In order to prove (B6), it is convenient to unfold $\mathbb{T}^2$ and the discontinuity of S_α on the plane $\mathbb{R}^2$. This is most easily done as follows. Points $A \in \mathbb{T}^2 = \mathbb{R}^2/\mathbb{Z}^2$ are represented by equivalence classes

$$[\mathbf{a}] := \{\mathbf{a} + \mathbf{n}, \mathbf{n} \in \mathbb{Z}^2\}, \quad \mathbf{a} \in [0,1)^2. \tag{B8}$$

Given A, $B \in \mathbb{T}^2$, let $A^b \in [\mathbf{a}]$ be such that

$$d_{\mathbb{T}^2}([\mathbf{a}],[\mathbf{b}]) = \|A^b - \mathbf{b}\|_{\mathbb{R}^2}.$$

Notice that

$$d_{\mathbb{T}^2}([\mathbf{a}],[\mathbf{b}]) = \|\mathbf{a} - \mathbf{b}\|_{\mathbb{R}^2} \text{ iff } \|\mathbf{a} - \mathbf{b}\|_{\mathbb{R}^2} \leqslant \frac{1}{2} \tag{B9}$$

(1a) (A,B) not crossing γ_{-1} means that the segment $(A^b,\mathbf{b})$ does not intersect γ_{-1}. Periodically covering the plane $\mathbb{R}^2$ by squares $[0,1)^2$, the γ_{-1} lines form a set of (parallel) straight lines $x_1 - x_2 = n \in \mathbb{Z}$; it follows that $(A^b,\mathbf{b})$ does not cross γ_{-1} iff

$$\lfloor A_1^b - A_2^b \rfloor = \lfloor b_1 - b_2 \rfloor, \tag{B10}$$

where the integral part on the r.h.s. takes values 0, −1, depending on which side of the diagonal γ_{-1} the point $\mathbf{b}$ lies within.

As $S_\alpha^\pm$ are not sensitive to the integer part of their arguments, their actions are the same on all elements of the equivalence classes (B8), that is

$$d_{\mathbb{T}^2}(S_\alpha^{-1}(A),S_\alpha^{-1}(B)) = d_{\mathbb{T}^2}(S_\alpha^{-1}([\mathbf{a}]),S_\alpha^{-1}([\mathbf{b}])) = d_{\mathbb{T}^2}(S_\alpha^{-1}(A^b),S_\alpha^{-1}(\mathbf{b})).$$

By expanding $\langle x \rangle = x - \lfloor x \rfloor$, using the definition of $S_\alpha^{-1}(\cdot)$ and putting together all integral contributions, condition (B10) yields

$$\begin{aligned} d_{\mathbb{T}^2}(S_\alpha^{-1}(A),S_\alpha^{-1}(B)) &= \min_{\mathbf{m} \in \mathbb{Z}^2} \|S_\alpha^{-1}(A) - S_\alpha^{-1}(B) + \mathbf{m}\|_{\mathbb{R}^2} \\ &= \min_{\mathbf{m}' \in \mathbb{Z}^2} \|S_\alpha^{-1} \cdot (A^b - \mathbf{b}) + \mathbf{m}'\|_{\mathbb{R}^2} = d_{\mathbb{T}^2}(S_\alpha^{-1} \cdot (A^b - \mathbf{b}),0). \end{aligned}$$

Applying (B7), since we assumed $d_{\mathbb{T}^2}(A,B) < \frac{1}{2}\eta^{-1}$, we estimate

$$\|S_\alpha^{-1} \cdot (A^b - \mathbf{b})\|_{\mathbb{R}^2} \leqslant \eta \|A^b - \mathbf{b}\|_{\mathbb{R}^2} = \eta d_{\mathbb{T}^2}(A,B) < \frac{1}{2}.$$

In particular, using (B9), the previous inequalities imply

$$d_{\mathbb{T}^2}(S_\alpha^{-1}\cdot(A^b-\mathbf{b}),0)=\|S_\alpha^{-1}\cdot(A^b-\mathbf{b})\|_{\mathbb{R}^2}\leqslant \eta d_{\mathbb{T}^2}(A,B).$$

(1b) Using the same argument as (1a), the union of γ_0 lines constitute a set of straight lines $x_1=n\in\mathbb{Z}$; therefore the segment $(A^b,\mathbf{b})$ does not cross γ_0 iff

$$\lfloor A_1^b\rfloor=\lfloor b_1\rfloor. \tag{B11}$$

As done before, by means of (B11), we arrive at

$$d_{\mathbb{T}^2}(S_\alpha(A),S_\alpha(B))=d_{\mathbb{T}^2}(S_\alpha(A^b),S_\alpha(\mathbf{b}))=d_{\mathbb{T}^2}(S_\alpha\cdot(A^b-\mathbf{b}),0).$$

The proof can now be completed exactly as for point (2a) before.

(2) We denote by $d_{\mathbb{T}^2}(\mathbf{x},\gamma)=\inf_{\mathbf{y}\in\gamma}d_{\mathbb{T}^2}(\mathbf{x},\mathbf{y})$ the distance of the point $\mathbf{x}\in\mathbb{T}^2$ from a curve $\gamma\in\mathbb{T}^2$. Then, from definition (18) we have:

$$\mathbf{x}\in\overline{\gamma}_{p-1}(\varepsilon)\Rightarrow\varepsilon\geqslant d_{\mathbb{T}^2}(\mathbf{x},\gamma_{p-1})=d_{\mathbb{T}^2}(\mathbf{x},\mathbf{y}^\star), \tag{B12}$$

where $\mathbf{y}^\star$ is the nearest point to $\mathbf{x}$ belonging to γ_{p-1}.

We distinguish two cases:

(2′) The segment $(\mathbf{x},\mathbf{y}^\star)$ does not cross (we stipulate that, if $\mathbf{y}^\star\in\gamma_{-1}$ or $\mathbf{x}\in\gamma_{-1}$, we are still in a noncrossing condition) γ_{-1}: From (B12) and point (1a), since $S_\alpha^{-1}(\mathbf{y}^\star)\in\gamma_p$ [see (16a)], we get

$$d_{\mathbb{T}^2}(S_\alpha^{-1}(\mathbf{x}),\gamma_p)\leqslant d_{\mathbb{T}^2}(S_\alpha^{-1}(\mathbf{x}),S_\alpha^{-1}(\mathbf{y}^\star))\leqslant\eta d_{\mathbb{T}^2}(\mathbf{x},\mathbf{y}^\star)\leqslant\eta\varepsilon.$$

Therefore $S_\alpha^{-1}(\mathbf{x})\in\overline{\gamma}_p(\eta\varepsilon)$.

(2″) The segment $(\mathbf{x},\mathbf{y}^\star)$ crosses γ_{-1}: In this case, there exists $\mathbf{z}\in\gamma_{-1}$ such that

$$d_{\mathbb{T}^2}(\mathbf{x},\mathbf{y}^\star)=d_{\mathbb{T}^2}(\mathbf{x},\mathbf{z})+d_{\mathbb{T}^2}(\mathbf{z},\mathbf{y}^\star). \tag{B13}$$

Then, from (B12) and (B13),

$$\varepsilon\geqslant d_{\mathbb{T}^2}(\mathbf{x},\mathbf{y}^\star)\geqslant d_{\mathbb{T}^2}(\mathbf{x},\mathbf{z}).$$

Since, according to (16), $S_\alpha^{-1}(\mathbf{z})\in\gamma_0$, from point (1a) we get

$$d_{\mathbb{T}^2}(S_\alpha^{-1}(\mathbf{x}),\gamma_0)\leqslant d_{\mathbb{T}^2}(S_\alpha^{-1}(\mathbf{x}),S_\alpha^{-1}(\mathbf{z}))\leqslant\eta\varepsilon,$$

that is $S_\alpha^{-1}(\mathbf{x})\in\overline{\gamma}_0(\eta\varepsilon)$.

(3) From point (2), it follows that when $0\leqslant\varepsilon\leqslant\frac{1}{2}$, for $p\in\mathbb{N}^+$,

$$\mathbf{x}\notin(\overline{\gamma}_p(\varepsilon)\cup\overline{\gamma}_0(\varepsilon))\Rightarrow S_\alpha(\mathbf{x})\notin\overline{\gamma}_{p-1}(\eta^{-1}\varepsilon). \tag{B14}$$

We prove by induction that when $0\leqslant\varepsilon\leqslant\frac{1}{2}$, for $m\in\mathbb{N}^+$,

$$\mathbf{x}\notin\bigcup_{p=0}^{m}\overline{\gamma}_p(\varepsilon)\Rightarrow S_\alpha(\mathbf{x})\notin\bigcup_{p=0}^{m-1}\overline{\gamma}_p(\eta^{-1}\varepsilon). \tag{B15}$$

For $m=1$, (B15) follows from (B14); if (B15) holds for $m=r$, then take

$$\mathbf{x}\notin\bigcup_{p=0}^{r+1}\overline{\gamma}_p(\varepsilon).$$

This means that

$$\mathbf{x}\notin\bigcup_{p=0}^{r}\overline{\gamma}_p(\varepsilon)$$

and $\mathbf{x}\notin(\overline{\gamma}_{r+1}(\varepsilon)\cup\overline{\gamma}_0(\varepsilon))$. Now, using the induction hypothesis and (B14), we get

$$\mathbf{x} \notin \bigcup_{p=0}^{r+1} \overline{\gamma_p}(\varepsilon) \Rightarrow S_\alpha(\mathbf{x}) \notin \bigcup_{p=0}^{r-1} \overline{\gamma_p}(\eta^{-1}\varepsilon)$$

$$S_\alpha(\mathbf{x}) \notin \overline{\gamma_r}(\eta^{-1}\varepsilon).$$

Setting $m=n-1$ and iterating q times the implication (B15) argument, we get

$$\mathbf{x} \notin \bigcup_{p=0}^{n-1} \overline{\gamma_p}(\varepsilon) \Rightarrow S_\alpha^q(\mathbf{x}) \notin \bigcup_{p=0}^{n-1-q} \overline{\gamma_p}(\eta^{-q}\varepsilon), \quad \forall\, 0 \leqslant q < n.$$

In particular $S_\alpha^q(\mathbf{x}) \notin \overline{\gamma_0}(\eta^{-q}\varepsilon)$, which leads to the lower bound

$$d_{\mathbb{T}^2}(S_\alpha^q(\mathbf{x}), \gamma_0) > \eta^{-q}\varepsilon, \quad \forall\, 0 \leqslant q < n,$$

where the result follows in view of definitions (10) and (19). ■

APPENDIX C. PROOF OF PROPOSITION 4.2

(a) In (16a), we have defined $\gamma_p = S_\alpha^{-p}(\gamma_0)$ where $S_\alpha^{-1}(\mathbf{x})$ (as well as $S_\alpha^{-p}(\mathbf{x})$) is a piecewise continuous mapping onto $\mathbb{T}^2$ with jump discontinuities across the γ_p lines due to the presence of the function $\langle\cdot\rangle$ in (9). Away from the discontinuities, $S_\alpha^{-p}(\mathbf{x})$ behaves as the matrix action $S_\alpha^{-p}\cdot\mathbf{x}$. We now want to estimate the length $l(\gamma_p)$; in order to do that, we unfold γ_p on the plane and calculate the length of the segment $\left\{\mathbf{x}\in\mathbb{R}^2 \middle| \mathbf{x} = S_\alpha^{-p}\cdot\binom{0}{y}, y\in[0,1)\right\}$, which, in its turn, is the image of γ_0 under the matrix action given by $S_\alpha^{-p}\cdot\mathbf{x}$. Therefore, using (B7), the result follows.

(b) Let $\overline{L}(\varepsilon)$ denote the set of points having distance from a segment of length L smaller or equal than ε: it has a volume (under the Lebesgue measure μ) given by

$$\mu(\overline{L}(\varepsilon)) = 2L\varepsilon + \pi\varepsilon^2,$$

where the last term on the r.h.s. takes into account rounding of the extremes of the strip by to semicircle of radius ε. Then (29b) follows from (29a).

(c) This follows from definition (19):

$$\mu(\overline{\Gamma}_n(\varepsilon)) = \mu\left(\bigcup_{p=0}^{n-1} \overline{\gamma_p}(\varepsilon)\right) \leqslant \sum_{p=0}^{n-1} \mu(\overline{\gamma_p}(\varepsilon)).$$

Using (29b), we can write:

$$\mu(\overline{\Gamma}_n(\varepsilon)) \leqslant 2\varepsilon \sum_{p=0}^{n-1} \eta^p + \sum_{p=0}^{n-1} \pi\varepsilon^2 = 2\varepsilon\frac{\eta^n - 1}{\eta - 1} + n\pi\varepsilon^2.$$

Finally the estimate $(x^p-1)/(x-1) \leqslant (\sqrt{2}+1)x^p$, valid for $x > \sqrt{2}$, yields

$$\mu(\overline{\Gamma}_n(\varepsilon)) \leqslant 2\varepsilon(\sqrt{2}+1)\eta^n + n\pi\varepsilon^2.$$

(d) By writing the left inclusion in (22) in terms of complementary sets, with $\varepsilon = \widetilde{N}/2N$, we get

$$\left[G_n^N\left(\frac{\widetilde{N}}{2N}\right)\right]^\circ \subseteq \overline{\Gamma}_n\left(\frac{\widetilde{N}}{2N} + \frac{1}{\sqrt{2}N}\right)$$

and so

$$\mu\left(\left[G_n^N\left(\frac{\tilde{N}}{2N}\right)\right]^\circ\right) \leqslant \mu\left(\overline{\Gamma}_n\left(\frac{\tilde{N}}{2N}+\frac{1}{\sqrt{2}N}\right)\right).$$

By substituting in (29c) $(\tilde{N}+\sqrt{2})/2N=\tilde{N}/2N+1/\sqrt{2}N$ in the place of ε, we get

$$\mu\left(\left[G_n^N\left(\frac{\tilde{N}}{2N}\right)\right]^\circ\right) \leqslant \frac{\tilde{N}+\sqrt{2}}{2N}(\sqrt{2}+1)\left(2\eta^n+\frac{n}{\sqrt{2}+1}\pi\frac{\tilde{N}+\sqrt{2}}{2N}\right). \tag{C1}$$

Finally, the r.h.s of (C1) can be estimated by the following upper bounds:

$$\pi\frac{\tilde{N}+\sqrt{2}}{2N}<2$$

$$\frac{n}{\sqrt{2}+1}<\eta^n$$

$$(\tilde{N}+\sqrt{2})(\sqrt{2}+1)<19\eta^{2n}$$

which hold for $\forall N>\tilde{N}$, $\eta\geqslant\sqrt{2}$, and $\forall n\in\mathbb{N}^+$. This ends the proof. ■

(Received 1 December 2004; accepted 28 March 2005; published online 20 May 2005)

The existence of a Lagrangian description for the second-order Riccati equation is analyzed and the results are applied to the study of two different nonlinear systems both related with the generalized Riccati equation. The Lagrangians are non-natural and the forces are not derivable from a potential. The constant value E of a preserved energy function can be used as an appropriate parameter for characterizing the behavior of the solutions of these two systems. In the second part the existence of two-dimensional versions endowed with superintegrability is proved. The explicit expressions of the additional integrals are obtained in both cases. Finally it is proved that the orbits of the second system, that represents a nonlinear oscillator, can be considered as nonlinear Lissajous figures © *2005 American Institute of Physics.* [DOI: 10.1063/1.1920287]

I. INTRODUCTION

Ince studied, in his well-known book of differential equations,[1] the following equation,

$$w'' + 3ww' + w^3 = q(z)$$

and proved that it has the general solution $w = u'/u$, where u is a general solution of the linear equation of the third order $u''' = q(z)u$. This equation was also studied by Davis in Ref. 2 as a particular case of the generalized Riccati equations (according to Davis the family of these nonlinear equations was first studied by E. Vessiot in 1895 and G. Vallenberg in 1899; see Refs. 3–5 for some more recent studies related with higher-order Riccati equations). Later on Leach *et al.*[6,7] considered the equation

$$\ddot{q} + q\dot{q} + \beta q^3 = 0 \tag{1}$$

and pointed out that "for $\beta = 1/9$ is linearizable, possesses eight symmetries and is completely integrable" and they add "consequently, we could expect that this remarkable mathematical property corresponds to an important physical one appearing (or disappearing) for this value which consequently would appear as a critical one." This particular $\beta = 1/9$ equation was also obtained in Ref. 8 in the study of nonlinear equations with the maximum number of symmetries (see Refs. 9–12, for the Lie symmetry approach to dynamical systems).

[a]Electronic mail: jfc@unizar.es
[b]Electronic mail: mfran@unizar.es
[c]Electronic mail: santander@fta.uva.es

Recently Chandrasekar *et al.*[13] have studied a generalization of this equation obtained as a particular case of the Lienard equation

$$\ddot{x} + f(x)\dot{x} + g(x) = 0$$

given by $f(x) = k\,x$ and $g(x) = (1/9)k\,x^3 + \lambda x$. Although this new equation also belongs to the generalized Riccati family studied by Davis and Leach *et al.*, they make use of a two step procedure to solve the problem: first they use the so-called Prelle-Singer method[14–17] for obtaining a set of time-dependent integrals of motion and secondly they use this time-dependent family in order to compute the solution. The result is interpreted, when $\lambda > 0$, as an "unusual Liénard type oscillator with properties of a linear harmonic oscillator." But we wish to call attention to one property discussed in the final part of the article (after finalizing with the Prelle-Singer method): the existence of a Lagrangian description.

The main objective of this article is to develop a deeper analysis of these nonlinear equations using the Lagrangian formalism as an approach. In fact, the starting point of our approach is the fact that the Riccati equation belongs to a family of nonlinear equations admitting a Lagrangian description. This has interesting consequences, the most important of them is that Riccati systems are systems endowed with a preserved energy function. We study the two nonlinear systems first in one dimension and then in two dimensions. Moreover we prove that the two-dimensional extensions are not only integrable but also superintegrable. We note that this situation has a certain similarity with the one-dimensional nonlinear oscillator studied by Mathews and Lakshmanan[18] that has been proved to admit a superintegrable two-dimensional version.[19]

The plan of this article is as follows: In Sec. II we present a Lagrangian approach to a family of nonlinear equations that includes the second-order Riccati equation as a particular case. Section III, devoted to the first nonlinear system ("dissipative"-looking system), is divided in three parts corresponding to the one-dimensional system, geometric formalism and symmetries, and two-dimensional system and super-integrability, respectively. Section. IV, that is devoted to the second nonlinear system ("nonlinear oscillator"), also first studies the $n=1$ system and then the two-dimensional system that, as we have pointed out, is also endowed with super-integrability. Finally in Sec. V we make some comments.

II. LAGRANGIAN FORMALISM AND SECOND-ORDER RICCATI EQUATIONS

In this article we shall consider the following nonlinear second-order equation

$$y'' + [b_0(t) + b_1(t)y]y' + a_0(t) + a_1(t)y + a_2(t)y^2 + a_3(t)y^3 = 0, \tag{2}$$

where we suppose that $a_3 > 0$ and the two functions b_0, b_1, are not independent but satisfy

$$b_0 = \frac{a_2}{\sqrt{a_3}} - \frac{a_3'}{2a_3}, \quad b_1 = 3\sqrt{a_3}.$$

The more important property of this equation is that it can be transformed into a third-order linear equation by the substitution

$$y(t) = \frac{1}{\sqrt{a_3(t)}}\frac{v'(t)}{v(t)}.$$

Thus Eq. (2), that is the natural second-order generalization of the wellknown Riccati equation, is therefore a nonlinear equation the solution of which can be expressed in terms of solutions of a linear equation of the third order. In fact, it can be considered as the particular $n=2$ case of a more general situation that can be approached by Lie theory or by the action of an operator R. From the Lie theory of symmetries of differential equations, the invariance of the n-order linear equation,

$$v^{(n)} + p_1(t)v^{(n-1)} + \cdots + p_n(t)v = 0,$$

under the vector field $X = v(\partial/\partial v)$, that represents the infinitesimal generator of dilations, means the existence of a change $v = e^u$ such that X becomes $X = \partial/\partial u$, and the transformed equation reduces to an equation of order $(n-1)$ for $y = u'$ that for the $n = 2$ reduces to the usual first-order Riccati equation. Alternatively if R denotes the following differential operator:

$$R = \frac{\mathrm{d}}{\mathrm{d}t} + y(t),$$

then the Riccati equation of order n is given by

$$(R^n + p_1 R^{n-1} + \cdots + p_{n+1}R + p_n)y + p_{n+1} = 0,$$

where $p_j = p_j(t)$, $j = 1, 2, \ldots, n+1$, are $n+1$ arbitrary functions. We note that these two methods lead to the subfamily of the nonlinear equations with the coefficient of the higher power equal to one; nevertheless the general Riccati equation is generated by the change $t = f(\tau)$ of the independent variable; for example for $n = 2$ we obtain

$$y'' + [p_1 + 3y]y' + p_3 + p_2 y + p_1 y^2 + y^3 = 0,$$

and after the time reparametrization we arrive at

$$\frac{\mathrm{d}^2 y}{\mathrm{d}\tau^2} + \left[\left(f' p_1 - \frac{f''}{f'}\right) + 3f' y\right]\frac{\mathrm{d}y}{\mathrm{d}\tau} + (f'^2 p_3) + (f'^2 p_2)y + (f'^2 p_1)y^2 + f'^2 y^3 = 0.$$

We are interested in the study of nonlinear systems given by (2) but first, in this section, we consider a more general family from which the second-order Riccati equation appears as a particular case.

At this point we recall that a Lagrangian function L is called 'natural' or 'of mechanical type' when it is of the form $L = T - V$, where T is a quadratic kinetic term and V is a potential function. Most of the known Lagrangian equations arise from Lagrangians of this particular type; nevertheless the Lagrangian formalism is well defined, not only for these specific functions but also for more general Lagrangian functions.

Proposition 1: The nonlinear second-order Riccati equation admits a Lagrangian description.

Proof: We first consider the following one degree of freedom Lagrangian:

$$L = \frac{1}{v_x + kU(x,t)}. \tag{3}$$

Then we arrive at the following second-order nonlinear equation:

$$\frac{\mathrm{d}^2 x}{\mathrm{d}t^2} + \left(\frac{3}{2}\right)kU_x'\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right) + \left(\frac{1}{2}\right)k^2 UU_x' + kU_t' = 0. \tag{4}$$

In the particular case of the function $U = U(x,t)$ being a quadratic function

$$U = c_0(t) + c_1(t)x + c_2(t)x^2,$$

Eq. (4) reduces to

$$\frac{\mathrm{d}^2 x}{\mathrm{d}t^2} + (b_0 + b_1 x)\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right) + a_0 + a_1 x + a_2 x^2 + a_3 x^3 = 0, \tag{5}$$

where the four functions a_0, a_1, a_2, a_3, are given by

$$a_0 = \tfrac{1}{2}c_0 c_1 + c_0', \quad a_1 = c_0 c_2 + \tfrac{1}{2}c_1^2 + c_1',$$

$$a_2 = \tfrac{3}{2}c_1c_2 + c_2', \quad a_3 = c_2^2,$$

and the two functions b_0 and b_1 satisfy the appropriate restrictions

$$b_0 = \tfrac{3}{2}c_1, \quad b_1 = 3c_2.$$

Thus, the second-order Riccati equation [Eq. (5)], that is a particular case of Eq. (4), is the Euler-Lagrange equation of the Lagrangian function (3) in the particular case of a quadratic function U.

As a corollary of this proposition we can state that, if the function U is time independent, then the nonlinear equation (4) has a first integral that can be interpreted as a preserved energy. The idea is as follows: if we restrict our study to the case of time-independent systems, that is, to nonlinear equations arising from a Lagrangian of the form

$$L = \frac{1}{v_x + kU(x)} \tag{6}$$

then we can define an associated Lagrangian energy E_L by the usual procedure

$$E_L = \Delta(L) - L, \quad \Delta = v_x \frac{\partial}{\partial v_x},$$

and we arrive to

$$E_L = \frac{-(2v_x + kU(x))}{(v_x + kU(x))^2}, \quad \frac{\mathrm{d}}{\mathrm{d}t}E_L = 0.$$

Note that L is non-natural and, as there is neither kinetic term T nor potential function V, the energy cannot be of the form $E_L = T + V$. Note also that a Lagrangian is defined up to certain ambiguities; that is, $\widetilde{L} = c_1L + \underset{\sim}{c_0}$ determines the same differential equation but it leads to an slightly different energy $\widetilde{E_L}$ given by $\widetilde{E_L} = c_1E_L - c_0$. In the natural case, c_1 is determined by the corresponding Riemannian metric (hence the classical one-half coefficient) and c_0 is absorbed in the potential; here we have just taken $c_1 = 1, c_0 = 0$. Concerning the negative sign, that could be considered as something inconvenient, it does not matter at all (it is only an aesthetic question); in fact it can be removed just by chosen $\widetilde{L} = -L$ as a new Lagrangian.

As for the natural case we can obtain the solution of the dynamics from the conservation law of the energy. If we assume that E_L takes the constant value $E_L = E$, then we arrive at

$$E\,v_x^2 + 2(1 + k\,E\,U(x))v_x + k(1 + k\,E\,U(x))U(x) = 0$$

and on solving for v_x and making separation of variables we arrive at

$$t - t_0 = -\int_{x_0}^{x} \frac{E\,\mathrm{d}x}{(1 + kEU(x)) \pm \sqrt{1 + kEU(x)}}. \tag{7}$$

The motion is confined to the region where $E \geqslant -1/(kU)$. To sum up, a time-independent system described by the nonlinear equation (4) is solvable and the solution of the dynamics is given (up to one integration) by (7).

A remarkable property is that the conservation of the energy E_L leads to a plus/minus sign in the expression for the velocity

$$\frac{\mathrm{d}x}{\mathrm{d}t} = \frac{-(1 + kEU(x)) \pm \sqrt{1 + kEU(x)}}{E}.$$

Thus, we obtain two different values for the velocity at the same point x. It is known that in the standard case of a particle in a potential $V(x)$ we also have two possibilities but both with the same

modulus (the positive value for the motion from left to right and the negative for the opposite motion from right to left). In this case the situation is different; we have a Lagrangian but not a potential and the two possible values differ, not just in the sign, but in the absolute value; thus the motions from left to right and from right to left take place at different velocities.

We close this section with the problem of the existence of alternative Lagrangians.

In differential geometric terms a time-independent Lagrangian function L determines an exact two-form ω_L defined as

$$\theta_L = \left(\frac{\partial L}{\partial v_x}\right) \mathrm{d}x, \quad \omega_L = -\,\mathrm{d}\,\theta_L,$$

in such a way that, when L is nonsingular, ω_L is symplectic and the dynamics is given by the vector field Γ_L solution of the equation

$$i(\Gamma_L)\omega_L = dE_L.$$

In this particular case ω_L and Γ_L are given by

$$\omega_L = \frac{2\mathrm{d}x \wedge \mathrm{d}v_x}{(v_x + kU(x))^3}, \quad \Gamma_L = v_x \frac{\partial}{\partial x} + F_x \frac{\partial}{\partial v_x}, \quad F_x = -\left(\frac{1}{2}\right) k(3v_x + kU(x))U_x'.$$

An important property of the Lagrangian formalism is that for one degree of freedom systems there exist many different equivalent Lagrangians.[20,21] A sketch of the proof is as follows: in a two-dimensional manifold all the symplectic forms must be proportional. Hence, for a one degree of freedom Lagrangian, any other symplectic form ω_2 must be proportional to ω_L, that is $\omega_2 = f\omega_L$. Then

$$i(\Gamma_L)\omega_2 = f\, i(\Gamma_L)\omega_L = f\mathrm{d}E_L.$$

The right-hand side is an exact one form if, and only if, $\mathrm{d}f \wedge \mathrm{d}E_L = 0$, which shows that f must be a function of E_L. In this case it can be proved that the new symplectic form ω_2 is derivable from an alternative Lagragian $L_2 \neq L$ for Γ_L.

In this particular case, starting with the Lagrangian (6) and assuming for the constant of motion f the particular expression $f = (-1/E_L)^{3/2}$, we have obtained the following function

$$L_2 = \sqrt{2v_x + kU(x)} \tag{8}$$

as a new alternative Lagrangian for the t-independent version of Eq. (4). This new Lagrangian, that is neither natural or of mechanical type, is equivalent to L in the sense that both determine the same dynamics. Nevertheless we must say that it is not clear whether L_2 will lead to simpler expressions for other dynamical properties; so, in the following, we only use the original Lagrangian (6).

III. LAGRANGIAN CONSERVATIVE APPROACH TO A "DISSIPATIVE"-LOOKING NONLINEAR SYSTEM

A. One-dimensional nonlinear system: Energy and integrability

We now apply the formalism introduced in Sec. II to the study of the following nonlinear equation:

$$\frac{\mathrm{d}^2x}{\mathrm{d}t^2} + 3kx\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right) + k^2x^3 = 0. \tag{9}$$

It is a special case of Eq. (2) and because of this is a Lagrangian equation. In fact, it is easy to verify that it can be obtained from the following Lagrangian function:

$$L = \frac{1}{v_x + kx^2}. \tag{10}$$

Two important properties are as follows.

(i) We note that the value $\beta = 1/9$, pointed out by Leach *et al.*[7] as the particular value introducing a high degree of regularity in the nonlinear problem (1), appears now as related with the Lagrangian origin of the equation. That is, only if $\beta = 1/9$, then Eq. (1) belongs to the Lagrangian family (9) arising from (10).

(ii) This equation looks like a dissipative equation with the damping term proportional to xv_x; nevertheless it is in fact a conservative system because of its Lagrangian origin. What happens is that the term conservative is usually considered in the Newtonian sense, that is, a particle moving in a one-dimensional potential and forces determined as the gradient of the potential. Here the force is a velocity-dependent force and conservative just means the existence of a preserved (non-Newtonian) energy function that is given by

$$E_L = \frac{-(2v_x + k\,x^2)}{(v_x + k\,x^2)^2}.$$

Next we turn to the solution of the dynamics. Instead of considering directly the nonlinear equation we can solve this problem by making use of the conservation law of the energy; if we assume $E_L = E$, then we arrive at

$$E\,v_x^2 + 2(1 + k\,Ex^2)v_x + k(1 + k\,Ex^2)x^2 = 0$$

and solving for v_x we obtain

$$\frac{\mathrm{d}x}{\mathrm{d}t} = \frac{-(1 + k\,Ex^2) \pm \sqrt{1 + k\,Ex^2}}{E}.$$

So, after integration, we arrive at

$$t = \frac{1}{kx}(1 \pm \sqrt{1 + k\,Ex^2})$$

which yields

$$x = \frac{2t}{kt^2 - E}$$

that represents the solution of the dynamics as a function of the constant value E of the Lagrangian energy (for ease of notation we give the solution for the particular initial conditions $(t_0 = 0, x_0 = 0)$). The system is well defined for $(k > 0, E < 0)$ and $(k < 0, E > 0)$, but for $(k < 0, E < 0)$ or $(k > 0, E > 0)$ it is singular at $t = \pm\sqrt{|E|/|k|}$. In fact the double change $(k, E) \to (-k, -E)$ is equivalent to a time-inversion (see Fig. 1).

Since $x(t)$ is the quotient of two polynomials in t, with the denominator of a higher degree than the numerator, the trajectories approach the origin when t increases. How can this behavior be compatible with the conservation of the energy? An analysis of the expression that E_L takes on the trajectories shows that it reduces to the quotient of two functions both going down as $t \to \infty$, but in such a way that the ratio remains constant. Moreover it can also be proved that the velocity v_x decreases as $t \to \infty$ in such a way that the particle approaches but never reaches the origin in the phase plane. The important point is that the dependence of E_L with respect to v_x is defined in such a way that even when $\mathrm{d}x/\mathrm{d}t$ decreases the value of E_L remains constant.

The phase space analysis shows that the origin is a nonelementary critical point for which the linear approximation is not valid. If we consider a small neighborhood of the point, then we find,

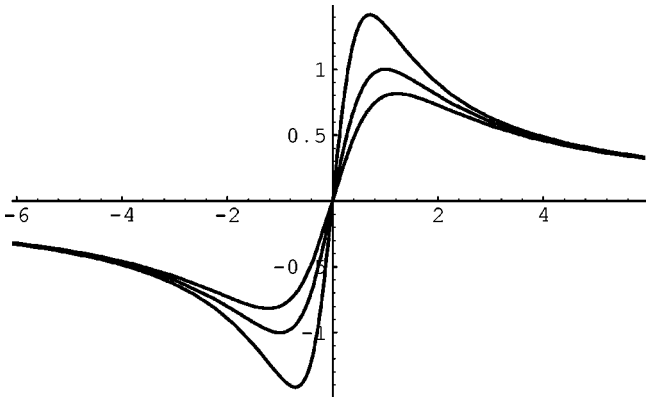

FIG. 1. Plot of x as a function of t, for $k=1$ and three different values of the energy: $E=-0.5$, $E=-1.0$, and $E=-1.5$.

when $k>0$, that it has four different sectors[22] (see Fig. 2): an elliptic sector (upper side), a hyperbolic sector (lower side) and two parabolic sectors (a source on the left and a sink on the right).

B. Symplectic formalism and master symmetries

It is known that the nonlinear equation (9) admits constants of motion depending explicitly on the time t.[13,16] Now we prove that this property is related with the fact that the Lagrangian (10) admits "master symmetries." This is in fact an important property, not only from the geometric point of view but also because it is directly related with the superintegrability of the two-dimensional version of this system.

A function T that satisfies the following property:

$$\frac{\mathrm{d}}{\mathrm{d}t}T\neq 0,\ldots,\quad \frac{\mathrm{d}^m}{\mathrm{d}t^m}T\neq 0,\quad \frac{\mathrm{d}^{m+1}}{\mathrm{d}t^{m+1}}T=0,$$

is called a generator of integrals of motion of degree m. Notice that this means that the function T is a nonconstant function generating a constant of motion by time derivation. If we denote by T_{x1} and T_{x2}, the functions

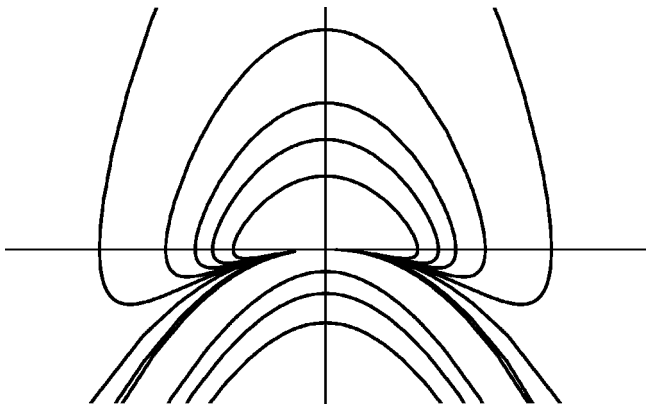

FIG. 2. Phase space trajectories, for $k=1$, in the neighborhood of the origin.

$$T_{x1} = \frac{1}{v_x + k\,x^2}, \quad T_{x2} = \frac{x}{v_x + k\,x^2},$$

then we have

$$\frac{\mathrm{d}}{\mathrm{d}t}T_{x2} = 1, \quad \frac{\mathrm{d}}{\mathrm{d}t}T_{x1} = k\,T_{x2}, \quad \frac{\mathrm{d}^2}{\mathrm{d}t^2}T_{x1} = k, \quad \frac{d^3}{dt^3}T_{x1} = 0.$$

Hence T_{x1} and T_{x2} are generators of integrals of motion for the Lagrangian (10).

In geometric terms this property is related with the existence of master symmetries.[23–27] If the dynamics is represented by a certain vector field Γ; then a vector field Z that satisfies the following two properties

$$[Z,\Gamma] = \widetilde{Z} \neq 0, \quad [\widetilde{Z},\Gamma] = 0,$$

is called a "master symmetry" of degree $m=1$ for Γ. If Z is such that

$$[Z,\Gamma] = \widetilde{Z} \neq 0, \quad [\widetilde{Z},\Gamma] \neq 0, \quad [[\widetilde{Z},\Gamma],\Gamma] = 0,$$

then it is called a master symmetry of degree $m=2$.

We focus our attention in the case of master symmetries given rise via $\widetilde{Z}$ to constants of motion. Let L be a time-independent Lagrangian, Z the Hamiltonian vector field of a certain function T, and suppose that Z is a (time-independent) master symmetry of Γ_L. Then the time-dependent vector field Y_Z determined by Z and defined as

$$Y_Z = Z + t[Z,\Gamma_L] + \tfrac{1}{2}t^2[[Z,\Gamma_L],\Gamma_L] + \ldots$$

is a time-dependent symmetry of Γ_L that, in the case $m=1$, satisfies

$$i(Y_Z)\Omega_E = \mathrm{d}[T - t\,\Gamma_L(T)]$$

where $\Omega_E = \omega_L + \mathrm{d}E_L \wedge \mathrm{d}t$. Hence the time-dependent function $J^t = T - t\,\Gamma_L(T)$ is a time-dependent constant of motion (for $m=2$ the corresponding constant J^t is quadratic in t).

We now return to the Lagrangian (10) and denote by Z_{x1} and Z_{x2}, the Hamiltonian vector fields of T_{x1} and T_{x2},

$$i(Z_{x1})\omega_L = \mathrm{d}T_{x1}, \quad i(Z_{x2})\omega_L = \mathrm{d}T_{x2},$$

which are given by

$$Z_{x1} = -\frac{1}{2}M_x\left(\frac{\partial}{\partial x} - 2kx\frac{\partial}{\partial v_x}\right),$$

$$Z_{x2} = -\frac{1}{2}M_x\left(x\frac{\partial}{\partial x} + (v_x - kx^2)\frac{\partial}{\partial v_x}\right),$$

where M_x denotes $M_x = v_x + k\,x^2$. Then we have

$$[Z_{x1},\Gamma_L] = -\,k\,Z_{x2}, \quad [[Z_{x1},\Gamma_L],\Gamma_L] = 0.$$

It is clear that Z_{x1} is a master symmetry. Concerning Z_{x2} it has some very interesting characteristics; it is a dynamical symmetry (i.e., $[Z_{x2},\Gamma_L]=0$) and it is a symplectic symmetry (that is, $\mathcal{L}_{Z_{x2}}\omega_L = 0$), but nevertheless it is not a Cartan symmetry of the Lagrangian system Γ_L because $Z_{x2}(E_L) \neq 0$. Recall that the two properties $\mathcal{L}_X\omega_L = 0$ and $[X,\Gamma_L]=0$ imply that $\mathcal{L}_X dE_L = 0$, but from this we only obtain that $X(E_L)$ must be a numerical constant.

As explained previously, the vector fields Z_{x1} and Z_{x2}, determine two new vector fields Y_1 and Y_2, given by

$$Y_1 = Z_{x2} + t[Z_{x2},\Gamma_L] = Z_{x2},$$

$$Y_2 = Z_{x1} + t[Z_{x1},\Gamma_L] + \tfrac{1}{2}t^2[[Z_{x1},\Gamma_L],\Gamma_L] = Z_{x1} - k\,t\,Z_{x2},$$

such that they satisfy

$$i(Y_1)\Omega_E = i(Z_{x2})\omega_L + Z_{x2}(E_L)dt = d[T_{x2} - t],$$

$$i(Y_2)\Omega_E = i(Z_{x1} - ktZ_{x2})\omega_L + Z_{x1}(E_L)\mathrm{d}t - ktZ_{x2}(E_L)\mathrm{d}t = \mathrm{d}\left[T_{x1} - ktT_{x2} + \tfrac{1}{2}kt^2\right].$$

Hence the two following functions:

$$J^t_{x1} = T_{x2} - t, \quad J^t_{x2} = T_{x1} - ktT_{x2} + \tfrac{1}{2}kt^2$$

are time-dependent integrals of motion determined by Z_{x1}, Z_{x2}, via Y_1, Y_2.

In the next subsection we see that these symmetries and these time-dependent integrals are the origin of the $n=2$ superintegrability.

C. Two-dimensional nonlinear system: Lagrangian formalism and superintegrability

We now want to study the nonlinear system

$$\frac{\mathrm{d}^2x}{\mathrm{d}t^2} + 3k_1x\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right) + k_1^2x^3 = 0,$$

$$\frac{\mathrm{d}^2y}{\mathrm{d}t^2} + 3k_2y\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right) + k_2^2y^3 = 0, \tag{11}$$

representing the $n=2$ version of the nonlinear equation, [Eq. (9)]. It is clear, from the results of $n=1$, that these two equations can be considered as the Lagrange equations arising from the following two-dimensional Lagrangian

$$L = \frac{1}{v_x + k_1x^2} + \frac{1}{v_y + k_2y^2}. \tag{12}$$

Therefore the dynamics is characterized by preserving the following Lagrangian energy:

$$E_L = -\frac{(2v_x + k_1x^2)}{(v_x + k_1x^2)^2} - \frac{(2v_y + k_2y^2)}{(v_y + k_2y^2)^2}.$$

The first consequence of the Lagrangian character of the equations is that, as there is no coupling between the two degrees of freedom, the two one-dimensional energies are integrals of motion

$$I_1 = -\frac{(2v_x + k_1x^2)}{(v_x + k_1x^2)^2}, \quad I_2 = -\frac{(2v_y + k_2y^2)}{(v_y + k_2y^2)^2}, \quad \frac{\mathrm{d}}{\mathrm{d}t}I_i = 0, \quad i = 1,2.$$

Our main goal in the study of this nonlinear problem is to prove that this system possesses the rather unusual property of superintegrability. At this point we recall that a system is called superintegrable if it is integrable in the Liouville–Arnold sense and, in addition, possesses more independent first integrals than degrees of freedom (see Refs. 28–36 for some articles published in these last years and Ref. 37 for a recent workshop on superintegrability). It is clear that, for this particular $n=2$ system, superintegrability means the existence of a third independent integral I_3 coupling the two degrees of freedom in similar way as the angular momentum for the isotropic linear harmonic oscillator.

The four functions

$$J^t_{x1} = T_{x2} - t, \quad J^t_{x2} = T_{x1} - k_1 t\, T_{x2} + \tfrac{1}{2}k_1 t^2,$$

$$J^t_{y1} = T_{y2} - t, \quad J^t_{y2} = T_{y1} - k_2 t\, T_{y2} + \tfrac{1}{2}k_2 t^2,$$

are time-dependent constants of motion

$$\frac{\mathrm{d}}{\mathrm{d}t}J^t_{xi} = 0, \quad \frac{\mathrm{d}}{\mathrm{d}t}J^t_{yi} = 0, \quad i = 1,2.$$

We can eliminate the time t by pairing these functions in two different ways and obtain the following two integrals of motion

$$I_3 = T_{x2} - T_{y2},$$

$$I_4 = k_2 T_{x1} + k_1 T_{y1} - k_1 k_2 T_{x2} T_{y2}$$

that take the form

$$I_3 = \frac{x}{v_x + k_1 x^2} - \frac{y}{v_y + k_2 y^2},$$

$$I_4 = \frac{k_2}{v_x + k_1 x^2} + \frac{k_1}{v_y + k_2 y^2} - \frac{k_1 k_2 xy}{(v_x + k_1 x^2)(v_y + k_2 y^2)}.$$

Hence, the nonlinear system given by the Eq. (11) and characterized by Lagrangian (12) is a superintegrable system.

In geometric terms the symplectic form ω_L and the dynamical vector field Γ_L are given by

$$\omega_L = \frac{2\,\mathrm{d}x \wedge \mathrm{d}v_x}{(v_x + kx^2)^3} + \frac{2\,\mathrm{d}y \wedge \mathrm{d}v_y}{(v_y + k_2 y^2)^3},$$

$$\Gamma_L = v_x \frac{\partial}{\partial x} + v_y \frac{\partial}{\partial y} + F_x \frac{\partial}{\partial v_x} + F_y \frac{\partial}{\partial v_y},$$

where $F_x = -k_1 x(3v_x + k_1 x^2)$ and $F_y = -k_2 y(3v_y + k_2 y^2)$. If we denote by Z_{xr} and Z_{yr}, the Hamiltonian vector fields of T_{xr} and T_{yr}, $r = 1,2$, then the vector field

$$X_3 = Z_{x2} - Z_{y2}$$

is a dynamical symmetry,

$$[X_3, \Gamma_L] = 0,$$

as well a Cartan symmetry,

$$X_3(E_L) = 0, \quad \mathcal{L}_{X_3}\omega_L = 0.$$

It determines the function I_3 as the corresponding Hamiltonian

$$i(X_3)\omega_L = \mathrm{d}I_3.$$

Similarly the vector field X_4 given by

$$X_4 = k_2 Z_{x1} + k_1 Z_{y1} - (k_1 k_2)(T_{y2} Z_{x2} + T_{x2} Z_{y2})$$

is also a dynamical symmetry as well a Cartan symmetry,

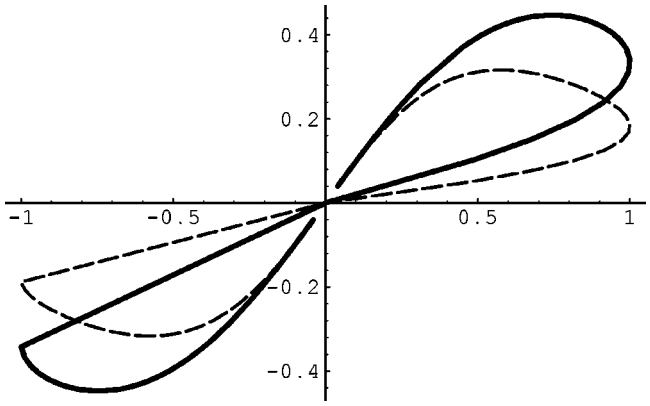

FIG. 3. "Figure eight" in the plane (x,y) corresponding to $k_1=k_2=1$ and energies $E_1=-1, E_2=-5$ (thick curve) and $E_1=-1, E_2=-10$ (dash curve).

$$[X_4,\Gamma_L]=0, \quad X_4(E_L)=0, \quad \mathcal{L}_{X_4}\omega_L=0$$

and determines the function I_4 as the corresponding Hamiltonian

$$i(X_4)\omega_L = \mathrm{d}I_4.$$

The main difference between these two symmetries is that X_3 is an exact symmetry of the Lagrangian, that is $X_3(L)=0$, and X_4 is a nonexact generalized Noether symmetry

$$X_4(L)=\frac{\mathrm{d}}{\mathrm{d}t}F_4, \quad F_4=-\frac{1}{2}\left(\frac{k_2}{M_x}+\frac{k_1}{M_y}\right),$$

so that I_4 is given by

$$i(X_4)\theta_L - F_4 = I_4.$$

An important property related with superintegrability is the existence of periodic orbits as, for example, in the Kepler problem or in the harmonic oscillator. This particular system is superintegrable but the motion, although bounded, is not periodic; instead, the trajectories are "almost closed." We have found that the trajectories in the plane (x,y) are in fact "figure eight" curves with the particle making a complete circuit as t goes from $-\infty$ to $+\infty$. The trajectory starts very close to the origin, passes through (0,0) only once and returns once more to the origin, but for $t\to-\infty$ and $t\to\infty$ only approaches (0,0) as a limit. Figure 3 shows two curves in the plane (x,y) corresponding to two different values of E_1 and E_2.

IV. LAGRANGIAN CONSERVATIVE APPROACH TO A NONLINEAR OSCILLATOR

A. One-dimensional system: Lagrangian formalism and integrability

We now consider the following non-natural Lagrangian

$$L=\frac{1}{kv_x+k^2x^2+w^2}, \tag{13}$$

where k and w are arbitrary constants; the notation w^2 for the new parameter clearly advances that it will be interpreted as a frequency. We arrive at the following nonlinear equation:

$$\frac{\mathrm{d}^2x}{\mathrm{d}t^2}+3kx\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)+k^2x^3+w^2x=0 \tag{14}$$

as well as to the following expression for the Lagrangian energy:

$$E_L = \frac{-(2kv_x + k^2x^2 + w^2)}{(kv_x + k^2x^2 + w^2)^2}.$$

We can solve this new nonlinear problem by using the same technique as in Eq. (9). Nevertheless we see that this new nonlinear equation is in fact a nonlinear oscillator and, because of this, we will use an approach that is as close as possible to the linear oscillator.

We denote by X and W_x the following two functions:

$$X = \frac{x}{(kv_x + k^2x^2 + w^2)}, \quad W_x = \frac{v_x + kx^2}{(kv_x + k^2x^2 + w^2)}.$$

Then we have the following two properties:

(i) The time evolution of X and W_x is given by

$$\frac{\mathrm{d}}{\mathrm{d}t}X = W_x, \quad \frac{\mathrm{d}}{\mathrm{d}t}W_x = -w^2X.$$

(ii) X and W_x are related by

$$w^2X + kxW_x = x.$$

Next we see that property (i) is related to the conservation of energy and property (ii) to the solution of the dynamics. In fact, from (i) we conclude that the function I_{XW} defined as

$$I_{XW} = W_x^2 + w^2X^2,$$

is an integral of the motion. We remark that, as the system is one-dimensional, the two integrals, E_L and I_{XW}, cannot be independent; in fact I_{XW} turns out to be the energy associate to an equivalent Lagrangian $\widetilde{L}$ of the form $\widetilde{L}=c_1L+c_2$. A simple calculation gives

$$\widetilde{E_L} = \Delta(\widetilde{L}) - \widetilde{L} = I_{XW} \quad \text{with } \widetilde{L} = \left(\frac{w}{k}\right)^2 L - \frac{1}{k^2}.$$

Also from (i) we arrive at

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}X + w^2X = 0, \quad \frac{\mathrm{d}^2}{\mathrm{d}t^2}W_x + w^2W_x = 0$$

so that X and W_x are given by

$$X = \left(\frac{1}{w}\right)A\sin(wt + \phi), \quad W_x = A\cos(wt + \phi), \quad A = \sqrt{E},$$

where E is the constant value of the new energy function $\widetilde{E_L}=I_{XW}$. These two expressions, together with property (ii), lead to the following trigonometric function for the solution of the dynamics:

$$x = \frac{w\sqrt{E}\sin(wt + \phi)}{1 - k\sqrt{E}\cos(wt + \phi)}.$$

Figure 4 represents $x(t)$ as a function of t for several values of the energy E in the regular oscillatory region ($0<E<1/k^2$). It is clear that for small values of E the oscillations are rather similar to the oscillations of the linear system, but for other values of E (roughly speaking, for $E>0.3/k^2$) the nonlinearity introduces deformations in the oscillations. For higher values of E the nonlinearity drastically changes the aspect of the solution. Figure 5 shows the phase portrait; it clearly shows that the motions from left to right and from right to left take place at different velocities.

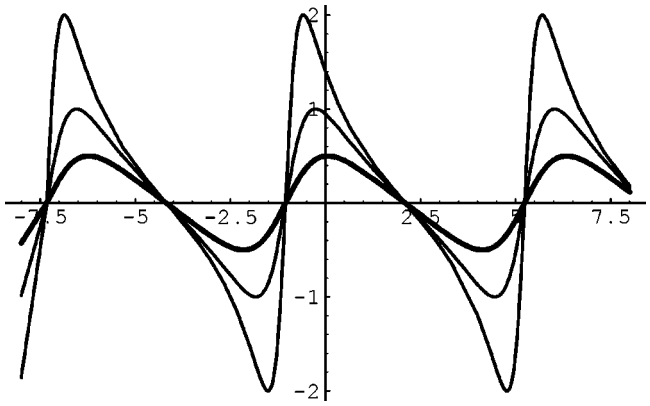

FIG. 4. Plot of x as a function of t, for $(k=1, w=1)$ and three different values of the energy: $E=0.2$ (small thick curve), $E=0.5$ (middle curve), and $E=0.8$ (curve with great oscillations). The $E=0.2$ curve is very similar to a pure sine or cosine curve but, for higher values of E, the plot shows clearly the effects of the nonlinearity.

B. Two-dimensional system: Superintegrability and nonlinear Lissajous figures

We now turn our attention to the two-dimensional version of this nonlinear oscillator. If we consider the following Lagrangian:

$$L = \frac{1}{k_1 v_x + k_1^2 x^2 + w_1^2} + \frac{1}{k_2 v_y + k_2^2 y^2 + w_2^2} \tag{15}$$

then we arrive at the following equations:

$$\frac{\mathrm{d}^2 x}{\mathrm{d}t^2} + 3\,k_1 x\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right) + k_1^2 x^3 + w_1^2 x = 0,$$

$$\frac{\mathrm{d}^2 y}{\mathrm{d}t^2} + 3\,k_2 y\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right) + k_2^2 y^3 + w_2^2 y = 0 \tag{16}$$

and to the following expression for the energy function:

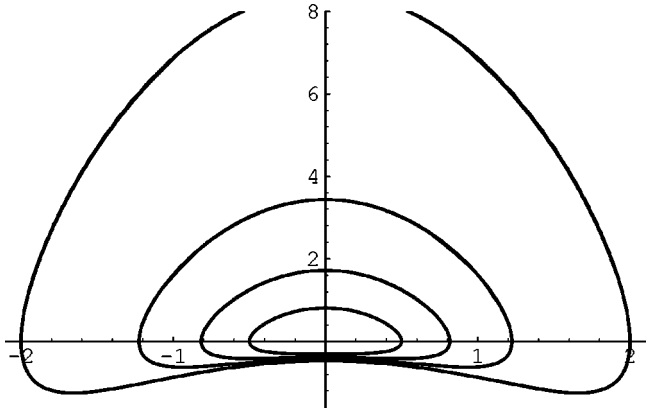

FIG. 5. Phase trajectories corresponding to four different values of the energy ($E=0.2$, 0.4, 0.6, and 0.8). The trajectories are closed curves representing periodic motions that for small values of E can be considered as rather similar to ellipses; for other values of E the curves modify their shape and they lengthen toward the upper side of the phase plane. The motion is asymmetric in the sense that the particle moves from right to left in a slowly way but returns, from left to right, with a much higher velocity that takes its maximum value at the center point $x=0$.

$$E_L = -\frac{(2\,k_1 v_x + k_1^2 x^2 + w_1^2)}{(k_1 v_x + k_1^2 x^2 + w_1^2)^2} - \frac{(2\,k_2 v_y + k_2^2 y^2 + w_2^2)}{(v_y + k_2 y^2 + w_2^2)^2}.$$

In this $n=2$ case we have two pairs of functions (X_j, W_j), $j=1,2$,

$$X_1 = \frac{x}{k_1 v_x + k_1^2 x^2 + w_1^2}, \quad W_1 = \frac{v_x + k_1 x^2}{k_1 v_x + k_1^2 x^2 + w_1^2},$$

$$X_2 = \frac{y}{k_2 v_y + k_2^2 y^2 + w_2^2}, \quad W_2 = \frac{v_y + k_2 y^2}{k_2 v_y + k_2^2 y^2 + w_2^2}$$

in such a way that we have

$$\frac{\mathrm{d}}{\mathrm{d}t} W_j = -w_j^2 X_j, \quad \frac{\mathrm{d}}{\mathrm{d}t} X_j = W_j$$

and

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2} X_j + w_j^2 X_j = 0, \quad \frac{\mathrm{d}^2}{\mathrm{d}t^2} W_j + w_j^2 W_j = 0.$$

A similar calculation shows that

$$x = \frac{w_1^2 X_1}{1 - k_1 W_1}, \quad y = \frac{w_2^2 X_2}{1 - k_2 W_2},$$

from which we obtain solution of the dynamics

$$x = \frac{w_1 \sqrt{E_1} \sin(w_1 t + \phi_1)}{1 - k_1 \sqrt{E_1} \cos(w_1 t + \phi_1)}, \quad y = \frac{w_2 \sqrt{E_2} \sin(w_2 t + \phi_2)}{1 - k_2 \sqrt{E_2} \cos(w_2 t + \phi_2)}.$$

We now study the superintegrability of the rational case, that is, $w_1 = n_1 w_0$ and $w_2 = n_2 w_0$, with n_1 and n_2 positive integral numbers.

Proposition 2: Let $\mathbb{K}_1$ and $\mathbb{K}_2$ be the following two functions:

$$\mathbb{K}_j = W_j + \mathrm{i}\, n_j w_0 X_j, \quad j = 1,2.$$

Then the complex functions $\mathbb{K}_{ij}$ defined as

$$\mathbb{K}_{ij} = \mathbb{K}_i^{n_j} (\mathbb{K}_j^*)^{n_i}, \quad i,j = 1,2,$$

are constants of the motion.

Proof: The time evolution of the functions $\mathbb{K}_1$ and $\mathbb{K}_2$ is given by

$$\frac{\mathrm{d}}{\mathrm{d}t} \mathbb{K}_j = \frac{\mathrm{d}}{\mathrm{d}t} W_j + \mathrm{i}\, n_j w_0 \frac{\mathrm{d}}{\mathrm{d}t} X_j = \mathrm{i}\, n_j w_0 \mathbb{K}_j, \quad j = 1,2.$$

On the other side we have

$$\frac{\mathrm{d}}{\mathrm{d}t} \mathbb{K}_{ij} = \mathbb{K}_i^{n_j - 1} (\mathbb{K}_j^*)^{n_i - 1} \left(n_j \mathbb{K}_j^* \frac{\mathrm{d}}{\mathrm{d}t} \mathbb{K}_i + n_i \mathbb{K}_i \frac{\mathrm{d}}{\mathrm{d}t} \mathbb{K}_j^* \right)$$

and from here the property follows by direct calculus.

Thus the three functions

$$I_1 = |\mathbb{K}_1|^2, \quad I_2 = |\mathbb{K}_2|^2, \quad I_{12} = \mathbb{K}_1^{n_2}(\mathbb{K}_2^*)^{n_1},$$

are constants of the motion. The two first functions, I_1 and I_2, are the two one degree of freedom energies; concerning I_{12}, as it has complex value

$$I_{12} = I_4 + \mathrm{i}\, I_3,$$

it determines not just one but two real constants of motion. Of course, if we consider I_3 as the new additional constant, I_4 is a function of I_1, I_2, and I_3. We thus conclude that the existence of superintegrabilty and periodic trajectories (Lissajous figures) is preserved by the nonlinearity.

We particularize these results for the two first commensurable cases. In the isotropic case, $w_1 = w_2 = w_0$, the two functions, I_3 and I_4, are given by

$$I_3 = X_1 W_2 - X_2 W_1 = \frac{(xv_y - yv_x) + (k_2 y - k_1 x)xy}{(k_1 v_x + k_1^2 x^2 + w_0^2)(k_2 v_y + k_2^2 y^2 + w_0^2)},$$

$$I_4 = W_1 W_2 + w_0^2 X_1 X_2 = \frac{(v_x + k_1 x^2)(v_y + k_2 y^2) + w_0^2 xy}{(k_1 v_x + k_1^2 x^2 + w_0^2)(k_2 v_y + k_2^2 y^2 + w_0^2)},$$

representing the nonlinear versions of the angular momentum and the nondiagonal component of the Fradkin tensor respectively.[38,39] In fact, when $k_1, k_2 \to 0$, these two function reduce to the appropriate expressions

$$\lim_{k\to 0} I_3 = \left(\frac{1}{w_0^4}\right)(xv_y - yv_x),$$

$$\lim_{k\to 0} I_4 = \left(\frac{1}{w_0^4}\right)(v_x v_y + w_0^2 xy).$$

Of course, for $w_0 \to 0$, we recover the I_3 obtained in the previous section; I_4 just reduces to a trivial numerical constant.

$$\lim_{w\to 0} I_3 = \frac{(xv_y - yv_x) + (k_2 y - k_1 x)xy}{k_1 k_2 (v_x + k_1 x^2)(v_y + k_2 y^2)},$$

$$\lim_{w\to 0} I_4 = \frac{1}{k_1 k_2}.$$

Figure 6 represents some closed trajectories in the plane (x,y); it is clear that for small energies the curves look rather similar to the ellipses of the linear case, but for other (not so small) values of E the curves lose their elliptic shape and adopt other not so symmetric forms.

Now, we consider the anisotropic case $w_1 = w_0, w_2 = 2w_0$. Then I_3 and I_4 are given by

$$I_3 = (X_1 W_2 - X_2 W_1) W_1 + w_0^2 X_1^2 X_2 = \frac{(v_x + k_1 x^2)[(xv_y - yv_x) + (k_2 y - k_1 x)xy] + w_0^2 x^2 y}{(k_1 v_x + k_1^2 x^2 + w_0^2)^2 (k_2 v_y + k_2^2 y^2 + 4w_0^2)},$$

$$I_4 = W_1^2 W_2 + w_0^2 (4X_2 W_1 - X_1 W_2) X_1 = \frac{(v_x + k_1 x^2)^2 (v_y + k_2 y^2) + w_0^2 [4yv_x - xv_y + (4k_1 x - k_2 y)xy]x}{(k_1 v_x + k_1^2 x^2 + w_0^2)^2 (k_2 v_y + k_2^2 y^2 + 4w_0^2)}.$$

Figure 7 represents two nonlinear Lissajous figures in the plane (x,y). The situation is similar to that of Fig. 6; close resemblance with the linear figures for small values of the energies and rather strange figures for other values of E. We must say that, in this case, the form is strongly dependent on the phase difference $\phi_{12} = \phi_1 - \phi_2$.

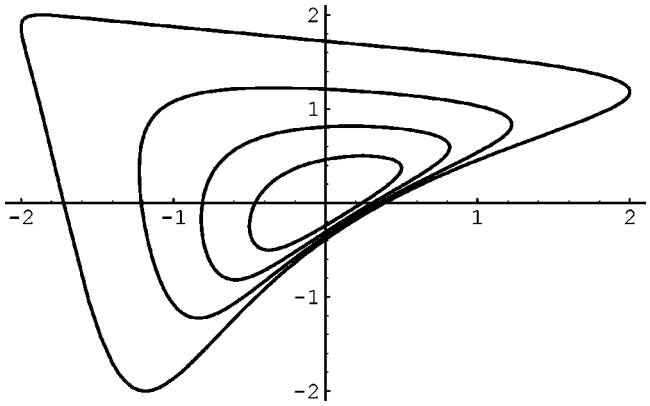

FIG. 6. Closed trajectories (ellipses in the linear case) in the plane (x,y) corresponding to $w_1=1, w_2=1$ and four different values of the energy ($E_1=E_2=0.2$, 0.4, 0.6 and 0.8).

V. FINAL COMMENTS

We have studied two nonlinear systems using, as starting point, the important property of the Lagrangian origin of the second-order Riccati equations. In this way we could use the constant value E of the energy as an appropriate parameter for characterizing the behavior of these two systems. Moreover we have proved the existence of two–dimensional versions endowed with superintegrability and we have obtained the explicit expressions of the additional integrals.

Concerning the superintegrability, we recall that most known superintegrable systems are superseparable systems, that is, systems that admit Hamilton–Jacobi separation of variables (Schrödinger in the quantum case) in more than one coordinate system. Nevertheless as all the systems studied in this paper are nonlinear systems with a nonstandard Lagrangian, the superintegrability has been proved by considering a different approach and without making use of the multiple separability. In spite of this the possible separation of variables in other coordinate systems than Cartesian ones must be studied.

We also mention that these two nonlinear systems can be generalized in several different ways by making use of the Lagrangian approach. First, we recall that we have proved in Sec. II the Lagrangian origin not only of the Riccati systems but also of the more general equation (4); this means that these more general equations could also be studied by making use of the conservation of the energy. Second, the Lagrangian (6) admits the following natural generalization

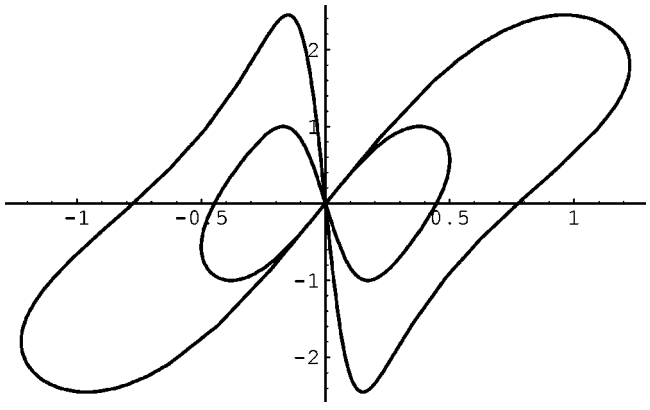

FIG. 7. Nonlinear Lissajous figures in the plane (x,y) corresponding to "figure eight" trajectories associated to $w_1=1, w_2=2$ and energies $E_1=E_2=0.2$ (small eight-looking curve) and $E_1=E_2=0.6$ (big butterfly-looking curve).

$$L = \frac{1}{m(x)v_x + k\,U(x)} \tag{17}$$

that leads to a nonlinear second-order equation with a position-dependent effective mass and an additional dissipative-looking term of the form $m'(x)v_x^2$. This new Lagrangian (17) seems interesting, not only because it generalizes (6) but also because it has a more direct geometrical interpretation since the linear function $m(x)v_x$ can be considered as associated to the one-form $\mu = m(x)dx$.

The Lagrangian (6) has, as associated Hamiltonian, the following function:

$$H = -2\sqrt{-p_x} - kU(x)p_x \tag{18}$$

that, in addition to its nonnatural character (as was to be expected), has the annoying presence of the momentum inside a root. In the particular case of the nonlinear oscillator the Hamiltonian is given as follows:

$$H = -\left[\frac{2w}{k^2}\sqrt{-kp_x} + \left(kx^2 + \frac{w^2}{k}\right)p_x\right] + \frac{1}{k^2}. \tag{19}$$

Nevertheless in this case we have an important property; in fact, if we make use of the canonical transformation $(x, p_x) \to (Q, P)$ given by

$$Q = \left(\frac{\sqrt{2}}{w}\right)x\sqrt{-kp_x}, \quad P = \left(\frac{\sqrt{2}}{k}\right)[1 - w\sqrt{-kp_x}],$$

then we arrive at

$$H = \tfrac{1}{2}(P^2 + w^2Q^2).$$

Hence the very peculiar Hamiltonian (19) and the standard linear oscillator are canonically related. Nevertheless note that this transformation has a nonpoint character and, because of this, it cannot be directly used in the Lagrangian approach. This brings up the question of the possible existence of similar nonpoint transformations for Hamiltonians obtained from other Riccati Lagrangians. We think that this possibility is an open question to be studied.

Finally, we mention the study of the quantized versions of all these nonlinear systems. We note that this question must be carried out only after the obtaining of the appropriate Hamiltonian versions (the direct quantum study of the Lagrangian equations appears as a difficult task). Nevertheless as the Lagrangians are nonstandard the Hamiltonians also appear with an unusual dependence of the momenta (see the previous expressions). In any case the possibility or impossibility of quantizing these systems is a matter that must be investigated.

(Received 27 January 2005; accepted 13 April 2005; published online 1 June 2005)

We consider a class of second order ordinary differential equations describing one-dimensional systems with a quasiperiodic analytic forcing term and in the presence of damping. As a physical application one can think of a resistor–inductor–varactor circuit with a periodic (or quasiperiodic) forcing function, even if the range of applicability of the theory is much wider. In the limit of large damping we look for quasiperiodic solutions which have the same frequency vector of the forcing term, and we study their analyticity properties in the inverse of the damping coefficient. We find that even the case of periodic forcing terms is nontrivial, as the solution is not analytic in a neighborhood of the origin: it turns out to be Borel summable. In the case of quasiperiodic forcing terms we need renormalization group techniques in order to control the small divisors arising in the perturbation series. We show the existence of a summation criterion of the series in this case also; however, this cannot be interpreted as Borel summability. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1926208]

I. INTRODUCTION

Consider the ordinary differential equation

$$\varepsilon\ddot{x} + \dot{x} + \varepsilon x^2 = \varepsilon f(\boldsymbol{\omega} t), \tag{1.1}$$

where $\boldsymbol{\omega} \in \mathbb{R}^d$ is the frequency vector, $f(\boldsymbol{\psi})$ is an analytic function,

$$f(\boldsymbol{\psi}) = \sum_{\boldsymbol{\nu} \in \mathbb{Z}^d} e^{i\boldsymbol{\nu}\cdot\boldsymbol{\psi}} f_{\boldsymbol{\nu}}, \tag{1.2}$$

with average $\alpha = a^2$, with $a > 0$ (hence $\langle f \rangle \equiv f_{\mathbf{0}} = \alpha$), and $\varepsilon > 0$ is a real parameter. Here and henceforth we denote with $\cdot$ the scalar product in $\mathbb{R}^d$. By the analyticity assumption of f there are two strictly positive constants F and ξ such that one has $|f_{\boldsymbol{\nu}}| \leqslant F e^{-\xi|\boldsymbol{\nu}|}$ for all $\boldsymbol{\nu} \in \mathbb{Z}^d$.

By writing $\gamma = 1/\varepsilon$ the equation becomes

$$\ddot{x} + \gamma\dot{x} + x^2 = f(\boldsymbol{\omega} t), \tag{1.3}$$

which describes a nonlinear electronic circuit, known as resistor–inductor–varactor circuit, subject to a quasiperiodic forcing function. Taking $d = 1$ and $f(\omega t) = \alpha + \beta \sin t$, this equation has been studied in Ref. 1, where, among other things, it has been found numerically that for γ large enough

[a)]Electronic mail: gentile@mat.uniroma3.it
[b)]Electronic mail: m.bartuccelli@surrey.ac.uk
[c)]Electronic mail: j.deane@surrey.ac.uk

there exists only one attracting periodic orbit and the corresponding period is $2\pi/\omega=2\pi$, the same as the forcing term. Furthermore one can prove analytically that such a periodic orbit is the only one in a neighborhood of radius $O(1/\gamma)$ around the point $(a,0)$.

Here we give some further analytical support to such numerical findings. In particular we show that, if we take as forcing term an analytic periodic function,

$$f(\psi)=\sum_{\nu\in\mathbb{Z}} e^{i\nu\psi}f_\nu, \quad f_0=\alpha>0, \tag{1.4}$$

then for ε small enough there is a $2\pi/\omega$-periodic solution, but this is not analytic in $\varepsilon=1/\gamma$ in a neighborhood the origin in the complex ε-plane. We find that such a solution is Borel summable.

We also show that by considering quasiperiodic forcing terms, as in (1.3), we still have a quasiperiodic solution with the same frequency vector $\boldsymbol{\omega}$ as the forcing term, but we can only say in general that such a solution is analytic in a domain with boundary crossing the origin.

Finally we shall see that considering more general nonlinearities introduces no further difficulties, and equations like

$$\ddot{x}+\gamma\dot{x}+g(x)=f(\boldsymbol{\omega}t), \quad \lim_{|x|\to\infty}\frac{|g(x)|}{|x|}=\infty, \tag{1.5}$$

with g and f both analytic in their arguments, can be dealt with essentially in the same way. Simply, we must impose a nondegeneracy condition on the function g, which reads as

$$\exists x_0 \text{ such that } g(x_0)=f_0 \quad \text{and } g'(x_0)\neq 0. \tag{1.6}$$

In the particular case of homogeneous $g(x)$, that is $g(x)=\sigma x^p$, with $p\geqslant 2$ an integer and $\sigma\in\mathbb{R}$, the condition is automatically satisfied if p is odd (for any value of σ), while it requires $\sigma f_0>0$ for p even, as assumed in (1.1).

The paper is organized as follows. For expository clearness we start with the case of periodic forcing terms. In Secs. II and III we show that a periodic solution with frequency ω in the form of a formal power series in ε (perturbation series) is well defined to all orders, and it admits a natural graphical representation. In Sec. IV we study further such a series, and we see that there is strong evidence to show that it diverges (even if we cannot exclude convergence definitely). The best bounds that we are able to provide for the coefficients grow as factorials. To obtain bounds which allow summability of the perturbation series we must perform a suitable summation in order to give the series a meaning. This is done in Sec. V, and the resummed series is found to represent a $2\pi/\omega$-periodic solution which is Borel summable in ε. To prove the latter property we rely on Nevanlinna's improvement of Watson's theorem.[12] In Sec. VI we consider the case of quasiperiodic forcing terms. We find that the perturbation series is well defined if the frequency vector of the forcing term satisfies a Diophantine condition, and, by using renormalization group techniques in order to deal with the small divisors problem, we find that the resummed series still converges to a quasiperiodic solution, and it defines a function analytic in a domain containing the origin in its boundary. We shall see that the bounds we find do not allow us any more to obtain Borel summability, unlike the case of periodic forcing terms. In Sec. VII we discuss how to extend the analysis to more general nonlinearities $g(x)$, by requiring the condition (1.6) to be satisfied.

The interest of the approach we propose is that it allows the use of perturbation theory which can be very natural in problems in which a small parameter appears. In fact analyticity in ε for ε close to 0 (that is in γ for γ large enough) could be proved very likely with other techniques (at least for periodic solutions in the case of periodic forcing terms), but a naive expansion in powers of ε is prevented by the lack of analyticity in a neighborhood of the origin. On the other hand, the perturbation series gives a very accurate description of the solution, hence it is important to know that such a series is an asymptotic series, and its use is fully justified. Finally we mention that the quasiperiodic solution we investigate is of physical relevance, hence it is useful to study its

properties. For instance in the case of the aforementioned resistor–inductor–varactor circuit in Ref. 1, for damping large enough, the $2\pi/\omega$-periodic solution is numerically found to attract any trajectory which remains bounded in phase space.

The techniques we use have been recently developed for problems of Hamiltonian stability, and are based on resummation methods that are familiar in quantum field theory (see Ref. 7 and references quoted therein). Here we show that they can be useful even in non-Hamiltonian problems with viscosity acting. We leave as an open problem to show whether the formal series of the periodic or quasiperiodic solutions are really divergent. We also note that we are not able to prove uniqueness of the quasiperiodic solutions we find by the resummation procedure, as in that case there is no uniqueness result as for analytic or Borel summable functions which one can rely upon. Furthermore, both for periodic and for quasiperiodic solutions, we cannot exclude existence of other solutions with the same rotation vector, which either are of a different form or even admit the same formal series, without being obtained through the same resummation procedure. Problems of the same kind were met in the study of hyperbolic lower-dimensional tori.[6]

II. FORMAL ANALYSIS

Consider first (1.1) for $d=1$, that is

$$\varepsilon\ddot{x} + \dot{x} + \varepsilon x^2 = \varepsilon f(\omega t), \tag{2.1}$$

with $f(\psi)$ given by (1.4). We look for bounded solutions (if any) which are analytic in ε, that is of the form

$$x(t) = \sum_{k=0}^{\infty} \varepsilon^k x^{(k)}(t). \tag{2.2}$$

Inserting (2.2) into (2.1) and equating terms of the same Taylor order we find the set of recursive equations

$$\dot{x}^{(0)} = 0,$$

$$\dot{x}^{(1)} = -\ddot{x}^{(0)} - x^{(0)2} + f, \tag{2.3}$$

$$\dot{x}^{(k)} = -\ddot{x}^{(k-1)} - \sum_{k_1+k_2=k-1} x^{(k_1)} x^{(k_2)}, \quad k \geqslant 2.$$

From the first equation (zeroth order) we obtain that $x^{(0)}$ must be constant, say $x^{(0)}=c_0$ with c_0 to be determined. The second equation (first order) can give a bounded solution only if $-c_0^2+\alpha=0$, which fixes $c_0=\sqrt{\alpha}=a$ and gives $x^{(1)}(t)$ as a periodic function with the same period of the forcing term,

$$x^{(1)}(t) = x^{(1)}(0) + \int_0^t \mathrm{d}t' (f(\omega t') - \alpha). \tag{2.4}$$

As each $x^{(k)}(t)$ depends on the functions $x^{(k')}(t)$ with $k' < k$, we expect that if there is any periodic solution then it must have the same period as the forcing term.

To continue the analysis to all orders it is more convenient to write the recursive equations (2.3) in Fourier space. The analysis to first order and the considerations above motivate us to write in (2.2),

$$x(t) = \sum_{k=0}^{\infty} \varepsilon^k x^{(k)}(t) = \sum_{k=0}^{\infty} \varepsilon^k \sum_{\nu\in\mathbb{Z}} e^{i\nu\omega t} x_\nu^{(k)}, \tag{2.5}$$

which inserted into (2.3) gives for $\nu \neq 0$,

$$x_\nu^{(0)} = 0,$$

$$x_\nu^{(1)} = \frac{f_\nu}{i\omega\nu}, \tag{2.6}$$

$$x_\nu^{(k)} = -(i\omega\nu)x_\nu^{(k-1)} - \frac{1}{i\omega\nu} \sum_{\substack{k_1+k_2=k-1 \\ k_1,k_2\geqslant 0}} \sum_{\nu_1+\nu_2=\nu} x_{\nu_1}^{(k_1)} x_{\nu_2}^{(k_2)}, \quad k \geqslant 2,$$

provided that one has for $\nu=0$,

$$\begin{aligned} 0 &= -x_0^{(0)2} + f_0, \\ 0 &= \sum_{\substack{k_1+k_2=k \\ k_1,k_2\geqslant 0}} \sum_{\nu_1+\nu_2=0} x_{\nu_1}^{(k_1)} x_{\nu_2}^{(k_2)}, \quad k \geqslant 1. \end{aligned} \tag{2.7}$$

If we set $x_0^{(k)}=c_k$ then the first of (2.7) fixes, as already noted,

$$c_0 = a = \sqrt{\alpha}, \tag{2.8}$$

because one has $f_0=\alpha>0$, while the second of (2.7) gives

$$\sum_{k'=0}^{k} \sum_{\nu_1\in\mathbb{Z}} x_{\nu_1}^{(k-k')} x_{-\nu_1}^{(k')} = 0. \tag{2.9}$$

The latter equation, by taking into account (2.8) and the first of (2.6), can be more conveniently written as

$$c_1 = 0, \quad c_k = -\frac{1}{2c_0} \sum_{k'=1}^{k-1} \sum_{\nu_1\in\mathbb{Z}} x_{\nu_1}^{(k-k')} x_{-\nu_1}^{(k')}, \quad k \geqslant 2, \tag{2.10}$$

which provides an iterative definition of the coefficients c_k as the right-hand side depends only on the coefficients $c_{k'}$ with $k'<k$. To deduce $c_1=0$ we used the first of (2.6), which, inserted into (2.9) for $k=1$, gives $2c_0c_1=0$, hence $c_1=0$ as $c_0\neq 0$.

The following result holds.

Lemma 2.1: *Consider (2.1) with f given by (1.4). Then there exists a formal power series solution (2.2) whose coefficients $x^{(k)}(t)$ are analytic in t. If f is a trigonometric polynomial, that is in (1.4) one has $|\nu|\leqslant N$ for some $N\in\mathbb{N}$, then for all $k\geqslant 0$ the functions $x^{(k)}(t)$ are trigonometric polynomials of order $[(k+1)/2]N$, where $[\cdot]$ denotes the integer part. This means that one has $x_\nu^{(2k)}=0$ and $x_\nu^{(2k-1)}=0$ for $|\nu|>kN$.*

Proof: The existence of a formal solution (2.2), with coefficients $x^{(k)}(t)$ analytic in t for all $k\geqslant 0$, follows from the analysis above. If f is a trigonometric polynomial of degree N, that the coefficients $x_\nu^{(k)}$ are trigonometric polynomials with the stated properties can be proved from (2.6) by induction on k. ■

Then the functions $x^{(k)}(t)$ are well defined to all orders. Before discussing the issue of convergence of the formal power series defining such functions we look for a graphical representation of the coefficients $x_\nu^{(k)}$.

III. GRAPHICAL REPRESENTATION AND TREE FORMALISM

We start by giving some abstract definitions.

Definition 3.1 (trees): *A tree θ is a graph, that is a connected set of points and lines, with no*

cycle, such that all the lines are oriented toward a unique point which has only one incident line. Such a point is called the root of the tree. All the points in a tree except the root are denoted nodes. The line entering the root is called the root line. The orientation of the lines in a tree induces a partial ordering relation between the nodes. We denote this relation by $\preccurlyeq$*, given two nodes* v *and* w*, we shall write* $w \preccurlyeq v$ *every time* v *is along the path (of lines) which connects* w *to the root.*

Given a tree θ, we can identify the following subsets in θ.

Definition 3.2 (endpoints): *We call* $E(\theta)$ *the set of endpoints in* θ*, that is the nodes which have no entering line. The endpoints can be represented either as* white bullets *or as* black bullets. *We call* $E_W(\theta)$ *the set of white bullets and* $E_B(\theta)$ *the set of black bullets. Of course* $E_W(\theta) \cup E_B(\theta) = E(\theta)$. *With each* $v \in E_W(\theta)$ *we associate a* mode *label* $\nu_v = 0$, *an* order *label* $k_v \in \mathbb{Z}_+$ *and a* node factor $F_v = c_{k_v}$. *With each* $v \in E_B(\theta)$ *we associate a* mode *label* $\nu_v \in \mathbb{Z}\setminus\{0\}$, *and a* node factor $F_v = f_{\nu_v}$.

Definition 3.3 (lines): *We denote with* $L(\theta)$ *the set of* lines *in* θ. *Each line* $\ell \in L(\theta)$ *leaves a point* v *and enters another one which we shall denote by* v'. *Since* ℓ *is uniquely identified with* v *(the point which* ℓ *leaves), we may write* $\ell = \ell_v$. *With each line* ℓ *we associate a* momentum *label* $\nu_\ell \in \mathbb{Z}$ *and a* propagator

$$g_\ell = \begin{cases} 1/(i\omega\nu_\ell), & \nu_\ell \neq 0, \\ 1, & \nu_\ell = 0, \end{cases} \tag{3.1}$$

and we say that the momentum ν_ℓ *flows through the line* ℓ. *The modes and the momenta are related as follows: if* $\ell = \ell_v$ *one has*

$$\nu_\ell = \sum_{i=1}^{s_v} \nu_{\ell_i} = \sum_{\substack{w \in E_B(\theta) \\ w \preccurlyeq v}} \nu_w, \tag{3.2}$$

where $\ell_1, \ldots, \ell_{s_v}$ *are the lines entering* v.

Definition 3.4 (vertices): *We denote by* $V(\theta)$ *the set of* vertices *in* θ, *that is the set of points which have at least one entering line. If* $V(\theta) \neq \emptyset$ *we call the vertex* v_0 *connected to the root the* last vertex *of the tree. If* s_v *denotes the number of lines entering* v *call* $\max_{v \in V(\theta)} s_v$ *the* branching number. *One can have either* $s_v = 1$ *or* $s_v = 2$. *We set* $V_s(\theta) = \{v \in V(\theta) : s_v = s\}$ *for* $s = 1, 2$; *of course* $V_1(\theta) \cup V_2(\theta) = V(\theta)$. *We define also* $V_0(\theta) = \{v \in V(\theta) : \nu_{\ell_v} = 0\}$; *one has* $V_0(\theta) \subset V_2(\theta)$. *We require that either* $V_0(\theta) = \emptyset$ *or* $V_0(\theta) = \{v_0\}$, *and that one can have* $v \in V_1(\theta)$ *only if* $\nu_{\ell_v} \neq 0$. *We associate with each vertex* $v \in V(\theta)$ *a* node factor

$$F_v = \begin{cases} -1, & s_v = 2 \quad \text{and } v \notin V_0(\theta), \\ -1/2c_0, & s_v = 2 \quad \text{and } v \in V_0(\theta), \\ -(i\omega\nu_{\ell_v})^2, & s_v = 1, \end{cases} \tag{3.3}$$

which is always well defined as $c_0 \neq 0$.

We call *equivalent* two trees which can be transformed into each other by continuously deforming the lines in such a way that they do not cross each other.

Let $\mathcal{T}_{k,\nu}$ be the set of inequivalent trees θ such that

(1) the number of vertices, the number of black bullets, and the order labels of the white bullets are such that we have

$$k_1 + k_2 + k_3 = k, \quad \text{if } \nu \neq 0,$$

$$k_1 + k_2 + k_3 = k + 1, \quad \text{if } \nu = 0, \tag{3.4}$$

if we set $k_1 = |V(\theta)|$, $k_2 = |E_B(\theta)|$, and $k_3 = \Sigma_{v \in E_W(\theta)} k_v$.

(2) The momentum flowing through the root line is ν.

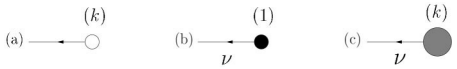

FIG. 1. Graphical representation of $x_0^{(k)}$, $x_\nu^{(1)}$, and $x_\nu^{(k)}$. For $\nu=0$ the latter reduces to the first graph, while for $k=1$ and $\nu \neq 0$ it reduces to the second graph. In the first graph the momentum is not shown as it is necessarily $\nu=0$.

We refer to $\mathcal{T}_{k,\nu}$ as the *set of trees of order k and total momentum* ν.

With the above definitions the following result holds.

Lemma 3.5: *For all* $k \geqslant 1$ *and all* $\nu \neq 0$ *one has*

$$x_\nu^{(k)} = \sum_{\theta \in \mathcal{T}_{k,\nu}} \mathrm{Val}(\theta), \quad \mathrm{Val}(\theta) = \left(\prod_{\ell \in L(\theta)} g_\ell \right) \left(\prod_{v \in E(\theta) \cup V(\theta)} F_v \right), \tag{3.5}$$

where $\mathrm{Val}: \mathcal{T}_{k,\nu} \to \mathbb{C}$ *is called the* value *of the tree. For* $k \geqslant 2$ *and* $\nu=0$ *one has*

$$x_0^{(k)} \equiv c_k = \sum_{\theta \in \mathcal{T}_{k,0}}{}^{*} \mathrm{Val}(\theta), \tag{3.6}$$

where $*$ *means that there are two lines entering the last vertex* v_0 *of* θ_0 *and neither one exits from an endpoint* v *with order label* $k_v=0$.

Proof: We can represent graphically $x_0^{(k)}=c_k$ as in Fig. 1(a), $x_\nu^{(1)}$, $\nu \neq 0$, as in Fig. 1(b), and, more generally, $x_\nu^{(k)}$ as in Fig. 1(c).

Then the third equation in (2.6) can be represented graphically as in Fig. 2, if we associate with the nodes and to the lines the node factors and the propagators, respectively, according to the definitions (3.1) and (3.3).

Analogously (2.10) is represented graphically as in Fig. 3, again if we use the graphical representations in Fig. 1 and associate with the lines and vertices the propagators (3.1) and the node factors (3.3), respectively.

Note that in this way we represent graphically each coefficient $x_\nu^{(k)}$ in terms of other coefficients $x_{\nu'}^{(k')}$, with $k' < k$, so that we can apply iteratively the graphical representation in Fig. 2 until only trees whose endpoints represent either $x_\nu^{(1)}$ with $\nu \neq 0$ (black bullets) or c_k are left (white bullets). This corresponds exactly to the expressions in (3.5) and (3.6). ■

To get familiar with the graphical representation (3.5) and (3.6) one should try to draw the trees which correspond to the first orders, and check that the sum of the values obtained with the graphical rules listed above gives exactly the same analytical expression which can be deduced directly from (2.6) and (2.10).

For instance for $k=2$ we obtain for $x_\nu^{(2)}$, $\nu \neq 0$, the graphical representation in Fig. 4 and for $c_2=x_0^{(2)}$ the graphical representation in Fig. 5.

For $k=3$ we obtain for $x_\nu^{(3)}$, $\nu \neq 0$, the graphical representation in Fig. 6 and for $c_3=x_0^{(3)}$ the graphical representation in Fig. 7, where we have explicitly used that $c_1=0$.

This can be continued to higher orders. In general a tree $\theta \in \mathcal{T}_{k,\nu}$ looks like in Fig. 8, where for simplicity no labels have been drawn other than the order labels of the white bullets. Note that each node can have only one or two entering lines, while the endpoints have no entering line at all. Moreover the momentum flowing through the line exiting a vertex v is equal to the sum of the

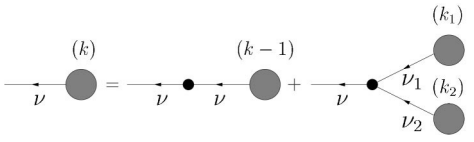

FIG. 2. Graphical representation of the third equation in (2.6) expressing the coefficient $x_\nu^{(k)}$ for $k \geqslant 2$ and $\nu \neq 0$ in terms of the coefficients $x_{\nu'}^{(k')}$ with $k' < k$. In the last graph one has the constraints $k_1+k_2=k-1$ and $\nu_1+\nu_2=\nu$.

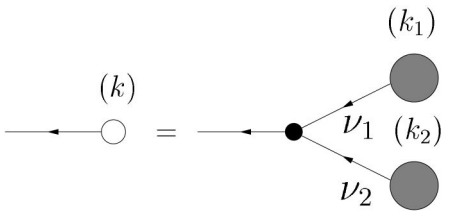

FIG. 3. Graphical representation of the equation (2.10) expressing the coefficient c_k for $k \geqslant 2$ in terms of the coefficients $x_{\nu'}^{(k')}$ with $k' < k$. Both k_1 and k_2 are strictly positive and $k_1 + k_2 = k$; moreover $\nu_1 + \nu_2 = 0$.

momenta flowing through the lines entering v, according to (3.2); this is a sort of conservation law. The order of the tree is given by the number of vertices and black bullets plus the sum of the order labels of the white bullets minus the number of vertices in $V_0(\theta)$. The latter is just $|V_0(\theta)| = 0$ if $\theta \in \mathcal{T}_{k,\nu}$, $\nu \neq 0$, and $|V_0(\theta)| = 1$ if $\theta \in \mathcal{T}_{k,0}$.

If a vertex v has $s_v = 1$, that is it has only one entering line ℓ, the latter cannot come out of a white bullet. Indeed if this occurs one should have $\nu_{\ell_v} = \nu_\ell = 0$, hence $F_v = 0$ by (3.3), so that the value of the tree containing such a vertex is zero.

Given a tree as in Fig. 8 we can represent each white bullet according to the graphical representation in Fig. 3, corresponding to the analytic formula (3.6), and expand again the two contributions $x_{\nu_1}^{(k_1)}$ and $x_{\nu_2}^{(k_2)}$ as sums of trees, and so on, iteratively, until the only white bullets which are left are the ones with order label $k = 0$. In this way we obtain a new graphical representation where the trees still look like those in Fig. 8, but now there are a few differences as follows:

(1) all the white bullets $v \in E_W(\theta)$ have order labels $k_v = 0$, and
(2) there can be lines $\ell \in L(\theta)$ with momentum $\nu_\ell = 0$ which come out of vertices, that is $V_0(\theta)$ can contain no element or more than one element.

Note that only lines coming out either from nodes in $V_0(\theta) \subset V_2(\theta)$ or from white bullets have vanishing momentum.

The order of the tree is then given by the number of elements of $V(\theta) \cup E_B(\theta)$ minus the number of elements of $V_0(\theta)$, that is $k = |V(\theta)| + |E_B(\theta)| - |V_0(\theta)|$. Of course $v_0 \in V_0(\theta)$ if and only if the momentum of the root line is vanishing, that is $\theta \in \mathcal{T}_{k,0}$ for some $k \geqslant 2$. It is important to stress that no line entering a vertex $v \in V_0(\theta)$ can come out of a white bullet (which now has necessarily an order label 0), because this would be against the constraint in the sum (3.6). This means that if two lines carrying zero momentum enter the same vertex v [so that $v \in V_0(\theta)$ according to (3.2)], then none of them can exit from a white bullet.

But up to these minor differences a tree representation like in (3.5) and (3.6) still holds. The advantage of these modified rules is that now the tree values are expressed no longer in terms of constants c_k to be determined, but only in terms of c_0 which is known. A tree drawn according these new rules is represented as in Fig. 8 with $k_1 = k_2 = k_3 = 0$ (and in particular a tree of this kind can contribute only to $x_\nu^{(k)}$ with $\nu \neq 0$). Note that we could avoid drawing the order labels associated with the endpoints, as they are uniquely determined as $k = 0$ for the white bullets and $k = 1$ for the black bullets. Of course, with respect to the caption of that figure, now the order k is given by the number of elements in $V(\theta)$ plus the number of elements in $E_B(\theta)$ minus the number of elements in $V_0(\theta)$.

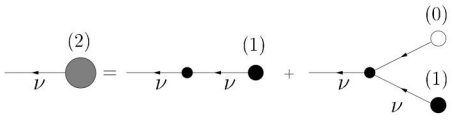

FIG. 4. Graphical representation of $x_\nu^{(2)}$ for $\nu \neq 0$. The second contribution must be counted twice, because there is also a tree with the white and black bullets exchanged; of course the latter has the same value.

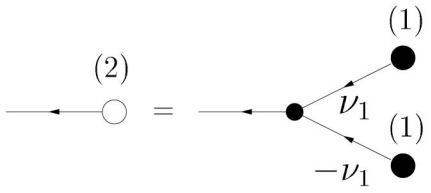

FIG. 5. Graphical representation of $c_2=x_0^{(2)}$. There is no contribution with any white bullet carrying order label $k=0$ and $k=1$ because of the restriction in the sum appearing in (3.6) and of the fact that $c_1=0$, respectively.

IV. FORMAL SOLUTIONS

The sum over the trees in (3.5) and (3.6), with the new definition of the set $\mathcal{T}_{k,\nu}$ given at the end of Sec. II, can be performed by summing over all possible "tree shapes" (that is trees without labels or *unlabeled trees*) and, for a fixed shape, over all possible assignments of mode labels. In the case of a trigonometric polynomial of degree N the latter can be bounded by $(2N)^{|E(\theta)|}$, because each endpoint v can have either a mode label $\nu_v \neq 0$, with $|\nu_v| \leqslant N$, or the mode label $\nu_v=0$, while the case of analytic functions (or even to obtain bounds which are uniform in N) must be discussed a little more carefully. The number of unlabeled trees with P nodes (vertices and endpoints) can be bounded by 2^{2P}.

Recall that $V_s(\theta)$ denotes the set of vertices v such that $s_v=s$; of course $V_1(\theta) \cup V_2(\theta)=V(\theta)$, and $V_0(\theta) \subset V_2(\theta)$. Analogously we can set

$$L_0(\theta)=\{\ell \in L(\theta):n_\ell=0,\},$$

$$L_1(\theta)=\{\ell \in L(\theta):\ell=\ell_v,v \in V_1(\theta)\}, \tag{4.1}$$

$$L_2(\theta)=L(\theta) \setminus (L_0(\theta) \cup L_1(\theta)),$$

with the splitting made in such a way that one has

$$\left|\prod_{v \in V_1(\theta)} F_v\right| \left|\prod_{\ell \in L_1(\theta)} g_\ell\right| \leqslant \prod_{\ell \in L_1(\theta)} |\omega \nu_\ell|, \quad \left|\prod_{\ell \in L_2(\theta)} g_\ell\right| \leqslant \prod_{\ell \in L_2(\theta)} \frac{1}{|\omega \nu_\ell|},$$

$$\left|\prod_{v \in V_0(\theta)} F_v\right| \leqslant \left(\frac{1}{2c_0}\right)^{|V_0(\theta)|}, \quad \left|\prod_{v \in E_W(\theta)} F_v\right| \leqslant c_0^{|E_W(\theta)|}, \tag{4.2}$$

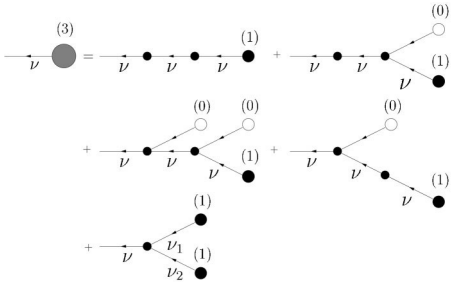

FIG. 6. Graphical representation of $x_\nu^{(3)}$ for $\nu \neq 0$. The second and fourth contributions must be counted twice, while the third one must be counted four times. There is no contribution with any white bullet carrying the order label $k=1$ as $c_1=0$.

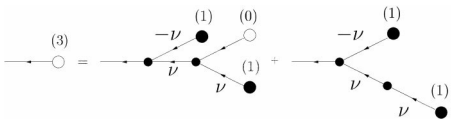

FIG. 7. Graphical representation of $c_3=x_0^{(3)}$. The second contribution must be counted twice, while the first one must be counted four times. There is no contribution with any white bullet carrying the order label $k=1$ as $c_1=0$.

$$\left|\prod_{v\in E_B(\theta)} F_v\right| \leqslant F^{|E_B(\theta)|} \prod_{v\in E_B(\theta)} e^{-\xi|\nu_v|},$$

where for each line ℓ one has $|\nu_\ell| \leqslant \Sigma_{v\in E_W(\theta)}|\nu_v|$.

The following result is useful when looking for bounds on the tree values.

Lemma 4.1: *Given a tree θ with branching number s one has $|E(\theta)| \leqslant (s-1)|V(\theta)|+1$. If k denotes the order of the tree θ, that is $|V(\theta)|-|V_0(\theta)|+|E_B(\theta)|=k$, one has the identity $|L_1(\theta)|+|L_2(\theta)|=k$, and the bounds $|V_1(\theta)| \leqslant k$, $|V_0(\theta)| \leqslant k-1$, $|E(\theta)| \leqslant k$ and $|E(\theta)|+|V(\theta)| \leqslant 2k-1$.*

Proof: It is a standard result on trees that one has $\Sigma_{v\in V(\theta)}(s_v-1)=|E(\theta)|-1$, so that the first bound follows. The bounds on $|V_1(\theta)|$, $|V_0(\theta)|$, $|E(\theta)|$ and $|E(\theta)|+|V(\theta)|$ can be easily proved by induction, while the identity $|L_1(\theta)|+|L_2(\theta)|=k$ follows from the observation that all lines in $L_1(\theta)$ and $L_2(\theta)$ come out either of vertices or of black bullets, and they have nonvanishing momentum. ■

Hence the number of lines in $L_1(\theta)$ is bounded by k, so that in (4.2) we can bound

$$\begin{aligned}\left(\prod_{\ell\in L_1(\theta)} |\omega\nu_\ell|\right)\left(\prod_{v\in E_B(\theta)} Fe^{-\xi|\nu_v|}\right) &\leqslant \left(\prod_{v\in E_B(\theta)} Fe^{-\xi|\nu_v|/2}\right)\left(\prod_{\ell\in L_1(\theta)} e^{-\xi|\nu_\ell|/2k}|\omega\nu_\ell|\right)\\ &\leqslant \left(\prod_{v\in E_B(\theta)} Fe^{-\xi|\nu_v|/2}\right)\left(\frac{2k|\omega|}{\xi}\right)^k, \qquad (4.3)\end{aligned}$$

and in the second line the product can be used to perform the sum over the Fourier labels—this gives a factor $F^kB_2^k$, with $B_2=2e^{-\xi/2}(1-\mathrm{e}^{-\xi/2})^{-1}$—while the last factor is bounded by $A_1B_1^k k!$, for some constants A_1 and B_1.

We can bound the value of a tree θ by using the bounds (4.2) and (4.3), and Lemma 4.1. If we define

$$\varepsilon_1^{-1} = \max\{B_1,|\omega|^{-1}\}\max\{c_0,FB_2\}\max\{1,(2c_0)^{-1}\}, \qquad (4.4)$$

with $c_0=\sqrt{\alpha}$, and take into account that the number of unlabeled trees in $\mathcal{T}_{k,\nu}$ is bounded by 2^{2k-1} (because each tree in $\mathcal{T}_{k,\nu}$ has at most $2k-1$ nodes), then

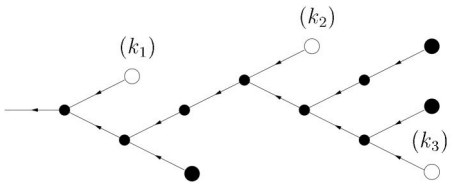

FIG. 8. Example of tree appearing in the graphical expansions (3.5) and (3.6). The number of lines entering any vertex v can be only either $s_v=1$ or $s_v=2$, while no line enters the endpoints. The order of the tree is given by the number of elements in $V(\theta)\setminus V_0(\theta)$ plus the number of elements in $E_B(\theta)$ plus the sum of the order labels of the white bullets. Then, if k_1, k_2, and k_3 are the order labels of the white bullets in the figure, the order of the tree is $k=k_1+k_2+k_3+10$ if $v_0 \in V_0(\theta)$ and $k=k_1+k_2+k_3+9$ if $v_0 \notin V_0(\theta)$. In the latter case one must have $k_1>0$ because of the constraint in the sum appearing in (3.6).

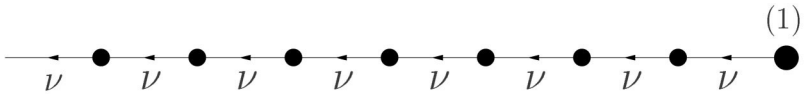

FIG. 9. Example of tree whose value grows as a factorial. If k is the order of the tree (hence there are $k-1$ vertices and 1 black bullet), then the value of the tree is given in (4.6).

$$|x_\nu^{(k)}| \leqslant A_1 \varepsilon_2^{-k} k\,!\,, \quad |x^{(k)}(t)| \leqslant A_1 \varepsilon_2^{-k} k\,!\,, \tag{4.5}$$

where we have set $\varepsilon_2 = \varepsilon_1 2^{-2}$.

A bound like (4.5) is obtained also in the case of forcing terms which are trigonometric polynomials, because in general we can bound the factors $|\omega\nu_\ell|$ in (4.2) only with kN (see Lemma 2.1), and this produces an overall bound proportional to $k!$ Note that in that case the bound B_2, arising from the sum over the Fourier labels, can be replaced with a factor $2N$, and B_1 can be replaced with $|\omega|N$.

Then we have proved the following result.

Proposition 4.2: *Given the equation (2.1) with f as in (1.4), there is only one periodic solution in the form of a formal power series, and the corresponding period is the same period $2\pi/\omega$ as the forcing term. The coefficients of such a formal power series satisfy the bounds (4.5).*

One could ask if the factorials arising in the bounds are only a technical problem, or whether they are a sign that the series really diverges. To order k one can easily provide examples of trees which grow like factorials; see for instance the tree represented in Fig. 9, where there are $k-1$ vertices with only one entering line. Then the corresponding value is

$$\mathrm{Val}(\theta) = (i\omega\nu)^{2(k-1)} \frac{1}{(i\omega\nu)^k} f_\nu = (i\omega\nu)^{k-2} f_\nu, \tag{4.6}$$

which behaves as $k!$ for large k. Furthermore it is unlikely that there are cancellations with the values of other trees because the value of any other tree $\theta \in \mathcal{T}_{k,\nu}$ can be proportional at most to $(i\omega\nu)^p$, with $p < k-2$ (strictly). Hence we expect that the coefficients $u_\nu^{(k)}$, even if well defined to all orders, grow like factorials, so preventing the convergence of the series.

The lack of analyticity is further supported by the following fact. If we consider (2.1) without the quadratic term and with $\alpha = 0$, that is

$$\varepsilon \ddot{x} + \dot{x} = f(\omega t), \quad f_0 = 0, \tag{4.7}$$

in Fourier space, we find $x_0 = 0$ and $i\omega\nu(1 + i\varepsilon\omega\nu)x_\nu = f_\nu$ for $\nu \neq 0$. Hence the equation is trivially solvable, and it gives

$$x(t) = \sum_{\nu \neq 0} \frac{f_\nu}{i\omega\nu(1 + i\varepsilon\omega\nu)} e^{i\omega\nu t}. \tag{4.8}$$

Of course the solution $x(t)$ of the linear equation is not analytic in ε (in a neighborhood of the origin) when f is an analytic function containing all the harmonics, as each point $\varepsilon = i/\omega\nu$ represents a singularity point for $x(t)$, and such points accumulate to the origin as $\nu \to \infty$. Then it is likely that also when the quadratic terms are taken into account the solution cannot be analytic. Therefore giving a meaning to the perturbation series requires some more work, and we discuss this next.

An important remark is that for any $k \geqslant 1$ there is no tree whose value can be bounded worse than proportionally to a factorial, as the estimates (4.5) show, indeed they have been obtained by bounding separately the value of each single tree. This observation will play an important role in the forthcoming analysis.

V. PERIODIC FORCING TERMS

To deal completely with the case of analytic functions and prove existence of the periodic solution, we must modify the graphical expansion envisaged in the preceding sections.

Let us come back to the equation (2.1), and write it in Fourier space. For $\nu \neq 0$ and denoting with x_ν the νth Fourier coefficient, we obtain

$$\varepsilon(i\omega\nu)^2 x_\nu + i\omega\nu\, x_\nu + \varepsilon \sum_{\nu_1+\nu_2=\nu} x_{\nu_1} x_{\nu_2} = \varepsilon f_\nu, \tag{5.1}$$

provided that for $\nu=0$ we have

$$\sum_{\nu_1+\nu_2=0} x_{\nu_1} x_{\nu_2} = 0. \tag{5.2}$$

Let us rewrite (5.1) as

$$\varepsilon(i\omega\nu)^2 x_\nu + i\omega\nu\, x_\nu + \mu\varepsilon \sum_{\nu_1+\nu_2=\nu} x_{\nu_1} x_{\nu_2} = \mu\varepsilon f_\nu, \tag{5.3}$$

and look for a solution $x(t)$ which is analytic in μ, which suggests us to write

$$x(t) = \sum_{k=0}^{\infty} \mu^k x^{[k]}(t). \tag{5.4}$$

Of course we want the value $\mu=1$ to be inside the analyticity domain. Note also that now $x^{[k]}$, the coefficient to order k, has a different meaning with respect to the previous expansion (1.4) in powers of ε, and for this reason with use a different symbol to denote it. We shall call the series (5.4) the *resummed series*, because the coefficients $x^{[k]}(t)$ depend on ε, and are given by the sum of infinitely many terms of the formal series (2.5).

Again for $k=0$ we must take $x_\nu^{[0]}=0$ for $\nu\neq 0$ and fix $c_0 \equiv x_0^{[0]} = \sqrt{\alpha}$, with $\alpha \equiv f_0$.

To order $k \geqslant 1$ (in μ) we obtain for $\nu \neq 0$,

$$i\omega\nu(1 + i\varepsilon\omega\nu) x_\nu^{[k]} = \varepsilon f_\nu \delta_{k,1} - \varepsilon \sum_{k_1+k_2=k-1} \sum_{\nu_1+\nu_2=\nu} x_{\nu_1}^{[k_1]} x_{\nu_2}^{[k_2]}, \tag{5.5}$$

while for $\nu=0$ we require

$$\sum_{k_1+k_2=k} \sum_{\nu_1+\nu_2=\nu} x_{\nu_1}^{[k_1]} x_{\nu_2}^{[k_2]} = 0. \tag{5.6}$$

By setting $c_k = x_0^{[k]}$ the latter equation can be written as [cf. (2.10)]

$$c_1 = 0, \quad c_k = -\frac{1}{2c_0} \sum_{k'=1}^{k-1} \sum_{\nu\in\mathbb{Z}} x_\nu^{[k-k']} x_{-\nu}^{[k']}, \quad k \geqslant 2. \tag{5.7}$$

Then we can proceed as in Sec. III, with some slight changes that we now explain. First of all note that (5.5) gives for $\nu \neq 0$,

$$x_\nu^{[0]} = 0,$$

$$x_\nu^{[1]} = \frac{\varepsilon f_\nu}{i\omega\nu(1 + i\varepsilon\omega\nu)},$$

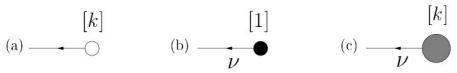

FIG. 10. Graphical representation of $x_0^{[k]}$, $x_\nu^{[1]}$, and $x_\nu^{[k]}$. For $\nu=0$ the latter reduces to the first graph, while for $k=1$ and $\nu\neq 0$ it reduces to the second graph. In the first graph the momentum is not shown as it is necessarily $\nu=0$.

$$x_\nu^{[k]} = -\frac{\varepsilon}{i\omega\nu(1+i\varepsilon\omega\nu)} \sum_{k_1+k_2=k-1} \sum_{\nu_1+\nu_2=\nu} x_{\nu_1}^{[k_1]} x_{\nu_2}^{[k_2]}, \quad k \geqslant 2. \tag{5.8}$$

Then the graphical representations of $x_0^{[k]}$, $x_\nu^{[1]}$, and $x_\nu^{[k]}$ are as in the previous case, with the only change in the representation of the order labels (because of the square brackets instead of the parentheses); see Fig. 10.

On the contrary the graphical representation of the third equation in (5.8) is as in Fig. 11.

At the end we obtain a tree expansion where the trees differ from the previous ones as they contain no vertex with only one entering line. With the previous notations this means that $L_1(\theta)=\emptyset$ and $V_1(\theta)=\emptyset$, hence $V(\theta)=V_2(\theta)$. Moreover also the propagators and the node factors of the vertices are different, as (3.1) and (3.2) must be replaced with

$$g_\ell = \begin{cases} 1/((i\omega\nu_\ell)(1+i\varepsilon\omega\nu_\ell)), & \nu_\ell \neq 0, \\ 1, & \nu_\ell = 0, \end{cases} \tag{5.9}$$

and, respectively,

$$F_v = \begin{cases} -\varepsilon, & v \notin V_0(\theta), \\ -1/2c_0, & v \in V_0(\theta), \end{cases} \tag{5.10}$$

and we recall once more that only vertices v with $s_v=2$ are allowed. Finally, the node factors associated with the endpoints are $F_v=c_{k_v}$ if v is a white bullet and $F_v=\varepsilon f_{\nu_v}$ if v is a black bullet.

As in Sec. III we can envisage an expansion in which all white bullets v have $k_v=0$ (simply by expanding iteratively in trees the white bullets of higher order). A tree appearing in this new expansion is represented in Fig. 12.

With the notations (4.1), we obtain the bounds

$$\left|\prod_{v\in V(\theta)\setminus V_0(\theta)} F_v\right| \leqslant |\varepsilon|^{|V(\theta)|}, \quad \left|\prod_{\ell\in L(\theta)} g_\ell\right| \leqslant \prod_{\ell\in L_2(\theta)} \frac{1}{|\omega\nu_\ell||1+i\varepsilon\omega\nu_\ell|},$$

$$\left|\prod_{v\in V_0(\theta)} F_v\right| \leqslant \left(\frac{1}{2c_0}\right)^{|V_0(\theta)|}, \quad \left|\prod_{v\in E_W(\theta)} F_v\right| \leqslant c_0^{|E_W(\theta)|}, \tag{5.11}$$

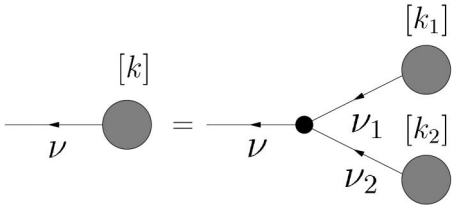

FIG. 11. Graphical representation of the second equation in (5.8) expressing the coefficient $x_\nu^{[k]}$ for $k\geqslant 2$ and $\nu\neq 0$ in terms of the coefficients $x_{\nu'}^{[k']}$ with $k'<k$. In the right-hand graph one has the constraints $k_1+k_2=k-1$ and $\nu_1+\nu_2=\nu$.

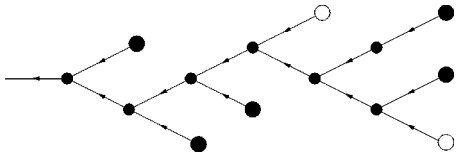

FIG. 12. Example of tree appearing in the new graphical expansion. The number of lines entering any vertex v can be only $s_v=2$. The order of the tree is given by $|B(\theta)|-|V_0(\theta)|$. All the white bullets have order labels (0), and additionally all the black bullets carry a label (1); hence we can avoid drawing explicitly such labels.

$$\left|\prod_{v\in E_B(\theta)} F_v\right| \leqslant F^{|E_B(\theta)|} \prod_{v\in E_B(\theta)} e^{-\xi|\nu_v|},$$

where we have again used the bound $|f_\nu|\leqslant Fe^{-\xi|\nu|}$, for suitable (strictly) positive constants F and ξ, which follows from the analyticity assumption on f.

For real ε we can bound each propagator by

$$|g_\ell| \leqslant \frac{1}{|\omega\nu_\ell|} \leqslant \frac{1}{|\omega|}, \tag{5.12}$$

so that the value of any tree $\theta\in\mathcal{T}_{k,\nu}$ can be bounded by

$$|\mathrm{Val}(\theta)| \leqslant |\varepsilon|^k|\omega|^{-k}(\max\{c_0,F\})^k(\max\{1,1/2c_0\})^k \prod_{v\in E_B(\theta)} e^{-\xi|\nu_v|}, \tag{5.13}$$

where we have again used Lemma 4.1. If we write

$$\prod_{v\in E_B(\theta)} e^{-\xi|\nu_v|} \leqslant e^{-\xi|\nu|/2}\left(\prod_{v\in E_B(\theta)} e^{-\xi|\nu_v|/2}\right), \tag{5.14}$$

we can proceed as in Sec. IV; we use the last product to perform the sum over the Fourier labels, which gives a factor B_2^k, whereas the sum over the unlabeled trees gives a factor 2^{2k-1}. At the end we obtain

$$|x_\nu^{(k)}| \leqslant \mu_2^{-k}, \quad |x^{(k)}(t)| \leqslant \mu_2^{-k}, \tag{5.15}$$

where we have set $\mu_2^{-1}=4|\omega|^{-1}\max\{1,1/2c_0\}\max\{FB_2,c_0\}|\varepsilon|$. Hence the radius of convergence μ_0 of the series expansion (5.4) is bounded as $\mu_0\geqslant\mu_2=O(1/|\varepsilon|)$, so that for ε small enough, say $|\varepsilon|<\varepsilon_3=(4|\omega|^{-1}\max\{1,1/2c_0\}\max\{FB_2,c_0\})^{-1}$, the value $\mu=1$ is inside the analyticity domain.

We can summarize the results found so far as follows.

Theorem 5.1: *Given the equation (2.1) with f analytic, there exists* $\varepsilon_0>0$ *such that for all real* ε *with* $|\varepsilon|<\varepsilon_0$ *there is only one periodic solution which admits a formal expansion in powers of* ε*, and the corresponding period is the same period* $2\pi/\omega$ *as the forcing term. An explicit bound is* $\varepsilon_0\geqslant\varepsilon_3=O(\omega)$.

Note that if ω is very large then very large values of ε are allowed.

We can investigate further the regularity properties in ε of the periodic solution found in Theorem 5.1, and see what happens for complex values of ε.

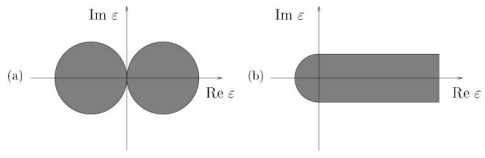

FIG. 13. (a) Region $\mathcal{C}_R$ in the complex ε-plane and (b) striplike region of analyticity $\mathcal{S}_B$ of the Borel transform. The region $\mathcal{C}_R$ is the union of two discs of radius $R/2$ and centers $(\pm R/2,0)$.

We need the following preliminary result [see Fig. 13(a) for the region $\mathcal{C}_R$].

Lemma 5.2: *Given* $\omega>0$ *and* $0<R<1/4\omega$ *let* $\mathcal{C}_R$ *be the pair of discs* $\mathcal{C}_R=\{\varepsilon:|\mathrm{Re}\,\varepsilon^{-1}|>R^{-1}\}$. *For all* $\varepsilon\in\mathcal{C}_R$ *and all* $\nu\in\mathbb{Z}\setminus\{0\}$ *one has* $|i\omega\nu(1+i\varepsilon\omega\nu)|\geqslant\omega/2$.

Proof: Write $\varepsilon=a+ib$ and $x=\omega\nu$, so that one has $|i\omega\nu(1+i\varepsilon\omega\nu)|=|x|\sqrt{(1-bx)^2+(ax)^2}\equiv F(x)$. If $\varepsilon\in\mathcal{C}_R$ one has $|a|\geqslant b^2/2R$. Fix $0<A<1$. If $|1-bx|\leqslant A$ then $\sqrt{(1-bx)^2+(ax)^2}\geqslant|ax|\geqslant b^2|x|/2R\geqslant|b|(1-A)/2R$, so that $F(x)\geqslant(1-A)^2/2R$. If $|1-bx|\geqslant A$ then $\sqrt{(1-bx)^2+(ax)^2}\geqslant A$, hence $F(x)\geqslant A|x|\geqslant\omega A$. Then choose $A=1-\sqrt{\omega R}\geqslant 1/2$; this gives $F(x)\geqslant\omega/2$. ■

Now fix $0<R<\bar{R}\equiv\varepsilon_3$ so small that $|\omega|R<1/4$, and consider the corresponding domain $\mathcal{C}_R$. We can apply Lemma 5.2 and deduce that any propagator g_ℓ is bounded by $|g_\ell|\leqslant 2/|\omega|$ for all $\varepsilon\in\mathcal{C}_R$.

This allows us to obtain the following result.

Proposition 5.3: *There exists* $R>0$ *small enough such that in the domain* $\mathcal{C}_R$ *one has the asymptotic expansion*

$$x(t)=\sum_{k=0}^{N-1}\varepsilon^k x^{(k)}(t)+\mathfrak{R}_N(\varepsilon),\quad |\mathfrak{R}_N(\varepsilon)|\leqslant AB^N N!\,|\varepsilon|^N, \tag{5.16}$$

where the constants A and B are uniform in N and in ε.

Proof: Write $x(t)$ as $x(t)=x_N(t)+\mathfrak{R}_N(t)$, where $x_N(t)$ is given by the sum of the first $N-1$ orders of the formal power series expansion of the solution $x(t)$ as in (5.16). For $\varepsilon\in\mathcal{C}_R$ the function (5.4) with $\mu=1$ is C^∞ in ε, hence we can estimate $\mathfrak{R}_N(\varepsilon)$ with a bound on the Nth derivative of $x(t)$ in $\mathcal{C}_R$, and this gives the bound in (5.16). ■

Of course the constants A and B in (5.16) are explicitly computable; in particular one finds $B=O(\varepsilon_3^{-1})$.

Then we are under the assumptions where Nevanlinna's theorem[11] (see also Ref. 12) can be applied, and hence the series for

$$\mathfrak{B}(t;\varepsilon)=\sum_{k=0}^{\infty}\frac{1}{k!}\varepsilon^k x^{(k)}(t) \tag{5.17}$$

converges for $|\varepsilon|<B$ [with B given in (5.16)] and has an analytic continuation to $\mathcal{S}_B=\{\varepsilon:\mathrm{dist}(\varepsilon,\mathbb{R}_+)<B\}$ [see Fig. 13(b)], satisfying for some constant K the bound $|\mathfrak{B}(t;\varepsilon)|\leqslant Ke^{|\varepsilon|/R}$ uniformly in every $\mathcal{S}_{B'}$ with $B'<B$. The function $x(t)$ can be represented as the absolutely convergent integral

$$x(t)=\frac{1}{\varepsilon}\int_0^\infty e^{-s/\varepsilon}\mathfrak{B}(t;s)\mathrm{d}s \tag{5.18}$$

for all $\varepsilon\in\mathcal{C}_R$, and this property can be stated by saying that $x(t)$ is Borel summable (in ε) and $\mathfrak{B}(t;\varepsilon)$ is its Borel transform.[9] This implies that the function given by the summation procedure described in Theorem 1 is unique. Therefore we have obtained the following result, which strengthens Theorem 1.

Theorem 5.4: *The solution given by Theorem 1 is Borel summable at the origin.*

Note that Watson's theorem cannot be invoked to obtain this result because the singularities are along the imaginary axis.

In particular if $f(\omega t)=\alpha+\beta\sin t$ then there is a periodic solution $x(t)=a+\varepsilon\beta\cos t+O(\varepsilon^2)$, with $a=\sqrt{\alpha}$, which has period 2π and moves around the fixed point $(x,\dot{x})=(a,0)$, and close to it within $O(\varepsilon)$. No other periodic solution analytic in ε can exist.

We conclude this section with two remarks. The summation criterion envisaged in this section is reminiscent of that used (in a more difficult situation) in Ref. 6 for hyperbolic lower-dimensional tori. However in that case we are not able to prove Borel summability because to order k the bounds were like $(k!)^\alpha$ for some $\alpha>1$. Neither extension to Watson's theorem[9]

analogous to the Nevanlinna–Sokal result (as those developed in Ref. 5) can be used because the exponent α is too large. We shall find a very similar situation in next section.

The lack of analyticity in ε in a neighborhood of the origin is due to the accumulation of singularity points along the imaginary axis in the complex ε-plane (where the quantity $1+i\varepsilon\omega\nu$ vanishes for $\nu\in\mathbb{Z}$). The analyticity domain is tangential to the imaginary axis, and this allows us to apply Nevanlinna's theorem. We find that this situation has some analogies with a different problem, the analyticity properties of rescaled versions of some dynamical systems, such as Siegel's problem[4] (and its linearization as considered in Ref. 10), the standard map[2] and generalized standard maps,[3] for complex rotation numbers tending to rational values in the complex plane. In those cases, however, only nontangential limits could be considered. Of course the situation is slightly more complicated there, because the set of accumulating singularity points is dense—and not only numerable as in the present case.

VI. QUASIPERIODIC FORCING TERMS

In the case of analytic quasiperiodic forcing terms, we shall assume a Diophantine condition on the rotation vector $\boldsymbol{\omega}$, that is

$$|\boldsymbol{\omega}\cdot\boldsymbol{\nu}| \geqslant C_0|\boldsymbol{\nu}|^{-\tau} \quad \forall\, \boldsymbol{\nu}\in\mathbb{Z}^d\setminus\{\mathbf{0}\}, \tag{6.1}$$

where $|\boldsymbol{\nu}|=|\boldsymbol{\nu}|_1\equiv|\nu_1|+\cdots+|\nu_d|$, and C_0 and τ are positive constants. We need $\tau\geqslant d-1$ in order to have a nonvoid set of vectors satisfying the condition (6.1), and $\tau>d-1$ in order to have a full measure set of such vectors. For simplicity (and without loss of generality) we can assume $C_0<\gamma/2$, with $\gamma=\min\{1,|c|\}$, where c is a suitable constant to be fixed as $c=-2c_0$, with $c_0=\sqrt{\alpha}$.

The equation of motion can be written in Fourier space as

$$i\boldsymbol{\omega}\cdot\boldsymbol{\nu}(1+i\varepsilon\boldsymbol{\omega}\cdot\boldsymbol{\nu})x_{\boldsymbol{\nu}}+\varepsilon\sum_{\boldsymbol{\nu}_1+\boldsymbol{\nu}_2=\boldsymbol{\nu}} x_{\boldsymbol{\nu}_1}x_{\boldsymbol{\nu}_2}=\varepsilon f_{\boldsymbol{\nu}}, \tag{6.2}$$

and the formal expansion for a quasiperiodic solution with frequency vector $\boldsymbol{\omega}$ reads as

$$x(t)=\sum_{k=0}^{\infty}\varepsilon^k x^{(k)}(t)=\sum_{k=0}^{\infty}\varepsilon^k\sum_{\boldsymbol{\nu}\in\mathbb{Z}^d} e^{i\boldsymbol{\nu}\cdot\boldsymbol{\omega}t}x_{\boldsymbol{\nu}}^{(k)}, \tag{6.3}$$

and to see that the coefficients $x_{\boldsymbol{\nu}}^{(k)}$ are well defined to all orders $k\geqslant 0$ one can proceed as in Sec. II, with no extra difficulty. In particular the Diophantine condition (6.1) is sufficient to assure analyticity in t of the coefficients $x^{(k)}(t)$.

Also the graphical representation can be worked out as in Sec. III. The only difference is that now the propagators of the lines with nonvanishing momentum $\boldsymbol{\nu}_\ell$, which is defined according to (3.2), with the vectors replacing the scalars, are given by $1/(i\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell)$, the node factors associated with the vertices v with $s_v=1$ are given by $F_v=-(i\boldsymbol{\omega}\cdot\boldsymbol{\nu}_{\ell_v})^2$, and the node factors associated with the black bullets v are given by $F_v=f_{\boldsymbol{\nu}_v}$, with $\boldsymbol{\nu}_v\in\mathbb{Z}^d\setminus\{\mathbf{0}\}$. All the other notations remain unchanged.

This yields that the propagators and the node factors can be bounded as in (4.2) and (4.3), with just a few differences of notation. More precisely one has

$$\left|\prod_{v\in V_1(\theta)}F_v\right|\left|\prod_{\ell\in L_1(\theta)}g_\ell\right|\leqslant\prod_{\ell\in L_1(\theta)}|\boldsymbol{\omega}||\boldsymbol{\nu}_\ell|, \quad \left|\prod_{\ell\in L_1(\theta)}g_\ell\right|\leqslant\prod_{\ell\in L_1(\theta)}\frac{1}{|\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell|}\leqslant C_0^{-1}|\boldsymbol{\nu}_\ell|^\tau,$$

$$\left|\prod_{v\in V_0(\theta)}F_v\right|\leqslant\left(\frac{1}{2c_0}\right)^{|V_0(\theta)|}, \quad \left|\prod_{v\in E_W(\theta)}F_v\right|\leqslant c_0^{|E_W(\theta)|}, \tag{6.4}$$

$$\left| \prod_{v \in E_B(\theta)} F_v \right| \leqslant F^{|E_B(\theta)|} \prod_{v \in E_B(\theta)} e^{-\xi|\boldsymbol{\nu}_v|},$$

where the only bound which introduces a real difficulty with respect to the case of periodic forcing terms is the second one in the first line. Indeed it is the source of a small divisors problem, which cannot be set only through the Diophantine condition (6.1).

To each order k we obtain for $x^{(k)}(t)$ a bound like $AB^k k!^{\max\{1,\tau\}}$, where the factor 1 arises from the propagators of the lines in $L_1(\theta)$ and the factor τ from those of the lines in $L_2(\theta)$ in (6.3). The last assertion is easily proved by reasoning as in (4.3), with $\max\{|\boldsymbol{\omega}||\boldsymbol{\nu}_\ell|, C_0^{-1}|\boldsymbol{\nu}_\ell|^\tau\} \leqslant \max\{C_0^{-1}, |\boldsymbol{\omega}|\}|\boldsymbol{\nu}_\ell|^{\max\{1,\tau\}}$ replacing ν_ℓ. In particular only for $d=2$ and $\tau=1$ we obtain the same bound proportional to $k!$ as in the case of periodic solution (of course with different constants A and B). Note that the vectors satisfying the Diophantine condition (6.1) with $\tau=1$ for $d=2$ is of zero measure but everywhere dense. An example of vector of this kind is $\boldsymbol{\omega}=(1,\gamma_0)$, where $\gamma_0 = (\sqrt{5}-1)/2$ is the golden section.

However, to deal with the problem of accumulation of small divisors and discuss the issue of convergence of the series, we need renormalization group techniques. The first step is just to introduce a multiscale decomposition of the propagators, and this leads naturally to the introduction of clusters and self-energy graphs into the trees. The discussion can be performed either as in Ref. 6 or as in Ref. 8 (and in Ref. 7). We choose to follow Ref. 8, which is more similar to the present problem because the propagators are scalar quantities and not matrices. In any case, with respect to the quoted reference, we shall use a multiscale decomposition involving only the quantities $|\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell|$, that is without introducing any dependence on ε in the compact support functions. Indeed this is more suitable to investigate the analyticity properties in ε, and, as we shall see, we shall not need to exclude any real value of ε in order to give a meaning to the resummed series, a situation more reminiscent of Ref. 6 than of Ref. 8.

In the following we confine ourselves to outlining the main differences with respect to Ref. 8. Let us introduce the functions ψ_n and χ_n, for $n \geqslant 0$, as in Ref. 8, Sec. 5. In particular $\psi_n(|x|) \neq 0$ implies $|x| \geqslant 2^{-(n+1)}C_0$ and $\chi_n(|x|) \neq 0$ implies $|x| \leqslant 2^{-n}C_0$. We shall define recursively the *renormalized propagators* $g_\ell^{[n]} = g^{[n]}(\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell;\varepsilon)$ and the *counterterms* $\mathcal{M}^{[n]}(\boldsymbol{\omega}\cdot\boldsymbol{\nu};\varepsilon)$ on scales n as

$$g^{[-1]}(x;\varepsilon) = 1, \quad M^{[-1]}(x;\varepsilon) = 0,$$

$$g^{[0]}(x;\varepsilon) = \frac{\psi_0(|x|)}{ix(1+i\varepsilon x)}, \quad M^{[0]}(x;\varepsilon) = \sum_{k=1}^{\infty} \sum_{T \in \mathcal{S}_{k,0}^{\mathcal{R}}} \mathcal{V}_T(x;\varepsilon),$$

$$g^{[n]}(x;\varepsilon) = \frac{\chi_0(|x|)\cdots\chi_{n-1}(|x|)\psi_n(|x|)}{ix(1+i\varepsilon x) + \mathcal{M}^{[n-1]}(x;\varepsilon)}, \tag{6.5}$$

$$\mathcal{M}^{[n]}(x;\varepsilon) = \mathcal{M}^{[n-1]}(x;\varepsilon) + \chi_0(|x|)\cdots\chi_{n-1}(|x|)\chi_n(|x|)M^{[n]}(x;\varepsilon),$$

$$M^{[n]}(x;\varepsilon) = \sum_{k=1}^{\infty} \sum_{T \in \mathcal{S}_{k,n}^{\mathcal{R}}} \mathcal{V}_T(x;\varepsilon),$$

where the set of renormalized self-energy graphs $\mathcal{S}_{k,n}^{\mathcal{R}}$ and the self-energy graphs $\mathcal{V}_T(x;\varepsilon)$ are defined as in Ref. 8, Sec. 6. We have explicitly used the fact that the first contribution to the self-energy graphs is of order $k=1$ (see Fig. 14). Note that one has $\chi_0(|x|)\cdots\chi_{n-1}(|x|)\chi_n(|x|) = \chi_n(|x|)$, so that if $g^{[n]}(x;\varepsilon) \neq 0$ then one has $2^{-(n+1)}C_0 \leqslant |x| \leqslant 2^{-(n-1)}C_0$.

Then one defines for $k \geqslant 1$

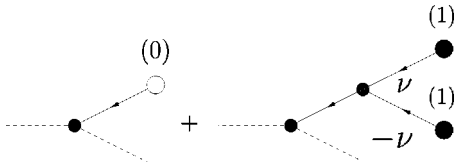

FIG. 14. Lower order contributions to the counterterm arising from self-energy graphs of order $k=1$ and $k=3$. The (dashed) external lines do not enter into the definition of self-energy graph, and they have been drawn only with the aim of helping to visualize the structure of the self-energy graph.

$$x_{\boldsymbol{\nu}}^{[k]} = \sum_{\theta \in \mathcal{T}_{k,\boldsymbol{\nu}}} \mathrm{Val}(\theta), \quad x_{\mathbf{0}}^{[k]} \equiv c_k = \sum_{\theta \in \mathcal{T}_{k,\mathbf{0}}}{}^{*}\mathrm{Val}(\theta), \tag{6.6}$$

where the tree value is defined as

$$\mathrm{Val}(\theta) = \left(\prod_{\ell \in L(\theta)} g_{\ell}^{[n_\ell]} \right) \left(\prod_{v \in E(\theta) \cup V(\theta)} F_v \right), \tag{6.7}$$

and, as before, $*$ means that there are two lines entering the last vertex v_0 of θ_0 and neither one exits from an endpoint v with order label $k_v=0$. For $k=1$ the second of (6.7) must be interpreted as $c_1=0$.

Furthermore one has

$$\begin{aligned} M^{[0]}(x;\varepsilon) &= M^{[0]}(0;\varepsilon) + O(\varepsilon^2 x), \\ M^{[0]}(0;\varepsilon) &= -2\varepsilon c_0 + M_2^{[0]}(0;\varepsilon), \quad M_2^{[0]}(0;\varepsilon) = O(\varepsilon^2), \end{aligned} \tag{6.8}$$

and an easy computation shows (cf. Fig. 14) that

$$M_2^{[0]}(0;\varepsilon) = \varepsilon^3 \frac{1}{c_0} \sum_{\boldsymbol{\nu} \neq \mathbf{0}} \psi_0^2(|\boldsymbol{\omega} \cdot \boldsymbol{\nu}|) \frac{|f_{\boldsymbol{\nu}}|^2}{(\boldsymbol{\omega} \cdot \boldsymbol{\nu})^2 (1 + (\varepsilon \boldsymbol{\omega} \cdot \boldsymbol{\nu})^2)} + O(\varepsilon^4), \tag{6.9}$$

so that in fact one has $M_2^{[0]}(0;\varepsilon)=O(\varepsilon^3)$.

Moreover to higher scales one has $M^{[n]}(x;\varepsilon)=M^{[n]}(0;\varepsilon)+O(\varepsilon^3 x)$, with

$$M^{[n]}(0;\varepsilon) = -\varepsilon^3 \frac{1}{c_0} \sum_{\boldsymbol{\nu} \neq \mathbf{0}} \sum_{n_1+n_2=n} \psi_{n_1}(|\boldsymbol{\omega} \cdot \boldsymbol{\nu}|) \psi_{n_2}(|\boldsymbol{\omega} \cdot \boldsymbol{\nu}|) \frac{|f_{\boldsymbol{\nu}}|^2}{(\boldsymbol{\omega} \cdot \boldsymbol{\nu})^2 (1 + (\boldsymbol{\omega} \cdot \boldsymbol{\nu})^2)} + O(\varepsilon^4), \tag{6.10}$$

so that each $M^{[n]}(0;\varepsilon)$ is a higher order correction to $M^{[0]}(0;\varepsilon)$ and it decays exponentially in n (because of the compact support functions).

The following result holds.

Lemma 6.1: *Assume that the renormalized propagators up to scale $n-1$ can be bounded as*

$$|g_{\ell}^{[n_\ell]}| \leq C_1^{-1} 2^{\beta n_\ell} \tag{6.11}$$

for some positive constants C_1 and β. Then for all $n' \leq n-1$ the number $N_{n'}(\theta)$ of lines on scale n' in θ is bounded by

$$N_{n'}(\theta) \leq K 2^{-n'/\tau} \sum_{v \in E_B(\theta)} |\boldsymbol{\nu}_v|, \tag{6.12}$$

for some positive constant K. If $|\varepsilon| < \varepsilon_0$, with ε_0 small enough, then for all $n' \leq n$ one has

$$|M^{[n']}(x;\varepsilon)| \leq D_1 |\varepsilon|^3 e^{-D_2 2^{n'/\tau}}, \quad |\partial_x M^{[n']}(x;\varepsilon)| \leq D_1 |\varepsilon|^3 e^{-D_2 2^{n'/\tau}}, \tag{6.13}$$

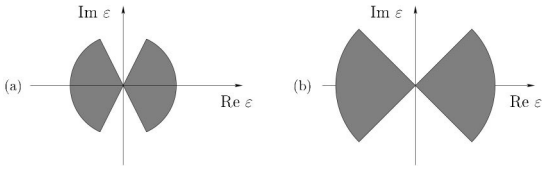

FIG. 15. Region $\mathcal{D}_{R,\lambda}$ in the complex ε-plane for $\lambda=\tan\pi/6$ (a) and for $\lambda=1$ (b). One can write $\lambda=\tan\varphi$, where φ is the angle between the imaginary axis and the line $a=\lambda b$.

for some C_1-independent positive constants D_1 and D_2. Only the constant D_1 depends on β. The constant ε_0 can be written as $\varepsilon_0=C_1C_2^{-\beta}C_3$, with C_2 and C_3 two positive constants independent of β and C_1.

Proof: The proof can be easily adapted from the proofs of Lemma 1 and Lemma 2 of Ref. 8.■

So we are left with the problem of proving that the renormalized propagators satisfy the bounds (6.11). To this end let us introduce the notation

$$F(x) = F_0(x) + c_1(\varepsilon)\varepsilon + c_2(\varepsilon,x)\varepsilon^2 x, \quad F_0(x) = ix(1+i\varepsilon x), \tag{6.14}$$

with $x=\boldsymbol{\omega}\cdot\boldsymbol{\nu}$ and the functions $c_1(\varepsilon)$ and $c_2(\varepsilon,x)$ such that $c_1(\varepsilon)=c+c_3(\varepsilon)\varepsilon$, with $c\neq 0$, and the functions $|c_2(\varepsilon,x)|$ and $|c_3(\varepsilon)|$ bounded by a constant c' uniformly (in ε and x). Recall that $\gamma=\min\{1,|c|\}$ and $C_0<\gamma/2$.

Fix $\lambda\in[0,1]$. Set $\mathcal{B}_R(0)=\{\varepsilon\in\mathbb{C}:|\varepsilon|<R\}$ and $\mathcal{D}_{R,\lambda}=\{\varepsilon=a+ib\in\mathcal{B}_{\lambda R}(0):|a|\geq\lambda|b|\}$ (see Fig. 15). The following result refines Lemma 5.2.

Lemma 6.2: *Given $0<R<1/4C_0$, let $\mathcal{C}_R$ be defined as in Lemma 5.2. For all $\varepsilon\in\mathcal{C}_R$ and all x one has $|F_0(x)|\geq\min\{C_0,|x|\}/2$, while for all $\varepsilon\in\mathcal{D}_{R,\lambda}$ one has $|F_0(x)|\geq\lambda|x|/2$.*

Proof: Write $\varepsilon=a+ib$, so that $|F_0(x)|=|x|\sqrt{(1-bx)^2+(ax)^2}$. For $\varepsilon\in\mathcal{C}_R$ set $A=1-\sqrt{C_0R}$. If $|x|\geq C_0$, for $|1-bx|\leq A$ one has $|F_0(x)|\geq|ax^2|\geq b^2x^2/2R\geq C_0/2$, while for $|1-bx|\geq A$ one has $|F_0(x)|\geq A|x|\geq|x|/2\geq C_0/2$. If $|x|\leq C_0$, for $|1-bx|\leq A$ one has $|F_0(x)|\geq|ax^2|\geq C_0/2\geq|x|/2$, while for $|1-bx|\geq A$ one has $|F_0(x)|\geq A|x|\geq|x|/2$. For $\varepsilon\in\mathcal{D}_{R,\lambda}$ set $A=1/2$, one finds $|F_0(x)|\geq\lambda|x|/2$. ■

Then the following result holds.

Lemma 6.3: *Set $x=\boldsymbol{\omega}\cdot\boldsymbol{\nu}$ and assume $|x|\leq C_0$. Then if R is small enough one has $|F(x)|\geq\lambda\gamma|x|/8$ for all $\varepsilon\in\mathcal{D}_{R,\lambda}$.*

Proof: Set $F_1(x)=F_0(x)+c\varepsilon$ and $\varepsilon=a+ib$. Then $F_1(x)=i(x+b(c-x^2))+a(c-x^2)$, and $|F(x)|\geq|F_1(x)|-c'|\varepsilon|^2(1+|x|)$. If $|x+b(c-x^2)|\geq|x|/2$ and $|bc|\geq 4|x|$ one has $|F_1(x)|\geq|c|\sqrt{b^2+a^2}/2\equiv|c\varepsilon|/2$, so that $|F(x)|\geq|c\varepsilon|/4\geq|cb|/4\geq|x|$. If $|x+b(c-x^2)|\geq|x|/2$ and $|bc|\leq 4|x|$ one has $|F_1(x)|\geq\gamma\max\{\sqrt{x^2+a^2},|\varepsilon|/4\}/2$, so that $|F(x)|\geq\gamma\sqrt{x^2+a^2}/4\geq\gamma|x|/4$. If $|x+b(c-x^2)|\leq|x|/2$ one has $|b(c-x^2)|\geq|x|/2$ and $|bc|\leq 3|x|$, which give $|\varepsilon|^2\leq 3|\varepsilon|\sqrt{a^2+x^2}/\gamma\leq 3\lambda R(|a|+|x|)/\gamma$, and $|F_1(x)|\geq|a(c-x^2)|\geq|a(c-x^2)|/2+(\lambda|x|/2)/2\geq\gamma\lambda(|a|+|x|)/4$, so that $|F(x)|\geq\gamma\lambda|x|/8$. ■

Then we can come back to the bounds of the renormalized propagators, and prove the following result.

Lemma 6.4: *If R is small enough for all $n\geq 0$ and all $\varepsilon\in\mathcal{D}_{R,\lambda}$ the renormalized propagators $g^{[n]}(x;\varepsilon)$ satisfy the bounds (6.11) with $\beta=1$ and $C_1=\lambda C_4$, with a λ-independent constant C_4.*

Proof: The proof can be done by induction on n. For $n=0$ the bound is trivially satisfied by Lemma 6.2. Assuming that the bounds hold for all $n'<n$ then we can apply Lemma 6.1 and deduce the bounds (6.13). In turn this implies that the renormalized propagators on scale n can be written as $g^{[n]}(x;\varepsilon)=1/F(x)$, with $F(x)$ written as in (6.14) for $c=-2c_0$ [cf. (6.8)], and for suitable functions $c_1(\varepsilon)$ and $c_2(\varepsilon,x)$, depending on n and satisfying the properties listed after (6.14) for some n-independent constant c'. Then by Lemma 6.3 the renormalized propagators $g^{[n]}(x;\varepsilon)$ satisfy the same bounds (6.11) with $C_1=O(\lambda)$ for $\varepsilon\in\mathcal{D}_{R,\lambda}$. ■

Of course for real ε the bound (6.11) is trivially satisfied, with $C_1=2^{-1}C_0$. This follows from Lemma 6.4 with $\lambda=1$, but it is obvious independently of that result because one has $c_1(\varepsilon)=c\varepsilon+O(\varepsilon^2)$, with $c=-2c_0\in\mathbb{R}$. If we want to take also complex values of ε, we have analyticity in a

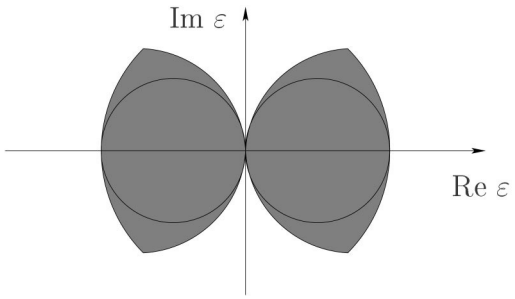

FIG. 16. Regions $\mathcal{D}_R$ and $\mathcal{C}_R$ in the complex ε-plane, $\mathcal{D}_R$ is the entire grey region, while $\mathcal{C}_R$ is the region contained inside the two circles.

domain D which can be written as $\mathcal{D}_R = \cup_{\lambda \in [0,1]} \mathcal{D}_{R,\lambda}$. One can easily realize that the region $\mathcal{C}_R$ is contained inside the domain $\mathcal{D}_R$ (cf. Fig. 16). Fix $\lambda = \tan \varphi$, with $\varphi \in [0, \pi/4]$ (see Fig. 15), for all such φ the line which forms an angle φ with the imaginary axis (see Fig. 15) and passes through the origin intersects the boundary of $\mathcal{D}_R$ at a distance $R \tan \varphi$ from the origin and the boundary of $\mathcal{C}_R$ at a distance $R \sin \varphi$. Hence we have an analyticity domain of the same form as in the case of periodic forcing terms. Nevertheless the results found so far do not allow us to obtain Borel summability, notwithstanding a circular analyticity domain $\mathcal{C}_R$ is found, as the bounds which are satisfied inside the region $\mathcal{C}_R$ are not uniform in ε (because of the dependence on λ).

Note that $\beta = 1$ in (6.11) is the same exponent appearing in the bounds of the propagators in the formal expansion. To obtain uniform bounds in a domain $\mathcal{C}_R$, for some value of R, we must allow larger values of β. The following result is obtained.

Lemma 6.5: *Set* $x = \boldsymbol{\omega} \cdot \boldsymbol{\nu}$ *and assume* $|x| < C_0$. *If* R *is small enough one has* $|F(x)| > \gamma |x|^2/2$ *for all* $\varepsilon \in \mathcal{C}_R$.

Proof: Set $F_1(x) = F_0(x) + c\varepsilon$ and $\varepsilon = a + ib$. If $|x + b(c - x^2)| \leq |x|/2$ one has $|b(c - x^2)| \geq |x|/2$ and $3|x| \geq |bc| \geq |x|/4$. Hence $|a(c - x^2)| \geq b^2 |c - x^2|/2R \geq |x|^2/16R|c|$, so that one has $|F_1(x)| \geq |a(c - x^2)| \geq |ac|/4 + |a(c - x^2)|/2 \geq \gamma(|a| + x^2/16Rc)/2$. On the other hand, one has $|\varepsilon|^2 = a^2 + b^2 \leq a^2 + 9x^2/c^2$, so that $|F(x)| \geq |F_1(x)| - 2c'|\varepsilon|^2 \geq |F_1(x)|/2 \geq \gamma x^2/2$. The case $|x + b(c - x^2)| \geq |x|/2$ can be discussed as in Lemma 6.3, and it gives $|F(x)| \geq \gamma |x|/4$. ■

Then we can prove the following result by proceeding exactly as in the proof of Lemma 8.

Lemma 6.6: *If* R *is small enough for all* $n \geq 0$ *and all* $\varepsilon \in \mathcal{C}_R$ *the renormalized propagators* $g^{[n]}(x; \varepsilon)$ *satisfy the bounds (6.11) with* $\beta = 2$ *and* C_1 *a suitable constant*.

The advantage of Lemma 6.4 with respect to Lemma 6.6 is that the bound of R is better, which means that the domain $\mathcal{C}_R$ contained inside $\mathcal{D}_R$ in the first case is larger than the domain $\mathcal{C}_R$ of the second case. The advantage of Lemma 6.6 is that it allows uniform bounds inside the corresponding domain $\mathcal{C}_R$ to be obtained. Nevertheless, because of the factor $\beta = 2$, a bound $AB^k k!^{2\tau}$ is obtained for the coefficients $x^{(k)}(t)$ of the formal solution, and a result analogous to Proposition 2 can be proved also for the present case, with $N!^{2\tau}$ replacing $N!$; we do not give the details as the proof is identical. Hence the bounds that we have are not good enough to obtain Borel summability in the case of quasiperiodic forcing terms, a situation strongly reminiscent of that encountered in Ref. 6. In fact at best one can set $\tau = 1$ for $d = 2$ (which, as noted above, corresponds to a set of Diophantine vectors of zero measure but everywhere dense), but this in turn implies a bound proportional to $N!^2$, which is not enough to apply Nevanlinna's theorem.

The conclusion is that the resummed series

$$x(t) = \sum_{k=0}^{\infty} \mu^k x^{[k]}(t), \tag{6.15}$$

where the coefficients $x^{[k]}(t)$ are given by

$$x^{[k]}(t) \sum_{\boldsymbol{\nu} \in \mathbb{Z}^d} e^{i\boldsymbol{\nu}\cdot\boldsymbol{\omega}t} x_{\boldsymbol{\nu}}^{[k]}, \tag{6.16}$$

with $x_{\boldsymbol{\nu}}^{[k]}$ defined by (6.6), is well defined and converges. In general it is not obvious—even if expected—that (6.15) solves the equation of motion (1.1). Indeed, unlike the case of periodic forcing terms, we have no result, such as Nevanlinna's theorem on Borel summability, which we can rely upon in order to link the resummed series to the formal series. Therefore we must check by hand that by expanding in powers of ε the resummed series we recover the formal power series (6.3). This means that the resummed series, which in principle could be unrelated to the equation of motion (because of the way it has been defined), in fact solves such an equation. Such a property can be proved by reasoning as in Ref. 8, Sec. 8. Again we omit the details, which can be easily worked out.

We can summarize our results in the following statement.

Theorem 6.7: *Given the equation (1.1) with f analytic in its argument and* $\boldsymbol{\omega}$ *satisfying the Diophantine condition (6.1), there exists* ε_0 *such that for all real* ε *with* $|\varepsilon| < \varepsilon_0$ *there is a quasi-periodic solution with the same frequency vector as the forcing term. Such a solution extends to a function analytic in the domain* $\mathcal{D}_R$ *shown in Fig. 16, with* $R = \varepsilon_0$.

The conclusion is that the summation criterion described here gives a well defined function, which is quasiperiodic and solves the equation of motion (1.1), but the criterion is not equivalent to Borel summability any more. In particular the issue of whether such quasiperiodic solutions are unique or not remains open, as in Ref. 6.

VII. EXTENSION TO MORE GENERAL NONLINEARITIES

When considering the equation (1.5) the formal analysis of Sec. II (and of Sec. VI in the case of quasiperiodic forcing terms) can be performed essentially in the same way. If we write

$$\begin{aligned} g(x) &= \sum_{p=0}^{\infty} \frac{1}{p!} g_p (x - c_0)^p, \quad g_p = \frac{\mathrm{d}^p g}{\mathrm{d}x^p}(c_0), \\ [g(x)]_{\boldsymbol{\nu}}^{(k)} &= \sum_{p=0}^{\infty} \frac{1}{p!} g_p \sum_{\substack{k_1 + \cdots + k_p = k \\ \nu_1 + \cdots + \nu_p = \nu}} x_{\boldsymbol{\nu}_1}^{(k_1)} \cdots x_{\boldsymbol{\nu}_p}^{(k_p)}, \quad k \geqslant 0, \end{aligned} \tag{7.1}$$

then the recursive equations for $\boldsymbol{\nu} \neq \mathbf{0}$ are

$$\begin{aligned} x_{\boldsymbol{\nu}}^{(0)} &= 0, \\ x_{\boldsymbol{\nu}}^{(1)} &= \frac{f_{\boldsymbol{\nu}}}{i\boldsymbol{\omega}\cdot\boldsymbol{\nu}}, \\ x_{\boldsymbol{\nu}}^{(k)} &= -(i\boldsymbol{\omega}\cdot\boldsymbol{\nu}) x_{\boldsymbol{\nu}}^{(k-1)} - \frac{1}{i\boldsymbol{\omega}\cdot\boldsymbol{\nu}} [g(x)]_{\boldsymbol{\nu}}^{(k-1)}, \quad k \geqslant 2, \end{aligned} \tag{7.2}$$

while the compatibility condition becomes $[g(x)]_{\mathbf{0}}^{(k)} = f_{\mathbf{0}} \delta_{k,0}$ for $k \geqslant 0$. The latter for $k = 0$ gives $g(c_0) = f_0$, while for $k \geqslant 1$ gives $g'(c_0) c_k + R(c_0, c_1, \ldots, c_{k-1}) = 0$, where the function $R(c_0, c_1, \ldots, c_{k-1})$ depends on the coefficients to all orders $k' < k$, hence, in particular, on the constants $c_0, \ldots, c_{k-1}$. Therefore the constants c_k can be fixed iteratively as

$$c_k = -\frac{1}{g'(c_0)} R(c_0, c_1, \ldots, c_{k-1}), \tag{7.3}$$

provided that one has $g'(c_0) \neq 0$, so that under the conditions (1.6) one has the formal solubility of the equations of motion (1.1). Note that the first condition in (1.6) requires $f_0 \in \mathrm{Ran}(g)$, and if such a condition is satisfied then the condition on the derivative is a genericity condition. Note also that the class of functions $g(x)$ which are not allowed depends on f (more precisely on its average f_0). For instance an explicit example of a function which does not satisfy (1.6) is $g(x) = 3x^2 - 2x^3$ if $f_0 = 1$.

The graphical representation differs from that of the preceding sections as now the number of lines entering a vertex v can assume any value $s_v \in \mathbb{N}$, and if $v \notin V_0(\theta)$ the corresponding node factor is

$$F_v = -\frac{\varepsilon}{s_v!} g_{s_v}, \tag{7.4}$$

which is bounded proportionally to some constant G to the power s_v. Since $\Sigma_{v \in V(\theta)}(s_v - 1) = |E(\theta)| - 1 \leqslant k - 1$ (by Lemma 4.1) this produces an overall constant G^{2k} in the tree value. Also the study of the convergence of both the formal series and the resummed series can then be performed as in the previous case, and no further difficulty arises. The constant c appearing after (6.14) becomes $-g'(c_0)$, instead of $-2c_0$, so that still one has $c \neq 0$ by the assumption (1.6).

A time discretization that preserves the super-integrability of the Calogero model is obtained by application of the integrable time discretization of the harmonic oscillator to the projection method for the Calogero model with continuous time. In particular, the difference equations of motion, which provide an explicit scheme for time integration, are explicitly presented for the two-body case. Numerical results exhibit that the scheme conserves all the (=3) conserved quantities of the (two-body) Calogero model with a precision of the machine epsilon times the number of iterations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1931043]

I. INTRODUCTION

Numerical analysis of dynamical systems has great importance and a wide variety of applications in science and engineering. The elaboration of schemes for numerical analysis has a long and continuous history of studies as well as a rich accumulation of techniques. Whenever one applies numerical analysis to the equations of motion, one must discretize the time evolution of the dynamical system that is originally described by differential equations because of the lack of the notion of infinity in numerical analysis. This leads to difference equations, which do not usually describe the same dynamical system as the original one: time discretization is typically accompanied by modification of the original system, which may cause a significant difference in the behavior of the solution from that of the original system, particularly after integration over a long period. Understanding and controlling such modifications are thus important in the quest for more accurate long-time integration in numerical analysis.

The symplectic integration method (see, for instance, Refs. 1–3), or the symplectic integrator, is one of the time discretizations that was invented in such a quest. Given a Hamiltonian $H^{(0)}$, it is designed so that its one-step $(=\tau)$ time evolution gives the exact one-step time evolution of a modified Hamiltonian $\tilde{H} := H^{(0)} + \tau H^{(1)} + \tau^2 H^{(2)} + \cdots$. Since the modified Hamiltonian is conserved by the flow of the symplectic integrator, the fluctuation of the value of the original Hamiltonian $H^{(0)}$, i.e., the total energy of the system with continuous time, is bounded, which is far more favorable than unbounded increase or decrease of the total energy that one usually observes in other nonsymplectic discretizations. This is the reason why the symplectic integration method shows better accuracy even after long-time integration.

However, even the symplectic integration method does not usually have modified constants of motion for all the constants of motion of a system, which often causes secular increase or decrease of the values of the constants of motion after long-time integration. For example, nonexistence of the modified constants of motion is proved for the two super-integrable models discretized by the symplectic integrator: the two-dimensional Harmonic oscillator with integer frequency ratio (except for the isotropic case) and the two-dimensional Kepler problem.[4,5] The orbits generated by the symplectic integrator are not closed, though those of the exact analytic solutions are closed, indeed.

Thus the following question naturally arises: are there any discretization schemes that preserve the (super-)integrability of (super-)integrable models? Actually, an extensive collection of the known integrable discretizations of integrable models is now available in the monograph[6] that was published in recent years. However, the super-integrable discretization of super-integrable models has not been studied that far yet. Quite recently, an affirmative answer to the question on the super-integrable discretization is shown for the Kepler problem for two- and three-dimensional cases,[7,8] where the integrable discretization of the harmonic oscillator[9] plays an essential role. The above super-integrable discretization conserves all the constants of motion, i.e., the Hamiltonian, the angular momentum and the Runge–Lenz vector, and generates a sequence of discrete points on the orbit of the exact analytic solution of the Kepler problem. And, of course, the orbit with the eccentricity less than unity is closed.

