak Hopf algebras but not Hopf algebras. As does the classic quantum group $U_q(\mathfrak{g})$, we will determine the basis and the group of weak Hopf algebra automorphisms of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$.

To determine the basis of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$, we first show that $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ can be written as a direct sum of its two ideals and one of them is just isomorphic to the classic quantum group $U_q(\mathfrak{g})$. Then we apply

a)Electronic mail: slyang@bjut.edu.cn

the PBW theorem for $U_q(\mathfrak{g})$ to describe a basis of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. If q is not a root of unity, the group of Hopf algebra automorphisms of $U_q(\mathfrak{g})$ was determined in Ref. 4. The case when q is a root of unity, was considered in recent work.[15] In the present paper, we will determine the group of weak Hopf algebra automorphisms of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ under the condition that q is not a root of unity. The method is to apply the result of Ref. 4, Corollary 4.3, and some technical lemmas.

The paper is organized as follows.

In Sec. II, we give some notations and the definition of weak Hopf algebra $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. The ideal to construct the algebra $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ and some basic properties are described. In Sec. III, we give the comultiplication of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ in order that it is a weak Hopf algebra but not a Hopf alegbra. The proof is somewhat basic and direct. In Sec. IV, we describe the basis of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ by the technique of Lusztig's constructing PBW basis of $U_q(\mathfrak{g})$. In the final section, we study and determine the group of Hopf automorphisms of $U_q(\mathfrak{g})$.

II. WEAK QUANTUM ALGEBRAS $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$

In this paper, we always assume that k is a field of characteristic 0. Let $\mathfrak{g}$ be a finite dimensional semisimple Lie algebra. For the simplicity, we can assume that $\mathfrak{g}$ is also simple. Then there is a finite positive symmetrizable Cartan matrix $\mathcal{C}=(a_{ij})_{n\times n}$ corresponding to it (see Ref. 8).

Now we let R be the root system of $\mathfrak{g}$ and we fix a basis $I=\{\alpha_1,\ldots,\alpha_n\}$ of R. Let W be the Weyl group of R. It is well known that there is a unique W-invariant scalar product $(,)$ on the vector space generated by R over the reals such that $(\alpha,\alpha)=2$ for all short roots α in R. Set for each $\alpha_i\in I$, $1\leqslant i\leqslant n$

$$d_i=\frac{(\alpha_i,\alpha_i)}{2}.$$

It is noted that $(\alpha_i,\alpha_j)=d_ia_{ij}=d_ja_{ji}$.

Let $q\in k$ and $q_i=q^{d_i}$, $1\leqslant i\leqslant n$. It is assumed that $q_i\neq\pm1, 0$ for all i. For an indeterminate x and an integer m, let

$$[m]_x=\frac{x^m-x^{-m}}{x-x^{-1}},\quad [m]!_x=[m]_x\cdots[1]_x,\quad [0]_x!=1,$$

and

$$\begin{bmatrix} m \\ s \end{bmatrix}_x=\frac{[m]!_x}{[s]!_x[m-s]!_x}.$$

One can review the definition of the quantized enveloping algebra $U_q=U_q(\mathfrak{g})$ by referring to Refs. 10, 9, and 13. For the completeness, we describe it here as follows. The algebra $U_q(\mathfrak{g})$ generated by $4n$ generators $e_i,f_i,k_i,k_i^{-1}(1\leqslant i\leqslant n)$ with the relations

$$k_ik_j=k_jk_i,\quad k_ik_i^{-1}=k_i^{-1}k_i=1, \tag{2.1}$$

$$k_ie_jk_i^{-1}=q_i^{a_{ij}}e_j,\quad k_if_jk_i^{-1}=q_i^{-a_{ij}}f_j, \tag{2.2}$$

$$e_if_j-f_je_i=\delta_{ij}\frac{k_i-k_i^{-1}}{q_i-q_i^{-1}}, \tag{2.3}$$

$$\sum_{s=0}^{1-a_{ij}}(-1)^s\begin{bmatrix} 1-a_{ij} \\ s \end{bmatrix}_{q_i}e_i^{1-a_{ij}-s}e_je_i^s=0,\quad \text{if } i\neq j, \tag{2.4}$$

$$\sum_{s=0}^{1-a_{ij}} (-1)^s \begin{bmatrix} 1-a_{ij} \\ s \end{bmatrix}_{q_i} f_i^{1-a_{ij}-s} f_j f_i^s = 0, \quad \text{if } i \neq j. \tag{2.5}$$

To generalize the invertibility condition (2.1), one way is to weaken the invertibility to regularity, in which instead of $\{k_i, k_i^{-1}\}$ by a pair $\{K_i, \overline{K_i}\}$ for all $1 \leqslant i \leqslant n$ subjecting to some relations. For example, we can introduce a projector J such that

$$J = K_i \overline{K_i} = \overline{K_i} K_i,$$

$$JK_i = K_i, \quad \overline{K_i} J = \overline{K_i},$$

$$J\overline{K_i} = \overline{K_i}, \quad K_i J = K_i$$

for $1 \leqslant i \leqslant n$. To generalize other relations of the definition, we need some terminologies for simplicity. For example, if E_i satisfies

$$K_j E_i = q_i^{a_{ij}} E_i K_j, \quad E_i \overline{K_j} = q_i^{a_{ij}} \overline{K_j} E_i, \quad \forall\, j, \tag{2.6}$$

we say E_i is type 1. Moreover, if E_i satisfies

$$K_j E_i \overline{K_j} = q_i^{a_{ij}} E_i, \quad \forall\, j, \tag{2.7}$$

we say E_i is type 2. The same convention holds for F_i by replacing E_i with F_i and a_{ij} with $-a_{ij}$ in the above relations.

We borrow some notations from Ref. 1, $2n$ simple generators E_i and F_i are listed by starting with the E_i followed by the F_i, where a 1 is to indicate the use of a type 1 generator and a 0 is to indicate the use of a type 2 generator. Then we write down a list of 0's and 1's in the order corresponding to the generators determined by their type. This gives a sequence d containing 0 and 1 in a binary representation of length $2n$. It is noted that d contains all the information on the relations with the generators E_i and F_j, all $K_j/\overline{K_j}$, and J. We write d in terms of its binary expansion,

$$\mathsf{d} = (\kappa_1, \ldots, \kappa_n | \overline{\kappa_1}, \ldots, \overline{\kappa_n})$$

where the bar separates the values representing the E_i and F_i, and where the κ_i and $\overline{\kappa_i}$ have values of either 0 or 1. Accordingly, we can say E_i and F_i, $\alpha_i \in I$ are type d in an obvious sense.

Now we can write down this generalization explicitly as follows.

Definition 2.1: The algebra $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ *is generated by the* $4n+1$ *variables* $E_i, F_i, K_i, \overline{K_i} (1 \leqslant i \leqslant n)$ *and* J *with the following relations: for all* $1 \leqslant i,j \leqslant n$,

$$J = K_i \overline{K_i}, \tag{2.8}$$

$$K_i \overline{K_j} = \overline{K_j} K_i, \quad K_i K_j = K_j K_i, \quad \overline{K_i}\,\overline{K_j} = \overline{K_j}\,\overline{K_i}, \tag{2.9}$$

$$JK_i = K_i, \quad J\overline{K_i} = \overline{K_i}, \tag{2.10}$$

$$E_i, \quad F_i \text{ are type } \mathsf{d}, \tag{2.11}$$

$$E_i F_j - F_j E_i = \delta_{ij} \frac{K_i - \overline{K_i}}{q_i - q_i^{-1}}, \tag{2.12}$$

$$\sum_{s=0}^{1-a_{ij}} (-1)^s \begin{bmatrix} 1-a_{ij} \\ s \end{bmatrix}_{q_i} E_i^{1-a_{ij}-s} E_j E_i^s = 0, \quad \text{if } i \neq j, \tag{2.13}$$

$$\sum_{s=0}^{1-a_{ij}} (-1)^s \begin{bmatrix} 1-a_{ij} \\ s \end{bmatrix}_{q_i} F_i^{1-a_{ij}-s} F_j F_i^s = 0, \quad \text{if } i \neq j. \tag{2.14}$$

The algebra $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ *is said to be a* d*-type* weak quantum algebra *associated to Lie algebra* $\mathfrak{g}$.

It is easy to see that there are 2^{2n} possible weak quantum algebras $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ corresponding to the sequence d in total.

It is easy to see that (2.9) and (2.10) generalize the relation (2.1), and the relations (2.11) and (2.12) generalize the corresponding relations (2.2) and (2.3). The notations P_i $(1 \leqslant i \leqslant n)$ are defined by

$$P_i^k = \begin{cases} K_i^k, & k > 0, \\ J, & k = 0, \\ \overline{K}_i^{-k}, & k < 0. \end{cases}$$

It is easy to see that P_i^k satisfy the regularity conditions

$$P_i^k P_i^{-k} P_i^k = P_t^k \tag{2.15}$$

for all $k \in \mathbb{Z}$.

There are some properties for $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ which are used later.

Lemma 2.2: The idempotent J *is in the center of* $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$.

Proof: Indeed, for K_j and $\overline{K}_j$, it follows from (2.9) and (2.10). For instance,

$$K_j J = K_j K_j \overline{K}_j = K_j \overline{K}_j K_j = J K_j.$$

For E_j, if it is type 1, then we have

$$J E_j = K_i \overline{K}_i E_j = q_i^{-a_{ij}} K_i E_j \overline{K}_i = E_j J$$

by (2.6) if E_i is type 2,

$$J E_i = K_i \overline{K}_i E_i = q_i^{-2} K_i \overline{K}_i K_i E_i \overline{K}_i = q_i^{-2} K_i E_i \overline{K}_i = q_i^{-2} K_i E_i \overline{K}_i K_i \overline{K}_i = E_i J$$

by (2.7). Hence, $JE_i = E_i J$ for all $i = 1, 2, \ldots, n$. The same argument for F_i by (2.11). □

If E_i is type 2, hence $K_j E_i \overline{K}_j = q_i^{a_{ij}} E_i$ for all $1 \leqslant j \leqslant n$, then

$$K_j E_i = K_j J E_i = K_j E_i J = K_j E_i \overline{K}_j K_j = q_i^{a_{ij}} E_i K_j$$

and $E_i \overline{K}_j = q_i^{a_{ij}} \overline{K}_j E_i$. Similarly, if F_i is type 2, we have

$$K_j F_i = q_i^{-a_{ij}} F_i K_j, \quad F_i \overline{K}_j = q_i^{-a_{ij}} \overline{K}_j F_i.$$

Now, it is straightforward to check by induction that E_i (respectively, F_i), $1 \leqslant i \leqslant n$, is type 1 or type 2, the following relations hold in $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$:

$$E_i^m K_j^n = q_i^{-mna_{ij}} K_i^n E_i^m, \quad F_i^m K_j^n = q_i^{mna_{ij}} K_j^n F_i^m,$$

$$E_i^m \overline{K}_j^n = q_i^{mna_{ij}} \overline{K}_j^n E_i^m, \quad F_i^m \overline{K}_j^n = q_i^{-mna_{ij}} \overline{K}_j^n F_i^m. \tag{2.16}$$

In particular, we have

$$E_i^m K_i^n = q_i^{-2mn} K_i^n E_i^m, \quad F_i^m K_i^n = q_i^{2mn} K_i^n F_i^m,$$
$$E_i^m \overline{K_i^n} = q_i^{2mn} \overline{K_i^n} E_i^m, \quad F_i^m \overline{K_i^n} = q_i^{-2mn} \overline{K_i^n} F_i^m. \tag{2.17}$$

III. THE WEAK HOPF ALGEBRA STRUCTURE OF $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$

To make the d-type weak quantum algebra $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$ be a weak Hopf algebra, we define three maps,

$$\Delta: \mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g}) \to \mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g}) \otimes \mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g}),$$

$$\varepsilon: \mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g}) \to k,$$

$$T: \mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g}) \to \mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g}),$$

as follows:

$$\Delta(K_i) = K_i \otimes K_i, \tag{3.1}$$

$$\Delta(\overline{K_i}) = \overline{K_i} \otimes \overline{K_i}, \tag{3.2}$$

$$\Delta(J) = J \otimes J, \tag{3.3}$$

$$\Delta(E_i) = \begin{cases} 1 \otimes E_i + E_i \otimes K_i, & E_i \text{ is type 1}, \\ J \otimes E_i + E_i \otimes K_i, & E_i \text{ is type 2}, \end{cases} \tag{3.4}$$

$$\Delta(F_i) = \begin{cases} F_i \otimes 1 + \overline{K_i} \otimes F_i, & F_i \text{ is type 1}, \\ F_i \otimes J + \overline{K_i} \otimes F_i, & F_i \text{ is type 2}, \end{cases} \tag{3.5}$$

$$\varepsilon(E_i) = \varepsilon(F_i) = 0, \quad \varepsilon(K_i) = \varepsilon(\overline{K_i}) = 1, \quad \varepsilon(J) = 1,$$

while the map T has the form

$$T(1) = 1, \tag{3.6}$$

$$T(E_i) = -E_i \overline{K_i}, \tag{3.7}$$

$$T_i(F_i) = -K_i F_i, \tag{3.8}$$

$$T(K_i) = \overline{K_i}, \tag{3.9}$$

$$T(\overline{K_i}) = K_i, T(J) = J. \tag{3.10}$$

Then we extend them to the whole $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$.

In Ref. 1, Sec IV, the authors investigated the algebra $\mathfrak{ws}\mathfrak{l}_q^{\mathrm{d}}(n)$ and claimed that $\mathfrak{ws}\mathfrak{l}_q^{\mathrm{d}}(n)$ is a weak Hopf algebra, of which no proof was given. In general, we yield the following.

Theorem 3.1: (Ref. 1, Sec. IV) $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$ *is a noncommutative and noncocommutative weak Hopf algebra with the weak antipode T, but not a Hopf algebra.*

In Ref. 1, the authors gave a classification in some sense of weak Hopf algebras corresponding to $U_q(\mathfrak{sl}_n)$. Similarly, we can follow the idea[1] to describe the isomorphism classes of weak Hopf algebras $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$. As a consequence, we have a lot of nontrivial examples of weak Hopf algebras for various sequences d.

The theorem follows from Lemma 3.2 and Lemma 3.3 below.

Lemma 3.2: $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ *is a bialgebra with comultiplication* Δ *and counit* ε.

Proof: It can be shown by direct calculation that the following relations hold:

$$\Delta(K_i)\Delta(\overline{K_j}) = \Delta(\overline{K_j})\Delta(K_i),$$

$$\Delta(J) = \Delta(K_i)\Delta(\overline{K_i}),$$

$$\Delta(J)\Delta(K_i) = \Delta(K_i),$$

$$\Delta(J)\Delta(\overline{K_i}) = \Delta(\overline{K_i}),$$

$$\varepsilon(K_i)\varepsilon(\overline{K_j}) = \varepsilon(\overline{K_i})\varepsilon(K_j),$$

$$\varepsilon(J)\varepsilon(K_i) = \varepsilon(K_i),$$

$$\varepsilon(J)\varepsilon(\overline{K_i}) = \varepsilon(\overline{K_i}),$$

$$\varepsilon(\overline{K_i})\varepsilon(E_i) = q^{-2}\varepsilon(E_i)\varepsilon(\overline{K_i}),$$

$$\varepsilon(\overline{K_i})\varepsilon(F_i) = q^{2}\varepsilon(F_i)\varepsilon(\overline{K_i}),$$

$$\varepsilon(E_i)\varepsilon(F_j) - \varepsilon(F_j)\varepsilon(E_i) = \delta_{ij}\frac{\varepsilon(K_i) - \varepsilon(\overline{K_i})}{q_i - q_i^{-1}}.$$

If E_i is type 1, then

$$\Delta(K_j)\Delta(E_i) = (K_j \otimes K_j)(1 \otimes E_i + E_i \otimes K_i) = K_j \otimes K_jE_i + K_jE_i \otimes K_jK_i = q_i^{a_{ij}}K_j \otimes E_iK_j + q_i^{a_{ij}}E_iK_j \otimes K_iK_j = q_i^{a_{ij}}\Delta(E_i)\Delta(K_j);$$

if E_i is type 2, then

$$\Delta(K_j)\Delta(E_i)\Delta(\overline{K_j}) = (K_j \otimes K_j)(J \otimes E_i + E_i \otimes K_i)(\overline{K_j} \otimes \overline{K_j}) = K_j\overline{K_j} \otimes K_jE_i\overline{K_j} + K_jE_i\overline{K_j} \otimes K_jK_i\overline{K_j} = q_i^{a_{ij}}J \otimes E_i + q_i^{a_{ij}}E_i \otimes K_i = q_i^{a_{ij}}\Delta(E_i).$$

Therefore, Δ keeps the relation (2.11) for E_i's. The similar argument can show that Δ also keeps the relation (2.11) for F_i's.

Now we examine the identity

$$\Delta(E_i)\Delta(F_j) - \Delta(F_j)\Delta(E_i) = \delta_{ij}\frac{\Delta(K_i) - \Delta(\overline{K_i})}{q_i - q_i^{-1}}.$$

The following cases should be considered:

(1) E_i is type 1 and F_i is type 1,

(2) E_i is type 1 and F_i is type 2,
(3) E_i is type 2 and F_i is type 1,
(4) E_i is type 2 and F_i is type 2.

For the case (2), it is noted that

$$E_i\overline{K_j} = q_i^{a_{ij}}\overline{K_j}E_i = q^{d_i a_{ij}}\overline{K_j}E_i = q^{(\alpha_i,\alpha_j)}\overline{K_j}E_i$$

and

$$K_iF_j = K_iF_jJ = K_iF_j\overline{K_j}K_i = q_j^{-a_{ji}}F_jK_i = q^{-d_ja_{ji}}F_jK_i = q^{-(\alpha_i,\alpha_j)}F_jK_i.$$

The later identity holds since $K_iJ=K_i$ and J is central in $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$. Then, it is easy to see that

$$\begin{aligned}\Delta(E_i)\Delta(F_j) - \Delta(F_j)\Delta(E_i) &= \overline{K_j}\otimes(E_iF_j - F_jE_i) + (E_iF_j - F_jE_i)\otimes K_i \\ &= \delta_{ij}\overline{K_j}\otimes\frac{K_i - \overline{K_i}}{q_i - q_i^{-1}} + \delta_{ij}\frac{K_i - \overline{K_i}}{q_i - q_i^{-1}}\otimes K_i \\ &= \delta_{ij}\frac{K_i\otimes K_i - \overline{K_i}\otimes\overline{K_i}}{q_i - q_i^{-1}} = \delta_{ij}\frac{\Delta(K_i) - \Delta(\overline{K_i})}{q_i - q_i^{-1}}.\end{aligned}$$

We have shown that Δ keeps the relation (2.12) for the case (2). For the other cases the proof is similar. To see the map Δ keeps the quantum Serre relations (2.13) and (2.14), we should consider several cases according to the type of $\{E_i,E_j\}$ or $\{F_i,F_j\}$ $(i\neq j)$. In fact, for each case, the argument is more or less the same as the case of $U_q(\mathfrak{g})$ (see Ref. 9, pp. 67 and 68).

Therefore, Δ and ε can be extended to algebra morphisms from $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$ to $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})\otimes\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$ and from $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$ to k, respectively.

By the above relations it can be shown that

$$(\Delta\otimes\mathrm{id})\Delta(X) = (\mathrm{id}\otimes\Delta)\Delta(X),$$

$$(\varepsilon\otimes\mathrm{id})\Delta(X) = (\mathrm{id}\otimes\varepsilon)\Delta(X) = X$$

for any $X=E_i,F_i,K_i$ or $\overline{K_i}$. Let μ and η be the product and the unit of $\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g})$, respectively, then $(\mathfrak{w}_q^{\mathrm{d}}(\mathfrak{g}),\mu,\eta,\Delta,\varepsilon)$ becomes a bialgebra. □

It is easy to see that

$$T(\overline{K_i})T(K_j) = T(K_j)T(\overline{K_i}),$$

$$T(J)T(K_i) = T(K_i),$$

$$T(J)T(\overline{K_i}) = T(\overline{K_i}),$$

$$T(F_j)T(E_i) - T(E_i)T(F_j) = \delta_{ij}\frac{T(K_i) - T(\overline{K_i})}{q_i - q_i^{-1}},$$

and E_i is either type 1 or type 2, the map T keeps the antirelation of (2.11). The argument for F_i is similar. Moreover, T also keeps the antirelation for quantum Serre relations. For example, for $1\leqslant i,j\leqslant n$ with $i\neq j$, let $r=1-a_{ij}$, we have

$$\sum_{s=0}^{r}(-1)^s\begin{bmatrix} r \\ s \end{bmatrix}_{q_i} T(E_i)^s T(E_j)T(E_i)^{r-s} = \sum_{s=0}^{r}(-1)^s\begin{bmatrix} r \\ s \end{bmatrix}_{q_i} (-1)^{r+1}(E_i\overline{K_i})^s(E_j\overline{K_j})(E_i\overline{K_i})^{r-s}$$

$$= -q_j^2 q_i^{r^2+r+ra_{ij}}\overline{K_i^r}\,\overline{K_j}\sum_{s=0}^{r}(-1)^{r-s}\begin{bmatrix} r \\ s \end{bmatrix}_{q_i} E_i^s E_j E_i^{r-s} = 0.$$

Here we use the formulas (2.16) and (2.17). The argument for F_i is similar. Therefore, T can be extended to an antialgebra morphism from $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ to $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$, respectively.

Recall that the convolution product in the bialgebra $(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}),\mu,\eta,\Delta,\varepsilon)$ is defined in the similar way to the standard one (see, e.g., Ref. 10) as

$$(f * g)(X) = \mu(f\otimes g)\Delta(X) \tag{3.11}$$

for all $f,g\in \mathrm{Hom}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}),\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$ and $X\in\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. It is noted that if E_i is type 2, then

$$JE_i = K_i\overline{K_i}E_i = q_i^{-2}K_i\overline{K_i}K_iE_i\overline{K_i} = q_i^{-2}K_iE_i\overline{K_i} = E_i.$$

The same argument shows that $F_iJ=F_iJ=F_i$ if F_i is type 2. Let id denote identity map in $\hom_k(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}),\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$.

Lemma 3.3: Let X be E_i,F_i,K_i, or $\overline{K_i}$, then

$$(\mathrm{id} * T * \mathrm{id})(X) = \mathrm{id}(X),$$

$$(T * \mathrm{id} * T)(X) = T(X).$$

Proof: It is easy for $X=K_i,\overline{K_i}$. We consider $X=E_i$, as an example. We set

$$\Delta_2 = (\mathrm{id}\otimes\Delta)\circ\Delta.$$

If E_i is type 1, then

$$\Delta_2(E_i) = 1\otimes 1\otimes E_i + 1\otimes E_i\otimes K_i + E_i\otimes K_i\otimes K_i.$$

It follows that

$$(\mathrm{id} * T * \mathrm{id})(E_i) = T(1)E_i + T(E_i)K_i + E_iT(K_i)K_i = E_i - E_i\overline{K_i}K_i + E_i\overline{K_i}K_i = \mathrm{id}(E_i),$$

and

$$(T * \mathrm{id} * T)(E_i) = T(1)T(E_i) + T(1)E_iT(K_i) + T(E_i)K_iT(K_i)$$
$$= -E_i\overline{K_i} + E_i\overline{K_i} - E_i\overline{K_i}K_i\overline{K_i} = -E_i\overline{K_i} = T(E_i).$$

If E_i is type 2, then

$$\Delta_2(E_i) = J\otimes J\otimes E_i + J\otimes E_i\otimes K_i + E_i\otimes K_i\otimes K_i.$$

It is also deduced that

$$(\mathrm{id} * T * \mathrm{id})(E_i) = J\ T(J)E_i + JT(E_i)K_i + E_iT(K_i)K_i = JE_i - E_i\overline{K_i}K_i + E_i\overline{K_i}K_i = JE_i = \mathrm{id}(E_i)$$

since $JE_i=E_i$, and

$$(T * \mathrm{id} * T)(E_i) = T(J)JT(E_i) + T(J)E_iT(K_i) + T(E_i)K_iT(K_i)$$
$$= -E_i\overline{K_i} + E_i\overline{K_i} - E_i\overline{K_i}K_i\overline{K_i} = -E_i\overline{K_i} = T(E_i).$$

As for F_i, the argument is similar. The proof of the lemma is finished. □

In order to conclude that the antipode axioms hold on arbitrary elements, the following two facts are to be used:

(a) the coproducts of the generators are bilinear expressions of generators;
(b) one of $(\mathrm{id}*T)(X)$ and $T*\mathrm{id}(X)$ is a central element of $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ for X being the generators $K_i, \overline{K_i}, E_i, F_i$.

The fact (a) is obvious. To see (b), we note the fact that $(\mathrm{id}*T)(X)=\varepsilon(X)J$ for $X=K_i, \overline{K_i}, E_i$ $(1\leqslant i\leqslant n)$ and F_i of type 2. Hence $(\mathrm{id}*T)(X)$ is in the center of $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$. However, if $X=F_i$ is type 1, the $(\mathrm{id}*T)(X)=(1-J)F_i$ may not be a central element, but $(T*\mathrm{id})(F_i)=\varepsilon(F_i)J$ is in the center. Similarly, $(T*\mathrm{id})(X)$ for $X=K_i, \overline{K_i}, F_i$ $(1\leqslant i\leqslant n)$ and E_i is of type 2, in the center of $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$. However, if $X=E_i$ is type 1, the $(T*\mathrm{id})(X)=(1-J)E_i$ may not be a central element, but $(\mathrm{id}*T)\times(E_i)$ is in the center of $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$. This means that (b) holds.

It is noted that $E_i(1-J)F_j=F_j(1-J)E_i$ for all $i,j\in\{1,2,\ldots,n\}$ by the relation (2.12). Therefore, if E_i (respectively, F_i) is type 1, $(T*\mathrm{id})(E_i)$ [respectively, $(\mathrm{id}*T)(F_i)$] commutates with all F_j (respectively, all E_j), and $K_j, \overline{K_j}$ $(1\leqslant j\leqslant n)$.

We should show the claim that if

$$(\mathrm{id}*T*\mathrm{id})(x)=x, \quad (T*\mathrm{id}*T)(x)=T(x),$$

$$(\mathrm{id}*T*\mathrm{id})(y)=y, \quad (T*\mathrm{id}*T)(y)=T(y),$$

for all x and y being generators $E_i, F_i, K_i, \overline{K_i}$, then

$$(\mathrm{id}*T*\mathrm{id})(xy)=xy, \quad (T*\mathrm{id}*T)(xy)=T(xy).$$

However, it is considerably direct by the above facts. Now, that the antipode axioms hold on arbitrary elements is obvious by induction.

If we assume that with the operations $\mu,\eta,\Delta,\varepsilon$ the algebra $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ would possess an antipode S so as to become a Hopf algebra, then S should satisfy $(S*\mathrm{id})(J)=\eta\varepsilon(J)$, and it would follow that $S(J)J=1$ and J is invertible. It is impossible since $J(1-J)=0$. This implies that $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ is not a Hopf algebra with the above operators. The proof of Theorem 3.1 is finished. □

It should be noted that if $\mathfrak{g}=\mathfrak{sl}_n$, the algebra $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ is just the mixtures $\mathfrak{wsl}_q^d(n)$ in Ref. 1. In particular, if $\mathfrak{g}=\mathfrak{sl}_2$, $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ where $\mathsf{d}=(1|1)$ [respectively, $\mathsf{d}=(0|0)$] coincides with $\mathfrak{wsl}_q(2)$ [respectively, $v\mathfrak{sl}_q(2)$] given in Ref. 12.

IV. THE BASIS OF $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$

One can find the relationship between $U_q(\mathfrak{g})$ and the quantum algebra $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ as follows.

Proposition 4.1: $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})/\langle J-1\rangle\cong U_q(\mathfrak{g})$.

Proof: It is obvious by cancelling K_i. □

In fact, we can give a more explicit relationship between $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$ and $U_q(\mathfrak{g})$. For this purpose, we let $w_q=\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})J$ and $\overline{w_q}=\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})(1-J)$. We have the following decomposition.

Proposition 4.2: As algebras $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})=w_q\oplus\overline{w_q}$. *Moreover,* $w_q\cong U_q(\mathfrak{g})$ *as Hopf algebras*.

Proof: Noting that J is a central idempotent, we see that w_q and $\overline{w_q}$ are ideals of $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$. It follows that

$$\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})=w_q\oplus\overline{w_q}$$

as algebras. Moreover, it is easy to see that w_q is generated by $E_iJ, F_iJ, K_i, \overline{K_i}$, and J subject to the relations (2.8)–(2.10) and

$$K_i(E_jJ)=q_i^{a_{ij}}(E_jJ)K_i, \quad \overline{K_i}(E_jJ)=q_i^{-a_{ij}}(E_jJ)\overline{K_i}, \tag{4.1}$$

$$K_i(F_jJ) = q_i^{-a_{ij}}(F_jJ)K_i, \quad \overline{K_i}(F_jJ) = q_i^{a_{ij}}(F_jJ)\overline{K_i}, \tag{4.2}$$

$$(E_iJ)(F_jJ) - (F_jJ)(E_iJ) = \delta_{ij}\frac{K_i - \overline{K_i}}{q_i - q_i^{-1}}, \tag{4.3}$$

$$\sum_{s=0}^{1-a_{ij}} (-1)^s \begin{bmatrix} 1-a_{ij} \\ s \end{bmatrix}_{q_i} (E_iJ)^{1-a_{ij}-s}(E_jJ)(E_iJ)^s = 0, \quad \text{if } i \neq j, \tag{4.4}$$

$$\sum_{s=0}^{1-a_{ij}} (-1)^s \begin{bmatrix} 1-a_{ij} \\ s \end{bmatrix}_{q_i} (F_iJ)^{1-a_{ij}-s}(F_jJ)(F_iJ)^s = 0, \quad \text{if } i \neq j. \tag{4.5}$$

Here J can be viewed as the identity of w_q. At this point of view w_q becomes a Hopf algebra, in which the comultiplication Δ is

$$\Delta(E_iJ) = J \otimes E_iJ + E_iJ \otimes K_i,$$

$$\Delta(F_iJ) = F_iJ \otimes J + \overline{K_i} \otimes F_iJ,$$

$$\Delta(K_i) = K_i \otimes K_i, \quad \Delta(\overline{K_i}) = \overline{K_i} \otimes \overline{K_i}.$$

The counit ε is

$$\varepsilon(E_iJ) = \varepsilon(F_iJ) = 0, \quad \varepsilon(K_i) = \varepsilon(\overline{K_i}) = 1.$$

The antipode S is

$$S(E_iJ) = -(E_iJ)\overline{K_i}, \quad S(F_iJ) = -K_i(F_iJ), \quad S(K_i) = \overline{K_i}, \quad S(\overline{K_i}) = K_i.$$

Let ρ be the algebra morphism from $U_q(\mathfrak{g})$ to w_q defined by

$$\rho(e_i) = E_iJ, \quad \rho(f_i) = F_iJ, \quad \rho(k_i) = K_i, \quad \rho(k_i^{-1}) = \overline{K_i}.$$

It is straightforward to see that ρ is a Hopf algebra isomorphism. □

For the ideal $\overline{w_q}$ of $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$, some conventions should be noted. Let

$$\mathsf{d} = (\kappa_1, \ldots, \kappa_n | \overline{\kappa_1}, \ldots, \overline{\kappa_n})$$

be a binary sequence. If κ_i (respectively, $\overline{\kappa_i}$), $1 \leqslant i \leqslant n$ is zero, and hence that E_i (respectively, F_i) is type 2, then $E_i(1-J)=0$ [respectively, $F_i(1-J)=0$]; if κ_i (respectively, $\overline{\kappa_i}$), $1 \leqslant i \leqslant n$ is nonzero, and hence that E_i (respectively, F_i) is type 1, then $E_i(1-J) \neq 0$ [respectively, $F_i(1-J) \neq 0$]. Let

$$\mathfrak{d} = \{i | \kappa_i \neq 0\} \text{ and } \overline{\mathfrak{d}} = \{i | \overline{\kappa_i} \neq 0\}$$

and

$$X_i = E_i(1-J), \quad Y_j = F_j(1-J),$$

where $i \in \mathfrak{d}$, $j \in \overline{\mathfrak{d}}$. It is easy to see that $\{X_i, Y_j | i \in \mathfrak{d}, j \in \overline{\mathfrak{d}}\} \cup \{1-J\}$ generate the ideal $\overline{w_q}$ with enjoying the first relation

$$X_iY_j = Y_jX_i \text{ for all } i \in \mathfrak{d}, j \in \overline{\mathfrak{d}} \tag{4.6}$$

from the relation (2.12).

To see what other relations X_i and Y_i enjoy, we consider the following two extreme cases:

(1) The case

$$\overline{\mathsf{d}} := (\underbrace{1,\cdots,1}_{n\text{copies}}|\underbrace{1,\cdots,1}_{n\text{copies}}).$$

In this case, $\mathfrak{d}=\{1,\ldots,n\}$ and $\overline{\mathfrak{d}}=\{1,\ldots,n\}$. From the quantum Serre relations (2.13) and (2.14), we get that

$$\sum_{s=0}^{1-a_{ij}}(-1)^s\begin{bmatrix}1-a_{ij}\\ s\end{bmatrix}_{q_i}(X_i)^{1-a_{ij}-s}X_j(X_i)^s=0,\ \text{if } i\neq j, \tag{4.7}$$

$$\sum_{s=0}^{1-a_{ij}}(-1)^s\begin{bmatrix}1-a_{ij}\\ s\end{bmatrix}_{q_i}(Y_i)^{1-a_{ij}-s}Y_j(Y_i)^s=0,\ \text{if } i\neq j, \tag{4.8}$$

and other relations corresponding to (2.8)–(2.11) would be vanished automatically. This means that the ideal $\overline{w_q}$ can be understood as an algebra generated by X_i, Y_i, $1\leqslant i\leqslant n$, with an identity $1-J$ subject to the relations (4.6)–(4.8).

(2) The case

$$\underline{\mathsf{d}} := (\underbrace{0,\cdots,0}_{n\text{copies}}|\underbrace{0,\cdots,0}_{n\text{copies}}).$$

In this case, $\mathfrak{d}$ and $\overline{\mathfrak{d}}$ are empty and $\overline{w_q}=k(1-J)$.

In general, three cases should be considered,

(1) $\mathfrak{d}\neq\emptyset$ and $\overline{\mathfrak{d}}=\emptyset$,
(2) $\mathfrak{d}=\emptyset$ and $\overline{\mathfrak{d}}\neq\emptyset$,
(3) $\mathfrak{d}\neq\emptyset$ and $\overline{\mathfrak{d}}\neq\emptyset$.

In the first case, as an algebra $\overline{w_q}$ is generated by X_i, $i\in\mathfrak{d}$ with an identity $1-J$ subject to the relations (4.7) with $i,j\in\mathfrak{d}$. In the second case, as an algebra $\overline{w_q}$ is generated by Y_i, $i\in\overline{\mathfrak{d}}$ with an identity $1-J$ subject to the relations (4.8) with $i,j\in\overline{\mathfrak{d}}$. In the third case, $\overline{w_q}$ can be viewed as an algebra generated by X_i, Y_j, $i\in\mathfrak{d}$, $j\in\overline{\mathfrak{d}}$ with an identity $1-J$ subject to the relations (4.6)–(4.8).

To consider the PBW basis of $\mathfrak{w}_q^{\mathsf{d}}(\mathfrak{g})$, we need some knowledge of braid groups. We define a simple reflection s_i by

$$s_i(\alpha_j)=\alpha_j-a_{ij}\alpha_i$$

for all i and j. Let W be the Weyl group of R; it is the subgroup of $\mathrm{GL}(\mathbb{Z}^n)$ generated by the refelctions $s_i(1\leqslant i\leqslant n)$. Let $\ell(w)$ be the usual length function on W with respect to the generators $\{s_1,\ldots,s_n\}$. Let R^+ be the set of positive roots of R with respect to the set of simple roots Π and $\ell_0=|R^+|$. For each pair $1\leqslant i,\ j\leqslant n$ with $i\neq j$, we let $r=-a_{ij}$.

As is known in Ref. 9, for each $1\leqslant i\leqslant n$, there is a unique automorphism $T_i: U_q(\mathfrak{g})\to U_q(\mathfrak{g})$ such that

$$T_i(e_i)=-f_ik_i, T_i(f_i)=-k_i^{-1}e_i,$$

$$T_i(k_\mu)=k_{s_i(\mu)},$$

$$T_i(e_j)=\sum_{k=0}^{r}(-1)^iq_i^{-k}e_i^{(r-i)}e_je_i^{(i)},$$

$$T_i(f_j) = \sum_{k=0}^{r} (-1)^i q_i^k f_i^{(i)} f_j f_i^{(r-i)}.$$

They are called Lusztig's symmetries. It is well known that $\{T_i | 1 \leqslant i \leqslant n\}$ satisfies the braid relations, that is

$$T_i T_j T_i = T_j T_i T_j, \quad \text{if } s_i s_j \text{ of order } 2,$$

$$T_i T_j T_i T_j = T_j T_i T_j T_i, \quad \text{if } s_i s_j \text{ of order } 4,$$

$$T_i T_j T_i T_j T_i T_j = T_j T_i T_j T_i T_j T_i, \quad \text{if } s_i s_j \text{ of order } 6.$$

Therefore, the above facts allow us to define for each $w \in W$ an automorphism T_w of $U_q(\mathfrak{g})$ as follows. For $w=1$ set $T_1=1$ (the identity). For $w \neq 1$ choose a reduced expression $w=s_{i_1}\cdots s_{i_m}$ and set

$$T_w = T_{i_1} \cdots T_{i_m}.$$

It is independent of the reduced expression. Let U_q^+ (respectively, U_q^- and U_q^0) be the subalgebra of $U_q(\mathfrak{g})$ generated by e_i (respectively, f_i and k_i, k_i^{-1}), $1 \leqslant i \leqslant n$. Let w_0 be the longest element in W and let $w_0 = s_{i_1}\cdots s_{i_t}$ be a reduced expression. Let $\mathbb{N}$ be the set of non-negative numbers. According to this order we denote $a=(a_t,\ldots,a_1) \in \mathbb{N}^{\ell_0}$ and

$$e^a = T_{i_1} \cdots T_{i_{t-1}}(e_{i_t}^{a_t}) \cdots T_{i_1} T_{i_2}(e_{i_3}^{a_3}) T_{i_1}(e_{i_2}^{a_2}) e_{i_1}^{a_1}. \tag{4.9}$$

The following theorem is well known.

Theorem 4.3: (cf. Ref. 9, Theorem 8.24) *The elements* e^a (respectively, f^a) *for* $a \in \mathbb{N}^{\ell_0}$, *are linearly independent and a basis of* U_q^+ (respectively, U_q^-).

We note that the multiplication map

$$U_q^- \otimes U_q^0 \otimes U_q^+ \to U_q(\mathfrak{g}), \quad u_1 \otimes u_2 \otimes u_3 \to u_1 u_2 u_3 \tag{4.10}$$

is an isomorphism of vector spaces.

For $s=(s_1,s_2,\ldots,s_n) \in \mathbb{Z}^n$, we define

$$P^s = P_1^{s_1} P_2^{s_2} \cdots P_n^{s_n}.$$

First, let us examine two examples.

Example 4.4: The set

$$\{F^b P^s E^a J | a,b \in \mathbb{N}^{\ell_0}, s \in \mathbb{Z}^n\} \cup \{F^b E^a (1-J) | a,b \in \mathbb{N}^{\ell_0}\}$$

forms a basis of $\overline{\mathfrak{w}_q^{\mathfrak{d}}}(\mathfrak{g})$.

Proof: Let w_q^0 be the subalgebra generated by $\{K_i, \overline{K_i} | 1 \leqslant i \leqslant n\}$. It is easy to see that P^s ($s \in \mathbb{Z}$) forms a basis of w_q^0.

Let w_q^+ (respectively, w_q^-) denote the subalgebra generated by $E_i J$ (respectively, $F_i J$), $1 \leqslant i \leqslant n$.

We replace e_{i_k} where $k=1,\ldots,t$ on the right-hand side of (4.9) by $E_{i_k} J$ [respectively, $E_{i_k}(1-J)$], and the corresponding left-hand side by $(EJ)^a$ [resppectively, $(E(1-J))^a$]. By Theorem 4.3 the set $\{(EJ)^a | a \in \mathbb{N}^{\ell_0}\}$ [respectively, $\{(FJ)^b | b \in \mathbb{N}^{\ell_0}\}$] forms a basis of w_q^+ (respectively, w_q^-). It is easy to see that

$$(FJ)^b P^s (EJ)^a = F^b P^s E^a J.$$

It follows from (4.10) that

$$\{F^aP^sE^bJ|a,b\in\mathbb{N}^{\ell_0},s\in\mathbb{Z}^n\}$$

forms a basis of w_q.

Similarly, $\{F^aE^b(1-J)|a,b\in\mathbb{N}^{\ell_0}\}$ forms a basis of $\overline{w_q}$. The proof is completed by Proposition 4.2. □

In a similar way we can get the following.

Example 4.5: The set

$$\{F^bP^sE^aJ|a,b\in\mathbb{N}^{\ell_0},s\in\mathbb{Z}^n\}\cup\{1-J\}$$

forms a basis of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$.

In general, let both i and j be in $\mathfrak{d}$ or in $\overline{\mathfrak{d}}$, we say that $i\sim j$ if there exist some sequence $i=\gamma_1,\ldots,\gamma_p=j$ in $\mathfrak{d}$, where γ_p is in $\mathfrak{d}$ or $\overline{\mathfrak{d}}$, p is some positive integer, such that $(\alpha_{\gamma_i},\alpha_{\gamma_{i+1}})\neq 0$ for all $i=1,\ldots,p-1$. This is an equivalent relation. Let $\mathfrak{s}$ and $\overline{\mathfrak{s}}$ be the set of equivalent classes on $\mathfrak{d}$ and $\overline{\mathfrak{d}}$, respectively. If $\mathfrak{e}$ is an element in $\mathfrak{s}$ or $\overline{\mathfrak{s}}$, it is obvious that $C_{\mathfrak{e}}=(a_{ij})_{i,j\in\mathfrak{e}}$ is also a symmetrizable Cartan matrix. If $\mathfrak{e}_1\neq\mathfrak{e}_2$ in $\mathfrak{s}$ or $\overline{\mathfrak{s}}$ and $i\in\mathfrak{e}_1$ and $j\in\mathfrak{e}_2$, then $E_iE_j=E_jE_i$ and $F_iF_j=F_jF_i$, and hence $X_iX_j=X_jX_i$ and $Y_iY_j=Y_jY_i$, respectively. Let $W_{\mathfrak{e}}$ be the Weyl group corresponding to the equivalent class $\mathfrak{e}$ on $\mathfrak{d}$ or $\overline{\mathfrak{d}}$. Let $w_0^{\mathfrak{e}}=s_{i_1}\cdots s_{i_{t_{\mathfrak{e}}}}$ be the longest element in $W_{\mathfrak{e}}$. Let $\ell_{\mathfrak{e}}=|w_0^{\mathfrak{e}}|=t_{\mathfrak{e}}$. We denote $a_{\mathfrak{e}}=(a_{t_{\mathfrak{e}}},\ldots,a_1)$ according to this order and

$$X_{\mathfrak{e}}^{a_{\mathfrak{e}}}=T_{i_1}\cdots T_{i_{t_{\mathfrak{e}}-1}}(E_{i_{t_{\mathfrak{e}}}}^{a_{t_{\mathfrak{e}}}})\cdots T_{i_1}T_{i_2}(E_{i_3}^{a_3})T_{i_1}(E_{i_2}^{a_2})E_{i_1}^{a_1}(1-J),\tag{4.11}$$

$$Y_{\mathfrak{e}}^{a_{\mathfrak{e}}}=T_{i_1}\cdots T_{i_{t_{\mathfrak{e}}-1}}(F_{i_{t_{\mathfrak{e}}}}^{a_{t_{\mathfrak{e}}}})\cdots T_{i_1}T_{i_2}(F_{i_3}^{a_3})T_{i_1}(F_{i_2}^{a_2})F_{i_1}^{a_1}(1-J).\tag{4.12}$$

It is noted that

$$X_iY_j=Y_jX_i$$

for all $i\in\mathfrak{d}$, $j\in\overline{\mathfrak{d}}$, and

$$\mathfrak{d}=\cup_{\mathfrak{e}\in\mathfrak{s}}\mathfrak{e},\quad \overline{\mathfrak{d}}=\cup_{\mathfrak{e}\in\overline{\mathfrak{s}}}\overline{\mathfrak{e}},$$

one sees that

$$\left\{\prod_{\mathfrak{e}\in\mathfrak{s}}X_{\mathfrak{e}}^{a_{\mathfrak{e}}}\prod_{\overline{\mathfrak{e}}\in\overline{\mathfrak{s}}}Y_{\overline{\mathfrak{e}}}^{b_{\overline{\mathfrak{e}}}}\middle|a_{\mathfrak{e}}\in\mathbb{N}^{\ell_{\mathfrak{e}}},b_{\overline{\mathfrak{e}}}\in\mathbb{N}^{\ell_{\overline{\mathfrak{e}}}}\right\}$$

forms a basis of $\overline{w_q}$. By Proposition 4.2 and the discussion above, we have the following.

Theorem 4.6: *The notations are kept as above. Then the set*

$$\{F^bP^sE^aJ|a,b\in\mathbb{N}^{\ell_0},s\in\mathbb{Z}^n\}\cup\left\{\prod_{\mathfrak{e}\in\mathfrak{s}}X_{\mathfrak{e}}^{a_{\mathfrak{e}}}\prod_{\overline{\mathfrak{e}}\in\overline{\mathfrak{s}}}Y_{\overline{\mathfrak{e}}}^{b_{\overline{\mathfrak{e}}}}\middle|a_{\mathfrak{e}}\in\mathbb{N}^{\ell_{\mathfrak{e}}},b_{\overline{\mathfrak{e}}}\in\mathbb{N}^{\ell_{\overline{\mathfrak{e}}}}\right\}$$

forms a basis of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$.

It is mentioned that the set

$$\{E^aP^sF^aJ|a,b\in\mathbb{N}^{\ell_0},s\in\mathbb{Z}^n\}\cup\left\{\prod_{\mathfrak{e}\in\mathfrak{s}}X_{\mathfrak{e}}^{a_{\mathfrak{e}}}\prod_{\overline{\mathfrak{e}}\in\overline{\mathfrak{s}}}Y_{\overline{\mathfrak{e}}}^{b_{\overline{\mathfrak{e}}}}\middle|a_{\mathfrak{e}}\in\mathbb{N}^{\ell_{\mathfrak{e}}},b_{\overline{\mathfrak{e}}}\in\mathbb{N}^{\ell_{\overline{\mathfrak{e}}}}\right\}$$

also forms a basis of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$.

Let us recall some basic facts used below. Let C be a coalgebra. If the set $\{C_n\}_{n\geqslant 0}$ of subspaces of C satisfies

(1) $C_n\subseteq C_{n+1}$ and $C=\cup_{n\geqslant 0}C_n$

(2) $\Delta(C_n) \subseteq \Sigma_{i=0}^{n} C_i \otimes C_{n-i}$,

then the set $\{C_n\}_{n\geqslant 0}$ is said to be a coalgebra filtration of C.

The following lemma is well known.

Lemma 4.7: (Ref. 14, Lemma 5.5.1) *Let H be a bialgebra which contains subspaces $A_0 \subset A_1$ such that*

(1) *A_0 is a (unital) subalgebra of H and A_1 is a left, and a right A_0-module*;
(2) *A_1 generates H as an algebra, and $1 \in A_0$*;
(3) *$\Delta A_0 \subseteq A_0 \otimes A_0$ and $\Delta(A_1) \subseteq A_1 \otimes A_0 + A_0 \otimes A_1$.*

Then, if we set $A_n = (A_1)^n$ for all $n \geqslant 1$, $\{A_n\}$ is a coalgebra filtration of H and $A_0 \supseteq H_0$, where H_0 is the coradical of H.

The element $x \in \mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ is said to be a grouplike element if $\Delta(x) = x \otimes x$. The set $G = G(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$ of all grouplike elements of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ can be determined.

A semigroup S is called regular, if for every $x \in S$, there exists a $y \in S$ such that $xyx = x$ and $yxy = y$ and a monoid is a semigroup with identity.

Proposition 4.8: The set of all grouplike elements is $G = \{P^s | s \in \mathbb{Z}^n\} \cup \{1\}$, which forms a regular monoid under the multiplication of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$.

Proof: Let G be the setup as above. Let $A_0 = kG$ and

$$A_1 = A_0\left(\sum_i kE_i + kF_i + A_0\right)A_0.$$

It is easy to see that $A_0 \subset A_1$ satisfies the hypotheses of Lemma 4.7 and $A_0 \subseteq H_0$. Hence $H_0 = A_0$. □

It is mentioned that $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ is a pointed bialgebra with the coradical kG by Proposition 4.8.

V. THE AUTOMORPHISM GROUP OF $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$

If $(A, m, \mu, \Delta, \varepsilon, T)$ is a (weak) Hopf algebra, then a (weak) Hopf algebra automorphism $\varphi: A \to A$ is an invertible algebra homomorphism satisfying

$$(\varphi \otimes \varphi) \circ \Delta = \Delta \circ \varphi,$$

$$\varepsilon = \varepsilon \circ \varphi,$$

$$\varphi \circ T = T \circ \varphi.$$

The group of Hopf algebra automorphisms of $U_q(\mathfrak{g})$ was determined by several authors. See, for example, Refs. 4 and 15. Inspired by these considerations, we would like to determine the group of weak Hopf algebra automorphisms of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ where q is not a root of unity.

Let $N = (k^*)^n$, and for $a = (a_1, \ldots, a_n) \in N$, we define a map $\phi_a: U_q(\mathfrak{g}) \to U_q(\mathfrak{g})$ by

$$\phi_a(k_i) = k_i, \quad \phi_a(e_i) = a_i e_i, \quad \phi_a(f_i) = a_i^{-1} f_i.$$

It is straightfoward to check that ϕ_a is a Hopf algebra automorphism of $U_q(\mathfrak{g})$. It is called N the group of diagonal automorphisms of $U_q(\mathfrak{g})$.

Recall that the Dynkin diagram of $\mathfrak{g}$ is the weight graph Γ with vertices $\mathfrak{n} = \{1, 2, \ldots, n\}$ such that vertices i and j are connected by $a_{ij}a_{ji}$ edges, and vertex i carries weight d_i. Let σ be a automorphsim of Dynkin diagram Γ, that is σ is a bijection of $\mathfrak{n}$ and

$$d_i a_{ij} = d_{\sigma(i)} a_{\sigma(i)\sigma(j)}$$

for all $1 \leqslant i, j \leqslant n$. If this is the case, there is an automorphism of Hopf algebra $U_q(\mathfrak{g})$, also denoted by σ, given by

$$\sigma(k_i) = k_{\sigma(i)}, \quad \sigma(e_i) = e_{\sigma(i)}, \quad \sigma(f_i) = f_{\sigma(i)}.$$

We denote by H the group of automorphisms of the Dynkin diagram. Also, H acts on N by the rules $\sigma\cdot a=(a_{\sigma(1)},\ldots,a_{\sigma(n)})$ and we have $\phi_a\sigma=\sigma\phi_{\sigma\cdot a}$. We will base on the following theorem to investigate the group of automorphisms of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$.

Theorem 5.1: (Ref. 4, Corollary 4.3; Ref. 18, Theorem 2.1) *The group of Hopf algebra automorphism of $U_q(\mathfrak{g})$ is the semidirect product $N\rtimes H$ of the group of diagonal automorphism N by the group of diagram automorphisms H.*

Moreover, we also need some basic lemmas.

Lemma 5.2: *If $x,y\in\overline{w_q}$, $a_x,b_y\neq 0$ and*

$$\Delta(x)=1\otimes x+x\otimes K_i+a_x(1-J)\otimes E_iJ,$$

$$\Delta(y)=\overline{K_i}\otimes y+y\otimes 1+b_yF_iJ\otimes(1-J),$$

then $x=a_xE_i(1-J)$ and $y=b_yF_i(1-J)$.

Proof: The notations $\mathfrak{d}$ and $\overline{\mathfrak{d}}$ are as in Sec. IV. Let $W_{\mathfrak{d}}$ be the Weyl group corresponding to $\mathfrak{d}$ and $w_{\mathfrak{d}}=s_{i_1}\cdots s_{i_{t_{\mathfrak{d}}}}$ be the longest element in $W_{\mathfrak{d}}$ and $\ell_{\mathfrak{d}}=t_{\mathfrak{d}}$. Similarly, we have the Weyl group $W_{\overline{\mathfrak{d}}}$, $w_{\overline{\mathfrak{d}}}=s_{j_1}\cdots s_{j_{t_{\overline{\mathfrak{d}}}-1}}$, $\ell_{\overline{\mathfrak{d}}}$ for the support set $\overline{\mathfrak{d}}$ in an obvious sense.

Let $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^+$ be the sub-bialgebra of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ generated by E_i, $1\leqslant i\leqslant n$ and the set G of group-likes of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. Let $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^-$ be the sub-bialgebra of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ generated by F_i, $1\leqslant i\leqslant n$ and G. We define a $\mathbb{N}[I]$-algebra gradation on $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^+$ [respectively, $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^-$] such that E_j^s (respectively, F_j^s) are homogeneous of degree $s\alpha_j\in\mathbb{N}[I]$ for $s\in\mathbb{N}$, $1\leqslant j\leqslant n$. We also set $\deg K_j=\deg\overline{K_j}=\deg J=0$ for all j. According to this gradation, $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^+$ [respectively, $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^-$] is also a graded coalgebra. It is obvious that $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^+(1-J)\subset\overline{w_q}$ has a basis $\{E^a(1-J)|a\in\mathbb{N}^{\ell_{\mathfrak{d}}}\}$. Similarly, $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})^-(1-J)\subset\overline{w_q}$ has a basis $\{F^b(1-J)|b\in\mathbb{N}^{\ell_{\overline{\mathfrak{d}}}}\}$.

It is easy to see the elements $E^a(1-J)$, $F^b(1-J)$ have a gradation $|a|$ and $|b|$, where

$$|a|=a_1\alpha_1+a_2s_{i_1}(\alpha_{i_2})+\cdots+a_{t_{\mathfrak{d}}}s_{i_1}s_{i_2}\cdots s_{i_{t_{\mathfrak{d}}-1}}(\alpha_{i_{t_{\mathfrak{d}}}}),$$

$$|b|=b_1\alpha_1+b_2s_{j_1}(\alpha_{j_2})+\cdots+b_{t_{\mathfrak{d}}}s_{j_1}s_{j_2}\cdots s_{j_{t_{\overline{\mathfrak{d}}}-1}}(\alpha_{i_{j_{\mathfrak{d}}}}).$$

Let

$$x=\sum_{a\in\mathbb{N}^{\ell_{\mathfrak{d}}},b\in\mathbb{N}^{\ell_{\overline{\mathfrak{d}}}}}x(a,b)E^aF^b(1-J)\in\overline{w_q},$$

where $\{E^aF^b(1-J)\}$ are linear independent. We have

$$\Delta(x)=\sum_{\substack{a\in\mathbb{N}^{\ell_{\mathfrak{d}}},b\in\mathbb{N}^{\ell_{\overline{\mathfrak{d}}}}\\ |s|+|t|=|a|\\ |x|+|y|=|b|}}x(a,b)a(s,t)b(x,y)E^sF^x\overline{K_{|y|}}\otimes E^tK_{|s|}F^y-\sum_{\substack{a\in\mathbb{N}^{\ell_{\mathfrak{d}}},b\in\mathbb{N}^{\ell_{\overline{\mathfrak{d}}}}\\ |s|+|t|=|a|\\ |x|+|y|=|b|}}x(a,b)a(s,t)b(x,y)E^sF^x\overline{K_{|y|}}J$$
$$\otimes E^tK_{|s|}F^yJ.$$

Hence,

$$\Delta(x) = \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}}, b\in\mathbb{N}^{\ell_\mathfrak{d}^-} \\ |x|+|y|=|b| \\ |a'|=|a|,|y|\neq 0}} x(a,b)a(0,a')b(x,y)F^x\overline{K}_{|y|}\otimes E^{a'}F^y(1-J)$$
$$+ \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}}, b\in\mathbb{N}^{\ell_\mathfrak{d}^-} \\ |s|+|t|=|a| \\ |b'|=|b|,|s|\neq 0}} x(a,b)a(s,t)b(b',0)E^sF^{b'}(1-J)\otimes E^tK_{|s|}$$
$$+ \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}}, b\in\mathbb{N}^{\ell_\mathfrak{d}^-} \\ |a'|=|a| \\ |b'|=|b|}} x(a,b)a(0,b')b(b',0)F^{b'}\otimes E^{a'} - \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}}, b\in\mathbb{N}^{\ell_\mathfrak{d}^-} \\ |a'|=|a| \\ |b'|=|b|}} x(a,b)a(0,b')b(b',0)F^{b'}J$$
$$\otimes E^{a'}J.$$

On the other hand, by the assumption we have

$$\Delta(x) = 1\otimes \sum_{a\in\mathbb{N}^{\ell_\mathfrak{d}}, b\in\mathbb{N}^{\ell_\mathfrak{d}^-}} x(a,b)E^aF^b(1-J) + \sum_{a\in\mathbb{N}^{\ell_\mathfrak{d}}, b\in\mathbb{N}^{\ell_\mathfrak{d}^-}} x(a,b)E^aF^b(1-J)\otimes K_i + a_x(1-J)\otimes E_iJ.$$

Comparing the above identities, we conclude that all $b=0$. Now we can rewrite x as

$$x = \sum_{a\in\mathbb{N}^{\ell_\mathfrak{d}}} x(a)E^a(1-J) \in \overline{w}_q$$

and

$$\sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}} \\ |s|+|t|=|a| \\ |s|\neq 0}} x(a)a(s,t)E^s(1-J)\otimes E^tK_{|s|} + \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}} \\ |a'|=|a|}} x(a)1\otimes E^{a'} - \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}} \\ |a'|=|a|}} x(a)J\otimes E^{a'}J$$
$$= \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}} \\ |s|+|t|=|a| \\ |s|\neq 0}} x(a)a(s,t)E^s(1-J)\otimes E^tK_{|s|} + 1\otimes \sum_{\substack{a\in\mathbb{N}^{\ell_\mathfrak{d}} \\ |a'|=|a|}} x(a)E^{a'}(1-J) + \sum_{a\in\mathbb{N}^{\ell_\mathfrak{d}}} x(a)(1-J)\otimes E^{a'}J$$
$$= 1\otimes \sum_{a\in\mathbb{N}^{\ell_\mathfrak{d}}} x(a)E^a(1-J) + \sum_{a\in\mathbb{N}^{\ell_\mathfrak{d}}} x(a)E^a(1-J)\otimes K_i + a_x(1-J)\otimes E_iJ.$$

Also, comparing the above identity, we conclude that $|a|=|a'|=i$, and hence $x=x(a)E_i(1-J)$. It follows that $x(a)=a_x$. The argument for F_i is similar. □

Lemma 5.3: Let φ be a Hopf algebra automorphism of w_q (the identity is J). Then there exists a unique way to extend φ to $\mathfrak{w}_q^\mathfrak{d}(\mathfrak{g})$ such that φ is an automorphism of weak Hopf algebra $\mathfrak{w}_q^\mathfrak{d}(\mathfrak{g})$.

Proof: Let φ be the automorphism of Hopf algebra w_q. By Lemma 5.1, the map φ is

$$K_i\to K_{\sigma(i)},\quad \overline{K_i}\to\overline{K}_{\sigma(i)},\quad E_iJ\to a_{\sigma(i)}E_{\sigma(i)}J,\quad F_iJ\to a_{\sigma(i)}^{-1}F_{\sigma(i)}J$$

for some automorphism σ of Dynkin diagram. Assume that φ can be extended to $\mathfrak{w}_q^\mathfrak{d}(\mathfrak{g})$ such that φ is an automorphism of $\mathfrak{w}_q^\mathfrak{d}(\mathfrak{g})$ as weak Hopf algebras. We must find suitable images of $\varphi(E_i(1-J))$ and $\varphi(F_i(1-J))$. For example, if E_i is type 2, we do nothing since $E_i(1-J)=0$. Assume that E_i is type 1 and $\varphi(E_i(1-J))=x$, then $x\neq 0$, $x\in\overline{w}_q$, and

$$\varphi(E_i) = \varphi(E_iJ + E_i(1-J)) = a_{\sigma(i)}E_{\sigma(i)}J + x.$$

Since φ is a coalgebra homomorphism, we have

$$a_{\sigma(i)}E_{\sigma(i)}J \otimes K_{\sigma(i)} + a_{\sigma(i)}J \otimes E_{\sigma(i)}J + \Delta(x) = (a_{\sigma(i)}E_{\sigma(i)}J + x) \otimes K_{\sigma(i)} + 1 \otimes (a_{\sigma(i)}E_{\sigma(i)}J + x).$$

It follows that

$$\Delta(x) = x \otimes K_{\sigma(i)} + 1 \otimes x + a_{\sigma(i)}(1-J) \otimes E_{\sigma(i)}J.$$

By Lemma 5.2, $x = a_{\sigma(i)}E_{\sigma(i)}(1-J)$. Similarly, we can get that $\varphi(F_i(1-J)) = a_{\sigma(i)}^{-1}F_{\sigma(i)}(1-J)$ if F_i is type 1, and nothing is done if F_i is of type 2. Of course, $\varphi(1)=1$. The lemma is proved. □

For $a=(a_1,\ldots,a_n) \in N$, we define a map $\phi_a : \mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}) \to \mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ by

$$\phi_a(K_i) = K_i, \quad \phi_a(\overline{K_i}) = \overline{K_i}, \quad \phi_a(E_i) = a_iE_i, \quad \phi_a(F_i) = a_i^{-1}F_i.$$

It is straightfoward to check that ϕ_a is a weak Hopf algebra automorphism of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. If $\sigma \in H$, then there is an automorphism of weak algebra $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$, also denoted by σ, given by

$$\sigma(K_i) = K_{\sigma(i)}, \quad \sigma(\overline{K_i}) = \overline{K}_{\sigma(i)}, \quad \sigma(E_i) = E_{\sigma(i)}, \quad \sigma(F_i) = F_{\sigma(i)}.$$

Recall that there is an action of H on N by the rules $\sigma \cdot a = (a_{\sigma(1)},\ldots,a_{\sigma(n)})$ and $\phi_a\sigma = \sigma\phi_{\sigma\cdot a}$.

Let $\mathrm{Aut}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$ be the group of automorphisms of weak Hopf algebra $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. The group $\mathrm{Aut}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$ can be determined by the following theorem.

Theorem 5.4: $\mathrm{Aut}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})) = N \rtimes H$.

Proof: Theorem A in Ref. 4 is the key to determine the group of automorphisms of Hopf algebra. But we do not know whether it is true or not for bialgebras (see Ref. 5); we cannot directly apply Theorem A to get the result.

Let $\varphi \in \mathrm{Aut}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$, since φ sends group-likes to group-likes, we have $\varphi(J) = P^s$ for some $s \in \mathbb{Z}^n$ by Proposition 4.8. If $s \neq 0$, since $J^2 = J$ we have $P^{2s} = P^s$, hence $P^s = J$ it follows that $P^sJ = J$. It is a contradiction for Theorem 4.6. Therefore, $s=0$ and $\varphi(J) = J$.

According to Proposition 4.2, $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}) = w_q \oplus \overline{w_q}$ and $w_q \cong U_q(\mathfrak{g})$ as Hopf algebras, where the notations w_q and $\overline{w_q}$ as before.

Let $\mathrm{inj}_q : w_q \to \mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$ be the inclusion defined by

$$J \to J, \quad E_iJ \to E_iJ, \quad F_iJ \to F_iJ, \quad K_i \to K_i, \quad \overline{K_i} \to \overline{K_i},$$

and then extend it by linearity. It is easy to see that inj_q is a weak Hopf algebra injection by Proposition 4.2. Let $\varphi \in \mathrm{Aut}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$, we see that $w_q = \mathrm{im}(\varphi \circ \mathrm{inj}_q)$ since $\varphi(J) = J$. This implies that $\varphi \circ \mathrm{inj}_q$ is an automorphism of Hopf algebra w_q and $\varphi \circ \mathrm{inj}_q \in N \rtimes H$ by Theorem 5.1. That is, the map $\varphi|_{w_q}$ is

$$K_i \to K_{\sigma(i)}, \quad \overline{K_i} \to \overline{K}_{\sigma(i)}, \quad E_iJ \to a_{\sigma(i)}E_{\sigma(i)}J, \quad F_iJ \to a_{\sigma(i)}^{-1}F_{\sigma(i)}J.$$

This implies that φ is

$$K_i \to K_{\sigma(i)}, \quad \overline{K_i} \to \overline{K}_{\sigma(i)}, \quad E_i \to a_{\sigma(i)}E_{\sigma(i)}, \quad F_i \to a_{\sigma(i)}^{-1}F_{\sigma(i)}$$

by Lemma 5.2. Hence $\varphi \in N \rtimes H$ and $\mathrm{Aut}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})) \subseteq N \rtimes H$. On the other hand, it is obvious that $N \rtimes H \subseteq \mathrm{Aut}(\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g}))$. The proof is completed. □

The more interesting problem is to determine the algebraic group of $\mathfrak{w}_q^{\mathfrak{d}}(\mathfrak{g})$. It is mentioned that Ref. 2 contributed to determine $\mathrm{Aut}_{\mathrm{Alg}}(U_q^+(\mathfrak{g}))$. A basic idea to approach the group $\mathrm{Aut}_{\mathrm{Alg}}(U_q^+(\mathfrak{g}))$ is to study its actions on natural sets.

On the uniqueness of solutions to gauge covariant Poisson equations with compact Lie algebras

Christofer Cronström[a)]
Department of Physical Sciences, Theoretical Physics Division FIN-00014, University of Helsinki, Finland

(Received 9 February 2005; accepted 22 April 2005; published online 17 June 2005)

It is shown, under rather general smoothness conditions on the gauge potential, which takes values in an arbitrary semisimple compact Lie algebra **g**, that if a (**g**-valued) solution to the gauge-covariant Laplace equation exists, which vanishes at spatial infinity, in the cases of 1,2,3,…, space dimensions, then the solution is identically zero. This result is also valid if the Lie algebra is merely compact. Consequently, a solution to the gauge-covariant Poisson equation is uniquely determined by its asymptotic radial limit at spatial infinity. In the cases of one or two space dimensions a related result is proved, namely that if a solution to the gauge-covariant Laplace equation exists, which is unbounded at spatial infinity, but with a certain dimension-dependent condition on the asymptotic growth of its norm, then the solution in question is a covariant constant. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1935427]

I. INTRODUCTION

Let **g** denote a semisimple compact Lie algebra and let Φ and $\mathcal{F}$ denote two **g**-valued functions on an n-dimensional Euclidean space R^n. Points in R^n are denoted by $x := (x^1, x^2, \ldots, x^n)$. The covariant Poisson equation is then the following:

$$\sum_{k=1}^{n} \boldsymbol{\nabla}_k(A)\boldsymbol{\nabla}^k(A)\Phi(x) = \mathcal{F}(x), \tag{1}$$

where $\boldsymbol{\nabla}_k(A)$ denotes the following gauge-covariant gradient,

$$\boldsymbol{\nabla}_k(A) := \partial_k + i[A_k,] \equiv \frac{\partial}{\partial x^k} + i[A_k(x),]. \tag{2}$$

In definition (2), the symbol $A := (A_1(x), A_2(x), \ldots, A_n(x))$ is a **g**-valued gauge potential,[1] and the symbol $[\ ,\ ]$ stands for the commutator of **g**-valued quantities. The covariant gradient with an upper index k, $\boldsymbol{\nabla}^k(A)$, is defined as follows:

$$\boldsymbol{\nabla}^k(A) := -\boldsymbol{\nabla}_k(A). \tag{3}$$

Other quantities with upper space indices are defined similarly; viz., if V_k is any quantity with a lower (subscript) space index, then its counterpart with an upper (superscript) space index V^k is given as follows:

$$V^k := -V_k, \quad k = 1,2,\ldots,n. \tag{4}$$

The covariant Poisson equation (1) is a second-order elliptic system of partial differential equations, which, together with appropriate boundary conditions, is supposed to determine the

a)Electronic mail: Christofer.Cronstrom@Helsinki.fi.

quantity $\Phi(x)$, when the inhomogeneous term $\mathcal{F}(x)$ and gauge potential $A(x)$, respectively, are given. These quantities are supposed to satisfy appropriate regularity conditions. We will return to the question of regularity conditions subsequently.

The Lie algebra $\mathbf{g}$ is specified by the (real-valued) structure constants $f_{ab}{}^{c}$ in the commutation relations of the Lie algebra generators T_a, $a=1,2,\ldots,\dim \mathbf{g}$,

$$[T_a,T_b]=if_{ab}{}^{c}T_c, \quad a,b=1,2,\ldots,\dim \mathbf{g}. \tag{5}$$

Here and in what follows, a summation of repeated Lie algebra indices, i.e., letters from the beginning of the Latin alphabet, over the range $1,2,\ldots,\dim \mathbf{g}$ is implied, unless otherwise stated.

From now on we will identify the Lie algebra generators with some specific Hermitian matrix representatives. For the purposes of this paper it does not matter which representation is chosen; in physical applications the choice of representations is related to the question of what types of other fields are coupled to the gauge fields, a question that is not our concern here.

Any $\mathbf{g}$-valued quantity is in the linear span of the generators T_a, thus

$$\Phi(x)=\Phi^a(x)T_a, \quad \mathcal{F}(x)=\mathcal{F}^a(x)T_a, \quad A_k(x)=A_k^a(x)T_a, \tag{6}$$

where all the components Φ^a, $\mathcal{F}^a$, and A_k^a are *real*.

The covariant Poisson equation (1) can naturally be written as a system of partial differential equations for the real-valued components Φ^a. Using the commutator algebra (5) one readily obtains the following system of equations:

$$\partial_k\partial^k\Phi^a-2f_{bc}{}^{a}A^{kb}\partial_k\Phi^c-f_{bc}{}^{a}(\partial_kA^{kb})\Phi^c+f_{bd}{}^{a}f_{ec}{}^{d}A_k^bA^{ke}\Phi^c=\mathcal{F}^a. \tag{7}$$

In the previous equation, summation over repeated space indices, one lower and one upper, is also implied.

For our purposes the compact matrix notation in Eq. (1) is preferable, and this will be used in what follows.

The gauge-covariant Poisson equation (1) on R^3 is one of the field equations (for fixed time) in either pure Yang–Mills theory, or Yang–Mills theory coupled to matter fields,[1] in four-dimensional Minkowski space. The gauge field $G_{\mu\nu}$ in Yang–Mills theory is as follows:

$$G_{\mu\nu}=\partial_\nu A_\mu-\partial_\mu A_\nu-i[A_\mu,A_\nu], \tag{8}$$

where Greek indices are Minkowski-space indices in the range (0, 1, 2, 3). The field equations are

$$\boldsymbol{\nabla}_\nu(A)G^{\mu\nu}(A)=j^\mu_{(m)}, \quad \mu=0,1,2,3, \tag{9}$$

where $j^\mu_{(m)}$ is a matter current constructed out of matter fields, e.g., fermionic and scalar fields.

The $\mu=0$ case of the equations (9) is Gauss' law,

$$\boldsymbol{\nabla}_k(A)G^{0k}=j^0_{(m)}, \tag{10}$$

which written in terms of the gauge potential components, is as follows:

$$\boldsymbol{\nabla}_k(A)\boldsymbol{\nabla}^k(A)A^0=j^0_{(m)}+\boldsymbol{\nabla}_k(A)\dot{A}^k, \tag{11}$$

where

$$\dot{A}_k(x)\equiv\partial_0A_k(x). \tag{12}$$

One physical application of the covariant Poisson equation (1) on R^3 is thus the implementation of Gauss' law by solving the equation (11) for the quantity A^0, with $j^0_{(m)}$ and $\dot{A}^k$ considered as known quantities. For this purpose one needs both existence and uniqueness theorems for equations of the form (1).

We will state and prove our main uniqueness theorems in detail for the equation (1) in Secs. III and IV. However, before that we collect in the next section a number of facts related to gauge transformations and inner products for semisimple compact Lie algebras that we need in the proofs.

II. ON GAUGE TRANSFORMATIONS AND LIE ALGEBRA INNER PRODUCTS

Let G denote the Lie group corresponding to the compact or semisimple compact Lie algebra defined by the equations (5) and let ω denote a mapping from R^n to G. In the vicinity of the unit element in G any such G-valued element ω can be obtained by exponentiating the Lie algebra, i.e.,

$$\omega(x) = e^{i\alpha^a T_a}, \tag{13}$$

where the parameters $\alpha^a(x), a=1,2,\ldots,\dim \mathbf{g}$ are sufficiently smooth real-valued functions that vary over a finite range.

A gauge transformation of a gauge potential $A \overset{\omega}{\rightarrow} A^\omega$ is then defined as follows for any sufficiently smooth G-valued function $\omega(x)$:

$$A_k(x) \overset{\omega}{\rightarrow} A_k^\omega(x) = \omega^{-1}(x)A_k(x)\omega(x) + i(\partial_k \omega^{-1}(x))\omega(x). \tag{14}$$

Let $U(x)$ be any differentiable $\mathbf{g}$-valued function and $\omega(x)$ likewise any differentiable G-valued function. Using Eq. (14), one readily shows that

$$\omega^{-1}(x)(\boldsymbol{\nabla}_k(A)U(x))\omega(x) = \boldsymbol{\nabla}_k(A^\omega)(\omega^{-1}(x)U(x)\omega(x)). \tag{15}$$

Applying the transformation (15) to the gauge-covariant Poisson equation (1), one obtains

$$\sum_{k=1}^{n} \boldsymbol{\nabla}_k(A^\omega)\boldsymbol{\nabla}^k(A^\omega)(\omega^{-1}(x)\Phi(x)\omega(x)) = \omega^{-1}(x)\mathcal{F}(x)\omega(x), \tag{16}$$

a result that will be used later.

If our Lie algebra is semisimple and compact, we use the following quantities h_{ab} as our Lie algebra metric. The quantities h_{ab} are defined in terms of the structure constants $f_{ab}{}^c$ as follows:

$$h_{ab} = -f_{ab'}{}^{c'} f_{bc'}{}^{b'}. \tag{17}$$

This is the so-called Killing form multiplied with -1 for convenience. It is known[2] that the form (17) is nondegenerate, and, furthermore, positive definite, if and only if the Lie algebra is semisimple and compact. The form (17) thus has an inverse, which we denote by h^{ab},

$$h^{ab}h_{bc} = \delta_c^a. \tag{18}$$

The form h_{ab} (h^{ab}) is used to lower (raise) Lie algebra indices.

For any two $\mathbf{g}$-valued quantities $U=U^aT_a$ and $V=V^aT_a$ we thus define their inner product (U,V) as follows:

$$(U,V) = h_{ab}U^aV^b. \tag{19}$$

The inner product (19) is invariant under the adjoint action of the group, i.e.,

$$(U,V) = (\omega^{-1}U\omega, \omega^{-1}V\omega), \quad \forall\ \omega \in G. \tag{20}$$

The norm $\|\ \|_g$ of any Lie algebra-valued quantity U is defined in terms of the inner product,

$$\|U\|_g := \sqrt{(U,U)}. \tag{21}$$

We also need the fact that for any three **g**-valued quantities U, V, and W the quantity $(U,[V,W])$ is cyclically symmetric,

$$(U,[V,W]) = (V,[W,U]) = (W,[U,V]) \tag{22}$$

The equations (22) follow directly from the fact that the quantities f_{abc} are antisymmetric under the interchange of any indices.

An immediate consequence of Eqs. (22) is the following useful identity:

$$\partial_k(U,V) = (\boldsymbol{\nabla}_k(A)U,V) + (U,\boldsymbol{\nabla}_k(A)V). \tag{23}$$

This identity is valid for any two differentiable **g**-valued quantities U and V and a smooth gauge potential A.

We finally note that one may drop the condition of semisimplicity above and require only the condition of compactness of the Lie algebra. One is still then guaranteed the existence of an inner product $(\ ,\ )$ in the Lie algebra that is positive definite and satisfies the condition (22) of cyclic symmetry.[3] In the considerations below one only needs these properties of the Lie algebra inner product. The results derived below are therefore also valid for the case of only compact Lie algebras, and not only for the case of *both* semisimple and compact Lie algebras.

III. UNIQUENESS THEOREMS IN THE CASES $n=1$ AND $n=2$

A. The one-dimensional case

In the case of one space dimension, the gauge-covariant Poisson equation (1) is fairly trivial. We nevertheless give a brief analysis also of this case for completeness. In one space dimension Eq. (1) becomes the following:

$$\boldsymbol{\nabla}_1(A)\boldsymbol{\nabla}^1(A)\Phi(x) = \mathcal{F}(x), \tag{24}$$

where we now use the notation x instead of x^1 for simplicity.

We then choose a G-valued quantity ω such that

$$A_1^{\omega}(x) \equiv \omega^{-1}(x)A_1(x)\omega(x) + i\left(\frac{d}{dx}\omega^{-1}(x)\right)\omega(x) = 0. \tag{25}$$

The condition (25) is equivalent to the differential equation

$$\frac{d}{dx}\omega(x) = -iA_1(x)\omega(x). \tag{26}$$

For any smooth gauge potential $A_1(x)$, the (matrix) differential equation (26) has a G-valued solution, determined apart from a constant initial value at some appropriate point in R^1. Then, applying a transform of the type given in Eq. (16) to Eq. (24), with the quantity ω determined by Eq. (26), one obtains

$$\frac{d^2}{dx^2}(\omega^{-1}\Phi\omega) = (\omega^{-1}\mathcal{F}\omega). \tag{27}$$

The question of uniqueness of the solution(s) to Eq. (27) is related to the number of solutions of the homogeneous equation corresponding to Eq. (27) under appropriate boundary conditions. The homogeneous equation in question,

$$\frac{d^2}{dx^2}(\omega^{-1}\Phi_h\omega) = 0, \tag{28}$$

has the general solution

$$\Phi_h(x) = \omega(x)\alpha\omega^{-1}(x)x + \omega(x)\beta\omega^{-1}(x), \tag{29}$$

where α and β are arbitrary constant **g**-valued quantities.

If it is required to find solutions $\Phi(x)$ to Eq. (24), which is equivalent to Eq. (27), which grow less rapidly than linearly with x for large x, then the following boundary condition at infinity must hold,

$$\lim_{|x|\to\infty} \frac{1}{x}\|\Phi(x)\|_g = 0. \tag{30}$$

Hence the difference of any two such solutions, which satisfies the homogeneous equation (28), and which is of the form Φ_h given in Eq. (29) above, must satisfy the condition

$$\lim_{|x|\to\infty} \frac{1}{x}\|\Phi_h(x)\|_g = \lim_{|x|\to\infty} \frac{1}{x}\sqrt{(\alpha,\alpha)x^2 + 2(\alpha,\beta)x + (\beta,\beta)} = 0. \tag{31}$$

Thus one must set $\alpha=0$ in Eq. (29). Hence, if a solution to Eq. (24) exists, which satisfies the condition (30), then the solution is unique apart from an additive *covariant constant*, i.e., a solution to the homogeneous equation of the form

$$\Phi_h(x) = \omega(x)\beta\omega^{-1}(x). \tag{32}$$

The solution (32) satisfies the condition of covariant constancy,

$$\boldsymbol{\nabla}_1(A)\Phi_h(x) = 0, \tag{33}$$

as a consequence of the condition (26) which determines the quantity ω.

Likewise, if one requires solutions which vanish at infinity, i.e., which satisfy the conditions

$$\lim_{|x|\to\infty} \|\Phi(x)\|_g = 0, \tag{34}$$

then one must have $\alpha=\beta=0$ in Eq. (29). Thus, if a solution to Eq. (24) exists, which satisfies the condition (34), then the solution is unique.

We can summarize the discussion above as follows.

Theorem 3.1: Assume that the gauge-covariant Poisson equation in one space dimension, Eq. (24), has a solution in the classic sense, i.e., a solution that is twice continuously differentiable in any finite interval in R^1, for a given smooth gauge potential $A_1(x)$ and for a given inhomogeneous term $\mathcal{F}(x)$, satisfying appropriate smoothness and asymptotic conditions in R^1. If such a solution grows less rapidly than linearly with increasing x, i.e., satisfies the condition (30), then the solution is unique apart from an additive covariant constant. Furthermore, if such a solution vanishes asymptotically in the sense of condition (34), then the solution is unique.

B. The two-dimensional case

We will now consider the gauge-covariant Poisson equation (1) in two-dimensional space R^2. We assume that this equation has solutions that are twice continuously differentiable in any finite domain in R^2, for a given smooth gauge potential $\mathbf{(}A_1(x^1,x^2),A_2(x^1,x^2)\mathbf{)}$ and a given inhomogeneous term $\mathcal{F}(x^1,x^2)$, which is supposed to satisfy appropriate smoothness and asymptotic conditions. Let there be two such solutions Φ_A and Φ_B, say. Then their difference,

$$\Phi_C := \Phi_A - \Phi_B, \tag{35}$$

satisfies the gauge-covariant Laplace equation, i.e., the homogeneous equation,

$$\boldsymbol{\nabla}_k(A)\boldsymbol{\nabla}^k(A)\Phi_C(x) = 0, \tag{36}$$

where summation over the space-index k in the range (1, 2) is implied here and in what follows. We then consider the quantity

$$-\nabla^2(\Phi_C,\Phi_C) \equiv \partial_k \partial^k(\Phi_C,\Phi_C). \tag{37}$$

Using the previously established formula (23) and Eq. (36), one obtains

$$-\nabla^2(\Phi_C,\Phi_C) = 2(\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C). \tag{38}$$

We then express the ∇^2 operator in terms of polar coordinates (r,θ) in the plane R^2,

$$\nabla^2 = \frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2}. \tag{39}$$

Integrating equation (38) over the variable θ in the range $(0,2\pi)$ one obtains

$$\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r}\right)\int_0^{2\pi} d\theta(\Phi_C,\Phi_C) = -2\int_0^{2\pi} d\theta(\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C). \tag{40}$$

We now consider Eq. (40) as an ordinary differential equation for the quantity $\int d\theta(\Phi_C,\Phi_C)$ as if the right-hand side of the equation were a known quantity. The general solution to this equation is then the following:

$$\int_0^{2\pi} d\theta(\Phi_C,\Phi_C) = \alpha \log r + \beta - 2(\log r)\int_0^r dr'\, r' \int_0^{2\pi} d\theta(\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C) + 2\int_0^r dr'\, r'(\log r') \int_0^{2\pi} d\theta(\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C), \tag{41}$$

where α and β are real constants.

In view of the assumed smoothness of the gauge potential A and assumed regularity of the solution Φ_C to the original equation (36), in particular in the vicinity of the origin $r=0$ in R^2, one readily concludes that the terms involving integrals in the expression (41) cannot generate logarithmic singularities at $r=0$, which could cancel the term $\alpha \log r$ in that expression. The logarithmic singularity in (41) must be expelled, and this can then only be achieved by setting $\alpha=0$. Hence, the general solution to the equation (40) when the regularity conditions at $r=0$ are taken into account, is

$$\int_0^{2\pi} d\theta(\Phi_C,\Phi_C) = \beta - 2(\log r)\int_0^r dr'\, r'\left(1 - \frac{\log r'}{\log r}\right)\int_0^{2\pi} d\theta(\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C), \tag{42}$$

where we now can identify the constant β as follows:

$$\beta = \left[\int_0^{2\pi} d\theta(\Phi_C,\Phi_C)\right]_{r=0} = 2\pi \|\Phi_C(0)\|_g^2. \tag{43}$$

We then consider the asymptotic properties of the solutions Φ_C. Let us impose the condition

$$\lim_{r\to\infty} \frac{1}{\log r}\int_0^{2\pi} d\theta(\Phi_C,\Phi_C) = 0. \tag{44}$$

Then Eq. (42) implies that

$$\lim_{r\to\infty} \int_0^r dr'\, r'\left(1 - \frac{\log r'}{\log r}\right)\int_0^{2\pi} d\theta(\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C) = 0. \tag{45}$$

The vanishing of the integral (45) in the limit $r\to\infty$ implies that the integrand must vanish, since the integrand is nonpositive (for $r>1$) in view of convention (3) and the positive definiteness of the Lie algebra inner product. But then, necessarily,

$$\nabla^k(A)\Phi_C = 0, \quad k = 1,2, \tag{46}$$

i.e., Φ_C is a covariant constant.

We can thus infer from the result above that if the gauge-covariant Poisson equation in R^2 has a twice continuously differentiable solution Φ, such that (Φ,Φ) is dominated by $\log r$ for large values of r, or more precisely, if the solution satisfies an asymptotic condition of the form (44), then the solution is unique apart from an additive covariant constant. Let us note, however, that the existence of a nonzero covariant constant in two (or more) dimensions places certain restrictions on the gauge potential A, which are related to the internal holonomy group.[4]

If one requires a more stringent asymptotic condition on the solutions to the gauge covariant Laplace equation than condition (44), namely the condition

$$\lim_{r\to\infty} \int_0^{2\pi} d\theta(\Phi_C,\Phi_C) \equiv \lim_{r\to\infty} \int_0^{2\pi} d\theta \|\Phi_C\|_g^2 = 0, \tag{47}$$

then Eqs. (42) and (43) imply as before that Eq. (46) is in force, but also that

$$\left[\int_0^{2\pi} d\theta(\Phi_C,\Phi_C)\right]_{r=0} = 0. \tag{48}$$

Taken together, Eqs. (46) and (48) imply that

$$\Phi_C(x^1,x^2) \equiv 0. \tag{49}$$

We have now demonstrated that the only solution to the gauge-covariant Laplace equation in two dimensions that vanishes at spatial infinity in the sense given by Eq. (47), is the identically vanishing solution. This gives rise to a uniqueness theorem for such solutions Φ to the inhomogeneous gauge-covariant Poisson equation, which have a given asymptotic behavior Φ^{as} at spatial infinity, or, more precisely, which satisfy a boundary condition of the form

$$\lim_{r\to\infty} \int_0^{2\pi} d\theta \|\Phi - \Phi^{\mathrm{as}}\|_g = 0. \tag{50}$$

Namely, suppose that there exist two solutions, Φ_A and Φ_B, say, to the gauge-covariant Poisson equation in two dimensions, which satisfy a boundary condition of the form (50) with some appropriate given asymptotic function Φ^{as}. Then their difference Φ_C satisfies the gauge-covariant Laplace equation (36) and the following boundary condition:

$$\begin{aligned} 0 &\leqslant \lim_{r\to\infty} \int_0^{2\pi} d\theta \|\Phi_C\|_g^2 = \lim_{r\to\infty} \int_0^{2\pi} d\theta \|\Phi_A - \Phi_B\|_g^2 = \lim_{r\to\infty} \int_0^{2\pi} d\theta \|(\Phi_A - \Phi^{\mathrm{as}}) - (\Phi_B - \Phi^{\mathrm{as}})\|_g^2 \\ &\leqslant \lim_{r\to\infty} \int_0^{2\pi} d\theta (\|\Phi_A - \Phi^{\mathrm{as}}\|_g + \|\Phi_B - \Phi^{\mathrm{as}}\|_g)^2 = 0. \end{aligned} \tag{51}$$

But then, in accordance with the reasoning above, Eq. (49) must be in force, i.e., $\Phi_A \equiv \Phi_B$. Thus, if a solution to the gauge-covariant Poisson equation in R^2 exists that has a given asymptotic limit in the sense given in Eq. (50), then the solution is unique.

We summarize the results obtained above on the gauge-covariant Poisson equation on R^2 as *Theorem 3.2*.

Theorem 3.2: Assume that the gauge-covariant Poisson equation in two space dimensions has a solution in the classic sense, i.e., a solution that is twice continuously differentiable in any finite domain in R^2, for a given smooth gauge potential $\mathbf{(}A_1(x^1,x^2),A_2(x^1,x^2)\mathbf{)}$ and for a given inhomogeneous term $\mathcal{F}(x^1,x^2)$, satisfying appropriate smoothness and asymptotic conditions in R^2.

If the squared norm $\|\Phi\|_g^2$ of such a solution grows less rapidly than logarithmically with increasing distance from the origin in R^2, i.e., satisfies the condition (44), then the solution is unique apart from an additive covariant constant.

Furthermore, if such a solution has a given asymptotic radial limit Φ^{as} in the sense of condition (50), then the solution is unique.

IV. UNIQUENESS THEOREM IN THE CASES $n \geqslant 3$

The analysis of the uniqueness of solutions to the gauge-covariant Poisson equation (1) in the cases $n \geqslant 3$ proceeds much in the same way as in the two-dimensional case considered in the previous section. Thus, we assume that the equation (1) has at least two solutions: $\Phi_A(x)$ and $\Phi_B(x)$, say, which are twice continuously differentiable in any finite domain in R^n, for any given sufficiently smooth gauge potential $\mathbf{(}A_1(x), A_2(x), \ldots, A_n(x)\mathbf{)}$ and given inhomogeneous term $\mathcal{F}(x)$, which satisfies appropriate smoothness and asymptotic conditions in R^n. We consider the difference $\Phi_C(x)$ of these solutions,

$$\Phi_C(x) = \Phi_A(x) - \Phi_B(x). \tag{52}$$

The function $\Phi_C(x)$ satisfies the gauge-covariant Laplace equation,

$$\sum_{k=1}^{n} \boldsymbol{\nabla}_k(A)\boldsymbol{\nabla}^k(A)\Phi_C = 0, \tag{53}$$

as well as such regularity and asymptotic conditions that follow from those conditions of a similar nature that are supposed to be valid for the solutions $\Phi_A(x)$ and $\Phi_B(x)$. In the equation (53) we have for clarity reinstated the explicit summation over the space index k and continue to use this notation below.

Again, using the previously established formula (23) and the equation (53), one obtains

$$\nabla^2(\Phi_C, \Phi_C) = -2\sum_{k=1}^{n} (\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C). \tag{54}$$

We then use spherical coordinates[5] on R^n,

$$x^1 = r \sin\theta_{n-1} \ldots \sin\theta_2 \sin\theta_1$$

$$x^2 = r \sin\theta_{n-1} \ldots \sin\theta_2 \cos\theta_1$$

$$\vdots$$

$$x^{n-1} = r \sin\theta_{n-1} \cos\theta_{n-2}$$

$$x^n = r \cos\theta_{n-1}, \tag{55}$$

where

$$r \geqslant 0, \quad 0 \leqslant \theta_1 < 2\pi, \quad 0 \leqslant \theta_k \leqslant \pi, \quad k \neq 1. \tag{56}$$

The Laplace operator ∇^2 expressed in terms of the spherical coordinates above is as follows:

$$\nabla^2 = \frac{1}{r^{n-1}}\frac{\partial}{\partial r}r^{n-1}\frac{\partial}{\partial r} + \frac{1}{r^2 \sin^{n-2}\theta_{n-1}}\frac{\partial}{\partial \theta_{n-1}}\sin^{n-2}\theta_{n-1}\frac{\partial}{\partial \theta_{n-1}} + \frac{1}{r^2 \sin^2\theta_{n-1}\sin^{n-3}\theta_{n-2}}\frac{\partial}{\partial \theta_{n-2}}\sin^{n-3}\theta_{n-2}\frac{\partial}{\partial \theta_{n-2}} + \cdots + \frac{1}{r^2 \sin^2\theta_{n-1}\cdots\sin^2\theta_2}\frac{\partial^2}{\partial \theta_1^2}. \tag{57}$$

We still need the invariant (normalized) measure $d\Omega_n$ on the sphere S^{n-1} in terms of the spherical coordinates above,

$$d\Omega_n = \frac{\Gamma\left(\frac{n}{2}\right)}{2\pi^{n/2}}\sin^{n-2}\theta_{n-1}\ldots\sin\theta_2\, d\theta_1\ldots d\theta_{n-1}. \tag{58}$$

Using the formulas (57) and (58), one obtains the following result from Eq. (54):

$$\frac{1}{r^{n-1}}\frac{\partial}{\partial r}\left(r^{n-1}\frac{\partial}{\partial r}\int d\Omega_n(\Phi_C,\Phi_C)\right) = -2\sum_{k=1}^{n}\int d\Omega_n(\boldsymbol{\nabla}_k(A)\Phi_C,\boldsymbol{\nabla}^k(A)\Phi_C), \tag{59}$$

where the integration over the angular variables $\theta_k, k=1,2,\ldots,n-1$ is over the complete range specified in (56). The equation (59) is now considered an ordinary differential equation for the quantity $\int d\Omega_n(\Phi_C,\Phi_C)$, under the assumption that the right-hand side of Eq. (59) is a known quantity. The general solution to Eq. (59) is then the following:

$$\int d\Omega_n(\Phi_C,\Phi_C) = \alpha r^{2-n} + \beta + \frac{2r^{2-n}}{n-2}\int_0^r dr'\, r'^{n-1}\int d\Omega_n\sum_{k=1}^{n}(\boldsymbol{\nabla}_k(A)\Phi_C,\boldsymbol{\nabla}^k(A)\Phi_C) - \frac{2}{n-2}\int_0^r dr'\, r'\int d\Omega_n\sum_{k=1}^{n}(\boldsymbol{\nabla}_k(A)\Phi_C,\boldsymbol{\nabla}^k(A)\Phi_C), \tag{60}$$

where α and β are so far undetermined real constants.

We now recall that the solutions Φ_C are supposed to be twice differentiable in any finite domain in R^n, in particular, in the vicinity of the origin $r=0$ in R^n. Moreover, the gauge potential A is supposed to be smooth, in particular near $r=0$ in R^n. From these conditions follow the estimates below, valid near $r=0$,

$$\left|\int_0^r dr'\, r'^{n-1}\int d\Omega_n\sum_{k=1}^{n}(\boldsymbol{\nabla}_k(A)\Phi_C,\boldsymbol{\nabla}^k(A)\Phi_C)\right| = O(r^n) \tag{61}$$

and

$$\left|\int_0^r dr'\, r'\int d\Omega_n\sum_{k=1}^{n}(\boldsymbol{\nabla}_k(A)\Phi_C,\boldsymbol{\nabla}^k(A)\Phi_C)\right| = O(r^2). \tag{62}$$

From the esimates (61) and (62) and the equation (60), it then follows that

$$\int d\Omega_n(\Phi_C,\Phi_C) = \alpha r^{2-n} + \beta + O(r^2), \tag{63}$$

in the vicinity of $r=0$. But the solution Φ_C is supposed to be regular, in particular near $r=0$. The singularity at $r=0$ that appears to be present in the general solution (60) must be made to disappear, and this can only happen if

$$\alpha = 0 \tag{64}$$

in Eq. (60), in accordance with the estimate (63). Then it also follows that

$$\beta = \left[\int d\Omega_n(\Phi_C, \Phi_C) \right]_{r=0} = \|\Phi_C(0)\|_g^2. \tag{65}$$

Using the conditions (64) and (65), one then finally obtains the following result:

$$\int d\Omega_n(\Phi_C, \Phi_C) = \|\Phi_C(0)\|_g^2 - \frac{2}{n-2} \int_0^r dr'\, r' \left(1 - \left(\frac{r'}{r} \right)^{n-2} \right) \int d\Omega_n \sum_{k=1}^{n} (\boldsymbol{\nabla}_k(A)\Phi_C, \boldsymbol{\nabla}^k(A)\Phi_C). \tag{66}$$

Let us emphasize that the equation (66) is a relation that is valid for any twice differentiable solution Φ_C to the gauge-covariant Laplace equation (53) with a smooth gauge potential A.

Assume now the following boundary condition at spatial infinity for the solution Φ_C to the gauge-covariant Laplace equation (53),

$$\lim_{r \to \infty} \int d\Omega_n(\Phi_C, \Phi_C) = 0. \tag{67}$$

In view of the convention (3) and the positive definiteness of the inner product (,), the condition (67) and the relation (66) together imply that

$$\boldsymbol{\nabla}^k(A)\Phi_C = 0, \quad k = 1, 2, \ldots, n, \tag{68}$$

and that

$$\|\Phi_C(0)\|_g^2 = 0. \tag{69}$$

But the conditions (68) and (69) then finally imply that

$$\Phi_C \equiv 0. \tag{70}$$

We have thus shown that the only twice differentiable solution Φ_C to the gauge-covariant Laplace equation (53) with a smooth gauge potential A, which vanishes at spatial infinity in the sense of the condition (67), is the identically vanishing solution (70).

The result above gives rise to a uniqueness theorem for the solutions to the gauge-covariant Poisson equation (1) in a space R^n of $n \geqslant 3$ dimensions, just as in the two-dimensional case. Namely, consider the following boundary conditions:

$$\lim_{r \to \infty} \int d\Omega_n \|\Phi - \Phi^{\mathrm{as}}\|_g = 0. \tag{71}$$

As has essentially already been demonstrated in the two-dimensional case, then the difference Φ_C, Eq. (52), of any two solutions Φ_A and Φ_B satisfying the asymptotic condition (71), vanishes at spatial infinity in the sense of Eq. (67). The difference in question also satisfies the gauge-covariant Laplace equation (53), and vanishes therefore identically, as has just been demonstrated above. Hence the solution to the gauge-covariant Poisson equation (1) is unique if one imposes the boundary conditions (71).

We summarize the result above as the following theorem of uniqueness:

Theorem 4: Assume that the gauge-covariant Poisson equation (1) in $n \geqslant 3$ space dimensions has a solution in the classic sense, i.e., a solution that is twice continuously differentiable in any finite domain in R^n, for a given smooth gauge potential $\mathbf{(}A_1(x), A_2(x), \ldots, A_n(x)\mathbf{)}$ and for a given inhomogeneous term $\mathcal{F}(x)$, satisfying appropriate smoothness and asymptotic conditions in R^n. If, furthermore, such a solution has a given asymptotic limit Φ^{as} in the sense of condition (71), then

the solution is *unique*.

V. SUMMARY AND DISCUSSION

In this paper a uniqueness theorem has been proved for the gauge-covariant Poisson equation in n-dimensional space R^n. The theorem has been obtained by considering the homogeneous counterpart of the Poisson equation in question, i.e., the gauge-covariant Laplace equation. It has been shown that the only solution to the gauge-covariant Laplace equation, which is twice continuously differentiable in any finite domain in R^n, and that vanishes at infinity, is the zero solution. This then proves the uniqueness of that solution of the corresponding Poisson equation, which satisfies appropriate conditions of regularity and has a given asymptotic radial limit.

In one or two dimensions the asymptotic conditions can be relaxed; it has been shown that in these cases the solutions, which may be unbounded at infinity, are unique apart from an additive covariant constant, even if one does not specify the asymptotic behavior of the solutions, but merely imposes certain specific limitations on the asymptotic growth of the solutions.

We have not touched upon the question of the existence of solutions in this paper. Such questions have been analyzed in depth in the three-dimensional case in a recent paper by Salmela,[6] who uses modern functional analytic methods in his study. The principal existence theorem proved by Salmela in R^3 is briefly as follows. There exists a weak solution to Eq. (1), which vanishes at infinity, provided that the Lie algebra norms of the potential components A_k are locally square integrable, and provided that the inhomogeneous term $\mathcal{F}(x)$ in that equation satisfies the following condition:

$$\int_{R^3} d^3x(1+|\mathbf{x}|^2)^{(1+\sigma)/2}\|\mathcal{F}\|_g^2 < \infty, \tag{72}$$

where σ is a number that can be chosen in the range $0<\sigma\leqslant 1$. It has further been shown by Salmela that solutions with nontrivial asymptotic behavior also exist under less stringent conditions than condition (72). Namely, if one can construct a function Φ_{as} such that

$$\int_{R^3} d^3x(1+|\mathbf{x}|^2)^{(1+\sigma)/2}\|\mathcal{F}-\boldsymbol{\nabla}_k(A)\boldsymbol{\nabla}^k(A)\Phi_{\text{as}}\|_g^2 < \infty, \tag{73}$$

then Eq. (1) has a weak solution,

$$\Phi(x) = Y(x) + \Phi_{\text{as}}(x), \tag{74}$$

where the quantity Y, which vanishes in the limit $|\mathbf{x}|\to\infty$, satisfies the equation

$$\boldsymbol{\nabla}_k(A)\boldsymbol{\nabla}^k(A)Y(x) = \mathcal{F}(x) - \boldsymbol{\nabla}_k(A)\boldsymbol{\nabla}^k(A)\Phi_{\text{as}}(x). \tag{75}$$

For more details we refer to the aforementioned paper by Salmela,[6] which also contains extensive references to physical applications of the gauge-covariant Poisson equations in R^3.

ACKNOWLEDGMENTS

I wish to express my gratitude to Antti Salmela for useful and enjoyable discussions on the topics presented in this paper. I am also indebted to Claus Montonen for important comments on the question of appropriate boundary conditions for gauge-covariant Poisson equations.

A Wannier function made from distributed Gaussians

Hasan Karabulut
Rize Faculty of Arts and Sciences, Physics Department, Karadeniz Technical University, 53100 Rize/Turkey

(Received 2 October 2004; accepted 11 May 2005; published online 17 June 2005)

A new Wannier function made from distributed Gaussians is reported. Convolution integrals of the Wannier functions are studied and analytical expressions for the convolution integral are given. A new expression for a set of coefficients introduced in an earlier publication [J. Math. Phys. **38**, 4815 (1997)] is derived. Using this new expression, the peculiar behavior of another set of coefficients introduced in the same publication in a particular limit is explained. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1946529]

I. INTRODUCTION

Distributed Gaussians are a set of identical Gaussians positioned with equal intervals. They are widely used as a basis set in variational calculations in molecular vibrations. The widespread use of this basis started in chemical physics computations by an important paper of Hamilton and Light.[1]

The Wannier functions are used in solid-state physics as orthogonal and localized basis sets.[2] One can make Wannier functions from any basis set formed by shifting a localized function at equal intervals. In particular, Wannier[3] reported a set of Wannier functions made from distributed Gaussians. Itakutti *et al.*[4] also reported Wannier functions made from distributed Gaussians, but they constructed them numerically and did not provide analytical expressions for the Gaussian coefficients.

In a paper[5] (hereafter called Paper 1) on distributed Gaussians, we introduced a set of orthogonal functions that are linear combinations of distributed Gaussians and called them distributed Gaussian polynomials. We also introduced a set of Wannier functions made from distributed Gaussians and suggested a general procedure to construct Wannier functions made from distributed Gaussians. At that time it escaped our attention that normalized distributed Gaussian polynomials become a Wannier function set in a particular limit. This is one of the results reported in this paper.

Other than introducing a Wannier function, we also introduced some sets of coefficients in Paper 1.[5] In this paper I study convolution integrals of Wannier functions and as a product of this, I introduce an expression for a set of coefficients called σ_n in Paper 1. Using this result, I explain peculiar behavior of another set of coefficients called $e_n(y)$ in Paper 1 as $y \to 1/4$.

In the next section I list some results from Paper 1 that are needed in the following sections. I felt it necessary to list them to make the new results in the following sections understandable. There are a couple of results that were stated in Paper 1 for a specific case, but here the more general statements are made. One important point that was unnoticed in Paper 1 is also stated in this section. The rest of the section are the results of Paper 1.

In this paper the Gaussians are written as $g_n(x)=\mathrm{e}^{-c^2(x-n)^2}=\mathrm{q}^{(x-n)^2}$, where $q=\mathrm{e}^{-c^2}$ and c^{-1} is related to the width of the Gaussians. In the text we will use mostly expressions with q. But there are some formulas that do not look pretty when c is replaced with $\sqrt{\ln(1/q)}$ in them. So some formulas contain both c and q and when you see them just remember that $q=\mathrm{e}^{-c^2}$.

In the Introduction above "we" refers to myself, Dr. Karabulut, and Professor Sibert, who are the authors of Paper 1. In the rest of the paper, as in a lecturing mode, "we" refers to me, Dr. Karabulut, and the audience.

II. SOME RESULTS GIVEN IN PAPER 1

Consider a chain of Gaussians

$$g_n(x) = g(x-n) = \mathrm{e}^{-c^2(x-n)^2} = \mathrm{q}^{(x-n)^2} \quad (n = 0,1,2,\ldots,\infty), \tag{1}$$

where $q = e^{-c^2}$. A set of orthogonal functions constructed from them was given in Paper 1[5] as

$$\Phi_n(x) = \sum_{k=0}^{n} \frac{(q;q)_n}{(q;q)_k (q;q)_{n-k}} (-1)^k \mathrm{q}^{-k/2} g_k(x); \quad (n = 0,1,2,\ldots,\infty), \tag{2}$$

where

$$(q;q)_k = (1-q)(1-q^2)(1-q^3)\cdots(1-q^k), \tag{3}$$

for $k>0$ and $(q;q)_0 \equiv 1$. We call these functions distributed Gaussian polynomials. They satisfy the recurrence relation[5]

$$\mathrm{q}^{-2x}\Phi_n(x) = d_{n-1}^n \Phi_{n-1}(x) + d_n^n \Phi_n(x) + d_{n+1}^n \Phi_{n+1}(x), \tag{4}$$

where d_{n-1}^n, d_n^n, and d_{n+1}^n are

$$d_{n+1}^n = -q^{-2(n+1/4)}, \tag{5}$$

$$d_n^n = (1+q-q^{n+1})q^{-2(n+1/4)}, \tag{6}$$

$$d_{n-1}^n = -(q-q^{n+1})q^{-2(n+1/4)}. \tag{7}$$

We can make Wannier functions from the distributed Gaussians. Wannier[3] reported one such Wannier function set and another one was reported in Paper 1. Appendix A of Karabulut[6] gives a short account of Bloch and Wannier functions and their properties. A set of Wannier functions made from distributed Gaussians can be written as

$$W_n(x) = \sum_{m=-\infty}^{\infty} c_m g(x-n-m), \tag{8}$$

where the c_m are

$$c_m = \int_0^1 \frac{\mathrm{e}^{\mathrm{i}\Theta(t)}}{\sqrt{Z(t)}} \mathrm{e}^{\mathrm{i}2\pi m t} \mathrm{d}t. \tag{9}$$

Here, $\Theta(t)$ is an arbitrary periodic $(\Theta(t+1)=\Theta(t))$ phase factor and $Z(t)$ is the norm of the unnormalized Bloch function

$$Z(t) = \int_0^1 \left| \sum_{n=-\infty}^{\infty} \mathrm{e}^{i2\pi n t} g(x-n) \right|^2 \mathrm{d}x. \tag{10}$$

Using the Poisson summation formula [cf. Eq. (A1) in Ref. 6] we get the expressions

$$Z(t) = \sqrt{\frac{\pi}{2c^2}} \sum_{n=-\infty}^{\infty} \mathrm{e}^{i2\pi n t} \mathrm{q}^{n^2/2}, \tag{11}$$

$$= \frac{\pi}{c^2} \sum_{n=-\infty}^{\infty} \mathrm{e}^{-2(\pi/c)^2(t-n)^2}. \tag{12}$$

The equality of the middle expression to the last is known as the Jacobi identity, which is simply the Fourier series of the periodic function in the last equation. Note also that $Z(t)$ is periodic with a period unity. An infinite number of different Wannier functions can be constructed from Gaussians. Different choices of the phase factor $\mathrm{e}^{\mathrm{i}\Theta(t)}$ yield different Wannier functions.

From Eq. (9), the c_n are the Fourier coefficients of the periodic function $\mathrm{e}^{\mathrm{i}\Theta(t)}/\sqrt{Z(t)}$. Therefore, if we know the Gaussian coefficients c_n of the Wannier functions, we can obtain the phase factor $\mathrm{e}^{\mathrm{i}\Theta(t)}$ as follows:

$$\mathrm{e}^{\mathrm{i}\Theta(t)} = \sqrt{Z(t)} \sum_{m=-\infty}^{\infty} c_m \mathrm{e}^{-\mathrm{i}2\pi mt}. \tag{13}$$

This function must have a unit modulus

$$\left|e^{\mathrm{i}\Theta(t)}\right|^2 = Z(t) \sum_{n=-\infty}^{\infty} \mathrm{e}^{\mathrm{i}2\pi nt} \xi_n = 1, \tag{14}$$

where the ξ_n are defined as

$$\xi_n = \sum_{m=-\infty}^{\infty} c_m c_{m+n}. \tag{15}$$

The coefficients ξ_n are symmetrical: $\xi_n = \xi_{-n}$. From Eq. (14) it is seen that the ξ_n are the Fourier coefficients of the periodic function $1/Z(t)$. Here, we obtain an interesting result. *Since the $Z(t)$ does not depend on the phase factor $\mathrm{e}^{\mathrm{i}\Theta(t)}$ chosen, the coefficients ξ_n should be independent of the phase factor too, in spite of the fact that the c_n coefficients in the defining relation, Eq. (15), depend on the phase factor. Hence, the ξ_n are the same for all Wannier functions made from Gaussians*. This important point was not stated in Paper 1.

The expression for $Z(t)$ given in Eqs. (11) and (12) and the fact that ξ_n are the Fourier coefficients of $1/Z(t)$ give us an integral representation for the ξ_n

$$\xi_n = \int_0^1 \frac{\mathrm{e}^{-\mathrm{i}2\pi nt}}{Z(t)} \mathrm{d}t = \sqrt{\frac{2c^2}{\pi}} \int_{-1/2}^{1/2} \frac{\cos(2\pi nt)}{\sum_{m=-\infty}^{\infty} \mathrm{q}^{m^2/2} \mathrm{e}^{\mathrm{i}2\pi mt}} \mathrm{d}t. \tag{16}$$

In Paper 1 the Wannier functions $W_n(x) = L_0^+(x-n)/\sqrt{w_\infty}$ were introduced. The $L_0^+(x)$ is given as

$$L_0^+(x) = \sum_{m=-\infty}^{\infty} b_n g(x-n), \tag{17}$$

where b_n are defined as

$$b_n = q^{-1/16} N(q) (-1)^n \mathrm{q}^{(|n|+n/2)} \alpha_n(q), \tag{18}$$

and the factor α_n are

$$\alpha_n(q) = \sum_{j=0}^{\infty} (-1)^j \mathrm{q}^{j(j+2|n|+1)}. \tag{19}$$

The factor $q^{-1/16}N(q)$ is the normalization factor to ensure $L_0^+(1/4) = 1$, which requires

$$q^{-1/16}N(q)\left(\sum_{n=-\infty}^{\infty}(-1)^n q^{(|n|+n/2)}\alpha_n(q)q^{(1/4-n)^2}\right)=1. \tag{20}$$

From this, the factor $N(q)$ is found as

$$N(q)=\left(\sum_{n=-\infty}^{\infty}(-1)^n q^{|n|}\alpha_n(q)q^{n^2}\right)^{-1}. \tag{21}$$

We prefer to define the normalization factor this way because the $N(q)$ will reappear in the formulas in the following sections. The $|n|$ is the absolute value of n. The $L_0^+(x-n)$ were called the "infinite chain Lagrange functions" in Paper 1. They satisfy the Lagrange function property $L_0^+(n+1/4)=\delta_{n0}$. In Paper 1 the w_∞ was defined as "the weights for the infinite chain quadrature," and it was given as

$$w_\infty=\frac{1}{\sum_{n=-\infty}^{\infty}(-1)^n e^{-2(\pi/c)^2 n^2}}. \tag{22}$$

Since $c_n=b_n/\sqrt{w_\infty}$ are the Gaussian coefficients in the Wannier function, the ξ_n coefficients can be expressed as $(\Sigma_{m=-\infty}^{\infty}b_m b_{m+n}\cdot)/w_\infty$. The coefficients $\Sigma_{m=-\infty}^{\infty}b_m b_{m+n}$ were called σ_n in Paper 1 and hence $\sigma_n=w_\infty\xi_n$.

Given a Wannier function $W_0(x)=\Sigma_{n=-\infty}^{\infty}a_n g(x-n)$, from Eq. (13), the $1/\sqrt{Z(t)}$ can be expressed as

$$\frac{1}{\sqrt{Z(t)}}=e^{-i\Phi(t)}\sum_{m=-\infty}^{\infty}a_m e^{-i2\pi mt}, \tag{23}$$

where $\Phi(t)$ is the phase associated with this Wannier function. Setting this for $1/\sqrt{Z(t)}$ and taking the general phase $\Theta(t)=\Phi(t)+\Gamma(t)$ in Eq. (9), we get

$$c_n=\sum_{m=-\infty}^{\infty}a_{n-m}\left(\int_0^1 e^{i\Gamma(t)}e^{i2\pi mt}dt\right). \tag{24}$$

The c_n are Gaussian coefficients of another Wannier function. Choosing $\Gamma(t)$ arbitrarily, we can generate many other Wannier functions. The integral in this expression is calculable for many phase factors $\Gamma(t)$; therefore, if we know one Wannier function Gaussian coefficients we can produce many other Wannier functions using it. Examples were given in Paper 1.

The results in Eqs. (13) and (24) were actually given in Paper 1 for the specific case of $W_n(x)=L_0^+(x-n)/\sqrt{w_\infty}$. But, the statements that they hold for arbitrary Wannier functions were not made in Paper 1.

III. A NEW WANNIER FUNCTION SET MADE FROM DISTRIBUTED GAUSSIANS

In this section we introduce a new Wannier function set made from distributed Gaussians. For this we need to normalize the distributed Gaussian polynomials, which was an important omission in Paper 1.

A. Normalization of the distributed Gaussian polynomials

Consider the integral

$$\int_{-\infty}^{\infty}\Phi_n(x)q^{-2x}\Phi_{n-1}(x)dx=d_n^{n-1}\|\Phi_n\|^2=d_{n-1}^{n}\|\Phi_{n-1}\|^2, \tag{25}$$

where $\|\Phi_n\|^2=\int_{-\infty}^{\infty}\Phi_n^2(x)dx$ and Eq. (4) and the orthogonality are invoked. Writing this as

$$\|\Phi_n\| = \|\Phi_{n-1}\| \sqrt{\frac{d_{n-1}^n}{d_n^{n-1}}}, \tag{26}$$

using the relations in Eqs. (5)–(7), and iterating this relation, we get

$$\|\Phi_n\| = \left(\frac{\pi}{2c^2}\right)^{1/4} q^{-n/2} \sqrt{(q,q)_n}. \tag{27}$$

This relation is useful for obtaining the normalized functions $\Phi_n(x)/\|\Phi_n\|$.

B. The new Wannier functions

The orthonormal functions $\Phi_n(x)/\|\Phi_n\|$ are written as

$$\Phi_n(x)/\|\Phi_n\| = \left(\frac{2c^2}{\pi}\right)^{1/4} \sum_{k=0}^{n} \frac{\sqrt{(q;q)_n}}{(q;q)_k (q;q)_{n-k}} (-1)^k \mathrm{q}^{(n-k)/2} g_k(x). \tag{28}$$

Because of the orthogonality relation the $\Phi_n(x)$ is orthogonal to $\Phi_0(x), \ldots, \Phi_{n-1}(x)$. This means that $\Phi_n(x)$ is orthogonal to all Gaussians $g(x-m)$ for $0 \leqslant m \leqslant n-1$. By shifting the normalized $\Phi_n(x)$ to the left by n (i.e., $\Phi_n(x+n)/\|\Phi_n\|$), we get a function orthogonal to Gaussians $g(x-m)$ with $-n \leqslant m \leqslant -1$. When we take the limit $n \to \infty$, the resulting function becomes orthogonal to all Gaussians centered on the negative integers and it is normalized by construction. In the above equation (28) the sign of the Gaussian centered at $x=n$ is $(-1)^n$. To make it positive, we multiply by $(-1)^n$ before taking the limit. The limit is

$$\Omega^-(x) = \lim_{n\to\infty} (-1)^n \Phi_n(x+n)/\|\Phi_n\|, \tag{29}$$

$$= \frac{(2c^2/\pi)^{1/4}}{\sqrt{(q;q)_\infty}} \sum_{m=0}^{\infty} \frac{(-1)^m}{(q;q)_m} \mathrm{q}^{m/2} g(x+m). \tag{30}$$

This function is orthogonal to all of the Gaussians $g(x-n)$ for $n<0$ and it is normalized.

Now, let us consider the integral

$$\int_{-\infty}^{\infty} \Omega^-(x-n)\Omega^-(x-m)\mathrm{d}x. \tag{31}$$

Since $\Omega^-(x)$ is normalized this integral is unity for $n=m$. For $n \neq m$ let us assume $n>m$ without loss of generality. Then, $\Omega^-(x-n)$ is orthogonal to all the Gaussians $g(x-k)$ for $k<n$. The $\Omega^-(x-m)$ contains Gaussians up to $g(x-m)$ and since $m<n$ the $\Omega^-(x-n)$ is orthogonal to all of them. Therefore, the integral vanishes for $n \neq m$. This argument proves that the $\Omega^-(x-n)$ functions are Wannier functions satisfying

$$\int_{-\infty}^{\infty} \Omega^-(x-n)\Omega^-(x-m)\mathrm{d}x = \delta_{nm}. \tag{32}$$

We have a minus sign on the $\Omega^-(x-n)$ for a purpose. The functions $\Omega^-(x)$ are a linear combination of the Gaussians centered on the negative integers and zero. The mirror symmetry of it, $\Omega^+(x)=\Omega^-(-x)$, is a linear combination of Gaussians centered on the positive integers and zero. The $\Omega^+(x-n)$ also satisfy the orthonormality conditions and they are equally valid Wannier functions. We use $\pm$ superscripts to distinguish them.

$\Omega^\pm(x)$ are related to the q-special functions that mathematicians study. The functions

$$E_q^{(\alpha)}(z) = \sum_{n=0}^{\infty} \frac{q^{\alpha n^2/2}}{(q,q)_n} z^n, \tag{33}$$

are introduced in Floreanini *et al.*[7] and some of their properties are studied in Atakishiyev.[8] They are some form of one parameter q-exponential functions and the $E_q^{(\alpha)}((1-q)z)$ reduces to e^z in the limit $q \to 1$. The Wannier functions constructed above can be expressed in terms of $E_q^{(\alpha)}(z)$ for $\alpha=2$ and $z=-q^{(1/2+2x)}$ as

$$\Omega^-(x) = \frac{(2c^2/\pi)^{1/4}}{\sqrt{(q;q)_\infty}} q^{x^2} E_q^{(2)}(-q^{(1/2+2x)}). \tag{34}$$

We showed that the $\Omega^{\pm}(x)$ are Wannier functions. Now, we can write the corresponding phase factor. The Gaussian coefficients in the $\Omega^+(x)$ are

$$c_n = \begin{cases} (2c^2/\pi)^{1/4}(-1)^n \mathrm{q}^{n/2}/(q;q)_n \sqrt{(q;q)_\infty} & n \geqslant 0 \\ 0 & n < 0 \end{cases}. \tag{35}$$

Then, from Eq. (13) the phase factor can be expressed as

$$\mathrm{e}^{\mathrm{i}\Theta(t)} = \left(\frac{2c^2}{\pi}\right)^{1/4} \sqrt{\frac{Z(t)}{(q;q)_\infty}} \sum_{m=0}^{\infty} (-1)^m \frac{\mathrm{q}^{m/2}}{(q;q)_m} \mathrm{e}^{-\mathrm{i}2\pi m t}. \tag{36}$$

From Eqs. (15) and (35), the ξ_n coefficients are expressed as

$$\xi_n = \sqrt{\frac{2c^2}{\pi}} \frac{(-1)^n}{(q;q)_\infty} \mathrm{q}^{|n|/2} \sum_{m=0}^{\infty} \frac{\mathrm{q}^m}{(q;q)_m (q;q)_{m+|n|}}. \tag{37}$$

The phase factor for the $\Omega^-(x)$ is the complex conjugate of the phase of $\Omega^+(x)$.

IV. THE CONVOLUTION INTEGRAL AND A NEW EXPRESSION FOR THE ξ_n COEFFICIENTS

Consider the convolution integral of the Wannier functions

$$I_q(z) = \int_{-\infty}^{\infty} W_0(x) W_0(x+z) \mathrm{d}x, \tag{38}$$

$$= \sqrt{\frac{\pi}{2c^2}} \sum_{n=-\infty}^{\infty} \xi_n \mathrm{q}^{(z-n)^2/2}. \tag{39}$$

Since the ξ_n is independent of the phase factor $\mathrm{e}^{\mathrm{i}\Theta(t)}$, the $I_q(z)$ is the same for all of the Wannier functions made from Gaussians. The Fourier transforms of $I_q(z)$ and $W_0(x)$ are

$$I_q^F(k) = \int_{-\infty}^{\infty} \mathrm{e}^{\mathrm{i}kz2\pi} I_q(z) \mathrm{d}z \tag{40}$$

$$W_0^F(k) = \int_{-\infty}^{\infty} \mathrm{e}^{\mathrm{i}kx2\pi} W_0(x) \mathrm{d}x. \tag{41}$$

From the convolution theorem of Fourier transforms, we have

$$I_q^F(k) = |W_0^F(k)|^2. \tag{42}$$

For a given localized function $u(x)$, the function set $u(x/d-n)$ for $(n=-\infty,\ldots,\infty)$ is called a distributed basis set made from $u(x)$. Here, d is the distance between the basis functions. In a recent paper Karabulut[6] has introduced a quantity $r(k,d)$ called the representation power, which is an effective measure of the ability of a distribution basis set to span a given function. The $r(k,d)$ turns out to be equal to $|W_0^F(kd)|^2$, where the $W_0^F(k)$ is the Fourier transform of the Wannier function made from the $u(x-n)$, $(n=-\infty,\ldots,\infty)$ set. Since the $r(k,d)$ is a property of the basis function $u(x)$ itself, it is absolutely necessary that $|W_0^F(k)|^2$ be independent of the phase factor $e^{i\Theta(t)}$. The $I_q^F(kd)$ is actually the representation power $r(k,d)$ and it is a very important quantity in the formalism presented in Karabulut.[6]

After these remarks about the significance of the convolution integral, we will derive three different representations for the $I_q(z)$. This function must have zeros at all the nonzero integers due to the orthogonality of Wannier functions, and it is a linear combination of Gaussians with a different width. It must be unity at $z=0$ due to the normalization of the Wannier functions. Since such Gaussians are a polynomial of $q^{-z}=e^{c^2z}$, we can immediately write an infinite product representation

$$I_q(z)=q^{z^2/2}\prod_{n=1}^{\infty}\left(\frac{q^{-z}-q^{-n}}{1-q^{-n}}\right)\left(\frac{q^{z}-q^{-n}}{1-q^{-n}}\right). \tag{43}$$

This product is a linear combination of Gaussians and it vanishes at all nonzero integers. It takes unity value for $z=0$. It is also symmetrical just like $I_q(z)$ is due to the symmetry of the ξ_n coefficients. So, it is the right function.

Another function that has the right zeros can be expressed as

$$I_q(z)=\kappa\frac{\sum_{n=-\infty}^{\infty}(-1)^n q^{(z-n-1/2)^2/2}}{q^{-z/2}-q^{z/2}}. \tag{44}$$

The coefficient κ is chosen to satisfy $I_q(0)=1$. This function also satisfies all of the properties of the $I_q(z)$ and, although it may not be obvious at first glance, it is also a linear combination of Gaussians centered at integers. To find the coefficients, we equate

$$\sum_{n=-\infty}^{\infty}h_n q^{(z-n)^2/2}=\frac{\sum_{n=-\infty}^{\infty}(-1)^n q^{(z-n-1/2)^2/2}}{q^{-z/2}-q^{z/2}}, \tag{45}$$

to obtain the following difference equation for the h_n:

$$h_{n-1}q^{-(n-1/2)}-h_n=(-1)^{n+1}q^{1/8}q^{-n/2}. \tag{46}$$

Solving this and putting it back into Eq. (44) we can write the $I_q(z)$ as

$$I_q(z)=N(\sqrt{q})\sum_{n=-\infty}^{\infty}(-1)^n\alpha_n(\sqrt{q})q^{|n|/2}q^{(z-n)^2/2}, \tag{47}$$

where the $N(q)$ is the function introduced in Eq. (21). The factor $N(\sqrt{q})$ ensures the normalization condition $I_q(0)=1$. Comparing this to Eq. (39), we find

$$\xi_n=\sqrt{\frac{2c^2}{\pi}}N(\sqrt{q})(-1)^n\alpha_n(\sqrt{q})q^{|n|/2}. \tag{48}$$

This is the explicit expression for the ξ_n coefficients we are looking for. The $\alpha_n(q)$ coefficients rapidly approach unity as $|n|$ gets larger. Hence, ξ_n decays as $q^{|n|/2}$ for large $|n|$ values. This result is not transparent from the other definition of ξ_n in Eq. (15).

It is interesting that the infinite chain Lagrange functions given in Eqs. (17), (18), (19), and (21) can be written as

$$L_0^+(x) = \mathrm{q}^{(x-1/4)/2} I_{q^2}(x - 1/4). \tag{49}$$

This is due to the fact that they both are square integrable functions having equally spaced zeros. For a function made from a linear combination of distributed Gaussians, once we fix the positions of zeros as $x_n = n + \delta$, where $-1/2 < \delta < 1/2$ and $n \neq 0$, and require that the function is square integrable, it is fixed up to a normalization factor. In the above formula the $\delta = 1/4$ for $L_0^+(x)$ and zero for $I_{q^2}(x)$. All such normalizable functions with equally spaced zeros can be expressed as $(\mathrm{const})\mathrm{q}^{2\delta(x-\delta)} I_{q^2}(x-\delta)$.

There are some identities we can derive from the ξ_n expression given in Eq. (48). Comparing Eq. (48) with Eq. (16), we get an interesting identity

$$\int_{-1/2}^{1/2} \frac{\cos(2\pi n t)}{\sum_{m=-\infty}^{\infty} q^{m^2/2} \mathrm{e}^{\mathrm{i}2\pi m t}} \mathrm{d}t = N(\sqrt{q})(-1)^n \alpha_n(\sqrt{q}) q^{|n|/2}. \tag{50}$$

Comparing Eqs. (48) and (37), we obtain

$$\sum_{m=0}^{\infty} \frac{q^m}{(q;q)_m (q;q)_{m+|n|}} = N(\sqrt{q})(q;q)_\infty \alpha_n(\sqrt{q}). \tag{51}$$

Finally, taking $n \to \infty$ limit of the above equation we obtain

$$\sum_{m=0}^{\infty} \frac{q^m}{(q;q)_m} = N(\sqrt{q})((q;q)_\infty)^2. \tag{52}$$

There is also another representation for the $I_q(z)$ function which shows how the $I_q(z)$ behaves. The nominator of Eq. (45) is periodic with period two, and it can be expressed as a Fourier series. The Fourier coefficients can be evaluated with the help of the Poisson summation formula. Then, we get another representation for the $I_q(z)$ as

$$I_q(z) = G(z)/G(0), \tag{53}$$

where the $G(z)$ is

$$G(z) = \sum_{n=0}^{\infty} (-1)^n \frac{\sin(2n+1)\pi z}{\sinh(c^2 z/2)} \mathrm{e}^{-(2n+1)^2 \pi^2 / 2c^2}, \tag{54}$$

and the $G(0)$ is

$$G(0) = \frac{2\pi}{c^2} \sum_{n=0}^{\infty} (-1)^n (2n+1) \mathrm{e}^{-(2n+1)^2 \pi^2 / 2c^2}. \tag{55}$$

For low values of c ($c < 1$ for example), only the $n = 0$ term is significant. For $c = 1$ the ratio of the $n = 1$ term to the $n = 0$ term is of order $\mathrm{e}^{-4\pi^2}$ and the second and higher terms are totally negligible. Therefore, the $I_q(z)$ is

$$I_q(z) \approx \frac{c^2}{2\pi} \frac{\sin \pi z}{\sinh(c^2 z/2)}, \tag{56}$$

to a high accuracy. The $I_q(z)$ decays as $\mathrm{e}^{-c^2|z|/2}$ asymptotically and in the limit $c \to 0$ ($q \to 1$) it approaches $\sin(\pi z)/\pi z$.

V. THE BEHAVIOR OF THE $e_n(y)$ COEFFICIENTS

Consider the sum

$$R(x,y) = \sum_{n=-\infty}^{\infty} \frac{L_0^+(x-n)}{\sqrt{w_\infty}} \frac{L_0^+(y-n)}{\sqrt{w_\infty}}, \tag{57}$$

$$= \frac{1}{w_\infty} \sum_{m=-\infty}^{\infty} e_m(y) \mathrm{q}^{(x-m)^2}, \tag{58}$$

where $e_n(y)$ is given as

$$e_n(y) = w_\infty \sum_{m=-\infty}^{\infty} \xi_m \mathrm{q}^{(y+m-n)^2}. \tag{59}$$

Let us recall at this point that $L_0^+(x)/\sqrt{w_\infty}$ is a Wannier function. Because of the Lagrange function property $L_0^+(n+1/4)=\delta_{n0}$ of the infinite chain Lagrange functions $L_0^+(x-n)$, if we set $y=1/4$ in the $R(x,y)$ only the $n=0$ term is nonzero and we get $L_0^+(x)/w_\infty$ result for the sum. Since the Gaussian coefficients of $L_0^+(x)$ are the b_n coefficients given in Eqs. (18), (19), and (21), the $e_n(y)$ coefficients approach the b_n coefficients as $y \to 1/4$. The b_n coefficients decay three times faster exponentially for positive indices than negative indices, and the $L_0^+(x)$ is an asymmetric function. The slower exponent (for $n<0$) is $-c^2|n|/2$ and the faster exponent (for $n>0$) is $-3c^2n/2$, as can be seen from Eq. (18). The $\ln|e_n(y)|$ coefficients versus n for $y=0.24$, $y=0.2499$, and $y=0.249\,999$ was plotted in Paper 1 (Fig. 1), and from the graph it was clear that for $n>0$ the $|e_n(y)|$ decays with the faster exponent for some time and after a visibly sharp turning point it starts decaying with the slower exponent. The turning point goes to infinity as $y \to 1/4$, and exactly at $y=1/4$ it decays with the faster exponent for all $n>0$. We (the authors) were not able to explain this behavior in Paper 1 because our new expression for the ξ_n coefficients was not available. Now that it is available, let us explain.

Consider the $e_n(y)$ coefficients

$$e_n(y) = w_\infty N(\sqrt{q}) \sum_{m=-\infty}^{\infty} (-1)^n \alpha_m(\sqrt{q}) \mathrm{q}^{|m|/2} \mathrm{q}^{(y+m-n)^2}, \tag{60}$$

for $n \gg 1$ and $y \approx 1/4$. Here, the constant $w_\infty N(\sqrt{q})$ is unimportant to the discussion. For large n, only m values near n contribute significantly. For large m values only the first two terms of the $\alpha_m(\sqrt{q})$ expansion

$$\alpha_m(\sqrt{q}) = 1 - \mathrm{q}^{|m|+1} + \text{higher order}, \tag{61}$$

are important. Then, the $e_n(y)$ can be written as

$$e_n(y) = w_\infty N(\sqrt{q}) \sum_{m=-\infty}^{\infty} (-1)^n \mathrm{q}^{|m|/2} \mathrm{q}^{(y+m-n)^2} \tag{62}$$

$$- w_\infty N(\sqrt{q}) q \sum_{m=-\infty}^{\infty} (-1)^n \mathrm{q}^{3|m|/2} \mathrm{q}^{(y+m-n)^2} + \text{H.O.}, \tag{63}$$

where H.O. stands for higher order terms. Now, since we assume that $n \gg 1$, the terms with negative values of m are order of $\mathrm{q}^{n^2/2}$ smaller than the terms making the main contribution around $m \approx n$. Therefore, replacing $\mathrm{q}^{|m|/2}$ and $\mathrm{q}^{3|m|/2}$ with $\mathrm{q}^{m/2}$ and $\mathrm{q}^{3m/2}$ we make an error of order $\mathrm{q}^{n^2/2}$, which is insignificant for large n but makes the sums manageable. We also expand the Gaussians

as $q^{(y+m-n)^2}=q^{y^2}q^{2y(m-n)}q^{(m-n)^2}$ and change the summation index from m to $m\rightarrow m+n$. Then, $e_n(y)$ becomes

$$e_n(y)\approx\left(w_\infty N(\sqrt{q})q^{y^2}\sum_{m=-\infty}^{\infty}(-1)^m q^{(1+4y)m/2}q^{m^2}\right)(-1)^n q^{n/2}$$
$$-\left(w_\infty N(\sqrt{q})q^{y^2+1}\sum_{m=-\infty}^{\infty}(-1)^m q^{(3/2+4y)m/2}q^{m^2}\right)(-1)^n q^{3n/2}+\text{H.O.} \tag{64}$$

The sum in the first parenthesis vanishes as $y\rightarrow 1/4$. To see this, consider the Jacobi triple product formula[9]

$$\sum_{n=-\infty}^{\infty}x^n q^{n^2}=\prod_{n=0}^{\infty}(1-q^{2n+2})(1+xq^{2n+1})(1+x^{-1}q^{2n+1}), \tag{65}$$

where $|q|<1$. If we take $x=-q^{(1+4y)/2}$, then the sum in the first parenthesis of Eq. (64) can be written as an infinite product. The term $(1+x^{-1}p^{2n+1})$ for $n=0$ becomes $(1-q^{(1-4y)/2})$, and this vanishes as $y\rightarrow 1/4$. Therefore, all other terms in the product can be seen as a constant factor when $y\approx 1/4$. The sum in the second parenthesis in Eq. (64) does not vanish for $y=1/4$; therefore, the entire sum can be taken as another constant for $y\approx 1/4$. The $e_n(y)$ can be written as

$$e_n(y)\approx[K_1(1-q^{(1-4y)/2})q^{n/2}+K_2 q^{3n/2}](-1)^n+\text{H.O.} \tag{66}$$

$$\approx[K_1(c^2/2)(1-4y)q^{n/2}+K_2 q^{3n/2}](-1)^n+\text{H.O.} \tag{67}$$

Here, K_1 and K_2 are two constants. In the second expression above, we took the Taylor series expansion of $q^{(1-4y)/2}$ and ignored the terms beyond the first two.

When y is very close to $1/4$, the second term dominates for the lower values of n but, as n gets larger, the first term begins to dominate. The higher order terms decay faster than $q^{3n/2}$ exponentially and they quickly die out, leaving the race between the two terms given above. Therefore, the $\ln(|e_n(y)|)$ versus n graph is a straight line for lower values of n with a slope $-3c^2/2$. After a visibly sharp turning point the graph becomes another straight line with a slope $-c^2/2$. This graph was given in Paper 1 (Fig. 1) without an explanation to why it behaves that way. Here, we have a clear explanation.

The turning point occurs for the n value where the two terms are approximately equal. This happens at $n\approx-\ln(|K_1c^2(1-4y)/2K_2|)/c^2$, which says that the turning point increases linearly with $-\ln(|1-4y|)/c^2$. Therefore, as $y\rightarrow 1/4$, the turning point goes to infinity, and exactly at $y=1/4$ the $e_n(y)$ decays with the faster exponent for all positive indices. The logarithmic dependence of the turning point to $|1-4y|$ explains why the turning point moves so slowly as $y\rightarrow 1/4$, which was clear from Fig. 1 given in Paper 1.

VI. SUMMARY

In this paper we obtained a new expression for the integrals of the squared distributed Gaussian polynomials and showed how to normalize them, a result that was missing in Paper 1. Using the normalized distributed Gaussian polynomials, we took a particular limit of them and constructed a new Wannier function set made from distributed Gaussians. There are only three Wannier functions made from distributed Gaussians in the literature to our knowledge; the one constructed by Wannier,[3] the one reported in Paper 1[5] as the normalized infinite chain Lagrange functions $(L_0^{\pm}(x-n)/\sqrt{w_\infty})$, and the one presented in this paper $(\Omega^{\pm}(x))$.

In addition to reporting a new Wannier function, we studied convolution integral of the Wannier functions and found three different representations for it. We have also presented a new expression for the ξ_n coefficients. The new expression is simpler in appearance than the first

prescription $\Sigma_{m=-\infty}^{\infty} c_{n+m} c_m$, and it also gives the asymptotic behavior of the ξ_n coefficients which is not easy to see from the $\Sigma_{m=-\infty}^{\infty} c_{n+m} c_m$ summation. The new expression also made it possible to explain the peculiar behavior of the $e_n(y)$ coefficients as $y \to 1/4$.

We also found some identities given in Eqs. (50), (51), and (52) as a result of discovery of a new Wannier function. They seem to result from the fact that the distributed Gaussians can be written as polynomials, and there is a quadrature to integrate Gaussians on an infinite chain. We leave it to mathematicians to assess the significance of these strange identities.

Using the Gaussian coefficients of the three reported Wannier functions and using the result stated in Eq. (24), one can construct many Wannier function sets depending on arbitrary number of parameters. Of course the target in this game is to construct the Wannier functions with the desired properties. I have been searching for the Wannier functions made from distributed Gaussians that satisfy

$$\int_{-\infty}^{\infty} W_n(x) \mathrm{e}^{2c^2 \eta x} W_m(x) \mathrm{d}x = \mathrm{e}^{2c^2 \eta (n+\epsilon(\eta))} \delta_{nm}, \tag{68}$$

in addition to the usual orthogonality condition

$$\int_{-\infty}^{\infty} W_n(x) W_m(x) \mathrm{d}x = \delta_{nm}. \tag{69}$$

The normalized infinite chain Lagrange functions $W_n(x) = L_0^+(x-n)/\sqrt{w_\infty}$ reported in Paper 1 is an example of this for $\eta = 1$ and $\epsilon(\eta) = 1/4$. I have not been able to find them for a general η value. In addition to the beauty of the mathematics involved, they are related to the discrete variable representation methods used in chemical physics calculations and hence they might have some practical value.

It is shown that a four-dimensional Kähler metric is pointwise Osserman if and only if it is either of constant holomorphic sectional curvature or a Ricci flat complex surface. Examples of Kähler Osserman metrics with nilpotent Jacobi operators of all possible degrees are given. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1938727]

I. INTRODUCTION

Pseudo-Riemannian metrics of signature other than Lorentzian and more specially, Ricci-flat indefinite Kähler metrics have received considerable attention in mathematical physics, mainly since the work of Ooguri and Vafa.[19] Indefinite Kähler Einstein metrics on complex surfaces have been classified by Petean[21] and more recently scalar flat indefinite Kähler surfaces have been considered by Kamada.[14] A classification of four-dimensional Lie groups admitting Ricci flat indefinite Kähler metrics have been obtained by Ovando.[20]

To a large extent, the geometry of a pseudo-Riemannian manifold (M,g) is the study of the curvature $R \in \otimes^4 T^*M$ which is defined by the Levi-Civita connection ∇. A pseudo-Riemannian manifold (M,g) is said to be *Osserman* if the eigenvalues of the Jacobi operators are constant on the unit pseudo-sphere bundles $S^{\pm}(M)$. Any two-point homogeneous space is Osserman and the converse is true in the Riemannian ($\dim M \neq 16$) and Lorentzian settings.[7,17,18,2,9] However there exist many nonsymmetric Osserman pseudo-Riemannian metrics in other signatures (cf. Refs. 10 and 12) and even symmetric Osserman spaces which are not of rank-one.[11,22] Moreover, besides the results in Refs. 3 and 11 a description of all four-dimensional Osserman metrics is not yet complete in dimension four.[5,15]

An algebraic curvature tensor in a four-dimensional vector space is Osserman if and only if it is Einstein self-dual for some orientation. Since self-duality and anti-self-duality are well understood in the Kähler setting, we obtain in Sec. II a complete description of the Osserman algebraic curvature tensors which may be Kähler for some complex structure. Based on those results, we show in Sec. III that a pointwise Osserman four-dimensional Kähler metric is either of constant holomorphic sectional curvature or Ricci flat. This should be contrasted with the general situation, where Osserman metrics exist whose Jacobi operators are nondiagonalizable with eigenvalues $\alpha = 4\beta \neq 0$.[8] Finally, part of Sec. III is dedicated to the construction of Osserman Kähler metrics, showing that all possible degrees of nilpotency of the Jacobi operators are realized at the differentiable level.

II. KÄHLER OSSERMAN ALGEBRAIC CURVATURE TENSORS

Here we will work in the pure algebraic level. Let V be a four-dimensional real vector space. Let $\mathcal{R}(V)\subset\otimes^4 V^*$ be the space of all *algebraic curvature tensors*, i.e., those tensors R having the symmetries of the curvature tensor R:

$$\begin{aligned} &R(x,y,z,w)=R(z,w,x,y)=-R(y,x,z,w),\\ &R(x,y,z,w)+R(y,z,x,w)+R(z,x,y,w)=0. \end{aligned} \tag{1}$$

If V is equipped with an indefinite inner product $\langle,\rangle$, then the Ricci and scalar curvatures of R are defined by

$$\mathrm{Ric}(x,y)=\mathrm{tr}(z\mapsto R(x,z)y),\quad \mathrm{Sc}=\mathrm{tr}\,\mathrm{Ric},$$

where the traces are considered with respect to $\langle,\rangle$. Moreover, the Weyl conformal curvature W is given by

$$\begin{aligned} W(x,y,z,w)=R(x,y,z,w)&+\frac{\mathrm{Sc}}{12}\{g(x,z)g(y,w)-g(y,z)g(x,w)\}\\ &-\frac{1}{2}\{\mathrm{Ric}_0(x,z)g(y,w)-\mathrm{Ric}_0(y,x)g(x,w)+g(x,z)\mathrm{Ric}_0(y,w)-g(y,x)\mathrm{Ric}_0(x,w)\}, \end{aligned}$$

where Ric_0 denotes the traceless Ricci tensor,

$$\mathrm{Ric}_0(x,y)=\mathrm{Ric}(x,y)-\frac{\mathrm{Sc}}{4}g(x,y).$$

Considering the algebraic curvature tensor R as an endomorphism of $\Lambda^2(V)$, we have the following well-known $O(2,2)$-decomposition

$$R\equiv\frac{\mathrm{Sc}}{12}\mathrm{Id}_{\Lambda^2(V)}+\frac{1}{2}\mathrm{Ric}_0+W{:}\Lambda^2(V)\to\Lambda^2(V). \tag{2}$$

Further if V is equipped with an orthogonal *complex structure* J, i.e., a linear endomorphism satisfying $J^2=-\mathrm{id}$ and $\langle Jx,Jy\rangle=\langle x,y\rangle$, a preferred orientation is given to $(V,J,\langle,\rangle)$ and the Hodge star operator $*:\Lambda^2(V)\to\Lambda^2(V)$ is defined by $\alpha\wedge *\beta=\langle\alpha,\beta\rangle$ vol for arbitrary two-forms α and β, where vol is the volume form of V and $\langle,\rangle$ denote the inner product on $\Lambda^2(V)$ induced from that in V. Since the inner product is of signature $(--++)$, $\Lambda^2(V)$ splits as $\Lambda^2(V)=\Lambda^2_+\oplus\Lambda^2_-$, where $\Lambda^2_\pm$ denotes the ±1-eigenspaces of the Hodge star operator, that is $\Lambda^2_\pm=\{\alpha\in\Lambda^2(V)/*\alpha=\pm\alpha\}$. Then we have a further splitting for the Weyl curvature tensor and (2) becomes

$$R\equiv\frac{\mathrm{Sc}}{12}\mathrm{Id}_{\Lambda^2(V)}+\frac{1}{2}\mathrm{Ric}_0+W_+ +W_-, \tag{3}$$

where $W_\pm=\frac{1}{2}(W\pm *W)$.

An algebraic curvature tensor on an oriented vector space is said to be *self-dual* (respectively, *anti-self-dual*) if $*W=W$, that is $W_-=0$ (respectively, $*W=-W$, that is $W_+=0$).[15] Self-dual algebraic curvature tensors are of interest when considering Osserman-type properties in view of the following

Theorem 1 (Refs. 1 and 13): *Let R be an algebraic curvature tensor on a four-dimensional vector space $(V,\langle,\rangle)$. The following are equivalent*

(i) *R is Osserman.*
(ii) *There is a choice of orientation on V such that R is Einstein self-dual.*

As a matter of notation, an algebraic curvature tensor on a Hermitian vector space $(V,J,\langle,\rangle)$ is

said to be a *Kähler algebraic curvature tensor* if and only if it satisfies

$$R(x,y,Jz,Jw) = R(Jx,Jy,z,w) = R(x,y,z,w). \tag{4}$$

Let $\{e_1,e_2,e_3,e_4\}$ be an orthonormal basis of $(V,J,\langle,\rangle)$ such that $Je_1=e_2$, $Je_3=e_4$ and, as a convention, we will assume e_1 and e_2 to be timelike while e_3 and e_4 are spacelike vectors. Now, local basis of the spaces of self-dual and anti-self-dual two-forms can be constructed as

$$\Lambda^2_{\pm} = \langle\{E_1^{\mp},E_2^{\mp},E_3^{\mp}\}\rangle,$$

where

$$E_1^{\mp} = \frac{e^1\wedge e^2 \mp e^3\wedge e^4}{\sqrt{2}},\ E_2^{\mp} = \frac{e^1\wedge e^3 \mp e^2\wedge e^4}{\sqrt{2}},\ E_3^{\mp} = \frac{e^1\wedge e^4 \pm e^2\wedge e^3}{\sqrt{2}}.$$

Observe that the induced metric on $\Lambda^2_{\pm}$ is of signature $(+--)$, in opposition to the positive definite case. Indeed $\langle E_1^{\mp},E_1^{\mp}\rangle=1$, $\langle E_2^{\mp},E_2^{\mp}\rangle=-1$, $\langle E_3^{\mp},E_3^{\mp}\rangle=-1$.

Denote by Ω the Kähler two-form associated to the indefinite Hermitian structure $(V,J,\langle,\rangle)$, defined by $\Omega(x,y)=\langle Jx,y\rangle$. Observe that with respect to the orthonormal basis above the Kähler form is given by $\Omega=-e^1\wedge e^2+e^3\wedge e^4$, which shows that Ω is a spacelike anti-self-dual two-form. It is worth remarking here that Ω and J induce opposite orientations on V in the $(--++)$-setting, while the orientations agree and Ω is a self-dual form in the positive definite case. Now, a characterization of Osserman Kähler algebraic curvature tensors can be obtained from Theorem 1 as follows.

Theorem 2: *Let R be an algebraic curvature tensor on a four-dimensional neutral vector space $(V,\langle,\rangle)$. Then R is Kähler Osserman with respect to some orthogonal complex structure J on V if and only if one of the following hold*

(i) R is an Einstein anti-self-dual algebraic curvature tensor, i.e.,

$$R = \frac{\mathrm{Sc}}{12}\mathrm{Id}_{\Lambda^2(V)} + W_-, \quad \textit{where } W_- = \frac{\mathrm{Sc}}{12}\begin{pmatrix} 2 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix},$$

(ii) R is a Ricci flat self-dual algebraic curvature tensor, i.e.,

$$R = \begin{pmatrix} W_+ & 0 \\ 0 & 0 \end{pmatrix}.$$

Moreover, an algebraic curvature tensor as in (i) determines a unique Kähler two-form, defined by the eigenspace corresponding to the distinguished eigenvalue of W_-, but algebraic curvature tensors given by (ii) are Kähler with respect to any positively oriented complex structure.

Proof: Recall from Theorem 1 that R is Osserman if and only if it is Einstein and self-dual or anti-self-dual. In the special framework of four-dimensional Kähler geometry the self-duality and anti-self-duality conditions are quite well understood. First of all recall that since the metric is indefinite of signature $(--++)$, the anti-self-dual part of a Kähler algebraic curvature tensor satisfies

$$W_- = \frac{\mathrm{Sc}}{12}\begin{pmatrix} 2 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix},$$

which shows that a Kähler algebraic curvature tensor is self-dual if and only if the scalar curvature vanishes. Hence, a self-dual Kähler algebraic curvature tensor is Osserman if and only if it is Ricci flat.

Recall that the space $\Lambda^2(V)$ on a neutral Hermitian vector space $(V,J,\langle,\rangle)$ decomposes into the J-invariant and J-anti-invariant subspaces $\Lambda^2(V)=\Lambda^{\text{inv}}\oplus\Lambda^{\text{anti}}$, where

$$\Lambda^{\text{inv}}=\{\alpha\in\Lambda^2(V)/\alpha(Jx,Jy)=\alpha(x,y)\},$$

$$\Lambda^{\text{anti}}=\{\alpha\in\Lambda^2(V)/\alpha(Jx,Jy)=-\alpha(x,y)\}.$$

Then $\Lambda^2(V)=\Lambda^2_+\oplus\Lambda^2_-$ also decomposes as

$$\Lambda^2_+=\Lambda^{\text{inv}}_0,\ \Lambda^2_-=\mathbb{R}\Omega\oplus\Lambda^{\text{anti}},$$

where Λ^{inv}_0 denotes the J-invariant two-forms orthogonal to Ω. Considering the induced map $J:\Lambda^2(V)\to\Lambda^2(V)$ defined by $J(x\wedge y)=Jx\wedge Jy$, an algebraic curvature tensor $R:\Lambda^2(V)\to\Lambda^2(V)$ is Kähler, i.e., it satisfies (4), if and only if $R\circ J=R$.

Hence, if a Kähler algebraic curvature tensor is self-dual, then it follows from (3) that the whole algebraic curvature tensor becomes

$$R=\begin{pmatrix}W_+ & 0\\ 0 & 0\end{pmatrix} \tag{5}$$

and any such algebraic curvature tensor is invariant by $J:\Lambda^2(V)\to\Lambda^2(V)$, and thus Kähler for any positively oriented orthogonal complex structure.

For a non-Ricci-flat Kähler algebraic curvature tensor, the Osserman condition is equivalent to anti-self-duality, i.e., $W_+=0$. Now, note that the self-dual part of the Weyl curvature tensor in neutral signature $(--++)$ represents the Bochner tensor,[5] and thus R is a Bochner-flat Einstein algebraic curvature tensor, from where it immediately follows that R is of constant holomorphic sectional curvature. Moreover, any algebraic curvature tensor given as in (i) is Kähler with respect to an orthogonal complex structure if and only if J is defined by the distinguished eigenvalue of W_-. □

Remark 3: A Ricci-flat Kähler Osserman algebraic curvature tensor is determined by the Jordan normal form of W_+. Moreover, since the induced inner product on $\Lambda^2_\pm$ is of Lorentzian signature, four different possibilities may occur for the self-dual curvature operator $\langle\hat{W}_+\alpha,\beta\rangle=W_+(\alpha,\beta)$ as follows (cf. Ref. 3)

(Ia) The self-dual curvature operator $\hat{W}_+$ is diagonalizable, i.e.,

$$\hat{W}_+=\begin{pmatrix}b+c & 0 & 0\\ 0 & -b & 0\\ 0 & 0 & -c\end{pmatrix}.$$

(Ib) The self-dual curvature operator $\hat{W}_+$ has a complex eigenvalue, i.e.,

$$\hat{W}_+=\begin{pmatrix}a & b & 0\\ -b & a & 0\\ 0 & 0 & -2a\end{pmatrix}.$$

(II) The self-dual curvature operator $\hat{W}_+$ has a double root of its minimal polynomial, i.e,

$$\hat{W}_+=\begin{pmatrix}a\pm 1 & \pm 1 & 0\\ \mp 1 & a\mp 1 & 0\\ 0 & 0 & -2a\end{pmatrix}.$$

(III) The self-dual curvature operator $\hat{W}_+$ has a triple root of its minimal polynomial, i.e,

$$\hat{W}_+ = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -\frac{\sqrt{2}}{2} \\ 0 & -\frac{\sqrt{2}}{2} & 0 \end{pmatrix}.$$

III. KÄHLER OSSERMAN METRICS

Although the structure of the Kähler Osserman algebraic curvature tensors is completely determined in Theorem 2, the situation is more complex as concerns the differentiable level. An algebraic curvature tensor is said to be *Jordan–Osserman* if the normal Jordan form of the Jacobi operators is constant on $S^{\pm}(V)$. It follows from the results in Ref. 3 that any Osserman algebraic curvature tensor is Jordan–Osserman in dimension four, but such equivalence is no longer true in higher dimensions (see, for example Ref. 4). Passing from the algebraic to the differentiable level the corresponding notions arise. A pseudo-Riemannian manifold is said to be *Osserman* (respectively, *Jordan–Osserman*) if the eigenvalues of the Jacobi operators (respectively, their normal Jordan forms) are constant on the pseudo-unit sphere bundles $S^{\pm}(M)$. The *pointwise* Osserman and Jordan–Osserman conditions correspond to the possibility of the eigenvalues and the Jordan normal form to vary from point to point on the manifold. Hence we have the following

Theorem 4: *A four-dimensional Kähler metric is pointwise Osserman if and only if it is an indefinite complex space form or a Ricci flat Kähler surface. Moreover, the Jacobi operators of a Jordan–Osserman four-dimensional Kähler metric which is not of constant holomorphic sectional curvature are nilpotent of degree two or three.*

Proof: It follows from Ref. 3, Sec. 5 that a four-dimensional Kähler Osserman manifold whose Jacobi operators are diagonalizable must be locally an indefinite complex space form. Moreover, no Jordan–Osserman four-manifold whose Jacobi operators have complex roots may exist (cf. Ref. 3, Theorem 6.4). Therefore only cases II and III in Remark 3 remain for consideration. Since the manifold is Ricci flat the Jacobi operators are three-step nilpotent for type III Jordan–Osserman metrics. Moreover, if the Jacobi operators are of type II it follows from Ref. 3 Corollary 7.3 that the Jacobi operators have a unique eigenvalue or two distinct eigenvalues α and $\beta=4\alpha$. Hence, the Ricci flatness implies that the Jacobi operators are two-step nilpotent.

Remark 5: It has been shown in Ref. 3 that a type II Jordan–Osserman four-manifold admits a parallel two-dimensional null plane field, and hence the metric corresponds to those discussed by Walker.[23] Further note the existence of Walker metrics which are Osserman but not Ricci flat. Indeed, any para-Kähler metric is necessarily Walker and therefore the class of Walker metrics contains that of paracomplex space forms.

Remark 6: Compact complex surfaces admitting a Ricci flat Kähler metric have been classified by Petean,[21] who showed that any such surface must be a complex torus, a hyperelliptic surface or a primary Kodaira surface. Moreover, he constructed explicit examples of Ricci flat Kähler metrics on any of such surfaces. It should be remarked that all examples in Ref. 21 are either flat or otherwise they have two-step nilpotent Jacobi operators.

Remark 7: Recently, left invariant Kähler structures on simply connected Lie groups have been classified in Ref. 20. It has been shown by Ovando that any such Ricci flat indefinite Kähler structure corresponds to one of the following:

- $\mathfrak{aff}(\mathbb{C})$

  The Lie algebra structure is given by $[e_1,e_3]=e_3$, $[e_1,e_4]=e_4$, $[e_2,e_3]=e_4$ and $[e_2,e_4]=-e_3$, the left-invariant metric is given by $a_{14}(e^1\otimes e^3-e^2\otimes e^4)-a_{13}(e^1\otimes e^4+e^2\otimes e^3)-s(e^1\otimes e^1+e^2\otimes e^2)$ and the complex structure satisfies $Je_2=e_1$, $Je_3=e_4$.

- $\mathfrak{r}_{4,-1,-1}$

  The Lie algebra structure is given by $[e_1,e_4]=-e_1$, $[e_2,e_4]=e_2$ and $[e_3,e_4]=e_3$, the left-invariant metric is given by $a_{13}(e^1\otimes e^2-e^3\otimes e^4)-a_{12}(e^1\otimes e^3+e^2\otimes e^4)-s(e^1\otimes e^1+e^4\otimes e^4)$ and the complex structure satisfies $Je_2=e_3$, $Je_4=e_1$.
- $\mathfrak{d}_{4,2}$

  The Lie algebra structure is given by $[e_1,e_2]=e_3$, $[e_1,e_4]=-2e_1$, $[e_2,e_4]=e_2$ and $[e_3,e_4]=-e_3$, the left-invariant metric is given by $a_{14}(e^1\otimes e^2+e^3\otimes e^4)+s(e^2\otimes e^2+e^4\otimes e^4)$ and the complex structure satisfies $Je_1=e_3$, $Je_2=e_4$.

Now, it follows after some calculations that in all the three cases above the Jacobi operators are two-step nilpotent or they vanish (if and only if $s=0$).

Kähler metrics with three-step nilpotent Jacobi operators

Four-dimensional indefinite Kähler Osserman manifolds with two-step nilpotent Jacobi operators are already known in the literature,[4] but there are only a few examples of Osserman four-manifolds with three-step nilpotent Jacobi operators (cf. Refs. 6 and 10). Moreover, the fact that locally symmetric four-dimensional Osserman manifolds may not have three-step nilpotent Jacobi operators[11] could suggest the nonexistence of Kähler Osserman metrics whose Jacobi operators are nilpotent of degree three.

A Walker manifold is a triple $(M,g,\mathcal{D})$ of an n-dimensional manifold, an indefinite metric g, and an r-dimensional parallel null distribution $\mathcal{D}$. Of special interest are manifolds admitting a field of null planes of maximum dimensionality ($r=n/2$). Since the dimension of a null plane is $r\leqslant\frac{1}{2}n$, the lowest possible case of a Walker metric is that of $(--++)$-manifolds admitting a field of parallel null two-planes. A canonical form for such metrics has been obtained by Walker in Ref. 23, showing the existence of suitable coordinates (x_1,x_2,x_3,x_4), where the metric expresses as

$$g_{(x,y,z,t)}=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & a(x_1,x_2,x_3,x_4) & c(x_1,x_2,x_3,x_4) \\ 0 & 1 & c(x_1,x_2,x_3,x_4) & b(x_1,x_2,x_3,x_4) \end{pmatrix}, \tag{6}$$

for some functions $a(x_1,x_2,x_3,x_4)$, $b(x_1,x_2,x_3,x_4)$, and $c(x_1,x_2,x_3,x_4)$. Further note that the plane field $\mathcal{D}$ is strictly parallel (i.e., there exists two orthogonal null parallel vector fields) if and only if the defining functions satisfy $a(x_3,x_4)$, $b(x_3,x_4)$, $c(x_3,x_4)$ and in such case coordinates can be specialized to obtain $a\equiv c\equiv 0$, $b(x_3,x_4)$ (cf. Ref. 23).

It follows after some straightforward calculations that the Levi-Civita connection of a Walker metric is given by

$$\nabla_{\partial_1}\partial_3=\tfrac{1}{2}a_1\partial_1+\tfrac{1}{2}c_1\partial_2,$$

$$\nabla_{\partial_1}\partial_4=\tfrac{1}{2}c_1\partial_1+\tfrac{1}{2}b_1\partial_2,$$

$$\nabla_{\partial_2}\partial_3=\tfrac{1}{2}a_2\partial_1+\tfrac{1}{2}c_2\partial_2,$$

$$\nabla_{\partial_2}\partial_4=\tfrac{1}{2}c_2\partial_1+\tfrac{1}{2}b_2\partial_2,$$

$$\nabla_{\partial_3}\partial_3=\tfrac{1}{2}\{a_3+ca_2+aa_1\}\partial_1+\tfrac{1}{2}\{2c_3-a_4+ba_2+ca_1\}\partial_2-\tfrac{1}{2}a_1\partial_3-\tfrac{1}{2}a_2\partial_4,$$

$$\nabla_{\partial_3}\partial_4 = \tfrac{1}{2}\{a_4 + cc_2 + ac_1\}\partial_1 + \tfrac{1}{2}\{b_3 + bc_2 + cc_1\}\partial_2 - \tfrac{1}{2}c_1\partial_3 - \tfrac{1}{2}c_2\partial_4,$$

$$\nabla_{\partial_4}\partial_4 = \tfrac{1}{2}\{2c_4 - b_3 + cb_2 + ab_1\}\partial_1 + \tfrac{1}{2}\{b_4 + bb_2 + cb_1\}\partial_2 - \tfrac{1}{2}b_1\partial_3 - \tfrac{1}{2}b_2\partial_4, \tag{7}$$

where a_k means partial derivative

$$\frac{\partial}{\partial x_k}a(x_1,x_2,x_3,x_4)$$

and ∂_k denotes the coordinate vector field $\partial/\partial k$, $k=1,\ldots,4$.

A g-orthogonal almost complex structure J on a Walker four-manifold is said to be proper if it defines a standard generator of a positive $\pi/2$ rotation on $\mathcal{D}$,[16] i.e., $J\partial_1=\partial_2$ and $J\partial_2=-\partial_1$. The whole almost complex structure can be recovered from this property to obtain in the canonical coordinates

$$J\partial_1 = \partial_2, \quad J\partial_2 = -\partial_1,$$

$$J\partial_3 = -c\partial_1 + \tfrac{1}{2}(a-b)\partial_2 + \partial_4, \tag{8}$$

$$J\partial_4 = \tfrac{1}{2}(a-b)\partial_1 + c\partial_2 - \partial_3.$$

Further note that the indefinite almost Hermitian structure (g,J) is Kähler if and only if[16]

$$a_1 = -b_1 = c_2 \quad a_2 = -b_2 = -c_1. \tag{9}$$

Next, let R denote the curvature tensor, taken with the sign convention $R(X,Y)=\nabla_{[X,Y]} - [\nabla_X,\nabla_Y]$. A straightforward calculation from (7) using (9) shows that the curvature tensor of a Kähler Walker metric is given by the following (see also Ref. 16, Appendix 1):

$$R_{1331} = R_{1342} = R_{1414} = R_{1432} = R_{2323} = R_{2442} = \tfrac{1}{2}c_{12},$$

$$R_{1341} = R_{1323} = R_{1442} = R_{2324} = \tfrac{1}{2}c_{11},$$

$$R_{1334} = R_{2434} = \tfrac{1}{2}(c_{24} - c_{13}),$$

$$R_{1434} = R_{2343} = \tfrac{1}{2}(c_{23} + c_{14}),$$

$$R_{3434} = \tfrac{1}{4}\{4c_{34} - 2a_{44} - 2b_{33} - (a_3 + 3b_3 - 2c_4)c_2 - (b_4 + 3a_4 - 2c_3)c_1 - (a+b)c_2^2 - (a+b)c_1^2\}. \tag{10}$$

Theorem 8: *A Kähler Walker metric* (6)–(8) *is Osserman if and only if the coefficient functions satisfy*

$$a(x_1,x_2,x_3,x_4) = x_1P(x_3,x_4) + x_2Q(x_3,x_4) + \xi(x_3,x_4),$$

$$b(x_1,x_2,x_3,x_4) = -x_1P(x_3,x_4) - x_2Q(x_3,x_4) + \eta(x_3,x_4), \tag{11}$$

$$c(x_1,x_2,x_3,x_4) = -x_1Q(x_3,x_4) + x_2P(x_3,x_4) + \gamma(x_3,x_4)$$

for any functions $P(x_3,x_4)$, $Q(x_3,x_4)$ *satisfying*

$$P_3 - Q_4 = 0 \tag{12}$$

and arbitrary functions $\xi(x_3,x_4)$, $\eta(x_3,x_4)$, and $\gamma(x_3,x_4)$. Moreover the Jacobi operators have zero eigenvalues and they satisfy one of the following

(i) The Jacobi operators vanish at those points where $P_4+Q_3=0$ and

$$(P^2+Q^2)(\xi+\eta)+P(\xi_3+3\eta_3-2\gamma_4)-Q(\eta_4+3\xi_4-2\gamma_3)+2(\xi_{44}-2\gamma_{34}+\eta_{33})=0,$$

(ii) the Jacobi operators are two-step nilpotent if and only if $P_4+Q_3=0$ and

$$(P^2+Q^2)(\xi+\eta)+P(\xi_3+3\eta_3-2\gamma_4)-Q(\eta_4+3\xi_4-2\gamma_3)+2(\xi_{44}-2\gamma_{34}+\eta_{33})\neq 0,$$

(iii) The Jacobi operators are three-step nilpotent otherwise.

Proof: As a matter of notation, let Ric and Sc denote the Ricci tensor and the scalar curvature of (M,g), defined by $\mathrm{Ric}(X,Y)=\mathrm{trace}\{Z\to R(X,Z)Y\}$ and $\mathrm{Sc}=\mathrm{trace\ Ric}$. Now it follows from (10) that the Ricci tensor and the scalar curvature of a Kähler Walker metric satisfies

$$\mathrm{Ric}_{13}=\mathrm{Ric}_{24}=c_{12},$$

$$\mathrm{Ric}_{14}=-\mathrm{Ric}_{23}=c_{11},$$

$$\mathrm{Ric}_{33}=c_{23}+c_{14}+\tfrac{1}{2}\{(a-b)c_{12}-2cc_{11}\}, \tag{13}$$

$$\mathrm{Ric}_{44}=c_{23}+c_{14}-\tfrac{1}{2}\{(a-b)c_{12}-2cc_{11}\},$$

$$\mathrm{Ric}_{34}=\tfrac{1}{2}\{2cc_{12}+(a-b)c_{11}\},$$

$$\mathrm{Sc}=4c_{12}. \tag{14}$$

Now, since any Osserman manifold is necessarily Einstein, a straightforward calculation from (13) shows that the Einstein tensor

$$G=\mathrm{Ric}-\frac{\mathrm{Sc}}{4}g$$

vanishes (equivalently the metric is Einstein) if and only if the following hold

$$\begin{gathered} G_{14}=-G_{23}=c_{11}\equiv 0,\\ G_{33}=c_{14}+c_{23}-\tfrac{1}{2}\{(a+b)c_{12}+2cc_{11}\}\equiv 0,\\ G_{34}=\tfrac{1}{2}(a-b)c_{11}\equiv 0,\\ G_{44}=c_{14}+c_{23}-\tfrac{1}{2}\{(a+b)c_{12}-2cc_{11}\}\equiv 0. \end{gathered} \tag{15}$$

Next note from (9) that $a_{11}+a_{22}=0$ for any Kähler Walker metric, and thus it follows from (15) and (9) that $a_{11}=a_{22}=a_{12}\equiv 0$, $c_{11}=c_{22}=c_{12}\equiv 0$, and $b_{11}=b_{22}=b_{12}\equiv 0$. Now, those conditions together with the Kähler ones at (9) show that the metric (6) must be necessarily given by (11). Now, a straightforward calculation shows that (15) reduces to

$$G_{33}=G_{44}=-Q_4+P_3\equiv 0, \tag{16}$$

which shows (12).

Now, in order to analyze the Osserman property, it is convenient to consider the normalized Jacobi operators $J_R(X)=g(X,X)^{-1}R_X$, where for any non-null vector $X=\Sigma X_i\partial_i$, the Jacobi operators $R_X=R(X,\cdot,)X$ of a metric (11) satisfying (12) are given by

$$R_X=\begin{pmatrix} A & B \\ 0 & {}^tA \end{pmatrix}, \tag{17}$$

where A and B are 2×2-matrices and moreover

$$A=\tfrac{1}{2}(P_4+Q_3)\begin{pmatrix} X_3X_4 & X_4^2 \\ -X_3^2 & -X_3X_4 \end{pmatrix}. \tag{18}$$

This shows that the characteristic polynomial of the Jacobi operators satisfy $\det(R_X-\lambda\mathrm{id})=\lambda^4$ and thus metrics (11) and (12) are Osserman with zero eigenvalues for the Jacobi operators.

Moreover, in order to analyze the minimal polynomial of the Jacobi operators, observe that $J_R(X)^{(3)}=0$ and that

$$J_R(X)^{(2)}=-\frac{1}{4}g(X,X)^{-1}(P_4+Q_3)^2\begin{pmatrix} 0 & 0 & X_4^2 & -X_3X_4 \\ 0 & 0 & -X_3X_4 & X_3^2 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Moreover, assuming $P_4+Q_3=0$, the Jacobi operators reduce to

$$R_X=-\frac{1}{4}\Xi\begin{pmatrix} 0 & 0 & X_4^2 & -X_3X_4 \\ 0 & 0 & -X_3X_4 & X_3^2 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

where

$$\Xi=(P^2+Q^2)(\xi+\eta)+P(\xi_3+3\eta_3-2\gamma_4)-Q(\eta_4+3\xi_4-2\gamma_3)+2(\xi_{44}-2\gamma_{34}+\eta_{33})$$

from where the result follows. □

Remark 9: As a consequence of Theorem 8 we have plenty of examples of Kähler Osserman metrics whose Jacobi operators are three-step nilpotent. Indeed, any metric

$$a(x_1,x_2,x_3,x_4)=x_1P(x_3,x_4)+x_2Q(x_3,x_4),$$

$$b(x_1,x_2,x_3,x_4)=-x_1P(x_3,x_4)-x_2Q(x_3,x_4),$$

$$c(x_1,x_2,x_3,x_4)=-x_1Q(x_3,x_4)+x_2P(x_3,x_4)$$

is Kähler Osserman if and only if the functions P and Q satisfy $P_3-Q_4=0$. Moreover, the corresponding Jacobi operators vanish (equivalently the metric is flat) if and only if $P_4+Q_3=0$. Otherwise the Jacobi operators are three-step nilpotent.

Remark 10: The Ricci operator $\langle\hat{\mathrm{Ric}}(X),Y\rangle=\mathrm{Ric}(X,Y)$ of a metric (6) satisfying the Kähler conditions (9) is given by

$$\hat{\mathrm{Ric}} = \begin{pmatrix} c_{12} & -c_{11} & c_{14}+c_{23}-\frac{1}{2}(a+b)c_{12} & -\frac{1}{2}(a+b)c_{11} \\ c_{11} & c_{12} & \frac{1}{2}(a+b)c_{11} & c_{14}+c_{23}-\frac{1}{2}(a+b)c_{12} \\ 0 & 0 & c_{12} & c_{11} \\ 0 & 0 & -c_{11} & c_{12} \end{pmatrix}$$

and hence the Ricci curvatures satisfy

$$\lambda = c_{12} \pm \sqrt{-c_{11}^2}. \tag{19}$$

Moreover, since the scalar curvature satisfies $\mathrm{Sc}=4c_{12}$, proceeding as in Theorem 8 it follows that a Kähler metric (6)–(9) is self-dual if and only if it is given by

$$a(x_1,x_2,x_3,x_4) = -2x_1x_2T(x_3,x_4) + x_1P(x_3,x_4) + x_2Q(x_3,x_4) + \xi(x_3,x_4),$$

$$b(x_1,x_2,x_3,x_4) = 2x_1x_2T(x_3,x_4) - x_1P(x_3,x_4) - x_2Q(x_3,x_4) + \eta(x_3,x_4),$$

$$c(x_1,x_2,x_3,x_4) = (x_1^2-x_2^2)T(x_3,x_4) - x_1Q(x_3,x_4) + x_2P(x_3,x_4) + \gamma(x_3,x_4).$$

Hence any self-dual metric as above has Ricci curvatures $\pm 2T(x_3,x_4)\sqrt{-1}$. Further note that even in case the Ricci curvatures are vanishing (i.e., $T\equiv 0$), the Ricci operator becomes

$$\hat{\mathrm{Ric}} = \begin{pmatrix} 0 & 0 & P_3-Q_4 & 0 \\ 0 & 0 & 0 & P_3-Q_4 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

which is nondiagonalizable unless (12) holds.

On Explicit point multimonopoles in SU(2) gauge theory

Alexander D. Popov[a)]
Institut für Theoretische Physik, Universität Hannover, Appelstraße 2, 30167 Hannover, Germany

(Received 8 March 2005; accepted 26 April 2005; published online 21 June 2005)

It is well known that the Dirac monopole solution with the U(1) gauge group embedded into the group SU(2) is equivalent to the SU(2) Wu–Yang point monopole solution having no Dirac string singularity. We consider a multicenter configuration of m Dirac monopoles and n antimonopoles and its embedding into SU(2) gauge theory. Using geometric methods, we construct an explicit solution of the SU(2) Yang–Mills equations which generalizes the Wu–Yang solution to the case of m monopoles and n antimonopoles located at arbitrary points in $\mathbb{R}^3$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1939987]

I. INTRODUCTION

Abelian magnetic monopoles play a key role in the dual superconductor mechanism of confinement[1] which has been confirmed by many numerical simulations of the lattice gluodynamics (see, e.g., Refs. 2 and 3 and references therein). Due to a dominant role of Abelian monopoles in the confinement phenomena, it is important to better understand how they arise in nonabelian pure gauge theories.

A spherically symmetric monopole solution of the SU(2) pure gauge field equations was obtained by Wu and Yang in 1969.[4] This solution is singular at the origin and smooth on $\mathbb{R}^3 - \{0\}$. Initially it was thought that it is genuinely nonabelian, yet later it was shown[5] that this solution is nothing but the Abelian Dirac monopole[6] in disguise. Note that the gauge potential of the finite-energy spherically symmetric 't Hooft–Polyakov monopole[7] approaches just the Wu–Yang gauge potential for large $r^2 = x^a x^a$.

In this article, we generalize the Wu-Yang solution to a configuration describing m monopoles and n antimonopoles with arbitrary locations in $\mathbb{R}^3$. This explicit solution to the Yang—Mills equations can also be used as a guide to the asymptotic $r \to \infty$ behavior of unknown finite-energy solutions in the Yang–Mills–Higgs theory, whose form for small r is determined by multiplying the solution by arbitrary functions and minimizing the energy functional, as was proposed in Ref. 8.

II. GENERIC U(1) CONFIGURATIONS

We consider the configuration of m Dirac monopoles and n antimonopoles located at points $\vec{a}_i = \{a_i^1, a_i^2, a_i^3\}$ with $i = 1, \ldots, m$ and $i = m+1, \ldots, m+n$, respectively. There are delta-function sources for the magnetic field at these points.

Let us introduce the following two regions in $\mathbb{R}^3$:

$$R^3_{N,m+n} := \mathbb{R}^3 - \{ \bigcup_{i=1}^{m+n} (x^1 = a_i^1, \quad x^2 = a_i^2, \quad x^3 \leqslant a_i^3) \},$$

[a)]On leave from Bogoliubov Laboratory of Theoretical Physics, JINR, Dubna, Russia; Electronic mail: popov@itp.uni-hannover.de

$$R^3_{S,m+n} := \mathbb{R}^3 - \{\bigcup_{i=1}^{m+n}(x^1 = a^1_i, \quad x^2 = a^2_i, \quad x^3 \geqslant a^3_i)\}. \tag{1}$$

For simplicity we restrict ourselves to the *generic* case

$$a^{1,2}_i \neq a^{1,2}_j \quad \text{for} \quad i \neq j, \tag{2}$$

when

$$R^3_{N,m+n} \cup R^3_{S,m+n} = \mathbb{R}^3 - \{\vec{a}_1, \ldots, \vec{a}_{m+n}\}, \tag{3}$$

and the two open sets are enough for describing the previous (m,n) configuration. Namely, the generic configuration of m Dirac monopoles and n antimonopoles is described by the gauge potentials

$$A^{N,m+n} = \sum_{j=1}^{m} A^{N,j} + \sum_{j=m+1}^{m+n} \overline{A}^{N,j}, \quad A^{S,m+n} = \sum_{j=1}^{m} A^{S,j} + \sum_{j=m+1}^{m+n} \overline{A}^{S,j}, \tag{4}$$

where $A^{N,m+n}$ and $A^{S,m+n}$ are well defined on $R^3_{N,m+n}$ and $R^3_{S,m+n}$, respectively. Here

$$A^{N,j} = A^{N,j}_a \mathrm{d}x^a \quad \text{with} \quad A^{N,j}_1 = \frac{\mathrm{i}x^2_j}{2r_j(r_j + x^3_j)}, \quad A^{N,j}_2 = -\frac{\mathrm{i}x^1_j}{2r_j(r_j + x^3_j)}, \quad A^{N,j}_3 = 0, \tag{5}$$

$$A^{S,j} = A^{S,j}_a \mathrm{d}x^a \quad \text{with} \quad A^{S,j}_1 = -\frac{\mathrm{i}x^2_j}{2r_j(r_j - x^3_j)}, \quad A^{S,j}_2 = \frac{\mathrm{i}x^1_j}{2r_j(r_j - x^3_j)}, \quad A^{S,j}_3 = 0, \tag{6}$$

where

$$x^c_j = x^c - a^c_j, \quad r^2_j = \delta_{ab} x^a_j x^b_j, \quad a,b,c = 1,2,3, \tag{7}$$

and $\overline{A}^{N,j} = -A^{N,j}$, $\overline{A}^{S,j} = -A^{S,j}$. On the intersection $R^3_{N,m+n} \cap R^3_{S,m+n}$ we have

$$A^{N,m+n} = A^{S,m+n} + \mathrm{d}\ln\left(\prod_{i=1}^{m}\left(\frac{\overline{y_i}}{y_i}\right)^{1/2}\prod_{j=m+1}^{m+n}\left(\frac{y_j}{\overline{y_j}}\right)^{1/2}\right), \tag{8}$$

where $y_j = x^1_j + \mathrm{i}x^2_j$ and overbar denotes a complex conjugation.

Remark: Note that in the case when $a^{1,2}_i = a^{1,2}_j$ for some $i \neq j$, one has to introduce more than two open sets covering the space $\mathbb{R}^3 - \{\vec{a}_1, \ldots, \vec{a}_{m+n}\}$ and define gauge potentials on each of these sets as well as transition functions on their intersections. However, for the case $\vec{a}_1 = \cdots = \vec{a}_{m+n} = \vec{a}$ the two sets (1) are again enough to cover $\mathbb{R}^3 - \{\vec{a}\}$ and the gauge potential (4)–(6) will describe $m-n$ monopoles (if $m > n$) or $n-m$ antimonopoles (if $m < n$) sitting on top of each other.

One can simplify expressions (4)–(8) by introducing functions of coordinates

$$w_j := \frac{y_j}{r_j - x^3_j} = \mathrm{e}^{\mathrm{i}\varphi_j}\cot\frac{\vartheta_j}{2}, \quad v_j := \frac{1}{w_j} = \frac{\overline{y_j}}{r_j + x^3_j} = \mathrm{e}^{-\mathrm{i}\varphi_j}\tan\frac{\vartheta_j}{2}, \tag{9}$$

where

$$x^1_j = r_j \sin\vartheta_j \cos\varphi_j, \quad x^2_j = r_j \sin\vartheta_j \sin\varphi_j, \quad x^3_j = r_j \cos\vartheta_j. \tag{10}$$

Note that $w_i \to \infty$ for $x^{1,2} \to a^{1,2}_i$, $x^3 \geqslant a^3_i$, and $v_i \to \infty$ for $x^{1,2} \to a^{1,2}_i$, $x^3 \leqslant a^3_i$. In terms of w_j and v_j the gauge potentials (4)–(6) have the form

$$A^{N,m+n} = \sum_{i=1}^{m} \frac{1}{2(1 + v_i\overline{v_i})}(\overline{v_i}\,\mathrm{d}v_i - v_i\,\mathrm{d}\overline{v_i}) + \sum_{i=m+1}^{m+n} \frac{1}{2(1 + v_i\overline{v_i})}(v_i\,\mathrm{d}\overline{v_i} - \overline{v_i}\,\mathrm{d}v_i), \tag{11}$$

$$A^{S,m+n}=\sum_{i=1}^{m}\frac{1}{2(1+w_i\overline{w_i})}(\overline{w_i}\,\mathrm{d}w_i-w_i\,\mathrm{d}\overline{w_i})+\sum_{i=m+1}^{m+n}\frac{1}{2(1+w_i\overline{w_i})}(w_i\,\mathrm{d}\overline{w_i}-\overline{w_i}\,\mathrm{d}w_i). \tag{12}$$

On the intersection $R^3_{N,m+n}\cap R^3_{S,m+n}$ of two domains (1) these configurations are related by the transformation

$$A^{N,m+n}=A^{S,m+n}+\mathrm{d}\ln\left(\prod_{i=1}^{m}\left(\frac{\overline{w_i}}{w_i}\right)^{1/2}\prod_{j=m+1}^{m+n}\left(\frac{w_j}{\overline{w_j}}\right)^{1/2}\right), \tag{13}$$

since $\overline{y_i}/y_i=\overline{w_i}/w_i$. Note that the transition function in (13) can also be written in terms of v_i by using the relation $v_i/\overline{v_i}=\overline{w_i}/w_i$.

For the Abelian curvature $F^{D,m+n}$ we have

$$\begin{aligned}F^{D,m+n}=\mathrm{d}A^{N,m+n}&=-\sum_{i=1}^{m}\frac{\mathrm{d}v_i\wedge\mathrm{d}\overline{v_i}}{(1+v_i\overline{v_i})^2}+\sum_{i=m+1}^{m+n}\frac{\mathrm{d}v_i\wedge\mathrm{d}\overline{v_i}}{(1+v_i\overline{v_i})^2}\\&=-\sum_{i=1}^{m}\frac{\mathrm{d}w_i\wedge\mathrm{d}\overline{w_i}}{(1+w_i\overline{w_i})^2}+\sum_{i=m+1}^{m+n}\frac{\mathrm{d}w_i\wedge\mathrm{d}\overline{w_i}}{(1+w_i\overline{w_i})^2}=\mathrm{d}A^{S,m+n}.\end{aligned} \tag{14}$$

It is not difficult to see that $F^{D,m+n}$ is singular only at points $\{\vec{a}_1,\ldots,\vec{a}_{m+n}\}$, where monopoles and antimonopoles are located.

III. POINT SU(2) CONFIGURATIONS

The generalization of the Wu–Yang SU(2) monopole[4] to a configuration describing m monopoles and n antimonopoles can be obtained as follows. Let us multiply Eq. (13) by the Pauli matrix σ_3 and rewrite it as

$$A^{N,m+n}\sigma_3=f^{(m,n)}_{NS}A^{S,m+n}\sigma_3(f^{(m,n)}_{NS})^{-1}+f^{(m,n)}_{NS}\mathrm{d}(f^{(m,n)}_{NS})^{-1}, \tag{15}$$

where

$$f^{(m,n)}_{NS}=\begin{pmatrix}\displaystyle\prod_{i=1}^{m}\left(\frac{w_i}{\overline{w_i}}\right)^{1/2}\prod_{j=m+1}^{m+n}\left(\frac{\overline{w_j}}{w_j}\right)^{1/2} & 0\\ 0 & \displaystyle\prod_{i=1}^{m}\left(\frac{\overline{w_i}}{w_i}\right)^{1/2}\prod_{j=m+1}^{m+n}\left(\frac{w_j}{\overline{w_j}}\right)^{1/2}\end{pmatrix}. \tag{16}$$

It can be checked by direct calculation that the transition matrix (16) can be split as

$$f^{(m,n)}_{NS}=(g^{(m,n)}_{N})^{-1}g^{(m,n)}_{S}, \tag{17}$$

where the 2×2 unitary matrices

$$g^{(m,n)}_{N}=\frac{1}{(1+\prod_{i=1}^{m+n}v_i\overline{v_i})^{1/2}}\begin{pmatrix}\displaystyle\prod_{j=1}^{m}v_j\prod_{k=m+1}^{m+n}\overline{v_k} & 1\\ -1 & \displaystyle\prod_{j=1}^{m}\overline{v_j}\prod_{k=m+1}^{m+n}v_k\end{pmatrix} \tag{18}$$

and

$$g_S^{(m,n)} = \frac{1}{(1+\prod_{i=1}^{m+n} w_i\overline{w_i})^{1/2}} \begin{pmatrix} 1 & \prod_{j=1}^{m} \overline{w_j} \prod_{k=m+1}^{m+n} w_k \\ -\prod_{j=1}^{m} w_j \prod_{k=m+1}^{m+n} \overline{w_k} & 1 \end{pmatrix} \tag{19}$$

are well defined on $R^3_{N,m+n}$ and $R^3_{S,m+n}$, respectively. Using formulas (9) and (10), one can rewrite these matrices in the coordinates x_i^a with explicit dependence on moduli $\vec{a}_i$ for $i=1,\ldots,m+n$.