The purpose of this paper is to present a super-integrable discretization of the Calogero model,[10,11]

$$H := \frac{1}{2}\sum_{i=1}^{N}(p_i^2+\omega^2 x_i^2)+\frac{1}{2}\sum_{\substack{i,j=1\\ i\neq j}}^{N}\frac{a^2}{(x_i-x_j)^2}. \tag{1.1}$$

The real-valued quantities p_i, x_i, ω, and a in the Hamiltonian are the canonical momentum and coordinate of the ith particle, the strength of the external harmonic confinement and the interaction parameter, respectively. The Calogero model ($\omega \neq 0$) with N degrees of freedom (corresponding to the N-body case) is maximally super-integrable in the sense that it has $2N-1$ constants of motion which are independent of each other.[12] The super-integrable structure of the Calogero model is built up by the Lax formulation,[13,14] with which the eigenvalue problem of an oscillating Hermitian matrix[15] is intrinsically involved. We shall present a discretization that preserves the above super-integrable structure of the Calogero model for the general N-body case. It gives, in particular, the explicit form of the difference equations of motion of the Calogero model for the two-body case that conserves all the three constants of motion as

$$\begin{aligned}\Delta_+ x_{1,n} = {} & \frac{1}{1+\dfrac{\omega^2\Delta t^2}{4}}\left[p_{1,n}-\frac{\omega^2}{2}x_{1,n}\Delta t\right]+\frac{1}{1+\dfrac{\omega^2\Delta t^2}{4}}\frac{2a}{x_{1,n}-x_{2,n}}M_{i,n}\Delta t-2\left[\frac{1-\dfrac{\omega^2\Delta t^2}{4}}{1+\dfrac{\omega^2\Delta t^2}{4}}x_{1,n}\right.\\ & \left.+\frac{1}{1+\dfrac{\omega^2\Delta t^2}{4}}p_{1,n}\Delta t\right]M_{r,n}\Delta t+\left[\frac{1-\dfrac{\omega^2\Delta t^2}{4}}{1+\dfrac{\omega^2\Delta t^2}{4}}(x_{1,n}+x_{2,n})+\frac{1}{1+\dfrac{\omega^2\Delta t^2}{4}}(p_{1,n}+p_{2,n})\Delta t\right]\\ & \times(M_{i,n}^2+M_{r,n}^2\Delta t^2)\Delta t,\end{aligned}$$

$$\Delta_+ p_{1,n} = -\frac{\omega^2}{1+\frac{\omega^2\Delta t^2}{4}}\left[x_{1,n}+\frac{1}{2}p_{1,n}\Delta t\right]+\frac{1-\frac{\omega^2\Delta t^2}{4}}{1+\frac{\omega^2\Delta t^2}{4}}\frac{2a}{x_{1,n}-x_{2,n}}M_{i,n}-2\left[\frac{1-\frac{\omega^2\Delta t^2}{4}}{1+\frac{\omega^2\Delta t^2}{4}}p_{1,n}\right.$$
$$\left.-\frac{\omega^2}{1+\frac{\omega^2\Delta t^2}{4}}x_{1,n}\Delta t\right]M_{r,n}\Delta t+\left[\frac{1-\frac{\omega^2\Delta t^2}{4}}{1+\frac{\omega^2\Delta t^2}{4}}(p_{1,n}+p_{2,n})-\frac{\omega^2}{1+\frac{\omega^2\Delta t^2}{4}}(x_{1,n}+x_{2,n})\Delta t\right]$$
$$\times(M_{i,n}^2+M_{r,n}^2\Delta t^2)\Delta t,$$

$$\Delta_+ x_{2,n} = \Delta_+ x_{1,n}\big|_{1\leftrightarrow 2}, \quad \Delta_+ p_{2,n} = \Delta_+ p_{1,n}\big|_{1\leftrightarrow 2}, \tag{1.2}$$

with

$$M_{i,n} := \frac{a}{\sqrt{4a^2\Delta t^2+Y_n^2}}, \quad M_{r,n} := \frac{2a^2}{4a^2\Delta t^2+Y_n^2+Y_n\sqrt{4a^2\Delta t^2+Y_n^2}},$$

$$Y_n := \left[1-\frac{\omega^2\Delta t^2}{4}\right](x_{1,n}-x_{2,n})^2+(p_{1,n}-p_{2,n})(x_{1,n}-x_{2,n})\Delta t,$$

where $x_{i,n}$, $p_{i,n}$, $i=1,2$, are the coordinate and the momentum of the ith particle at the nth discrete time. The symbol Δ_+ denotes the advanced time difference defined by

$$\Delta_+ A_n := \frac{A_{n+1}-A_n}{\Delta t}, \tag{1.3}$$

for an arbitrary variable A_n (e.g., $A_n=x_{i,n}, p_{i,n}$) with the discrete time n.

The paper is organized as follows. In Sec. II, we present a brief summary of the projection method[15] (for review, see Refs. 16–18, for example), which gives a solution to the initial value problem of the Calogero model with continuous time. The Lax equations for the Calogero model provide a map from the Calogero model into the matrix-valued harmonic oscillator and also play an essential role in our discretization. Applying the integrable discretization for the harmonic oscillator,[9] we discretize the projection method in Sec. III. A discrete analogue of the Lax equations, which we call the dLax equations, is derived as a natural consequence of the discretization. In Sec. IV, we present the explicit forms of the dLax equations of the Calogero model for the two-body case, which are equivalent to the difference equations of motion (1.2). They provide an explicit scheme for the time integration of the model. Numerical results obtained by our integrable discretization as well as by two other discretization schemes, namely, the symplectic Euler and energy conservation methods, are also presented. Section V is dedicated to the summary and concluding remarks.

II. PROJECTION METHOD

In terms of the Lax pair for the Calogero–Moser model,[14]

$$L_{ij}(t) := p_i(t)\delta_{ij}+\frac{ia}{x_i(t)-x_j(t)}(1-\delta_{ij}),$$

$$M_{ij}(t) := \sum_{k(\neq i)} \frac{ia}{(x_i(t)-x_k(t))^2}\delta_{ij} - \frac{ia}{(x_i(t)-x_j(t))^2}(1-\delta_{ij}), \quad i,j=1,2,\ldots,N, \tag{2.1}$$

as well as a diagonal matrix

$$D(t) := \mathrm{diag}(x_1(t),x_2(t),\ldots,x_N(t)),$$

the canonical equation of motion for the Calogero model (1.1) can be cast into the Lax form,

$$\frac{\mathrm{d}L}{\mathrm{d}t} = [L,M] - \omega^2 D,$$

$$\frac{\mathrm{d}D}{\mathrm{d}t} = [D,M] + L,$$

where $[A,B] := AB - BA$, or equivalently,

$$\frac{\mathrm{d}L^{\pm}}{\mathrm{d}t} = [L^{\pm},M] \pm i\omega L^{\pm}, \tag{2.2}$$

where

$$L^{\pm}(t) := L(t) \pm i\omega D(t). \tag{2.3}$$

The Lax equations (2.2) allow the following relation between the products of L^+ and L^- and the Hamiltonian

$$\frac{\mathrm{d}}{\mathrm{d}t}((L^+)^{l_1}(L^-)^{m_1}\cdots) = [(L^+)^{l_1}(L^-)^{m_1}\cdots,M] + i\omega(l_1+\cdots-(m_1+\cdots))(L^+)^{l_1}(L^-)^{m_1}\cdots,$$

for any non-negative integers $l_1, m_1, \ldots$. Iterated use of the above formula yields

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\left(\prod_i \mathrm{Tr}\left(\overrightarrow{\prod_j}(L^+)^{l_{i,j}}(L^-)^{m_{i,j}}\right)\right) &= \sum_i \prod_{i\neq k} \mathrm{Tr}\left(\overrightarrow{\prod_j}(L^+)^{l_{i,j}}(L^-)^{m_{i,j}}\right)\mathrm{Tr}\left[\overrightarrow{\prod_l}(L^+)^{l_{k,l}}(L^-)^{m_{k,l}},M\right] \\ &\quad + \sum_{k,l}(l_{k,l}-m_{k,l})\prod_i \mathrm{Tr}\left(\overrightarrow{\prod_j}(L^+)^{l_{i,j}}(L^-)^{m_{i,j}}\right) \\ &= \sum_{k,l}(l_{k,l}-m_{k,l})\prod_i \mathrm{Tr}\left(\overrightarrow{\prod_j}(L^+)^{l_{i,j}}(L^-)^{m_{i,j}}\right),\end{aligned}$$

where

$$\overrightarrow{\prod_j} A_j := A_1A_2\cdots.$$

Thus the constants of motion of the Calogero model can be constructed by taking the trace of any products of L^+ and L^- of the following form:

$$\prod_i \mathrm{Tr}\left(\overrightarrow{\prod_j}(L^+)^{l_{i,j}}(L^-)^{m_{i,j}}\right), \quad \text{if } \sum_{i,j} l_{i,j} = \sum_{i,j} m_{i,j}, \tag{2.4}$$

which includes the constants of motion given in Ref. 12. Considering the case $a=0$ where the matrices $L^{\pm}$ become diagonal, one can confirm the quantities given Eq. (2.4) above include at least

(and also at most) $2N-1$ constants of motion that are independent of each other. For example, one confirms

$$C_1 := \mathrm{Tr}\, L^+ \,\mathrm{Tr}\, L^- = \left(\sum_{i=1}^{N} p_i\right)^2 + \omega^2 \left(\sum_{i=1}^{N} x_i\right)^2,$$

$$I_1 := \mathrm{Tr}\, L^+ L^- = 2H, \quad I_2 = \mathrm{Tr}(L^+)^2 \mathrm{Tr}(L^-)^2, \tag{2.5}$$

are constants of motion of the Calogero model (1.1) that are independent of each other. Note that the relations satisfied by the Lax pairs[19,20]

$$[L^+, L^-] = -2i\omega[L, D] = -2\omega a(T - E), \quad T_{ij} := 1, \quad E_{ij} := \delta_{ij},$$

$$M^t[1, \ldots, 1] = 0, \quad [1, \ldots, 1]M = 0, \quad [\Leftrightarrow TM = MT = 0], \tag{2.6}$$

particularly the relations in the second line of Eq. (2.6) which we call the sum-to-zero property, have played a crucial role in the quantum analogue of the Lax formulation.

The initial value problem of the Calogero model can be solved by the projection method,[15] in which the Lax formulation presented above plays a crucial role. This method can be formulated in an analogous way to the Dirac picture in the time-dependent perturbation theory of quantum mechanics. Let us introduce $L_D^{\pm}$, the $L^{\pm}$ matrix in the "Dirac picture" by

$$L^{\pm}(t) =: e^{\pm i\omega t} L_D^{\pm}(t), \quad L^{\pm}(0) = L_D^{\pm}(0). \tag{2.7}$$

Then the Lax equation (2.2) is rewritten as

$$\frac{\mathrm{d}L_D^{\pm}}{\mathrm{d}t} = [L_D^{\pm}, M],$$

which has the same form as the Heisenberg equation in the Dirac picture with the time-dependent perturbation $M(t) := M(x_1(t), x_2(t), \ldots, x_N(t))$.

The above equation allows the formal solution as

$$L_D^{\pm}(t) = U^{\dagger}(0,t) L^{\pm}(0) U(0,t), \tag{2.8}$$

where the time-evolution unitary matrix $U(t',t)$ is given by the Dyson series of $M(t)$,

$$U(t',t) := \sum_{k=0}^{\infty} \int_{t'}^{t} \mathrm{d}t_k \int_{t'}^{t_k} \mathrm{d}t_{k-1} \cdots \int_{t'}^{t_2} \mathrm{d}t_1 M(t_1) \cdots M(t_{k-1}) M(t_k), \tag{2.9}$$

which has the semigroup property,

$$U(0,t) := U[\mathbf{x}(0), \mathbf{p}(0); a, \omega; t] = U[\mathbf{x}(0), \mathbf{p}(0); a, \omega; t'] U[\mathbf{x}(t'), \mathbf{p}(t'); a, \omega; t - t'] = U(0,t') U(t',t),$$

$$U^{\dagger}(0,t) = U(t,0). \tag{2.10}$$

Note that $U(t',t)$ has a constant eigenvector ${}^t[1, \ldots, 1]$ whose eigenvalue is unity,

$$U(t',t)\,{}^t[1, \ldots, 1] = {}^t[1, \ldots, 1], \quad [1, \ldots, 1] U(t',t) = [1, \ldots, 1] \Leftrightarrow U(t',t)T = TU(t',t) = T. \tag{2.11}$$

This property of $U(t',t)$ is a consequence of the sum-to-zero property of the matrix M in Eq. (2.6).

Substitution of the formal solution (2.8) into Eqs. (2.3) and (2.7) gives the following solution of the initial value problem of the Lax equation (2.2):

$$D(t) = U^{\dagger}(0,t)\frac{e^{i\omega t}L^{+}(0) - e^{-i\omega t}L^{-}(0)}{2i\omega}U(0,t),$$

$$L(t) = U^{\dagger}(0,t)\frac{e^{i\omega t}L^{+}(0) + e^{-i\omega t}L^{-}(0)}{2}U(0,t), \tag{2.12}$$

which means that the eigenvalues of the time-dependent Hermitian matrix $[e^{i\omega t}L^{+}(0) - e^{-i\omega t}L^{-}(0)]/2i\omega$ give the solution of the initial value problem of the Calogero model. The time-evolution unitary matrix $U(0,t)$, which has been formally introduced as the Dyson series of $M(t)$, is given here as the diagonalizing matrix.

The unitary matrix $U(0,t)$ provides a map of the Calogero model into the matrix-valued harmonic oscillator. Let us introduce the matrices

$$X^{\pm}(t) \coloneqq U(0,t)L^{\pm}(t)U^{\dagger}(0,t) = P(t) \pm i\omega Q(t),$$

$$P(t) \coloneqq U(0,t)L(t)U^{\dagger}(0,t), \quad Q(t) \coloneqq U(0,t)D(t)U^{\dagger}(0,t). \tag{2.13}$$

Substituting $X^{\pm}$ into the Lax equation (2.2), we have

$$\frac{\mathrm{d}X^{\pm}}{\mathrm{d}t} = \pm i\omega X^{\pm}, \tag{2.14}$$

which are equivalent to the equations of motion of the harmonic oscillator,

$$\frac{\mathrm{d}P}{\mathrm{d}t} = -\omega^2 Q, \quad \frac{\mathrm{d}Q}{\mathrm{d}t} = P. \tag{2.15}$$

Thus we confirm that the Lax equations of the Calogero model (2.2) can be mapped to the equations of motion of the matrix-valued harmonic oscillator, Eqs. (2.14) and (2.15). Though the Hermitian matrices $P(t)$ and $Q(t)$ can possess $2N^2$ parameters for their initial values, their definitions (2.13) introduce the restriction in the initial values,

$$P(0) = L(0), \quad Q(0) = D(0), \tag{2.16}$$

whose number $2N$ is the same as that of the Calogero model. The solution of the initial value problem of the above equations of motion is given by

$$Q(t) = D(0)\cos\omega t + \frac{L(0)}{\omega}\sin\omega t, \quad P(t) = L(0)\cos\omega t - \omega D(0)\sin\omega t [\Leftrightarrow X^{\pm}(t) = e^{\pm i\omega t}L^{\pm}(0)]. \tag{2.17}$$

Substitution of the above solution (2.17) into the definition of $P(t)$ and $Q(t)$ in Eq. (2.13) reproduces the solution of the initial value problem of the Calogero model (2.12). In particular, the coordinates of the Calogero model is given by the eigenvalues of the matrix-valued harmonic oscillator $Q(t)$ in Eq. (2.17). That is the essence of the projection method.

The restrictions on the initial values (2.16) can be explained in terms of the constraints on the variables $Q(t)$ and $P(t)$. From Eqs. (2.6) and (2.13), one can derive

$$[Q(t),P(t)] = U(0,t)[D(t),L(t)]U^{\dagger}(0,t) = iaU(0,t)(T-E)U^{\dagger}(0,t).$$

By use of the property of the time-evolution unitary matrix (2.11), one obtains

$$[Q,P] = ia(T-E), \tag{2.18}$$

which poses $N(N-1)$ constraints on the "unconstrained" variables $Q(t)$ and $P(t)$ given by two Hermitian matrices whose off-diagonal elements are pure imaginaries, i.e.,

$$Q_{ij}(t) := q_{ii}(t)\delta_{ij} + iq_{ij}(t), \quad P_{ij}(t) := p_{ii}(t)\delta_{ij} + ip_{ij}(t),$$

$$q_{ii}(t), \quad q_{ij}(t), \quad p_{ii}(t), \quad p_{ij}(t) \in \mathbb{R}, \quad q_{ij}(t) = -q_{ji}(t), \quad p_{ij}(t) = -p_{ji}(t). \tag{2.19}$$

The above restriction (2.19) is consistent with the solution of the initial value problem (2.17). The number of the independent variables in $Q(t)$ and $P(t)$ given by Eq. (2.19) is $N(N+1)$. One thus reproduces the number of the initial values $2N$ as the degrees of freedom of the constrained system, $N(N+1)-N(N-1)=2N$. The transformation (2.13) thus should be interpreted as a map of the Calogero model into the harmonic oscillator (2.15) of the Hermitian matrix given by Eq. (2.19) with the constraints (2.18).

III. INTEGRABLE DISCRETIZATION

As we have discussed in the preceding section, the equations of motion (the Lax equation) of the Calogero model can be mapped to those of the matrix-valued harmonic oscillator. We thus begin with the integrable discretization of the matrix-valued harmonic oscillator, whose difference equations of motion are given as

$$\Delta_+ Q_n = \tfrac{1}{2}(P_{n+1} + P_n),$$

$$\Delta_+ P_n = -\tfrac{1}{2}\omega^2(Q_{n+1} + Q_n), \tag{3.1}$$

where Q_n and P_n are Hermitian matrices whose initial values are fixed as $Q_0=D(0)$ and $P_0=L(0)$ so as to relate them with the difference analogue of the Calogero model. The difference equations given above have the same form as those for one-dimensional harmonic oscillator discretized by the energy conservation scheme,[9] which is nothing but the implicit midpoint rule giving a symplectic integration method of order 2 (see Theorem VI.3.4 in Ref. 1).

As in Eq. (2.13), we introduce the variables

$$X_n^{\pm} := P_n \pm i\omega Q_n.$$

This brings the difference equations of motion into

$$\Delta_+ X_n^{\pm} = \pm \tfrac{1}{2} i\omega (X_{n+1}^{\pm} + X_n^{\pm}),$$

which is equivalent to

$$\left(1 \mp \tfrac{1}{2} i\omega\Delta t\right) X_{n+1}^{\pm} = \left(1 \pm \tfrac{1}{2} i\omega\Delta t\right) X_n^{\pm}. \tag{3.2}$$

Defining the rescaled time step by

$$\Delta\tau := \frac{2}{\omega} \arctan \frac{\omega\Delta t}{2}, \tag{3.3}$$

the recursion relation (3.2) is rewritten as

$$X_{n+1}^{\pm} = \frac{1 \pm \dfrac{i\omega\Delta t}{2}}{1 \mp \dfrac{i\omega\Delta t}{2}} X_n^{\pm} = e^{\pm i\omega\Delta\tau} X_n^{\pm}.$$

Thus the solution of the initial value problem of the discrete harmonic oscillator is

$$X_n^{\pm} = e^{\pm in\omega\Delta\tau} X_0^{\pm},$$

or

$$Q_n = D(0)\cos n\omega\Delta\tau + \frac{1}{\omega}L(0)\sin n\omega\Delta\tau,$$

$$P_n = L(0)\cos n\omega\Delta\tau - \omega D(0)\sin n\omega\Delta\tau, \tag{3.4}$$

in terms of Q_n and P_n. The above solution (3.4) is exactly the same as that for the harmonic oscillator with the continuous time (2.17) up to time rescale (3.3).

The recursion relation (3.2) provides us with an efficient way to construct the constants of motion of the discrete harmonic oscillator. Consider an arbitrary product of X^+_{n+1} and X^-_{n+1} like $(X^+_{n+1})^{l_1}(X^-_{n+1})^{m_1}\cdots$, for $l_1, m_1 = 0,1,2,\ldots$, and reverse the time for one discrete time step using the recursion relation (3.2). Then one obtains

$$(X^+_{n+1})^{l_1}(X^-_{n+1})^{m_1}\cdots = e^{i\omega l_1\Delta\tau}(X^+_n)^{l_1}e^{-i\omega m_1\Delta\tau}(X^-_n)^{m_1}\cdots = e^{i\omega(l_1+\cdots-(m_1+\cdots))\Delta\tau}(X^+_n)^{l_1}(X^-_n)^{m_1}\cdots . \tag{3.5}$$

Taking the trace of the above relation, one obtains

$$\mathrm{Tr}\left(\prod_j^{\rightarrow}(X^+_{n+1})^{l_j}(X^-_{n+1})^{m_j}\right) = \exp\left(i\omega\Delta\tau\sum_k(l_k - m_k)\right)\mathrm{Tr}\left(\prod_j^{\rightarrow}(X^+_n)^{l_j}(X^-_n)^{m_j}\right).$$

Thus one can construct constants of motion of the discrete harmonic oscillator in a way parallel to what is done for the Calogero model (2.4) by

$$\prod_i \mathrm{Tr}\left(\prod_j^{\rightarrow}(X^+_n)^{l_{i,j}}(X^-_n)^{m_{i,j}}\right), \quad \text{when } \sum_{i,j} l_{i,j} = \sum_{i,j} m_{i,j}$$

as well as the matrix-valued constants of motion by

$$(X^+_{n+1})^{l_1}(X^-_{n+1})^{m_1}\cdots = (X^+_n)^{l_1}(X^-_n)^{m_1}\cdots ,$$

when $l_1+\cdots = m_1+\cdots$. In particular, the following quantity,

$$[X^+_n, X^-_n] = -2\omega a(T-E)[=[X^+_0, X^-_0]] \tag{3.6}$$

is conserved since it is a special case of the above matrix-valued constants of motion. Note that the constants of motion of the matrix-valued harmonic oscillator with continuous time can be given by the same formulas.

As we have confirmed, the solution of the harmonic oscillator with discrete time (3.4) and that with the continuous time (2.17) agree up to time rescale (3.3). Thus the eigenvalue of Q_n must trace the same trajectory of the Calogero model with continuous time. We shall discuss it more in detail.

Since the relations $Q_n = Q(n\Delta\tau)$ and $P_n = P(n\Delta\tau)$ hold as a consequence of Eqs. (2.17), (3.3), and (3.4), we also have analogous relations with (2.13) for Q_n and P_n,

$$D_n = U_n^\dagger Q_n U_n = D(n\Delta\tau), \quad L_n = U_n^\dagger P_n U_n = L(n\Delta\tau),$$

$$(D_n)_{ij} := x_{i,n}\delta_{ij}, \quad (L_n)_{ij} := p_{i,n}\delta_{ij} + \frac{ia}{x_{i,n}-x_{j,n}}(1-\delta_{ij}), \tag{3.7}$$

where the unitary matrix U_n is also given by the corresponding matrix in the theory for the model with continuous time

$$U_n = U(0, n\Delta\tau). \tag{3.8}$$

Introduce $L^\pm_n$ in analogy with $L^\pm$ in Eq. (2.3), i.e.,

$$L_n^{\pm} := L_n \pm i\omega D_n = U_n^{\dagger} X_n^{\pm} U_n \tag{3.9}$$

and substitute it into the recursion relation (3.2). Then one obtains

$$\left(1 \mp \tfrac{1}{2} i\omega\Delta t\right) U_{n+1} L_{n+1}^{\pm} U_{n+1}^{\dagger} = \left(1 \pm \tfrac{1}{2} i\omega\Delta t\right) U_n L_n^{\pm} U_n^{\dagger}.$$

By multiplying with $U_n^{\dagger}$ on the left and U_{n+1} on the right, one obtains a recursion relation of the matrices $L_n^{\pm}$,

$$\left(1 \mp \tfrac{1}{2} i\omega\Delta t\right) S_n L_{n+1}^{\pm} = \left(1 \pm \tfrac{1}{2} i\omega\Delta t\right) L_n^{\pm} S_n,$$

$$S_n := U_n^{\dagger} U_{n+1}, \tag{3.10}$$

which we shall call the discrete Lax equations, or in short, the dLax equations. They will play an essential role in the construction of the constants of motion for the discrete time model. From the definition of the unitary matrix S_n and using the semigroup property of the time-evolution unitary matrix $U(t',t)$ (2.10), one obtains

$$S_n := U_n^{\dagger} U_{n+1} = U(n\Delta\tau, (n+1)\Delta\tau) = S_n[\mathbf{x}_n, \mathbf{p}_n; a, \omega; \Delta t],$$

$$U_n = S_1 S_2 \cdots S_{n-1}, \quad U_0 = E. \tag{3.11}$$

This indicates that S_n is the one-step time-evolution matrix. We should note that *the discrete inhomogeneous Lax's equation* introduced for the Calogero–Moser model [the Hamiltonian (1.1) with $\omega=0$] in Ref. 21 inspired us with the above recursion equation (3.10). However, the explicit forms of the Lax pair and the derivation of the recursion relation of this paper are different from those in Ref. 21.

The recursion relation (3.10) can be interpreted as the discrete time analogue of the Lax equation of the Calogero model because of the following two reasons. The first reason is that the dLax equations (3.10) reduces to the Lax equations of the Calogero model (2.2) in the continuous time limit, $\Delta t \to 0$. The other reason is that the dLax equations also conserve the constants of motion of the Calogero model with continuous time. We shall discuss them more in detail.

From the Taylor expansions of $L_{n+1}=L((n+1)\Delta\tau)$ and $S_n=U(t'=n\Delta\tau, t=(n+1)\Delta\tau)$ together with the expression in the formal Dyson series (2.9) at $t=n\Delta\tau$, one obtains

$$L_{n+1}^{\pm} \sim L_n^{\pm} + \frac{\mathrm{d}L_n^{\pm}}{\mathrm{d}t}\Delta t + O(\Delta t^2),$$

$$S_n \sim E + M_n \Delta t + O(\Delta t^2), \quad M_n := M(n\Delta\tau). \tag{3.12}$$

Substitution of the above expressions into the dLax equations (3.10) yields

$$\left(1 \mp \frac{1}{2} i\omega\Delta t\right)(E + M_n\Delta t)\left(L_n^{\pm} + \frac{\mathrm{d}L_n^{\pm}}{\mathrm{d}t}\Delta t\right) = \left(1 \pm \frac{1}{2} i\omega\Delta t\right) L_n^{\pm}(E + M_n\Delta t).$$

Dividing the above relation by Δt and taking the limit $\Delta t \to 0$, one gets

$$\frac{\mathrm{d}L_n^{\pm}}{\mathrm{d}t} = [L_n^{\pm}, M_n] \pm i\omega L_n^{\pm},$$

which is nothing but the Lax equation of the Calogero model with continuous time.

In a way parallel to the construction of the constants of motion of the discrete harmonic oscillator, one can construct the constants of motion of the dLax equations (3.10). Using the definition (3.9) of $L_n^{\pm}$ in Eq. (3.5) and multiplying by $U_n^{\dagger}$ and U_{n+1}, respectively, from the left and the right, one gets

$$S_n(L_{n+1}^+)^{l_1}(L_{n+1}^-)^{m_1}\cdots = e^{i\omega l_1\Delta\tau}(L_n^+)^{l_1}e^{-i\omega m_1\Delta\tau}(L_n^-)^{m_1}\cdots S_n = e^{i\omega(l_1+\cdots-(m_1+\cdots))\Delta\tau}(L_n^+)^{l_1}(L_n^-)^{m_1}\cdots S_n.$$

Thus one has

$$(L_{n+1}^+)^{l_1}(L_{n+1}^-)^{m_1}\cdots = e^{i\omega(l_1+\cdots-(m_1+\cdots))\Delta\tau}S_n^\dagger(L_n^+)^{l_1}(L_n^-)^{m_1}\cdots S_n.$$

Since the trace of an arbitrary product of matrices is invariant under any cyclic change of the order of the matrices, one has

$$\mathrm{Tr}\left(\overrightarrow{\prod_j}(L_{n+1}^+)^{l_j}(L_{n+1}^-)^{m_j}\right) = \exp\left(i\omega\Delta\tau\sum_k(l_k-m_k)\right)\mathrm{Tr}\left(\overrightarrow{\prod_j}(L_n^+)^{l_j}(L_n^-)^{m_j}\right),$$

which leads to

$$\prod_i \mathrm{Tr}\left(\overrightarrow{\prod_j}(L_{n+1}^+)^{l_{i,j}}(L_{n+1}^-)^{m_{i,j}}\right) = \exp\left(i\omega\Delta\tau\sum_{k,l}(l_{k,l}-m_{k,l})\right)\prod_i \mathrm{Tr}\left(\overrightarrow{\prod_j}(L_n^+)^{l_{i,j}}(L_n^-)^{m_{i,j}}\right).$$

One thus concludes that

$$\prod_i \mathrm{Tr}\left(\overrightarrow{\prod_j}(L_n^+)^{l_{i,j}}(L_n^-)^{m_{i,j}}\right) \tag{3.13}$$

gives the constant of motion of the dLax equations (3.10) when

$$\sum_{i,j} l_{i,j} = \sum_{i,j} m_{i,j}.$$

This is in complete agreement with the situation for the Calogero model with continuous time (2.4).

Since $L_n^\pm$ should have the same form as $L^\pm$ for the continuous time model, the commutator between L_n^+ and L_n^- also should be a constant matrix as in Eq. (2.6). In the continuous time theory, this constant matrix is associated with the nontrivial constraints of the matrix-valued harmonic oscillator (2.18). One can observe the same situations in our discrete time model (3.10). Substitution of Eq. (3.9) into $[L_n^+,L_n^-]$ with the help of Eq. (3.6) yields

$$[L_n^+,L_n^-] = U_n^\dagger[X_n^+,X_n^-]U_n = U_n^\dagger(-2\omega a(T-E))U_n.$$

Since U_n and also S_n are made from the time-evolution unitary matrix $U(t',t)$ as in Eqs. (3.8) and (3.11), they also have a constant eigenvector ${}^t[1,\ldots,1]$ whose eigenvalues are unity,

$$U_n\,{}^t[1,\ldots,1] = {}^t[1,\ldots,1], \quad [1,\ldots,1]U_n = [1,\ldots,1] \Leftrightarrow U_nT = TU_n = T,$$

$$S_n\,{}^t[1,\ldots,1] = {}^t[1,\ldots,1], \quad [1,\ldots,1]S_n = [1,\ldots,1] \Leftrightarrow S_nT = TS_n = T. \tag{3.14}$$

Thus one immediately obtains

$$[L_n^+,L_n^-] = -2\omega a(T-E), \tag{3.15}$$

using the property (3.14) of U_n. The relation (3.15) is also equivalent to

$$[D_n,L_n] = ia(T-E).$$

Note that Eq. (3.7) provides the most general form of L_n that satisfies the above relation together with the diagonal matrix $(D_n)_{ij}=x_i\delta_{ij}$.

IV. DIFFERENCE EQUATIONS OF MOTION

Though we have developed an integrable discretization for the Calogero model in the preceding section, the difference equations of motion we have obtained is nevertheless a formal expression. An explicit expression for S_n is necessary in order to obtain the dLax equations for the Calogero model explicitly. To do this, we restrict the number of particles to two in the discussion of the explicit form of the S_n matrix.

From the dLax equations (3.10), one obtains

$$L_{n+1} \pm i\omega D_{n+1} := L_{n+1}^{\pm} = \frac{1 \pm \frac{1}{2}i\omega\Delta t}{1 \mp \frac{1}{2}i\omega\Delta t} S_n^{\dagger} L_n^{\pm} S_n.$$

Solution of the above equations with respect to D_{n+1} and L_{n+1} are given by

$$D_{n+1} = \frac{1}{2i\omega} S_n^{\dagger} \left[\frac{1 + \frac{1}{2}i\omega\Delta t}{1 - \frac{1}{2}i\omega\Delta t} L_n^{+} - \frac{1 - \frac{1}{2}i\omega\Delta t}{1 + \frac{1}{2}i\omega\Delta t} L_n^{-} \right] S_n,$$

$$L_{n+1} = \frac{1}{2} S_n^{\dagger} \left[\frac{1 + \frac{1}{2}i\omega\Delta t}{1 - \frac{1}{2}i\omega\Delta t} L_n^{+} + \frac{1 - \frac{1}{2}i\omega\Delta t}{1 + \frac{1}{2}i\omega\Delta t} L_n^{-} \right] S_n. \tag{4.1}$$

Since D_{n+1} is diagonal, S_n diagonalizes

$$\frac{1 + \frac{1}{2}i\omega\Delta t}{1 - \frac{1}{2}i\omega\Delta t} L_n^{+} - \frac{1 - \frac{1}{2}i\omega\Delta t}{1 + \frac{1}{2}i\omega\Delta t} L_n^{-}.$$

S_n thus can be constructed from the eigenvectors $\mathbf{v}_{i,n}$, $i=1,\ldots,N$ of the above matrix. Normalized eigenvectors $\mathbf{s}_{i,n}$ that constitute $S_n=[\mathbf{s}_{1,n}\cdots\mathbf{s}_{N,n}]$ should have the following form,

$$\mathbf{s}_{i,n} = \frac{\mathbf{v}_{i,n}}{\sum_{j=1}^{N} (\mathbf{v}_{i,n})_j} \Rightarrow \sum_{j=1}^{N} (\mathbf{s}_{i,n})_j = 1 \tag{4.2}$$

so as to satisfy the condition (3.14). Ordering of the eigenvectors $\mathbf{s}_{i,n}$ is uniquely determined by the Taylor expansion of S_n (3.12), or equivalently

$$\lim_{\Delta t \to 0} S_n = E. \tag{4.3}$$

Considering the Eqs. (4.1)–(4.3) all together, one confirms that

$$S_n = E + \frac{2ai\Delta t}{Y_n - 2ai\Delta t + \sqrt{4a^2\Delta t^2 + Y_n^2}} \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} = E + (iM_{i,n}\Delta t - M_{r,n}\Delta t^2) \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}$$
$$\sim E + M_n \Delta t \quad (\Delta t \to 0) \tag{4.4}$$

gives the explicit form of the S_n matrix of the dLax equations for the Calogero model for the two-body case. It is straightforward to verify that the dLax equations (3.10) with the above S_n matrix (4.4) yields the difference equations of motion (1.2) shown in the introduction.

In order to confirm how well the dLax equations (3.10) with the S_n matrix (4.4) or the difference equations of motion (1.2) of the Calogero model with discrete time trace the behavior of that with continuous time, the explicit expression of the analytic solution for the continuous-time model is of great help, which is given by the eigenvalues of $Q(t)$ in Eq. (2.17). But there is another derivation. Since $U(t',t)$ is related to S_n according to Eq. (3.11) with $t' := n\Delta\tau$ and $t := (n+1)\Delta\tau$, one can obtain the explicit form of $U(t',t)$ for the two-body case from that of S_n (4.4),

$$U(t',t) = E + \frac{\dfrac{2ai\sin\omega(t-t')}{\omega}}{\mathcal{Y} - \dfrac{2ai\sin\omega(t-t')}{\omega} + \sqrt{\dfrac{4a^2\sin^2\omega(t-t')}{\omega^2} + \mathcal{Y}^2}} \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix},$$

$$\mathcal{Y} := (x_1 - x_2)^2 \cos\omega(t-t') + (p_1 - p_2)(x_1 - x_2)\frac{\sin\omega(t-t')}{\omega}. \tag{4.5}$$

Substitution of the explicit forms of $U(0,t)$ (4.5) and $L^{\pm}(0)$ for the two-body case into Eq. (2.12), one obtains the explicit form of the analytic solution of the two-body Calogero model with continuous time,

$$\begin{aligned} x_1(t) &= \frac{1}{2}\left[(x_{1,0} + x_{2,0})\cos\omega t + \frac{1}{\omega}(p_{1,0} + p_{2,0})\sin\omega t \right] \\ &+ \frac{1}{2(x_{1,0} - x_{2,0})} \sqrt{\frac{4a^2\sin^2\omega t}{\omega^2} + \left[(x_{1,0} - x_{2,0})^2\cos\omega t + (p_{1,0} - p_{2,0})(x_{1,0} - x_{2,0})\frac{\sin\omega t}{\omega} \right]^2} \\ &=: x_1[\mathbf{x}_0, \mathbf{p}_0; a, \omega; t], \end{aligned}$$

$$\begin{aligned} p_1(t) &= \frac{1}{2}[(p_{1,0} + p_{2,0})\cos\omega t - \omega(x_{1,0} + x_{2,0})\sin\omega t] \\ &+ \frac{1}{2(x_{1,0} - x_{2,0})\sqrt{\dfrac{4a^2\sin^2\omega t}{\omega^2} + \left[(x_{1,0} - x_{2,0})^2\cos\omega t + (p_{1,0} - p_{2,0})(x_{1,0} - x_{2,0})\dfrac{\sin\omega t}{\omega} \right]^2}} \\ &\times \left[\frac{2a^2\sin 2\omega t}{\omega} + \left[(x_{1,0} - x_{2,0})^2\cos\omega t + (p_{1,0} - p_{2,0})(x_{1,0} - x_{2,0})\frac{\sin\omega t}{\omega} \right] \right. \\ &\left. \times [-\omega(x_{1,0} - x_{2,0})^2\sin\omega t + (p_{1,0} - p_{2,0})(x_{1,0} - x_{2,0})\cos\omega t] \right] =: p_1[\mathbf{x}_0, \mathbf{p}_0; a, \omega; t], \end{aligned}$$

$$x_2(t) = x_1(t)|_{1\leftrightarrow 2}, \quad p_2(t) = p_1(t)|_{1\leftrightarrow 2}. \tag{4.6}$$

The above expressions are used to numerically display the exact analytic results in the following figures. The initial values, the interaction parameter, the strength of the external harmonic well are set at $(x_1, p_1, x_2, p_2)|_{t=0} = (-4.00, 5.00, 2.00, 1.00)$, $a = 3.00$ and $\omega = 0.314$ throughout the numerical calculation in the following.

Figure 1 presents the time evolution of the coordinates and the momenta generated by the analytic solution and the difference equations of motion (1.2) that gives the super-integrable discretization. The time step in the super-integrable discretization is set at $\Delta t = 1.00$. The relation between the time t and the number of iterations n is given by $n = t/\Delta\tau$ where $\Delta\tau = 0.991\,903$. The time interval $240 \times (2\pi/\omega) = 4802 \leqslant t \leqslant 4842 = 242 \times (2\pi/\omega)$ corresponds to $4841 \leqslant n \leqslant 4881$ in terms of the number of iterations for the discrete case. As has been confirmed by the correspondence between the matrices L and D for the super-integrable discretization and those for the continuous time model (3.7), the solution of the discrete equations of motion (1.2) gives a sequence of canonical variables that are "sampled" from the orbit of the exact analytic solution, i.e.,

$$x_{i,n} = x_i(t = n\Delta\tau), \quad p_{i,n} = p_i(t = n\Delta\tau). \tag{4.7}$$

Even though the coordinates and the momenta generated by the difference equations of motion (1.2) are computed through sufficiently large numbers of iterations, they are in quite good agree-

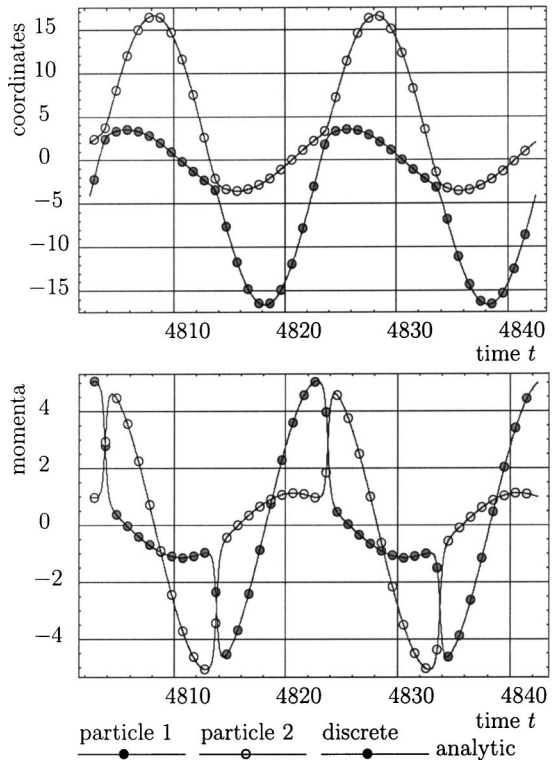

FIG. 1. The time evolution of the coordinates and the momenta generated by the analytic solution and the difference equations of motion (1.2).

ment with those of the exact analytic solution, which gives a good numerical confirmation of the correspondence (4.7).

One can confirm the precise agreement of the two solutions in a more reliable manner by observing the relative errors of the constants of motion. Using Eq. (2.4) [or Eq. (3.13)], we have already given three constants of motion of the Calogero model (2.5). Note that C_1 and I_1 correspond to the Hamiltonian for the center of mass and the Calogero Hamiltonian, respectively. Those three constants of motion give a set of independent conserved quantities. But just for convenience, we introduce a set of slightly modified constants of motion,

$$C_1 = (p_1 + p_2)^2 + \omega^2(x_1 + x_2)^2,$$

$$C_2 := 2I_1 - C_1 = (p_1 - p_2)^2 + \omega^2(x_1 - x_2)^2 + \frac{4a^2}{(x_1 - x_2)^2},$$

$$C_3 := \frac{I_1^2 - I_2}{4\omega^2} = (x_1 p_2 - x_2 p_1)^2 + \frac{2a^2(x_1^2 + x_2^2)}{(x_1 - x_2)^2}. \tag{4.8}$$

Note that C_2 is the Hamiltonian for the relative coordinates and C_3 can be interpreted as a "modified quadratic angular momentum." We use the above C_i's, $i=1,2,3$, for numerical calculation.

Figure 2 presents the relative errors of the constants of motion $C_i^{\mathrm{si}} := C_{i,n}/C_{i,0}$, $n=t/\Delta\tau$ of the discrete solutions given by the super-integrable discretization (1.2). The offsets $[=(i-1)\times 1.0]$ are added for convenience of presentation. Even though one sees the growth of errors caused by round-off errors that is inevitable in any numerical analysis, one confirms that all the constants of motion are conserved with a precision of the machine epsilon times the number of iterations. Thus

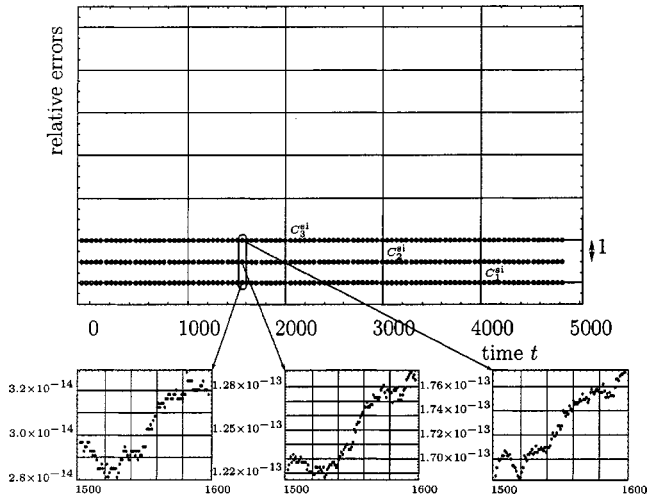

FIG. 2. The relative errors of the constants of motion $C_i^{\mathrm{si}} := C_{i,n}/C_{i,0}$, $n = t/\Delta\tau$, of the discrete solutions given by the super-integrable discretization (1.2).

one concludes that Fig. 2 presents a direct numerical verification of the fact that the difference equation of motion (1.2) preserves the super-integrability of the Calogero model.

Let us compare the above results with numerical demonstrations by two other discretizations. The first one is the energy conservation scheme (see pp. 159–161 in Ref. 1),

$$\Delta_+ x_{i,n} = \tfrac{1}{2}(p_{i,n+1} + p_{i,n}),$$

$$\Delta_+ p_{i,n} = -\frac{1}{2}\omega^2(x_{i,n+1} + x_{i,n}) + \sum_{\substack{j=1 \\ j\neq i}}^{N} \frac{a^2((x_{i,n+1} - x_{j,n+1}) + (x_{i,n} - x_{j,n}))}{(x_{i,n+1} - x_{j,n+1})^2 (x_{i,n} - x_{j,n})^2}, \tag{4.9}$$

which keeps two constants of motion C_1 and I_1 (consequently, C_2) exactly for arbitrary number of particles N. As one can see, the scheme (4.9) is an implicit scheme, which involves numerical solution of simultaneous algebraic equations. The other scheme is the symplectic Euler method (see Theorem VI.3.3 in Ref. 1),

$$\Delta_+ x_{i,n} = p_{i,n},$$

$$\Delta_+ p_{i,n} = -\omega^2 x_{i,n+1} + \sum_{\substack{j=1 \\ j\neq i}}^{N} \frac{2a^2}{(x_{i,n+1} - x_{j,n+1})^3}, \tag{4.10}$$

which is an explicit scheme. Note that Δ_+ denotes the advanced time difference (1.3).

Figures 3 and 4 present the relative errors $C_i^{\mathrm{ec,se}} := C_{i,n}/C_{i,0}$, $n = t/\Delta t$ of the discrete solution given by the energy conservation scheme (ec) and the symplectic Euler method (se) for the two body case ($N=2$). We should note that we do not present all the data of each relative errors to keep the size of the data file reasonable and that the offsets $[=(i-1)\times 1.0]$ are added for convenience of presentation. The initial condition, the coupling parameter and the strength of the harmonic confinement are the same as those given for the numerical calculation that gives Figs. 1 and 2. The discrete time step is set at $\Delta t = 0.200$ for these schemes.

One observes that the relative errors of the energies (C_1^{ec} and C_2^{ec}) calculated by the energy conservation scheme (4.9) remain within the order of the machine epsilon ($=10^{-16}$) times the number of iteration ($=t/\Delta t$), which gives a numerical confirmation that the energies are conserved

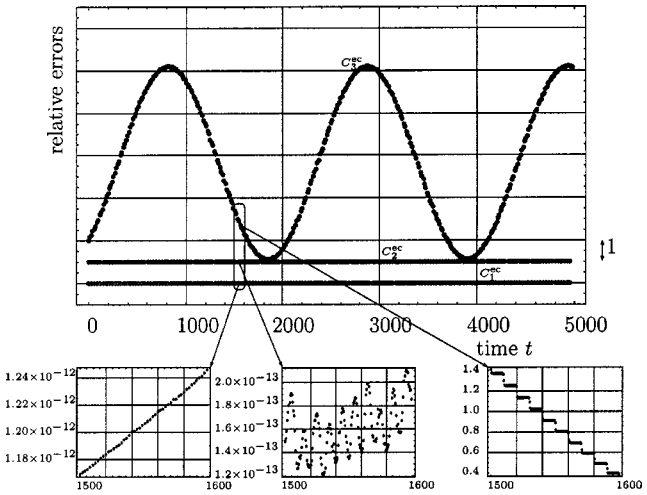

FIG. 3. The relative errors of the constants of motion, $C_i^{\mathrm{ec}} := C_{i,n}/C_{i,0}$, $n=t/\Delta t$, of the discrete solution given by the energy conservation scheme (4.9).

by the scheme. On the other hand, one also confirms that the relative errors (except for C_1^{ec} and C_2^{se}) are much larger than the order of machine epsilon times the number of iteration, even though one cannot observe growth of the relative errors in both two figures. These errors are not brought about by the round-off errors at the order of machine epsilon times the number of iteration, but by the schemes themselves. One perceives that there is a clear distinction between Fig. 2 or the super-integrable discretization (1.2) and Figs. 3 and 4 or the energy conservation scheme (4.9) and the symplectic Euler method (4.10).

One of the characteristics of the super-integrable system is that its bounded orbit is always closed in the phase space and, in particular, in the configuration space. As presented in Fig. 5, the orbit in the x_1–x_2 plane, or the "Lissajous plot" in other words, thus provides the distinctest way of comparing the three discretizations. The time interval of the Lissajous plots is $0 \leqslant t \leqslant 200$, which corresponds to 10 periods of motion. While the orbits generated by the energy conservation

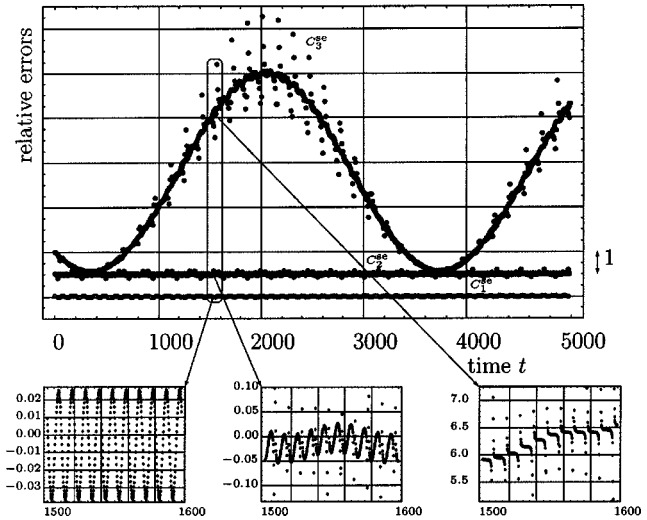

FIG. 4. The relative errors of the constants of motion, $C_i^{\mathrm{se}} := C_{i,n}/C_{i,0}$, $n=t/\Delta t$, of the discrete solution given by the symplectic Euler method (4.10).

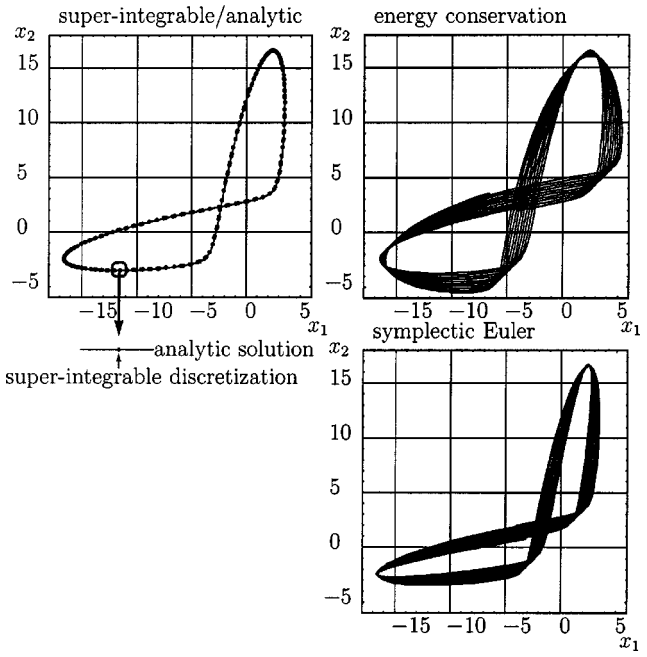

FIG. 5. The "Lissajous plots."

scheme and the symplectic Euler method are not closed, the orbit by the super-integrable discretization is always on that of the exact analytic solution, which is, of course, closed.

V. SUMMARY AND CONCLUDING REMARKS

The aim of the paper was to present a time discretization for the Calogero model that maintains its super-integrable structure. As discussed in Sec. II, the super-integrable structure of the original Calogero model is provided by the Lax formulation and the projection method, which are closely related to the equations of motion of the harmonic oscillator. With the help of the integrable discretization of the harmonic oscillator,[9] the Lax formulation and the projection method are discretized. As a consequence, a time discretization that preserves the super-integrability of the Calogero model is presented in Sec. III. In particular for the two-body case, an explicit form of the difference equations of motion (1.2) is obtained in Sec. IV. The difference equations give an explicit scheme for time integration. Numerical results by the super-integrable discretization (1.2) together with comparison with those by the energy conservation scheme (4.9) as well as the symplectic Euler method (4.10) are presented in five figures in Sec. IV, which give a intuitive numerical verification of the super-integrability of the scheme.

Last, we should give several remarks on previous studies that are relevant to the present work. In Refs. 21–23 (and also in Ref. 6), integrable discretizations of the rational Calogero–Moser model (the case $\omega=0$) and its trigonometric, elliptic and "relativistic" (a q-difference generalization with respect to space coordinates) generalizations were presented. The structure of the projection method also underlies these integrable discretizations, but the interaction parameter of the continuous-time models and the time step of the discrete-time models are related with each other in the integrable discretizations above. On the other hand, our discretization preserves not only the integrability but also the super-integrablity of the Calogero model and both the time-step Δt and the interaction parameter a independently appear in the discrete equations of motion. Thus our discretization is apparently different from that of the previous studies. The possibility of the mutual penetration of the particles in the time-discrete model was reported in Ref. 21, which is certainly unlike the continuous-time case. But the scheme given there is implicit and it could not provide a way to verify this possibility. In our super-integrable discretization of the present work,

however, we gave an explicit scheme of the Calogero model for the two-body case (1.2) and numerically observed in Fig. 1 that there was no penetration of the particles. And this observation should be the same for the Calogero–Moser case corresponding to the limit $\omega \to 0$ of the present work. The comparison of the two different discretizations together with additional consideration on the super-integrability of the rational Calogero–Moser model[24] will be presented in a separate paper. Further studies on the trigonometric, elliptic and relativistic Calogero–Moser model along the line of our super-integrable discretization of the Calogero model as well as to obtain explicit forms of the difference equations of motion for general *N*-body case (or at least three-body case) is worthy of interest.

ACKNOWLEDGMENTS

Most of this work was carried out during the one-year stay of H.U. at CRM, Université de Montréal and at McGill University hosted by L.V. H.U. would like to express his sincere gratitude for their warm hospitality. This author is also supported by a grant for his research activities abroad from the Ministry of Education, Culture, Sports, Science and Technology of Japan. This work initially started in 2001 when H.U. visited H.Y. at National Astronomical Observatory of Japan (NAOJ) with a financial support of NAOJ. The work of L.V. is supported in part through a grant from NSERC. The work of H.Y. is supported in part by the Grant-in-Aid for Scientific Research of Japan Society for the Promotion of Science (JSPS), No. 15540224.

(Received 11 October 2004; accepted 8 April 2005; published online 13 June 2005)

We use algebraic Bäcklund transformations (BTs) to construct explicit solutions of the modified 2+1 chiral model from $T^2\times\mathbb{R}$ to SU(n), where T^2 is a 2-torus. Algebraic BTs are parametrized by $z\in\mathbb{C}$ (poles) and holomorphic maps π from T^2 to $\mathrm{Gr}(k,\mathbb{C}^n)$. We apply Bäcklund transformations with carefully chosen poles and π's to construct infinitely many solutions of the 2+1 chiral model that are (i) doubly periodic in space variables and periodic in time, i.e., triply periodic, (ii) homoclinic in the sense that the solution u has the same stationary limit u_0 as $t\to\pm\infty$ and is tangent to a stable linear mode of u_0 as $t\to\infty$ and is tangent to an unstable mode of u_0 as $t\to-\infty$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1929688]

I. THE 2+1 CHIRAL MODEL

A *wave map* $J:\mathbb{R}^{2,1}\to\mathrm{SU}(n)$ is a critical point of the functional

$$\mathcal{E}(J)=\int_{\mathbb{R}^3}\|J^{-1}J_x\|^2+\|J^{-1}J_y\|^2-\|J^{-1}J_t\|^2\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}t,$$

where $\|\xi\|^2=-\mathrm{tr}(\xi^2)$, and x, y, t are the standard space–time variables. The Euler–Lagrange equation of $\mathcal{E}$ is

$$(J^{-1}J_t)_t-(J^{-1}J_x)_x-(J^{-1}J_y)_y=0. \tag{1.1}$$

This equation is also called *the* 2+1 *chiral model*.

The *Ward equation* (or the *modified* 2+1 *chiral model*) is the following equation for $J:\mathbb{R}^{2,1}\to\mathrm{SU}(n)$:

$$(J^{-1}J_t)_t-(J^{-1}J_x)_x-(J^{-1}J_y)_y-[J^{-1}J_t,J^{-1}J_y]=0. \tag{1.2}$$

This equation is obtained by a dimension reduction and a gauge fixing of the self-dual Yang–Mills equation on $\mathbb{R}^{2,2}$ (cf. Ref. 11). We call a solution of the Ward equation a *Ward map*. The Ward equation is completely integrable and many techniques from integrable systems can be used to construct explicit solutions.[8,10,12]

We consider Ward maps satisfying the doubly periodic boundary condition in the space variables, i.e., Ward maps from $T^2\times\mathbb{R}$ to SU(n), where $T^2=S^1\times S^1$. Using the standard trick of writing a second order differential equation as a first order system on the tangent bundle of the

a)Electronic mail: daibo@math.pku.edu.cn
b)Electronic mail: cterng@math.uci.edu

phase space, we can view the Ward equation as a dynamical system on the tangent bundle $T(C^\infty(T^2,\mathrm{SU}(n)))$. The goal of this paper is to construct periodic and homoclinic orbits of this dynamical system.

A Ward map $J:T^2\times\mathbb{R}\to\mathrm{SU}(n)$ independent of t is a harmonic map from T^2 to $\mathrm{SU}(n)$. Equation for harmonic maps from T^2 to $\mathrm{SU}(n)$ is integrable. Techniques from integrable systems were used to construct harmonic maps from T^2 to SU(2) by Hitchin (Ref. 3), and from T^2 to $\mathrm{SU}(n)$ by Burstall, *et al.*[1]

A Ward map from $S^1\times S^1\times\mathbb{R}$ to $\mathrm{SU}(n)$ independent of the second variable is a wave map from $S^1\times\mathbb{R}$ to $\mathrm{SU}(n)$. Such wave maps were studied by Terng and Uhlenbeck in Ref. 9.

A solution u of an evolution PDE is *homoclinic* if u tends to the same stationary solution u_0 as $t\to\pm\infty$ and is tangent to a stable linear mode of u_0 as $t\to+\infty$ and is tangent to an unstable linear mode of u_0 as $t\to-\infty$. The existence of homoclinic orbits for a finite dimensional dynamical system indicates the chaotic behavior of the system (cf. Ref. 4). It is known that soliton equations in one space and one time variable (for example, sine-Gordon, KdV, and NLS), viewed as dynamical systems on certain function spaces, admit homoclinic orbits. Shatah and Strauss[6] proved that there are homoclinic wave maps from $S^1\times\mathbb{R}$ to S^2, and Terng and Uhlenbeck[9] proved the same result for wave maps from $S^1\times\mathbb{R}$ to any compact symmetric space. There have been many works concerning whether homoclinic orbits persist under small perturbation of these soliton equations in one space and one time variable (cf. Refs. 5 and 7, and references therein).

One result of this paper is the existence of infinitely many Ward maps from $T^2\times\mathbb{R}$ to $\mathrm{SU}(n)$ that are periodic in time. In other words, we prove that there are infinitely many triply periodic solutions of the Ward equation. Another result of this paper is to show that the Ward equation has infinitely many homoclinic orbits. We give an outline of our method next.

The 1-soliton Ward maps from $\mathbb{R}^{2,1}$ to $\mathrm{SU}(n)$ can be constructed as follows (cf. Ref. 11). Let $z\in\mathbb{C}\backslash\mathbb{R}$ be a constant, $V=(v_{ij})$ a meromorphic map from $\mathbb{C}$ to the space $\mathcal{M}^0_{n\times k}$ of rank k complex $n\times k$ matrices, $\pi(x,y,t)$ the Hermitian projection of $\mathbb{C}^n$ onto the subspace spanned by the k columns of $V(w)$, where

$$w=x+\frac{(z-z^{-1})y}{2}+\frac{(z+z^{-1})t}{2}.$$

Let $\pi^\perp=I-\pi$. Then

$$\hat{J}_{z,V}(x,y,t)=\pi^\perp(x,y,t)+\frac{\overline{z}}{z}\pi(x,y,t)$$

is a solution of the Ward equation. It has constant determinant, so we can normalize it to get a Ward map from $\mathbb{R}^{2,1}$ to $\mathrm{SU}(n)$,

$$J_{z,V}(x,y,t)=\left(\frac{z}{\overline{z}}\right)^{k/n}\left(\pi^\perp(x,y,t)+\frac{\overline{z}}{z}\pi(x,y,t)\right).$$

$J_{z,V}$ (or $\hat{J}_{z,V}$) will be called a *Ward* 1-*soliton*. If all entries of $V(w)$ are rational functions in w, then $J_{z,V}$ is a smooth Ward map and is asymptotically constant as $|(x,y)|\to\infty$. If all entries of V are elliptic functions of same periods, then $J_{z,V}$ is a smooth Ward map from $T^2\times\mathbb{R}$ to $\mathrm{SU}(n)$.

Algebraic Bäcklund transformations (BTs) for the Ward equation were constructed in Ref. 2. These are transformations that generate new Ward maps from a given Ward map and 1-solitons $J_{z,V}$ by a simple algebraic method.

We apply algebraic Bäcklund transformations repeatedly to 1-solitons associated to elliptic functions to construct infinitely many triply periodic Ward maps to $\mathrm{SU}(n)$.

Note that if the image of J lies in an Abelian subgroup of $\mathrm{SU}(n)$, then the Ward equation for J becomes the linear wave equation. For example, let m be an integer, and $a=\mathrm{diag}(im,-im)$. Then

$$J_0(x,y,t) = \exp(-(x+y)a)$$

is a doubly periodic, stationary Ward map, whose image lies in SO(2).

We apply algebraic BTs $2k$ times to J_0 with carefully chosen poles and projections to construct homoclinic Ward maps J_{2k} from $T^2\times\mathbb{R}$ to SU(n), and prove that J_{2k} tends to $(-1)^k J_0$ as $|t|\to\infty$ and J_{2k} are homoclinic.

This paper is organized as follows: We review the Lax pair and algebraic Bäcklund transformations for the Ward equation in Sec. II, and use elliptic functions to construct triply periodic Ward maps in Sec. III. In the last section, we construct (i) homoclinic Ward maps from $T^2\times\mathbb{R}$ to SU(n) that tend to stationary solutions, (ii) homoclinic Ward maps that tend to periodic solutions.

II. EXTENDED WARD MAPS AND BÄCKLUND TRANSFORMATIONS

The Ward equation is integrable in the sense that it can be written as the compatibility condition for a system of linear equations involving a spectral parameter $\lambda\in\mathbb{C}$. In fact, we have the following theorem (cf. Ref. 11):

Theorem 2.1: *Let* $J:\mathbb{R}^{2,1}\to\mathrm{SU}(n)$ *be a Ward map,* $\mathrm{d}x^2+\mathrm{d}y^2-\mathrm{d}t^2$ *be the Lorentzian metric on* $\mathbb{R}^{2,1}$,

$$u=\frac{t+y}{2},\quad v=\frac{t-y}{2}, \tag{2.1}$$

$A=J^{-1}J_u$, *and* $B=J^{-1}J_x$. *Then the following linear PDE system is solvable for* $\psi:\mathbb{R}^{2,1}\times\mathbb{C}\to\mathrm{GL}(n,\mathbb{C})$:

$$\begin{aligned}(\lambda\partial_x-\partial_u)\psi&=A\psi,\\ (\lambda\partial_v-\partial_x)\psi&=B\psi.\end{aligned} \tag{2.2}$$

Conversely, suppose $\mathcal{O}$ *is an open subset of* 0 *in* $\mathbb{C}$ *and* $\psi:\mathbb{R}^{2,1}\times\mathcal{O}\to\mathrm{GL}(n,\mathbb{C})$ *is a smooth map so that*

$$A:=(\lambda\psi_x-\psi_u)\psi^{-1},\quad B:=(\lambda\psi_v-\psi_x)\psi^{-1}$$

are independent of $\lambda\in\mathcal{O}$ *and* ψ *satisfies the* $U(n)$*-reality condition*

$$\psi(x,u,v,\overline{\lambda})^*\psi(x,u,v,\lambda)=I, \tag{2.3}$$

Then

$$J(x,y,t)=\psi(x,y,t,0)^{-1}$$

is a smooth solution of the Ward equation and $J^{-1}J_u=A$ *and* $J^{-1}J_x=B$.

A solution $\psi(x,y,t,\lambda)$ of (2.2) that satisfies the $U(n)$-reality condition (2.3) is called an *extended Ward map* and $J=\psi(\cdots,0)^{-1}$ the associated Ward map.

Given $z\in\mathbb{C}$ and a Hermitian projection π of $\mathbb{C}^n$, let

$$h_{z,\pi}(\lambda)=\pi^{\perp}+\frac{\lambda-z}{\lambda-\overline{z}}\pi=I+\frac{\overline{z}-z}{\lambda-\overline{z}}\pi,$$

where $\pi^{\perp}=I-\pi$. A direct computation implies that $h_{z,\pi}$ satisfies the $U(n)$-reality condition (2.3).

Let $V=(v_{ij}):\mathbb{C}\to\mathcal{M}^0_{n\times k}(\mathbb{C})$ be a meromorphic map, and $\pi(x,y,t)$ the Hermitian projection onto the subspace spanned by the columns of $V(w)$, where

$$w=x+zu+z^{-1}v,$$

and u, v are the light cone coordinates in the yt plane defined by (2.1). Since the entries of V are meromorphic functions, the projection π is smooth on $\mathbb{R}^{2,1}$. Set

$$\psi(x,y,t,\lambda) = h_{z,\pi(x,y,t)}(\lambda) = \pi^{\perp}(x,y,t) + \frac{\lambda - z}{\lambda - \bar{z}}\pi(x,y,t).$$

A direct computation implies that both $(\lambda\psi_x - \psi_u)\psi^{-1}$ and $(\lambda\psi_v - \psi_x)\psi^{-1}$ are independent of λ. By Theorem 2.1, ψ is an extended solution of the Ward equation and the associated Ward map is the 1-soliton,

$$J_{z,V}(x,y,t) = \left(\frac{z}{\bar{z}}\right)^{k/n}\psi(x,y,t,0)^{-1} = \left(\frac{z}{\bar{z}}\right)^{k/n}\left(\pi^{\perp}(x,y,t) + \frac{\bar{z}}{z}\pi(x,y,t)\right),$$

where $(z/\bar{z})^{k/n}$ is a normalizing constant to make $\det(J_{z,V}) = 1$.

The 1-soliton Ward map $J_{z,V}$ is a travelling wave because

$$w = x + zu + z^{-1}v = (x - v_1 t) + k_1(y - v_2 t) + ik_2(y - v_2 t),$$

where $z = re^{i\theta}$, $v_1 = -2r\cos\theta/(1+r^2)$, $v_2 = (1-r^2)/(1+r^2)$, and $k_1 + ik_2 = (z - z^{-1})/2$. Thus $J_{z,V}$ is a travelling wave with constant velocity $\vec{v} = [-2r\cos\theta/(1+r^2), (1-r^2)/(1+r^2)]$ on the xy plane. In particular, $J_{i,V}$ is a stationary Ward map, i.e., a harmonic map from $\mathbb{C}$ to SU(n).

The following theorem was proved in Ref. 2, which gives an algebraic method to produce new extended Ward maps from a given one.

Theorem 2.2 (Bäcklund transformation): *Let $\psi(x,y,t,\lambda)$ be an extended solution of the Ward equation and $J = \psi(\cdots,0)^{-1}$ the associated Ward map from $\mathbb{R}^{2,1}$ to* SU(n). *Choose $z \in \mathbb{C}\backslash\mathbb{R}$ such that $\psi(x,y,t,\lambda)$ is holomorphic and nondegenerate at $\lambda = z$. Let $h_{z,\pi(x,y,t)}(\lambda)$ be an extended* 1*-soliton solution, and $\tilde{\pi}(x,y,t)$ the Hermitian projection of $\mathbb{C}^n$ onto*

$$\psi(x,y,t,z)\mathrm{Im}(\pi(x,y,t)).$$

Then

$$\psi_1(x,y,t,\lambda) = h_{z,\tilde{\pi}(x,y,t)}(\lambda)\psi(x,,y,t,\lambda)$$

is a new extended solution to the linear system (2.2) with

$$(A,B) \to (A + (\bar{z} - z)\tilde{\pi}_x, B + (\bar{z} - z)\tilde{\pi}_v),$$

and the new Ward map is

$$J_1(x,y,t) = \left(\frac{z}{\bar{z}}\right)^{k/n} J(x,y,t)\left(\frac{\bar{z}}{z}\tilde{\pi}(x,y,t) + \tilde{\pi}^{\perp}(x,y,t)\right).$$

We will denote $\psi_1 = h_{z,\pi} * \psi$ and $J_1 = h_{z,\pi} * J$, the Bäcklund transformation generated by $h_{z,\pi}$.

III. PERIODIC WARD MAPS FROM $T^2 \times \mathbb{R}$ TO SU(n)

We use algebraic BTs to construct Ward maps into SU(n) that are either doubly periodic in space variables or triply periodic.

First we construct 1-soliton Ward maps that are doubly periodic. Let $z = re^{i\theta}$,

$$w(x,y,t) = x + zu + z^{-1}v = x + \frac{z - z^{-1}}{2}y + \frac{z + z^{-1}}{2}t,$$

and $\alpha = a + ib$. A direct computation shows that

$$w\left(x + a - \frac{k_1}{k_2}b, y + \frac{b}{k_2}, t\right) = w(x,y,t) + \alpha,$$

where $k_1 + ik_2 = (z - z^{-1})/2$. Let $f: \mathbb{C} \to \mathbb{C}$ be a meromorphic function such that $f(w + \alpha) = f(w)$ (i.e., periodic with period α), and

$$g(x,y,t) = f(w) = f(x + zu + z^{-1}v).$$

A direct computation shows that

$$g(x,y,t) = g\left(x + a - \frac{k_1}{k_2}b, y + \frac{b}{k_2}, t\right).$$

Hence

(1) if $\alpha = 2\pi$, then g is 2π-periodic in x;
(2) if $\alpha = 2\pi(k_1 + ik_2) = \pi(z - z^{-1})$, then g is 2π-periodic in y.

This shows that if each entry v_{ij} of the meromorphic map $V = (v_{ij}) : \mathbb{C} \to \mathcal{M}^0_{n\times k}(\mathbb{C})$ satisfies $v_{ij}(w + 2\pi) = v_{ij}(w + \pi(z - z^{-1})) = v_{ij}(w)$, i.e., an elliptic function with periods 2π and $\pi(z - z^{-1})$, then the 1-soliton $J_{z,V}$ is a doubly periodic Ward map with respect to the lattice $2\pi(\mathbb{Z}\times\mathbb{Z})$. An example of elliptic function is the well-known Weierstrass $\wp$-function

$$\wp(w) = \frac{1}{w^2} + \sum_{\gamma\in\Lambda\setminus\{0\}} \left(\frac{1}{(w-\gamma)^2} - \frac{1}{\gamma^2}\right),$$

where Λ is the lattice in $\mathbb{C}$ generated by 2π and $\pi(z - z^{-1})$. Other elliptic functions can be generated by Weierstrass $\wp$-functions and Jacobi elliptic functions. It is clear that $J_{z,V}$ is time periodic if and only if the ratio of the velocity, $v_1/v_2 = (-2r\cos\theta)/(1 - r^2)$, is rational.

Similar computation implies that given any rank 2 lattice Λ of $\mathbb{C}$ there are 1-soliton Ward maps from $\mathbb{C}/\Lambda\times\mathbb{R}$ to SU(n). Moreover, some of these 1-solitons are periodic in time, i.e., triply periodic. In particular, we get the following.

Theorem 1: *Let* $\tau = c_1 + ic_2$ *with* $c_2 \neq 0$, $\Lambda = \mathbb{Z}2\pi + \mathbb{Z}\tau$, $z = re^{i\theta}$ *a constant, and* $a + ib = c_1 + [(z - z^{-1})/2]c_2$. *If each entry* v_{ij} *of the meromorphic map* $V : \mathbb{C} \to \mathcal{M}^0_{n\times k}(\mathbb{C})$ *is an elliptic function with periods* 2π *and* $a + ib$, *then the extended* 1*-soliton solution* $h_{z,\pi}$ *is doubly periodic with periods* 2π *and* τ *and the associated* 1*-soliton,*

$$J_{z,V} = e^{i2k\theta/n} h_{z,\pi}(0)^{-1} = e^{i2k\theta/n}(\pi^{\perp} + e^{-2i\theta}\pi)$$

is a Ward map from $\mathbb{C}/\Lambda\times\mathbb{R}$ *to* SU(n), *where* $e^{i2k\theta/n}$ *is a normalizing constant, and* $\pi(x,y,t)$ *is the projection onto the subspace spanned by the columns of* $V(x + zu + z^{-1}v)$. *Moreover,*

(1) *if* $r \neq 1$ *and there exist integers* m_1, m_2 *such that*

$$\frac{2\cos\theta}{r - r^{-1}} = \frac{2\pi m_1 + m_2 c_1}{m_2 c_2},$$

then $J_{z,V}$ *is periodic in time with period* $T = [m_2 c_2 (r + r^{-1})/(r - r^{-1})]$,
(2) *if* $r = 1$ *and* $\cos\theta \neq 0$, *then* $J_{z,V}$ *is periodic in time with period* $T = 2\pi/\cos\theta$.

In the rest of the section we consider only the square torus. We will construct k-soliton Ward maps from $T^2\times\mathbb{R}$ to SU(n) that are also time periodic. To do this, we define

$$\mathcal{Z} = \{z = re^{i\theta} \in \mathbb{C}\setminus\mathbb{R} \,|\, z = e^{i\theta} \neq \pm i \text{ or } \cos\theta/(r - r^{-1}) \in \mathbb{Q}\},$$

where $\mathbb{Q}$ denotes the set of rational numbers. We have seen that for each $z \in \mathcal{Z}$, we can construct time periodic 1-solitons to the Ward equation. Moreover, the time period T depends on z only. In fact, the period function $T : \mathcal{Z} \to \mathbb{R}$ is defined as follows:

$$T(z)=\begin{cases}\dfrac{2\pi}{\cos\theta}, & \text{if } z=e^{i\theta}\neq\pm i,\\ \dfrac{2\pi m_2(r+r^{-1})}{r-r^{-1}}, & \text{if } z=re^{i\theta},\quad \dfrac{2\cos\theta}{r-r^{-1}}=\dfrac{m_1}{m_2}.\end{cases}\tag{3.1}$$

Apply Bäcklund transformations repeatedly with some rational conditions on the poles $z_1,\dots,z_m$ to get the following.

Theorem 3.2: *Let $\{z_1,\dots,z_m\}$ be a set of finite points in $\mathcal{Z}$ such that $z_i\neq z_j$, $\overline{z_j}$ for all $i\neq j$, and $h_{z_i,\pi_i}(\lambda)$ extended 1-soliton solutions leading to doubly periodic Ward maps, where $i,j=1,\dots,m$. Let $T_i=T(z_i)$ be the time period defined in* (3.1). *Let J_1 be the Ward map associated to h_{z_1,π_1}, i.e., $J_1=h_{z_1,\pi_1}(0)^{-1}$. Let J_m be the Ward map obtained by applying $m-1$ Bäcklund transformations to J_1,*

$$J_m=h_{z_m,\pi_m}*(\cdots*(h_{z_2,\pi_2}*J_1)\cdots).\tag{3.2}$$

If T_j/T_1 are rational numbers for all $2\leqslant j\leqslant m$, then J_m is a Ward map from $T^2\times\mathbb{R}$ to $SU(n)$ and is periodic in time. In other words, J_m is a triply periodic solution of the Ward equation.

Proof: We prove the two-soliton case. By Theorem 2, we have

$$h_{z_2,\pi_2}*h_{z_1,\pi_1}=h_{z_2,\tilde{\pi}_2}h_{z_1,\pi_1},$$

where $\operatorname{Im}\tilde{\pi}_2=h_{z_1,\pi_1}(z_2)\operatorname{Im}\pi_2=[I+(\overline{z_1}-z_1)/(z_2-\overline{z_1})\pi_1]\operatorname{Im}\pi_2$. Note that $\tilde{\pi}_2$ is periodic in time because π_1 and π_2 are time periodic and T_2/T_1 is rational. Thus we see that $h_{z_2,\pi_2}*h_{z_1,\pi_1}$ is time periodic, and so is the associated Ward map. The general case can be proved by induction. □

IV. HOMOCLINIC WARD MAPS

It is known that solutions of the sine-Gordon equation (SGE)

$$q_{tt}-q_{xx}=\sin q$$

give rise to wave maps from $\mathbb{R}^{1,1}$ to S^2. Breather solutions are 2-soliton solutions of the SGE that are periodic in the x variable. Shatah and Strauss proved in Ref. 6 that wave maps from $S^1\times\mathbb{R}$ to S^2 corresponding to breather solutions of the sine-Gordon equation are homoclinic wave maps. Applying Bäcklund transformation $2k$ times with carefully placed poles, Terng and Uhlenbeck constructed $2k$ soliton solutions for the sine-Gordon equation that are periodic in the space variable, and showed that the corresponding wave maps from $S^1\times\mathbb{R}$ to S^2 are also homoclinic. More generally they proved that there are homoclinic wave maps from $S^1\times\mathbb{R}$ into any compact symmetric space.[9]

In this section, we apply Bäcklund transformations with carefully chosen poles and Hermitian projections even times to certain stationary wave map into SO(2) to construct homoclinic Ward maps from $T^2\times\mathbb{R}$ to SU(n). To make the construction more illuminating, we will work on the SU(2) model. The SU(n) model is similar.

Let $m>0$ be an integer, and $a=\operatorname{diag}(im,-im)\in\mathrm{su}(2)$. It is easy to check that

$$\psi(\lambda)(x,y,t)=\psi(x,y,t,\lambda)=e^{((1-\lambda)x+(1+\lambda-\lambda^2)u-v)a}.\tag{4.1}$$

is an extended Ward map. So

$$J_0(x,y,t)=\psi(x,y,t,0)^{-1}=e^{-(x+u-v)a}=e^{-(x+y)a}$$

is a stationary Ward map, which is doubly periodic in the space variables. Note that J_0 is a harmonic map from T^2 to SO(2).

Next we compute the linearization of the Ward equation at the stationary solution $J_0 = e^{-(x+y)a}$, as well as its stable and unstable subspaces. Let $\mathcal{M} = C^\infty(T^2 \times \mathbb{R}, \mathrm{SU}(2))$. Then we can give a natural trivialization of the tangent bundle $T\mathcal{M}$ as follows. Given a curve $\gamma: (-\epsilon, \epsilon) \to \mathcal{M}$ with $\gamma(0) = J$, we identify the tangent vector $\gamma'(0)$ as

$$(\gamma(0), \gamma(0)^{-1}\gamma'(0)) = (J, J^{-1}\delta J).$$

This identifies $T\mathcal{M} = \mathcal{M} \times C^\infty(T^2 \times \mathbb{R}, \mathrm{su}(2))$.

Set $J^{-1}\delta J = \eta$. Compute directly to get

$$\begin{aligned}\delta(J^{-1}J_x) &= -(J^{-1}\delta J)J^{-1}J_x + J^{-1}(\delta J)_x \\ &= -\eta(J^{-1}J_x) + J^{-1}(J\eta)_x = -\eta(J^{-1}J_x) + J^{-1}(J_x\eta + J\eta_x) = \eta_x + [J^{-1}J_x, \eta].\end{aligned}$$

The computation for $\delta(J^{-1}J_y)$ and $\delta(J^{-1}J_t)$ is similar. So the linearization of the Ward equation at $J_0 = e^{-(x+y)a}$ is

$$\begin{aligned}&(\eta_t + [J^{-1}J_t, \eta])_t - (\eta_x + [J^{-1}J_x, \eta])_x - (\eta_y + [J^{-1}J_y, \eta])_y - [\eta_t + [J^{-1}J_t, \eta], J^{-1}J_y] \\ &\quad - [J^{-1}J_t, \eta_y + [J^{-1}J_y, \eta]] = \eta_{tt} - \eta_{xx} - \eta_{yy} + [a, \eta_x + \eta_y - \eta_t] = 0. \qquad (4.2)\end{aligned}$$

We note that the linearization at $J = -e^{-(x+y)a}$ is the same one. Write (4.2) in terms of entries $\eta = \begin{pmatrix} ir & \xi \\ -\bar{\xi} & -ir \end{pmatrix}$ to get

$$r_{tt} - r_{xx} - r_{yy} = 0, \qquad (4.3a)$$

$$\xi_{tt} - \xi_{xx} - \xi_{yy} + 2im(\xi_x + \xi_y - \xi_t) = 0. \qquad (4.3b)$$

This system is linear with constant coefficients, so it can be solved by Fourier series. Let

$$\xi = \sum_{j,l \in \mathbb{Z}} b_{jl}(t) e^{i(jx+ly)}$$

be the Fourier series expansion of ξ. Then by (4.3b), we have

$$b_{jl}'' - 2imb_{jl}' + (j^2 + l^2 - 2m(j+l))b_{jl} = 0,$$

where $'$ means differentiation with respect to t. Its auxiliary equation is

$$\gamma^2 - 2im\gamma + j^2 + l^2 - 2m(j+l) = 0.$$

It has roots

$$\gamma = im \pm \sqrt{m^2 - (j-m)^2 - (l-m)^2}.$$

Stable (unstable, respectively) modes come from $\mathrm{Re}(\gamma) < 0$ [$\mathrm{Re}(\gamma) > 0$, respectively]. So for $(j,l) \in \mathbb{Z}^2$ with $(j-m)^2 + (l-m)^2 < m^2$, there are stable and unstable modes corresponding to roots $im \mp \sqrt{m^2 - (j-m)^2 - (l-m)^2}$, respectively. Similar computation shows that the auxiliary equation for (4.3a) has only purely imaginary roots. So the above computation gives the following.

Proposition 4.1: Let $a = \mathrm{diag}(im, -im)$ *and* $J = \pm e^{-(x+y)a}$, *where* $m > 0$ *is an integer. Let*

$$B\mathbb{Z}_m = \{(j,l) \in \mathbb{Z}^2 | (j-m)^2 + (l-m)^2 < m^2\}.$$

Then

(1) *the unstable subspace of the linearization of the Ward equation at* J *is*

$$\oplus \{W_{jl}^+ | (j,l) \in B\mathbb{Z}_m\},$$

where W_{jl}^+ *is spanned by*

$$\eta_{jl}^{+}(c) = e^{\sqrt{m^2-(j-m)^2-(l-m)^2}t}\begin{pmatrix} 0 & ce^{i(jx+ly+mt)} \\ -\bar{c}e^{-i(jx+ly+mt)} & 0 \end{pmatrix}$$

with constant $c \in \mathbb{C}$.

(2) *The stable subspace at* J *is*

$$\oplus\{W_{jl}^{-} | (j,l) \in B\mathbb{Z}_m\},$$

where W_{jl}^{-} *is spanned by*

$$\eta_{jl}^{-}(c) = e^{-\sqrt{m^2-(j-m)^2-(l-m)^2}t}\begin{pmatrix} 0 & ce^{i(jx+ly+mt)} \\ -\bar{c}e^{-i(jx+ly+mt)} & 0 \end{pmatrix}$$

with $c \in \mathbb{C}$.

Let $z = re^{i\theta} \in \mathbb{C}\backslash\mathbb{R}$, $f(w)$ a meromorphic function on $\mathbb{C}$, $q(w) = \binom{1}{f(w)}$, $w = x + zu + z^{-1}v$, and $\pi(x,y,t)$ the Hermitian projection of $\mathbb{C}^2$ onto $\mathbb{C}q(w)$. Let ψ be the extended solution given by (4.1) and $J_0 = \psi^{-1}|_{\lambda=0} = e^{-a(x+y)}$ the associated Ward map. Consider the Bäcklund transformation $h_{z,\pi} * \psi$. We will find conditions on z and $f(w)$ so that $h_{z,\pi} * J_0$ is doubly periodic in space variables. By Theorem 2.2, we have

$$\psi_1 = h_{z,\pi} * \psi = h_{z,\tilde{\pi}}\psi, \tag{4.4}$$

where $\operatorname{Im}\tilde{\pi} = \mathbb{C}\tilde{q}$ and

$$\tilde{q}(x,y,t) = \psi(z)q(w) = e^{((1-z)x+(1+z-z^2)u-v)a}\begin{pmatrix} 1 \\ f(w) \end{pmatrix} \sim \begin{pmatrix} 1 \\ e^{2im((z-1)x+(z^2-z-1)u+v)}f(w) \end{pmatrix}.$$

Here "$q_1 \sim q_2$" means $\mathbb{C}q_1 = \mathbb{C}q_2$. From the formula

$$J_1 = h_{z,\pi} * J_0 = J_0\frac{1}{|z|}(\bar{z}\tilde{\pi} + z\tilde{\pi}^{\perp}),$$

we see that it is doubly periodic if and only if $\tilde{q}$ is. For this purpose, we try the following form of

$$f(w) = e^{2im(\alpha-z)w},$$

where $\alpha \in \mathbb{C}$ is a constant. Substitute this into $\tilde{q}(x,y,t)$ to get

$$e^{2im((z-1)x+(z^2-z-1)u+v)}f(w) = e^{2im((\alpha-1)x+((\alpha-1)z-1)u+\alpha z^{-1}v)} = e^{im(2(\alpha-1)x+((\alpha-1)z-\alpha z^{-1}-1)y+((\alpha-1)z+\alpha z^{-1}-1)t)}.$$

It is doubly periodic in x and y with period 2π if and only if

$$2m(\alpha-1) =: -j \in \mathbb{Z}, \tag{4.5a}$$

$$m((\alpha-1)z - \alpha z^{-1} - 1) =: -l \in \mathbb{Z}. \tag{4.5b}$$

From (4.5a), we have $\alpha = (2m-j)/2m$. Compute the imaginary part of (4.5b) to get

$$(\alpha-1)r\sin\theta + \alpha r^{-1}\sin\theta = 0.$$

Since $r > 0$, we see $0 < \alpha < 1$. This implies that $0 < j < 2m$, and $r = \sqrt{(2m-j)/j}$. By (4.5b) again, we have

$$m((\alpha-1)z - \alpha z^{-1} - 1) = -\sqrt{j(2m-j)}\cos\theta - m = -l.$$

It follows that

$$\sqrt{j(2m-j)}\cos\theta = l-m.$$

Hence l must satisfy

$$|l-m| < \sqrt{j(2m-j)}, \tag{4.6}$$

and $\cos\theta=[(l-m)/\sqrt{j(2m-j)}]$. It is easy to verify that the conditions for (j,l) are equivalent to $(j,l)\in\mathbb{Z}^2$, $(j-m)^2+(l-m)^2<m^2$, i.e., $(j,l)\in B\mathbb{Z}_m$. Therefore if we choose the following data: $(j,l)\in B\mathbb{Z}_m$, $z=re^{i\theta}$ with $r=\sqrt{(2m-j)/j}$, $\cos\theta=(l-m)/\sqrt{j(2m-j)}$, $\sin\theta>0$, $\alpha=(2m-j)/2m$, then $\mathrm{Im}\,\tilde{\pi}(x,y,t)=\mathbb{C}\tilde{q}(x,y,t)$, where

$$\tilde{q}(x,y,t)=\begin{pmatrix} 1 \\ e^{\sqrt{m^2-(j-m)^2-(l-m)^2}t}e^{-i(jx+ly+mt)} \end{pmatrix}$$

is doubly periodic in x and y. It follows that

$$\tilde{\pi}(x,y,t)=\frac{1}{1+e^{2A}}\begin{pmatrix} 1 & e^{A}e^{i(jx+ly+mt)} \\ e^{A}e^{-i(jx+ly+mt)} & e^{2A} \end{pmatrix},$$

where $A=\sqrt{m^2-(j-m)^2-(l-m)^2}t$. Therefore we obtain the following Ward map from $T^2\times\mathbb{R}$ to SU(2):

$$J_1=e^{-(x+y)a}\frac{1}{|z|}(\bar{z}\tilde{\pi}(x,y,t)+z\tilde{\pi}^{\perp}(x,y,t))=e^{-(x+y)a}(e^{-i\theta}\tilde{\pi}(x,y,t)+e^{i\theta}\tilde{\pi}^{\perp}(x,y,t)). \tag{4.7}$$

We now analyze the asymptotic behavior of J_1 as $t\to\pm\infty$. It is easy to see that

$$\tilde{\pi}\to\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \quad \text{as } t\to+\infty,$$

and

$$\tilde{\pi}\to\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \quad \text{as } t\to-\infty.$$

So

$$J_1\to e^{-(x+y)a}\begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{pmatrix} \quad \text{as } t\to+\infty$$

and

$$J_1\to e^{-(x+y)a}\begin{pmatrix} e^{-i\theta} & 0 \\ 0 & e^{i\theta} \end{pmatrix} \quad \text{as } t\to-\infty.$$

Thus $J_1: T^2\times\mathbb{R}\to\mathrm{SU}(2)$ is a heteroclinic Ward map. To construct homoclinic maps, we apply Bäcklund transformation again.

Choose $z_2=-\bar{z}$, and $\pi_2(x,y,t)$ Hermitian projection of $\mathbb{C}^2$ onto $\mathbb{C}q_2$, where $q_2=\binom{1}{f_2(w_2)}$, $f_2(w_2)=e^{2im(\alpha+\bar{z})w_2}$, $\alpha=(2m-j)/2m$, and $w_2=x-\bar{z}u-\bar{z}^{-1}v$. Now apply Bäcklund transformation to ψ_1 [defined by (4.4)] generated by $h_{-\bar{z},\pi_2(x,y,t)}$ to get

$$\psi_2=h_{-\bar{z},\pi_2(x,y,t)}*\psi_1=h_{-\bar{z},\tilde{\pi}_2(x,y,t)}\psi_1,$$

where $\mathrm{Im}\,\tilde{\pi}_2(x,y,t)=\mathbb{C}\tilde{q}_2(x,y,t)$ and

$$\tilde{q}_2 = \psi_1(-\overline{z})q_2 = h_{z,\tilde{\pi}(x,y,t)}(-\overline{z})\psi(-\overline{z})\begin{pmatrix} 1 \\ f_2(w_2) \end{pmatrix} \sim \left(I + \frac{\overline{z}-z}{-2\overline{z}}\tilde{\pi}(x,y,t)\right)\begin{pmatrix} 1 \\ e^A e^{-i(jx+(2m-l)y+mt)} \end{pmatrix}. \tag{4.8}$$

Here $A=\sqrt{m^2-(j-m)^2-(l-m)^2}t$. Note that $\tilde{q}(x,y,t)$ is doubly periodic in x and y. Therefore

$$J_2 = J_0\frac{1}{|z|}(z\tilde{\pi}+z\tilde{\pi}^{\perp})\frac{1}{|z_2|}(\overline{z_2}\tilde{\pi}_2+z_2\tilde{\pi}_2^{\perp}) = J_0(e^{-i\theta}\tilde{\pi}+e^{i\theta}\tilde{\pi}^{\perp})(-e^{i\theta}\tilde{\pi}_2-e^{-i\theta}\tilde{\pi}_2^{\perp})$$

is a Ward map from $T^2\times\mathbb{R}$ to SU(2), where $J_0=e^{-(x+y)a}$.

Next we study the asymptotic behavior of J_2. First look at the behavior of J_2 as $t\to-\infty$. Set

$$\xi = e^{\sqrt{m^2-(j-m)^2-(l-m)^2}t}, \quad f_1 = e^{-i(jx+ly+mt)}, \quad f_2 = e^{-i(jx+(2m-l)y+mt)}.$$

Then $\lim_{t\to-\infty}\xi=0$. Write

$$\tilde{q}_1 = \tilde{q} = \begin{pmatrix} 1 \\ \xi f_1 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} + \xi f_1\begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

So the projection $\tilde{\pi}_1=\tilde{\pi}$ onto $\mathbb{C}\tilde{q}_1$ is

$$\tilde{\pi}_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \xi\begin{pmatrix} 0 & \overline{f_1} \\ f_1 & 0 \end{pmatrix} + O(\xi^2).$$

Write $\alpha_1=(z-\overline{z})/2\overline{z}$. Then by (4.8) we have

$$\tilde{q}_2 = (I+\alpha_1\tilde{\pi}_1)\begin{pmatrix} 1 \\ \xi f_2 \end{pmatrix} = (I+\alpha_1\tilde{\pi}_1)\left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + \xi f_2\begin{pmatrix} 0 \\ 1 \end{pmatrix}\right) = \begin{pmatrix} 1+\alpha_1 \\ 0 \end{pmatrix} + \alpha_1\xi f_1\begin{pmatrix} 0 \\ 1 \end{pmatrix} + \xi f_2\begin{pmatrix} 0 \\ 1 \end{pmatrix} + O(\xi^2)$$
$$\sim \begin{pmatrix} 1 \\ 0 \end{pmatrix} + \beta_1\xi f_1\begin{pmatrix} 0 \\ 1 \end{pmatrix} + \beta_2\xi f_2\begin{pmatrix} 0 \\ 1 \end{pmatrix} + O(\xi^2),$$

where $\beta_1=\alpha_1/(1+\alpha_1)$, $\beta_2=1/(1+\alpha_1)$. So the projection $\tilde{\pi}_2$ onto $\mathbb{C}\tilde{q}_2$ is

$$\tilde{\pi}_2 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \xi\begin{pmatrix} 0 & \overline{\beta_1 f_1} \\ \beta_1 f_1 & 0 \end{pmatrix} + \xi\begin{pmatrix} 0 & \overline{\beta_2 f_2} \\ \beta_2 f_2 & 0 \end{pmatrix} + O(\xi^2).$$

From the above computation, we see

$$\lim_{t\to-\infty}\tilde{\pi}_i = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad i=1,2.$$

Substitute $\tilde{\pi}_i$ into J_2 to get

$$J_2 = J_0(e^{-i\theta}\tilde{\pi}+e^{i\theta}\tilde{\pi}^{\perp})(-e^{i\theta}\tilde{\pi}_2-e^{-i\theta}\tilde{\pi}_2^{\perp})$$
$$= J_0\left(\begin{pmatrix} e^{-i\theta} & 0 \\ 0 & e^{i\theta} \end{pmatrix} + \xi\begin{pmatrix} 0 & -2i\sin\theta\overline{f_1} \\ -2i\sin\theta f_1 & 0 \end{pmatrix} + O(\xi^2)\right)$$
$$\times\left(\begin{pmatrix} -e^{i\theta} & 0 \\ 0 & -e^{-i\theta} \end{pmatrix} + \xi\begin{pmatrix} 0 & -2i\sin\theta\overline{\beta_1 f_1} \\ -2i\sin\theta\beta_1 f_1 & 0 \end{pmatrix} + \xi\begin{pmatrix} 0 & -2i\sin\theta\overline{\beta_2 f_2} \\ -2i\sin\theta\beta_2 f_2 & 0 \end{pmatrix}\right.$$
$$\left. + O(\xi^2)\right) = J_0\left(-I + \xi\begin{pmatrix} 0 & c_1\overline{f_1} \\ -\overline{c_1}f_1 & 0 \end{pmatrix} + \xi\begin{pmatrix} 0 & c_2\overline{f_2} \\ -\overline{c_2}f_2 & 0 \end{pmatrix} + O(\xi^2)\right),$$

where c_1, $c_2\in\mathbb{C}$ are constants. It follows that $\lim_{t\to-\infty}J_2=-J_0$. Note that

$$\xi\begin{pmatrix} 0 & c_i\overline{f_i} \\ -\overline{c_i}f_i & 0 \end{pmatrix}, \quad i=1,2$$

is equal to the unstable mode $\eta^+_{j_i,l_i}(c_i)$ at $-J_0$ given in Proposition 4.1, where $(j_1,l_1)=(j,l)$ and $(j_2,l_2)=(j,2m-l)$. In other words, we have shown

$$\lim_{t\to-\infty}\left(J_2+J_0+J_0\sum_{i=1}^{2}\eta^+_{j_i,l_i}(c_i)\right)=0. \tag{4.9}$$

To analyze the asymptotic behavior of J_2 as $t\to+\infty$, we set

$$\rho=e^{-\sqrt{m^2-(j-m)^2-(l-m)^2}t}, \quad h_1=e^{i(jx+ly+mt)}, h_2=e^{i(jx+(2m-l)y+mt)}.$$

Then $\lim_{t\to+\infty}\rho=0$. A similar computation implies that

(1) $\tilde{q}_1$ is parallel to $\binom{\rho h_1}{1}$.

(2)

$$\tilde{\pi}_1=\begin{pmatrix}0&0\\0&1\end{pmatrix}+\rho\begin{pmatrix}0&h_1\\\overline{h_1}&0\end{pmatrix}+O(\rho^2),$$

and

$$\tilde{\pi}_2=\begin{pmatrix}0&0\\0&1\end{pmatrix}+\rho\begin{pmatrix}0&\gamma_1h_1\\\overline{\gamma_1}\overline{h_1}&0\end{pmatrix}+\rho\begin{pmatrix}0&\gamma_2h_2\\\overline{\gamma_2}\overline{h_2}&0\end{pmatrix}+O(\rho^2)$$

for some constants γ_1, γ_2.

(3)

$$J_2=J_0\left(-I+\rho\begin{pmatrix}0&d_1h_1\\-\overline{d_1}\overline{h_1}&0\end{pmatrix}+\rho\begin{pmatrix}0&d_2h_2\\-\overline{d_2}\overline{h_2}&0\end{pmatrix}+O(\rho^2)\right)$$

for some constants d_1, d_2. It follows that $\lim_{t\to+\infty}J_2=-J_0$.

(4)

$$\lim_{t\to+\infty}\left(J_2+J_0+J_0\sum_{i=1}^{2}\eta^-_{j_i,l_i}(d_i)\right)=0. \tag{4.10}$$

Formulas (4.9) and (4.10) imply that $J_2:T^2\times\mathbb{R}\to\mathrm{SU}(2)$ is a homoclinic Ward map.

Applying Bäcklund transformations even times, with pairs of poles and Hermitian projections chosen as above, we obtain more homoclinic Ward maps. The case for $m<0$ is similar. We summarize the above discussion to give the following.

Theorem 4.2: *Let m be a nonzero integer, $a=\mathrm{diag}(im,-im)$, and $J_0=e^{-(x+y)a}$. Choose $(j_{2k-1},l_{2k-1})\in\mathbb{Z}^2$ such that*

$$(j_{2k-1}-m)^2+(l_{2k-1}-m)^2<m^2, \quad m<l_{2k-1}$$

and $(j_{2k-1},l_{2k-1})\neq(j_{2h-1},l_{2h-1})$ for $1\leqslant k<h\leqslant N$. Let $(j_{2k},l_{2k})=(j_{2k-1},2m-l_{2k-1})$, $z_s=\sqrt{(2m-j_s)/[j_s]}e^{i\theta_s}$ with $\cos\theta_s=\mathrm{sgn}(m)[(l_s-m)/\sqrt{j_s(2m-j_s)}]$, and $\sin\theta_s=\mathrm{sgn}(m)\sqrt{1-\cos^2\theta_s}$, $s=1,\ldots,2N$. Let π_s be the Hermitian projection onto $\mathbb{C}\binom{1}{f_s(w_s)}$, where $f_s(w_s)=e^{i(2m-j_s-2mz_s)w_s}$ and $w_s=x+z_su+z_s^{-1}v$. Let

$$J_{2N}(x,y,t)=h_{z_{2N},\pi_{2N}}*(\cdots*(h_{z_1,\pi_1}*J_0(x,y,t))\cdots) \tag{4.11}$$

be the Ward map obtained by applying $2N$ Bäcklund transformations to J_0. Then $J_{2N}:T^2\times\mathbb{R}$

$\to SU(2)$ *is a homoclinic Ward map. Moreover,* $J_{2N} \to (-1)^N J_0$ *as* $t \to \pm\infty$.

Proof: We have shown the $N=1$ case. For general N, we use induction and the calculation is similar. □

The above construction can be generalized to SU(n) model easily.

Corollary 4.3: Let m, p be integers, $m \neq 0$, $1 \leqslant p \leqslant n-1$,

$$a = \begin{pmatrix} i(n-p)mI_p & 0 \\ 0 & -ipmI_{n-p} \end{pmatrix} \in \mathrm{su}(n),$$

$\psi = e^{((1-\lambda)x+(1+\lambda-\lambda^2)u-v)a}$ *the extended solution, and* $J_0 = e^{-(x+y)a}$ *the associated Ward map. Choose* $(j_{2k-1}, l_{2k-1}) \in \mathbb{Z}^2$ *such that*

$$\left(j_{2k-1} - \frac{nm}{2}\right)^2 + \left(l_{2k-1} - \frac{nm}{2}\right)^2 < \left(\frac{nm}{2}\right)^2, \quad \frac{nm}{2} < l_{2k-1}$$

and $(j_{2k-1}, l_{2k-1}) \neq (j_{2h-1}, l_{2h-1})$ *for* $1 \leqslant k < h \leqslant N$. *Let* $(j_{2k}, l_{2k}) = (j_{2k-1}, nm - l_{2k-1})$, $z_s = \sqrt{(nm-j_s)/[j_s]}e^{i\theta_s}$ *with* $\cos\theta_s = \mathrm{sgn}(m)[(l_s - nm/2)/\sqrt{j_s(nm-j_s)}]$, *and* $\sin\theta_s = \mathrm{sgn}(m)\sqrt{1-\cos^2\theta_s}$, $s = 1, \ldots, 2N$. *Let* $\pi_s(x,y,t)$ *be the Hermitian projection of* $\mathbb{C}^n$ *onto*

$$\mathbb{C}(1, \ldots, 1, f_s(w_s), \ldots f_s(w_s))^T,$$

where 1 *is repeated p times,* $f_s(w_s) = e^{i(nm-j_s-nmz_s)w_s}$ *is repeated* $(n-p)$ *times,* $w_s = x + z_s u + z_s^{-1} v$. *Let*

$$J_{2N}(x,y,t) = h_{z_{2N},\pi_{2N}} * (\cdots * (h_{z_1,\pi_1} * J_0(x,y,t)) \cdots) \tag{4.12}$$

be the Ward map obtained by applying $2N$ *Bäcklund transformations to* J_0. *Then* $J_{2N}: T^2 \times \mathbb{R} \to SU(n)$ *is a homoclinic Ward map. Moreover,* $J_{2N} \to (-1)^N J_0$ *as* $t \to \pm\infty$.

The method discussed above can also produce Ward maps, which are homoclinic to (time) periodic orbits. There are only some minor changes in the construction, so we just list the main steps for the SU(2) model.

(i) Let $m > 0$ be an integer, and $b = \mathrm{diag}(im, -im)$. Then

$$\psi = e^{(x+(\lambda+2)u)b}$$

is an extended solution, and the associated Ward map is

$$J_0 = \psi^{-1}|_{\lambda=0} = e^{-(x+2u)b} = e^{-(x+y+t)b},$$

which is triply periodic in the variables x, y, t.

(ii) Set $\eta = J^{-1}\delta J$. Then the linearization of the Ward equation at J_0 is

$$\eta_{tt} - \eta_{xx} - \eta_{yy} + [b, \eta_x + 2\eta_y - 2\eta_t] = 0.$$

The unstable subspace of the linearization of the Ward equation at J_0 is $\oplus W_{jl}^+$, where $(j,l) \in \mathbb{Z}^2$, $(j-m)^2 + (l-2m)^2 < m^2$, and W_{jl}^+ is spanned by

$$e^{\sqrt{m^2-(j-m)^2-(l-2m)^2}\,t}\begin{pmatrix} 0 & ce^{i(jx+ly+2mt)} \\ -\overline{c}e^{-i(jx+ly+2mt)} & 0 \end{pmatrix}$$

with constant $c \in \mathbb{C}$. The stable subspace at J_0 is $\oplus W_{jl}^-$, where (j,l) satisfies the same condition, and W_{jl}^- is spanned by

$$e^{-\sqrt{m^2-(j-m)^2-(l-2m)^2}\,t}\begin{pmatrix} 0 & ce^{i(jx+ly+2mt)} \\ -\overline{c}e^{-i(jx+ly+2mt)} & 0 \end{pmatrix}$$

with constant $c \in \mathbb{C}$.

(iii) Choose $(j,l)\in\mathbb{Z}^2$ with $(j-m)^2+(l-2m)^2<m^2$. Apply Bäcklund transformation $h_{z_1,\pi_1}*\psi$, where $z_1=re^{i\theta}$ with $r=\sqrt{(2m-j)/j}$, $\cos\theta=(l-2m)/\sqrt{j(2m-j)}$, $\sin\theta>0$, $\pi_1(x,y,t)$ is the Hermitian projection of $\mathbb{C}^2$ onto $\mathbb{C}\binom{1}{e^{2im\alpha_1 w_1}}$, $\alpha_1=(2m-j)/2m$, and $w_1=x+z_1u+z_1^{-1}v$. Then

$$\psi_1=h_{z_1,\pi_1}*\psi=h_{z_1,\tilde{\pi}_1}\psi,$$

where $\tilde{\pi}_1$ is the projection onto

$$\psi(z_1)\mathrm{Im}\,\pi_1=\mathbb{C}\begin{pmatrix}1\\ e^{\sqrt{m^2-(j-m)^2-(l-2m)^2}t}e^{-i(jx+ly+2mt)}\end{pmatrix}.$$

(iv) Choose $(j_2,l_2)=(j,4m-l)\in\mathbb{Z}^2$. Apply Bäcklund transformation again to get

$$\psi_2=h_{z_2,\pi_2}*\psi_1=h_{z_2,\tilde{\pi}_2}\psi_1.$$

Here $z_2=-\overline{z_1}$, and $\pi_2(x,y,t)$ is the Hermitian projection onto $\mathbb{C}q$, where $q=\binom{1}{e^{2im\alpha_2 w_2}}$, $\alpha_2=\alpha_1$, and $w_2=x-\overline{z_1}u-\overline{z_1}^{-1}v$. Then $\tilde{\pi}_2(x,y,t)$ is the projection onto

$$\mathbb{C}h_{z_1,\tilde{\pi}_1}(-\overline{z_1})\begin{pmatrix}1\\ e^{\sqrt{m^2-(j-m)^2-(l-2m)^2}t}e^{-i(jx+(4m-l)y+2mt)}\end{pmatrix}.$$

(v)

$$J_2=\psi_2^{-1}|_{\lambda=0}=J_0(e^{-i\theta}\tilde{\pi}_1+e^{i\theta}\tilde{\pi}_1^{\perp})(-e^{i\theta}\tilde{\pi}_2-e^{-i\theta}\tilde{\pi}_2^{\perp})$$

is a Ward map from $T^2\times\mathbb{R}$ to SU(2). Analyzing the asymptotic behavior of J_2 as $t\to\pm\infty$, we see that J_2 is transversal and homoclinic to the periodic orbit $-J_0$. Applying Bäcklund transformations even times with pairs of poles and Hermitian projections chosen similarly, we obtain more Ward maps which are homoclinic to $\pm J_0$.

The construction of homoclinic orbits to (time) periodic solutions for the SU(n) model is similar. Thus we have the following.

Theorem 4.4: *Let m, p be integers, $m\neq 0$, $1\leqslant p\leqslant n-1$,*

$$b=\begin{pmatrix}i(n-p)mI_p & 0\\ 0 & -ipmI_{n-p}\end{pmatrix}\in\mathrm{su}(n),$$

$\psi=e^{(x+(\lambda+2)u)b}$ the extended solution, and $J_0=e^{-(x+y+t)b}$ the associated Ward map. Choose $(j_{2k-1},l_{2k-1})\in\mathbb{Z}^2$ such that

$$\left(j_{2k-1}-\frac{nm}{2}\right)^2+(l_{2k-1}-nm)^2<\left(\frac{nm}{2}\right)^2,\quad nm<l_{2k-1}$$

and $(j_{2k-1},l_{2k-1})\neq(j_{2h-1},l_{2h-1})$ for $1\leqslant k<h\leqslant N$. Let $(j_{2k},l_{2k})=(j_{2k-1},2nm-l_{2k-1})$, $z_s=\sqrt{(nm-j_s)/[j_s]}e^{i\theta_s}$ with $\cos\theta_s=\mathrm{sgn}(m)[(l_s-nm)/\sqrt{j_s(nm-j_s)}]$, and $\sin\theta_s=\mathrm{sgn}(m)\sqrt{1-\cos^2\theta_s}$, $s=1,\ldots,2N$. Let $\pi_s(x,y,t)$ be the Hermitian projection of $\mathbb{C}^n$ onto

$$\mathbb{C}(1,\ldots,1,f_s(w_s),\ldots f_s(w_s))^T,$$

where 1 is repeated p times, $f_s(w_s)=e^{i(nm-j_s)w_s}$ is repeated $(n-p)$ times, and $w_s=x+z_su+z_s^{-1}v$. Let

$$J_{2N}(x,y,t)=h_{z_{2N},\pi_{2N}}*(\cdots*(h_{z_1,\pi_1}*J_0(x,y,t))\cdots)$$

be the Ward map obtained by applying $2N$ Bäcklund transformations to J_0. Then $J_{2N}:T^2\times\mathbb{R}\to SU(n)$ is a homoclinic Ward map. Moreover, $J_{2N}\to(-1)^NJ_0$ as $t\to\pm\infty$.

(Received 15 December 2004; accepted 28 March 2005; published online 18 May 2005)

In this paper we study the integrability of natural Hamiltonian systems with a homogeneous polynomial potential. The strongest necessary conditions for their integrability in the Liouville sense have been obtained by a study of the differential Galois group of variational equations along straight line solutions. These particular solutions can be viewed as points of a projective space of dimension smaller by one than the number of degrees of freedom. We call them Darboux points. We analyze in detail the case of two degrees of freedom. We show that, except for a radial potential, the number of Darboux points is finite and it is not greater than the degree of the potential. Moreover, we analyze cases when the number of Darboux points is smaller than maximal. For two degrees of freedom the above-mentioned necessary condition for integrability can be expressed in terms of one nontrivial eigenvalue of the Hessian of potential calculated at a Darboux point. We prove that for a given potential these nontrivial eigenvalues calculated for all Darboux points cannot be arbitrary because they satisfy a certain relation which we give in an explicit form. We use this fact to strengthen maximally the necessary conditions for integrability and we show that in a generic case, for a given degree of the potential, there is only a finite number of potentials which satisfy these conditions. We also describe the nongeneric cases. As an example we give a full list of potentials of degree four satisfying these conditions. Then, investigating the differential Galois group of higher order variational equations, we prove that, except for one discrete family, among these potentials only those which are already known to be integrable are integrable. We check that a finite number of potentials from the exceptional discrete family are not integrable, and we conjecture that all of them are not integrable. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1917311]

I. INTRODUCTION

We consider $\mathbb{C}^{2n}$ as a symplectic linear space with canonical variables $\boldsymbol{q}=(q_1,\ldots,q_n)$, $\boldsymbol{p}=(p_1,\ldots,p_n)$. We are interested in Hamiltonian systems defined by Hamilton's function of the form

[a)]Electronic mail: maciejka@astro.ia.uz.zgora.pl
[b)]Electronic mail: maria.przybylska@astri.uni.torun.pl

$$H = \frac{1}{2}\sum_{i=1}^{n} p_i^2 + V(\boldsymbol{q}), \tag{1.1}$$

where $V=V(\boldsymbol{q}) \in \mathbb{C}[\boldsymbol{q}]$ is a homogeneous polynomial of degree $k>2$. The canonical Hamilton's equations have the well-known form

$$\frac{\mathrm{d}}{\mathrm{d}t}\boldsymbol{q} = \boldsymbol{p}, \quad \frac{\mathrm{d}}{\mathrm{d}t}\boldsymbol{p} = -V'(\boldsymbol{q}), \tag{1.2}$$

where by $V'(\boldsymbol{q})$ we denote the gradient of $V(\boldsymbol{q})$. The classical problem concerns integrability of such systems.

To simplify our further exposition it is convenient to notice the following fact. It is easy to show that if Hamilton's equations (1.2) are integrable with potential $V(\boldsymbol{q})$, then they are integrable also with potential $V_A(\boldsymbol{q}) := V(A\boldsymbol{q})$, where $A \in \mathrm{PO}(n,\mathbb{C}) \subset \mathrm{GL}(n,\mathbb{C})$. Here by $\mathrm{PO}(n,\mathbb{C})$ we denote a group of $n \times n$ complex matrices A such that $AA^T = \alpha E$ where $\alpha \in \mathbb{C}^\star$. Thus, when we discuss integrability, we identify potentials V and V_A, for all $A \in \mathrm{PO}(n,\mathbb{C})$, and we say that they are equivalent. Later in this paper often a potential means a class of equivalent potentials and the phrase "potential V is integrable" means that the corresponding system (1.2) is integrable. By integrability we understand the integrability in the Liouville sense with first integrals which are complex meromorphic functions.

In spite of a very long history and numerous approaches little is known about the integrability of (1.2). In fact, an application of the direct method,[16,15] and the Painlevé test[9–12,20,39,40] gave only several examples of integrable systems for which additional first integrals are polynomials of low degrees. The most general result based on the direct method was obtained by Nakagawa and Yoshida.[37] These authors proved that if Hamiltonian system (1.2) with two degrees of freedom and a homogeneous potential of degree $k \geqslant 5$ admits an additional polynomial first integral F such that $\deg_p F \leqslant 4$, then it admits an additional polynomial first integral F such that $\deg_p F \leqslant 2$.

At the beginning of the 1980s Ziglin[43,44] developed an elegant theory which relates the integrability of Hamiltonian systems with properties of the monodromy group of variational equations along a particular solution. The Ziglin theory gives conditions necessary for integrability of a complex system with an arbitrary holomorphic Hamiltonian. Yoshida[42] used this theory to formulate a criterion for the integrability of system (1.2) with a homogeneous potential which is not necessarily a polynomial. The Yoshida criterion was formulated only for systems with two degrees of freedom and it has the form of inequalities. Thus, for systems depending on parameters, these values of parameters for which the system satisfies the necessary conditions for integrability form open sets in the space of parameters.

At the end of the previous century the Ziglin theory was considerably extended. Roughly speaking, the necessary conditions for integrability were expressed in terms of the differential Galois group[41] of variational equations. This approach was developed by Baider, Churchill, Morales, Ramis, Rod, Simó, and Singer, see Refs. 5 and 30, and references therein. It was shown that if the investigated system is integrable in the Liouville sense, then the identity component of the differential Galois group of the variational equations along a particular solution is Abelian, see Ref. 30 and Sec. I of Appendix A. For Hamiltonian systems (1.2) with homogeneous potential these conditions, as shown in Refs. 30 and 32, are much stronger than those given by Yoshida and they are applicable for systems with an arbitrary number of degrees of freedom. To describe them we have to introduce several definitions.

A nonzero point $\boldsymbol{d} \in \mathbb{C}^n$ is called a *Darboux point* of system (1.2) if it is a solution of

$$V'(\boldsymbol{d}) = \gamma \boldsymbol{d}, \tag{1.3}$$

where $\gamma \in \mathbb{C}^\star = \mathbb{C}\backslash\{0\}$. A Darboux point defines a two-dimensional plane in $\mathbb{C}^{2n}$ invariant with respect to the flow of the system (1.2). In fact, if $\boldsymbol{d}$ satisfies (1.3), then

$$\boldsymbol{q}(t) = \varphi(t)\boldsymbol{d}, \quad \boldsymbol{p}(t) = \dot{\varphi}(t)\boldsymbol{d} \tag{1.4}$$

is a solution of the system (1.2), provided that $\varphi(t)$ satisfies

$$\ddot{\varphi} = -\gamma\varphi^{k-1}.$$

From our definition of a Darboux point it follows that it is a point $[d_1:d_2:\cdots:d_n]$ of projective space $\mathbb{CP}^{n-1}$ for which its homogeneous coordinates satisfy (1.3).

The variational equations along solution (1.4) have the form

$$\dot{\boldsymbol{x}} = \boldsymbol{y}, \quad \dot{\boldsymbol{y}} = -\varphi(t)^{k-2}V''(\boldsymbol{d})\boldsymbol{x}. \tag{1.5}$$

Hessian $V''(\boldsymbol{d})$ of the potential V calculated at a Darboux point $\boldsymbol{d}$ is a symmetric matrix. Hence, in a generic case, there exists a complex orthogonal $n\times n$ matrix A such that the canonical transformation

$$\boldsymbol{x} = A\boldsymbol{\eta}, \quad \boldsymbol{y} = A\boldsymbol{\xi},$$

transforms system (1.5) to the form

$$\dot{\eta}_i = \xi_i, \quad \dot{\xi}_i = -\hat{\lambda}_i\varphi(t)^{k-2}\eta_i, \quad i = 1, \ldots, n,$$

or simply

$$\ddot{\eta}_i = -\hat{\lambda}_i\varphi(t)^{k-2}\eta_i, \quad i = 1, \ldots, n, \tag{1.6}$$

where $(\hat{\lambda}_1, \ldots, \hat{\lambda}_n)$ are eigenvalues of $V''(\boldsymbol{d})$. One of them, let us say $\hat{\lambda}_n$, is equal to $\gamma(k-1)$. For a given energy $e \in \mathbb{C}^\star$ the phase curve Γ_e associated with particular solution $\varphi(t)$ is, for $k \neq 0$, a hyperelliptic curve given by

$$\dot{\varphi}^2 = 2\frac{\gamma}{k}(\varepsilon - \varphi^k), \quad e = \frac{\gamma}{k}\varepsilon. \tag{1.7}$$

As was observed by Yoshida,[42] each of equations (1.6) can be transformed to the hypergeometric equation. It can be done by the following change of the independent variable:

$$t \to z := \frac{1}{\varepsilon}\varphi(t)^k. \tag{1.8}$$

As

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}x = \dot{z}^2x'' + \ddot{z}x', \quad {}' \equiv \frac{\mathrm{d}}{\mathrm{d}z},$$

after transformation (1.8) Eq. (1.6) reads

$$z(1-z)\eta_i'' + \left(\frac{k-1}{k} - \frac{3k-2}{2k}z\right)\eta_i' + \frac{\lambda_i}{2k}\eta_i = 0, \tag{1.9}$$

where $i=1,\ldots,n$, and $\lambda_i=\hat{\lambda}_i/\gamma$. Here we note that λ_i are eigenvalues of $\gamma^{-1}V''(\boldsymbol{d})$. Equation (1.9) is a hypergeometric differential equation for which the differences of exponents at $z=0$, $z=1$, and $z=\infty$ are

$$\frac{1}{k}, \quad \frac{1}{2}, \quad \frac{1}{2k}\sqrt{(k-2)^2 + 8k\lambda_i},$$

respectively.

Now, as variational equations have the form of a direct product of Eq. (1.9), their differential Galois group is also a direct product of the differential Galois groups of Eq. (1.9). All cases when the identity component of the differential Galois group of hypergeometric differential equation is solvable are known, see Ref. 17. This fact combined with Theorem A.1 was used by Morales-Ruiz and Ramis to formulate in Ref. 34 a general theorem concerning the integrability of Hamiltonian systems with a homogeneous potential. Here, we formulate this theorem for a polynomial homogeneous potential.

Theorem 1.1: *If Hamiltonian system (1.2) with polynomial homogeneous potential* $V(\boldsymbol{q})$ *of degree* $k>2$ *is meromorphically integrable in the Liouville sense, then for Darboux point values of* (k,λ_i) for $i=1,\ldots,n$ *belong to the following list*

$$1.\ \left(k,p+\frac{k}{2}p(p-1)\right),\quad 2.\ \left(k,\frac{1}{2}\left[\frac{k-1}{k}+p(p+1)k\right]\right),$$

$$3.\ \left(3,-\tfrac{1}{24}+\tfrac{1}{6}(1+3p)^2\right),\quad 4.\ \left(3,-\tfrac{1}{24}+\tfrac{3}{32}(1+4p)^2\right),$$

$$5.\ \left(3,-\tfrac{1}{24}+\tfrac{3}{50}(1+5p)^2\right),\quad 6.\ \left(3,-\tfrac{1}{24}+\tfrac{3}{50}(2+5p)^2\right),$$

$$7.\ \left(4,-\tfrac{1}{8}+\tfrac{2}{9}(1+3p)^2\right),\quad 8.\ \left(5,-\tfrac{9}{40}+\tfrac{5}{18}(1+3p)^2\right),$$

$$9.\ \left(5,-\tfrac{9}{40}+\tfrac{1}{10}(2+5p)^2\right),$$

where p is an integer.

Note that for a given k the eigenvalue $\lambda_n=k-1$ does not give a restriction for integrability. We called it the trivial eigenvalue. Here it is important to notice the following fact. Let $\boldsymbol{d}$ be a Darboux point of potential V. Then an equivalent potential V_A has a Darboux point $\tilde{\boldsymbol{d}}=A^T\boldsymbol{d}$ as we have

$$V_A'(\tilde{\boldsymbol{d}})=A^TV'(AA^T\boldsymbol{d})=A^TV'(\alpha\boldsymbol{d})=\alpha^{k-1}A^TV'(\boldsymbol{d})=\tilde{\gamma}\tilde{\boldsymbol{d}},$$

where $\tilde{\gamma}=\gamma\alpha^{k-1}$. Moreover, $\gamma^{-1}V''(\boldsymbol{d})$ and $\tilde{\gamma}^{-1}V_A''(\tilde{\boldsymbol{d}})$ have the same eigenvalues. Hence, these eigenvalues and the number of Darboux points characterize classes of equivalent potentials.

Theorem 1.1 gives the strongest known necessary conditions for the integrability of system (1.2). However, a problem appears again when the potential depends on parameters. Applying it we quickly distinguish *infinitely* many families of potentials for which these conditions are satisfied.

Although it seems that this problem is unavoidable, the aim of this paper is to show that at least for systems with two degrees of freedom it is not like that.

First of all, it is obvious that the more Darboux points of considered potential we know, the more conditions for its integrability we have. Hence, it is crucial to know how many Darboux points for a given potential exist, and how the number of Darboux points depends on parameters.

The second problem is more delicate and less obvious. Assume that for a given potential we found all Darboux points. Each of them gives us $n-1$ nontrivial eigenvalues which appear in the necessary conditions for integrability. The question is if all of these eigenvalues can be arbitrary. In other words, we ask if there exists a universal relation between all the eigenvalues calculated for all Darboux points.

In this paper we analyze the above-noted problems for the case of two degrees of freedom. In this case for a Darboux point $\boldsymbol{d}$ there is only one nontrivial eigenvalue

$$\lambda=\gamma^{-1}\mathrm{Tr}\,V''(\boldsymbol{d})-(k-1).$$

We show that for a generic homogeneous polynomial of degree k there exist k Darboux points. For each Darboux point we calculate the "shifted" nontrivial eigenvalue

$$\Lambda = \lambda - 1 = \gamma^{-1}\mathrm{Tr}\, V''(\boldsymbol{d}) - k.$$

Then, one of the main results of this paper is following.

Theorem 1.2: *Assume that a homogeneous polynomial potential $V(q_1, q_2)$ of degree $k>2$ has k different Darboux points. Then the shifted eigenvalues Λ_i calculated for these points satisfy the following relation*

$$\sum_{i=1}^{k} \frac{1}{\Lambda_i} = -1. \tag{1.10}$$

Our next result shows the importance of the above theorem. To formulate it let us denote by $\mathcal{V}_k$ the set of all homogeneous potentials V of degree k which have k different Darboux points. For each $V \in \mathcal{V}_k$ we have properly defined a collection $\mathbf{\Lambda}_V = \{\Lambda_1, \ldots, \Lambda_k\}$ of the shifted eigenvalues. Let $\mathcal{L}_k$ denote a set of all $\mathbf{\Lambda}_V$, for $V \in \mathcal{V}_k$, and $\mathcal{I}_k$ a set of those elements of $\mathcal{L}_k$ which correspond to the integrable potentials. Combining Theorem 1 with our Theorem 2 we prove the following.

Theorem 1.3: *For all $k>2$ set $\mathcal{I}_k$ is at most finite.*

As we will show, the assumption about the number of Darboux points in the above-mentioned theorems can be relaxed.

Having the above-noted results it is natural to ask for more. For example, it is natural to ask if we can give necessary and sufficient conditions for the integrability of system (1.2) for a polynomial potential of a fixed degree k. Obviously Theorem 1.1 and our above-mentioned results are not sufficient for this task—we need stronger necessary conditions for the integrability than those in Theorem 1.1. Hopefully, there exists a theorem by Morales-Ruiz, Ramis, and Simó[31] which gives the desired conditions. These conditions are expressed in terms of properties of the differential Galois group of higher order variational equations around a particular solution, see Sec. II of Appendix A.

In Ref. 23 we performed a detailed analysis of homogeneous potentials of degree three. Investigating this case we found a particular case of relation (1.10) and we noticed that without this relation it is hopeless to distinguish all integrable potentials. However, using the above-mentioned theorem of Morales-Ruiz, Ramis, and Simó we were able to give necessary and sufficient conditions for integrability of a homogeneous potential of degree three.

In this paper we investigate the case of a homogeneous potential of degree $k=4$. It appears that case $k=4$ is much more complicated than case $k=3$. Nevertheless, we performed our analysis almost up to the end, i.e., we give a full list of integrable potentials of degree four and we show that, except for one discrete but infinite family, the remaining potentials are not integrable. It seems that all potentials from the exceptional discrete family are not integrable but we are able to show this only for a finite number of potentials from this family.

The plan of this paper is the following. Section II contains general results concerning systems with two degrees of freedom. In Sec. III we analyze Hamiltonian system (1.2) with a homogeneous potential of degree 4. Section IV contains some general remarks and comments.

As to Sec. II, after showing some preliminary facts in Sec. II A, we analyze in Sec. II B the question about the number of Darboux points for a given homogeneous potential. The main results of this section are Lemma 2.2, which characterizes potentials without Darboux points, and Lemma 2.3 together with Corollary 2.2 which explain how the positions of Darboux points determine the potential. In Sec. II B we analyze the question about the number of Darboux points for a given potential. First we reduce the problem to counting the number of equilibria of an auxiliary system. Then the problem is reduced to an investigation of roots of two polynomials. Here, besides general facts about the finiteness of the number of Darboux points, in Lemma 2.2 we characterize cases when there are no Darboux points. In Sec. II C we introduce a meromorphic differential form such that the Darboux points are contained in its poles. The residue of this form at a simple Darboux point is the inverse of the shifted eigenvalue. Theorem 2.1 is a more general version of Theorem 1.2 formulated above. However, as we believe, the most important result in this section is Theo-

rem 2.3, which generalizes Theorem 1.2 "almost" maximally. We close this section with Theorem 2.4 showing that, generically, when the number of Darboux points is not maximal, then the potential is not integrable.

An analysis of integrability of homogeneous polynomial potentials of degree four given in Sec. III, starts from distinguishing cases when there are no Darboux points, when there is a multiple or exactly one Darboux point. In all these cases the potential depends on parameters and either Theorem 1.1 or our Theorem 1.2 is not applicable. In Sec. III B we give a list of all potentials satisfying the necessary conditions of Theorems 1.1 and 1.2. It contains only nine potentials. Three of them are known integrable potentials. The remaining ones are not integrable as we show in Sec. III C using the higher order variational equations. We also prove that potentials without Darboux points and those with a multiple Darboux point are not integrable. The only case when our investigation of the integrability is not performed until the end is a discrete but infinite family of potentials with one simple Darboux point. We were able to show only that a finite number of potentials from this family is not integrable.

In the Appendices, to make the paper self-contained, we give formulation of basic theoretical facts about differential Galois approach to the integrability.

II. TWO DEGREES OF FREEDOM

A. Preliminaries

As we already mentioned, a Darboux point can be considered as a point in a projective space. For $n=2$ it is $\mathbb{CP}^1$. This is why it is convenient to consider coordinates $(q_1,q_2)\in\mathbb{C}^2$ as the homogeneous coordinates $[q_1:q_2]$ on $\mathbb{CP}^1$. We identify the affine part of $\mathbb{CP}^1$ with points $[1:q_2]\in\mathbb{CP}^1$ and we parametrize it by coordinate $z=q_2/q_1$, $q_1\neq 0$. The other coordinate $\zeta=q_1/q_2$ is used to parametrize points in a neighborhood of infinity.

A linear transformation $\boldsymbol{q}\mapsto A\boldsymbol{q}$, $A\in\mathrm{PO}(2,\mathbb{C})$, induces an action of $\mathrm{PO}(2,\mathbb{C})$ on $\mathbb{CP}^1$ defined in the following way. For $A\in\mathrm{PO}(2,\mathbb{C})$ given by

$$A=\begin{bmatrix} a & b \\ -b & a \end{bmatrix}, \quad a^2+b^2\neq 0, \tag{2.1}$$

we have $\tau_A:\mathbb{CP}^1\to\mathbb{CP}^1$ given by

$$\tau_A([q_1:q_2])=[aq_1+bq_2:-bq_1+aq_2].$$

Thus, in the affine part of $\mathbb{CP}^1$ this action is

$$\tau_A(z)=\frac{az-b}{bz+a}, \tag{2.2}$$

and the image of the line at infinity $[0:q_2]$ is $\tau_A(\infty)=a/b$.

The group of matrices (2.1) forms a proper subgroup $\mathrm{PO}(2,\mathbb{C})^\circ$ of $\mathrm{PO}(2,\mathbb{C})$. It is the identity component of $\mathrm{PO}(2,\mathbb{C})$. Group $\mathrm{PO}(2,\mathbb{C})$ also contains a diagonal subgroup D_a which consists of matrices $A=\mathrm{diag}(a,-a)$, $a\in\mathbb{C}^\star$. For $A\in\mathrm{D}_a$ we have $\tau_A(z)=-z$, and $\tau_A(\infty)=\infty$. It is easy to check that $\tau_A\circ\tau_{A^T}=id$.

The following two propositions characterize the basic properties of the above-defined Möbius action. The easy proofs of them we left to the reader.

Proposition 2.1: If for $p\in\mathbb{CP}^1$ *we have* $\tau_A(p)=p$ *for all* $A\in\mathrm{PO}(2,\mathbb{C})^\circ$, *then* $p=[1:\pm i]$.

Proposition 2.2: For $p,\tilde{p}\in\mathbb{CP}^1\setminus\{[1:+i],[1:-i]\}$ *there exists* $A\in\mathrm{PO}(2,\mathbb{C})$ *such that* $\tilde{p}=\tau_A(p)$.

Let $V\in\mathbb{C}[q_1,q_2]$ be a homogeneous polynomial of degree $k>0$. We have

$$V(q_1,q_2)=q_1^kV(1,q_2/q_1)=q_2^kV(q_1/q_2,1),$$

and we define $v(z):=V(1,z)$ and $w(\zeta):=V(\zeta,1)$. Obviously v and w are nonzero polynomials of degree not greater than k. Moreover, we have

$$w(\zeta) = \zeta^k v(1/\zeta). \tag{2.3}$$

Hence if we write

$$v(z) = \sum_{i=0}^{k} v_{k-i} z^i, \tag{2.4}$$

then

$$w(\zeta) = \sum_{i=0}^{k} v_i \zeta^i. \tag{2.5}$$

If V_A is equivalent to V, i.e. $V_A(\boldsymbol{q}) = V(A\boldsymbol{q})$ for some $A \in \mathrm{PO}(2,\mathbb{C})^\circ$, then $v_A(z) := V_A(1,z)$ is given by

$$v_A(z) = (a + bz)^k v(\tau_A(z)), \tag{2.6}$$

and similarly, $w_A(\zeta) := V_A(\zeta, 1)$ has the form

$$w_A(\zeta) = (-b\zeta + a)^k w(\tau_{A^T}(\zeta)). \tag{2.7}$$

Simple calculations show the following.

Proposition 2.3: If $z_\star$ is a root of polynomial v, then $\tau_{A^T}(z_\star)$ is a root of polynomial v_A. If $\zeta_\star$ is a root of polynomial w, then $\tau_A(\zeta_\star)$ is a root of polynomial w_A.

By the above-mentioned property and Proposition 2.2 we can choose among all equivalent potentials such a representative V, for which polynomial v (or w) has one root in an arbitrary point of $\mathbb{CP}^1 \setminus \{[1:+i],[1:-i]\}$. This is always possible except for cases when all linear factors of V have the form $(q_2 \pm iq_1)$, i.e., when potential V has the following form:

$$V_{k,l} = \alpha(q_2 - iq_1)^l (q_2 + iq_1)^{k-l}, \quad l = 0, \ldots, k, \quad \alpha \in \mathbb{C}^\star. \tag{2.8}$$

We called the above potentials exceptional.

To prove some general statements it is convenient to assume that for a given potential V we can find an equivalent one V_A such that it contains monomial $q_1 q_2^{k-1}$ with a nonzero coefficient.

Lemma 2.1: Assume that $V \neq V_{l,l}$. If for all potentials V_A equivalent to V coefficient of monomial $q_1 q_2^{k-1}$ vanishes, then $V = 0$.

Proof: For a given V of degree k the coefficient of monomial $q_1 q_2^{k-1}$ is equal to v_1 in (2.4). From (2.5) it follows that $v_i = w'(0)$. Let us assume that for all $A \in \mathrm{PO}(2,\mathbb{C})^\circ$ we have $w_A'(0) = 0$. Then from (2.5) and (2.7) we obtain

$$w_A(\zeta) = a^k \sum_{i=0}^{k} v_i (\zeta + x)^i (1 - x\zeta)^{k-i}, \tag{2.9}$$

where $x = b/a$. Thus

$$w_A'(0) = a^k \sum_{i=0}^{k} v_i (i x^{i-1} - (k-i)x^{i+1}) = a^k \sum_{j=0}^{k} [(j+1)v_{j+1} - (k-j+1)v_{j-1}] x^j, \tag{2.10}$$

where we assumed that $v_{-1} = v_{k+1} = 0$. The above expression vanishes for all $x \neq \pm i$, hence it vanishes for all x. This implies that

$$(j+1)v_{j+1} - (k-j+1)v_{j-1} = 0 \quad \text{for } j = 0, \ldots, k.$$

Putting $\boldsymbol{v} = [v_0, \ldots, v_k]^T$, we rewrite the above-noted equation in the form

$$M\boldsymbol{v} = \boldsymbol{0}, \quad \boldsymbol{v} = [v_0, \ldots, v_k]^T, \tag{2.11}$$

where $(k+1)\times(k+1)$ matrix M has the form

$$M = \begin{bmatrix} 0 & -1 & 0 & 0 & 0 & \ldots & 0 & 0 & 0 \\ k & 0 & -2 & 0 & 0 & \ldots & 0 & 0 & 0 \\ 0 & k-1 & 0 & -3 & 0 & \ldots & 0 & 0 & 0 \\ 0 & 0 & k-2 & 0 & -4 & \ldots & 0 & 0 & 0 \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ 0 & 0 & 0 & 0 & 0 & \ldots & -(k-2) & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \ldots & 0 & -(k-1) & 0 \\ 0 & 0 & 0 & 0 & 0 & \ldots & 2 & 0 & -k \\ 0 & 0 & 0 & 0 & 0 & \ldots & 0 & 1 & 0 \end{bmatrix}. \tag{2.12}$$

Its determinant is given by

$$\det M = \begin{cases} (k!!)^2 & \text{for odd } k \\ 0 & \text{otherwise.} \end{cases}$$

The above finishes the proof for odd k. When $k=2l$ for some $l \in \mathbb{N}$, then, as it is easy to show, the rank of matrix M is k. Hence, it has a one-dimensional kernel. This kernel is spanned by vector $\boldsymbol{v}^r = [v_0^r, \ldots, v_{2l}^r]^T$, where

$$v_{2i+1}^r = 0, \quad v_{2i}^r = \binom{l}{i}, \quad \text{for } i = 0, \ldots, l.$$

To finish the proof it is enough to notice that

$$(1+z^2)^{2l} = \sum_{i=0}^{2l} v_i^r z^i.$$

□

As it is well known a homogeneous polynomial $V \in \mathbb{C}^2[q_1, q_2]$ of degree k can be written uniquely as a product of linear forms

$$V = \prod_{i=1}^{k} (\alpha_i q_1 + \beta_i q_2), \tag{2.13}$$

where

$$|\alpha_i| + |\beta_i| \neq 0 \quad \text{for } i = 1, \ldots, k.$$

Thus, for $A \in \mathrm{PO}(2, \mathbb{C})$ we have

$$V_A = \prod_{i=1}^{k} (\alpha_i' q_1 + \beta_i' q_2), \tag{2.14}$$

where

$$[\alpha_i', \beta_i'] = [\alpha_i, \beta_i]A \quad \text{for } i = 1, \ldots, k.$$

If $\alpha_i^2 + \beta_i^2 = 0$ for $i = 1, \ldots, k$, then $V = V_{k,l}$ for some $l \in \{0, \ldots, k\}$. Assume that $V \neq V_{k,l}$. Then for some $i_0 \in \{0, \ldots, k\}$, we have $\alpha_{i_0}^2 + \beta_{i_0}^2 \neq 0$, and we can find $A \in \mathrm{PO}(2, \mathbb{C})$ such that $\beta_{i_0}' = 0$ or $\alpha_{i_0}' = 0$.

Proposition 2.4: Assume that a homogeneous potential of degree k is not exceptional, then it is equivalent to $V = q_1 \widetilde{V}$, *where* $\widetilde{V}$ *is a homogeneous polynomial of degree* $k-1$.

The above observation was made by Hietarinta in Ref. 16. The above proposition shows that we can assume that $v_k = 0$ in (2.4) if the potential is not exceptional. Additionally, a nonzero coefficient of the potential can be normalized to one, so an equivalent class of potentials depends at most on $k-1$ parameters.

In the literature concerning searches for integrable potentials it is customary to assume that we can always normalize a homogeneous potential in such a way that the coefficient of monomial $q_1 q_2^{k-1}$ vanishes, see, e.g., Ref. 37. But, generally this claim is wrong even if we exclude the exceptional potentials, see Ref. 11.

Remark 2.1: As it was shown in Ref. 16, exceptional potentials $V_{k,0}$, $V_{0,k}$, $V_{k-1,1}$, $V_{1,k-1}$, *and* $V_{k,k}$ *are integrable for all k. Nothing is known about the integrability of the remaining exceptional potentials.*

B. Darboux points

It is convenient to introduce the following auxiliary system:

$$\dot{q}_1 = -\gamma q_1 + \frac{\partial V}{\partial q_1}, \quad \dot{q}_2 = -\gamma q_2 + \frac{\partial V}{\partial q_2}, \quad \gamma \in \mathbb{C}^\star. \tag{2.15}$$

The Jacobian matrix of the right-hand sides of the above-noted system is

$$J(\boldsymbol{q}) = V''(\boldsymbol{q}) - \gamma E. \tag{2.16}$$

A Darboux point of potential V is a nonzero equilibrium of system (2.15). Moreover, if $\boldsymbol{d}$ is an equilibrium of (2.15), then the matrix of linearizations of (2.15) at $\boldsymbol{d}$ is

$$J(\boldsymbol{d}) = V''(\boldsymbol{d}) - \gamma E.$$

Hence, if $(\lambda\gamma, \gamma(k-1))$ are the eigenvalues of $V''(\boldsymbol{d})$, then the eigenvalues of $J(\boldsymbol{d})$ are $(\gamma\Lambda, \gamma(k-2))$, where $\Lambda = \lambda - 1$. Notice that

$$\Lambda = \frac{1}{\gamma}\mathrm{Tr}\, V''(\boldsymbol{d}) - k = \frac{1}{\gamma}\mathrm{Tr}\, J(\boldsymbol{d}) - (k-2). \tag{2.17}$$

We show that this quantity does not depend on a representative of the Darboux point and hence it is a well-defined function of a Darboux point. In fact, let $\boldsymbol{d}$ and $\widetilde{\boldsymbol{d}}$ represent the same Darboux point, i.e., $\boldsymbol{d} = \alpha\widetilde{\boldsymbol{d}}$ for some $\alpha \in \mathbb{C}^\star$. Thus we have

$$V'(\boldsymbol{d}) = \gamma\boldsymbol{d}, \quad V'(\widetilde{\boldsymbol{d}}) = \widetilde{\gamma}\widetilde{\boldsymbol{d}}, \quad \text{where } \widetilde{\gamma} = \frac{\gamma}{\alpha^{k-2}}.$$

As a consequence

$$\Lambda = \frac{1}{\gamma}\mathrm{Tr}\, V''(\boldsymbol{d}) - k = \frac{\alpha^{k-2}}{\gamma}\mathrm{Tr}\, V''(\widetilde{\boldsymbol{d}}) - k = \frac{1}{\widetilde{\gamma}}\mathrm{Tr}\, V''(\widetilde{\boldsymbol{d}}) - k.$$

Let us introduce new coordinates $x = q_1$ and $z = q_2/q_1$. In new variables Eq. (2.15) has the form

$$\dot{x} = -\gamma x + x^{k-1}h(z), \quad \dot{z} = x^{k-2}g(z), \tag{2.18}$$

where

$$h(z) = kv(z) - zv'(z), \quad g(z) = (1+z^2)v'(z) - kzv(z), \tag{2.19}$$
$$v(z) = V(1,z) = \sum_{i=0}^{k} v_{k-i}z^i.$$

Notice that $\deg g \leqslant k$ and $\deg h \leqslant k-1$. To express the coefficients of polynomials h and g in terms of coefficients of v, let us write

$$g(z) = \sum_{i=0}^{k} g_{k-i}z^i, \quad h(z) = \sum_{i=0}^{k-1} h_{k-1-i}z^i. \tag{2.20}$$

Then, from the definition of polynomials g and h we obtain

$$g_j = -(j+1)v_{j+1} + (k-j+1)v_{j-1}, \quad j = 0, \ldots, k, \tag{2.21}$$

and

$$h_j = (j+1)v_{j+1}, \quad j = 0, \ldots, k-1, \tag{2.22}$$

where we assumed that $v_{-1} = v_{k+1} = 0$. From the above it follows that $g_0 = -v_1$, and $h_0 = v_1$.

A direct inspection of the highest order terms of the right-hand sides of the definitions of g and h shows the following.

Proposition 2.5: Let us denote $l = \deg v$. *If* $l < k$, *then* $\deg g = l+1$ *and* $\deg h = l$. *If* $l = k$, *then* $\deg g \leqslant k$ *and* $\deg h \leqslant k-1$. *Moreover, if* $v_1 \neq 0$, *then* $\deg g = k$ *and* $\deg h = k-1$.

Proposition 2.6: If V is a homogeneous potential of degree k and $V \neq V_{l,l}$ *when* $k = 2l$, *then the number of Darboux points is finite and it is at most k.*

Proof: Darboux points $[q_1 : q_2]$ with $q_1 \neq 0$ are given by solutions (x,z), $x \neq 0$ of the following system:

$$x^{k-2}h(z) = \gamma, \quad x^{k-2}g(z) = 0. \tag{2.23}$$

Hence, their z coordinates are roots of $g(z)$. Thus their number is finite provided that $g \neq 0$. If $g = 0$, then solving differential equation (2.19) we find that $v(z) = \alpha(1+z^2)^{k/2}$, i.e., $V = \alpha(q_1^2 + q_2^2)^{k/2}$.

Let us note that we can always assume that for all Darboux points $q_1 \neq 0$. In fact, if $[0 : d_2]$, $d_2 \neq 0$, is a Darboux point, then

$$\frac{\partial V}{\partial q_1}(0, d_2) = v_1 d_2^{k-1} = 0.$$

But from Lemma 2.1 it follows that we can always assume that $v_1 \neq 0$. Hence, $d_2 = 0$. We have a contradiction.

By Proposition 2.5 the highest possible degree of g is k, and this is why the number of Darboux points cannot be greater than k. □

Corollary 2.1: For a generic homogeneous potential of degree k there exist k Darboux points.

It is important to underline that not all roots of $g(z)$ are Darboux points. Note that it can happen that $g(z)$ and $h(z)$ have a common root $z_\star$, and then for this $z = z_\star$ system (2.23) has no solution.

Proposition 2.7: Polynomials $g(z)$ *and* $h(z)$ *have a common root* $z_\star$ *if and only if* $z_\star$ *is a multiple root of* $v(z)$.

Proof: If $z_\star$ is a multiple root of $v(z)$, then $v(z_\star) = v'(z_\star) = 0$, and from (2.19) it follows that $g(z_\star) = h(z_\star) = 0$.

From (2.19) we have $zh(z)+g(z)=v'(z)$. Thus if $g(z_\star)=h(z_\star)=0$, then $v'(z_\star)=0$, but this, together with $h(z_\star)=0$, implies that $v(z_\star)=0$. Hence, $z_\star$ is a multiple root of $v(z)$. □

Now we want to check if there exists at least one Darboux point for a given potential. To this end it is important to know a relation between the multiplicities of common roots of polynomials v and g.

For a polynomial $p\in\mathbb{C}[z]$ by $\mathrm{mult}(p,z_\star)$ we denote the multiplicity of $p(z)$ at $z=z_\star$.

Let us assume that $v(z)=(z-z_\star)^l\tilde{v}(z)$ where $l\geqslant 1$ and $\tilde{v}(z_\star)\neq 0$. Then from the definition of g we obtain

$$g(z)=(z-z_\star)^{l-1}\{(1+z^2)[l\tilde{v}(z)+(z-z_\star)\tilde{v}'(z)]-kz(z-z_\star)\tilde{v}(z)\}. \tag{2.24}$$

Thus, $g(z)$ is divisible by $(z-z_\star)^{l-1}$. We have $g(z)=(z-z_\star)^{l-1}\tilde{g}(z)$ where

$$\tilde{g}(z)=(1+z^2)[l\tilde{v}(z)+(z-z_\star)\tilde{v}'(z)]-kz(z-z_\star)\tilde{v}(z).$$

This implies that

$$\tilde{g}(z_\star)=l(1+z_\star^2)\tilde{v}(z_\star).$$

But $\tilde{v}(z_\star)\neq 0$, hence, if $z_\star\neq\pm i$ we have $\tilde{g}(z_\star)\neq 0$, and the multiplicity of $z_\star$ as a root of g is $l-1$. Hence, we conclude with the following.

Proposition 2.8: Assume that $z_\star\neq\pm i$ *and* $l=\mathrm{mult}(v,z_\star)\geqslant 1$, *then* $\mathrm{mult}(g,z_\star)=l-1$.

Let $z_\star=i$, then instead of (2.24) we obtain

$$g(z)=(z-i)^l[l(z+i)\tilde{v}(z)+(1+z^2)\tilde{v}'(z)-kz\tilde{v}(z)]. \tag{2.25}$$

Thus $g(z)$ is divisible by $(z-i)^l$, so $g(z)=(z-i)^l\tilde{g}(z)$ where

$$\tilde{g}(z)=l(z+i)\tilde{v}(z)+(1+z^2)\tilde{v}'(z)-kz\tilde{v}(z). \tag{2.26}$$

Hence we have

$$\tilde{g}(i)=(2l-k)i\tilde{v}(i). \tag{2.27}$$

As we obtain similar relations for $z_\star=-i$, we can formulate the following proposition.

Proposition 2.9: Assume that $l=\mathrm{mult}(v,z_\star)\geqslant 1$ *for* $z_\star=\pm i$. *If* $2l=k$, *then* $\mathrm{mult}(g,z_\star)>l$ *else* $\mathrm{mult}(g,z_\star)=l$.

Applying a similar reasoning it is easy to prove the following proposition.

Proposition 2.10: If $l=\mathrm{mult}(v,z_\star)\geqslant 1$, *then* $\mathrm{mult}(h,z_\star)=l-1$.

Now, we are ready to characterize potentials without Darboux points more precisely.

Lemma 2.2: If potential V *of degree* $k>2$ *does not have Darboux points, then all its linear factors are multiple. Moreover,* $V=V_{k,l}$ *for some* $l=2,\ldots,k-1$, *except for the case when* $k=2l$ *and* V *has a factor* $(q_2\pm iq_1)$ *with multiplicity* l.

Proof: By Proposition 2.7, if potential V has no Darboux points, then all roots of polynomial v are multiple and all of them are roots of polynomials g and h. Moreover, the only roots of g are those of v.

We have to prove only the second part of the proposition. By Lemma 2.1 we can assume that $v_1\neq 0$, and hence $\deg v=k-1$ or $\deg v=k$. Moreover, under this assumption $\deg g=k$, see Proposition 2.5. Polynomial v can be written in the form

$$v=\alpha\prod_{i=1}^{s}(z-z_i)^{l_i},\quad \sum_{i=1}^{s}l_i=m\in\{k-1,k\},$$

where integers $l_i>1$, for $i=1,\ldots,s$. By assumption, the only roots of g are z_i, so we can write it in the following form:

$$g = \beta \prod_{i=1}^{s} (z - z_i)^{n_i}, \quad \sum_{i=1}^{s} n_i = k,$$

where integers $n_i > 0$ for $i = 1, \ldots, s$. If $z_i \neq i$, then, by Proposition 2.8, $n_i = l_i - 1$, and we have

$$k = \sum_{i=1}^{s} n_i = \sum_{i=1}^{s} l_i - s = m - s,$$

and this is only possible when $s = 0$. Hence, among z_i we must have one or two equal to $\pm i$. Let us put $z_{s-1} = i$ and $z_s = -i$. For even k we assume that $l_{s-1} \neq k/2$ and $l_{s-1} \neq k/2$. Then, by Proposition 2.9, we have $n_{s-1} = l_{s-1}$ and $n_s = l_s$. Thus we obtain

$$k = \sum_{i=1}^{s} n_i = \sum_{i=1}^{s} l_i - (s - 2) = m + 2 - s.$$

So, $k - m = 2 - s \geqslant 0$, and hence there are at most two roots of v which are $\pm i$. □

In a case when $\pm i$ is a root of v with multiplicity $k/2$, as two examples in the following show, there exist potentials $V \neq V_{k,l}$ without a Darboux point.

Example 1:

$$V = (q_2 - iq_1)^2 (q_2 - aq_1)^2, \quad a \neq -i, \tag{2.28}$$

then

$$v(z) = (z - i)^2 (z - a)^2, \quad g(z) = 2(a + i)(z - a)(z - i)^3.$$

Thus, in fact, the above potential does not have any Darboux point for an arbitrary $a \neq \mp i$.

Example 2: Potential

$$V = (q_2 - iq_1)^4 (q_2 - aq_1)^2 (q_2 - bq_1)^2$$

has no Darboux points provided $ab = -1$ or $a = b$.

Thus, one parameter families of potentials without Darboux points can appear. This is not incidental—it can be proved that potentials of even degree k with factor $(q_2 \pm iq_1)^{k/2}$ and without Darboux points form at most one parameter families.

To determine the position of Darboux points for a given potential of degree $k > 2$ we have to solve a polynomial equation of degree k. Thus it seems that in a general case when $k > 4$ there are no analytical tools to study the integrability by means of Darboux points. We show that it is not like that.

Lemma 2.3: For odd $k > 2$, *the roots of polynomial* g *determine polynomial* v *uniquely up to a multiplicative constant*.

Proof: Without any loss of the generality we can assume that $\deg g = k$. Let z_i for $i = 1, \ldots, k$ be roots of g. To prove our lemma, we need to show that coefficients of polynomial v are uniquely determined by coefficients of polynomial g. For an arbitrary k we have relation (2.21) which can be rewritten as a system of linear equations

$$\boldsymbol{g} = M\boldsymbol{v}, \quad \boldsymbol{g}^T = [g_0, \ldots, g_k], \quad \boldsymbol{v}^T = [v_0, \ldots, v_k],$$

where matrix M is given by (2.12). As we know that for odd k $\det M \neq 0$, this finishes the proof.□

Corollary 2.2: For odd degree k, *the positions of* k *Darboux points of a potential determine this potential uniquely up to a multiplicative constant.*

For even k the rank of matrix M is k. Hence, for even k we have one parameter families of potentials having the same Darboux points. The reason for this fact is obvious if we notice that at a Darboux point the gradient of the potential is parallel to the radius vector. Hence, for even k potential V and $V + \alpha(q_1^2 + q_2^2)^{k/2}$ have the same Darboux points.

C. Necessary conditions for integrability

Now, we want to define a function $\Lambda:\mathbb{CP}^1\to\mathbb{C}$ which for a Darboux point with coordinate z gives $\Lambda(z)$—the eigenvalue defined by (2.17) for this point.

The Jacobian matrix of the right-hand sides of (2.18) has the form

$$J=\begin{bmatrix} -\gamma+(k-1)x^{k-2}h(z) & x^{k-1}h'(z) \\ (k-2)x^{k-3}g(z) & x^{k-2}g'(z) \end{bmatrix}, \tag{2.29}$$

hence

$$\frac{1}{\gamma}\mathrm{Tr}\,J-(k-2)=(1-k)\gamma+x^{k-2}[(k-1)h(z)+g'(z)].$$

The above quantity, when evaluated at a Darboux point, is equal to the eigenvalue defined by (2.17). To eliminate x from the above expression we notice that at a Darboux point we have

$$x^{k-2}=\frac{\gamma}{h(z)}.$$

The above considerations lead to the following definition of $\Lambda(z)$:

$$\Lambda(z)=\frac{g'(z)}{h(z)}. \tag{2.30}$$

Notice that if $z_\star$ is a multiple Darboux point, then $\Lambda(z_\star)=0$.

On the projective line $\mathbb{CP}^1$, where Darboux points are located, we define a meromorphic differential form ω which in coordinate z is given by

$$\omega=\frac{h(z)}{g(z)}\mathrm{d}z, \tag{2.31}$$

and in coordinate $\zeta=1/z$ by

$$\omega=-\frac{h(1/\zeta)}{g(1/\zeta)}\frac{\mathrm{d}\zeta}{\zeta^2}. \tag{2.32}$$

Let us denote by $\hat{\mathcal{V}}_{k,l}$ a set of homogeneous potentials of degree k which satisfy the following conditions:

C1: potential $V\in\hat{\mathcal{V}}_{k,l}$ has $0<l\leqslant k$ simple Darboux points, and

C2: if $(\pm iq_1+q_2)$ is a linear factor of V, then it has multiplicity 1.

We prove the following.

Theorem 2.1: *For $V\in\hat{\mathcal{V}}_{k,l}$ the following relation holds true:*

$$\sum_{i=1}^{l}\frac{1}{\Lambda_i}=-1. \tag{2.33}$$

Proof: For a given potential $V\in\hat{\mathcal{V}}_{k,l}$ we choose such a representative that $v_1\neq 0$. Then all its Darboux points are located in the affine part of $\mathbb{CP}^1$, and $\deg g=k$ and $\deg h=k-1$. Let z_i, for $i=1,\ldots,k$, denote roots of polynomial g. First we consider the case $l=k$. By assumption all roots of g are simple and, moreover, polynomials g and h are relatively prime. We put $\Lambda_i=\Lambda(z_i)$ for $i=1,\ldots,k$. The residue of ω at z_i for $i=1,\ldots,k$ is given by

$$\operatorname{res}(\omega, z_i) = \frac{h(z_i)}{g'(z_i)} = \frac{1}{\Lambda_i}. \tag{2.34}$$

Moreover, the residue of ω at infinity is

$$\operatorname{res}(\omega, \infty) = -\frac{h_0}{g_0} = 1. \tag{2.35}$$

Thus, by the Residue Theorem[28] we prove the theorem for $l=k$.

If $l<k$ we can assume that first l roots of g are simple and they are the Darboux points, and we put again $\Lambda_i=\Lambda(z_i)$ for $i=1,\ldots,l$. But now polynomials g and h are not relatively prime. Let p be a monic common factor of g and h. Then we can write $g=pg_1$ and $h=ph_1$ where g_1 and h_1 are relatively prime. We show that $\deg p=k-l$. In fact, $h(z_\star)=g(z_\star)=0$ if and only if $z_\star \in \{z_{l+1},\ldots,z_k\}$. By Proposition 2.7 $z_\star$ is also a multiple root of v. It is important to notice that $z_\star \neq \pm i$ by condition C2. So, from Propositions 2.8 and 2.9 we deduce that $\operatorname{mult}(g,z_\star) = \operatorname{mult}(h,z_\star)$. This proves our claim that $\deg p=k-l$.

Thus, we have

$$\omega = \frac{h(z)}{g(z)}\mathrm{d}z = \frac{h_1(z)}{g_1(z)}\mathrm{d}z, \tag{2.36}$$

and all finite poles of this form are Darboux points z_i, $i=1,\ldots,l$. Moreover

$$\frac{1}{\Lambda_i} = \frac{h(z_i)}{g'(z_i)} = \frac{p(z_i)h_1(z_i)}{p'(z_i)g_1(z_i)+p(z_i)g_1'(z_i)} = \frac{h_1(z_i)}{g_1'(z_i)} = \operatorname{res}(\omega, z_i), \tag{2.37}$$

for $i=1,\ldots,l$, and $\operatorname{res}(\omega,\infty)=1$. This finishes the proof. □

For each $V \in \hat{\mathcal{V}}_{k,l}$ we have properly defined a collection $\mathbf{\Lambda}_V=\{\Lambda_1,\ldots,\Lambda_l\}$. Let $\mathcal{L}_{k,l}$ denote a set of all $\mathbf{\Lambda}_V$, for $V \in \hat{\mathcal{V}}_{k,l}$, and $\mathcal{I}_{k,l}$ a set of those elements of $\mathcal{L}_{k,l}$ which correspond to the integrable potentials. Our main result in this section is formulated in the following theorem.