Substituting (17) into (15), we obtain

$$A^{N,m+n} g_N^{(m,n)} \sigma_3 (g_N^{(m,n)})^\dagger + g_N^{(m,n)} \mathrm{d}(g_N^{(m,n)})^\dagger = A^{S,m+n} g_S^{(m,n)} \sigma_3 (g_S^{(m,n)})^\dagger + g_S^{(m,n)} \mathrm{d}(g_S^{(m,n)})^\dagger =: A^{(m,n)}_{su(2)}, \tag{20}$$

where by construction $A^{(m,n)}_{\mathrm{su}(2)}$ is well defined on $R^3_{N,m+n} \cup R^3_{S,m+n} = \mathbb{R}^3 - \{\vec{a}_1,\ldots,\vec{a}_{m+n}\}$. Geometrically, the existence of splitting (17) means that Dirac's nontrivial U(1) bundle over $\mathbb{R}^3 - \{\vec{a}_1,\ldots,\vec{a}_{m+n}\}$ trivializes when being embedded into an SU(2) bundle. The matrices (18) and (19) define this trivialization since $f_{NS}^{(m,n)} \mapsto \widetilde{f}_{NS}^{(m,n)} = g_N^{(m,n)} f_{NS}^{(m,n)} (g_S^{(m,n)})^{-1} = \mathbf{1}_2$.

Remark: Recall that we consider generic configurations with conditions (2). In the case of $a_i^{1,2}$ coinciding for some $i \neq j$, one has $R^3_{N,m+n} \cup R^3_{S,m+n} \neq \mathbb{R}^3 - \{\vec{a}_1,\ldots,\vec{a}_{m+n}\}$ and the gauge potential (20) can have singularities outside $R^3_{N,m+n} \cup R^3_{S,m+n}$. For example, in the case $m=2$, $n=0$, $a_1^{1,2} = a_2^{1,2} = 0$, and $a_1^3 = -a_2^3 = a$, the gauge potential describing two separated monopoles will be singular on the interval $-a \leqslant x^3 \leqslant a$. To have nonsingular $A^{(2,0)}_{\mathrm{su}(2)}$ one should consider $a_1^{1,2} \neq a_2^{1,2}$ or to use three open sets covering $\mathbb{R}^3 - \{\vec{a}_1, \vec{a}_2\}$ instead of two ones.

The field strength for the configuration (20) is given by

$$F^{(m,n)}_{\mathrm{su}(2)} = \mathrm{d}A^{(m,n)}_{\mathrm{su}(2)} + A^{(m,n)}_{\mathrm{su}(2)} \wedge A^{(m,n)}_{\mathrm{su}(2)} = \mathrm{i} F^{D,m+n} Q_{(m,n)}, \tag{21}$$

where the su(2)-valued matrix

$$Q_{(m,n)} := -\mathrm{i} g_N^{(m,n)} \sigma_3 (g_N^{(m,n)})^\dagger = -\mathrm{i} g_S^{(m,n)} \sigma_3 (g_S^{(m,n)})^\dagger \tag{22}$$

is well defined on $R^3_{N,m+n} \cup R^3_{S,m+n}$. It is easy to see that $Q^2_{(m,n)} = -1$ and $Q_{(m,n)}$ may be considered as the generator of the group U(1) embedded into SU(2). Then the Abelian nature of the configuration (20) and (21) becomes obvious. Further, for

$$A^{(m,n)}_{\mathrm{su}(2)} = A^{(m,n)}_a \mathrm{d}x^a, \quad F^{(m,n)}_{\mathrm{su}(2)} = \tfrac{1}{2} F^{(m,n)}_{ab} \mathrm{d}x^a \wedge \mathrm{d}x^b \tag{23}$$

one can easily show that

$$\partial_a F^{(m,n)}_{ab} + [A^{(m,n)}_a, F^{(m,n)}_{ab}] = \mathrm{i}(\partial_a F^{D,m+n}_{ab}) Q_{(m,n)} \tag{24}$$

and therefore on the space $\mathbb{R}^3 - \{\vec{a}_1,\ldots,\vec{a}_{m+n}\}$ we have

$$\partial_a F^{(m,n)}_{ab} + [A^{(m,n)}_a, F^{(m,n)}_{ab}] = 0, \tag{25}$$

which follows from the field equations describing m Dirac monopoles and n antimonopoles. Note that the solution (20)–(23) of the SU(2) gauge theory can be embedded in any larger gauge theory following, e.g., Ref. 9.

IV. POINT MONOPOLES VIA RIEMANN–HILBERT PROBLEMS

Here we want to rederive the described configurations by solving a matrix Riemann-Hilbert problem. For simplicity, we restrict ourselves to the case of m monopoles.

Let us consider the Bogomolny equations[10]

$$F_{ab} = \epsilon_{abc} D_c \chi, \tag{26}$$

where $D_c = \partial_c + [A_c, \cdot]$ and the fields $A_a, F_{ab} = \partial_a A_b - \partial_b A_a + [A_a, A_b]$ and χ take values in the Lie algebra $u(q)$. Obviously, in the Abelian case $D_c\chi = \partial_c \chi$. Note that for the gauge fields $F^{D,m}$ given by (14) we have

$$F^{D,m}_{ab} = \epsilon_{abc} \partial_c \phi^{(m)} \quad \text{with} \quad \phi^{(m)} = \sum_{k=1}^{m} \frac{\mathrm{i}}{2r_k}. \tag{27}$$

Analogously, for the field $F^{(m)}_{ab}$ from (23) we have

$$F^{(m)}_{ab} = \epsilon_{abc} D_c \Phi^{(m)} \quad \text{with} \quad \Phi^{(m)} = \mathrm{i}\phi^{(m)} Q_{(m)}, \tag{28}$$

where $\phi^{(m)}$ is given in (27) and $Q_{(m)}$ in (22). Thus, both U(1) and SU(2) multimonopoles as well as (m,n) configurations (11)–(14) and (20)–(22) can be considered as solutions of the Bogomolny equations (26). In fact, the second order pure Yang–Mills equations for $F^{D,m}_{ab}$ and $F^{(m)}_{ab}$ can be obtained by differentiating (27) and (28), respectively. Moreover, in pure SU(2) Yang–Mills theory in (3+1)-dimensional Minkowski space, one can choose the component A_0 of the gauge potential $A = A_0 \mathrm{d}t + A_a \, \mathrm{d}x^a$ to be nonzero and proportional to $\Phi^{(m)}$ (the Abelian case is similar). Then the configuration $\{A^{(m)}_0, A^{(m)}_a\}$ will be a static multidyon solution of the Yang–Mills equations.

Recall that the Bogomolny equations (26) can be obtained as the compatibility conditions of the linear system

$$\left[D_{\bar{y}} - \frac{\lambda}{2}(D_3 + \mathrm{i}\chi) \right] \psi = 0, \quad \left[\frac{1}{2}(D_3 - \mathrm{i}\chi) + \lambda D_y \right] \psi = 0, \tag{29}$$

where $D_{\bar{y}} = \frac{1}{2}(D_1 + \mathrm{i}D_2)$, $D_y = \frac{1}{2}(D_1 - \mathrm{i}D_2)$, and the auxiliary $q \times q$ matrix $\psi(x^a, \lambda)$ depends holomorphically on a new variable $\lambda \in U \subset \mathbb{C}P^1$. Such matrices ψ can be found via solving a parametric Riemann–Hilbert problem which is formulated in the monopole case as follows.[11] Suppose we are given a $q \times q$ matrix f_{+-} depending holomorphically on

$$\eta = y - 2\lambda x^3 - \lambda^2 \bar{y} \tag{30}$$

and λ for $\lambda \in U_+ \cap U_-$, where $U_+ = \mathbb{C}P^1 - \{\infty\}$ and $U_- = \mathbb{C}P^1 - \{0\}$. Then for each fixed $(x^a) \in \mathbb{R}^3$ and $\lambda \in S^1 \subset U_+ \cap U_-$ one should factorize this matrix-valued function,

$$f_{+-}(x,\lambda) = \psi_+^{-1}(x,\lambda)\psi_-(x,\lambda), \tag{31}$$

in such a way that ψ_+ and ψ_- extend holomorphically in λ onto subsets of U_+ and U_-, respectively. In order to insure that $A^\dagger_a = -A_a$ and $\chi^\dagger = -\chi$ in (29) with $\psi = \psi_\pm$ one should also impose the (reality) conditions

$$f^\dagger_{+-}(x, -\bar{\lambda}^{-1}) = f_{+-}(x,\lambda), \quad \psi^\dagger_+(x, -\bar{\lambda}^{-1}) = \psi^{-1}_-(x,\lambda). \tag{32}$$

After finding such $\psi_\pm$ for an educated guess of f_{+-}, one can get A_a and χ from the linear system (29) with the matrix function ψ_+ or ψ_- instead of ψ. Namely, from (29) we get

$$A_{\bar{y}} := \frac{1}{2}(A_1 + \mathrm{i}A_2) = \psi_+ \partial_{\bar{y}} \psi_+^{-1}|_{\lambda=0}, \quad A_3 - \mathrm{i}\chi = \psi_+ \partial_3 \psi_+^{-1}|_{\lambda=0}, \tag{33}$$

$$A_y := \frac{1}{2}(A_1 - \mathrm{i}A_2) = \psi_- \partial_y \psi_-^{-1}|_{\lambda=\infty}, \quad A_3 + \mathrm{i}\chi = \psi_- \partial_3 \psi_-^{-1}|_{\lambda=\infty}. \tag{34}$$

For more details see Refs. 11 and 12 and references therein.

The construction of U(1) multimonopole solutions via solving the Riemann–Hilbert problem for the function

$$f_{+-}^{D,m}=\frac{\lambda^m}{\prod_{k=1}^m \eta_k}=:\rho_m \quad \text{with} \quad \eta_k=\eta-h(a_k^1,a_k^2,a_k^3,\lambda)=(1-\lambda^2)x_k^1+\mathrm{i}(1+\lambda^2)x_k^2-2\lambda x_k^3 \tag{35}$$

was discussed in Ref. 12 and here we describe only the SU(2) case. The ansatz for $f_{+-}^{(m)}$ which satifies (32) only for odd m was written down in Appendix C of Ref. 12. Here we introduce the ansatz

$$f_{+-}^{(m)}=\begin{pmatrix}\rho_m & \lambda^{-m}\\ (-1)^m\lambda^m & \rho_m^{-1}+(-1)^m\rho_m^{-1}\end{pmatrix} \tag{36}$$

satisfying the reality condition (32) for any m. It is not difficult to see that

$$f_{+-}^{(m)}=\begin{pmatrix}1 & 0\\ (-1)^m\lambda^m\rho_m^{-1} & 1\end{pmatrix}\begin{pmatrix}f_{+-}^{D,m} & 0\\ 0 & (f_{+-}^{D,m})^{-1}\end{pmatrix}\begin{pmatrix}1 & \lambda^{-m}\rho_m^{-1}\\ 0 & 1\end{pmatrix}\sim\begin{pmatrix}f_{+-}^{D,m} & 0\\ 0 & (f_{+-}^{D,m})^{-1}\end{pmatrix}, \tag{37}$$

where the diagonal matrix in (37) describes the Dirac line bundle L [the U(1) gauge group] embedded into the rank 2 complex vector bundle [the SU(2) gauge group] as $L\oplus L^{-1}$. This gives another proof of the equivalence of U(1) and SU(2) point monopole configurations (see Ref. 12 for more details). Furthermore, the matrix (36) can be split as follows:

$$f_{+-}^{(m)}=(\psi_+^{(m)})^{-1}\psi_-^{(m)}, \tag{38}$$

where

$$\psi_+^{(m)}=\hat{\psi}_+^{(m)}\begin{pmatrix}1 & 0\\ (-1)^{m+1}\lambda^m\rho_m^{-1} & 1\end{pmatrix}, \quad \psi_-^{(m)}=\hat{\psi}_-^{(m)}\begin{pmatrix}1 & -\lambda^{-m}\rho_m^{-1}\\ 0 & 1\end{pmatrix}, \tag{39}$$

$$\hat{\psi}_+^{(m)}=g_S^{(m)}\begin{pmatrix}\psi_+^{S,m} & 0\\ 0 & (\psi_+^{S,m})^{-1}\end{pmatrix}, \quad \hat{\psi}_-^{(m)}=g_N^{(m)}\begin{pmatrix}\psi_-^{N,m} & 0\\ 0 & (\psi_-^{N,m})^{-1}\end{pmatrix}, \tag{40}$$

$$\psi_+^{S,m}=\prod_{i=1}^m\psi_+^S(x_i^a,\lambda), \quad \psi_+^S(x_i^a,\lambda)=\xi_+(x_i^a)-\lambda\xi_+^{-1}(x_i^a)\overline{y_i}, \quad \xi_+(x_i^a)=(r_i-x_i^3)^{1/2}, \tag{41}$$

$$\psi_-^{N,m}=\prod_{i=1}^m\psi_-^N(x_i^a,\lambda), \quad (\psi_-^N(x_i^a,\lambda))^{-1}=\xi_-(x_i^a)\overline{y_i}+\lambda^{-1}\xi_-^{-1}(x_i^a), \quad \xi_-(x_i^a)=(r_i+x_i^3)^{-1/2}. \tag{42}$$

The explicit form of $g_N^{(m)}$ and $g_S^{(m)}$ is given in (18) and (19). Note that both $\psi_\pm^{(m)}$ and $\hat{\psi}_\pm^{(m)}$ satisfy the reality conditions (32).

Formulas (38)–(42) solve the parametric Riemann–Hilbert problem for our $f_{+-}^{(m)}$ restricted to a contour on $\mathbb{C}P^1$ which avoids all zeros of the function $\Pi_{k=1}^m\eta_k$. Substituting (39)–(42) into formulas (33) and (34), we get

$$A_{\bar{y}}^{(m)}=\hat{g}_S^{(m)}\partial_{\bar{y}}(\hat{g}_S^{(m)})^{-1}, \quad A_y^{(m)}=\hat{g}_N^{(m)}\partial_y(\hat{g}_N^{(m)})^{-1}, \quad A_3^{(m)}=g_S^{(m)}\partial_3(g_S^{(m)})^\dagger=g_N^{(m)}\partial_3(g_N^{(m)})^\dagger, \tag{43}$$

$$\chi^{(m)}=\frac{\mathrm{i}}{2}(\hat{g}_S^{(m)}\partial_3(\hat{g}_S^{(m)})^{-1}-\hat{g}_N^{(m)}\partial_3(\hat{g}_N^{(m)})^{-1}), \tag{44}$$

where

$$\hat{g}_S^{(m)} = g_S^{(m)} \begin{pmatrix} \xi_+ & 0 \\ 0 & \xi_+^{-1} \end{pmatrix} \text{ with } \quad g_S^{(m)} = \frac{1}{(\prod_{i=1}^m (r_i - x_i^3)^2 + \prod_{i=1}^m y_i \overline{y_i})^{1/2}} \begin{pmatrix} \prod_{j=1}^m (r_j - x_j^3) & \prod_{j=1}^m \overline{y_j} \\ -\prod_{j=1}^m y_j & \prod_{j=1}^m (r_j - x_j^3) \end{pmatrix}, \tag{45}$$

$$\hat{g}_N^{(m)} = g_N^{(m)} \begin{pmatrix} \xi_-^{-1} & 0 \\ 0 & \xi_- \end{pmatrix} \text{ with } \quad g_N^{(m)} = \frac{1}{(\prod_{i=1}^m (r_i + x_i^3)^2 + \prod_{i=1}^m y_i \overline{y_i})^{1/2}} \begin{pmatrix} \prod_{j=1}^m \overline{y_j} & \prod_{j=1}^m (r_j + x_j^3) \\ -\prod_{j=1}^m (r_j + x_j^3) & \prod_{j=1}^m y_j \end{pmatrix} \tag{46}$$

and

$$\xi_+ = \prod_{k=1}^m \xi_+(x_k^a) = \prod_{k=1}^m (r_k - x_k^3)^{1/2}, \quad \xi_- = \prod_{k=1}^m \xi_-(x_k^a) = \prod_{k=1}^m (r_k + x_k^3)^{-1/2}. \tag{47}$$

It is not difficult to see that the configuration (43) coincides with (20) and $\chi^{(m)}$ from (44) with $\Phi^{(m)}$ from (28). Thus, we have derived SU(2) multimonopole point-like solutions via a parametric Riemann–Hilbert problem.

Nonlocal symmetries and the Kaup–Kupershmidt equation

Enrique G. Reyes[a)]
Departamento de Matemáticas y Ciencias de la Computación, Universidad de Santiago de Chile, Casilla 307 Correo 2, Santiago, Chile

(Received 21 December 2004; accepted 26 April 2005; published online 21 June 2005)

Computational and geometric aspects of nonlocal (infinitesimal) symmetries of nonlinear partial differential equations are considered. In particular, the relation of nonlocal symmetries with classical, generalized and internal symmetries is briefly discussed. A nonlocal symmetry for the Kaup–Kupershmidt equation is introduced and studied in some detail. Some explicit particular solutions are found with its help, and a Darboux-like transformation is also obtained. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1939988]

I. INTRODUCTION

Let $\Xi(x,t,u,\ldots)=0$ be a scalar partial differential equation. An infinitesimal (generalized) symmetry of $\Xi=0$ is a smooth function G depending on x, t, u and a finite number of derivatives of u such that for any solution $u(x,t)$ to $\Xi=0$, the deformed function $u(x,t)+\tau G(x,t)$ is also a solution to first order in τ. At least at a formal level[5,10,34] an infinitesimal generalized symmetry G allows one to generate new solutions from old ones, and indeed, if G depends at most on x, t, u and u_x, one can find a one-parameter group of transformations on the space of first order jets of the trivial bundle $(x,t,u)\mapsto(x,t)$ which "sends solutions to solutions."[26,32,34]

The adjective "infinitesimal" will be omitted hereafter. It is of great interest to extend the symmetry concept, since symmetries are of fundamental importance in the theory of differential equations.[34] A natural generalization is provided by *nonlocal symmetries*, first studied rigorously by Vinogradov and Krasil'shchik[45]: In analogy with the generalized symmetry case, by a nonlocal symmetry of $\Xi(x,t,u,\ldots)=0$ one means, intuitively (a formal definition will be given in Sec. III) a function G which depends on x, t, u, a finite number of x derivatives of u *and for example integrals of u*, such that for any solution $u(x,t)$ of $\Xi=0$, the function $u(x,t)+\tau G(u(x,t))$ is also a solution to first order in τ.

That these symmetries are important has been gradually acknowledged in the literature on geometric aspects of differential equations. For example, they were used in the important paper[45] to generate the hierarchy of Korteweg-de-Vries equations and to derive the Hopf–Cole transformation from symmetry considerations; in the late 1980s they were employed by Bluman *et al.*[9] and Bluman and Kumei[8] to find linearizing transformations for nonlinear partial differential equations, and by Akhatov *et al.*[3] to obtain group classification results and special solutions for equations of thermal conductivity and gas dynamics; in 1992, Fushchych and Tychnin[12] used them to classify linearizable equations. Nonlocal symmetries also appear naturally in integrable systems,[2,11] symmetry reduction of ordinary differential equations,[1] and in the theory of recursion operators.[3,15,16,20,26]

A satisfactory geometric formulation of nonlocal symmetries taking into account the requirement that a symmetry—be it local or not—should (at least formally) transform solutions into solutions, has been developed by Krasil'shchik and Vinogradov, see Refs. 45 and 24–26, and references therein. Their theory is based on an extension, also due to them, of the formal geometry of partial differential equations,[5,26,34] the theory of "coverings" and "diffieties." Explicit compu-

[a)]Electronic mail: ereyes@lauca.usach.cl; ereyes@fermat.usach.cl

tations of nonlocal symmetries (in the Krasil'shchik-Vinogradov sense) appear in Refs. 45 and 26, and have been also carried out by Galas[13] (for KdV, Harry Dym, and AKNS), Leo *et al.*[27,28] (for KdV and Harry Dym), and Reyes[41,42] (for Camassa-Holm, Hunter-Saxton, and KdV). Galas' work has been further considered in Ref. 43. In the papers (Refs. 13, 27, 28, and 41–43) it is also shown how to use these new symmetries to obtain Darboux transformations and/or special solutions for the equations at hand.

It is interesting and natural to study the existence of nonlocal symmetries for equations other than the ones considered in (Refs. 13, 27, 28, 41, and 42) since, in contradistinction with generalized symmetries,[5,26,34] finding them is not an algorithmic task. For instance, the nonlocal symmetries appearing in the articles just cited depend not simply on integrals of the dependent variables, but on solutions to nontrivial first order systems of differential equations.

The goals of this article are to review some aspects of nonlocal symmetries in a form as concrete as possible, to make some preliminary remarks on their relation with other types of symmetries, and to present a new nontrivial example of the theory. A short review of classical, generalized and internal symmetries is in Sec. II (three main classes of *local* symmetries, see Refs. 5 and 14) and nonlocal symmetries are discussed in Sec. III. Although the author's debt to the work of I. Krasil'shchik and A. Vinogradov[24–26] is evident, the presentation of nonlocal symmetries appearing in this work is slightly different to the one in these references, as it does not rely explicitly on the formal differential geometry of infinite dimensional manifolds and their coverings. The article then focuses on the Kaup-Kupershmidt equation

$$q_t = q_{xxxxx} + 5qq_{xxx} + \frac{25}{2}q_x q_{xx} + 5q^2 q_x. \tag{1}$$

Eq. (1) has been chosen because to the author's knowledge no fifth order equation has been considered before from the point of view of nonlocal symmetries, and also because this particular equation has proven to be difficult to analyze by standard means: Kaup[21] introduced Eq. (1) in 1980 and found a solitary wave solution for it using inverse scattering techniques, but its N-soliton solutions have been found only in the last four years,[19,30,37,38,31,46] and other classes of exact solutions for (1) do not appear to have been much considered at all, except perhaps for Refs. 17 and 47.

The Kaup–Kupershmidt equation and its nonlocal symmetry are studied in Sec. IV. As is the case in Refs. 13, 27, 28, 41, and 42, this nonlocal symmetry depends on solutions to first order systems of differential equations determined by (1). Finally, in Sec. V a Darboux-like transformation for Eq. (1) is deduced from the computations carried out in Sec. IV, and some particular solutions are explicitly constructed, using again the results of Sec. IV.

Below and henceforth, independent variables will be denoted by $x^1,\dots,x^n$ and dependent variables by $u^1,\dots,u^m$. The space of dependent and independent variables will be denoted by E. Partial derivatives

$$\frac{\partial^k u^\alpha}{\partial x^{j_1}\cdots\partial x^{j_k}} \tag{2}$$

with respect to (not necessarily different) independent variables $x^{j_1},\dots,x^{j_k}$ will be denoted by $u^\alpha_{x^{j_1}\cdots x^{j_k}}$ or simply by $u^\alpha_{j_1,\dots,j_k}$, and of course u^α_0 will be identified with u^α. Multi-indices will be also used, following the conventions of Ref. 34: A multi-index J will be **either** an *unordered* k-tuple of integers $J=(j_1,\dots,j_k)$, $1\leqslant j_1,\dots,j_k\leqslant n$, with *length* $\#J=k$ indicating how many derivatives are being taken, **or** $J=0$. In the second case, the length of J is $\#J=0$. In this notation, the derivative (2) will be represented simply by u^α_J.

II. ON LOCAL SYMMETRIES OF DIFFERENTIAL EQUATIONS

A. Classical symmetries

Let $\Xi_a(x^i,u^\alpha,\dots,u^\alpha_J)=0$ be an nth order system of partial differential equations, and let V be a vector field on the space E,

$$V=\sum_{i=1}^{n}\xi^i(x^j,u^\beta)\frac{\partial}{\partial x^i}+\sum_{\alpha=1}^{m}\varphi^\alpha(x^j,u^\beta)\frac{\partial}{\partial u^\alpha}.$$

The nth *prolongation* of V is given by the formula

$$pr^{(n)}V=\sum_{i=1}^{n}\xi^i\frac{\partial}{\partial x^i}+\sum_{\alpha=1}^{m}\sum_{0\leqslant\#J\leqslant n}\varphi^\alpha_J\frac{\partial}{\partial u^\alpha_J}, \tag{3}$$

where the functions φ^α_J are obtained inductively by means of

$$\varphi^\alpha_{Ji}=D_i\varphi^\alpha_J-\sum_{k=1}^{n}D_i(\xi^k)u^\alpha_{Jk},\quad \varphi^\alpha_0=\varphi^\alpha, \tag{4}$$

and the *total derivatives* D_i are the formal derivations

$$D_i=\frac{\partial}{\partial x^i}+u^\alpha_i\frac{\partial}{\partial u^\alpha}+u_{i_1i}\frac{\partial}{\partial u^\alpha_{i_1}}+u_{i_1i_2i}\frac{\partial}{\partial u^\alpha_{i_1i_2}}+\cdots. \tag{5}$$

The vector V is a *classical symmetry* of $\Xi_a=0$ if the equations $pr^{(n)}V(\Xi_a)=0$ hold whenever $u^\alpha(x^i)$ is a solution to $\Xi_a=0$.[5,10,26,34] It can be rigorously proven[34] that if V is a classical symmetry, and the system $\Xi_a=0$ satisfies some mild technical conditions, for each value of τ the transformation $x^i\mapsto x^i(\tau)$, $u^\alpha\mapsto u^\alpha(\tau)$ determined by the flow equations:

$$\frac{dx^i}{d\tau}=\xi^i(x^j,u^\beta),\quad \frac{du^\alpha}{d\tau}=\varphi^\alpha(x^j,u^\beta), \tag{6}$$

sends solutions of $\Xi_a=0$ to solutions of the same system.

B. Generalized symmetries

A *differential function* is a smooth function depending on the variables x^i, u^α, and a finite number of partial derivatives of u^α.[34] *Generalized vector fields* on the space E are first order operators of the form

$$V=\sum_{i=1}^{n}\xi^i\frac{\partial}{\partial x^i}+\sum_{\alpha=1}^{m}\varphi^\alpha\frac{\partial}{\partial u^\alpha},$$

in which the functions ξ^i and φ^α are arbitrary differential functions.[5,34] In analogy with II.A., V is a *generalized symmetry* of the system $\Xi_a=0$ if and only if $prV(\Xi_a)=0$ whenever $u^\alpha(x^i)$ is a solution of $\Xi_a=0$, in which prV is now the *infinite prolongation* of the generalized vector field V,

$$prV=\sum_{i=1}^{n}\xi^i\frac{\partial}{\partial x^i}+\sum_{\alpha=1}^{m}\sum_{\#J\geqslant 0}\varphi^\alpha_J\frac{\partial}{\partial u^\alpha_J}, \tag{7}$$

and the functions φ^α_J are given as before by Eq. (4). It can be proven that it is enough[5,26,34] to consider generalized symmetries of the form

$$V = \sum_{\alpha=1}^{m} G^{\alpha} \frac{\partial}{\partial u^{\alpha}}. \tag{8}$$

In this case the condition $prV(\Xi_a)=0$ says that the "infinitesimal deformation" $u^{\alpha}(x^i) + \tau G^{\alpha}(u^{\alpha}(x^i))$ solves $\Xi_a=0$ to first order in τ whenever $u^{\alpha}(x^i)$ is a solution of $\Xi_a=0$, and one recovers the preliminary definition of generalized symmetries given in the Introduction. If $u_0^{\alpha}(x^i)$ is a solution to $\Xi_a=0$ and V is a generalized symmetry as in (8), then for any τ the solution $u^{\alpha}(x^i,\tau)$ to the Cauchy problem

$$\frac{\partial u^{\alpha}}{\partial \tau} = G^{\alpha}, \quad u^{\alpha}(x^i,0) = u_0^{\alpha}(x^i) \tag{9}$$

is also a solution to $\Xi_a=0$.[34] In spite of the formal character of this result,[5,10,34] generalized symmetries are of great interest: they are an essential ingredient of Noether's theorem[34] and, they are one of the most important indicators of integrability available for partial differential equations.[32,34]

C. Internal symmetries

In order to introduce internal symmetries one has to dwell a little deeper on the geometry of differential equations.[5,26,34]

Assume that E has a trivial bundle structure, $E=X\times U\to X$, in which X is the space of variables x^i and U is the space of variables u^{α}. Let J^NE be the Nth order jet bundle of E equipped with local coordinates

$$(x^1,\ldots,x^n,u^1,\ldots,u^m,u^1_{j_1},\ldots u^m_{j_1},\ldots,u^1_{j_1j_2\ldots j_k},\ldots,u^m_{j_1j_2\ldots j_k}),$$

in which $J=(j_1,j_2,\ldots,j_k)$ runs over all multi-indices of length at most N, and let $J^{\infty}E$ be the *infinity jet bundle* of E equipped with coordinates

$$(x^1,\ldots,x^n,u^1,\ldots,u^m,u^1_1,\ldots u^m_n,\ldots,u^1_{j_1j_2\ldots j_k},\ldots,u^m_{j_1j_2\ldots j_k},\ldots) \tag{10}$$

in which $J=(j_1,j_2,\ldots,j_k)$ runs now over *all* multi-indices of length $\#J\geqslant 0$.

An Nth order system $\Xi_a=0$ defines a locus in J^NE, and one assumes that this locus can be restricted to a submanifold S^N of J^NE which fibers over X. The kth *prolongation* of $\Xi_a=0$, $k\geqslant 1$, is the system of differential equations

$$D_K\Xi_a = 0, \quad 0 \leqslant \#K \leqslant k \tag{11}$$

in which $D_K=D_{k_1}D_{k_2}\cdots D_{k_p}$ if $K=(k_1,\ldots,k_p)$. For each $k\geqslant 1$ one restricts the locus in $J^{N+k}E$ determined by (11) to a submanifold S^{N+k} of $J^{N+k}E$, and one further assumes that S^{N+k} fibers over S^{N+k-1}. The "tower" $S^N\leftarrow S^{N+1}\leftarrow\cdots$ determines a sub-bundle S^{∞} of $J^{\infty}E$ locally described by the set of points (10) that satisfy $\Xi_a=0$ and all its differential consequences (11). This subbundle is called the *equation manifold* of the system $\Xi_a=0$.

A few facts on the geometry of $J^{\infty}E$ need to be recalled: Smooth functions on $J^{\infty}E$ are the differential functions defined before, and vector fields on $J^{\infty}E$ are formal series

$$X = A_i \frac{\partial}{\partial x^i} + \sum_{\#J\geqslant 0} B_J^{\alpha} \frac{\partial}{\partial u_J^{\alpha}}, \tag{12}$$

in which A_i, B_J^{α} are differential functions. Differential k-forms are finite linear combinations of terms $Adx^{i_1}\wedge\cdots\wedge dx^{i_p}\wedge du_{J_1}^{\alpha_1}\wedge\cdots\wedge du_{J_q}^{\alpha_q}$ in which $p+q=k$ and A is smooth. A differential form ω is a *contact form* if $j^{\infty}(s)^*\omega=0$ for all local sections $s:(x^i)\mapsto(x^i,u^{\alpha}(x^i))$ of E, in which $j^{\infty}(s)$ is the *infinite prolongation* of s given by $j^{\infty}(s)(x^i)=(x^i,u^{\alpha}(x^i),\ldots,u_J^{\alpha}(x^i),\ldots)$. The space of contact forms on $J^{\infty}E$ will be denoted by $C(J^{\infty}E)$.

All the foregoing constructions remain valid, via pull-back, on the equation manifold S^∞ of a system of partial differential equations $\Xi_a=0$.

An (infinitesimal) *contact transformation* is a vector field X on $J^\infty E$ such that $X(C(J^\infty E))\subseteq C(J^\infty E)$ (that is, the Lie derivative of any contact form with respect to X is again a contact form). A contact transformation X is an *external* symmetry of a system of differential equations $\Xi_a=0$ if $X(\Xi_a)=0$ on solutions to $\Xi_a=0$. An *internal* symmetry of $\Xi_a=0$ is a vector field X *on* S^∞ such that $X(C(S^\infty))\subseteq C(S^\infty)$ (Refs. 5, 14, and 26, and references therein), in which $C(S^\infty)$ denotes the space of contact forms on S^∞.

If $\Xi_a=0$ is of order N, one defines *mutatis mutandis* contact transformations on $J^N E$ and internal symmetries on S^N. The following basic result holds.[5]

Theorem 1. *Let $\Xi_a=0$ be a system of equations of order N and let W be a vector field on S^N. If W is an internal symmetry and $V=\pi(W)$ is the projection of W to the bundle E, then V is a generalized symmetry of the system $\Xi_a=0$.* Moreover, $W=(prV)|_{S^N}$.

An "S^∞" version of this result is in Ref. 26 and references therein. The precise relations among classical, generalized and internal symmetries, however, are quite subtle.[5,14] For instance,[5] if a system $\Xi_a=0$ satisfies a technical condition, then every internal symmetry on S^N is obtained by restriction to S^N of a *first order* generalized symmetry of $\Xi_a=0$.

One would argue that nonlocal symmetries should be properly considered as generalizing the class of *internal* symmetries. Some comments to support this point of view are at the end of Sec. III.

III. NONLOCAL SYMMETRIES

The discussion of nonlocal symmetries given in this section is an operational version of the deep geometric theory of Krasil'shchik and Vinogradov.[45,24–26] There are at least two reasons why one would consider their viewpoint as the most satisfactory theory of nonlocalities for differential equations: First, their approach is completely general; there are no a priori restrictions on the *form* nonlocal objects may take, as it happens for instance in Refs. 10 and 20. Second, Krasil'shchik and Vinogradov take naturally into account the fact that there are examples of nonlocal symmetries[13,22,27,28,41,42] which make sense *only if defined on solutions* of a given differential equation.

The following notation will be used: For some extra variables δ_b (to be identified below with new dependent variables) and smooth functions Y_{ib} depending on x^i, u^α, δ_b, and x^i derivatives of u^α, one sets

$$\tilde{D}_i = D_i + \sum_{b=1}^{N} Y_{ib}\frac{\partial}{\partial \delta_b}, \tag{13}$$

and for a given system $\Xi_a=0$ of partial differential equations one defines

$$\widetilde{\Xi}_* = \left(\sum_L \frac{\partial \Xi_a}{\partial u_L^\alpha}\tilde{D}_L\right) = \begin{pmatrix} \dfrac{\partial \Xi_1}{\partial u^1} + \cdots + \dfrac{\partial \Xi_1}{\partial u_I^1}\tilde{D}_I & \dfrac{\partial \Xi_1}{\partial u^2} + \cdots + \dfrac{\partial \Xi_1}{\partial u_J^2}\tilde{D}_J & \cdots \\ \dfrac{\partial \Xi_2}{\partial u^1} + \cdots + \dfrac{\partial \Xi_2}{\partial u_K^1}\tilde{D}_K & \cdots & \cdots \\ \vdots & & \end{pmatrix}. \tag{14}$$

Definition 1: Let $\Xi_a(x^i,u^\alpha,\ldots,u^\alpha_{J_a})=0$ $(i=1,\ldots,n;\ \alpha=1,\ldots,m)$ *be a system of partial differential equations and let* $\{\gamma_b : b=1,2,\ldots,N\}$ *be a new collection of dependent variables. An ordered* $(m+N)$*-tuple of functions* (G^α,H_b)*, depending on the variables* x^i, u^α, γ_b *and finite numbers of* x^i *derivatives of* u^α*, is a nonlocal symmetry of* $\Xi_a=0$ *if there exist functions* X_{ib} *depending on* x^i, u^α, γ_b and x^i*-derivatives of* u^α*, such that the equations*

$$\tilde{D}_i(X_{jb}) = \tilde{D}_j(X_{ib}), \quad i,j=1,2,\ldots,n, \quad b=1,2,\ldots,N, \tag{15}$$

$$\widetilde{\Xi}_*(G) = 0, \tag{16}$$

$$\widetilde{D}_i(H_b) = \widetilde{D}_\tau(X_{ib}), \tag{17}$$

hold whenever $u^\alpha(x^i)$ *is a solution to* $\Xi_a = 0$.

The operators $\widetilde{D}_i$ *are defined as in* (13) *with* Y_{ib} *replaced by the functions* X_{ib} *and* δ_b *replaced by the functions* γ_b*; the matrix* $\widetilde{\Xi}_*$ *in Eq.* (16) *is the matrix* (14) *determined by the system of equations* $\Xi_a = 0$ *and the operators* $\widetilde{D}_i$*; the vector G is* $(G^1, G^2, \ldots, G^m)^t$*; and finally, the operator* $\widetilde{D}_\tau$ *appearing in* (17) *is given by*

$$\widetilde{D}_\tau = \sum_{\alpha=1}^{m} \sum_{\#K \geqslant 0} \widetilde{D}_K(G^\alpha) \frac{\partial}{\partial u_K^\alpha} + \sum_{c=1}^{N} H_c \frac{\partial}{\partial \gamma_c}. \tag{18}$$

The new dependent variables γ_b are the "nonlocal variables," the operators $\widetilde{D}_i$ *satisfying Eq.* (15) are the new total derivatives of the theory, and the corresponding matrix $\widetilde{\Xi}_*$ is the nonlocal version of the *formal linearization* of the system $\Xi_a = 0$. The space $\widetilde{N}$ described locally as the set of coordinates $(x^i, u^\alpha, \ldots, u_J^\alpha, \ldots, \gamma_b)$ and equipped with total derivative operators $\widetilde{D}_i$ satisfying Eq. (15), is said to be a *covering* of the equation manifold S^∞ of the system $\Xi_a = 0$.

Note that Eq. (16) depends only on the functions G^α and the symmetry of equations at hand. Following Krasil'shchik and Vinogradov[24,26,45] one says that the functions G^α are the *shadow* of the nonlocal symmetry (G^α, H_b). It is important to stress that, basically due to the amazing freedom one has to define nonlocal objects (see, e.g.. Refs. 18, 22, and 44), there is no general algorithmic method to find shadows, in contradistinction with the local theory as explained in Refs. 10, 26, and 34.

Example 1: The Kaup–Kupershmidt equation,

$$q_t = q_{xxxxx} + 5qq_{xxx} + (25/2)q_x q_{xx} + 5q^2 q_x, \tag{19}$$

is the integrability condition of the linear problem $\Psi_x = X\Psi$ and $\Psi_t = T\Psi$, in which X and T are given by[33]

$$X = \begin{bmatrix} 0 & 1/(4\lambda^2) \\ -\lambda^2 q & 0 \end{bmatrix} \tag{20}$$

and

$$T = \begin{bmatrix} -(q_{xxx}/4 + qq_x) & (q_{xx}/2 + q^2)/(4\lambda^2) \\ -\lambda^2(q_{xxxx} + 9qq_{xx}/2 + 4q_x^2 + q^3) & q_{xxx}/4 + qq_x \end{bmatrix}. \tag{21}$$

Set $\Psi = (\alpha, \delta)^t$. Then, one checks (using Anderson's VESSIOT package, for instance, see Ref. 4) that

$$G = \alpha^3 \delta \tag{22}$$

is a shadow of a nonlocal symmetry for (19).

An important issue is to motivate Definition 1: First, one should certainly modify the total derivative operators D_i defined in (5), since one wishes to introduce new dependent variables (the "nonlocal variables" of the theory) and total derivatives should take them into account. The operators $\widetilde{D}_i$ appearing in Definition 1 are these new total derivatives, and since one expects $\widetilde{D}_j\widetilde{D}_i = \widetilde{D}_i\widetilde{D}_j$, the equations $\widetilde{D}_i(X_{jb}) = \widetilde{D}_j(X_{ib})$ should hold *on solutions to* $\Xi_a = 0$.

Now, the total derivatives $\widetilde{D}_i$ satisfy $\widetilde{D}_i(\gamma_b) = X_{ib}$, and these equations are compatible because (15) holds. Since *on solutions to the system of equations* $\Xi_a = 0$ the total derivatives $\widetilde{D}_i$ should become ordinary partial derivatives, one concludes that the equations

$$\frac{\partial \gamma_b}{\partial x^i} = X_{ib} \tag{23}$$

should hold for each index b whenever $u^\alpha(x^i)$ is a solution to $\Xi_a=0$. These compatible equations specify the relation between the variables u^α and γ_b whenever $u^\alpha(x^i)$ is a solution to $\Xi_a=0$.

Next, if (G^α, H_b) is a nonlocal symmetry, the deformed variables $u^\alpha+\tau G^\alpha$ should satisfy $\Xi_a=0$ to first order in τ, as in the generalized symmetry case. This means that the equation

$$\frac{\partial \Xi_a}{\partial u^\alpha} u^\alpha_\tau + \frac{\partial \Xi_a}{\partial u^\alpha_{i_1}} u^\alpha_{i_1\tau} + \cdots + \frac{\partial \Xi_a}{\partial u^\alpha_J} u^\alpha_{J_\tau} = 0 \tag{24}$$

should hold whenever $u^\alpha(x^i)$ is a solution to $\Xi_a=0$ and $u^\alpha_\tau = G^\alpha$. Computing $u^\alpha_{i\tau} = u^\alpha_{\tau i}$ on solutions $u^\alpha(x^i)$, one finds

$$u^\alpha_{i\tau} = \frac{\partial G^\alpha}{\partial x^i} = \frac{\partial G^\alpha}{\partial x^i} + \frac{\partial G^\alpha}{\partial u^\beta} u^\beta_i + \cdots + \frac{\partial G^\alpha}{\partial u^\beta_K} u^\beta_{Ki} + \frac{\partial G^\alpha}{\partial \gamma_b} \gamma_{b,i} \tag{25}$$

$$= D_i G^\alpha + \sum_{b=1}^{N} X_{ib} \frac{\partial G^\alpha}{\partial \gamma_b} = \tilde{D}_i G^\alpha. \tag{26}$$

Hence, Eq. (24) becomes

$$\frac{\partial \Xi_a}{\partial u^\alpha} G^\alpha + \frac{\partial \Xi_a}{\partial u^\alpha_{i_1}} \tilde{D}_{i_1} G^\alpha + \cdots + \frac{\partial \Xi_a}{\partial u^\alpha_J} \tilde{D}_J G^\alpha = 0$$

for each index a, and so Eq. (16) should hold.

Finally, not only the dependent variables u^α are deformed, but also the nonlocal variables γ_b—related to u^α by Eq. (23)—change as u^α change (see e.g., Refs. 13, 27, 28, 41, and 42). This change is measured by the deformation $\gamma_b \mapsto \gamma_b + \tau H_b$. One expects that for each index b the function $\gamma_b + \tau H_b$ satisfies (23) to first order in τ whenever $u^\alpha(x^i)$ is a solution to $\Xi_a=0$. Equivalently,

$$\frac{\partial H_b}{\partial x^i} = \frac{\partial X_{ib}}{\partial \tau} \tag{27}$$

whenever $u^\alpha(x^i)$ is a solution to $\Xi_a=0$ and $\gamma_{b,\tau}=H_b$. Expanding one finds,

$$\frac{\partial H_b}{\partial x^i} = \frac{\partial H_b}{\partial x^i} + \frac{\partial H_b}{\partial u^\alpha} u^\alpha_i + \frac{\partial H_b}{\partial u^\alpha_{i_1}} u^\alpha_{i_1 i} + \cdots + \frac{\partial H_b}{\partial u^\alpha_J} u^\alpha_{Ji} + \cdots + \frac{\partial H_b}{\partial \gamma_c} \gamma_{c,i} = D_i H_b + \frac{\partial H_b}{\partial \gamma_c} X_{ic} = \tilde{D}_i H_b$$

and

$$\begin{aligned} \frac{\partial X_{ib}}{\partial \tau} &= \frac{\partial X_{ib}}{\partial u^\alpha} u^\alpha_\tau + \frac{\partial X_{ib}}{\partial u^\alpha_{i_1}} u^\alpha_{i_1\tau} + \cdots + \frac{\partial X_{ib}}{\partial u^\alpha_J} u^\alpha_{J_\tau} + \cdots + \frac{\partial X_{ib}}{\partial \gamma_c} \gamma_{c\tau} \\ &= \frac{\partial X_{ib}}{\partial u^\alpha} G^\alpha + \frac{\partial X_{ib}}{\partial u^\alpha_{i_1}} \tilde{D}_{i_1} G^\alpha + \cdots + \frac{\partial X_{ib}}{\partial u^\alpha_J} \tilde{D}_J G^\alpha + \frac{\partial X_{ib}}{\partial \gamma_c} H_c = \tilde{D}_\tau X_{ib} \end{aligned}$$

that is, (27) is precisely Eq. (17).

The foregoing discussion tells one how to construct nonlocal symmetries *starting from a shadow* G^α: In the process of finding G^α one also finds a collection of new dependent variables ξ_d, and a corresponding collection of compatible equations

$$\frac{\partial \xi_d}{\partial x^i} = Z_{id}(x^i, u^\alpha, u^\alpha_{x^j}, \ldots, u^\alpha_{x^{j_1}\ldots x^{j_i}}, \xi_d), \tag{28}$$

stating how these new variables are related to the original variables u^α. One has to see how ξ_d change as u^α change under the deformation $u^\alpha \mapsto u^\alpha + \tau G^\alpha$. Formally differentiate (28) with respect to τ, and simplify using $u^\alpha_\tau = G^\alpha$. One obtains a compatible system of first order equations for $\xi_{d,\tau}$ of the form

$$\frac{\partial \xi_{d,\tau}}{\partial x^i} = \widetilde{Z}_{id}(x^i, u^\alpha, u^\alpha_{x^k}, \ldots, u^\alpha_{x^{k_1}\ldots x^{k_i}}, \xi_d, \xi_{d,\tau}), \tag{29}$$

which has to be solved for $\xi_{d,\tau}$ assuming (28). If (29) has a solution in terms of x^i, u^α,..., u^α_J, and ξ_d, one is done. If not, add new dependent variables, η_e say, related to u^α and ξ_d by further compatible differential equations

$$\frac{\partial \eta_e}{\partial x^i} = Y_{ie}(x^i, u^\alpha, u^\alpha_{x^j}, \ldots, u^\alpha_{x^{j_1}\ldots x^{j_i}}, \xi_d, \eta_e), \tag{30}$$

and write $\xi_{d,\tau} = F_d(x^i, u^\alpha, \ldots, u^\alpha_{x^{k_1}\ldots x^{k_d}}, \xi_d, \eta_e)$. Now find $\eta_{e,\tau}$, and so on. Eventually one will obtain a set of new dependent variables collectively called γ_b, a corresponding set of functions X_{ib} and compatible equations

$$\frac{\partial \gamma_b}{\partial x^i} = X_{ib}(x^i, u^\alpha, u^\alpha_{x^j}, \ldots, u^\alpha_{x^{j_1}\ldots x^{j_i}}, \gamma_c), \tag{31}$$

and a corresponding set of infinitesimal variations of the form

$$\frac{\partial \gamma_b}{\partial \tau} = H_b(x^i, u^\alpha, \ldots, u^\alpha_{x^{k_1}\ldots x^{k_b}}, \gamma_c). \tag{32}$$

Define total derivatives $\widetilde{D}_i$ by (13) with functions Y_{ib} replaced by X_{ib}. Then, (G^α, H_b) is a bona fide nonlocal symmetry. It is a theorem due to Khorkova, see Refs. 25 and 26 and references therein, that one can always construct a nonlocal symmetry starting from a shadow. Examples appear in Refs. 10, 13, 25, 27, 28, 41, and 42.

Example 2: It was proven in Ref. 45 that

$$G = (2S_x - uS)\mathrm{e}^{-(1/2)\int u \mathrm{d}x}, \tag{33}$$

in which S satisfies $S_t = S_{xx}$, is a shadow of a nonlocal symmetry of Burgers equation $u_t = u_{xx} + uu_x$. Consider an extra dependent variable γ_1 defined by the compatible equations $\gamma_{1,x} = u = X_{11}$ and $\gamma_{1,t} = u_x + \frac{1}{2}u^2 = X_{21}$, and set $G^1 = (2S_x - uS)\exp(-(1/2)\gamma_1)$. Compute $\gamma_{1,\tau x} = \gamma_{1,x\tau} = u_\tau = (2S_x - uS)\mathrm{e}^{-(1/2)\gamma_1} = (2S\mathrm{e}^{-(1/2)\gamma_1})_x$. Thus, $\gamma_{1,\tau} = 2S\exp\left(-\frac{1}{2}\gamma_1\right)$, and one can define $H_1 = 2S\exp\left(-\frac{1}{2}\gamma_1\right)$. The deformations $u \mapsto u + \tau G^1$ and $\gamma_1 \mapsto \gamma_1 + \tau H_1$ satisfy the equations

$$u_t = u_{xx} + uu_x, \quad \gamma_{1,x} = u, \quad \gamma_{1,t} = u_x + \tfrac{1}{2}u^2$$

to first order in τ, and (G^1, H_1) is therefore a nonlocal symmetry for Burgers equation. This example is further examined in Refs. 10, 25, and 39.

Now consider flows of nonlocal symmetries. First of all, one has the following.

Proposition 1: Let $\Xi_a(x^i, u^\alpha, \ldots) = 0$ *be a system of partial differential equations. Assume that* $\{\gamma_b\}$ *is a finite set of nonlocal variables and that* $\widetilde{D}_i = D_i + \Sigma X_{ib}\partial/\partial\gamma_b$ *satisfy Eq.* (15). If G^α *and* H_b *are functions depending on the variables* x^i, u^α, γ_b *and finite numbers of* x^i *derivatives of* u^α *such that* (G^α, H_b) *is a nonlocal symmetry of* $\Xi_a = 0$, *the vector field*

$$G^\alpha \frac{\partial}{\partial u^\alpha} + H_b \frac{\partial}{\partial \gamma_b} \tag{34}$$

is a generalized symmetry of the augmented system

$$\Xi_a = 0, \quad \frac{\partial \gamma_b}{\partial x^i} = X_{ib}. \tag{35}$$

Conversely, if (34) is a generalized symmetry of the system (35), (G^α, H_b) *is a nonlocal symmetry of* $\Xi_a = 0$.

Proof: The vector field (34) is a generalized symmetry of the system (35) if and only if the linearized equations

$$\Xi_{a,\tau} = 0, \quad \frac{\partial}{\partial \tau}\left(\frac{\partial \gamma_b}{\partial x^i}\right) = X_{ib,\tau} \tag{36}$$

with $u^\alpha_\tau = G^\alpha$ and $\gamma_{b,\tau} = H_b$ are satisfied whenever $u^\alpha(x^i)$ and $\gamma_b(x^i)$ are solutions to (35). But, as it can be seen from Eq. (25), the equation $\Xi_{a,\tau} = 0$ is precisely $\tilde{\Xi}_*(G^\alpha)^T = 0$, and this equation holds because (G^α, H_b) is a nonlocal symmetry. Also, the second equation appearing in (36) is equivalent to $H_{b,x^i} = X_{ib,\tau}$ on solutions to (35), and the discussion following Eq. (27) shows that this condition holds if (G^α, H_b) is a nonlocal symmetry. The converse is also clear. □

Example 3: The nonlinear thermal conductivity equation

$$u_t = \left(\frac{u_x}{1+u^2}\right)_x \tag{37}$$

is discussed by Akhatov *et al.*[3] It follows from the analysis of Ref. 3 that the differential function $G = 1 + u^2 + v u_x$, in which v is a potential defined by the equations

$$v_x = u, \quad v_t = \frac{v_{xx}}{1+v_x^2}, \tag{38}$$

is the shadow of a nonlocal symmetry for (37). Proceeding as in Example 2 one easily obtains the genuine nonlocal symmetry $(1 + u^2 + v u_x, x + v v_x)$, and therefore one can conclude that the system of equations (37) and (38), possess the first order generalized symmetry

$$(1 + u^2 + v u_x)\frac{\partial}{\partial u} + (x + v v_x)\frac{\partial}{\partial v}.$$

One says that a nonlocal symmetry is *of type* Γ if it depends on a finite number of nonlocal variables $\Gamma = \{\gamma_b\}$. The following corollary is immediate from Proposition 1 and the well known fact that generalized symmetries of a given system of equations form a Lie algebra:[26,34,36]

Corollary 1: Let $\Xi_a(x^i, u^\alpha, \ldots) = 0$ *be a system of partial differential equations. Assume that* $\Gamma = \{\gamma_b\}$ *is a finite set of nonlocal variables and that* $\tilde{D}_i = D_i + \Sigma X_{ib} \partial / \partial \gamma_b$ *satisfy Eq. (15). Then, the set of all nonlocal symmetries of type* Γ *of* $\Xi_a = 0$ *forms a Lie algebra.*

Remark 1: It seems it was generally believed that a much stronger form of Corollary 1 should hold, namely, that the collection of evolutionary vector fields (8) with coefficients depending on *arbitrary* nonlocal variables should form a Lie algebra. Sanders and Wang, (see Ref. 36, and references therein) showed that this is in fact not true, as these vector fields *do not* satisfy the Jacobi identity. Olver *et al.*[36] and Olver[35] have recently developed a formal calculus of nonlocal evolutionary vector fields of a very general kind which does not suffer of this handicap. Some comments on the problem of equipping the collection of "all" nonlocal symmetries of a given equation with a Lie algebra structure appear in Ref. 25.

Corollary 2: If $u_0^\alpha(x^i)$ *and* $\gamma_b^0(x^i)$ *are solutions to the augmented system (35), the Cauchy problem*

$$\frac{\partial u^\alpha}{\partial \tau} = G^\alpha, \quad \frac{\partial \gamma_b}{\partial \tau} = H_b,$$

$$u^\alpha(x^i,0)=u_0^\alpha(x^i),\quad \gamma_b(x^i,0)=\gamma_b^0(x^i),$$

determines one-parameter family of solutions to the augmented system (35). Therefore nonlocal symmetries send solutions to the original system $\Xi_a=0$ *to solutions of the same system.*

A subtler issue concerns the relation between nonlocal and internal symmetries. Consider the shadows of nonlocal symmetries for the Burger and Kaup–Kupershmidt equations introduced in Examples 2 and 1, respectively, and let the equation manifolds of these equations, S^∞_{Burger} and S^∞_{KK} respectively, be submanifolds of the infinite jet bundles $J^\infty E_{\text{Burger}}$ and $J^\infty E_{\text{KK}}$. The vector fields determined by (33) and (22),

$$\left[(2S_x-uS)\exp\left(-\frac{1}{2}\int u dx\right)\right]\frac{\partial}{\partial u} \tag{39}$$

(for Burger's) and

$$\alpha^3\delta\frac{\partial}{\partial u} \tag{40}$$

(for Kaup–Kupershmidt) are quite different:

(a) In the case of (39) it should be possible, intuitively, to add an extra dependent variable u_{-1} satisfying $D_x u_{-1}=u$ to the infinite jet bundle $J^\infty E_{\text{Burger}}$, in which $D_x=\partial/\partial x+u_x\partial/\partial u+u_{xx}\partial/\partial u_x+\cdots$, see Eq. (5). In the Krasil'shchik–Vinogradov scheme[26] this would correspond to building a manifold N equipped with coordinates $(x^i,u,\ldots,u_{-1})$ which "covers" $J^\infty E_{\text{Burger}}$. (As stated in Remark 1, the construction of N as a manifold with a well-defined tangent bundle is not trivial: it is necessary to set up a special formal machinery in order to construct Lie algebras of vector fields with nonlocal coefficients.[36,35]). The vector field (39) would then be a vector field on N *which would restrict* to (a covering of) the equation manifold S^∞_{Burger}, thereby determining a shadow of a nonlocal symmetry of Burger's equation.

(b) On the other hand, it is hard to see how one could make the procedure above work in the Kaup–Kupershmidt case: it does not seem appropriate to consider the variables α and δ appearing in (40) as functions on some universal manifold covering $J^\infty E_{\text{KK}}$. A more natural point of view is to think of the vector field (40) as defined only on a covering of the equation manifold S^∞_{KK}, *independently* of whether or not one can extend it to a vector field on a covering of the infinite jet bundle $J^\infty E_{\text{KK}}$.

Thus, it would seem reasonable to call the nonlocal symmetry induced by (40) an *internal* nonlocal symmetry, and to claim that nonlocal symmetries provide an interesting and natural generalization of the class of (local) *internal* symmetries. One wonders if an analysis like the one performed in Ref. 5 for these symmetries can be made in this nonlocal setting.

IV. THE KAUP-KUPERSHMIDT EQUATION

The theory reviewed in the previous sections will be now applied to the interesting Kaup–Kupershmidt equation[21,30,31,37,38,46]

$$q_t=q_{xxxxx}+5qq_{xxx}+\frac{25}{2}q_xq_{xx}+5q^2q_x. \tag{41}$$

As a first remark, recall from Example 1 that Eq. (41) is the integrability condition of the linear problem[33]

$$\begin{pmatrix}\psi_{1,x}\\ \psi_{2,x}\end{pmatrix}=\begin{bmatrix}0 & 1/(4\eta^2)\\ -\eta^2 q & 0\end{bmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \tag{42}$$

$$\begin{pmatrix}\psi_{1,t}\\ \psi_{2,t}\end{pmatrix}=\begin{bmatrix}-(\frac{1}{4}q_{xxx}+qq_x) & (\frac{1}{2}q_{xx}+q^2)/(4\eta^2)\\ -\eta^2(q_{xxxx}+\frac{9}{2}qq_{xx}+4q_x^2+q^3) & \frac{1}{4}q_{xxx}+qq_x\end{bmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}. \tag{43}$$

As is well known, equations which are the integrability condition of linear problems *with parameter*, $\Psi_x=X\Psi$, $\Psi_t=T\Psi$, in which X, T belong to a given (matrix) Lie algebra $\tilde{g}$, are of great interest because, in principle, they can be investigated by means of scattering/inverse scattering techniques.[6,7,21] A key point in this theory, however, is that the parameter must be *intrinsic*[29] and it is generally agreed that this means (at least) that one cannot eliminate it by means of a simple gauge transformation

$$X\mapsto AXA^{-1}+\left[\frac{\partial}{\partial x}A\right]A^{-1},\quad T\mapsto ATA^{-1}+\left[\frac{\partial}{\partial t}A\right]A^{-1}, \tag{44}$$

in which A is an invertible matrix belonging to the Lie group with Lie algebra $\tilde{g}$. In the case at hand, the parameter η appearing in (42) and (43) *can* be removed by applying a gauge transformation (44) with $A\in SL(2,\mathbf{R})$ given simply by

$$A=\begin{bmatrix}\eta & 0\\ 0 & 1/\eta\end{bmatrix}.$$

[And indeed, the linear problem with intrinsic parameter used to analyze Eq. (41) via scattering/inverse scattering is an $sl(3,\mathbf{R})$-valued problem, see Refs. 6, 7, and 21].

However, one would claim that linear problems without parameter may also be of interest. For example, a linear problem with a removable parameter[29] for the Burgers equation yields, nonetheless, the linearizing Hopf–Cole transformation[39,40] and, as it will be seen momentarily, the linear problem (42) and (43) allows one to find a *nontrivial* nonlocal symmetry for the Kaup–Kupershmidt equation which in turn yields nontrivial particular solutions to (41).

The nonlocal symmetry of Kaup–Kupershmidt to be considered here depends on solutions to first order systems of equations determined by Eq. (41) via its $sl(2,\mathbf{R})$-valued associated linear problem (42), (43). These systems can be understood geometrically,[39,40] but they can also be built from scratch:

First, set $\alpha=\psi_2/\psi_1$. The linear problem (42) and (43) yields the Pfaffian system[33]

$$\alpha_x=-\eta^2q-\frac{\alpha^2}{4\eta^2}, \tag{45}$$

$$\alpha_t=-\eta^2q_{xxxx}-\frac{9}{2}\eta^2qq_{xx}-4\eta^2q_x{}^2-\eta^2q^3+\left(\frac{1}{2}q_{xxx}+2qq_x\right)\alpha-\left(\frac{q_{xx}}{8\eta^2}+\frac{q^2}{4\eta^2}\right)\alpha^2, \tag{46}$$

and one checks that (45) and (46) is completely integrable for $\alpha(x,t)$ whenever $q(x,t)$ is a solution to Eq. (41). The function $\alpha(x,t)$ is said to be a *quadratic pseudopotential* for the Kaup–Kupershmidt equation.

Second, write Eq. (46) in the form $U_t=V_x$ for some functions U and V using Eq. (45), and define a potential δ satisfying $\delta_x=U$, $\delta_t=V$ on solutions of Eq. (41). After a straightforward computation, one obtains that δ is determined by the following equations:

$$\delta_x=-\frac{\alpha}{2\eta^2}, \tag{47}$$

$$\delta_t=\frac{1}{2}q_{xxx}+2qq_x-\alpha\left(\frac{q_{xx}}{4\eta^2}+\frac{q^2}{2\eta^2}\right). \tag{48}$$

The proposition below then holds. Its proof is a (rather long) computation which is best performed by using a symbolic computation package such as the MAPLE package VESSIOT:[4]

Proposition 2: With the foregoing notations, the vector field

$$V_G = \alpha \exp(-2\delta)\frac{\partial}{\partial q} \tag{49}$$

is the shadow of a nonlocal symmetry for the Kaup-Kupershmidt equation (41).

One now extends this shadow to a nonlocal symmetry for (41). Set

$$q_\tau = \alpha \exp(-2\delta), \tag{50}$$

and find the variations of α and δ with respect to the parameter τ. Taking τ derivatives in Eq. (45) one obtains

$$\alpha_{x\tau} = -\eta^2 q_\tau - \frac{1}{2\eta^2}\alpha\alpha_\tau = -\eta^2\alpha\exp(-2\delta) - \frac{1}{2\eta^2}\alpha\alpha_\tau.$$

Multiplying by the integrating factor $\exp(\int \alpha/2\eta^2 \mathrm{d}x)$ and using (47), one finds

$$\alpha_\tau = -\frac{2}{3}\eta^4\exp(-2\delta) + C\exp(\delta), \tag{51}$$

in which C is independent of x. Now take derivative with respect to τ in (47):

$$\delta_{x\tau} = -\frac{1}{2\eta^2}\alpha_\tau = \frac{\eta^2}{3}\exp(-2\delta) - \frac{C}{2\eta^2}\exp(\delta).$$

Since the right-hand side of this equation is not a total x derivative, simply define a further potential β by means of

$$\beta_x = \frac{\eta^2}{3}\exp(-2\delta) - \frac{C}{2\eta^2}\exp(\delta) \tag{52}$$

and set

$$\delta_\tau = \beta. \tag{53}$$

In order to determine β one needs to compute $\beta_t = \delta_{\tau t} = \delta_{t\tau}$ taking into account Eqs. (50), (51), and (53). Before doing this, it is instructive to try to find β_τ by differentiating Eq. (52) with respect to τ:

$$\begin{aligned}\beta_{x\tau} &= -2\delta_\tau\frac{\eta^2}{3}\exp(-2\delta) - \frac{C}{2\eta^2}\delta_\tau\exp(\delta)\\ &= -2\beta\left[\frac{\eta^2}{3}\exp(-2\delta) + \frac{C}{4\eta^2}\exp(\delta)\right] = -2\beta\left[\beta_x + \frac{3C}{4\eta^2}\exp(\delta)\right],\end{aligned} \tag{54}$$

in which (52) has been used. The right-hand side of Eq. (54) is not a total x derivative *unless* $C=0$, and if $C=0$, Eq. (54) implies that

$$\beta_\tau = -\beta^2. \tag{55}$$

It follows that $C=0$ is necessary and sufficient for obtaining a nonlocal symmetry with shadow (49) depending only on the nonlocal variables α, δ, and β, in analogy with the examples worked out in Refs. 13, 22, 27, 28, 41, and 42, and this condition will be used henceforth. It seems plausible to conjecture that if $C\neq 0$ one would obtain instead an infinite dimensional extension of the shadow (49). An example of such an extension (for Burger's) is in Ref. 26.

The foregoing discussion implies that the following result holds.

Theorem 2: *Consider the pseudopotential α determined by Eqs.* (45) and (46), *and the*

potential δ *given by* (47) and (48). *Define* β *by means of*

$$\beta_x = \frac{\eta^2}{3}\exp(-2\delta), \tag{56}$$

$$\beta_t = \exp(-2\delta)\left\{\left(-\frac{1}{3}q_{xx} - \frac{5}{12}q^2\right)\eta^2 + \frac{1}{2}\alpha q_x - \frac{3}{8}\frac{\alpha^2 q}{\eta^2} - \frac{3}{64}\frac{\alpha^4}{\eta^6}\right\}. \tag{57}$$

These equations are compatible whenever $q(x,t)$, $\alpha(x,t)$, *and* $\delta(x,t)$ *solve Eqs.* (41) and (45)–(48). *Moreover, the vector field*

$$W = \alpha\exp(-2\delta)\frac{\partial}{\partial q} - \frac{2}{3}\eta^4\exp(-2\delta)\frac{\partial}{\partial \alpha} + \beta\frac{\partial}{\partial \delta} - \beta^2\frac{\partial}{\partial \beta} \tag{58}$$

is a (generalized) symmetry for the compatible system of equations (41), (45)–(48), (56), and (57), *and therefore it determines a bona fide nonlocal symmetry for the Kaup-Kupershmidt equation* (41).

One can check this result independently of the previous discussion, using the MAPLE package VESSIOT.[4] Note that this nonlocal symmetry is of the type called *internal* in the discussion appearing at the end of Sec. III. The interesting problem of studying the Lie algebra structure of all internal nonlocal symmetries of type $\Gamma=\{\alpha,\delta,\beta\}$ for Kaup–Kupershmidt remains open.

The flow of the vector field (58) can be explicitly found: as explained in Sec. II one only needs to solve the system of equations:

$$\frac{\partial q}{\partial \tau} = \alpha\exp(-2\delta); \quad \frac{\partial \alpha}{\partial \tau} = -\frac{2}{3}\eta^4\exp(-2\delta); \tag{59}$$

$$\frac{\partial \delta}{\partial \tau} = \beta; \quad \frac{\partial \beta}{\partial \tau} = -\beta^2; \tag{60}$$

with initial conditions

$$q(x,t,0) = q_0; \quad \alpha(x,t,0) = \alpha_0; \quad \delta(x,t,0) = \delta_0; \quad \beta(x,t,0) = \beta_0, \tag{61}$$

in which q_0, α_0, δ_0, and β_0 are arbitrary particular solutions to the compatible system (41), (45)–(48), (56), and (57). One finds the formulas

$$q(\tau) = \frac{\alpha_0\tau\exp(-2\delta_0)}{\beta_0\tau+1} - \frac{\eta^4\exp(-4\delta_0)}{3(\beta_0\tau+1)^2}\tau^2 + q_0; \tag{62}$$

$$\alpha(\tau) = \frac{-2\eta^4\tau\exp(-2\delta_0)}{3(\beta_0\tau+1)} + \alpha_0; \tag{63}$$

$$\delta(\tau) = \ln|\beta_0\tau+1| + \delta_0; \tag{64}$$

$$\beta(\tau) = \frac{1}{\tau+1/\beta_0}. \tag{65}$$

The theory of Secs. II and III implies the following result:

Corollary 3: Assume that the functions q_0, α_0, δ_0, and β_0 *are arbitrary particular solutions to the compatible system of equations* (41), (45)–(48), (56), and (57). *Then, the function* $q(x,t,\tau)$ *given by Eq.* (62) *solves the Kaup–Kupershmidt equation for any value of the parameter* τ.

V. A DARBOUX TRANSFORM AND PARTICULAR SOLUTIONS TO KAUP–KUPERSHMIDT

A. A Darboux-like transform

Following an observation made by Schiff,[43] the analysis of Sec. IV allows one to find a Darboux-like transformation for Kaup–Kupershmidt. Starting from (62), one simply eliminates α_0 and δ_0 using Eqs. (45), (47), and (56):

$$\begin{aligned} q(\tau) &= q_0 + \frac{\alpha_0 \tau \exp(-2\delta_0)}{\beta_0 \tau + 1} - \frac{\eta^4 \exp(-4\delta_0)}{3(\beta_0 \tau + 1)^2} \tau^2 \\ &= q_0 + \frac{\tau}{\beta_0 \tau + 1}(-2\eta^2)\delta_{0,x} \exp(-2\delta_0) - \frac{1}{3}\tau^2 \frac{(\eta^2 \exp(-2\delta_0))^2}{(\beta_0 \tau + 1)^2} \\ &= q_0 + \frac{\tau \eta^2}{\beta_0 \tau + 1}(\exp(-2\delta_0))_x - \frac{1}{3}\tau^2 \frac{(\eta^2 \exp(-2\delta_0))^2}{(\beta_0 \tau + 1)^2} \\ &= q_0 + \frac{3\tau \beta_{0,xx}}{\beta_0 \tau + 1} - \frac{3\tau^2 \beta_{0,x}^2}{(\beta_0 \tau + 1)^2}, \end{aligned}$$

and therefore $q(\tau)$ and q_0 are related by

$$q(\tau) = q_0 + 3\frac{\partial^2}{\partial x^2} \ln(\beta_0 \tau + 1), \tag{66}$$

in which β_0 is any solution to the compatible system of equations (56) and (57). This is analogous to the Darboux transform for Kaup–Kupershmidt recently discussed in Refs. 31 and 46. Making a slight change of notation, eliminating subscripts and writing $\overline{q} = q(\tau)$ and $B = \beta\tau + 1$, these comments can be stated as follows.

Proposition 3: The Kaup–Kupershmidt equation (41) *is invariant under the transformation* $q \mapsto \overline{q}$, *in which*

$$\overline{q} = q + 3(\ln B)_{xx}. \tag{67}$$

In this equation the functions q and B are related by

$$q = -\frac{B_{xxx}}{B_x} + \frac{3}{4}\left(\frac{B_{xx}}{B_x}\right)^2, \tag{68}$$

and $B(x,t)$ *is a solution to*

$$B_t = -5\frac{B_{xxxx}B_{xx}}{B_x} + \frac{65}{4}\frac{B_{xxx}B_{xx}^2}{B_x^2} - \frac{135}{16}\frac{B_{xx}^4}{B_x^3} + B_{xxxxx} - \frac{15}{4}\frac{B_{xxx}^2}{B_x}. \tag{69}$$

Equations (68) and (69) are found easily from (45), (56), and (57).

B. Examples of particular solutions

For $q_0 = 0$, one obtains the following formulas from Eqs. (45)–(48), (56), and (57):

$$\alpha_0(x,t) = \frac{1}{\dfrac{x}{4\eta^2} + c_\alpha} \tag{70}$$

$$\delta_0(x,t) = -2 \ln\left|\frac{x}{4\eta^2} + c_\alpha\right| + c_\delta \tag{71}$$

$$\beta_0(x,t) = \frac{4}{15}\eta^4 \exp(-2c_\delta)\left(\frac{x}{4\eta^2} + c_\alpha\right)^5 - \frac{3}{64}\frac{1}{\eta^6}\exp(-2c_\delta)t + c_\beta, \tag{72}$$

in which c_α, c_δ, and c_β are constant. Replacing these equations into (62) [or, equivalently, replacing (72) into the transform (66)], one finds the following family of rational solutions to the Kaup–Kupershmidt equation:

$$q(x,t,\tau) = \frac{\left(\frac{x}{4\eta^2} + c_\alpha\right)^3 \exp(-2c_\delta)\tau}{\tau\left[\exp(-2c_\delta)\left(\frac{4\eta^4}{15}\left(\frac{x}{4\eta^2} + c_\alpha\right)^5 - \frac{3}{64}\frac{t}{\eta^6}\right) + c_\beta\right] + 1} - \frac{1}{3}\frac{\left(\frac{x}{4\eta^2} + c_\alpha\right)^8 \exp(-4c_\delta)\tau^2\eta^4}{\left(\tau\left[\exp(-2c_\delta)\left(\frac{4\eta^4}{15}\left(\frac{x}{4\eta^2} + c_\alpha\right)^5 - \frac{3}{64}\frac{t}{\eta^6}\right) + c_\beta\right] + 1\right)^2}. \tag{73}$$

Since the Kaup–Kupershmidt equation is invariant under x and t translations, one can set $c_\alpha = c_\beta = 0$ and, by scaling the parameter τ, one can choose $c_\delta = 0$. The family of solutions (73) is thus equivalent to

$$q(x,t,\tau) = -15\frac{\tau x^3(720\tau t - 15360\eta^6 + x^5\tau)}{(-x^5\tau + 180\tau t - 3840\eta^6)^2}, \tag{74}$$

a rational solution depending on the parameters τ and η. It would be of interest to study it in more detail, perhaps along the lines of Kovalyov's[23] analysis of a class of singular solutions for KdV. Setting $\mu = 3840\eta^6/\tau$, one can write (74) as

$$q(x,t,\mu) = -15\frac{x^3(720t - 4\mu + x^5)}{(-x^5 + 180t - \mu)^2}. \tag{75}$$

The limit $\mu \to \infty$ reproduces the seed solution $q_0 = 0$. On the other hand, note that $\eta = 0$ is a pole of the linear problem (42) and (43), but—reflecting the fact that the parameter η can be "gauged away"—the value $\eta = 0$ (or equivalently, $\mu = 0$) yields a well defined rational solution to Eq. (41).

A second family of solutions which can be obtained from $q_0 = 0$ is the following: Instead of (70)–(72), take $\alpha_0 = 0$, $\delta_0 = 0$, and $\beta_0 = (\eta^2/3)x + c_\beta$. Then, Eq. (62) yields the stationary solution

$$q(x,t,\tau) = \frac{-\eta^4\tau^2}{3\left(\tau\left(\frac{\eta^2}{3}x + c_\beta\right) + 1\right)^2}.$$

Setting $\tau\eta^2 = 3\mu$ and using again the invariance of Kaup–Kupershmidt under x translations, one can write this solution as

$$q(x,\mu) = \frac{-3\mu^2}{(\mu x + 1)^2}. \tag{76}$$

This stationary solution was used in Ref. 46 to obtain examples of "extended" N-soliton solutions to Kaup–Kupershmidt, that is, solutions which approach asymptotically to solitons or to static bell shaped waves as $t \to \infty$.

Assume now that $q_0 = 1/4$ and take $\eta = 1$ for simplicity. The functions α_0, δ_0, and β_0 become

$$\alpha_0 = -\tan\left(\frac{x}{4} + \frac{t}{64}\right), \tag{77}$$

$$\delta_0 = -2\ln\left|\cos\left(\frac{x}{4} + \frac{t}{64}\right)\right|, \tag{78}$$

$$\beta_0 = \frac{1}{24}\sin\left(x + \frac{t}{16}\right) + \frac{1}{3}\sin\left(\frac{x}{2} + \frac{t}{32}\right) + \frac{x}{8} - \frac{5t}{128}. \tag{79}$$

Replacing these functions into (62), one obtains a one-parameter family of trigonometric solutions to Kaup–Kupershmidt,

$$q(x,t,\tau) = \frac{-\cos^4\left(\frac{x}{4} + \frac{t}{64}\right)\tan\left(\frac{x}{4} + \frac{t}{64}\right)\tau}{\tau\left[\frac{1}{24}\sin\left(x + \frac{t}{16}\right) + \frac{1}{3}\sin\left(\frac{x}{2} + \frac{t}{32}\right) + \frac{x}{8} - \frac{5t}{128}\right] + 1} - \frac{1}{3}\frac{\tau^2\cos^8\left(\frac{x}{4} + \frac{t}{64}\right)}{\left(\tau\left[\frac{1}{24}\sin\left(x + \frac{t}{16}\right) + \frac{1}{3}\sin\left(\frac{x}{2} + \frac{t}{32}\right) + \frac{x}{8} - \frac{5t}{128}\right] + 1\right)^2} + \frac{1}{4}. \tag{80}$$

This solution is almost, but not quite, a function of the sum $s = x/4 + t/64$: the potential β_0 (and hence the solution $q(x,t,\tau)$) fails to depend only on s. As is the case with (74), this solution is singular along a curve in the (x,t) plane.

Now consider the solutions appearing from the choices $q_0 = -1/4$ and $\eta = 1$. In this case the functions α_0, δ_0, and β_0 read

$$\alpha_0 = \tanh\left(\frac{x}{4} + \frac{t}{64}\right), \tag{81}$$

$$\delta_0 = -2\ln\left|\cosh\left(\frac{x}{4} + \frac{t}{64}\right)\right|, \tag{82}$$

$$\beta_0 = \frac{1}{24}\sinh\left(x + \frac{t}{16}\right) + \frac{1}{3}\sinh\left(\frac{x}{2} + \frac{t}{32}\right) + \frac{x}{8} - \frac{5t}{128}, \tag{83}$$

and the corresponding one–parameter family of solutions to Kaup–Kupershmidt is

$$q(x,t,\tau)=\frac{\cosh^4\left(\frac{x}{4}+\frac{t}{64}\right)\tanh\left(\frac{x}{4}+\frac{t}{64}\right)\tau}{\tau\left[\frac{1}{24}\sinh\left(x+\frac{t}{16}\right)+\frac{1}{3}\sinh\left(\frac{x}{2}+\frac{t}{32}\right)+\frac{x}{8}-\frac{5t}{128}\right]+1}$$
$$-\frac{1}{3}\frac{\tau^2\cosh^8\left(\frac{x}{4}+\frac{t}{64}\right)}{\left(\tau\left[\frac{1}{24}\sinh\left(x+\frac{t}{16}\right)+\frac{1}{3}\sinh\left(\frac{x}{2}+\frac{t}{32}\right)+\frac{x}{8}-\frac{5t}{128}\right]+1\right)^2}-\frac{1}{4}. \tag{84}$$

Finally, take the stationary solution (76) as seed solution q_0. The functions α_0, δ_0 and β_0 read:

$$\alpha_0=6\frac{\eta^2\mu((\mu x+1)^2+1)}{((\mu x+1)^2-3)(\mu x+1)}, \tag{85}$$

$$\delta_0=-2\ln((\mu x+1)^2-3)+\ln(\mu x+1), \tag{86}$$

$$\beta_0=\frac{1}{3}\eta^2\left(\frac{1}{7}\mu^6x^7+\mu^5x^6+\frac{3}{5}\mu^4x^5-7\mu^3x^4-\mu^2x^3+33x^2\mu-65x-81\frac{1}{(\mu x+1)\mu}\right)-576\mu^4\eta^2t. \tag{87}$$

Setting $\xi=\tau\eta^2$ and using (62) [or the transform (66)], one can write the corresponding family of solutions $q(x,t,\xi,\mu)$ as

$$q(x,t,\xi,\mu)=\frac{6\xi\mu[(\mu x+1)^2-3]^3[(\mu x+1)^2+1]}{(\mu x+1)^3(1/3\xi[P(x,\mu)-81Q(x,\mu)]-576\mu^4\xi t+1)}$$
$$-\frac{1/3\xi^2[(\mu x+1)^2-3]^8}{(1/3\xi[P(x,\mu)-81Q(x,\mu)]-576\mu^4\xi t+1)^2(\mu x+1)^4}-3\frac{\mu^2}{(\mu x+1)^2}, \tag{88}$$

in which

$$P(x,\mu)=\frac{1}{7}\mu^6x^7+\mu^5x^6+\frac{3}{5}\mu^4x^5-7\mu^3x^4-\mu^2x^3+33x^2\mu-65x, \tag{89}$$

$$Q(x,\mu)=\frac{1}{\mu(\mu x+1)}. \tag{90}$$

This solution approaches asymptotically the stationary solution $q(x)=-24/x^2$ as $\mu\to\infty$, whereas the seed solution q_0 is recovered in the limit $t\to\infty$.

(Received 26 November 2004; accepted 22 April 2005; published online 22 June 2005)

The quantum trigonometric Calogero–Sutherland models related to Lie algebras admit a parametrization in which the dynamical variables are the characters of the fundamental representations of the algebra. We develop here this approach for the case of the exceptional Lie algebra E_6. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1933088]

I. INTRODUCTION

The so-called Calogero–Sutherland or Calogero–Moser models were introduced by Calogero,[1] who studied, from the quantum standpoint, the dynamics on the infinite line of a set of pairwise interacting particles through rational plus quadratic potentials, and found that the problem was exactly solvable. Soon afterwards, Sutherland[2] arrived to similar results for the quantum problem on the circle, this time with trigonometric interaction, and Moser[3] showed that the classical version of both models enjoyed integrability in the Liouville sense. The identification of the general scope of these discoveries came with the works of Olshanetsky and Perelomov,[4–6] who realized that it was possible to associate models of this kind to all the root systems of the simple Lie algebras, and that all these models were integrable, both in the classical and in the quantum framework;[7,8] see also Ref. 9 for a complete treatment of these topics. Nowadays, there is a widespread interest in this type of integrable system, and many mathematical and physical applications for them have been found, see for instance Ref. 10.

The Calogero-Sutherland Hamiltonian associated to the root system of a simple Lie algebra L can be written as a second-order differential operator whose variables are the characters of the fundamental representations of the algebra. As it was shown in the papers,[11–13] and later in Refs. 14–19 this approach gives the possibility of developing some systematic procedures to solve the Schrödinger equation and determine important properties of the eigenfunctions, such as recurrence relations or generating functions for some subsets of them. For the moment, the approach has been used only for classical algebras of A_n and D_n type, and recently[19] for the exceptional algebra E_6 for a special value of the coupling constant for which the eigenfunctions are proportional to the characters of the ireducible representations of the algebra. The aim of this paper is to show how to generalize the treatment of Ref. 19 to arbitrary values of the coupling constant and to extend some of the particular results found there to the general case.

II. THE CALOGERO–SUTHERLAND MODEL FOR E_6 IN z-VARIABLES

The Hamiltonian operator for the trigonometric Calogero–Sutherland model related to the root system of a simple Lie algebra has the generic form

$$H = \frac{1}{2}(p,p) + \sum_{\alpha \in \mathcal{R}^+} \kappa_\alpha(\kappa_\alpha - 1)\sin^{-2}(\alpha,q),$$

where $\mathcal{R}^+$ is the set of positive roots, q and p are vectors of dimension r=rank of the algebra, (,) is the usual Euclidean scalar product in $\mathbf{R}^r$, and the coupling constants κ_α are such that $\kappa_\alpha = \kappa_\beta$ if $\|\alpha\| = \|\beta\|$. In particular, because E_6 is simply laced (for all details about the structure of E_6 needed to follow the main text, see Appendix A), the Calogero–Sutherland model associated to E_6 depends only on one coupling constant κ. To write H in a more explicit way, it is convenient to use the orthonormal basis $\{e_i, i=1,\ldots,6\}$ which is related to the generating system of the Appendix A through $\varepsilon_i = e_i - \frac{1}{6}\Sigma_{j=1}^6 e_j$. The expression of q and p in this basis is simply $q = \Sigma_{i=1}^6 q_i e_i$, $p = \Sigma_{i=1}^6 p_i e_i$, while the simple roots are given by

$$\alpha_1 = e_1 - e_2,$$

$$\alpha_2 = \frac{1}{2}\left(-1 + \frac{\sqrt{3}}{3}\right)\sum_{j=1}^{3} e_j + \frac{1}{2}\left(1 + \frac{\sqrt{3}}{3}\right)\sum_{j=4}^{6} e_j,$$

$$\alpha_k = e_{k-1} - e_k, \quad k = 3,4,5,6.$$

The q coordinates are assumed to take values in the interval $[0,\pi]$, and therefore the Hamiltonian can be interpreted as describing the dynamics of a system of six particles moving on the circle, but notice that there is not translational invariance. We recapitulate some important facts about this model which follow from the general structure of the quantum Calogero–Sutherland models related to Lie algebras.[8,9] The ground state energy and (non-normalized) wave function are

$$E_0(\kappa) = 2(\rho,\rho)\kappa^2 = 156\kappa^2,$$

$$\Psi_0^\kappa(q) = \prod_{\alpha \in \mathcal{R}^+} \sin^\kappa(\alpha,q),$$

with ρ being the Weyl vector, while the excited states depend on a six-tuple of quantum numbers $\mathbf{m} = (m_1, m_2, m_3, m_4, m_5, m_6)$, and satisfy the Schrödinger equation

$$H\Psi_{\mathbf{m}}^\kappa = E_{\mathbf{m}}(\kappa)\Psi_{\mathbf{m}}^\kappa,$$

$$E_{\mathbf{m}}(\kappa) = 2(\lambda + \kappa\rho, \lambda + \kappa\rho), \tag{1}$$

where λ is the highest weight of the irreducible representation of E_6 labelled by $\mathbf{m}$, i.e., $\lambda = \Sigma_{i=1}^6 m_i \lambda_i$. By substitution in (1) of

$$\Psi_{\mathbf{m}}^\kappa(q) = \Psi_0^\kappa(q)\Phi_{\mathbf{m}}^\kappa(q), \tag{2}$$

we are led to the eigenvalue problem

$$\Delta^\kappa \Phi_{\mathbf{m}}^\kappa = \varepsilon_{\mathbf{m}}(\kappa)\Phi_{\mathbf{m}}^\kappa \tag{3}$$

with

$$\Delta^{\kappa} = -\frac{1}{2}\Delta - \kappa \sum_{\alpha \in \mathcal{R}^+} \mathrm{ctg}(\alpha, q)(\alpha, \nabla_q), \tag{4}$$

and

$$\varepsilon_{\mathbf{m}}(\kappa) = E_{\mathbf{m}}(\kappa) - E_0(\kappa) = 2(\lambda, \lambda + 2\kappa\rho). \tag{5}$$

Taking into account that $A^{-1}_{jk} = (\lambda_j, \lambda_k)$, it is possible to give a more explicit expression for $\varepsilon_{\mathbf{m}}(\kappa)$,

$$\varepsilon_{\mathbf{m}}(\kappa) = 2 \sum_{j,k=1}^{6} A^{-1}_{jk} m_j m_k + 4\kappa \sum_{j,k=1}^{6} A^{-1}_{jk} m_j. \tag{6}$$

Now the main problem is to solve (3). As it has been shown for other algebras,[11–13,17] the best way to do this is to use a set of independent variables which are invariant under the Weyl symmetry of the Hamiltonian, namely the characters $z_k, k = 1, \ldots, 6$, of the six fundamental representations of the Lie algebra E_6. We can infer from (4) the structure of Δ^{κ} when written in the z variables,

$$\Delta^{\kappa} = \sum_{j,k=1}^{6} a_{jk}(z) \partial_{z_j} \partial_{z_k} + \sum_{j=1}^{6} [b_j^{(0)}(z) + \kappa b_j^{(1)}(z)] \partial_{z_j}. \tag{7}$$

As a matter of fact, the eigenfunctions of $\Delta^{(0)}$ and $\Delta^{(1)}$ are (proportional to) the monomial symmetric functions $M_\lambda = \Sigma_{s \in W} \exp[2i(s\lambda, q)]$ (W is the Weyl group) and the characters $\boldsymbol{\chi}_\lambda$ of the irreducible representations of the algebra E_6, respectively.[8] Thus, knowing the characters $z_i = \boldsymbol{\chi}_{\lambda_i}$ of the fundamental representations and the products $z_i z_j$ through the Clebsch–Gordan series for the algebra, we are able to find the Hamiltonian $\Delta^{(1)}$, that is, we obtain the coefficients $a_{jk}(z)$ entering in the expression of all the Hamiltonians Δ^{κ} and also the coefficients $b_j^{(0)}(z) + b_j^{(1)}(z)$. In the previous paper[19] we computed the needed Clebsch–Gordan series and showed these coefficients.

On the other hand, knowing enough monomial symmetric functions in terms of the fundamental characters, $M_\lambda(z)$, we can complete the form of Δ^{κ}, for we know that

$$\Delta^{(0)} M_\lambda = \varepsilon_{\mathbf{m}}(0) M_\lambda = 2(\lambda, \lambda) M_\lambda, \tag{8}$$

a system of linear equations which can be solved for the coefficients $b_j^{(0)}(z)$, $j = 1, \ldots, 6$. To this end, remind that the characters can be expanded as sums of monomial functions,[20]

$$\boldsymbol{\chi}_\lambda = M_\lambda + a_1 M_{\mu_1} + a_2 M_{\mu_2} + \cdots,$$

where the set of μ_k entering in the expansion is easy to determine: they are the dominant weights such that $\mu_i = \lambda - \Sigma_{j=1}^{6} n_j \alpha_j$ with $n_j \geqslant 0$ and $(\mu_i, \alpha_k) \geqslant 0$ for the six simple roots α_k. The coefficients a_k, on the other hand, represent the multiplicities of the weights μ_i in the representation with highest weight λ. Here it will suffice to deal with the following expansions:

$$\boldsymbol{\chi}^{(27)}_{100000} = z_1 = M^{(27)}_{100000},$$

$$\boldsymbol{\chi}^{(78)}_{010000} = z_2 = M^{(72)}_{010000} + aM^{(1)}_{000000},$$

$$\boldsymbol{\chi}^{(351)}_{001000} = z_3 = M^{(216)}_{001000} + bM^{(27)}_{000001},$$

$$\boldsymbol{\chi}^{(2925)}_{000100} = z_4 = M^{(720)}_{000100} + cM^{(270)}_{100001} + dM^{(72)}_{010000} + eM^{(1)}_{000000},$$

$$\boldsymbol{\chi}^{(351)}_{000010} = z_5 = M^{(216)}_{000010} + bM^{(27)}_{100000},$$

$$\chi^{(27)}_{000001} = z_6 = M^{(27)}_{000001},$$

$$\chi^{(650)}_{100001} = z_1 z_6 - z_2 - 1 = M^{(270)}_{100001} + fM^{(72)}_{010000} + gM^{(1)}_{000000}, \tag{9}$$

where the form of χ_{100001} comes from the list in Ref. 19 and the numbers appearing in parentheses as superscripts are either the dimensions of the representations or the dimensions of the linear spaces generated by the orbits of the Weyl group corresponding to the monomial functions. The former can be computed from the Weyl dimension formula, while the latter follow easily from the fact that the Weyl group of the subalgebra of E_6 obtained by removing from the Dynkin diagram the dots corresponding to the weight defining the monomial function acts trivially on such a weight, for instance, removing the dot associated to λ_1 we obtain the Dynkin diagram of D_5, and hence

$$\dim M_{100000} = \frac{|W_{E_6}|}{|W_{D_5}|} = \frac{2^7 \cdot 3^4 \cdot 5}{\frac{1}{2}10!!} = 27,$$

and so on.

While the dimensions shown in (9) suffice for fixing $a=6$, $b=5$, for the computation of remaining multiplicities we need to use the Freudenthal formula[21]

$$n_\mu = \frac{\sum_{\alpha>0} \sum_{k=1}^{\infty} 2n_{\mu+k\alpha}(\mu + k\alpha, \alpha)}{(\lambda + \mu + 2\rho, \lambda - \mu)}. \tag{10}$$

Here n_μ stands for the multiplicity of the weight μ in the representation of highest weight λ, the first sum extends over positive roots, and ρ is the Weyl vector. The application of the Freudenthal formula is quite easy for the representations at stake. Let us see, for instance, how to compute c in (9). In this case $\lambda=\lambda_4$ and $c=n_\mu=n_{\lambda_1+\lambda_6}$. The scalar product of the vector $\beta=\lambda-\mu=\alpha_2+\alpha_3+2\alpha_4+\alpha_5$ with μ is $(\beta,\mu)=0$ and, due to the fact that the length of $\mu+\alpha$, with α a positive root, is $|\mu+\alpha|=(|\mu|^2+2+2(\mu,\alpha))^{\frac{1}{2}}$, the only roots entering in (10) are the positive roots α such that $(\mu,\alpha)=0$, because otherwise $|\mu+\alpha|>|\mu+\beta|=|\lambda|$ and $\mu+\alpha$ would lie outside of the weight diagram for the representation R_λ. Looking at the table of positive roots in Appendix A, we check that there are 12 of them with $(\mu,\alpha)=0$. For all of these, $\mu+\alpha$ lies on the orbit of λ, and thus $n_{\mu+\alpha}=1$. This gives

$$c = n_{\lambda_1+\lambda_6} = 12\frac{2(\mu,\alpha) + 2(\alpha,\alpha)}{(\lambda_4 + \lambda_1 + \lambda_6 + 2\sum_{i=1}^{6} \lambda_i, \alpha_1 + \alpha_3 + 2\alpha_4 + \alpha_5)} = 12\frac{2\cdot 0 + 2\cdot 2}{2 + 2\cdot 5} = 4.$$

To compute d we proceed much in the same way. Now $\mu=\lambda_2$ and $\beta=\lambda-\mu=\alpha_1+\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+\alpha_6$. It follows that $(\mu,\beta)=1$, and thus only positive roots with $(\mu,\alpha)=0$ or $(\mu,\alpha)=1$ enter in the Freudenthal formula. There are 20 positive roots with $(\mu,\alpha)=1$, and for them $n_{\mu+\alpha}=1$ because they are in the orbit of λ. The number of positive roots with $(\mu,\alpha)=0$ is 15, and for them $\mu+\alpha$ lies in the orbit of $\lambda_1+\lambda_6$, so that their multiplicities are $n_{\mu+\alpha}=4$. This gives $d=n_{\lambda_2}=15$. Once we know c and d, we compute e by balancing dimensions in (9), and obtain $e=45$. A similar use of the Freudenthal formula gives $f=5$, and therefore $g=20$.[22]

With all the coefficients in (9) being fixed, we can now solve for the monomial functions corresponding to the fundamental weights. We find

$$M_{100000} = z_1,$$

$$M_{010000} = z_2 - 6,$$

$$M_{001000} = z_3 - 5z_6,$$

$$M_{000100} = z_4 - 4z_1z_6 + 9z_2 + 9,$$

$$M_{000010} = z_5 - 5z_1,$$

$$M_{000001} = z_6.$$

The remaining step is to substitute these monomials in (8) and to solve the linear system for the coefficients $b_j^{(0)}(z)$; the outcome is

$$b_1^{(0)}(z) = \tfrac{8}{3}z_1, \quad b_2^{(0)}(z) = 4(z_2 - 6), \quad b_3^{(0)}(z) = \tfrac{20}{3}z_3 - 20z_6,$$

$$b_4^{(0)}(z) = 12z_4 - 16z_1z_6 - 24z_2 + 36, \quad b_5^{(0)}(z) = \tfrac{20}{3}z_5 - 20z_1, \quad b_6^{(0)}(z) = \tfrac{8}{3}z_6.$$

With this and the form of $\Delta^{(1)}$ given in Ref. 19, we can now write the full set of coefficients in (7),

$$a_{11}(z) = \tfrac{8}{3}z_1^2 - 4z_3 - 20z_6,$$

$$a_{12}(z) = 2z_1z_2 - 26z_1 - 10z_5,$$

$$a_{13}(z) = \tfrac{10}{3}z_1z_3 + 18 - 12z_2 - 6z_4 - 18z_1z_6,$$

$$a_{14}(z) = 4z_1z_4 + 18z_1 - 10z_1z_2 - 18z_5 - 8z_2z_5 - 8z_3z_6 + 8z_6^2,$$

$$a_{15}(z) = \tfrac{8}{3}z_1z_5 - 10z_3 - 26z_6 - 10z_2z_6,$$

$$a_{16}(z) = \tfrac{4}{3}z_1z_6 - 36 - 12z_2,$$

$$a_{22}(z) = 4z_2^2 - 36 - 12z_2 - 4z_4 - 16z_1z_6,$$

$$a_{23}(z) = 4z_2z_3 - 24z_1^2 + 14z_3 - 8z_1z_5 - 2z_6 - 10z_2z_6,$$

$$a_{24}(z) = 6z_2z_4 - 18z_2 - 12z_2^2 - 10z_1z_3 + 24z_4 - 6z_3z_5 + 26z_1z_6 - 8z_1z_2z_6 - 10z_5z_6,$$

$$a_{25}(z) = 4z_2z_5 - 2z_1 - 10z_1z_2 + 14z_5 - 8z_3z_6 - 24z_6^2,$$

$$a_{26}(z) = 2z_2z_6 - 10z_3 - 26z_6,$$

$$a_{33}(z) = \tfrac{20}{3}z_3^2 + 28z_1 - 24z_1z_2 - 4z_1z_4 + 32z_5 - 8z_2z_5 - 16z_1^2z_6 + 8z_3z_6 - 12z_6^2,$$

$$a_{34}(z) = 8z_3z_4 + 10z_1^2 - 10z_1^2z_2 + 18z_3 - 2z_2z_3 - 6z_1z_2z_5 - 10z_5^2 - 18z_6 + 8z_2z_6 - 10z_2^2z_6 - 8z_1z_3z_6 + 20z_4z_6 + 8z_1z_6^2,$$

$$a_{35}(z) = \tfrac{16}{3}z_3z_5 - 36 + 24z_2 - 12z_2^2 - 10z_1z_3 + 24z_4 - 16z_1z_6 - 8z_1z_2z_6 - 10z_5z_6,$$

$$a_{36}(z) = \tfrac{8}{3}z_3z_6 - 26z_1 - 10z_1z_2 - 10z_5,$$

$$a_{44}(z) = 12z_4^2 - 8z_1^3 - 12z_2^3 + 36z_1z_3 - 12z_1z_2z_3 - 36z_4 + 36z_2z_4 + 16z_1^2z_5 - 36z_3z_5 - 4z_2z_3z_5 - 8z_1z_5^2 - 36z_1z_6 + 28z_1z_2z_6 - 8z_1z_2^2z_6 - 8z_3^2z_6 + 16z_1z_4z_6 + 36z_5z_6 - 12z_2z_5z_6 + 16z_3z_6^2 - 8z_6^3,$$

$$a_{45}(z) = 8z_4z_5 - 18z_1 + 8z_1z_2 - 10z_1z_2^2 - 10z_3^2 + 20z_1z_4 + 18z_5 - 2z_2z_5 + 8z_1^2z_6 - 6z_2z_3z_6 - 8z_1z_5z_6 + 10z_6^2 - 10z_2z_6^2,$$

$$a_{46}(z) = 4z_4z_6 + 8z_1^2 - 18z_3 - 8z_2z_3 - 8z_1z_5 + 18z_6 - 10z_2z_6,$$

$$a_{55}(z) = \tfrac{20}{3}z_5^2 - 12z_1^2 + 32z_3 - 8z_2z_3 + 8z_1z_5 + 28z_6 - 24z_2z_6 - 4z_4z_6 - 16z_1z_6^2,$$

$$a_{56}(z) = \tfrac{10}{3}z_5z_6 + 18 - 12z_2 - 6z_4 - 18z_1z_6,$$

$$a_{66}(z) = \tfrac{8}{3}z_6^2 - 20z_1 - 4z_5,$$

$$b_1(z) = b_1^{(0)}(z) + \kappa b_1^{(1)}(z) = \left(32\kappa + \tfrac{8}{3}\right)z_1,$$

$$b_2(z) = b_2^{(0)}(z) + \kappa b_2^{(1)}(z) = (44\kappa + 4)z_2 + 24(\kappa - 1),$$

$$b_3(z) = b_3^{(0)}(z) + \kappa b_3^{(1)}(z) = \left(60\kappa + \tfrac{20}{3}\right)z_3 + 20(\kappa - 1)z_6,$$

$$b_4(z) = b_4^{(0)}(z) + \kappa b_4^{(1)}(z) = (84\kappa + 12)z_4 + (\kappa - 1)(16z_1z_6 + 24z_2 - 36),$$

$$b_5(z) = b_5^{(0)}(z) + \kappa b_5^{(1)}(z) = \left(60\kappa + \tfrac{20}{3}\right)z_5 + 20(\kappa - 1)z_1,$$

$$b_6(z) = b_6^{(0)}(z) + \kappa b_6^{(1)}(z) = \left(32\kappa + \tfrac{8}{3}\right)z_6.$$

III. COMPUTATION OF POLYNOMIALS AND DEFORMED CLEBSCH–GORDAN SERIES

The eigenfunctions $\Phi_{\mathbf{m}}^{\kappa}(q)$ are polynomials when expressed in z variables, $\Phi_{\mathbf{m}}^{\kappa}(q) = P_{\mathbf{m}}^{\kappa}(z)$. The Schrödinger equation can then be solved by applying a systematic procedure, which is suitable to be implemented in a computer program able to carry out symbolic calculations. We propose two alternative methods to find the Schrödinger eigenfunctions.

(1) Given a weight $n_1\lambda_1 + n_2\lambda_2 + n_3\lambda_3 + n_4\lambda_4 + n_5\lambda_5 + n_6\lambda_6$, let us denote $z^{\mathbf{n}} = z_1^{n_1}z_2^{n_2}z_3^{n_3}z_4^{n_4}z_5^{n_5}z_6^{n_6}$. Thus, Δ^{κ} acting on $z^{\mathbf{n}}$ gives

$$\Delta^{\kappa} z^{\mathbf{n}} = \sum_{\beta \in \Lambda} k_{\beta,\mathbf{n}}(\kappa) z^{\mathbf{n}-\beta}, \tag{11}$$

where Λ includes only integral linear combinations of the simple roots with non-negative coefficients and, of course, in the exponent of (11) we express β in the basis of fundamental weights. In particular, $k_{0,\mathbf{n}}(\kappa) = \varepsilon_{\mathbf{n}}(\kappa)$. The polynomials $P_{\mathbf{m}}(z)$ can be written as

$$P^{\kappa}_{\mathbf{m}}(z) = \sum_{\mu \in Q^+(\mathbf{m})} c_{\mu}(\kappa) z^{\mathbf{m}-\mu}, \quad c_0 = 1,$$

where again the μ in $Q^+(\mathbf{m})$ are integral linear combinations of the simple roots with non-negative coefficients such that they do not give rise to negative powers of the z's. By substituting in the Schrödinger equation we find the iterative formula

$$c_{\mu}(\kappa) = \frac{1}{\varepsilon_{\mathbf{m}}(\kappa) - \varepsilon_{\mathbf{m}-(\mu)}(\kappa)} \sum_{\beta \in \Lambda, \beta \neq 0} k_{\beta,\mathbf{m}-(\mu-\beta)}(\kappa) c_{\mu-\beta}(\kappa).$$

To use this formula in practice, one should take into account the heights of the μ's, because each coefficient c_{μ} can depend only on some of the c_{ν} such that $\mathrm{ht}(\nu) < \mathrm{ht}(\mu)$.

(2) The product $z_1^{m_1} z_2^{m_2} z_3^{m_3} z_4^{m_4} z_5^{m_5} z_6^{m_6}$ can be expanded on the basis of the orthogonal polynomials $P^{\kappa}_{\mathbf{m}}(z)$ as

$$z_1^{m_1} z_2^{m_2} z_3^{m_3} z_4^{m_4} z_5^{m_5} z_6^{m_6} = P^{\kappa}_{\mathbf{m}}(z) + \sum_{\beta \in S_{\mathbf{m}}} n_{\beta}(\kappa) P^{\kappa}_{\mathbf{m}-\beta}(z),$$

where $S_{\mathbf{m}}$ is the set of all integral dominant weights β such that $\mathbf{m}-\beta$ is a linear integral combination of the simple roots with non-negative coefficents, i.e., $\mathbf{m}-\beta$ belongs to the cone of positive roots. Furthermore, the operator $\Delta^{\kappa} - \varepsilon_{\mathbf{n}}(\kappa)$ annihilates the character $P^{\kappa}_{\mathbf{n}}$. Taking this into account, we can obtain the eigenfunctions using the formula

$$P^{\kappa}_{\mathbf{m}} = \left\{ \prod_{\beta \in S_{\mathbf{m}}} (\Delta^{\kappa} - \varepsilon_{\mathbf{m}-\beta}(\kappa)) \right\} z^{\mathbf{m}}.$$

Through any of these methods, it is possible to compute the characters rather quickly. As an illustration, we offer a list of polynomials and monomial functions in Appendix B. For a similar list of characters, see Ref. 19.

Once we have a method for the computation of the polynomials, we can extend it to produce an algorithm for calculating deformed Clebsch–Gordan series for the product of them. Suppose that we want to obtain the series for $P^{\kappa}_{\mathbf{m}} \times P^{\kappa}_{\mathbf{n}}$. We list the possible dominant weights entering in the series arranged by heights

$$P^{\kappa}_{\mathbf{m}} \times P^{\kappa}_{\mathbf{n}} = P^{\kappa}_{\mathbf{m}+\mathbf{n}} + n_{\mu_1}(\kappa) P^{\kappa}_{\mu_1} + n_{\mu_2}(\kappa) P^{\kappa}_{\mu_2} + \cdots .$$

The coefficient $n_{\mu_1}(\kappa)$ is simply the difference between the coefficients of z^{μ_1} in $P^{\kappa}_{\mathbf{m}} \times P^{\kappa}_{\mathbf{n}}$ and in $P^{\kappa}_{\mathbf{m}+\mathbf{n}}$. Then, $n_{\mu_2}(\kappa)$ is the difference between the coefficient of z^{μ_2} in $P^{\kappa}_{\mathbf{m}} \times P^{\kappa}_{\mathbf{n}}$ and the sum of the corresponding coefficients in $P^{\kappa}_{\mathbf{m}+\mathbf{n}}$ and $P^{\kappa}_{\mu_1}$, and so on. As an example, we present a list with all the quadratic deformed Clebsch–Gordan series in Appendix C.

IV. SOME RECURRENCE RELATIONS

The approach we are describing is also useful to find the form of the recurrence relations for products $z_j P^{\kappa}_{\mathbf{m}}(z)$. Considered in full generality, these recurrence relations are extremely complicated, but for some special cases they can be written in explicit form. Let us consider, for instance, the recurrence relation for $z_1 P^{\kappa}_{n\lambda_1}$ with arbitrary n. If we express the weights of the representation R_{λ_1} (which are all the combinations $\varepsilon_i \pm \varepsilon$, $-\varepsilon_i - \varepsilon_j$) in the basis of fundamental weights, we see that there are only three whose coefficients for λ_i, $i \neq 1$, are all non-negative, namely $\lambda_1, -\lambda_1 + \lambda_3$ and $-\lambda_1 + \lambda_6$. Hence, the form of the series should be

$$z_1 P^{\kappa}_{n00000} = P^{\kappa}_{(n+1)00000} + a_n(\kappa) P^{\kappa}_{(n-1)01000} + b_n(\kappa) P^{\kappa}_{(n-1)00001}, \tag{12}$$

where we must fix $a_n(\kappa)$ and $b_n(\kappa)$. Now, solving the Schrödinger equation by means of the first of the two methods described in Sec. III, one finds

$$P^{\kappa}_{n00000} = z_1^n + \frac{(1-n)n}{n+\kappa-1} z_1^{n-2} z_3 + \frac{(1-n)n\kappa(n+5\kappa-2)}{(n+\kappa-1)(n+\kappa-2)(n+4\kappa-1)} z_1^{n-2} z_6 + \cdots ,$$

$$P^{\kappa}_{(n-1)01000} = z_1^{n-1} z_3 + \frac{10\kappa^3 - 5(1+3n)\kappa^2 - 2(-1-9n+5n^2)\kappa - n(2-3n+n^2)}{(n+\kappa-2)(n+\kappa-1)(n+7\kappa)} z_1^{n-1} z_6 + \cdots ,$$

$$P^{\kappa}_{(n-1)00001} = z_1^{n-1} z_6 + \cdots .$$

Substituting in (12), we can solve for $a_n(\kappa)$ and $b_n(\kappa)$ with the results

$$a_n(\kappa) = \frac{n(n+2\kappa-1)}{(n+\kappa)(n+\kappa-1)},$$

$$b_n(\kappa) = \frac{n(n+3\kappa)(n+5\kappa-1)(n+8\kappa-1)}{(n+\kappa-1)(n+4\kappa-1)(n+4\kappa)(n+7\kappa)}.$$

We list below the series of the form $z_1 P^{\kappa}_{n\lambda_k}$ obtained through the same procedure,

$$z_1 P^{\kappa}_{0n0000} = P^{\kappa}_{1n0000} + c_n(\kappa) P^{\kappa}_{0(n-1)0010} + d_n(\kappa) P^{\kappa}_{1(n-1)0000},$$

$$z_1 P^{\kappa}_{00n000} = P^{\kappa}_{10n000} + e_n(\kappa) P^{\kappa}_{00(n-1)100} + f_n(\kappa) P^{\kappa}_{10(n-1)001} + g_n(\kappa) P^{\kappa}_{01(n-1)000},$$

$$z_1 P^{\kappa}_{000n00} = P^{\kappa}_{100n00} + h_n(\kappa) P^{\kappa}_{010(n-1)10} + i_n(\kappa) P^{\kappa}_{001(n-1)01} + j_n(\kappa) P^{\kappa}_{110(n-1)00} + k_n(\kappa) P^{\kappa}_{000(n-1)10},$$

$$z_1 P^{\kappa}_{0000n0} = P^{\kappa}_{1000n0} + l_n(\kappa) P^{\kappa}_{0100(n-1)1} + p_n(\kappa) P^{\kappa}_{0010(n-1)0} + q_n(\kappa) P^{\kappa}_{0000(n-1)1},$$

$$z_1 P^{\kappa}_{00000n} = P^{\kappa}_{10000n} + r_n(\kappa) P^{\kappa}_{01000(n-1)} + s_n(\kappa) P^{\kappa}_{00000(n-1)},$$

where

$$c_n(\kappa) = \frac{n(-1+n+5\kappa)}{(-1+n+\kappa)(n+4\kappa)},$$

$$d_n(\kappa) = \frac{2n(n+2\kappa)(-1+n+6\kappa)(-1+n+8\kappa)(-1+2n+12\kappa)}{(-1+n+\kappa)(-1+n+3\kappa)(n+7\kappa)(-1+2n+11\kappa)(2n+11\kappa)},$$

$$e_n(\kappa) = \frac{n(-1+n+3\kappa)}{(-1+n+\kappa)(n+2\kappa)},$$

$$f_n(\kappa) = \frac{2n(n+2\kappa)(-1+n+4\kappa)(-1+n+6\kappa)(-1+2n+8\kappa)}{(-1+n+\kappa)(-1+n+3\kappa)(n+5\kappa)(-1+2n+7\kappa)(2n+7\kappa)},$$

$$g_n(\kappa) = \frac{n(n+\kappa)(n+3\kappa)(-1+n+5\kappa)(-1+n+6\kappa)(-1+2n+11\kappa)}{(-1+n+\kappa)(-1+n+2\kappa)(n+4\kappa)(n+5\kappa)^2(-1+2n+7\kappa)},$$

$$h_n(\kappa) = \frac{n(-1+n+4\kappa)}{(-1+n+\kappa)(n+3\kappa)},$$

$$i_n(\kappa) = \frac{n(n+\kappa)(-1+n+3\kappa)(-1+n+4\kappa)(-1+2n+7\kappa)}{(-1+n+\kappa)(-1+n+2\kappa)(n+3\kappa)^2(-1+2n+5\kappa)},$$

$$j_n(\kappa) = \frac{6n(n+\kappa)(n+2\kappa)(-1+n+4\kappa)(-1+n+5\kappa)(-1+2n+8\kappa)(-1+3n+11\kappa)}{(-1+n+\kappa)(-1+n+2\kappa)(n+4\kappa)(-1+2n+5\kappa)(2n+7\kappa)(-1+3n+10\kappa)(3n+10\kappa)},$$

$$k_n(\kappa) = \frac{3n(n+\kappa)(n+2\kappa)(-1+n+4\kappa)(-1+n+5\kappa)(2n+5\kappa)(-1+2n+8\kappa)}{(-1+n+\kappa)(-1+n+2\kappa)(n+4\kappa)^2(-1+2n+5\kappa)(-1+2n+6\kappa)(2n+7\kappa)} \times \frac{(-1+2n+9\kappa)(-1+3n+12\kappa)}{(-1+3n+10\kappa)(3n+11)\kappa},$$

$$l_n(\kappa) = \frac{n(-1+n+5\kappa)}{(-1+n+\kappa)(n+4\kappa)},$$

$$p_n(\kappa) = \frac{n(n+\kappa)(-1+n+4\kappa)(-1+n+5\kappa)(-1+2n+9\kappa)}{(-1+n+\kappa)(-1+n+2\kappa)(n+4\kappa)^2(-1+2n+7\kappa)},$$

$$q_n(\kappa) = \frac{2n(n+2\kappa)(n+3\kappa)(-1+n+6\kappa)(-1+n+8\kappa)(-1+2n+12\kappa)}{(-1+n+\kappa)(-1+n+3\kappa)(n+5\kappa)(n+7\kappa)(-1+2n+7\kappa)(2n+11\kappa)}$$

$$r_n(\kappa) = \frac{n(-1+n+6\kappa)}{(-1+n+\kappa)(n+5\kappa)},$$

$$s_n(\kappa) = \frac{n(n+3\kappa)(-1+n+9\kappa)(-1+n+12\kappa)}{(-1+n+\kappa)(-1+n+4\kappa)(n+8\kappa)(n+11\kappa)}.$$

Note that the series $z_6 P^{\kappa}_{n\lambda_j}$ immediately follow by duality.

V. CONCLUSIONS

In this paper, we have shown how to solve the Schrödinger equation for the trigonometric Calogero–Sutherland model related to the Lie algebra E_6 and we have explored some properties of the energy eigenfunctions. The main point is that the use of a Weyl-invariant set of variables, the characters of the fundamental representations, leads to a formulation of the Schrödinger equation by means of a second order differential operator which is simple enough to make feasible a recursive method for the treatment of the spectral problem. The eigenfunctions provide a complete system of orthogonal polynomials in six variables, and these polynomials obey recurrence relations which are deformations of the Clebsch–Gordan series of the algebra. The structure of some of these recurrence relations has been fixed.

APPENDIX A: SUMMARY OF RESULTS ON THE LIE ALGEBRA E_6

In this section, we review some standard facts about the root and weight systems of the Lie algebra E_6, with the aim of fixing the notation and help the reader to follow the rest of the paper. More extensive and sound treatments of these topics can be found in many excellent textbooks, see for instance Refs. 21 and 23.

The complex Lie algebra E_6, the lowest-dimensional one in the E-family of exceptional Lie algebras in the Cartan–Killing classification, has dimension 78 and rank 6, as the name suggests. From the geometrical point of view, it admits (with some subtleties, see Ref. 24) an interpretation which extends the standard-one for the classical algebras, in the same way that these correspond to the isometries of projective spaces over the first three normed division algebras—$\mathrm{SO}(n+1) \simeq \mathrm{Isom}(\mathbf{R}P^n)$, $\mathrm{SU}(n+1) \simeq \mathrm{Isom}(\mathbf{C}P^n)$, $\mathrm{Sp}(n+1) \simeq \mathrm{Isom}(\mathbf{H}P^n)$—$F_4$, E_6, E_7, and E_8 are the Lie algebras of the projective planes over extensions of the octonions, giving rise to the so-called "magic square:" $F_4 \simeq \mathrm{Isom}(\mathbf{O}P^2)$, $E_6 \simeq \mathrm{Isom}[(\mathbf{C}\otimes\mathbf{O})P^2]$, $E_7 \simeq \mathrm{Isom}[(\mathbf{H}\otimes\mathbf{O})P^2]$, $E_8 \simeq \mathrm{Isom}[(\mathbf{O}\otimes\mathbf{O})P^2]$. In physics, the most remarkable role played by E_6 is in the heterotic 10-dimensional $E_8 \times E_8$ superstring theory when the extra six dimensions are compactified to a manifold of SU(3) holonomy. In such a case, one of the E_8 breaks to an E_6 which gives the grand unification group of four-dimensional physics.[25] The Dynkin diagram of E_6, see Fig. 1, encodes the Euclidean relations among the simple roots, which are

$$(\alpha_i, \alpha_i) = 2, \quad i = 1,2,3,4,5,6,$$

$$(\alpha_4, \alpha_i) = -1, \quad i = 2,3,5,$$

$$(\alpha_1, \alpha_3) = (\alpha_5, \alpha_6) = -1,$$

$$(\alpha_i, \alpha_j) = 0, \quad \text{in all other cases.}$$

Therefore, the Cartan matrix reads

$$A = \begin{pmatrix} 2 & 0 & -1 & 0 & 0 & 0 \\ 0 & 2 & 0 & -1 & 0 & 0 \\ -1 & 0 & 2 & -1 & 0 & 0 \\ 0 & -1 & -1 & 2 & -1 & 0 \\ 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & 0 & -1 & 2 \end{pmatrix}.$$

We will use a realization of the simple roots in terms of a generating system $\{\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \varepsilon_6, \varepsilon\}$ of $\mathbf{R}^7$ (endowed with the standard Euclidean metric) satisfying $\varepsilon_1+\varepsilon_2+\varepsilon_3+\varepsilon_4+\varepsilon_5+\varepsilon_6=0$, $(\varepsilon_i, \varepsilon_j)=-\frac{1}{6}+\delta_{ij}$, $(\varepsilon, \varepsilon)=\frac{1}{2}$, and $(\varepsilon, \varepsilon_j)=0$.[21] With reference to this system, we have

$$\alpha_1 = \varepsilon_1 - \varepsilon_2, \quad \alpha_2 = \varepsilon_4 + \varepsilon_5 + \varepsilon_6 + \varepsilon,$$

TABLE I. Heights of positive roots.

Height	Positive roots
1	$\alpha_1,\ \alpha_2,\ \alpha_3,\ \alpha_4,\ \alpha_5,\ \alpha_6$
2	$\alpha_1+\alpha_3,\ \alpha_3+\alpha_4,\ \alpha_4+\alpha_5,\ \alpha_5+\alpha_6,\ \alpha_2+\alpha_4$
3	$\alpha_1+\alpha_3+\alpha_4,\ \alpha_3+\alpha_4+\alpha_5,\ \alpha_4+\alpha_5+\alpha_6,\ \alpha_2+\alpha_3+\alpha_4,$ $\alpha_2+\alpha_4+\alpha_5$
4	$\alpha_1+\alpha_3+\alpha_4+\alpha_5,\ \alpha_3+\alpha_4+\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+\alpha_4,$ $\alpha_2+\alpha_3+\alpha_4+\alpha_5,\ \alpha_2+\alpha_4+\alpha_5+\alpha_6$
5	$\alpha_1+\alpha_3+\alpha_4+\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+\alpha_4+\alpha_5,$ $\alpha_2+\alpha_3+2\alpha_4+\alpha_5,\alpha_2+\alpha_3+\alpha_4+\alpha_5+\alpha_6$
6	$\alpha_1+\alpha_2+\alpha_3+2\alpha_4+\alpha_5,\ \alpha_1+\alpha_2+\alpha_3+\alpha_4+\alpha_5+\alpha_6,$ $\alpha_2+\alpha_3+2\alpha_4+\alpha_5+\alpha_6$
7	$\alpha_1+\alpha_2+2\alpha_3+2\alpha_4+\alpha_5,\ \alpha_2+\alpha_3+2\alpha_4+2\alpha_5+\alpha_6,$ $\alpha_1+\alpha_2+\alpha_3+2\alpha_4+\alpha_5+\alpha_6$
8	$\alpha_1+\alpha_2+2\alpha_3+2\alpha_4+\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+2\alpha_4+2\alpha_5+\alpha_6$
9	$\alpha_1+\alpha_2+2\alpha_3+2\alpha_4+2\alpha_5+\alpha_6$
10	$\alpha_1+\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+\alpha_6$
11	$\alpha_1+2\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+\alpha_6$

$$\alpha_3=\varepsilon_2-\varepsilon_3,\quad \alpha_4=\varepsilon_3-\varepsilon_4,$$

$$\alpha_5=\varepsilon_4-\varepsilon_5,\quad \alpha_6=\varepsilon_5-\varepsilon_6. \tag{A1}$$

The positive roots, which are given by all linear combinations of the forms

$$\varepsilon_i-\varepsilon_j,\quad \varepsilon_i+\varepsilon_j+\varepsilon_k+\varepsilon,\quad 2\varepsilon,\quad i\neq j\neq k, \tag{A2}$$

can be classified by heights as indicated in Table I. The fundamental weights λ_k follow from the equation $\alpha_i=\Sigma_{j=1}^{4}A_{ji}\lambda_j$. They are

$$\lambda_1=\varepsilon_1+\varepsilon,$$

$$\lambda_2=2\varepsilon,$$

$$\lambda_3=\varepsilon_1+\varepsilon_2+2\varepsilon,$$

$$\lambda_4=\varepsilon_1+\varepsilon_2+\varepsilon_3+3\varepsilon,$$

$$\lambda_5=\varepsilon_1+\varepsilon_2+\varepsilon_3+\varepsilon_4+2\varepsilon,$$

$$\lambda_6=\varepsilon_1+\varepsilon_2+\varepsilon_3+\varepsilon_4+\varepsilon_5+\varepsilon.$$

The geometry of the weight system is summarized by the relations

$$(\lambda_i,\lambda_j)=A_{ij}^{-1},$$

with (A_{ij}^{-1}) being the inverse Cartan matrix. The Weyl vector is

$$\rho = \frac{1}{2} \sum_{\alpha \in \mathcal{R}^+} \alpha = \sum_{i=1}^{6} \lambda_i = 8\alpha_1 + 11\alpha_2 + 15\alpha_3 + 21\alpha_4 + 15\alpha_5 + 8\alpha_6,$$

with $\mathcal{R}^+$ being the set of positive roots of the algebra. The Weyl formula for dimensions applied to the irreducible representation associated to the integral dominant weight $\lambda = m_1\lambda_1 + m_2\lambda_2 + m_3\lambda_3 + m_4\lambda_4 + m_5\lambda_5 + m_6\lambda_6$ gives

$$\dim R_\lambda = \prod_{\alpha \in \mathcal{R}^+} \frac{(\alpha, \lambda + \rho)}{(\alpha, \rho)} = \frac{P}{2^5 \cdot 3^5 \cdot 4^5 \cdot 5^4 \cdot 6^3 \cdot 7^3 \cdot 8^2 \cdot 9 \cdot 10 \cdot 11},$$

where P is a product extended to the set of positive roots in which the root $\alpha = \Sigma_{i=1}^6 c_i \alpha_i$ contributes with a factor $\mathrm{ht}(\alpha) + \Sigma_{i=1}^6 c_i m_i$ where $\mathrm{ht}(\alpha)$ is the height of α. In particular, for the fundamental representations, one finds

$$\dim R_{\lambda_1} = 27, \quad \dim R_{\lambda_2} = 78,$$

$$\dim R_{\lambda_3} = 351, \quad \dim R_{\lambda_4} = 2925,$$

$$\dim R_{\lambda_5} = 351, \quad \dim R_{\lambda_6} = 27.$$

Note that, these dimensions reflect the fact, coming from the $\mathbf{Z}_2$ symmetry (duality) of the Dynkin diagram, that the representations R_{λ_1} and R_{λ_6} are complex conjugates. The same is true for R_{λ_3} and R_{λ_5}, while R_{λ_2} (the adjoint representation) and R_{λ_4} are real.

APPENDIX B: SOME POLYNOMIALS AND MONOMIAL FUNCTIONS

We list here the polynomials up to degree two, and the monomial functions up to degree three. Some of them are omitted for they can be obtained by duality.

Polynomials:

$$P^\kappa_{200000} = z_1^2 - \frac{2z_3}{1+\kappa} - \frac{10\kappa z_6}{(1+\kappa)(1+4\kappa)},$$

$$P^\kappa_{110000} = z_1 z_2 - \frac{5z_5}{1+4\kappa} + \frac{(6 - 95\kappa + 24\kappa^2) z_1}{(1+4\kappa)(2+11\kappa)},$$

$$P^\kappa_{020000} = z_2^2 - \frac{2z_4}{1+\kappa} - \frac{8\kappa z_1 z_6}{(1+\kappa)(1+3\kappa)} + \frac{6(-1+\kappa)(1-\kappa+6\kappa^2) z_2}{(1+\kappa)(1+3\kappa)(3+11\kappa)} + \frac{18(-1+\kappa)(2+13\kappa-7\kappa^2+6\kappa^3)}{(1+\kappa)(1+3\kappa)(2+11\kappa)(3+11\kappa)},$$

$$P^\kappa_{101000} = z_1 z_3 - \frac{3z_4}{1+2\kappa} + \frac{(-2-35\kappa+10\kappa^2) z_1 z_6}{(1+2\kappa)(2+7\kappa)} - \frac{6(-1+\kappa)(2+15\kappa) z_2}{(1+2\kappa)(1+4\kappa)(2+7\kappa)} + \frac{9(-2+17\kappa)}{(1+2\kappa)(1+4\kappa)(2+7\kappa)},$$

$$P^{\kappa}_{011000} = z_2 z_3 - \frac{4z_1 z_5}{1+3\kappa} + \frac{5(-1+\kappa)(-2+3\kappa)z_2 z_6}{(1+3\kappa)(2+7\kappa)} - \frac{4(-1+7\kappa)z_1^2}{(1+3\kappa)(1+5\kappa)} + \frac{6(-4+51\kappa+311\kappa^2+41\kappa^3+105\kappa^4)z_3}{(1+3\kappa)(1+5\kappa)(2+7\kappa)(3+11\kappa)} + \frac{6(-16+17\kappa+673\kappa^2-245\kappa^3+75\kappa^4)z_6}{(1+3\kappa)(1+5\kappa)(2+7\kappa)(3+11\kappa)},$$

$$P^{\kappa}_{002000} = z_3^2 - \frac{2z_1 z_4}{1+\kappa} - \frac{2(-1+\kappa)z_2 z_5}{(1+\kappa)(1+2\kappa)} - \frac{8\kappa z_1^2 z_6}{(1+\kappa)(1+3\kappa)} + \frac{2(-3+7\kappa+49\kappa^2+37\kappa^3+30\kappa^4)z_3 z_6}{(1+\kappa)(1+2\kappa)(1+3\kappa)(3+7\kappa)} - \frac{2(-1+\kappa)\kappa(17+69\kappa)z_1 z_2}{(1+\kappa)(1+2\kappa)(1+3\kappa)(3+7\kappa)} + \frac{(-1+\kappa)(42+291\kappa+478\kappa^2+59\kappa^3+150\kappa^4)z_6^2}{(1+\kappa)(1+2\kappa)(1+3\kappa)(2+7\kappa)(3+7\kappa)} + \frac{12(6+27\kappa+41\kappa^2+103\kappa^3+3\kappa^4)z_5}{(1+\kappa)(1+2\kappa)(1+3\kappa)(2+7\kappa)(3+7\kappa)} - \frac{6(-2-7\kappa+58\kappa^2-433\kappa^3+24\kappa^4)z_1}{(1+\kappa)(1+2\kappa)(1+3\kappa)(2+7\kappa)(3+7\kappa)},$$

Extensions of representations of the *CAR* algebra to the Cuntz algebra $\mathcal{O}_2$—the Fock and the infinite wedge

Katsunori Kawamura[a)]

(Received 7 February 2005; accepted 27 April 2005; published online 23 June 2005)

Fermions are expressed by polynomials of canonical generators of the Cuntz algebra $\mathcal{O}_2$ and they generate the U(1)-fixed point subalgebra $\mathcal{A}\equiv\mathcal{O}_2^{\mathrm{U}(1)}$ of $\mathcal{O}_2$ by the canonical gauge action. We extend the Fock and the infinite wedge representations of $\mathcal{A}$ to permutative representations of $\mathcal{O}_2$. By these extensions, the boson-fermion correspondence is rewritten by canonical generators of $\mathcal{O}_2$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1939989]

I. INTRODUCTION

Let $\mathcal{A}_0$ be the Clifford algebra generated by fermions $a_n, a_n^*, n\in\mathbf{N}\equiv\{1,2,3,\ldots\}$ which satisfy the canonical anticommutation relations (=*CAR*):

$$a_n a_m^* + a_m^* a_n = \delta_{n,m} I, \quad a_n^* a_m^* + a_m^* a_n^* = a_n a_m + a_m a_n = 0 \tag{1.1}$$

for $n,m\in\mathbf{N}$. $\mathcal{A}_0$ always has unique C*-norm $\|\cdot\|$ and the completion $\mathcal{A}\equiv\overline{\mathcal{A}_0}$ with respect to $\|\cdot\|$ is called the *CAR algebra* in theory of operator algebras.[6] In Refs. 1–4, we construct several polynomial embeddings of $\mathcal{A}$ into the Cuntz algebras $\mathcal{O}_N$. For example, if s_1, s_2 are canonical generators of $\mathcal{O}_2$, that is, they satisfy

$$s_i^* s_j = \delta_{ij} I \quad (i,j=1,2), \quad s_1 s_1^* + s_2 s_2^* = I, \tag{1.2}$$

then

$$a_1 \equiv s_1 s_2^*, \quad a_n \equiv \sum_{J\in\{1,2\}^{n-1}} (-1)^{n_2(J)} s_J s_1 s_2^* s_J^* \quad (n\geqslant 2) \tag{1.3}$$

satisfy (1.1) where $n_2(J)\equiv\Sigma_{l=1}^k (j_l-1)$ and $s_J=s_{j_1}\cdots s_{j_k}$, $s_J^*=s_{j_k}^*\cdots s_{j_1}^*$ for $J=(j_1,\ldots,j_k)$, and $C^*\langle\{a_n\in\mathcal{O}_2 : n\in\mathbf{N}\}\rangle$ coincides with a fixed-point subalgebra $\mathcal{O}_2^{\mathrm{U}(1)}$ of $\mathcal{O}_2$ by the canonical gauge action. Put a linear map ζ on $\mathcal{O}_2$ by

$$\zeta(x)\equiv s_1 x s_1^* - s_2 x s_2^* \quad (x\in\mathcal{O}_2). \tag{1.4}$$

Then $a_n=\zeta(a_{n-1})$ for each $n\geqslant 2$. In this sense, $\{a_n\}_{n\in\mathbf{N}}$ in (1.3) is called the recursive fermion system (=RFS) in $\mathcal{O}_2$.

In this article, we extend the Fock and the infinite wedge representations[12,13] of $\mathcal{A}$ to permutative representations of $\mathcal{O}_2$ under identification of $\mathcal{A}$ as $\mathcal{O}_2^{\mathrm{U}(1)}\subset\mathcal{O}_2$ by (1.3). At first, we give our main theorem for abstract formulations of representations of $\mathcal{A}$.

Theorem 1.1 *(i) Let $(\mathcal{H}_F,\pi_F)$ be the Fock representation of $\mathcal{A}$, that is, $(\mathcal{H}_F,\pi_F)$ is a cyclic representation with a cyclic vector $\Omega\in\mathcal{H}_F$ such that*

$$\pi_F(a_n)\Omega = 0 \quad (\forall n\in\mathbf{N}).$$

Then $(\mathcal{H}_F,\pi_F)$ is extended to an irreducible representation $(\mathcal{H}_F,\tilde{\pi}_F)$ of $\mathcal{O}_2$ defined by

a)Electronic-mail: kawamura@kurims.kyoto-u.ac.jp

$$\tilde{\pi}_F(s_1) \equiv L, \quad \tilde{\pi}_F(s_2) \equiv \pi(a_1^*) \cdot L$$

where L is the one-sided shift operator on $\mathcal{H}_F$ defined by

$$L\Omega \equiv \Omega, \quad L\pi_F(a_{n_1}^* \cdots a_{n_k}^*)\Omega \equiv \pi_F(a_{n_1+1}^* \cdots a_{n_k+1}^*)\Omega$$

for each $n_1, \ldots, n_k \in \mathbf{N}$ and $k \in \mathbf{N}$. (ii) Let $(\Lambda^{\infty/2}V, \pi_{\infty,+})$ be the infinite wedge representation of $\mathcal{A}$, that is, $(\Lambda^{\infty/2}V, \pi_{\infty,+})$ is a cyclic representation with a cyclic vector $|\mathrm{vac}\rangle_+ \in \Lambda^{\infty/2}V$ such that

$$\psi_{-k}|\mathrm{vac}\rangle_+ = \psi_k^*|\mathrm{vac}\rangle_+ = 0 \quad \left(\forall k \in \mathbf{Z} + \tfrac{1}{2}, k > 0\right)$$

where

$$\psi_k \equiv \pi_{\infty,+}(a_{2k+1}), \quad \psi_{-k} \equiv \pi_{\infty,+}(a_{2k}) \quad \left(k \in \mathbf{Z} + \tfrac{1}{2}, k > 0\right) \tag{1.5}$$

and $\mathbf{Z} + \frac{1}{2} \equiv \{n + 1/2 : n \in \mathbf{Z}\}$. Then $(\Lambda^{\infty/2}V, \pi_{\infty,+})$ is extended to an irreducible representation $(\Lambda^{\infty/2}V \oplus \Lambda^{\infty/2}V^*, \Pi)$ of $\mathcal{O}_2$ which satisfies

$$\Pi(s_1 s_2)|\mathrm{vac}\rangle_+ = |\mathrm{vac}\rangle_+.$$

Both representations, $(\mathcal{H}, \tilde{\pi}_F)$ and $(\Lambda^{\infty/2}V \oplus \Lambda^{\infty/2}V^*, \Pi)$, of $\mathcal{O}_2$ in Theorem 1.1 are permutative representations[5,8,9] and they are not equivalent to each other. Well-known Fock and infinite wedge representations are just realizations of those in Theorem 1.1. The extension for a concrete infinite wedge is given Sec. IV.

On the other hand, the boson-fermion correspondence on the infinite wedge representation is given by

$$\alpha_n = \sum_{k \in \mathbf{Z} + \frac{1}{2}} \psi_{k-n}\psi_k^* \quad (n \in \mathbf{Z} \setminus \{0\}). \tag{1.6}$$

$\{a_n\}_{n \in \mathbf{Z}}$ satisfies $\alpha_{-n} = \alpha_n^*$, $\alpha_n\alpha_m - \alpha_m\alpha_n = n \cdot \delta_{n,-m} I$. By identifying s_i and $\Pi(s_i)$ in Theorem 1.1 (ii) and combining (1.3) and (1.5), we have

$$\begin{aligned} \psi_k &= \sum_{J \in \{1,2\}^{2k}} (-1)^{n_2(J)} s_J s_1 s_2^* s_J^* \\ \psi_{-k} &= \sum_{J \in \{1,2\}^{2k-1}} (-1)^{n_2(J)} s_J s_1 s_2^* s_J^* \end{aligned} \quad \left(k \in \mathbf{Z} + \frac{1}{2}, k > 0\right).$$

From these and (1.6), we have a direct expression of bosons by canonical generators of $\mathcal{O}_2$ as follows:

$$\alpha_n = \sum_{l \in \mathbf{N}} \rho^{2l-2}(X_n) + B_n \quad (n \geqslant 1) \tag{1.7}$$

where

$$X_n \equiv \rho(s_1 s_2^* \zeta^{2n}(s_2 s_1^*)) + \zeta^{2n}(s_1 s_2^*) s_2 s_1^* \quad (n \geqslant 1), \tag{1.8}$$

$$B_1 \equiv -s_1 s_2 s_1^* s_2^*, \quad B_n \equiv \rho(B_{n-1}^*) - s_1 \zeta^{2n-2}(s_2 s_1^*) s_2^* \quad (n \geqslant 2), \tag{1.9}$$

ζ is in (1.4) and ρ is the canonical endomorphism of $\mathcal{O}_2$, that is, $\rho(x) \equiv s_1 x s_1^* + s_2 x s_2^*$ for $x \in \mathcal{O}_2$. Further $\alpha_n^*|\mathrm{vac}\rangle_+ = B_n^*|\mathrm{vac}\rangle_+$ for each $n \geqslant 1$.

In Sec. II, we review representations of $\mathcal{A}$ and $\mathcal{O}_2$ and the RFS. In Sec. III, we introduce a branching function system on the space of Maya diagrams and review the infinite wedge space and its dual space. In Sec. IV, we show extensions of the Fock and the infinite wedge representations to $\mathcal{O}_2$. A relation between a branching law of a permutative representation of $\mathcal{O}_2$ and the extension of the infinite wedge is concretely illustrated.

II. RECURSIVE FERMION SYSTEM AND PERMUTATIVE REPRESENTATIONS OF $\mathcal{O}_2$

Both $\mathcal{O}_2$ and the *CAR* algebra

$$CAR \equiv C^*\langle\{a_n : n \in \mathbf{N}\}\rangle$$

($=\mathcal{A}$ in Sec. I) are simple, infinite dimensional, noncommutative C*-algebras.[6,7] Remark that $a_n^* \in CAR$ for each $n \in \mathbf{N}$ by definition of C*-algebra. Unital $*$-homomorphisms (specially, unital $*$-representations) from these algebras to other algebras are always faithful. Algebras which are generated by generators s_1, s_2 in (1.2) and a_n, $n \in \mathbf{N}$ in (1.1) are unique up to $*$-isomorphisms, respectively. Therefore their representations are determined by only operators on a Hilbert space, which satisfy relations of their generators without ambiguity. In this article, a representation and an embedding always mean a unital $*$-representation and a unital $*$-embedding, respectively.

A. Representations of *CAR* and the RFS

We review representations of *CAR* in theory of operator algebras in Ref. 6.

Definition 2.1: Let $(\mathcal{H}, \pi)$ *be a representation of CAR.* (i) $(\mathcal{H}, \pi)$ *is the (abstract)Fock representation of CAR if there is a cyclic unit vector* $\Omega \in \mathcal{H}$ *such that* $\pi(a_n)\Omega = 0$ *for each* $n \in \mathbf{N}$. Ω *is called the vacuum of* $(\mathcal{H}, \pi)$. *We denote* $(\mathcal{H}, \pi)$ *by* $\mathcal{H}_{\mathrm{Fock}}$ *simply.* (ii) $(\mathcal{H}, \pi)$ *is* $P[12]$ *if there is a cyclic unit vector* $\Omega \in \mathcal{H}$ *such that* $\pi(a_{2n-1})\Omega = \pi(a_{2n}^*)\Omega = 0$ $(\forall n \in \mathbf{N})$. (iii) $(\mathcal{H}, \pi)$ *is* $P[21]$ *if there is a cyclic unit vector* $\Omega \in \mathcal{H}$ *such that* $\pi(a_{2n-1}^*)\Omega = \pi(a_{2n})\Omega = 0$ $(\forall n \in \mathbf{N})$.

For consistency with after statements, any Ω in the above is normalized. $\mathcal{H}_{\mathrm{Fock}}$, $P[12]$, $P[21]$ appear in Ref. 5 as components of irreducible decomposition of permutative representation of $\mathcal{O}_2$, which are called "atom." This fact is explained in *Proposition 2.6*.

Proposition 2.2: All of $\mathcal{H}_{\mathrm{Fock}}$, $P[12]$, $P[21]$ *are unique up to unitary equivalences and irreducible. Any two of* $\mathcal{H}_{\mathrm{Fock}}$, $P[12]$, $P[21]$ *are not unitarily equivalent*.

Proof: See (5.18) in Refs. 4 and 5. In the Appendix, their inequivalences are shown. ■

By Proposition 2.2, symbols $\mathcal{H}_{\mathrm{Fock}}$, $P[12]$ and $P[21]$ make sense as equivalence classes of representations. Since fermions are often treated as operators on a concrete Hilbert space, any representation which is different with the Fock representation in only permutation of creations and annihilations and their phase factors, are called the Fock representation, too in such situation. In this article, we do not call such representation by the Fock representation.

We review a concrete example: Put $H \equiv l_2(\mathbf{N})$ and the completely antisymmetric Fock space $F_-(H) \equiv \mathbf{C}\Omega \oplus \bigoplus_{k=1}^{\infty} H^{\wedge k}$, $H^{\wedge k} \equiv P_-^{(k)} H^{\otimes k}$ where $P_-^{(k)}$ is the antisymmetrizer on $H^{\otimes k}$ defined by $P_-^{(k)}(v_1 \otimes \cdots \otimes v_k) \equiv (\sqrt{k!})^{-1/2} \sum_{\sigma \in \mathfrak{S}_k} \mathrm{sgn}(\sigma) \cdot v_{\sigma(1)} \otimes \cdots \otimes v_{\sigma(k)}$ for $k \geqslant 1$. We denote $v_1 \wedge \cdots \wedge v_k = P_-^{(k)}(v_1 \otimes \cdots \otimes v_k)$. We see $v_{\sigma(1)} \wedge \cdots \wedge v_{\sigma(k)} = \mathrm{sign}(\sigma)(v_1 \otimes \cdots \otimes v_k)$ for each $\sigma \in \mathfrak{S}_k$. For $f \in H$, define $A^*(f)\Omega \equiv f$, $A^*(f)v \equiv f \wedge v$ for $f \in H$, $v \in H^{\wedge n}$, $n \geqslant 1$. $A(f)$ is defined by the adjoint operator of $A^*(f)$ on $F_-(H)$. We see that $A(f)\Omega = 0$ for each $f \in H$. Then $A(f)A^*(g) + A^*(g)A(f) = \langle f|g\rangle I$ for each f, $g \in H$. For the canonical basis $\{e_n\}_{n \in \mathbf{N}}$ of $H = l_2(\mathbf{N})$, put $\pi_F(a_n) \equiv A(e_n)$ for $n \in \mathbf{N}$. Then $(F_-(H), \pi_F)$ is a representation of *CAR*. $(F_-(H), \pi_F)$ is the (concrete)Fock representation.

Let s_1, s_2 be canonical generators of $\mathcal{O}_2$. Define an embedding

$$\varphi_S : CAR \hookrightarrow \mathcal{O}_2; \quad \varphi_S(a_n) \equiv \zeta^{n-1}(s_1 s_2^*) \quad (n \geqslant 1) \tag{2.1}$$

where ζ is in (1.4). For example, $\varphi_S(a_1) = s_1 s_2^*$, $\varphi_S(a_2) = s_1 s_1 s_2^* s_1^* - s_2 s_1 s_2^* s_2^*$. We call φ_S by the standard embedding of *CAR* into $\mathcal{O}_2$. $C^*\langle\{\varphi_S(a_n)\}_{n \in \mathbf{N}}\rangle = \mathcal{O}_2^{\mathrm{U}(1)} = \{x \in \mathcal{O}_2 : \forall z \in \mathrm{U}(1), \gamma_z(x) = x\} \cong UHF_2$ where γ is the canonical U(1)-action of $\mathcal{O}_2$, $\gamma_z(s_i) \equiv z s_i$ for $z \in \mathrm{U}(1) \equiv \{z \in \mathbf{C} : |z| = 1\}$ and $i = 1, 2$. By identifying a_n and $\varphi_S(a_n)$, a_n's coincide with those in (1.3) and we have the following intertwining relations.

Lemma 2.3: For $n \geqslant 1$,

$$s_1 a_n = a_{n+1} s_1, \quad s_1 a_n^* = a_{n+1}^* s_1, \quad s_2 a_n = -a_{n+1} s_2, \quad s_2 a_n^* = -a_{n+1}^* s_2,$$

$$s_1^* a_{n+1} = a_n s_1^*, \quad s_1^* a_{n+1}^* = a_n^* s_1^*, \quad s_2^* a_{n+1} = -a_n s_2^*, \quad s_2^* a_{n+1}^* = -a_n^* s_2^*.$$

B. Permutative representations of $\mathcal{O}_2$ and their branching laws

Permutative representations of the Cuntz algebras are well-studied.[5,8,9]. We introduce two permutative representations of $\mathcal{O}_2$ according to Ref. 10.

Definition 2.4: A representation $(\mathcal{H}, \pi)$ of $\mathcal{O}_2$ is $P(1)$ (respectively, $P(12)$) if there is a cyclic unit vector $\Omega \in \mathcal{H}$ such that $\pi(s_1)\Omega = \Omega$ (respectively $\pi(s_1 s_2)\Omega = \Omega$). We call Ω by the GP vector of $(\mathcal{H}, \pi)$.

Both $P(1)$ and $P(12)$ exist uniquely up to unitary equivalences, and they are irreducible and not unitarily equivalent each other.

Assume that $(\mathcal{H}, \pi)$ is $P(12)$ of $\mathcal{O}_2$ with the GP vector Ω and α is an automorphism of $\mathcal{O}_2$ defined by $\alpha(s_1) \equiv s_2$, $\alpha(s_2) \equiv s_1$. Define an operator U on $\mathcal{H}$ by

$$U\Omega \equiv \pi(s_2)\Omega, \quad U\pi(s_J)\Omega \equiv \pi(\alpha(s_J)s_2)\Omega \quad (J \in \{1,2\}^k, k \geqslant 1). \tag{2.2}$$

Then U is a unitary which satisfies $U^2 = I$ and $\mathrm{Ad}\, U \circ \pi = \pi \circ \alpha$. In consequence, $(\mathcal{H}, \pi, U)$ is a covariant representation of a C^*-dynamical system $(\mathcal{O}_2, \alpha, \mathbf{Z}_2)$.

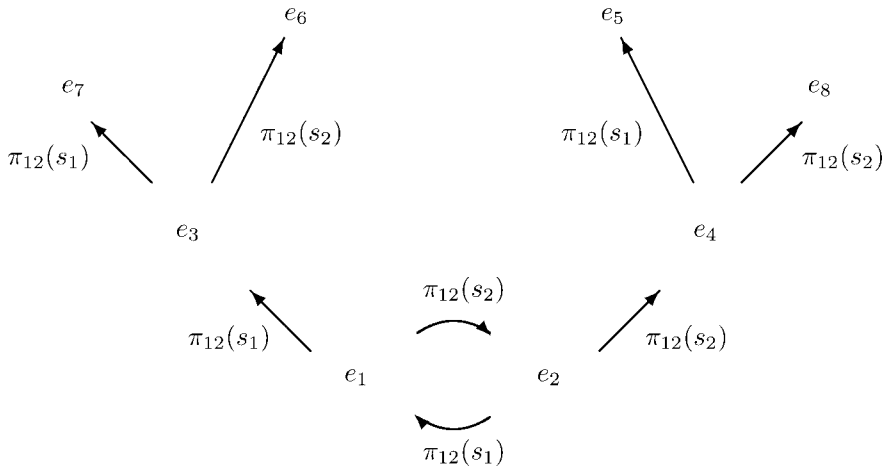
Example 2.5: (i) Define a representation $(l_2(\mathbf{N}), \pi_S)$ of $\mathcal{O}_2$ by

$$\pi_S(s_1)e_n \equiv e_{2n-1}, \quad \pi_S(s_2)e_n \equiv e_{2n} \quad (n \in \mathbf{N}).$$

Then $(l_2(\mathbf{N}), \pi_S)$ is $P(1)$. We call $(l_2(\mathbf{N}), \pi_S)$ by the *standard representation* of $\mathcal{O}_2$. (ii) Define a representation $(l_2(\mathbf{N}), \pi_{12})$ of $\mathcal{O}_2$ by

$$\pi_{12}(s_1)e_{2n-1} \equiv e_{4n-1}, \quad \pi_{12}(s_1)e_{2n} \equiv e_{4n-3}, \quad \pi_{12}(s_2)e_n \equiv e_{2n} \quad (n \in \mathbf{N}).$$

The action of s_1, s_2 on the canonical basis of $l_2(\mathbf{N})$ is illustrated as follows:



This system looks like the Fock representation with two vacuums e_1 and e_2. This diagram appears in Secs. III and IV again. $(l_2(\mathbf{N}), \pi_{12})$ is $P(12)$. Remark that $\pi_{12}(s_1 s_2)e_1 = e_1$ is expressed as a cycle in the previous diagram. For this type of example, see Ref. 11.

By φ_S in (2.1), we identify *CAR* and a subalgebra $\varphi_S(CAR) = \mathcal{O}_2^{\mathrm{U}(1)} \subset \mathcal{O}_2$. For a representation $(\mathcal{H}, \pi)$ of $\mathcal{O}_2$, we have the restriction $(\mathcal{H}, \pi|_{CAR})$ of $(\mathcal{H}, \pi)$ on *CAR*.

Proposition 2.6: ([2]) The following branching laws hold:

$$P(1)|_{CAR} = \mathcal{H}_{\mathrm{Fock}}, \quad P(12)|_{CAR} = P[12] \oplus P[21].$$

Specially, all of these are irreducible decompositions.

We consider the branching of $P(12)$ on *CAR* more.

Lemma 2.7: Let $(\mathcal{H}, \pi)$ be $P(12)$ of $\mathcal{O}_2$ with the GP vector $\Omega_1 \equiv \Omega$ and put $\Omega_2 \equiv \pi(s_2)\Omega_1$.

Then we have the following:

$$\pi(a_{2k-1})\Omega_1 = 0, \quad \pi(a_{2k})\Omega_1 = (-1)^{k-1}\pi(s_{(12)^{k-1}s_1s_1})\Omega_1,$$

$$\pi(a^*_{2k-1})\Omega_1 = (-1)^{k-1}\pi(s_{(12)^{k-1}s_2s_2})\Omega_1, \quad \pi(a^*_{2k})\Omega_1 = 0,$$

$$\pi(a_{2k-1})\Omega_2 = (-1)^{k-1}\pi(s_{(21)^{k-1}s_1})\Omega_1, \quad \pi(a_{2k})\Omega_2 = 0,$$

$$\pi(a^*_{2k-1})\Omega_2 = 0, \quad \pi(a^*_{2k})\Omega_2 = (-1)^{k}\pi(s_2s_{(12)^{k-1}s_2s_2})\Omega_1$$

for each $k \in \mathbf{N}$.

Proof: By $\pi(\zeta(x)s_2)\Omega_1 = -\pi(s_2x)\Omega_1$ for any $x \in \mathcal{O}_2$, statements hold. ■

Let $V_{12} \equiv \pi(CAR)\Omega_1$, $V_{21} \equiv \pi(CAR)\Omega_2$. Then $\mathcal{H} = V_{12} \oplus V_{21}$ and we see that

	V_{12}	V_{21}
vacuum	Ω_1	Ω_2
creation	a^*_{2k-1}, a_{2k}	a_{2k-1}, a^*_{2k}
annihilation	a_{2k-1}, a^*_{2k}	a^*_{2k-1}, a_{2k}

where $k \in \mathbf{N}$. Specially,

$$\begin{aligned} &\pi(a_1)\Omega_2 = \pi(s_1)\Omega_1, \quad \pi(a_2)\Omega_1 = \pi(s_1s_1)\Omega_1, \\ &\pi(a^*_1)\Omega_1 = \pi(s_2)\Omega_2, \quad \pi(a^*_2)\Omega_2 = -\pi(s_2s_2)\Omega_2. \end{aligned} \tag{2.3}$$

If α is the $\mathbf{Z}_2$ action on $\mathcal{O}_2$ and a_n is the *RFS* in $\mathcal{O}_2$, then $\alpha(a_n) = (-1)^{n-1}a^*_n$. Hence U in (2.2) satisfies

$$U\Omega_1 = \Omega_2, \quad U\Omega_2 = \Omega_1, \quad U\pi(a_K a^*_L)\Omega_1 = (-1)^{|K|_1+|L|_1}\pi(a^*_K a_L)\Omega_2$$

where $a_K \equiv a_{k_1}\cdots a_{k_n}$, $|K|_1 \equiv \Sigma_{i=1}^n(k_i - 1)$ for $K = \{k_1, \ldots, k_n\} \subset \mathbf{N}$. Hence $UV_{12} = V_{21}$.

Example 2.8: (i) In Example 2.5 (i), $\pi_S \circ \varphi_S$ is $\mathcal{H}_{\mathrm{Fock}}$ with the vacuum e_1. See [Ref. 3] for more detail. (ii) In Example 2.5 (ii), we consider $\pi_{12} \circ \varphi_S$. Then $(l_2(2\mathbf{N}-1), \pi_{12} \circ \varphi_S)$ is $P[12]$ and $(l_2(2\mathbf{N}), \pi_{12} \circ \varphi_S)$ is $P[21]$. If we identify a_n and $(\pi_{12} \circ \varphi_S)(a_n)$, then

$$a_{2n-1}e_1 = a^*_{2n}e_1 = a_{2n}e_2 = a^*_{2n-1}e_2 = 0,$$

$$a_{2n}e_1 = (-1)^{n-1}e_{4^{n-1}\cdot 6+1}, \quad a^*_{2n-1}e_1 = (-1)^{n-1}e_{4^{n-1}\cdot 3+1},$$

$$a_{2n-1}e_2 = (-1)^{n-1}e_{4^{n-1}\cdot 3+2}, \quad a^*_{2n}e_2 = (-1)^{n}e_{4^{n-1}\cdot 6+2}$$

for each $n \in \mathbf{N}$. These statements are shown by using $(\pi_{12}(s_1s_2))^m e_n = e_{4^{m(n-1)+1}}$ for each $m, n \in \mathbf{N}$. Specially, when $n_2 > n_1$,

$$a_{2n_1}a_{2n_2}e_1 = (-1)^{n_2-1}e_{3\cdot(2^{2n_2-1}+2^{2n_1-1})+1}.$$

III. A BRANCHING FUNCTION SYSTEM ON THE INFINITE WEDGE

We review a representation of the fermion algebra which is called the *infinite wedge space*[12,13] according to notation in Ref. 13. In order to extend this representation to $\mathcal{O}_2$, we introduce the dual infinite wedge space at once and a branching function system on them.

A. Maya diagram

Denote $\mathbf{Z}+\frac{1}{2}\equiv\{n+\frac{1}{2}:n\in\mathbf{Z}\}$. Put

$$\mathbf{Z}_{+/2}\equiv\{n+1/2:n\in\mathbf{Z},n\geqslant 0\},\quad \mathbf{Z}_{-/2}\equiv\{n-1/2:n\in\mathbf{Z},n\leqslant 0\}.$$

For a subset $S\subset\mathbf{Z}+\frac{1}{2}$, define $\Delta_{\pm}(S)\subset\mathbf{Z}+\frac{1}{2}$ by

$$\Delta_{\pm}(S)\equiv(S\setminus\mathbf{Z}_{\mp/2})\cup(\mathbf{Z}_{\mp/2}\setminus S). \tag{3.1}$$

Remark the sign of both sides.

Definition 3.1: An element in $\mathcal{M}_{\pm}\equiv\{S\subset\mathbf{Z}+\frac{1}{2}:\#\Delta_{\pm}(S)<\infty\}$ *is called a Maya diagram. Specially,* $\mathbf{Z}_{\mp/2}\in\mathcal{M}_{\pm}$ *is called the vacuum in* $\mathcal{M}_{\pm}$.

We see that $\mathcal{M}_{+}\cap\mathcal{M}_{-}=\emptyset$ and $\mathcal{M}_{\pm}=\{-S:S\in\mathcal{M}_{\mp}\}$ where $-S\equiv\{-k:k\in S\}$. There are $\max S$ for any $S\in\mathcal{M}_{+}$ and $\min S$ for any $S\in\mathcal{M}_{-}$, and $\#S=\infty$ for any $S\in\mathcal{M}_{\pm}$. Therefore we can always parameterize as follows: $S=\{t_i:i\in\mathbf{N}\}$ such that $t_i>t_{i+1}$ for $i\geqslant 1$ when $S\in\mathcal{M}_{+}$, and $S=\{t_i:i\in\mathbf{N}\}$ such that $t_i<t_{i+1}$ for $i\geqslant 1$ when $S\in\mathcal{M}_{-}$.

We illustrate $S\in\mathcal{M}_{\pm}$ by a two-sided infinite sequence consisting of symbols ○ and ● along the lattice $\mathbf{Z}+\frac{1}{2}$ as follows: For $S\in\mathcal{M}_{\pm}$, put ○ at $k\in\mathbf{Z}+\frac{1}{2}$ when $k\in S$, and put ● at $k\in\mathbf{Z}+\frac{1}{2}$ when $k\notin S$. For example, if $\{-5/2,-1/2,3/2,7/2\}\subset S$ and $\{-7/2,-3/2,1/2,5/2\}\cap S=\emptyset$, then

⋯	−7/2	−5/2	−3/2	−1/2	1/2	3/2	5/2	7/2	⋯
⋯	•	∘	•	∘	•	∘	•	∘	⋯

By this illustration, $\mathcal{M}_{\pm}$ are the following sets:

$$\mathcal{M}_{+}=\{\cdots\circ\circ*****\bullet\bullet\cdots\},\quad \mathcal{M}_{-}=\{\cdots\bullet\bullet*****\circ\circ\cdots\}$$

where ****** is taken any finite sequence consisting of ○ and ●. Specially,

vacuum	$\mathbf{Z}_{-/2}\in\mathcal{M}_{+}$	$\cdots\circ\circ\circ\circ\bullet\bullet\bullet\bullet\cdots$
dual vacuum	$\mathbf{Z}_{+/2}\in\mathcal{M}_{-}$	$\cdots\bullet\bullet\bullet\bullet\circ\circ\circ\circ\cdots$

B. A branching function system on the space of Maya diagrams

Put the space of all Maya diagrams

$$\mathcal{M}\equiv\mathcal{M}_{+}\cup\mathcal{M}_{-}.$$

We give a branching function system on $\mathcal{M}$. Put $S_{\pm}\equiv S\cap\mathbf{Z}_{\pm/2}$, $S_{+1}\equiv\{k+1:k\in S\}$ and $S_{\pm,+1}\equiv(S_{\pm})_{+1}$. For $S\in\mathcal{M}$, define

$$g_1(S)\equiv-(S_{+,+1}\cup S_{-}\cup\{1/2\}),\quad g_2(S)\equiv-(S_{+,+1}\cup S_{-}). \tag{3.2}$$

Then $g=\{g_1,g_2\}$ is a branching function system on $\mathcal{M}$, that is, g_1 and g_2 are injective maps on $\mathcal{M}$, $g_1(\mathcal{M})\cap g_2(\mathcal{M})=\emptyset$ and $g_1(\mathcal{M})\cup g_2(\mathcal{M})=\mathcal{M}$. Further,

$$g_1(\mathcal{M})=\{S\in\mathcal{M}:-1/2\in S\},\quad g_2(\mathcal{M})=\{S\in\mathcal{M}:-1/2\notin S\},$$

$$g_1^{-1}(S)=-\{(S_{-}\setminus\{-1/2\})_{+1}\cup S_{+}\},\quad g_2^{-1}(S)=-(S_{-,+1}\cup S_{+}).$$

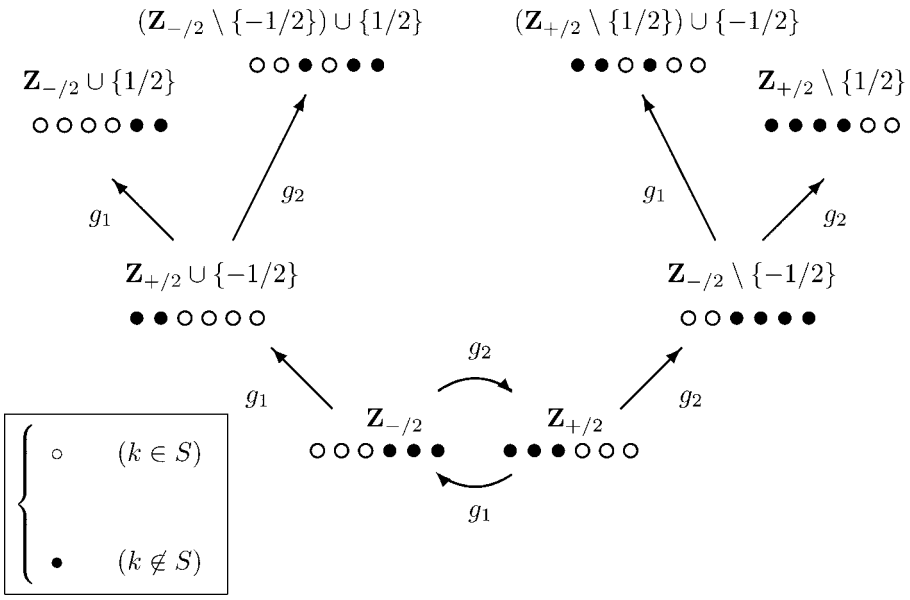
If $\theta(S)\equiv\mathbf{Z}+\frac{1}{2}\setminus S$, then $\theta^2=id$, $\theta(\mathcal{M}_{\pm})=\mathcal{M}_{\mp}$, $\theta(\mathbf{Z}_{\pm/2})=\mathbf{Z}_{\mp/2}$, and $g_2=\theta\circ g_1\circ\theta$.

Lemma 3.2: Denote $S_{\pm n}\equiv\{k\pm n:k\in S\}$, $S_{\pm,+n}\equiv(S_{\pm})_{+n}$. *Then the followings hold:* (i) $(g_1\circ g_2)^n(S)=S_{-,-n}\cup S_{+,+n}\cup\{-1/2,\ldots,-(n-1)-1/2\}$ *for* $n\in\mathbf{N}$. (ii) $(g_1\circ g_2)^{-n}(S)=(S_{-,+n})_{-}\cup S_{+,-n}$ *for* $n\in\mathbf{N}$. (iii) *Put* $h_n(S)\equiv(g_{12}^{n-1}\circ g_1\circ g_2^{-1}\circ(g_{12}^{n-1})^{-1})(S)$ *and* $k_n(S)\equiv(g_{12}^{n-1}\circ g_1\circ g_1\circ(g_{12}^{-1})^n)(S)$ *for* $n\in\mathbf{N}$. *Then*

$$h_n(S) = S \cup \{-(n-1) - 1/2\}, \quad k_n(S) = S \cup \{n - 1 + 1/2\} \quad (n \in \mathbf{N}).$$

We illustrate g by Maya diagrams:

S	$g_1(S)$	$g_2(S)$
$\mathbf{Z}_{-/2}$	$\mathbf{Z}_{+/2} \cup \{-1/2\}$	$\mathbf{Z}_{+/2}$
$\mathbf{Z}_{+/2}$	$\mathbf{Z}_{-/2}$	$\mathbf{Z}_{-/2} \setminus \{-1/2\}$
$\mathbf{Z}_{+/2} \cup \{-1/2\}$	$\mathbf{Z}_{-/2} \cup \{1/2\}$	$(\mathbf{Z}_{-/2} \setminus \{-1/2\}) \cup \{1/2\}$
$\mathbf{Z}_{-/2} \setminus \{-1/2\}$	$(\mathbf{Z}_{+/2} \setminus \{1/2\}) \cup \{-1/2\}$	$\mathbf{Z}_{+/2} \setminus \{1/2\}$
$\vdots$	$\vdots$	$\vdots$



C. The infinite wedge representation of *CAR* and its dual

We introduce the infinite wedge space by a Hilbert space of Maya diagrams. For a set Λ, $l_2(\Lambda)$ is a complex Hilbert space with a complete orthonormal basis $\{e_\lambda\}_{\lambda \in \Lambda}$ and $\dim l_2(\Lambda) = \#\Lambda$.

Definition 3.3: For $\mathcal{M}_\pm$,

$$\Lambda^{\infty/2}V^{\#} \equiv l_2(\mathcal{M}), \quad \Lambda^{\infty/2}V \equiv l_2(\mathcal{M}_+), \quad \Lambda^{\infty/2}V^* \equiv l_2(\mathcal{M}_-)$$

are called the bi-infinite wedge space, the infinite wedge space and the dual infinite wedge space, respectively.

We see that $\Lambda^{\infty/2}V^{\#} = \Lambda^{\infty/2}V \oplus \Lambda^{\infty/2}V^*$. By definition, $\Lambda^{\infty/2}V^{\#}$, $\Lambda^{\infty/2}V$ and $\Lambda^{\infty/2}V^*$ have canonical basis $\{e_S : S \in \mathcal{M}\}$, $\{e_S : S \in \mathcal{M}_+\}$, and $\{e_S : S \in \mathcal{M}_-\}$, respectively. Usually, the symbol $\Lambda^{\infty/2}V$ means a subspace of $l_2(\mathcal{M}_+)$ consisting of finite linear combinations of $\{e_S : S \in \mathcal{M}_+\}$.[12,13] We denote

$$|\mathrm{vac}\rangle_\pm \equiv e_{\mathbf{Z}_{\mp/2}}.$$

Since there are $\max S$ for any $S \in \mathcal{M}_+$ and $\min S$ for any $S \in \mathcal{M}_-$, and $\#S = \infty$ for any $S \in \mathcal{M}_\pm$, we can denote

$$t_1 \wedge t_2 \wedge \cdots = e_S \quad \text{when } S = \{t_i : \forall\, i \in \mathbf{N}, t_i > t_{i+1}\} \in \mathcal{M}_+,$$

$$t_1 \wedge t_2 \wedge \cdots = e_S \quad \text{when } S = \{t_i : \forall\, i \in \mathbf{N}, t_i < t_{i+1}\} \in \mathcal{M}_-.$$

Then we see that

$$|\mathrm{vac}\rangle_+ = \left(-\tfrac{1}{2}\right) \wedge \left(-\tfrac{3}{2}\right) \wedge \left(-\tfrac{5}{2}\right) \wedge \cdots, \quad |\mathrm{vac}\rangle_- = \tfrac{1}{2} \wedge \tfrac{3}{2} \wedge \tfrac{5}{2} \wedge \cdots.$$

For a permutation $\sigma \in \mathfrak{S}_k$ $k \geqslant 2$, define

$$t_{\sigma(1)} \wedge \cdots \wedge t_{\sigma(k)} \wedge t_{k+1} \wedge \cdots \equiv \mathrm{sgn}(\sigma) \cdot t_1 \wedge \cdots \wedge t_k \wedge t_{k+1} \wedge \cdots.$$

By these definitions, "$\wedge$" seems the exterior product of infinite vectors.

Define a family $\{\psi_k\}_{k \in \mathbf{Z}+\frac{1}{2}}$ of operators on $\Lambda^{\infty/2}V^{\#}$ by

$$\psi_k e_S \equiv \begin{cases} (-1)^{d_S(k)} \cdot e_{S \cup \{k\}} & (k \notin S), \\ 0 & (\text{otherwise}) \end{cases} \quad (S \in \mathcal{M})$$

where $d_S(k) \equiv \min\{\#\{x \in S : x > k\}, \#\{x \in S : x < k\}\}$. We simply denote

$$\psi_k e_S = (-1)^{d_S(k)} \cdot \chi_{S^c}(k) \cdot e_{S \cup \{k\}}$$

where χ_{S^c} is the characteristic function on $S^c \equiv \left(\mathbf{Z}+\frac{1}{2}\right) \setminus S$. We can easily check that the definition of ψ_k coincides with the following ordinary definition:

$$\psi_k v = k \wedge v \quad \left(v \in \Lambda^{\infty/2}V^{\#}, k \in \mathbf{Z}+\tfrac{1}{2}\right).$$

Lemma 3.4: (i) The adjoint ψ_k^* of ψ_k is given by

$$\psi_k^* e_S = (-1)^{d_{S \setminus \{k\}}(k)} \cdot \chi_S(k) \cdot e_{S \setminus \{k\}} \quad \left(k \in \mathbf{Z}+\tfrac{1}{2}, S \in \mathcal{M}\right).$$

(ii) $\psi_k \psi_k^* e_S = \chi_S(k) \cdot e_S$ for $k \in \mathbf{Z}+\frac{1}{2}$ and $S \in \mathcal{M}$. (iii) $\psi_k \psi_l^* + \psi_l^* \psi_k = \delta_{kl} I$ for $k, l \in \mathbf{Z}+\frac{1}{2}$ and other anticommutators vanish. We see that

$$\psi_{-k}|\mathrm{vac}\rangle_+ = \psi_k^*|\mathrm{vac}\rangle_+ = 0,$$

$$\psi_k|\mathrm{vac}\rangle_+ = k \wedge |\mathrm{vac}\rangle_+, \quad \psi_{-k}^*|\mathrm{vac}\rangle_+ = (-1)^{k-1/2} \cdot e_{\mathbf{Z}_{-/2} \setminus \{-k\}}$$

for $k \in \mathbf{Z}+\frac{1}{2}$, $k > 0$. In the same way, we see that

	$\Lambda^{\infty/2}V$	$\Lambda^{\infty/2}V^*$
vacuum	$\lvert\mathrm{vac}\rangle_+$	$\lvert\mathrm{vac}\rangle_-$
creation	ψ_{-k}^*, ψ_k	ψ_{-k}, ψ_k^*
annihilation	ψ_{-k}, ψ_k^*	ψ_{-k}^*, ψ_k

where $k \in \mathbf{Z}+\frac{1}{2}$, $k > 0$.

Definition 3.5: A representation $(\Lambda^{\infty/2}V^{\#}, \pi_\infty)$ of CAR defined by

$$\pi_\infty(a_{2n-1}) \equiv \psi_{-n+1/2}, \quad \pi_\infty(a_{2n}) \equiv \psi_{n-1/2} \quad (n \in \mathbf{N}) \tag{3.3}$$

is called the bi-infinite wedge representation of CAR.

On the other hand,

$$\psi_k = \pi_\infty(a_{2k+1}), \quad \psi_{-k} = \pi_\infty(a_{2k}) \quad \left(k \in \mathbf{Z}+\tfrac{1}{2}, k > 0\right). \tag{3.4}$$

Proposition 3.6: (i) The following irreducible decomposition of representations of CAR holds:

$$\Lambda^{\infty/2}V^{\#} = \Lambda^{\infty/2}V \oplus \Lambda^{\infty/2}V^*.$$

(ii) If we denote

$$\pi_{\infty,+} \equiv \pi_\infty|_{\Lambda^{\infty/2}V}, \quad \pi_{\infty,-} \equiv \pi_\infty|_{\Lambda^{\infty/2}V^*},$$

then $(\Lambda^{\infty/2}V, \pi_{\infty,+})$ is $P[12]$ and $(\Lambda^{\infty/2}V^*, \pi_{\infty,-})$ is $P[21]$.

$(\Lambda^{\infty/2}V, \pi_{\infty,+})$ and $(\Lambda^{\infty/2}V^*, \pi_{\infty,-})$ are called the *infinite wedge representation* and the *dual-infinite wedge representation* of *CAR*, respectively.

IV. STANDARD EXTENSIONS OF REPRESENTATIONS OF *CAR*

In order to show extension theorems, we prepare a notion, "standard extension" of a representation of *CAR* to $\mathcal{O}_2$ as follows.

Definition 4.1: Let φ_S be the standard embedding of CAR into $\mathcal{O}_2$ in (2.1). For a representation $(\mathcal{H}, \pi)$ of CAR, $(\tilde{\mathcal{H}}, \tilde{\pi})$ is the standard extension of $(\mathcal{H}, \pi)$ to $\mathcal{O}_2$ if $\mathcal{H}$ is a closed subspace of $\tilde{\mathcal{H}}$ such that

$$(\tilde{\pi} \circ \varphi_S)|_{\mathcal{H}} = \pi. \tag{4.1}$$

A. Standard extension of the Fock representation

Theorem 4.2: *Let $(\mathcal{H}, \pi)$ be the Fock representation of CAR with the vacuum Ω in Definition 2.1. Put two operators $\tilde{\pi}(s_1)$, $\tilde{\pi}(s_2)$ on $\mathcal{H}$ by*

$$\tilde{\pi}(s_1)\Omega \equiv \Omega, \quad \tilde{\pi}(s_1)\pi(a^*_{n_1}\cdots a^*_{n_k})\Omega \equiv \pi(a^*_{n_1+1}\cdots a^*_{n_k+1})\Omega,$$

$$\tilde{\pi}(s_2)\Omega \equiv \pi(a^*_1)\Omega, \quad \tilde{\pi}(s_2)\pi(a^*_{n_1}\cdots a^*_{n_k})\Omega \equiv \pi(a^*_1 a^*_{n_1+1}\cdots a^*_{n_k+1})\Omega$$

for $n_1 < n_2 < \cdots < n_k$, $n_j \in \mathbf{N}$, $j = 1, \ldots, k$, $k \geqslant 1$. Then the followings hold:

(i) *$(\mathcal{H}, \tilde{\pi})$ is a representation of $\mathcal{O}_2$.*
(ii) *$\tilde{\pi} \circ \varphi_S = \pi$.*
(iii) *$(\mathcal{H}, \tilde{\pi})$ is $P(1)$ with the GP vector Ω.*

This proof is given by direct computation and Lemma 2.3. For more detail, see Sec. III C in Ref. 3. Clearly, $(\tilde{\mathcal{H}} \equiv \mathcal{H}, \tilde{\pi})$ in Theorem 4.2 is the standard extension of the Fock representation. Theorem 1 (i) about an operator L follows from Theorem 4.2 as another expression of this extension.

B. Standard extension of the infinite wedge

For $g = \{g_1, g_2\}$ in (3.2), define a representation $(\Lambda^{\infty/2}V^{\#}, \Pi)$ of $\mathcal{O}_2$ by

$$\Pi(s_1)e_S \equiv (-1)^{d_+(S)}e_{g_1(S)}, \quad \Pi(s_2)e_S \equiv (-1)^{d_+(S)}e_{g_2(S)} \quad (S \in \mathcal{M}_+),$$

$$\Pi(s_1)e_S \equiv (-1)^{d'_-(S)}e_{g_1(S)}, \quad \Pi(s_2)e_S \equiv (-1)^{d_-(S)}e_{g_2(S)} \quad (S \in \mathcal{M}_-)$$

where $d_+(S) \equiv \#(S \cap \mathbf{Z}_{+/2}) + \#(\mathbf{Z}_{-/2} \backslash S)$ and $d'_-(S) \equiv \#(\mathbf{Z}_{+/2} \backslash S)$, $d_-(S) \equiv \#(\mathbf{Z}_{+/2} \backslash S) + \#(S \cap \mathbf{Z}_{-/2})$.

Lemma 4.3: When $K = \{k_1, \ldots, k_n\}$ and $L = \{l_1, \ldots, l_m\} \subset \mathbf{Z}_{+/2}$ satisfy $k_1 > \cdots > k_n$ and $l_1 < \cdots < l_m$,

$$\Pi(s_1)|\mathrm{vac}\rangle_+ = \psi_{-1/2}|\mathrm{vac}\rangle_- = e_{\mathbf{Z}_{+/2} \cup \{-1/2\}}, \quad \Pi(s_2)|\mathrm{vac}\rangle_+ = |\mathrm{vac}\rangle_-,$$

$$\Pi(s_1)|\mathrm{vac}\rangle_- = |\mathrm{vac}\rangle_+, \quad \Pi(s_2)|\mathrm{vac}\rangle_- = \psi^*_{-1/2}|\mathrm{vac}\rangle_+ = e_{\mathbf{Z}_{-/2} \backslash \{-1/2\}}.$$

$$\Pi(s_1)e_{\mathbf{Z}_{-/2} \cup K \backslash (-L)} = (-1)^{n+m}e_{\mathbf{Z}_{+/2} \cup (-K^*_{+1}) \backslash L},$$

$$\Pi(s_2)e_{\mathbf{Z}_{-/2} \cup K \backslash (-L)} = (-1)^{n+m}e_{\mathbf{Z}_{+/2} \cup (-K_{+1}) \backslash L},$$

$$\Pi(s_1)e_{\mathbf{Z}_{+/2}\cup(-K)\setminus L} = (-1)^m e_{\mathbf{Z}_{-/2}\cup K\setminus(-L_{+1})},$$

$$\Pi(s_2)e_{\mathbf{Z}_{+/2}\cup(-K)\setminus L} = (-1)^{m+n} e_{\mathbf{Z}_{-/2}\cup K\setminus(-L^*_{+1})}$$

where $K_{+1} \equiv \{k+1 : k \in K\}$ *and* $K^*_{+1} \equiv K_{+1} \cup \{1/2\}$.

Proposition 4.4: (i) $(\Lambda^{\infty/2}V^{\#}, \Pi)$ *is* $P(12)$. *(ii) If* π_∞, $\pi_{\infty,\pm}$ *are in Proposition 3.6, then* $\Pi \circ \varphi_S = \pi_\infty$. *Specially,*

$$(\Lambda^{\infty/2}V, \pi_{\infty,+}) = (\Lambda^{\infty/2}V, (\Pi \circ \varphi_S)|_{\Lambda^{\infty/2}V}) \sim P[12],$$

$$(\Lambda^{\infty/2}V^*, \pi_{\infty,-}) = (\Lambda^{\infty/2}V^*, (\Pi \circ \varphi_S)|_{\Lambda^{\infty/2}V^*}) \sim P[21].$$

Proof: (i) By Lemma 4.3, $\Pi(s_1 s_2)|\mathrm{vac}\rangle_+ = |\mathrm{vac}\rangle_+$. By definition of g_1, g_2, $(\Lambda^{\infty/2}V^{\#}, \Pi)$ is $P(12)$. (ii) Identify $\varphi_S(a_n)$ and a_n for each $n \in \mathbf{N}$. By Lemma 3.2 and Lemma 4.3, we can check the following:

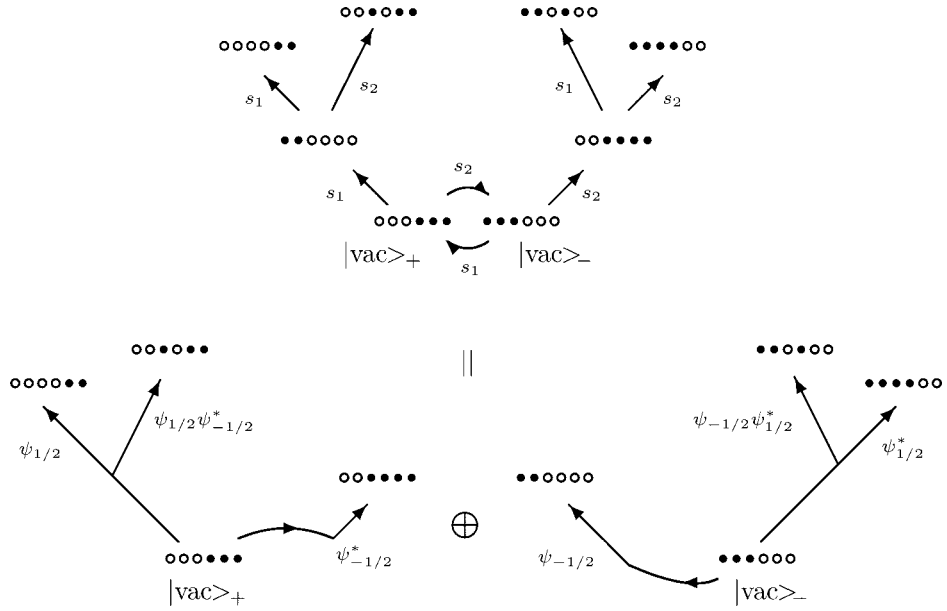
$$\Pi(a_{2n-1})|\mathrm{vac}\rangle_+ = \Pi(a_{2n})|\mathrm{vac}\rangle_- = \Pi(a^*_{2n})|\mathrm{vac}\rangle_+ = \Pi(a_{2n-1})^*|\mathrm{vac}\rangle_- = 0,$$

$$\Pi(a_{2n})|\mathrm{vac}\rangle_+ = \psi_{n-1/2}|\mathrm{vac}\rangle_+, \quad \Pi(a_{2n-1})|\mathrm{vac}\rangle_- = \psi_{-n+1/2}|\mathrm{vac}\rangle_-,$$

$$\Pi(a^*_{2n-1})|\mathrm{vac}\rangle_+ = \psi^*_{-n+1/2}|\mathrm{vac}\rangle_+, \quad \Pi(a^*_{2n})|\mathrm{vac}\rangle_- = \psi^*_{n-1/2}|\mathrm{vac}\rangle_-$$

for each $n \in \mathbf{N}$. By Lemma 4.3, $\Pi(a_n) = \pi_\infty(a_n)$ for each $n \in \mathbf{N}$. ■

The branching law $\Pi|_{CAR} = \pi_{\infty,+} \oplus \pi_{\infty,-}$ is illustrated by Maya diagrams as follows:



We try to interpret this branching law from a physical standpoint. *Before* the symmetry breaking of $\mathcal{O}_2$ to *CAR*, the vacuum and the dual vacuum are coupled as a cycle: $|\mathrm{vac}\rangle_+ \overset{s_2}{\to} |\mathrm{vac}\rangle_- \overset{s_1}{\to} |\mathrm{vac}\rangle_+$. *After* the symmetry breaking, they are decomposed into two independent vacua of fermions. A $\mathbf{Z}_2$ symmetry between $\Lambda^{\infty/2}V$ and $\Lambda^{\infty/2}V^*$ are just a unitary U in (2.2) on $\Lambda^{\infty/2}V^{\#}$ which satisfies $Us_1U^* = s_2$.

C. Boson-fermion correspondence described by $\mathcal{O}_2$

By using the standard extension of the infinite wedge, we consider correspondence among boson, fermion, and generators of the Cuntz algebra $\mathcal{O}_2$. Under identification of $\Pi(s_i)$ and s_i for $i=1,2$ in Proposition 4.4, we have the following:

$$\psi_k = \zeta^{2k}(s_1 s_2^*), \quad \psi_{-k} = \zeta^{2k-1}(s_1 s_2^*) \quad \left(k \in \mathbf{Z} + \tfrac{1}{2}, k > 0\right)$$

where ζ is in (1.4). From this, we have the following recurrence formulas:

Proposition 4.5:

$$\psi_{1/2} = \zeta(s_1 s_2^*), \quad \psi_{-1/2} = s_1 s_2^*,$$

$$\psi_{k+1} = \zeta^2(\psi_k), \quad \psi_{-k-1} = \zeta^2(\psi_{-k}) \quad \left(k \in \mathbf{Z} + \tfrac{1}{2}, k > 0\right).$$

Intertwining relations are given as follows:

$$s_i \psi_k = (-1)^{i-1} \psi_{-(k+1)} s_i, \quad s_i \psi_{-k} = (-1)^{i-1} \psi_k s_i,$$

$$s_i \psi_k^* = (-1)^{i-1} \psi_{-(k+1)}^* s_i, \quad s_i \psi_{-k}^* = (-1)^{i-1} \psi_k^* s_i$$

for $i=1,2$ and $k \in \mathbf{Z} + \frac{1}{2}$, $k>0$.