Theorem 2.2: *For all $k>2$ sets $\mathcal{I}_{k,l}$ for $l=1,\ldots,k$ are at most finite.*

Proof: For a potential $V \in \mathcal{V}_{k,l}$ its Darboux points are simple, hence $\Lambda_i \neq 0$ for $i=1,\ldots,l$. Thus, we can introduce quantities $X_i=1/\Lambda_i$. Using them we rewrite (2.33) in the form

$$\sum_{i=1}^{l} X_i = -1. \tag{2.38}$$

If the system is integrable, then, according to Theorem 1.1, each Λ_i belongs to a certain infinite set I_k for $i=1,\ldots,l$. From the list given in the thesis of Theorem 1.1 we deduce that sets I_k have the following properties:

1. $I_k=\{a_n^{(k)} \in \mathbb{Q}\setminus\{0\} \,|\, a_n^{(k)} > -1, n \in \mathbb{N}\}$,
2. for each k the sequence $\{a_n^{(k)}\}$ has only one accumulation point at infinity.

Hence X_i belong to a set $\mathcal{X}_k$ with the properties

1. $\mathcal{X}_k=\{x_n^{(k)} \in \mathbb{Q}\setminus\{0\} \,|\, x_n^{(k)} \in (-\infty,-1)\cup(0,\infty), n \in \mathbb{N}\}$.
2. For each k the sequence $\{x_n^{(k)}\}$ has only one accumulation point at 0. In particular, for each k only a finite number of $x_n^{(k)}$ take negative values not greater than -1.

From relation (2.38) it follows that at least one of X_i is negative. However, if X_i is negative, then it is not greater than -1. Hence, not all of X_i are negative. So assume that X_i for $i=m+1,\ldots,l$ are negative for some $0<m<l$. There is only finitely many choices for $X_{m+1},\ldots,X_l$. For each of them we can rewrite relation (2.38) in the form

$$\sum_{i=1}^{m} X_i = c > 0. \tag{2.39}$$

But by Lemma B.1, the above equation has at most a finite number of solutions $(X_1,\ldots,X_m) \in \mathcal{X}_k^m$. As we have finitely many possibilities for a choice of m, this finishes the proof. □

It is important to remark that these potentials $V \in \mathcal{V}_{k,l}$ for which $\mathbf{\Lambda}_V \in \mathcal{I}_{k,l}$ satisfy only the necessary conditions for integrability of Theorem 1.1 thus, not all of them are integrable.

A natural question appears: what happens when a potential V has a multiple Darboux point? To answer it let us rewrite (2.33) in the following form:

$$\sum_{i=1}^{l} \prod_{\substack{j=1 \\ j\neq i}}^{l} \Lambda_j = -\prod_{j=1}^{l} \Lambda_j. \tag{2.40}$$

Assume now that two Darboux points, let us say z_{l-1} and z_l, coincide, and $h(z_l)\neq 0$. Then, from (2.30), we have immediately that $\Lambda_{l-1}=\Lambda_l=0$. But when Λ_l and Λ_{l-1} tend to 0, then both sides of (2.40) vanish and hence, in such a case, Λ_i for $i=1,\ldots,l-2$ can be arbitrary. Hence, condition C1 imposed on potentials in Theorem 2.1 cannot be weakened.

The following example shows that condition C2 cannot be weakened either.

Example 3: Let

$$V = (q_2 - iq_1)^2(q_2 - aq_1), \quad a \neq \pm i.$$

For this potential we have

$$v = (z-i)^2(z-a), \quad g = (z-i)^2[(a+2i)z + 1 - 2ia], \quad h = -(z-i)[(a+2i)z - 3ia].$$

Thus, if $a\neq -2i$, then $z_\star=(2ia-1)/(a+2i)$ is the only simple Darboux point. It is easy to check that for this point we have $\Lambda(z_\star)=1$. Hence, for the considered potential, relation (2.33) is not valid, but, of course, it is not a counterexample for Theorem 2.1 as $V\notin \hat{\mathcal{V}}_{3,1}$. In fact, one can show that $\hat{\mathcal{V}}_{3,1}=\emptyset$.

The above example shows, among others, the need for a more careful investigation of condition C2.

Assume that potential V of degree k contains a linear factor (q_2-iq_1) with multiplicity $r>1$, $r\neq k/2$, but, if V has also a factor (q_2+iq_1), then its multiplicity is one. Moreover, we assume that V has the maximal number $l=k-r$ of simple Darboux points. For such potential we have

$$v = (z-i)^r \tilde{v}(z),$$

where $\tilde{v}(z)$ has only simple roots. By the results of Sec. II B, we also have

$$g = (z-i)^r \tilde{g}(z), \quad h = (z-i)^{r-1}\tilde{h}(z),$$

where

$$\tilde{g}(z) = [(r-k)z + ir]\tilde{v}(z) + (1+z^2)\tilde{v}'(z),$$

$$\tilde{h}(z) = [(k-r)z - ik]\tilde{v}(z) - z(z-i)\tilde{v}'(z),$$

and polynomials $\tilde{g}(z)$ and $\tilde{h}(z)$ are relatively prime and $h(i)\neq 0$. Hence, we have

$$\omega = \frac{h(z)}{g(z)}\mathrm{d}z = \frac{\widetilde{h}(z)}{g_1(z)}\mathrm{d}z, \quad g_1(z) = (z-i)\widetilde{g}(z).$$

Now, if z_i, for $i=1,\ldots,k-r$, denote the Darboux points, then, by the same arguments as in the proof of Theorem 2.1, we have

$$\mathrm{res}(\omega, z_i) = \frac{1}{\Lambda_i}.$$

But now, differential form ω has one additional simple pole at $z=i$. The residue of ω at this point is equal to

$$\mathrm{res}(\omega, i) = \frac{\widetilde{h}(i)}{g_1'(i)}.$$

But

$$g_1'(z) = \widetilde{g}(z) + (z-i)\widetilde{g}'(z),$$

so

$$g_1(i) = \widetilde{g}(i) = i(2r-k)\widetilde{v}(i).$$

As $\widetilde{h}(i) = -ir\widetilde{v}(i)$, we have

$$\mathrm{res}(\omega, i) = \frac{r}{k-2r}.$$

The residue of ω at infinity is 1, hence, invoking the Residue Theorem, we obtain the following relation:

$$\sum_{i=1}^{l} \frac{1}{\Lambda_i} = -1 - \frac{r}{k-2r}. \tag{2.41}$$

One can notice that in the above reasoning we can drop the assumption that the number of Darboux points is maximal, provided that if V has the factor (q_2+iq_1), then it has multiplicity one.

We can apply formula (2.41) to the potential from Example 3. For $k=3$, $l=1$ and $r=2$ from (2.41) we have $\Lambda_1=1$, i.e., exactly what we obtained by direct calculation.

The above considerations show that we can strengthen considerably our results modifying condition C2. Thus, instead of $\hat{\mathcal{V}}_{k,l}$, we define a bigger class of potentials $\mathcal{V}_{k,l}$. A homogeneous potential V belongs to $\mathcal{V}_{k,l}$ iff it satisfies two conditions:

V1: V has $0<l\leqslant k$ simple Darboux points, and

V2: if $(q_2\pm iq_1)$ is a linear factor of V, then its multiplicity is not $k/2$.

For $x,y\in\mathbb{R}$ we define

$$\theta_{x,y} := \begin{cases} 0 & \text{for } x<y, \\ 1 & \text{for } x\geqslant y. \end{cases}$$

The following theorem is a generalization of Theorem 2.1.

Theorem 2.3: *Let $V\in\mathcal{V}_{k,l}$, and $r_\pm$ be the respective multiplicities of linear factors $(q_2\pm iq_1)$ of V. Then*

$$\sum_{i=1}^{l} \frac{1}{\Lambda_i} = -1 - \theta_{r_+,2}\frac{r_+}{k-2r_+} - \theta_{r_-,2}\frac{r_-}{k-2r_-}. \tag{2.42}$$

Proof: We have already proved this theorem for a case when r_+ or r_- is smaller than 2. Thus

let us assume that $r_\pm \geqslant 2$. Under this assumption, for a potential V, we have

$$v = (z-i)^{r_+}(z+i)^{r_-}\tilde{v}(z),$$

where $\tilde{v}(z)$ is not divisible by $(z \pm i)$. Moreover, we also have

$$g = (z-i)^{r_+}(z+i)^{r_-}\tilde{g}(z), \quad h = (z-i)^{r_+-1}(z+i)^{r_--1}\tilde{h}(z),$$

where

$$\tilde{g}(z) = (z^2+1)\tilde{v}'(z) + [z(r_+ + r_- - k) + i(r_+ - r_-)]\tilde{v}'(z),$$

$$\tilde{h}(z) = [z^2(k - r_+ - r_-) + z(r_- - r_+) + k]\tilde{v}(z) - z(z^2+1)\tilde{v}'(z).$$

Let us assume for simplicity that the number of Darboux points is maximal, i.e., $l = k - r_+ - r_-$. Now, the differential form ω can be written as

$$\omega = \frac{h(z)}{g(z)}\mathrm{d}z = \frac{\tilde{h}(z)}{g_1(z)}\mathrm{d}z, \quad g_1(z) = (z^2+1)\tilde{g}(z),$$

where $\tilde{h}(z)$ and $g_1(z)$ are relatively prime. The only poles ω are all Darboux points z_i, the infinity and $\pm i$. Notice that

$$\tilde{h}(\pm i) = 2r_\pm \tilde{v}(\pm i),$$

and

$$g_1'(\pm i) = \pm 2i\tilde{g}(\pm i) = 2(k - 2r_\pm)v(\pm i).$$

Hence, we have

$$\mathrm{res}(\omega, \pm i) = \frac{r_\pm}{k - r_\pm}.$$

As the residue of ω at a Darboux point z_i is $1/\Lambda_i$, and at infinity it is 1, we have formula (2.42). We analyze a case when the number of Darboux points is smaller than maximal similarly as in the proof of Theorem 2.1. □

For $\mathcal{V}_{k,l}$, we keep the definitions of sets $\mathcal{L}_{k,l}$ and $\mathcal{I}_{k,l}$. An easy modification of the proof of Theorem 2.2 allows one to formulate the following.

Corollary 2.3: The thesis of Theorem 2.2 is valid for classes of potentials $\mathcal{V}_{k,l}$.

It is not difficult to write a general algorithm allowing one to find all elements of sets $\mathcal{I}_{k,l}$. Relation (2.33), or (2.42) gives a strong restriction, and sets $\mathcal{I}_{k,l}$ contain only a few elements. We analyzed case $k=3$ in detail in Ref. 23. As it was shown in that paper set $\mathcal{I}_{3,3}$ contains only four elements

$$\mathcal{I}_{3,3} = \{\{-1,-1,1\}\{-2/3,4,4\},\{-7/8,14,14\},\{-2/3,7/3,14\}\}.$$

For further usage, we determined set $\mathcal{I}_{4,4}$. It has five elements listed in Table I. Moreover, we find that $\mathcal{I}_{4,3} = \mathcal{I}_{4,2} = \emptyset$.

Remark 2.2: One can ask if there exists a relation of the form (2.42) *for a potential of degree $k=2l$ with a factor $(q_2 - iq_1)^l$. For such case we can try to calculate the residue of form ω at $z = i$, however, this residue depends on the coefficients of the potential.*

TABLE I. Elements of set $\mathcal{I}_{4,4}$.

Element	$\{\Lambda_1,\Lambda_2,\Lambda_3,\Lambda_4\}$
1	$\{-1,-1,2,2\}$
2	$\{-5/8,5,5,5\}$
3	$\{-5/8,2,20,20\}$
4	$\{-5/8,27/8,27/8,135\}$
5	$\{-5/8,2,14,35\}$

D. Reconstruction of the potential

When we try to apply the results obtained in Sec. II C for an investigation of potential of a given degree we meet the following problem: how to determine the coefficients of the potential knowing $\{\Lambda_1,\ldots,\Lambda_l,\}\in\mathcal{I}_{k,l}$.

A possible approach to this problem is the following. Let us assume a generic situation: potential V of degree k has the maximal number of simple Darboux points. Let z_i and Λ_i denote their coordinates and eigenvalues, for $i=1,\ldots,k$. Then, points (z_i,Λ_i) are contained in an algebraic subset $\mathcal{D}$ of $\mathbb{C}^2$ defined by zeros of two polynomials $g,f\in\mathbb{C}[z,\Lambda]$:

$$g(z)=0,\quad f(z,\Lambda):=h(z)\Lambda-g'(z)=0. \tag{2.43}$$

If by $I=\langle g,f\rangle$ we denote the ideal in $\mathbb{C}[z,\Lambda]$ generated by g and f, then $\mathcal{D}$ is just an algebraic variety associated with this ideal, i.e., in the algebraic geometry notation $\mathcal{D}=\mathbf{V}(I)$. Under our genericity assumption, the resultant $G=R(g,f,z)\in\mathbb{C}[\Lambda]$ of g and f with respect to z does not vanish, and $\deg G\leqslant k$. Moreover, by the extension theorem, see Ref. 8, Chap. 3, for each root $\Lambda_\star$ of G there exits $z_\star$ such that $(z_\star,\Lambda_\star)\in\mathcal{D}$. On the other hand, if $z_\star$ is a Darboux point and $\Lambda_\star$ the corresponding eigenvalue, then $\Lambda_\star$ is a root of the resultant G. Hence, $\{\Lambda_1,\ldots,\Lambda_k\}$ are roots of the resultant G.

The above observation allows one to investigate the general case when coefficients of polynomial V are unspecified. Again we make the assumption that there exists the maximal number of Darboux points, and without loss of generality we put $v_1=-1$. Then $g,f\in\mathbb{C}[z,\Lambda,v_0,v_2,\ldots,v_k]$, and $\mathcal{D}\subset\mathbb{C}^{k+2}$. The resultant $G=R(g,f,z)$ is an element of $\mathbb{C}[\Lambda,v_0,v_2,\ldots,v_k]$, and $\deg_\Lambda G\leqslant k$, but using the genericity arguments we can assume that $\deg_\Lambda G=k$. If we write

$$G=\sum_{m=0}^{k}G_{k-m}\Lambda^m,$$

where $G_m\in\mathbb{C}[v_0,v_2,\ldots,v_k]$ for $m=0,\ldots,k$, then the basic symmetric polynomials τ_m of $(\Lambda_1,\ldots,\Lambda_k)$ are given by the well-known formulas:

$$\tau_m=(-1)^m\frac{G_m}{G_0}\in\mathbb{C}(v_0,v_2\ldots,v_k),\quad m=1,\ldots,k. \tag{2.44}$$

When $(\Lambda_1,\ldots,\Lambda_k)$ is given, then we have to solve the above equations for unknown $(v_0,v_2,\ldots,v_k)$.

Notice that $(\Lambda_1,\ldots,\Lambda_k)$ is not an arbitrary point in $\mathbb{C}^n$. According to our assumptions, relation (2.33) is satisfied and this implies that $\tau_k=-\tau_{k-1}$, see (2.40). Hence, among all equations (2.44) only $k-1$ are independent. As we have k unknowns, the solutions of these equations generically form one parameter families. But we know that the equivalent potentials have the same eigenvalues. Thus we can choose a representative in each class of equivalent potentials. e.g., fixing the value of one coefficient. Then, solving (2.44) we obtain at most a finite number of solutions.

The above ideas need modifications when the number of Darboux points is smaller than maximal. We do not discuss this question here, but an example of such an analysis is given in the next section.

Theorems 2.1 and 2.3 cannot be applied in a case when the investigated potential has a non-simple Darboux point. Let us describe such potentials.

Proposition 2.11: If a homogeneous potential V has a multiple Darboux point $z_\star \in \mathbb{CP}^1$, then $z_\star \neq \pm i$.

Proof: If i is a Darboux point, then $v(i)=0$, see (2.19). Hence, $v(z)=(z-i)\tilde{v}(z)$, and, moreover, $\tilde{v}(i)\neq 0$, for otherwise i is not a Darboux point. Hence, $\mathrm{mult}(v,i)=1$, and, by Proposition 2.9, $\mathrm{mult}(g,i)=1$, so i is a simple Darboux point. □

By the above proposition, if V has a multiple Darboux point, we can assume that it is located in an arbitrary point of $\mathbb{CP}^1$, except points $\pm i$. If we locate it at $z=0$, then $g(z)$ has a root at this point with multiplicity greater than one and $h(0)\neq 0$. Thus,

$$g_k = v_{k-1} = 0, \quad g_{k-1} = -kv_k + 2v_{k-2} = 0, \quad h_{k-1} = kv_k \neq 0.$$

Hence we can formulate the following proposition.

Proposition 2.12: If a homogeneous potential of degree $k>2$ has a nonsimple Darboux point, then it is equivalent to the following one:

$$V = \sum_{i=1}^{k} v_{k-i} q_1^{k-i} q_2^i, \quad \textit{where} \quad v_{k-1}=0, \quad v_{k-2}=\frac{k}{2}v_k, \quad v_k \neq 0. \tag{2.45}$$

Thus, in the space of all homogeneous potentials of degree k those with a multiple Darboux point are contained in a hyperplane of codimension two.

E. A case when the number of Darboux points is not maximal

If a potential does not have the maximal number of Darboux points, then, as we showed, it has a linear factor $(\alpha q_1+\beta q_2)$ with multiplicity $l>1$. By a generic potential without the maximal number of Darboux points we understand a potential for which $l=2$, i.e., when we have the smallest possible degeneration, and additionally, $\alpha^2+\beta^2\neq 0$. The aim of this section is to show that such potentials are not integrable, or, more precisely, Hamiltonian system (1.2) does not admit an additional *rational* first integral.

If V is a generic potential without the maximal number of Darboux points, then we can assume that it has the form

$$V = q_2^2 \tilde{V}(q_1, q_2), \tag{2.46}$$

where $\deg \tilde{V}=k-2$ and $\tilde{V}(q_1,0)\neq 0$.

Theorem 2.4: *Hamiltonian system* (1.2) *with potential* (2.46) *does not admit an additional rational first integral.*

Proof: Equations of motion have the following form:

$$\begin{aligned} \dot{q}_1 &= p_1, \quad \dot{p}_1 = -q_2^2 \frac{\partial \tilde{V}}{\partial q_1}, \\ \dot{q}_2 &= p_2, \quad \dot{p}_2 = -q_2^2 \frac{\partial \tilde{V}}{\partial q_2} - 2q_2\tilde{V}. \end{aligned} \tag{2.47}$$

Hence, they admit the following particular solution:

$$q_1(t) = At + B, \quad p_1(t) = A, \quad q_2(t) = p_2(t) = 0, \tag{2.48}$$

where $A, B \in \mathbb{C}$. The variational equations for this solution have the form

$$\ddot{x}_1 = 0, \quad \ddot{x}_2 = -2\widetilde{V}(q_1(t),0)x_2, \tag{2.49}$$

and the second one is the normal variational equation. According to our assumption $\widetilde{V}(q_1,0) \neq 0$, we have

$$\widetilde{V}(q_1(t),0) = C(At+B)^{k-2}, \quad C \neq 0. \tag{2.50}$$

We fix $B=0$ and take A such that $2CA^{k-2}=-1$. Then the normal variational equation reads

$$\ddot{x} = t^m x, \quad m = k-2 > 0. \tag{2.51}$$

For this equation the infinity is the only singular point and it is an irregular singularity. We show that for an arbitrary $m>0$ this equation has no Liouvillian solutions, and, hence its differential Galois group is $\mathrm{SL}(2,\mathbb{C})$. To this end we apply the Kovacic algorithm[18] which is formulated for an equation $\ddot{x}=rx$ with an arbitrary rational $r=r(t)$. Three cases are distinguished in this algorithm. For Eq. (2.51) only Case 1 is possible. For an odd m the necessary conditions for the existence of a Liouvillian solution, given in Ref. 18 (Theorem, p. 8) are not satisfied. This proves our claim for odd m. When $m=2l$ is even we have to pass the first step of the algorithm for Case 1. According to it, we have to calculate the following numbers:

$$\alpha_\infty^\pm = \frac{1}{2}\left(\pm\frac{b}{a} - \nu\right), \tag{2.52}$$

where a, b, and ν are defined as follows. Let us expand $\sqrt{r}$ into the Laurent series at infinity, and let

$$[\sqrt{r}]_\infty = at^\nu + \cdots + d,$$

be the indicated part of this series. So, for our case $\nu=l$ and $a=1$. Number b is the coefficient of $t^{\nu-1}$ in $r-[\sqrt{r}]_\infty^2$. Hence in our case $b=0$, and thus $\alpha_\infty^\pm = -l/2 < 0$. But this, according to the next step of the algorithm, implies that the considered equation does not pass the algorithm for Case 1. As it is the only possible case, this proves our claim.

Thus the differential Galois group of the normal variational equation (2.51) is $\mathrm{SL}(2,\mathbb{C})$, so it is not Abelian. By Theorem 4.3 from Ref. 30 this shows that the considered Hamiltonian system does not admit an additional rational first integral. □

III. APPLICATION: INTEGRABLE POTENTIALS OF DEGREE FOUR

When $k=4$ all exceptional potentials are integrable with a polynomial additional first integral. Thus, we exclude them from our consideration. Moreover, according to Ref. 11, those potentials from which we cannot remove monomial $q_1q_2^3$ using a rotation are also integrable. Hence, we can assume that the potential has the form

$$V = \tfrac{1}{4}\widetilde{a}q_1^4 + \tfrac{1}{3}bq_1^3q_2 + \tfrac{1}{2}cq_1^2q_2^2 + \tfrac{1}{4}\widetilde{d}q_2^4 = \tfrac{1}{4}aq_1^4 + \tfrac{1}{3}bq_1^3q_2 + \tfrac{1}{4}dq_2^4 + \tfrac{1}{4}c(q_1^2+q_2^2)^2, \tag{3.1}$$

where

$$\widetilde{a} = a + c, \quad \widetilde{d} = d + c.$$

We put $z=q_2/q_1$. Then polynomial $v(z)=V(1,z)$ has the form

$$v(z) = \tfrac{1}{4}a + \tfrac{1}{3}bz + \tfrac{1}{4}dz^4 + \tfrac{1}{4}c(1+z^2)^2.$$

For this v, polynomials g and h, see (2.19), are the following:

$$g(z) = \tfrac{1}{3}b - az - bz^2 + dz^3, \quad h(z) = a + c + bz + cz^2. \tag{3.2}$$

Notice that if $c+d\neq 0$, then $q_1=0$, $q_2=1/\sqrt{c+d}$ is the only Darboux point with the first coordinate equal to zero. For this point its z coordinate is infinity. We denote $z_0=\infty$. Direct calculations show that for this point we have $\Lambda_0=-d/(c+d)$. Thus z_0 is a multiple Darboux point if $d=0$ and $c\neq 0$.

Our further analysis is divided into three steps. First, we distinguish those parameters' values for which V given by (3.1) does not have any Darboux points or has a multiple Darboux point. When a potential has no Darboux points Theorem 1.1 cannot be applied. When a potential has a multiple Darboux point, then neither Theorem 2.1 nor Theorem 2.3 can be used. It appears that the case when the potential has only one simple Darboux point is very peculiar. In the next step, we distinguish potentials with more than one simple Darboux point such that for them $\{\Lambda_1,\ldots,\Lambda_l\}\in\mathcal{I}_{4,l}$ for $l=2,3,4$. In this way we obtain a list of the distinguished potentials for which the necessary conditions of Theorem 1.1 for the integrability are satisfied. In the last step of our analysis, we apply the higher order variational equations for a study of the integrability of the distinguished potentials. Sections III A–III C correspond to the described steps.

A. Special cases

First, we distinguish potentials (3.1) which do not have Darboux points, as for them Theorem 1.1 is not applicable.

Proposition 3.1: Potential (3.1) *has no Darboux point if and only if it is equivalent to*

$$V_0 = \alpha(q_2 - iq_1)^2 q_2^2, \quad \alpha\in\mathbb{C}^\star. \tag{3.3}$$

Proof: Assume that potential (3.1) has no Darboux point. Then, in particular there is no Darboux point at infinity, so $c=-d$. Then we have

$$v(z) = \tfrac{1}{4}(a-d) + \tfrac{1}{3}bz - \tfrac{1}{2}dz^2.$$

By Lemma 2.2, $v(z)$ must have only multiple factors, so necessarily $d\neq 0$, and

$$2b^2 + 9(a-d)d = 0.$$

Then we can rewrite $v(z)$ in the following form:

$$v(z) = -\frac{1}{2}d(z-z_\star)^2, \quad z_\star = \frac{b}{2d},$$

and this gives

$$g(z) = d(z-z_\star)(z^2 - 2z_\star z - 1).$$

But the only root of g can be $z_\star$, and thus $z_\star=\pm i$. Both choices of $z_\star$ give a potential equivalent to (3.3). □

Our next attempt is to decide whether (3.1) has exactly one simple Darboux point.

Proposition 3.2: Potential (3.20) has exactly one simple Darboux point iff it is equivalent to

$$V_1 = \alpha q_2^4, \quad \alpha\in\mathbb{C}^\star, \tag{3.4}$$

or

$$V_2 = \tfrac{1}{2}\alpha q_1^2(q_1+iq_2)^2 + \tfrac{1}{4}(q_1^2+q_2^2)^2, \quad \alpha\in\mathbb{C}^\star. \tag{3.5}$$

Proof: If $z=\infty$ is the only simple Darboux point of potential (3.1), then $c+d\neq 0$. Moreover, we have $d\neq 0$, for otherwise the infinity is a double Darboux point. Thus $\deg g=3$, and $\deg h\leqslant 2$. None of the roots of g is a Darboux point, so h has at least one root. The only roots of g are those of polynomial h, hence we can write

$$g(z) = d(z - z_1)(z - z_2)^2. \tag{3.6}$$

A comparison with (3.2) gives the following identities:

$$b + 3dz_1z_2^2 = 0, \quad a + dz_2(2z_1 + z_2) = 0, \quad b - d(z_1 + 2z_2) = 0. \tag{3.7}$$

As z_1 and z_2 are roots of h, thus we have two more equations

$$a + c + bz_1 + cz_1^2 = 0, \quad a + c + bz_2 + cz_2^2 = 0. \tag{3.8}$$

Subtracting them we obtain

$$(z_1 - z_2)[b + c(z_1 + z_2)] = 0. \tag{3.9}$$

If $z_1 = z_2$, then from (3.7) we obtain $z_1^3 = z_1$. Thus either $z_1 = z_2 = 0$, or $z_1 = z_2 = \pm i$. In the first case $a = b = c = 0$, so the potential has the form (3.4). In the second case, when $z_1 = z_2 = i$, we have $a = 3d$ and $b = 3id$. As $c + d \neq 0$ we can put $c + d = 1$, and then we obtain potential (3.5). The choice $z_1 = z_2 = -i$ gives a potential equivalent to (3.5).

We show that case $z_1 \neq z_2$ is impossible. Let us assume that $z_1 \neq z_2$. Then, necessarily, $c \neq 0$, and from the fact that z_i are roots h we have

$$b = -c(z_1 + z_2), \quad a + c = cz_1z_2. \tag{3.10}$$

The above equations together with (3.7) form a system of linear homogeneous equations for unknown (a, b, c, d) with the following matrix of coefficients:

$$M = \begin{bmatrix} 0 & 1 & 0 & 3z_1z_2^2 \\ 1 & 0 & 0 & z_2(z_2 + 2z_1) \\ 0 & -1 & 0 & z_1 + 2z_2 \\ 0 & 1 & z_1 + z_2 & 0 \\ 1 & 0 & 1 - z_1z_2 & 0 \end{bmatrix}. \tag{3.11}$$

Let M_l denote lth 4×4 minor of the above matrix (obtained by scratching its l-row). We have

$$-M_1 = z_1 + z_2(2 + z_1^2 + z_1z_2 + z_2^2), \tag{3.12}$$

and

$$-M_3 = 2z_1^2z_2 + z_2^3 + 3z_1^2z_2^3. \tag{3.13}$$

But from Eq. (3.7) it follows that $3z_1z_2^2 = -z_1 - 2z_2$, hence we can rewrite M_3 in the following form:

$$-M_3 = z_2(z_1 - z_2)^2. \tag{3.14}$$

As all minors must vanish, we have immediately that $M_3 = M_1 = 0$ implies that $z_1 = z_2$, and this is a contradiction with our assumption that $z_1 \neq z_2$.

Now, we have to investigate the second possibility when infinity is not a Darboux point. Then we have $c = -d$, and polynomials v, g, and h have the forms

$$\begin{aligned} v(z) &= \tfrac{1}{4}(a - d) + \tfrac{1}{3}bz - \tfrac{1}{2}dz^2, \\ g(z) &= \tfrac{1}{3}b - az - bz^2 + dz^3, \\ h(z) &= (a - d) + bz - dz^2. \end{aligned} \tag{3.15}$$

First let us assume that $d \neq 0$. Then we can write

$$g = d(z - z_1)(z - z_2)(z - z_3).$$

We assume that z_3 is a Darboux point, so $z_2 \neq z_3$ and $z_1 \neq z_3$. Moreover, because z_1 and z_2 are not Darboux points they must be multiple roots of v. Hence, $z_1 = z_2$, and

$$2b^2 + 9(a - d)d = 0, \quad z_1 = \frac{b}{3d}.$$

But then

$$g(z) = d(z - z_1)(z^2 - 2zz_1 - 1), \quad h(z) = -d(z - z_1)(z - 2z_1).$$

However, z_1 must be a double root of g, but this is only possible when $z_1 = \pm i$. This implies that z_1 is the triple root of g and that there is no Darboux point. We have a contradiction, so $d = 0$.

Now, if $b \neq 0$, then deg $g = 2$ but g cannot have two distinct roots. In fact, only one of them can be a Darboux point and the second must be a multiple root of v. As now deg $v = 1$, it is impossible. Hence, g has one double root which is a Darboux point, so it is not a simple Darboux point. This implies that $b = 0$, and hence potential has the form (3.4). □

Let us notice here that potential V_2 does not belong to $\mathcal{V}_{4,1}$ as it has factor $(q_2 - iq_1)^2$.

Theorems 2.1 and 2.3 are not applicable when potential (3.1) has factor $(q_2 \pm iq_1)^2$. However, when $(z \pm i)^2$ is a factor of v, then, by Proposition 2.9, it is a factor of polynomial g with multiplicity at least 3, so the potential has at most one Darboux point. By similar arguments—when $(q_2 \pm iq_1)^3$ is a factor of potential (3.1), then it has at most one Darboux point. Hence, for a case when there exist two or three simple Darboux points we can apply Theorem 2.1.

What remains to be considered is a case when there exists a multiple Darboux point.

Proposition 3.3: Assume that potential (3.1) has a multiple Darboux point. Then it is equivalent to the following one:

$$V_3 = \tfrac{1}{4}aq_1^4 + \tfrac{1}{3}bq_1^3q_2 + \tfrac{1}{4}(q_1^2 + q_2^2)^2. \tag{3.16}$$

Proof: If the infinity is a multiple Darboux point, then, as we already mentioned, $d = 0$ and $c \neq 0$. Hence, in this case the potential is equivalent to (3.16). If a multiple Darboux point is not the infinity, then, by Proposition 2.11, it is different from $\pm i$. Thus, making a proper rotation, we can move it to infinity and then the obtained potential is equivalent to (3.16). □

B. Potentials with more than one simple Darboux point

Let us consider g and $f = h(z)\Lambda - g'(z)$ as polynomials in $\mathbb{C}[z, \Lambda, a, b, c, d]$. The resultant of g and f with respect to z is proportional to polynomial $G \in \mathbb{C}[\Lambda, a, b, c, d]$ which has the following form:

$$G = 3dG_0 - 3cG_0\Lambda + G_2\Lambda^2 + G_3\Lambda^3, \tag{3.17}$$

where

$$G_0 = 4b^4 + 3b^2(a^2 - 3d^2) + 6ad(2a^2 + 3b^2),$$

$$G_2 = -3[b^2 - ac + 3(a + c)d][3acd + 3a^2(c + d) + b^2(4c + 3d)], \tag{3.18}$$

$$G_3 = -3b^4(c + d) + 9(a + c)[cd + a(c + d)]^2 + 2b^2c[9a(c + d) + c(8c + 9d)].$$

It can be checked that G_3 up to a constant factor is the resultant of polynomials g and h with respect to z. Moreover, dG_0 is proportional to the discriminant of polynomial g. Polynomial g has at most three roots which we denote by z_1, z_2, and z_3. If z_i is a Darboux point, then we put $\Lambda_i = \Lambda(z_i)$. Of course Λ_i are roots of polynomial (3.17).

In the generic case, we have four Darboux points, thus necessarily $c+d\neq 0$ and $G_3\neq 0$. Without any loss of the generality we can assume $c+d=1$. All Darboux points are simple if to the above assumption we add $dG_0\neq 0$. As $\Lambda_0=-d$, $c=1-d$, and

$$\Lambda_1\Lambda_2\Lambda_3=-3d\frac{G_0}{G_3},$$

$$\Lambda_1\Lambda_2+\Lambda_2\Lambda_3+\Lambda_3\Lambda_1=-3c\frac{G_0}{G_3}, \tag{3.19}$$

$$\Lambda_1+\Lambda_2+\Lambda_3=-\frac{G_2}{G_3},$$

for given $\{\Lambda_0,\Lambda_1,\Lambda_2,\Lambda_3\}$ we have three equations for two unknowns a, b. Of course these equations are not independent. Solving them we find explicit values of coefficients a, b, c, and d. Note that having an element of $\mathcal{I}_{4,4}$, we have generally four different choices for Λ_0.

Elements of $\mathcal{I}_{4,4}$ are listed in Table I. Using them we solve the respective equations (3.19). Then, we select those solutions which give nonequivalent potentials listed in the following:

$$V_4=\tfrac{1}{4}aq_1^4+q_2^4, \tag{3.20}$$

$$V_5=4q_1^4+3q_1^2q_2^2+\tfrac{1}{4}q_2^4, \tag{3.21}$$

$$V_6=2q_1^4+\tfrac{3}{2}q_1^2q_2^2+\tfrac{1}{4}q_2^4, \tag{3.22}$$

$$V_7=\frac{151-880\sqrt{7}}{124}q_1^4+\frac{-20i}{31}(14+11\sqrt{7})q_1^3q_2+\frac{21}{2}q_1^2q_2^2+\frac{1}{4}q_2^4, \tag{3.23}$$

$$V_8=\tfrac{272}{3}q_1^4+68q_1^2q_2^2+\tfrac{1}{4}q_2^4, \tag{3.24}$$

$$V_9=-\frac{19\,472}{205}q_1^4+i\frac{4608}{41}\sqrt{\frac{446}{215}}q_1^3q_2+68q_1^2q_2^2+\frac{1}{4}q_2^4, \tag{3.25}$$

$$V_{10}=\frac{782\,329}{390\,720}q_1^4+\frac{-247i}{3256}\sqrt{\frac{3}{5}}q_1^3q_2+\frac{3}{2}q_1^2q_2^2+\frac{1}{4}q_2^4, \tag{3.26}$$

$$V_{11}=\frac{663-608\sqrt{86}}{428}q_1^4-\frac{2i}{107}(305+76\sqrt{86})q_1^3q_2+\frac{15}{2}q_1^2q_2^2+\frac{1}{4}q_2^4, \tag{3.27}$$

$$V_{12}=\frac{663+608\sqrt{86}}{428}q_1^4+\frac{2i}{107}(305-76\sqrt{86})q_1^3q_2+\frac{15}{2}q_1^2q_2^2+\frac{1}{4}q_2^4. \tag{3.28}$$

The first and second elements of Table I give potential V_4 and V_5, respectively. Potentials V_6 and V_7 correspond to the third element. The last two elements of Table I give the remaining five potentials. The first two of them correspond to the fourth element in Table I.

As $\mathcal{I}_{4,2}=\mathcal{I}_{4,3}=\emptyset$, the above gives the full list of the distinguished potentials.

C. Integrability of distinguished potentials

Among potentials V_i, $i=0,\ldots,12$ there are integrable ones. Namely, V_1, V_4, V_5, and V_6 are the known integrable potentials, see Refs. 15 and 16. Moreover, potential V_2 is integrable when $\alpha=-2$, see Ref. 11.

Now, our aim is to investigate the integrability of the remaining distinguished potentials. Our main tools are Theorem A.2 and Lemma A.1.

Let us consider potential (3.1) when $c+d\neq 0$. Without loss of the generality we can put $c+d=1$. Then Hamilton's equations of motion have a family of particular solutions associated with the Darboux point whose first coordinate vanishes. These solutions $\varphi(t,e)=(0,q_2(t),0,p_2(t))$ for given energy e are determined by

$$\dot{q}_2(t)^2+\tfrac{1}{2}q_2(t)^4=2e,\quad p_2(t)=\dot{q}_2(t). \tag{3.29}$$

If we put $q_2^2=-2v$, then the above equation transforms into

$$\dot{v}^2=4v^2-g_2v-g_3,\quad g_2=4e,\quad g_3=0. \tag{3.30}$$

Hence, $v=\wp(t)$ is the nondegenerated Weierstrass function with invariants g_2, g_3, provided $e\neq 0$. The variational equations along particular solutions have the following form:

$$\frac{\mathrm{d}}{\mathrm{d}t}\begin{bmatrix}\xi_1\\ \xi_2\\ \xi_3\\ \xi_4\end{bmatrix}=\begin{bmatrix}0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\\ 2c\wp(t) & 0 & 0 & 0\\ 0 & 6\wp(t) & 0 & 0\end{bmatrix}\begin{bmatrix}\xi_1\\ \xi_2\\ \xi_3\\ \xi_4\end{bmatrix}. \tag{3.31}$$

Notice that the above variational equations are equivalent to the direct product of two Lamé equations

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}\xi_i=n_i(n_i+1)\wp(t)\xi_i,\quad i=1,2, \tag{3.32}$$

where $n_2=2$ and $n_1(n_1+1)=2c$. Now let us assume that $n_1\in\mathbb{Z}\setminus\{-1,0\}$. Under this assumption, for both equations we have the Lamé-Hermite case (see Appendix A 3). Hence, the differential Galois group of variational equations (3.31) is Abelian, and the necessary integrability conditions of Theorem 1 are fulfilled for arbitrary $a,b\in\mathbb{C}$. To prove the nonintegrability of the system for such cases we apply the higher order variational equations, see Appendix A 2. Because of the form of first-order variational equations investigation of the differential Galois group of higher order variational equations reduces to a local analysis, see Lemma A.1 in Appendix A 3.

Thus, for further calculations, we need the explicit form of nonhomogeneous terms in higher order variational equations (A4). The first of them is

$$\boldsymbol{f}_2=-q_2(t)[0,0,\xi_1^{(1)}(b\xi_1^{(1)}+2c\xi_2^{(1)}),c(\xi_1^{(1)})^2+3(\xi_2^{(1)})^2]^T, \tag{3.33}$$

where $\xi_i^{(1)}\equiv\xi_i$ for $i=1,\ldots,4$. The fundamental matrix $\boldsymbol{X}(t)$ of the homogeneous system (3.31) has the following form:

$$\boldsymbol{X}(t)=\begin{bmatrix}x_1(t) & x_2(t) & 0 & 0\\ 0 & 0 & y_1(t) & y_2(t)\\ \dot{x}_1(t) & \dot{x}_2(t) & 0 & 0\\ 0 & 0 & \dot{y}_1(t) & \dot{y}_2(t)\end{bmatrix}. \tag{3.34}$$

Here $x_1(t)$ and $x_2(t)$ are linearly independent solutions of Eq. (3.32) with $i=1$ chosen in such a way that $x_1(t)\dot{x}_2(t)-x_2(t)\dot{x}_1(t)=1$; similarly, $y_1(t)$ and $y_2(t)$ are linearly independent solutions of Eq. (3.32) with $i=2$ chosen in such a way that $y_1(t)\dot{y}_2(t)-y_2(t)\dot{y}_1(t)=1$. Thus, the inverse of $\mathbf{X}(t)$ is the following:

$$\boldsymbol{X}^{-1}(t)=\begin{bmatrix} \dot{x}_2(t) & 0 & -x_2(t) & 0 \\ -\dot{x}_1(t) & 0 & x_1(t) & 0 \\ 0 & -\dot{y}_2(t) & 0 & y_2(t) \\ 0 & \dot{y}_1(t) & 0 & -y_1(t) \end{bmatrix}. \tag{3.35}$$

In a neighborhood of $t=0$ solutions $x_1(t)$ and $x_2(t)$ have the following expansions:

$$\begin{aligned} x_1(t)&=t^{n_1+1}\left(1+\frac{n_1(n_1+1)g_2}{80(2n_1+5)}t^4+\cdots\right), \\ x_2(t)&=t^{-n_1}\left(-\frac{1}{2n_1+1}+\frac{n_1(n_1+1)g_2}{80(2n_1+1)(2n_1-3)}t^4+\cdots\right), \end{aligned} \tag{3.36}$$

where dots denote the higher order terms with respect to t. Expansions for $y_1(t)$ and $y_2(t)$ have form (3.36) with $n_1=2$. Furthermore, expansion of $q_2(t)$ is the following:

$$q_2(t)=\frac{i}{\sqrt{2}}\left(\frac{2}{t}+\frac{g_2}{20}t^3+\cdots\right). \tag{3.37}$$

According to Lemma A.1, to prove that the investigated potential is not integrable, we have to show that a logarithmic term in a local solution of the second variational equation appears. To this end, it is enough to show that at least one component of $\boldsymbol{\mu}^{(2)}=\mathbf{X}^{-1}(t)\boldsymbol{f}_2$ has a first-order pole at $t=0$, see formulas (A5) and (A6). In all further calculations we take

$$\boldsymbol{\xi}^{(1)}=[x_2(t),0,\dot{x}_2(t),0]^T.$$

Then, the first two components of $\boldsymbol{\mu}^{(2)}$ are

$$\mu_1^{(2)}=bq_2(t)x_2(t)^3, \quad \mu_2^{(2)}=-bq_2(t)x_1(t)x_2(t)^2. \tag{3.38}$$

Now, we are ready to prove the following.

Lemma 3.1: Potential (3.16) is integrable if and only if $a=b=0$.

Proof: For potential (3.16) $n_1=1$, so

$$x_1(t)=t^2+\cdots, \quad x_2(t)=-\tfrac{1}{3}t^{-1}+\cdots,$$

where dots denote the higher order terms with respect to t. Hence, from (3.38), we obtain

$$\mu_2^{(2)}=-ib\frac{\sqrt{2}}{9t}+\cdots.$$

Thus, by Lemma A.1 if $b\neq 0$, then potential (3.16) is not integrable.

Assume that $b=0$, and continue our calculations up to the third order. Solutions of the second-order variational equations have the form

$$\boldsymbol{\xi}^{(2)}=[0,z(t),0,\dot{z}(t)]^T, \quad z(t)=\frac{i\sqrt{2}}{36t}+\cdots.$$

Now, the second component of $\boldsymbol{\mu}^{(3)}=\mathbf{X}^{-1}(t)\boldsymbol{f}_3$ is

$$\mu_1^{(3)}=-x_1(t)x_2(t)((a+1)x_2(t)^2+2q_2(t)z(t))=\frac{a}{27t}+\cdots.$$

Thus, $\mu_2^{(3)}$ has a simple pole at $t=0$ with a nonzero residue for $a\neq 0$. Hence, again by Lemma A.1, if $b=0$ but $a\neq 0$, then potential (3.16) is not integrable. □

Lemma 3.2: Hamiltonian system (1.2) with potential $V=V_i$ for $i=7,\ldots,12$ does not admit an additional meromorphic first integral.

Proof: We proceed similarly as in the proof of the previous lemma. The only complication which appears is connected with the fact that, for the investigated potentials $n_1>1$, and an analysis of the leading terms of the Laurent series expansions is not sufficient. Moreover, to find a logarithmic term for some potentials we have to continue calculations up to the fifth-order variational equations. To perform this task we use the computer algebra, and conclusions are the following. For potentials V_7 and V_8 we have $n_1=6$ and $n_1=16$, respectively, and for them we find a logarithmic term in solutions of the fifth-order variational equations. For V_9 we have $n_1=16$ but a logarithmic term appears in solutions of the second-order variational equations. For potentials V_{10}, we have $n_1=2$, and a logarithmic term appears in solutions of the fifth-order variational equations. For the last two potentials, V_{11} and V_{12}, we have $n_1=5$, and a logarithmic term appears in solutions of the second-order variational equations. □

For potential V_0 Theorem 1.1 is not applicable. Nevertheless, we show the following.

Lemma 3.3: *Hamiltonian system (1.2) with potential $V=V_0$ does not admit an additional rational first integral.*

Proof: A proof follows from Theorem 2.4. □

The most difficult case is potential (3.5). Let us define three sets

$$J_1=\{p+2p(p-1)|p\in\mathbb{Z}\},\quad J_2=\left\{\frac{3}{8}+2p(p+1)|p\in\mathbb{Z}\right\},\tag{3.39}$$

$$J_3=\left\{-\frac{1}{8}+\frac{2}{9}(1+3p)^2|p\in\mathbb{Z}\right\}.\tag{3.40}$$

Then a direct application of Theorem 1.1 gives the following.

Proposition 3.4: *If Hamiltonian system (1.2) with potential $V=V_2$ given by (3.5) admits an additional meromorphic first integral, then*

$$c:=1-\alpha\in J_1\cup J_2\cup J_3.\tag{3.41}$$

Hence, we have three infinite families for investigation. When $c\in J_1$, then the variational equations along the particular solution corresponding to the only Darboux point have the form (3.31) with arbitrary $n_1\in\mathbb{Z}$. In this case, we can can apply Lemma A.1 for proving nonintegrability for small values of $|n_1|$. In this way we showed the following.

Proposition 3.5: If Hamiltonian system (1.2) with potential $V=V_2$ admits an additional meromorphic first integral, and $c\in J_1$, then either $c=3$, or $c=p+2p(p-1)$ for $|p|>12$, $p\in\mathbb{Z}$.

When $c\in J_2\cup J_3$, then we cannot apply Lemma A.1 because the Lamé equation corresponding to the normal variational equation is not in the Lamé–Hermite case. For these cases we applied the direct search for a polynomial first integral. Namely, for a given $p\in\mathbb{Z}$ we fixed $c=3/8+2p(p+1)$, and we looked for a polynomial first integral of degree not greater than 50. We checked that there is no such integral for $|p|\leqslant 6$. We checked similar cases when $c\in J_3$. Let us note that from Ref. 24 it follows that if the considered system possesses a rational additional first integral, then it possesses a polynomial one.

The above considerations justify our conjecture that potential V_2 given by (3.5) is integrable only when $\alpha=-2$.

IV. FINAL REMARKS

A natural question appears if it is possible to generalize the obtained results to higher dimensions. The answer to this question is positive and our paper on this subject is in preparation. However a generalization to higher dimensions is not so simple and new problems appear. We just remark that dimension two is distinguished for many reasons. The most important one is that in higher dimensions a homogeneous polynomial does not factor into linear forms.

Here it is worth mentioning that our approach is closely related with investigations of the integrability and uniformization properties of general homogeneous polynomial differential equations. For such a system a Darboux point is a point where the vector field is parallel to the radial direction. As is well known, see, e.g., Ref. 19, with each Darboux point we can associate the Kovalevskaya matrix. A necessary condition for the existence of polynomial first integrals can be expressed in a form of resonance relations among the eigenvalues of the Kovalevskaya matrix. Moreover, if all solutions of the investigated system are single-valued, then necessarily all the eigenvalues of the Kovalevskaya matrix are integers and the matrix is semi-simple (this is the statement of the Lapunov theorem). For quadratic three-dimensional systems Jean Moulin Ollagnier[36] showed that the eigenvalues of the Kovalevskaya matrix taken over all simple Darboux points cannot take arbitrary values. In other words there exist certain universal relations among them. A new geometrical interpretation of the Kovalevskaya–Lapunov analysis was done by Gulliot in his Ph.D. thesis.[13] From the point of view of extension of the results given in this paper into higher dimensions, the most important part of Refs. 13 and 14 concern an application of a Baum–Bott–like theorem for proving the above-mentioned relations among the eigenvalues of the Kovalevskaya matrix taken over all simple Darboux points.

We would like to mention that the results of this paper can be applied for an investigation of integrability of nonhomogeneous potentials. In fact, a polynomial potential $V(\boldsymbol{q})$ can be written in the form of the sum of homogeneous components

$$V(\boldsymbol{q}) = V_{\min}(\boldsymbol{q}) + \ \ldots \ + V_{\max}(\boldsymbol{q}),$$

where $V_{\min}(\boldsymbol{q})$ and $V_{\max}(\boldsymbol{q})$ are the homogeneous components of the lowest and the highest orders, respectively. It can be shown (see, e.g., Ref. 16) that if Hamiltonian system (1.2) with polynomial potential $V(\boldsymbol{q})$ is integrable, then potentials $V_{\min}(\boldsymbol{q})$ and $V_{\max}(\boldsymbol{q})$ are integrable.

Another question concerns an extension of the results of Sec. III to homogeneous potentials of degree higher than four. Here the main problem is connected with the fact that if $\deg V > k$, then the variational equations for a Darboux point are no longer a product of Lamé equations, and we have no tool as effective as Lemma A.1 for application of the higher order variational equations.

Our last observation is the following. In all integrable cases the differential Galois group of the normal variational equations is either contained in the triangular subgroup of $\mathrm{SL}(2,\mathbb{C})$, or it is an imprimitive of $\mathrm{SL}(2,\mathbb{C})$. We do not know an example of a natural Hamiltonian system when this group is a primitive finite group. The question is if it is a general property of natural Hamiltonian systems.

ACKNOWLEDGMENTS

We would like to thank Jean Moulin Ollagnier, Henryk Żołądek, and Sergei Yakovenko for discussions and hints which were crucial for this paper. We also thank Zbroja (Urszula Maciejewska) for her linguistic help. APPENDIX A: DIFFERENTIAL GALOIS EXTENSION OF ZIGLIN THEORY

1. Basic theorem

Let M^n be a complex analytic manifold and $\boldsymbol{v}$ a holomorphic vector field on M^n. We consider the following differential equation:

$$\frac{\mathrm{d}}{\mathrm{d}t}\boldsymbol{x} = \boldsymbol{v}(\boldsymbol{x}), \quad \boldsymbol{x} \in M^n, \quad t \in \mathbb{C}. \tag{A1}$$

Let $\boldsymbol{\varphi}(t)$ be a nonequilibrium solution of (A1). Its maximal analytic continuation defines a Riemann surface Γ with local coordinate t. Together with system (A1), we consider the variational equations (VEs) along Γ, i.e.,

$$\dot{\boldsymbol{\xi}} = T(\boldsymbol{v})\boldsymbol{\xi}, \quad T(\boldsymbol{v}) = \frac{\partial \boldsymbol{v}}{\partial \boldsymbol{x}}, \quad \boldsymbol{\xi} \in T_\Gamma M^n. \tag{A2}$$

The order of this system can be reduced by one. To do this we consider the induced system on the normal bundle $N := T_\Gamma M / T\Gamma$ of Γ,[19] i.e.,

$$\dot{\eta} = \pi_\star(T(\boldsymbol{v})\pi^{-1}\eta), \quad \eta \in N, \tag{A3}$$

where $\pi: T_\Gamma M \to N$ is the projection. The system of $s = n-1$ equations obtained in this way yields the so-called normal variational equations (NVEs).

Now, assume that M^n is symplectic, i.e., there exists a symplectic form ω on M^n and $n = 2m$. Moreover, let us assume also that vector field $\boldsymbol{v}$ is a Hamiltonian vector field, i.e., there exists a holomorphic function $H: M^n \to \mathbb{C}$ such that $\omega(\boldsymbol{v}, \boldsymbol{u}) = \mathrm{d}H \cdot \boldsymbol{u}$ for arbitrary vector field $\boldsymbol{u}$. For a given particular solution $\varphi(t)$ we fix the energy level $e = H(\varphi(t))$. Restricting (A1) to this level, we obtain a well-defined system on $(n-1)$ dimensional manifold with a known particular solution $\varphi(t)$. For this restricted system we perform the reduction of order of variational equations. Thus, the normal variational equations for a Hamiltonian system with $m = n/2$ degrees of freedom have dimension $s = 2(m-1)$.

In Ref. 43 Ziglin formulated a theorem which gives necessary conditions for the Hamiltonian system governed by a Hamilton's function H. These conditions are expressed in terms of the monodromy group of NVEs for a nonequilibrium particular solution. Later Ziglin investigations were developed by Baider, Churchill, Morales-Ruiz, Rod, Simó, and Singer by a differential Galois approach, see Refs. 7, 5, 35, 30, 32, 33, 1, and 2. The main theorem of this theory formulates necessary conditions for integrability of the investigated Hamiltonian system in terms of the differential Galois group on NVEs (or VEs), and can be formulated in the following way.

Theorem A.1: *Assume that a Hamiltonian system is meromorphically integrable in the Liouville sense in a neighborhood of the analytic phase curve* Γ, *and that NVEs (VEs) along* Γ *are Fuchsian. Then the identity component of the differential Galois group of NVEs (and of VEs) associated with* Γ *is Abelian*.

In a case when NVEs are not Fuchsian, then a necessary condition for the integrability is the same: the identity component of the differential Galois group of NVEs (and of VEs) must be Abelian. However, generally, we have to restrict the class of first integrals to the rational functions. For a discussion of this point, see Ref. 30, Chap. 4.

Applications of the above theorem can be found in the already cited papers and in Refs. 4, 3, 29, 22, 21, and 25–27.

2. Higher order variational equations

To explain in a simple way the idea of higher variational equations it is convenient to assume that $M^n = \mathbb{C}^n$, and to identify vector field $\boldsymbol{v}$ with a map $\boldsymbol{v}: \mathbb{C}^n \ni \boldsymbol{x} \mapsto \boldsymbol{v}(\boldsymbol{x}) \in T_x\mathbb{C}^n \simeq \mathbb{C}^n$. Now, if $\boldsymbol{\varphi}(t)$ is a particular solution of Eq. (A1), we put

$$\boldsymbol{x} = \boldsymbol{\varphi}(t) + \varepsilon\boldsymbol{\xi}^{(1)} + \varepsilon^2\boldsymbol{\xi}^{(2)} + \cdots + \varepsilon^k\boldsymbol{\xi}^{(k)} + \cdots,$$

where ε is a formal small parameter. Inserting the above-noted expansion into Eq. (A1) and comparing terms of the same order with respect to ε, we obtain the following chain of linear nonhomogeneous equations:

$$\frac{\mathrm{d}}{\mathrm{d}t}\boldsymbol{\xi}^{(k)} = \boldsymbol{A}(t)\boldsymbol{\xi}^{(k)} + \boldsymbol{f}_k(\boldsymbol{\xi}^{(1)}, \ldots, \boldsymbol{\xi}^{(k-1)}), \quad k = 1, 2, \ldots, \tag{A4}$$

where

$$\boldsymbol{A}(t) = \frac{\partial \boldsymbol{v}}{\partial \boldsymbol{x}}(\boldsymbol{\varphi}(t)),$$

and $\boldsymbol{f}_1 \equiv 0$. For a given k Eq. (A4) is called the kth order variational equation. We denote by $\boldsymbol{X}(t)$ the fundamental matrix of the homogeneous system, i.e., $n \times n$ matrix satisfying

$$\frac{\mathrm{d}}{\mathrm{d}t}\boldsymbol{X} = \boldsymbol{A}(t)\boldsymbol{X}, \quad \boldsymbol{X}(0) = \boldsymbol{E},$$

where $\boldsymbol{E}$ is the identity matrix. Then the solutions of kth order variational equations for $k > 1$ are given by

$$\boldsymbol{\xi}^{(k)}(t) = \boldsymbol{X}(t)\boldsymbol{c}(t), \tag{A5}$$

where $\boldsymbol{c}(t)$ is a solution of

$$\frac{\mathrm{d}}{\mathrm{d}t}\boldsymbol{c} = \boldsymbol{X}^{-1}(t)\boldsymbol{f}_k. \tag{A6}$$

There is an appropriate framework allowing to define the differential Galois group of the kth order variational equation, for details see Refs. 30 and 31. The following theorem was formulated in Ref. 31.

Theorem A.2: *Assume that a Hamiltonian system is meromorphically integrable in the Liouville sense in a neighborhood of the analytic curve* Γ. *Then the identity component of the differential Galois group of the kth order variational equations is Abelian for any* $k \in \mathbb{N}$.

Here we note that in Theorem A.1 the necessary conditions were obtained from an analysis of the first-order variational equations.

3. Lamé equation and higher order variational equations

The Lamé equation in the Weierstrass form reads

$$\frac{\mathrm{d}^2 y}{\mathrm{d}t^2} = (A\wp(t) + B)y, \tag{A7}$$

where A and B are, in general, complex parameters and $\wp(t)$ is the elliptic Weierstrass function with invariants g_2, g_3. In other words, $\wp(t)$ is a solution of the differential equation

$$\dot{v}^2 = f(v), \quad f(v) = 4v^3 - g_2 v - g_3.$$

Parameters A, B, g_2, and g_3 are such that the discriminant $\Delta = g_2^3 - 27g_3^2 \neq 0$.

Classically, the Lamé equation (A7) is written with the parameter n instead of A related by the formula $A = n(n+1)$. It is possible to prove that the Lamé equation is solvable only in the following cases:

1. the Lamé and Hermite case (see, e.g., Ref. 38). Then $n \in \mathbb{Z}$ and the three other parameters are arbitrary,
2. the Brioschi–Halphen–Crowford case (see, e.g., Refs. 6 and 38). In this case $m := n + \frac{1}{2} \in \mathbb{N}$, and additionally B, g_2, g_3 should satisfy an appropriate algebraic condition,
3. the Baldassarri case.[6] Then $n + \frac{1}{2} \in \frac{1}{3}\mathbb{Z} \cup \frac{1}{4}\mathbb{Z} \cup \frac{1}{5}\mathbb{Z} \setminus \mathbb{Z}$, and there are additional algebraic conditions on B, g_2, g_3.

In the Lamé-Hermite case one solution is an elliptic function expressed in terms of $\wp$ and $\wp'$.

Let us assume that for a Hamiltonian system with two degrees of freedom the higher order variational equations have the form (A4) with

$$\boldsymbol{A}(t)=\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ A_1\wp(t)+B_1 & 0 & 0 & 0 \\ 0 & A_2\wp(t)+B_2 & 0 & 0 \end{bmatrix}. \tag{A8}$$

Thus, the first-order variational equations are equivalent to a product of two Lamé equations. Additionally, we assume that both copies of the Lamé equations belong to the Lamé–Hermite case, i.e., $A_i=n_i(n_i+1)$, $n_i\in\mathbb{Z}$ for $i=1,2$.

In the described situation we can check whether the differential Galois group of the higher order variational equations is Abelian investigating only the local monodromy around singularity $t=0$ of $\wp(t)$, for details see Refs. 30 and 31.

Lemma A.1: Under the assumption formulated above, the Galois group of higher order variational equations is Abelian if and only if their local monodromy around the singular point is the identity.

To apply the above lemma we just have to check if in the local solutions around $t=0$ of the second variational equations a logarithmic term appears. If it is so, then we have an obstacle for the integrability, if it is not so, we have to check if such term appears in a local solution of the third-order variational equations. This process can be continued up to an arbitrary high order.

For examples of application of the above lemma, see Refs. 27 and 33.

APPENDIX B: TECHNICAL LEMMA

We consider the following equation:

$$X_1+\cdots+X_m=c,\quad c>0. \tag{B1}$$

We look for its solutions $\boldsymbol{X}=(X_1,\ldots,X_m)\in\mathcal{X}^m$ where $\mathcal{X}$ is defined in the following way:

$$\mathcal{X}=\{x_n\in(0,\infty)|n\in\mathbb{N}\}, \tag{B2}$$

where $\lim_{n\to\infty}x_n=0$. We prove the following lemma.

Lemma B.1: For arbitrary $c>0$ Eq. (B1) *has at most a finite number of solutions in $\mathcal{X}^m$.*

Proof: We prove this lemma by induction with respect to m. For $m=1$ the statement of the lemma is evidently true. So, assume that it is true for $m-1$. We have to show that it is true for m. Let us assume the opposite: let $\boldsymbol{X}_p\in\boldsymbol{X}^m$, $p\in\mathbb{N}$ be an infinite sequence of different solutions of Eq. (B1). Points $\boldsymbol{X}_p$ belong to the compact set

$$T_c=\{(x_1,\ldots,x_m)\in\mathbb{R}^m|x_i\geqslant 0,\quad x_1+\cdots+x_m=c\}.$$

Thus, there exists a subsequence of $\boldsymbol{X}_p$ which tends to a certain $\tilde{\boldsymbol{X}}\in T_c$. Hence, we can assume that $\boldsymbol{X}_p=(X_{1,p},\ldots,X_{m,p})$ is chosen in such a way that $\lim_{p\to\infty}\boldsymbol{X}_p=\tilde{\boldsymbol{X}}$. Note that it cannot happen that all sequences $\{X_{i,p}\}$ for $i=1,\ldots,m$ contain infinitely many different numbers. In fact, if it is the case, then, for each $i=1,\ldots,m$ there exist a monotonically increasing series of integers $\{n_p\}$ such that $X_{i,p}=x_{n_p}$. But then each sequence $\{X_{i,p}\}$ converges to 0 which is impossible as their sum converges to a positive value. Hence, for at least one $i\in\{1,\ldots,m\}$, let us say $i=m$, sequence $\{X_{m,p}\}$ is constant for $p\geqslant p_0$. Note that $X_{m,p_0}<c$. As a result, we arrived to conclusion that there exist infinitely many solutions of equation

$$X_1+\cdots+X_{m-1}=c'$$

in $\mathcal{X}^{m-1}$ for certain $c'>0$. A contradiction with the inductive assumption finishes the proof. □

(Received 15 March 2005; accepted 20 April 2005; published online 10 June 2005)

For the Chaplygin's nonholonomic constrained systems, the constraint manifold can be endowed with Riemann–Cartan geometric structure by nonholonomic mapping into a Riemann manifold. The two kinds of existing dynamics, nonholonomic dynamics and vakonomic dynamics, are compared in the framework of Riemann–Cartan geometry. It is proved that the equations of motion for nonholonomic and vakonomic dynamics are described by the equations of autoparallel and geodesic trajectories on the Riemann–Cartan constraint manifold, respectively. If the metricity condition of Riemann–Cartan connection is satisfied, the torsion (contorsion) of the Riemann–Cartan manifold characterizes the difference between the autoparallel and geodesic trajectories as well as the distinction between the nonholonomic and vakonomic equations. © *2005 American Institute of Physics.*

I. INTRODUCTION

Constrained systems are common dynamical systems in modern physics, mechanics and engineering,[1–13] which can be classified into holonomic and nonholonomic ones according to the Frobenius integrability condition of constraints the systems are subject to. Unlike a holonomic system, a nonholonomic system cannot be reduced to a free system with lower degrees of freedom in general. Furthermore, there exist two inequivalent dynamical theories on nonholonomic constrained systems. One is based on Hamilton's principle of lease action. Similar to treating holonomic constrained systems, the constraints are directly incorporated into Lagrangian $L \rightarrow L + \lambda^{\alpha} f_{\alpha}$ with λ^{α} being Lagrange multipliers treated as independent dynamical variables. The dynamical equations derived from the theory can be canonicalized since such a way to incorporate constraints into a dynamical description does not influence on the symplectic structure of phase space of the systems. This dynamics is usually referred to as vakonomic dynamics (variational axiomatic kind).[14,15] The other is based on d'Alembert–Lagrange principle (or Hölder's principle, Gauss's principle) satisfying the condition of ideal constraints. Chetaev's condition on variation of coordinates induced from the nonholonomic constraints is utilized to realize the ideal constraints. Such a theory is not canonically Lagrangian or Hamiltonian, and is called nonholonomic dynamics.[1,11] The above two dynamics are equivalent for holonomic systems.

The paradox that different dynamics can be derived from the same nonholonomic constrained system just because of beginning with different acknowledged principles makes nonholonomic

[a)]Electronic mail: guoyongxin@lnu.edu.cn

constrained systems and their relating theories become a focus of research and disputation.[16–19] Therefore, it has been an important work to compare the two dynamics of nonholonomic systems.

In this paper, nonholonomic dynamics of Chaplygin's linear constrained systems[20] is compared with the corresponding vakonomic dynamics in the framework of Riemann–Cartan geometry.[21,22] In Sec. II, we briefly review the method to construct a Riemann–Cartan manifold by using a nonholonomic mapping[23–28] from a Riemann manifold. In Sec. III, the calculus of nonholonomic variations is discussed on the manifold. The nonholonomic variations are classified into three kinds. In Sec. IV, the two kinds of equations of motion, nonholonomic and vakonomic, for linear nonholonomic constrained systems are proved to describe the autoparallel and geodesic trajectories on the manifold, respectively. Some simple examples are illustrated in Sec. V ended with a concluding remark. The Einstein's summation convention is used throughout this paper and $i, j=1,2,\ldots,n$; $\mu, \nu, \sigma, \rho, \lambda, \tau=1,2,\ldots,m$; $\alpha, \beta=m+1, m+2,\ldots,n$.

II. RIEMANN–CARTAN CONSTRAINT MANIFOLD

A general system is usually subject to two kinds of constraints, the holonomic and the nonholonomic. Suppose that the configuration space of the system is n-dimensional Riemann manifold Q with local coordinates $\{q^i\}$ after the holonomic constraints are reduced. The metric tensor field on manifold Q is defined by the Hessian of nondegenerate Lagrangian L. The configuration space can be further deformed into Riemann–Cartan manifold with both curvature and torsion by the nonholonomic constraints imposed.

Suppose the system is subject to $(n-m)$ linear nonholonomic constraints:

$$\dot{q}^\alpha = \varepsilon^\alpha_\mu(q^\nu)\dot{q}^\mu, \tag{1}$$

where $\{\dot{q}^\mu, \dot{q}^\alpha\}$ are generalized velocities of the system. These constraints are suitable to characterize most linear constrained systems. The systems subjected to such constraints are called Chaplygin's nonholonomic constrained systems.

A m-dimensional constraint manifold M with local coordinates $\{q^\mu\}$ can be constructed by the constraint equations (1). As a subspace of Riemann manifold Q, however, the constraint manifold M is not its invariant embedded submanifold since the vector fields on the constraint manifold M are not involutive due to anholonomy of the constraints (1). Nevertheless, the tangent space of the constraint manifold M can be embedded into the tangent space of Riemann manifold Q by a nonholonomic mapping $i_T: TM \to TQ$:

$$v^i = \varepsilon^i_\mu(q^\nu)v^\mu, \quad v^\mu \in T_qM, \tag{2}$$

induced by the constraints (1), where $\varepsilon^i_\mu = \varepsilon^\alpha_\mu$ if i takes $\alpha = m+1, m+2,\ldots,n$; $\varepsilon^i_\mu = \delta^\nu_\mu$ if i takes $\nu = 1,2,\ldots,m$. This mapping can induce a nonholonomic mapping i_q:

$$q^i(c_q) = \int_{c_q} \varepsilon^i_\mu(q)\mathrm{d}q^\mu \tag{3}$$

from the equivalence class $\langle q^\mu(t)\rangle$ of all paths on manifold M to that on manifold Q, where c_q denotes any path $q^\mu(t)$ on manifold M. The integrals can be classified according to the end points of paths $c_{q(t)}$ if the same initial point of the integrals is fixed, i.e., each point of $c_{q(t)}$ corresponds to an equivalence class of integrals $q^i(c_{q(t)})$. $\{q^i(c_{q(t)})\}$ can be recognized as pseudo-coordinates on manifold M. If the constraints are integrable, the above-noted integrals are independent of paths on M and $q^i(c_{q(t)})$ reduce to $q^i(t)$, the function of end point t of path $c_{q(t)}$. Then path $q^\mu(t) \in M$ corresponds to path $q^i(t) \in Q$ pointwise, i.e., $q^i = q^i(q^\mu)$.

It can be verified that the metric and connection on manifold M can be induced from the nonholonomic mappings (2) and (3) in the same way as in Ref. 23 by generalizing the Euclid space taken as auxiliary space to the Riemann manifold Q. First, the metric g_{ij} on Riemann

manifold Q induces the metric $g_{\mu\nu}$ on manifold M. According to the mapping (2), $u^i=\varepsilon^i_\mu u^\mu$, $v^j=\varepsilon^j_\nu v^\nu$, for $u^i,v^j\in T_{i_q(q)}Q$ and $u^\mu,v^\nu\in T_qM$. Then $(u,v)=g_{ij}u^iv^j=g_{ij}\varepsilon^i_\mu\varepsilon^j_\nu u^\mu v^\nu=(\varepsilon_\mu,\varepsilon_\nu)u^\mu v^\nu$. Therefore, the induced metric on manifold M is

$$g_{\mu\nu}=(\varepsilon_\mu,\varepsilon_\nu)=g_{ij}\varepsilon^i_\mu\varepsilon^j_\nu. \tag{4}$$

Second, the mappings (2) and (3) induce a connection on manifold M,

$$\Gamma^\sigma_{\mu\nu}=g^{\sigma\rho}(\varepsilon_\rho,\partial_\mu\varepsilon_\nu)=g^{\sigma\rho}g_{ij}\varepsilon^i_\rho\partial_\mu\varepsilon^j_\nu. \tag{5}$$

It is easy to verify the metricity condition of the connection, i.e., compatible condition of the connection with metric, $D_\mu g_{\nu\sigma}=0$, which makes the length of a vector invariant while parallel-transporting it along a path on manifold M. But the connection is asymmetric, i.e., $\Gamma^\sigma_{\nu\mu}\neq\Gamma^\sigma_{\mu\nu}$, whose antisymmetric part is named torsion of the connection:

$$S^\sigma_{\mu\nu}=\Gamma^\sigma_{[\mu\nu]}=\tfrac{1}{2}(\Gamma^\sigma_{\mu\nu}-\Gamma^\sigma_{\nu\mu})=\tfrac{1}{2}g^{\sigma\rho}g_{ij}\varepsilon^i_\rho(\partial_\mu\varepsilon^j_\nu-\partial_\nu\varepsilon^j_\mu). \tag{6}$$

Obviously, $S^\sigma_{\nu\mu}=0$ if the integrability condition of constraints, $\partial_\mu\varepsilon^j_\nu-\partial_\nu\varepsilon^j_\mu=0$, is satisfied.

Such an asymmetric connection compatible with metric is referred to as Riemann–Cartan connection. The constraint manifold M is then a Riemann–Cartan manifold with torsion $S^\sigma_{\mu\nu}$ and curvature

$$R^{\rho\tau}_{\mu\nu}=\tfrac{1}{2}g^{\rho\lambda}g^{\tau\sigma}g_{ij}(f^i_{\mu\lambda}f^j_{\nu\sigma}-f^i_{\nu\lambda}f^j_{\mu\sigma}), \tag{7}$$

where

$$f^i_{\mu\nu}=D_\mu\varepsilon^i_\nu=\partial_\mu\varepsilon^i_\nu-\Gamma^\sigma_{\mu\nu}\varepsilon^i_\sigma. \tag{8}$$

On the Riemann–Cartan constraint manifold M there exist two kinds of special curves, geodesic and autoparallel trajectories, as follows:

$$\ddot{q}^\mu+\overline{\Gamma}^\mu_{\nu\sigma}\dot{q}^\nu\dot{q}^\sigma=0, \tag{9a}$$

$$\ddot{q}^\mu+\Gamma^\mu_{\nu\sigma}\dot{q}^\nu\dot{q}^\sigma=0, \tag{9b}$$

where $\overline{\Gamma}^\mu_{\nu\sigma}=\frac{1}{2}g^{\mu\lambda}(\partial_\sigma g_{\nu\lambda}+\partial_\nu g_{\sigma\lambda}-\partial_\lambda g_{\nu\sigma})$ is Riemann–Christoffel connection. It can be proved in the following that the difference of shortness from straightness on Riemann–Cartan manifold can geometrically characterize the "inexplicable" deviation of vakonomic dynamics from nonholonomic dynamics.

III. NONHOLONOMIC VARIATIONS ON RIEMANN–CARTAN CONSTRAINT MANIFOLD

Let c_q and $\overline{c_q}$ be smooth curves connecting any two fixed points q^i_1 and q^i_2 on n-dimensional Riemann manifold Q. Consider a function $q^i(t,\alpha)\in C^2$ of two parameters, satisfying $q^i(t,0)=q^i(t)$, $q^i(t,1)=\overline{q^i}(t)$; $q^i(t_1,\alpha)=q^i_1$, $q^i(t_2,\alpha)=q^i_2$. Denote the differential along any path by $\mathrm{d}q^\mu=\partial_t q^i(t,\alpha)\mathrm{d}t\doteq v^i\mathrm{d}t$ while the variation of the path is denoted by $\delta q^i=\partial_\alpha q^i(t,\alpha)\mathrm{d}\alpha\doteq w^i\mathrm{d}\alpha$ with fixed ends condition

$$\delta q^i|_{t_{1,2}}=0,\qquad w^i|_{t_{1,2}}=0. \tag{10}$$

The vector field $w^i(q^j)\in T_qQ$ is called variation vector field on manifold Q. As in Ref. 23, denote d_v and d_w the derivative along vector fields v and w, respectively. The above-noted definition leads to the following commutation relation of differential and variational operations:

$$\mathrm{d}_w v^i-\mathrm{d}_v w^i=0, \tag{11}$$

which simply determine the variation of velocity. To define a variation it is necessary to specify the variation of velocity as well as the variation vector field.

A variation vector field $w^\mu(q^\nu) \in T_qM$ can also be defined on manifold M with torsion. The commutation relation (11) on Riemann manifold Q, however, cannot be simply transplanted to the constraint manifold M. Relation (11) leads to

$$\mathrm{d}_w(v^i - \varepsilon^i_\mu v^\mu) + (\partial_\mu \varepsilon^i_\rho - \partial_\rho \varepsilon^i_\mu) v^\rho w^\mu + \varepsilon^i_\mu (\mathrm{d}_w v^\mu - \mathrm{d}_v w^\mu) - \mathrm{d}_v (w^i - \varepsilon^i_\mu w^\mu) = 0. \tag{12}$$

Let $\varepsilon^\mu_i \doteq g^{\mu\nu} g_{ij} \varepsilon^j_\nu$ with $\varepsilon^\mu_i \varepsilon^i_\nu = \delta^\mu_\nu$; $\varepsilon^\mu_i \varepsilon^j_\mu = \delta^j_i$. Using this condition and the connection coefficients (5) obtained in last section, we are led to

$$\partial_\rho \varepsilon^i_\mu = \varepsilon^i_\sigma \Gamma^\sigma_{\rho\mu}, \quad \partial_\rho \varepsilon^\mu_i = -\varepsilon^\nu_i \Gamma^\mu_{\rho\nu}. \tag{13}$$

By the definition (6), it follows that

$$(\partial_\mu \varepsilon^i_\rho - \partial_\rho \varepsilon^i_\mu) = 2\varepsilon^i_\sigma S^\sigma_{\mu\rho}. \tag{14}$$

Therefore relation (12) can be transformed into

$$\mathrm{d}_w(v^i - \varepsilon^i_\mu v^\mu) + \varepsilon^i_\mu (\mathrm{d}_w v^\mu - \mathrm{d}_v w^\mu) - \mathrm{d}_v (w^i - \varepsilon^i_\mu w^\mu) = 2\varepsilon^i_\sigma S^\sigma_{\rho\mu} v^\rho w^\mu. \tag{15}$$

Because of the existence of torsion tensor $S^\sigma_{\rho\mu}$ the variation vector field on the constraint manifold M cannot satisfy the following conditions simultaneously:

$$d_v(w^i - \varepsilon^i_\mu w^\mu) = 0, \tag{16a}$$

$$d_w v^\mu - d_v w^\mu = 0, \tag{16b}$$

$$d_w(v^i - \varepsilon^i_\mu v^\mu) = 0, \tag{16c}$$

which means that unlike the case of holonomic systems, there does not exist a free variation on the manifold M. The unfree variation vector field w and the corresponding differential d_w are named nonholonomic variations. The first condition imposed on the variation of coordinates is induced from the constraints and is called Chetaev's condition. The second is the commutation relation of differential and variational operations which leads to the existence of smooth local coordinate net formed by the integral curves of vector fields v^μ and w^μ. The third condition is an invariance of constraint conditions with respect to the variation operation, making the variation of velocities be unfree.

According to relation (15), the nonholonomic variation can be classified into the following three kinds.

(1) Hölder's variation. Choose the first two relations from the last equations, i.e.,

$$\mathrm{d}_v(w^i_\mathrm{h} - \varepsilon^i_\mu w^\mu_\mathrm{h}) = 0, \quad \mathrm{d}_{w_\mathrm{h}} v^\mu - \mathrm{d}_v w^\mu_\mathrm{h} = 0. \tag{17}$$

It follows from (15) that

$$\mathrm{d}_{w_\mathrm{h}}(v^i - \varepsilon^i_\mu v^\mu) = 2\varepsilon^i_\sigma S^\sigma_{\rho\mu} v^\rho w^\mu_\mathrm{h}, \tag{18}$$

which indicates how the constraint conditions vary with respect to Hölder's variation due to the torsion of manifold M.

(2) Suslov's variation. Suppose that

$$\mathrm{d}_v(w^i_\mathrm{s} - \varepsilon^i_\mu w^\mu_\mathrm{s}) = 0, \quad \mathrm{d}_{w_\mathrm{s}}(v^i - \varepsilon^i_\mu v^\mu) = 0. \tag{19}$$

It leads from the relation (15) to

$$\mathrm{d}_{w_s} v^\sigma - \mathrm{d}_v w_s^\sigma = 2S^\sigma_{\rho\mu} v^\rho w_s^\mu, \tag{20}$$

which means that Suslov's variation does not commute with differentiation of coordinates. Making use of covariant differentiation,

$$D_v w_s^\sigma = \mathrm{d}_v w_s^\sigma + \Gamma^\sigma_{\rho\mu} v^\rho w_s^\mu, \quad D_{w_s} v^\sigma = \mathrm{d}_{w_s} v^\sigma + \Gamma^\sigma_{\rho\mu} w_s^\rho v^\mu. \tag{21}$$

The variation of velocity v^σ can be specified by

$$D_v w_s^\sigma - D_{w_s} v^\sigma = 0. \tag{22}$$

(3) Vakonomic variation. Let

$$\mathrm{d}_{w_v} v^\mu - \mathrm{d}_v w_v^\mu = 0, \quad \mathrm{d}_{w_v}(v^i - \varepsilon^i_\mu v^\mu) = 0. \tag{23}$$

Then it is referred from (15) that the Chetaev's conditions cannot be satisfied and are replaced with corresponding conditions

$$\mathrm{d}_v(w_v^i - \varepsilon^i_\mu w_v^\mu) = 2\varepsilon^i_\sigma S^\sigma_{\mu\rho} v^\rho w_v^\mu. \tag{24}$$

It should be pointed that all the three kinds of variations satisfy the fixed ends conditions

$$w^\mu|_{t_1} = w^\mu|_{t_2} = 0. \tag{25}$$

IV. NONHOLONOMIC VERSUS VAKONOMIC EQUATIONS ON CONSTRAINT MANIFOLD

We apply Suslov's variation and vakonomic variation to variational principle to get two kinds of dynamical equations for the Chaplygin's nonholonomic constrained systems.

First, we make use of Suslov's variation to check the recently discovered stationary action principle[25]

$$\mathrm{d}_{w_s} S = \mathrm{d}_{w_s} \int_{t_1}^{t_2} \mathcal{L}(q^\mu, v^\mu)\mathrm{d}t = 0. \tag{26}$$

Computing the variation directly and making use of the above variation condition (20) and fixed ends conditions (25), one can derive the equations of motion

$$\frac{\partial \mathcal{L}}{\partial q^\mu} - \mathrm{d}_v\left(\frac{\partial \mathcal{L}}{\partial v^\mu}\right) = 2S^\rho_{\mu\nu}\frac{\partial \mathcal{L}}{\partial v^\rho} v^\nu, \tag{27}$$

which describes nonholonomic dynamics on the constraint manifold M.

We concern the geometric property of nonholonomic equations (27). Substitute $\mathcal{L} = \frac{1}{2} g_{\mu\nu}(q) v^\mu v^\nu$ into Eq. (27), then

$$g_{\mu\nu}\dot{v}^\nu + (\overline{\Gamma}_{\mu\nu\rho} - 2S_{\rho\nu\mu}) v^\rho v^\nu = 0, \tag{28}$$

where $S_{\rho\nu\mu} = g_{\rho\lambda} S^\lambda_{\nu\mu}$, $\overline{\Gamma}_{\mu\nu\rho} = g_{\mu\lambda}\overline{\Gamma}^\lambda_{\nu\rho}$ and $\overline{\Gamma}^\lambda_{\nu\rho}$ is Christoffel symbols. Considering the geometric relation

$$\overline{\Gamma}_{\mu\nu\rho} - 2S_{\rho\nu\mu} = g_{\mu\lambda}\Gamma^\lambda_{\nu\rho} \tag{29}$$

and lift the index μ, then

$$D_v v^\lambda = \dot{v}^\lambda + \Gamma^\lambda_{\nu\rho} v^\rho v^\nu = 0. \tag{30}$$

Thus it can be seen that the equations of motion for nonholonomic dynamics describe the autoparallels of Riemann–Cartan constraint manifold M.

Second, apply the vakonomic variation to the action on the manifold M, the stationary action principle

$$\mathrm{d}_{w_v} S = \mathrm{d}_{w_v} \int_{t_1}^{t_2} \mathcal{L}(q^\mu, v^\mu)\mathrm{d}t = 0 \tag{31}$$

simply leads to vakonomic equations

$$\mathrm{d}_v \left(\frac{\partial \mathcal{L}}{\partial v^\mu} \right) - \frac{\partial \mathcal{L}}{\partial q^\mu} = 0. \tag{32}$$

In fact, it is Euler–Lagrange equations. Substitute $\mathcal{L} = \frac{1}{2} g_{\mu\nu}(q) v^\mu v^\nu$ into Eq. (32), then

$$\overline{D}_v v^\lambda = \dot{v}^\lambda + \overline{\Gamma}^\lambda_{\nu\rho} v^\rho v^\nu = 0, \tag{33}$$

which are the geodesic equations on Riemann–Cartan constraint manifold M. In the following we verify that the geodesic equations (33) are just a geometrical representation of vakonomic equations for Chaplygin's nonholonomic constrained systems in Riemann–Cartan constraint manifold.

Let L be a Lagrangian of a dynamical system on the Riemann manifold Q. Rewrite $(n-m)$ nonholonomic constraints (1) the system is subject to as follows:

$$f^\alpha = v^\alpha - \varepsilon^\alpha_\mu v^\mu = 0. \tag{34}$$

Based on Hamilton's principle of least action, the vakonomic equations

$$[L]_i = -\lambda_\alpha [f^\alpha]_i - \mathrm{d}_v(\lambda_\alpha) \frac{\partial f^\alpha}{\partial v^i} \tag{35}$$

can be derived by the method of Lagrange multipliers. Using the notations $\lambda_i = \delta^\alpha_i \lambda_\alpha$, $f^i = v^i - \varepsilon^i_\mu v^\mu = 0$ in order to map the equations onto the constraint manifold M conveniently, the vakonomic equations are then equivalent to

$$[L]_i = -\lambda_j [f^j]_i - \mathrm{d}_v \lambda_j \frac{\partial f^j}{\partial v^i}. \tag{36}$$

It can be derived by simple computation:

$$\frac{\partial f^j}{\partial v^i} = \delta^j_i - \delta^\mu_i \varepsilon^j_\mu, \quad \frac{\partial f^j}{\partial q^i} = -\delta^\nu_i \varepsilon^j_\sigma \Gamma^\sigma_{\nu\mu} v^\mu, \quad [f^j]_i = 2\delta^\nu_i \varepsilon^j_\sigma S^\sigma_{\mu\nu} v^\nu. \tag{37}$$

Substitute it into the vakonomic equations, then

$$[L]_i = -2\delta^\nu_i \lambda_j \varepsilon^j_\sigma S^\sigma_{\mu\nu} v^\nu + \mathrm{d}_v \lambda_i + \mathrm{d}_v \lambda_j \varepsilon^j_\mu \delta^\mu_i. \tag{38}$$

Supposing the Lagrangian L on Riemann manifold Q is independent of coordinates q^α and neglecting any integral constants, the Lagrange multipliers can be found out from the above equations

$$\lambda_i = -\varepsilon^\mu_i \frac{\partial L}{\partial v^\mu}, \quad \mathrm{d}_v \lambda_i = -\varepsilon^\mu_i D_v \left(\frac{\partial L}{\partial v^\mu} \right) \tag{39}$$

along with the reduction of vakonomic equations onto the constraint manifold M:

$$[L]_\mu = 2S^\sigma_{\mu\nu} v^\nu \frac{\partial L}{\partial v^\sigma} - D_v\left(\frac{\partial L}{\partial v^\mu}\right). \tag{40}$$

For a mechanical system, $L=\frac{1}{2}g_{\mu\nu}v^\mu v^\nu$, the above equations can be transformed into

$$g_{\mu\nu}\overline{D}_v v^\nu + g_{\mu\nu} D_v v^\nu = 2g_{\nu\sigma} S^\nu_{\mu\rho} v^\rho v^\sigma. \tag{41}$$

Expand further, then

$$2g_{\mu\nu}\overline{D}_v v^\nu + (K_{\mu\rho\sigma} - S_{\sigma\mu\rho}) v^\rho v^\sigma = 0, \tag{42}$$

where $K_{\mu\rho\sigma}=g_{\mu\nu}K^\nu_{\rho\sigma}=g_{\mu\nu}(\Gamma^\nu_{\rho\sigma}-\overline{\Gamma}^\nu_{\rho\sigma})$, $S_{\sigma\mu\rho}=g_{\nu\sigma}S^\nu_{\mu\rho}$. Substitute the geometric relation

$$K_{\mu\rho\sigma} - S_{\sigma\mu\rho} = K_{\rho\mu\sigma} = -K_{\sigma\mu\rho} \tag{43}$$

into the above equation, we finally obtain Eq. (33), a geodesic representation of vakonomic equations on the constraint manifold M.

Remark 1: We have not applied Hölder's variation to the action because the result is the same as that of the vakonomic variation if we did for the particular action, which does not imply that Hölder's variation cannot give any new result for general nonholonomic systems.

Remark 2: On the Riemann–Cartan manifold M satisfying the metricity of connection the autoparallel trajectories will coincide with the geodesic ones if the torsion vanishes. In this case the nonholonomic equations also coincide with the vakonomic ones. However, it does not mean that the constraints are integrable in the sense of Frobenius theorem although inverse proposition is certainly true. This fact will be illustrated by example 3 of Sec. V.

V. ILLUSTRATIVE EXAMPLES

Now we are going to show by the following simple examples how the interrelation between the nonholonomic and vakonomic equations can be geometrically characterized on a Riemann–Cartan manifold.

Example 1: We illustrate the above result by the following example of a nonholonomically constrained particle with the Lagrangian $L=\frac{1}{2}(\dot{x}^2+\dot{y}^2+\dot{z}^2)$ and the nonholonomic constraint $\dot{z}=y\dot{x}$.

By means of the usual method, the nonholonomic and vakonomic equations are given by

$$\ddot{x} + \frac{y\dot{x}\dot{y}}{1+y^2} = 0, \quad \ddot{y} = 0, \tag{44a}$$

$$\ddot{x} + \frac{2y\dot{x}\dot{y}}{1+y^2} = 0, \quad \ddot{y} - y\dot{x}^2 = 0, \tag{44b}$$

respectively. We will illustrate that they describe autoparallel and geodesic trajectories on a two-dimensional Riemann–Cartan constraint manifold M with local coordinates (x,y).

Let x,y; $\dot{x},\dot{y}$ play the role of the q^μ, $\dot{q}^\mu$ and $z,\dot{z}$ the role of the q^α, $\dot{q}^\alpha$ in our discussion of the general theory. Obviously, $i,j=1,2,3$; $\mu,\nu=1,2$; $\alpha=3$ and

$$\varepsilon^1_1 = 1, \varepsilon^1_2 = 0, \varepsilon^2_1 = 0, \varepsilon^2_2 = 1; \quad \varepsilon^3_1 = y, \varepsilon^3_2 = 0.$$

The metric $g_{\mu\nu}$ and $g^{\mu\nu}$ take the form

$$(g_{\mu\nu}) = \begin{pmatrix} 1+y^2 & 0 \\ 0 & 1 \end{pmatrix}, \quad (g^{\mu\nu}) = \begin{pmatrix} \frac{1}{1+y^2} & 0 \\ 0 & 1 \end{pmatrix}.$$

The nonvanishing coefficients of the corresponding Christoffel symbols are given by

$$\overline{\Gamma}^2_{11} = -y, \quad \overline{\Gamma}^1_{12} = \overline{\Gamma}^1_{21} = \frac{y}{1+y^2}.$$

Then the geodesic equations on the manifold M,

$$\ddot{q}^1 + 2\overline{\Gamma}^1_{12}\dot{q}^1\dot{q}^2 = 0, \quad \ddot{q}^2 + \overline{\Gamma}^2_{11}\dot{q}^1\dot{q}^1 = 0,$$

take the form of vakonomic equations (44b) after a replacement of q^1,q^2 with x,y.

It can be verified that the only one nonvanishing coefficient of Riemann–Cartan connection on the manifold M is

$$\Gamma^1_{21} = \frac{y}{1+y^2}.$$

Then the autoparallel equations

$$\ddot{q}^1 + \Gamma^1_{21}\dot{q}^2\dot{q}^1 = 0, \quad \ddot{q}^2 = 0$$

are simply the nonholonomic equations (44a) if the coordinates q^1,q^2 are replaced with x,y.

Example 2: A special Chaplygin sleigh. Let us consider the free motion of a sleigh on a horizontal plane in the case when the projection of the center of mass coincides with the point of contact of a sharp wheel and the plane. We suppose the simplified sleigh has unit mass and unit moment of inertia in $R^2 \times T^1$ with coordinates (x,y,φ), subjected to the nonholonomic constraint $\dot{y} = \dot{x}\tan\varphi$. Then the regular Lagrangian is given by $L = \frac{1}{2}(\dot{x}^2 + \dot{y}^2 + \dot{\varphi}^2)$.

We discuss the two kinds of differential equations on the Riemann–Cartan submanifold M of $R^2 \times T^1$ in the following. As is well known, the reduced nonholonomic and vakonomic equations for the system on M are given by

$$\ddot{x} + \dot{x}\dot{\varphi}\tan\varphi = 0, \quad \ddot{\varphi} = 0, \tag{45a}$$

$$\ddot{x} + 2\dot{x}\dot{\varphi}\tan\varphi = 0, \quad \ddot{\varphi} - \dot{x}^2\tan\varphi\sec^2\varphi = 0, \tag{45b}$$

respectively.

Take $i,j = 1,2,3$; $\mu,\nu = 1,2$; $\alpha = 3$. Denote $q^\mu,\dot{q}^\mu$ by x,φ; $\dot{x},\dot{\varphi}$ and $q^\alpha,\dot{q}^\alpha$ by $y,\dot{y}$. Obviously,

$$\varepsilon^1_1 = 1, \varepsilon^1_2 = 0, \varepsilon^2_1 = 0, \varepsilon^2_2 = 1; \quad \varepsilon^3_1 = \tan\varphi, \varepsilon^3_2 = 0.$$

The metric $g_{\mu\nu}$ and $g^{\mu\nu}$ take the form

$$(g_{\mu\nu}) = \begin{pmatrix} \sec^2\varphi & 0 \\ 0 & 1 \end{pmatrix}, \quad (g^{\mu\nu}) = \begin{pmatrix} \cos^2\varphi & 0 \\ 0 & 1 \end{pmatrix}.$$

Then the nonvanishing coefficients of the corresponding Christoffel symbols are given by

$$\overline{\Gamma}^2_{11} = -\tan\varphi\sec^2\varphi, \quad \overline{\Gamma}^1_{12} = \overline{\Gamma}^1_{21} = \tan\varphi.$$

The Riemann–Cartan connection is simple to compute with only one nonvanishing coefficient

$$\Gamma^1_{21} = \tan\varphi.$$

It is very easy to verify that the following autoparallel and geodesic equations,

$$\ddot{x} + \Gamma^1_{21}\dot{\varphi}\dot{x} = 0, \quad \ddot{\varphi} = 0,$$

$$\ddot{x} + 2\Gamma^1_{12}\dot{x}\dot{\varphi} = 0, \quad \ddot{\varphi} + \Gamma^2_{11}\dot{x}\dot{x} = 0,$$

are just the nonholonomic and vakonomic equations (45a) and (45b), respectively, by substituting the above nonvanishing connection coefficients into them.

Example 3: Consider the problem of a vertically rolling disk which is another paradigm of nonholonomic systems. Choose the following appropriate generalized coordinates: the coordinates (x,y) of the center of mass of the disk, the azimuthal angle ψ which determines the position of the disk, and angle ϕ describing its internal rotation.

Setting the mass of the disk equal to 1 for simplicity, the Lagrangian is given by $L=\frac{1}{2}(\dot{x}^2+\dot{y}^2)+\frac{1}{2}(I_1\dot{\phi}^2+I_2\dot{\psi}^2)$ where I_1 and I_2 are moments of inertia. This regular Lagrangian leads to Hessian metric g_{ij} with nonvanishing diagonal elements: $g_{11}=I_1$, $g_{22}=I_2$, $g_{33}=1$, $g_{44}=1$. The nonholonomic constraints are given by the condition of rolling without slipping

$$\dot{x} = (R\cos\psi)\dot{\phi}, \quad \dot{y} = (R\sin\psi)\dot{\phi},$$

where R is the radius of the disk. Following the usual procedure for setting up the nonholonomic and vakonomic equations, we can consider the two kinds of equations of motion as the same and simply read

$$(R^2 + I_1)\ddot{\phi} = 0, \quad I_2\ddot{\psi} = 0. \tag{46}$$

Making use of the following notational identifications: $(q^1,q^2,q^3,q^4)=(\phi,\psi;x,y)$, the above constraints leads to

$$\varepsilon^1_1 = 1, \varepsilon^1_2 = \varepsilon^2_1 = 0, \varepsilon^2_2 = 1; \quad \varepsilon^3_1 = R\cos\psi, \varepsilon^3_2 = 0, \varepsilon^4_1 = R\sin\psi, \varepsilon^4_2 = 0$$

from which the metrics are given by

$$(g_{\mu\nu}) = \begin{pmatrix} R^2 + I_1 & 0 \\ 0 & I_2 \end{pmatrix}, \quad (g^{\mu\nu}) = \begin{pmatrix} \frac{1}{R^2+I_1} & 0 \\ 0 & \frac{1}{I_2} \end{pmatrix}.$$

It is straightforward to compute in the same way as the above examples that all of the coefficients of Riemann–Christoffel and Riemann–Cartan connections vanish,

$$\overline{\Gamma}^{\mu}_{\nu\sigma} = 0, \quad \Gamma^{\mu}_{\nu\sigma} = 0 \quad (\mu,\nu,\sigma = 1,2),$$

which means that the autoparallel coincides with the geodesic and satisfies the same equations

$$\ddot{\phi} = 0, \quad \ddot{\psi} = 0.$$

They are equivalent to Eq. (46).

This example indicates that similar to the autoparallel and geodesic, the difference between nonholonomic and vakonomic dynamics for Chaplygin's nonholonomic constrained systems is determined by the torsion of the corresponding Riemann–Cartan constraint manifold. The integrability of the constraints is an efficient but not a necessary condition for the coincidence of the two dynamics.

Concluding remark. If a system is subject to Chaplygin's nonholonomic constraints, its configuration space is no longer a Riemann manifold but a Riemann–Cartan manifold with torsion, on which the free variation operation does not exist. The stationary action principles on the constraint manifold with respect to Suslov's variation and vakonomic variation lead to autoparallel equations and geodesic equations on the manifold, respectively. This result accords with principle of inertia and principle of control theory.

Similar to the geometrization of gravitational fields in general relativity and gravitational gauge theories, a system subject to Chaplygin's nonholonomic constraints in an Euclidean or a Riemann space is equivalent to a free system in a Riemann–Cartan space. By means of this

geometrization the seeming inconsistency between nonholonomic and vakonomic dynamics can be replaced by harmonious geometric relations: straightness and shortness on the same Riemann–Cartan manifold. The result are applicable to most autonomous nonholonomic constrained systems, which can be generalized to nonautonomous ones by means of the theory of connection on a contact manifold or a one-jet bundle in the forthcoming contribution.

Using the theory of large deviations, we analyze the phase transition structure of the Curie–Weiss–Potts spin model, which is a mean-field approximation to the nearest-neighbor Potts model. It is equivalent to the Potts model on the complete graph on n vertices. The analysis is carried out both for the canonical ensemble and the microcanonical ensemble. Besides giving explicit formulas for the microcanonical entropy and for the equilibrium macrostates with respect to the two ensembles, we analyze ensemble equivalence and nonequivalence at the level of equilibrium macrostates, relating these to concavity and support properties of the microcanonical entropy. The Curie–Weiss–Potts model is the first statistical mechanical model for which such a detailed and rigorous analysis has been carried out. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904507]

I. INTRODUCTION

The nearest-neighbor Potts model, introduced in Ref. 40, takes its place next to the Ising model as one of the most versatile models in equilibrium statistical mechanics.[49] Section I C of Ref. 49 presents a mean-field approximation to the Potts model, defined in terms of a mean interaction averaged over all the sites in the model. We refer to this approximation as the Curie–Weiss–Potts model. Both the nearest-neighbor Potts model and the Curie–Weiss–Potts model are defined by sequences of probability distributions of n spin random variables that may occupy one of q different states $\theta^1, \ldots, \theta^q$, where $q \geqslant 3$. For $q=2$ the Potts model reduces to the Ising model while the Curie–Weiss–Potts model reduces to the much simpler mean-field approximation to the Ising model known as the Curie–Weiss model.[14]

Two ways in which the Curie–Weiss–Potts model approximates the Potts model, and in fact gives rigorous bounds on quantities in the Potts model, are discussed in Refs. 31 and 39. Probabilistic limit theorems for the Curie–Weiss–Potts model are proved in Ref. 19, including the law of large numbers and its breakdown as well as various types of central limit theorems. The model is also studied in Ref. 20, which focuses on a statistical estimation problem for two parameters defining the model.

In order to carry out the analysis of the model in Refs. 19 and 20, detailed information about the structure of the set of canonical equilibrium macrostates is required, including the fact that it exhibits a discontinuous phase transition as the inverse temperature β increases through a critical value β_c. This information plays a central role in the present paper, in which we use the theory of large deviations to study the equivalence and nonequivalence of the sets of equilibrium mac-

rostates for the microcanonical and canonical ensembles. An important consequence of the discontinuous phase transition exhibited by the canonical ensemble in the Curie–Weiss–Potts model is the implication that the nearest-neighbor Potts model on $\mathbb{Z}^d$ also undergoes a discontinuous phase transition whenever d is sufficiently large (Ref. 4, Theorem 2.1).

In Ref. 15 the problem of the equivalence of the microcanonical and canonical ensembles was completely solved for a general class of statistical mechanical models including short-range and long-range spin models and models of turbulence. This problem is fundamental in statistical mechanics because it focuses on the appropriate probabilistic description of statistical mechanical systems. While the theory developed in Ref. 15 is complete, our understanding is greatly enhanced by the insights obtained from studying specific models. In this regard the Curie–Weiss–Potts model is an excellent choice, lying at the boundary of the set of models for which a complete analysis involving explicit formulas is available.

For the Curie–Weiss–Potts model ensemble equivalence at the thermodynamic level is studied numerically in Ref. 29, Secs. 3–5. This level of ensemble equivalence focuses on whether the microcanonical entropy is concave on its domain; equivalently, whether the microcanonical entropy and the canonical free energy, the basic thermodynamic functions in the two ensembles, can each be expressed as the Legendre–Fenchel transform of the other (Ref. 15, pp. 1036–1037). Nonconcave anomalies in the microcanonical entropy partially correspond to regions of negative specific heat and thus thermodynamic instability.

The present paper significantly extends Ref. 29, Secs. 3–5 by analyzing rigorously ensemble equivalence at the thermodynamic level and by relating it to ensemble equivalence at the level of equilibrium macrostates via the results in Ref. 15. As prescribed by the theory of large deviations, the set $\mathcal{E}^u$ of microcanonical equilibrium macrostates and the set $\mathcal{E}_\beta$ of canonical equilibrium macrostates are defined in (2.4) and (2.3). These macrostates are, respectively, the solutions of a constrained minimization problem involving probability vectors on $\mathbb{R}^q$ and a related, unconstrained minimization problem. The equilibrium macrostates for the two ensembles are probability vectors describing equilibrium configurations of the model in each ensemble in the thermodynamic limit $n\to\infty$. For each $i=1,2,\ldots,q$, the ith component of an equilibrium macrostate gives the asymptotic relative frequency of spins taking the spin-value θ^i.

Defined via conditioning on the energy per particle, the microcanonical ensemble expresses the conservation of physical quantities such as the energy. Among other reasons, the mathematically more tractable canonical ensemble was introduced by Gibbs[22] in the hope that in the $n\to\infty$ limit the two ensembles are equivalent; i.e., all asymptotic properties of the model obtained via the microcanonical ensemble could be realized as asymptotic properties obtained via the canonical ensemble. Although most textbooks in statistical mechanics, including Refs. 1, 22, 28, 35, 41, and 44, claim that the two ensembles always give the same predictions, in general this is not the case.[48] There are many examples of statistical mechanical models for which nonequivalence of ensembles holds over a wide range of model parameters and for which physically interesting microcanonical equilibria are often omitted by the canonical ensemble. Besides the Curie–Weiss–Potts model, these models include the mean-field Blume–Emery–Griffiths model,[2,3,18] the Hamiltonian mean-field model,[12,36] the mean-field $X-Y$ model,[11] models of turbulence,[6,16,21,33,42] models of plasmas,[34,45] gravitational systems,[23–25,37,47] and a model of the Lennard-Jones gas.[5] It is hoped that our detailed analysis of ensemble nonequivalence in the Curie–Weiss–Potts model will contribute to an understanding of this fascinating and fundamental phenomenon in a wide range of other settings.

In the present paper, after summarizing the large deviation analysis of the Curie–Weiss–Potts model in Sec. II, we give explicit formulas for the elements of $\mathcal{E}_\beta$ and the elements of $\mathcal{E}^u$ in Secs. III and IV. This analysis shows that $\mathcal{E}_\beta$ exhibits a discontinuous phase transition at a critical inverse temperature β_c and that $\mathcal{E}^u$ exhibits a continuous phase transition at a critical energy u_c. The implications of these different phase transitions concerning ensemble nonequivalence are studied graphically in Sec. V and rigorously in Sec. VI, where we exhibit a range of values of the energy u for which the microcanonical equilibrium macrostates are not realized canonically; i.e., $\mathcal{E}^u$ is disjoint from $\mathcal{E}_\beta$ for all β. As described in the main theorem in Ref. 15 and summarized here

in Theorem 5.1, this range of values of the energy is precisely the set on which the microcanonical entropy is not concave. The analysis of this bridge between ensemble nonequivalence at the thermodynamic level and ensemble nonequivalence at the level of equilibrium macrostates is one of the main contributions of Ref. 15 for general models and of the present paper for the Curie–Weiss–Potts model. In a sequel to the present paper,[9] we will extend our analysis of the Curie–Weiss–Potts model to the so-called Gaussian ensemble[7,8,26,27,30,46] to show, among other results, that for each value of the energy for which the microcanonical and canonical ensembles are nonequivalent, we can find a Gaussian ensemble that is fully equivalent with the microcanonical ensemble.[10]

II. SETS OF EQUILIBRIUM MACROSTATES FOR THE TWO ENSEMBLES

Let $q \geqslant 3$ be a fixed integer and define $\Lambda = \{\theta^1, \theta^2, \ldots, \theta^q\}$, where the θ^i are any q distinct vectors in $\mathbb{R}^q$. In the definition of the Curie–Weiss–Potts model, the precise values of these vectors is immaterial. For each $n \in \mathbb{N}$ the model is defined by spin random variables $\omega_1, \omega_2, \ldots, \omega_n$ that take values in Λ. The canonical and microcanonical ensembles for the model are defined in terms of probability measures on the configuration spaces Λ^n, which consist of the microstates $\omega = (\omega_1, \ldots, \omega_n)$. We also introduce the n-fold product measure P_n on Λ^n with identical one-dimensional marginals

$$\overline{\rho} = \frac{1}{q}\sum_{i=1}^{q} \delta_{\theta^i}.$$

Thus for all $\omega \in \Lambda^n$, $P_n(\omega) = 1/q^n$. For $n \in \mathbb{N}$ and $\omega \in \Lambda^n$ the Hamiltonian for the q-state Curie–Weiss–Potts model is defined by

$$H_n(\omega) = -\frac{1}{2n}\sum_{j,k=1}^{n} \delta(\omega_j, \omega_k),$$

where $\delta(\omega_j, \omega_k)$ equals 1 if $\omega_j = \omega_k$ and equals 0 otherwise. The energy per particle is defined by

$$h_n(\omega) = \frac{1}{n} H_n(\omega).$$

For inverse temperature $\beta \in \mathbb{R}$ and subsets B of Λ^n the canonical ensemble is the probability measure $P_{n,\beta}$ defined by

$$P_{n,\beta}\{B\} = \frac{1}{\sum_{\omega \in \Lambda^n} \exp[-n\beta h_n(\omega)]} \cdot \sum_{\omega \in B} \exp[-n\beta h_n(\omega)].$$

For energy $u \in \mathbb{R}$ and $r > 0$ the microcanonical ensemble is the conditioned probability measure $P_n^{u,r}$ defined by

$$P_n^{u,r}\{B\} = P_n\{B | h_n \in [u - r, u + r]\}.$$

The key to our analysis of the Curie–Weiss–Potts model is to express both the canonical and the microcanonical ensembles in terms of the empirical vector

$$L_n = L_n(\omega) = (L_{n,1}(\omega), L_{n,2}(\omega), \ldots, L_{n,q}(\omega)),$$

the ith component of which is defined by

$$L_{n,i}(\omega) = \frac{1}{n}\sum_{j=1}^{n} \delta(\omega_j, \theta^i).$$

This quantity equals the relative frequency with which $\omega_j, j \in \{1, \ldots, n\}$, equals θ^i. L_n takes values in the set of probability vectors

$$\mathcal{P} = \left\{ \nu \in \mathbb{R}^q : \nu = (\nu_1, \nu_2, \ldots, \nu_q), \text{ each } \nu_i \geqslant 0, \sum_{i=1}^{q} \nu_i = 1 \right\}.$$

As we will see, each probability vector in $\mathcal{P}$ represents a possible equilibrium macrostate for the model.

There is a one-to-one correspondence between $\mathcal{P}$ and the set $\mathcal{P}(\Lambda)$ of probability measures on Λ, $\nu \in \mathcal{P}$ corresponding to the probability measure $\Sigma_{i=1}^{q} \nu_i \delta_{\theta^i}$. The element $\rho \in \mathcal{P}$ corresponding to the one-dimensional marginal $\overline{\rho}$ of the prior measures P_n is the uniform vector having equal components $1/q$.

We denote by $\langle \cdot, \cdot \rangle$ the inner product on $\mathbb{R}^q$. Since

$$\sum_{i=1}^{q} \sum_{j=1}^{n} \delta(\omega_j, \xi^i) \cdot \sum_{k=1}^{n} \delta(\omega_k, \xi^i) = \sum_{j,k=1}^{n} \delta(\omega_j, \omega_k),$$

it follows that the energy per particle can be rewritten as

$$h_n(\omega) = -\frac{1}{2n^2} \sum_{j,k=1}^{n} \delta(\omega_j, \omega_k) = -\frac{1}{2} \langle L_n(\omega), L_n(\omega) \rangle;$$

i.e.,

$$h_n(\omega) = \widetilde{H}(L_n(\omega)), \quad \text{where } \widetilde{H}(\nu) = -\tfrac{1}{2}\langle \nu, \nu \rangle \quad \text{for } \nu \in \mathcal{P}. \tag{2.1}$$

We call $\widetilde{H}$ the energy representation function.

We appeal to the theory of large deviations to define the sets of microcanonical equilibrium macrostates and canonical equilibrium macrostates. Sanov's theorem states that with respect to the product measures P_n, the empirical vectors L_n satisfy the large deviation principle (LDP) on $\mathcal{P}$ with rate function given by the relative entropy $R(\cdot|\rho)$ (Ref. 14, Theorem VIII.2.1). For $\nu \in \mathcal{P}$ this is defined by

$$R(\nu|\rho) = \sum_{i=1}^{q} \nu_i \log(q\nu_i).$$

We express this LDP by the formal notation $P_n\{L_n \in \mathrm{d}\nu\} \approx \exp[-nR(\nu|\rho)]$. The LDPs for L_n with respect to the two ensembles $P_{n,\beta}$ and $P_n^{u,r}$ in the thermodynamic limit $n \to \infty$, $r \to 0$ can be proved from the LDP for the P_n-distributions of L_n as in Theorems 2.4 and 3.2 in Ref. 15, in which minor notational changes have to be made. We express these LDPs by the formal notation

$$P_{n,\beta}\{L_n \in \mathrm{d}\nu\} \approx \exp[-nI_\beta(\nu)] \quad \text{and } P_n^{u,r}\{L_n \in \mathrm{d}\nu\} \approx \exp[-nI^u(\nu)], \tag{2.2}$$

where for $\nu \in \mathcal{P}$

$$I_\beta(\nu) = R(\nu|\rho) - \frac{\beta}{2}\langle \nu, \nu \rangle - \text{const}$$

and

$$I^u(\nu) = \begin{cases} R(\nu|\rho) - \text{const} & \text{if } -\frac{1}{2}\langle \nu, \nu \rangle = u, \\ \infty & \text{otherwise.} \end{cases}$$

The constants appearing in the definitions of I_β and I^u have the properties that $\inf_{\nu \in \mathcal{P}} I_\beta(\nu) = 0$ and $\inf_{\nu \in \mathcal{P}} I^u(\nu) = 0$. Thus I_β and I^u map $\mathcal{P}$ into $[0, \infty)$.

As the formulas in (2.2) suggest, if $I_\beta(\nu) > 0$ or $I^u(\nu) > 0$, then ν has an exponentially small probability of being observed in the corresponding ensemble in the thermodynamic limit. Hence it makes sense to define the corresponding sets of equilibrium macrostates to be

$$\mathcal{E}_\beta = \{\nu \in \mathcal{P} : I_\beta(\nu) = 0\} \quad \text{and} \quad \mathcal{E}^u = \{\nu \in \mathcal{P} : I^u(\nu) = 0\}.$$

A rigorous justification for this is given in Ref. 15, Theorem 2.4(d). Using the formulas for I_β and I^u, we see that

$$\mathcal{E}_\beta = \left\{ \nu \in \mathcal{P} : \nu \text{ minimizes } R(\nu|\rho) - \frac{\beta}{2}\langle \nu, \nu \rangle \right\} \tag{2.3}$$

and

$$\mathcal{E}^u = \left\{ \nu \in \mathcal{P} : \nu \text{ minimizes } R(\nu|\rho) \text{ subject to } -\tfrac{1}{2}\langle \nu, \nu \rangle = u \right\}. \tag{2.4}$$

Each element ν in $\mathcal{E}_\beta$ and $\mathcal{E}^u$ describes an equilibrium configuration of the model in the corresponding ensemble in the thermodynamic limit. The ith component ν_i gives the asymptotic relative frequency of spins taking the value θ^i.

The set $\mathcal{E}^u$ is defined for all u for which the constraint in the definition of I^u is satisfied for some $\nu \in \mathcal{P}$. Otherwise, $\mathcal{E}^u$ is not defined. If $\mathcal{E}^u$ is defined, then $\mathcal{E}^u$ is nonempty; if $\mathcal{E}^u$ is not defined, then we shall set $\mathcal{E}^u = \varnothing$.

The question of equivalence of ensembles at the level of equilibrium macrostates focuses on the relationships between $\mathcal{E}^u$, defined in terms of the constrained minimization problem in (2.4), and $\mathcal{E}_\beta$, defined in terms of the related, unconstrained minimization problem in (2.3). We will focus on this question in Secs. V and VI after we determine the structures of $\mathcal{E}_\beta$ and $\mathcal{E}^u$ in the next two sections.

III. FORM OF $\mathcal{E}_\beta$ AND ITS DISCONTINUOUS PHASE TRANSITION

In this section we derive the form of the set $\mathcal{E}_\beta$ of canonical equilibrium macrostates for all $\beta \in \mathbb{R}$. This form is given in Theorem 3.1, which shows that with respect to the canonical ensemble the Curie–Weiss–Potts model undergoes a discontinuous phase transition at the critical inverse temperature

$$\beta_c = \frac{2(q-1)}{q-2} \log(q-1). \tag{3.1}$$

In order to describe the form of $\mathcal{E}_\beta$, we introduce the function ψ that maps $[0, 1]$ into $\mathcal{P}$ and is defined by

$$\psi(w) = \left(\frac{1 + (q-1)w}{q}, \frac{1-w}{q}, \ldots, \frac{1-w}{q} \right); \tag{3.2}$$

the last $q-1$ components all equal $(1-w)/q$. Recalling that ρ is the uniform vector in $\mathcal{P}$ having equal components $1/q$, we see that $\rho = \psi(0)$.

Theorem 3.1: *For $\beta > 0$ let $w(\beta)$ be the largest solution of the equation*

$$w = \frac{1 - e^{-\beta w}}{1 + (q-1)e^{-\beta w}}. \tag{3.3}$$

The following conclusions hold.

(a) *The quantity* $w(\beta)$ *is well defined and lies in* $[0, 1]$. *It is positive, strictly increasing, and differentiable for* $\beta \in (\beta_c, \infty)$ *and satisfies* $w(\beta_c) = (q-2)/(q-1)$ *and* $\lim_{\beta \to \infty} w(\beta) = 1$.

(b) *For* $\beta \geqslant \beta_c$, *define* $\nu^1(\beta) = \psi(w(\beta))$ *and let* $\nu^i(\beta)$, $i = 2, \ldots, q$, *denote the points in* $\mathbb{R}^q$ *obtained by interchanging the first and ith components of* $\nu^1(\beta)$. *Then the set* $\mathcal{E}_\beta$ *defined in* (2.3) *has the form*

$$\mathcal{E}_\beta = \begin{cases} \{\rho\} & \text{for } \beta < \beta_c, \\ \{\rho, \nu^1(\beta_c), \nu^2(\beta_c), \ldots, \nu^q(\beta_c)\} & \text{for } \beta = \beta_c, \\ \{\nu^1(\beta), \nu^2(\beta), \ldots, \nu^q(\beta)\} & \text{for } \beta > \beta_c. \end{cases} \tag{3.4}$$

For $\beta \geqslant \beta_c$, *the vectors in* $\mathcal{E}_\beta$ *are all distinct and each* $\nu^i(\beta)$ *is continuous. The vector* $\nu^1(\beta_c)$ *is given by*

$$\nu^1(\beta_c) = \psi(w(\beta_c)) = \psi\left(\frac{q-2}{q-1}\right) = \left(1 - \frac{1}{q}, \frac{1}{q(q-1)}, \ldots, \frac{1}{q(q-1)}\right); \tag{3.5}$$

the last $q-1$ *components all equal* $1/q(q-1)$.

The form of $\mathcal{E}_\beta$ for $\beta > 0$ is proved in Appendix B from a new convex-duality theorem proved in Appendix A and from the complicated calculation of the global minimum points of a related function given in Theorem 2.1 in Ref. 19. The form of $\mathcal{E}_\beta$ for $\beta \leqslant 0$ is also determined in Appendix B. The other assertions in Theorem 3.1 are proved in Theorem 2.1 in Ref. 19.

For $\beta > 0$ the form of $\mathcal{E}_\beta$ reflects a competition between disorder, as represented by the relative entropy $R(\nu|\rho)$, and order, as represented by the energy representation function $-\frac{1}{2}\langle \nu, \nu \rangle$. For small $\beta > 0$, $R(\nu|\rho)$ predominates. Since $R(\nu|\rho)$ attains its minimum of 0 at the unique vector ρ, we expect that for small β, $\mathcal{E}_\beta$ should contain a single vector. On the other hand, for large $\beta > 0$, $-\frac{1}{2}\langle \nu, \nu \rangle$ predominates. This function attains its minimum at $\nu^1 = (1, 0, \ldots, 0)$ and at the vectors ν^i, $i = 1, \ldots, q$, obtained by interchanging the first and ith components of ν^1. Hence we expect that for large β, $\mathcal{E}_\beta$ should contain q distinct vectors $\nu^i(\beta)$ having the property that $\nu^i(\beta) \to \nu^i$ as $\beta \to \infty$. The major surprise of the theorem is that for $\beta = \beta_c$, $\mathcal{E}_\beta$ consists of the $q+1$ distinct vectors ρ and $\nu^i(\beta_c)$ for $i = 1, 2, \ldots, q$.

The discontinuous bifurcation in the composition of $\mathcal{E}_\beta$ from 1 vector for $\beta < \beta_c$ to $q+1$ vectors for $\beta = \beta_c$ to q vectors for $\beta > \beta_c$ corresponds to a discontinuous phase transition exhibited by the canonical ensemble. In Fig. 2 in Sec. V this phase transition is shown together with the continuous phase transition exhibited by the microcanonical ensemble. The latter phase transition and the form of the set of microcanonical equilibrium macrostates are the focus of the next section.

IV. FORM OF $\mathcal{E}^u$ AND ITS CONTINUOUS PHASE TRANSITION

We now turn to the form of the set $\mathcal{E}^u$ for all $u \in \left[-\frac{1}{2}, -1/2q\right]$, which is the set of u for which $\mathcal{E}^u$ is nonempty. In the specific case $q = 3$ part (c) of Theorem 4.2 gives the form of $\mathcal{E}^u$, the calculation of which is much simpler than the calculation of the form of $\mathcal{E}_\beta$. The proof is based on the method of Lagrange multipliers, which also works for general $q \geqslant 4$ provided the next conjecture on the form of the elements in $\mathcal{E}^u$ is valid. The validity of this conjecture has been confirmed numerically for all $q \in \{4, 5, \ldots, 10^4\}$ and all $u \in \left(-\frac{1}{2}, -1/2q\right)$ of the form $u = -\frac{1}{2} + 0.02k$, where k is a positive integer.

Conjecture 4.1: For any $q \geqslant 4$ *and all* $u \in \left(-\frac{1}{2}, -1/2q\right)$, *there exist* $a \neq b \in (0, 1)$ *such that modulo permutations, any* $\nu \in \mathcal{E}^u$ *has the form* $(a, b, \ldots, b)$, *the last* $q-1$ *components of which all equal* b.

Parts (a) and (b) of Theorem 4.2 are proved for general $q \geqslant 3$. Part (c) shows that modulo permutations, for $q = 3$, $\nu \in \mathcal{E}^u$ has the form $(a(u), b(u), b(u))$ and determines the precise formulas for $a(u)$ and $b(u)$. As specified in part (d), for $q \geqslant 4$ we can also determine the precise formula for $\nu \in \mathcal{E}^u$ provided Conjecture 4.1 is valid.

Theorem 4.2 shows that with respect to the microcanonical ensemble the Curie–Weiss–Potts model undergoes a continuous phase transition as u decreases from the critical energy value $u_c = -1/2q$. This contrast with the discontinuous phase transition exhibited by the canonical ensemble is closely related to the nonequivalence of the microcanonical and canonical ensembles for a range of u. Ensemble equivalence and nonequivalence will be explored in the next section, where we will see that it is reflected by support and concavity properties of the microcanonical entropy. An explicit formula for the microcanonical entropy is given in Theorem 4.3.

Theorem 4.2: *For $u \in \mathbb{R}$ we define $\mathcal{E}^u$ by* (2.4). *The following conclusions hold.*

(a) *For any $q \geqslant 3$, $\mathcal{E}^u$ is nonempty if and only if $u \in \left[-\frac{1}{2}, -1/2q\right]$. This interval coincides with the range of the energy representation function $\tilde{H}(\nu) = -\frac{1}{2}\langle \nu, \nu \rangle$ on $\mathcal{P}$.*

(b) *For any $q \geqslant 3$, $\mathcal{E}^{-1/2q} = \{\rho\} = \{(1/q, 1/q, \ldots, 1/q)\}$ and*

$$\mathcal{E}^{-1/2} = \{(1,0,\ldots,0),(0,1,\ldots,0),\ldots,(0,0,\ldots,1)\}.$$

(c) *Let $q=3$. For $u \in \left(-\frac{1}{2}, -1/2q\right)$, $\mathcal{E}^u$ consists of the three distinct vectors $\{\mu^1(u), \mu^2(u), \mu^3(u)\}$, where $\mu^1(u) = (a(u), b(u), b(u))$,*

$$a(u) = \frac{1 + \sqrt{2(-6u-1)}}{3} \quad \text{and } b(u) = \frac{2 - \sqrt{2(-6u-1)}}{6}. \tag{4.1}$$

The vectors $\mu^i(u)$, $i=2,3$, denote the points in $\mathbb{R}^3$ obtained by interchanging the first and the ith components of $\mu^1(u)$.

(d) *Let $q \geqslant 4$ and assume that Conjecture* 4.1 *is valid. Then for $u \in \left(-\frac{1}{2}, -1/2q\right)$, $\mathcal{E}^u$ consists of the q distinct vectors $\{\mu^1(u), \ldots, \mu^q(u)\}$, where $\mu^1(u) = (a(u), b(u), \ldots, b(u))$,*

$$a(u) = \frac{1 + \sqrt{(q-1)(-2qu-1)}}{q} \quad \text{and } b(u) = \frac{q - 1 - \sqrt{(q-1)(-2qu-1)}}{(q-1)q}.$$

The last $q-1$ components of $\mu^1(u)$ all equal $b(u)$, and the vectors $\mu^i(u)$, $i=2,\ldots,q$, denote the points in $\mathbb{R}^q$ obtained by interchanging the first and the ith components of $\mu^1(u)$.

We return to part (b) of Theorem 4.2 in order to discuss the nature of the phase transition exhibited by the microcanonical ensemble. The functions $a(u)$ and $b(u)$ given in (4.1) are both continuous for $u \in \left[-\frac{1}{2}, -1/2q\right]$ and satisfy

$$\lim_{u \to (-1/2q)^-} a(u) = \lim_{u \to (-1/2q)^-} b(u) = \frac{1}{q} = a\left(-\frac{1}{2q}\right) = b\left(-\frac{1}{2q}\right).$$

Therefore, for $i=1,\ldots,q$, $\lim_{u \to (-1/2q)^-} \mu^i(u) = \rho$. It follows that the microcanonical ensemble exhibits a continuous phase transition as u decreases from $u_c = -1/2q$, the unique equilibrium macrostate ρ for $u = u_c$ bifurcating continuously into the q distinct macrostates $\mu^i(u)$ as u decreases from its maximum value. This is rigorously true for $q=3$. Provided Conjecture 4.1 is true, it is also true for $q \geqslant 4$, as one easily checks using part (d) of Theorem 4.2.

Before proving Theorem 4.2, we introduce the microcanonical entropy

$$s(u) = -\inf\left\{R(\nu|\rho) : \nu \in \mathcal{P}, -\tfrac{1}{2}\langle \nu, \nu \rangle = u\right\}. \tag{4.2}$$

As we will see in the next section, this function plays a crucial role in the analysis of ensemble equivalence and nonequivalence for the Curie–Weiss–Potts model. The domain of s is the set $\operatorname{dom} s = \{u \in \mathbb{R} : s(u) > -\infty\}$; for $u \notin \operatorname{dom} s$, we set $s(u) = -\infty$. Since $R(\nu|\rho) < \infty$ for all $\nu \in \mathcal{P}$, $\operatorname{dom} s$ equals the range of $\tilde{H}(\nu) = -\frac{1}{2}\langle \nu, \nu \rangle$ on $\mathcal{P}$, which is the interval $\left[-\frac{1}{2}, -1/2q\right]$ [Theorem 4.2(a)].

Since $0 \leqslant R(\nu|\rho)$ for all $\nu \in \mathcal{P}$, $s(u) \in [-\infty, 0]$ for all u. The continuity of $R(\nu|\rho)$ on $\mathcal{P}$ and the compactness of the constraint set in (4.2) guarantee that for $u \in \operatorname{dom} s$ the infimum in the definition of $s(u)$ is attained for some $\nu \in \mathcal{P}$. Since $R(\nu|\rho) > R(\rho|\rho) = 0$ for all $\nu \neq \rho$, it follows that s attains its maximum of 0 at the unique value $-1/2q = -\frac{1}{2}\langle \rho, \rho \rangle$.

As we have just seen, $s(-1/2q)=0$. For $u\in\left(-\frac{1}{2},-1/2q\right)$, according to parts (c) and (d) of Theorem 4.2, $\mathcal{E}^u$ consists of the unique vector $\mu^1(u)$ modulo permutations. Since for $i=2,3,\ldots,q$, $R(\mu^i(u)|\rho)=R(\mu^1(u)|\rho)$, we conclude that

$$s(u)=-R(\mu^1(u)|\rho)=-a(u)\log(qa(u))-(q-1)b(u)\log(qb(u)).$$

Finally, for $u=-\frac{1}{2}$, modulo permutations $\mathcal{E}^u$ consists of the unique vector (1, 0,…,0) [see (4.7)], and so $s\left(-\frac{1}{2}\right)=-R((1,0,\ldots,0)|\rho)=-\log q$. The resulting formulas for $s(u)$ are recorded in the next theorem, where we distinguish between $q=3$ and $q\geqslant 4$.

Theorem 4.3: *We define the microcanonical entropy* $s(u)$ *in* (4.2). *The following conclusions hold.*

(a) $\operatorname{dom} s=\left[-\frac{1}{2},-1/2q\right]$; *for any* $u\in\operatorname{dom} s$, $u\neq -1/2q$, $s(u)<s(-1/2q)=0$; *and* $s\left(-\frac{1}{2}\right)=-\log q$.

(b) *Let* $q=3$. *Then for* $u\in\left(-\frac{1}{2},-1/2q\right)=\left(-\frac{1}{2},-\frac{1}{6}\right)$,

$$s(u)=-\frac{1+\sqrt{2(-6u-1)}}{3}\log(1+\sqrt{2(-6u-1)})-\frac{2-\sqrt{2(-6u-1)}}{3}\log\left(\frac{2-\sqrt{2(-6u-1)}}{2}\right). \tag{4.3}$$

(c) *Let* $q\geqslant 4$ *and assume that Conjecture* 4.1 *is valid. Then for* $u\in\left(-\frac{1}{2},-1/2q\right)$,

$$s(u)=-\frac{1+\sqrt{(q-1)(-2qu-1)}}{q}\log(1+\sqrt{(q-1)(-2qu-1)})-\frac{q-1-\sqrt{(q-1)(-2qu-1)}}{q}\log\left(\frac{q-1-\sqrt{(q-1)(-2qu-1)}}{q-1}\right). \tag{4.4}$$

We now turn to the proof of Theorem 4.2, which gives the form of $\mathcal{E}^u$. We start by proving part (a). The set $\mathcal{E}^u$ of microcanonical equilibrium macrostates consists of all $\nu\in\mathcal{P}$ that minimize the relative entropy $R(\nu|\rho)$ subject to the constraint that

$$\widetilde{H}(\nu)=-\tfrac{1}{2}\langle\nu,\nu\rangle=u.$$

Let $u=-\frac{1}{2}r^2$. Since $\mathcal{P}$ consists of all non-negative vectors in $\mathbb{R}^q$ satisfying $\nu_1+\cdots+\nu_q=1$, the constraint set in the minimization problem defining $\mathcal{E}^u$ is given by

$$C(u)=C\left(-\tfrac{1}{2}r^2\right)=\left\{\nu\in\mathbb{R}^q:\nu_1\geqslant 0,\ldots,\nu_q\geqslant 0,\sum_{j=1}^q\nu_j=1,\sum_{j=1}^q\nu_j^2=r^2\right\}. \tag{4.5}$$

Geometrically, $C\left(-\frac{1}{2}r^2\right)$ is the intersection of the non-negative orthant of $\mathbb{R}^q$, the hyperplane consisting of $\nu\in\mathbb{R}^\sigma$ that satisfy $\nu_1+\cdots+\nu_q=1$, and the hypersphere in $\mathbb{R}^q$ with center 0 and radius r. Clearly, $C(u)\neq\emptyset$ if and only if u lies in the range of the energy representation function $\widetilde{H}(\nu)=-\frac{1}{2}\langle\nu,\nu\rangle$ on $\mathcal{P}$. Because $0\leqslant R(\nu|\rho)<\infty$ for all $\nu\in C(u)$, the range of $\widetilde{H}$ on $\mathcal{P}$ also equals the set of u for which $\mathcal{E}^u\neq\emptyset$.

The geometric description of $C(u)$ makes it straightforward to determine those values of u for which this constraint set is nonempty. The smallest value of r for which $C\left(-\frac{1}{2}r^2\right)\neq\emptyset$ is obtained when the hypersphere of radius r is tangent to the hyperplane, the point of tangency being $\rho=(1/q,1/q,\ldots,1/q)$, the closest probability vector to the origin. The hypersphere and the hyperplane are tangent when $r=1/\sqrt{q}$, which coincides with the distance from the center of the hypersphere to the hyperplane. It follows that the largest value of u for which $C(u)\neq\emptyset$, and thus $\mathcal{E}^u\neq\emptyset$, is $u=-\frac{1}{2}r^2=-1/2q$. In this case

$$C\left(-\frac{1}{2q}\right)=\{\rho\}=\left\{\left(\frac{1}{q},\frac{1}{q},\ldots,\frac{1}{q}\right)\right\}=\mathcal{E}^{-1/2q}. \tag{4.6}$$

For all sufficiently large r, $C(-\frac{1}{2}r^2)$ is empty because the hypersphere of radius r has empty intersection with the intersection of the hyperplane and the non-negative orthant of $\mathbb{R}^q$. The largest value for r for which this does not occur is found by subtracting the two equations defining the hyperplane and the hypersphere. Since each $\nu_i \in [0,1]$, it follows that

$$0 \leqslant \sum_{i=1}^{q} \nu_i(1-\nu_i) = 1 - r^2,$$

and this in turn implies that $r^2 \leqslant 1$. Thus $r=1$ is the largest value for r for which $C(-\frac{1}{2}r^2) \neq \emptyset$. We conclude that the smallest value of u for which $C(u) \neq \emptyset$, and thus $\mathcal{E}^u \neq \emptyset$, is $u=-\frac{1}{2}r^2=-\frac{1}{2}$. The set $\mathcal{E}^{-\frac{1}{2}}$ consists of the points at which the hyperplane intersects each of the positive coordinate axes; i.e.,

$$\mathcal{E}^{-1/2} = \{(1,0,\ldots,0),(0,1,\ldots,0),\ldots,(0,0,\ldots,1)\}. \tag{4.7}$$

This completes the proof of part (a) of Theorem 4.2.

For $u \in [-\frac{1}{2}, -1/2q]$, we now determine the form $\mathcal{E}^u$ as specified in parts (b)–(d) of Theorem 4.2. Part (b) considers any $q \geqslant 3$ and the values $u=-1/2q$ and $u=-\frac{1}{2}$, part (c) $q=3$ and $u \in (-\frac{1}{2}, -1/2q)$, and part (d) $q \geqslant 4$ and $u \in (-\frac{1}{2}, -1/2q)$. Part (b) has already been proved; for $u=-1/2q$ and $u=-\frac{1}{2}$, the sets $\mathcal{E}^u$ are given in (4.6) and (4.7).

We now consider $q \geqslant 3$ and $u \in (-\frac{1}{2}, -1/2q)$. For $\nu \in \mathcal{P}$ define

$$K(\nu) = \sum_{j=1}^{q} \nu_j \quad \text{and } \tilde{H}(\nu) = -\tfrac{1}{2}\langle \nu, \nu \rangle.$$

By definition $\nu=(\nu_1,\ldots,\nu_q) \in \mathcal{E}^u$ if and only if ν minimizes $R(\nu|\rho)=\Sigma_{j=1}^q \nu_j \log(q\nu_j)$ subject to the constraints $K(\nu)=1$, $\tilde{H}(\nu)=u$, and $\nu_1 \geqslant 0,\ldots,\nu_q \geqslant 0$. For $u \in (-\frac{1}{2}, -1/2q)$ we divide into two parts the calculation of the form of $\nu \in \mathcal{E}^u$. First we use Lagrange multipliers to solve the constrained minimization problem when $\nu_1 > 0,\ldots,\nu_1 > 0$. Then we argue that the vectors ν found via Lagrange multipliers solve the original constrained minimization problem when $\nu_1 \geqslant 0,\ldots,\nu_q \geqslant 0$.

We introduce Lagrange multipliers γ and λ. Any critical point of $R(\nu|\rho)$ subject to the constraints $K(\nu)=1$, $\tilde{H}(\nu)=u$, and $\nu_1 > 0$, $\nu_2 > 0,\ldots,\nu_q > 0$ satisfies

$$\nabla R(\nu|\rho) = \gamma \nabla K(\nu) + \lambda \nabla \tilde{H}(\nu),$$

$$K(\nu) = 1,$$

$$\tilde{H}(\nu) = u,$$

$$\nu_j > 0 \quad \text{for } j = 1,2,\ldots,q.$$

This system of equations is equivalent to

$$1 + \log(q\nu_j) = \gamma - \lambda\nu_j \quad \text{for } j = 1,2,\ldots,q, \tag{4.8}$$

$$\sum_{j=1}^{q} \nu_j = 1,$$

$$-\frac{1}{2}\sum_{j=1}^{q} \nu_j^2 = u,$$

$$\nu_j > 0 \quad \text{for } j = 1,2,\ldots,q.$$

By the strict concavity of the logarithm, the first equation can have at most two solutions. Hence modulo permutations, there exists $n \in \{0,1,\ldots,q\}$ and distinct numbers $a,b \in (0,1)$ such that the first n components of any critical point ν all equal a and the last $q-n$ components of ν all equal b. The second and third equations in (4.8) take the form

$$na + (q-n)b = 1 \quad \text{and } na^2 + (q-n)b^2 = -2u. \tag{4.9}$$

If $n=0$, then $b=1/q$, while if $n=q$, then $a=1/q$. Both cases correspond to $\nu = (1/q,\ldots,1/q) = \rho$ and $u=-1/2q$, which does not lie in the open interval $\left(-\frac{1}{2},-1/2q\right)$ currently under consideration.

We now focus on $n \in \{1,\ldots,q-1\}$. In this case the two solutions of (4.9) are

$$a_1(n) = \frac{n - \sqrt{n(q-n)(-2qu-1)}}{nq}, \quad b_1(n) = \frac{q-n+\sqrt{n(q-n)(-2qu-1)}}{(q-n)q} \tag{4.10}$$

and

$$a_2(n) = \frac{n + \sqrt{n(q-n)(-2qu-1)}}{nq}, \quad b_2(n) = \frac{q-n-\sqrt{n(q-n)(-2qu-1)}}{(q-n)q}. \tag{4.11}$$

Since $u \in \left(-\frac{1}{2},-1/2q\right)$, these quantities are all well defined and $a_j(n) \neq b_j(n)$ for $j=1,2$. In addition,

$$a_1(q-n) = b_2(n) \quad \text{and } b_1(q-n) = a_2(n).$$

This means that the point having the first n components $a_2(n)$ and the last $q-n$ components $b_2(n)$ equals, modulo permutations, the point having the first $q-n$ components $a_1(q-n)$ and the last n components $b_1(q-n)$.

Thus, without loss of generality, we can seek solutions of the system (4.8) having the first n components $a_2(n)$ and the last $q-n$ components $b_2(n)$. While $a_2(1)$ and $b_2(1)$ are always positive for all $u \in \left(-\frac{1}{2},-1/2q\right)$, $b_2(n)$ might be negative for some $n \in \{2,\ldots,q-1\}$ and some $u \in \left(-\frac{1}{2},-1/2q\right)$. In this case the positivity constraint in the last line of (4.8) excludes such values of n and u.

We give full details when $q=3$, the case considered in part (c) of Theorem 4.2. When $q=3$, the interval $\left(-\frac{1}{2},-1/2q\right)$ equals $\left(-\frac{1}{2},-1/6\right)$ and we have $n \in \{1,2\}$. For $n=1$ and $n=2$ (4.11) takes the form

$$a_2(1) = \frac{1+\sqrt{2(-6u-1)}}{3}, \quad b_2(1) = \frac{2-\sqrt{2(-6u-1)}}{6}$$

and

$$a_2(2) = \frac{2+\sqrt{2(-6u-1)}}{6}, \quad b_2(2) = \frac{1-\sqrt{2(-6u-1)}}{3}.$$

For $u \in \left(-\frac{1}{2},-\frac{1}{4}\right)$, $b_2(2)$ is negative and hence a solution of (4.8) cannot have the form $(a_2(2),a_2(2),b_2(2))$. We conclude that when $u \in \left(-\frac{1}{2},-\frac{1}{4}\right)$, $\nu=(a_2(1),b_2(1),b_2(1))$ is, modulo permutations, the unique solution of (4.8) and thus the unique minimizer of $R(\nu|\rho)$ subject to the constraints in the last three lines of (4.8). For $u \in \left[-\frac{1}{4},-\frac{1}{6}\right)$, a straightforward calculation shows that

$$R((a_2(1),b_2(1),b_2(1))|\rho) < R((a_2(2),a_2(2),b_2(2))|\rho).$$

It follows again that $\nu=(a_2(1),b_2(1),b_2(1))$ is, modulo permutations, the unique minimizer of $R(\nu|\rho)$ subject to the constraints in the last three lines of (4.8). This completes the proof that for

$q=3$ and any $u \in \left(-\frac{1}{2}, -\frac{1}{6}\right)$, $\nu=(a_2(1), b_2(1), b_2(1))$ is, modulo permutations, the unique minimizer of $R(\mu|\rho)$ subject to the constraints $K(\nu)=1$, $\widetilde{H}(\nu)=u$, and $\nu_1>0$, $\nu_2>0$, $\nu_3>0$.

We now prove for $q=3$ that the minimizers found via Lagrange multipliers when $K(\nu)=1$, $\widetilde{H}(\nu)=u$, and $\nu_1>0$, $\nu_2>0$, $\nu_3>0$ also minimize $R(\nu|\rho)$ subject to the constraints $K(\nu)=1$, $\widetilde{H}(\nu)=u$, and $\nu_1 \geqslant 0$, $\nu_2 \geqslant 0$, $\nu_3 \geqslant 0$. If $\nu=(\nu_1, \nu_2, \nu_3)$ satisfies the latter constraints and has two components equal to zero, then modulo permutations $\nu=(1,0,0)$ and $\widetilde{H}(\nu)=u=-\frac{1}{2}$, which does not lie in the open interval $\left(-\frac{1}{2}, -\frac{1}{6}\right)$ currently under consideration. Thus we only have to consider the case where ν has one component equal to zero; i.e, $\nu=(0, a_0, b_0)$ with $a_0 \geqslant b_0$. In this case the second and third equations in (4.8) have the solution

$$a_0 = \frac{1+\sqrt{-4u-1}}{2}, \quad b_0 = \frac{1-\sqrt{-4u-1}}{2}.$$

We now claim that modulo permutations the unique minimizer of $R(\nu|\rho)$ subject to the constraints $K(\nu)=1$, $\widetilde{H}(\nu)=u$, and $\nu_1 \geqslant 0$, $\nu_2 \geqslant 0$, $\nu_3 \geqslant 0$ has the form $(a_2(1), b_2(1), b_2(1))$ found in the preceding paragraph. The claim follows from the calculation

$$R((a_2(1), b_2(1), b_2(1))|\rho) < R((0, a_0, b_0)|\rho),$$

which is valid for all $u \in \left(-\frac{1}{2}, -\frac{1}{6}\right)$. This completes the proof of part (c) of Theorem 4.2, which gives the form of $\nu \in \mathcal{E}^u$ for $q=3$ and $u \in \left(-\frac{1}{2}, -\frac{1}{6}\right)$.

We now turn to part (d) of Theorem 4.2, which gives the form of $\mathcal{E}^u$ for $q \geqslant 4$ and $u \in \left(-\frac{1}{2}, -1/2q\right)$. If, as in the case $q=3$, we knew that modulo permutations, the minimizers have the form $(a, b, \ldots, b)$ as specified in Conjecture 4.1, then as in the case $q=3$ we would be able to derive explicit formulas for these minimizers. If Conjecture 4.1 is true, then it is easily verified that modulo permutations, $\mathcal{E}^u$ consists of the unique point $\nu=(a_2(1), b_2(1), \ldots, b_2(1))$, where $a_2(1)$ and $b_2(1)$ are defined in (4.11) for $u \in \left(-\frac{1}{2}, -1/2q\right)$. This gives part (d) of Theorem 4.2. The proof of the theorem is complete.

At the end of Sec. VI we will see that there exists an explicit value of $u_0 \in \left(-\frac{1}{2}, -1/2q\right)$ such that Conjecture 4.1 is valid for any $q \geqslant 4$ and all $u \in \left(-\frac{1}{2}, u_0\right]$. Hence for these values of u the form of $\nu \in \mathcal{E}^u$ given in part (d) of Theorem 4.2 and the formula for $s(u)$ given in part (c) of Theorem 4.3 are both rigorously true.

V. EQUIVALENCE AND NONEQUIVALENCE OF ENSEMBLES

As we saw in Sec. III, the set $\mathcal{E}_\beta$ of canonical equilibrium macrostates undergoes a discontinuous phase transition as β increases through $\beta_c=[2(q-1)/(q-2)]\log(q-1)$, the unique macrostate ρ bifurcating discontinuously into the q distinct macrostates $\nu^{(i)}(\beta)$. By contrast, as we saw in Sec. IV, the set $\mathcal{E}^u$ of microcanonical equilibrium macrostates undergoes a continuous phase transition as u decreases from $u_c=-1/2q$, the unique macrostate ρ bifurcating continuously into the q distinct macrostates $\mu^i(u)$. The different continuity properties of these phase transitions shows already that the canonical and microcanonical ensembles are nonequivalent. In this section we study this nonequivalence in detail and relate the equivalence and nonequivalence of these two sets of equilibrium macrostates to concavity and support properties of the microcanonical entropy s defined in (4.2). This is done with the help of Fig. 2, which is based on the form of s in Fig. 1 and on the results on ensemble equivalence and nonequivalence in Theorem 5.1. In Figs. 3 and 4 at the end of the section we give, for $q=3$, a beautiful geometric representation of $\mathcal{E}_\beta$ and $\mathcal{E}^u$ that also shows the ensemble nonequivalence for a range of u.

We start by stating in Theorem 5.1 results on ensemble equivalence and nonequivalence for the Curie–Weiss–Potts model. Theorem 5.1 summarizes Theorems 4.4, 4.6, and 4.8 in Ref. 15, which apply to a wide range of statistical mechanical models. The Curie–Weiss–Potts model is a special case. In this special case, we will show that the values of u and β in part (a)(i) of the next theorem are related by the thermodynamic formula $s'(u)=\beta$ [Theorem 6.2(b)]. For $u \in \text{dom } s$ the

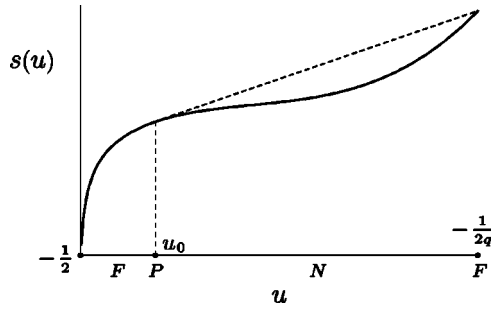

FIG. 1. Schematic graph of $s(u)$, showing the set $F=(-\frac{1}{2},u_0)\cup\{-1/2q\}$ of full ensemble equivalence, the singleton set $P=\{u_0\}$ of partial equivalence, and the set $N=(u_0,-1/2q)$ of nonequivalence. For $u\in F\cup P=(-\frac{1}{2},u_0]\cup\{-1/2q\}$, $s(u)=s^{**}(u)$; for $u\in N$, $s(u)<s^{**}(u)$ and the graph of s^{**} consists of the dotted line segment with slope β_c. The slope of s at $-\frac{1}{2}$ is ∞.

possible relationships between $\mathcal{E}^u$ and $\mathcal{E}_\beta$, given in part (a) of Theorem 5.1, are that either the ensembles are fully equivalent, partially equivalent, or nonequivalent. According to part (b) of the theorem, canonical equilibrium macrostates are always realized microcanonically—i.e., lie in $\mathcal{E}^u$ for some u—while according to part (a)(iii), microcanonical equilibrium macrostates are in general not realized canonically—i.e., do not lie in $\mathcal{E}_\beta$ for any β. It follows that the microcanonical ensemble is the richer of the two ensembles.

Theorem 5.1: *We define* s *by* (4.2) *and* $\mathcal{E}_\beta$ *and* $\mathcal{E}^u$ *by* (2.3) and (2.4). *The following conclusions hold.*

(a) *For fixed* $u\in\mathrm{dom}\,s$ *one of the following three possibilities occurs.*

(i) *Full equivalence: There exists* $\beta\in\mathbb{R}$ *such that* $\mathcal{E}^u=\mathcal{E}_\beta$. *This is the case if and only if* s *has a strictly supporting line at* u *with slope* β; *i.e.,*

$$s(v)<s(u)+\beta(v-u)\ \text{for all}\ v\neq u.$$

(ii) *Partial equivalence: There exists* $\beta\in\mathbb{R}$ *such that* $\mathcal{E}^u\subset\mathcal{E}_\beta$ *but* $\mathcal{E}^u\neq\mathcal{E}_\beta$. *This is the case if and only if* s *has a nonstrictly supporting line at* u *with slope* β; *i.e.,*

$$s(v)\leqslant s(u)+\beta(v-u)\ \textit{for all}\ v\in\mathbb{R}\ \textit{with equality for some}\ v\neq u.$$

(iii) *Nonequivalence: For all* $\beta\in\mathbb{R}$, $\mathcal{E}^u\cap\mathcal{E}_\beta=\emptyset$. *This is the case if and only if* s *has no supporting line at* u; *i.e., for any* $\beta\in\mathbb{R}$ *there exists* v *such that* $s(v)>s(u)+\beta(v-u)$.

(b) *Canonical is always realized microcanonically: For* $\nu\in\mathcal{P}$ *we define* $\widetilde{H}(\nu)=-\frac{1}{2}\langle\nu,\nu\rangle$. *Then for any* $\beta\in\mathbb{R}$,

$$\mathcal{E}_\beta=\bigcup_{u\in\widetilde{H}(\mathcal{E}_\beta)}\mathcal{E}^u.$$

We next relate ensemble equivalence and nonequivalence with concavity and support properties of s in the Curie–Weiss–Potts model. For $q=3$ an explicit formula for s is given in part (b) of Theorem 4.3. If Conjecture 4.1 is true, then the formula for s given in part (c) of Theorem 4.3 is also valid for $q\geqslant 4$. Figure 1 exhibits all the concavity and support features of s. However, Fig. 1 is not the actual graph of s but a schematic graph that accentuates the shape of s together with the intervals of strict concavity and nonconcavity of s. For arbitrary $q\geqslant 3$, as discussed in the second paragraph after Theorem 6.2, the concavity and support features of s exhibited in Fig. 1 follow from Theorems 5.1 and 6.2.

Concavity properties of s are defined in reference to the double-Legendre–Fenchel transform s^{**}, which can be characterized as the smallest concave, upper semicontinuous function that satisfies $s^{**}(u)\geqslant s(u)$ for all $u\in\mathbb{R}$ (Ref. 10, Proposition A.2). For $u\in\mathrm{dom}\,s$ we say that s is concave at u if $s(u)=s^{**}(u)$ and that s is not concave at u if $s(u)<s^{**}(u)$. Also, we say that s is

strictly concave at $u \in \operatorname{dom} s$ if s has a strictly supporting line at u and that s is strictly concave on a convex subset A of $\operatorname{dom} s$ if s is strictly concave at each $u \in A$. If s is strictly concave at u, then a straightforward argument shows that s is concave at u, as one expects [Ref. 10, Lemma 4.1(a)].

According to Fig. 1 and Theorem 5.1, there exists $u_0 \in \left(-\frac{1}{2}, -1/2q\right)$ with the following properties:

(i) s is strictly concave on the interval $\left(-\frac{1}{2}, u_0\right)$ and at the point $-1/2q$. Hence for $u \in F = \left(-\frac{1}{2}, u_0\right) \cup \{-1/2q\}$ the ensembles are fully equivalent [Theorem. 5.1(a)(i)]. In fact, for $u \in \operatorname{int} F = \left(-\frac{1}{2}, u_0\right)$, $\mathcal{E}^u = \mathcal{E}_\beta$ with β given by the thermodynamic formula $\beta = s'(u)$ [Theorem 6.2(b)].

(ii) s is concave but not strictly concave at u_0 and has a nonstrictly supporting line at u_0 that also touches the graph of s over the right-hand endpoint $-1/2q$. Hence for $u = u_0$ the ensembles are partially equivalent in the sense that there exists $\beta \in \mathbb{R}$ such that $\mathcal{E}^u \subset \mathcal{E}_\beta$ but $\mathcal{E}^u \neq \mathcal{E}_\beta$ [Theorem 5.1(a)(ii)]. In fact, β equals the critical inverse temperature β_c defined in (3.1).

(iii) s is not concave on the interval $N = (u_0, -1/2q)$ and has no supporting line at any $u \in N$ [Ref. 10, Theorem A.4(c)]. Hence for $u \in N$ the ensembles are nonequivalent in the sense that for all $\beta \in \mathbb{R}$, $\mathcal{E}^u \cap \mathcal{E}_\beta = \emptyset$ [Theorem 5.1(a)(iii)].

As we have just seen, u_0 can be characterized in terms of concavity and support properties of s. The quantity u_0 can also be characterized in terms of mapping properties of $\widetilde{H}(\nu) = -\frac{1}{2}\langle \nu, \nu \rangle$. Using this characterization, we give an explicit formula for u_0 in (6.2).

We point out two additional features of Fig. 1. First, although $\mathcal{E}^u \neq \emptyset$ for u equal to the left-hand endpoint $-\frac{1}{2}$ of $\operatorname{dom} s$, we do not include this point in the set F of full ensemble equivalence. Indeed, s is not strictly concave at $-\frac{1}{2}$ because there is no strictly supporting line at $-\frac{1}{2}$; as one can see in (5.1), the slope of s at $-\frac{1}{2}$ is ∞. Nevertheless, by introducing the limiting set

$$\mathcal{E}_\infty = \{(1,0,\ldots,0),(0,1,\ldots,0),\ldots,(0,0,\ldots,1)\} = \lim_{\beta \to \infty} \mathcal{E}_\beta,$$

we can extend full ensemble equivalence to $u = -\frac{1}{2}$ since $\mathcal{E}^{-1/2} = \mathcal{E}_\infty$.

Second, for u in the interval N of ensemble nonequivalence, the graph of s^{**} is affine; this is depicted by the dotted line segment in Fig. 1. The slope of the affine portion of the graph of s^{**} equals the critical inverse temperature β_c defined in (3.1). This can be proved using concave-duality relationships involving s^{**} and the canonical free energy. The quantity β_c also satisfies an equal-area property, first observed by Maxwell (Ref. 28, p. 45) and explained in the context of another spin model in Ref. 18, p. 535.

The relationships stated in items (i), (ii), and (iii) above give valuable insight into equivalence and nonequivalence of ensembles in the Curie–Weiss–Potts model. These relationships are illustrated in Fig. 2. In this figure we exhibit the graph of s' and the sets $\mathcal{E}_\beta$ and $\mathcal{E}^u$ in order to compare the phase transitions in the two ensembles and to understand the implications for ensemble equivalence and nonequivalence. In order to accentuate properties of s', $\mathcal{E}_\beta$, and $\mathcal{E}^u$ that are related to ensemble equivalence and nonequivalence, we focus on $q = 8$. In presenting the graph of s' and the form of $\mathcal{E}^u$, we assume that for $q = 8$ Conjecture 4.1 is valid. We then appeal to part (c) of Theorem 4.3, which gives an explicit formula for s, and to part (d) of Theorem 4.2, which gives an explicit formula for the elements of $\mathcal{E}^u$. The derivative s', graphed in the top left plot in Fig. 2, is given by

$$s'(u) = \sqrt{\frac{q-1}{-2qu-1}}\left[\log\left(1+\sqrt{(q-1)(-2qu-1)}\right) - \log\left(1-\sqrt{\frac{-2qu-1}{q-1}}\right)\right]. \tag{5.1}$$

The canonical phase diagram, given in the top right plot in Fig. 2, summarizes the description of $\mathcal{E}_\beta$ given in Theorem 3.1 and shows the discontinuous phase transition exhibited by this ensemble at $\beta_c = [2(q-1)/(q-2)]\log(q-1) = \frac{7}{3}\log 7$. The solid line in this plot for $\beta < \beta_c$ represents the common value $\frac{1}{8}$ of each of the components of ρ, which is the unique phase for $\beta < \beta_c$. For $\beta > \beta_c$ there are eight phases given by $\nu^1(\beta)$ together with the vectors $\nu^i(\beta)$ obtained by inter-

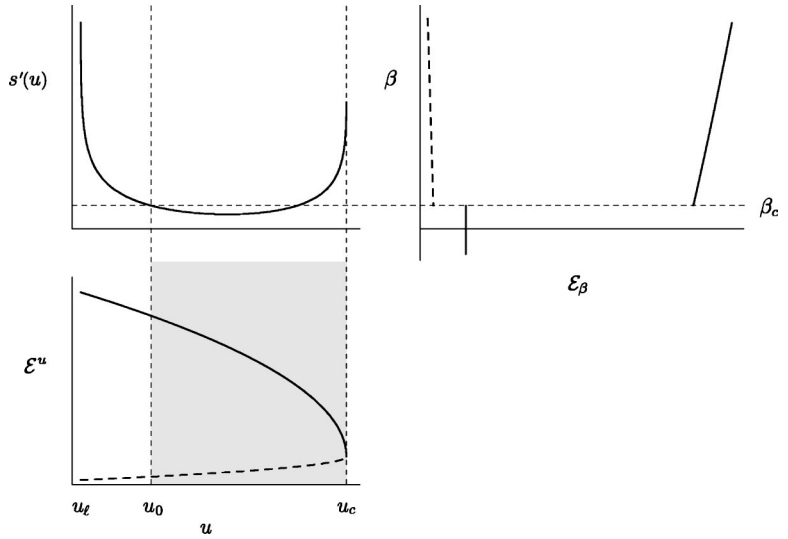

FIG. 2. For $q=8$ the top right plot shows $\mathcal{E}_\beta$, the top left plot the graph of $s'(u)$ for $u \in \operatorname{dom} s=[u_\ell,u_c]=\left[-\frac{1}{2},-1/2q\right]$, and the bottom left plot $\mathcal{E}^u$. The discontinuous phase transition at β_c in the top right plot and the continuous phase transition at u_c in the bottom left plot imply that the ensembles are nonequivalent for all $u \in N=(u_0,u_c)$. On this interval s is not concave and s^{**} is affine with slope β_c. The shaded area in the bottom left plot corresponds to the region of nonequivalence of ensembles delineated by $u \in N$.

changing the first and ith components of $\nu^1(\beta)$. Finally, for $\beta=\beta_c$ there are nine phases consisting of ρ and the vectors $\nu^i(\beta_c)$ for $i=1,2,\ldots,8$. The solid and dashed curves in the top right plot in Fig. 2 show the first component and the last seven, equal components of $\nu^1(\beta)$ for $\beta \in [\beta_c,\infty)$. The first component is a strictly increasing function equal to $\frac{7}{8}$ for $\beta=\beta_c$ and increasing to 1 as $\beta \to \infty$ while the last seven, equal components are strictly decreasing functions equal to $\frac{1}{56}$ for $\beta=\beta_c$ and decreasing to 0 as $\beta \to \infty$.

The microcanonical phase diagram, given in the bottom left plot in Fig. 2, summarizes the description of $\mathcal{E}^u$ given in Theorem 4.2 and shows the continuous phase transition exhibited by this ensemble as u decreases from the maximum value $u_c=-1/2q=-\frac{1}{16}$. The single phase ρ for $u=-\frac{1}{16}$ is represented by the point lying over this value of u. For $u \in \left[-\frac{1}{2},-\frac{1}{16}\right)$ there are eight phases given by $\mu^1(u)$ together with the vectors $\mu^i(u)$ obtained by interchanging the first and ith components of $\mu^1(u)$. The solid and dashed curves in the bottom left plot in Fig. 2 show the first component $a(u)$ and the last seven, equal components $b(u)$ of $\mu^1(u)$ for $u \in \left[-\frac{1}{2},-\frac{1}{16}\right)$. The first component is a strictly increasing function of $-u$ equal to $\frac{1}{8}$ for $u=-\frac{1}{16}$ and increasing to 1 as $u \to \left(-\frac{1}{2}\right)^+$, while the last seven, equal components are strictly decreasing functions of $-u$ equal to $\frac{1}{8}$ for $u=-\frac{1}{16}$ and decreasing to 0 as $u \to \left(-\frac{1}{2}\right)^+$.

The different nature of the two phase transitions—discontinuous in the canonical ensemble versus continuous in the microcanonical ensemble—implies that the two ensembles are not fully equivalent for all values of u. By necessity, the set $\mathcal{E}_\beta$ of canonical equilibrium macrostates must omit a set of microcanonical equilibrium macrostates. Further details concerning ensemble equivalence and nonequivalence can be seen by examining the graph of s', given in the top left plot of Fig. 2. This graph, which is the bridge between the canonical and microcanonical phase diagrams, shows that s' is strictly decreasing on the interval $\operatorname{int} F=\left(-\frac{1}{2},u_0\right)$, which is the interior of the set F of full ensemble equivalence. The critical value β_c equals the slope of the affine portion of the graph of s^{**} over the interval $N=(u_0,-1/2q)$ of ensemble nonequivalence. This affine portion is represented in the top left plot of Fig. 2 by the horizontal dashed line at β_c.

Figure 2 exhibits the full equivalence of ensembles that holds for $u \in \operatorname{int} F=\left(-\frac{1}{2},u_0\right)$ [Theorem 6.2(a)]. For u in this interval the solid and dashed curves representing the components of $\mu^1(u) \in \mathcal{E}^u$ can be put in one-to-one correspondence with the solid and dashed curves representing the

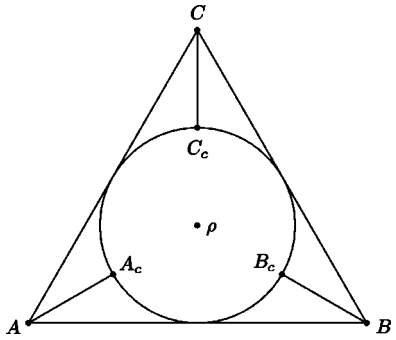

FIG. 3. Graphical representation of the set $\mathcal{E}_\beta$ of canonical equilibrium macrostates for $q=3$ showing the maximal circle of intersection corresponding to $u=u_0$; the vector ρ; the unit-coordinate vectors A, B, and C; and the macrostates $A_c=\nu^1(\beta_c)$, $B_c=\nu^2(\beta_c)$, and $C_c=\nu^3(\beta_c)$. The line segments $\overline{A_cA}$, $\overline{B_cB}$, and $\overline{C_cC}$ represent the elements of $\mathcal{E}_\beta$ for $\beta>\beta_c$.

same two components of $\nu^1(\beta)\in\mathcal{E}_\beta$ for $\beta\in(\beta_c,\infty)$. As we remarked earlier, the values of u and β are related by the thermodynamic formula $s'(u)=\beta$ [Theorem 6.2(b)]. Full equivalence of ensembles also holds for $u=-1/2q\in F$, the right-hand endpoint of the interval on which s is finite. The solid vertical line in the top right plot for $\beta<\beta_c$, which represents the unique canonical phase ρ, is collapsed in the bottom left plot to the single energy value $u=-1/2q$, which corresponds to the unique microcanonical phase ρ. This collapse shows that the canonical notion of temperature is somewhat ill-defined at $u=-1/2q$ since there are infinitely many values of β associated with this energy value. This feature of the Curie–Weiss–Potts model is not present, for example, in the mean-field Blume–Emery–Griffiths spin model, which also exhibits nonequivalence of ensembles.[18]

By comparing the top right and bottom left plots, we see that the elements of $\mathcal{E}^u$ cease to be related to those of $\mathcal{E}_\beta$ for $u\in N=(u_0,-1/2q)$, which is the interval on which s is not concave. For any energy value u in this interval no $\nu\in\mathcal{E}_\beta$ exists that can be put in correspondence with an equivalent equilibrium empirical vector contained in $\mathcal{E}^u$. Thus, although the equilibrium macrostates corresponding to $u\in N$ are characterized by a well-defined value of the energy, it is impossible to assign an inverse temperature β to those macrostates from the viewpoint of the canonical ensemble. In other words, the canonical ensemble is blind to all energy values u contained in the interval N of nonconcavity of s. This is closely related to the presence of the discontinuous phase transition seen in the canonical ensemble.

The quantity u_0 defined in (6.2) plays a central role in the analysis of phase transitions and ensemble equivalence in the Curie–Weiss–Potts model. First, as we saw in our discussion of Fig. 1, u_0 separates the interval $(-\frac{1}{2},u_0)$ of strict concavity of s and of full ensemble equivalence from the interval $(u_0,-1/2q)$ of nonconcavity of s and of ensemble nonequivalence. Second, part (a) of Lemma 6.1 shows that u_0 equals the limiting mean energy $\tilde{H}(\nu^1(\beta_c))$ in the canonical equilibrium macrostate $\nu^1(\beta)$ as $\beta\to(\beta_c)^+$. In Figs. 3 and 4 we present for $q=3$ a third, geometric interpretation of u_0 that is also related to ensemble nonequivalence.

Before explaining this third, geometric interpretation of u_0, we recall that according to part (a) of Theorem 4.2 specialized to $q=3$, $\mathcal{E}^u$ is nonempty, or equivalently the constraint set in (4.5) is nonempty, if and only if $u\in[-\frac{1}{2},-1/2q]=[-\frac{1}{2},-\frac{1}{6}]$. Geometrically, the energy constraint $\tilde{H}(\nu)=-\frac{1}{2}\langle\nu,\nu\rangle=u$ corresponds to the sphere in $\mathbb{R}^3$ with center 0 and radius $\sqrt{-2u}$. This sphere intersects the set $\mathcal{P}$ of probability vectors if and only if $u\in[-\frac{1}{2},-\frac{1}{6}]$. For $u=-\frac{1}{6}$, the sphere is tangent to $\mathcal{P}$ at the unique point ρ while for $u=-\frac{1}{2}$, the hypersphere intersects $\mathcal{P}$ at the q unit-coordinate vectors. The intersection of the sphere and $\mathcal{P}$ undergoes a phase transition at u_0 in the following sense. For $u\in[u_0,-\frac{1}{6})$ the sphere intersects $\mathcal{P}$ in a circle while for $u\in[-\frac{1}{2},u_0)$, the sphere intersects $\mathcal{P}$ in a proper subset of a circle; the complement of this subset lies outside the nonnegative octant of $\mathbb{R}^3$. For $u=u_0=-\frac{1}{4}$, the circle of intersection is maximal and is tangent to the boundary of $\mathcal{P}$.

The set $\mathcal{E}_\beta$ of canonical equilibrium macrostates for $q=3$ is represented in Fig. 3. In this figure

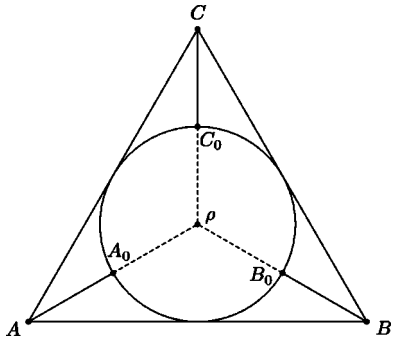

FIG. 4. Graphical representation of the set $\mathcal{E}^u$ of microcanonical equilibrium macrostates for $q=3$ showing the maximal circle of intersection corresponding to $u=u_0$; the vector ρ; the unit-coordinate vectors A, B, and C; and the macrostates $A_0=\mu^1(u_0)$, $B_0=\mu^2(u_0)$, and $C_0=\mu^3(u_0)$. The solid-line segments $\overline{A_0A}$, $\overline{B_0B}$, and $\overline{C_0C}$ represent the elements of $\mathcal{E}^u$ that are realized canonically. The dashed-line segments $\overline{\rho A_0}$, $\overline{\rho B_0}$, and $\overline{\rho C_0}$ represent the elements of $\mathcal{E}^u$ that are not realized canonically.

the maximal circle of intersection corresponding to $u=u_0=-\frac{1}{4}$ is shown together with the vector ρ at its center; the points A, B, and C representing the respective unit-coordinate vectors (1,0,0), (0,1,0), and (0,0,1); and the points A_c, B_c, and C_c representing the respective equilibrium macrostates $\nu^1(\beta_c)$, $\nu^2(\beta_c)$, and $\nu^3(\beta_c)$. These three macrostates lie on the maximal circle of intersection since $\widetilde{H}(\nu^1(\beta_c))=u_0$ [Lemma 6.1(b)]. For $\beta>\beta_c$ all $\nu\in\mathcal{E}_\beta$ have two equal components, and as $\beta\to\infty$ these vectors converge to the unit-coordinate vectors A, B, and C. Hence for $\beta>\beta_c$ the equilibrium macrostates $\nu^1(\beta)$, $\nu^2(\beta)$, and $\nu^3(\beta)$ are represented by the open line segments $\overline{A_cA}$, $\overline{B_cB}$, and $\overline{C_cC}$.

The set $\mathcal{E}^u$ of microcanonical equilibrium macrostates for $q=3$ is represented in Fig. 4. In this figure the maximal circle of intersection corresponding to $u=u_0=-\frac{1}{4}$ is shown together with the vector ρ at its center; the points A, B, and C representing the unit-coordinate vectors; and the points A_0, B_0, and C_0 representing the respective equilibrium macrostates $\mu^1(u_0)$, $\mu^2(u_0)$, and $\mu^3(u_0)$. For $u\in\left(-\frac{1}{2},-\frac{1}{6}\right)$ all $\nu\in\mathcal{E}^u$ have two equal components, and as $u\to\left(-\frac{1}{2}\right)^+$ they converge to the unit coordinate vectors A, B, and C. Hence for $u\in\left(-\frac{1}{2},-\frac{1}{6}\right)$ the equilibrium macrostates $\mu^1(u)$, $\mu^2(u)$, and $\mu^3(u)$ are represented by the open line segments $\overline{\rho A}$, $\overline{\rho B}$, and $\overline{\rho C}$. As we saw in the preceding section, for each $u\in\left(-\frac{1}{2},-\frac{1}{6}\right)$ the macrostates $\mu^1(u)$, $\mu^2(u)$, and $\mu^3(u)$ lie on the intersection of the sphere of radius $\sqrt{-2u}$ with $\mathcal{P}$. In particular, $A_0=\mu^1(u_0)$, $B_0=\mu^2(u_0)$, and $C_0=\mu^3(u_0)$ lie on the maximal circle of intersection.

The distinguishing feature of Fig. 4 is the three open dashed-line segments $\overline{\rho A_0}$, $\overline{\rho B_0}$, and $\overline{\rho C_0}$ representing the elements of $\mathcal{E}^u$ that are not realized canonically; namely, $\mu^1(u)$, $\mu^2(u)$, and $\mu^3(u)$ for $u\in\left(u_0,-\frac{1}{6}\right)$. The three half open solid-line segments $\overline{A_0A}$, $\overline{B_0B}$, and $\overline{C_0C}$ represent the elements of $\mathcal{E}^u$ that are realized canonically; namely, $\mu^1(u)$, $\mu^2(u)$, and $\mu^3(u)$ for $u\in\left(-\frac{1}{2},u_0\right]$. For each such u the value of β for which $\mathcal{E}^u=\mathcal{E}_\beta$ is determined by the equation $\widetilde{H}(\nu^1(\beta))=u$ [Theorem 6.2(a)]. Thus in Fig. 3 the corresponding elements of $\mathcal{E}_\beta$ lie on the intersection of the sphere of radius $\sqrt{-2u}$ and $\mathcal{P}$.

This completes our discussion of equivalence and nonequivalence of ensembles. In the next section we will prove a number of statements concerning ensemble equivalence and nonequivalence that have been determined graphically.

VI. PROOFS OF EQUIVALENCE AND NONEQUIVALENCE OF ENSEMBLES

Using the general results of Ref. 15, we stated in the preceding section the equivalence and nonequivalence relationships that exist between $\mathcal{E}^u$ and $\mathcal{E}_\beta$ and verified these relationships using the plots of these sets for $q=8$ given in Fig. 2. Our purpose in the present section is to prove these relationships using mapping properties of the mean energy function $u(\beta)$ defined for $\beta\neq\beta_c$ by

$$u(\beta) = \begin{cases} \widetilde{H}(\rho) = -\dfrac{1}{2q} & \text{for } \beta < \beta_c, \\ \widetilde{H}(\nu^1(\beta)) = -\frac{1}{2}\langle \nu^1(\beta), \nu^1(\beta)\rangle & \text{for } \beta > \beta_c. \end{cases} \tag{6.1}$$

Here $\nu^1(\beta)$ is the unique canonical equilibrium macrostate modulo permutations for $\beta > \beta_c$ [Theorem 3.1]. According to the next lemma, for $\beta > \beta_c$, $u(\beta)$ is continuous and strictly decreasing and $u(\beta) < -1/2q$, which equals the mean energy for $\beta < \beta_c$. It follows that as β increases through β_c, $u(\beta)$ is discontinuous, jumping down from $-1/2q$ to $\widetilde{H}(\nu^1(\beta))$. This discontinuity in $u(\beta)$ mirrors in a natural way the discontinuity in $\mathcal{E}_\beta$ as β increases through β_c.

We use the same notation u_0 for the quantity defined in (6.2) as for the quantity u_0 appearing in Fig. 1 in Sec. V because these two quantities coincide. Indeed, with u_0 defined in (6.2), we prove in Theorem 6.2 that the largest open interval on which full equivalence of ensembles holds is $\text{int } F = \left(-\frac{1}{2}, u_0\right)$. This coincides with the interior of the interval F shown in Fig. 1. As that figure exhibits, int F is the largest open interval on which s is strictly concave; by Theorem 5.1, that open interval coincides with the largest open interval on which full equivalence of ensembles holds.

Lemma 6.1: For $\beta \in [\beta_c, \infty)$ we define $\nu^1(\beta)$ as in part (b) *of Theorem 3.1 and we define*

$$u_0 = \frac{-q^2 + 3q - 3}{2q(q-1)}. \tag{6.2}$$

The following conclusions hold.

(a) $-\frac{1}{2} < u_0 < -1/2q$ *and* $\lim_{\beta \to (\beta_c)^+} u(\beta) = \widetilde{H}(\nu^1(\beta_c)) = u_0$.

(b) *The function mapping*

$$\beta \in (\beta_c, \infty) \mapsto u(\beta) = \widetilde{H}(\nu^1(\beta)) = -\tfrac{1}{2}\langle \nu^1(\beta), \nu^1(\beta)\rangle$$

is a strictly decreasing, differentiable bijection onto the interval $\left(-\frac{1}{2}, u_0\right)$.

Proof: (a) The inequalities involving u_0 follow immediately from the inequality $q \geqslant 3$. The relationship $\widetilde{H}(\nu^1(\beta_c)) = u_0$ is easily determined using the explicit form of $\nu^1(\beta_c)$ given in (3.5). That $\lim_{\beta \to (\beta_c)^+} u(\beta) = \widetilde{H}(\nu^1(\beta_c))$ follows from the definition of $u(\beta)$ and the continuity of $\nu^1(\beta)$ for $\beta \geqslant \beta_c$.

(b) For $w \in \mathbb{R}$ define

$$f(w) = -\frac{1}{2}\left(\frac{[1 + (q-1)w]^2}{q^2} + (q-1)\frac{[1-w]^2}{q^2} \right).$$

For $\beta \in (\beta_c, \infty)$ we use the formula for $\nu^1(\beta)$ given in part (b) of Theorem 3.1 to write $u(\beta) = -f(w(\beta))$. The quantity $w(\beta)$ is positive and strictly increasing, and for all $w > 0$,

$$f'(w) = \frac{(q-1)w}{q} > 0.$$

As the composition of two strictly increasing functions, for $\beta \in (\beta_c, \infty)$, $-u(\beta)$ is strictly increasing and thus $u(\beta)$ is strictly decreasing. In addition, since $\lim_{\beta \to \infty} w(\beta) = 1$ [Theorem 3.1(a)], we have $\lim_{\beta \to \infty} u(\beta) = -\frac{1}{2}$, and by part (a) of this lemma

$$\lim_{\beta \to (\beta_c)^+} u(\beta) = \widetilde{H}(\nu(\beta_c)) = u_0.$$

It follows that the function mapping $\beta \in (\beta_c, \infty) \mapsto u(\beta)$ is a strictly decreasing, differentiable bijection onto the interval $\left(-\frac{1}{2}, u_0\right)$. This completes the proof of part (b). ■

Mapping properties of $u(\beta)$ play an important role in the next theorem, in which we prove that the sets F, P, and N defined in (6.3) correspond to full equivalence, partial equivalence, and

nonequivalence of ensembles. For $u \in F$ we consider three subcases in order to indicate the value of β for which $\mathcal{E}^u = \mathcal{E}_\beta$; for $u \in \text{int } F = (-\frac{1}{2}, u_0)$, β and u are related by $\beta = s'(u)$ and $u = u(\beta)$. Part (c) shows an interesting degeneracy in the equivalence-of-ensemble picture, the set $\mathcal{E}^u$ for $u = -1/2q$ corresponding to all $\mathcal{E}_\beta$ for $\beta < \beta_c$. This is related to the fact that for all such values of β, $\mathcal{E}_\beta = \{\rho\}$ and thus the mean energy $u(\beta)$ equals $-1/2q$.

Theorem 6.2: *We define* $s(u)$ *in* (4.2), $u(\beta)$ *in* (6.1), $\mathcal{E}_\beta$ *in* (2.3), *and* $\mathcal{E}^u$ *in* (2.4). *We also define* β_c *in* (3.1) *and* u_0 *in* (6.2). *The sets*

$$F = \left(-\tfrac{1}{2}, u_0\right) \cup \left\{-\frac{1}{2q}\right\}, \quad P = \{u_0\}, \quad \text{and } N = \left(u_0, -\frac{1}{2q}\right) \tag{6.3}$$

have the following properties.

(a) *Full equivalence on* int F: *For* $u \in \text{int } F = (-\frac{1}{2}, u_0)$, *there exists a unique* $\beta \in (\beta_c, \infty)$ *such that* $\mathcal{E}^u = \mathcal{E}_\beta$; β *satisfies* $u(\beta) = \tilde{H}(\nu^1(\beta)) = u$.

(b) *For* $u \in \text{int } F = (-\frac{1}{2}, u_0)$, s *is differentiable. The values* u *and* β *for which* $\mathcal{E}^u = \mathcal{E}_\beta$ *in part* (a) *are also related by the thermodynamic formula* $s'(u) = \beta$.

(c) *Full equivalence at* $-1/2q$: *For* $u = -(1/2q) \in F$, $\mathcal{E}^{-1/2q} = \mathcal{E}_\beta$ *for any* $\beta < \beta_c$.

(d) *Partial equivalence on* P: *For* $u \in P = \{u_0\}$, $\mathcal{E}^{u_0} \subset \mathcal{E}_{\beta_c}$ *but* $\mathcal{E}^{u_0} \neq \mathcal{E}_{\beta_c}$. *In fact,* $\mathcal{E}_{\beta_c} = \mathcal{E}^{u_0} \cup \mathcal{E}^{-1/2q}$.

(e) *Nonequivalence on* N: *For any* $u \in N = (u_0, -1/2q)$, $\mathcal{E}^u \cap \mathcal{E}_\beta = \emptyset$ *for all* $\beta \in \mathbb{R}$.

In reference to the properties of s given in part (b), one can show that the function mapping $u \in (-\frac{1}{2}, u_0) \mapsto s'(u)$ is a strictly decreasing, differentiable bijection onto the interval (β_c, ∞) and that this bijection is the inverse of the bijection mapping $\beta \in (\beta_c, \infty) \mapsto u(\beta)$.

Before we prove the theorem, it is instructive to compare its assertions with those in Theorem 5.1, which formulates ensemble equivalence and nonequivalence in terms of support properties of s. These support properties can be seen in the schematic plot of the the graph of s in Fig. 1. We start with part (a) of Theorem 6.2, which states that for any $u \in \text{int } F = (-\frac{1}{2}, u_0)$ there exists a unique $\beta \in (\beta_c, \infty)$ such that $\mathcal{E}^u = \mathcal{E}_\beta$. As promised in part (a)(i) of Theorem 5.1, this β is the slope of a strictly supporting line to the graph of s at u, and so s is strictly concave on int F. The situation that holds when $u = -1/2q$ [Theorem 6.2(c)] is also consistent with part (a)(i) of Theorem 5.1. For this value of u, which is the isolated point of the set F of full equivalence, there exist infinitely many strictly supporting lines to the graph of s, the possible slopes of which are all $\beta \in (-\infty, \beta_c)$. On the other hand, when $u = u_0$, which is the only value lying in the set P of partial equivalence, we have $\mathcal{E}^{u_0} \subset \mathcal{E}_{\beta_c}$ but $\mathcal{E}^{u_0} \neq \mathcal{E}_{\beta_c}$ [Theorem 6.2(d)]. In combination with part (a)(ii) of Theorem 5.1, it follows that there exists a nonstrictly supporting line at u_0 with slope β_c and that s is concave at u_0 but not strictly concave. Finally, for $u \in N = (u_0, -1/2q)$, we have $\mathcal{E}^u \cap \mathcal{E}_\beta = \emptyset$ for all $\beta \in \mathbb{R}$ [Theorem 6.2(e)]. In accordance with part (a)(iii) of Theorem 5.1, s has no supporting line at any $u \in N$, and by Theorem A.4 in Ref. 10 s is not concave at any $u \in N$.

Proof of Theorem 6.2: (a) For $\beta > \beta_c$ part (b) of Theorem 3.1 and part (b) of Theorem 5.1 imply that

$$\mathcal{E}_\beta = \{\nu^1(\beta), \ldots, \nu^q(\beta)\} = \bigcup_{u \in \tilde{H}(\mathcal{E}_\beta)} \mathcal{E}^u.$$

The symmetry of $\tilde{H}$ with respect to permutations implies that $\tilde{H}(\mathcal{E}_\beta) = \{\tilde{H}(\nu^1(\beta))\}$. Thus for any $\beta > \beta_c$

$$\mathcal{E}_\beta = \mathcal{E}^{\tilde{H}(\nu^1(\beta))}. \tag{6.4}$$

Since for any $u \in \text{int } F = (-\frac{1}{2}, u_0)$ there exists a unique $\beta \in (\beta_c, \infty)$ satisfying $u(\beta) = \tilde{H}(\nu^1(\beta)) = u$ [Lemma 6.1(b)], it follows that $\mathcal{E}^u = \mathcal{E}_\beta$.

(b) The differentiability of s on int F is proved in part (b) of Theorem 6.3, which depends only on part (a) of the present theorem. By part (a) of the present theorem and part (a) of Theorem 5.1, s has a strictly supporting line at each $u \in \text{int } F$. It follows that s is strictly concave on int F and

thus concave on int F [Ref. 10, Lemma 4.1(a)]; i.e., $s(u)=s^{**}(u)$ for all $u \in \text{int } F$. The differentiability of s on int F [Theorem 6.3(b)] combined with part (a) of Theorem A.3 in Ref. 10 implies that $s'(u)=\beta$.

(c) By (4.6) and part (b) of Theorem 3.1,

$$\mathcal{E}^{-1/2q}=\{\rho\}=\mathcal{E}_\beta \quad \text{for any } \beta<\beta_c. \tag{6.5}$$

(d) By part (b) of Theorem 3.1, symmetry, and part (a) of Lemma 6.1,

$$\tilde{H}(\mathcal{E}_{\beta_c})=\{\tilde{H}(\rho),\tilde{H}(\nu^1(\beta_c))\}=\left\{-\frac{1}{2q},u_0\right\}.$$

Hence by (6.4) and (6.5),

$$\mathcal{E}_{\beta_c}=\bigcup_{u\in\tilde{H}(\mathcal{E}_{\beta_c})}\mathcal{E}^u=\mathcal{E}^{-1/2q}\cup\mathcal{E}^{u_0}=\{\rho\}\cup\mathcal{E}^{u_0}.$$

However, $\rho\notin\mathcal{E}^{u_0}$ since ρ does not satisfy the constraint $\tilde{H}(\rho)=u_0$. It follows that $\mathcal{E}^{u_0}\subset\mathcal{E}_{\beta_c}$ but that $\mathcal{E}^{u_0}\neq\mathcal{E}_{\beta_c}$.

(e) If $u\in N$, then $u\notin\left(-\frac{1}{2},u_0\right)$, and so by part (b) of Lemma 6.1 $u\neq\tilde{H}(\nu^1(\beta))$ for any $\beta\in(\beta_c,\infty)$. Since by (6.4) $\mathcal{E}_\beta=\mathcal{E}^{\tilde{H}(\nu^1(\beta))}$ for all $\beta>\beta_c$, it follows that for all $\beta>\beta_c$,

$$\mathcal{E}^u\cap\mathcal{E}^{\tilde{H}(\nu^1(\beta))}=\emptyset$$

and thus that $\mathcal{E}^u\cap\mathcal{E}_\beta=\emptyset$. For any $\beta<\beta_c$ (6.5) states that $\mathcal{E}_\beta=\mathcal{E}^{-1/2q}=\{\rho\}$. Since $u\in N$, we have $u\neq -1/2q$ and thus $\mathcal{E}^{-1/2q}\cap\mathcal{E}^u=\emptyset$. It follows that $\mathcal{E}^u\cap\mathcal{E}_\beta=\emptyset$ for any $\beta<\beta_c$. Finally, for $\beta=\beta_c$ part (b) of Theorem 3.1 states that $\mathcal{E}_{\beta_c}=\{\rho,\nu^1(\beta_c),\ldots,\nu^q(\beta_c)\}$. However, since $\tilde{H}(\rho)=-(1/2q)\notin N$ and $\tilde{H}(\nu^i(\beta_c))=u_0\notin N$, none of the vectors in $\mathcal{E}_{\beta_c}$ satisfies the constraint $\tilde{H}(\nu)=u$. Thus $\mathcal{E}^u\cap\mathcal{E}_{\beta_c}=\emptyset$. We have proved $\mathcal{E}^u\cap\mathcal{E}_\beta=\emptyset$ for all $\beta\in\mathbb{R}$. The proof of the theorem is complete. ■

We end this section by showing that for arbitrary $q\geqslant 4$ and u in the equivalence sets $F\cup P=\left(-\frac{1}{2},u_0\right]\cup\{-1/2q\}$ the formulas for $\mathcal{E}^u$ and $s(u)$ given in part (d) of Theorem 4.2 and part (c) of Theorem 4.3 are rigorously true. Our strategy is to use the equivalence of the microcanonical and canonical ensembles for $u\in F\cup P$ and the fact that the form of $\mathcal{E}_\beta$ is known exactly for all β. Thus, we translate the form of $\nu\in\mathcal{E}_\beta$, as given in part (b) of Theorem 3.1, into the form of $\nu\in\mathcal{E}^u$ for $u\in F\cup P$. For $\beta\in[\beta_c,\infty)$, the last $q-1$ components of $\nu^1(\beta)\in\mathcal{E}_\beta$ are given by

$$\nu_j^1(\beta)=\frac{1-w(\beta)}{q}, \tag{6.6}$$

and these components are not equal to the first component. Since for each $u\in F\cup P$ there exists $\beta\in[\beta_c,\infty]$ such that either $\mathcal{E}^u=\mathcal{E}_\beta$ or $\mathcal{E}^u\subset\mathcal{E}_\beta$, it follows that modulo permutations all $\nu\in\mathcal{E}^u$ have their last $q-1$ components equal to each other. That is, modulo permutations there exist numbers a and b in $[0,1]$ such that $\nu=(a,b,\ldots,b)$. The possible values of a and b are easily determined by considering the constraints satisfied by $\nu\in\mathcal{E}^u$. These constraints are

$$a+(q-1)b=1 \quad \text{and } a^2+(q-1)b^2=-2u.$$

The two solutions of these equations are

$$a_1=\frac{1-\sqrt{(q-1)(-2qu-1)}}{q}, \quad b_1=\frac{q-1+\sqrt{(q-1)(-2qu-1)}}{(q-1)q}$$

and

$$a_2 = \frac{1 + \sqrt{(q-1)(-2qu-1)}}{q}, \quad b_2 = \frac{q - 1 - \sqrt{(q-1)(-2qu-1)}}{(q-1)q}.$$

Of the two values b_1 and b_2, only b_2 has the form given in (6.6) with

$$w(\beta) = \frac{\sqrt{(q-1)(-2qu-1)}}{q-1} \in [0,1].$$

We conclude that modulo permutations each $\nu \in \mathcal{E}^u$ has the form $(a_2, b_2, \ldots, b_2)$, in which the last $q-1$ components all equal b_2. This coincides with the formula for $\mu^1(u)$ given in part (d) of Theorem 4.2, which in turn gives the explicit formula for $s(u)$ in part (c) of Theorem 4.3. This information is summarized in part (a) of the next theorem. The differentiability of s on $\operatorname{int} F$, which is stated in part (b), is an immediate consequence of the explicit formula for $s(u)$.

Theorem 6.3: *We define* u_0 *in* (6.2). *The following conclusions hold.*

(a) *For arbitrary* $q \geqslant 4$ *and* u *in the equivalence sets* $F \cup P = (-\frac{1}{2}, u_0] \cup \{-1/2q\}$ *the formulas for* $\mathcal{E}^u$ *and* $s(u)$ *given in part* (d) *of Theorem* 4.2 *and part* (c) *of Theorem* 4.3 *are rigorously true.*

(b) *For arbitrary* $q \geqslant 4$, s *is differentiable on the interval* $\operatorname{int} F = (-\frac{1}{2}, u_0)$ *and* $s'(u)$ *is given by* (5.1).

APPENDIX A: TWO RELATED MAXIMIZATION PROBLEMS

Theorem A.1 is a new result on the maximum points of certain functions related by convex duality. It is formulated for a finite, differentiable, convex function F on $\mathbb{R}^\sigma$ and its Legendre–Fenchel transform,

$$F^*(z) = \sup_{x \in \mathbb{R}^\sigma} \{\langle x, z\rangle - F(x)\}.$$

The domain of F^* is the set $\operatorname{dom} F^* = \{z \in \mathbb{R}^\sigma : F^*(z) < \infty\}$. With only minor changes in notation the theorem is also valid for a finite, Gateaux-differentiable, convex function on a Hilbert space.

Theorem A.1 will be applied in Appendix B to prove that for $\beta > 0$, $\mathcal{E}_\beta$ has the form given in part (b) of Theorem 3.1. Another application of Theorem A.1 is given in Proposition 3.4 in Ref. 17. It is used there to determine the form of the set of canonical equilibrium macrostates for another important spin system known as the mean-field Blume–Emery–Griffiths model.

Theorem A.1: *Let* σ *be a positive integer and* F *a finite, differentiable, convex function mapping* $\mathbb{R}^\sigma$ *into* $\mathbb{R}$. *Assume that* $\sup_{z \in \mathbb{R}^\sigma}\{F(z) - \frac{1}{2}\|z\|^2\} < \infty$ *and that* $F(z) - \frac{1}{2}\|z\|^2$ *attains its supremum. The following conclusions hold:*

(a) $\sup_{z \in \mathbb{R}^\sigma}\{F(z) - \frac{1}{2}\|z\|^2\} = \sup_{z \in \operatorname{dom} F^*}\{\frac{1}{2}\|z\|^2 - F^*(z)\}$.

(b) $\frac{1}{2}\|z\|^2 - F^*(z)$ *attains its supremum on* $\operatorname{dom} F^*$,

(c) *the global maximum points of* $F(z) - \frac{1}{2}\|z\|^2$ *coincide with the global maximum points of* $\frac{1}{2}\|z\|^2 - F^*(z)$.

Proof: We define the subdifferential of F^* at $z_0 \in \mathbb{R}^\sigma$ by

$$\partial F^*(z_0) = \{y \in \mathbb{R}^\sigma : F^*(z) \geqslant F^*(z_0) + \langle y, z - z_0\rangle \text{ for all } z \in \mathbb{R}^\sigma\}.$$

We also define the domain of ∂F^* to be the set of $z_0 \in \mathbb{R}^\sigma$ for which $\partial F^*(z_0) \neq \emptyset$. The proof of the theorem uses three properties of Legendre–Fenchel transforms (see Ref. 43 for background).

(1) F^* is a convex, lower semicontinuous function mapping $\mathbb{R}^\sigma$ into $\mathbb{R}\cup\{\infty\}$, and for all $z \in \mathbb{R}^\sigma$, $F^{**}(z)=(F^*)^*(z)$ equals $F(z)$ [Ref. 14, Theorem VI.5.3(a),(e)].
(2) If for some $z_0 \in \mathbb{R}^\sigma$ and $z \in \mathbb{R}^\sigma$ we have $z=\nabla F(z_0)$, then $F(z_0)+F^*(z)=\langle z_0,z\rangle$ [Ref. 14, Theorems VI.3.5(d) and VI.5.3(c)], and so $z \in \operatorname{dom} F^*$. In particular, if $z=z_0$, then $z_0 \in \operatorname{dom} F^*$ and $F(z_0)+F^*(z_0)=\|z_0\|^2$.
(3) For $z_0 \in \operatorname{dom} F^*$ and $y \in \partial F^*(z_0)$ we have $F(y)+F^*(z_0)=\langle y,z_0\rangle$ [Ref. 14, Theorem VI.5.3(c),(d)]. In particular, if $y=z_0$, then $F(z_0)+F^*(z_0)=\|z_0\|^2$.

We first prove part (a), which is a special case of Theorem C.1 in Ref. 13. Let $M=\sup_{z\in\mathbb{R}^\sigma}\{F(z)-\|z\|^2/2\}$. Since for any $z \in \operatorname{dom} F^*$ and x in $\mathbb{R}^\sigma$,

$$F^*(z) + M \geqslant \langle x,z\rangle - F(x) + M \geqslant \langle x,z\rangle - \|x\|^2/2,$$

we have

$$F^*(z) + M \geqslant \sup_{x\in\mathbb{R}^\sigma}\{\langle x,z\rangle - \|x\|^2/2\} = \|z\|^2/2.$$

It follows that $M \geqslant \|z\|^2/2 - F^*(z)$ and thus that $M \geqslant \sup_{z\in\operatorname{dom} F^*}\{\|z\|^2/2 - F^*(z)\}$. To prove the reverse inequality, let $N=\sup_{z\in\operatorname{dom} F^*}\{\|z\|^2/2-F^*(z)\}$. Then for any $z \in \mathbb{R}^\sigma$ and $x \in \operatorname{dom} F^*$

$$\|z\|^2/2 + N \geqslant \langle x,z\rangle - \|x\|^2/2 + N \geqslant \langle x,z\rangle - F^*(x).$$

Since $F^*(x)=\infty$ for $x \notin \operatorname{dom} F^*$, it follows from property 1 that

$$\|z\|^2/2 + N \geqslant \sup_{x\in\operatorname{dom} F^*}\{\langle x,z\rangle - F^*(x)\} = F(z)$$

and thus that $N \geqslant \sup_{z\in\mathbb{R}^\sigma}\{F(z)-\|z\|^2/2\}$.

In order to prove parts (b) and (c) of Theorem A.1, let z_0 be any point in $\mathbb{R}^\sigma$ at which $F(z) - \frac{1}{2}\|z\|^2$ attains its supremum. Then $z_0=\nabla F(z_0)$, and so by the last line of property (2), $z_0 \in \operatorname{dom} F^*$ and $F(z_0)+F^*(z_0)=\|z_0\|^2$. Part (a) now implies that

$$\sup_{z\in\mathbb{R}^\sigma}\left\{F(z) - \tfrac{1}{2}\|z\|^2\right\} = F(z_0) - \tfrac{1}{2}\|z_0\|^2 = \tfrac{1}{2}\|z_0\|^2 - F^*(z_0) = \sup_{z\in\operatorname{dom} F^*}\left\{\tfrac{1}{2}\|z\|^2 - F^*(z)\right\}.$$

We conclude that $\frac{1}{2}\|z\|^2 - F^*(z)$ attains its supremum on $\operatorname{dom} F^*$ at z_0. Not only have we proved part (b), but also we have proved half of part (c); namely, any global maximizer of $F(z)-\frac{1}{2}\|z\|^2$ is a global maximizer of $\frac{1}{2}\|z\|^2 - F^*(z)$.

Now let z_0 be any point at which $\frac{1}{2}\|z\|^2 - F^*(z)$ attains its supremum. Then for any $z \in \mathbb{R}^\sigma$

$$\tfrac{1}{2}\langle z_0,z_0\rangle - F^*(z_0) \geqslant \tfrac{1}{2}\langle z,z\rangle - F^*(z).$$

It follows that for any $z \in \mathbb{R}^\sigma$,

$$F^*(z) \geqslant F^*(z_0) + \tfrac{1}{2}(\langle z,z\rangle - \langle z_0,z_0\rangle) \geqslant F^*(z_0) + \langle z_0, z - z_0\rangle$$

and thus that $z_0 \in \partial F^*(z_0)$. By the last line of property (3) this implies that $F(z_0)+F^*(z_0)=\|z_0\|^2$. In conjunction with part (a) this in turn implies that

$$\sup_{z\in\operatorname{dom} F^*}\left\{\tfrac{1}{2}\|z\|^2 - F^*(z)\right\} = \tfrac{1}{2}\|z_0\|^2 - F^*(z_0) = F(z_0) - \tfrac{1}{2}\|z_0\|^2 = \sup_{z\in\mathbb{R}^\sigma}\left\{F(z) - \tfrac{1}{2}\|z\|^2\right\}.$$

We conclude that $F(z)-\frac{1}{2}\|z\|^2$ attains its supremum at z_0. This completes the proof of the theorem. ■

APPENDIX B: FORM OF $\mathcal{E}_\beta$

We first derive the form of $\mathcal{E}_\beta$ for $\beta>0$ as given in part (b) of Theorem 3.1. We then prove that $\mathcal{E}_\beta=\{\rho\}$ for all $\beta\leqslant 0$.

$\mathcal{E}_\beta$ is defined as the set of $\nu \in \mathcal{P}$ that minimize $R(\nu|\rho) - (\beta/2)\langle \nu, \nu\rangle$. Since $\beta > 0$, this is equivalent to

$$\mathcal{E}_\beta = \left\{ \nu \in \mathcal{P} : \nu \text{ maximizes } \frac{1}{2}\langle \nu, \nu\rangle - \frac{1}{\beta} R(\nu|\rho) \right\}. \tag{B1}$$

This maximization problem has the form of the right-hand side of part (a) of Theorem A.1; viz.,

$$\sup_{\nu \in \mathcal{P}} \left\{ \frac{1}{2}\langle \nu, \nu\rangle - \frac{1}{\beta} R(\nu|\rho) \right\} = \sup_{\nu \in \operatorname{dom} F^*} \left\{ \frac{1}{2}\|\nu\|^2 - F^*(\nu) \right\}$$

with $F^*(\nu) = (1/\beta) R(\nu|\rho)$.

In order to determine the function F having this Legendre–Fenchel transform, for $z \in \mathbb{R}^q$ we define the finite, differentiable, convex function

$$\Gamma(z) = \log\left(\sum_{i=1}^{q} e^{z_i} \frac{1}{q} \right) \tag{B2}$$

and set $\Gamma_\beta(z) = (1/\beta)\Gamma(\beta z)$. Since for $\nu \in \mathbb{R}^q$ (Ref. 14, Theorem VIII.2.2),

$$\Gamma^*(\nu) = \begin{cases} R(\nu|\rho) & \text{for } \nu \in \mathcal{P}, \\ \infty & \text{otherwise}, \end{cases}$$

it follows that for $\nu \in \mathbb{R}^q$,

$$(\Gamma_\beta)^*(\nu) = \sup_{z \in \mathbb{R}^q} \left\{ \langle z, \nu\rangle - \frac{1}{\beta}\Gamma(\beta z) \right\} = \frac{1}{\beta}\Gamma^*(\nu) = \begin{cases} \frac{1}{\beta} R(\nu|\rho) & \text{for } \nu \in \mathcal{P}, \\ \infty & \text{otherwise}. \end{cases}$$

Thus $F(z) = (1/\beta)\Gamma(\beta z)$. By part (a) of Theorem A.1,

$$\sup_{z \in \mathbb{R}^q} \left\{ \frac{1}{\beta}\Gamma(\beta z) - \frac{1}{2}\|z\|^2 \right\} = \sup_{\nu \in \mathcal{P}} \left\{ \frac{1}{2}\langle \nu, \nu\rangle - \frac{1}{\beta} R(\nu|\rho) \right\},$$

and by part (b) of the theorem the global maximum points of $\Gamma(\beta z) - \frac{1}{2}\|z\|^2$ and $\frac{1}{2}\langle \nu, \nu\rangle - (1/\beta) R(\nu|\rho)$ coincide.

Equation (B1) now implies that

$$\mathcal{E}_\beta = \left\{ z \in \mathbb{R}^q : z \text{ maximizes } \frac{1}{\beta}\Gamma(\beta z) - \frac{1}{2}\|z\|^2 \right\} = \left\{ z \in \mathbb{R}^q : z \text{ minimizes } \frac{\beta}{2}\|z\|^2 - \Gamma(\beta z) \right\}.$$

We summarize this discussion in the following corollary. Part (b) of the corollary is proved in part (b) of Theorem 2.1 in Ref. 19.

Corollary B.1: We define the finite, convex, continuous function Γ *in* (B2). *The following conclusions hold*.

(a) $\mathcal{E}_\beta$ *coincides with the set of global minimum points of*

$$G_\beta(z) = \frac{\beta}{2}\|z\|^2 - \log \sum_{i=1}^{q} e^{\beta z_i} = \frac{\beta}{2}\|z\|^2 - \Gamma(\beta z) - \log q.$$

(b) *For* $0 < \beta < \beta_c$, $\beta = \beta_c$, *and* $\beta > \beta_c$ *the set of global minimum points of* G_β *has the form given by the right-hand side of* (3.4) [*Theorem* 3.1(b)].

Corollary B.1 completes the proof of Theorem 3.1. Kiessling's proof of this corollary based on Lagrange multipliers is given in Appendix B of Ref. 20. Continuous analogues of the corollary are mentioned in Refs. 32, 33, and 38, but are not proved there.

We now show that for all $\beta \leqslant 0$, $\mathcal{E}_\beta = \{\rho\}$. This is obvious for $\beta = 0$ since $\nu = \rho$ is the unique vector in $\mathcal{P}$ that minimizes $R(\nu|\rho)$. Our goal is to prove that for $\beta < 0$, $\nu = \rho$ is also the unique vector in $\mathcal{P}$ that minimizes $R(\nu|\rho) - (\beta/2)\langle \nu, \nu \rangle$. Let $\overline{\nu}$ be a point in $\mathcal{P}$ at which $R(\nu|\rho) - (\beta/2) \times \langle \nu, \nu \rangle$ attains its infimum. For any $i = 1, 2, \ldots, q$,

$$\frac{\partial\left(R(\nu|\rho) - \dfrac{\beta}{2}\langle \nu, \nu \rangle\right)}{\partial \nu_i} = \log \nu_i + 1 - \beta \nu_i,$$

which is negative for all sufficiently small $\nu_i > 0$. It follows that $\overline{\nu}$ does not lie on the relative boundary of $\mathcal{P}$; i.e., $\overline{\nu_j} > 0$ for all $i = 1, 2, \ldots, q$. We complete the proof by showing that for any $1 \leqslant j < k \leqslant q$, $\overline{\nu_j} = \overline{\nu_k}$. Since ρ is the only point in $\mathcal{P}$ satisfying these equalities, we will be done.

Given $a \in (0, 1)$, we consider the reduced two-variable problem of minimizing $R(\nu|\rho) - (\beta/2)\langle \nu, \nu \rangle$ over $\nu_j > 0$ and $\nu_k > 0$ under the constraint $\nu_j + \nu_k = a$; all the other components ν_i are fixed and equal $\overline{\nu_i}$. Setting $\nu_k = a - \nu_j$, we define

$$F(\nu_j) = R(\nu|\rho) - \frac{\beta}{2}\langle \nu, \nu \rangle.$$

Differentiating with respect to ν_j shows that any global minimizer ν_j must satisfy

$$F'(\nu_j) = \log \nu_j - \log(a - \nu_j) - \beta(2\nu_j - a) = 0.$$

Since

$$F''(\nu_j) = \frac{1}{\nu_j} + \frac{1}{a - \nu_j} - 2\beta > 0,$$

$F'(\nu_j)$ is strictly increasing from negative values for all ν_j near 0 to positive values for all ν_j near a. It follows that the only root of $F'(\nu_j) = 0$ is $\nu_j = a/2$ and thus that $\nu_k = a/2 = \nu_j$. Being a global minimizer of $R(\nu|\rho) - (\beta/2)\langle \nu, \nu \rangle$ over $\mathcal{P}$, $\overline{\nu}$ is also a global minimizer of the reduced two-variable problem. Since $a \in (0, 1)$ is arbitrary, it follows that for any distinct pair of indices $\overline{\nu_j} = \overline{\nu_k}$. This completes the proof.

The general non-degenerate *p*-adic operators of ultrametric diffusion are introduced. Bases of eigenvectors for the introduced operators are constructed and the corresponding eigenvalues are computed. The long-time relaxation behavior of the ultrametric diffusion generated by the introduced operators are investigated. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1858447]

I. INTRODUCTION

Ultrametric diffusions (which are generated by ultrametric pseudodifferential operators) have important applications to models of complex systems. For example, in the papers of Refs. 1 and 2 it was shown that the Parisi matrix in the theory of spin glasses is related to a *p*-adic pseudodifferential operator. Ultrametric diffusion models were investigated in relation with models of relaxation in complex systems, see for instance.[3,4] In the recent works,[1,5,6] *p*-adic models of ultrametric diffusion has been discussed in connection with description of protein dynamics and characteristic types of relaxation in complex systems. In these papers the equivalence of the basin-to-basin kinetics approach, which describes relaxation in complex systems, and ultrametric diffusion models was mentioned. The mathematical theory of ultrametric diffusion was investigated in Refs. 7–9. Applications to biological models was discussed in Ref. 10. All of the above motivates the investigation of more general ultrametric pseudodifferential operators and more general models of ultrametric diffusion. In the paper of Ref. 11 a wide class of *p*-adic pseudodifferential operators was constructed and investigated with the help of basis of *p*-adic wavelets, constructed in Ref. 12. In the present paper we construct an even more general class of *p*-adic pseudodifferential operators.

The structure of the present paper is as follows.

In Sec. II we discuss the basin-to-basin kinetics models from the point of view of ultrametric diffusion theory.

In Sec. III we discuss different classes of *p*-adic models of ultrametric diffusion.

In Sec. IV we discuss the operators, investigated in Ref. 11 and give a new parametrization for kernels of such operators.

In Sec. V we introduce a new family of *p*-adic models of ultrametric diffusion, build the eigenbases for their generators, and compute the corresponding eigenvalues.

In Sec. VI we investigate the properties of ultrametric diffusion, generated by the constructed operators.

II. RELATION TO BASIN-TO-BASIN KINETICS

Ultrametric diffusion models are naturally related to the basin-to-basin kinetics approach proposed a rather long time ago. This relation was mentioned in the paper of Ref. 5 Here we

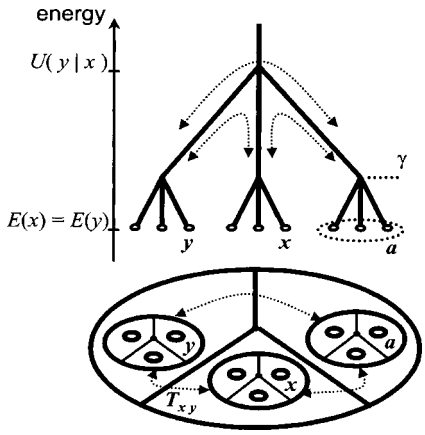

FIG. 1. A hierarchy of basins and activation barriers in the basin-to-basin kinetic approach. For an explanation of the notations see the text.

reproduce this discussion in more details in order to use it to introduce new classes of integration kernels for operators of ultrametric diffusion. The basin-to-basin kinetics approach was widely used in a computer study of the dynamics constrained by rough multidimensional energy landscapes.[13–16] In this approach, the kinetics of a complex system is approximated using separation of the space of states of the system into basins and separation of the corresponding time scales of transitions between the basins. The basin-to-basin kinetics approach can be outlined as follows. Let us consider a system that is described by a particle performing random walk in a rough energy landscape. The system is supposed to be arriving to the nearest quasiequilibrium state (the nearest local minimum on the energy landscape) from any initial state in the time, which is much smaller compared to the lifetime of this quasiequilibrium state. Therefore, we will reduce our consideration to the set of local minima of the energy landscape. Further, we assume that the set of local minima can be represented as a union of hierarchically nested subsets. These subsets we will call the basins of minima. Each of the basins is a union of the nonoverlapping basins of the smaller size (subbasins), each of these smaller basins is a union of the still smaller ones, etc. Moreover, we assume that the larger basins are separated by the higher activation barriers, and the smaller sub-basins are separated by the lower barriers, i.e., if the basin A is a sub-basin of the basin B, then the activation barriers between the maximal sub-basins of A is smaller than the activation barriers between the maximal sub-basins of B. The basin hierarchy corresponds to the hierarchy of the configuration rearrangements, and the hierarchy of the activation barriers corresponds to the hierarchy of characteristic times of these rearrangements.

More definitely, a basin-to-basin approximation of kinetics of a system with a rough energy landscape reduces to the following.

(I) In the basin-to-basin approximation, the space of states is divided into basins, each basin is divided into sub-basins in hierarchical way, and so on.
(II) The rate of transition probability between two states in the different basins depends only on the basins and does not depend on the states themselves.

Thus, the basin-to-basin kinetics can be understood as a diffusion (more definitely, as a jump process) in the ultrametric space.[1,5,6] In this language the property (I) corresponds to ultrametricity of the space of states, and the property (II) takes the form of local constancy of the rate of transition probability.

The multidimensional energy surface can be represented by a tree—a "skeleton" of a hierarchical landscape[14–17] (Fig. 1). This tree reflects the hierarchy of nestings and it is directed (i.e., it is a tree with a partial order). The vertices of the tree correspond to the basins, the partial order describes the ordering of the basins (i.e., the vertex A is larger than B if the corresponding basin A contains the basin B). The local minima of the landscapes correspond to minimal vertices with

respect to the introduced ordering. In the general case for a finite or an infinite tree, the set of local minima will be described by the absolute of the tree. The absolute of any tree has a natural structure of ultrametric space. Therefore a description of a rough energy landscape in terms of hierarchically nested basins is equivalent to the introduction of the ultrametric space of states.

The transition probability T_{xy} between the states y and x is determined by the position of the vertex $U(y|x)$ in which the tree branches into the paths going to the points x and y, and by the energies $E(x)$ and $E(y)$ of the states x and y (Fig. 1). In particular, if all the local minima have the same energy, then T_{xy} is determined only by the vertex $U(y|x)$, i.e., the transition probabilities has the property of permutation symmetry $T_{xy}=T_{yx}$.

III. *p*-ADIC MODELS OF ULTRAMETRIC DIFFUSION

The well-known example of an ultrametric space is the field of p-adic numbers $\mathbb{Q}_p$. In the works of Refs. 1, 5, and 6, p-adic description of ultrametric diffusion is introduced in the following way. The system states are parametrized by the p-adic coordinate x, a basin of states corresponds to the p-adic disk $B_\gamma(a)$ (Fig. 1). The p-adic disk $B_\gamma(a)$, is a set of all p-adic numbers $\{x:|x-a|_p \leqslant p^\gamma\}$, for which the p-adic distance from the disk center $a(a\in\mathbb{Q}_p)$ is less than or equal to the radius p^γ, where γ is an integer ($\gamma\in\mathbb{Z}$). The parameters γ and a distinguish the p-adic disks $B_\gamma(a)$.

To describe the system evolution we introduce the probability distribution function $f(x,t)$ that depends on the p-adic coordinate x and the real time t: the integral,

$$\int_B f(x,t)d\mu(x)$$

[$d\mu(x)$ is the Haar measure on $\mathbb{Q}_p$ (Ref. 7), is the probability of finding the system in the set B at time t.

The evolution of the function $f(x,t)$ is described by the equation

$$\frac{\partial f(x,t)}{\partial t} = -\int_{\mathbb{Q}_p} (T_{yx}f(x,t) - T_{xy}f(y,t))d\mu(y). \tag{1}$$

This is the master equation for ultrametric diffusion, and the linear integral operator on the rhs of (1);

$$Tf(x) = \int_{\mathbb{Q}_p} (T_{yx}f(x) - T_{xy}f(y))d\mu(y) \tag{2}$$

is called the operator of ultrametric diffusion.

The non-negative kernel T_{xy} is equal to the rate of transition from the state y to the state $x(T_{xy}:\mathbb{Q}_p\times\mathbb{Q}_p\mapsto\mathbb{R}_+)$. We consider the kernels T_{xy}, which are locally constant outside any vicinity of $x=y$. The complex-valued function $g(x)$, defined on $\mathbb{Q}_p$, is called locally constant, if

$$\forall x\in\mathbb{Q}_p,\quad \exists\,\gamma\in\mathbb{Z},\quad \forall\, z\in\mathbb{Q}_p:|z|_p\leqslant p^\gamma \Rightarrow g(x+z)=g(x).$$

In the simplest case the operators of ultrametric diffusion can be introduced by the kernels T^0_{xy} satisfying the following conditions:

(i)

$$\text{for fixed}\quad y,\quad \forall\, x,z\in\mathbb{Q}_p:|z|_p\leqslant|x-y|_p \Rightarrow T^0_{(x+z)y}=T^0_{xy},$$

$$\text{for fixed}\quad x,\quad \forall\, y,z\in\mathbb{Q}_p:|z|_p\leqslant|x-y|_p \Rightarrow T^0_{x(y+z)}=T^0_{xy}; \tag{3}$$

(ii)

$$T^0_{xy} = T^0_{yx},$$

i.e., the kernel T^0_{xy} is symmetric (and the corresponding operator is Hermitian, since T^0_{xy} is a real-valued function);

(iii)

$$\forall a \in \mathbb{Q}_p, \quad T^0_{xy} = T^0_{x-ay-a},$$

i.e., the kernel T^0_{xy} has the property of translation invariance.

In the following we will denote by T^0 the operator of ultrametric diffusion, and by T^0_{xy} the corresponding kernel. The general form of the kernels T^0_{xy} is given by the series

$$T^0_{xy} = \sum_{\gamma=-\infty}^{\infty} T^{(\gamma)} \delta_{p^\gamma, |x-y|_p}, \tag{4}$$

where δ is the Kronecker delta. The kernels T^0 can be equivalently described by the functions dependent only on p-adic norm of the difference of x and y: $T^0_{x,y} = \rho(|x-y|_p)$. The coefficients $T^{(\gamma)}$ of the series (4) and the function $\rho(|x-y|_p)$ are connected by the relation $T^{(\gamma)} = \rho(p^\gamma)$.

The properties (i)–(iii) allow us to use the p-adic Fourier transformation to compute the eigenvalues of the operator. If the series $\Sigma_{\gamma=0}^{\infty} p^\gamma T^{(\gamma)}$ converges, the eigenvalues of the operator T^0 are determined by the expression[7]

$$\lambda^0_\gamma = p^\gamma T^{(\gamma)} + (1 - p^{-1}) \sum_{\gamma' = \gamma+1} p^{\gamma'} T^{(\gamma')}.$$

Every eigenvalue λ^0_γ is infinitely degenerate.

The operators of the form T^0 were discussed in the context of p-adic mathematical physics. When the kernel has the form with

$$T_{xy} = \frac{p^\alpha - 1}{1 - p^{-1-\alpha}} |x-y|_p^{-(1+\alpha)}, \quad \alpha > 0,$$

the operator T^0 is the Vladimirov operator of p-adic fractional derivation.[7] Its eigenvalues are given by $\lambda_\gamma = p^{(1-\gamma)\alpha}$, $\gamma \in \mathbb{Z}$. Different examples of the operators T^0 have been recently investigated in Ref. 6.

In the context of basin-to-basin kinetics, the operator symmetry (hermiticity) property means that all the local minima of the energy landscape have equal energy. The translation invariance of the kernel means that the transition between x and y depends only on the ultrametric distance between x and y.

The translationally invariant operators T^0 are related to the Parisi matrices (see Refs. 1 and 2) that were used in the replica approach to spin glasses.[18] However, it is not very natural to assume that the energy landscapes of many other disordered systems (for instance, the energy landscapes of clusters, macromolecular structures, and biopolymers, discussed, for example, in Ref. 15) are described by the operators with translationally invariant kernels. Therefore, the ultrametric diffusion operators, more general than T^0, are of great importance.

Generally, the ultrametric diffusion operator T can be defined by (2), where the kernel satisfies some weaker conditions than conditions (i)–(iii). In the present paper we consider translationally *noninvariant* operators of ultrametric diffusion satisfying the hermiticity property. We will examine two types of such operators, T^{I} and T^{II}.

A family of operators of p-adic diffusion T^{I} has been recently investigated in the paper.[11] The local constancy conditions for these operators are given by (3), as well as for T^0, but T^{I} differs from T^0 by violating the condition (iii).

The kernel T^{I}_{xy} is described by the expression

$$T^{\mathrm{I}}_{xy} = \sum_{\gamma=-\infty}^{\infty} \sum_{n\in\mathbb{Q}_p/\mathbb{Z}_p} T^{(\gamma n)} \delta_{1,|p^{\gamma}x - p^{\gamma}y|_p} \Omega(p^{\gamma}x - n), \tag{5}$$

where the factor group $\mathbb{Q}_p/\mathbb{Z}_p$ is identified with a set of the fractions $\Sigma_{\gamma=1}^{k} n_{\gamma} p^{-\gamma}$, $n_{\gamma}=0,\ldots,p-1$, k is any natural number, and the coefficients $T^{(\gamma n)} \geqslant 0$. The function $\Omega(|x|_p)$ is an indicator of the p-adic disk,

$$\Omega(|x|_p) = \begin{cases} 1, & |x|_p \leqslant 1, \\ 0, & |x|_p > 1. \end{cases}$$

It was shown that if the series $\Sigma_{\gamma'=\gamma}^{\infty} p^{\gamma'} T^{(\gamma' n)}$ converges, the eigenvalues of the corresponding operator are given by

$$\lambda^{\mathrm{I}}_{\gamma n} = p^{\gamma} T^{(\gamma n)} + (1 - p^{-1}) \sum_{\gamma'=\gamma+1}^{\infty} p^{\gamma'} \sum_{n'\in\mathbb{Q}_p/\mathbb{Z}_p} T^{(\gamma' n')} \delta_{n', np^{\gamma'}}, \tag{6}$$

and, in general, are $p-1$ times degenerate. The eigenvalue $\lambda^{\mathrm{I}}_{\gamma n}$ corresponds to the eigenvectors

$$\varphi_{\gamma n j}(x) = p^{-\gamma/2} \chi_p(p^{\gamma-1} j x) \Omega(|p^{\gamma}x - n|_p), \tag{7}$$

where $j=1,\cdots,p-1$. Here the function $\chi_p(x)=\exp(2\pi i\{x\}_p)$ is an additive character on the field $\mathbb{Q}_p$, the symbol $\{x\}_p$ denotes a fractional part of the p-adic number. Recall that if the canonical decomposition of the p-adic number x is given by

$$x = p^{\gamma} \sum_{\mu=0}^{\infty} x_{\mu} p^{\mu}, \quad x_{\mu} = 0,\cdots,p-1, \quad x_0 \neq 0, \tag{8}$$

then the fractional part of the number x is determined by the following expression:

$$\{x\}_p = \begin{cases} 0, & \gamma \geqslant 0, \\ p^{\gamma}(x_0 + x_1 + \ldots + x_{|\gamma|-1} p^{|\gamma|-1}), & \gamma < 0. \end{cases}$$

As shown in Ref. 12, the set of vectors (7) forms an orthonormal basis in $L^2(\mathbb{Q}_p)$, which was called there the basis of p-adic wavelets.

In the present paper, in Sec. IV, we propose a new general expression for the kernel T^{I} and show the equivalence of this expression with (5).

In Sec. V we introduce the new type of transitionally noninvariant kernel, T^{II}, satisfying the weaker [compared with (3)] condition of local constancy:

$$\text{for fixed } y, \quad \forall x, \quad z\in\mathbb{Q}_p : |z|_p \leqslant p^{-1}|x-y|_p \Rightarrow T^{\mathrm{II}}_{(x+z)y} = T^{\mathrm{II}}_{xy}$$

$$\text{for fixed } x, \quad \forall y, \quad z\in\mathbb{Q}_p : |z|_p \leqslant p^{-1}|x-y|_p \Rightarrow T^{\mathrm{II}}_{x(y+z)} = T^{\mathrm{II}}_{xy} \tag{9}$$

Note that operator T^{II} is more general compared to T^{I}, but in some cases (see Sec. V) the operators T^{I} and T^{II} are identically equal, for instants when $p=2$.

We introduce the kernel T^{II} both in the functional form and in the form of a series, and we show the equivalence of these definitions. In this section, we find the eigenfunctions of the introduced operator, which form the basis in $L^2(\mathbb{Q}_p)$, compute the corresponding eigenvalues, and show that the eigenvalues, in general, are nondegenerate.

In Sec. VI, we investigate the properties of ultrametric diffusion, generated by the operators T^{I} and T^{II}. We consider the relaxation of the initially localized state. We show that the inhomogeneities of the landscape described by the translationally noninvariant kernels T^{I} and T^{II} are not

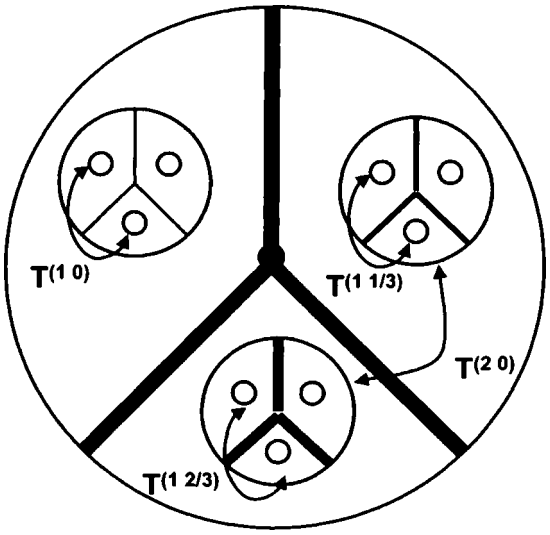

FIG. 2. The scheme of the transitions corresponding to the operator T^{I} with $p=3$. The lines of different thickness correspond to the different transition probabilities $T^{(\gamma n)}$ between the p-adic disks, which are marked by the circles.

essential for long-time relaxation, i.e., the asymptotics for the relaxation, correspondent to kernels T^{0}_{xy}, T^{I}_{xy}, T^{II}_{xy} will be the same for the cases when the corresponding kernels are naturally related in the way described in Sec. IV.

IV. TRANSLATIONALLY NONINVARIANT OPERATORS OF ULTRAMETRIC DIFFUSION T^{I}

In the present section we propose a new expression for the kernel T^{I} and show that this new expression is equivalent to the already known one. Expression (5) implies, that if $x\in B_{\gamma}(p^{-\gamma}n)$ and y satisfies the condition $|x-y|_p=p^{\gamma}$, then the kernel T^{I}_{xy} is equal to $T^{(\gamma n)}$. In this case, we can illustrate the basin-to-basin transitions with the help of the scheme in Fig. 2. The given transition scheme allows us to construct the expression of the operator T^{I}. To construct a new expression for the kernel T^{I}_{xy}, we use the following approach. The integration kernel T^{I}_{xy} of the operator should depend on the two arguments: (i) on the size of the minimal disk containing x and y, which is equal to the distance $|x-y|_p$; (ii) on the argument distinguishing the disk among the other disks of the same size. For the last purpose we fix the disk center. Since any point belonging to an ultrametric disk is its center, we will take as the center of the minimal disk, containing x and y the following:

$$\frac{\{x|x-y|_p\}_p}{|x-y|_p}=\begin{cases}\displaystyle\sum_{\mu=\log_p|x-y|_p+1}^{\log_p|x|_p} p^{-\mu}x_{\mu}, & |x|_p>|x-y|_p,\\ 0, & |x|_p\leqslant|x-y|_p,\end{cases} \tag{10}$$

where x_{μ} are the coefficients of the canonical decomposition (8) of the p-adic number x. Therefore, the kernel of the operator T^{I} can be represented by the function

$$\rho(|x-y|_p,\{x|x-y|_p\}_p). \tag{11}$$

The function (11) obviously do not have the translational invariance property. For this function the following proposition is satisfied.

Proposition 1: *The function (11) is symmetric with respect to the $x\mapsto y$, $y\mapsto x$ permutation. The function (11) satisfies the conditions (3) and (5). Moreover, any function satisfying the condition (5) can be represented in the form (11). Therefore the representations of the kernel T^{I} in the forms (11) and (5) are equivalent, and the equivalence is given by the relation*

$$T^{(\gamma n)} = \rho(p^{\gamma}, n), \quad \gamma \in \mathbb{Z}, \quad n \in \mathbb{Q}_p/\mathbb{Z}_p. \tag{12}$$

Proof: Let us prove the permutation symmetry: $\{y|x-y|_p\}_p = \{x|y-x|_p\}_p$. It follows that

$$\{x|x-y|_p\}_p - \{y|x-y|_p\}_p = \{(x-y)|x-y|_p\}_p = 0.$$

For proving the rest of the proposition, we will show at first that any function of the form (11) can be represented in the form (5). Actually, for any $x \in B_{\gamma}(p^{-\gamma}n)(n \in \mathbb{Q}_p/\mathbb{Z}_p)$ and any $y \in \mathbb{Q}_p$ satisfying the condition $|x-y|_p = p^{\gamma}$, we have $\{x|x-y|_p\}_p = \{n\}_p = n$. Hence,

$$\rho(|x-y|_p, \{x|x-y|_p\}_p) = \sum_{\gamma=-\infty}^{\infty} \sum_{n \in \mathbb{Q}_p/\mathbb{Z}_p} \rho(p^{\gamma}, n)\, \delta_{1,|p^{\gamma}x - p^{\gamma}y|_p}\, \Omega(p^{\gamma}x - n).$$

This means that the function (11) can be represented in the form of the series (5) with the coefficients $T^{(\gamma n)} = \rho(p^{\gamma}, n)$.

On the other hand, since no special restrictions are imposed on the function (11), then for all $\gamma \in \mathbb{Z}$ and $n \in \mathbb{Q}_p/\mathbb{Z}_p$ we can put $\rho(p^{\gamma}, n) = T^{(\gamma n)}$. Therefore the representations of the kernel T^{I} in the forms (11) and (5) are equivalent, and the equivalence is given by (12).

From the equivalence, it follows that the functions (11) and (5) have the same properties. In particular, the function (11) satisfies the condition (3). □

V. TRANSLATIONALLY NONINVARIANT OPERATORS OF ULTRAMETRIC DIFFUSION T^{II} AND THE BASIS OF GENERALIZED *p*-ADIC WAVELETS

Define the family of the operators of ultrametric diffusion T^{II}, with locally constant kernels of the most general form

$$T^{\mathrm{II}}_{xy} = \sum_{\gamma=-\infty}^{\infty} \sum_{n \in \mathbb{Q}_p/\mathbb{Z}_p} \sum_{\substack{j,k=0 \\ k \neq j}}^{p-1} T^{(\gamma njk)} \Omega(p|p^{\gamma}x - n - j|_p) \Omega(p|p^{\gamma}y - n - k|_p), \tag{13}$$

where $T^{(\gamma njk)} = T^{(\gamma nkj)} \geqslant 0$.

Theorem 2: *The function of the form (13) is symmetric with respect to permutation of the arguments, positive, and satisfies the condition (9).*

Moreover, an arbitrary positive symmetric function satisfying (9) can be represented in the form (13).

Proof: The positivity of T^{II}_{xy} is obvious. Permutation symmetry is obvious.

Prove that T^{II}_{xy} given by (13) satisfies (9). This property is easy to check for any product of two indicator functions in (13). By linearity, this proves that T^{II}_{xy} satisfy (9).

Vice versa, it is easy to see that the kernel (13) for x, y lying in the disks with the center in $p^{-\gamma}(n+j)$ and $p^{-\gamma}(n+k)$ correspondingly and the radius $p^{\gamma-1}$, takes the value $T^{(\gamma njk)}$.

Since all the space $x, y \in \mathbb{Q}_p \times \mathbb{Q}_p$ is the disjoint union of such subsets, therefore, taking an arbitrary positive and symmetric with respect to j, k coefficients $T^{(\gamma njk)}$, we are able to construct an arbitrary symmetric positive kernel satisfying (9). □

The kernel T^{II} can be equivalently described in the functional form.

Proposition 3: *The function,*

$$\rho(|x-y|_p, \{x|x-y|_p\}_p, \ \{xp^{-1}|x-y|_p\}_p, \ \{yp^{-1}|x-y|_p\}_p), \tag{14}$$

satisfies the condition (9). Moreover, any function satisfying the condition (9) can be represented in the form (14).

Under condition of symmetry of the function (14) with respect to permutation of x and y, the kernel T^{II} can be equivalently represented in the forms (14) and (13), and the equivalence is given by the relation

$$T^{(\gamma njk)} = \rho(p^{\gamma}, n, p^{-1}(n+j), p^{-1}(n+k)). \tag{15}$$

Proof: Let us show first that any function of the form (14) can be represented in the form (13). Actually, any x and y lying in the disks of the radius $p^{\gamma-1}$ with the centers in $p^{-\gamma}n+p^{-\gamma}j$ and $p^{-\gamma}n+p^{-\gamma}k$ ($n\in\mathbb{Q}_p/\mathbb{Z}_p$, j, $k=0,\ldots,p-1$ and $j\neq k$) can be represented in the form

$$x = p^{-\gamma}(n+j+pz_x), \quad |z_x|_p \leqslant 1,$$

$$y = p^{-\gamma}(n+k+pz_y), \quad |z_y|_p \leqslant 1.$$

When it follows that at $j\neq k$, $|x-y|_p = p^{\gamma}$, $\{x|x-y|_p\}_p = n$ and

$$\{xp^{-1}|x-y|_p\}_p = \{p^{-1}(n+j)+z_x\}_p = p^{-1}(n+j),$$

$$\{yp^{-1}|x-y|_p\}_p = \{p^{-1}(n+k)+z_y\}_p = p^{-1}(n+k).$$

Hence,

$$\rho(|x-y|_p, \{x|x-y|_p\}_p, \{xp^{-1}|x-y|_p\}_p, \{yp^{-1}|x-y|_p\}_p)$$
$$= \sum_{\gamma=-\infty}^{\infty} \sum_{n\in\mathbb{Q}_p/\mathbb{Z}_p} \rho(p^{\gamma}, n, p^{-1}(n+j), p^{-1}(n+k))\Omega(p|p^{\gamma}x-n-j|_p)\Omega(p|p^{\gamma}y-n-k|_p).$$

Thus, the function (14) can be represented in the form of the series (13), whose coefficients are determined by (15).

On the other hand, since no restrictions (except for permutation symmetry) are imposed on the function of the type (14), then for all $\gamma\in\mathbb{Z}$ and $n\in\mathbb{Q}_p/\mathbb{Z}_p$, j, $k=0,\ldots,p-1 (j\neq k)$ we can put $\rho(p^{\gamma}, n, p^{-1}(n+j), p^{-1}(n+k))$ to be equal to $T^{(\gamma njk)}$. Therefore the representations of the kernel in the forms (14) and (13) are equivalent.

Moreover, for the function (14) and the series (13), respectively, the condition of symmetry with respect to permutation of x and y in (14) and of the symmetry of the coefficients $T^{(\gamma njk)}$ with respect of permutation of j and k, are equivalent.

From this equivalence, it follows that the function (14) satisfies the condition (9), and any function satisfying the condition (9) can be represented in the form (14). □

Proposition 4: *If $T^{(\gamma njk)}$ in (13) does not depend on j and k, then the operator T^{II} reduces to T^{I}.*

Proof: Consider the kernel T^{II}_{xy} under the condition that $T^{(\gamma njk)}$ is independent on j and k:

$$T^{\mathrm{II}}_{xy} = \sum_{\gamma,n} T^{(\gamma n)} \sum_{j=0}^{p-1} \Omega(p|p^{\gamma}x-n-j|_p) \sum_{\substack{k=0 \\ k\neq j}}^{p-1} \Omega(p|p^{\gamma}y-n-k|_p). \tag{16}$$

Using the formula

$$\Omega(|p^{\gamma}x-n|_p) = \Omega(p^{-\gamma}|x-p^{-\gamma}n|_p) = \sum_{j=0}^{p-1} \Omega(p^{-\gamma+1}|x-p^{-\gamma}n-p^{-\gamma}j|_p) = \sum_{j=0}^{p-1} \Omega(p|p^{-\gamma}x-n-j|_p), \tag{17}$$

as well as the property of indicators of the disks

$$\Omega(|x-a|_p)\Omega(|y-a|_p) = \Omega(|x-a|_p)\Omega(|x-y|_p),$$

for the sum on j and k in (16) we have

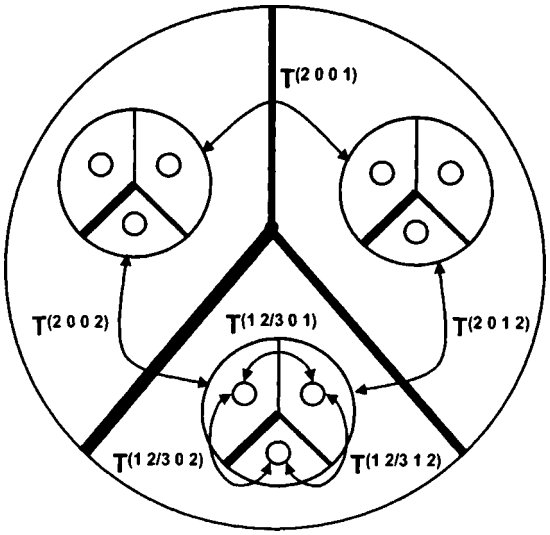

FIG. 3. The scheme of the transitions corresponding to the operator T^{II} with $p=3$.

$$\sum_{j=0}^{p-1}\Omega(p|p^{\gamma}x-n-j|_p)\sum_{\substack{k=0\\k\neq j}}^{p-1}\Omega(p|p^{\gamma}y-n-k|_p)$$

$$=\sum_{j=0}^{p-1}\Omega(p|p^{\gamma}x-n-j|_p)(\Omega(|p^{\gamma}y-n|_p)-\Omega(p|p^{\gamma}y-n-j|_p))$$

$$=\Omega(|p^{\gamma}x-n|_p)(\Omega(|p^{\gamma}y-n|_p)-\Omega(p|p^{\gamma}y-p^{\gamma}x|_p))$$

$$=\Omega(|p^{\gamma}x-n|_p)(\Omega(|p^{\gamma}y-p^{\gamma}x|_p)-\Omega(p|p^{\gamma}y-p^{\gamma}x|_p))$$

$$=\Omega(|p^{\gamma}x-n|_p)\,\delta_{1,|p^{\gamma}x-p^{\gamma}y|_p}.$$

□

Note that the operators T^{I} and T^{II} are identically equal for $p=2$. Actually, in this case the expression (13) contains only $T^{(\gamma n01)}$ and $T^{(\gamma n10)}$. Since $T^{(\gamma n01)}=T^{(\gamma n10)}$, from Proposition 4 it follows that $T^{\mathrm{I}}_{xy}=T^{\mathrm{II}}_{xy}$.

Unlike for the operator T^{I}, the kernel of the operator T^{II} formally depends on a couple of additional functions: $\{xp^{-1}|x-y|_p\}_p$ and $\{yp^{-1}|x-y|_p\}_p$. We will explain the meaning of these functions. Consider the transition between the states x and y (see Fig. 3). The probability for $x\mapsto y$ transition depends on a relative position of the basins between which the transition is carried out. Let x and y belong to the basin described by the p-adic disk $B_{\gamma}(a)$ of the radius $p^{\gamma}=|x-y|_p$ with the center in $a=\{xp^{\gamma}\}_p p^{-\gamma}$. Then the radii of the disks $B_{\gamma-1}(b)$ and $B_{\gamma-1}(c)$, between which the transition is carried out, are equal to $p^{-1}|x-y|_p$, and the disk centers are determined by the functions $b=\{xp^{\gamma-1}\}_p p^{-\gamma+1}$, $c=\{yp^{\gamma-1}\}_p p^{-\gamma+1}$.

Now we will construct the basis of eigenfunctions of the operator T^{II}.

Consider the $p\times p$ matrix $(\mathbf{W}^{(\gamma n)})_{ls}$ with matrix elements equal to $-T^{(\gamma njk)}$ for $j\neq k$ and equal to $\sum_{\substack{k=0\\k\neq l}}^{p-1}T^{(\gamma nkl)}$ for the diagonal elements:

$$\mathbf{W}^{(\gamma n)}_{ls}=\delta_{sl}\sum_{\substack{k=0\\k\neq l}}^{p-1}T^{(\gamma nlk)}-(1-\delta_{sl})T^{(\gamma nls)}. \tag{18}$$

It is easy to see that $\mathbf{W}^{(\gamma n)}$ is a real symmetric $p\times p$ matrix. Moreover, the matrix is positive.

Lemma 5: *The matrix* $\mathbf{W}^{(\gamma n)}$ *defined by (18) is positive.*

Proof: Compute the Hermitian form [we omit the (γn) index]

$$\langle z,\mathbf{W}z\rangle=\sum_{s=0}^{p-1}|z_s|^2\sum_{\substack{l=0\\ l\neq s}}^{p-1}W_{sl}-\sum_{s=0}^{p-1}\sum_{\substack{l=0\\ l\neq s}}^{p-1}z_s^*z_lW_{sl}=\sum_{s=0}^{p-1}\sum_{\substack{l=0\\ l\neq s}}^{p-1}W_{sl}(|z_s|^2-z_s^*z_l).$$

Combining the terms containing W_{sl} and W_{ls} and using the fact that $T^{(ls)}$ is a real symmetric matrix with non-negative entries, we obtain, for the combination of the terms

$$T_{sl}(|z_s|^2+|z_l|^2-z_s^*z_l-z_l^*z_s)\geqslant 0,$$

which proves the positivity and finishes the proof of the lemma. □

The matrix $\mathbf{W}^{(\gamma n)}$ has p non-negative eigenvalues. Let us assume that the jth $(j=1,\ldots,p-1)$ eigenvector has the coordinates $h^k_{\gamma nj}$, $k=0,\ldots,p-1$ and corresponds to the eigenvalue $\lambda_j^{(\gamma n)}$:

$$\sum_{k=0}^{p-1}W_{lk}^{(\gamma n)}h^k_{\gamma nj}=\lambda_j^{(\gamma n)}h^l_{\gamma nj}.$$

It is easy to see that the matrix $\mathbf{W}^{(\gamma n)}$ has the zero eigenvalue, which corresponds to the eigenvector with equal matrix elements: $h^k_{\gamma n0}=p^{-1/2}$ for all $k=0,\ldots,p-1$. Since eigenvectors are orthonormal we have

$$\sum_{k=0}^{p-1}h^{*k}_{\gamma nj}h^k_{\gamma nj'}=\delta_{jj'},\quad j,j'=0,\ldots,p-1. \tag{19}$$

Consider the function $\psi_{\gamma nj}(x)$ of the form

$$\psi_{\gamma nj}(x)=p^{(1-\gamma)/2}\sum_{k=0}^{p-1}h^k_{\gamma nj}\Omega(p|p^\gamma x-n-k|_p),$$

$$\gamma\in\mathbb{Z},\quad n\in\mathbb{Q}_p/\mathbb{Z}_p,\quad j=1,\ldots,p-1. \tag{20}$$

Note that $\psi_{\gamma nj}(x)$ is a locally constant function, constant on disks of the radius $p^{\gamma-1}$ and $\psi_{\gamma nj}(x)\in L^2(\mathbb{Q}_p)$. The functions $\psi_{\gamma nj}(x)$ we will call the generalized p-adic wavelets.

For further computations we use the following identity:

$$\Omega(p|p^\gamma x-n-k|_p)\Omega(p|p^{\gamma'}x-n'-l|_p)=\delta_{p^{\gamma'-\gamma(n+k),n'+l}}\theta(\gamma'-\gamma)\Omega(p|p^\gamma x-n-k|_p)+\delta_{n+k,p^{\gamma-\gamma'}(n'+l)}\times(1-\theta(\gamma'-\gamma))\Omega(p|p^{\gamma'}x-n'-l|_p), \tag{21}$$

where

$$\theta(\gamma)=\begin{cases}1, & \gamma>0,\\ 0, & \gamma\leqslant 0,\end{cases}$$

and $\delta_{p^{\gamma'-\gamma(n+k),n'+l}}$ is the Kronecker symbol on the group $\mathbb{Q}_p/p\mathbb{Z}_p$:

$$\Omega(|p^{\gamma'-\gamma}(n+k)-(n'+l)|_p)=\delta_{p^{\gamma'-\gamma(n+k),n'+l}},\quad \text{for } \gamma'\geqslant\gamma.$$

Theorem 6: *The set of functions* $\{\psi_{\gamma nj}(x)\}$, $\gamma\in\mathbb{Z}$, $n\in\mathbb{Q}_p/\mathbb{Z}_p$, $j=1,\ldots,p-1$ *is an orthonormal basis in* $L^2(\mathbb{Q}_p)$.

Proof: Consider the scalar product

$$p^{(\gamma-1)/2}p^{(\gamma'-1)/2}\langle\psi_{\gamma nj},\psi_{\gamma' n' j'}\rangle=\int_{Q_p}\sum_{s=0}^{p-1}h_{\gamma nj}^{*s}\Omega(p|p^{\gamma}x-n-s|_p)\sum_{l=0}^{p-1}h_{\gamma' n' j'}^{l}\Omega(p|p^{\gamma'}x-n'-l|_p)d\mu(x).$$

Using (21) we compute the following:

$$\begin{aligned}p^{(\gamma-1)/2}p^{(\gamma'-1)/2}\langle\psi_{\gamma nj},\psi_{\gamma' n' j'}\rangle&=\sum_{s=0}^{p-1}h_{\gamma nj}^{*s}\sum_{l=0}^{p-1}h_{\gamma' n' j'}^{l}\int_{Q_p}\Big(\delta_{p^{\gamma'-\gamma(n+s),n'+l}}\theta(\gamma'-\gamma)\Omega(p|p^{\gamma}x-n-s|_p)\\&\quad+\delta_{n+s,p^{\gamma-\gamma'(n'+l)}}(1-\theta(\gamma'-\gamma))\Omega(p|p^{\gamma'}x-n'-l|_p)\Big)d\mu(x)\\&=\sum_{s=0}^{p-1}h_{\gamma nj}^{*s}\sum_{l=0}^{p-1}h_{\gamma' n' j'}^{l}\Big(\delta_{p^{\gamma'-\gamma(n+s),n'+l}}\theta(\gamma'-\gamma)p^{\gamma-1}\\&\quad+\delta_{n+s,p^{\gamma-\gamma'(n'+l)}}(1-\theta(\gamma'-\gamma))p^{\gamma'-1}\Big).\end{aligned}$$

In this expression, if the first term is nonzero and $\gamma'>\gamma$, then $\delta_{p^{\gamma'-\gamma(n+s),n'+1}}$ does not depend on s, and we obtain the summation on s of the form $\Sigma_{s=0}^{p-1}h_{\gamma nj}^{*s}$ that is equal to zero for $j>0$.

In the same way, we prove that the second term does not vanish only for $\gamma'=\gamma$. This proves that

$$p^{(\gamma-1)/2}p^{(\gamma'-1)/2}\langle\psi_{\gamma nj},\psi_{\gamma' n' j'}\rangle=\delta_{\gamma\gamma'}\delta_{nn'}p^{\gamma-1}\sum_{s=0}^{p-1}h_{\gamma nj}^{*s}h_{\gamma nj'}^{s}=\delta_{\gamma\gamma'}\delta_{nn'}\delta_{\gamma\gamma'}p^{\gamma-1}\|h_{(\gamma n)j}\|^2,$$

which implies that $\{\psi_{\gamma nj}\}$ is an orthonormal system of functions.

To prove that the set of vectors $\{\psi_{\gamma nj}\}$ is an orthonormal basis [is total in $L^2(\mathbb{Q}_p)$] we use the Parseval identity. Since the set of indicators (characteristic functions) of p-adic disks is total in $L^2(\mathbb{Q}_p)$, it is enough to check the Parseval identity for the indicator $\Omega(p|p^{\gamma}x-n-s|_p)$. We have for the scalar product of the indicator and the wavelet,

$$\langle\Omega(p|p^{\gamma}x-n-s|_p),\psi_{\gamma' n' j'}\rangle=p^{(1-\gamma')/2}\sum_{l=0}^{p-1}h_{\gamma' n' j'}^{l}p^{\gamma-1}\Big(\delta_{p^{\gamma'-\gamma n,n'+l}}\theta(\gamma'-\gamma)+\delta_{\gamma\gamma'}\delta_{nn'}\delta_{sl}\Big).$$

Summing up the wavelets, we get

$$\begin{aligned}&\sum_{\gamma' n' j'}|\langle\Omega(p|p^{\gamma}x-n-s|_p),\psi_{\gamma' n' j'}(x)\rangle|^2\\&\quad=p^{\gamma-1}\left[\sum_{j'}|h_{\gamma nj'}^{s}|^2+p^{\gamma-1}\sum_{\gamma'>\gamma;n' j'}p^{1-\gamma'}\sum_{l=0}^{p-1}|h_{\gamma' n' j'}^{l}|^2\delta_{p^{\gamma'-\gamma_n,n'+l}}\right].\end{aligned}\tag{22}$$

Using the normalization condition we get

$$\sum_{j=1}^{p-1}h_{\gamma nj}^{*s}h_{\gamma nj}^{s}=1-p^{-1},\tag{23}$$

which implies for (22),

$$(1-p^{-1})p^{\gamma-1}\left[1+p^{\gamma-1}\sum_{\gamma'>\gamma}p^{1-\gamma'}\right]=(1-p^{-1})p^{\gamma-1}(1-p^{-1})^{-1}=p^{\gamma-1},$$

which proves the Parseval identity.

In the next theorem we prove that the constructed in the theorem above basis is an eigenbasis of the ultrametric diffusion operator T^{II} and compute the corresponding eigenvalues.

Theorem 7: *Let the kernel (13) satisfy the condition of convergence of the series*

$$\sum_{\gamma>0}\sum_{k=1}^{p-1} p^{\gamma}T^{(\gamma 0k0)}. \tag{24}$$

Then the operator (2) is a well defined operator in $L^2(\mathbb{Q}_p)$ *with the dense domain and the generalized p-adic wavelets* $\psi_{\gamma nj}$ *are eigenvectors for the operator* T^{II}:

$$T^{\mathrm{II}}\psi_{\gamma nj} = \lambda^{\mathrm{II}}_{\gamma nj}\psi_{\gamma nj},$$

with the eigenvalues

$$\lambda^{\mathrm{II}}_{\gamma nj} = p^{\gamma-1}\lambda_j^{(\gamma n)} + \sum_{\substack{\gamma' n' lk \\ l\neq k}} p^{\gamma'-1}T^{(\gamma' n' lk)}\delta_{p^{\gamma'-\gamma_{n,n'+l}}}\theta(\gamma'-\gamma). \tag{25}$$

Proof: Consider the action of the operator on the wavelet $\psi_{\gamma jn}$:

$$\begin{aligned} p^{(\gamma-1)/2}T^{\mathrm{II}}\psi_{\gamma nj}(x) &= p^{(\gamma-1)/2}\int T^{\mathrm{II}}_{xy}(\psi_{\gamma nj}(x)-\psi_{\gamma nj}(y))d\mu(y) \\ &= p^{\gamma'-1}\sum_{\substack{\gamma' n' lk \\ l\neq k}} T^{(\gamma' n' lk)}\Omega(p|p^{\gamma'}x-n'-l|_p)\sum_{s=0}^{p-1} h^s_{\gamma nj}\Omega(p|p^{\gamma}x-n-s|_p) \\ &\quad - \sum_{\substack{\gamma' n' lk \\ l\neq k}} T^{(\gamma' n' lk)}\Omega(p|p^{\gamma'}x-n'-l|_p)\sum_{s=0}^{p-1} h^s_{\gamma nj} \\ &\quad \times\int \Omega(p|p^{\gamma'}y-n'-k|_p)\Omega(p|p^{\gamma}y-n-s|_p)d\mu(y). \end{aligned}$$

Using (21) for $p^{(\gamma-1)/2}T^{\mathrm{II}}\psi_{\gamma nj}(x)$, we compute the following:

$$\begin{aligned} &\sum_{\substack{\gamma' n' lk \\ l\neq k}} T^{(\gamma' n' lk)}\sum_{s=0}^{p-1} h^s_{\gamma nj}\Big[\delta_{p^{\gamma'-\gamma(n+s),n'+l}}\theta(\gamma'-\gamma)p^{\gamma'-1}\Omega(p|p^{\gamma}x-n-s|_p) \\ &\quad + [\delta_{n+s,p^{\gamma-\gamma'}(n'+l)} - \delta_{n+s,p^{\gamma-\gamma'}(n'+k)}](1-\theta(\gamma'-\gamma))p^{\gamma'-1}\Omega(p|p^{\gamma'}x-n'-l|_p) \\ &\quad - \delta_{p^{\gamma'-\gamma(n+s),n'+k}}\theta(\gamma'-\gamma)p^{\gamma-1}\Omega(p|p^{\gamma'}x-n'-l|_p)\Big]. \end{aligned}$$

We prove that the term proportional to $1-\theta(\gamma'-\gamma)$ is equal to the following:

$$[\delta_{n+s,p^{\gamma-\gamma'}(n'+l)} - \delta_{n+s,p^{\gamma-\gamma'}(n'+k)}](1-\theta(\gamma'-\gamma)) = \delta_{\gamma\gamma'}\delta_{nn'}(\delta_{sl}-\delta_{sk})$$

and

$$\sum_{s=0}^{p-1} h^s_{\gamma nj}\delta_{p^{\gamma'-\gamma(n+s),n'+k}}\theta(\gamma'-\gamma) = \delta_{p^{\gamma'-\gamma_{n,n'+k}}}\theta(\gamma'-\gamma)\sum_{s=0}^{p-1} h^s_{\gamma nj} = 0,$$

since for $j=1,\ldots,p-1$, we have $\Sigma_{s=0}^{p-1}h^s_{\gamma nj}=0$.

This implies for $p^{(\gamma-1)/2}T^{\mathrm{II}}\psi_{\gamma nj}(x)$ the following:

$$p^{(\gamma-1)/2}T^{\mathrm{II}}\psi_{\gamma nj}(x)=\left[\sum_{\substack{\gamma' n' lk\\ l\neq k}} T^{(\gamma' n' lk)}\delta_{p^{\gamma'-\gamma_{n,n'+l}}}\theta(\gamma'-\gamma)p^{\gamma'-1}\right]\sum_{s=0}^{p-1}h^s_{\gamma nj}\Omega(p|p^{\gamma}x-n-s|_p)$$
$$+p^{\gamma-1}\sum_{s=0}^{p-1}h^s_{\gamma nj}\sum_{\substack{lk\\ l\neq k}}T^{(\gamma nlk)}(\delta_{sl}-\delta_{sk})\Omega(p|p^{\gamma}x-n-l|_p).$$

Consider

$$\sum_{s=0}^{p-1}h^s_{\gamma nj}\sum_{\substack{lk\\ l\neq k}}T^{(\gamma nlk)}(\delta_{sl}-\delta_{sk})\Omega(p|p^{\gamma}x-n-l|_p)$$

$$=\sum_{l=0}^{p-1}\Omega(p|p^{\gamma}x-n-l|_p)\sum_{s=0}^{p-1}\left(\delta_{sl}\sum_{\substack{lk\\ l\neq k}}T^{(\gamma nlk)}-(1-\delta_{sl})T^{(\gamma nls)}\right)h^s_{\gamma nj}$$
$$=\sum_{l=0}^{p-1}\Omega(p|p^{\gamma}x-n-l|_p)\lambda^{(\gamma n)}_j h^l_{\gamma nj}=p^{(\gamma-1)/2}\lambda^{(\gamma n)}_j\psi_{\gamma nj}(x).$$

Finally, we obtain

$$T^{\mathrm{II}}\psi_{\gamma nj}(x)=\left[p^{\gamma-1}\lambda^{(\gamma n)}_j+\sum_{\substack{\gamma' n' lk\\ l\neq k}}p^{\gamma'-1}T^{(\gamma' n' lk)}\delta_{p^{\gamma'-\gamma_{n,n'+l}}}\theta(\gamma'-\gamma)\right]\psi_{\gamma nj}(x).$$

Using the condition of convergence of the series (24) we obtain the proof of the theorem. □

VI. RELAXATION PROBLEM

Let us consider the relaxation problem formulated analogously to that in Refs. 1, 5, and 6 (see also the references therein). In these works, the evolution of probability distribution was described by the equation of the form (1) with the ultrametric diffusion operator of the type T^0. The initial distribution was taken homogeneous on $\mathbb{Z}_p$ [i.e., $f(x,0)=\Omega(|x|_p)$].

Consider the relaxation function of the system, $R(t)$, which describes the evolution of population of the system in the set where the initial distribution was concentrated. In the case when the initial distribution is the characteristic function of the unit ball with the center in zero, this reduces to

$$R(t)=\langle\Omega(|x|_p),e^{-Tt}\Omega(|x|_p)\rangle=\int_{\mathbb{Z}_p}f(x,t)d\mu(x).$$

It is known (see, in particular, Refs. 1, 3, 5, 6, and 19), for the case when the ultrametric diffusion is generated by T^0, the relaxation function $R(t)$ takes the form

$$R^0(t)=\langle\Omega(|x|_p),e^{-T^0t}\Omega(|x|_p)\rangle=(p-1)\sum_{\gamma=1}^{\infty}p^{-\gamma}\exp(-\lambda^0_{\gamma}t). \tag{26}$$

Let us investigate the relaxation behavior for the cases, when the ultrametric diffusion is generated by the operators T^{I} and T^{II}. The initial distribution we will take to be equal to the characteristic function of the disk:

$$f(x,0)=\Omega(|x-a|_p),\quad |a|_p=p^N,\quad N\geqslant 1 \tag{27}$$

and consider the relaxation function

$$R^{\mathrm{I}}(t) = \langle \Omega(|x-a|_p), e^{-T^{\mathrm{I}}t}\Omega(|x-a|_p)\rangle,$$

and R^{II}, defined analogously.

A. The operator T^{I}

Find the coefficients of the decomposition of the initial condition (27) in the basis of p-adic wavelets (7):

$$C_{\gamma nj} = \langle \Omega(|x-a|_p), \varphi_{\gamma nj}(x)\rangle = \varphi_{\gamma nj}(a)\,\theta(\gamma).$$

The solution of the Cauchy problem for the ultrametric diffusion equation (1) with the operator T^{I} and the initial condition (27) takes the form

$$f^{\mathrm{I}}(x,t) = \sum_{\gamma=1}^{\infty} \sum_{n\in \mathbb{Q}_p/\mathbb{Z}_p} \sum_{j=1}^{p-1} e^{-\lambda^{\mathrm{I}}_{\gamma n}t}\varphi_{\gamma nj}(a)\varphi^{*}_{\gamma nj}(x).$$

Then the relaxation function $R^{\mathrm{I}}(t)$ is given by the expression

$$R^{\mathrm{I}}(t) = \sum_{\gamma=1}^{\infty} \sum_{n\in \mathbb{Q}_p/\mathbb{Z}_p} \sum_{j=1}^{p-1} e^{-\lambda^{\mathrm{I}}_{\gamma n}t}|\varphi_{\gamma nj}(a)|^2 = (p-1)\sum_{\gamma=1}^{\infty} \sum_{n\in \mathbb{Q}_p/\mathbb{Z}_p} p^{-\gamma}e^{-\lambda^{\mathrm{I}}_{\gamma n}t}\Omega(|p^{\gamma}a-n|_p).$$

Taking into account that $|a|_p = p^N$ and $N \geqslant 1$, let us divide the series into the two parts: for $\gamma \leqslant N$ and for $\gamma > N$. For the second part the values of all the indicators are equal to one only if $n=0$; otherwise they are equal to zero. Hence, for the relaxation function $R^{\mathrm{I}}(t)$ we get

$$R^{\mathrm{I}}(t) = (p-1)\sum_{\gamma=1}^{N} p^{-\gamma}e^{-t\lambda^{\mathrm{I}}_{\gamma,p^{\gamma}a}} + (p-1)\sum_{\gamma=N+1}^{\infty} p^{-\gamma}e^{-t\lambda^{\mathrm{I}}_{\gamma 0}t}. \tag{28}$$

B. The operator T^{II}

The solution of the Cauchy problem for the ultrametric diffusion equation (1) with the operator T^{II} and the initial condition (27) takes the form

$$f^{\mathrm{II}}(x,t) = \sum_{\gamma=1}^{\infty} \sum_{n\in \mathbb{Q}_p/\mathbb{Z}_p} \sum_{j=1}^{p-1} e^{-\lambda^{\mathrm{II}}_{\gamma nj}t}\psi^{*}_{\gamma nj}(x)\psi_{\gamma nj}(a).$$

Then the relaxation function $R^{\mathrm{II}}(t)$ is given by the expression

$$R^{\mathrm{II}}(t) = \sum_{\gamma=1}^{\infty} \sum_{n\in \mathbb{Q}_p/\mathbb{Z}_p} \sum_{j=1}^{p-1} e^{-\lambda^{\mathrm{II}}_{\gamma nj}}|\psi_{\gamma nj}(a)|^2 = \sum_{\gamma=1}^{\infty} \sum_{n\in \mathbb{Q}_p/\mathbb{Z}_p} \sum_{j=1}^{p-1} e^{-\lambda^{\mathrm{II}}_{\gamma nj}}p^{1-\gamma}\sum_{k=0}^{p-1}|h^{k}_{\gamma nj}|^2\Omega(p|p^{\gamma}a-n-k|_p).$$

Taking into account that $|a|_p = p^N$ and $N \geqslant 1$, for the relaxation function $R^{\mathrm{II}}(t)$, we get

$$R^{\mathrm{II}}(t) = \sum_{\gamma=1}^{N} \sum_{j=1}^{p-1} \sum_{k=0}^{p-1} e^{-\lambda^{\mathrm{II}}_{\gamma nj}t}p^{1-\gamma}|h^{k}_{\gamma nj}|^2\delta_{p^{\gamma}a-k,n} + \sum_{\gamma=N+1}^{\infty} p^{-\gamma}\sum_{j=1}^{p-1} p|h^{0}_{\gamma 0j}|^2 e^{-\lambda^{\mathrm{II}}_{\gamma 0j}t}.$$

Comparing the formulas (26) and (28), we see that the long-time relaxation behavior for ultrametric diffusions generated by the operators T^0 and T^I coincide [i.e., the functions $R^0(t)$ and $R^{\mathrm{I}}(t)$ have the same asymptotic]. This shows that the particular properties of the energy landscape, such as local inhomogeneities, are not important for long-time behavior of the corresponding diffusion. Note that the given result generalizes the special case considered in the work[20] by Yoshino.

For the cases of the operators of the type T^{II}, the relaxation function behavior becomes more complicated. Note that if the landscape deviations from the regularity are small:

$$|\lambda^{\mathrm{II}}_{\gamma 0 j} - \langle \lambda^{\mathrm{II}}_{\gamma 0 j} \rangle_j| \ll \langle \lambda^{\mathrm{II}}_{\gamma 0 j} \rangle_j,$$

where $\langle \lambda^{\mathrm{II}}_{\gamma 0 j} \rangle_j = (p-1)^{-1} \Sigma_{j=1}^{p-1} \lambda^{\mathrm{II}}_{\gamma 0 j}$, then by (23) the long-time relaxation $R^{\mathrm{I}}(t)$ is a good approximation of the relaxation $R^{\mathrm{II}}(t)$.

Planar (x,z) mixtures discrete Boltzmann equations with species either in odd or even |x|+|z| values

Henri Cornille
Service SPHT, CEA/Saclay 91191, Gif-sur-Yvette, France

(Received 30 June 2004; accepted 21 December 2004; published online 3 June 2005)

We present large size "physical" discrete Boltzmann equations or discrete velocity models results for binary mixtures of gas (light mass 1 and heavy mass M) in a half-plane (coordinates x,z, interface at $z=0$ without velocities except the rest-particle) where the sums $|\mathbf{x}|+|\mathbf{z}|$ are either odd or even for heavy or light species. The models fill all integer coordinates $z\neq 0$ of the plane with only a z spatial dependence [densities with $(\pm x, z)$ are equal]. Here, to previous results, we generalize with new mathematical tools, to any binary mixture with M ratio of any even to odd values, $M=2\mathbf{p}/(2\mathbf{q}+1)$ and ratio of odd to odd values $M=(2\mathbf{p}+1)/(2\mathbf{q}+1)$, $\mathbf{p},\mathbf{q}$ arbitrary integers. With only binary collisions, we construct large size "physical" discrete models (only mass, energy, and momentum along the z-axis invariants, without other invariants which are called spurious). We prove the existence of a "physical" square (diagonals along the x and z axes) grid where for the first component all $|x|+|z|\leqslant$ a sufficient value (function of $\mathbf{p}$ and $\mathbf{q}$) while for the other "physical" components we add 2, 4, etc., to the sufficient value. The numerical "physical" applications, with only binary collisions, could be done with this grid. The heavy species Hausdorff' dimension has the limit 2 when the number of velocities $\rightarrow\infty$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1868892]

I. INTRODUCTION

Contrary to many previous DBE (discrete BE) or DVMs (review papers in Ref. 1), in the continuous BE we only have binary collisions (no multiple), only physical invariants: mass, energy, momentum (no additional called spurious invariants) and not a finite number of velocities v_i. Now, there is an evolution in DBE: no multiple collisions, no spurious invariants and finite number of v_i which can be extended to an infinite number. Concerning finite DBE (versus continuous BE) velocities v_i, Cercignani,[2] in 1994, studying, at a homogeneous equilibrium state, the energy to the mass ratio for a single-gas (not mixtures), concluded that the associated rate (linked to the temperature) would be a drawback for DBE with a finite number of v_i. A partial answer to this criticism is to compare with the planar $d_H\simeq=2$ Hausdorff dimension of the DBE when the number of $v_i\rightarrow\infty$ and the intermediate models with a finite number of v_i. We can start with a finite "physical" v_i model and, with "physical tools," we enlarge the model in the whole plane and we must prove that each intermediate square-grid is "physical."

The first paper, trying to satisfy these criteria (except the planar extension) was for two $25v_i$ mixture models, discussed by Cercignani–Bobylev,[3] but with powerful computers spurious invariants were found.[4] With simple geometrical restrictions of these $25v_i$ (Cornille–Cercignani[3]) explained why only one was physical (new collisions eliminate the spurious invariant). "Physical" binary mixture models (light species, mass 1; heavy, $M>1$) tiling all the integers of the x,z plane were presented[5] with only binary collisions (particular M values), starting with "physical" models and extending, with physical tools, to new "physical." For the distribution of the heavy species different geometrical structures were found: squares, octagons, same number for the light and heavy species. In Refs. 3–5, the lack was missing constraints for the flows.

Half-space[6] (without velocities parallel to the interface) mixtures models were presented (Fig. 1). In particular models with $|\mathbf{x}|+|\mathbf{z}|$ either even (light species) or odd (heavy species) were found

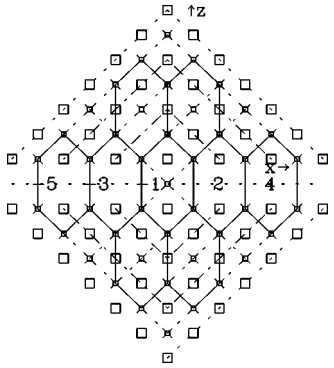

FIG. 1. $|x|+|z|$ odd (heavy), even (light). Here, $|x|+|z|\leqslant 7$.

for some M values and M even. The problem is whether this geometrical structure can exist for any rational fractional M values. Here we prove this same geometrical structure for 2 classes of ratios $M=2\mathbf{p}/(2\mathbf{q}+1)$ (even–odd) and $M=(2\mathbf{p}+1)/(2\mathbf{q}+1)$ (odd-odd). with $\mathbf{p}$ and $\mathbf{q}$ positive integers. The difficulty for the proofs, contrary to Refs. 2, 5, and 6, is the existence of two different arbitrary parameters. As in the continuum treatment of the problem and in DBE or DVMs[7,6,5] the spatial dependence of the gas is assumed to be one-dimensional depending upon the z variable. Associated physical properties for the boundaries of both the half-space and the two parallel interfaces problems were studied.[7] For single-gas Maxwellians at the interface, it was shown[6,7] how the impinging densities $z<0$ can be deduced from the emerging ones $z>0$. We recall recent interests in DBE, DVMs.[8] Here we only construct large size physical half-space models, filling all $z\neq 0$ coordinates. Like in Refs. 3–6, we require a restriction: the occupation of a site (x,z) without more than one particle.

Very often, in the literature, only numerical or geometrical regular grids are presented, but without the proof that the intermediate models are "physical" (no spurious). For the present models, it is clear that the components of the grid are squares (diagonals along the x,z axes) with $|x|+|z|$ either odd (heavy species) or even (light species). The important and nontrivial problem is to find the smallest $|x|+|z|$ value (or at least a sufficient value) such that the model is "physical" for all light and heavy densities with $|x|+|z|\leqslant$ that value. The tail of the first physical component grid (see Fig. 3 for $M=4/3$ and $|x|+|z|\leqslant 6$) depends on p,q while (tool 1.2) for the second, third, etc. (no spurious invariant) we add 2,4, etc., to that value. When p,q increase, the sufficient "physical" value increases too and it is the reason why we must reject the previous grid works without this research of the sufficient value for "physical" models.

The difficulties are binary collisions only physical invariants and half-space. For the two classes presented of M ratios mixtures, Secs. II and III the preliminary physical models have eight independent densities (six heavy, two light) and seven collisions (one with light and heavy). The previous tools, insufficient for the present study, (1, 2, etc., new densities), for the extensions of physical models are presented below 1.1–2 for one species in squares, rectangles or mixing collisions (three known).

Physical tools (Refs. 3–5) in order to enlarge "physical" models: Starting with a preliminary simple "physical" (no spurious invariants) model, we can for new "physical" add new momenta:

1.1: Four momenta of the same species of a physical mixture model being along rectangles or squares, to three (x_i,z_i) belonging to a previous physical DBE, DVMs we can include the last one (x_4,z_4).

For a mixing collision (light and heavy), if three belong to a physical model, we can add the last one,

$$f(a_1,b_1)F(x_1,z_1) - f(a_2,b_2)F(x_2,z_2) \to a_1 + x_1 = a_2 + x_2,$$
$$b_1 + z_1 = b_2 + z_2, x_1^2 + z_1^2 - x_2^2 - z_2^2 = M(a_2^2 + b_2^2 - a_1^2 - b_1^2). \tag{1}$$

We call the velocities, momenta, densities $\vec{v}_i=\vec{p}_i$, f_i (light species), $\vec{V}_j$, $\vec{P}_j=M\vec{V}_j$, F_j (heavy).

1.2: In mixture models with a light density for the rest-particle $f_0(0,0)$, if we prove that for $z\geqslant 0$ the light densities with $|x|+|z|=0,2,4$ are physical, then we can add (Refs. 5 and 6) all light densities with $|x|+|z|$ even. For the extension, if we start with half-space $|x|+|z|$ even $\leqslant 2c$, $\notin (\pm 2c,0)$, we can extend (with squares, rectangles three known) to $\leqslant 2c+2$, $2c+4$, etc. If the heavy densities with $|x|+|z|=1,3$ belong to a physical model, we can also add all heavy densities with $|x|+|z|$ odd. Similarly, the extension of the heavy is from $2c+1=3$ to $2c+1=5,7,\ldots$.

In Secs. II and III, we only have two light independent densities for the physical preliminary model, so that we cannot apply directly the two [1.2] results. However we show first that we can extend the heavy species in all odd values and second, with new collisions mixing heavy and light species we obtain other light values. The extensions for the light to $|x|+|z|=0,2,4$ and all even values are only found with the introductions of other tools which are explained below.

1.3: In some cases we can include 2,3, etc., new densities.[5,6] Starting with the old conservation laws of a previous "physical" model, with new densities we associate arbitrary constants to the evolution equations and we must have new collisions X_k including some previous densities with values fixed for each conservation law. For each new collision X_k the sum of these constants must be zero, and we must verify that the arbitrary constants are fixed, giving the right values of each conservation law: $[M_L],[M_l]$ for the macroscopic heavy and light masses and $[J],[2E]$ for the momentum along z and the energy. These starting mixture models are physical 2.1a, 3.1.

In 2.1b, 3.1, for the extension of the heavy species in the whole plane, we add new heavy squares, rectangles (three known) and with $|x|+|z|=1,3$ we extend to all odd values.

For the light species, in 2.2, 3.2–3.4, we have not this tool (three previous) but, from the extension of the heavy species, we have new collisions mixing heavy and light species and for instance in 2.1b, we can add four independent light physical but not for the Sec. III model. In both cases we do not have the light with $|x|+|z|=0,2,4$ and contrary to Ref. 6, we cannot use the 1.2 tool. The main problem remains to add the light in all the plane. We consider mainly collisions with light densities, including necessarily some old light. For the light mass conservation we have $M_l^{\text{old}}, M_l^{\text{new}}$ and we must only have $0=M_l^{\text{old}}+M_l^{\text{new}}$. For the old physical $f(x,z)$ the evolution equations $l(x,z)$ is multiplied by 1 for $x=0$ and 2 for $x\neq 0$. For the new $f(x,z)$, we associate arbitrary parameter $\mathbf{a}(\mathbf{x},\mathbf{z})$. In any collision, the sum of the old and new parameters must give zero. So we have a linear system of the number of collisions with these new $a(x,z)$ including the old values for the old densities. We try to find all $a(x,z)$ as linear combinations of arbitrary: a_0 (associated to the rest-particle f_0) and few other $a(x,z)$ called a_1,a_2, etc. Finally we try to find crucial relations, leading to $a_0=1$ and all the $a(x,z)$ having the physical value of a light mass conservation law. We must solve this linear system and the new model $M_l^{\text{old}}+M_l^{\text{new}}$ must only have $a(x,z)=1,2$ for $x=0,\neq 0$. We explicit the new necessary method used in Secs. II and III.

First, in Sec. II we have with very few collisions: $a(q-1,3q+1)$ only function of a_0 and $a(q,3q+2)=2$ Second Figs. 4(a)–4(c), we follow a path parallel to the $z=x$ axis,$(a(0,2q)=2-a_0)$ with $x=1,2$, etc., and get for $x=q-1$, q the previous $a(x,z)$ functions of both a_0, a_1 and $\mathbf{q}$. The compatibility with all $\mathbf{q}$ values leads to only $\mathbf{a}_0=\mathbf{1}$ and all $a(x,z)$ physical.

First, in Sec. III starting physical model, we have $a(x,x)=2$ for $x=2q-1$ and with few collisions $a(1,4q-3)$ function of only $\mathbf{a}_0$. Second, Fig. 5(b), we follow a path parallel to the $z=-x$ axis with $a(x,-x+4q-2)$ and x decreasing $2p-3$, $2p-5,\ldots,1$ giving another $a(1,4q-3)$ relation function of both $\mathbf{a}_0,\mathbf{q}$ and the compatibility still leads to $\mathbf{a}_0=\mathbf{1}$ and all $a(x,z)$ physical.

In 2.2, for the $2\mathbf{p}/(2\mathbf{q}+1)$, $\mathbf{q}\geqslant 1$ model, $(q=0$ in Ref. 6), we add new $f(x,z)$, $a(x,z)$ and for a set of these arbitrary parameters called a_k, $k=1,\ldots,q-1,q$ which are k or q dependent, we prove that they are linear combination of two, a_1,a_2. On the other hand $a_q=2$ and $a_{q-1}=10-8a_0$.

Comparing the two different explicit expressions (q-dependent or not), we deduce that $a_0=1$ and the arbitrary parameters a_k only have the physical values giving a "physical" model.

For $q=1,2,3$ and later for $2p/(2q+1)$, we give the sufficient values such that the model with all $|x|+|z|\leqslant$ that value be physical, giving the first $P=1$ component of the physical squares (diagonals along the x,z axes) grid, the second, third, etc., $P=2, 3, \ldots$ component being found adding 2,4, etc., to the sufficient value. The light and heavy densities having almost the same number of densities in large squares (extensions of Fig. 1), we study (in some examples), the Hausdorff's dimension of only the heavy species. We show that the large limit value is $d_H\to 2$ and notice that the P-square grid must be very large to approach this limit.

In 3.2–3.4, for the $(2\mathbf{p}+\mathbf{1})/(2\mathbf{q}+\mathbf{1})$ model, in order to extend the light species f, we still associate $a(x,z)$ and, for a pedagogical study, first we limit to $q=1,2$ with only the previous 1.1–2 tools and finally giving a general proof for q arbitrary with our generalized tool. We show two expressions for $a(1,4q-3)$, one with only a_0 and another with $\mathbf{q}$. The compatibility gives $a_0=1$ and all correct "physical" $a(x,z)$ values.

1.4: The presented models, filling all integer coordinates, have a regular grid (mesh-step 1). We can generalize[2–5] with a mesh-step h finite: $(\vec{v}\to h\vec{v},\vec{P}\to h\vec{P})$ and $\vec{v}^2\to(h\vec{v})^2,\vec{P}^2\to(h\vec{P})^2$ (collisions still valid). For the construction of physical models we present sets of P selected physical domains and we know (advantage to the standard numerical discretizations) that in all intermediate steps we have no spurious invariants. For brevity we write **Aj**,**Bk** for Appendix **Aj**,**Bk**. In the sequel, for a set y_s, we define $y_{i,j,\ldots,q}=\sum_{s=i}^{s=q}y_s$ and $y_{i,j}^{-}=y_i-y_j$.

For the heavy P^{th} squares grid with diagonals along the x,z axes, $|x|+|z|\leqslant\nu$, the Hausdorff dimension $d_H=\log N_\nu/\log L_\nu)$, we have $N_\nu=\nu(\nu+1)$ for the number of heavy densities and for the sizes $L_\nu=\sqrt{2}\nu$. We get $d_H\to 2$ when $\nu\to\infty$.

II. HEAVY MASS RATIO OF EVEN TO ODD: $M=2p/(2q+1)>1$ (Figs. 2–4)

2.1: Heavy species filling all $|x|+|z|$ odd, Fig. 2(a), only six light. First in 2.1a, we prove that a simple mixture model (six individual heavy and two light) is physical. We write the evolution equations as sums of collisions and eliminating successively these collisions we find three invariants IV, I, II for both the heavy and light masses conservations. For the momentum along z and the energy, we find the last invariant III. Second in 2.1b, with the simple tool of collisions in squares, rectangles (three known), we show that in the previous mixture physical model, the heavy species can be extended in the whole plane with $|x|+|z|$ odd and, with the new heavy, we can extend (four individual, four new light) a little bit the light species. However, with the Sec. I tools, we do not have sufficient light densities (only six), to extend in the plane.

2.1a: Starting physical model, Fig. 2(a) with six heavy $F_i(\pm x,z)$, two light $f_j(\pm x,z)$ densities [equal for $(\pm x, z)$]. We write both the mixing Γ and six heavy Ω_i collisions. We write the evolution equations $l_i=(\partial_t+z_i\partial_z)f_i$ [or $z_i\partial_z f(x_i,z_i)$] and L_j associated to f_i,F_j which are sums of collisions Γ,Ω_i where $f_i(F_j)$ are in the lost terms. We deduce the physical invariants.

Lemma 1, Fig. 2(a): With collisions, six Ω_i and one Γ mixing light and heavy densities, we show that the mixture (2.1) model with six heavy F, two light f is physical (no spurious invariants). We find four invariants I–II–III–IV equivalent to the four conservation laws, two for the heavy mass M_L, one for the light M_l, and only one new for both the momentum J and energy $2E$,

$$F_1(0,2p-3),\quad F_2(\pm1,2p-2),\quad F_3(\pm2,2p-1),\quad F_4(0,2p+1),\quad F_5(0,2p-1),\quad F_6(\pm1,2p),\tag{2.1}$$

$$f_q(\pm q,q),\quad f_{q+1}(\pm(q+1),q+1)\quad \text{densities equal for}(\pm x,z),$$

$$\Gamma=F_5(0,2p-1)f(q+1,q+1)-F_6(1,2p)f(q,q),\quad \Omega_1=F_5F_4-F_6^2,$$
$$\mathbf{i=0,1}\to\Omega_{2+i}=F_1F_{5-i}-F_{2+i}^2,\quad \Omega_{4+i}=F_{5-i}F_{3-i}-F_6F_{2+i},\quad \Omega_6=F_1F_6-F_3F_2,\tag{2.2}$$

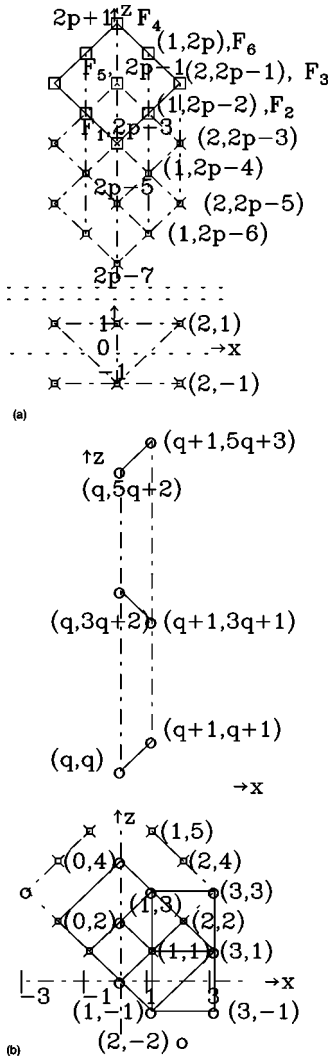

FIG. 2. $M=2_p/(2_q+1)$, $|x|+|z|$ odd.

$$\Gamma = l_q(q,q) = -\,l_{q+1}(q+1,q+1) \to M_l/2 = l(q,q) + l(q+1,q+1) = 0 \text{ IV},\ L_{1+3i} = -\,\Omega_{2-i,3} - 2\Omega_{6-i},$$

$$L_{2+i} = \Omega_{2+i,4+i,6} - \Omega_{5-i}, \quad L_5 = -\,2\Gamma - \Omega_{1,2} - 2\Omega_4, \quad L_6 = \Gamma + \Omega_{1,4,5} - \Omega_6. \tag{2.3}$$

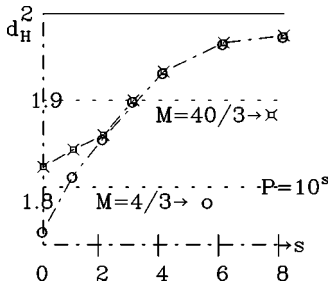

FIG. 3. $M=2_p/3f(x,z)$.

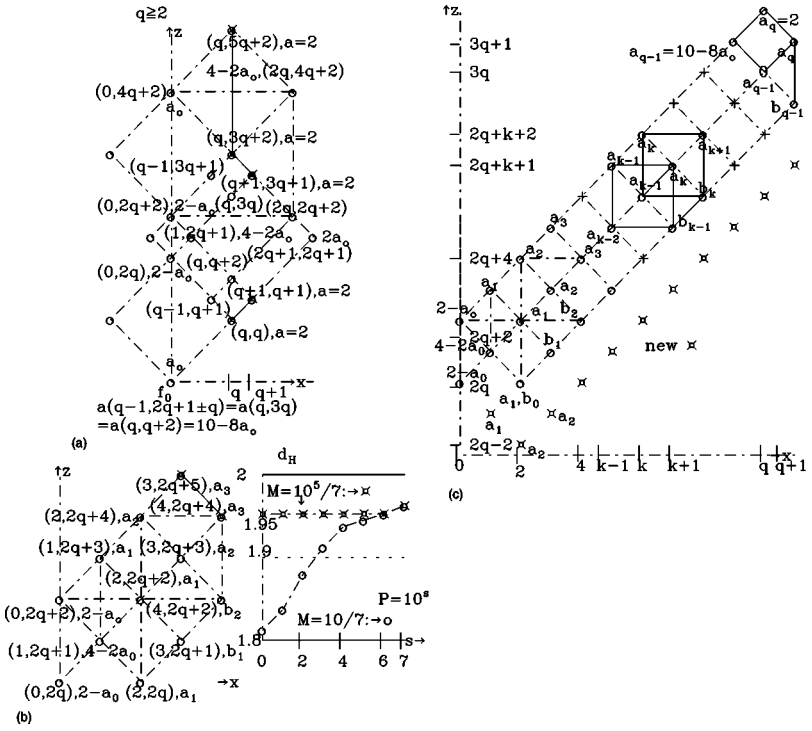

FIG. 4. $M=2_p/(2_q+1)$. (a) $q\geqslant 2$. (b) $(x,z)\to f(x,z)$. (c) $f(x,z)\to|x|+|z|$.

For the reader not familiarized with DBE, DVMs, we explain the coefficients 1 or 2 in the collisions. In Γ, we have one F_5 but two equal $F_6(\pm 1,2p)$ and consequently two collisions with Γ for L_6 and -2Γ for L_5. For the heavy mass we eliminate successively Γ,Ω_1 and get two invariants I, II. For the heavy mass conservation, we have a coefficient 1 for the L_i with $x_i=0$ (densities along the z axis), but two for $\pm x_i\neq 0$. For the momentum conservation J, we multiply the L_i,l_j by the z values of the associated densities and get for J and the energy $2E$, another invariant III. For the $2E$ conservation, we multiply with (x^2+z^2) for the heavy, still with M for the light,

$$L_5+2L_6=\Omega^-_{1,2}+2\Omega^-_{5,6}\to L_{4,5}+2L_6=-\Omega_{2,3}-2\Omega_6=L_1=-L_{2,3}\to \mathrm{I}{:}L_{2,3,4,5}+2L_6=0,$$
$$\mathrm{II}{:}L_{1,2,3}=0\to M_L=\mathrm{I}+\mathrm{II}=L_{1,4,5}+2L_{236}=0, \tag{2.4}$$

$$J=2ql_q+2(q+1)l_{q+1}+(2p-3)L_1+(2p-1)L_5+(2p+1)L_4+2(2p-2)L_2+2(2p-1)L_3+4pL_6$$
$$=2pM_L+[-2\mathrm{II}+\mathrm{III}]=0\to \mathrm{III}:=L_4-L_{1,5}-2L_2+2l_q=0, \tag{2.5}$$

$$2E=(2p-3)^2L_1+(2p-1)^2L_5+(2p+1)^2L_4+2(1+4p^2)L_6+2(4+(2p-1)^2)L_3+2(1+(2p-2)^2)$$
$$\times L_2+[q^2l_q+(q+1)^2l_{q+1}(q+1)2]8p/(2q+1)=(4p^2+1)M_L+2\mathrm{II}+4p(\mathrm{III}-2\mathrm{II}). \tag{2.6}$$

2.1b, Fig. 2(a) Lemma 2: Heavy $\mathbf{F}(\mathbf{x},\mathbf{z})$ filling all $|\mathbf{x}|+|\mathbf{z}|$ odd and only two light $\mathbf{f}(\mathbf{x},\mathbf{z})$. With heavy collisions in squares and rectangles and 3 $F\in$ (2.1), we add six new individual $F(x,z)$,

$$F(\pm x,z)\to(\pm x,z(p)\neq 0){:}\alpha=0,2{:}(2,2p-3-\alpha)(1,2p-4-\alpha),(0,2p-5-\alpha) \tag{2.7}$$

and $p\to p-1\to p-2$, etc. Physical F satisfy $|x|+|z|=1,3\to$ all odd but only two light f.

Proof of (2.7): With squares, rectangles (three known) Fig. 2(a), we add to (2.1), the last heavy $\overline{F}$,

$$F_3(2,2p-1)F_1(0,2p-3)-F_5(0,2p-1)\overline{F(2,2p-3)},$$
$$F_1(0,2p-3)F(2,2p-3)-F_2(1,2p-2)\overline{F(1,2p-4)},\quad p\neq 2,$$
$$F(1,2p-4)F(-1,2p-4)-F_1(0,2p-3)\overline{F(0,2p-5)}. \tag{2.8}$$

Similarly we get new heavy $F:\overline{(2,2p-5)}$, $\overline{(1,2p-6)}$, $\overline{(0,2p-7)}$ with $p\to p-1,\ldots,p-2,\ldots$.

Lemma 3: Physical DVMs with more light densities, six f, Fig. 2(b). With mixing collisions (three known), we now have six individual light $f(\pm x,z)$ [written (x,z)]

$$(\pm q,q),(\pm(q+1),q+1)\text{new}(\pm q,3q+2),(\pm q,5q+2),(\pm(q+1),3q+1),(\pm(q+1),5q+3). \tag{2.9}$$

Proof of (2.9), Fig. 2(b): To the (2.1) with two light $f(q,q)$, $f(q+1,q+1)$, we add successively four new $f\overline{(x,z)}$ with mixing collisions (F with $|x|+|z|$ odd) giving six physical $f(x,z)$,

$$f(q,q)F(x,2p+1+q)-\overline{f(q,3q+2)}F(x,2p-1-q)\ \text{either } x,q \text{ odd or even},$$

$$f(q,3q+2)F(x,4p+q)-\overline{f(q,5q+2)}F(x,4p-q),\quad |x|+q \text{ odd},$$

$$f(q+1,q+1)F(x,2p+q)-\overline{f(q+1,3q+1)}F(x,2p-q),\quad |x|+q \text{ odd},$$

$$f(q+1,3q+1)F(0,z+2(q+1))-\overline{f(q+1,5q+3)}F(0,z),\quad z \text{ odd}. \tag{2.10}$$

2.2: $M=2\mathbf{p}/(2\mathbf{q}+1)>1$, $\mathbf{q}\geqslant 1$. Light species filling all $|x|+|z|$ even, Figs. 3 and 4.

Our aim is to prove for the light species that for the sum of the $a(x,z)l(x,z)$ [l associated to $f(x,z)$ and $a(x,z)$ arbitrary], exists only one invariant, the light mass M_l and the only $a(x,z)$ possible values are (like for old physical densities $a=1,2$) 1, $x=0$ and 2, $x\neq 0$. For the old physical M_l^{old}, in (2.9) these six $a(\pm x\neq 0,z)=2$ values are satisfied but not for the new M_l^{new}. The $M_l=M_l^{\text{old}}+M_l^{\text{new}}=0$ is linear combination of the vanishing collisions and we must find constraints for the new $a(x,z)$ giving only the physical values. We obtain general physical results in 2.2a, b, c for arbitrary $\mathbf{q}$ and, in Lemma 4, Appendix A1, for a pedagogical reason, we give an independent $M=2p/3$, $q=1$ proof of a physical model.

Lemma 4, A1, Fig. 3: The $M=2\mathbf{p}/3$, $\mathbf{q}=1$ model is physical with a M_1 conservation law.

For $M=2\mathbf{p}/3$, A1, the physical $|x|+|z|$ are $\leqslant 2p+3$ for heavy and $\leqslant 6$ for the light species, With the 1.2 tool we can extend the physical light to 8,10, …,$2p+2$ or the heavy to $2p+5$, $2p+7$, $2p+9$, etc., giving $P=1,2$,etc., squares grid with diagonals along the x,z axes where all coordinates are filled for $|x|+|z|\leqslant \nu=2p+1+2P$ by heavy (odd) or light (even) physical species. In Fig. 3, we give the Hausdorff' dimension d_H for the heavy species with $M=4/3$, $40/3$, giving the same values for $P\geqslant 100$ and $\to d_H\sim 2$ for more and more P-squares-grid.

In 2.2a, for $\mathbf{q}$ arbitrary, we add new light $f(x,z)$ densities so that the associated arbitrary parameters $a(x,z)$ depend only on the arbitrary a_0 linked to the rest-particle f_0.

Adding light collisions, valid only for $q=1,2$, we find $a_0=1$, leading to a new physical mixture $M=2\mathbf{p}/5$, Appendix A2 model which can be extended to all light densities with $|x|+|z|$ even.

In 2.2b, $\mathbf{q}$ arbitrary, we add (light collisions) three associated $a(x,z)$ parameters. As application, the $M=2\mathbf{p}/7$, Appendix A model is physical in the whole plane.

In 2.2c, Appendix A, $\mathbf{q}$ arbitrary, the new $a(x,z)$ depend on more and more arbitrary parameters, but we prove that they only have the physical light species values.

2.2a, Fig. 4(a), general arbitrary $\mathbf{q}$ *results for the light species:* We add, to the physical light $f(x,z)$ with $a(x,z)=2$, (2.1)–(2.9), new light densities with collisions, but their associated (2.12) and (2.13) arbitrary $a(x,z)$ values, coming from vanishing collisions, depend on $a_0=a(0,0)$. So the light mass conservation law has two invariants, one spurious except $q=1$ with $a_0=1$, Appendix A.

For arbitrary $\mathbf{q}$, with collisions (three known), we get new $a(x,z)$ values which depend only on a_0,

$$\text{old, } \lambda = 0, 2q+2, \quad 2 = a(q, q+\lambda) = a(q+1, 3q+1+\lambda) = a(q, 5q+2) = a(q+1, q+1),$$

$$\begin{aligned}\text{new, } a(0,4q+2) &= a(2q+1,2q+1)/2 = a_0, \quad a(0,2q) = a(0,2q+2) = 2 - a_0 = a(2q,4q+2)/2 \\ &= a(1,2q+1)/2, \quad a(2q,2q+2) = 8 - 6a_0, \quad a(q,q+2) = a(q,3q) = 10 - 8a_0 \\ &= a(q-1 \neq 0, q+1) = a(q-1 \neq 0, 3q+1), \quad a(2q-1,2q+1) = 16 - 14a_0.\end{aligned} \tag{2.11}$$

[See Eqs. (2.12) and (2.13).]

Proof for (2.12) and (2.13) with one mixing Γ and 11 light different collisions,

$$\text{new, } \Gamma = f\overline{(2q+1,2q+1)}F(0,2p-2q-1) - f_0F(2q+1,2p) \to a(2q+1,2q+1) = 2a_0,$$

$$f_0f\overline{(0,4q+2)} - f^2(2q+1,2q+1) \to a(0,4q+2) = 2a_0 - a_0 = a_0, \quad f_0f\overline{(0,2q)} - f^2(q,q),$$

$$\begin{aligned}f_0f\overline{(0,2q+2)} - f^2(q+1,q+1) \to a(0,2q) &= a(0,2q+2) = 2 - a_0, \\ & f(q,3q+2)f(q,5q+2) - f(0,4q+2)f\overline{(2q,4q+2)}, \\ & f(0,2q+2)f(0,2q) - f^2\overline{(1,2q+1)}, \\ & f(2q,4q+2)f(0,2q+2) - \\ & f(0,4q+2)f\overline{(2q,2q+2)}, \to a(2q,4q+2) = a(1,2q+1) \\ = a(2q,2q+2)/2 + a_0 &= 4 - 2a_0,\end{aligned} \tag{2.12}$$

$$a(q,q+2) = a(q-1,q+1) = a(q-1,3q+1) = a(q,3q) = 10 - 8a_0, \quad a(2q-1,2q+1) = 16 - 14a_0,$$

$$\begin{aligned}& f(2q,2q+2)f(q+1,q+1) - f(2q+1,2q+1)f\overline{(q,q+2)}, \\ & f(2q,2q+2)f(q,q) - f(2q+1,2q+1) \\ & f\overline{(q-1,q+1)}, \quad f(q-1,q+1)f(q+1,3q+1) - f(q+1,q+1)f\overline{(q-1,3q+1)}, \\ & f(q-1,3q+1)f(q+1,3q+1) - f(q,3q+2)f\overline{(q,3q)}, f(q,3q)f(q,q+2) - f(1,2q \\ & +1)f\overline{(2q-1,2q+1)}\end{aligned} \tag{2.13}$$

Adding collisions valid for $q=1,2$ we get $a_0=1$ and $M=2\mathbf{p}/5$ in A2 is a physical model.

Lemma 5, Appendix A: With (2.12) and (2.13), the model $M=2\mathbf{p}/5$, $\mathbf{p}\geqslant 3$, $\mathbf{q}=2$ is physical.

In (2.12) and (2.13) for $\mathbf{q}=2$, $\mathbf{p}\geqslant 4$, the highest physical $|x|+|z|$ are $\leqslant \nu = 2p+5$ for heavy (12 for light) species with $P=1$. With the 1.2 tool we enlarge the light species $\leqslant 2p+6$, $2p+8$, $2p+10$, etc., and the heavy to $\nu = 2p+7$, $2p+9$, etc., giving the $P=2,3$, etc., squares grid.

2.2b: In Fig. 4(b) we add with squares (three known) to (2.12) and (2.13) new general $\mathbf{q}$, $\mathbf{a}(\mathbf{x},\mathbf{z})$ results,

$$\begin{aligned}\text{old, (2.12) and (2.13), } 2 - a_0 &= a(0,2q) = a(0,2q+2) = a(1,2q+1)/2, \\ & a(q+1,3q+1) = 2, \text{etc.}, \text{ new; } a_k, b_k,\end{aligned} \tag{2.14}$$

$$a_1 := a(1,2q+3) = a(2,2q+2) = a(2,2q), \quad a_2 = a(2,2q+4) = a(3,2q+3) = 3a_1 + 4(a_0 - 2),$$

$$b_1 := a(3,2q+1) = 2a_1 + 2(a_0 - 2) = a_2 - a_1 + 2(2 - a_0), \quad b_2 = a(4,2q+2) = 4a_1 + 6(a_0 - 2), \tag{2.15}$$

$$a_3 := a(4,2q+4) = a(3,2q+5) = 6a_1 + 10(a_0 - 2).$$

Fig. 4(b), Proof for (2.14) and (2.15): We define new a_k, b_k with collisions [three physical $f(x,z)$],

$$\begin{aligned}
&f(0,2q+2)\overline{f(2,2q+2)} - f(1,2q+1)\overline{f(1,2q+3)},\\
&\quad f(0,2q+2)\overline{f(2,2q)} - f(0,2q)\overline{f(2,2q+2)} \to a_1 := a(1,2q+3) = a(2,2q+2) = a(2,2q),\\
&\quad f(0,2q+2)\overline{f(3,2q+3)} - f(1,2q+1)\overline{f(2,2q+4)} \to a_2 = a(2,2q+4) = a(3,2q+3),\\
&\quad f(1,2q+3)f(2,2q) - f(0,2q+2)\overline{f(3,2q+1)},
\end{aligned} \tag{2.16}$$

$$f(1,2q+1)f(3,2q+3) - f(1,2q+3)f(3,2q+1) \to b_1 := a(3,2q+1) = 2a_1 + 2(a_0 - 2) = a_2 - a_1 + 2(2 - a_0), \quad a_2 := 3a_1 + 4(a_0 - 2),$$

$$f(2,2q+4)f(3,2q+1) - f(1,2q+3)\overline{f(4,2q+2)} \to b_2 := a(4,2q+2) = a_2 - a_1 + b_1 = 4a_1 + 6(a_0 - 2),$$

$$\begin{aligned}
&\overline{f(4,2q+4)}f(2,2q+2) - f(2,2q+4)f(4,2q+2)\\
&\qquad \to a_3 := a(4,2q+4) = a_2 - a_1 + b_2 = 6a_1 + 10(a_0 - 2), f(4,2q+4)f(2,2q+4)\\
&\qquad - \overline{f(3,2q+5)}f(3,2q+3) \to a(3,2q+5) = a_3.
\end{aligned} \tag{2.17}$$

Lemma 6, Appendix A3: The $M = 2\mathbf{p}/7$, $\mathbf{p} \geqslant 4$, $\mathbf{q} = 3$ model is physical with (2.12)–(2.15).

The highest $|x| + |z|$ value for the preliminary physical square grid being $2p+7$ (heavy $p \geqslant q+1 = 4$) and $6q+2 = 20$ (light), we enlarge heavy or light with the highest $\nu = 2p+12$, giving the first $P = 1$ component physical grid and $2p+10+2P$ for $P = 2$, etc. In Fig. 4(b), we present d_H for the heavy species, $M = 10/7$, $10^5/7$ with the same comment as previously for $M = 2p/3$.

2.2c, $M = 2\mathbf{p}/(2\mathbf{q}+1)$: General proof for light filling all $|x| + |z|$ even, Fig 4(c).

We could go on and study $2p/9$, $2p/11$, but with proofs more and more tedious, so in Appendix A, we give a proof for arbitrary $\mathbf{q}$ integer. In (2.14) and (2.15) we have given a_2, a_3 in terms of a_0, a_1 and we define in (2.16) and (2.17), a_k (function of k, a_0, a_1), that we apply to (2.11) and (2.13),

$$a_k = a(k+1,2q+k+1) = a(k,2q+k+2), \quad k = 1,2,\ldots,q \text{ and explicit } a_k \text{ in (3a5) and (3a6)},$$

$$(2\,.\,11) \to a_q = a(q,3q+2) = 2 \text{ (physical value)}, \quad (3a2) \to a_{q-1} = a(q-1,3q+1) = 10 - 8a_0.$$

We shall deduce (2.19), with Lemma 7, the physical values $a_0 = 1$, $a_k = 2$, $k = 1,\ldots,q$.

Lemma 7, Appendix A4:

$$a_k = a(k+1,2q+k+1) = k(k+1)a_1/2 + (k(k+1) - 2)(a_0 - 2). \tag{2.18}$$

With a collision Λ_k, we get (2.17) and with light collisions deduce (2.18) a relation between $a_{k-\lambda}$, $\lambda = 0,1,2,k-1$, k giving the new $a_4, a_5, \ldots, a_k$ of (2.16). For the crucial relations leading to $a_0 = 1$, giving two linear independent a_0, a_1 relations, we use the (2.16), a_k result (function of a_1, a_0) for $k = q$, $a_q = 2$ and $k = q-1$, $a_{q-1} = 10 - 8a_0$ and get the physical value $a_0 = 1$,

$$q(q+1)a_1/2 + (q(q+1) - 2)a_0 - 2(q(q+1) - 1) = 0,$$

$$q(q-1)a_1/2+(q(q-1)+6)a_0-2(q(q-1)+3)=0\rightarrow a_0=1,\quad a_1=2\rightarrow a_k=b_k=2. \tag{2.19}$$

With light collisions in squares and rectangles (three previous known) densities, we can include $|x|+|z|=0,2,4$ and all even values. In Fig. 4(c), from the physical model including integer coordinates of $z=2q+2+x$, $z=2q+x$, $2q-2+x$, we can add $z=2q-4+x$, $2q-6+x$, … .

Due to $a_q(x,z)$ in (2.17), we have for the light $|x|+|z|\leqslant 4q+2$ with $p\geqslant q+1$, but in (2.12), $\leqslant 6q+2$ for the light and $2p+2q+1$ for the heavy. For the first component (no spurious invariant) physical grid we enlarge either the light or the heavy with the highest $|x|+|z|\leqslant 2p+2q+2$ and $2p+2q+4$ for the second $P=2$ physical grid with all integer coordinates filled.

For the physical P-grid we consider, like in Fig. 1, squares with diagonals along the x and z axes with $|x|+|z|\leqslant\nu$ with $-\nu\leqslant z\leqslant\nu$. We have $\nu(\nu+1)$ heavy densities and for the Hausdorff's dimension d_H of the heavy species we have $d_H=\log(\nu(\nu+1))/\log(\nu\sqrt{2})\rightarrow 2$ when $\nu\rightarrow\infty$. For the examples given in Figs. 3, 4, and 4(b), we have $\nu=3M+2P+1$ and $\nu=7M+2P+5$.

III. $M=(2\mathbf{p}+1)/(2\mathbf{q}+1)$, FILLING EITHER $|x|+|z|$ ODD (HEAVY) OR EVEN (LIGHT)

In 3.1, we start with an eight individual F_i, f_j physical model and extend the heavy in the plane.

In 3.2, we add eight light $f(x,z)$ with associated $a(x,z)$ parameters which only depend on a_0.

In 3.3, Appendix B1, with $a_0=1$, the $M=(2\mathbf{p}+1)/3$, $\mathbf{q}=1$ planar model is physical.

In 3.4, B2–B3 the light f_i have associated arbitrary parameters a_0,a_1,a_2,a_3, etc. For $\mathbf{q}=2$, the model is physical and for q arbitrary, both $a_0=1$ and the other only have the physical values.

3.1 Lemma 8: With only two $f(x,z)$, the heavy species $F(x,z)$ fills all $|x|+|z|$ odd.

We start with the same six heavy (2.1), Fig. 2(a) model (with $\mathbf{p}\rightarrow\mathbf{p}+1$) but the two light are different. The heavy Ω_i collisions (2.2) are with the same F_i but not the mixture collision,

$$\text{heavy, } F_i(x,z)\text{:(2a1) but } p\rightarrow p+1;\quad \text{light, } f(x,2q+1\pm 2)\ x \text{ odd} \tag{3.1}$$

$$\Gamma=f(x,2q-1)F_4(0,2p+3)-f(x,2q+3)F_1(0,2p-1)\rightarrow\Gamma=l(x,2q+3)=-l(x,2q-1)\rightarrow M_l/2$$
$$=l(x,2q-1)+l(x,2q+3)=\mathrm{IV}=0,\quad L_4=-2\Gamma-\Omega_{1,3}-2\Omega_5,\quad L_1=2\Gamma-\Omega_{2,3}-2\Omega_6,$$

$$L_5=-\Omega_{1,2}-2\Omega_4,\quad L_6=\Omega_{1,4,5}-\Omega_6,\quad \mathbf{i}=\mathbf{0},\mathbf{1}\rightarrow L_{2+i}=\Omega_{2+i,4+i,6}-\Omega_{5-i}. \tag{3.2}$$

For the heavy mass M_L we eliminate successively Γ,Ω_3, get two invariants and $M_L=\mathrm{I}+\mathrm{II}$: For the momentum and the energy, we must only find another invariant III,

$$-\Omega_{1,2}-2\Omega_4=L_{1,4}+2L_3=L_5=-L_{2,6}\rightarrow\ \mathrm{I}:\ L_{1,2,4,6}+2L_3=0,\quad \mathrm{II}:\ L_{2,5,6}=0, \tag{3.3}$$

$$J=\sum c_i(p)L_i[(2\mathrm{a}5)\text{ with } p\rightarrow p+1]+2\sum_{\pm}(2q+1\pm 2)l(x,2q+1\pm 2)=2pM_L+2qM_l+\mathrm{III},$$

$$\mathrm{III}=L^{-}_{5,1}+3L_4+2L_3+4L_6+8l(x,2q+3),$$

$$2E=\sum d_i(p)L_i[(2\mathrm{a}6)\text{ with } p\rightarrow p+1]+2\sum_{\pm}[(x^2+(2p+1\pm 2)^2)l(x,2q+1\pm 2)=\text{const } M_l$$
$$+4p^2M_L+(4p+2)\mathrm{III}+3\mathrm{I}-\mathrm{II}]. \tag{3.4}$$

The mixture (3.1) model with two f is physical. Like in Lemma 2, with squares [$p\rightarrow p-1$, etc., in (2.7)], we extend the physical heavy species in $|x|+|z|=1,3$ and to all odd values of the plane.

3.2: General results for the light of $M=(2\mathbf{p}+1)/(2\mathbf{q}+1)$, $\mathbf{q}$ arbitrary Figs. 5(a)–5(c).

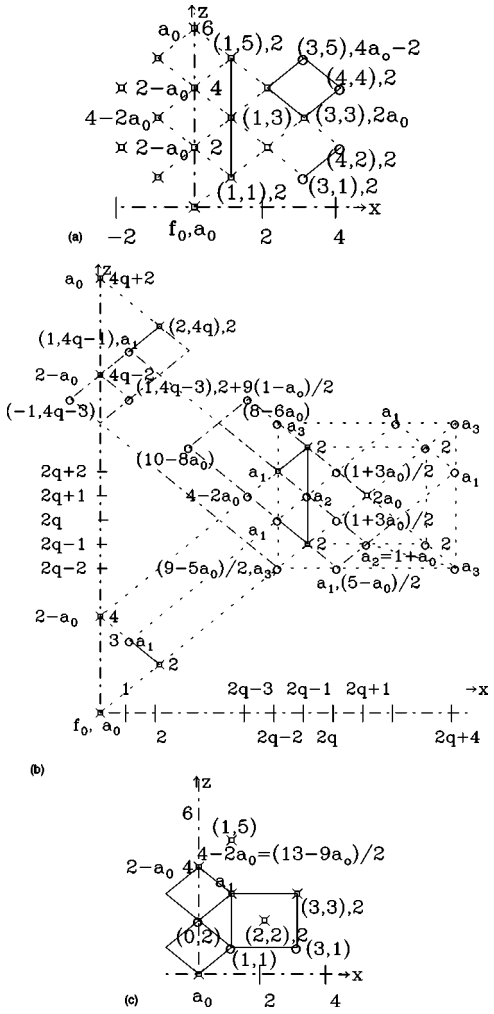

FIG. 5. (a) $M=(2_p+1)/3$. (b) $M=(2_p+1)/(2_q+1)$. (c) $M=(2_p+1)/5$.

Choosing $x=2q-1$ in (3.1), we start with the two light $f(x=2q-1,2q+1\pm2)$ [collision Γ in (3.1)], belonging to the previous physical mixture model. We add eight new $f(x,z)$ with associated arbitrary parameters $a(x,z)$ and show that they only depend on $a(0,0):=a_0$ (for f_0). At this stage the models do not satisfy $a(0,z)=1$, $a(x\neq0,z)=2$ and so are not "physical." In other sections, we prove that $a_0=1$, leading to "physical" models.

Lemma 9: With collisions, we add eight new light $f(\overline{x,z})$, $a(x,z)$ functions of $a_0=a(0,0)$,

$$\text{old, } 2=a(2q-1,2q+1\pm2);\quad \text{new, } 2=a(2,2)=a(2,4q)=2(\text{physical}), \tag{3.5}$$

$$a(0,4q+2)=a_0=a(2q+1,2q+1)/2,\quad a(0,4q-2)=a(0,4)=2-a_0=a(2q-3,2q+1)/2. \tag{3.6}$$

Proof of (3.5) and (3.6) with squares, rectangles (threeknown), old, $f(2q-1,2q-1)$, $F(x,2(p-q)),F(x,2(p+q+1))$; new, $f_0,f(2q+1,2q+1),f(0,4q\pm2),f(0,4),f(2,2),f(2,4q),f(2q-3,2q+1)$,

$$\Gamma_1=\overline{f(0,4q+2)}F(x,2(p-q))-f_0F(x,2(p+q+1))\rightarrow a(0,4q+2)=a_0,\quad x \text{ odd},$$

$$f_0 f(0,4q+2) - f^2\overline{(2q+1,2q+1)} \to a(2q+1,2q+1) = 2a_0, \quad f_0 f\overline{(0,4q-2)} - f^2(2q-1,2q-1),$$

$$f(0,4q+2)f\overline{(0,4)} - f^2(2q-1,2q+3) \to a(0,4) = a(0,4q-2) = 2 - a_0,$$

$$f(0,4)f(0,4q-2) - f^2\overline{(2q-3,2q+1)} \to a(2q-3,2q+1) = 4 - 2a_0,$$

$$f_0 f(0,4) - f^2\overline{(2,2)}, \quad f(0,4q+2)f(0,4q-2) - f^2(2,4q) \to a(2,2) = a(2,4q) = 2.$$

3.3: Lemma 10, Appendix B1: Fig. 5(a). The $M=(2\mathbf{p}+1)/3$, $\mathbf{q}=1$, $\mathbf{p}\geqslant 2$ model is physical.

For the first physical square grid, the highest $|x|+|z|$ are $2p+3$, 8 for heavy and light species. For $p>2$ we enlarge the light up to $2p+4$ for the first grid and $2p+6$, etc., for the second.

3.4: New general light results for $M=(2\mathbf{p}+1)/(2\mathbf{q}+1)$, filling $|x|+|z|$ even, Figs. 5(b) and 5(c).

Lemma 11: With the proof that $a_0=1$, the models $M=(2\mathbf{p}+1)/(2\mathbf{q}+1)$ are physical.

To the general old (3.5) and (3.6) results, we add new ones with new collisions. In addition to a_0, we add new arbitrary parameters a_1, a_2, etc., and we must prove that they only have the physical values. The method is simple, but tedious. In Appendix B2 with $a_1=a(1,4q-1)=(5-a_0)/2$, we get a physical $M=(2\mathbf{p}+1)/5$ model. In B 2–B 3, (3.11)–(3.13), we get a first $a(1,4q-3)$ function of a_0 and starting with $a(x,z)$ z and x of the order of $2q$, we obtain successively higher z and smaller x values and a second $a(1,4q-3)$ function of both a_0 and q. The compatibility requires $a_0=1$ and all $a(x,z)$ have the correct physical values 1 or 2 for the light mass conservation law. We start with $a(x,z)$ given in (3.5) and (3.6).

First Fig. 5(b), in B 2, with (3.5) and (3.6) and new collisions we define $a_1=\overline{a_1}$, a_2, a_3 and with (3.7)–(3.11), find $a_1=\overline{a_1}=(5-a_0)/2$ and a first $a(1,4q-3)$ function of a_0,

$$a_1 \coloneqq a(1,4q-1) = \overline{a_1} \coloneqq a(2q-2,2q) = a(1,3), \tag{3.7}$$

$$a_2 \coloneqq a(2q-1,2q+1) = 2a_1 - 4 + 2a_0, \tag{3.8}$$

$$2 = a(2q+c,2q+d), \quad c=-1,3, \quad d=-1,3, \quad a_3 \coloneqq a(2q+c,2q+d), \quad c=-2,4, \quad d=-2,4, \tag{3.9}$$

$$a_2 = 1 + a_0, \quad 2a_1 = 5 - a_0, \quad 2a(2q,2q) = 1 + 3a_0, \tag{3.10}$$

$$a_3 = (9-5a_0)/2, \quad a(1,4\mathbf{q}-3) = (13-9a_0)/2 = 2 + 9(1-a_0)/2. \tag{3.11}$$

Fig. 5(c), B2: $a_0=1$ with (3.5)–(3.11), the $M=(2\mathbf{p}+1)/5$, $\mathbf{q}=2$ model is physical.

$q=2$: For the first physical square grid, the highest $|x|+|z|$ are $2p+7$, 14 for heavy and light species. For $p>3$ we enlarge the light up to $2p+8$ for the first grid and $2p+10$, … for the second.

Second Fig. 5(b), in B 3, with collisions $\overline{\Lambda_i}(\beta)$ we deduce in (3.12) and (3.13) some general $a(x,z)$ which only depend on a_0, (x decreasing, z increasing, β odd). giving a second $a(1,4q-3)$ relation,

$$\beta = 3,5,\ldots, \quad a(2q-\beta,2q+\beta-2) = 2 + (1-a_0)(\beta-1)^2/2 \to a(1,4q-3), \tag{3.12}$$

$$\beta = 2q-1, \tag{3.13}$$

(3.11)–(3.13) $\to (1-a_0)[2(q-1)^2-9/2]=0 \to \mathbf{a}_0=1$ $\forall q\geqslant 1$ integer $\to a_1=a_2=a_3=2 \to a(0,z)=1$, $a(x\neq 0,z)=2 \to$ correct light mass values for physical mixture. With squares and rectangles (three f known), we can extend to all $|x|+|z|$ even values.

$q\geqslant 2$: For the first square grid, the highest $|x|+|z|$ are $2p+2q+3$ for the heavy species [$F(1,2(p+q+1))$ in (3.5)] and $4p+2q$ for the light [$f(2q+3.2q+3)$ in (4a9bis), B 3]. With the

heavy higher or smaller than the light if $p \gtrless q+3/2$, we enlarge the light or the heavy for the first square grid. For the second, third, etc., we add 2,4, etc., to both the heavy and light first square grid.

IV. CONCLUSION

If we recall the previous discussions, about "physical" or not 13 and 25 velocities models ($M=2,5$), the present physical models (filling all the half-plane without spurious invariants), with two arbitrary parameters, **p** and **q** represent some progress. In the previous works with only one arbitrary parameter or here for the explicit examples with p arbitrary but only $q=1,2,3$ we see that the proofs are more simple. However for planar models with 2 continuous coordinates, it seems clear for DVMs, DBE that we must extend the models with two arbitrary parameters and here we have presented a successful method for one species.

First in the starting physical model or adding few collisions, we retain two different $a(x,z)$ (with x,z coordinates differing of const **q**) with values depending on a_0, etc., but not on **q**. Second we seek a path linking the two $a(x,z)$, such that we can explicitly find the intermediate new $a(x,z)$ while the last depend not only on a_0, etc., but also on q. Then we have compatibilities depending on q and we must check whether or not the only possibility is $a_0=1$, etc., and physical $a(x,z)$ values.

Here we use mainly one general tool for $|x|+|z|$ odd (heavy) or even (light) and we have a similar number of heavy or light (also f_0) densities. Consequently, contrary to other distributions of the two species in the plane (octagons, dodecagons etc., for the heavy), only the heavy mass value M will be important for the physical studies. For any fractional rational M value with the same geometrical repartition of the light and heavy species, another task is for physical applications (previously for single gas[7,6]). Another problem is to see whether or not, a similar geometrical planar structure for heavy and light, could exist or not, for some irrational M values?

On the other hand we have proved the existence of "physical" (no spurious) square (diagonals along the x and z axes) grid with the first square component $|x|+|z| \leqslant$ a sufficient value which depends on the p and q parameters but which becomes very large when $\mathbf{p},\mathbf{q}$ increases while for the other larger squares of the grid, we add 2,4, etc., to that value. This means that for physical applications we cannot start with the same square grid first component for different p,q models and that the first square grid is very large when p,q increase. This constraint is not particular to the present models. For numerical regular grids filling the plane (without proof of no spurious invariants), similar problems can occur. Our main result is that the numerical calculations can be done in a "physical" square grid without spurious invariants but we must be careful for the tail of the starting first square which has been determined while for the additional squares of the grid, it is sufficient to add 2,4, etc.

Starting with a physical mixture model where the constants associated to the evolution equations for the light mass conservation law are either 1 or 2, we cannot apply directly the simple tools (except for q very small) of adding new light densities giving new physical models. So we are in the obligation to introduce arbitrary parameters $a(x,z)$ associated to the new $f(x,z)$, $l(x,z):a_0$ (rest-particle) and a_k, $k=1,2$, etc. Starting with a preliminary physical model with known old evolution equations, we add these new $a(x,z)$ and the vanishing new collisions are linear combinations of the new (unknown) and old (known) parameters. As explained above, the solution is to find for the same particular $a(x,z)$ two different values, but only one depending on **q** and the compatibilities $\forall q$, leading to all $a(x,z)$ having only the correct physical values.