Proof of (1.7): If $n \geqslant 0$, then we can decompose

$$\alpha_n = A_n + B_n + C_n$$

where $A_n \equiv \Sigma_{k \in \mathbf{Z}+1/2, k>n} \psi_{k-n} \psi_k^*$, $B_n \equiv \Sigma_{k \in \mathbf{Z}+1/2, n>k>0} \psi_{k-n} \psi_k^*$ and $C_n \equiv \Sigma_{k \in \mathbf{Z}+1/2, k<0} \psi_{k-n} \psi_k^*$. By Proposition 4.5,

$$A_n + C_n = \sum_{l \in \mathbf{N}} \rho^{2n-2}(X_n), \quad X_n \equiv \psi_{1/2} \psi_{n+1/2}^* + \psi_{-n-1/2} \psi_{-1/2}^*$$

where we use $\zeta(x)\zeta(y) = \rho(xy)$ for each $x, y \in \mathcal{O}_2$. This implies (1.8). Further, we have $B_1 = -s_1 s_2 s_1^* s_2^*$,

$$B_{2k} = -\sum_{1 \leqslant l \leqslant k} \rho^{2(l-1)} \{\rho(s_2 \zeta^{4(k-l)}(s_1 s_2^*) s_1^*) + s_1 \zeta^{4(k-l)+2}(s_2 s_1^*) s_2^*\},$$

$$B_{2k+1} = -\rho^{2k}(s_1 s_2 s_1^* s_2^*) - \sum_{1 \leqslant l \leqslant k} \rho^{2(l-1)} \{\rho(s_2 \zeta^{4(k-l)+2}(s_1 s_2^*) s_1^*) + s_1 \zeta^{4(k-l)+4}(s_2 s_1^*) s_2^*\}$$

for each $k \in \mathbf{N}$. Hence the recurrence formula (1.9) of B_n is obtained. ■

Remark that α_n is an unbounded operator on a Hilbert space $\Lambda^{\infty/2} V$ and the previous equations make sense on a dense domain in $\Lambda^{\infty/2} V$.

In the same way, the *energy* defined by

$$H \equiv \sum_{k \in \mathbf{Z}+1/2} k{:}\psi_k \psi_k^*{:} = \sum_{k \in \mathbf{Z}+1/2 : k>0} k(\psi_k \psi_k^* + \psi_{-k}^* \psi_{-k})$$

is rewritten as follows:

$$H = \sum_{l \in \mathbf{N}} (l - 1/2) \rho^{2l-2}(s_1 s_1 s_1^* s_1^* + s_2 s_1 s_1^* s_2^* + s_2 s_2^*).$$

ACKNOWLEDGMENT

The authors would like to thank Yukiko Konishi and Rei Inoue for their good advice.

APPENDIX: INEQUIVALENCES AMONG $\mathcal{H}_{\mathrm{Fock}}$, $P[12]$, $P[21]$

Assume that $\mathcal{H}_{\mathrm{Fock}}$ and $P[12]$ are equivalent. Then there is a cyclic representation $(\mathcal{H},\pi)$ of *CAR* with two cyclic vectors Ω and Ω' such that $\pi(a_n)\Omega=0$ and $\pi(a_{2n-1})\Omega'=\pi(a_{2n}^*)\Omega'=0$ for each $n\in\mathbf{N}$. We identify $\pi(a_n)$ and a_n for each $n\in\mathbf{N}$. We see that $\mathcal{H}$ has a complete orthonormal basis $\{a_F^*\Omega:F\in\mathcal{F}(\mathbf{N})\}$ where $\mathcal{F}(\mathbf{N})$ is the set of all finite subsets of $\mathbf{N}$ and $a_\emptyset^*\equiv I$, $a_F^*\equiv a_{n_1}^*\cdots a_{n_k}^*$ when $F=\{n_1,\ldots,n_k\}$ and $n_1<\cdots<n_k$. Hence we can denote $\Omega'=\Sigma_F c_F a_F^*\Omega$ for suitable $c_F\in\mathbf{C}$. Then there are $n_0\in\mathbf{N}$ and $F_0\in\mathcal{F}(\mathbf{N})$ such that $2n_0\notin F_0$ and $c_{F_0}\neq 0$. This implies

$$a_{2n_0}a_{F_0}^*\Omega=0. \tag{A1}$$

We see that

$$\langle a_n a_F^*\Omega|a_n a_{F'}^*\Omega\rangle=\delta_{F,F'}\cdot\chi_F(n)\cdot\chi_{F'}(n) \tag{A2}$$

for each $(n,F)\in\mathbf{N}\times\mathcal{F}(\mathbf{N})$. By assumption of Ω' and anticommutation relations of a_n's,

$$\|a_{2n}\Omega'\|=\|\Omega'\|\ (\forall n\in\mathbf{N}). \tag{A3}$$

By (A1)–(A3),

$$\|\Omega'\|^2=\|a_{2n_0}\Omega'\|^2=\left\|\sum_F c_F a_{2n_0}a_F^*\Omega\right\|^2\leqslant\sum_{F\neq F_0}|c_F|^2<\|\Omega'\|^2.$$

This is contradiction. Hence $\mathcal{H}_{\mathrm{Fock}}$ and $P[12]$ are not equivalent. In the same way, inequivalences among $\mathcal{H}_{\mathrm{Fock}}$, $P[21]$, and $P[12]$ are shown. ■

Consider the blow up results for $W^{2,2}(\mathbb{R}^N)$ solutions of a quasilinear Schrödinger equation $iu_t+\Delta u+\beta|u|^{p-2}u+\theta(\Delta|u|^2)u=0$, $u_{|_{t=0}}=u_0(x), x\in\mathbb{R}^N$. When $|x|u_0 \in L^2(\mathbb{R}^N)$, we show that the $W^{2,2}(\mathbb{R}^N)$ solutions must blow up for any $\beta\geqslant 0$, $\theta \in \mathbb{R}$ and some restriction on p. We also show that the radial symmetric solutions in $W^{2,2}(\mathbb{R}^N)$ must blow up at finite time without assuming $|x|u_0\in L^2(\mathbb{R}^N)$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1941089]

I. INTRODUCTION

Porkolab and Goddman[13] have proposed the following nonlinear Schrödinger equation:

$$iu_t + u_{xx} + q(|u|^2)u - (|u|^2)_{xx} = 0, \tag{1.1}$$

and Refs. 15,14 have derived (1.1) for various physical situation. Equations similar to (1.1) in the case of higher spatial dimensions has been derived in the study of theory of superfluids, dissipative quantum mechanics, see Refs. 3,5,6 and the references therein. Considering the model problem

$$\begin{aligned} &iu_t + \Delta u + \beta|u|^{p-2}u + \theta(\Delta|u|^2)u = 0, \quad x \in \mathbb{R}^N, \\ &u_{|_{t=0}} = u_0(x), \quad x \in \mathbb{R}^N, \end{aligned} \tag{QSE}$$

$u:=u(x,t):\mathbb{R}^N\times\mathbb{R}_+\to\mathbb{C}$ is a complex-valued function, $i^2=-1$. β, θ are real constants and $p>2$. $\Delta=\Sigma_{j=1}^N(\partial^2/\partial x_j^2)$ is the standard Laplacian operator.

Mathematical difficulties in the study of problem (QSE) are due to the presence of the quasilinear term $(\Delta|u|^2)u$. There are some results about the existence of stationary solutions of problem (QSE). In a series of works, Liu-Wang-Wang[9,10] have shown the existence of standing waves solutions, i.e., a solution of form $e^{iwt}v(x)$ of (QSE). Local well posedness or global well posedness for small initial data of (QSE) is known, see, e.g., Refs. 6 and 12. However, the general global existence result for the Cauchy problem (QSE) is still open.

In this paper, we study the "blowing up" phenomena for the Cauchy problem (QSE). More precisely, we have the following.

Theorem 1.1: *Suppose that* $u(t)\in W^{2,2}(\mathbb{R}^N)(N\geqslant 1)$ *is a solution of (QSE) and*

[a)]Author to whom correspondence should be addressed: Institute of Applied Physics and Computational Mathematics, P.O. Box 8009(28 Branch), Beijing 100088, People's Republic of China.

(1) $u_0 \in W^{2,2}(\mathbb{R}^N)$, $\beta \geqslant 0$ *and* $4+(4/N) \leqslant p < 2\cdot 2^* := 2\times 2^*$, *here and after*, $2^* = 2N/(N-2)$ *if* $N \geqslant 3$ *and* $2^* = +\infty$ *otherwise*;
(2) $\nabla |u_0|^2 \in L^2(\mathbb{R}^N)$;
(3) $E(0) = \int (|\nabla u_0|^2 - (2\beta/p)|u_0|^p + (\theta/2)|\nabla |u_0|^2|^2) \leqslant 0$;
(4) $\mathrm{Im} \int \bar{u}_0 x \nabla u_0 < 0$ *and* $|x|u_0 \in L^2(\mathbb{R}^N)$;

here and after, $\bar{u}$ *is the complex conjugate of* u. *Then there exists a* $T_0 > 0$ *such that*

$$\lim_{t \to T_0^-} \| \nabla u \|^2_{L^2(\mathbb{R}^N)} = +\infty.$$

So that $\|u\|_{W^{2,2}(\mathbb{R}^N)}$ *blows up in finite time.*

Remark 1.2: (a) When $\theta = 0$, *a similar result has been obtained by Glassey.*[2] *(b) If choosing* $u_0(x) = \lambda e^{-i|x|^2} \varphi(x)$ *with* $\lambda > 0$ *and real-valued function* $\varphi(x) \in \mathcal{S}$, *the Schwartz space of rapidly decreasing functions in* $\mathbb{R}^N$, *then a direct computation gives* $\mathrm{Im} \int \bar{u}_0(x) x \nabla u_0(x) = -2\lambda^2 \int |x|^2 |\varphi|^2$, *so that* (4) *always holds in this case. Since* $p > 4$, (3) *also holds for some* λ *large.*

Note that the existence of T_0 obtained in Theorem 1.1 depends (see the proof of Theorem 1.1) on the existence of $L^2(\mathbb{R}^N)$ norm of $|x|u_0$. If $\int |x|^2 |u_0|^2 = \infty$ (this is possible, say, $u_0 \notin L^2(\mathbb{R}^N, |x|^2\, dx)$), then we cannot get the existence of such T_0. Furthermore, some numerical computations suggest that the weight restriction of $L^2(\mathbb{R}^N, |x|^2\, dx)$ is not necessarily needed for the blow up of solutions, see e.g., Ref. 7, Sec. 5 for the case of $\theta = 0$. Our next purpose is to improve this result. That is, we will remove the restriction of $u_0 \in L^2(\mathbb{R}^N, |x|^2\, dx)$ and prove that the radially symmetric solutions in $W^{2,2}(\mathbb{R}^N)$ [possibly not in $L^2(\mathbb{R}^N, |x|^2\, dx)$] blow up at finite time.

Theorem 1.3: *Suppose that* $u(t) \in W_r^{2,2}(\mathbb{R}^N) = \{u \in W^{2,2}(\mathbb{R}^N); u(x) = u(|x|)\} (N \geqslant 2)$ *is a radially symmetric solution of (QSE) and*

(i) $u_0(x) \in W_r^{2,2}(\mathbb{R}^N)$, $\beta \geqslant 0$ *and* $4+(4/N) \leqslant p \leqslant 6$ *if* $6 < 2\cdot 2^*$ *and* $4+(4/N) \leqslant p < 2\cdot 2^*$ *if* $6 > 2\cdot 2^*$;
(ii) $\nabla |u_0|^2 \in L^2(\mathbb{R}^N)$;
(iii) $E(0) = \int (|\nabla u_0|^2 - (2\beta/p)|u_0|^p + (\theta/2)|\nabla |u_0|^2|^2) < 0$;

then there is T *such that*

$$\lim_{t \to T^-} \| \nabla u \|^2_{L^2(\mathbb{R}^N)} = +\infty.$$

Remark 1.4: When $\theta = 0$, *Ogawa et al.*[11] *have proved the blow up of the radial solution of (QSE) for* $2+(4/N) \leqslant p < \min\{2^*, 6\}$ *and* $N \geqslant 2$.

Remark 1.5: When $\theta = 0$, $p = 2+(4/N)$ *is the critical exponent for the blowing up of Cauchy problem (QSE). When* $\theta \neq 0$, *we need to increase the value of* p. *However, it seems that the presence of quasilinear term can relax the restriction of* p *in some sense since we allow* $p = 6$ *in Theorem 1.3.*

This paper is organized as follows. The forthcoming section is due to the proof of Theorem 1.1. In Sec. III, we give some lemmas which are useful in the proof of Theorem 1.3. The final section contains the proof of Theorem 1.3.

We end this introduction by some notations. Throughout this paper, all integrals are taken over $\mathbb{R}^N$ unless stated otherwise, $W^{k,q}(\mathbb{R}^N)$ and $L^q(\mathbb{R}^N)$ are standard Sobolev spaces with standard norms. $L^2(\mathbb{R}^N, |x|^2\, dx)$ is a weighted Sobolev space. By C we denote a generic positive constant whose value can vary from line to line. Re (Im) denotes the real (imaginary) part for the complex value.

II. PROOF OF THEOREM 1.1

In this section, we will prove Theorem 1.1. The proof suggests that we not only give the existence of blowing up time, but also give an upper bound estimate for the blowing up time. The methods are adapted from those in Glassey,[2] see also Ref. 1, but we need to overcome the additional difficulty created by the quasilinear term.

Proof of Theorem 1.1: Multiplying (QSE) by $\bar{u}$, integrating by parts and taking the imaginary part, we can get that

$$\int |u|^2 = \int |u_0|^2. \tag{2.1}$$

Multiplying (QSE) by $\bar{u}_t$ and taking the real part, we have that

$$\mathrm{Re}\int (\Delta u\bar{u}_t + \beta|u|^{p-2}u\bar{u}_t + \theta(\Delta|u|^2)u\bar{u}_t) = \frac{d}{\mathrm{d}t}\int \left(-\frac{1}{2}|\nabla u|^2 + \frac{\beta}{p}|u|^p - \frac{\theta}{4}|\nabla |u|^2|^2\right) = 0.$$

It follows that

$$E(t) = \int \left(|\nabla u|^2 - \frac{2\beta}{p}|u|^p + \frac{\theta}{2}|\nabla |u|^2|^2\right) = E(0). \tag{2.2}$$

Denote $D(t) = \int r^2|u|^2\,\mathrm{d}x$. We have that

$$\begin{aligned}\frac{\mathrm{d}D(t)}{\mathrm{d}t} &= 2\,\mathrm{Re}\int r^2\bar{u}u_t = -2\,\mathrm{Im}\int r^2\bar{u}\Delta u = 2\,\mathrm{Im}\int (r^2\nabla u\nabla\bar{u} + 2x\bar{u}\nabla u)\\ &= 4\,\mathrm{Im}\int \bar{u}x\nabla u := -4D_1(t),\end{aligned} \tag{2.3}$$

in here $D_1(t) = -\mathrm{Im}\int \bar{u}x\nabla u$.

$$\begin{aligned}\frac{\mathrm{d}D_1(t)}{\mathrm{d}t} &= -\,\mathrm{Im}\int (\bar{u}_t x\nabla u + \bar{u}x\nabla u_t) = \mathrm{Im}\int (2x\nabla\bar{u} + N\bar{u})u_t\\ &= \mathrm{Re}\int (2x\nabla\bar{u} + N\bar{u})(\Delta u + \beta|u|^{p-2}u + \theta(\Delta|u|^2)u).\end{aligned} \tag{2.4}$$

Note that

$$\begin{aligned}\mathrm{Re}\int (2x\nabla\bar{u} + N\bar{u})\Delta u &= -\,\mathrm{Re}\int [\nabla u\nabla(2x\nabla\bar{u}) + N\nabla u\nabla\bar{u}]\\ &= -N\int |\nabla u|^2 - 2\int |\nabla u|^2 - \int x\nabla|\nabla u|^2 = -2\int |\nabla u|^2,\end{aligned} \tag{2.5}$$

$$\begin{aligned}\mathrm{Re}\int (2x\nabla\bar{u} + N\bar{u})|u|^{p-2}u &= N\int |u|^p + \int |u|^{p-2}x\nabla|u|^2 = N\int |u|^p + \frac{2}{p}\int x\nabla|u|^p\\ &= N\int |u|^p + \frac{2}{p}\int xd|u|^p = \frac{N(p-2)}{p}\int |u|^p,\end{aligned} \tag{2.6}$$

$$\begin{aligned}\mathrm{Re}\int (2x\nabla\bar{u} + N\bar{u})(\Delta|u|^2)u &= \mathrm{Re}\int N(\Delta|u|^2)|u|^2 + \int (x\nabla|u|^2)(\Delta|u|^2)\\ &= -N\int |\nabla|u|^2|^2 - \int \nabla|u|^2\nabla(x\nabla|u|^2) = -(N+1)\int |\nabla|u|^2|^2\\ &\quad -\frac{1}{2}\int x\nabla|\nabla|u|^2|^2\end{aligned}$$

$$= -(N+1)\int |\nabla |u|^2|^2 + \frac{N}{2}\int |\nabla |u|^2|^2 = -\frac{N+2}{2}\int |\nabla |u|^2|^2. \tag{2.7}$$

Thus

$$\frac{dD_1(t)}{dt} = -2\int |\nabla u|^2 + \frac{N\beta(p-2)}{p}\int |u|^p - \frac{\theta(N+2)}{2}\int |\nabla |u|^2|^2. \tag{2.8}$$

Combining this with the expression of $E(t)=E(0)\leqslant 0$ and $p\geqslant 4+(4/N)$, we know that

$$\frac{dD_1(t)}{dt} = -\left((N+2)E(t) - N\int |\nabla u|^2 + \frac{(4N+4-Np)\beta}{p}\int |u|^p\right) \geqslant N\int |\nabla u|^2 > 0. \tag{2.9}$$

Therefore

$$D_1(t) \geqslant D_1(0) = -\operatorname{Im}\int \bar{u}_0 x\nabla u_0 > 0. \tag{2.10}$$

It now follows from (2.3) that $dD(t)/dt < 0$ and

$$D(t) \leqslant D(0) = \int r^2|u_0|^2. \tag{2.11}$$

Because of

$$|D_1(t)| = D_1(t) = -\operatorname{Im}\int \bar{u}x\nabla u \leqslant \left(\int r^2|u|^2\right)^{1/2}\left(\int |\nabla u|^2\right)^{1/2} \leqslant D(0)^{1/2}\|\nabla u\|_{L^2(\mathbb{R}^N)}, \tag{2.12}$$

there holds

$$D_1(t)^2 \leqslant D(0)\|\nabla u\|_{L^2}^2 \leqslant \frac{D(0)}{N}\frac{dD_1(t)}{dt}.$$

So $dD_1(t)/dt \geqslant ND_1(t)^2/D(0)$ and $D_1(0) = -\operatorname{Im}\int \bar{u}_0 x\nabla u_0 > 0$. It follows that

$$D_1(t) \geqslant 1\Big/\left(\frac{1}{D_1(0)} - \frac{Nt}{D(0)}\right).$$

Let $T^* = D(0)/ND_1(0)$, then there is $T_0 \leqslant T^*$ such that

$$\lim_{t\to T_0^-}\|\nabla u\|_{L^2}^2 \geqslant \lim_{t\to T_0^-}\frac{D_1(t)}{D(0)^{1/2}} = +\infty. \tag{2.13}$$

So that $\|u\|_{W^{2,2}(\mathbb{R}^N)}$ blows up in finite time. The proof is complete. □

III. SOME LEMMAS

In this section, we state some lemmas which are useful in what follows. The first is about decay property for radially symmetric functions in $W^{1,2}(\mathbb{R}^N)$ which is due to Lin *et al.*[8]

Lemma 3.1: Let u be radially symmetric in $W^{1,2}(\mathbb{R}^N)$ *and* $N\geqslant 2$. *Then for any* $R>0$, *u satisfies*

$$\|u\|_{L^\infty(R<r)} \leqslant CR^{-(N-1)/2}\|u\|_{L^2(R<r)}^{1/2}\|\nabla u\|_{L^2(R<r)}^{1/2}, \tag{3.1}$$

where $r=|x|$ and C is a constant independent of u and R.

Next, we prove a general identity which is a generalization for those obtained in Lin *et al.*[8] in the case of $\theta=0$, see also Refs. 4 and 11.

Lemma 3.2: Suppose that $\Psi=(\Psi_1,\Psi_2,\ldots,\Psi_N)$ is a vector valued function in $(W^{3,\infty}(\mathbb{R}^N))^N$ and $2<p<22^*$. Then the $W^{2,2}(\mathbb{R}^N)$ solution $u(t)$ of (QSE) satisfies

$$\begin{aligned}\operatorname{Im}\int \Psi u_0\nabla\bar{u}_0-\operatorname{Im}\int \Psi u(t)\nabla\bar{u}(t)=\int_0^t\Bigg\{2\operatorname{Re}\int\sum_{k,j}u_k\Psi_{kj}\bar{u}_j+\frac{\beta(2-p)}{p}\int|u|^p(\nabla\cdot\Psi)\\ -\frac{1+\theta}{2}\int|u|^2\Delta(\nabla\cdot\Psi)+\theta\int\sum_{k,j}(|u|^2)_k\Psi_{kj}(|u|^2)_j\\ +\frac{\theta}{2}\int|\nabla|u|^2|^2(\nabla\cdot\Psi)\Bigg\}\mathrm{d}\tau,\end{aligned}\tag{3.2}$$

in here $u_k=(\partial/\partial x_k)u$, $(|u|^2)_k=(\partial/\partial x_k)|u|^2$, and $\Psi_{kj}=\partial/\partial_{x_k}\Psi_j$, all summations are taken from 1 to N.

Proof: Keep the following in mind,

$$iu_t=-\Delta u-\beta|u|^{p-2}u-\theta(\Delta|u|^2)u,\tag{3.3}$$

$$-i\bar{u}_t=-\Delta\bar{u}-\beta|u|^{p-2}\bar{u}-\theta(\Delta|u|^2)\bar{u}.\tag{3.4}$$

Now multiplying (3.3) by $\Psi\bar{u}$ and integrating by parts, we have first that

$$i\int u_t(\Psi\bar{u})=i\frac{d}{\mathrm{d}t}\int\Psi u\nabla\bar{u}-i\int\Psi u\nabla\bar{u}_t.$$

It follows that

$$i\frac{d}{\mathrm{d}t}\int\Psi u\nabla\bar{u}+i\int(\nabla\cdot\Psi)u\bar{u}_t=i\int u_t(\Psi\bar{u})+i\int\Psi u\nabla\bar{u}_t+i\int(\nabla\cdot\Psi)u\bar{u}_t.\tag{3.5}$$

Combining this with (3.3) and (3.4), we get that

$$\begin{aligned}i\frac{d}{\mathrm{d}t}\int\Psi u\nabla\bar{u}+i\int(\nabla\cdot\Psi)u\bar{u}_t=i\int u_t(\Psi\nabla\bar{u})-i\int\bar{u}_t\Psi\nabla u=\int(-\Delta u-\beta|u|^{p-2}u-\theta(\Delta|u|^2)u)\\ \times(\Psi\nabla\bar{u})+\int(-\Delta\bar{u}-\beta|u|^{p-2}\bar{u}-\theta(\Delta|u|^2)\bar{u})(\Psi\nabla u).\end{aligned}\tag{3.6}$$

Direct computations can arrive at

$$\begin{aligned}-\int\Delta u(\Psi\nabla\bar{u})=\int\nabla u\nabla(\Psi\nabla\bar{u})=\int\sum_k u_k\sum_j(\Psi_{kj}\bar{u}_j+\Psi_j\bar{u}_{jk})\\ =\int\sum_{k,j}u_k\Psi_{kj}\bar{u}_j+\int\sum_j\Psi_j\sum_k u_k\bar{u}_{kj},\end{aligned}$$

$$-\int\Delta\bar{u}(\Psi\cdot\nabla u)=\int\sum_{k,j}\bar{u}_k\Psi_{kj}u_j+\int\sum_j\Psi_j\sum_k\bar{u}_k u_{kj},$$

and hence

$$\int [-\Delta u(\Psi\nabla\bar{u})-\Delta\bar{u}(\Psi\cdot\nabla u)]=2\,\mathrm{Re}\int\sum_{k,j}u_k\Psi_{kj}\bar{u}_j+\int\Psi\cdot\nabla|\nabla u|^2$$
$$=2\,\mathrm{Re}\int\sum_{k,j}u_k\Psi_{kj}\bar{u}_j-\int(\nabla\cdot\Psi)|\nabla u|^2. \tag{3.7}$$

Similarly

$$\int(-\beta|u|^{p-2}u(\Psi\nabla\bar{u})-\Delta\bar{u}-\beta|u|^{p-2}\bar{u}(\Psi\nabla u))=\frac{2\beta}{p}\int(\nabla\cdot\Psi)|u|^p, \tag{3.8}$$

$$\int(-\theta(\Delta|u|^2)u(\Psi\nabla\bar{u})-\theta(\Delta|u|^2)\bar{u}(\Psi\nabla u))=-\theta\int(\Delta|u|^2)\Psi\nabla|u|^2=\theta\int\nabla|u|^2\nabla(\Psi\nabla|u|^2)$$
$$=\theta\int\sum_{k,j}(|u|^2)_k\Psi_{kj}(|u|^2)_j-\frac{\theta}{2}\int(\nabla\cdot\Psi)|\nabla|u|^2|^2. \tag{3.9}$$

Therefore

$$i\frac{d}{dt}\int\Psi u\nabla\bar{u}+i\int(\nabla\cdot\Psi)u\bar{u}_t=2\,\mathrm{Re}\int\sum_{k,j}u_k\Psi_{kj}\bar{u}_j-\int(\nabla\cdot\Psi)|\nabla u|^2+\frac{2\beta}{p}\int(\nabla\cdot\Psi)|u|^p$$
$$+\theta\int\sum_{k,j}(|u|^2)_k\Psi_{kj}(|u|^2)_j-\frac{\theta}{2}\int(\nabla\cdot\Psi)|\nabla|u|^2|^2. \tag{3.10}$$

Using (3.4), we know that

$$i\int(\nabla\cdot\Psi)u\bar{u}_t=\int(\nabla\cdot\Psi)(u\Delta\bar{u}+\beta|u|^p+\theta(\Delta|u|^2)|u|^2). \tag{3.11}$$

Similar calculations show that

$$\int(\nabla\cdot\Psi)u\Delta\bar{u}=-\int(\nabla\cdot\Psi)|\nabla u|^2-\int\nabla\bar{u}u\nabla(\nabla\cdot\Psi), \tag{3.12}$$

$$\theta\int(\nabla\cdot\Psi)(\Delta|u|^2)|u|^2=-\theta\int(\nabla\cdot\Psi)|\nabla|u|^2|^2+\frac{\theta}{2}\int\Delta(\nabla\cdot\Psi)|u|^4. \tag{3.13}$$

It follows that

$$i\frac{d}{dt}\int\Psi u\nabla\bar{u}=2\,\mathrm{Re}\int\sum_{k,j}u_k\Psi_{kj}\bar{u}_j+\frac{\beta(2-p)}{p}\int(\nabla\cdot\Psi)|u|^p+\int\nabla\bar{u}u\nabla(\nabla\cdot\Psi)$$
$$+\theta\int\sum_{k,j}(|u|^2)_k\Psi_{kj}(|u|^2)_j+\frac{\theta}{2}\int(\nabla\cdot\Psi)|\nabla|u|^2|^2-\frac{\theta}{2}\int\Delta(\nabla\cdot\Psi)|u|^2. \tag{3.14}$$

Taking real part in (3.14), we get that

$$\int \Psi u_0 \nabla \bar{u}_0 - \int \Psi u \nabla \bar{u} = \int_0^t \Bigg\{ 2\,\mathrm{Re} \int \sum_{k,j} u_k \Psi_{kj} \bar{u}_j + \frac{\beta(2-p)}{p} \int (\nabla \cdot \Psi)|u|^p + \theta \int \sum_{k,j} (|u|^2)_k \Psi_{kj} (|u|^2)_j + \frac{\theta}{2} \int (\nabla \cdot \Psi) |\nabla |u|^2|^2 - \frac{1+\theta}{2} \int \Delta(\nabla \cdot \Psi)|u|^2 \Bigg\} \mathrm{d}\tau. \tag{3.15}$$

This completes the proof. □

IV. PROOF OF THEOREM 1.3

In this section, we will prove Theorem 1.3. The idea is to take a suitable weight function Ψ and use Lemma 3.2, which has been used by Ogawa *et al.*[11] in the case of $\theta=0$. But when $\theta \neq 0$, the method used in Ref. 11 does not work. Hence, here we choose an appropriate weight function Ψ and some estimates. To proceed, we need some preparations.

Let $\phi:[0,\infty)\to\mathbb{R}_+$ be a function with bounded third order derivatives and be such that

$$\phi(s) = \begin{cases} s, & 0 \leqslant s < \frac{1}{2}, \\ s - \left(s - \frac{1}{2}\right)^3, & \frac{1}{2} \leqslant s < \frac{1}{2} + \frac{\sqrt{3}}{3}, \\ \text{smooth}, \phi' < 0, & \frac{1}{2} + \frac{\sqrt{3}}{3} \leqslant s < 2, \\ 0, & 2 \leqslant s, \end{cases}$$

and $\phi'(s) \leqslant 1$. Let m be a large positive constant to be determined later, we set

$$\phi_m(r) = m\phi\left(\frac{r}{m}\right).$$

Clearly

$$\left| \frac{\partial^\alpha}{\partial r^\alpha} \phi_m(r) \right| \leqslant \frac{C_\alpha}{m^{\alpha-1}}, \quad \text{for } \alpha = 0,1,2,3. \tag{4.1}$$

Denote $r=|x|$ and choose Ψ as follows:

$$\Psi(x) = \frac{x}{r}\phi_m(r) \quad \text{and } \Psi_j(x) = \frac{x_j}{r}\phi_m(r).$$

Direct computations show that

$$\Psi_{kj} = \begin{cases} \delta_{kj}, & 0 \leqslant r < \frac{1}{2}m, \\ \left(\frac{\delta_{kj}}{r} - \frac{x_k x_j}{r^3}\right)\phi_m(r) + \frac{x_k x_j}{r^3}\phi_m'(r), & \frac{1}{2}m \leqslant r < \left(\frac{1}{2} + \frac{\sqrt{3}}{3}\right)m, \\ \left(\frac{\delta_{kj}}{r} - \frac{x_k x_j}{r^3}\right)\phi_m(r) + \frac{x_k x_j}{r^3}\phi_m'(r),\ \phi' < 0, & \left(\frac{1}{2} + \frac{\sqrt{3}}{3}\right)m \leqslant r < 2m, \\ 0, & 2m \leqslant r, \end{cases} \tag{4.2}$$

where $k, j = 1, 2, \ldots, N$ and

$$\Delta(\nabla\cdot\Psi)=\sigma(r)$$
$$=\begin{cases}0, & 0\leqslant r<\frac{1}{2}m,\\ \phi_m^{(3)}+(N-1)\left\{\frac{2}{r}\phi_m''+\frac{N-3}{r^2}\phi_m'-\frac{N-3}{r^3}\phi_m\right\}, & \frac{1}{2}m<r<\left(\frac{1}{2}+\frac{\sqrt{3}}{3}\right)m,\\ \phi_m^{(3)}+(N-1)\left\{\frac{2}{r}\phi_m''+\frac{N-3}{r^2}\phi_m'-\frac{N-3}{r^3}\phi_m\right\},\ \phi'<0, & \left(\frac{1}{2}+\frac{\sqrt{3}}{3}\right)m\leqslant r<2m,\\ 0, & 2m\leqslant r.\end{cases}\tag{4.3}$$

Proof of Theorem 1.3: Arguing by a contradiction, we assume $u(t)\in W_r^{2,2}(\mathbb{R}^N)$ and $\|\nabla u\|_{L^2(\mathbb{R}^N)}$ exists globally. Using the fact that

$$\frac{\theta}{2}\int_{r<(m/2)}|\nabla|u|^2|^2=E(t)-\int|\nabla u|^2+\frac{2\beta}{p}\int|u|^p-\frac{\theta}{2}\int_{r>(m/2)}|\nabla|u|^2|^2,$$

we substitute the relations (4.2) and (4.3) into (3.2) to get that

$$\begin{aligned}\mathrm{Im}\int\Psi u_0\nabla\bar{u}_0-\mathrm{Im}\int\Psi u(t)\nabla\bar{u}(t)=\int_0^t\Bigg\{&2\int_{r<(m/2)}|\nabla u|^2+2\int_{r>(m/2)}\phi_m'(r)|\nabla u|^2+(N+2)E(t)\\&-(N+2)\int|\nabla u|^2-\frac{1+\theta}{2}\int_{r>(m/2)}\sigma(r)|u|^2\\&+\frac{2\beta(N+2)}{p}\int|u|^p+\frac{N\beta(2-p)}{p}\int_{r<(m/2)}|u|^p\\&+\frac{\beta(2-p)}{p}\int_{r>(m/2)}\left(\frac{N-1}{r}\phi_m(r)+\phi_m'(r)\right)|u|^p\\&+\theta\int_{r>(m/2)}\left(\frac{3}{2}\phi_m'(r)+\frac{N-1}{2r}\phi_m(r)-\frac{N+2}{2}\right)|\nabla|u|^2|^2\Bigg\}\mathrm{d}\tau.\end{aligned}\tag{4.4}$$

Now from the construction of ϕ, we know that

$$\frac{3}{2}\phi_m'(r)+\frac{N-1}{2r}\phi_m(r)-\frac{N+2}{2}\leqslant 0\quad\text{for } r\geqslant\frac{m}{2}.$$

Equations (4.1) and (4.3) imply that for some positive constant C,

$$|\sigma(r)|\leqslant Cm^{-2}.$$

Combining these with $p\geqslant 4+(4/N)$, we obtain that

$$\begin{aligned}\mathrm{Im}\int\Psi u_0\nabla\bar{u}_0-\mathrm{Im}\int\Psi u(t)\nabla\bar{u}(t)\leqslant\int_0^t\Bigg\{&(N+2)E(t)-N\int|\nabla u|^2+Cm^{-2}\|u\|_{L^2}^2\\&+C\int_{r>(m/2)}|u|^p\Bigg\}\mathrm{d}\tau.\end{aligned}\tag{4.5}$$

Noticing from Lemma 3.1 that

$$\int_{r>(m/2)} |u|^p \leqslant \|u\|^{p-2}_{L^\infty[r>(m/2)]} \int_{r>(m/2)} |u|^2 \leqslant Cm^{[-(N-1)(p-2)/2]} \|u\|^{(p+2)/2}_{L^2[r>(m/2)]} \| \nabla u\|^{(p-2)/2}_{L^2}. \quad (4.6)$$

If $p=6$, then

$$\int_{r>(m/2)} |u|^p \leqslant Cm^{-2(N-1)} \|u\|^4_{L^2[r>(m/2)]} \| \nabla u\|^2_{L^2} \leqslant Cm^{-2(N-1)} \|u\|^4_{L^2} \| \nabla u\|^2_{L^2}. \quad (4.7)$$

Combining with (2.1), we know that the right-hand side of (4.7) can be dominated by $-N\int |\nabla u|^2$ for m large. It follows that there is a positive constant η_1 such that

$$\mathrm{Im} \int \Psi u_0 \nabla \bar{u}_0 - \mathrm{Im} \int \Psi u(t) \nabla \bar{u}(t) \leqslant - \eta_1 t.$$

If $p<6$, then we can apply Young inequality directly to (4.6) that

$$\int_{r>(m/2)} |u|^p \leqslant \varepsilon \| \nabla u\|^2_{L^2} + C_\varepsilon m^{-\gamma} \|u\|^{[(p+2)(6-p)/8]}_{L^2},$$

with $\gamma=(N-1)(p-2)(6-p)/8$. Choosing ε small and using (2.1), we can get that for m large there is a positive constant η_2 such that

$$\mathrm{Im} \int \Psi u_0 \nabla \bar{u}_0 - \mathrm{Im} \int \Psi u(t) \nabla \bar{u}(t) \leqslant - \eta_2 t.$$

Thus in any cases, we have for some positive constant η such that

$$\mathrm{Im} \int \Psi u_0 \nabla \bar{u}_0 - \mathrm{Im} \int \Psi u(t) \nabla \bar{u}(t) \leqslant - \eta t. \quad (4.8)$$

Set $\Phi(r)=\int_0^r \phi_m(s)\mathrm{d}s$. Since $\Phi \in L^\infty(\mathbb{R}^N)$ and

$$\nabla \Phi(r) = \frac{x}{r} \phi_m(r) = \Psi(x),$$

we can use (3.4) to get that

$$\begin{aligned} i \int \Phi u \bar{u}_t &= \int (\Phi u \triangle \bar{u} + \Phi \beta |u|^p + \Phi \theta(\triangle |u|^2)|u|^2) \\ &= - \int \Psi u \nabla \bar{u} - \int \Phi(| \nabla u|^2 - \beta |u|^p - \theta(\triangle |u|^2)|u|^2). \end{aligned} \quad (4.9)$$

Taking the imaginary part in (4.9), we know that

$$\mathrm{Re} \int \Phi u \bar{u}_t = - \mathrm{Im} \int \Psi u \nabla \bar{u}.$$

Since

$$\frac{d}{\mathrm{d}t} \int \Phi |u|^2 = 2 \,\mathrm{Re} \int \Phi u \bar{u}_t \quad \text{for } t \in [0,\infty),$$

we can get that

$$\int \Phi|u|^2 \leqslant -\eta t^2 - 2t\,\mathrm{Im}\int \Psi u_0 \nabla \bar{u}_0 + \int \Phi|u_0|^2. \tag{4.10}$$

Therefore the left-hand side of (4.10) becomes negative at finite time, which implies a contradiction since $\Phi(r)>0$ except when $r=0$. Hence $\|\nabla u\|_{L^2(\mathbb{R}^N)}$ must blow up at finite time. The proof is complete.

(Received 20 February 2005; accepted 6 May 2005; published online 24 June 2005)

The result of classical invariant theory commonly referred to as Cayley's lemma is reviewed. Its analog in the invariant theory of Killing tensors defined in pseudo-Riemannian spaces of constant curvature is formulated and proven. Illustrative examples are provided. © *2005 American Institute of Physics.*

I. INTRODUCTION

Recent years have seen the appearance of new areas of mathematics bridging the gap between classical invariant theory (CIT) and differential geometry. They have brought about novel techniques proving their worth in various areas of mathematical physics, in particular, the theory of *integrable and superintegrable Hamiltonian systems* (see Horwood *et al.*,[12] and the relevant reference therein). At the same time the classical invariant theory of homogeneous polynomials itself resurrected once again through new aspects of the Lie group theory (notably, the generalizations of the moving frames method due to Fels and Olver[8,9] and Kogan,[14] see also the relevant references therein), the rise of the modern computer algebra and new applications in other areas of mathematics (see Hilbert[11] and Olver[24] for a complete review and related references). Thus, McLenaghan *et al.* in their pioneering paper[16] successfully planted the underlying ideas of CIT into the fertile field of the (geometric) study of Killing tensors defined in pseudo-Riemannian manifolds of constant curvature, which ultimately bore the fruit of a new theory (see also Refs. 12, 17, 28, 29, 4, and 18–21). The resulting *invariant theory of Killing tensors* (ITKT) shares many of the same essential features with the original CIT. In light of the fact that "Mathematics is the study of analogies between analogies,"[25] we wish to continue developing ITKT by establishing more analogies with CIT. One of the most famous problems solved by Cayley around the time CIT was conceived was the problem of the determination of the infinitesimal action of $SL(2,\mathbb{R})$ in the vector spaces of the binary forms $\mathcal{Q}^n(\mathbb{R}^2)$ of an *arbitrary degree n*. Interestingly, this was done before the emergence of the formal theory of Lie groups in order to develop a tractable procedure for computing the *invariants* and *covariants* of such vector spaces under the action of $SL(2,\mathbb{R})$. The people working in ITKT routinely encounter similar problems that boil down to finding effective and efficient ways for computing the invariants and covariants of the isometry group action in the vector spaces of Killing tensors defined in pseudo-Riemannian spaces of constant curvature. Of particular importance is the case when the vector spaces in question are the vector spaces of Killing tensors defined in two-dimensional pseudo-Riemannian manifolds. Let $\mathbb{R}^2_1$ be the Minkowski plane. In this paper we formulate and solve the problem of finding the infinitesimal action of the isometry group $I(\mathbb{R}^2_1)$ *in the vector space* $\mathcal{K}^n_0(\mathbb{R}^2_1)$ *of Killing tensors of* arbitrary valence n.

This problem represents a natural analog of the classical problem solved by Arthur Cayley in 1856 (i.e., the so-called *Cayley's Lemma*), while establishing the foundations of CIT.

[a)]Electronic mail: jyue@dal.ca

The paper is organized as follows. In Sec. II we briefly review Cayley's lemma in CIT. In Sec. III we review basic facts about ITKT. An analog of Cayley's lemma in ITKT is formulated and proven in Sec. IV. Finally, in Sec. V we make concluding remarks.

II. CAYLEY'S LEMMA

As is well known, the *main object* of study in CIT is a vector space of homogeneous polynomials under the action of the general linear group (or its subgroups), while the *main problem* is that of the determination of the functions of the parameters of the vector space in question that remain fixed under the action of the group. These functions, called *invariants*, are very useful in solving various classification problems. In this study the vector spaces of particular importance are the spaces of *binary forms*, or homogeneous polynomials of degree n in two variables, originally referred to by Arthur Cayley[3] as *quantics*.

Let $\mathcal{Q}^n(\mathbb{R}^2)$ denote the vector space of binary forms of degree n over the reals. Then the dimension d of the space is $n+1$, and an element $\boldsymbol{Q}(x,y)$ of $\mathcal{Q}^n(\mathbb{R}^2)$ is given by

$$\boldsymbol{Q}(x,y)=\sum_{i=0}^{n}\binom{n}{i}a_i x^{n-i}y^i, \quad (x,y)\in\mathbb{R}^2. \tag{1}$$

The special linear group $SL(2,\mathbb{R})$ acts on the space $\mathcal{Q}^n(\mathbb{R}^2)$ by linear substitutions, which yield the corresponding transformation rules

$$\tilde{a}_i=\tilde{a}_i(a_0,\ldots,a_n,\alpha,\beta,\gamma,\delta), \quad i=0,\ldots,n, \tag{2}$$

where $\alpha,\beta,\gamma,\delta\in\mathbb{R},(\alpha\delta-\beta\gamma=1)$ are local coordinates that parametrize the group. Note dim $SL(2,\mathbb{R})=3$. The formulas (2) can be derived explicitly.[24] The problem reduces to finding all of the $SL(2,\mathbb{R})$-invariants of $\mathcal{Q}^n(\mathbb{R})^2$, or those functions defined over Σ, the parameter space spanned by $(a_0,\ldots,a_n)$, that remain unchanged under the transformations (2):

$$\mathcal{I}=F(\tilde{a}_0,\ldots,\tilde{a}_n)=F(a_0,\ldots,a_n). \tag{3}$$

Note that in the case of $SL(2,\mathbb{R})$ action the invariants appear to be of weight zero due to the condition $\alpha\delta-\beta\gamma=1$.

One way to determine the fundamental invariants is to use the infinitesimal generators of the Lie algebra of the group, by which we mean their counterparts in the parameter space Σ satisfying the same commutator relations as the generators defined in the original space. Thus, a function $F(a_0,\ldots,a_n)$ is an *invariant* if and only if it is annihilated by the generators of the Lie algebra defined in the parameter space Σ. This is a short description of Sophus Lie's *method of the infinitesimal generators*.

Another powerful method, about which we shall not dwell in this article, is Élie Cartan's *method of moving frames*, which has been recently brought back to light.[8,9,23,24,1,2,14,4,28–30]

Arthur Cayley's main contributions to the development of CIT appeared during the period 1854–1878 in his famous "ten memoirs on quantics." Having introduced the notion of an abstract group, he was the first to recognize that the action of a Lie group on a vector space can be investigated by studying its "infinitesimal action," that is the corresponding Lie algebra. In spite of the fact that Cayley thought of this as of something pertinent only to the general linear group and its subgroups, his results in this area may be considered as a precursor to Sophus Lie's theory of abstract Lie groups that was developed later in the 19th century. More specifically, in his "second memoirs on quantics"[3] Arthur Cayley considers (in modern mathematical language) the problem of the determination of the action of the Lie group $SL(2,\mathbb{R})$ on the vector space $\mathcal{Q}^n(\mathbb{R}^2)$ in conjunction with the problem of computing the invariants. The main result is the subject of the following lemma (Cayley,[3] see also Olver[24]).

Lemma 2.1 (Cayley, 1856): *The action of* $SL(2,\mathbb{R})$ *on the vector space* $\mathcal{Q}^n(\mathbb{R}^2)$ *of binary homogeneous polynomials of degree n defined by (1) has the following infinitesimal generators in the corresponding parameter space* Σ:

$$\boldsymbol{V}^{-} = na_1\partial_{a_0} + (n-1)a_2\partial_{a_1} + \cdots + 2a_{n-1}\partial_{a_{n-2}} + a_n\partial_{a_{n-1}},$$

$$\boldsymbol{V}^{0} = -na_0\partial_{a_0} + (2-n)a_1\partial_{a_1} + \cdots + (n-2)a_{n-1}\partial_{a_{n-1}} + na_n\partial_{a_n},$$

$$\boldsymbol{V}^{+} = a_0\partial_{a_1} + 2a_1\partial_{a_2} + \cdots + (n-1)a_{n-2}\partial_{a_{n-1}} + na_{n-1}\partial_{a_n}, \tag{4}$$

where $\partial_{a_i} = \partial/\partial_{a_i}, i = 0, \ldots, n$.

Observe that the vector fields (4) enjoy the following commutator relations:

$$[\boldsymbol{V}^{-}, \boldsymbol{V}^{0}] = -2\boldsymbol{V}^{-}, \quad [\boldsymbol{V}^{+}, \boldsymbol{V}^{0}] = 2\boldsymbol{V}^{+}, \quad [\boldsymbol{V}^{-}, \boldsymbol{V}^{+}] = \boldsymbol{V}^{0}, \tag{5}$$

which confirm that the generators (4) represent the action of $SL(2,\mathbb{R})$ in the parameter space Σ. In view of the above, solving the problem of the determination of the $SL(2,\mathbb{R})$-invariants of $\mathcal{Q}^n(\mathbb{R}^2)$ now amounts to solving the corresponding system of PDEs determined by the generators (4):

$$\boldsymbol{V}^{-}(F) = 0, \quad \boldsymbol{V}^{0}(F) = 0, \quad \boldsymbol{V}^{+}(F) = 0 \tag{6}$$

for a (analytic) function F defined in Σ. The following fundamental theorem on invariants of a regular Lie group aciton (see Olver[24] tells us that the number of fundamental $SL(2,\mathbb{R})$-invariants is $n+1-s$, where $s \leqslant 3$ is the dimension of the orbits (wherever the dimension of the orbits is constant).

Theorem 2.1: *Let G be a Lie group acting regularly on an m-dimensional manifold M with s-dimensional orbits. Then, in a neighborhood N of each point* $x_0 \in M$, *there exist* $m-s$ *functionally independent G-invariants* $\Delta_1, \ldots, \Delta_{m-s}$. *Any other G-invariant* $\mathcal{I}$ *defined near* x_0 *can be locally uniquely expressed as an analytic function of the fundamental invariants through* $\mathcal{I} = F(\Delta_1, \ldots, \Delta_{m-s})$.

Therefore for each particular n the general solution to the system (6) will take the form

$$\mathcal{I} = F(\Delta_1, \ldots, \Delta_{n+1-s}),$$

where $\Delta_i, i = 1, \ldots, n+1-s$ are the fundamental $SL(2,\mathbb{R})$-invariants. To determine s and the subspaces of Σ where the isometry group acts with orbits of the same dimension, one employs the result of the following proposition.[24]

Proposition 2.1: *Let a Lie group G act on X,* *is the corresponding Lie algebra and let* $x \in X$. *The vector space* $S|_x = \mathrm{Span}\{\mathbf{V}_i(x) \,|\, \mathbf{V}_i \in \ \}$ *spanned by all vector fields determined by the infinitesimal generators at x coincides with the tangent space to the orbit* $\mathcal{O}_x$ *of G that passes through x, so* $S|_x = T\mathcal{O}_x|_x$. *In particular, the dimension of* $\mathcal{O}_x$ *equals the dimension of* $S|_x$. *Moreover, the isotropy subgroup* $G_x \subset G$ *has dimension* $\dim G - \dim \mathcal{O}_x = r - s$.

To illustrate the procedure, let us recall a well-known example.[24]

Example 2.1: Consider $\mathcal{Q}^2(\mathbb{R}^2)$-the vector space of quadratic homogeneous polynomials defined over reals. The elements of $\mathcal{Q}^2(\mathbb{R}^2)$ assume

$$Q(x,y) = a_0x^2 + 2a_1xy + a_2y^2 \quad (x,y) \in \mathbb{R}^2. \tag{7}$$

The (local) action of $SL(2,\mathbb{R})$ on the parameter space $\Sigma \simeq \mathbb{R}^3$ generated by a_0, a_1, and a_2 is represented by the vector fields

$$\boldsymbol{V}^{-} = 2a_1\partial_{a_0} + a_2\partial_{a_1},$$

$$\boldsymbol{V}^{0} = 2a_0\partial_{a_0} - 2a_2\partial_{a_2},$$

TABLE I. The settings for the corresponding problems in CIT and ITKT.

Theory	Vector space	Group	Dimension of the space	Dimension of the orbits
CIT	$\mathcal{Q}^n(\mathbb{R}^2)$	$SL(2,\mathbb{R})$	$n+1$	$\leqslant 3$
ITKT	$\mathcal{K}^n(\mathbb{R}^2_1)$	$I(\mathbb{R}^2_1)$	$\frac{1}{2}(n+1)(n+2)$	$\leqslant 3$

$$\boldsymbol{V}^+ = a_0\partial_{a_1} + 2a_1\partial_{a_2}, \tag{8}$$

obtained via the standard technique of exponentiation, which can also be derived from the above lemma. Observe that only two of the vector fields (8) are linearly independent, therefore there is (almost everywhere) $3-2=1$ fundamental invariant. Indeed, solving the system of PDEs (6) yields the solution: $\mathcal{I}=F(\Delta_1)$, where $\Delta_1=a_0a_2-a_1^2$. The group acts with orbits of two types: $a_0=a_1=a_2=0$, an orbit of dimension 0 and the level sets of Δ_1 (i.e., $\Delta_1=0$ and $\Delta_1\neq 0$), both of which are orbits of dimension 2.

Now let us briefly turn our attention to ITKT (for more details see the next section). There the underlying space is a pseudo-Riemannian manifold $(M,\boldsymbol{g})$ of constant curvature. The vector spaces in question are the vector spaces of (generalized) Killing tensors. Our notations are consistent with those introduced in Ref. 16. Thus, $\mathcal{K}_0^n(M)$ denotes the vector space of generalized contravariant Killing tensors of valence n and order zero (or, the standard Killing tensors) defined on $(M,\boldsymbol{g})$. The group acting on $\mathcal{K}_0^n(M)$ is the isometry group $I(M)$ of $(M,\boldsymbol{g})$. Since Cayley's problem concerns binary forms it will be natural to investigate in this respect the Killing tensors of arbitrary valence n defined in pseudo-Riemannian manifolds of dimension two, for example, the Minkowski plane $\mathbb{R}^2_1$. Accordingly, the vector space that we shall study is $\mathcal{K}_0^n(\mathbb{R}^2_1), n\geqslant 1$. A comparison of the two problems is given in Table I. Having made these observations, we are now in the position to formulate an ITKT version of the problem considered by Cayley.[3]

Problem 2.1: Consider the action of $I(\mathbb{R}^2_1)$ *on* $\mathcal{K}_0^n(\mathbb{R}^2_1)$. *Determine a representation of the corresponding Lie algebra* $i(\mathbb{R}^2_1)$ *on the parameter space* Σ of $\mathcal{K}_0^n(\mathbb{R}^2_1)$, $n\geqslant 2$.

In Sec. III we establish the requisite language to be used for solving Problem 2.1 in Sec. IV.

III. INVARIANT THEORY OF KILLING TENSORS

Developed recently as an analog of CIT, the invariant theory of Killing tensors (ITKT) has been first and foremost effectively employed in the study of those integrable and superintegrable Hamiltonian systems[12,16,17,19–21,28] for which the Killing tensors of valence two having normal eigenvectors play a pivotal role. Other applications include classifications of Hamiltonian systems admitting first integrals that are polynomials in the momenta determined by Killing tensors of higher valences.[13,18,29] In what follows, we briefly discuss the main features of the theory.

Let $(M,\boldsymbol{g})$ be an m-dimensional pseudo-Riemannian manifold of constant curvture.

Definition 3.1: A symmetric contravariant tensor $\boldsymbol{K}$ *of valence n defined on* $(M,\boldsymbol{g})$ *is said to be a generalized Killing tensor (GKT) of order p if and only if*

$$[[\ldots[\boldsymbol{K},\boldsymbol{g}],\boldsymbol{g}],\ldots\boldsymbol{g}] = 0 \quad (p+1 \text{ brackets}), \tag{9}$$

where $[,]$ *denotes the Schouten bracket.*

It is easy to see, taking into the account the $\mathbb{R}$-bilinear properties of the Schouten bracket, that GKTs of the same valence and order constitute a *vector space*. We observe next that such a vector space specified by the system of overdetermined PDEs (9) includes the subspace of the standard Killing tensors of valence n defined on $(M,\boldsymbol{g})$ by the system of overdetermined PDEs

$$[\boldsymbol{K},\boldsymbol{g}] = 0. \tag{10}$$

Hence, we conclude that the GKTs of order zero are the standard Killing tensors (KTs). Recall that the concept of a generalized Killing tensor defined on the Minkowski space $\mathbb{R}^m_1$ was introduced by

Nikitin and Prilipko[22] [see also Appendix A of the monograph (Ref. 10)] as generalized symmetries of the Klein-Gordon-Fock equation. In addition, the authors determined the formulas for the dimensions of the vector spaces of GKTs. Alternatively, these tensors have been independently reintroduced in a more general setting by Eastwood[6,7] within the framework of the study of overdetermined systems of PDEs by the methods of representation theory. Thus, it has been demonstrated that the vector space of the solutions of the overdetermined system of PDEs (9) is preserved by the action induced by $SL(m+1,\mathbb{R})$. In this view the author defines such a vector space as an irreducible representation of $\mathfrak{sl}(m+1,\mathbb{R})$ (see also Ref. 15), and then derives the formula for the dimension of the vector space $\mathcal{K}_p^n(M)$ of the generalized Killing tensors of valence n and order p defined on $(M,\boldsymbol{g})$. Thus, the dimension d of the vector space $\mathcal{K}_p^n(M), p\geqslant 0$ is determined by the *Nikitin-Prilipko-Eastwood (NPE) formula* given by

$$d=\dim \mathcal{K}_p^n(M)=\frac{p+1}{m}\binom{n+m-1}{m-1}\binom{p+n+m}{m-1}, \tag{11}$$

where $m=\dim(M,\boldsymbol{g})$. We immediately recognize that for $p=0$ the formula (11) reduces to the *Delong-Takeuchi-Thompson (DTT) formula*.[5,31,32] In this view the elements of $\mathcal{K}_p^n(M)$ are specified by d arbitrary parameters $a_0,\ldots,a_{d-1}$, where d is given by (11).

Example 3.1: Consider the vector space $\mathcal{K}_0^2(\mathbb{R}_1^2)$ of Killing tensors of valence two and order zero defined in Minkowski plane. Solving the Killing tensor equation (10) in the pseudo-Cartesian coordinates (t,x) yields the general formula[17,21]

$$\boldsymbol{K}=\begin{pmatrix} a_0+2a_3x+a_5x^2 & a_1+a_3t+a_4x+a_5tx \\ a_1+a_3t+a_4x+a_5tx & a_2+2a_4t+a_5t^2 \end{pmatrix}. \tag{12}$$

The arbitrary constants of integration $a_0,\ldots,a_5$ represent the dimension of the space $\mathcal{K}_0^2(\mathbb{R}_1^2)$. Formula (12) is an ITKT analog of the general formula (7) in CIT. The three generators of the Lie group $I(\mathbb{R}_1^2)$ acting on $\mathbb{R}_1^2$ are given by (Killing vector fields)

$$\boldsymbol{T}=\partial_t,\quad \boldsymbol{X}=\partial_x,\quad \boldsymbol{H}=x\partial_t+t\partial_x \tag{13}$$

corresponding to translations and hyperbolic rotations, having the commutator relations

$$[\boldsymbol{T},\boldsymbol{X}]=0,\quad [\boldsymbol{T},\boldsymbol{H}]=\boldsymbol{X},\quad [\boldsymbol{X},\boldsymbol{H}]=\boldsymbol{T}. \tag{14}$$

We note that in the case of vector spaces of Killing tensors defined in $\mathbb{R}_1^2$, the generators (13) are not connected via any nontrivial relations. This is also true for any other two-dimensional pseudo-Riemannian manifold of constant curvature. In this view, for a fixed $n\geqslant 1$ the dimension of the corresponding vector space $\mathcal{K}_0^n(\mathbb{R}_1^2)$ can be computed, for example, by employing the well-known formula for the dimension of the space $\mathrm{Sym}^r(M)$ of symmetric $(r,0)$-tensors defined over an m-dimensional manifold:

$$\dim \mathrm{Sym}^r(M)\binom{m+r-1}{r}. \tag{15}$$

Now $m=\dim i(\mathbb{R}_1^2)=3$ and $r=n$. Therefore we have from (15)

$$\dim \mathcal{K}_0^n(\mathbb{R}_1^2)=\tfrac{1}{2}(n+1)(n+2). \tag{16}$$

For spaces of higher dimensions the formula (16) is no longer valid due to the existence of additional nontrivial relations among the generators of the Lie algebra of Killing vectors (i.e., the "syzygy modules problem"[5]). Note the formula (16) agrees with (11). Indeed, (16) is a particular case of (11) corresponding to $p=0,m=2$. Note that for a given vector space $\mathcal{K}_0^n(M), n\geqslant 1$ defined on $(M,\boldsymbol{g})$ the corresponding isometry group $I(M)$ acts as an automorphism: $I(M):\mathcal{K}_0^n(M)\rightarrow\mathcal{K}_0^n(M)$.

This key observation led to the emergence of ITKT.[16] More specifically, the isometry group $I(M)$ acting on M induces the corresponding transformation laws on the parameters $a_0,\ldots,a_{d-1}$ of the vector space $\mathcal{K}_0^n(M)$:

$$\tilde{a}_i = \tilde{a}_i(a_0,\ldots,a_{d-1},g_1,\ldots,g_r), \quad i=0,\ldots,d-1, \tag{17}$$

where $g_1,\ldots,g_r$ are local coordinates on $I(M)$ that parametrize the group, $r=\dim I(M)=\frac{1}{2}m(m+1)$ and d is given by (11). The formulas (17), which we obtain from the standard tensor transformation laws for the elements of the vector space $\mathcal{K}_0^n(M)$ represent the isometry group $I(M)$ action in the vector space.

Clearly, the transformation formulas (17) are analogu of the corresponding transformation formulas in CIT [see, for example, (2)]. It must be mentioned, however, that in the case of ITKT they are computationally more difficult to obtain.

Definition 3.2: A smooth function $\mathcal{I}:\Sigma\to\mathbb{R}$ *defined over the parameter space* Σ *of* $\mathcal{K}_0^n(M)$ *is said to be an* $I(M)$*-invariant of* $\mathcal{K}_0^n(M)$ *if it satisfies the condition*

$$\mathcal{I}=F(a_0,\ldots,a_{d-1})=F(\tilde{a}_0,\ldots,\tilde{a}_{d-1}),$$

under the transformation laws (17).

We remark that in a similar way the ITKT-analogues of the CIT-concepts of a *covariant* and *joint invariant* have been introduced in Ref. 28. In complete analogy with CIT, we can in principle determine the space of $I(M)$-invariants by employing the (Sophus Lie's) method of infinitesimal generators. To do so, one has to determine the (infinitesimal) action of $I(M)$ in the corresponding parameter space Σ.

We note that the procedure originally devised in McLenaghan *et al.*[16] can be effectively employed to derive the generators of the Lie algebra in Σ that is isomorphic to the Lie algebra $i(M)$ of $I(M)$. We briefly review the *MST-procedure* here.

Let $\{\boldsymbol{X}_1,\ldots,\boldsymbol{X}_r\}$ be the generators of the Lie algebra $i(M)$ (Killing vector fields) of the Lie group $I(M)$. Consider Diff Σ, that is the group of all diffeomorphisms on Σ, defining the corresponding space Diff $\mathcal{K}_0^n(M)$, whose elements are determined by the elements of Diff Σ in an obvious way.

Let $\boldsymbol{K}^0\in$ Diff $\mathcal{K}_0^n(M)$. Note $\boldsymbol{K}^0$ is determined by d parameters

$$a_i^0=a_i^0(a_0,\ldots,a_{d-1}), \quad i=0,\ldots,d-1$$

which are functions of $a_0,\ldots,a_{d-1}$. Define now a map π: Diff $\mathcal{K}_0^n(M)\to\mathcal{X}(\Sigma)$ given by

$$\boldsymbol{K}^0\to\sum_{i=0}^{d-1}a_i^0(a_0,\ldots,a_{d-1})\partial_{a_i}. \tag{18}$$

To specify the action of $I(M)$ in Σ, we have to find the counterparts of the generators $\boldsymbol{X}_1,\ldots,\boldsymbol{X}_r$ in $\mathcal{X}(\Sigma)$. Consider the composition $\pi\circ\mathcal{L}$, where $\mathcal{L}$ is the Lie derivative operator. Let $\boldsymbol{K}$ be the general Killing tensor of $\mathcal{K}_0^n(M)$ [see, for example, (12)]. Next define

$$\boldsymbol{V}_i=\pi\circ\mathcal{L}_{\boldsymbol{X}_i}\boldsymbol{K}, \quad i=1,\ldots r. \tag{19}$$

The composition map

$$\pi\circ\mathcal{L}:i(M)\to\mathcal{X}(\Sigma)$$

maps the generators $\boldsymbol{X}_1,\ldots,\boldsymbol{X}_r$ to $\mathcal{X}(\Sigma)$. Finally, we check that the vector fields $\boldsymbol{V}_i, i=1,\ldots,r$ satisfy the same commutator relations as the original $\boldsymbol{X}_i, i=1,\ldots,r$. This can be checked on a case by case basis. We remark that this step is actually redundant, since it has been proven[15] in general that Killing tensors can be expressed as irreducible representations of $GL(n,\mathbb{R})$ so that the vector fields (19) satisfy the same commutator relations as the original generators of $i(M)$. Thus, the Lie algebra generated by (19) is isomorphic to the Lie algebra $i(M)$ of the isometry group $I(M)$ and we

can use (19) to solve the problem of the determination of the $I(M)$-invariants of $\mathcal{K}_0^n(M)$ by solving the corresponding system of PDEs:

$$\boldsymbol{V}_i(F) = 0, \quad i = 1, \ldots, r. \tag{20}$$

The MST-procedure stated above is based on *Lie derivative deformations* of tensors (see, for example, Ref. 27, which is an analog of the standard technique of exponentiation used in CIT to determine corresponding infinitesimal gernerators. We also note that the generators (19) can be alternatively determined from the parameter transformation laws (17), representing the group action in Σ, when the latter are available. It is, however, increasingly difficult, and often impossible to determine (19) using (17) for vector spaces of Killing tensors of higher valence or defined in pseudo-Riemannian manifolds of higher dimensions.

To illustrate the effectiveness of the MST procedure, let us consider the following example.[17,21,28]

Example 3.2: Consider again $\mathcal{K}_0^2(\mathbb{R}_1^2)$, using (12), (13), (18), and (19) we arrive at the corresponding generators:

$$\boldsymbol{V}_1 = a_3\partial_{a_1} + 2a_4\partial_{a_2} + a_5\partial_{a_4},$$

$$\boldsymbol{V}_2 = a_4\partial_{a_1} + 2a_3\partial_{a_0} + a_5\partial_{a_3}, \tag{21}$$

$$\boldsymbol{V}_3 = -2a_1\partial_{a_0} - a_4\partial_{a_3} - (a_0 + a_2)\partial_{a_1} - 2a_1\partial_{a_2} - a_3\partial_{a_4}.$$

It is easy to check that the Lie algebra generated by (21) is isomorphic to the Lie algebra $i(\mathbb{R}_1^2) = \mathcal{K}_0^1(\mathbb{R}_1^2)$ generated by (13). We conclude therefore that the vector fields (21) represent the infinitesimal action of $I(\mathbb{R}_1^2)$ in Σ. Our next observation is that the orbits of the $I(\mathbb{R}_1^2)$-action have dimension three wherever the vector fields (21) are linearly independent. Therefore in that subspace of Σ we expect to derive $6-3=3$ fundamental $I(\mathbb{R}_1^2)$-invariants.

Using the method of characteristics to solve the system (20) defined by the vector fields (21), we arrive at the following result:

Theorem 3.1: *Any algebraic $I(\mathbb{R}_1^2)$-invariant $\mathcal{I}$ of the subspace of the parameter space Σ of $\mathcal{K}_0^2(\mathbb{R}_1^2)$ defined by the condition that the vector fields (21) are linearly independent can be (locally) uniquely expressed as an analytic function*

$$\mathcal{I} = F(\Delta_1, \Delta_2, \Delta_3), \tag{22}$$

where the fundamental invariants $\Delta_i, i = 1, 2, 3$ are given by

$$\Delta_1 = a_5,$$

$$\Delta_2 = (a_0 - a_2)a_5 - a_3^2 + a_4^2,$$

$$\Delta_3 = (a_3^2 + a_4^2 - a_5(a_0 + a_2))^2 - 4(a_5a_1 - a_3a_4)^2. \tag{23}$$

The fundamental $I(\mathbb{R}_1^2)$-invariant Δ_3 presented above was first derived in Ref. 17 and 21 and used to generate *discrete-$I(\mathbb{R}_1^2)$*-invariants, which were in turn employed to classify orthogonal coordinate webs in the Minkowski plane $\mathbb{R}_1^2$. The same problem was solved in Ref. 28 by employing the $I(\mathbb{R}_1^2)$-invariants and covariants of $\mathcal{K}_0^2(\mathbb{R}_1^2)$.

IV. AN ITKT ANALOG OF CAYLEY'S LEMMA

In this section we solve Problem 2.1 presented in Sec. II. The vector space $\mathcal{K}_0^n(\mathbb{R}_1^2)$ appears to be a natural counterpart of the vector space $\mathcal{Q}^n(\mathbb{R}^2)$ in CIT. To proceed, we need to first derive a

general formula for the elements of $\mathcal{K}_0^n(\mathbb{R}_1^2)$ [i.e., an analog of (1)]. Note each $\boldsymbol{K}\in\mathcal{K}_0^n(\mathbb{R}_1^2)$ is determined by the $(n+1)(n+2)/2$ parameters that appear in the $n+1$ components of the form

$$K^{i_1\cdots i_p j_1\cdots j_{n-p}}, \tag{24}$$

where $i_1=\cdots=i_p=1, j_1=\cdots=j_{n-p}=2, p=0,\ldots,n$.

To derive the formulas for the components (24), we solve the Killing tensor equation (10) in pseudo-Cartesian coordinates (t,x), which reduces to the following system of PDEs:

$$\partial_t K^{i_1\cdots i_n}=0, \quad \partial_x K^{j_1\cdots j_n}=0,$$

$$(n-p+1)\partial_x K^{i_1\cdots i_p j_1\cdots j_{n-p}} = p\partial_t K^{i_1\cdots i_{p-1} j_1\cdots j_{n-p+1}}, \tag{25}$$

where $p=0,\ldots,n$. As a consequence of (25), we readily obtain the necessary differential conditions:

$$\begin{aligned} \partial_x^{p+1} K^{i_1\cdots i_p j_1\cdots j_{n-p}}&=0,\\ \partial_t^{n-p+1} K^{i_1\cdots i_p j_1\cdots j_{n-p}}&=0. \end{aligned} \tag{26}$$

Solving the PDEs (25) and (26) we arrive at the following general formulas for the components (the parameters in the formulas are constants of integration):

$$K^{i_1\cdots i_p j_1\cdots j_{n-p}} = \begin{cases} \displaystyle\sum_{i=0}^{n-p}\left[\binom{n-p}{i} t^i \sum_{j=0}^{p}\binom{p}{j} a_{pij}x^j\right] & \text{if } n\geqslant p\geqslant\left[\dfrac{n+1}{2}\right] \\ \displaystyle\sum_{i=0}^{p}\left[\binom{p}{i} x^i \sum_{j=0}^{n-p}\binom{n-p}{j} b_{pij}t^j\right] & \text{if } 0\leqslant p\leqslant\left[\dfrac{n+1}{2}\right] \end{cases}, \tag{27}$$

where the parameters a_{pij}, b_{pij} are to be determined (at this stage they are inserted for mere convenience). We immediately recognize that the formula (27) is the ITKT analog of the general formula (1) exhibited in Sec. II. The parameters a_{pij}, b_{pij} can be determined by following the general procedure of solving the system of PDEs (25). We consider separately two cases: n is even and n is odd.

The parameters of each of the $n+1$ components can be organized into groups in such a way that the parameters of one group are completely determined by the parameters of the other (see the illustrative examples to follow). After relabeling the parameters, we obtain the following two schemes (corresponding to $n=2k$ and $n=2k+1$, respectively), which specify the arrangements of the parameters of the first groups of the components. Once they are specified, the parameters of the other groups can be determined accordingly.

Case 1: $n=2k$

$$\begin{array}{lcccccc} \text{Step } 1: & a_0^1 & a_1^1 & \cdots & a_{n-2}^1 & a_{n-1}^1 & a_n^1, \\ & b_0^1 & b_1^1 & \cdots & b_{n-2}^1 & b_{n-1}^1 & a_n^1; \\ \text{Step } 2: & a_0^2 & a_1^2 & \cdots & a_{n-3}^2 & a_{n-2}^2 & b_{n-1}^1, \\ & b_0^2 & b_1^2 & \cdots & b_{n-3}^2 & a_{n-2}^2 & a_{n-1}^1; \\ & & & \vdots & & & \\ \text{Step } \dfrac{n}{2}: & a_0^{n/2} & a_1^{n/2} & a_2^{n/2} & b_1^{(n-2)/2} & \cdots & b_{(n+2)/2}^1, \\ & b_0^{n/2} & b_1^{n/2} & a_2^{n/2} & a_1^{(n-2)/2} & \cdots & a_{(n+2)/2}^1; \\ \text{Step } (n+2)/2: & a_0^{(n+2)/2} & b_1^{n/2} & b_2^{(n-2)/2} & b_3^{(n-4)/2} & \cdots & b_{n/2}^1. \end{array} \tag{28}$$

Case 2: $n=2k+1$

$$
\begin{array}{lcccccc}
\text{Step } 1: & a_0^1 & a_1^1 & \cdots & a_{n-2}^1 & a_{n-1}^1 & a_n^1, \\
 & b_0^1 & b_1^1 & \cdots & b_{n-2}^1 & b_{n-1}^1 & a_n^1; \\
\text{Step } 2: & a_0^2 & a_1^2 & \cdots & a_{n-3}^2 & a_{n-2}^2 & b_{n-1}^1, \\
 & b_0^2 & b_1^2 & \cdots & b_{n-3}^2 & a_{n-2}^2 & a_{n-1}^1. \\
 & & & \vdots & & & \\
\text{Step } (n-1)/2: & a_0^{(n-1)/2} & a_1^{(n-1)/2} & a_2^{(n-1)/2} & a_3^{(n-1)/2} & \cdots & b_{(n+3)/2}^1, \\
 & b_0^{(n-1)/2} & b_1^{(n-1)/2} & b_2^{(n-1)/2} & a_3^{(n-1)/2} & \cdots & a_{(n+3)/2}^1; \\
\text{Step } (n+1)/2: & a_0^{(n+1)/2} & a_1^{(n+1)/2} & b_2^{(n-1)/2} & b_3^{(n-3)/2} & \cdots & b_{(n+1)/2}^1, \\
 & b_0^{(n+1)/2} & a_1^{(n+1)/2} & a_2^{(n-1)/2} & a_3^{(n-3)/2} & \cdots & a_{(n+1)/2}^1.
\end{array}
\tag{29}
$$

The parameters that appear in the general solution to (27) are now organized in two schemes according the cases of n being even (28) and odd (29) respectively.

More specifically, given $2(n+1)-1$ parameters

$$
a_0^1,\ldots,a_{n-1}^1,a_n^1, \quad b_0^1,\ldots,b_{n-1}^1,a_n^1
$$

we write down the first and the last components of $\boldsymbol{K}\in\mathcal{K}^n(\mathbb{R}_1^2)$:

$$
K^{11\cdots11}=\left[a_0^1+\binom{n}{1}a_1^1x+\binom{n}{2}a_2^1x^2+\cdots+\binom{n}{n-1}a_{n-1}^1x^{n-1}+a_n^1x^n\right],
$$

$$
K^{22\cdots22}=\left[b_0^1+\binom{n}{1}b_1^1t+\binom{n}{2}b_2^1t^2+\cdots+\binom{n}{n-1}b_{n-1}^1t^{n-1}+a_n^1t^n\right].
$$

Next, for $2(n-1)-1$ new parameters

$$
a_0^2,\ldots,a_{n-3}^2,a_{n-2}^2;b_0^2,\ldots,b_{n-3}^2,a_{n-2}^2
$$

we then have the second and penultimate components of $\boldsymbol{K}$ [see (27)], each of which is the sum of two polynomials, the first having been determined by the newly specified parameters and the other by the parameters determined previously,

$$
\begin{aligned}
K^{11\cdots12}=&\left[a_0^2+\binom{n-1}{1}a_1^2x+\cdots+\binom{n-1}{n-2}a_{n-2}^2x^{n-2}+b_{n-1}^1x^{n-1}\right]\\
&+t\left[a_1^1+\binom{n-1}{1}a_2^1x+\cdots+\binom{n-1}{n-2}a_{n-1}^1x^{n-2}+a_n^1x^{n-1}\right],
\end{aligned}
$$

$$
\begin{aligned}
K^{22\cdots21}=&\left[b_0^2+\binom{n-1}{1}b_1^2t+\cdots+\binom{n-1}{n-2}a_{n-2}^2t^{n-2}+a_{n-1}^1t^{n-1}\right]\\
&+x\left[b_1^1+\binom{n-1}{1}b_2^1t+\cdots+\binom{n-1}{n-2}b_{n-1}^1t^{n-2}+a_n^1t^{n-1}\right].
\end{aligned}
$$

To clarify the process more, let us consider the next step (if any). Thus, given $2(n-3)-1$ new parameters

$$
a_0^3,\ldots,a_{n-5}^3,a_{n-4}^3;b_0^3,\ldots,b_{n-5}^3,a_{n-4}^3
$$

we write down the next two components:

$$K^{11\cdots122}=\left[a_0^3+\binom{n-2}{1}a_1^3x+\cdots+\binom{n-2}{n-4}a_{n-4}^3x^{n-4}+\binom{n-2}{n-3}b_{n-3}^2x^{n-3}+b_{n-2}^1x^{n-2}\right]$$
$$+2t\left[a_1^2+\binom{n-2}{1}a_2^2x+\cdots+\binom{n-2}{n-4}a_{n-3}^2x^{n-4}+\binom{n-2}{n-3}a_{n-2}^2x^{n-3}+b_{n-1}^1x^{n-2}\right]$$
$$+t^2\left[a_2^1+\binom{n-2}{1}a_3^1x+\cdots+\binom{n-2}{n-4}a_{n-2}^1x^{n-4}+\binom{n-2}{n-3}a_{n-1}^1x^{n-3}+a_n^1x^{n-2}\right],$$

$$K^{22\cdots211}=\left[b_0^3+\binom{n-2}{1}b_1^3t+\cdots+\binom{n-2}{n-4}a_{n-4}^3t^{n-4}+\binom{n-2}{n-3}a_{n-3}^2t^{n-3}+a_{n-2}^1t^{n-2}\right]$$
$$+2x\left[b_1^2+\binom{n-2}{1}b_2^2t+\cdots+\binom{n-2}{n-4}b_{n-3}^2t^{n-4}+\binom{n-2}{n-3}a_{n-2}^2t^{n-3}+a_{n-1}^1t^{n-2}\right]$$
$$+x^2\left[b_2^1+\binom{n-2}{1}b_3^1t+\cdots+\binom{n-2}{n-4}b_{n-2}^1t^{n-4}+\binom{n-2}{n-3}b_{n-1}^1t^{n-3}+a_n^1t^{n-2}\right].$$

We continue this process in both directions (i.e., going "downwards" and "upwards") until it is terminated in the middle of (27). In this view, counting the steps in both cases, it is easy to see that the dimension of the space $d=\dim \mathcal{K}_0^n(\mathbb{R}_1^2)=\frac{1}{2}(n+1)(n+2), n\geqslant 1$ gets decomposed as follows.

$$d=\begin{cases}[2(n+1)-1]+[2(n-1)-1]+\cdots+[2\times 1-1] & \text{if } n \text{ is even}\\ [2(n+1)-1]+[2(n-1)-1]+\cdots+[2\times 2-1] & \text{if } n \text{ is odd}\end{cases}. \tag{30}$$

The auxiliary problem of finding the general form for the elements $\boldsymbol{K}\in\mathcal{K}_0^n(\mathbb{R}_1^2)$ is therefore completely solved.

We immediately notice that the general solution (12) can be relabeled following the scheme (28) as follows:

$$\mathbf{K}=\begin{pmatrix}a_0^1+2a_1^1x+a_2^1x^2 & (a_0^2+b_1^1x)+t(a_1^1+a_2^1x)\\ (a_0^2+b_1^1x)+t(a_1^1+a_2^1x) & b_0^1+2b_1^1t+a_2^1t^2\end{pmatrix}. \tag{31}$$

To illustrate our results, consider more examples.

Example 4.1: $\mathcal{K}_0^4(\mathbb{R}_1^2)$. Note $d=\dim \mathcal{K}_0^4(\mathbb{R}_1^2)=15$. Following the formula (27) and the coefficient scheme (29),

$$K^{1111}=a_0^1+4a_1^1x+6a_2^1x^2+4a_3^1x^3+a_4^1x^4,$$

$$K^{1112}=(a_0^2+3a_1^2x+3a_2^2x^2+b_3^1x^3)+t(a_1^1+3a_2^1x+3a_3^1x^2+a_4^1x^3),$$

$$K^{1122}=(a_0^3+2b_1^2x+b_2^1x^2)+2t(a_1^2+2a_2^2x+b_3^1x^2)+t^2(a_2^1+2a_3^1x+a_4^1x^2), \tag{32}$$

$$K^{1222}=(b_0^2+3b_1^2t+3a_2^2t^2+a_3^1t^3)+x(b_1^1+3b_2^1t+3b_3^1t^2+a_4^1t^3),$$

$$K^{2222}=b_0^1+4b_1^1t+6b_2^1t^2+4b_3^1t^3+a_4^1t^4.$$

Example 4.2: $\mathcal{K}^5(\mathbb{R}_1^2)$. $d=\dim \mathcal{K}_0^5(\mathbb{R}_1^2)=21$.

$$K^{11111}=a_0^1+5a_1^1x+10a_2^1x^2+10a_3^1x^3+5a_4^1x^4+a_5^1x^5,$$

$$K^{11112}=(a_0^2+4a_1^2x+6a_2^2x^2+4a_3^2x^3+b_4^1x^4)+t(a_1^1+4a_2^1x+6a_3^1x^2+4a_4^1x^3+a_5^1x^4),$$

$$K^{11122} = (a_0^3 + 3a_1^3 x + 3b_2^2 x^2 + b_3^1 x^3) + 2t(a_1^2 + 3a_2^2 x + 3a_3^2 x^2 + b_4^1 x^3) + t^2(a_2^1 + 3a_3^1 x + 3a_4^1 x^2 + a_5^1 x^3),$$

$$K^{11222} = (b_0^3 + 3a_1^3 t + 3a_2^2 t^2 + a_3^1 t^3) + 2x(b_1^2 + 3b_2^2 t + 3a_3^2 t^2 + a_4^1 x^3) + x^2(b_2^1 + 3b_3^1 t + 3b_4^1 t^2 + a_5^1 t^3),$$

$$K^{12222} = (b_0^2 + 4b_1^2 t + 6b_2^2 t^2 + 4a_3^2 t^3 + a_4^1 t^4) + x(b_1^1 + 4b_2^1 t + 6b_3^1 t^2 + 4b_4^1 t^3 + a_5^1 t^4),$$
$$K^{22222} = b_0^1 + 5b_1^1 t + 10b_2^1 t^2 + 10b_3^1 t^3 + 5b_4^1 t^4 + a_5^1 t^5. \tag{33}$$

In principle, following the parameter scheme given above, i.e., using formulas (27)–(29), one can now write down explicitly the general form of the elements of $\mathcal{K}_0^n(\mathbb{R}_1^2)$ for an arbitrary n easily.

To solve Problem 2.1, we employ the MST-procedure[16] outlined in the previous section.

Using the formulas (19) and (27)–(29), we obtain the general formulas for the vector fields representing the infinitesimal action of the isometry group $I(\mathbb{R}_1^2)$ on the parameter space. As above, we have two cases corresponding to (28) and (29), respectively.

Case 1: $n=2k$

$$\begin{aligned}
\boldsymbol{V}_1 = \;& a_1^1\partial_{a_0^2} + a_2^1\partial_{a_1^2} + \cdots + a_{n-1}^1\partial_{a_{n-2}^2} \\
& + 2a_1^2\partial_{a_0^3} + 2a_2^2\partial_{a_1^3} + \cdots + 2a_{n-3}^2\partial_{a_{n-4}^3} \\
& \vdots \\
& + \frac{n}{2}a_1^{\frac{n}{2}}\partial_{a_0^{(n+2)/2}} \\
& + \frac{n+2}{2}b_1^{n/2}\partial_{b_0^{n/2}} + \frac{n}{2}a_2^{n/2}\partial_{b_1^{n/2}} \\
& \vdots \\
& + (n-1)b_1^2\partial_{b_0^2} + (n-2)b_2^2\partial_{b_1^2} + \cdots 2b_{n-2}^2\partial_{bn-3}^2 \\
& + nb_1^1\partial_{b_0^1} + (n-1)b_2^1\partial_{b_1^1} + \cdots + a_n^1\partial_{b_{n-1}^1};
\end{aligned} \tag{34}$$

$$\begin{aligned}
\boldsymbol{V}_2 = \;& b_1^1\partial_{b_0^2} + b_2^1\partial_{b_1^2} + \cdots + b_{n-1}^1\partial_{a_{n-2}^2} \\
& + 2b_1^2\partial_{b_0^3} + 2b_2^2\partial_{b_1^3} + \cdots + 2b_{n-3}^2\partial_{a_{n-4}^3} \\
& \vdots \\
& + \frac{n}{2}b_1^{\frac{n}{2}}\partial_{a_0^{(n+2)/2}} \\
& + \frac{n+2}{2}a_1^{n/2}\partial_{a_0^{n/2}} + \frac{n}{2}a_2^{n/2}\partial_{a_1^{n/2}} \\
& \vdots \\
& + (n-1)a_1^2\partial_{a_0^2} + (n-2)A_2^2\partial_{a_1^2} + \cdots + 2a_{n-2}^2\partial_{an-3}^2 \\
& + na_1^1\partial_{a_0^1} + (n-1)a_2^1\partial_{a_1^1} + \cdots + a_n^1\partial_{a_{n-1}^1};
\end{aligned} \tag{35}$$

$\boldsymbol{V}_3=$

$$
\begin{aligned}
&-na_0^2\partial_{a_0^1}-(n-1)a_1^2\partial_{a_1^1}-\cdots-2a_{n-2}^2\partial_{a_{n-2}^1}-b_{n-1}^1\partial_{a_{n-1}^1}\\
&-[(n-1)a_0^3+a_0^1]\partial_{a_0^2}-\cdots-[2b_{n-3}^2+a_{n-3}^1]\partial_{a_{n-3}^2}\\
&\vdots\\
&-\frac{n}{2}[a_0^{\frac{n}{2}}+b_0^{\frac{n}{2}}]\partial_{a_o^{(n+2)/2}}-\cdots-[a_{n-2}^1+b_{n-2}^1]\partial_{a_{n-2}^2}\\
&\vdots\\
&-[(n-1)b_0^3+b_0^1]\partial_{b_0^2}-\cdots-[2a_{n-3}^2+b_{n-3}^1]\partial_{b_{n-3}^2}\\
&-nb_0^2\partial_{b_0^1}-(n-1)b_1^2\partial_{b_1^1}-\cdots-2a_{n-2}^2\partial_{b_{n-2}^1}-a_{n-1}^1\partial_{b_{n-1}^1}.
\end{aligned}
\tag{36}
$$

Case 2: $n=2k+1$

$\boldsymbol{V}_1=$

$$
\begin{aligned}
&a_1^1\partial_{a_0^2}+a_2^1\partial_{a_1^2}+\cdots+a_{n-1}^1\partial_{a_{n-2}^2}\\
&+2a_1^2\partial_{a_0^3}+2a_2^2\partial_{a_1^3}+\cdots+2a_{n-3}^2\partial_{a_{n-4}^3}\\
&\vdots\\
&+\frac{n+1}{2}a_1^{(n+1)/2}\partial_{b_0^{(n+1)/2}}\\
&+\frac{n+3}{2}b_1^{(n-1)/2}\partial_{b_0^{(n-1)/2}}+\frac{n+1}{2}b_1^{(n-1)/2}\partial_{b_1^{(n-1)/2}}+\frac{n-1}{2}a_3^{(n-1)/2}\partial_{b_2^{(n-1)/2}}\\
&\vdots\\
&+(n-1)b_1^2\partial_{b_0^2}+(n-2)b_2^2\partial_{b_1^2}+\cdots 2a_{n-2}^2\partial_{b_{n-3}^2}\\
&+nb_1^1\partial_{b_0^1}+(n-1)b_2^1\partial_{b_1^1}+\cdots+2b_{n-1}^1\partial_{b_{n-2}^1}+a_n^1\partial_{b_{n-1}^1};
\end{aligned}
\tag{37}
$$

$\boldsymbol{V}_2=$

$$
\begin{aligned}
&b_1^1\partial_{b_0^2}+b_2^1\partial_{b_1^2}+\cdots+b_{n-1}^1\partial_{a_{n-2}^2}\\
&+2b_1^2\partial_{b_0^3}+2b^2\partial_{b_1^3}+\cdots+2b_{n-3}^2\partial_{a_{n-4}^3}\\
&\vdots\\
&+\frac{n+1}{2}a_1^{(n+1)/2}\partial_{a_0^{(n+1)/2}}\\
&+\frac{n+3}{2}a_1^{(n-1)/2}\partial_{a_0^{(n-1)/2}}+\frac{n+1}{2}a_2^{(n+1)/2}\partial_{b_1^{(n-1)/2}}+\frac{n-1}{2}a_3^{(n-1)/2}\partial_{a_2^{(n-1)/2}}\\
&\vdots\\
&+(n-1)a_1^2\partial_{a_0^2}+(n-2)a_2^2\partial_{a_1^2}+\cdots+2a_{n-2}^2\partial_{a_{n-3}^2}\\
&+na_1^1\partial_{a_0^1}+(n-1)a_2^1\partial_{a_1^1}+\cdots+2a_{n-1}^1\partial_{a_{n-2}^1}+a_n^1\partial_{a_{n-1}^1};
\end{aligned}
\tag{38}
$$

$$
\begin{aligned}
\boldsymbol{V}_3 = & \\
& -na_0^2\partial_{a_0^1} - (n-1)a_1^2\partial_{a_1^1} - \cdots 2a_{n-2}^2\partial_{a_{n-2}^1} - b_{n-1}^1\partial_{a_{n-1}^1} \\
& -[(n-1)a_0^3 + a_0^1]\partial_{a_0^2} - \cdots - [2b_{n-3}^2 + a_{n-3}^1]\partial_{a_{n-3}^2} \\
& \vdots \\
& -\left[\frac{n+1}{2}b_0^{\frac{n+1}{2}} + \frac{n-1}{2}a_0^{\frac{n-1}{2}}\right]\partial_{a_0^{(n+1)/2}} \\
& -\frac{n-1}{2}\left[a_1^{\frac{n-1}{2}} + b_1^{\frac{n-1}{2}}\right]\partial_{a_1^{\frac{n+1}{2}}} - \cdots - [a_{n-2}^1 + b_{n-2}^1]\partial_{a_{n-2}^2} \\
& -\left[\frac{n+1}{2}a_0^{\frac{n+1}{2}} + \frac{n-1}{2}b_0^{\frac{n-1}{2}}\right]\partial_{b_0^{\frac{(n+1)}{2}}} \\
& \vdots \\
& -[(n-1)b_0^3 + b_0^1]\partial_{b_0^2} - \cdots - [2a_{n-3}^2 + b_{n-3}^1]\partial_{b_{n-3}^2} \\
& -nb_0^2\partial_{b_0^1} - (n-1)b_1^2\partial_{b_1^1} - \cdots - 2a_{n-2}^2\partial_{b_{n-2}^1} - a_{n-1}^1\partial_{b_{n-1}^1}.
\end{aligned}
\tag{39}
$$

We remark that in both cases the vector fields $\boldsymbol{V}_1, \boldsymbol{V}_2$, and $\boldsymbol{V}_3$ correspond to the generators $\boldsymbol{T}, \boldsymbol{X}$, and $\boldsymbol{H}$ given by (13), respectively. Moreover, it is easy to verify directly that the vector fields $-\boldsymbol{V}_1, -\boldsymbol{V}_2$, and $-\boldsymbol{V}_3$ satisfy the same commutator relations (14) as $\boldsymbol{T}, \boldsymbol{X}$, and $\boldsymbol{H}$. We conclude therefore that $\boldsymbol{V}_i, i=1, 2, 3$ represent the infinitesimal action of the isometry group $I(\mathbb{R}_1^2)$ on the parameter space Σ defined by $\mathcal{K}_0^n(\mathbb{R}_1^2)$ for each $n \geqslant 1$ and we have proven an ITKT analog of Lemma 2.1 of Cayley:[3]

Theorem 4.1: *The action of the isometry group $I(\mathbb{R}_1^2)$ on the vector space $\mathcal{K}_0^n(\mathbb{R}_1^2)$ has the infinitesimal generators (34)–(36) when n is even and (37)–(39) when n is odd.*

Example 4.3: $\mathcal{K}_0^4(\mathbb{R}_1^2)$. Using Theorem 4.1,

$$
\boldsymbol{V}_1 = a_1^1\partial_{a_0^2} + a_2^1\partial_{a_1^2} + a_3^1\partial_{a_2^2} + 2a_1^2\partial_{a_0^3} + 3b_1^2\partial_{b_0^2} + 2a_2^2\partial_{b_1^2} + 4b_1^1\partial_{b_0^1} + 3b_2^1\partial_{b_1^1} + 2b_3^1\partial_{b_2^1} + a_4^1\partial_{b_3^1},
\tag{40}
$$

$$
\boldsymbol{V}_2 = b_1^1\partial_{b_0^2} + b_2^1\partial_{b_1^2} + b_3^1\partial_{a_2^2} + 2b_1^2\partial_{a_0^3} + 3a_1^2\partial_{a_0^2} + 2a_2^2\partial_{a_1^2} + 4a_1^1\partial_{b_0^1} + 3a_2^1\partial_{b_1^1} + 2a_3^1\partial_{b_2^1} + a_4^1\partial_{a_3^1},
\tag{41}
$$

$$
\begin{aligned}
\boldsymbol{V}_3 = & -4a_0^2\partial_{a_0^1} - 3a_1^2\partial_{a_1^1} - 2a_2^2\partial_{a_2^1} - b_3^1\partial_{a_3^1} - (3a_0^3 + a_0^1)\partial_{a_0^2} - (2b_1^2 + a_1^1)\partial_{a_1^2} - 2(a_0^2 + b_0^2)\partial_{a_0^3} - (a_2^1 + b_2^1)\partial_{a_2^2} \\
& -(3a_0^3 + b_0^1)\partial_{b_0^2} - (2a_1^2 + b_1^1)\partial_{b_1^2} - 4b_0^2\partial_{b_0^1} - 3b_1^2\partial_{b_1^1} - 2a_2^2\partial_{b_2^1} - a_3^1\partial_{b_3^1}.
\end{aligned}
\tag{42}
$$

Example 4.4: $\mathcal{K}_0^5(\mathbb{R}_1^2)$. Using again Theorem 4.1,

$$
\begin{aligned}
\boldsymbol{V}_1 = & a_1^1\partial_{a_0^2} + a_2^1\partial_{a_1^2} + a_3^1\partial_{a_2^2} + a_4^1\partial_{a_3^2} + 2a_1^2\partial_{a_0^3} + 2a_2^2\partial_{a_1^3} + 3a_1^3\partial_{b_0^3} + 4b_1^2\partial_{b_0^2} + 3b_2^2\partial_{b_1^2} + 2a_3^2\partial_{b_2^2} + 5b_1^1\partial_{b_0^1} \\
& + 4b_2^1\partial_{b_1^1} + 3b_3^1\partial_{b_2^1} + 2b_4^1\partial_{b_3^1} + a_5^1\partial_{b_4^1},
\end{aligned}
\tag{43}
$$

$$
\begin{aligned}
\boldsymbol{V}_2 = & b_1^1\partial_{b_0^2} + b_2^1\partial_{b_1^2} + b_3^1\partial_{b_2^2} + b_4^1\partial_{a_3^2} + 2b_1^2\partial_{b_0^3} + 2a_2^2\partial_{a_1^3} + 3a_1^3\partial_{a_0^3} + 4a_1^2\partial_{a_0^2} + 3a_2^2\partial_{a_1^2} + 2a_3^2\partial_{a_2^2} + 5a_1^1\partial_{a_0^1} \\
& + 4a_2^1\partial_{a_1^1} + 3a_3^1\partial_{a_2^1} + 2a_4^1\partial_{a_3^1} + a_5^1\partial_{a_4^1},
\end{aligned}
\tag{44}
$$

$$\begin{aligned}\boldsymbol{V}_3 = &-5a_0^2\partial_{a_0^1} - 4a_1^2\partial_{a_1^1} - 3a_2^2\partial_{a_2^1} - 2a_3^2\partial_{a_3^1} - b_4^1\partial_{a_4^1} - (4a_0^3 + a_0^1)\partial_{a_0^2} - (3a_1^3 + a_1^1)\partial_{a_1^2} - (2b_2^2 + a_2^1)\partial_{a_2^2} \\ &- (3b_0^3 + 2a_0^2)\partial_{a_0^3} - 2(b_1^2 + a_1^2)\partial_{a_1^3} - (a_3^1 + b_3^1)\partial_{a_3^2} - (3a_0^3 + 2b_0^2)\partial_{b_0^3} - (4b_0^3 + b_0^1)\partial_{b_0^2} - (3a_1^3 + b_1^1)\partial_{b_1^2} \\ &- (2a_2^2 + b_2^1)\partial_{b_2^2} - 5b_0^2\partial_{b_0^1} - 4b_1^2\partial_{b_1^1} - 3b_2^2\partial_{b_2^1} - 2a_3^2\partial_{b_3^1} - a_4^1\partial_{b_4^1}. \end{aligned} \tag{45}$$

Using the result of Theorem 4.1 one can compute the $I(\mathbb{R}_1^2)$-invariants:

Theorem 4.2: *Any function* $I:\Sigma\to\mathbb{R}$ *is an* $I(\mathbb{R}_1^2)$*-invariant of* $\mathcal{K}_0^n(\mathbb{R}_1^2)$ *if and only if it satisfies the infinitesimal invariance criteria*

$$\boldsymbol{V}_i(I) = 0, \quad i = 1,2,3, \tag{46}$$

where Σ *is the parameter space and* $\boldsymbol{V}_i, i=1, 2, 3$ *are given in Theorem 4.1.*

Corollary 4.1: *The parameter* a_n^1 *[refer to the formulas* (28) and (29) *when n is even and odd, respectively] is a fundamental* $I(\mathbb{R}_1^2)$*-invariant of* $\mathcal{K}_0^n(\mathbb{R}_1^2)$.

In view of Theorem 4.2 the problem of the determination of the space of $I(\mathbb{R}_1^2)$-invariants reduces to solving the system of linear PDEs resulting from the vector fields in Theorem 4.1. For larger values of n the problem becomes very challenging computationally. The method of characteristics may fail, in which case one can employ the method of undetermined coefficients in conjuncture with the result of the fundameatal theorem on invariants of a regular Lie group action (Theorem 2.1), as well as computer algebra. This technique was used with a remarkable success in Horwood *et al.*[12] to solve the problem of the determination of the space of $I(\mathbb{R}^3)$-invariants of $\mathcal{K}_0^2(\mathbb{R}^3)$, where $\mathbb{R}^3$ denotes the Euclidean space.

Theorem 4.1 also entails the corresponding criteria for $I(\mathbb{R}_1^2)$-covariants (see Ref. 28 for more details) of $\mathcal{K}_0^n(\mathbb{R}_1^2)$.

Theorem 4.3: *Let* $\mathcal{K}_0^n(\mathbb{R}_1^2)$ *be the vector space of Killing tensors of valence n defined in the Minkowski plane* $\mathbb{R}_1^2$. *A function* $C:\Sigma\times\mathbb{R}_1^2\to\mathbb{R}$ *is an* $I(\mathbb{R}_1^2)$*-covariant of* $\mathcal{K}^n(\mathbb{R}_1^2)$ *if and only if it satisfies the infinitesimal invariance conditions*

$$\begin{aligned}(\boldsymbol{V}_1 + \boldsymbol{T})(C) &= 0, \\ (\boldsymbol{V}_2 + \boldsymbol{X})(C) &= 0, \\ (\boldsymbol{V}_3 + \boldsymbol{H})(C) &= 0,\end{aligned} \tag{47}$$

where Σ *is the parameter space*, $\boldsymbol{T}$,$\boldsymbol{X}$, *and* $\boldsymbol{H}$ *are given in* (13) *and* $\boldsymbol{V}_i$, $i=1, 2, 3$ *are specified in Theorem 4.1.*

V. CONCLUSIONS

In this article we have formulated and proven an ITKT analog of Cayley's Lemma in CIT. A similar result for the vector space $\mathcal{K}_0^n(\mathbb{R}^2), n\geqslant 1$ (where $\mathbb{R}^2$ denotes the Euclidean plane) can be obtained *mutatis mutandis*. A more challenging problem is to extend the result to two-dimensional spaces of nonzero curvature, namely when the underlying manifold is $\mathbb{S}^2$ (two-sphere) or $\mathbb{H}^2$ (hyperbolic plane). The work in this direction is under way.[1,2,26]

In a forthcoming article[30] we will present a natural continuation of the project initiated here, namely the determination of all fundamental invariants of vector spaces of Killing tensors of arbitrary valence defined in the Minkowski plane, employing the inductive version of the moving frames method.[14]

ACKNOWLEDGMENTS

The author wishes to thank his thesis advisor Roman Smirnov for introducing him to the subject and formulating the problem. He also expresses his gratitude for valuable discussions and

suggestions pertinent to this research with Michael Eastwood, Joshua Horwood, Keith Johnson, Ray McLenaghan, Dorette Pronk, and Dennis The. The research was supported by an Izaak Walton Killam Scholarship.

(Received 23 September 2004; accepted 19 May 2005; published online 30 June 2005)

Summation formulas are obtained for products of associated Lagurre polynomials by means of the Green's function K for the Hamiltonian $H_0=-d^2/\mathrm{d}x^2+x^2+Ax^{-2}$ $(A>0)$. K is constructed by an application of a Mercer-type theorem that arises in connection with integral equations. The approach introduced in this paper may be useful for the construction of wider classes of generating function. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1952581]

I. INTRODUCTION AND MAIN RESULTS

Since the early development of quantum mechanics, highly singular potentials have attracted much attention. Two main reasons for this are (1) regular perturbation theory can fail badly for such potentials, and (2) in physics one often encounters phenomenological potentials that are strongly singular at the origin such as certain types of nucleon-nucleon interaction, and singular models of fields in arbitrary dimensions. A specific family of singular quantum Hamiltonians known as generalized harmonic oscillators given by

$$H(\lambda)=H_0+\frac{\lambda}{x^\alpha}=-\frac{d^2}{\mathrm{d}x^2}+x^2+\frac{A}{x^2}+\frac{\lambda}{x^\alpha}\quad(A\geqslant 0,\alpha>0,\lambda\geqslant 0)\tag{1.1}$$

and acting in the Hilbert space $L_2(0,\infty)$ have been subject to intensive investigation recently. For a background and brief history of these problems we refer the reader to the summary in Ref. 1. We have shown[1,2] that the set of eigenfunctions of $H_0=H(0)$, namely

$$\psi_n(x)\equiv(-1)^n\sqrt{\frac{2(\gamma)_n}{n!\Gamma(\gamma)}}x^{\gamma-1/2}e^{-x^2/2}\,{}_1F_1(-n;\gamma;x^2)\ \text{with}\ \gamma\equiv 1+\frac{1}{2}\sqrt{1+4A}\quad(n=0,1,2,\ldots),\tag{1.2}$$

constitutes an orthonormal basis for the Hilbert space $L_2(0,\infty)$. Here ${}_1F_1$ stands for the confluent hypergeometric function defined in terms of the associated Laguerre polynomials $L_n^{\gamma-1}(z)$ by

$${}_1F_1(-n;\gamma;z)=\frac{n!}{(\gamma)_n}L_n^{\gamma-1}(z).\tag{1.3}$$

This basis has proven to be useful in providing a complete variational study[1–5] of the spectrum of $H(\lambda)$ for arbitrary fixed $A\geqslant 0$, and λ, $\alpha>0$. The advantage over earlier studies in the Hermite basis $A=0$ was that for $A>0$ the H_0 basis itself derives from a singular problem with the term

A/x^2. In the present paper. we explore another aspect of this basis. We shall prove that the eigenfunctions $\psi_n(x)$ satisfy the following identity:

$$\sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{4n+2\gamma} = \begin{cases} w(x)v(y) & \text{for } 0 \leqslant y \leqslant x, \\ v(x)w(y) & \text{for } 0 \leqslant x \leqslant y. \end{cases} \tag{1.4}$$

where

$$w(x)v(y) = 2^{-1}\sqrt{xy}K_\nu\left(\frac{x^2}{2}\right)I_\nu\left(\frac{y^2}{2}\right), \quad \text{where } \nu = \tfrac{1}{2}(\gamma-1).$$

In particular, we have, for $x=y$, that

$$\sum_{n=0}^{\infty} \frac{|\psi_n(x)|^2}{4n+2\gamma} = 2^{-1}xK_\nu\left(\frac{x^2}{2}\right)I_\nu\left(\frac{x^2}{2}\right). \tag{1.5}$$

Here $I_\nu(x)$ and $K_\nu(x)$ are modified Bessel functions of the first and second kind, respectively. There are direct applications for these identities. An obvious application is that it can been seen as complimentary identity for Watson's famous result[6] (see also, Ref. 7, p. 140, formula 14),

$$\sum_{n=0}^{\infty} \frac{(\gamma)_n}{n!(1+n)} {}_1F_1(-n;\gamma;x)\,{}_1F_1(-n;\gamma;y) = {}_1F_1(1;\gamma;y)\left(\Gamma(\gamma-1)x^{1-\gamma}e^x - \frac{1}{\gamma-1}\,{}_1F_1(1;\gamma;x)\right), \tag{1.6}$$

valid for $x \geqslant y \geqslant 0$. Second, it can be used in theory of coherent states to provide, for example, normalization factors of class of coherent states labeled by confluent hypergeometric functions. Third, there are standard techniques known for generating closed form sums for products of hypergeometric functions and related polynomials, such as Laguerre polynomials. Srivastava *et al.*[8–10] have discussed many different techniques that can be used for such purposes. It is noteworthy that the use of a kernel of a differential equation and a Mercer-type theorem is not an idea that has been well explored in this context. It is our goal in the present paper to show the usefulness of this approach to the construction of generating functions.

In order to prove our main results, we organize the paper as follows. In Sec. II, we introduce two linearly independent solutions of the second-order homogeneous differential equation $H_0u = [-(d^2/dx^2)+(x^2+Ax^{-2})]u=0$. In Sec. III, we construct the Green's function of H_0 and study some of its properties. The majorization of the Kernel operator $K(x,y)$ is investigated in Sec. IV. In Sec. V, we introduce and prove a Mercer-type theorem that allows us to conclude the absolute and uniform convergence of the kernel $K(x,y)$ on the Hilbert space $L_2(0,\infty)$, and consequently prove our main results, Theorem 1 and Theorem 2, from which formulas (1.4) and (1.5) follow immediately.

II. SECOND-ORDER DIFFERENTIAL EQUATION AND ITS SOLUTIONS

If we set $u(z)=z^\alpha\psi(z)$ with $z=\frac{1}{2}x^2$, we can easily show $H_0u=0$ reduces to

$$\frac{d^2\psi}{dz^2} + \frac{\left(2\alpha+\frac{1}{2}\right)}{z}\frac{d\psi}{dz} - \left[1 + \frac{4\alpha\left(\alpha-\frac{1}{2}\right)-A}{4z^2}\right]\psi(z) = 0. \tag{2.1}$$

If we adjust α so that $\psi(z)$ satifies the modified Bessel function

$$\frac{d^2\psi}{dz^2} + z^{-1}\frac{d\psi}{dz} - [\nu^2z^{-2}+1]\psi(z) = 0,$$

we obtain, for $\alpha=\frac{1}{4}$ and $\nu=\frac{1}{4}\sqrt{1+4A}$, and from the basis $\{\sqrt{x}I_\nu(x^2/2), \sqrt{x}K_\nu(x^2/2)\}$, the two linearly independent solutions

$$v(x) = B\sqrt{x}I_\nu\left(\frac{x^2}{2}\right), \quad w(x) = C\sqrt{x}K_\nu\left(\frac{x^2}{2}\right), \tag{2.2}$$

where B and C are constants to be determined. We note that, the Wronskian of $I_\nu(z)$ and $K_\nu(z)$ satisfies [Ref. 6, p. 80, formula (90)]

$$I_\nu(z)K'_\nu(z) - I'_\nu(z)K_\nu(z) = -z^{-1},$$

which equation we divide by $I_\nu^2(z)$ and thereby obtain the derivative of the quotient $(K_\nu/I_\nu)(z)$, namely

$$\left(\frac{K_\nu}{I_\nu}\right)'(z) = z^{-1}I_\nu^{-2}(z).$$

We integrate this expression from z to ∞ [using the properties $K_\nu(\infty)=0$ and $I_\nu(\infty)=\infty$] and thus we arrive at

$$\left(\frac{K_\nu}{I_\nu}\right)(z) = \int_z^\infty \frac{1}{\xi I_\nu^2(\xi)}\mathrm{d}\xi. \tag{2.3}$$

On the other hand, we make the replacements $z=x^2/2$, $K_\nu(x^2/2)=C^{-1}x^{-1/2}w(x)$, and $I_\nu(x^2/2)=B^{-1}x^{-1/2}v(x)$ in the immediately preceding formula, and find

$$\frac{K_\nu(x^2/2)}{I_\nu(x^2/2)} = \frac{B}{C}\times\frac{\omega(x)}{v(x)} = \int_{x^2/2}^\infty \frac{1}{\xi I_\nu^2(\xi)}\mathrm{d}\xi,$$

where in the last integral we make the substitution $I_\nu(\xi)=B^{-1}(2\xi)^{-1/4}v(\sqrt{2\xi})$ thereby giving us

$$\frac{B}{C}\times\frac{w(x)}{v(x)} = \int_{\xi=x^2/2}^\infty \xi^{-1}\left[\frac{v(\sqrt{2\xi})}{B(\sqrt{2\xi})}\right]^{-2}\mathrm{d}\xi = 2B^2\int_{\xi=x^2/2}^\infty \frac{1}{2\xi v^2(\sqrt{2\xi})(2\xi)^{-1/2}}\mathrm{d}\xi = 2B^2\int_{r=x}^\infty \frac{1}{v^2(r)}\mathrm{d}r.$$

The last integral expression was obtained via the substitution $r=\sqrt{2\xi}$. Equating the first expression with the last in the above equations leads to

$$\frac{w(x)}{v(x)} = 2BC\int_{r=x}^\infty \frac{1}{v^2(r)}\mathrm{d}r \quad \text{or equivalently } w(x) = 2BCv(x)\int_{r=x}^\infty \frac{1}{v^2(r)}\mathrm{d}r. \tag{2.4}$$

However, reduction of the order of the original differential equation implies that

$$v(x)\int_{r=x}^\infty \frac{1}{v^2(r)}\mathrm{d}r$$

is the other solution of $H_0u=0$, independent of $v(x)$, which result lets us conclude that $2BC=1$ or $BC=1/2$.

III. MAPPING PROPERTIES OF THE GREEN'S FUNCTION IN $L_2(0,\infty)$

For the operator

$$H_0 = -\frac{d^2}{\mathrm{d}x^2} + (x^2 + Ax^{-2}), \tag{3.1}$$

the linear space $D(H_0)$, consisting of all functions $u\in C^2(0,\infty)\cap C[0,\infty)$ with $u(0)=0$, becomes a normed linear space by setting $\|u\|_\infty \equiv \sup|u([0,\infty))|$. For the Green's function of the linear transformation $H_0: D(H_0)\mapsto C[0,\infty)$, we now formulate a well-known result from the theory of ordi-

nary differential equations, which may be easily arrived at from the properties of Green's function as stated in Refs. 11–13.

Lemma 1: *The differential operator H_0 maps $D(H_0)$ bijectively onto $C[0,\infty)$ by means of $H_0^{-1}: f \mapsto u$, where*

$$(H_0^{-1})f(x) = u(x) \equiv w(x)\int_{\xi=0}^{x} v(\xi)f(\xi)\mathrm{d}\xi + v(x)\int_{\xi=x}^{\infty} w(\xi)f(\xi)\mathrm{d}\xi, \tag{3.2}$$

with $\|H_0^{-1}f\|_\infty \leqslant 4A^{-1/2}\|f\|_\infty$.

Proof: The boundedness of H_0^{-1} is simply a consequence of the inequality

$$v(x)\int_{\xi=x}^{\infty} [v(\xi)]^{-2}\,\mathrm{d}\xi \leqslant \frac{\sqrt{2}}{a}[v(x)]^{-1}, \tag{3.3}$$

where $a \equiv \sqrt[4]{A}$, the value of x where the potential $q_A(x) = x^2 + Ax^{-2}$ assumes its minimum. Indeed, since the function $q_A(x)$ assumes its minimum value $q_A(\sqrt[4]{A}) = 2\sqrt{A} = 2a^2$ at the point $x = a \equiv \sqrt[4]{A}$, we note that

$$v(x) = v(x') + (x-x')v'(x') + \int_{\xi=x'}^{x} (x-\xi)q_A(\xi)v(\xi)\mathrm{d}\xi \quad \text{for } 0 \leqslant x' \leqslant x,$$

and from this directly deduce

$$v(x) \geqslant v(x') + 2a^2\int_{\xi=x'}^{x} (x-\xi)v(\xi)\mathrm{d}\xi \quad \text{for } 0 \leqslant x' \leqslant x.$$

By substituting $v(\xi) \geqslant v(x') + 2a^2\int_{\eta=x'}^{\xi}(\xi-\eta)v(\eta)\mathrm{d}\eta$ into the previous integral inequality, we further arrive at

$$v(x) \geqslant \left\{1 + \frac{1}{2!}2a^2(x-x')^2\right\}v(x') + \frac{1}{3!}(2a^2)^2\int_{\xi=x'}^{x}(x-\xi)^3 v(\xi)\mathrm{d}\xi \quad \text{for } 0 \leqslant x' \leqslant x.$$

Iterating this procedure leads to $v(x) \geqslant v(x')\cosh\sqrt{2a}(x-x')$ for $x \geqslant x' \geqslant 0$. In particular

$$v(x) \geqslant 2^{-1}\exp(\sqrt{2}a(x-x'))v(x') \quad \text{for } x \geqslant x' \text{ and } v(x) \geqslant 2^{-1}\exp(\sqrt{2}a(x-a))v(a) \quad \text{for } x \geqslant a,$$

which can also be written in the form $v(x') \leqslant 2\exp(-\sqrt{2}a(x-x'))v(x)$ for $x \geqslant x' \geqslant 0$ and this in turn leads to

$$\int_{\xi=a}^{x} v(\xi)\mathrm{d}\xi \leqslant \frac{\sqrt{2}}{a}v(x).$$

This result is also evident from the integration of the inequality $v(\xi) \leqslant 2\exp(-\sqrt{2}a(x-\xi))v(x)$ with respect to ξ on the interval (a,x). As a result of $v(\xi) \geqslant 2^{-1}\exp(\sqrt{2}a(\xi-x))v(x)$ for all $\xi \geqslant x$, or by means of $[v(\xi)]^{-2} \leqslant 4\exp(2\sqrt{2}a(x-\xi))[v(x)]^{-2}$, leads to the inequality

$$\int_{\xi=x}^{\infty}[v(\xi)]^{-2}\,\mathrm{d}\xi \leqslant 4\int_{\xi=x}^{\infty}\exp(2\sqrt{2}a(x-\xi))\mathrm{d}\xi \times [v(x)]^{-2} \leqslant \frac{\sqrt{2}}{a}[v(x)]^{-2},$$

which proves (3.3). The injective nature of $H_0^{-1}: C[0,\infty) \to D(H_0)$ is demonstrated as follows. Let $u(x)$ be a solution of $H_0u = 0$ with $u(0) = 0$, whence $u(x) = B\omega(x) + Cv(x)$. On account of the asymptotic behavior of $w(x)$ and $v(x)$ as $x \to 0^+$, namely $w(x)$ and $v(x) \to \infty$ and 0, respectively, as $x \to 0^+$, combined with $\|u\|_\infty < \infty$ leads to $B = 0$, that is to say $u(x) = Cv(x)$; however, the asymptotic behavior of $v(x)$, namely

$$v(x) = \frac{1}{\sqrt{\pi x}} e^{x^2/2}[1 + O(x^2)]$$

as $x \to \infty$, implies that $C=0$. Thus $H_0: D(H_0) \to C[0,\infty)$ is bijective. This completes the proof.■

We have therefore that the Green's function $K(x,y)$ of the differential operator $H_0: D(H_0) \to C[0,\infty)$, which permits us to write the action of H_0^{-1} in terms of integration on $[0,\infty)$, has the integral representation

$$H_0^{-1} f(x) = \int_0^\infty K(x,y) f(y) \mathrm{d}y, \tag{3.4}$$

where

$$K(x,y) = \begin{cases} w(x)v(y) & \text{for } 0 \leqslant y \leqslant x, \\ v(x)w(y) & \text{for } 0 \leqslant x \leqslant y. \end{cases} \tag{3.5}$$

It thus becomes evident that the kernel $K(x,y)$ is a continuous non-negative function on $[0,\infty) \times [0,\infty)$ because, for $\nu = \frac{1}{2}(\gamma - 1) = \frac{1}{4}\sqrt{1+4A}$, $\sqrt{x} I_\nu(x^2/2)$ and $\sqrt{x} K_\nu(x^2/2)$ are continuous on $[0, \infty)$ and $(0, \infty)$, respectively, and, furthermore, both are positive on $(0, \infty)$. Thus $K(x,y)$ is continuous on $[0,\infty) \times [0,\infty) \backslash \{(0,0)\}$.

For the continuity at (0,0) we again turn to the asymptotic behavior of $w(x)$ and $v(x)$ as $x \to 0^+$. In the lower sector $\{(x,y): 0 \leqslant \mathrm{arctg}(y/x) \leqslant \pi/4\}$ of the first quadrant of the (x,y) plane, we have that

$$\begin{aligned} K(x,y) = w(x)v(y) &= \frac{1}{4\pi\nu} x^{1/2-2\nu}[1 + O(x^\epsilon)] y^{1/2+2\nu}[1 + O(y^4)] \\ &= \frac{1}{4\pi\nu} (xy)^{1/2} (y/x)^{2\nu} [1 + O(y^4)][1 + O(x^\epsilon)] \to 0 \quad \text{as} (x,y) \to (0,0), \end{aligned}$$

because in this sector $|y/x| \leqslant 1$. Consequently, $K(x,y)$ is continuous in the lower sector $\{(x,y): 0 \leqslant \mathrm{arctg}(y/x) \leqslant \pi/4\}$, whereas the symmetry of $K(x,y)$, i.e. $K(x,y) = K(y,x)$, guarantees the continuity in upper sector $\{(x,y): \pi/4 \leqslant \mathrm{arctg}(y/x) \leqslant \pi/2\}$ of the first quadrant of the (x,y) plane.

We know further that $H_0 u \equiv -d^2u/\mathrm{d}x^2 + [x^2 + Ax^{-2}]u = 0$ $(A > 0)$ is a symmetric lower semibounded operator in the Hilbert space $L_2(0,\infty)$ with domain of definition consisting of all $L_2(0,\infty)$ functions u vanishing at 0, having absolutely continuous derivative $u' \in L_2(0,\infty)$, on $[0, \infty)$ such that $[x^2 + Ax^{-2}]u(x)$ is also an $L_2(0,\infty)$ function in x. Since the linear manifold $C_0^\infty(0,\infty)$, of all complex valued infinitely differentiable function on $(0, \infty)$ with compact support, lies dense in this domain of definition of H_0 as well as in $L_2(0,\infty)$, we readily conclude that the domain of definition of H_0 is also a dense subset of $L_2(0,\infty)$. Thus H_0 possesses a Friedrichs' extension, which extension we again denote by H_0, and this extension (Ref. 14, Secs. 7.2–7.3 and Ref. 15, p. 335) is a self-adjoint operator in $L_2(0,\infty)$. For $H_0\psi_n = E_n\psi_n$ and because the orthonormalized set of eigenfunctions (1.2) with corresponding eigenvalues $E_n = 4n + 2\gamma = 4n + 2 + \sqrt{1+4A}$ of H_0 forms[1] a complete orthonormal set of functions of the Hilbert space $L_2(0,\infty)$, we shall have that the spectrum of this Friedrichs' extension H_0 is a purely point-spectrum, consisting only of the simple eigenvalues $E_n = 4n + 2\gamma = 4n + 2 + \sqrt{1+4A}$. Thus the spectral family $\{P_\mu: \mu \in \Re\}$ of H_0, which is an "increasing" projection-operator valued Saltus function on the set $\Re$ of real numbers (Ref. 17, p. 92 and Ref. 15, Chap. I, Sec. 7), is

$$P_\mu \equiv \begin{cases} 0 & \text{for } -\infty < \mu < 2\gamma, \\ \psi_0 \otimes \psi_0 & \text{for } 4(0) + 2\gamma \leqslant \mu < 4(1) + 2\gamma, \\ \psi_0 \otimes \psi_0 + \psi_1 \otimes \psi_1 & \text{for } 4(1) + 2\gamma \leqslant \mu < 4(2) + 2\gamma, \\ \psi_0 \otimes \psi_0 + \psi_1 \otimes \psi_1 + \psi_2 \otimes \psi_2 & \text{for } 4(2) + 2\gamma \leqslant \mu < 4(3) + 2\gamma, \\ \cdots, & \\ \sum_{k=0}^{n-1} \psi_k \otimes \psi_k & \text{for } 4(n-1) + 2\gamma \leqslant \mu < 4(n) + 2\gamma, \\ \cdots. & \end{cases} \tag{3.6}$$

For any two $L_2(0,\infty)$ functions ψ and ϕ, the expression $\psi \otimes \phi$ denotes the operator of rank 1 defined by

$$(\phi \otimes \psi) f(x) \equiv \langle f | \psi \rangle \phi(x) = \left[\int_{\xi=0}^{\infty} f(\xi) \overline{\psi(\xi)} \mathrm{d}\xi \right] \times \phi(x) = \int_{\xi=0}^{\infty} (\phi \otimes \psi)(x,\xi) f(\xi) \mathrm{d}\xi, \tag{3.7}$$

with L_2 kernel $(\phi \otimes \psi)(x,y) \equiv \phi(x)\overline{\psi(y)}$ on $L_2(0,\infty)$, which in our case turns out to be an integral operator. It is further clear that the spectral family $\{P_\mu : \mu \in \Re\}$ is increasing in μ, i.e., $P_\lambda \leqslant P_\mu$ for $\lambda \leqslant \mu$, as well as continuous from the right, i.e., $P_\mu = P_{\mu+0}$, in the sense of strong convergence (denoted by $\rightarrow$) in the Hilbert space $L_2(0,\infty)$. Moreover, $P_\mu \rightarrow 0$ or I (the identity operator) according as $\mu \rightarrow -\infty$ or ∞. In consequence, the spectral decomposition (Ref. 15, Sec. 120, p. 320) of our self-adjoint operator H_0 allows H_0 to be represented (as well as functions of H_0) as a Stieltjes integral of μ (functions of μ) with respect to the spectral family $\{P_\mu\}$ on the set $\Re = (-\infty,\infty)$ of real numbers. This turns out to be

$$H_0 = \int_{-\infty}^{\infty} \mu d_\mu P_\mu \tag{3.8}$$

with

$$D(H_0) = \left\{ f \in L_2(0,\infty) : \int_{-\infty}^{\infty} \mu^2 d_\mu \| P_\mu f \|^2 = \sum_{n=0}^{\infty} (4n + 2\gamma)^2 |\langle f | \psi_n \rangle|^2 < \infty \right\}$$

and

$$H_0^{-1} = \int_{-\infty}^{\infty} \mu^{-1} d_\mu P_\mu = \sum_{n=0}^{\infty} (4n + 2\gamma)^{-1} [P_{4n+2\gamma} - P_{4n+2\gamma-0}] = \sum_{n=0}^{\infty} (4n + 2\gamma)^{-1} (\psi_n \otimes \psi_n), \tag{3.9}$$

where $P_{4n+2\gamma} - P_{4n+2\gamma-0} = \psi_n \otimes \psi_n$ is the projection onto the eigenspace (LH) (ψ_n) spanned by the single eigenfunction ψ_n for each of the integers $n \geqslant 0$. The abbreviation (LH) stands for "the linear hull of whatever is between the two brackets to its immediate right," and "linear hull" means the set of all linear combinations. Consequently, the Green's function $K(x,y)$ of the differential operator H_0, namely the kernel of our self-adjoint operator H_0 restricted to the previous domain $D(H_0)$, takes on the form

$$K(x,y) = \sum_{n=0}^{\infty} (4n + 2\gamma)^{-1} (\psi_n \otimes \psi_n)(x,y) = \sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{4n + 2\gamma} \quad \text{a.e. on} [0,\infty) \times [0,\infty) \tag{3.10}$$

with respect to Lebesgue measure on $[0,\infty)^2 = [0,\infty) \times [0,\infty)$, which shall turn out to be a positive L_2 kernel on $[0,\infty)$ with "finite double norm" (Ref. 19, p. 13). Herein we must emphasize the almost everywhere (a.e.) nature of the immediately preceding equality. The finite double norm of kernel $K(x,y)$ is defined as

$$|||K||| \equiv \sqrt{\int_0^\infty \int_0^\infty |K(x,y)|^2 \, dy \, dx} = \sqrt{\sum_{n=0}^{\infty} (4n+2\gamma)^{-2}} < \infty, \tag{3.11}$$

and consequently many of the ideas, but not all, that led to of Mercer's theorem (Ref. 19, p. 127) are applicable. However, because $\Sigma_{n=0}^{\infty}(4n+2\gamma)^{-1}=\infty$, it cannot be expected that all of the results of Mercer's theorem carry over; specifically, K as an operator "on" the Hilbert space $L_2(0,\infty)$ fails to be an operator of trace class.

IV. MAJORIZATION PROPERTY OF THE KERNEL OF OPERATOR K ON $L_2(0,\infty)$

Let us now call the extension of H_0 to all of $L_2(0,\infty)$ the operator K, which is an operator "on" $L_2(0,\infty)$ [instead of "in" $L_2(0,\infty)$]. We may do this, on account (Ref. 19, Theorem 4.5.1, p. 63) of the fact that kernel $K(x,y)$ is an L_2 kernel and therefore the norm relation

$$\|K\| \leqslant |||K||| \equiv \sqrt{\int_0^\infty \int_0^\infty |K(x,y)|^2 \, dy \, dx} = \sqrt{\sum_{n=0}^{\infty} (4n+2\gamma)^{-2}} < \infty, \tag{4.1}$$

guarantees that operator K has domain of definition $D(K)=L_2(0,\infty)$. Herein, $\|K\|$ and $|||K|||$ denote the operator norm of K and double norm of its kernel $K(x,y)$, respectively. The action of K on $L_2(0,\infty)$ is

$$(Kf)(x) = \int_0^\infty K(x,y)f(y)dy = \sum_{n=0}^{\infty} \frac{\langle f|\psi_n\rangle}{4n+2\gamma}\psi_n(x) \quad \text{a.e. in } x \text{ on } [0,\infty), \tag{4.2}$$

and moreover, this operator K on $L_2(0,\infty)$ is also the Friedrichs' extension of H_0. We first consider the kernel $K(x,y)$ as the Green's function of H_0, and note that the completeness of the orthonormal basis $\{\psi_n : n \geqslant 0\}$, where the normalized eigenfunction ψ_n corresponds to the simple eigenvalue $\lambda_n=4n+2\gamma$, entails that

$$\langle Kf|g\rangle = \sum_{n=0}^{\infty} \frac{\langle f|\psi_n\rangle\langle\psi_n|g\rangle}{4n+2\gamma} \quad \text{for all } f \text{ and } g \in L_2(0,\infty). \tag{4.3}$$

In particular, we replace f and g herein by the sequence of $L_2(0,\infty)$ functions $\delta_n(x)$, tending weakly towards the Dirac-δ function $\delta(x)$, defined by

$$\delta_n(x) \equiv n[1-n|x|] \quad \text{for } |x| \leqslant 1/n \text{ and } 0 \text{ otherwise on the set } \Re,$$

where $\Re$ is the set of real numbers. It becomes immediately clear, that out of $\langle Kf|f\rangle$ always exceeding each of the finite sums $\Sigma_{k=0}^{N}[4n+2\gamma]^{-1}|\langle f|\psi_k\rangle|^2$, the inequality

$$\langle K\delta_n(\cdot-x)|\delta_n(\cdot-x)\rangle \geqslant \sum_{k=0}^{N} \frac{\langle\delta_n(\cdot-x)|\psi_n\rangle\langle\psi_n|\delta_n(\cdot-x)\rangle}{4n+2\gamma} \quad \text{for all } N \geqslant 0$$

implies, by way of letting $n\to\infty$ and holding $x\geqslant 0$ fixed, that

$$K(x,x) \geqslant \sum_{k=0}^{N} [4n+2\gamma]^{-1}|\psi_k(x)|^2 \quad \text{for all } N \geqslant 0.$$

Therefore, it follows that

$$\sum_{n=0}^{\infty} \frac{|\psi_n(x)|^2}{4n+2\gamma} \leqslant K(x,x) \quad \text{for all } x \in [0,\infty),$$

where the function $K(x,x)$ has the precise form given by $\left(\nu=\frac{1}{4}\sqrt{1+4A}\right)$

$$K(x,x) = w(x)v(x) = 2^{-1}xI_\nu\left(\frac{x^2}{2}\right)K_\nu\left(\frac{x^2}{2}\right) \tag{4.4}$$

as well as asymptotic behavior as $x \to 0^+$ and ∞, respectively, given by

$$K(x,x) = \begin{cases} \dfrac{1}{\sqrt{1+4A}}x[1+O(x^\epsilon)] & \text{for } x \to 0^+, \\ 2^{-1}x^{-1}[1+O(x^{-2})] & \text{for } x \to \infty. \end{cases} \tag{4.5}$$

V. MERCER THEOREM TYPE PROPERTIES OF THE KERNEL $K(x,y)$

From the asymptotic behavior (4.5) of the majorizing function $K(x,x)$ of $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}|\psi_n(x)|^2$ as well as the continuity of $K(x,x)$ on $[0,\infty)$, we readily see that if we let $M_\infty \equiv \sup\{K(x,x): x \in [0,\infty)\}$, the above asymptotic behavior guarantees that $M_\infty < \infty$, then

$$\sum_{n=0}^{\infty} \frac{|\psi_n(x)|^2}{4n+2\gamma} \leqslant M_\infty \quad \text{for all } x \in [0,\infty). \tag{5.1}$$

It therefore follows that $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}|\psi_n(x)|^2$ converges for all $x \in [0,\infty)$. Moreover, the Cauchy-Schwarz inequality allows us to write for all non-negative integers N that

$$\sum_{n=N}^{\infty} \frac{|\psi_n(x)\psi_n(y)|}{4n+2\gamma} \leqslant \left\{\sum_{n=N}^{\infty} \frac{|\psi_n(x)|^2}{4n+2\gamma}\right\}^{1/2} \times \left\{\sum_{n=N}^{\infty} \frac{|\psi_n(y)|^2}{4n+2\gamma}\right\}^{1/2} \quad \text{for all } x,y \in [0,\infty). \tag{5.2}$$

It further follows that the series $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}\psi_n(x)\psi_n(y)$ converges absolutely, because out of the immediately preceding inequality shall follow

$$\sum_{n=N}^{\infty} \frac{|\psi_n(x)\psi_n(y)|}{4n+2\gamma} \leqslant \left\{\sum_{n=N}^{\infty} \frac{|\psi_n(x)|^2}{4n+2\gamma}\right\}^{1/2} \times \sqrt{M_\infty} \quad \text{for all } x \in [0,\infty),$$

$$\sum_{n=N}^{\infty} \frac{|\psi_n(x)\psi_n(y)|}{4n+2\gamma} \leqslant \left\{\sum_{n=N}^{\infty} \frac{|\psi_n(y)|^2}{4n+2\gamma}\right\}^{1/2} \times \sqrt{M_\infty} \quad \text{for all } y \in [0,\infty). \tag{5.3}$$

Let $\epsilon > 0$. It then follows that, for every $y \in [0,\infty)$, there exists an integer $N = N(y)$ such that

$$\sum_{n=N}^{\infty} \frac{|\psi_n(x)\psi_n(y)|}{4n+2\gamma} \leqslant \epsilon\sqrt{M_\infty} \tag{5.4}$$

for all $x \in [0,\infty)$, provided $N = N(y)$ is chosen sufficiently large; and there exists correspondingly for every $x \in [0,\infty)$ an integer $N = N(x)$ such that

$$\sum_{n=N}^{\infty} \frac{|\psi_n(x)\psi_n(y)|}{4n+2\gamma} \leqslant \epsilon\sqrt{M_\infty} \tag{5.5}$$

for all $x \in [0,\infty)$, provided $N = N(x)$ is chosen sufficiently large. These two statements (5.4) and (5.5) are valid because the series $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}|\psi_n(x)|^2$ is majorized by the constant M_∞ on $[0,\infty)$. Hence we are led to the following Mercer-type theorem.

Theorem 1: *The kernel $K(x,y)$ of the operator K on the Hilbert space $L_2(0,\infty)$ with spectral decomposition $K = \Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}(\psi_n \otimes \psi_n)$ possesses the following property: the convergence of the series*

$$\sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{4n+2\gamma} = K(x,y) \tag{5.6}$$

is absolute and uniform on every compact subset of $[0,\infty)\times[0,\infty)$.

Proof: The series $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}|\psi_n(x)\psi_n(y)|$ is uniformly convergent in x on $[0,\infty)$ for every $y\geqslant 0$, as well as uniformly convergent in y on $[0,\infty)$ for every $x\geqslant 0$, as evident from (5.4) and (5.5). Therefore $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}\psi_n(x)\psi_n(y)$ represents a continuous function in variable x on $[0,\infty)$ for every $y\geqslant 0$, as, well as a continuous function in variable y on $[0,\infty)$ for every $x\geqslant 0$. For every $L_2(0,\infty)$ function f the Fourier expansion of Kf has the form

$$(Kf)(x) = \int_0^{\infty} K(x,y)f(y)\mathrm{d}y = \sum_{n=0}^{\infty} \frac{\langle f|\psi_n\rangle}{4n+2\gamma}\psi_n(x) \quad \text{a.e. in } x \text{ on } [0,\infty)$$

and possesses the following property:

$$\begin{aligned}\sum_{n=N}^{\infty}\left|\frac{\langle f|\psi_n\rangle}{4n+2\gamma}\psi_n(x)\right| &\leqslant \left\{\sum_{n=N}^{\infty}|\langle f|\psi_n\rangle|^2\right\}^{1/2}\left\{\sum_{n=N}^{\infty}\frac{|\psi_n(x)|^2}{(4n+2\gamma)^2}\right\}^{1/2}\\ &\leqslant \left\{\sum_{n=N}^{\infty}|\langle f|\psi_n\rangle|^2\right\}^{1/2}\left\{\sum_{n=N}^{\infty}\frac{|\psi_n(x)|^2}{(4n+2\gamma)}\right\}^{1/2} \leqslant \left\{\sum_{n=N}^{\infty}|\langle f|\psi_n\rangle|^2\right\}^{1/2}\times\sqrt{M_{\infty}},\end{aligned}$$

and therefore the sum $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}\langle f|\psi_n\rangle\psi_n(x)$ is an absolutely and uniformly convergent series of continuous functions on $[0,\infty)$ whose limit is continuous on $[0,\infty)$, and hence

$$(Kf)(x) = \int_0^{\infty} K(x,y)f(y)\mathrm{d}y = \sum_{n=0}^{\infty} \frac{\langle f|\psi_n\rangle}{4n+2\gamma}\psi_n(x) \quad \text{for all } x[0,\infty).$$

Since in the series $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}(\psi_n\otimes\psi_n)$ the set of kernels $\{(\psi_n\otimes\psi_n): n\geqslant 0\}$ constitutes an orthonormal set of $L_2(0,\infty)$ kernels, the Riesz-Fischer theorem, combined with $K(x,y)=\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}(\psi_n\otimes\psi_n)(x,y)$ a.e. on $[0,\infty)\times[0,\infty)$ and the fact that $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-2}<\infty$, leads to

$$\left|\left\|K-\sum_{n=0}^{\infty}\frac{\psi_n\otimes\psi_n}{4n+2\gamma}\right\|\right| = \left\{\int_0^{\infty}\int_0^{\infty}\left|K(x,y)-\sum_{n=0}^{\infty}\frac{\psi_n(x)\psi_n(y)}{4n+2\gamma}\right|\mathrm{d}y\,\mathrm{d}x\right\}^{1/2} = 0$$

and furthermore to

$$\int_0^{\infty}\left[K(x,y)-\sum_{n=0}^{\infty}\frac{\psi_n(x)\psi_n(y)}{4n+2\gamma}\right]f(y)\mathrm{d}y = 0 \quad \text{for all } f\in L_2(0,\infty).$$

Now let C denote any compact interval $[a,b]$ contained in $[0,\infty)$, and consider the immediately preceding equality for all functions continuous on C and vanishing on $[0,\infty)\backslash C$. Note that these functions belong to $L_2[0,\infty)$. This in turn implies that

$$\int_C\left[K(x,y)-\sum_{n=0}^{\infty}\frac{\psi_n(x)\psi_n(y)}{4n+2\gamma}\right]f(y)\mathrm{d}y = 0$$

for all $x\in C$ and f continuous on C with $f([0,\infty)\backslash C)=0$. By choosing f for any arbitrary, however momentarily, fixed $x\in C$ as follows:

$$f(y) = K(x,y) - \sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{4n+2\gamma} \quad \text{and} \quad f([0,\infty)\setminus C) \equiv 0,$$

where for this fixed $x \in C$ the series represents a continuous function in variable y on set C vanishing on $[0,\infty)\setminus C$, and substituting it into the immediately above equality, we obtain that

$$\int_C \left| K(x,y) - \sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{4n+2\gamma} \right|^2 \mathrm{d}y = 0 \quad \text{for all } x \in C.$$

Because the integrand above is a continuous function of y on the compact subset C, which is an arbitrary finite closed interval contained in $[0, \infty)$, we obtain

$$K(x,y) - \sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{4n+2\gamma} = 0 \quad \text{for all } x,y \in [0,\infty),$$

which, for $x=y \in [0,\infty)$, specifically yields

$$K(x,x) = \sum_{n=0}^{\infty} \frac{|\psi_n(x)|^2}{4n+2\gamma} \quad \text{for all } x \in [0,\infty).$$

We now invoke Dini's theorem, which states "Every monotone sequence of real valued continuous functions on a compact metric space with continuous limit, converges uniformly to its limit." Hence by Dini's theorem (Ref. 17, p.66) the convergence of $K(x,x)=\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}|\psi_n(x)|^2$ is therefore uniform on every compact subset of $[0, \infty)$, and therefore the series $\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}\psi_n(x)\psi_n(y)$ converges absolutely and uniformly on every compact subset of $[0,\infty)\times[0,\infty)$ with limit $K(x,y)$, i.e., $K(x,y)=\Sigma_{n=0}^{\infty}[4n+2\gamma]^{-1}\psi_n(x)\psi_n(y)$ for all $(x,y)\in[0,\infty)\times[0,\infty)$. This completes the proof. □

Again we note that this is only a Mercer-type theorem, because it makes no conclusion about the operator K or its $L_2(0,\infty)$ kernel $K(x,y)$ being of trace class; whereas Mercer's theorem makes an affirmative statement (Ref. 15, pp. 245–246), see also Refs. 16–19, concerning the trace class nature of operator K. As consequence of this Mercer-type theorem for our Green's function $K(x,y)$, we return to the property of the spectral decomposition of the operator K discussed before, because any complex valued function $W(\mu)$ of the real variable μ on $(-\infty,\infty)$ determines (Ref. 15, Secs. 127 and 128) an operator $W(K)$ in $L_2(0,\infty)$ defined by

$$W(K) = \int_{-\infty}^{\infty} W(\mu) d_\mu P_\mu = \sum_{n=0}^{\infty} W(4n+2\gamma)[P_{4n+2\gamma} - P_{4n+2\gamma-0}] = \sum_{n=0}^{\infty} W(4n+2\gamma)(\psi_n \otimes \psi_n),$$

whose domain of definition $D(W(K))$ consists of all $L_2(0,\infty)$ functions satisfying

$$\int_{-\infty}^{\infty} |W(\mu)|^2 d_\mu < P_\mu f|f\rangle = \int_{-\infty}^{\infty} |W(\mu)|^2 d_\mu \|P_\mu f\|^2 = \sum_{n=0}^{\infty} |W(4n+2\gamma)|^2 |\langle f|\psi_n\rangle|^2 < \infty.$$

It is clearly evident that the operators $W(K)$ are always densely defined, regardless of the function W considered on $\Re=(-\infty,\infty)$, because every domain of definition $D(W(K))$ always contains (LH) $(\psi_n(n\geqslant 0))$. Thus we have that the inverse $[\lambda I-K]^{-1}$ of the operator $\lambda \mathrm{I}-K$, in the normed algebra of bounded linear operators on $L_2(0,\infty)$, comes about from the complex valued function $W(\mu)=[\lambda-\mu]^{-1}$ of the real variable μ and takes the form

$$[\lambda I - K]^{-1} = \int_{-\infty}^{\infty} [\lambda - \mu]^{-1} d_\mu P_\mu = \sum_{n=0}^{\infty} [\lambda - (4n + 2\gamma)]^{-1} [P_{4n+2\gamma} - P_{4n+2\gamma-0}]$$

$$= \sum_{n=0}^{\infty} [\lambda - 4n - 2\gamma]^{-1} (\psi_n \otimes \psi_n),$$

provided $\lambda \notin \sigma(K) = \{4n+2\gamma : n$ a non-negative integer$\}$, namely the spectrum of operator K in the algebra of bounded linear operators on $L_2(0,\infty)$, with continuous kernel

$$[\lambda - \cdot\,]^{-1}(x,y) = \sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{\lambda - 4n - 2\gamma} \quad \text{for all } (x,y) \in [0,\infty) \times [0,\infty),$$

where the convergence is absolute on $[0,\infty)\times[0,\infty)$ and uniform on every compact subset of $[0,\infty)\times[0,\infty)$. We may consequently summarize our results in the following two theorems.

Theorem 2: *The $C[0,\infty)$-function $K(x,x)$ arising out of the Green's function of the differential operator $H_0 = -(d^2/dx^2) + x^2 + Ax^{-2}$ $(A > 0)$ satisfies*

$$\sum_{n=0}^{\infty} \frac{|\psi_n(x)|^2}{4n + 2\gamma} = K(x,x) = w(x)v(x) = 2^{-1} x\, I_{\frac{1}{2}(\gamma-1)}\left(\frac{x^2}{2}\right) K_{\frac{1}{2}(\gamma-1)}\left(\frac{x^2}{2}\right),$$

where $\gamma = 1 + \frac{1}{2}\sqrt{1+4A}$, with uniform convergence on every compact subset of $[0,\infty)$. $K(x,x)$ has the asymptotic behavior

$$K(x,x) = \begin{cases} \dfrac{1}{\sqrt{1+4A}} x[1 + O(x^{\epsilon})] & \text{for } x \to 0^+, \\ 2^{-1} x^{-1}[1 + O(x^{-2})] & \text{for } x \to \infty. \end{cases}$$

Theorem 3: *The continuous kernel $K(x,y)$ on $[0,\infty)\times[0,\infty)$, arising from the Green's function of the differential operator $H_0 = -(d^2/dx^2) + x^2 + Ax^{-2}$ $(A > 0)$ satisfies*

$$K(x,y) = \sum_{n=0}^{\infty} \frac{\psi_n(x)\psi_n(y)}{4n + 2\gamma} = \begin{cases} w(x)v(y) & \text{for } 0 \leqslant y \leqslant x, \\ w(x)w(y) & \text{for } 0 \leqslant x \leqslant y. \end{cases}$$

on $[0,\infty)\times[0,\infty)$ with convergence being absolute and uniform on every compact subset of $[0,\infty)\times[0,\infty)$, where

$$w(x)v(y) = 2^{-1}\sqrt{xy} K_{\frac{1}{2}(\gamma-1)}\left(\frac{x^2}{2}\right) I_{\frac{1}{2}(\gamma-1)}\left(\frac{y^2}{2}\right).$$

.

We further conclude that, for the orthonormal basis $\{\psi_n(x) : n \geqslant 0\}$, (1.2), of the Hilbert space $L_2(0,\infty)$, the two summation formulas (1.4) and (1.5) follows immediately.

Comparing symmetries and conservation laws of nonlinear telegraph equations

G. W. Bluman[a] and Temuerchaolu[b]
Department of Mathematics, University of British Columbia, Vancouver, BC, Canada V6T 1Z2

(Received 8 February 2005; accepted 18 March 2005; published online 6 July 2005)

A comparison is made between the symmetries and conservation laws admitted by nonlinear telegraph (NLT) systems. Such systems are not variational. Unlike the situation for variational systems where all conservation laws arise from symmetries, there are many NLT systems that admit more conservation laws than symmetries. The results are summarized in a table which includes the numbers of symmetries and conservation laws for each NLT system. It is also indicated when symmetries map conservation laws to other conservation laws. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1915292]

I. INTRODUCTION

In this paper, we consider the problem of comparing the multipliers of conservation laws and the point symmetries of a given nonlinear system of partial differential equations (PDEs) that is not variational, i.e., whose associated Fréchet derivative is not self-adjoint. As a protypical example, we consider nonlinear telegraph (NLT) systems of the form

$$H_1[u,v] = v_t - F(u)u_x - G(u) = 0,$$

$$H_2[u,v] = u_t - v_x = 0. \tag{1}$$

One physical example related to system (1) is represented by the equations of telegraphy of a two-conductor transmission line with v as the current in the conductors, u as the voltage between the conductors, $G(u)$ as the leakage current per unit length, $F(u)$ as the differential capacitance, t as a spatial variable and x as time.[1] Another physical example related to system (1) is the equation of motion of a hyperelastic homogeneous rod whose cross-sectional area varies exponentially along the rod. Here u is the displacement gradient related to the difference between a spatial Eulerian coordinate and a Lagrangian coordinate x, v is the velocity of a particle displaced by this difference, $G(u)$ is essentially the stress-tensor, $F(u)=\lambda G'(u)$ for some constant λ, and t is time (see Refs. 2 and 3).

A point symmetry

$$x^* = x + \hat{\xi}(x,t,u,v)\varepsilon + O(\varepsilon^2),$$

$$t^* = t + \hat{\tau}(x,t,u,v)\varepsilon + O(\varepsilon^2),$$

$$u^* = u + \hat{\eta}(x,t,u,v)\varepsilon + O(\varepsilon^2),$$

[a]Electronic mail: bluman@math.ubc.ca
[b]Permanent address: Inner Mongolia University of Technology, Hohhot, People's Republic of China. Electronic mail: tmchaolu@impu.edu.cn

$$v^* = v + \hat{\zeta}(x,t,u,v)\varepsilon + O(\varepsilon^2), \tag{2}$$

with corresponding infinitesimal generator (in evolutionary form)

$$X = \eta\partial_u + \zeta\partial_v$$

is admitted by system (1)[4–6] if and only if

$$\left.\begin{aligned} X^{(1)}H_1[u,v]\Big|_{\substack{H_1[u,v]=0,\\ H_2[u,v]=0}} &= 0,\\ X^{(1)}H_2[u,v]\Big|_{\substack{H_1[u,v]=0,\\ H_2[u,v]=0}} &= 0, \end{aligned}\right. \tag{3}$$

where $X^{(1)}$ is the first extension of X and

$$\eta = \hat{\eta}(x,t,u,v) - \hat{\xi}(x,t,u,v)u_x - \hat{\tau}(x,t,u,v)u_t,$$

$$\zeta = \hat{\zeta}(x,t,u,v) - \hat{\xi}(x,t,u,v)v_x - \hat{\tau}(x,t,u,v)v_t.$$

The Fréchet derivative associated with system (1) is the linear operator

$$L[u] = \begin{bmatrix} D_t & -D_x \\ -F'(u)u_x - F(u)D_x - G'(u) & D_t \end{bmatrix}, \tag{4}$$

and it yields the linearized system of (1) given by

$$L[u]\begin{bmatrix}\Phi\\ \Psi\end{bmatrix}\Big|_{\substack{H_1[u,v]=0,\\ H_2[u,v]=0}} = 0 \tag{5}$$

in terms of total derivative operators D_x and D_t. It is easy to show that a point symmetry of system (3) is any solution $(\Phi,\Psi)=(\eta,\zeta)$ of the linearized system (5).

On the other hand, a set of multipliers

$$\xi = \xi(x,t,U,V), \quad \phi = \phi(x,t,U,V), \tag{6}$$

yields a conservation law of system (1) if and only if

$$\left.\begin{aligned} E_U[\xi(x,t,U,V)H_1[U,V] + \phi(x,t,U,V)H_2[U,V]] &\equiv 0,\\ E_V[\xi(x,t,U,V)H_1[U,V] + \phi(x,t,U,V)H_2[U,V]] &\equiv 0, \end{aligned}\right. \tag{7}$$

for *all* differentiable functions $U(x,t)$ and $V(x,t)$, where

$$E_U = \frac{\partial}{\partial U} - D_x\frac{\partial}{\partial U_x} - D_t\frac{\partial}{\partial U_t}, \quad E_V = \frac{\partial}{\partial V} - D_x\frac{\partial}{\partial V_x} - D_t\frac{\partial}{\partial V_t}$$

are Euler operators. One can show that a necessary condition for $\{\xi(x,t,U,V),\phi(x,t,U,V)\}$ to be a set of multipliers for a conservation law of system (1) is that

$$L^*[u]\begin{bmatrix}\xi(x,t,u,v)\\ \phi(x,t,u,v)\end{bmatrix}\Big|_{\substack{H_1[u,v]=0,\\ H_2[u,v]=0}} = 0, \tag{8}$$

where in terms of the Fréchet derivative operator $L[u]$, the adjoint operator $L^*[u]$ is the unique operator having the property that

$$[\alpha,\beta]L[u]\begin{bmatrix}\Phi\\ \Psi\end{bmatrix}-[\Phi,\Psi]L^*[u]\begin{bmatrix}\alpha\\ \beta\end{bmatrix}$$

is a divergence expression for any differentiable functions α, β, Φ, and Ψ.[4,7–9] It is easy to show that for the Fréchet derivative operator $L[u]$ defined by (4), one has

$$L^*[u]=\begin{bmatrix}-D_t & F(u)D_x-G'(u)\\ D_x & -D_t\end{bmatrix}.$$

In the study of physical systems, the importance of conservation laws is well known, including connections with integrability, linearization and modern numerical methods. Conservation laws are intrinsic properties of field equations since they must hold for any posed data. Familiarly, conservation laws are derived from variational principles through Noether's theorem.[4,5] A given system of PDEs (linear or nonlinear) can be directly obtained from a variational principle if and only if its Fréchet derivative is *self-adjoint*,[4,10] i.e., $L^*[u]=L[u]$. Noether's theorem yields a conservation law for any point symmetry (2) that leaves invariant the action functional of the variational principle. This is equivalent to the Euler operator annihilating the scalar product of the multipliers and the given system of PDEs' functions in which solutions (u,v) are replaced by arbitrary differentiable functions (U,V), i.e., system (7). Consequently, any set of multipliers for a conservation law of a system of PDEs having a variational principle must also be admitted symmetries of the given system. Hence, when a system of PDEs has an associated self-adjoint Fréchet derivative, its multipliers for conservation laws are a subset of its admitted symmetries.

It is well known that for a linear system of PDEs, any solution of its adjoint system yields a set of multipliers for a conservation law since for any linear operator L, a divergence expression is yielded by $vLu-uL^*v$. Moreover, from this it follows that if a given nonlinear system of PDEs can be mapped into a linear system by a point or contact transformation, then its infinite number of admitted symmetries exhibit this linear system and its infinite number of multipliers for conservation laws exhibit the adjoint of this linear system.[5,11,12]

It is easy to show that for any $F(u)$ and $G(u)$, the NLT system (1) is *not* self-adjoint. The extra conditions beyond the necessary condition (8) for $\xi(x,t,U,V)$, $\phi(x,t,U,V)$ to be multipliers for a conservation law of system (1) are given in Refs. 7–9. At first sight, one might think that a given system (1) admits more point symmetries (2) which involve four unknowns $\{\hat{\xi},\hat{\tau},\hat{\eta},\hat{\zeta}\}$ than sets of multipliers of the form (6) which involve only two unknowns $\{\xi,\phi\}$. However, we will show that for many NLT systems (1), there are more admitted sets of multipliers of the form (6) than admitted point symmetries (2).

The point symmetry and conservation law classifications of the NLT system (1) have been separately investigated in Refs. 13 and 14, respectively. In Ref. 15, it is shown how to obtain new conservation laws from the action of an admitted symmetry on a known conservation law.

In Sec. II, we give the determining equations for point symmetries and multipliers admitted by NLT systems (1). We present the Symmetry and Conservation Law Classification Table for NLT systems (1) and show that when (1) is not linearizable, there are many cases where it can admit, nontrivially, one symmetry and four, three, two or zero conservation laws as well as cases where it can admit, nontrivially, zero symmetries and four or two conservation laws. We also comment on situations when a symmetry maps a conservation law into another conservation law(s). Further comments are presented in Sec. III.

II. COMPARISON OF SYMMETRIES AND CONSERVATION LAWS FOR NLT SYSTEMS

By inspection, any NLT system (1) obviously admits, as point symmetries, translations $t\to t+\varepsilon_1$, $v\to v+\varepsilon_2$, and $x\to x+\varepsilon_3$, corresponding to admitted infinitesimal generators $X_1=u_t\partial_u+v_t\partial_v$, $X_2=\partial_v$, and $X_3=u_x\partial_u+v_x\partial_v$, respectively, as well as a set of multipliers $(\xi,\phi)=(0,1)$ since the second PDE of any NLT system (1) is written as a conservation law. Any additional admitted point symmetries or sets of multipliers for conservation laws are considered to be nontrivial.

A point symmetry (2) admitted by an NLT system (1) is represented by any solution $\{\hat{\xi}(x,t,u,v),\hat{\tau}(x,t,u,v),\hat{\eta}(x,t,u,v),\hat{\zeta}(x,t,u,v)\}$ of the linear determining system of PDEs[4–6]

$$\hat{\xi}_v - \hat{\tau}_u = 0,$$

$$\hat{\eta}_u - \hat{\psi}_v + \xi_x - \tau_t = 0,$$

$$G(u)\hat{\eta}_v + \hat{\eta}_t - \hat{\psi}_x + G(u)\hat{\tau}_x = 0,$$

$$\hat{\xi}_u - F(u)\hat{\tau}_v = 0,$$

$$\hat{\psi}_u - G(u)\hat{\tau}_u - F(u)\hat{\eta}_v = 0,$$

$$G(u)\hat{\xi}_v + \hat{\xi}_t - F(u)\hat{\tau}_x = 0,$$

$$[\hat{\psi}_v - \hat{\tau}_t - 2G(u)\hat{\tau}_v - \hat{\eta}_u + \hat{\xi}_x]F(u) - F'(u)\hat{\eta} = 0,$$

$$[\hat{\psi}_v - \hat{\tau}_t - G(u)\hat{\tau}_v]G(u) - F(u)\hat{\eta}_x - G'(u)\hat{\eta} + \hat{\psi}_t = 0. \tag{9}$$

The complete solution of the determining system (9) is presented in Ref. 13.

A set of multipliers for a conservation law of an NLT system (1) is represented by any solution $\{\xi(x,t,U,V),\phi(x,t,U,V)\}$ of the linear determining system of PDEs[7,9]

$$\phi_V - \xi_U = 0,$$

$$\phi_U - F(U)\xi_V = 0,$$

$$\phi_x - \xi_t - G(U)\xi_V = 0,$$

$$F(U)\xi_x - \phi_t - G(U)\xi_U - G'(U)\xi = 0. \tag{10}$$

The complete solution of the determining system (10) and the corresponding conservation laws are presented in Ref. 14.

Equivalence transformations[10,11] simplify the symmetry and conservation law classifications of NLT systems (1). In particular, in Refs. 13 and 14, it is shown how to obtain the corresponding conservation law for any $(\overline{F}(u),\overline{G}(u))$ pair related to the conservation law for a given $(F(u),G(u))$ pair through any similarity transformation

$$\overline{F}(u) = \gamma F(\alpha u + \beta), \quad \overline{G}(u) = \delta G(\alpha u + \beta) + \rho. \tag{11}$$

In the following Symmetry and Conservation Law Classification Table (Table I), we list and compare the additional admitted nontrivial symmetries and nontrivial conservation laws for all possible pairs $(F(u),G(u))$, modulo any similarity transformation (11). For each such pair, we indicate the number of additional admitted point symmetries, the number of additional admitted conservation laws, list all such admitted point symmetries in evolutionary form, show where to find such admitted conservation laws in Ref. 14, and state pertinent comments. Most important, in the comments column we indicate where an admitted symmetry can map a conservation law to

(2) It can happen that a nonvariational system of PDEs can become variational through a differential substitution. For example, the Korteweg–de Vries equation

$$u_t + uu_x + u_{xxx} = 0$$

is not variational but becomes variational after the differential substitution $u=\Gamma_x$. One can show that the differential substitution $(u,v)=(\Gamma_x,\Delta_x)$, leads to an NLT system (1) that is variational if

TABLE I. (*Continued.*)

$G(u)$	$F(u)$		Number of additional point symmetries; listing of symmetries	Number of additional conservation laws; see Ref. 14 for conservation laws	Comments; symmetry mappings of conservation laws (Ref. 15)
$\tan u$	$\tan^2 u+\delta$ $[\delta\neq 0,1]$	0		4 Table 8: Case 2 with $\beta_1=1$, $\beta_2=0$, $\beta_3=\delta-1$	〃
	$\tan^2 u$ $+\alpha_1\tan u+\alpha_2$ $[\alpha_1^2\neq 4\alpha_2, \alpha_1\neq 0]$	0		4 Table 8: Case 1 with $\beta_1=1$, $\beta_2=\alpha_1$, $\beta_3=\alpha_2-1$	〃
	$(\tan u+\delta)^2$	0		2 Table 8: Case 3 with $\beta_1=1$, $\beta_2=2\delta$, $\beta_3=\delta^2-1$	〃
	1	0		2 Table 8: Case 3 with $\beta_3=1$, $\beta_1=\beta_2=0$	〃

and only if $G(u)=\text{const}$ [in this variational case, the NLT system (1) is linearizable by a hodograph transformation].

(3) In general, suppose a system of PDEs with two dependent variables (u,v) and two independent variables (x,t) is not variational but becomes variational through the differential substitution $(u,v)=(\Gamma_x,\Delta_x)$, then an admitted point symmetry

$$\eta=\hat{\eta}(x,t,\Gamma,\Delta)-\hat{\xi}(x,t,\Gamma,\Delta)\Gamma_x-\hat{\tau}(x,t,\Gamma,\Delta)\Gamma_t,$$

$$\zeta=\hat{\eta}(x,t,\Gamma,\Delta)-\hat{\xi}(x,t,\Gamma,\Delta)\Delta_x-\hat{\tau}(x,t,\Gamma,\Delta)\Delta_t,$$

of the variational system would yield multipliers of the form $\{\xi(x,t,U,V),\phi(x,t,U,V)\}$ of the given system, if and only if $\hat{\tau}(x,t,\Gamma,\Delta)=0$ and $\hat{\eta}$, $\hat{\zeta}$ and $\hat{\xi}$ do not depend explicitly on Γ and Δ (otherwise, such a set of multipliers yields a set of nonlocal multipliers and nonlocal symmetries of the given system). Conversely, suppose the given system admits a conservation law resulting from a set of multipliers of the form $\{\xi(x,t,U,V),\phi(x,t,U,V)\}$, then such a set of multipliers yields a point symmetry admitted by the variational system if and only if $\xi_V=\xi_{UU}=\phi_U=\phi_{VV}=0$ [otherwise, such a set of multipliers would yield a local (but not point) symmetry admitted by the variational system].

(4) In general, for a nonvariational system of PDEs, there is a direct connection between conservation laws and symmetries if the system is linear or directly linearizable by a point or contact transformation. For the other exhibited cases, in view of the previous two remarks it would be interesting to investigate if there exist nonlocal symmetries directly connected to the conservation laws.

(Received 24 December 2004; accepted 3 May 2005; published online 7 July 2005)

In this paper, we consider a simplified two fluid system of equations in plasma under some conditions. The existence, uniqueness, and the behavior of solitary waves at infinity for the system are proved by ordinary differential equations methods. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1941088]

I. INTRODUCTION

Since the end of 1960s, nonlinear propagation of solitary waves in plasma have been studied extensively. For example, in laser target shooting, people have observed many phenomena such as the density hollow near the critical surface, the vortex solitary wave propagating due to collapse, the solitons emerging when laser beam self-focusing in nonlinear medium, Langmuir soliton emerging from high frequency longitudinal electric field, and optic solitons emerging from high frequency transverse electric fields. With the development of experimental technology, more and more interesting soliton phenomena are observed in the interaction between plasma and laser. At the same time, some results obtained in theoretical study and electronic computer numerical simulations are confirmed by experiments. Here, we refer the readers to Refs. 2, 6, 8, 10, and 11 and references therein.

The system of two-fluid dynamics are composed of equations for electrons and for ions. Here we assume that $\vec{B}=0$, $T_i=0$, $T_e=\text{const}$, then dynamics equations for ions are

$$\frac{\partial n_i}{\partial t}+\nabla\cdot n_i\vec{v_i}=0, \tag{1.1}$$

$$n_iM\left(\frac{\partial\vec{v_i}}{\partial t}+\vec{v_i}\cdot\nabla\vec{v_i}\right)=n_ie\vec{E}, \tag{1.2}$$

dynamics equations for electrons are

$$\frac{\partial n_e}{\partial t}+\nabla\cdot n_e\vec{v_e}=0, \tag{1.3}$$

$$n_em\left(\frac{\partial\vec{v_e}}{\partial t}+\vec{v_e}\cdot\nabla\vec{v_e}\right)=-T_e\nabla n_e-n_e e\vec{E}, \tag{1.4}$$

and Maxwell equations are

$$\nabla\times\vec{E}=0, \tag{1.5}$$

$$\frac{\partial \vec{E}}{\partial t} = -4\pi e(n_i \vec{v_i} - n_e \vec{v_e}), \tag{1.6}$$

where n_i is the number density of ion, n_e the number density of electron, $\vec{v}_i$ the velocity of ion, $\vec{v}_e$ the velocity of electron, M the mass of ion, m the mass of electron, T_i the temperature of ion, T_e the temperature of electron, e is electronic charge, $\vec{E}$ the intensity of the electric field, $\vec{B}$ the intensity of the magnetic field,

$$\nabla = \vec{i}\frac{\partial}{\partial x} + \vec{j}\frac{\partial}{\partial y} + \vec{k}\frac{\partial}{\partial z}.$$

.

Under some technical treatment, (1.1)–(1.7) reduces to the following simplified two-fluid system:

$$\frac{\partial n_i}{\partial t} + \nabla \cdot n_i \vec{v_i} = 0, \tag{1.7}$$

$$n_i M\left(\frac{\partial \vec{v_i}}{\partial t} + \vec{v_i} \cdot \nabla \vec{v_i}\right) = n_i e \vec{E_l}, \tag{1.8}$$

$$\nabla \cdot \vec{E}_l = 4\pi e(n_i - n_l), \tag{1.9}$$

$$\vec{E}_l = -\frac{T_e \nabla n_l}{n_l} - \frac{e^2}{2m\omega_p{}^2} \nabla \overline{\vec{E}_h{}^2}, \tag{1.10}$$

$$\frac{\partial^2 \vec{E_h}}{\partial t^2} - c^{*2}\nabla^2 \vec{E_h} + c^{*2} \nabla \nabla \cdot \vec{E_h} - v_e{}^2 \nabla \nabla \cdot \vec{E_h} = -\frac{4\pi n_l e^2}{m} \vec{E_h}, \tag{1.11}$$

where the suffix l and h are the lower and higher frequency parts respectively, $v_e{}^2 = T_e/m$, $\omega_p = 4\pi n_l e^2/m$, $n_e = n_l + n_h$, c^* the velocity of light, $\overline{\vec{E}_h{}^2} = (1/2T)\int_{t-T}^{t+T} \vec{E}_h{}^2 \mathrm{d}t$. For more details, the readers can refer to Ref. 14. The system of equations (1.7)–(1.11) are self-contained. And it has at least three kinds of waves, the ion acoustic wave, the plasma wave, and the light wave. Each wave contains a nonlinear term producing space coacervation, for the ion acoustic wave it is the transport term $\vec{v}_i \cdot \nabla \vec{v}_i$, while for the plasma wave and the light wave it is the one in Eq. (1.11). Three kinds of waves all contain a dispersion term. For the ion acoustic wave it is the charge separate term $\nabla \cdot \vec{E}_l$, for the plasma wave it is $v_e{}^2 \nabla^2 \vec{E}_h$, and for the light wave it is $c^{*2}\nabla^2 \vec{E}_h$. When the interactions between the nonlinear terms and the dispersion terms reach to a certain equilibrium, the acoustic solitons, the plasma solitons, and the light solitons are produced.

For the simplified system of two-fluid dynamics (1.7)–(1.11), if we take units of the physical quantities as $[t] = (M/4\pi n_0 e^2)^{1/2} = \omega_{p_i}{}^{-1}$, $[x] = (T_e/4\pi n_0 e^2)^{1/2} = \lambda_D$, $[v] = [x]/[t] = (T_e/M)^{1/2}$, $[n_l] = n_0$, $[\phi] = (T_e/e)(E_i - \nabla \phi)$, $[|\epsilon|^2] = 4\pi n_0 T_e$, we can obtain the dimensionless form of the system

$$\frac{\partial n_i}{\partial t} + \nabla \cdot n_i \vec{v_i} = 0, \tag{1.12}$$

$$\frac{\partial \vec{v_i}}{\partial t} + \vec{v_i} \cdot \nabla \vec{v_i} = -\nabla \phi, \tag{1.13}$$

$$\nabla^2\phi = n_l - n_i = \exp(\phi - |\epsilon|^2) - n_i, \tag{1.14}$$

$$n_l = \exp(\phi - |\epsilon|^2), \tag{1.15}$$

$$\frac{2i}{\omega_p}\frac{\partial\epsilon}{\partial t} - \frac{1}{\omega_p^2}\frac{\partial^2\epsilon}{\partial t^2} = -\nu\nabla^2\epsilon + (\exp(\phi - |\epsilon|^2) - 1)\epsilon, \tag{1.16}$$

$$E_l = -\nabla\phi, \tag{1.17}$$

where ϵ is the higher frequency electric field, $\omega_p=(M/m)^{1/2}$, $\nu=1$ if $\overline{E_h}$ is the intensity of the longitudinal field, while $\nu=c^{*2}/v_e^2$ if $\overline{E_h}$ is the intensity of the transverse field.

In the following, we only discuss the one-dimensional case, therefore $\vec{v}_i=v$. Suppose

$$\epsilon(x,t) = \psi(x-ct)\exp(-ipt+iqx), \tag{1.18}$$

and n_i, v, and ϕ are the functions of $\xi=x-ct$. Substituting (1.18) into (1.16) and setting its real part and imaginary part to zero, respectively, we get from (1.12)–(1.14) and (1.16) the plane solitary wave equations

$$\left(\nu - \frac{c^2}{\omega_p^2}\right)\frac{d^2\psi}{d\xi^2} = (\exp(\phi-\psi^2) - 1 + a^2)\psi, \tag{1.19}$$

$$\frac{d^2\phi}{d\xi^2} = \exp(\phi-\psi^2) - \frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}}, \tag{1.20}$$

$$n_i = \frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}}, \tag{1.21}$$

$$n_l = \exp(\phi-\psi^2), \tag{1.22}$$

where c is the propagation velocity of the solitary wave, $a^2=\nu q^2-(p/\omega_p)^2-(2p/\omega_p)>0$, $\nu q=(c/\omega_p)[1+(p/\omega_p)]$.

There are many papers which concern the existence of approximate solutions for the equations (1.19)–(1.22), cf. Refs. 5, 6, 10, and 11. For the longitudinal wave $\nu=1$, by expanding n_i, n_l untill ϕ and ψ^2 terms, one has $n_l=1+\phi-\psi^2$, $n_i=1+(\phi/c^2)$. Supposing $n_i=n_l$, one can replace the equation (1.19) (c^2/ω_p^2 is ignored) by the following equation:

$$\frac{d^2\psi}{d\xi^2} = \left(\frac{1}{c^2-1}\psi^2 + a^2\right)\psi. \tag{1.23}$$

Hence the solution of (1.19) and (1.20) are

$$\psi = a\sqrt{2(1-c^2)}\,\operatorname{sech} a\xi \tag{1.24}$$

$$\phi = -2a^2c^2\operatorname{sech}^2 a\xi, \tag{1.25}$$

where $0<c<1$. The single-peaked symmetry solution (1.24) and (1.25) are soliton solutions of Zakharov equations, which is consistent with the numerical calculation for development of the initial wave packet of Zakharov equations and the interactions of solitons made by Makhankov, etc.

By taking higher order terms appropriately from expansions of n_i and n_l, one obtains the Makhanhov-Nishikawa solitary wave solution (ϕ,ψ) where ϕ is symmetric and ψ is antisymmetric. Near the region $c^2\simeq 1$, $0<c<1$, by taking ϕ and ψ of the same order of magnitude and expanding n_i and n_l to quadric terms of ϕ and ψ, one can have the equations

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}\xi^2}=(\phi+a^2)\psi, \tag{1.26}$$

$$\frac{\mathrm{d}^2\phi}{\mathrm{d}\xi^2}=-\frac{1-c^2}{c^2}\phi--\frac{3-c^4}{2c^4}\phi^2-\psi^2, \tag{1.27}$$

the solution of which is given by

$$\psi=A\ \mathrm{sech}\ a\xi\tanh a\xi, \tag{1.28}$$

$$\phi=B\ \mathrm{sech}^2\ a\xi, \tag{1.29}$$

where $A^2=6a^2[4a^2-1+(1/c^2)]$, $B=-6a^2$, and a, c satisfy $a^2=c^2(1-c^2)/(9-c^4)$.

In the simplified two-fluid system of equations (1.12)–(1.17), by taking the higher frequency oscillatory part as zero, one can obtain soliton in ion acoustic waves, cf. Ref. 6, p. 19. Considering the one-dimensional case, and supposing $T_i=0$, $\vec{v}_i=v_i$, one gets the dimensionless form

$$\frac{\partial n_i}{\partial t}+\frac{\partial n_i v_i}{\partial x}=0, \tag{1.30}$$

$$\frac{\partial v_i}{\partial t}+v_i\frac{\partial v_i}{\partial x}=-\frac{\partial\phi}{\partial x}, \tag{1.31}$$

$$\frac{\partial^2\phi}{\partial x^2}=\exp(\phi)-n_i. \tag{1.32}$$

By letting $\xi=x-ct$ and supposing that $n_i\to 1$, $v_i\to 0$, $\phi\to 0$ as $|x|\to\infty$, one may obtain

$$\frac{\mathrm{d}^2\phi}{\mathrm{d}\xi^2}=\exp(\phi)-\frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}}, \tag{1.33}$$

$$n_i=\frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}}, \tag{1.34}$$

$$n_i(c-v_i)=c, \tag{1.35}$$

Assuming that $c>1$, $\delta_c=c-1\ll 1$, one gets the equation

$$\frac{1}{2}\left(\frac{\mathrm{d}\phi}{\mathrm{d}\xi}\right)^2=\frac{1}{3}\phi^2(3\delta_c-\phi).$$

The solution of the above equation is

$$\phi = 3(c-1)\operatorname{sech}^2\left(\sqrt{\frac{c-1}{2}}(x-ct)\right), \tag{1.36}$$

where the peak value of the solitary wave is $3(c-1)$. If letting $\xi=\delta_0^{1/2}(x-t)$, $\tau=\delta_0^{3/2}t$, the ion acoustic wave equations (1.30)–(1.32) reduce to the so-called KdV equation.

In the present paper, we are interested in finding the existence of solitary waves for the simplified two-fluid system of equations under some conditions by rigorous mathematical theories. In the equations (1.19) and (1.20), by letting $\varphi=\sqrt{2}\psi$, we can obtain

$$-\omega_0\frac{d^2\varphi}{d\xi^2} = \left[-\exp\left(\phi-\frac{\varphi^2}{2}\right)+1-a^2\right]\varphi, \tag{1.37}$$

$$\frac{d^2\phi}{d\xi^2} = \exp\left(\phi-\frac{\varphi^2}{2}\right) - \frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}}, \tag{1.38}$$

where $\omega_0=\nu-(c^2/\omega_p^2)>0$. Supposing that $n_i\to 1$, $v_i\to 0$, φ, $\phi\to 0$ as $|x|\to\infty$, in order to solve the equations (1.37) and (1.38) we may consider

$$-\omega_0\frac{d^2\varphi}{d\xi^2} = \left[-\exp\left(\phi-\frac{\varphi^2}{2}\right)+1-a^2\right]\varphi, \quad \text{in } \mathbb{R},$$

$$\frac{d^2\phi}{d\xi^2} = \exp\left(\phi-\frac{\varphi^2}{2}\right) - \frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}}, \quad \text{in } \mathbb{R}, \quad (P_1)$$

$$\varphi, \quad \phi \in W^{1,2}(\mathbb{R}),$$

where

$$W^{1,2}(\mathbb{R}) := \{u; u \in L^2(\mathbb{R}), \nabla u \in L^2(\mathbb{R})\}$$

with the norm

$$\|u\| := |u|_2 + |\nabla u|_2,$$

where $|.|_2$ denotes the norm in $L^2(\mathbb{R})=\{u; \int_{\mathbb{R}}|u(\xi)|^2\,d\xi<+\infty\}$. We note that if (φ_0,ϕ_0) is a solution for (P_1) when $a\geqslant 1$, then $\varphi_0=0$ (the details will be given in Sec. II). So we can discuss the existence of solutions for the following problem:

$$\frac{d^2\phi}{d\xi^2} = \exp(\phi) - \frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}},$$
$$\phi\to 0 \quad \text{as } |\xi|\to 0, \quad \exists\, \xi_0 \text{ such that } \phi(\xi_0)>0, \quad 1-\frac{2\phi(\xi_0)}{c^2}>o, \tag{P_2}$$

By ordinary differential equations methods, cf. Refs. 4 and 3, we obtain existence of a nontrivial solution ϕ for (P_2) and the solution is unique up to translations of the origin. Moreover we can prove the exponential decay of the solution at infinity by a standard argument of ordinary differential equations in Ref. 12. Therefore we can obtain a nontrivial solitary wave $(0,\phi)$ for the system of equations (1.12)–(1.17).

In Sec. II, we shall give the main results, Theorems 2.1 and 2.2, and the proof of Theorems 2.1 and 2.2.

II. THE MAIN RESULTS

Now we can state our main results.

Theorem 2.1: If (φ,ϕ) is a solution of (P_1) for $a\geqslant 1$, then $\varphi=0$.

Proof: From the first equation of the system (P_1),

$$-\omega_0\frac{d^2\varphi}{d\xi^2}=\left[-\exp\left(\phi-\frac{\varphi^2}{2}\right)+1-a^2\right]\varphi,\quad \text{in } \mathbb{R},$$

we note that $d^2\varphi/d\xi^2$ and φ have the same sign since $\omega>0$ and $-\exp[\phi-(\varphi^2/2)]+1-a^2<0$ when $a\geqslant 1$. On the other hand, since $\varphi\in W^{1,2}(\mathbb{R})$, by Sobolev embedding theorem (Ref. 1, Theorem 5.4) φ tends to zero as $\xi\to 0$, and φ is continuous, bounded. Thus φ takes either positive maximum or negative minimum, which is impossible because $d^2\varphi/d\xi^2$ and φ have the same sign. Therefore the only possibility left is that $\varphi=0$.

Theorem 2.2: The problem (P_2) has a nontrivial solution ϕ if and only if $1<c<c_0$, where $c_0:=\inf\{c;c>1,-\exp(c^2/2)+c^2+1>0\}$. Furthermore, if $1<c<c_0$, then the solution ϕ is unique up to translations of the origin, and it satisfies (after a suitable translation of the origin) the following:

(i) $\phi(\xi)=\phi(-\xi)$, $\xi\in\mathbb{R}$ (ϕ is radial),
(ii) $\phi(\xi)>0$, $\xi\in\mathbb{R}$,
(iii) $\phi(0)=\xi_1$, $\xi_1:=\inf\{\xi;\xi>0,-\exp(\xi)-c^2\sqrt{1-(2\xi/c^2)}+c^2+1>0\}$,
(iv) $\phi'(\xi)<0$, $\xi>0$, where the prime indicates the derivative,
(v) ϕ, ϕ', ϕ'' have exponential decay at infinity, i.e., there exists C, $\delta>0$ such that

$$0\leqslant\phi(\xi),\ |\phi'(\xi)|,|\phi''(\xi)|\leqslant C\exp(-\delta|\xi|),\quad \xi\in\mathbb{R}.$$

Proof: Under the assumptions of Theorem 2.2, one solution of (P_2) can be obtained as the solution of the initial value problem

$$\frac{d^2\phi}{d\xi^2}=\exp(\phi)-\frac{1}{\sqrt{1-\dfrac{2\phi}{c^2}}}=h(\phi),\qquad (P_3)$$
$$\phi(0)=\xi_1,\quad \phi'(0)=0.$$

The other solutions are obtained by translations, $\phi(\xi)=\phi(\xi+\xi^*),\xi^*\in\mathbb{R}$ being a constant.

By the definition of c_0 and $1<c<c_0$, there exists $\xi_1>0$ such that

$$\xi_1:=\inf\{\xi;\xi>0,-\exp(\xi)-c^2\sqrt{1-(2\xi/c^2)}+c^2+1>0\},\quad h(\xi_1)>0. \tag{2.1}$$

On the other hand, if (2.1) holds, then $H(\xi_1)=-\exp(\xi_1)-c^2\sqrt{1-(2\xi_1/c^2)}+c^2+1=0$, thus $1<c<c_0$.

Let ϕ denote the solution of (P_3). This solution exists and is unique on a certain maximal interval $(-\overline{\xi},\overline{\xi})$. Multiplying the equation in (P_3) by ϕ' and integrating from 0 to ξ yields

$$-\frac{1}{2}\left(\frac{d\phi}{d\xi}\right)^2=-\exp(\phi)-c^2\sqrt{1-\frac{2\phi}{c^2}}+c^2+1,\quad |\xi|<\overline{\xi}. \tag{2.2}$$

A bounded solution of Eq. (2.2) exists if and only if $H(\xi)$ has a root in the interval $(0,c^2/2)$. It is easy to see that $H(0)=H'(0)=0$. In addition, when $c>1$, there is ϕ_0 such that $\phi_0<c^2/2$, $H'(\phi)<0$ for $0<\phi<\phi_0$ and $H'(\phi)>0$ for $\phi_0<\phi<c^2/2$. We can see that $H(\xi)$ have a root in the interval $(0,c^2/2)$ if and only if $H(c^2/2)>0$. And the function $H(c^2/2)=-\exp(c^2/2)+c^2+1$ has exactly one positive root $c_0>1$. In conclusion, we obtain that (P_2) admits the solitary wave solution if and only if $1<c<c_0$.

By ordinary differential equations methods, we can prove $\overline{\xi}=+\infty$, (i), (ii), (iii), (iv), and (v). For more details of the proof of the above statements, one can refer to Refs. 3 and 12.

Remark 2.3: By variational methods, in order to find the solutions for the problem (P_1), we can find the critical points of the following functional:

$$I(\varphi,\phi)=\frac{1}{2}\int\left(\omega_0\left(\frac{\mathrm{d}\varphi}{\mathrm{d}\xi}\right)^2+a^2\varphi^2\right)-\frac{1}{2}\int\left(\left(\frac{\mathrm{d}\phi}{\mathrm{d}\xi}\right)^2+b\phi^2\right)-\int F(\varphi,\phi), \tag{2.3}$$

where $b>0$, $F(\varphi,\phi)=e^{\phi-(\varphi^2/2)}-1+c^2\sqrt{1-(2\phi/c^2)}-c^2+\frac{1}{2}\varphi^2-(b\phi^2/2)$, φ, $\phi\in W^{1,2}(\mathbb{R})$, $\int\cdot$ denoting $\int_{\mathbb{R}}\cdot\,\mathrm{d}\xi$. There are three difficulties in considering the existence of critical points of the functional (2.3). The first is the functional (2.3) is not always continuous and differential at all $(\varphi,\phi)\in W^{1,2}(\mathbb{R})\times W^{1,2}(\mathbb{R})$. The second is the functional (2.3) is strongly indefinite in the sense that it is neither bounded from above nor from below even under some compact perturbations. The last is the loss of compactness, that is, the imbedding $W^{1,2}(\mathbb{R})\hookrightarrow L^q(\mathbb{R})(2\leqslant q<2^*=\infty)$ is not compact because $\mathbb{R}$ is an unbounded domain. In Theorem 2.1 and Theorem 2.2, we have proved the existence, the behavior at infinity and uniqueness of solitary waves for (P_1) when $a\geqslant 1$, $1<c<c_0$. For example, if $p=-\omega_p$, then $a=1$. However, we cannot deal with the problem (P_1) when $0<a<1$, $0<c<1$, because the Euler functional (2.3) associated with (P_1) is strongly indefinite. Since the embedding $W^{1,2}_{\mathrm{O}(N)}(\mathbb{R})\hookrightarrow L^q(\mathbb{R})(2\leqslant q<2^*=\infty)$ is not compact $[W^{1,2}_{\mathrm{O}(N)}(\mathbb{R})$ is the set of all spherically symmetric functions in $W^{1,2}(\mathbb{R})]$, we cannot use the method in Ref. 7, where its authors used principle of symmetric criticality and limit index theory to obtain critical points for a strongly indefinite functional. As $F(\varphi,\phi)$ in (2.3) is not always positive or bounded from below, we also cannot use the general linking theorem in Refs. 9 and 13 to obtain the existence of critical points for the functional (2.3). Meanwhile, (0, 0) is a trivial solution for the problem (P_1), the Leray-Schauder fixed point theorem cannot be used to solve the existence of solutions for (P_1). In the future work, we shall consider the problem (P_1) when $0<a<1$, $0<c<1$ by other methods.

A new energy-based stochastic extension of the Schrödinger equation for which the wave function collapses after the passage of a finite amount of time is proposed. An exact closed-form solution to the dynamical equation, valid for all finite-dimensional quantum systems, is presented and used to verify explicitly that reduction of the state vector to an energy eigenstate occurs. A time-change technique is introduced to construct a "clock" variable that relates the asymptotic and the finite-time collapse models by means of a nonlinear transformation. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1990108]

The idea that Brownian motion might play a role in models for the collapse of the wave function was first envisaged by Wiener and Siegel.[1] Although that specific proposal did not in the end fully account for the correct probability law, a number of authors have subsequently proposed and developed dynamical collapse models driven by Brownian motion that have the key property of being compatible with the probabilistic hypotheses of standard quantum mechanics. Progress in this area over the last two decades can be broadly classified into two categories: (a) models based on the idea of "spontaneous localization" of the wave function,[2] and (b) models based on the notion of collapse of the state vector to an energy eigenstate.[3] See, e.g., the articles cited in Ref. 4 for accounts of these approaches.

The energy-based collapse models, with which we are concerned here, have the physical property that the expectation of the future energy of the system is given by the initial energy. It has been argued on phenomenological grounds[5] that the characteristic time scale for collapse to an energy eigenstate in such models is of the order

$$\tau_R \approx \left(\frac{2.8\ \text{MeV}}{\Delta H}\right)^2 \text{s}, \tag{1}$$

where ΔH is the initial energy uncertainty, and it has been demonstrated that the choice (1) is consistent with empirical observations for a number of different examples of quantum systems.[6] The time scale τ_R is indicative of the time it takes for the wave function to reach the immediate vicinity of an energy eigenstate. That is to say, after the passage of several multiples of τ_R, the state of the system is, with a high degree of probability, nearly indistinguishable from one of the energy eigenstates. It should be emphasised, however, that strict collapse, in these models, is achieved only asymptotically in time, and it has hitherto been unknown how to formulate a consistent dynamical collapse model that exhibits a complete reduction of the state vector in a finite period of time.