We recall that for single-gas (only one species), the hexagons models give problems: one spurious relation or necessity of a multiple collision. However for the present mixture models filling either $|x|+|z|$ odd (heavy) or even (light), we present in Fig. 1, physical hexagons for the light species (sides $2,\sqrt{2}$) including the center (except along the x axis). However, for the missing centers, if we give up half-space, we can include successively physical centers $\underline{f(\pm(2q+2),0)}$, $q=0,1$, etc., integer, with the collisions: $f(\pm(2q+1),1)f(\pm(2q+1),-1)-f(\pm 2q,0)\underline{f(\pm(2q+2),0)}$.

Our proofs of physical models are done with all integers filling the plane, we recall 1.4 that, with scaling, they were generalized with a mesh-step finite, but as small as we want.

APPENDIX A: MODELS $M=2p/(2q+1)>1$ (APPENDIX A 1–A 4)

A 1 Lemma 4, Fig. 3: The $M=2\mathbf{p}/3$, $\mathbf{q}=1$ model is physical with a M_1 conservation law, old $f(x,z)$, $a(x,z)=2$: (1,1),(2,2), 2,4),(1,5)$\in$ Physical mixture (2.9) model, new $f(x,z)$, $a(x,z)$ arbitrary: (0,0),(3,3),(0,2),(1,3),(3,1),(3,±1), (2,−2), (A1).

Proof of A1: The new f satisfy eight collisions [three known, adding the last $f(\overline{x,z})$] with sums of $a(x,z)$ equal in lost and gain terms,

$$f(\overline{3,3})F(0,2p-3)-f_0F(3,2p)\rightarrow a(3,3)=2a_0,\quad f_0f(\overline{0,2})-f^2(1,1),f(0,2)f(2,2)-f(\overline{1,3})f(1,1) \tag{A1}$$

$$\rightarrow a(0,2)=a(1,3)/2=2-a_0,\quad f(1,3)f(\overline{3,1})-f(1,1)f(3,3),f_0f(3,1)-f(1,-1)f(2,2),f(1,1),$$

$$f(\overline{3,-1})-f(3,1)f(1,-1),\quad f_0f(3,-1)-f(1,1)f(\overline{2,-2})\rightarrow 4a_0-2=a(3,1)=a(1,-1)-2(a_0-1)$$

$$=a(3,-1)-6(a_0-1)=a(2,-2)-8(a_0-1),f(2,-2)F(0,2p+1)-f(1,-1)F(1,2p)\rightarrow a(2,-2)$$

$$=a(1,-1)\rightarrow a_0=1,f_0f(\overline{0,4})-f(2,2)^2a(0,4)=a(0,z)=1,a(x\neq 0,z)=2\rightarrow \text{A1}.$$

In (A1) we have three $(x,z)\rightarrow|x|+|z|=6$ and other $|x|+|z|=0,2,4\rightarrow$ all even values.

A 2, Lemma 5: *With* (2.12) and (2.13), the model $M=2\mathbf{p}/5$, $\mathbf{p}\geqslant 3$, $\mathbf{q}=2$ is physical.

Proof: (2.9), (2.12), and (2.13), $q=2\rightarrow a(2,2)=a(3,3)=a(3,7)=2$, $a(0,4)=2-a_0=a(1,5)/2$, $a(1,7)=a(1,3)=10-8a_0$, $a(3,5)=16-14a_0$. We add $f(3,7)f(1,5)-f(1,7)f(\overline{3,5})\rightarrow a(3,5)=6a_0-4=16-14a_0\rightarrow a_0=1\rightarrow a(0,4)=1,a(1,3)=a(1,7)=a(3,5)=2$,
$\rightarrow f(\overline{0,2})f(0,4)-f(1,3)^2\rightarrow a(0,2)=1,\quad f(0,2)f(2,2)-f(\overline{1,1})f(1,3)\rightarrow a(1,1)=2\rightarrow|x|+|z|=0,2,4\rightarrow$ all even values for light densities.

A 3, Lemma 6: The $M=2\mathbf{p}/7$, $\mathbf{p}\geqslant 4$, $\mathbf{q}=3$, Figs. 4(a) and 4(b) model is physical with (2.12)–(2.15).

Proof: (2.12)–(2.15) $\rightarrow a_3=a(4,10)=a(4,2q+4)=a(q+1,3q+1)=2=6a_1+10(a_0-2)$, (2.13) and (2.14) $\rightarrow a_2=a(3,9)=a(q,3q)=10-8a_0=a(3,2q+3)=3a_1+4(a_0-2)\rightarrow 3a_1=11-5a_0=18-12a_0\rightarrow a_0=1\rightarrow a_1=a_2=a_3=2$, etc.

The physical $a(0,z)=1$, $a(x\neq 0,z)=2$ for the light, have $z\geqslant q=3$ [Fig. 4(a)], but with squares, rectangles (three known) giving lower z values we get for the light, $|x|+|z|=0,2,4\rightarrow$ all even.

A 4, Proof for Lemma 7, light collisions $a_k=k(k+1)a_1/2+(k(k+1)-2)(a_0-2)$(2.16),

$$\Lambda_k=f(k,2q+k+2)f(1,2q+1)-f(k+1,2q+k+1)f(0,2q+2)\text{ with (3a1)}\rightarrow a_k:=a(k+1,2q+k+1)=a(k,2q+k+2),\quad\forall\, k=1,2,q,\quad b_k:=a(k+2,2q+k),\quad k=1,q-1,$$

$$(2\,.\,14)\rightarrow b_0=a(2,2q)=a(2,2q+2)=a_1\quad\text{and } b_1=a(3,2q+1)=2a_1+2(a_0-2)\text{(A2)}.$$

We have defined a_k,b_k and previous a_k, $k=1,2,3$ in (2.14) and (2.15) are generalized $\forall k>3$.

Collisions: $f(k+1,2q+k+1)f(k+1,2q+k-1)-f(k,2q+k)f(k+2,2q+k)$, $f(k+2,2q+k+2)f(k,2q+k)-f(k,2q+k+2)f(k+2,2q+k)$, $\rightarrow b_k=b_{k-1}+a_k-a_{k-1}=a_{k-1}+a_{k+1}-a_k$, $k\geqslant 2$.

Collisions: $f(k+2-k',2q+k-k')f(k,2q+k+2)-f(k-k',2q+k+2-k')f(k+2,2q+k)\rightarrow b_k=b_{k-2}+a_k-a_{k-2}..=b_{k-k'}+a_k-a_{k-k'}..=b_1+a_k-a_1=a_1+a_k+2(a_0-2)\rightarrow a_{k+1}=2a_k-a_{k-1}+a_1+2(a_0-2)\rightarrow a_k=2a_{k-1}+a_1-a_{k-2}+2(a_0-2)$, $k\geqslant 3$ (2.18). (2.16) for a_k was satisfied for a_2,a_3 in (2.14) and (2.15), now with the last (2.18), we verify also for a_4,a_5,

$$a_4=2a_3+a_1-a_2+2(a_0-2)=10a_1+18(a_0-2),a_5=2a_4+a_1-a_3+2(a_0-2)=15a_1+28(a_0-2).$$

For the (2.16) proof, we substitute a_{k-1}, a_{k-2} [written with (2.16)] into the last (2.18) and verify the (2.16) a_k. For b_k, with (2.18) we get $b_k=(k(k+1)+2)a_1/2+k(k+1)(a_0-2)$.

APPENDIX B: MODELS WITH $M=(2p+1)/(2q+1)>1$ (APPENDIX B 1–B 3)

B 1, Lemma 10, Fig. 5(a). With $a_0=1(f_0)$, the model $M=(2\mathbf{p}+1)/3$, $\mathbf{q}=1$ is physical. For a collision with the four $a(x,z)$ functions of a_0, the compatibility leads to $a_0=1$.

$$\text{old, } f\colon \to 2 = a(1,1) = a(1,5) = a(2,2) = a(2,4),$$
$$a(0,6) = a_0, \quad a(0,2) = a(0,4) = 2 - a_0 = a(1,3)/2, a(3,3) = 2a_0,$$

$$\text{new, } f\colon f(4,2), f(4,4), f(3,5), f(3,1) \to a(x, z \neq 0) = 1, 2(x = 0, \neq 0).$$

Proof: $\Gamma_2 = f\overline{(4,2)}F(2p,z) - f(2,2)F(2p+2,z) \to a(4,2) = 2$ (physical), odd $z=1,3$, etc.,

$$f(2,4)f(4,2) - f(2,2)f\overline{(4,4)} \to a(4,4) = 2(\text{physical}), \quad f(1,5)f(3,3) - f(1,3)f\overline{(3,5)} \to a(3,5)$$
$$= 4a_0 - 2, \quad f(2,4)f(4,4) - f(3,5)f(3,3) \to 6(1 - a_0) = 0, \to 1 = a_0$$
$$= a(0,i), i = 0,2,4, a(4,2) = a(2,2) = a(1,3) = 2, \quad f(2,2)f(4,2)$$
$$- f(3,3)f\overline{(3,1)} \to a(3,1) = 2, \to |x| + |z| = 0,2,4, \text{even}\ . \tag{B1}$$

B 2, Proof for (B2) and (B3): We introduce arbitrary $a_1(\overline{a_1}=a_1)$ and a_2 function of a_0, a_1,

$$f\overline{(1,4q-1)}f(2q-1,2q+3) - f\overline{(2q-2,2q+2)}f(2,4q) \to a_1 := a(1,4q-1) = a(2q-2,2q+2),$$

$$f\overline{(2q-2,2q)}f(2,2) - f(1,3)f(2q-1,2q-1) \to \overline{a_1} := a(2q-2,2q) = a(1,3), \tag{B2}$$

$$f(2q-2,2q)f(2q+1,2q+1) - f(2q-1,2q-1)f\overline{(2q,2q+2)} \to \overline{a_1} + 2a_0 - 2 = a(2q,2q+2),$$

$$f(2q-2,2q+2)f(2q+1,2q+1) - f(2q-1,2q+3)f\overline{(2q,2q)} \to a_1 + 2a_0 - 2 = a(2q,2q),$$

$$f(2q-2,2q+2)f(2q,2q) - f(2q-2,2q)f(2q,2q+2) \to a_1 = \overline{a_1}, \quad f(2q-2,2q+2)f(2q-2,2q)$$
$$- f(2q-3,2q+1)f\overline{(2q-1,2q+1)} \to a_2 := a(2q-1,2q+1) = 2a_1 - 4 + 2a_0. \tag{B3}$$

Fig. 5(b): Proof for (B4)–(B6) with (3.5), (3.6), (B2), and (B3). We get a_1, a_2, a_3, $a(1,4q-3)$ in terms of a_0,

$$\Gamma_2 = f(2q+3,2q-1)F(2p-1,z) - f(2q-1,2q-1)F(2p+3,z), f(2q-1,2q+3)f(2q+3,2q-1)$$
$$- f(2q-1,2q-1)f(2q+3,2q+3), \to 2 = a(2q+\lambda,2q+\mu), \lambda = -1,3, \quad \mu = -1,3\ , \tag{B4}$$

$$f(2q-2,2q)f(2q+3,2q+3) - f(2q-1,2q-1)f\overline{(2q+2,2q+4)} \to a_1 = a(2q+2,2q+4),$$

$$\Gamma_3 = f(2q+4,2q-2)F(2p-2,z) - f(2q-2,2q-2)F(2p+4,z), \quad \Gamma_4 = f(2q-2,2q+4)F(x,2p$$
$$- 2) - f(2q-2,2q-2)F(x,2p+4), \quad f(2q+4,2q+4)f(2q-2,2q-2) - f(2q-2,2q$$
$$+ 4)f(2q+4,2q-2) \to a_3 := a(2q+\lambda,2q+\mu), \quad \lambda = -2,4, \quad \mu = -2,4, \quad f(2q-2,2q$$
$$+ 2)f(2q+4,2q-2) - f(2q-2,2q-2)f\overline{(2q+4,2q+2)} \to a_1 = a(2q+4,2q$$
$$+ 2), \quad f\overline{(2q-1,2q+1)}f(2q+4,2q+2) - f(2q+2,2q+4)f(2q+1,2q-1), \quad f(2q-1,2q$$
$$+ 1)f(2q+1,2q-1) - f(2q-1,2q-1)f(2q+1,2q+1) \to a_2 = a(2q \mp 1,2q \pm 1) = 1 + a_0$$
$$= 2a_1 - 4 + 2a_0 \to 2a_1 = 5 - a_0, \quad 2a(2q,2q) = 1 + 3a\ , \tag{B5}$$

$$f(2q+4,2q+2)f(2q-2,2q)-f(2q+2,2q+4)\overline{f(2q,2q-2)}\to a_1=a(2q,2q-2),\quad f(2q-2,2q)f(2q,2q-2)-f(2q,2q)\overline{f(2q-2,2q-2)}\to a_3=a(2q-2,2q-2)=(9-5a_0)/2,\quad f(2q-2,2q-2)f(1,4q-1)-f(2q,2q)\overline{f(-1,4q-3)}\to \mathbf{a}(\pm 1,4\mathbf{q}-3)=(13-9\mathbf{a}_0)/2\ . \tag{B6}$$

Figure 5(c) with (3.5)–(3.11) $\to \mathbf{a}_0=1$ the $M=(2\mathbf{p}+1)/5$, $\mathbf{q}=2$ model is physical,

$$a(0,4)=2-a_0,\quad 2=a(2,2)=a(3,3),\quad a(1,5)=4-2a_0=(13-9a_0)/2\to a_0=1,\quad a(1,5)=2,\quad a_1=(5-a_0)/2=2=a(1,3).$$

For $|x|+|z|=0,2,4$ only $a(0,2)=1$, $a(1,1)=a(3,1)=2$ are missing but given with: $f(0,j+1)f(0,j-1)-f^2(1,j)$, $j=3,\ 1$, $f(1,1)f(3,3)-f(1,3)f(3,1)\to|x|+|z|$ all even values.

B 3, Fig.5(b): With (B4) $a(2q+\lambda,2q+\lambda)=2$, $\lambda=-1,\ 3$ and a collision $f(2q-\beta,2q+\beta-2)f(2q+3,2q+3)-f(2q-\beta+4,2q+\beta+2)f(2q-1,2q-1)$, we get

$$\mathbf{A}(\beta)=\mathbf{a}(2\mathbf{q}-\beta,2\mathbf{q}+\beta-2)=a(2q-\beta+4,2q+\beta+2)\ . \tag{B7}$$

With squares (three known) and collisions $\overline{\Lambda}_i(\beta)$, we successively get (B8) and (B9),

$$\overline{\Lambda}_1(\beta)=f(2q-\beta,2q+\beta+2)f(2q-\beta,2q+\beta-2)-f(2q-\beta+2,2q+\beta)f(2q-\beta-2,2q+\beta),$$

$$\overline{\Lambda}_2(\beta)=f(2q-\beta,2q+\beta-2)f(2q-\beta+4,2q+\beta+2)-f(2q-\beta+4,2q+\beta+2)f(2q-\beta,2q+\beta+2).$$

We start with $\overline{\Lambda}_1(1)$, successfully with (B7) and $\overline{\Lambda}_2(\beta)$, $\overline{\Lambda}_1(\beta)$, $\beta=3,5,7,\ldots$ we get

$$a(2q-3,2q+1)=4-2a_0,\quad a(2q-3,2q+5)=8-6a_0,\quad a(2q-5,2q+3)=10-8a_0,\quad a(2q-5,2q+7)=18-16a_0,\quad a(2q-7,2q+5)=20-18a_0,\quad a(2q-7,2q+9)=32-30a_0,\ldots\ . \tag{B8}$$

Going on, we deduce general $a(x,z)$ with x decreasing, z increasing, β odd,

$$\beta=1,3,5,\ldots,A(\beta)=a(2q-\beta,2q+\beta-2)=2+(1-a_0)(\beta-1)^2/2,$$

$$B(\beta)=a(2q-\beta,2q+\beta+2)=2+(1-a_0)(\beta-1)(\beta+3)/2 \tag{B9}$$

that we verify in $\overline{\Lambda}_i(\beta)$, $i=1,\ 2$ with $A(\beta)+B(\beta)=A(\beta+2)+B(\beta-2)=4+(1-a_0)(\beta^2-1)$, $2A(\beta)=B(\beta-4)+B(\beta)=4+(1-a_0)(\beta-1)^2$.

Exponential convergence of coupled diffusion processes

Fuxi Zhang[a)]

(Received 8 July 2004; accepted 12 April 2005; published online 8 June 2005)

The coupled diffusion process, which describes Brownian motors, is an important model in the physics related to biophenomena. We address the exponential convergence of the Markov semigroup of a coupled diffusion process, and show the spectral gap inequality and Log-Sobolev inequality by comparing them with those of related diffusion processes. At the end of the paper, we provide sufficient conditions for a coupled diffusion process to converge exponentially. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1931040]

I. INTRODUCTION

Coupled diffusion processes (or CDP for short) model the systems of molecular motors, which attract much interest from physicists and biologists in recent years.[2,9,12,4,8,16] In the biological phenomena such as proteins in muscle fibers and eucariotic intracellular transport, macromolecules move along filaments called the track. It is crucial that there are several inner states of the macromolecules, and the chemical reaction causes transitions of the macromolecules among different inner states, while free energy of the chemical reaction can be converted to mechanical energy through ratchet effects.[7,3,17] The macromolecule thus becomes a motor, and is called a Brownian particle coupled with a chemical reaction. The motion of the motor along the filament is steplike, and the process is modelled as a Brownian motion at small scales in the level of nanometer and nanosecond. The impact of underlying chemical reaction can be considered as a particle source,[10,11] hence the Fokker–Planck equation of ρ_k, the probability density of the particles in the kth inner state, should be

$$\frac{\partial \rho_k(x,t)}{\partial t} + \frac{\partial \mathcal{J}_k(x,t)}{\partial x} = -q_{kk}(x)\rho_k(x,t) + \sum_{l;l\neq k} q_{lk}(x)\rho_l(x,t),$$

where q_{kl} describes the rate of the underlying chemical reaction,

$$\mathcal{J}_k = \mu_k^{-1}(-\kappa_B T\,\partial\,\rho_k/\partial x - \rho_k\,\partial\,W_k/\partial x + \rho_k f_{\text{ext}})$$

is the particle current, μ_k and κ_B are constants, T is the temperature, W_k is the potential along the filament, and f_{ext} is an external force field. In experimental situations, motors are observed moving long filaments towards their extremities. In other words, there is a net directional movement of the particle.[2,12,11,17] The potential of force along the filaments is generally periodic, and asymmetry within a period is indispensable for this phenomena.[8] Ratchet effect is related to the phenomena of stochastic resonance.[1,16,13] We refer to Ref. 16 as a comprehensive paper about the systems of molecular motors.

According to the ideas in Refs. 8 and 16, there are two components in describing the state of a particle at time t. One is the inner state of the motor, which is denoted by K_t, and the other is the space position of the motor, which is denoted by X_t. In this paper, we consider systems without external force fields, hence $\{(K_t,X_t): t\geqslant 0\}$ is a homogeneous Markov process with state space $\mathbb{X}=\{1,\ldots,N\}\times\mathbb{R}^d$, and obeys the following mechanism:

[a)]Electronic mail: zhangfxi@math.pku.edu.cn

$$\mathrm{d}X_t = \sqrt{\mathbf{A}}(K_t,X_t)d\mathbf{B}_t + \left(\mathbf{b} + \tfrac{1}{2}\nabla^T\mathbf{A}\right)(K_t,X_t)\mathrm{d}t,$$

$$\mathbf{P}(K_{t+\Delta t} = l | K_t = k, X_t) = q_{kl}(X_t)\Delta t + o(\Delta t), \quad l \neq k,$$

where $\mathbf{A}(k,x)$ is a $d\times d$ positive definite matrix, $\mathbf{b}(k,x)$ is a d-dimensional vector, $q_{kl}(x)\geqslant 0$, and $\{\mathbf{B}_t : t\geqslant 0\}$ is a Brownian motion on $\mathbb{R}^d$. Denote

$$\mathcal{L}_k = \tfrac{1}{2}\nabla\cdot(\mathbf{A}(k,\cdot)\nabla) + \mathbf{b}(k,\cdot)\cdot\nabla.$$

Then the generator of $\{(K_t,X_t) : t\geqslant 0\}$ has the following form:

$$\mathcal{L}f(k,x) = \mathcal{L}_k f(k,x) + \sum_{l:l\neq k} q_{kl}(x)(f(l,x) - f(k,x)).$$

Suppose the coefficients are smooth. In order that there is no explosion and that the process is not reducible, we suppose $q_{kl}(x)$ is bounded for all k, l, and for any k, l, there are $r\geqslant 0$, $k_1,\ldots,k_r$ and $x_1,\ldots,x_{r+1}\in\mathbb{R}^d$ such that

$$q_{kk_1}(x_1)q_{k_1k_2}(x_2)\cdots q_{k_{r-1}k_r}(x_r)q_{k_rl}(x_{r+1}) > 0.$$

In Ref. 14, we construct a CDP with generator $\mathcal{L}$ under the above assumptions.

In this paper, we address the exponential convergence of the CDP. Let $\{T(t) : t\geqslant 0\}$ be the semigroup of a Markov process, μ be its invariant distribution. We say that $T(t)$ converges exponentially if there exists $\delta>0$ such that for any $f\in L^2(\mathbb{X},\mu)$,

$$\|T(t)f - E_\mu f\| \leqslant C(f)e^{-\delta t}, \tag{1}$$

where $E_\mu f = \int f\,\mathrm{d}\mu$, $\|\cdot\|$ is the L^2 norm with respect to μ, and $C(f)$ is a constant relying on f. Let $\{\overline{T}(t) : t\geqslant 0\}$ be the symmetrization of $\{T(t) : t\geqslant 0\}$ with respect to μ. It is already known that

$$\|T(t)f - E_\mu f\| \leqslant \|\overline{T}(t)f - E_\mu f\|.$$

Hence we are only concerned with the case that $T(t)$ is symmetric. In this case, its generator $\mathcal{A}$ is self-adjoint in $L^2(\mu)$, and Eq. (1) is equivalent to that

$$\langle \mathcal{A}f, f\rangle \leqslant -\delta\|f - E_\mu f\|^2, \quad \forall\, f\in\mathcal{D}(\mathcal{A}), \tag{2}$$

where $\langle\cdot,\cdot\rangle$ is the inner product in $L^2(\mu)$, $\mathcal{D}(\mathcal{A})$ is the domain of $\mathcal{A}$. We say that $\mathcal{A}$ satisfies the spectral gap inequality, or $\mathcal{A}$ has a spectral gap if it satisfies (2). Another inequality, which ensures (1) is the log–Sobolev inequality. We call that $\mathcal{A}$ satisfies the log–Sobolev inequality with constant $c(>0)$ if

$$E_\mu f^2 \log f^2 - E_\mu f^2 \log E_\mu f^2 \leqslant -c\langle \mathcal{A}f, f\rangle, \quad \forall\, f\in\mathcal{D}(\mathcal{A}).$$

In this paper, when we mention the spectral gap (log–Sobolev) inequality about a generator, the probability measure is taken as its symmetric distribution.

The problem whether the generator satisfies the spectral gap inequality or the log–Sobolev inequality attracts much attention. For diffusion processes, there exist already considerable references, e.g., Refs. 5 and 6. The spectral gap inequality as well as the log–Sobolev inequality has a multiplying property, if two reversible Markov processes satisfy the spectral gap (log–Sobolev) inequality, then the independent coupling of them also does, whose generator is the sum of those of the two independent processes. Although the CDP is not an independent coupling of a Q process and a diffusion process, its generator is naturally separated into two parts explicitly. One is a diffusion generator caused by $\{X_t : t\geqslant 0\}$ and the other is a Q matrix caused by $\{K_t : t\geqslant 0\}$. We use the fact that the Q matrix is finite and negative in some sense to show that in the specific model of CDP, the spectral gap inequality can be simplified into those of diffusion processes. It is much better than the multiplying property. Let $q_{kk}(x) = -\Sigma_{l:l\neq k}q_{kl}(x)$ and $\mathbf{Q}(x) = (q_{kl}(x))$. Suppose

$\{(K_t, X_t): t \geqslant 0\}$ is a reversible CDP with initial distribution θ. Hence $\mathcal{L}$ is symmetric in $L^2(\mathbb{X}, \theta)$. In the beginning of Sec. II, we show that this implies the existence of symmetric densities of $\mathcal{L}_k$ and $\mathbf{Q}(x)$.

Theorem 1: *If $\mathcal{L}_k$ satisfies the spectral gap inequality for all k, then $\mathcal{L}$ also does.*

Theorem 2: *Suppose θ is a product measure. If $\mathcal{L}_k$ and $\mathbf{Q}(x)$ satisfy the log–Sobolev inequality with constant c for all k and x, then $\mathcal{L}$ also does.*

II. THE RELATIONSHIP BETWEEN $\mathcal{D}(\mathcal{L})$ AND $\mathcal{D}(\mathcal{L}_k)$

We begin this section with discussing the relationship of the symmetric measure of $\mathcal{L}$ with those of $\mathcal{L}_k$ and $\mathbf{Q}(x)$. Since $\{(K_t, X_t): t \geqslant 0\}$ is reversible, $V = \log \theta$ is a potential of $2\mathbf{A}^{-1}\mathbf{b}$, and $\{\theta(k,x): k = 1, \ldots, N\}$ is a reversible measure of the Q-matrix $\mathbf{Q}(x)$ for any $x \in \mathbb{R}^d$. Since the CDP is unexploded and $\mathbf{Q}$ is bounded, the diffusion process generated by $\mathcal{L}_k$ is unexploded. Therefore, the normalization of $\theta(k, \cdot)$ on $\{(k,x): \mathbb{R}^d\}$,

$$\rho_k(x) = \theta(k,x)/\pi_k, \quad \text{where } \pi_k = \int \theta(k,x)\mathrm{d}x,$$

is a reversible distribution density of $\mathcal{L}_k$.

For the sake of the reader, we recall the construction of the process in Ref. 14. Let

$$C(\mathbb{R}^d) = \text{the set of all bounded continuous functions on } \mathbb{R}^d;$$

$$C(\mathbb{X}) = \text{the set of all bounded continuous functions on } \mathbb{X};$$

$$C_0(\mathbb{X}) = \{f \in C(\mathbb{X}): \lim_{|x| \to +\infty} f(k,x) = 0, \forall\, k\};$$

$$C_0^\infty(\mathbb{X}) = \{f \in C(\mathbb{X}):\ f \text{ is smooth and has a compact support}\};$$

$$\mathbb{B}_n = \{(k,x): |x| < n\};$$

$$C_0(\mathbb{B}_n) = \{f \in C(\mathbb{X}): f|_{\mathbb{B}_n^c} = 0\};$$

$$C_0^\infty(\mathbb{B}_n) = \{f \in C_0^\infty(\mathbb{X}): \mathrm{supp}(f) \subset \mathbb{B}_n\}.$$

For any $\lambda > 0$ and $g \in C_0(\mathbb{B}_n)$, there is a unique solution of $(\lambda - \mathcal{L})f = g$ in $C_0(\mathbb{B}_n)$, which is denoted by $R_n(\lambda)g$. Choose h_n such that

$$h_n \in C_0^\infty(\mathbb{B}_n), \quad 0 \leqslant h_n \leqslant 1, \quad h_n|_{\mathbb{B}_{n-1}} = 1. \tag{3}$$

Then for any $\lambda > 0$ and nonnegative $g \in C(\mathbb{X})$, $R_n(\lambda)(h_n g)$ increases pointwise. Hence $R_n(\lambda)(h_n g)$ converges pointwise for any $g \in C(\mathbb{X})$. Denote the limit by $R(\lambda)g$. Then it belongs to $C(\mathbb{X})$ and is a global solution of $(\lambda - \mathcal{L})f = g$. $R(\lambda)$ is a positive continuous linear operator on $C(\mathbb{X})$, and $\|R(\lambda)g\|_\infty \leqslant \|g\|_\infty/\lambda$, where $\|\cdot\|_\infty$ is the supremum norm. Moreover, we show in Ref. 14 the following.

Lemma 2.1: *If $g_n \in C_0(\mathbb{B}_n)$ is non-negative and increases to $g \in C(\mathbb{X})$ as $n \to \infty$, then $R_n(\lambda)g_n$ increases to $R(\lambda)g$.*

Let $\hat{C}(\mathbb{X})$ be the minimal Banach space containing $C_0(\mathbb{X})$ and invariant under $\{R(\lambda): \lambda > 0\}$. Then $\{R(\lambda)|_{\hat{C}(X)}: \lambda > 0\}$ is a resolvent according to $\mathcal{L}$ with domain $\mathcal{D}(\mathcal{L}) = R(\lambda)\hat{C}(\mathbb{X})$. Hence it corresponds to a contraction semigroup $\{S(t): t \geqslant 0\}$ on $\hat{C}(\mathbb{X})$. Moreover, $C_0^\infty(\mathbb{X}) \subset \mathcal{D}(\mathcal{L})$.

Recall that θ is an invariant distribution. In order not to cause ambiguity, we denote by $\mathcal{D}(\mathcal{L}, L^2)$ the domain of $\mathcal{L}$ in the space $L^2(\mathbb{X}, \theta)$, by $\{\tilde{S}(t): t > 0\}$ and $\{\tilde{R}(\lambda): \lambda > 0\}$ the correspond-

ing Markov semigroup and resolvent. Then they are extensions of $\{S(t):t>0\}$ and $\{R(\lambda)|_{\hat{C}(X)}:\lambda>0\}$, respectively. The following proposition tells us $\{\tilde{R}(\lambda):\lambda>0\}$ is in fact an extension of $\{R(\lambda):\lambda>0\}$. As to $\mathcal{L}_k$, recall that ρ_k is its invariant distribution. Let $\mathcal{D}(\mathcal{L}_k,L^2)$, $\tilde{R}^{(k)}(\lambda)$, $R_n^{(k)}(\lambda)$, and $R^{(k)}(\lambda)$ be the corresponding notation.

Proposition 2.2: *For any* $\lambda>0$ *and any* $k\in\{1,\ldots,N\}$,

$$\tilde{R}(\lambda)|_{C(\mathbb{X})}=R(\lambda),\quad \tilde{R}^{(k)}(\lambda)|_{C(\mathbb{R}^d)}=R^{(k)}(\lambda).$$

Proof: For any non-negative function $f\in C(\mathbb{X})$, choose $f_n\in C_0^\infty(\mathbb{X})$ such that $0\leqslant f_n\leqslant f$ and f_n increases to f as $n\to\infty$. On the one hand, by Lemma 2.1, $R_n(\lambda)f_n$ increases to $R(\lambda)f$. This together with that $R_n(\lambda)f_n\leqslant R(\lambda)f_n\leqslant R(\lambda)f$ implies that $R(\lambda)f_n$ converges to $R(\lambda)f$. On the other hand, $R(\lambda)f_n=\tilde{R}(\lambda)f_n$ since $f_n\in C_0^\infty(\mathbb{X})\subset\mathcal{D}(\mathcal{L})$. Notice that f_n converges to f in L^2. $\tilde{R}(\lambda)f_n$ converges to $\tilde{R}(\lambda)f$ in L^2 since $\tilde{R}(\lambda)$ is continuous with respect to the L^2 norm. Therefore,

$$R(\lambda)f=\lim_{n\to+\infty}R(\lambda)f_n=\lim_{n\to+\infty}\tilde{R}(\lambda)f_n=\tilde{R}(\lambda)f,$$

i.e., $\tilde{R}(\lambda)|_{C(\mathbb{X})}=R(\lambda)$. As to $\mathcal{L}_k$, the result holds by the same deduction. □

Proposition 2.2 implies that

$$R(\lambda)C(\mathbb{X})=\tilde{R}(\lambda)C(\mathbb{X})\subset\tilde{R}(\lambda)L^2(\mathbb{X},\theta)=\mathcal{D}(\mathcal{L},L^2).$$

Proposition 2.3: $R(\lambda)C(\mathbb{X})$ *is a kernel of* $(\mathcal{L},\mathcal{D}(\mathcal{L},L^2))$, *i.e., it is a dense subset under the graph norm:* $\|f\|_{\mathcal{L}}=\|f\|+\|\mathcal{L}f\|$ *for any* $f\in\mathcal{D}(\mathcal{L},L^2)$.

Proof: For any $f\in\mathcal{D}(\mathcal{L},L^2)$, there exists $g\in L^2(\mathbb{X},e^V)$ such that $f=\tilde{R}(\lambda)g$. Since $C(\mathbb{X})$ is dense in $L^2(\mathbb{X},e^V)$, there exists $g_n\in C(\mathbb{X})$ such that $\lim_{n\to+\infty}\|g_n-g\|=0$. Hence $f_n=\tilde{R}(\lambda)g_n$ converges to f in L^2, which implies that $\mathcal{L}f_n=\lambda f_n-g_n$ converges to $\lambda f-g=\mathcal{L}f$ in L^2. In other words, f_n converges to f in $\|\cdot\|_{\mathcal{L}}$. This together with Proposition 2.2 yields the result. □

Proposition 2.4: *For any* $\lambda>0$,

$$R(\lambda)C(\mathbb{X})\subset\{f:f(k,\cdot)\in R^{(k)}(\lambda)C(\mathbb{R}^d),\ \forall\ k\}.$$

Proof: Suppose $f\in C(\mathbb{X})$. We assume that $f\geqslant 0$ first. Let $f_n=fh_n$, $g=R(\lambda)f$, $g_n=R_n(\lambda)f_n$, where h_n satisfies (3). Since $(\lambda-\mathcal{L})g_n=f_n$, $g_n(k,\cdot)$ is a solution of

$$(\lambda-\mathcal{L}_k)\varphi=f_n(k,\cdot)+\sum_{l=1}^N q_{kl}g_n(l,\cdot),$$

in $C_0(\mathbb{B}_n)$. Therefore,

$$\begin{aligned}g_n(k,\cdot)&=R_n^{(k)}(\lambda)\left(f_n(k,\cdot)+\sum_{l=1}^N q_{kl}g_n(l,\cdot)\right)\\&=R_n^{(k)}(\lambda)f_n(k,\cdot)+R_n^{(k)}(\lambda)\left(\sum_{l:l\neq k}q_{kl}g_n(l,\cdot)\right)-R_n^{(k)}(\lambda)(-q_{kk}g_n(k,\cdot)).\end{aligned}\tag{4}$$

By Lemma 2.1, since f_n increases to f, g_n increases to g. Hence as $n\to+\infty$, the non-negative functions $f_n(k,\cdot)$, $\Sigma_{l:l\neq k}q_{kl}g_n(l,\cdot)$, and $-q_{kk}g_n(k,\cdot)$ in $C_0(\mathbb{B}_n)$, respectively, increase to $f(k,\cdot)$, $\Sigma_{l:l\neq k}q_{kl}g(l,\cdot)$, and $-q_{kk}g(k,\cdot)$. Notice that $\mathbf{Q}$ is bounded, and f, $g\in C(\mathbb{X})$. The limit functions belong to $C(\mathbb{X})$. By Lemma 2.1, the right most functions in (4) converge as $n\to+\infty$, and

$$R(\lambda)f(k,\cdot) = \lim_{n\to+\infty} g_n(k,\cdot)$$
$$= R^{(k)}(\lambda)f(k,\cdot) + R^{(k)}(\lambda)\left(\sum_{l:l\neq k} q_{kl}g(l,\cdot)\right) - R^{(k)}(\lambda)(-q_{kk}g(k,\cdot)) \in R^{(k)}(\lambda)C(\mathbb{R}^d).$$

Then, for any $f\in C(\mathbb{X})$ and any k,

$$R(\lambda)f(k,\cdot) = R(\lambda)f^+(k,\cdot) - R(\lambda)f^-(k,\cdot) \in R^{(k)}(\lambda)C(\mathbb{R}^d),$$

which implies the result. □

Proposition 2.4 together with Proposition 2.3 yields that there exists a dense subset of $\mathcal{D}(\mathcal{L},L^2)$ contained in $\mathcal{D}(\mathcal{L}_1,L^2)\oplus\cdots\oplus\mathcal{D}(\mathcal{L}_N,L^2)$.

III. PROOFS OF THE MAIN RESULTS

Lemma 3.1 *(Ref. 15, Theorem XIII.1): Suppose $\mathcal{A}$ is self-adjoint on the Hilbert space $\mathcal{H}$, and is bounded above. Let*

$$\mu(\mathcal{A},g_1,\ldots,g_n) = \sup\{\langle \mathcal{A}g,g\rangle : g\in\mathcal{D}(\mathcal{A}),\|g\|=1,\langle g,g_i\rangle = 0, i=1,\ldots,n\},$$

$$\mu_n(\mathcal{A}) = \inf\{\mu(\mathcal{A},g_1,\ldots,g_n): g_1\ldots,g_n\in\mathcal{H}\}.$$

Then either $\mu_n(\mathcal{A}) = \sup\sigma_{\mathrm{ess}}(\mathcal{A})$, or $\sigma(\mathcal{A})\cap(\mu_n(\mathcal{A}),\infty)$ is a finite set.

Proof of Theorem 1: Recall that $\pi_k = \int\theta(k,x)\mathrm{d}x$, and $\rho_k(x) = \theta(k,x)/\pi_k$ is the symmetric distribution of $\mathcal{L}_k$. Given k, since $\mathcal{L}_k$ has a spectral gap, there exists $\delta_k>0$ such that for any $F\in\mathcal{D}(\mathcal{L}_k,L^2)$,

$$\langle \mathcal{L}_kF,F\rangle_{\rho_k} \leqslant -\delta_k\left(\int F^2(x)\rho_k(x)\mathrm{d}x - \left(\int F(x)\rho_k(x)\mathrm{d}x\right)^2\right),$$

where $\langle\cdot,\cdot\rangle_{\rho_k}$ is the inner product in $L^2(\mathbb{R}^d,\rho_k)$. By Proposition 2.4, for any $f\in R(\lambda)C(\mathbb{X})$, $f(k,\cdot)\in\mathcal{D}(\mathcal{L}_k,L^2)$ for any k, hence

$$\langle \mathcal{L}f,f\rangle = \sum_{k=1}^N \pi_k\langle \mathcal{L}_kf(k,\cdot),f(k,\cdot)\rangle_{\rho_k} + \sum_{k,l=1}^N\int\theta(k,x)q_{kl}(x)f(k,x)f(l,x)\mathrm{d}x \leqslant \sum_{k=1}^N \pi_k\langle \mathcal{L}_kf(k,\cdot),f(k,\cdot)\rangle_{\rho_k}$$
$$\leqslant -\sum_{k=1}^N \pi_k\delta_k\left(\int f^2(k,x)\rho_k(x)\mathrm{d}x - \left(\int f(k,x)\rho_k(x)\mathrm{d}x\right)^2\right)$$
$$\leqslant -\delta\|f\|^2 + M\sum_{k=1}^N \pi_k\left(\int f(k,x)\rho_k(x)\mathrm{d}x\right)^2, \tag{5}$$

where $\delta=\delta_1\wedge\cdots\wedge\delta_N$, $M=\delta_1\vee\cdots\vee\delta_N$, and the first inequality holds since $\mathbf{Q}(x)$ is a generator and hence negative. By Proposition 2.3, for any $f\in\mathcal{D}(\mathcal{L},L^2)$, there are $f_n\in R(\lambda)C(\mathbb{X})$, $n\geqslant 1$, such that

$$\lim_{n\to+\infty}\|f_n - f\|_{\mathcal{L}} = 0. \tag{6}$$

On the one hand, (5) holds for f_n since $f_n\in R(\lambda)C(\mathbb{X})$. On the other hand, $f_n(k,\cdot)$ converges to $f(k,\cdot)$ in $L^2(\mathbb{R}^d,\rho_k)$, hence also in L^1. It follows that

$$\lim_{n\to+\infty}\int f_n(k,x)\rho_k(x)\mathrm{d}x = \int f(k,x)\rho_k(x)\mathrm{d}x.$$

This together with (6) yields that (5) holds for f, since it holds for f_n. Let 1_k be the function which is 1 in the kth $\mathbb{R}^d$ and vanishes outside, i.e.,

$$1_k(l,x)=\begin{cases}1, & \text{if } l=k,\\ 0, & \text{otherwise.}\end{cases}$$

Then $\langle f,1_k\rangle=0$ if and only if $\int_{R^d} f(k,x)\rho_k(x)\mathrm{d}x=0$. Therefore, by (5), $\mu(\mathcal{L},1_1,\ldots,1_N)\leqslant-\delta$. Hence $\mu_N(\mathcal{L})\leqslant-\delta<0$. It follows that $\mathcal{L}$ has a spectral gap since $\mathcal{L}$ has only finite spectra in $(\mu_N(\mathcal{L}),0]$. □

Proof of Theorem 2: To simplify the notation, for any function f on $\mathbb{X}$, we denote $f_k(x)=f(k,x)$ and $\vec{f}(x)=(f_1(x),\ldots,f_N(x))$. Let $\varphi:(\mathbb{R}^+)^N\to\mathbb{R}$,

$$\varphi(\vec{g})=E_{\pi}\vec{g}\log\vec{g}-E_{\pi}\vec{g}\log E_{\pi}\vec{g}=\sum_{k=1}^{N}\pi_k g_k\log g_k-\left(\sum_{k=1}^{N}\pi_k g_k\right)\log\left(\sum_{k=1}^{N}\pi_k g_k\right).$$

Now we check that the Hessian matrix of φ is positive semidefinite, and hence φ is convex in $\vec{g}$. Notice that

$$\frac{\partial\varphi}{\partial g_k}(\vec{g})=\pi_k\left(\log g_k-\log\sum_{l=1}^{N}\pi_l g_l\right),$$

$$\frac{\partial^2\varphi}{\partial g_k\,\partial g_l}(\vec{g})=\begin{cases}\pi_k/g_k-\pi_k^2\left(\sum_{r=1}^{N}\pi_r g_r\right)^{-1}, & \text{if } k=l,\\ -\pi_k\pi_l\left(\sum_{r=1}^{N}\pi_r g_r\right)^{-1}, & \text{if } k\neq l.\end{cases}$$

For any vector $\vec{v}$ with dimension N,

$$\begin{aligned}\vec{v}^T\,\mathrm{Hess}(\varphi)(g)\vec{v}&=\sum_{k=1}^{N}\pi_k v_k^2/g_k-\left(\sum_{k,l=1}^{N}\pi_k\pi_l v_k v_l\right)\left(\sum_{r=1}^{N}\pi_r g_r\right)^{-1}\\&=\sum_{k=1}^{N}\pi_k v_k^2/g_k-\left(\sum_{k=1}^{N}\pi_k v_k\right)^2\left(\sum_{r=1}^{N}\pi_r g_r\right)^{-1}\end{aligned}$$

is non-negative since

$$\left(\sum_{k=1}^{N}\pi_k v_k\right)^2=\left(\sum_{k=1}^{N}(\pi_k g_k)^{1/2}((\pi_k/g_k)^{1/2}v_k)\right)^2\leqslant\left(\sum_{k=1}^{N}\pi_k g_k\right)\left(\sum_{k=1}^{N}\pi_k v_k^2/g_k\right).$$

Hence φ is convex. Thus for any non-negative function g on $\mathbb{X}$,

$$\varphi(E_{\rho}\vec{g})\leqslant E_{\rho}\varphi(\vec{g})=\int\varphi(\vec{g}(x))\rho(x)\mathrm{d}x.$$

For any $f\in R(\lambda)C(\mathbb{X})$, let $g=f^2$, and it follows that

$$\begin{aligned}E_{\theta}f^2\log f^2-E_{\theta}f^2\log E_{\theta}f^2&=E_{\pi}(E_{\rho}f^2\log f^2-E_{\rho}f^2\log E_{\rho}f^2)+(E_{\pi}(E_{\rho}f^2\log E_{\rho}f^2)\\&\quad-E_{\pi}E_{\rho}f^2\log E_{\pi}E_{\rho}f^2)=\sum_{k=1}^{N}\pi_k(E_{\rho}f^2(k,\cdot)\log f^2(k,\cdot)\\&\quad-E_{\rho}f^2(k,\cdot)\log E_{\rho}f^2(k,\cdot))+\varphi(E_{\rho}\vec{g})\leqslant-c\sum_{k=1}^{N}\pi_k E_{\rho}\langle\mathcal{L}_k f(k,\cdot),f(k,\cdot)\rangle_{\rho}\end{aligned}$$

$$+E_\rho\varphi(\vec{g}) \leqslant -c\sum_{k=1}^{N}\int (\mathcal{L}_k f(k,x))f(k,x)\pi_k\rho(x)\mathrm{d}x - c\int \sum_{k=1}^{N}\pi_k f(k,x)$$
$$\times\left(\sum_{k=1}^{N} q_{kl}(x)f(l,x)\right)\rho(x)\mathrm{d}x = -c\langle \mathcal{L}f,f\rangle,$$

where the first inequality holds since $f(k,\cdot)\in D(\mathcal{L}_k,L^2)$. For any $f\in\mathcal{D}(\mathcal{L},L^2)$, take $f_n\in R(\lambda)C(\mathbb{X})$ such that $\lim_{n\to+\infty}\|f_n-f\|_{\mathcal{L}}=0$. Choose a subsequence, which is still denoted by f_n, such that it converges almost surely. By the Fatou lemma,

$$E_\theta f^2\log f^2 1_{\{|f|\geqslant 1\}} \leqslant \lim_{n\to+\infty}\inf E_\theta f_n^2\log f_n^2 1_{\{|f_n|\geqslant 1\}}.$$

By the bounded convergence theorem,

$$E_\theta f^2\log f^2 1_{\{|f|<1\}} \leqslant \lim_{n\to+\infty} E_\theta f_n^2\log f_n^2 1_{\{|f_n|\geqslant 1\}}.$$

Hence

$$E_\theta f^2\log f^2 - E_\theta f^2\log E_\theta f^2 \leqslant \lim_{n\to+\infty}\inf(E_\theta f_n^2\log f_n^2 - E_\theta f_n^2\log E_\theta f_n^2)$$
$$\leqslant \lim_{n\to+\infty}\inf -c\langle \mathcal{L}f_n,f_n\rangle = -c\langle \mathcal{L}f,f\rangle,$$

which implies the result. □

At the end of this paper, we give a sufficient condition for the CDP to have a spectral gap. In fact, we show the following.

Lemma 3.2: *Let $\mathcal{L}=\frac{1}{2}\Delta+\frac{1}{2}\nabla V.\nabla$ be a generator of a diffusion process, and e^V be a reversible density. Suppose there is a multiplication operator $\widetilde{U}$, relative compact with respect to the Laplace operator Δ and having a lower bound, and $\delta>0$ such that*

$$U \triangleq \tfrac{1}{4}|\nabla V|^2+\tfrac{1}{2}\Delta V \geqslant \widetilde{U}+\delta. \tag{7}$$

Then $\mathcal{L}$ has a spectral gap.

This together with Theorem 1 yields the following.

Proposition 3.3: *Let*

$$\mathcal{L}f(k,x) = \tfrac{1}{2}\Delta f(k,x) + \tfrac{1}{2}\nabla V(k,x)\cdot\nabla f(k,x) + \sum_{l:l\neq k} q_{kl}(x)(f(l,x)-f(k,x)),$$

where q_{kl} is bounded. Let e^V be the reversible density. If for all k, $V(k,x)$ satisfies the condition in Lemma 3.2, then $\mathcal{L}$ has a spectral gap.

Remark 3.4: If $\liminf_{|x|\to+\infty}U(x)>0$, *then* (7) *holds. In this case, there exist $M,\delta,R>0$ such that $U\geqslant -M$ and $U(x)>\delta$ whenever $|x|>R$. Hence $U\geqslant\widetilde{U}+\delta$, where $\widetilde{U}:=-(M+\delta)1_{|x|<R}$ is relative compact with respect to Δ in $L^2(\mathbb{R}^d,\mathbf{m})$.*

Proof of Lemma 3.2: Let

$$\Phi: L^2(\mathbb{R}^d,e^V)\to L^2(\mathbb{R}^d,\mathbf{m}),\quad f\mapsto e^{V/2}f.$$

Then Φ is an isomorphism. Hence $\widetilde{\mathcal{L}}=\Phi\mathcal{L}\Phi^{-1}=\frac{1}{2}(\Delta-U)$ is self-adjoint on $L^2(\mathbb{R}^d,\mathbf{m})$ and has the same family of spectra as $\mathcal{L}$ in $L^2(\mathbb{R}^d,e^V)$. Now we check that $\widetilde{\mathcal{L}}$ has a spectral gap in $L^2(\mathbb{R}^d,\mathbf{m})$.

Since $\widetilde{U}$ is relative compact with respect to Δ, $\Delta-\widetilde{U}$ has the same essential spectra as Δ. Therefore,

$$\sigma_{\mathrm{ess}}(\Delta - \tilde{U}) = \sigma_{\mathrm{ess}}(\Delta) = (-\infty, 0].$$

It follows that $\sup \sigma_{\mathrm{ess}}(\Delta - \tilde{U}) = 0$. Notice that $\tilde{U}$ is bounded below, which implies that $\Delta - \tilde{U}$ is bounded above. By Lemma 3.1, $\mu_n(\Delta - \tilde{U}) < \delta/2$ for large n. Hence

$$\mu_n(\Delta - U) \leqslant \mu_n(\Delta - \tilde{U} - \delta) = \mu_n(\Delta - \tilde{U}) - \delta < -\delta/2. \tag{8}$$

It is concluded that the spectra of $\Delta - U$ in $[-\delta/2, 0]$ are discrete. Hence $\Delta - U$ has a spectral gap, which implies that $\tilde{\mathcal{L}} = (\Delta - U)/2$ does. Therefore, $\mathcal{L}$ has a spectral gap. □

Observability of the scattering cross-section through phase decoherence

Timothy R. Field
Departments of Electrical and Computer Engineering and Mathematics, McMaster University, Hamilton, Ontario, Canada L8S 4L8

(Received 25 December 2004; accepted 11 April 2005; published online 9 June 2005)

We derive the stochastic dynamics for scattering of a wavelike field from a large population of scatterers whose dynamics is arbitrary. This leads to a result concerning the observability of the scattering cross section in terms of the resultant phase fluctuations that is independent of the population dynamics. An emergent concept is a certain notion of an ideal filter. The diffusion based model of *K*-scattering arises as a special case. The experimental implications of the results in a variety of contexts are discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1926147]

I. INTRODUCTION

Motivated by the possible application of the recent results on electromagnetic scattering from random media to more general situations (e.g., medical imaging, wireless communications) than those encompassed by the *K*-distribution model (Field and Tough, 2003a, 2003b), the paper describes an interesting result in connection with inference of the scattering cross section or population, in local time. A special case of the result was reported previously in Field and Tough (2003b) [see paragraph above Eq. (2.35) therein], stating that the instantaneous values of the cross section are deducible through the phase fluctuations in the scattered field. This was demonstrated in the context of *K*-scattering. Intriguingly, the same result holds for an arbitrary population. More precisely, given the structure of a random walk model, component phase and step number fluctuations, the result holds for an arbitrary specification of population dynamics. In this sense, the result is a geometrical feature of (the dynamical extension of) Jakeman's random walk model with step number fluctuations (Jakeman, 1980), and as such should apply to a large number of experimental situations involving interference effects of wavelike fields arising from random populations. From a filtering point of view, the result represents an improvement on Kalman–particle filtering methods, since an *exact* expression for the hidden state (the population level) in terms of the additional phase degrees of freedom can be derived.

We adopt the consistent notation throughout for a continuous time stochastic processes q_t, with Ito differential $\mathrm{d}q_t$, and and squared volatility $\mathrm{d}q_t^2$.[1]

II. RANDOM WALK MODEL

It is well known that Rayleigh scattering can be described by a random walk model for the scattered field amplitude (cf. Jakeman, 1980; Tough, 1987; Jakeman and Tough, 1988) with a fixed number of steps. The pertinent expression for the resultant field amplitude according to this model is

[1]Thus the notation $\mathrm{d}q_t^2$, as occurs, e.g., for the phase process in Theorem 3.5, means that the differential is taken *before* the square.

$$\mathcal{E}_t^{(N)} = \sum_{j=1}^{N} \overbrace{a_j \exp[i\varphi_t^{(j)}]}^{s^{(j)}} \tag{2.1}$$

with (constant) population size N, random phasor step $s^{(j)}$, and form factors a_j.

In the aforementioned references all components of this expression are in effect considered at a given instant of time, thus not addressing the question of continuous time evolution properties or dynamics. This extra structure is supplied by a (phase) diffusion model (Field and Tough, 2003b) which takes the component phases $\{\varphi_t^{(j)}\}$ to be a collection of (displaced) Wiener processes evolving on a suitable time scale. Thus $\varphi_t^{(j)} = \Delta^{(j)} + \mathcal{B}^{\frac{1}{2}} W_t^{(j)}$, with component random initialization $\Delta^{(j)}$ uniformly distributed on the interval $[0, 2\pi)$. In situations where the component phasors $s^{(j)}$ are aligned initially (e.g., for the received $T2$ signal arising in magnetic resonance imaging, described, e.g., by Brown and Semelka, 2003 and discussed in Sec. IV) $\Delta^{(j)}$ are identical for all j, whereas in some cases [e.g., the statistical description of radar scattering from the sea surface, cf. Sec. 4(b) in Field and Tough, 2003a] it is more appropriate to draw $\Delta^{(j)}$ independently. In any case, these primitive assumptions enable us to derive the dynamics of Rayleigh scattering, essentially from first principles. The stochastic differential of (2.1), according to Ito's formula (e.g., Oksendal, 1998; Karatzas and Shreve, 1988), is given by

$$\mathrm{d}\mathcal{E}_t^{(N)} = \sum_{j=1}^{N} a_j \left(i\, \mathrm{d}\varphi_t^{(j)} - \frac{1}{2} \mathrm{d}\varphi_t^{(j)2} \right) \exp\left[i\varphi_t^{(j)} \right]. \tag{2.2}$$

If we write $\mathrm{d}\zeta_t$ for the first term on the right-hand side above, then for $t \geqslant T$, where T is the phase decoherence time such that $\{\varphi_t^{(j)} | t \geqslant T\}$ have negligible correlation, we have $|\mathrm{d}\zeta_t|^2 = (\Sigma_j a_j^2)\ \mathcal{B}\, \mathrm{d}t$, and therefore $\mathrm{d}\zeta_t = (\Sigma_j a_j^2)^{1/2} \mathcal{B}^{1/2}\, \mathrm{d}\xi_t$ where ξ_t is a complex-valued Wiener process (satisfying $|\mathrm{d}\xi_t|^2 = \mathrm{d}t$, $\mathrm{d}\xi_t^2 = 0$). Defining the (normalized) Rayleigh amplitude by $\gamma_t = \lim_{N\to\infty}[\mathcal{E}_t^{(N)} / N^{\frac{1}{2}}]$ leads to the resultant dynamics (cf. Field and Tough, 2003b).

Proposition 2.1: *For sufficiently large times $t \geqslant T$ the dynamics of Rayleigh scattering is given by the complex Ornstein–Uhlenbeck equation*

$$\mathrm{d}\gamma_t = -\tfrac{1}{2} \mathcal{B} \gamma_t\, \mathrm{d}t + \mathcal{B}^{\frac{1}{2}} \langle a^2 \rangle^{\frac{1}{2}}\, \mathrm{d}\xi_t. \tag{2.3}$$

If $\{\Delta^{(j)}\}$ are assumed independent then the result holds for arbitrarily small times.

If we rescale the (Rayleigh) amplitude according to $\gamma_t \mapsto \langle a^2 \rangle^{-1/2} \gamma_t$, then the rescaled field satisfies (2.3) with the form factors equal to unity. In what follows we shall therefore assume the field to be scaled in this way, i.e., $\langle a^2 \rangle = 1$. In the case of a fluctuating number of steps $N \mapsto N_t$ in (2.1), we define the (continuous-valued) cross section as $x_t = \lim_{N_t \to \infty}[N_t / \overline{N}]$. The resultant (normalized) amplitude $\psi_t = \lim_{N\to\infty}[\mathcal{E}^{(N_t)} / \overline{N}]$ therefore has the compound representation

$$\psi_t = x_t^{\frac{1}{2}} \gamma_t, \tag{2.4}$$

where $\gamma_t = \lim_{N\to\infty}[\mathcal{E}_t^{(N_t)} / N_t^{\frac{1}{2}}]$, and in which x_t and γ_t are independent processes. The intensity z_t has the compound representation $z_t = x_t u_t$, where $u_t = |\gamma_t|^2$ is the instantaneous intensity of the component (unit power) Rayleigh process (cf. the analysis of asymptotic behavior and propagators in Secs. III and IV of Field and Tough, 2003b).

It is perhaps worth clarifying at this point the precise meaning and definitions of the various amplitudes that have occurred in the exposition of the random walk model. We begin with $\mathcal{E}$, as the superposition of N random phasors, where N is fixed. For a large population, $N \to \infty$, and the root mean square (rms) of $\mathcal{E}$ tends to infinity. Thus, to obtain a finite resultant in the limit of an asymptotically large number of scatterers, we define a normalized Rayleigh amplitude γ, by dividing through by the rms value $N^{\frac{1}{2}}$. (Equivalently, we could absorb this normalization into the form factors a_j.) The term Rayleigh refers to the fact the the number of scatterers is fixed. In the general case that the scattering population fluctuates in time, we define the normalized amplitude

ψ as in the case of Rayleigh scattering, dividing $\mathcal{E}$ by the rms value $\overline{N^{\frac{1}{2}}}$, where now the number of terms N_t in the random walk fluctuates. Rearranging the resulting expression produces the compound representation of the resultant amplitude (2.4), for a general scattering process. The Rayleigh amplitude is then recovered if the cross section is unity.

The corresponding dynamical situation for weak scattering processes, i.e., where the field ψ_t lies in (weak) superposition with a coherent offset signal ϱ_t, is described in Field and Tough (2005).

III. GENERALIZED POPULATION DYNAMICS

In this section we propose a general scheme for describing scattering/interference of wavelike fields from random media, for which the statistical characteristics of the (scattering) population are taken to be arbitrary. With regard to the cross section and intensity variables, in Bayesian terms one may write $\mathbb{P}(x|z) \propto \mathbb{P}(z|x)\mathbb{P}(x)$ and interpret $\mathbb{P}(z|x)$ as the likelihood function L, $\mathbb{P}(x)$ as the prior P and $\mathbb{P}(x|z)$ as the posterior distribution. In K-scattering the constant (with respect to x) of proportionality is the reciprocal K-distribution for the intensity z. Our development shall entail the following, that we (1) preserve the likelihood L as the Rayleigh distribution, cf. the universality of arguments of central limit theorem type, (2) modify the prior P, i.e., consider general (endogenous) population dynamics appropriate to more complex population processes, under the assumption that x_t remains an Ito process (cf. Field and Tough, 2003a), and (3) preserve the mathematical structure of the random walk model (2.1) describing the resultant amplitude process.

Accordingly we specify that the underlying signal x_t is an Ito process that satisfies the generalized (in the sense of its relationship with the K-scattering model) stochastic differential equation (SDE)

$$\mathrm{d}x_t = \mathcal{A}b_t\,\mathrm{d}t + (2\mathcal{A}\Sigma_t)^{\frac{1}{2}}\,\mathrm{d}W_t^{(x)} \tag{3.1}$$

in which the drift and diffusion parameters b_t, Σ_t are, respectively, (real-valued) stochastic processes, not necessarily Ito processes, adapted to the filtration $\mathcal{F}_t^{(x)}$ corresponding to the Wiener process $W_t^{(x)}$. In other words, the continuous population dynamics is taken to lie within the general category of Ito processes. The special case of a diffusive population behavior arises when the SDE parameters are functions of state, i.e., $b_t = b(t,x_t)$ and $\Sigma_t = \Sigma(t,x_t)$ for given functions $b(\cdot,\cdot)$ and $\Sigma(\cdot,\cdot)$, in which case a corresponding Fokker–Planck description for the time evolution of the probability density is possible (e.g. Risken, 1989). The case of K-scattering (a special type of diffusion model) is obtained by setting $b(t,x) = (\alpha - x)$, $\Sigma(t,x) = x$, and arises as the continuous-valued (large N) limit of the birth–death–immigration (BDI) model (see Bartlett, 1966; Field and Tough, 2003b). We shall not require that x_t be a diffusion in what follows, however. The generalized dynamics of the resultant amplitude process can now be derived according to the scheme outlined at the end of Sec. II. For arbitrary γ_t, x_t an application of Ito's formula to (2.4) yields

$$\frac{\mathrm{d}\psi_t}{\psi_t} = \frac{\mathrm{d}\gamma_t}{\gamma_t} + \frac{\mathrm{d}x_t}{2x_t} - \frac{\mathrm{d}x_t^2}{8x_t^2}. \tag{3.2}$$

This enables the resultant amplitude dynamics to be calculated under the assumption that γ_t is a unit power Rayleigh process according to (2.3), with unit form factors.

Proposition 3.1: *The generalized resultant amplitude dynamics is given by*

$$\frac{\mathrm{d}\psi_t}{\psi_t} = \left[\mathcal{A}\left(\frac{b_t}{2x_t} - \frac{\Sigma_t}{4x_t^2}\right) - \frac{1}{2}\mathcal{B}\right]\mathrm{d}t + \left(\frac{\mathcal{A}\Sigma_t}{2x_t^2}\right)^{\frac{1}{2}}\mathrm{d}W_t^{(x)} + \left(\frac{\mathcal{B}^{\frac{1}{2}}}{\gamma_t}\right)\mathrm{d}\xi_t. \tag{3.3}$$

Observe that $\partial/\partial\mathcal{B}$ acting on the drift/volatility parameters in (3.3) yields expressions that are independent of b_t, Σ_t, as expected from the endogenous specification of population dynamics (3.1). Using the vanishing of the Ito products $\mathrm{d}\xi_t^2$, $\mathrm{d}\xi_t\,\mathrm{d}W_t^{(x)}$ and the property $|\mathrm{d}\xi_t|^2 = \mathrm{d}t$ the above result yields the squared amplitude fluctuations as follows.

Corollary 3.2:

$$\left(\frac{\mathrm{d}\psi_t}{\psi_t}\right)^2 = \frac{\mathcal{A}\Sigma_t}{2x_t^2}\mathrm{d}t, \tag{3.4}$$

$$|\mathrm{d}\psi_t|^2 = \left(\frac{\mathcal{A}\Sigma_t z_t}{2x_t^2} + \mathcal{B}x_t\right)\mathrm{d}t. \tag{3.5}$$

The generalized intensity dynamics can be computed from Proposition 3.1 and the identity $\mathrm{d}z_t \equiv \psi_t\,\mathrm{d}\psi_t^* + \psi_t^*\,\mathrm{d}\psi_t + \mathrm{d}\psi_t\,\mathrm{d}\psi_t^*$.

Proposition 3.3: *The generalized intensity SDE is given by*

$$\mathrm{d}z_t = \left[\mathcal{A}\left(\frac{b_t z_t}{x_t}\right) + \mathcal{B}(x_t - z_t)\right]\mathrm{d}t + (2\mathcal{A}\Sigma_t)^{\frac{1}{2}}\left(\frac{z_t}{x_t}\right)\mathrm{d}W_t^{(x)} + (2\mathcal{B}x_t z_t)^{\frac{1}{2}}\,\mathrm{d}W_t^{(r)}, \tag{3.6}$$

where

$$(\gamma_t^*\,\mathrm{d}\xi_t + \gamma_t\,\mathrm{d}\xi_t^*) \equiv \left(\frac{2z_t}{x_t}\right)^{\frac{1}{2}}\mathrm{d}W_t^{(r)}. \tag{3.7}$$

The intensity squared volatility is

$$\mathrm{d}z_t^2 = 2z_t\left(\frac{\mathcal{A}\Sigma_t z_t}{x_t^2} + \mathcal{B}x_t\right)\mathrm{d}t. \tag{3.8}$$

The propositions above reduce to the appropriate expressions in *K*-scattering (cf. Field and Tough, 2003a, 2003b) for appropriate choice of b, Σ. In respect of the generalized resultant phase dynamics, recall (Field and Tough, 2003b) the identity for the phase differential in terms of the amplitude

$$\mathrm{d}\theta_t \equiv \Im\left[\frac{\mathrm{d}\psi_t}{\psi_t} - \frac{1}{2}\left(\frac{\mathrm{d}\psi_t}{\psi_t}\right)^2\right], \tag{3.9}$$

where $\Im$ denotes the imaginary part. Since the right-hand side of (3.4) is *real* valued, only the first term on the right-hand side of (3.9) contributes to $\mathrm{d}\theta_t$, in respect of which

$$\Im\left[\frac{\mathrm{d}\psi_t}{\psi_t}\right] = \frac{\mathcal{B}^{\frac{1}{2}}}{2i}\left(\frac{\mathrm{d}\xi_t}{\gamma_t} - \frac{\mathrm{d}\xi_t^*}{\gamma_t^*}\right). \tag{3.10}$$

Thus we can deduce the phase behavior for a general population.

Proposition 3.4: *The generalized resultant phase dynamics is given by the SDE,*

$$\mathrm{d}\theta_t = \left(\frac{\mathcal{B}x_t}{2z_t}\right)^{\frac{1}{2}}\mathrm{d}W_t^{(\theta)}, \tag{3.11}$$

where $W_t^{(\theta)}$ *satisfies*

$$\frac{1}{i}(\gamma_t^*\,\mathrm{d}\xi_t - \gamma_t\,\mathrm{d}\xi_t^*) \equiv \left(\frac{2z_t}{x_t}\right)^{\frac{1}{2}}\mathrm{d}W_t^{(\theta)}. \tag{3.12}$$

Observe that, in contrast to the situation for the resultant amplitude and intensity SDEs (3.3) and (3.6), this is *functionally* identical to the corresponding result in *K*-scattering (i.e., independent of the population parameters b_t, Σ_t), the essential difference lying in the *evolutionary* structure of the processes x_t, z_t. Observe from (3.7) and (3.12) that the radial and angular fluctuations in the

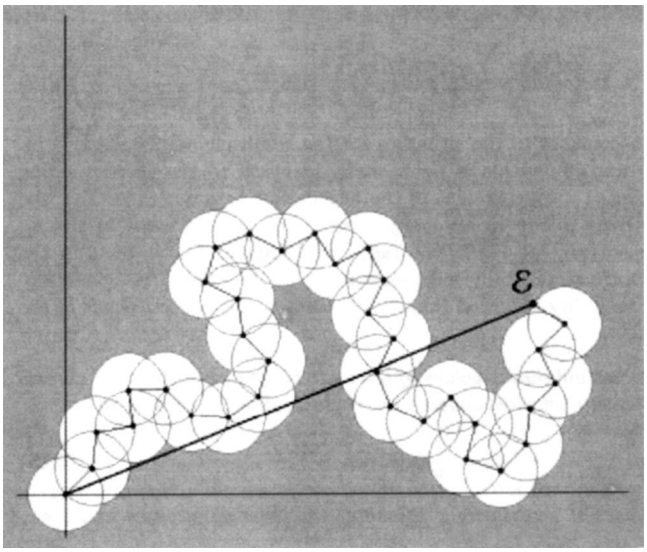

FIG. 1. Geometry of random walk for generalized scattering process—generically (almost everywhere) each component phasor point lies on two circles.

resultant amplitude are statistically independent in the general case. The squared phase volatility obtained from (3.11) leads to the central result of the paper.

Theorem 3.5: *The instantaneous values of the scattering cross section are observable through the intensity-weighted squared phase fluctuations according to*

$$x_t = \frac{2}{\mathcal{B}} z_t \, \mathrm{d}\theta_t^2 / \mathrm{d}t \tag{3.13}$$

if x_t is an Ito process, not necessarily a diffusion, and throughout space and time.

The (experimental) significance of this result is that the relation (3.13) is exact and moreover independent of the dynamics of x_t. The result resembles (but is distinct from) the minimal variance of the intensity-weighted phase derivative discussed in Jakeman *et al.*, (2001), for differentiable processes. In the present situation however, the processes considered are not differentiable, and instead the *squared* phase differential arises. Since the elements of the random walk model (2.1), preserved by the generalized framework given in the exposition of this section for dealing with general populations, are the only essential ingredients involved here, the result is geometrical in nature (cf. Fig. 1). With regard to this geometry, the derivations above show that the dynamics of the resultant field are not affected if the radii for each component phasor are drawn independently from an arbitrary probability distribution. (The result of the theorem was anticipated from a physical point of view previously in Field and Tough, 2003a; see discussion following Proposition 4.1. therein.)

A slight complication is posed in the computation of $\mathrm{d}\theta_t^2$ from experimental data, owing to the discontinuous-valued behavior of θ_t at coordinate intervals of 2π. This is resolved by instead using the (continuous-valued) phase-wrapped process $w_t = \exp(i\theta_t)$, whose stochastic differential is $\mathrm{d}w_t = \exp(i\theta_t)\left[i\,\mathrm{d}\theta_t - \frac{1}{2}\mathrm{d}\theta_t^2\right]$, which enables the squared phase fluctuations to be computed from the single-valued process w_t via $|\mathrm{d}w_t|^2 = \mathrm{d}\theta_t^2$. In respect of discrete-time implementation, we remark that if W_t is a Wiener process, then $\delta W_t = W_{t+h} - W_t$ is normally distributed as $\mathcal{N}(0,h)$, so that its square is a chi-squared $\chi^2(1)$ variable. The sum of n such variables is therefore distributed as $\chi^2(n)$, from which an estimate of $\mathrm{d}q_t^2$ from δq_t can be obtained (via the weak law of large numbers) by considering the interval from t to $t+\delta t$ divided into n pulse intervals each of length

h and letting $n\to\infty$ before taking the limit $\delta t\to \mathrm{d}t$ (Howison, private communication; see also Higham, 2004 and the exposition to Sec. 4 in Field and Tough, 2003a). In this respect we observe the following significant result.

Proposition 3.6: *In order to achieve an improved signal to noise ratio (SNR), it is sufficient merely to increase the pulse-rate n, without necessarily requiring a high amplitude signal* x_t.

The implications of this idea are discussed in Sec. IV in an experimental context, and illustrated with some synthetically generated data. The structure of (3.1) and (3.6) could be interpreted as an instance of the generalized Kalman filter (see Chap. 6 in Oksendal, 1998) in which the unknown state x_t is to be estimated from observations of z_t. It is significant that in this situation the dynamics of the filter stem from first principles and that the resulting statistics are non-Gaussian (notwithstanding the Gaussian nature of the Wiener process). The noise originates through two components, namely the intrinsic system noise $W_t^{(x)}$ which derives from fluctuations in the (endogenously specified) population model, and the measurement noise ξ_t arising from the particulars of the wavelike interference effects. The latter should be viewed as an exogenous device whose purpose is to probe the true underlying state of the system that is of primary interest, in this case the signal x_t.

Our development has demonstrated (an instance of) how, instead of attempting to filter the received signal to eliminate the noise (e.g., via a Kalman or particle filter), one can exploit the statistical fluctuation properties of the noise in order to infer the *exact* values of the underlying signal. This notion might appropriately be termed an *ideal filter* and constitutes a shift of viewpoint from the various conventional approaches to enhancement of signal to noise.

IV. EXPERIMENTAL IMPLICATIONS

A study of some synthetically generated data provides a clear illustration of the consequences of Theorem 3.5 in a variety of experimental contexts. The theoretical results are conveniently substantiated using synthetic data, as such enables direct verification of the accuracy of the state estimation from the observations, the precise value of the hidden state being known from the simulation. One can then compare the values of the state inferred from the observations alone, with the exact values of the underlying hidden state recorded in the simulation. The cross section was chosen to satisfy the SDE (3.1) with $b(t,x)=\alpha-x$, $\Sigma(t,x)=x$ so that x_t is a gamma variate and the process thus generated is appropriate to the types of scattering data found in radar applications (cf. Field and Tough, 2003a). Resultant amplitude data was simulated via integration of (3.3), which is achieved most effectively by a separate numerical integration of the (independent) component SDEs (2.3) and (3.1). We emphasize however, that the same types of numerical results as demonstrated below should hold for an arbitrary population, as shown theoretically in Theorem 3.5. For the purposes of the simulation, α was chosen to be large, to avoid numerical difficulties that can arise due to the singular behavior in the phase fluctuations at zeros of the intensity, implied by (3.11). The results of the simulation are provided in Fig. 2, which shows time series for the observed intensity, the exact cross section generated in the simulation (i.e., the unknown state one is trying to estimate), and the values of this state inferred from the observations of the scattered amplitude alone. The estimate of the state follows from Theorem 3.5 which, for discretely sampled data, implies

$$z_i\delta\theta_i^2 \propto x_i n_i^2, \tag{4.1}$$

where i is a discrete time index and $\{n_i\}$ are an independent collection of $\mathcal{N}(0,1)$ distributed random variables. Applying a smoothing average $\langle\cdot\rangle_\Delta$ to the left-hand side (the observations) of (4.1) with window $\mathbf{\Delta}=[t_0-\Delta,t_0+\Delta]$ yields an approximation to x_{t_0}, with an error that tends to zero as the number of pulses inside $\mathbf{\Delta}$ tends to infinity and $\Delta\to 0$ (see discussion of χ^2 statistic following Theorem 3.5).[2] On the other hand, smoothing the z_t time series, for any choice of parameter Δ, does not yield the desired close correlation with x_t; indeed any such attempt to

[2]We assume here that the sample paths of x_t are continuous, which is a consequence of (3.1).

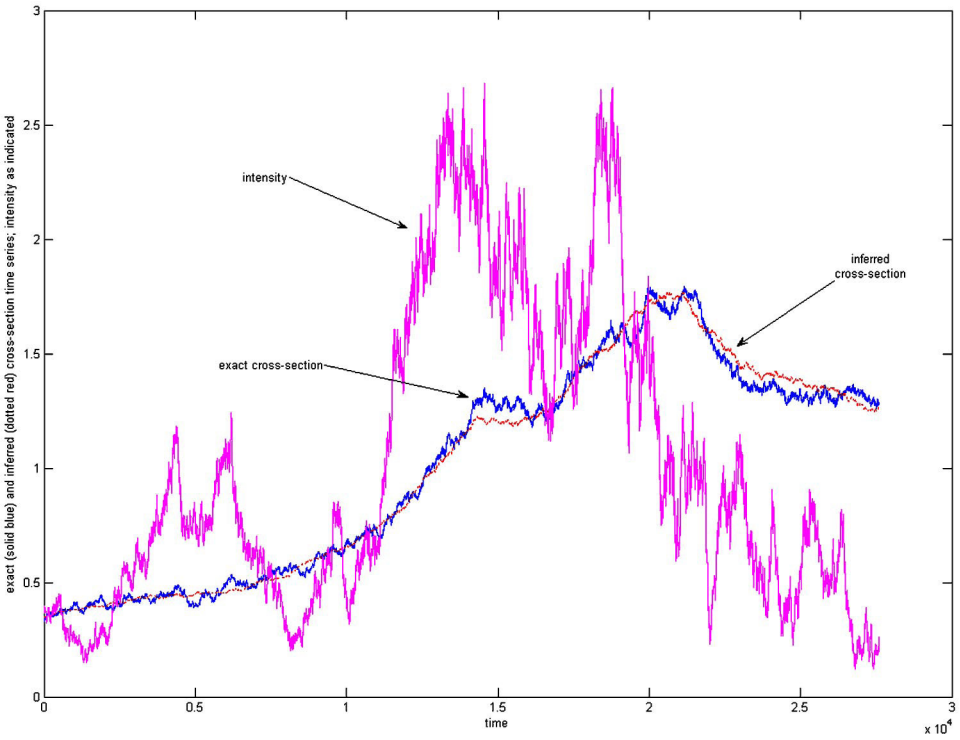

FIG. 2. (Color online) Estimation of the scattering cross section/population after relaxation time T through the effect of phase decoherence. (For parameter values $\alpha=10$, $\Delta=1200$ pulses, $\mathcal{A}=10^{-5}$, $\mathcal{B}=10^{-4}$ the figure shows a statistical correlation between the exact and inferred cross-section time series of 0.9954.)

decorrelate the speckle pattern merely produces an intensity profile with the same general shape as the original z_t, with oscillations on a time scale approximately equal to Δ.

The application of related earlier ideas in SDE theory to optical propagation and radar scattering has been reported in Sec. 4 of Field and Tough, (2003a). The current results should be of additional value in these types of experiments, through the ability to estimate the underlying scattering cross section for general scattering populations, in real time. When applied to experimental data, the results herein provide means for studying the behavior of random media based on statistical analysis of the inferred cross section alone, which has hitherto been regarded as the hidden state of the system. The electromagnetic scattering process should then appropriately be viewed as a secondary exogenous device, whose purpose is merely to extract the real time behavior of the underlying scattering cross section, where the latter is the object of primary interest.

Our results also suggest the application to the physics of magnetic resonance (MR) imaging and spectroscopy. The random medium (e.g., brain tissue) lies inside a background magnetic field B_0, with which the constituent (proton) spin vectors are aligned, in their minimum energy configuration. An applied RF pulse causes resonant absorption to occur, so that the spins realign, typically at a pulse flip angle of 90° to B_0. Radiation of this absorbed energy gives rise to the received MR signal (the free induction decay or FID), which is detected through the generation of electromotive force in a coil apparatus, due to the time varying local magnetic field.[3] The MR signal has the usual in-phase (I) and quadrature-phase (Q) components familiar from radio theory, and thus corresponds to the amplitude process $\Psi=I+iQ$ for each point in space. For a perfectly homogeneous (total) magnetic field throughout the medium, each spin vector precesses at the Larmor frequency ω_0 about the longitudinal axis, where ω_0 is given by the Larmor equation ω_0

[3]This effect is the result of Faraday's law, i.e., Maxwell's vector equation $\nabla\times\mathbf{E}=-\partial\mathbf{B}/\partial t$ integrated around a loop.

$= \gamma B_0$ and γ is the (local) gyromagnetic ratio (e.g., Brown and Semelka, 2003). (In the radar scattering situation described above, ω_0 corresponds to the Doppler frequency, arising from bulk wave motion in the scattering surface.) However, the local inhomogeneities in the net magnetic field, due to the local magnetic properties of the medium, give rise to a process known as spin–spin or $T2$ relaxation constituting the (random) exchange of energy between neighboring spins. These local perturbations in the total magnetic field can reasonably be considered as independent for each component spin, so that the dynamics of each spin vector can be modeled as a phase diffusion process with (transverse) resultant as in (2.1) and phase initializations $\{\Delta^{(j)}\}$ equal. After sufficient relaxation time $t \geqslant T$ has elapsed, phase decoherence occurs. In principle this enables the spin population to be tracked according to Theorem 3.5, and thus real time MR images to be generated. This application is explored in greater depth, and from a less detailed mathematical perspective, in Field, (2005).

(Received 16 May 2004; accepted 9 March 2005; published online 12 May 2005)

We investigate Lorentzian space–times where all zeroth and first order curvature invariants vanish and discuss how this class differs from the one where all curvature invariants vanish (VSI). We show that for VSI space–times all components of the Riemann tensor and its derivatives up to some fixed order can be made arbitrarily small. We discuss this in more detail by way of examples. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904707]

I. INTRODUCTION

Recently it was proven that in four-dimensional Lorentzian space–times all of the scalar invariants constructed from the Riemann tensor and its covariant derivatives are zero if and only if the space–time is of Petrov (P)-type III, N or O, all eigenvalues of the Ricci tensor are zero and hence of Plebański–Petrov (PP)-type N or O (Ref. 1) and the common multiple null eigenvector of the Weyl and Ricci tensors is geodesic, shear-free, expansion-free, and twist-free; let us refer to these space–times as vanishing scalar invariant (VSI) space–times. VSI space–times include the well-known *pp*-wave space–times.[2]

Since all of the scalar curvature invariants vanish, all VSI space–times are exact solutions of higher-order Lagrangian based theories (in which the action is given by higher order scalar corrections to the usual general relativistic action based on the Ricci scalar). It has subsequently been argued that, as in the case of *pp*-waves, VSI space–times are exact solutions in string theory,[3–5] when supported by appropriate bosonic massless fields of the string (such as, for example, a dilaton and an antisymmetric massless field). Solutions of classical field equations for which the counter terms required to regularize quantum fluctuations vanish (i.e., they suffer no quantum corrections to all loop orders) are also of importance because they offer insights into the behavior of the full quantum theory.[6]

In particular fundamental field theories only certain specific types of higher order corrections occur (cf. Refs. 7–9), and so for a space–time to be a solution of a particular field theory to all orders, with a specific effective action containing only certain higher order correction terms, it may not be necessary for *all* curvature invariants to vanish. Consequently it is also of interest to determine the set of spacetimes for which (only) the zeroth order curvature invariants vanish (i.e., algebraic scalar invariants constructed from the Riemann tensor), denoted VSI$_0$, those space–times for which (only) the zeroth *and* first order curvature invariants vanish (i.e., scalar invariants constructed from the Riemann tensor and its first covariant derivative), denoted VSI$_1$, and so on. In fact, it was proven in Ref. 1 that if all of the zeroth, first, and second order curvature invariants vanish, then necessarily all scalar curvature invariants vanish; so that VSI$_2$ is equivalent to the set of VSI space–times.

Let us first recall some properties of VSI space–times. Utilizing a complex null tetrad in the Newman–Penrose (NP) formalism it was shown that for P-types III and N the repeated null vector of the Weyl tensor ℓ^α is geodesic, shear-free, expansion-free, and twist-free (and the NP coefficients κ, σ, and ρ are consequently zero), and the Ricci tensor has the form

$$R_{\alpha\beta} = -2\Phi_{22}\ell_\alpha\ell_\beta + 4\Phi_{21}\ell_{(\alpha}m_{\beta)} + 4\Phi_{12}\ell_{(\alpha}\overline{m}_{\beta)}, \tag{1}$$

in terms of the nonzero Ricci components Φ_{ij}. For P-type O, the Weyl tensor vanishes and so it suffices that the Ricci tensor has the form (1). All of these space–times belong to Kundt's class,[10] and the metrics for all VSI space–times are displayed in Ref. 1. The generalized *pp*-wave solutions are of P-type N, PP-type O (so that the Ricci tensor has the form of null radiation) with $\tau=0$, and admit a covariantly constant null vector field.[2] The Ricci tensor (1) has four vanishing eigenvalues, and the PP-type is N for $\Phi_{12}\neq 0$ or O for $\Phi_{12}=0$. It is known that the energy conditions are violated in the PP-type N models[11] and hence attention is usually concentrated on the more physically interesting PP-type O case, which in the nonvacuum case corresponds to pure radiation.

It is well known that the necessary and sufficient conditions for space–times for which the zeroth order algebraic scalar curvature invariants vanish (VSI_0) are of P-type III, N or O and PP-type N or O. Moreover, the repeated principal null direction of Weyl must be aligned with an eigenvector of the Ricci tensor. The last condition follows from the vanishing of the mixed invariants (see Sec. 3.1 of Ref. 1). Next we determine the VSI_1 space–times.

II. VSI_1

We begin by assuming VSI_0 and determine the conditions which imply VSI_1. From the Bianchi identities it follows for VSI_0 that $\kappa=0$. The invariants used here are all constructed from spinors that are symmetrized before and after contractions. Since contractions are always performed with symmetrized spinors we need only give the number of indices contracted between any two spinors. In particular, we shall make use of the following invariant, $I_1\equiv(\nabla\Psi)^2(\nabla\overline{\Psi})^2$. Here $(\nabla\Psi)^2$ is used to indicate the contraction over four indices of two copies of $\nabla_{(AA'}\Psi_{BCDE)}$. The result is then symmetrized and contracted with its conjugate to give I_1.

A. Petrov-type III

Using $\Psi_3\neq 0$ with PP-type N or O, we have from the Bianchi identities that $\sigma\Psi_3=\rho\Phi_{12}$ and $\kappa=0$. Applying $\kappa=0$ throughout, we find that two of the Bianchi identities yield the following relation:

$$D\Psi_3 = \rho\Phi_{21} + \overline{\sigma}\Phi_{12} + 2(\rho-\varepsilon)\Psi_3. \tag{2}$$

Computing I_1 and using (2), we obtain

$$I_1 = \tfrac{576}{625}[81(\sigma\overline{\sigma}\Psi_3\overline{\Psi}_3)^2 + \sigma\overline{\sigma}\Psi_3\overline{\Psi}_3 X\overline{X} + (X\overline{X})^2], \tag{3}$$

where $X=\rho\Phi_{21}+\overline{\sigma}\Phi_{12}+5\rho\Psi_3$.

The vanishing of I_1 necessarily implies that $\sigma=0$, thus from the Bianchi identities $\rho\Phi_{12}=0$. If $\rho=0$ we get VSI. If $\Phi_{12}=0$ then (3) becomes $I_1=576(\rho\overline{\rho}\Psi_3\overline{\Psi}_3)^2$ which vanishes when $\rho=0$, giving VSI with PP-type O (null radiation).

B. Petrov-type N

Using $\kappa=0$ in the Bianchi identities we find that $\rho\Phi_{21}=-\overline{\sigma}\Phi_{12}$ and $\rho\Phi_{12}=0$. Therefore if $\Phi_{12}\neq 0$ then $\rho=0$ implies that $\sigma=0$, hence we recover VSI. If $\Phi_{12}=0$ then two of the Bianchi identities combine to yield $\sigma\Psi_4=\rho\Phi_{22}$. The conditions $\kappa=\Phi_{12}=0$ and $\sigma\Psi_4=\rho\Phi_{22}$ are necessary to characterize the VSI_1 PP-O null radiation models. Suppose that $\sigma=0$; then either $\rho=0$ and we have VSI, or $\rho\neq 0$ and $\Phi_{22}=0$ which necessarily characterizes the vacuum VSI_1 models. (See Ref. 12.)

To show sufficiency, we assume $\kappa=\Phi_{12}=0$ and then note that the remaining curvature components, Ψ_4 and Φ_{22}, both have boost weight -2. In the compacted (GHP) formalism[13] the relevant operators have boost weight 0 or 1 and the only spin coefficients with positive boost

weight are σ and ρ with weights 1; it follows that the covariant derivative of either Ψ_{ABCD} or $\Phi_{AB\dot{A}\dot{B}}$ will have components with only negative boost weight. Therefore, all zeroth and first order curvature invariants vanish, implying VSI_1.

C. Petrov-type O

The freedom in the frame can be used here to consider PP-type N and PP-type O null radiation separately, and it follows trivially from the Bianchi identities that $\kappa=\sigma=\rho=0$, so that we obtain VSI. Therefore all Petrov type O VSI_0 are VSI from the Bianchi identities.

In summary, the only space–times in the class VSI_1 that are not VSI are of P-type N and all have $\kappa=\Phi_{12}=0$. The first of these VSI_1 models have $\sigma\Psi_4=\rho\Phi_{22}$; exact solutions were found by Plebański.[11] The second of the VSI_1 models have $\sigma=\Phi_{22}=0$, and these are the vacuum Petrov-type N solutions with $\rho=\Theta+i\omega\neq 0$. If $\omega=0$ these solutions belong to the Robinson–Trautman class and all are known.[11] If $\omega\neq 0$ then the only twisting, vacuum, P-type N solution known is that of Hauser.[11]

There are other cases that may also be of interest. Notice the example in Ref. 14 in which there are scalar curvature invariants that are nonzero (constant, depending on a cosmological constant) while all higher order scalar curvature invariants are zero.

III. ε-PROPERTY

A scalar invariant for a matrix is a polynomial of the matrix entries that is invariant with respect to all changes of basis. It is easy to characterize all such invariants. Let M be an $n\times n$ matrix. The characteristic polynomial of M is given by

$$p_M(x)=\det(xI-M)=x^n+\sum_{j=1}^{n}(-1)^j\sigma_j(M)x^{n-j}.$$

The expressions $\sigma_j(M)$ are called the elementary symmetric polynomials of M and are the scalar invariants of M [$\sigma_1(M)$ is just the trace of M and $\sigma_n(M)$ is the determinant]. All other scalar invariants can be given as polynomials of $\sigma_1(M),\sigma_2(M),\ldots,\sigma_n(M)$. A matrix M for which the characteristic polynomial is just x^n is nilpotent. Now a matrix with the ε-property, i.e., the property that all entries can be made smaller than every given ε by a change of basis, must be nilpotent.[15] The converse is also true, that is, every nilpotent matrix necessarily possesses the ε-property. Therefore, a matrix is VSI_0 if and only if it is nilpotent. Hence we anticipate that VSI space–times will have the ε-property, and this is what we prove next.

Theorem: For and only for VSI space–times (in arbitrary dimension D and C^∞ metric) one can find, for arbitrarily large N and for arbitrarily small ε, a tetrad in which all components of the Riemann tensor and its derivatives up to order N are smaller than ε.

Proof: For non-VSI space–times there always exist a nonvanishing curvature invariant. Its value of course does not depend on the choice of the tetrad and thus there does not exist a tetrad with the desired property. It was proven in Ref. 1 that in four-dimensional VSI space–times the boost weight of all components of the Riemann tensor and its derivatives is negative. Thus with an appropriate boost we can make all components of the Riemann tensor and its derivatives up to a desired order N arbitrarily small.[16,17] □

It was pointed out by Penrose in Ref. 18 that P-types III and N have "the property that gravitational density can be made as small as we please by a suitable choice of time axis (following the wave)." It turns out that for VSI_0 space–times, not only the gravity density but the energy-momentum tensor can be made arbitrarily small by an appropriate boosting of the frame. In the case of VSI_1 space–times we can also make the first derivatives of the Riemann tensor essentially undetectable, and for VSI space–times it is possible to do this for arbitrarily large derivatives as well. Since experiments measure tetrad components of the Riemann tensor and as every experiment has some sensitivity limit, we can effectively, by an appropriate boost, "locally transform away" the Riemann tensor and its derivatives.

It is of interest to consider if any of the VSI space–times satisfy the following stronger ε-property. We shall say that the Riemann tensor has the uniform ε-property if, given an arbitrarily small ε, there exists a tetrad in which the components of the Riemann tensor and all of its derivatives are smaller than ε. Not all VSI space–times satisfy the uniform ε-property; this is shown by considering P-type N vacuum VSI space–times with $\tau \neq 0$. Let us denote

$$X_k = C_{abcd;e_1\cdots e_k} n^a \bar{m}^b n^c \bar{m}^d m^{e_1} \cdots m^{e_k}, \quad Y_k = C_{abcd;e_1\cdots e_k} \delta(n^a \bar{m}^b n^c \bar{m}^d m^{e_1} \cdots m^{e_k}). \tag{4}$$

By induction on k we shall show that the component $C_{2424;3\cdots 3} = X_k = -k!\,\tau^k \Psi_4$ for all orders k. From Ref. 1 we have the following relations:

$$\kappa = \sigma = \rho = \epsilon = 0, \quad \tau = \pi = 2\beta = 2\alpha, \quad \lambda = \mu = (2/3)\gamma, \tag{5}$$

where all of these spin coefficients are real, and ν is nonzero and complex as well. The Bianchi identities and NP equations then give

$$\delta\Psi_4 = -\tau\Psi_4, \quad D\Psi_4 = 0, \quad \delta\tau = \tau^2, \quad D\tau = 0. \tag{6}$$

It can be shown directly that $X_1 = C_{2424;3} = -\tau\Psi_4$, and using strong induction we assume that X_k has the required form. In general, the following recursive relation holds $X_k = \delta X_{k-1} - Y_{k-1}$, consequently this implies that $Y_{k-1} = 2(k-1)!\,\tau^k \Psi_4$. Similarly, $X_{k+1} = \delta X_k - Y_k$, and on expanding Y_k we observe that it is composed of terms with boost weight -2 and -1, but the boost weight -1 terms vanish as a result of a similar proof found in Ref. 1. To show this we note that in this case we have

$$\text{Þ}\Psi_4 = 0, \quad \text{Þ}\tau = 0, \quad \text{Þ}\rho' = -2\tau^2 = \text{Þ}\sigma', \quad \text{Þ}\kappa' = 6\tau\rho' \tag{7}$$

with commutators [19]

$$\text{Þ}\check{\partial} - \check{\partial}\text{Þ} = \tau\text{Þ}, \quad \text{Þ}\text{Þ}' - \text{Þ}'\text{Þ} = 2\tau(\check{\partial} + \check{\partial}') - (p+q)\tau^2.$$

Assuming that η is a tetrad component of the Weyl tensor of arbitrary order k with boost weight -2 such that $\text{Þ}\eta = 0$, it is straightforward to show that the following boost weight -1 scalars,

$$\text{Þ}^3(\kappa'\eta), \quad \text{Þ}^2(\sigma'\eta), \quad \text{Þ}^2(\rho'\eta), \quad \text{Þ}(\tau\eta), \quad \text{Þ}(\tau'\eta), \quad \text{Þ}\check{\partial}\eta, \quad \text{Þ}\check{\partial}'\eta, \quad \text{Þ}^2\text{Þ}'\eta$$

all vanish. Therefore Y_k consists of only the boost weight -2 term, hence we have that $Y_k = -2\tau X_k$ and thus $X_{k+1} = -(k+1)!\,\tau^{k+1}\Psi_4$. Since the component $C_{2424;3\cdots 3}$ can be made arbitrarily large by increasing the order, in this case the Riemann tensor cannot therefore satisfy the uniform ε-property.

A subclass of the VSI space–times for which the uniform ε-property is satisfied are those in which $\nabla^{(N)} R_{abcd} = 0$, where (N) denotes N covariant derivatives. Since only a finite set of components of the Riemann tensor and its derivatives are nonzero, then by an appropriate boost all components of the Riemann tensor and its derivatives can be made smaller than ε. In the case of $N=1$ we have the VSI symmetric spaces in which $\nabla_e R_{abcd} = 0$ (cases in which $N>1$ will be referred to as higher order symmetric spaces); we shall show that this class is nonempty. We consider the following line-element:

$$\mathrm{d}s^2 = 2h\,\mathrm{d}u^2 + 2\,\mathrm{d}u\,\mathrm{d}v - \mathrm{d}x^2 - \mathrm{d}y^2 \tag{8}$$

and solve $\nabla_e R_{abcd} = 0$, assuming that $h = h(u,x,y)$. After an appropriate coordinate transformation, which preserves the form of the metric, we find that $h = k(x^2+y^2) + c^2(x^2-y^2)$ where k and c are arbitrary constants. Using the NP tetrad $\ell^a = \delta^a_v, n^a = \delta^a_u - h\delta^a_v$ and $m^a = (i\delta^a_x - \delta^a_y)/\sqrt{2}$ it follows that the only nonvanishing spin coefficient is ν with Φ_{22} and Ψ_4 being constants. If $k=0$ and $c \neq 0$ we recover the P-type N vacuum symmetric space,[11] if $k \neq 0$ and $c=0$ we obtain the P-type O, PP-type O null radiation symmetric space.[11] These VSI symmetric spaces clearly satisfy the uniform ε-property. In P-type III it is known that no symmetric spaces exist;[11] however, the possibility

remains that P-type III VSI space–times satisfying the uniform ε-property may exist (for example, if $\nabla^{(N)}R_{abcd}=0$ for $N>1$).

To illustrate a higher order symmetric space, consider (8) with $h=g(u)(x^2-y^2)$, a subclass of the P-type N vacuum VSI space–times with $\tau=0$. Next, apply a boost so that $l'=Al$ and $n'=A^{-1}n$ where the boost parameter $A=Cg'(u)$ with C constant. Dropping the primes and working in the boosted frame we have the following nonvanishing scalars, $\nu=-\sqrt{2}g(y+ix)/A^2$, $\gamma=A'/(2A^2)$, and $\Psi_4=-2g/A^2$. It follows that the Weyl tensor has the form [20]

$$C_{abcd}=\tfrac{1}{2}C_{2i2j}\{\ell_a m_b^{(i)}\ell_c m_d^{(j)}\}, \tag{9}$$

where $i,j=3,4, m^{(3)}=\overline{m}$, and $m^{(4)}=m$, the only nonvanishing Weyl tetrad components are $C_{2i2i}=2g/A^2$. Let $X_0=C_{2i2i}$, then (9) is $C_{abcd}=\frac{1}{2}X_0\{\ell_a m_b^{(i)}\ell_c m_d^{(i)}\}$ and

$$\nabla_e C_{abcd}=\tfrac{1}{2}X_1\ell_e\{\ell_a m_b^{(i)}\ell_c m_d^{(i)}\}, \tag{10}$$

where $X_1=\Delta X_0+4\gamma X_0$. It can be shown that the nth order covariant derivative of the Weyl tensor has the following simple form:

$$\nabla_{e_n}\cdots\nabla_{e_1}C_{abcd}=\tfrac{1}{2}X_n\ell_{e_n}\cdots\ell_{e_1}\{\ell_a m_b^{(i)}\ell_c m_d^{(i)}\}. \tag{11}$$

Proceeding inductively, we obtain the following recurrence relation $X_n=\Delta X_{n-1}+2(n+1)\gamma X_{n-1}$. From (11) we have that the only nonvanishing nth order tetrad components of the Weyl tensor will be $C_{2i2i;2\cdots2}$. Again, by induction, one can show that $X_n=2A^{(n-1)}/(CA^{n+2})$ for all $n\geqslant 1$ (denoting the $n-1$ derivative of A as $A^{(n-1)}$ and $A^{(0)}=A$).

We now have an expression for the nth order derivatives of the tetrad components of the Weyl tensor

$$C_{2i2i;2\cdots2}=\frac{2g^{(n)}}{(Cg')^{n+2}}, \tag{12}$$

where it is assumed that $g'\neq 0$, otherwise the boost is degenerate. Therefore, for any $n\geqslant 2$ we can obtain an nth order symmetric space simply by setting $g(u)$ to be any polynomial in u of degree $n-1$. All of these VSI space–times will satisfy the uniform ε-property; more generally this is also satisfied if there exists a constant M such that $|g^{(n)}|\leqslant M$ for all n and $g'\neq 0$. On the other hand, we can use (12) to find examples of VSI space–times that do not satisfy the uniform ε-property. It is known [21] that every geodesic of (8) is either of type 1 or type 2, where type 1 refers to geodesics in the 2-surface u and ν constant and type 2 refers to geodesics in the 2-surface x and y constant. Let us consider type 2 geodesics, and set $x=x_0$, $y=y_0$. We find that the tangent vectors are given by $w^a=(a,b/(2a)-ag(u)(x_0^2-y_0^2),0,0)$ and parametrized by u. Here, $\dot{u}=a$ is a constant and $b=1$ or 0 for timelike or null geodesics, respectively. The NP tetrad defined above is parallel propagated along such geodesics, hence from (12) if the uniform ε-property is not satisfied at some order k then we obtain a parallel propagated curvature singularity of order k. That is, the curvature components of order k in a parallel propagated frame become unbounded along the geodesic; when $k=0$ we recover the definition[22] of a parallel propagated curvature singularity. In Ref. 23, geodesic motion in vacuum Kundt-type N solutions with $\tau\neq 0$ have revealed the existence of parallel propagated curvature singularities of order 0.

IV. CONCLUSION

We have determined the necessary and sufficient conditions that characterize VSI$_1$ space–times. Assuming VSI$_0$, we have shown that in P-type III, VSI$_1$ implies VSI and in P-type O, VSI$_0$ implies VSI. The only proper VSI$_1$ space–times occur in P-type N and PP-type O with $\kappa=\Phi_{12}=0$. In addition, the nonvacuum VSI$_1$ space–times are further characterized by $\sigma\Psi_4=\rho\Phi_{22}$, and the vacuum space–times have $\sigma=\Phi_{22}=0$. It has been shown that the ε-property offers an alternative characterization of the VSI space–times, in the sense that only for VSI space–times can a tetrad be found in which the Riemann tensor and its derivatives up to any fixed order can be made

arbitrarily small. A strengthening of the ε-property leads us to define the uniform ε-property; this condition determines a subclass of the VSI space–times where there exists a tetrad in which the components of the Riemann tensor and all of its derivatives can be made arbitrarily small. Some examples of VSI space–times satisfying the uniform ε-property have been presented.

The Maurer–Cartan structure of BRST differentials

Jining Gao
Department of Mathematics, North Carolina State University, Raleigh, North Carolina 27695-8205

(Received 9 June 2004; accepted 5 March 2005; published online 12 May 2005)

In this paper, we construct a sequence of generators of the BRST complex and reformulate the BRST differential so that it acts on elements of the complex much like the Maurer–Cartan differential acts on left-invariant forms. Thus our BRST differential is formally analogous to the differential defined on the BRST formulation of the Chevalley–Eilenberg cochain complex of a Lie algebra. Moreover, for an important class of physical theories, we show that in fact the differential is a Chevalley–Eilenberg differential. As one of the applications of our formalism, we show that the BRST differential provides a mechanism which permits us to extend a nonintegrable system of vector fields on a manifold to an integrable system on an extended manifold. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904708]

I. INTRODUCTION

Homological algebra has become an indispensable tool for the rigorous formulation of a wide variety of developments in theoretical physics. Applications of these techniques to physics has become so pervasive that they have gradually become identified as a new category of mathematical physics which has been called "cohomological physics" (Refs. 1, 3, and 9). One of the fruitful branches of this theory is the "cohomology" formulation of the BRST theory of constraints. Indeed the point of BRST theory is to replace the cohomology of the reduced space of a physical theory by the cohomology of a homological resolution of the space P being constrained.

In more detail, assume that P is a symplectic manifold and that one has a system of first class constraints on P. Let Σ denote the constraint surface defined as the set of zeros of the constraints. These constraints may or may not be independent. If they are independent they are called irreducible constraints and otherwise they are reducible. The Hamiltonian vector fields of the symplectic manifold P define a possibly singular foliation of Σ and the smooth functions on Σ which are constant on the leaves of this "foliation" are said to be gauge invariant and are called the observables of the theory. There is a differential d, called the longitudinal differential, defined on a certain (dual) Chevalley–Eilenberg complex with coefficients in the algebra $C^\infty(\Sigma)$ whose cohomology in degree zero in the irreducible case is the space of observables. It is clear in the literature that the zero degree cohomology of a certain complex is the space of observables but it is not clear that the complex is a Chevalley–Eilenberg complex and that the longitudinal differential is a Maurer–Cartan differential. These facts are established here in a rigorous manner.

BRST symmetry was developed in order to replace the original gauge symmetry on the constraint surface by a symmetry on the entire phase space P in such a manner that the longitudinal differential d could be extended to a differential S called the BRST differential to be defined on an enlarged complex in such a way that the BRST cohomology in degree zero is precisely the set of observables on Σ. The procedure is nontrivial even in the irreducible case but even more convoluted in the reducible case. An interesting question has to do with whether the BRST differential is a Maurer–Cartan differential (in the sense defined in Sec. II) and whether or not it is actually a Chevalley–Eilenberg differential defined on a (dual) Chevalley–Eilenberg complex as was the case for the longitudinal differential in the irreducible case.

Throughout the paper we almost always use the term BRST to refer to the version developed by Batalin, Fradkin, and Vilkovisky (Refs. 5 and 7) since our differentials are usually defined via an antibracket. This convention is in harmony with the usage of Henneaux and Teitelboim.[6]

The second section is devoted mainly to showing that in the case of irreducible constraints the BRST differential S is in fact a Maurer–Cartan differential and that it is a (dual) Chevalley–Eilenberg differential defined on a Chevalley–Eilenberg complex. Throughout the paper we restrict our attention to bosonic constraints for simplicity of exposition. It is shown that in the case one has a Hamiltonian system subject to bosonic irreducible constraints that the fact that $S^2=0$ implies the existence of a possibly singular "foliation" of the phase space P which agrees with the "foliation" of the constrained space defined by gauge symmetries. Generally, the BRST differential has an expansion

$$S = \delta + d + s_1 + \cdots + s_n + \cdots .$$

The Koszul–Tate differential δ and the longitudinal differential d are well understood but the other terms of the expansion are less well understood. We completely characterize s_1 in the irreducible case. Finally, in this chapter we also consider systems whose constraints are reducible. In particular we introduce a concept which we call an n-reducible complex. This is precisely the idea needed to formulate reducible physical theories rigorously. We show that every differential on such a complex is a mildly generalized Maurer–Cartan differential. In particular we show that the BRST differential is such a generalized Maurer–Cartan differential in the reducible case.

II. THE MAURER–CARTAN STRUCTURE OF BRST DIFFERENTIAL FOR THE IRREDUCIBLE CONSTRAINTS

Let (P,ω) be a n-dimensional symplectic manifold and let $\{,\}$ be the Poisson bracket defined by ω on the algebra of smooth functions $C^\infty(P)$. Assume that G_a, $a=1,\ldots,M$ are constraint functions which satisfy the condition:

$$\{G_a,G_b\} = C^c_{ab}G_c, \tag{2.1}$$

where C^c_{ab} are structure functions on P and let Σ be the constraint surface which is determined by the set of zeros of G_a. When (2.1) is satisfied we say that the constraints G_a are *first class constraints*. The Hamiltonian vector fields X_a corresponding to the functions G_a are defined by $X_a(f)=\{f,G_a\}$ for $f\in C^\infty(P)$. The fields X_a satisfy the condition $[X_a,X_b]\approx C^c_{ab}X_c$, i.e., the equation holds only on Σ, or as we say, they hold only "on shell." Under certain conditions the fields X_a define a foliation of Σ. Functions $f\in C^\infty(\Sigma)$ which are constant on the leaves of the foliation are said to be "gauge invariant" and are called classical observables.

In quantum field theory, it is difficult to utilize path integrals of functionals defined on the space of observables because they are only defined on the constraint surface. To overcome this difficulty the phase space P is extended and the gauge symmetry is replaced by BRST symmetries in a such way that the path integral can be utilized on functionals defined on arbitrary functions on the extended phase space. More precisely, to achieve this, one introduces an antighost variable P_a for every constraint function G_a and a differential δ called the Koszul–Tate differential which is defined on the complex $C[P_a]\otimes C^\infty(P)$ as follows:

$$\delta P_a = -G_a, \tag{2.2}$$

$$\delta f = 0, \tag{2.3}$$

where $f\in C^\infty(P)$. Additionally, new variables η^a are introduced which are in one-to-one correspondence with the space of independent gauge symmetries and another differential d called the longitudinal differential is defined on the complex $C^\infty(P)\otimes C[\eta^b]$ in a manner similar to the difinition of the Chevalley–Eilenberg differential. This differential is designed to implement the gauge symmetries. One extends δ and d to all of $C[P_a]\otimes C[\eta^b]$ by requiring that $\delta(\eta^a)=0$ and

$dP_a=0$. In some cases $\delta+d$ is a differential on the complex $C[P_a]\otimes C^\infty(P)\otimes C[\eta^b]$ whose square is zero and whose cohomology is precisely the space of classical observables. Often this fails to be true and $\delta+d$ must be extended by homological perturbation theory to obtain the (BFV version of the) BRST differential $S=\delta+d+s_1+\cdots$ in order to obtain the observables as zero degree cohomology classes. The differential S is clearly quite different from the longitudinal differential d, but we will show that S satisfies conditions totally analogous to those characterizing d in Henneaux and Teitelboim (Ref. 6, p. 117–119) in the case when the constraint functions are irreducible and bosonic.

Let $\Omega=C[P_a]\otimes C^\infty(P)\otimes C[\eta^b]$ and consider $\Omega^*=\oplus_{p=0}^\infty\Omega^p$, where Ω^p is the subset of Ω having ghost number p (defined below). For simplicity, we introduce the notation $\omega^I=\eta^{b_1}\cdots\eta^{b_{p+1}}P_{a_p}\cdots P_{a_1}$, and $\Omega^1=\{\alpha\in\Omega\,|\,\alpha=u_I\omega^I,u_I\in C^\infty(P)\}$ where I is the multi-index $(b_1,\ldots,b_{p+1},a_1,\ldots,a_p)$. Obviously the elements ω^I generate all Ω^p for $p\geqslant 1$. For completeness and clarity, we first describe our parity conventions as follows:

$$\epsilon(P_a)=\epsilon(G_a)+1=\epsilon(\eta^a),\quad \epsilon(AB)=\epsilon(A)+\epsilon(B). \tag{2.4}$$

Moreover the ghost number grading referred to above is defined as follows.

(1) The pure ghost number of each element of Ω is simply its degree as a polynomial in η^a.
(2) The antighost number of each element of Ω is its degree as a polynomial in P_a.
(3) The ghost number of each element x is the number puregh$(x)-$antigh(x). Notice that for A, $B\in\Omega$, gh$(AB)=$gh$(A)+$gh(B) and that $\epsilon(\omega^I)=1$ whenever $\epsilon(G_a)=0$. With these conventions, we will show that the BRST differential is essentially the Chevalley–Eilenberg differential when the constraints are bosonic and irreducible.

First, we recall how the Chevalley–Eilenberg differential is formulated in BRST notation. Let $\mathcal{G}$ be a Lie algebra spanned by a basis $\{e_i\}$ and $\mathcal{A}$ a commutative associative algebra. Let the mapping $\rho:\mathcal{G}\to\mathrm{End}(\mathcal{A})$ be a representation of $\mathcal{G}$ with representation space $\mathcal{A}$. Introduce a ghost variable η^i for every element e_i of the basis $\{e_i\}$. Let A denote the Z-graded algebra $\mathcal{A}\otimes C[\eta^1,\eta^2,\ldots]$ with the grading defined by the ghost number. The Chevalley–Eilenberg differential $d=d_{\mathrm{CE}}$ is defined on generators of the complex A as follows:

$$\mathrm{d}f=\rho(e_a)(f)\,\eta^a, \tag{2.5}$$

$$\mathrm{d}\eta^a=-\tfrac{1}{2}C^a_{cb}\eta^b\eta^c, \tag{2.6}$$

where f, $C^c_{ab}\in\mathcal{A}$. The mapping $d=d_{\mathrm{CE}}$ is extended to the entire graded algebra A by the Leibniz law

$$d(\alpha\beta)=(\mathrm{d}\alpha)\beta+(-1)^{\deg\alpha}\alpha(\mathrm{d}\beta). \tag{2.7}$$

Any differential which satisfies the conditions (2.5) and (2.6) will be called a Maurer–Cartan differential. Moreover we will say that d is a Chevalley–Eilenberg differential whenever there exists a Lie algebra $\mathcal{G}$ and a representation ρ into the endomorphisms of some commutative associative algebra $\mathcal{A}$ satisfying not only (2.6) but also (2.5) and (2.7). We do not require that our Lie algebra $\mathcal{G}$ be finite dimensional but our Lie algebras are finitely generated as modules over our algebra $\mathcal{A}$.

If we choose $\mathcal{A}=C^\infty(\Sigma)$ where Σ is the constraint surface defined above and if $e_a=X_a$, then the longitudinal differential is a Chevalley–Eilenberg differential of this type. In this case the vector fields X_a must be restricted to Σ and the Lie algebra is the subalgebra of vector fields on Σ spanned by the X_a over the algebra $C^\infty(\Sigma)$. The fact that this is a sub-Lie algebra follows from the identity $[X_a,X_b]=C^d_{ab}X_d+X_{C^d_{ab}}G_d$. The other properties follow immediately. We want to obtain an "off shell" version of this result.

Since $\epsilon(\omega^I)=1$ and $\mathrm{gh}(\omega^I)=1$ we call the set of monomials ω^I multighosts. Moreover, for the BRST differential S, it follows from $S\omega^I \in \Omega^2$, that

$$S\omega^K = -\tfrac{1}{2}C^K_{IJ}\omega^I\omega^J, \tag{2.8}$$

where $C^K_{IJ}=C^K_{JI}\in C^\infty(P)$. Similarly, for $f\in\Omega^0$, one has that $Sf=(\rho_I f)\omega^I$, since $Sf\in\Omega^1$. To summarize, we have following theorem.

Theorem 1: *If the constraint functions $\{G_a\}$ are irreducible and bosonic, the relevant BRST differential S defined on the complex $C[P_a]\otimes C^\infty(P)\otimes C[\eta^b]$ above is a Maurer–Cartan differential,*

$$Sf = (\rho_I f)\omega^I, \tag{2.9}$$

$$S\omega^K = -\tfrac{1}{2}C^K_{IJ}\omega^I\omega^J. \tag{2.10}$$

Notice that even though the longitudinal differential d is not nilpotent on the space $C[P_a]\otimes C^\infty(P)\otimes C[\eta^b]$, its BRST extension S is nilpotent and so is a differential. To determine how the BRST differential S and the longitudinal differential d are related, we compare the following formulas with the formulas (2.5) and (2.6):

$$Sf = (\rho_I f)\omega^I = (X_a f)\eta^a + s_1 f + \cdots + s_n f + \cdots, \tag{2.11}$$

$$S\eta^a = -\tfrac{1}{2}C^a_{cb}\eta^b\eta^c + s_1\eta^a + \cdots.$$

Note that the terms on the right-hand sides of (2.5) and (2.6) are summands of the right-hand side of these equations.

We claim that the BRST differential S is essentially a Chevalley–Eilenberg differential in the case that the constraints are bosonic and irreducible. The required Lie algebra is a sub-Lie algebra of the Lie algebra $\mathcal{X}(P)$ of all vector fields on P. Because of the way S has been extended to products, each of the mappings ρ_I defined by Eq. (2.9) above is a derivation of $C^\infty(P)$ and so is a vector field on P. We consider the submodule $\mathcal{G}(\rho)$ of $\mathcal{X}(P)$ spanned by the vector fields ρ_I over $C^\infty(P)$. We eventually show that it is a sub-Lie algebra of $\mathcal{X}(P)$. Each element of $\mathcal{G}(\rho)$ clearly acts as a derivation of the algebra $\mathcal{A}=C^\infty(P)$ and therefore is in $\mathrm{End}(\mathcal{A})$. Once we establish the fact that $\mathcal{G}(\rho)$ is a Lie algebra we will have the required data in order to show that S is a Chevalley–Eilenberg differential. First we need a lemma which is of interest in its own right.

Lemma 2: Assume that the constraints are bosonic and irreducible and consider the BRST differential S on the complex $C[P_a]\otimes C^\infty(P)\otimes C[\eta^b]$. Let $\rho=\rho_I$ denote the "representation" defined by the identities in Theorem 1. Then

$$S^2 f = \tfrac{1}{2}([\rho_J,\rho_I]f - C^K_{JI}(\rho_K)f)\omega^J\omega^I.$$

Moreover if $S^2 f=0$ for all $f\in C^\infty(P)$, then

$$S^2\omega^K = -\tfrac{1}{6}\{[\rho_I,[\rho_J,\rho_E]]^K + [\rho_J,[\rho_E,\rho_I]]^K + [\rho_E,[\rho_I,\rho_J]]^K\}.$$

Proof: We prove the first identity by noticing that since S is an odd derivation, we have

$$S^2 f = S((\rho_I f)\omega^I) = S(\rho_I f)\omega^I + (\rho_I f)S\omega^I. \tag{2.12}$$

It follows from the identities of Theorem 1 that

$$S^2 f = (\rho_J \rho_I)(f)\omega^J \omega^I + (\rho_I f)\left(-\tfrac{1}{2} C^I_{JK} \omega^J \omega^K\right) \tag{2.13}$$

$$= \tfrac{1}{2}[(\rho_J \rho_I) f - (\rho_I \rho_J) f]\omega^J \omega^I - \tfrac{1}{2} C^I_{JK} \omega^J \omega^K \rho_I f \tag{2.14}$$

$$= \tfrac{1}{2}[\rho_J, \rho_I] f \omega^J \omega^I - \tfrac{1}{2} C^K_{JI} \omega^J \omega^I (\rho_K) f \tag{2.15}$$

$$= \tfrac{1}{2}([\rho_J, \rho_I] f - C^K_{JI}(\rho_K) f)\omega^J \omega^I. \tag{2.16}$$

Thus the first of the two identities is true. We now prove the second identity. Since $S\omega^K = -\frac{1}{2} C^K_{IJ} \omega^I \omega^J$, where $I = (b_1, \ldots, b_{p+1}, a_1, \ldots, a_p)$ and $J = (\tilde{b}_1, \ldots, \tilde{b}_{p+1}, \tilde{a}_1, \ldots, \tilde{a}_p)$, we have

$$\begin{aligned}
S^2 \omega^K &= -\tfrac{1}{2}(S C^K_{IJ})\omega^I \omega^J - \tfrac{1}{2} C^K_{IJ} d\omega^I \omega^J + \tfrac{1}{2} C^K_{IJ} \omega^I d\omega^J \\
&= -\tfrac{1}{2}(\rho_E C^K_{IJ})\omega^E \omega^I \omega^J - \tfrac{1}{2} C^K_{IJ}\left(-\tfrac{1}{2} C^I_{\tilde{K}\tilde{L}} \omega^{\tilde{K}} \omega^L\right)\omega^J + \tfrac{1}{2} C^K_{IJ} \omega^I \left(-\tfrac{1}{2} C^J_{MN} \omega^M \omega^N\right) \\
&= -\tfrac{1}{2} \rho_E C^K_{IJ} \omega^E \omega^I \omega^J + \tfrac{1}{4} C^K_{IJ} C^I_{\tilde{K}\tilde{L}} \omega^{\tilde{K}} \omega^L \omega^J - \tfrac{1}{4} C^K_{IJ} C^J_{MN} \omega^I \omega^M \omega^N \\
&= -\tfrac{1}{2} \rho_E C^K_{IJ} \omega^E \omega^I \omega^J + \tfrac{1}{2} C^K_{IJ} C^I_{\tilde{K}\tilde{L}} \omega^{\tilde{K}} \omega^L \omega^J \\
&= -\tfrac{1}{6}(\rho_E C^K_{IJ} + \rho_I C^K_{JE} + \rho_J C^K_{EI})\omega^I \omega^J \omega^E + \tfrac{1}{6}(C^K_{MI} C^M_{JE} + C^K_{MJ} C^M_{EI} + C^K_{ME} C^M_{IJ})\omega^I \omega^J \omega^E \\
&\quad + \tfrac{1}{6}(\rho_E C^K_{IJ} + \rho_I C^K_{JE} + \rho_J C^K_{EI})\omega^I \omega^J \omega^E - \tfrac{1}{6}(C^K_{IM} C^M_{JE} + C^K_{JM} C^M_{EI} + C^K_{EM} C^M_{IJ})\omega^I \omega^J \omega^E.
\end{aligned} \tag{2.17}$$

Next notice that if we assume that $S^2 f = 0$ for all $f \in C^\infty(P)$, then $[\rho_J, \rho_E] = C^M_{JE} \rho_M$, $[\rho_E, \rho_I] = C^M_{EI} \rho_M$, $[\rho_I, \rho_J] = C^M_{IJ} \rho_M$, and we have

$$[\rho_I, [\rho_J, \rho_E]] = [\rho_I, C^M_{JE} \rho_M] = (\rho_I C^M_{JE})\rho_M + C^M_{JE}[\rho_I, \rho_M] \tag{2.18}$$

$$= (\rho_I C^M_{JE})\rho_M + C^M_{JE} C^K_{IM} \rho_K \tag{2.19}$$

$$= (\rho_I C^K_{JE} + C^M_{JE} C^K_{IM})\rho_K. \tag{2.20}$$

It follows that

$$[\rho_J, [\rho_E, \rho_I]] = (\rho_J C^M_{EI})\rho_M + C^M_{EI} C^K_{JM} \rho_K \tag{2.21}$$

$$= (\rho_J C^K_{EI} + C^M_{EI} C^K_{JM})\rho_K \tag{2.22}$$

and

$$[\rho_E, [\rho_I, \rho_J]] = (\rho_E C^M_{IJ})\rho_M + C^M_{IJ} C^K_{EM} \rho_K \tag{2.23}$$

$$= (\rho_E C^K_{IJ} + C^M_{IJ} C^K_{EM})\rho_K. \tag{2.24}$$

It follows from this last calculation that the negative of the sum of the Kth components of the right-hand sides of the last three equations is precisely six times the right-hand side of the identity for $S^2 \omega^K$ [see (2.17)]. The lemma follows.

Corollary 3: Assume that the constraints are bosonic and irreducible and consider the BRST differential S on the complex $C[P_a] \otimes C^\infty(P) \otimes C[\eta^b]$. *Since in fact* $S^2 = 0$ *we have that* $\mathcal{G}(\rho)$ *is a Lie subalgebra of* $\mathcal{X}(P)$ *with generators the set of vector fields* $\{\rho_I\}$ *on* $C^\infty(P)$.

Corollary 4: If the constraints of a Hamiltonian system are bosonic and irreducible, then the BRST differential is a Chevalley–Eilenberg differential on the complex $\mathcal{A} \otimes C[\omega^I]$ *where the alge-*

bra $\mathcal{A}$ is the algebra of smooth functions on P and where the ω^I are called multighosts instead of ghosts. Recall that the ω^I freely generate $\mathcal{A}\otimes C[\omega^I]$ as a module over $\mathcal{A}$.

Proof: The proof was outlined in the observations just prior to the lemma. The only gap in the argument was that we had not yet proved that $\mathcal{G}(\rho)$ is a Lie algebra which we now see is a corollary of the lemma.

Remark: The longitudinal differential d was initially defined "on shell," that is to say the underlying manifold was the constraint surface Σ. Formulated on this surface the square of d is zero and its cohomology in degree zero is the set of classical observables. The fact that d squares to zero "on shell" is related to the fact that the Hamiltonian vector fields X_a close under Lie brackets "on shell." They need not close "off shell."

In order to use the path integral formalism it is useful to extend the formalism "off shell." When the longitudinal differential d is extended "off shell" it no longer squares to zero and in fact the BRST differential was constructed to repair this defect.[6]

The fact that the BRST differential squares to zero "off shell" suggests that one should be able to supplement the vector fields X_a with other fields to obtain an integrable system which "foliates" P in such a manner that the possibly singular leaves provides the "foliation" of Σ provided by the Hamiltonian vector fields. We now show that this is true.

Recall that the generators ρ_I of the Lie algebra $\mathcal{G}(\rho)$ correspond to the multighosts $\omega^I = \eta^{b_1}\cdots\eta^{b_{p+1}}P_{a_p}\cdots P_{a_1}$ where I is the multi-index $(b_1,\ldots,b_{p+1},\ a_1,\ldots,a_p)$. In the case $p=0$ it is understood that ω^I is simply η^b for some index b. Thus the equation $S(f)=(\rho_I f)\omega^I$ of Theorem 1 has the terms $(\rho_a f)\eta^a$ as certain of its summands, where d is the exterior differential and s_k is a derivation which increases the antighost degree by k. Recall that these latter terms correspond to the longitudinal differential d in the expansion

$$S = \delta + d + s_1 + \cdots + s_n + \cdots . \tag{2.25}$$

of the BRST differential. Indeed for every $f\in C^\infty(P)$,

$$Sf = (\rho_a f)\eta^a + (\rho_I f)\omega^I + \cdots , \tag{2.26}$$

where antidegree $(\omega^I)\geqslant 1$, and we see that $\rho_a f$ is exactly the action of X_a on f. Consequently the ρ_a are simply the Hamiltonian vector fields X_a. The supplementary vector fields we require to obtain an integrable system are defined by $X_I=\rho_I$.

As an immediate consequence of these observations we have the following theorem.

Theorem 5: *The longitudinal differential d is defined in terms of the Hamiltonian vector fields X_i which form an open gauge algebra since $[X_i,X_j]\approx C_{ij}^k X_k$. Since $S^2=0$, there exists additional vector fields X_I on P such that $[X_i,X_j]=C_{ij}^k X_k + C_{ij}^I X_I$, and the fields X_i, X_I define an integrable system in the sense that they generate a subalgebra $\mathcal{G}(\rho)$ of the Lie algebra of all vector fields of P.*

We now determine further conditions imposed on the ρ_K by the fact that S is nilpotent.

Using (2.25) and the fact that $S^2=0$, the first three terms of the expansion of S^2 in terms of the antighost degree yields

$$\delta^2 = 0, \tag{2.27}$$

$$[\delta,d] = 0, \tag{2.28}$$

$$d^2 = -[\delta,s_1]. \tag{2.29}$$

By a calculation similar to the one in the proof of the lemma, and for arbitrary $f\in C^\infty(P)$ we have

$$d^2 f = \tfrac{1}{2}([\rho_i, \rho_j] f - C_{ij}^k \rho_k f)\, \eta^i \eta^j, \tag{2.30}$$

$$[\delta, s_1] f = (\delta s_1 f + s_1 \delta f) \tag{2.31}$$

$$= \delta s_1 f = \delta(\rho_{ab}^c f \eta^a \eta^b P_c), \tag{2.32}$$

where the ρ_{ab}^c are defined by the equation $s_1 f = \omega^I f = \rho_{ab}^c f \eta^a \eta^b P_c$ and the multi-index I is (abc). It follows that

$$[\delta, s_1] f = (\rho_{ab}^c f)\, \eta^a \eta^b P_c \tag{2.33}$$

$$= -(G_c)(\rho_{ab}^c f)\, \eta^a \eta^b. \tag{2.34}$$

Using the three identities above and comparing (2.30) with (2.34), we have

$$[X_j, X_i] = C_{ji}^k X_k + G_c \rho_{ij}^c. \tag{2.35}$$

Since ω^I is a derivation for each multi-index I we see that each ρ_{ij}^c is also a derivation on $C^\infty(P)$; we distinguish it from the derivation ρ_k by referring to it as a second order derivation.

We now show how these results may be applied to Hamiltonian systems having first-class constraints restricting our remarks to the case where P is R^n for some positive integer n. We adopt the same conventions as in Ref. 6 (pp. 52–53), in particular, let $G_a (a = 1, \ldots, M)$ denote the constraint functions of the system. Define vectors $X_a = X_a^\lambda \partial_\lambda$ via $X_a^\lambda = \omega^{\lambda\mu} \partial_\mu G_a$, where the matrix of components of the antisymmetric tensor $(\omega^{\lambda\mu})$ is the inverse of the matrix $\omega_{\mu\nu}$ of components of the symplectic structure ω on P. We observe that, for each $F \in C^\infty(P)$,

$$X_a F = X_a^\lambda \partial_\lambda F = \{F, G_a\}. \tag{2.36}$$

We know that if X_a^λ corresponds to G_a and X_b^λ corresponds to G_b then $[X_a, X_b]^\lambda$ corresponds to $[G_a, G_b]$. Moreover,

$$[X_a, X_b]^\lambda = \omega^{\lambda\mu} \partial_\mu (C_{ab}^c G_c) \tag{2.37}$$

$$= C_{ab}^c X_c^\lambda + G_c \omega^{\lambda\mu} \partial_\mu C_{ab}^c \approx C_{ab}^c X_c^\lambda. \tag{2.38}$$

Off the constraint surface, the second term on the right-hand side of (2.38) does not vanish unless $\partial_\mu C_{ab}^c = 0$. Thus $X_a^\lambda (a = 1, \ldots, M)$ form a closed distribution only on shell $G_a = 0$.

For the remainder of this section we provide a detailed calculation which determine consistency conditions for the summand s_1 (2.25).

First we determine the action of s_1 on the ghosts η^α. Since the vector fields $\{X_a\}$ satisfy the Jacobi identity it follows from a computation similar to the one of Lemma 2.2 that $d^2 \eta^a = 0$. Combined with the facts that $d^2 = -[\delta, s_1]$ and that $s_1 \eta^\alpha$ has antighost number one we have $s_1 \eta^\alpha = C_{abc}^{d\alpha} \eta^a \eta^b \eta^c P_d$. Then,

$$0 = -(\delta s_1 + s_1 \delta)\, \eta^\alpha = -\delta s_1 \eta^\alpha = C_{abc}^{d\alpha} \eta^a \eta^b \eta^c G_d. \tag{2.39}$$

Therefore $C_{abc}^{d\alpha} \eta^a \eta^b \eta^c G_d = 0$ and consequently we obtain the following consistency condition:

$$C_{abc}^{d\alpha} G_d = 0. \tag{2.40}$$

At this point we derive other consistency conditions which are required in order to compute $s_1 P_a$. Since d increases the ghost number by one we can write $dP_a = \eta^c C_{ca}^b P_b$ and

$$d^2P_a = d(dP_a) = d(\eta^c C^b_{ca} P_b) = (d\eta^c) C^b_{ca} P_b - \eta^c d(C^b_{ca} P_b)$$
$$= \left(-\tfrac{1}{2} C^c_{de} \eta^d \eta^e\right) P_b C^b_{ca} - \eta^c (\rho_d(C^b_{ca})\eta^d P_b + C^b_{ca} dP_b)$$
$$= -\tfrac{1}{2} C^c_{de} C^b_{ca} \eta^d \eta^e P_b - \rho_d(C^b_{ca})\eta^c \eta^d P_b - C^b_{ca} \eta^c (\eta^e C^d_{eb} P_d)$$
$$= \left(-\tfrac{1}{2} C^b_{ce} C^d_{ba} - C^b_{ca} C^d_{eb} - \rho_e(C^d_{ca})\right) \eta^c \eta^e P_d. \tag{2.41}$$

Since s_1 increases the antighost number by one we can write $s_1 P_a = C^{ef}_{cda} \eta^c \eta^d P_e P_f$. It follows that

$$\delta s_1 P_a = \delta(C^{ef}_{cda} \eta^c \eta^d P_e P_f) \tag{2.42}$$

$$= C^{ef}_{cda} \eta^c \eta^d ((\delta P_e) P_f - P_e \delta P_f) \tag{2.43}$$

$$= C^{ef}_{cda} \eta^c \eta^d (-G_e P_f + G_f P_e) \tag{2.44}$$

$$= -C^{ef}_{cda} G_e \eta^c \eta^d P_f + C^{ef}_{cda} G_f \eta^c \eta^d P_e \tag{2.45}$$

$$= 2C^{ef}_{cda} \eta^c \eta^d P_e G_f \tag{2.46}$$

and

$$s_1 \delta P_a = s_1(-G_a) = -s_1 G_a \tag{2.47}$$

$$= -(\rho^e_{cd} G_a) \eta^c \eta^d P_e. \tag{2.48}$$

Thus

$$(\delta s^1 + s^1 \delta) P_a = (2C^{ef}_{cda} G_f - \rho^e_{cd}(G_a)) \eta^c \eta^d P_e \tag{2.49}$$

$$= (2C^{df}_{cea} G_f - \rho^d_{ce}(G_a)) \eta^c \eta^e P_d. \tag{2.50}$$

Since $d^2 = -[\delta, s^1]$, by comparing (2.41) and (2.50) we have the following consistency conditions:

$$C^{df}_{cea} G_f = \tfrac{1}{2}\left(\rho^d_{ce}(G_a) + \rho_e(C^d_{ca}) + \tfrac{1}{2} C^b_{ce} C^d_{ba} + C^b_{ca} C^d_{eb}\right). \tag{2.51}$$

Notice that in case the constraint functions are irreducible this condition is equivalent to requiring that the left-hand side of (2.51) vanish "on shell."

In the last few paragraphs we have obtained consistency conditions (2.40) and (2.51) which are necessary in order to determine the action of s_1 on the generators. We have not attempted to determine the coefficients $C^{d\alpha}_{abc}$ and C^{df}_{cea} in the consistency equations since they can only guarantee the existence of perturbation terms of s_1.

III. THE MAURER–CARTAN STRUCTURE OF BRST DIFFERENTIAL UNDER THE REDUCIBLE CONSTRAINTS

In the preceding section we dealt only with irreducible constraints. In this section, we will generalize some of our results to include systems of reducible constraints. To achieve that, we introduce the concept of an *n*-reducible complex as follows.

Definition: Let $\Omega^* = \oplus_{n=0}^{\infty} \Omega^n$ be a graded algebra and assume that Ω^0 is an algebra such that Ω^* is a Ω^0-module. Let $A^p = \oplus_{n=0}^{p} \Omega^n$. If A^p is a finitely generated Ω^0-module and each component $\Omega^k (k > p)$ is generated by A^p, we call the complex Ω^* a *p*-reducible complex.

We are interested in investigating differentials on *p*-reducible complexes. First consider some examples of *p*-reducible complexes.

Example 1: Let R^n be *n*-dimensional Euclidean space and $\Omega^k(R^n)$ be the space of *k*-forms.

Since R^n has a global coordinate chart $(x^1,\ldots,x^n)$, every k-form can be written as

$$\omega = \omega_{i_1\cdots i_k} \mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_k}, \tag{3.1}$$

where $\omega_{i_1\cdots i_k}$ are smooth functions which belong to the space of 0-forms $\Omega^0(R^n)$, and where the 1-forms $\mathrm{d}x^1,\cdots,\mathrm{d}x^n$ generate all differential forms in $\Omega^k(R^n)$ over $\Omega^0(R^n)$ for $k\geqslant 1$. The complex $\Omega^*(R^n)=\oplus_{k=0}^n \Omega^k(R^n)$ is then a 1-reducible complex. The exterior differential d is defined as follows:

$$\mathrm{d}f = (\partial_i f)\mathrm{d}x^i, \tag{3.2}$$

$$d(\mathrm{d}x^i) = 0, \tag{3.3}$$

where $f\in\Omega^0(R^n)$, $\mathrm{d}x^i\in\Omega^1(R^n)$. One then extends the definition above to the entire space $\Omega^*(R^n)$ via the Leibniz formula.

Example 2 (Chevalley–Eilenberg cohomology): Let a pair (d,A) be a Chevalley–Eilenberg differential with its related complex $A=\mathcal{A}\otimes C[\eta^1,\eta^2,\ldots]$ discussed earlier. Obviously, the graded algebra A is generated by ghosts $\eta^1,\eta^2,\ldots$ over the underlying algebra $\mathcal{A}$ and consequently the complex A is a 1-reducible complex.

Example 3 (auxillary differential Δ): Typical kth reducible complexes arise from BRST operators in case the system is subject to $(k-1)$-reducible constraint conditions.

In BRST theory, a specific differential called the auxillary differential Δ is introduced to deal with longitudinal differentials defined on constraint surfaces subject to higher order reducibility conditions. Let Σ be a constraint surface and $\{\eta^{a_0}\}$ be the original ghosts (see Ref. 6 pp. 217–218).

Assume that Σ is defined by constraints which satisfy kth order reducibility conditions. In this case the reducibility of the constraints can be written as

$$Z^{a_{k-1}}_{a_k} Z^{a_{k-2}}_{a_{k-1}} = (-1)^{\epsilon_{a_{k-2}}} C^{a_{k-2},a_0}_{a_k} G_{a_0}, \tag{3.4}$$

$$k=1,\ldots,L, \quad a_k = 1,\ldots,m_k \tag{3.5}$$

for some m_k and appropriate functions $Z^{a_{k-1}}_{a_k}$ (see Ref. 6, p. 210).

Introduce higher order ghost variables η^{a_k} along with a differential Δ as follows:

$$\mathrm{puregh}(\eta^{a_k}) = k+1, \quad \epsilon(\eta^{a_k}) = \epsilon_{a_k} + k + 1, \tag{3.6}$$

$$\Delta F = 0, \quad \Delta\eta^{a_k} = \eta^{a_{k+1}} Z^{a_k}_{a_{k+1}} (-1)^{\epsilon_{a_k}+k+1}, \tag{3.7}$$

where F is an arbitary function on the constraint surface. To complete the definition of the auxillary differential Δ, one needs to introduce an auxillary grading as follows:

$$\mathrm{aux}(z^A) = 0 = \mathrm{aux}(\eta^{a_0}), \quad \mathrm{aux}(\eta^{a_k}) = k. \tag{3.8}$$

One then has that $\mathrm{aux}(\Delta)=1$ and that $\mathrm{puregh}(A)=\mathrm{aux}(A)+\deg(A)$. The complex $\Omega=C^\infty(\Sigma)\otimes C[\eta^{a_0},\eta^{a_1},\ldots,\eta^{a_k}]$ is then a $(k+1)$-reducible complex.

At this point, we characterize the differential on an arbitrary n-reducible complex and thereby generalize Theorem 1. We adopt the convention of the left action for d. Obviously, a differential d on a reducible complex Ω^* is uniquely and totally determined by its values on the space $A^p=\Omega^0\oplus\overline{A^p}$ and the Leibniz rule, where $\overline{A^p}=\oplus_{n=1}^p \Omega^n$. In order to see this in more detail we first assume that the finitely generated Ω^0 module A^p has a finite basis denoted by $(\omega^i_n)_{1\leqslant n\leqslant p}$ where the subindex means that $\omega^i_n\in\Omega^n$. Notice that the basis (ω^i_n) generates all the elements of every component Ω^k for $k>p$. With this notation, we define a differential d on the space A^p as follows:

$$\mathrm{d}f = (\rho^1_j f)\omega^j_1, \tag{3.9}$$

$$d\omega_m^i = -\tfrac{1}{2}\Sigma_{1\leqslant n\leqslant m} C_{jkn}^i \omega_{m-n+1}^j \omega_n^k, \tag{3.10}$$

where $f \in \Omega^0$ and the ρ_j^1 are derivations of Ω^0. If the complex Ω^* is a 1-reducible complex, the basis has only elements of the form ω_1^i and the formulas (3.9) and (3.10) reduce to

$$df = (\rho_j f)\omega_1^j \tag{3.11}$$

$$d\omega_1^i = -\tfrac{1}{2} C_{jk}^i \omega_1^j \omega_1^k \tag{3.12}$$

analogous to the formulas given by the Chevalley–Eilenberg differential.

The definition of the Koszul–Tate differential δ is then modified to reflect the reducibility conditions above. In the reducible case the longitudinal differential is not nilpotent on the space of $C^\infty(\Sigma)\otimes C[\eta^a]$, but is nilpotent on the subalgebra of longitudinal forms. In order to overcome this defect, an equivalent differential D (Ref. 6) is introduced such that $H^*(D)=H^*(d)$. At this point one has "differentials" δ and D on the extended space $\Omega^*=C[P_{a_0}, P_{a_1}, \ldots]\otimes C^\infty(\Sigma)\otimes C[\eta^{a_1}, \eta^{a_2}, \ldots]$ and it is possible to show that a BRST differential $S=\delta+D+s_1+\cdots$ defined on the complex Ω^* exists. It can be seen that the longitudinal complex $C^\infty(\Sigma)\otimes C[\eta^a]$ and the BRST complex Ω^* are both n-reducible complexes for appropriate n. Therefore we obtain the following generalization of Theorem 1. (See Refs. 2, 4, 8, and 10.)

Theorem 6: *If the constraints are bosonic and reducible the BRST differential has a structure similar to that of the longitudinal differential.*

(Received 2 March 2005; accepted 18 March 2005; published online 16 May 2005)

In this paper, an explicit expression for the Casimir operator (or the Casimir invariant) of the inhomogeneous group ISL(n,R) in its enveloping algebra is proposed, which using contractions of the tensorial indices of the generating operators P^{ρ} and E^{ν}_{μ} may be presented in the following [slightly more comprehensible as Eq. (1)] form. The Casimir is obtained by symmetrizing this expression. This tensor form is useful in the classification of particles in affine gravitational gauge theories; such as that based on ISL($4,R$). It is also proven that the Casimir of ISL(n,R) can be decomposed in terms of the Casimirs of its little groups, a key point in the posterior construction of its irreducible representations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1915291]

I. INTRODUCTION

The special affine group ISL(n,R) is the semidirect product of the Abelian group of translations in n dimensions and the special linear, SL(n,R). The ISL($4,R$) group has been chosen as the gauge group in gauge theories of gravity;[1] therefore, the knowledge of its Casimirs will be necessary not only to investigate the irreducible representations of this group, but also to provide these theories with a wave equation.[2] It has been conjectured that a gauge theory for quantum gravity can be developed by enlarging the Poincare group to the group IGL($4,R$)[5]. However, the lack of invariants of this group,[3] prevents to classify the elementary particles of a theory based on that gauge group. Therefore, ISL($4,R$) is the best selection.[1,4] The group ISL(n,R) has a subgroup, the Poincare group, from which stems its importance in physics. The eigenvalues of the Casimir of the group ISL(n,R) provide quantum numbers to classify the particles of these theories in the same way that the eigenvalues of the Casimirs of the Poincare groups allow us to classify the particles according to their mass and spin. The eigenvalues of the Casimir of ISL(n,R) label the irreducible representations of the group. The invariants are also useful ingredients in the decomposition of reducible representations into irreducible ones. In the case of gauge theories of gravity based on ISL(n,R), it is important to decompose the unitary irreducible representations of the group ISL(n,R) into the unitary irreducible representations of the Poincare subgroup. This would bring a physical insight into the behavior of the elementary particles of these theories. In Sec. II, we construct the formula for the Casimir of ISL(n,R). In Sec. III, we discuss the induction proof used to guarantee the general validation of the formula for the Casimir of ISL(n,R). Finally in Sec. IV, the algebraic decomposition of ISL(n,R) is achieved.

II. CONSTRUCTION OF THE FORMULA FOR THE CASIMIR OF ISL(n,R)

In Ref. 3 it is proved that the group ISL(n,R) has one invariant. And in Ref. 6 it is proved that the order of this invariant is $\frac{1}{2}n(n+1)$. Based on this proof, the standard procedure for constructing

---

[a)]Present address: Institute for Advanced Technology, The University of Texas at Austin, Ausin, Texas 78712.

invariants by contracting tensorial indices with the Levi–Civita antisymmetric pseudotensor and the generators of the Lie group,[7] we found a formula for the invariant of ISL(n,R). This expression is given by

$$\begin{aligned} \textit{Casimir ISL}(n,R) = \{ & \zeta^{\rho_1[(\theta_{11})\rho_2]\ldots,[(\theta_{n-2,1},\ldots,\theta_{n-2,n-2})\rho_{n-1}]}_{\xi_0\alpha_1,\ldots,\alpha_{n-1}\beta_1[\beta_2(\gamma_{11})],\ldots,[\beta_{n-1}(\gamma_{n-2,1},\ldots,\gamma_{n-2,n-2})]} \\ & \times P^{\xi_0}P^{\alpha_1}\cdots P^{\alpha_{n-1}}E^{\beta_1}_{\rho_1}E^{[\beta_2(\gamma_{11})]}_{[(\theta_{11})\rho_2]}\cdots E^{[\beta_{n-1}(\gamma_{n-2,1},\ldots,\gamma_{n-2,n-2})]}_{[(\theta_{n-2,1},\ldots,\theta_{n-2,n-2})\rho_{n-1}]}\}_{\textit{symmetrized}}, \end{aligned} \tag{1}$$

$$\xi_0,\theta_{ij},\gamma_{ij},\alpha_l,\rho_k,\beta_m = 0,1,\ldots,n-1, \quad i,j = 1,2,\ldots,n-2, \quad l,k,m = 1,2,\ldots,n-1,$$

where

$$E^{[\beta_2(\gamma_{11})]}_{[(\theta_{11})\rho_2]} = E^{\beta_2}_{\theta_{11}}E^{\gamma_{11}}_{\rho_2}$$

and

$$E^{[\beta_{n-1}(\gamma_{n-2,1},\ldots,\gamma_{n-2,n-2})]}_{[(\theta_{n-2,1},\ldots,\theta_{n-2,n-2})\rho_{n-1}]} = E^{\beta_{n-1}}_{\theta_{n-2,1}}E^{\gamma_{n-2,1}}_{\theta_{n-2,2}}\cdots E^{\gamma_{n-2,n-3}}_{\theta_{n-2,n-2}}E^{\gamma_{n-2,n-2}}_{\rho_{n-1}},$$

where $\zeta^{\cdots}_{\ldots\ldots}$ is given by the expression

$$\zeta^{\cdots}_{\ldots\ldots} = \epsilon_{\xi_0\beta_1\cdots\beta_{n-1}}(\delta_{\rho_1\alpha_1}\cdots\delta_{\rho_{n-1}\alpha_{n-1}})((\delta_{\theta_{11}\gamma_{11}})(\delta_{\theta_{21}\gamma_{21}}\delta_{\theta_{22}\gamma_{22}})\cdots(\delta_{\theta_{n-2,1}\gamma_{n-2,1}}\cdots\delta_{\theta_{n-2,n-2}\gamma_{n-2,n-2}})). \tag{2}$$

The E^{β}_{α} are the generators of the general linear group GL(n,R) in the Weyl basis[2] and the P^{α} are the generators of the Abelian subgroup of ISL(n,R). In formula (1), the following substitution must be carried out:

$$\mathbf{E}^{\alpha}_{\alpha} = E^{\alpha}_{\alpha} - E^{\alpha+1}_{\alpha+1}. \tag{3}$$

The commutation relations of ISL(n,R), are given then by

$$[P^{\rho},P^{\nu}] = 0, \quad [P^{\rho},E^{\nu}_{\mu}] = \delta_{\mu\rho}P^{\nu}, \quad [E^{\nu}_{\mu},E^{\tau}_{\lambda}] = \delta_{\nu\lambda}E^{\tau}_{\mu} - \delta_{\mu\tau}E^{\nu}_{\lambda}. \tag{4}$$

The E^{α}_{α}, the generators of the general linear group GL(n,R), are substituted by the traceless generators $\mathbf{E}^{\alpha}_{\alpha}$ of the special linear group SL(n,R). In Eq. (2), we define $\epsilon_{\xi_0}=1$.

III. THE INDUCTION PROOF

In Ref. 8, it is proved that the invariant of ISL(n,R) can be obtained by solving a system of linear first order partial differential equations (LFPDE). The system of LFPDE can trivially be solved for $n=1$. Thus, the first part of the induction is proven. In order to prove the second part of the induction method, we assume the formula is valid for $n=k$ and then prove that it is valid for $n=k+1$.

We can construct a scalar of the order required by Lemma 1, in Ref. 6, to be the invariant of ISL$(k+1,R)$. According to this lemma, the order of the invariant in the generators of this group should be $\frac{1}{2}(k+1)(k+2)$. In this same reference, it is proven that the invariant for this group would be of $k+1$ order in the generators of the translations. Therefore the invariant for ISL$(k+1,R)$ must be of $k+1$ order in the translations and of $\frac{1}{2}k(k+1)$ order in the nontranslations generators of the group ISL$(k+1,R)$. That is, the invariant of ISL$(k+1,R)$ must be different from the invariant for ISL(k,R) by a factor given by

$$P^{\alpha_k}E^{[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-1})]}_{[(\theta_{k-1,1},\ldots,\theta_{k-1,k-1})\rho_k]}. \tag{5}$$

If we take into account the form of the invariants of ISL(n,R) for $n=1,2,3,4$ (Ref. 6) the formula we are assuming valid for $n=k$ and the factor given above, we can construct a scalar given by

$$\begin{aligned} \textit{Casimir ISL}(k+1,R) = \{ & \zeta^{\rho_1[(\theta_{11})\rho_2],\ldots,[(\theta_{k-2,1},\ldots,\theta_{k-2,k-2})\rho_{k-1}][(\theta_{k-1,1},\ldots,\theta_{k-1,k-1})\rho_k]}_{\xi_0\alpha_1,\ldots,\alpha_{k-1}\alpha_k\beta_1[\beta_2(\gamma_{11})],\ldots,[\beta_{k-1}(\gamma_{k-2,1},\ldots,\gamma_{k-2,k-2})][\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-1})]} \\ & \times P^{\xi_0}P^{\alpha_1}\cdots P^{\alpha_{k-1}}P^{\alpha_k}E^{\beta_1}_{\rho_1}E^{[\beta_2(\gamma_{11})]}_{[(\theta_{11})\rho_2]}\cdots E^{[\beta_{k-1}(\gamma_{k-2,1},\ldots,\gamma_{k-2,k-2})]}_{[(\theta_{k-2,1},\ldots,\theta_{k-2,k-2})\rho_{k-1}]} \\ & \times E^{[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-1})]}_{[(\theta_{k-1,1},\ldots,\theta_{k-1,k-1})\rho_k]}\}_{\textit{symmetrized}}. \end{aligned} \tag{6}$$

This formula coincides with the Eq. (1) for $n=k+1$. However, the proof is not yet complete, since the scalar that we have constructed to be the invariant of ISL($k+1,R$) could be zero. Therefore, we must prove that the scalar given by Eq. (5) is not zero.

IV. THE ALGEBRAIC DECOMPOSITION OF ISL(N,R)

The proof that the scalar given by Eq. (5) does not vanish is based on an algebraic decomposition of the Casimir of ISL(n,R) in terms of the Casimirs of its little groups. This decomposition allows an immediate classification of the existent particles in a theory based on ISL(n_1,R), with n_1 any number.[5] Then making all the translations equal zero except P^0 in Eq. (5). That is,

$$\xi_0 = \alpha_1 = \cdots = \alpha_k = 0,$$

therefore

$$\rho_1 = \rho_2 = \cdots = \rho_k = 0.$$

Hence, the Casimir with all the translations zero except P^0 is given by

$$\begin{aligned} \textit{Casimir ISL}(k+1,R) = \{ & (P^0)^{k+1}\zeta^{0[(\theta_{11})0],\ldots,[(\theta_{k-1,1},\ldots,\theta_{k-1,k-1})0]}_{00,\ldots,0\beta_1[\beta_2(\gamma_{11})],\ldots,[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-1})]}E^{\beta_1}_0E^{\gamma_{11}}_0\cdots E^{\gamma_{k-1,k-1}}_0 \\ & \times E^{\beta_2}_{\theta_{11}}E^{[\beta_3(\gamma_{21})]}_{[(\theta_{21})\theta_{22}]}\cdots E^{[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-2})]}_{[(\theta_{k-1,1},\ldots,\theta_{k-1,k-2})\theta_{k-1,k-1}]}\}_{\textit{symmetrized}}, \end{aligned} \tag{7}$$

where

$$\begin{aligned} \zeta^{0[(\theta_{11})0],\ldots,[(\theta_{k-1,1},\ldots,\theta_{k-1,k-1})0]}_{00,\ldots,0\beta_1[\beta_2(\gamma_{11})],\ldots,[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-1})]} = & \epsilon_{0\beta_1\cdots\beta_k}(\delta_{\theta_{11}\gamma_{11}}\delta_{\theta_{22}\gamma_{22}}\cdots\delta_{\theta_{k-1,k-1}\gamma_{k-1,k-1}})((\delta_{\theta_{21}\gamma_{21}}) \\ & \times(\delta_{\theta_{31}\gamma_{31}}\delta_{\theta_{32}\gamma_{32}})\cdots(\delta_{\theta_{k-1,1}\gamma_{k-1,1}}\cdots\delta_{\theta_{k-1,k-2}\gamma_{k-1,k-2}})). \end{aligned} \tag{8}$$

The terms of Eq. (6) with the $\theta=0$ generated by the contraction of the Levi–Civita pseudotensor cancel out by antisymmetry.

Therefore, the indices β,θ,γ can be shifted; instead of running from $0,1,\ldots,k$ they will run from $0,1,\ldots,k-1$. *This defines an isomorphism* between the subset of the generators, belonging to the factor which multiply P^{k+1} in Eq. (6), of the Lie algebra of ISL($k+1,R$) and the Lie algebra of ISL(k,R). Hence Eq. (7) can be given by

$$\begin{aligned} \zeta^{\theta_{11}[(\theta_{21})\theta_{22}],\ldots,[(\theta_{k-1,1},\ldots,\theta_{k-1,k-2})\theta_{k-1,k-1}]}_{\beta_1\gamma_{11}\gamma_{22},\ldots,\gamma_{k-1,k-1}\beta_2[\beta_3(\gamma_{21})],\ldots,[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-2})]} = & \epsilon_{\beta_1\cdots\beta_k}(\delta_{\theta_{11}\gamma_{11}}\delta_{\theta_{22}\gamma_{22}}\cdots\delta_{\theta_{k-1,k-1}\gamma_{k-1,k-1}})((\delta_{\theta_{21}\gamma_{21}}) \\ & \times(\delta_{\theta_{31}\gamma_{31}}\delta_{\theta_{32}\gamma_{32}})\cdots(\delta_{\theta_{k-1,1}\gamma_{k-1,1}}\cdots\delta_{\theta_{k-1,k-2}\gamma_{k-1,k-2}})). \end{aligned} \tag{9}$$

The basis elements of the Lie algebra of the group ISL(n,R) can be represented by the $n+1$ by $n+1$ matrices given by

$$\begin{pmatrix} \mathrm{SL}(n,R) & P \\ 0 & 0 \end{pmatrix},$$

where P are the generators of the group of translations, and SL(n,R) are the generators of the special linear group in n dimensions. Therefore, the E^{α}_0 generators of the Eq. (6) can be considered as the translations P^{α} generators of the little group ISL(k,R) of $(p^0,0,0,\ldots,0_k)$.[9]

Using Eq. (8), Eq. (6) can be written in the following form:

$$\textit{Casimir ISL}(k+1,R) = \{(P^0)^{k+1}\zeta^{\theta_{11}[(\theta_{21})\theta_{22}],\ldots,[(\theta_{k-1,1},\ldots,\theta_{k-1,k-2})\theta_{k-1,k-1}]}_{\beta_1\gamma_{11}\gamma_{22},\ldots,\gamma_{k-1,k-1}\beta_2[\beta_3(\gamma_{21})],\ldots,[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-2})]}E_0^{\beta 1}E_0^{\gamma_{11}}\cdots E_0^{\gamma_{k-1,k-1}} \times E_{\theta_{11}}^{\beta_2}E_{[(\theta_{21})\theta_{22}]}^{[\beta_3(\gamma_{21})]}\cdots E_{[(\theta_{k-1,1},\ldots,\theta_{k-1,k-2})\theta_{k-1,k-1}]}^{[\beta_k(\gamma_{k-1,1},\ldots,\gamma_{k-1,k-2})]}\}_{symmetrized}. \tag{10}$$

To take advantage of the isomorphism given above, we make the following substitution:

$$\beta_1 \to \xi_0, \beta_2 \to \beta_1, \beta_3 \to \beta_2, \ldots, \beta_k \to \beta_{k-1},$$

$$\theta_{11} \to \rho_1, \theta_{22} \to \rho_2, \ldots, \theta_{k-1,k-1} \to \rho_{k-1},$$

$$\gamma_{11} \to \alpha_1, \gamma_{22} \to \alpha_2, \ldots, \gamma_{k-1,k-1} \to \alpha_{k-1},$$

$$\theta_{21} \to \theta_{11}, (\theta_{31} \to \theta_{21}, \theta_{32} \to \theta_{22}), \ldots, (\theta_{k-1,1} \to \theta_{k-2,1}, \theta_{k-1,2} \to \theta_{k-2,2}, \ldots, \theta_{k-1,k-2} \to \theta_{k-2,k-2}),$$

$$\gamma_{21} \to \gamma_{11}, (\gamma_{31} \to \gamma_{21}, \gamma_{32} \to \gamma_{22}), \ldots, (\gamma_{k-1,1} \to \gamma_{k-2,1}, \gamma_{k-1,2} \to \gamma_{k-2,2}, \ldots, \gamma_{k-1,k-2} \to \gamma_{k-2,k-2}),$$

and by substituting into Eq. (9), we obtain

$$\textit{Casimir ISL}(k+1,R) = \{(P^0)^{k+1}(\textit{Casimir ISL}(k,R))\}_{symmetrized}. \tag{11}$$

We have obtained the Casimir of the little group ISL(k,R) from the Casimir of the group ISL$(k+1,R)$. We arrive at the same result if we take any of the other translations.

From the above discussion, it is clear that the Casimir of ISL$(k+1,R)$ given by Eq. (5) does not vanish, as claimed. This completes the induction proof. We conclude that the formula given by Eq. (1) is valid for any integer n.

V. CONCLUSION

Although the formula for the Casimir of ISL(n,R) has been written in the Weyl basis, this does not limit its application range. The advantage of our formula for ISL(n,R), over other possible formulation, is its immediate physical and mathematical application as shown above in the little group Casimir decomposition of ISL(n,R).

In gauge theories of gravity based on the group ISL$(4,R)$, it should be verified for the correct usage of the Casimir operator. The reason is that in these theories, the group ISO (1,3) must be a subgroup of the gauge group. This group has a different Lie algebra than that of the group ISO (4) which is a subgroup of ISL$(4,R)$. The applications of a deunitarizing inner automorphism,[4] which changes some of the generators of the group ISL(n,R) by a factor $\sqrt{-1}$, is necessary to extend the range of application of our formula. To avoid confusion we suggest using the notation ISL$(1,n-1,R)$ for the group that has as a subgroup ISO$(1,n-1)$.