The purpose of this article is to introduce a new class of energy-based models for which the collapse is completed after the passage of a specified time interval T. Further, we obtain an exact closed-form expression for the state vector process that solves the dynamical equation. We show that, remarkably, the finite-time collapse model and the standard infinite-time collapse models are related by a time transformation of the form

$$\tau(t) = \frac{tT}{T-t}, \tag{2}$$

where t is the clock time of the finite-time collapse model, and τ is the clock time in the asymptotic collapse model. Thus the finite-time collapse model can be viewed as a "fast-forwarded" version of the asymptotic collapse model.

We begin by stating the main results of the paper. *Let the dynamics of the state-vector process* $\{|\psi_t\rangle\}$ *be given by the following stochastic Schrödinger equation:*

$$\mathrm{d}|\psi_t\rangle = -\mathrm{i}\hat{H}|\psi_t\rangle \mathrm{d}t - \tfrac{1}{8}\sigma_t^2(\hat{H}-H_t)^2|\psi_t\rangle \mathrm{d}t + \tfrac{1}{2}\sigma_t(\hat{H}-H_t)|\psi_t\rangle \mathrm{d}W_t. \tag{3}$$

Here

$$H_t = \frac{\langle\psi_t|\hat{H}|\psi_t\rangle}{\langle\psi_t|\psi_t\rangle} \tag{4}$$

is the expectation value of the Hamiltonian $\hat{H}$ *in the state* $|\psi_t\rangle$, $\{W_t\}$ *is the Wiener process, and* $\sigma_t = \sigma T/(T-t)$*, where* σ *is a parameter. Then starting from an arbitrary initial state* $|\psi_0\rangle$ *the wave function collapses to an energy eigenstate at time* T*. Energy is conserved in expectation, and the probability of collapse to a state of energy* E_i $(i=1,2,3,\ldots,n)$ *is in accordance with the Born law*

$$\pi_i = \frac{\langle\psi_0|\hat{\Pi}_i|\psi_0\rangle}{\langle\psi_0|\psi_0\rangle}, \tag{5}$$

where $\hat{\Pi}_i$ *is the projection operator onto the Hilbert subspace of states with energy* E_i*.*

Our model (3) contains two parameters, namely, the reduction time T and the energy volatility parameter σ, which has the units $(\text{energy})^{-1}(\text{time})^{-1/2}$. An application of the Ito product rule

$$\mathrm{d}(X_tY_t) = X_t(\mathrm{d}Y_t) + (\mathrm{d}X_t)Y_t + (\mathrm{d}X_t)(\mathrm{d}Y_t) \tag{6}$$

shows that the normalization of $|\psi_t\rangle$ is preserved under (3), so $\mathrm{d}\langle\psi_t|\psi_t\rangle = 0$, and that $\{H_t\}$ satisfies

$$\mathrm{d}H_t = \sigma_t V_t \mathrm{d}W_t, \tag{7}$$

where

$$V_t = \frac{\langle\psi_t|(\hat{H}-H_t)^2|\psi_t\rangle}{\langle\psi_t|\psi_t\rangle} \tag{8}$$

is the energy variance. It follows from (7) that the energy process $\{H_t\}$ has no drift and thus satisfies the conservation law

$$\mathbb{E}[H_u|\{W_s\}_{0\leqslant s\leqslant t}] = H_t \tag{9}$$

for $0\leqslant t\leqslant u$, where $\mathbb{E}[-|\{W_s\}_{0\leqslant s\leqslant t}]$ denotes conditional expectation given the trajectory of the Wiener process from time 0 up to time t.

To verify the collapse property we shall examine the dynamics of the energy variance process $\{V_t\}$. In particular, by use of the Ito rule (6) together with Jensen's inequality we deduce that

$$\bar{V}_t \leqslant V_0 - \int_0^t \sigma_s^2 \bar{V}_s^2 \mathrm{d}s, \tag{10}$$

where $\bar{V}_t = \mathbb{E}[V_t]$ is the unconditional expectation of the energy variance, which is nonnegative. Since $\bar{V}_t \leqslant \bar{V}_s$ for $s\leqslant t$, the inequality (10) remains valid if we replace $\bar{V}_s$ with $\bar{V}_T$ in the integrand. It follows for any $t\leqslant T$ that

$$\bar{V}_t \leqslant V_0 - \sigma^2 \frac{tT}{T-t} \bar{V}_T^2. \tag{11}$$

Now suppose it were the case that $\bar{V}_T > 0$. Then there would exist a time

$$t_0 = \frac{V_0 T}{V_0 + \sigma^2 T \bar{V}_T^2} < T \tag{12}$$

such that the right-hand side of (11) vanishes and hence such that $\bar{V}_{t_0} = 0$. This contradicts our supposition, and hence we conclude that $\bar{V}_T = 0$, and thus $V_T = 0$ with probability one.

To verify the Born law we must show that the conditional transition probability

$$\pi_{it} = \frac{\langle \psi_t | \hat{\Pi}_i | \psi_t \rangle}{\langle \psi_t | \psi_t \rangle} \tag{13}$$

is conserved in expectation, i.e., that $\pi_i = \mathbb{E}[\pi_{it}]$ for $t \leqslant T$. This follows from an application of Ito's rule, which implies that $\mathrm{d}\pi_{it} = \sigma_t (E_i - H_t)\pi_{it} \mathrm{d}W_t$ and thus that $\{\pi_{it}\}$ has no drift. Because $\mathbb{E}[\pi_{iT}]$ is the probability of collapse to a state with energy E_i, the conservation law shows that this is given by the Born probability π_i.

We now proceed to investigate the dynamical equation (3) further, with a view to obtaining a closed-form solution. First we observe that (3) can be cast into an integral form that incorporates the initial condition. In particular, it follows from (3) that

$$|\psi_t\rangle = \hat{U}_t \hat{M}_t^{1/2} |\psi_0\rangle, \tag{14}$$

where $\hat{U}_t = \mathrm{e}^{-\mathrm{i}\hat{H}t}$ is the standard unitary evolutionary operator associated with $\hat{H}$, and

$$\hat{M}_t = \frac{\exp(\hat{H}\int_0^t \sigma_s (\mathrm{d}W_s + \sigma_s H_s \mathrm{d}s) - \frac{1}{2}\hat{H}^2 \int_0^t \sigma_s^2 \mathrm{d}s)}{\exp(\int_0^t \sigma_s H_s (\mathrm{d}W_s + \sigma_s H_s \mathrm{d}s) - \frac{1}{2}\int_0^t \sigma_s^2 H_s^2 \mathrm{d}s)} \tag{15}$$

is a positive operator-valued process. Next we introduce a process $\{W_t^*\}$ defined by

$$W_t^* = W_t + \int_0^t \sigma_s H_s \mathrm{d}s. \tag{16}$$

With respect to the Wiener measure $\mathbb{P}$, under which $\{W_t\}$ is a standard Brownian motion, $\{W_t^*\}$ is a Brownian motion with drift. Therefore, by the well-known theorem of Girsanov there exists a measure $\mathbb{Q}$ with the property that $\{W_t^*\}$ is a $\mathbb{Q}$-Brownian motion for $t \in [0, T)$. Since the dynamical law (3) preserves the normalization of $|\psi_t\rangle$, it follows from (14) that $\langle \psi_0 | \hat{M}_t | \psi_0 \rangle = \langle \psi_0 | \psi_0 \rangle$ for $t \in [0, T)$, and hence that

$$\hat{M}_t = \frac{1}{\Phi_t} \exp\left(\hat{H} \int_0^t \sigma_s \mathrm{d}W_s^* - \frac{1}{2}\hat{H}^2 \int_0^t \sigma_s^2 \mathrm{d}s \right), \tag{17}$$

where

$$\Phi_t = \exp\left(\int_0^t \sigma_s H_s \mathrm{d}W_s^* - \frac{1}{2}\int_0^t \sigma_s^2 H_s^2 \mathrm{d}s \right) = \frac{\langle \psi_0 | \exp(\hat{H}\int_0^t \sigma_s \mathrm{d}W_t^* - \frac{1}{2}\hat{H}^2 \int_0^t \sigma_s^2 \mathrm{d}t) | \psi_0 \rangle}{\langle \psi_0 | \psi_0 \rangle}. \tag{18}$$

We recall that at time t the probability of reduction to a state with energy E_i is given by (13). By use of (14), the commutation relation $[\hat{M}_t, \hat{\Pi}_i] = 0$, and the normalization condition $\langle \psi_0 | \hat{M}_t | \psi_0 \rangle = \langle \psi_0 | \psi_0 \rangle$, it follows then that

$$\pi_{it} = \frac{\langle \psi_0 | \hat{\Pi}_i \hat{M}_t | \psi_0 \rangle}{\langle \psi_0 | \psi_0 \rangle}. \tag{19}$$

Substituting (17) into this relation we thus obtain

$$\pi_{it} = \frac{\langle \psi_0 | \hat{\Pi}_i \exp(\hat{H} \int_0^t \sigma_s \mathrm{d}W_s^* - \frac{1}{2}\hat{H}^2 \int_0^t \sigma_s^2 \mathrm{d}s) | \psi_0 \rangle}{\langle \psi_0 | \exp(\hat{H} \int_0^t \sigma_s \mathrm{d}W_s^* - \frac{1}{2}\hat{H}^2 \int_0^t \sigma_s^2 \mathrm{d}s) | \psi_0 \rangle} = \frac{\pi_i \exp(E_i \int_0^t \sigma_s \mathrm{d}W_s^* - \frac{1}{2}E_i^2 \int_0^t \sigma_s^2 \mathrm{d}s)}{\Sigma_i \pi_i \exp(E_i \int_0^t \sigma_s \mathrm{d}W_s^* - \frac{1}{2}E_i^2 \int_0^t \sigma_s^2 \mathrm{d}s)}. \tag{20}$$

Recalling that $\sigma_s = \sigma T/(T-s)$, we find it convenient now to introduce a process $\{\xi_t\}$ defined by

$$\xi_t = (T-t) \int_0^t \frac{1}{T-s} \mathrm{d}W_s^*. \tag{21}$$

We observe that the right-hand side of (21) is an integral representation for a *Brownian bridge*[7] in the $\mathbb{Q}$ measure. Substituting (21) into (20) we infer that the reduction probability π_{it} can be expressed in terms of the variable ξ_t as follows:

$$\pi_{it} = \frac{\pi_i \exp\left(\frac{\sigma \xi_t E_i T - \frac{1}{2}\sigma^2 E_i^2 t T}{T-t} \right)}{\Sigma_i \pi_i \exp\left(\frac{\sigma \xi_t E_i T - \frac{1}{2}\sigma^2 E_i^2 t T}{T-t} \right)}. \tag{22}$$

Further, on account of the relation $H_t = \Sigma_i E_i \pi_{it}$ for the energy process, we deduce that:

$$H_t = \frac{\Sigma_i \pi_i E_i \exp\left(\frac{\sigma \xi_t E_i T - \frac{1}{2}\sigma^2 E_i^2 t T}{T-t} \right)}{\Sigma_i \pi_i \exp\left(\frac{\sigma \xi_t E_i T - \frac{1}{2}\sigma^2 E_i^2 t T}{T-t} \right)}. \tag{23}$$

In view of the exact solution to the asymptotic collapse model obtained in Ref. 8, the fact that H_t and π_{it} can be expressed as functions of ξ_t and t suggests there might be a simple representation for ξ_t in terms of elementary random data that can be specified without reference to the state-vector process. If so, we can substitute such a representation for ξ_t into (23) to obtain a closed-form solution to the stochastic equation, in place of the integral representation (14) which implicitly depends on $\{|\psi_t\rangle\}$.

We thus proceed as follows: we define a process $\{\beta_t\}$ by the relation

$$\beta_t = \xi_t - \sigma t H_T, \tag{24}$$

where H_T is the terminal value of the energy. We claim that the random variables β_t and H_T are independent. To establish their independence it suffices to verify that

$$\mathbb{E}[\mathrm{e}^{x\beta_t + yH_T}] = \mathbb{E}[\mathrm{e}^{x\beta_t}]\mathbb{E}[\mathrm{e}^{yH_T}] \tag{25}$$

for arbitrary x, y. Using the tower property of conditional expectation we have

$$\mathbb{E}[\mathrm{e}^{x\beta_t + yH_T}] = \mathbb{E}[\mathrm{e}^{x\xi_t}\mathbb{E}[\mathrm{e}^{(y-\sigma t x)H_T} | \xi_t]]. \tag{26}$$

Let us consider the inner expectation $\mathbb{E}[\mathrm{e}^{(y-\sigma t x)H_T} | \xi_t]$. Using expression (22) for the conditional probability distribution of the terminal energy H_T we obtain

$$\mathbb{E}[\mathrm{e}^{(y-\sigma t x)H_T} | \xi_t] = \Phi_t^{-1} \sum_i \pi_i \mathrm{e}^{(y-\sigma t x)E_i} \exp\left(\frac{\sigma \xi_t E_i T - \frac{1}{2}\sigma^2 E_i^2 t T}{T-t} \right).$$

Now $\{\Phi_t\}$ is the density process for changing the measure from $\mathbb{Q}$ to $\mathbb{P}$. That is to say, the expectation $\mathbb{E}$ under $\mathbb{P}$, in which $\{W_t\}$ is a standard Brownian motion, is related to the expectation $\mathbb{E}^{\mathbb{Q}}$ under $\mathbb{Q}$, in which $\{W_t^*\}$ is a standard Brownian motion, according to

$$\mathbb{E}[X_u|\{W_s\}_{0\leqslant s\leqslant t}] = \frac{1}{\Phi_t}\mathbb{E}^{\mathbb{Q}}[\Phi_u X_u|\{W_s\}_{0\leqslant s\leqslant t}], \tag{27}$$

for any random variable X_u that can be expressed as a functional of the trajectory $\{W_s\}_{0\leqslant s\leqslant u}$. Thus making use of the fact that $\{\xi_t\}$ is a Brownian bridge under $\mathbb{Q}$, we deduce, after some rearrangement of terms, that

$$\mathbb{E}[\mathrm{e}^{x\beta_t+yH_T}] = \sum_i \pi_i\, \mathrm{e}^{yE_i}\, \mathrm{e}^{[t(T-t)/2T]x^2}. \tag{28}$$

Here we have used the facts that if g is a zero-mean Gaussian random variable with variance γ^2, then $\mathbb{E}[\mathrm{e}^{xg}]=\mathrm{e}^{(1/2)\gamma^2x^2}$, and that the variance of the Brownian bridge $\{\xi_t\}$ is $t(T-t)/T$. This proves the independence of $\{\beta_t\}$ and H_T.

The result (28) also establishes that under $\mathbb{P}$ the process $\{\beta_t\}$ is Gaussian, and has mean zero and variance $t(T-t)/T$ for $t\in[0,T)$. A similar line of argument shows for $s\leqslant t$ that the covariance of β_s and β_t is

$$\mathrm{Cov}[\beta_s,\beta_t] = s(T-t)/T. \tag{29}$$

Therefore we conclude that $\{\beta_t\}$ is a $\mathbb{P}$-Brownian bridge. As a consequence, there exists a Brownian motion $\{B_t\}$ such that $\{\beta_t\}$ admits an integral representation:

$$\beta_t = (T-t)\int_0^t \frac{1}{T-s}\mathrm{d}B_s. \tag{30}$$

Thus we have verified that the process $\{\xi_t\}$ can be expressed in the form

$$\xi_t = \sigma t H_T + \beta_t, \tag{31}$$

where H_T is the terminal energy, and $\{\beta_t\}$ is an independent Brownian bridge.

Conversely, *given a discrete random variable H_T taking the values $\{E_i\}$ with probability $\{\pi_i\}$, and given an independent Brownian bridge process $\{\beta_t\}$ on the interval $[0,T]$, we can use the ansatz* (31) *as a basis for constructing a closed-form solution to the dynamical equation* (3).

The argument can be sketched as follows. First, given $\{\xi_t\}$ as defined above in terms of H_T and $\{\beta_t\}$, let $\pi_{it}=\mathbb{P}(H_T=E_i|\,\xi_t)$ be the conditional probability that H_T takes the value E_i when the value of ξ_t is specified. It follows by use of the Bayes formula that

$$\mathbb{P}(H_T=E_i|\xi_t) = \frac{\pi_i\rho(\xi_t|H_T=E_i)}{\Sigma_i\pi_i\rho(\xi_t|H_T=E_i)}, \tag{32}$$

where

$$\rho(\xi_t|H_T=E_i) = \sqrt{\frac{T}{2\pi t(T-t)}}\exp\left(-\frac{(\xi_t-\sigma tE_i)^2T}{2t(T-t)}\right). \tag{33}$$

Expression (33) can be deduced from the fact that conditional on $H_T=E_i$ the variable ξ_t in (31) is normally distributed with mean σtE_i and variance $t(T-t)/T$. Thus, we recover the expression (22) for $\{\pi_{it}\}$. Then by an application of Ito calculus we obtain

$$\mathrm{d}\pi_{it} = \sigma_t(E_i-H_t)\pi_{it}\mathrm{d}W_t, \tag{34}$$

where now the process $\{W_t\}$ is *defined* in terms of $\{\xi_t\}$ by the relation

$$W_t = \int_0^t \frac{1}{T-s}(\xi_s - \sigma T H_s)\mathrm{d}s + \xi_t, \tag{35}$$

and $\{H_t\}$ is defined by $H_t = \Sigma_i \pi_{it} E_i$. The process $\{W_t\}$ thus determined turns out to be a standard Brownian motion. This can be demonstrated by showing that $\{W_t\}$ satisfies $\mathbb{E}[W_t|\{W_u\}_{0\leqslant u\leqslant s}] = W_s$ for $s \leqslant t$ and $(\mathrm{d}W_t)^2 = \mathrm{d}t$. Finally, if we write

$$|\phi_i\rangle = \frac{\hat{\Pi}_i|\psi_0\rangle}{\langle\psi_0|\hat{\Pi}_i|\psi_0\rangle^{1/2}} \tag{36}$$

for the standard Lüders states, then the state vector $\{|\psi_t\rangle\}$ that solves (3) can be written in the form

$$|\psi_t\rangle = \mathrm{e}^{-\mathrm{i}\hat{H}t}\sum_i \sqrt{\pi_{it}}|\phi_i\rangle, \tag{37}$$

or, more explicitly,

$$|\psi_t\rangle = \sum_i \frac{\sqrt{\pi_i}\exp\left(-\mathrm{i}E_i t + \frac{1}{2}E_i\sigma_t\xi_t - \frac{1}{4}E_i^2\int_0^t\sigma_s^2\mathrm{d}s\right)}{\sqrt{\Sigma_i \pi_i \exp\left(\frac{1}{2}E_i\sigma_t\xi_t - \frac{1}{4}E_i^2\int_0^t\sigma_s^2\mathrm{d}s\right)}}|\phi_i\rangle, \tag{38}$$

where $\sigma_s = \sigma T/(T-s)$, and $\xi_t = \sigma t H_T + \beta_t$. A straightforward calculation shows that $|\psi_t\rangle \to |\phi_k\rangle$ as $t \to T$, if we set $H_T = E_k$ in (38). By taking the stochastic differential of (38), and using (35), we are led back to the starting point (3), which directly verifies that (38) is the solution to the dynamical equation (3).

We thus conclude that the substitution of (31) in (23) yields a closed-form expression for the energy process in terms of the exogenously specifiable independent data $\{H_T\}$ and $\{\beta_t\}$. As a consequence, we are able to directly simulate the solution to the stochastic equation, as well as the associated energy evolution $\{H_t\}$, for an arbitrary finite-dimensional quantum system.

Next, we remark on the interpretation of the finite-time collapse model (3). First we observe (cf. Ref. 7) that if $\{B_t\}$ is a standard Brownian motion on the interval $[0,T]$, then the process $\{\widetilde{B}_\tau\}$ defined by

$$\widetilde{B}_\tau = \int_0^{\tau T/(\tau+T)} \frac{T}{T-s}\mathrm{d}B_s \tag{39}$$

is a standard Brownian motion on the time interval $[0,\infty)$. In particular, let us introduce a new time variable by the relation $\tau(t) = tT/(T-t)$, and define

$$\eta_\tau = \frac{T}{T-t}\xi_t = \left(1 + \frac{\tau}{T}\right)\xi_{\tau T/(\tau+T)}. \tag{40}$$

Then Eq. (31) can be put into the form

$$\eta_\tau = \frac{\sigma t T H_T}{T-t} + \frac{T\beta_t}{T-t} = \sigma\tau H_T + \int_0^t \frac{T}{T-s}\mathrm{d}B_s, \tag{41}$$

on account of the integral representation (30). Making use of relations (39) and

$$t = \frac{\tau T}{\tau + T}, \tag{42}$$

we thus deduce that

$$\eta_\tau = \sigma\tau H_T + \widetilde{B}_\tau. \tag{43}$$

However, this is the ansatz (cf. Ref. 8) that determines *asymptotic* collapse to an energy eigenstate. That is to say, the expectation $H_\tau = \mathbb{E}[H_T | \eta_\tau]$ determines the energy process $\{H_\tau\}$ associated with the standard energy-based infinite-time collapse models. Therefore, if we take the infinite-time collapse model and replace the time variable t with a clock $\tau(t)$, then as $t \to T$, the clock $\tau(t)$ "ticks" faster and faster. Eventually, in a system for which time is measured by "internal" time t, the collapse takes place in a finite time interval T, whereas in a system for which time is measured by the clock variable $\tau(t)$, the collapse takes place asymptotically as $\tau \to \infty$.

In summary, we have introduced a consistent energy-based collapse model that achieves state reduction in finite time, thus meeting the "challenge" posed in Ref. 9. We have verified the collapse property directly by solving the dynamical equation (3) explicitly for the state-vector process $\{|\psi_t\rangle\}$ in terms of independently specifiable random data. We have also obtained closed form expressions for the energy process $\{H_t\}$ and the reduction probability process $\{\pi_{it}\}$. An argument based on a time-change shows that the finite-time collapse model is related to the infinite-time collapse model by a nonlinear transformation of the time variable.

The no-cloning theorem says there is no quantum copy machine which can copy any one-qubit state. Inner product preserving was always used to prove the no-cloning of nonorthogonal states. In this paper we show that the no-cloning of nonorthogonal states does not require inner product preserving and discuss the minimal properties which a linear operator possesses to copy two different states at the same device. In this paper, we obtain the following necessary and sufficient condition. For any two different states $|\psi\rangle=a|0\rangle+b|1\rangle$ and $|\varphi\rangle=c|0\rangle+d|1\rangle$, assume that a linear operator L can copy them, that is, $L(|\psi,0\rangle)=|\psi,\psi\rangle$ and $L(|\varphi,0\rangle)=|\varphi,\varphi\rangle$. Then the two states are orthogonal if and only if $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are unit length states. Thus we only need linearity and that $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are unit length states to prove the no-cloning of nonorthogonal states. It implies that inner product preserving is not necessary for the no-cloning of nonorthogonal states. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1996327]

I. INTRODUCTION

The no-cloning theorem from the work of Wootters and Zurek said there is no quantum copy machine which can copy any quantum state.[1–3] The authors in Refs. 1 and 4 demonstrated if a quantum copy machine can copy two basis states, then it cannot copy their suppositions. Another version of the no-cloning theorem was stated in Ref. 5. The authors in Refs. 6–8 used inner product preserving to show that nonorthogonal states cannot be cloned by a unitary operator. The no-cloning theorem was extended to mixed states by Barnum *et al.*[3] Some authors presented approximate copies of qubits.[4,8] Mor suggested a type of the no-cloning principle and discussed various cases in which orthogonal states cannot be cloned in principle.[9]

Let $|0\rangle$ and $|1\rangle$ be the basis states of a one-qubit system and $|0,0\rangle$, $|0,1\rangle$, $|1,0\rangle$ and $|1,1\rangle$ be the basis states of a two-qubit system.

Let $|\psi\rangle=a|0\rangle+b|1\rangle$, where a and b are complex and

$$\|a\|^2+\|b\|^2=1. \tag{1}$$

Let $|\varphi\rangle=c|0\rangle+d|1\rangle$, where c and d are complex and

[a)]Electronic mail: dli@math.tsinghua.edu.cn

$$\|c\|^2 + \|d\|^2 = 1. \tag{2}$$

Assume that a linear operator L can copy states $|\psi\rangle$ and $|\varphi\rangle$, that is, $L(|\psi,0\rangle)=|\psi,\psi\rangle$ and $L(|\varphi,0\rangle)=|\varphi,\varphi\rangle$. By tensor product $|\psi,\psi\rangle=(a|0\rangle+b|1\rangle)\otimes(a|0\rangle+b|1\rangle)=a^2|0,0\rangle+ab|0,1\rangle+ab|1,0\rangle+b^2|1,1\rangle$. By the linearity of L, $L(|\psi,0\rangle)=aL(|0,0\rangle)+bL(|1,0\rangle)$. So we get

$$aL(|0,0\rangle) + bL(|1,0\rangle) = a^2|0,0\rangle + ab|0,1\rangle + ab|1,0\rangle + b^2|1,1\rangle. \tag{3}$$

From that $L(|\varphi,0\rangle)=|\varphi,\varphi\rangle$, similarly we get

$$cL(|0,0\rangle) + dL(|1,0\rangle) = c^2|0,0\rangle + cd|0,1\rangle + cd|1,0\rangle + d^2|1,1\rangle. \tag{4}$$

Since $|\psi\rangle$ and $|\varphi\rangle$ are different, the determinant of the coefficient matrix

$$ad - bc \neq 0. \tag{5}$$

Thus from Eqs. (3) and (4) we get by Gramer's rule the following $L(|0,0\rangle)$ and $L(|1,0\rangle)$: $L(|0,0\rangle)=(1/(ad-bc))((a^2d-bc^2)|0,0\rangle+bd(a-c)|0,1\rangle+bd(a-c)|1,0\rangle+bd(b-d)|1,1\rangle)$, $L(|1,0\rangle)=(1/(ad-bc))(ac(c-a)|0,0\rangle+ac(d-b)|0,1\rangle+ac(d-b)|1,0\rangle+(ad^2-b^2c)|1,1\rangle)$.

In this paper $\|x\|$ denotes the norm of $|x\rangle$ or a complex number x. Let $|\alpha\rangle=L(|0,0\rangle)$ and $|\beta\rangle=L(|1,0\rangle)$, $P=\|a^2d-bc^2\|^2+2\|bd(a-c)\|^2+\|bd(b-d)\|^2$ and $Q=\|ac(c-a))\|^2+2\|ac(d-b)\|^2+\|ad^2-b^2c\|^2$. Then

$$\|\alpha\|^2 = P/\|(ad - bc)\|^2 \tag{6}$$

and

$$\|\beta\|^2 = Q/\|(ad - bc)\|^2. \tag{7}$$

II. LEMMA 1

Assume that a linear operator L can copy different states $|\psi\rangle$ and $|\varphi\rangle$. If $|\psi\rangle$ and $|\varphi\rangle$ are orthonormal, then $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are orthonormal.

Proof: First let us prove that $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are unit length states. Since $|\psi\rangle$ and $|\varphi\rangle$ are orthonormal, $\langle\psi|\varphi\rangle=0$, i.e.,

$$a\overline{c} + b\overline{d} = 0 \tag{8}$$

where $\overline{c}$ and $\overline{d}$ are complex conjugates of c and d, respectively. From Eq. (8) we obtain that $\|a\|^2\|c\|^2=\|b\|^2\|d\|^2$. By using Eqs. (1) and (2) $\|a\|^2\|c\|^2=(1-\|a\|^2)(1-\|c\|^2)$. It follows that $\|a\|^2+\|c\|^2=1$. We can as well get $\|b\|^2+\|d\|^2=1$.

We assume that a, b, c, and d are all real. It is not hard to extend the results in this paper to complex a, b, c, and d. Thus we obtain that

$$a^2 + c^2 = 1, \tag{9}$$

$P=(a^2d-bc^2)^2+2(bd(a-c))^2+(bd(b-d))^2$ and $Q=(ac(c-a))^2+2(ac(d-b))^2+(ad^2-b^2c)^2$. In P and Q, simultaneously replacing b^2 by $(1-a^2)$ [see Eq. (1)] and d^2 by $(1-c^2)$ [see Eq. (2)], respectively, P and Q are reduced into the following forms:

$$P = 2 + 2bda^2 + 2bdc^2 - a^2 - c^2 - 4a^2c^2db + 4ac^3 + 4a^3c - 4a^3c^3 - 4ac - 2bd, \tag{10}$$

$$Q = -4a^3c^3 - 4a^2c^2db + a^2 - 2ac + 2ac^3 + 2a^3c + c^2. \tag{11}$$

Let us compute P and Q when $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal. Replacing bd by $-ac$ [see Eq. (8)] and using Eq. (9) in Eqs. (10) and (11), respectively, we obtain that $P=(a^2+c^2)^2=1$ and $Q=(1+2ac)(a^2+c^2)-2ac=1$.

Next let us compute the determinant of the coefficient matrix in Eq. (5) when $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal. Simultaneously replacing b^2 by $(1-a^2)$ [see Eq. (1)] and d^2 by $(1-c^2)$ [see Eq. (2)] and bd by $-ac$ [see Eq. (8)] and using Eq. (9), we derive that $\|ad-bc\|^2=(a^2+c^2)=1$.

From Eqs. (6) and (7) and the above it is easy to get $\|\alpha\|=1$ and $\|\beta\|=1$. That is, $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are unit length states.

Second, we show that $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are orthogonal. After omitting the factor the inner product of $L(|0,0\rangle)$ and $L(|1,0\rangle)$ is $(a^2d-bc^2)ac(c-a)+2bd(a-c)ac(d-b)+bd(b-d)(ad^2-b^2c)$ (replacing b^2 by $(1-a^2)$ [see Eq. (1)] and d^2 by $(1-c^2)$ [see Eq. (2)])

$$=-(a-c)(a^3cd-bd^2ac+b^2dac-ac^3b-b^2d+bd^2)$$

(using $a^2+b^2=1$ and $c^2+d^2=1$)

$$=-(a-c)(d-b)(ac+bd).$$

Equation (8) implies that $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are orthogonal.

Examples: The following combinations of a, b, c, and d satisfy $ac+bd=0$, that is, $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal. It is easy to verify that $\|\alpha\|^2=1=\|\beta\|^2$.

1. $a=\sqrt{2}/2$, $b=\sqrt{2}/2$, $c=\sqrt{2}/2$, $d=-\sqrt{2}/2$.
2. $a=\sqrt{3}/2$, $b=1/2$, $c=1/2$, $d=-\sqrt{3}/2$.
3. $a=3/5$, $b=4/5$, $c=4/5$, $d=-3/5$.

Remark: However, that $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are orthogonal cannot guarantee that $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal. For example, $|\psi\rangle=a|0\rangle+b|1\rangle$ and $|\varphi\rangle=a|0\rangle-b|1\rangle$, where $a^2+b^2=1$ and $a\neq\pm b$. Though $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are orthogonal, $\langle\psi|\varphi\rangle\neq 0$, namely, $|\psi\rangle$ and $|\varphi\rangle$ are not orthogonal.

Corollary: For any two orthogonal states, there is a unitary operator which can copy them.

Proof: Let $|\psi\rangle=a|0\rangle+b|1\rangle$ and $|\varphi\rangle=c|0\rangle+d|1\rangle$ be orthogonal states. Let the truth table be the following matrix L.

	$\|0,0\rangle$	$\|0,1\rangle$	$\|1,0\rangle$	$\|1,1\rangle$
$\|0,0\rangle$	$\frac{a^2d-bc^2}{ad-bc}$	$\frac{bd(a-c)}{ad-bc}$	$\frac{bd(a-c)}{ad-bc}$	$\frac{bd(b-d)}{ad-bc}$
$\|0,1\rangle$	0	$-\sqrt{2}/2$	$\sqrt{2}/2$	0
$\|1,0\rangle$	$\frac{ac(c-a)}{ad-bc}$	$\frac{ac(d-b)}{ad-bc}$	$\frac{ac(d-b)}{ad-bc}$	$\frac{ad^2-b^2c}{ad-bc}$
$\|1,1\rangle$	0	$-\sqrt{2}/2$	$\sqrt{2}/2$	0

It is easy to verify that L is unitary by Lemma 1 and not hard to show that $L(|\psi,0\rangle)=|\psi,\psi\rangle$ and $L(|\varphi,0\rangle)=|\varphi,\varphi\rangle$.

III. LEMMA 2

Assume that a linear operator L can copy two different states $|\psi\rangle$ and $|\varphi\rangle$. If $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are unit length states, then $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal.

Proof: Since $\|\alpha\|=1$, from Eq. (6) we obtain that $P=\|ad-bc\|^2$, and since $\|\beta\|=1$, from Eq. (7) we get that $Q=\|ad-bc\|^2$. Thus $P-Q=0$. Using Eqs. (10) and (11), equation $P-Q=0$ is reduced into the following one:

$$2+2bda^2+2bdc^2-2a^2-2c^2+2ac^3+2a^3c-2ac-2bd=2(a^2+c^2-1)(ac+bd-1)=0.$$

There are two cases. *Case 1*: $a^2+c^2=1$ and *case 2*: $ac+bd=1$. We shall show that in case 1 $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal and case 2 does not occur.

Case 1 in which $a^2+c^2=1$: By simultaneously replacing b^2 by $(1-a^2)$ [see Eq. (1)] and d^2 by

$(1-c^2)$ [see Eq. (2)], it is reduced that $(ac)^2-(bd)^2=(ac)^2-(1-a^2)(1-c^2)=-1+c^2+a^2=0$. Hence $(ac)^2-(bd)^2=(ac-bd)(ac+bd)=0$. There are two subcases.

1.1 *Subcase 1.1*: $ac+bd=0$, that is, $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal.
1.2 *Subcase 1.2*: $ac-bd=0$, that is,

$$ac=bd. \tag{12}$$

We shall show that in subcase 1.2 $|\psi\rangle$ and $|\varphi\rangle$ are also orthogonal. Let us first compute the determinant of the coefficient matrix (5). Simultaneously replacing b^2 by $(1-a^2)$ [see Eq. (1)], d^2 by $(1-c^2)$ [see Eq. (2)] and bd by ac [see Eq. (12)], we derive that $(ad-bc)^2=a^2d^2-2acbd+b^2c^2=a^2(1-c^2)-2ac(ac)+(1-a^2)c^2=a^2-4a^2c^2+c^2$. Using $a^2+c^2=1$, it follows that $(ad-bc)^2=1-4a^2c^2=(1-2ac)(1+2ac)$. By requirement for the determinant of the coefficient matrix in Eq. (5), $(ad-bc)^2=(1-2ac)(1+2ac)\neq 0$.

Next let us compute P in Eq. (10) and Q in Eq. (11) by replacing bd by ac [see Eq. (12)] and using $a^2+c^2=1$. We get that $P=1-8a^3c^3=(1-2ac)(4a^2c^2+2ac+1)$ and $\|\alpha\|^2=(4a^2c^2+2ac+1)/(1+2ac)$; $Q=1-8a^3c^3=(1-2ac)(4a^2c^2+2ac+1)$ and $\|\beta\|^2=(4a^2c^2+2ac+1)/(1+2ac)$. Let $\|\alpha\|^2=\|\beta\|^2=1$. Then $ac=0$. From $ac=bd$, we obtain $ac+bd=0$. In other words, $|\psi\rangle$ and $|\varphi\rangle$ are also orthogonal for subcase 1.2.

Consequently when $a^2+c^2=1$, we derive that $ac+bd=0$, namely, $|\psi\rangle$ and $|\varphi\rangle$ are orthogonal.

Case 2 in which $ac+bd=1$: We shall show that case 2 does not occur. If $ac+bd=1$, then $(ac+bd)^2-1=a^2c^2+2acbd+b^2d^2-1=0$. Simultaneously replacing b^2 by $(1-a^2)$ [see Eq. (1)], d^2 by $(1-c^2)$ [see Eq. (2)] and bd by $(1-ac)$, we infer that $a^2c^2+2ac(1-ac)+(1-a^2)(1-c^2)-1=-(a-c)^2=0$. It follows that $a=c$.

Next let us compute the determinant of the coefficient matrix (5) in the case $ac+bd=1$. Simultaneously replacing b^2 by $(1-a^2)$ [see Eq. (1)], d^2 by $(1-c^2)$ [see Eq. (2)], and bd by $(1-ac)$, we derive that $(ad-bc)^2=a^2d^2-2adbc+b^2c^2=a^2(1-c^2)-2ac(1-ac)+(1-a^2)c^2=(a-c)^2$. By the requirement for the determinant of the coefficient matrix in Eq. (5) $ad-bc\neq 0$, it follows that $a\neq c$.

Therefore this case contradicts our hypothesis for the determinant of the coefficient matrix $ad-bc\neq 0$ in Eq. (5). In other words, case 2 does not happen.

IV. THE NO-CLONING OF NONORTHOGONAL STATES DOES NOT REQUIRE INNER PRODUCT PRESERVING

The authors always used inner product preserving to prove the no-cloning of nonorthogonal states.[6–8] From Lemma 2, it is easy to see that we only need linearity and that $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are unit length states to prove the no-cloning of nonorthogonal states. It shows that inner product preserving is not necessary for the no-cloning of nonorthogonal states.

The following examples show when $|\psi\rangle$ and $|\varphi\rangle$ are not orthogonal, $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are not unit length states. When $a=3/5$, $b=4/5$, $c=3/5$. and $d=-4/5$, $\|\alpha\|^2=18/25$ and $\|\beta\|^2=337/225$; when $a=\sqrt{3}/2$, $b=1/2$, $c=\sqrt{3}/2$, and $d=-1/2$, $\|\alpha\|^2=5/6$, $\|\beta\|^2=3/2$.

V. CLONING LEADS TO INFINITY OF PROBABILITY AMPLITUDE

Let $|\gamma\rangle=c|0\rangle+d|1\rangle$, where $\|c\|^2+\|d\|^2=1$ and $c\neq 0$. Assume that a linear operator L can copy states $|1\rangle$ and $|\gamma\rangle$, that is, $L(|1,0\rangle)=|1,1\rangle$ and $L(|\gamma,0\rangle)=|\gamma,\gamma\rangle$. By the linearity of L and tensor product, it is easy to derive that $L(|0,0\rangle)=c|0,0\rangle+d|0,1\rangle+d|1,0\rangle+|((d^2-d)/c)|1,1\rangle$. Let $d<0$. Then d tends to -1 as c approaches 0 since $\|c\|^2+\|d\|^2=1$. Therefore the norm of probability amplitude $((d^2-d)/c)$ of state $|1,1\rangle$ tends to plus infinity as c approaches 0. For example, when $c=3/5$ and $d=-4/5$, $\|(d^2-d)/c\|=12/5$. It contradicts that the norm of probability amplitude should be 1 or less than 1.

Let $|\phi\rangle=L(|0,0\rangle)$. Then the norm of $|\phi\rangle$ is $\|\phi\|^2=\|c\|^2+\|d\|^2+\|d\|^2+\|(d^2-d)/c\|^2$ and clearly $\|\phi\|>1$. Notice that the norm of $|0,0\rangle$ is 1. It says again that cloning contradicts the norm preserving. For example, when $c=3/5$ and $d=-4/5$, $\|\phi\|=\sqrt{77/45}>1$.

VI. CONCLUSION

As is well known, the no-cloning theorem has far-reaching consequences for quantum information and quantum computing. Nielsen thought "what if we allow cloning devices that are not unitary?" is a good question which has been the subject of much investigation. See page 532 in Ref. 10.

In this paper we demonstrate that it only needs linearity and that $L(|0,0\rangle)$ and $L(|1,0\rangle)$ are unit length states to prove the no-cloning of nonorthogonal states. Clearly we do not require norm preservation for any state. It means that we do not make any use of unitarity. In theory, it is possible to derive a deeper result than the no-cloning principle by using the unitarity. Intuitively it seems that it is easier to implement the operator required in this paper than a unitary operator.

Quantum channels and representation theory

William Gordon Ritter
Department of Physics, Harvard University, Cambridge, Massachusetts 02138

(Received 9 February 2005; accepted 11 May 2005; published online 2 August 2005)

In the study of d-dimensional quantum channels ($d \geqslant 2$), an assumption which includes many interesting examples, and which has a natural physical interpretation, is that the corresponding Kraus operators form a representation of a Lie algebra. Physically, this is a symmetry algebra for the interaction Hamiltonian. This paper begins a systematic study of channels defined by representations; the famous Werner-Holevo channel is one element of this infinite class. We show that the channel derived from the defining representation of $\mathfrak{su}(n)$ is a depolarizing channel for all n, but for most other representations this is not the case. Since the standard Bloch sphere only exists for the qubit representation of $\mathfrak{su}(2)$, we develop a consistent generalization of Bloch's technique. By representing the density matrix as a polynomial in Lie algebra generators, we determine a class of positive semidefinite matrices which represent quantum states for various channels defined by finite-dimensional representations of semisimple Lie algebras. We also give a general method for finding positive semidefinite matrices using Lie algebraic trace identities. This includes an analysis of channels based on the exceptional Lie algebra $\mathfrak{g}_2$ and the Clifford algebra. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1945768]

I. INTRODUCTION

A quantum channel is a model for a particular snapshot of the time evolution of a density matrix, and especially for the evolution of pure into mixed states. Let $\mathcal{H}$ be a Hilbert space of dimension n, and let $\mathfrak{gl}(\mathcal{H})$ denote the vector space of all linear transformations $\mathcal{H} \to \mathcal{H}$. A map $\mathcal{E}: \mathfrak{gl}(\mathcal{H}) \to \mathfrak{gl}(\mathcal{H})$ is said to be *completely positive* (*CP*) if it is linear and $\mathcal{E} \otimes \mathbf{1}$ is positive on $\mathcal{H} \otimes \mathcal{H}'$ for all $\mathcal{H}'$. The map is said to be *trace-preserving* if $\operatorname{Tr} \mathcal{E}(A) = \operatorname{Tr} A$ for all $A \in \mathfrak{gl}(\mathcal{H})$.

Definition 1: A CPT map *(or* stochastic map *or* channel*) is a completely positive, trace-preserving linear transformation* $\mathcal{E}: \mathfrak{gl}(\mathcal{H}) \to \mathfrak{gl}(\mathcal{H})$.

Of central importance to the current work is a famous theorem of Kraus[1] which gives a simple representation of any quantum channel.

Theorem 1 (Kraus decomposition): *For any quantum channel* $\mathcal{E}$, *there exists a finite set of operators*

$$M_0, M_1, M_2, \ldots, M_k, \quad \text{where } k \leqslant (\dim \mathcal{H})^2,$$

such that

$$\mathcal{E}(\boldsymbol{\rho}) = \sum_{\mu} M_\mu \boldsymbol{\rho} M_\mu^\dagger \quad \text{with} \sum_{\mu} M_\mu^\dagger M_\mu = \mathbf{1}. \tag{1}$$

In this situation, (1) *is called the* Kraus representation, *the* operator sum representation *or the* Stinespring form, *while* $\Sigma_\mu M_\mu^\dagger M_\mu = \mathbf{1}$ *is sometimes called the* normalization condition *and is just the statement that the map is trace preserving.*

A proof of this theorem may be found in the original article of Kraus,[1] or in the book by Nielsen and Chuang.[2] We simply note that the converse, namely that any operator of the form (1)

satisfies the conditions of Definition 1, is clearly true. A stochastic map may also be obtained as the partial trace of a unitary conjugation on a larger space; see Ruskai,[3] Sec. III D for a discussion. The representation (1) is sometimes called the *Stinespring form* since its existence follows from the Stinespring dilation theorem.[4]

This is a general framework, and in order to obtain explicit results, further assumptions are necessary. A mathematically elegant assumption with important physical consequences is that the possible errors introduced in the decoherence process are not arbitrary, but that they correspond to the action of the infinitesimal generators of a Lie group G of continuous symmetries. For example, the *qubit depolarizing channel* is a model of a decohering qubit with an $\mathfrak{su}_2$ symmetry. With probability p an error occurs, which is implemented by one of the generators of the Lie algebra $\mathfrak{su}_2$ in its two-dimensional irreducible representation. These generators admit direct physical interpretations as bit-flip errors, phase-flip errors, or combinations of those. The qubit depolarizing channel admits a beautiful generalization to a channel with k possible errors based on a d-dimensional representation $\mathcal{H}$ of a k-dimensional Lie algebra $\mathfrak{g}$.

The situation just described, in which the error generators live in a matrix representation of a semisimple Lie algebra, arises naturally in the model of Markovian dynamics considered by Lidar, Chuang, and Whaley.[5] This was shown to have important consequences for the possibility of decoherence-free dynamics; see Lidar and Whaley,[6] and references therein for an up-to-date review. The present work may be considered as a further exploration of the consequences of that model.

Suppose the M_μ span the space of Hermitian operators, so that $\mu=0,\ldots,n^2-1$. Define $\lambda_0=\mathbf{1}$ and let λ_a for $a\geqslant 1$ denote the n-dimensional Gell-Mann matrices, which are standard generators for the Lie algebra $\mathfrak{su}_n$. Then $\{\lambda_\mu\}$ is a basis for the space of Hermitian matrices. Taking M_0 proportional to the identity, there exist constants U_{ab} such that $M_a=\Sigma_b U_{ab}\lambda_b$. If U is a unitary matrix, then we may take each M_μ proportional to λ_μ without changing the quantum channel defined by these Kraus operators.

In the latter case, one may readily calculate $\Sigma_\mu M_\mu \rho M_\mu^\dagger$, since ρ itself may be expanded in the λ_μ basis, and the Gell-Mann matrices in any dimension satisfy elegant product identities. This leads to a simple, elegant and explicit formula for the action of the $\mathfrak{su}_n$ channel; if $\rho=(1/d)\mathbf{1}+\Sigma_\mu v_\mu \lambda_\mu$ then the channel multiplies v by a scalar given in Sec. III. This is a wonderful calculational tool, and also has physical significance. A quantum channel models the interaction of a decohering system with its environment, and the identification of the M_μ as generators of a Lie algebra is related to symmetry of the interaction Hamiltonian.[5]

The generalizations of the $\mathfrak{su}_n$ calculations to other Lie algebras and to higher-dimensional representations are illuminating, and have not appeared in the literature before. These cases necessarily have the property that not all of the Hermitian matrices in that dimension are linear combinations of representation matrices, so direct generalization of the calculational method for $\mathfrak{su}_n$ will not work, and a new idea is required. This is the subject of Sec. IV. We give a detailed analysis of the spin-1 representation; however, many of the formulas we use there generalize readily to higher spin. In an interesting twist, the spin-one case turns out to be a generalization of the Werner-Holevo channel. Section V analyzes two channels, based, respectively, on the exceptional algebra $\mathfrak{g}_2$ and the Clifford algebra.

In Sec. VI we generalize some aspects of the Bloch sphere to density matrices constructed from Lie algebra representations. It is shown that for each representation, there is a class of positive semidefinite, Hermitian trace-one density operators parametrized by a closed, bounded (hence compact) submanifold of Euclidean space, which we term the Bloch manifold. Explicit bounds are given on the size of these manifolds. A general method is given for finding the Bloch manifold exactly, using trace identities.

II. QUANTUM CHANNELS FROM LIE ALGEBRA REPRESENTATIONS

This section contains our notations and conventions for the generalized depolarizing channels which will be studied in detail in later sections. The possibility of defining a quantum channel

based on a representation of a compact Lie algebra was mentioned briefly, but never elaborated upon, in a paper of Gregoratti and Werner.[7] In any case, it is not necessary that the Lie algebra be compact.

A. Pure Lie algebra channels

It is a standard convention[8,9] to normalize the canonical generators for the defining representation of $\mathfrak{su}_n$ so that

$$\mathrm{Tr}(\lambda_a \lambda_b) = 2\delta_{ab}. \tag{2}$$

This has the desirable feature that the canonical generators for $n=2$ are the Pauli matrices, and those for $n=3$ are the familiar Gell-Mann matrices, while inserting factors of 2 in certain formulas. With convention (2), these generators will be orthogonal but not orthonormal with respect to the Killing form. We return to this point below.

On a general semisimple Lie algebra, the Killing form K is defined as

$$K(X,Y) = \mathrm{Tr}(\mathrm{ad}(X) \circ \mathrm{ad}(Y): \mathfrak{g} \to \mathfrak{g}),$$

where the trace is taken in the adjoint representation. At the moment we focus on semisimple algebras $\mathfrak{g}$, for which the Killing form is nondegenerate. Let α be an irreducible representation of $\mathfrak{g}$, let X_i be any basis of $\mathfrak{g}$, and let X_i' denote the dual basis with respect to the Killing form. The Casimir operator

$$C_2(\alpha) = \sum_i \alpha(X_i)\alpha(X_i')$$

does not depend on the choice of basis, and by Schur's lemma is proportional to the identity, so we write $C_2(\alpha) = c_2(\alpha)\mathbf{1}$. If X_i is orthonormal with respect to K, then $C_2(\alpha) = \Sigma_i \alpha(X_i)^2$. For reducible representations, $C_2(\alpha)$ may not be proportional to the identity.

Definition 2 (Lie algebra channel: Let $\mathfrak{g}$ *denote a Lie algebra of dimension* k, *with basis* $\{X_i : i = 1, \ldots, k\}$. *Let* α *be an irreducible* $\mathfrak{g}$*-representation on the Hilbert space* $\mathcal{H}$. *The* generalized depolarizing channel *or* Lie algebra channel *is defined to be the channel in which an error occurs conditionally with probability* p, *causing an initial state* $|\psi\rangle \in \mathcal{H}$ *to evolve into an ensemble of the* k *states* $\alpha(X_i)|\psi\rangle$, *all with equal likelihood.*

The Kraus operators for the channel of Definition 2 are given by

$$M_0 = \sqrt{1-p}\mathbf{1}, \quad M_i = \sqrt{\Lambda p}\alpha(X_i), \tag{3}$$

where Λ is a normalization constant which will be fixed momentarily. The operators M_μ are Hermitian if the representation is unitary and if $p \in [0,1]$, and are constrained to satisfy $\Sigma_\mu M_\mu M_\mu = \mathbf{1}$, which fixes the value of the constant Λ appearing in (3). By definition,

$$\sum_\mu M_\mu^2 = (1-p)\mathbf{1} + \Lambda p \sum_i \alpha(X_i)^2.$$

If $\Sigma_i \alpha(X_i)^2 = Z \cdot \mathbf{1}$, where Z is a constant (which in most cases we can take to be real), then

$$\Lambda = \frac{1}{Z}.$$

If X_i is orthonormal with respect to the Killing form, then $Z = c_2(\alpha)$. More generally, if the basis satisfies

$$K(X_i, X_j) = \mathfrak{n}\,\delta_{ij}, \quad \mathfrak{n} > 0,$$

then it can be rescaled to an orthonormal basis by a single constant. In this situation,

$$Z = \mathfrak{n}\, c_2(\alpha), \quad \Lambda = \frac{1}{Z}. \tag{4}$$

Defining the Killing norm by $\|x\|_K^2 = K(x,x)$, we note that if

$$\|X_i\|_K \neq \|X_j\|_K,$$

for some pair of indices i, j, then the normalization condition cannot be satisfied.

What if the representation is reducible? Suppose $\mathcal{H} = V \oplus W$ as a direct sum of irreducible $\mathfrak{g}$-modules, and X_i is orthonormal with respect to K. Then there exist independent constants Z_V and Z_W such that the operator

$$C_2(\alpha) = \sum_i \alpha(X_i)^2 = \begin{pmatrix} Z_V & 0 \\ 0 & Z_W \end{pmatrix}$$

as a block decomposition on $V \oplus W$. If $Z_V \neq Z_W$, then it is not possible for the Kraus operators (3) to give a trace-preserving map. On the other hand, if $Z_V = Z_W$ then they do define a CPT map even though the representation is reducible.

What if $p > 1$? Then $M_0 = i\sqrt{p-1}\mathbf{1}$, and we have

$$\sum_\mu M_\mu M_\mu^\dagger = (2p-1)\mathbf{1}.$$

Thus the map cannot be trace-preserving unless $p = 1$, which is a contradiction. A similar argument shows that $p < 0$ does not give a trace-preserving map. Thus, if we wish to study the framework of Definition 2, then we must limit ourselves to $p \in [0,1]$.

We summarize the results of the last few paragraphs in a theorem.

Theorem 2 (normalization): *Consider the Kraus operators*,

$$M_0 = (1-p)^{1/2}\mathbf{1} \quad \textit{and } M_i = (\Lambda p)^{1/2}\alpha(X_i),$$

for $i = 1, \ldots, k$. *If*

(i) $p \in [0,1]$,
(ii) *The representation* α *of* $\mathfrak{g}$ *is a direct sum of irreducible representations all with the same quadratic Casimir, and*
(iii) $\exists\ \mathfrak{n} > 0$ *such that* $K(X_i, X_j) = \mathfrak{n}\,\delta_{ij}$ *for all* i, j,

then $\Sigma_\mu M_\mu M_\mu = \mathbf{1}$ *with* Λ *given by* Eq. (4). *Conversely, if any of (i)–(iii) is not satisfied, then (except in trivial cases) there does not exist* Λ *s.t.* $\Sigma_\mu M_\mu M_\mu = \mathbf{1}$, *and the M's do not give rise to a quantum channel.*

The coefficients of the M_μ in (3) admit a natural "probability of error" interpretation, but in Sec. II B we investigate the possibility of modifying them to complex coefficients in order to obtain a channel. We find that no new channels arise unless one is willing to promote the coefficients to operators.

Using (1), the Lie algebra channel has the explicit Kraus decomposition

$$\boldsymbol{\rho} \to \mathcal{E}(\boldsymbol{\rho}) = (1-p)\boldsymbol{\rho} + \frac{p}{Z}\sum_{i=1}^{k} \alpha(X_i)\boldsymbol{\rho}\,\alpha(X_i). \tag{5}$$

As is proven in standard textbooks[9] (see Theorem 8.9), the trace of any generator of any representation of a compact simple Lie algebra is zero, so in particular, the $\alpha(X_i)$ are traceless. Moreover, it is clear that this transformation satisfies the defining properties for a quantum channel, given here as Definition 1.

Two operator-sum representations

$$\sum_{\mu} M_{\mu}\boldsymbol{\rho}M_{\mu}^{\dagger} \quad \text{and} \sum_{\nu} N_{\nu}\boldsymbol{\rho}N_{\nu}^{\dagger}$$

describe the same channel if and only if there exists a unitary matrix $U_{\nu\mu}$ such that $N_{\nu}=U_{\nu\mu}M_{\mu}$. Therefore, it is immaterial which basis of the Lie algebra that we use, as long as the two bases are related by a $U(N)$ similarity transformation. As noted in Theorem 2, in order to build a channel satisfying the normalization condition, we are forced to use a basis satisfying "orthonormality," $K(X_i,X_j)=\mathfrak{n}\,\delta_{ij}$. But any two "orthonormal" bases in this sense are related by a unitary transformation, so the CPT map constructed above is independent of the basis chosen for $\mathfrak{g}$.

Given a Lie algebra $\mathfrak{g}$ and a representation α on a vector space of dimension d, the CPT map (5) is a model for decoherence through a d-level noisy quantum channel, with errors that are not completely arbitrary; rather, they transform the state in a way determined by the representation of $\mathfrak{g}$.

The channels (5) have an extremely interesting structure. For a certain subclass of possible Lie algebra representations, the channel (5) has an action which, like the qubit case, is most simply described by a Bloch parametrization with polarization vector $v\in\mathbb{R}^k$, where $k=\dim\mathfrak{g}$. In these cases, we show that (5) decreases the length of v, and so deserves the title generalized depolarizing channel. In other cases of interest, a single Bloch vector is not sufficient, but the action of the channel can be described by similar rescalings of symmetric 2-tensors or higher-rank objects.

A natural step, which we begin in the next section, is to calculate the expression (5) explicitly in certain representations of classical Lie algebras.

Remark 1: When we use the terminology "the $\mathfrak{g}$-channel," where $\mathfrak{g}$ is a semisimple Lie algebra, the fundamental representation of $\mathfrak{g}$ is implied. Examples of fundamental representations include the n-dimensional defining representation of $\mathfrak{su}_n$, and the seven-dimensional irrep of G_2.

It is easy to see that the Lie algebra channel (5) always has the property of being *doubly stochastic*, i.e., $\mathcal{E}(\mathbf{1})=\mathbf{1}$. See, for example, Ref. 7 for further discussion.

B. A note on coefficients and extensions

As discussed prior to Theorem 2, for $p\notin[0,1]$ the transformation defined by (5) is CP but not T, and it is possible to recover a CPT map (channel) only if we consider different coefficients for the Kraus operators (3). To this end, let us first consider

$$M_0=m_0\mathbf{1} \quad \text{and } M_i=\frac{\tilde{m}}{\sqrt{Z}}\alpha(X_i), \tag{6}$$

where m_0, $\tilde{m}\in\mathbb{C}$ are some complex constants. Then to obtain a trace-preserving map, we require

$$\sum_{\mu} M_{\mu}^{\dagger}M_{\mu}=|m_0|^2+|\tilde{m}|^2=1\,.$$

This condition is equivalent to the statement that the point $(m_0,\tilde{m})\in\mathbb{C}^2\cong\mathbb{R}^4$ lies in the unit 3-sphere $S^3\subset\mathbb{R}^4$.

We can now view the coefficients of the Kraus operators (3) as the projection $S^3\to S^1$. Introduce a parameter $q\in[-1,1]$ such that $p=q^2$, and write (3) as $M_0=\pm\sqrt{1-q^2}\mathbf{1}$, and $M_i=(q/\sqrt{Z})\alpha(X_i)$. Then ignoring $\sqrt{Z}$, the coefficients of M_i and M_0 give a point on the unit circle. Further, m_0 and $\tilde{m}$ only enter through the square of their magnitude, so the two additional parameters associated to projecting from the 3-sphere are fictitious, and (5) is in fact the most general channel of this kind.

A nontrivial generalization is obtained by promoting m_0 and $\tilde{m}$ to *operators*. However this "generalization" is a special case of a well-known operation which extends an existing channel $\mathcal{E}_B$ using any set of operators which satisfy the normalization condition (1). Given two sets of Kraus operators $A_1,\ldots,A_r$ and $B_1,\ldots,B_s$ acting on the same vector space and satisfying

$$\sum_{i=1}^{r} A_i^\dagger A_i = \sum_{j=1}^{s} B_j^\dagger B_j = \mathbf{1},$$

we note that the set of operators

$$\{A_1, \ldots, A_{r-1}, B_1 A_r, \ldots, B_s A_r\} \tag{7}$$

also satisfies the normalization condition, because

$$\sum_{j=1}^{s} (B_j A_r)^\dagger B_j A_r = A_r^\dagger A_r.$$

This construction is *natural* with respect to the channel $\mathcal{E}_B$ defined by B_i, in the sense that if $\{B_i'\}$ is another set of Kraus operators defining the same channel, then the channel defined by (7) is also the same. Naturality does not hold for the A operators, but this will not concern us here. We call this procedure *the extension of $\mathcal{E}_B$ by the A operators, on the element A_r.*

For example, one may notice that the operators $Z^{-1/2}\alpha(X_i)$ of the preceding section satisfy the normalization condition since the sum of their squares is a Casimir element, and the normalization constant Z cancels the numerical factor. Consider this the B-channel, and extend it on every element by the same set of Kraus operators. This yields a "double $\mathfrak{g}$-channel" with Kraus operators

$$\left\{ \frac{1}{Z} X_i X_j : i,j = 1, \ldots, k \right\}. \tag{8}$$

These operators generate the image of $\mathfrak{g} \otimes \mathfrak{g}$ under the universal homomorphism expressed in the commutative diagram (18).

This underscores the fact that, aside from the basic examples of quantum channels provided by Sec. II A, many further examples may be obtained by extension, as in (7). As in the basic Lie algebra channels, computations with extended channels are facilitated by the existence of nontrivial identities which exist among the representation matrices. Channel (8) is interesting because for many representations, the matrices $\alpha(X_i)$ do not span the entire space of traceless $d \times d$ matrices, but the set of products $\alpha(X_i)\alpha(X_j)$ spans a subspace of larger dimension. Therefore the extension leading to (8) is a way of generating a channel whose Kraus operators come closer to spanning the space of all matrices in the appropriate dimension. If a density matrix were written as $\rho = \Sigma_{ij} w_{ij} X_i X_j$, and if the representation satisfies an identity for reduction of products of six generators, then one can calculate the action of (8) on ρ explicitly.

We are now in a position to interpret the channel defined by (6) with complex coefficients m_0, $\tilde{m}$ as the extension (7) of the identity channel with the unusual Kraus representation $B_1 = m_0 \mathbf{1}$, $B_2 = \tilde{m}\mathbf{1}$ by the nontrivial Lie algebra channel $A_i = Z^{-1/2}\alpha(X_i)$ on the element B_2. We may use naturality in B to rotate to the case $\tilde{m} = q \in [-1, 1]$ and $m_0 = \pm\sqrt{1-q^2}$ whence we recover (5), so there is no advantage to complexifying the coefficients. Given any channel whose set of Kraus operators do not contain $\mathbf{1}$, we can always extend it so that they do contain the identity by this method.

For the rest of this paper, we will assume that the Kraus operators take the form (3) in order to retain the beautiful probabilistic interpretation given by Definition 2. As we continue, we will keep in mind that extensions are possible, and develop methods which easily generalize.

III. THE $_n$ CHANNEL

A. Bloch methods for $_n$

The $\mathfrak{su}_n$ channel, our first example, is the channel built from the n-dimensional defining representation (also called standard representation) of $\mathfrak{su}_n$. It is simpler than most other channels

studied in this paper, because it admits a complete solution. Its action on any arbitrary input density matrix can be calculated in closed form using the Bloch parametrization, and in all cases it is a depolarizing channel.

One reason for the beauty and simplicity of the $\mathfrak{su}_n$ channel is that any n-dimensional density matrix admits a Bloch vector parametrization in terms of $\mathfrak{su}_n$ generators. This is because $k \equiv \dim(\mathfrak{su}_n) = n^2 - 1$ is only one less than n^2, the dimension over $\mathbb{R}$ of the space of $n \times n$ Hermitian matrices.

Any $n \times n$ Hermitian matrix ρ may be represented as

$$\rho = \frac{1}{n}(\mathrm{tr}(\rho)\mathbf{1} + T), \quad T \in \mathfrak{su}_n,$$

and having chosen a basis X_a for $\mathfrak{su}_n$, it follows that

$$T = \sum_{a=1}^{k} v_a X_a \equiv v \cdot X,$$

for some coefficient vector v. In analogy with the well-known parametrization of the 2×2 density matrices as the interior of a sphere, we will refer to v as the *Bloch vector*.

For $n \geqslant 3$ it may be hard to visualize the geometry of the space of density matrices in terms of the geometry of v. This question was first considered in the $n=3$ case by MacFarlane *et al.*[8] Section VI undertakes a systematic study of the geometry of the space of v which lead to a valid density matrix in various representations. We call this space the *Bloch manifold* and give details of the geometry for a number of important examples, including all representations of $\mathfrak{su}_2$, and the n-dimensional irrep of $\mathfrak{su}_n$.

B. The standard representation

In this section, we take α to be the standard representation of $\mathfrak{su}_n$ on a vector space $\mathcal{H}$ of dimension n. For simplicity, we let X_i denote both the generator of $\mathfrak{su}_n$ and its image under this representation. One could now compute the quadratic Casimir in the standard way using roots and weights, but it will turn out that the value of this Casimir as well as all other properties we will need to obtain a complete solution to the $\mathfrak{su}_n$ channel follow from the single relation

$$X_i X_j = \beta \delta_{ij} \mathbf{1} + \sum_k Q_{ijk} X_k \tag{9}$$

for some constant β and tensor Q_{ijk}. Of course, this relation is just the decomposition of a Hermitian matrix into a trace part with trace $n\beta\delta_{ij}$, and a linear combination of the X_k, which generate the space of traceless matrices.

Elements of the standard basis of $\mathfrak{su}_n$ are called Gell-Mann matrices, and they satisfy

$$\mathrm{Tr}(X_i X_j) = 2\delta_{ij},$$

so $\beta = 2/n$. Many properties of the Q tensor already follow from the single assumption that X_i generate a Lie algebra. It is immediate that $Q_{[ij]k} = i f_{ijk}$ where $[ij]$ denotes antisymmetrization, and f_{ijk} is $1/2$ times the structural tensor of the Lie algebra. It follows that

$$Q_{ijk} = d_{ijk} + i f_{ijk}$$

for some d_{ijk} symmetric in the first two indices. Also, (9) implies

$$\{X_i, X_j\} = \frac{4}{n}\delta_{ij}\mathbf{1} + 2\sum_l d_{ijl} X_l.$$

Multiplying by X_k and taking the trace yields

$$d_{ijk} = \tfrac{1}{4}\mathrm{Tr}(\{X_i, X_j\}X_k),$$

therefore the d-tensor is *completely* symmetric, and interchange of any two indices has the effect of complex conjugating Q. Since $\Sigma_i X_i X_i$ is a multiple of the identity,

$$\sum_i d_{iik} = \frac{1}{2}\mathrm{Tr}\left(\left(\sum_i X_i X_i\right)X_k\right) = 0. \tag{10}$$

It follows from the associativity of matrix multiplication that

$$f_{ijm}f_{klm} = \frac{2}{n}(\delta_{ik}\delta_{jl} - \delta_{il}\delta_{jk}) + d_{ikm}d_{jlm} - d_{jkm}d_{ilm}$$

with a sum over m implied. Contracting j and k and using (10) yields

$$d_{ijm}d_{ljm} = f_{ijm}f_{jlm} + \left(2n - \frac{4}{n}\right)\delta_{il}.$$

By a general property of compact semisimple Lie algebras, the structure constants satisfy

$$f_{ijk}f_{ljk} = n\delta_{il}. \tag{11}$$

Therefore, $d_{ijm}d_{ljm} = [n - (4/n)]\delta_{il}$. Using this and (11), we obtain

$$Q_{ijm}Q_{ljm} = d_{ijm}d_{ljm} - f_{ijm}f_{ljm} = -\frac{4}{n}\delta_{il}. \tag{12}$$

C. Solution of the $_n$ channel

For this basis of $\mathfrak{su}_n$, $Z = 2k/n$, where $k = n^2 - 1$. The action of the channel

$$\boldsymbol{\rho} \to \mathcal{E}(\boldsymbol{\rho}) = (1-p)\boldsymbol{\rho} + \frac{pn}{2k}\sum_{i=1}^{k} X_i \boldsymbol{\rho} X_i$$

on the density matrix

$$\boldsymbol{\rho} = \frac{1}{n}(\mathrm{tr}(\boldsymbol{\rho})\mathbf{1} + v \cdot X)$$

is given by

$$\mathcal{E}(\boldsymbol{\rho}) = \frac{\mathrm{tr}(\boldsymbol{\rho})}{n}\mathbf{1} + \frac{1-p}{n}v \cdot X + \frac{p}{2k}\sum_{i,j} v_j X_i X_j X_i. \tag{13}$$

Using (9) to expand the triple product, we have

$$\sum_{j,i} v_j X_i X_j X_i = \beta v \cdot X + \beta \sum_{i,j} v_a Q_{iji}\mathbf{1} + \sum_{i,j,k,a} v_j Q_{ijk} Q_{kia} X_a.$$

Since $\mathcal{E}(\boldsymbol{\rho})$ has unit trace, it must be the case that $\Sigma_i Q_{iji} = 0$. The same conclusion also follows from (10), but it is amusing to see that $\Sigma_i Q_{iji}$ must vanish because this is a CPT map. Therefore,

$$\mathcal{E}(\boldsymbol{\rho}) = \frac{\mathrm{tr}(\boldsymbol{\rho})}{n}\mathbf{1} + \frac{1-p+p/k}{n}v \cdot X + \frac{p}{2k}\sum_{i,j,k,a} v_j Q_{ijk} Q_{kia} X_a. \tag{14}$$

Using (12), we have finally

$$\mathcal{E}(\boldsymbol{\rho}_v) = \frac{1}{n}(\mathrm{tr}(\boldsymbol{\rho})\mathbf{1} + f(p,n)v \cdot X),$$

where

$$f(p,n) = 1 - p - \frac{p}{k} = \frac{(1-p)n^2 - 1}{n^2 - 1}. \tag{15}$$

In the qubit case, $f(p,2) = 1 - 4p/3$, which is consistent with standard results.

D. Properties of the solution

The $\mathfrak{su}_n$ channel maps an initial density matrix to a linear combination of itself and the identity, i.e., it has the form

$$\Delta_\lambda(\boldsymbol{\rho}) = \lambda\boldsymbol{\rho} + \left(\frac{1-\lambda}{n}\right)\mathbf{1}. \tag{16}$$

This is the standard definition of the n-dimensional depolarizing channel. The information-carrying capacity of this channel was studied in great detail by King,[10] where notably the Amosov-Holevo-Werner[11] conjecture was established for channels which are products of a depolarizing channel with an arbitrary channel. Channels based on representations of semisimple algebras generically do not take the form (16), except possibly on special subsets of the space of density matrices; see Theorem 3.

The depolarizing channel on an n-dimensional Hilbert space satisfies complete positivity if and only if

$$\frac{1}{1-n^2} \leqslant \lambda \leqslant 1.$$

The $\mathfrak{su}_n$ channel has the form (16) for $\lambda = f(p,n)$. Note that the relation

$$\frac{-1}{n^2-1} \leqslant f(p,n) \leqslant 1$$

holds for all $n \geqslant 2$. In fact, $f(p,n)$ saturates both of these inequalities at the endpoints of the allowed range, $0 \leqslant p \leqslant 1$.

Knowing that the $\mathfrak{su}_n$ channel is depolarizing allows an easy calculation of the minimal von Neumann output entropy,

$$S_{\min} = \frac{-np}{1+n}\ln\left(\frac{np}{n^2-1}\right) - \left(1 - \frac{np}{1+n}\right)\ln\left(1 - \frac{np}{1+n}\right),$$

with large n behavior $\lim_{n\to\infty} S_{\min}/\ln(n) = p$.

At the special value $p = 1 - n^{-2}$, the $\mathfrak{su}_n$ channel is a constant map from $\mathbb{R}^{n^2-1}$ into the space of density matrices,

$$\mathcal{E}(\boldsymbol{\rho}_v) = \frac{1}{n}\mathbf{1} \quad \text{for all } v, \quad \text{at } p = p_c \equiv 1 - n^{-2}. \tag{17}$$

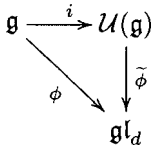
Physically, if the probability of error happens to be $p = p_c$, then $\mathfrak{su}_n$-decoherence evolves an arbitrary initial density matrix into a completely uniform ensemble consisting of pure states with equal probabilities. This is the "worst" value of p, in the sense that all information about the initial density matrix has been lost. This result is *stable* in the sense that if p is only approximately equal to the critical value, the initial density matrix decoheres into an approximately uniform ensemble. We will see in Sec. IV that for other Lie algebra channels, there are critical values of p which generalize (17).

IV. OTHER REPRESENTATIONS

A. General remarks

In the n-dimensional standard representation of $\mathfrak{su}_n$, the representation matrices $\alpha(X_i)$ span the space of all traceless Hermitian matrices, and thus an arbitrary initial density matrix can be expressed in terms of the $\alpha(X_i)$ and the identity. As we consider higher-dimensional representations, the representation matrices become increasingly sparse in the space of all traceless matrices, and thus only some fraction of the set of all possible density matrices can be expressed in the form $d_\alpha^{-1}\mathbf{1}+\Sigma_i v_i \alpha(X_i)$. Also for higher-dimensional irreducible representations, (9) does not hold. Therefore, ideas are needed to further extend our analysis to irreps which have higher dimension than the fundamental representation. This is the subject of Sec. IV. Let $d=d_\alpha$ denote the dimension of the representation α, and $\mathfrak{gl}_d$ as usual denotes the associative algebra of all $d\times d$ matrices.

A representation ϕ of $\mathfrak{g}$ lifts to a unique associative algebra homomorphism $\tilde{\phi}$ of the universal enveloping algebra $\mathcal{U}(\mathfrak{g})$, by the universal property most elegantly expressed in the commutative diagram



(18)

The action of $\tilde{\phi}$ is simply to convert the tensor product to matrix multiplication, i.e., $\tilde{\phi}(x\otimes y)=\phi(x)\cdot\phi(y)$, etc. The interesting property about this commutative diagram, and one which gives a computational method for Lie algebra channels, is that if ϕ is an irreducible faithful representation and if $\mathfrak{g}$ is a semisimple Lie algebra, then $\tilde{\phi}$ is surjective.

This surjectivity has the consequence that for *any representation* of said Lie algebra, *every* density matrix can be represented as a linear combination of products of the representation matrices. In other words, the calculational method outlined in this section will always work. Before continuing our discussion of this, let us consider a simple but nontrivial example, the spin-1 channel, in complete detail.

B. The spin-1 channel

Consider the spin-1 representation of $\mathfrak{su}_2$. We use standard angular momentum notation, in which

$$J_1=\frac{1}{\sqrt{2}}\begin{pmatrix}0&1&0\\1&0&1\\0&1&0\end{pmatrix},\quad J_2=\frac{1}{\sqrt{2}}\begin{pmatrix}0&-i&0\\i&0&-i\\0&i&0\end{pmatrix},\quad J_3=\begin{pmatrix}1&0&0\\0&0&0\\0&0&-1\end{pmatrix}.$$

Before generalizing to arbitrary density matrices, we restrict attention to the simpler example of density matrices $\boldsymbol{\rho}$ which are of the form

$$\boldsymbol{\rho}_v=\tfrac{1}{3}(\mathbf{1}+v\cdot J),\quad v\in\mathbb{R}^3. \tag{19}$$

Then

$$\mathcal{E}(\boldsymbol{\rho}_v)=\frac{1}{3}\mathbf{1}+\frac{1-p}{3}v\cdot J+\frac{p}{6}\sum_{a,b}v_b J_a J_b J_a. \tag{20}$$

The relation analogous to (9) does not hold, i.e., J_aJ_b is not a linear combination of $\mathbf{1}$ and $\{J_i: i=1,\ldots,3\}$. In this special case, the triple product appearing in (20) simplifies considerably,

$$J_a J_b J_a = \delta_{ab} J_a \quad \text{(no sum)}, \tag{21}$$

which implies that

$$\mathcal{E}(\boldsymbol{\rho}_v) = \frac{1}{3}\left(\mathbf{1} + \left(1 - \frac{p}{2}\right) v \cdot J\right). \tag{22}$$

This takes the form (19) with $v \to [1-(p/2)]v$. Thus, for 3×3 density matrices admitting a Bloch parametrization, the spin-1 channel scales the Bloch vector by a number between $1/2$ and 1.

Interestingly, we can go further and find a Bloch-type picture of the spin-1 channel on a general density matrix. The six elements of the form

$$J_{(a}J_{b)} \equiv \tfrac{1}{2}(J_a J_b + J_b J_a),$$

together with J_1, J_2, and J_3, span the space of 3×3 matrices. Therefore an arbitrary 3×3 density matrix $\boldsymbol{\rho}$ can be written as

$$\boldsymbol{\rho}_{v,w} = v \cdot J + \sum_{a,b} w_{ab} J_{(a}J_{b)} \tag{23}$$

for some vector v and symmetric tensor w.

We use standard physics normalizations which entail that for the spin-s representation in $d = 2s+1$ dimensional space,

$$\sum_a J_a^2 = \lambda\, \mathbf{1} \quad \Rightarrow \quad \operatorname{tr}(J_a J_b) = \frac{d\lambda}{3}\delta_{ab},$$

where $\lambda = s(s+1)$. Then we have

$$\operatorname{tr}(\boldsymbol{\rho}_{v,w}) = \frac{d\lambda}{3}\operatorname{tr}(w).$$

It follows that in order to have a density matrix, we require $\operatorname{tr}(w) = 3(d\lambda)^{-1}$. For $s=1$, $\operatorname{tr}(w) = 1/2$.

Theorem 3 (action of the spin-1 channel): *The action of the spin-1 channel on the vector and symmetric tensor are $v \to v'$ and $w \to w'$, where*

$$\begin{aligned} v_a &\to v_a{}' = \left(1 - \frac{p}{2}\right) v_a, \\ w_{ab} &\to w_{ab}{}' = \left(1 - \frac{3p}{2}\right) w_{ab} + \frac{p}{4}\delta_{ab}. \end{aligned} \tag{24}$$

Proof: The asymmetric quadruple product identity

$$\sum_i J_i J_j J_k J_i = \delta_{jk}\mathbf{J}^2 - J_k J_j \tag{25}$$

implies the symmetrized identity

$$\sum_i J_i J_{(a} J_{b)} J_i = \delta_{ab}\mathbf{J}^2 - J_{(a}J_{b)}. \tag{26}$$

We refer to identities of the form (25) and (26) as "$4 \to 2$ identities," because they relate degree 4 polynomials in the generators to degree 2 polynomials. Using $4 \to 2$ identities and (21), a straightforward calculation shows that $\mathcal{E}(\boldsymbol{\rho}_{v,w})$ is equal to

$$\left(1-\frac{p}{2}\right)v\cdot J+\left(1-\frac{3p}{2}\right)\sum_{a,b}w_{ab}J_{(a}J_{b)}+p\,\mathrm{tr}(w)\mathbf{1},$$

which implies the stated result, since for spin-1, we have $\mathrm{tr}(w)=1/2$ and $\mathbf{1}=\Sigma_{a,b}\frac{1}{2}\delta_{ab}J_{(a}J_{b)}$. □

Theorem 3 shows that $p=2/3$ is a sort of critical value; the channel at $p=2/3$ maps an arbitrary initial $\boldsymbol{\rho}$ into a density matrix with a Bloch representation; $\mathcal{E}(\boldsymbol{\rho})=d^{-1}(\mathbf{1}+v\cdot J)$. These are a three-dimensional set within the eight-dimensional space of all 3×3 density operators. This is reminiscent of the critical value $p=1-n^{-2}$ for the $\mathfrak{su}_n$ channel, but now there is no value of p for which the channel outputs pure noise.

It is possible to iterate formula (24), with interesting results. Clearly, after n applications of the channel, $v\rightarrow[1-(p/2)]^n v$. Consider a W-state, i.e., a state of the form

$$\boldsymbol{\rho}_w=\sum_{a,b}w_{ab}J_{(a}J_{b)},$$

and let $\mathcal{E}^n$ denote n applications of the spin-1 channel.

Theorem 4 (iteration formula): *The action of $\mathcal{E}^n$ on w is the following:*

$$w\underset{\mathcal{E}^n}{\longrightarrow}F^{(n)}(p)(\mathbf{1}-6w)+w,$$

where $F^{(n)}(p)$ is a degree n polynomial in p, determined as follows. $F^{(1)}(p)=1-3p/2$, and the $F^{(n)}$ for $n>1$ are determined by the recursion relation

$$F^{(n+1)}(p)=\left(1-\frac{3p}{2}\right)F^{(n)}(p)+\frac{p}{4}.$$

Interestingly, this recursion relation has the same coefficients as the transformation (24) of w itself.

C. Higher spin representations

Note that the triple product (21) and quadruple product (25) identities are simply certain elements of the ideal $\mathcal{I}=\ker(\tilde{\phi})$, where $\tilde{\phi}$ is the representation of the universal enveloping algebra, as in (18). The larger this ideal, the more product identities there will be in the representation of interest. For higher spin, we have the following $3\rightarrow 1$ identity in the spin-s representation of $\mathfrak{su}_2$:

$$\sum_{i=1}^{3}J_iJ_aJ_i=(\lambda-1)J_a,\quad \text{where } \lambda=s(s+1). \tag{27}$$

There is also a generalization of the $4\rightarrow 2$ identity valid for general spin-s,

$$\sum_{i=1}^{3}J_iJ_aJ_bJ_i=(\lambda-2)J_aJ_b+\lambda\delta_{ab}\mathbf{1}-J_bJ_a.$$

The latter has the more convenient symmetrized form,

$$\sum_{i=1}^{3}J_iJ_{(a}J_{b)}J_i=(\lambda-3)J_{(a}J_{b)}+\lambda\delta_{ab}\mathbf{1}. \tag{28}$$

Theorem 5 (higher spin channel): *Let J_1, J_2, J_3 be canonical generators for the spin-s representation of $\mathfrak{su}_2$ in dimension $d=2s+1$, and let $\mathcal{E}_s$ denote the spin-s channel. Defining $\boldsymbol{\rho}_{v,w}=v\cdot J+\Sigma_{a,b}w_{ab}J_{(a}J_{b)}$, we have*

$$\mathrm{tr}(\boldsymbol{\rho}_{v,w})=1\Leftrightarrow\ \mathrm{tr}(w)=\frac{3}{d\lambda},$$

where $\lambda = s(s+1)$. *The action of the spin-s channel is*

$$\mathcal{E}_s(\rho_{v,w}) = \left(1 - \frac{p}{\lambda}\right) v \cdot J + \left(1 - \frac{3p}{\lambda}\right) w_{ab} J_{(a} J_{b)} + p \operatorname{tr}(w) \mathbf{1}.$$

Proof: A straightforward application of (27) and (28). □

Thus, the action of the spin channel is more complicated than the scaling of a single vector. It is the scaling of a series of symmetric tensors, by different scale factors. This shows that the spin-s channels are never depolarizing channels.

At the critical value $p = \lambda/3$, the channel maps an arbitrary $\rho_{v,w}$ into a matrix with a Bloch representation,

$$\mathcal{E}_s(\boldsymbol{\rho}_{v,w})\big|_{p=\lambda/3} = \frac{1}{d}\mathbf{1} + \frac{2}{3} v \cdot J.$$

It follows that if $p = \lambda/3$, then the channel maps an initial density matrix of the form (23) with $v = 0$ into pure noise.

For spin-1, an arbitrary density matrix may be represented as (23), and for higher spin, these are a proper submanifold of the convex cone of all density matrices. For spin-3/2, an arbitrary density matrix may be written in the form

$$\sum_{a,b} w_{ab} J_{(a} J_{b)} + \sum_{a,b,c} u_{abc} J_{(a} J_b J_{c)},$$

where w and u are completely symmetric tensors. The U-term is traceless, and so we require the W-term to have trace one. As discussed prior to Theorem 3, this means that $\operatorname{tr}(w) = 3/(d\lambda) = 1/5$.

D. Finding *v* and *w* from *ρ* in higher spin and pure states

In this brief section we show how to invert the relation (23) for the density operator, and find the coefficient vector v and symmetric tensor w. We do the analysis at arbitrary spin, although for spin higher than 1, not all density matrices have the form (23). The methods will generalize assuming the relevant trace identities can be found.

As in Theorem 5, let J_1, J_2, J_3 be canonical generators for the spin-s representation of $\mathfrak{su}_2$. Note that

$$\operatorname{Tr}(J_a J_b) = \frac{1}{3} d\lambda \, \delta_{ab} \quad \text{and} \quad \operatorname{Tr}(J_a J_b J_c) = i \frac{d\lambda}{6} \epsilon_{abc},$$

where $\lambda = s(s+1)$ and $d = 2s+1$, and ϵ_{abc} is the Levi-Civita alternating symbol. It follows immediately from (23) that

$$v_a = \frac{3}{d\lambda} \operatorname{Tr}(\rho J_a).$$

To find w, note the trace identity

$$\operatorname{Tr}(J_{(a} J_{b)} J_{(j} J_{k)}) = f_1(s) \tfrac{1}{2}(\delta_{ak}\delta_{bj} + \delta_{bk}\delta_{aj}) + f_2(s)\delta_{ab}\delta_{jk},$$

where f_i are functions of s, given by

$$f_1 = \operatorname{tr}(J_{(1} J_{2)})^2 = \frac{\lambda d(d^2-4)}{30},$$

$$f_2 = \operatorname{tr}(J_1^2 J_2^2) = \frac{\lambda d(1+2\lambda)}{30}.$$

By calculating $\operatorname{tr}(\rho J_{(j} J_{k)})$, we find

$$w_{jk} = \frac{1}{f_1}\left(\mathrm{tr}(\rho J_{(j}J_{k)}) - f_2\,\mathrm{tr}(w)\,\delta_{jk}\right) = \frac{30}{\lambda d(d^2-4)}\mathrm{tr}(\rho J_{(j}J_{k)}) - \frac{2\lambda+1}{d^2-4}\mathrm{tr}(w)\,\delta_{jk}.$$

For spin-1, $f_1=1/2$, $f_2=1$, and $d\lambda=6$ so

$$v_a = \tfrac{1}{2}\mathrm{tr}(\rho J_a) \quad \text{and } w_{jk} = \mathrm{tr}(\rho J_{(j}J_{k)}) - \tfrac{1}{2}\delta_{jk}.$$

This gives another way to find pure states, if $\rho=|\psi\rangle\langle\psi|$ then

$$v_a = \tfrac{1}{2}\langle J_a\rangle_\psi \quad \text{and } w_{jk} = \langle J_{(j}J_{k)}\rangle_\psi - \tfrac{1}{2}\delta_{jk}. \tag{29}$$

In conclusion, if the pure state $\rho=|\psi\rangle\langle\psi|$ has a representation of the form (23), then we can find its Bloch vector and w-matrix easily.

E. Relation to the Werner-Holevo channel and a new conjecture

Datta[12] has shown that the spin-1 channel at $p=1$ is equivalent to the Werner-Holevo channel[13]

$$\mathcal{E}_{\mathrm{WH}}(\rho) = \frac{1}{d-1}(\mathrm{tr}(\rho)\mathbf{1} - \rho^T). \tag{30}$$

Recall that in our notation, $M_0=\sqrt{1-p}\mathbf{1}$, so taking $p=1$ eliminates the identity from the set of Kraus operators. For $p<1$ and for the spin-s representation with $s>1$, we may view the spin channel as a generalization of the WH channel.

Amosov *et al.*[11] conjectured that ν_q is multiplicative for tensor product channels,

$$\nu_q(\mathcal{E}^{\otimes m}) \equiv \sup_{\Gamma\in\mathcal{D}(\mathcal{H}^{\otimes m})} \|\mathcal{E}^{\otimes m}(\Gamma)\|_q = \nu_q(\mathcal{E})^m, \tag{31}$$

where $\nu_q(\mathcal{E})=\sup_{\gamma\in\mathcal{D}(\mathcal{H})}\|\mathcal{E}(\gamma)\|_q$ is the maximal ℓ_q-norm. Equation (31) is often called the ℓ_q *multiplicativity relation* or the *AHW conjecture*. Giovannetti *et al.*[14] have conjectured that (31) holds for the Werner-Holevo channel when $d\geqslant 2^{q-1}$.

The Werner-Holevo channel became famous as a counterexample to the AHW conjecture.[11] We infer by Datta's equivalence that the spin-1 channel at $p=1$ gives precisely the same counterexample to the AHW conjecture, stated below. Therefore, multiplicativity does not hold generically in Lie algebra channels. Once it was established that the AHW conjecture does not hold for all $q\geqslant 1$, it was natural to conjecture[15] that it holds for $1\leqslant q\leqslant 2$, and this was recently proved for the WH channel by Alicki and Fannes.[16] If this is true, one would expect additional counterexamples with values of q approaching 2. However, none have yet been reported, except for the WH channel which gives a sequence of counterexamples with q increasing from 4.79 as the dimension d increases. Ruskai, in a private communication to the author, suggested the possibility that Lie algebra channels might provide additional counterexamples with special properties.

Conjecture 1: Lie algebra channels generate counterexamples to the AHW conjecture for a sequence of values of q approaching the boundary of the region in q-space where multiplicativity begins to hold for all channels, assuming there is such a region.

A preliminary investigation in this direction seems promising, and we hope to address this more fully in a future paper.

V. EXCEPTIONAL LIE ALGEBRAS AND CLIFFORD ALGEBRAS

A. Channels based on the exceptional algebra G_2

Let e_j $(j=0,\ldots,7)$ denote the standard basis for the octonions $\mathbb{O}$, where e_0 is the unit. Our notation is compatible with that of Baez,[17] and the proofs of our statements about the octonion algebra can be found there. The Lie group G_2 is the automorphism group of $\mathbb{O}$, so the Lie algebra $\mathfrak{g}_2$ is the derivation algebra of the octonions,

$$\mathfrak{g}_2 = \mathfrak{der}(\mathbb{O}).$$

Derivations act trivially on the identity, and the imaginary octonions $\mathrm{Im}(\mathbb{O})$ form the fundamental seven-dimensional irreducible representation of $\mathfrak{g}_2$.

It is known that if $\mathcal{A}$ is an alternative, nonassociative algebra (such as the octonions), any pair of elements $x,y \in \mathcal{A}$ define a derivation $D(x,y):\mathcal{A}\to\mathcal{A}$ by

$$D(x,y)a = [[x,y],a] - 3[x,y,a], \tag{32}$$

where $[a,b,x]$ denotes the associator $(ab)x - a(bx)$. When $\mathcal{A}$ is a normed division algebra, every derivation is a linear combination of derivations of this form. For the octonion algebra, the elements

$$D(e_1,e_i), \quad D(e_2,e_j), \quad \text{and } D(e_4,e_k)$$

for all $i>1$, $j>2$, and $k>4$, are linearly independent and there are 14 such elements, so they are a basis for $\mathfrak{g}_2$. Define the notation

$$d_{i,j} = \tfrac{1}{2}D(e_i,e_j).$$

This is one possible basis for the Lie algebra $\mathfrak{g}_2$, but we will use another more suited for our purposes. The fact[18] that the six-dimensional sphere S^6 may be viewed as a $G_2/\mathrm{SU}(3)$ coset space, implies a corresponding decomposition of the algebra:

$$\mathfrak{g}_2 = \mathfrak{m} + \mathfrak{h}, \quad \mathfrak{h} \cong \mathfrak{su}_3,$$

where $\mathfrak{m}$ is a six-dimensional subspace. We find a basis adapted to this decomposition. The basis vectors for $\mathfrak{m}$ are simply expressed as $m_i = d_{1,i+1}$, while

$$h_1 = d_{12} + 2d_{47}, \quad h_2 = d_{13} - 2d_{46}, \quad h_3 = d_{14} - 2d_{27},$$

$$h_4 = d_{15} + 2d_{26}, \quad h_5 = d_{16} - 2d_{25}, \quad h_6 = d_{17} + 2d_{24},$$

$$h_7 = \sqrt{3}d_{23}, \quad h_8 = d_{23} + 2d_{45}$$

are a basis for $\mathfrak{su}_3$. Let

$$\beta = \frac{i}{\sqrt{24}}\left(\{m_1,\ldots,m_6\} \cup \frac{1}{\sqrt{3}}\{h_1,\ldots,h_8\}\right)$$

denote a corresponding basis for $\mathfrak{g}_2$. Interestingly, β is an orthonormal basis of $\mathfrak{g}_2$ with respect to the trace form on the seven-dimensional representation space,

$$\mathrm{Tr}_{\mathrm{Im}(\mathbb{O})}(\beta_i\beta_j) = \tfrac{1}{2}\delta_{ij}, \quad \text{therefore } \sum_{i=1}^{14} \beta_i^2 = I_7.$$

The $\mathfrak{g}_2$ channel acts as

$$\mathcal{E}(\boldsymbol{\rho}) = (1-p)\boldsymbol{\rho} + p\sum_{i=1}^{14} \beta_i \boldsymbol{\rho}\, \beta_i.$$

Assume $\boldsymbol{\rho}$ has a Bloch representation with $\mathbf{v} \in \mathbb{R}$,[14]

$$\boldsymbol{\rho} = \tfrac{1}{7}(I_7 + \mathbf{v}\cdot\boldsymbol{\beta}), \tag{33}$$

then as an intermediate step,

$$\mathcal{E}(\boldsymbol{\rho}) = \frac{1-p}{7}(I + \mathbf{v}\cdot\boldsymbol{\beta}) + \frac{p}{7}\sum_{i=1}^{14}(\beta_i^2 + v_a\beta_i\beta_a\beta_i).$$

The sum of β_i^2 gives the identity, with a factor of $p/7$ to cancel the $-p/7$, and (miraculously) the term which is cubic in β's vanishes identically. This is due to the following remarkable $3\to 0$ identity

$$\sum_i \beta_i\beta_a\beta_i = 0 \quad \text{for all } a,$$

as may be checked explicitly. Therefore, the $\mathfrak{g}_2$ channel (restricted to its Bloch manifold) is the simplest of all. It is a true depolarizing channel, shrinking its Bloch vector by a factor of $1-p$,

$$\mathcal{E}(\boldsymbol{\rho}) = \tfrac{1}{7}(I + (1-p)\mathbf{v}\cdot\boldsymbol{\beta}).$$

We emphasize, however, that the $\mathfrak{g}_2$ channel is almost certainly *not* a depolarizing channel outside the Bloch manifold, though we have not proven this.

B. Channels based on the Clifford algebra

Let $\langle,\rangle$ be a nondegenerate bilinear form on V, a d-dimensional vector space. A representation of the Clifford algebra associated to $(V,\langle,\rangle)$ is a map $\gamma: V\to\mathfrak{gl}(V)$ satisfying

$$\{\gamma(x),\gamma(y)\} = \langle x,y\rangle\mathbf{1},$$

where the left-hand side is an anticommutator. The representation is *Hermitian* if the image of γ is contained in $H(V)$, the (Hilbert) space of Hermitian operators on V.

Theorem 6 (Clifford algebra channel): *Given a Hermitian representation of the Clifford algebra, and a finite collection of nonzero vectors* $x_1, x_2, \ldots, x_n \in \mathbb{R}^d$, *then*

$$\mathcal{E}_{C\ell}(\boldsymbol{\rho}) \equiv \left(\sum_{i=1}^{n}\langle x_i,x_i\rangle\right)^{-1}\sum_{i=1}^{n}\gamma(x_i)\boldsymbol{\rho}\,\gamma(x_i) \tag{34}$$

is a CPT map.

Proof: The operator is completely positive because it is already in the form of an operator sum representation. We check that it is trace preserving. By cyclicity of the trace,

$$\mathrm{Tr}(\mathcal{E}_{C\ell}(\boldsymbol{\rho})) = \left(\sum_{i=1}^{n}\langle x_i,x_i\rangle\right)^{-1}\sum_{i=1}^{n}\mathrm{Tr}(\boldsymbol{\rho}\,\gamma(x_i)^2).$$

However, $\gamma(x_i)^2 = \frac{1}{2}\{\gamma(x_i),\gamma(x_i)\} = \langle x_i,x_i\rangle\mathbf{1}$ using the Clifford algebra. The sum of such terms decouples from $\mathrm{Tr}(\boldsymbol{\rho})$ and exactly cancels the prefactor.

Although the proof of Theorem 6 is trivial, the result may not be easily obtained by inspecting any of the standard matrix representations. Taking the Weyl representation of the γ matrices in $d=4$, writing out the CPT map $\gamma(x)\boldsymbol{\rho}\gamma(x)+\gamma(y)\boldsymbol{\rho}\gamma(y)$ for general x, y, $\boldsymbol{\rho}$ as an explicit matrix takes a full page.

As we have seen in other examples, the computational methods used in this paper are most effective when an arbitrary density matrix can be written in terms of the generators of the symmetry algebra. For the Weyl representation of the Clifford algebra, there is a convenient basis consisting of antisymmetric combinations of γ matrices, which we summarize in the following:

$\mathbf{1}$	one of these
γ^μ	four of these
$\gamma^{\mu\nu} = \frac{1}{2}[\gamma^\mu,\gamma^\nu] = \gamma^{[\mu}\gamma^{\nu]}$	six of these
$\gamma^{\mu\nu\rho} = \gamma^{[\mu}\gamma^\nu\gamma^{\rho]} = i\epsilon^{\mu\nu\rho\sigma}\gamma_\sigma\gamma^5$	four of these

$$\gamma^{\mu\nu\rho\sigma} = \gamma^{[\mu}\gamma^{\nu}\gamma^{\rho}\gamma^{\sigma]} = -i\epsilon^{\mu\nu\rho\sigma}\gamma^5 \qquad \text{one of these}$$

These 16 matrices form a basis for the space $\mathfrak{gl}(\mathbb{R}^4)$. One can therefore write any 4×4 density matrix as a linear combination of these matrices with coefficients that are tensors of rank 4, and use γ matrix identities to calculate the action of the CPT map (34).

VI. THE BLOCH MANIFOLD

A. General results

The Bloch manifold is a geometrical space which is naturally associated to a certain representation of a semisimple Lie algebra $\mathfrak{g}$, by asking the question, which linear combinations of the generators of $\mathfrak{g}$ in that representation are positive-definite, trace-one Hermitian matrices, i.e., physical states? For any preferred class of matrices (such as those with non-negative eigenvalues) one can define a manifold from a representation in a similarly basis-dependent way, but for the application to quantum physics, we restrict interest to density matrices.

Since the action of the $\mathfrak{su}_n$ channel is most simply expressed as a rescaling of the Bloch vector and any n-level density matrix admits a Bloch representation, all that remains for a complete mathematical description of the $\mathfrak{su}_n$ channel is to know the set of vectors $v \in \mathbb{R}^{n^2-1}$ which correspond to positive-definite matrices.

The simplest example of why this is an important question for other representations is formula (22), which gives the action of the spin-1 channel on density matrices admitting a Bloch representation as

$$\mathcal{E}(\boldsymbol{\rho}_v) = \frac{1}{3}\left(\mathbf{1} + \left(1 - \frac{p}{2}\right) v \cdot J\right).$$

Thus, the spin-1 channel also rescales the Bloch vector and it is of interest to know which Bloch vectors give rise to physical states.

In any representation which has a $3 \to 1$ identity, i.e., an expression for $\Sigma_i \alpha(X_i)\alpha(X_j)\alpha(X_i)$ in terms of the generators $\alpha(X_k)$, it follows that any density matrix admitting a Bloch representation transforms very simply under the action of the Lie algebra channel.

Definition 3 (Bloch manifold): Choose a set of generators $\{X_i\}$ *of a semisimple Lie algebra* $\mathfrak{g}$, *and an irreducible representation* $\alpha: \mathfrak{g} \to \mathfrak{gl}(\mathcal{H})$ *on a* d_α*-dimensional Hilbert space* $\mathcal{H}$. *The* Bloch manifold $\mathcal{V}$ *(in the* X_i *basis) is defined to be the set of vectors* $v \in \mathbb{R}^k$ ($k = \dim \mathfrak{g}$), *such that*

$$\boldsymbol{\rho}(v) = \frac{1}{d_\alpha}\left(\mathbf{1} + \sum_i v_i \alpha(X_i)\right), \tag{35}$$

is a positive semidefinite, Hermitian matrix. A density matrix which can be written in the form (35) *is said to possess a* Bloch representation, *and the point* $v \in \mathcal{V}$ *is said to be a* valid Bloch vector.

Theorem 7 (closure property): *The Bloch manifold is a closed set in* $\mathbb{R}^k$.

Proof: The matrix $\boldsymbol{\rho}(v)$ is positive iff the lowest eigenvalue $\lambda_{\min}$ of $\mathbf{1} + \Sigma_i v_i \alpha(X_i)$ lies in the set $[0, +\infty)$. The lowest eigenvalue of a matrix is a continuous function of the matrix, so $\lambda_{\min}$ is a continuous function of v. The inverse image of the closed set $[0, +\infty)$ must be closed.

Theorem 8 (general Bloch manifold bound): *Let* α *be a d-dimensional representation of* $\mathfrak{g}$, *let* $k = \dim(\mathfrak{g})$, *and let* X_a *be an orthogonal basis of* $\mathfrak{g}$ *with respect to the Killing form. Then for some constant N*,

$$\mathrm{Tr}(\alpha(X_a)\alpha(X_b)) = Nd\ \delta_{ab}.$$

Moreover, if v is a valid Bloch vector, then

$$v^2 \leqslant \frac{d-1}{N}. \tag{36}$$

In the notation of Sec. II, $N=Z/\dim(\mathfrak{g})$.

Proof: The density matrix $\boldsymbol{\rho}=d^{-1}(\mathbf{1}+v_a\alpha(X_a))$ must satisfy $\mathrm{tr}(\boldsymbol{\rho}^2)\leqslant 1$. But

$$\mathrm{tr}(\boldsymbol{\rho}^2)=d^{-1}(1+Nv^2) \tag{37}$$

which implies the desired result. □

If $\{X_j'\}$ is a second basis of $\mathfrak{g}$, related to the original basis by a matrix A, then the Bloch manifold in the X' basis consists of A^T applied to the Bloch manifold in the X basis. If $\det(A)=1$, this yields an isometric copy of the original manifold, but otherwise the manifold has been stretched in some way. We will see examples of Lie algebra representations which are analogous to the qubit representation, in the sense that the Bloch manifold is a closed ball in some preferred basis.

B. The Bloch manifold for all $\mathfrak{su}_2$ representations

As an example, we give the Bloch manifold relevant to the spin-j representation of $\mathfrak{su}_2$. Let I_{2j+1} be the $(2j+1)$-dimensional identity matrix, and the J_i are the standard generators in the spin-j representation. Let $E_{\min}$ denote the lowest eigenvalue of a matrix. Then

$$E_{\min}\left(I_{2j+1}+\sum_{i=1}^{3}v_iJ_i\right)=1-j\|v\|.$$

The next result follows immediately.

Theorem 9: *The valid Bloch vectors for the spin-j representation of* $\mathfrak{su}_2$ *(with the standard basis) are elements of a closed ball in* $\mathbb{R}^3$ *with radius* $1/j$.

Thus, the picture of the Bloch manifold as a closed ball is not necessarily particular to the qubit system, however, it is certainly not *always* a closed ball. As we shall see below, the Bloch manifold for the defining representation of $\mathfrak{su}_n$ with $n>2$ is a proper subset of the analogous closed ball. To complete the $\mathfrak{su}_2$ case, we remark that the radius receives a multiplicative constant if we rescale the generators; however, the radius always scales as one inverse power of the dimension of the representation.

C. A Bloch submanifold from the Cartan subalgebra

We discuss a method which works for any Lie algebra representation and which always gives a nonempty set of positive semidefinite Hermitian trace-one operators which take the form $\rho=d^{-1}(\mathbf{1}+\Sigma_i v_i\alpha(X_i))$. In Bloch space this set is the interior of a convex polyhedron.

Let $H_1,\ldots,H_r$ denote a basis for the Cartan subalgebra of $\mathfrak{g}$, with $r=\mathrm{rank}(\mathfrak{g})$. As they commute, we may simultaneously diagonalize all $\alpha(H_i)$, and let $h_i^{\,j}$ denote the jth diagonal element of $\alpha(H_i)$. Each vector h^j with components $(h_1^{\,j},h_2^{\,j},\ldots,h_r^{\,j})$ is a weight vector for the given representation.

Assume that the basis $\{X_i\}$ has the Cartan generators $H_1,\ldots,H_r$ as its first r elements. Consider $v\in\mathbb{R}^k$ which are zero except for the first r components. Let $\mathcal{P}$ be the set of $v\in\mathbb{R}^r$ such that $\mathbf{1}+\Sigma_{i=1}^r v_i\alpha(H_i)$ is positive semidefinite. The positivity condition is $1+\Sigma_{i=1}^r v_i h_i^{\,j}\geqslant 0(\forall\ j=1,\ldots,d)$. The solutions of each linear inequality $v\cdot h^j\geqslant -1$ define a half-space $\mathbb{H}_j\subset\mathbb{R}^r$, and the valid Bloch vectors lie in their intersection. A bounded intersection of a finite set of half-spaces is called a *polytope*. If one of the weights h^j is the zero vector, it satisfies $v\cdot h^j\geqslant -1$ for all v.

Definition 4: Define the Bloch-Cartan polytope *as*

$$\mathcal{P}=\{v|v\cdot h^j\geqslant -1\ \ \forall\ \ j\}=\bigcap_{j=1}^{d_\alpha}\mathbb{H}_j. \tag{38}$$

For representations of non-Abelian Lie algebras, $\mathcal{P}\subsetneq\mathcal{V}$. *A priori*, an intersection of half-spaces is either a finite or semi-infinite polyhedron; however (36) implies $v^2\leqslant(d-1)/N$, so $\mathcal{P}$ is always bounded. This provides a geometric proof that a semisimple rank r algebra will not have any irreps

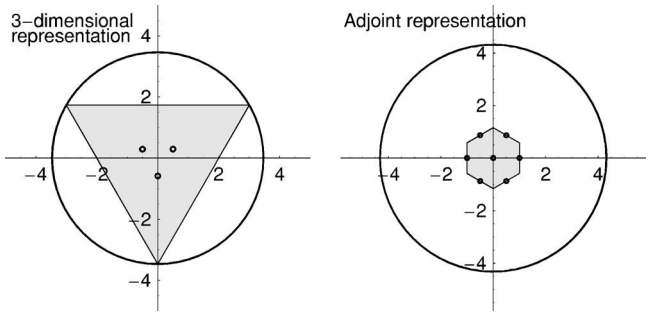


FIG. 1. The shaded region is the intersection of the linear inequalities $v \cdot h^j \geqslant -1$, where h^j are the weight vectors for the indicated representation of $\mathfrak{su}_3$, shown as small circles. Points in the shaded region represent positive semidefinite density matrices. The outer circle shows Bloch vectors which saturate the bound (36).

of dimension smaller than $r+1$, since we need $r+1$ half-spaces to define a finite polyhedron in $\mathbb{R}^r$.

Figure 1 shows two examples for $\mathfrak{su}_3$. This algebra has $r=\mathrm{rank}(\mathfrak{su}_3)=2$ Cartan generators so the Bloch-Cartan polytope can be drawn in $\mathbb{R}^2$. With the conventions of Georgi,[9] the weight vectors h^1, h^2, h^3 for the three-dimensional representation of $\mathfrak{su}_3$ are $\left(\pm\frac{1}{2}, \sqrt{3}/6\right)$ and $(0, -\sqrt{3}/3)$, and the convention $\mathrm{Tr}(T_a T_b)=\frac{1}{2}\delta_{ab}$ for the Gell-Mann matrices implies $N=1/6$. The bound (36) then gives $|v| \leqslant \sqrt{12}$. Note that $v^2=12$ is precisely the circumscribing circle of the polygon. Therefore, in this case our simple method using the Cartan subalgebra produces points up to and including the boundary of the Bloch manifold. These may or may not include pure states. For the adjoint representation $N=3/8$ and the bound (36) gives a boundary circle larger than the polygon by a factor of $\sqrt{14}$.

D. The Bloch manifold for the standard representation of $\mathfrak{su}_n$

We now discuss the structure of the Bloch manifold for the defining representation of $\mathfrak{su}_n$. First, Theorem 8 with $N=2/n$ gives a simple bound,

$$v^2 \leqslant \frac{n(n-1)}{2}. \tag{39}$$

By Descartes' rule of signs, an algebraic equation of degree D with real roots

$$\sum_{j=0}^{D} (-1)^j a_j x^{n-j} = \prod_{i=1}^{D} (x - x_i) = 0, \quad x_i \in \mathbb{R}$$

has all roots non-negative if and only if $a_i \geqslant 0$ for all $i=0,\ldots,D$. Such an equation arises as the characteristic polynomial for a Hermitian matrix. Therefore the Bloch manifold for the n-dimensional irrep of $\mathfrak{su}_n$ is given by the set of $v \in \mathbb{R}^{n^2-1}$ such that the characteristic polynomial $\mathrm{ch}_{\boldsymbol{\rho}(v)}(x)$ has only non-negative coefficients. Some related results for $\mathfrak{su}_n$ were recently reported by Kimura.[19]

The coefficients a_i can be calculated for any specific example using $a_0=1$ and Newton's formula,

$$a_j = \frac{1}{j}\sum_{q=1}^{j} (-1)^{q-1} c_q a_{j-q}, \tag{40}$$

where $c_q=\Sigma_i x_i^q=\mathrm{tr}(\boldsymbol{\rho}(v)^q)$. The largest value of j that we need to consider is $j=d$, the dimension of the Hilbert space.

Naturally, calculating $c_q=\mathrm{tr}(\boldsymbol{\rho}^q)$ reduces to calculating the traces of products of at most q generators of $\mathfrak{su}_n$. Since

$$a_1 = c_1 = 1 \quad \text{and } a_2 = \tfrac{1}{2}(1 - c_2),$$

the condition $a_2 \geqslant 0$ is equivalent to $\operatorname{tr} \boldsymbol{\rho}^2 \leqslant 1$, which leads to (39).

Using (40), the condition $a_3 \geqslant 0$ reduces to $c_3 \geqslant 1/2(3c_2 - 1)$, but c_2 is given by (37), and a similar calculation shows that

$$c_3 \equiv \operatorname{tr} \boldsymbol{\rho}^3 = \frac{1}{n^3}(n + 6v^2 + 2v_a v_b v_c d_{abc}).$$

The calculations up to this point have been valid for $\mathfrak{su}_n$ for all n. To completely solve the problem for $n > 3$, we need to know $c_4, c_5, \ldots, c_n$. However, we can completely calculate the Bloch manifold for the $\mathfrak{su}_3$ channel in closed form. For $n = 3$, we note that

$$\det(v \cdot \lambda) = \tfrac{2}{3} d_{ijk} v_i v_j v_k$$

so the condition $c_3 \geqslant 1/2(3c_2 - 1)$ (for $n = 3$) can be expressed as $\det(v\lambda) > -1$ and $v^2 \leqslant 1 + \det(v\lambda)$. Therefore, the Bloch manifold for the **3** of $\mathfrak{su}_3$ admits the following expression, beautiful in its simplicity:

$$\mathcal{V}_{\mathfrak{su}_3} = \{v \in \mathbb{R}^8 : v^2 \leqslant \min(3, 1 + \det(v\lambda))\}. \tag{41}$$

E. Bloch manifold for the seven of G_2.

In our calculation of the $\mathfrak{g}_2$ channel, we explicitly constructed a basis β of $\mathfrak{g}_2$ using its definition as $\mathfrak{Der}(\mathbb{O})$. This basis was normalized so that

$$\sum_a \beta_a^2 = \mathbf{1}, \quad \operatorname{tr}(\beta_a \beta_b) = \frac{1}{2}\delta_{ab}.$$

Theorem 8 gives

$$|v| \leqslant 2\sqrt{21}.$$

This proves that the $\mathfrak{g}_2$ Bloch manifold is contained in a closed ball of radius about 9.2. However, the true radius is much smaller, as we will now show. By $\mathfrak{g}_2$ symmetry, the β's satisfy the identity

$$\operatorname{tr}(v\beta)^q = 0, \quad (\forall\ v \in \mathbb{R}^{14}), \quad q \text{ odd},$$

where $v\beta = \Sigma_i v_i \beta_i$. Further, for certain even values of q, $\operatorname{tr}(v\beta)^q$ may have a simple expression. For example,

$$\operatorname{tr}(v\beta)^2 = \frac{v^2}{2}, \quad \operatorname{tr}(v\beta)^4 = (\operatorname{tr}(v\beta)^2)^2 = \frac{v^4}{4}. \tag{42}$$

The $\mathfrak{g}_2$ trace identity $\operatorname{tr}(v\beta)^4 = (\operatorname{tr}(v\beta)^2)^2$ is not easy to prove. It is true because for $\mathfrak{g}_2$ and some other algebras, every fourth-order Casimir invariant is expressible in terms of the second-order invariant, as shown by Okubo.[20] Recently a simpler proof, together with other interesting trace identities, was given by Macfarlane and Pfeiffer,[21] see their Eq. (4.36).

Enforcing $c_3 \geqslant 1/2(3c_2 - 1)$ gives a refinement,

$$|v| \leqslant 2\sqrt{7} \approx 5.3.$$

Requiring $a_4 \geqslant 0$ gives $v^2 \leqslant 8(10 - \sqrt{65})$, so $|v| \leqslant 3.93$. The coefficients are such that $a_5 \geqslant 0$ for all v, and $\operatorname{tr}(v\beta)^n$ for $n \geqslant 6$ has no simple expression analogous to (42), so we have taken the simple analysis of the $\mathfrak{g}_2$ Bloch manifold as far as it will go.

F. Pure states in the Bloch manifold

Let the representation matrices be denoted by $X_a, a=1,\ldots,k$. If v is in the Bloch manifold, so that

$$\boldsymbol{\rho}_v = d^{-1}\left(\mathbf{1} + \sum_a v_a X_a\right)$$

is a density matrix, it is particularly easy to determine whether $\boldsymbol{\rho}$ is pure. If the products $X_a X_b$ are linearly independent from X_a (i.e., there is no $2\to 1$ identity) then $\boldsymbol{\rho}^2 \neq \boldsymbol{\rho}$ and the state is never pure.

On the other hand, if the representation has a $2\to 1$ identity of the type satisfied by the fundamental representation of $\mathfrak{su}_n$,

$$X_a X_b = \beta \delta_{ab}\mathbf{1} + \sum_c Q_{abc} X_c, \tag{43}$$

then there can be pure states, and we have a complete characterization of them.

Theorem 10 (pure Bloch states): *If the* $2\to 1$ *identity* (43) *holds, then a Bloch state* $\boldsymbol{\rho}_v$ *is pure if and only if*

$$1 + \beta v^2 = d \quad \textit{and} \sum_{a,b} v_a v_b Q_{abc} = \left(1 - \frac{2}{d}\right) v_c,$$

for all $c=1,\ldots,k$.

Proof: This follows from $\boldsymbol{\rho}_v{}^2 = (1/d^2)(1+\beta v^2)\mathbf{1} + (1/d^2)\Sigma_{abc}(2v_c + v_a v_b Q_{abc})X_c$. □

It is interesting to see how Theorem 10 specializes to $d=2$. In that case, $Q_{abc}=0$ and also $1 - 2/d = 0$, so the second equation is always satisfied. The first equation amounts to $v^2 = 1/\beta$, and $\beta = 1$, so this just says that v is on the boundary of the Bloch sphere, which is the well-known characterization of pure states.

Unfortunately, $2\to 1$ identities almost never hold, excepting of course the fundamental representation of $\mathfrak{su}_n$, because products $X_a X_b$ tend to be linearly independent from the representation matrices X_a if the dimension of the vector space is large enough to allow this.

G. Summary of Bloch manifold technology

The Bloch manifold is defined to contain the positive-semidefinite density matrices and is given (in a certain basis) by the solution of a system of polynomial inequalities in the components of the Bloch vector v. These inequalities come from enforcing positivity of the density matrix, $\boldsymbol{\rho}_v \geqslant 0$. It is easy to see that the Bloch manifold is bounded within a ball, by enforcing the inequality $\mathrm{tr}(\boldsymbol{\rho}^2) \leqslant 1$. The Bloch manifold for the **3** of $\mathfrak{su}_3$ can be calculated exactly, and also in principle for $\mathfrak{g}_2$. In the latter case, it is bounded within a ball of radius < 3.93. In any representation of any Lie algebra, if a $2\to 1$ identity (43) holds, then pure states lie on the surface of a sphere of squared radius $(d-1)/\beta$.

What we have defined and studied here should rightly be called the *linear Bloch manifold*, because already for the spin-1 channel, one needs to represent the density matrix as $v\cdot J + \Sigma_{a,b} w_{ab} J_{(a} J_{b)}$. So the full geometry of the space of 3×3 density matrices is described by placing nontrivial conditions on both v and w, and similar remarks apply in higher dimensions.

The positivity constraint $\boldsymbol{\rho} \geqslant 0$ can always be solved by the method of Sec. VI D, but its complete solution requires knowledge of $\mathrm{tr}(\boldsymbol{\rho}^q)$ for all $q \leqslant d$ for a d-dimensional quantum system. Also, $\boldsymbol{\rho}$ itself may not be representable as a linear combination of generators, but will require products of m generators where m grows with the dimension. Thus to apply the method of Sec. VI D, one needs a trace identity for a product of md generators. The study of such identities is an active branch of research.[21]

VII. CONCLUSIONS

The main results are as follows:

(1) Definition 2 and Theorem 2 which define the Lie algebra channel and provide conditions for this channel to be trace-preserving (and hence physically realizable),
(2) identification of the $\mathfrak{su}(n)$ channel (in its standard representation) as a depolarizing channel,
(3) computation of the action of the $\mathfrak{su}(2)$ channel in its Three-dimensional representation (the spin-1 case) on a general Hermitian 3×3 matrix, and on some special pure states,
(4) definition and analysis of channels based on the exceptional Lie algebra $\mathfrak{g}_2$ and the Clifford algebra,
(5) a description of the positive semidefinite matrices which represent quantum states for various Lie algebra channels, and a general method for proving positivity from Lie algebraic trace identities.

In conclusion, the mathematical problems posed by quantum information theory and, more generally, by finite-dimensional quantum systems often involve computations which are most easily handled using techniques from representation theory of Lie algebras. In many cases, the feasibility of these calculations rests on the availability of trace identities,[20,21] of which many are known but surely many more remain to be discovered.

It is remarkable and unexpected by this author how much the theory of quantum channels and the classical theory of Lie algebras seem to dovetail. In some cases, classical results about Lie algebras receive independent proofs based on physical intuition. This is surely a math/physics bridge.

We address the problem of constructing positive operator-valued measures (POVMs) in finite dimension n consisting of n^2 operators of rank one which have an inner product close to uniform. This is motivated by the related question of constructing symmetric informationally complete POVMs (SIC-POVMs) for which the inner products are perfectly uniform. However, SIC-POVMs are notoriously hard to construct and, despite some success of constructing them numerically, there is no analytic construction known. We present two constructions of approximate versions of SIC-POVMs, where a small deviation from uniformity of the inner products is allowed. The first construction is based on selecting vectors from a maximal collection of mutually unbiased bases and works whenever the dimension of the system is a prime power. The second construction is based on perturbing the matrix elements of a subset of mutually unbiased bases. Moreover, we construct vector systems in $\mathbb{C}^n$ which are almost orthogonal and which might turn out to be useful for quantum computation. Our constructions are based on results of analytic number theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1998831]

I. INTRODUCTION

A. Background

A basic question in quantum mechanics is how to obtain information about the state of a given physical system by using suitable measurements. Even in the case when many identically prepared copies of the system are available, it is a nontrivial task to devise a measurement procedure that uniquely identifies the given quantum state from the statistical data produced by the measurements. Note that this holds true even in the case where the complete statistics, that is, the probabilities for the different measurement outcomes, is known.

We next describe the possible measurements of the quantum system in more detail and first remark that all systems considered in this paper are of finite dimension n. If the state of the quantum system is given by an $n \times n$ density matrix, then the complete measurement statistics of one fixed *von Neumann measurement* is not sufficient to reconstruct the state. Indeed, this follows from the fact that the statistics of a fixed von Neumann measurement determines at most $n-1$ real parameters (specified by the probabilities of the measurement outcomes), whereas a general density matrix is determined by n^2-1 free real parameters.

In fact, it is possible to perform a more general measurement procedure on a quantum system, namely a *positive operator-valued measure*, or POVM for short (see Refs. 33 and 34). A POVM is described by a collection of positive operators $E_i \geqslant 0$, called POVM elements, that partition the identity, that is, $\Sigma_i E_i = I_n$. If the state of the quantum system is given by the density matrix ρ, then the probability p_i to observe outcome i in the POVM is given by the Born rule

$$p_i = \mathrm{tr}(\rho E_i), \tag{1}$$

where $\mathrm{tr}(A)$ denotes the trace of a complex matrix A. The task is to devise a POVM with operators E_i such that the state ρ is uniquely specified by the probabilities p_i in (1). The POVM is then called *informationally complete*, or simply an IC-POVM, and they appear to have been first studied in Ref. 38. A particularly interesting question is whether a POVM exists on $\mathbb{C}^n$ that consists of n^2 POVM elements E_i of rank one. Counting the number of parameters determined by the measurement, we see that n^2 is indeed the minimal possible number of such POVM elements. In this case E_i is a subnormalized projector, that is, $E_i = \Pi_i / n$ for projectors $\Pi_i = |\psi_i\rangle\langle\psi_i|$ corresponding to some vectors $|\psi_i\rangle$ in $\mathbb{C}^n$. In Ref. 12 it has been shown that IC-POVMs exist in all dimensions and in Ref. 15 a method has been given how to construct IC-POVMs by taking a fixed fiducial start vector $|\psi\rangle$ and taking the orbit of this vector under a (projective) group operation.

As an example of this type, consider the normalized states $|\psi_1\rangle, \ldots, |\psi_4\rangle$ defined as follows:

$$|\psi_1\rangle = \frac{1}{3}\begin{pmatrix} 1 \\ 2+2i \end{pmatrix}, \quad |\psi_2\rangle = \frac{1}{3}\begin{pmatrix} 2+2i \\ 1 \end{pmatrix},$$

$$|\psi_3\rangle = \frac{1}{3}\begin{pmatrix} 1 \\ -2-2i \end{pmatrix}, \quad |\psi_4\rangle = \frac{1}{3}\begin{pmatrix} 2+2i \\ -1 \end{pmatrix}.$$

Then the rank one operators defined by $E_i = 1/2|\psi_i\rangle\langle\psi_i|$ are given by

$$E_1 = \frac{1}{18}\begin{pmatrix} 1 & 2-2i \\ 2+2i & 8 \end{pmatrix}, \quad E_2 = \frac{1}{18}\begin{pmatrix} 8 & 2+2i \\ 2-2i & 1 \end{pmatrix},$$

$$E_3 = \frac{1}{18}\begin{pmatrix} 1 & -2+2i \\ -2-2i & 8 \end{pmatrix}, \quad E_4 = \frac{1}{18}\begin{pmatrix} 8 & -2-2i \\ -2+2i & 1 \end{pmatrix},$$

and it can be verified easily that $E_1+E_2+E_3+E_4 = I_4$ is the identity matrix and that the matrices E_1, E_2, E_3, E_4 are linearly independent. For the possible inner products between two POVM elements E_i and E_j where $i \neq j$ we obtain that $\mathrm{tr}(E_i E_j) \in \{4/81, 49/324\}$.

Our goal is to find IC-POVMs on $\mathbb{C}^n$ such that $n^2\mathrm{tr}(E_i E_j)$ is "small" for distinct POVM elements $E_i = |\psi_i\rangle\langle\psi_i|/n$ and $E_j = |\psi_j\rangle\langle\psi_j|/n$. In Sec. I C we make precise what we mean by the inner products being small and briefly summarize previous work on the problem.

B. Notation

We use the Landau notation to compare the asymptotics of two functions $f, g: \mathbb{N} \to \mathbb{C}$. We recall that $f(n) = o(g(n))$ means $\lim_{n\to\infty} f(n)/g(n) = 0$. Furthermore, $f(n) = O(g(n))$ means that there exists a constant $c > 0$, such that $|f(n)| \leqslant c g(n)$ for all $n \geqslant 1$. Throughout the paper, the implied

constants in the symbols "o" and "O" may occasionally, where obvious, depend on an integer parameter d and a small real parameter $\varepsilon>0$, and are absolute otherwise.

For an integer $n\geqslant 1$ we denote by $\mathbb{C}^n$ the n-dimensional vector space over the complex numbers $\mathbb{C}$. For two vectors $|\psi\rangle=(a_1,\ldots,a_n)\in\mathbb{C}^n$ and $|\varphi\rangle=(b_1,\ldots,b_n)\in\mathbb{C}^n$, we use

$$\langle\psi|\varphi\rangle=\sum_{i=1}^{n}\bar{a}_i b_i$$

to denote their inner product. We also define $\delta_{i,j}=1$ if $i=j$ and 0 otherwise. We denote the identity matrix of size $n\times n$ by I_n, the all-ones matrix of size n by $J_n=[1]_{i,j=1}^{n}$. We use $\mathrm{diag}(a_1,\ldots,a_n)$ to denote the $n\times n$ diagonal matrix which has $a_1,\ldots,a_n$ on the main diagonal. For matrices A and B, we use $A\oplus B$ to denote their block-diagonal direct sum.

For a real z and an integer m we use the notation $\mathbf{e}_m(z)=\exp(2\pi\iota z/m)$, where $\iota=\sqrt{-1}$.

We use $\mathbb{F}_q$ to denote the finite field of q elements, and we also assume that for a prime p, the field $\mathbb{F}_p$ is represented by the set $\{0,\ldots,p-1\}$.

As we have mentioned, we use $\mathrm{tr}(A)$ to denote the trace of a complex matrix A. On the other hand, for an element $a\in\mathbb{F}_q$ we use $\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(a)$ to denote its trace in the prime subfield $\mathbb{F}_p$ of $\mathbb{F}_q$ (see Ref. 31). That is, if $q=p^m$ for a prime p and a positive integer m, then

$$\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(a)=\sum_{j=0}^{m-1}a^{p^j}.$$

C. Previously known results

A particularly appealing case of IC-POVMs arises when, furthermore, all of the inner products of the vectors $|\psi_i\rangle$ are small. An extremal case in this sense arises when we are given a system of n^2 normalized vectors $\{|\psi_i\rangle: i=1,\ldots,n^2\}$ in $\mathbb{C}^n$ for which

$$|\langle\psi_i|\psi_j\rangle|^2=\frac{1}{n+1},\quad 1\leqslant i<j\leqslant n^2. \tag{2}$$

Indeed, for any system of k vectors $|\psi_1\rangle,\ldots,|\psi_k\rangle$ in $\mathbb{C}^n$ for which the absolute values of pairwise inner products are constant $|\langle\psi_i|\psi_j\rangle|^2=\alpha$, where $\alpha\in\mathbb{R}$ (for $1\leqslant i<j\leqslant k$), the so-called special bound holds[23] which says that $k\leqslant n(1-\alpha)/(1-n\alpha)$. Specializing $\alpha=1/(n+1)$ we obtain that n^2 is the largest possible number of vectors satisfying (2).

A system of vectors as in (2), respectively the corresponding POVMs, are called *symmetric informationally complete POVMs*, or SIC-POVMs for short. They have several very desirable properties; see Ref. 12 for a discussion in the context of the quantum de Finetti theorem and more generally in their Bayesian approach to quantum mechanics and its interpretation.[11] Furthermore, see Refs. 18 and 19 for their role in establishing the quantumness of a Hilbert space and the related question about optimal intercept-resend eavesdropping attacks on quantum cryptographic schemes. Explicit analytical constructions of sets satisfying (2) have been given for dimensions $n=2,3,4,5$ in Ref. 50, Sec. 3.4, and Ref. 41, for dimension $n=6$ in Ref. 20, for dimensions $n=7,19$ in Ref. 1, and for dimension $n=8$, see Ref. 24. While it has been conjectured that SIC-POVMs exist in all dimensions (Ref. 50, Sec. 3.4, or Ref. 41) and numerical evidence exists for dimensions up to 45 (see Ref. 41), it is a difficult task to explicitly construct systems of vectors which satisfy (2). There are no known infinite families of SIC-POVMs and, in fact, it is not even clear if there are SIC-POVMs for infinitely many n.

D. Our results

In the first part (Sec. II) of this paper we relax condition (2) on the inner products slightly and allow that

$$|\langle\psi_i|\psi_j\rangle|^2 \leqslant \frac{1+o(1)}{n}, \quad 1 \leqslant i < j \leqslant n^2. \tag{3}$$

The purpose of the first part of this paper is to show that infinite families of systems of n^2 normalized vectors which satisfy (3) and give rise to IC-POVMs exist. We call the rank one projectors obtained from such systems of vectors *approximately symmetric informationally complete POVMs*, or ASIC-POVMs for short. Here we show that when $n=p^r$ is a power of a prime p, ASIC-POVMs can be constructed.

In the second part (Sec. III) of the paper we explore properties of other approximately symmetric vector systems where we do not require the properties of completeness and informational completeness but require the property of approximate symmetry. We also relax (3) further by allowing that the inner products be bounded from above by $|\langle\psi_i|\psi_j\rangle| \leqslant (2+o(1))/\sqrt{n}$ and by dropping the requirement that the vectors give rise to a POVM. This additional freedom then allows us to construct bases in all dimensions n. Besides their general mathematical interest in constructing such vector systems they might be useful in quantum cryptographic scenarios which generalize the BB84 setting,[7] such as the protocols described in Refs. 8, 39, and 40. See also Ref. 14 for an analysis of general schemes for quantum key distribution where the sender uses arbitrary quantum states and the receiver's measurement is replaced by a POVM.

Besides approximations to SIC-POVMs we also consider approximations to *mutually unbiased bases* (MUBs). Since we also need MUBs for our construction of ASIC-POVMs we briefly recall their definition. A maximal set of MUBs is given by a set of n^2+n vectors in $\mathbb{C}^n$ which are the elements of $n+1$ orthonormal bases $\mathcal{B}_k=\{|\psi_{k,1}\rangle, \ldots, |\psi_{k,n}\rangle\}$ of $\mathbb{C}^n$ where $k=0, \ldots, n$. Hence,

$$\langle\psi_{k,i}|\psi_{k,j}\rangle = \delta_{i,j}, \tag{4}$$

and the defining property is the mutual unbiasedness, given by

$$|\langle\psi_{k,i}|\psi_{\ell,j}\rangle| = \frac{1}{\sqrt{n}} \tag{5}$$

for $0 \leqslant k, \ell \leqslant n$, $k \neq \ell$, and $1 \leqslant i, j \leqslant n$. Starting from Refs. 26, 42, and 49, an extensive growing body of research explores MUBs and their constructions (see Refs. 2, 4, 6, 13, 17, 21, 27, 36, 37, and 48 and references therein). However, so far maximally sets of $n+1$ MUBs in dimension n are only known to exist in any dimension $n=p^r$ which is a power of a prime $p \geqslant 3$ (see Ref. 27 for an overview and some of such constructions). The main construction is based on Gaussian sums and in the case of prime $n=p$ can be described as

$$|\psi_{k,j}\rangle = \frac{1}{\sqrt{p}}(\mathbf{e}_p(ku^2+ju))_{u=1}^p, \quad 1 \leqslant k,j \leqslant p,$$

and also $\mathcal{B}_0$ being a standard orthonormal basis, that is, $|\psi_{0,j}\rangle=(\delta_{j,u})_{u=1}^p$.

One can use additive characters over an arbitrary finite field to extend this construction to an arbitrary prime power $n=p^r$. However, the condition that $n=p^r$ is a prime power is still somewhat too restrictive and unnatural for quantum computation. So a natural question arises whether MUBs exist for every positive integer n. In the second part we consider vector systems where we relax the conditions (3) and (5). We use exponential sums to construct vector systems for any dimension n which

- satisfy (4) but instead of (5) all other inner products are $O(n^{-1/4})$;
- are normalized but instead of (2) all other inner products are at most $(2+o(1))n^{-1/2}$.

We call vector systems of n^2+n vectors in $\mathbb{C}^n$ which satisfy (4), and instead of (5) the condition

$$|\langle\psi_i|\psi_j\rangle|^2 \leqslant \frac{1+o(1)}{n}, \quad 1 \leqslant i < j \leqslant n^2+n,$$

approximately mutually unbiased bases, or AMUBs for short.

We also construct some vector systems using multiplicative and mixed character sums, which

- satisfy (4) and, assuming some natural and widely believed conjecture on the distribution of primes in arithmetic progressions, all other inner products are $O(n^{-1/2}\log n)$;
- in the special case of $n=p-1$, where p is a prime, form AMUBs.

Interestingly, our arguments use both the classical bound of Weyl[47] (see also Refs. 25 and 43) as well as the more recent, but no less celebrated, bounds of Weil[45] (see also Refs. 30, 31, and 46). Besides exponential sum techniques we also use some recent results about the gaps between prime numbers from Ref. 3. We conclude with some conjectures and open questions concerning our constructions in Sec. IV.

II. CONSTRUCTING ASIC-POVMS

A. Preliminaries

We begin by giving a definition of the vectors and associated rank one operators we are interested in.

Definition 1 (ASIC-POVMs): Suppose that n is a positive integer. Let $\mathcal{A}=\{|\psi_i\rangle : i=1,\ldots,n^2\}$ *be a set of vectors in* $\mathbb{C}^n$. *Let* $\mathcal{E}=\{E_i=|\psi_i\rangle\langle\psi_i|/n : i=1,\ldots,n^2\}$ *be the corresponding set of subnormalized projection operators. If* $\mathcal{E}$ *satisfies the conditions*

(i) $\Sigma_{i=1}^{n^2} E_i = I_n$ (completeness/POVM condition),
(ii) *the matrices* E_i *are linearly independent as elements of* $\mathbb{C}^{n\times n}$ (informational completeness), *and*
(iii) $|\langle\psi_i|\psi_j\rangle|^2 = n^2\,\mathrm{tr}(E_iE_j) \leqslant (1+o(1))n^{-1}$ *for* $1\leqslant i<j\leqslant n^2$ (approximate symmetry),

then we call $\mathcal{E}$ *an* approximately symmetric informationally complete POVM, *or ASIC-POVM for short*.

We remark that, in fact, sometimes we also refer to the corresponding set $\mathcal{A}$ as an ASIC-POVM.

In the subsequent sections, we present two different constructions that give rise to infinite families of ASIC-POVMs. The first construction is based on the observation that a set of $n+1$ mutually unbiased bases in $\mathbb{C}^n$ gives rise to an IC-POVM, cf. Refs. 26 and 49. However, this IC-POVM consists of n^2+n rank-one operators; thus, it is an overcomplete generating set of the vector space of all $n\times n$ matrices. In our first construction in Sec. II C we show how to select n^2 projectors that allow us to derive an ASIC-POVM. The second construction in Sec. II D starts from all vectors contained in n of the $n+1$ MUBs. We show that by slightly perturbing the components of these vectors it is possible to obtain an ASIC-POVM.

B. POVMs and frames

Suppose that $\mathcal{A}=\{|\psi_i\rangle \in \mathbb{C}^n 1\leqslant i\leqslant n^2\}$ is a system of n^2 vectors of unit norm, such that $\mathcal{A}$ spans $\mathbb{C}^n$ and the associated subnormalized projectors $E_i=|\psi_i\rangle\langle\psi_i|/n$ satisfy $n^2\,\mathrm{tr}(E_iE_j)=(1+o(1))n^{-1}$ whenever $i\neq j$.

We would like to have that the subnormalized projectors E_i form a POVM, but, unfortunately, the completeness relation $\Sigma_{i=1}^{n^2}E_i=I_n$ is in general not satisfied. However, there is a way to fix this using a technique described in Ref. 12: Define a positive semidefinite Hermitian operator G by

$$G = \sum_{i=1}^{n^2} E_i.$$

Since $\mathcal{A}$ spans $\mathbb{C}^n$, the inequality $\langle\varphi|G|\varphi\rangle = \Sigma_i |\langle\psi_i|\varphi\rangle|^2 > 0$ holds for any nonzero vector $|\varphi\rangle$ in $\mathbb{C}^n$, so G is even positive definite. It follows that G^{-1} exists and is positive definite, and we can form the uniquely determined positive definite square root $G^{-1/2}$. The n^2 rank-one operators

$$\mathcal{E} = \{F_i = G^{-1/2} E_i G^{-1/2} : 1 \leqslant i \leqslant n^2\}$$

form a POVM, since $\Sigma_i F_i = G^{-1/2} G G^{-1/2} = I_n$.

Clearly, if the operators E_i are linearly independent, then so are the operators F_i. Therefore, the procedure preserves information completeness.

In general, if we switch from the rank-one operators E_i to the rank-one operators F_i, then $\mathrm{tr}(F_i F_j) \leqslant (1+o(1))/n^3$ might not hold for some $i \neq j$. However, if G^{-1} is close to the identity matrix, then approximate symmetry is preserved as well.

We now mention some connections between POVMs and the theory of frames.[5,9,16]

Definition 2 (Frames): A set $\mathcal{F} = \{|\psi_i\rangle : 1 \leqslant i \leqslant N\}$ of vectors in $\mathbb{C}^n$ is called a frame *if there exist real numbers a and b, with $0 < a \leqslant b$, such that*

$$a\langle\varphi|\varphi\rangle \leqslant \sum_{i=1}^{N} |\langle\varphi|\psi_i\rangle|^2 \leqslant b\langle\varphi|\varphi\rangle$$

holds for all $|\varphi\rangle \in \mathbb{C}^n$.

If $a=b$, then the frame is called a tight frame, *and if $a=b=1$, then the frame is called a* Parseval frame.

We can associate with the frame $\mathcal{F}$ its *frame operator* $G = \Sigma_{k=1}^{N} |\psi_k\rangle\langle\psi_k|$. If we are given a frame $\mathcal{F}$ with frame operator G, then

$$\mathcal{G} = \{G^{-1/2}|v\rangle : |v\rangle \in \mathcal{F}\}$$

is a Parseval frame (see Ref. 10, Theorem 4.2). The projectors associated with $\mathcal{G}$ form a POVM, since $\Sigma_{v\in\mathcal{F}} G^{-1/2}|v\rangle\langle v|G^{-1/2} = G^{-1/2} G G^{-1/2} = I$ holds.

If we have a Parseval frame $\mathcal{G}$ in $\mathbb{C}^n$ with n^2 elements such that the associated projection operators are linearly independent and the frame elements satisfy the approximate symmetry (3), then by definition the projectors corresponding to the frame $\mathcal{G}$ form an ASIC-POVM.

C. Construction I: Pruning MUBs

The first construction of ASIC-POVMs is based on the idea to select a suitable collection of n^2 vectors from a set of n^2+n vectors that form a maximal set of $n+1$ mutually unbiased bases of $\mathbb{C}^n$. Our goal is to choose n^2 vectors such that the corresponding projection operators are linearly independent. We recall a known fact that belongs to the folklore of mutually unbiased bases; it is implicitly contained in Refs. 26 and 49, and more explicitly in Ref. 22, and our proof is based on the latter.

Lemma 3: Suppose that $\mathcal{B}_a = \{v_{a,b} : 0 \leqslant b < n\}$, with $0 \leqslant a \leqslant n$, are $n+1$ mutually unbiased bases of $\mathbb{C}^n$, and let

$$\mathcal{P} = \{|v_{a,b}\rangle\langle v_{a,b}| : 0 \leqslant a \leqslant n, 0 \leqslant b < n\}$$

denote the associated set of n^2+n projectors. The n^2 projection operators in $\mathcal{P}^* = \{|v_{a,b}\rangle \times \langle v_{a,b}| : (a,b) = (0,0)$ or $b \neq 0\} \subset \mathcal{P}$ are linearly independent.

Proof: First, suppose that a linear relation

$$\sum_{a=0}^{n}\sum_{b=0}^{n-1}\gamma_{a,b}|v_{a,b}\rangle\langle v_{a,b}| = 0 \tag{6}$$

holds for some $\gamma_{a,b}\in\mathbb{C}$. We are going to show that this has some rather strong consequences for the coefficients $\gamma_{a,b}$. If we apply the projection operators from $\mathcal{P}$ and take the trace, then we obtain a linear system of equations $A\mathbf{g}=0$, where

$$A = [\mathrm{tr}(|v_{a,b}\rangle\langle v_{a,b}||v_{c,d}\rangle\langle v_{c,d}|)]_{(a,b),(c,d)}$$

and $\mathbf{g}=(\gamma_{a,b})$ is a column vector. The matrix A is block circulant,

$$A = \begin{pmatrix} I_n & \frac{1}{n}J_n & \cdots & \frac{1}{n}J_n & \frac{1}{n}J_n \\ \frac{1}{n}J_n & I_n & \cdots & \frac{1}{n}J_n & \frac{1}{n}J_n \\ \ddots & \ddots & & \ddots & \ddots \\ \frac{1}{n}J_n & \frac{1}{n}J_n & \cdots & \frac{1}{n}J_n & I_n \end{pmatrix},$$

with $n\times n$ identity matrices in the diagonal blocks, and multiples of the $n\times n$ all-one matrix in the off-diagonal blocks.

If we subtract two equations in $A\mathbf{g}=0$ that belong to the same block row, then we find that $\gamma_{a,b}=\gamma_{a,d}$ holds for all $0\leqslant b,d<n$ and all indices a. Therefore, the coefficients $\gamma_{a,b}$ do not depend on the value of b.

Finally, suppose that the left-hand side of (6) consists of a linear combination of projectors belonging to the set $\mathcal{P}^*$, meaning that the coefficients $\gamma_{a,b}=0$ when $a\neq 0$ and $b=0$. It follows that $\gamma_{a,b}=0$ holds whenever $a\neq 0$, since $\gamma_{a,b}=\gamma_{a,0}$ by our previous observation. Therefore, the left-hand side of (6) reduces to

$$\sum_{b=0}^{n-1}\gamma_{0,b}|v_{0,b}\rangle\langle v_{0,b}| = \sum_{b=0}^{n-1}\gamma_{0,0}|v_{0,b}\rangle\langle v_{0,b}| = 0.$$

Thus, we must have $\gamma_{0,0}=0$. Therefore, we can conclude that the projectors in P^* are linearly independent, as claimed. □

We also recall the basic construction of MUBs in prime power dimension; see, for instance, Refs. 27 and 49.

Lemma 4: Let q be a power of a prime $p\geqslant 3$. Define

$$|\psi_{a,b}\rangle = q^{-1/2}(\mathbf{e}_p(\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(ax^2+bx)))_{x\in\mathbb{F}_q}\in\mathbb{C}^q.$$

Then the standard basis $\mathcal{B}_0$ together with the bases $\mathcal{B}_a=\{|\psi_{a,b}\rangle : b\in\mathbb{F}_q\}$, $a\in\mathbb{F}_q$, form a set of $q+1$ mutually unbiased bases of $\mathbb{C}^q$.

Our first construction of ASIC-POVMs is given in the next theorem.

Theorem 5: *Let q be a power of a prime $p\geqslant 3$. Let*

$$|\psi_{a,b}\rangle = q^{-1/2}(\mathbf{e}_p(\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(ax^2+bx)))_{x\in\mathbb{F}_q}\in\mathbb{C}^q$$

for all $(a,b)\in\mathbb{F}_q\times\mathbb{F}_q^{\times}$ and $|\psi_{a,0}\rangle=(\delta_{a,x})_{x\in\mathbb{F}_q}$ for all $a\in\mathbb{F}_q$. We define $E_{a,b}=|\psi_{a,b}\rangle\langle\psi_{a,b}|/q$ and

$$G = \sum_{a\in\mathbb{F}_q}\sum_{b\in\mathbb{F}_q}E_{a,b}.$$

Then the set $\{F_{a,b}: a,b\in\mathbb{F}_q\}$, with $F_{a,b}=G^{-1/2}E_{a,b}G^{-1/2}$, is an ASIC-POVM.

Proof: The linear independence of the operators $E_{a,b}$ follows from Lemma 3. It remains to

show that the matrix G^{-1} is close to the identity and that $F_{a,b}=G^{-1/2}|\psi_{a,b}\rangle\langle\psi_{a,b}|G^{-1/2}$ indeed forms an ASIC-POVM. First, we explicitly compute the frame operator G. We have

$$G=\frac{1}{q}\sum_{(a,b)\in\mathbb{F}_q\times\mathbb{F}_q^\times}|\psi_{a,b}\rangle\langle\psi_{a,b}|+\frac{1}{q}I_q=\frac{1}{q^2}\Bigg(\sum_{x,y,a,b\in\mathbb{F}_q}\mathbf{e}_p(\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(a(x^2-y^2)+b(x-y)))|x\rangle\langle y|$$

$$-\sum_{x,y,a\in\mathbb{F}_q}\mathbf{e}_p(\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(a(x^2-y^2)))|x\rangle\langle y|\Bigg)+\frac{1}{q}I_q.$$

We notice that $\langle x|G|x\rangle=1$ for $x\in\mathbb{F}_q$, $\langle x|G|-x\rangle=-1/q$ for $x\in\mathbb{F}_q^\times$, and $\langle x|G|y\rangle=0$ for $x,y\in\mathbb{F}_q$ with $x\neq\pm y$. Therefore, we can express the operator G in the form

$$G=I_q-\frac{1}{q}Q+\frac{1}{q}|0\rangle\langle 0|,\quad\text{where } Q=\sum_{x\in\mathbb{F}_q}|x\rangle\langle -x|.$$

Using the structure of G, it follows that the inverse is given by

$$G^{-1}=\left(1+\frac{1}{q^2-1}\right)I_q+\frac{q}{q^2-1}Q-\frac{1}{q-1}|0\rangle\langle 0|.$$

Observe that the set of vectors $\{|\psi_{a,b}\rangle:(a,b)\in\mathbb{F}_q\times\mathbb{F}_q^\times\}$ is invariant under Q, since $Q|\psi_{a,b}\rangle=|\psi_{a,-b}\rangle$. Recall that by Lemma 4 the bounds

$$|\langle\psi_{a,b}|\psi_{c,d}\rangle|\leqslant q^{-1/2}$$

hold, whenever $(a,b)\neq(c,d)$. Defining $|\tilde{\psi}_{a,b}\rangle=G^{-1/2}|\psi_{a,b}\rangle$ we get

$$F_{a,b}=G^{-1/2}E_{a,b}G^{-1/2}=|\tilde{\psi}_{a,b}\rangle\langle\tilde{\psi}_{a,b}|/q$$

and obtain that

$$q^2\mathrm{tr}(F_{a,b}F_{c,d})=|\langle\tilde{\psi}_{a,b}|\tilde{\psi}_{c,d}\rangle|^2=|\langle\psi_{a,b}|G^{-1}|\psi_{c,d}\rangle|^2\leqslant\left|\left(1+\frac{1}{q^2-1}\right)\langle\psi_{a,b}|\psi_{c,d}\rangle\right|^2+\left|\left(\frac{q}{q^2-1}\right)\right.$$

$$\left.\times\langle\psi_{a,b}|\psi_{c,-d}\rangle\right|^2+\left(\frac{1}{q(q-1)}\right)^2\leqslant\frac{1}{q}\left(1+\frac{1}{q^2-1}\right)^2+\frac{1}{q}\left(\frac{q}{q^2-1}\right)^2+\left(\frac{1}{q(q-1)}\right)^2$$

$$=\frac{1+o(1)}{q}.$$

This shows that the rank-one operators $F_{a,b}$ form an ASIC-POVM. □

D. Construction II: Perturbing MUBs

We now describe a second, different, method to obtain a set of n^2 vectors such that the corresponding projectors span the space of all $n\times n$ matrices. This construction of ASIC-POVMs works for all dimensions n such that n is an odd prime number.

We note that all arithmetic operations in any expression involving elements of $\mathbb{F}_p$ and real numbers are performed over the real numbers (where each element of $\mathbb{F}_p$ is represented by an integer in the range $[0,p-1]$). For example, for a real $r\in\mathbb{R}$ and $a,x\in\mathbb{F}_p$, the power r^{ax} means r^u, where the integer $u=ax$ can be of size $(p-1)^2$.

Theorem 6: *Let p be an odd prime number, and let $0<r<1$ be a real number. For $a,b\in\mathbb{F}_p$ define*

$$|\varphi_{a,b}\rangle=\sqrt{\frac{1-r^{2a}}{1-r^{2pa}}}(r^{ax}\mathbf{e}_p(ax^2+bx))_{x\in\mathbb{F}_p}\in\mathbb{C}^p,$$

and let $E_{a,b}=|\varphi_{a,b}\rangle\langle\varphi_{a,b}|/p$. *Then the* $E_{a,b}$ *are linearly independent. Furthermore, let*

$$G=\sum_{a,b\in\mathbb{F}_p}E_{a,b}.$$

Then for $r=1-p^{-3}$ *the set* $\{F_{a,b}:a,b\in\mathbb{F}_p\}$, *with* $F_{a,b}=G^{-1/2}E_{a,b}G^{-1/2}$, *is an ASIC-POVM*.

Proof: First, we show that the matrices $E_{a,b}$ are linearly independent. Note that instead of considering the normalized vectors $|\varphi_{a,b}\rangle$ it is possible to consider the vectors $|\tilde{\varphi}_{a,b}\rangle=(r^{ax}\mathbf{e}_p(ax^2+bx))_{x\in\mathbb{F}_p}$ and to show that the corresponding projectors $\tilde{E}_{a,b}=|\tilde{\varphi}_{a,b}\rangle\langle\tilde{\varphi}_{a,b}|$ are linearly independent.

We use the technique introduced in Ref. 15 to check whether the matrices $\tilde{E}_{a,b}$ are linearly independent. To each $n\times n$ matrix $\tilde{E}_{a,b}$ we associate a state $|\tilde{E}_{a,b}\rangle$ which is simply the rowwise concatenation of the entries of $\tilde{E}_{a,b}$ as a vector of length n^2. Then the matrices $\tilde{E}_{a,b}$ are linearly independent if and only if the matrix $S=(1/p)\Sigma_{a,b\in\mathbb{F}_p}|\tilde{E}_{a,b}\rangle\langle\tilde{E}_{a,b}|$ has full rank. We obtain

$$pS=\sum_{a,b\in\mathbb{F}_p}|\tilde{E}_{a,b}\rangle\langle\tilde{E}_{a,b}|=\sum_{\substack{a\in\mathbb{F}_p\\x,y,u,v\in\mathbb{F}_p}}r^{a(x+y+u+v)}\mathbf{e}_p(a(x^2-y^2-u^2+v^2))\times\sum_{b\in\mathbb{F}_p}\mathbf{e}_p(b(x-y-u+v))|x,y\rangle$$

$$\times\langle u,v|=p\sum_{\substack{a\in\mathbb{F}_p\\x,y,u,v\in\mathbb{F}_p}}r^{a(x+y+u+v)}\mathbf{e}_p(a(x^2-y^2-u^2+v^2))\,\delta_{x-y,u-v}|x,y\rangle\langle u,v|.$$

The rows of S are labeled by pairs (x,y), with $x,y\in\mathbb{F}_p$, and the columns by pairs (u,v), with $u,v\in\mathbb{F}_p$. We first note that S can be written as a block-diagonal matrix of p submatrices, each of size $p\times p$, if the rows and columns of S are suitably rearranged. For $0\leqslant i\leqslant(p-1)$, we define the sets $\mathcal{L}_i=\{(x,x+i):x\in\mathbb{F}_p\}$ (we treat i as an element of $\mathbb{F}_p$ so $x+i$ is computed in $\mathbb{F}_p$, too). We now order the rows and columns according to the list $\mathcal{L}=\cup_{i=0}^{p-1}\mathcal{L}_i$. With respect to this basis we obtain that

$$S=A_0\oplus A_1\oplus\cdots\oplus A_{p-1},$$

with $p\times p$ matrices

$$A_i=\left[\sum_{a\in\mathbb{F}_p}r^{a(x+y+u+v)}\mathbf{e}_p(a(x^2-y^2-u^2+v^2))\right]_{x,u\in\mathbb{F}_p},$$

where $y=x+i$ and $v=u+i$. Hence, we obtain that

$$A_i=\left[\sum_{a\in\mathbb{F}_p}r^{2a(x+u+i)}\mathbf{e}_p(2ai(u-x))\right]_{x,u\in\mathbb{F}_p}$$

and have to show that this matrix is invertible for $0\leqslant i\leqslant(p-1)$. In order to do so, we first observe that $x\mapsto x-i/2$ defines a permutation of the rows of any $p\times p$ matrix and that similarly $u\mapsto u-i/2$ defines a permutation of the columns (hereafter $i/2$ is computed in $\mathbb{F}_p$). Applying both the row and the column permutation to A_i we obtain the matrix

$$B_i=\left[\sum_{a\in\mathbb{F}_p}r^{2a(x+y)}\mathbf{e}_p(2ai(u-x))\right]_{x,u\in\mathbb{F}_p}.$$

Note further that $x\mapsto x/2$ and $y\mapsto y/2$ induce permutations of the rows and columns of any $p\times p$ matrix. Applying this to B_i we obtain the matrix

$$C_i=\left[\sum_{a\in\mathbb{F}_p}r^{a(u+x)}\mathbf{e}_p(ai(u-x))\right]_{x,u\in\mathbb{F}_p}=\left[\sum_{a\in\mathbb{F}_p}(r^x\mathbf{e}_p(-ix))^a(r^u\mathbf{e}_p(iu))^a\right]_{x,u\in\mathbb{F}_p}$$

$$=[(r\mathbf{e}_p(-i))^{xk}]_{x,k=0}^{p-1}\times[(r\mathbf{e}_p(i))^{\ell u}]_{\ell,u=0}^{p-1}.$$

Since $|r\mathbf{e}_p(i)|=|r\mathbf{e}_p(-i)|=r$ and $0<r<1$, by the property of Vandermonde matrices[32] we conclude that C_i is invertible for all $i=0,\ldots,p-1$, which implies that the matrices B_i, A_i, and finally S are invertible. Arguing as in the proof of Theorem 5 we have established the informational completeness of the projectors corresponding to the normalized vectors $|\varphi_{a,b}\rangle$.

Next, for $r=1-p^{-3}$ we derive the bound

$$|\langle\varphi_{a,b}|\varphi_{c,d}\rangle| \leqslant \frac{1+o(1)}{\sqrt{p}}, \quad (a,b)\neq(c,d). \tag{7}$$

We have

$$|\langle\varphi_{a,b}|\varphi_{c,d}\rangle| = \sqrt{\frac{1-r^{2a}}{1-r^{2pa}}}\sqrt{\frac{1-r^{2c}}{1-r^{2pc}}}\left|\sum_{x\in\mathbb{F}_p} r^{(a+c)x}\mathbf{e}_p(\alpha x^2+\beta x)\right|, \tag{8}$$

where $\alpha=a-c$ and $\beta=c-d$.

We frequently use that $r^t=1+O(t/p^3)$ for any $t=O(p^3)$. In particular,

$$\begin{aligned}\sqrt{\frac{1-r^{2a}}{1-r^{2pa}}}\sqrt{\frac{1-r^{2c}}{1-r^{2pc}}} &= \left(\sum_{x\in\mathbb{F}_p} r^{2ax}\right)^{-1/2}\left(\sum_{x\in\mathbb{F}_p} r^{2cx}\right)^{-1/2} \leqslant \left(\sum_{x\in\mathbb{F}_p} r^{2px}\right)^{-1}\\ &= (p(1+O(1/p)))^{-1} = (1+o(1))p^{-1}.\end{aligned}$$

Furthermore,

$$\begin{aligned}\left|\sum_{x\in\mathbb{F}_p} r^{(a+c)x}\mathbf{e}_p(\alpha x^2+\beta x)\right| &\leqslant \left|\sum_{x\in\mathbb{F}_p}(1+O(1/p))\mathbf{e}_p(\alpha x^2+\beta x)\right| \leqslant \left|\sum_{x\in\mathbb{F}_p}\mathbf{e}_p(\alpha x^2+\beta x)\right| + O(1)\\ &\leqslant \sqrt{p}+O(1).\end{aligned}$$

Substituting the above bounds in (8), we derive (7).

Next, we note that $E_{a,b}=|\varphi_{a,b}\rangle\langle\varphi_{a,b}|/p$ and $G=\Sigma_{a,b\in\mathbb{F}_p}E_{a,b}$. We now compute the frame operator G and show that G^{-1} is close to the identity. Similarly to the proof of Theorem 5, this implies that $F_{a,b}=G^{-1/2}E_{a,b}G^{-1/2}$ indeed forms an ASIC-POVM. We have

$$\begin{aligned}G &= \left(\sum_{\substack{a,b\in\mathbb{F}_p\\ x,y,\in\mathbb{F}_p}} \frac{1-r^{2a}}{p(1-r^{2pa})} r^{a(x+y)}\mathbf{e}_p(a(x^2-y^2)+b(x-y))|x\rangle\langle y|\right)\\ &= \left(\sum_{\substack{a\in\mathbb{F}_p\\ x,y,\in\mathbb{F}_p}} \frac{1-r^{2a}}{1-r^{2pa}} r^{a(x+y)}\mathbf{e}_p(a(x^2-y^2))\,\delta_{x,y}|x\rangle\langle y|\right) = \operatorname{diag}\left(\sum_{a\in\mathbb{F}_p}\frac{1-r^{2a}}{1-r^{2pa}}r^{2ax} : x\in\mathbb{F}_p\right).\end{aligned}$$

Recalling that $r=1-p^{-3}$, from the Taylor expansion we obtain that

$$\frac{1-r^{2a}}{1-r^{2pa}} = \frac{1+o(1)}{p}.$$

Hence

$$\sum_{a\in\mathbb{F}_p}\frac{1-r^{2a}}{1-r^{2pa}}r^{2ax} = \frac{1+o(1)}{p}\sum_{a\in\mathbb{F}_p} r^{2ax} = \frac{1+o(1)}{p}(p+O(1)) = 1+o(1).$$

Finally, we deduce that

$$p^2\operatorname{tr}(F_{a,b}F_{c,d}) = |\langle\widetilde{\varphi}_{a,b}|\widetilde{\varphi}_{c,d}\rangle|^2 = |\langle\varphi_{a,b}|G^{-1}|\varphi_{c,d}\rangle|^2 = (1+o(1))|\langle\varphi_{a,b}|\varphi_{c,d}\rangle|^2 = \frac{1+o(1)}{p},$$

which implies that the rank-one operators $F_{a,b}$ form an ASIC-POVM. □

III. RELAXED MUBs AND SIC-POVMs

A. Motivation

The constructions in the previous sections required the existence of $n+1$ mutually unbiased bases in $\mathbb{C}^n$. Currently, it is not known whether such extremal sets of mutually unbiased bases exist when n is divisible by two distinct primes. We show that approximately mutually unbiased bases exists in all dimensions. Furthermore, we show that if we slightly relax the ASIC-POVM condition, then we can obtain in any dimension systems of vectors that approximate SIC-POVMs. For these constructions, we need some results about the distribution of primes and bounds on exponential sums, which we summarize below.

These constructions work in any dimension n but attain its maximal strength for n of a certain arithmetic structure. In particular, if $n=p-1$ for a prime p, then we show the existence of AMUBs in $\mathbb{C}^n$. It is not known whether maximal sets of MUBs in these dimensions exist.

Besides the general mathematical interest in the vector systems derived in this section, we expect that our approach and the new technique introduced in the following will lend themselves to some further applications in quantum information processing.

B. Analytic number theory background

First of all we recall a remarkable result of Ref. 3 on gaps between consecutive primes.

Lemma 7: For any sufficiently large x, any interval of the form $[x-x^{0.525},x]$ contains a prime number.

We now need some bounds of exponential sums with polynomials.

Let p be a prime number and let $\mathbb{F}_p$ be a field of p elements. We always assume that $\mathbb{F}_p$ is represented by the elements $\{0,\ldots,p-1\}$.

The following statement is a variant of the celebrated *Weil bound* (see Example 12 of Appendix 5 of Ref. 46 as well as Theorem 3 of Chap. 6 in Ref. 30 and Theorem 5.41 and comments to Chap. 5 of Ref. 31).

Lemma 8: Let χ be a nontrivial multiplicative character of $\mathbb{F}_p$ of order s. Suppose that $G(X)\in\mathbb{F}_p[X]$ is not, up to a nonzero multiplicative constant, an sth power in $\mathbb{F}_p[X]$. Then for any polynomial $F(X)\in\mathbb{F}_p[X]$ of degree d we have

$$\left|\sum_{u=1}^{p}\mathbf{e}_p(F(u))\chi(G(u))\right|\leqslant(d+\nu-1)p^{1/2},$$

where ν is the number of distinct roots of G in the algebraic closure of $\mathbb{F}_p$.

We now use Lemma 8 to estimate some mixed exponential sums with two exponential functions.

Lemma 9: Let $F(X)\in\mathbb{F}_p[X]$ be of degree $d\geqslant 2$. Then, for any integer k,

$$\left|\sum_{u=1}^{p}\mathbf{e}_p(F(u))\mathbf{e}_n(ku)\right|=\begin{cases}O(p^{2/3}), & \text{if } d=2,\\ O(p^{3/4}), & \text{if } d\geqslant 3.\end{cases}$$

Proof: Because each term in our sum is of absolute value $|\mathbf{e}_p(F(u))\mathbf{e}_n(ku)|=1$, for every integer $v\geqslant 0$ we have

$$\sum_{u=1}^{p}\mathbf{e}_p(F(u))\mathbf{e}_n(ku)=\sum_{u=1}^{p}\mathbf{e}_p(F(u+v))\mathbf{e}_n(k(u+v))+O(v).$$

Thus for every positive integer m we have

$$m\sum_{u=1}^{p}\mathbf{e}_p(F(u))\mathbf{e}_n(ku)=\sum_{v=0}^{m-1}\sum_{u=1}^{p}\mathbf{e}_p(F(u+v))\mathbf{e}_n(k(u+v))+O(m^2).$$

Therefore

$$\left|\sum_{u=1}^{p}\mathbf{e}_p(F(u))\mathbf{e}_n(ku)\right|\leqslant\frac{1}{m}W+O(m), \tag{9}$$

where

$$W=\left|\sum_{u=1}^{p}\sum_{v=0}^{m-1}\mathbf{e}_p(F(u+v))\mathbf{e}_n(k(u+v))\right|=\left|\sum_{u=1}^{p}\mathbf{e}_n(ku)\sum_{v=0}^{m-1}\mathbf{e}_p(F(u+v))\mathbf{e}_n(kv)\right|$$
$$\leqslant\sum_{u=1}^{p}\left|\sum_{v=0}^{m-1}\mathbf{e}_p(F(u+v))\mathbf{e}_n(kv)\right|.$$

By the Cauchy inequality we obtain

$$W^2\leqslant p\sum_{u=1}^{p}\left|\sum_{v=0}^{m-1}\mathbf{e}_p(F(u+v))\mathbf{e}_n(kv)\right|^2=p\sum_{v,w=0}^{m-1}\mathbf{e}_n(k(v-w))\sum_{u=1}^{p}\mathbf{e}_p(F(u+v)-F(u+w)).$$

We now examine the polynomial $F_{v,w}(U)=F(U+v)-F(U+w)$. By the Taylor formula we have

$$F_{v,w}(U)=F(U+v)-F(U+w)=\sum_{\nu=0}^{d-1}\frac{F^{(\nu)}(v)-F^{(\nu)}(w)}{\nu!}U^{\nu}.$$

Clearly $F^{(d-1)}(v)=F^{(d-1)}(w)$ is possible only for $v=w$. For such m pairs of v and w we estimate the sum over u trivially as p. Otherwise we estimate these sums as $(d-2)p^{1/2}$ by Lemma 8, getting

$$W^2=\begin{cases}O(mp^2), & \text{if } d=2,\\ O(mp^2+m^2p^{3/2}), & \text{if } d\geqslant 3.\end{cases}$$

Thus by (9)

$$\left|\sum_{u=1}^{p}\mathbf{e}_p(F(u))\mathbf{e}_n(ku)\right|=\begin{cases}O(m^{-1/2}p+m), & \text{if } d=2,\\ O(m^{-1/2}p+p^{3/4}+m), & \text{if } d\geqslant 3.\end{cases}$$

Taking $m=\lceil p^{2/3}\rceil$ we conclude the proof.

We also need a special case of the classical *Weyl bound* which we present in the following form (see Lemma 3.6 of Ref. 25 or Lemma 2.4 of Ref. 43 for a similar statement in full generality).

Lemma 10: Let $F(X)\in\mathbb{F}_p[X]$ be of degree $d\geqslant 2$. Then for any fixed $\varepsilon>0$ and any integer $h\leqslant p$,

$$\left|\sum_{u=1}^{h}\mathbf{e}_p(F(u))\right|=O\left(h^{1+\varepsilon}\left(\frac{1}{h}+\frac{1}{p}+\frac{p}{h^d}\right)^{1/2^{d-1}}\right).$$

C. Arbitrary dimensions

We now describe a construction of a vector system, which satisfies (4) exactly and also gives a certain approximation to (5). In fact we are able to get n^d+1 (rather than $n+1$) orthogonal bases with this property, where $d\geqslant 1$ is any integer.

Let $\mathcal{F}_d$ be the set of polynomials of the form

$$f(X) = \sum_{\nu=2}^{d+1} a_\nu X^\nu$$

with integer coefficients in the range $0 \leqslant a_\nu \leqslant n-1$, $\nu = 2, \ldots, d+1$. Thus $\#\mathcal{F}_d = n^d$. Let p be the smallest prime with $p \geqslant n$. For each $f \in \mathcal{F}_d$ we consider the basis

$$\mathcal{B}_f = \{|\psi_{f,1}\rangle, \ldots, |\psi_{f,n}\rangle\}, \quad \text{where } |\psi_{f,i}\rangle = \frac{1}{\sqrt{n}}(\mathbf{e}_p(f(u))\mathbf{e}_n(iu))_{u=1}^n. \tag{10}$$

Theorem 11: *For any integer $d \geqslant 1$, the standard basis and the n^d bases $\mathcal{B}_f$, $f \in \mathcal{F}_d$, given by* (10) *are orthonormal and satisfy also*

$$\langle \psi_{g,j} | \psi_{f,i} \rangle = \begin{cases} O(n^{-1/3}), & \text{if } d = 1, \\ O(n^{-1/4}), & \text{if } d \geqslant 2, \end{cases}$$

where $f, g \in \mathcal{F}_d \cup \{0\}$, $f \neq g$, $1 \leqslant i, j \leqslant n$.

Proof: The orthonormality of each basis follows from the identity

$$\langle \psi_{f,j} | \psi_{f,i} \rangle = \frac{1}{n} \sum_{u=1}^{n} \mathbf{e}_n((i-j)u) = \delta_{i,j}.$$

Clearly, if $f \in \mathcal{F}_d$ and $g = 0$ (or $f = 0$ and $g \in \mathcal{F}_d$) then $|\langle \psi_{g,j} | \psi_{f,i} \rangle| = n^{-1/2}$. Thus it remains to estimate

$$\langle \psi_{g,j} | \psi_{f,i} \rangle = \frac{1}{n} \sum_{u=1}^{n} \mathbf{e}_p(f(u) - g(u))\mathbf{e}_n((i-j)u)$$

for $f, g \in \mathcal{F}_d$, $f \neq g$ and $1 \leqslant i, j \leqslant n$.

Because

$$|\mathbf{e}_n(f(u) - g(u) + (i-j)u)| = 1$$

and by Lemma 7 we have

$$\begin{aligned} \frac{1}{n} \sum_{u=1}^{n} \mathbf{e}_p(f(u) - g(u))\mathbf{e}_n((i-j)u) &= \frac{1}{n} \sum_{u=1}^{p} \mathbf{e}_p(f(u) - g(u))\mathbf{e}_n((i-j)u) + O\left(\frac{|p-n|}{n}\right) \\ &= \frac{1}{n} \sum_{u=1}^{p} \mathbf{e}_p(f(u) - g(u))\mathbf{e}_n((i-j)u) + O(n^{-0.475}). \end{aligned}$$

Hence,

$$\langle \psi_{g,j} | \psi_{f,i} \rangle = \frac{1}{n} \sum_{u=1}^{p} \mathbf{e}_p(f(u) - g(u))\mathbf{e}_n((i-j)u) + O(n^{-0.475}).$$

Because $f(X) - g(X)$ is a polynomial of degree at least 2, Lemma 9 yields

$$\sum_{u=1}^{p} \mathbf{e}_p(f(u) - g(u))\mathbf{e}_n((i-j)u) = \begin{cases} O(p^{2/3}) = O(n^{2/3}), & d = 1, \\ O(p^{3/4}) = O(n^{3/4}), & d \geqslant 2, \end{cases}$$

which concludes the proof. □

As before, let p be the smallest prime with $p \geqslant n$. We consider n^2 vectors

$$\mathcal{B} = \{|\psi_f\rangle : f \in \mathcal{F}_2\}, \quad \text{where } |\psi_f\rangle = \frac{1}{\sqrt{n}}(\mathbf{e}_p(f(u)))_{u=1}^n. \tag{11}$$

Theorem 12: *Let p be the smallest prime with $p \geqslant n$. Then, the vector system $\mathcal{B}$ of n^2 vectors given by* (11) *is normalized and also satisfies*

$$|\langle \psi_g | \psi_f \rangle| \leqslant (2 + O(n^{-1/10}))n^{-1/2},$$

where $f, g \in \mathcal{F}_2$, $f \neq g$.

Proof: Obviously, we have

$$|\langle \psi_f | \psi_f \rangle| = 1, \quad f \in \mathcal{F}_2.$$

Put $h = p - n$. Then for $f, g \in \mathcal{F}_2$, $f \neq g$, we have

$$|\langle \psi_g | \psi_f \rangle| = \frac{1}{n} \left| \sum_{u=1}^{n} \mathbf{e}_p(f(u) - g(u)) \right| \leqslant \frac{1}{n} \left| \sum_{u=1}^{p} \mathbf{e}_p(f(u) - g(u)) \right| + \frac{1}{n} \left| \sum_{u=1}^{h} \mathbf{e}_p(f(n+u) - g(n+u)) \right|.$$

By Lemmas 8 and 10 we have

$$\begin{aligned} |\langle \psi_g | \psi_f \rangle| &\leqslant 2p^{1/2}n^{-1} + O\left(h^{1+\varepsilon} n^{-1} \left(\frac{1}{h} + \frac{1}{p} + \frac{p}{h^3} \right)^{1/4} \right) \\ &= 2p^{1/2}n^{-1} + O(n^{-1}(h^{3/4+\varepsilon} + h^{1+\varepsilon}p^{-1/4} + h^{1/4+\varepsilon}p^{1/4})). \end{aligned}$$

By Lemma 7 we see that $h = O(p^{0.525})$, therefore

$$h^{3/4+\varepsilon} + h^{1+\varepsilon}p^{-1/4} + h^{1/4+\varepsilon}p^{1/4} = O(p^{2/5}) = O(n^{2/5})$$

for sufficiently small ε and sufficiently large p. Noting that

$$p^{1/2} = (n + O(n^{0.525}))^{1/2} = n^{1/2}(1 + O(n^{-0.475}))^{1/2} = n^{1/2} + O(n^{0.2625})$$

we finish the proof. □

D. Special dimensions

Here we give some improvements of the constructions of Sec. III C for the values of n for which the smallest prime p with $p \equiv 1 \pmod{n}$ is sufficiently small.

Let p be the smallest prime such that $p \equiv 1 \pmod{n}$. Let $\mathcal{X}_n$ be the set of n characters of order n modulo p and $\mathcal{U}_n$ be the subgroup of residues of order n in $\mathbb{F}_p^\times$. In particular $\#\mathcal{U}_n = n$. It is known that $\mathcal{X}_n$ is a cyclic group, so for some character $\chi \in \mathcal{X}_n$ all other characters of $\mathcal{X}_n$ are given be the powers χ^i, $i = 1, \ldots, n$.

For $f \in \mathbb{F}_p[X]$ of degree at most d and the above character $\chi \in \mathcal{X}_n$ we define

$$\mathcal{B}_f = \{|\psi_{f,1}\rangle, \ldots, |\psi_{f,n}\rangle\} \quad \text{where } |\psi_{f,i}\rangle = \frac{1}{\sqrt{n}} (\mathbf{e}_p(f(u))\chi(u)^i)_{u \in \mathcal{U}_n}. \tag{12}$$

Let $\mathcal{G}_d$ be the set of polynomials of the form

$$f(X) = \sum_{\nu=1}^{d} a_\nu X^\nu,$$

with integer coefficients in the range $0 \leqslant a_\nu \leqslant n-1$, $\nu = 2, \ldots, d+1$.

Theorem 13: *For any integer $d \geqslant 1$, the standard basis and the n^d bases $\mathcal{B}_f$, $f \in \mathcal{G}_d$, given by* (12) *are orthonormal and satisfy also*

$$|\langle \psi_{g,j} | \psi_{f,i} \rangle| \leqslant dp^{1/2}n^{-1},$$

where $f, g \in \mathcal{F}_d \cup \{0\}$, $f \neq g$, $1 \leqslant i, j \leqslant n$.

Proof: We have

$$\langle \psi_{f,j} | \psi_{f,i} \rangle = \frac{1}{n} \sum_{u \in \mathcal{U}_n} \chi(u)^{i-j} = \begin{cases} 1, & i = j, \\ 0, & i \neq j, \end{cases} \qquad 1 \leqslant i,j \leqslant n.$$

We also have

$$\langle \psi_{g,j} | \psi_{f,i} \rangle = \frac{1}{n} \sum_{u \in \mathcal{U}_n} \mathbf{e}_p(f(u) - g(u)) \chi(u)^{i-j} = \frac{1}{p-1} \sum_{x=0}^{p-1} \mathbf{e}_p(f(x^{(p-1)/n}) - g(x^{(p-1)/n})) \chi(x^{(p-1)/n})^{i-j}.$$

Now, using Lemma 8, we conclude the proof. □

Corollary 14: Let p be a prime and let n=p−1. Then an AMUB exists in dimension n.

Proof: We apply Theorem 13 for $p=n+1$ and for $d=1$. Hence, we have n^2+1 orthonormal bases such that inner products between their components are all bounded by $(n+1)^{1/2}n^{-1}=n^{-1/2}+O(n^{-1})$. □

IV. REMARKS AND OPEN QUESTIONS

The questions about finding SIC-POVMs and MUBs can be reformulated as a spherical design question in the vector space $\mathbb{C}^n$ (see Zauner's thesis[50] and also Refs. 28 and 41). Thus it is possible that the techniques of Ref. 29, as well as of more recent works (see a very inspiring survey[35]), may apply to the problem of constructing systems of n^2 equiangular lines in $\mathbb{C}^n$, that is, SIC-POVMs. In fact, it is quite possible that with some adjustments they may also apply to MUBs.

It is widely believed, see Ref. 44, but remains unproved, that the smallest prime $p \equiv 1 \pmod{n}$ satisfies the bound

$$p = O(n \log^2 n).$$

In this case, the bound of Theorem 13 becomes $O(n^{-1/2} \log n)$. Thus, it is quite possible that the construction of Sec. III D is always superior to those of Sec. III C.

Finally, we remark that many of the results of this paper remain unchanged if one uses prime powers $q=p^r$ (and thus general finite fields $\mathbb{F}_q$) instead of just primes p. In particular, Corollary 14 holds true in this more general setting. Hence, in summary, we have shown that ASIC-POVMs and AMUBs exist for any prime power dimension q. Moreover, we have shown that approximate versions of mutually unbiased bases and SIC-POVMs exist in any dimension if we are slightly more liberal about our constraints on the angles.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 082105 (2005)

Geometry of the Schrödinger equation and stochastic mass transportation

Stephan Völlinger
Mathematical Stochastics, Eckerstraβe 1, Freiburg, Germany

(Received 25 February 2005; accepted 15 June 2005; published online 8 August 2005)

The Schrödinger equation is deduced from a geometric principle. Lagrange, Hamilton-Jacobi, and Hamilton formalisms are defined almost analogously to the deterministic case, which can be identified as geometric optic. The form of these formalisms is identical to the deterministic formalisms. Furthermore, it will be shown how the deterministic case is "superficial" to the stochastic one if Planck's constant is very small. An elementary proof of Heisenberg's uncertainty relation finishes the paper. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1998835]

I. INTRODUCTION AND STATEMENT OF THE MAIN RESULT

The Austrian physician Erwin Schrödinger, who discovered, in 1926, the equation governing quantum mechanics,[1] considered in 1931 the following problem:

"A cloud of independent identical particles may be known to initial and final times. What is the most probable state of the cloud to intermediate times?"

Schrödinger chose as a starting point for his research the *a posteriori* equivalence[2,3] of the Schrödinger equation

$$i\partial_t\psi = -\frac{1}{2}\Delta\psi + V\psi, \quad \psi:[0,T]\times\mathbb{R}^n \to \mathbb{C}$$

to the pair of parabolic diffusion equations

$$\partial_t\phi + \frac{1}{2}\Delta\phi + c\phi = 0, \quad -\partial_t\hat{\phi} + \frac{1}{2}\Delta\hat{\phi} + c\hat{\phi} = 0,$$

where the real-valued functions ϕ, $\hat{\phi}$ and c are defined by

$$\phi = e^{R+S}, \quad \hat{\phi} = e^{R-S}, \quad R,S:[0,T]\times\mathbb{R}^n \to \mathbb{R}, \quad c = -V - 2\partial_t S - (\nabla S)^2,$$

if $\psi = e^{R+iS}$. Schrödinger wanted to transform the complex-valued problem into a "real" space. See also Ref. 4 (or Ref. 5 for a more detailed explanation), where the connection of the heat flow equation to Feynman's path integral is treated.

Irrespective of the detailed words in Schrödinger's problem and irrespective of the equivalence to dual parabolic pairs, we want to give a solution in the framework of a geodesic variational problem. We do research on the problem of "geometry of the Schrödinger equation," i.e.,

We look for solutions of the Schrödinger equation, under an eventually prescribed Riemannian structure, where initial and final time absolute squares of the ψ-function are given at the outset.

We will show that this problem is deeply related to a geodesic problem. The real-valued, Euclidean version will be identified as stochastic mass transportation.

The research on the observer variant, a topologically global defined geodesic variational problem and its symmetries, is of a very historical origin. It stands at the beginning of a theory of formal deduction, and was considered by Euclid in 300 B.C.[6] The idea of the shortest connection between two points of a space is the central point of Euclid's geometry.

In the physical applications the variational formalism appears as a principle of least action. It will be shown that also the Schrödinger equation is determined by a Hamiltonian version of a variational problem, where the Lagrangian version is given by stochastic mass transportation. A remarkable point is that the form of the Hamiltonian problem is identical to the form of the deterministic case given in classical (point) mechanics, what also holds true for the Lagrangian version. Variation of the stochastic mass transportation problem leads to the following nonlinear partial differential equation (PDE):

$$\partial_t v + \nabla_v v - \nabla_u u - \frac{\hbar}{2}\Delta u = -\nabla V,$$

called the stochastic Newton equation, with current velocity v and entropic velocity u (see Sec. II A). The stochastic Newton equation generalizes Newton's law and follows from the Schrödinger equation

$$\hbar i \partial_t \psi = H\psi = -\frac{1}{2}\hbar^2 \Delta\psi + V\psi.$$

The energy conservation law for stochastic mass transportation is ruled by the entropy action law. The quantum mechanical energy $\langle \psi, H\psi\rangle$ of a solution ψ of the Schrödinger equation is a constant of the motion. The entropy action law for $[0,T]$,

$$W_{QM}(\psi) := T\langle \psi, H\psi\rangle = W_{kin}(\psi) + W_{pot}(\psi) - \frac{\hbar}{2}\Delta\mathrm{Entrop}(|\psi_T|^2, |\psi_0|^2),$$

shows that the classical action at time T has an additional dissipative term, the negative Gibbs-Boltzmann entropy difference of ψ_T and ψ_0.

The fact that ψ is complex valued can be explained in the framework of a phase space structure. The real-valued Lagrangian version is imbedded as a tangential space analogously to the deterministic formalism. The Itô diffusion equation

$$dY_t = b(t, Y_t)dt + \sqrt{\hbar} dB_t$$

acts as tangential criteria of $b = DY$ referring to the diffusion Y_t.

Such a Lagrangian phase space structure was introduced by Otto[7] (or Ref. 8 where the idea is presented) for deterministic mass transportation. A density way $t \to \varrho_t$ has the tangent φ if the continuity equation

$$\partial_t \varrho_t + \mathrm{div}(\varrho_t \nabla \varphi) = 0$$

holds true. The relevant metric for this differential geometry is given by

$$\langle \dot{\varrho}_t, \dot{\varrho}_t\rangle := \int (\nabla \varphi_t)^2 \varrho_t \, dx.$$

In Ref. 8 the equivalence of the geodesic distance for this metric to the time-independent formulation of the deterministic mass transportation problem, also known as the Wasserstein distance, is (heuristically) shown.

A further new work in this connection is that by Hall and Reginatto,[9] where the authors add a fluctuation term to the classical variational problem of geometric optics by using certain heuristic conditions, to derive the form of the fluctuation term by a transformation property of the spatial uncertainty, called the "exact uncertainty principle," which finally leads to the Schrödinger equa-

tion. The "exact uncertainty principle" is a special case of the Cramér-Rao inequality, well known in information theory. The explanations in Ref. 9 suggest a proof of Heisenberg's uncertainty relation, which is the characteristic of quantum dynamics, and so an exact proof is given in Sec. VII. Note especially that the entropy action law shows that a main assertion in Ref. 9 is, in general, not true.

In opposite direction to Ref. 9, this paper derives the Schrödinger equation directly from a geodesic problem, given by Lagrangian stochastic mass transportation. The advantage of this derivation is the equivalence to classical variational principles

$$\delta \int L(t,x,\dot{x})dt \overset{!}{=} 0, \quad \text{time marginal values!}$$

In the limit, where "zoomout problems" are considered, such that Planck's constant $\hbar$ is very small and the motion is microscopic, the geometry of the Euclidean space is recovered.

This paper wants to introduce a new connection between differential geometry and stochastics. The main result is to generalize the Euclidean space and to show how the classical geometry is "superficial" to the stochastic case. The primary target is to treat the geometry of the Schrödinger equation problem mathematically. Further physical data, like the magnetic vector potential $\vec{A}$ in the Schrödinger equation

$$i\hbar\partial_t\psi = \left(\sum_k \left(\frac{\hbar}{i}\partial_k - A_k\right)\left(\frac{\hbar}{i}\partial_k - A_k\right) + V\right)\psi$$

is ignored. (But see Ref. 10, where $\vec{A}$ is implemented.)

Main result: The geometry of the Schrödinger equation problem, where we look for solutions in a Euclidean setting, is governed in its Lagrangian version by a "pure" geodesic variational problem. The classical geometry can be obtained by a zoomout formalism.

II. PRELIMINARIES

A. Stochastic preliminaries

The following preliminaries are taken under technical modifications from Refs. 10–12 and can be compared there. Detailed proofs can be found in Ref. 13.

Let $T \in \mathbb{R}^+$ and $(\Omega, \mathcal{T}_t)$, $t \in [0,T]$ be a filtrated sample space. For the whole work we can set $\Omega = C^0([0,T],\mathbb{R}^n)$ and $\mathcal{T}_t := \sigma(X_s, 0 \leqslant s \leqslant t)$, where $X_s(c) = c(s)$, and $c \in \Omega$ is the coordinate mapping, i.e., the common Wiener space setting. Following Ref. 10, expectations referring to a measure on $(\Omega, \mathcal{T}_T)$ are denoted by E if they are not expressed as integrals.