(Received 28 January 2005; accepted 18 March 2005; published online 17 May 2005)

It is shown that the α^2-dynamo of magnetohydrodynamics, the hydrodynamic Squire equation as well as an interpolation model of $\mathcal{PT}$-symmetric quantum mechanics are closely related as spectral problems in Krein spaces. For the α^2-dynamo and the $\mathcal{PT}$-symmetric model the strong similarities are demonstrated with the help of a 2×2 operator matrix representation, whereas the Squire equation is reinterpreted as a rescaled and Wick-rotated $\mathcal{PT}$-symmetric problem. Based on recent results on the Squire equation the spectrum of the $\mathcal{PT}$-symmetric interpolation model is analyzed in detail and the Herbst limit is described as spectral singularity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1915293]

I. INTRODUCTION

Non-Hermitian $\mathcal{PT}$-symmetric quantum mechanical systems[1–8] are known to possess spectral sectors with purely real eigenvalues as well as sectors with pairs of complex conjugate eigenvalues. Changes of certain system parameters can lead to spectral phase transitions from one sector to the other. The physics in the two sectors has been identified with phases of unbroken $\mathcal{PT}$-symmetry (real eigenvalues) and spontaneously broken $\mathcal{PT}$-symmetry (pairwise complex conjugate eigenvalues).[1,2] From a mathematical point of view, non-Hermitian $\mathcal{PT}$-symmetric Hamiltonians are self-adjoint operators in Krein spaces[9–11]—Hilbert spaces with an additional indefinite metric structure—and the two spectral sectors correspond to Krein space states of positive or negative type (real eigenvalues) and neutral (isotropic) states (pairwise complex conjugate eigenvalues).

Apart from $\mathcal{PT}$-symmetric quantum mechanics (PTSQM), it is known that a certain class of spherically symmetric mean-field dynamo models[12] of magnetohydrodynamics (MHD) can be described by self-adjoint operators in Krein spaces as well.[13] These models show similar spectral phase transitions from real to pairwise complex conjugate eigenvalues[14]—and only the physical interpretation differs from that in PTSQM. For dynamos it simply consists in a transition from nonoscillatory states to oscillatory states.

In the present paper, we are going to briefly describe the underlying structural operator theoretic parallels between PTSQM models and the spherically symmetric MHD α^2-dynamo (Sec. II). The discussion will be illustrated with the help of a $\mathcal{PT}$-symmetric interpolation between a harmonic oscillator placed in a square well and an empty square well (Sec. III). This interpolation shows a rich structure of spectral phase transitions with a couple of unexpected features. Furthermore, we will show in Sec. IV that the eigenvalue problem of the $\mathcal{PT}$-symmetric (intermediate) interpolation model with linear complex potential (purely complex electrical field) within the square well is mathematically identical to the eigenvalue problem of the rescaled and Wick-rotated

Squire equation of hydrodynamics which describes the normal vorticity of a plane channel flow (Couette flow) with linear transversal velocity profile. Recent Airy function based results on the Squire equation allow us to analytically describe the spectral behavior of the PTSQM model in the limiting case when the width of the square well tends to infinity. In this limit we reproduce the Herbst model[15] with its empty spectrum. The limiting behavior occurs as a blowing-up of the spectrum to infinity along three directions on the complex plane—leaving behind a spectrally empty region at any fixed finite distance from the origin of the spectral plane. In Sec. V we briefly sketch some links of the obtained results to other physical setups and analytical techniques.

II. KREIN SPACE PROPERTIES OF $\mathcal{PT}$-SYMMETRIC QUANTUM MODELS AND OF THE SPHERICALLY SYMMETRIC MHD α^2-DYNAMO

A. $\mathcal{PT}$-symmetric quantum models

In their seminal letter[1] Bender and Boettcher identified $\mathcal{PT}$-symmetry as the essential property of the non-Hermitian quantum system,

$$H\psi(x) = E\psi(x), \quad H = -\frac{d^2}{dx^2} + gx^2(ix)^\nu, \tag{1}$$

which ensures the reality of its spectrum for exponents $\nu \in [0,2)$ and $\psi(x) \in \tilde{\mathcal{H}} = L_2(-\infty,\infty)$.[16] This allowed them not only to extend an earlier conjecture of Bessis and Zinn-Justin [whose numerical results indicated that quantum systems with complex potential $V(x) = ix^3$ might have a purely real spectrum], but also initiated the still lasting intensive study of generalized $\mathcal{PT}$-symmetric non-Hermitian systems.[17] Such systems are characterized by a $\mathcal{PT}$-symmetric Hamiltonian H,

$$[\mathcal{PT}, H] = 0, \tag{2}$$

where $\mathcal{P}$ denotes a reflection

$$\mathcal{P}x\mathcal{P} = -x, \quad \mathcal{P}\psi(x) = \psi(-x),$$

while the time-reversal operator $\mathcal{T}$ performs complex conjugation,

$$\mathcal{T}i\mathcal{T} = -i, \quad \mathcal{T}\psi(x) = \psi(x)^*. \tag{3}$$

Because both operators $\mathcal{P}$ and $\mathcal{T}$ are involution operators,

$$\mathcal{P}^2 = I, \quad \mathcal{T}^2 = I,$$

they induce natural $\mathbb{Z}_2$-gradings of the Hilbert space $\tilde{\mathcal{H}}$. For our subsequent analysis it suffices to consider the subclass of models which can be defined solely over the real line $x \in \mathbb{R}$. For such models the $\mathcal{T}$-induced $\mathbb{Z}_2$-grading corresponds to a splitting of the wave functions $\psi \in \tilde{\mathcal{H}}$ into real and imaginary components (what is of no direct physical interest in a quantum mechanical context; additionally one would have to work in a real Hilbert space with doubled dimension compared to the original complex one), whereas $\mathcal{P}$ induces a $\mathbb{Z}_2$-grading into parity even and parity odd components,

$$\psi(x) = \psi_+(x) + \psi_-(x), \quad \mathcal{P}\psi_\pm(x) = \psi_\pm(-x) = \pm\psi_\pm(x). \tag{4}$$

The corresponding $\mathbb{Z}_2$-graded Hilbert space splits as

$$\tilde{\mathcal{H}} = \mathcal{H}_+ \oplus \mathcal{H}_-, \quad \psi_\pm \in \mathcal{H}_\pm.$$

In the case of a simple $\mathcal{PT}$-symmetric one-particle system with Hamiltonian

$$H = -\partial_x^2 + V_+(x) + iV_-(x), \quad V_\pm(-x) = \pm V_\pm(x), \quad \Im V_\pm = 0 \tag{5}$$

it holds

$$H = \mathcal{P}H^\dagger\mathcal{P} \tag{6}$$

and $\mathcal{P}$ is a so called fundamental (canonical) operator symmetry[9,10] of H—i.e., H is $\mathcal{P}$-pseudo-Hermitian in the sense of Refs. 4 and 5. Operators with an involutive fundamental symmetry are known to be symmetric—and for appropriately chosen domain [boundary conditions for the functions $\psi(x)$] even self-adjoint—in a Krein space $\mathcal{K}$. For $\mathcal{P}$-pseudo-Hermitian operators over the real line this Krein space $\mathcal{K}_\mathcal{P}$ is given as[11,18,19]

$$(\mathcal{K}_\mathcal{P}, [.,.]_\mathcal{P}), \quad [\psi,\phi]_\mathcal{P} = (\psi, \mathcal{P}\phi) = \int_{C\subseteq\mathbb{R}} \psi^*(x)\mathcal{P}\phi(x)\mathrm{d}x = \int_{C\subseteq\mathbb{R}} \psi^*(x)\phi(-x)\mathrm{d}x. \tag{7}$$

Depending on the concrete problem, the integration in (7) is performed over a finite interval, $C=[-a,a]$, or over the complete real line, $C=(-\infty,\infty)\sim\mathbb{R}$. From (5) and (6) one immediately finds

$$[H\psi,\phi]_\mathcal{P} = [\psi, H\phi]_\mathcal{P}.$$

The Krein space inner (scalar) product $[\psi,\phi]_\mathcal{P}$ has the following properties:

(i) It coincides with the more general $\mathcal{PT}$ inner product of Bender *et al.*,[6,7]

$$(\psi,\phi)_{\mathcal{PT}} = \int_{C\subset\mathbb{C}} [\mathcal{PT}\psi(x)]\phi(x)\mathrm{d}x$$

when the integration path $C\subset\mathbb{C}$ of the latter integral is restricted to (an interval of) the real line, $C\subseteq\mathbb{R}$,

$$(\psi,\phi)_{\mathcal{PT}} = \int_{C\subseteq\mathbb{R}} [\mathcal{PT}\psi(x)]\phi(x)\mathrm{d}x = \int_{C\subseteq\mathbb{R}} [\mathcal{P}\psi(x)^*]\phi(x)\mathrm{d}x = \int_{C\subseteq\mathbb{R}} \psi(x)^*\mathcal{P}\phi(x) = [\psi,\phi]_\mathcal{P}.$$

(ii) In contrast to the "usual" positive definite metric structure of the Hilbert space $\tilde{\mathcal{H}} = \mathcal{H}_+ \oplus \mathcal{H}_-$,

$$(\tilde{\mathcal{H}}, (.,.)), \quad (\psi,\phi) = \int_{C\subseteq\mathbb{R}} \psi^*(x)\phi(x)\mathrm{d}x = \int_{C\subseteq\mathbb{R}} (\psi_+^*\phi_+ + \psi_-^*\phi_-)\mathrm{d}x,$$

with non-negative norm

$$\|\psi\|^2 = (\psi,\psi) = \|\psi_+\|^2 + \|\psi_-\|^2 \geqslant 0,$$

the scalar product $[\psi,\phi]_\mathcal{P}$ defines an indefinite metric structure in the Krein space $\mathcal{K}_\mathcal{P} = \mathcal{H}_+ \oplus \mathcal{H}_-$, what is easily seen from the decomposition (4)

$$[\psi,\phi]_\mathcal{P} = \int_{C\subseteq\mathbb{R}} (\psi_+^*\phi_+ - \psi_-^*\phi_-)\mathrm{d}x.$$

(iii) In rough analogy with timelike, spacelike, and lightlike (isotropic) vectors in Minkowski space, one distinguishes Krein space vectors of positive type, $[\psi_+,\psi_+]_\mathcal{P} = \|\psi_+\|^2 > 0$, of negative type, $[\psi_-,\psi_-]_\mathcal{P} = -\|\psi_-\|^2 < 0$, and neutral (isotropic) vectors,

$$[\psi,\psi]_\mathcal{P} = 0, \quad \psi = \psi_+ + \psi_-, \quad \|\psi_+\|^2 = \|\psi_-\|^2.$$

In order to make the structural Krein space analogies of PTSQM models and MHD dynamo setups maximally transparent, we rewrite the eigenvalue problem, $H\psi=E\psi$, for the $\mathcal{PT}$-symmetric Hamiltonian (5) in an equivalent 2×2 matrix operator representation. Introducing the projection operators

$$P_{\pm} := \tfrac{1}{2}(I \pm \mathcal{P})$$

we decompose wave function ψ and Hamiltonian H (see, e.g., Ref. 9) as

$$\psi = P_+\psi + P_-\psi = \psi_+ + \psi_-,$$

$$H = P_+HP_+ + P_-HP_+ + P_+HP_- + P_-HP_-.$$

In terms of the notation

$$H_{\pm\pm} := P_{\pm}HP_{\pm} = -\partial_x^2 + V_+(x), \quad H_{\pm\mp} := P_{\pm}HP_{\mp} = iV_-(x) \tag{8}$$

this gives

$$\begin{pmatrix} H_{++} & H_{+-} \\ H_{-+} & H_{--} \end{pmatrix}\begin{pmatrix} \psi_+ \\ \psi_- \end{pmatrix} = E\begin{pmatrix} \psi_+ \\ \psi_- \end{pmatrix}, \quad \mathcal{P} = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}, \tag{9}$$

where

$$H_{\pm\pm} = H_{\pm\pm}^{\dagger}, \quad H_{+-} = -H_{-+}^{\dagger}. \tag{10}$$

If one replaces the matrix entries in (9) and (10) by appropriate constants one arrives at the schematic two-level model

$$H_H\begin{pmatrix} u \\ v \end{pmatrix} = E\begin{pmatrix} u \\ v \end{pmatrix}, \quad H_H = \begin{pmatrix} c+a & b \\ -b^* & c-a \end{pmatrix}, \quad a,c \in \mathbb{R}, \tag{11}$$

which may be read as an elementary exemplification of Heisenberg's linear-algebraic approach[20] to ($\mathcal{PT}$-symmetric) quantum mechanics and which was intensively studied in Refs. 6, 7, 18, and 21–23.

B. The spherically symmetric MHD α^2-dynamo

The magnetic fields of planets, stars, and galaxies are maintained by homogeneous dynamo effects, which can be successfully described within magnetohydrodynamics (MHD). One of the simplest dynamos is the spherically symmetric mean-field α^2-dynamo in its kinematic regime. This dynamo model is capable to play a similar paradigmatic role in MHD dynamo theory like the harmonic oscillator in quantum mechanics (QM). Its operator matrix has the form (see the Appendix for a few comments on the origin of this operator matrix and on the physics of α^2-dynamos)[13]

$$\hat{H}_l[\alpha] = \begin{pmatrix} -Q[1] & \alpha \\ Q[\alpha] & -Q[1] \end{pmatrix} \tag{12}$$

and consists of formally self-adjoint blocks

$$Q[\alpha] := p\alpha p + \alpha\frac{l(l+1)}{r^2},$$

where $p=-i(\partial_r+1/r)$ denotes the radial momentum operator. The operator $\hat{H}_l[\alpha]$ is defined over an interval $\Omega=[0,1]\ni r$ and acts on two-component vectors ϕ which describe the coupled

l-modes of the poloidal and toroidal magnetic field components of a mean-field dynamo model with helical turbulence function (α-profile) $\alpha(r)$.

Although the dynamo model is not $\mathcal{PT}$-symmetric, its operator $\hat{H}_l[\alpha]$ shares a basic underlying symmetry with PTSQM Hamiltonians—a $\mathbb{Z}_2$-graded pseudo-Hermiticity (J-pseudo-Hermiticity)[5,14] which is induced by the fundamental (canonical) symmetry,

$$\hat{H}_l[\alpha] = J\hat{H}_l^{\dagger}[\alpha]J, \quad J = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}.$$

Similar to the reflection operator $\mathcal{P}$ in (6), the operator J is unitary and involutive

$$J^{\dagger} = J^{-1}, \quad J^2 = I.$$

The boundary conditions on the vector function ϕ are set at $r=1$ (the rescaled surface radius of the star or planet whose fluid/plasma motion maintains the dynamo effect) and it is assumed that $\alpha(r>1)\equiv 0$. In the case of physically idealized boundary conditions at $r=1$ (see, e.g., Ref. 24), the domain $\mathcal{D}(\hat{H}_l[\alpha])$ of the operator $\hat{H}_l[\alpha]$ consists of functions ϕ such that

$$\mathcal{D}(\hat{H}_l[\alpha]) := \left\{ \phi = \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix} : \phi \in \tilde{\mathcal{H}} \equiv \mathcal{H} \oplus \mathcal{H}, \mathcal{H} = L_2(\Omega, r^2\,\mathrm{d}r), \Omega = [0,1], \phi(1) = 0, r\phi(r)|_{r\to 0} \to 0 \right\},$$

and $\hat{H}_l[\alpha]$ is self-adjoint in a Krein space

$$(\mathcal{K}_{\mathcal{J}}, [.,.]_{\mathcal{J}}), \quad [\psi,\phi]_J = \int_0^1 \psi^{\dagger} J \phi r^2\,\mathrm{d}r, \quad [\hat{H}_l\chi,\phi]_J = [\chi,\hat{H}_l\phi]_J.$$

It should be noted that for physically realistic boundary conditions

$$\hat{B}_l\phi|_{r=1} = 0, \quad \hat{B}_l = \mathrm{diag}[\partial_r + (l+1)/r, 1] \tag{13}$$

there exists no appropriate Krein space which could make the operator $\hat{H}_l[\alpha]$ J-self-adjoint.

The structures of PTSQM models and the α^2-dynamo can be compared most explicitly after passing from $\mathcal{K}_{\mathcal{J}}$ to an equivalent Krein space $\mathcal{K}_{\mu}$ with diagonal metric operator μ and redefined Hilbert spaces components, $L_2(\Omega, r^2\,\mathrm{d}r) \mapsto L_2(\Omega, \mathrm{d}r)$. The diagonalization yields

$$J \mapsto \mu := \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} = S^{-1}JS, \quad S = \frac{1}{\sqrt{2}}\begin{pmatrix} I & -I \\ I & I \end{pmatrix}, \tag{14}$$

$$\hat{H}_l[\alpha] \mapsto \check{H}_l[\alpha] = S^{-1}\hat{H}_l[\alpha]S = \frac{1}{2}\begin{pmatrix} Q[\alpha-2]+\alpha & -Q[\alpha]+\alpha \\ Q[\alpha]-\alpha & Q[-\alpha-2]-\alpha \end{pmatrix}, \tag{15}$$

$$\phi \mapsto \check{\phi} = \begin{pmatrix} \phi_+ \\ \phi_- \end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix} \phi_2+\phi_1 \\ \phi_2-\phi_1 \end{pmatrix}, \tag{16}$$

whereas the unitary mapping $U: L_2(\Omega, r^2\,\mathrm{d}r) \mapsto L_2(\Omega, \mathrm{d}r)$ simplifies the structure of $Q[\alpha]$ and leads in (15) and (16) to the additional replacements

$$\phi_{1,2} \mapsto f_{1,2} := r\phi_{1,2}, \quad Q[\alpha] \mapsto q[\alpha] := rQ[\alpha]r^{-1} = -\partial_r\alpha(r)\partial_r + \alpha(r)\frac{l(l+1)}{r^2}. \tag{17}$$

By inspection of (8)–(10) and (14)–(17) we find that, in the chosen Krein space representations of the PTSQM model and the α^2-dynamo, the block structures of the metrics (involution operators) $\mathcal{P}$ and μ coincide, $\mathcal{P}=\mu$, but that the blocks of the $\mathcal{PT}$-symmetric Hamiltonian and the dynamo operator show significant structural differences [in a very rough analogy, the alpha profile $\alpha(r)$ has

some similarities to a position depending mass, as it was studied for QM models, e.g., in Ref. 25],

$$H_{\pm\pm} = -\partial_x^2 + V_+(x) \quad \leftrightarrow \quad -q[1] \pm \frac{q[\alpha]+\alpha}{2},$$

$$H_{\pm\mp} = iV_-(x) \quad \leftrightarrow \quad \mp\frac{q[\alpha]-\alpha}{2}.$$

It is clear that these differences in the differential expressions (as well as the different boundary conditions on the two-component eigenfunctions) will lead to different global behaviors of the corresponding operator spectra. Nevertheless, both types of systems share the same Krein-space induced features of level crossings, what will be briefly sketched in the next section.

C. Spectral phase transitions

Since the first PTSQM paper[1] of Bender and Boettcher it is known that $\mathcal{PT}$-symmetric Hamiltonians have a real spectrum when $\mathcal{PT}$-symmetry is an exact symmetry and not spontaneously broken (the corresponding eigenfunctions are invariant under a $\mathcal{PT}$-transformation), whereas spontaneously broken $\mathcal{PT}$-symmetry is connected with complex energies. [We recall that this follows from (2) and (3), the eigenvalue equation $H\psi=E\psi$ and its $\mathcal{PT}$-transformed, $H\mathcal{PT}\psi=E^*\mathcal{PT}\psi$. For real eigenvalues, $E=E^*$, it is natural to set $\psi=\mathcal{PT}\psi$, whereas $E\neq E^*$ necessarily implies $\psi \neq \mathcal{PT}\psi$.] A consistent PTSQM applicability and interpretation of the complex-energy states remains an open question up to now (cf., e.g., Ref. 26). For convenience, we shall call these states "unphysical" here.

The mathematically most interesting questions of PTSQM concern the transition between the physical and unphysical domains of their parameters. In the simple two-state model (11) it is easy to deduce that the quantized energies E are real ("physical") for $|a|>|b|$ while they form complex-conjugate pairs in the "unphysical" regime where $|a|<|b|$.[7,18] The boundary of its PTSQM applicability coincides with the double-cone hypersurface in parameter space where $|a|=|b|$. One easily verifies that whenever $|b|$ approaches $|a|$, the separate eigenenergies $E_\pm$ as well as the corresponding two independent bound-state eigenvectors coalesce and coincide. On the critical hypersurface the remaining (geometrical) eigenvector becomes supplemented by a so called associated vector (algebraic eigenvector)[14] and the Hamiltonian matrix H acquires a Jordan-block canonical structure.[14,27] The latter cannot be diagonalized and it only gives the doubly degenerate and real single "exceptional-point" eigenvalue $E=E_{(\mathrm{EP})}=c$ (cf., e.g., Ref. 28 for more details).

An exhaustive and consistent bound-state interpretation of the Schrödinger-type equation (1) is more difficult. For example, it requires the restriction of the range of exponents to a finite interval of $\nu\in(-1,2)$ for $\psi(x)\in L_2(-\infty,\infty)$ as usual defined on the real line.[1] A rigorous proof of the reality of the energies turned out unexpectedly difficult.[16,29] For larger exponents ν, the real line must be replaced by an appropriately deformed contour in the complex plane.[1,2]

A systematic analytical study of phase transition points is still lacking for PTSQM models; the same concerns efficient mathematical tools for deriving their location in parameter space. Similar to the double-cone hypersurfaces for the simple matrix model (11), one expects more complicated (and more interesting) global phase-transition hypersurfaces in case of the Schrödinger-type systems. Knowing the location of these phase transition hypersurfaces, one would know the boundaries of the "physical" regions of exact $\mathcal{PT}$-symmetry.

For the α^2-dynamo both types of eigenvalues—real ones as well as pairwise complex conjugate ones—have a clear physical meaning. They simply correspond to nonoscillatory and oscillatory dynamo states, respectively. But again it is of utmost interest to know the parameter configurations for which transitions between the two types of states (phases) occur. In the recent paper,[30] strong numerical indications were presented that magnetic field reversals (interchanges of North and South poles as they are evident from paleomagnetic data on the Earth magnetic field[31]) are induced by a special type of nonlinear dynamics in the vicinity of spectral phase transition points. [In the concrete case, the nonlinear transition mechanism between kinematic and saturated dy-

namo regime (a brief outline of the corresponding physics can be found in the Appendix) was simulated with the help of a so called α-quenching (see, e.g., Ref. 32) which simulates the nonlinear back-reaction of the induced magnetic fields on the α-profile $\alpha(r)$.]

The qualitative features of the real-to-complex phase transitions are essentially the same for PTSQM models and for the MHD α^2-dynamo. They correspond to transitions from Krein space states of positive and negative type to pairwise neutral (isotropic) states[11,14]—and a square-root branching of the spectral Riemann surface.[33,34] Such transitions are a generic feature of Krein-space setups and they are new compared with setups in Hilbert spaces with purely positive metric structures as in "usual" QM. The square-root branching behavior is easily seen by passing from the linear eigenvalue problems for the 2×2-operator matrices H and $\hat{H}_l[\alpha]$ of Eqs. (9) and (12),

$$(H-E)\psi=0, \quad (\hat{H}_l[\alpha]-\lambda)\phi=0,$$

via substitutions

$$\psi=\begin{pmatrix} \psi_+ \\ -\frac{1}{H_{+-}}[H_{++}-E]\psi_+ \end{pmatrix}, \quad \phi=\begin{pmatrix} \phi_1 \\ \frac{1}{\alpha}[Q(1)+\lambda]\phi_1 \end{pmatrix}$$

to the equivalent quadratic operator pencils

$$\left\{(H_{--}-E)\frac{1}{H_{+-}}(H_{++}-E)-H_{-+}\right\}\psi_+=0,$$

$$\left\{(Q[1]+\lambda)\frac{1}{\alpha}(Q[1]+\lambda)-Q[\alpha]\right\}\phi_1=0.$$

Both pencils are of the same generic operator type

$$L[\lambda]\psi=[A_2\lambda^2+A_1\lambda+A_0]\psi=0$$

with a scalar product

$$(\psi,L[\lambda]\psi)=a_2\lambda^2+a_1\lambda+a_0=0, \quad a_j:=(\psi,A_j\psi)$$

which can be used to deduce the local square-root branching behavior of the spectrum

$$\lambda_{1,2}=\frac{1}{2a_2}(-a_1\pm\sqrt{a_1^2-4a_0a_2}).$$

A typical α^2-dynamo spectrum with a large number of real-to-complex transitions is presented in Fig. 1 (see also Refs. 14 and 35). These crossings with real-to-complex transition occur at exceptional points (in the sense of Kato[36]) of (square root) branching type[37,38] and the corresponding eigenvalues have geometric multiplicity one and algebraic multiplicity two.[14] In contrast, crossings without real-to-complex transitions are of the same type as level crossings in Hermitian systems[11]–with geometric and algebraic multiplicity two.[39] Finally, we note that although locally crossings with real-to-complex transitions occur, in general, only between two spectral branches, globally much more branches are involved in mutual crossings (see Fig. 1). This reflects the fact that in general the spectrum forms a multisheet Riemann surface over the parameter space of the theory (see, e.g., Refs. 33, 34, and 40).

In the next section, we will analyze the spectral behavior of a $\mathcal{PT}$-symmetric interpolation model where we will find a similar rich structure of real-to-complex transitions as for the α^2-dynamo.

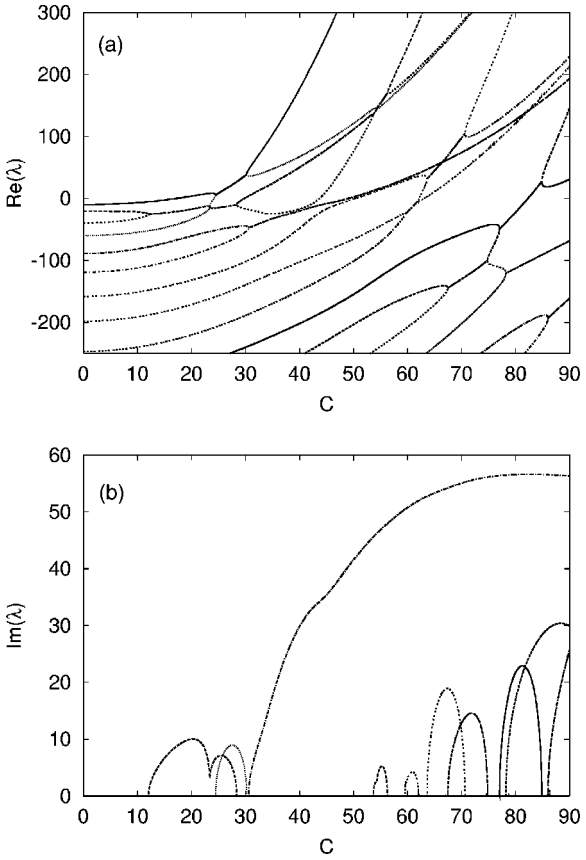

FIG. 1. Real and imaginary components of the α^2-dynamo spectrum as functions of the scale factor C of an α-profile $\alpha(r)=C\times(1-26.09\times r^2+53.64\times r^3-28.22\times r^4)$ in the case of angular mode number $l=1$ and physically realistic boundary conditions (13). The concrete coefficients in the quartic polynomial $\alpha(r)$ have their origin in numerical simulations of the field reversal dynamics (see Ref. 30). Only the imaginary components with $\Im\lambda\geqslant 0$ are shown. The complex conjugate ($\Im\lambda\leqslant 0$)-components are omitted for sake of brevity.

III. $\mathcal{PT}$-SYMMETRIC INTERPOLATION BETWEEN SQUARE WELL AND HARMONIC OSCILLATOR

In Schrödinger-type models (1) over the open real line $x\in(-\infty,\infty)$ a PTSQM-related separation of the "physical" and "unphysical" domains is, in general, a mathematically highly nontrivial problem. Its resolution requires a fairly subtle and rigorous mathematical argumentation.[16,29] A typical result of the WKB analysis of Ref. 1 was that in a half-open interval of $\nu\in[0,2)$ the energies remain real and that the $\mathcal{PT}$-symmetry of the wave functions remains unbroken. In parallel, a characteristic unphysical behavior of the system (1) has been found in the half-open interval of $\nu\in[-1,0)$, where at any $\nu<0$ all the sufficiently high-lying energies E_n with $n>n_0(\nu)$ "decay" in complex-conjugate pairs, $\Im E_n\neq 0$. Moreover, the spectrum becomes empty in the Herbst–Hamiltonian limit of the leftmost $\nu=-1$.[1]

A. Toy model $\mathcal{PT}$-symmetric differential equation

In the present section, we are going to extend the consideration of the Schrödinger-type system (1) to exponents from the interval $\nu\in[-2,0]$. The endpoints of this interval correspond to the purely real-valued Hermitian-system spectra of a freely moving particle with shifted off-set energy (for $\nu=-2$) and a harmonic oscillator (for $\nu=0$). For the exponents $\nu\in(-2,0)$ we expect a phase of spontaneously broken $\mathcal{PT}$-symmetry with an involved picture of real-to-complex spectral phase transitions.

In order to keep the numerical analysis sufficiently simple and robust, we assume the system located in a square well (box) of *finite* width $2b<\infty$ and Dirichlet boundary conditions imposed at the walls, $\psi(x=\pm b)=0$, i.e., we introduce an IR cutoff at the low-energy end of the spectrum (various aspects of square-well-related PTSQM setups have been earlier considered, e.g., in Refs. 11, 41, and 42). This enables us to rescale Eq. (1) to the equivalent equation

$$[-\partial_y^2 + G\, y^2 (iy)^\nu]\psi[x(y)] = \mu(E)\psi[x(y)] \tag{18}$$

with parameter-independent boundary conditions

$$\psi[x(\pm 1)] = 0, \tag{19}$$

but rescaled coupling constant and energy

$$G = g\, b^{4+\nu}, \quad \mu(E) = b^2 E.$$

In this notation, the original bound-state problem (1) with asymptotic Dirichlet boundary conditions at $x\to\pm\infty$ is replaced by the equivalent new problem defined within a fixed finite interval $[-1,1]$. In the limit of very small $b\approx 0$ the potential term becomes negligible, $G\approx 0$, and the interaction degenerates to an infinitely deep square well (box) at all ν. A completely similar situation occurs for systems with any nonvanishing finite b, but very small exponents, $\nu\approx -2$. In both extremal cases the problem remains exactly solvable. The original Bender–Boettcher problem corresponds to the strong-coupling limit, $G\to\infty$, $b\to\infty$, with g hold fixed, $g=G\, b^{-4-\nu}=\text{const}$.

For finite coupling constants $0<G<\infty$ one expects the energy spectrum to be divided into the following three sectors: into a low-energy sector with states which are involved in real-to-complex phase transitions, into an intermediate sector, where the ν-dependent energies still remain real, and into a high-energy sector with almost ν-independent purely real eigenvalues whose states experience only a small perturbations from the complex interaction term. The division into low energy and intermediate-and-high energy sectors has been qualitatively described in a recent paper[11] by Langer and Tretter who considered a square well model with an arbitrary $\mathcal{PT}$-symmetric potential V as perturbation. Starting from the energy spectrum of the empty square well, $\mu_k=k^2\pi^2/4$, $k=1, 2, \ldots$, they showed that there are no real-to-complex phase transitions for levels $k>k_s$ with k_s as the lowest level satisfying the supremum bound $\|V\|_\infty<(2k_s+1)\pi^2/8$. In case of our model with potential $V(y)=gb^{4+\delta}y^2(iy)^\nu$ the supremum norm (see, e.g., Ref. 43) reads (for $\nu\geqslant -2$)

$$\|V\|_\infty = \sup_{y\in[-1,1]} |V(y)| = |V(\pm 1)| = |g| b^{4+\nu}$$

so that it is ensured that there are no phase transitions for levels

$$k > k_s(b) > \frac{1}{2}\left[\frac{8}{\pi^2}|g| b^{4+\nu} - 1\right]. \tag{20}$$

According to Ref. 11 it holds for the corresponding real eigenvalues μ_k, $|\mu_k - k^2\pi^2/4| < |g| b^{4+\nu}$. The supremum bound is safe, but at the same time rather rough.[44] The subsequent exact numerical analysis shows that, depending on the concrete exponents ν, the real-to-complex phase transitions in the model (18) stop at much lower energy levels.

B. The emergence of $\Im E\neq 0$ on certain finite subintervals of $\nu\in(-2,0)$

In the generic case with $\nu\in(-2,0)$ and $b>0$, we have solved Eqs. (18) and (19) numerically by means of a shooting technique with a fifth-order Runge–Kutta method, utilizing and adapting standard routines from numerical recipes.[45] The corresponding code had been validated extensively in earlier work by comparison with known analytical results and other numerical results in dynamo theory and quantum mechanics.

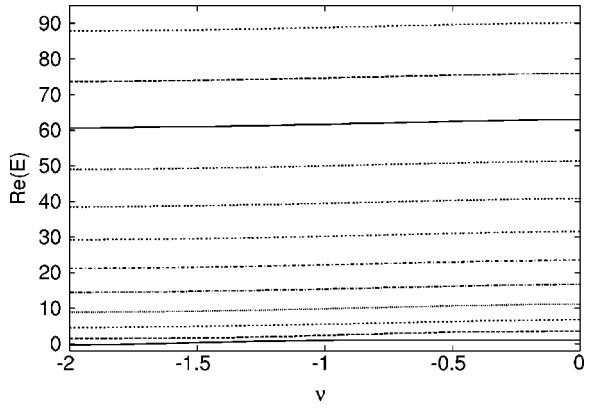

FIG. 2. Spectrum of the $\mathcal{PT}$-symmetric interpolation Hamiltonian $H=-\partial_x^2+x^2(ix)^\nu$ as function of the exponent ν for the cutoff length $b=2$. All eigenvalues are real and almost independent of ν. The spectrum is only slightly deviating from that of an empty square well.

A sample of the results of such a study is depicted in Figs. 2–6, where we have chosen $g=1$ and displayed the first few energy levels $E(\nu)$ over the entire interval $\nu \in (-2,0)$ for the sequence of values $b=2$, 4, 6, 7. The important results of this numerical experiment are the following:

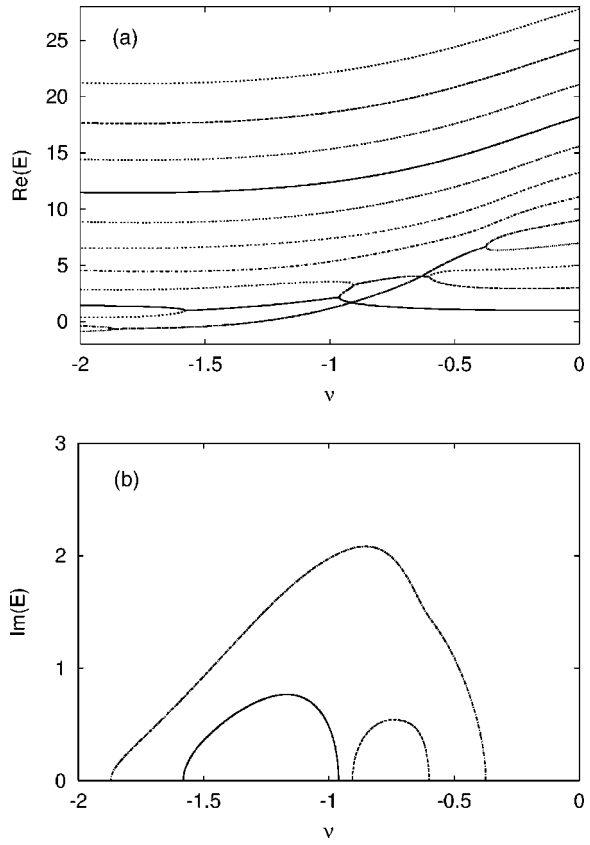

FIG. 3. Real and imaginary components of the spectrum in the case of a cutoff length $b=4$ [complex conjugate ($\Im\lambda \leqslant 0$) components omitted, as well as further higher lying levels without real-to-complex transitions]. The low-energy sector with its multiple real-to-complex transitions starts to form.

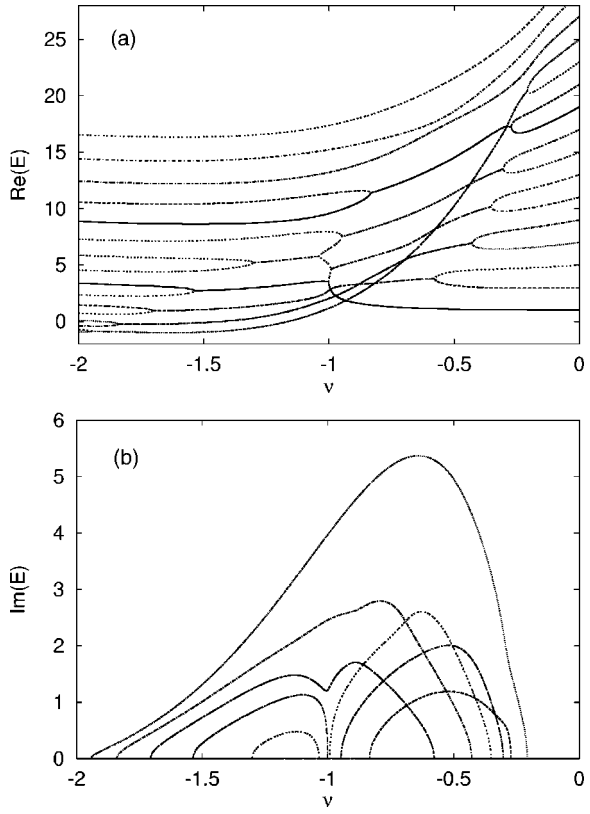

FIG. 4. Spectrum for a cutoff length $b=6$.

(i) At all sufficiently small b, as sampled in Fig. 2, the energy spectrum exhibits a more or less ν-independent square-well form.

(ii) At not too large b the spectrum, as sampled in Fig. 3, proves clearly separated into the high-lying part (where the energies still preserve their approximate ν independence), an intermediate perturbative part (where the perceivably ν-dependent energies still remain all real) and the low-lying part (where one encounters the first real-to-complex phase transitions).

(iii) The actual lowest level numbers $k_c(b)$ (critical level numbers) of the modes which are not involved in real-to-complex transitions lie much below the safe supremum bounds $k_s(b)$ of inequality (20). Choosing, for example, the exponents $\nu=-1/2$ and $\nu=-3/2$ we read off that

$$\nu=-1/2,\quad b=\begin{cases}2\\4\\6\\7\end{cases},\quad k_s(b)>\begin{cases}4.08\\51.4\\213\\367\end{cases},\quad k_c(b)=\begin{cases}1\\6\\14\\22\end{cases},$$

$$\nu=-3/2,\quad b=\begin{cases}2\\4\\6\\7\end{cases},\quad k_s(b)>\begin{cases}1.79\\12.5\\35.2\\52.1\end{cases},\quad k_c(b)=\begin{cases}1\\5\\9\\11\end{cases}.$$

(iv) Starting from the "intermediate width" region, sampled at $b=6$ in Fig. 4, we find that the *left-hand half* of the picture exhibits a clear transition from the slightly non-Hermitian

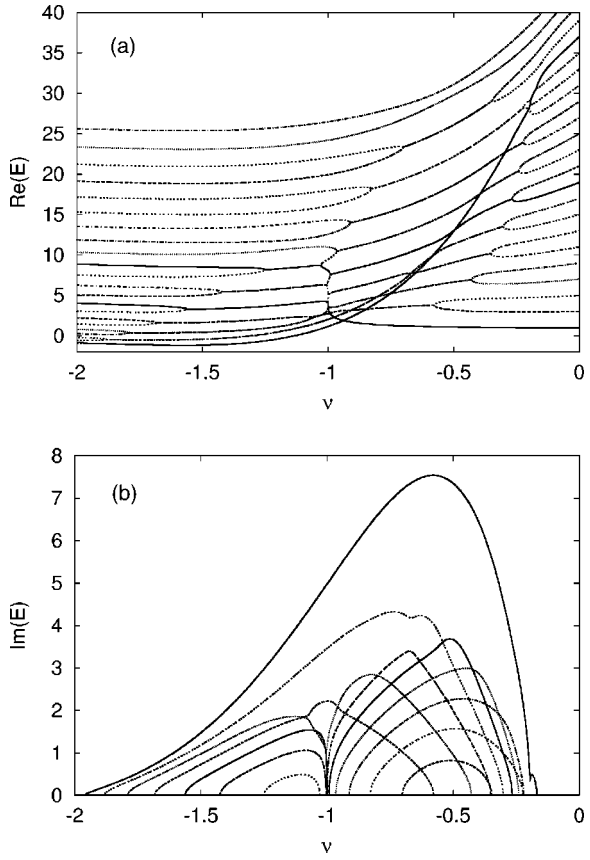

FIG. 5. At a cutoff length $b=7$ the generic structure of the spectrum is clearly visible. The weblike pattern of the real components (a) contains purely real branches in the vicinity of the left ($\nu=-2$) and right ($\nu=0$) endpoints of the considered interval as well as a chain of purely real intermediate segments in the vicinity of $\nu=-1$. (See Fig. 6 for a detailed view.) The increasing number of imaginary components (b) with high gradients $|\partial_\nu E(\nu\approx -1)| \gg 1$ which accumulate in the vicinity of $\nu=-1$ are first indications of the formation of a local spectral singularity at $\nu=-1$.

square well regime (with the higher energies all real) to its more strongly non-Hermitian extension where for all exponents ν not too distant from $\nu=-2$ the purely imaginary and finite component of the potential resembles the spatially antisymmetric part of the exactly solvable $\mathcal{PT}$-symmetric Heavyside step potential within a square well considered in Ref. 41. This explains why in Figs. 3–5 the continuing decrease of ν makes the respective two or three lowest pairs of the energies merge and complexify.

(v) At "sufficiently large" cutoffs b, all the *real* low-lying energies depicted in the *right-hand halves* of Figs. 4 and 5 obviously stabilize and approach the $b\to\infty$ limiting pattern as published in Refs. 1 and 16. In particular, we see that the ground-state energy remains real and that it starts growing more quickly only when the values of ν move down and closer to the Herbst limit of $\nu\to -1^+$. We observe that in a more appropriate way this growing real branch should be interpreted as a special type of ladder-shaped merger of intermediate real segments which actually correspond to level pairs with higher mode numbers. A zoomed view on this peculiarity is presented in Fig. 6, where it is clearly visible that a chain of exceptional points is located on this branch with alternating complex-valued segments branching off to the left and to the right. These segments fit, after further complex-to-real transitions, to the real eigenvalues of the $\nu\to 0$ and $\nu\to -2$ limit models.

(vi) When the cutoff b is increased the following simultaneous changes in the spectrum can be observed. In the upper low-energy region with $\nu>-1$ step by step more and more level pairs become twisted into the complex sector. With a "slight delay in b" and at $\nu<-1$ the lower of the twisted levels undergo a second pairwise real-to-complex transition with the

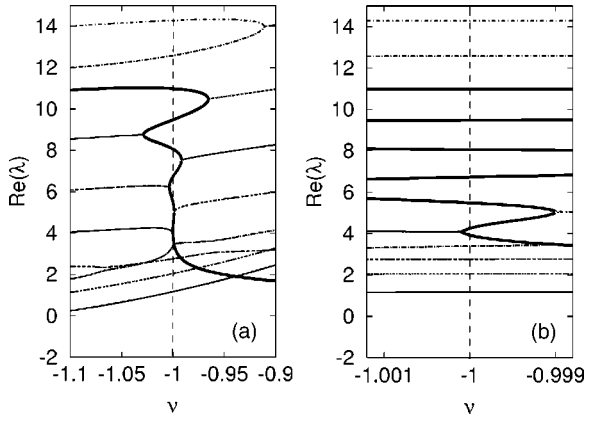

FIG. 6. The purely real curve (high-lighted fat) in the vicinity of $\nu=-1$ (cutoff length $b=7$) is formed by intermediate real segments between complex valued segments which branch off to the left and to the right. This leads to a ladderlike structure with exceptional points as nodes. The zoomed picture in (b) shows that the "oscillations" of the real curve about the line $\nu=-1$ persist also at its lower end, but with strongly reduced "amplitude." When the cutoff is slightly increased to $b\gtrsim 7$ the lowest exceptional (real-to-complex transition) point (b) will cross the line $\nu=-1$ and will in the region $\nu>-1$ coalesce with the other (nearest) exceptional point. As a result, one intermediate segment will be removed from the real curve and a purely complex-valued branch pair will smoothly tend from "far left" ($\nu<-1$) to "far right" ($\nu>-1$)—similar to the lower lying purely complex branches visible in the graphics.

levels below them. A sort of web structure is forming with a purely real branch remaining between the left ($\nu<-1$) and right ($\nu>-1$) purely complex (twisted) spectral regions. The complex-valued level pairs are branching off from the real branch forming a ladder-shaped structure. At the low-energy end of this ladder a second process occurs. The left ($\nu<-1$) complex level pairs are passing the line $\nu=-1$ and move to the right of it. There, at some $\nu>-1$ the corresponding exceptional point merges with an exceptional point of a right branch. As a result, one of the real segments between left and right off-branching levels disappears and a smooth complex-valued branch forms which extends over a large ν interval and whose imaginary components are increasing very fast when b is increased. It remains the real branch which becomes more and more vertical whereas the complex branch is not intersecting with it (the real component of the complex branch is coinciding at one point with the real branch but the imaginary components are not coinciding).

Analyzing the sequence of Figs. 2–6 we observe that, when the cutoff b is increased, a rather special (and seemingly inextricable) branch pattern of real and complex eigenvalues is forming in the vicinity of the exponent $\nu=-1$. [The phenomenon may be generic since in Ref. 46, the "wiggly upwards" spectral pattern has also been detected for a very different one-parametric family of asymptotically exponential $\mathcal{PT}$-symmetric potentials $V(x)=-(i\sinh x)^{\beta}$ near the Herbst-type exponent $\beta=1$.] The extreme steepness of an increasing number of imaginary branches and their accumulation at $\nu=-1$ (see Figs. 4 and 5) as well as the occurrence of the almost vertical real branch (Fig. 6) are indicating the formation of a local spectral singularity with $\partial_\nu E|_{\nu\to-1}\to\pm\infty$ at the (almost) vertical segments of the real-valued branch as well as on the imaginary branches close to the exceptional points of the "ladder" structure. From the figures it is not at all obvious how this pattern is compatible with the Herbst limit of an empty spectrum for $b\to\infty$ at $\nu=-1$. We will resolve this interesting puzzle in the next section.

IV. THE HERBST LIMIT AND ITS RELATION TO THE SQUIRE EQUATION OF HYDRODYNAMICS

In Ref. 15 it was shown by Herbst that the spectrum of a Hamiltonian with imaginary linear potential (imaginary homogeneous electric field) over the real line $x\in\mathbb{R}$ is empty. The differential expression of the corresponding operator coincides with that of the $\mathcal{PT}$-symmetric Schrödinger-type equation (18) with exponent $\nu=-1$,

$$[-\partial_y^2 - igb^3 y]\psi(y) = b^2 E\psi(y), \quad \psi(y = \pm 1) = 0. \tag{21}$$

The only difference of (21) compared to the Herbst model is in the Dirichlet boundary conditions at $y=\pm 1$ which restrict the system to a box (square well). Due to this analogy and for sake of brevity, we will call the model (21) a "Herbst box."

We start our consideration by noticing that Eq. (21) and the spectral function $\mu(b,E)=b^2E$ are invariant under the rescaling $b\mapsto g^{-1/3}b$, $E\mapsto g^{2/3}E$ so that henceforth we can set $g=1$, without loss of generality. The corresponding Herbst box Hamiltonian we denote as

$$H_{Hb}(b) \coloneqq -\partial_y^2 - ib^3 y. \tag{22}$$

Equation (21) itself is of Airy type and its solutions can be expressed as

$$\psi(y) = C_1 A_1[\xi(y)] + C_2 A_2[\xi(y)],$$

$$\xi(y) \coloneqq e^{i(\pi/3)}[-iby - E],$$

where $C_{1,2}=$const, and $A_1(\xi)$, $A_2(\xi)$ are any two of the Airy functions $\mathrm{Ai}(\xi)$, $\mathrm{Ai}(q\xi)$, $\mathrm{Ai}(q^2\xi)$ with $q \coloneqq e^{i2\pi/3}$. As usual, the boundary conditions lead to a characteristic determinant which defines the spectrum of the eigenvalue problem. In case of Eq. (21), it reads

$$\Delta(E) = A_1(\xi_+)A_2(\xi_-) - A_1(\xi_-)A_2(\xi_+) = 0, \quad \xi_\pm \coloneqq \xi(y = \pm 1). \tag{23}$$

Characteristic determinants of this type (built over Airy functions) have been intensively studied since 1995 in a paper series of Stepin[47,48] and Shkalikov *et al.*[49] (for related work see also Ref. 50) on the spectral properties of the Squire equation of hydrodynamics (the corresponding physical background can be found, e.g., in Refs. 51 and 52)

$$H_{\mathrm{Sq}}(\varepsilon) \coloneqq i\varepsilon\partial_y^2 + y, \quad (H_{\mathrm{Sq}} - \lambda)\chi = 0, \quad \chi(y = \pm 1) = 0, \quad \varepsilon \coloneqq (\tilde{\alpha}R)^{-1}. \tag{24}$$

Before we make the (obviously existing) relation of this model to the Herbst box model explicit, we briefly review a few of its properties.

The Squire equation (24) describes the normal vorticity of a plane Couette flow with linear velocity profile. The parameter $\tilde{\alpha}>0$ denotes a real-valued wave number which originates from the decomposition of a two-dimensional flow perturbation,

$$\Psi(x,y,t) = \chi(y)e^{i\tilde{\alpha}(x-\lambda t)},$$

$R>0$ is the Reynolds number and ε—the viscosity. The spectrum of H_{Sq} was found to have a Y-shaped form.[48,49,51] All the eigenvalues are located in a close vicinity of the three segments $(1,-i/\sqrt{3}]$, $(-1,-i/\sqrt{3}]$, $[-i/\sqrt{3},-i\infty)$. In the limit of large $R\to\infty$, $\tilde{\alpha}\geqslant 1$ and correspondingly small $\varepsilon\to 0^+$ the eigenvalue problem (24) turns into a singular perturbation problem and its eigenvalues show a remarkable limiting behavior. For $\varepsilon\to 0^+$, more and more eigenvalues "move in" from $-i\infty$ along the line $[-i/\sqrt{3},-i\infty)$, merge pairwise in the vicinity of the point $-i/\sqrt{3}$, and depart then (again pairwise) to move symmetrically along the segments $[1,-i/\sqrt{3}]$, $[-1,-i/\sqrt{3}]$ and to "fill" them step by step—leaving the Y-shape invariant. The process was described in Ref. 48 as a special type of transition from a discrete spectrum to a continuous one. Explicitly, the following asymptotic estimates were found in Refs. 48 and 49:

$$\lambda_n \sim -i\varepsilon\frac{\pi^2 n^2}{4} \in [-i/\sqrt{3},-i\infty), \quad n\to\infty, \tag{25}$$

$$\lambda_n^{\pm} \sim \pm 1 \pm \varepsilon^{1/3} s_n e^{\pm i\pi/6} \in (\pm 1,-i/\sqrt{3}], \quad \varepsilon\to 0^+, \tag{26}$$

where s_n are the zeros of the Airy function

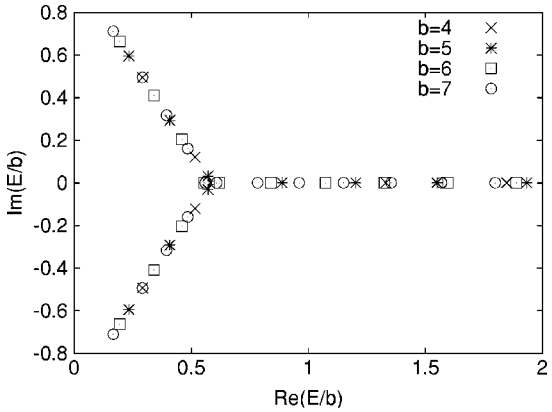

FIG. 7. The rescaled Herbst-box spectrum $E/b=i\lambda(\epsilon=b^{-3})$ coincides with the Wick-rotated Y-shaped spectrum of the Squire operator $H_{\mathrm{Sq}}(\varepsilon)$.

$$\mathrm{Ai}(s_n)=0, \quad s_n \in \mathbb{R}_-.$$

One clearly sees that the smaller ε is chosen the smaller the distances between the eigenvalues become—leading in the limit $\varepsilon \to 0$ to a quasicontinuous spectrum.

Noticing that the pairwise merging and splitting (level crossing) of the eigenvalues occurs at $\lambda^+ \sim \lambda^- \sim -i/\sqrt{3}$, it is easy to estimate that the value ε_n, for which this crossing is connected with the nth Airy function root s_n, is given by

$$\varepsilon_n^{1/3} \sim \frac{2}{|s_n|\sqrt{3}}. \tag{27}$$

Let us utilize the above results now for the Herbst-box model. A simple comparison of the eigenvalue problems (21) (for $g=1$) and (24) shows that these problems may be made coinciding if one sets

$$i\varepsilon^{-1}[H_{\mathrm{Sq}}(\varepsilon)-\lambda]\chi(y) \stackrel{!}{=} \mathcal{P}[H_{\mathrm{Hb}}(b)-b^2E]\mathcal{P}[\mathcal{P}\psi(y)]=0$$

and identifies

$$b^3=\varepsilon^{-1}, \quad E=ib\lambda, \quad \mathcal{P}H_{\mathrm{Hb}}(b)\mathcal{P}=i\varepsilon^{-1}H_{\mathrm{Sq}}(\varepsilon), \quad \mathcal{P}\psi(y)=\chi(y). \tag{28}$$

This means that the two models are related by the combined action of a rescaling, a Wick rotation and a coordinate reflection $\mathcal{P}$.

With the help of the estimates (25) and (26) it is now an easy task to explain the behavior of the Herbst-box spectrum $E(b)$.

(i) The rescaled spectrum $E(b)/b=i\lambda(\varepsilon=b^{-3})$ (shown in Fig. 7) is simply the Wick-rotated version of the original shape-invariant "Y" of the Squire operator $H_{\mathrm{Sq}}(\varepsilon)$. With increasing $b=\varepsilon^{-1/3}$ more and more eigenvalues "move in" from $+\infty$ and "fill" the two complex conjugate branches $(i,1/\sqrt{3}]$, $(-i,1/\sqrt{3}]$ of the "Y" as well as the half-line $[1/\sqrt{3},+\infty)$—in a similar way as in the original $\lambda(\varepsilon \to 0)$ limit. For $b \to \infty$ the spectrum becomes quasicontinuous on the rotated "Y."

(ii) Due to the shape invariance of $E(b)/b$, the spectrum $E(b)=ib\lambda(b^{-3})$ itself inflates when b increases. It is located in the close vicinity of the segments $(ib,b/\sqrt{3}]$, $(-ib,b/\sqrt{3}]$, $[b/\sqrt{3},+\infty)$ and moves with $b \to \infty$ to infinity—leaving (for sufficiently high b) an empty region at any fixed finite distance from the origin of the spectral E plane. Hence, we find (as required) that for $b \to \infty$ the Herbst-box spectrum turns into the empty spectrum of the original Herbst model over the real line $\mathbb{R}$.

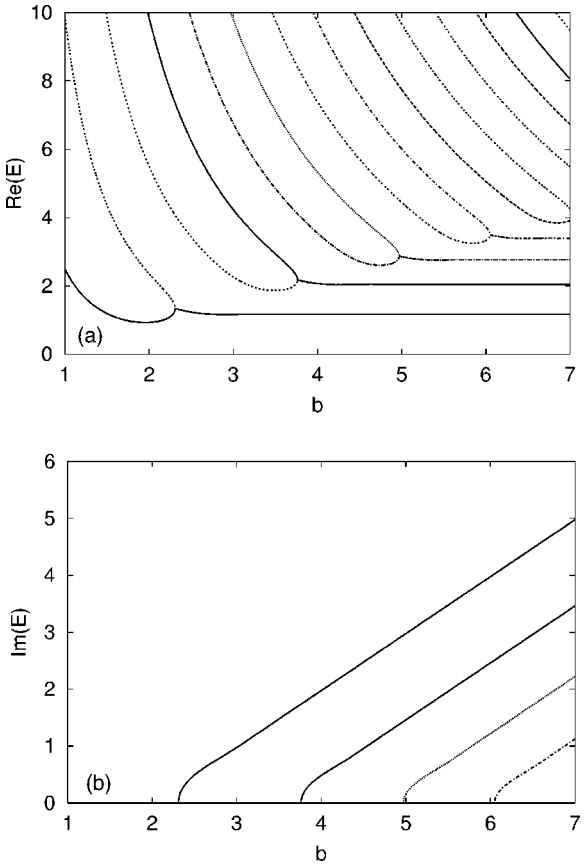

FIG. 8. Real and imaginary components of the Herbst-box spectrum as functions of the cutoff length b [complex conjugate ($\Im\lambda \leqslant 0$)-components omitted]. The asymptotical behavior of the complex-valued branches is clearly visible (constant real components and linear b dependence of the imaginary components).

(iii) For finite b, the asymptotic estimates (25) and (26) map into

$$E_k \sim \frac{\pi^2 k^2}{4b^2} \in b \times [1/\sqrt{3}, +\infty), \quad k \to \infty, \tag{29}$$

$$E_n^{\pm} \sim \pm ib \pm is_n e^{\pm i\pi/6} \in b \times (\pm i, 1/\sqrt{3}], \quad b \to \infty, \tag{30}$$

and we identify (29) as the pure square well spectrum

$$\mu(b, E_k) = b^2 E_k \sim \pi^2 k^2/4 \in b^3 \times [1/\sqrt{3}, +\infty) \tag{31}$$

of the high-energy sector which is almost not affected by the $\mathcal{PT}$-symmetric interaction. In contrast, the low-energy sector described by (30) shows a purely linear scaling behavior of the imaginary energy components $\Im E_n^{\pm}$, whereas the real components remain asymptotically fixed when b increases. This situation is also clearly visible from the numerical results presented in Fig. 8. The graphics of the equivalent spectrum $\mu(b, E)$, depicted in Fig. 9, provides a complementary description and shows how (for increasing b) the b-independent eigenvalues $\mu(b, E_k)$ of Eq. (31) leave the high-energy sector, obtain an explicit b dependence in the intermediate-energy sector and finally coalesce and split into complex conjugate pairs.

(iv) From the form of the spectral branches on the E plane (rotated "Y") it is clear that the level crossings in the vicinity of $E \sim b/\sqrt{3}$ correspond to the typical real-to-complex phase tran-

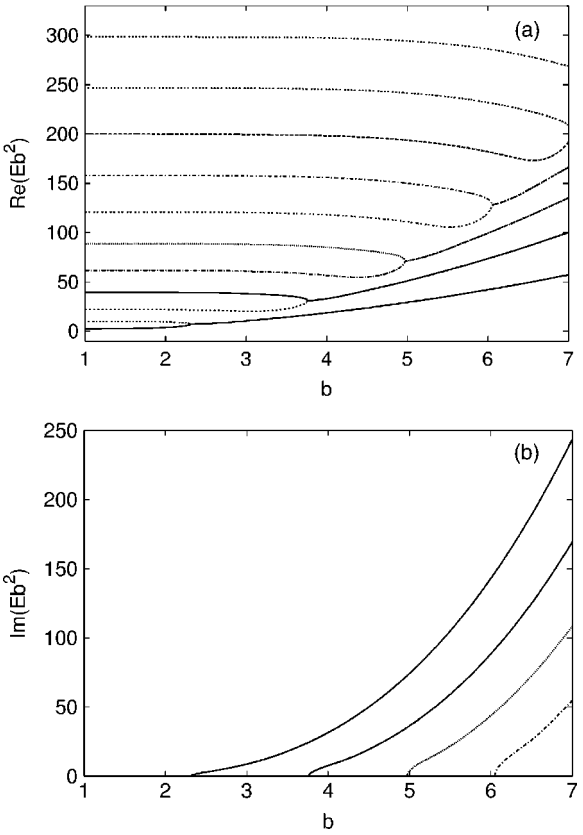

FIG. 9. The rescaled Herbst-box spectrum $\mu(b,E)=b^2E$ allows a complementary view on the transition from the high-energy sector to the intermediate and low-energy sector.

sitions of $\mathcal{PT}$-symmetric models in Krein spaces. With the help of relation (27) the cutoff-scales b_n and positions E_n of the level crossings can be roughly estimated as

$$b_n \sim |s_n|\sqrt{3}/2, \quad E_n \sim |s_n|/2. \tag{32}$$

One can use the explicit values of these b_n ($b_1 \approx 2.02$, $b_2 \approx 3.54$, $b_3 \approx 4.78$, $b_4 \approx 5.88$, $b_5 \approx 6.87$, $b_6 \approx 7.81$,…), to roughly derive the number of the lowest uncrossed modes in the cases $b=2,4,6,7$. For $b=2,4,6$ the result exactly coincides with the level crossing pattern shown (at $\nu=-1$) in Figs. 2–4, whereas the value b_5 is clearly smaller than the actual transition value $b_{5(c)}$ for which according to Figs. 6(b) and 8 holds $b_{5(c)} \gtrsim 7$. For completeness, we note that the asymptotic approximation[48] of the Airy function roots

$$|s_n| = \left[\frac{3\pi}{2}\left(n-\frac{1}{4}\right)\right]^{2/3} + O(n^{-4/3}), \quad n \to \infty$$

together with (32) yields the following rough estimate for the lowest purely real-valued mode:

$$k_a > \frac{4}{3\pi}\left(\frac{2}{\sqrt{3}}b\right)^{3/2} + \frac{1}{2}.$$

The scaling dimension $\kappa_a=3/2$ of this bound is only one-half of the scaling dimension $\kappa_s=4+\nu=3$ of the corresponding supremum bound (20). The exact positions of the level crossing points are given by the multiple roots of the characteristic determinant, $\Delta(E)$

$=0$, $\partial_E\Delta(E)=0$. This equation system can be simplified via Wronskian $W[A_1(.),A_2(.)]$ to yield the conditions

$$A_{1,2}(\xi_+) = \pm A_{1,2}(\xi_-)$$

(see Ref. 48 for the details). Plugging the numerical results from the eigenvalue solver into this equation with $A_{1,2}(\xi)$ chosen as in Ref. 48, $A_1(\xi) := \mathrm{Ai}(\xi)$, $A_2(\xi) := \mathrm{Ai}(q^2\xi)$, selects the condition $A_{1,2}(\xi_+)=A_{1,2}(\xi_-)$ and satisfies it within numerical working precision. For the same data holds $A_{1,2}(\xi_+) \neq -A_{1,2}(\xi_-)$.

(v) The spectral behavior $E(b)$ for increasing cutoff b can be summarized as follows. At the beginning, the real eigenvalues from the high-energy sector decrease as $E_k \sim \pi^2 k^2/(4b^2)$—moving into the intermediate energy region. When b approaches $b_n \sim |s_n|\sqrt{3}/2$ from below, the real eigenvalues $\{E_{2n-1}, E_{2n}\}$ (corresponding to a pair of positive and negative Krein space states[11]) coalesce at $E_{2n-1} \sim E_{2n} \sim |s_n|/2$ and a real-to-complex transition occurs $\{E_{2n-1}, E_{2n}\} \to \{E_n^+, E_n^-\}$. When b is further increased the real energy components remain fixed $\Re E_n^{\pm} \approx |s_n|/2$ [see Fig. 8(a)], whereas the imaginary components blow up linearly along the asymptotes $\Im E_n^{\pm} \sim \pm b \pm s_n\sqrt{3}/2$ [Fig. 8(b)].

Let us, for finite b, relate the obtained Herbst-box results to the spectral behavior of the $\mathcal{PT}$-symmetric interpolation model of the preceding section. Apart from the obvious one-to-one correspondence of the high-energy sectors [see (31)], a clear identification is immediately possible for those Herbst-box eigenvalues which are close to the imaginary axis and which have the largest imaginary components. These eigenvalues are located on the branches with the largest imaginary components in Figs. 3–5 (which stay complex when ν passes through the Herbst-box value $\nu=-1$). It is clearly visible from these figures that, for increasing b, the imaginary components are blowing up, whereas the real components remain asymptotically constant.

So far, we have found a clear correspondence for those regions on the Herbst-box "Y" which are located away from the center of the "Y" with its real-to-complex phase transitions. A more subtle situation occurs in the vicinity of this center. The corresponding Herbst box eigenvalues will map into points located close to (or on) the forming (almost) vertical segment of the purely real branch depicted in Fig. 6. From the zoomed graphics in Fig. 6(b) we observe that the purely real and almost vertical branch of the interpolation model "oscillates" around the Herbst-box line at $\nu=-1$ with strongly decreasing "amplitude" to its low-energy part. With increasing b this "decreasing amplitude" effect becomes stronger and the "oscillations" are only traceable with the help of an appropriately increased zooming scale. Nevertheless, it can be read off that the real-to-complex transition of the Herbst-box spectrum follows qualitatively the same scheme for any finite b. The real eigenvalues of the Herbst box are all located on the purely real branch of the interpolation model and the real-to-complex transition occurs when the lowest exceptional point on this branch moves from the left sector $\nu<-1$ through the Herbst-box value $\nu=-1$ into the right sector $\nu>-1$—to coalesce afterwards with the next higher exceptional point from the right sector. With this passing of the left-sector exceptional point through the line $\nu=-1$ the Herbst-box eigenvalues become pairwise complex conjugate with strongly increasing imaginary components [due to the asymptotically diverging gradient $\partial_\nu E(b\to\infty)|_{\nu\approx -1} \to \pm\infty$]. The real-to-complex transition with subsequently increasing imaginary components are illustrated in Fig. 10.

Finally, we note that in the limit $b\to\infty$, the lowest-lying intersection of the purely real branch with the Herbst-box line $\nu=-1$ moves away to infinity like $b/\sqrt{3}$ (the lower bound of the real segment $[b/\sqrt{3},\infty)$ of the Herbst-box "Y") so that the real branch itself remains for any finite energy in the right sector $\nu>-1$—approaching the Herbst-box line asymptotically. This reproduces the earlier observations of Refs. 1 and 16 for the spectrum of the Bender–Boettcher problem over the real line. Additionally, our Herbst-box results predict for this problem diverging imaginary components at $\nu=-1: |\Im E(b\to\infty, \nu\to -1)| \to \infty$. Taking these observations together we once more see that in the limit $b\to\infty$ a spectral singularity is forming at $\nu=-1$ with $|E(b\to\infty, \nu\to -1)| \to \infty$, $|\partial_\nu E(b\to\infty, \nu\to -1)| \to \infty$.

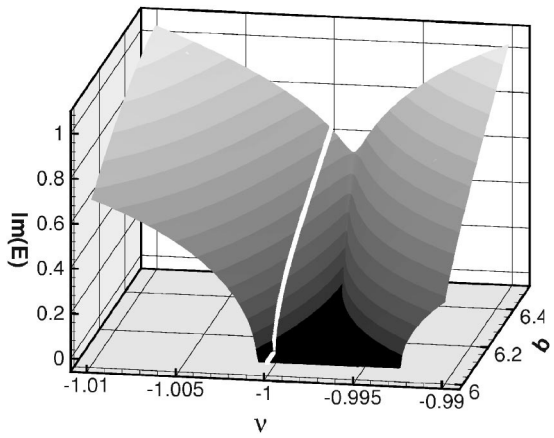

FIG. 10. Concrete example for the generic merging process of two complex-valued spectral branches (present here for $b<b_{\mathrm{coal}}\approx 6.36$) into a single complex-valued branch for $b>b_{\mathrm{coal}}$. The two exceptional (real-to-complex transition) points existing for $b<b_{\mathrm{coal}}$ are located on the plane $(\nu,b,\Im E=0)$ and coalesce at $b=b_{\mathrm{coal}}$. The corresponding point $(\nu_{\mathrm{coal}}\approx -0.9983>-1, b_{\mathrm{coal}}\approx 6.36, \Im E=0)$ is the starting (cusp) point of a sharp "valley" of the nonvanishing imaginary component which steeply grows and smooths when $b>b_{\mathrm{coal}}$ is further increased. The white curve marks the Herbst-box values. Before the two exceptional points coalesce, the left one of these points crosses the Herbst-box configuration at $(\nu=-1, b=b_c\approx 6.02, \Im E=0)$ and a real-to-complex transition occurs for the Herbst-box model.

V. CONLUSIONS

In the present paper we considered three models emerging in different physical setups, but which are closely related with each other by their underlying mathematical structure as spectral problems in Krein spaces. The models are a one-dimensional $\mathcal{PT}$-symmetric quantum mechanical interpolation setup defined over a square well of finite width $2b$, the spherically symmetric MHD α^2-dynamo as well as the Squire equation of hydrodynamics. For the PTSQM model and the α^2-dynamo we made their close relation transparent by transforming them into a 2×2 matrix operator representation with coinciding block structure of the Krein space metric (involution operator). In the case of the Squire equation we showed that the corresponding spectral problem is connected with a $\mathcal{PT}$-symmetric eigenvalue problem by a rescaling and Wick rotation. (It is clear that, apart from the Squire equation, there will exist other hydrodynamic equations which can be structurally identified as Wick-rotated $\mathcal{PT}$-symmetric systems in Krein spaces.)

Based on recent results on the spectrum of the Squire equation, we performed a qualitative analysis of the $\mathcal{PT}$-symmetric quantum mechanical interpolation model for arbitrary square well widths (cutoffs) $2b$. This allowed us to trace the emergence of the Herbst limit with its empty spectrum as a spectral singularity and to fit our results to those of the Bender–Boettcher equation over the real line. We obtained a rich structure of multiple spectral phase transitions from purely real eigenvalues to pairs of complex conjugate ones—as it was to expect for spectral problems in Krein spaces.

A deeper insight into the Herbst-box spectrum and a possible extension of the present results to $\mathcal{PT}$-symmetric Hamiltonians of the type $H_{M,N}=-\partial_x^2+x^{2M}(ix)^N$, $M,N=1,2,3,\ldots$ over square wells can probably be achieved by representing the characteristic determinant $\Delta(E)$ in (23) via Hadamar product representation of the Airy functions[53] as a spectral determinant of Bethe-ansatz type[16,29,54] and studying it by similar cocycle functional equations as in Ref. 55.

A question which was not touched in the present paper concerns the orthogonality of the Herbst-box eigenfunctions. For the Squire equation it is known that its eigenfunctions show a strong nonorthogonality[47,51] (due to the non-normality of the Squire operator) for eigenvalues in the vicinity of the branch point center of the "Y" (pseudospectral techniques[50,51,56] play an important role in this case). Our above considerations indicate on a link of this issue with the forming spectral singularity $|\partial_\nu E(\nu\approx -1, b\gg 1)|\gg 1$ in the vicinity of the almost vertical segments of the purely real branch in the spectrum of the $\mathcal{PT}$-symmetric interpolation model.

Finally, we would like to note two issues which seem of relevance for future considerations. The first one is in developing efficient mathematical tools to find the hypersurfaces in parameter space where spectral phase transitions of the real-to-complex type occur. [A two-step method similar in spirit was successfully used, e.g., in higher-dimensional gravitational models to obtain the stability regions in the moduli (parameter) space of these models (step one, find the critical hypersurfaces; step two, identify the stability/instability properties of the model aside from these hypersurfaces).[57]] Knowing these hypersurfaces, one would know the boundaries which separate the parameter space regions with unbroken $\mathcal{PT}$-symmetry from regions with spontaneously broken $\mathcal{PT}$-symmetry. In case of α^2-dynamos the corresponding knowledge would allow for a more precise prediction of configurations with tendency to magnetic field reversals. The second issue concerns methods for solving inverse spectral problems in Krein spaces. Such methods would be extremely helpful for the data analysis of the dynamo experiments which are planned for the near future at seven sites around the world.[58]

APPENDIX: A FEW COMMENTS ON THE PHYSICS OF MHD α^2-DYNAMOS

The dynamo operator $\hat{H}_l[\alpha]$ originates from the MHD mean-field induction equation (cf. Ref. 12)

$$\partial_t \mathbf{B} = \boldsymbol{\nabla} \times (\alpha \mathbf{B}) + \nu_m \Delta \mathbf{B} \tag{A1}$$

for the magnetic field **B**. This equation results from averaging over small scale turbulences in the velocity field of the electrically conducting fluid (or plasma) which drives the dynamo. The helical turbulence function $\alpha(x)$ [also called α-profile (in general setups, α is not a scalar function but a tensor[12])] encodes the net effect of the small scale physics on the large scale (mean) magnetic field **B**. For certain topologically nontrivial helical velocity and **B**-field configurations an inverse cascade effect occurs which induces an energy transfer from small-scale structures to large-scale structures (inverse to the energy transfer in usual turbulence cascades where the energy is pumped from large-scale structures into smaller structures until it finally dissipates and transforms into thermal energy). For sufficiently strong inverse cascade effects the advection term $\boldsymbol{\nabla} \times (\alpha \mathbf{B})$ starts to dominate over the diffusion term $\nu_m \Delta \mathbf{B}$ (ν_m is the magnetic diffusivity) and the magnetic field strength starts to grow exponentially. This kinematic dynamo effect (growing **B** field for a given velocity field of the fluid) is followed by a saturated dynamo regime where a balance between the dynamo effect and the back-reaction of the induced magnetic field on the velocity field (via Navier–Stokes equation) prevents a further growth of the field strength **B**. For completeness, we note that an MHD dynamo is an open system in which part of the kinetic energy of the conducting fluid (or plasma) transforms into magnetic field energy.

The dynamo eigenvalue problem

$$\hat{H}_l[\alpha]\phi_{l,n} = \lambda_{l,n}\phi_{l,n}, \quad \phi_{l,n}(t) \sim \exp \lambda_{l,n} t \tag{A2}$$

follows from the induction equation (A1) via a double decomposition: decomposing the **B** field into poloidal and toroidal components (what leads to the two-component vector structure of $\phi_{l,n}$) and expanding them further into spherical harmonics. In the simplest (toy model) case of a spherically symmetric dynamo configuration the corresponding modes decouple completely and one arrives at the spherical l-mode projection (12) and (A2) (the subscript n denotes the radial mode number).

Up to now only a single exactly solvable α^2-dynamo model is known—the model with constant α-profile.[12] Its spectrum is discrete, real,[59] bounded above and, depending on the value of

α, it is either completely negative (for α below a critical α_c: $\alpha < \alpha_c$) or it contains a finite number of positive eigenvalues $\lambda_{l,n} > 0$. The dynamo effect is dominated by these latter eigenmodes. In practice, it usually suffices to concentrate the analysis on the dominating upper most growing mode (or a few of the upper most modes) for dipole ($l=1$) and quadrupole ($l=2$) configurations. (There exist no "s-wave" α^2-dynamos with $l=0$.[12,13])

The spectral properties of the dynamo operator $\hat{H}_l[\alpha]$ are becoming much richer for inhomogeneous α-profiles $\alpha(r) \neq$ const, when real-to-complex transitions occur—as discussed in Sec. II C and shown in Fig. 1.

(Received 20 August 2004; accepted 7 March 2005; published online 20 May 2005)

The Feynman integral for the Schrödinger propagator is constructed as a generalized function of white noise, for a linear space of potentials spanned by finite (signed) measures of bounded support and Laplace transforms of such measures, i.e., locally singular as well as rapidly growing at infinity. Remarkably, all these propagators admit a perturbation expansion. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904162]

I. INTRODUCTION

On a mathematical level of rigor, the construction of Feynman integrals for quantum mechanical propagators will have to be done for specific classes of potentials. In particular, the Feynman integrand has been identified as a well-defined generalized function in white noise space, e.g., for the following classes of potentials:

(i) (signed) finite measures which are "small" at infinity,[7,15]
(ii) Fourier transforms of measures,[18]
(iii) Laplace transforms of finite measures.[13]

Potentials in the third space are locally smooth but may grow rapidly at infinity, a prominent example is the Morse potential. On the other hand, the first of these classes includes locally singular potentials such as the Dirac delta function. It is also important for the construction of Feynman integrals with boundary conditions.[2] Hence it would be desirable to admit potentials which are linear combinations of elements from the first and third space. The present paper addresses this problem: we show the existence of Feynman integrals solving the propagator equation for such potentials.

II. WHITE NOISE ANALYSIS

In this section we briefly recall the concepts and results of white noise analysis used throughout this work (see, e.g., Refs. 1, 4, 5, 8, 11, 12, 14, and 16 for a detailed explanation).

The starting point of (one-dimensional) white noise analysis is the real Gelfand triple

[a)]Electronic mail: mfaria@uma.pt
[b)]Electronic mail: oliveira@cii.fc.ul.pt
[c)]Electronic mail: streit@physik.uni-bielefeld.de

$$S(\mathbb{R}) \subset L^2(\mathbb{R}) \subset S'(\mathbb{R}),$$

where $L^2 := L^2(\mathbb{R})$ is the real Hilbert space of all square integrable functions with respect to the Lebesgue measure, $\mathcal{S} := S(\mathbb{R})$ and $\mathcal{S}' := S'(\mathbb{R})$ are the real Schwartz spaces of test functions and tempered distributions, respectively. In the sequel we denote the norm on L^2 by $|\cdot|$, the corresponding inner product by $(\cdot,\cdot)$, and the dual pairing between $\mathcal{S}'$ and $\mathcal{S}$ by $\langle\cdot,\cdot\rangle$. The dual pairing $\langle\cdot,\cdot\rangle$ and the inner product $(\cdot,\cdot)$ are connected by

$$\langle f,\xi\rangle = (f,\xi), \quad f \in L^2, \quad \xi \in \mathcal{S}.$$

By $\{|\cdot|_p\}_{p\in\mathbb{N}}$ we denote a family of Hilbert norms topologizing the space $\mathcal{S}$.

Let $\mathcal{B}$ be the σ-algebra generated by the cylinder sets on $\mathcal{S}'$. Through the Minlos theorem one may define the white noise measure space $(\mathcal{S}',\mathcal{B},\mu)$ by giving the characteristic function

$$C(\xi) := \int_{\mathcal{S}'} e^{i\langle\omega,\xi\rangle}\, \mathrm{d}\mu(\omega) = e^{-1/2|\xi|^2}, \quad \xi \in \mathcal{S}.$$

Within this formalism a version of the (one-dimensional) Wiener Brownian motion is given by

$$B(t) := \langle\omega, \mathbb{1}_{[0,t)}\rangle, \quad \omega \in \mathcal{S}',$$

where $\mathbb{1}_A$ denotes the indicator function of a set A.

Now let us consider the complex Hilbert space $L^2(\mu) := L^2(\mathcal{S}',\mathcal{B},\mu)$. As this space quite often shows to be too small for applications, to proceed further we shall construct a Gelfand triple around the space $L^2(\mu)$. More precisely, first we shall choose a space of white noise test functions contained in $L^2(\mu)$ and then we work on its larger dual space of distributions. In our case we will use the space $(\mathcal{S})^{-1}$ of generalized white noise functionals or Kondratiev distributions and its well-known subspace $(\mathcal{S})'$ of Hida distributions (or generalized Brownian functionals) with corresponding Gelfand triples

$$(\mathcal{S})^1 \subset L^2(\mu) \subset (\mathcal{S})^{-1}$$

and

$$(\mathcal{S}) \subset L^2(\mu) \subset (\mathcal{S})'.$$

Instead of reproducing the explicit construction of $(\mathcal{S})^{-1}$ and $(\mathcal{S})'$ (see, e.g., Refs. 1 and 5), in Theorems 1 and 2 below we will define both spaces by their T-transforms. Given a $\Phi \in (\mathcal{S})^{-1}$, there exist $p,q \in \mathbb{N}_0$ such that we can define for every

$$\xi \in U_{p,q} := \{\xi \in \mathcal{S} : 2^q |\xi|_p^2 < 1\}$$

the T-transform of Φ by

$$T\Phi(\xi) := \langle\langle \Phi, \exp(i\langle\cdot,\xi\rangle)\rangle\rangle. \tag{1}$$

Here $\langle\langle\cdot,\cdot\rangle\rangle$ denotes the dual pairing between $(\mathcal{S})^{-1}$ and $(\mathcal{S})^1$ which is defined as the bilinear extension of the inner product on $L^2(\mu)$. In particular, for Hida distributions Φ, definition (1) extends to $\xi \in \mathcal{S}$. By analytic continuation, the definition of T-transform may be extended to the underlying complexified space $\mathcal{S}_{\mathbb{C}}$ of $\mathcal{S}$.

In order to define the spaces $(\mathcal{S})^{-1}$ and $(\mathcal{S})'$ through their T-transforms we need the following two definitions.

Definition 1: A function $F: U \to \mathbb{C}$ is holomorphic on an open set $U \subset \mathcal{S}_{\mathbb{C}}$ if

(1) *for all $\theta_0 \in U$ and any $\theta \in \mathcal{S}_{\mathbb{C}}$ the mapping $\mathbb{C} \ni \lambda \mapsto F(\lambda\theta + \theta_0)$ is holomorphic on some neighborhood of $0 \in \mathbb{C}$,*
(2) *F is locally bounded.*

Definition 2: A function $F:\mathcal{S}\to\mathbb{C}$ is called a U-functional whenever

(1) *for every $\xi_1,\xi_2\in\mathcal{S}$ the mapping $\mathbb{R}\ni\lambda\mapsto F(\lambda\xi_1+\xi_2)$ has an entire extension to $\lambda\in\mathbb{C}$,*
(2) *there exist constants $K_1,K_2>0$ such that*

$$|F(z\xi)|\leqslant K_1\exp(K_2|z|^2\|\xi\|^2),\quad \forall\, z\in\mathbb{C},\ \xi\in\mathcal{S}$$

for some continuous norm $\|\cdot\|$ on $\mathcal{S}$.

We are now ready to state the aforementioned characterization results.

Theorem 1: (Ref. 10) *Let $0\in U\subset\mathcal{S}_{\mathbb{C}}$ be an open set and $F:U\to\mathbb{C}$ be a holomorphic function on U. Then there is a unique $\Phi\in(\mathcal{S})^{-1}$ such that $T\Phi=F$. Conversely, given a $\Phi\in(\mathcal{S})^{-1}$ the function $T\Phi$ is holomorphic on some open set in $\mathcal{S}_{\mathbb{C}}$ containing 0. The correspondence between F and Φ is a bijection if one identifies holomorphic functions which coincide on some open neighborhood of 0 in $\mathcal{S}_{\mathbb{C}}$.*

Theorem 2: (Refs. 9 and 17) *The T-transform defines a bijection between the space $(\mathcal{S})'$ and the space of U-functionals.*

As a consequence of Theorem 1 one may derive the next two statements. The first one concerns the convergence of sequences of generalized white noise functionals and the second one the Bochner integration of families of the same type of generalized functionals. Similar results exist for Hida distributions (see, e.g., Ref. 5).

Theorem 3: *Let $(\Phi_n)_{n\in\mathbb{N}}$ be a sequence in $(\mathcal{S})^{-1}$ such that there are $p,q\in\mathbb{N}_0$ so that*

(1) *all $T\Phi_n$ are holomorphic on $U_{p,q}:=\{\theta\in\mathcal{S}_{\mathbb{C}}:2^q|\theta|_p^2<1\}$,*
(2) *there exists a $C>0$ such that $|T\Phi_n(\theta)|\leqslant C$ for all $\theta\in U_{p,q}$ and all $n\in\mathbb{N}$,*
(3) *$(T\Phi_n(\theta))_{n\in\mathbb{N}}$ is a Cauchy sequence in $\mathbb{C}$ for all $\theta\in U_{p,q}$.*

Then $(\Phi_n)_{n\in\mathbb{N}}$ converges strongly in $(\mathcal{S})^{-1}$.

Theorem 4: *Let $(\Lambda,\mathcal{F},\nu)$ be a measure space and $\lambda\mapsto\Phi_\lambda$ be a mapping from Λ to $(\mathcal{S})^{-1}$. We assume that there exists a $U_{p,q}\subset\mathcal{S}_{\mathbb{C}},p,q\in\mathbb{N}_0$, such that*

(1) *$T\Phi_\lambda$ is holomorphic on $U_{p,q}$ for every $\lambda\in\Lambda$,*
(2) *the mapping $\lambda\mapsto T\Phi_\lambda(\theta)$ is measurable for every $\theta\in U_{p,q}$,*
(3) *there is a $C\in L^1(\Lambda,\mathcal{F},\nu)$ such that*

$$|T\Phi_\lambda(\theta)|\leqslant C(\lambda),\quad \forall\,\theta\in U_{p,q},\quad \nu-a.a.\lambda\in\Lambda.$$

Then there exist $p',q'\in\mathbb{N}_0$, which only depend on p,q, such that Φ_λ is Bochner integrable. In particular,

$$\int_\Lambda \Phi_\lambda\,\mathrm{d}\nu(\lambda)\in(\mathcal{S})^{-1}$$

and $T(\int_\Lambda\Phi_\lambda\,\mathrm{d}\nu(\lambda))$ is holomorphic on $U_{p',q'}$. One has

$$\left\langle\!\left\langle\int_\Lambda\Phi_\lambda\,\mathrm{d}\nu(\lambda),\varphi\right\rangle\!\right\rangle=\int_\Lambda\langle\langle\Phi_\lambda,\varphi\rangle\rangle\mathrm{d}\nu(\lambda),\quad\forall\,\varphi\in(\mathcal{S})^1.$$

III. THE FREE FEYNMAN INTEGRAL

We follow Refs. 3 and 6 in viewing the Feynman integral as a weighted average over Brownian paths. We use a slight change in the definition of the paths, which are here modeled by

$$x(\tau) = x - \sqrt{\frac{\hbar}{m}}\int_\tau^t \omega(s)\mathrm{d}s := x - \sqrt{\frac{\hbar}{m}}\langle \omega, \mathbb{1}_{(\tau,t]}\rangle, \quad \omega \in \mathcal{S}'.$$

That is, instead of fixing the starting point of the paths, we fix the endpoint x at time t. In the sequel we set $\hbar = m = 1$. Correspondingly, the Feynman integrand for the free motion is defined by

$$I_0 := I_0(x,t|y,t_0) := N\exp\left(\frac{i+1}{2}\int_{\mathbb{R}} \omega^2(\tau)\mathrm{d}\tau\right)\delta(x(t_0)-y),$$

where, informally, N is a normalizing factor, more precisely, $N\exp(\cdot)$ is a Gauss kernel (see, e.g., Refs. 5 and 15). We recall that the Donsker delta function $\delta(x(t_0)-y)$ is used to fix the starting point of the paths at time $t_0 < t$. The T-transform of the free Feynman integrand

$$TI_0(\xi) = \frac{1}{\sqrt{2\pi i(t-t_0)}}\exp\left(-\frac{i}{2}\int_{\mathbb{R}} \xi^2(\tau)\mathrm{d}\tau\right)\exp\left(\frac{i}{2(t-t_0)}\left(\int_{t_0}^t \xi(\tau)\mathrm{d}\tau + x - y\right)^2\right) \tag{2}$$

is a U-functional and we use it to define I_0 as a Hida distribution (see Ref. 3).

From the physical point of view, equality (2) clearly shows that the Feynman integral $TI_0(0)$ is the free particle propagator

$$\frac{1}{\sqrt{2\pi i(t-t_0)}}\exp\left(\frac{i}{2(t-t_0)}(x-y)^2\right).$$

Besides this particular case, even for nonzero ξ the T-transform of I_0 has a physical interpretation. Integrating formally by parts we find

$$TI_0(\xi) = \int_{\mathcal{S}'} I_0(\omega)\exp\left(-i\int_{t_0}^t x(\tau)\dot{\xi}(\tau)\mathrm{d}\tau\right)\mathrm{d}\mu(\omega)\exp\left(-\frac{i}{2}\int_{[t_0,t]^c} \xi^2(\tau)\mathrm{d}\tau + ix\xi(t) - iy\xi(t_0)\right).$$

The term $\exp(-i\int_{t_0}^t x(\tau)\dot{\xi}(\tau)\mathrm{d}\tau)$ would thus correspond to a time-dependent potential $W(x,t) = \dot{\xi}(t)x$. In fact, it is straightforward to verify that

$$\Theta(t-t_0)\cdot TI_0(\xi) = K_0^{(\xi)}\exp\left(-\frac{i}{2}\int_{[t_0,t]^c} \xi^2(\tau)\mathrm{d}\tau + ix\xi(t) - iy\xi(t_0)\right),$$

where Θ is the Heaviside function and

$$K_0^{(\xi)} := K_0^{(\xi)}(x,t|y,t_0) := \frac{\Theta(t-t_0)}{\sqrt{2\pi i|t-t_0|}}\exp\left(-\frac{i}{2}\int_{t_0}^t \xi^2(\tau)\mathrm{d}\tau\right)\exp\left(\frac{i}{2|t-t_0|}\left(\int_{t_0}^t \xi(\tau)\mathrm{d}\tau + x - y\right)^2\right)$$
$$\times \exp(iy\xi(t_0) - ix\xi(t))$$

is the Green function corresponding to the potential W, i.e., $K_0^{(\xi)}$ obeys the Schrödinger equation

$$\left(i\partial_t + \frac{1}{2}\partial_x^2 - \dot{\xi}(t)x\right)K_0^{(\xi)}(x,t|y,t_0) = i\delta(t-t_0)\,\delta(x-y). \tag{3}$$

IV. INTERACTIONS

In the sequel $\mathcal{K}_1$ denotes the linear space of all potentials V on $\mathbb{R}$ of the form

$$V(x) = \int_{\mathbb{R}} e^{\alpha x}\,\mathrm{d}m(\alpha), \quad x \in \mathbb{R},$$

where m is a complex measure on the Borel sets on $\mathbb{R}$ fulfilling the condition

$$\int_{\mathbb{R}} e^{C|\alpha|} d|m|(\alpha) < \infty, \quad \forall\, C > 0 \tag{4}$$

(cf. Ref. 13), and $\mathcal{K}_2$ denotes the space of all potentials V on $\mathbb{R}$ which are generalized functions of the type

$$V(x) = \int_{\mathbb{R}} \delta(x-y)\mathrm{d}m(y), \quad x \in \mathbb{R},$$

where $\mathrm{d}m(y) := V(y)\mathrm{d}y$ is a finite signed Borel measure of bounded support (cf. Ref. 7).

Remark 5: *A Lebesgue dominated convergence argument shows that potentials in $\mathcal{K}_1$ are restrictions to the real line of entire functions.*[13] *In particular, they are locally bounded and smooth.*

Our aim is to define the Feynman integrand

$$I := I_0 \cdot \exp\left(-i\int_{t_0}^{t} V(x(\tau))\mathrm{d}\tau\right) \tag{5}$$

for a potential V of the form $V=V_1+V_2$, $V_i \in \mathcal{K}_i$,

$$V_1(x) = \int_{\mathbb{R}} e^{\alpha x}\, \mathrm{d}m_1(\alpha), \quad V_2(x) = \int_{\mathbb{R}} \delta(x-y)\mathrm{d}m_2(y), \tag{6}$$

where

$$x(\tau) = x - \int_{\tau}^{t} \omega(s)\mathrm{d}s, \quad \omega \in \mathcal{S}',$$

as before. In order to do this, first we must give a meaning to the heuristic expression (5). In Theorem 7 it will be shown that I is indeed a well-defined generalized white noise functional. Second, it has to be proven that the expectation of I solves the Schrödinger equation for the potential V.

As a first step we expand the exponential in (5) into a perturbation series. This leads to

$$\begin{aligned} I = \sum_{n=0}^{\infty} \frac{(-i)^n}{n!} \sum_{k=0}^{n} \binom{n}{k} k! \int_{\Delta_k} d^k\tau \int_{t_0}^{t} d^{n-k}s \\ \times \int_{\mathbb{R}^k}\int_{\mathbb{R}^{n-k}} I_0 \exp\left(\sum_{l=1}^{n-k} \alpha_l x(s_l)\right) \prod_{j=1}^{k} \delta(x(\tau_j)-x_j) \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) \prod_{j=1}^{k} \mathrm{d}m_2(x_j), \end{aligned} \tag{7}$$

where $\Delta_k := \{(\tau_1,\ldots,\tau_k) : t_0 < \tau_1 < \cdots < \tau_k < t\}$. In the above expression the integrals over $\Delta_k, \mathbb{R}^k$ and $[t_0,t]^{n-k}, \mathbb{R}^{n-k}$ disappear, respectively, for $k=0$ and $k=n$. Our aim is to apply Theorems 3 and 4 to show the existence of the above series and integrals. However, first we must establish the pointwise multiplication of generalized functionals

$$I_0 \exp\left(\sum_{l=1}^{n-k} \alpha_l x(s_l)\right) \prod_{j=1}^{k} \delta(x(\tau_j)-x_j)$$

as a well-defined generalized functional. Due to the characterization result Theorem 2 it is enough to define this product through its T-transform. Arguing informally, for $\xi \in \mathcal{S}$ we are led to

$$T\left(I_0 \exp\left(\sum_{l=1}^{n-k} \alpha_l x(s_l)\right)\prod_{j=1}^{k} \delta(x(\tau_j)-x_j)\right)(\xi)$$
$$= \int_{\mathcal{S}'} I_0 \exp\left(\sum_{l=1}^{n-k} \alpha_l x(s_l)\right)\prod_{j=1}^{k} \delta(x(\tau_j)-x_j)\exp(i\langle\omega,\xi\rangle)\mathrm{d}\mu(\omega)$$
$$= \exp\left(x\sum_{l=1}^{n-k}\alpha_l\right)\cdot T\left(I_0\prod_{j=1}^{k}\delta(x(\tau_j)-x_j)\right)\left(\xi+i\sum_{l=1}^{n-k}\alpha_l \mathbb{1}_{(s_l,t]}\right).$$

The product $I_0\Pi_{j=1}^{k}\delta(x(\tau_j)-x_j)$ is a slight generalization of the free Feynman integrand I_0, with more than just one delta function, and may be defined by its T-transform,

$$T\left(I_0\prod_{j=1}^{k}\delta(x(\tau_j)-x_j)\right)(\xi) = \exp\left(-\frac{i}{2}\int_{[t_0,t]^c}\xi^2(s)\mathrm{d}s + ix\xi(t)-iy\xi(t_0)\right)\prod_{j=1}^{k+1}K_0^{(\xi)}(x_j,\tau_j|x_{j-1},\tau_{j-1})$$
$$= \exp\left(-\frac{i}{2}\int_{\mathbb{R}}\xi^2(s)\mathrm{d}s\right)\prod_{j=1}^{k+1}\left\{\frac{1}{\sqrt{2\pi i(\tau_j-\tau_{j-1})}}\right.$$
$$\left.\times\exp\left(\frac{i}{2(\tau_j-\tau_{j-1})}\left(\int_{\tau_{j-1}}^{\tau_j}\xi(s)\mathrm{d}s + x_j - x_{j-1}\right)^2\right)\right\}. \tag{8}$$

Here $\tau_0 := t_0$, $x_0 := y$, $\tau_{k+1} := t$, and $x_{k+1} := x$. Clearly the explicit formula (8) is continuously extendable to all $\xi \in L^2$ which allows an extension of $T(I_0\Pi_{j=1}^{k}\delta(x(\tau_j)-x_j))$ to the argument $\xi + i\Sigma_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}$.

Proposition 6: The product

$$\Phi_{n,k} := I_0 \exp\left(\sum_{l=1}^{n-k}\alpha_l x(s_l)\right)\prod_{j=1}^{k}\delta(x(\tau_j)-x_j)$$

defined by

$$T\Phi_{n,k}(\xi) = T\left(I_0\prod_{j=1}^{k}\delta(x(\tau_j)-x_j)\right)\left(\xi+i\sum_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}\right)\exp\left(x\sum_{l=1}^{n-k}\alpha_l\right)$$
$$= \exp\left(-\frac{i}{2}\int_{\mathbb{R}}\left(\xi(s)+i\sum_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}(s)\right)^2\mathrm{d}s\right)\prod_{j=1}^{k+1}\frac{1}{\sqrt{2\pi i(\tau_j-\tau_{j-1})}}$$
$$\times\exp\left(\sum_{j=1}^{k+1}\frac{i}{2(\tau_j-\tau_{j-1})}\left(\int_{\tau_{j-1}}^{\tau_j}\left(\xi(s)+i\sum_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}(s)\right)\mathrm{d}s + x_j - x_{j-1}\right)^2\right)\exp\left(x\sum_{l=1}^{n-k}\alpha_l\right)$$

is a Hida distribution.

Proof: It is obvious that the latter explicit formula fulfills the first part of Definition 2, analyticity. In order to prove that $\Phi_{n,k}$ is a Hida distribution by application of Theorem 2, we must only show that $T\Phi_{n,k}$ also obeys a bound as in the second part of Definition 2. For every $\theta \in \mathcal{S}_{\mathbb{C}}$ we have

$$
\begin{aligned}
|T\Phi_{n,k}(\theta)| \leqslant \exp\left(|x|\sum_{l=1}^{n-k}|\alpha_l|\right)\prod_{j=1}^{k+1}\frac{1}{\sqrt{2\pi(\tau_j-\tau_{j-1})}}\left|\exp\left(-\frac{i}{2}\int_{\mathbb{R}}\theta^2(s)\mathrm{d}s\right.\right.\\
\left.\left.+\sum_{l=1}^{n-k}\alpha_l\int_{\mathbb{R}}\theta(s)\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s\right)\right|\left|\exp\left(\sum_{j=1}^{k+1}\frac{i}{2(\tau_j-\tau_{j-1})}\left(\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s\right)^2\right)\right|\\
\times\left|\exp\left(\sum_{j=1}^{k+1}\frac{1}{\tau_{j-1}-\tau_j}\left(\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s\right)\sum_{l=1}^{n-k}\alpha_l\left(\int_{\tau_{j-1}}^{\tau_j}\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s\right)\right)\right|\\
\times\left|\exp\left(\sum_{j=1}^{k+1}\frac{i(x_j-x_{j-1})}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\left(\theta(s)+i\sum_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}(s)\right)\mathrm{d}s\right)\right|
\end{aligned}
$$

which is majorized by

$$
\begin{aligned}
|T\Phi_{n,k}(\theta)| &\leqslant \prod_{j=1}^{k+1}\frac{1}{\sqrt{2\pi(\tau_j-\tau_{j-1})}}\exp(2\|\theta\|^2)\exp\left((|x|+t-t_0+\|\theta\|^2)\sum_{l=1}^{n-k}|\alpha_l|\right)\\
&\quad\times\exp\left(4\max_{0\leqslant j\leqslant k+1}|x_j|\sum_{l=1}^{n-k}|\alpha_l|\right)\exp\left(\max_{0\leqslant j\leqslant k+1}(|x_j|^2)\right)\\
&=: C(\tau_1,\ldots,\tau_k;\alpha_1,\ldots,\alpha_{n-k};x_1,\ldots,x_k;\theta)\\
&=: C
\end{aligned}
\tag{9}
$$

independent of $s_1,\ldots,s_{n-k}$, where

$$
\|\theta\| := \sup_{s\in[t_0,t]}|\theta(s)|+\int_{t_0}^{t}|\dot{\theta}(s)|\mathrm{d}s+|\theta|
$$

is a continuous norm on $\mathcal{S}_{\mathbb{C}}$, cf. Appendix below. This estimate for $T\Phi_{n,k}$ is of the form required in Definition 2, which completes the proof. ■

According to Proposition 6, all $\Phi_{n,k}$ are Hida distributions and thus also generalized white noise functionals with $T\Phi_{n,k}$ entire on $\mathcal{S}_{\mathbb{C}}$. Moreover, each $T\Phi_{n,k}(\theta)$ is a measurable function of $\tau_1,\ldots,\tau_k;\ s_1,\ldots,s_{n-k};\ \alpha_1,\ldots,\alpha_{n-k};\ x_1,\ldots,x_k$ for every $\theta\in\mathcal{S}_{\mathbb{C}}$. Hence, in order to apply Theorem 4 to prove the existence of the integrals in I, we must only find a suitable integrable bound for $|T\Phi_{n,k}(\theta)|$. Since the measure m_1 fulfills the integrability condition (4) and the signed measure m_2 is finite and has support contained in some bounded interval $[-a,a]$, $a>0$, one may infer the integrability of C for every $\theta\in\mathcal{S}_{\mathbb{C}}$,

$$
\begin{aligned}
&\left|\int_{\Delta_k}d^k\tau\int_{t_0}^{t}d^{n-k}s\int_{\mathbb{R}^k}\prod_{j=1}^{k}\mathrm{d}m_2(x_j)\int_{\mathbb{R}^{n-k}}\prod_{l=1}^{n-k}d|m_1|(\alpha_l)C\right|\\
&\quad\leqslant\exp(2\|\theta\|^2+b^2)(t-t_0)^{n-k}\int_{\Delta_k}\prod_{j=1}^{k+1}\frac{1}{\sqrt{2\pi(\tau_j-\tau_{j-1})}}d^k\tau\left|\int_{\mathbb{R}}\mathrm{d}m_2(x)\right|^k\\
&\quad\times\left(\int_{\mathbb{R}}\exp((|x|+4b+t-t_0+\|\theta\|^2)|\alpha|)d|m_1|(\alpha)\right)^{n-k},
\end{aligned}
$$

where $b:=\max\{a,|y|,|x|\}$. Thus, according to Theorem 4, there exists an open set $U\subset\mathcal{S}_{\mathbb{C}}$ independent of n such that

$$I_{n,k} := \int_{\Delta_k} d^k\tau \int_{t_0}^{t} d^{n-k}s \int_{\mathbb{R}^k} \int_{\mathbb{R}^{n-k}} \Phi_{n,k} \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) \prod_{j=1}^{k} \mathrm{d}m_2(x_j) \in (\mathcal{S})^{-1}$$

for each $k \leqslant n$ and every $n \in \mathbb{N}$, and all $TI_{n,k}$ are holomorphic on U. To conclude the existence of I we must only prove that the series in n converges in $(\mathcal{S})^{-1}$ in the strong sense. This follows from Theorem 3. In fact, due to (7), for every $\theta \in U$ one has

$$|TI(\theta)| \leqslant \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{k=0}^{n} \binom{n}{k} k! |TI_{n,k}(\theta)|,$$

where the right-hand side is upper bounded by the factor $\exp(2\|\theta\|^2 + b^2)$ times the Cauchy product of the convergent series

$$\left(\sum_{n=0}^{\infty} \frac{1}{n!} \left((t-t_0) \int_{\mathbb{R}} e^{(|x|+4b+t-t_0+\|\theta\|^2)|\alpha|} d|m_1|(\alpha) \right)^n \right) \left(\sum_{n=0}^{\infty} \left| \int_{\mathbb{R}} \mathrm{d}m_2(x) \right|^n \int_{\Delta_n} \prod_{j=1}^{n+1} \frac{1}{\sqrt{2\pi(\tau_j - \tau_{j-1})}} d^n\tau \right)$$

$$= \exp\left((t-t_0) \int_{\mathbb{R}} e^{(|x|+4b+t-t_0+\|\theta\|^2)|\alpha|} d|m_1|(\alpha) \right) \sum_{n=0}^{\infty} \left| \int_{\mathbb{R}} \mathrm{d}m_2(x) \right|^n \int_{\Delta_n} \prod_{j=1}^{n+1} \frac{1}{\sqrt{2\pi(\tau_j - \tau_{j-1})}} d^n\tau.$$

We note that the latter series converges because

$$\int_{\Delta_n} \prod_{j=1}^{n+1} \frac{1}{\sqrt{2\pi(\tau_j - \tau_{j-1})}} d^n\tau = \left(\frac{\Gamma(1/2)}{\sqrt{2\pi}} \right)^{n+1} \frac{(t-t_0)^{(n-1)/2}}{\Gamma\left(\frac{n+1}{2} \right)}$$

is rapidly decreasing in n.

In this way we have proved the following result.

Theorem 7: *For every $V_1 \in \mathcal{K}_1$ and $V_2 \in \mathcal{K}_2$ of the form (6), the*

$$I := \sum_{n=0}^{\infty} \frac{(-i)^n}{n!} \sum_{k=0}^{n} \binom{n}{k} k! \int_{\Delta_k} d^k\tau \int_{t_0}^{t} d^{n-k}s \int_{\mathbb{R}^k} \int_{\mathbb{R}^{n-k}} I_0 \exp\left(\sum_{l=1}^{n-k} \alpha_l x(s_l) \right)$$
$$\times \prod_{j=1}^{k} \delta(x(\tau_j) - x_j) \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) \prod_{j=1}^{k} \mathrm{d}m_2(x_j)$$

exists as a generalized white noise functional. The series converges strongly in $(\mathcal{S})^{-1}$ and the integrals exist in the sense of Bochner integrals. Therefore we may express the T-transform of I by

$$TI(\theta) = \sum_{n=0}^{\infty} \frac{(-i)^n}{n!} \sum_{k=0}^{n} \binom{n}{k} k! \int_{\Delta_k} d^k\tau \int_{t_0}^{t} d^{n-k}s \int_{\mathbb{R}^k} \int_{\mathbb{R}^{n-k}} T\left(I_0 \exp\left(\sum_{l=1}^{n-k} \alpha_l x(s_l) \right) \prod_{j=1}^{k} \delta(x(\tau_j) - x_j) \right)(\theta)$$
$$\times \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) \prod_{j=1}^{k} \mathrm{d}m_2(x_j)$$

for every θ in a neighborhood $\{\theta \in \mathcal{S}_{\mathbb{C}} : 2^q |\theta|_p^2 < 1\}$ of zero, for some p, $q \in \mathbb{N}_0$.

According to Theorem 7, I is a well-defined generalized white noise functional. In order to conclude that I defines a Feynman integrand it remains to show that the expectation $TI(0)$ of I solves the Schrödinger equation for a potential $V = V_1 + V_2$, $V_i \in \mathcal{K}_i$. As in the free motion case we consider, more generally,

$$K^{(\theta)}(x,t|y,t_0) := \Theta(t-t_0)TI(\theta)\exp\left(\frac{i}{2}\int_{[t_0,t]^c}\theta^2(\tau)\mathrm{d}\tau + iy\theta(t_0) - ix\theta(t)\right).$$

Insertion of $TI(\theta)$ as given in Theorem 7, with

$$T\left(I_0\exp\left(\sum_{l=1}^{n-k}\alpha_l x(s_l)\right)\prod_{j=1}^{k}\delta(x(\tau_j)-x_j)\right)$$

as in Proposition 6, yields

$$K^{(\theta)}(x,t|y,t_0) = \sum_{n=0}^{\infty} K_n^{(\theta)}(x,t|y,t_0),$$

with

$$\begin{aligned}K_n^{(\theta)}(x,t|y,t_0) := {}& \frac{(-i)^n}{n!}\int_{t_0}^{t} d^n s\int_{\mathbb{R}^n}\prod_{l=1}^{n}\mathrm{d}m_1(\alpha_l)K_0^{(\theta_n)}(x,t|y,t_0)\\ &+\sum_{k=1}^{n-1}\frac{(-i)^{n-k}}{(n-k)!}\int_{t_0}^{t} d^{n-k}s\int_{\mathbb{R}^{n-k}}\prod_{l=1}^{n-k}\mathrm{d}m_1(\alpha_l)G_k^{(\theta_{n-k})}(x,t|y,t_0)+G_n^{(\theta)}(x,t|y,t_0),\end{aligned} \tag{10}$$

where we have set $\theta_{n-k} := \theta_{n-k}(s_1,\ldots,s_{n-k},\alpha_1,\ldots,\alpha_{n-k}) := \theta + i\Sigma_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}$ for $k=0,\ldots,n-1$, $\theta_0 := \theta$, and

$$G_k^{(\theta_{n-k})}(x,t|y,t_0) := (-i)^k\int_{\Delta_k} d^k\tau\int_{\mathbb{R}^k}\prod_{j=1}^{k}\mathrm{d}m_2(x_j)\prod_{j=1}^{k+1}K_0^{(\theta_{n-k})}(x_j,\tau_j|x_{j-1},\tau_{j-1})$$

for $k=1,\ldots,n$, $n>0$.

We expect $K^{(\theta)}$ to be the propagator corresponding to the potential $W(x,t)=V(x)+\dot{\theta}(t)x$.

Theorem 8: *$K^{(\theta)}(x,t|y,t_0)$ is a Green function for the Schrödinger equation*

$$(i\partial_t + \tfrac{1}{2}\partial_x^2 - \dot{\theta}(t)x - V(x))K^{(\theta)}(x,t|y,t_0) = i\delta(t-t_0)\delta(x-y). \tag{11}$$

In particular, $K(x,t|y,t_0) := TI(0)$ is a Feynman integral solving

$$i\partial_t K(x,t|y,t_0) = (-\tfrac{1}{2}\partial_x^2 + V(x))K(x,t|y,t_0) \quad \text{for } t > t_0. \tag{12}$$

Remark 3: K corresponds to a unitary evolution whenever $H=-\frac{1}{2}\partial_x^2+V$ has a unique self-adjoint extension.

Proof: Let us consider an interval $[T_0,T]$ such that $[t_0,t]\subset[T_0,T]$. Estimates similar to those done in the proof of Proposition 6 show that $K_n^{(\theta)}(\cdot,\cdot|y,t_0)$ is locally integrable on $\mathbb{R}\times[T_0,T]$ with respect to $\mathrm{d}m_2\times\mathrm{d}t$ and the Lebesgue measure. Therefore, we may regard $K_n^{(\theta)}$ as a distribution on $\mathcal{D}(\Omega) := \mathcal{D}(\mathbb{R}\times[T_0,T])$,

$$\langle K_n^{(\theta)}(\cdot,\cdot|y,t_0),\varphi\rangle = \int_{\mathbb{R}}\mathrm{d}x\int_{T_0}^{T}\mathrm{d}t\,K_n^{(\theta)}(x,t|y,t_0)\varphi(x,t), \quad \varphi\in\mathcal{D}(\Omega).$$

And we may also define a distribution $V_2K_n^{(\theta)}$ by setting

$$\langle V_2 K_n^{(\theta)}(\cdot,\cdot|y,t_0),\varphi\rangle = \int_{\mathbb{R}} \mathrm{d}m_2(x) \int_{T_0}^{T} \mathrm{d}t\, K_n^{(\theta)}(x,t|y,t_0)\varphi(x,t), \quad \varphi \in \mathcal{D}(\Omega).$$

To abbreviate we introduce the notation $\hat{L} := i\partial_t + \frac{1}{2}\partial_x^2 - \dot{\theta}(t)x$ and $\hat{L}^*$ for the dual operator. According to (10), observe that for any test function $\varphi \in \mathcal{D}(\Omega)$ one finds

$$\begin{aligned}\langle \hat{L} K_n^{(\theta)},\varphi\rangle = {} & \frac{(-i)^n}{n!}\left\langle \int_{t_0}^{\cdot} d^n s \int_{\mathbb{R}^n} \prod_{l=1}^{n} \mathrm{d}m_1(\alpha_l) K_0^{(\theta_n)}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi \right\rangle \\ & + \sum_{k=1}^{n-1} \frac{(-i)^{n-k}}{(n-k)!}\left\langle \int_{t_0}^{\cdot} d^{n-k} s \int_{\mathbb{R}^{n-k}} \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) G_k^{(\theta_{n-k})}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi \right\rangle + \langle G_n^{(\theta)}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi\rangle, \end{aligned} \tag{13}$$

where

$$\begin{aligned} & \frac{(-i)^n}{n!}\left\langle \int_{t_0}^{\cdot} d^n s \int_{\mathbb{R}^n} \prod_{l=1}^{n} \mathrm{d}m_1(\alpha_l) K_0^{(\theta_n)}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi \right\rangle \\ & \quad = \frac{(-i)^{n-1}}{(n-1)!}\left\langle V_1 \int_{t_0}^{\cdot} d^{n-1} s \int_{\mathbb{R}^{n-1}} \prod_{l=1}^{n-1} \mathrm{d}m_1(\alpha_l) K_0^{(\theta_{n-1})}(\cdot,\cdot|y,t_0), \varphi \right\rangle, \end{aligned} \tag{14}$$

cf. Ref. 13, and

$$\langle G_n^{(\theta)}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi\rangle = \langle V_2 G_{n-1}^{(\theta)}(\cdot,\cdot|y,t_0),\varphi\rangle, \tag{15}$$

cf. Refs. 15 and 7. The generic case (13) is intermediate between (14) and (15) and is dealt with by a combination of the corresponding techniques. This yields

$$\begin{aligned} & \left\langle \int_{t_0}^{\cdot} d^{n-k} s \int_{\mathbb{R}^{n-k}} \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) G_k^{(\theta_{n-k})}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi \right\rangle \\ & \quad = i(n-k)\left\langle V_1 \int_{t_0}^{\cdot} d^{n-k-1} s \int_{\mathbb{R}^{n-k-1}} \prod_{l=1}^{n-k-1} \mathrm{d}m_1(\alpha_l) G_k^{(\theta_{n-k-1})}(\cdot,\cdot|y,t_0), \varphi \right\rangle \\ & \qquad + \left\langle V_2 \int_{t_0}^{\cdot} d^{n-k} s \int_{\mathbb{R}^{n-k}} \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) G_{k-1}^{(\theta_{n-k})}(\cdot,\cdot|y,t_0), \varphi \right\rangle, \end{aligned}$$

for any $k=2,\ldots,n-2$,

$$\begin{aligned} & \left\langle \int_{t_0}^{\cdot} d^{n-1} s \int_{\mathbb{R}^{n-1}} \prod_{l=1}^{n-1} \mathrm{d}m_1(\alpha_l) G_1^{(\theta_{n-1})}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi \right\rangle \\ & \quad = i(n-1)\left\langle V_1 \int_{t_0}^{\cdot} d^{n-2} s \int_{\mathbb{R}^{n-2}} \prod_{l=1}^{n-2} \mathrm{d}m_1(\alpha_l) G_1^{(\theta_{n-2})}(\cdot,\cdot|y,t_0), \varphi \right\rangle \\ & \qquad + \left\langle V_2 \int_{t_0}^{\cdot} d^{n-1} s \int_{\mathbb{R}^{n-1}} \prod_{l=1}^{n-1} \mathrm{d}m_1(\alpha_l) K_0^{(\theta_{n-1})}(\cdot,\cdot|y,t_0), \varphi \right\rangle \end{aligned}$$

and

$$\left\langle \int_{t_0}^{\cdot} ds \int_{\mathbb{R}} \mathrm{d}m_1(\alpha_1) G_{n-1}^{(\theta_1)}(\cdot,\cdot|y,t_0), \hat{L}^*\varphi \right\rangle$$
$$= i\langle V_1 G_{n-1}^{(\theta)}(\cdot,\cdot|y,t_0),\varphi\rangle + \left\langle V_2 \int_{t_0}^{\cdot} ds \int_{\mathbb{R}} \mathrm{d}m_1(\alpha_1) G_{n-2}^{(\theta_1)}(\cdot,\cdot|y,t_0),\varphi \right\rangle.$$

As a result

$$\langle \hat{L} K_n^{(\theta)},\varphi\rangle = \frac{(-i)^{n-1}}{(n-1)!}\left\langle (V_1+V_2)\int_{t_0}^{\cdot} d^{n-1}s \int_{\mathbb{R}^{n-1}} \prod_{l=1}^{n-1} \mathrm{d}m_1(\alpha_l) K_0^{(\theta_{n-1})}(\cdot,\cdot|y,t_0),\varphi \right\rangle$$
$$+ \sum_{k=1}^{n-2} \frac{(-i)^{n-k-1}}{(n-k-1)!}\left\langle V_1 \int_{t_0}^{\cdot} d^{n-k-1}s \int_{\mathbb{R}^{n-k-1}} \prod_{l=1}^{n-k-1} \mathrm{d}m_1(\alpha_l) G_k^{(\theta_{n-k-1})}(\cdot,\cdot|y,t_0),\varphi \right\rangle$$
$$+ \sum_{k=2}^{n-1} \frac{(-i)^{n-k}}{(n-k)!}\left\langle V_2 \int_{t_0}^{\cdot} d^{n-k}s \int_{\mathbb{R}^{n-k}} \prod_{l=1}^{n-k} \mathrm{d}m_1(\alpha_l) G_{k-1}^{(\theta_{n-k})}(\cdot,\cdot|y,t_0),\varphi \right\rangle$$
$$+ \langle (V_1+V_2) G_{n-1}^{(\theta)}(\cdot,\cdot|y,t_0),\varphi\rangle,$$

which is equivalent to

$$\langle \hat{L} K_n^{(\theta)},\varphi\rangle = \langle (V_1+V_2) K_{n-1}^{(\theta)},\varphi\rangle, \quad \varphi \in \mathcal{D}(\Omega),$$

for any $n \geqslant 1$. Using (3) and summing over n, we obtain (11). ■

We conclude by an observation which is obvious from the above construction but somewhat unexpected given that the Hamiltonians with potentials in the class $\mathcal{K}_2$ will in general not admit a perturbative expansion (see, e.g., Ref. 13 for more on this).

Proposition 9: For any potential $V=g(V_1+V_2)$ with $V_i \in \mathcal{K}_i$, the solution K of the propagator equation (12) is analytic in the coupling constant g.

ACKNOWLEDGMENTS

One of the authors (M.J.O.) would like to express her gratitude to José Luís da Silva for helpful discussions and also the generous hospitality of Custódia Drumond and CCM during a very pleasant stay at Funchal during the Madeira Math Encounters XXIII. This work was supported by FCT POCTI, FEDER.

APPENDIX: AN ESTIMATE

For the proof of Proposition 6, we need to estimate

$$|T\Phi_{n,k}(\theta)| \leqslant \exp\left(|x|\sum_{l=1}^{n-k}|\alpha_l|\right)\prod_{j=1}^{k+1}\frac{1}{\sqrt{2\pi(\tau_j-\tau_{j-1})}}\left|\exp\left(-\frac{i}{2}\int_{\mathbb{R}}\theta^2(s)\mathrm{d}s\right.\right.$$
$$\left.\left.+\sum_{l=1}^{n-k}\alpha_l\int_{\mathbb{R}}\theta(s)\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s\right)\right|\left|\exp\left(\sum_{j=1}^{k+1}\frac{i}{2(\tau_j-\tau_{j-1})}\left(\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s\right)^2\right)\right|$$
$$\times\left|\exp\left(\sum_{j=1}^{k+1}\frac{1}{\tau_{j-1}-\tau_j}\left(\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s\right)\sum_{l=1}^{n-k}\alpha_l\left(\int_{\tau_{j-1}}^{\tau_j}\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s\right)\right)\right|$$
$$\times\left|\exp\left(\sum_{j=1}^{k+1}\frac{i(x_j-x_{j-1})}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\left(\theta(s)+i\sum_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}(s)\right)\mathrm{d}s\right)\right|.$$

We shall now estimate, consecutively, the exponents occuring in the above expression.

Using the Cauchy–Schwarz inequality we may approximate

$$\left|\exp\left(\sum_{l=1}^{n-k}\alpha_l\int_{\mathbb{R}}\theta(s)\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s\right)\right| \leqslant \exp\left(\sum_{l=1}^{n-k}|\alpha_l|\left(\int_{\mathbb{R}}|\theta(s)|^2\,\mathrm{d}s\right)^{1/2}\sqrt{t-s_l}\right) \leqslant \exp\left(\sqrt{t-t_0}|\theta|\sum_{l=1}^{n-k}|\alpha_l|\right)$$

and, similarly,

$$\left|\sum_{j=1}^{k+1}\frac{i}{2(\tau_j-\tau_{j-1})}\left(\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s\right)^2\right| \leqslant \frac{1}{2}|\theta|^2,$$

as well as

$$\begin{aligned}
&\left|\sum_{j=1}^{k+1}\frac{1}{\tau_{j-1}-\tau_j}\left(\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s\right)\sum_{l=1}^{n-k}\alpha_l\left(\int_{\tau_{j-1}}^{\tau_j}\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s\right)\right| \\
&\quad\leqslant \sum_{j=1}^{k+1}\frac{1}{\tau_j-\tau_{j-1}}\left(\int_{\tau_{j-1}}^{\tau_j}|\theta(s)|\mathrm{d}s\right)(\tau_j-\tau_{j-1})\sum_{l=1}^{n-k}|\alpha_l| \\
&\quad= \sum_{l=1}^{n-k}|\alpha_l|\int_{t_0}^{t}|\theta(s)|\mathrm{d}s \\
&\quad\leqslant \sqrt{t-t_0}|\theta|\sum_{l=1}^{n-k}|\alpha_l|.
\end{aligned}$$

In order to estimate the exponential of the function

$$\begin{aligned}
\sum_{j=1}^{k+1}\frac{i(x_j-x_{j-1})}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\left(\theta(s)+i\sum_{l=1}^{n-k}\alpha_l\mathbb{1}_{(s_l,t]}(s)\right)\mathrm{d}s &= \sum_{j=1}^{k+1}\frac{i(x_j-x_{j-1})}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s \\
&\quad+\sum_{l=1}^{n-k}\alpha_l\sum_{j=1}^{k+1}\frac{x_{j-1}-x_j}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s,
\end{aligned}$$

first we proceed as in Ref. 18, i.e.,

$$\begin{aligned}
\sum_{j=1}^{k+1}\frac{x_j-x_{j-1}}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s &= \frac{x}{t-\tau_k}\int_{\tau_k}^{t}\theta(s)\mathrm{d}s-\frac{y}{\tau_1-t_0}\int_{t_0}^{\tau_1}\theta(s)\mathrm{d}s \\
&\quad+\sum_{j=1}^{k}x_j\left(\frac{\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s}{\tau_j-\tau_{j-1}}-\frac{\int_{\tau_j}^{\tau_{j+1}}\theta(s)\mathrm{d}s}{\tau_{j+1}-\tau_j}\right).
\end{aligned}$$

By the mean value theorem

$$\sum_{j=1}^{k}x_j\left(\frac{\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s}{\tau_j-\tau_{j-1}}-\frac{\int_{\tau_j}^{\tau_{j+1}}\theta(s)\mathrm{d}s}{\tau_{j+1}-\tau_j}\right)=\sum_{j=1}^{k}x_j(\theta(r_j)-\theta(r_{j+1})),$$

where $r_j\in(\tau_{j-1},\tau_j)$. Therefore

$$\begin{aligned}
\left|\sum_{j=1}^{k+1}\frac{i(x_j-x_{j-1})}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\theta(s)\mathrm{d}s\right| &\leqslant (|x|+|y|)\sup_{[t_0,t]}|\theta|+\max_{1\leqslant j\leqslant k}|x_j|\sum_{j=1}^{k}\left|\int_{r_j}^{r_{j+1}}\dot{\theta}(s)\mathrm{d}s\right| \\
&\leqslant 2\max_{0\leqslant j\leqslant k+1}|x_j|\left(\sup_{[t_0,t]}|\theta|+\int_{t_0}^{t}|\dot{\theta}(s)|\mathrm{d}s\right).
\end{aligned}$$

Now let us consider the sum

$$\sum_{l=1}^{n-k}\alpha_l\sum_{j=1}^{k+1}\frac{x_{j-1}-x_j}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s.$$

Since $s_l\in[t_0,t]$, there is a $j_0\in\{0,1,\ldots,k\}$ such that $s_l\in[\tau_{j_0},\tau_{j_0+1}]$. This fact allows to rewrite the second sum in the latter expression as

$$x_{j_0+1}-x+(x_{j_0+1}-x_{j_0})\frac{s_l-\tau_{j_0+1}}{\tau_{j_0+1}-\tau_{j_0}}$$

leading to

$$\left|\sum_{l=1}^{n-k}\alpha_l\sum_{j=1}^{k+1}\frac{x_{j-1}-x_j}{\tau_j-\tau_{j-1}}\int_{\tau_{j-1}}^{\tau_j}\mathbb{1}_{(s_l,t]}(s)\mathrm{d}s\right|\leqslant 4\max_{0\leqslant j\leqslant k+1}|x_j|\sum_{l=1}^{n-k}|\alpha_l|.$$

Inserting these estimates we obtain

$$|T\Phi_{n,k}(\theta)|\leqslant\exp\left(|x|\sum_{l=1}^{n-k}|\alpha_l|\right)\prod_{j=1}^{k+1}\frac{1}{\sqrt{2\pi(\tau_j-\tau_{j-1})}}\exp(|\theta|^2)\exp\left(2\sqrt{t-t_0}|\theta|\sum_{l=1}^{n-k}|\alpha_l|\right)$$
$$\times\exp\left(2\max_{0\leqslant j\leqslant k+1}|x_j|\left(\sup_{[t_0,t]}|\theta|+\int_{t_0}^{t}|\dot{\theta}(s)|\mathrm{d}s\right)\right)\exp\left(4\max_{0\leqslant j\leqslant k+1}|x_j|\sum_{l=1}^{n-k}|\alpha_l|\right).$$

Now we introduce the norm

$$\|\theta\|:=\sup_{s\in[t_0,t]}|\theta(s)|+\int_{t_0}^{t}|\dot{\theta}(s)|\mathrm{d}s+|\theta|.$$

With respect to this norm one may bound the previous expression by

$$\exp\left(|x|\sum_{l=1}^{n-k}|\alpha_l|\right)\prod_{j=1}^{k+1}\frac{1}{\sqrt{2\pi(\tau_j-\tau_{j-1})}}\exp(\|\theta\|^2)\exp\left(2\sqrt{t-t_0}\|\theta\|\sum_{l=1}^{n-k}|\alpha_l|\right)$$
$$\times\exp\left(2\max_{0\leqslant j\leqslant k+1}|x_j|\|\theta\|\right)\exp\left(4\max_{0\leqslant j\leqslant k+1}|x_j|\sum_{l=1}^{n-k}|\alpha_l|\right).$$

Then we use

$$\sqrt{t-t_0}\|\theta\|\leqslant\tfrac{1}{2}(t-t_0+\|\theta\|^2)$$

and

$$2\max_{0\leqslant j\leqslant k+1}|x_j|\|\theta\|\leqslant\max_{0\leqslant j\leqslant k+1}(|x_j|^2)+\|\theta\|^2$$

to obtain the desired estimate (9).

(Received 16 March 2005; accepted 29 March 2005; published online 23 May 2005)

We consider the self-dual Yang–Mills equations in seven dimensions. Modifying the t'Hooft construction of instantons in $d=4$, we find N-instanton $7d$ solutions which depend on $8N$ effective parameters and are E_6 invariant. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1920307]

I. INTRODUCTION

The pure Yang–Mills (YM) theory defined in the four-dimensional Euclidean space has a rich and interesting structure even at the classical level. The discovery of regular solutions to the YM field equations, which correspond to absolute minimum of the action (Belavin *et al.*),[1] has led to an intensive study of such a classical theory. One hopes that a deep understanding of the classical theory will be invaluable when one tries to quantize such a theory.

In the past few years, increased attention has been paid to gauge field equations in space-time of dimension greater than four, with a view to obtaining physically interesting theories via dimensional reduction.[2] Such equations appear in the many-dimensional theory of supergravity, in the low-energy effective theory of d-branes, and in M theory.[3] Using solutions of the YM equations in $d>4$ makes it possible to obtain soliton solutions in these theories.[4] It is known also that the YM theory in d dimensions may be reduced to the Yang-Mills-Higgs (YMH) theory in $k<d$ dimensions.[5] Hence, solutions of the YMH equations in $d=4$ may be obtained from solutions of the YM equations in $d>4$ dimensions.

In Ref. 6, the 4D self-dual Yang–Mills equations was generalized to the higher-dimensional linear relations (CDFN equations)

$$c_{mnps}F^{ps}=\lambda F_{mn}, \tag{1}$$

where the numerical tensor c_{mnps} is completely antisymmetric and $\lambda=\text{const}$ is a nonzero eigenvalue. It is obvious that these equations lead to the full YM equation, via the Bianchi identity. Several self-dual solutions of (1) were found in Ref. 7.

The paper is organized as follows. Sections II and III contain well-known facts about the Cayley–Dickson algebras and their derivations. In Sec. IV multi-instanton solutions of the G_2-invariant CDFN equations are found. In Sec. V the E_6 invariance of these solutions are proved.

II. CAYLEY–DICKSON ALGEBRAS

Let A be an algebra with an involution $x\to\overline{x}$ over a field F of characteristic $\neq 2$. Given a nonzero $\alpha\in F$, we define a multiplication on the vector space $(A,\alpha)=A\oplus A$ by

$$(x_1,y_1)(x_2,y_2)=(x_1x_2-\alpha\overline{y_2}y_1,y_2x_1+y_1\overline{x_2}).$$

This makes (A,α) an algebra over F. It is clear that A is isomorphically embedded into (A,α) and $\dim(A,\alpha)=2\dim A$. Let $e=(0,1)$. Then, $e^2=-\alpha$ and $(A,\alpha)=A\oplus Ae$. Given any $z=x+ye$ in (A,α) we suppose $\overline{z}=\overline{x}-ye$. Then, the mapping $z\to\overline{z}$ is an involution in (A,α).

a)Electronic mail: loginov@ivanovo.ac.ru

Starting with the base field F, the Cayley–Dickson construction leads to the following sequence of alternative algebras:

(1) F, the base field.
(2) $\mathbb{C}(\alpha)=(F,\alpha)$, a field if $x^2+\alpha$ is the irreducible polynomial over F; otherwise, $\mathbb{C}(\alpha)\simeq F\oplus F$.
(3) $\mathbb{H}(\alpha,\beta)=(\mathbb{C}(\alpha),\beta)$, a generalized quaternion algebra. This algebra is associative but not commutative.
(4) $\mathbb{O}(\alpha,\beta,\gamma)=(\mathbb{H}(\alpha,\beta),\gamma)$, a Cayley–Dickson algebra. It is easy to prove that this algebra is nonassociative.

The algebras in (1)–(4) are called composition. Any of them has the nondegenerate quadratic form (norm) $n(x)=x\overline{x}$, such that $n(xy)=n(x)n(y)$. The norm $n(x)$ defines the scalar product

$$(x,y)=\tfrac{1}{2}(\overline{x}y+\overline{y}x), \tag{2}$$

which is invariant with respect to all automorphisms of the composition algebra. It is known also that over the field $\mathbb{R}$ of real numbers, the above construction gives three split algebras (e.g., if $\alpha=\beta=\gamma=-1$) and four division algebras (if $\alpha=\beta=\gamma=1$): the fields of real $\mathbb{R}$ and complex $\mathbb{C}$ numbers, the algebras of quaternions $\mathbb{H}$ and octonions $\mathbb{O}$, taken with the Euclidean norm $n(x)$. Finally, note that any composition algebra is alternative, i.e., in any of them the associator

$$(x,y,z)=(xy)z-x(yz), \tag{3}$$

is skew symmetric over x,y,z. Note also that any simple nonassociative alternative algebra is isomorphic to the Cayley–Dickson algebra $\mathbb{O}(\alpha,\beta,\gamma)$.

As with any finite-dimensional algebra, the Cayley–Dickson algebra may be defined by "a multiplication table" in some fixed basis. For that we consider a real linear space A equipped with a nondenerate symmetric metric g of signature (8,0) or (4,4). Choose the basis $1,e_1,\ldots,e_7$ in A such that

$$g=\mathrm{diag}(1,\alpha,\beta,\alpha\beta,\gamma,\alpha\gamma,\beta\gamma,\alpha\beta\gamma), \tag{4}$$

where $\alpha,\beta,\gamma=\pm 1$. Define the multiplication

$$e_ie_j=-g_{ij}+c_{ij}{}^{k}e_k, \tag{5}$$

where the structural constants $c_{ijk}=g_{ks}c_{ij}{}^{s}$ are completely antisymmetric and different from 0 only if

$$c_{123}=c_{145}=c_{167}=c_{246}=c_{275}=c_{374}=c_{365}=1.$$

The multiplication (5) transforms A into a real linear algebra. It can easily be checked that A is isomorphic to $\mathbb{O}(\alpha,\beta,\gamma)$.

III. DERIVATIONS

Recall that a derivation of an algebra A is a linear transformation D of A, satisfying

$$(xy)D=(xD)y+x(yD),$$

for all $x,y\in A$. The derivations of Cayley–Dickson algebra may be described in intrinsic terms. Namely, let A be a Cayley–Dickson algebra. Then, for any $x,y\in A$ the mapping

$$D_{x,y}:z\to 2[z,[x,y]]+6(z,x,y), \tag{6}$$

is a derivation of A. Therefore, we have the linear mapping $\Lambda^2\to\mathrm{der}\,A$. Since any Cayley–Dickson algebra is simple, it follows that this mapping is surjective. In addition, the following relations:

$$D_{x,yz} = D_{y,xz} + D_{z,yx}, \tag{7}$$

$$[D_{x,y}, D_{z,t}] = D_{(xD_{z,t}),y} + D_{x,(yD_{z,t})}, \tag{8}$$

are true. Note also that the derivations algebra der A is a simple exceptional Lie algebra of type g_2.

Since the associator (3) of Cayley–Dickson algebra is skew symmetric over its arguments, it follows that we can define the completely antisymmetric tensor c_{ijkl} by

$$(e_i, e_j, e_k) = 2c_{ijk}{}^{l} e_l. \tag{9}$$

It is easy to prove that this tensor satisfies the following identities:

$$c_{ijs}c_{kl}{}^{s} = g_{ik}g_{jl} - g_{il}g_{jk} + c_{ijkl}, \tag{10}$$

$$c_{ijps}c_{kl}{}^{ps} = 4(g_{ik}g_{jl} - g_{il}g_{jk}) + 2c_{ijkl}, \tag{11}$$

and has the nonzero components

$$c_{4567} = c_{2367} = c_{2345} = c_{1357} = c_{1364} = c_{1265} = c_{1274} = 1.$$

Further, it follows from (2) and (9) that the tensor c_{ijkl} is invariant with respect to all automorphisms of algebra A. Noting that the group aut A is isomorphic to the Lie group of type G_2, we see that the tensor c_{ijkl} is G_2 invariant. Finally, rewriting the identity (7) in the form

$$c_i{}^{jk} D_{jk} = 0,$$

where the derivation $\frac{1}{8} D_{e_i,e_j}$ is denoted by the symbol D_{ij}, we get the following relations:

$$c_{ij}{}^{kl} D_{kl} = -2D_{ij}. \tag{12}$$

Since the algebra der A is a Lie algebra of type g_2 (or g_2' in the noncompact case), it follows that it may be considered as a subalgebra of the Lie algebra so(m,n) of type so(7) or so(3, 4). Hence, there exists the projector c^{+}_{ijkl} of one onto the subspace der A. Usually this projector is chosen in the form (see Ref. 7)

$$c^{+}_{ijkl} = \tfrac{1}{6}(2g_{ik}g_{lj} - 2g_{il}g_{jk} - c_{ijkl}). \tag{13}$$

In addition, it is easily shown that the derivations

$$D_{ij} = \tfrac{3}{2} c_{ij}^{+kl} E_{kl}, \tag{14}$$

where generators E_{kl} of the Lie algebra so(m,n) satisfy the switching relations

$$[E_{ij}, E_{kl}] = g_{k[i} E_{\ j]l} - g_{l[i} E_{\ j]k}.$$

Besides, it follows from (11) that

$$c_{ij}{}^{ps} c^{+}_{klps} = -2c^{+}_{ijkl}. \tag{15}$$

Comparing (14) and (15), we again obtain the identity (12).

IV. SOLUTIONS

Recall that the self-dual equations have been successfully tackled by the twister techniques, and in the case of finite action solutions by the algebraic ADHM construction.[8] A generalization of the ADHM construction for Eqs. (1) which break SO($4n$) up into $\mathrm{Sp}(1) \times \mathrm{Sp}(n)/Z_2$ was found in Ref. 9. However, in dimensions 7 and 8 there exists an exceptional G_2-covariant [respectively, Spin(7)-covariant] duality which is connected with the octonionic algebra. Therefore, the search of generalized ADHM construction in $d=7$ and 8 appears very attractive.

Such attempt was done in the recent paper.[10] In it the generalized ADHM construction in $d=8$ was built with the help of the algebra $L(\mathbb{O})$ of left multiplications of octonionic algebra $\mathbb{O}$. Unfortunately, calculating the field strength in that paper's Sec. V and proving its self-duality, the authors incorrectly use the equality $L[L(xy)z]=L(xyz)$, where $L(xyz)=x(yz)$ and $x,y,z\in\mathbb{O}$. By nonassociativity of the octonionic algebra, it would not be done (cp. Ref. 11).

Nevertheless, it is easy to get multi-instanton solutions (but not a generalized ADHM construction) of CDFN equations in seven dimensions. We choose the ansatz A_m in the form

$$A_m = \frac{\lambda^\dagger y^i}{1+y^\dagger y} D_{mi}, \tag{16}$$

where y is a column vector with the elements $y_1,\ldots,y_N$ of Cayley–Dickson algebra such that

$$y^\dagger = (y_1^k,\ldots,y_N^k)\overline{e_k}, \quad y_I^k \in \mathbb{R},$$

$$\lambda^\dagger = (\lambda_1,\ldots,\lambda_N), \quad \lambda_I \in \mathbb{R}^+,$$

$$y_I^k = (b_{IJ}^k + \delta_{IJ}x^k)\lambda_J, \quad b_{IJ}^k = b_{JI}^k.$$

Using the identities (8)–(10), we get the field strength

$$F_{mn} = -\frac{\lambda^\dagger\{(2+2y^\dagger y - y^i y_i^\dagger)D_{mn} + 3c^{+\ is}_{mn} D_{sj} y^j y_i^\dagger\}\lambda}{(1+y^\dagger y)^2},$$

where the tensor c^+_{ijkl} is defined by the equality (13). Now, it follows from (12) and (15) that the field strength F_{mn} satisfies the CDFN equations (1) for the Euclidean as for the pseudo-Euclidean metric of the form (4).

This construction of multi-instanton solutions of the CDFN equations may be easy to extend in eight dimensions. It is sufficient to take the projector f^+_{ijkl} of the algebra Lie of type so(8) or so(4,4) onto the subalgebra so(7) or so(3,4), respectively, in place of c^+_{ijkl}, to define the elements D'_{ij} of the form (14), and to prove an analog of the identity (15) (see Ref. 7). Then, choosing the ansatz A'_m in the form

$$A'_m = \frac{\lambda^\dagger y^i}{1+y^\dagger y} D'_{mi}, \tag{17}$$

where the indexes $m,i\in\{0,\ldots,7\}$, we can obtain the following expression for the field strength:

$$F'_{mn} = -\frac{1}{3}\frac{\lambda^\dagger\{(6+6y^\dagger y - 3y^i y_i^\dagger)D'_{mn} + 8f^{+\ is}_{mn} D'_{sj} y^j y_i^\dagger\}\lambda}{(1+y^\dagger y)^2}.$$

Obviously, the N-instanton solutions (16) and (17) depend on $8N$ and $9N$ effective parameters, respectively, and are a generalization of the t'Hooft solution in $d=4$ (see e.g., Ref. 12).

V. E_6 INVARIANCE

Let A be a real Cayley–Dickson algebra with the involution $x\to\overline{x}$, and let A_3 be the algebra of all 3×3 matrix with elements of A. Consider the set

$$J = \{(x_{ij}) \in A_3 | (\overline{x_{ij}}) = (x_{ji})\}.$$

The set J is a commutative nonassociative algebra with respect to the product

$$x\circ y = \tfrac{1}{2}(xy+yx).$$

The algebra J satisfies the identity

$$(x^2y)x = x^2(yx),$$

and is said to be an exceptional Jordan algebra.

Denote 3×3 matrix (x_{ij}) with the unique nonzero element $x_{ij}=1$ by the symbol ε_{ij} and choose in J the basis

$$E_1 = \varepsilon_{11}, \quad X_1(e_i) = e_i\varepsilon_{23} + \overline{e_i}\varepsilon_{32},$$

$$E_2 = \varepsilon_{22}, \quad X_2(e_j) = e_j\varepsilon_{31} + \overline{e_j}\varepsilon_{13},$$

$$E_3 = \varepsilon_{33}, \quad X_3(e_k) = e_k\varepsilon_{12} + \overline{e_k}\varepsilon_{21}, \tag{18}$$

where $e_0=1, e_1, \ldots, e_7$ is the standard basis of A. It can easily be checked that

$$E_\alpha \circ X_\beta(e_i) = \begin{cases} 0, & \text{if } \alpha = \beta, \\ \frac{1}{2}X_\beta(e_i), & \text{if } \alpha \neq \beta, \end{cases} \tag{19}$$

$$X_\alpha(e_i) \circ X_\beta(e_j) = \begin{cases} \delta_{ij}(E - E_\alpha), & \text{if } \alpha = \beta, \\ \frac{1}{2}X_\gamma(\overline{e_j e_i}), & \text{if } \alpha \neq \beta, \end{cases} \tag{20}$$

where E is the identity 3×3 matrix, and $(\alpha\beta\gamma)=(123),(231),(312)$.

It is well known (see, e.g., Ref. 13) that the derivations algebra der J is a simple exceptional Lie algebra of the type f_4. Since there is an isomorphic enclosure of the algebra g_2 into f_4, we can consider (16) as a field that takes its values in der J. To prove the F_4 invariance of these solutions, we find the trace of the matrix

$$X_\beta = \left\{[X_\alpha(e_i), X_\beta(e_j), X_\alpha(e_k)] - \tfrac{1}{2}[X_\alpha(e_i), X_\alpha(e_j), X_\alpha(e_k)]\right\} \circ X_\beta(e_l), \tag{21}$$

where $i,j,k \neq 0$, and we do not sum on the recurring indexes. Using (9), (19), and (20), we prove that

$$X_\beta = \tfrac{1}{2}c_{ijkl}(E - E_\beta),$$

and hence

$$\operatorname{tr} X_\beta = c_{ijkl}.$$

Since a trace of matrix in J is invariant with respect to all automorphisms of J, we prove the F_4 invariance of solutions of the corresponding CDFN equations.

Moreover, it can be proved that the tensor c_{ijkl} is E_6 invariant. Indeed, the group E_6 is a group of linear transformations of the space J that preserves the norm

$$n(X) = x_{11}x_{22}x_{33} + (x_{12}x_{23})x_{31} + x_{13}(x_{32}x_{21}) - x_{11}x_{23}x_{32} - x_{22}x_{31}x_{13} - x_{33}x_{12}x_{21},$$

where $X=(x_{ij}) \in J$. Choose an element X in the form

$$X = X_1 + X_2 - X_3 + E_1 + E_2,$$

where matrices E_α and X_β are defined by the relations (18) and (21), respectively. Then, it follows easily that the norm

$$n(X) = c_{ijkp}.$$

Since the group F_4 can be isomorphically enclosed into the group E_6, we prove the E_6 invariance of the found solutions.

Inversible Max-Plus algebras and integrable systems

Tomoshiro Ochiai and Jose C. Nacher
Graduate School of Mathematical Sciences, The University of Tokyo, Tokyo 153-8914, Japan

(Received 18 March 2005; accepted 5 April 2005; published online 24 May 2005)

We present an extended version of max-plus algebra which includes the inverse operator of "max." This algebra enables us to ultradiscretize the system including subtractions and obtain new ultradiscrete equations. The known ultradiscrete equations can also be recovered by this construction. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1925247]

I. INTRODUCTION

An integrable system is one of the main subjects in mathematics and physics. Especially, soliton equations and integrable lattice models that have been studied as integrable systems in a variety of view points. Recently, because of the development of computer sciences, discrete and ultradiscrete versions of integral system have been attracting a great deal of attention. The ultradiscretization of soliton equations and other various important equations are intensively studied.[1–8] Moreover, it is known that the various ultradiscrete soliton equations are obtained from a solvable vertex model in statistical mechanics in a certain limiting procedure.[9,10] The key formula for the ultradiscretization is given by

$$\lim_{\epsilon \to +0} \epsilon \log(e^{X/\epsilon} + e^{Y/\epsilon}) = \max(X, Y) \tag{1.1}$$

for arbitrary real numbers X and Y. Using this formula, it is known that the field of real numbers can be transformed into the so-called "max-plus" algebra, which is well known in integrable systems. But the main difficulty for the usual ultradiscretization procedure is that there is no operator corresponding to the subtraction "$-$" (see Fig. 1). Therefore, so far, we cannot deal with the ultradiscretization of integral systems that include the subtraction.

In this paper, in order to solve this difficulty, we define an extended version of max-plus algebra called "inversible Max-Plus algebra," which includes the usual max-plus algebra and the operator corresponding to the subtraction:[1]

$$x \times y \to X + Y$$

$$x/y \to X - Y$$

$$x + y \to \max(X, Y)$$

$$x - y \to \ ?\ ?$$

FIG. 1. Ultra-discretization

[1]In this paper, we consider "Max" and "max" as different operators. We use "max" for the usual maximum operator, while we use "Max" for the inversible maximum operator, which is the new operator of our novel inversible algebra. The same holds for "Plus" ("plus") and "Minus" ("minus") operators.

Our construction is as follows. We shall define a Max-Plus algebra as $\mathbf{Z}$-module A with the operation $\mathrm{Max}: A \times A \to A$ satisfying

$$(\alpha + \beta) + \gamma = \alpha + (\beta + \gamma), \tag{1.2}$$

$$\mathrm{Max}(\mathrm{Max}(\alpha, \beta), \gamma) = \mathrm{Max}(\alpha, \mathrm{Max}(\beta, \gamma)), \tag{1.3}$$

$$\mathrm{Max}(\alpha + \beta, \alpha + \gamma) = \alpha + \mathrm{Max}(\beta, \gamma), \tag{1.4}$$

for $\alpha, \beta, \gamma \in A$. Max-Plus subalgebra and homomorphism are defined in the usual manner. The basic example is $\mathbf{Z}$ which is the ring of integer with $\mathrm{Max}(n,m) = \max(n,m)$, where $\max(n,m)$ stands for the maximum of the pair n and m.

In this paper, we explicitly construct Max-Plus algebra Ω and Ω_0 with $P: \Omega_0 \to \mathbf{Z}$ such that

(1) $\Omega \supset \Omega_0$ as Max-Plus algebra,
(2) $P: \Omega_0 \to \mathbf{Z}$ as Max-Plus homomorphism,
(3) There exists an element $\eta \in \Omega$ such that

$$\mathrm{Max}(\mathrm{Max}(\alpha, \beta), \beta + \eta) = \alpha \tag{1.5}$$

for arbitrary $\alpha, \beta \in \Omega$

We call Ω the inversible Max-Plus algebra, due to the inversible property of the Max operator (1.5).

It is known that we can construct ultradiscrete (UD) equation on $\mathbf{Z}$ from standard discrete partial differential equations (PDEs) satisfying certain conditions through the usual ultradiscretization procedure. But, using our constructions, we can construct UD equation on Ω from any discrete PDEs, even if they include the subtraction. If this UD equation and its solution on Ω belong to Ω_0, the projection P gives the UD equation and solutions on $\mathbf{Z}$ explained previously. As an application, we apply this inversible Max-Plus algebra Ω to a periodic recursive equation and obtain an UD periodic equation on Ω and $\mathbf{Z}$. Further, we apply this algebra to the ultradiscretization of the equation of motion for a free particle in physics.

Computational Biology: On the other hand, it is also worth noting the possible application of our new algebra in the emergent field of bioinformatics. Recently, the postsequence era has provided a huge wealth of biological data at the gene and molecular levels. Many mathematical and computational tools (e.g., boolean networks, hidden Markov model, and stochastic approach) are currently being used to study the relationships among thousands of basic building blocks of life as proteins, chemical compounds, and genes. However, the relationship and connection among these tools is unclear, and consequently, the research community usually considers them as separate and independent approaches. In contrast, we believe that the mentioned techniques are related to each other and even more, UD is the missing link between computational or discrete mathematics and the usual mathematics. More precisely, the computational mathematics and the usual matemathics are connected by the UD procedure given in this paper. Therefore, UD may shed light on the relation between two of the most used methods in molecular systems biology as boolean networks and stochastic processes. Consequently, we believe that further studies on this issue may contribute to improve the current techniques used in bioinformatics and enlighten the advances in the postgenomic era.

II. INVERSIBLE MAX-PLUS ALGEBRAS

A. Definition of $\tilde{\mathbf{Z}}$

Let $\mathbf{Z}_2 = \{0, \eta\}$ be the finite group of order two (i.e., $0+0=0$, $0+\eta=\eta$, $\eta+\eta=0$,) and set

$$\tilde{\mathbf{Z}} = \mathbf{Z} \oplus \mathbf{Z}_2 \cup \{-\infty\} = \{x + \xi | x \in \mathbf{Z}, \xi \in \mathbf{Z}_2\} \cup \{-\infty\}.$$

First, we shall define the "max" operator on $\tilde{\mathbf{Z}}$ (i.e., $\max: \tilde{\mathbf{Z}} \times \tilde{\mathbf{Z}} \to \tilde{\mathbf{Z}}$) as follows. For $a = x + \xi \in \mathbf{Z} \oplus \mathbf{Z}_2$, $a' = x' + \xi' \in \mathbf{Z} \oplus \mathbf{Z}_2$, set

$$\max(a, -\infty) = a,$$

$$\max(-\infty, -\infty) = -\infty,$$

and

$$\max(a, a') = \begin{cases} a & (x > x') \\ a & (x = x' \text{ and } \xi = \xi') \\ a' & (x < x') \\ -\infty & (x = x' \text{ and } \xi \neq \xi'). \end{cases}$$

Second, we shall define the "plus" operator on $\tilde{\mathbf{Z}}$ (i.e., $\text{plus}: \tilde{\mathbf{Z}} \times \tilde{\mathbf{Z}} \to \tilde{\mathbf{Z}}$) as follows. For $a = x + \xi \in \mathbf{Z} \oplus \mathbf{Z}_2$ and $a' = x' + \xi' \in \mathbf{Z} \oplus \mathbf{Z}_2$, set

$$\text{plus}(a, a') = (x + x') + (\xi + \xi'),$$

$$\text{plus}(a, -\infty) = -\infty,$$

$$\text{plus}(-\infty, -\infty) = -\infty.$$

In the sequel, we write $a + b$ for $\text{plus}(a, b)$ for the matter of convenience.

If $a \neq a' + \eta$, the order relations $a > a'$, $a < a'$ and $a = a'$ are defined by

$$a > a' \Leftrightarrow x > x',$$

$$a < a' \Leftrightarrow x < x',$$

$$a = a' \Leftrightarrow x = x' \text{ and } \xi = \xi'.$$

If $a \neq \eta$, define the absolute value $|a|$ by

$$|a| = \max(a, 0) + \max(-a, 0).$$

B. Definition of Ξ

Set

$$\tilde{\mathbf{Z}}^n = \{(a_1, \ldots, a_n) | a_1, \ldots, a_n \in \tilde{\mathbf{Z}}\}.$$

For a matter of convenience, an element $(a_1, \ldots, a_n)$ is denoted by $\mathbf{a}$ or $(a_i)_{i=1}^n$.

Set $\Xi = \cup_{n=1}^{\infty} \tilde{\mathbf{Z}}^n / \sim$, where the union is disjoint and the equivalence relation "$\sim$" is generated by

$$(\ldots, a_i, \ldots, a_j, \ldots) \sim (\ldots, a_j, \ldots, a_i, \ldots), \tag{2.1}$$

$$(a_1, \ldots, a_n, b, b + \eta) \sim (a_1, \ldots, a_n, -\infty), \tag{2.2}$$

$$(a_1, \ldots, a_n, -\infty) \sim (a_1, \ldots, a_n). \tag{2.3}$$

An element $(a_1,\ldots,a_n)$ is called irreducible, if n is minimum in its equivalence class. We remark that we can introduce the order relations into $a_1,\ldots,a_n$, if $(a_1,\ldots,a_n)$ is irreducible.

If there is no danger of confusion, the equivalence class defined by $(a_1,\ldots,a_n)$ is also denoted by $(a_1,\ldots,a_n)$.

Let us define "$\overline{\text{Max}}$" and "Plus" operators on $\Xi=\cup_{n=1}^{\infty}\tilde{\mathbf{Z}}^n/\sim$ (i.e., $\overline{\text{Max}}:\Xi\times\Xi\to\Xi$ and $\text{Plus}:\Xi\times\Xi\to\Xi$) as follows. For $\mathbf{a}=(a_i)_{i=1}^n=(a_1,\ldots,a_n)\in\Xi$ and $\mathbf{b}=(b_i)_{i=1}^m=(b_1,\ldots,b_m)\in\Xi$, set

$$\overline{\text{Max}}(\mathbf{a},\mathbf{b})=(a_1,\ldots,a_n,b_1,\ldots,b_m), \tag{2.4}$$

$$\begin{aligned}\text{Plus}(\mathbf{a},\mathbf{b})&=(a_i+b_j)_{i=1\ j=1}^{n\quad m}\\&=(a_1+b_j,\ldots,a_n+b_j)_{j=1}^m\\&=(a_1+b_1,a_2+b_1,\ldots,a_n+b_1,a_1+b_2,\ldots,a_n+b_m).\end{aligned} \tag{2.5}$$

In the sequel, we write $\mathbf{a}+\mathbf{b}$ for $\text{Plus}(\mathbf{a},\mathbf{b})$ for the matter of convenience.

Lemma 2.1: The previous definition is well defined.

Proof: It is enough to show that the definition is invariant under relations (2.1)–(2.3).

First, we will show the $\overline{\text{Max}}$ operator is invariant under relations (2.1)–(2.3). For $\mathbf{a}=(a_1,\ldots,a_i,\ldots,a_j,\ldots,a_n)$, $\mathbf{a}'=(a_1,\ldots,a_j,\ldots,a_i,\ldots,a_n)$, and $\mathbf{b}=(b_1,\ldots,b_m)$, we have

$$\begin{aligned}\overline{\text{Max}}(\mathbf{a},\mathbf{b})&=(a_1\ldots,a_i,\ldots,a_j,\ldots,a_n,b_1,\ldots,b_m)\\&=(a_1,\ldots,a_j,\ldots,a_i,\ldots,a_n,b_1,\ldots,b_m)=\overline{\text{Max}}(\mathbf{a}',\mathbf{b}),\end{aligned}$$

which shows the invariance under relation (2.1). For $\mathbf{a}=(a_1,\ldots,a_n,c,c+\eta)$, $\mathbf{a}'=(a_1,\ldots,a_n,-\infty)$, and $\mathbf{b}=(b_1,\ldots,b_m)$, we have

$$\overline{\text{Max}}(\mathbf{a},\mathbf{b})=(a_1\ldots,a_n,c,c+\eta,b_1,\ldots,b_m)=(a_1,\ldots,a_n,-\infty,b_1,\ldots,b_m)=\overline{\text{Max}}(\mathbf{a}',\mathbf{b}),$$

which shows the invariance under relation (2.2). For $\mathbf{a}=(a_1\ldots,a_n,-\infty)$, $\mathbf{a}'=(a_1,\ldots,a_n)$, and $\mathbf{b}=(b_1,\ldots,b_m)$, we have

$$\overline{\text{Max}}(\mathbf{a},\mathbf{b})=(a_1\ldots,a_n,-\infty,b_1,\ldots,b_m)=(a_1,\ldots,a_n,b_1,\ldots,b_m)=\overline{\text{Max}}(\mathbf{a}',\mathbf{b}),$$

which shows the invariance under relation (2.3).