Definition 1: (a) A *diffusion* is a measure P on $\mathcal{T}_T$ and a $\sigma(X_t)$-measurable stochastic process $Y:[0,T]\times\Omega \to \mathbb{R}^n$, i.e., $\sigma(Y_t) \subset \sigma(X_t)$, with continuous path and second moments $\forall t$ such that the differential quotients

$$\lim_{\Delta t \to 0^+} E_t \frac{\Delta Y_t^i}{\Delta t} = b^i(t, Y_t), \quad i = 1, \ldots, n,$$

$$\lim_{\Delta t \to 0^+} E_t \frac{\Delta Y_t^i \Delta Y_t^j}{\Delta t} = \sigma^{ij}(t, Y_t), \quad i,j = 1, \ldots, n, \tag{1}$$

exist $\forall t \in [0,T]$. E_t is the conditioned expectation referring to P under $\mathcal{T}_t$, i.e., $E_t(.) = E(.|\mathcal{T}_t)$. $(\sigma^{ij})_{ij}$ is a measurable function on $[0,T]\times\mathbb{R}^n$ with values in the symmetric, positive definite matrices. $(\sigma^{ij})_{ij}$ is called *diffusion matrix*. b is a measurable function on $[0,T]\times\mathbb{R}^n$ with values in $\mathbb{R}^n$, called the *drift*. The limit is supposed to exist in the $L^2(P)$-sense for the drift and in the $L^1(P)$-sense for the diffusion matrix. Especially $b^i(t,Y_t) \in L^2(P)\,\forall\, t \in [0,T]$ and $\sigma^{ij}(t,Y_t) \in L^1(P)\,\forall\, t \in [0,T]$. This definition shall include the case that the limit for the drift exists only in the L^1-sense, but is in

$L^2(P)$. Only diffusions with diffusion matrix $h\cdot id$, $h\in\mathbb{R}^+$, will play a role within this paper.

A diffusion, referring to the Lebesgue measure absolutely continuous distribution Y_t^P, is called *smooth* if the densities $\varrho_t dx = P[X_t \in dx]$ are smooth and bounded, i.e., $\varrho_t \in C^\infty \cap L^\infty$, and furthermore b^i and σ^{ij}, $i,j=1,\ldots,n$, are given on $\{\varrho(t,x)>0\}$, are C^∞ differentiable, and $\int b^2\varrho\, dx$ $<$const is independent of t. The C^∞ property can be weakened to enough differentiability in the respective situation.

Finally

$$D(Y_t) := \lim_{\Delta t\to 0^+} \frac{1}{\Delta t} E(Y_{t+\Delta t} - Y_t | \mathcal{T}_t) = b(t,Y_t) \tag{2}$$

is the *forward derivative* of a diffusion Y_t.

(b) $C_0^\infty(O;\mathbb{R})$, $O\subset\mathbb{R}^m$, open are the C^∞-differentiable functions $\mathbb{R}^m\to\mathbb{R}$ with compact support in O, i.e., $\varphi\in C_0^\infty \Leftrightarrow \mathrm{supp}(\varphi)\subset O$ compact.

Proposition 2: (Differential Itô formula analog.[12] See Ref. 10.) Let Y_t be a diffusion referring to P. For every real-valued function $\chi(t,x)\in C_0^\infty([0,T]\times\mathbb{R}^n;\mathbb{R})$ we have in the $L^1(P)$-sense

$$D\chi(t,Y_t) = \left(\frac{1}{2}\sigma^{ij}\partial_{i,j}^2 + b^i\partial_i + \partial_t\right)\chi(t,Y_t) \quad \text{(Sum convention !)}. \tag{3}$$

Proof: By Taylor's formula! See Ref. 13.

Proposition 3: (See Ref. 10.) Let Y_t be a diffusion referring to P. Let $\sigma^{ij}(t,x)$, $b^i(t,x):[0,T]\times\mathbb{R}^n\to\mathbb{R}\in L^\infty\cap C^0$, $i,j=1,\ldots,n$, and

$$\int_0^T \int b^2(t,Y_t)\, dP\, dt < \infty. \tag{4}$$

For the distributions Y_t^P we have [in the weak sense of (6)] the *Fokker-Planck equation*

$$\partial_t Y_t^P = \frac{1}{2}\partial_{i,j}^2(\sigma^{ij}Y_t^P) - \mathrm{div}(bY_t^P), \quad Y_0^P \text{ given}. \tag{5}$$

Proof: It can be shown that $t\mapsto\int\chi(t,Y_t)\, dP$ is continuously differentiable and that the Fokker-Planck equation holds true in the following weak sense:

The function $t\mapsto\int\chi(t,Y_t)\, dP$ is absolutely continuous and

$$\int \chi(t,Y_t)dP - \int \chi(0,Y_0)dP = \int_0^t \int \left(\frac{\sigma^{ij}}{2}\partial_{i,j}^2 + b^i\partial_i + \partial_t\right)\chi(t,Y_t)dP\, dt,$$

$$\forall\,\chi\in C_0^\infty([0,T]\times\mathbb{R}^n;\mathbb{R}), \quad \forall\, t\in[0,T], \tag{6}$$

where the continuous differentiability is weakened to absolute continuity. The integrability condition (4) is necessary, such that this definition makes sense. See Ref. 13.

Remark 4: (a) Let Y_t^P be absolutely continuous referring to the Lebesgue measure $\forall t$, with $\varrho_t dx = P[X_t\in dx]$. Let ϱ be continuous and b, σ be continuous on $\{\varrho>0\}$. Then the weak Fokker-Planck equation referring to the test function space $C_0^\infty(\{\varrho>0\};\mathbb{R})$ holds true without boundedness of σ and b. Proof of Proposition 3 still remains correct if the test function class is restricted to $\{\varrho>0\}$.

(b) If Y_t is a smooth diffusion referring to P, then the Fokker-Planck equation holds true in the classical sense on $\{\varrho>0\}$.

The *backward derivative* of a diffusion Y_t is defined by

$$D_*(Y_t) := \lim_{\Delta t \to 0^+} \frac{1}{\Delta t} E(Y_t - Y_{t-\Delta t} | \mathcal{T}_t^*) = \lim_{\Delta t \to 0^+} E_t^* \frac{\Delta^* Y_t}{\Delta t}, \tag{7}$$

where $\mathcal{T}_t^* := \sigma(X_s, t \leqslant s \leqslant T)$ and the topology of the convergence will be explained in the next proposition. The *backward drift* b_* is defined by

$$D_* Y_t =: b_*(t, Y_t). \tag{8}$$

Proposition 5: (Partial integration for stochastic derivatives. See Ref. 10.) Let Y_t be a smooth diffusion referring to P, with diffusion matrix $h \cdot id$, $h \in \mathbb{R}^+$. The integrability conditions

$$\int_0^T \int b^2(t, Y_t)\, dP\, dt < \infty, \quad \text{respectively} \int_0^T \int (\nabla \ln \varrho(t, Y_t))^2\, dP\, dt < \infty, \tag{9}$$

may hold true, where $\nabla \ln \varrho(t,x)$ is defined on $\{\varrho(t,x) > 0\}$ and is equal to zero elsewhere. The backward derivative exists in the following weak sense,

$$\lim_{\Delta t \to 0^+} \int_0^T \int \left(E_t^* \frac{\Delta^* Y_t}{\Delta t} \right)^i f(t, Y_t)\, dP\, dt = \int_0^T \int b_*^i(t, Y_t) f(t, Y_t) dP\, dt,$$

$$\forall i = 1, \ldots, n, \quad \forall f \in C_0^\infty(\{\varrho(t,x) > 0\} \cap (0,T) \times \mathbb{R}^n; \mathbb{R}), \tag{10}$$

where on $\{\varrho(t,x) > 0\}$

$$b_* = b - h \nabla \ln \varrho. \tag{11}$$

The partial integration formula

$$\int_0^T E(Df(t, Y_t) g(t, Y_t))\, dt = -\int_0^T E(f(t, Y_t) D_* g(t, Y_t))\, dt + Ef(T, Y_T) g(T, Y_T) - Ef(0, Y_0) g(0, Y_0) \tag{12}$$

holds true for arbitrary C^∞-differentiable functions $g : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ and $f : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ where g and/or f may have compact support in $\{\varrho(t,x) > 0\}$.

Proof: See Ref. 13.

Remark 6: (a) See also Ref. 14, where the time inversion on the Wiener space is treated.

(b) It is not hard to see that with the smoothness of the diffusion and the fact that the test functions have compact support in $\{\varrho(t,x) > 0\}$, the backward derivative exists in the following stochastic Sobolev-sense

$$\int \int Y_t^i Df(t, Y_t)\, dP\, dt = \int_0^T \int b_*^i(t, Y_t) f(t, Y_t)\, dP\, dt,$$

$$\forall i = 1, \ldots, n, \quad \forall f \in C_0^\infty(\{\varrho(t,x) > 0\} \cap (0,T) \times \mathbb{R}^n; \mathbb{R}). \tag{13}$$

(c) Let Y_t be a smooth diffusion referring to P with diffusion matrix $h \cdot id$, $h \in \mathbb{R}^+$. The forward and backward derivatives of a $C_0^\infty([0,T] \times \mathbb{R}^n; \mathbb{R})$-function $f(t, Y_t)$ are calculated according to

$$Df(t, Y_t) = \left(\frac{h}{2} \Delta + b^j \partial_j + \partial_t \right) f(t, Y_t),$$

$$D_* f(t,Y_t) = \left(-\frac{h}{2}\Delta + b_*^j \partial_j + \partial_t \right) f(t,Y_t), \tag{14}$$

where the Laplace operator is defined by the $\mathbb{R}^n$ in which the diffusion takes on its values.

(d) See Ref. 10 for the transformation of drift vectors and diffusion matrices in coordinates.

(e) The following *backward Fokker-Planck equation* on $\{\varrho(t,x)>0\}$ holds true:

$$\partial_t \varrho = -\frac{h}{2}\Delta\varrho - \operatorname{div}(b_*\varrho). \tag{15}$$

Definition 7: The *entropic velocity* on $\{\varrho(t,x)>0\}$ is defined by

$$u := \frac{1}{2}(b - b_*) \tag{16}$$

and the *current velocity* on $\{\varrho(t,x)>0\}$ by

$$v := \frac{1}{2}(b + b_*). \tag{17}$$

We have $u=(h/2)\nabla \ln \varrho = h\nabla \ln \sqrt{\varrho}$ on $\{\varrho(t,x)>0\}$. Averaging (in $\mathbb{R}$) over forward and backward Fokker-Planck equations leads to the *continuity equation* on $\{\varrho(t,x)>0\}$:

$$\partial_t \varrho = -\operatorname{div}(v\varrho). \tag{18}$$

Proposition 8: (Interpretation of the current velocity.) Let $\xi(t,x):[0,T]\times\mathbb{R}^n\to\mathbb{R}^n$ and $p(t,x):[0,T]\times\mathbb{R}^n\to\mathbb{R}$ be a classically differentiable solution of the continuity equation $\partial_t p + \operatorname{div}(\xi p)=0$, $p(0,x)=p_0(x)$ (ξ and p_0 are given). Then we have for the flow T_t of the vector field ξ [i.e., $(d/dt)T_t=\xi(t,T_t)$] $T_{t\#}p_0=p_t$, where the "push-forward" $T_{t\#}p_0$ of a density function p_0 is defined by

$$\int T_{t\#}p_0(y)f(y)dy = \int p_0(x) f(T_t(x))dx \;\forall\, f \in C_0^0(\mathbb{R}^n). \tag{19}$$

If, conversely, T_t classically differentiable is given and $T_{t\#}p_0=p_t$, then for the vector field $\xi(t,x)=d/dtT_t(x)$ the continuity equation holds true.

Proof: See Ref. 13.

Definition 9: The meaning of the *stochastic acceleration* $\frac{1}{2}(DD_*+D_*D)Y_t$ of a smooth diffusion Y_t referring to P with diffusion matrix $h\cdot id$ will become clear in Sec. III B. It can be calculated in detail by

$$\begin{aligned}
\int_0^T \int \frac{1}{2}(DD_* + D_*D)Y_t \eta(t,Y_t)\, dP\, dt &= \int_0^T \int \frac{1}{2}(Db_* + D_*b)(t,Y_t)\,\eta(t,Y_t)\, dP\, dt \\
&= \int_0^T \int \frac{1}{2}\left(\left(\frac{h}{2}\Delta + b^j\partial_j + \partial_t\right) b_* + \left(-\frac{h}{2}\Delta + b_*^j\partial_j + \partial_t\right) b \right) \\
&\quad (t,Y_t)\,\eta(t,Y_t)\, dP\, dt = \int_0^T \int \left(\partial_t v + \nabla_v v - \nabla_u u - \frac{h}{2}\Delta u \right) \\
&\quad \times (t,Y_t)\,\eta(t,Y_t)\, dP\, dt, \\
&\quad \forall\ \eta \in C_0^\infty(\{\varrho>0\};\mathbb{R}),
\end{aligned}$$

where ∇ denotes the Levy-Civita connection of the Euclidean space, i.e., $(\nabla_v v)^i = v\cdot\nabla v^i$, $i=1,\ldots,n$.

The whole treatment of validity on $\{\varrho(t,x)>0\}$ tries to avoid problems with the, by definition, eventual singularities of b and b_* on $\{\varrho=0\}$.

A further possibility to define diffusions is given by Itô diffusion equations $dY_t=b(t,Y_t)dt+\varkappa(t,X_t)dB_t$, for a Brownian motion B_t. The equation with drift b and diffusion coefficient $\varkappa$ (Ref. 12) is valid by definition, if the integral version holds true:[12]

$$Y_t = Y_0 + \int_0^t b(s,Y_s)\,ds + \int_0^t \varkappa(s,X_s)dB_s. \tag{20}$$

Itô diffusions are Markovian.

Lemma 10: Let $h>0$ and $b:[0,T]\times\mathbb{R}^n\to\mathbb{R}^n$ be measurable. Let $|b(t,x)|\leqslant K(1+|x|)\,\forall\, t\in[0,T]$ with a constant $K\in\mathbb{R}^+$. The Itô diffusion equation $dX_t=b(t,X_t)dt+\sqrt{h}dB_t$, $0\leqslant t\leqslant T$, has a weak solution,[12] with arbitrary initial distribution μ, such that X_t is a Brownian motion referring to a measure $\bar{P}$ and such that the Brownian motion (B_t,P) starts in 0, i.e., for every probability measure μ on $\mathbb{R}^n$ there exist Brownian motions $(\Omega,\mathcal{T}_t,X_t,\bar{P})$ and $(\Omega,\mathcal{T}_t,B_t,P)$ such that the Itô diffusion equation holds true and $P^{X_0}=\mu$.

Proof: See Ref. 13.

Remark 11: (a) Notice that in Lemma 10 a stronger version of a weak solution is constructed. $(\Omega,\mathcal{T}_t,X_t,\bar{P})$ is given at the outset as canonical Brownian motion (with X_t as coordinate mapping)!

(b) Let the drift vector $b(t,x)$ and the Itô diffusion equation $dY_t=b(t,Y_t)\,dt+\sqrt{h}dB_t$, (B_t,P) Brownian motion be given. If

$$\int_0^T \int b^2(t,Y_t)dP\,dt<\infty, \tag{21}$$

then the forward derivative exists in the $L^2(P)$-sense for a.e. t and we have $DY_t=b(t,Y_t)$. Furthermore,

$$\lim_{\Delta t\to 0^+} E_t\frac{\Delta Y_t^i \Delta Y_t^j}{\Delta t}=\begin{Bmatrix} 0 & \text{if } i\neq j \\ h & \text{if } i=j \end{Bmatrix} \text{ in } L^1(P) \text{ for a.e. } t. \tag{22}$$

If $\int b^2(t,Y_t)\,dP<\infty\,\forall\, t$, then the assertions hold true $\forall t$.

Proof: See Ref. 13.

B. Analysis of the Fokker-Planck equation

We state theorems concerning the existence, regularity, and uniqueness of the Fokker-Planck equation, needed for the stochastic mass transportation problem. Detailed proofs are given inspired by Ref. 15 in Ref. 13. Compared to Ref. 15 we adapt premises and do technical modifications. Note especially that Ref. 15 works spatially on the torus. The transfer of the proofs to $\mathbb{R}^n$ is surely not trivial.

A *weak solution* of the Fokker-Planck equation in $[0,T]\times\mathbb{R}^n$ with diffusion $h\cdot id$, given by $\varrho:[0,T]\times\mathbb{R}^n\to\mathbb{R}\in L^1$ [ϱ may $\forall t$ be represented, to the data $b:\{\varrho>0\}\to\mathbb{R}^n\cup\{(\pm\infty,\ldots,\pm\infty)\}$, measurable drift and $\varrho_0:\mathbb{R}^n\to\mathbb{R}\in L^1$], is defined by the following:

The function $t\mapsto\int\chi(t,x)\varrho\,dx$ is absolutely continuous and we have

$$\int \chi(t,x)\varrho\,dx-\int\chi(0,x)\varrho\,dx=\int_0^t\int\left(\frac{h}{2}\Delta+b^i(s,x)\partial_i+\partial_s\right)\chi(s,x)\varrho(s,x)\,dx\,ds,$$

$$\forall\,\chi\in C_0^\infty([0,T]\times\mathbb{R}^n;\mathbb{R}),\quad \forall\, t\in[0,T]. \tag{23}$$

In addition the integrability condition

$$\int_0^T \int b^2 \varrho \, dx \, dt < \infty \tag{24}$$

may hold true, such that this definition is in $\mathbb{R}$.

Theorem 12: (Existence.) Let $b:[0,T]\times\mathbb{R}^n\to\mathbb{R}^n\in L^\infty\cap C^0$ and $\varrho_0:\mathbb{R}^n\to\mathbb{R}^+\in L^1$, $\int\varrho_0\,dx=1$. Then there is a positive weak solution of the Fokker-Planck equation in L^1 with diffusion $h\cdot id$. Especially $\varrho(t,x)\geqslant 0$ is given naturally $\forall t$ and we have $\varrho(0,x)=\varrho_0(x)$, respectively $\int\varrho(t,x)\,dx=1\,\forall t$. If $\varrho_0\in L^\infty(\mathbb{R}^n;\mathbb{R}^+)$, then we have $\varrho\in L^\infty([0,T]\times\mathbb{R}^n;\mathbb{R}^+)$.

Proof: See Ref. 13.

Theorem 13: (Regularity.) Let $\varrho:[0,T]\times\mathbb{R}^n\to\mathbb{R}^+\in L^\infty$ and $b:\{\varrho>0\}\to\mathbb{R}^n\cup\{\pm\infty\}$ (measurable) (explicitly given on $\{\varrho>0\}$) constitute a positive weak solution of the Fokker-Planck equation with diffusion $h\cdot id$. Let $\int b^2\varrho dx<\text{const}$ be independent of t. Then it follows that $\varrho\in W^{(0,1),2}_{loc}([0,T]\times\mathbb{R}^n;\mathbb{R})$, i.e., $\varrho\in L^2_{loc}(\varrho\in L^\infty)$ and there is $\forall i=1,\ldots,n$ a $\partial_i\varrho:[0,T]\times\mathbb{R}^n\to\mathbb{R}\in L^2_{loc}$, such that

$$\int_0^T\int \partial_i\varrho\varphi\,dx\,dt=(-1)\int_0^T\int\varrho\partial_i\varphi\,dx\,dt,\quad \forall\,\varphi\in C_0^\infty([0,T]\times\mathbb{R}^n;\mathbb{R}). \tag{25}$$

If, in addition, $\varrho(t,x)\in L^1(\mathbb{R}^n;\mathbb{R})\,\forall t$ and $\|\varrho\|_{L^1(\mathbb{R}^n;\mathbb{R})}\leqslant\text{const}$ independent of t, then $\partial_i\varrho\in W^{(0,1),2}([0,T]\times\mathbb{R}^n;\mathbb{R})$, $i=1,\ldots,n$.

Proof: See Ref. 13.

See also the regularity result in Ref. 14.

The *relative entropy*

$$\int\varrho_1(x)\ln\frac{\varrho_1(x)}{\varrho_2(x)}\,dx \tag{26}$$

of two densities ϱ_1 and ϱ_2 will be important in the following proof.

Theorem 14: (Uniqueness.) Let $\varrho_{1/2}:[0,T]\times\mathbb{R}^n\to\mathbb{R}^+\in L^\infty$ be positive weak solutions of the Fokker-Planck equation with diffusion $h\cdot id$, and $b_{1/2}:\{\varrho_{1/2}>0\}\to\mathbb{R}^n\cup\{(\pm\infty,\ldots,\pm\infty)\}$ be measurable and $\int b_{1/2}^2\varrho_{1/2}\,dx<\text{const}$ be independent of t. Let $\varrho_{1/2}(t,x)\in L^1(\mathbb{R}^n;\mathbb{R})\,\forall t$ and $\|\varrho_{1/2}\|_{L^1(\mathbb{R}^n;\mathbb{R})}\leqslant\text{const}$ independent of t. If the entropies $\int\varrho_{1/2}\ln\varrho_{1/2}\,dx$ exist in $\mathbb{R}$ at the times 0 and T, then uniqueness at time T holds (in the class with the given premises), i.e., if $b_1=b_2$ and $\varrho_1(0,x)=\varrho_2(0,x)$, then $\varrho_1(T,x)=\varrho_2(T,x)$.

Proof: See Ref. 13.

Corollary 15: For the conditions for a weak solution of the Fokker-Planck equation stated in Theorem 14, we have that the entropic velocity $u=1_{\{\varrho>0\}}(h/2)\nabla\ln\varrho$ is in $L^2(\varrho)$, i.e.,

$$\int_0^T\int u^2\varrho\,dx\,dt<\infty. \tag{27}$$

Furthermore, the existence of the entropy in $\mathbb{R}$ at the times T and 0 implies the existence of the entropy at all times $t\in[0,T]$. It follows that uniqueness at all times holds true (in the class with the given premises).

Proof: See Ref. 13.

C. Existence of diffusions

Smooth diffusions, by definition, can have singularities in the points where the distribution density disappears. Lemma 10 is not applicable to construct a diffusion with diffusion matrix $h\cdot id$, $h\in\mathbb{R}^+$, where a drift with singularities is given. Especially in Sec. IV we will look for diffusions with drift vector $\nabla(A+B)$, where $\psi=e^{A+iB}$ is a differentiable solution of the Schrödinger equation. A zero point of such a solution implies necessarily that $A=-\infty$, respectively there is a singularity

for the drift $\nabla(A+B)$. $A+B$ is bounded from above on compact sets. Nevertheless, it is possible to construct Itô diffusion equations $dY_t=\nabla(A+B)(t,Y_t)\,dt+hdB_t$ whereas the condition $|\nabla(A+B)\times(t,x)|\leqslant K(1+|x|)$ in Lemma 10 is not satisfied.

Remark 16: The literature on the existence of diffusions with singular drift is very extensive. See, e.g., Refs. 2, 3, 10, and 16–19 as reference.

The stationary (time independent) case was first treated by Albeverio and Høegh-Krohn.[17]

The case of a compact manifold as configuration space is considered in Ref. 10.

Carlen[16] shows weak existence of a diffusion measure, in the sense that the Martingale characterization for diffusions holds true, from an analytical viewpoint. Singular drift vectors b, b_* and densities ϱ, fulfilling the Fokker-Planck equation in a weak sense, are given at the outset. The central point is to solve a parabolic equation and to obtain a fundamental solution $p_*(y,t;x,s)$. The integrability condition $\int\int(u^2+v^2)\varrho\,dx\,dt<\infty$ is required, which is naturally given in the framework of the Yasue variational problem introduced in Sec. III. Using p_* a measure on $(\mathbb{R}^n)^{\mathbb{R}_+}$ ($\mathbb{R}^n$ one-point compactification) is constructed. If only this measure is constructed, it is left to show that an honest diffusion with the prescribed data is given.

The existence theory of Carlen's diffusions was extended by Guerra[20] using continuity arguments.

With an analogous integrability condition like Ref. 4, Zheng[18] shows, with technically different methods, by using tightness results, the existence of weak solutions of diffusion measures, in the sense that the Martingale property is fulfilled. Regularity conditions are required and regular ψ functions, fulfilling the Fokker-Planck equation on compact manifolds, are considered. An intrinsic feature of these proofs is that under certain conditions, with probability one, the process never visits the sets $\{\varrho=0\}$.

In Ref. 19 strong solutions, where the Fokker-Planck equation with singular drift (at $\{\varrho=0\}$) is given, are constructed. Stopping time methods are used and unattainability criteria of the nodal sets are given. Further conditions on the integrability of certain derivatives of ϱ and the entropic velocity v are needed.

III. STOCHASTIC MASS TRANSPORTATION

A. Definition of stochastic mass transportation

Let χ_1 and χ_2 be two density functions on $\mathbb{R}^n$, which take values in Ω_1 and Ω_2. The normalization

$$\int_{\Omega_1}\chi_1(x)\,dx=\int_{\Omega_2}\chi_2(y)\,dy=1 \tag{28}$$

may hold true. The *deterministic* (L^2-) *mass transportation problem* (see Refs. 21–23), referring to a quadratic cost function, seeks to transform χ_1 into χ_2 by an L^2-optimal transport mapping D, i.e., if the "push forward" $D_\#\chi:\Omega_2\to\mathbb{R}^+$ of a density function χ by the mapping $D:\Omega_1\to\Omega_2$ is as before defined by

$$\int_{\Omega_2}D_\#\chi(y)f(y)\,dy=\int_{\Omega_1}\chi(x)f(D(x))\,dx\;\forall\,f\in C^0(\Omega_2), \tag{29}$$

then the deterministic mass transportation minimizes the functional

$$\int_{\Omega_1}|x-D(x)|^2\chi_1(x)\,dx\overset{!}{=}\inf_D,\quad\text{where } D_\#\chi_1=\chi_2. \tag{30}$$

The square root of this minimal expression is called the *Wasserstein distance* of χ_1 and χ_2. Necessary for a minimum is the nonlinear Monge-Ampère equation

$$\chi_2(D(x))\det((\partial_jD^i)_{ij}(x))=\chi_1(x). \tag{31}$$

The main result in this connection is that D exists and is the gradient of a convex function[24,25] (see also Refs. 21 and 23 as reference). Hereby the second derivatives in the Monge-Ampère equation are justified.

The connection to geodesics can be seen if the interpolation of χ_1 and χ_2 by D is considered in a time continuous setting. The following result is due to Brenier and Benamou[26] [see Ref. 23 for a precise definition of the space of pairs (v,ϱ)].

Let $\varrho_0,\ \varrho_1 \in \mathbb{R}^n \to \mathbb{R}$ be given with $\int \varrho_0(x)\,dx = \int \varrho_1(x)\,dx = 1$ and $T \in \mathbb{R}^+$. The minimization problem

$$\int_0^T \int v^2 \varrho \, dx \, dt \overset{!}{=} \inf_{v,\varrho};$$

$$v:[0,T] \times \mathbb{R}^n \to \mathbb{R}^n \in C^1,$$

$$\varrho:[0,T] \times \mathbb{R}^n \to \mathbb{R}^+ \in C^1, \quad \int \varrho_t \, dx = 1,$$

$$\varrho(0,\,.\,) = \varrho_0, \quad \varrho(T,\,.\,) = \varrho_T, \quad \partial_t \varrho + \operatorname{div}(\varrho v) = 0 \tag{32}$$

takes on its minimum in the unique pair (v,ϱ) defined by the convex function Φ belonging to the non-time-continuous transport problem by

$$\int f(t,x)\varrho(t,x)\,dt\,dx = \int f\left(t, x + \frac{\nabla\Phi - x}{T}\right)\varrho_0(x)\,dt\,dx,$$

$$\int f(t,x)\varrho(t,x)v(t,x)\,dt\,dx = \int \frac{\nabla\Phi - x}{T} f\left(t, x + \frac{\nabla\Phi - x}{T}\right)\varrho_0(x)\,dt\,dx \;\forall\, f \in C^0. \tag{33}$$

The variational formalism is equal to geometric optics. The time continuous, straight convex connection $x + t(\nabla\Phi - x)/T$, $t \in [0,T]$, constitutes the way of light.

Definition 17: (*Euclidean h-stochastic* (L^2-) *mass transportation*, see also Ref. 27 for a variant.) In analogy, let the stochastic mass transportation to the data $\mu_{0/T}$ probability measures on $\mathbb{R}^n$, T, $h \in \mathbb{R}^+$, be defined as follows:

$$\int_0^T \int b^2(t,Y_t)\,dP\,dt \overset{!}{=} \inf_{b,P,B},$$

$$b:[0,T] \times \mathbb{R}^n \to \mathbb{R}^n,$$

$$dY_t = b(t,Y_t)\,dt + \sqrt{h}\,dB_t, \quad Y^P_{0/T} = \mu_{0/T}. \tag{34}$$

$(\Omega, \mathcal{T}_t, B_t, P)$ is a Brownian motion with start in 0 and $(\Omega, \mathcal{T}_t, Y_t, \bar{P})$ is a Brownian motion with initial distribution $\bar{P}^{Y_0}$. The infimum is taken over all Itô diffusion equations, which satisfy the marginal conditions. $(\Omega, \mathcal{T}_t, Y_t, \bar{P})$ can be given at the outset as canonical Brownian motion on $\mathbb{R}^n$ with initial distribution μ, i.e., as before, $\Omega = C^0([0,T)], \mathbb{R}^n)$, $Y_t = X_t$ is the coordinate mapping $X_t(c) = c(t)$, $\mathcal{T}_t$ is the σ-Algebra constituted by X_s, $s \leqslant t$, and $\bar{P}$ is the usual construction of the Wiener measure with initial distribution. The definition above is a Markovian variant of stochastic mass transportation. The minimization can alternatively take place over all triples (b,P,Y), where Y is a diffusion referring to P with diffusion matrix $h \cdot id$ and drift b. What counts is what the triple produces after an application of the picture measure theorem, namely a picture density and drift which fulfill a Fokker-Planck equation.

Proposition 18: Let $\varrho_{0/T} \in L^\infty \cap L^1$ be positive, $|\varrho_{0/T}|_{L^1}=1$, and the entropies $\int \varrho_{0/T} \ln \varrho_{0/T}\, dx$ may exist in $\mathbb{R}$. Let $(\Omega, \mathcal{T}_t, X_t, \bar{P})$ be the canonical Brownian motion with initial distribution $\bar{P}^{X_0}$. The following variational problems can be reformulated in each other:

(I)

$$\int_0^T \int b^2(t,x)\varrho \, dx \, dt \overset{!}{=} \inf_{b,\varrho},$$

$$b:[0,T] \times \mathbb{R}^n \to \mathbb{R}^n \in L^\infty \cap C^0,$$

$$\varrho:[0,T] \times \mathbb{R}^n \to \mathbb{R}^+ \in L^\infty, \quad \int \varrho_t \, dx = 1,$$

$$\varrho(0,x) = \varrho_0, \quad \varrho(T,x) = \varrho_T,$$

$$\partial_t \varrho + \operatorname{div}(\varrho b) - \frac{1}{2} h \Delta \varrho,$$

weak Fokker-Planck equation!

(II)

$$\int_0^T \int b^2(t,X_t)\, dP\, dt \overset{!}{=} \inf_{b,P,B},$$

$$b:[0,T] \times \mathbb{R}^n \to \mathbb{R} \in L^\infty \cap C^0,$$

$$dX_t = b(t,X_t)\, dt + \sqrt{h} dB_t,$$

$(\Omega, \mathcal{T}_t, B_t, P)$ Brownian motion with start in 0, such that

$$P[X_0 \in dx] = \varrho_0 dx, \quad P[X_T \in dx] = \varrho_T dx.$$

Proof: "(II)$\Rightarrow$(I)" The assertion follows by the picture measure theorem and the fact that because of Proposition 3 and Remark 11(b) (or Theorem 12) the stochastic diffusion equations $dX_t = b(t,X_t)\, dt + \sqrt{h} dB_t$ lead to a weak Fokker-Planck equation $\partial_t \varrho + \operatorname{div}(\varrho b) - \frac{1}{2} h \Delta \varrho = 0$, where $\varrho(t,x)\, dx = P[X_t \in dx]$, such that the conditions in (I) are fulfilled.

"(I)$\Rightarrow$(II)" Let b be given. Because b is bounded, according to Lemma 10 there is a weak solution $(\Omega, \mathcal{T}_t, B_t, P)$ of the diffusion equation with initial distribution density ϱ_0. This weak solution again leads to a weak Fokker-Planck equation according to Proposition 3 and Remark 11(b) (respectively, Theorem 12). Especially because of Theorem 13 the conditions of Theorem 13 are fulfilled. By Corollary 15 we can apply the uniqueness at all times. ϱ is therefore uniquely characterized by ϱ_0. Especially the time marginal condition for T is true. The equality of both functionals again is a conclusion of the picture measure theorem. Q.E.D.

Remark 19: The Brownian motion $(\Omega, \mathcal{T}_t, X_t, \bar{P})$ with initial distribution $\bar{P}^{X_0}$ is given at the outset. $(\Omega, \mathfrak{T}_t, X_t, \bar{P})$ is called the *reality* of the transport problem. Let $(\Omega, \mathcal{T}_t, B_t, P)$ be a minimizing solution. B_t is called the *observer* to the time marginal densities ϱ_0, ϱ_T at time T. P is called the observed *deviation* of the reality.

B. Lagrange formalism

The Lagrangian formalism for a point dynamical system on $\mathbb{R}^n$ possesses a stochastic generalization. For an elementary Lagrangian $L(x(t),\dot{x}(t))=\frac{1}{2}\langle\dot{x}(t),\dot{x}(t)\rangle-V(x(t))$, with a Riemannian metric $\langle .,. \rangle$, this generalization is defined by stochastic mass transportation including a potential term concerning V. The Euler-Lagrange equation of the variational problem is given by the stochastic Newton equation. Hereby Newton's law is generalized.

Definition 20: (Variational problem.) Let a variational functional $F: V \to \mathbb{R}$ be defined on a linear *concurrence space* K, such that constraints for F may hold. Let the problem be *homogeneous*, i.e., there is a subspace $U \subset K$, called *variational space*, such that for $f \in K$ it follows that $f+u \in K \ \forall u \in U$. An element f out of the concurrence space is called *stationary* referring to variation with U exactly if $(d/d\varepsilon)|_{\varepsilon=0} F(f+\varepsilon u)=0 \ \forall u \in U$, where existence of the derivatives may be given without restriction. We denote $\delta F(f) \overset{!}{=} 0$, to underline the search for a stationary solution.

The Lagrangian formalism for a point dynamical system on $\mathbb{R}^n$ with a Lagrangian L is given by

$$\delta\left(\int_0^1 L(t,x(t),\dot{x}(t))\,dt\right)\overset{!}{=}0, \quad \text{time marginal values } x(0),x(1). \tag{35}$$

The variation takes place referring to all differentiable ways with a compact support in $[0,1]$ and over the concurrence space of all differentiable ways which fulfill the time marginal conditions. The Euler-Lagrange equations for this problem are[28]

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{x}}-\frac{\partial L}{\partial x}=0. \tag{36}$$

The well-known stochastic generalization is given by the *Yasue h-problem:*[10,29,30]

$$J(Y) \coloneqq \int_0^T \int \left(\frac{1}{2}L(t,Y,DY)+\frac{1}{2}L(t,Y,D_*Y)\right)dP\,dt, \tag{37}$$

$\delta J(Y) \overset{!}{=} 0$. Variation takes place over the concurrence space of diffusions (Y,P), such that Y is a diffusion referring to P with drift b, the functional is in $\mathbb{R}$, and, furthermore, $P[Y_0 \in dx]=\varrho_0 dx$, $P[Y_T \in dx]=\varrho_T dx$. We seek a smooth solution (Y,P) with diffusion matrix $h \cdot id$.

Reformulating (and simplifying) the variational formalism compared to Refs. 29, 10, and 30 we do variation in the space of diffusions. A smooth diffusion Y_t with $\varrho(t,x)dx=P[Y_t \in dx]$, such that the time marginal conditions are fulfilled, is stationary if for all probability vectors $\xi=\eta(t,Y_t)$, $\eta:[0,T]\times\mathbb{R}^n \to \mathbb{R}^n$, differentiable with compact support in $\{\varrho>0\}\cap[0,T]\times\mathbb{R}^n$ we have: $(d/d\varepsilon)|_{\varepsilon=0} J(Y+\varepsilon\xi)=0$. As can be seen according to the proof of Proposition 2, $Y+\varepsilon\xi$ is again a diffusion referring to P. Furthermore, the time marginal conditions are true for $Y+\varepsilon\xi$, because of the compactness of the support of η. $Y+\varepsilon\xi$ is therefore an element of the concurrence space of diffusions. We find by variational calculus

$$\left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} J(Y+\varepsilon\xi)=\int_0^T\int\left(\frac{1}{2}\partial_{x_i}L(t,Y,DY)\xi^i+\frac{1}{2}\partial_{x_i}L(t,Y,D_*Y)\xi^i+\frac{1}{2}\partial_{q_i}L(t,Y,DY)D\xi^i\right.$$
$$\left.+\frac{1}{2}\partial_{q_i}L(t,Y,D_*Y)D_*\xi^i\right)dP\,dt \quad \text{(Sum convention !)}$$

where we have to justify the commutation of integration and differentiation. A justification can be given by the usual argumentations. See, e.g. Ref. 31, Sec. 11.Satz 2. The proof transfers obviously,

without which it is important that the integration takes place over a probability space Ω instead of $\mathbb{R}^n$. The following criteria must be true if we define

$$g(t,c,\varepsilon) \vdots \frac{1}{2}L(t,(Y+\varepsilon\xi)(t,c),D(Y+\varepsilon\xi)(t,c)) + \frac{1}{2}L(t,(Y+\varepsilon\xi)(t,c),D_*(Y+\varepsilon\xi)(t,c)), \quad c \in \Omega:$$

There is a $\kappa > 0$ such that

(I) $\varepsilon \mapsto g(t,c,\varepsilon)$ is continuously differentiable in ε, $\forall\ \varepsilon \in [-\kappa,\kappa]$ for every $(t,c) \in [0,T] \times \Omega$.

(II) $(t,c) \mapsto g(t,c,\varepsilon)$ is integrable for time and probability space for every $\varepsilon \in [-\kappa,\kappa]$.

(III) There is a (positive) integrable function $F(t,c)$ dominating $|(d/d\varepsilon)(g(t,c,\varepsilon))|\ \forall \varepsilon \in [-\kappa,\kappa]$.

To fulfill (I) the Lagrangian must be differentiable. For (II) the diffusions must allow integration, i.e., the drift has to be in $L^2(P)$ if L is quadratic in the velocity component. For (III) we can use the compactness of the support of η.

With the partial integration of Proposition 5 we have, using the compactness of the support of η,

$$\frac{d}{d\varepsilon}\bigg|_{\varepsilon=0} J(Y+\varepsilon\xi) \overset{!}{=} 0\ \forall\ \xi \Leftrightarrow \int_0^T \int \left(\frac{1}{2}\partial_{x_i}L(t,Y,DY) + \frac{1}{2}\partial_{x_i}L(t,Y,D_*Y) - \frac{1}{2}D_*\partial_{q_i}L(t,Y,DY) - \frac{1}{2}D\partial_{q_i}L(t,Y,D_*Y)\right)\xi^i\, dP\, dt \overset{!}{=} 0, \quad \forall\ \xi = \eta(t,Y_t). \tag{38}$$

Because η can be chosen arbitrarily the integrand is necessarily zero, i.e., the stochastic Euler-Lagrange equations are fulfilled. If the elementary Lagrangian

$$L(x,q) = \frac{1}{2}\langle q,q\rangle_{\text{Eucl}} - V(x) \tag{39}$$

is considered, with the Euclidean metric $\langle .,. \rangle_{\text{Eucl}}$ and a real-valued potential $V: \mathbb{R}^n \to \mathbb{R}$, $V \in C^1$, for which we have

$$\int_0^T \int |V(Y_t)| dP\, dt < \infty \Rightarrow \int_0^T \int |V(Y_t + \varepsilon\,\eta(t,Y_t))| dP\, dt < \infty$$

$$\forall\, \varepsilon \in [-\kappa,\kappa] \text{ for a } \kappa > 0, \quad \forall\ \eta \in C_0^\infty,$$

because $|V|$ is locally bounded, a short calculation with Proposition 5 shows immediately

$$\int_0^T \int \left(-\frac{1}{2}(DD_* + D_*D)Y - \nabla V(Y)\right)\xi\, dP\, dt = 0 \quad \forall\ \xi_t = \eta(t,Y_t). \tag{40}$$

If Y is a smooth stationary solution with diffusion matrix $h \cdot id$, we thereby have, if we calculate the stochastic acceleration $\frac{1}{2}(DD_*+D_*D)$ as in Sec. II A, the stochastic Newton equation[10]

$$\partial_t v + \nabla_v v - \nabla_u u - \frac{h}{2}\Delta u = -\nabla V. \tag{41}$$

The equation is obviously valid in $[0,T] \times \mathbb{R}^n$, at least in the points where the picture density is not zero, i.e., in the points where a validity is of interest.

The *quasi-Euclidean h-stochastic Yasue problem*, with elementary Lagrangian, is defined as follows

$$J_q(Y) := \int_0^T \int \left(\frac{1}{2}b^2(t,Y_t) - V(Y_t)\right) dP\, dt - \frac{1}{2}h\Delta\mathrm{Entrop}(p_T,p_0), \tag{42}$$

$\delta J_q(Y) \overset{!}{=} 0$. Variation takes place over the concurrence space of diffusions (Y,P), such that Y is a diffusion referring to P with drift b, the functional is in $\mathbb{R}$, and, furthermore, $P[Y_0 \in dx] = \varrho_0 dx$, $P[Y_T \in dx] = \varrho_T dx$. We seek a smooth solution (Y,P) with diffusion matrix $h \cdot id$.

The marginal densities ϱ_0 and ϱ_T are given differentiable probability densities such that their entropy is in $\mathbb{R}$. The Gibbs-Boltzman entropy difference

$$\Delta\mathrm{Entrop}(\varrho_T,\varrho_0) = \left(\int \varrho_T \ln \varrho_T\, dx - \int \varrho_0 \ln \varrho_0\, dx\right) \quad \text{(the integral is defined on } \{\varrho_{0/T} > 0\}) \tag{43}$$

of the time marginal densities ϱ_0 and ϱ_T is only introduced because of energy conservation. It is obviously stationarily irrelevant, but note that the gradient flow referring to the entropy functional is the heat flow equation. $\Delta\mathrm{Entrop}(\varrho_T,\varrho_0)$ can be alternatively implemented into the functional, as will be shown in the following.

Proposition 21: (Entropy interpolation.) Let ϱ be a classical differentiable (strong) solution of the Fokker-Planck equation in $[0,T]\times\mathbb{R}^n$ with diffusion $h \cdot id$ and drift b. Let $\varrho > 0$ be in $L^\infty([0,t]\times\mathbb{R}^n;\mathbb{R})$ and $L^1(\mathbb{R}^n;\mathbb{R})$ with $\int \varrho\, dx = 1\ \forall t$. Let $b \in L^2(\varrho)$, i.e., on $\{\varrho > 0\}$ we have

$$\int_0^T \int b^2 \varrho\, dx\, dt < \infty. \tag{44}$$

Furthermore, $\varrho(0,x)$ and $\varrho(T,x)$ may have an entropy in $\mathbb{R}$ and the entropic velocity $u = (h/2)\nabla \ln \varrho$ may also be in $L^2(\varrho)$, i.e., on $\{\varrho > 0\}$

$$\int_0^T \int u^2 \varrho\, dx\, dt < \infty. \tag{45}$$

Then also the current velocity $v = b - u$ is in $L^2(\varrho)$ and we have the entropy interpolation

$$h\Delta\mathrm{Entrop}(\varrho_T,\varrho_0) = 2\int_0^T \int (v \cdot u)\varrho\, dx\, dt. \tag{46}$$

Proof: The strong validity of the Fokker-Planck equation implements the weak validity (referring to C_0^∞ as test functions). Let $B_{1/\varepsilon}(0)$ be the open ball with radius $1/\varepsilon$ at $0 \in \mathbb{R}^n$, for $\varepsilon > 0$. Let $f_\varepsilon : [0,T]\times\mathbb{R}^n \to [0,1] \in C_0^\infty$ be a plateau function, such that $f_\varepsilon|_{[0,T]\times B_{1/\varepsilon}(0)} \equiv 1$ and $\partial_i f_\varepsilon$, $\partial_t f_\varepsilon$ are uniformly bounded in ε for $i = 1,\ldots,n$. Let $\delta > 0$, then $\ln[(f_\varepsilon\varrho + \delta)/(f_\varepsilon + \delta)] \in C_0^\infty$ and we have by the weak Fokker-Planck equation and shifting

$$\int \varrho(T,x) \ln \frac{f_\varepsilon\varrho + \delta}{f_\varepsilon + \delta}(T,x)\, dx - \int \varrho(0,x) \ln \frac{f_\varepsilon\varrho + \delta}{f_\varepsilon + \delta}(0,x) dx = \int_0^T \int \left(\varrho b \nabla \ln \frac{f_\varepsilon\varrho + \delta}{f_\varepsilon + \delta}\right.$$
$$\left. - \nabla \varrho \nabla \ln \frac{f_\varepsilon\varrho + \delta}{f_\varepsilon + \delta} + \varrho\partial_t \ln \frac{f_\varepsilon\varrho + \delta}{f_\varepsilon + \delta}\right) dx\, dt =: \int_0^T \int (\mathrm{I} - \mathrm{II} + \mathrm{III})\, dx\, dt.$$

We see

$$\int_0^T \int \mathrm{I}\, dx\, dt = \int_0^T \int \left(\varrho b \cdot \frac{\nabla(f_\varepsilon\varrho)}{f_\varepsilon\varrho + \delta} - \varrho b \cdot \frac{\nabla f_\varepsilon}{f_\varepsilon + \delta}\right) dx\, dt,$$

$$\int_0^T \int \mathrm{II}\, dx\, dt = \int_0^T \int \left(\nabla \varrho \cdot \frac{\nabla (f_\varepsilon \varrho)}{f_\varepsilon \varrho + \delta} - \nabla \varrho \cdot \frac{\nabla f_\varepsilon}{f_\varepsilon + \delta} \right) dx\, dt,$$

$$\int_0^T \int \mathrm{III}\, dx\, dt = \int_0^T \int \left(\varrho \frac{\partial_t (f_\varepsilon \varrho)}{f_\varepsilon \varrho + \delta} - \varrho \frac{\partial_t f_\varepsilon}{f_\varepsilon + \delta} \right) dx\, dt.$$

The limit $\lim_{\delta \to 0} \lim_{\varepsilon \to 0}$ can be executed and it follows with $\varrho = e^{\ln \varrho} \Rightarrow \nabla \varrho = \varrho \nabla \ln \varrho$ (on $\{\varrho > 0\}$)

$$\Delta \mathrm{Entrop}(\varrho_T, \varrho_0) = \frac{2}{h} \int_0^T \int (v \cdot u) \varrho \, dx\, dt.$$

The limits are obvious, if we use the integrability

$$\int_0^T \int \frac{\nabla \varrho \cdot \nabla \varrho}{\varrho} \, dx\, dt < \infty.$$

Because of $\nabla \varrho \cdot \nabla \varrho \leqslant \max\{1, \|\varrho\|_{L^\infty}\} \nabla \varrho \cdot \nabla \varrho / \varrho$ we have $\varrho \in W^{(0,1),2}([0,T] \times \mathbb{R}^n; \mathbb{R})$, e.g., the limit $\lim_{\delta \to 0}$ in

$$\lim_{\delta \to 0} \lim_{\varepsilon \to 0} \int \varrho(T,x) \ln \frac{f_\varepsilon \varrho + \delta}{f_\varepsilon + \delta}(T,x)\, dx = \int \varrho(T,x) \ln \varrho(T,x)\, dx$$

is obtained by considering positive and negative parts and applying the theorem of monotone convergence. The limit $\lim_{\varepsilon \to 0}$ is clear, because pointwise convergence and domination holds true. Q.E.D.

Corollary 22: For a smooth diffusion (Y_t, P), $\varrho(t,x)\, dx = P[Y_t \in dx]$, with diffusion matrix $h \cdot id$ and with entropies $\int \varrho(0/T, x) \ln \varrho(0/T, x)\, dx$ in $\mathbb{R}$ at the times 0 and T the entropy interpolation of Proposition 21 is valid.

Proof: Smooth diffusions with the given properties fulfill the conditions of Proposition 21, especially the integrability condition referring to the entropic velocity given according to Corollary 15. Q.E.D.

It follows that for a smooth diffusion Y_t, with diffusion matrix $h \cdot id$, we have

$$\int_0^T \int v^2(t, Y_t)\, dP\, dt < \infty, \quad \int_0^T \int u^2(t, Y_t)\, dP\, dt < \infty$$

and

$$\begin{aligned} \int_0^T \int b^2(t, Y_t)\, dP\, dt - h \Delta \mathrm{Entrop}(\varrho_T, \varrho_0) &= \int_0^T \int (v(t, Y_t) + u(t, Y_t))^2\, dP\, dt \\ &\quad - 2 \int_0^T \int (v(x,t) \cdot u(x,t)) \varrho \, dx\, dt \\ &= \int_0^T \int (v^2(t, Y_t) + u^2(t, Y_t))\, dP\, dt. \end{aligned}$$

Theorem 23: For an elementary Lagrangian $L(x,q) = \frac{1}{2} \langle q, q \rangle_{eukl} - V(x)$ and for a smooth diffusion Y_t, with diffusion matrix $h \cdot id$, we have

$$J(Y)=\int_0^T\int\left(\frac{1}{2}L(Y,DY)\,dP\,dt+\frac{1}{2}L(Y,D_*Y)\right)dP\,dt=\int_0^T\int\left(\frac{1}{2}v^2(t,Y_t)+\frac{1}{2}u^2(t,Y_t)\right.$$
$$\left.-V(Y_t)\right)dP\,dt=\int_0^T\int\left(\frac{1}{2}(v(t,Y_t)+u(t,Y_t))^2-\frac{1}{2}2v(t,Y_t)\cdot u(t,Y_t)-V(Y_t)\right)dP\,dt$$
$$=\int_0^T\int L(Y,DY)\,dP\,dt-\frac{1}{2}h\Delta\mathrm{Entrop}(\varrho_T,\varrho_0)=J_q(Y). \tag{47}$$

Proof: $DY=b=u+v$ and $D_*Y=b_*=v-u$. Q.E.D.

Analogously the quasi-Euclidean functional $\int_0^T\int L(Y,DY)\,dP\,dt-\frac{1}{2}h\Delta\mathrm{Entrop}(\varrho_T,\varrho_0)$ can be variated. The same variational calculus shows that for stationary solutions Y we have

$$\int_0^T\int(-D_*DY-\nabla V(Y))\xi\,dP\,dt=0\quad\forall\,\xi_t=\eta(t,Y_t). \tag{48}$$

Corollary 24: The condition for a smooth diffusion Y, with diffusion matrix $h\cdot id$, to be a stationary solution of the problems (37) and (42) (with elemantary Lagrangian) is equivalent to

$$-\frac{h}{2}\Delta v+\nabla_v u-\nabla_u v+\partial_t u=0,\quad DD_*Y=D_*DY=-\nabla V(Y). \tag{49}$$

Proof: We have

$$DD_*Y^i=Db_*^i=\left(\frac{h}{2}\Delta+b^j\partial_j+\partial_t\right)b_*^i=\frac{h}{2}\Delta(v^i-u^i)+v^j\partial_j(v^i-u^i)+u^j\partial_j(v^i-u^i)+\partial_t(v^i-u^i)$$

and

$$D_*DY^i=D_*b^i=\left(-\frac{1}{2}\Delta+b_*^j\partial_j+\partial_t\right)b^i=-\frac{h}{2}\Delta(v^i+u^i)+v^j\partial_j(v^i+u^i)-u^j\partial_j(v^i+u^i)+\partial_t(v^i+u^i).$$

The direct comparison of $\frac{1}{2}(DD_*+D_*D)Y$ and D_*DY leads to

$$\partial_t v+\nabla_v v-\nabla_u u-\frac{h}{2}\Delta u=-\nabla V$$

according to the Yasue problem and

$$-\frac{h}{2}\Delta(v+u)+\nabla_v(v+u)-\nabla_u(v+u)+\partial_t(v+u)=-\nabla V$$

according to the quasi-Euclidean Yasue problem. It follows

$$-\frac{h}{2}\Delta v+\nabla_v u-\nabla_u v+\partial_t u=0$$

for a stationary solution Y of both problems. Furthermore we have $DD_*Y-D_*DY=-2(-(h/2)\Delta v+\nabla_v u-\nabla_u v+\partial_t u)=0$. Q.E.D.

Remark 25: (a) Therefore a stochastic generalization of Newton's law (see Ref. 10)

$$force=mass\times acceleration=mass\times\ddot{x}$$

holds for stationary solutions, where here mass was set identical to one and the two derivatives have to be interpreted as execution of forward and backward derivative, one behind the other respectively.

(b) If the Lagrangian is elementary and $V\equiv 0$, then the *h-stochastic mass transportation* is

defined by minimizing the h-Yasue functional (in the space of general diffusions where we seek for solutions in the space of diffusions with diffusion matrix $h \cdot id$). Analogously let the *quasi-Euclidean h-stochastic mass transportation* be defined by minimizing the quasi-Euclidean h-Yasue functional. A minimizing solution is necessarily stationary.

If in addition we consider a potential $V \leqslant 0$ for the minimization problems, this will be denoted by the expression Lagrangian stochastic mass transportation.

The stochastic mass transportation problem can as well be considered under the constraint that the solution has to be in a certain Riemannian structure, e.g., in the space of diffusions with diffusion matrix $h \cdot id$. Hereby a reachability problem is defined (that of course may not be well posed). Especially the unconstrained transport problem may lead to a general diffusion with contravariant diffusion matrix $(\sigma^{ij})_{ij}$ as an eventual solution. The covariant metric tensor of the problem is given by $(\sigma_{ij})_{ij}$.[10]

The following paragraph will show that solutions of the Schrödinger equation lead to stationary solutions of the Yasue problem. If one has a solution of the Schrödinger equation

$$i\hbar \partial_t \psi = -\frac{\hbar^2}{2m} \Delta \psi + V\psi,$$

with a point mass m, and states the Yasue problem with initial and end density $|\psi_{0/T}|^2$, the m will be a part of the solution of the problem and does not have to be given at the outset!

If one minimizes the stochastic mass transportation problem in the space of diffusions with diffusion matrix $h \cdot id$, then the problem can obviously be restricted to this space. By that a solution of the Euclidean h-stochastic mass transportation problem in Definition 1 is obtained. For a fixed initial density ϱ_0, the reachable end densities ϱ_T, so-constructed solutions of the minimization problem, are called *Euclidean h-stochastic shortest geodesics*.

The hereby demonstrated geodesic theory requires the clarification of the following problems:
(I) existence,
(II) uniqueness,
(III) regularity,
(IV) characterization of reachability, and
(V) an injectivity radius theorem.

IV. GEOMETRY OF THE SCHRÖDINGER EQUATION

A. Hamilton-Jacobi formalism

The Hamilton-Jacobi formalism is characterized by the Hamiltonian action function, which describes the evolution of the action wave of a point dynamical system out of a singular point. Or, equivalently, for a geodesic system where the potential is equal to zero it describes the evolution of the distance spheres. The Hamiltonian action function is determined by the Hamilton-Jacobi equation. Almost analogously to the deterministic case such an action function can be defined for the stochastic scenario, such that this function fulfills almost analogous properties.

The results in this subparagraph are taken from Ref. 10, and so we restrict to a brief sketch of proofs.

Consider the flow $\Phi^w(s;x,T)$ of a time-independent differentiable vector field $w:[0,\mathbb{R}] \times \mathbb{R}^n \to \mathbb{R}^n$, where $\Phi^w(s;x,T)$ is the flow at time s, if the flow is localized to time T in x. Let $L(x,q)=\frac{1}{2}\langle q,q\rangle - V(x)$ be an elementary Lagrangian, with a Riemannian metric $\langle .,. \rangle$. The *Hamiltonian action function* $S^w(T,x)$ of the system is defined by

$$S^w(T,x) := -\int_T^0 L(\Phi^w(s;x,T), w(t,\Phi^w(s;x,T)))\, ds. \tag{50}$$

It describes the evolution of the surfaces of constant action out of a singular point. Application of the total derivative (d/dT) leads to $(d/dT)S^w(T,x)=L(x,w(T,x)) := L^w$. We seek for stationary solutions of the functional $S^w(x,T)$ where we variate w without time marginal constraints. The

execution of the total derivative shows that we have to consider intrinsic dependencies such that $d/dT =: D^w = \partial_t + w^i \partial_i$. Let w be a stationary solution and $\delta w + w = \tilde{w}$. Then

$$D^w(S^w - S^{\tilde{w}}) = D^w S^w - D^{\tilde{w}} S^{\tilde{w}} + (D^w - D^{\tilde{w}}) S^{\tilde{w}} = L^{\tilde{w}} - L^w - \delta w^i \partial_i S^{\tilde{w}} = L^{\tilde{w}} - L^w - \delta w^i \partial_i S^w + o(\delta w).$$

Now $L^{\tilde{w}} - L^w = \Sigma_i w^i \delta w^i + o(\delta w)$ and $S^{\tilde{w}} - S^w = -\int_T^0 (d/ds)(S^{\tilde{w}} - S^w)\, ds$, because $S^{\tilde{w}}$ and S^w are equal to zero at time 0. Therefore

$$S^{\tilde{w}} - S^w = -\int_T^0 \sum_i (w^i - \partial_i S^w)\, \delta w^i\, ds + o(\delta w) \quad \forall\ \delta w.$$

We can conclude the Hamilton-Jacobi condition

$$w = \nabla S, \tag{51}$$

which shows together with $D^w S^w = L^w$, i.e., $\partial_t S^w + v^i \partial_i S^w = \frac{1}{2}\langle w, w\rangle - V$, the Hamilton-Jacobi equation

$$\partial_t S^w + \frac{1}{2}(\nabla S^w)^2 + V = 0. \tag{52}$$

The analogous stochastic formalism was considered by Guerra and Morato[10,32] and will be sketched here, because the following theorem taken from Ref. 10 and especially the stochastic Hamilton-Jacobi condition (62) will have effects on the next subparagraph. Let L_{GM} be the Lagrangian (Guerra-Morato Lagrangian)

$$L_{GM}(x,q) = \frac{1}{2}\langle q, q\rangle_{\text{Eucl}} + \frac{\hbar}{2}\partial_i q^i - V(x) \tag{53}$$

and let the variational functional be given by

$$I(b) = \int_0^T \int L_{GM}(X_t, b(t, X_t))\, dP\, dt. \tag{54}$$

$\hbar$ is *Planck's constant* from quantum mechanics, which later will enter into the validity of the Schrödinger equation. The variation will take place over the drift of the diffusion equation $dX_t = b(t, X_t)\, dt + \sqrt{\hbar} dB_t$; (B_t, P) is a Brownian motion, where the end density at time T is kept fixed. These diffusion equations can be constructed by time inversion on the Wiener space.[14] Especially weak solution methods can be applied and X_t can be chosen as coordinate mapping as usual. I is, following Nelson,[10] critical in the sense of Guerra-Morato in a differentiable b, if for all differentiable δb, with compact support, such that the diffusion, with diffusion matrix $\hbar \cdot id$, belonging to $\tilde{b} := b + \delta b$ has the same end density at time T as the diffusion belonging to b, if

$$I(b) - I(\tilde{b}) = I - \tilde{I} = o(\delta b). \tag{55}$$

Define $P[X_s \in dx] = \varrho dx$ and $R = (\hbar/2) \ln \varrho$, such that $\nabla R = u$. Then we have for $b = u + v = \nabla R + \nabla S$ the Fokker-Planck equation $\partial_t \varrho + \text{div}(b\varrho) - \frac{1}{2}\hbar \Delta \varrho = 0$, respectively the continuity equation $\partial_t \varrho + \text{div}(v\varrho) = 0$. Define, furthermore, the Hamiltonian action function referring to the drift b as follows:

$$S^b(T,x) := -E_T^b\left(\int_T^0 L_{GM}(X_s, b(s, X_s))\, ds | X_T = x\right) \tag{56}$$

with the factorized conditioned expectation associated to the diffusion measure referring to b conditioned under $X_T = x$.[33] We may have[10]

$$D^b S^b(T,X_T) = \lim_{\Delta t \to 0} \frac{1}{\Delta t}\left(E_T^b \int_T^{T+\Delta t} L_{GM}(X_s, b(s,X_s))\, ds \right) = L_{GM}(X_T, b(T,X_T)),$$

and with $D^b S^b(t,X_t) = (\partial_t + b^i \partial_i + (\hbar/2)\Delta) S^b(t,X_t)$

$$\begin{aligned} D^b(S^b - S^{\tilde{b}}) &= D^b S^b - D^{\tilde{b}} S^{\tilde{b}} + (D^b - D^{\tilde{b}}) S^{\tilde{b}} = L_{GM}^{\tilde{b}} - L_{GM}^b - \delta b^i \partial_i S^{\tilde{b}} = L_{GM}^{\tilde{b}} - L_{GM}^b - \delta b^i (\partial_i S^b + O(\delta b)) \\ &= L_{GM}^{\tilde{b}} - L_{GM}^b - \delta b^i \partial_i S^b + o(\delta b). \end{aligned} \tag{57}$$

Now we have $L_{GM}^{\tilde{b}} - L_{GM}^b = \Sigma_i b^i \delta b^i + (\hbar/2)\partial_i \delta b^i + o(\delta b)$ and

$$-E^b \int_T^0 D^b(S^{\tilde{b}} - S^b)\, ds = E^b S^{\tilde{b}}(T,X_T) - E^b S^b(T,X_T) = E^{\tilde{b}} S^{\tilde{b}}(T,X_T) - E^b S^b(T,X_T) = -I^{\tilde{b}} + I^b \tag{58}$$

because $S^{\tilde{v}}$ and S^v disappear identically at time 0 and because X_T has an identical picture distribution density ϱ_T referring to the measures belonging to $\tilde{b}$ and b. Therefore we have by (56)–(58)

$$I^{\tilde{b}} - I^b = E^b \int_T^0 \sum_i \left(b^i - \partial_i S^b + \frac{\hbar}{2}\partial_i \right) \delta b^i\, ds + o(\delta b)\ \forall\ \delta b. \tag{59}$$

But with $P[X_s \in dx] = \varrho dx$ and $R = (\hbar/2)\ln \varrho$, respectively $\nabla R = u$, we obtain by shifting in (59) (δb has compact support)

$$E^b \frac{\hbar}{2}\partial_i \delta b^i(s,X_s) = \int \frac{\hbar}{2}\partial_i \delta b^i \varrho\, dx = \int \sum_i u^i \delta b^i \varrho\, dx. \tag{60}$$

Because of $b^i - u^i = v^i$ we finally have by (59) and (60)

$$I^{\tilde{b}} - I^b = E^b \int_T^0 \sum_i (v^i - \partial_i S^b) \delta b^i\, ds + o(\delta b)\ \forall\ \delta b. \tag{61}$$

Theorem 26:[10] In the sense of Guerra-Morato stationary solutions b fulfills necessarily the Hamilton-Jacobi condition, i.e., with $S^b = S$ we have

$$v = \nabla S. \tag{62}$$

The current velocity is necessarily a gradient of a scalar function. We have the stochastic Hamilton-Jacobi equation

$$\partial_t S + \frac{1}{2}(\nabla S)^2 - \frac{1}{2}(\nabla R)^2 - \frac{\hbar}{2}\Delta R + V = 0, \tag{63}$$

from which we can conclude by differentiation the stochastic Newton equation and which is inclusively the validity of the continuity equation $\partial_t e^{(2/\hbar)R} + \mathrm{div}(v e^{(2/\hbar)R}) = 0$ equivalent to the Schrödinger equation.

Proof: (See Ref. 10.) The Hamilton-Jacobi condition follows from the preceding explanations. The stochastic Hamilton-Jacobi condition together with $D^b S = L^b$, i.e., $(\partial_t + b^i \partial_i + (\hbar/2)\Delta) S^b = \frac{1}{2}\langle b, b\rangle + (\hbar/2)\partial_i b^i - V(x)$, leads to the stochastic Hamilton-Jacobi equation. An application of ∂_i shows

$$\partial_t v^i + \frac{1}{2}\partial_i\left(\sum_j v^j v^j \right) - \frac{1}{2}\partial_i\left(\sum_j u^j u^j \right) - \frac{1}{2}\partial_i \Delta(\hbar R) + \partial_i V = 0,$$

i.e., the stochastic Newton equation from Sec. III B:

$$\partial_t v^i + \sum_j v^j \partial_i v^j - \sum_j u^j \partial_i u^j - \frac{1}{2}\Delta(\hbar u^i) + \partial_i V = 0.$$

An easy calculation shows that the stochastic Hamilton-Jacobi equation together with the equation

$$\partial_t R + \nabla R \cdot \nabla S + \frac{\hbar}{2}\Delta S = 0$$

and the substitution $\psi := e^{(1/\hbar)(R+iS)}$ is just the Schrödinger equation

$$\hbar i \partial_t \psi = -\frac{\hbar^2}{2}\Delta\psi + V\psi$$

in real and imaginary parts, respectively. The equation

$$\partial_t R + \nabla R \cdot \nabla S + \frac{\hbar}{2}\Delta S = 0$$

is concluded from $\varrho = e^{(2/\hbar)R}$ and $\partial_t \varrho + \mathrm{div}(v\varrho) = 0$ by differentiation of ϱ. Q.E.D.

Remark 27: (a) The formula (56) gives a geometric meaning to the Guerra-Morato functional by the phase function S.

(b) By shifting on the other side in (54), what has to be justified appropriately, it can easily be shown that

$$\int_0^T \int \left(\frac{1}{2}v^2(t,x) - \frac{1}{2}u^2(t,x) - V(x)\right)\varrho \, dx \, dt = \int_0^T \int L_{GM}(x, b(t,x))\varrho \, dx \, dt. \tag{64}$$

Therefore the following problem,

$$\delta\left(\int_0^T \int \left(\frac{1}{2}v^2 - \frac{1}{2}u^2 - V\right)\varrho \, dx \, dt\right) \overset{!}{=} 0,$$

$$u = \frac{\hbar}{2}\nabla \ln \varrho, \quad \partial_t \varrho + \mathrm{div}(v\varrho) = 0,$$

probability density time marginal constraints for ϱ, is considered. The given Hamilton-Jacobi problem is sufficient for the stationarity of the Yasue formalism, whereas both problems differ like day and night by the sign in the functional. This fact will be explained by the formalism of stochastic Legendre transformations in Sec. V.

B. Hamilton formalism

In analogy to the Hamiltonian and Lagrangian formalisms of a (point) geodesic variational problem the Schrödinger equation can be thought of as a necessary and sufficient stationary condition for the Hamiltonian formalism of a stochastic geodesic variational problem. The Schrödinger equation can be deduced directly from a Hamiltonian problem that has, compared to the point problem, an almost similar exterior form.

By a Legendre transformation of the Lagrangian formalism

$$H(x,g) = g \cdot \dot{x} - L(x,\dot{x}), \tag{65}$$

where the derivative component is substituted by a new variable g, the Hamilton formalism with Hamiltonian H (Ref. 28) is obtained:

$$\delta\left(\int_0^1 (\dot{x}(t)\cdot g(t) - H(x(t),g(t)))\,dt\right) \overset{!}{=} 0, \tag{66}$$

time marginal values for $x(0), x(1)$, free time marginal values for g.

Variation leads to the canonical equations[28]

$$\dot{x} = \frac{\partial H}{\partial g}, \quad \dot{g} = -\frac{\partial H}{\partial x} \tag{67}$$

as stationarity criteria.

Consider now for $[0,T]$ the time-dependent, complex-valued, and differentiable functions on $\mathbb{R}^n$, which may furthermore be spatially quadratically integrable. These functions constitute in the spatial closure with the canonical Hermitian metric

$$\langle \varphi, \chi \rangle := \int \varphi \bar{\chi}\, dx, \tag{68}$$

a Hilbert space. Well known in quantum mechanics is Planck's constant $\hbar$, the Hamilton operator

$$H = -\frac{1}{2}\hbar^2 \Delta_{\mathbb{C}} + V, \tag{69}$$

with a real-valued potential $V \in C^1$, and the momentum operator

$$-i\hbar\nabla_{\mathbb{C}}. \tag{70}$$

$\nabla_{\mathbb{C}}$ acts as gradient and $\Delta_{\mathbb{C}}$ as Laplace operator on the complex-valued functions of the Euclidean space.

Compared to general dynamical systems of (point) mechanics on symplectic manifolds (M,ω) the quantum mechanical formalism implements the restriction of the motion on a Lagrangian submanifold intrinsically (compare Ref. 34 for that issue). Nevertheless, the quantum mechanical formalism is a model of a phase space.

Remark 28: Well known in quantum mechanics is that for bounded and time-independent observable operators A (Hermitian) and solutions of the Schrödinger equation ψ we have

$$\frac{d}{dt}\langle \psi, A\psi \rangle = \frac{i}{\hbar}\langle \psi, [A,H]\psi \rangle. \tag{71}$$

Especially the quantum mechanical energy $\langle \psi, H\psi \rangle$ is a constant of the motion, because the commutator $[H,H]=HH-HH$ is trivially equal to zero.

Lemma 29: Let $\psi = e^{(1/\hbar)(R+iS)}$ be a differentiable solution of the Schrödinger equation $\hbar i \partial_t \psi = H\psi$. Then we have on $\{|\psi|^2 > 0\}$, with $j := -(i\hbar/2)(\bar{\psi}\nabla\psi - \nabla\bar{\psi}\psi)$,

$$\text{(I)} \quad j = |\psi|^2 \nabla S,$$

$$\text{(II)} \quad \operatorname{div}(j) + \partial_t |\psi|^2 = 0,$$

$$\text{(III)} \quad \partial_t |\psi|^2 + \operatorname{div}(\nabla\phi |\psi|^2) - \frac{1}{2}\hbar\Delta|\psi|^2 = 0,$$

where $\phi = (S+R)$. Note especially that the continuity equation (20) holds true according to (II) and the Fokker-Planck equation (6) according to (III).

Proof: Elementary calculation! The third identity follows, e.g., from the first and the second with

$$\partial_t|\psi|^2 = -\operatorname{div} j = -\operatorname{div}(|\psi|^2 \nabla S)$$
$$= -\operatorname{div}(|\psi|^2 \nabla \phi - |\psi|^2 \nabla R) \overset{|\psi|^2\nabla R = 1/2\hbar\nabla|\psi|^2}{=} -\operatorname{div}\left(\nabla\phi|\psi|^2 - \frac{1}{2}\hbar\,\nabla\,|\psi|^2\right).$$

Q.E.D.

Theorem 30: (Entropy action law.) Let $\psi = e^{(1/\hbar)(R+iS)}: [0,T]\times\mathbb{R}^n \to \mathbb{C} \in L^\infty$ be a differentiable solution of the Schrödinger equation, with $R: [0,T]\times\mathbb{R}^n \to \mathbb{R}\cup\{-\infty\}$. The condition in Proposition 21 for $b = \nabla(R+S)$, $\varrho = |\psi|^2$ and $u = \nabla R$ may hold true. Then we have the entropy action law

$$T\langle\psi, H\psi\rangle = \frac{1}{2}\int_0^T \int b^2|\psi|^2 dx\,dt + \int_0^T \int V|\psi|^2 dx\,dt - \frac{\hbar}{2}\Delta\mathrm{Entrop}(|\psi_T|^2, |\psi_0|^2), \tag{72}$$

where $v = \nabla S$.

Remark 31: If we interpret $b = u + v$ as kinematical active drift, then the common energy conservation has an additional dissipative term, given by the negative Gibbs-Boltzman entropy difference of final and initial absolute square of ψ. Notice that the pair (b, ϱ) is Lagrangian, whereas $\psi = e^{(1/\hbar)(R+iS)}$ is Hamiltonian. The entropy action law is the Lagrangian energy conservation expression.

Proof: $\langle\psi, H\psi\rangle$ is constant $\forall t$ according to the preceding Remark 28. We have

$$\int_0^T \langle\psi, H\psi\rangle\,dt = -\frac{1}{2}\hbar^2\int_0^T \langle\psi, \Delta_{\mathbb{C}}\psi\rangle\,dt + \int_0^T\int V|\psi|^2\,dx\,dt = \frac{1}{2}\hbar^2\int_0^T\int (\nabla_{\mathbb{C}}\psi\cdot\nabla_{\mathbb{C}}\psi)\,dx\,dt$$
$$+ \int_0^T\int V|\psi|^2\,dx\,dt = \frac{1}{2}\hbar^2\int_0^T\int \left(\frac{1}{\hbar}\nabla_{\mathbb{C}}(R+iS)\cdot\frac{1}{\hbar}\nabla_{\mathbb{C}}(R+iS)\right)|\psi|^2\,dx\,dt$$
$$+ \int_0^T\int V|\psi|^2\,dx\,dt = \frac{1}{2}\hbar^2\left(\int_0^T\int \left(\frac{1}{\hbar}\nabla(R+S)\cdot\frac{1}{\hbar}\nabla(R+S)\right)|\psi|^2\,dx\,dt\right.$$
$$\left. - 2\frac{1}{2}\int_0^T\int (\nabla R\cdot\nabla S)|\psi|^2\,dx\,dt\right) + \int_0^T\int V|\psi|^2\,dx\,dt.$$

With Lemma 29 and the calculations in Proposition 21 the assertion follows. Q.E.D.

Definition 32: Let two variational functionals F_1, F_2 on linear concurrence spaces K_1, K_2 be given. Constraints for F_1, F_2 may hold. Let the problems be homogenous, with variational spaces $U_{1/2} \subset K_{1/2}$, such that for elements $f \in K_{1/2}$ fulfilling the constraints $f+u \in K_{1/2}\,\forall\, u \in U_{1/2}$. The functionals are called *stationary equivalent* referring to the respective variational spaces exactly if the stationary solutions are in $K_1 \cap K_2$ and the stationarity conditions

$$F_{1/2}(f) < \infty, \quad \frac{d}{d\varepsilon}F_{1/2}(f+\varepsilon u) \overset{!}{=} 0, \tag{73}$$

for $f \in K_{1/2}$ stationary and $\forall u \in U_{1/2}$ are equivalent.

Theorem 33: Let $\varrho_{0/T}$, $\varrho_{0/T} > 0$, $\int \varrho_{0/T}\,dx = 1$, $\varrho_{0/T}$ differentiable and with compact support be given. Consider the concurrence space $K_1 := \{\varphi: [0,T]\times\mathbb{R}^n \to \mathbb{C} \backslash \varphi$ is differentiable, spatially quadratically integrable, and has compact support$\}$ of the variational problem

$$\delta F_1 \overset{!}{=} 0, \quad \text{with } U_1 = \{\delta\psi\,|\,\delta\psi \in C_0^\infty([0,T]\times\mathbb{R}^n \to \mathbb{C})\},$$

$$\text{where } F_1(\varphi) := \int_0^T \langle\varphi, i\hbar(\nabla_{\mathbb{C}}\cdot\dot{x} - \nabla_{\mathbb{C}}\cdot\dot{x}^T)\varphi - H\varphi\rangle\,dt, \quad \varphi \in K_1,$$

$$\text{with the constraints } |\varphi(0,.)|^2 = \varrho_0, \quad |\varphi(T,.)|^2 = \varrho_T, \tag{74}$$

where the operator $\nabla_C \cdot \dot{x} - \nabla_C \cdot \dot{x}^T$ is defined by

$$\int_0^T \int \overline{f(\nabla_C \cdot \dot{x} - \nabla_C \cdot \dot{x}^T)\varphi}\, dx\, dt := \int_0^T \int \left(\frac{1}{n}\sum_{j=1}^n (\partial_j \overline{f(-x_j \partial_t \varphi)}) + \frac{1}{n}\sum_{j=1}^n (\partial_t \overline{f(x_j \partial_j \varphi)}) \right) dx\, dt \; \forall\, f \in C_0^\infty.$$

Then the Schrödinger equation gives the Eulerian variational expression of the problem.

Remark 34: Notice the formal equivalence of the form of the variational functional (74) and of the functional given in point mechanics (66).

Proof: The problem is homogeneous referring to the variational space U_1. Let $\psi \in K_1$ be a differentiable stationary solution, i.e., the functional may be finite in ψ and the stationarity criteria

$$0 \overset{!}{=} \frac{d}{d\varepsilon}\bigg|_{\varepsilon=0} \int_0^T \langle \psi', i\hbar(\nabla_C \cdot \dot{x} - \nabla_C \cdot \dot{x}^T)\psi' - H\psi' \rangle\, dt, \quad \psi' = \psi + \varepsilon\, \delta\psi \; \forall\; \delta\psi \in U_1$$

may hold true. Executing the differentiation $(d/d\varepsilon)|_{\varepsilon=0}$ and shifting $\delta\psi$ (compact support!) free leads together with

$$\left\langle \psi, \frac{1}{n}\sum_{j=1}^n \partial_j(x_j \partial_t \delta\psi) \right\rangle = \langle -\partial_t \psi, \delta\psi \rangle + \left\langle \frac{1}{n}\sum_{j=1}^n \partial_j(x_j \partial_t \psi), \delta\psi \right\rangle$$

to

$$\begin{aligned} 0 &= \int_0^T \langle \psi, i\hbar(\nabla_C \cdot \dot{x} - \nabla_C \cdot \dot{x}^T)\delta\psi - H\delta\psi \rangle\, dt + \int_0^T \langle \delta\psi, i\hbar(\nabla_C \cdot \dot{x} - \nabla_C \cdot \dot{x}^T)\psi - H\psi \rangle\, dt \\ &= \int_0^T \Bigg(-i\hbar(\langle -\partial_t \psi, \delta\psi \rangle + \langle \nabla_C \cdot \dot{x}\psi, \delta\psi \rangle - \langle \nabla_C \cdot \dot{x}\psi, \delta\psi \rangle + \langle \delta\psi, \nabla_C \cdot \dot{x}\psi \rangle - \langle \delta\psi, -\partial_t \psi \rangle \\ &\quad - \langle \delta\psi, \nabla_C \cdot \dot{x}\psi \rangle) + \left(-\left\langle -\frac{1}{2}\hbar^2 \Delta_C \psi + V\psi, \delta\psi \right\rangle - \left\langle \delta\psi, -\frac{1}{2}\hbar^2 \Delta_C \psi + V\psi \right\rangle \right) \Bigg) dt \quad \forall\; \delta\psi, \end{aligned}$$

where time marginal expressions disappear because of $|\delta\psi(0,.)| = |\delta\psi(T,.)| = 0$. Therefore

$$0 = \int_0^T \left\langle i\hbar\partial_t \psi - \left(-\frac{1}{2}\hbar^2 \Delta_C \psi + V\psi \right), \delta\psi \right\rangle dt + \int_0^T \left\langle \delta\psi, i\hbar\partial_t \psi - \left(-\frac{1}{2}\hbar^2 \Delta_C \psi + V\psi \right) \right\rangle dt \quad \forall\; \delta\psi,$$

i.e., the Schrödinger equation $i\hbar\partial_t \psi - \left(-\frac{1}{2}\hbar^2 \Delta_C \psi + V\psi\right) = 0$ as necessary and sufficient stationarity criteria. Q.E.D.

Proposition 35: Let K_1 be given as in Theorem 33. Consider the concurrence space $K_2 = \{(R,S) \backslash R, S : [0,T] \times \mathbb{R}^n \to \mathbb{R}, e^{(1/\hbar)(R+iS)} \in K_1\}$. Then the following variational problems are, under the "up-to-constants-injection" $K_2 \hookrightarrow K_1$ (see remark), stationary equivalent:

(I) The problem (74) (with classical exterior form).

(II) The problem

$$\delta F_2(R,S) \overset{!}{=} 0,$$

$$F_2(R,S) := \int_0^T \int \left(\partial_t S + \frac{1}{2}(\nabla S)^2 + \frac{1}{2}(\nabla R)^2 + V \right) \varrho\, dx\, dt,$$

$$R, S \in V_2, \quad \varrho := e^{(2/\hbar)R},$$

$$\text{with the constraints } \varrho(0,\,.\,)=\varrho_0,\quad \varrho(T,\,.\,)=\varrho_T.$$

(III) And finally the problem [see Remark 27(b)]

$$\delta F_3(R,S)\overset{!}{=}0,$$

$$F_3(R,S) := \int_0^T \int \left(\frac{1}{2}(\nabla S)^2-\frac{1}{2}(\nabla R)^2-V\right)\varrho\, dx\, dt,$$

$$R,S\in V_2,\quad \varrho := e^{(2/\hbar)R},$$

$$\text{with the constraints } \partial_t\varrho+\operatorname{div}(\nabla S\varrho)=0$$

$$\text{and } \varrho(0,\,.\,)=\varrho_0,\quad \varrho(T,\,.\,)=\varrho_T.$$

Remark 36: The transition of an element of K_1 to an element of K_2, i.e., the construction of a representation $\psi=e^{A+iB}$, is done by covering theory. B is a lift for the covering $\exp(i\,.\,):\mathbb{R}\to S^1$, which can be aligned arbitrarily by a constant $\lambda\in S^1$.

A constant $\lambda\in S^1$ is not relevant for the motion. The fundamental group of $\mathbb{R}^n$ is trivial. The lift of the mapping $\psi/|\psi|:\mathbb{R}^n\to S^1$ exists if only $\psi\neq 0$. We can continue the lift up to the boundary of $\mathbb{R}^n\backslash\psi^{-1}(0)$ in connected components, what can be done because of the differentiability in such a way that B is bounded on compact sets. (See Ref. 35 for covering theory.)

Proof: It follows by shifting (compact support)

$$-i\hbar\int_0^T\langle(\nabla_{\mathbb{C}}\cdot\dot{x})\psi,\psi\rangle\,dt=-i\hbar\int_0^T\langle\psi,(\nabla_{\mathbb{C}}\cdot\dot{x})\psi\rangle\,dt-\int_0^T\langle i\hbar\partial_t\psi,\psi\rangle\,dt+\text{marginal term}.$$

So we obtain the problem

$$\delta\left(\int_0^T(\langle i\hbar\partial_t\psi,\psi\rangle-\langle\psi,H\psi\rangle)\,dt\right)\overset{!}{=}0,$$

$$|\psi(0,\,.\,)|^2=\varrho_0,\quad |\psi(T,\,.\,)|^2=\varrho_T$$

because marginal terms are irrelevant for the stationary character of the variational problem. (The inspection of the so-obtained problem leads immediately to the Schrödinger equation as stationarity criteria.) Furthermore, we have with $\psi=e^{(1/\hbar)(R+iS)}$

$$\int_0^T\langle i\hbar\partial_t\psi,\psi\rangle\,dt=+i\hbar\int_0^T\int\frac{1}{\hbar}(\partial_tR+i\partial_tS)|\psi|^2\,dx\,dt\overset{|\psi|^2\partial_tR=1/2\hbar\partial_t|\psi|^2}{=}-\int_0^T\int\partial_tS|\psi|^2\,dx\,dt$$
$$+i\hbar^2\frac{1}{2}\int_0^T\partial_t\int|\psi|^2\,dx\,dt=-\int_0^T\int\partial_tS|\psi|^2\,dx\,dt,$$

whereby we have shown the stationary equivalence of (I) and (II) by ordinary reformulation, if in addition we use that we have, analogously to the proof in Theorem 30,

$$-\frac{1}{2}\hbar^2\int_0^T \langle \psi, \Delta\psi\rangle\, dt = \frac{1}{2}\hbar^2\int_0^T \int (\nabla_{\mathbb{C}}\psi\cdot\nabla_{\mathbb{C}}\psi)\, dx\, dt$$
$$= \frac{1}{2}\hbar^2\int_0^T \int \left(\frac{1}{\hbar}\nabla_{\mathbb{C}}(R+iS)\cdot\frac{1}{\hbar}\nabla_{\mathbb{C}}(R+iS)\right)p\, dx\, dt$$
$$= \frac{1}{2}\int_0^T \int ((\nabla R)^2 + (\nabla S)^2)|\psi|^2\, dx\, dt.$$

If for $\psi = e^{(1/\hbar)(R+iS)}$ the Fokker-Planck equation on $\{|\psi|^2 > 0\}$,

$$\partial_t|\psi|^2 + \mathrm{div}\big(|\psi|^2\,\nabla\,(R+S)\big) - \frac{1}{2}\hbar\Delta|\psi|^2 = 0,$$

holds true, then we have the continuity equation on $\{|\psi|^2 > 0\}$:

$$\partial_t|\psi|^2 + \mathrm{div}(|\psi|^2\,\nabla\,S) = 0.$$

If we add the continuity equation as additional constraint to problem (II), the stationary character will not change. (We can immediately calculate the validity of the continuity equation by variation of S in F_2. See also Proposition 44.) We will obtain a stationary equivalent problem. We have

$$-\int_0^T \int \partial_t S|\psi|^2\, dx\, dt \overset{\text{Shifting}}{=} \text{marginal term} + \int_0^T \int S\partial_t|\psi|^2\, dx\, dt \underset{\text{equation}}{\overset{\text{Continuity}-}{=}} \text{marginal term}$$
$$-\int_0^T \int S\,\mathrm{div}(|\psi|^2\,\nabla\,S)\, dx\, dt = \text{marginal term} + \int_0^T \int (\nabla S)^2|\psi|^2\, dx\, dt$$

such that we can conclude the stationary equivalence of the problems (II) and (III). Q.E.D.

Remark 37: Solutions of the Schrödinger equation ψ are naturally normalized. The unitary operator e^{-tiH}, defined by spectral integration theory, determines for ψ_0 the solution by $\psi_t = e^{-tiH}\psi_0$. The time marginal densities $\varrho_{0/T}$ have necessarily the same norm. In other cases the problem would be ill-posed.

V. TRANSFORMATIONS

A. Stochastic Legendre transformations

The point dynamical Legendre transformation is a pointwise transformation between the Hamiltonian and Lagrangian functions. The dependency of the Lagrangian of the derivative variable is transformed to a dependency of a new variable in the Hamiltonian. In the stochastic case this transformation is obtained by augmenting the tangential structure given by the Fokker-Planck equation into the functional.

The Legendre transformation between Hamiltonian and Lagrangian is given in point dynamics by

$$L(x,\dot{x}) = g\cdot\dot{x} - H(x,g), \tag{75}$$

where g is a new variable.

The stochastic formalism is given, where the case of an elementary Lagrangian $L(x,q) = \frac{1}{2}\langle q,q\rangle - V(x)$ is considered, by variation of the Yasue h-problem (37)

$$\delta F(R,S) = \delta\left(\int_0^T \int \left(\frac{1}{2}(\nabla R(t,x))^2 + \frac{1}{2}(\nabla S(t,x))^2 - V(x)\right)\varrho\, dx\, dt\right) \overset{!}{=} 0,$$

$$v = \nabla S, \quad \varrho = e^{(2/h)R}, \quad \partial_t \varrho + \mathrm{div}(v\varrho) = 0,$$

and time marginal constraints.

Notice that the variation is done referring to general diffusions, but we seek a solution with diffusion matrix $h \cdot id$. Now the goal is to augment the constraints into the functional.

Definition 38: Let $F(R,S) = \int_0^T \int \mathcal{F}(R,S)\, dx\, dt$ be a scalar functional of the real-valued functions S and R, defined on a space-time. We seek stationary solutions, with variation referring to C_0^∞, under the constraint given by a scalar differential equation $G(R,S,\nabla S,\nabla R,(\partial_{ij}S)_{ij},(\partial_{ij}R)_{ij}) = 0$. Then a scalar functional given by $K(R,S) = \int_0^T \int \mathcal{K}(R,S)\, dx\, dt$ is called *functional augmentation* of F and G exactly if for instance $\delta K/\delta S = 0$ is equivalent to the constraint and $\delta K/\delta R = 0$ is sufficient for the stationarity of F under the constraint, where, for instance, $\delta K/\delta R$ is the functional notation for the Eulerian variational expression referring to a variation of R, i.e.,

$$\left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} \int_0^T \int \mathcal{K}(R + \varepsilon\,\delta R, S)\, dx\, dt = \int_0^T \int \frac{\delta K}{\delta R}(R,S)\,\delta R\, dx\, dt \quad \forall\ \delta R \in C_0^\infty. \tag{76}$$

Theorem 39: (*Stochastic Legendre transformation* and existence of a functional augmentation for stochastic mass transportation.) A functional augmentation for the Yasue h-problem is given by the variational problem Proposition 35 (II):

$$\delta\left(\int_0^T \int \left(\partial_t S(t,x) + \frac{1}{2}(\nabla R(t,x))^2 + \frac{1}{2}(\nabla S(t,x))^2 + V(x) \right) \varrho\, dx\, dt \right) \overset{!}{=} 0,$$

$$\varrho = e^{(2/h)R}, \quad \text{time marginal constraints!}$$

Proof: One finds immediately that variation $\delta/\delta S$ leads to the continuity equation. The rest follows by the argumentations in Secs. IV A and IV B, because the variation $\delta/\delta R$ leads to the stochastic Hamilton-Jacob equation (63) as stationarity criteria, as can be calculated easily by

$$\begin{aligned}
&\left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} \int_0^T \int \left[\partial_t S + \frac{1}{2}(\nabla(R + \varepsilon\,\delta R))^2 + \frac{1}{2}(\nabla S)^2 + V \right] e^{(2/h)(R+\varepsilon\,\delta R)}\, dx\, dt \\
&= \int_0^T \int \left[(2\partial_t S + (\nabla S)^2 + (\nabla R)^2 + 2V)\frac{1}{h}\varrho - \mathrm{div}(\nabla R\,\varrho) \right] \delta R\, dx\, dt \\
&= \int_0^T \int \left[\left(\frac{2}{h}\partial_t S + \frac{1}{h}(\nabla S)^2 - \frac{1}{h}(\nabla R)^2 - \Delta R + \frac{2}{h}V \right) \right] \varrho\,\delta R\, dx\, dt, \quad \forall\ \delta R,
\end{aligned}$$

i.e., the stochastic Hamilton-Jacobi equation

$$\partial_t S + \frac{1}{2}(\nabla S)^2 - \frac{1}{2}(\nabla R)^2 - \frac{h}{2}\Delta R = -V$$

holds. Q.E.D.

Remark 40: (a) The problem of finding a functional augmentation has, at least directly, nothing to do with the method of Lagrangian multipliers, which is used to solve variational problems under constraints. In this method the variational expression $F + \lambda G$ is considered to be equal to zero. The additional parameter λ and the integration constants are obtained by the constraints and the marginal conditions.

(b) Note that the potential in the Hamiltonian has a positive sign. The transition to the Lagrange problem produces a negative sign. Hereby we can detect, as in the classical case, the transition from the Hamiltonian (kinetic energy + potential energy) to the Lagrangian (kinetic energy − potential energy) formalism.

B. Stochastic symplectic transformations

Symplectic geometry is, for the main example, the research on a cotangential space T^*M of a manifold M with a given nondegenerated two-form ω on T^*M. The topological basis of the here-introduced stochastic symplectic geometry is now the research on the stochastic analysis of pairs of scalar functions on a space-time that are suitably put together to a complex-valued function and such that in addition a Hermitian scalar product is given. This structure is determined by the momentum operator and its Fourier transformation, the operator of multiplication with the identity, i.e., we do research on the stochastic analysis of a Hermitian line bundle on a space-time.

In the case of symplectic topology with the Hamiltonian $H(x,g)$ we have the canonical equations (67)

$$\dot{x} = \frac{\partial H}{\partial g}, \quad \dot{g} = -\frac{\partial H}{\partial x}$$

as in Sec. IV B which can be deduced from $\omega(X_H, .) = dH(.)$, with the Hamiltonian vector field X_H. A symplectomorphism $\Theta: T^*M \to T^*M$ preserves the two-form $\Theta^*\omega = \omega$ and the canonical equations (with the transformed Hamiltonian).

In the framework of stochastic symplectic geometry analogous canonical equations are given by (variation of ϱ instead of R exactly as in Theorem 39)

$$\partial_t \varrho = \frac{\delta H}{\delta S}, \quad \partial_t S = -\frac{\delta H}{\delta \varrho},$$

where the here elementary Hamiltonian functional is defined by

$$H(\varrho, S) = \int_0^T \int \left(\frac{1}{2}(\nabla R(t,x))^2 + \frac{1}{2}(\nabla S(t,x))^2 + V(x) \right) \varrho \, dx \, dt, \quad \varrho = e^{(2/h)R}.$$

The stochastic canonical equations are constituted by the stochastic Hamilton-Jacobi equation (63) and the continuity equation (20).

Definition 41: A *stochastic symplectomorphism*

$$\Theta: (\varrho(t,x), S(t,x)) \to (\varrho'(t',x'), S'(,t',x')) \tag{77}$$

is in analogy a transformation that preserves the form of the stochastic canonical equations (see also Ref. 28, definition of canonical transformations).

Example 42: It is well known that the Fourier transformation $F(\psi(t,x)) = \psi^F(t,p)$ preserves the validity of the Schrödinger equation $i\hbar\partial_t\psi = \frac{1}{2}p^2\psi - V\psi$ also for the momentum representation of the ψ function $\psi^F(t,p)$.

VI. ZOOMOUT GEOMETRIES

A. An elementary zoomout formalism

Consider an observer who measures the Planck constant $\hbar$ to a special value (and therefore has a normalized space-time scale). The geodesic problem defined by stochastic mass transportation, for the marginal densities $\varrho_{0/T}$ and to the data T and $\hbar$, is a viewpoint of an $\hbar$-associated dynamical process. By decreasing $\hbar$ and "compactifying" the time marginal densities a "zoomout" is defined. With this zoomout technique the "absolute" geodesic problem on the Euclidean space can be recovered by the limit $\hbar \to 0$. The Euclidean problem is, so to speak, "superficial" to the stochastic one. Therefore a possibility to establish the continuity of the quantum world is given.

Proposition 43: (Case of constant time marginal densities.) If we solve for

$$u = \nabla R \text{ and } v = \nabla S, \tag{78}$$

the Yasue $\hbar$-problem with a trivial potential, then for

$$\hbar\widetilde{R} = R \text{ and } \hbar\widetilde{S} = S \text{ with } \psi = e^{\widetilde{R}+i\widetilde{S}} = e^{(1/\hbar)(R+iS)} \tag{79}$$

the Schrödinger equation is valid, where we obviously can add a potential. So if we are interested in the Schrödinger equation, we have to consider the problem (for a trivial potential)

$$\int_0^T \int (\hbar^2(\nabla\widetilde{S})^2 + \hbar^2(\nabla\widetilde{R})^2)\varrho\, dx\, dt \overset{!}{=} \text{Min},$$

$$\varrho = e^{2\widetilde{R}}, \quad \partial_t\varrho + \operatorname{div}(\hbar\,\nabla\,\widetilde{S}\varrho) = 0,$$

$$\text{probability time marginal densities for } \varrho. \tag{80}$$

The problem (80) obviously tends formally with $\hbar \to 0$, where the time marginal densities are fixed, to the time-continuous deterministic mass transportation problem (32)

$$\int_0^T \int (\nabla S(t,x))^2\varrho\, dx\, dt \overset{!}{=} \text{Min},$$

$$\partial_t\varrho + \operatorname{div}(\nabla S\varrho) = 0,$$

$$\text{probability time marginal densities for } \varrho,$$

because we can substitute $\hbar v \hat{=} v$ in the space of possible solutions. Especially the minima will not change under such a substitution and will tend to each other for $\hbar \to 0^+$ as can be seen as follows. Let (S,ϱ) and $(S^\hbar,\varrho^\hbar)$ without restriction be differentiable minimizers of the deterministic, respectively the stochastic mass transportation problem. Then we have with $\varrho = e^{2\widetilde{R}}$, respectively $\varrho^\hbar = e^{2\widetilde{R}^\hbar}$,

$$\int_0^T \int (\nabla S)^2\varrho\, dx\, dt \leqslant \int_0^T \int (\nabla S^\hbar)^2\varrho^\hbar\, dx\, dt + \int_0^T \int \hbar^2(\nabla\widetilde{R}^\hbar)^2\varrho^\hbar\, dx\, dt \leqslant \int_0^T \int (\nabla S)^2\varrho\, dx\, dt + \int_0^T \int \hbar^2(\nabla\widetilde{R})^2\varrho\, dx\, dt.$$

The square root of the quantum mechanical action tends to the Wasserstein distance given in Sec. III A.

Proposition 44: (Case of compactified time marginal densities.) Let $0 < \hbar \leqslant 1$ be given. An observer associated to this $\hbar$ solves the problem

$$\int_0^T \int (\hbar^2(v(t,X_t)^2) + \hbar^2(\nabla R(t,X_t))^2)\, dP\, dt \overset{!}{=} \text{Min},$$

$$dX_t = b(t,X_t)dt + \sqrt{\hbar}dB_t,$$

$$(B_t,P) \text{ Brownian motion},$$

$$\text{probability time marginal densities } \varrho_{0/T} \text{ for } \varrho$$

$$(\text{i.e., } \varrho\, dx = P[X_t \in dx] = e^{(2/\hbar)R}dx, \quad \partial_t\varrho + \operatorname{div}(\hbar v\varrho) = 0). \tag{81}$$

If $\hbar$ is very small now, then also the time marginal densities for ϱ are compactified. For $\hbar \to 0$ this will lead to a compactification of the time marginal densities $\varrho_{0/T}^{\hbar}$ of the problem for $\hbar$ at their expectation values, which may exist, i.e., there will be a compactification to the Dirac measures of the expectations. This is modeled by

$$\varrho_{0/T}^{\hbar}(x) := \varrho_{0/T}\left(\frac{1}{h(\hbar)}(x - EX_t) + EX_t\right)\left(\frac{1}{h(\hbar)}\right)^n,$$

with $h(\hbar) \to 0$ for $\hbar \to 0$, which can be chosen appropriately. The by $(1/h(\hbar))^n$ normalized transformed time marginal densities are again probability densities in $\mathbb{R}^n$. For a "zoomed out" $\hbar$ we so obtain the problem

$$\int_0^T \int (\hbar^2(v(t,x)^2) + \hbar^2(\nabla R(t,x))^2)\varrho \, dx \, dt \overset{!}{=} \text{Min},$$

$$\varrho = e^{(2/\hbar)R}, \quad \partial_t \varrho + \operatorname{div}(\hbar v \varrho) = 0,$$

$$\varrho(0,x) = \varrho_0^{\hbar}(x), \quad \varrho(T,x) = \varrho_T^{\hbar}(x). \tag{82}$$

The new time marginal densities define a *zoomout*. The problem (82) tends formally for $\hbar \to 0$ to the deterministic mass transportation with delta distribution time marginal densities, because we can substitute $\hbar v \widehat{=} v$, i.e.,

$$\int_0^T \int (v(t,x)^2)\varrho \, dx \, dt \overset{!}{=} \text{Min},$$

$$\partial_t \varrho + \operatorname{div}(v\varrho) = 0, \quad \varrho(0,x) = \delta_{E_0}(x), \quad \varrho(T,x) = \delta_{E_1}(x),$$

$$E_0 = \int x\varrho_0(x) \, dx, \quad E_1 = \int x\varrho_1(x) \, dx.$$

But this problem is solved by the Euclidean geodesic between the expectation values of ϱ_0 and ϱ_T. A macroscopical observer with a very small $\hbar$, who observes a microscopical motion, will therefore visualize a Euclidean geodesic.

Remark 45: The connection of both cases can be seen by considering a large number of bosonic particles and executing a zoomout according to Proposition 44, whereby a cloud of bosonic particles appears.

B. Interpretation

The following "explanations" cannot be understood as well. But it should be emphasized clearly that to find a model for the quantum mechanical measurement problem is serious, besides the fact that a contradiction to human reason may be the case.

Interpretation 46: The Yasue problem (with elementary Lagrangian)

$$\delta\left(\int E\left(\frac{1}{4}b^2(t,X_t) + \frac{1}{4}b_*^2(t,X_t) - V(X_t)\right) dt\right) \overset{!}{=} 0$$

under certain variational formalisms is known in stochastic mechanics. See e.g., Ref. 30 where in V.5 the variant

$$\delta\left(\int E\left(\frac{1}{2}b(t,X_t)b_*(t,X_t) - V(X_t)\right) dt\right) \overset{!}{=} 0$$

is discussed. Because $b=u+v$ and $b_*=v-u$ this problem is just the Guerra-Marato problem because of Remark 27b). In Ref. 30 it is explained that the Guerra-Morato variation leads to the stochastic Hamilton-Jacobi equation, as demonstrated in sec. IV A. The equation is called the Madelung fluid equation there. New in this paper is that it was discovered that the Guerra-Morato problem, analogously to the deterministic case, is obtained by applying a stochastic Legendre transformation to the Yasue problem. The variation of the so-obtained Hamiltonian problem leads to the Schrödinger equation, which can be understood as suitable complex-valued unition of continuity and stochastic Hamilton-Jacobi equation. The transformation

$$\psi = e^{(1/\hbar)(R+iS)} \rightleftarrows (\varrho, b),$$

Fokker - Plank equation:

$$\partial_t \varrho + \operatorname{div}(b\varrho) - \frac{\hbar}{2}\Delta\varrho = 0$$

shall be called the *Madelung transformation*.

Compared to the Yasue problem, where the backward derivative term has to be interpreted, the Lagrangian quasi-Euclidean Yasue problem

$$\delta\left(\int E\left(\frac{1}{2}b^2(t,X_t) - V(X_t)\right)dt - \Delta\text{Entrop}\right) \overset{!}{=} 0$$

is clearly recognizable as a geometric problem. It has the advantage that it has the "pure" form of a geodesic functional

$$\delta\left(\int \langle \dot{x}_t, \dot{x}_t\rangle \, dt\right) \overset{!}{=} 0.$$

The time derivative in $\dot{x}$ has to be interpreted as validity of an Itô diffusion equation.

By the geodesic problem Schrödinger's basic law of nature can be found by a reasonable formalism.

The transition to the Yasue problem can be understood as time-symmetric variant.

The entropy time marginal term is stationary irrelevant, but it belongs to the "(B_t, P)" in the Itô equation

$$dX_t = b(t,X_t)\, dt + dB_t,$$

because the heat flow equation is the gradient flow for the entropy functional. Furthermore, it enters in the entropy action law, such that energy is preserved. Note that $(X_t, \bar{P})$ induces a natural time orientation by the direction of the entropic expansion.

The here demonstrated zoomout formalism shows how the classical geodesic formalism is "superficial" to the stochastic formalism. Compared to semiclassical analysis,[36–38] where the limit $\hbar \to 0$ is considered, in the transition of stochastic to deterministic mass transportation, the geodesic variational problems transfer. In comparison to semiclassical analysis, where, e.g., the behavior of the spectrum of the Schrödinger operator is analyzed for $\hbar \to 0$, the stochastic geodesic problem shows the direct geometric connection to the classical case, therefore hits the problem much more directly, and casts a new bright light on the quantum mechanical correspondence principle. Especially the theory does not try to model the particle phenomena by single trajectories of the underlying path space; the particle phenomena is obtained by a zoomout projection.

The background field hypothesis in Ref. 10 is replaced allusively by a, compared to set theoretic topology, more difficult treatment of a theory of a topological view. As suggested in Remark 19 an absolute entropic expansion is given at the outset and every observed drift, respectively diffusion movement, is a subjective interpretation of a single one-particle phase. The solu-

tion of the stochastic geodesic problem leads to an observer as defined in Remark 19. Especially we do not have an observer-independent motion within this concept, as, e.g., in set theoretic topology. There is no information of reality without observation. There is an equivalence principle, which states that information and reality are one and the same. We have to note that this concept is just mathematically obvious, especially concerning the fact that the quantum mechanical measurement problematic consists of experimentally proven contradictions to human reason. This general topological concept may not be seen as mathematically ensured and has to be found in detail.

For a more physical treatment of the analytical side of the Hamiltonian problem, see Ref. 39.

For an interesting nonquantum mechanical physical application of stochastic mechanics to the constitution of the system of planets, the morphology of galaxies and the formation of wind zones and the rings of planets study Ref. 40.

VII. EXAMPLES

Example 1: Wave packets. Let the potential V in the Hamilton operator be equal to zero. Then the planar waves $Ae^{i(\vec{k}\cdot\vec{r}-\omega t)}$ are solutions of the Schrödinger equation, where the wave vector $\vec{k}$, $\omega=\frac{1}{2}\hbar^2k^2$, and A a constant normalization factor are given. By superposition we obtain the wave packets

$$\psi(t,\vec{r}) = \frac{1}{(2\pi)^{n/2}} \int \hat{\psi}_0(\vec{k}) e^{i(\vec{k}\cdot\vec{r}-\omega(\vec{k})t)}\, d\vec{k}; \quad \omega(\vec{k}) = \frac{1}{2}\hbar^2k^2 \tag{83}$$

as solutions, as can be easily shown. $\psi_0(\vec{r})$ is the Fourier transformation of $\hat{\psi}_0(\vec{k})$:

$$\psi_0(\vec{r}) = \frac{1}{(2\pi)^{n/2}} \int \hat{\psi}_0(\vec{k}) e^{i(\vec{k}\cdot\vec{r})}\, d\vec{k}.$$

The Schrödinger equation with trivial potential is the necessary and sufficient stationarity condition for the Hamiltonian version of the stochastic mass transportation problem. Therefore, in analogy, the wave packets are stochastic Euclidean geodesics.

Example 2: Hydrogen atom. (See Ref. 41.) The Hamilton operator of the hydrogen atom (in $\mathbb{R}^3$) is defined by $H=-(\hbar^2/2m)\Delta+Ze^2/|x|$, with system constants e, Z and the reduced mass m. We consider the ground state given by

$$\psi(t,x) = Ne^{(-|x|/a-iEt/\hbar)} = e^{(\hbar/m)(R+iS)}, \tag{84}$$

$a=\hbar^2/me^2Z$ is the Bohr radius and $E=-\hbar^2/2ma^2$ is the ground state energy. The normalization constant N can be shown to be equal to $2a$, but is unimportant to calculate the entropic, respectively the current velocity, because

$$Ne^{(-|x|/a-iEt/\hbar)} = e^{\ln N+(-|x|/a-iEt/\hbar)} = e^{(m/\hbar)(R+iS)}$$

Therefore

$$\frac{m}{\hbar}R = \ln N - \frac{|x|}{a}, \text{ respectively } \frac{m}{\hbar}\, S = \frac{Et}{\hbar},$$

and the gradient of a constant term is equal to zero such that we have the drift

$$b = \nabla\,(R+S) = \frac{-\hbar}{am}\,\nabla\,|x| = -\frac{\hbar x}{am|x|}.$$

The ground state diffusion equation fulfills $[(t,x)\mapsto x/|x| \in L^{\infty} \overset{1.1.10}{\Rightarrow} \exists$ of a weak solution$]$

$$dX_t = -\frac{\hbar}{am}\frac{X_t}{|X_t|}dt + \sqrt{\frac{\hbar}{m}}dB_t.$$

Then in this connection the analog of Newton's law holds for the reduced mass of the electron.

Proposition 47: We have on $\{X_t \neq 0\}$

$$mD_*DX_t = mDD_*X_t = \frac{m}{2}(DD_* + D_*D)X_t = -Ze^2\frac{X_t}{|X_t|^3}. \tag{85}$$

Proof: Because of the diffusion equation we see immediately that $DX_t = -(\hbar/am)(X_t/|X_t|)$ and $D_*X_t = +(\hbar/am)(X_t/|X_t|)$.

As in Sec. II A we have

$$D(f(X_t)) = \nabla f(X_t)\cdot DX_t + \frac{\hbar}{2m}\Delta f(X_t),$$

$$D_*(f(X_t)) = \nabla f(X_t)\cdot D_*X_t - \frac{\hbar}{2m}\Delta f(X_t).$$

Especially for $f(x) = x/|x|$ we have $\nabla f\cdot DX_t = \nabla f\cdot D_*X_t = 0$ and $\Delta f(x) = -2x/|x|^3$, such that as in Corollary 24

$$DD_*X_t = D_*DX_t = -\frac{\hbar^2}{m^2 a}\frac{X_t}{|X_t|^3}.$$

Q.E.D.

Remark 48: The notation of mass and the treatment of mass for the transition from Lagrangian to Hamiltonian formalism in general is an open problem. For simplicity we can set $m=1$.

Example 3: Harmonic oscillator. The one-dimensional, normalized harmonic oscillator is given by the Hamilton operator $H = -\frac{1}{2}(\partial^2/\partial x^2) + \frac{1}{2}x^2$. The function

$$\psi(t,x) = \exp\left(-\frac{1}{2}(x - ae^{-it})^2 - \frac{a^2}{4}(1 - e^{-2it}) - \frac{it}{2}\right) = e^{R+iS}, \quad a \in \mathbb{R},$$

solves the one-dimensional Schrödinger equation $i(\partial\psi/\partial t) = -\frac{1}{2}(\partial^2\psi/\partial x^2) + \frac{1}{2}x^2\psi$. We see

$$R = -\frac{1}{2}(x^2 - 2ax\cos t) + \mathrm{Konst}(t),\ S = -\frac{1}{2}(2ax\sin t) + \mathrm{Konst}(t),$$

respectively

$$b = \frac{\partial}{\partial x}(R+S) = (-x + a\cos(t) - a\sin(t)),$$

$$b_* = \frac{\partial}{\partial x}(S-R) = (+x - a\cos(t) - a\sin(t)).$$

The diffusion equation belonging to b [$|b| \leqslant \mathrm{Konst}(1+|x|) \overset{1.1.10}{\Rightarrow} \exists$ of a weak solution] is given by

$$dX_t = (-X_t + a\cos(t) - a\sin(t))dt + dB_t.$$

We calculate

$$DD_*X_t = Db_* = \left(b\partial_x + \partial_t + \frac{1}{2}\frac{\partial^2}{\partial x^2}\right)b_* = +b + a\sin t - a\cos t = -x$$

and

$$D_*DX_t = D_*b = \left(b_*\partial_x + \partial_t - \frac{1}{2}\frac{\partial^2}{\partial x^2}\right)b = -b_* - a\sin t - a\cos t = -x$$

as in Corollary 24.

Example 4: Heisenberg's uncertainty relation. Heisenberg's uncertainty relation is the historic characteristic feature of time continuous quantum mechanical behavior. Expectation of momentum and spatial localization never can be measured sharply at the same time. The focus of one variable immediately implies that the other smears. It can be shown that this inequality follows more or less elementarily from the formalism developed in this paper, as was suggested in Ref. 9 for the case of dimension $n=1$, but was not executed concretely. Especially the entropy action law can be seen as a Lagrangian version of Heisenberg's uncertainty relation. This can be expressed by the fact that to focus we have to work against the entropy functional.

Lemma 49: (Special case of the Cramér-Rao inequality[42] for a probability variable that is the estimator of the parameter constituted by itself.) Let ϱ be a, in ∞, rapidly enough decreasing, differentiable probability density (of a probability variable X with first and second moments) in $\mathbb{R}^n$. Then we have [if $E(\nabla \ln \varrho(X))^2 < \infty$]

$$\text{variance}(\varrho) \geqslant \text{Fisherlength}^2(\varrho) := (E(\nabla \ln \varrho(X))^2)^{-1}.$$

Therefore the quadratic Fisher length is a measure for the minimal variance of a probability variable.

Proof: (1) We have

$$E\nabla \ln \varrho(X) = \int \nabla \ln \varrho(x)\varrho(x)\,\mathrm{dx} \overset{\text{in the i-th component}}{=} \int \partial_i \ln \varrho(x)\varrho(x)\,dx = \int \cdots \int \partial_i \varrho(x)\,dx_1 \cdots dx_n$$

$$= \int \cdots \int \left(\int \partial_i \varrho(x)\,dx_i\right) dx_1\, d\hat{x}_i\, dx_n = 0.$$

It follows that $E[(\nabla \ln \varrho(X) - E\nabla \ln \varrho(X))\cdot(X-EX)] = E[\nabla \ln \varrho(X)\cdot X]$.

(2) According to the Cauchy-Schwarz inequality we have

$$(E[(\nabla \ln \varrho(X) - E\nabla \ln \varrho(X))\cdot(X-EX)])^2 \leqslant E[(\nabla \ln \varrho(X) - E\nabla \ln \varrho(X))^2]E[(X-EX)^2],$$

i.e., with (1),

$$(E[\nabla \ln \varrho(X)\cdot X])^2 \leqslant \text{ variance } (\varrho)(\text{Fisherlength}^2\ (\varrho))^{-1}.$$

It is left to show (where without restriction ϱ decreases rapidly enough, such that we can shift ∂_i without spatial marginal terms)

$$(E[\nabla \ln \varrho(X)\cdot X])^2 = \left(\int \left(\sum_{i=1}^{n} \partial_i \varrho(x) x_i\right) dx\right)^2 = \left(-\int n\varrho(x)\,dx\right)^2 = n^2 \geqslant 1.$$

Q.E.D.

For concluding the uncertainty relation we define for the momentum operator (70) $p = -i\hbar\nabla$ in $\psi = e^{(1/\hbar)(R+iS)}$ (referring to a normalized solution of the Schrödinger equation)

$$\Delta p^2 \overset{\text{Formal}}{=} \langle (p-\langle p\rangle)^2\rangle \overset{\text{Formal}}{=} \langle p^2\rangle - \langle p\rangle^2 \overset{\text{Definition}}{=} \langle \psi, -\hbar^2\Delta_{\mathbb{C}}\psi\rangle - \langle \psi, (-i\hbar\nabla_{\mathbb{C}})\psi\rangle^2 = \langle \psi, -\hbar^2\Delta_{\mathbb{C}}\psi\rangle - \left(\int |\psi|^2(\nabla S - i\nabla R)\, dx\right)^2$$

(The term $\int |\psi|^2 \nabla R\, dx = 0$ according to the lemma .)

$$= \langle \psi, -\hbar^2\Delta_{\mathbb{C}}\psi\rangle - \left(\int |\psi|^2 \nabla S\, dx\right)^2 \overset{\text{As in } 3.2}{=} \int ((\nabla S)^2 + (\nabla R)^2)|\psi|^2\, dx - \left(\int |\psi|\nabla S\, dx\right)^2$$

$$= \int \left((\nabla S)^2 + \left(\frac{\hbar}{2}\nabla \ln|\psi|^2\right)^2\right)|\psi|^2\, dx - \left(\int |\psi|^2 \nabla S\, dx\right)^2 \geqslant \frac{\hbar^2}{4}\int (\nabla \ln|\psi|^2)^2|\psi|^2\, dx$$

$$= \frac{\hbar^2}{4}(\text{Fisherlength}^2(|\psi|^2))^{-1}$$

where the estimation is done by the Schwarz inequality in $L^2(|\psi|^2)$,

$$\left(\int \nabla S|\psi|^2\, dx\right)^2 \leqslant 1\int (\nabla S)^2|\psi|^2\, dx.$$

With Lemma 49 we can conclude Heisenberg's uncertainty relation

$$\Delta p\Delta x \geqslant \frac{\hbar}{2},$$

where $\Delta x^2 = \text{variance}(|\psi|^2)$, i.e., Δx is the standard deviation.

Remark 50: (a) As can be seen in the proof of the lemma the more sharp estimations

$$\text{variance}(\varrho) \geqslant n^2\ \text{Fisherlength}^2(\varrho), \quad \text{respectively } \Delta p\Delta x \geqslant \frac{n\hbar}{2},$$

hold true.

(b) The fact that the expectation of the entropic velocity disappears identically is a corollary of its own interest.

Danksagung

Ich danke Ludger Rüschendorf für interessante Diskussionen, immer ein offenes Ohr gehabt zu haben und für die zielgerichtete Versorgung mit der Information, die diese Arbeit ermöglicht und inspiriert hat. Für wertvolle Hinweise, Überarbeitungsvorschläge und Literaturverweise danke ich außerdem S. Albeverio, H. Stephan, und H. Spohn. We obtain the band edge eigenstates and the midband states for the complex, generalized associated Lamé potentials $V^{PT}(x)=-a(a+1)m\,\mathrm{sn}^2(y,m)-b(b+1)m\,\mathrm{sn}^2(y+K(m),m)-f(f+1)m\,\mathrm{sn}^2(y+K(m)+iK'(m),m)-g(g+1)m\,\mathrm{sn}^2(y+iK'(m),m)$, where $y\equiv ix+\beta$, and there are four parameters a, b, f, g. By construction, this potential is PT-invariant since it is unchanged by the combined parity (P) and time reversal (T) transformations. This work is a substantial generalization of previous work with the associated Lamé potentials $V(x)=a(a+1)m\,\mathrm{sn}^2(x,m)+b(b+1)m\,\mathrm{sn}^2(x+K(m),m)$ and their corresponding PT-invariant counterparts $V^{PT}(x)=-V(ix+\beta)$, both of which involving just two parameters a,b. We show that for many integer values of a,b,f,g, the PT-invariant potentials $V^{PT}(x)$ are periodic problems with a finite number of band gaps. Further, using supersymmetry, we construct several additional, complex, PT-invariant, periodic potentials with a finite number of band gaps. We also point out the intimate connection between the above generalized associated Lamé potential problem and Heun's differential equation. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2000207]

I. INTRODUCTION

In the past few years, Bender and others[1,2] have looked at several complex potentials with PT-symmetry, that is, potentials which remain invariant under the combined parity (P) and time reversal (T) operations. They have shown that the energy eigenvalues are real when PT-symmetry is unbroken, whereas they occur in complex conjugate pairs when PT-symmetry is spontaneously broken. However, there have been relatively few papers discussing periodic potentials with PT-symmetry.[3,4] Recently, we[4] have constructed several classes of analytically solvable, complex, PT-invariant, periodic potentials with the special feature that they possess just a finite number of band gaps. The purpose of this paper is to substantially increase this list of solvable periodic potentials.

A few years ago, we obtained the band edges of the associated Lamé (AL) potentials[5]

$$V(x) = a(a+1)m\,\mathrm{sn}^2(x,m) + b(b+1)m\,\mathrm{sn}^2(x+K(m),m)$$
$$= a(a+1)m\,\mathrm{sn}^2(x,m) + b(b+1)m\frac{\mathrm{cn}^2(x,m)}{\mathrm{dn}^2(x,m)}. \quad (1)$$

Here, $\mathrm{sn}(x,m)$, $\mathrm{cn}(x,m)$, $\mathrm{dn}(x,m)$ are Jacobi elliptic functions with elliptic modulus parameter $m(0\leqslant m\leqslant 1)$. They are doubly periodic functions with periods $[4K(m),i2K'(m)]$, $[4K(m), 2K(m)+i2K'(m)]$, $[2K(m),i4K'(m)]$, respectively (Ref. 13), where $K(m)\equiv\int_0^{\pi/2}\mathrm{d}\theta[1-m\sin^2\theta]^{-1/2}$ denotes the complete elliptic integral of the first kind, and $K'(m)\equiv K(1-m)$. For simplicity, from now on, we will not explicitly display the modulus parameter m as an argument of Jacobi elliptic functions. It was shown that the AL potentials with integral values of a, b are periodic potentials with a finite number of band gaps.[6] We also constructed and studied the

PT-invariant potentials $V^{PT}(x) \equiv -V(ix+\beta)$ obtained from the AL potentials via the anti-isospectral transformation of variables $x \to ix+\beta$.[4]

In this paper, we make a substantial generalization of our previous work. We consider the four parameter family of generalized associated Lamé (GAL) potentials

$$\begin{aligned} V(x) &= a(a+1)m\,\mathrm{sn}^2(x,m) + b(b+1)m\,\mathrm{sn}^2(x+K(m),m) + f(f+1)m\,\mathrm{sn}^2(x+K(m)+iK'(m),m) \\ &\quad + g(g+1)m\,\mathrm{sn}^2(x+iK'(m),m) \\ &= a(a+1)m\,\mathrm{sn}^2(x,m) + b(b+1)m\frac{\mathrm{cn}^2(x,m)}{\mathrm{dn}^2(x,m)} + f(f+1)\frac{\mathrm{dn}^2(x,m)}{\mathrm{cn}^2(x,m)} + g(g+1)\frac{1}{\mathrm{sn}^2(x,m)}. \end{aligned} \tag{2}$$

In contrast to the AL potentials of Eq. (1) where there are two parameters a,b and the two terms correspond to real translations of the independent variable x by 0 and $K(m)$, the GAL potentials of Eq. (2) have four parameters a,b,f,g and the four terms correspond to complex translations of the independent variable x by 0, $K(m)$, $K(m)+iK'(m)$, $iK'(m)$. Although the GAL potentials are real, they do have singularities on the real axis coming from the zeros of the Jacobi elliptic functions $\mathrm{sn}(x)$ and $\mathrm{cn}(x)$ in the last two terms. Consequently, we will focus our attention on the PT-invariant versions of the GAL potentials, which are given by

$$\begin{aligned} V^{PT}(x) &= -a(a+1)m\,\mathrm{sn}^2(y,m) - b(b+1)m\,\mathrm{sn}^2(y+K(m),m) - f(f+1)m\,\mathrm{sn}^2(y+K(m)+iK'(m),m) \\ &\quad - g(g+1)m\,\mathrm{sn}^2(y+iK'(m),m) \\ &= -a(a+1)m\,\mathrm{sn}^2(y,m) - b(b+1)m\frac{\mathrm{cn}^2(y,m)}{\mathrm{dn}^2(y,m)} - f(f+1)\frac{\mathrm{dn}^2(y,m)}{\mathrm{cn}^2(y,m)} - g(g+1)\frac{1}{\mathrm{sn}^2(y,m)} \\ &\equiv [a(a+1),b(b+1),f(f+1),g(g+1)], \end{aligned} \tag{3}$$

where

$$y = ix + \beta, \tag{4}$$

with β being an arbitrary constant. We shall frequently use the notation $[a(a+1),\ b(b+1),\ f(f+1),\ g(g+1)]$ to denote $V^{PT}(x)$. In this notation, PT-invariant ordinary Lamé potentials are denoted by $[a(a+1),\ 0,\ 0,\ 0]$, and PT-invariant AL potentials are denoted by $[a(a+1),\ b(b+1),\ 0,\ 0]$. Here, the arbitrary constant β is chosen so as to avoid the singularities of the Jacobi elliptic functions on the real axis. We show that several of these periodic potentials for specific integer values of a,b,f,g have a finite number of band gaps. Looking at the symmetry of these potentials, we are in fact tempted to conjecture that many (and perhaps all) of these potentials with integral values of the parameters a,b,f,g also have a finite number of band gaps. It would be nice if this conjecture could be proved.

In addition, we also discover a huge class of midband states when at least one of the parameters a,b,f,g is half-integral. As a special case, we find some new midband eigenstates of the associated Lamé potentials. Further, we show that the Schrödinger equation for the generalized AL potential is intimately connected with the celebrated Heun's differential equation.[7] In fact, using the exact solutions obtained in this paper, one can immediately obtain the corresponding solutions of Heun's equation. In another related paper,[8] we use this connection and discover a wide class of new quasiperiodic solutions of Heun's equation.

Finally, using the exact eigenstates of the GAL potentials (3) and the machinery of supersymmetric quantum mechanics,[9] we construct several more potentials with finite band-gaps. There is one important point involved here using which we are in fact able to construct many more supersymmetric partner potentials corresponding to a given potential. The key point to note is that normally, in supersymmetric quantum mechanics,[9] given a potential $V_-(x)$, the ground state wave function $\psi_0(x)$ is used to construct the superpotential $W(x) = -\psi_0'(x)/\psi_0(x)$, which then yields the supersymmetric (SUSY) partner potential $V_+(x) = W^2 + W'$. If one uses any excited state wave function $\psi(x)$ of $V_-(x)$ to construct a superpotential $W(x)$, then the original potential $V_-(x)$ is

recovered correctly (by construction), but the corresponding partner potential $V_+(x)$ turns out to be singular on the real x-axis due to the zeros of the excited state wave function $\psi(x)$. However, as has been noticed recently,[10] if we consider PT-symmetric complex potentials, then the singularity is not on the real axis. Besides, as we have stressed previously,[4,11] in the case of doubly periodic potentials composed of Jacobi elliptic functions, both $V(x)$ and $V^{\mathrm{PT}}(x)$ can be simultaneously periodic even though their periods are different. In this way, by starting from the analytically solvable Lamé and associated Lamé potentials and using the excited state band edges of the corresponding PT-symmetric potentials, we discover a wide range of analytically solvable, complex PT-invariant periodic potentials with a finite number of band gaps. As an illustration, we discuss a few of these potentials in detail.

The plan of the paper is the following. In Sec. II we discuss the PT-invariant GAL potentials (3) in some detail and obtain band edges as well as midband states of several of these potentials. As a byproduct we also obtain some solutions of the AL potentials (which we had missed in earlier work[5,6]). Further, we show that the class of potentials $[a(a+1), 0, 0, g(g+1)]$ have finite number of band gaps in case a,g are integers. In Sec. III we start from the energy eigenstates obtained in Sec. II and using both the ground state as well as excited state wave functions, obtain periodic PT-invariant potentials with a finite number of band gaps. In Sec. IV we briefly discuss the connection between the solutions of the potentials (3) and Heun's differential equation.

II. SOLUTIONS FOR THE GENERALIZED ASSOCIATED LAMÉ (GAL) POTENTIALS

A few years ago, we obtained analytic solutions of the associated Lamé potentials (1)[5,6] and showed that when a,b are integers, then the resulting potentials all had a finite number of band gaps. The purpose of this section is to show that the complex PT-invariant GAL potentials as given by Eq. (3) are also quasiexactly solvable. In particular, we show that the band edges or midband states of these problems can be obtained depending on whether $a+b+f+g$ (or $a-b-f-g$) is an integer or an arbitrary noninteger number. It should be noted that we are considering PT-invariant potentials (3), since the corresponding real potentials (2) are singular on the real axis.

It may be worthwhile explaining the underlying basic idea here, even though it has been well established by us before.[4] Note that if $\psi(x)$ is a solution of the Schrödinger equation for the real potential $V(x)$ with energy E, then $\psi(ix+\beta)$ is a solution of the Schrödinger equation for the complex potential $-V(ix+\beta)$ with energy $-E$, where β is an arbitrary nonzero constant. The potential $-V(ix+\beta)$, generated by the anti-isospectral transformation $x \to ix+\beta$,[12] is clearly PT symmetric and will be denoted by $V^{\mathrm{PT}}(x)$. Further, if $\psi(x)$ and $\psi(ix+\beta)$ satisfy appropriate boundary conditions, they are eigenfunctions of $V(x)$ and $V^{\mathrm{PT}}(x)$, respectively. The ordering of energy levels for $V^{\mathrm{PT}}(x)$ is the opposite of the ordering of energy levels for $V(x)$.

In this paper, our main focus is on the Schrödinger equation ($\hbar=2m=1$)

$$-\frac{d^2}{dx^2}\psi(x) + V^{\mathrm{PT}}(x)\psi(x) = E\psi(x), \tag{5}$$

where $V^{\mathrm{PT}}(x)$ is the potential given by Eq. (3). Equation (5) is called the generalized associated Lamé equation, and we are seeking its eigenstates and midband states.

A. Symmetries

At this stage, it is worth pointing out the symmetries of the PT-invariant GAL potential (3) and hence the corresponding Schrödinger equation (5).

(1) The potential (3) and hence the Schrödinger equation (5) remains unchanged when any one (or more) of the four parameters a,b,f,g change to $-a-1$, $-b-1$, $-f-1$, $-g-1$, respectively.
(2) Under the translation $y \to y+K(m)$, the GAL potential $[a(a+1),b(b+1),f(f+1),g(g+1)]$ goes to the potential $[b(b+1), a(a+1), g(g+1), f(f+1)]$. Hence, both GAL potentials must have the same energy eigenvalues and the corresponding energy eigenfunctions are simply related, $y \to y+K(m)$, i.e.,

$$E^{\mathrm{PT}}(b,a,g,f;m) = E^{\mathrm{PT}}(a,b,f,g;m), \quad \psi(y,b,a,g,f;m) \propto \psi(y+K(m),a,b,f,g;m). \tag{6}$$

(3) Similarly, by considering the translations $y \to y+K(m)+iK'(m)$, and $y \to y+iK'(m)$, it is easy to show that

$$E^{\mathrm{PT}}(f,g,a,b;m) = E^{\mathrm{PT}}(a,b,f,g;m), \quad \psi(y,f,g,a,b;m) \propto \psi(y+K(m)+iK'(m),a,b,f,g;m), \tag{7}$$

$$E^{\mathrm{PT}}(g,f,b,a;m) = E^{\mathrm{PT}}(a,b,f,g;m), \quad \psi(y,g,f,b,a;m) \propto \psi(y+iK'(m),a,b,f,g;m). \tag{8}$$

Thus, once we obtain the eigenvalues and eigenfunctions of a given GAL potential $[a(a+1),b(b+1),f(f+1),g(g+1)]$, then we immediately know the eigenvalues and eigenfunctions of three other potentials, $[b(b+1),a(a+1),g(g+1),f(f+1)]$, $[f(f+1),g(g+1),a(a+1),b(b+1)]$, and $[g(g+1),f(f+1),b(b+1),a(a+1)]$. Therefore, it suffices to present results for only one of the four potentials.

B. Duality relations

We shall now derive some remarkable relations relating the quasiexactly solvable eigenvalues and eigenfunctions (corresponding either to the band edges or midband states) of two GAL potentials at two different values m and $1-m$ of the modulus parameter.

To that purpose we start from the Schrödinger equation (5) for the PT-invariant GAL potential (3). On using the relations[13]

$$\sqrt{m}\,\mathrm{sn}(y,m) = -\,\mathrm{dn}[iy+K'(m)+iK(m),1-m],$$

$$\mathrm{dn}(y,m) = \sqrt{1-m}\,\mathrm{sn}[iy+K'(m)+iK(m),1-m], \tag{9}$$

$$\sqrt{m}\,\mathrm{cn}(y,m) = i\sqrt{1-m}\,\mathrm{cn}[iy+K'(m)+iK(m),1-m],$$

and defining a variable $w=iy+K'(m)+iK(m)$, the Schrödinger equation (5) takes the form

$$\psi''(w) - \left[a(a+1)(1-m)\mathrm{sn}^2(w,1-m) + g(g+1)(1-m)\frac{\mathrm{cn}^2(w,1-m)}{\mathrm{dn}^2(w,1-m)} + f(f+1)\frac{\mathrm{dn}^2(w,1-m)}{\mathrm{cn}^2(w,1-m)} + b(b+1)\frac{1}{\mathrm{sn}^2(w,1-m)} \right]\psi(w) = -[a(a+1)+b(b+1)+f(f+1)+g(g+1)+E]\psi(w). \tag{10}$$

On comparing Eqs. (5) and (10) we then have the remarkable relations

$$E^{\mathrm{PT}}(a,b,f,g,m) = -[a(a+1)+b(b+1)+f(f+1)+g(g+1)] - E^{\mathrm{PT}}(a,g,f,b,1-m),$$
$$\psi(y,m) \propto \psi(iy+K'(m)+iK(m),1-m), \tag{11}$$

which is valid for the QES states corresponding to either the band edges or midband states. Note that here, a,b,f,g can be arbitrary (real) numbers and are not restricted to integer values. This is a very powerful relation which has several interesting consequences. One immediate important consequence of Eq. (11) is that for arbitrary integer values of a,g, the potential $[a(a+1),0,0,g(g+1)]$ has only a finite number of band gaps. This happens because, for $f=g=0$, one has

$$E^{\mathrm{PT}}(a,b,0,0,m) = -[a(a+1)+b(b+1)] - E^{\mathrm{PT}}(a,0,0,g=b,1-m), \tag{12}$$

so that both the potentials must have the same number of band edges and band gaps and we have already proved[6] that the AL potentials have a finite number of band gaps in case a,b are integers.

C. QES solutions

Let us now seek solutions of the Schrödinger Equation (5) for the PT-invariant GAL potential (3). On making the ansatz

$$\psi(x) = \mathrm{dn}^{-b}(y)\mathrm{sn}^{-g}(y)\mathrm{cn}^{-f}(y)\,\phi(y), \quad y = ix + \beta, \tag{13}$$

it is easily shown that ϕ satisfies the equation

$$\phi''(y) + 2\left[mb\frac{\mathrm{sn}(y)\mathrm{cn}(y)}{\mathrm{dn}(y)} - g\frac{\mathrm{cn}(y)\mathrm{dn}(y)}{\mathrm{sn}(y)} + f\frac{\mathrm{dn}(y)\mathrm{sn}(y)}{\mathrm{cn}(y)}\right]\phi'(y) + [Qm\,\mathrm{sn}^2(y) - R]\phi(y) = 0, \tag{14}$$

where

$$Q = (b+g+f)(b+g+f-1) - a(a+1), \quad R = E + (f+g)^2 + m(g+b)^2. \tag{15}$$

It is well known[14] that this is a quasiexactly solvable (QES) problem. We shall now systematically consider solutions of Eq. (14) for several special cases and then finally consider the most general case.

D. $b=f=g=0$

The simplest possibility is when three out of the four parameters a,b,f,g are zero. For example, when $b=f=g=0$, then the problem reduces to the PT-invariant version of the well-studied Lamé potential problem. We might add here that, instead of a, if any one of the other parameters b,f,g is nonzero, one still has a potential which is strictly isospectral to the PT invariant Lamé potential. It may be noted that while the Lamé potential is a periodic potential with (real) period $2K(m)$, the PT-invariant Lamé potential has real period $2K'(m)$. Further, the band-edge eigenvalues, eigenfunctions, and the discriminant Δ of $V^{\mathrm{PT}}(x)$ are related to those of Lamé potential by[4]

$$E_j^{\mathrm{PT}}(m) = -E_{2a-j}(m), \quad \psi_j^{\mathrm{PT}}(x,m) \propto \psi_{2a-j}(ix+\beta,m), \quad j = 0,1,2,\ldots,2a,$$
$$\Delta^{\mathrm{PT}}(E,m) = \Delta[E + a(a+1), 1-m]. \tag{16}$$

From Eq. (11), it follows that the PT-invariant Lamé band-edge eigenvalues and eigenfunctions, for integral a satisfy the remarkable relations ($j=0,1,2,\ldots,2a$)

$$E_j^{\mathrm{PT}}(m) = -a(a+1) - E_{2a-j}^{\mathrm{PT}}(1-m), \quad \psi_j(y,m) \propto \psi_{2a-j}(iy + K'(m) + iK(m), 1-m). \tag{17}$$

We would like to add here that even the midband states satisfy (for half-integral a) relations analogous to (17),

$$E_j(m) = a(a+1) - E_{a-1/2-j}(1-m), \quad \psi_j(y,m) \propto \psi_{a-1/2-j}(iy + K'(m) + iK(m), 1-m), \tag{18}$$

where $j=0,1,2,\ldots,a-1/2$. Note the remarkable fact that for any integer a, all bands and band gaps exchange their role as one goes from the Lamé potential to its PT-invariant version $V^{\mathrm{PT}}(x)$.[4]

The next simple possibility is when two of the four parameters a,b,f,g are zero. Here there are three distinct possibilities which we discuss one by one.

E. $f=g=0$

In this case the problem reduces to the PT-invariant AL potential which we have already discussed at great length.[5,6] Note that if either a or b is zero (or -1), then this potential reduces to the PT-invariant of the Lamé potential. As previously shown by us,[6] for arbitrary integral values of a and b, AL potentials are exactly solvable problems with finite number of band gaps for which one can write down the form of all the band-edge eigenfunctions, as we do below. We note here that when $a>b$ are both integers, then there are precisely a bound bands (some of which are

unusual in that both the band edges are of the same period), same (a) number of band gaps and all the $2a+1$ band edges are analytically known beyond which there is a continuum band extending to $E=\infty$. Note that if $b>a$, then also there are b bound bands and b band gaps and the corresponding eigenfunctions are simply obtained from the $a>b$ case by the transformation $x\to x+K(m)$ while the $a=b$ case essentially corresponds to the Lamé potential $[a(a+1),0,0,0]$. Without any loss of generality, we shall only consider AL potentials with $a>b$.

The form of the $2a+1$ band edge eigenfunctions of the AL potential depends on whether $a-b$ is an odd or an even integer. For example, when $b=a-2p-1$ ($p=0, 1, 2,\ldots$), then there are

$$p \text{ eigenstates of the form } \mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}(x)F_{p-1}[\mathrm{sn}^2(x)],$$

$$p+1 \text{ eigenstates of the form } \mathrm{dn}^{a-2p}(x)F_p[\mathrm{sn}^2(x)],$$

$$a-p \text{ eigenstates of the form } \mathrm{cn}(x)\mathrm{dn}^{2p+1-a}(x)F_{a-p-1}[\mathrm{sn}^2(x)],$$

$$a-p \text{ eigenstates of the form } \mathrm{sn}(x)\mathrm{dn}^{2p+1-a}(x)F_{a-p-1}[\mathrm{sn}^2(x)].$$

On the other hand, when $b=a-2p$, there are

$$p \text{ eigenstates of the form } \mathrm{cn}(x)\mathrm{dn}^{a-2p+1}(x)F_{p-1}[\mathrm{sn}^2(x)],$$

$$p \text{ eigenstates of the form } \mathrm{sn}(x)\mathrm{dn}^{a-2p+1}(x)F_{p-1}[\mathrm{sn}^2(x)],$$

$$a-p \text{ eigenstates of the form } \mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}^{2p-a}(x)F_{a-p-1}[\mathrm{sn}^2(x)],$$

$$a-p+1 \text{ eigenstates of the form } \mathrm{dn}^{2p-a}(x)F_{a-p}[\mathrm{sn}^2(x)].$$

Here $F_n[\mathrm{sn}^2(x)]$ denotes a polynomial in $\mathrm{sn}^2(x)$ of order n.

We would like to restate here that all the eigenstates of the PT-invariant version of the AL potentials are immediately obtained from the known eigenfunctions of the associated Lamé problem and the ordering of energy levels of these is the opposite of the corresponding AL problem. Hence, this is also an exactly solvable problem with a finite number (a) of band gaps and $2a+1$ known band edges when both a,b are integers.

F. $b=f=0$

Following our discussion for the AL case, without any loss of generality we assume here that $a>g$. In this case, one obtains $n+1$ QES solutions when $a+g=n$ (or $g-a=n+1$) with $n=01,2,\ldots$. The QES solutions for $n=0,1,2,3,4$ are given in Table I. In particular, for any choice of $a(a+1)$, Table I lists the eigenstates for various values of $g(g+1)$. The general form of these eigenfunctions is obtained from the corresponding AL eigenfunctions as given in Table 3 of Ref. 5 by simply interchanging $\mathrm{dn}(y)$ and $\mathrm{sn}(y)$.

A few remarks are in order.

(1) Since we are considering the case ($b=f=0$), the duality relation (11) takes the form

$$E^{\mathrm{PT}}(a,0,0,g;m) = -[a(a+1)+g(g+1)] - E^{\mathrm{PT}}(a,b=g,0,0;1-m),$$
$$\psi(y,a,0,0,g;m) \propto \psi(iy+K'(m)+iK(m),a,b=g,0,0;1-m). \tag{19}$$

Using Table 3 of Ref. 5 and this duality relation, it is straightforward to obtain all the QES eigenstates, thereby providing an independent check on the results given in Table I. Further, it follows that for arbitrary integer values of a and g, $[a(a+1),0,0,g(g+1)]$ is an exactly

TABLE I. Energy eigenstates of PT-invariant GAL potentials with $b=f=0$, $g=n-a$, $n=0, 1, 2,\ldots$;

2	$(a-3)(a-2)$	$-(1+m)(a^2-2a+2)\pm 2\delta_1$	$\frac{[E+(1+m)(a-2)^2]\mathrm{sn}^2(y)+2(2a-3)}{\mathrm{sn}^2(y)}$
3	$(a-4)(a-3)$	$-(a^2-2a+2)-(a^2-4a+5)m\pm 2\delta_2$	$\frac{[[E+(a-2)^2+m(a-3)^2]\mathrm{sn}^2(y)+2(2a-5)]\mathrm{cn}(y)}{\mathrm{sn}^3(y)}$
3	$(a-4)(a-3)$	$-(a^2-4a+5)-(a^2-2a+2)m\pm 2\delta_3$	$\frac{[[E+(a-3)^2+m(a-2)^2]\mathrm{sn}^2(y)+2(2a-5)]\mathrm{dn}(y)}{\mathrm{sn}^3(y)}$
4	$(a-5)(a-4)$	$-(1+m)(a^2-4a+5)\pm 2\delta_4$	$\frac{[[E+(1+m)(a-3)^2]\mathrm{sn}^2(y)+2(2a-7)]\mathrm{cn}(y)\mathrm{dn}(y)}{\mathrm{sn}^4(y)}$

solvable potential problem with a finite number (a) of bandgaps. From the duality relation (19), it follows that for integer values of a,g,

$$E_j^{\mathrm{PT}}(a,0,0,g;m) = -[a(a+1)+g(g+1)] + E_j(a,b=g,0,0;1-m), \tag{20}$$

and hence the corresponding discriminants Δ are related by

$$\Delta^{\mathrm{PT}}(E,m;a,0,0,g) = \Delta[E+a(a+1)+g(g+1),1-m;a,b=g,0,0]. \tag{21}$$

(2) Following the structure of the eigenfunctions of the AL potentials as given above, it is now straightforward to write down the general form of the eigenfunctions for arbitrary value of n. However, to obtain the corresponding eigenvalues, one needs to solve cubic and higher order equations.

(3) Under the transformation $y \to y+iK'(m)$ followed by the interchange of a and g (note $b=f=0$), the Schrödinger equation (5) for the GAL potential (3) remains unchanged. Thus it follows that under the interchange of a with g, the eigenvalue spectrum must remain unaltered. Clearly, this is only possible if either the energy eigenvalues remain unchanged under this transformation, or if two of the eigenvalues go into each other. It is easy to verify from Table I that the eigenvalues corresponding to the eigenfunctions of period $2iK'(m)$ remain unaltered under $a \to g$ while the other eigenvalues go into each other under this transformation.

(4) Similarly, From Table 3 of Ref. 5, it is easy to check that for the AL potentials (1), the eigenvalues corresponding to the eigenfunctions of period $2K(m)$ remain unaltered under $a \to b$ while the other eigenvalues go into each other under this transformation. This happens because the AL potentials remain unaltered under the transformation $y \to y+K(m)$ followed by the interchange of a with b.

Summarizing, we have discovered exactly solvable potential problems with a finite number of band gaps when a,g are arbitrary integers. In fact everything about these potentials can be derived from previously known results for AL potentials.

TABLE II. Energy eigenstates of PT-invariant GAL potentials with parameters $b=g=0$, $f=n-a$, $n=0, 1, 2,\ldots$; $\delta_5\equiv\sqrt{(a-1+m)^2-(2a-1)m}$, $\delta_6\equiv\sqrt{(a-1+2m)^2-3(2a-1)m}$, $\delta_7\equiv\sqrt{(a-2+2m)^2-(2a-1)m}$, $\delta_8\equiv\sqrt{(a-2+3m)^2-3(2a-1)m}$.

G. $b=g=0$

In this case, one obtains $n+1$ QES solutions when $a+f=n$ with $n=0,1,2,\ldots$. The solutions for $n=0,1,2,3,4$ are given in Table II. In particular, for any choice of $a(a+1)$, Table II lists the eigenstates for various values of $f(f+1)$. The general form of these eigenfunctions is simply obtained from the corresponding AL eigenfunctions as given in Table 2 of Ref. 5 by interchanging $\mathrm{dn}(y)$ and $\mathrm{cn}(y)$.

Some comments are in order at this stage.

(1) The form of eigenfunctions for arbitrary value of n is easily written down following the structure of the AL eigenfunctions given in the preceding section.

(2) From Eq. (11) it follows that the potential (3) with $b=g=0$ is a self-dual potential, satisfying

$$E_{j_1}^{\mathrm{PT}}(a,f,m) = -[a(a+1)+f(f+1)] - E_{j_2}^{\mathrm{PT}}(a,f,1-m). \tag{22}$$

Using Table II, it is easily checked that indeed this is true, for any values of a,f. In particular, whereas δ_5,δ_8 are invariant under $m\to 1-m$, $\delta_6\leftrightarrow\delta_7$ under the same transformation.

(3) Under the transformation $y\to y+K(m)+iK'(m)$ followed by the interchange of a and f (note $b=g=0$), the Schrödinger equation (5) for the GAL potential (3) remains unchanged. Thus it follows that under the interchange of a with f, the eigenvalue spectrum must remain unaltered. Clearly, this is only possible if either the energy eigenvalues remain unchanged under this transformation, or if two of the eigenvalues go into each other. It is easy to verify from Table II that the eigenvalues corresponding to the eigenfunctions of period $2K(m)+2iK'(m)$ remain unaltered under $a\to f$ while the other eigenvalues go into each other under this transformation. In particular, while δ_5,δ_8 are invariant under $a\leftrightarrow f$, $\delta_6\leftrightarrow\delta_7$ under the same transformation.

TABLE III. Energy eigenstates of PT-invariant GAL potentials with $f=0$, $g=n-a-b$, $n=0, 1, 2,\ldots$; $\delta_9 \equiv \sqrt{[(1+m)(a-1)+b]^2-(2a-1)(2a+2b-3)m}$, $\delta_{10} \equiv \sqrt{[a+b-1+m(a-2)]^2-(2a-1)(2a+2b-5)m}$.

3	$-(1+m)-(a+b-1)^2-m(a-2)^2\pm 2\delta_{10}$	$\frac{[[E+(a+b-2)^2+m(a-3)^2]\mathrm{sn}^2(y)+2(2a+2b-5)]\mathrm{cn}(y)}{\mathrm{sn}^3(y)}$

H. $f=0$

Let us consider the case when only one out of the four parameters a,b,f,g is zero. As an illustration, we discuss the case $f=0$. In fact, as described below, once we know the eigenstates of this problem, the eigenstates of the other three problems corresponding to either b or g or a equal to zero are immediately obtainable, since the four potentials are related by translations of the independent variable.

For the case $f=0$, one obtains $(n+2)/2[(n+1)/2]$ QES solutions when n is even [odd]. Here $a+b+g=n$ with $n=0,1,2,\ldots$. The QES solutions for $n=0,1,2,3$ are given in Table III. In particular, for any choice of $a(a+1)$, Table III lists the eigenstates for various values of $(b+g)(b+g+1)$.

Some remarks are appropriate.

(1) By looking at the structure of the QES eigenfunctions in Table III, it is easy to write down the nature of eigenfunctions for the general case.

(2) From Table III, it is easily checked that the duality relation

$$E^{\mathrm{PT}}(a,b,g,m) = -[a(a+1)+b(b+1)+g(g+1)] - E^{\mathrm{PT}}(a,g,b,1-m) \tag{23}$$

is indeed satisfied. In particular, both δ_9,δ_{10} are invariant under $b \leftrightarrow g$ followed by $m \to 1-m$.

(3) Under the transformation $y \to y+K(m)$ followed by the interchange of a and b, and replacing g by f, the Schrödinger equation (5) for the GAL potential (3) with $f=0$ goes over to the Schrödinger equation for the GAL potential (3) with $g=0$. Hence, under the interchange of a and b and replacing g by f, all the energy eigenvalues of the potential (3) with $f=0$ must go over into those of (3) with $g=0$, while the corresponding eigenfunctions are simply obtained from Table III by replacing y by $y+K(m)$.

(4) Using similar reasoning it also follows that under the interchange of a with g and replacing b by f, all the energy eigenvalues of the GAL potential (3) with $f=0$ go over to those of potential (3) with $b=0$ while the corresponding eigenfunctions are obtained from Table III by replacing y by $y+iK'(m)$. And finally, under the interchange of b with g and replacing a by f, all the energy eigenvalues of the GAL potential (3) with $f=0$ go over to those of potential (3) with $a=0$, while the corresponding eigenfunctions are easily obtained from Table III by replacing y by $y+K(m)+iK'(m)$.

TABLE IV. Energy eigenstates of PT-invariant GAL potentials with $f=2n-a-b-g$, $n=0, 1, 2,\ldots$; $\delta_{11}\equiv\sqrt{[(a+b-1)+m(1-b-g)]^2-(2a-1)(1-2g)m}$.

n	E	$\mathrm{sn}^g(y)\mathrm{dn}^b(y)\mathrm{cn}^{-(a+b+g)}(y)\psi$
0	$-(a+b)^2-m(g+b)^2$	1
1	$-(a+b-1)^2-m(b+g-1)^2-(1+m)\pm 2\delta_{11}$	$\dfrac{[E+(a+b-2)^2+m(b+g)^2]\mathrm{sn}^2(y)-2(2g-1)}{\mathrm{cn}^2(y)}$

I. The general case: *a*,*b*,*f*,*g* all nonzero

Finally, let us discuss the most general case when all four parameters are nonzero. In this case one obtains $n+1$ solutions when $a+b+f+g=2n$ with $n=0,1,2,\ldots$. The QES solutions for $n=0$, 1 are given in Table IV.

(1) It is easy to see that in the general case, the eigenfunction is of the form

$$\psi=\mathrm{sn}^{-g}(y)\mathrm{cn}^{-f}(y)\mathrm{dn}^{-b}(y)\sum_{k=0}^{n}A_k\,\mathrm{sn}^{2k}(y), \tag{24}$$

while the corresponding eigenvalues are solutions of a $n+1$th order equation.

(2) It can be checked from Table IV that δ_{11} is invariant under $b\leftrightarrow g$ followed by $m\rightarrow 1-m$.

(3) The GAL potential (3) and hence the corresponding Schrödinger equation (5) is invariant under the transformation $y\rightarrow y+K(m)$ followed by the interchange of a with b and f with g. Hence, under the interchange of a with b and f with g, all the eigenvalues of the GAL system must either remain invariant or go into each other. In fact it is easily checked from Table IV that all the eigenvalues are invariant under the interchange of a with b and f with g. Extending this argument, in fact one finds that all the eigenvalues are also invariant under $a\leftrightarrow f$, $b\leftrightarrow g$ as well as under $a\leftrightarrow g$, $b\leftrightarrow f$.

J. Midband states

So far we have discussed the results for the PT-invariant GAL potentials, which give eigenvalues and eigenfunctions corresponding to the band edges. It may be noted that in all these cases, while a,b,f,g need not be integers, either $a+b+f+g$ or $a-b-f-g$ is always integral. We now show that when at least one of a, b, f, g is half-integral and either $a+b+f+g$ and/or $a-b-f-g$ is an arbitrary number (being an integer is of course a very special case here), then one can obtain doubly degenerate eigenstates which correspond to midband states. In fact depending on whether we want b or f or g to be half-integral (with the other two parameters being integral), we need to use different trial solutions. Therefore, we shall consider all three cases one by one.

Case 1. b half-integral: We start from Eq. (14) and further substitute the ansatz

$$\phi(y)=[\mathrm{cn}(y)+i\,\mathrm{sn}(y)]^tZ(y), \tag{25}$$

where t is any real number. After lengthy but straightforward algebra, one can show that $Z(y)$ satisfies the equation

$$Z''(y)+\left[2it\,\mathrm{dn}(y)+2mb\frac{\mathrm{sn}(y)\mathrm{cn}(y)}{\mathrm{dn}(y)}-2g\frac{\mathrm{cn}(y)\mathrm{dn}(y)}{\mathrm{sn}(y)}+2f\frac{\mathrm{dn}(y)\mathrm{sn}(y)}{\mathrm{cn}(y)}\right]Z'(y)+\left[-(R+t^2)\right.$$
$$\left.+(Q+t^2)m\,\mathrm{sn}^2(y)-2itg\frac{\mathrm{cn}(y)}{\mathrm{sn}(y)}+2itf(1-m)\frac{\mathrm{sn}(y)}{\mathrm{cn}(y)}+imt(2b+2f+2g-1)\mathrm{sn}(y)\mathrm{cn}(y)\right]Z(y)$$
$$=0, \tag{26}$$

where R and Q are as given by Eq. (15). Not surprisingly, $Z(y)=$constant is a solution with energy $E=-(4t^2+m)/4$ provided $f=g=0$, $b=1/2$, $a=t-1/2$ (i.e., $b+f+g=1/2$).

One can build solutions for higher values of $b+f+g$ from here. In particular, for $b+f+g=2M+1/2$, we consider the ansatz ($M=0,1,2,\ldots$)

$$Z(y)=\sum_{k=0}^{M} A_k\,\mathrm{sn}^{2k}(y)+\mathrm{cn}(y)\mathrm{sn}(y)\sum_{k=0}^{M-1} B_k\,\mathrm{sn}^{2k}(y), \tag{27}$$

while if $b+f+g=2M+3/2$ then we consider the ansatz ($M=0,1,2,\ldots$)

$$Z(y)=\mathrm{cn}(y)\sum_{k=0}^{M} A_k\,\mathrm{sn}^{2k}(y)+\mathrm{sn}(y)\sum_{k=0}^{M} B_k\,\mathrm{sn}^{2k}(y). \tag{28}$$

Substitution into Eq. (26) and simplification yields analytic expressions for the energy eigenvalues and eigenfunctions for arbitrary M for $b=1/2$ and $b=3/2$. In particular, for $b=1/2$, we find that

$$b=1/2,\quad f=p,\quad f+g=N,\quad a=t-1/2,\quad E=-[t^2+m(g+b)^2], \tag{29}$$

where both f,g are non-negative integers satisfying $f+g=N$ with $N=0,1,2,\ldots$.

Similarly, when $b=3/2$, $a=t-1/2$, $f=p$, $f+g=N$ we find that

$$E=m(2g+1)-[1+t^2+m(g+b)^2]\pm\sqrt{(2g+1)^2m^2+4m(N+1)(f-g)+4(1-m)t^2}, \tag{30}$$

where, f and g are again non-negative integers. In all these cases, the corresponding eigenfunctions have the form as given above in Eqs. (27) and (28). For small values of N, the explicit coefficients A_k,B_k appearing in the eigenfunction expressions can be easily written down. For example, for $b=1/2$ and $N=1$, the eigenfunction is $Z(y)=A\,\mathrm{cn}(y)+B\,\mathrm{sn}(y)$ with $A/B=it$ in case $f=1$, $g=0$ while $B/A=-it$ in case $g=1$, $f=0$.

For the special case of $f=g=0$ and $t\neq 1/2$, these results represent the generalization of results obtained by us previously[6] in the case of AL potential. Further, for $f=g=0$, $t=1/2$, the results obtained above match with the energy eigenvalue expressions obtained in Ref. 6 (as they should).

Several comments can be readily made.

(1) Since, in the variable y, the GAL potential (3) has period $2K(m)$ as well as $2iK'(m)$, hence $\psi(y)$ and $\psi(y+2K(m))$ as well as $\psi(y+2iK'(m))$ are all eigenfunctions of the GAL equation with the same eigenvalue. As a consequence, $\phi(y)=[\mathrm{cn}(y)-i\,\mathrm{sn}(y)]^tZ(y)$ is also the eigenfunction with the *same* eigenvalue. Thus for any nonintegral t, each level is doubly degenerate. The same remark also applies to the other two solutions (when f or g is half-integral) discussed below.

(2) There is one remarkable symmetry associated with Eq. (26). In particular, notice that this equation is invariant under $t\to -t$ followed by $i\to -i$ (where $i=\sqrt{-1}$). But under this transformation, the ansatz (25) becomes

$$\phi(y)=[\mathrm{cn}(y,m)-i\,\mathrm{sn}(y,m)]^{-t}. \tag{31}$$

Hence it follows that the energy eigenvalues must be independent of sign of t, i.e., they must be a function of t^2. Similar remarks also apply in the other two cases discussed below (i.e., when f,g are half-integral).

(3) For integral t, both a,b are half-integral and these solutions reduce to those discussed in the preceding section and in that case they correspond to QES band-edge eigenstates.

(4) Here we have obtained solutions $\psi(y)$ in which $a=t-1/2$, $f=p$, $g=N-p$, and $b=1/2$ or $3/2$. In view of the symmetries of the GAL potentials, we then also have solutions $\psi(y+K(m))$ with the same energy in the case $b=t-1/2$, $g=p$, $f=N-p$, and a is either $1/2$ or $3/2$. Similarly we have solutions $\psi(y+K(m)+iK'(m))$ with the same energy in the case $f=t-1/2$, $a=p$, $b=N-p$, and $g=1/2$ or $3/2$. Further, we also have solutions $\psi(y+iK'(m))$ with the same energy in the case $g=t-1/2$, $a=N-p$, $b=p$, and $f=1/2$ or $3/2$.

Case 2. f half-integral: We start from Eq. (14) and further substitute the ansatz

$$\phi(y) = [\mathrm{dn}(y) + ik\,\mathrm{sn}(y)]^t Z(y), \tag{32}$$

where t is any real number and $k=\sqrt{m}$. After some lengthy but straightforward algebra, one finds that $Z(y)$ satisfies the equation

$$Z''(y) + \left[2ikt\,\mathrm{cn}(y) + 2mb\frac{\mathrm{sn}(y)\mathrm{cn}(y)}{\mathrm{dn}(y)} - 2g\frac{\mathrm{cn}(y)\mathrm{dn}(y)}{\mathrm{sn}(y)} + 2f\frac{\mathrm{dn}(y)\mathrm{sn}(y)}{\mathrm{cn}(y)} \right] Z'(y) + \left[-(R+mt^2) + (Q+t^2)m\,\mathrm{sn}^2(y) - 2itkg\frac{\mathrm{dn}(y)}{\mathrm{sn}(y)} - 2iktb(1-m)\frac{\mathrm{sn}(y)}{\mathrm{dn}(y)} + ikt(2b+2f+2g-1)\mathrm{sn}(y)\mathrm{dn}(y) \right] Z(y) = 0, \tag{33}$$

where R and Q are as given by Eq. (15). Not surprisingly, $Z(y)=$constant is a solution with energy $E=-(4mt^2+1)/4$ provided $b=g=0$, $f=1/2$, $a=t-1/2$ (i.e. $b+f+g=1/2$).

One can build solutions for higher values of $b+f+g$ from here. In particular, in the case $b+f+g=2M+1/2$, we consider the ansatz ($M=0,1,2,\ldots$)

$$Z(y) = \sum_{k=0}^{M} A_k\,\mathrm{sn}^{2k}(y) + \mathrm{sn}(y)\mathrm{dn}(y)\sum_{k=0}^{M-1} B_k\,\mathrm{sn}^{2k}(y), \tag{34}$$

while if $b+f+g=2M+3/2$ then we consider the ansatz ($M=0,1,2,\ldots$)

$$Z(y) = \mathrm{dn}(y)\sum_{k=0}^{M} A_k\,\mathrm{sn}^{2k}(y) + \mathrm{sn}(y)\sum_{k=0}^{M} B_k\,\mathrm{sn}^{2k}(y). \tag{35}$$

On substituting this ansatz in Eq. (33) and making algebraic simplifications, we obtain analytic expressions for the energy eigenvalues and eigenfunctions for arbitrary M for $f=1/2$ and $f=3/2$. In particular, for $f=1/2$, we find that

$$f = 1/2, \quad b+g=N, \quad a=t-1/2, \quad E=-[mt^2+(g+f)^2], \tag{36}$$

where both b,g are non-negative integers satisfying $b+g=N$ with $N=0,1,2,\ldots$.

Similarly, when $f=3/2$, $a=t-1/2$, $b+g=N$ we find that

$$E = (2g+1) - [(1+t^2)m + (g+f)^2] \pm \sqrt{(2g+1)^2 + 4m(N+1)(b-g) - 4m(1-m)t^2}, \tag{37}$$

where, b and g are again non-negative integers. In all these cases, the corresponding eigenfunctions have the form as given above in Eqs. (34) and (35). For small values of N, the explicit coefficients A_k, B_k in the eigenfunction expressions can be easily written down. Further, as in the half-integral b case, one can write down three more solutions with the same energy.

Case 3. g half-integral: We start from Eq. (14) and further substitute the ansatz

$$\phi(y) = [\mathrm{dn}(y) + k\,\mathrm{cn}(y)]^t Z(y), \tag{38}$$

where t is any real number. After algebraic simplification, it is easy to show that $Z(y)$ satisfies the equation

$$Z''(y) + \left[-2kt\,\mathrm{sn}(y) + 2mb\frac{\mathrm{sn}(y)\mathrm{cn}(y)}{\mathrm{dn}(y)} - 2g\frac{\mathrm{cn}(y)\mathrm{dn}(y)}{\mathrm{sn}(y)} + 2f\frac{\mathrm{dn}(y)\mathrm{sn}(y)}{\mathrm{cn}(y)} \right] Z'(y) + \left[-R + (Q+t^2)m\,\mathrm{sn}^2(y) - 2ktb\frac{\mathrm{cn}(y)}{\mathrm{dn}(y)} - 2ktf\frac{\mathrm{dn}(y)}{\mathrm{cn}(y)} + kt(2b+2f+2g-1)\mathrm{cn}(y)\mathrm{dn}(y) \right] \times Z(y) = 0, \tag{39}$$

where R and Q are as given by Eq. (15). Not surprisingly, $Z(y)=$constant is a solution with energy $E=-(1+m)/4$ provided $b=f=0$, $g=1/2$, $a=t-1/2$ (i.e., $b+f+g=1/2$).

One can build solutions for higher values of $b+f+g$ from here. In particular, in the case $b+f+g=2M+1/2$, we consider the ansatz ($M=0,1,2,\ldots$)

$$Z(y)=\sum_{k=0}^{M} A_k\,\mathrm{sn}^{2k}(y)+\mathrm{cn}(y)\mathrm{dn}(y)\sum_{k=0}^{M-1} B_k\,\mathrm{sn}^{2k}(y), \tag{40}$$

while if $b+f+g=2M+3/2$ then we consider the ansatz ($M=0,1,2,\ldots$)

$$Z(y)=\mathrm{cn}(y,m)\sum_{k=0}^{M} A_k\,\mathrm{sn}^{2k}(y)+\mathrm{dn}(y)\sum_{k=0}^{M} B_k\,\mathrm{sn}^{2k}(y). \tag{41}$$

Substituting this ansatz in Eq. (39) and simplifying, one gets analytic expressions for the energy eigenvalues and eigenfunctions for arbitrary M for $b=1/2$ and $b=3/2$. In particular, for $b=1/2$, we find that

$$g=1/2,\quad b+f=N,\quad a=t-1/2,\quad E=-[(f+g)^2+m(g+b)^2], \tag{42}$$

where both b,f are non-negative integers satisfying $b+f=N$ with $N=0,1,2,\ldots$.

Similarly, when $g=3/2$, $a=t-1/2$, $b+f=N$ we find that

$$E=1+2f+(2b+1)m-[(f+g)^2+m(g+b)^2]\pm\sqrt{(1-m)[(2f+1)^2-(2b+1)^2m]+4mt^2}, \tag{43}$$

where, b and f are again non-negative integers. In all these cases, the corresponding eigenfunctions have the form as given in Eqs. (40) and (41). For small values of N, the coefficients A_k,B_k appearing in the eigenfunctions can be easily written down. Further, as in the half-integral b case, one can write down three more solutions with the same energy.

III. SUPERSYMMETRY AND POTENTIALS WITH A FINITE NUMBER OF BAND GAPS

We shall now start with the ground state as well as the excited state eigenfunctions of various PT-invariant GAL potentials discussed in the preceding section and using supersymmetry obtain the corresponding SUSY partner potentials. In this manner, we obtain many periodic potentials $V_+(x)$ with a finite number of band gaps. As emphasized in the introduction, unlike real potentials, if we take a complex PT-invariant potential, then even if we start with an excited state wave function and calculate the corresponding superpotential W, the singularities in W and hence $V_+(x)$ are not on the real axis, and do not cause problems.

A. Supersymmetry partners of PT-invariant Lamé potentials

The simplest case is when only one parameter, (say a) is nonzero. This gives the PT-invariant Lamé potential

$$V(x)=-a(a+1)m\,\mathrm{sn}^2(y). \tag{44}$$

For concreteness, take $a=1$, which yields $V(x)=-2m\,\mathrm{sn}^2(y)$. Here, the three band-edge eigenfunctions (in order of increasing energy eigenvalues) are $\mathrm{sn}(y)$, $\mathrm{cn}(y)$, $\mathrm{dn}(y)$. It is easily computed that corresponding to these three eigenstates, the corresponding partner potentials (up to a constant) are $V_+(x)=-2m\,\mathrm{sn}^2(y+K(m))$, $-2m\,\mathrm{sn}^2(y+iK'(m))$, $-2m\,\mathrm{sn}^2(y+K(m)+iK'(m))$ which are all strictly isospectral potentials to the original Lamé potential. Thus, in this case we do not obtain any different solvable potentials by using supersymmetry.

Now consider the case $a=2$. All the five band-edge eigenvalues and eigenfunctions of the PT-invariant Lamé potential $V(x)=-6m\,\mathrm{sn}^2(y)$ have already been given by us in Table 4 of Ref. 11. Starting from any of the five band-edge eigenfunctions and calculating the corresponding

TABLE V. The five supersymmetric partner potentials of the PT-invariant Lamé potential $V_-^{PT}(x)=-6m\,\mathrm{sn}^2(y)$. Here $y=ix+\beta$ and $\delta\equiv\sqrt{1-m+m^2}$. All partner potentials have a period $2K'(m)$.

E	$\psi^{(-)}$	$V_+(x)$
$-2(1+m)-2\delta$	$1+\frac{E}{2}\,\mathrm{sn}^2(y)$	$6m\,\mathrm{sn}^2(y)+E-\frac{2E^2\mathrm{sn}^2(y)\mathrm{cn}^2(y)\mathrm{dn}^2(y)}{\left(1+\frac{E}{2}\mathrm{sn}^2(y)\right)}$
$-4-m$	$\mathrm{sn}(y)\mathrm{cn}(y)$	$-2m[\mathrm{sn}^2(y)+\mathrm{sn}^2(y+K(m)+iK'(m))+\mathrm{sn}^2(y+iK'(m)]-E$
$-1-4m$	$\mathrm{sn}(y)\mathrm{dn}(y)$	$-2m[\mathrm{sn}^2(y)+\mathrm{sn}^2(y+K(m))+\mathrm{sn}^2(y+iK'(m)]-E$
$-1-m$	$\mathrm{cn}(y)\mathrm{dn}(y)$	$-2m[\mathrm{sn}^2(y)+\mathrm{sn}^2(y+K(m))+\mathrm{sn}^2(y+K(m)+iK'(m)]-E$
$-2(1+m)+2\delta$	$1+\frac{E}{2}\,\mathrm{sn}^2(y)$	$6m\,\mathrm{sn}^2(y)+E-\frac{2E^2\,\mathrm{sn}^2(y)\mathrm{cn}^2(y)\mathrm{dn}^2(y)}{\left(1+\frac{E}{2}\mathrm{sn}^2(y)\right)}$

superpotentials, we obtain five different supersymmetric partner potentials all of which have the same band-edge energy eigenvalues as given in Table 4 of Ref. 11. In Table V we have given the expressions for these five different strictly isospectral potentials. It is worth noting that out of these five potentials, three are self-isospectral—they are the PT-invariant GAL potentials [2,2,2,0]. Hence, truly speaking, we only have three genuinely different potentials, all having the same band-edge energies. For each of these cases, using the formalism of supersymmetric quantum mechanics,[9] we can easily obtain expressions for the corresponding five eigenstates. Now, again by starting from these eigenfunctions, we can construct still different partner potentials but with identical band edges. In this way, one could construct a large number of periodic potentials with five band edges and two band gaps, all strictly isospectral to the PT-invariant Lamé potential (44) with $a=2$.

Similarly, if we consider the PT-invariant Lamé potential (44) with $a=3$, then we have seven band-edge eigenfunctions and eigenvalues all of which are analytically known and are given in Table 1 of Ref. 4. Again, using supersymmetry, we can obtain seven different partner potentials V_+ all with the same band-edge eigenvalues. By starting from any one of them and using other eigenfunctions recursively, we can in principle construct a huge class of isospectral potentials. Particular mention may be made of the case when we start from the eigenfunction $\mathrm{sn}(y)\mathrm{cn}(y)\mathrm{dn}(y)$ of the potential $V(x)=-12m\,\mathrm{sn}^2(y)$. It is easily shown that the corresponding partner potential V_+ (up to a constant) is given by

$$V(x)=-m[6\,\mathrm{sn}^2(y)+2\,\mathrm{sn}^2(y+K(m))+2\,\mathrm{sn}^2(y+iK'(m))+2\,\mathrm{sn}^2(y+K(m)+iK'(m))]. \tag{45}$$

Thus, we see that the PT-invariant GAL potential [6,2,2,2] has precisely three bands, three band gaps, and seven band edges, since it is the supersymmetric partner of the PT-invariant Lamé potential (44) with $a=3$. The process described above is readily extended to any Lamé potential with integer a. We can start from any of the $2a+1$ band edges and obtain the corresponding supersymmetric partner potentials all having the same band edges.

We have shown that the SUSY partners of the PT-invariant Lamé potentials [6,0,0,0] and [12,0,0,0] are the potentials [2,2,2,0] and [6,2,2,2], respectively. What about the higher Lamé potentials? In this connection, it is amusing to notice that the band edges of the PT-invariant Lamé potential [20,0,0,0] and the potential [6,6,6,2] (which follow from Table IV) are identical. For example, out of nine band edges, the six band-edge energy eigenvalues of [20,0,0,0] are given by

$$E = -5(m+2) \pm \sqrt{4m^2 - 9m + 9}, \quad E = -5(1+m) \pm 2\sqrt{4m^2 + m + 4},$$
$$E = 5(1+2m) \pm 2\sqrt{9m^2 - 9m + 4}. \tag{46}$$

It is easily seen from Table IV that exactly the same eigenvalues are obtained when a,b,f,g take the values (2,2,−3,1), (2,−3,2,1), (−3,2,2,1). Similarly, one can show that the three remaining eigenvalues of [20,0,0,0] satisfy the same cubic equation as [6,6,6,2] when a, b, f, g take the values (2,2,2,−2).

In fact, one can show that the number (and structure) of band edges of the PT-invariant Lamé potential $[2a(2a+1),0,0,0]$ is the same as the QES states of the potential $[a(a+1), a(a+1), a(a+1), (a-1)a]$. For example, for this PT-invariant Lamé potential it is well known that out of the $4a+1$ band edges of the Lamé potential, a states each are of the form $\mathrm{cn}(y)\mathrm{sn}(y)F_{a-1}(\mathrm{sn}^2(y))$, $\mathrm{cn}(y)\mathrm{dn}(y)F_{a-1}(\mathrm{sn}^2(y))$, $\mathrm{dn}(y)\mathrm{sn}(y)F_{a-1}(\mathrm{sn}^2(y))$, while the remaining $a+1$ states are of the form $F_a(\mathrm{sn}^2(y))$. Using Table IV, it is easily shown that there are again $4a+1$ QES states of the potential $[a(a+1), a(a+1), a(a+1), (a-1)a]$, out of which a QES states each are obtained when a,b,f,g are of the form a, a, $a-1$, $a-1$, or a, $a-1$, a, $a-1$, or $a-1,a,a,a-1$, while $a+1$ QES states are obtained when a, b, f, g are of the form a, a, a, $-a$. In fact we believe that all the band-edge eigenvalues of the potentials $[2a(2a+1),0,0,0]$ and $[a(a+1), a(a+1), a(a+1), (a-1)a]$ are identical. While this is easily shown for low values of a, at the moment, a general proof is still lacking.

Similarly, one can show that the number (as well as the structure) of band edges of the PT-invariant Lamé potential $[(2a-1)2a,0,0,0]$ is the same as the QES states of the potential $[a(a+1), (a-1)a, (a-1)a, (a-1)a]$. For example, it is well known that out of the $4a-1$ band edges of the PT-invariant Lamé potential, a states each are of the form $\mathrm{cn}(y)F_{a-1}(\mathrm{sn}^2(y))$, $\mathrm{dn}(y)F_{a-1}(\mathrm{sn}^2(y))$, $\mathrm{sn}(y)F_{a-1}(\mathrm{sn}^2(y))$, while the remaining $a-1$ states are of the form $\mathrm{sn}(y)\mathrm{cn}(y)\mathrm{dn}(y)F_{a-2}(\mathrm{sn}^2(y))$. Using Table IV, it is easily shown that there are $4a-1$ QES states of the potential $[a(a+1),(a-1)a,(a-1)a,(a-1)a]$, out of which a QES states each are obtained when a,b,f,g are of the form a, $-a$, $a-1$, $a-1$, or a, $a-1$, $-a$, $a-1$, or a, $a-1$, $a-1$, $-a$, while $a-1$ QES states are obtained when a, b, f, g are of the form $-a-1$, $a-1$, $a-1$, $a-1$. In fact we believe that all the band-edge eigenvalues of the potentials $[(2a-1)2a,0,0,0]$ and $[a(a+1),(a-1)a,(a-1)a, (a-1)a]$ are identical. While this is easily shown for low values of a, a general proof is not available.

On the basis of these results, we then conjecture that the potentials $[a(a+1), a(a+1), a(a+1), (a-1)a]$, for integer a, have the same band edges as the Lamé potential $[2a(2a+1), 0, 0, 0]$ and hence these potentials also have precisely $2a$ band gaps and $(4a+1)$ band edges, all of which are known in principle. Further, the potentials $[a(a+1), (a-1)a, (a-1)a, (a-1)a]$ have the same band edges as the Lamé potential $[(2a-1)2a, 0, 0, 0]$ and hence are also potentials with a finite number $(2a-1)$ of band gaps. It would be nice to have a general proof.

B. Supersymmetry partners of PT-invariant associated Lamé potentials

We start our discussion with the $a=2$, $b=1$ associated Lamé potential and its corresponding PT-invariant potential $V^{\mathrm{PT}}(x) = -6m\,\mathrm{sn}^2(y) - 2m\,\mathrm{cn}^2(y)/\mathrm{dn}^2(y)$. All five band-edge eigenvalues and eigenfunctions for this potential have been given by us in Table 3 of Ref. 11. As established previously,[5,11] this is a self-isospectral potential and hence using the band-edge eigenfunction $\mathrm{dn}^2(y)$ does not give any partner potential. However, if instead we use the remaining four band-edge eigenfunctions, then one gets four SUSY partner potentials which are strictly isospectral to the PT-invariant [6,2,0,0] potential.

Let us now consider the PT-invariant AL potential $[a(a+1),(a-2)(a-1),0,0]$, i.e., the potential (3) with $b=a-2$, $f=g=0$. As shown by us,[5] one of its exact band-edge eigenfunctions is $\psi(x) = \mathrm{cn}(y)\mathrm{dn}^{a-1}(y)$. It is easy to see that the corresponding partner potential V_+ (up to a constant) is the potential $[(a-1)a,(a-1)a,2,0]$. Thus we immediately conclude that the PT-invariant potential $[(a-1)a,(a-1)a,2,0]$ is strictly isospectral to the PT-invariant AL potential $[a(a+1),(a-2)(a$

$-1),0,0]$. In the special case when both a,b are integers, in view of our results on AL potentials,[6] it then follows that the GAL potential $[(a-1)a,\ (a-1)a,\ 2,\ 0]$ has a band gaps and a bands, out of which $b=a-2$ bands are rather unusual.

Note that if instead we use $\psi(x)=\mathrm{sn}(y)\mathrm{dn}^{a-1}(y,m)$, which is also one of the exact eigenfunctions of the above AL potential, then nothing different is obtained. In particular, the corresponding partner potential is $[(a-1)a,(a-1)a,0,2]$ which is strictly isospectral to the potential $[(a-1)a,\ (a-1)a,\ 2,\ 0]$.

Let us now consider the PT-invariant AL potential $[a(a+1),(a-3)(a-2),0,0]$, i.e., the potential (3) with $b=a-3$, $f=g=0$. As shown by us,[5] one of its exact band-edge eigenfunctions is $\psi(x)=\mathrm{sn}(y)\mathrm{cn}(y)\mathrm{dn}^{a-2}(y)$. It is easy to see that the corresponding partner potential V_+ (up to a constant) is the potential $[(a-1)a,(a-2)(a-1),2,2]$ in the notation of (3). Thus we immediately conclude that when a, b are integers, then this PT-invariant potential is strictly isospectral to the AL potential $[a(a+1),(a-3)(a-2),0,0]$, has a band gaps and a bands, out of which $b=a-3$ bands are rather unusual.

We can generalize the above arguments. In particular, we find that the number (and even structure) of the potentials $[(a-p)(a-p+1),(a-p-1)(a-p),p(p+1),p(p+1)]$ is the same as the AL potentials $[a(a+1),(a-2p-1)(a-2p),0,0]$. For example, as remarked in the preceding section, if $b=a-2p-1$ $(p=0,1,2,\ldots)$, then there are p eigenstates of the form $\mathrm{sn}(y)\mathrm{cn}(y)\mathrm{dn}(y)F_{p-1}(\mathrm{sn}^2(y))$, $p+1$ eigenstates of the form $\mathrm{dn}^{a-2p}(y)F_p(\mathrm{sn}^2(y))$, $a-p$ eigenstates of the form $\mathrm{cn}(y)\mathrm{dn}^{2p+1-a}(y)F_{a-p-1}(\mathrm{sn}^2(y))$, and also $a-p$ eigenstates of the form $\mathrm{sn}(y)\mathrm{dn}^{2p+1-a}(y)F_{a-p-1}(\mathrm{sn}^2(y))$. Using Table IV it is easy to show that for the GAL potential $[(a-p)(a-p+1),\ (a-p-1)(a-p),p(p+1),p(p+1)]$, there are p eigenstates of the form $\mathrm{sn}^{-p}(y)\mathrm{cn}^{-p}(y)\mathrm{dn}^{1+p-a}(y)F_{p-1}(\mathrm{sn}^2(y))$, $p+1$ eigenstates of the form $\mathrm{dn}^{a-p}(y)\mathrm{cn}^{-p}(y)\mathrm{sn}^{-p}(y)F_p(\mathrm{sn}^2(y))$, $a-p$ eigenstates of the form $\mathrm{cn}^{p+1}(y)\mathrm{sn}^{-p}(y)\mathrm{dn}^{p+1-a}(y)F_{a-p-1}(\mathrm{sn}^2(y))$, and also $a-p$ eigenstates of the form $\mathrm{sn}^{p+1}(y)\mathrm{cn}^{-p}(y)\mathrm{dn}^{p+1-a}(y)F_{a-p-1}(\mathrm{sn}^2(y))$. In fact we believe that all the band-edge eigenvalues of the potentials $[a(a+1),(a-2p)(a-2p+1),0,0]$ and $[(a-p)(a-p+1),(a-p-1)(a-p),\ p(p+1),p(p+1)]$ are identical. While this is easily shown for low values of a and p, a general proof is still lacking.

Similarly, we can show that the number (and even structure) of the potentials $[(a-p)(a-p+1),(a-p)(a-p+1),p(p+1),(p-1)p]$ is the same as the AL potentials $[a(a+1),(a-2p)(a-2p+1),0,0]$. In particular, for the AL potential, as shown in Sec. II, when $b=a-2p$, then there are p eigenstates of the form $\mathrm{cn}(x)\mathrm{dn}^{a-2p+1}(x)F_{p-1}(\mathrm{sn}^2(x))$, p eigenstates of the form $\mathrm{sn}(x)\mathrm{dn}^{a-2p+1}(x)F_{p-1}(\mathrm{sn}^2(x))$, $a-p$ eigenstates of the form $\mathrm{sn}(x)\mathrm{cn}(x)\mathrm{dn}^{2p-a}(x)F_{a-p-1}(\mathrm{sn}^2(x))$, and $a-p+1$ eigenstates of the form $\mathrm{dn}^{2p-a}(x)F_{a-p}(\mathrm{sn}^2(x))$. It is easily shown that for the potential $[(a-p)(a-p+1),(a-p)(a-p+1),p(p+1),(p-1)p]$, there are $4a-1$ QES states of similar form. In particular, there are p eigenstates of the form $\mathrm{sn}^{-p}(y)\mathrm{cn}^{1-p}(y)\mathrm{dn}^{p-a}(y)F_{p-1}(\mathrm{sn}^2(y))$, p eigenstates of the form $\mathrm{dn}^{a+1-p}(y)\mathrm{cn}^{1-p}(y)\mathrm{sn}^{-p}(y)F_{p-1}(\mathrm{sn}^2(y))$, $a-p+1$ eigenstates of the form $\mathrm{cn}^{p}(y)\mathrm{sn}^{-p}(y)\mathrm{dn}^{p-a}(y)F_{a-p}(\mathrm{sn}^2(y))$ and also $a-p$ eigenstates of the form $\mathrm{sn}^{p+1}(y)\mathrm{cn}^{1-p}(y)\mathrm{dn}^{p-a}(y)F_{a-p-1}(\mathrm{sn}^2(y))$. In fact we believe that all the band-edge eigenvalues of the potentials $[a(a+1),(a-2p)(a-2p+1),0,0]$ and $[(a-p)(a-p+1),(a-p)(a-p+1),p(p+1),(p-1)p]$ are identical. While this is easily shown for low values of a and p, we do not yet have a general proof.

C. SUSY partners of potentials with $b=f=0$

Let us now consider the SUSY partners of the potential $[a(a+1),0,0,g(g+1)]$ which for integral values of a,g, is a problem with a finite number of band gaps. By exactly following the above discussion about the PT-invariant AL potential, we can construct a host of potentials with a finite number of band gaps. For example, by starting from the potential $[6,0,0,2]$ and following the procedure as in the AL case, we can easily obtain four SUSY partner potentials, all with two band gaps.

From Table I we observe that for integral a, two of the exact eigenfunctions of the potential $[a(a+1),0,0,(a-2)(a-1)]$ with a band gaps are $\mathrm{cn}(y)\mathrm{sn}^{a-2}(y)$ and $\mathrm{dn}(y)\mathrm{sn}^{a-2}(y)$. It is easily seen

that if we start with either of these eigenfunctions, then the corresponding SUSY partner potential with the same finite (a) number of band gaps is the potential $[(a-1)a,2,0,(a-1)a]$(or its isospectral partner $[(a-1)a,0,2,(a-1)a]$).

From Table I we also observe that one of the exact eigenfunctions of the potential $[a(a+1),0,0,(a-3)(a-2)]$ is $\mathrm{cn}(y,m)\mathrm{dn}(y,m)\mathrm{sn}^{a-3}(y,m)$. On starting with this eigenfunction, it is easily shown that the corresponding SUSY partner potential is $[(a-1)a,2,2,(a-2)(a-1)]$ which therefore must also be a potential with finite (a) number of band gaps when a is an integer.

Similarly, by starting from the finite band-gap potentials $[a(a+1),0,0,(a-2p-1)(a-2p)]$ as well as $[a(a+1),0,0,(a-2p)(a-2p+1)]$, and following the discussion in the case of PT-invariant AL potential, it is easily shown that the corresponding GAL potentials with the same (finite) number of band gaps are $[(a-p)(a-p+1),p(p+1),p(p+1),(a-p-1)(a-p)]$ and $[(a-p)(a-p+1),p(p+1),(p-1)p,(a-p)(a-p+1)]$, respectively, where a and p are positive integers.

D. SUSY partners of potentials with $b=g=0$

Let us now consider the SUSY partners of the PT-invariant potential $[a(a+1),0,f(f+1),0]$. From Table II we observe that two of the exact eigenfunctions of the potential $[a(a+1),0,(a-2)\times(a-1),0]$ are $\mathrm{sn}(y)\mathrm{cn}^{a-2}(y)$ and $\mathrm{dn}(y)\mathrm{cn}^{a-2}(y)$. It is easily seen that if we start with either of these eigenfunctions, then the corresponding GAL potentials turn out to be $[(a-1)a,2,(a-1)a,0]$ or $[(a-1)a,0,(a-1)a,2]$. Since we know that the potentials $[a(a+1),a(a-1),2,0]$ as well as $[a(a+1),2,0,(a-1)a]$ have a finite number of band gaps, we conjecture that maybe the potential $[a(a+1),2,(a-1)a,0]$ also has only a finite number (a) of band gaps when a is an integer.

From Table II we also observe that one of the exact eigenfunctions of the potential $[a(a+1),0,(a-3)(a-2),0]$ is $\mathrm{sn}(y)\mathrm{dn}(y)\mathrm{cn}^{a-3}(y)$. Starting with this eigenfunction, it is easily shown that the corresponding SUSY partner potential is $[(a-1)a,2,(a-2)(a-1),2]$. Again, since for integer a, the potential $[(a-1)a,(a-2)(a-1),2,2]$ has only a finite number of band gaps, it is tempting to conjecture that the same may also be true for the potential $[(a-1)a,2,(a-2)(a-1),2]$.

Similarly, by starting from the finite band-gap potentials $[a(a+1),0,(a-2p-1)(a-2p),0]$ as well as $[a(a+1),0,(a-2p)(a-2p+1),0]$, and following the discussion in the case of PT-invariant AL potentials, it is easily shown that the corresponding SUSY partners with the same number of band gaps are the GAL potentials $[(a-p)(a-p+1),p(p+1),p(p+1),(a-p-1)(a-p)]$ and $[(a-p)\times(a-p+1),p(p+1),(p-1)p,(a-p)(a-p+1)]$, respectively, when a and p are integers.

E. SUSY partners of potentials with $f=0$

Let us now consider the SUSY partners of the potential $[a(a+1),b(b+1),0,g(g+1)]$. From Table III we observe that one of the exact eigenfunctions is $\mathrm{dn}^{-b}(y)\mathrm{sn}^{-g}(y)$ when $a+b+g=0$. If we start with this eigenfunction, then the corresponding SUSY partner potential turns out to be $[(a-1)a,(b-1)b,0,(g-1)g]$.

From Table III we also observe that an exact eigenfunction of the potential $[a(a+1),b(b+1),0,g(g+1)]$ is $\mathrm{cn}(y)\mathrm{dn}^{-b}(y)\mathrm{sn}^{-g}(y)$ when $a+b+g=1$. Starting with this eigenfunction, it is easily shown that the corresponding SUSY partner potential is $[(a-1)a,(b-1)b,2,(g-1)g]$.

In summary, we have discovered a large number of complex PT-invariant periodic potentials with a finite number of band gaps, many occurring when the parameters a,b,c,d have specific integer values. This leads us to make the plausible conjecture that all GAL potentials (3) for integer values of a,b,f,g have a finite number of band gaps, but there is as yet no formal proof.

IV. HEUN'S EQUATION AND THE GENERALIZED ASSOCIATED LAMÉ EQUATION

In this section, we point out an interesting connection between Heun's differential equation[7] and the generalized associated Lamé equation (5). This connection enables us to use the various solutions of Eq. (5) obtained in this paper to write down several solutions of Heun's equation which have apparently not been studied in the mathematics literature.

The canonical form of Heun's equation is given by[7]

$$\left[\frac{d^2}{dx^2}+\left(\frac{\gamma}{x}+\frac{\delta}{x-1}+\frac{\epsilon}{x-c}\right)\frac{d}{dx}+\frac{\alpha\beta x-q}{x(x-1)(x-c)}\right]G(x)=0, \tag{47}$$

where α, β, γ, δ, ϵ, q, c are real parameters, except that $c\neq 0,1$ and the first five parameters are constrained by the relation

$$\gamma+\delta+\epsilon=\alpha+\beta+1. \tag{48}$$

If we make the transformation $x=\mathrm{sn}^2(y,m)$, then Heun's equation takes the form[7]

$$F''(y)+\left[(1-2\epsilon)m\frac{\mathrm{sn}(y)\mathrm{cn}(y)}{\mathrm{dn}(y)}+(1-2\delta)\frac{\mathrm{sn}(y)\mathrm{dn}(y)}{\mathrm{cn}(y)}+(2\gamma-1)\frac{\mathrm{cn}(y)\mathrm{dn}(y)}{\mathrm{sn}(y)}\right]F'(y)$$
$$-[4mq-4\alpha\beta m\,\mathrm{sn}^2(y)]F(y)=0, \tag{49}$$

where $[G(x)\equiv F(y)]$ and $m=1/c$. It is interesting to note that Eq. (49) is very similar to the ϕ equation (14) which we have analyzed in great detail. In particular, with the identification

$$b=\tfrac{1}{2}-\epsilon,\quad f=\tfrac{1}{2}-\delta,\quad g=\tfrac{1}{2}-\gamma,\quad b+f+g=\tfrac{1}{2}-\alpha-\beta,\quad 4\alpha\beta=Q,\quad 4mq=R, \tag{50}$$

all the results discussed above can be immediately used to obtain different solutions of Heun's equation. It turns out that using the midband states obtained in Sec. II, one generates quasiperiodic solutions of Heun's equation (49), which we discuss in a separate presentation.[8]

(Received 27 December 2004; accepted 17 June 2005; published online 15 August 2005)

We investigate the so-called localizable information of bipartite states and a parallel notion of information deficit. Localizable information is defined as the amount of information that can be concentrated by means of classical communication and local operations where only maximally mixed states can be added for free. The information deficit is defined as difference between total information contents of the state and localizable information. We consider a larger class of operations, the so-called PPT operations, which in addition preserve maximally mixed state (PPT-PMM operations). We formulate the related optimization problem as a semidefinite program with suitable constraints. We then provide bound for fidelity of transition of a given state into product pure state on Hilbert space of dimension d. This allows to obtain a general upper bound for localizable information (and also for information deficit). We calculated the bounds exactly for Werner states and isotropic states in any dimension. Surprisingly it turns out that related bounds for information deficit are equal to relative entropy of entanglement (in the case of Werner states, regularized one). We compare the upper bounds with lower bounds based on simple protocol of localization of information. © *2005 American Institute of Physics.*

I. INTRODUCTION

In recent developments[1,2] an idea of localizing (or concentrating) information in paradigm of distant laboratories was devised. It originated from the concept of drawing thermodynamical work from heat bath and an additional physical system used as entropy sink (see, e.g., Refs. 3 and 4). Namely, using one qubit in pure state, one can draw $kT\ln 2$ of work[5] from heat bath of temperature T. More generally, using n qubit state ρ one can draw $n-S(\rho)$ of work. (We neglect the obvious factor $\ln kT$, counting work in bits.) In Ref. 1 this idea was applied to the distant laboratory paradigm. There are distant parties, who share some n qubit quantum state, and have local heat baths of temperature T. If the parties can communicate quantum information, then they can use the shared state to draw $n-S(\rho)$ bits of work. This can be achieved, by sending the whole subsystem to one party. The party can then draw work from local heat bath by use of the total state. However, if they can only use local operations and classical communication (LOCC), then they usually will not be able to draw such amount of work. Indeed, if they try to send all subsystems to one party, the state will be decohered, due to transmission via classical channel. Thus all quantum correlations will disappear, which will result in increase of entropy of the state to some value $S'>S$, so that we will observe a difference between total information $n-S$ and information localizable by LOCC. The difference is called quantum deficit and denoted by Δ.

Since it represents the information that must be destroyed during travel through classical channel, it reports quantumness of correlations of a state. In this way tracing what is local, we can also understand what is nonlocal.

The basic problem arises. *Given a quantum compound state, how much information can be localized by LOCC?* Or, equivalently, *how large is quantum deficit for a given state?* For pure state the answer is known,[2] the amount of information that cannot be localized is precisely the entanglement of formation of the state,[6] given by entropy of the subsystem. However, for mixed states even separable states can have nonzero deficit. Thus the deficit can account for quantumness that is not covered by entanglement. One could also expect that deficit is the measure of all quantumness of correlations, so that reasonable entanglement measures should not exceed it. In any case, it is important to evaluate deficit for different states.

In Ref. 2 the problem of localizing information into a subsystem was translated into a problem of distilling pure local states. In this paper, basing on this concept, we provide general upper bound for the localizable information, which gives in turn lower bound for information deficit. We compute the bound for symmetric states, like Werner states[7] and isotropic states.[8] We use the method of semidefinite programming following Rains approach to the problem of entanglement distillation.[9] Though our problem is quite opposite, instead of singlets, we want to draw pure product states, the technique can be still applied, and the bounds we obtain share some features of Rains bound for distillable entanglement. Even more suprisingly, the bounds for information deficit obtained for Werner and isotropic states are just *equal* to Rains bounds for those states, which in turn are equal to relative entropy of entanglement (regularized in the case of Werner states). We also present lower bounds, obtained by some specific protocols of localizing information.

II. PRELIMINARIES

In this section we will provide some definitions. The set of linear operators on Hilbert space $\mathcal{H}$ will be denoted as $\mathcal{B}(\mathcal{H})$. By $\mathcal{H}$ we will mean finite dimensional Hilbert space with a fixed isomorphism to $\mathcal{C}^d$, where $d=\dim \mathcal{H}$. For a vector $|\psi\rangle \in \mathcal{H}$, the projector $P=|\psi\rangle\langle\psi|$ is a pure state represented by this vector. Any mixed state is a mixture of such projectors, i.e., it is of the form $\rho=\Sigma_i p_i|\psi_i\rangle\langle\psi_i|$, where $\{p_i\}$ is a probability distribution. Equivalently, a state is positive operator on $\mathcal{H}$ with trace one.

We will need the notion of positive and negative parts of the operator. An operator A is Hermitian if $A=A^\dagger$ where $\dagger$ denotes Hermitian conjugation. The set of Hermitian operators acting on $\mathcal{H}$ will be denoted as $\chi(\mathcal{H})$. For Hermitian operator $H \in \mathcal{B}(\mathcal{H})$ positive H_+ and negative H_- parts are defined by $H_+ - H_- = H$ and $H_+ H_- = 0$, i.e., $H_+ = \Sigma_i \lambda_i^+ |\psi_i^+\rangle\langle\psi_i^+|$, $H_- = \Sigma_i \lambda_i^- |\psi_i^-\rangle\langle\psi_i^-|$ where $\lambda_i^+ (\lambda_i^-)$ are non-negative (negative) eigenvalues and $\psi_i^\pm$ are corresponding eigenvectors.

Trace norm and operator norm will be denoted by $\|.\|_{\mathrm{tr}}$ and $\|.\|_{\mathrm{op}}$, respectively, where

$$\|A\|_{\mathrm{tr}} = \mathrm{Tr}|\sqrt{AA^\dagger}|, \tag{1}$$

$$\|A\|_{\mathrm{op}} = \sup_{\|\psi\|=1} \|A|\psi\rangle\|. \tag{2}$$

We shall consider composite quantum systems which are represented by tensor product of Hilbert spaces $\mathcal{H}_{AB} = \mathcal{H}_A \otimes \mathcal{H}_B \simeq C^{d_A} \otimes C^{d_B}$, where $\mathcal{H}_A$ and $\mathcal{H}_B$ are spaces of subsystems A and B. There are two kinds of states, separable and entangled ones. Separable state ϱ_{sep} can be written as a convex combination of products of states

$$\varrho_{\mathrm{sep}} = \sum_k p_k \rho_k^A \otimes \sigma_k^B, \tag{3}$$

where ρ_k^A and ρ_k^B are states acting on Hilbert spaces $\mathcal{H}_A$ and $\mathcal{H}_B$, respectively. Entangled state are those that cannot be written in form (3).

Some of the obtained results will hold for any bipartite states, and some will be shown for specific classes of the states. We shall consider two well known classes of symmetric states, Werner states[7] and isotropic states,[8] which we recall here.

The Werner states are the states acting on Hilbert space $\mathcal{C}^d \otimes \mathcal{C}^d$, which do not change if subjected to the same unitary transformation to both subsystems,

$$\varrho = U \otimes U \varrho U^\dagger \otimes U^\dagger \tag{4}$$

for any unitary U. Such states have the following form:[7]

$$\varrho_W = \frac{1}{d^2 + \mathrm{d}\beta}(I + \beta V), \quad -1 \leqslant \beta \leqslant 1, \tag{5}$$

where V is a unitary flip operator V acting on Hilbert space $\mathcal{C}^d \otimes \mathcal{C}^d$ system defined by $V\phi \otimes \varphi = \varphi \otimes \phi$. Another useful form of ϱ_W is

$$\varrho_W = p\frac{P_A}{N_A} + (1-p)\frac{P_S}{N_S}, \tag{6}$$

where $P_S = (I+V)/2$ and $P_A = I - P_S$ are projectors onto symmetric and antisymmetric subspaces of total space, respectively. $N_A = (d^2-d)/2$ and $N_S = (d^2+d)/2$ are the dimensions of the antisymmetric and symmetric subspaces, respectively.

The isotropic states are those bipartite states which are invariant under $U \otimes \bar{U}$ transformations[8] (where $\bar{U}$ is complex comjugate of U). They are of the following form:

$$\varrho_{\mathrm{iso}} = \lambda P_+ + \frac{1-\lambda}{d^2} I, \qquad \lambda \in \left[-\frac{1}{d}, 1\right], \tag{7}$$

where P_+ is a projector onto maximally entangled state $|\psi\rangle_+ = \Sigma_{k=1}^d (1/\sqrt{d})|kk\rangle$ (which one can call the singlet state) and I/d^2 is the maximally mixed state.

We will consider states that have more than two subsystems, however we will always consider a distinguished cut dividing groups of subsystems into two groups. For example, we can have state $\rho_{AA'B'}$ which is tripartite, though from our point of view it is a bipartite state of two subsystems AA' and B.

In the paper we consider some transformations of the bipartite state. Apart from transformations that have physical meaing it is good, for technical reasons, to consider some purely mathematical transformations as well. For this reason we recall here the operation of partial transposition, and its basic properties. Namely it is a linear map $\Gamma : \mathcal{B}(\mathcal{H}_A \otimes \mathcal{H}_B) \to \mathcal{B}(\mathcal{H}_A \otimes \mathcal{H}_B)$ which acts on a state with matrix elements ρ_{ijkl},

$$\rho_{AB} = \sum_{i,k=1}^{d_A} \sum_{j,l=1}^{d_B} \rho_{ijkl} |ij\rangle\langle kl| \tag{8}$$

as the following permutation:

$$\rho_{AB}^\Gamma = \sum_{i,k=1}^{d_A} \sum_{j,l=1}^{d_B} \rho_{ijkl} |il\rangle\langle kj|. \tag{9}$$

The state is written in a canonical product basis $\{|ij\rangle\}$. This map has useful properties. For any operators A and B one has

$$(\Gamma_1) \quad \mathrm{Tr}\, A^\Gamma = \mathrm{Tr}\, A,$$

$$(\Gamma_2) \quad \mathrm{Tr}\, A^\Gamma B = \mathrm{Tr}\, A B^\Gamma,$$

$$(\Gamma_3) \quad \mathrm{Tr}(AB) = \mathrm{Tr}\, A^{\Gamma} B^{\Gamma},$$

$$(\Gamma_4) \quad (A^{\Gamma})^{\Gamma} = A,$$

$$(\Gamma_5) \quad \Gamma \text{ preserves Hermiticity}. \tag{10}$$

Note, that (Γ_2) follows from (Γ_1), (Γ_3), and (Γ_4), but we state it separately for clarity. The operator ρ^{Γ} depends on the chosen basis $\{|ij\rangle\}$, however its eigenvalues do not.

In QIT one investigates processing of quantum state by means of different subclasses of all physical operations. In this paper we consider the following classes, given below.

Class of *quantum operations* (QO) is the set of completely positive,[10,11] trace preserving maps (CPTP) i.e. (as it has been shown by Choi and Kraus[10–13]), for Hilbert spaces $\mathcal{H}_1$, $\mathcal{H}_2$, with dimensions d_1 and d_2 respectively,

$$\mathrm{QO} = \left\{ \Lambda : \pi(\mathcal{H}_1) \to \pi(\mathcal{H}_2) \middle| \forall_{B \in \pi(\mathcal{H}_1)} \Lambda(B) = \sum_{i=1}^{d_1 d_2} V_i B V_i^{\dagger}, V_i : \mathcal{H}_1 \to \mathcal{H}_2, \sum_{i=1}^{d_1 d_2} V_i^{\dagger} V_i = I \right\} \tag{11}$$

the operators V_i are often referred to as Kraus operators.

Quantum operation can be composed out of the following operations:

(i) unitary transformations, $\rho \to U \rho U^{\dagger}$;
(ii) adding ancilla, $\rho \to \rho \otimes \sigma$;
(iii) discarding subsystem $\rho_{AB} \to \rho_A = \mathrm{Tr}_B \rho_{AB}$.

Class of *noisy operations* (NO) is a subclass of the QO class. This differs from them by restriction that we allow adding only maximally mixed ancillas, i.e., $\sigma = I/d$ where d is dimension of the added system.

Class of *local quantum operations and classical communication* (LOCC) is defined for states from $\pi(\mathcal{H}_A \otimes \mathcal{H}_B)$. By LOCC operations on the bipartite system of n_{AB} qubits we mean all operations that can be composed out of

(i) local unitary transformations $\rho_{AB} \to U_A \otimes U_B \rho_{AB} U_A^{\dagger} \otimes U_B^{\dagger}$,
(ii) sending subsystem down completely decohering (dephasing) channel $\rho_{AA'B} \to \rho_{AB'B} = I_{AB} \otimes \Lambda$ where $\Lambda : \mathcal{B}(\mathcal{H}_{A'}) \to \mathcal{H}_{B'}$ is a composition of the complete von Neumann measurement performed on subsystem A' given by

$$\Lambda'(\cdot) = \sum_i P_i(\cdot) P_i, \tag{12}$$

where P_i are one-dimensional projectors satisfying $\Sigma_i P_i = I_{A'}$ and an operation that transfers subsystem A' into B' (the spaces $\mathcal{H}_{B'}$ and $\mathcal{H}_{A'}$ must be equal, and we assume some fixed isomorphism between them; then the map of transfer acts simply as identity on AB tensored with the isomorphism),
(iii) adding local ancilla $\rho_{AB} \to \rho_{A'} \otimes \rho_{AB}$,
(iv) discarding local subsystem $\rho_{A'AB} \to \rho_{AB} = \mathrm{Tr}_{A'} \rho_{A'AB}$.

Class of *noisy quantum operations and classical communication* (NLOCC) is a subclass of the LOCC class. The difference is that we allow to add only the maximally mixed state as an ancilla.

By NLOCC operations on the bipartite system of n_{AB} qubits we mean all operations that can be composed out of

(i) local unitary transformations,
(ii) sending subsystem from the down completely decohering (dephasing) channel,
(iii) adding ancilla in the maximally mixed state,
(iv) discarding local subsystem.

Class of *PPT* operations. They have been introduced by Rains in Ref. 14 and are defined as those CPTP maps Λ, which conjugated with partial transposition, $\Gamma\circ\Lambda\circ\Gamma$ are still legitimate CPTP maps.

Class of *PPT maps which preserves maximally mixed state* (PPT-PMM) is given by the intersection of class of PPT operations, and those linear maps $\Lambda:\mathcal{H}_1\to\mathcal{H}_2$ with $d_{\text{in}}=\dim\mathcal{H}_1$ and $d_{\text{out}}=\dim\mathcal{H}_2$, which satisfies

$$\Lambda\left(\frac{\mathrm{I}}{d_{\text{in}}}\right)=\frac{\mathrm{I}}{d_{\text{out}}}. \tag{13}$$

In the context of distant laboratory paradigm, all but the two last classes have operational meaning, while the last two ones are some abstract subclasses of quantum operations. For these classes, the following inclusions holds:

$$\text{NLOCC}\subset\text{PPT-PMM}\subset\text{QO},\quad \text{NLOCC}\subset\text{LOCC}\subset\text{QO},\quad \text{NLOCC}\subset\text{NQ}\subset\text{QO}. \tag{14}$$

Using this, one can study features of operational class NLOCC, considering mathematical, i.e., more easy to deal with, PPT-PMM class.

A. Paradigm of localizing information

In any paradigm of manipulating states by operations the basic notion is *rate of transition*. Given a class of operations, one can ask, at what rate it is possible to transform state ρ into σ, given large amount of n independent copies of ρ, where ρ and σ act on Hilbert space $\mathcal{H}=\mathcal{H}_A\otimes\mathcal{H}_B$,

$$\rho^{\otimes n}\to\sigma^{\otimes m}. \tag{15}$$

In our case the target state σ will be a pure product state $|0\rangle|0\rangle$ on Hilbert space $C^2\otimes C^2$, and the class of allowed operations will be the NLOCC class, since we consider the scenario introduced in Ref. 1. Namely, Alice and Bob are given some bipartite state ρ acting on $\mathcal{C}^d\otimes\mathcal{C}^d$ and their task is to obtain from this state the greatest possible amount of $C^2\otimes C^2$ systems in bipartite pure product state $|0\rangle|0\rangle$ by means of noisy operations and classical communication. Clearly, to achieve this goal they should try to avoid producing much entropy, since any entropy increase would decrease the amount of desired (pure) output systems. The task can be viewed as localizing information, since the bipartite system in the pure product state has the maximal amount of local information contents.

To state it formally we provide here definition of *localizable information* I_l.

Definition 1: For any given state $\rho_{AB}\in\mathcal{C}^d\otimes\mathcal{C}^d$ *let us consider sequence* P_n *of NLOCC operations such that* $P_n(\rho_{AB}^{\otimes n})=\sigma_n$, *where* σ_n *acting on* $(\mathcal{C}^2\otimes\mathcal{C}^2)^{\otimes m_n}$.

Set of operations $\mathcal{P}\equiv\cup_{n=1}^{\infty}\{P_n\}$ *is called a protocol of localizing information if there holds*

$$\lim_{n\to\infty}\|\sigma_n-P_{00}^{\otimes m_n}\|_{\text{Tr}}=0, \tag{16}$$

with $P_{00}=|00\rangle\langle 00|$ *acting on* $\mathcal{C}_2\otimes\mathcal{C}_2$. *For given protocol* $\mathcal{P}$, *its rate is given by*

$$r_{\mathcal{P}}(\rho_{AB})=\lim_{n,d_n\to\infty}\sup\frac{2m_n}{n}. \tag{17}$$

Then the localizable information of state ρ_{AB} *is given by*

$$I_l(\rho_{AB})=\sup_{\mathcal{P}} r_{\mathcal{P}}(\rho_{AB}). \tag{18}$$

We will write $r_{\mathcal{P}}$ omitting the state ρ_{AB} if it will not lead to confusion. Please note, that for any protocol $\mathcal{P}$, its rate $r_{\mathcal{P}}$ gives the lower bound on optimal rate, i.e., on localizable information I_l. It

is then easy to obtain a bound on I_l by considering protocol $\mathcal{P}$ which needs only one-way (say from Alice to Bob) communication. A rate gained by such one-way protocol will be denoted as $r_{\mathcal{P}}^{\rightarrow}$.

Please note, that this definition is nontrivial, due to the choice of class of allowed operations. We can see it when replacing in the above definition NLOCC class with larger class of quantum operations NO.[15,2,16] The information which can be localized is in this case (due to Schumacher compression) equal to the information contents of the state, i.e., $I_{\mathrm{tot}}=n-S(\rho_{AB})$, where n is the number of qubit the state ρ_{AB} occupies. The completely trivial answer is obtained only when one uses operations without the prefix N, i.e., either QO or LOCC. Then the quantity would be always equal to infinity, because within these classes it is possible to add unlimited amount of systems in pure state.

Having defined localizable information we can proceed to recall here the definition of information deficit. The information deficit Δ equals difference between the mentioned total information content of the state I_{tot} and the localizable information I_l

Definition 2: For any bipartite state ρ_{AB} which acts on Hilbert space $\mathcal{H}_A\otimes\mathcal{H}_B$, the information deficit Δ is given by

$$\Delta(\rho_{AB}) = n - S(\rho_{AB}) - I_l(\rho_{AB}), \tag{19}$$

where $n=\log d_A+\log d_B$ is the number of qubits which ρ_{AB} occupies.

This quantity tells us to what extent the optimal process of localizing information is irreversible. In other words, how much of the total information content of the state is of the nonlocal form in a sense that it cannot be transformed into a local form, but gets destroyed during the localization process. For technical reasons, instead of norm condition (16) we will consider condition for fidelity,

$$\lim_{n\to\infty} \widetilde{F}(\sigma_n, P_{00}^{\otimes d_n}) = 1. \tag{20}$$

Those conditions are shown to be equivalent in Ref. 17. Fidelity is defined as

$$\widetilde{F}(\rho,\sigma) = \mathrm{Tr}\sqrt{\sqrt{\sigma}\rho\sqrt{\sigma}}. \tag{21}$$

In our case the state σ is pure so that we have a simpler expression,

$$F(\rho,\sigma) = \sqrt{\mathrm{Tr}\,\rho\sigma}. \tag{22}$$

Now, the monotonicity of the square root, allows for considering the quantity $F(\rho,\sigma)=\mathrm{Tr}\,\rho\sigma$.

Since the information deficit Δ reports some nonlocality of the state, it would be of great interest to compare this quantity with the well-known functions of nonlocal parameters of the state—entanglement measures. Let us here recall the main definitions of the entanglement measures, that we shall refer to when comparing with information deficit Δ. For any states ϱ and σ acting on $\mathcal{C}^d\otimes\mathcal{C}^{d'}$ we have, among others, the following functions:

(1) *Entanglement of distillation E_D* (Ref. 6) is a maximal number of singlets per copy distillable by LOCC operations from the state ϱ in asymptotic regime of $n\to\infty$ copies.
(2) *Entanglement of formation*[6] E_f is defined as

$$E_f(\rho) = \inf_{\{p_i,\rho_i\}} \sum_i p_i S(\rho_{\mathrm{red}}^i), \tag{23}$$

where the infimum is taken over all decompositions of state ρ, i.e., ensembles $\{p_i,\rho_i\}$ satisfying $\rho=\Sigma_i p_i\rho_i$, and $S(\rho_{\mathrm{red}}^i)$ being von Neumann entropy of the subsystem of state ρ^i.
(3) *Entanglement cost E_c* (Refs. 6 and 18) is the minimal number of singlets per copy needed to create a state ϱ by LOCC operations in asymptotic regime of $n\to\infty$ copies.
(4) *Relative entropy of entanglement E_R* (Ref. 19) is defined as follows:

$$E_R(\varrho) = \inf_{\sigma_{\text{sep}}} S(\varrho|\sigma), \tag{24}$$

where $S(\varrho|\sigma) = \text{tr}\,\varrho \log_2 \varrho - \text{tr}\,\varrho \log_2 \sigma$ is relative entropy and the infimum is taken over all separable states σ.

For an entanglement measure E, its regularization is denoted by E^∞ given by $\lim_{n\to\infty}[E(\varrho^{\otimes n})/n]$. In this paper we will consider regularized relative entropy of entanglement E_r^∞. Comparison of work deficit with E_f will also be important, for it has been proven[18] that regularized entanglement of formation E_f^∞ equals entanglement cost of the state E_c.

In this paper we will not use definitions of these entanglement measures. We will only need values of those measures for the mentioned symmetric states, which one can find in the literature.

III. BOUNDS ON THE FIDELITY OF TRANSITIONS

Given a quantum mixed state ρ one may ask how much of the information it contains which can be concentrated to a local form.[1] In other words, how many pairs of pure *product* states P_{00} can one achieve from ρ per copy of ρ in asymptotic regime under noisy local operations and classical communication (NLOCC).[2] The class of NLOCC maps is rather difficult to deal with. Then similarly as in entanglement theory, it is more convenient to consider some larger class that has clear mathematical characterization. In Ref. 14 a class of PPT maps was introduced which is larger than LOCC. In our case, the analogous larger class will be PPT-PMM maps. If we are able to get upper bound for the rate of distillation of pure product states with this class it will be also upper bound for rate achievable by NLOCC maps. Our analysis of the rate under PPT-PMM maps, will be analogous to the analysis of distillation of entanglement in Ref. 9. Having fixed the rate of conversion from ρ to P_{00} we evaluate the fidelity of conversion, i.e., the overlap of the current output with desired output. If the fidelity can approach 1 in limit of many input copies, the rate is attainable.

Let us then fix the rate r which means, that for n input copies of a given state we will obtain $m = \lfloor nr/2 \rfloor$ output copies. The m pairs are in a final joint state $\rho' = \Lambda(\rho^{\otimes n})$, where Λ is an operation of conversion. In the following we will assume, that operations of conversion (operations) are PPT-PMM. Then we will maximize the following quantity:

$$F_n = \text{Tr}[P_{00}^{\otimes m} \Lambda(\rho^{\otimes n})]. \tag{25}$$

The fidelity F is a function of n, since the rate r is fixed. Our general argument will be the following. If for given rate F optimized over such operations is smaller than one, then the rate is not achievable. Infimum over such rates is the upper bound for the optimal achievable rate, hence for I_L.

We will optimize F in two stages. First we will change the problem of optimization over Λ to optimization over set of some positive operators Π, which fulfills some (rather complicated) constraints. We will however not optimize F over those constraints. Rather, in second stage by duality method used in semidefinite programming we will find the bound on F expressed as infimum over Hermitian operators (without any additional constraints). We will then obtain bounds for localizable information for Werner and isotropic states by choosing appropriate Hermitian operator or by optimizing over a class of Hermitian operators.

It is useful to observe, that since Λ is a CPTP map we have

$$\text{Tr}[P_{00}^{\otimes m} \Lambda(\rho^{\otimes n})]\, \text{Tr}\left[P_{00}^{\otimes m} \sum_i V_i \rho^{\otimes n} V_i^\dagger \right] = \text{Tr}\left[\sum_i V_i^\dagger P_{00}^{\otimes m} V_i \rho^{\otimes n} \right], \tag{26}$$

where V_i are Kraus operators of the map. We used here the fact $\text{Tr}\,AB = \text{Tr}\,BA$ for any operators A and B. The map $\Sigma_i V_i^\dagger(\cdot)V_i \equiv \Lambda^\dagger$ is called dual map (with respect to Λ). It is clearly a CP map too (yet it need not be trace preserving). The meaning of dual maps to NLOCC operations is exhibited in Ref. 20. Here we are interested in the following operator:

$$\Pi = \Lambda^{\dagger}(P_{00}^{\otimes m}). \tag{27}$$

We can write fidelity by means of Π as follows:

$$F = \sup_{\Pi} \mathrm{Tr}[\rho^{\otimes n}\Pi], \tag{28}$$

where supremum is taken over all Π of the form (27). Let us now prove the following fact, which amounts to the first stage of optimization.

Fact 1: For given rate r and the number of input copies n of any state $\rho \in \mathcal{B}(C^d \otimes C^d)$, *the optimal fidelity is bounded by*

$$F \leqslant \sup_{\Pi} \mathrm{Tr}[\Pi(\rho^{\otimes n})], \tag{29}$$

where

$$0 \leqslant \Pi \leqslant I, \quad \Pi^{\Gamma} \geqslant 0, \quad \mathrm{Tr}\,\Pi = 2^{n(2\log d - r)} \equiv K. \tag{30}$$

This problem is a particular example of so-called semidefinite program. After proving the above fact we will provide the dual problem, which give bound for fidelity in the original problem (29).

Proof: We need to show that Π satisfies the displayed constraints. To this end we will use previously mentioned properties of partial transposition. Let us first check if the Π defined above operator fulfills the stated constraints. Actually, we will see, that $0 \leqslant \Pi \leqslant I$ is a consequence of the fact that Λ is CPTP map and that $P_{00}^{\otimes m} \leqslant \mathrm{I}$, and positivity of Π^{Γ} is a consequence of Λ being PPT map and the fact that $(P_{00}^{\otimes m})^{\Gamma} \geqslant 0$. We will use P instead of $P_{00}^{\otimes m}$ for convenient notation.

Positivity of Π is rather clear, since—as it came up—$\Lambda^{\dagger}$ is a positive map. Comparing Π with identity is simple, too. For any state σ we have $\sigma \leqslant \mathrm{I}$, which implies that for any positive operator A,

$$\mathrm{Tr}\,[\Lambda(A)\sigma] \leqslant \mathrm{Tr}\,\Lambda(A) = \mathrm{Tr}\,A, \tag{31}$$

where the equality expresses the fact that Λ is trace preserving. This however is equivalent to the

$$\mathrm{Tr}\,[A\Lambda^{\dagger}(\sigma)] \leqslant \mathrm{Tr}[AI] \tag{32}$$

which for $\sigma = P$ gives $\Pi \leqslant I$. To check positivity of partially transposed Π we need to show, that for any state σ,

$$\mathrm{Tr}\,[\sigma[\Lambda^{\dagger}(P)]^{\Gamma}] \geqslant 0. \tag{33}$$

Applying (Γ_2) of Eq. (11) one gets

$$\mathrm{Tr}\,[\sigma^{\Gamma}\Lambda^{\dagger}(P)] \geqslant 0, \tag{34}$$

what by definition of dual map is equivalent to

$$\mathrm{Tr}\,[\Lambda(\sigma^{\Gamma})P] \geqslant 0. \tag{35}$$

Applying subsequently (Γ_1) and (Γ_3) one ends up with

$$\mathrm{Tr}\,[(\Gamma\Lambda\Gamma)(\sigma)P^{\Gamma}] \geqslant 0, \tag{36}$$

which is true, since both $(\Gamma\Lambda\Gamma)(\sigma)$ and P^{Γ} are positive operators. First because Λ is a PPT map and second because P is a product state for which Peres separability criterion guarantees positivity of partial transposition.

To prove the last property of Π we use the fact that Λ is PMM, we then obtain

$$\mathrm{Tr}\,\Pi \equiv \mathrm{Tr}\,\Lambda^{\dagger}(P)\mathrm{I}_{\mathrm{in}} = d_{\mathrm{in}}\,\mathrm{Tr}\,P\Lambda\left(\frac{\mathrm{I}_{\mathrm{in}}}{d_{\mathrm{in}}}\right) = d_{\mathrm{in}}\,\mathrm{Tr}\,P\frac{I}{d_{\mathrm{out}}} = \frac{d_{\mathrm{in}}}{d_{\mathrm{out}}} = K, \tag{37}$$

where $d_{\mathrm{in}}=d^{2n}$ and $d_{\mathrm{out}}=2^{2m}$. This ends the proof. ■

Now, in a second stage of optimization of the fidelity, we can rearrange our task, using the concept of duality in semidefinite programming.

Theorem 1: *For any state* ρ *acting on Hilbert space* $\mathcal{C}^d\otimes\mathcal{C}^d$ *and a fixed rate* r,

$$F \leqslant \inf_{D\in\chi(\mathcal{H})}[\mathrm{Tr}(\rho - D)_+ + K\lambda_{\max}(D^{\Gamma})], \tag{38}$$

where $\lambda_{\max}(D^{\Gamma})$ *is the maximal eigenvalue of Hermitian operator* D^{Γ} *and* $K=2^{n(2\log d-r)}$.

Proof: By just adding and subtracting proper terms which is similar to the Lagrange multipliers method, using (Γ_2) we can state that for any operators A, B, and for any real parameter λ, we have

$$\mathrm{Tr}\,\Pi\rho = \mathrm{Tr}\,A - \mathrm{Tr}(-\rho + A - B^{\Gamma} + \lambda I)\Pi + \lambda K - \mathrm{Tr}\,A(I-\Pi) - \mathrm{Tr}\,B\Pi^{\Gamma} + \lambda(\mathrm{Tr}\,\Pi - K). \tag{39}$$

Now if A and B are positive operators and $A\geqslant\rho+B^{\Gamma}-\lambda\mathrm{I}$ we have

$$\mathrm{Tr}\,\Pi\rho \leqslant \mathrm{Tr}\,A + \lambda K, \tag{40}$$

since absent terms on the right-handside (RHS) are nonpositive according to the constraints on Π. Then

$$\sup_{\Pi}\mathrm{Tr}\,\Pi\rho \leqslant \inf_{A,B,\lambda}\mathrm{Tr}\left[A + \lambda\frac{K}{d^2}I\right], \tag{41}$$

where $A\geqslant 0$, $B\geqslant 0$, $A-B^{\Gamma}+\lambda I\geqslant\rho, \lambda\in R$. By introducing variable $D=\lambda I-B$ it can be changed into the following form:

$$F \leqslant \inf_{\substack{A\geqslant 0, B\geqslant 0\\ A\geqslant\rho-D^{\Gamma}\\ D=\lambda\mathrm{I}-B,\lambda\in R}}\mathrm{Tr}\left[A + \lambda\frac{K}{d^2}I\right]. \tag{42}$$

Taking subsequently infimum over D, A, and B we obtain

$$F \leqslant \inf_{D}\left\{\inf_{\substack{A\geqslant 0\\ A\geqslant\rho-D^{\Gamma}}}[\mathrm{Tr}\,A] + \inf_{\substack{B\geqslant 0\\ \lambda\mathrm{I}=D+B,\lambda\in R}}\mathrm{Tr}\left[\lambda\frac{K}{d^2}I\right]\right\}, \tag{43}$$

where D (as a combination of positive operators) is a Hermitian operator. Having D fixed one can easily minimize two separate terms over A and B, respectively. Concerning the first term, since $A\geqslant 0$ and $A\geqslant\rho-D^{\Gamma}$, the eigenvalues λ_i^A of A must be greater than zero, and greater than the eigenvalues $\lambda_i^{\rho,D}$ of the $\rho-D^{\Gamma}$ operator. Thus we have $\lambda_i^A=\max(\lambda_i^{\rho,D},0)$ which gives

$$\inf_{\substack{A\geqslant 0\\ A\geqslant\rho-D^{\Gamma}}}[\mathrm{Tr}\,A] = \mathrm{Tr}(\rho - D^{\Gamma})_+. \tag{44}$$

Turning now to the second term, one can see, that $\lambda I-D\geqslant 0$, hence λ must be not less than maximal eigenvalue of D, thus we end up with

$$\inf_{\substack{B\geqslant 0\\ \lambda I=D+B\\ \lambda\in R}} \operatorname{Tr}\left[\lambda\frac{K}{d^2}I\right]K\lambda_{\max}(D). \tag{45}$$

This leds to the formula

$$F\leqslant \inf_{D\in\chi(\mathcal{H})}\{\operatorname{Tr}(\rho-D^{\Gamma})_{+}+K\lambda_{\max}(D)\}. \tag{46}$$

By Γ_4 and Γ_5 any Hermitian operator D is of the form $\tilde{D}^{\Gamma}$, where $\tilde{D}$ is also Hermitian operator, hence we can rewrite the formula in the following way:

$$F\leqslant \inf_{D\in\chi(\mathcal{H})}\{\operatorname{Tr}(\rho-D)_{+}+K\lambda_{\max}(D^{\Gamma})\}, \tag{47}$$

which ends the proof. ■

The above result, gives us the condition on F with much simpler constraints—we optimize over a set of Hermitian operators. Analogously, one can prove a similar theorem for the case of not equal dimensions, i.e., for $\rho\in(\mathcal{C}^{d_1}\otimes\mathcal{C}^{d_2})^{\otimes n}$.

IV. BOUND FOR RATE OF CONCENTRATING INFORMATION

In the preceding section we showed that the fidelity of concentrating information by NLOCC is bounded by

$$F\leqslant \inf_{D\in\chi(\mathcal{H})}\operatorname{Tr}(\varrho^{\otimes n}-D)_{+}+2^{n(2\log_2 d-r)}\lambda_{\max}(D^{\Gamma}). \tag{48}$$

Starting from this inequality we can find two bounds for the rate r (by PPT-PMM operations) denoted by B_1 and B_2. The bound B_1 is weaker than B_2, however we derive it separately, as the proof for B_1 is more transparent than that for B_2.

Theorem 2: *For any states ϱ acting on Hilbert space $\mathcal{C}^d\otimes\mathcal{C}^d$*

$$r\leqslant 2\log_2 d+\log_2\lambda_{\max}(|\varrho^{\Gamma}|)\equiv B_1(\varrho), \tag{49}$$

where $\lambda_{\max}(|\varrho^{\Gamma}|)$ is maximal eigenvalue of operator $|\varrho^{\Gamma}|$.

Proof: We will show that inequality (49) must be true to make the fidelity converge to 1. Let us choose in (48) $D=\varrho^{\otimes n}$. Then

$$F\leqslant \limsup_{n\to\infty}2^{n(2\log_2 d-r)}\lambda_{\max}((\varrho^{\otimes n})^{\Gamma}). \tag{50}$$

The requirement $F\to 1$ is equivalent to condition

It implies

$$r\leqslant 2\log_2 d+\limsup_{n\to\infty}\frac{1}{n}\log_2\lambda_{\max}(\varrho^{\Gamma})^{\otimes n}. \tag{52}$$

Notice that

$$\limsup_{n\to\infty}\frac{1}{n}\log_2\lambda_{\max}(\varrho^{\Gamma})^{\otimes n}=\limsup_{n\to\infty}\frac{1}{n}\log_2(\max|\lambda(\varrho^{\Gamma})|)^n=\limsup_{n\to\infty}\log_2\lambda_{\max}(|\varrho^{\Gamma}|)$$
$$=\log_2\lambda_{\max}(|\varrho^{\Gamma}|).$$

Then we have

$$r \leqslant 2\log_2 d + \log_2 \lambda_{\max}(|\varrho^{\Gamma}|). \tag{53}$$

This ends the proof.

Theorem 3: *For any states ϱ and σ acting on Hilbert space $\mathcal{C}^d \otimes \mathcal{C}^d$,*

$$r(\varrho) \leqslant 2\log_2 d + S(\varrho|\sigma) + \log_2 \lambda_{\max}(|\sigma^{\Gamma}|) \equiv B_2(\varrho,\sigma). \tag{54}$$

Remark 1: Notice, that $\lambda_{\max}(|\varrho^{\Gamma}|) = \|\sigma^{\Gamma}\|_{\mathrm{op}}$. Then the bound can be written as

$$B_2(\varrho,\sigma) = 2\log_2 d + S(\varrho|\sigma) + \log_2 \|\sigma^{\Gamma}\|_{\mathrm{op}}. \tag{55}$$

It is interesting to compare this expression this formula with Rains bound for PPT distillable entanglement D:

$$D \leqslant S(\varrho|\sigma) + \log_2 \|\sigma^{\Gamma}\|_{\mathrm{Tr}}. \tag{56}$$

Proof: Let $S = S(\varrho\,|\,\sigma)$ and $L = \log_2 \lambda_{\max}(|\sigma^{\Gamma}|) = \log_2 \|\sigma^{\Gamma}\|_{\mathrm{op}}$. We will show that if

$$r - 2\log_2 d \equiv x > S + L \tag{57}$$

then F cannot converge to 1. We have

$$F \leqslant \mathrm{Tr}(\varrho^{\otimes n} - D)_+ + 2^{-nx}\lambda_{\max}(D^{\Gamma}). \tag{58}$$

Let us take

$$D = 2^{ny}\sigma^{\otimes n}, \tag{59}$$

where $S < y < x - L$. (We can find such y, because $x > S + L$)

Notice that

$$2^{-nx}\lambda_{\max}[(2^{ny}\sigma^{\otimes n})^{\Gamma}] \leqslant 2^{n(y-x+L)}. \tag{60}$$

Then

$$F \leqslant \mathrm{Tr}(\varrho^{\otimes n} - 2^{ny}\sigma^{\otimes n})_+ + 2^{n(y-x+L)}, \tag{61}$$

$2^{n(y-x+L)}$ converges to 0 because

$$y - x + L < 0. \tag{62}$$

The first term in (61) cannot converge to 1 because $y > S(\varrho\,|\,\sigma)$, as shown by Rains.[9] (It follows from quantum Stein lemma, see, e.g., Ref. 21.) This ends the proof.

Remark 2: To obtain the full strength of bound of Theorem 3, one should optimize over the choices of state σ. In what follows, we will say that σ is optimal for ϱ if

$$B_2(\varrho,\sigma) = \min_{\sigma'} B_2(\varrho,\sigma') \overset{\mathrm{d}f}{=} B_2(\varrho), \tag{63}$$

where σ' ranges over all states acting on $C^d \otimes C^d$.

V. RESULTS FOR WERNER AND ISOTROPIC STATES

In this section we will find bounds for the rate of states possessing high symmetry, Werner states, and isotropic ones, as well as compare bounds B_1 and B_2 with each other.

Let us start with the Werner state. We describe our results for the Werner state of the form (5). Using Theorem 2 we obtained the following bound:

$$B_1 = \begin{cases} 2\log_2 d - \log_2(d^2 + \mathrm{d}\beta) & \text{for } -\frac{2}{d} < \beta < 0, \\ 2\log_2 d + \log_2\left|\frac{1+\mathrm{d}\beta}{d^2+\mathrm{d}\beta}\right| & \text{for } 0 \leqslant \beta \leqslant 1 \quad \text{and} \quad -1 \leqslant \beta \leqslant -\frac{2}{d}. \end{cases} \tag{64}$$

If we want to find the bound using Theorem 3 we must optimize $B_2(\varrho,\sigma)$. As in Ref. 9, it boils down to minimizing only over the Werner states. It is due to the following facts. First, any state ϱ if subjected to random transformation of form $U\otimes U$ (called $U\otimes U$ twirling) becomes the Werner state,

$$\int U\otimes U\varrho U^\dagger\otimes U^\dagger \,\mathrm{d}U=\varrho_W. \tag{65}$$

Second, the value of $B_2(\varrho,\sigma)$ is nonincreasing after the twirling operation. Third, $B_2(\varrho,\sigma)$ is a convex function, because the quantities S and L possess these properties. Then for any state σ,

$$\begin{aligned} B_2(\varrho_W,\sigma)&=\int B_2(\varrho_W,\sigma)\mathrm{d}U\int B_2(U\otimes U\varrho_W U^\dagger\otimes U^\dagger, U\otimes U\sigma U^\dagger\otimes U^\dagger)\mathrm{d}U\\ &\geqslant B_2\left(\int U\otimes U\varrho_W U^\dagger\otimes U^\dagger\,\mathrm{d}U,\int U\otimes U\sigma U^\dagger\otimes U^\dagger\,\mathrm{d}U\right)\\ &=B_2\left(\varrho_W,\int U\otimes U\sigma U^\dagger\otimes U^\dagger\,\mathrm{d}U\right)=B_2(\varrho_W,\sigma_W), \end{aligned}$$

where σ_W is a Werner state. Thus, we can see that for any state σ we can find such Werner state σ_W, which gives no greater value of B_2 than σ. This fact simplifies our calculation to optimize $B_2(\varrho_W,\sigma)$ on Werner state. Now, we can find the smallest value of $B_2(\varrho_W,\sigma_W)$, where ϱ_W is given by the formula ((5)) and σ_W is of the following form:

$$\varrho_W=\frac{1}{d^2+\mathrm{d}\alpha}(I+\alpha V),\quad -1\leqslant\alpha\leqslant 1. \tag{66}$$

In this case $B_2(\varrho_W,\sigma)$ is a function of three parameters, d, β, and α, where the first two parameters are fixed. So to optimize $B_2(\varrho_W,\sigma)[\alpha]$ it is enough to find a minimum of this function depending on α. This way we obtain the following value of $B_2(\varrho)$,

$$B_2=\begin{cases} 2\log_2 d-S(\varrho_W)-\frac{d^2+d}{2}\frac{1+\beta}{d^2+\mathrm{d}\beta}\log_2\frac{d-2}{d}-\frac{d^2-d}{2}\frac{1-\beta}{d^2+\mathrm{d}\beta}\log_2\frac{d+2}{d} & \text{for } -1\leqslant\beta<\frac{-3d}{d^2+2},\\ 2\log_2 d-S(\varrho_W)-\frac{d^2+d}{2}\frac{1+\beta}{d^2+\mathrm{d}\beta}\log_2(1+\alpha)-\frac{d^2-d}{2}\frac{1-\beta}{d^2+\mathrm{d}\beta}\log_2(1-\alpha) & \text{for } \frac{-3d}{d^2+2}\leqslant\beta<\frac{-1}{d},\\ 2\log_2 d-S(\varrho_W) & \text{for } \dfrac{-1}{d}\leqslant\beta\leqslant 1, \end{cases} \tag{67}$$

where $\alpha=(1+d\beta)/(d+\beta)$. The entropy $S(\varrho_W)$ is given by

$$S(\varrho_W)=-\frac{d^2-d}{2}\frac{1-\beta}{d^2+\mathrm{d}\beta}\log_2\frac{1-\beta}{d^2+\mathrm{d}\beta}-\frac{d^2+d}{2}\frac{1+\beta}{d^2+\mathrm{d}\beta}\log_2\frac{1+\beta}{d^2+\mathrm{d}\beta}. \tag{68}$$

We have obtained two upper bounds for the amount of information one can localize. Of course B_2 is not always worse than B_1, so we will consider B_1 only to compare with B_2. Now, we would like to find a lower bound for I_l. To this end we shall consider some NLOCC (one-way) protocol $\mathcal{P}$ for concentrating information to the local form. The amount of information we can concentrate using $\mathcal{P}$ is a lower bound for I_l. Our protocol $\mathcal{P}$ is the following: (i) Alice makes an optimal complete von Neumann measurement represented by $P_i=|i\rangle\langle i|$ on her subsystem. (ii) After that she sends her part to Bob. Alice can do this, because after measurement her part of the state is classical-like and classical channel does not destroy it, if she does it adequately, i.e., sometimes before sending she should perform some unitary operation to avoid changing the state by the channel. (iii) Bob upon

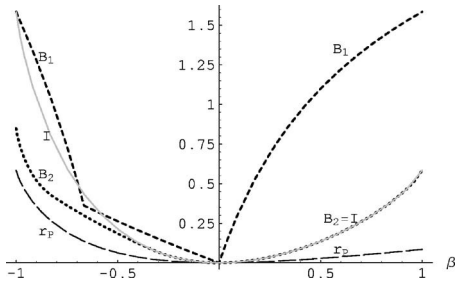

FIG. 1. The dashed lines represent bounds of rate for Werner states $(d=3)(r_{\mathcal{P}}^{\rightarrow} \leqslant B_2 \leqslant B_1)$ and continuous line represents quantity described by $I=2\log_2 d-S(\varrho)$. Note that B_2 is equal to the information content of the state in the whole range of separability $\left(\beta \geqslant -\frac{1}{3}\right)$.

receiving the whole state can extract $2\log_2 d-S(\varrho'_{AB})$ bits of information, where ϱ'_{AB} is obtained from ϱ_{AB} by Alice's operation (i) and (ii).

Lemma V.1: For state ϱ_{AB} acting on Hilbert space $\mathcal{C}^d \otimes \mathcal{C}^d$ with maximally mixed subsystem A by use of the protocol $\mathcal{P}$, we can concentrate to local form $r_{\mathcal{P}}^{\rightarrow}$ information, where $r_{\mathcal{P}}^{\rightarrow}$ is described by

$$r_{\mathcal{P}}^{\rightarrow} = \sup_{P_i}\left(\log_2 d - \sum_i p_i S(\varrho_B^i)\right),$$

$$\text{where } p_i = \mathrm{tr}(\varrho_{AB} P_i \otimes I) \quad \text{and } \varrho_B^i = \frac{1}{p_i}\mathrm{tr}_A(P_i \otimes I \varrho_{AB} P_i \otimes I). \tag{69}$$

Proof: After sending by Alice her part, Bob possesses the whole state and can extract $2\log_2 d-S(\varrho'_{AB})$, where $\varrho'_{AB}=\Sigma_i p_i |i\rangle\langle i| \otimes \varrho_B^i$. The states $|i\rangle$ are orthogonal and it implies that $S(\varrho'_{AB})=H(p_i)+\Sigma_i p_i S(\varrho'^i_B)$. Shannon entropy $H(p_i)$ is the amount to entropy of Alice's part after her measurement. We know, that entropy cannot decrease after measurement but also cannot increase, because it is maximal. It implies that $H(p_i)=\log_2 d$. Then we have

$$r_{\mathcal{P}}^{\rightarrow} = 2\log_2 d - S(\varrho'_{AB}) = 2\log_2 d - \left[\log_2 d + \sup_{P_i}\left(\sum_i p_i S(\varrho'^i_B)\right)\right] = \log_2 d - \sup_{P_i}\left(\sum_i p_i S(\varrho'^i_B)\right).$$

This ends the proof.

For Werner states $r_{\mathcal{P}}^{\rightarrow}$ is achieved by any measurement of Alice. It follows from the fact that ϱ_W is $U \otimes U$ invariant. We obtain

$$r_{\mathcal{P}}^{\rightarrow}(\varrho_W) = \log_2 d + \frac{1+\beta}{d+\beta}\log_2(1+\beta) - \log_2(d+\beta). \tag{70}$$

Let us here compare the bounds for amount of localizable information with each other.

Figure 1 shows lower and upper bounds for rate in comparison to information content of state. For Werner states bound B_2 is much better than B_1. For separable state B_2 is trivial, it coincides with information contents of state $I=2\log_2 d-S(\varrho)$. For entangled states it is better than I.

Looking at Fig. 2 we can see B_2 and $r_{\mathcal{P}}^{\rightarrow}$ for some different dimensions of Hilbert space of the Werner state. Continuous lines represent bounds for $d=3$, the long dashed lines bounds for $d=4$ and the short dashed lines for $d=5$.

Now, let us present results for the isotropic state. For these states the bound B_1 is given by

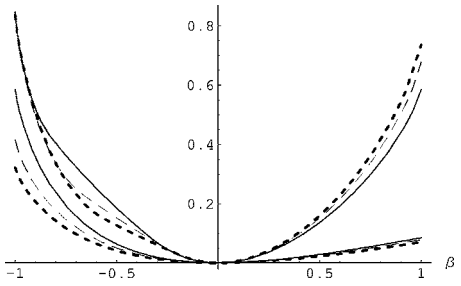

FIG. 2. Upper bound B_2 and lower bound $r_{\vec{\mathcal{P}}}$ of rate for the Werner states ($d=3,4,5$).

$$B_1 = \begin{cases} \log_2[-\lambda(d+1)+1] & \text{for } \lambda < 0, \\ \log_2[\lambda(d-1)+1] & \text{for } \lambda \geqslant 0. \end{cases} \tag{71}$$

Using the same arguments as for the Werner state we can show that if we want to find the value of $B_2(\varrho_{\text{iso}})$ we should optimize $B_2(\varrho_{\text{iso}},\sigma)$ on the isotropic state. Analogously, as in the previous case, we can find out that

$$B_2 = \begin{cases} 2\log_2 d - S(\varrho_{\text{iso}}) & \text{for } \dfrac{-1}{d^2-1} \leqslant \lambda \leqslant \dfrac{1}{d+1}, \\ 2\log_2 d - S(\varrho_{\text{iso}}) + \log_2 \dfrac{1+p(d-1)}{1-p} - \dfrac{1+\lambda(d^2-1)}{d^2}\log_2 \dfrac{1-p}{1+p(d^2-1)} & \text{for } \dfrac{1}{d+1} \leqslant \lambda \leqslant 1. \end{cases} \tag{72}$$

where $p=[(d+1)\lambda-1]/[(1-d^2)(\lambda-1)+d]$. The entropy of the isotropic state is given by

$$S(\varrho_{\text{iso}}) = -\frac{1+\lambda(d^2-1)}{d^2}\log_2\frac{1+\lambda(d^2-1)}{d^2} - \frac{(1-\lambda)(d^2-1)}{d^2}\log_2\frac{1-\lambda}{d^2}. \tag{73}$$

Isotropic state possesses similar properties as the Werner states, so if we want to obtain a value of $r_{\vec{\mathcal{P}}}$ we should proceed similarly for that family of state. Then we have

$$r_{\vec{\mathcal{P}}} = \log_2 d + \left(\lambda + \frac{1-\lambda}{d}\right)\log_2\left(\lambda + \frac{1-\lambda}{d}\right) + (d-1)\frac{1-\lambda}{d}\log_2\left(\frac{1-\lambda}{d}\right). \tag{74}$$

For the isotropic state the bound B_2 is better again than B_1 and also only for entangled isotropic state the upper bound is nontrivial. The upper and lower bounds agree for P_+ and are obviously equal to $\log_2 d$. The bounds and information content are compared in Fig. 3 for $d=3$. The upper dashed line represents B_2, the lower $r_{\vec{\mathcal{P}}}$. The gray continuous line is the information content of state, i.e., $2\log_2 d - S(\varrho_{\text{iso}})$.

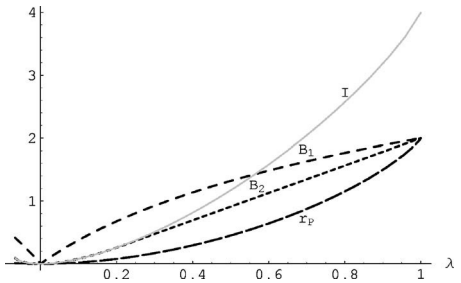

FIG. 3. The dashed lines represent bounds of rate for isotropic states ($d=3$) and continuous line represents information content of state. Note that B_2 is equal to $I=2\log_2 d - S(\varrho)$ for the whole range of separability [$\lambda \leqslant 1/(1+d)$]).

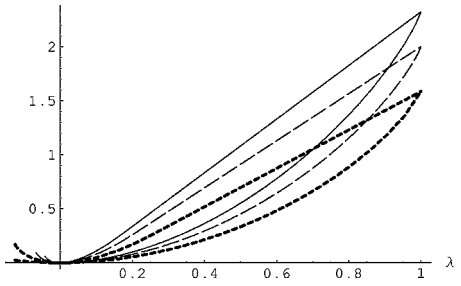

FIG. 4. Upper bound B_2 and lower bound $r_{\mathcal{P}}^{\rightarrow}$ of rate for isotropic states ($d=3,4,5$).

In Fig. 4 quantities B_2 and $r_{\mathcal{P}}^{\rightarrow}$ are compared for some different dimension ($d=3,4,5$).

VI. COMPARING QUANTUM DEFICIT WITH MEASURES OF ENTANGLEMENT

As one knows, quantum deficit Δ can be treated as a measure of quantum correlations.[1] Having bound localizable information we can find bounds for Δ. We can do this, because quantum deficit is defined as a difference between total information and information I_l, which can be localized by NLOCC (19) and we know that I_l is bounded by information localizable by using PPT-PMM operations. That is, by $I_l \leqslant B_2$ we have lower bound δ_B on quantum deficit,

$$\delta_B(\varrho) = 2\log_2 d - S(\varrho) - B_2. \tag{75}$$

On the other hand, we have considered particular NLOCC protocol, namely the one which uses only one-way communication. This gives $I_l \geqslant r_{\mathcal{P}}^{\rightarrow}$, which in turn gives upper bound δ_P on quantum deficit,

$$\delta_P(\varrho) = 2\log_2 d - S(\varrho) - r_{\mathcal{P}}^{\rightarrow}. \tag{76}$$

Quantum deficit is believed to be a more general measure of "quantumness" of state, than measures of entanglement. It is then interesting to compare it with some known entanglement measures.

We now compare bounds on Δ with the relative entropy of entanglement and entanglement of formation of the bipartite state.

The regularized relative entropy of entanglement E_R^{∞} for Werner states is given by[22]

$$E_R^{\infty}\begin{cases} \log_2\frac{d-2}{d} + \frac{(d-1)(1-\beta)}{2(d+\beta)}\log_2\frac{d+2}{d-2} & \text{for } -1 \leqslant \beta \leqslant -\frac{3d}{d^2+2}, \\ 1 - H\left(\frac{(d-1)(1-\beta)}{2(d+\beta)}\right) & \text{for } -\frac{3d}{d^2+2} \leqslant \beta \leqslant -\frac{1}{d}, \\ 0 & \text{for } -\frac{1}{d} \leqslant \beta \leqslant 1. \end{cases} \tag{77}$$

Entanglement of formation is described by the following formula:

$$E_F\begin{cases} H\left(\frac{1}{2}\left(1 - \sqrt{1 - \left(\frac{1+d\beta}{d+\beta}\right)^2}\right)\right) & \text{for } -1 \leqslant \beta \leqslant -\frac{1}{d}, \\ 0 & \text{for } -\frac{1}{d} < \beta \leqslant 1. \end{cases} \tag{78}$$

We can see in Fig. 5 the graphs of δ_B , δ_P, E_F, and E_R^{∞} for the Werner states. We obtain that δ_B and E_R^{∞} are equal. For Werner states with $\beta < 0.42$ we have that quantum deficit is not greater than entanglement of formation, $\Delta \leqslant E_F$.

Let us now pass to isotropic states. For entangled ones with parameter $\lambda \in (1/(d+1), 1)$ the relative entropy of entanglement E_R is given by

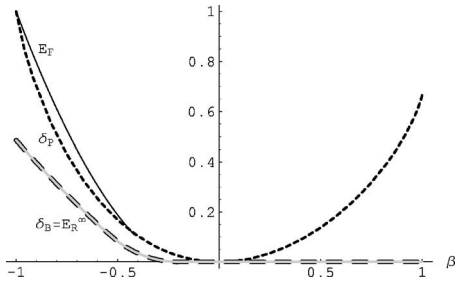

FIG. 5. The dashed lines represent upper and lower bounds of Δ for Werner states ($d=5$), grey continuous regularized relative entropy of entanglement E_R^∞ and black continuous entanglement of formation E_F.

$$E_R = \log_2 d + f \log_2 f + (1-f)\log_2 \frac{1-f}{d-1}, \tag{79}$$

where $f=[(d^2-1)\lambda+1]/d^2$. For another isotropic states it is zero. The formula of entanglement of formation can be found in Ref. 23. For nonseparable states it is in the form of

$$E_F(\varrho) = \mathrm{co}(g(\gamma)), \tag{80}$$

$$g(\gamma) = (H_2(\gamma) + (1-\gamma)\log_2(d-1)), \tag{81}$$

where $\gamma=(1/d^2)(\sqrt{d\lambda+[(1-\lambda)/d]}+\sqrt{(d-1)[(d^2-1)(1-\lambda)/d]})^2$ and co means a convex hull.[23] In Fig. 6 we can see graphs of two measures of entanglement and bounds for Δ.

We can notice that the graphs of δ_B agree with E_R. Similary as for the Werner states we have $\delta_B=E_R$. δ_P is greater than E_F for most isotropic states. (We do not know, if it is true for all isotropic states.) For maximally entangled state P_+ all these quantities are equal.

VII. FIDELITY FOR DISTILLATION OF LOCAL PURE STATES AND SINGLETS

The well-known counterpart of a qubit which represents the unit of local information is ebit—one bit of entanglement, represented by singled state, i.e., unit of nonlocal information. It has been stated in Ref. 24 that these two forms of information are complementary. If one distills maximal possible amount of one type of information, possibility of gaining the second type disappears. The optimal protocol in the case of pure initial state $\psi_{AB}^{\otimes n}$, in which both types are obtained with some ratios, has been also shown there. We will find a bound for the fidelity of such transition, in which both qubits and ebits are drawn in an NLOCC protocol in case of general mixed state $\rho_{AB}^{\otimes n}$. One can view this as a *purity distillation protocol*, because purity in general has two extreme forms, purely local and purely nonlocal. This is due to the fact, that any nonproduct pure state, is asymptotically equivalent to the singlet state under the set of NLOCC operations.[2] To this end—as before—we will consider a broader class than the NLOCC, namely the class PPT-

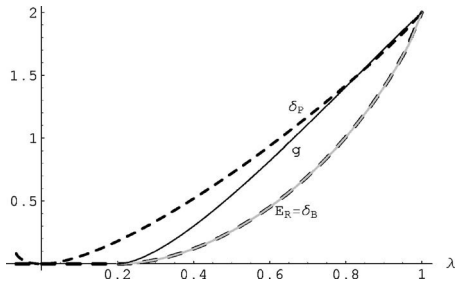

FIG. 6. The dashed lines represent bounds for Δ for isotropic states ($d=3$), grey continuous regularized relative entropy of entanglement E_R, and black continuous $g(\gamma)$ (whose convex hull is entanglement of formation E_F).

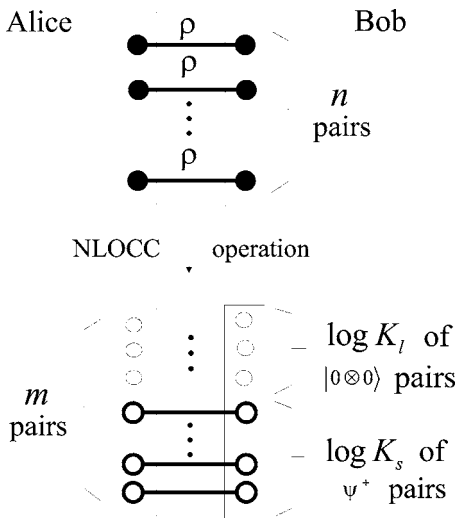

FIG. 7. Scenario of distillation of pure states in their two extremal forms, purely local (product) states and purely nonlocal (maximally entangled) states. The fixed rates of transition gives the proportion of the number of input copies n of state ρ to the numbers of output copies of *local* states ($\log K_l$) and singlet states ($\log K_s$).

PMM. This time we must fix two rates, one which tells us how many pure local qubits we would like to obtain (r_l), but also how many singlet states (r_s) will be acheived per n copies of input state (see Fig. 7).

Namely

$$r_s = \frac{\log K_s}{n}, \quad r_l = \frac{2m - 2\log K_s}{n}, \tag{82}$$

where n is the number of input states, m is the number of qubits that output states occupy (both pure qubits, and singlets together) and $\log K_s$ is the output number of singlet states. We get less than $2m/n$ pure qubits since $\log K_s$ singlets use up $2\log K_s$ qubits out of $2m$ final. We should maximize the fidelity of transition,

$$F = \mathrm{Tr}[P_+^{\otimes \log K_s} \otimes P_{00}^{\otimes (m-\log K_s)} \Lambda(\rho^{\otimes n})], \tag{83}$$

where $P_+^{\otimes \log K_s}$ is the projector onto the singlet state on $\mathcal{C}^{K_s} \otimes \mathcal{C}^{K_s}$. Instead of tensor product of singlets and product states, we can equally well consider the output state as the same singlet state embedded in the larger Hilbert space $\mathcal{C}^m \otimes \mathcal{C}^m$. Thus we shall maximize the following quantity:

$$F = \mathrm{Tr}[P_+^{K_s} \Lambda(\rho^{\otimes n})], \tag{84}$$

where K_s reminds that P_+ is of less dimension than the whole Hilbert space it is embedded in. The rest of the space is occupied by pure local qubits, i.e., the second resource drawn in this process.

Consequently we will first consider the fidelity in terms of the $\Pi = \Lambda^\dagger(P_+^{K_s})$ operator where $\Lambda^\dagger$ is dual (hence CP) to the Λ which is CPTP from assumption.

Analogously as in Sec. III we can obtain the following fact.

Fact 2: For given rates r_l, r_s and the number of input copies n, the optimal fidelity is given by

$$F \leqslant \sup_{\Pi} \mathrm{Tr}[\Pi(\rho^{\otimes n})], \tag{85}$$

where

$$0 \leqslant \Pi \leqslant \mathrm{I}, \quad \frac{-\mathrm{I}}{K_s} \leqslant \Pi^\Gamma \leqslant \frac{\mathrm{I}}{K_s}, \quad \mathrm{Tr}[\Pi] = 2^{n(2\log d - r_l - 2r_s)} \equiv K. \tag{86}$$

Passing to the dual problem, after some algebra we get the following.

Theorem 4: *For any state* ρ *acting on* $C^d \otimes C^d$ *and rates* r_l *and* r_s *we have*

$$F \leqslant \inf_D \left\{ \mathrm{Tr}(\rho - D)_+ + \inf_\lambda \left[\frac{1}{K_s} \mathrm{Tr}|D^\Gamma - \lambda I| + \lambda K \right] \right\}, \tag{87}$$

where infimum are taken over all Hermitian operators D *and all real numbers* λ, *respectively*, $K = 2^{n(2 \log d - r_l - 2r_s)}$ *and* $K_s = 2^{nr_s}$.

It is not easy to obtain nontrivial results. Suppose that we want to apply analogous ideas to those applied in Sec. IV. Let us rewrite fidelity as follows (for some fixed D):

$$F \leqslant \mathrm{Tr}(\rho^{\otimes n} - D) + 2^{-nr_s} \mathrm{Tr}|D^\Gamma - \lambda I| + \lambda 2^{n(2 \log d - r_l)}. \tag{88}$$

The simplest approach would be to force first terms to vanish by choosing $D = \varrho^{\otimes n}$. However, even by this simplification it is very difficult to find any bound for rates.

Yet, there are also "higher level" problems. Namely the main problem within the connection between distillation of entanglement and the paradigm of localizing information, is whether distillation process consumes local information.[25] It seems that our class of operations cannot feel this problem at all. Indeed, it is likely, that any distillation process is a map that preserves a maximally mixed state.[26] Thus one should perhaps improve the approach, by imposing more stringent constraints on class of operations. This is because for initial maximally mixed state, we impose only final maximally mixed state. However generically, the final dimension is smaller than the initial one. This means that some tracing out must take place, and we do not require the state that was traced out to be maximally mixed. Thus in our class, pure ancillas can be added, under the condition that they are finally traced out.

VIII. DISCUSSION

In this paper we have investigated *localizable information* and associated *information deficit* of the quantum bipartite states. We used the fact, that localizable information can be defined as the amount of pure local qubits (per input copy) that can be distilled by means of classical communication and local operations that do not allow adding local ancilla in the nonmaximally mixed state.

We considered a larger class of operations which we called PPT-PMM operations. They are those PPT operations which preserve the maximally mixed state. Then we managed to formulate the problem of distillation of pure product qubits in terms of semidefinite program. Using duality concept in semidefinite programming we have obtained bound for fidelity of transition from given state to pure product ones by PPT-PMM operations. In this way we have found a general upper bound for the amount of localizable information of arbitrary state. The bound was denoted B_2 (we also obtained a simpler, but weaker bound B_1). It gives bound δ_B for information deficit.

We were able to evaluate exactly the value of the bound B_2 for states exhibiting high symmetry—Werner states and isotropic states. Quite surprisingly, the obtained related lower bound δ_B for information deficit turned out to coincide with relative entropy of entanglement in the case of isotropic states, and with regularized relative entropy of entanglement for Werner states. In other words, in those two cases, our bound for information deficit, turned out to be equal to Rains bound for distillable entanglement.

We have also analyzed a simple lower bound r_P for localizable information, and a parallel upper bound δ_P for information deficit. We compared the latter bound with entanglement of formation. In particular we obtained that for Werner states ($d=3$), in entangled region it is strictly smaller than entanglement of formation. If one believes that information deficit is a measure of total quantumness of correlations, the conclusion would be that either E_F is nonadditive for some Werner states, or, which is more likely, it is additive, i.e., equal to entanglement cost E_c, but E_c does not describe the entanglement present in the state in this case. Rather it includes also the entanglement that got dissipated during formation of the state.

We have also discussed possibility of application of our approach to the problem of simultaneous distillation of singlets and pure local states. We provided bound for fidelity in this case. However it is likely, that the chosen class of operations is too large to describe information consumption in the process of distillation of entanglement.

There are a lot of open problems, which we have not addressed in this paper. For example, the question of continuity of the localizable information. For operationally defined quantities such as I_l, this is usually not an easy question. However one can hope that I_l continues to some extent. Namely, in Ref. 27 Vidal has proven some continuity properties of distillable entanglement E_D. Though distillable entanglement is quite an opposite quantity to localizable information (cf. Ref. 24) it is also operationally defined. Moreover I_l and E_D are both based on the notion of distillation.[2] In this context, the techniques used in Ref. 27 may be fruitful for investigations of continuity of localizable information.

An important open question is also the connection between information deficit and entanglement measures. In particular, it is intriguing, how general is the equality of our lower bound for deficit, and the relative entropy of entanglement E_r—upper bound for distillable entanglement.

Another interesting question arises in the context of phenomenon of locking[28–30] where removing a single qubit can result in a big change of a quantity. It is likely that I_l cannot be locked, due to its relations with relative entropy distance (see Ref. 31 in this context). However, we have not been able to prove it.

Finally, we believe that our results will stimulate further research on the properties of localizable information and information deficit, as well as their relations with other quantum informational quantites.

(Received 19 May 2005; accepted 22 June 2005; published online 17 August 2005)

We present an explicit numerical method to obtain the Cartan-Khaneja-Glaser decomposition of a general element $G \in \mathrm{SU}(2^N)$ in terms of its "Cartan" and "non-Cartan" components. This effectively factors G in terms of group elements that belong in $\mathrm{SU}(2^n)$ with $n<N$, a procedure that can be iterated down to $n=2$. We show that every step reduces to solving the zeros of a matrix polynomial, obtained by truncation of the Baker-Campbell-Hausdorff formula, numerically. All computational tasks involved are straightforward and the overall truncation errors are well under control. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2008210]

I. INTRODUCTION

In their seminal paper, Khaneja and Glaser[1] presented a generic method to decompose "large" unitary elements in terms of "smaller" ones. The initial unitaries can be viewed as evolution operators of a multipartite system of spin-1/2's or as quantum algorithms acting on qubits. Experimentally it is only possible to control the interactions between a small number of subsystems at a time. Hence, this decomposition is of particular interest. It allows us to address questions such as how to optimize a dynamical evolution in terms of control procedures applied to a small number of spins or how a certain quantum algorithm can be obtained with the smallest possible number of experimentally feasible one and two qubit gates.

In particular, Khaneja and Glaser show that any element of the Lie group $\mathbf{G}=\mathrm{SU}(2^N)$ is, up to local unitaries in $\mathrm{SU}(2)^{\otimes N}$, determined by components generated from certain Abelian subalgebras $\mathfrak{h}_n$ and $\mathfrak{f}_n$, $n=2,\ldots,N$, of the Lie algebra $\mathfrak{su}(2^N)$. This is achieved by employing iteratively the Cartan decomposition

$$G = K' H K'',$$

where H is generated by $\mathfrak{h}_n(\mathfrak{f}_n)$ and the factors K' and K'' belong to the subgroup $\mathbf{K}\subset\mathbf{G}$ generated by a particular subalgebra orthogonal to $\mathfrak{h}_n(\mathfrak{f}_n)$. These relevant substructures are specified in terms of a fortunate choice of basis for $\mathfrak{su}(2^n)$ that can be obtained recurrently for $n=2,\ldots,N$.

The beauty of this result and its promising applications in quantum algorithms,[2,3] control theory, quantum error correction,[4] or the quantification of entanglement in multi-partite systems[5] have motivated the search for a constructive method to perform the decompositions for any given matrix $G \in \mathrm{SU}(2^N)$. Although substantial work has been done on the first non-trivial instance SU(4),[6,7] little seems to be known so far for the higher N case.[8]

Here we address the decomposition problem for the general group $\mathrm{SU}(2^N)$. Employing a convenient truncation of the Baker-Campbell-Hausdorff (BCH) formula, we show that the prob-

[a)]Electronic mail: henrique.saearp@imperial.ac.uk

lem allows for a numerical algorithm to calculate all such **KHK** decompositions with controlled error. Hence, we can perform the full Khaneja-Glaser decomposition of a general element $G \in \mathrm{SU}(2^N)$ with arbitrary computational precision.

This article is organized as follows. In Sec. II we briefly review the Khaneja-Glaser decomposition[1] and establish the formalism for our approach. In Sec. III we reinterpret the problem in terms of the BCH formula; we explain how a truncation of the BCH series renders our problem solvable by straightforward numerical tasks. In Sec. IV we give a user-friendly summary of the essential steps involved and we finally conclude in Sec. V.

II. THE KHANEJA-GLASER DECOMPOSITION

We consider the compact semi-simple Lie group $\mathbf{G}=\mathrm{SU}(2^N)$ and a particular compact closed subgroup $\mathbf{K}\subset\mathbf{G}$; we denote by $\mathfrak{g}=\mathfrak{su}(2^N)$ the Lie algebra of $\mathbf{G}$ and by $\mathfrak{k}\subset\mathfrak{g}$ the Lie algebra of $\mathbf{K}$ understood as a subalgebra of $\mathfrak{g}$. Since $\mathbf{G}$ is semi-simple, the Killing form $\langle .,. \rangle$ is non-degenerate and defines a bi-invariant metric on $\mathbf{G}$. Hence, we can define $\mathfrak{m}=\mathfrak{k}^{\perp}$ to be the orthogonal complement of $\mathfrak{k}$ with respect to the metric. Notice that, in general, the vector space $\mathfrak{m}\subset\mathfrak{g}$ is *not* a subalgebra. Since $\mathfrak{m}$ is determined by $\mathfrak{k}$ and the Killing metric, we shall refer to this structure as the *Lie algebra pair* $(\mathfrak{g},\mathfrak{k})$.

We shall adopt the following typographic conventions in most cases:

$\mathbf{G}$	capital bold	group or subgroup
G	capital italic	element of $\mathbf{G}$
$\mathfrak{g}$	German fraktur	Lie algebra or subspace
g	normal	element of $\mathfrak{g}$

The only exception to the choice of fonts just stated will be the familiar Pauli matrices, seen as elements of $\mathfrak{su}(2)$, which will be denoted by majuscules

$$X=\frac{\mathbf{i}}{2}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad Y=\frac{\mathbf{i}}{2}\begin{pmatrix}0 & -\mathbf{i}\\ \mathbf{i} & 0\end{pmatrix},\quad Z=\frac{\mathbf{i}}{2}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}$$

and the 2×2 identity matrix

$$I=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}.$$

Finally, we shall use an abbreviated normalized notation for their tensor products given by

$$A_1A_2\ldots B_j\ldots A_k \doteq \left(\frac{2}{\mathbf{i}}\right)^{k-1} A_1\otimes A_2\otimes\ldots\otimes B_j\otimes\ldots\otimes A_k,\quad \begin{matrix}A_i=X,Y,Z\\ B_j=I.\end{matrix}$$

For example, $YXI=\frac{\mathbf{i}}{2}\begin{pmatrix}0 & -\mathbf{i}\\ \mathbf{i} & 0\end{pmatrix}\otimes\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\otimes\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}$.

A. Cartan decomposition

Definition 1: *A* Cartan decomposition *of* $\mathfrak{g}$ *is an orthogonal split of* $\mathfrak{g}$,

$$\mathfrak{g}=\mathfrak{k}\oplus\mathfrak{m}$$

given by a Lie algebra pair $(\mathfrak{g},\mathfrak{k})$ *satisfying the commutation relations*

$$[\mathfrak{k},\mathfrak{k}]\subset\mathfrak{k},\quad [\mathfrak{m},\mathfrak{k}]\subset\mathfrak{m},\quad [\mathfrak{m},\mathfrak{m}]\subset\mathfrak{k}. \tag{1}$$

In this case $(\mathfrak{g},\mathfrak{k})$ *is called a* symmetric Lie algebra pair.

Remark 2: *The appearently artificial conditions in the above definition have an interpretation in Riemannian geometry:* $\mathfrak{g}=\mathfrak{k}\oplus\mathfrak{m}$ *is a Cartan decomposition if and only if the quotient manifold* $\mathbf{G}/\mathbf{K}=\exp(\mathfrak{m})$ *is a* globally Riemannian symmetric space.[9] *Such a space possesses a canonical*

global involution *(i.e., an automorphism s of the space onto itself such that* $s^2=I$*) which induces naturally a linear involution* s_* *on* $\mathfrak{g}$ *that preserves the Lie algebra structure* $[.,.]$. *Since* s_* *squares to identity, its eigenvalues must be* ± 1, *and the subspaces* $\mathfrak{k}$ *and* $\mathfrak{m}$ *emerge, respectively, as the* $+1$ *and* -1*-eigenspaces of* s_*.

We can start exploring the Cartan decomposition $\mathfrak{g}=\mathfrak{k}\oplus\mathfrak{m}$ by noticing that if $\mathfrak{h}\subset\mathfrak{m}$ is a subalgebra of $\mathfrak{g}$ then, by (1), $\mathfrak{h}$ is automatically Abelian. Since $\mathfrak{m}$ itself is not in general a subalgebra of $\mathfrak{g}$, it is natural to look for a *maximal* (Abelian) subalgebra $\mathfrak{h}\subset\mathfrak{m}$.

Definition 3: *A* Cartan subalgebra *of the pair* $(\mathfrak{g},\mathfrak{k})$ *is a maximal (in* $\mathfrak{m}$*) Abelian subalgebra* $\mathfrak{h}\subset\mathfrak{m}$.

From now on we shall assume that the Cartan subalgebra $\mathfrak{h}$ refers to the pair $(\mathfrak{g},\mathfrak{k})$ unless stated otherwise. The following *Proposition* shows that the whole $\mathfrak{m}$ is obtained from $\mathfrak{h}$ by the adjoint action of $\mathbf{K}$ and that there is only one such $\mathfrak{h}$ up to this action. In the context of the particular application we have in mind, this means $\mathfrak{h}$ carries the "essential" information about $\mathfrak{m}$.

Proposition 4: *Let* $\mathfrak{h}$ *and* $\mathfrak{h}'$ *be two Cartan subalgebras; then*

1. $\mathfrak{m}=\bigcup_{K\in\mathbf{K}}\mathrm{Ad}_K(\mathfrak{h})$;
2. $\mathfrak{h}'=\mathrm{Ad}_K(\mathfrak{h})$ *for some element* $K\in\mathbf{K}$.

Proof: *Please see* Appendix B. ■

Denote $\mathbf{H}=\exp(\mathfrak{h})\subset\mathbf{G}$ the subgroup generated by $\mathfrak{h}$. The Cartan decomposition theorem states that any group element $G\in\mathbf{G}$ can be written as an element $H\in\mathbf{H}$ together with left- and right-multiplications by elements of $\mathbf{K}$:

Theorem 5 (Cartan decomposition): *The Cartan decomposition* $\mathfrak{g}=\mathfrak{k}\oplus\mathfrak{m}$ *induces a* Cartan decomposition *of the group* $\mathbf{G}$,

$$\mathbf{G}=\mathbf{KHK}, \tag{2}$$

where $\mathbf{H}=\exp(\mathfrak{h})$.

The Cartan decomposition of a given element $G\in\mathbf{G}$ *has the form*

$$G=K_0\underbrace{K_1HK_1^\dagger}_{M}=K_0M, \tag{3}$$

where $K_0,K_1\in\mathbf{K}$, $H\in\mathbf{H}$ *and* $M=K_1HK_1^\dagger\in\exp(\mathfrak{m})$.

Proof: *Since* $\mathbf{G}/\mathbf{K}=\exp(\mathfrak{m})$, *there exist* $K_0\in\mathbf{K}$ *and* $M\in\exp(\mathfrak{m})$ *such that* $G=K_0M$. *Let* $m=\log(M)\in\mathfrak{m}$; *from* Proposition 4, *item* 1, *there exists* $K_1\in\mathbf{K}$ *such that* $\mathrm{Ad}_{K_1}m=h\in\mathfrak{h}$, *so*

$$G=K_0\exp(m)=K_0\exp(\mathrm{Ad}_{K_1^\dagger}h)=K_0K_1\underbrace{\exp(h)}_{H}K_1^\dagger.$$

■

B. The Khaneja-Glaser basis

The Khaneja-Glaser basis[1] for arbitrary $\mathfrak{su}(2^n)$ makes explicit all the structures which concern us. In particular, the splitting $\mathfrak{g}=\mathfrak{k}\oplus\mathfrak{m}$ and the Cartan subalgebras $\mathfrak{h}_n$ and $\mathfrak{f}_n$ are manifest.

We start with a familiar example:

Example 6: *For* $n=2$, *we propose basis elements for the Lie algebra* $\mathfrak{su}(4)$ *and organize them into subspaces* $\mathfrak{m}_2$ *and* $\mathfrak{k}_2$ *as follows:*

$\mathfrak{su}(4)$				
$\mathfrak{m}_2$			$\mathfrak{k}_2$	
XX	XY	XZ	XI	IX
YY	YZ	YX	YI	IY
ZZ	ZX	ZY	ZI	IZ
$\cup$				
$\mathfrak{h}_2$				

(4)

$$\mathfrak{h}_2 = \mathrm{span}\{XX, YY, ZZ\}$$

$$\mathfrak{f}_2 = \{0\}$$

Now we obtain the *Khaneja-Glaser basis* for $\mathfrak{su}(2^n)$ by a relatively simple iteration process starting from $\mathfrak{su}(4)$, as summarized in the following:

$\mathfrak{su}(2^n)$			
$\mathfrak{m}_n$		$\mathfrak{k}_n$	
$I^{n-1}\otimes X$	$I^{n-1}\otimes Y$	$I^{n-1}\otimes Z$	
		$\widehat{\mathfrak{k}_n}$	
$\mathfrak{su}(2^{n-1})\otimes X$	$\mathfrak{su}(2^{n-1})\otimes Y$	$\mathfrak{su}(2^{n-1})\otimes Z$	$\mathfrak{su}(2^{n-1})\otimes I$
		$\mathfrak{k}_{n,1}$	$\mathfrak{k}_{n,0}$
$\cup$		$\cup$	
$\mathfrak{h}_n$		$\mathfrak{f}_n$	

$$I^{n-1} = I^{\otimes(n-1)} = \underbrace{I\otimes..\otimes I}_{n-1}$$

NB.: Terms of the form $\mathfrak{su}(2^{n-1})\otimes A$ denote the set obtained by tensoring each element of $\mathfrak{su}(2^{n-1})$ with the matrix $A=X,Y,X,I$; in all cases we consider the span of the basis elements over $\mathbb{R}$.

Notice that for $n>2$ two successive Cartan decompositions can be performed. First, the expected one referring to the pair $(\mathfrak{su}(2^n),\mathfrak{k}_n)$, with Cartan subalgebra $\mathfrak{h}_n$. In the terms of *Theorem 5*, this means we can write $G\in \mathrm{SU}(2^n)$ as $G=K'HK''$ with $H\in \exp(\mathfrak{h}_n)$ and $K',K''\in \exp(\mathfrak{k}_n)$. However, the decomposition of $\mathfrak{k}_n$ given by diagram (4) is

$$\mathfrak{k}_n = \mathfrak{k}_{n,1} \oplus \mathfrak{k}_{n,0} \oplus \mathrm{span}\{I^{n-1}Z\} \simeq \mathfrak{su}(2^{n-1}) \oplus \mathfrak{su}(2^{n-1}) \oplus \mathfrak{u}(1),$$

where both $\mathfrak{k}_{n,1}$ and $\mathfrak{k}_{n,0}$ are canonically isomorphic to $\mathfrak{su}(2^{n-1})$. Since our aim is to iteratively decompose the factors $K^{(j)}$ until they eventually reduce to "local" unitaries in $\mathrm{SU}(2)^{\otimes N}$ and non-local "Cartan" factors, we would expect $\mathfrak{k}_n$ to generate something of the form $\mathrm{SU}(2^{n-1}) \otimes \mathrm{SU}(2)$. Thus, there is a $\mathfrak{su}(2^{n-1})$ component too many in $\mathfrak{k}_n$ that we need to factor away in order to define the complete recurrence step.

A closer look at $\mathfrak{k}_n$ reveals another Lie Algebra pair, thereby clearing the way for a second Cartan decomposition: we just have to leave aside the "complex phase" generated by $I^{n-1}Z$ [see diagram (4)] that can be seen as a "local" transformation under the inclusion $\mathrm{U}(1) \hookrightarrow \mathrm{SU}(2)$. Let $\widehat{\mathfrak{k}_n} = \mathfrak{k}_{n,1} \oplus \mathfrak{k}_{n,0}$ denote the subalgebra obtained from $\mathfrak{k}_n$ in this manner, so that $\mathfrak{k}_n = \widehat{\mathfrak{k}_n} \oplus \mathfrak{u}(1) \hookrightarrow \widehat{\mathfrak{k}_n} \oplus \mathfrak{su}(2)$. Accordingly, given a group element $K = \exp(k) \in \mathbf{K}$, let us write $\hat{K} = \exp(\hat{k})$, where $\hat{k} \in \widehat{\mathfrak{k}_n}$ is obtained from $k \in \mathfrak{k}$ by eliminating the component spanned by $I^{n-1}Z$. This is well defined as $I^{n-1}Z$ commutes with every element in $\mathfrak{k}_n$.

It is now straightforward to check that $(\widehat{\mathfrak{k}_n}, \mathfrak{k}_{n,0})$ is also a Lie algebra pair,[1] whose Cartan subalgebra we call $\mathfrak{f}_n$. Hence, we can apply *Theorem 5* again to decompose the factors $\widehat{K'}$ and $\widehat{K''}$ into elements of $\exp(\mathfrak{f}_n)$ together with left and right multiplication by some new factors generated by $\mathfrak{k}_{n,0}$. This time the orthogonal subalgebra $\mathfrak{k}_{n,0} = \mathfrak{su}(2^{n-1}) \otimes I$ is canonically isomorphic to $\mathfrak{su}(2^{n-1})$, so it generates $\exp(\mathfrak{k}_{n,0} \oplus \mathrm{span}\{I^{n-1}Z\}) \simeq SU(2^{n-1}) \otimes SU(2)$. Thus, we have accomplished the complete nth recurrence step that yields the decomposition

$$G = K^{(1)}F^{(1)}K^{(2)}HK^{(3)}F^{(2)}K^{(4)},$$

with $F^{(j)} \in \exp(\mathfrak{f}_n)$, $H \in \exp(\mathfrak{h}_n)$ and $K^{(j)} \in \mathrm{SU}(2^{n-1}) \otimes \mathrm{SU}(2)$.

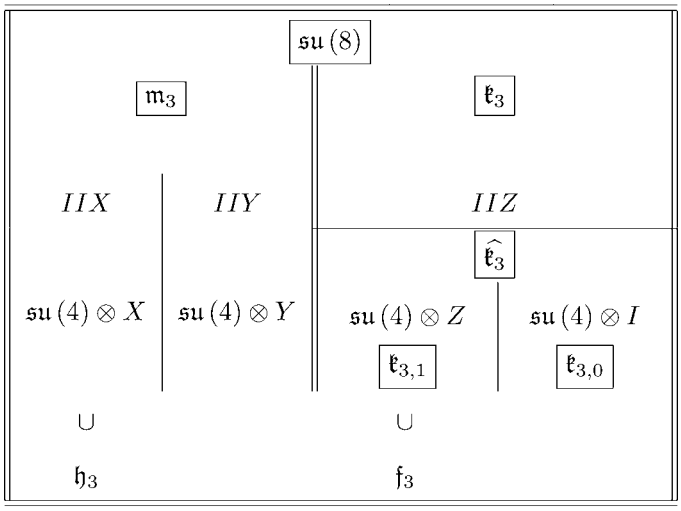
Note, finally, that we are particularly interested in the "Cartan" factors, i.e. those generated by the Cartan subalgebras $\mathfrak{h}_n$ of $(\mathfrak{su}(2^n), \mathfrak{k}_n)$ and $\mathfrak{f}_n$ of $(\widehat{\mathfrak{k}_n}, \mathfrak{k}_{n,0})$, that emerge in each step. It is thus convenient to know explicitly a set of basis elements for each of these subalgebras. This can be achieved by the following recurrence formula, starting from $\mathfrak{h}_2 = \mathrm{span}\{XX, YY, ZZ\}$,

$$\left.\begin{array}{l} \mathfrak{h}_n = \mathrm{span}\,\mathfrak{a}(n) \\ \mathfrak{f}_n = \mathrm{span}\,\mathfrak{b}(n) \end{array}\right\}, \; n = 2, ..., N \tag{5}$$

$$\boxed{\begin{array}{l} \mathfrak{a}(2) = \{XX, YY, ZZ\}, \mathfrak{b}(2) = \{0\} \\ \mathfrak{s}(n) = \bigcup_{j=2}^{n} \mathfrak{a}(j) \otimes I^{n-j} \\ \mathfrak{a}(n+1) = \{I^n, \mathfrak{s}(n)\} \otimes X \\ \mathfrak{b}(n+1) = \{\mathfrak{s}(n)\} \otimes Z \end{array}}$$

The *Example* below illustrates all the above constructions for the first non-trivial case $\mathfrak{su}(8)$:

Example 7: $n = 3 : \mathfrak{su}(8)$



$$\mathfrak{h}_3 = \mathrm{span}\{IIX, XXX, YYX, ZZX\}$$

$$\mathfrak{f}_3 = \mathrm{span}\{XXZ, YYZ, ZZZ\}$$

C. The Baker-Campbell-Hausdorff formula

The matrix Lie algebra $\mathfrak{g}$ is noncommutative and thus, for general elements $a,b\in\mathfrak{g}$, the product of exponentials $e^a e^b$ does not coincide with the exponential of their sum, e^{a+b}. In fact the expression for $\log(e^a e^b)$ has an infinite series of correction terms and is known as the *BCH formula*, after Baker-Campbell-Hausdorff.

Although the original formula was rather complicated and computationally unpractical, a remarkable simplification made by Dynkin[10,11] expresses all the terms as successive commutators of a and b,

$$\log(e^a e^b) = \sum_{i,j=1}^{\infty} T_{i,j}(a,b).$$

Here $T_{i,j}(a,b)$ denotes the homogeneous term of degree i in a and degree j in b; its expression is

$$T_{i,j}(a,b) = \frac{1}{i+j}\sum_{(i_1,j_1,\ldots,i_k,j_k)} \frac{(-1)^{k-1}}{k}\frac{1}{i_1!\,j_1!\ldots i_k!\,j_k!}[a^{i_1}b^{j_1}\ldots a^{i_k}b^{j_k}],$$

where we abbreviate $[a^{i_1}b^{j_1}\ldots a^{i_k}b^{j_k}]=\underbrace{[a,\ldots[a}_{i_1},\underbrace{[b,\ldots[b}_{j_1},[a,\ldots[b,\underbrace{[a,\ldots[a}_{i_k},\underbrace{[b,\ldots,b]\ldots]}_{j_k}$

and the sum ranges over all possible $2k$-uples of non-negative integers $(i_1,j_1,\ldots,i_k,j_k)$ such that

$$\sum_{c=1}^{k} i_c = i,\ \sum_{c=1}^{k} j_c = j \quad \text{and} \quad i_c + j_c > 0.$$

The first few terms are

$$\log(e^a e^b) = a + b + \frac{1}{2}[a,b] + \frac{1}{12}[a,[a,b]] + \frac{1}{12}[b,[b,a]] + \frac{1}{24}[a,[b,[a,b]]] + \frac{1}{120}(\ldots) \qquad (6)$$

and the higher order coefficients after $\frac{1}{120}$ decrease quickly (see, e.g., Ref. 12). This will motivate us later on to perform convenient truncations on this convergent series.

III. NUMERICAL ALGORITHM FOR THE KHK DECOMPOSITION

In this section we will develop a technique that allows the explicit numerical calculation of the components of a general group element $G \in \mathbf{G}$ under Cartan decomposition. The idea is to consider the Cartan decomposition (3) in the light of the BCH expansion (6). Let $g \in \mathfrak{g}$, $m \in \mathfrak{m}$, and $k \in \mathfrak{k}$ be the generators of G, M, and K_0, respectively. Then (3) reads

$$G = e^g = e^k e^m. \tag{7}$$

Since the matrix G is given, (3) shows that k can be obtained from m (and vice-versa) by

$$k = k(m) = \log(Ge^{-m}). \tag{8}$$

Hence, the decomposition problem is reduced to finding m.

A. Determining *m*

First, taking logarithms in (3), we obtain

$$g = \log(e^k e^m). \tag{9}$$

We then apply (6) to expand g in terms of successive brackets of k and m. In light of *Remark 2* we can easily deduce that each of the brackets belongs in either $\mathfrak{k}$ or $\mathfrak{m}$. Hence, the expansion is split into two orthogonal components,

$$\begin{aligned} g &= k + m + \underbrace{\frac{1}{2}[k,m]}_{\in \mathfrak{m}} + \underbrace{\frac{1}{12}[k,[k,m]]}_{\in \mathfrak{m}} + \underbrace{\frac{1}{12}[m,[m,k]]}_{\in \mathfrak{k}} + \underbrace{\frac{1}{24}[k,[m,[k,m]]]}_{\in \mathfrak{k}} + \cdots \\ &= g_{\mathfrak{k}} + g_{\mathfrak{m}}, \end{aligned}$$

where

$$g_{\mathfrak{k}} = k + \tfrac{1}{12}[m,[m,k]] + \tfrac{1}{24}[k,[m,[k,m]]] + \cdots \in \mathfrak{k}, \tag{10}$$

$$g_{\mathfrak{m}} = m + \tfrac{1}{2}[k,m] + \tfrac{1}{12}[k,[k,m]] + \cdots \in \mathfrak{m}. \tag{11}$$

Note that computing $g_{\mathfrak{k}}$ and $g_{\mathfrak{m}}$ from g is a straightforward task since the Khaneja-Glaser basis (4) makes explicit the partition $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{m}$.

At this stage we can use (3) to eliminate $k = k(m)$ in either of the equations (10) or (11). Choosing (11) whose first few terms are simpler we obtain

$$g_{\mathfrak{m}} = g_{\mathfrak{m}}(m) = m + \tfrac{1}{2}[k(m),m] + \tfrac{1}{12}[k(m),[k(m),m]] + \cdots, \tag{12}$$

which is an infinite series with rapidly decreasing coefficients. As $g_{\mathfrak{m}}(m)$ is a converging series we can truncate it so that the resulting equation will provide an *approximation* of m with an error that decreases by including higher commutator terms. If we call $\widetilde{P}_p(m)$ the truncation that includes all terms with up to p commutators, i.e.,

$$g_{\mathfrak{m}}(m) = \widetilde{P}_p(m) + \text{further terms}, \tag{13}$$

we can in principle solve

$$P_p(m) \equiv \widetilde{P}_p(m) - g_{\mathfrak{m}} = 0 \tag{14}$$

with respect to the single matrix variable m. However, the expression of $k(m)$ given by (3) is rather complicated. So we propose using again the BCH expansion to obtain

$$k(m) = \log(e^g e^{-m}) = g - m - \tfrac{1}{2}[g,m] - \tfrac{1}{12}[g,[g,m]] + \tfrac{1}{12}[m,[m,g]] \ldots . \tag{15}$$

As before, we can truncate (15) to a term that includes all qth order brackets. This yields a polynomial $Q_q(m)$ that approximates $k(m)$ as well as we desire at the cost of taking extra high-order commutators

$$k(m) = Q_q(m) + \text{further terms}. \tag{16}$$

After both truncations, Eq. (14) is approximated by

$$0 = P_p(m) \simeq -g_{\mathfrak{m}} + m + \tfrac{1}{2}[Q_q(m),m] + \tfrac{1}{12}[Q_q(m),[Q_q(m),m]] + \ldots,$$

where $P_p(m)$ is now a polynomial in one matrix variable with matrix coefficients. Our problem of finding m has thus been reduced to finding the zeros of a polynomial. This can be easily performed with a numerical algorithm.[13] The accuracy of the result can be increased by including more terms in the truncated series P_p and Q_q, i.e., increasing p and q. Specifically, we prove in Appendix A that, in this way, the errors in determining m by the truncation procedure are well under control.

Example 8*: Take the "first order" truncations* $p=1, q=1$*:*

$$P_1(m) = -g_{\mathfrak{m}} + m + \tfrac{1}{2}[k(m),m],$$

$$Q_1(m) = g - m - \tfrac{1}{2}[g,m].$$

Then, approximating $k(m) \simeq Q_1(m)$*, we obtain*

$$P_1(m) \simeq -g_{\mathfrak{m}} + m + \tfrac{1}{2}\left[g - m - \tfrac{1}{2}[g,m],m\right] = -g_{\mathfrak{m}} + m + \tfrac{1}{2}[g,m] - \tfrac{1}{4}[m,[m,g]].$$

B. The $M=K_1HK_1^\dagger$ decomposition

Once m is known, it remains to find the subgroup element $K_1^\dagger \in \mathbf{K}$ whose adjoint action rotates M onto $H=e^h, h \in \mathfrak{h}$.

Lemma 9*: The following properties are associated to* $\mathbf{H}=\exp(\mathfrak{h})$*:*

1. $\mathbf{H}$ *is a torus (compact connected Abelian Lie subgroup) of* $\mathbf{G}$*;*
2. *any vector* $v \in \mathfrak{h}$ *whose 1-parameter subgroup* $\{\exp(tv)\}$ *is dense in* $\mathbf{H}$ *is centralized in* $\mathfrak{m}$ *just by* $\mathfrak{h}$*:*

$$\{u \in \mathfrak{m} | [u,v] = 0\} = \mathfrak{h} \tag{17}$$

Proof: *See, e.g., Spaces of Constant Curvature (Sec. 8.6).*[14] ■

As shown in *Appendix* B, the first necessary ingredient to perform the decomposition $M=K_1HK_1^\dagger$ is some vector $v \in \mathfrak{h}$ that generates a dense 1-parameter subgroup $\exp(tv) \subset \mathfrak{h}$. This may seem abstract, but since we have an explicit basis (5) for $\mathfrak{h}$, it suffices to take any irrational combination of the Cartan generators.

Example 10: *In* $\mathfrak{su}(8)$*, take, e.g.,*

$$v = IIX + \pi\,.\,XXX + \pi^2\,.\,YYX + \pi^3\,.\,ZZX.$$

The reluctant reader may verify that, indeed, the centralizer of such v *in* $\mathfrak{m}$ *is just* $\mathfrak{h}$.

Now, we may define $f_{v,m}$ as in Appendix B to be given by

$$f_{v,m}(K) = \langle v, \mathrm{Ad}_K(m)\rangle = \sum_{a,b,c,d} C_{ad}^c C_{bc}^d v^a (K^\dagger m K)^b \tag{18}$$

and recover K_1 numerically as a minimum of $f_{v,m}$.

We conclude that m can be rotated into $h=\mathrm{Ad}_{K_1}(m)$. Thus we have completed the decomposition

$$G = K_0 K_1 e^h K_1^\dagger.$$

IV. STEP-BY-STEP SUMMARY

What we have described so far consists of the main building blocks necessary to perform the Khaneja-Glaser decomposition. Here, we will summarize all the steps one needs to take when given an arbitrary unitary $G \in \mathrm{SU}(2^n)$.

1. Calculate its (matrix) logarithm $g=\log(G) \in \mathfrak{g}=\mathfrak{su}(2^n)$.
2. Compute the Khaneja-Glaser basis following the recurrence in diagram (4); take $g_\mathfrak{m}$, the component of g on the subspace $\mathfrak{m}_n$.
3. Truncate (12) including pth commutators to get $\tilde{P}_p(m)$; let $P_p(m)=\tilde{P}_p(m)-g_\mathfrak{m}$.
4. Truncate (15) including qth commutator to get $Q_q(m)$, as in (16).
5. Replace $Q_q(m)$ for $k(m)$ in the expression of $P_p(m)$ obtained in 3, so that $P_p(m)$ becomes a polynomial in m.
6. Solve the zeros of $P_p(m)$ to get a solution m to (14).
7. Use m from item 6 above to calculate $K_0=Ge^{-m}$ as in (3).
8. Compute $\mathfrak{h}_n$ following (5); order its elements $\{u_j\}$, e.g., alphabetically and define $v=\Sigma \pi^{j-1} u_j$ to satisfy the density hypothesis of *Lemma 9*.
9. Use m and v to define $f_{v,m}(K)=\Sigma_{a,b,c,d} C_{ad}^c C_{bc}^d v^a (K^\dagger m K)^b$ as in (18); minimize f on $\mathbf{K}=\exp(\mathfrak{k}_n)$ to find K_1.
10. Calculate $h=K_1^\dagger m K_1$, and thus $H=\exp(h)$.
11. Assembling the results from items 7, 9. and 10, obtain

$$G = K_0 K_1 H K_1^\dagger.$$

12. Repeat the above steps for $G=\widehat{K_0 K_1}$ and then for $G=\widehat{K_1^\dagger}$, replacing $\mathfrak{k}_n \to \mathfrak{k}_{n,0}$, $\mathfrak{m}_n \to \mathfrak{k}_{n,1}$ and $\mathfrak{h}_n \to \mathfrak{f}_n$.
13. Items 11 and 12 yield the decomposition

$$G = K^{(1)} F^{(1)} K^{(2)} H K^{(3)} F^{(2)} K^{(4)},$$

with $F^{(j)} \in \exp(\mathfrak{f}_n)$, $H \in \exp(\mathfrak{h}_n)$, and $K^{(j)} \in \mathrm{SU}(2^{n-1}) \otimes \mathrm{SU}(2)$.

14. Decrease $n \to n-1$ and iterate this process to further decompose each factor $K^{(j)} \in \mathrm{SU}(2^{n-1}) \otimes \mathrm{SU}(2)$ until they all reduce to a product of Cartan factors $F_n^{(j)}$ and $H_n^{(l)}$ and local unitaries in $\mathrm{SU}(2)^{\otimes N}$.

NB.: As far as accuracy in step 6 is concerned, tasks 3 to 5 should be performed in light of *Appendix* A. Namely, truncations at higher order should be tried until numerical errors are satisfactory, which will happen after a finite number of attempts.

V. CONCLUSIONS

As the advances in quantum technologies move beyond the control of one or two spins, or qubits, it is important to minimize the overall cost of processing quantum information. The Khaneja-Glaser decomposition of SU(2^N) offers an upper bound for this optimization procedure given by 4^{N-1} multi-local $\mathrm{SU}(2)^{\otimes N}$ rotations together with $4^{N-1}-1$ purely entangling operations. The latter can be reduced, if desired, into bipartite interactions, or two-qubit gates. Moreover, in Ref. 15, Nielsen gives lower bounds for such optimization. Here we exploit the Khaneja-Glaser approach to build a constructive method for decomposing a general unitary in terms of its local unitary components. Abstract as it may seem, the decomposition problem can be cast in such a way that can be easily solved by a numerical algorithm that can be found at *http://cam.qubit.org/users/jiannis/lie_solve[1].tar.gz*.

Finally, one should notice that the solutions we obtained are not necessarily unique. In general, neither the zeros of the matrix polynomials, $P_p(m)$, nor the minima of the functions, f, are

unique. In particular, viewing the minimization procedure from the equivalent point of view of the diagonalization of the matrix m, where K_1 is constructed out of the eigenvectors of m, there are many equivalent solutions depending on the particular ordering of the eigenvectors. Moreover, one should also take into account that the exponential function has a natural 2π periodicity and the adjoint action is $\mathbb{Z}_2$-symmetric.[6,7] While our approach is not concerned with the actual parametrizations of the group elements, this is an important issue which should be addressed in the future.

ACKNOWLEDGMENTS

We would like to thank Gregório Malajovich for very fruitful correspondence and for writing the program to find the zeros of our polynomials. We also thank Tim Perutz for drawing our attention to Rouché's theorem. This work was partially supported by the Royal Society.

APPENDIX A: ACCURACY OF BCH TRUNCATIONS

Here, a generalized version of Rouché's theorem[16] is employed to show that the truncations performed in Sec. III A yield a rigorous approximation for the zeros of (12).

Theorem 11: *Let $\varphi,\psi:\mathbb{C}^r\to\mathbb{C}^r$ be holomorphic functions and $D\subset\mathbb{C}^r$ be an open domain such that neither φ nor ψ have zeros on ∂D; if*

$$|\varphi(m)-\psi(m)|<|\varphi(m)|+|\psi(m)|,\quad \forall\, m\in\partial D, \tag{A1}$$

then φ and ψ have the same number of zeros in D.

NB.: We adopt, e.g., the norm $|\varphi|=\max_{i,j}|\varphi_{ij}|$, but the argument holds for any L^p-norm.

Let $r=2^{2n}$ be the number of entries of a matrix $m\in\mathfrak{su}(2^n)$, seen as a complex vector. Consider then a BCH-type series $\varphi(m)$ and its truncated version $\psi(m)=P_p(m)$ containing all its terms of up to p successive brackets, calling $R_p(m)$ the truncation remainder

$$\varphi(m)=P_p(m)+R_p(m).$$

Suppose $\hat{m}\in\mathfrak{su}(2^n)$ is a zero of $P_p(m)$; then $\varphi(m)$ will also have a zero inside the polydisc $D=\Delta_\delta(\hat{m})\subset\mathbb{C}^r$ of radius $\delta>0$ about $\hat{m}$ if the following (stronger) instance of (A1) holds:

$$|R_p(m)|<|P_p(m)|,\quad \forall\, m\in\partial\Delta_\delta(\hat{m}). \tag{A2}$$

In other words, $\hat{m}$ approximates at least one zero of $\varphi(m)$ with error inferior to an arbitrarily chosen δ.

All we have to show is that condition (A2) holds for suitably large p; this is a relatively straightforward consequence of the uniform convergence of the BCH series $\varphi(m)=\lim_{p\to\infty}P_p(m)$, as we will now see. For any (small) $\varepsilon_0>0$, there is a p_0 such that

$$p>p_0\Rightarrow|P_p(m)-P_{p_0}(m)|<\varepsilon_0,\quad \forall\, m, \tag{A3a}$$

hence

$$|P_p(m)|>|P_{p_0}(m)|-\varepsilon_0,\quad \forall\, m. \tag{A3b}$$

In particular, if m_0 is a zero of $P_{p_0}(m)$, Eq. (A3a) restricted to the boundary $\partial\Delta_\delta(m_0)$ implies that all polynomials $P_p(m)$, $p>p_0$, also have at least one zero inside $\Delta_\delta(m_0)$, by Rouché's theorem.

On the other hand, convergence also implies $\lim_{p\to\infty}|R_p(m)|=0$, hence, for a given $\varepsilon_1>0$, there is p_1 such that

$$p>p_1\Rightarrow|R_p(m)|<\varepsilon_1,\quad \forall\, m. \tag{A4}$$

Set $\varepsilon_1=\min_{m\in\partial\Delta_\delta(m_0)}|P_{p_0}(m)|-\varepsilon_0$; assuming this is positive (if not, take a larger p_0 for a smaller ε_0), take some $p>\max\{p_0,p_1\}$ and find $m_1\in\Delta_\delta(m_0)$ such that $P_p(m_1)=0$. Then consider any smaller polydisc $\Delta_{\delta'}(m_1)\subset\Delta_\delta(m_0)$, and restrict Eqs. (A3b) and (A4) to its boundary. We obtain

$$|R_p(m)| < |P_p(m)|, \quad \forall\, m \in \partial\Delta_{\delta'}(m_1),$$

thus, by Rouché's theorem again, $\varphi(m)=P_p(m)+R_p(m)$ has a zero inside $\Delta_{\delta'}(m_1)\subset\Delta_\delta(m_0)$.

APPENDIX B: PROOF OF PROPOSITION 4

In this *Appendix* we will develop the proof of *Proposition 4*, following Ref. 14 (Sec. 8.3). This argument contains most of the crucial elements to understanding the **KHK** decomposition in detail.

Proof of Proposition 4.

1. Given $m \in \mathfrak{m}$, we want to find $K_1^\dagger \in \mathbf{K}$ whose action rotates m onto some element h of the Cartan subalgebra $\mathfrak{h}$. First, take any $v \in \mathfrak{h}$ that generates a dense 1-parameter subgroup $\exp(tv)\subset\mathbf{H}=\exp(\mathfrak{h})$, as in *Lemma 9* and define the function

$$f_{v,m} = f:\mathbf{K} \to \mathbb{R},$$

$$K \mapsto f(K) = \langle v, \mathrm{Ad}_K(m)\rangle, \tag{B1}$$

where $\langle a,b\rangle=\mathrm{tr}(\mathrm{ad}_a\,\mathrm{ad}_b)$ is the Killing form on $\mathfrak{g}$. Since f is continuous and $\mathbf{K}$ is compact, f admits an absolute minimum $K_1 \in \mathbf{K}$. If we consider a local perturbation of K_1 by e^{tk}, for any $k \in \mathfrak{k}$, we have

$$0 = \left.\frac{d}{dt}\right|_{t=0} f(e^{tk}K_1) = \left.\frac{d}{dt}\right|_{t=0} \langle v,\ \mathrm{Ad}_{e^{tk}}\,\mathrm{Ad}_{K_1}(m)\rangle$$

$$\langle v, [k, \underbrace{\mathrm{Ad}_{K_1}(m)}_{h}]\rangle = \mathrm{tr}(\mathrm{ad}_v \mathrm{ad}_{[k,h]})$$

$$= \mathrm{tr}(\mathrm{ad}_v(\mathrm{ad}_k\,\mathrm{ad}_h - \mathrm{ad}_h\,\mathrm{ad}_k)) \overset{\text{(c.p.t.)}}{=} \mathrm{tr}(\mathrm{ad}_{[h,v]}\mathrm{ad}_k)$$

$$\Leftrightarrow \langle [h,v],k\rangle = 0, \quad \forall\, k \in \mathfrak{k}.$$

But the Killing form is non-degenerate on $\mathfrak{k}$, so we must have $[h,v]=0$ and thus $h \in \mathfrak{h}$, as v is centralized by $\mathfrak{h}$; hence, we have shown that

$$m = \mathrm{Ad}_{K_1^\dagger}(h),\ h \in \mathfrak{h}.$$

2. By 1. there exists $K \in \mathbf{K}$ such that

$$\mathrm{Ad}_K(v) \in \mathfrak{h}'.$$

Now take centralizers on both sides. ■

In quantum mechanics the statistics of the outcomes of a measuring apparatus is described by a positive operator valued measure (POVM). A quantum channel transforms POVMs into POVMs, generally irreversibly, thus losing some of the information retrieved from the measurement. This poses the problem of *which POVMs are "undisturbed," i.e., they are not irreversibly connected to another POVM*. We will call such POVMs *clean*. In a sense, the clean POVMs would be "perfect," since they would not have any additional "extrinsical" noise. Quite unexpectedly, it turns out that such a "*cleanness*" property is largely unrelated to the convex structure of POVMs, and there are clean POVMs that are not extremal and vice versa. In this article we solve the cleannes classification problem for number n of outcomes $n \leqslant d$ (d dimension of the Hilbert space), and we provide a set of either necessary or sufficient conditions for $n > d$, along with an iff condition for the case of informationally complete POVMs for $n = d^2$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2008996]

I. INTRODUCTION

The new quantum information technology[1] has resurrected the interest in the theory of quantum measurements[2] and quantum open systems,[3,4] shifting the interest from applications to high-sensitivity and high-precision experiments[5] to its use in quantum information processing.[6] Depending on the particular kind of quantum processing—e.g., teleportation,[7,8] entanglement detection,[9] and distillation[10]—that are used in quantum computation[1,6] and quantum cryptography,[11] various new types of quantum measurements are now needed. The theory for engineering new quantum measurements optimized according to given criteria has been pioneered since the late 1960s by many authors[12] who concurred to the making of the quantum estimation theory,[13] the ancestor of the modern quantum information theory.

The general strategy of quantum estimation theory is to optimize the output statistics of the measuring apparatus according to a given criterion/fidelity, which depends on the specific use of

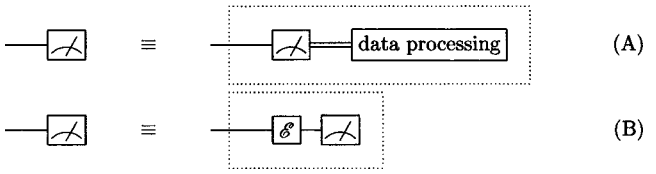

FIG. 1. There are two ways of processing POVMs: (a) the *postprocessing* of the output data and (b) *preprocessing* of the input state by a quantum channel. The postprocessing cannot generally achieve the same result of a *preprocessing:* the postprocessing is purely classical, whereas the preprocessing is quantum.

the measurement, the outcome statistics of the measurement for all possible input states being described by a positive operator valued measure (POVM).[13] POVMs form a convex set, where convex combinations correspond to random choices among different apparatuses. Most optimization problems actually resort to minimize a concave function on such a convex set, thereby optimization can be restricted to its extremal points, where concave functions attain their minimum. Coincidentally, due to the specific form of the optimization function, in many applications the optimal POVMs turn out to have unit rank—e.g., for phase estimation on pure states[13,14]—and this has led to the widespread belief that optimality is synonym of rank-one, whereas for sufficiently large dimension, and typically for optimization with input mixed states, the rank of extremal POVMs can be easily larger than one, as shown in Refs. 15–17.

In a specific application the optimal POVM does not necessarily attain the whole accessible information. At first sight, this assertion may appear contradictory: how a POVM can be optimal, if it wastes accessible information? However, once the measurement is performed, no other possibility for optimization is left apart from the processing of the outcome—*postprocessing* for short—and, being purely classical, the postprocessing cannot generally achieve the same result of a *preprocessing* by a quantum channel. The situation is depicted in Fig. 1. Clearly, the preprocessing can change the POVM irreversibly, reducing the information from the measurement. On the other hand, it is possible that a POVM optimal for a given criterion is obtainable from another *cleaner* one via an irreversible preprocessing as in Fig. 1(b). This means that in some cases we need to give up some *quantity* of information for the *quality* of the information.

The above-mentioned scenario poses the problem of *which POVMs are "undisturbed,"* namely *are not irreversibly connected to another POVM*. We will call such POVMs *clean*—in a sense a clean POVM would be "perfect," since it would not have any additional "extrinsical" noise, or it has lost no information irreversibly. Quite surprisingly, as announced, in this article we will see that the *cleanness* property of the POVM is largely unrelated to its extremality, and there are clean POVMs that are not extremal and vice versa. The problem of classifying clean POVMs turns out to be more difficult than that of classifying extremal ones, and in this article we will give a complete classification of clean POVMs only for a number n of outcomes $n \leqslant d$, whereas for $n > d$ we will give a set of interesting necessary conditions, and an iff condition for the case of informationally complete POVMs for $n = d^2$. Clearly, the need for a number of outcomes $n > d$ can be required by the particular optimization problem (see, e.g., Refs. 18 and 19), however, no more than $n = d^2$ elements are needed, which is the maximum number of outcomes for extremality.[15] Davies[20] proved d^2 to be an upper bound for the maximal cardinality of the POVM needed to attain the accessible information, and still it is debated if d^2 outcomes are actually needed (the cases of Refs. 18 and 19 proved that the lower bound is actually larger than d). This difficulties reflect those in classifying cleanness for $n > d$. In a sense it is clear that d^2 elements are needed to retrieve the accessible information, when the kind of information needs to be decided after the measurement has been performed. Indeed, an extremal POVM with d^2 outcomes is versatile to any kind of information encoding, as it is "informationally complete,"[21] namely it makes it possible to estimate any ensemble average by changing only the data processing of the outcomes (such an extremal measurement with d^2 elements can be proved to exist for any dimension d[15]). Clearly, for an extremal informationally complete measurement, a further optimization step can be achieved at the level of data processing,[22,23] once the kind of information of interest has been decided. Thus,

the postprocessing of the measurement is still a useful tool in retrieving the right information from a measurement.

The article is organized as follows. After introducing some notations and prerequisites in Sec. II, in Sec. III we state some general results about channels and POVMs which will be used throughout the article. In Sec. IV we analyze the convex set of channels connecting two POVMs. Section V is devoted to a complete analysis of the classical postprocessing, and give a complete characterization of "cleanness" under postprocessing. Section VI addresses the problem of the preprocessing ordering of POVMs, namely if a POVM is "cleaner" than another, and when they are "equivalent," which corresponds to the possibility of reversing the action of the channel connecting the two POVMs. Section VIII shows that for dimension $d=2$ equivalence under cleanness is the same as unitary equivalence. Section IX fully solves the case of number of outcomes $n \leqslant d$, and gives some interesting alternative theorems for the case of *effects*, namely the two-outcome POVMs. Section X analyzes the case of informationally complete POVMs, giving also an iff condition characterizing the clean POVMs. Section XI gives some conditions for rank-one measurements. Finally, we conclude the paper in Sec. XII with a list of most relevant results and of the main open problems.

II. NOTATION AND PREREQUISITES

Throughout this article we will consider a quantum system with Hilbert space H with finite dimension $d=\dim(\mathsf{H})$, and denote by S the set of states on H (corresponding to a positive unit-trace operator on H), and by $\mathsf{B}(\mathsf{H})$ the algebra of bounded operators on H. We will use capital script fonts e.g., $\mathcal{A},\mathcal{B},\ldots$, to denote operator algebras in $\mathsf{B}(\mathsf{H})$, and with the symbol $\mathcal{A}'$ we will denote the commutant of $\mathcal{A}$, namely the algebra defined as $\mathcal{A}' \doteq \{Y \in \mathsf{B}(\mathsf{H}) \,|\, [X,Y]=0, X \in \mathcal{A}\}$. Completely positive trace-preserving (CPT) and identity-preserving maps on S and $\mathsf{B}(\mathsf{H})$, respectively—all generally referred to as *channels*—will be denoted by capital calligraphic letters, e.g., $\mathcal{A},\mathcal{B},\ldots$, whereas we will always use capital Roman letters for operators. We will restrict attention to POVMs $\{P_e\}_{e\in\mathsf{E}}$ with finite sampling space E, namely

$$P_e \geqslant 0, \quad \forall\, e \in \mathsf{E}, \quad \sum_{e\in\mathsf{E}} P_e = I. \tag{1}$$

We will extensively use the vector notation $\mathbf{P} \equiv \{P_e\}$, $\mathsf{E}(\mathbf{P})$ denoting the sampling space of $\mathbf{P}$, and $|\mathbf{P}|$ the cardinality of $\mathsf{E}(\mathbf{P})$. The vector notation will be naturally extended to tensor products—e.g., $\mathbf{P}\otimes\mathbf{Q}$ for the POVM $\{P_e \otimes Q_f\}_{e\in\mathsf{E}(\mathbf{P}),f\in\mathsf{E}(\mathbf{Q})}$ on $\mathsf{H}\otimes\mathsf{H}$—and to functionals—e.g., $\mathrm{Tr}[\rho\mathbf{P}]$ for the vector of probabilities $\mathrm{Tr}[\rho P_e]$. By $\mathsf{Span}(\mathbf{P})$ we will denote the linear operator space spanned by the POVM elements $\{P_e\}_{e\in\mathsf{E}(\mathbf{P})}$, and by $\mathsf{Rng}(\mathbf{P})$ the range of the POVM $\mathbf{P}$, which is defined as the following convex subset of $\mathbb{R}_+^{|\mathbf{P}|}$

$$\mathsf{Rng}(\mathbf{P}) \doteq \{\mathbb{R}_+^{|\mathbf{P}|} \ni \boldsymbol{p} = \mathrm{Tr}[\rho\mathbf{P}], \quad \rho \in \mathsf{S}\}. \tag{2}$$

The convex set of POVMs with cardinality N will be denoted by $\mathcal{P}_N$.

Finally, we will use the symbol $|A\rangle\rangle$ to denote the following bipartite vector in $\mathsf{H}\otimes\mathsf{H}$

$$|A\rangle\rangle \doteq \sum_{m,n=1}^{d} A_{m,n}|m\rangle|n\rangle, \tag{3}$$

where $A \in \mathsf{B}(\mathsf{H})$ is the operator corresponding to the $d\times d$ matrix with elements $A_{m,n}$ on the basis $\{|n\rangle\}$. One can easily verify the following useful identities

$$A \otimes B^{\mathsf{T}}|C\rangle\rangle = |ACB\rangle\rangle,$$

$$\mathrm{Tr}_1[|A\rangle\rangle\langle\langle B|] = A^{\mathsf{T}}B^*, \tag{4}$$

$$\mathrm{Tr}_2[|A\rangle\rangle\langle\langle B|] = AB^\dagger,$$

where X^T denotes the transpose in the basis $\{|n\rangle\}$, while X^* is the complex conjugate in the same basis. Tr_i denotes the partial trace on the ith space.

III. USEFUL LEMMAS ABOUT CHANNELS AND POVMs

In the following we will name a map $\mathcal{E}$ *spectrum-width decreasing* when it reduces the "spectral width" of a real symmetric operator X, namely when

$$[\lambda_m(\mathcal{E}(X)), \lambda_M(\mathcal{E}(X))] \subseteq [\lambda_m(X), \lambda_M(X)], \tag{5}$$

$\lambda_M(X)$ and $\lambda_m(X)$ denoting the maximum and minimum eigenvalues of X, respectively.

Lemma III.1: Channels are spectrum-width decreasing.

Proof: Consider the eigenvector $|\psi_j\rangle$ of $\mathcal{E}(X)$ corresponding to the eigenvalue $\lambda_j(\mathcal{E}(X))$. One has

$$\lambda_j(\mathcal{E}(X)) = \mathrm{Tr}[\mathcal{E}(X)|\psi_j\rangle\langle\psi_j|] = \mathrm{Tr}[X\mathcal{E}^\mathsf{T}(|\psi_j\rangle\langle\psi_j|)] \in [\lambda_m(X), \lambda_M(X)], \tag{6}$$

since the dual map $\mathcal{E}^\mathsf{T}$ is CPT. ■

Notice that in the above-mentioned lemma the identity-preserving condition is crucial, since the lemma would not hold for a CPT map $\mathcal{E}$, e.g., $\mathcal{E}(\rho)=|\psi\rangle\langle\psi|$, and the spectral width increases from $[\lambda_m(\rho), \lambda_M(\rho)]$ to $[0, 1]$.

The inverse of a non-unitary invertible channel is necessarily not completely positive.

Theorem III. 2 (Wigner): *Any invertible channel has CP inverse iff it is unitary*.

Proof: Let $\mathcal{E}_1$ and $\mathcal{E}_2$ be two channels such that $\mathcal{E}_2^\mathsf{T} \circ \mathcal{E}_1^\mathsf{T}(\rho)=\rho$. Hence:

$$|\psi\rangle\langle\psi| = \sum_{ij} B_j A_i |\psi\rangle\langle\psi| A_i^\dagger B_j^\dagger, \quad \forall\, |\psi\rangle, \tag{7}$$

where A_i and B_j are canonical Kraus representations for $\mathcal{E}_1$ and $\mathcal{E}_2$, respectively. Since all terms in the sum are positive, this means that $B_j A_i|\psi\rangle = \beta_{ij}^{\psi}|\psi\rangle$, for all $|\psi\rangle$ and all i,j. By linearity, it is clear that β_{ij} cannot depend on $|\psi\rangle$, implying that $B_j A_i = \beta_{ij} I$, for all i,j.

We can now prove that $\beta_{ij} \neq 0$, for all i,j. Otherwise, there exists a couple of operators B_k and A_l for which $B_k A_l = 0$. These two operators must both be noninvertible, since, if one is invertible, the other has to be null, and we can without loss of generality (w.l.o.g.) drop it from the Kraus representation (7). Let us fix the couple k,l for which $B_k A_l = 0$, namely both are not invertible. Now, the only possibility to have $B_j A_i = \beta_{ij} I$ for all i,j is that $B_k A_i = 0$ for all i (since B_k is not invertible, whence necessarily $B_k A_i$ cannot be full rank), and analogously $B_j A_l = 0$ for all j. In this case, all B_j's supports would be forced to be contained in the orthogonal complement to the range of A_l (which is strictly contained in the full Hilbert space), and this would be in contradiction with the normalization condition $\Sigma_j B_j^\dagger B_j = I$. Therefore, $\beta_{ij} \neq 0$ for all i,j, and the operators A_i and B_j are all invertible. This allows us to write

$$\begin{aligned} B_j &= \beta_{ij} A_i^{-1}, \quad \forall\, j, \\ A_i &= \beta_{ij} B_j^{-1}, \quad \forall\, i, \end{aligned} \tag{8}$$

whence all B_j's are proportional to each other, and analogously for the A_i. In other words, the Kraus representations of $\mathcal{E}_1$ and $\mathcal{E}_2$ are made of only one operator. This means that $\mathcal{E}_1$ and $\mathcal{E}_2$ are unitary, one the inverse of the other.

The converse direction is trivial. In Corollary X.4, we will prove that the inverse map of an invertible nonunitary channel is indeed nonpositive. ■

Theorem III.3 (Chefles, Jozsa, Winter): *Consider two sets of pure states on* H *with the same cardinality. There exist two channels mapping the elements of the first set to the corresponding elements of the second set and vice versa, iff the two sets of states are unitarily equivalent*.

Proof: See Ref. 24. ■

Lemma III.4. (Lindblad): A channel $\mathcal{E}$ stabilizes an algebra $\mathcal{S}\subseteq\mathsf{B}(\mathsf{H})$, namely

$$\mathcal{E}(X)=X, \quad \forall\, X\in\mathcal{S}, \tag{9}$$

iff the operators $\{E_k\}$ of any Kraus form $\mathcal{E}(X)=\Sigma_k E_k^\dagger X E_k$ belong to the commutant $\mathcal{S}'$ of the algebra $\mathcal{S}$.

Proof: See Ref. 25. ■

Finally let us state some results about extendiblity of completely positive maps (mostly taken from Ref. 26). To this end let us consider a linear subset $\mathcal{S}$ of $\mathsf{B}(\mathsf{H})$ which contains the identity and is closed under adjoints—each set $\mathcal{S}$ of this type will be called in the following an *operator system*. It is easy to see that $\mathcal{S}$ is generated (as a linear space) by its positive elements. It makes therefore sense to speak about positive maps $\mathcal{E}:\mathcal{S}\to\mathcal{A}$ into an algebra $\mathcal{A}$ and we can define also *complete positivity* in the usual way. Now the question arises whether such an $\mathcal{E}$ can be extended *as a completely positive map* to $\mathsf{B}(\mathsf{H})$. The following theorem gives a positive answer (Ref. 26, Theorems 6.2 and 7.5):

Theorem III.5. (Arveson's extension theorem): *Each completely positive map $\mathcal{E}:\mathcal{S}\to\mathsf{B}(\mathsf{H})$ defined on an operator system $\mathcal{S}\subset\mathsf{B}(\mathsf{H})$ can be extended to a completely positive map on $\mathsf{B}(\mathsf{H})$.*

If $\mathcal{E}$ is only positive (and not necessarily completely positive) a similar result is not available (cf. the corresponding discussion in Sec. VII). An important exception arises however, if the algebra $\mathcal{A}$ is abelian (Ref. 26, Theorem 3.9).

Theorem III.6: *If $\mathcal{E}:\mathcal{S}\to\mathcal{A}$ is positive, $\mathcal{S}$ an operator system and $\mathcal{A}$ an abelian algebra, the map $\mathcal{E}$ is completely positive.*

IV. THE CONVEX SET OF CHANNELS CONNECTING TWO POVMs

We now analyze the convex set of channels connecting two given POVMs **P** and **Q**, in equations

$$\mathcal{C}_{\mathbf{PQ}}=\{\mathcal{E}\ \text{channel}|\mathcal{E}(\mathbf{P})=\mathbf{Q}\}. \tag{10}$$

The extremal elements of $\mathcal{C}_{\mathbf{PQ}}$ can be characterized in terms of the operators $\{E_i\}$ of the canonical Krauss decomposition by the following theorem.

Theorem IV.1: *The map $\mathcal{E}\in\mathcal{C}_{\mathbf{PQ}}$ is extremal iff for some element P_k of the POVM* **P** *the operators $\{E_i^\dagger P_k E_j\}_{ij}$ made with the canonical Kraus operators $\{E_i\}$ of the map are linearly independent.*

Proof: First we show by contradiction that the condition is sufficient. In fact, suppose that $\mathcal{E}$, with $\{E_i^\dagger P_k E_j\}_{ij}$ linearly independent, is not extremal in $\mathcal{C}_{\mathbf{PQ}}$. Then there exist two different channels $\mathcal{E}_\pm\in\mathcal{C}_{\mathbf{PQ}}$ such that

$$\mathcal{E}=\tfrac{1}{2}(\mathcal{E}_+ +\mathcal{E}_-). \tag{11}$$

Upon defining $\mathcal{P}\equiv\mathcal{E}_+-\mathcal{E}$, clearly one has $\mathcal{P}(\mathbf{P})=0$ and $\mathcal{E}\pm\mathcal{P}=\mathcal{E}_\pm$, which are channels. Then $R_{\mathcal{E}_\pm}\equiv R_{\mathcal{E}}\pm R_{\mathcal{P}}\geqslant 0$, where for any channel $\mathcal{E}$ the positive operator $R_{\mathcal{E}}$ in linear correspondence with $\mathcal{E}$ is defined as $R_{\mathcal{E}}=\Sigma_j|E_j\rangle\rangle\langle\langle E_j|$ for $\{E_j\}$ Kraus operators of $\mathcal{E}$.[27] This implies that $\mathsf{Supp}(R_{\mathcal{P}})\subseteq\mathsf{Supp}(R_{\mathcal{E}})$, namely there exists a nonvanishing matrix p_{ij} such that $R_{\mathcal{P}}=\Sigma_{ij}p_{ij}|E_i\rangle\rangle\langle\langle E_j|$. As a consequence we have

$$\mathcal{P}(P_k)=\sum_{ij}p_{ij}E_i^\dagger P_k E_j=0, \quad \forall\, k. \tag{12}$$

This contradicts the hypothesis. The proof that it is also necessary is now straightforward. Suppose indeed that the operators $\{E_i^\dagger P_k E_j\}_{ij}$ are linearly dependent. Then there exists a nonvanishing matrix of coefficients a_{ij} such that $\Sigma_{ij}a_{ij}E_i^\dagger P_k E_j=0$ for all k. If we define $p_{ij}=\kappa(a_{ij}+a_{ij}^*)$, then the map $\mathcal{P}(X)=\Sigma_{ij}p_{ij}E_j^\dagger X E_i$ will annihilate all elements of the POVM **P**, namely $\mathcal{P}(\mathbf{P})=0$. Moreover,

for a sufficiently small $\kappa \neq 0$ both maps $\mathcal{E}_{\pm}=\mathcal{E}\pm\mathcal{P}$ will be channels and will belong to $\mathcal{C}_{\mathbf{PQ}}$. This implies that $\mathcal{E}=\frac{1}{2}(\mathcal{E}_{+}+\mathcal{E}_{-})$, namely $\mathcal{E}$ is not extremal. ■

One can prove that either any element of the border of $\mathcal{C}_{\mathbf{PQ}}$ is also an element of the border of the full convex set of channels, or $\mathcal{C}_{\mathbf{PQ}} \equiv \{\mathcal{E}\}$. This comes from the definition of the border of a convex set

Definition IV.2: For a convex set $\mathcal{C}$, an element $p \in \mathcal{C}$ belongs to its boundary $\partial\mathcal{C}$ if and only if there exists $q \in \mathcal{C}$ such that

$$p + \epsilon(q-p) \in \mathcal{C}, \quad p - \epsilon(q-p) \notin \mathcal{C}, \quad \forall\, \epsilon \in [0,1],. \tag{13}$$

or, equivalently iff there exists $q \in \mathcal{C}$ such that for all $\epsilon > 0$ for which $p+\epsilon q \in \mathcal{C}$ then $p-\epsilon q \notin \mathcal{C}$.

We will now prove the following lemma.

Lemma IV.3: The border of the convex $\mathcal{C}_{\mathbf{PQ}}$ is a subset of the border of the convex of all channels.

Proof: Consider a channel $\mathcal{E} \in \mathcal{C}_{\mathbf{PQ}}$ and a "perturbation" $\mathcal{P}$ such that $\mathcal{E}+\epsilon\mathcal{P} \in \mathcal{C}_{\mathbf{PQ}} \forall\, \epsilon \in [0, 1]$. By definition $\mathcal{P}(P_i)=0$ for all P_i, whence, if $\mathcal{E}-\epsilon\mathcal{P}$ is completely positive, then it necessarily belongs to $\mathcal{C}_{\mathbf{PQ}}$. Therefore, the only way to have $\mathcal{E}$ on the border of $\mathcal{C}_{\mathbf{PQ}}$ is to have $\mathcal{E}-\epsilon\mathcal{P}$ not CP, namely $\mathcal{E}$ lies on the border of the convex of all channels. ■

A "geometrical" proof is also the following. Since the constraint defining $\mathcal{C}_{\mathbf{PQ}}$ is linear, then $\mathcal{C}_{\mathbf{PQ}}$ is a linear section of the convex of all channels, whence its border belongs to the border of the convex of all channels.

Remark: Notice that the convex set $\mathcal{C}_{\mathbf{II}}$ will coincide with that of all channels, $\mathbf{I}=\{I\}$ denoting the trivial POVM.

Remark: From Lemma IV.3 it follows that when two POVMs are connected by a channel they can be always connected by a border channel, apart from the case in which the connecting channel is unique.

V. POSTPROCESSING

The most general postprocessing of a POVM, is a shuffling of the POVM elements with conditional probability $p(i|j)$, corresponding to the mapping

$$Q_i = \sum_j p(i|j) P_j. \tag{14}$$

When two POVMs $\mathbf{P}$ and $\mathbf{Q}$ are connected by a mapping of the form (14) for some conditional probability $p(i|j)$ we will write $\mathbf{P} >_p \mathbf{Q}$, and say that the POVM $\mathbf{P}$ is *cleaner under postprocessing*—for short *postprocessing cleaner*—than the POVM $\mathbf{Q}$. Notice that a relation of the form (14) is meaningful generally for $|\mathbf{P}| \neq |\mathbf{Q}|$, with the number of outcomes changing from input to output.

Relevant examples of post processing are:

(i) identification of two outcomes, e.g., j and k are identified with the same outcome l, corresponding to $p(n|j)=\delta_{ln}$, $p(n|k)=\delta_{ln}$ and

(ii) permutation π of outcomes, corresponding to $p(\pi(j)|k)=\delta_{jk}$.

The relation $>_p$ is a pseudo-ordering, since it is

(i) reflexive, corresponding to

$$\mathbf{P} >_p \mathbf{P}, \quad p(i|j) = \delta_{ij}; \tag{15}$$

(ii) transitive, i.e., $\mathbf{P} >_p \mathbf{Q} >_p \mathbf{R}$, corresponding to

$$R_i = \sum_j p(i|k) Q_k,\ Q_k = \sum_j p'(k|j) P_j, \Rightarrow R_i = \sum_j p''(i|j) P_j,$$

$$p''(i|j) = \sum_k p(i|k)p'(k|j). \tag{16}$$

An equivalence relation under postprocessing can be defined as follows.

Definition V.1: The POVMs $\mathbf{P}$ *and* $\mathbf{Q}$ *are* postprocessing equivalent—*in symbols* $\mathbf{P} \simeq_p \mathbf{Q}$—*iff both relations* $\mathbf{P} \succ_p \mathbf{Q}$ *and* $\mathbf{Q} \succ_p \mathbf{P}$ *hold.*

We are now in position to define *cleanness under postprocessing*, namely

Definition V.2: A POVM $\mathbf{P}$ *is* postprocessing clean *if for any POVM* $\mathbf{Q}$ *such that* $\mathbf{Q} \succ_p \mathbf{P}$, *then also* $\mathbf{P} \succ_p \mathbf{Q}$ *holds, namely* $\mathbf{P} \simeq_p \mathbf{Q}$.

The characterization of cleanness under postprocessing (classical) is much easier than that of cleanness under preprocessing (quantum), and is given by the following theorem.

Theorem V.3: *A POVM* $\mathbf{P}$ *is postprocessing clean iff it is rank-one.*

Proof: First notice that a POVM $\mathbf{P}$ with elements having rank higher than one are not postprocessing clean. In fact, in this case one can diagonalize all the POVM elements and consider the POVM $\mathbf{P}'$ made of rank-one projections over all eigenvectors multiplied by the corresponding eigenvalue. Then, clearly $\mathbf{P}' \succ_p \mathbf{P}$ by identification of outcomes. In equations

$$P_i = \sum_{k_i} |\lambda_{k_i}^{(i)}\rangle\langle\lambda_{k_i}^{(i)}|, \quad P'_{i,k} = |\lambda_k^{(i)}\rangle\langle\lambda_k^{(i)}|, \Rightarrow \mathbf{P}' \succ_p \mathbf{P}, \tag{17}$$

corresponding to the identification of outcomes

$$p(i|j,k_j) = \delta_{ij} \,\forall\, k_j. \tag{18}$$

Reversely, all rank-one POVMs are postprocessing clean, namely if $\mathbf{Q} \succ_p \mathbf{P}$, then also $\mathbf{P} \simeq_p \mathbf{Q}$ must hold. In fact, suppose that $\mathbf{P}$ is rank one and that there exists a POVM $\mathbf{Q}$ such that $\mathbf{Q} \succ_p \mathbf{P}$, namely

$$P_i = \sum_j p(i|j)Q_j. \tag{19}$$

Now, since all elements P_i are rank one, the elements Q_j are necessarily proportional to P_i for all the indices j such that $p(i|j) \neq 0$, namely also $\mathbf{Q}$ is rank one, with

$$p(i|j)Q_j = \alpha_j P_i, \tag{20}$$

with $\Sigma_j \alpha_j = 1$, and $\alpha_j \geqslant 0$. For a fixed j, $p(i|j) = 0$ for at least one i, otherwise all the P_i's would be proportional. For the same reason, for a fixed i, $p(i|j) = 0$ for at least one j. We can then collect the indices i such that $p(i|j) \neq 0$ in the set $I(j)$, and write

$$Q_j = \sum_i p(i|j)Q_j = \sum_{i \in I(j)} p(i|j)Q_j = \sum_{i \in I(j)} \alpha_j P_i. \tag{21}$$

Finally, it is immediately verified that

$$q(j|i) = \begin{cases} \alpha_j, & i \in I(j) \\ 0 & \text{otherwise} \end{cases} \tag{22}$$

is a conditional probability since for all i one has $\Sigma_j q(j|i) = \Sigma_j \alpha_j = 1$. Therefore, from Eq. (21) it follows that we have also $\mathbf{P} \succ_p \mathbf{Q}$, namely $\mathbf{P} \simeq_p \mathbf{Q}$. ■

VI. PREPROCESSING: ORDERING AND EQUIVALENCE OF POVMs

The action of channels allows to define the following pseudo-ordering.

Definition VI.1: Given the POVMs $\mathbf{P}$ *and* $\mathbf{Q}$ *with* $|\mathbf{P}| = |\mathbf{Q}|$ *we define* $\mathbf{P} \succ \mathbf{Q}$ *iff there exists a channel* $\mathcal{E}$ *such that*

$$\mathbf{Q} = \mathcal{E}(\mathbf{P}), \tag{23}$$

and we will say that the POVM $\mathbf{P}$ *is cleaner than the POVM* $\mathbf{Q}$.

Definition VI.2: We call a POVM $\mathbf{P}$ *"clean" iff for any POVM* $\mathbf{Q}$ *such that* $\mathbf{Q}\succ\mathbf{P}$ *one also has* $\mathbf{P}\succ\mathbf{Q}$.

It is easily proved that the relation $\succ$ is transitive and reflexive, namely it is a pseudo-ordering. Let us now define the following relation

Definition VI.3: We say that the two POVMs $\mathbf{P}$ *and* $\mathbf{Q}$ *are equivalent—denoted as* $\mathbf{P}\simeq\mathbf{Q}$*—when one has both* $\mathbf{P}\succ\mathbf{Q}$ *and* $\mathbf{Q}\succ\mathbf{P}$.

Clearly $\simeq$ is an equivalence relation. The pseudo-ordering $\succ$ now defines a partial ordering between equivalence classes. Indeed define the ordering between classes as follows:

$$[\mathbf{P}]\succcurlyeq[\mathbf{Q}] \quad \text{iff} \quad \mathbf{P}'\succ\mathbf{Q}', \quad \forall\,\mathbf{P}'\in[\mathbf{P}], \quad \mathbf{Q}'\in[\mathbf{Q}]. \tag{24}$$

The above-mentioned ordering is consistently defined, since $\mathbf{P}',\mathbf{P}''\in[\mathbf{P}]$ means both $\mathbf{P}'\succ\mathbf{P}''$ and $\mathbf{P}''\succ\mathbf{P}'$, whence, by transitivity $\mathbf{P}''\succ\mathbf{P}'\succ\mathbf{Q}'\succ\mathbf{Q}''$, and the ordering does not depend on the chosen elements of the equivalence classes. This proves the consistency of the definition of $\succcurlyeq$. Therefore, in the following we can consider a single element $\mathbf{P}$ instead of the class $[\mathbf{P}]$. In this way we can easily prove reflexivity $[\mathbf{P}]\succcurlyeq[\mathbf{P}]$, since $\mathbf{P}\succ\mathbf{P}$, and transitivity

$$[\mathbf{P}]\succcurlyeq[\mathbf{Q}], \quad [\mathbf{Q}]\succcurlyeq[\mathbf{R}]\Rightarrow[\mathbf{P}]\succcurlyeq[\mathbf{R}], \tag{25}$$

since $\mathbf{P}\succ\mathbf{Q}$, $\mathbf{Q}\succ\mathbf{R}$ implies $\mathbf{P}\succ\mathbf{R}$ by transitivity of $\succ$. Now let us consider the case when both $[\mathbf{P}]\succcurlyeq[\mathbf{Q}]$ and $[\mathbf{Q}]\succcurlyeq[\mathbf{P}]$. Then we have $\mathbf{P}\succ\mathbf{Q}$ and $\mathbf{Q}\succ\mathbf{P}$, namely $[\mathbf{P}]\equiv[\mathbf{Q}]$. ■

One would be tempted to conjecture that the relation $\simeq$ is equivalent to unitary equivalence, which is defined through

Definition VI.4: The POVMs $\mathbf{P}$ *and* $\mathbf{Q}$ *are unitarily equivalent, for short* $\mathbf{P}\simeq_U\mathbf{Q}$ *iff there exists a unitary operator* U *such that* $\mathbf{Q}=U\mathbf{P}U^\dagger$.

However, as we will see in the following, there exist equivalent POVMs which are not unitarily equivalent.

We have now the following necessary condition for equivalence under preprocessing

Theorem VI.5: *If* $\mathbf{P}\simeq\mathbf{Q}$ *then for each event* $e\in\mathsf{E}(\mathbf{P})$ *we have*

$$\lambda_M(P_e)=\lambda_M(Q_e)\equiv\lambda_M(e), \quad \lambda_m(P_e)=\lambda_m(Q_e)\equiv\lambda_m(e). \tag{26}$$

Proof: By Lemma III.1 we have both $\lambda_M(P_i)\geqslant\lambda_M(Q_i)$ and $\lambda_M(P_i)\leqslant\lambda_M(Q_i)$, and similarly for the minimum eigenvalues. ■

VII. PREPROCESSING: POSITIVE MAPS AND RELATED THEOREMS

There are two interesting variants of the relation $\succ$ just introduced, which help to get a more geometric insight into the structure. The first arises, if we replace the completely positive map $\mathcal{E}$ in Definition VI.1 by positive (but not necessarily *completely* positive) one. Hence we can define for two POVMs $\mathbf{P}$, $\mathbf{Q}$ with $|\mathbf{P}|=|\mathbf{Q}|$

$$\mathbf{P}\gg\mathbf{Q}\Leftrightarrow\mathbf{Q}=\mathcal{E}(\mathbf{P}), \quad \mathcal{E}\ \text{positive}. \tag{27}$$

It is obvious that $\mathbf{P}\succ\mathbf{Q}$ implies $\mathbf{P}\gg\mathbf{Q}$ but the other way round does not hold. This can be seen, if we consider an informationally complete POVM $\mathbf{P}$ and define $\mathbf{Q}=\Theta(\mathbf{P})$, where Θ denotes the transposition map (i.e. $\Theta(A)=A^\mathsf{T}$). Positivity of Θ implies $\mathbf{P}\gg\mathbf{Q}$. But Θ is only positive and not completely positive and it is the only map which connects $\mathbf{P}$ and $\mathbf{Q}$. The latter follows from informational completeness of $\mathbf{P}$, because this implies that the elements of $\mathbf{P}$ are a basis of $\mathsf{B}(\mathsf{H})$. Hence $\mathbf{P}\succ\mathbf{Q}$ *does not hold.*

Now consider the *ranges* $\mathsf{Rng}(\mathbf{P})$, $\mathsf{Rng}(\mathbf{Q})$ of $\mathbf{P}$ and $\mathbf{Q}$, defined in Eq. (2). If $\boldsymbol{p}\in\mathsf{Rng}(\mathbf{Q})$ there is by definition a density operator ρ with $\boldsymbol{p}=\mathrm{Tr}[\mathbf{Q}\rho]$. Hence, $\mathbf{P}\gg\mathbf{Q}$ implies

$$\boldsymbol{p}=\mathrm{Tr}[\mathbf{Q}\rho]=\mathrm{Tr}[\mathcal{E}(\mathbf{P})\rho]=\mathrm{Tr}[\mathbf{P}\mathcal{E}^\mathsf{T}(\rho)] \tag{28}$$

and therefore we get $\boldsymbol{p}\in\mathsf{Rng}(\mathbf{P})$. This observation motivates the definition:

$$\mathbf{P} \supset_r \mathbf{Q} \Leftrightarrow \mathsf{Rng}(\mathbf{Q}) \subset \mathsf{Rng}(\mathbf{P}). \tag{29}$$

According to our previous discussion we get in this way a hierarchy of relations

$$\mathbf{P} \succ \mathbf{Q} \Rightarrow \mathbf{P} \succcurlyeq \mathbf{Q} \Rightarrow \mathbf{P} \supset_r \mathbf{Q}. \tag{30}$$

We have already seen that the direction of the implication between $\succ$ and $\succcurlyeq$ cannot be reversed. For $\succcurlyeq$ and $\supset_r$ this is more difficult. To see that they are (very) closely related, consider the linear hull $\mathsf{Span}(\mathbf{P})$ of the elements of $\mathbf{P}$, which is obviously an *operator system* (cf. Sec. III). Hence we can speak about positive linear maps from $\mathsf{Span}(\mathbf{P})$ to $\mathsf{Span}(\mathbf{Q})$. This fact can be used to characterize the relation $\supset_r$ in the following way.

Proposition VII.1: Consider two POVMs $\mathbf{P}$, $\mathbf{Q}$ *with* $|\mathbf{P}|=|\mathbf{Q}|$. *Then the following statements are equivalent:*

(i) $\mathbf{P} \supset_r \mathbf{Q}$
(ii) *There is a (unique) positive map* $\mathcal{E}$: $\mathsf{Span}(\mathbf{P}) \to \mathsf{Span}(\mathbf{Q})$ *with* $\mathcal{E}(\mathbf{P})=\mathbf{Q}$.

Proof: The implication (ii)$\Rightarrow$(i) is trivial. Hence consider only the other direction. Here, the idea is to define the map $\mathcal{E}$ by

$$\mathcal{E}(P_e) = Q_e, \quad \forall\, e \in \mathsf{E}. \tag{31}$$

This map is well defined because we have (by assumption) for each density operator ρ a second density operator σ such that $\mathrm{Tr}[Q_e\rho]=\mathrm{Tr}[P_e\sigma]$ holds for all $e \in \mathsf{E}$. Hence if $\Sigma_e \lambda_e P_e = 0$ for some real λ_e we get

$$\sum_{e\in\mathsf{E}} \lambda_e \mathrm{Tr}[\rho Q_e] = \sum_{e\in\mathsf{E}} \lambda_e \mathrm{Tr}[\sigma P_e] = \mathrm{Tr}\left[\sigma \sum_{e\in\mathsf{E}} \lambda_e P_e\right] = 0. \tag{32}$$

Since ρ is arbitrary this implies $\Sigma_e \lambda_e Q_e = 0$. Therefore $\mathcal{E}$ defined in (31) is well defined, as stated. Using the same reasoning we can show that $\mathcal{E}$ is positive, which concludes the proof. ■

The difference between condition (ii) of this lemma and the definition of $\succcurlyeq$ in Eq. (27) is the *domain* of the the map $\mathcal{E}$. The following counter example which is taken (in a slightly modified form) from Ref. 26 shows that such a map is in general *not extendible* as a positive map to $\mathsf{B}(\mathsf{H})$.

Consider the diagonal 4×4 matrix $X=\mathrm{diag}(1,i,-1,-i)$ and the operator system $\mathcal{S}$ spanned by $I, X, X^\dagger$. It is easy to see that a general element $A=aI+bX+cX^\dagger$ is Hermitian iff $c=b^*$ and $a=a^*$ hold, and it is positive iff in addition $a \geqslant 2\max(|\Re b|, |\Im b|)$ hence,

$$A \geqslant 0 \Rightarrow c = b^*, \quad a \geqslant \sqrt{2}|b|. \tag{33}$$

Now consider the linear map

$$\mathcal{S} \ni A = aI + bX + cX^\dagger \mapsto \mathcal{E}(A) = \begin{pmatrix} a & \sqrt{2}b \\ \sqrt{2}c & a \end{pmatrix} \otimes I_2, \tag{34}$$

where I_2 denotes the 2×2 unit matrix. Since a 2×2 matrix is positive iff its diagonal elements and its determinant are positive, positivity of $\mathcal{E}$ follows directly from Eq. (33). On the other hand we have $\|\mathcal{E}(I)\|=1$ and $\|\mathcal{E}(X)\|=\sqrt{2}$. Since $\|X\|=1$ this implies $\|\mathcal{E}\| \geqslant \sqrt{2} > \|\mathcal{E}(I)\|$. But a positive map from a C^* algebra $\mathcal{A}$ into a a C^* algebra $\mathcal{B}$ always satisfies (Ref. 26, Corollary 2.9) $\|\mathcal{E}\|=\|\mathcal{E}(I)\|$. Hence the map defined in Eq. (34) can not be extended to $\mathsf{B}(\mathbb{C}^4)$—not even to the abelian algebra generated by $I, X, X^\dagger$. As a consequence of this reasoning we have shown that $\mathbf{P} \supset_r \mathbf{Q}$ *does not imply* $\mathbf{P} \succcurlyeq \mathbf{Q}$.

Hence positive maps can in general not be extended as a *positive* map to a bigger algebra. A very important special case arises, however, if the map $\mathcal{E}$ is *completely* positive. In this case a completely positive extension always exists (cf. Theorem III.5) This fact can be used along with Proposition VII.1 to get an interesting characterisation of $\succ$ in terms of ranges.

Theorem VII.2: *Consider two POVMs* $\mathbf{P}$, $\mathbf{Q}$ *with* $|\mathbf{P}|=|\mathbf{Q}|$. *Then the following statements are equivalent:*

(i) $\mathbf{P}\succ\mathbf{Q}$
(ii) *There is an informationally complete POVM* $\mathbf{M}$ *such that* $\mathbf{P}\otimes\mathbf{M}\supset_r\mathbf{Q}\otimes\mathbf{M}$
(iii) $\mathbf{P}\otimes\mathbf{M}\supset_r\mathbf{Q}\otimes\mathbf{M}$ *holds for all POVMs* $\mathbf{M}$.

Proof: The implication (i)$\Rightarrow$(iii) follows from the fact that (i) implies the existence of a map $\mathcal{E}$ such that $\mathbf{Q}=\mathcal{E}(\mathbf{P})$, and trivially the map $\mathcal{E}\otimes\mathcal{I}$ connects $\mathbf{P}\otimes\mathbf{M}$ with $\mathbf{Q}\otimes\mathbf{M}$, whence the statement via Eq. (29). Implication (i)$\Rightarrow$(ii) is just a special case of the previous one. Implication (iii)$\Rightarrow$(ii) is trivial. Hence only (ii)$\Rightarrow$(i) remains to be shown.

To this end note that informational completeness of $\mathbf{M}$ implies

$$\mathsf{Span}(\mathbf{Q}\otimes\mathbf{M})=\mathsf{Span}(\mathbf{Q})\otimes\mathsf{B}(\mathsf{H}), \tag{35}$$

and similarly for $\mathbf{P}\otimes\mathbf{M}$. Therefore we have [according to (ii) and Proposition VII.1] a unique positive map

$$\mathcal{F}:\mathsf{Span}(\mathbf{P})\otimes\mathsf{B}(\mathsf{H})\rightarrow\mathsf{Span}(\mathbf{Q})\otimes\mathsf{B}(\mathsf{H}) \tag{36}$$

with

$$\mathcal{F}(\mathbf{P}\otimes\mathbf{M})=\mathbf{Q}\otimes\mathbf{M}. \tag{37}$$

If we can show that $\mathcal{F}$ has the form

$$\mathcal{F}=\mathcal{E}\otimes\mathcal{I} \tag{38}$$

with a positive map $\mathcal{E}$: $\mathsf{Span}(\mathbf{P})\rightarrow\mathsf{Span}(\mathbf{Q})$ and the identity $\mathcal{I}$ on $\mathsf{B}(\mathsf{H})$, the theorem is proved because:

- Due to Eq. (38) and positivity of $\mathcal{F}$ the map $\mathcal{E}$ is completely positive as a map on the *operator system* $\mathsf{Span}(\mathbf{P})$. Hence by theorem III.5 it is extendible to a completely positive map on $\mathsf{B}(\mathsf{H})$.
- Eqs. (37) and (38) imply $\mathcal{E}(\mathbf{P})=\mathbf{Q}$ and therefore $\mathbf{P}\succ\mathbf{Q}$.

To prove Eq. (38) firstly note that (ii) implies $\mathbf{P}\supset_r\mathbf{Q}$. This follows from (with $e\in\mathsf{E}(\mathbf{Q})$ and a density matrix ρ on H):

$$\mathrm{Tr}[\rho Q_e]=\mathrm{Tr}\left[\frac{\rho\otimes I}{d}\left(Q_e\otimes\sum_{f\in\mathsf{E}(\mathbf{M})}M_f\right)\right] \tag{39}$$

$$=\sum_{f\in\mathsf{E}(\mathbf{M})}\mathrm{Tr}\left[(Q_e\otimes M_f)\left(\rho\otimes\frac{I}{d}\right)\right] \tag{40}$$

because we have by assumption a density matrix σ on $\mathsf{H}\otimes\mathsf{H}$ such that

$$\mathrm{Tr}\left[(\mathbf{Q}\otimes\mathbf{M})\left(\rho\otimes\frac{I}{d}\right)\right]=\mathrm{Tr}[(\mathbf{P}\otimes\mathbf{M})\sigma] \tag{41}$$

which in turn implies

$$\mathrm{Tr}[\rho Q_e]=\sum_{f\in\mathsf{E}(\mathbf{M})}\mathrm{Tr}[(P_e\otimes M_f)\sigma] \tag{42}$$

$$=\mathrm{Tr}\left[P_e\otimes\left(\sum_{f\in\mathsf{E}(\mathbf{M})}M_f\right)\sigma\right] \tag{43}$$

$$= \mathrm{Tr}[(P_e \otimes I)\sigma] = \mathrm{Tr}[P_e \, \mathrm{Tr}_2 \, \sigma], \tag{44}$$

where Tr_2 denotes the partial trace over the second tensor factor. Hence $\mathrm{Tr}[\rho\mathbf{Q}] = \mathrm{Tr}[(\mathrm{Tr}_2\sigma)\mathbf{P}]$ which implies $\mathbf{P} \supset_r \mathbf{Q}$ as stated.

Now we can apply again Propostion VII.1 and get a positive map $\mathcal{E}$: $\mathsf{Span}(\mathbf{P}) \to \mathsf{Span}(\mathbf{Q})$ satisfying $\mathcal{E}(\mathbf{P}) = \mathbf{Q}$ and therefore $\mathcal{E} \otimes \mathcal{I}(\mathbf{P} \otimes \mathbf{M}) = \mathbf{Q} \otimes \mathbf{M}$. Since $\mathcal{F}$ is uniquely determined by Eq. (37) this implies $\mathcal{F} = \mathcal{E} \otimes \mathcal{I}$, which completes the proof. ■

This theorem gives a clear geometric picture for the relation $\succ$ and it helps to understand the difference between $\succ$ and $\gg$: if $\mathbf{P} \gg \mathbf{Q}$ holds we find for each *separable state* ρ on $\mathsf{H} \otimes \mathsf{H}$ a second separable state σ such that $\mathrm{Tr}[\mathbf{Q} \otimes \mathbf{M}\rho] = \mathrm{Tr}[\mathbf{P} \otimes \mathbf{M}\sigma]$. Hence, if $\mathbf{P} \succ \mathbf{Q}$ does not hold (but $\mathbf{P} \gg \mathbf{Q}$) there must be an *entangled* state ρ such that the probability vector $\mathrm{Tr}[\mathbf{Q} \otimes \mathbf{M}\rho]$ can not be reproduced by any expectation value of $\mathbf{P} \otimes \mathbf{M}$. This can be rephrased as follows: If $\mathbf{P} \gg \mathbf{Q}$ holds but not $\mathbf{P} \succ \mathbf{Q}$ we can reproduce the distribution of outcomes of $\mathbf{Q}$ measurements on *one system* by appropriate $\mathbf{P}$ measurements, but there is information about entangled states which can be gained only by $\mathbf{Q}$ and not by $\mathbf{P}$.

A second special case of Proposition VII.1 arises, when $\mathbf{Q}$ is abelian (i.e., all elements of the POVM commute). In this case the map $\mathcal{E}$ constructed in Proposition VII.1 is a map into an abelian algebra and therefore completely positive. Hence we get

Theorem VII.3: *Consider two POVMs* $\mathbf{P}, \mathbf{Q}$ *with* $|\mathbf{P}| = |\mathbf{Q}|$ *and assume that* $\mathbf{Q}$ *is abelian. Then* $\mathbf{P} \supset_r \mathbf{Q}$ *and* $\mathbf{P} \succ \mathbf{Q}$ *are equivalent*.

Proof: According to Proposition VII.1 there is a positive map $\mathcal{E}$ from $\mathsf{Span}(\mathbf{P})$ into the abelian C^* algebra $\mathcal{A}$ generated by the elements of $\mathbf{Q}$. According to Theorem III.6 this map is completely positive and by Theorem III.5 therefore extendible as a completely positive map to $\mathsf{B}(\mathsf{H})$. Hence $\mathbf{P} \supset_r \mathbf{Q}$ implies $\mathbf{P} \succ \mathbf{Q}$. Since the other implication is trivial the proof is completed. ■

Note that a similar result does not hold if $\mathbf{P}$ is abelian and $\mathbf{Q}$ is not. The counter example given after Proposition VII.1 applies even in this case.

The result from Theorem VII.3 is very useful, in particular because the range $\mathsf{Rng}(\mathbf{P})$ of an abelian POVM has a very simple structure, which is completely characterized by the joint eigenvalues of the elements of $\mathbf{P}$. To see this, consider a joint set of eigenvectors ψ_α, $\alpha = 1, \ldots, d$ and

$$P_e = \sum_{\alpha=1}^{d} \lambda_{e,\alpha} |\psi_\alpha\rangle\langle\psi_\alpha|, \quad \forall \, e \in \mathsf{E}. \tag{45}$$

The joint eigenvalues vectors

$$\boldsymbol{\lambda}_\alpha = (\lambda_{e,\alpha})_{e \in \mathsf{E}} \in \mathbb{R}^{|\mathbf{P}|} \tag{46}$$

form a set of probability vectors (in the case of joint degeneracies of the elements of $\mathbf{P}$ some of them may coincide) and for each convex linear combination

$$\boldsymbol{p} = \sum_{\alpha=1}^{d} p_\alpha \boldsymbol{\lambda}_\alpha, \quad p_\alpha \geqslant 0, \quad \sum_\alpha p_\alpha = 1 \tag{47}$$

we can find a density operator ($\rho = \Sigma_\alpha p_\alpha |\psi_\alpha\rangle\langle\psi_\alpha|$ will do) such that $\boldsymbol{p} = \mathrm{Tr}[\rho\mathbf{P}]$ holds. Hence the *convex hull* of the $\boldsymbol{\lambda}_\alpha$ satisfies $\mathrm{conv}(\boldsymbol{\lambda}_1, \ldots, \boldsymbol{\lambda}_d) \subset \mathsf{Rng}(\mathbf{P})$. On the other hand we have for each density operator ρ:

$$\mathrm{Tr}[\rho\mathbf{P}] = \sum_{\alpha=1}^{d} \langle\psi_\alpha, \rho\psi_\alpha\rangle \boldsymbol{\lambda}_\alpha \tag{48}$$

which implies $\mathrm{Tr}[\rho\mathbf{P}] \in \mathrm{conv}(\boldsymbol{\lambda}_1, \ldots, \boldsymbol{\lambda}_d)$. Hence we have just shown the following proposition

Proposition VII.4: The range $\mathsf{Rng}(\mathbf{P})$ *of an abelian POVM* $\mathbf{P}$ *coincides with the convex hull of the* $\boldsymbol{\lambda}_1, \ldots, \boldsymbol{\lambda}_d$.

The most simple example arises in the case of *effects*, i.e., measurements with two outcomes.

Obviously, each effect is abelian and has the form $\mathbf{P}=\{P, I-P\}$ with a positive operator $P \leqslant I$. If $\mu_1, \ldots, \mu_d$ are the eigenvalues of P given in decreasing order we get $\boldsymbol{\lambda}_\alpha=(\mu_\alpha, 1-\mu_\alpha)$. Hence all $\boldsymbol{\lambda}_\alpha \in \mathbb{R}^2$ are located on the graph of the function $\mathbb{R} \ni x \mapsto 1-x \in \mathbb{R}$, and $\boldsymbol{\lambda}_1$ respectively $\boldsymbol{\lambda}_d$ are the outermost points. This leads immediately to the following characterization of the relation $\succ$ for effects:

Theorem VII.5: *The effect* $\mathbf{P}$ *is "cleaner" than the effect* $\mathbf{Q}$, *i.e.* $\mathbf{P} \succ \mathbf{Q}$ *iff*

$$[\lambda_M(P), \lambda_m(P)] \supseteq [\lambda_M(Q), \lambda_m(Q)]. \tag{49}$$

Corollary VII.6: *Given two effects* $\mathbf{P}$ *and* $\mathbf{Q}$, *then* $\mathbf{P} \simeq \mathbf{Q}$ *iff* $\lambda_M(P)=\lambda_M(Q)$ *and* $\lambda_m(P)=\lambda_m(Q)$.

VIII. PREPROCESSING: EQUIVALENCE IN DIMENSION TWO

For dimension two the cleanness equivalence $\simeq$ and the unitary equivalence $\simeq_U$ coincide.

Theorem VIII.1: *For two-level systems* $\mathbf{P} \simeq \mathbf{Q}$ *iff* $\mathbf{P} \simeq_U \mathbf{Q}$.

Proof: If all the elements of both POVM are trivial, i.e., $P_e=\alpha_e I$ and $Q_e=\beta_e I$, $\forall e$, then the thesis follows easily. Therefore, we will focus on the nontrivial case, in which there exists at least one element P_i of $\mathbf{P}$ (or Q_i of $\mathbf{Q}$) that is nontrivial. Then, first, also Q_i (or P_i) is not proportional to the identity, since otherwise $P_i=\mathcal{F}(Q_i)=\alpha_i \mathcal{F}(I)=\alpha_i I$, which contradicts the hypothesis. Second, by Theorem VI.5 one has

$$P_i = \lambda_M(i) |\phi_M^{(i)}\rangle\langle\phi_M^{(i)}| + \lambda_m(i) |\phi_m^{(i)}\rangle\langle\phi_m^{(i)}|, \tag{50}$$

$$Q_i = \lambda_M(i) |\psi_M^{(i)}\rangle\langle\psi_M^{(i)}| + \lambda_m(i) |\psi_m^{(i)}\rangle\langle\psi_m^{(i)}|. \tag{51}$$

Now, by hypothesis, there exist channels $\mathcal{E}$ and $\mathcal{F}$ such that $Q_i=\mathcal{E}(P_i)$ and $P_i=\mathcal{F}(Q_i)$. Then, by linearity,

$$Q_i = \lambda_M(i) \mathcal{E}(|\phi_M^{(i)}\rangle\langle\phi_M^{(i)}|) + \lambda_m(i) \mathcal{E}(|\phi_m^{(i)}\rangle\langle\phi_m^{(i)}|). \tag{52}$$

We will now consider

$$\mathrm{Tr}[Q_i |\psi_M^{(i)}\rangle\langle\psi_M^{(i)}|] = \lambda_M(i) = \mathrm{Tr}[P_i \mathcal{E}^\mathsf{T}(|\psi_M^{(i)}\rangle\langle\psi_M^{(i)}|)], \tag{53}$$

and this clearly implies that $\mathcal{E}^\mathsf{T}(|\psi_M^{(i)}\rangle\langle\psi_M^{(i)}|)=|\phi_M^{(i)}\rangle\langle\phi_M^{(i)}|$. Analogous arguments lead to the conclusion that $\mathcal{E}^\mathsf{T}(|\psi_m^{(i)}\rangle\langle\psi_m^{(i)}|)=|\phi_m^{(i)}\rangle\langle\phi_m^{(i)}|$, and moreover $\mathcal{F}^\mathsf{T}(|\phi_M^{(i)}\rangle\langle\phi_M^{(i)}|)=|\psi_M^{(i)}\rangle\langle\psi_M^{(i)}|$ and $\mathcal{F}^\mathsf{T}(|\phi_m^{(i)}\rangle\langle\phi_m^{(i)}|)=|\psi_m^{(i)}\rangle\langle\psi_m^{(i)}|$. By collecting all the eigenstates of nondegenerate P_i's and Q_i's in two sets, namely,

$$\begin{aligned} \mathcal{E}^\mathsf{T}&:\{|\psi_M^{(i)}\rangle\langle\psi_M^{(i)}|, |\psi_m^{(i)}\rangle\langle\psi_m^{(i)}|\}_i \mapsto \{|\phi_M^{(i)}\rangle\langle\phi_M^{(i)}|, |\phi_m^{(i)}\rangle\langle\phi_m^{(i)}|\}_i \\ \mathcal{F}^\mathsf{T}&:\{|\phi_M^{(i)}\rangle\langle\phi_M^{(i)}|, |\phi_m^{(i)}\rangle\langle\phi_m^{(i)}|\}_i \mapsto \{|\psi_M^{(i)}\rangle\langle\psi_M^{(i)}|, |\psi_m^{(i)}\rangle\langle\psi_m^{(i)}|\}_i, \end{aligned} \tag{54}$$

and applying Theorem III.3 it follows that there exists a unitary U such that $Q_i=UP_iU^\dagger$ for all nontrivial Q_i's. Clearly, the same unitary transformation maps the trivial elements. ■

IX. PREPROCESSING: CLEANNESS FOR NUMBER OF OUTCOMES $n \leqslant d$

Lemma IX.1: For fixed number of elements $n \leqslant d$ *the POVM* $\mathbf{P}$ *is clean iff* $\lambda_M(P_i)=1$ *for all* i. *Such condition is also equivalent to* $\lambda_m(P_i)=0$ *with multiplicity at least* $n-1$, *and each vector which is eigenvector with unit eigenvalue for some element* P_j *must belong to the kernel of all other POVM elements*.

Proof: We first prove that the condition is also equivalent to $\lambda_m(P_i)=0$ for all i. Indeed, consider a normalized eigenvector $|u\rangle$ of P_j with eigenvalue 1, and suppose by absurd that some element P_i has $\lambda_m(P_i)>0$. Then

$$\langle u|u\rangle = \sum_k \langle u|P_k|u\rangle = \langle u|P_j|u\rangle + \langle u|P_i|u\rangle + \sum_{k\neq i,j} \langle u|P_k|u\rangle > 1, \tag{55}$$

and in order to have no contradiction one must have $\langle u|P_i|u\rangle = 0$, namely $\lambda_m(P_i) = 0$. Notice that Eq. (55) also implies that $\langle u|P_k|u\rangle = 0$ for all $k \neq j$, namely the same eigenvector $|u\rangle$ of P_j is eigenvector of all P_k for all $k \neq j$. Moreover, since there must be at least n vectors as $|u\rangle$, each being eigenvector of a different element P_j corresponding to unit eigenvalue, and since any two vectors must be orthogonal (since for some j they are eigenvectors corresponding to different eigenvalues of P_j), this means that the 0 eigenvalue for each POVM element must have multiplicity at least $n-1$, and all the eigenvectors of any element with eigenvalue 1 are in the kernel of the remaining elements.

We now prove that the condition is sufficient. Suppose that a POVM $\mathbf{Q}$ exists such that $\mathbf{Q} > \mathbf{P}$. Then by Lemma III.1 $\{0,1\} \subseteq \mathsf{Sp}(Q_i)$ for all i. We then need to prove that in this case $\mathbf{P} \simeq \mathbf{Q}$. From now on we will denote by $|u\rangle_i^P$ an eigenvector of P_i with eigenvalue 1 and by $|u\rangle_i^Q$ the same for Q_i. The proof is constructive: consider the map with Stinespring form $\mathcal{E}(X) = V^\dagger(I \otimes X)V$, where

$$V = \sum_i \sqrt{P_i} \otimes |u\rangle_i^Q, \tag{56}$$

and the notation $T = O \otimes |u\rangle$ denotes the operator defined as $T|\psi\rangle = O|\psi\rangle \otimes |u\rangle$ for all $|\psi\rangle \in \mathsf{H}$. It is clear that $\mathcal{E}(Q_i) = P_i$. Similarly, consider the map $\mathcal{F}(X) = W^\dagger(I \otimes X)W$, where

$$W = \sum_i \sqrt{Q_i} \otimes |u\rangle_i^P. \tag{57}$$

This is such that $\mathcal{F}(P_i) = Q_i$. We proved that POVMs $\mathbf{P}$ such that $\lambda_M(P_i) = 1$ for all i are clean. We will now prove that it is also a necessary condition. Consider indeed a generic POVM $\mathbf{Q}$ such that at least for one outcome j $\lambda_M(Q_j) < 1$. Then one can consider any POVM $\mathbf{P}$ with $\lambda_M(P_i) = 1$ for all i and construct the isometry

$$W = \sum_i \sqrt{Q_i} \otimes |u\rangle_i^P. \tag{58}$$

It is clear that the Stinespring form $W^\dagger(I \otimes X)W$ defines a channel $\mathcal{E}$ such that $\mathcal{E}(P_i) = Q_i$ for all i. Then $\mathbf{P} > \mathbf{Q}$. Moreover, by hypothesis $\lambda_M(P_j) > \lambda_M(Q_j)$ and then it is impossible that $\mathbf{P} \simeq \mathbf{Q}$. ■

An immediate corollary is the following

Corollary IX.2: The only clean elements with $n = d$ are the observables.

Proof: In Lemma IX.1 for $n = d$ the iff condition is equivalent to have eigenvalue 0 with multiplicity $d-1$ for each POVM element, namely each POVM element is rank one, and they are orthogonal. ■

Allowing mapping between POVMs with different number of outcomes, the situation simplifies:

Theorem IX.3: *For $n \leqslant d$ outcomes the set of clean POVMs coincides with the set of observables.*

Proof: Consider a generic POVM P_i with $i = 1, \ldots, n \leqslant d$. This can be always regarded as the preprocessing of any desired observable $\{|i\rangle\langle i|\}_{i=1,\ldots,d}$. In fact, using the isometry from H to $\mathsf{H}^{\otimes 2}$

$$V = \sum_{i=1}^{n} \sqrt{P_i} \otimes |i\rangle, \tag{59}$$

the following channel expressed in the Stinespring form

$$\mathcal{M}(X) = V^\dagger(I \otimes X)V \tag{60}$$

gives

$$\mathcal{M}(|i\rangle\langle i|) = P_i, \quad i = 1, \dots d. \tag{61}$$

For a POVM with $n < d$ outcomes (strictly), notice that it is equivalent to a POVM with d outcomes and $d-n$ vanishing elements. On the other hand, for $n < d$ there is no channel that can increase the number of outcomes back to d, whence a POVM with $n < d$ outcomes cannot be clean. For $n = d$ Corollary IX.2 asserts that the only clean POVMs are the observables. ■

X. PREPROCESSING: ORDERING OF INFORMATIONALLY COMPLETE POVMs

Lemma X.1: If the POVM $\mathbf{Q}$ *is infocomplete then every* $\mathbf{P}$ *such that* $\mathbf{P} > \mathbf{Q}$ *is infocomplete, too.*

Proof: For d^2 outcomes POVMs, $\mathbf{P}$ and $\mathbf{Q}$ are infocomplete iff their elements are linearly independent. Suppose by absurd that there exists a nonnull vector of d^2 coefficients c_i such that $\sum_{i=1}^{d^2} c_i P_i = 0$, then also

$$\mathcal{E}\left(\sum_{i=1}^{d^2} c_i P_i\right) = 0 = \sum_{i=1}^{d^2} c_i Q_i = 0, \tag{62}$$

which contradicts the hypothesis.

If the number of outcomes is greater than d^2, suppose

$$\mathcal{E}(X) = 0, \tag{63}$$

for some $X \neq 0$, namely $\mathcal{E}$ would have non trivial kernel, in which case $\mathsf{Span}(\mathbf{Q}) \subseteq \mathsf{Rng}(\mathcal{E}) \subset \mathsf{B}(\mathsf{H})$, which contradicts the hypothesis that $\mathbf{Q} = \mathcal{E}(\mathbf{P})$ is infocomplete. Then $\mathcal{E}$ is invertible. Now, $\mathbf{P}$ must be infocomplete, otherwise the inverse of $\mathcal{E}$ would not have full rank, which is absurd. ■

The above theorem is immediately extended to any linearly independent POVM $\mathbf{Q}$. More interestingly, for any infocomplete POVM $\mathbf{P}$ one can prove the following lemma

Lemma X.2: If the POVM $\mathbf{P}$ *is infocomplete then every* $\mathbf{Q}$ *such that* $\mathbf{P} \simeq \mathbf{Q}$ *is infocomplete, too.*

Proof: It follows immediately from definition of $\simeq$ and Lemma X.1. ■

On the other hand, each POVM that is equivalent to an infocomplete one, is also unitarily equivalent to it, namely, more precisely

Theorem X.3: If $\mathbf{P}$ *is an infocomplete POVM, then* $\mathbf{P} \simeq \mathbf{Q}$ *iff* $\mathbf{P} \simeq_U \mathbf{Q}$.

Proof: Since the POVMs $\mathbf{P}$ and $\mathbf{Q}$ must be both infocomplete by the previous lemma, then the maps $\mathcal{E}$ and $\mathcal{F}$ are uniquely defined, and are the inverse of each other. Then, by Theorem III.2 $\mathcal{E}(X) = UXU^\dagger$ for some unitary U. ■

An alternative elegant proof of the above theorem would be the following.

Proof: By hypothesis, there exist $\mathcal{E}$ and $\mathcal{F}$ such that $\mathcal{E}(\mathbf{P}) = \mathbf{Q}$ and $\mathcal{F}(\mathbf{Q}) = \mathbf{P}$. This means that $\mathcal{F} \circ \mathcal{E}$ stabilizes the algebra generated by $\mathbf{P}$, that is $\mathsf{Span}(\mathbf{P}) \equiv \mathsf{B}(\mathsf{H})$. On the other hand, the commutant of an infocomplete POVM is only the identity, since $[P_i, X] = 0$ for all i implies $[A, X] = \sum_i a_i [P_i, X] = 0$ for all $A \in \mathsf{B}(\mathsf{H})$. This fact along with Lemma III.4 implies that $\mathcal{F} \circ \mathcal{E}$ is the identical map. The thesis is then a straightforward consequence of Theorem III.2. ■

Corollary X.4: For each non unitary invertible channel $\mathcal{E}$ *on* $\mathsf{B}(\mathsf{H})$ *there exists at least a pure state* $\psi \in \mathsf{H}$ *such that* $\mathcal{E}^{\mathsf{T}-1}(|\psi\rangle\langle\psi|) \ngeq 0$.

Proof: Let us consider an extremal POVM with d^2 rank-one elements $\{|\alpha_i\rangle\langle\alpha_i|\}$ $i = 1, \dots, d^2$ (according to Ref. 15 such a POVM always exists for any dimension d, and it is necessarily informationally complete). Assuming $\mathcal{E}$ invertible, let's consider $Q_i = \mathcal{E}^{-1}(|\alpha_i\rangle\langle\alpha_i|)$. The POVM $|\alpha_i\rangle\langle\alpha_i|$ is clean since it is rank-one. However, since it is also infocomplete, then Q_i cannot be itself a POVM, otherwise according to Theorem X.3 it would be unitarily equivalent to $|\alpha_i\rangle\langle\alpha_i|$. Moreover, being both $|\alpha_i\rangle\langle\alpha_i|$ and Q_i infocomplete, the map $\mathcal{E}$ would be univocally defined, whence itself unitary, contrarily to the hypothesis. Then, $\{Q_i\}$ is not a POVM. However, since the map $\mathcal{E}$ is a channel, whence $\mathcal{E}^{-1}$ must be identity preserving, one has $\sum_i Q_i = I$, then necessarily at least one element Q_j cannot be positive, namely there exists a vector $\psi \in \mathsf{H}$ for which

$$\langle\psi|Q_j|\psi\rangle < 0. \tag{64}$$

This inequality can be rewritten as follows:

$$\mathrm{Tr}[|\psi\rangle\langle\psi|\mathcal{E}^{-1}(|\alpha_j\rangle\langle\alpha_j|)] = \mathrm{Tr}[\mathcal{E}^{\mathsf{T}-1}(|\psi\rangle\langle\psi|)|\alpha_j\rangle\langle\alpha_j|] < 0, \tag{65}$$

namely $\mathcal{E}^{\mathsf{T}-1}(|\psi\rangle\langle\psi|)$ is not positive. ■

We have also the following interesting theorem.

Theorem X.5: *Every channel $\mathcal{F}$ which maps the set of states S surjectively on itself, i. e. such that $\mathcal{F}(\mathsf{S})\equiv\mathsf{S}$, is necessarily unitary.*

Proof: First, suppose that $\mathcal{F}$ is invertible, then $\mathcal{F}$ must be unitary, otherwise $\mathcal{F}^{-1}(\mathsf{S})=\mathsf{S}$ would not be possible by Lemma X.4. On the other hand, if $\mathcal{F}$ is not invertible, then its range must have dimension strictly smaller than d^2. Now, consider a rank-one infocomplete POVM $\mathbf{P}$ with $|\mathbf{P}|=d^2$. Clearly, some POVM element cannot belong to $\mathcal{F}(\mathsf{S})$, and this proves that $\mathcal{F}(\mathsf{S})\subset\mathsf{S}$ strictly, since such normalized POVM elements are just pure states. ■

For qubits this theorem has the simple geometric interpretation that the Bloch sphere transformed under $\mathcal{F}^{-1}$ for any invertible non unitary $\mathcal{F}$ becomes an ellipsoid which contains elements outside the Bloch sphere.