Second, we will show the Plus operator is invariant under relation (2.1)–(2.3). For $\mathbf{a}=(a_1,\ldots,a_i,\ldots,a_j,\ldots,a_n)$, $\mathbf{a}'=(a_1,\ldots,a_j,\ldots,a_i,\ldots,a_n)$, and $\mathbf{b}=(b_1,\ldots,b_m)$, we have

$$\begin{aligned}\mathbf{a}+\mathbf{b}&=(a_1+b_k,\ldots,a_i+b_k,\ldots,a_j+b_k,\ldots,a_n+b_k)_{k=1}^m\\&=(a_1+b_k,\ldots,a_j+b_k,\ldots,a_i+b_k,\ldots,a_n+b_k)_{k=1}^m=\mathbf{a}'+\mathbf{b},\end{aligned}$$

which shows the invariance under relation (2.1). For $\mathbf{a}=(a_1\ldots,a_n,c,c+\eta)$, $\mathbf{a}'=(a_1,\ldots,a_n,-\infty)$, and $\mathbf{b}=(b_1,\ldots,b_m)$, we have

$$\mathbf{a}+\mathbf{b}=(a_1+b_k,\ldots,a_n+b_k,c+b_k,c+\eta+b_k)_{k=1}^m=(a_1+b_k,\ldots,a_n+b_k,-\infty+b_k)_{k=1}^m=\mathbf{a}'+\mathbf{b},$$

which shows the invariance under relation (2.2). For $\mathbf{a}=(a_1,\ldots,a_n,-\infty)$, $\mathbf{a}'=(a_1,\ldots,a_n)$, and $\mathbf{b}=(b_1,\ldots,b_m)$, we have

$$\mathbf{a}+\mathbf{b}=(a_1+b_k,\ldots,a_n+b_k,-\infty+b_k)_{k=1}^m=(a_1+b_k,\ldots,a_n+b_k)_{k=1}^m=\mathbf{a}'+\mathbf{b},$$

which shows the invariance under relation (2.3). □

Lemma 2.2: For $\mathbf{a},\mathbf{b},\mathbf{c}\in\Xi$, we have the following identities:

$$(\mathbf{a}+\mathbf{b})+\mathbf{c}=\mathbf{a}+(\mathbf{b}+\mathbf{c}), \tag{2.6}$$

$$\overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a},\mathbf{b}),\mathbf{c})=\overline{\mathrm{Max}}(\mathbf{a},\overline{\mathrm{Max}}(\mathbf{b},\mathbf{c})), \tag{2.7}$$

$$\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{b},\mathbf{a}+\mathbf{c})=\mathbf{a}+\overline{\mathrm{Max}}(\mathbf{b},\mathbf{c}), \tag{2.8}$$

$$\overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a},\mathbf{b}),\mathbf{b}+\eta)=\mathbf{a}. \tag{2.9}$$

Proof: Suppose $\mathbf{a}=(a_1,\ldots,a_n)$, $\mathbf{b}=(b_1,\ldots,b_m)$, and $\mathbf{c}=(c_1,\ldots,c_l)$. The proof is straightforward from (2.4) and (2.5). First formula (2.6) is obtained by the following computation:

$$(\mathbf{a}+\mathbf{b})+\mathbf{c}=(a_i+b_j+c_k)_{i=1}^{n}{}_{j=1}^{m}{}_{k=1}^{l}=\mathbf{a}+(\mathbf{b}+\mathbf{c}).$$

Second formula (2.7) is obtained by the following computation:

$$\overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a},\mathbf{b}),\mathbf{c})=(a_1\ldots,a_n,b_1,\ldots,b_m,c_1,\ldots,c_l)=\overline{\mathrm{Max}}(\mathbf{a},\overline{\mathrm{Max}}(\mathbf{b},\mathbf{c})).$$

Third formula (2.8) is obtained by the following computation:

$$\begin{aligned}\mathbf{a}+\overline{\mathrm{Max}}(\mathbf{b},\mathbf{c})&=\mathbf{a}+(b_1,\ldots,b_m,c_1,\ldots,c_l)\\&=(b_1+a_i,\ldots,b_m+a_i,c_1+a_i,\ldots,c_l+a_i)_{i=1}^{n}\\&=\overline{\mathrm{Max}}((b_1+a_i,\ldots,b_m+a_i)_{i=1}^{n},(c_1+a_i,\ldots,c_l+a_i)_{i=1}^{n})=\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{b},\mathbf{a}+\mathbf{c}).\end{aligned}$$

Last formula (2.9) is obtained by the following computation:

$$\overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a},\mathbf{b}),\mathbf{b}+\eta)=(a_1\ldots,a_n,b_1,\ldots,b_m,b_1+\eta,\ldots,b_m+\eta)=(a_1\ldots,a_n)=\mathbf{a}.$$

□

C. Definition of Φ

Set $\Phi=\Xi\times\Xi'/\sim$, where $\Xi'=\Xi\backslash\{(-\infty)\}$ and the equivalence relation is given by

$$(\mathbf{a},\mathbf{b})\sim(\mathbf{a}',\mathbf{b}')\Leftrightarrow\mathbf{a}+\mathbf{b}'=\mathbf{a}'+\mathbf{b}, \tag{2.10}$$

for $(\mathbf{a},\mathbf{b}),(\mathbf{a}',\mathbf{b}')\in\Xi\times\Xi'$. The equivalence class of $(\mathbf{a},\mathbf{b})$ is denoted by $\mathbf{a}-\mathbf{b}$. Then, we have

$$\Phi=\{\mathbf{a}-\mathbf{b}|\mathbf{a}\in\Xi,\mathbf{b}\in\Xi'\}.$$

Next, we will define Max, Plus, and "Minus" operators on Φ (i.e., Max: $\Phi\times\Phi\to\Phi$, Plus: $\Phi\times\Phi\to\Phi$ and Minus: $\Phi\times\Phi\to\Phi$) as follows. For $\alpha=\mathbf{a}-\mathbf{b}\in\Phi$ and $\alpha'=\mathbf{a}'-\mathbf{b}'\in\Phi$, set

$$\mathrm{Max}(\alpha,\alpha')=\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{b}',\mathbf{a}'+\mathbf{b})-(\mathbf{b}+\mathbf{b}'), \tag{2.11}$$

$$\mathrm{Plus}(\alpha,\alpha')=(\mathbf{a}+\mathbf{a}')-(\mathbf{b}+\mathbf{b}'), \tag{2.12}$$

$$\mathrm{Minus}(\alpha,\alpha')=(\mathbf{a}+\mathbf{b}')-(\mathbf{b}+\mathbf{a}'). \tag{2.13}$$

In the sequel, for the matter of convenience, we write $\alpha+\alpha'$ and $\alpha-\alpha'$ for $\mathrm{Plus}(\alpha,\alpha')$ and $\mathrm{Minus}(\alpha,\alpha')$ respectively.

Lemma 2.3: The previous definition is well defined.

Proof: First, we will show the Max operator is invariant under relation (2.10). For $\mathbf{a}-\mathbf{b}=\mathbf{a}'-\mathbf{b}'\in\Phi$ and $\mathbf{c}-\mathbf{d}\in\Phi$, we have

$$\begin{aligned}\mathrm{Max}(\mathbf{a}-\mathbf{b},\mathbf{c}-\mathbf{d}) &= \overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d},\mathbf{c}+\mathbf{b})-(\mathbf{b}+\mathbf{d})\\ &= \overline{\mathrm{Max}}(\mathbf{a}+\mathbf{b}'+\mathbf{d},\mathbf{c}+\mathbf{b}+\mathbf{b}')-(\mathbf{b}+\mathbf{b}'+\mathbf{d})\\ &= \overline{\mathrm{Max}}(\mathbf{a}'+\mathbf{b}+\mathbf{d},\mathbf{c}+\mathbf{b}+\mathbf{b}')-(\mathbf{b}+\mathbf{b}'+\mathbf{d})\\ &= \overline{\mathrm{Max}}(\mathbf{a}'+\mathbf{d},\mathbf{c}+\mathbf{b}')-(\mathbf{b}'+\mathbf{d})=\mathrm{Max}(\mathbf{a}'-\mathbf{b}',\mathbf{c}-\mathbf{d}),\end{aligned}$$

which shows the invariance under relation (2.10).

Second, we will show the Plus operator is invariant under relation (2.10). For $\mathbf{a}-\mathbf{b}=\mathbf{a}'-\mathbf{b}' \in \Phi$ and $\mathbf{c}-\mathbf{d}\in\Phi$, we have

$$\begin{aligned}(\mathbf{a}-\mathbf{b})+(\mathbf{c}-\mathbf{d}) &= (\mathbf{a}+\mathbf{c})-(\mathbf{b}+\mathbf{d})=(\mathbf{a}+\mathbf{b}'+\mathbf{c})-(\mathbf{b}+\mathbf{b}'+\mathbf{d})=(\mathbf{a}'+\mathbf{b}+\mathbf{c})-(\mathbf{b}+\mathbf{b}'+\mathbf{d})\\ &= (\mathbf{a}'+\mathbf{c})-(\mathbf{b}'+\mathbf{d})=(\mathbf{a}'-\mathbf{b}')+(\mathbf{c}-\mathbf{d}),\end{aligned}$$

which shows the invariance under relation (2.10).

Third, we will show the minus operator is invariant under relation (2.10). For $\mathbf{a}-\mathbf{b}=\mathbf{a}'-\mathbf{b}' \in \Phi$ and $\mathbf{c}-\mathbf{d}\in\Phi$, we have

$$\begin{aligned}(\mathbf{a}-\mathbf{b})-(\mathbf{c}-\mathbf{d}) &= (\mathbf{a}+\mathbf{d})-(\mathbf{b}+\mathbf{c})=(\mathbf{a}+\mathbf{b}'+\mathbf{d})-(\mathbf{b}+\mathbf{b}'+\mathbf{c})=(\mathbf{a}'+\mathbf{b}+\mathbf{d})-(\mathbf{b}+\mathbf{b}'+\mathbf{c})\\ &= (\mathbf{a}'+\mathbf{d})-(\mathbf{b}'+\mathbf{c})=(\mathbf{a}'-\mathbf{b}')-(\mathbf{c}-\mathbf{d}),\end{aligned}$$

which shows the invariance under relation (2.10). □

Next, we shall show that Φ has the Max-Plus algebra structures (1.2)–(1.4) and the inversible property (1.5). More precisely, we have the following lemma.

Lemma 2.4: For $\alpha,\beta,\gamma\in\Phi$, we have the following identities:

$$(\alpha+\beta)+\gamma=\alpha+(\beta+\gamma), \tag{2.14}$$

$$\mathrm{Max}(\mathrm{Max}(\alpha,\beta),\gamma)=\mathrm{Max}(\alpha,\mathrm{Max}(\beta,\gamma)), \tag{2.15}$$

$$\mathrm{Max}(\alpha+\beta,\alpha+\gamma)=\alpha+\mathrm{Max}(\beta,\gamma), \tag{2.16}$$

$$\mathrm{Max}(\mathrm{Max}(\alpha,\beta),\beta+\eta)=\alpha. \tag{2.17}$$

Proof: Suppose $\alpha=\mathbf{a}-\mathbf{b}$, $\beta=\mathbf{c}-\mathbf{d}$, and $\gamma=\mathbf{e}-\mathbf{f}$. First identity (2.14) is obtained by the following computation:

$$(\alpha+\beta)+\gamma=(\mathbf{a}+\mathbf{c}+\mathbf{e})-(\mathbf{b}+\mathbf{d}+\mathbf{f})=\alpha+(\beta+\gamma).$$

Second identity (2.15) is obtained by the following computation:

$$\begin{aligned}\mathrm{Max}(\mathrm{Max}(\alpha,\beta),\gamma &= \mathrm{Max}(\mathrm{Max}(\mathbf{a}-\mathbf{b},\mathbf{c}-\mathbf{d}),\mathbf{e}-\mathbf{f})\\ &= \mathrm{Max}(\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d},\mathbf{c}+\mathbf{b})-(\mathbf{b}+\mathbf{d}),\mathbf{e}-\mathbf{f})\\ &= \overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d},\mathbf{c}+\mathbf{b})+\mathbf{f},\mathbf{e}+\mathbf{b}+\mathbf{d})-(\mathbf{b}+\mathbf{d}+\mathbf{f})\\ &= \overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d}+\mathbf{f},\mathbf{c}+\mathbf{b}+\mathbf{f}),\mathbf{e}+\mathbf{b}+\mathbf{d})-(\mathbf{b}+\mathbf{d}+\mathbf{f})\\ &= \overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d}+\mathbf{f},\overline{\mathrm{Max}}(\mathbf{c}+\mathbf{b}+\mathbf{f},\mathbf{e}+\mathbf{b}+\mathbf{d}))-(\mathbf{b}+\mathbf{d}+\mathbf{f})\\ &= \overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d}+\mathbf{f},\overline{\mathrm{Max}}(\mathbf{c}+\mathbf{f},\mathbf{e}+\mathbf{d})+\mathbf{b})-(\mathbf{b}+\mathbf{d}+\mathbf{f})\\ &= \mathrm{Max}(\mathbf{a}-\mathbf{b},\overline{\mathrm{Max}}(\mathbf{c}+\mathbf{f},\mathbf{e}+\mathbf{d})-(\mathbf{d}+\mathbf{f}))\\ &= \mathrm{Max}(\mathbf{a}-\mathbf{b},\mathrm{Max}(\mathbf{c}-\mathbf{d},\mathbf{e}-\mathbf{f}))=\mathrm{Max}(\alpha,\mathrm{Max}(\beta,\gamma)).\end{aligned}$$

Third identity (2.16) is obtained by the following computation:

$$\begin{aligned}\mathrm{Max}(\alpha+\beta,\alpha+\gamma) &= \mathrm{Max}((\mathbf{a}-\mathbf{b})+(\mathbf{c}-\mathbf{d}),(\mathbf{a}-\mathbf{b})+(\mathbf{e}-\mathbf{f}))\\ &= \mathrm{Max}((\mathbf{a}+\mathbf{c})-(\mathbf{b}+\mathbf{d}),(\mathbf{a}+\mathbf{e})-(\mathbf{b}+\mathbf{f}))\\ &= \overline{\mathrm{Max}}((\mathbf{a}+\mathbf{c})+(\mathbf{b}+\mathbf{f}),(\mathbf{a}+\mathbf{e})+(\mathbf{b}+\mathbf{d}))-(\mathbf{b}+\mathbf{d}+\mathbf{b}+\mathbf{f})\\ &= \mathbf{a}-\mathbf{b}+\overline{\mathrm{Max}}(\mathbf{c}+\mathbf{f},\mathbf{e}+\mathbf{d}))-(\mathbf{d}+\mathbf{f})\\ &= \mathbf{a}-\mathbf{b}+\mathrm{Max}(\mathbf{c}-\mathbf{d},\mathbf{e}-\mathbf{f})=\alpha+\mathrm{Max}(\beta,\gamma).\end{aligned}$$

Final identity (2.17) is obtained by the following computation:

$$\begin{aligned}\mathrm{Max}(\mathrm{Max}(\alpha,\beta),\beta+\eta) &= \mathrm{Max}(\mathrm{Max}(\mathbf{a}-\mathbf{b},\mathbf{c}-\mathbf{d}),\mathbf{c}-\mathbf{d}+\eta)\\ &= \mathrm{Max}(\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d},\mathbf{c}+\mathbf{b})-(\mathbf{b}+\mathbf{d}),\mathbf{c}+\eta-\mathbf{d})\\ &= \overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d},\mathbf{c}+\mathbf{b})+\mathbf{d},\mathbf{c}+\eta+\mathbf{b}+\mathbf{d})-(\mathbf{b}+\mathbf{d}+\mathbf{d})\\ &= \overline{\mathrm{Max}}(\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{d}+\mathbf{d},\mathbf{c}+\mathbf{b}+\mathbf{d}),\mathbf{c}+\mathbf{b}+\mathbf{d}+\eta)-(\mathbf{b}+\mathbf{d}+\mathbf{d})\\ &= \mathbf{a}+\mathbf{d}+\mathbf{d}-(\mathbf{b}+\mathbf{d}+\mathbf{d})=\mathbf{a}-\mathbf{b}=\alpha.\end{aligned}$$

□

D. Definition of inversible Max-Plus algebra Ω

For the matter of convenience, a one-component element $\mathbf{a}=(a)\in\Phi$ is denoted by a, and $\mathbf{b}=(0,-b_1,\ldots,-b_n)\in\Phi$ is denoted by $[b_1,\ldots,b_n]$, if there is no danger of confusion.

Lemma 2.5: We have

$$[a_1,\ldots,a_n]+[b_1,\ldots,b_n]=[\{a_i\}_{i=1}^n,\{b_i\}_{i=1}^m,\{a_i+b_j\}_{i=1\ j=1}^{n\ m}].$$

Proof: The computation is straightforward as follows:

$$\begin{aligned}[a_1,\ldots,a_n]+[b_1,\ldots,b_n] &= (0,-a_1,\ldots,-a_n)+(0,-b_1,\ldots,-b_n)\\ &= (0,\{-a_i\}_{i=1}^n,\{-b_i\}_{i=1}^m,\{-a_i-b_j\}_{i=1\ j=1}^{n\ m})\\ &= [\{a_i\}_{i=1}^n,\{b_i\}_{i=1}^m,\{a_i+b_j\}_{i=1\ j=1}^{n\ m}].\end{aligned}$$

□

Define a subset Ω of Φ by

$$\Omega=\{a+[b_1,\ldots,b_n]-[c_1,\ldots,c_m]\,|\,n,m\in\mathbf{N},a\in\tilde{\mathbf{Z}},b_i\in\tilde{\mathbf{Z}}_+,c_i\in\tilde{\mathbf{Z}}_+\},\tag{2.18}$$

where

$$\tilde{\mathbf{Z}}_+=\{x\in\mathbf{Z}\,|\,x\geqslant 0\}\cup\{x+\eta\in\mathbf{Z}\oplus\mathbf{Z}_2\,|\,x>0\}.$$

For $a+[b_1,\ldots,b_n]-[c_1,\ldots,c_m]\in\Omega$, we call "$a$" *a leading term* and "$[b_1,\ldots,b_n]-[c_1,\ldots,c_m]$" *a correction term*.

Lemma 2.6: We have

$$\Omega=\Phi.$$

Remark: Ω also has the Max-Plus algebra structures (1.2)–(1.4) and the inversible property (1.5), because of *Lemma 2.4*.

Proof: By definition, it is clear that $\Omega\subset\Phi$. Therefore, it is enough to show that $\Phi\subset\Omega$. For $\alpha=(a_1,\ldots,a_n)-(b_1,\ldots,b_m)\in\Phi$, we may assume that $(a_1,\ldots,a_n)$ and $(b_1,\ldots,b_m)$ are irreducible and $a_1\geqslant\ldots\geqslant a_n$ and $b_1\geqslant\ldots\geqslant b_n$, without loss of generality. Then, we have

$$(a_1,\ldots,a_n)-(b_1,\ldots,b_m)=a_1-b_1+(0,-(a_1-a_2),\ldots,-(a_1-a_n))-(0,-(b_1-b_2),\ldots,-(b_1-b_m))=a_1-b_1+[(a_1-a_2),\ldots,(a_1-a_n)]-[(b_1-b_2),\ldots,(b_1-b_m)]\in\Omega.$$

Here, we have used $(a_1-a_i)\in\tilde{\mathbf{Z}}_+(i=2,\ldots,n)$ and $(b_1-b_i)\in\tilde{\mathbf{Z}}_+(i=2,\ldots,m)$. □

Next, in the following two theorems, we shall express Plus, Minus and Max operators in Ω.

Theorem 2.7: *For* $\alpha=a+[b_1,\ldots,b_n]-[c_1,\ldots,c_m]\in\Omega$ *and* $\alpha'=a'+[b'_1,\ldots,b'_p]-[c'_1,\ldots,c'_q]\in\Omega$, *the result of the computation of Plus and Minus operators is given by*

$$\alpha+\alpha'=a+a'+C_+(\alpha,\alpha'),\tag{2.19}$$

$$\alpha-\alpha'=a-a'+C_-(\alpha,\alpha'),\tag{2.20}$$

where the correction terms C_+,C_- *are given by*

$$C_+(\alpha,\alpha')=[\{b_i\}_{i=1}^n,\{b'_i\}_{i=1}^p,\{b_i+b'_j\}_{i=1\ j=1}^{n\ p}]-[\{c_i\}_{i=1}^m,\{c'_i\}_{i=1}^q,\{c_i+c'_j\}_{i=1\ j=1}^{m\ q}],$$

$$C_-(\alpha,\alpha')=[\{b_i\}_{i=1}^n,\{c'_i\}_{i=1}^q,\{b_i+c'_j\}_{i=1\ j=1}^{n\ p}]-[\{c_i\}_{i=1}^m,\{b'_i\}_{i=1}^p,\{c_i+b'_j\}_{i=1\ j=1}^{m\ p}].$$

Proof: The computation is straightforward from Lemma 2.5 □.

Next, we express Max operator in Ω. For arbitrary $\alpha=a+[b_1,\ldots,b_n]\in\Omega$ and $\alpha'=a'+[b'_1,\ldots,b'_m]\in\Omega$ with irreducible expressions (i.e., $[b_1,\ldots,b_n]$ and $[b'_1,\ldots,b'_m]$ are irreducible), we may assume that $b_1\leqslant\cdots\leqslant b_n$ and $b'_1\leqslant\cdots\leqslant b'_m$, without loss of generality. Then, we have the following theorem.

Theorem 2.8: *(1) For* $\alpha=a+[b_1,\ldots,b_n]\in\Omega$ *and* $\alpha'=a'+[b'_1,\ldots,b'_m]\in\Omega$ *with* $b_1\leqslant\ldots\leqslant b_n$ *and* $b'_1\leqslant\cdots\leqslant b'_m$, *the expression of* $\mathrm{Max}(\alpha,\alpha')$ *is given as follows.*

If $a\neq a'+\eta$, we have

$$\mathrm{Max}(\alpha,\alpha')=\max(a,a')+C_m(\alpha,\alpha'),\tag{2.21}$$

where the correction term C_m is given by

$$C_m(\alpha,\alpha')=[|a-a'|,\{b_i+\max(a'-a,0)\}_{i=1}^n,\{b'_i+\max(a-a',0)\}_{i=1}^m].$$

If $a=a'+\eta$, we have

$$\mathrm{Max}(\alpha,\alpha')=\begin{cases}a-b_{k+1}+[\{b_i-b_{k+1}\}_{i=k+2}^n,\{b'_i-b_{k+1}+\eta\}_{i=k+1}^m]\\ \qquad\text{if } {}^{\exists}k<n,m \text{ s.t. } b_i=b'_i(1\leqslant i\leqslant k)\\ \qquad\qquad\text{and } ((b_{k+1}<b'_{k+1}) \text{ or } (b_{k+1}=b'_{k+1}+\eta))\\ a-b_{m+1}+[\{b_i-b_{m+1}\}_{i=m+2}^n]\\ \qquad\text{if } b_i=b'_i \text{ for } 1\leqslant i\leqslant m<n,\\ -\infty \quad \text{if } b_i=b'_i \text{ for } 1\leqslant i\leqslant m=n.\end{cases}\tag{2.22}$$

Remark 1: We will extend the above formula for general cases as follows. For

$$\alpha=a+[b_1,\ldots,b_n]-[c_1,\ldots,c_m]\in\Omega,$$

$$\alpha'=a'+[b'_1,\ldots,b'_p]-[c'_1,\ldots,c'_q]\in\Omega,$$

the expression of $\mathrm{Max}(\alpha,\alpha')$ can be computed by using (2.21) and (2.22) and the identity

$$\mathrm{Max}(\alpha,\alpha') = \mathrm{Max}(a+[b]+[c'],a'+[b']+[c]) - ([c]+[c']). \tag{2.23}$$

Here, notice that the first term on the right-hand side of (2.23) can be computed by (2.21) and (2.22).

Remark 2: In (2.22), for $[b_1,\ldots,b_n]$ and $[b'_1,\ldots,b'_m]$, we can assume that there are only the following three cases:

1. There exists $k\in\mathbf{N}$ and $k<n,m$ such that $b_i=b'_i$ $(i=1,\cdots,k)$ and $((b_{k+1}<b'_{k+1})$ or $(b_{k+1}=b'_{k+1}+\eta))$,
2. $m<n$ and $b_i=b'_i$ $(i=1,\cdots,m)$, and
3. $m=n$ and $b_i=b'_i$ $(i=1,\cdots,m)$,

without loss of generality. These three cases (1, 2 and 3) correspond to the first, second, and third cases in (2.22) respectively.

Proof of Theorem 2.8: Let us consider the case $a\neq a'+\eta$. Without loss of generality, we can assume that $a\geqslant a'$. Then, we have

$$\begin{aligned}\mathrm{Max}(\alpha,\alpha') &= \mathrm{Max}((a,a-b_1,\ldots,a-b_n),(a',a'-b'_1,\ldots,a'-b'_m))\\ &= (a,a-b_1,\ldots,a-b_n,a',a'-b'_1,\ldots,a'-b'_m)\\ &= a+(0,-b_1,\ldots,-b_n,-(a-a'),-(b'_1+a-a'),\ldots,-(b'_m+a-a'))\\ &= a+[a-a',b_1,\ldots,b_n,b'_1+a-a',\ldots,b'_m+a-a'],\end{aligned}$$

which shows that (2.21) holds for $a\geqslant a'$. We can prove (2.21) for the other case $a<a'$ in the same way.

Next, let us consider the case $a=a'+\eta$. First, we consider the first case in (2.22). (i.e., there exists $k\in\mathbf{N}$ and $k<n,m$ such that $b_i=b'_i$ $(i=1,\ldots,k)$ and $b_{k+1}<b'_{k+1}$.) In this case, we have

$$\begin{aligned}\mathrm{Max}(\alpha,\alpha') &= (a,a-b_1,\ldots,a-b_n,a',a'-b'_1,\ldots,a'-b'_m)\\ &= (a-b_{k+1},\ldots,a-b_n,a'-b'_{k+1},\ldots,a'-b'_m) = a-b_{k+1}+(0,-(b_{k+2}-b_{k+1}),\ldots,\\ &\quad -(b_n-b_{k+1}),-(b'_{k+1}-b_{k+1}+\eta),\ldots,-(b'_m-b_{k+1}+\eta))\\ &= a-b_{k+1}+[\{b_i-b_{k+1}\}_{i=k+2}^{n},\{b'_i-b_{k+1}+\eta\}_{i=k+1}^{m}],\end{aligned}$$

which shows the first case in (2.22). Second, we consider the second case in (2.22) (i.e., $m<n$ and $b_i=b'_i$ $(i=1,\ldots,m)$. In this case, we have

$$\begin{aligned}\mathrm{Max}(\alpha,\alpha') &= (a,a-b_1,\ldots,a-b_n,a',a'-b'_1,\ldots,a'-b'_m)\\ &= (a-b_{m+1},\ldots,a-b_n) = a-b_{m+1}+(0,-(b_{m+2}-b_{m+1}),\ldots,-(b_n-b_{m+1}))\\ &= a-b_{m+1}+[\{b_i-b_{m+1}\}_{i=m+2}^{n}],\end{aligned}$$

which shows the second case in (2.22). Third, we consider the third case in (2.22) (i.e., $m=n$ and $b_i=b'_i$ $(i=1,\ldots,m)$.) In this case, we have

$$\mathrm{Max}(\alpha,\alpha') = (a,a-b_1,\ldots,a-b_n,a',a'-b'_1,\ldots,a'-b'_n) = -\infty,$$

which shows the third case in (2.22). □

III. APPLICATIONS

A. Projection to the usual max-plus algebra Z

Let Ω_0 be a subset of Ω defined by $\Omega_0=\{a+[b_1,\ldots,b_n]-[c_1,\ldots.c_m]\in\Omega\,|\,a\in\mathbf{Z}\}\subset\Omega$. For $\alpha=a+[b_1,\ldots,b_n]-[c_1,\ldots.c_m]\in\Omega_0$, define a projection map P: $\Omega_0\to\mathbf{Z}$ by

$$\mathrm{P}(\alpha) = a. \tag{3.1}$$

Lemma 3.1: Ω_0 *is Max-Plus subalgebra.*

Proof: It is clear from (2.21), (2.19), and (2.20). Notice that $a, a' \in \mathbf{Z}$.

Theorem 3.2: *The map P:* $\Omega_0 \to \mathbf{Z}$ *is a homomorphism map with respect to Max, Plus, Minus operators. More precisely, for* $\alpha = a + [b_1, \ldots, b_n] - [c_1, \ldots . c_m] \in \Omega_0$ *and* $\alpha' = a' + [b'_1, \ldots, b'_p] - [c'_1, \ldots, c'_q] \in \Omega_0$, *we have*

$$\mathrm{P}(\mathrm{Max}(\alpha, \alpha')) = \max(a, a'),$$

$$\mathrm{P}(\alpha + \alpha') = a + a',$$

$$\mathrm{P}(\alpha - \alpha') = a - a'.$$

Proof: It is clear from (2.21), (2.19), and (2.20). Notice that $a, a' \in \mathbf{Z}$.

B. Faithful representation on Ω

For any positive real number ϵ and $a = x + \xi \in \tilde{\mathbf{Z}}$, set $\overline{a} = x + \overline{\xi} \in \mathbf{C}$, where

$$\overline{\xi} = \begin{cases} i\pi\epsilon & (\xi = \eta) \\ 0 & (\xi = 0). \end{cases}$$

For $\alpha = (a_i)_{i=1}^n - (b_i)_{i=1}^m = (a_1, \ldots, a_n) - (b_1, \ldots, b_m) \in \Phi$, define a map $\mathrm{R}_\epsilon : \Phi \to \mathbf{C}$ by

$$\mathrm{R}_\epsilon(\alpha) = \epsilon \log\left(\sum_i e^{\overline{a_i}/\epsilon}\right) - \epsilon \log\left(\sum_i e^{\overline{b_i}/\epsilon}\right) = \epsilon \log(e^{\overline{a_1}/\epsilon} + \ \ldots\ + e^{\overline{a_n}/\epsilon}) - \epsilon \log(e^{\overline{b_1}/\epsilon} + \ \ldots\ + e^{\overline{b_m}/\epsilon}).$$

Here we set $e^{\overline{a_i}/\epsilon}$ to be zero, if $a_i = -\infty$.

Lemma 3.3: The previous definition $\mathrm{R}_\epsilon : \Phi \to \mathbf{C}$ is well defined.

Proof: First, we shall show that the definition is invariant under relations (2.1)–(2.3). For $\mathbf{a} = (a_1, \ldots, a_i, \ldots, a_j, \ldots, a_n)$, $\mathbf{a}' = (a_1, \ldots, a_j, \ldots, a_i, \ldots, a_n)$, and $\mathbf{b} = (b_1, \ldots, b_m)$, we have

$$\begin{aligned} \mathrm{R}_\epsilon(\mathbf{a} - \mathbf{b}) &= \mathrm{R}_\epsilon((a_1, \ldots, a_i, \ldots, a_j, \ldots, a_n) - (b_1, \ldots, b_m)) \\ &= \epsilon \log(e^{\overline{a_1}/\epsilon} + \cdots + e^{\overline{a_i}/\epsilon} + \cdots + e^{\overline{a_j}/\epsilon} + \cdots + e^{\overline{a_n}/\epsilon}) - \epsilon \log(e^{\overline{b_1}/\epsilon} + \cdots + e^{\overline{b_m}/\epsilon}) \\ &= \epsilon \log(e^{\overline{a_1}/\epsilon} + \cdots + e^{\overline{a_j}/\epsilon} + \cdots + e^{\overline{a_i}/\epsilon} + \cdots + e^{\overline{a_n}/\epsilon}) - \epsilon \log(e^{\overline{b_1}/\epsilon} + \cdots + e^{\overline{b_m}/\epsilon}) \\ &= \mathrm{R}_\epsilon((a_1, \ldots, a_j, \ldots, a_i, \ldots, a_n) - (b_1, \ldots, b_m)) = \mathrm{R}_\epsilon(\mathbf{a}' - \mathbf{b}), \end{aligned}$$

which shows the invariance under relation (2.1). For $\mathbf{a} = (a_1 \ldots, a_n, c, c + \eta)$, $\mathbf{a}' = (a_1, \ldots, a_n, -\infty)$, and $\mathbf{b} = (b_1, \ldots, b_m)$, we have

$$\begin{aligned} \mathrm{R}_\epsilon(\mathbf{a} - \mathbf{b}) &= \mathrm{R}_\epsilon((a_1, \ldots, a_n, c, c + \eta) - (b_1, \ldots, b_m)) \\ &= \epsilon \log(e^{\overline{a_1}/\epsilon} + \cdots + e^{\overline{a_n}/\epsilon} + e^{\overline{c}/\epsilon} + e^{\overline{c + \eta}/\epsilon}) - \epsilon \log(e^{\overline{b_1}/\epsilon} + \cdots + e^{\overline{b_m}/\epsilon}) \\ &= \epsilon \log(e^{\overline{a_1}/\epsilon} + \cdots + e^{\overline{a_n}/\epsilon} + e^{\overline{c}/\epsilon} + e^{\overline{c}/\epsilon + i\pi}) - \epsilon \log(e^{\overline{b_1}/\epsilon} + \cdots + e^{\overline{b_m}/\epsilon}) \\ &= \epsilon \log(e^{\overline{a_1}/\epsilon} + \cdots + e^{\overline{a_n}/\epsilon} + e^{\overline{c}/\epsilon} - e^{\overline{c}/\epsilon}) - \epsilon \log(e^{\overline{b_1}/\epsilon} + \cdots + e^{\overline{b_m}/\epsilon}) \\ &= \epsilon \log(e^{\overline{a_1}/\epsilon} + \cdots + e^{\overline{a_n}/\epsilon}) - \epsilon \log(e^{\overline{b_1}/\epsilon} + \cdots + e^{\overline{b_m}/\epsilon}) = \mathrm{R}_\epsilon(\mathbf{a}' - \mathbf{b}), \end{aligned}$$

which shows the invariance under relation (2.2). For $\mathbf{a} = (a_1, \ldots, a_n, -\infty)$, $\mathbf{a}' = (a_1, \ldots, a_n)$, and $\mathbf{b} = (b_1, \ldots, b_m)$, we have

$$\mathrm{R}_\epsilon(\mathbf{a}-\mathbf{b}) = \mathrm{R}_\epsilon((a_1,\ldots,a_n,-\infty)-(b_1,\ldots,b_m))$$
$$= \epsilon\log(e^{\overline{a_1}/\epsilon}+\cdots+e^{\overline{a_n}/\epsilon}) - \epsilon\log(e^{\overline{b_1}/\epsilon}+\cdots+e^{\overline{b_m}/\epsilon}) = \mathrm{R}_\epsilon(\mathbf{a}'-\mathbf{b}),$$

which shows the invariance under relation (2.3).

Second, we shall show that the definition is invariant under relation (2.10). Suppose $(a_1,\ldots,a_n)-(b_1,\ldots,b_m)=(a_1',\ldots,a_p')-(b_1',\ldots,b_q')$. Then we have

$$(a_i+b_j')_{i=1\ j=1}^{n\ \ q} = (a_i'+b_j)_{i=1\ j=1}^{p\ \ m}.$$

Then, it follows that

$$\epsilon\log\left(\sum_{i=1}^{n}\sum_{j=1}^{q} e^{\overline{a_i+b_j'}/\epsilon}\right) = \epsilon\log\left(\sum_{i=1}^{p}\sum_{j=1}^{m} e^{\overline{a_i'+b_j}/\epsilon}\right). \tag{3.2}$$

Then, we have

$$\mathrm{R}_\epsilon((a_1,\ldots,a_n)-(b_1,\ldots,b_m)) = \epsilon\log\left(\sum_{i=1}^{n} e^{\overline{a_i}/\epsilon}\right) - \epsilon\log\left(\sum_{j=1}^{m} e^{\overline{b_j}/\epsilon}\right)$$
$$= \epsilon\log\left(\sum_{i=1}^{p} e^{\overline{a_i'}/\epsilon}\right) - \epsilon\log\left(\sum_{j=1}^{q} e^{\overline{b_j'}/\epsilon}\right) + \epsilon\log\left(\sum_{i=1}^{n}\sum_{j=1}^{q} e^{\overline{a_i+b_j'}/\epsilon}\right)$$
$$- \epsilon\log\left(\sum_{i=1}^{p}\sum_{j=1}^{m} e^{\overline{a_i'+b_j}/\epsilon}\right) = \epsilon\log\left(\sum_{i=1}^{p} e^{\overline{a_i'}/\epsilon}\right) - \epsilon\log\left(\sum_{j=1}^{q} e^{\overline{b_j'}/\epsilon}\right)$$
$$= \mathrm{R}_\epsilon((a_1',\ldots,a_p')-(b_1',\ldots,b_q')),$$

which shows the invariance under relation (2.10). Here, we have used (3.2) in the third line. □

For any positive real number ϵ, define a map $\mathrm{Max}_\epsilon:\mathbf{C}\times\mathbf{C}\to\mathbf{C}$ by

$$\mathrm{Max}_\epsilon(a,b) = \epsilon\log(e^{a/\epsilon}+e^{b/\epsilon}),$$

where $a,b\in\mathbf{C}$. Here, we remark that $\mathbf{C}$ with Max_ϵ has the Max-Plus algebra structures (1.2)–(1.4).

Theorem 3.4: *(1) The map* $\mathrm{R}_\epsilon:\Phi\to\mathbf{C}$ *is a representation of* Φ. *More precisely, for* $\alpha,\alpha'\in\Phi$, *we have*

$$\mathrm{R}_\epsilon(\mathrm{Max}(\alpha,\alpha')) = \mathrm{Max}_\epsilon(\mathrm{R}_\epsilon(\alpha),\mathrm{R}_\epsilon(\alpha')), \tag{3.3}$$

$$\mathrm{R}_\epsilon(\alpha+\alpha') = \mathrm{R}_\epsilon(\alpha)+\mathrm{R}_\epsilon(\alpha'), \tag{3.4}$$

$$\mathrm{R}_\epsilon(\alpha-\alpha') = \mathrm{R}_\epsilon(\alpha)-\mathrm{R}_\epsilon(\alpha'). \tag{3.5}$$

(2) If $\mathrm{R}_\epsilon(\alpha)=0$ *for any* ϵ, *then* $\alpha=0$.

Proof: (1) First, we will prove (3.3) as follows. For $\alpha=\mathbf{a}-\mathbf{b}=(a_1,\ldots,a_n)-(b_1,\ldots,b_m)\in\Phi$ and $\alpha=\mathbf{a}'-\mathbf{b}'=(a_1',\ldots,a_p')-(b_1',\ldots,b_q')\in\Phi$, we have

$$
\begin{aligned}
\mathrm{R}_\epsilon(\mathrm{Max}(\alpha,\alpha')) &= \mathrm{R}_\epsilon(\overline{\mathrm{Max}}(\mathbf{a}+\mathbf{b}',\mathbf{a}'+\mathbf{b})-(\mathbf{b}+\mathbf{b}')) \\
&= \mathrm{R}_\epsilon(((a_i+b_j')_{i=1}^{n\ q}{}_{j=1},(a_k'+b_l)_{k=1}^{p\ m}{}_{l=1})-(b_i+b_j')_{i=1}^{m\ q}{}_{j=1}) \\
&= \epsilon\log\left(\sum_{i,j} e^{\overline{a_i+b_j'}/\epsilon}+\sum_{i,j} e^{\overline{a_i'+b_j}/\epsilon}\right)-\epsilon\log\left(\sum_{i,j} e^{\overline{b_i+b_j'}/\epsilon}\right) \\
&= \epsilon\log\left(\frac{\sum_i e^{\overline{a_i}/\epsilon}}{\sum_i e^{\overline{b_i}/\epsilon}}+\frac{\sum_i e^{\overline{a_i'}/\epsilon}}{\sum_i e^{\overline{b_i'}/\epsilon}}\right)=\mathrm{Max}_\epsilon\left(\epsilon\log\left(\frac{\sum_i e^{\overline{a_i}/\epsilon}}{\sum_i e^{\overline{b_i}/\epsilon}}\right),\epsilon\log\left(\frac{\sum_i e^{\overline{a_i'}/\epsilon}}{\sum_i e^{\overline{b_i'}/\epsilon}}\right)\right) \\
&= \mathrm{Max}_\epsilon\left(\epsilon\log\left(\sum_i e^{\overline{a_i}/\epsilon}\right)-\epsilon\log\left(\sum_i e^{\overline{b_i}/\epsilon}\right),\epsilon\log\left(\sum_i e^{\overline{a_i'}/\epsilon}\right)-\epsilon\log\left(\sum_i e^{\overline{b_i'}/\epsilon}\right)\right) \\
&= \mathrm{Max}_\epsilon(\mathrm{R}_\epsilon(\alpha),\mathrm{R}_\epsilon(\alpha')),
\end{aligned}
$$

which shows (3.3). Second, we will prove (3.4) as follows:

$$
\begin{aligned}
\mathrm{R}_\epsilon(\mathrm{Max}(\alpha+\alpha')) &= \mathrm{R}_\epsilon((\mathbf{a}+\mathbf{a}')-(\mathbf{b}+\mathbf{b}')) \\
&= \mathrm{R}_\epsilon(((a_i+a_j')_{i=1}^{n\ p}{}_{j=1}-(b_i+b_j')_{i=1}^{m\ q}{}_{j=1}) \\
&= \epsilon\log\left(\sum_{i,j} e^{\overline{a_i+a_j'}/\epsilon}\right)-\epsilon\log\left(\sum_{i,j} e^{\overline{b_i+b_j'}/\epsilon}\right) \\
&= \epsilon\log\left(\sum_i e^{\overline{a_i}/\epsilon}\right)-\epsilon\log\left(\sum_i e^{\overline{b_i}/\epsilon}\right)+\epsilon\log\left(\sum_i e^{\overline{a_i'}/\epsilon}\right)-\epsilon\log\left(\sum_i e^{\overline{b_i'}/\epsilon}\right) \\
&= \mathrm{R}_\epsilon(((a_i)_{i=1}^n-(b_i)_{i=1}^m)+\mathrm{R}_\epsilon(((a_i')_{i=1}^n-(b_j')_{i=1}^q)=\mathrm{R}_\epsilon(\alpha)+\mathrm{R}_\epsilon(\alpha').
\end{aligned}
$$

This shows (3.4). We can obtain (3.5) in the same way.

(2) For $\alpha=(a_1,\ldots,a_n)-(b_1,\ldots,b_m)\in\Phi$, it is assumed that α is irreducible and $a_1\geqslant\cdots\geqslant a_n$ and $b_1\geqslant\cdots\geqslant b_n$. Then, we have

$$
\mathrm{R}_\epsilon(\alpha)=\epsilon\log(e^{\overline{a_1}/\epsilon}+\cdots+e^{\overline{a_n}/\epsilon})-\epsilon\log(e^{\overline{b_1}/\epsilon}+\cdots+e^{\overline{b_m}/\epsilon})=0.
$$

Hence, we have

$$
e^{\overline{a_1}/\epsilon}+\cdots+e^{\overline{a_n}/\epsilon}=e^{\overline{b_1}/\epsilon}+\cdots+e^{\overline{b_m}/\epsilon}.
$$

This equation is equal to

$$
e^{\overline{a_1}/\epsilon}(1+e^{-\overline{(a_1-a_2)}/\epsilon}+\cdots+e^{-\overline{(a_1-a_n)}/\epsilon})=e^{\overline{b_1}/\epsilon}(1+e^{-\overline{(b_1-b_2)}/\epsilon}+\cdots+e^{-\overline{(b_1-b_m)}/\epsilon}).
$$

Considering $\epsilon\to+0$, we have $a_1=b_1$. By using inductive argument, we obtain

$$
(a_1,\ldots,a_n)=(b_1,\ldots,b_m),
$$

which shows $\alpha=0$. □

C. Ultradiscrete recursive equation

Define $\mathrm{UD}:\mathbf{Z}\to\Omega$ by

$$
\mathrm{UD}(n)=\begin{cases}0+[\underbrace{0,\ldots,0}_{k-1}] & \text{if } n=k\\ -\infty & \text{if } n=0\\ \eta+[\underbrace{0,\ldots,0}_{k-1}] & \text{if } n=-k.\end{cases}
$$

Let $P:\mathbf{R}^n\to\mathbf{R}$ be a polynomial function of finite degree given by

$$P(x_1, \ldots, x_n) = \sum_{i_1,\ldots,i_n=1}^{N} a_{i_1\ldots i_n} x_1^{i_1} \ldots x_n^{i_n},$$

where $a_{i_1\cdots i_n} \in \mathbf{Z}$, $x_i \in \mathbf{R}$. For $P(x_1, \ldots, x_n)$, define its UD polynomial $P_{UD}: \Omega^n \to \Omega$ by

$$P_{UD}(X_1, \ldots, X_n) = \underset{i_1,\ldots,i_n=1}{\overset{N}{\mathrm{Max}}} (\mathrm{UD}(a_{i_1\ldots i_n}) + i_1 X_1 + \cdots + i_n X_n),$$

where $X_i \in \Omega$.

More generally, let $F: \mathbf{R}^n \to \mathbf{R}$ a rational function given by

$$F(x_1, \ldots, x_n) = \frac{P(x_n, \ldots, x_1)}{Q(x_n, \ldots, x_1)},$$

where P and Q are polynomial functions of finite degree. Then, we define its UD equation $F_{UD}: \Omega^n \to \Omega$ by

$$F_{UD}(X_1, \ldots, X_n) = P_{UD}(X_1, \ldots, X_n) - Q_{UD}(X_1, \ldots, X_n). \tag{3.6}$$

Remark: (3.6) is just obtained by the following transformations:

$$x_i \times y_j \to X_i + Y_j,$$

$$x_i / y_j \to X_i - Y_j,$$

$$x_i + y_j \to \mathrm{Max}(X_i, Y_j),$$

$$x_i - y_j \to \mathrm{Max}(X_i, Y_j + \eta),$$

$$a_{i_1\cdots i_n} \to \mathrm{UD}(a_{i_1\cdots i_n}). \tag{3.7}$$

This is the final mapping we want (i.e., the mapping from the usual algebra to the inversible Max-Plus algebra Ω). Here, we remark that the missing correspondence in Fig. 1 (i.e., $x - y \to ??$) is now clear, since this correspondence is given by $x_i - y_j \to \mathrm{Max}(X_i, Y_j + \eta)$ in the previous transformation.

Theorem 3.5: *Suppose a periodic recursive equation*

$$x_{n+1} = F(x_1, \ldots, x_n) = \frac{P(x_n, \ldots, x_1)}{Q(x_n, \ldots, x_1)} \tag{3.8}$$

on $\mathbf{R}$ *has period k (i.e.,* $x_{n+k} = x_n$*), then its UD periodic recursive equation*

$$X_{n+1} = F_{UD}(X_1, \ldots, X_n) = P_{UD}(X_1, \ldots, X_n) - Q_{UD}(X_1, \ldots, X_n)$$

on Ω *also has period k (i.e.,* $X_{n+k} = X_n$*).*

Proof: Substituting $x_n = e^{R_\epsilon(X_n)/\epsilon}$ into (3.8), we have

$$
\begin{aligned}
e^{R_\epsilon(X_{n+1})/\epsilon} &= \frac{P(e^{R_\epsilon(X_n)/\epsilon}, \ldots, e^{R_\epsilon(X_1)/\epsilon})}{Q(e^{R_\epsilon(X_n)/\epsilon}, \ldots, e^{R_\epsilon(X_1)/\epsilon})} \\
&= \frac{\sum_{i_1,\ldots,i_n=1}^{N} a_{i_1\cdots i_n} e^{(i_1 R_\epsilon(X_1)+\cdots+i_n R_\epsilon(X_n))/\epsilon}}{\sum_{i_1,\ldots,i_n=1}^{N} b_{i_1\cdots i_n} e^{(i_1 R_\epsilon(X_1)+\cdots+i_n R_\epsilon(X_n))/\epsilon}} \\
&= \frac{\sum_{i_1,\ldots,i_n=1}^{N} e^{(\epsilon \log a_{i_1\cdots i_n}+R_\epsilon(i_1X_1+\cdots+i_nX_n))/\epsilon}}{\sum_{i_1,\ldots,i_n=1}^{N} e^{(\epsilon \log b_{i_1\cdots i_n}+R_\epsilon(i_1X_1+\cdots+i_nX_n))/\epsilon}} \\
&= \frac{\sum_{i_1,\ldots,i_n=1}^{N} e^{R_\epsilon(U(a_{i_1\cdots i_n})+i_1X_1+\cdots+i_nX_n)/\epsilon}}{\sum_{i_1,\ldots,i_n=1}^{N} e^{R_\epsilon(U(b_{i_1\cdots i_n})+i_1X_1+\cdots+i_nX_n)/\epsilon}}.
\end{aligned}
$$

Here, in the last line, we have used

$$
\begin{aligned}
\epsilon \log a_{i_1\cdots i_n} &= \underbrace{\epsilon \log e^{0/\epsilon} + \cdots + e^{0/\epsilon}}_{a_{i_1\cdots i_n}} \\
&= R_\epsilon((\underbrace{0, \ldots, 0}_{a_{i_1\cdots i_n}})) \\
&= R_\epsilon(0 + [\underbrace{0, \ldots, 0}_{a_{i_1\cdots i_n}-1}]) \\
&= R_\epsilon(U(a_{i_1\cdots i_n})).
\end{aligned}
$$

Then, we have

$$
\begin{aligned}
R_\epsilon(X_{n+1}) &= \operatorname*{Max}_{i_1,\ldots,i_n=1}^{N}{}_\epsilon (R_\epsilon(U(a_{i_1\cdots i_n}) + i_1X_1 + \cdots + i_nX_n)) - \operatorname*{Max}_{i_1,\ldots,i_n=1}^{N}{}_\epsilon (R_\epsilon(U(b_{i_1\cdots i_n}) + i_1X_1 + \cdots + i_nX_n)) \\
&= R_\epsilon(\operatorname*{Max}_{i_1,\ldots,i_n=1}^{N} (U(a_{i_1\cdots i_n}) + i_1X_1 + \cdots + i_nX_n) - \operatorname*{Max}_{i_1,\ldots,i_n=1}^{N} (U(b_{i_1\cdots i_n}) + i_1X_1 + \cdots + i_nX_n)).
\end{aligned}
$$

Hence, we finally obtain

$$
\mathrm{R}_\epsilon(X_{n+1}) = \mathrm{R}_\epsilon(P_{UD}(X_1, \ldots, X_n) - Q_{UD}(X_1, \ldots, X_n)).
$$

On the other hand, we have $\mathrm{R}_\epsilon(X_{n+k}) = \mathrm{R}_\epsilon(X_n)$ from $x_{n+k} = x_n$. This implies $X_{n+k} = X_n$. □

IV. EXAMPLES

A. Simplest example with subtraction

Let us consider the most simple identity

$$
x + y - y = x. \tag{4.1}
$$

Although this identity is simple, we cannot ultradiscretize this identity by the usual UD procedure (1.1) due to the subtraction $(-y)$ in the left-hand side of this identitiy (4.1). However, by using our ultradiscretization mapping (3.6) [or (3.7)] to the inversible Max-Plus algebra Ω, we can ultradiscretize this identity (4.1) as follows:

$$
\mathrm{Max}(\mathrm{Max}(X, Y), Y + \eta) = X.
$$

For example, if we take $X = 1$ and $Y = 3$ in this equation, we have

$$\mathrm{Max}(\mathrm{Max}(1,3),3+\eta)=\mathrm{Max}(3+[2],3+\eta)=1.$$

This example clearly exhibits the inversible property (1.5) of the Max operator on Ω, which does not exist in usual max operator on $\mathbf{Z}$.

B. Periodic recursive equations

Next, we will give some examples of periodic recursive equations.

1. Example without subtraction

It is known that the periodic recursive equation

$$x_{n+1}=\frac{x_n+1}{x_{n-1}}$$

has period 5. Then, from Theorem 3.5, we find that its UD equation

$$X_{n+1}=\mathrm{Max}(X_n,0)-X_{n-1} \tag{4.2}$$

also has period 5. For example, we have

$$X_1=1,\quad X_2=5,\quad X_3=4+[5],\quad X_4=-1+[4,5],\quad X_5=-4+[1,5,6]-[5],\quad X_6=1,\quad X_7=5. \tag{4.3}$$

Remark: If $X_i\in\Omega_0$ for all i, then we can act the projection map $\mathrm{P}:\Omega_0\to\mathbf{Z}$ for both sides of Eq. (4.2). Then, we have

$$Y_{n+1}=\max(Y_n,0)-Y_{n-1}, \tag{4.4}$$

where $Y_i=P(X_i)$. For example, we have

$$Y_1=1,\quad Y_2=5,\quad Y_3=4,\quad Y_4=-1,\quad Y_5=-4,\quad Y_6=1,\quad Y_7=5,$$

which correspond to (4.3). This equation also has period 5.

Here we remark that this usual UD equation (4.4) on $\mathbf{Z}$ can also be obtained by the usual ultradiscretization procedure $\lim_{\epsilon\to+0}\epsilon\log(e^{X/\epsilon}+e^{Y/\epsilon})=\max(X,Y)$ given by (1.1).

In the following paragraph, we will give an example which cannot be ultradiscretized by the usual ultradiscretization procedure (1.1). Therefore, in the next example, our mapping to the inversible Max-Plus algebra (3.6) [or (3.7)] will be essentially necessary, instead of the usual ultradiscretization procedure (1.1).

2. Example with subtraction

The periodic recursive equation

$$x_{n+1}=\frac{x_n-1}{x_n+1}$$

has period 4. Then, from Theorem 3.5, we find that its UD equation

$$X_{n+1}=\mathrm{Max}(X_n,\eta)-\mathrm{Max}(X_n,0) \tag{4.5}$$

also has period 4. For example,

$$X_1 = 2, \quad X_2 = [2 + \eta] - [2], \quad X_3 = -2 + \eta, \quad X_4 = \eta + [2] - [2 + \eta], \quad X_5 = 2. \tag{4.6}$$

Remark: We cannot act the projection map $\mathrm{P}:\Omega_0 \to \mathbf{Z}$ for both sides of Eqs. (4.5) and (4.6), since all the variables X_i do not belong to Ω_0. Therefore, this is a new type of UD equations, which cannot be obtained by the usual ultradiscretization procedure (1.1).

C. Equation of motion for a free particle

1. Continuous equation

The equation of motion for a free particle is given by

$$\ddot{x} = 0. \tag{4.7}$$

The energy conservation law is given by

$$e = \tfrac{1}{2}(\dot{x})^2 = \text{constant}. \tag{4.8}$$

2. Discrete equation

It is known that the discrete version of the equation of motion (4.7) is given by

$$x_{n+2} = 2x_{n+1} - x_n, \tag{4.9}$$

and the discrete version of the energy conservation law (4.8) is given by

$$h_n = \sqrt{2e_n} = x_{n+1} - x_n = \text{constant}. \tag{4.10}$$

Here we remark that the discrete equations (4.9) and (4.10) cannot be ultradiscretized by the usual procedure (1.1), since there exists subtraction in (4.9) and (4.10). However, by using our ultradiscretization mapping (3.6) [or (3.7)] to the inversible Max-Plus algebra Ω, we can ultradiscretize both Eqs. (4.9) and (4.10), which will be explained in the following paragraph.

3. Ultradiscrete equation

Finally, by using our ultradiscretization mapping (3.6) [or (3.7)], the discrete equation (4.9) can be transformed into

$$X_{n+1} = \mathrm{Max}(X_n + [0], X_{n-1} + \eta), \tag{4.11}$$

which is the UD version of the equation of motion for a free particle.

In the same way, from (4.10), we obtain the UD version of the energy conservation for a free particle as follows:

$$H_n = \mathrm{Max}(X_{n+1}, X_n + \eta). \tag{4.12}$$

4. Trajectory of the UD equation of motion for a free particle

Repeatedly using (4.11) with the initial condition $X_1 = 0$ and $X_2 = 1$, we can obtain the trajectory of the free particle as follows:

$$X_1 = 0,$$

$$X_2 = 1,$$

$$X_3 = 1 + [0, 1 + \eta],$$

$$X_4 = 1 + [0, 0, 1 + \eta, 1 + \eta],$$

$$\vdots$$

$$X_n = 1 + [0^{n-2}, (1 + \eta)^{n-2}],$$

where 0^{n-2} [respectively, $(1+\eta)^{n-2}$] denotes the array of $n-2$ zeros [respectively, $(1+\eta)$]. For example, $[0^3, (1+\eta)^3]$ denotes $[0,0,0,1+\eta,1+\eta,1+\eta]$. Here we remark that the trajectory of the leading term of X_n $(n=1,2,\cdots)$ is suddenly stopped after $n \geqslant 2$, while the correction terms are still changing.

It is worth noticing that although the trajectory of the leading term of X_n is suddenly stopped in the UD world, the energy H_n is still conserved as follows:

$$H_1 = \mathrm{Max}(X_2, X_1 + \eta) = 1 + [1 + \eta],$$

$$H_2 = \mathrm{Max}(X_3, X_2 + \eta) = 1 + [1 + \eta],$$

$$\vdots$$

$$H_n = \mathrm{Max}(X_{n+1}, X_n + \eta) = 1 + [1 + \eta].$$

For the future work, it would be interesting to study the ultradiscretization of the well known theory (e.g., soliton theory, chaos theory, classical mechanics, etc.), using the inversible Max-Plus algebra Ω and its mapping (3.6) [or (3.7)].

A nested sequence of projectors and corresponding braid matrices $\hat{R}(\theta)$. 1. Odd dimensions

A. Chakrabarti[a)]
Centre de Physique Théorique,[b)] *Ecole Polytechnique, 91128 Palaiseau Cedex, France*

(Received 13 January 2004; accepted 9 March 2005; published online 25 May 2005)

A basis of N^2 projectors, each an $N^2\times N^2$ matrix with constant elements, is implemented to construct a class of braid matrices $\hat{R}(\theta)$, θ being the spectral parameter. Only odd values of N are considered here. Our ansatz for the projectors P_α appearing in the spectral decomposition of $\hat{R}(\theta)$ leads to exponentials $\exp(m_\alpha\theta)$ as the coefficient of P_α. The sums and differences of such exponentials on the diagonal and the antidiagonal, respectively, provide the $(2N^2-1)$ nonzero elements of $\hat{R}(\theta)$. One element at the center is normalized to unity. A class of supplementary constraints imposed by the braid equation leaves $\frac{1}{2}(N+3)(N-1)$ free parameters m_α. The diagonalizer of $\hat{R}(\theta)$ is presented for all N. Transfer matrices $t(\theta)$ and $L(\theta)$ operators corresponding to our $\hat{R}(\theta)$ are studied. Our diagonalizer signals specific combinations of the components of the operators that lead to a quadratic algebra of N^2 constant $N\times N$ matrices. The θ dependence factors out for such combinations. $\hat{R}(\theta)$ is developed in a power series in θ. The basic difference arising for even dimensions is made explicit. Some special features of our $\hat{R}(\theta)$ are discussed in a concluding section. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1900291]

I. INTRODUCTION

In Sec. 8 of Ref. 1 a sequence of projectors with constant elements and particularly simple and convenient properties were introduced for arbitrary dimension N (i.e., $N^2\times N^2$ matrices). For the case $N=2$ they provide the spectral resolutions of the six-vertex and the eight-vertex models (Secs. 6 and 7 of Ref. 1, citing other sources). Along with N the set of projectors is enlarged in number and in dimension systematically at each step to give what we called a "nested sequence." The projectors were presented Ref. 1 for all N and their basic features were studied, including diagonalization, for arbitrary N. But no higher dimensional braid matrices were constructed on such bases. That was "beyond the scope" of that paper. Here we enlarge the scope and present explicit constructions for all *odd* N. Even dimensions will be studied separately elsewhere. Such a separation corresponds to strikingly different features arising in the respective cases.

After obtaining explicitly $\hat{R}(\theta)$ the corresponding transfer matrices $t(\theta)$ and $L(\theta)$ operators are studied. They are found to lead to a remarkable class of quadratic algebra (Sec. IV). Development of $\hat{R}(\theta)$ in powers of the spectral parameter θ is also studied (Sec. V). Basic differences arising for even dimensions are pointed out. (Sec. VI). The special features of our class of solutions are discussed in conclusion (Sec. VII). Construction of our solutions is presented in Appendix A and some basic results concerning $t(\theta)$ and $L(\theta)$ are collected together in Appendix B.

II. BRAID MATRICES FOR ODD DIMENSIONS (ANSATZ AND SOLUTIONS)

We start by specifying our notations and conventions in detail since they turn out to be crucial in successful construction of the solutions. Thus, rather than using the simple and elegant notation of Sec. 8 of Ref. 1 for our projectors we introduce in the following a structure better suited to our present purpose.

Let

$$N = 2p - 1 \quad (p = 2,3, \dots)$$

and

$$\overline{i} = N - i + 1 \quad (i + \overline{i} = 2p,\ \overline{\overline{i}} = i)$$

so that for

$$i = 1,2, \dots ,(p-1),$$

respectively,

$$\overline{i} = (2p-1),(2p-2), \dots ,(p+1)$$

and

$$\overline{p} = p.$$

The $N^2 \times N^2$ braid matrix $\hat{R}(\theta)$, with the spectral parameter θ, is given in terms of its components as

$$\hat{R}(\theta) = (\hat{R}(\theta))_{ab,cd}(ab) \otimes (cd), \tag{2.1}$$

where (a,b,c,d) take values in the domain $(i,\overline{i},p)$ and (ab) is the $N \times N$ matrix with only one nonzero element, unity, at row a and column b.

The basis of projectors is given by (with $\epsilon = \pm$) the set

$$P_{pp} = (pp) \otimes (pp),$$

$$2P_{pi(\epsilon)} = (pp) \otimes (((ii) + (\overline{i}\overline{i})) + \epsilon((i\overline{i}) + (\overline{i}i))),$$

$$2P_{ip(\epsilon)} = (((ii) + (\overline{i}\overline{i})) + \epsilon((i\overline{i}) + (\overline{i}i))) \otimes (pp), \tag{2.2}$$

$$2P_{ij(\epsilon)} = (((ii) \otimes (jj) + (\overline{i}\overline{i}) \otimes (\overline{j}\overline{j})) + \epsilon((i\overline{i}) \otimes (j\overline{j}) + (\overline{i}i) \otimes (\overline{j}j))),$$

$$2P_{\overline{ij}(\epsilon)} = (((ii) \otimes (\overline{j}\overline{j}) + (\overline{i}\overline{i}) \otimes (jj)) + \epsilon((i\overline{i}) \otimes (\overline{j}j) + (\overline{i}i) \otimes (j\overline{j}))).$$

Condensing the triplets $(i,j,\epsilon),(i,p,\epsilon),\dots$ and also (pp) into $(\alpha,\beta,\dots)$ the basis (2.2) satisfies

$$P_\alpha P_\beta = \delta_{\alpha\beta} P_\alpha, \quad \sum_\alpha P_\alpha = I_{N^2 \times N^2}. \tag{2.3}$$

The total number of P_α is

$$1 + 4(p-1) + 4(p-1)^2 = (2p-1)^2 = N^2.$$

They have, apart from the overall factor $\frac{1}{2}$ for all projectors except P_{pp}, only the constant elements

$(\pm 1,0)$. There is, for example, no q in our formalism. The braid matrix is *postulated* in the spectrally resolved form

$$\hat{R}(\theta) = P_{pp} + \sum_{i,\epsilon} (f_{pi}^{(\epsilon)}(\theta) P_{pi(\epsilon)} + f_{ip}^{(\epsilon)}(\theta) P_{ip(\epsilon)}) + \sum_{i,j,\epsilon} (f_{ij}^{(\epsilon)}(\theta) P_{ij(\epsilon)} + f_{ij}^{(\epsilon)}(\theta) P_{\bar{ij}(\epsilon)}). \tag{2.4}$$

The coefficient of P_{pp} is normalized to unity. The (N^2-1) functions $f_{ab}^{(\epsilon)}$ are to be extracted from the constraints imposed by the braid equation

$$\hat{R}_{12}(\theta)\hat{R}_{23}(\theta+\theta')\hat{R}_{12}(\theta') = \hat{R}_{23}(\theta')\hat{R}_{12}(\theta+\theta')\hat{R}_{23}(\theta). \tag{2.5}$$

Here (suppressing θ)

$$\hat{R}_{12} = \hat{R} \otimes I_{N\times N}, \quad \hat{R}_{23} = I_{N\times N} \otimes \hat{R}.$$

In terms of the coefficients $(\hat{R}(\theta))_{ab,cd}$ defined in (2.1) one obtains [summing over the repeated indices (l,m,n)]

$$(\hat{R}(\theta))_{al,cm}(\hat{R}(\theta+\theta'))_{mn,ef}(\hat{R}(\theta'))_{lb,nd} = (\hat{R}(\theta'))_{cl,em}(\hat{R}(\theta+\theta'))_{ab,ln}(\hat{R}(\theta))_{nd,mf}. \tag{2.6}$$

This corresponds to the point $(ab)\otimes(cd)\otimes(ef)$ of the base space $V\otimes V\otimes V$. Our ansatz (2.4) along with (2.2) implies very strong constraints (typical of *odd* dimensions). The solutions are obtained in Appendix A. One has

$$f_{ab}^{(\epsilon)}(\theta) = \exp(m_{ab}^{(\epsilon)}\theta), \quad (ab) = (pi),(ip),(ij),(\bar{ij}), \tag{2.7}$$

where the parameters $m_{ab}^{(\epsilon)}$ are all independent *except* that for each i,

$$m_{ij}^{(\epsilon)} = m_{\bar{ij}}^{(\epsilon)}, \quad (\bar{j} = 2p - j). \tag{2.8}$$

The constraints (2.7) and (2.8) are *necessary and sufficient*. Thus for $N=3$ one has

$$\hat{R}(\theta) = \begin{pmatrix} a_+ & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_- \\ 0 & b_+ & 0 & 0 & 0 & 0 & 0 & b_- & 0 \\ 0 & 0 & a_+ & 0 & 0 & 0 & a_- & 0 & 0 \\ 0 & 0 & 0 & c_+ & 0 & c_- & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & c_- & 0 & c_+ & 0 & 0 & 0 \\ 0 & 0 & a_- & 0 & 0 & 0 & a_+ & 0 & 0 \\ 0 & b_- & 0 & 0 & 0 & 0 & 0 & b_+ & 0 \\ a_- & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_+ \end{pmatrix} \tag{2.9}$$

where

$$\begin{aligned} a_\pm &= \tfrac{1}{2}(e^{m_{11}^{(+)}\theta} \pm e^{m_{11}^{(-)}\theta}), \\ b_\pm &= \tfrac{1}{2}(e^{m_{12}^{(+)}\theta} \pm e^{m_{12}^{(-)}\theta}), \\ c_\pm &= \tfrac{1}{2}(e^{m_{21}^{(+)}\theta} \pm e^{m_{21}^{(-)}\theta}). \end{aligned} \tag{2.10}$$

The six parameters remaining after application of (2.8) (which imposes the repetation of $a_\pm$) are all *independent*. For $m_{ab}^{(-)} = m_{ab}^{(+)}$ one obtains hyperbolic functions as particular cases. For all N, the nonzero elements are confined to *the diagonal and the antidiagonal* as above with a common

element, unity, at the center. Apart from the normalized element, the coefficients of the projectors are simply exponentials. The total number of independent parameters $m_{ab}^{\pm}$ is

$$(2p-1)^2 - 1 - 2(p-1)^2 = 2(p^2-1) = \tfrac{1}{2}(N+3)(N-1). \tag{2.11}$$

Note that the coefficient of P_{pp} in (2.4) has to be nonzero for $\hat{R}(\theta)$ to be invertible and hence can safely be normalized to unity. Indeed, each coefficient in (2.4) has to be nonzero for $\hat{R}(\theta)$ to be invertible. This is more evident after diagonalization (Sec. III). For even N there is *no* index $p=\overline{p}$. In Appendix A the crucial role of the index p will be made more evident. The projectors $P_{pi(\epsilon)}$ and $P_{ip(\epsilon)}$ will be seen to impose the highly constrained solutions (2.7) with (2.8).

Implementing (2.8) one obtains from (2.4)

$$\hat{R}(\theta) = P_{pp} + \sum_{i,\epsilon} (f_{pi}^{(\epsilon)}(\theta) P_{pi(\epsilon)} + f_{ip}^{(\epsilon)}(\theta) P_{ip(\epsilon)}) + \sum_{i,j,\epsilon} f_{ij}^{(\epsilon)}(\theta)(P_{ij(\epsilon)} + P_{i\overline{j}(\epsilon)}). \tag{2.12}$$

Defining

$$\widetilde{P}_{ij(\epsilon)} = P_{ij(\epsilon)} + P_{i\overline{j}(\epsilon)} \tag{2.13}$$

and conserving all other projectors as before one obtains a basis of $(2p^2-1)$ projectors still satisfying (2.3) where now the indices summed over are (i,j,ϵ), (i,p,ϵ), (p,i,ϵ), (pp).

Now

$$\hat{R}(\theta) = P_{pp} + \sum_{i,\epsilon} (f_{pi}^{(\epsilon)}(\theta) P_{pi(\epsilon)} + f_{ip}^{(\epsilon)}(\theta) P_{ip(\epsilon)}) + \sum_{i,j,\epsilon} f_{ij}^{(\epsilon)}(\theta) \widetilde{P}_{ij(\epsilon)}. \tag{2.14}$$

In this basis *all* the $\frac{1}{2}(N+3)(N-1)$ parameters are independent. When they are all chosen to be distinct (and different from 1) the polynomial equation [of $\frac{1}{2}(N+3)(N-1)$ degree and with distinct roots] satisfied by $\hat{R}(\theta)$ and the projectors in terms of $\hat{R}(\theta)$ are obtained, respectively, as in (1.5) and (1.6) of Ref. 1. The initial basis, due to the symmetry and simplicity of the projectors, is most convenient for certain purposes. The second one has the virtue of eliminating constraints. Each should be implemented according to the context.

If two or more of the $\frac{1}{2}(N+3)(N-1)$ free parameters are allowed to coincide, then introducing the sum of the corresponding projectors [as in (2.13)] the basis can again be redefined [as in (2.14)]. The degree of the minimal polynomial equation satisfied by $\hat{R}(\theta)$ diminishes correspondingly.

Our matrices all satisfy

$$\hat{R}(-\theta)\hat{R}(\theta) = I, \quad \hat{R}(0) = I. \tag{2.15}$$

III. DIAGONALIZATION

Our general approach to diagonalization is presented step by step in Sec. 9 of Ref. 1.

The matrix M that diagonalizes each projector P_α of (2.3) [namely, P_{pp}, $P_{pi(\epsilon)}$, $P_{ip(\epsilon)}$, $P_{ij(\epsilon)}$, $P_{i\overline{j}(\epsilon)}$ of (2.2)] and hence $\hat{R}(\theta)$ of (2.4) is given below. As compared to the results of Sec. 8 of Ref. 1, M is presented here in our current notations. Set

$$\begin{aligned}\sqrt{2}M &= \sqrt{2}M^{-1} \\ &= \sqrt{2}(pp)\otimes(pp) + (pp)\otimes\left(\sum_i ((ii) - (i\overline{i}) + (\overline{i}i) + (\overline{i}\overline{i}))\right) + \left(\sum_i ((ii) - (i\overline{i}) + (\overline{i}i) + (\overline{i}\overline{i}))\right)\otimes(pp) \\ &\quad + \sum_{i,j}\Big(((ii) - (i\overline{i}))\otimes((jj) + (\overline{j}\overline{j})) + ((\overline{i}i) + (\overline{i}\overline{i}))\otimes((\overline{j}j) + (\overline{j}\overline{j}))\Big).\end{aligned} \tag{3.1}$$

One verifies in a straightforward fashion (with $\epsilon = \pm 1$ on the right) that

$$MP_{pp}M^{-1} = (pp) \otimes (pp),$$

$$2MP_{pk(\epsilon)}M^{-1} = (pp) \otimes ((1+\epsilon)(kk) + (1-\epsilon)(\overline{kk})),$$

$$2MP_{kp(\epsilon)}M^{-1} = ((1+\epsilon)(kk) + (1-\epsilon)(\overline{kk})) \otimes (pp), \tag{3.2}$$

$$2MP_{kl(\epsilon)}M^{-1} = (1+\epsilon)(kk) \otimes (ll) + (1-\epsilon)(\overline{kk}) \otimes (\overline{ll}),$$

$$2MP_{k\bar{l}(\epsilon)}M^{-1} = (1+\epsilon)(kk) \otimes (\overline{ll}) + (1-\epsilon)(\overline{kk}) \otimes (ll).$$

Hence taking account of (2.8) [i.e., $f_{ij}^{(\epsilon)}(\theta) = f_{\bar{i}\bar{j}}^{(\epsilon)}(\theta)$] one obtains

$$\begin{aligned} 2M\hat{R}(\theta)M^{-1} = {} & 2(pp) \otimes (pp) + \sum_{i,\epsilon} \Big(f_{pi}^{(\epsilon)}(\theta)((1+\epsilon)(pp) \otimes (ii) + (1-\epsilon)(pp) \otimes (\overline{ii})) + f_{ip}^{(\epsilon)}(\theta)((1+\epsilon) \\ & \times (ii) \otimes (pp) + (1-\epsilon)(\overline{ii}) \otimes (pp))\Big) \sum_{i,j,\epsilon} \Big(f_{ij}^{(\epsilon)}(\theta)((1+\epsilon)((ii) \otimes (jj) + (ii) \otimes (\overline{jj})) + (1 \\ & - \epsilon)((\overline{ii}) \otimes (jj) + (\overline{ii}) \otimes (\overline{jj})))\Big). \end{aligned} \tag{3.3}$$

For $N=3$ this gives

$$M\hat{R}(\theta)M^{-1} \equiv \hat{R}_d(\theta) = (e^{m_{11}^{(+)}\theta}, e^{m_{12}^{(+)}\theta}, e^{m_{11}^{(+)}\theta}, e^{m_{21}^{(+)}\theta}, 1, e^{m_{21}^{(-)}\theta}, e^{m_{11}^{(-)}\theta}, e^{m_{12}^{(-)}\theta}, e^{m_{11}^{(-)}\theta})_{(\mathrm{diag})}. \tag{3.4}$$

The diagonalizer is

$$\sqrt{2}M = \sqrt{2}M^{-1} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \end{pmatrix}. \tag{3.5}$$

The generalizations of (3.4) and (3.5) for all N are quite evident.

If an $\hat{R}(\theta)$ satisfying the braid equation (2.5) is diagonalized the corresponding $\hat{R}_d(\theta)$, in general, does *not* directly satisfy (2.5). This is evident from all the examples of Ref. 1. The general explanation is simple. Interpolated factors of the type $M_{12}M_{23}^{-1}$ will be lacking in the latter case as compared to the former. If $\hat{R}(\theta)$ is diagonal to *start with* (2.6) reduces to

$$(\hat{R}(\theta))_{aa,bb}(\hat{R}(\theta+\theta'))_{bb,cc}(\hat{R}(\theta'))_{aa,bb} = (\hat{R}(\theta'))_{bb,cc}(\hat{R}(\theta+\theta'))_{aa,bb}(\hat{R}(\theta))_{bb,cc}. \tag{3.6}$$

The braid equation is satisfied if, for each (a,b),

$$(\hat{R}(\theta))_{aa,bb}(\hat{R}(\theta'))_{aa,bb} = (\hat{R}(\theta+\theta'))_{aa,bb} \tag{3.7}$$

i.e., if

$$(\hat{R}(\theta))_{aa,bb} = e^{m_{ab}\theta}, \tag{3.8}$$

where the parameters m_{ab} are mutually *independent*. Now, conversely, if $\hat{R}(\theta)$ is conjugated as

$$\hat{R}'(\theta) = A\hat{R}(\theta)A^{-1} \tag{3.9}$$

in general, $\hat{R}'(\theta)$ will no longer satisfy the braid equation since such products as $A_{12}^{-1}A_{23}$ will depend on the structure of A. The structure of our M is such that for arbitrary odd N,

$$M^{-1}\hat{R}_d(\theta)M$$

continues to satisfy the braid equation *provided*

$$m_{ij}^{(\epsilon)} = m_{\bar{i}\bar{j}}^{(\epsilon)}.$$

Thus it is seen how the $2(p-1)^2$ crucial constraints (2.8), the structure of our nested sequence of projectors and that of our M are all linked.

The relevance of our M to the algebra of the L-operators is pointed out at the end of Sec. IV after displaying the crucial algebraic structure arising there.

IV. $L(\theta)$-OPERATORS AND TRANSFER MATRICES

A general discussion, citing relevant sources, is presented in Appendix B. Here the basic results concerning the $N\times N$ realizations of the N^2 blocks of the transfer matrix $t(\theta)$ and the operator $L^+(\theta)$ are used in the context of braid matrices constructed in Sec. II and Appendix A

In (B22) and (B23) we show in a transparent fashion why, unless (B16) is generalized, say, by implementing central operators in the argument of $\hat{R}(\theta-\theta')$, one cannot obtain an $L^-(\theta)\neq L^+(\theta)$. We do not study such general structures here and hence consider only the above-mentioned fundamental realizations of $L^+(\theta)$ with the standard prescription for coproduct. This will, in any case, provide a subalgebra in an appropriately generalized quasi-Hopf structure. This $L^+(\theta)$ and $t(\theta)$, as shown in (B28), are related (for the fundamental $N\times N$ representations of blocks) as

$$t(\theta) = PL^+(\theta)P, \quad (t_{ab}(\theta))_{cd} = (L_{cd}^+(\theta))_{ab}. \tag{4.1}$$

In studying multistate statistical models corresponding to our $\hat{R}(\theta)$ (see the comments and references in Sec. VII) the algebra of the blocks of $t(\theta)$ is particularly relevant. In our case this algebra is found (see the following) to be very simply related to the corresponding one for $L^+(\theta)$. So one can start either with $L^+(\theta)$ or $t(\theta)$ and then obtain the other easily. We choose to display the remarkable structure that emerges first in terms of $L^+(\theta)$. We start with (B14), i.e.,

$$L^+(\theta) = \hat{R}(\theta)P. \tag{4.2}$$

In terms of the matrices (ab) defined below (2.1), one obtains

$$L_{(pp)}^+ = (pp) \equiv X_{pp},$$

$$e^{-m_{ip}^{(\epsilon)}\theta}(L_{ip}^+(\theta) + \epsilon L_{\bar{i}\bar{p}}^+(\theta)) = (pi) + \epsilon(\bar{p}\bar{i}) \equiv X_{pi}^{(\epsilon)},$$

$$e^{-m_{pi}^{(\epsilon)}\theta}(L_{pi}^+(\theta) + \epsilon L_{\bar{p}\bar{i}}^+(\theta)) = (ip) + \epsilon(\bar{i}\bar{p}) \equiv X_{ip}^{(\epsilon)}, \tag{4.3}$$

$$e^{-m_{ij}^{(\epsilon)}\theta}(L_{ij}^+(\theta) + \epsilon L_{\bar{i}\bar{j}}^+(\theta)) = (ij) + \epsilon(\bar{i}\bar{j}) \equiv X_{ij}^{(\epsilon)},$$

$$e^{-m_{\bar{i}\bar{j}}^{(\epsilon)}\theta}(L_{\bar{i}\bar{j}}^+(\theta) + \epsilon L_{ij}^+(\theta)) = (\bar{j}\bar{i}) + \epsilon(ji) \equiv X_{ji}^{(\epsilon)}.$$

In the last equation (2.8) has been implemented, i.e.,

$$m_{\bar{ij}}^{(\epsilon)} = m_{ij}^{(\epsilon)}.$$

From these one obtains

$$\begin{aligned} 2L_{ij}^{+}(\theta) &= (e^{m_{ij}^{(+)}\theta}X_{ij}^{(+)} + e^{m_{ij}^{(-)}\theta}X_{ij}^{(-)}), \\ 2L_{\bar{ij}}^{+}(\theta) &= (e^{m_{ij}^{(+)}\theta}X_{ij}^{(+)} - e^{m_{ij}^{(-)}\theta}X_{ij}^{(-)}), \end{aligned} \tag{4.4}$$

and so on.

For $N=3$ one obtains (with $\epsilon=\pm 1$ in the matrices on the right)

$$L_{22}^{+}(\theta) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

$$L_{12}^{+}(\theta) + \epsilon L_{\bar{12}}^{+}(\theta) = e^{m_{12}^{(\epsilon)}\theta}\begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & \epsilon \\ 0 & 0 & 0 \end{pmatrix},$$

$$L_{21}^{+}(\theta) + \epsilon L_{\bar{21}}^{+}(\theta) = e^{m_{21}^{(\epsilon)}\theta}\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & \epsilon & 0 \end{pmatrix}, \tag{4.5}$$

$$L_{11}^{+}(\theta) + \epsilon L_{\bar{11}}^{+}(\theta) = e^{m_{11}^{(\epsilon)}\theta}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \epsilon \end{pmatrix},$$

$$L_{\bar{11}}^{+}(\theta) + \epsilon L_{11}^{+}(\theta) = e^{m_{11}^{(\epsilon)}\theta}\begin{pmatrix} 0 & 0 & \epsilon \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

The constant $N\times N$ matrices $X_{ab}^{(\epsilon)}$, where X_{pp} has only one nonzero element, unity, and all the others only two [(1, 1) or $(1,-1)$] specify a quadratic algebra. We give in the following only the *nonzero* bilinear products, all others vanishing. Further results, such as commutators, can be systematically obtained from those to follow:

$$\begin{aligned} &X_{pp}X_{pp} = X_{pp}, \quad X_{pp}X_{pi}^{(\epsilon)} = X_{pi}^{(\epsilon)}, \quad X_{ip}^{\epsilon}X_{pp} = X_{ip}^{\epsilon}, \\ &X_{pi}^{(\epsilon)}X_{ip}^{(\epsilon')} = (1+\epsilon\epsilon')X_{pp}, \quad X_{ip}^{(\epsilon)}X_{pj}^{(\epsilon')} = X_{ij}^{(\epsilon\epsilon')} + \epsilon X_{\bar{ij}}^{(\epsilon\epsilon')}, \\ &X_{pi}^{(\epsilon)}X_{ij}^{(\epsilon')} = X_{pj}^{(\epsilon\epsilon')}, \quad X_{ij}^{(\epsilon)}X_{jp}^{(\epsilon')} = X_{ip}^{(\epsilon\epsilon')}, \\ &X_{pi}^{(\epsilon)}X_{\bar{ij}}^{(\epsilon')} = \epsilon X_{pi}^{(\epsilon\epsilon')}, \quad X_{\bar{ji}}^{(\epsilon)}X_{ip}^{(\epsilon')} = \epsilon\epsilon' X_{jp}^{(\epsilon\epsilon')}, \\ &X_{ij}^{(\epsilon)}X_{jk}^{(\epsilon')} = X_{ik}^{(\epsilon\epsilon')}, \quad X_{ij}^{(\epsilon)}X_{\bar{jk}}^{(\epsilon')} = \epsilon X_{\bar{ik}}^{(\epsilon\epsilon')}, \end{aligned} \tag{4.6}$$

$$X_{ji}^{(\epsilon)} X_{ik}^{(\epsilon')} = X_{jk}^{(\epsilon\epsilon')}, \quad X_{ji}^{(\epsilon)} X_{ik}^{(\bar{\epsilon}')} = \epsilon X_{jk}^{(\epsilon\epsilon')}.$$

(No sum over repeated indices.)

Note that

$$C_1 \equiv \frac{1}{N}\left(X_{pp} + \sum_i X_{ii}^{(+)}\right) = \frac{1}{N} I_{N\times N}. \tag{4.7}$$

Hence $(X_{pp} - C_1)$ and $(X_{ii}^{(+)} - 2C_1)$, along with the others give an algebra of N^2 traceless matrices.

Higher dimensional realizations are given by the coproducts

$$\Delta L = L \dot{\otimes} L. \tag{4.8}$$

Here $\dot{\otimes}$ implies tensor product combined with matrix multiplication. The prescription can be implemented repeatedly in a straightforward fashion. But it leads, in general, to reducible structures. A systematic study of extraction of irreducible components is beyond the scope of this paper. Let us, however, take a closer look at the structure of the algebra (4.6) and the special role of the index p.

The generators without p (i.e., $X_{ij}^{(\epsilon)}$, $X_{\bar{i}\bar{k}}^{(\epsilon)}$) form a closed subalgebra. The generators with a single p (i.e., $X_{pi}^{(\epsilon)}$, $X_{ip}^{(\epsilon)}$) provide a semidirect product structure with the preceding set. But now to close it one has to extend the first set to a direct product structure by including X_{pp}.

From (4.1) and (4.3) it can be shown that $t(\theta)$ and $L^+(\theta)$ are essentially related through the interchange of the roles of $X_{pi}^{(\epsilon)}$ and $X_{ip}^{(\epsilon)}$. Thus for $N=3$ there is an interchange of $b_\pm$ and $c_\pm$. One obtains for this case

$$t(\theta) = \begin{pmatrix} a_+ & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_- \\ 0 & 0 & 0 & c_+ & 0 & c_- & 0 & 0 & 0 \\ 0 & 0 & a_- & 0 & 0 & 0 & a_+ & 0 & 0 \\ 0 & b_+ & 0 & 0 & 0 & 0 & 0 & b_- & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & b_- & 0 & 0 & 0 & 0 & 0 & b_+ & 0 \\ 0 & 0 & a_+ & 0 & 0 & 0 & a_- & 0 & 0 \\ 0 & 0 & 0 & c_- & 0 & c_+ & 0 & 0 & 0 \\ a_- & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_+ \end{pmatrix}, \tag{4.9}$$

$$L^+(\theta) = \begin{pmatrix} a_+ & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_- \\ 0 & 0 & 0 & b_+ & 0 & b_- & 0 & 0 & 0 \\ 0 & 0 & a_- & 0 & 0 & 0 & a_+ & 0 & 0 \\ 0 & c_+ & 0 & 0 & 0 & 0 & 0 & c_- & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & c_- & 0 & 0 & 0 & 0 & 0 & c_+ & 0 \\ 0 & 0 & a_+ & 0 & 0 & 0 & a_- & 0 & 0 \\ 0 & 0 & 0 & b_- & 0 & b_+ & 0 & 0 & 0 \\ a_- & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_+ \end{pmatrix}. \tag{4.10}$$

From these the 3×3 blocks can be read off.

We close this section by pointing out the relevance of our diagonalizer M of Sec. III to the structure of $L^+(\theta)$ [and hence of $t(\theta)$]. If one constructs

$$ML_+(\theta)M^{-1} \tag{4.11}$$

precisely the combinations on the left of the set (4.3) are seen to emerge. Thus our M leads directly to the remarkable structure (4.6).

V. θ EXPANSION

Let us start with the following notations and conventions

(1) The condensed notation $(\alpha,\beta,\ldots)$ of (2.3) implies for each index α either (pp) or a triplet (p,i,ϵ), $(i,j,\epsilon),\ldots$, and so on. We introduce sum over α' where in $\Sigma_{\alpha'}$ the index (pp) is *excluded*. As for the other projectors one may consider alternatively either the basis given by (2.12) or that by (2.14).

(2) We also define

$$H \equiv \sum_{\alpha'} m_{\alpha'} P_{\alpha'} \tag{5.1}$$

when, using (2.3),

$$H^n = \left(\sum_{\alpha'} m_{\alpha'} P_{\alpha'}\right)^n = \sum_{\alpha'} m_{\alpha'}^n P_{\alpha'}. \tag{5.2}$$

Now one can expand as follows (with $n \geqslant 1$):

$$\begin{aligned}\hat{R}(\theta) &= P_{pp} + \sum_{\alpha'} e^{m_{\alpha'}\theta} P_{\alpha'} = P_{pp} + \sum_{\alpha'}\left(1 + \sum_n \frac{(m_{\alpha'}\theta)^n}{n!}\right) P_{\alpha'} \\ &= I + \sum_n \frac{\theta^n}{n!}\left(\sum_{\alpha'} m_{\alpha'}^n P_{\alpha'}\right) = I + \sum_n \frac{\theta^n}{n!} H^n = e^{\theta H}\end{aligned} \tag{5.3}$$

Addition of $P_{pp}=(I-\Sigma_{\alpha'}P_{\alpha'})$ to H corresponds to a change of normalization of $\hat{R}(\theta)$ along with an evident redefinition $m_{\alpha'}\to(m_{\alpha'}-1)$. None of the considerations below are affected by such a redefinition $(\Sigma_{\alpha'}\to\Sigma_{\alpha})$ of H. More generally, say for q-deformed (A,B,C,D)-type algebras, if $\hat{R}(\theta)$ is spectrally resolved on a complete basis of projectors (Sec. II, Ref. 1), setting $l_i(\theta)=lnk_i(\theta)$ and normalizing suitably one obtains, following the steps leading to (5.3),

$$\hat{R}(\theta) = \sum_i k_i(\theta) P_i = \sum_i e^{l_i(\theta)} P_i = e^{(\Sigma_i l_i(\theta) P_i)} \tag{5.4}$$

Here, in general, upon expansion in powers of θ the exponents $l_i(\theta)$ lead to fairly involved structures. In our present case θ is simply a factor in the exponent. Hence the situation is much simpler. Using (5.3) the braid equation becomes (with $H_{12}=H\otimes I$, $H_{23}=I\otimes H$)

$$e^{\theta H_{12}} e^{(\theta+\theta')H_{23}} e^{\theta' H_{12}} = e^{\theta' H_{23}} e^{(\theta+\theta')H_{12}} e^{\theta H_{23}}. \tag{5.5}$$

Setting, with $(n,n',n'')\geqslant 1$,

$$S = \sum_n \frac{\theta^n}{n!} H_{12}^n, \quad S' = \sum_{n'} \frac{\theta'^{n'}}{n'!} H_{12}^{n'}, \quad S'' = \sum_{n''} \frac{(\theta+\theta')^{n''}}{n''!} H_{23}^{n''}. \tag{5.6}$$

The left-hand side of (5.5) is

$$(\text{L.H.S.}) = (I+S)(I+S'')(I+S') = I + (S+S'+S'') + (SS' + SS'' + S''S') + SS''S' \tag{5.7}$$

The (R.H.S.) is obtained from the (L.H.S.) via the following interchanges:

$$(12) \leftrightarrow (23), \quad \theta \leftrightarrow \theta'. \tag{5.8}$$

Now let us compare the coefficients of $\theta^r \theta'^s$ for different pairs (r,s) on both sides of (5.5).

The linear and the quadratic terms on both sides are found to be symmetric under (5.8) and hence cancel. Among the cubic terms only the coefficients of

$$\theta\theta'(\theta + \theta')$$

are found to lead to a nontrivial relation. One obtains, on regrouping terms,

$$[[H_{12},H_{23}],H_{12}] = [[H_{23},H_{12}],H_{23}]. \tag{5.9}$$

Compare this with (2.5). See also the remarks in Sec. VII.

But from (5.2) one obtains

$$H_{12}^2 = \sum_{\alpha'} m_{\alpha'}^2 (P_{\alpha'})_{12}, \quad H_{23}^2 = \sum_{\alpha'} m_{\alpha'}^2 (P_{\alpha'})_{23}. \tag{5.10}$$

Hence in terms of the projectors one obtains

$$\sum_{\alpha',\beta',\gamma'} m_{\alpha'} m_{\beta'} m_{\gamma'} ((P_{\alpha'})_{12}(P_{\beta'})_{23}(P_{\gamma'})_{12} - (P_{\alpha'})_{23}(P_{\beta'})_{12}(P_{\gamma'})_{23})$$

$$= \frac{1}{2} \sum_{\alpha',\beta'} m_{\alpha'} m_{\beta'} (m_{\alpha'} - m_{\beta'}) ((P_{\alpha'})_{12}(P_{\beta'})_{23} - (P_{\alpha'})_{23}(P_{\beta'})_{12}). \tag{5.11}$$

Since there are $\frac{1}{2}(N+3)(N-1)$ independent parameters m_α, comparing coefficients of distinct triplets on each side one obtains a series of results. We will not display them explicitly. In Sec. 3 of Ref. 2 we have studied analogous reductions (from trilinear to bilinear forms) for q-deformed unitary, orthogonal, and symplectic cases. There they were studied in the context of "modified braid equations" (Refs. 3 and 4) presented as a complementary facet of Baxterization (i.e., the introduction of a spectral parameter). Here we *started* from the θ-dependent form (2.5) and implemented our θ expansion leading to the hierarchy starting with (5.9) and (5.11). Without attempting to analyze how the higher order members of the hierarchy can be reduced in order, in successive steps, we just mention the following point concerning (5.11).

In (1.18) of Ref. 2, even for the orthogonal and the symplectic cases the modified braid equation could be expressed in terms of tensored $(\hat{R}(\theta))^{\pm 1}$ by expressing the projectors in their terms using the minimal (cubic) polynomial equation satisfied by $\hat{R}(\theta)$. For the unitary case (with a quadratic polynomial) the task was much more simple. In our present case, despite various particularly simple aspects, the order of the minimal polynomial increases as N^2 instead of remaining fixed as for the cases mentioned before. Hence relations of the type (5.11) are best considered in terms of projectors themselves.

Expansions in terms of the spectral parameter have been considered in the context of Yangian Double and central extensions.[5,6] We intend to study elsewhere analogous aspects generalizing our class of braid matrices.

VI. COMPARISON WITH EVEN DIMENSIONAL CASES

The sequence of projectors presented in Sec. 8 of Ref. 1 is a direct generalization of the basis arising in the spectral resolution of the six-vertex and the eight-vertex braid matrices. From the abundant literature on such models the most directly relevant sources are cited in Secs. 6 and 7 of Ref. 1. These 4×4 projectors are (with $\epsilon = \pm 1$ in the matrices)

$$2P_{1(\epsilon)} = \begin{pmatrix} 1 & 0 & 0 & \epsilon \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \epsilon & 0 & 0 & 1 \end{pmatrix}, \quad 2P_{2(\epsilon)} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & \epsilon & 0 \\ 0 & \epsilon & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{6.1}$$

But even for this simplest member ($N=2$) of the hierarchy the coefficients in

$$\hat{R}(\theta) = \sum_{\epsilon} (f_{1(\epsilon)}(\theta)P_{1(\epsilon)} + f_{2(\epsilon)}(\theta)P_{2(\epsilon)}) \tag{6.2}$$

are not constrained to simple exponentials as for $N=(2p-1)$. For the eight-vertex model (see sources cited in Sec. 7 of Ref. 1) one obtains

$$f_{1(\pm)}(\theta) = \frac{g_{(\pm)}(\theta)}{g_{(\pm)}(-\theta)}, \quad f_{2(\pm)}(\theta) = \frac{h_{(\pm)}(\theta)}{h_{(\pm)}(-\theta)}, \tag{6.3}$$

where with $z=e^{\theta}$, two parameters p and q and

$$(x;a)_{\infty} = \prod_{n \geqslant 0} (1 - xa^n), \tag{6.4}$$

$$g_{\pm}(z) = (\mp p^{1/2}q^{-1}z;p)_{\infty}(\mp p^{1/2}qz^{-1};p)_{\infty}, \tag{6.5}$$

$$h_{\pm}(z) = (q^{1/2}z^{-1/2} \pm q^{-1/2}z^{1/2})(\mp pq^{-1}z;p)_{\infty}(\mp pqz^{-1};p)_{\infty}. \tag{6.6}$$

The question of normalization is discussed in Sec. 7 of Ref. 1. In the trigonometric six-vertex limit one obtains (as in Sec. 6 of Ref. 1)

$$f_{1(\pm)}(\theta) = 1, \quad f_{2(+)}(\theta) = \frac{\cosh \frac{1}{2}(\gamma - \theta)}{\cosh \frac{1}{2}(\gamma + \theta)}, \quad f_{2(-)}(\theta) = \frac{\sinh \frac{1}{2}(\gamma - \theta)}{\sinh \frac{1}{2}(\gamma + \theta)}. \tag{6.7}$$

The reason for such a scope is that [unlike $p=\overline{p}$ for $N=(2p-1)$] for even N there is *no* index $i=\overline{i}$. The successive stages of the construction of solutions in Appendix A make it amply explicit how the presence of a $p(=\overline{p})$, along with the structure of the projectors in our nested sequence, constrains the coefficients to be simply exponentials. The generalization for $N=2n$ $(n>1)$ of the hyperbolic and elliptic solutions displayed above will be explored elsewhere implementing our basis of projectors.

VII. DISCUSSION

In Ref. 1 braid matrices were studied systematically via their spectral resolutions on appropriate bases of projectors. Such a study was already initiated in previous works (Refs. 2 and 7) and led to canonical factorization and diagonalization in Ref. 1. In Sec. 8 of Ref. 1 this approach was taken to its limit. In the other sections almost all *known* braid matrices of interest were studied via spectral resolutions. In Sec. 8 a basis of projectors (called a "nested sequence") with particularly simple, attractive properties was hopefully presented for constructing new classes of braid matrices in all dimensions. In such a basis, satisfying (2.3), one has N^2 matrices, each $N^2 \times N^2$ and with only constant elements [see (2.2) and (6.1)]. They can be considered as the most simple and symmetric generalizations of projectors appearing in the six-vertex and the eight-vertex models. But the central question was not addressed in Ref. 1. Can such a basis of projectors be dressed up with suitable coefficients to provide a braid matrix satisfying (2.5)? While the number of coefficients increases as N^2 the number of trilinear constraints on them corresponding to the products of $N^3 \times N^3$ matrices increases much faster. Hence the question. In this paper we present an affirmative answer and explicit solutions for all *odd N*. The even-N case will be studied elsewhere.

Let us note some basic features of our solutions in the context of the formulation in Ref. 1. The canonically factorizable form of the coefficients[1] give

$$\hat{R}(\theta) = \sum_i \frac{f_i(\theta)}{f_i(-\theta)} P_i. \tag{7.1}$$

This is evidently compatible with (2.7) since

$$e^{m\theta} = (e^{(1/2)m\theta})(e^{-(1/2)m\theta})^{-1}.$$

But in Ref. 1 we systematically extracted (see the relevant discussion in Ref. 1) the standard (non-Baxterized) braid matrices satisfying

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12} = \hat{R}_{23}\hat{R}_{12}\hat{R}_{23} \tag{7.2}$$

as the limits

$$\lim_{\theta\to\pm\infty} \hat{R}(\theta) = (\hat{R})^{\pm 1}. \tag{7.3}$$

For our present class of solutions however each coefficient $e^{m_\alpha\theta}$ either diverges or vanishes in the above-mentioned limits. So rather than the Baxterization of a preexisting (7.2) to (2.5) this class can be considered (see Sec. V) to be an exponentiation of

$$[[H_{12},H_{23}],H_{12}] = [[H_{23},H_{12}],H_{23}] \tag{7.4}$$

to

$$\hat{R}_{12}(\theta)\hat{R}_{23}(\theta+\theta')\hat{R}_{12}(\theta') = \hat{R}_{23}(\theta')\hat{R}_{12}(\theta+\theta')\hat{R}_{23}(\theta) \tag{7.5}$$

since, as shown in Sec. V, the passage

$$H \equiv \sum_{\alpha'} m_{\alpha'} P_{\alpha'} \to \hat{R}(\theta) = e^{\theta H}$$

corresponds to one from (7.4) to (7.5).

One may compare this with the well-known so-called "classical" r-matrix equation obtained by expanding the q-dependent YB matrix $R(\theta)(=P\hat{R}(\theta))$ satisfying

$$R_{12}(\theta)R_{13}(\theta+\theta')R_{23}(\theta') = R_{23}(\theta')R_{13}(\theta+\theta')R_{12}(\theta) \tag{7.6}$$

in powers of $h(=\ln q)$. One obtains for

$$R_q(\theta) = I + 2hr(\theta) + O(h^2),$$

$$[r_{12}(\theta),(r_{13}(\theta+\theta') + r_{23}(\theta'))] + [r_{13}(\theta+\theta'),r_{23}(\theta')] = 0. \tag{7.7}$$

This has only single commutators. In our case there is no q. Expanding in powers of θ we obtain as the first nontrivial relation Eq. (7.4) with double commutators and with the two sides still directly related through the interchange $(12)\leftrightarrow(23)$. In the extensive literature concerning r-matrices one may note in particular a classification of solutions (Ref. 8). Our projectors lead to a solution of (7.4) with $\frac{1}{2}(N+3)(N-1)$ parameters for $N=(2p-1)$. A more general study, starting from (7.4) should be worthwhile.

We repeat a feature noted in Sec. V. Our class of solutions has many particularly simple aspects. But the number of projectors (P_α) and that of the parameters (m_α) increase as N^2 with the dimension. The degree of the minimal polynomial equation satisfied by $\hat{R}(\theta)$ increases with them. This is in sharp contrast with well-known cases corresponding to q-deformed unitary, orthogonal, and symplectic cases. There the structures of the projectors are much less simple. But their number

does not increase with the dimension. As noted below (2.14), the degree of the minimal polynomial can be lowered by allowing some of the free parameters to coincide, giving simpler subcases. But our solution is more general.

For $m^{+}_{ab} > m^{-}_{ab}$ all the nonzero elements of our $\hat{R}(\theta)$ are positive and hence can be consistently interpreted as Boltzmann weights of a multistate statistical model. In Sec. 11 of Ref. 1 the possibility of a class of multistate model was briefly indicated and compared with one proposed in Ref. 9. (See also Sec. 4 of Ref. 10.) In both cases $(2N^2-N)$ elements out of N^4 ones of $\hat{R}(\theta)$ are nonzero. Here we have $(2N^2-1)$ nonzero weights. Moreover the explicit solution of Ref. 9 (and Ref. 10) restricts the number of parameters as in the six-vertex model (Sec. VI). For our present class there is scope for more parameters, their possible number increasing with the dimension. More generally, since the distribution and the magnitudes of the weights are quite different, as compared to the references above, all the essential properties and features will be different (e.g., the partition function, the eigenvalues of the transfer matrix, the detailed content of the structure arising, say, from the Bethe ansatz, the algebra of the L-operators, the associated quantum Hamiltonian, possible knot invariants and also the associated noncommutative spaces). But an adequate exploration of such aspects will be a major enterprise which can only be attempted in future works. Here, we have presented the explicit braid matrix from which all will follow and briefly indicated the possibilities in certain directions (such as the L-operators).

ACKNOWLEDGMENT

It is a pleasure to thank Daniel Arnaudon. Using a program, he verified for the first member of our hierarchy of solutions that the constraints obtained here are not only sufficient but also necessary. This was reassuring.

APPENDIX A: SOLVING THE BRAID EQUATION

In (2.6), namely,

$$(\hat{R}(\theta))_{al,cm}(\hat{R}(\theta+\theta'))_{mn,ef}(\hat{R}(\theta'))_{lb,nd} = (\hat{R}(\theta'))_{cl,em}(\hat{R}(\theta+\theta'))_{ab,ln}(\hat{R}(\theta))_{nd,mf} \tag{A1}$$

corresponding to the site $(ab)\otimes(cd)\otimes(ef)$ one has to implement the content of the ansatz (2.4). From (2.2) and (2.4) one obtains the following nonzero elements of $\hat{R}(\theta)$. The arguments θ are suppressed in (A2) to simplify the notation and the subscripts correspond to the sites $(ab)\otimes(cd)$,

$$\begin{aligned}
\hat{R}_{pp,pp} &= 1,\\
\hat{R}_{pp,ii} &= \tfrac{1}{2}(f^{(+)}_{pi} + f^{(-)}_{pi}) = \hat{R}_{pp,\bar{i}\bar{i}},\\
\hat{R}_{pp,,i\bar{i}} &= \tfrac{1}{2}(f^{(+)}_{pi} - f^{(-)}_{pi}) = \hat{R}_{pp,\bar{i}i},\\
\hat{R}_{ii,pp} &= \tfrac{1}{2}(f^{(+)}_{ip} + f^{(-)}_{ip}) = \hat{R}_{\bar{i}\bar{i},pp},\\
\hat{R}_{i\bar{i},pp} &= \tfrac{1}{2}(f^{(+)}_{ip} - f^{(-)}_{ip}) = \hat{R}_{\bar{i}i,pp},\\
\hat{R}_{ii,jj} &= \tfrac{1}{2}(f^{(+)}_{ij} + f^{(-)}_{ij}) = \hat{R}_{\bar{i}\bar{i},\bar{j}\bar{j}},\\
\hat{R}_{i\bar{i},j\bar{j}} &= \tfrac{1}{2}(f^{(+)}_{ij} - f^{(-)}_{ij}) = \hat{R}_{\bar{i}i,\bar{j}j},
\end{aligned} \tag{A2}$$

$$\hat{R}_{ii,jj\overline{\ }\overline{\ }} = \tfrac{1}{2}(f_{ij}^{(+)} + f_{ij}^{(-)}) = \hat{R}_{\overline{ii},jj},$$

$$\hat{R}_{\overline{ii},jj\overline{\ }\overline{\ }} = \tfrac{1}{2}(f_{ij}^{(+)} - f_{ij}^{(-)}) = \hat{R}_{ii,jj\overline{\ }\overline{\ }}.$$

These are the *only* nonzero elements, the total number being

$$1 + 8(p-1) + 8(p-1)^2 = 2(2p-1)^2 - 1 = 2N^2 - 1$$

Note the following points:

- The elements above all being situated on the diagonal and the antidiagonal there are none of the type $\hat{R}_{ii,jj\overline{\ }}$, $\hat{R}_{ii,jj\overline{\ }}$ and so on.
- In the product $(ab)\otimes(cd)\otimes(ef)$ for a given a, b can only be a or $\overline{a}$ for the coefficient to be nonzero. This holds also for the other pairs.
- Among (a,b,c,d,e,f) the number of with (or without) bar must be even for the coefficient to be nonzero. This is one consequence of (A2). However, in such countings one must keep in mind that $p=\overline{p}$.

The preceding considerations simplify considerably the computations as we analyze systematically the different classes of $(ab)\otimes(cd)\otimes(ef)$ with novanishing coefficients, lowering the multiplicity of (pp) in the triple product above by steps.

Case (1) The case $(pp)\otimes(pp)\otimes(pp)$ is trivial since (A1) reduces to

$$1 = 1.$$

Case (2) Next consider the classes (with $(ab)\neq(pp)$)

$$(1):\ (pp)\otimes(pp)\otimes(ab),$$

$$(2):\ (ab)\otimes(pp)\otimes(pp),$$

$$(3):\ (pp)\otimes(ab)\otimes(pp).$$

From our previous remarks it follows that it is sufficient to consider the possibilities

$$(ab) = (ii), (\overline{ii}).$$

Note also that in (A2) $\hat{R}_{pp,ii} = \hat{R}_{pp,\overline{ii}}$ and so on.

For (1), (A1) is easily seen to reduce to

$$\hat{R}(\theta+\theta'))_{pp,ab} = \hat{R}(\theta'))_{pp,ac}\ \hat{R}(\theta))_{pp,cb}. \tag{A3}$$

Analogous treatments of the subcases (1), (2), (3) lead, respectively (implementing (A2) with $\epsilon=\pm$ and also both possibilities for (ab) mentioned above) to the constraints

$$f_{pi}^{(\epsilon)}(\theta+\theta') = f_{pi}^{(\epsilon)}(\theta) f_{pi}^{(\epsilon)}(\theta'), \tag{A4}$$

$$f_{ip}^{(\epsilon)}(\theta+\theta') = f_{ip}^{(\epsilon)}(\theta) f_{ip}^{(\epsilon)}(\theta'), \tag{A5}$$

$$\begin{aligned} &f_{pi}^{(+)}(\theta) f_{pi}^{(+)}(\theta') f_{ip}^{(+)}(\theta+\theta') + f_{pi}^{(-)}(\theta) f_{pi}^{(-)}(\theta') f_{ip}^{(-)}(\theta+\theta') \\ &\quad = f_{pi}^{(+)}(\theta+\theta') f_{ip}^{(+)}(\theta) f_{ip}^{(+)}(\theta') + f_{pi}^{(-)}(\theta+\theta') f_{ip}^{(-)}(\theta) f_{ip}^{(-)}(\theta'). \end{aligned} \tag{A6}$$

On implementing (A4) and (A5) one reduces (A6) to an identity. Then from the first two one obtains the solutions

$$f_{pi}^{(\epsilon)}(\theta) = e^{m_{pi}^{(\epsilon)}\theta}, \tag{A7}$$

$$f_{ip}^{(\epsilon)}(\theta) = e^{m_{ip}^{(\epsilon)}\theta} \tag{A8}$$

the indeterminates $m_{pi}^{(\epsilon)}$, $m_{ip}^{(\epsilon)}$ being independent parameters.

Continuing to reduce the multiplicity of (pp) and remembering the restrictions implied by (A2) we start by considering successively the cases

$$(4)\text{: } (pp) \otimes (ii) \otimes (jj),$$

$$(5)\text{: } (pp) \otimes (\overline{ii}) \otimes (j\overline{j}),$$

$$(6)\text{: } (pp) \otimes (\overline{ii}) \otimes (jj).$$

The last one survives with nonzero coefficient since $p=\overline{p}$. We present directly the results, the derivations being straightforward.

Defining

$$A_{ab}(\theta) \equiv f_{ab}^{(+)}(\theta) + f_{ab}^{(-)}(\theta), \quad B_{ab}(\theta) \equiv f_{ab}^{(+)}(\theta) - f_{ab}^{(-)}(\theta)$$

one obtains, respectively, from the above-mentioned cases

$$A_{ij}(\theta+\theta') = f_{ij}^{(+)}(\theta) f_{ij}^{(+)}(\theta') + f_{ij}^{(-)}(\theta) f_{ij}^{(-)}(\theta'), \tag{A9}$$

$$A_{pi}(\theta)A_{pi}(\theta')B_{ij}(\theta+\theta') + B_{pi}(\theta)B_{pi}(\theta')B_{ij}(\theta+\theta') = A_{pi}(\theta+\theta')(B_{ij}(\theta)A_{ij}(\theta') + A_{ij}(\theta)B_{ij}(\theta')), \tag{A10}$$

$$A_{pi}(\theta)B_{pi}(\theta')A_{ij}(\theta+\theta') + B_{pi}(\theta)A_{pi}(\theta')A_{ij}(\theta+\theta') = B_{pi}(\theta+\theta')(A_{ij}(\theta')A_{ij}(\theta) + B_{ij}(\theta')B_{ij}(\theta)). \tag{A11}$$

Taking account of (A4) and (A5) [and hence of (A7) and (A8)] and noting that keeping $(\theta+\theta')$ fixed one can vary ψ in

$$\theta = \phi + \psi, \quad \theta' = \phi - \psi,$$

one finds that the last three equations are satisfied if

$$f_{ij}^{(\epsilon)}(\theta) = f_{ij}^{(\epsilon)}(\theta) \tag{A12}$$

and

$$f_{ij}^{(\epsilon)}(\theta) f_{ij}^{(\epsilon)}(\theta') = f_{ij}^{(\epsilon)}(\theta+\theta'). \tag{A13}$$

These are found to be *necessary* and *sufficient*. Hence

$$f_{ij}^{(\epsilon)}(\theta) = f_{ij}^{(\epsilon)}(\theta) = e^{m_{ij}^{(\epsilon)}\theta}. \tag{A14}$$

Permutation of the factors of the cases (4, 5, 6) above [such as $(ii)\otimes(pp)\otimes(jj)$ and so on] can be shown to lead to no supplementary constraints.

Finally one considers the cases

$$(ab) \otimes (cd) \otimes (ef),$$

where no factor is (pp). For each subcase the constraints implied by (A1) along with (A2) are

easily extracted. It is found that they are *all* satisfied by implementing (A12) and (A13). Since the subcases are treated quite similarly, it is sufficient to display two of them. We present again only the final steps. For

$$(ii) \otimes (jj) \otimes (kk)$$

with no barred index, (A13) reduces (A1), in terms of A_{ab} defined above, to

$$\text{L.H.S.} = \tfrac{1}{4} A_{ij}(\theta + \theta') A_{jk}(\theta + \theta') = \text{R.H.S.} \tag{A15}$$

Similarly, for

$$(\overline{ii}) \otimes (jj) \otimes (\overline{kk})$$

one obtains finally

$$\text{L.H.S.} = \tfrac{1}{4} B_{ij}(\theta + \theta') B_{jk}(\theta + \theta') = \text{R.H.S.} \tag{A16}$$

In both cases, apart from the exponential form for each f, (A14) is essential. Thus we have verified the solution announced in (2.7) and (2.8). It is instructive to compute explicitly the case (2.9) where one has only $(i, \overline{i}, p)$ with

$$i = 1, \quad p = 2.$$

One finds that (2.10) is sufficient. Moreover, if one sets

$$m_{11}^{(\epsilon)} \neq m_{11}^{(\epsilon)} \tag{A17}$$

so that $a_{\pm}$ is not repeated as in (2.9), the braid equation is *not* satisfied. This is an example of the necessity of (A14).

As a check, the solution for $N=3$ was also obtained [instead of directly using (A1) and (A2)] by computing the triple tensor products of the projectors in (2.5).

APPENDIX B: *L*-OPERATORS AND TRANSFER MATRICES (FUNDAMENTAL REPRESENTATIONS)

Here we collect together some known results (citing sources to follow) coherently with our notations and conventions and emphasize certain aspects arising in the presence of the spectral parameter θ.

For non-Baxterized braid matrices (without θ) satisfying

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12} = \hat{R}_{23}\hat{R}_{12}\hat{R}_{23} \tag{B1}$$

the FRT equations for the L-operators [Eq. (2.3) of Ref. 11] can be expressed in our notations as

$$\hat{R} L_2^{\pm} L_1^{\pm} = L_2^{\pm} L_1^{\pm} \hat{R}, \tag{B2}$$

$$\hat{R} L_2^{+} L_1^{-} = L_2^{-} L_1^{+} \hat{R}. \tag{B3}$$

Here $\hat{R}$ is a $N^2 \times N^2$ matrix for any N and

$$L_1 = L \otimes I_{N\times N}, \quad L_2 = I_{N\times N} \otimes L.$$

Writing these in terms of components (as will be done in the following for the θ-dependent case) it can be shown that the lowest dimensional realizations of the N^2 blocks $L_{ab}^{\pm}$ (each $N \times N$) can be obtained in our notations, i.e., with

$$\hat{R} = \hat{R}_{ab,cd}(ab) \otimes (cd) \tag{B4}$$

as

$$(L^{+}_{ab})_{cd} = \hat{R}_{ad,cb}, \tag{B5}$$

$$(L^{-}_{ab})_{cd} = \hat{R}^{-1}_{ad,cb}, \tag{B6}$$

or

$$L^{+} = \hat{R}P = (PR)P = R_{21}, \tag{B7}$$

$$L^{-} = \hat{R}^{-1}P = (R^{-1}P)P = R^{-1}. \tag{B8}$$

Apart from differences of notations and conventions these correspond (to cite only one source) to Eq. (4.9) of Ref. 12. In the familiar $L^{\pm}$ of $Sl_q(2)$, implementing 2×2 realizations of $(q^{\pm H}, X_{\pm})$ one obtains (B7) and (B8), which however hold for *any* $\hat{R}$ satisfying (B1).

Now let us introduce θ. Corresponding to (B1) and (B2) one now has, respectively,

$$\hat{R}_{12}(\theta-\theta')\hat{R}_{23}(\theta)\hat{R}_{12}(\theta') = \hat{R}_{23}(\theta')\hat{R}_{12}(\theta)\hat{R}_{23}(\theta-\theta'), \tag{B9}$$

$$\hat{R}(\theta-\theta')L^{\pm}_{2}(\theta)L^{\pm}_{1}(\theta') = L^{\pm}_{2}(\theta')L^{\pm}_{1}(\theta)\hat{R}(\theta-\theta'). \tag{B10}$$

[The corresponding situation for (B3) will be discussed in the following.]

In terms of components one writes

$$(\hat{R}(\theta-\theta'))_{al,cm}(\hat{R}(\theta))_{mn,ef}(\hat{R}(\theta'))_{lb,nd} = (\hat{R}(\theta'))_{cl,em}(\hat{R}(\theta))_{ab,ln}(\hat{R}(\theta-\theta'))_{nd,mf}, \tag{B11}$$

$$(\hat{R}(\theta-\theta'))_{al,cm}(L^{\pm}(\theta)_{mf})_{en}(L^{\pm}(\theta')_{ld})_{nb} = (L^{\pm}(\theta')_{cm})_{el}(L^{\pm}(\theta)_{an})_{lb}(\hat{R}(\theta-\theta'))_{nd,mf}. \tag{B12}$$

One finds that [considering $L^{+}(\theta)$ to start with]

$$(L^{+}(\theta)_{ab})_{cd} = (\hat{R}(\theta))_{ad,cb} \tag{B13}$$

or

$$L^{+}(\theta) = \hat{R}(\theta)P = PR(\theta)P = R_{21}(\theta) \tag{B14}$$

is a solution. This is strictly analogous to (B7). The same solution evidently holds for $L^{-}(\theta)$. But if one wants to avoid the degeneracy

$$L^{-}(\theta) = L^{+}(\theta) \tag{B15}$$

can one obtain a different solution for $L^{-}(\theta)$ analogous to (B8)? We show below in a particularly transparent fashion that there is an obstruction if one directly generalizes (B3) as

$$\hat{R}(\theta-\theta')L^{+}_{2}(\theta)L^{-}_{1}(\theta') = L^{-}_{2}(\theta')L^{+}_{1}(\theta)\hat{R}(\theta-\theta'). \tag{B16}$$

When this is further generalized by introducing a central operator in the argument of $\hat{R}(\theta-\theta')$ on one side (or in a different fashion on each side) and thus distinguish the two arguments, there can be a way out. (Reference 13 is a review article citing numerous sources. Particularly relevant is Sec. 2.1.4.) But let us consider the consequences of (B16) combined with (B13) and (B14) and the basic properties (2.15), i.e.,

$$\hat{R}(-\theta) = \hat{R}^{-1}(\theta), \quad \hat{R}(0) = I. \tag{B17}$$

From (B14) and (B17),

$$L^{+}(0) = P, \quad L^{+}(0)_{ab} = (ba). \tag{B18}$$

[This has no counterpart for (B7).]

Hence setting $\theta=0$ in (B16), using (B16) and (B17) and then writing θ for θ' one obtains

$$\hat{R}^{-1}(\theta)P_2L_1^{-}(\theta) = L_2^{-}(\theta)P_1\hat{R}^{-1}(\theta). \tag{B19}$$

Writing (B19) in terms of components analogously to (B12) one obtains

$$(\hat{R}(-\theta))_{al,cm}(\delta_{mn}\delta_{fe})(L^{-}(\theta)_{ld})_{nb} = (L^{-}(\theta)_{cm})_{el}(\delta_{ab}\delta_{nl})(\hat{R}(-\theta))_{nd,mf} \tag{B20}$$

or

$$(\hat{R}^{-1}(\theta))_{al,cm}(L^{-}(\theta)_{ld})_{mb}\delta_{ef} = \delta_{ab}(L^{-}(\theta)_{cm})_{el}(\hat{R}^{-1}(\theta))_{ld,mf}. \tag{B21}$$

Hence, finally,

$$(\hat{R}^{-1}(\theta)L^{-}(\theta)P) \otimes I = I \otimes (L^{-}(\theta)P\hat{R}^{-1}(\theta)). \tag{B22}$$

For

$$L^{-}(\theta) = L^{+}(\theta) = \hat{R}(\theta)P, \quad L^{-}(\theta)P = \hat{R}(\theta) \tag{B23}$$

(B22) is trivially satisfied (furnishing a convincing check). But a distinct solution for $L^{-}(\theta)$ reducing (say, as $\theta\rightarrow\infty$) to (B8) is no longer available in the general case if (B16) is strictly maintained. One obtains (B8) easily from the symmetry of (B1) under inversion since, unlike for (B16), the orders of (θ,θ') on each side do not enter in that context. But even apart from that (B18) now imposes the constraint (B22), linear in $L^{-}(\theta)$. We do not consider in this paper generalizations of (B16) leading to quasi-Hopf structures for consistent coproducts.

We now consider transfer matrices and note how the lowest dimensional representations can be extracted from those of the L-operators. The transfer matrix $t(\theta)$ has to satisfy

$$\hat{R}(\theta-\theta')(t(\theta)\dot{\otimes}t(\theta')) = (t(\theta')\dot{\otimes}t(\theta))\hat{R}(\theta-\theta'), \tag{B24}$$

where $\dot{\otimes}$, combining tensor and matrix products, leads to

$$(t(\theta)\dot{\otimes}t(\theta')) = (t(\theta)\otimes I)(I\otimes t(\theta')) = t_1(\theta)\,.\,t_2(\theta'). \tag{B25}$$

Write (B24) as

$$(P\hat{R}(\theta-\theta')P)(P(t_1(\theta)P)(Pt_2(\theta')P) \;= (Pt_1(\theta')P)(Pt_2(\theta)P)(P\hat{R}(\theta-\theta')P) \tag{B26}$$

or

$$\hat{R}_{21}(\theta-\theta')t_2(\theta)t_1(\theta') = t_2(\theta')t_1(\theta)\hat{R}_{21}(\theta-\theta'). \tag{B27}$$

Now comparing (B27) with (B10) and (B14) one finds the solution

$$t(\theta) = (P\hat{R}(\theta)P)P = P\hat{R}(\theta) = R(\theta). \tag{B28}$$

In the absence of θ, i.e., for (B1), this corresponds (with some notational differences) to the realization ρ_{+} of Eq. (4.5) of Ref. 12. But corresponding to (B8), unavailable in our context, there is another realization ρ_{-} in Ref. 12. We are concerned only with (B28). Products analogous to (4.8)

of our Sec. IV lead to higher dimensional transfer matrices corresponding to longer chains as successive sites are added.

Aspects of a new class of braid matrices: Roots of unity and hyperelliptic *q* for triangularity, *L*-algebra, link-invariants, noncommutative spaces

A. Chakrabarti[a)]
Centre de Physique Théorique, Ecole Polytechnique, 91128 Palaiseau Cedex, France

(Received 4 February 2005; accepted 28 March 2005; published online 25 May 2005)

Various properties of a class of braid matrices, presented before, are studied considering $N^2\times N^2 (N=3,4,\ldots)$ vector representations for two subclasses. For $q=1$ the matrices are nontrivial. Triangularity ($\hat{R}^2=I$) corresponds to polynomial equations for q, the solutions ranging from roots of unity to hyperelliptic functions. The algebras of L operators are studied. As a crucial feature one obtains $2N$ central, grouplike, homogenous quadratic functions of L_{ij} constrained to equality among themselves by the *RLL* equations. They are studied in detail for $N=3$ and are proportional to I for the fundamental 3×3 representation and hence for all iterated coproducts. The implications are analyzed through a detailed study of the 9×9 representation for $N=3$. The Turaev construction for link invariants is adapted to our class. A skein relation is obtained. Noncommutative spaces associated to our class of $\hat{R}$ are constructed. The transfer matrix map is implemented, with the $N=3$ case as example, for an iterated construction of noncommutative coordinates starting from an $(N-1)$ dimensional commutative base space. Further possibilities, such as multistate statistical models, are indicated. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1924701]

I. INTRODUCTION

A new class of braid matrices was presented in previous papers. The most convenient formulation can be found in Sec. 3 of Ref. 1. This is based on two previous works.[2,3] For ready reference we summarize below the essential features. In succeeding sections, the different properties of such braid matrices will be studied. Remarkable aspects will be encountered. We will *always* be concerned with $N^2\times N^2$ vector representations of braid matrices ($N=3, 4, \ldots$).

For proper appreciation one should start by noting explicitly the links *and* the crucial differences with the standard $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ braid matrices. Our approach is consistently via spectral resolutions, i.e., in terms of projectors.

The Baxterized braid matrices (depending on a spectral parameter θ) satisfy

$$\hat{R}_{12}(\theta)\hat{R}_{23}(\theta+\theta')\hat{R}_{12}(\theta')=\hat{R}_{23}(\theta')\hat{R}_{12}(\theta+\theta')\hat{R}_{23}(\theta), \tag{1.1}$$

where

$$\hat{R}_{12}=\hat{R}\otimes I_N, \quad \hat{R}_{23}=I_N\otimes\hat{R},$$

and I_N is the $N\times N$ identity matrix.

For the standard $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ cases (see sources cited in Sec. 2 of Ref. 1) one has

[a)]Laboratoire Propre du CNRS UPR A.0014. Electronic mail: chakra@cpht.polytechnique.fr

$$\hat{R}(\theta) = P_+ + v(\theta)P_- + w(\theta)P_0, \tag{1.2}$$

where the projectors satisfy

$$P_i P_j = \delta_{ij} P_i, \quad P_+ + P_- + P_0 = I_{N^2}. \tag{1.3}$$

All θ dependence is in $v(\theta)$ and $w(\theta)$. The projectors depend only on q.

The elegant canonical formulation (Sec. 2, Ref. 1) gives the following $v(\theta)$ and $w(\theta)$, where

$$q = \exp h.$$

One has for each case (independently of N)

$$v(\theta) = \frac{\sinh(h-\theta)}{\sinh(h+\theta)} \tag{1.4}$$

and two solutions for $w(\theta)$,

$$\mathrm{SO}_q(2n+1), \quad w(\theta) = \frac{\cosh\left(\left(n+\frac{1}{2}\right)h-\theta\right)}{\cosh\left(\left(n+\frac{1}{2}\right)h+\theta\right)}, \quad \frac{\sinh\left(\left(n-\frac{1}{2}\right)h-\theta\right)}{\sinh\left(\left(n-\frac{1}{2}\right)h+\theta\right)} v(\theta); \tag{1.5}$$

$$\mathrm{SO}_q(2n), \quad w(\theta) = \frac{\cosh(nh-\theta)}{\cosh(nh+\theta)}, \quad \frac{\sinh((n-1)h-\theta)}{\sinh((n-1)h+\theta)} v(\theta); \tag{1.6}$$

$$\mathrm{Sp}_q(2n), \quad w(\theta) = \frac{\sinh((n+1)h-\theta)}{\sinh((n+1)h+\theta)}, \quad \frac{\cosh(nh-\theta)}{\cosh(nh+\theta)} v(\theta). \tag{1.7}$$

In contrast, for our class (Sec. 3, Ref. 1), *conserving* the projectors but changing the coefficients, we have

$$v(\theta) = 1, \quad w(\theta) = \frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}, \tag{1.8}$$

where

$$e^{\eta} + e^{-\eta} = ([N-\epsilon]+\epsilon) = \frac{q^{N-\epsilon} - q^{-N+\epsilon}}{q-q^{-1}} + \epsilon \tag{1.9}$$

and $\epsilon = \pm 1$ when the P_i are those for $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$, respectively. [An overall ambiguity of sign for the right-hand side of (1.9) has been fixed to assure real η for real q. This will be maintained throughout, though complex q will be considered later.]

We adopt the following notations for our $\hat{R}(\theta)$ when (1.8) is implemented:

(a) when P_i are those for SO_q our $\hat{R}(\theta)$ is of type $\hat{o}(N)$,

(b) when P_i are those for Sp_q our $\hat{R}(\theta)$ is of type $\hat{p}(N)$.

This is to signal the provenance of the projectors and also at the same time the fact that the coefficients (1.8) often lead to startlingly different properties as compared to the standard cases [from (1.4) to (1.7)].

For (1.8) we obtain

$$\hat{R}(\theta) = P_+ + P_- + \frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)} P_0 = I + \left(\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)} - 1\right) P_0. \tag{1.10}$$

For completeness we give P_0 explicitly.[4,5] Let the n-tuple $(\rho_1, \rho_2, \ldots, \rho_N)$ be defined as follows for the respective cases indicated:

$$\mathrm{SO}_q(2n+1), \quad \left(n-\tfrac{1}{2}, n-\tfrac{3}{2}, \ldots, \tfrac{1}{2}, 0, -\tfrac{1}{2}, \ldots, -n+\tfrac{1}{2}\right), \tag{1.11}$$

$$\mathrm{SO}_q(2n), \quad (n-1, n-2, \ldots, 1, 0, 0, -1, \ldots, -n+1), \tag{1.12}$$

$$\mathrm{Sp}_q(2n), \quad (n, n-1, \ldots, 1, -1, \ldots, -n). \tag{1.13}$$

Define correspondingly for

$$\mathrm{SO}_q(N), \quad \epsilon = 1 \quad (i = 1, \ldots, N; \quad N = 2n, 2n+1), \tag{1.14}$$

$$\mathrm{Sp}_q(2n), \quad \epsilon = 1 \quad (i \leqslant n), \quad \epsilon = -1 \quad (i > n) \quad (i = 1, \ldots, 2n). \tag{1.15}$$

Set

$$i' = N + 1 - i. \tag{1.16}$$

Then corresponding to (1.11) and (1.12), in notations most suitable for us,

$$([N-1]+1)P_0 = \sum_{i,j=1}^{N} q^{(\rho_{i'} - \rho_j)} (ij) \otimes (i'j') \equiv P_0' \tag{1.17}$$

and corresponding to (1.13) and (1.15),

$$([N+1]-1)P_0 = \sum_{i,j=1}^{N} q^{(\rho_{i'} - \rho_j)} \epsilon_i \epsilon_j (ij) \otimes (i'j') \equiv P_0'. \tag{1.18}$$

Here (ij) denotes the $N \times N$ matrix with 1 at (row i, column j) and zero elsewhere.

These standard P_0 will be *carried over* to our $\hat{o}(2n+1)$, $\hat{o}(2n)$, $\hat{p}(2n)$. We do not indicate the q dependence explicitly [by denoting $\hat{o}_q(2n+1)$, for example] since for $q=1$ our constructions remain nontrivial. Our $\hat{R}$ matrices are *not* q deformations of a "classical" limit for a particular value of q such as 1. This is just one of the remarkable features to be studied below.

For $N=3$, the 9×9 projector P_0 is given by

$$(q+1+q^{-1})P_0 \equiv P_0' = \begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q^{-1} & 0 & q^{-\frac{1}{2}} & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q^{-\frac{1}{2}} & 0 & 1 & 0 & q^{\frac{1}{2}} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & q^{\frac{1}{2}} & 0 & q & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{vmatrix}. \tag{1.19}$$

This is the case that will be studied here extensively as the simplest example. For all N a basic feature is the proportionality of the rows with nonzero elements. This has important consequences. It remains here to display briefly the "pre-Baxterized" situation. Our canonical forms ensure, among various aspects studied in Ref. 1,

$$\hat{R}(-\theta) = (\hat{R}(\theta))^{-1}, \quad \hat{R}(0) = I_{N^2}. \tag{1.20}$$

The limits

$$\theta \to \pm\infty, \quad \hat{R}(\theta) \to \hat{R}^{\pm 1}$$

satisfy the (non-Baxterized, θ-independent) braid equation

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12} = \hat{R}_{23}\hat{R}_{12}\hat{R}_{23}, \tag{1.21}$$

where one can substitute $\hat{R}^{-1}$ for $\hat{R}$.

For the standard cases,

$$(\mathrm{SO}_q(N)), \quad \hat{R}^{\pm 1} = P_+ - q^{\mp 2}P_- + q^{\mp N}P_0, \tag{1.22}$$

$$(\mathrm{Sp}_q(N)), \quad \hat{R}^{\pm 1} = P_+ - q^{\mp 2}P_- - q^{\mp (N+2)}P_0 \tag{1.23}$$

satisfy *cubic* equations. For our cases, with η given by (1.9), one has for all N the *quadratic* equation

$$(e^{\eta}\hat{R}) - (e^{\eta}\hat{R})^{-1} = (e^{\eta} - e^{-\eta})I \tag{1.24}$$

or

$$(\hat{R} - I)(\hat{R} + e^{-2\eta}I) = 0. \tag{1.25}$$

From (1.10), as $\theta \to \pm\infty$,

$$\hat{R}^{\pm 1} = I - (1 + e^{\mp 2\eta})P_0 = I - e^{\mp \eta}(e^{\eta} + e^{-\eta})P_0 = I - e^{\mp \eta}P_0'. \tag{1.26}$$

The last equation follows from (1.9), (1.17), and (1.18). Note that though P_0' is *not* a projector in (1.26), $\hat{R}$ is inverted by inverting the coefficient of P_0' due to the relation

$$P_0'^2 = (e^{\eta} + e^{-\eta})P_0'.$$

Other properties of $\hat{R}$ will be introduced later as they become directly relevant.

II. WHAT q FOR TRIANGULARITY?

A braid matrix for vector representation is called "triangular" if

$$\hat{R}^2 = I. \tag{2.1}$$

For the standard cases $(A, B, C, D)_q$ this is obtained trivially for $q = 1$. This is well known. But for comparison with our case let us briefly indicate how this happens for $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$.

For the projectors in (1.2) and (1.3) denote

$$(P_i)_{q=1} = \mathsf{P}_i \quad (i = +, -, 0) \tag{2.2}$$

and let

$$P = \sum_{i,j} (ij) \otimes (ji), \quad P^2 = I. \tag{2.3}$$

[Acting on the left P permutes specific rows and acting on the right the corresponding columns. This evident feature is mentioned since it plays a crucial role below (2.40).]

From (1.22) and (1.23) substituing the known explicit forms[4,5] of the projectors for $q = 1$, with upper and lower signs for the two cases, respectively,

$$\hat{R} = \mathsf{P}_+ - \mathsf{P}_- \pm \mathsf{P}_0 = \pm (I - 2\mathsf{P}_{\mp}) = P. \tag{2.4}$$

Hence

$$\hat{R}^2 = P^2 = I, \quad R = P\hat{R} = I \tag{2.5}$$

for both cases.

For $GL_q(N)$ one obtains the same result even more simply.

For our class $q=1$ gives a quite nontrivial situation, as emphasized already in Ref. 3. Denoting for all $N=(3,4,\ldots)$,

$$(\eta)_{q=1} = \hat{\eta}$$

from (1.9),

$$e^{\hat{\eta}} + e^{-\hat{\eta}} = N, \quad (1 + e^{\mp 2\hat{\eta}}) = \frac{2N}{N \pm (N^2-4)^{1/2}} \neq 2, \tag{2.6}$$

and from (1.26),

$$(\hat{R}^{\pm 1})_{q=1} = I - (1 + e^{\mp 2\hat{\eta}})\mathsf{P}_0, \quad \hat{R}^2 \neq 1. \tag{2.7}$$

The generalized Hecke condition is now

$$(e^{\hat{\eta}}\hat{R}) - (e^{\hat{\eta}}\hat{R})^{-1} = (e^{\hat{\eta}} - e^{-\hat{\eta}})I. \tag{2.8}$$

This cannot be conjugated to

$$(\hat{R} - I)(\hat{R} + I) = 0. \tag{2.9}$$

For (2.1) we need for our case

$$\eta = 0, \tag{2.10}$$

when

$$\hat{R} = I - 2P_0, \quad \hat{R}^2 = I + 4(P_0^2 - P_0) = I.$$

Hence from (1.9) for $\hat{o}(N)$ and $\hat{p}(N)$, respectively,

$$[N \mp 1] \pm 1 = e^{\eta} + e^{-\eta} = 2 \tag{2.11}$$

or, respectively,

$$\text{(A)} \quad q^{N-2} + q^{N-4} + \cdots + q^{-N+4} + q^{-N+2} = 1 \quad (N = 3,4,\ldots), \tag{2.12}$$

$$\text{(B)} \quad q^{N} + q^{N-2} + \cdots + q^{-N+2} + q^{-N} = 3 \quad (N = 4,6,\ldots). \tag{2.13}$$

The degrees of the polynomials can be lowered by changing variables as follows for the different cases. To start with (A) is divided into two subclasses,

$$(\text{A})_1, \quad N = 2n + 2 \quad (n = 1,2,\ldots).$$

Set

$$p = q^2, \quad Y = p + p^{-1} \tag{2.14}$$

when

$$q = \pm p^{\frac{1}{2}} = \pm \frac{1}{\sqrt{2}}(Y + \sqrt{Y^2 - 4})^{1/2}. \tag{2.15}$$

From (2.12),

$$S_n \equiv (p^n + p^{-n}) + (p^{n-1} + p^{-n+1}) + \cdots + (p^2 + p^{-2}) + (p + p^{-1}) = 0. \tag{2.16}$$

Note that for $(\mathrm{A})_1$ the right-hand side cancels with $p^0 = 1$. Now to express S_n in terms of Y implementing

$$S_{n+1} = YS_n - S_{n-1} + Y - 2 \tag{2.17}$$

one obtains finally

$$\begin{aligned} S_n = Y^n + Y^{n-1} - \binom{n-1}{1} Y^{n-2} - \binom{n-2}{1} Y^{n-3} + \binom{n-2}{2} Y^{n-4} \\ + \binom{n-3}{2} Y^{n-5} + \cdots + (-1)^r \left(\binom{n-r}{r} Y^{n-2r} + \binom{n-r-1}{r} Y^{n-2r-1} \right) + \cdots + c_1 Y + c_0, \end{aligned} \tag{2.18}$$

where

$$\begin{gathered} c_1 = (-1)^{s-1} s \quad (n = 2s, r = s-1), \quad c_1 = (-1)^s (s+1) \quad (n = 2s+1, r = s), \\ c_0 = -2 \quad (n = 2 + 4m, 3 + 4m;\ m = 0, 1, 2, \ldots), \quad c_0 = 0 \quad (n \neq 2 + 4m, 3 + 4m). \end{gathered} \tag{2.19}$$

Explicitly,

$$\begin{gathered} S_1 = Y, \\ S_2 = Y^2 + Y - 2 = (Y-1)(Y+2), \\ S_3 = Y^3 + Y^2 - 2Y - 2 = (Y+1)(Y^2 - 2), \\ S_4 = Y^4 + Y^3 - 3Y^2 - 2Y, \\ S_5 = Y^5 + Y^4 - 4Y^3 - 3Y^2 + 3Y, \\ S_6 = Y^6 + Y^5 - 5Y^4 - 4Y^3 + 6Y^2 + 3Y - 2, \\ S_7 = Y^7 + Y^6 - 6Y^5 - 5Y^4 + 10Y^3 + 6Y^2 - 4Y - 2, \\ S_8 = Y^8 + Y^7 - 7Y^6 - 6Y^5 + 15Y^4 + 10Y^3 - 10Y^2 - 4Y, \\ S_9 = Y^9 + Y^8 - 8Y^7 - 7Y^6 + 21Y^5 + 15Y^4 - 20Y^3 - 10Y^2 + 5Y, \end{gathered} \tag{2.20}$$

and so on.

$$(\mathrm{A})_2: \quad N = 2m + 1 \quad (m = 1, 2, \ldots).$$

Set

$$z = q + q^{-1}, \quad q^{\pm 1} = \tfrac{1}{2}(z \pm \sqrt{z^2 - 4}). \tag{2.21}$$

Retaining only the odd powers in (2.18) and (2.20) and adapting notations one obtains

$$\Sigma_{(2m-1)} = (q^{2m-1} + q^{-2m+1}) + (q^{2m-3} + q^{-2m+3}) + \cdots + (q + q^{-1})$$
$$= z^{2m-1} - \binom{2m-2}{1} z^{2m-3} + \binom{2m-3}{2} z^{2m-5} + \cdots$$
$$+ (-1)^r \binom{2m-r-1}{r} z^{2m-2r-1} + \cdots + (-1)^{m-1} mz. \tag{2.22}$$

Explicitly [noting that in contrast with (2.16) there is now 1 on the right-hand side below]

$$\Sigma_{N-2} = 1 \quad (N = 3,5,\ldots), \tag{2.23}$$

where

$$\Sigma_1 = z,$$

$$\Sigma_3 = z^3 - 2z,$$

$$\Sigma_5 = z^5 - 4z^3 + 3z, \tag{2.24}$$

$$\Sigma_7 = z^7 - 6z^5 + 10z^3 - 4z,$$

$$\Sigma_9 = z^9 - 8z^7 + 21z^5 - 20z^3 + 5z,$$

and so on.

Comparing (2.12) and (2.13) one sees that (B) is obtained from $(\mathrm{A})_1$, with now a nonzero right-hand side, as

$$\text{(B)} \quad S_n = 2 \quad \left(n = \frac{N}{2} = 2,3,\ldots\right). \tag{2.25}$$

Without trying to be exhaustive let us first point out some simple possibilities, particularly when (2.1) is obtained for q a *root of unity*. (See the relevant remarks in the concluding section.)

For $\hat{o}(3)$ one has from (2.23),

$$\Sigma_1 = q + q^{-1} = 1, \quad q = \frac{1}{2} + i\frac{\sqrt{3}}{2} = e^{i(\pi/3)}, \quad q^6 = 1. \tag{2.26}$$

For $\hat{o}(4)$ one has from (2.16) and (2.20),

$$Y = q^2 + q^{-2} = 0, \quad q = e^{i(\pi/4)}, \quad q^8 = 1. \tag{2.27}$$

Moreover, whenever $c_0 = 0$ from (2.19), i.e., for

$$\hat{o}(4), \hat{o}(10), \hat{o}(12), \ldots, \tag{2.28}$$

Y can be factorized and (2.27) is a solution.

For $\hat{o}(6)$ the two roots of

$$S_2 = (Y-1)(Y+2) = 0$$

correspond to

$$q^{12} = 1, \quad q^4 = 1. \tag{2.29}$$

For $\hat{o}(8)$ the roots of S_3 give

$$q^6 = 1, \quad q^{16} = 1. \tag{2.30}$$

For $\hat{o}(10)$ and $\hat{o}(12)$ [apart from (2.27)] one must solve *cubic* and *quartic* equations, respectively. We do not present this standard algebra here. For odd N one has again a cubic in z for $\hat{o}(5)$.

For $\hat{o}(14)$ onwards for $\hat{o}(2n)$ one has polynomials of sixth and higher degrees [already for Y before obtaining q from (2.15)]. Hence one needs *hyperelliptic* functions for Y.

For $\hat{o}(7)$ and $\hat{p}(10)$ one has quintics and *elliptic* solutions, respectively, for $z=(q+q^{-1})$ and $Y=(q^2+q^{-2})$. For higher dimensions one again encounters hyperelliptic functions here.

It is known[6,7] that the general case on a complex field

$$f(x) = a_0 x^n + a_1 x^{n-1} + \cdots + a_n = 0 \tag{2.31}$$

can be solved in terms of theta functions of zero arguments and the period matrix of the hyperelliptic curves

$$F^2 = x(x-1)f(x), \quad F^2 = x(x-1)(x-2)f(x) \tag{2.32}$$

for odd n and even n, respectively.

For quintics[7] one can, alternatively, implement further successive changes of variables (Tschirnhausen transformations) to obtain standard forms (the Bring–Jerrard quintic or the Brioschi quintic leading to the Jacobi sextic) which can be solved directly using elliptic functions. All this is however very complicated.

The coeffficients a_i of (2.31) are very special ones (binomial integers) for our case. What special (hopefully simplifying) features might they induce in the corresponding elliptic and hyperelliptic functions? An answer to this question is beyond the scope of this paper.

Let us contemplate the simplest case, that of $\hat{o}(3)$ with (2.26) giving

$$\hat{R} = I - \begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q^{-1} & 0 & q^{-\frac{1}{2}} & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q^{-\frac{1}{2}} & 0 & 1 & 0 & q^{\frac{1}{2}} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & q^{\frac{1}{2}} & 0 & q & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{vmatrix}, \tag{2.33}$$

where $q=e^{i(\pi/3)}$.

Remarkably this satisfies

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12} = \hat{R}_{23}\hat{R}_{12}\hat{R}_{23}$$

along with

$$\hat{R}^2 = I.$$

A nonexistence theorem: For the standard cases [see (2.3), (2.4), and (2.5)],

$$(\hat{R})_{q=1} = P, \quad \hat{R}^2 = P^2 = I.$$

For the nonstandard Jordanian case (see Refs. 8 and 9 citing basic sources) considering again vector representations

$$\hat{R} = F^{-1}PF, \quad \hat{R}^2 = I, \tag{2.34}$$

where F is obtained through a "contraction".[8,9] Thus the Yang–Baxter matrix

$$R = P\hat{R} = (PF^{-1}P)F = F_{21}^{-1}F \tag{2.35}$$

is a "Drinfeld twist" of unity. This leads to various interesting features[8,9] making triangularity inherent without rendering $\hat{R}$ trivial. Can our constructions above (for $\eta=0$) be expressed as a conjugation of P as in (2.34)? *A priori* such a possibility cannot be discarded.

However, using our diagonalizers (see Appendix B of Ref. 1 for explicit constructions) one can prove quite simply and generally that *no* invertible F exists that can realize (2.34).

It is sufficient to consider $\hat{o}(3)$. Higher dimensions can be treated in a strictly parallel fashion. The essential result for us is that the diagonalizer M gives for (1.26),

$$M\hat{R}^{\pm 1}M^{-1} = (-e^{\mp 2\eta}, 1, 1, 1, 1, 1, 1, 1, 1)_{(\mathrm{diag})}. \tag{2.36}$$

For $\eta=0$, when $\hat{R}^2=I$, one thus obtains

$$M\hat{R}^{\pm 1}M^{-1} = (-1, 1, 1, 1, 1, 1, 1, 1, 1)_{(\mathrm{diag})} \equiv D. \tag{2.37}$$

Now assume that an F exists for our $\hat{R}$ satisfying (2.34). Then

$$MF^{-1}PFM^{-1} = D. \tag{2.38}$$

Defining

$$G = FM^{-1} \tag{2.39}$$

since $D^2=I$,

$$G = PGD. \tag{2.40}$$

The action of P here for the 9×9 case [see (2.3)] leaves the rows 1, 5, and 9 untouched and interchanges the pairs of rows

$$(2,4), (3,7), (6,8).$$

Now consider the action of D after parametrizing G in terms of parameters arbitrary to start with. In rows 1, 5, and 9 the first element is constrained to be zero the others being unrestricted. If row 2 is parametrized as

$$(a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9) \tag{2.41}$$

then row 4 must be

$$(-a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9). \tag{2.42}$$

Hence with arbitrary a_1, r_i denoting the row i,

$$(r_2 - r_4) = (2a_1, 0, 0, 0, 0, 0, 0, 0, 0). \tag{2.43}$$

Similarly, in evident notations,

$$(r_3 - r_5) = (2b_1, 0, 0, 0, 0, 0, 0, 0, 0), \tag{2.44}$$

$$(r_6 - r_8) = (2c_1, 0, 0, 0, 0, 0, 0, 0, 0). \tag{2.45}$$

This evidently implies that the determinant

$$\Delta G = 0. \tag{2.46}$$

Hence G is not invertible. Hence neither is $F=GM$.

This contradicts the assumption that an invertible F exists giving (2.34) for our $\hat{R}$.

III. *L*- ALGEBRA (GROUPLIKE CENTRAL ELEMENTS)

Before writing down the *RLL* equations and the implied constraints we signal the most remarkable features to emerge in Secs. III and IV. We will study them mostly in the context of the simplest case $\hat{o}(3)$, i.e., $N=3$.

(1) In the L^+ subalgebra one obtains $2N$ central, grouplike elements constrained to equality by the *RLL* equations. There are $2N$ corresponding ones for the L^- subalgebra.
(2) In standard cases grouplike elements are usually associated to "quantum determinants." But our above-mentioned sets have no determinantlike structure at all. Each one is the sum of N quadratic terms (no negetive signs).
(3) In the 3×3 fundamental representation of the L operators for $\hat{o}(3)$ these elements are proportional to I_3. Consistently with their grouplike property and centrality they are proportional to I_9 for the 9×9 coproduct representations. The explicit verification of this involves remarkable cancellations. Iterated coproducts of course lead to $I_{3^{2^p}}$ at the pth stage.
(4) In the standard cases, we are used to the coproducts being reducible. Thus the 9×9 coproducts $\Delta L^{\pm}_{ij}$ for $\mathrm{SO}_q(3)$ can be conjugated to block-diagonal forms corresponding to the familiar irreducible components $(9\times 9\rightarrow 5\times 5\oplus 3\times 3\oplus 1\times 1)$ or in terms of angular momenta $(1\times 1\rightarrow 2\oplus 1\oplus 0)$. But here one encounters obstructions in a systematic search for block diagonalizations. This is of course consistent with the central elements announced above being proportional to I. But since such a search reveals special features of the generators this aspect of the 9×9 coproduct mentioned above will be treated explicitly in the next section.

Let us now formulate the *RLL* constraints. The *FRT* equations[4] for the $L^{\pm}$ operators are, in our notations,

$$\hat{R}L^{\pm}_2L^{\pm}_1 = L^{\pm}_2L^{\pm}_1\hat{R}, \tag{3.1}$$

$$\hat{R}L^{+}_2L^{-}_1 = L^{-}_2L^{+}_1\hat{R} \quad (\hat{R}^{-1}L^{-}_2L^{+}_1 = L^{+}_2L^{-}_1\hat{R}^{-1}). \tag{3.2}$$

Here $\hat{R}$ is a $N^2\times N^2$ matrix satisfying (1.21) and $L^{\pm}$ have each N^2 components $L^{\pm}_{ij}(i,j=1,2,\ldots,N)$ arranged in a $N\times N$ matrix form with

$$L^{\pm}_2 = I_N\otimes L^{\pm}, \quad L^{\pm}_1 = L^{\pm}\otimes I_N. \tag{3.3}$$

From (1.26), with P'_0 given by (1.17) and (1.18),

$$\hat{R}^{\pm 1} = I + \lambda_{\pm}P'_0, \quad \lambda_{\pm} = -e^{\mp\eta}. \tag{3.4}$$

Here from (1.9), $\lambda_{\pm}$ are the roots of

$$\lambda + \lambda^{-1} + ([N\mp 1]\pm 1) = 0 \tag{3.5}$$

and, in particular, for $\hat{o}(3)$ of

$$\lambda + \lambda^{-1} + (q + 1 + q^{-1}) = 0. \tag{3.6}$$

This simple change of notation $(\eta\rightarrow\lambda)$ will permit below a compact, unified treatment of L^+ and L^- due to the symmetry,

$$(\lambda_+, L^+, L^-) \rightleftharpoons (\lambda_-, L^-, L^+). \tag{3.7}$$

This is a special feature of our class. We will often suppress below the superscripts and subscripts of L and λ, respectively, when dealing with (3.1) and write L_{ij} and λ.

From (3.1) and (3.4) one has

$$P'_0L^{\epsilon}_2L^{\epsilon}_1 = L^{\epsilon}_2L^{\epsilon}_1P'_0, \quad (\epsilon = \pm). \tag{3.8}$$

In these equations $\lambda_{\pm}$ do *not* appear explicitly. They do however appear for (3.2).

A. L^+ and L^- subalgebras

The grouplike elements belong to these subalgebras since the coproducts are defined separately for each. The *RLL* constraints lead to $(2N^2-1)$ equations for each subalgebra which separate into three subsets of $N(N-1)$, $N(N-1)$, $(2N-1)$, respectively. The total number is easily understood as follows.

The diagonalizer M (see Appendix B, Ref. 1) gives

$$MP_0'M^{-1} \approx (1,0,0,\ldots,0)_{(\mathrm{diag})}. \tag{3.9}$$

Conjugating the factors on both sides of (3.8) by M only the row 1 survives on the left and only the column 1 on the right. These have each N^2 elements and one element in common. Hence the result.

It is convenient to start by deriving some results in a form valid, more generally, for the whole algebra as follows. We consider $\hat{o}(N)$ for definiteness, the modifications for $\hat{p}(N)$ are evident.

Along with (1.17) and (3.3), for $N \geqslant 3$, we write

$$L_2L_1' = \sum_{i,j,k,l} L_{kl}L_{ij}'(ij) \otimes (kl), \tag{3.10}$$

where

$$L_2L_1' = L_2^{\epsilon}L_1^{\epsilon'}, \quad (\epsilon, \epsilon^1) = (+,+),(-,-),(+,-),(-,+).$$

One can show that (with $i' = N-i+1$).

$$P_0'L_2L_1' = \sum_{i,k,l} q^{-\rho_i} S_{lk}^{(1)}(ik) \otimes (i'l), \tag{3.11}$$

$$L_2'L_1P_0' = \sum_{i,k,l} q^{-\rho_i} S_{lk}^{(2)}(ki) \otimes (li'), \tag{3.12}$$

where

$$S_{lk}^{(1)} = \sum_j q^{-\rho_j} L_{j'l}L_{jk}', \tag{3.13}$$

$$S_{lk}^{(2)} = \sum_j q^{-\rho_j} L_{lj'}'L_{kj}. \tag{3.14}$$

We now go back to our subalgebras by setting $\epsilon = \epsilon'$, i.e., $L' = L$.

For $l \neq k'(l+k \neq N+1)$ one obtains from (3.8), due to the structure of P_0,

$$S_{lk}^{(1)} = \sum_j q^{-\rho_j} L_{j'l}L_{jk} = 0. \tag{3.15}$$

and

$$S_{lk}^{(2)} = \sum_i q^{-\rho_i} L_{li'}L_{ki} = 0. \tag{3.16}$$

Each set $(S^{(1)}, S^{(2)})$ corresponds to $N(N-1)$ equations and

$$S^{(1)} \to S^{(2)} \rightleftharpoons L_{ij} \to L_{ji}. \tag{3.17}$$

For

$$l + k = N + 1$$

one obtains (i and j assuming each value *independently* with $i+i'=j+j'=N+1$)

$$q^{-\rho_i} S^{(1)}_{ii'} = q^{-\rho_j} S^{(2)}_{jj'} \quad (i = 1,\ldots,N;\ j = 1,\ldots,N). \tag{3.18}$$

The equality of these $2N$ quadratic expressions give $(2N-1)$ equations. We will denote this set as $\hat{S}_3$. This provides the grouplike central elements. We will study this set in detail for $\hat{o}(3)$. For $N=3$ one obtains from (3.18),

$$q^{-\frac{1}{2}} S^{(1)}_{13} = S^{(1)}_{22} = q^{\frac{1}{2}} S^{(1)}_{31} = q^{-\frac{1}{2}} S^{(2)}_{13} = S^{(2)}_{22} = q^{\frac{1}{2}} S^{(2)}_{31}. \tag{3.19}$$

Or explicitly (with L all L^+ or all L^- below),

$$\begin{aligned}
(\hat{S}_3), \quad & L_{11}L_{33} + q^{-\frac{1}{2}} L_{21}L_{23} + q^{-1} L_{31}L_{13} \\
& = q^{\frac{1}{2}} L_{12}L_{32} + L_{22}L_{22} + q^{-\frac{1}{2}} L_{32}L_{12} \\
& = qL_{13}L_{31} + q^{\frac{1}{2}} L_{23}L_{21} + L_{33}L_{11} = L_{11}L_{33} + q^{-\frac{1}{2}} L_{12}L_{32} \\
& + q^{-1} L_{13}L_{31} = q^{\frac{1}{2}} L_{21}L_{23} + L_{22}L_{22} + q^{-\frac{1}{2}} L_{23}L_{21} \\
& = qL_{31}L_{13} + q^{\frac{1}{2}} L_{32}L_{12} + L_{33}L_{11}.
\end{aligned} \tag{3.20}$$

We denote the sets (3.15) and (3.16) by $\hat{S}_1$ and $\hat{S}_2$, respectively. For $N=3$ the first set is

$$\hat{S}_1,$$

$$\begin{aligned}
& q^{-\frac{1}{2}} L_{31}L_{11} + L_{21}L_{21} + q^{\frac{1}{2}} L_{11}L_{31} = 0, \\
& q^{-\frac{1}{2}} L_{32}L_{11} + L_{22}L_{21} + q^{\frac{1}{2}} L_{12}L_{31} = 0, \\
& q^{-\frac{1}{2}} L_{31}L_{12} + L_{21}L_{22} + q^{\frac{1}{2}} L_{11}L_{32} = 0, \\
& q^{-\frac{1}{2}} L_{33}L_{12} + L_{23}L_{22} + q^{\frac{1}{2}} L_{13}L_{32} = 0, \\
& q^{-\frac{1}{2}} L_{32}L_{13} + L_{22}L_{23} + q^{\frac{1}{2}} L_{12}L_{33} = 0, \\
& q^{-\frac{1}{2}} L_{33}L_{13} + L_{22}L_{23} + q^{\frac{1}{2}} L_{13}L_{33} = 0.
\end{aligned} \tag{3.21}$$

The set $\hat{S}_2$ is obtained immediately from $\hat{S}_1$ via (3.17).

We now show how the sets $(\hat{S}_1, \hat{S}_2, \hat{S}_3)$ imply the two basic properties of the members of $\hat{S}_3$, that they are (1) central and (2) grouplike.