By definition, and according to Theorem X.3 an infocomplete POVM $\mathbf{P}$ is clean iff $\mathcal{E}^{-1}(\mathbf{P})$ is not a POVM for all invertible non unitary maps $\mathcal{E}$. This means that as soon as the set S of states is transformed by $\mathcal{E}^{-1}$, the POVM is able to detect at least one of the points in $\mathcal{E}^{-1}(\mathsf{S})-\mathsf{S}$, say $\mathcal{E}^{-1}(|\psi\rangle\langle\psi|)$, since the "probability distribution" corresponding to $\mathcal{E}^{-1}(|\psi\rangle\langle\psi|)$ is no longer positive.

XI. PREPROCESSING: ORDERING OF RANK-ONE POVMs

Intuitively one thinks that a rank-one POVM is clean. This is actually true, and it is more precisely stated by theorem XI.2 in this section. In order to prove it, we first need the following

Lemma XI.1: If the POVM $\mathbf{Q}$ is rank-one (i.e. each element Q_i can be written as $Q_i=|w_i\rangle\langle w_i|$), then for any POVM $\mathbf{P}$ such that $\mathbf{P}\succ\mathbf{Q}$, also $\mathbf{P}$ is rank one, and $\mathrm{Tr}[P_i]=\mathrm{Tr}[Q_i]$, $\forall i$.

Proof: Consider the following normalized vectors

$$|\widetilde{w}_i\rangle = \frac{1}{\sqrt{N_i}}|w_i\rangle, \quad Q_i = N_i|\widetilde{w}_i\rangle\langle\widetilde{w}_i|, \tag{66}$$

where $N_i=\mathrm{Tr}[Q_i]=\|w_i\|^2$, whence $\Sigma_i N_i=d$. Suppose $\mathbf{P}\succ\mathbf{Q}$, and $\mathcal{E}(\mathbf{P})=\mathbf{Q}$. Then one can easily verify the following identity:

$$N_i = \mathrm{Tr}[Q_i|\widetilde{w}_i\rangle\langle\widetilde{w}_i|] = \mathrm{Tr}[\mathcal{E}(P_i)|\widetilde{w}_i\rangle\langle\widetilde{w}_i|] = \mathrm{Tr}[P_i\mathcal{E}^{\mathsf{T}}(|\widetilde{w}_i\rangle\langle\widetilde{w}_i|)]. \tag{67}$$

Now, by the CPT property of $\mathcal{E}^{\mathsf{T}}$, $\mathcal{E}^{\mathsf{T}}(|\widetilde{w}_i\rangle\langle\widetilde{w}_i|)$ is a state and clearly the last expression in Eq. (67) is less than or equal to the maximum eigenvalue $\lambda_M(P_i)$ of P_i. We have than the following situation:

$$N_i \leqslant \lambda_M(P_i) \leqslant \mathrm{Tr}[P_i]. \tag{68}$$

By the normalization and positivity of POVMs, we have that $d=\Sigma_i N_i=\Sigma_i\mathrm{Tr}[P_i]$ and $N_i\geqslant 0$, $\mathrm{Tr}[P_i]\geqslant 0$. These conditions along with Eq. (68) imply

$$N_i \equiv \mathrm{Tr}[P_i] \ \ \forall\, i, \tag{69}$$

and this in turn implies $\lambda_M(P_i)=\mathrm{Tr}[P_i]$, namely P_i is rank one. ■

We will now prove the following theorem.

Theorem XI.2: *If $\mathbf{Q}$ is rank one, then $\mathbf{P}\succ\mathbf{Q}$ iff $\mathbf{P}\simeq_U\mathbf{Q}$. Namely, rank-one POVMs are clean.*

Proof: First, notice that by Lemma XI.1, $\mathbf{P}\succ\mathbf{Q}$ implies that $\mathbf{P}$ is rank one with $\mathrm{Tr}[P_i]=\mathrm{Tr}[Q_i]$, for all i. We have then

$$P_i = |v_i\rangle\langle v_i| = M_i|\widetilde{v}_i\rangle\langle\widetilde{v}_i|, \quad \|\widetilde{v}_i\| = 1, \tag{70}$$

$$Q_i = |w_i\rangle\langle w_i| = M_i|\widetilde{w}_i\rangle\langle\widetilde{w}_i|, \quad \|\widetilde{w}_i\| = 1, \tag{71}$$

where $M_i \equiv \mathrm{Tr}[P_i] = \mathrm{Tr}[Q_i]$, consistently with Lemma XI.1. Now, by hypothesis we have

$$M_i = \mathrm{Tr}[\mathcal{E}(P_i)|\widetilde{w}_i\rangle\langle\widetilde{w}_i|] = \mathrm{Tr}[P_i\mathcal{E}^{\mathsf{T}}(|\widetilde{w}_i\rangle\langle\widetilde{w}_i|)] = M_i\,\mathrm{Tr}[|\widetilde{v}_i\rangle\langle\widetilde{v}_i|\mathcal{E}^{\mathsf{T}}(|\widetilde{w}_i\rangle\langle\widetilde{w}_i|)]. \tag{72}$$

As a consequence, necessarily $\mathrm{Tr}[|\widetilde{v}_i\rangle\langle\widetilde{v}_i|\mathcal{E}^{\mathsf{T}}(|\widetilde{w}_i\rangle\langle\widetilde{w}_i|)] = 1$, and by CPT property of $\mathcal{E}^{\mathsf{T}}$ this implies $\mathcal{E}^{\mathsf{T}}(|\widetilde{w}_i\rangle\langle\widetilde{w}_i|) \equiv |\widetilde{v}_i\rangle\langle\widetilde{v}_i|$. Notice that since $\mathcal{E}^{\mathsf{T}}(I) = \Sigma_i M_i \mathcal{E}^{\mathsf{T}}(|\widetilde{w}_i\rangle\langle\widetilde{w}_i|) = \Sigma_i M_i |\widetilde{v}_i\rangle\langle\widetilde{v}_i| = I$, then $\mathcal{E}^{\mathsf{T}}$ and $\mathcal{E}$ are unital, namely both CPT and CPI. Then, by applying Theorem III.3 one has $\mathbf{P} \simeq_U \mathbf{Q}$. The converse is trivial. ■

XII. CONCLUSIONS

In this paper we have introduced the notion of *clean* POVMs, namely which are not irreversibly connected to another POVM via a quantum channel. We used the adjective clean for such POVMs in the sense that they are not affected by extrinsical quantum noise from the action of a channel which is in principle avoidable. We have seen that, quite unexpectedly, the *cleanness* property is largely unrelated to the convex structure of POVMs, and there are clean POVMs that are not extremal and extremal POVMs that are not clean.

The classification problem of POVMs cleanness turned out to be much harder than that of their extremality, and in this paper we gave a complete classification of clean POVMs only for number n of outcomes $n \leqslant d$ (d dimension of the Hilbert space), whereas for $n > d$ we gave a set of either necessary or sufficient conditions, and an iff condition for the case of informationally complete POVMs for $n = d^2$. The difficulty for classifying the case $n > d$ reflects analogous difficulties in the theory of quantum measurements in assessing the maximal POVM cardinality needed to attain the accessible information, cardinality whose lower bound has been shown to be actually larger than d.[18,19]

The novel issue of clean POVMs naturally opens new problems in the theory of quantum information and quantum measurements. Besides the problem of the general classification of cleanness, it raises the problem of characterizing all POVMs achievable from a given one via a quantum channel, or, reversely, of all POVMs which can be evolved toward a given one via a quantum channel. These are only initial steps toward a thorough analysis of the general problem of the partial ordering induced by channels on the convex set of measurements, an issue which is not an academic mathematical problem, but which is relevant for engineering new quantum measurements with minimal available resources.

The potential $(iz)^m$ generates real eigenvalues only, under symmetric rapid decay boundary conditions

Kwang C. Shin[a)]
Department of Mathematics, University of Missouri, Columbia, Missouri 65211

(Received 21 February 2005; accepted 7 July 2005; published online 23 August 2005)

We consider the non-Hermitian eigenvalue problems $-u''(z)\pm(iz)^m u(z)=\lambda u(z)$, $m\geqslant 3$, under *every* rapid decay boundary condition that is symmetric with respect to the imaginary axis in the complex z plane. We prove that the eigenvalues λ are all real and positive. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2009667]

I. INTRODUCTION

For integers $m\geqslant 3$ fixed and $1\leqslant \ell \leqslant m-1$, we are considering the non-Hermitian eigenvalue problems

$$(H_\ell u)(z) := \left[-\frac{d^2}{dz^2}+(-1)^\ell (iz)^m\right] u(z)=\lambda u(z) \quad \text{for some } \lambda\in\mathbb{C}, \tag{1}$$

with the boundary condition that

$$u(z)\to 0 \text{ exponentially, as } z\to\infty \text{ along the two rays } \arg z=-\frac{\pi}{2}\pm\frac{\ell+1}{m+2}\pi. \tag{2}$$

If a non-constant function u along with a complex number λ solves (1) with the boundary condition (2), then we call λ an *eigenvalue of* H_ℓ and u an *eigenfunction associated with the eigenvalue* λ. It is known that any solution of (1) is entire (analytic on the complex plane). In Section 7.4 of Ref. 1, Hille shows that every solution of (1) is either decaying to zero or blowing up exponentially as z tends to infinity along any ray $\{z\in\mathbb{C}:\arg z=\text{const.}\}$, except along $m+2$ critical rays where the transition between decaying and blowing-up sectors might occur. Along these $m+2$ critical rays, any non-constant solution decays algebraically. We will explain these asymptotic properties of the solution in Sec. II.

Before we state our main theorem, we first introduce some known facts about the eigenvalues λ of H_ℓ, facts due to Hille[1] and Sibuya.[2]

Proposition 1: *For* $1\leqslant\ell\leqslant m-1$, *the eigenvalues* λ *of* H_ℓ *are the zeros of a certain entire function of order* $\frac{1}{2}+1/m\in(\frac{1}{2},1)$. *In particular, the eigenvalues have the following properties.*

(i) *eigenvalues are discrete;*
(ii) *all eigenvalues are simple; and*
(iii) *infinitely many eigenvalues exist.*

For our purposes, we will need to examine the proof of this proposition in some detail. In Lemmas 7 and 8, we prove that the eigenvalues are zeros of certain entire functions of order $\frac{1}{2}+1/m\in(\frac{1}{2},1)$, due to Sibuya.[2] Then claims (i) and (iii) are consequences of the Hadamard factorization theorem, whereas claim (ii) is due to Hille.[1]

[a)]Electronic mail:kcshin@math.missouri.edu

In this paper, we will prove the following main theorem regarding the positivity of the eigenvalues.

Theorem 2. *The eigenvalues* λ *of* H_ℓ *for integers* $1 \leqslant \ell \leqslant m-1$ *are all real and positive*.

One can show that the eigenvalues of H_ℓ are the same as those of $H_{m-\ell}$, by using the reflection $z \mapsto -z$. The case $\ell = 1$ of the theorem is due to Dorey *et al.*[3] Also when m is even and $\ell = m/2$, one can see that H_ℓ in $L^2(\mathbb{R})$ is Hermitian and hence, $\lambda \in \mathbb{R}$. In all other cases, Theorem 2 is new and provides the first result of its kind for boundary conditions that neither cluster near the negative imaginary axis nor lie on the real axis. We will explain how Theorem 2 covers *every* symmetric rapid decay condition when we discuss admissible boundary conditions in Sec. II.

For the rest of the Introduction, we will mention brief history and give some background about our main problem and our method of proof. Then in Sec. II, we will introduce work of Hille[1] and Sibuya[2] about some properties of solutions of (1). In Sec. III, we establish an induction step on ℓ, which is the key element in our proof of Theorem 2. More precisely, we will prove that for $1 \leqslant \ell \leqslant m/2-1$, every eigenvalue λ of $H_{\ell+1}$ is real and positive if all eigenvalues σ of H_ℓ lie in the sector $|\arg \sigma| \leqslant 2\pi/(m+2)$ in the complex plane. In Sec. IV, we will outline a proof of the induction basis $\ell = 1$, that is, the eigenvalues of H_1 lie in the sector $|\arg \lambda| \leqslant 2\pi/(m+2)$ (in fact, $\arg \lambda = 0$; see Refs. 3 and 4). We then prove Theorem 2 by induction on ℓ and the reflection $z \mapsto -z$. In the last section, we mention some open problems.

A. History and overview of the method

In this subsection, we introduce some earlier work related with Theorem 2. Also, we discuss our method of the proof of Theorem 2.

The Hamiltonians with the potential $\pm(iz)^m$ have been studied in many physics and mathematics papers, either under a boundary condition on the real axis,[5–7] $u(\pm\infty + 0i) = 0$, or under the boundary condition (2) with the $\ell = 1$ case.[3,4,8] Also, Bender and Turbiner[9] considered all the boundary conditions (2) with $1 \leqslant \ell \leqslant m-1$.

Caliceti *et al.*[5] and Simon[6] studied the Hamiltonians $-\mathrm{d}^2/\mathrm{d}x^2 + x^2 + \beta x^m$ on the real line, where $\beta \in \mathbb{C} \backslash \mathbb{R}_-$ and integers $m \geqslant 3$, and they proved compactness of the resolvent and discreteness of the spectrum. Regarding the reality of the eigenvalues, Caliceti *et al.*[5] showed that the eigenvalues for $(-\mathrm{d}^2/\mathrm{d}x^2) + x^2 + \beta x^{2n+1}$ are real if β is small enough.

Recently, a conjecture of Bessis and Zinn-Justin has been verified by Dorey *et al.*[3] and extended by Shin.[4] That is, the eigenvalues λ of

$$\left[-\frac{\mathrm{d}^2}{\mathrm{d}z^2} - (iz)^3 + \beta z^2 \right] u(z) = \lambda u(z), \quad u(\pm\infty + 0i) = 0 \quad \text{for } \beta \in \mathbb{R}, \tag{3}$$

are all real and positive. Dorey *et al.*[3] verified for the case $\beta = 0$, and later Shin[4] extended it for the case $\beta \in \mathbb{R}$.

In fact, Dorey *et al.*[3] have proved more. They studied the following eigenvalue problem:

$$\left[-\frac{\mathrm{d}^2}{\mathrm{d}z^2} - (iz)^{2M} - \alpha(iz)^{M-1} + \frac{l(l+1)}{z^2} \right] u(z) = \lambda u(z), \tag{4}$$

under the boundary condition (2) with $\ell = 1$, and M, α, l being all real. They proved that for $M > 1, \alpha < M + 1 + |2l+1|$, the eigenvalues are all real, and for $M > 1, \alpha < M + 1 - |2l+1|$, they are all positive. A special case of (4) is the potential iz^3 (when $M = \frac{3}{2}, \alpha = l = 0$), which is the $\beta = 0$ version of the Bessis and Zinn-Justin (BZJ) conjecture, but their results do not cover the $\beta \neq 0$ version.

Later, Shin[4] studied the following eigenvalue problem:

$$-\left[\frac{d^2}{dz^2}+(iz)^m+a_1(iz)^{m-1}+a_2(iz)^{m-2}+\cdots+a_{m-1}(iz)\right]u(z)=\lambda u(z),$$

with the boundary condition (2) with $\ell=1$, where $a_k\in\mathbb{R}$ for all k. He proved that if for some $1\leqslant j\leqslant m/2$ we have $(j-k)a_k\geqslant 0$ for all k, then the eigenvalues λ are all real and positive.[4] This covers the full BZJ conjecture.

The proof of our main theorem, Theorem 2, has four parts. The first part follows closely the method of Dorey *et al.*,[3] developing functional equations for spectral determinants, expressing them in factored forms and estimating eigenvalues by Green's transform. The second part establishes an induction step on $1\leqslant\ell\leqslant m/2$ and estimates eigenvalues by Green's transform again. In the third part, we use the result of Dorey *et al.*[3] that says the eigenvalues of H_1 are all real and positive (also, see Theorem 2 in Ref. 4). This induction basis, along with the induction step established in the second part, proves our main theorem for $1\leqslant\ell\leqslant m/2$. Last, we use the reflection $z\mapsto -z$ to cover $m/2<\ell\leqslant m-1$. Of course both this paper, and Dorey *et al.*[3] and Shin[4] are indebted to the work of Sibuya.[2]

B. $\mathcal{PT}$-symmetric oscillators

The above-mentioned Hamiltonians are not Hermitian in general, and hence the reality of eigenvalues is not obviously guaranteed. However, these Hamiltonians share a common symmetry, the so-called $\mathcal{PT}$ symmetry. A $\mathcal{PT}$-symmetric Hamiltonian is a Hamiltonian which is invariant under the combination of the parity operation $\mathcal{P}(:z\mapsto -\bar{z})$ (an over bar denotes the complex conjugate) and the time reversal operation $\mathcal{T}(:i\mapsto -i)$. These $\mathcal{PT}$-symmetric Hamiltonians have arisen in recent years in a number of physics papers[10–20] and other references mentioned previously, which support that some $\mathcal{PT}$-symmetric Hamiltonians have real eigenvalues only. The work of Dorey *et al.*[3] and Shin,[4] and the results in this paper, prove rigorously that some $\mathcal{PT}$-symmetric Hamiltonians indeed have real eigenvalues only.

We also know that if $H=-d^2/dz^2+V(z)$ is $\mathcal{PT}$ symmetric and if $V(z)$ is a polynomial, then $V(z)=Q(iz)$ for some real polynomial Q, because $\overline{V(-\bar{z})}=V(z)$. Thus, Re $V(z)$ is an even function and Im $V(z)$ is an odd function. Certainly, (1) is a $\mathcal{PT}$-symmetric Hamiltonian. Moreover, if $u(z)$ is an eigenfunction of H_ℓ associated with the eigenvalue $\lambda\in\mathbb{C}$, then so is $\overline{u(-\bar{z})}$, associated with the eigenvalue $\bar{\lambda}$.

II. PROPERTIES OF THE SOLUTIONS

In this section we will introduce some definitions and known facts related to Eq. (1). One of our main tasks is to identify the eigenvalues as being zeros of certain entire functions, in Lemmas 7 and 8. But first, we rotate Eq. (1) as follows because some known facts, which are related to our argument throughout, are directly available for this rotated equation.

Fix the integer $m\geqslant 3$. Let u be a solution of (1) and let $v(z)=u(-iz)$. Then v solves

$$-v''(z)+[(-1)^{\ell+1}z^m+\lambda]v(z)=0.$$

The boundary condition (2) of u becomes that $v(z)\to 0$ exponentially as $z\to\infty$ along the two rays

$$\arg z=\pm\frac{\ell+1}{m+2}\pi.$$

Throughout this paper, we will use the complex number

$$\omega=\exp\left[\tfrac{2\pi i}{m+2}\right].$$

When ℓ is even, it will be convenient to rotate it once more, letting $w(z):=v(\omega^{1/2}z)$ so that $w(z)$ solves

$$-w''(z)+[z^m+\omega\lambda]w(z)=0.$$

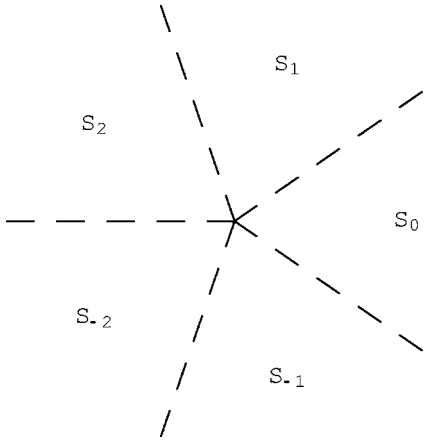

FIG. 1. The Stokes sectors S_j of (5) with $m=3$. The dashed rays are the critical rays: $\arg z = \pm\pi/5, \pm 3\pi/5, \pi$.

We mention that Hille[1] and Sibuya[2] have studied the general equation of the form

$$-v''(z) + [z^m + P(z) + \lambda]v(z) = 0,$$

where $P(z)$ is a polynomial of degree less than m. We proceed now to summarize work of Hille[1] and expand on some work of Sibuya[2] for $P \equiv 0$, that is, for

$$-v''(z) + [z^m + \lambda]v(z) = 0, \quad \text{where } m \geqslant 3. \tag{5}$$

A. Results of Hille

It is known that every solution of (5) has simple asymptotic behavior near infinity.[1] We will explain this asymptotic behavior using the following.

Definition: Consider the equation

$$g''(z) + \left[b_m z^m + b_{m-1} z^{m-1} + \cdots + b_1 z + b_0\right] g(z) = 0, \tag{6}$$

where $b_k \in \mathbb{C}$ for $0 \leqslant k \leqslant m$ with $b_m \neq 0$. Let

$$\theta_j = \frac{2j\pi - \arg b_m}{m+2} \quad \text{for } j \in \mathbb{Z},$$

where we choose $-\pi < \arg b_m \leqslant \pi$. For $j \in \mathbb{Z}$ we call the open sectors

$$S_j = \{z \in \mathbb{C} : \theta_j < \arg z < \theta_{j+1}\} \tag{7}$$

the *Stokes sectors* of (6). Also we call the rays $\{\arg z = \theta_j\}$ the *critical rays*.

In particular, the Stokes sectors of (5) are

$$S_j = \left\{ z \in \mathbb{C} : \frac{(2j-1)\pi}{m+2} < \arg z < \frac{(2j+1)\pi}{m+2} \right\} \quad \text{for } j \in \mathbb{Z}. \tag{8}$$

See Fig. 1.

Now we are ready to introduce some asymptotic behavior of solutions of (5), due to Hille.[1]

Lemma 3: *Let v be a non-constant solution of (5) (with no boundary conditions imposed). Then the following hold.*

(i) *In each Stokes sector S_j, the solution v is asymptotic to*

$$(\text{const.})z^{-m/4}\exp\left[\pm\frac{2}{m+2}z^{(m+2)/2}\right] \tag{9}$$

as $z\to\infty$ *in every closed subsector of* S_j.

(ii) *If* v *decays to zero in* S_j, *for some* $j\in\mathbb{Z}$, *then it must blow up in* S_{j-1} *and* S_{j+1}. *(However, it is possible for* v *to blow up in many adjacent Stokes sectors.) Moreover, the asymptotic expansion (9) is valid with the same constant for the three consecutive Stokes sectors* $S_{j-1}\cup cl(S_j)\cup S_{j+1}$, *where* $cl(S_j)$ *is the closure of* S_j.

(iii) *For each Stokes sector* S_j, *there exists a solution of (5) that decays in* S_j, *and there exists a solution of (5) that blows up in* S_j. *And any solution of (5) can be expressed as a linear combination of these two solutions*.

Proof: See the Section 7.4 in Ref. 1 for a proof. □

Remark: In Lemma 3, we state some asymptotic behavior of solutions of (5). In the general case, the corresponding Stokes sectors of (6) are given by (7). With these Stokes sectors, Lemma 3 holds though the asymptotic expansion (9) becomes more complicated due to more complicated potentials.

Note that Lemma 3 (iii) implies Proposition 1 (ii). More precisely, if an eigenvalue were not simple, then Eq. (1) would have two linearly independent solutions satisfying the boundary condition in (2). Hence, any solution of (1) could be expressed as a linear combination of these solutions. So there would be no solution of (1) that blows up in either of the two Stokes sectors containing the rays in (2). This contradicts Lemma 3 (iii). Therefore, every eigenvalue is simple.

From now on, we denote S_j the Stokes sectors of (5).

B. Admissible boundary conditions

Note, in particular, that the asymptotic expansion (9) implies that for each j, $v(z)$ either decays to zero or blows up exponentially, as z approaches infinity in closed subsectors of S_j. Also, the asymptotic expansion (9) implies that if $v(z)\to 0$ as $z\to\infty$ along one ray in S_j, then $v(z)\to 0$ as $z\to\infty$ along every ray in S_j. Likewise, if $v(z)\to\infty$ as $z\to\infty$ along one ray in S_j, then $v(z)\to\infty$ as $z\to\infty$ along every ray in S_j.

Let u be an eigenfunction of H_ℓ. Then the above-mentioned observation shows that when $\ell=2n-1$ is odd, the boundary condition (2) for H_ℓ is equivalent to having $v(z)=u(-iz)$ decaying to zero as $z\to\infty$ along rays in S_{-n} and S_n. (Note that the rays $\arg z=\pm[(\ell+1)/(m+2)]\pi$ are center rays of S_{-n} and S_n.) Also, when $\ell=2n$ is even, the boundary condition (2) for H_ℓ is equivalent to having $w(z)=u(-i(\omega^{1/2}z))$ decaying to zero as $z\to\infty$ along the rays in S_{-n-1} and S_n.

As we see, one needs not choose the two rays being symmetric, as in (2), so long as they stay in the Stokes sectors that are symmetric with respect to the imaginary axis.

Next, we will show that for each $j\in\mathbb{Z}$, there exist two linearly independent solutions of (5) decaying to zero algebraically as $z\to\infty$ along the critical ray $\arg(z)=\theta_j$. Then, this implies that every solution of (5) decays to zero algebraically as z tends to infinity along the critical ray since the solution can be expressed as a linear combination of two linearly independent solutions of (5). To this end, we will use Lemma 3.

Equation (5) has two solutions f_{j-1} and f_j, decaying in S_{j-1} and in S_j, respectively. Then it is not difficult to see that f_{j-1} blows up in S_j and hence, f_{j-1} and f_j are linearly independent. Moreover, the asymptotic expansions (9) of f_{j-1} and f_j are valid as $z\to\infty$ in $S_{j-2}\cup\text{cl}(S_{j-1})\cup S_j$ and in $S_{j-1}\cup\text{cl}(S_j)\cup S_{j+1}$, respectively. Note that the critical ray $\arg(z)=\theta_j$ is contained in both sectors. Finally, since $\text{Re}(z^{(m+2)/2})=0$ for all z on the critical ray, we see that both f_{j-1} and f_j [and hence all solutions of (5)] decay to zero algebraically as z tends to infinity along the critical ray $\arg(z)=\theta_j$. [Incidently, the Stokes sectors S_j are the sectors where $\text{Re}(z^{(m+2)/2})$ keeps a constant sign.]

One might wonder why we do not consider the eigenvalue problem

$$\left[-\frac{d^2}{dz^2}-(-1)^{\ell}(iz)^m\right]u(z)=\lambda u(z),$$

under the boundary condition (2). [Here we have the opposite sign in front of $(-1)^{\ell}$, compared to (1).] In this case, under the rotation $v(z)=u(-iz)$ and $w(z)=v(\omega^{1/2}z)$ if necessary, the two rays in (2) map to two of the critical rays of (5). So we have algebraic decay of the solution. Thus, if one requires the eigenfunction decay to zero exponentially, there are no eigenvalues, whereas if one requires the eigenfunction decay to zero merely algebraically, then every complex number λ is an eigenvalue. Hence, we have no interest in this case.

Now we are ready to explain how Theorem 2 covers every symmetric rapid decay boundary condition. When ℓ is odd, Eq. (1) becomes $-u''(z)-(iz)^m u(z)=\lambda u(z)$. In this case, the negative imaginary axis is the center of a Stokes sector and the critical rays are $\arg z=-\pi/2\pm(2k-1)\pi/(m+2)$ for integers $1\leqslant k\leqslant(m+3)/2$. The two rays in (2) are not critical rays and they are, in fact, centers of the Stokes sectors. When ℓ is increased by 2, the rays in (2) move, away from the negative imaginary axis, to the centers of adjacent Stokes sectors. So Theorem 2 covers all symmetric rapid decay boundary condition for the potential $-(iz)^m$. Similarly, one can see that when ℓ is even, Theorem 2 covers all symmetric rapid decay boundary condition for the potential $(iz)^m$.

So far in this subsection, we have discussed all possible symmetric decaying boundary conditions, except the "imaginary axis" boundary condition that $u(z)$ decays to zero as $z\to\infty$ along the both ends of the imaginary axis when m is even. In this case, if $u(z)$ is an eigenfunction of $-u''(z)-(iz)^m u(z)=\lambda u(z)$ satisfying this "imaginary axis" boundary condition, then $\lambda\in\mathbb{R}$ since $v(z):=u(-iz)$ is an eigenfunction of the Hermitian equation

$$-v''(z)+z^m v(z)=-\lambda v(z),\quad v(\pm\infty+0i)=0.$$

Next, we briefly mention nonsymmetric decaying boundary conditions. Let us consider, as an example,

$$\left[-\frac{d^2}{dz^2}-(iz)^m\right]u(z)=\lambda u(z),$$

under the boundary condition that $u(z)$ decays to zero exponentially as z tends to infinity along the rays $\arg z=-(\pi/2)+2\pi/(m+2)$ and $\arg z=-(\pi/2)-4\pi/(m+2)$. Set $u_1(z):=u(\omega^{-1/2}z)$. Then $u_1(z)$ solves

$$\left[-\frac{d^2}{dz^2}+(iz)^m\right]u_1(z)=\omega^{-1}\lambda u_1(z),$$

under the boundary condition (2) with $\ell=2$. Theorem 2 shows that $\omega^{-1}\lambda$ is real and positive and hence, λ is not real. In general, if we impose a decaying boundary condition along the two rays in some Stokes sectors that are not symmetric with respect to the imaginary axis, then the eigenvalues are not real and positive.

Finally, we mention that the integer ℓ in (1) and (2) equals to the number of Stokes sectors between the two sectors where we impose the boundary condition (2).

C. Results of Sibuya

We will introduce Sibuya's results, but first we define the order of an entire function g as

$$\text{order}(g)=\limsup_{r\to\infty}\frac{\log\log M(r,g)}{\log r},$$

where $M(r,g)=\max\{|g(re^{i\theta})|:0\leqslant\theta\leqslant 2\pi\}$ for $r>0$. If for some positive real numbers σ,c_1,c_2, we have $M(r,g)\leqslant c_1\exp[c_2 r^{\sigma}]$ for all large r, then the order of g is finite and less than or equal to σ. In this paper, we choose $\arg z^{\alpha}=\alpha\arg z$ for $-\pi<\arg z\leqslant\pi$ and $\alpha\in\mathbb{R}$.

Now we are ready to introduce some existence results and asymptotic estimates of Sibuya.[2] The existence of an entire solution with a specified asymptotic representation for fixed λ, is presented as well as an asymptotic expansion of the value of the solution at $z=0$ as λ tends to infinity. These results are in Theorems 6.1, 7.2, 19.1, and 20.1 of Sibuya's book.[2] The following is a special case of these theorems that is enough for our later argument.

Proposition 4: *Equation (5) admits a solution* $f(z,\lambda)$ *with the following properties.*

(i) $f(z,\lambda)$ *is an entire function of* (z,λ).

(ii) $f(z,\lambda)$ *and* $f'(z,\lambda)=(\mathrm{d}/\mathrm{d}z)f(z,\lambda)$ *admit the following asymptotic expansions. Let* $\varepsilon>0$. *Then*

$$f(z,\lambda) = z^{-m/4}(1+O(z^{-1/2}))\exp\left[-\frac{2}{m+2}z^{(m+2)/2}\right],$$

$$f'(z,\lambda) = -z^{m/4}(1+O(z^{-1/2}))\exp\left[-\frac{2}{m+2}z^{(m+2)/2}\right],$$

as z *tends to infinity in the sector* $|\arg z|\leqslant 3\pi/(m+2)-\varepsilon$, *uniformly on each compact set of the complex* λ*-plane.*

(iii) *Properties* (i) *and* (ii) *uniquely determine the solution* $f(z,\lambda)$ of (5)).

(iv) *For each fixed* $\delta>0$, f *and* f' *also admit the asymptotic expansions,*

$$f(0,\lambda) = [1+o(1)]\lambda^{-1/4}\exp\left[K\lambda^{1/2+1/m}\right], \tag{10}$$

$$f'(0,\lambda) = -[1+o(1)]\lambda^{1/4}\exp\left[K\lambda^{1/2+1/m}\right], \tag{11}$$

as λ *tends to infinity in the sector* $|\arg\lambda|\leqslant\pi-\delta$, *where*

$$K = \int_0^\infty \left(\sqrt{1+t^m}-\sqrt{t^m}\right)\mathrm{d}t. \tag{12}$$

(v) *The entire functions* $\lambda\mapsto f(0,\lambda)$ *and* $\lambda\mapsto f'(0,\lambda)$ *have orders* $\frac{1}{2}+1/m$.

Proof: In Sibuya's book,[2] see Theorem 6.1 for a proof of (i) and (ii); Theorem 7.2 for a proof of (iii); and Theorem 19.1 for a proof of (iv). And (v) is a consequence of (iv) along with Theorem 20.1. Note that properties (i), (ii) and (iv) are summarized on pages 112 and 113 of Sibuya's book.[2] □

The next thing we want to introduce is the Stokes multiplier. Let $f(z,\lambda)$ be the function in Proposition 4. Note that $f(z,\lambda)$ decays to zero exponentially as $z\to\infty$ in S_0, and blows up in $S_{-1}\cup S_1$. Then, the function

$$f_k(z,\lambda) := f(\omega^{-k}z,\omega^{-mk}\lambda), \tag{13}$$

obtained by rotating $f(z,\omega^{-mk}\lambda)$ in the z variable, solves (5). It is clear that $f_0(z,\lambda)=f(z,\lambda)$, and that $f_k(z,\lambda)$ decays in S_k and blows up in $S_{k-1}\cup S_{k+1}$ since $f(z,\omega^{-mk}\lambda)$ decays in S_0. Since no non-constant solution decays in two adjacent Stokes sectors, f_k and f_{k+1} are linearly independent and hence, any solution of (5) can be expressed as a linear combination of these two. Especially, for some coefficients $C_{j,k}(\lambda)$ and $D_{j,k}(\lambda)$,

$$f_j(z,\lambda) = C_{j,k}(\lambda)f_k(z,\lambda)+D_{j,k}(\lambda)f_{k+1}(z,\lambda), \quad j,k\in\mathbb{Z}. \tag{14}$$

These $C_{j,k}(\lambda)$ and $D_{j,k}(\lambda)$ are called the *Stokes multipliers of* f_j *with respect to* f_k *and* f_{k+1}.

Then,

$$C_{j,k}(\lambda) = \frac{W_{j,k+1}(\lambda)}{W_{k,k+1}(\lambda)}, \quad D_{j,k}(\lambda) = -\frac{W_{j,k}(\lambda)}{W_{k,k+1}(\lambda)}, \tag{15}$$

where $W_{j,k}=f_jf_k'-f_j'f_k$ is the Wronskian of f_j and f_k. Since both f_j and f_k are solutions of the same linear equation (5), the Wronskians are constant functions of z. Also, since f_k and f_{k+1} are linearly independent, $W_{k,k+1}\neq 0$ for all $k\in\mathbb{Z}$. In the next lemma, we will show that the Wronskian $W_{k,k+1}(\lambda)$ is constant, which is needed in the proof of our main theorem.

Lemma 5: *For each* $k\in\mathbb{Z}, W_{k,k+1}(\lambda)=-2\omega^{-m/4-k-1}$, *that is independent of* λ.

Proof: Since $f_k(z,\lambda)=f(\omega^{-k}z,\omega^{-mk}\lambda)$, we get

$$f_{k+1}(z,\lambda) = f(\omega^{-(k+1)}z,\omega^{-m(k+1)}\lambda) = f_k(\omega^{-1}z,\omega^{-m}\lambda) = f_k(\omega^{-1}z,\omega^2\lambda), \quad \text{by } \omega^{m+2}=1.$$

This along with $f_{k+1}'(z,\lambda)=\omega^{-1}f_k'(\omega^{-1}z,\omega^2\lambda)$, one can show that

$$W_{j+1,k+1}(\lambda) = \omega^{-1}W_{j,k}(\omega^2\lambda). \tag{16}$$

Using Proposition 4 (ii) and

$$W_{-1,0}(\lambda) = f_{-1}f_0' - f_0f_{-1}' = f(\omega z,\omega^{-2}\lambda)f'(z,\lambda) - f(z,\lambda)\omega f'(\omega z,\omega^{-2}\lambda),$$

one can show that as z tends to infinity in S_0 (for which above-mentioned asymptotics are valid),

$$\begin{aligned} W_{-1,0}(\lambda) &= -(\omega z)^{-m/4}z^{m/4}(1+O(z^{-1/2}))\exp\left[-\frac{2}{m+2}(\omega z)^{(m+2)/2} - \frac{2}{m+2}z^{(m+2)/2}\right] \\ &\quad + z^{-m/4}\omega(\omega z)^{m/4}(1+O(z^{-1/2}))\exp\left[-\frac{2}{m+2}(\omega z)^{(m+2)/2} - \frac{2}{m+2}z^{(m+2)/2}\right] \\ &= -2\omega^{-m/4}(1+O(z^{-1/2})) \quad \text{since } \omega^{(m+2)/2}=-1. \end{aligned}$$

Finally,

$$W_{-1,0}(a,\lambda) = -2\omega^{-m/4}. \tag{17}$$

Thus (16) and (17) complete the proof. □

In the next lemma, we will show that the Wronskians $W_{k,0}(\lambda)$ for $2\leq k\leq m$ have orders $\frac{1}{2}+1/m$, which is needed in establishing the induction step in Theorem 11 and proving existence of the eigenvalues under various boundary conditions. This lemma is due to Sibuya,[2] but we give a full proof here.

Lemma 6: *For each* $2\leq k\leq m$, *the Wronskian* $W_{k,0}(\lambda)$ *has its order* $\frac{1}{2}+\frac{1}{m}\in\left(\frac{1}{2},1\right)$.

Proof: First, we look at

$$W_{k,0}(\lambda) = f_k(z,\lambda)f_0'(z,\lambda) - f_0(z,\lambda)f_k'(z,\lambda) = f(0,\omega^{2k}\lambda)f'(0,\lambda) - f(0,\lambda)\omega^{-k}f'(0,\omega^{2k}\lambda), \tag{18}$$

where we take $z=0$ since the Wronskian is independent of z. Then the Wronskian $W_{k,0}(\lambda)$ has order less than or equal to $\frac{1}{2}+1/m$ because each term in the right hand side of (18) has order $\frac{1}{2}+1/m$ by Lemma 4 (v). So in order to show $W_{k,0}(\lambda)$ has order equal to $\frac{1}{2}+1/m$, it suffices to show that there exist $c_1>0$ and $c_2>0$ such that $|W_{k,0}(\lambda)|\geq c_1\exp[c_2|\lambda|^{1/2+1/m}]$ for all large $|\lambda|$ along some ray.

Next, we examine the right-hand side of (18) along the ray

$$\arg\lambda \equiv \theta = \pi - \frac{4\pi}{m+2},$$

by using the asymptotic expansions (10) and (11). Note that $\theta\in(-\pi+\delta,\pi-\delta)$, for all $0<\delta<\pi/(m+2)$. Recall that the expansions (10) and (11) are valid when $\lambda\to\infty$ in $|\arg\lambda|\leq\pi-\delta$. Since

$$\arg(\omega^{2k}\lambda) \equiv \theta_* = \theta + \frac{4k\pi}{m+2} - 2\pi \quad \text{for } 2 \leqslant k \leqslant \frac{m+2}{2}, \tag{19}$$

we have

$$-\pi < -\frac{m\pi}{m+2} < \theta_* < \theta < \frac{m\pi}{m+2} < \pi \quad \text{for } 2 \leqslant k \leqslant \frac{m+2}{2}. \tag{20}$$

Thus,

$$f(0,\omega^{2k}\lambda) = [1+o(1)]|\lambda|^{-1/4}e^{-i\theta_*/4}\exp\left[K|\lambda|^{1/2+1/m}e^{i[(m+2)/2m]\theta_*}\right],$$

$$f'(0,\omega^{2k}\lambda) = -[1+o(1)]|\lambda|^{-1/4}e^{-i\theta_*/4}\exp\left[K|\lambda|^{1/2+1/m}e^{i[(m+2)/2m]\theta_*}\right].$$

This along with (18) yields

$$\begin{aligned}
W_{k,0}(\lambda) &= -[1+o(1)]|\lambda|^{1/4}e^{i\theta/4}|\lambda|^{-1/4}e^{-i\theta_*/4}\exp\left[K|\lambda|^{1/2+1/m}\left(e^{i(1/2+1/m)\theta}+e^{i(1/2+1/m)\theta_*}\right)\right] \\
&\quad +[1+o(1)]|\lambda|^{-1/4}e^{-i\theta/4}\omega^{-k}|\lambda|^{1/4}e^{i\theta_*/4}\exp\left[K|\lambda|^{1/2+1/m}\left(e^{i(1/2+1/m)\theta}+e^{i(1/2+1/m)\theta_*}\right)\right] \\
&= \left[-e^{i(\theta-\theta_*)/4}+\omega^{-k}e^{i(\theta_*-\theta)/4}\right][1+o(1)]\exp\left[K|\lambda|^{1/2+1/m}\left(e^{i(1/2+1/m)\theta}+e^{i(1/2+1m)\theta_*}\right)\right] \\
&= -2i\omega^{-k/2}[1+o(1)]\exp\left[K|\lambda|^{1/2+1/m}\left(e^{i(1/2+1/m)\theta}+e^{i(1/2+1/m)\theta_*}\right)\right],
\end{aligned}$$

where the last step is by $\theta-\theta_*=2\pi-4k\pi/(m+2)$. So when $\arg\lambda=\pi-4\pi/(m+2)$, we have

$$\mathrm{Re}\left[e^{i(1/2+1/m)\theta}+e^{i(1/2+1/m)\theta_*}\right] = \mathrm{Re}\left[\cos\left(\frac{m+2}{2m}\theta\right)+\cos\left(\frac{m+2}{2m}\theta_*\right)\right] > 0,$$

where the last step is by (20).

So for $2\leqslant k\leqslant(m+2)/2$, since $K>0$, there exists $c_2>0$ such that $|W_{k,0}(\lambda)| \geqslant \exp[c_2|\lambda|^{1/2+1/m}]$ for all large $|\lambda|$ on the ray $\arg\lambda=\pi-4\pi/(m+2)$. Thus the order of $W_{k,0}(\lambda)$ for $2\leqslant k\leqslant(m+2)/2$ is $1/2+1/m$.

Certainly, the Wronskian $W_{k,0}(\lambda)$ for $2\leqslant k\leqslant(m+2)/2$ is blowing up in some other directions as well. If one finds θ and θ_* satisfying (20), the above argument will show that $W_{k,0}(\lambda)$ is blowing up along $\arg\lambda=\theta$.

Next for $(m+2)/2<k\leqslant m$, one can choose $\theta=-\pi+4\pi/(m+2)$ and θ_* by (19), and then follow an argument similar to the above to conclude that the order of $W_{k,0}(\lambda)$ is $1/2+1/m$. Or one uses an index change to reduce to the case already considered. That is,

$$\begin{aligned}
W_{k,0}(\lambda) &= W_{k-(m+2),0}(\lambda) \\
&= \omega^{m+2-k}W_{0,m+2-k}(\omega^{-2(m+2-k)}\lambda) \quad \text{by (16)} \\
&= -\omega^{m+2-k}W_{m+2-k,0}(\omega^{-2(m+2-k)}\lambda).
\end{aligned}$$

Then since $2\leqslant m+2-k<(m+2)/2$, we know the order of $W_{m+2-k,0}(\omega^{2(m+2-k)}\lambda)$ is $1/2+1/m$, and hence so is the order of $W_{k,0}(\lambda)$ for $(m+2)/2<k\leqslant m$. This completes the proof. □

D. Further results of Sibuya; identifying the eigenvalues as zeros of certain entire functions

We can relate the zeros of $C_{-n,n-1}(\lambda)$ and $D_{-n,n}(\lambda)$ with the eigenvalues of H_ℓ. First, we study the case when ℓ is odd, as follows.

Lemma 7: *Let $\ell=2n-1$ be odd, with $1\leqslant\ell\leqslant m-1$. Then the following are equivalent:*

(i) *a complex number λ is an eigenvalue of H_ℓ;*
(ii) *λ is a zero of the entire function $C_{-n,n-1}(\lambda)$; and*
(iii) *λ is a zero of the entire function $D_{-n,n}(\lambda)$.*

Moreover, the orders of the entire functions $C_{-n,n-1}(\lambda)$ and $D_{-n,n}(\lambda)$ are $\frac{1}{2}+1/m \in (\frac{1}{2},1)$.

Hence, the eigenvalues are discrete because they are zeros of a non-constant entire function. Note that the Stokes multipliers $C_{-n,n-1}(\lambda)$ and $D_{-n,n}(\lambda)$ are called *spectral determinants* or *Evans functions*.

Proof: Suppose that λ is an eigenvalue of H_{2n-1} with the corresponding eigenfunction u. We let $v(z)=u(-iz)$. Then v solves

$$-v''(z)+(z^m+\lambda)v(z)=0,$$

and decays in $S_{-n}\cup S_n$. Since $f_{-n}(z,\lambda)$ is another solution of this equation that decays in S_{-n}, we see that $f_{-n}(z,\lambda)$ is a multiple of v. Similarly $f_n(z,\lambda)$ is a multiple of v. Since

$$f_{-n}(z,\lambda)=C_{-n,n-1}(\lambda)f_{n-1}(z,\lambda)+D_{-n,n-1}(\lambda)f_n(z,\lambda), \tag{21}$$

and since $f_{n-1}(z,\lambda)$ blows up in S_n, we conclude that $C_{-n,n-1}(\lambda)=0$.

Conversely, we suppose that $C_{-n,n-1}(\lambda)=0$ for some $\lambda\in\mathbb{C}$. Then from (21) we see that $f_{-n}(z,\lambda)$ is a constant multiple of $f_n(z,\lambda)$. Thus both are decaying in $S_{-n}\cup S_n$, and hence $u(z)\coloneqq f_{-n}(iz,\lambda)$ is an eigenfunction of H_{2n-1} associated with the eigenvalue λ.

Similarly, since

$$f_{-n}(z,\lambda)=C_{-n,n}(\lambda)f_n(z,\lambda)+D_{-n,n}(\lambda)f_{n+1}(z,\lambda),$$

we see that λ is an eigenvalue of H_{2n-1} if and only if $D_{-n,n}(\lambda)=0$.

Finally, since $W_{k,k+1}(\lambda)$ is a constant by Lemma 5 and since $W_{k,0}(\lambda)$ for $2\leqslant k\leqslant m$ has order $\frac{1}{2}+\frac{1}{m}$ by Lemma 6, we see from (15) that $C_{-n,n-1}(\lambda)$ and $D_{-n,n}(\lambda)$ are of order $\frac{1}{2}+\frac{1}{m}\in(\frac{1}{2},1)$. This completes the proof. □

Second, we can relate the zeros of $C_{-n-1,n-1}(\lambda)$ and $D_{-n-1,n}(\lambda)$ with the eigenvalues of H_ℓ, when ℓ is even, as follows.

Lemma 8: *Let $\ell=2n$ be even, with $1\leqslant\ell\leqslant m-1$. Then the following are equivalent:*

(i) *a complex number λ is an eigenvalue of H_ℓ;*
(ii) *λ is a zero of the entire function $\lambda\mapsto C_{-n,n}(\omega^{-1}\lambda)$; and*
(iii) *λ is a zero of the entire function $\lambda\mapsto D_{-n-1,n}(\omega\lambda)$.*

Moreover, the orders of the entire functions $\lambda\mapsto C_{-n,n}(\omega^{-1}\lambda)$ and $\lambda\mapsto D_{-n-1,n}(\omega\lambda)$ are $\frac{1}{2}+\frac{1}{m}\in(\frac{1}{2},1)$.

Note again that the Stokes multipliers $C_{-n,n}(\omega^{-1}\lambda)$ and $D_{-n-1,n}(\omega\lambda)$ are spectral determinants or Evans functions.

Proof: Let u be an eigenfunction of H_{2n} associated with the eigenvalue λ. Then $v(z)\coloneqq u(-iz)$ solves

$$v''(z)+z^m v(z)=\lambda v(z).$$

Next we set $w_1(z)\coloneqq v(\omega^{-1/2}z)$. Then $w_1(z)$ solves

$$-w_1''(z)+[z^m+\omega^{-1}\lambda]w_1(z)=0. \tag{22}$$

One can then check that the boundary condition of H_{2n} becomes that $w_1(z)\to 0$ as $z\to\infty$ in $S_{-n}\cup S_{n+1}$. Then like we did for Lemma 7, since

$$f_{-n}(z,\omega^{-1}\lambda)=C_{-n,n}(\omega^{-1}\lambda)f_n(z,\omega^{-1}\lambda)+D_{-n,n}(\omega^{-1}\lambda)f_{n+1}(z,\omega^{-1}\lambda),$$

λ is an eigenvalue of H_{2n} if and only if $C_{-n,n}(\omega^{-1}\lambda)=0$.

Similarly, we let $w_2(z)\coloneqq v(\omega^{1/2}z)$. Then $w_2(z)$ solves

$$-w_2''(z)+[z^m+\omega\lambda]w_2(z)=0, \tag{23}$$

and the boundary condition of H_{2n} becomes that $w_2(z)\to 0$ as $z\to\infty$ in $S_{-n-1}\cup S_n$. Then since

$$f_{-n-1}(z,\omega\lambda) = C_{-n-1,n}(\omega\lambda) f_n(z,\omega\lambda) + D_{-n-1,n}(\omega\lambda) f_{n+1}(z,\omega\lambda),$$

λ is an eigenvalue of H_{2n} if and only if $D_{-n-1,n}(\omega\lambda)=0$. This completes the proof. □

Next we want infinite product representations of the entire functions $f(0,\lambda)$ and $f'(0,\lambda)$. Recall that the integer $m \geqslant 3$ is fixed.

Lemma 9: *The functions $f(0,\lambda)$ and $f'(0,\lambda)$ have infinitely many zeros $E_j<0$ and $E'_j<0$, respectively. Moreover, they admit the following infinite product representations:*

$$f(0,\lambda) = A_1 \prod_{j=1}^{\infty} \left(1 - \frac{\lambda}{E_j}\right) \quad \textit{for some } A_1 \in \mathbb{C}\setminus\{0\}. \tag{24}$$

$$f'(0,\lambda) = A_2 \prod_{j=1}^{\infty} \left(1 - \frac{\lambda}{E'_j}\right) \quad \textit{for some } A_2 \in \mathbb{C}\setminus\{0\}. \tag{25}$$

Proof: We know that $f(0,\lambda)$ and $f'(0,\lambda)$ have orders $\frac{1}{2}+1/m \in (0,1)$ by Proposition 4 (v), and hence by the Hadamard factorization theorem (see, for example, Theorem 14.2.6 on page 199 of Ref. 21), we know $f(0,\lambda)$ and $f'(0,\lambda)$ have infinite product representations (24) and (25) where $f(0,E_j)=0$ and $f'(0,E'_j)=0$ for all $j \in \mathbb{N}$. So in order to complete the proof, we need to show $E<0$ if $f(0,E)=0$, and $E'<0$ if $f'(0,E')=0$.

Suppose $f(0,E_*)=0$ or $f'(0,E_*)=0$. By the definition, we know that $f(z,E_*)$ solves

$$-f''(z,E_*) + z^m f(z,E_*) = -E_* f(z,E_*),$$

and decays to zero exponentially in S_0. (Note that $-\mathrm{d}^2/\mathrm{d}x^2+x^m$ is Hermitian in $L^2([0,+\infty))$.) In order to show $E_*<0$, we multiply this equation by $\overline{f(z,E_*)}$ and integrate over the positive real axis to get

$$-\int_0^\infty f''(x,E_*)\overline{f(x,E_*)}\mathrm{d}x + \int_0^\infty x^m |f(x,E_*)|^2 \mathrm{d}x = -E_* \int_0^\infty |f(x,E_*)|^2 \mathrm{d}x.$$

Next we integrate the first term by parts, and use $f(0,E_*)=0$ or $f'(0,E_*)=0$. Clearly the left-hand side of the resulting equation is positive, and hence we conclude $E_*<0$. This completes the proof. □

Next, we will introduce a symmetry lemma, regarding $f(z,\lambda)$ and $f(z,\lambda)$.

Lemma 10: *For each $\lambda \in \mathbb{C}$,*

$$\overline{f(\bar{z},\lambda)} = f(z,\bar{\lambda}), \quad \overline{f'(\bar{z},\lambda)} = f'(z,\bar{\lambda}). \tag{26}$$

Proof: This lemma for $z=0$ is contained in Lemma 8 in Ref. 4, and in fact that is all we will need in this paper. A proof of this lemma is essentially the same as that of Lemma 8 in Ref. 4. So we omit the proof here. □

III. THE INDUCTION STEP

In proving Theorem 2, we will use induction on ℓ. The induction step will be provided by the following theorem.

Theorem 11: *If $1 \leqslant \ell \leqslant m/2-1$ and all the eigenvalues of H_ℓ lie in the sector $|\arg\cdot| \leqslant 2\pi/(m+2)$, then every eigenvalue of $H_{\ell+1}$ is real and positive.*

Proof of Theorem 11 (Case I: *$\ell=2n-1$ is odd, with $1 \leqslant n \leqslant \frac{m}{4}$*): Suppose that all the eigenvalues σ_j of H_{2n-1} lie in the sector $|\arg\sigma_j| \leqslant 2\pi/(m+2)$. That is, zeros σ_j of the entire function $\sigma \mapsto D_{-n,n}(\sigma)$ lie in the sector $|\arg\sigma| \leqslant 2\pi/(m+2)$ (see Lemma 7). We will show that every eigenvalue λ of H_{2n} is real and positive.

Suppose $u(z)$ is an eigenfunction of H_{2n} associated with the eigenvalue λ. Then $u(z)$ solves

$$-u''(z)+(iz)^m u(z)=\lambda u(z),$$

and decays to zero as z tends to infinity along the two rays $\arg z=-\pi/2\pm(2n+1)\pi/(m+2)$. Set $v(z)=u(-iz)$. Then $v(z)$ solves

$$v''(z)+z^m v(z)=\lambda v(z), \tag{27}$$

and decays to zero as z tends to infinity along the two rays $\arg z=\pm(2n+1)\pi/(m+2)$.

Next we let $w(z)=v(\omega^{-1/2}z)$ so that $w(z)$ solves

$$-w''(z)+[z^m+\omega^{-1}\lambda]w(z)=0, \tag{28}$$

and decays to zero as z tends to infinity along the two rays $\arg z=(2n+2)\pi/(m+2)$, $-2n\pi/(m+2)$, the center rays of S_{n+1} and S_{-n}.

Then we examine

$$f_{-n}(z,\omega^{-1}\lambda)=C_{-n,n}(\omega^{-1}\lambda)f_n(z,\omega^{-1}\lambda)+D_{-n,n}(\omega^{-1}\lambda)f_{n+1}(z,\omega^{-1}\lambda),$$

or equivalently,

$$f(\omega^n z,\omega^{-2n-1}\lambda)=C_{-n,n}(\omega^{-1}\lambda)f(\omega^{-n}z,\omega^{2n-1}\lambda)+D_{-n,n}(\omega^{-1}\lambda)f(\omega^{-n-1}z,\omega^{2n+1}\lambda). \tag{29}$$

Since $C_{-n,n}(\omega^{-1}\lambda)=0$ by Lemma 8, we get $D_{-n,n}(\omega^{-1}\lambda)\neq 0$.

Next we will show that $|D_{-n,n}(\omega^{-1}\lambda)|\leqslant 1$ when λ is an eigenvalue of H_{2n} with $\operatorname{Im}\lambda\geqslant 0$. To this end, we evaluate the Eq. (29) and its differentiated form at $z=0$ to get

$$f(0,\omega^{-2n-1}\lambda)=D_{-n,n}(\omega^{-1}\lambda)f(0,\omega^{2n+1}\lambda), \tag{30}$$

$$\omega^n f'(0,\omega^{-2n-1}\lambda)=\omega^{-n-1}D_{-n,n}(\omega^{-1}\lambda)f'(0,\omega^{2n+1}\lambda). \tag{31}$$

Since λ is an eigenvalue, so is $\bar{\lambda}$. Thus,

$$f(0,\omega^{-2n-1}\bar{\lambda})=D_{-n,n}(\omega^{-1}\bar{\lambda})f(0,\omega^{2n+1}\bar{\lambda}),$$

$$\omega^n f'(0,\omega^{-2n-1}\bar{\lambda})=\omega^{-n-1}D_{-n,n}(\omega^{-1}\bar{\lambda})f'(0,\omega^{2n+1}\bar{\lambda}).$$

We take the complex conjugates of these, and apply (26) at $z=0$ to get

$$f(0,\omega^{2n+1}\lambda)=\overline{D_{-n,n}(\omega^{-1}\bar{\lambda})}f(0,\omega^{-2n-1}\lambda),$$

$$\omega^{-n}f'(0,\omega^{2n+1}\lambda)=\omega^{n+1}\overline{D_{-n,n}(\omega^{-1}\bar{\lambda})}f'(0,\omega^{-2n-1}\lambda).$$

So these along with (30) and (31) imply

$$D_{-n,n}(\omega^{-1}\lambda)\overline{D_{-n,n}(\omega^{-1}\bar{\lambda})}=1. \tag{32}$$

Clearly the order of the entire function $\sigma\mapsto D_{-n,n}(\sigma)$ is $\frac{1}{2}+1/m\in(0,1)$. So by the Hadamard factorization theorem we have

$$D_{-n,n}(\lambda)=B\prod_{j=1}^{\infty}\left(1-\frac{\lambda}{\sigma_j}\right)\quad\text{for some } B\in\mathbb{C}\setminus\{0\},$$

where the σ_j are the zeros of $D_{-n,n}(\sigma)$, and so $|\arg\sigma_j|\leqslant 2\pi/(m+2)$ for all $j\in\mathbb{N}$, by hypothesis.

Thus,

$$\left|\frac{D_{-n,n}(\omega^{-1}\lambda)}{D_{-n,n}(\omega^{-1}\bar{\lambda})}\right| = \prod_{j=1}^{\infty}\left|\frac{1-\dfrac{\omega^{-1}\lambda}{\sigma_j}}{1-\dfrac{\omega^{-1}\bar{\lambda}}{\sigma_j}}\right| = \prod_{j=1}^{\infty}\left|\frac{\omega\sigma_j-\lambda}{\omega\sigma_j-\bar{\lambda}}\right| \leqslant 1, \quad \text{when } \operatorname{Im}\lambda \geqslant 0, \tag{33}$$

since $\operatorname{Im}(\omega\sigma_j)\geqslant 0$ for all $j\in\mathbb{N}$. This along with (32) implies

$$|D_{-n,n}(\omega^{-1}\lambda)| \leqslant 1 \quad \text{when } \operatorname{Im}\lambda \geqslant 0.$$

Since the non-constant entire function $f(z,\omega^{2n+1}\lambda)$ solves

$$-f''(z,\omega^{2n+1}\lambda)+[z^m+\omega^{2n+1}\lambda]f(z,\omega^{2n+1}\lambda)=0,$$

we know $f(0,\omega^{2n+1}\lambda)$ and $f'(0,\omega^{2n+1}\lambda)$ cannot be zero at the same time. Otherwise, $f(z,\omega^{2n+1}\lambda)=0$ for all $z\in\mathbb{C}$.

Suppose that $f(0,\omega^{2n+1}\lambda)\neq 0$. Then we get

$$1 \geqslant |D_{-n,n}(\omega^{-1}\lambda)| = \prod_{j=1}^{\infty}\left|\frac{1-\dfrac{\omega^{-2n-1}\lambda}{E_j}}{1-\dfrac{\omega^{2n+1}\lambda}{E_j}}\right| = \prod_{j=1}^{\infty}\left|\frac{\omega^{2n+1}E_j-\lambda}{\omega^{2n+1}E_j-\bar{\lambda}}\right| \geqslant 1 \quad \text{when } \operatorname{Im}\lambda\geqslant 0,$$

where the last inequality holds since $\operatorname{Im}(\omega^{2n+1}E_j)\leqslant 0$ if $0\leqslant\arg(\omega^{2n+1})\leqslant\pi$, by Lemma 9 (this is where we use $1\leqslant n\leqslant m/4$). So we obtain

$$|D_{-n,n}(\omega^{-1}\lambda)| = 1 \quad \text{when } \operatorname{Im}\lambda\geqslant 0. \tag{34}$$

Similarly, when $f'(0,\omega^{2n+1}\lambda)\neq 0$,

$$1 \geqslant |D_{-n,n}(\omega^{-1}\lambda)| = \prod_{j=1}^{\infty}\left|\frac{1-\dfrac{\omega^{-2n-1}\lambda}{E'_j}}{1-\dfrac{\omega^{2n+1}\lambda}{E'_j}}\right| = \prod_{j=1}^{\infty}\left|\frac{\omega^{2n+1}E'_j-\lambda}{\omega^{2n+1}E'_j-\bar{\lambda}}\right| \geqslant 1 \quad \text{when } \operatorname{Im}\lambda\geqslant 0,$$

where the E'_j are zeros of $f'(0,E)$. So we again have (34). Hence (33) along with combining (32) and (34) yields

$$\prod_{j=1}^{\infty}\left|\frac{\omega\sigma_j-\lambda}{\omega\sigma_j-\bar{\lambda}}\right| = 1. \tag{35}$$

Since $|\arg\sigma_j|\leqslant 2\pi/(m+2)$ for all $j\in\mathbb{N}$, we know $\operatorname{Im}(\omega\sigma_j)\geqslant 0$ for all $j\in\mathbb{N}$. Moreover, $\operatorname{Im}(\omega\sigma_j)>0$ for some j since both σ_j and $\overline{\sigma_j}$ are eigenvalues of the $\mathcal{PT}$-symmetric oscillator H_{2n-1}. Therefore, from (35) we conclude $\lambda=\bar{\lambda}$, and so λ is real.

We still need to show positivity of the eigenvalues. The function $v(z)$ solves (27) and we know $\lambda\in\mathbb{R}$. Also, one can check that $\overline{v(\bar{z})}$ solves the same equation. Since the eigenvalues are simple, $v(z)$ and $\overline{v(\bar{z})}$ must be linearly dependent, and hence $v(z)=c\overline{v(\bar{z})}$ for some $c\in\mathbb{C}$. Since $|v(z)|$ and $|v(\bar{z})|$ agree on the real line, we see that $|c|=1$ and $|v(z)|=|v(\bar{z})|$ for all $z\in\mathbb{C}$. That is, $|v(x+iy)|$ is even in y. From this we have that

$$0 = \frac{\partial}{\partial y}|v(x+iy)|^2\Big|_{y=0} = -2\operatorname{Im}\big(v'(x)\overline{v(x)}\big) \quad \text{for all } x\in\mathbb{R}. \tag{36}$$

Let $g(r)=v(re^{i\theta})$ for $2n\pi/(m+2)<\theta<(2n+2)\pi/(m+2)$. Then $g(r)$ satisfies

$$e^{-2i\theta}g''(r)+e^{mi\theta}r^m g(r)=\lambda g(r).$$

Multiplying this by $\overline{g(r)}$ and integrating the resulting equation over $r\in[0,\infty)$ yield

$$e^{-2i\theta}\int_0^\infty g''(r)\overline{g(r)}\mathrm{d}r+e^{mi\theta}\int_0^\infty r^m|g(r)|^2\mathrm{d}r=\lambda\int_0^\infty|g(r)|^2\mathrm{d}r.$$

Next we integrate the first term by parts and multiply the resulting equation by $e^{i\theta}$ to have

$$-e^{-i\theta}g'(0)\overline{g(0)}-e^{-i\theta}\int_0^\infty|g'(r)|^2\mathrm{d}r+e^{(m+1)i\theta}\int_0^\infty r^m|g(r)|^2\mathrm{d}r=\lambda e^{i\theta}\int_0^\infty|g(r)|^2\mathrm{d}r.$$

Then we use $e^{-i\theta}g'(0)=v(0)$ and take the imaginary parts to get, for all $2n\pi/(m+2)<\theta<(2n+2)\pi/(m+2)$,

$$\sin\theta\int_0^\infty|g'(r)|^2\mathrm{d}r+\sin[(m+1)\theta]\int_0^\infty r^m|g(r)|^2\mathrm{d}r=\lambda\sin\theta\int_0^\infty|g(r)|^2\mathrm{d}r.$$

We evaluate this at $\theta=(2n+1)\pi/(m+1)$ to have $\lambda>0$. Note that since $1\leqslant n\leqslant(m-2)/4$, we see that $2n\pi/(m+2)<\theta=(2n+1)\pi/(m+1)<(2n+2)\pi/(m+2)$. □

Proof of Theorem 11 (Case II: $\ell=2n$ *is even, with* $1\leqslant n\leqslant(m-2)/4$): Suppose that all the eigenvalues τ_j of H_{2n} lie in the sector $|\arg\tau|\leqslant 2\pi/(m+2)$. Equivalently, zeros of the entire function $\tau\mapsto D_{-n-1,n}(\omega\tau)$ lie in the sector $|\arg\tau|\leqslant 2\pi/(m+2)$. We will show that every eigenvalue λ of H_{2n+1} is real and positive.

First, we examine $D_{-n-1,n}(\tau)$. From Lemma 8 (iii), the zeros of $\tau\mapsto D_{-n-1,n}(\omega\tau)$ are the eigenvalues τ_j of H_{2n}, which lie in the sector $|\arg\tau|\leqslant 2\pi/(m+2)$, by hypothesis. So

$$D_{-n-1,n}(\omega\tau)=B_1\prod_{j=1}^\infty\left(1-\frac{\tau}{\tau_j}\right)\quad\text{for some } B_1\in\mathbb{C}-\{0\},$$

where $\mathrm{Im}(\omega\tau_j)\geqslant 0$ for all $j\in\mathbb{N}$. Hence,

$$D_{-n-1,n}(\lambda)=B_1\prod_{j=1}^\infty\left(1-\frac{\omega^{-1}\lambda}{\tau_j}\right).$$

Thus, since $\mathrm{Im}(\omega\tau_j)\geqslant 0$,

$$\left|\frac{D_{-n-1,n}(\lambda)}{D_{-n-1,n}(\bar\lambda)}\right|=\prod_{j=1}^\infty\left|\frac{1-\dfrac{\omega^{-1}\lambda}{\tau_j}}{1-\dfrac{\omega^{-1}\bar\lambda}{\tau_j}}\right|=\prod_{j=1}^\infty\left|\frac{\omega\tau_j-\lambda}{\omega\tau_j-\bar\lambda}\right|\leqslant 1\quad\text{when Im}\,\lambda\geqslant 0.\tag{37}$$

Next, we suppose that $u(z)$ is an eigenfunction of H_{2n+1} associate with the eigenvalue λ. That is, $u(z)$ solves

$$-u''(z)+(-1)^{2n+1}(iz)^m u(z)=\lambda u(z),$$

and decays to zero as z tends to infinity along the two rays $\arg z=-\pi/2\pm(2n+2)\pi/(m+2)$. Set $v(z)=u(-iz)$. Then $v(z)$ solves

$$-v''(z)+(z^m+\lambda)v(z)=0, \tag{38}$$

and decays to zero as z tends to infinity along the two rays $\arg z=\pm(2n+2)\pi/(m+2)$, the center rays of S_{n+1} and S_{-n-1}.

We take a close look at

$$f_{-n-1}(z,\lambda)=C_{-n-1,n}(\lambda)f_n(z,\lambda)+D_{-n-1,n}(\lambda)f_{n+1}(z,\lambda). \tag{39}$$

Since $C_{-n-1,n}(\lambda)=0$ by Lemma 7, $D_{-n-1,n}(\lambda)\neq 0$. So

$$f(\omega^{n+1}z,\omega^{-2n-2}\lambda)=D_{-n-1,n}(\lambda)f(\omega^{-n-1}z,\omega^{2n+2}\lambda). \tag{40}$$

We will show that $|D_{-n-1,n}(\lambda)|\leqslant 1$ when λ is an eigenvalue of H_{2n+1} with $\operatorname{Im}\lambda\geqslant 0$.

Suppose $f(0,\omega^{-2n-2}\lambda)\neq 0$. Since λ is an eigenvalue, so is $\bar{\lambda}$. We replace λ by $\bar{\lambda}$ in (40), and then evaluate the resulting equation at $z=0$ to get

$$f(0,\omega^{-2n-2}\bar{\lambda})=D_{-n-1,n}(\bar{\lambda})f(0,\omega^{2n+2}\bar{\lambda}).$$

Then we take the complex conjugate of this and apply (26) so that we have

$$f(0,\omega^{2n+2}\lambda)=\overline{D_{-n-1,n}(\bar{\lambda})}f(0,\omega^{-2n-2}\lambda).$$

Combining this with (40) at $z=0$ yields

$$\overline{D_{-n-1,n}(\bar{\lambda})}D_{-n-1,n}(\lambda)=1, \tag{41}$$

where we used $f(0,\omega^{-2n-2}\lambda)\neq 0$.

Similarly, when $f'(0,\omega^{-2n-2}\lambda)\neq 0$, we get (41) again.

Eq. (41) along with the inequality in (37) implies $|D_{-n-1,n}(\lambda)|\leqslant 1$ when λ is an eigenvalue of H_{2n+1} with $\operatorname{Im}\lambda\geqslant 0$. So from (40) at $z=0$ we have

$$1\geqslant|D_{-n-1,n}(\lambda)|=\prod_{j=1}^{\infty}\left|\frac{1-\dfrac{\omega^{-2n-2}\lambda}{E_j}}{1-\dfrac{\omega^{2n+2}\lambda}{E_j}}\right|=\prod_{j=1}^{\infty}\left|\frac{\omega^{2n+2}E_j-\lambda}{\omega^{2n+2}E_j-\bar{\lambda}}\right|\geqslant 1\quad\text{when }\operatorname{Im}\lambda\geqslant 0, \tag{42}$$

where the last inequality holds since $\operatorname{Im}(\omega^{2n+2}E_j)\leqslant 0$ if $0\leqslant\arg(\omega^{2n+2})\leqslant\pi$ (this is where we use $1\leqslant n\leqslant(m-2)/4$). Then like in the proof for the case ℓ odd, we have $|D_{-n-1,n}(\lambda)|=1$, which is also obtained when $f(0,\omega^{-2n-2}\lambda)=0$ (and hence $f'(0,\omega^{-2n-2}\lambda)\neq 0$.) Therefore, we conclude $\lambda=\bar{\lambda}$, and so λ is real, like in the proof of the case ℓ odd.

We still need to show positivity of the eigenvalues λ. Recall that $\lambda\in\mathbb{R}$ and that $v(z)=u(-iz)$ solves (38). Let $g(r)=v(re^{i\theta})$. Then,

$$e^{-2i\theta}g''(r)+e^{mi\theta}r^m g(r)=\lambda g(r).$$

We multiply this by $\overline{g(r)}$ and integrate over $r\in[0,\infty)$ to get

$$e^{-2i\theta}\int_0^{\infty}g''(r)\overline{g(r)}\mathrm{d}r+e^{mi\theta}\int_0^{\infty}r^m|g(r)|^2\mathrm{d}r=\lambda\int_0^{\infty}|g(r)|^2\mathrm{d}r.$$

Since $v(z)$ decays exponentially to zero as z tends to infinity in $S_{n+1}\cup S_{-n-1}$, we have integrability for $(2n+1)\pi/(m+2)<\theta<(2n+3)\pi/(m+2)$.

Note that since $\lambda\in\mathbb{R}$, Eq. (36) is valid for this case as well. We integrate the first term by parts and multiply the resulting equation by $e^{i\theta}$ to get

$$-e^{-i\theta}g'(0)\overline{g(0)}-e^{-i\theta}\int_0^\infty |g'(r)|^2\mathrm{d}r+e^{(m+1)i\theta}\int_0^\infty r^m|g(r)|^2\mathrm{d}r=\lambda e^{i\theta}\int_0^\infty |g(r)|^2\mathrm{d}r.$$

Then we use $e^{-i\theta}g'(0)=v(0)$ and take the imaginary parts with using (36) to get, for all $(2n+1)\pi/(m+2)<\theta<(2n+3)\pi/(m+2)$,

$$\sin\theta\int_0^\infty |g'(r)|^2\mathrm{d}r+\sin[(m+1)\theta]\int_0^\infty r^m|g(r)|^2\mathrm{d}r=\lambda\sin\theta\int_0^\infty |g(r)|^2\mathrm{d}r.$$

Evaluating this at $\theta=(2n+1)\pi/(m+1)$ proves $\lambda>0$. Note that since $1\leqslant n\leqslant(m-2)/4$, we see that $(2n+1)\pi/(m+2)<\theta=(2n+1)\pi/(m+1)<(2n+3)\pi/(m+2)$. □

IV. PROOF OF THEOREM 2

In proving Theorem 2, our induction basis is provided by the following lemma that is due to Dorey *et al.*[3] (also, see Shin[4]).

Lemma 12: *The eigenvalues* λ *of* H_1 *are all real and positive.*

Here we will give an outline of the proof.

Proof: Let λ be an eigenvalue of H_1 with the corresponding eigenfunction $u(z)$. Set $v(z)=u(-iz)$. Then $v(z)$ decays in $S_{-1}\cup S_1$ and solves

$$-v(z)+(z^m+\lambda)v(z)=0.$$

Since

$$f_{-1}(z,\lambda)=C_{-1,0}(\lambda)f_0(z,\lambda)+D_{-1,0}(\lambda)f_1(z,\lambda), \tag{43}$$

$C_{-1,0}(\lambda)=0$. Moreover, we know that from (15) and (16), and Lemma 5,

$$|D_{-1,0}(\lambda)|=\left|\frac{W_{-1,0}(\lambda)}{W_{0,1}(\lambda)}\right|=1.$$

Next, we use infinite product forms of either (43) when $f_{-1}(0,\lambda)\neq 0$, or its differentiated form when $f'_{-1}(0,\lambda)\neq 0$ at $z=0$. Then like in the proof of Theorem 11, one can show that $\lambda>0$. Note that the hypothesis in Theorem 11 is needed for showing $|D_{-1,0}(\lambda)|=1$ only. □

Now we are ready to prove Theorem 2.

Proof of Theorem 2. For integers $1\leqslant\ell\leqslant m/2$, the theorem easily follows from induction on ℓ along with Theorem 11 and Lemma 12.

For $m/2<\ell\leqslant m-1$, suppose that λ is an eigenvalue of H_ℓ with the corresponding eigenfunction $u_1(z)$. Let $u(z):=u_1(-z)$. Then $u(z)$ solves $-u''(z)+(-1)^\ell(-iz)^m u(z)=\lambda u(z)$, that is, $u(z)$ solves

$$-u''(z)+(-1)^{m-\ell}(iz)^m u(z)=\lambda u(z).$$

Next, we examine the boundary condition. It is clear that since $u_1(z)$ decays along the two rays $\arg z=-\pi/2\pm[\ell+1/(m+2)]\pi$, we see that $u(z)$ decays along the two rays

$$\arg z=-\pi-\frac{\pi}{2}+\frac{\ell+1}{m+2}\pi=-\frac{\pi}{2}-\frac{(m-\ell)+1}{m+2}\pi,$$

$$\arg z=\pi-\frac{\pi}{2}-\frac{\ell+1}{m+2}\pi=-\frac{\pi}{2}+\frac{(m-\ell)+1}{m+2}\pi.$$

This is the boundary condition (2) with $m-\ell$ in the place of ℓ. Hence, $u(z)$ is an eigenfunction of $H_{m-\ell}$ associated with the eigenvalue λ. Since $m/2<\ell\leqslant m-1$, we see that $1\leqslant m-\ell<m/2$. So $\lambda>0$. This completes the proof. □

Remark: Our method in this paper closely follows the $\ell=1$ method of Dorey *et al.*[3] and Shin.[4]

One big difference is that if $\ell=1$ then $|D_{-1,0}(\sigma)|=1$ for all $\sigma\in\mathbb{C}$, whereas for $1<\ell<m-1$, the corresponding functions $\sigma\mapsto D_{-n,n}(\omega^{-1}\sigma)$ in (29) and $\sigma\mapsto D_{-n-1,n}(\sigma)$ in (39) are entire functions of order $\frac{1}{2}+1/m$. However, when λ is an eigenvalue of $H_{\ell+1}$, under some hypothesis on the eigenvalues σ of H_ℓ we are able to show that $|D_{-n,n}(\omega^{-1}\lambda)|=1$ for $\ell=2n-1$ odd, and $|D_{-n-1,n}(\lambda)|=1$ for $\ell=2n$ even. This is the new and main idea in proving the induction step, Theorem 11.

V. CONCLUSIONS

In this paper, we proved that for each integer $1\leqslant\ell\leqslant m-1$, the eigenvalues $\lambda\in\mathbb{C}$ of

$$-u''(z)+(-1)^\ell(iz)^m u(z)=\lambda u(z),$$

under the boundary condition that $u(z)\to 0$ exponentially, as $z\to\infty$ along the two rays $\arg z=-\pi/2\pm(\ell+1)/(m+2)$, are all real and positive. And we studied other boundary conditions. Due to asymptotic behavior of the solution $u(z)$ as $z\to\infty$, if the Stokes sectors that contain the two ray where we impose the boundary condition are symmetric with respect to the imaginary axis, then the eigenvalues are all real and positive, except the case when the two Stokes sectors contain the imaginary axis. For all other rapid decaying boundary conditions, either there is no eigenvalue or the eigenvalues are not real.

It will be interesting to consider the eigenvalue problem with more general polynomial potentials $(-1)^\ell(iz)^m+P(iz)$ where $P(z)$ is a real polynomial with degree less than m, under the boundary condition (2).

It is known that some $\mathcal{PT}$-symmetric oscillators with some cubic and quartic polynomial potentials have nonreal eigenvalues.[13,14,16,17] One would like to classify when $\mathcal{PT}$-symmetric oscillators with polynomial potentials have nonreal eigenvalues.

(Received 10 September 2004; accepted 26 May 2005; published online 25 July 2005)

The SU(2) Yang-Mills-Higgs theory supports the existence of monopoles, antimonopoles, and vortex rings. In this paper, we would like to present new exact static antimonopole-monopole-antimonopole (A-M-A) configurations. The net magnetic charge of these configurations is always −1, while the net magnetic charge at the origin is always +1 for all positive integer values of the solution's parameter m. However, when m increases beyond 1, vortex rings appear coexisting with these AMA configurations. The number of vortex rings increases proportionally with the value of m. They are located in space where the Higgs field vanishes along rings. We also show that a single-point singularity in the Higgs field does not necessarily correspond to a structureless 1-monopole at the origin but to a zero-size monopole-antimonopole-monopole (MAM) structure when the solution's parameter m is odd. This monopole is the Wu-Yang-type monopole and it possesses the Dirac string potential in the Abelian gauge. These exact solutions are a different kind of Bogomol'nyi-Prasad-Sommerfield (BPS) solutions as they satisfy the first-order Bogomol'nyi equation but possess infinite energy due to a point singularity at the origin of the coordinate axes. They are all axially symmetrical about the z-axis. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1996832]

I. INTRODUCTION

The SU(2) Yang-Mills-Higgs (YMH) field theory, with the Higgs field in the adjoint representation, possesses magnetic monopole, multimonopole, antimonopoles, and vortex rings solutions.[1–8] The only spherically symmetric monopole solution is the unit magnetic charge monopole. The 't Hooft–Polyakov monopole solution with nonzero Higgs mass and Higgs self-interaction is numerically and spherically symmetrical.[1,2] Multimonopole solutions possess at most axial symmetry.[3]

The model with nonvanishing Higgs vacuum expectation value but vanishing Higgs potential possesses exact monopole and multimonopole solutions which can be obtained by solving the first-order Bogomol'nyi equations.[9] These solutions satisfying the Bogomol'nyi-Prasad-Sommerfield (BPS) limit possess minimal energies. Exact monopole and multimonopoles solutions exist in the BPS limit,[2,3] while outside the BPS limit, when the Higgs field potential is nonvanishing, only numerical solutions are known. Asymmetric multimonopole solutions with no rotational symmetry are numerical solutions even in the BPS limit.[4]

At present, the different exact configurations of monopoles found are the BPS multimonopole solutions of magnetic charges M greater than unity with all the magnetic charges superimposed into a single point in space.[3] These superimposed multimonopole solutions possess axial and mirror symmetries. Following these works, finitely separated 1-monopoles were also constructed.[4,5]

Numerical axially symmetric non-Bogomol'nyi monopole-antimonopole chain solutions were

[a]Electronic mail: rosyteh@usm.my

also found to exist both in the limit of a vanishing Higgs potential as well as in the presence of a finite Higgs potential. Recently, numerical BPS axially symmetric vortex rings solutions have also been reported.[6]

We have reported on the existence of a different type of BPS static monopole-antimonopole solution in Ref. 7. This solution, which is exact and axially symmetric, represents two separate antimonopoles located at equal distances along the z-axis from a 1-monopole which is located at the origin. We have also shown that the extended ansatz of Ref. 7 possesses more multimonopole-antimonopole configurations, together with their anticonfigurations.[8] These configurations possess either radial, axial, or mirror symmetries about the z-axis, and they represent different combinations of monopoles, multimonopole, and antimonopoles.

In general, configurations of the YMH field theory with a unit magnetic charge are spherically symmetric,[1,2] while multimonopole configurations with magnetic charges greater than unity possess at most axial symmetry.[3] However, we have emphasized in a recent work[10] that unit magnetic charge configurations are not necessarily spherically symmetric. By employing the ansatz of Ref. 7, we have found an exact unit magnetic charge solution that does not even possess axial symmetry but only mirror symmetry about a vertical plane through the z-axis. However, the converse is true, and it has been shown that multimonopole solutions cannot possess spherical symmetry.[11] We would also like to mention that, within the ansatz of Ref. 7, half-monopole solutions have also been reported.[10]

In this paper we would like to present new static axially symmetric antimonopole-monopole-antimonopole (A-M-A) configurations of the SU(2) YMH theory with the Higgs field in the adjoint representation. Here, the Higgs field vanishes either at points corresponding to antimonopoles or at rings corresponding to vortex loops. The net magnetic charge of these configurations is always -1, while the net magnetic charge at the origin, $r=0$, is always $+1$ for all positive integer values of the solution's parameter m. However, when m increases beyond 1, vortex rings appear coexisting with these A-M-A configurations. The number of vortex rings in the configuration is equal to $(m-1)$, where $m \geqslant 1$. They are located horizontally in space where the Higgs field is zero along rings. Hence, this family of solutions all lies in the topologically nontrivial sector with topogical charge -1.

The two antimonopoles of the solutions are located at the two zeros of the Higgs field along the z-axis, while the Wu-Yang-type 1-monopole is located at a point singularity of the Higgs field at the origin. We also show that this single-point singularity in the Higgs field need not correspond to a structureless 1-monopole at the origin but to a zero-size monopole-antimonopole-monopole (MAM) structure when m is odd. These exact solutions are a different kind of BPS solution as they satisfy the first-order Bogomol'nyi equation, but possess infinite energy due to a point singularity at the origin of the coordinate axes.

We briefly review the SU(2) Yang-Mills-Higgs field theory and discuss the boundary conditions of these solutions in Sec. II. We discuss the magnetic ansatz and its formulation in Sec. III and present the solutions in Sec. IV. We end with some comments in Sec. V.

II. THE SU(2) YANG-MILLS-HIGGS THEORY

The SU(2) group admits the triplet Yang-Mills gauge fields potential A_μ^a which when coupled to a scalar Higgs triplets field Φ^a in $3+1$ dimensions gives the SU(2) YMH theory.[12] The index a is the SU(2) internal space index and, for a given a, Φ^a is a scalar whereas A_μ^a is a vector under Lorentz transformation. The SU(2) YMH Lagrangian is given by

$$\mathcal{L} = -\frac{1}{4}F_{\mu\nu}^a F^{a\mu\nu} + \frac{1}{2}D^\mu \Phi^a D_\mu \Phi^a - \frac{1}{4}\lambda\left(\Phi^a\Phi^a - \frac{\mu^2}{\lambda}\right)^2, \tag{1}$$

where the Higgs field mass, μ, and the strength of the Higgs potential, λ, are constants. The vacuum expectation value of the Higgs field is then $\mu/\sqrt{\lambda}$. The Lagrangian (1) is gauge invariant under the set of independent local SU(2) transformations at each space–time point. The covariant derivative of the Higgs field and the gauge field strength tensor are given, respectively, by

$$D_\mu \Phi^a = \partial_\mu \Phi^a + \epsilon^{abc} A_\mu^b \Phi^c, \tag{2}$$

$$F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + \epsilon^{abc} A_\mu^b A_\nu^c. \tag{3}$$

Since the gauge field coupling constant g can be scaled away, we can set g to 1 without any loss of generality. The metric used is $g_{\mu\nu}=(-+++)$. The SU(2) internal group indices a, b, c run from 1 to 3 and the spatial indices are μ, ν, $\alpha=0$, 1, 2, and 3 in Minkowski space.

The equations of motion that follow from the Lagrangian (1) are

$$D^\mu F_{\mu\nu}^a = \partial^\mu F_{\mu\nu}^a + \epsilon^{abc} A^{b\mu} F_{\mu\nu}^c = \epsilon^{abc} \Phi^b D_\nu \Phi^c,$$

$$D^\mu D_\mu \Phi^a = -\lambda \Phi^a \left(\Phi^b \Phi^b - \frac{\mu^2}{\lambda} \right). \tag{4}$$

The tensor to be identified with the Abelian electromagnetic field, as proposed by 't Hooft,[1,13] is

$$F_{\mu\nu} = \hat{\Phi}^a F_{\mu\nu}^a - \epsilon^{abc} \hat{\Phi}^a D_\mu \hat{\Phi}^b D_\nu \hat{\Phi}^c = \partial_\mu A_\nu - \partial_\nu A_\mu - \epsilon^{abc} \hat{\Phi}^a \partial_\mu \hat{\Phi}^b \partial_\nu \hat{\Phi}^c, \tag{5}$$

where $A_\mu = \hat{\Phi}^a A_\mu^a$, $\hat{\Phi}^a = \Phi^a / |\Phi|$, $|\Phi| = \sqrt{\Phi^a \Phi^a}$. Hence, the Abelian electric field is $E_i = F_{0i}$, and the Abelian magnetic field is $B_i = -\frac{1}{2} \epsilon_{ijk} F_{jk}$, where the indices i, j, $k = 1, 2, 3$. The topological magnetic current, which is also the topological current density of the system, is[13]

$$k_\mu = \frac{1}{8\pi} \epsilon_{\mu\nu\rho\sigma} \epsilon_{abc} \partial^\nu \hat{\Phi}^a \partial^\rho \hat{\Phi}^b \partial^\sigma \hat{\Phi}^c. \tag{6}$$

Therefore, the corresponding conserved topological magnetic charge is

$$M = \int d^3x k_0 = \frac{1}{8\pi} \int \epsilon_{ijk} \epsilon^{abc} \partial_i (\hat{\Phi}^a \partial_j \hat{\Phi}^b \partial_k \hat{\Phi}^c) d^3x = \frac{1}{8\pi} \oint d^2\sigma_i (\epsilon_{ijk} \epsilon^{abc} \hat{\Phi}^a \partial_j \hat{\Phi}^b \partial_k \hat{\Phi}^c) = \frac{1}{4\pi} \oint d^2\sigma_i B_i. \tag{7}$$

Our work is restricted to the static case where $A_0^a = 0$ with massless Higgs field and vanishing self-interaction. The magnitude of the Higgs field vanishes as $1/r$ at large r. However, this does not affect the Abelian magnetic field of the solutions, as this magnetic field depends only on the unit vector of the Higgs field. It is in this limit that the solutions are solved using both the second-order Euler-Lagrange equations and the Bogomol'nyi equations, $B_i^a \pm D_i \Phi^a = 0$. The $\pm$ sign corresponds to monopoles and antimonopoles, respectively, for the usual BPS solutions.[13] In our case, the A-M-A configuration is solved with the $+$ sign, and its anticonfiguration, that is, the M-A-M configuration, is solved with the $-$ sign.[8]

III. THE ANSATZ AND ITS FORMULATION

The static gauge fields and Higgs field which will lead to the axially symmetric vortex rings solutions are given, respectively, by[7]

$$A_\mu^a = \frac{1}{r} \psi(r) (\hat{\theta}^a \hat{\phi}_\mu - \hat{\phi}^a \hat{\theta}_\mu) + \frac{1}{r} R(\theta) (\hat{\phi}^a \hat{r}_\mu - \hat{r}^a \hat{\phi}_\mu),$$

$$\Phi^a = \Phi_1 \hat{r}^a + \Phi_2 \hat{\theta}^a, \tag{8}$$

where $\Phi_1 = (1/r)\psi(r)$, $\Phi_2 = (1/r)R(\theta)$. The spherical coordinate orthonormal unit vectors, $\hat{r}^a$, $\hat{\theta}^a$, and $\hat{\phi}^a$, are defined by

$$\hat{r}^a = \sin\theta \cos\phi \delta_1^a + \sin\theta \sin\phi \delta_2^a + \cos\theta \delta_3^a,$$

$$\hat{\theta}^a = \cos\theta\cos\phi\delta_1^a + \cos\theta\sin\phi\delta_2^a - \sin\theta\delta_3^a,$$

$$\hat{\phi}^a = -\sin\phi\delta_1^a + \cos\phi\delta_2^a, \tag{9}$$

where $r=\sqrt{x^i x_i}$, $\theta=\cos^{-1}(x_3/r)$, and $\phi=\tan^{-1}(x_2/x_1)$. The gauge field strength tensor and the covariant derivative of the Higgs field are given, respectively, by

$$\begin{aligned} F_{\mu\nu}^a = {} & \frac{1}{r^2}\hat{r}^a\{\dot{R} + R\cot\theta + 2\psi - \psi^2\}(\hat{\phi}_\mu\hat{\theta}_\nu - \hat{\phi}_\nu\hat{\theta}_\mu) + \frac{1}{r^2}\hat{\theta}^a\{R(1-\psi)\}(\hat{\phi}_\mu\hat{\theta}_\nu - \hat{\phi}_\nu\hat{\theta}_\mu) \\ & + \frac{1}{r^2}\{\hat{r}^a R(1-\psi) + \hat{\theta}^a(r\psi' + R\cot\theta - R^2)\}(\hat{r}_\mu\hat{\phi}_\nu - \hat{r}_\nu\hat{\phi}_\mu) \\ & + \frac{1}{r^2}\hat{\phi}^a\{-(r\psi' + \dot{R})\}(\hat{r}_\mu\hat{\theta}_\nu - \hat{r}_\nu\hat{\theta}_\mu), \end{aligned} \tag{10}$$

$$\begin{aligned} D_\mu\Phi^a = {} & \frac{1}{r^2}\{\hat{r}^a(r\psi' - \psi - R^2) - \hat{\theta}^a R(1-\psi)\}\hat{r}_\mu + \frac{1}{r^2}\{-\hat{r}^a R(1-\psi) + \hat{\theta}^a(\dot{R} + \psi - \psi^2)\}\hat{\theta}_\mu \\ & + \frac{1}{r^2}\{\hat{\phi}^a(\psi - \psi^2 + R\cot\theta - R^2)\}\hat{\phi}_\mu. \end{aligned} \tag{11}$$

Here, prime means $\partial/\partial r$ and dot means $\partial/\partial\theta$. The gauge-fixing condition that we used here is the radiation or Coulomb gauge, $\partial^i A_i^a = 0$, $A_0^a = 0$.

The ansatz (8) is substituted into the equations of motion (4) as well as the Bogomol'nyi equations with the positive sign, and the resulting equations of motion are just two first-order differential equations

$$r\psi' + \psi - \psi^2 = -p, \tag{12}$$

$$\dot{R} + R\cot\theta - R^2 = p, \tag{13}$$

where p is an arbitary constant. Equation (12) is exactly solvable for all real values of p and the integration constant can be scaled away by letting $r \to r/c$, where c is the arbitrary integration constant. Hence, without any loss in generality, c is set to unity. In order to obtain solutions of ψ with $(2m+1)$ powers of r, we can write $p=m(m+1)$, where m is real. By doing so, the solutions of the Riccati equation (13) can be exactly solved in terms of the Legendre functions of the first and second kind. For the solutions of Eq. (13) to be regular along the z-axis, we require $R(\theta)$ to vanish when $\theta=0$ and $\theta=\pi$. To achieve these boundary conditions, the integration constant of Eq. (13) is set to zero and m is restricted to take integer values. The solutions for ψ and R are then given, respectively, by

$$\psi(r) = \frac{(m+1) - mr^{2m+1}}{1 + r^{2m+1}},$$

$$R(\theta) = (m+1)\left\{\cot\theta - \frac{P_{m+1}(\cos\theta)}{P_m(\cos\theta)}\csc\theta\right\}, \tag{14}$$

where P_m is the Legendre polynomial of degree m, and $m=0,1,2,3,\ldots$. Hence, the boundary conditions of the solutions, Eq. (14), are $\psi(0)=m+1$, $\psi(\infty)=-m$, $R(0)=R(\pi)=0$.

In the BPS limit, the energy can be written in the form

$$E = \mp \int \partial_i (B_i^a \Phi^a) d^3x + \int \frac{1}{2}(B_i^a \pm D_i \Phi^a)^2 d^3x = \mp \int \partial_i (B_i^a \Phi^a) d^3x = 4\pi M \frac{\mu}{\sqrt{\lambda}}, \tag{15}$$

where M is the "topological charge" when the vacuum expectation value of the Higgs field, $\mu/\sqrt{\lambda}$, is nonzero coupled with some nontrivial topological structure of the fields at large r.

The energy density $\partial_i(B_i^a \Phi^a)$ of the non-Abelian system is finite everywhere and vanishes as $1/r^2$ at large r except at the origin $r=0$ due to the presence of a point singularity there and along singular planes where $P_m(\cos\theta)$ vanishes. The two antimonopoles which are regular antimonopoles and the vortex rings are located at points and rings where the Higgs field, $r\Phi^a$, vanishes, respectively. The monopole at the origin is of a different nature and is located where the Higgs field is singular. In the Abelian gauge, this monopole carries a Dirac string singularity.

The topological charge is also related to another gauge invariant quantity of the system as given by Eq. (7)

$$M_\infty = \frac{1}{8\pi} \oint d^2\sigma_i \, (\epsilon_{ijk} \epsilon^{abc} \hat{\Phi}^a \partial_j \hat{\Phi}^b \partial_k \hat{\Phi}^c)|_{r\to\infty}. \tag{16}$$

The magnetic charges enclosed by the sphere at infinity can be associated with the zeros of the Higgs field, $r\Phi^a$, and at points where $\hat{\Phi}^a$ becomes indeterminate. The positions of the two antimonopole do correspond to the two point zeros of the Higgs field in the A-M-A solutions. However, the Wu-Yang-type 1-monopole is not located at the zeros of the Higgs field but at the origin of the coordinate axes where the Higgs field is singular.

From the ansatz (8), $A_\mu = \hat{\Phi}^a A_\mu^a = 0$. Hence, from Eq. (5), the Abelian electric field is zero and the Abelian magnetic field is independent of the gauge fields A_μ^a. To calculate for the 't Hooft Abelian magnetic field B_i, we rewrite the Higgs field of Eq. (8) from the spherical to the Cartesian coordinate system[6–8]

$$\Phi^a = \Phi_1 \hat{r}^a + \Phi_2 \hat{\theta}^a + \Phi_3 \hat{\phi}^a = \tilde{\Phi}_1 \delta^{a1} + \tilde{\Phi}_2 \delta^{a2} + \tilde{\Phi}_3 \delta^{a3}, \tag{17}$$

where

$$\tilde{\Phi}_1 = \sin\theta\cos\phi\Phi_1 + \cos\theta\cos\phi\Phi_2 - \sin\phi\Phi_3 = |\Phi|\cos\alpha\sin\beta,$$

$$\tilde{\Phi}_2 = \sin\theta\sin\phi\Phi_1 + \cos\theta\sin\phi\Phi_2 + \cos\phi\Phi_3 = |\Phi|\cos\alpha\cos\beta,$$

$$\tilde{\Phi}_3 = \cos\theta\Phi_1 - \sin\theta\Phi_2 = |\Phi|\sin\alpha. \tag{18}$$

The Higgs unit vector is then simplified to

$$\hat{\Phi}^a = \cos\alpha\sin\beta\delta^{a1} + \cos\alpha\cos\beta\delta^{a2} + \sin\alpha\delta^{a3}, \tag{19}$$

where

$$\sin\alpha = \frac{\psi\cos\theta - R\sin\theta}{\sqrt{\psi^2 + R^2}}, \quad \beta = \frac{\pi}{2} - \phi,$$

and the Abelian magnetic field is found to reduce to only the $\hat{r}_i$ and $\hat{\theta}_i$ components

$$B_i = \frac{1}{r^2\sin\theta}\left\{\frac{\partial\sin\alpha}{\partial\theta}\frac{\partial\beta}{\partial\phi} - \frac{\partial\sin\alpha}{\partial\phi}\frac{\partial\beta}{\partial\theta}\right\}\hat{r}_i + \frac{1}{r\sin\theta}\left\{\frac{\partial\sin\alpha}{\partial\phi}\frac{\partial\beta}{\partial r} - \frac{\partial\sin\alpha}{\partial r}\frac{\partial\beta}{\partial\phi}\right\}\hat{\theta}_i + \frac{1}{r}\left\{\frac{\partial\sin\alpha}{\partial r}\frac{\partial\beta}{\partial\theta} - \frac{\partial\sin\alpha}{\partial\theta}\frac{\partial\beta}{\partial r}\right\}\hat{\phi}_i,$$

$$=-\frac{1}{r^2\sin\theta}\left\{\frac{\partial\sin\alpha}{\partial\theta}\right\}\hat{r}_i+\frac{1}{r\sin\theta}\left\{\frac{\partial\sin\alpha}{\partial r}\right\}\hat{\theta}_i. \tag{20}$$

Since $\sin\alpha$ is a nonsingular function except at the points where the Higgs field, $r\Phi^a$, vanishes, the 't Hooft magnetic field is regular everywhere except at the locations of the A-M-A and the vortex rings.

By noticing that the magnetic field, Eq. (20), can also be written as

$$B_i=\epsilon_{ijk}\partial^j(\sin\alpha)\partial^k\beta,$$

$$=\epsilon_{ijk}\partial^j(\sin\alpha\partial^k\beta), \tag{21}$$

we found that a suitable Maxwell four-vector gauge potential for this 't Hooft magnetic field is

$$\mathcal{A}_0=0,$$

$$\mathcal{A}_i=(\sin\alpha-1)\partial_i\beta=-\frac{(\sin\alpha-1)}{r\sin\theta}\hat{\phi}_i. \tag{22}$$

This gauge potential also satisfies the Coulomb gauge condition, $\partial^i\mathcal{A}_i=0$. The function $\sin\alpha$ is a bounded function of r and θ, and it is not smooth and discontinuous only when the profile function $R(\theta)$ is singular. When $m=0$, the gauge potential Eq. (22) is just the usual Dirac string potential and it is singular along the negative z-axis. However, when $m>0$, the gauge potential $\mathcal{A}_i$ possesses a broken Dirac string singularity. This Dirac string singularity extends from the origin to $z=-\sqrt[2m+1]{(m+1)/m}$ along the negative z-axis and from $z=\sqrt[2m+1]{(m+1)/m}$ to infinity along the positive z-axis. The gauge potential, $\mathcal{A}_i$, is only discontinuous at values of θ when $R(\theta)$ is singular.

From Eq. (21), it is obvious that the magnetic field is always perpendicular to the gradient of $\sin\alpha$. Hence, the magnetic field lines lie on the line $\sin\alpha=k$, $-1<k<1$, and $\phi=$constant. By plotting $\sin\alpha=k$ on a vertical plane through the origin, we manage to draw the magnetic field lines for the configurations when $m=1$, Fig. 2; $m=2$, Fig. 6; and $m=3$, Fig. 8.

Defining the Abelian field magnetic flux as

$$\Omega=4\pi M=\oint d^2\sigma_i B_i=\int B_i(r^2\sin\theta\,d\theta)\hat{r}_i d\phi, \tag{23}$$

the magnetic charge enclosed by the sphere at infinity, M_∞, is calculated to be

$$M_\infty=-\left.\frac{1}{2}\sin\alpha\right|_{0,r\to\infty}^{\pi}=-1,\quad \text{when } m=1,2,3,\ldots;M_\infty=1,\quad \text{when } m=0. \tag{24}$$

From Eq. (24), we can conclude that the total magnetic charge M of these axially symmetric solutions does not depend on the degree of the Legendre polynomial when $m>0$. Hence, the net magnetic charge of the system when $m>0$ is always -1. By letting M_0 be the net magnetic charge when the radius of the enclosing sphere tends to zero at the origin, we get

$$M_0=-\left.\frac{1}{2}\sin\alpha\right|_{0,r\to0}^{\pi}=1,\quad m=0,1,2,3,\ldots. \tag{25}$$

Similarly, the net magnetic charge, M_0, at the point singularity of the solution is independent of the value of m. In fact, it is true that for positive nonzero m, when $r<\sqrt[2m+1]{(m+1)/m}$, the topological magnetic charge is $+1$, and when $r>\sqrt[2m+1]{(m+1)/m}$, the topological magnetic charge is -1. Hence, there is a 1-monopole located at $r=0$ and two antimonopoles located along the z-axis at $r=\sqrt[2m+1]{(m+1)/m}$.

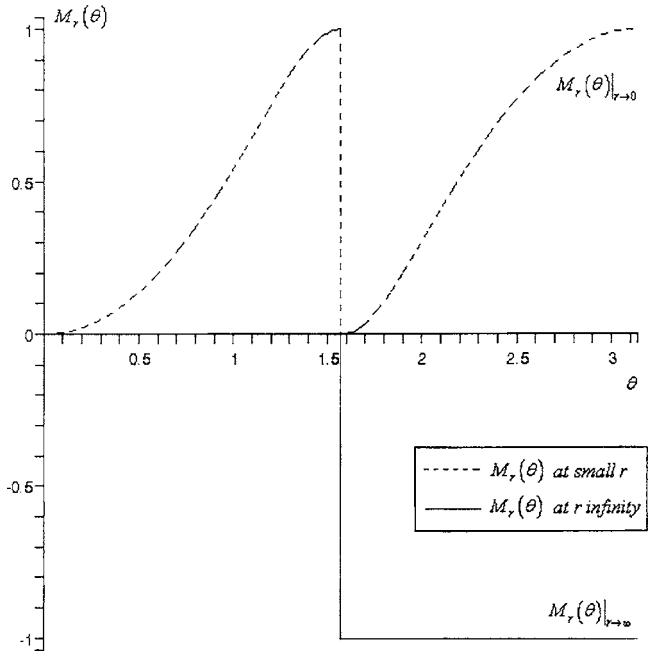

FIG. 1. A plot of $M_r(\theta)$ at small r close to zero and $M_r(\theta)$ at r infinity when $m=1$, versus θ.

We also notice that we can write the net magnetic flux per 4π sterad passing through the spherical surface of a partial enclosing sphere of radius r, sustaining an angle θ at the origin with the positive z-axis as

$$M_r(\theta) = -\left.\frac{(\psi(r)\cos\theta - R(\theta)\sin\theta)}{2\sqrt{\psi^2(r)+R^2(\theta)}}\right|_0^\theta = \frac{1}{2}\left\{\frac{\psi}{|\psi|} - \sin\alpha\right\}. \tag{26}$$

IV. MONOPOLE, ANTIMONOPOLES, AND VORTEX RINGS

The first member of this series of axially symmetric solutions is when $m=0$. As discussed in our previous work,[7] this solution is the Wu-Yang-type monopole located at $r=0$. This radially symmetric monopole with its magnetic field, $B_i=(1/r^2)\hat{r}_i$, has the vector potential $\mathcal{A}_i$ given by Eq. (22). This is just the Dirac string gauge potential, $\mathcal{A}_\mu=(1/r)\tan(\frac{1}{2}\theta)\hat{\phi}_\mu$, which is singular along the negative z-axis.

When $m=1$, the configuration is the second member of the axially symmetric monopole solutions. This configuration is similar to the (A1) solution of Refs. 7 and 8 with gauge potentials and Higgs field given by

$$A^a_\mu = \frac{1}{r}\left\{\frac{2-r^3}{1+r^3}\right\}(\hat{\theta}^a\hat{\phi}_\mu - \hat{\phi}^a\hat{\theta}_\mu) + \frac{1}{r}\tan\theta(\hat{\phi}^a\hat{r}_\mu - \hat{r}^a\hat{\phi}_\mu),$$

$$\Phi^a = \frac{1}{r}\left\{\frac{2-r^3}{1+r^3}\right\}\hat{r}^a + \frac{1}{r}\tan\theta\hat{\theta}^a. \tag{27}$$

It was first thought to consist of a 1-monopole at $r=0$, surrounded by two antimonopoles located at the point zeros of the Higgs field at $z=\pm\sqrt[3]{2}=\pm 1.2599$. However, a closer study of this solution reveals that the 1-monopole actually has a zero-size MAM structure along the z-axis and hence possesses a net unit magnetic charge. The MAM structure can be read from the plots of Eq. (26), $M_r(\theta)$ versus θ for the cases of $r\to 0$ and $r\to\infty$; see Fig. 1. The plot at $r\to\infty$ indicates that there

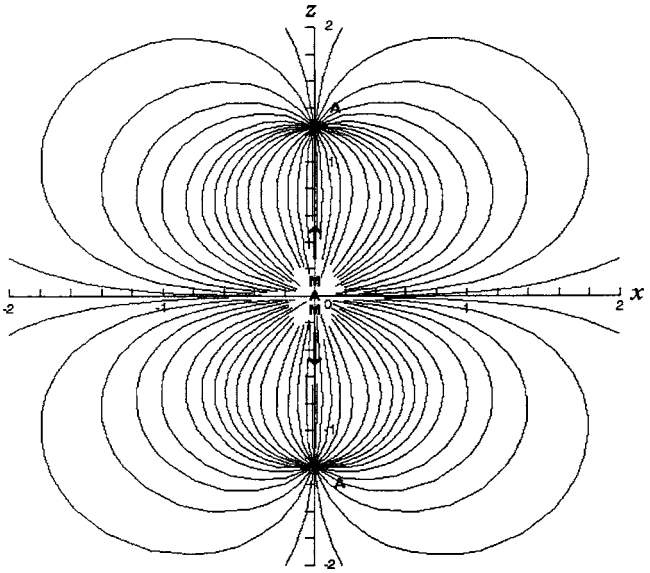

FIG. 2. A plot of the magnetic field lines when $m=1$ along a vertical plane through the z-axis. At large r, all the field lines are concentrated radially inward along the equatorial plane. The two antimonopoles are located along the z-axis at $z=\pm 1.2599$.

is zero flux through the spherical shell at infinity when $\theta \neq \pi/2$ rad. Hence, all the flux at infinity is radially inward along the equatorial plane toward the origin, $r=0$, giving a net topological charge of -1 for the $m=1$ configuration. The radial component of the magnetic field at large r is just a Dirac delta function of θ, given by $B_r=-(2/r^2\sin\theta)\delta[\theta-(\pi/2)]$. Hence, the singularity of the solution $R(\theta)$ at the equatorial plane $\theta=\pi/2$ gives rise to a Dirac delta function singularity in the magnetic field. The antimonopole at the positive z-axis interacts with the nearest MAM 1-monopole at $r=0$ to form a dipole pair; similarly, the antimonopole at the negative z-axis interacts with the other MAM 1-monopole at $r=0$ to form the other dipole pair, leaving behind an antimonopole at the origin; see Fig. 2. At large distances all the magnetic fields above and below the equatorial plane are being screened off by the two dipole pairs along the z-axis, leaving behind a Dirac delta function magnetic field along the plane of singularity, $\theta=\pi/2$.

At finite $r<\sqrt[3]{2}$, the radial component of the magnetic field is a regular function of r and θ but not smooth at $\theta=\pi/2$. In fact, at $\theta=\pi/2$, B_r possesses a negative Dirac delta function singularity, indicating an antimonopole at the center of the composite 1-monopole. Figure 1 shows that at small r, the net flux through the upper $(0<\theta<\pi/2)$ and lower $(\pi/2<\theta<\pi)$ spherical shell is $+4\pi$ each and the flux through the circle at constant r and $\theta=\pi/2$ is -4π, hence indicating a MAM structure for the 1-monopole at the origin.

By plotting the magnetic field lines of this configuration, we can confirm that at large r all the magnetic field lies in the equatorial plane and is pointing radially inward as the net magnetic charge M_∞ is -1. A plot of the magnetic field lines is shown in Fig. 2. Hence, the pole at the center of the composite monopole is an antimonopole surrounded by two 1-monopoles at zero range from each other and yet they do not annihilate each other. The antimonopoles situated at $z=\pm\sqrt[3]{2}$ form dipole pairs with the nearest 1-monopoles of the MAM structure, thus screening off all the magnetic field above and below the equatorial plane at r infinity. There is no vortex ring in this configuration. The Abelian gauge potential, $\mathcal{A}_\mu=-[\sin\alpha-1]/(r\sin\theta)\hat{\phi}_\mu$, possesses a Dirac string singularity along the negative z-axis for $0<r<\sqrt[3]{2}$ and along the positive z-axis for $r>\sqrt[3]{2}$ to infinity.

The vortex ring appears when $m=2$, that is, when the gauge field potentials and Higgs field are, respectively

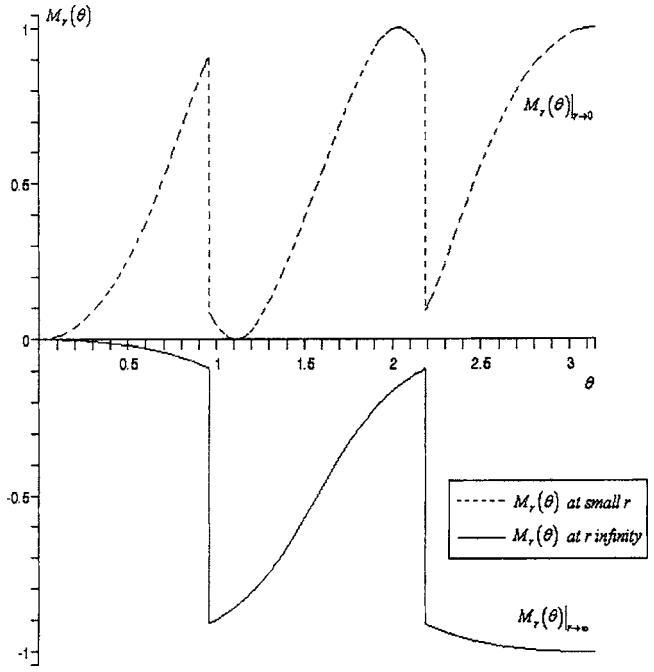

FIG. 3. A plot of $M_r(\theta)$ at r close to zero and $M_r(\theta)$ at r infinity, when $m=2$, versus θ.

$$A^a_\mu = \frac{1}{r}\left\{\frac{3-2r^5}{1+r^5}\right\}(\hat{\theta}^a\hat{\phi}_\mu - \hat{\phi}^a\hat{\theta}_\mu) + \frac{1}{r}\left\{\frac{6\cos\theta\sin\theta}{3\cos^2\theta - 1}\right\}(\hat{\phi}^a\hat{r}_\mu - \hat{r}^a\hat{\phi}_\mu),$$

$$\Phi^a = \frac{1}{r}\left\{\frac{3-2r^5}{1+r^5}\right\}\hat{r}^a + \frac{1}{r}\left\{\frac{6\cos\theta\sin\theta}{3\cos^2\theta - 1}\right\}\hat{\theta}^a. \tag{28}$$

The plots of the magnetic flux, Eq. (26), versus θ, for values of $r\to 0$ and r at infinity, Fig. 3, reveal that the 1-monopole at $r=0$ has an MAMAM structure. However, only the monopole at the center has unit charge. All the other four poles have charge less than unity. Hence, there exist a vortex point both above and below the 1-monopole.

The two outer regular antimonopoles are located at the two point zeros of the Higgs field at $z=\pm\sqrt[5]{3/2}=\pm 1.0845$, Fig. 4, and the vortex ring is located along the ring of radius 1.0845 on the equatorial plane where the Higgs field vanishes, Fig. 5. The magnetic field lines of this one vortex ring solution is shown in Fig. 6.

The two vortex rings solution is the next solution of this series of axially symmetric monopole configurations with parameter $m=3$. The gauge field potentials and Higgs field are, respectively, given by

$$A^a_\mu = \frac{1}{r}\left\{\frac{4-3r^7}{1+r^7}\right\}(\hat{\theta}^a\hat{\phi}_\mu - \hat{\phi}^a\hat{\theta}_\mu) + \frac{3\tan\theta}{r}\left\{\frac{5\cos^2\theta - 1}{5\cos^2\theta - 3}\right\}(\hat{\phi}^a\hat{r}_\mu - \hat{r}^a\hat{\phi}_\mu),$$

$$\Phi^a = \frac{1}{r}\left\{\frac{4-3r^7}{1+r^7}\right\}\hat{r}^a + \frac{3\tan\theta}{r}\left\{\frac{5\cos^2\theta - 1}{5\cos^2\theta - 3}\right\}\hat{\theta}^a. \tag{29}$$

As usual, the two point antimonopoles are situated at the two point zeros, $z=\pm\sqrt[7]{4/3}=\pm 1.0420$, of the Higgs field. The two vortex rings are located horizontally at $r=1.0420$ and $\theta=1.1071$ ($\pi - 1.1071$) rad. Again, from the plots of magnetic flux, $M_r(\theta)|_{r\to 0}$ and $M_r(\theta)|_{r\to\infty}$, Fig. 7, of Eq. (26), together with the plot of the magnetic field lines, Fig. 8, we can conclude that the structure

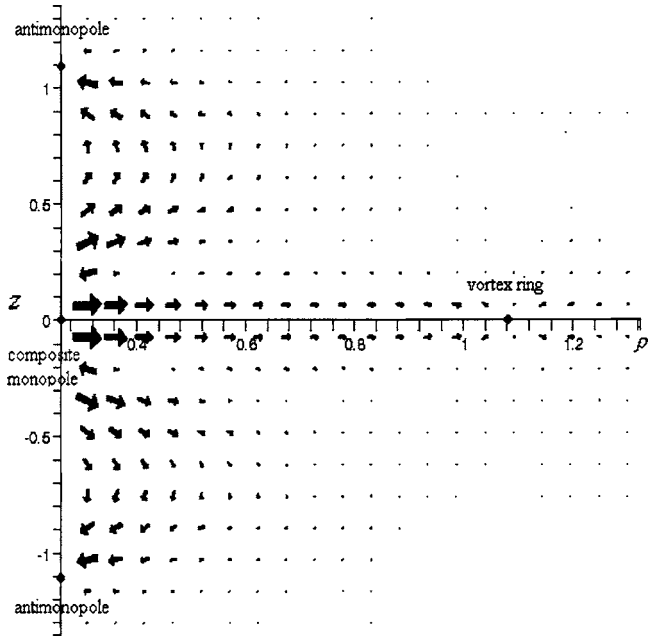

FIG. 4. The Abelian magnetic field of the $m=2$ solution at finite distances showing the presence of the two dipole pairs along the z-axis and the vortex ring at $z=0$, $\rho=1.0845$.

of the composite 1-monopole at the origin is MAMAMAM, with an antimonopole at the center. The three poles in the center, MAM, possess unity charge, whereas the other four poles possess charge less than unity. Hence, there exist a vortex point both above and below the MAM 1-monopole. Hence, by induction, we conclude that the number of A and M "poles" in the composite monopole is equal to $2m+1$, and when m is even, the pole in the center of the structure

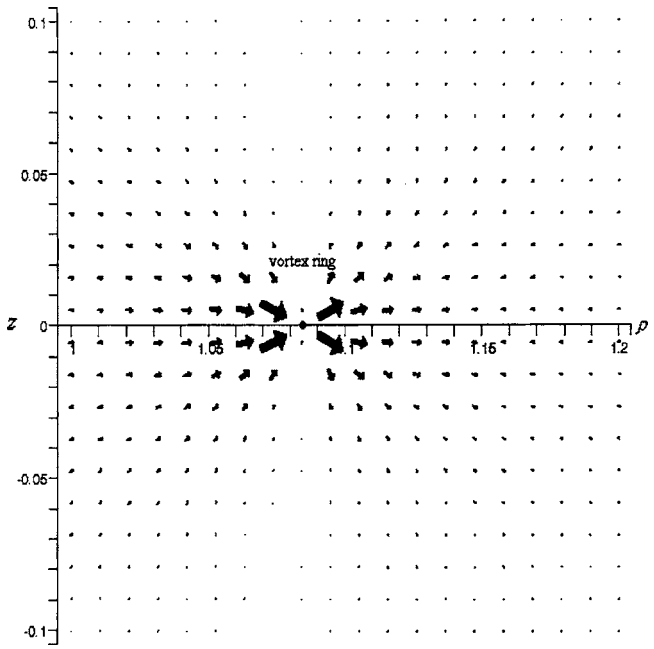

FIG. 5. The Abelian magnetic field of the $m=2$ solution at distances close to $z=0$ and $\rho=1.0845$ showing the presence of the vortex ring.

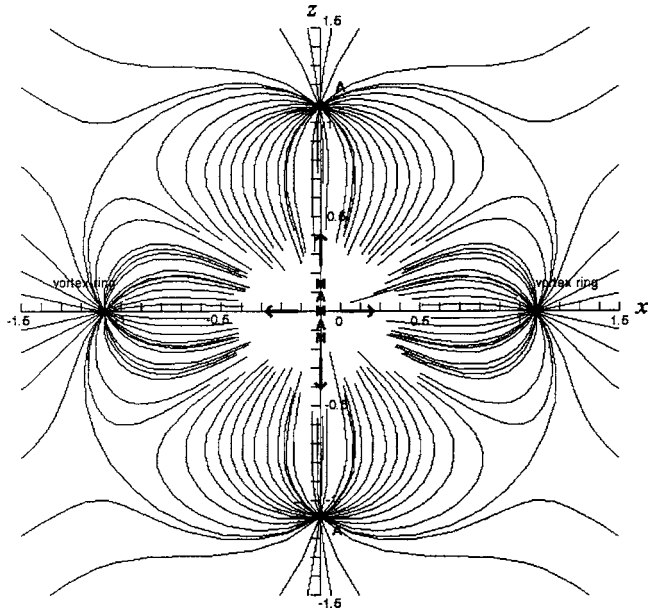

FIG. 6. A plot of the magnetic field lines when $m=2$ along a vertical plane through the z-axis. The vortex ring is situated horizontally at equal distances from the origin as the two antimonopoles at $z=\pm 1.0845$.

is a monopole and when m is odd, we have an antimonopole or a MAM 1-monopole in the center of the structure.[6] The number of vortex rings in the solution increases with m and is equal to $(m-1)$.

V. COMMENTS

We have obtained exact axially symmetric A-M-A configurations of the SU(2) YMH theory which are characterized by a positive integer parameter m. The 1-monopole which is located at the

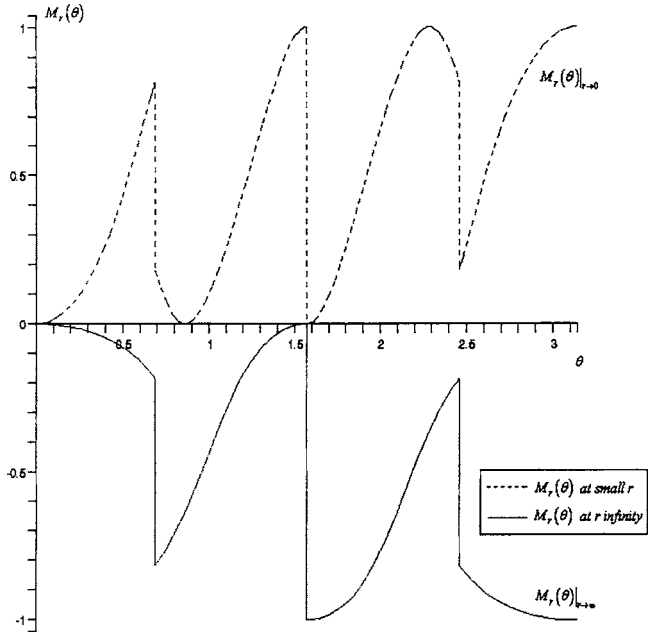

FIG. 7. A plot of $M_r(\theta)$ at r close to zero and $M_r(\theta)$ at r infinity, when $m=3$, versus θ.

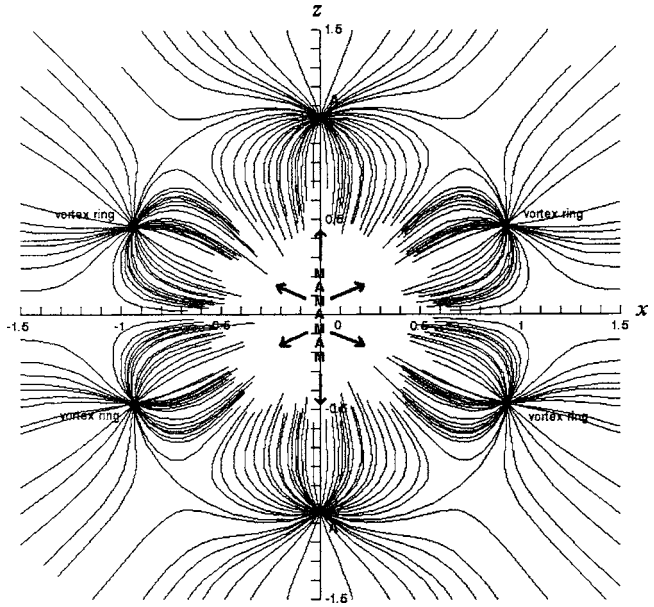

FIG. 8. A plot of the magnetic field lines when $m=3$ along a vertical plane through the z-axis. The two vortex rings are situated horizontally at equal distances from the origin as the two antimonopoles at $z=\pm 1.0420$.

origin, $r=0$, where the Higgs field is singular, is a Wu-Yang-type monopole. The two regular outer antimonopoles are located at the two point zeros of the Higgs field along the z-axis at $z=\pm\sqrt[2m+1]{(m+1)/m}$. When the parameter m exceeds unity, vortex rings start to appear around the z-axis. The number of vortex rings in the solution is equal to $(m-1)$.

Further investigations reveal that the 1-monopole at the origin possesses structure. It corresponds to a zero-size composite monopole with its axis lying along the z-axis. By induction, we conclude that the number of "poles" in the composite monopole is given by $2m+1$. When m is even, the center of the structure corresponds to a 1-monopole M and, when m is odd, it corresponds to an antimonopole or a MAM 1-monopole. We have analyzed the solutions for the cases of $m=0$, 1, 2, and 3, with 1-monopole given by M, MAM, MAMAM, and MAMAMAM, respectively. The MA and AM above and below the 1-monopole when $m=2$ and 3 can be thought of as a vortex point as the magnetic charges of these poles are less than unity.

There are two types of singularities in solutions (14). The point singularity at the origin, $r=0$, gives rise to a Wu-Yang-type monopole, M or MAM. This monopole possesses the usual Dirac string potential in the Abelian gauge when $m=0$. However, when $m=1,2,3,\ldots$, the Dirac string is broken into two parts. The string stretches from $z=0$ to $z=-\sqrt[2m+1]{(m+1)/m}$ along the negative z-axis and from $z=\sqrt[2m+1]{(m+1)/m}$ to positive infinity along the positive z-axis.

The singularities in $R(\theta)$ when $P_m(\cos\theta)=0$ give rise to plane singularities. The number of singular planes in the solution is equal to m. Hence, when $m=1$, the singular plane is the equatorial plane. The Abelian magnetic field possesses a negative Dirac delta function singularity along this plane, $B_r=-2/(r^2\sin\theta)\delta[\theta-(\pi/2)]$. Similarly, when $m=2$, the singular planes are $\theta=0.9553$ and 2.1863 rad, and when $m=3$, the singular planes are $\theta=0.6847$, 0, and 2.4569 rad. In all these solutions, the Abelian magnetic fields possess negative Dirac delta function singularity along these planes as the Abelian gauge potentials are discontinuous at these values of θ.

Numerical static axially symmetric M-A-M-… chain at finite pole separation has also been discussed in Ref. 6. These numerical solutions belong to the topologically trivial sector when the total number of poles and antipoles is even and to the topological unit sector when the total number of poles and antipoles is odd. We have only managed to find odd total number of poles and antipoles in our solutions. Similar to the results of Ref. 6, we have a monopole at the center of the

composite 1-monopole when m is even and an antimonopole in the center when m is odd. Also similar is that our solutions have zero magnetic dipole moment as the number of poles in our solutions is odd.

Unlike the monopole solutions of Ref. 6, our A-M-A poles here are of unit charge only. We did not manage to get monopoles and antimonopoles of charge equal to two units for our axially symmetric monopoles solutions. In fact, we have not found any M-monopoles with finite separations when $|M| \geqslant 2$.

We would also like to mention that, for every monopole, antimonopole, vortex rings solution that we have discussed so far, there always exists an anticonfiguration of the configurations discussed. This can be done by changing the ϕ winding number in the ansatz (8) from +1 to −1 and solving the Bogomol'nyi equation with the negative sign.[8]

We would also like to mention that one-half topological magnetic charge monopole is obtained when the parameter m is set to $-\frac{1}{2}$ in the solution, Eq. (14).[10]

Extending the Picard-Fuchs system of local mirror symmetry

Brian Forbes[a] and Masao Jinzenji[b]
Division of Mathematics, Graduate School of Science, Hokkaido University, Kita-ku, Sapporo, 060-0810, Japan

(Received 1 April 2005; accepted 15 June 2005; published online 1 August 2005)

We propose an extended set of differential operators for local mirror symmetry. If X is Calabi-Yau such that $\dim H_4(X,\mathbb{Z})=0$, then we show that our operators fully describe mirror symmetry. In the process, a conjecture for intersection theory for such X is uncovered. We also find operators on several examples of type $X=K_S$ through similar techniques. In addition, open string Picard-Fuchs systems are considered. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1996441]

I. INTRODUCTION

For some time now, mirror symmetry has been successfully used to make enumerative predictions on certain Calabi-Yau manifolds. While mirror symmetry for the compact Calabi-Yau has been extensively studied, local mirror symmetry is relatively new, and a complete formulation does not yet exist.

The first unified treatment of local mirror symmetry was written down in Ref. 3, in the case that the space looks like $X=K_S$, where S is a Fano surface and K_S is its canonical bundle. Very recently,[10] the work of Ref. 3 was formulated more mathematically. With the ideas of Ref. 10, we are able to determine all information relevant for mirror symmetry directly from the Picard-Fuchs equations of the mirror. These techniques are limited to the case that X satisfies $b_2(X)=b_4(X)$.

The aim of this paper is to further the program of local mirror symmetry. We propose a set of differential operators, whose solutions contain the usual local mirror symmetry solutions as a subset. In the event that the space in question contains no 4 cycle, the operators completely solve the problem for an arbitrary number of Kähler parameters. For the more traditional mirror symmetry constructions of Ref. 3, our methods still complete missing data; however, a general formulation here is lacking.

The key point in the construction of the extended Picard-Fuchs system is the determination of triple intersection numbers of Kähler classes for open Calabi-Yau manifolds. Up to now, a natural definition of triple intersection numbers of Kähler classes on open Calabi-Yau manifolds is not known, but in this paper, we search for triple intersection numbers that are "natural" from the point of view of mirror symmetry in the sense of the following conjecture.

Conjecture 1: Consider the A-model on a Calabi-Yau threefold X. Let u_i *be the logarithm of the B-model complex deformation parameter* z_i *obtained from the toric construction of the mirror Calabi-Yau manifold* $\hat{X}$*. Then the B-model Yukawa coupling* $C_{u_iu_ju_k}$ *of* $\hat{X}$ *obtained from the A-model Yukawa coupling of X via the mirror map is a rational function in* $z_i=\exp(u_i)$*. Moreover, its denominator consists of the factors of the defining equation of the discriminant locus of* $\hat{X}$*.*

Since the triple intersection number is just the constant term of the B-model Yukawa coupling $C_{u^iu^ju^k}$, the above conjecture imposes constraints on these triple intersection numbers.

We regard the existence of such intersection theory as an interesting analogue of the physical predictions arising from large N duality, e.g., Ref. 7. Recall that in Ref. 7, the postulated large N

[a]Electronic mail: brian@math.sci.hokudai.ac.jp
[b]Electronic mail: jin@math.sci.hokudai.ac.jp

dual of $X=\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$ led to a fractional triple intersection number for $\mathbb{P}^1\hookrightarrow X$. We find a similar fractional intersection theory, and this is done via calculations which are independent of a large N dual. Hence, we may think of this intersection theory as a prediction for what one would find if computations were done on a large N dual theory.

With these intersection numbers in hand, we can construct an extended quantum cohomology ring of X and an associated Gauss-Manin system. In the examples treated in this paper, this quantum cohomology ring satisfies Poincare duality as a compact threefold, even if X is an open Calabi-Yau threefold. Let t_i be coordinates on the complexified Kähler moduli space of X. With this Gauss-Manin system, we can write down differential equations for $\psi_0(t_i)$, the function associated to the identity element of the quantum cohomology ring. Then we can rewrite these differential equations by using the mirror map $t_i=t_i(z_*)$. Our assertion in this paper is that the differential equations so obtained are the extension of the Picard-Fuchs operators obtained from the standard toric construction of $\hat{X}$. Moreover, the extended Picard-Fuchs system has all the properties that the Picard-Fuchs system associated to a compact Calabi-Yau threefold should have a unique triple log solution, B-model Yukawa couplings, etc. These extended Picard-Fuchs systems give us a very simple derivation of B-model Yukawa couplings of local mirror symmetry known in some special cases. In particular, we can compute B-model Yukawa couplings of any K_S case. Therefore, we can see the global behavior of the instanton expansion of local mirror symmetry. We expect that the extended Picard-Fuchs system can be derived from the B-model point of view. The results of this paper gives us some useful guidelines of such a construction, since extended Picard-Fuchs systems have a very elegant form in some cases.

One problem in the construction is that in some cases, the constraints obtained from the above conjecture are not strong enough to determine all the triple intersection numbers. In other words, we have some real moduli parameters in the triple intersection numbers. Yet, we can still construct the extended Picard-Fuchs system for each value of the moduli parameters, and these systems have all the properties desired for a Picard-Fuchs system associated to a compact Calabi-Yau threefold. In the case that $b_4(X)=b_6(X)=0$, we find unique triple intersection numbers compatible with the above conjecture by considering the change of the prepotential under flops. Hence, our construction of an extended Picard-Fuchs system has no ambiguity in this situation.

We should mention that our constructions do not lead to Gromov-Witten invariants on the spaces we consider. Rather, the differential systems we find have the property that all Gromov-Witten invariants can be derived purely as solutions of our differential systems, a feature which was absent in the original work.[3] Moreover, we believe that through the study of such systems, we will come closer to a formulation of local mirror symmetry on all Calabi-Yau purely in terms of the complex geometry of the mirror.

Here is the organization of the paper. Section II spells out the generalities of the Gauss-Manin system and intersection theory for open Calabi-Yau manifolds. In Sec. III, we thoroughly consider $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$, giving a PF operator for mirror symmetry and a geometric view of the meaning of the operator. Section IV is the generalization, which spells out a conjecture on how to deal with all X such that $\dim H_4(X,\mathbb{Z})=0$. This is subsequently applied to several cases and shown to produce the expected results. Section V explores the application of our techniques to open string theory on $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$, while Secs. VI and VII work through examples of type K_S. Some of the results for our more unwieldy examples are collected in the appendixes.

II. THE MAIN STRATEGY: OVERVIEW OF THE GAUSS-MANIN SYSTEM

Let X be a noncompact Calabi-Yau threefold, and choose a basis $\{k_i\}$ for $H^{1,1}(X,\mathbb{C})$. Suppose that we have obtained "natural" classical triple intersection numbers $\langle k_a k_b k_c\rangle\in\mathbb{Q}$ for two cycles on X under the assumption of Conjecture 1. Suppose also that we know the instanton part of the prepotential for X. Recall that the prepotential is the generating function of Gromov-Witten invariants for X; then we denote this instanton part by $\mathcal{F}^{\text{inst}}(t_*)$, where t_a is the Kähler deformation parameter associated to the Kähler form k_a $[a=1,\ldots,h^{1,1}(X)]$. With this data, we can construct an A-model Yukawa coupling for X,

$$Y_{abc}(t_*) = \langle k_a k_b k_c \rangle + \frac{\partial^3 \mathcal{F}^{\text{inst}}(t_*)}{\partial t_a \, \partial t_b \, \partial t_c}. \tag{1}$$

Using the classical intersection numbers $\langle k_a k_b k_c \rangle$, we can construct a virtual basis $m_\alpha [\alpha = 1, \ldots, h^{1,1}(X)]$ of formal 4 cycles with the following property. If $\eta_{a\alpha}$ is the virtual intersection matrix of 2 cycles and formal 4 cycles, then with respect to the basis m_α, we have

$$\eta_{a\alpha} := \delta_{a\alpha}. \tag{2}$$

With this setup, we obtain a (virtually compactified) quantum cohomology ring of X, which is the usual cohomology ring with a deformed product, defined as follows:

$$\begin{gathered} k_a \circ 1 = k_a, \\ k_a \circ k_b = \sum_{c,\gamma} Y_{abc}(t_*) \eta^{c\gamma} m_\gamma = \sum_{\gamma} Y_{ab\gamma}(t_*) m_\gamma, \\ k_a \circ m_\alpha = Y_{a\alpha 0} v = \delta_{a\alpha} v, \\ k_a \circ v = 0. \end{gathered} \tag{3}$$

Above, we have taken advantage of a standard feature of the quantum cohomology ring, namely

$$Y_{a\alpha 0} = \eta_{a\alpha}. \tag{4}$$

Here v is the formal volume form of X and we use the subscript 0 to denote the identity 1 of this quantum cohomology ring. Then we consider a system of partial differential equations,

$$\begin{gathered} \partial_a \psi_0 = \psi_a, \\ \partial_a \psi_b = \sum_{c,\gamma} Y_{abc}(t_*) \eta^{c\gamma} \psi_\gamma = \sum_{\gamma} Y_{ab\gamma}(t_*) \psi_\gamma, \\ \partial_a \psi_\alpha = Y_{a\alpha 0} \psi_v = \delta_{a\alpha} \psi_v, \\ \partial_a \psi_v = 0. \end{gathered} \tag{5}$$

Next, we consider the inverse matrix $(Y_a^{-1}(t_*))^{bc}$ of $(Y_a(t_*))_{bc} := Y_{abc}(t_*)$. From (5), we obtain,

$$\psi_\alpha = \sum_{b,c} \eta_{\alpha c} \cdot (Y_a^{-1}(t_*))^{cb} \partial_a \partial_b \psi_0 = \sum_{b} (Y_a^{-1}(t_*))^{\alpha b} \partial_a \partial_b \psi_0. \tag{6}$$

Since ψ_α is unique for each α, we must impose integrability conditions

$$\sum_{c} (Y_a^{-1}(t_*))^{\alpha c} \partial_a \partial_c \psi_0 = \sum_{c} (Y_b^{-1}(t_*))^{\alpha c} \partial_b \partial_c \psi_0 \quad (a \neq b) \tag{7}$$

for any $a, b \in \{1, 2, \ldots, h^{1,1}(X)\}$. We have another integrability condition from the third line of (5):

$$\partial_a \left(\sum_{c} (Y_a^{-1}(t_*))^{ac} \partial_a \partial_c \psi_0 \right) = \partial_b \left(\sum_{c} (Y_b^{-1}(t_*))^{bc} \partial_b \partial_c \psi_0 \right) \quad (a \neq b),$$

$$\partial_b\left(\sum_c (Y_a^{-1}(t_*))^{ac}\partial_a\partial_c\psi_0\right)=0 \quad (a\neq b), \tag{8}$$

for any $a, b\in\{1,2,\ldots,h^{1,1}(X)\}$. Finally, we can derive differential equations from the fourth line of (5),

$$\partial_a^2\left(\sum_c (Y_a^{-1}(t_*))^{ac}\partial_a\partial_c\psi_0\right)=0. \tag{9}$$

Our strategy in this paper is to translate the equations (7)–(9) in terms of the mirror map

$$t_a=t_a(z_*) \tag{10}$$

into the differential equations of the complex deformation parameters z_a of the mirror manifold $\hat{X}$. Of course, in the one parameter case, the equations (7) and (8) become trivial, and the only nontrivial equation is

$$\partial_t^2\left(\frac{1}{Y_{ttt}}\right)\partial_t^2\psi_0(t)=0, \tag{11}$$

which follows from (9) with the identification $t=t_1$.

In the following, we will explicitly compute (7)–(9) in many examples, and we find that these equations are highly overdetermined. Therefore, in this paper, we will choose the minimal independent set of equations for an extended Picard-Fuchs system.

By construction, the Picard-Fuchs system so obtained has a solution space given by

$$\left(1,t_1,\ldots,t_{h^{1,1}(X)},\frac{\partial\mathcal{F}}{\partial t_1},\ldots,\frac{\partial\mathcal{F}}{\partial t_{h^{1,1}(X)}},2\mathcal{F}-\sum_{a=1}^{h^{1,1}(X)} t_a\frac{\partial\mathcal{F}}{\partial t_a}\right) \tag{12}$$

for some function $\mathcal{F}$ which is smooth in the t_i. Then $\mathcal{F}$ is that relevant for the counting of Gromov-Witten invariants.

III. MIRROR SYMMETRY FOR LOCAL $\mathbb{P}^1$

A. A Picard-Fuchs operator for local $\mathbb{P}^1$

Before diving into the details of Gauss-Manin systems and the like, we will first take a simple-minded look at a familiar example, namely $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$. We will see that in trying to apply the techniques of local mirror symmetry to this basic case, we are inevitably led to introduce the generalized intersection theory explained in the introduction. In fact, this is the example that originally motivated the investigations of this paper.

Recall the symplectic quotient definition of $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$,

$$X=\{(w_1,\ldots,w_4)\in\mathbb{C}^4-Z:|w_1|^2+|w_2|^2-|w_3|^2-|w_4|^2=r\}/S^1. \tag{13}$$

Above, $Z=\{w_1=w_2=0\}$, $r\in\mathbb{R}^+$ and

$$S^1:(w_1,\ldots,w_4)\to(e^{i\theta}w_1,e^{i\theta}w_2,e^{-i\theta}w_3,e^{-i\theta}w_4), \quad \theta\in S^1.$$

We can naively employ the methods of Ref. 10 to produce a Picard-Fuchs operator associated to the mirror Calabi-Yau $\hat{X}$ of X. The family $\hat{X}$ is described as[9]

$$\hat{X}_z=\{(u,v,y_1,y_2)\in\mathbb{C}^2\times(\mathbb{C}^*)^2:uv+1+y_1+y_2+zy_1y_2^{-1}=0\}. \tag{14}$$

Then Ref. 10 provides a recipe for dealing with noncompact period integrals for such an $\hat{X}$. They are defined by

$$\Pi_\Gamma(z) = \int_\Gamma \frac{du\, dv\, dy_1\, dy_2/(y_1 y_2)}{uv + 1 + y_1 + y_2 + z y_1 y_2^{-1}}$$

for $\Gamma \in H_4(\mathbb{C}^2 \times (\mathbb{C}^*)^2 - \hat{X}, \mathbb{Z})$. As usual, we utilize the GKZ formalism in order to exhibit a differential operator which annihilates the Π_Γ. One finds

$$\mathcal{D} = (1-z)\theta^2, \quad \theta = z\frac{d}{dz} \tag{15}$$

as the relevant PF operator.

This is a puzzling situation. Clearly, the solutions of $\mathcal{D}f=0$ are given by $\{1, \log z\}$. This is sensible, because noncompact PF systems always have a constant solution,[3] and the mirror map is trivial for $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$, leading to a $\log z$ solution. However, there is no double-logarithmic solution, because $\mathcal{D}$ is only of order 2. Hence, we have no function $\mathcal{F}$ with which to count holomorphic curves on X! But, since X contains exactly 1 holomorphic curve, we know that the sought after function should be of the form

$$\mathcal{F}(z) = K\frac{(\log z)^3}{6} + \sum_{n>0}\frac{z^n}{n^3}. \tag{16}$$

Here K is a classical triple intersection number for $\mathbb{P}^1 \hookrightarrow X$. Also, notice that the leading factor of $1-z$ in front of $\mathcal{D}$, while naturally appearing through the techniques of the GKZ formalism, is auxiliary to the solution set of $\mathcal{D}$.

At this point, we can gain a bit of insight from the compact case. Recall[4] that in the event of a compact Calabi-Yau X with one Kähler parameter, there is always a flat coordinate t in which the Picard-Fuchs operator for the mirror family is given as

$$\mathcal{D}_{\text{compact}}(t) = \partial_t^2\left(\frac{1}{Y}\right)\partial_t^2, \tag{17}$$

which is the same as formula (11). This is reminiscent of our situation (15), upon making the identification $t=\log z$.

If one surrendered to the impulse of emulating the above compact expression, one would be compelled to work with the following modified differential operator:

$$\mathcal{D} \to \mathcal{D}' = \theta^2\mathcal{D}.$$

Rewrite this as

$$\theta^2(1-z)\theta^2 = \theta^2\left(\frac{1}{1-z}\right)^{-1}\theta^2.$$

By comparison with (17), it is natural to identify the Yukawa coupling Y of $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$ as

$$Y = \frac{1}{1-z}. \tag{18}$$

And indeed, the condition that $Y=\theta^3\mathcal{F}$, which follows from the form of $\mathcal{D}'$, yields the expected function $\mathcal{F}$ (16), if we take $K=1$. Later, we will find that a more natural choice for generalization is $K=1/2$.

The resulting period vector of solutions for $\mathcal{D}'f=0$ is

$$\Pi' = (1, \log z, \theta\mathcal{F}, 2\mathcal{F} - (\log z)\theta\mathcal{F}),$$

which is of the same type as encountered when dealing with the compact Calabi-Yau. Hence, we have found a cure for mirror symmetry on $X = \mathcal{O}(-1) \oplus \mathcal{O}(-1) \to \mathbb{P}^1$; the operator $\theta^2\mathcal{D}$ reproduces all relevant data to describe mirror symmetry for X.

We can also view this $\theta^2\mathcal{D}$ from the vantage of the Frobenius method. The geometry of X is determined by the set of vertices $\{\nu_0, \ldots, \nu_3\} = \{(0,0), (1,0)(0,1), (1,1)\}$, together with a choice of triangulation of the resulting toric graph. These give rise to the lattice vector $l = (1, -1, -1, 1)$, and identify z as the correct variable on the complex moduli space of $\hat{X}$. Then the solutions of our extended PF operator $\theta^2\mathcal{D}$ can be generated, via the Frobenius method, from the function $\omega_0(z, \rho) = \Sigma_{n \geqslant 0} c(n, \rho) z^{n+\rho}$, with $c(n, \rho)^{-1} = \Gamma(1+n+\rho)^2 \Gamma(1-n-\rho)^2$. It is a simple matter to verify that

$$\Pi' = (\omega_0(z,0), \partial_\rho \omega_0(z,\rho)|_{\rho=0}, \partial_\rho^2 \omega_0(z,\rho)|_{\rho=0}, \partial_\rho^3 \omega_0(z,\rho)|_{\rho=0}).$$

Clearly this had to be the case, since the extension of the original $\mathcal{D}$ on the left-hand side by each factor of θ adds one more Frobenius-generated solution.

B. PF extensions and Riemann surfaces

In physics literature,[1,10] a frequently used technique of local mirror symmetry is to consider periods on a Riemann surface $\Sigma \hookrightarrow \hat{X}$, rather than periods of the full mirror geometry $\hat{X}$. In this section, we will review evidence in favor of this approach.

Looking back at the mirror geometry (14), this can be rewritten as

$$\hat{X}_z = \{uv + 1 + y_1 + y_2 + z y_1 y_2^{-1} = uv + f(z, y_1, y_2) = 0\},$$

which is a hypersurface in $\mathbb{C}^2 \times (\mathbb{C}^*)^2$. Notice that there is an imbedded Riemann surface in this space, defined as

$$\Sigma_z = \{(y_1, y_2) \in (\mathbb{C}^*)^2 : f(z, y_1, y_2) = 0\}. \tag{19}$$

In fact, this statement applies not only to the local $\mathbb{P}^1$ case, but to all toric local mirror symmetry constructions.[1] Now take $(a_0, \ldots, a_3)$ as homogeneous coordinates on the moduli spaces of $\hat{X}$ and Σ, i.e.,

$$\hat{X}_a = \{uv + a_0 + a_1 y_1 + a_2 y_2 + a_3 z y_1 y_2^{-1} = uv + f(a, y_1, y_2) = 0\}.$$

Recall that the GKZ operators are differential operators $\{\mathcal{L}_i\}$ in the variables a, such that

$$\mathcal{L}_i \int_\Gamma \frac{du\, dv\, dy_1\, dy_2/(y_1 y_2)}{uv + f(a, y_1, y_2)} = 0, \quad \forall\, i.$$

We can recover the PF operators from the GKZ operators via a canonical reduction on the homogeneous moduli space.

With these things in mind, we note the following.

Proposition 1: The GKZ operators associated to the geometry $\hat{X}$ are the same as those associated to Σ.

Proof: Notice that Σ is a complex dimension 1 noncompact Calabi-Yau manifold. In particular, it makes sense to define the period integrals of Σ as

$$\Pi_\gamma^\Sigma(a) = \int_\gamma \frac{dy_1\, dy_2/(y_1 y_2)}{f(a,y_1,y_2)}$$

with $\gamma \in H_2((\mathbb{C}^*)^2 - \Sigma, \mathbb{Z})$. Let $\mathcal{L}$ be a GKZ operator on the moduli space of Σ_a, so that $\mathcal{L}\Pi_\gamma^\Sigma(a) = 0$. If a_i are homogeneous coordinates on the moduli space of Σ, then $\mathcal{L}$ is a homogeneous polynomial (say, of degree n) in ∂_{a_i}. We obtain

$$\mathcal{L}\frac{1}{f(a,y_1,y_2)} = \frac{P_\mathcal{L}(y_1,y_2)}{f(a,y_1,y_2)^{n+1}}, \tag{20}$$

where $P_\mathcal{L}$ is a polynomial in y_1, y_2 which is identically zero. We now want to apply this $\mathcal{L}$ to period integrals in $\hat{X}_a$. Recall that these are given as

$$\Pi_\Gamma^{\hat{X}}(a) = \int_\Gamma \frac{du\, dv\, dy_1\, dy_2/(y_1 y_2)}{uv + f(a,y_1,y_2)} \tag{21}$$

for $\Gamma \in H_4(\mathbb{C}^2 \times (\mathbb{C}^*)^2 - \hat{X}, \mathbb{Z})$. Then operating on the left-hand side of the integral, we find

$$\mathcal{L}\frac{1}{uv + f(a,y_1,y_2)} = \frac{P_\mathcal{L}(y_1,y_2)}{(uv + f(a,y_1,y_2))^{n+1}}$$

because the additive factor of uv in the period integrals of $\hat{X}$ is independent of a. Since $P_\mathcal{L} \equiv 0$, we have demonstrated that $\mathcal{L}\Pi_\Gamma^{\hat{X}}(a) = 0$. Clearly the converse of this statement is also true, so the proposition follows. □

Note that, as pointed out in Ref. 10, there is a subtlety in terms of the scaling properties of the period integrals on $\hat{X}_a$ and Σ_a; this scaling difference implies that the PF operators we derive from the above $\mathcal{L}$ will be different on Σ_z and $\hat{X}_z$. In the following, we will ignore this point, and carry on as though the period integrals on Σ_z actually reproduce the same PF operators.

As the geometry of Σ is far simpler than that of $\hat{X}$, this proposition will greatly aid the search for a geometric interpretation of our extended Picard-Fuchs operator. We will explore this in the next section.

C. Geometric interpretation through the Riemann surface

First, we will give a brief description of what "adding extra period integrals" means (which we are doing, via the extended PF operator) in the context of the space $\hat{X}$. This follows the lead of, e.g., Refs. 9 and 2.

Recall that mirror symmetry between compact spaces X and $\hat{X}$ means, in particular, that $\dim H^{1,1}(X) = \dim H^{2,1}(\hat{X})$. Hence, for every 2 cycles of X, we can expect a mirror 3 cycle of $\hat{X}$. Let $\dim H_3(\hat{X},\mathbb{Z}) = n$, and take Γ_i, $\Gamma_j \in H_3(\hat{X},\mathbb{Z})$ with Poincaré duals α_i, $\alpha_j \in H^3(\hat{X},\mathbb{Z})$. Then there is a symplectic structure on $H_3(\hat{X},\mathbb{Z})$, defined by the intersection pairing

$$(\Gamma_i,\Gamma_j) = \int_{\hat{X}} \alpha_i \wedge \alpha_j.$$

In the compact case, we can find a basis $\{\Phi_1,\ldots,\Phi_{n/2}, \Psi_1,\ldots,\Psi_{n/2}\}$ for $H_3(\hat{X},\mathbb{Z})$ satisfying

$$(\Phi_i,\Phi_j) = (\Psi_i,\Psi_j) = 0, \quad (\Phi_i,\Psi_j) = \delta_{ij}.$$

Next, consider the case in which X and $\hat{X}$ are noncompact. Here, we find there is no such nice construction. In fact, we can explicitly exhibit this failure in the example we are considering, $\mathcal{O}(-1) \oplus \mathcal{O}(-1) \to \mathbb{P}^1$. First, rewrite the equation for the mirror $\hat{X}$,

$$\hat{X}_z = \{(\tilde{u},v,\tilde{y}_1,\tilde{y}_2) \in \mathbb{C}^2 \times (\mathbb{C}^*)^2 : \tilde{u}v + z + \tilde{y}_1 + \tilde{y}_2 + \tilde{y}_1\tilde{y}_2 = 0\},$$

where we have taken $\tilde{y}_i = y_i^{-1}$ and $\tilde{u} = u/y_1y_2$. Set $z = 1-a$, where $a \in \mathbb{R}^+$. Then

$$\hat{X}_z = \{\tilde{u}v + 1 + \tilde{y}_1 + \tilde{y}_2 + \tilde{y}_1\tilde{y}_2 = a\},$$

and we can identify a 3 cycle,

$$\Gamma_1 = \hat{X}_z \cap \{\tilde{u} = \bar{v}, \tilde{y}_2 = \bar{\tilde{y}}_1\} = \{v\bar{v} + (1+\tilde{y}_1)\overline{(1+\tilde{y}_1)} = a\}.$$

It is easy to verify that this cycle has no symplectic dual in $H_3(\hat{X},\mathbb{Z})$.

We may, however, define a noncompact symplectic dual for Γ_1. This proceeds as follows. Let $p \in \Gamma_1$, and take $\tilde{\Gamma}_1 = (N_{\Gamma_1/\hat{X}})_p$. Then $\tilde{\Gamma}_1$ intersects Γ_1 in a point, and could be thought of as a dual; however, integrals over $\tilde{\Gamma}_1$ may not be well defined. Instead take

$$\tilde{\Gamma}_1^{\lambda} = \{v \in (N_{\Gamma_1/\hat{X}})_p : \|v\| \leqslant \lambda\}, \quad \lambda \in \mathbb{R}^+.$$

The norm $\| \|$ is defined with respect to the metric inherited from $\mathbb{C}^2 \times (\mathbb{C}^*)^2$. Set

$$\Omega_{\hat{X}} = \mathrm{Res}_{\{uv+f(z,y_1,y_2)=0\}}\left(\frac{du\, dv\, dy_1\, dy_2/(y_1y_2)}{uv + f(z,y_1,y_2)}\right).$$

We recall the proposal of Ref. 9 for dealing with the "missing" period integrals for local mirror symmetry. Specifically for the local $\mathbb{P}^1$ case we are considering, Ref. 9 makes the claim that the period integral which is the symplectic dual of the mirror map represents a truncated volume of the (noncompact) 4 cycle which is dual to the $\mathbb{P}^1$. In our notation, this means we should be considering $\int_{\tilde{\Gamma}_1^{\lambda}} \Omega_{\hat{X}}$ as periods of the noncompact geometry $\hat{X}$. Mathematically, this means that the definition of noncompact period integrals of $\hat{X}$ are to be taken as all $\int_{\Gamma} \Omega_{\hat{X}}$ for $\Gamma \in H_3(\hat{X},\mathbb{Z}) \oplus (H_3(\hat{X},\mathbb{Z}))_c$. Here, the subscript c indicates compactly supported homology. In view of Proposition 1, one can then make the following.

Definition 1: Let $\hat{X}$ be the noncompact Calabi-Yau hypersurface,

$$\hat{X} = \{(u,v,y_1,y_2) \in \mathbb{C}^2 \times (\mathbb{C}^*)^2 : uv + f(z,y_1,y_2) = 0\}$$

and Σ the imbedded Riemann surface $\Sigma_z = \hat{X} \cap \{u=v=0\}$. Then the period integrals of $\hat{X}$ are defined to be

$$\Pi_{\gamma}(z) = \int_{\gamma} \mathrm{Res}_{f=0}\left(\frac{dy_1\, dy_2/(y_1y_2)}{f(z,y_1,y_2)}\right)$$

for $\gamma \in H_1(\Sigma,\mathbb{Z}) \oplus (H_1(\Sigma,\mathbb{Z}))_c$.

In the next section, we will apply this definition to $\mathcal{O}(-1) \oplus \mathcal{O}(-1) \to \mathbb{P}^1$, and see that the explicit evaluation of the period integrals on Σ gives the same answer as the extended PF operator of Sec. III A.

D. Period integrals for local $\mathbb{P}^1$

Before describing the cycles of Σ and computing their associated integrals, we will need to make use of the following proposition. This will give a (1, 0) form $\alpha \in H_1(\log(\Sigma),\mathbb{Z})$, which can be integrated over lines in Σ. Some of the arguments below can be found in Ref. 13.

Proposition 2: Let Σ be as above, and choose $\gamma \in H_1(\Sigma,\mathbb{Z}) \oplus (H_1(\Sigma,\mathbb{Z}))_c$. Then

$$\int_{\gamma} \mathrm{Res}_{f=0}\left(\frac{dy_1\, dy_2/(y_1y_2)}{f(z,y_1,y_2)}\right) = -\int_{\gamma} \log y_2 \frac{dy_1}{y_1} = -\int_{\gamma} \log y_1 \frac{dy_2}{y_2}.$$

Proof: Let $T(\gamma)$ be a tubular neighborhood of γ in Σ. We first claim that the same GKZ operators annihilate both of the following types of integrals:

$$\int_{T(\gamma)} \frac{dy_1\, dy_2/(y_1y_2)}{f(z,y_1,y_2)}, \quad \int_{T(\gamma)} \log(f) dy_1\, dy_2/(y_1y_2). \tag{22}$$

In fact, we can see this immediately from the proof of Proposition 1. That is, if $\mathcal{L}$ is a degree n GKZ operator annihilating $\int_{T(\gamma)}(dy_1\, dy_2/(y_1y_2)/f(z,y_1,y_2))$, then as before write

$$\mathcal{L}\frac{1}{f(z,y_1,y_2)} = \frac{P_{\mathcal{L}}(y_1,y_2)}{f(z,y_1,y_2)^{n+1}}, \tag{23}$$

where $P_{\mathcal{L}}(y_1,y_2) \equiv 0$. Then it follows immediately that $\mathcal{L}\log(f) = P_{\mathcal{L}}(y_1,y_2)/f^n \equiv 0$, as claimed.

Now, note that we are only interested in computations of period integrals as they arise as solutions of the GKZ system. Therefore, since they are both annihilated by the same system, we have that

$$\int_{T(\gamma)} \frac{dy_1\, dy_2/(y_1y_2)}{f(z,y_1,y_2)} = \int_{T(\gamma)} \log(f) dy_1\, dy_2/(y_1y_2). \tag{24}$$

The rest of the proof is then straightforward,

$$\int_\gamma \mathrm{Res}_{f=0}\left(\frac{dy_1\, dy_2/(y_1y_2)}{f(z,y_1,y_2)}\right) = \int_\gamma \mathrm{Res}_{f=0}(\log(f) dy_1\, dy_2/(y_1y_2)) = -\int_\gamma \mathrm{Res}_{f=0}\left(d(\log(f))\log y_2 \frac{dy_1}{y_1}\right)$$
$$= -\int_\gamma \mathrm{Res}_{f=0}\left(\frac{df}{f}\log y_2 \frac{dy_1}{y_1}\right) = -\int_\gamma \log y_2 \frac{dy_1}{y_1}.$$

This argument applies equally well upon exchanging y_1 and y_2. □

With this proposition in hand, we can take up the task of working out period integrals on local $\mathbb{P}^1$. Recall that the original, unmodified PF operator for this space was found to be $\mathcal{D} = (1-z)\theta^2$, with solution set $\{1, \log z\}$. We will at first content ourselves with finding cycles $\gamma_0, \gamma_1 \in H_1(\Sigma,\mathbb{Z})$ whose period integrals reproduce these solutions. To this end, note that the defining equation

$$\Sigma = \{(y_1,y_2) \in (\mathbb{C}^*)^2 : 1 + y_1 + y_2 + zy_1y_2^{-1} = 0\} \tag{25}$$

can be solved in two ways,

$$y_1 = \frac{-1-y_2}{1+zy_2^{-1}}, \quad y_2^{\pm} = \frac{-1-y_1 \pm \sqrt{(1+y_1)^2 - 4zy_1}}{2}.$$

Now, since y_1 and y_2 are $\mathbb{C}^*$ variables, we can define three elements of $H_1(\Sigma,\mathbb{Z})$ from these equations,

$$\gamma_0 = \left\{(y_1,y_2) \in (\mathbb{C}^*)^2 : y_1 = \frac{-1-y_2}{1+zy_2^{-1}},\ |y_2| = \epsilon\right\},$$

$$\tau_\pm = \left\{(y_1,y_2) \in (\mathbb{C}^*)^2 : y_2^{\pm} = \frac{-1-y_1 \pm \sqrt{(1+y_1)^2 - 4zy_1}}{2},\ |y_1| = \epsilon\right\}.$$

Then, two of these must be responsible for the solution set $\{1, \log z\}$. To motivate the correct choice of cycles, let us first look closely at the mirror construction that originally provided Eq. (25). Starting with the description

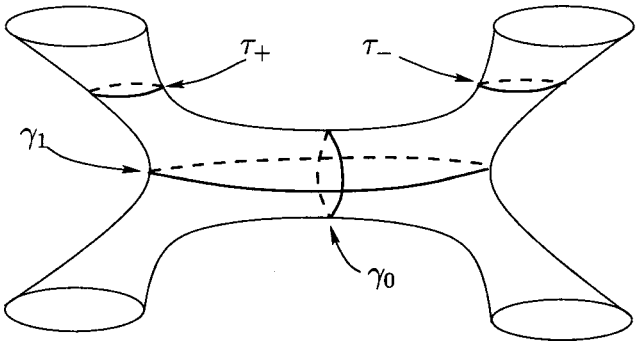

FIG. 1. 1-cycles on Σ. $\{\gamma_0, \tau_+, \tau_-\}$ is a basis for $H_1(\Sigma, \mathbb{Z})$.

$$\mathcal{O}(-1) \oplus \mathcal{O}(-1) \to \mathbb{P}^1 = \{(w_1, \ldots, w_4) \in \mathbb{C}^4 - Z : |w_1|^2 + |w_2|^2 - |w_3|^2 - |w_4|^2 = r\}/S^1,$$

from Ref. 2, the mirror geometry can be characterized as

$$\{uv + x_1 + \cdots + x_4 = 0 : x_1 x_2 x_3^{-1} x_4^{-1} = z, x_i = 1 \text{ for some } i\}.$$

Here u, $v \in \mathbb{C}$ and $x_i \in \mathbb{C}^*$. Also, the x_i obey $|x_i| = \exp(-|w_i|^2)$, and $|z| = e^{-r}$. To arrive at the form (25), we set $x_3 = 1$ and solved for x_1 in the constraint $x_1 x_2 x_3^{-1} x_4^{-1} = z$. Finally, the identification $y_1 = x_4$, $y_2 = x_2$ was made. Note that in choosing $x_3 = 1$, we are working in a specific coordinate patch on the Riemann surface. This coordinate patch is convenient for the problem at hand, as we now explain.

We can motivate the final choice of variables x_2, x_4 on Σ as follows. On $\mathcal{O}(-1) \oplus \mathcal{O}(-1) \to \mathbb{P}^1$, $[w_1, w_2]$ are homogeneous coordinates on the base $\mathbb{P}^1$, while w_3, w_4 are coordinates on each respective $\mathcal{O}(-1)$ factor. In order to study curves which start from the $\mathbb{P}^1$ and move off into a normal direction, we should use a coordinate patch with one base and one fiber variable, i.e., w_2, w_4. The mirror variables are then x_2, x_4, and hence our choice of them as local variables on Σ. To be more precise, the locus where $w_3 = w_4 = 0$, we thus have a bound $0 \leqslant |w_2|^2 \leqslant r$. Then $|y_2| = \exp(-|w_2|^2)$ implies that $1 \geqslant |y_2| \geqslant e^{-r} = |z|$; taking these considerations together, we may accurately label Fig. 1.

Proposition 3: Let γ_0, $\tau_\pm$ be as described above, and set $\gamma_1 = [\tau_+] + [\tau_-]$, with the sum taken in $H_1(\Sigma, \mathbb{Z})$. Then

$$\int_{\gamma_0} \log y_1 \frac{dy_2}{y_2}, \quad \int_{\gamma_1} \log y_2 \frac{dy_1}{y_1}$$

span the space of solutions $\{1, \log(z)\}$ of the PF operator $(1-z)\theta^2$.

Proof: The first integral is trivial,

$$\int_{\gamma_0} \log y_1 \frac{dy_2}{y_2} = \int_{|y_2|=\epsilon} \log\left(\frac{-1-y_2}{1+zy_2^{-1}}\right)\frac{dy_2}{y_2} = \int_{|y_2|=\epsilon} \left(i\pi + \log\left(\frac{1+y_2}{1+zy_2^{-1}}\right)\right)\frac{dy_2}{y_2}$$

and this is a constant. Of course, the branch cut of log must be taken to lie off the negative real axis. For the second,

$$\int_{\gamma_1} \log y_2 \frac{dy_1}{y_1} = \int_{\tau_+} \log y_2^+ \frac{dy_1}{y_1} + \int_{\tau_-} \log y_2^- \frac{dy_1}{y_1} = \int_{|y_1|=\epsilon} \log(y_2^+ y_2^-)\frac{dy_1}{y_1} = \int_{|y_1|=\epsilon} \log(zy_1)\frac{dy_1}{y_1}$$
$$= \text{const} + 2\pi i \log z.$$

□

Next, we turn to locating a period integral based on Definition 1. Since the constraint $1 \geqslant |y_2|$

$\geqslant |z|$ only applies in regions with $w_3=w_4=0$, outside of this locus, it is sensible to define a path on Σ as follows. Let $\lambda<|z|$ be real, and take a smooth increasing function $\sigma:[0,1]:\to\Sigma$ such that $\sigma(0)=\lambda$, $\sigma(1)=z$. Then

$$\gamma_2(\lambda)=\left\{(y_1,y_2)\in(\mathbb{C}^*)^2:y_1=\frac{-1-y_2}{1+zy_2^{-1}},\ y_2=\sigma[0,1],\ y_1\neq 1\right\}$$

defines an element of $(H_1(\Sigma,\mathbb{Z}))_c$.

Proposition 4: Let Σ, γ_2 be defined as above. Then

$$\theta\mathcal{F}=\int_{\gamma_2}\log y_1\frac{dy_2}{y_2},$$

where $\theta=z(d/dz)$ and $\theta\mathcal{F}$ is the double-logarithmic solution of the extended PF operator $\mathcal{D}'=\theta^2(1-z)\theta^2$ associated to the mirror of the local model $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$.

Proof: The computation is straightforward,

$$\int_{\gamma_2}\log y_1\frac{dy_2}{y_2}=\int_\lambda^z\log\left(\frac{-1-y_2}{1+zy_2^{-1}}\right)\frac{dy_2}{y_2}=\int_\lambda^z\left(i\pi+\sum_{n>0}\frac{(-y_2)^n}{n}-\sum_{n>0}\frac{(-zy_2^{-1})^n}{n}\right)\frac{dy_2}{y_2}$$

$$=\text{const}+(\lambda-\text{dependent})+\sum_{n>0}\frac{(-z)^n}{n^2}=(\theta\mathcal{F})(-z).$$

In order to achieve the result, we should have z rather than $-z$ in the above. However, this is accounted for by the fact that $\arg(y_2)$ is not determined in local mirror symmetry, and hence we are free to use the variable $y_2'=e^{i\pi}y_2$ in place of y_2. □

Notice that, with this definition of period integrals, the logarithmic terms of $\theta\mathcal{F}$ are not uniquely determined, as they depend on λ. It is for this reason that λ dependent terms are disregarded in the calculation.

It may seem that the choice of γ_2 is artificial, since we could have equally well chosen an increasing function $\sigma':[0,1]\to\Sigma$ with $\sigma'(0)=1$, $\sigma'(1)=\lambda>1$. However, it is easy to show that this is equivalent; if

$$\gamma_2'(\lambda)=\left\{(y_1,y_2)\in(\mathbb{C}^*)^2:y_1=\frac{-1-y_2}{1+zy_2^{-1}},\ y_2=\sigma'[0,1],\ y_1\neq 1\right\},$$

then

$$\lim_{\lambda\to\infty}\left(\theta\int_{\gamma_2'}\log y_1\frac{dy_2}{y_2}\right)=\sum_{n>0}\frac{(-z)^n}{n},$$

so the two approaches are interchangeable.

Thus, we have demonstrated that the ordinary period integrals obtained by integrating a meromorphic 1-form on Σ over a basis of $H_1(\Sigma,\mathbb{Z})$ is not sufficient to provide all the information we need, from the perspective of mirror symmetry. We must also consider "noncompact cycles" in order to fill in the missing data, which is what we showed in this section.

IV. MIRROR SYMMETRY FOR TORIC TREES

In this section, we will exhibit Picard-Fuchs operators for a broad class of noncompact threefolds X such that $\dim H_4(X,\mathbb{Z})=0$.

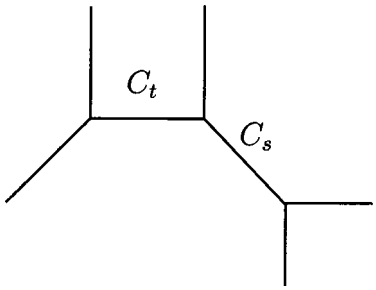

FIG. 2. Toric diagram for X_1.

A. Ordinary Picard-Fuchs systems

Our first interest will be to take a look at the PF systems one would arrive at through use of existing local mirror symmetry techniques. We wish to understand exactly how much information one might recover through these systems alone, in order to determine an appropriate fix.

Let us clarify what we are exploring here. Let $\{l^1,\ldots,l^n\}\subset\mathbb{Z}^m$ be a choice of basis for the secondary fan of a noncompact toric Calabi-Yau threefold X satisfying $\dim H_4(X,\mathbb{Z})=0$. Recall that we can derive all solutions of the Picard-Fuchs system on the mirror $\hat{X}$ to X by taking appropriate linear combinations of derivatives (in ρ) of the generating function $\omega(z,p)=\Sigma_{n>0}c(n,\rho)z^{n+\rho}$. Here z is the complex variable on the complex structure moduli space of $\hat{X}$, which we note is canonically identified by the basis vectors $\{l^1,\ldots,l^n\}$. In the above expression, $c(n,\rho)^{-1}=\Pi_i\Gamma(1+\Sigma_k l_i^k(n_k+\rho_k))$, where we are using the convention that $l^k=(l_1^k,\ldots,l_m^k)$. Then we want to look at the functions

$$\Pi_{ij}=(\partial_{\rho_i}\partial_{\rho_j}\omega(z,\rho))_{\rho=0}. \tag{26}$$

Our interest in this section, then, is to ascertain how much information we can find by looking at the Π_{ij}. In so doing, we will gain a better understanding of what to do in order to remedy mirror symmetry in this situation. Note that if X satisfies $\dim H_4(X,\mathbb{Z})=0$, then there is no linear combination of the Π_{ij}'s that is a solution of the associated PF system. But, we could consider a simple extension of a given PF system $\{\mathcal{D}_1,\mathcal{D}_2,\ldots\}$ of the form $\{\theta_1\mathcal{D}_1,\theta_2\mathcal{D}_2,\ldots\}$ which would have all the Π_{ij} as solutions.

Example 1: Consider the space

$$X_1=\{-2|w_1|^2+|w_2|^2+|w_3|^2=t_R,\ |w_1|^2-|w_2|^2+|w_4|^2-|w_5|^2=s_R\}/(S^1)^2,$$

where $(w_1,\ldots,w_5)\in\mathbb{C}^5-(\{w_2=w_3=0\}\cup\{w_1=w_4=0\}\cup\{w_4=w_5=0\})$, and s_R, t_R are positive real numbers. Choose s, $t\in\mathbb{C}$ satisfying $\mathrm{Re}(s)=s_R$, $\mathrm{Re}(t)=t_R$. Then X_1 contains two curves C_t, C_s with respective normal bundles $\mathcal{O}\oplus\mathcal{O}(-2)$ and $\mathcal{O}(-1)\oplus\mathcal{O}(-1)$ in X_1. Note also that s_R, t_R determine the radius of each respective curve. We have that $b_2=2$ and $b_4=0$.

From Ref. 16 we can draw a planar trivalent graph for X_1 corresponding to the torus weights. Using the rules of that paper, we find the toric skeleton shown in Fig. 2. Through the GKZ formalism, we have the PF operators associated to X_1,

$$\begin{aligned}\mathcal{D}_1&=\theta_1(\theta_1-\theta_2)-z_1(2\theta_1-\theta_2)(2\theta_1-\theta_2+1),\\ \mathcal{D}_2&=(2\theta_1-\theta_2)\theta_2-z_2(\theta_1-\theta_2)\theta_2,\\ \mathcal{D}_3&=\theta_1\theta_2-z_1z_2(2\theta_1-\theta_2)\theta_2.\end{aligned} \tag{27}$$

Let s, t be the logarithmic solutions of this system. From physics[5,11] the instanton part of the prepotential in s, t variables is

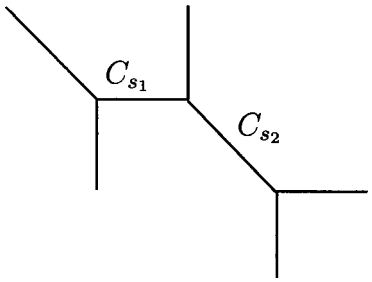

FIG. 3. Toric diagram for X_2.

$$\mathcal{F}_1^{\text{inst}} = \sum_{n>0} \frac{e^{ns}}{n^3} + \frac{e^{n(s+t)}}{n^3} - \frac{e^{nt}}{n^3}. \tag{28}$$

The Frobenius functions are

$$\Pi_{11}(s,t) = 0,$$

$$\Pi_{12}(s,t) = \sum_{n>0} \frac{e^{n(t+s)}}{n^2} - \frac{e^{ns}}{n^2}, \tag{29}$$

$$\Pi_{22}(s,t) = 2\sum_{n>0} \frac{e^{ns}}{n^2}.$$

We have neglected the logarithmic terms of each function. Notice that there is no linear combination of Π_{ij}'s that we can take to reproduce the term $\Sigma_{n>0} e^{nt}/n^2$. Apparently, the PF system cannot see the curve with normal bundle $\mathcal{O}\oplus\mathcal{O}(-2)$.

Example 2: Next, consider the space

$$X_2 = \{|w_1|^2 + |w_2|^2 - |w_3|^2 - |w_4|^2 = s_{1,R}, -|w_1|^2 - |w_3|^2 + |w_4|^2 + |w_5|^2 = s_{2,R}\}/(S^1)^2,$$

with $(w_1,\ldots,w_5) \in \mathbb{C}^5 - (\{w_1=w_2=0\}\cup\{w_4=w_5=0\}\cup\{w_2=w_5=0\})$. Also $s_{i,R} \in \mathbb{R}^+$ and we choose $s_i \in \mathbb{C}$ with $\text{Re}(s_i)=s_{i,R}$. We again have $b_2=2$, $b_4=0$, and now $\mathcal{N}_{C_i/X_2} \cong O(-1)\oplus\mathcal{O}(-1)$ for each i. Notice that we can flop from X_2 to X_1, if $l^1=(1,1,-1,-1,0)$ and $l^2=(-1,0,-1,1,1)$, then the combinations l^1+l^2, $-l^2$ give the secondary fan for X_1. The planar trivalent toric graph for X_2 is given in Fig. 3. We have the PF system from the mirror manifold,

$$\mathcal{D}_1 = (\theta_1 - \theta_2)\theta_1 - z_1(-\theta_1 - \theta_2)(-\theta_1 + \theta_2),$$

$$\mathcal{D}_2 = (\theta_2 - \theta_1)\theta_2 - z_2(-\theta_2 - \theta_1)(-\theta_2 + \theta_1), \tag{30}$$

$$\mathcal{D}_3 = \theta_1\theta_2 - z_1z_2(\theta_1 + \theta_2 + 1)(\theta_1 + \theta_2).$$

Let s_i be the logarithmic solutions. Using the same conventions as example 1, we find

$$\Pi_{11}(s_1,s_2) = \sum_{n>0} \frac{e^{ns_1}}{n^2} - \frac{e^{ns_2}}{n^2},$$

$$\underset{12}{\Pi}(s_1,s_2)=0,$$

with $\Pi_{22}=-\Pi_{11}$. Again, these expressions already include the mirror map. Let us take a look at the prepotential,

$$\mathcal{F}_2^{\text{inst}}=\sum_{n\geqslant 0}\frac{e^{ns_1}}{n^3}+\frac{e^{ns_2}}{n^3}-\frac{e^{n(s_1+s_2)}}{n^3}.$$

Then we see that

$$\underset{11}{\Pi}=\frac{\partial\mathcal{F}_2^{\text{inst}}}{\partial s_1}-\frac{\partial\mathcal{F}_2^{\text{inst}}}{\partial s_2}.$$

However, the cross term corresponding to $C_{s_1+s_2}$ cannot be detected from the Π_{ij}'s. Our work with example 1 suggests the reason for the problem with the $C_{s_1+s_2}$ curve. To exhibit this, recall that the lattice vectors $\{l^1,l^2\}$ for this geometry are

$$\begin{pmatrix} l^1 \\ l^2 \end{pmatrix}=\begin{pmatrix} 1 & 1 & -1 & -1 & 0 \\ 0 & -1 & -1 & 1 & 1 \end{pmatrix}.$$

Each vector represents a curve C_{s_i} in X_2. Then $C_{s_1+s_2}$ is determined by the single vector

$$l^1+l^2=\begin{pmatrix} 1 & 0 & -2 & 0 & 1 \end{pmatrix}.$$

This curve satisfied $\mathcal{N}_{C_{s_1+s_2}/X_2}\cong\mathcal{O}\oplus\mathcal{O}(-2)$. Hence, we do not expect that we can retrieve its information from the PF system.

We have performed similar computations for three and four parameter cases, all of which support this general principle. This leads us to the following.

Conjecture 2: Let X be a noncompact toric Calabi-Yau threefold with $\dim H_4(X,\mathbb{Z})=0$, *and say* $\{l^1,\ldots l^m\}$ *define X via symplectic quotient. Let* $\omega=\Sigma_{n>0}c(n,\rho)z^{n+\rho}$ *be the generating function for*

$$\Pi_{ij}^{\text{inst}}=\sum_n\left(\partial_{\rho_i}\partial_{\rho_j}c(n,\rho)\right)\big|_{\rho=0}z^n \tag{31}$$

with $c(n,\rho)^{-1}=\Pi_i\Gamma(1+\Sigma_k l_i^k(n_k+\rho_k))$. *If* $\mathcal{F}$ *is the prepotential, and* $s_i=\partial_{\rho_i}\omega|_{\rho=0}$ *for each i such that* $l^i=(1\ \ 1\ \ -1\ \ -1\ \ 0\ \ \ldots\ \ 0)$ (*up to a permutation of the columns of* l^i), *then there are rational numbers* $m_{ij}\in\mathbb{Q}$ *such that*

$$\sum_{i,j}m_{ij}\Pi_{ij}^{\text{inst}}=\sum_i(-1)^{i-1}\frac{\partial\mathcal{F}^{\text{inst}}}{\partial s_i}.$$

Here, $\mathcal{F}^{\text{inst}}$ is the instanton part of the prepotential. We use the notation Π_{ij}^{inst} to distinguish these functions from the usual derivatives of ω (i.e., $\Pi_{ij}=\partial_{\rho_i}\partial_{\rho_j}\omega|_{\rho=0}$). We remark that no linear combination of the Π_{ij} is a solution of the associated PF system; yet, since these functions are essential to the counting of Gromov-Witten invariants in usual mirror symmetry constructions, we have tested the limits of the information they carry. This conjecture is equivalent to the statement that although we cannot detect curves with normal bundle $\mathcal{O}\oplus\mathcal{O}(-2)$ via the Π_{ij}, we can exhibit all curves with normal bundle $\mathcal{O}(-1)\oplus\mathcal{O}(-1)$ using these functions.

Let us now briefly recap what we have explored, and what we have learned, in this section. First, from general principles we know that the PF systems have no double-logarithmic solutions, and hence there are no curve-counting functions on these spaces. Second, we looked at the functions Π_{ij} to determine if we could fix the problem by simply considering some basic extended system (e.g, $\{\mathcal{D}_1,\mathcal{D}_2,\ldots\}\to\{\theta_1\mathcal{D}_1,\theta_2\mathcal{D}_2,\ldots\}$). However, the absence of curves with normal bundle

$\mathcal{O}\oplus\mathcal{O}(-2)$ in the functions Π_{ij} means that we must work a little harder to find the right extended systems. We will now turn to this task, by seeking a way to include such curves in the differential systems.

B. Two building blocks of solutions

Assume X is a noncompact Calabi-Yau threefold such that $\dim H_4(X,\mathbb{Z})=0$, and that every two cycle $C\hookrightarrow X$ has normal bundle $\mathcal{O}\oplus\mathcal{O}(-2)$ or $\mathcal{O}(-1)\oplus\mathcal{O}(-1)$. We will refer to these as t and s curves, respectively, in the following. Then, as any such space X is obtained by gluing s and t curves together in some way, it is reasonable to expect that we can solve all these models by extension from the two basic one parameter cases

$$X_s=\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1,$$

$$X_t=\mathcal{O}\oplus\mathcal{O}(-2)\to\mathbb{P}^1.$$

We have already exhibited the solution on X_s. We will now modify this slightly to allow extension to the general cases, and subsequently demonstrate a similar solution on X_t.

Recall, from Sec. II A, the differential operator for X_s,

$$\widetilde{\mathcal{D}}_1=\theta_s^2(1-z_s)\theta_s^2.$$

As before, $\theta_s=z_s d/\mathrm{d}z_s$, and $\widetilde{Y}_1=1/(1-z_s)$ is the Yukawa coupling. Note that this expression for $\widetilde{Y}_1$ implies a classical triple intersection number 1 for $\mathbb{P}^1\hookrightarrow X_s$.

We will now need to make a slightly different choice of Yukawa coupling on X_s. Recall[17,7] that, in the context of the toric flop $s\to -s$, the natural value for the triple intersection number is $1/2$. There is a simple proof for this, which we give now. From Sec. II A, we had the prepotential on local $\mathbb{P}^1$ with arbitrary triple intersection number [Eq. (16)],

$$\mathcal{F}(z)=K\frac{(\log z)^3}{6}+\sum_{n>0}\frac{z^n}{n^3}. \tag{32}$$

A flop of the $\mathbb{P}^1$ on X_s is the same as a change of variables $z\to 1/z$ in the prepotential

$$\mathcal{F}^{\mathrm{flop}}(z)=K\frac{(-\log z)^3}{6}+\sum_{n>0}\frac{z^{-n}}{n^3}. \tag{33}$$

Taking the difference of these,

$$\mathcal{F}(z)-\mathcal{F}^{\mathrm{flop}}(z)=-\tfrac{1}{3}K(\log z)^3. \tag{34}$$

We have ignored the terms including $\sqrt{-1}$, since the Yukawa coupling is insensitive to them. Then according to Witten,[17] we are supposed to find

$$\mathcal{F}(z)-\mathcal{F}^{\mathrm{flop}}(z)=-\tfrac{1}{6}(\log z)^3, \tag{35}$$

and hence $K=1/2$ is uniquely determined. Recall that the result[17] cited here was derived by considering the analytic continuation of the instanton sum across a flop; the difference in intersection pairings between the geometries X_s and X_{-s} was shown to be -1, which is equivalent to Eq. (35).

This means that we should really be using

$$Y_1 = \frac{1}{2} + \frac{z_s}{1 - z_s}$$

for the Yukawa coupling. We obtain the following differential operator describing mirror symmetry for X_s:

$$\mathcal{D}_1 = \theta_s^2 \left(\frac{2(1 - z_s)}{1 + z_s} \right) \theta_s^2.$$

Next, let us turn to X_t. Note that the naturally occurring PF operator on the mirror to $\mathcal{O} \oplus \mathcal{O}(-2) \to \mathbb{P}^1$, which is $\mathcal{D}_2' = \theta_t^2 - z_t(2\theta_t)(2\theta_t + 1)$, has no curve information, since there is no double-logarithmic solution. Moreover, the second Frobenius derivative of the generating function of solutions has no instanton part. Yet, in view of the solution on X_s, we can easily exhibit a Picard-Fuchs operator for X_t; it is given by

$$\mathcal{D}_2 = \partial_t^2 (1/Y_2) \partial_t^2.$$

Here

$$t(z) = \log(z_t) + 2 \sum_{n>0} \frac{(2n-1)!}{n!^2} z_t^n$$

is the mirror map for X_t, and Y_2 is the Yukawa coupling on X_t, which in these coordinates is

$$Y_2 = - \frac{1 + e^t}{2(1 - e^t)}.$$

Let us briefly discuss the motivation for this choice of Y_2. First of all, we take an overall minus sign on the instanton part of Y_2 relative to the X_s case, because of considerations coming from the topological vertex.[11] Also, the constant term of $-1/2$ is determined from Conjecture 1, i.e., from the requirement of rationality of the B-model Yukawa coupling.

Then, as in the compact case, it follows automatically that the solutions Π_t of $\mathcal{D}_2 \Pi_t = 0$ are given as

$$\Pi_t = \left(1, t, \frac{\partial \mathcal{F}}{\partial t}, t \frac{\partial \mathcal{F}}{\partial t} - 2\mathcal{F} \right),$$

where $\mathcal{F}$ is a holomorphic function in t such that $\partial^3 \mathcal{F} / \partial t^3 = Y_2$. Then it is a simple matter to write down an explicit differential operator on the mirror of X_t, by a change of coordinates for $\mathcal{D}_2$. We find

$$\mathcal{D}_2 = \theta_t^4 - z_t(2\theta_t + 2)(2\theta_t + 1)^2 \theta_t + (z_t)^2 (2\theta_t + 4)(2\theta_t + 3)(2\theta_t + 1) 2\theta_t \quad \left(\theta_t := z_t \frac{d}{\mathrm{d}z_t} \right). \tag{36}$$

The solutions of (36) are generated by the Fröbenius function,

$$w(z_t, \rho) := \sum_{n=0}^{\infty} \frac{1}{\Gamma(1 - 2n - 2\rho)(\Gamma(1 + n + \rho))^2} \left(1 + \sum_{j=1}^{n} \frac{\rho}{j + \rho} \right) z_t^{n+\rho}.$$

We can easily check that the vector space

$$\left\langle 1, t, \frac{\partial \mathcal{F}}{\partial t}, 2\mathcal{F} - t \frac{\partial \mathcal{F}}{\partial t} \right\rangle_{\mathbb{C}},$$

is equal to the vector space

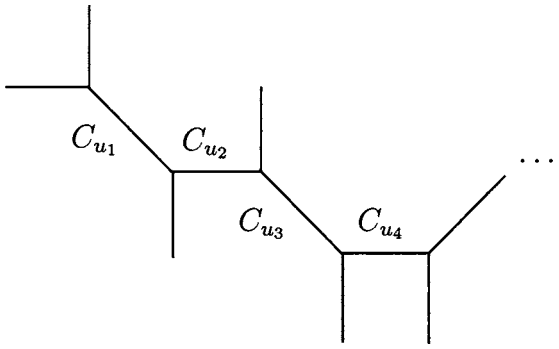

FIG. 4. X containing a string of curves.

$$\langle w(z_t,0), \partial_\rho w(z_t,0), \partial_\rho^2 w(z_t,0), \partial_\rho^3 w(z_t,0)\rangle_{\mathbb{C}}.$$

Hence, we have demonstrated the existence of mirror symmetry for both X_s and X_t, in terms of solutions of differential operators. It should be noted that $\mathcal{D}_1$, $\mathcal{D}_2$ cannot be derived from any GKZ system on these spaces.

We close this section by making a general remark about the constructions here. Note that, on X_t, we have simply taken the known results of Gromov-Witten invariants and translated this into a Picard-Fuchs equation on the mirror. Yet, we view this as an important step towards our ultimate goal, which is a formulation of local mirror symmetry purely in terms of the complex geometry of the mirror $\hat{X}_t$. By a careful study of such operators, we hope to better understand exactly why local mirror symmetry fails on spaces such as X_t.

C. Mirror symmetry when dim $H_4(X,\mathbb{Z})=0$

We can use the results of the preceding section to find a general solution for such spaces, as follows. We are interested in noncompact toric Calabi-Yau threefolds X with dim $H_4(X,\mathbb{Z})=0$ such that for each $C \in H_2(X,\mathbb{Z})$, we have

$$\mathcal{N}_{C/X} \cong \mathcal{O}(-1) \oplus \mathcal{O}(-1)$$

or

$$\mathcal{N}_{C/X} \cong \mathcal{O} \oplus \mathcal{O}(-2).$$

Let $\{C_{s_1},\ldots,C_{s_m},C_{t_1},\ldots,C_{t_n}\}$ is a basis of $H_2(X,\mathbb{Z})$, where $\mathcal{N}_{C_{s_i}/X} \cong \mathcal{O}(-1)\oplus\mathcal{O}(-1)$, $\mathcal{N}_{C_{t_j}/X} \cong \mathcal{O} \oplus \mathcal{O}(-2)\,\forall\, i,j$, and $u=(s_1,\ldots,s_m,t_1,\ldots,t_n)$.

From the topological vertex formalism, the authors of Ref. 11 were able to determine the instanton part of the prepotential for the class of examples we are considering. Explicitly,

$$\mathcal{P}^{\text{inst}} = \sum_{C_s}\sum_{k>0}\frac{e^{ks}}{k^3} - \sum_{C_t}\sum_{k>0}\frac{e^{kt}}{k^3}.$$

Here, the sum over C_s represents the sum over all curves $C_s \hookrightarrow X$ such that $N_{C_s/X} \cong \mathcal{O}(-1)\oplus\mathcal{O}(-1)$, and similarly for the sum over C_t.

As explained in the introduction, our problem reduces to that of defining a consistent (triple) intersection theory on X. Thanks to the simple structure of X, together with our preliminary choice of intersection numbers for $\mathcal{O}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$ and $\mathcal{O}\oplus\mathcal{O}(-2)\to\mathbb{P}^1$, there is in fact a unique choice. We will first give the general definition, and afterward explain its significance through an example. To give the prescription for intersection theory for the general case, we will only consider X with the toric diagram as shown in Fig. 4. That is, only two curves in X are allowed to

intersect at any point. Hence, we exclude cases where three curves meet at one point in X, etc. With this restriction, we can introduce an ordering on the curves in X,

$$C_{u_1} < C_{u_2} < C_{u_3} < \cdots .$$

Define a function

$$\mathrm{sgn}: H_2(X,\mathbb{Z}) \to \{1,-1\}$$

so that $\mathrm{sgn}(C)=1$ if $\mathcal{N}_{C/X} \cong \mathcal{O}(-1)\oplus\mathcal{O}(-1)$, and $\mathrm{sgn}(C)=-1$ otherwise. With these conventions, we can now state our conjecture on intersection theory.

Definition 2: Let X and u be as above. Then the classical intersection numbers for X are given by

$$K_{abc} = \frac{1}{2}\sum_{C\notin\mathcal{A}} \mathrm{sgn}([C_{abc}]+[C]), \tag{37}$$

where the sum is taken in homology, and

$$[C_{abc}] = [C_{u_a}] + \sum_{C_{u_a}<C_\alpha<C_{u_b}} [C_\alpha] + [C_{u_b}] + \sum_{C_{u_b}<C_\beta<C_{u_c}} [C_\beta] + [C_{u_c}].$$

The sum is taken away from the set $\mathcal{A}=\{[C_{u_a}],[C_{u_b}],\ldots,[C_{u_a}+C_{u_{a+1}}],\ldots\}$.

This formula can be most simply understood as follows. The curve of minimum volume containing all three curves C_{u_a}, C_{u_b}, and C_{u_c} can be represented by the homology class

$$[C_{abc}] = [C_{u_a}] + \sum_{C_{u_a}<C_\alpha<C_{u_b}} [C_\alpha] + [C_{u_b}] + \sum_{c_{u_b}<C_\beta<C_{u_c}} [C_\beta] + [C_{u_c}].$$

Then each term of the sum $[C_{abc}]+[C]$ corresponds to a curve in X containing C_{abc}.

For example, consider the case $a=b=c$. Then both of the sums collapse, we are left with only $\mathrm{sgn}([C_{u_a}]+[C])$. The sum will contribute $\pm 1/2$ for each curve containing C_{u_a}, depending on the normal bundle of that curve.

Let us now apply this definition to a concrete case. Consider again the instanton part of the prepotential from example 1 above, Eq. (28),

$$\mathcal{F}^{\mathrm{inst}} = \sum_{n>0} \frac{e^{ns}}{n^3} + \frac{e^{n(s+t)}}{n^3} - \frac{e^{nt}}{n^3}.$$

Then, e.g.,

$$\frac{\partial^3 \mathcal{F}^{\mathrm{inst}}}{\partial s^3} = \sum_{n>0} (e^{ns} + e^{n(s+t)}).$$

Both the s curve and the $s+t$ curve have normal bundle $\mathcal{O}(-1)\oplus\mathcal{O}(-1)$ (this can be seen from the toric diagram, or directly from the vectors defining the secondary fan). Thus, each curve should have an intersection number equal to $1/2$, which implies

$$K_{sss} = \tfrac{1}{2} + \tfrac{1}{2} = 1.$$

By applying similar reasoning, we obtain the other intersection numbers $K_{tss}=K_{tts}=1/2$, $K_{ttt}=0$.

In fact, we can provide a simple argument as to why this is the correct choice of intersection theory for this class of examples. We must only verify that the intersection numbers are consistent under the analytic continuation of the prepotential through a flop transformation. And indeed, the numbers given above are the unique ones that satisfy this requirement.

D. Extended Picard-Fuchs system for X_1 and X_2

In this section, we derive an extended PF system under the assumption of the conjecture given in the preceding section. The operators $\mathcal{D}_i$ appearing below are the same as in Sec. IV A. First, we look at the example X_1. In this case, we start from four A-model Yukawa couplings,

$$\begin{aligned} Y_{ttt} &:= -\frac{e^t}{1-e^t} + \frac{e^{s+t}}{1-e^{s+t}}, \\ Y_{tts} &:= \frac{1}{2} + \frac{e^{s+t}}{1-e^{s+t}}, \\ Y_{tss} &:= \frac{1}{2} + \frac{e^{s+t}}{1-e^{s+t}}, \\ Y_{sss} &:= 1 + \frac{e^s}{1-e^s} + \frac{e^{s+t}}{1-e^{s+t}}. \end{aligned} \tag{38}$$

The constant part of each Yukawa coupling is given by the conjecture, and the instanton (nonconstant) part was taken from Ref. 11. By solving (27), we obtain mirror maps $s=s(z_1,z_2)$ and $t=t(z_1,z_2)$. In particular, the Jacobian of these mirror maps are written in terms of simple functions, as follows:

$$\frac{\partial t}{\partial u_1} = \frac{1}{\sqrt{1-4z_1}}, \quad \frac{\partial t}{\partial u_2} := 0, \quad \frac{\partial s}{\partial u_1} = \frac{1}{2}\frac{-1+4z_1+\sqrt{1-4z_1}}{-1+4z_1}, \quad \frac{\partial s}{\partial u_2} = 1, \tag{39}$$

where $u_i=\log(z_i)$. With this data, we can compute the B-model Yukawa couplings in u^i coordinates, and they turn out to be rational functions in z_i whose denominators are given by the divisor of the defining equation of discriminant locus of $\hat{X}_1$,

$$\mathrm{dis}(\hat{X}_1) = (1-z_2+z_1z_2^2)(1-4z_1). \tag{40}$$

The explicit results are given as follows:

$$\begin{aligned} Y_{111} &= -\frac{1}{2}\frac{z_1(-4z_1+5-7z_2+12z_1z_2+2z_2^2-5z_1z_2^2+4z_1^2z_2^2)}{(1-z_2+z_1z_2^2)(-1+4z_1)^2}, \\ Y_{112} &= -\frac{1}{2}\frac{(1-2z_1-z_2+4z_1z_2-z_1z_2^2+2z_1^2z_2^2)}{(1-z_2+z_1z_2^2)(-1+4z_1)}, \\ Y_{122} &= -\frac{1}{2}\frac{(-1+z_2+z_1z_2^2)}{(1-z_2+z_1z_2^2)}, \\ Y_{222} &= \frac{1-z_1z_2^2}{1-z_2+z_1z_2^2}. \end{aligned} \tag{41}$$

These results show that the conjecture given in the preceding section is compatible with Conjecture 1 in Sec. I. Therefore, we can construct an extended PF system by using the strategy outlined in Sec. II. For brevity, we introduce here the following notation:

$$M_a^{\alpha}(t_*) := \sum_b (Y_a^{-1}(t_*))^{\alpha b}\partial_a\partial_b\psi_0. \tag{42}$$

In the case of X_1, we have two integrability conditions given in (7),

$$M_1^1(s,t) = M_2^1(s,t), \quad M_1^2(s,t) = M_2^2(s,t), \tag{43}$$

where we use the subscripts 1 and 2 for s and t. By explicit computation, these two conditions turn out to be the same, and translated into a differential equation in z_i variables by using (39) and (41), we obtain

$$((1 + z_2 + z_1z_2^2)\mathcal{D}_1 + \mathcal{D}_2 + z_2\mathcal{D}_3)\psi_0 = 0. \tag{44}$$

Next, we consider the second integrability condition given in (8),

$$\partial_1 M_1^1(s,t) = \partial_2 M_2^2(s,t), \quad \partial_2 M_1^1(s,t) = 0, \quad \partial_1 M_2^2(s,t) = 0. \tag{45}$$

By explicit computation, we found that the second and third conditions are translated into one rational differential equation,

$$\theta_2\mathcal{D}_1\psi_0 = 0. \tag{46}$$

The first condition is also translated into a rational differential equation but the result is very complicated. We do not have to use this equation because we can say that (44) and (46) are a minimal set of extended PF operators for X_1. The reason is the following. Let us consider the large radius limit of (44) and (46),

$$(\theta_1^2 + \theta_1\theta_2 - \theta_2^2)\psi_0 = 0, \quad (\theta_1^2\theta_2 - \theta_1\theta_2^2)\psi_0 = 0. \tag{47}$$

These conditions are equivalent to the relations of the classical cohomology ring of $\bar{X}_1$,

$$k_t^2 + k_tk_s - k_s^2 = 0, \quad k_t^2k_s - k_tk_s^2 = 0, \tag{48}$$

which reproduces the conjectured triple intersection numbers, up to an overall scaling. From this fact, we can see that (44) and (46) give us a complete set of relations for the classical cohomology ring of X_1 at the large radius limit. Since the PF equations are nothing but the noncommutative version of the relations of the quantum cohomology ring of X_1, which reduce to relations of classical cohomology at the large radius limit,[8] we can propose the following set of differential operators as an extended PF system:

$$\begin{aligned}\widetilde{\mathcal{D}}_1 &= (1 + z_2 + z_1z_2^2)\mathcal{D}_1 + \mathcal{D}_2 + z_2\mathcal{D}_3,\\ \widetilde{\mathcal{D}}_2 &= \theta_2\mathcal{D}_1.\end{aligned} \tag{49}$$

We checked that the solution space of (49) is given by

$$\left\langle 1, t, s, \frac{\partial\mathcal{F}}{\partial t}, \frac{\partial\mathcal{F}}{\partial s}, 2\mathcal{F} - t\frac{\partial\mathcal{F}}{\partial t} - s\frac{\partial\mathcal{F}}{\partial s}\right\rangle_{\mathbb{C}}. \tag{50}$$

Of course, we can derive the B-model Yukawa couplings (41) by using (49) as the starting point. An explicit example of this kind of computation will be given in Sec. VI of this paper.

We can also construct an extended PF system of X_2 in the same way as X_1. Here, we briefly present the data of this construction. The starting point is the A-model Yukawa couplings,

$$Y_{111} := \frac{e^{s_1}}{1 - e^{s_1}} - \frac{e^{s_1+s_2}}{1 - e^{s_1+s_2}},$$

$$
\begin{aligned}
Y_{112} &:= -\frac{1}{2} - \frac{e^{s_1+s_2}}{1-e^{s_1+s_2}},\\
Y_{122} &:= -\frac{1}{2} - \frac{e^{s_1+s_2}}{1-e^{s_1+s_2}},\\
Y_{222} &:= \frac{e^{s_2}}{1-e^{s_2}} - \frac{e^{s_1+s_2}}{1-e^{s_1+s_2}}.
\end{aligned}
\tag{51}
$$

Let us introduce the logarithm of the B-model coordinates z_i,

$$
u_1 = \log(z_1), \quad u_2 = \log(z_2). \tag{52}
$$

By solving (30), we obtain the mirror maps $s_1=s_1(z_1,z_2)$ and $s_2=s_2(z_1,z_2)$ and their Jacobian,

$$
\begin{aligned}
&\frac{\partial s_1}{\partial u_1} = \frac{1}{2}\frac{(-\sqrt{1-4z_1z_2}-1+4z_1z_2)}{(4z_1z_2-1)}, \quad \frac{\partial s_1}{\partial u_2} = -\frac{1}{2}\frac{(-1+4z_1z_2+\sqrt{1-4z_1z_2})}{(4z_1z_2-1)},\\
&\frac{\partial s_2}{\partial u_1} = -\frac{1}{2}\frac{(-1+4z_1z_2+\sqrt{1-4z_1z_2})}{(4z_1z_2-1)}, \quad \frac{\partial s_2}{\partial u_2} = \frac{1}{2}\frac{(-\sqrt{1-4z_1z_2}-1+4z_1z_2)}{(4z_1z_2-1)}.
\end{aligned}
\tag{53}
$$

With this data, we can compute the B-model Yukawa couplings in u^i,

$$
\begin{aligned}
Y_{111} &= \frac{1}{2}z_1\frac{(5z_1z_2-2-12z_1z_2^2+7z_2+4z_2^3z_1-5z_2^2-4z_1^2z_2^2)}{(z_2-1+z_1)(4z_1z_2-1)^2},\\
Y_{112} &= \frac{1}{2}\frac{(1-z_1-z_2-z_1z_2-z_2z_1^2+z_1z_2^2+4z_1^2z_2^2+4z_2^2z_1^3-4z_2^3z_1^2)}{(z_2-1+z_1)(4z_1z_2-1)^2},\\
Y_{122} &= \frac{1}{2}\frac{(1-z_2-z_1-z_2z_1-z_1z_2^2+z_2z_1^2+4z_2^2z_1^2+4z_1^2z_2^3-4z_1^3z_2^2)}{(z_1-1+z_2)(4z_2z_1-1)^2},\\
Y_{222} &= \frac{1}{2}z_2\frac{(5z_2z_1-2-12z_2z_1^2+7z_1+4z_1^3z_2-5z_1^2-4z_2^2z_1^2)}{(z_1-1+z_2)(4z_2z_1-1)^2},
\end{aligned}
\tag{54}
$$

and they turn out to be rational functions in z_i whose denominators are divisors of defining equation of discriminant locus of $\hat{X}_2$,

$$
\mathrm{dis}(\hat{X}_2) = (1-z_1-z_2)(1-4z_1z_2). \tag{55}
$$

The derivation of the extended PF system by using the recipe in Sec. II proceeds in the same way as X_1. In this case, we must only consider

$$
M_1^1(s_1,s_2) = M_2^1(s_1,s_2), \quad M_1^2(s_1,s_2) = M_2^2(s_1,s_2) \tag{56}
$$

and

$$
\partial_1 M_1^1(s_1,s_2) = \partial_2 M_2^2(s_1,s_2), \quad \partial_2 M_1^1(s_1,s_2) = 0, \quad \partial_1 M_2^2(s_1,s_2) = 0. \tag{57}
$$

Equation (56) gives us one differential equation for ψ_0 with rational function coefficients in z_i,

$$
(\mathcal{D}_1 + \mathcal{D}_2 + (1+z_1+z_2)\mathcal{D}_3)\psi_0 = 0. \tag{58}
$$

As for (57), the second and the third conditions give us a differential equation for ψ_0,

$$(\theta_1 - \theta_2)\mathcal{D}_3\psi_0 = 0, \tag{59}$$

and the first one gives us a complicated rational differential equation. For the same reasoning as X_1, we can propose an extended PF system for X_2 as follows:

$$\begin{aligned}\widetilde{\mathcal{D}}_1 &:= \mathcal{D}_1 + \mathcal{D}_2 + (1 + z_1 + z_2)\mathcal{D}_3,\\ \widetilde{\mathcal{D}}_2 &:= (\theta_1 - \theta_2)\mathcal{D}_3.\end{aligned} \tag{60}$$

We have also constructed an extended PF system for a three parameter space X_3, in order to further test the conjecture made in the preceding section. Specifically, X_3 satisfies $\dim H_2(X,\mathbb{Z}=3)$, $\dim H_4(X,\mathbb{Z}=0)$, and is defined by the following vectors:

$$\begin{pmatrix} l^1 \\ l^2 \\ l^3 \end{pmatrix} = \begin{pmatrix} 1 & 1 & -1 & -1 & 0 & 0 \\ 0 & -1 & -1 & 1 & 1 & 0 \\ 0 & -1 & 1 & 0 & -1 & 1 \end{pmatrix}. \tag{61}$$

The results are collected in Appendix A.

V. ADDING OPEN STRINGS TO $\dot{\mathcal{O}}(-1)\oplus\mathcal{O}(-1)\to\mathbb{P}^1$

So far, we have been able to demonstrate the existence of differential operators which determine mirror symmetry for noncompact toric Calabi-Yau manifolds which have no 4 cycle. One may also wonder what the applications are to the PF system derived for open string mirror symmetry.[14,6] Briefly, we recall that in Ref. 14, a system of Picard-Fuchs differential operators for open strings was proposed. By considering the toric data arising from a noncompact toric Calabi-Yau threefold X and a Lagrangian submanifold $L\subset X$,[14] gives a method of associated PF differential equations, whose solutions are then shown to reproduce known open string mirror symmetry data,[6] subsequently identified the integrals which correspond to these differential operators. Below, we will see that in some cases, the PF system of Ref. 14 also requires extension.

Recall[1,6] that open string mirror symmetry is a local isomorphism of moduli spaces $(\mathcal{X},\mathcal{L})$ and $(\hat{\mathcal{X}},\mathcal{C})$; X and $\hat{X}$ are Calabi-Yau manifolds which are mirror in the usual sense, and $L\subset X$ is Lagrangian, while $C\subset\hat{X}$ is holomorphic. In the case at hand, $(\mathcal{X},\mathcal{L})$ will be given by

$$X_r = \{(w_1,\ldots,w_4) \in \mathbb{C}^4 - Z : |w_1|^2 + |w_2|^2 - |w_3|^2 - |w_4|^2 = r\}/S^1,$$

together with either

$$L_{r,c} = X_r \cap \left\{ |w_2|^2 - |w_4|^2 = c, \quad |w_3|^2 - |w_4|^2 = 0, \quad \sum_i \arg(w_i) = 0 \right\} \tag{62}$$

or

$$L'_{r,c} = X_r \cap \left\{ |w_2|^2 - |w_4|^2 = 0, \quad |w_3|^2 - |w_4|^2 = c, \quad \sum_i \arg(w_i) = 0 \right\}. \tag{63}$$

There are then local moduli space isomorphisms $(\mathcal{X},\mathcal{L})\cong(\hat{\mathcal{X}},\mathcal{C})$, $(\mathcal{X},\mathcal{L}')\cong(\hat{\mathcal{X}},\mathcal{C}')$, where

$$\hat{X}_{z_1} = \{(u,v,y_1,y_2) \in \mathbb{C}^2 \times (\mathbb{C}^*)^2 : uv + 1 + y_1 + y_2 + z_1 y_1 y_2^{-1} = 0\},$$

$$C_{z_1,z_2} = \hat{X}_{z_1} \cap \{y_2^{-1} y_1 = z_2, \quad y_1 = 1\}, \tag{64}$$

$$C'_{z_1,z_2} = \hat{X}_{z_1} \cap \{y_2^{-1} y_1 = 1, \quad y_1 = z_2\}. \tag{65}$$

The detailed derivation of these spaces is given in Ref. 1. One mathematical implication of open string mirror symmetry is that the geometry of $(\hat{X}, C)$ should determine the genus 0 open Gromov-Witten invariants of (X, L). This means that there should be functions defined on the moduli space $(\hat{\mathcal{X}}, \mathcal{C})$ which count holomorphic maps $f: D = \{z \in \mathbb{C} : |z| \leqslant 1\} \to X$ such that $f(\partial D) \subset L$. Furthermore, in many cases such functions can be derived from an open string Picard-Fuchs system on $(\hat{X}, C)$. However, for the case at hand, it will be shown that the same sort of modification of the PF system, proposed for ordinary closed mirror symmetry, is also necessary in the open string setting.

We turn to the PF system on the moduli spaces $(\hat{\mathcal{X}}, \mathcal{C})$ and $(\hat{\mathcal{X}}, \mathcal{C}')$.

From Ref. 6, we can define "open period integrals" on $(\hat{\mathcal{X}}, \mathcal{C})$ by

$$\Pi_\Gamma(z_1, z_2) = \int_\Gamma \frac{du\, dv\, dy_1\, dy_2/(y_1 y_2)}{(uv + 1 + y_1 + y_2 + z_1 y_1 y_2^{-1})(y_1 - z_2 y_2)(y_1 - 1)}, \tag{66}$$

$\Gamma \in H_4(\mathbb{C}^2 \times (\mathbb{C}^*)^2 - \hat{X}, \hat{X} - C, \mathbb{Z})$. Then the derivations in Ref. 6 lead to a Picard-Fuchs system for $(\hat{\mathcal{X}}, \mathcal{C})$, given as

$$\begin{aligned} \mathcal{D}_1 &= \theta_1(\theta_1 + \theta_2) - z_1 \theta_1(\theta_1 + \theta_2), \\ \mathcal{D}_2 &= \theta_2(\theta_1 + \theta_2) - z_2 \theta_2(\theta_1 + \theta_2), \end{aligned} \tag{67}$$

$\theta_i = z_i(d/dz_i)$. These operators satisfy $\mathcal{D}_i \Pi_\Gamma(z_1, z_2) = 0$. This is exactly the noncompact PF system of the vectors $l^1 = (1, 1, -1, -1, 0, 0)$, $l^2 = (0, 1, 0, -1, 1, -1)$, and agrees with the results of Ref. 14.

As was shown in Ref. 3, the solution space of $\{\mathcal{D}_1, \mathcal{D}_2\}$ can be obtained, using the Frobenius method, from a function $\omega_0(z, \rho) = \Sigma_{n \geqslant 0} c(n, \rho) z_1^{n_1 + \rho_1} z_2^{n_2 + \rho_2}$, where $c(n, \rho)$ is

$$\begin{aligned} &\Gamma(1 + n_1 + \rho_1)\Gamma(1 + n_1 + \rho_1 + n_2 + \rho_2)\Gamma(1 - n_1 - \rho_1)\Gamma(1 - n_1 - \rho_1 - n_2 - \rho_2)\Gamma(1 + n_2 + \rho_2) \\ &\times \Gamma(1 - n_2 - \rho_2). \end{aligned} \tag{68}$$

According to Ref. 15, the solutions are expected to be $(1, t_1, t_2, W_1, W_2, \ldots)$. t_1 and t_2 give the open string mirror map, and this is trivial for the present example, so we have $t_i(z) = \log(z_i)$. Also, the W_i count disks on (X, L).

Upon looking at the equations of (X, L), we can make the following geometric observation about a map $f: D \to X$ with $f(\partial D) \subset L$. In the region where $w_3 = w_4 = 0$, L will intersect the $\mathbb{P}^1$ of X; hence, such an f must obey $f(D) \subset \mathbb{P}^1$. Then the natural interpretation of the variable z_2 is as a parameter controlling the size of a holomorphic disk $f(D)$ in X. It is therefore expected that one of the double-logarithmic solutions of (67) will look like

$$W_1(z_2) = \sum_{n > 0} \frac{z_2^n}{n^2}, \tag{69}$$

where the log terms have been disregarded due to ambiguity.[1] And indeed, it is the case that $W_1(z_2) = (\partial_{\rho_2}^2 \omega_0)|_{\rho = 0}$. The problem, though, is that $(\partial_{\rho_2}^2 \omega_0)|_{\rho = 0}$ is not a solution of (67). The easiest way to see this is to note that W_1 is independent of z_1, and (67) reduces to $\mathcal{D}_2 = (1 - z_2)\theta_2^2$ if $z_1 = 0$. The minimal resolution of this issue, which continues in the spirit of extended operators, is to instead work with the system

$$\{\mathcal{D}_1, \theta_2 \mathcal{D}_2\}. \tag{70}$$

W_1 is indeed a solution of these higher order operators.

Similarly, we can perform calculations on the family $(\hat{X}, C')$. This moduli space is given by vectors $k^1 = l^1$, $k^2 = (0, 0, 1, -1, 1, -1)$, and the open string PF system we arrive at is

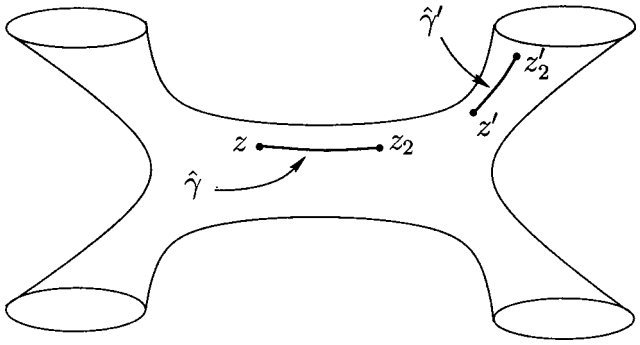

FIG. 5. Real curves defining open string periods on Σ.

$$\mathcal{D}_1' = \theta_1^2 - z_1(\theta_1 - \theta_2)(\theta_1 + \theta_2),$$
$$\mathcal{D}_2' = (\theta_2 - \theta_1)\theta_2 - z_2(\theta_1 + \theta_2)\theta_2. \tag{71}$$

Again, analogously to the above, let ω_0' be the generator of solutions of $\{\mathcal{D}_1', \mathcal{D}_2'\}$. Then there is a disc counting function

$$\partial_{\rho_2}^2 \omega_{0\rho=0}' = W'(z_1, z_2) = \sum_{n_2 > n_1 \geqslant 0} \frac{(-1)^{n_1}(n_1 + n_2 - 1)!}{(n_1\,!)^2(n_2 - n_1)\,!\,n_2} z_1^{n_1} z_2^{n_2} \tag{72}$$

which agrees with the result of Ref. 1. Yet, once again we have the problem of this not being a solution of the given PF system, the same modification gives the system $\{\mathcal{D}_1', \theta_2\mathcal{D}_2'\}$. W' is now among the solutions of this.

Next, we will give an open string period integral definition for these degenerate situations. For motivation, let us review some geometric facts about $(\hat{\mathcal{X}}, \mathcal{C})$. Let y be a local coordinate on Σ. Then following Ref. 1, we can think of the curve C as

$$C_{z_1,z_2} = \hat{X}_{z_1} \cap \{v = 0, y = z_2\} = \mathbb{C} \times \{z_2 \in \Sigma\}.$$

Then the coordinate on $C \cong \mathbb{C}$ is u, and z_2 parametrizes a family of curves in Σ.

Earlier, it was noted that the problem of period integrals was reducible to that of integrals on Σ. Here it is beneficial to make the same simplification. Notice that, when projected to Σ, the family of curves $\{C_{z_1,y} | y \in [z, z_2]\}$ becomes a real curve connecting z to z_2. Hence, the sensible extension of Definition 1 to open strings is the following.

Definition 3: Let $\hat{X}$, Σ be as given in Definition 1, and C as above. Choose z, $z_2 \in \Sigma$ and $\hat{\gamma} \in H_1(\Sigma, \{z, z_2\}, \mathbb{Z})$. Then the open period integrals of $(\hat{\mathcal{X}}, \mathcal{C})$ are defined to be

$$W(z_1, z_2) = \int_{\hat{\gamma}} \mathrm{Res}_{f=0}\left(\frac{dy_1\, dy_2/(y_1 y_2)}{f(z_1, y_1, y_2)} \right).$$

For the purposes of the definition, z is considered to be fixed on Σ, and z_2 is taken as a parameter. In the local $\mathbb{P}^1$ example, the relevant curves $\hat{\gamma}$ are shown in Fig. 5. Note that these are smooth real curves, so that, e.g., $\hat{\gamma}:[0,1] \to \Sigma$ is smooth and such that $\hat{\gamma}(0) = z$, $\hat{\gamma}(1) = z_2$, and similarly for $\hat{\gamma}'$. In Fig. 5, we have abused notation and set $\hat{\gamma} = \hat{\gamma}[0,1]$.

We now move on to the evaluation of these, and show agreement with the solutions of the proposed extended open string PF system of the last section. There are two integrals associated to the curves of the figure, and their calculation proceeds as follows:

$$W(z_1,z_2)=\int_{\hat{\gamma}}\log y_1\frac{dy_2}{y_2}=\int_z^{z_2}\log\left(\frac{-1-y_2}{1+z_1y_2^{-1}}\right)\frac{dy_2}{y_2}=\sum_{n>0}\frac{(-z_2)^n}{n^2}-\sum_{n>0}\frac{(-z_2^{-1}z_1)^n}{n^2}.$$

We also find

$$W'(z_1,z_2)=\int_{\hat{\gamma}'}\log y_2\frac{dy_1}{y_1}=\int_z^{z_2}\log\left(\frac{-1-y_1-\sqrt{(1+y_1)^2-4z_1y_1}}{2}\right)\frac{dy_1}{y_1}.$$

This integral is more difficult to directly evaluate, but as in Ref. 1 we can simply note that

$$z_2\frac{d}{dz_2}W'=\log\left(\frac{-1-z_2-\sqrt{(1+z_2)^2-4z_1z_2}}{2}\right).$$

After Taylor expanding about $z_1=0$ and integrating the result in z_2, this matches (72).

VI. MORE GENERAL LOCAL GEOMETRIES

We have come a long way toward a more complete picture of the differential equations governing local mirror symmetry. However, we have yet to test these ideas in the domain of applicability of Ref. 3; namely, local Calabi-Yau manifolds K_S, where S is a Fano surface and K_S is its canonical bundle. The system of differential operators as given in Ref. 3 is not complete unless

$$\dim H_2(S)=\dim H_4(S). \tag{73}$$

Notice the only surface S satisfying this condition is $\mathbb{P}^2$. We should give some explanation as to what we mean by complete. Assume that there exists a physical definition for a prepotential $\mathcal{F}$ for K_S. Then a double-logarithmic solution W of the Picard-Fuchs system on K_S will satisfy $W=\Sigma_i a_i^W\partial\mathcal{F}/\partial t_i$ for some rational numbers a_i^W, where t_i are logarithmic solutions of the system. Then we cannot integrate the functions W to a single prepotential $\mathcal{F}$ unless there are $\dim H_2(S)$ double-logarithmic solutions; since the set of independent double-logarithmic solutions has the same cardinality as $\dim H_4(S)$, we see that the condition (73) is required. We will now test our techniques on such cases.

A. One one-parameter example

The simplest, though rather trivial, example is $K_{\mathbb{P}^2}=\mathcal{O}(-3)\to\mathbb{P}^2$. This can be defined as a symplectic quotient,

$$K_{\mathbb{P}^2}=\{(w_1,\ldots,w_4)\in\mathbb{C}^4-Z:|w_1|^2+|w_2|^2+|w_3|^2-3|w_4|^2=r\}/S^1,$$

where $Z=\{w_1=w_2=w_3=0\}$, $r\in\mathbb{R}^+$ and the S^1 action is given as $(w_1,\ldots,w_4)\to(e^{i\theta}w_1,e^{i\theta}w_2,e^{i\theta}w_3,e^{-3i\theta}w_4)$. The original paper[3] associates a Picard-Fuchs system here, which is ultimately derivable from the period integrals of the mirror

$$\hat{X}_z=\{(u,v,y_1,y_2)\in\mathbb{C}^2\times(\mathbb{C}^*)^2:uv+1+y_1+y_2+zy_1^{-1}y_2^{-1}=0\}.$$

Again, from Ref. 10,

$$\Pi_\Gamma(z)=\int_\Gamma\frac{du\,dv\,dy_1\,dy_2/(y_1y_2)}{uv+1+y_1+y_2+zy_1^{-1}y_2^{-1}}$$

for $\Gamma\in H_4(\mathbb{C}^2\times(\mathbb{C}^*)^2-\hat{X},\mathbb{Z})$ are the period integrals. Then we immediately recover the well-known PF operator

$$\mathcal{D} = \theta^3 + z(3\theta)(3\theta+1)(3\theta+2), \quad \theta = z\frac{d}{dz},$$

whose solution space is generated by a function $\omega_0(z,\rho)=\Sigma_{n\geqslant 0}c(n,\rho)z^{n+\rho}$. Here, the coefficients can be written $c(n,\rho)^{-1}=\Gamma(1-3n-3\rho)\Gamma(1+n+\rho)^3$. If we write the solutions in the variable $t=\partial_\rho\omega_0|_{\rho=0}$, we get $\Pi=(1,t,\partial\mathcal{F}/\partial t)$. Naturally, this implies that in the t variable, it must be the case that

$$\mathcal{D} = \partial_t\left(\frac{\partial^3\mathcal{F}}{\partial t^3}\right)^{-1}\partial_t^2.$$

Then, we can again give a compactified operator $\partial_t\mathcal{D}$ which possesses a completed set of solutions, i.e., the solution space can be written as

$$\left(1, t, \frac{\partial\mathcal{F}}{\partial t}, 2\mathcal{F} - t\frac{\partial\mathcal{F}}{\partial t}\right). \tag{74}$$

It is actually equivalent to just work with

$$\theta\mathcal{D} = \theta(\theta^3 + z(3\theta)(3\theta+1)(3\theta+2))$$

on account of the invertibility of the Jacobian. This is our extended PF operator.

B. Completing mirror symmetry for Hirzebruch surfaces

One parameter spaces of type K_S have already been exhausted, by the $K_{\mathbb{P}^2}$ case. We will now turn to the two-parameter spaces, namely the canonical bundle over the Hirzebruch surfaces F_0, F_1, F_2. As is well known,[3] the instanton part of the double-log arithmic solution of the standard PF system is given by a linear combination of the $\partial\mathcal{F}_{\text{inst}}/\partial t_a$. This fact tells us that the standard PF system of K_S already includes the information coming from $Y_a^{-1}(t_*)$ in (6). Therefore, we can take a short cut in the process of constructing an extended PF system on K_S. Examples of this explicit construction will be given in the next section.

The symplectic quotient description is given by

$$K_{F_n} = \{-2|w_1|^2 + |w_2|^2 + |w_3|^2 = r_1^n,\ (-2+n)|w_1|^2 - n|w_2| + |w_4|^2 + |w_5|^2 = r_2^n\}/(S^1)^2$$

where $(w_1,\ldots,w_5)\in\mathbb{C}^5 - Z_n$. That is, the vectors in the secondary fan are

$$\begin{pmatrix} l_n^1 \\ l_n^2 \end{pmatrix} = \begin{pmatrix} -2 & 1 & 1 & 0 & 0 \\ -2+n & -n & 0 & 1 & 1 \end{pmatrix}.$$

The methods of Ref. 3 lead to PF operators, K_{F_0},

$$\mathcal{D}_1^0 = \theta_1^2 - z_1(2\theta_1+2\theta_2)(2\theta_1+2\theta_2+1),$$

$$\mathcal{D}_2^0 = \theta_2^2 - z_2(2\theta_1+2\theta_2)(2\theta_1+2\theta_2+1);$$

K_{F_1},

$$\mathcal{D}_1^1 = \theta_1(\theta_1-\theta_2) - z_1(2\theta_1+\theta_2)(2\theta_1+\theta_2+1),$$

$$\mathcal{D}_2^1 = \theta_2^2 - z_2(2\theta_1+\theta_2)(\theta_1-\theta_2);$$

K_{F_2},

$$\mathcal{D}_1^2 = \theta_1(\theta_1-2\theta_2) - z_1 2\theta_1(2\theta_1+1),$$

$$\mathcal{D}_2^2 = \theta_2^2 - z_2(2\theta_2 - \theta_1)(2\theta_2 - \theta_1 + 1).$$

For each respective system, we let t_1^n, t_2^n be the logarithmic solutions. Each case comes equipped with a single double-logarithmic solution W_n. If ω^n is the generating function of solutions on K_{F_n} and $\Pi_{ij}^n = \partial_{\rho_i}\partial_{\rho_j}\omega^n|_{\rho=0}$, then we can write these as

$$W_0 = \Pi_{12}^0, \quad W_1 = \Pi_{11}^1 + 2\Pi_{12}^1, \quad W_2 = \Pi_{11}^2 + \Pi_{12}^2.$$

Taking $\mathcal{F}_n$ for the prepotential on K_{F_n}, we have the following equalities:

$$W_n = 2\frac{\partial \mathcal{F}_n}{\partial t_1^n} + (2-n)\frac{\partial \mathcal{F}_n}{\partial t_2^n}.$$

By a comparison of power series, we can demonstrate that the Π_{ij}^n contain all the information necessary to derive the (instanton part of) the prepotential on K_{F_n}. We find

$$\begin{pmatrix} \Pi_{11}^n \\ \Pi_{12}^n \end{pmatrix} = \begin{pmatrix} 0 & 4 \\ 2 & -3n+2 \end{pmatrix} \begin{pmatrix} \partial \mathcal{F}_n/\partial t_1^n \\ \partial \mathcal{F}_n/\partial t_2^n \end{pmatrix}. \tag{75}$$

The equality above holds at the level of instanton parts of $\mathcal{F}_n$. We will now investigate the classical terms of these prepotentials.

First, we give here the discriminant locus of K_{F_n} where the corresponding mirror hypersurface $\hat{K}_{F_n}$ becomes singular,

$$\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_0}) = 1 - 8(z_1 + z_2) + 16(z_1 - z_2)^2, \tag{76}$$

$$\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_1}) = (1 - 4z_1)^2 - z_2 + 36z_1z_2 - 27z_1z_2^2, \tag{77}$$

$$\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_2}) = (1 - 4z_1)^2 - 64z_1^2z_2. \tag{78}$$

In the K_{F_2} case, there is another component of the discriminant locus defined by $1-4z_2$; we note that this appears in the B-model Yukawa couplings. With these results, Naka determined the B-model Yukawa couplings of K_{F_n} with respect to $u=\log(z_1)$, $v=\log(z_2)$ variables by assuming compatibility with the instanton expansion given by the double-logarithmic solution, and that they should be written in terms of simple rational functions multiplied by $1/\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_n})$,[12] $n=0$,

$$Y_{uuu} = \frac{-4z_1^2 + 4z_2^2 - 4z_1 - 2z_2 + \frac{1}{4}}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_0})}, \quad Y_{uuv} = \frac{4z_1^2 - 4z_2^2 + 2z_2 - \frac{1}{4}}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_0})},$$

$$Y_{uvv} = \frac{-4z_1^2 + 4z_2^2 + 2z_1 - \frac{1}{4}}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_0})}, \quad Y_{vvv} = \frac{4z_1^2 - 4z_2^2 - 2z_1 - 4z_2 + \frac{1}{4}}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_0})};$$

$n=1$,

$$Y_{uuu} = -\frac{((-162x+9)z_1z_2^2 + (96x-4)z_1^2 + (216x-14)z_1z_2 + (5-48x)z_1 - 6x(z_2-1))}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_1})},$$

$$Y_{uuv} = -\frac{((324x-18)z_1z_2^2 + (8-192x)z_1^2 + (25-432x)z_1z_2 + (96x-6)z_1 + (12x-1)(z_2-1))}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_1})},$$

$$Y_{uvv} = -\frac{((36-648x)z_1z_2^2+(384x-16)z_1^2+(864x-44)z_1z_2+(8-192x)z_1-(24x-1)(z_2-1))}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_1})},$$

$$Y_{vvv} = -\frac{((1296x-72)z_1z_2^2+(32-768x)z_1^2+(76-1728x)z_1z_2+(384x-16)z_1+(48x-2)(z_2-1)-z_2)}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_1})},$$

$n=2$,

$$Y_{uuu} = \frac{-1}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_2})}, \quad Y_{uuv} = \frac{2z_1-\frac{1}{2}}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_2})},$$

$$Y_{uvv} = \frac{-z_2(8z_1-1)}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_2})(1-4z_2)}, \quad Y_{vvv} = \frac{-z_2\left(24z_1z_2+2z_1-2z_2-\frac{1}{2}\right)}{\mathrm{dis}(\hat{\mathbf{K}}_{\mathbf{F}_2})(1-4z_2)^2}. \tag{79}$$

In the $n=1$ case, there exists a moduli parameter x that leaves the instanton part of Y_{ijk} invariant. (In the $n=0$ case, we also have one moduli parameter if we do not assume symmetry between u and v.) In other words, we cannot determine the value of x from the compatibility of the instanton numbers. The aim of this section is to give a derivation of these Yukawa couplings by using an extended set of Picard-Fuchs operators of local F_n as the starting point. First, we notice that (79) tells us of the existence of a natural classical triple intersection theory on K_{F_n} compatible with the instanton expansion, $n=0$,

$$\langle k_uk_uk_u\rangle = \tfrac{1}{4}, \quad \langle k_uk_uk_v\rangle = -\tfrac{1}{4}, \quad \langle k_uk_vk_v\rangle = -\tfrac{1}{4}, \quad \langle k_vk_vk_v\rangle = \tfrac{1}{4};$$

$n=1$,

$$\langle k_uk_uk_u\rangle = -6x, \quad \langle k_uk_uk_v\rangle = -1+12x, \quad \langle k_uk_vk_v\rangle = -24x+1, \quad \langle k_vk_vk_v\rangle = -2+48x;$$

$n=2$,

$$\langle k_uk_uk_u\rangle = -1, \quad \langle k_uk_uk_v\rangle = -\tfrac{1}{2}, \quad \langle k_uk_vk_v\rangle = 0, \quad \langle k_vk_vk_v\rangle = 0. \tag{80}$$

In (80), we denote the classical triple intersection numbers of Kähler forms k_u, k_v by $\langle k_uk_uk_u\rangle$, etc. Therefore, we must reproduce (80) from the information obtained from some extended PF system. The key idea of constructing such an extended system becomes more clear upon looking at the triple log series obtained from the generating hypergeometric series of the solution of the PF system,

$$w(u,v,r_1,r_2) := \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} \frac{1}{\prod_{j=0}^{4}\Gamma(1+l_j^1(m+r_1)+l_j^2(n+r_2))}\exp((m+r_1)u+(n+r_2)v). \tag{81}$$

It is well known that $w(u,v,r_1,r_2)|_{(r1,r2)=(0,0)}=1$ is the trivial solution of the PF system, and that the log arithmic solutions $\partial_{r_i}w(u,v,r_1,r_2)|_{(r1,r2)=(0,0)}$ gives us the mirror map t^i. Then we consider the relation between the triple log series $W_{ijk}(u,v) := \partial_{r_i}\partial_{r_j}\partial_{r_k}w(u,v,r_1,r_2)|_{(r1,r2)=(0,0)}$ and the prepotential $\mathcal{F}(t^1,t^2)$ of K_{F_n}. Surprisingly, the classical intersection number (80) is determined from the following assumption:

$$\frac{1}{6}\langle k_u k_u k_u\rangle \cdot W_{111}(u(t_*),v(t_*)) + \frac{1}{2}\langle k_u k_u k_v\rangle \cdot W_{112}(u(t_*),v(t_*)) + \frac{1}{2}\langle k_u k_v k_v\rangle \cdot W_{122}(u(t_*),v(t_*))$$

$$+ \frac{1}{6}\langle k_v k_v k_v\rangle \cdot W_{222}(u(t_*),v(t_*)) = t_1\frac{\partial \mathcal{F}(t_*)}{\partial t_1} + t_2\frac{\partial \mathcal{F}(t_*)}{\partial t_2} - 2\mathcal{F}(t_*), \tag{82}$$

that holds in mirror symmetry of compact Calabi-Yau threefolds if we look at the logarithmic part of the triple log functions. In the $n=0$, 2 cases, we can determine classical intersection number (80) uniquely from the instanton expansion of the right-hand side of (82), but in the $n=1$ case, we have one moduli parameter x that leaves the instanton expansion invariant. Therefore, this situation is the same as in Naka's result. With these intersection numbers, we can construct the set of relations of the classical cohomology ring of K_{F_n} in the sense of Sec. II as follows:
$n=0$,

$$k_u^2 + k_v^2 = 0, \quad k_u k_v^2 - k_u^2 k_v = 0;$$

$n=1$,

$$(24x-1)(k_u^2 - k_u k_v) - (18x-1)k_v^2 = 0, \quad 2k_u k_v^2 + k_v^3 = 0 \quad \left(x \neq \tfrac{1}{24}\right),$$

$$k_v^2 = 0, \quad 2k_u^3 - k_u^2 k_v = 0 \quad \left(x = \tfrac{1}{24}\right);$$

$n=2$,

$$k_v^2 = 0, \quad k_u^3 - 2k_u^2 k_v = 0. \tag{83}$$

With this set up, we can construct an extended Picard-Fuchs system of K_{F_n} that has the same principle part as (83), and is constructed from the linear combination of $\mathcal{D}_i$, $\theta_1\mathcal{D}_i$, $\theta_2\mathcal{D}_i$ ($i=1, 2$), $n=0$,

$$\tilde{\mathcal{D}}_1^0 = \mathcal{D}_1^0 + \mathcal{D}_2^0, \quad \tilde{\mathcal{D}}_2^0 = \theta_1\mathcal{D}_2^0 - \theta_2\mathcal{D}_1^0;$$

$n=1$,

$$\tilde{\mathcal{D}}_1^1 = (24x-1)\mathcal{D}_1^1 - (18x-1)\mathcal{D}_2^1, \quad \tilde{\mathcal{D}}_2^1 = (2\theta_1+\theta_2)\tilde{\mathcal{D}}_2^1 \quad \left(x \neq \tfrac{1}{24}\right),$$

$$\tilde{\mathcal{D}}_1^1 = \mathcal{D}_2^1, \quad \tilde{\mathcal{D}}_2^1 = (2\theta_1+\theta_2)\mathcal{D}_1^1 \quad \left(x = \tfrac{1}{24}\right),$$

$n=2$,

$$\tilde{\mathcal{D}}_1^2 = \mathcal{D}_2^2, \quad \tilde{\mathcal{D}}_2^2 = \theta_1\mathcal{D}_1^2. \tag{84}$$

In the remaining part of this section, we briefly discuss the derivation of the Yukawa coupling of F_0 in (79) by using (84) as the starting point. The other cases can be done in exactly the same way as in this computation. First, we use the standard definition of the B-model Yukawa coupling of mirror symmetry for a compact Calabi-Yau threefold,

$$Y_{ijk} = \int_M \Omega \wedge \partial_i\partial_j\partial_k\Omega. \tag{85}$$

In the case of K_{F_n}, the existence of M and of a global holomomorphic three form Ω are not guaranteed, but we proceed here by assuming the existence of such an M and Ω. We also apply the standard results obtained from Kodaira-Spencer theory on a compact Calabi-Yau threefold to the computation on M. It is easy to show the following formula by application of this machinery:

$$\int_M \Omega \wedge \partial_i\partial_j\partial_k\partial_l\Omega = \frac{1}{2}(\partial_i Y_{jkl} + \partial_j Y_{ikl} + \partial_k Y_{ijl} + \partial_l Y_{ijk}). \tag{86}$$

Next, we derive two relations among different Yukawa couplings obtained from $\theta_1(\mathcal{D}_1^0+\mathcal{D}_2^0)\Omega = \theta_2(\mathcal{D}_1^0+\mathcal{D}_2^0)\Omega=0$,

$$\begin{aligned} Y_{uuu} + Y_{uvv} - 4(z_1+z_2)(Y_{uuu} + 2Y_{uuv} + Y_{uvv}) = 0, \\ Y_{uuv} + Y_{vvv} - 4(z_1+z_2)(Y_{uuv} + 2Y_{uvv} + Y_{vvv}) = 0. \end{aligned} \tag{87}$$

We can also derive another relation from $(\theta_1\mathcal{D}_2^0 - \theta_2\mathcal{D}_1^0)\Omega=0$,

$$Y_{uuv} - 4z_1(Y_{uuv} + 2Y_{uvv} + Y_{vvv}) = Y_{uvv} - 4z_2(Y_{uuu} + 2Y_{uuv} + Y_{uvv}). \tag{88}$$

Since (87) and (88) are linear relations, we can easily solve them and obtain

$$\begin{aligned} Y_{uuu} &= (1 - 16z_1 - 8z_2 - 16z_1^2 + 16z_2^2)S(u,v), \\ Y_{uuv} &= (-1 + 8z_2 + 16z_1^2 - 16z_2^2)S(u,v), \\ Y_{uuv} &= (-1 + 8z_1 + 16z_2^2 - 16z_1^2)S(u,v), \\ Y_{vvv} &= (1 - 16z_2 - 8z_1 - 16z_2^2 + 16z_1^2)S(u,v). \end{aligned} \tag{89}$$

where $S(u,v)$ is an unknown function at this stage. Then we can derive differential equations of $S(u,v)$ from the relations $((\theta_1)^2-(\theta_2)^2)\mathcal{D}_2^0\Omega=((\theta_1)^2-(\theta_2)^2)\mathcal{D}_1^0\Omega=0$ and (86) by substituting the right-handside (rhs) of (89). These operations result in the following differential equations of $S(u,v)$:

$$\begin{aligned} \frac{\partial_u S(u,v)}{S(u,v)} &= \frac{8z_1 - 32z_1^2 + 32z_1z_2}{1 - 8z_1 - 8z_2 + 16z_1^2 - 32z_1z_2 + 16z_2^2}, \\ \frac{\partial_v S(u,v)}{S(u,v)} &= \frac{8z_2 - 32z_2^2 + 32z_1z_2}{1 - 8z_1 - 8z_2 + 16z_1^2 - 32z_1z_2 + 16z_2^2}. \end{aligned} \tag{90}$$

We can immediately solve the above equations and obtain

$$S(u,v) = (\text{const})\frac{1}{1 - 8z_1 - 8z_2 + 16z_1^2 - 32z_1z_2 + 16z_2^2}. \tag{91}$$

Finally, the classical intersection numbers in (80) tell us that $(\text{const})=\frac{1}{4}$.

VII. THE DEL PEZZO SURFACE K_{dP_2}

We can also look to a three-parameter model, in order to determine what we might expect in more general situations (Fig. 6). The examples of the two-parameter case might cause one to hope that, for every local geometry of the form K_S, we can extend the original PF system to give a complete description of mirror symmetry from the B-model geometry alone. Here we will demonstrate that this is indeed the case for K_{dP_2}. However, it is no longer necessary to use a higher order system for three and higher parameter cases; we can find a complete set of solutions by "forgetting" about some of the originally proposed local mirror symmetry operators.

The symplectic quotient description of K_{dP_2} may be written as

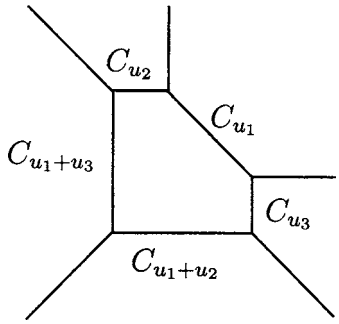

FIG. 6. The del Pezzo dP_2. Each curve C_{u_i} corresponds to a vector l^i.

$$\left\{(w_1,\ldots,w_6)\in\mathbb{C}^6-Z:\sum_{k=1}^{6} l_k^i|w_k|^2=r_i\,,i=1,2,3\right\}/(S^1)^3$$

with the vectors

$$\begin{pmatrix} l^1 \\ l^2 \\ l^3 \end{pmatrix} = \begin{pmatrix} -1 & 1 & -1 & 1 & 0 & 0 \\ -1 & -1 & 1 & 0 & 0 & 1 \\ -1 & 0 & 1 & -1 & 1 & 0 \end{pmatrix}.$$

Note that $b_2=3$ and $b_4=1$. This comes with PF operators

$$\begin{aligned}
\mathcal{D}_1 &= (\theta_1-\theta_2)(\theta_1-\theta_3)-z_1(\theta_1+\theta_2+\theta_3)(\theta_1-\theta_2-\theta_3),\\
\mathcal{D}_2 &= (\theta_2+\theta_3-\theta_1)\theta_2-z_2(\theta_1+\theta_2+\theta_3)(\theta_2-\theta_1),\\
\mathcal{D}_3 &= (\theta_2+\theta_3-\theta_1)\theta_3-z_3(\theta_1+\theta_2+\theta_3)(\theta_3-\theta_1),\\
\mathcal{D}_4 &= \theta_2(\theta_1-\theta_3)-z_1z_2(\theta_1+\theta_2+\theta_3+1)(\theta_1+\theta_2+\theta_3),\\
\mathcal{D}_5 &= \theta_3(\theta_1-\theta_2)-z_1z_3(\theta_1+\theta_2+\theta_3+1)(\theta_1+\theta_2+\theta_3).
\end{aligned} \tag{92}$$

Let $\mathcal{F}$, t_1, t_2, t_3 and the Π_{ij}'s be as before. Then Ref. 3 provides a single double-logarithmic solution W, corresponding to the 4 cycle in the base of the A-model geometry, which satisfies

$$W=\Pi_{11}+\Pi_{12}+\Pi_{13}+\Pi_{23}=\frac{\partial\mathcal{F}}{\partial t_1}+\frac{\partial\mathcal{F}}{\partial t_2}+\frac{\partial\mathcal{F}}{\partial t_3}.$$

The naive approach in this case suggests that we need to add two 4 cycles to the A-model geometry. Using as motivation the notion that each double-logarithmic solution of the system should correspond to a 4 cycle on the mirror, we are led to work with a system consisting of three of the original five PF differential operators. For reasons to be discussed shortly, we will use the set

$$\begin{aligned}
\tilde{\mathcal{D}}_1 &= (6x+2y-1)(\mathcal{D}_1-\mathcal{D}_2-\mathcal{D}_3)-x(\mathcal{D}_2+\mathcal{D}_3),\\
\tilde{\mathcal{D}}_2 &= (5x+y-1)(\mathcal{D}_2+\mathcal{D}_3+\mathcal{D}_4+\mathcal{D}_5)+(x+y)(\mathcal{D}_4+\mathcal{D}_5),
\end{aligned} \tag{93}$$

$$\widetilde{\mathcal{D}}_3 = (x-y-1)(\mathcal{D}_2 - \mathcal{D}_3 + \mathcal{D}_4 - \mathcal{D}_5) + (x-y)(\mathcal{D}_4 - \mathcal{D}_5),$$

where x and y are real free parameters. If we set $(x,y)=(0,0)$, we can easily show that a basis of the solution space with double-logarithmic singularities is three dimensional, and is provided by

$$\Pi_{12} = \frac{\partial \mathcal{F}}{\partial t_2}, \quad \Pi_{13} = \frac{\partial \mathcal{F}}{\partial t_3}, \quad \Pi_{11} + \Pi_{23} = \frac{\partial \mathcal{F}}{\partial t_1}. \tag{94}$$

Hence, we can recover the full prepotential from solutions of the PF system alone. We expect that this phenomenon will continue to hold true in all cases of the type K_S.

The extended PF system of K_{dP_2} (93) is derived in the same way as K_{F_n}. Let us introduce the logarithm of the standard B-model coordinates z_i,

$$u_1 = \log(z_1), \quad u_2 = \log(z_2), \quad u_3 = \log(z_3), \tag{95}$$

and consider the generating function of solutions of the PF system (92),

$$w(u_1,u_2,u_3,r_1,r_2,r_3) := \sum_{n_1=0}^{\infty}\sum_{n_2=0}^{\infty}\sum_{n_3=0}^{\infty} \frac{1}{\prod_{j=0}^{5}\Gamma(1+l_j^1(n_1+r_1)+l_j^2(n_2+r_2)+l_j^3(n_3+r_3))} \times \exp((n_1+r_1)u_1+(n_2+r_2)u_2+(n_3+r_3)u_3). \tag{96}$$

The mirror map of K_{dP_2} is given by

$$t_i(u_*) := \partial_{r_i} w(u_1,u_2,u_3,r_1,r_2,r_3)_{r_i=0}. \tag{97}$$

From the triple-logarithmic function

$$W_{ijk}(u_1,u_2,u_3) := \partial_{r_i}\partial_{r_2}\partial_{r_3} w(u_1,u_2,u_3,r_1,r_2,r_3)_{r_i=0}, \tag{98}$$

obtained from (96), we can find the classical triple intersection number $\langle k_{u_i}k_{u_j}k_{u_m}\rangle$ of Kähler forms k_{u_i} by assuming the following relation:

$$\begin{aligned}
&\frac{1}{6}\langle k_{u_1}k_{u_1}k_{u_1}\rangle W_{111}(u_1(t_*),u_2(t_*),u_3(t_*)) + \frac{1}{6}\langle k_{u_2}k_{u_2}k_{u_2}\rangle W_{222}(u_1(t_*),u_2(t_*),u_3(t_*)) \\
&\quad + \frac{1}{6}\langle k_{u_3}k_{u_3}k_{u_3}\rangle W_{333}(u_1(t_*),u_2(t_*),u_3(t_*)) + \frac{1}{2}\langle k_{u_1}k_{u_1}k_{u_2}\rangle W_{112}(u_1(t_*),u_2(t_*),u_3(t_*)) \\
&\quad + \frac{1}{2}\langle k_{u_1}k_{u_2}k_{u_2}\rangle W_{122}(u_1(t_*),u_2(t_*),u_3(t_*)) + \frac{1}{2}\langle k_{u_2}k_{u_2}k_{u_3}\rangle W_{223}(u_1(t_*),u_2(t_*),u_3(t_*)) \\
&\quad + \frac{1}{2}\langle k_{u_2}k_{u_3}k_{u_3}\rangle W_{233}(u_1(t_*),u_2(t_*),u_3(t_*)) + \frac{1}{2}\langle k_{u_1}k_{u_1}k_{u_3}\rangle W_{113}(u_1(t_*),u_2(t_*),u_3(t_*)) \\
&\quad + \frac{1}{2}\langle k_{u_1}k_{u_3}k_{u_3}\rangle W_{133}(u_1(t_*),u_2(t_*),u_3(t_*)) + \langle k_{u_1}k_{u_2}k_{u_3}\rangle W_{123}(u_1(t_*),u_2(t_*),u_3(t_*)) \\
&= t_1\frac{\partial \mathcal{F}(t_*)}{\partial t_1} + t_2\frac{\partial \mathcal{F}(t_*)}{\partial t_2} + t_3\frac{\partial \mathcal{F}(t_*)}{\partial t_3} - 2\mathcal{F}(t_*),
\end{aligned} \tag{99}$$

where we used instanton expansion part of $\mathcal{F}(t_1,t_2,t_3)$ read off from the double-logarithmic solution of (92). Taking the symmetry between k_{u_2} and k_{u_3} into account, we found the following classical intersection numbers with two free parameters (in this case, we have four moduli parameters unless we assume symmetry between k_{u_2} and k_{u_3}) x and y:

$$\langle k_{u_1}k_{u_1}k_{u_1}\rangle = -1+6x+2y, \quad \langle k_{u_2}k_{u_2}k_{u_2}\rangle = -y, \quad \langle k_{u_3}k_{u_3}k_{u_3}\rangle = -y, \quad \langle k_{u_1}k_{u_1}k_{u_2}\rangle = -3x-y,$$

$$\langle k_{u_1}k_{u_2}k_{u_2}\rangle = x+y, \quad \langle k_{u_2}k_{u_2}k_{u_3}\rangle = -x, \quad \langle k_{u_2}k_{u_3}k_{u_3}\rangle = -x, \quad \langle k_{u_1}k_{u_1}k_{u_3}\rangle = -3x-y,$$

$$\langle k_{u_1}k_{u_3}k_{u_3}\rangle = x+y, \quad \langle k_{u_1}k_{u_2}k_{u_3}\rangle = -1+2x. \tag{100}$$

With this data, we can construct a complete set of relations of k_{u^i} that reproduce (100) as follows:

$$R_1 = (6x+2y-1)(p_1-p_2-p_3) - x(p_2+p_3),$$

$$R_2 = (5x+y-1)(p_2+p_3+p_4+p_5) + (x+y)(p_4+p_5), \tag{101}$$

$$R_3 = (x-y-1)(p_2-p_3+p_4-p_5) + (x-y)(p_4-p_5),$$

where

$$p_1 = (k_{u_1}-k_{u_2})(k_{u_1}-k_{u_3}), \quad p_2 = k_{u_2}(k_{u_2}+k_{u_3}-k_{u_1}), \quad p_3 = k_{u_3}(k_{u_2}+k_{u_3}-k_{u_1}),$$

$$p_4 = k_{u_2}(k_{u_1}-k_{u_3}), \quad p_5 = k_{u_3}(k_{u_1}-k_{u_2}). \tag{102}$$

The extended PF system (93) is obtained from linear combinations of the $\mathcal{D}_i$'s that reduce to (101) at the large radius limit. Of course, we can compute the B-model Yukawa coupling of K_{dP_2} by using (93) as the starting point in the same way as F_0, and we collect the resulting Yukawa couplings in Appendix B.

VIII. CONCLUSION

Through a variety of examples, we have seen the emergence of a set of differential operators for local mirror symmetry. In this sense, we may view this as a next step towards a complete treatment of the program initiated in Ref. 3. There are, however, some outstanding issues. First, our constructions have taken for granted the instanton expansion from the A model. In principle, we would like to be able to canonically associate an extended Picard-Fuchs system to a B-model geometry without reference to the A model. Second, it would be interesting to exhibit a family of Calabi-Yau manifolds parametrized by a complex structure such that the period integrals agreed with the ones we find as solutions to the extended Picard-Fuchs system. We leave these questions for future work.

APPENDIX A: AN EXTENDED PICARD-FUCHS SYSTEM FOR X_3

Here, we apply our conjecture on intersection theory for X satisfying $\dim H_4(X,\mathbb{Z})=0$ to a three-parameter example, in order to more fully explore its applicability. We will work with

$$X_3 = \{(w_1,\ldots,w_6) \in \mathbb{C}^6 - Z : \sum_{k=1}^{6} l_k^i |w_k|^2 = r_i, \quad i=1,2,3\}/(S^1)^3$$

where

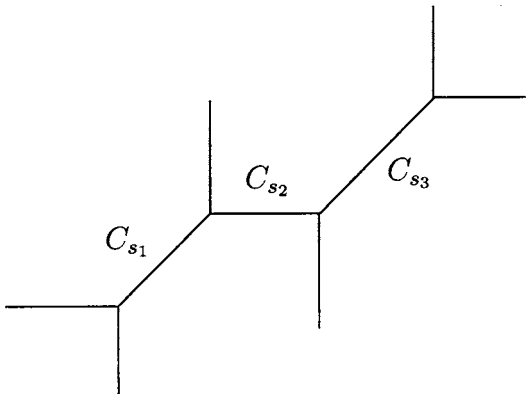

FIG. 7. Toric graph for X_3.

$$\begin{pmatrix} l^1 \\ l^2 \\ l^3 \end{pmatrix} = \begin{pmatrix} 1 & 1 & -1 & -1 & 0 & 0 \\ 0 & -1 & -1 & 1 & 1 & 0 \\ 0 & -1 & 1 & 0 & -1 & 1 \end{pmatrix}. \tag{A1}$$

The toric graph is provided in Fig. 7. Then X_3 has no 4 cycle, and for each curve C_{s_i} corresponding to the secondary fan vector l^i, we have that $\mathcal{N}_{C_{s_i}/X_3} \cong \mathcal{O}(-1) \oplus \mathcal{O}(-1)$.

By making use of the instanton parts given in Ref. 11 and our conjecture, we immediately have the Yukawa couplings.

A-**model Yukawa couplings of** X_3 **(with respect to** s_i**)**,

$$Y_{111} = \frac{1}{2} + \frac{e^{s_1}}{1-e^{s_1}} - \frac{e^{s_1+s_2}}{1-e^{s_1+s_2}} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{113} = \frac{1}{2} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{113} = \frac{1}{2} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{333} = \frac{1}{2} + \frac{e^{s_3}}{1-e^{s_3}} - \frac{e^{s_3+s_2}}{1-e^{s_3+s_2}} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{112} = -\frac{e^{s_1+s_2}}{1-e^{s_1+s_2}} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{233} = -\frac{e^{s_3+s_2}}{1-e^{s_3+s_2}} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{122} = -\frac{e^{s_1+s_2}}{1-e^{s_1+s_2}} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{223} = -\frac{e^{s_3+s_2}}{1-e^{s_3+s_2}} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{222} = \frac{e^{s_2}}{1-e^{s_2}} - \frac{e^{s_1+s_2}}{1-e^{s_1+s_2}} - \frac{e^{s_3+s_2}}{1-e^{s_3+s_2}} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}},$$

$$Y_{123} = \frac{1}{2} + \frac{e^{s_1+s_2+s_3}}{1-e^{s_1+s_2+s_3}}, \tag{A2}$$

Once we have these, the rest of the calculations are routine. We list the results here.

Ordinary Picard-Fuchs system of X_3,

$$\begin{aligned}
\mathcal{D}_1 &= \theta_1(\theta_1-\theta_2-\theta_3) - z_1(\theta_1-\theta_2)(\theta_1+\theta_2-\theta_3),\\
\mathcal{D}_2 &= (\theta_2-\theta_1)(\theta_2-\theta_3) - z_2(\theta_2+\theta_3-\theta_1)(\theta_2+\theta_1-\theta_3),\\

(Received 13 January 2005; accepted 3 June 2005; published online 5 August 2005)

Superselection and constraints occur together in many gauge theories, and here we begin a study of such systems. Our main focus will be to analyze compatibility questions between constraining and superselection, and we will develop an example modelled on QED in which our framework is realized. We proceed from a generalization of Doplicher-Roberts superselection theory to the case of the nontrivial center, and a set of Dirac quantum constraints and find conditions under which the superselection structures will survive constraining in some form. This involves an analysis of the restriction and factorization of superselection structures. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1985038]

I. INTRODUCTION

In heuristic quantum field theory, there are many examples of systems which contain global charges (hence superselection structure) as well as a local gauge symmetry (hence constraints). Most of these systems cannot currently be written in a consistent mathematical framework, due to the presence of interactions. Nevertheless, the mathematical structure of superselection by itself has been properly developed (cf. Refs. 1–3), as well as the mathematical structure of quantum constraints (Refs. 4–6), hence one can at least abstractly consider systems which contain both. This will be the focus of our investigations in this paper, which is a first step in this direction. We will address the natural intertwining questions for the two structures, as well as compatibility issues. Unfortunately, in spite of our physical motivation the discussion will be unavoidably technical, but we have an interesting model which goes at least part way to illustrating our general setting.

The class of physical systems with both superselection and constraints, is a large one. One of the most important examples in this class, is that of a quantized local gauge field, acting on a fermion field. It has a Gauss law constraint (implementing the local gauge transformations) as well as a set of global charges (leading to superselection). An important feature of it, is that the global gauge transformations preserve the set of constraints, and we will assume this property for the systems we analyze. There are plenty of other examples of systems satisfying this property, e.g., the constraints can be independent of the global gauge group, for instance, they can be equations of motion, or restriction to a submanifold. Or there may be two or more local gauge symmetries which commute (e.g., isospin and electromagnetism), in which case the Gauss law constraint of one symmetry will commute with the global charges of the other.

We will be concerned with the question of under what conditions (and how much of) the

[a)]Electronic mail: baumg@rz.uni-potsdam.de
[b)]Electronic mail: hendrik@maths.unsw.edu.au

superselection structures will survive the constraining procedure. Since charge is a physically measurable quantity, this should survive constraining, which removes nonphysical information from the system.

For superselection, we will use the Doplicher-Roberts theory which originated in the Doplicher-Haag-Roberts concept of admissible representations.[2] In the context of a local net of von Neumann algebras on Minkowski space with a distinguished vacuum representation π_0, a representation π is *admissible* if on the C*-algebra associated to the causal complement of any double cone, π is unitarily equivalent to π_0. In physical terms this means that π and the vacuum π_0 cannot be distinguished at spacelike infinity (e.g., if the only difference is a finite charge in some bounded set). The unitary equivalence classes of admissible representations (e.g., corresponding to different total charges) are in bijection with a class of "canonical endomorphisms" by $\pi \cong \pi_0 \circ \rho$, and this leads to the study of these endomorphisms, and the construction of a *Hilbert system* from them. These concepts will all be defined and discussed in Sec. II, where we include recent results for an observable algebra with nontrivial center (cf. Ref. 7). The Doplicher-Haag-Roberts theory is presently not directly applicable to QED due to the presence of massless particles, however we were able to realize the abstract Doplicher-Roberts version explicitly in our model, using the global charge.

For quantum constraints, we will use the framework developed by Grundling and Hurst[4,8,5] which is based on Dirac's constraint theory, and produced physically correct results on application to QEM and other systems. The basic idea is to select those cyclic representations of the field algebra, where the cyclic vector is annihilated by the constraints. The observables consist of those elements of the field algebra which map a vector annihilated by the constraints to another such vector in any representation. These satisfy a "weak commutativity" condition with the constraints, so can be identified with Dirac's observables. There are quite a number of diverse quantum constraint methods available in the literature at various levels of rigour (cf. Ref. 6). The one we use here is the most congenial from the point of view of C*-algebraic methods, and we summarize it in Sec. III. In fact, in Ref. 5 it was shown that this method can avoid indefinite inner product representations (endemic to gauge theories), yet it produced the same results as those obtained from such representations.

In Sec. IV we collect our main results. The proofs for these are in Sec. VI, and in Sec. V we present our example which is based on the Maxwell equation in (interacting) QED.

II. FUNDAMENTALS OF SUPERSELECTION

In this section we summarize the structures from superselection theory which we need. For proofs, we refer to the literature if possible.

The superselection problem in algebraic quantum field theory, as stated by the Doplicher-Haag-Roberts (DHR) selection criterion, led to a profound body of work, culminating in the general Doplicher-Roberts (DR) duality theory for compact groups. The DHR criterion selects a distinguished class of "admissible" representations of a quasilocal algebra $\mathcal{A}$ of observables, where the center is trivial, i.e., $Z(\mathcal{A}) = \mathbb{C}1$, or even $\mathcal{A}$ is assumed to be simple. This corresponds to the selection of a DR-category $\mathcal{T}$ of "admissible" endomorphisms of $\mathcal{A}$. Furthermore, from this endomorphism category $\mathcal{T}$ the DR-analysis constructs a C*-algebra $\mathcal{F} \supset \mathcal{A}$ together with a compact group action $\alpha: \mathcal{G} \ni g \to \alpha_g \in \mathrm{Aut}\,\mathcal{F}$ such that

(i) $\mathcal{A}$ is the fixed point algebra of this action,
(ii) $\mathcal{T}$ coincides with the category of all "canonical endomorphisms" of $\mathcal{A}$ (cf. Sec. II C).

$\mathcal{F}$ is called a Hilbert extension of $\mathcal{A}$ in Ref. 3. Physically, $\mathcal{F}$ is identified as a field algebra and $\mathcal{G}$ with a global gauge group of the system. $\{\mathcal{F}, \alpha_{\mathcal{G}}\}$ is uniquely determined by $\mathcal{T}$ up to $\mathcal{A}$-module isomorphisms. Conversely, $\{\mathcal{F}, \alpha_{\mathcal{G}}\}$ determines uniquely its category of all canonical endomorphisms. Therefore one can state the equivalence of the "selection principle," given by $\mathcal{T}$ and the "symmetry principle," given by $\mathcal{G}$. This duality is one of the crucial theorems of the Doplicher-Roberts theory.

In contrast to the original theory of Doplicher and Roberts, we allow here a nontrivial center for $\mathcal{A}$. The reason for this is that when there are constraints present, the system contains nonphysical information, so there is no physical reason why $\mathcal{A}$ should be simple. Only after eliminating the constraints should one require the final observable algebra to be simple, hence having trivial center. Now a duality theorem for a C*-algebra with nontrivial center has been proven recently,[7,9] establishing a bijection between distinguished categories of endomorphisms of $\mathcal{A}$ and Hilbert extensions of $\mathcal{A}$ satisfying some additional conditions, of which the most important is $\mathcal{A}' \cap \mathcal{F} = Z(\mathcal{A})$ (i.e., the relative commutant is assumed to be minimal). This will be properly explained below. This condition has already been used by Mack and Schomerus[10] as a "new principle."

A. Basic properties of Hilbert systems

Below $\mathcal{F}$ will always denote a unital C*-algebra. A Hilbert space $\mathcal{H} \subset \mathcal{F}$ is called algebraic if the scalar product $\langle \cdot, \cdot \rangle$ of $\mathcal{H}$ is given by $\langle A, B \rangle \mathbb{1} := A^* B$ for $A, B \in \mathcal{H}$. Henceforth we consider only finite-dimensional algebraic Hilbert spaces. The support $\operatorname{supp} \mathcal{H}$ of $\mathcal{H}$ is defined by $\operatorname{supp} \mathcal{H} := \Sigma_{j=1}^{d} \Phi_j \Phi_j^*$, where $\{\Phi_j | j = 1, \ldots, d\}$ is any orthonormal basis of $\mathcal{H}$. *Unless otherwise specified, we assume below that each algebraic Hilbert space $\mathcal{H}$ considered, satisfies* $\operatorname{supp} \mathcal{H} = \mathbb{1}$.

We also fix a compact C*-dynamical system $\{\mathcal{F}, \mathcal{G}, \alpha\}$, i.e., $\mathcal{G}$ is a compact group and $\alpha: \mathcal{G} \ni g \to \alpha_g \in \operatorname{Aut} \mathcal{F}$ is a pointwise norm-continuous morphism. For $\gamma \in \hat{\mathcal{G}}$ (the dual of $\mathcal{G}$) its spectral projection $\Pi_\gamma \in \mathcal{L}(\mathcal{F})$ is defined by

$$\Pi_\gamma(F) := \int_{\mathcal{G}} \overline{\chi_\gamma(g)} \alpha_g(F) \mathrm{d}g \quad \text{for all } F \in \mathcal{F},$$

where

$$\chi_\gamma(g) := \dim \gamma \cdot \operatorname{Tr} \pi(g), \quad \pi \in \gamma$$

and its spectral subspace $\Pi_\gamma \mathcal{F}$ satisfies $\Pi_\gamma \mathcal{F} = \text{clo-span}\{\mathcal{L} \subset \mathcal{F}\}$ where $\mathcal{L}$ runs through all invariant subspaces of $\mathcal{F}$ which transform under $\alpha_\mathcal{G}$ according to γ (cf. Ref. 11). Define the spectrum of $\alpha_\mathcal{G}$ by

$$\operatorname{spec} \alpha_\mathcal{G} := \{\gamma \in \hat{\mathcal{G}} | \Pi_\gamma \neq 0\}.$$

Our central object of study is the following.

Definition 2.1: The C*-*dynamical system* $\{\mathcal{F}, \mathcal{G}, \alpha\}$ *is called a* Hilbert system *if for each* $\gamma \in \hat{\mathcal{G}}$ *there is an algebraic Hilbert space* $\mathcal{H}_\gamma \subset \mathcal{F}$, *such that* $\alpha_\mathcal{G}$ *acts invariantly on* $\mathcal{H}_\gamma$, *and the unitary representation* $\mathcal{G} \upharpoonright \mathcal{H}_\gamma$ *is in the equivalence class* $\gamma \in \hat{\mathcal{G}}$.

Remark 2.2: Note that for a Hilbert system $\{\mathcal{F}, \mathcal{G}, \alpha\}$ we have necessarily that the algebraic Hilbert spaces satisfy $\mathcal{H}_\gamma \subset \Pi_\gamma \mathcal{F}$ for all γ, and hence that $\operatorname{spec} \alpha_\mathcal{G} = \hat{\mathcal{G}}$, i.e., the spectrum is *full*. The morphism $\alpha: \mathcal{G} \to \operatorname{Aut} \mathcal{F}$ is necessarily faithful. So, since $\mathcal{G}$ is compact and $\operatorname{Aut} \mathcal{F}$ is Hausdorff with respect to the topology of pointwise norm convergence, α is a homeomorphism of $\mathcal{G}$ onto its image. Thus $\mathcal{G}$ and $\alpha_\mathcal{G}$ are isomorphic as topological groups.

We are mainly interested in Hilbert systems whose fixed point algebras coincide such that they appear as extensions of it.

Definition 2.3: A Hilbert system $\{\mathcal{F}, \mathcal{G}, \alpha\}$ *is called a* Hilbert extension *of a C*-algebra* $\mathcal{A} \subset \mathcal{F}$ *if* $\mathcal{A}$ *is the fixed point algebra of* $\mathcal{G}$. *Two Hilbert extensions* $\{\mathcal{F}_i, \mathcal{G}, \alpha^i\}$, $i = 1, 2$ *of* $\mathcal{A}$ *(with respect to the same group* $\mathcal{G}$*) are called* $\mathcal{A}$-module isomorphic *if there is an isomorphism* $\tau: \mathcal{F}_1 \to \mathcal{F}_2$ *such that* $\tau(A) = A$ *for* $A \in \mathcal{A}$, *and* τ *intertwines the group actions, i.e.,* $\tau \circ \alpha_g^1 = \alpha_g^2 \circ \tau$.

Remark 2.4: (i) Group automorphisms of $\mathcal{G}$ lead to $\mathcal{A}$-module isomorphic Hilbert extensions of $\mathcal{A}$, i.e., if $\{\mathcal{F}, \mathcal{G}, \alpha\}$ is a Hilbert extension of $\mathcal{A}$ and ξ an automorphism of $\mathcal{G}$, then the Hilbert extensions $\{\mathcal{F}, \mathcal{G}, \alpha\}$ and $\{\mathcal{F}, \mathcal{G}, \alpha \circ \xi\}$ are $\mathcal{A}$-module isomorphic. So the Hilbert system $\{\mathcal{F}, \mathcal{G}, \alpha\}$ depends, up to $\mathcal{A}$-module isomorphisms, only on $\alpha_\mathcal{G}$, which is isomorphic to $\mathcal{G}$. In other words, up to $\mathcal{A}$-module isomorphism we may identify $\mathcal{G}$ and $\alpha_\mathcal{G} \subset \operatorname{Aut} \mathcal{F}$ neglecting the action α which has

no relevance from this point of view. Therefore in the following, unless it is otherwise specified, we use the notation $\{\mathcal{F},\mathcal{G}\}$ for a Hilbert extension of $\mathcal{A}$, where $\mathcal{G}\subset \mathrm{Aut}\,\mathcal{F}$.

(ii) As mentioned above, examples of Hilbert systems arise in DHR-superselection theory (cf. Refs. 3 and 2). There are also constructions by means of tensor products of Cuntz algebras (cf. Ref. 12). In these examples the relative commutant of the fixed point algebra $\mathcal{A}$, hence also its center, is trivial. Another construction for $\mathcal{G}=\mathbb{T}$, by means of the loop group $C^\infty(S^1,\mathbb{T})$ is in Ref. 13, and for this $Z(\mathcal{A})$ is nontrivial.

Remark 2.5: A Hilbert system $\{\mathcal{F},\mathcal{G}\}$ is a highly structured object; we list some important facts and properties (for details, consult Refs. 2 and 3).

(i) The spectral projections satisfy

$$\Pi_{\gamma_1}\Pi_{\gamma_2}=\Pi_{\gamma_2}\Pi_{\gamma_1}=\delta_{\gamma_1\gamma_2}\Pi_{\gamma_1},$$

$$\|\Pi_\gamma\|\leqslant d(\gamma)^{3/2},\quad d(\gamma):=\dim(\mathcal{H}_\gamma),$$

$$\Pi_\gamma\mathcal{F}=\mathrm{span}(\mathcal{A}\mathcal{H}_\gamma),\quad \Pi_\iota\mathcal{F}=\mathcal{A},$$

where $\iota\in\hat{\mathcal{G}}$ denotes the trivial representation of $\mathcal{G}$.

(ii) Each $F\in\mathcal{F}$ is uniquely determined by its projections $\Pi_\gamma F$, $\gamma\in\hat{\mathcal{G}}$, i.e., $F=0$ iff $\Pi_\gamma F=0$ for all $\gamma\in\hat{\mathcal{G}}$, cf. Corollary 2.6 of Ref. 9.

(iii) A useful *-subalgebra of $\mathcal{F}$ is

$$\mathcal{F}_{\mathrm{fin}}:=\{F\in\mathcal{F}|\Pi_\gamma F\neq 0 \text{ for only finitely many } \gamma\in\hat{\mathcal{G}}\}$$

which is dense in $\mathcal{F}$ with respect to the C*-norm (cf. Ref. 14).

(iv) In $\mathcal{F}$ there is an $\mathcal{A}$-scalar product given by $\langle F,G\rangle_{\mathcal{A}}:=\Pi_\iota FG^*$, with respect to which the spectral projections are symmetric, i.e., $\langle\Pi_\gamma F,G\rangle_{\mathcal{A}}=\langle F,\Pi_\gamma G\rangle_{\mathcal{A}}$ for all $F,G\in\mathcal{F}$, $\gamma\in\hat{\mathcal{G}}$. Using the $\mathcal{A}$-scalar product one can define a norm on $\mathcal{F}$, called the $\mathcal{A}$-norm,

$$|F|_{\mathcal{A}}:=\|\langle F,F\rangle_{\mathcal{A}}\|^{1/2},\quad F\in\mathcal{F}.$$

Note that $|F|_{\mathcal{A}}\leqslant\|F\|$ and that $\mathcal{F}$ in general is not closed with respect to the $\mathcal{A}$-norm. Then for each $F\in\mathcal{F}$ we have that $F=\Sigma_{\gamma\in\hat{\mathcal{G}}}\Pi_\gamma F$ where the sum on the right-hand side is convergent with respect to the $\mathcal{A}$-norm but not necessarily with respect to the C*-norm $\|\cdot\|$. We also have Parseval's equation, $\langle F,F\rangle_{\mathcal{A}}=\Sigma_{\gamma\in\hat{\mathcal{G}}}\langle\Pi_\gamma F,\Pi_\gamma F\rangle_{\mathcal{A}}$, cf. Proposition 2.5 in Ref. 9. Moreover $|\Pi_\gamma|_{\mathcal{A}}=1$ for all $\gamma\in\hat{\mathcal{G}}$, where $|\cdot|_{\mathcal{A}}$ denotes the operator norm of Π_γ with respect to the norm $|\cdot|_{\mathcal{A}}$ in $\mathcal{F}$.

(v) Generally for a Hilbert system, the assignment $\gamma\to\mathcal{H}_\gamma$ is not unique. If $U\in\mathcal{A}$ is unitary then also $U\mathcal{H}_\gamma\subset\Pi_\gamma\mathcal{F}$ is a $\mathcal{G}$-invariant algebraic Hilbert space carrying the representation $\gamma\in\hat{\mathcal{G}}$. Each $\mathcal{G}$-invariant algebraic Hilbert space $\mathcal{K}$ which carries the representation γ is of this form, i.e., there is a unitary $V\in\mathcal{A}$ such that $\mathcal{K}=V\mathcal{H}_\gamma$. For a general $\mathcal{G}$-invariant algebraic Hilbert space $\mathcal{H}\subset\mathcal{F}$, we may have that $\mathcal{G}\restriction\mathcal{H}$ is not irreducible, i.e., it need not be of the form $\mathcal{K}=V\mathcal{H}_\gamma$. Below we will consider further conditions on the Hilbert system to control the structure of these.

(vi) Given two $\mathcal{G}$-invariant algebraic Hilbert spaces $\mathcal{H}$, $\mathcal{K}\subset\mathcal{F}$, then $\mathrm{span}(\mathcal{H}\cdot\mathcal{K})$ is also a $\mathcal{G}$-invariant algebraic Hilbert space which we will briefly denote by $\mathcal{H}\cdot\mathcal{K}$. It is a realization of the tensor product $\mathcal{H}\otimes\mathcal{K}$ within $\mathcal{F}$ and carries the tensor product of the representations of $\mathcal{G}$ carried by $\mathcal{H}$ and $\mathcal{K}$ in the obvious way.

(vii) Let $\mathcal{H}$, $\mathcal{K}$ be two $\mathcal{G}$-invariant algebraic Hilbert spaces, but not necessarily of support 1. Then there is a natural isometric embedding $\mathcal{J}:\mathcal{L}(\mathcal{H},\mathcal{K})\to\mathcal{F}$ given by

$$\mathcal{J}(T) := \sum_{j,k} t_{j,k} \Psi_j \Phi_k^*, \quad t_{j,k} \in \mathbb{C}, \quad T \in \mathcal{L}(\mathcal{H},\mathcal{K}),$$

where $\{\Phi_k\}_k$, $\{\Psi_j\}_j$ are orthonormal bases of $\mathcal{H}$ and $\mathcal{K}$, respectively, and where

$$T(\Phi_k) = \sum_j t_{j,k} \Psi_j,$$

i.e., $(t_{j,k})$ is the matrix of T with respect to these orthonormal bases. One has

$$T(\Phi) = \mathcal{J}(T) \cdot \Phi, \quad \Phi \in \mathcal{H}.$$

This implies the following: if $T_j \in \mathcal{L}(\mathcal{H}_j,\mathcal{K}_j)$, $j=1, 2$, hence $T_1 \otimes T_2 \in \mathcal{L}(\mathcal{H}_1\mathcal{H}_2,\mathcal{K}_1\mathcal{K}_2)$, then $\mathcal{J}(T_1 \otimes T_2)\Phi_1\Phi_2 = \mathcal{J}(T_1)\Phi_1\mathcal{J}(T_2)\Phi_2$ for $\Phi_j \in \mathcal{H}_j$. Moreover $\mathcal{J}(T) \in \mathcal{A}$ iff $T \in \mathcal{L}_\mathcal{G}(\mathcal{H},\mathcal{K})$, where $\mathcal{L}_\mathcal{G}(\mathcal{H},\mathcal{K})$ denotes the linear subspace of $\mathcal{L}(\mathcal{H},\mathcal{K})$ consisting of all intertwining operators of the representations of $\mathcal{G}$ on $\mathcal{H}$ and $\mathcal{K}$ (cf. Ref. 3, p. 222).

B. The category of $\mathcal{G}$-invariant algebraic Hilbert spaces

The $\mathcal{G}$-invariant algebraic Hilbert spaces $\mathcal{H}$ of $\{\mathcal{F},\mathcal{G}\}$ form the objects of a category $\mathcal{T}_\mathcal{G}$ associated to $\{\mathcal{F},\mathcal{G}\}$ whose arrows are given by the elements of $(\mathcal{H},\mathcal{K}) := \mathcal{J}(\mathcal{L}_\mathcal{G}(\mathcal{H},\mathcal{K})) \subset \mathcal{A}$. It is already large enough to carry all tensor products of the representations of $\mathcal{G}$ on its objects by Remark 2.5(vi) (though not necessarily subrepresentations and direct sums). First, let us state some of its rich structure (cf. Refs. 3 and 12).

Proposition 2.6: For $\{\mathcal{F},\mathcal{G}\}$ the category $\mathcal{T}_\mathcal{G}$ is a tensor C*-category, *i.e., the arrow spaces $(\mathcal{H},\mathcal{K})$ are Banach spaces such that*

(i) *with respect to composition of arrows R, S we have $\|R \circ S\| \leqslant \|R\| \, \|S\|$,*
(ii) *there is an antilinear involutive contravariant functor $*: \mathcal{T}_\mathcal{G} \to \mathcal{T}_\mathcal{G}$ such that $\|R^* \circ R\| = \|R\|^2$ for all arrows R with the same range and domain (here the functor * is given by the involution in $\mathcal{F}$).*
(iii) *There is an associative product $\cdot$ on* Ob $\mathcal{T}_\mathcal{G}$ *and an identity object $1 \in$* Ob $\mathcal{T}_\mathcal{G}$ *(i.e., $1 \cdot \mathcal{H} = \mathcal{H} = \mathcal{H} \cdot 1$) and there is an associative bilinear product $\times$ of the arrows, such that if $R \in (\mathcal{H},\mathcal{K})$ and $R' \in (\mathcal{H}',\mathcal{K}')$ then $R \times R' \in (\mathcal{H} \cdot \mathcal{H}', \mathcal{K} \cdot \mathcal{K}')$. Moreover we require that for R, R' as above,*

$$1_\iota \times R = R \times 1_\iota = R, \quad (R \times R')^* = R^* \times R'^*, \tag{1}$$

where $1_\iota \in (1,1)$ is the identity arrow, as well as the interchange law

$$(S \circ R) \times (S' \circ R') = (S \times S') \circ (R \times R'),$$

whenever the left-hand side is defined. Here in $\mathcal{T}_\mathcal{G}$, the product $\cdot$ is given by the product of $\mathcal{F}$, the identity object is $1 := \mathbb{C}\,\mathbb{I}$ and the product $\times$ is defined by

$$R \times R' := \mathcal{J}(T \otimes T'),$$

for $R = \mathcal{J}(T)$, $R' = \mathcal{J}(T')$, where $T \in \mathcal{L}_\mathcal{G}(\mathcal{H},\mathcal{K})$, $T' \in \mathcal{L}_\mathcal{G}(\mathcal{H}',\mathcal{K}')$. Note that $(1,1) = (\mathbb{C}\,\mathbb{I}, \mathbb{C}\,\mathbb{I}) = \mathbb{C}\,\mathbb{I}$, i.e., $1_\iota = \mathbb{I}$.

$\mathcal{T}_\mathcal{G}$ has additional important structures (permutation and conjugation), which we will consider below in Sec. II D.

We need to examine conditions on $\{\mathcal{F},\mathcal{G}\}$ to ensure that $\mathcal{T}_\mathcal{G}$ carries subrepresentations and direct sums.

Definition 2.7: Let $\mathcal{H}$, $\mathcal{K} \in$ Ob $\mathcal{T}_\mathcal{G}$*, and define $\mathcal{H} < \mathcal{K}$ to mean that there is an orthoprojection E on $\mathcal{K}$ such that $E\mathcal{K}$ is invariant with respect to $\mathcal{G}$ and the representation $\mathcal{G}|\mathcal{H}$ is unitarily equivalent to $\mathcal{G}|E\mathcal{K}$. Call $\mathcal{H}$ a* subobject *of $\mathcal{K}$.*

It is easy to see that $<$ is a partial order. Note that $\mathcal{H}<\mathcal{K}$ iff there is an isometry $V \in \mathcal{L}_{\mathcal{G}}(\mathcal{H},\mathcal{K})$ such that $VV^* =: E$ is a projection of $\mathcal{K}$, i.e., $V\mathcal{H}=E\mathcal{K}$. Then $\mathcal{J}(V) \in \mathcal{A}$ and $E\mathcal{K} = \mathcal{J}(V)\cdot\mathcal{H}$.

If $E \in \mathcal{L}_{\mathcal{G}}(\mathcal{K})$ is an orthoprojection $0<E<\mathbb{I}$, i.e., E is a reducing projection for the representation of $\mathcal{G}$ on $\mathcal{K}$, then the question arises whether there is an object $\mathcal{H}$ such that the representations on $\mathcal{H}$ and $E\mathcal{K}$ are unitarily equivalent. This suggests the concept of *closedness* of $\mathcal{T}_{\mathcal{G}}$ with respect to subobjects.

Definition 2.8: The category $\mathcal{T}_{\mathcal{G}}$ is closed with respect to subobjects *if to each $\mathcal{K} \in Ob\ \mathcal{T}_{\mathcal{G}}$ and to each nontrivial orthoprojection $E \in \mathcal{L}_{\mathcal{G}}(\mathcal{K})$ there is an isometry $\hat{V} \in \mathcal{A}$ with $\hat{V}\hat{V}^* = \mathcal{J}(E)$. In this case $\mathcal{H} := \hat{V}^*\cdot\mathcal{K}$ is a subobject $\mathcal{H}<\mathcal{K}$ assigned to E, where $\hat{V}=\mathcal{J}(V)$ for some isometry $V \in \mathcal{L}_{\mathcal{G}}(\mathcal{H},\mathcal{K})$ with $VV^*=E$.*

Next, we consider when an object of $\mathcal{T}_{\mathcal{G}}$ carries the direct sum of the representations of two other objects. If V, $W \in \mathcal{A}$ are isometries with $VV^*+WW^*=\mathbb{I}$ and $\mathcal{H}$, $\mathcal{K} \in \mathrm{Ob}\ \mathcal{T}_{\mathcal{G}}$ then we call the algebraic Hilbert space $V\mathcal{H}+W\mathcal{K}$ of support 1 a direct sum of $\mathcal{H}$ and $\mathcal{K}$. It is $\mathcal{G}$-invariant and carries the direct sum of the representations on $\mathcal{H}$ and $\mathcal{K}$ but in general depends on the choice of isometries V, W. We define the following.

Definition 2.9: (i) The category $\mathcal{T}_{\mathcal{G}}$ is closed with respect to direct sums *if to each $\mathcal{H}_1$, $\mathcal{H}_2 \in \mathrm{Ob}\ \mathcal{T}_{\mathcal{G}}$ there is an object $\mathcal{K} \in \mathrm{Ob}\ \mathcal{T}_{\mathcal{G}}$ and there are isometries V_1, $V_2 \in \mathcal{A}$ with $V_1V_1^*+V_2V_2^*=\mathbb{I}$ such that $\mathcal{K}=V_1\mathcal{H}_1+V_2\mathcal{H}_2$ [then $V_1 \in (\mathcal{H}_1,\mathcal{K})$ and $V_2 \in (\mathcal{H}_2,\mathcal{K})$ follow].*

(ii) A C^*-algebra $\mathcal{A}$ satisfies Property B *if there are isometries V_1, $V_2 \in \mathcal{A}$ such that $V_1V_1^* + V_2V_2^*=\mathbb{I}$. A Hilbert system $\{\mathcal{F},\mathcal{G}\}$ is said to satisfy* Property B *if its fixed point algebra $\mathcal{A} := \Pi_\iota\mathcal{F}$ satisfies Property B.*

Remark 2.10: For a Hilbert system $\{\mathcal{F},\mathcal{G}\}$ we have the following.

(i) It satisfies Property B iff $\mathcal{T}_{\mathcal{G}}$ is closed with respect to direct sums.
(ii) For non-Abelian $\mathcal{G}$, the category $\mathcal{T}_{\mathcal{G}}$ is closed with respect to subobjects iff it is closed with respect to direct sums iff it has Property B, cf. Proposition 3.5 of Ref. 9.
(iii) In the case that $\mathcal{G}$ is Abelian, the theory simplifies. This is because we already have Pontryagin's duality theorem, hence it is not necessary to consider closure under subobjects and direct sums to obtain a duality theory.

C. The category of canonical endomorphisms

The main aim of DR theory is to obtain an intrinsic structure on $\mathcal{A}$ from which we can reconstruct the Hilbert system $\{\mathcal{F},\mathcal{G}\}$ in an essentially unique way. Here we want to transport the rich structure of $\mathcal{T}_{\mathcal{G}}$ to $\mathcal{A}$.

Definition 2.11: To each $\mathcal{G}$-invariant algebraic Hilbert space $\mathcal{H}\subset\mathcal{F}$ there is assigned a corresponding inner endomorphism $\rho_{\mathcal{H}} \in \mathrm{End}\ \mathcal{F}$ *given by*

$$\rho_{\mathcal{H}}(F) := \sum_{j=1}^{d(\mathcal{H})} \Phi_j F \Phi_j^*,$$

where $\{\Phi_j | j=1,\ldots,d(\mathcal{H})\}$ is any orthonormal basis of $\mathcal{H}$. Note that $\rho_{\mathcal{H}}$ preserves $\mathcal{A}$. A canonical endomorphism *is the restriction of an inner endomorphism to $\mathcal{A}$, i.e., it is of the form $\rho_{\mathcal{H}}\restriction\mathcal{A} \in End\ \mathcal{A}$.*

Remark 2.12: (i) The definition of the canonical endomorphisms uses $\mathcal{F}$ explicitly. The question arises whether the canonical endomorphisms can be characterized by intrinsic properties within $\mathcal{A}$. This interplay between the $\rho_{\mathcal{H}}$ and the $\rho_{\mathcal{H}}\restriction\mathcal{A}$ plays an essential role in the DR theory. Below, we omit the restriction symbol and regard the $\rho_{\mathcal{H}}$ also as endomorphisms of $\mathcal{A}$.

(ii) If the emphasis is only on the representation γ and not on its corresponding algebraic Hilbert space $\mathcal{H}_\gamma$, we will write ρ_γ instead of $\rho_{\mathcal{H}_\gamma}$.

(iii) Note that $\Phi A=\rho_{\mathcal{H}}(A)\Phi$ for all $\Phi \in \mathcal{H}$ and $A \in \mathcal{A}$.

(iv) Note that the identity endomorphism ι is assigned to $\mathcal{H}=\mathbb{C}\,\mathbb{I}$, i.e., $\rho_{\mathbb{C}\mathbb{I}} := \iota$.

(v) Let $\mathcal{H}$, $\mathcal{K}$ be as before, then $\rho_{\mathcal{H}}\circ\rho_{\mathcal{K}}=\rho_{\mathcal{H}\cdot\mathcal{K}}$.

(vi) The map ρ from Ob $\mathcal{T}_{\mathcal{G}}$ to the canonical endomorphisms is in general not injective. In fact we have the following: if $\mathcal{H}$, $\mathcal{K}\in$ Ob $\mathcal{T}_{\mathcal{G}}$, then $\rho_{\mathcal{H}}\restriction\mathcal{A}=\rho_{\mathcal{K}}\restriction\mathcal{A}$ iff $\Psi^*\Phi\in\mathcal{A}'\cap\mathcal{F}$ for all $\Phi\in\mathcal{H}$, $\Psi\in\mathcal{K}$, cf. Proposition 3.9 in Ref. 9.

Definition 2.13: Define $\mathcal{T}$ to be the category with objects the canonical endomorphisms, and arrows the intertwiner spaces, where the intertwiner space *of canonical endomorphisms σ, $\tau\in$ End $\mathcal{A}$ is*

$$(\sigma,\tau):=\{X\in\mathcal{A}\,|\,X\sigma(A)=\tau(A)X \text{ for all } A\in\mathcal{A}\},$$

and this is a complex Banach space. For $A\in(\sigma,\sigma')$, $B\in(\tau,\tau')$, we define $A\times B:=A\sigma(B)\in(\sigma\tau,\sigma'\tau')$. We will say that σ, $\tau\in$ End $\mathcal{A}$ are mutually disjoint *if $(\sigma,\tau)=\{0\}$ when $\sigma\neq\tau$.*

Remark 2.14: (i) We have $(\iota,\iota)=Z(\mathcal{A}):=$ center of $\mathcal{A}$.

(ii) The composition of two canonical endomorphisms [which corresponds to products of the generating Hilbert spaces, see Remark 2.13 (v), i.e., to tensor products of representations] satisfies the correct compatibility conditions with the product $\times$ of intertwiners to ensure that $\mathcal{T}$ is a C*-tensor category cf. Proposition 2.6 and Ref. 1. The identity object is ι.

(iii) Recall the isometry $\mathcal{J}:\mathcal{L}_{\mathcal{G}}(\mathcal{H},\mathcal{K})\to\mathcal{A}$ encountered in Remark 2.5 (vii). We claim that its image is in fact contained in $(\rho_{\mathcal{H}},\rho_{\mathcal{K}})$. To see this, let $\Phi\in\mathcal{H}$, $A\in\mathcal{A}$, and $T\in\mathcal{L}_{\mathcal{G}}(\mathcal{H},\mathcal{K})$. Then

$$\mathcal{J}(T)\rho_{\mathcal{H}}(A)\Phi=\mathcal{J}(T)\Phi\cdot A=T(\Phi)\cdot A=\rho_{\mathcal{K}}(A)T(\Phi)=\rho_{\mathcal{K}}(A)\mathcal{J}(T)\cdot\Phi$$

hence

$$\mathcal{J}(T)\rho_{\mathcal{H}}(A)=\rho_{\mathcal{K}}(A)\mathcal{J}(T),$$

i.e., $\mathcal{J}(T)\in(\rho_{\mathcal{H}},\rho_{\mathcal{K}})$ or

$$(\mathcal{H},\mathcal{K})=\mathcal{J}(\mathcal{L}_{\mathcal{G}}(\mathcal{H},\mathcal{K}))\subseteq(\rho_{\mathcal{H}},\rho_{\mathcal{K}}). \tag{2}$$

In general, the inclusion is proper. Note that for $R\in(\mathcal{H},\mathcal{K})$, $R'\in(\mathcal{H}',\mathcal{K}')$ we have $\mathcal{J}(R\otimes R')=R\rho_{\mathcal{H}}(R')$, i.e., $\times$ restricted to the $(\mathcal{H},\mathcal{K})$'s coincides with the definition of $\times$ in Proposition 2.6 of the category $\mathcal{T}_{\mathcal{G}}$.

Next we would like to define the concepts of subobject and direct sums on Ob $\mathcal{T}$ compatibly with those on Ob $\mathcal{T}_{\mathcal{G}}$ under the morphism ρ. Recall that $\mathcal{H}<\mathcal{K}$ iff we have an isometry $V\in\mathcal{L}_{\mathcal{G}}(\mathcal{H},\mathcal{K})$ and a projection $E\in\mathcal{L}_{\mathcal{G}}(\mathcal{K})$ with $V\mathcal{H}=E\mathcal{K}=\mathcal{J}(E)\cdot\mathcal{K}=\mathcal{J}(V)\cdot\mathcal{H}$. Then by (2) we get that $\mathcal{J}(V)\in(\rho_{\mathcal{H}},\rho_{\mathcal{K}})$ and $\mathcal{J}(E)\in(\rho_{\mathcal{K}},\rho_{\mathcal{K}})$.

Note that if $\mathcal{L}=V\mathcal{H}+W\mathcal{K}$ for isometries V, $W\in\mathcal{A}$ with $VV^*+WW^*=\mathbb{1}$, then $V\in(\rho_{\mathcal{H}},\rho_{\mathcal{L}})$ and $W\in(\rho_{\mathcal{K}},\rho_{\mathcal{L}})$.

Definition 2.15: (i) $\tau\in$ Ob $\mathcal{T}$ is a subobject *of $\sigma\in$ Ob $\mathcal{T}$, denoted $\tau<\sigma$, if there is an isometry $V\in(\tau,\sigma)$. In this case $\tau(\cdot)=V^*\sigma(\cdot)V$ and $VV^*=:E\in(\sigma,\sigma)$ follow.*

(ii) $\lambda\in$ Ob $\mathcal{T}$ is a direct sum *of σ, $\tau\in$ Ob $\mathcal{T}$, if there are isometries $V\in(\sigma,\lambda)$, $W\in(\tau,\lambda)$ with $VV^*+WW^*=\mathbb{1}$ such that*

$$\lambda(\cdot)=V\sigma(\cdot)V^*+W\tau(\cdot)W^*.$$

Remark 2.16: (i) The subobject relation $\tau<\sigma$ is again a partial order, because $\tau<\sigma$ and $\sigma<\mu$ imply the existence of isometries $V\in(\tau,\sigma)$, $W\in(\sigma,\mu)$. Then $WV\in(\tau,\mu)$ is also an isometry, i.e., $\tau<\mu$.

(ii) A direct sum as defined above is only unique up to unitary equivalence, i.e., if λ, λ' are direct sums of σ, $\tau\in$ Ob $\mathcal{T}$, then there is a unitary $U\in(\lambda,\lambda')$.

(iii) We have $\rho_{V\mathcal{H}+W\mathcal{K}}(\cdot)=V\rho_{\mathcal{H}}(\cdot)V^*+W\rho_{\mathcal{K}}(\cdot)W^*$ where the isometries V, $W\in\mathcal{A}$ satisfy $VV^*+WW^*=\mathbb{1}$. Also, if $\mathcal{H}<\mathcal{K}$, then $\tau:=\rho_{\mathcal{H}}<\rho_{\mathcal{K}}=:\sigma$. However, this does not mean that the partial order $\tau<\sigma$ can be *defined* by $\mathcal{H}<\mathcal{K}$ because the transitivity can be violated for some choices of $\mathcal{H}$, $\mathcal{K}$, cf. Remark 2.12 (vi).

The closedness of $\mathcal{T}$ with respect to direct sums is defined by the closedness of $\mathcal{T}_\mathcal{G}$ with respect to direct sums. The closedness with respect to subobjects for $\mathcal{T}$ is defined by the closedness with respect to subobjects for $\mathcal{T}_\mathcal{G}$ in the following sense: If

$$\lambda = \rho_\mathcal{H} \in \mathrm{Ob}\,\mathcal{T} \tag{3}$$

is given then for all $\mathcal{H}$ satisfying (3) and to each nontrivial projection $E \in \mathcal{J}(\mathcal{L}_\mathcal{G}(\mathcal{H}))$ there is an isometry $V \in \mathcal{A}$ with $VV^* = E$. Then we have the following.

Proposition 2.17: If $\{\mathcal{F},\mathcal{G}\}$ is non-Abelian and satisfies Property B then $\mathcal{T}$ is closed with respect to direct sums and subobjects.

D. Connection between $\mathcal{T}_\mathcal{G}$ and $\mathcal{T}$ and further structures

In the following we assume that $\{\mathcal{F},\mathcal{G}\}$ satisfies Property B.

There is a very important relation between the two categories $\mathcal{T}_\mathcal{G}$ and $\mathcal{T}$, obtained as follows. The two assignments $\rho: \mathrm{Ob}\,\mathcal{T}_\mathcal{G} \to \mathcal{T}$ (by $\mathcal{H} \to \rho_\mathcal{H}$) and $\mathcal{J}: \mathcal{L}_\mathcal{G}((\mathcal{H},\mathcal{K})) \to (\rho_\mathcal{H},\rho_\mathcal{K})$ combine into a faithful categorial morphism from $\mathcal{T}_\mathcal{G}$ to $\mathcal{T}$ which is compatible with direct sums and subobjects [cf. Remark 2.16 (iii)] but is not full in general, i.e., the inclusion in Eq. (2) is improper for some $\mathcal{H}$ and $\mathcal{K}$. If $\mathcal{A}' \cap \mathcal{F} = \mathbb{C}\,\mathbb{1}$, then this categorial morphism becomes an isomorphism, cf. Proposition 3.12 in Ref. 9.

The category $\mathcal{T}_\mathcal{G}$ has the following additional structures (Refs. 3 and 12).

Proposition 2.18: For $\{\mathcal{F},\mathcal{G}\}$ the category $\mathcal{T}_\mathcal{G}$ satisfies

(1) *it has a* permutation structure, *i.e., a map ϵ from* $\mathrm{Ob}\,\mathcal{T}_\mathcal{G} \times \mathrm{Ob}\,\mathcal{T}_\mathcal{G}$ *into the arrows such that*

- (i) $\epsilon(\mathcal{H},\mathcal{K}) \in (\mathcal{H}\mathcal{K},\mathcal{K}\mathcal{H})$ *is a unitary*,
- (ii) $\epsilon(\mathcal{H},\mathcal{K})\epsilon(\mathcal{K},\mathcal{H}) = \mathbb{1}$,
- (iii) $\epsilon(1,\mathcal{H}) = \epsilon(\mathcal{H},1) = \mathbb{1}$,
- (iv) $\epsilon(\mathcal{H}\mathcal{K},\mathcal{L}) = \epsilon(\mathcal{H},\mathcal{L})\rho_\mathcal{H}(\epsilon(\mathcal{K},\mathcal{L}))$,
- (v) $\epsilon(\mathcal{H}',\mathcal{K}')A \times B = B \times A\epsilon(\mathcal{H},\mathcal{K})$ *for all* $A \in (\mathcal{H},\mathcal{H}')$, $B \in (\mathcal{K},\mathcal{K}')$.

For $\mathcal{T}_\mathcal{G}$ the permutation structure is given by

$$\epsilon(\mathcal{H},\mathcal{K}) := \mathcal{J}(\Theta(\mathcal{H},\mathcal{K})) = \sum_{j,k} \Psi_j \Phi_k \Psi_j^* \Phi_k^*,$$

where Θ is the flip operator $\mathcal{H}\otimes\mathcal{K} \to \mathcal{K}\otimes\mathcal{H}$, and where $\{\Phi_k\}_k$, $\{\Psi_j\}_j$ are orthonormal bases of $\mathcal{H}$ and $\mathcal{K}$, respectively.

(2) *It has a* conjugation structure, *i.e., for each $\mathcal{H} \in \mathrm{Ob}\,\mathcal{T}_\mathcal{G}$ there is a conjugated object $\bar{\mathcal{H}} \in \mathrm{Ob}\,\mathcal{T}_\mathcal{G}$, carrying the conjugated representation of $\mathcal{G}$ and there are conjugate arrows $R_\mathcal{H} \in (1,\bar{\mathcal{H}}\mathcal{H})$, $S_\mathcal{H} = \epsilon(\bar{\mathcal{H}},\mathcal{H})R_\mathcal{H}$ such that*

$$S_\mathcal{H}^* \rho_\mathcal{H}(R_\mathcal{H}) = \mathbb{1}, \quad R_\mathcal{H}^* \rho_{\bar{\mathcal{H}}}(S_\mathcal{H}) = \mathbb{1}.$$

For $\mathcal{T}_\mathcal{G}$ we have $\mathcal{R}_\mathcal{H} := \Sigma_j \bar{\Psi}_j \Psi_j$, where $\{\bar{\Psi}_j\}_j$ is an orthonormal basis of $\bar{\mathcal{H}}$. If $\mathcal{H}$ carries the representation $\oplus_j \gamma_j$, $\gamma_j \in \hat{\mathcal{G}}$, then $\bar{\mathcal{H}}$ is given by a direct sum of $\mathcal{H}_{\overline{\gamma_j}}$, where $\overline{\gamma_j} \in \hat{\mathcal{G}}$ represents the conjugated representation of γ_j.

Remark 2.19: Using the categorial morphism from $\mathcal{T}_\mathcal{G}$ to $\mathcal{T}$ we equip $\mathcal{T}$ with the image permutation and conjugation structures of those on $\mathcal{T}_\mathcal{G}$. Note that for the image permutation structure in $\mathcal{T}$, property (v) need not hold for *all* arrows [cf. Remark 2.14 (iii)].

For the next definition, observe first that from the operations defined for an abstract tensor category (cf. Proposition 2.6), we can define isometries and projections in its arrow spaces, i.e., an arrow $V \in (\lambda,\tau)$ is an isometry if $V^* \circ V = 1_\lambda$, and an arrow $E \in (\lambda,\lambda)$ is a projection if $E = E^* = E \circ E$.

Definition 2.20: An (abstract) DR category *is an (abstract) tensor C^*-category $\mathcal{C}$ with* $(1,1)$

$=\mathbb{C}\,\mathbb{I}$ *which has a permutation and a conjugation structure, and has direct sums and subobjects, i.e., to all objects* λ, σ *there is an object* τ *and isometries* $V\in(\lambda,\tau)$, $W\in(\sigma,\tau)$ *such that* $VV^*+WW^*=1_\tau$, *and to each nontrivial projection* $E\in(\lambda,\lambda)$ *there is an object* σ *and an isometry* $V\in(\sigma,\lambda)$ *such that* $E=VV^*$.

If the Hilbert system $\{\mathcal{F},\mathcal{G}\}$ satisfies Property B then $\mathcal{T}_\mathcal{G}$ is an example of a DR category, but not necessarily $\mathcal{T}$ [since property (v) in Proposition 2.18 need not hold for all arrows]. However, if additionally $\mathcal{A}'\cap\mathcal{F}=\mathbb{C}\,\mathbb{I}$ holds then also $\mathcal{T}$ is a DR category.

E. Duality theorems

Unless otherwise specified, in the following we assume Property B for $\{\mathcal{F},\mathcal{G}\}$ when $\mathcal{G}$ is non-Abelian. The DR theorem produces a bijection between pairs

$$\{\mathcal{A},\mathcal{T}\} \quad \text{and } \{\mathcal{F},\mathcal{G}\},$$

where $\mathcal{T}$ is a DR category of unital endomorphisms of the unital C*-algebra $\mathcal{A}$ with $Z(\mathcal{A})=\mathbb{C}\,\mathbb{I}$, and $\{\mathcal{F},\mathcal{G}\}$ is a Hilbert extension of $\mathcal{A}$ having trivial relative commutant, i.e., $\mathcal{A}'\cap\mathcal{F}=\mathbb{C}\,\mathbb{I}$ (see Refs. 1,15, and 16). The DR theorem says that in the case of Hilbert extensions of $\mathcal{A}$ with trivial relative commutant, the category $\mathcal{T}$ of all canonical endomorphisms can indeed be characterized intrinsically by their abstract algebraic properties as endomorphisms of $\mathcal{A}$ and a corresponding bijection can be established.

In this section we want to state how to obtain such a bijection for C*-algebras $\mathcal{A}$ with nontrivial center $\mathcal{Z}\supset\mathbb{C}\,\mathbb{I}$. A first problem is that the category $\mathcal{T}_\mathcal{G}$ and $\mathcal{T}$ *need not* be isomorphic anymore, cf. Remark 2.14 (iv) and Remark 2.12 (vi), since now we have

$$\mathbb{C}\,\mathbb{I}\neq\mathcal{Z}\subseteq\mathcal{A}'\cap\mathcal{F}.$$

We will investigate in the following the class of Hilbert extensions $\{\mathcal{F},\mathcal{G}\}$ with compact group $\mathcal{G}$ and where the relative commutant satisfies the following *minimality* condition.

Definition 2.21: A Hilbert system $\{\mathcal{F},\mathcal{G}\}$ *is called* minimal *if the condition*

$$\mathcal{A}'\cap\mathcal{F}=Z(\mathcal{A}) \tag{4}$$

is satisfied.

Then we have (cf. Proposition 4.3 of Ref. 9) the following.

Proposition 2.22: Let $\{\mathcal{F},\mathcal{G}\}$ *be a given Hilbert system. Then* $\mathcal{A}'\cap\mathcal{F}=Z(\mathcal{A})$ *iff* $(\rho_\gamma,\rho_{\gamma'})=\{0\}$ *for* $\gamma\neq\gamma'$, *i.e., iff the set* $\{\rho_\gamma|\,\gamma\in\hat{\mathcal{G}}\}$ *is mutually disjoint.*

Observe that in any Hilbert system, for each $\tau\in\mathrm{Ob}\,\mathcal{T}$ the space $\mathfrak{h}_\tau:=\mathcal{H}_\tau Z(\mathcal{A})$ (where $\mathcal{H}_\tau$ is a $\mathcal{G}$-invariant algebraic Hilbert space) is a $\mathcal{G}$-invariant right Hilbert $Z(\mathcal{A})$-module, i.e., there is a nondegenerate inner product taking its values in $Z(\mathcal{A})$ and it is $\langle A,B\rangle=A^*B$. Now we have (cf. Proposition 3.1 of Ref. 17) the following.

Proposition 2.23: Let $\{\mathcal{F},\mathcal{G}\}$ *be a given minimal Hilbert system, then the correspondence* $\tau\leftrightarrow\mathfrak{h}_\tau$ *is a bijection. Thus* $\mathfrak{h}_\tau=\mathcal{H}_\tau Z(\mathcal{A})$ *is independent of the choice of* $\mathcal{H}_\tau$, *providing that* $\tau=\rho_{\mathcal{H}_\tau}$. *This bijection satisfies the conditions*

$$\sigma\circ\tau\leftrightarrow\mathfrak{h}_\sigma\cdot\mathfrak{h}_\tau,$$

$$\lambda=(\mathrm{Ad}\,V)\circ\sigma+(\mathrm{Ad}\,W)\circ\tau\leftrightarrow\mathfrak{h}_\lambda=V\mathfrak{h}_\sigma+W\mathfrak{h}_\tau.$$

Thus for minimal Hilbert systems, the $Z(\mathcal{A})$-modules $\mathfrak{h}_\tau$ are uniquely determined by their canonical endomorphisms τ, even though the choice of $\mathcal{H}_\tau$ is not unique. We are now interested in those choices of $\mathcal{H}_\tau$ which are compatible with products.

Definition 2.24: A Hilbert system $\{\mathcal{F},\mathcal{G}\}$ *is called* regular *if there is an assignment* $\sigma\to\mathcal{H}_\sigma$ *from* Ob $\mathcal{T}$ *to* $\mathcal{G}$*-invariant algebraic Hilbert spaces in* $\mathcal{F}$ *such that*

(i) $\sigma=\rho_{\mathcal{H}_\sigma}$, *i.e.,* σ *is the canonical endomorphism of* $\mathcal{H}_\sigma$,

(ii) $\sigma\circ\tau\to\mathcal{H}_\sigma\cdot\mathcal{H}_\tau$.

In a minimal Hilbert system regularity means that there is a "representing" Hilbert space $\mathcal{H}_\tau\subset\mathfrak{h}_\tau$ for each τ with $\mathfrak{h}_\tau=\mathcal{H}_\tau Z(\mathcal{A})$ such that the compatibility relation (ii) holds.

If a Hilbert system is minimal and $Z(\mathcal{A})=\mathbb{C}1$ then it is necessarily regular. Thus a class of examples which are trivially minimal and regular, is provided by DHR-superselection theory. A nontrivial example of a minimal and regular Hilbert system is constructed in Ref. 9.

Then we obtain, cf. Theorem 4.9 of Ref. 9, the following.

Theorem 2.25: *Let $\{\mathcal{F},\mathcal{G}\}$ be a minimal and regular Hilbert system, then $\mathcal{T}$ contains a* C**-subcategory $\mathcal{T}_\mathbb{C}$ with the same objects*, $\mathrm{Ob}\,\mathcal{T}_\mathbb{C}=\mathrm{Ob}\,\mathcal{T}$, *and arrows* $(\sigma,\tau)_\mathbb{C}:=(\mathcal{H}_\sigma,\mathcal{H}_\tau)=\mathcal{J}(\mathcal{L}_\mathcal{G}(\mathcal{H}_\sigma,\mathcal{H}_\tau))\subset(\sigma,\tau)$ *such that*

P.1, $\mathcal{T}_\mathbb{C}$ *is a DR-category* [*in particular* $(\iota,\iota)_\mathbb{C}=\mathbb{C}1$],

P.2, $(\sigma,\tau)=(\sigma,\tau)_\mathbb{C}\sigma(Z(\mathcal{A}))=\tau(Z(\mathcal{A}))(\sigma,\tau)_\mathbb{C}\sigma(Z(\mathcal{A}))$.

Remark 2.26: (i) The conditions P.1 and P.2 imply that each basis of $(\sigma,\tau)_\mathbb{C}$ is simultaneously a module basis of (σ,τ) modulo $\sigma(\mathcal{Z}(\mathcal{A}))$ as a right module, i.e., the module (σ,τ) is free.

(ii) We will call the DR-subcategory $\mathcal{T}_\mathbb{C}$ in Theorem 2.25 admissible. If "minimality" is omitted from the hypotheses of Theorem 2.25, then property P.1 remains valid, but not P.2. In this case $\mathcal{T}_\mathbb{C}$ is a DR-subcategory only. A construction of an example with admissible subcategory can be found in Ref. 9.

The converse of Theorem 2.25 is also true, and states the main duality result, cf. Ref. 7.

Theorem 2.27: *Let $\mathcal{T}$ be a C*-tensor category of unital endomorphisms of $\mathcal{A}$ and let $\mathcal{T}_\mathbb{C}$ be an admissible (DR-) subcategory. Then there is a minimal and regular Hilbert extension $\{\mathcal{F},\mathcal{G}\}$ of $\mathcal{A}$ such that $\mathcal{T}$ is isomorphic to the category of all canonical endomorphisms of $\{\mathcal{F},\mathcal{G}\}$. Moreover, if $\mathcal{T}_\mathbb{C}$, $\mathcal{T}'_\mathbb{C}$ are two admissible subcategories of $\mathcal{T}$, then the corresponding Hilbert extensions are $\mathcal{A}$-module isomorphic iff $\mathcal{T}_\mathbb{C}$ is* equivalent *to $\mathcal{T}'_\mathbb{C}$, i.e., iff there is a map V from* Ob $\mathcal{T}$ *to the arrows such that*

$$V_\lambda\in(\lambda,\lambda),\quad V_\lambda \text{ is unitary, and } V_{\lambda\circ\sigma}=V_\lambda\times V_\sigma,$$

$$(\lambda,\sigma)'_\mathbb{C}=V_\sigma(\lambda,\sigma)_\mathbb{C}V_\lambda^*\subset(\lambda,\sigma)$$

and we have the following compatibility relations for the corresponding permutators ϵ, ϵ' and conjugates R_λ, R'_λ:

$$\epsilon'(\lambda,\sigma)=(V_\sigma\times V_\lambda)\cdot\epsilon(\lambda,\sigma)\cdot(V_\lambda\times V_\sigma)^*$$

$$R'_\lambda=V_{\bar\lambda\circ\lambda}R_\lambda,\quad S'_\lambda=\epsilon'(\lambda,\bar\lambda)R'_\lambda.$$

Thus, in minimal and regular Hilbert systems there is an intrinsic characterization of the category of all canonical endomorphisms in terms of $\mathcal{A}$ only. Moreover, up to $\mathcal{A}$-module isomorphisms, there is a bijection between minimal and regular Hilbert extensions and C*-tensor categories $\mathcal{T}$ of unital endomorphisms of $\mathcal{A}$ with admissible subcategories.

Note that Theorem 2.27 is a generalization of the DR theorem for the case of nontrivial center $Z(\mathcal{A})\supset\mathbb{C}1$, i.e., it contains the case of the DR theorem, in that if $Z(\mathcal{A})=\mathbb{C}1$ then $\mathcal{T}$ itself is admissible (hence a DR-category) and the corresponding Hilbert extensions have trivial relative commutant.

F. Hilbert systems with Abelian groups

If $\mathcal{G}$ is Abelian the preceding structure simplifies radically. Specifically, $\hat{\mathcal{G}}$ is a discrete Abelian group (the character group), each $\mathcal{H}_\gamma$, $\gamma\in\hat{\mathcal{G}}$ is one-dimensional with a generating unitary U_γ, hence the canonical endomorphisms $\rho_{\mathcal{H}_\gamma}$ (denoted by ρ_γ) are in fact automorphisms, necessarily

outer on $\mathcal{A}$. Since $\rho_{\gamma_1}\circ\rho_{\gamma_2}=\rho_{\gamma_1\gamma_2}$ in this case the set Γ of all canonical endomorphisms $\rho_{\mathcal{H}_\gamma}$ is a group with the property $\hat{\mathcal{G}}\cong\Gamma/\mathrm{int}\,\mathcal{A}$. Hence it is not necessary to consider direct sums, i.e., Property B for $\mathcal{A}$ can be dropped.

In the case $Z(\mathcal{A})=\mathbb{C}\mathbb{1}$ the permutators ϵ (restricted to $\hat{\mathcal{G}}\times\hat{\mathcal{G}}$) are elements of the second cohomology group $H^2(\hat{\mathcal{G}})$ and

$$U_{\gamma_1}\cdot U_{\gamma_2}=\omega(\gamma_1,\gamma_2)U_{\gamma_1\circ\gamma_2},$$

where

$$\epsilon(\gamma_1,\gamma_2)=\frac{\omega(\gamma_1,\gamma_2)}{\omega(\gamma_2,\gamma_1)}$$

and ω is a corresponding 2-cocycle. The field algebra $\mathcal{F}$ is just the ω-twisted discrete crossed product of $\mathcal{A}$ with $\hat{\mathcal{G}}$ (see, e.g., Ref. 2, p. 86ff for details). For the case $Z(\mathcal{A})\supset\mathbb{C}\mathbb{1}$ see Ref. 18 (though the minimal case is not mentioned there).

III. KINEMATICS FOR QUANTUM CONSTRAINTS

In this section we give a brief summary of the method of imposing quantum constraints, developed by Grundling and Hurst.[4,8,5] Our starting point is the following.

Definition 3.1: A quantum system with constraints *is a pair* $(\mathcal{B},\mathcal{C})$ *where the* system algebra $\mathcal{B}$ *is a unital* C^**-algebra containing the* constraint set $\mathcal{C}=\mathcal{C}^*$. *A* constraint condition *on* $(\mathcal{B},\mathcal{C})$ *consists of the selection of the physical state space by*

$$\mathfrak{S}_D:=\{\omega\in\mathfrak{S}(\mathcal{B})\,|\,\pi_\omega(C)\Omega_\omega=0\ \ \forall\ C\in\mathcal{C}\},$$

where $\mathfrak{S}(\mathcal{B})$ *denotes the state space of* $\mathcal{B}$, *and* $(\pi_\omega,\mathcal{H}_\omega,\Omega_\omega)$ *denotes the GNS data of* ω. *The elements of* $\mathfrak{S}_D$ *are called* Dirac states. *The case of* unitary constraints *means that* $\mathcal{C}=\mathcal{U}-\mathbb{I},\mathcal{U}\subset\mathcal{B}_u$, *and for this we will also use the notation* $(\mathcal{B},\mathcal{U})$.

The assumption is that all physical information is contained in the pair $(\mathcal{B},\mathfrak{S}_D)$. Examples of constraint theories as defined here, have been worked out in detail for various forms of electromagnetism cf. Refs. 4,19, and 5.

For the case of unitary constraints we have the following equivalent characterizations of the Dirac states [cf. Ref. 4, Theorem 2.19 (ii)]:

$$\mathfrak{S}_D=\{\omega\in\mathfrak{S}(\mathcal{B})\,|\,\omega(U)=1\ \ \forall\ U\in\mathcal{U}\} \tag{5}$$

$$=\{\omega\in\mathfrak{S}(\mathcal{B})\,|\,\omega(FU)=\omega(F)=\omega(UF)\ \ \forall\ F\in\mathcal{B},U\in\mathcal{U}\}. \tag{6}$$

Moreover, the set $\{\alpha_U:=\mathrm{Ad}(U)\,|\,U\in\mathcal{U}\}$ of automorphisms of $\mathcal{B}$ leaves every Dirac state invariant, i.e., we have $\omega\circ\alpha_U=\omega$ for all $\omega\in\mathfrak{S}_D$, $U\in\mathcal{U}$.

For a general constraint set $\mathcal{C}$, observe that we have

$$\mathfrak{S}_D=\{\omega\in\mathfrak{S}(\mathcal{B})\,|\,\omega(C^*C)=0\ \ \forall\ C\in\mathcal{C}\}=\{\omega\in\mathfrak{S}(\mathcal{B})\,|\,\mathcal{C}\subseteq N_\omega\}=\mathcal{N}^\perp\cap\mathfrak{S}(\mathcal{B}).$$

Here $N_\omega:=\{F\in\mathcal{B}\,|\,\omega(F^*F)=0\}$ is the left kernel of ω and $\mathcal{N}:=\cap\{N_\omega\,|\,\omega\in\mathfrak{S}_D\}$, and $\mathcal{N}^\perp$ denotes the annihilator of $\mathcal{N}$ in the dual of $\mathcal{B}$. Now $\mathcal{N}=\text{clo-span}(\mathcal{B}\mathcal{C})$ because every closed left ideal is the intersection of the left kernels which contains it (cf. 3.13.5 in Ref. 20). Thus $\mathcal{N}$ is the left ideal generated by $\mathcal{C}$. Since $\mathcal{C}$ is self-adjoint and contained in $\mathcal{N}$ we conclude

$$\mathcal{C}\subset\mathrm{C}^*(\mathcal{C})\subset\mathcal{N}\cap\mathcal{N}^*=\text{clo-span}(\mathcal{B}\mathcal{C})\cap\text{clo-span}(\mathcal{C}\mathcal{B}),$$

where $\mathrm{C}^*(\cdot)$ denotes the C^*-algebra in $\mathcal{B}$ generated by its argument. Then we have (cf. Ref. 5) the following.

Theorem 3.2: *For the Dirac states we have*

(i) $\mathfrak{S}_D \neq \emptyset$ *iff* $\mathbb{I} \notin \mathrm{C}^*(\mathcal{C})$ *iff* $\mathbb{I} \notin \mathcal{N} \cap \mathcal{N}^* =: \mathcal{D}$.
(ii) $\omega \in \mathfrak{S}_D$ *iff* $\pi_\omega(\mathcal{D})\Omega_\omega = 0$.
(iii) *An extreme Dirac state is pure*.

We will call a constraint set $\mathcal{C}$ first class if $\mathbb{I} \notin \mathrm{C}^*(\mathcal{C})$, and this is the nontriviality assumption which we henceforth make (Ref. 21, Sec. 3).

Now define

$$\mathcal{O} := \{F \in \mathcal{B} | [F,D] := FD - DF \in \mathcal{D} \ \forall D \in \mathcal{D}\}.$$

Then $\mathcal{O}$ is the C^*-algebraic analog of Dirac's observables (the weak commutant of the constraints).[22] Then (cf. Ref. 5) we have the following.

Theorem 3.3: *With the preceding notation we have*

(i) $\mathcal{D} = \mathcal{N} \cap \mathcal{N}^*$ *is the unique maximal* C^**-algebra in* $\cap\{\mathrm{Ker}\,\omega | \omega \in \mathfrak{S}_D\}$. *Moreover* $\mathcal{D}$ *is a hereditary* C^**-subalgebra of* $\mathcal{B}$.
(ii) $\mathcal{O} = M_{\mathcal{B}}(\mathcal{D}) := \{F \in \mathcal{B} | FD \in \mathcal{D} \ni DF \ \forall D \in \mathcal{D}\}$, *i.e., it is the relative multiplier algebra of* $\mathcal{D}$ *in* $\mathcal{B}$.
(iii) $\mathcal{O} = \{F \in \mathcal{B} | [F,\mathcal{C}] \subset \mathcal{D}\}$, *hence* $\mathcal{C}' \cap \mathcal{B} \subseteq \mathcal{O}$.
(iv) $\mathcal{D} = \text{clo-span}(\mathcal{O}\mathcal{C}) = \text{clo-span}(\mathcal{C}\mathcal{O})$.
(v) *For the case of unitary constraints, i.e.,* $\mathcal{C} = \mathcal{U} - \mathbb{1}$, *we have* $\mathcal{U} \subset \mathcal{O}$ *and* $\mathcal{O} = \{F \in \mathcal{B} | \alpha_U(F) - F \in \mathcal{D} \ \forall U \in \mathcal{U}\}$ *where* $\alpha_U := \mathrm{Ad}\, U$.

Thus $\mathcal{D}$ is a closed two-sided ideal of $\mathcal{O}$ and it is proper when $\mathfrak{S}_D \neq \emptyset$ [which we assume here by $\mathbb{I} \notin \mathrm{C}^*(\mathcal{C})$]. Since the traditional observables are $\mathcal{C}' \cap \mathcal{B}$, by (iii) we see that these are in $\mathcal{O}$. In general $\mathcal{O}$ can be much larger than $\mathcal{C}' \cap \mathcal{B}$.

Define the *maximal* C^**-algebra of physical observables as*

$$\mathcal{R} := \mathcal{O}/\mathcal{D}.$$

The factoring procedure is the actual step of imposing constraints. This method of constructing $\mathcal{R}$ from $(\mathcal{B},\mathcal{C})$ is called the T-procedure in Ref. 4, and it defines a map T from first class constraint pairs $(\mathcal{B},\mathcal{C})$ to unital C^*-algebras by $T(\mathcal{B},\mathcal{C}) := \mathcal{R} = \mathcal{O}/\mathcal{D}$. We require that after the T-procedure all physical information is contained in the pair $(\mathcal{R},\mathfrak{S}(\mathcal{R}))$, where $\mathfrak{S}(\mathcal{R})$ denotes the set of states on $\mathcal{R}$. Now, it is possible that $\mathcal{R}$ may not be simple (Ref. 4, Sec. 2), and this would not be acceptable for a physical algebra. So, using physical arguments, one would in practice choose a C^*-subalgebra $\mathcal{O}_c \subset \mathcal{O}$ containing the traditional observables $\mathcal{C}'$ such that

$$\mathcal{R}_c := \mathcal{O}_c/(\mathcal{D} \cap \mathcal{O}_c) \subset \mathcal{R}$$

is simple. The following result justifies the choice of $\mathcal{R}$ as the algebra of physical observables (cf. Theorem 2.20 in Ref. 4).

Theorem 3.4: *There exists a* w^**-continuous isometric bijection between the Dirac states on* $\mathcal{O}$ *and the states on* $\mathcal{R}$.

Insofar as the physics is now specified by $\mathcal{R}$, this suggests that we call two constraint sets equivalent if they produce the same $\mathcal{R}$. More precisely two constraint sets $\mathcal{C}_1 \subset \mathcal{B} \supset \mathcal{C}_2$ are called equivalent, denoted $\mathcal{C}_1 \sim \mathcal{C}_2$, if they select the same set of Dirac states, cf. Ref. 5. In fact

$$\mathcal{C}_1 \sim \mathcal{C}_2 \quad \text{iff clo-span}(\mathcal{B}\mathcal{C}_1) = \text{clo-span}(\mathcal{B}\mathcal{C}_2) \quad \text{iff } \mathcal{D}_1 = \mathcal{D}_2.$$

The hereditary property of $\mathcal{D}$ can be further analyzed, and we list the main points (the proofs are in Appendix A of Ref. 5).

Denote by π_u the universal representation of $\mathcal{B}$ on the universal Hilbert space $\mathcal{H}_u$ (Ref. 20, Sec. 3.7). $\mathcal{B}''$ is the strong closure of $\pi_u(\mathcal{B})$ and since π_u is faithful we make the usual identification of $\mathcal{B}$ with a subalgebra of $\mathcal{B}''$, i.e., generally omit explicit indication of π_u. If $\omega \in \mathfrak{S}(\mathcal{B})$, we will use the same symbol for the unique extension of ω from $\mathcal{B}$ to $\mathcal{B}''$.

Theorem 3.5: *For a constrained system* $(\mathcal{B},\mathcal{C})$ *there exists a projection* $P \in \mathcal{B}''$ *such that*

(i) $\mathcal{N}=\mathcal{B}''P\cap\mathcal{B}$,
(ii) $\mathcal{D}=P\mathcal{B}''P\cap\mathcal{B}$,
(iii) $\mathcal{S}_D=\{\omega\in\mathcal{S}(\mathcal{B})\,|\,\omega(P)=0\}$,
(iv) $\mathcal{O}=\{A\in\mathcal{B}\,|\,PA(\mathbb{I}-P)=0=(\mathbb{I}-P)AP\}=P'\cap\mathcal{B}$.

A projection satisfying the conditions of Theorem 3.5 is called *open* in Ref. 20.

What this theorem means, is that with respect to the decomposition

$$\mathcal{H}_u=P\mathcal{H}_u\oplus(\mathbb{I}-P)\mathcal{H}_u$$

we may rewrite

$$\mathcal{D}=\left\{F\in\mathcal{B}|F=\begin{pmatrix}D&0\\0&0\end{pmatrix},D\in P\mathcal{B}P\right\}$$

and

$$\mathcal{O}=\left\{F\in\mathcal{B}|F=\begin{pmatrix}A&0\\0&B\end{pmatrix},A\in P\mathcal{B}P,B\in(\mathbb{I}-P)\mathcal{B}(\mathbb{I}-P)\right\}.$$

It is clear that, in general, $\mathcal{O}$ can be much greater than the traditional observables $\mathcal{C}'\cap\mathcal{B}$. Next we show how to identify the final algebra of physical observables $\mathcal{R}$ with a subalgebra of $\mathcal{B}''$.

Theorem 3.6: *For P as above we have*

$$\mathcal{R}\cong\left\{F\in\mathcal{B}|F=\begin{pmatrix}0&0\\0&A\end{pmatrix}\right\}=(\mathbb{I}-P)(P'\cap\mathcal{B})\subset\mathcal{B}''.$$

Below we will need to consider a constraint system contained in a larger algebra, specifically, $\mathcal{C}\subset\mathcal{A}\subset\mathcal{F}$ where $\mathcal{C}$ is a first-class constraint set, and $\mathcal{A}$, $\mathcal{F}$ are unital C*-algebras. Now there are two constrained systems to consider; $(\mathcal{A},\mathcal{C})$ and $(\mathcal{F},\mathcal{C})$. The first one produces the algebras $\mathcal{D}\subset\mathcal{O}\subseteq\mathcal{A}$, and the second produces $\mathcal{D}_\mathcal{F}\subset\mathcal{O}_\mathcal{F}\subseteq\mathcal{F}$, where as usual,

$$\mathcal{N}=\text{clo-span}(\mathcal{AC}),\quad \mathcal{D}=\mathcal{N}\cap\mathcal{N}^*,\quad \mathcal{O}=M_\mathcal{A}(\mathcal{D})$$

and

$$\mathcal{N}_\mathcal{F}=\text{clo-span}(\mathcal{FC}),\quad \mathcal{D}_\mathcal{F}=\mathcal{N}_\mathcal{F}\cap\mathcal{N}_\mathcal{F}^*,\quad \mathcal{O}_\mathcal{F}=M_\mathcal{F}(\mathcal{D}_\mathcal{F}).$$

Then we have (cf. Theorem 3.2 of Ref. 8) the following.

Theorem 3.7: *Given as above* $\mathcal{C}\subset\mathcal{A}\subset\mathcal{F}$ *then*

$$\mathcal{N}_\mathcal{F}\cap\mathcal{A}=\mathcal{N},\quad \mathcal{D}_\mathcal{F}\cap\mathcal{A}=\mathcal{D},\quad \text{and}\quad \mathcal{O}_\mathcal{F}\cap\mathcal{A}=\mathcal{O}.$$

Hence $\mathcal{R}=\mathcal{O}/\mathcal{D}=(\mathcal{O}_\mathcal{F}\cap\mathcal{A})/(\mathcal{D}_\mathcal{F}\cap\mathcal{A})$.

IV. SUPERSELECTION WITH CONSTRAINTS

Next we would like to consider systems containing both constraints and superselection. There is a choice in how to define this problem mathematically, so let us consider the physical background. Perhaps the most important example, is that of a local gauge theory. It usually has a set of global charges (leading to superselection) as well as a Gauss law constraint (implementing the local gauge symmetry), and possibly also other constraints associated with the field equation. Only if the gauge group is Abelian will the Gauss law constraint commute with the global charge, since the Gauss law constraint takes its values in the Lie algebra of the gauge group. Thus, for non-Abelian local gauge theories we do not expect the constraints to be in the algebra of gauge invariant observables $\mathcal{A}$ of the superselection theory of the global charge. This problem is however not as serious as it looks. The reason is that while the global gauge group does not preserve the individual Gauss law constraints, it does preserve the set of these, hence it also preserves the set

of Dirac states selected by them. Thus we can replace the original constraint set by an equivalent constraint (i.e., selecting the same set of Dirac states) which is invariant under the global gauge group. Such an equivalent constraint is given by the projection in Theorem 3.5. It comes at the cost of slightly enlarging the system algebra $\mathcal{B}$, since P is in the universal von Neumann algebra of $\mathcal{B}$. We can avoid this cost if clo-span($\mathcal{C}$) is separable, since then there is an equivalent constraint in $\mathcal{B}$ itself, cf. Theorem 3.4 of Ref. 5.

We therefore will assume below that the constraints are in $\mathcal{A}$. This will include a large class of physical examples, as mentioned in Sec. I.

Let now $(\mathcal{A},\mathcal{C})$ be a first-class constraint system, hence we have the associated algebras $\mathcal{D}\subset\mathcal{O}\subseteq\mathcal{A}$, and $\mathcal{R}=\mathcal{O}/\mathcal{D}$. In addition, let $\mathcal{A}$ have a superselection structure, i.e., there is a given Hilbert extension $\{\mathcal{F},\mathcal{G}\}$ of $\mathcal{A}$. Thus the category $\mathcal{T}$ of canonical endomorphisms of $\mathcal{A}$ defines a selection criterion of unital endomorphisms of $\mathcal{A}$. In the case that the Hilbert extension is minimal and regular, the superselection structure of $\mathcal{T}$ is given within $\mathcal{A}$ without any reference to the Hilbert extension.

Then the following natural questions arise:

(1) what compatibility conditions should be satisfied in order to pass the superselection structure through T, thus obtaining a superselection structure on $T(\mathcal{A},\mathcal{C})=\mathcal{R}$?
(2) what is the relation between $T(\mathcal{A},\mathcal{C})$ and $T(\mathcal{F},\mathcal{C})$ where $\mathcal{F}$ is the field algebra generated from $\mathcal{T}$?

An inverse question also arises, i.e.,

(3) if $\mathcal{R}$ has a superselection structure, what is the weakest structure one can expect on $\mathcal{A}$ which would produce this superselection structure on $\mathcal{R}$ via T? (One should call this a *weak* superselection structure.)

To address (1) and (2), recall that the map T consists of a restriction (of $\mathcal{A}$ to $\mathcal{O}$) followed by a factoring ($\mathcal{O}\to\mathcal{O}/\mathcal{D}$). So, we first work out the compatibility conditions involved with restrictions and factoring maps.

Since $\mathcal{C}\subset\mathcal{A}\subset\mathcal{F}$, there are two constrained systems to consider; $(\mathcal{A},\mathcal{C})$ and $(\mathcal{F},\mathcal{C})$. The first one produces the algebras $\mathcal{D}\subset\mathcal{O}\subseteq\mathcal{A}$, and the second produces $\mathcal{D}_{\mathcal{F}}\subset\mathcal{O}_{\mathcal{F}}\subseteq\mathcal{F}$ (cf. Theorem 3.7). Now since $\mathcal{C}\subset\mathcal{A}$, the $\mathcal{G}$-invariant part of $\mathcal{F}$, it follows that $\mathcal{G}$ preserves the set of Dirac states, hence $\mathcal{G}$ preserves both $\mathcal{D}_{\mathcal{F}}$ and $\mathcal{O}_{\mathcal{F}}$, i.e., $g\mathcal{D}_{\mathcal{F}}=\mathcal{D}_{\mathcal{F}}$ and $g\mathcal{O}_{\mathcal{F}}=\mathcal{O}_{\mathcal{F}}$ for all $g\in\mathcal{G}$.

We denote the restriction of $\mathcal{G}$ to $\mathcal{O}_{\mathcal{F}}$ by $\beta_g:=g\restriction\mathcal{O}_{\mathcal{F}}$. The homomorphism $\beta:\mathcal{G}\ni g\to\beta_g\in\mathrm{Aut}\,\mathcal{O}_{\mathcal{F}}$ is not necessarily injective but β is again pointwise norm-continuous, hence $\mathcal{G}/\mathcal{K}$ is compact where $\mathcal{K}:=\mathrm{Ker}\,\beta$. The isomorphism $\tilde{\beta}:\mathcal{G}/\mathcal{K}\to\beta_{\mathcal{G}}$ by $\tilde{\beta}(g\mathcal{K}):=\beta_g$ is also a topological one (cf. p. 58 of Ref. 23). Note that $\widehat{(\mathcal{G}/\mathcal{K})}=\{\gamma\in\hat{\mathcal{G}}\,|\,\gamma(k)=1 \text{ for all } k\in\mathcal{K}\}\supseteq\mathrm{spec}\,\beta_{\mathcal{G}}$.

The spectral projections Π_γ^β of $\beta_{\mathcal{G}}$ are given by the restriction to $\mathcal{O}_{\mathcal{F}}$ of the spectral projections Π_γ of $\mathcal{G}$, i.e., $\Pi_\gamma^\beta X=\Pi_\gamma X$ for $X\in\mathcal{O}_{\mathcal{F}}$.

We now have the following:

(I) *Restriction problem:* Find conditions to guarantee that the C*-dynamical system $\{\mathcal{O}_{\mathcal{F}},\mathcal{G},\beta\}$ is a Hilbert system $\{\mathcal{O}_{\mathcal{F}},\beta_{\mathcal{G}}\}$. Thus we must find conditions to ensure there are algebraic Hilbert spaces in $\Pi_\gamma^\beta\mathcal{O}_{\mathcal{F}}$ for $\gamma\in\widehat{(\mathcal{G}/\mathcal{K})}$. (Note that this is stronger than what we need; we only need a Hilbert system on $\mathcal{R}_{\mathcal{F}}$ after factoring out by $\mathcal{D}_{\mathcal{F}}$.)
(II) *Factoring problem:* Find conditions to guarantee that under the map $\mathcal{O}_{\mathcal{F}}\to\mathcal{R}_{\mathcal{F}}:=\mathcal{O}_{\mathcal{F}}/\mathcal{D}_{\mathcal{F}}$ the factoring through of the action of $\mathcal{G}$ to $\mathcal{R}_{\mathcal{F}}$ is a Hilbert system corresponding to a DR-category. This is of course a special case of the general problem for homomorphic images of Hilbert systems under factoring by invariant ideals. The reason why we require $Z(\mathcal{A})=\mathbb{C}\mathbb{1}$ for $\mathcal{R}_{\mathcal{F}}$ is because after implementing constraints, the final physical algebra should be simple.

Below we list our major results; since some proofs are lengthy, we defer these to Sec. VI to preserve the main flow of ideas.

A. Restricting a superselection structure

We consider now for the system above the restriction problem (I), i.e., we are given a Hilbert extension $\{\mathcal{F},\mathcal{G}\}$ of $\mathcal{A}$, containing constraints $\mathcal{C}\subset\mathcal{A}$, and we need to examine when $\{\mathcal{O}_\mathcal{F},\beta_\mathcal{G}\}$ is a Hilbert system.

Theorem 4.1: *(i)* $\{\mathcal{O}_\mathcal{F},\mathcal{G},\beta\}$ *has fixed point algebra* $\mathcal{O}$. *Moreover,* $Z(\mathcal{A})\subseteq Z(\mathcal{O})$.

(ii) For any $\mathcal{G}$ *-invariant algebraic Hilbert space* $\mathcal{H}_\gamma\subset\Pi_\gamma\mathcal{F}$ *we have either* $\mathcal{H}_\gamma\cap\mathcal{O}_\mathcal{F}=\{0\}$, *or* $\mathcal{H}_\gamma\subset\mathcal{O}_\mathcal{F}$. *In the latter case we have* $\gamma\in\widehat{\mathcal{G}/\mathcal{K}}$ *where* $\mathcal{K}=\mathrm{Ker}\,\beta$, *and*

$$\mathcal{H}_\gamma\subset\Pi_\gamma\mathcal{O}_\mathcal{F}=\text{clo-span}(\mathcal{O}\mathcal{H}_\gamma).$$

(iii) Let $\sigma\in\mathrm{Ob}\,\mathcal{T}$, *with* $\mathcal{H}_\sigma\subset\mathcal{F}$ *a* $\mathcal{G}$ *-invariant algebraic Hilbert space such that* $\sigma=\rho_{\mathcal{H}_\sigma}$. *If* $\mathcal{H}_\sigma\subset\mathcal{O}_\mathcal{F}$, *then* $\sigma(\mathcal{D})\subseteq\mathcal{D}$ *and* $\sigma(\mathcal{O})\subseteq\mathcal{O}$. *Thus* σ *restricts to* $\mathcal{O}$, $\sigma\restriction\mathcal{O}\in\mathrm{End}\,\mathcal{O}$.

The central condition for $\{\mathcal{O}_\mathcal{F},\mathcal{G},\beta\}$ to be a Hilbert system $\{\mathcal{O}_\mathcal{F},\beta_\mathcal{G}\}$ with respect to the factor group $\mathcal{G}/\mathcal{K}$ is $\mathcal{H}_\gamma\subset\mathcal{O}_\mathcal{F}$, i.e., $\mathcal{H}_\gamma\subset\Pi^\beta_\gamma\mathcal{O}_\mathcal{F}$ for all $\gamma\in\widehat{\mathcal{G}/\mathcal{K}}$.

Next, we develop an internal criterion on $\mathcal{A}$ to guarantee that a given $\mathcal{H}\in\mathrm{Ob}\,\mathcal{T}_\mathcal{G}$ is contained in $\mathcal{O}_\mathcal{F}$.

Theorem 4.2: *(i) Given the Hilbert extension* $\{\mathcal{F},\mathcal{G}\}$ *of the constrained system* $\mathcal{C}\subset\mathcal{A}$ *assumed here, we have for any* $\mathcal{G}$*-invariant algebraic Hilbert space* $\mathcal{H}$ *that*

$$\mathcal{H}\subset\mathcal{O}_\mathcal{F}\quad\text{iff}\quad\mathcal{D}\sim\rho_\mathcal{H}(\mathcal{D}),\quad\text{i.e., }\mathcal{D}=\text{clo-span}(\mathcal{A}\rho_\mathcal{H}(\mathcal{D}))\cap\text{clo-span}(\rho_\mathcal{H}(\mathcal{D})\mathcal{A}).$$

(ii) For all σ, $\tau\in\mathrm{Ob}\,\mathcal{T}$ *with* $\mathcal{H}_\sigma$, $\mathcal{H}_\tau\subset\mathcal{O}_\mathcal{F}$ *we have*

$$(\sigma,\tau)_\mathcal{A}\subseteq(\sigma\restriction\mathcal{O},\tau\restriction\mathcal{O})_\mathcal{O}.$$

Observe that $\mathcal{D}\sim\rho_\mathcal{H}(\mathcal{D})$ implies that $\rho_\mathcal{H}(\mathcal{D})\subseteq\mathcal{D}$.

Corollary 4.3: We have that $\{\mathcal{O}_\mathcal{F},\mathcal{G}/\mathcal{K},\tilde{\beta}\}$ *is a Hilbert system* $\{\mathcal{O}_\mathcal{F},\beta_\mathcal{G}\}$ with respect to $\mathcal{G}/\mathcal{K}$ *iff* $\mathcal{D}\sim\rho_\gamma(\mathcal{D})$ *holds for all* $\gamma\in\widehat{\mathcal{G}/\mathcal{K}}$. *In particular, if* $\mathcal{D}\sim\rho_\gamma(\mathcal{D})$ *holds for all* $\gamma\in\hat{\mathcal{G}}$ *then* $\mathcal{G}/\mathcal{K}\cong\mathcal{G}$ *i.e.,* $\mathcal{K}$ *is trivial.*

While the condition $\mathcal{D}\sim\rho_\gamma(\mathcal{D})$ is exact for $\mathcal{H}_\gamma\subset\mathcal{O}_\mathcal{F}$, it may not be in practice that easy to verify. We therefore consider alternative conditions which will allow the main structures involved with Hilbert extensions to survive the restriction of $\{\mathcal{F},\mathcal{G}\}$ to $\{\mathcal{O}_\mathcal{F},\beta_\mathcal{G}\}$.

Recalling the definition of subobjects, introduce the notation $E\simeq\mathbb{1}(\mathrm{mod}\,\mathcal{A})$ for a projection $E\in\mathcal{A}$ to mean that there is an isometry $V\in\mathcal{A}$, $V^*V=\mathbb{1}$ such that $VV^*=E$ (i.e., Murray-von Neumann equivalence of E and $\mathbb{1}$).

Definition 4.4: We say the constraint set $\mathcal{C}\subset\mathcal{A}$ *is an* E-constraint set *if for each projection* $E\in\mathcal{O}$ *such that* $E\simeq\mathbb{1}(\mathrm{mod}\,\mathcal{A})$, *we have that* $E\simeq\mathbb{1}(\mathrm{mod}\,\mathcal{O})$.

The E-constraint condition will ensure the survival of decomposition relations of restrictable canonical endomorphisms.

Proposition 4.5: Let $\{\mathcal{F},\mathcal{G}\}$ *be a Hilbert system and let* $\mathcal{C}\subset\mathcal{O}$ *be an E-constraint set,* $\sigma\in\mathrm{Ob}\,\mathcal{T}$ *and* $\mathcal{H}_\sigma\subset\mathcal{O}_\mathcal{F}$ *a* $\mathcal{G}$*-invariant algebraic Hilbert space. Then*

(i) *to each decomposition*

$$\sigma(\cdot)=\sum_j V_j\rho_{\gamma_j}(\cdot)V_j^*,\quad V_j\in(\rho_{\gamma_j},\sigma)_\mathcal{A},$$

where $\gamma_j\in\hat{\mathcal{G}}$ *and* $V_j\in\mathcal{A}$ *are isometries, there corresponds a decomposition on* $\mathcal{O}$, *i.e., there are* $\mathcal{G}$*-invariant algebraic Hilbert spaces* $\mathcal{K}_j\subset\mathcal{O}_\mathcal{F}$, *which carry the representation* γ_j *and with canonical endomorphisms* $\tau_j:=\rho_{\mathcal{K}_j}\restriction\mathcal{O}\in\mathrm{End}\,\mathcal{O}$ *such that on* $\mathcal{O}$,

$$\sigma(\cdot)=\sum_j W_j\tau_j(\cdot)W_j^*,\quad W_j\in(\tau_j,\sigma)_\mathcal{O},$$

where $W_j\in\mathcal{O}$ *are isometries.*

(ii) *Let* $\{\mathcal{F},\hat{\mathcal{G}}\}$ *in addition satisfies Property B and let* $\tau<\sigma\in\mathcal{T}$ *in the sense of* $\mathcal{A}$, *i.e., there is*

an isometry $V \in (\tau,\sigma)_{\mathcal{A}}$, *and let* $\mathcal{H}_\sigma \subset \mathcal{O}_{\mathcal{F}}$. *Then there is a corresponding Hilbert space* $\mathcal{H}_\tau \subset \mathcal{O}_{\mathcal{F}}$, *i.e.,* $\tau\restriction\mathcal{O} < \sigma\restriction\mathcal{O} \in \mathrm{End}\,\mathcal{O}$ *also in the sense of* $\mathcal{O}$.

Theorem 4.6: *Let the Hilbert system* $\{\mathcal{F},\mathcal{G}\}$ *satisfy Property B where* $\mathcal{G}$ *is a group with a distinguished irreducible representation* $\gamma_0 \in \hat{\mathcal{G}}$ *such that every irreducible representation of* $\mathcal{G}$ *is contained in a tensor representation of* γ_0. *Let* $\mathcal{C} \subset \mathcal{A}$ *be an E-constraint set then* $\mathcal{H}_{\gamma_0} \subset \mathcal{O}_{\mathcal{F}}$ *implies that* $\{\mathcal{O}_{\mathcal{F}}, \beta_{\mathcal{G}}\}$ *is a Hilbert system.*

Proof: This follows from Proposition 4.5, by making use of the obvious fact that $\mathcal{H}_\tau \subset \mathcal{O}_{\mathcal{F}} \supset \mathcal{H}_\sigma$ implies that $\mathcal{H}_\tau \cdot \mathcal{H}_\sigma \subset \mathcal{O}_{\mathcal{F}}$ for $\sigma,\ \tau \in \mathrm{Ob}\,\mathcal{T}$. □

If the group $\mathcal{G}$ is isomorphic to $U(N)$ then it satisfies the condition of Theorem 4.6.

The property of being an E-constraint set can be characterized in terms of the open projection $P \in \mathcal{A}''$ corresponding to the constraints (cf. Theorem 3.5). Observe that if there is an $E \in \mathcal{O}$ with $E \simeq \mathbb{I}(\mathrm{mod}\,\mathcal{A})$, then the set of isometries

$$\mathcal{V}_E := \{V \in \mathcal{A} \,|\, VV^* = E, V^*V = \mathbb{I}\}$$

is nonempty. We have the following.

Proposition 4.7: Let $E \in \mathcal{O}$ *with* $E \simeq \mathbb{I}(\mathrm{mod}\,\mathcal{A})$, *then* $\mathcal{V}_E \cap \mathcal{O} \neq \emptyset$ *iff for each* $V \in \mathcal{V}_E$ *there is a*

$$U \in \mathcal{U}_E := \{U \in \mathcal{A} \,|\, U^*U = E = UU^*\}$$

such that $VPV^* = UPU^*$.

B. Morphisms of general Hilbert systems

Recall that the second step in the enforcement of constraints, is the factoring $\mathcal{O}_{\mathcal{F}} \to \mathcal{R}_{\mathcal{F}} := \mathcal{O}_{\mathcal{F}}/\mathcal{D}_{\mathcal{F}}$. We now consider problem (II), the factoring problem, first in a general context. Consider a morphism of C*-algebras $\xi: \mathcal{F} \to \mathcal{L} = \xi(\mathcal{F})$. This specifies the subgroup of automorphisms

$$\mathrm{Aut}_\xi\,\mathcal{F} := \{\alpha \in \mathrm{Aut}\,\mathcal{F} \,|\, \alpha(\mathrm{Ker}\,\xi) \subseteq \mathrm{Ker}\,\xi\}$$

and a homomorphism $\mathrm{Aut}_\xi\,\mathcal{F} \to \mathrm{Aut}\,\mathcal{L}$ by $\alpha \to \alpha^\xi$ where $\alpha^\xi(\xi(F)) := \xi(\alpha(F))$ for all $F \in \mathcal{F}$. Henceforth let $\{\mathcal{F},\mathcal{G}\}$ be a Hilbert system with Property B and $\mathcal{G} \subset \mathrm{Aut}_\xi\,\mathcal{F}$. Our task will be to find the best conditions to ensure that $\{\mathcal{L},\mathcal{G}^\xi\}$ is a Hilbert system associated with a category described in Theorem 2.25. We will denote the spectral projections of $\mathcal{G}$ (respectively, $\mathcal{G}^\xi$) by Π_γ (respectively, Π^ξ_γ). (Recall that in the context of the T-procedure, we have that $\mathcal{G}$ preserves $\mathcal{D}_{\mathcal{F}}$ due to the invariance of the constraints under $\mathcal{G}$. So the current analysis applies.)

Theorem 4.8: *Given a Hilbert system* $\{\mathcal{F},\mathcal{G}\}$ *and a unital morphism* $\xi: \mathcal{F} \to \mathcal{L} = \xi(\mathcal{F})$, *such that* $\mathcal{G} \subset \mathrm{Aut}_\xi\,\mathcal{F}$, *then we have*

(i) $\{\mathcal{L},\mathcal{G}^\xi\}$ *is a Hilbert system and* $\mathcal{G} \cong \mathcal{G}^\xi$.
(ii) *If* $\mathcal{H}_\gamma \subset \Pi_\gamma \mathcal{F}$ *is an invariant algebraic Hilbert space for* $\mathcal{G}$, *then so is* $\xi(\mathcal{H}_\gamma) \subset \Pi^\xi_\gamma \mathcal{L}$ *for* $\mathcal{G}^\xi$.
(iii) *Let* $\mathcal{N}_\gamma$ *be any orthonormal basis for* $\xi(\mathcal{H}_\gamma)$, *then* $\cup\{\mathcal{N}_\gamma \,|\, \gamma \in \hat{\mathcal{G}}\}$ *is a left module basis of* $\xi(\mathcal{F}_{\mathrm{fin}})$ with respect to $\xi(\mathcal{A})$, *i.e., the "essential part" of* ξ *is its action on* $\mathcal{A}$.
(iv) *The fixed point algebra of* $\mathcal{L}$ with respect to $\mathcal{G}^\xi$ *is exactly* $\xi(\mathcal{A})$, *and* $\xi(\mathcal{F}_{\mathrm{fin}}) = \mathcal{L}_{\mathrm{fin}}$.
(v) *If* $\{\mathcal{F},\mathcal{G}\}$ *has Property B, so does* $\{\mathcal{L},\mathcal{G}^\xi\}$.

Thus corresponding to the two Hilbert systems $\{\mathcal{F},\mathcal{G}\}$ and $\{\mathcal{L},\mathcal{G}^\xi\}$ we now have the two categories $\mathcal{T}$ and $\mathcal{T}^\xi$, respectively. Moreover we have the following.

Corollary 4.9: Under the conditions of Theorem 4.8 we have that

(i) *for any canonical endomorphism* $\lambda \in \mathrm{Ob}\,\mathcal{T}$,

$$\lambda(\mathrm{Ker}\,\xi \cap \mathcal{A}) \subseteq \mathrm{Ker}\,\xi \cap \mathcal{A}.$$

Hence there is a well-defined map $\mathrm{Ob}\,\mathcal{T} \ni \lambda \to \lambda^\xi \in \mathrm{Ob}\,\mathcal{T}^\xi$, *given by* $\lambda^\xi(\xi(A)) := \xi(\lambda(A))$ *for all* $A \in \mathcal{A}$.

(ii) *The map* $\mathrm{Ob}\,\mathcal{T}\ni\lambda\to\lambda^\xi\in\mathrm{Ob}\,\mathcal{T}^\xi$ *is compatible with products, direct sums and subobjects. It also preserves unitary equivalence.*

We have that $(\mathrm{Ob}\,\mathcal{T})^\xi\subseteq\mathrm{Ob}\,\mathcal{T}^\xi$, and we now claim that up to unitary equivalence, we have in fact equality.

Theorem 4.10: *Under the conditions of Theorem 4.8 we have that*

(i) *if* $\sigma\in\mathrm{Ob}\,\mathcal{T}^\xi$, *then there is always a* $\lambda\in\mathrm{Ob}\,\mathcal{T}$ *such that* λ^ξ *is unitarily equivalent to* σ, *i.e., each unitary equivalence class in* $\mathrm{Ob}\,\mathcal{T}^\xi$ *contains at least one element of the form* λ^ξ.

(ii) *The map* $\mathrm{Ob}\,\mathcal{T}\ni\lambda\to\lambda^\xi\in\mathrm{Ob}\,\mathcal{T}^\xi$ *produces an isomorphism between the sets of unitary equivalence classes of* $\mathrm{Ob}\,\mathcal{T}$ *and* $\mathrm{Ob}\,\mathcal{T}^\xi$ *which is compatible with products direct sums and subobjects.*

The relation between the arrows of the two categories is however less direct.

Lemma 4.11: Under the conditions of Theorem 4.8 we have

$$\xi((\sigma,\tau)_{\mathcal{A}})\subseteq(\sigma^\xi,\tau^\xi)_{\xi(\mathcal{A})}.$$

Next we show that $\mathrm{Ker}\,\xi$ is uniquely determined by $\mathrm{Ker}\,\xi\cap\mathcal{F}_{\mathrm{fin}}$.

Proposition 4.12: Under the conditions of Theorem 4.8 we have that

(i) $\mathrm{Ker}\,\xi\cap\mathcal{F}_{\mathrm{fin}}=\mathrm{Span}\{(\mathrm{Ker}\,\xi\cap\mathcal{A})\mathcal{H}_\gamma|\,\gamma\in\hat{\mathcal{G}}\}$,

(ii) $\mathrm{Ker}\,\xi=\mathrm{clo}_{|\cdot|_{\mathcal{A}}}(\mathrm{Ker}\,\xi\cap\mathcal{F}_{\mathrm{fin}})\cap\mathcal{F}$.

Thus $\mathrm{Ker}\,\xi$ is in fact uniquely determined by $\mathrm{Ker}\,\xi\cap\mathcal{A}$, as is already suggested by Theorem 4.8 (iii). Since $\mathcal{F}$ is in general not complete with respect to $|\cdot|_{\mathcal{A}}$, the intersection with $\mathcal{F}$ in Proposition 4.12 (ii) is necessary.

Theorem 4.8 suggests that we consider the following subcategory of $\mathcal{T}^\xi$.

Definition 4.13: The subcategory $\xi(\mathcal{T})$ *of* $\mathcal{T}^\xi$ *is defined by the objects*

$$\mathrm{Ob}\,\xi(\mathcal{T}):=(\mathrm{Ob}\,\mathcal{T})^\xi$$

and the arrows

$$(\sigma^\xi,\tau^\xi)^{(0)}_{\xi(\mathcal{A})}:=\xi((\sigma,\tau)_{\mathcal{A}}).$$

By Theorem 4.10 the sets of all unitary equivalence classes of $\mathrm{Ob}\,\xi(\mathcal{T})$ and $\mathrm{Ob}\,\mathcal{T}^\xi$ coincide, each equivalence class of $\mathrm{Ob}\,\xi(\mathcal{T})$ is a subset of the corresponding equivalence class of $\mathrm{Ob}\,\mathcal{T}^\xi$, but in general these equivalence classes are much larger.

Lemma 4.11 says that the arrow sets $(\sigma^\xi,\tau^\xi)_{\xi(\mathcal{A})}$ of the objects of $\mathrm{Ob}\,\xi(\mathcal{T})$ considered as objects of $\mathrm{Ob}\,\mathcal{T}^\xi$ are in general larger than the corresponding arrow sets in $\xi(\mathcal{T})$. The reason is that an element $X=\xi(Y)$, $Y\in\mathcal{A}$, belongs to $(\sigma^\xi,\tau^\xi)_{\xi(\mathcal{A})}$ iff $Y\sigma(A)-\tau(A)Y\in\mathrm{Ker}\,\xi$ for all $A\in\mathcal{A}$. The arrow sets coincide only if this relation already implies $Y\sigma(A)-\tau(A)Y=0$.

C. Morphisms of minimal and regular Hilbert systems

Recall now that by Theorems 2.25 and 2.27 we have an equivalence between minimal and regular Hilbert systems with Property B and the endomorphism category $\mathcal{T}$ with an admissible subcategory $\mathcal{T}_{\mathbb{C}}$. We called a subcategory $\mathcal{T}_{\mathbb{C}}$ *admissible* if it satisfies conditions P.1 and P.2 in Theorem 2.25.

As in the last section, we consider a unital morphism $\xi:\mathcal{F}\to\mathcal{L}=\xi(\mathcal{F})$, and recall by Proposition 4.12 that ξ is determined by its action on $\mathcal{A}$. Now while it is obvious that $\xi(Z(\mathcal{A}))\subseteq Z(\xi(\mathcal{A}))$, we require below the stronger condition

$$\xi(Z(\mathcal{A})) = Z(\xi(\mathcal{A})). \tag{7}$$

When $\xi(\mathcal{A})$ is a simple C*-algebra (as we require for the final observables after a T-procedure), the condition (7) will be satisfied.

Theorem 4.14: *Given a minimal and regular Hilbert system* $\{\mathcal{F},\mathcal{G}\}$ *with Property B, and a unital morphism* $\xi:\mathcal{F}\to\mathcal{L}=\xi(\mathcal{F})$ *such that* $\mathcal{G}\subset \mathrm{Aut}_\xi \mathcal{F}$ *and condition (7) holds, then*

(i) *there is a DR-subcategory* $\mathcal{T}^\xi_{\mathbb{C}}$ *of* $\xi(\mathcal{T})$,
(ii) *property P.2 is satisfied for* $\mathcal{T}^\xi_{\mathbb{C}}$ *iff* $\xi(\mathcal{A})'\cap\xi(\mathcal{F})=\xi(Z(\mathcal{A}))$. *In this case the subcategory* $\mathcal{T}^\xi_{\mathbb{C}}$ *is admissible*.
(iii) *If* $\xi(\mathcal{A})'\cap\xi(\mathcal{F})=\xi(Z(\mathcal{A}))$, *then*

$$(\sigma^\xi,\tau^\xi)_{\xi(\mathcal{A})} = \xi((\sigma,\tau)_{\mathcal{A}})$$

for all $\sigma,\ \tau\in \mathrm{Ob}\,\mathcal{T}$, *where we made use of the notation and result in Corollary 4.9.*
(iv) *In this case choose* $\mathcal{H}_\gamma\in \mathrm{Ob}\,\mathcal{T}_{\mathcal{G}}$. *Then*

$$\mathcal{M}^\xi := \{\rho_{\xi(\mathcal{H}_\gamma)} | \gamma\in\hat{\mathcal{G}}\}\subset \mathrm{Ob}\ \xi(\mathcal{T})$$

is a complete system of (irreducible) and mutually disjoint objects of $\mathrm{Ob}\ \xi(\mathcal{T})$.

D. The inverse problem

Theorem 4.15: *Let* $\mathcal{A}$ *be a unital C*-algebra with Property B, and let* $\mathcal{T}$ *be a C*-tensor category of unital endomorphisms of* $\mathcal{A}$. *Let* $\mathcal{T}$ *have an admissible subcategory* $\mathcal{T}_{\mathbb{C}}$ *whose arrow spaces are denoted by* $(\sigma,\tau)_{\mathbb{C}}$. *Furthermore, let* ξ *be a unital morphism of* $\mathcal{A}$ *such that*

(i) $\xi(Z(\mathcal{A}))=Z(\xi(\mathcal{A}))$,
(ii) $\lambda(\mathrm{Ker}\,\xi)\subseteq\mathrm{Ker}\,\xi$ *for all* $\lambda\in\mathrm{Ob}\,\mathcal{T}$. *Thus we can define endomorphisms* $\lambda^\xi\in\mathrm{End}\,\xi(\mathcal{A})$ *by* $\lambda^\xi(\xi(A)):=\xi(\lambda(A))$ *for all* $A\in\mathcal{A}$ *and a category* $\xi(\mathcal{T})$ *with objects*

$$\mathrm{Ob}\ \xi(\mathcal{T}) := \{\lambda^\xi | \lambda\in \mathrm{Ob}\ \mathcal{T}\} \tag{8}$$

and arrows $(\sigma^\xi,\tau^\xi)_{\xi(\mathcal{A})}$, *which is closed with respect to direct sums and products*,
(iii) $\xi((\sigma,\tau)_{\mathcal{A}})=(\sigma^\xi,\tau^\xi)_{\xi(\mathcal{A})}$ *for all* $\sigma,\ \tau\in\mathrm{Ob}\,\mathcal{T}$.

Then there is a subcategory $\mathcal{T}^\xi_{\mathbb{C}}$ *of* $\xi(\mathcal{T})$ *with* $\mathrm{Ob}\,\mathcal{T}^\xi_{\mathbb{C}}=\mathrm{Ob}\,\xi(\mathcal{T})$ *which is admissible for* $\xi(\mathcal{T})$.

Thus by Theorem 2.27 there are Hilbert extensions $\mathcal{F}$ *and* $\mathcal{F}^\xi$ *corresponding to* $\mathcal{T}$ *and* $\xi(\mathcal{T})$, *repectively. Moreover, the Hilbert extension* $\mathcal{F}^\xi$ *of* $\xi(\mathcal{A})$ *can be chosen in such a way that it is the homomorphic image of* $\mathcal{F}$ *under a morphism which is an extension of* ξ. *That is*, $\mathcal{F}^\xi=\tilde{\xi}(\mathcal{F})$ *where* $\tilde{\xi}$ *is a morphism of* $\mathcal{F}$ *such that* $\tilde{\xi}(A)=\xi(A)$ *for all* $A\in\mathcal{A}$.

Remark 4.16: A posteriori, the set of objects $\mathrm{Ob}\,\xi(\mathcal{T})$ defined in (8) could be enlarged by filling up the unitary equivalence classes of each λ^ξ by *all* τ with $\tau=\mathrm{Ad}\,V\circ\xi(\lambda)$, where $V\in\xi(\mathcal{A})$ is unitary. This corresponds to the objects of the category $\mathcal{T}^\xi$ of Definition 4.13. In this case we must also add additional arrows, so if $\tau_i=\mathrm{Ad}\,V_i\circ\xi(\lambda_i)$, $i=1,2$, then we also need

$$(\tau_1,\tau_2)_{\xi(\mathcal{A})} := V_2(\tau_1^\xi,\tau_2^\xi)_{\xi(\mathcal{A})}V_1^{-1}.$$

However, for the application of Theorem 2.27 this is not necessary.

E. Superselection structures left after constraining

Recall that the enforcement of constraints by T-procedure produces a final physical algebra $\mathcal{R}$. This algebra is usually assumed to be simple; if it is not, then the physics is not fully defined, and one should extend the constraint set $\mathcal{C}\subset\mathcal{A}$ to make $\mathcal{R}$ simple (the choice of the extension needs to be physically motivated).

In the preceding sections we examined which conditions need to be satisfied by a Hilbert extension $\{\mathcal{F},\mathcal{G}\}$ of $\mathcal{A}$ for its structure to pass through the two parts of the T-procedure. Here we combine these to produce conditions on the initial system which will ensure that we obtain a Hilbert extension of $\mathcal{R}$. We will also examine when this final Hilbert extension is regular (and this produces then a DR-category via simplicity of $\mathcal{R}$).

Theorem 4.17: *Let $\{\mathcal{F},\mathcal{G}\}$ be a Hilbert extension of $\mathcal{A}$, and let $\mathcal{C}\subset\mathcal{A}$ be a first-class constraint set such that $\mathcal{D}\sim\rho_\gamma(\mathcal{D})$ holds for all $\gamma\in\widehat{\mathcal{G}/\mathcal{K}}$. Then $\{\mathcal{R}_\mathcal{F},\beta_\mathcal{G}\}$ is a Hilbert extension of $\mathcal{R}$, where $\mathcal{R}_\mathcal{F}=\xi(\mathcal{O}_\mathcal{F})$, and ξ is the factor map $\mathcal{O}_\mathcal{F}\to\mathcal{O}_\mathcal{F}/\mathcal{D}_\mathcal{F}$.*

Proof: By Corollary 4.3 it follows from the hypotheses that $\{\mathcal{O}_\mathcal{F},\beta_\mathcal{G}\}$ is a Hilbert extension of $\mathcal{O}$. Since the constraint set $\mathcal{C}\subset\mathcal{A}$ is $\mathcal{G}$-invariant, we have that $\alpha(\mathcal{D}_\mathcal{F})=\mathcal{D}_\mathcal{F}$ for all $\alpha\in\beta_\mathcal{G}\subset\mathrm{Aut}\,\mathcal{O}_\mathcal{F}$, i.e., $\beta_\mathcal{G}\subset\mathrm{Aut}_\xi\,\mathcal{O}_\mathcal{F}$. (Recall the discussion in the introductory part of Sec. IV.) Thus by Theorem 4.8 it follows that $(\beta_\mathcal{G})^\xi\cong\beta_\mathcal{G}$, and that

$$\{\xi(\mathcal{O}_\mathcal{F}),(\beta_\mathcal{G})^\xi\}=\{\mathcal{R}_\mathcal{F},\beta_\mathcal{G}\}$$

is a Hilbert extension of $\mathcal{R}=\xi(\mathcal{O})$. ■

Next, we would like to examine when a Hilbert extension as in Theorem 4.17 will produce a minimal and regular Hilbert extension of $\mathcal{R}$ (with Property B).

First recall the requirement for a Hilbert system $\{\mathcal{F},\mathcal{G}\}$ to be regular, there is an assignment $\sigma\to\mathcal{H}_\sigma$ from $\mathrm{Ob}\,\mathcal{T}$ to $\mathcal{G}$-invariant algebraic Hilbert spaces in $\mathcal{F}$ such that

(i) $\sigma=\rho_{\mathcal{H}_\sigma}$, i.e., σ is the canonical endomorphism of $\mathcal{H}_\sigma$,
(ii) $\sigma\circ\tau\to\mathcal{H}_\sigma\cdot\mathcal{H}_\tau$,

that is, the assignment is compatible with products.

We now want to check whether this property also survives the map $T:\{\mathcal{F},\mathcal{G}\}\to\{\mathcal{R}_\mathcal{F},\beta_\mathcal{G}\}$.

Proposition 4.18: Let $\mathcal{T}$ satisfy regularity. Let $\mathcal{D}\sim\rho_\gamma(\mathcal{D})$ for all $\gamma\in\widehat{\mathcal{G}/\mathcal{K}}$, then $\{\mathcal{R}_\mathcal{F},\beta_\mathcal{G}\}$ satisfies regularity, i.e., there is an assignment $\sigma\to\mathcal{H}_\sigma$ such that

(i) $\sigma=\rho_{\mathcal{H}_\sigma}$, *i.e., σ is the canonical endomorphism of $\mathcal{H}_\sigma$*,
(ii) $\sigma\circ\tau\to\mathcal{H}_\sigma\cdot\mathcal{H}_\tau$.

Proof: Given the assignment $\sigma\to\mathcal{H}_\sigma$ in $\mathcal{F}$, then whenever $\sigma=\rho_\gamma$, $\gamma\in\widehat{\beta_\mathcal{G}}$ we have

$$\sigma\to\mathcal{H}_\sigma\subset\mathcal{O}_\mathcal{F}\to\mathcal{R}_\mathcal{F},$$

where the last map is ξ, so the assignment which we take for this proposition is $\sigma\to\xi(\mathcal{H}_\sigma)$. Then (i) and (ii) are automatic. □

Second, we consider Property B.

Proposition 4.19: Let $\{\mathcal{F},\mathcal{G}\}$ satisfy Property B, let $\mathcal{G}$ be non-Abelian and $\mathcal{C}\subset\mathcal{A}$ be an E-constraint set. If $\mathcal{D}\sim\rho_\gamma(\mathcal{D})$ for all $\gamma\in(\widehat{\mathcal{G}/\mathcal{K}})$, then $\{\mathcal{O}_\mathcal{F},\beta_\mathcal{G}\}$ satisfies Property B.

Proof: First $\{\mathcal{O}_\mathcal{F},\beta_\mathcal{G}\}$ is a Hilbert extension of $\mathcal{O}$ with respect to $\mathcal{G}/\mathcal{K}$ because of Corollary 4.3. Choose a $\mathcal{G}$-invariant Hilbert space $\mathcal{H}\subset\mathcal{O}_\mathcal{F}\subset\mathcal{F}$ which is not irreducible, i.e., there is a projection $E\in\mathcal{J}(\mathcal{L}_\mathcal{G}(\mathcal{H}))$, $0<E<\mathbb{1}$. Then one has $E\in(\rho_\mathcal{H},\rho_\mathcal{H})_\mathcal{A}\subset(\rho_\mathcal{H}\restriction\mathcal{O},\rho_\mathcal{H}\restriction\mathcal{O})_\mathcal{O}\subset\mathcal{O}$ by Theorem 4.2 (ii). By Property B we get closure under subobjects, so there is a $V\in\mathcal{A}$, $V^*V=\mathbb{1}$, $VV^*=E$. In other words, $E\cong\mathbb{1}(\mathrm{mod}\,\mathcal{A})$. Similarly we obtain $\mathbb{1}-E\cong\mathbb{1}(\mathrm{mod}\,\mathcal{A})$. Since $\mathcal{C}$ is an E-constraint set and $E\in\mathcal{O}$ we get that $E\cong\mathbb{1}(\mathrm{mod}\,\mathcal{O})$ and $\mathbb{1}-E\cong\mathbb{1}(\mathrm{mod}\,\mathcal{O})$ and this is the assertion. ■

Finally, we need to consider whether the requirement

$$\mathcal{A}'\cap\mathcal{F}=Z(\mathcal{A})$$

passes through the T-procedure. In full generality, this is a very hard problem, because both stages of the T-procedure can eliminate or create elements of $\mathcal{A}'$. In fact, since $\mathcal{A}'\cap\mathcal{F}\subset\mathcal{D}'\cap\mathcal{F}\subset\mathcal{O}_\mathcal{F}$ and $Z(\mathcal{A})\subset Z(\mathcal{O})$, we can only deduce from $\mathcal{A}'\cap\mathcal{F}=Z(\mathcal{A})$ that $\xi(\mathcal{A}'\cap\mathcal{F})=\xi(Z(\mathcal{A}))$. On the other hand, $\mathcal{R}'\cap\mathcal{R}_\mathcal{F}=Z(\mathcal{R})$ iff

$$A \in \mathcal{O}_{\mathcal{F}} \quad \text{and } [A,\mathcal{O}] \subset \mathcal{D}_{\mathcal{F}} \text{ implies } A \in \mathcal{O} + \mathcal{D}_{\mathcal{F}}$$

which can be true in general for more elements than those in $\xi(\mathcal{A}' \cap \mathcal{F})$.

We do have from Theorem 4.2 and Proposition 2.22 the following condition.

Proposition 4.20: Let $\{\mathcal{F},\mathcal{G}\}$ be a minimal Hilbert extension of $\mathcal{A}$, and let $\mathcal{C} \subset \mathcal{A}$ be a first-class constraint set such that $\mathcal{D} \sim \rho_\gamma(\mathcal{D})$ holds for all $\gamma \in \widehat{\mathcal{G}/\mathcal{K}}$. If the disjointness of canonical endomorphisms survives the restriction to $\mathcal{O}$ then the Hilbert system $\{\mathcal{O}_{\mathcal{F}}, \beta_{\mathcal{G}}\}$ is minimal, i.e., $\mathcal{O}' \cap \mathcal{O}_{\mathcal{F}} = \mathcal{Z}(\mathcal{O})$.

V. EXAMPLE