(1) Exploiting systematically the sets $\hat{S}_i$ one can pass through different chains of intermediate steps. One possible sequence is as follows:

$$q^{\frac{1}{2}} L_{11}L_{23}L_{21} = q^{-\frac{1}{2}} L_{12}L_{32}L_{11} - q^{-\frac{1}{2}} L_{13}L_{21}L_{21} + q^{\frac{1}{2}} L_{12}L_{12}L_{31}, \tag{3.22}$$

$$qL_{11}L_{13}L_{31} = q^{-1} L_{13}L_{31}L_{11} - q^{-\frac{1}{2}} L_{13}L_{21}L_{21} - q^{\frac{1}{2}} L_{12}L_{12}L_{31}. \tag{3.23}$$

Summing these with $L_{11}L_{33}L_{11}$ one obtains [using again (3.20) in the last step]

$$L_{11}(qL_{13}L_{31}+q^{\frac{1}{2}}L_{23}L_{21}+L_{33}L_{11}) = (L_{11}L_{33}+q^{-\frac{1}{2}}L_{12}L_{32}+q^{-1}L_{13}L_{31})L_{11}$$
$$= (qL_{13}L_{31}+q^{\frac{1}{2}}L_{23}L_{21}+L_{33}L_{11})L_{11}. \tag{3.24}$$

Thus L_{11}, and similarly each L_{ij} can be shown to commute with the members of $\hat{S}_3$. Hence the latter are central.

(2) The rule for coproducts[4] (with L either L^+ or L^- throughout) is

$$\Delta L_{ij} = \sum_k L_{ik} \otimes L_{kj}. \tag{3.25}$$

Hence

$$\Delta L_{ab}\Delta L_{cd} = \sum_{i,j} L_{ai}L_{cj} \otimes L_{ib}L_{jd}. \tag{3.26}$$

Now let us start with the first member of $\hat{S}_3$ and compute the sum

$$\Sigma = \Delta L_{11}\Delta L_{33} + q^{-\frac{1}{2}}\Delta L_{21}\Delta L_{23} + q^{-1}\Delta L_{31}\Delta L_{13}. \tag{3.27}$$

Collecting terms and systematically implementing $\hat{S}_1$, $\hat{S}_2$ many terms cancel leaving

$$\Sigma = (L_{11}L_{33}+q^{-\frac{1}{2}}L_{21}L_{23}+q^{-1}L_{31}L_{13}) \otimes (L_{11}L_{33}+q^{-\frac{1}{2}}L_{21}L_{23}+q^{-1}L_{31}L_{13}). \tag{3.28}$$

Thus this and similarly the other members of $\hat{S}_3$ are grouplike.

For $\hat{o}(4)$ the eight members of $\hat{S}_3$ satisfy

$$q^{-1}S^{(1)}_{14} = S^{(1)}_{23} = S^{(1)}_{32} = qS^{(1)}_{41} = q^{-1}S^{(2)}_{14} = S^{(2)}_{23} = S^{(2)}_{32} = qS^{(2)}_{41}. \tag{3.29}$$

Their centrality and grouplike property can be established in strict analogy to the $\hat{o}(3)$ case. Moreover they indicate how the generalization for higher N can be carried out. Our presentation here will be limited to $\hat{o}(3)$.

B. Beyond the $L^{\pm}$ subalgebras

We now consider the "mixed" case (3.2). The major feature now is the explicit involvement of $\lambda_{\pm}$ [see (3.4) and (3.5)] in the constraints,

$$(I+\lambda_+P'_0)L^+_2L^-_1 = L^-_2L^+_1(I+\lambda_+P'_0), \tag{3.30}$$

$$(I+\lambda_-P'_0)L^-_2L^+_1 = L^+_2L^-_1(I+\lambda_-P'_0). \tag{3.31}$$

But even when P'_0 does not contribute, namely at

$$(ij)\otimes(kl), \quad (kl)\neq(i'j'),$$

one obtains simple but probing constraints. Retaining only such rows and columns one obtains a "reduced" matrix of $N(N-1)\times N(N-1)$ dimensions. For $N=3$ this corresponds to the suppression of rows and columns (3,5,7) leaving a 6×6 matrix. Using for this reduced case, for all N, the subscript r one extracts from (3.30) and (3.31),

$$(L^{\epsilon}_2L^{\epsilon'}_1)_{(r)} = (L^{\epsilon'}_2L^{\epsilon}_1)_{(r)}. \tag{3.32}$$

For $\epsilon=\epsilon'$ this is trivial, but not now, and one can go further as follows.

Since λ satisfies a quadratic equation one can linearize all polynomials in λ using λ_+ and $\lambda_-=(\lambda_+)^{-1}$. The symmetry of (3.30) and (3.31),

$$(\lambda_+ \to \lambda_-) \rightleftharpoons (L^+ \to L^-) \tag{3.33}$$

indicates the parametrization where the λ dependence is explicitly (and only) in the coefficient as

$$L^{\epsilon}_{ij} = A_{ij} + \lambda_{\epsilon} B_{ij}. \tag{3.34}$$

Now injecting (3.34) in (3.32) one obtains for each element of the *reduced matrix* ($L^{\pm}_{ab}$, $L^{\pm}_{cd}$, and so on)

$$(\lambda_+ - \lambda_-)(A_{ab}B_{cd} - B_{ab}A_{cd}) = 0, \quad (\lambda_+ \neq \lambda_-). \tag{3.35}$$

Thus the λ dependence is simply factored out for this reduced martix. Even when L^+ and L^- are considered in the context of the respective subalgebras they must satisfy (3.35). This will indeed be found to be the case in the explicit realizations of the following section.

We now come to parts where both I and P'_0 contribute and hence λ is directly involved. Instead of $\hat{S}_3$ of (3.20) one now has for $\hat{o}(3)$ nine relations of the type

$$\lambda_+(qL'_{31}L_{13} + q^{\frac{1}{2}}L'_{32}L_{12} + L'_{33}L_{11}) - (qL_{13}L'_{31} + q^{\frac{1}{2}}L_{23}L'_{21} + L_{33}L'_{11}) = q(L_{33}L'_{11} - L'_{33}L_{11}). \tag{3.36}$$

Instead of $\hat{S}_1$, $\hat{S}_2$ one now has equations of the type

$$\lambda_+(q^{-\frac{1}{2}}L_{31}L'_{11} + L'_{21}L_{21} + q^{\frac{1}{2}}L_{11}L'_{31}) = q^{\frac{1}{2}}(L'_{31}L_{11} - L_{31}L'_{11}) = (L'_{21}L_{21} - L_{21}L'_{21}) = q^{-\frac{1}{2}}(L'_{11}L_{31} - L_{11}L'_{31}). \tag{3.37}$$

For $\epsilon=\epsilon'$ one recovers the results for the subalgebras. We have obtained a systematic formulation of the full set of 81 constraints for $\hat{o}(3)$ exploiting certain symmetries. This will not be reproduced here. The generalizations of the results of this section for $N>3$ can be obtained fairly systematically.

C. From $L^{\pm}$ to $L(\theta)$

Since our $\hat{R}$ satisfies a quadratic equation (1.24) all the three FRT equations (3.1) and (3.2) can be condensed into a *single* one by defining in analogy to

$$\hat{R}(\theta) = \frac{e^{\eta+\theta}\hat{R} - e^{-\eta-\theta}\hat{R}^{-1}}{e^{\eta+\theta} - e^{-\eta-\theta}}, \tag{3.38}$$

$$L(\theta) = \frac{e^{\eta+\theta}L^+ - e^{-\eta-\theta}L^-}{e^{\eta+\theta} - e^{-\eta-\theta}}. \tag{3.39}$$

It can be shown that[10,11]

$$\hat{R}(\theta-\theta')L_2(\theta)L_1(\theta') = L_2(\theta')L_1(\theta)\hat{R}(\theta-\theta') \tag{3.40}$$

contains effectively all the three FRT equations. One can write (3.38), i.e., (1.10) as

$$\hat{R}(\theta) = 1 - \frac{\sinh\theta}{\sinh(\eta+\theta)}P'_0. \tag{3.41}$$

IV. FUNDAMENTAL AND COPRODUCT REPRESENTATIONS

Here we will study the $\hat{o}(3)$ fundamental (3×3) and the coproduct (9×9) representations. They illustrate the significance of the remarks (3) and (4) at the beginning of Sec. III. This will be commented upon at the end. Specific symmetries of the matrices obtained will be displayed. They might be helpful in a more systematic study of representations.

The general prescription for the fundamental representations ($N\times N$ blocks for all N) is as follows (see Appendix B of Ref. 11 for a systematic presentation citing basic sources):

$$L(\theta)=\hat{R}(\theta)P, \quad (L(\theta))_{q\to\pm\infty}=L^{\pm}=\hat{R}^{\pm 1}P. \tag{4.1}$$

A Hopf algebra can be defined[4,10] for L using

$$(L^{\pm})^{-1}=PL^{\mp}P=(L^{\mp})_{21}. \tag{4.2}$$

From (3.4), (3.6), and (4.1) one obtains (for the fundamental representations)

$$L=\begin{vmatrix} L_{11} & L_{12} & L_{13}\\ L_{21} & L_{22} & L_{23}\\ L_{31} & L_{32} & L_{33}\end{vmatrix},$$

$$\begin{aligned} L_{11}&=\begin{vmatrix}1&0&0\\0&0&0\\0&0&\lambda\end{vmatrix}, \quad L_{12}=\begin{vmatrix}0&0&0\\1&0&0\\0&q^{-\frac{1}{2}}\lambda&0\end{vmatrix}, \quad L_{13}=\begin{vmatrix}0&0&0\\0&0&0\\(1+q^{-1}\lambda)&0&0\end{vmatrix},\\ L_{21}&=\begin{vmatrix}0&1&0\\0&0&q^{\frac{1}{2}}\lambda\\0&0&0\end{vmatrix}, \quad L_{22}=\begin{vmatrix}0&0&0\\0&(1+\lambda)&0\\0&0&0\end{vmatrix}, \quad L_{23}=\begin{vmatrix}0&0&0\\q^{-\frac{1}{2}}\lambda&0&0\\0&1&0\end{vmatrix},\\ L_{31}&=\begin{vmatrix}0&0&(1+q\lambda)\\0&0&0\\0&0&0\end{vmatrix}, \quad L_{32}=\begin{vmatrix}0&q^{\frac{1}{2}}\lambda&0\\0&0&1\\0&0&0\end{vmatrix}, \quad L_{33}=\begin{vmatrix}\lambda&0&0\\0&0&0\\0&0&1\end{vmatrix}. \end{aligned} \tag{4.3}$$

One sets $\lambda=(\lambda_+,\lambda_-,\lambda(\theta))$ for $L=(L^+,L^-,L(\theta))$, respectively. One obtains $\lambda(\theta)$ directly from (3.39).

Note that (3.34) is evidently satisfied with

$$L_{11}^{\pm}=\begin{vmatrix}1&0&0\\0&0&0\\0&0&0\end{vmatrix}+\lambda_{\pm}\begin{vmatrix}0&0&0\\0&0&0\\0&0&1\end{vmatrix}\equiv A_{11}+\lambda_{\pm}B_{11},$$

and so on.

Now we consider the 9×9 coproducts of (4.3) given by

$$\Delta L_{ij}^{\pm}=\sum_k L_{ik}^{\pm}\otimes L_{kj}^{\pm}.$$

We will not present the easily obtained 9×9 matrices but the symmetries they exhibit for the reason mentioned before. Define the following (r_1,r_2): reflections about the diagonal and the antidiagonal, respectively,

$$f{:}(q\to q^{-1})(r_2r_1), \quad f(A)\equiv fA.$$

Then in terms of 3×3 blocks $A_{ij},\ldots,E_3$ (not exhibited here) one obtains with $(ij=11, 12, 13)$ and $(i'j'=33, 32, 31)$, respectively (and noting that λ is invariant for $q\to q^{-1}$)

$$\Delta L_{ij}=\begin{vmatrix} A_{ij} & 0 & 0 \\ B_{ij} & 0 & 0 \\ C_{ij} & q^{-\frac{1}{2}}\lambda B_{ij} & \lambda A_{ij} \end{vmatrix}, \quad f\Delta L_{ij}=\Delta L_{i'j'}=\begin{vmatrix} \lambda f A_{ij} & q^{\frac{1}{2}}\lambda f B_{ij} & f C_{ij} \\ 0 & 0 & f B_{ij} \\ 0 & 0 & f A_{ij} \end{vmatrix}, \tag{4.4}$$

$$\Delta L_{21}=\begin{vmatrix} 0 & D_1 & 0 \\ q^{-\frac{1}{2}}\lambda D_2 & D_3 & q^{\frac{1}{2}}\lambda D_1 \\ 0 & D_2 & 0 \end{vmatrix}, \quad f\Delta L_{21}=\Delta L_{23}=\begin{vmatrix} 0 & fD_2 & 0 \\ q^{-\frac{1}{2}}\lambda f D_1 & fD_3 & q^{\frac{1}{2}}\lambda f D_2 \\ 0 & fD_1 & 0 \end{vmatrix}, \tag{4.5}$$

$$\Delta L_{22}=f\Delta L_{22}=\begin{vmatrix} 0 & E_1 & 0 \\ q^{-\frac{1}{2}}\lambda f E_1 & E_3 & q^{\frac{1}{2}}\lambda E_1 \\ 0 & fE_1 & 0 \end{vmatrix}. \tag{4.6}$$

Having displayed the symmetries we now study in more detail the three generators ΔL_{ii}. For the standard cases the L_{ii} can be obtained directly in diagonal forms for irreducible representations[4] and through appropriate conjugations for reducible ones. For our 3×3 representation also they are diagonal with their sum proportional to I. But for the 9×9 coproducts above they are not diagonal. They do not commute mutually and hence cannot be diagonalized simultaneously. To better understand the structure encountered let us try to diagonalize the sum $(\Sigma_i \Delta L_{ii})$. Define

$$\mu=(q^{\frac{1}{2}}-q^{-\frac{1}{2}}), \quad z=(q^{\frac{1}{2}}+q^{-\frac{1}{2}}), \quad k=(q+4+q^{-1})^{-\frac{1}{2}}. \tag{4.7}$$

Set

$$\sqrt{2}N=\begin{vmatrix} 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & zk & 0 & 2k & 0 & zk & 0 & 0 \\ 0 & 0 & \sqrt{2}k & 0 & -\sqrt{2}zk & 0 & \sqrt{2}k & 0 & 0 \\ \sqrt{2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{2} \end{vmatrix}. \tag{4.8}$$

This is orthogonal, i.e.,

$$N^{-1}=N^T.$$

One obtains

$$N(\Delta L_{11}+\Delta L_{22}+\Delta L_{33})N^{-1}=\lambda(-y,y,y,-y,3,3,-y,-y,-y)_{(\mathrm{diag})}, \quad y=(q+1+q^{-1}). \tag{4.9}$$

The eigenvalues can be permuted through evident supplementary conjugations.

We have thus diagonalized the sum. Now let us look at the component terms. One has [denoting by (bd) a block diagonal structure]

$$N(\Delta L_{ii})N^{-1} = (\alpha_i, \beta_i, \gamma_i, \delta_i)_{(bd)} \quad (i = 1,2,3), \tag{4.10}$$

where

$$\alpha_1 = \frac{1}{2}\begin{vmatrix} 1 & 1 \\ -1 & -1 \end{vmatrix}, \quad \alpha_3 = \frac{\lambda^2}{2}\begin{vmatrix} 1 & -1 \\ 1 & -1 \end{vmatrix}, \quad \alpha_2 = \frac{1}{2}\begin{vmatrix} \lambda^2+1 & \lambda^2-1 \\ -\lambda^2+1 & -\lambda^2-1 \end{vmatrix}, \tag{4.11}$$

$$\beta_1 = \frac{\lambda^2}{2}\begin{vmatrix} -1 & -1 \\ 1 & 1 \end{vmatrix}, \quad \beta_3 = \frac{1}{2}\begin{vmatrix} -1 & 1 \\ -1 & 1 \end{vmatrix}, \quad \beta_2 = \frac{1}{2}\begin{vmatrix} -\lambda^2-1 & \lambda^2-1 \\ -\lambda^2+1 & \lambda^2+1 \end{vmatrix}, \tag{4.12}$$

$$\delta_1 = \begin{vmatrix} 1 & 0 \\ 0 & \lambda^2 \end{vmatrix}, \quad \delta_3 = \begin{vmatrix} \lambda^2 & 0 \\ 0 & 1 \end{vmatrix}, \quad \delta_2 = \begin{vmatrix} 0 & 0 \\ 0 & 0 \end{vmatrix}, \tag{4.13}$$

$$\gamma_1 = \frac{\lambda}{2}\begin{vmatrix} 3 & \mu k & \sqrt{2}(2+q^{-1})k \\ \mu k & 3z^2k^2 & \sqrt{2}(2+q^{-1})\mu k^2 \\ -\sqrt{2}(2+q)k & -\sqrt{2}(2+q)\mu k^2 & -2(z^2-1)k^2 \end{vmatrix}, \tag{4.14}$$

$$\gamma_3 = \frac{\lambda}{2}\begin{vmatrix} 3 & \mu k & -\sqrt{2}(2+q)k \\ \mu k & 3(1-2k^2) & -\sqrt{2}(2+q)\mu k^2 \\ \sqrt{2}(2+q^{-1})k & \sqrt{2}(2+q^{-1})\mu k^2 & -2(1-3k^2) \end{vmatrix}, \tag{4.15}$$

$$\gamma_2 = \frac{\lambda}{2}\begin{vmatrix} 0 & -2\mu k & \sqrt{2}\mu z k \\ -2\mu k & 12k^2 & \sqrt{2}\mu^2 z k^2 \\ \sqrt{2}\mu z k & \sqrt{2}\mu^2 z k^2 & -2(z^2-1)z^2k^2 \end{vmatrix}. \tag{4.16}$$

Note that

$$\alpha_1^2 = \alpha_3^2 = \beta_1^2 = \beta_3^2 = \begin{vmatrix} 0 & 0 \\ 0 & 0 \end{vmatrix}. \tag{4.17}$$

Such nilpotent matrices are *nondiagonalizable*.

It has been explicitly verified that not only $N(\Delta L_{ij})N^{-1}(i \neq j)$ are not correspondingly block diagonalized but *all* their nonzero elements lie systematically outside the blocks arising for $N(\Delta L_{ii})N^{-1}$. One can examine larger blocks, say, $(6 \otimes 6 \oplus 3 \otimes 3)$ after permuting the γ_i and δ_i blocks. But one finds that the whole 9×9 space is needed for $N(\Delta L_{ij})N^{-1}$. These results will not be displayed here though particularly for $q=1$ they aquire relatively simple forms. One can implement further conjugations and permutations but the essential features persist.

For the 3×3 representations all the members of $\hat{S}_3$ in (3.20) say, for example,

$$L_{11}L_{33} + q^{-\frac{1}{2}}L_{21}L_{23} + q^{-1}L_{31}L_{13} = \lambda I_3. \tag{4.18}$$

Also

$$L_{11} + L_{22} + L_{33} = (1+\lambda)I_3. \tag{4.19}$$

The members of $\hat{S}_3$ being grouplike (4.18) gives for the 9×9 coproducts $\lambda^2 I_9$. This has been verified explicitly. But $(\Sigma_i \Delta L_{ii})$ behaves quite differently as shown above.

The obstructions encountered in reduction of the 9×9 coproducts to smaller dimensional irreducible components [via block diagonalization in a fashion analogous, say, to the case of $SO_q(3)$] is consistent with the central $\hat{S}_3$ operators being proportional to I. But our study of ΔL_{ii}

reveals specific properties of these generators for higher dimensional representations (such as symmetries and nondiagonalizable blocks). This can be helpful in a more systematic study of representations. The symmetries displayed in (4.4), (4.5), and (4.6) stem from those of P_0 and hence should be significant more generally.

V. LINK INVARIANTS (TURAEV CONSTRUCTION)

A. Construction of "enhanced" operators

Given a matrix satisfying the braid equation the Turaev construction[12] of an enhanced Yang–Baxter operator (EY B) leads to explicit construction of invariants (invariant under Markov moves of first and second types) for oriented links. Such an enhanced system[12,13] consists of a $N^2\times N^2$ braid matrix $\hat{R}$, an $N\times N$ matrix f and elements (a,b), all invertible, satisfying the relations

$$\hat{R}^{\pm 1} f\otimes f = f\otimes f\hat{R}^{\pm 1}, \tag{5.1}$$

$$tr_2(\hat{R}^{\pm 1} f\otimes f) = a^{\pm 1} bf, \tag{5.2}$$

where one defines

$$tr_2\left(\sum_{ijkl} c_{ij,kl}(ij)\otimes(kl)\right) = \sum_{ij}\left(\sum_k c_{ij,kk}\right)(ij). \tag{5.3}$$

Let us first obtain (f,a,b) for our class of $\hat{R}$. Our spectral resolution and the properties of the projector P_0 [and hence of P_0' defined in (1.17) and (1.18)] render the constructions particularly transparent.

Define the *diagonal* $N\times N$ matrices f for the cases

(1) $\hat{o}(N),\ N=2n+1,\ n=1,2,\ldots,$

(2) $\hat{o}(N),\ N=2n,\ n=2,3,\ldots,$

(3) $\hat{p}(N),\ N=2n,\ n=2,3,\ldots,$

respectively, as follows:

(1) $$f=(q^{-(2n-1)},q^{-(2n-3)},\ldots,q^{-1},1,q,\ldots,q^{(2n-3)},q^{(2n-1)})(\text{diag}), \tag{5.4}$$

(2) $$f=(q^{-(2n-2)},q^{-(2n-4)},\ldots,q^{-2},1,1,q^2,\ldots,q^{(2n-4)},q^{(2n-2)})(\text{diag}), \tag{5.5}$$

(3) $$f=(q^{-2n},q^{-(2n-2)},\ldots,q^{-2},q^2,\ldots,q^{(2n-2)},q^{2n})(\text{diag}). \tag{5.6}$$

Note the following facts:

(1) The N diagonal elements of f, in each case, are the nonzero diagonal elements of the corresponding P_0' [related to the projector as $P_0=(trP_0')^{-1}P_0'$], the remaining $N(N-1)$ diagonal elements of P_0' being zero. Hence [with upper and lower signs for $\hat{o}(N)$ and $\hat{p}(N)$, respectively],

$$T\equiv trf = trP_0' = [N\mp 1]\pm 1 = -(\lambda_+ + \lambda_-) = e^{-\eta}+e^{\eta}, \tag{5.7}$$

where $e^{\pm\eta}$ are the roots of

$$e^{2\eta} - Te^{\eta} + 1 = 0. \tag{5.8}$$

(2) The $N^2\times N^2$ matrix $f\otimes f$, in each case, has 1 on rows *and* columns,

$$(N, 2N-1, 3N-2, \ldots, (N^2-N+1)).$$

These are precisely ones on which P_0' has nonzero elements. Hence directly (without further computations) we obtain

$$P_0' f \otimes f = f \otimes f P_0'. \tag{5.9}$$

(3) Using (1.17), (1.18), and (5.3) one obtains

$$tr_2(P_0' f \otimes f) = f. \tag{5.10}$$

Now from (5.9) and (5.10) it follows immediately,

$$\hat{R}^{\pm 1} f \otimes f = (I - e^{\mp \eta} P_0') f \otimes f = f \otimes f (I - e^{\mp \eta} P_0') = f \otimes f \hat{R}^{\pm 1} \tag{5.11}$$

and

$$tr_2(\hat{R}^{\pm 1} f \otimes f) = tr_2((I - e^{\mp \eta} P_0') f \otimes f) = (T - e^{\mp \eta}) f = e^{\pm \eta} f. \tag{5.12}$$

Hence

$$tr_2(\hat{R}^{\pm 1} f \otimes f) = a^{\pm 1} b f \quad (a = e^{\eta},\ b = 1). \tag{5.13}$$

Thus we have obtained for our $\hat{R}$, in terms of f introduced above, the enhanced operator

$$(\hat{R}, f, e^{\eta}, 1).$$

Our f is strictly analogous to those of Turaev for $\mathrm{SO}_q(2n+1)$, $\mathrm{SO}_q(2n)$, $\mathrm{Sp}_q(2n)$, respectively. But whereas for the standard cases a (α in the notation of Ref. 12) is also a simple power of q, for us it involves the square root of a Laurent polynomial in q. One obtains with $\delta = (1, 2, 0)$ for $\hat{o}(2n+1)$, $\hat{o}(2n)$, $\hat{p}(2n)$, respectively,

$$T = (q^{-2n+\delta} + q^{-2n-2+\delta} + \cdots + q^{2n+2-\delta} + q^{2n-\delta} + \delta) \tag{5.14}$$

and

$$a^{\pm 1} = e^{\pm \eta} = \tfrac{1}{2}(T \pm \sqrt{T^2 - 4}). \tag{5.15}$$

This is the crucial aspect for our class of $\hat{R}$. For the simplest case $\hat{o}(3)$ one obtains

$$a^{\pm 1} = \tfrac{1}{2}(q + 1 + q^{-1}) \pm \tfrac{1}{2}((q + 3 + q^{-1})(q - 1 + q^{-1}))^{\frac{1}{2}} \tag{5.16}$$

giving for $q = 1$,

$$a^{\pm 1} = \tfrac{3}{2} \pm \tfrac{1}{2}\sqrt{5}. \tag{5.17}$$

In general, for $q = 1$, as for the standard case f reduces to the $N \times N$ unit matrix but as emphasized before our $\hat{R}$ remains nontrivial and

$$a^{\pm 1} = \tfrac{1}{2}N \pm \tfrac{1}{2}\sqrt{N^2 - 4} \quad (N = 3, 4, \ldots). \tag{5.18}$$

The discussion of Sec. II shows that for solutions of (2.10),

$$\eta = 0, \quad a = 1, \tag{5.19}$$

implying a complex root of unity q for $N=3$ but finally elliptic and hyperelliptic ones as N increases. (Overcrossings and undercrossings degenerate for $\hat{R}=\hat{R}^{-1}$.)

[*Comparison of notations:* The present author is often confused by different significances of the same symbol (and vice versa) encountered elsewhere. The following points might be helpful in our context.

Turaev's R (Ref. 12) satisfying the braid equation (his Eq. 1),

$$R_1R_2R_1 = R_2R_1R_2,$$

is our $\hat{R}$. Our R is $P\hat{R}$, where

$$P(ij)\otimes(kl) = (kj)\otimes(il), \quad (ij)\otimes(kl)P = (il)\otimes(kj), \quad P(ij)\otimes(kl)P = (kl)\otimes(ij),$$

and R satisfies the Yang–Baxter equation,

$$R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}.$$

It must also be clearly noted that if σ (or τ) is defined as

$$\sigma(ij)\otimes(kl) = (kl)\otimes(ij) = P(ij)\otimes(kl)P,$$

then

$$\sigma R = PRP = R_{21} = \hat{R}P$$

does not satisfy the braid equation above (satisfied by $\hat{R}$). Moreover, since

$$P(f\otimes f)P = f\otimes f, \quad P^2 = I,$$

the condition (5.1) implies also (for the YB matrix R)

$$R^{\pm1}f\otimes f = f\otimes fR^{\pm1}.$$

This form is presented in Sec. 15.2.2 of Ref. 13. But $\hat{R}$ cannot be replaced by R in (5.2). The symbol I denotes σR in Sec. 15.2.2 of Ref. 13 and $-\sigma R$ at the end of Sec. 15.2.5.]

B. Link invariants and skein relation

We follow the presentation of Ref. 12 and Sec. 15 of Ref. 13 with some changes of notations. Let $\rho(\beta)$ be the representation of the braid β associated to $\hat{R}$ and let $\alpha(\beta)$ be the "augmentation homomorphism" changing by ±1 corresponding to the actions of $T^{\pm1}$, the generators of the braid group.

Define for our case (with $b=1$).

$$\mathsf{P}(\beta) = a^{-\alpha(\beta)}tr(\rho_m(\beta)\cdot f^{\otimes m}), \tag{5.20}$$

ρ_m being the endomorphism of $V^{\otimes m}$ associated to $\hat{R}$.

Using appropriately the properties (5.1) and (5.2) of f such a $\mathsf{P}(\beta)$ can be shown to be Markov invariant and provide an invariant of oriented links. Markov moves are defined, for example, in Sec. 15.1 of Ref. 13 and the proof of invariance of $\mathsf{P}(\beta)$ is given in Sec. 15.2 following Ref. 12.

For an "unknot" (no crossing) one has

$$\mathsf{P}(\circ) = tr\, f = T. \tag{5.21}$$

Using standard notations $(\overline{L_+},\overline{L_-},\overline{L_0})$ corresponding to one point of the projection of a braid differing by an overcrossing, undercrossing, and no crossing, respectively, one obtains in our case [following the steps below Eq. (6), Sec. 15.2 of Ref. 13]

$$x\mathsf{P}(\overline{L_+}) + y\mathsf{P}(\overline{L_-}) + z\mathsf{P}(\overline{L_0}) = a^{-\alpha(\beta)}tr((x\hat{R}^{-1} + y\hat{R} + zI) \otimes id^{\otimes 2} \otimes id^{\otimes(m-2)} \cdot \rho_m(\beta) \cdot f^{\otimes m}). \tag{5.22}$$

Now for our case,

$$e^{\eta}\hat{R} - e^{-\eta}\hat{R}^{-1} = (e^{\eta} - e^{-\eta})I. \tag{5.23}$$

Hence setting

$$x = -e^{-\eta}, \quad y = e^{\eta}, \quad z = -(e^{\eta} - e^{-\eta}) \tag{5.24}$$

one obtains the skein relation

$$e^{-\eta}\mathsf{P}(\overline{L_+}) - e^{\eta}\mathsf{P}(\overline{L_-}) = (e^{-\eta} - e^{\eta})\mathsf{P}(\overline{L_0}). \tag{5.25}$$

One can now exploit this relation along with (5.21) in well-known fashions to construct invariant polynomials. (See also Ref. 14 where a large number of sources are cited.) We will not present a full study of this aspect. Our aim has been to indicate the roles played by our coefficients $e^{\pm\eta}$ (an ingredient of our $\hat{R}$) in this context. This has been achieved in our brief treatment.

VI. FROM $\hat{R}$ TO NONCOMMUTATIVE SPACES

A. Coordinates, differentials, and mobile frames

We implement well-known prescriptions[15–17] in the context of our class of $\hat{R}$. For the $N^2 \times N^2$ matrix $\hat{R}$ satisfying

$$(\hat{R} - I)(\hat{R} + e^{-2\eta}I) = 0, \tag{6.1}$$

where for $\hat{o}(N)$, $\hat{p}(N)$, respectively,

$$e^{\eta} + e^{-\eta} = [N \mp 1] \pm 1,$$

let the coordinates $(x_1, x_2, \ldots, x_N)$ and the differentials $(\xi_1, \xi_2, \ldots, \xi_N)$ be ordered in N columns x and ξ, respectively.

The prescriptions for the associated covariant differential geometries satisfying the Leibnitz rule[15–17] are

$$(1) \qquad (\hat{R} - I)x \otimes x = 0, \quad x \otimes \xi = e^{2\eta}\hat{R}\xi \otimes x, \quad (\hat{R} + e^{-2\eta}I)\xi \otimes \xi = 0, \tag{6.2}$$

$$(2) \qquad (\hat{R} + e^{-2\eta}I)x \otimes x = 0, \quad x \otimes \xi = -\hat{R}\xi \otimes x, \quad (\hat{R} - I)\xi \otimes \xi = 0. \tag{6.3}$$

We concentrate below on (6.2). The set (6.3) can be treated analogously, essentially interchanging the roles of x and ξ [except for the (x, ξ) commutators].

From our previous definitions,

$$\hat{R} = I - e^{\mp\eta}P_0'.$$

Hence from (6.2),

$$P_0'x \otimes x = 0. \tag{6.4}$$

The set of constraints (6.4) reduces to a *single* one due to the proportionality of the nonzero rows of P_0'. This one is easy to write down for all N from (1.17) and (1.18). One obtains for

$$\hat{o}(3), \quad q^{-\frac{1}{2}}x_1x_3 + x_2x_2 + q^{\frac{1}{2}}x_3x_1 = 0, \tag{6.5}$$

$$\hat{o}(4), \quad q^{-1}x_1x_4 + x_2x_3 + x_3x_2 + qx_4x_1 = 0, \tag{6.6}$$

$$\hat{p}(4), \quad q^{-2}x_1x_4 + q^{-1}x_2x_3 - qx_3x_2 - q^2x_4x_1 = 0, \tag{6.7}$$

and so on. Consider now the constraints involving ξ with the $\hat{o}(3)$ case as example.

Define

$$\Pi = (q^{-\frac{1}{2}}\xi_1x_3 + \xi_2x_2 + q^{\frac{1}{2}}\xi_3x_1), \tag{6.8}$$

$$\Pi' = (q^{-\frac{1}{2}}\xi_1\xi_3 + \xi_2\xi_2 + q^{\frac{1}{2}}\xi_3\xi_1). \tag{6.9}$$

Now from (6.2) for $N=3$ with

$$e^{\eta} + e^{-\eta} = (q + 1 + q^{-1}),$$

one has

$$x_i\xi_j = e^{2\eta}\xi_ix_j \quad (i + j \neq 4), \tag{6.10}$$

$$x_1\xi_3 = e^{2\eta}\xi_1x_3 - e^{\eta}q^{-\frac{1}{2}}\Pi, \quad x_2\xi_2 = e^{2\eta}\xi_2x_2 - e^{\eta}\Pi, \quad x_3\xi_1 = e^{2\eta}\xi_3x_1 - e^{\eta}q^{\frac{1}{2}}\Pi, \tag{6.11}$$

$$\xi_i\xi_j = 0 \quad (i + j \neq 4), \tag{6.12}$$

$$q^{-\frac{1}{2}}\xi_1\xi_3 = y^{-1}q^{-1}\Pi', \quad \xi_2\xi_2 = y^{-1}\Pi', \quad q^{\frac{1}{2}}\xi_3\xi_1 = y^{-1}q\Pi', \quad y = (q + 1 + q^{-1}). \tag{6.13}$$

Note the consistency of the sum of the equations (6.13). For $N>3$,

$$\xi_i\xi_j = 0 \quad [i + j \neq (N + 1)]. \tag{6.14}$$

The coefficients of (Π, Π') are now obtained from (1.17) and (1.18), they are proportional to the nonzero elements in a row of P_0'. Also η will now be as below (6.1).

We now briefly consider the construction of mobile frames[17,18] (or "stehbeins" in the terminology of the authors cited). Let

$$\theta = \sum_i \theta_i\xi_i, \tag{6.15}$$

such that

$$[\theta, x_i] = 0. \tag{6.16}$$

From (6.2) and (6.16), remembering that in our conventions

$$\hat{R} = \hat{R}_{ij,kl}(ij) \otimes (kl)$$

and indicating all summations explicitly (and using the $L^{\pm}$ of Secs. III and IV),

$$\left(\sum_k \theta_k\xi_k\right)x_i = e^{-2\eta}\sum_{k,a,b} \theta_k\hat{R}^{-1}_{ka,ib}x_a\xi_b = e^{-2\eta}\sum_{k,a,b} \theta_k(\hat{R}^{-1}P)_{kb,ia}x_a\xi_b$$
$$= e^{-2\eta}\sum_{k,a,b} (\theta_kL^-_{kb,ia}x_a)\xi_b = x_i\left(\sum_b \theta_b\xi_b\right). \tag{6.17}$$

Hence

$$x_i\theta_j = e^{-2\eta}\sum_{k,l}\theta_k L^{-}_{kj,il}x_l. \tag{6.18}$$

Thus one obtains the commutators of (x_i,θ_j). For $N=3$, setting

$$\theta_1 x_1 + \theta_2 x_2 + \theta_3 x_1 = \tau, \tag{6.19}$$

$$x_i\theta_i = e^{-2\eta}\tau - e^{-\eta}\theta_{i'}x_{i'} \quad (i=1,2,3),$$

$$x_1\theta_2 = -e^{-\eta}q^{\frac{1}{2}}\theta_3 x_2, \quad x_1\theta_3 = -e^{-\eta}\theta_3 x_1,$$

$$x_2\theta_1 = -e^{-\eta}q^{\frac{1}{2}}\theta_2 x_3, \quad x_2\theta_3 = -e^{-\eta}q^{-\frac{1}{2}}\theta_2 x_1,$$

$$x_3\theta_1 = -e^{-\eta}\theta_1 x_3, \quad x_3\theta_2 = -e^{-\eta}q^{-\frac{1}{2}}\theta_1 x_2. \tag{6.20}$$

Generalizations for $N>3$ are obtained analogously.

In Ref. 17 different solutions of θ [three solutions for $\mathrm{So}_q(3)$] are presented. They involve a dilatation operator and inverses of coordinates, a radius r being defined. We consider no extensions of our algebras or such solutions for θ in the present work.

B. Towers of noncommutative $(x_1,\ldots,x_N)$ on a commutative $(N-1)$-base space

In Eq. (1.3) of Ref. 4 it is pointed out that the mapping, implementing the transfer matrix t,

$$\delta(x_i) = \sum_k t_{ik}\otimes x_k \equiv (tx)_i \tag{6.21}$$

provides an iterative sequence of solutions. Since

$$\hat{R}(t\otimes I)(I\otimes t) = (t\otimes I)(I\otimes t)\hat{R} \tag{6.22}$$

for any polynomial of $f(\hat{R})$, if

$$f(\hat{R})(x\otimes x) = 0,$$

$$(t\otimes I)(I\otimes t)f(\hat{R})(x\otimes x) = f(\hat{R})(t\otimes I)(I\otimes t)(x\otimes x), \quad = f(\hat{R})(tx)\otimes(tx) = 0. \tag{6.23}$$

This is the mapping (6.21). It can evidently be iterated as

$$\delta((t^n x)\otimes(t^n x)) = (t^{n+1}x)\otimes(t^{n+1}x). \tag{6.24}$$

We denote this as

$$x^{(n)} \to x^{(n+1)}.$$

We note here a remarkable possibility, starting again with $\hat{o}(3)$ as an example.

Choose as the starting point a *commutative* solution of (6.5) as follows. With parameters $(a,b)\geqslant 0$ the following surface satisfies (6.5):

$$\begin{aligned} &x_1^{(0)} = a, \quad x_3^{(0)} = -b, \quad x_2^{(0)} = \pm\left((q^{\frac{1}{2}}+q^{-\frac{1}{2}})ab\right)^{\frac{1}{2}}, \\ &x_1^{(0)} = -a, \quad x_3^{(0)} = b, \quad x_2^{(0)} = \pm\left((q^{\frac{1}{2}}+q^{-\frac{1}{2}})ab\right)^{\frac{1}{2}}. \end{aligned} \tag{6.25}$$

As (a,b) varies through real, non-negative values one obtains a double cone whose projections on the (1,3) plane covers the second and the fourth quadrants. The vertices meet at the origin. The projections of the contours $x_2=$const on the (1,3) plane are parabolas. The origin is invariant under δ.

Now we implement δ as in (6.21) to obtain

$$x_i^{(1)} = (tx^{(0)})_i. \tag{6.26}$$

Consider for simplicity the 3×3 fundamental t-matrices. These are given by [compare (4.1) and see the reference cited above it]

$$t = t^+ = P\hat{R} = R = P(\hat{R}P)P = L_{21}^+ \tag{6.27}$$

and

$$t = t^- = P\hat{R}^{-1} = P(R^{-1}P) = (\hat{R}^{-1})_{21} = L_{21}^-. \tag{6.28}$$

We treat below $t^\pm$ together by setting correspondingly (for $N=3$)

$$\lambda = \lambda_\pm = \lambda^{\pm 1}, \quad (\lambda + \lambda^{-1} + y = 0). \tag{6.29}$$

For the fundamental representations of t our map gives

$$x_1^{(1)} = \begin{vmatrix} x_1^{(0)} & 0 & 0 \\ x_2^{(0)} & 0 & 0 \\ (1+q\lambda)x_3^{(0)} & q^{\frac{1}{2}}\lambda x_2^{(0)} & \lambda x_1^{(0)} \end{vmatrix}, \tag{6.30}$$

$$x_2^{(1)} = \begin{vmatrix} 0 & x_1^{(0)} & 0 \\ q^{\frac{1}{2}}\lambda x_3^{(0)} & (1+\lambda)x_2^{(0)} & q^{-\frac{1}{2}}\lambda x_1^{(0)} \\ 0 & x_3^{(0)} & 0 \end{vmatrix}, \tag{6.31}$$

$$x_3^{(1)} = \begin{vmatrix} \lambda x_3^{(0)} & q^{-\frac{1}{2}}\lambda x_2^{(0)} & (1+q^{-1}\lambda)x_1^{(0)} \\ 0 & 0 & x_2^{(0)} \\ 0 & 0 & x_3^{(0)} \end{vmatrix}. \tag{6.32}$$

The symmetries signalled above (4.4) reappear. Iteration now may proceed as

$$(x_i^{(0)}, x_i^{(1)}) \to (x_i^{(n)}, x_i^{(n+1)}).$$

At each stage, given *only* (6.5) for $x_i^{(n)}$ [and (6.29) for λ], $x_i^{(n+1)}$ also satisfies (6.5) and hence

$$(\hat{R} - I)x^{(n+1)} \otimes x^{(n+1)} = 0. \tag{6.33}$$

This has been verified explicitly. Moreover at each stage one can implement any chosen representation of t (say, the 9×9 rather than the 3×3). Thus one may obtain varied sequences in the iterations. The illustration above is sufficient for our purpose. Let us compare this construction with a parallel possibility for $SO_q(3)$. We refer to the results of Example 4.1.22 of Ref. 17. But for easier comparison with our results above we change the basis from the circular components to our type as

$$(x_-, y, x_+) \to (x_1, x_2, x_3).$$

Now (4.1.61) of Ref. 17 is

$$x_1x_2 = qx_2x_1, \quad x_3x_2 = q^{-1}x_2x_3, \quad (x_3x_1 - x_1x_3) = (q^{\frac{1}{2}} - q^{-\frac{1}{2}})x_2^2. \tag{6.34}$$

There are now three constraints as compared to a single one for (6.5). But one can choose the *commutative* (1, 3) plane (as compared to the double cone before) as the starting point by setting

$$x_2^{(0)} = 0, \quad x_1^{(0)}x_3^{(0)} = x_3^{(0)}x_1^{(0)}. \tag{6.35}$$

This satisfies all three constraints (6.34). Using the 3×3 t-matrix blocks for $SO_q(3)$ [and setting $\kappa=(q-q^{-1})$] one obtains

$$x_1^{(n+1)} = \begin{vmatrix} qx_1^{(n)} & 0 & 0 \\ 0 & x_1^{(n)} & 0 \\ 0 & 0 & q^{-1}x_1^{(n)} \end{vmatrix}, \tag{6.36}$$

$$x_2^{(n+1)} = \begin{vmatrix} x_2^{(n)} & \kappa x_1^n & 0 \\ 0 & x_2^{(n)} & q^{-\frac{1}{2}}\kappa x_1^n \\ 0 & 0 & x_2^{(n)} \end{vmatrix}, \tag{6.37}$$

$$x_3^{(n+1)} = \begin{vmatrix} q^{-1}x_3^{(n)} & q^{-\frac{1}{2}}\kappa x_2^n & \kappa(1-q^{-1})x_1^n \\ 0 & x_3^{(n)} & \kappa x_2^n \\ 0 & 0 & qx_3^{(n)} \end{vmatrix}. \tag{6.38}$$

Starting the iteration from (6.35) at each step x_i^n satisfies (6.34). As before one can use more general realizations of the t-matrix at any step. One may note that for this case

$$(q=1) \to x_i^{(n+1)} = I_3 \otimes x_i^{(n)}.$$

This is consistent with $\hat{R}=I$ for $q=1$ in the standard cases. But, as emphasized before, there is no such triviality for our class for any value of q (including 1). Note also that for our class the matrices $x_i^{(1)}$ and the iterated ones are noninvertible. This is a general feature for our class.

In the examples above one *starts* with a classical surface and iterating as above makes it more and more "fuzzy" in this specific sense. This should be compared with the "fuzzy sphere" of Ref. 17 (Sec. 7.2) where one starts fuzzy and a smooth surface is approached as a limit. One moves in opposite senses in the two formalisms.

So far we have studied the coordinate space (x_i) only. It must be noted carefully that one cannot obtain a consistent nontrivial set $\xi_i^{(0)}$ corresponding to $x_i^{(0)}$. This is evident from (6.10) to (6.13) where q is not restricted. So the whole covariant prescription can be introduced at a noncommutative stage only. This however does not alter the fact that one can build sequences of noncommutative (x_i) starting from a smooth surface.

For $N>3$, with (6.6) and (6.7) as simplest examples, one has evidently more flexibility in choosing $\xi_i^{(0)}$. Without going into details we indicate below for $\hat{o}(4)$ the stuctures (valid more generally) induced by our type of iterations,

$$\hat{o}(4), \quad \lambda + \lambda^{-1} + (q^2 + 2 + q^{-2}) = 0,$$

$$x_1^{(n+1)} = \begin{vmatrix} x_1^{(n)} & 0 & 0 & 0 \\ x_2^{(n)} & 0 & 0 & 0 \\ x_3^{(n)} & 0 & 0 & 0 \\ (1+\lambda)x_4^{(n)} & q^{-1}\lambda x_3^{(n)} & q^{-1}\lambda x_2^{(n)} & q^{-2}\lambda x_1^{(n)} \end{vmatrix}, \tag{6.39}$$

$$x_2^{(n+1)} = \begin{vmatrix} 0 & x_1^{(n)} & 0 & 0 \\ 0 & x_2^{(n)} & 0 & 0 \\ q\lambda x_4^{(n)} & (1+\lambda)x_3^{(n)} & \lambda x_2^{(n)} & q^{-1}\lambda x_1^{(n)} \\ 0 & x_4^{(n)} & 0 & 0 \end{vmatrix}, \tag{6.40}$$

$$x_3^{(n+1)} = \begin{vmatrix} 0 & 0 & x_1^{(n)} & 0 \\ q\lambda x_4^{(n)} & \lambda x_3^{(n)} & (1+\lambda)x_2^{(n)} & q^{-1}\lambda x_1^{(n)} \\ 0 & 0 & x_3^{(n)} & 0 \\ 0 & 0 & x_4^{(n)} & 0 \end{vmatrix}, \tag{6.41}$$

$$x_4^{(n+1)} = \begin{vmatrix} q^2\lambda x_4^{(n)} & q\lambda x_3^{(n)} & q\lambda x_2^{(n)} & (1+\lambda)x_1^{(n)} \\ 0 & 0 & 0 & x_2^{(n)} \\ 0 & 0 & 0 & x_3^{(n)} \\ 0 & 0 & 0 & x_4^{(n)} \end{vmatrix}. \tag{6.42}$$

The analogous structures for $\hat{p}(4)$ have also been obtained. The structures of the matrices are quite similar to those for $\hat{o}(4)$. The q dependence of the coefficients show typical differences along with sign changes. They will not be reproduced here. In each case, for all N, there is in each matrix one row and one column with nonzero elements. How they shift with i of $x_i^{(n)}$ should already be fairly apparent from the two preceding examples.

VII. REMARKS

We have started to explore the contents of a class of braid matrices presented previously. Unsurprisingly our study remains incomplete in all directions. We briefly indicate below perspectives of further developments.

For the standard cases (q-deformed unitary and orthogonal algebras) we have studied extensively elsewhere representations for q a root of unity.[19,20] (These two references cite many other sources.) We introduced "the method of fractional parts" for this purpose. Here we have noted (Sec. II) how certain roots of unity give triangularity ($\hat{R}^2 = I$) for different dimensions. A study of our L-algebras for such cases along similar lines can be of interest.

Our other solutions for triangularity involve elliptic aand hyperelliptic q with integer (binomial) coefficients in the defining equations. The roles of such functions deserve further explorations. Higher genus curves have appeared before[21,22] in the construction of statistical models as solutions of star–triangle (or Yang–Baxter) relations. There such curves are necessary ingredients of the solutions. In our case the situation is quite different. Our class of braid matrices have been obtained for *any* q. One can even set $q=1$ and still have interesting solutions. Our special values of q appear only when the additional constraint of triangularity is imposed and depend on the dimension N.

We have obtained some important general features of our L-algebras [see, for example, the equations from (3.11) to (3.18)]. But the explicit study of realizations is limited to 3×3 and 9×9 ones for $\hat{o}(3)$. This has already shown the crucial role of the central, grouplike elements we have constructed, thus achieving a principal goal. But a more general study of the L-algebras is desirable. Quadratic[23] and higher degree[24] homogenous algebras have been studied from a functional point of view yielding, for example, the Poincare series. (More sources are cited in Ref. 24.) The Poincare series for our algebra would show whether, and if so what, irreducible representations interpolate the $N^{2^p}\times N^{2^p}$ dimensional coproduct representations (corresponding, as pointed out in Sec. IV, to the central $\hat{S}_3$ elements proportional to $I_{N^{2^p}}$) obtained by iterating the coproduct prescription. We are unable to answer this question definitively at present, although attempts to

realize intermediate dimensional ones (between 3×3 and 9×9) exploiting the symmetries pointed out in Sec. IV seem to encounter obstructions. Our detailed study of the 9×9 case gives an idea of the features to be expected more generally.

The Turaev construction for link invariants turns out to be elegantly adaptable to our case. Systematic construction of invariant polynomials and possibility of generalizations to invariants of three-manifolds will be studied elsewhere.

Noncommutative geometries associated with our $\hat{R}$ have been presented indicating possible constructions of "noncommutative towers" on classical base spaces of dimensions $<N$. Here again a deeper study of the differential geometries remains to be done. Possible roles of our special values of q corresponding to triangularity should be interesting to explore in this context.

It follows from (1.10) or (3.41) along with (1.17) that for $\hat{o}(N)$, real positive q and

$$-\eta<\theta<0,$$

the elements of $\hat{R}(\theta)$ are all non-negetive (either zero or real positive). Hence such an $\hat{R}(\theta)$ along with the corresponding transfer matrix $t(\theta)$ [obtainable from $\hat{R}(\theta)$] can furnish the basis of a multistate statistical model. The elements of $\hat{R}(\theta)$ provide the Boltzmann weights. This class of model will be studied in a following paper.

The prescription (2.11) corresponds to real η. But the value $i\pi$ of η with -2 in (2.11) is also a solution with evident corresponding shifts for the right hand sides of two following equations. We will not discuss these cases separately here.

Our P_0 can easily be shown to lead to a Temperley-Lieb algebra. Constructions from this point of view citing numerous sources can be found in Ref. 25. Since in our case P_0 is already given (and well-known) we solve for the coefficient η in terms of the q appearing in P_0. Solving for the elements of P_0 in terms of the parameter of the coefficient (as is done in the approach of Ref. 25 and in the sources cited here) would have been impossibly complicated. Our excercise in Sec. II, for particularly simple case ($\eta=0$) gives an idea.

ACKNOWLEDGMENT

Commutation relations for functions of operators

Mark K. Transtrum[a] and Jean-François S. Van Huele[b]
Department of Physics and Astronomy, Brigham Young University, Provo, Utah 84602

(Received 18 January 2005; accepted 4 April 2005; published online 2 June 2005)

We derive an expression for the commutator of functions of operators with constant commutations relations in terms of the partial derivatives of these functions. This result extends the well-known commutation relation between one operator and a function of another operator. We discuss the range of applicability of the formula with examples in quantum mechanics. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1924703]

I. INTRODUCTION

A characteristic feature of quantum theory is the appearance of noncommuting operators. It is perhaps most conspicuous in one-dimensional quantum mechanics where the position and momentum operators obey the canonical commutation relation

$$[x,p] \equiv xp - px = i\hbar. \tag{1}$$

In the coordinate representation of wave mechanics where the position operator x is realized by x multiplication and the momentum operator p by $\hbar/i$ times the derivation with respect to x, one can easily check that the canonical commutation relation Eq. (1) is identically satisfied by applying the commutation operator on a test wave function $\psi(x)$,

$$[x,p]\psi(x) = x\frac{\hbar}{i}\frac{\mathrm{d}\psi(x)}{\mathrm{d}x} - \frac{\hbar}{i}\frac{\mathrm{d}}{\mathrm{d}x}(x\psi(x)) = \frac{\hbar}{i}x\psi'(x) - \frac{\hbar}{i}\psi(x) - \frac{\hbar}{i}x\psi'(x) = i\hbar\psi(x). \tag{2}$$

For quantum mechanics in three-dimensional space the commutation relations are generalized to

$$[x_i,p_j] = i\hbar\delta_{i,j} \tag{3}$$

and augmented with new commutation relations

$$[x_i,x_j] = [p_i,p_j] = 0, \tag{4}$$

expressing the independence of the coordinates and of the momenta in the different dimensions.

When independent quantum mechanical systems are combined to form larger systems such as multiparticle systems, the commutation rules for the operators within the individual systems are preserved and augmented with vanishing commutation relations for operators acting on the different systems. Tensor products of the quantum mechanical spaces and of the operators that operate on them accommodate this extension naturally.

In the Heisenberg picture of quantum mechanics where the operators carry the time dependence of the system under consideration, the evolution of an individual operator A is determined by its commutator with the Hamiltonian operator H, the generator of the time evolution:

[a]Electronic mail: mktranstrum@hotmail.com
[b]Electronic mail: vanhuele@byu.edu

$$\frac{dA}{dt} = \frac{1}{i\hbar}[A,H] = 0. \tag{5}$$

Depending on the specific expression of the operators A and H in terms of the position and momentum operators, the evaluation of the commutators in a set of equations like Eq. (5) can become quite involved with implications on the integrability of the resulting differential equations.

The importance of evaluating commutators in quantum mechanics and the corresponding problem in quantum field theory is illustrated by the vast literature on the subject. Many sources and textbooks in quantum mechanics, starting with Dirac's seminal text [Dirac (1958)], state the canonical commutation relations either by postulating them, or by deriving them from their classical analogs, the canonical Poisson brackets, and then go on to show that they imply the following commutation between the position operator x and any reasonable function of the momentum operator $f(p)$:

$$[x, f(p)] = i\hbar f'(p) \tag{6}$$

and its symplectic twin

$$[p, f(x)] = -i\hbar f'(x), \tag{7}$$

where the ($'$) symbol denotes differentiation with respect to the variable. The derivation of Eqs. (6) and (7) is a typical and almost obligatory exercise in a modern text on quantum mechanics. The standard way of proceeding is to consider the commutator of x with increasing powers of p, to use induction, and to develop a Taylor expansion of the function f.

It may come as a surprise therefore that a further generalization of Eqs. (6) and (7) is never given. In fact we were not able to find an expression for the commutator of a function of x with a function of p in the literature. The present paper provides such an expression [Eq. (18) below when applied to $x_1 = x$ and $x_2 = p$] and goes a few steps further by giving the general commutator for functions of an arbitrary number of operators, with the restriction that all these operators have known commutation relations amongst themselves and that their commutators do not involve further operators (q-numbers) but only constants (c-numbers). To be specific, our formula does apply to functions of standard position and momentum operators in multiple dimensions and for multiple particles, as well as for functions of multiple raising and lowering (creation and annihilation) ladder operators, but it does not generally apply, for example, to functions of angular momentum operators. When dealing with angular momentum operators, one would need to reexpress them as functions of position and momentum, and then apply the formula to those operators directly. It does apply to functions of noncommuting position and momentum operators as considered in noncommutative space–time extensions of quantum theory [Snyder (1947), Jackiw (2001)] but only to the extent that the noncommutative operators obey constant, i.e., c-number, commutation relations.

In this paper, our approach to the problem is constructive. We state our general result first, consider simple cases, make use of the induction process, and proceed by generalization. Unless otherwise noted, we assume that the functions of the operators are well behaved in the sense that they can be expanded in Taylor series. In Sec. V we comment on the applicability of the formulas and give specific examples. In the Appendix we discuss correlations in the values of some summation indices that appear in our formulas and on the notation we developed to accommodate them.

II. ASSUMPTIONS

We begin by stating the definition of the commutator and list two properties that follow directly from this definition. The definition of the commutator, Eq. (8), linearity, Eq. (9), and Leibnitz's rule, Eq. (10), will all be used explicitly in our derivations

$$[A,B] = AB - BA, \tag{8}$$

$$[A,\alpha B + C] = \alpha[A,B] + [A,C], \tag{9}$$

$$[AB,C] = A[B,C] + [A,C]B. \tag{10}$$

In addition to the above-noted relations, we will use a third, well-known commutator relation between an operator and a function of another operator. Given two operators x_1 and x_2 with a constant commutation relation c, such that $[x_1,x_2]=c$, it can be shown that

$$[x_1, f(x_2)] = cf'(x_2), \tag{11}$$

where $f(x_2)$ is an analytic function with a Taylor expansion. We will accept this relation here and refer to our introductory section or to a text on quantum mechanics, e.g., Merzbacher (1998), for an outline of its derivation. For the canonical position and momentum in quantum mechanics, the constant c takes the value $i\hbar$.

III. GENERAL RESULT

The most general result that we present in this paper involves the commutator of two functions of an arbitrary number of operators. Given n operators $x_1,\ldots,x_n$ such that $[x_i,x_j]=c_{ij}$, where c_{ij} are c-numbers, we will show that

$$[f(x_1,\ldots,x_n),g(x_1,\ldots,x_n)] = \underbrace{\sum_{k_{1,2}}\sum_{k_{1,3}}\sum_{k_{2,3}}\cdots\sum_{k_{n-1,n}}}\left(\prod_{j=2}^{n}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right) \times (\partial_{x_1}^{k_1}\ldots\partial_{x_n}^{k_n}g\partial_{x_1}^{k_1'}\ldots\partial_{x_n}^{k_n'}f - \partial_{x_1}^{k_1}\ldots\partial_{x_n}^{k_n}f\partial_{x_1}^{k_1'}\ldots\partial_{x_n}^{k_n'}g), \tag{12}$$

where

$$k_i = \sum_{j=i+1}^{n} k_{ij} \tag{13}$$

and

$$k_i' = \sum_{j=1}^{i-1} k_{ji}. \tag{14}$$

The index of each summation ranges from zero to infinity ($i=0-\infty$) with the restriction that the indices within the underbrace ($\underbrace{\ }$) are not all simultaneously zero. We will use the underbrace throughout the paper to indicate this restriction. We refer to the Appendix for a further discussion of the summation indices and the underbrace. We notice that only dummy indices k_{ij} with $i<j$ appear in the summation.

If the restriction that the indices cannot be simultaneously zero did not apply, there would be a term with no partial derivatives on the right-hand side of Eq. (12). That term would be $gf-fg=[g,f]=-[f,g]$. Therefore, an equivalent statement of Eq. (12) reads

$$\sum_{k_{1,2}=0}^{\infty}\sum_{k_{1,3}=0}^{\infty}\sum_{k_{2,3}=0}^{\infty}\cdots\sum_{k_{n-1,n}=0}^{\infty}\left(\prod_{j=2}^{n}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right)(\partial_{x_1}^{k_1}\ldots\partial_{x_n}^{k_n}g\partial_{x_1}^{k_1'}\ldots\partial_{x_n}^{k_n'}f - \partial_{x_1}^{k_1}\ldots\partial_{x_n}^{k_n}f\partial_{x_1}^{k_1'}\ldots\partial_{x_n}^{k_n'}g) = 0. \tag{15}$$

We will derive the generalized commutation relation Eq. (12), and we note that Eq. (15) is an equivalent, more compact statement that does not contain commutators of functions explicitly.

All the results presented in this paper are special cases of this general result. We derive the result by constructing increasingly complex intermediate results in Sec. IV.

IV. DERIVATIONS

We start by looking at the effect of increasing the power of x_1 in Eq. (11),

$$[x_1^2, f(x_2)] = [x_1, f(x_2)]x_1 + x_1[x_1, f(x_2)]$$
$$= cf'(x_2)x_1 + x_1 cf'(x_2) = 2cx_1 f'(x_2) - c[x_1, f'(x_2)] = 2cx_1 f'(x_2) - c^2 f''(x_2). \quad (16)$$

We next show by induction that this result can be extended to an arbitrary power n,

$$[x_1^n, f(x_2)] = \sum_{k=1}^{n} (-1)^{k+1} \binom{n}{k} c^k x_1^{n-k} f^{(k)}(x_2). \quad (17)$$

Proof of Eq. (17): Equations (11) and (16) correspond to the cases $n=1$ and $n=2$ of the result to be derived. We consider a general n and expand the commutator using Leibnitz's rule applied to $x_1^n = x_1 x_1^{n-1}$:

$$[x_1^n, f(x_2)] = x_1[x_1^{n-1}, f(x_2)] + [x_1, f(x_2)]x_1^{n-1}$$
$$= \sum_{k=1}^{n-1} (-1)^{k+1} \binom{n-1}{k} c^k x_1^{n-k} f^{(k)}(x_2) + cf'(x_2)x_1^{n-1} = \sum_{k=1}^{n-1} (-1)^{k+1} \binom{n-1}{k} c^k x_1^{n-k} f^{(k)}(x_2)$$
$$+ cx_1^{n-1} f'(x_2) - \sum_{k=1}^{n-1} (-1)^{k+1} \binom{n-1}{k} c^{k+1} x_1^{n-1-k} f^{(k+1)}(x_2) = ncx_1^{n-1} f'(x_2)$$
$$+ \sum_{k=2}^{n-1} (-1)^{k+1} \binom{n-1}{k} c^k x_1^{n-k} f^{(k)}(x_2) + \sum_{k=2}^{n-1} (-1)^{k+1} \binom{n-1}{k-1} c^k x_1^{n-k} f^{(k)}(x_2)$$
$$+ (-1)^{n+1} c^n f^{(n)}(x_2) = \sum_{k=1}^{n} (-1)^{k+1} \binom{n}{k} c^k x_1^{n-k} f^{(k)}(x_2).$$

In the third line we used the identity $f'(x_2)x_1^{n-1} = x_1^{n-1} f'(x_2) - [x_1^{n-1}, f'(x_2)]$, and in the fourth line we have redefined the index of the second summation to range from two to $n-1$ and have written the nth term outside the summation. In the final line we have combined all terms under a single summation. This completes the proof of Eq. (17).

We now extend the left argument of the commutator to include an analytic function of x_1 and proceed by considering its Taylor expansion

$$[f(x_1), g(x_2)] = \left[\sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(0) x_1^n, g(x_2) \right]$$
$$= \sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(0)[x_1^n, g(x_2)] = \sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(0) \sum_{k=1}^{n} \binom{n}{k} (-1)^{(k+1)} c^k x_1^{n-k} g^{(k)}(x_2).$$

Interchanging the order of the summations, we find that we can write the result in terms of derivatives of the original function, $f(x_1)$. The result is

$$[f(x_1), g(x_2)] = -\sum_{k=1}^{\infty} \frac{(-c)^k}{k!} f^{(k)}(x_1) g^{(k)}(x_2). \quad (18)$$

We pause to comment on this new result. The double summation introduced by the Taylor expansions has been reduced to a single sum. Somehow in the expression for the commutator of

the two functions only the contributions from products of identical orders of derivatives survive. In a quantum mechanical context we see that the powers of position and momentum decrease simultaneously and make room for factors of $i\hbar$ factors as required by dimensional analysis.

We will now consider two analytic functions of two operators, $f(x_1,x_2)$ and $g(x_1,x_2)$. We want to write these as some expansion. We could use the one-dimensional Taylor expansion in x_1 and write

$$f(x_1,x_2) = \sum_{n=0}^{\infty} \phi_n(x_2) x_1^n,$$

where the coefficients are now functions of the operator x_2. Instead, we simply observe that expansions exist (either as Taylor series or otherwise) and write them generally as

$$f(x_1,x_2) = \sum_{n=0}^{\infty} \phi_n(x_2) f_n(x_1) \tag{19}$$

and

$$g(x_1,x_2) = \sum_{m=0}^{\infty} \gamma_m(x_2) g_m(x_1). \tag{20}$$

Since x_1 and x_2 do not commute we have made a choice in Eqs. (19) and (20) in writing all the x_2-dependence to the left of the x_1-dependence in every term in the sum. The ordering does affect the explicit expression for ϕ_n and γ_m but the final result can be obtained no matter what ordering is chosen. What matters is that one choice has been made and will be used consistently throughout the derivation. The final result will be formally independent of the specific choice of ϕ_n, f_n, γ_n, and g_n and will be expressed in terms of $f(x_1,x_2)$ and $g(x_1,x_2)$ only.

Now we can consider the commutator:

$$\begin{aligned}[f(x_1,x_2),g(x_1,x_2)] &= \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} [\phi_n(x_2) f_n(x_1), \gamma_m(x_2) g_m(x_1)] \\ &= \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} (\phi_n(x_2)\gamma_m(x_2)[f_n(x_1),g_m(x_1)] + \phi_n(x_2)[f_n(x_1),\gamma_m(x_2)]g_m(x_1) \\ &\quad + [\phi_n(x_2),\gamma_m(x_2)]g_m(x_1) f_n(x_1) + \gamma_m(x_2)[\phi_n(x_2),g_m(x_1)]f_n(x_1))\end{aligned}$$

and notice that simplification occurs because the commutators of two functions of the same operator vanish, resulting in

$$[f(x_1,x_2),g(x_1,x_2)] = \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} (\phi_n(x_2)[f_n(x_1),\gamma_m(x_2)]g_m(x_1) + \gamma_m(x_2)[\phi_n(x_2),g_m(x_1)]f_n(x_1)).$$

Now we are in a position to apply Eq. (18) for two functions of a single operator each

$$\begin{aligned}[f(x_1,x_2),g(x_1,x_2)] = \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} &\left(\phi_n(x_2)\left(-\sum_{k=1}^{\infty} \frac{(-c)^k}{k!} f_n^{(k)}(x_1)\gamma_m^{(k)}(x_2)\right) g_m(x_1) \right. \\ &\left. + \gamma_m(x_2)\left(\sum_{k=1}^{\infty} \frac{(-c)^k}{k!} g_m^{(k)}(x_1)\phi_n^{(k)}(x_2)\right) f_n(x_1)\right).\end{aligned}$$

Interchanging the order of the summations and factoring without commuting, we obtain

$$[f(x_1,x_2),g(x_1,x_2)] = -\sum_{k=1}^{\infty}\left(\frac{(-c)^k}{k!}\sum_{n=0}^{\infty}\phi_n(x_2)f_n^{(k)}(x_1)\sum_{m=0}^{\infty}\gamma_m^{(k)}(x_2)g_m(x_1)\right) + \sum_{k=1}^{\infty}\left(\frac{(-c)^k}{k!}\sum_{m=0}^{\infty}\gamma_m(x_2)g_m^{(k)}(x_1)\sum_{n=0}^{\infty}\phi_n^{(k)}(x_2)f_n(x_1)\right).$$

We now observe that the original function can be reassembled

$$\sum_{n=0}^{\infty}\phi_n(x_2)f_n^{(k)}(x_1) = \frac{\partial^k}{\partial x_1^k}\left(\sum_{n=0}^{\infty}\phi_n(x_2)f_n(x_1)\right) = \frac{\partial^k}{\partial x_1^k}f(x_1,x_2) \tag{21}$$

with similar formulas for partial derivatives of f with respect to x_2, and for g with respect to x_1 and x_2 and conclude that

$$[f(x_1,x_2),g(x_1,x_2)] = \sum_{k=1}^{\infty}\frac{(-c)^k}{k!}\left(\frac{\partial^k g}{\partial x_1^k}\frac{\partial^k f}{\partial x_2^k} - \frac{\partial^k f}{\partial x_1^k}\frac{\partial^k g}{\partial x_2^k}\right). \tag{22}$$

In Eq. (22) we have omitted the arguments of the functions from the expression for brevity. We will continue to do so wherever there is no ambiguity in the arguments of the functions.

Before we can derive our formula for two functions of an arbitrary number of operators, we must prove one more formula giving the commutator of a function of an arbitrary number of operators and a function of one operator.

Given $n-1$ operators x_i, $i=1\ldots(n-1)$ that each have a constant commutation relation with another given operator x_n, such that $[x_i,x_n]=c_{in}$ then

$$[f(x_1,\ldots,x_{n-1}),g(x_n)] = -\underbrace{\sum_{k_1}\cdots\sum_{k_{n-1}}}\left(\prod_{i=1}^{n-1}\frac{(-c_{in})^{k_i}}{k_i!}\right)(\partial_{x_1}^{k_1}\ldots\partial_{x_{n-1}}^{k_{n-1}}f\partial_{x_n}^{k}g), \tag{23}$$

where

$$k = \sum_{i=1}^{n-1}k_i.$$

We prove Eq. (23) by induction.

For $n=2$ Eq. (23) becomes

$$[f(x_1\ldots x_{n-1},g(x_n)] = -\underbrace{\sum_{k_1}}\left(\prod_{i=1}^{1}\frac{(-c_{1,2})^{k_i}}{k_i!}\right)\partial_{x_1}^{k_1}f\partial_{x_2}^{k}g = -\sum_{k=1}^{\infty}\frac{(-c_{1,2})^k}{k!}\partial_{x_1}^{k}f\partial_{x_2}^{k}g$$

which we recognize as equivalent to Eq. (18), derived earlier.

Now we consider an arbitrary n and, in analogy with Eq. (19), write

$$f(x_1,\ldots,x_{n-1}) = \sum_{m=0}^{\infty}\phi_m(x_{n-1})f_m(x_1,\ldots,x_{n-2}).$$

We expand the commutator using Leibnitz's rule to obtain

$$[f,g] = \sum_{m=0}^{\infty}(\phi_m[f_m,g] + [\phi_m,g]f_m).$$

We evaluate the first commutator using Eq. (23) since the left argument is now a function of $n-2$ operators. We evaluate the second commutator using Eq. (18). The result is

$$[f,g] = -\sum_{m=0}^{\infty}\left(\phi_m \underbrace{\sum_{k_1}\cdots\sum_{k_{n-2}}}\left(\prod_{i=1}^{n-2}\frac{(-c_{in})^{k_i}}{k_i!}\right)\partial_{x_1}^{k_1}\cdots\partial_{x_{n-2}}^{k_{n-2}} f_m \partial_{x_n}^{k} g\right) - \sum_{m=0}^{\infty}\sum_{k_{n-1}=1}^{\infty}\frac{(-c_{n-1,n})^{\kappa_{n-1}}}{k_{n-1}!}(\partial_{x_{n-1}}^{k_{n-1}}\phi_m)(\partial_{x_n}^{k_{n-1}} g) f_m \tag{24}$$

where

$$k = \sum_{i=1}^{n-1} k_i. \tag{25}$$

In the second term we apply the definition of the commutator Eq. (8) and Eq. (23) since again it involves a function of $n-2$ operators,

$$(\partial_{x_n}^{k_{n-1}} g) f_m = f_m(\partial_{x_n}^{k_{n-1}} g) + \underbrace{\sum_{k_1}\cdots\sum_{k_{n-2}}}\left(\prod_{i=1}^{n-2}\frac{(-c_{in})^{k_i}}{k_i!}\right)(\partial_{x_1}^{k_1}\cdots\partial_{x_{n-2}}^{k_{n-2}} f_m)(\partial_{x_n}^{k} g) \tag{26}$$

In the last term, we have used k defined in Eq. (25). Substituting this into Eq. (24) we have

$$\begin{aligned}[f,g] = &-\sum_{m=0}^{\infty}\left(\phi_m \underbrace{\sum_{k_1}\cdots\sum_{k_{n-2}}}\left(\prod_{i=1}^{n-2}\frac{(-c_{in})^{k_i}}{k_i!}\right)(\partial_{x_1}^{k_1}\cdots\partial_{x_{n-2}}^{k_{n-2}} f_m)(\partial_{x_n}^{k} g)\right) - \sum_{m=0}^{\infty}\left(\sum_{k_{n-1}=1}^{\infty}\left(\frac{(-c_{n-1,n})^{k_{n-1}}}{k_{n-1}!}\right)\right.\\ &\left.\times(\partial_{x_{n-1}}^{k_{n-1}}\phi_m) f_m(\partial_{x_n}^{k_{n-1}} g)\right) - \sum_{m=0}^{\infty}\underbrace{\sum_{k_1}\cdots\sum_{k_{n-2}}}\sum_{k_{n-1}=1}^{\infty}\left(\prod_{i=1}^{n-2}\frac{(-c_{in})^{k_i}}{k_i!}\right)\left(\frac{(-c_{n-1,n})^{k_{n-1}}}{k_{n-1}!}\right)\\ &\times(\partial_{x_{n-1}}^{k_{n-1}}\phi_m)\ (\partial_{x_1}^{k_1}\cdots\partial_{x_{n-2}}^{k_{n-2}} f_m)(\partial_{x_n}^{k} g).\end{aligned} \tag{27}$$

Since all terms contain derivatives of ϕ_m next to derivatives of f_m, we can eliminate the summation over m by using the observation made in Eq. (21) and write Eq. (27) in terms of the original function f. We also combine factors

$$\left(\prod_{i=1}^{n-2}\frac{(-c_{in})^{k_i}}{k_i!}\right)\left(\frac{(-c_{n-1,n})^{k_{n-1}}}{k_{n-1}!}\right) = \prod_{i=1}^{n-1}\frac{(-c_{in})^{k_i}}{k_i!}$$

to get

$$\begin{aligned}[f,g] = &-\underbrace{\sum_{k_1}\cdots\sum_{k_{n-2}}}\left(\prod_{i=1}^{n-2}\frac{(-c_{in})^{k_i}}{k_i!}\right)(\partial_{x_1}^{k_1}\cdots\partial_{x_{n-2}}^{k_{n-2}} f)(\partial_{x_n}^{k} g) - \sum_{k_{n-1}=1}^{\infty}\left(\frac{(-c_{n-1,n})^{k_{n-1}}}{k_{n-1}!}\right)(\partial_{x_{n-1}}^{k_{n-1}} f)(\partial_{x_n}^{k_{n-1}} g)\\ &-\underbrace{\sum_{k_1}\cdots\sum_{k_{n-2}}}\sum_{k_{n-1}=1}^{\infty}\left(\prod_{i=1}^{n-1}\frac{(-c_{in})^{k_i}}{k_i!}\right)(\partial_{x_1}^{k_1}\cdots\partial_{x_{n-2}}^{k_{n-2}}\partial_{x_{n-1}}^{k_{n-1}} f)(\partial_{x_n}^{k} g)\end{aligned} \tag{28}$$

We observe that in the first term, the indices of the summations are not simultaneously zero. In the last term, the first $n-2$ indices are not simultaneously zero. Thus, the first term corresponds to the case $k_{n-1}=0$. The second term is the case in which $k_1 \ldots k_{n-2}$ are simultaneously zero, and the third term is the case in which the indices of neither group are simultaneously zero. Therefore, these three terms can be collected into one term as we elaborate in the Appendix. This concludes the proof of Eq. (23).

We are now ready to prove our main result, Eq. (12). This proof will again proceed by induction.

First, we consider the case $n=2$:

$$[f(x_1,x_2),g(x_1,x_2)] = \sum_{\underbrace{k_{1,2}}} \left(\prod_{j=2}^{2} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \right) ((\partial_{x_1}^{k_1}\partial_{x_2}^{k_2} g)(\partial_{x_1}^{k_1'}\partial_{x_2}^{k_2'} f) - (\partial_{x_1}^{k_1}\partial_{x_2}^{k_2} f)(\partial_{x_1}^{k_1'}\partial_{x_2}^{k_2'} g))$$

$$= \sum_{k=1}^{\infty} \frac{(-c_{1,2})^k}{k!} (\partial_{x_1}^{k} g \partial_{x_2}^{k} f - \partial_{x_1}^{k} f \partial_{x_2}^{k} g),$$

where we have used Eqs. (13) and (14) to find that $k_1=k_2'=k_{1,2}$ and $k_2=k_1'=0$. We recognize that this is just the result derived in Eq. (22).

We now consider an arbitrary value of n. We write the functions in analogy with Eqs. (19) and (20)

$$f(x_1, \ldots, x_n) = \sum_{m=0}^{\infty} \phi_m(x_n) f_m(x_1, \ldots, x_{n-1})$$

$$g(x_1, \ldots, x_n) = \sum_{p=0}^{\infty} \gamma_p(x_n) g_p(x_1, \ldots, x_{n-1}).$$

Applying Leibnitz's rule to $[f,g]$ we have

$$[f,g] = \sum_{m=0}^{\infty} \sum_{p=0}^{\infty} ([\phi_m, \gamma_p] g_p f_m + \gamma_p [\phi_m, g_p] f_m + \phi_m [f_m, \gamma_p] g_p + \phi_m \gamma_p [f_m, g_p]).$$

We observe that the first commutator vanishes since it involves the single operator x_n. We use Eq. (23) to evaluate the second and third terms. We use Eq. (12) to evaluate the last term, since both arguments are functions of $n-1$ operators. The result is

$$\begin{aligned}
[f,g] = & \sum_{m=0}^{\infty} \sum_{p=0}^{\infty} \gamma_p \left(\underbrace{\sum_{k_{1,n}} \cdots \sum_{k_{n-1,n}}} \left(\prod_{i=1}^{n-1} \frac{(-c_{in}^{k_{in}})}{k_{in}!} \right) (\partial_{x_1}^{k_{1,n}} \ldots \partial_{x_{n-1}}^{k_{n-1,n}} g_p)(\partial_{x_n}^{k_n} \phi_m) \right) f_m \\
& - \sum_{m=0}^{\infty} \sum_{p=0}^{\infty} \phi_m \left(\underbrace{\sum_{k_{1,n}} \cdots \sum_{k_{n-1,n}}} \left(\prod_{i=1}^{n-1} \frac{(-c_{in}^{k_{in}})}{k_{in}!} \right) (\partial_{x_1}^{k_{1,n}} \ldots \partial_{x_{n-1}}^{k_{n-1,n}} f_m)(\partial_{x_n}^{l_n} \gamma_p) \right) g_p \\
& + \sum_{m=0}^{\infty} \sum_{p=0}^{\infty} \phi_m \gamma_p \left(\underbrace{\sum_{k_{1,2}} \cdots \sum_{k_{n-2,n-1}}} \left(\prod_{j=2}^{n-1} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \right) \right) (\partial_{x_1}^{\kappa_1} \ldots \partial_{x_{n-1}}^{\kappa_{n-1}} g_p)(\partial_{x_1}^{k_1'} \ldots \partial_{x_{n-1}}^{k_{n-1}'} f_m) \\
& - \sum_{m=0}^{\infty} \sum_{p=0}^{\infty} \phi_m \gamma_p \left(\underbrace{\sum_{k_{1,2}} \cdots \sum_{k_{n-2,n-1}}} \left(\prod_{j=2}^{n-1} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \right) \right) (\partial_{x_1}^{\kappa_1} \ldots \partial_{x_{n-1}}^{\kappa_{n-1}} f_m)(\partial_{x_1}^{k_1'} \ldots \partial_{x_{n-1}}^{k_{n-1}'} g_p)
\end{aligned} \tag{29}$$

where we have used the abbreviation

$$\kappa_i = \sum_{j=i+1}^{n-1} k_{ij} \tag{30}$$

and k_i' is defined in Eq. (14).

First, we notice that the first two terms of Eq. (29) can be combined:

$$\underbrace{\sum \cdots \sum}_{k_{1n} \quad k_{n-1n}} \left(\prod_{j=2}^{n-1} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \right) ((\partial_{x_1}^{k_{1n}} \ldots \partial_{x_{n-1}}^{k_{n-1n}} g) \partial_{x_n}^{k_n} f - (\partial_{x_1}^{k_{1n}} \ldots \partial_{x_{n-1}}^{k_{n-1n}} f) \partial_{x_n}^{k_n} g).$$

Next, we notice that ϕ_m and γ_p commute. Also, using the definition of the commutator we can change the order of $\phi_m(\partial_{x_1}^{k_1} \ldots \partial_{x_{n-1}}^{k_{n-1}} g_p)$ and $\gamma_p(\partial_{x_1}^{k_1} \ldots \partial_{x_{n-1}}^{k_{n-1}} f_m)$. We use Eq. (23) to evaluate these commutators. After substitution into Eq. (29), the result is:

$$\begin{aligned}
[f,g] = & \underbrace{\sum \cdots \sum}_{k_{1n} \quad k_{n-1n}} \left(\prod_{j=2}^{n-1} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \right) (\partial_{x_1}^{k_{1,n}} \ldots \partial_{x_{n-1}}^{k_{n-1,n}} g \partial_{x_n}^{k_n} f - \partial_{x_1}^{k_{1,n}} \ldots \partial_{x_{n-1}}^{k_{n-1,n}} f \partial_{x_n}^{k_n} g) \\
& + \sum_{m=0}^{\infty} \sum_{p=0}^{\infty} \left(\underbrace{\sum \cdots \sum}_{k_{1,2} \quad k_{n-2,n-1}} \left(\prod_{j=2}^{n-1} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \right) \right) \times \{ \gamma_p (\partial_{x_1}^{\kappa_1} \ldots \partial_{x_{n-1}}^{\kappa_{n-1}} g_p) \phi_m (\partial_{x_1}^{k_1'} \ldots \partial_{x_{n-1}}^{k_{n-1}'} f_m) \\
& - \phi_m (\partial_{x_1}^{\kappa_1} \ldots \partial_{x_{n-1}}^{\kappa_{n-1}} f_m) \gamma_p (\partial_{x_1}^{k_1'} \ldots \partial_{x_{n-1}}^{k_{n-1}'} g_p) \} \\
& + \sum_{m=0}^{\infty} \sum_{p=0}^{\infty} \left(\underbrace{\sum \cdots \sum}_{k_{1,2} \quad k_{n-2,n-1}} \underbrace{\sum \cdots \sum}_{k_{1,n} \quad k_{n-1,n}} \left(\prod_{j=2}^{n-1} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!} \right) \right) \\
& \times \{ \gamma_p (\partial_{x_1}^{\kappa_1 + k_{1,n}} \ldots \partial_{x_{n-1}}^{\kappa_{n-1} + k_{n-1,n}} g_p) (\partial_{x_n}^{k_{1,n} + \ldots + k_{n-1,n}} \phi_m) (\partial_{x_1}^{k_1'} \ldots \partial_{x_{n-1}}^{k_{n-1}'} f_m) \\
& - \phi_m (\partial_{x_1}^{\kappa_1 + k_{1,n}} \ldots \partial_{x_{n-1}}^{\kappa_{n-1} + k_{n-1,n}} f_m) (\partial_{x_n}^{k_{1,n} + \ldots + k_{n-1,n}} \gamma_p) (\partial_{x_1}^{k_1'} \ldots \partial_{x_{n-1}}^{k_{n-1}'} g_p) \}.
\end{aligned}$$

Combining factors

$$\left(\prod_{j=2}^{n-1} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_i j}}{k_{ij}!} \right) \left(\prod_{i=1}^{n-1} \frac{(-c_{in})^{k_{in}}}{k_{in}!} \right) = \prod_{j=2}^{n} \prod_{i=1}^{j-1} \frac{(-c_{ij})^{k_{ij}}}{k_{ij}!},$$

and rearranging the summations, we get

$$[f,g]=\underbrace{\sum_{k_{1,n}}\cdots\sum_{k_{n-1,n}}}\left(\prod_{j=2}^{n-1}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right)((\partial_{x_1}^{k_{1,n}}\cdots\partial_{x_{n-1}}^{k_{n-1,n}}g)(\partial_{x_n}^{k_n}f)-(\partial_{x_1}^{k_{1,n}}\cdots\partial_{x_{n-1}}^{k_{n-1,n}}f)(\partial_{x_n}^{k_n}g))$$

$$+\underbrace{\sum_{k_{1,2}}\cdots\sum_{k_{n-2,n-1}}}\left(\prod_{j=2}^{n-1}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right)((\partial_{x_1}^{\kappa_1}\cdots\partial_{x_{n-1}}^{\kappa_{n-1}}g)(\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}f)-(\partial_{x_1}^{\kappa_1}\cdots\partial_{x_{n-1}}^{\kappa_{n-1}}f)$$

$$\times(\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}g))+\underbrace{\sum_{k_{1,2}}\cdots\sum_{k_{n-2,n-1}}}\underbrace{\sum_{k_{1,n}}\cdots\sum_{k_{n-1,n}}}\left(\prod_{j=2}^{n}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right)\{(\partial_{x_1}^{\kappa_1+k_{1,n}}\cdots\partial_{x_{n-1}}^{\kappa_{n-1}+k_{n-1,n}}g)$$

$$\times(\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}\partial_{x_n}^{k_{1,n}+\cdots+k_{n-1,n}}f)-(\partial_{x_1}^{\kappa_1+k_{1,n}}\cdots\partial_{x_{n-1}}^{\kappa_{n-1}+k_{n-1,n}}f)(\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}\partial_{x_n}^{k_{1,n}+\cdots+k_{n-1,n}}g)\}.$$

Now we observe that

$$\kappa_i+k_{in}=\sum_{j=i+1}^{n-1}k_{ij}+k_{in}=k_i$$

and that

$$k_{1,n}+\ \ldots\ +k_{n-1,n}=k'_n$$

in accordance with Eqs. (13) and (14), which allows us to write

$$[f,g]=\underbrace{\sum_{k_{1,n}}\cdots\sum_{k_{n-1,n}}}\left(\prod_{j=2}^{n-1}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right)((\partial_{x_1}^{k_{1,n}}\cdots\partial_{x_{n-1}}^{k_{n-1,n}}g)(\partial_{x_n}^{k_n}f)-(\partial_{x_1}^{k_{1,n}}\cdots\partial_{x_{n-1}}^{k_{n-1,n}}f)(\partial_{x_n}^{k_n}g))$$

$$+\underbrace{\sum_{k_{1,2}}\cdots\sum_{k_{n-2,n-1}}}\left(\prod_{j=2}^{n-1}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right)((\partial_{x_1}^{k_1}\cdots\partial_{x_{n-1}}^{k_{n-1}}g)(\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}f)-(\partial_{x_1}^{k_1}\cdots\partial_{x_{n-1}}^{k_{n-1}}f)$$

$$\times(\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}g))+\underbrace{\sum_{k_{1,2}}\cdots\sum_{k_{n-2,n-1}}}\underbrace{\sum_{k_{1,n}}\cdots\sum_{k_{n-1,n}}}\left(\prod_{j=2}^{n}\prod_{i=1}^{j-1}\frac{(-c_{ij})^{k_{ij}}}{k_{ij}!}\right)((\partial_{x_1}^{k_1}\cdots\partial_{x_{n-1}}^{k_{n-1}}g)$$

$$\times(\partial_{x_n}^{k'_n}\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}f)-(\partial_{x_1}^{k_1}\cdots\partial_{x_{n-1}}^{k_{n-1}}f)(\partial_{x_n}^{k'_n}\partial_{x_1}^{k'_1}\cdots\partial_{x_{n-1}}^{k'_{n-1}}g)).$$

Finally, we observe the ranges of the groups of indices. The first term does not contain the indices $k_{1,2},\ldots,k_{n-2,n-1}$ and, therefore, corresponds to the term in which they are simultaneously zero. Also, the indices $k_{1,n},\ldots,k_{n-1,n}$ do not appear in the second term, which then corresponds to the term in which they are simultaneously zero. The third term has both sets of indices. Thus the three terms can be combined (see the Appendix) noting that all the indices range from zero to infinity, but are not simultaneously zero. Upon doing so, the equation becomes (12), completing the proof.

V. DISCUSSION AND IMPLEMENTATION

The main result of this paper is Eq. (12). It gives a formula for the commutator of two functions of noncommuting operators. It can actually be written more compactly in the form of Eq. (15) in which both the left-hand side and the constraints on the summation indices have been removed. Equation (15) actually looks so simple that one wonders if it cannot be derived trivially from some general statement, instead of through the long and convoluted induction processes

presented in Sec. IV. We have not been able to do so. Equation (12) applies to reasonable functions f and g which have converging Taylor series. In the derivation, we interchanged the order of the summations, thereby replacing a series by another, a step that is valid when both series converge. We used the linearity of the derivative to derive term by term, a process that is again valid for converging series with converging derivatives. Of course all formulas apply also to all finite or truncated series such as those that appear when evaluating expressions to any finite order of perturbation theory for example. That is the spirit in which the formulas were derived and the area where they are most likely to find their domain of applicability. Since x_1 and x_2 in Eq. (22) and $x_1, x_2 \ldots, x_n$ in Eq. (12) are operators, the derivatives and partial derivatives need to be explained further. Already in Eq. (11) the derivative symbol refers to a derivative with respect to an operator. In the one-dimensional case Eq. (11) can easily be interpreted as the operator replacement of the derivative of a function with respect to a scalar variable. The prescription becomes: take the ordinary derivative of the function and replace in the resulting expression every occurrence of the variable x by an operator X. So for instance, denoting operators with capitals for now, the procedure to find the operator derivative in a particular case gives

$$(e^{3X})' \to (e^{3x})' = 3e^{3x} \to 3(e^{3X}).$$

When the function depends on two or more noncommuting operators however, an operational definition of the derivative needs to be supplied. We follow Louisell (1964) to define the derivative with respect to an operator in terms of the derivative with respect to a scalar parameter λ:

$$\partial_x f(x,p) = \lim_{\lambda \to 0} \frac{\partial}{\partial \lambda} f(x+\lambda, p). \tag{31}$$

and

$$\partial_{x_i} f(x_1, \ldots, x_i, \ldots, x_n) = \lim_{\lambda \to 0} \frac{\partial}{\partial \lambda} f(x_1, \ldots, x_i + \lambda, \ldots, x_n). \tag{32}$$

This definition reduces to the ordinary derivative shown above in the one-dimensional case:

$$\partial_x e^{3x} = \lim_{\lambda \to 0} \frac{\partial}{\partial \lambda} e^{3(x+\lambda)} = \lim_{\lambda \to 0} 3e^{3(x+\lambda)} = 3e^{3x}. \tag{33}$$

Let us now apply this definition for operator derivatives to a function of two operators x and p as an example of a situation that might arise in the evaluation of Eq. (12). It is clear that, as a result of the noncommutativity of x and p the ordinary composition or chain rule,

$$(f(g(x)))' = f'(g(x))g'(x) = g'(x)f'(g(x)) \tag{34}$$

cannot be applied without ambiguity since, for example,

$$\partial_x(\cos(xp)) \neq -\sin(xp)p \neq p(-\sin(xp) \quad \neq 1/2(-\sin(xp)\ p + p(-\sin(xp)). \tag{35}$$

For the exponential function however, we can follow Wilcox (1967) and adapt a result from Snider (1964) to obtain

$$\partial_x(e^{f(x,p)}) = \int_0^1 \mathrm{d}u e^{(1-u)f(x,p)}(\partial_x f(x,p))e^{uf(x,p)} \tag{36}$$

which can itself be used to get an explicit expression for the derivative operator in Eq. (35) above

$$\partial_x(\cos(xp)) = -\int_0^1 \mathrm{d}u \cos[(1-u)xp]p \sin(uxp) - \int_0^1 \mathrm{d}u \sin[(1-u)xp]p \cos(uxp). \tag{37}$$

This result is indeed quite different from that obtained from a naive application of the chain rule for derivatives with respect to commuting variables. Furthermore the result in Eq. (37) can be checked to any order of an expansion in powers of x or p. The derivative of a polynomial truncation of the cosine function yields the result obtained by truncation of the trigonometric functions in Eq. (37). We have developed algorithms for manipulating any polynomial expression of noncommuting operators [Transtrum and Van Huele (to be published)]. That linearity and Leibnitz's rule apply to the operational derivative follows from the fact that these properties are preserved in Eq. (31).

Finally we use Eq. (12) to derive the torque equation in the Heisenberg picture of quantum mechanics as an illustration of a commutator of two functions, one of which (only) can be expanded in a finite power series of its operators.

Consider the commutator of the nonrelativistic Hamiltonian,

$$H = \frac{p_x^2 + p_y^2 + p_z^2}{2m} + V(x,y,z),$$

with the z component of the angular momentum, $L_z = xp_y - yp_x$. Since the only nonvanishing commutators are $[x,p_x]=[y,p_y]=[z,p_z]=i\hbar$, the formula simplifies to

$$[L_z(x,y,p_x,p_y),H(x,y,z,p_x,p_y,p_z)] = \underbrace{\sum_k \sum_l \sum_m}_{} \frac{(-i\hbar)^{k+l+m}}{k!l!m!} \times ((\partial_x^k \partial_y^l \partial_z^m H)(\partial_{p_x}^k \partial_{p_y}^l \partial_{p_z}^m L_z) - (\partial_x^k \partial_y^l \partial_z^m L_z)(\partial_{p_x}^k \partial_{p_y}^l \partial_{p_z}^m H)) \tag{38}$$

By inspection, it is obvious that all mixed partial derivatives of L_z that occur in the above formula vanish. So, the above formula further simplifies to

$$\begin{aligned}[L_z,H] &= \sum_{k=1}^{\infty} \frac{(-i\hbar)^k}{k!}((\partial_x^k H)(\partial_{p_x}^k L_z) - (\partial_x^k L_z)(\partial_{p_x}^k H)) + \sum_{k=1}^{\infty} \frac{(-i\hbar)^k}{k!}((\partial_y^k H)(\partial_{p_y}^k L_z) - (\partial_y^k L_z)(\partial_{p_y}^k H)) \\ &\quad + \sum_{k=1}^{\infty} \frac{(-i\hbar)^k}{k!}((\partial_z^k H)(\partial_{p_z}^k L_z) - (\partial_z^k L_z)(\partial_{p_z}^k H)) \\ &= (-i\hbar)\left((\partial_x V)(-y) - p_y \frac{p_x}{m} + (\partial_y V)(x) - (-p_x)\frac{p_y}{m}\right) = (-i\hbar)((\partial_y V)x - (\partial_x V)y). \end{aligned} \tag{39}$$

Therefore

$$\frac{dL_z}{dt} = \frac{1}{i\hbar}[L_z,H] = xF_y - yF_x. \tag{40}$$

We recognize the torque about the z axis as expected.

In conclusion, we have presented an expression for the commutator of two functions of an arbitrary number of noncommuting operators whose commutators are constants. The formula is derived constructively using the induction process. The resulting expression involves partial derivatives of the functions with respect to the noncommuting operators. These partial derivatives can be evaluated directly in some simple cases or in general through series expansions and ordering algorithms to any order.

APPENDIX: NOTATION FOR SUMMATION INDICES

In this appendix we comment on the use of our notation for the summation indices as they appear in Eqs. (12)–(14). First of all $k_1=k_n'=0$ for any n. We include these terms to see the symmetry in the formula.

Second, we note that when the summation indices have two subscripts, we separate the subscripts by commas when at least one of them involves a number. Thus we write $k_{1,2}$, $k_{1,i}$, and $k_{i-1,j}$, but k_{ij} instead of $k_{i,j}$. Similarly, we write $c_{1,2}$, $c_{1,i}$, and $c_{i-1,j}$, but c_{ij} instead of $c_{i,j}$. The simplification $c_{1,2}=c$ was made in the part of Sec. IV leading to Eq. (22).

Finally we discuss the correlation between the summation indices and the related underbrace notation in more depth. Throughout the paper, we frequently use notation of the form

$$\underbrace{\sum_{k_1}\cdots\sum_{k_n}} f(k_1,\ldots,k_n),$$

where the underbrace indicates that the summations range from zero to infinity but are not simultaneously zero. We will explain some of the properties associated with these expressions.

In the case that the underbrace includes only one index, that index cannot be zero, and the expression can be rewritten in more standard notation:

$$\underbrace{\sum_{k_1}} f(k_1)=\sum_{k_1=1}^{\infty} f(k_1).$$

Now, we consider the case that the underbrace contains two indices. Both cannot be zero simultaneously, but one can be zero as long as the other is nonzero. Thus, there are two summations which account for the cases in which one of the indices is zero. There is also the case that neither index is zero and a third term accounts for this:

$$\underbrace{\sum_{k_1}\sum_{k_2}} f(k_1,k_2)=\sum_{k_1=1}^{\infty} f(k_1,k_2=0)+\sum_{k_2=1}^{\infty} f(k_1=0,k_2)+\sum_{k_1=1}^{\infty}\sum_{k_2=1}^{\infty} f(k_1,k_2).$$

We observe here that this result implies that

$$\underbrace{\sum_{k_1}\sum_{k_2}} f(k_1,k_2)=\underbrace{\sum_{k_1}} f(k_1,k_2=0)+\underbrace{\sum_{k_2}} f(k_1=0,k_2)+\underbrace{\sum_{k_1}}\underbrace{\sum_{k_2}} f(k_1,k_2),$$

which we will generalize shortly.

It follows from the above argument, that, if there are n indices, $k_1,\ldots,k_n$, in an expression of the form

$$\underbrace{\sum_{k_1}\cdots\sum_{k_n}} f(k_1,\ldots,k_n),$$

there will be $\binom{n}{1}$ terms in which one index is nonzero, $\binom{n}{2}$ terms in which two indices are nonzero, and so forth. Thus, there will be

$$\sum_{k=1}^{n} \binom{n}{k} = 2^n - 1$$

terms altogether. For large numbers of indices, the underbrace notation is clearly more compact; however, for computational purposes, it will be necessary to expand the underbrace notation as we have done here for the cases $n=1$ and $n=2$.

Now we consider a situation that arises frequently in the derivations presented in this paper. This involves the case in which there are two groups of indices, $k_1,\ldots,k_n$ and $l_1,\ldots,l_m$ in an expression of the form

$$\underbrace{\sum_{k_1}\cdots\sum_{k_n}\sum_{l_1}\cdots\sum_{l_m} f},$$

where f depends on each of the indices. We show that the underbrace has the following property:

$$\underbrace{\sum_{k_1}\cdots\sum_{k_n}\sum_{l_1}\cdots\sum_{l_m} f} = \underbrace{\sum_{k_1}\cdots\sum_{k_n} f} + \underbrace{\sum_{l_1}\cdots\sum_{l_m} f} + \underbrace{\sum_{k_1}\cdots\sum_{k_n}} \underbrace{\sum_{l_1}\cdots\sum_{l_m} f}$$

which is an identity used often throughout the paper. Given a little thought, this expression seems reasonable, but we will present a slightly more rigorous proof.

The proof is not complicated; we simply count the number of terms on either side of the equation. The left-hand side of the equation has $2^{n+m}-1$ terms. The right-hand side has $2^n-1+2^m-1+(2^n-1)(2^m-1)=2^{n+m}-1$ terms. Since all of the terms on the the right involve summations in which some of the indices range from zero to infinity but are not simultaneously zero, we conclude that each term on the right-hand side of the equation also appears on the left with no repeated terms. Since both sides of the equation have equal numbers of terms, we conclude that the two expressions are equivalent.

Stationary van Hove limit

Jan Dereziński[a] and Rafał Früboes[b]
Department of Mathematical Methods in Physics, Warsaw University, Hoża 74, 00-682, Warsaw, Poland

(Received 22 December 2004; accepted 14 March 2005; published online 7 June 2005)

The weak coupling (van Hove) limit of one parameter groups of contractions is studied by the stationary approach. We show that the resolvent of the properly renormalized and rescaled generator of a contractive semigroup has a limit as the coupling constant goes to zero. This limit is the resolvent of the generator of a certain contractive semigroup. Our results can be viewed as a stationary counterpart to the well known results about the weak coupling limit obtained by the time-dependent approach, due to Davies. We compare both approaches. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904509]

I. INTRODUCTION

Let $\mathcal{X}$ be a Banach space with a distinguished bounded projection P. Suppose that U_t^λ is a one parameter strongly continuous group of isometries on $\mathcal{X}$ generated by $L_\lambda := L_0 + \lambda Q$. Assume that P commutes with the free dynamics $U_t^0 = \mathrm{e}^{tL_0}$ or equivalently P commutes with L_0. Our main object of interest is the reduced dynamics

$$\mathbb{R} \ni t \mapsto PU_t^\lambda P$$

as an operator on Ran P.

The reduced dynamics was studied in a series of papers[4,5] and in the book[6] by Davies. First he showed that the reduced dynamics after appropriately rescaling, i.e.,

$$t \mapsto PU_{t/\lambda^2}^\lambda P,$$

can be approximated, as the coupling constant λ goes to zero, by a certain one parameter semigroup on Ran P depending on λ. The generator of this semigroup is a quadratic polynomial in λ^{-1}. By the convergence we mean that for each fixed time t the norm of the difference between the resulting semigroup and the reduced rescaled dynamics tends to zero as $|\lambda|$ becomes smaller. We will call this result, for the reasons that soon become clear, the pointwise (in time) van Hove limit with the first order term.

The second result obtained by Davies describes the case with $PQP = 0$. He proved that the reduced dynamics with a rescaled time renormalized by the free evolution, i.e.,

$$t \mapsto U_{-t/\lambda^2}^0 PU_{t/\lambda^2}^\lambda P, \tag{1.1}$$

has a limit, for each fixed time t, as the coupling constant λ goes to zero. The limit is a one parameter semigroup, independent of λ. The generator of the resulting semigroup is often called the Davies generator. We will call this limit the pointwise (in time) van Hove limit without the first order term.

One can distinguish two approaches to semigroups, the time-dependent approach and the stationary approach. The former concentrates on the study of semigroups themselves. The latter

[a]Electronic mail: jan.derezinski@fuw.edu.pl
[b]Electronic mail: rafal.fruboes@fuw.edu.pl

focuses at the resolvent of their generators. Davies used the time-dependent approach, both in the choice of the assumptions for his results and in their statements. In our paper we use mostly the stationary approach.

Our main results are contained in three theorems. First in Theorem 3.1 we study, the stationary van Hove limit for the reduced dynamics as the coupling constant λ goes to zero. More precisely, we describe the asymptotics of the rescaled resolvent of L_λ reduced by P by the resolvent of a certain operator $A_{\lambda,0}$. This is the stationary counterpart to the first result of Davies.

Theorem 3.2 describes the case without the first order term ($PQP=0$). We additionally assume that the spectrum of PL_0P consist of isolated points. We obtain a simple asymptotics of the Laplace transform of (1.1) given by the resolvent of a certain operator Γ independent of λ commuting with PL_0P. We prove that the operator Γ is the generator of a contractive semigroup. This is the stationary counterpart to the second result of Davies.

The main results about the stationary van Hove limit involve resolvents. They have, however, easy time-dependent corollaries, which we call the smeared out weak coupling limit. By this we mean that the difference of the rescaled restricted dynamics and the approximating dynamics averaged over time with some continuous function of compact support tends to zero as the coupling constant goes to zero. This version of the result is also contained in Theorems 3.1 and 3.2.

In Theorem 3.3 we show how one can obtain pointwise (in time) van Hove limit without the first order term starting from the stationary van Hove limit.

Theorem 3.5 gives conditions when one can apply both the time-dependent method of Davies and our stationary results. We also find out that the semigroup obtained in the van Hove limit is generated by the so-called level shift operator, see Refs. 9–11 and 7.

In the physical literature one can trace back the weak coupling limit to works of Wigner–Weisskopf, Pauli and also van Hove.[18–20] First rigorous mathematical treatment of this issue comes from Davies,[4–6] who gave both its abstract theory and presented applications to open quantum systems (see also Ref. 14).

In his papers, Davies uses the time-dependent approach, i.e., he works with the restricted dynamics. The key step in this approach is the construction of the resulting semigroup by the integral formula (e.g., Theorem 3.1.33 in Ref. 3). The use of this formula induces technical assumptions which may be not easy to verify. For the convenience of the reader we describe the result of Davies in Theorem 3.4.

In our approach to the weak coupling limit, instead of working with the perturbed dynamics, we investigate the resolvent of the perturbed generator. We use some regularity assumptions for resolvents which seem easier to verify in some circumstances. In particular our regularity assumptions are closely related to the so-called limiting absorption principle which can be investigated with help of the so-called Mourre theory.[8]

We end this introduction with a description of the main physical motivation of our work—an application of the van Hove limit to open quantum systems. We essentially follow Ref. 14, see also Refs. 4 and 5. For more information, especially concerning the relationship of the van Hove limit to applications of the method of the level shift operator to the return to equilibrium, we refer the reader to Ref. 11. For related analysis of open quantum systems see also Refs. 15–17.

Let us consider a quantum mechanical system which consists of two parts—the small system $\mathcal{S}$ and the reservoir part $\mathcal{R}$. To describe $\mathcal{S}$ one chooses appropriate Hilbert space $\mathcal{H}_\mathcal{S}$. Then the states are given by density matrices (i.e., trace class normalized positive operators on $\mathcal{H}_\mathcal{S}$). The time evolution of the isolated small system $\mathcal{S}$ is implemented by the Hamiltonian $H_\mathcal{S}$. In a similar way we describe the reservoir part $\mathcal{R}$. We have Hilbert space $\mathcal{H}_\mathcal{R}$, the Liouvillean $L_\mathcal{R}$ (the generator of the time evolution) and density matrices on $\mathcal{H}_\mathcal{R}$. Let us additionally assume that there exists a stationary state, denoted $\omega_\mathcal{R}$, of $\mathcal{R}$ for the evolution implemented by $L_\mathcal{R}$.

The time evolution of whole system $\mathcal{S}+\mathcal{R}$ is given by self-adjoint operator

$$L_\lambda := H_\mathcal{S} \otimes \mathbf{1}_\mathcal{R} + \mathbf{1}_\mathcal{S} \otimes L_\mathcal{R} + \lambda V$$

acting on $\mathcal{H} := \mathcal{H}_\mathcal{S} \otimes \mathcal{H}_\mathcal{R}$ where V is some interaction operator and $\lambda \in \mathbb{R}$. Hence for any density matrix χ on $\mathcal{H}_\mathcal{S} \otimes \mathcal{H}_\mathcal{R}$ its evolution is given by

$$U_t^\lambda \chi := e^{-tiL_\lambda} \chi e^{tiL_\lambda}.$$

Assume that the initial state of $\mathcal{S}+\mathcal{R}$ is $\rho \otimes \omega_\mathcal{R}$ for some density matrix ρ on $\mathcal{H}_\mathcal{S}$. Then after time t the state of $\mathcal{S}+\mathcal{R}$ is given by $U_t^\lambda(\rho \otimes \omega_\mathcal{R})$. If we treat $\mathcal{R}$ just as a device which induces changes of $\mathcal{S}$ and we want only to know what happens to $\mathcal{S}$, then to obtain the state of $\mathcal{S}$ at time t we take the partial trace over the degrees of freedom of $\mathcal{R}$,

$$\rho(t) := \mathrm{tr}_\mathcal{R}(U_t^\lambda(\rho \otimes \omega_\mathcal{R})). \tag{1.2}$$

Note that the action of U_t^λ can be extended to the whole space of the trace class operators $B^1(\mathcal{H}_\mathcal{S} \otimes \mathcal{H}_\mathcal{R})$. Recall that $B^1(\mathcal{H}_\mathcal{S} \otimes \mathcal{H}_\mathcal{R})$ is a Banach space under the norm $\|\cdot\|_1 = \mathrm{tr}|\cdot|$ and U_t^λ is a one parameter strongly continuous group of isometries on $B^1(\mathcal{H}_\mathcal{S} \otimes \mathcal{H}_\mathcal{R})$. If we introduce the operator

$$P: B^1(\mathcal{H}_\mathcal{S} \otimes \mathcal{H}_\mathcal{R}) \to B^1(\mathcal{H}_\mathcal{S}) \otimes \omega_\mathcal{R} \subset B^1(\mathcal{H}_\mathcal{S} \otimes \mathcal{H}_\mathcal{R}),$$

$$PW := \mathrm{tr}_\mathcal{R}(W) \otimes \omega_\mathcal{R},$$

then P is a projection of norm one and the equation (1.2) can be rewritten

$$\rho(t) \otimes \omega_\mathcal{R} := PU_t^\lambda P(\rho \otimes \omega_\mathcal{R}).$$

Note also that $[U_t^0, P] = 0$. Therefore, we have a setup, where we can apply our results. In the weak coupling limit we obtain completely positive semigroup of contractions which is sometimes called a quantum dynamical Markov semigroup. Hence starting with a fully reversible dynamics for the whole system, we end up with an irreversible evolution of the small subsystem. Now, in the weak coupling approximation, when we study the small system we may exchange complicated object $PU_t^\lambda P$ for a semigroup and use it in order to determine physical quantities. However there is a price to be paid—the results that we get in this approximation are typically the lowest order nonvanishing corrections in the coupling constant to the real quantities.

II. PRELIMINARIES

Notation: Let $\mathcal{X}$ be a Banach space. For a linear operator L on $\mathcal{X}$, $\mathrm{sp}\, L$ denotes its spectrum and $\mathrm{Dom}\, L$ its domain. If Ξ is an isolated bounded subset of $\mathrm{sp}\, L$ then the spectral projection of L onto Ξ, defined by the usual integral formula,[13] is denoted $\mathbf{1}_\Xi(L)$. If e is an isolated point of $\mathrm{sp}\, L$, then we will write $\mathbf{1}_e(L)$ for $\mathbf{1}_{\{e\}}(L)$.

Let $\mathbf{1}^{v v}$ be a distinguished bounded projection on $\mathcal{X}$. It will be convenient to denote $\mathbf{1}^{\overline{v v}} := \mathbf{1} - \mathbf{1}^{v v}$. We also introduce closed subspaces

$$\mathcal{X}^v := \mathbf{1}^{v v}\mathcal{X}, \quad \mathcal{X}^{\overline{v}} := \mathbf{1}^{\overline{v v}}\mathcal{X} = \mathrm{Ker}\, \mathbf{1}^{v v},$$

so that $\mathcal{X}$ is decomposed into a direct sum

$$\mathcal{X} = \mathcal{X}^v \oplus \mathcal{X}^{\overline{v}}. \tag{2.1}$$

Any operator H on $\mathcal{X}$ satisfying

$$\mathrm{Dom}(H) = (\mathrm{Dom}(H) \cap \mathcal{X}^v) \oplus (\mathrm{Dom}(H) \cap \mathcal{X}^{\overline{v}})$$

can be written with respect to the decomposition (2.1) as

$$H=\begin{bmatrix} H^{vv} & H^{v\overline{v}} \\ H^{\overline{v}v} & H^{\overline{v}\overline{v}} \end{bmatrix} = H^{vv}+H^{v\overline{v}}+H^{\overline{v}v}+H^{\overline{v}\overline{v}}. \tag{2.2}$$

Obviously $H^{vv}=\mathbf{1}^{vv}H\mathbf{1}^{vv}$, etc. In particular

$$\mathbf{1}:=\begin{bmatrix} \mathbf{1}^{vv} & 0 \\ 0 & \mathbf{1}^{\overline{v}\overline{v}} \end{bmatrix}.$$

For $e\in i\mathbb{R}$ and for $\alpha\geqslant 0$ we denote

$$\mathbf{Wedge}(e,\alpha):=\{z\in\mathbb{C}:\operatorname{Re} z>0,|\operatorname{Im}(z-e)|\leqslant\alpha\operatorname{Re} z\}.$$

III. MAIN RESULTS

Let L_0 be the generator of a one parameter strongly continuous group of isometries $t\mapsto e^{tL_0}$ on the Banach space $\mathcal{X}$. Recall that L_0 is norm closed, norm densely defined, conservative operator (i.e., both L_0 and $-L_0$ are dissipative) and $\operatorname{sp} L_0\subset i\mathbb{R}$.[3,6]

Let $\mathbf{1}^{vv}$ be a distinguished projection on $\mathcal{X}$ such that $\|\mathbf{1}^{vv}\|=1$. Assume that $\mathbf{1}^{vv}$ commutes with L_0 or equivalently $[\mathbf{1}^{vv},e^{tL_0}]=0$ for all t. Then the operator L_0 written with respect to the decomposition (2.1) has the form

$$L_0=\begin{bmatrix} L_0^{vv} & 0 \\ 0 & L_0^{\overline{v}\overline{v}} \end{bmatrix}. \tag{3.1}$$

We write for shortness $E:=L_0^{vv}$. Note that E generates a one parameter strongly continuous group of isometries on $\mathcal{X}^v$.

Let Q with $\operatorname{Dom} L_0\subset\operatorname{Dom} Q$ be another operator that we will treat as a perturbation of L_0. Fix $\lambda_0>0$. We assume that for $0\leqslant\lambda<\lambda_0$ the operator

$$L_\lambda:=L_0+\lambda Q,$$

defined on $\operatorname{Dom} L_\lambda=\operatorname{Dom} L_0$ is the generator of a one parameter strongly continuous semigroup of contractions on $\mathcal{X}$.

We will assume that the off-diagonal elements of Q, i.e., $Q^{\overline{v}v}$ and $Q^{v\overline{v}}$ are bounded. We also assume that for all $0\leqslant\lambda<\lambda_0$ operator $E+\lambda Q^{vv}$ generates a group of isometries on $\mathcal{X}^v$.

Note that if L_λ with bounded $Q^{\overline{v}v}$ and $Q^{v\overline{v}}$ generates a group of isometries then $E+\lambda Q^{vv}$ generates a group of isometries on $\mathcal{X}^v$.

A. Van Hove limit—stationary approach

In this section we discuss the van Hove limit under the assumptions involving the resolvent of L_λ. The statement of our result is similar to the statement of the results of Davies, which we recall later.

1. Van Hove limit with the first order term

Theorem 3.1: *Assume that for all* $0\leqslant\lambda<\lambda_0$ *:*

(i) *For all* $\xi>0$ *we have* $\xi\notin\operatorname{sp}(L_\lambda^{\overline{v}\overline{v}})$,
(ii) *there exists an operator* $\Gamma_0\in B(\mathcal{X}^v)$ *such that, for any* $\xi>0$,

$$\Gamma_0:=\lim_{\lambda\searrow 0} Q^{v\overline{v}}(\lambda^2\xi\mathbf{1}^{\overline{v}\overline{v}}-L_\lambda^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}v}. \tag{3.2}$$

[*Note that the right-hand side (RHS) of (3.2) may depend on* ξ*. We assume that it does not*].

Let

$$A_{\lambda,0} := E + \lambda Q^{vv} + \lambda^2 \Gamma_0. \tag{3.3}$$

Then the following holds:

(1) Γ_0 *generates a semigroup of contractions on* $\mathcal{X}^v$.
(2) $A_{\lambda,0}$ *generates a semigroup of contractions on* $\mathcal{X}^v$.
(3) *For each* $\xi > 0$,

$$\lim_{\lambda \searrow 0} (\mathbf{1}^{vv}(\xi 1 - \lambda^{-2} L_\lambda)^{-1} \mathbf{1}^{vv} - (\xi \mathbf{1}^{vv} - \lambda^{-2} A_{\lambda,0})^{-1}) = 0. \tag{3.4}$$

(4) *For any* $f \in C_0([0,\infty[)$

$$\lim_{\lambda \searrow 0} \int_0^\infty f(\sigma)(\mathbf{1}^{vv} e^{\sigma \lambda^{-2} L_\lambda} \mathbf{1}^{vv} - e^{\sigma \lambda^{-2} A_{\lambda,0}}) \mathrm{d}\sigma = 0. \tag{3.5}$$

Note that above we use the notation $(z\mathbf{1}^{\overline{vv}} - L_\lambda^{\overline{vv}})^{-1}$ for the inverse of the operator $z\mathbf{1}^{\overline{vv}} - L_\lambda^{\overline{vv}}$ restricted to $\mathcal{X}^{\overline{v}}$. We will often use a similar notation without a comment.

2. Van Hove limit without the first order term

In this section we describe two versions of the van Hove limit without the first order term. In the first we either work at the resolvents or smear out the dynamics in time. In the second, we work at the dynamics pointwise in time. The statement of the second result is essentially the same as that of Davies, however assumptions are different.

We will need the following additional assumptions.

Assumption 3.A: $\mathrm{sp}\, E$ *is a finite set.*

Note that Assumption 3.A implies that we can write

$$\mathbf{1}^{vv} = \sum_{e \in \mathrm{sp}\, E} \mathbf{1}_e(E).$$

Assumption 3.B: $Q^{vv} = 0$.

Theorem 3.2: *Let Assumptions 3.A and 3.B hold. Assume additionally that*

(i) *for* $0 \leqslant \lambda < \lambda_0$, *for each* $e \in \mathrm{sp}\, E$ *and for all* $\xi > 0$ *we have* $e + \xi \notin \mathrm{sp}(L_\lambda^{\overline{vv}})$,
(ii) *there exists an operator* $\Gamma \in B(\mathcal{X}^v)$ *such that, for any* $\xi > 0$,

$$\Gamma := \sum_{e \in \mathrm{sp}\, E} \lim_{\lambda \searrow 0} \mathbf{1}_e(E) Q^{v\overline{v}}((e + \lambda^2 \xi)\mathbf{1}^{\overline{vv}} - L_\lambda^{\overline{vv}})^{-1} Q^{\overline{v}v} \mathbf{1}_e(E). \tag{3.6}$$

[*Note that the RHS of (3.6) may depend on* ξ. *We assume that it does not*].

(iii) *For any* $e, e' \in \mathrm{sp}\, E$, $e \neq e'$ *and* $\xi > 0$,

$$\lim_{\lambda \searrow 0} \lambda \mathbf{1}_e(E) Q^{v\overline{v}}((e + \lambda^2 \xi)\mathbf{1}^{\overline{vv}} - L_\lambda^{\overline{vv}})^{-1} Q^{\overline{v}v} \mathbf{1}_{e'}(E) = 0,$$

$$\lim_{\lambda \searrow 0} \lambda \mathbf{1}_{e'}(E) Q^{v\overline{v}}((e + \lambda^2 \xi)\mathbf{1}^{\overline{vv}} - L_\lambda^{\overline{vv}})^{-1} Q^{\overline{v}v} \mathbf{1}_e(E) = 0.$$

Then the following holds:

(1) Γ *generates semigroup of contractions on* $\mathcal{X}^v$,
(2) $[E, \Gamma] = 0$,
(3) *for each* $\xi > 0$ *we have*

$$\lim_{\lambda \searrow 0} \sum_{e \in \mathrm{sp}\, E} \mathbf{1}_e(E) \mathbf{1}^{vv} (\xi 1 - \lambda^{-2}(L_\lambda - e1))^{-1} \mathbf{1}^{vv} = (\xi \mathbf{1}^{vv} - \Gamma)^{-1}, \tag{3.7}$$

(4) *for any* $f \in C_0([0,\infty[)$,

$$\lim_{\lambda\searrow 0}\int_0^\infty f(\sigma)(e^{-\sigma\lambda^{-2}E}\mathbf{1}^{vv}e^{\sigma\lambda^{-2}L_\lambda}\mathbf{1}^{vv}-e^{\sigma\Gamma})\mathrm{d}\sigma=0. \tag{3.8}$$

Theorem 3.3: *Let assumptions 3.A and 3.B hold. Assume additionally that*

(i) *for* $0\leqslant\lambda<\lambda_0$ *and all* $\xi\in\mathbb{C}$, $\mathrm{Re}\,\xi>0$, *we have* $\xi\notin\mathrm{sp}(L_\lambda^{\overline{vv}})$,

(ii) *for all* $\alpha_0\geqslant 0$ *and for any* $\xi\in\mathrm{Wedge}(0,\alpha_0)$, *there exists an operator* $\Gamma\in B(\mathcal{X}^v)$ *such that,*

$$\Gamma:=\sum_{e\in\mathrm{sp}\,E}\lim_{\lambda\searrow 0}\mathbf{1}_e(E)Q^{v\overline{v}}((e+\lambda^2\xi)\mathbf{1}^{\overline{vv}}-L_\lambda^{\overline{vv}})^{-1}Q^{\overline{v}v}\mathbf{1}_e(E), \tag{3.9}$$

[*Note that the RHS of (3.9) may depend on* ξ. *We assume that it does not*].

(iii) *For each* $e\in\mathrm{sp}\,E$ *we have*

$$\sup_{\mathrm{Re}\,\xi>0;0\leqslant\lambda<\lambda_0}\|Q^{v\overline{v}}((e+\lambda^2\xi)\mathbf{1}^{\overline{vv}}-L_\lambda^{\overline{vv}})^{-1}Q^{\overline{v}v}\|<\infty.$$

Then,

(1) *all statemants of the Theorem 3.2 hold. Besides (3) holds in a stronger form, for* $\alpha_0\geqslant 0$ *the formula (3.7) is valid for each* $\xi\in\mathrm{Wedge}(0,\alpha_0)$.

(2) *Let* $\psi\in\mathcal{X}^v$. *For* $\sigma\geqslant 0$ *we have*

$$\lim_{\lambda\searrow 0}(e^{-\sigma\lambda^{-2}E}\mathbf{1}^{vv}e^{\sigma\lambda^{-2}L_\lambda}\mathbf{1}^{vv}-e^{\sigma\Gamma})\psi=0 \tag{3.10}$$

uniformly for $\sigma\in[\tau_0,\tau_1]$ *for any fixed* $0<\tau_0\leqslant\tau_1<\infty$.

B. Van Hove limit—time-dependent approach

In this section we discuss the van Hove limit under the assumptions involving the dynamics. In Theorem 3.4 we recall the original approach to the van Hove limit due to Davies.[4–6] (Strictly speaking, Davies assumed that the perturbation Q is bounded. In Theorem 3.4 we impose slightly less restrictive assumptions, which can be handled by an essentially the same proof.)

Let L_0, Q, and $\mathbf{1}^{vv}$ be the same as before. Clearly, $L_\lambda^{\overline{vv}}$ generates a semigroup on $\mathcal{X}^{\overline{v}}$. Therefore, we can define the operator

$$K(\lambda,\tau):=\int_{x=0}^{\lambda^{-2}\tau}e^{-xL_\lambda^{vv}}Q^{v\overline{v}}e^{xL_\lambda^{\overline{vv}}}Q^{\overline{v}v}\,\mathrm{d}x. \tag{3.11}$$

The following theorem describes the van Hove limit for the dynamics in both cases—with and without the first order term.

Theorem 3.4: *Assume additionally that*

(i) *for all* $\tau_1>0$ *there is a constant* $C>0$ *such that* $\|K(\lambda,\tau)\|<C$ *for* $|\lambda|\leqslant 1$ *and* $0\leqslant\tau\leqslant\tau_1$.

(ii) *There exists bounded operator* K *on* $\mathcal{X}^v$ *such that if* $0<\tau_0\leqslant\tau_1<\infty$ *then*

$$\lim_{\lambda\searrow 0}(\sup_{\tau_0\leqslant\tau\leqslant\tau_1}\|K(\lambda,\tau)-K\|)=0.$$

Then the following holds:

(1)

$$\lim_{\lambda\searrow 0}\Big(\sup_{0\leqslant t\leqslant\tau_1}\|\mathbf{1}^{vv}e^{t\lambda^{-2}L_\lambda}\mathbf{1}^{vv}-e^{t\lambda^{-2}(E+\lambda Q^{vv}+\lambda^2K)}\|\Big)=0. \tag{3.12}$$

(2) *If additionally Assumptions 3.A and 3.B hold then*

$$\lim_{\lambda \searrow 0} \left(\sup_{0 \leqslant t \leqslant \tau_1} \| e^{-t\lambda^{-2}E} \mathbf{1}^{vv} e^{t\lambda^{-2}L_\lambda} \mathbf{1}^{vv} - e^{tK^\natural} \| \right) = 0, \tag{3.13}$$

where

$$K^\natural := \sum_{e \in \mathrm{sp}\, E} \mathbf{1}_e(E) K \mathbf{1}_e(E) = \lim_{a \to \infty} \frac{1}{2a} \int_{-a}^{a} e^{tE} K e^{-tE}\, \mathrm{d}t.$$

Let us recall how the operators $K(\lambda, \tau)$ are motivated. If we treat the off-diagonal elements of L_λ as a (bounded) perturbation of the diagonal part of L_λ then, by a well-known formula, we have

$$e^{tL_\lambda} = e^{t(L_\lambda^{vv} + L_\lambda^{\overline{vv}})} + \lambda \int_{s=0}^{t} e^{(t-s)(L_\lambda^{vv} + L_\lambda^{\overline{vv}})} (Q^{v\overline{v}} + Q^{\overline{v}v}) e^{sL_\lambda}\, \mathrm{d}s.$$

Using this formula one gets

$$\mathbf{1}^{vv} e^{\lambda^{-2}\tau L_\lambda} \mathbf{1}^{vv} = \mathbf{1}^{vv} e^{\lambda^{-2}\tau L_\lambda^{vv}} + \int_{\sigma=0}^{\tau} \mathbf{1}^{vv} e^{\lambda^{-2}(\tau-\sigma)L_\lambda^{vv}} K(\lambda, \tau - \sigma) \mathbf{1}^{vv} e^{\lambda^{-2}\sigma L_\lambda} \mathbf{1}^{vv}\, \mathrm{d}\sigma.$$

Now we discuss how one can obtain the van Hove limit for the resolvents under time-dependent assumptions. In fact we show when one can use both stationary and time-dependent approaches. We will concentrate on the case without the first order term.

Theorem 3.5: *Let Assumptions 3.A and 3.B hold. Assume additionally that*

(i) *for* $0 \leqslant \lambda < \lambda_0$ *and all* $z \in \mathbb{C}$, $\mathrm{Re}\, z > 0$ *we have* $z \notin \mathrm{sp}(L_\lambda^{\overline{vv}})$,

(ii) $\int_0^\infty \sup_{0 \leqslant \lambda < \lambda_0} \| Q^{v\overline{v}} e^{sL_\lambda^{\overline{vv}}} Q^{\overline{v}v} \| \mathrm{d}s < \infty$,

(iii) *for any* $s > 0$, $\lim_{\lambda \searrow 0} Q^{v\overline{v}} e^{sL_\lambda^{\overline{vv}}} Q^{\overline{v}v} = Q^{v\overline{v}} e^{sL_0^{\overline{vv}}} Q^{\overline{v}v}$.

Then

(1) *The assumptions of both Theorem 3.2 and Theorem 3.4 hold. Moreover, we have*

$$K^\natural = \Gamma.$$

(2) *The following limits exist, coincide and equal to* Γ:

$$\lim_{\epsilon \searrow 0} \sum_{e \in \mathrm{sp}\, E} \mathbf{1}_e(E) Q^{v\overline{v}} ((e + \epsilon)\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1} Q^{\overline{v}v} \mathbf{1}_e(E)$$

$$= \lim_{\epsilon \searrow 0} \sum_{e \in \mathrm{sp}\, E} \int_0^\infty e^{-\epsilon s} \mathbf{1}_e(E) Q e^{sL_0} Q e^{-sL_0} \mathbf{1}_e(E) \mathrm{d}s. \tag{3.14}$$

Note that the assumptions of Theorem 3.5 are stronger than that of Theorem 3.3 and Theorem 3.4 (2).

The operator (3.14) is often called the level shift operator. It is used to describe the second order shift of eigenvalues of L_λ.[7,9–11]

IV. PROOFS

Lemma 4.1: For $0 \leqslant \lambda < \lambda_0$ *the operator*

$$\widetilde{L}_\lambda = \begin{bmatrix} 0 & \lambda Q^{v\overline{v}} \\ \lambda Q^{\overline{v}v} & L_0^{\overline{vv}} + \lambda Q^{\overline{v}v} \end{bmatrix}$$

defined on $\mathrm{Dom}(\widetilde{L}_\lambda) = \mathcal{X}^v \oplus \mathrm{Dom}(L_0^{\overline{vv}})$ *generates a semigroup of contractions on* $\mathcal{X}$.

Proof: Let $0 \leqslant \lambda < \lambda_0$. The operator $\widetilde{L}_\lambda$ is densely defined. By the Lumer-Phillips theorem

(Theorem 3.1.16 in Ref. 3) it is sufficient to show that (I) $\widetilde{L}_\lambda$ is dissipative, (II) for some $\epsilon>0$ we have $\epsilon \notin \mathrm{sp}(\widetilde{L}_\lambda)$.

Step (I): For $0\leqslant\lambda$ the operator,

$$Z := L_\lambda - L_\lambda^{v\overline{v}}$$

with the domain $\mathrm{Dom}(Z)=\mathrm{Dom}(E)\oplus\mathrm{Dom}(L_0^{\overline{v}\overline{v}})$ is densely defined and dissipative. Hence, by Proposition 3.1.15 in Ref. 3, Z is closable and its closure is dissipative. But the closure of Z coincides with $\widetilde{L}_\lambda$.

Step (II): For $0\leqslant\lambda<\lambda_0$ the operator $L_\lambda-\lambda(Q^{v\overline{v}}+Q^{\overline{v}v})$ generates a semigroup such that for $\mathrm{Re}\, z>\|\lambda(Q^{v\overline{v}}+Q^{\overline{v}v})\|$ we have $z\notin \mathrm{sp}(L_\lambda-\lambda(Q^{v\overline{v}}+Q^{\overline{v}v}))$ and

$$\|(z\mathbf{1}-(L_\lambda-\lambda(Q^{v\overline{v}}+Q^{\overline{v}v})))^{-1}\|\leqslant(\mathrm{Re}\, z-\|\lambda(Q^{v\overline{v}}+Q^{\overline{v}v})\|)^{-1}.$$

Hence, for all $\epsilon>\epsilon_0$ for some ϵ_0 large enough,

$$\|(\epsilon\mathbf{1}-(\widetilde{L}_\lambda-\lambda(Q^{v\overline{v}}+Q^{\overline{v}v})))^{-1}(\lambda(Q^{v\overline{v}}+Q^{\overline{v}v}))\|<1.$$

Hence, by the Neumann theorem, $\epsilon\mathbf{1}-\widetilde{L}_\lambda$ is invertible for all $\epsilon\geqslant\epsilon_0$, and so $\epsilon\notin\mathrm{sp}(\widetilde{L}_\lambda)$. □

By the Feshbach projection method,[1,2,7,8] if $z\notin\mathrm{sp}(L_\lambda)\cup\mathrm{sp}(L_\lambda^{\overline{v}\overline{v}})$ then the restricted resolvent is given by

$$\mathbf{1}^{vv}(z\mathbf{1}-L_\lambda)^{-1}\mathbf{1}^{vv}=G_v^{-1}(z),$$

where

$$G_v(z)=z\mathbf{1}^{vv}-E-\lambda Q^{vv}-\lambda^2Q^{v\overline{v}}(z\mathbf{1}^{\overline{v}\overline{v}}-L_\lambda^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}v}.$$

Hence

$$\mathbf{1}^{vv}(\xi-\lambda^{-2}L_\lambda)^{-1}\mathbf{1}^{vv}=\lambda^2G_v^{-1}(\lambda^2\xi).$$

In what follows we will use these facts without a comment. (See Refs. 4 and 15–17.)

Proof of Theorem 3.1:

(1) By Lemma 4.1, the operator $\widetilde{L}_\lambda$ generates a semigroup of contractions, which for $\xi>0$ implies

$$\|(\xi\mathbf{1}^{vv}-\lambda^2Q^{v\overline{v}}(\xi\mathbf{1}^{\overline{v}\overline{v}}-L_\lambda^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}v})^{-1}\|=\|\mathbf{1}^{vv}(\xi\mathbf{1}-\widetilde{L}_\lambda)^{-1}\mathbf{1}^{vv}\|\leqslant\xi^{-1}.$$

Hence, for all $\xi>\xi_0>0$, the operator $(\xi\mathbf{1}^{vv}-Q^{v\overline{v}}(\lambda^2\xi\mathbf{1}^{\overline{v}\overline{v}}-L_\lambda^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}v})^{-1}$ is uniformly bounded. We know that for any $\xi>0$,

$$\lim_{\lambda\searrow0}(\xi\mathbf{1}^{\overline{v}\overline{v}}-Q^{v\overline{v}}(\xi\lambda^2\mathbf{1}^{\overline{v}\overline{v}}-L_\lambda^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}v})=\xi\mathbf{1}^{\overline{v}\overline{v}}-\Gamma_0. \tag{4.1}$$

Therefore, for all $\xi>\xi_0$, the operator $\xi\mathbf{1}^{vv}-\Gamma_0$ is invertible on $\mathcal{X}^v$ and

$$\|(\xi\mathbf{1}^{vv}-\Gamma_0)^{-1}\|\leqslant\xi^{-1}.$$

Hence Γ_0 generates a semigroup of contractions on $\mathcal{X}^v$ (Theorem 2.21 and Corollary 2.22 in Ref. 6).

(2) Let $0\leqslant\lambda<\lambda_0$. Since $E+\lambda Q^{vv}$ generates a group of isometries and Γ_0 is bounded and dissipative then the result follows from Theorem 3.1.32 in Ref. 3.

(3) Let $0<\lambda<\lambda_0$. Recall that for $\xi>0$,

$$\|\lambda^2G_v^{-1}(\lambda^2\xi)\|\leqslant\xi^{-1}, \tag{4.2}$$

$$\|(\xi \mathbf{1}^{v\bar{v}} - \lambda^{-2} A_{\lambda,0})^{-1}\| \leqslant \xi^{-1}, \tag{4.3}$$

$$\lim_{\lambda \searrow 0} Q^{v\bar{v}} (\lambda^2 \xi \mathbf{1}^{\bar{v}\bar{v}} - L_\lambda^{\bar{v}\bar{v}})^{-1} Q^{\bar{v}\bar{v}} = \Gamma_0. \tag{4.4}$$

For any $\xi > 0$ we have

$$\begin{aligned} &\|\mathbf{1}^{vv}(\xi \mathbf{1} - \lambda^{-2} L_\lambda)^{-1} \mathbf{1}^{vv} - (\xi \mathbf{1}^{vv} - \lambda^{-2} A_{\lambda,0})^{-1}\| \\ &\quad = \|\lambda^2 G_v^{-1}(\lambda^2 \xi)(Q^{v\bar{v}}(\lambda^2 \xi \mathbf{1}^{\bar{v}\bar{v}} - L_\lambda^{\bar{v}\bar{v}})^{-1} Q^{\bar{v}\bar{v}} - \Gamma_0)(\xi \mathbf{1}^{vv} - \lambda^{-2} A_{\lambda,0})^{-1}\|. \end{aligned}$$

Hence by (4.2)–(4.4) the RHS of the above expression tends to zero as λ tends to zero.

(4) For $\xi > 0$, by the Laplace transform, we have

$$\mathbf{1}^{vv}(\xi \mathbf{1} - \lambda^{-2} L_\lambda)^{-1} \mathbf{1}^{vv} - (\xi \mathbf{1}^{vv} - \lambda^{-2} A_{\lambda,0})^{-1} = \int_0^\infty e^{-\xi\sigma} (\mathbf{1}^{vv} e^{\lambda^{-2}\sigma L_\lambda} \mathbf{1}^{vv} - e^{\lambda^{-2}\sigma A_{\lambda,0}}) \mathrm{d}\sigma.$$

Hence by (3.4) we get

$$\lim_{\lambda \searrow 0} \int_0^\infty e^{-\xi\sigma} (\mathbf{1}^{vv} e^{\lambda^{-2}\sigma L_\lambda} \mathbf{1}^{vv} - e^{\lambda^{-2}\sigma A_{\lambda,0}}) \mathrm{d}\sigma = 0. \tag{4.5}$$

By the Stone–Weierstrass theorem, the family of functions

$$[0, \infty[\ni \sigma \mapsto e^{-\xi\sigma} \in \mathbb{R}, \quad \xi > 0$$

forms an algebra which is dense in continuous functions of compact support on $[0, \infty[$. This fact together with (4.5) implies (3.5). □

Lemma 4.2: Let E be the generator of a group of isometries. Let e be an isolated point in $\mathrm{sp}(E)$. *Then e is a semisimple eigenvalue which means $E\mathbf{1}_e(E) = e\mathbf{1}_e(E)$ and $\|\mathbf{1}_e(E)\| = 1$.*

Proof: Let e be an isolated point in $\mathrm{sp}(E)$. Then for any $\epsilon > 0$,

$$\|((e + \epsilon)\mathbf{1}^{vv} - E)^{-1}\| \leqslant \epsilon^{-1}. \tag{4.6}$$

So for $z \in \{z \in \mathbb{C} : \mathrm{dist}(e, z) < \delta\} \setminus \{e\}$ for some $\delta > 0$ we have

$$(z\mathbf{1}^{vv} - E)^{-1} = \mathbf{1}_e(E)(z - e)^{-1} + h(z), \tag{4.7}$$

where h is an analytic function on $\{z \in \mathbb{C} : \mathrm{dist}(e, z) < \delta\}$. Hence e is semisimple. But (4.7) also implies that

$$\lim_{\epsilon \searrow 0} \epsilon((e + \epsilon)\mathbf{1}^{vv} - E)^{-1} = \mathbf{1}_e(E)$$

and hence, by (4.6), we get $\|\mathbf{1}_e(E)\| = 1$. □

For an isolated point $e \in \mathrm{sp}\, E$ let us write for shortness

$$\mathbf{1}^{ee} := \mathbf{1}_e(E), \quad \mathbf{1}^{\underline{e}\underline{e}} := \mathbf{1}^{vv} - \mathbf{1}_e(E),$$

$$\mathcal{X}^e := \mathrm{Ran}\, \mathbf{1}_e(E), \quad \mathcal{X}^{\underline{e}} := \mathrm{Ran}\, \mathbf{1}^{\underline{e}\underline{e}}$$

then

$$\mathcal{X}^v = \mathcal{X}^e \oplus \mathcal{X}^{\underline{e}}. \tag{4.8}$$

If $e', e \in \mathrm{sp}\, E$ and $A \in B(\mathcal{X}^v)$ then we denote $A^{e'e} := \mathbf{1}^{e'e'} A \mathbf{1}^{ee}$.

Proof of Theorem 3.2: (2) follows immediately if we note that Lemma 4.2 implies $E = \Sigma_{e \in \mathrm{sp}\, E} e\mathbf{1}_e(E)$ and that we have $\Gamma := \Sigma_{e \in \mathrm{sp}\, E} \mathbf{1}_e(E) \Gamma \mathbf{1}_e(E)$.

(3) Let $e \in \mathrm{sp}\, E$. Set

$$G_\lambda(\xi,e) := \xi \mathbf{1}^{v v} + \lambda^{-2}(e\mathbf{1}^{v v} - E) - Q^{v\bar{v}}((\lambda^2\xi + e)\mathbf{1}^{\bar{v}\bar{v}} - L_\lambda^{\bar{v}\bar{v}})^{-1}Q^{\bar{v}v}.$$

For $\xi > 0$ we have

$$G_\lambda(\xi,e)^{-1} = \mathbf{1}^{v v}(\xi + \lambda^{-2}(e - L_\lambda))^{-1}\mathbf{1}^{v v}.$$

This and the dissipativity of L_λ implies the bound

$$\|G_\lambda(\xi,e)^{-1}\| \leqslant \xi^{-1}. \tag{4.9}$$

Write for shortness G instead of $G_\lambda(\xi,e)$.

Decompose $G = G_{\mathrm{diag}} + G_{\mathrm{off}}$ into its diagonal and off-diagonal part,

$$G_{\mathrm{diag}} := \sum_{e' \in \mathrm{sp}\, E} \mathbf{1}^{e'e'} G \mathbf{1}^{e'e'},$$

$$G_{\mathrm{off}} := \sum_{e' \in \mathrm{sp}\, E} \mathbf{1}^{e'e'} G \mathbf{1}^{\underline{e}'\underline{e}'} = \sum_{e' \in \mathrm{sp}\, E} \mathbf{1}^{\underline{e}'\underline{e}'} G \mathbf{1}^{e'e'}.$$

First we would like to show that for $\xi > 0$ and small enough λ, G_{diag} is invertible. By the Neumann theorem, it is easy to see that $\mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{diag}}$ is invertible on $\mathrm{Ran}\, \mathbf{1}^{\underline{e}\underline{e}}$ for small enough λ. Moreover, we have

$$\|\mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{diag}}^{-1}\| \leqslant c\lambda^2. \tag{4.10}$$

It is more complicated to prove that $\mathbf{1}^{ee} G_{\mathrm{diag}}$ is invertible on $\mathrm{Ran}\, \mathbf{1}^{ee}$.

We fix $\xi > 0$. We know that G is invertible and $\|G^{-1}\| \leqslant \xi^{-1}$. Hence we can write

$$G_{\mathrm{diag}} G^{-1} = 1 - G_{\mathrm{off}} G^{-1}.$$

Therefore

$$\mathbf{1}^{ee} G_{\mathrm{diag}} G^{-1} = \mathbf{1}^{ee} - \mathbf{1}^{ee} G_{\mathrm{off}} \mathbf{1}^{\underline{e}\underline{e}} G^{-1},$$

$$\mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{diag}} G^{-1} = \mathbf{1}^{\underline{e}\underline{e}} - \mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{off}} G^{-1}. \tag{4.11}$$

The latter identity can be for small enough λ transformed into

$$\mathbf{1}^{\underline{e}\underline{e}} G^{-1} = G_{\mathrm{diag}}^{-1} \mathbf{1}^{\underline{e}\underline{e}} - G_{\mathrm{diag}}^{-1} \mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{off}} G^{-1}. \tag{4.12}$$

We insert (4.12) into the first identity of (4.11) to obtain

$$\mathbf{1}^{ee} G_{\mathrm{diag}} G^{-1} = \mathbf{1}^{ee} - \mathbf{1}^{ee} G_{\mathrm{off}} \mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{diag}}^{-1} + \mathbf{1}^{ee} G_{\mathrm{off}} \mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{diag}}^{-1} G_{\mathrm{off}} G^{-1}. \tag{4.13}$$

We multiply (4.13) from the right by $\mathbf{1}^{ee}$ to get

$$\mathbf{1}^{ee} G_{\mathrm{diag}} \mathbf{1}^{ee} G^{-1} \mathbf{1}^{ee} = \mathbf{1}^{ee} + \mathbf{1}^{ee} G_{\mathrm{off}} \mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{diag}}^{-1} G_{\mathrm{off}} G^{-1} \mathbf{1}^{ee}. \tag{4.14}$$

Now, using

$$\lim_{\lambda \searrow 0} \|\lambda G_{\mathrm{off}}\| = 0, \tag{4.15}$$

(4.9) and (4.10) we obtain

$$\lim_{\lambda \searrow 0} \mathbf{1}^{ee} G_{\mathrm{off}} \mathbf{1}^{\underline{e}\underline{e}} G_{\mathrm{diag}}^{-1} G_{\mathrm{off}} G^{-1} \mathbf{1}^{ee} = 0.$$

Thus, for small enough λ,

$$\mathbf{1}^{ee}G_{\mathrm{diag}}B_1 = \mathbf{1}^{ee},$$

where

$$B_1 := \mathbf{1}^{ee}G^{-1}\mathbf{1}^{ee}(\mathbf{1}^{ee} + \mathbf{1}^{ee}G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G^{-1}\mathbf{1}^{ee})^{-1}.$$

Similarly, for small enough λ, we find B_2 such that

$$B_2\mathbf{1}^{ee}G_{\mathrm{diag}} = \mathbf{1}^{ee}.$$

This implies that $\mathbf{1}^{ee}G_{\mathrm{diag}}$ is invertible on $\mathrm{Ran}\,\mathbf{1}^{ee}$.

Next, we can write

$$G^{-1} = G_{\mathrm{diag}}^{-1} - G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G_{\mathrm{diag}}^{-1} + G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G^{-1}.$$

Hence

$$\mathbf{1}^{ee}G^{-1} = \mathbf{1}^{ee}G_{\mathrm{diag}}^{-1}(\mathbf{1} - G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1} + G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G^{-1}). \tag{4.16}$$

Therefore, for a fixed ξ, by (4.9), (4.10), and (4.15), we see that as $\lambda \searrow 0$ we have

$$-G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1} + G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G^{-1} \to 0.$$

Therefore, for small enough λ, we can invert the expression in the prentheses of (4.16). Consequently,

$$\begin{aligned}\mathbf{1}^{ee}(G_{\mathrm{diag}}^{-1} - G^{-1}) = \mathbf{1}^{ee}G^{-1}&(1 - G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1} + G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G^{-1})^{-1}\\ &\times (G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1} - G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}G^{-1}).\end{aligned} \tag{4.17}$$

Therefore, for a fixed ξ, by (4.9), (4.10), and (4.15), we see that as $\lambda \searrow 0$ we have

$$\mathbf{1}^{ee}(G_{\mathrm{diag}}^{-1} - G^{-1}) \to 0. \tag{4.18}$$

Equations (4.9) and (4.18) imply that $\mathbf{1}^{ee}G_{\mathrm{diag}}^{-1}$ is uniformly bounded as $\lambda \searrow 0$. We know that

$$\mathbf{1}^{ee}G_{\mathrm{diag}} \to \mathbf{1}^{ee}\xi - \mathbf{1}^{ee}\Gamma. \tag{4.19}$$

Therefore, $\xi\mathbf{1}^{ee} - \mathbf{1}^{ee}\Gamma$ is invertible on $\mathrm{Ran}\,\mathbf{1}^{ee}$ and

$$\mathbf{1}^{ee}G_{\mathrm{diag}}^{-1} \to (\mathbf{1}^{ee}\xi - \mathbf{1}^{ee}\Gamma)^{-1}.$$

Using again (4.18) we see that

$$\mathbf{1}^{ee}G^{-1} \to (\mathbf{1}^{ee}\xi - \mathbf{1}^{ee}\Gamma)^{-1}. \tag{4.20}$$

Summing up (4.20) over e we obtain

$$\sum_{e\in \mathrm{sp}\,E} \mathbf{1}^{ee}G_{\lambda}(\xi,e)^{-1} \to (\xi\mathbf{1}^{vv} - \Gamma)^{-1}, \tag{4.21}$$

which ends the proof of (3).

(1) We have

$$\sum_{e\in \mathrm{sp}\,E} \mathbf{1}^{ee}G_{\lambda}(\xi,e)^{-1} = \sum_{e\in \mathrm{sp}\,E}\int_0^{\infty} e^{-t(\xi+\lambda^{-2}e)}\mathbf{1}^{ee}e^{tL_{\lambda}/\lambda^2}\mathbf{1}^{vv}\,\mathrm{d}t = \int_0^{\infty} e^{-t\xi}e^{-tE/\lambda^2}\mathbf{1}^{vv}e^{tL_{\lambda}/\lambda^2}\mathbf{1}^{vv}\,\mathrm{d}t. \tag{4.22}$$

Clearly, $\|e^{-tE/\lambda^2}\mathbf{1}^{vv}e^{tL_{\lambda}/\lambda^2}\mathbf{1}^{vv}\| \leqslant 1$. Therefore,

$$\left\| \sum_{e \in \operatorname{sp} E} \mathbf{1}^{ee} G_\lambda(\xi,e)^{-1} \right\| \leqslant \xi^{-1}.$$

Hence, by (4.21),

$$\|(\xi \mathbf{1}^{vv} - \Gamma)^{-1}\| \leqslant \xi^{-1},$$

which means that Γ is the generator of a semigroup of contractions.

(4) To prove this we repeat the argument used in the proof of Theorem 3.1.

Proof of Theorem 3.3:

(1) Follows by a simple modification of the argument used in Theorem 3.2.

(2) For $e \in \operatorname{sp} E$ and for $\operatorname{Re} \xi > 0$ we denote

$$G_\lambda(\xi,e) := \xi \mathbf{1}^{vv} + \lambda^{-2}(e\mathbf{1}^{vv} - E) - Q^{v\overline{v}}((\lambda^2\xi + e)\mathbf{1}^{\overline{v}\overline{v}} - L_\lambda^{\overline{v}\overline{v}})^{-1} Q^{\overline{v}v}.$$

Obviously

$$G_\lambda(\xi,e)^{-1} = \mathbf{1}^{vv}(\xi + \lambda^{-2}(e - L_\lambda))^{-1}\mathbf{1}^{vv}$$

and

$$\|G_\lambda(\xi,e)^{-1}\| \leqslant \operatorname{Re} \xi^{-1}. \tag{4.23}$$

Let $\psi \in \mathcal{X}^v$. Let $\omega_0 > 0$ and $\sigma \geqslant 0$. By the inverse Laplace transform (Ref. 12 Chap. XI) and by the proof of Theorem 3.2, uniformly for $0 < \tau_0 \leqslant \sigma \leqslant \tau_1$, we get

$$\begin{aligned}
&(e^{-\sigma\lambda^{-2}E}\mathbf{1}^{vv}e^{\sigma\lambda^{-2}L_\lambda}\mathbf{1}^{vv} - e^{\sigma\Gamma})\psi \\
&\quad = \frac{1}{2\pi i} \lim_{R\to\infty} \int_{\omega_0 + i[-R,R]} e^{\sigma\xi} \sum_{e \in \operatorname{sp} E} (\mathbf{1}^{ee}((\xi + \lambda^{-2}e)\mathbf{1} - \lambda^{-2}L_\lambda)^{-1}\mathbf{1}^{vv} - (\xi\mathbf{1}^{ee} - \Gamma^{ee})^{-1})\psi \, \mathrm{d}\xi \\
&\quad = \frac{1}{2\pi i} \sum_{e \in \operatorname{sp} E} \lim_{R\to\infty} \int_{-R}^{R} f_\lambda(y,e) i \, \mathrm{d}y,
\end{aligned}$$

where

$$f_\lambda(y,e) := e^{\sigma(\omega_0 + iy)}(\mathbf{1}^{ee}G_\lambda(\omega_0 + iy,e)^{-1} - ((\omega_0 + iy)\mathbf{1}^{ee} - \Gamma^{ee})^{-1})\psi.$$

For each $e \in \operatorname{sp} E$,

$$\left\| \frac{d}{dy} f_\lambda(y,e) \right\| \leqslant e^{\sigma\omega_0} 2(\sigma\omega_0^{-1} + \omega_0^{-2})\|\psi\|.$$

This shows that the family $f_\lambda(y,e)$ is equicontinuous as $\lambda \to 0$.

For any fixed $R > 0$ if only $\alpha_0 = (R+1)/\omega_0$ then $\xi = \omega_0 + iy \in \operatorname{Wedge}(0,\alpha_0)$ hence, by (1), we get the pointwise convergence $f_\lambda(y,e) \to 0$ as $\lambda \searrow 0$ for $y \in [-R,R]$. Finally pointwise convergence together with equicontinuity implies uniform convergence on compacts, so for any fixed $R > 0$,

$$\lim_{\lambda \searrow 0} \int_{-R}^{R} f_\lambda(y,e)\psi i \, \mathrm{d}y = \int_{-R}^{R} \lim_{\lambda \searrow 0} f_\lambda(y,e)\psi i \, \mathrm{d}y = 0.$$

To end the proof it is sufficient to show that for each $e \in \operatorname{sp} E$,

$$\lim_{R\to\infty} \sup_{0 \leqslant \lambda < \lambda_0} \left\| \int_{|y|>R} f_\lambda(y,e) i \, \mathrm{d}y \right\| = 0.$$

Since Γ^{ee} is independent of λ we need only to show that

$$\lim_{R\to\infty}\sup_{0\leqslant\lambda<\lambda_0}\left\|\int_{|y|>R} e^{\sigma(\omega_0+iy)}\mathbf{1}^{ee}G_\lambda(\omega_0+iy,e)^{-1}\psi\,\mathrm{d}y\right\|=0. \tag{4.24}$$

Decompose $G_\lambda(\xi,e)$ into its diagonal and off-diagonal part,

$$G_{\mathrm{diag}}:=\sum_{e'\in\mathrm{sp}\,E}\mathbf{1}^{e'e'}G_\lambda(\xi,e)\mathbf{1}^{e'e'}=\xi\mathbf{1}^{ee}-T_\lambda(\xi,e)^{ee}+\sum_{e'\in\mathrm{sp}\,E;e'\neq e}((\xi-\lambda^{-2}(e'-e))\mathbf{1}^{e'e'}$$
$$-T_\lambda(\xi,e)^{e'e'}),$$

$$G_{\mathrm{off}}:=\sum_{e'\in\mathrm{sp}\,E}\mathbf{1}^{e'e'}G_\lambda(\xi,e)\mathbf{1}^{e'\underline{e}'}=\sum_{e'\in\mathrm{sp}\,E}\mathbf{1}^{e'\underline{e}'}G_\lambda(\xi,e)\mathbf{1}^{e'e'}=\sum_{e'\in\mathrm{sp}\,E}T_\lambda(\xi,e)^{e'\underline{e}'},$$

where

$$T_\lambda(\xi,e):=Q^{v\overline{v}}((\lambda^2\xi+e)\mathbf{1}^{\overline{v}\overline{v}}-L_0^{\overline{v}\overline{v}}-\lambda Q^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}v}.$$

By the assumption for each $e\in\mathrm{sp}\,E$

$$\sup_{\mathrm{Re}\,\xi>0;0\leqslant\lambda<\lambda_0}\|T_\lambda(\xi,e)\|<C<\infty. \tag{4.25}$$

In the rest of the proof we write for shortness $G=G_\lambda(\xi,e)$ and $T=T_\lambda(\xi,e)$.

Fix $e\in\mathrm{sp}\,E$ and let $\xi:=\omega_0+iy$. Fix $\omega_0>C+1$. Then, by the Neumann theorem, the operator $\mathbf{1}^{ee}G_{\mathrm{diag}}=\xi\mathbf{1}^{ee}-T^{ee}$ is invertible on $\mathcal{X}^e$ and we have

$$\|(\xi\mathbf{1}^{ee}-T^{ee})^{-1}\|\leqslant(|y|-C)^{-1}\quad\text{for }|y|>C. \tag{4.26}$$

Note that for each $e'\in\mathrm{sp}\,E$, $e'\neq e$ the operator $\lambda^{-2}(e'-e)\mathbf{1}^{e'e'}$ generates a group of isometries on $\mathcal{X}^{e'}$. Hence the operator $\mathbf{1}^{e'e'}G_{\mathrm{diag}}=(\xi-\lambda^{-2}(e'-e))\mathbf{1}^{e'e'}-T^{e'e'}$ is invertible on $\mathcal{X}^{e'}$ and we have

$$\|((\xi-\lambda^{-2}(e'-e))\mathbf{1}^{e'e'}-T^{e'e'})^{-1}\|\leqslant(\omega_0-C)^{-1}<1. \tag{4.27}$$

This shows that G_{diag} is invertible on $\mathcal{X}^v$. We have

$$\mathbf{1}^{ee}G^{-1}=\mathbf{1}^{ee}G_{\mathrm{diag}}^{-1}(\mathbf{1}^{ee}-G_{\mathrm{off}}\mathbf{1}^{\underline{e}e}G^{-1})=\xi^{-1}(\mathbf{1}^{ee}+T^{ee}(\xi\mathbf{1}^{ee}-T^{ee})^{-1})(\mathbf{1}^{ee}-G_{\mathrm{off}}\mathbf{1}^{\underline{e}e}G^{-1})$$
$$=\xi^{-1}(\mathbf{1}^{ee}+T^{ee}(\xi\mathbf{1}^{ee}-T^{ee})^{-1})(\mathbf{1}^{ee}-G_{\mathrm{off}}\mathbf{1}^{\underline{e}e}G_{\mathrm{diag}}^{-1}+G_{\mathrm{off}}\mathbf{1}^{\underline{e}e}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}\mathbf{1}^{ee}G^{-1}).$$

Now, using (4.23) and (4.25)–(4.27), we get for $|y|>C$,

$$\|\xi^{-1}T^{ee}(\xi\mathbf{1}^{ee}-T^{ee})^{-1}(\mathbf{1}^{ee}-G_{\mathrm{off}}\mathbf{1}^{\underline{e}e}G^{-1})\|\leqslant D_1(\omega_0^2+y^2)^{-1/2}(|y|-C)^{-1}$$

$$\|\xi^{-1}G_{\mathrm{off}}\mathbf{1}^{\underline{e}e}G_{\mathrm{diag}}^{-1}G_{\mathrm{off}}\mathbf{1}^{ee}G^{-1}\|\leqslant D_1(\omega_0^2+y^2)^{-1/2}(|y|-C)^{-1}$$

for some $D_1>0$ independent of λ. Hence to prove (4.24) if suffices to show that

$$\lim_{R\to\infty}\sup_{|\lambda|<\lambda_0}\left\|\int_{|y|>R}e^{\sigma(\omega_0+iy)}(\omega_0+iy)^{-1}(\mathbf{1}^{ee}-G_{\mathrm{off}}\mathbf{1}^{\underline{e}e}G_{\mathrm{diag}}^{-1})\psi\,\mathrm{d}y\right\|=0.$$

The first term in the above expression is independent of λ hence we need only to consider the second term. We have

$$\mathbf{1}^{\underline{e}e}G_{\mathrm{diag}}^{-1}=\sum_{e'\in\mathrm{sp}\,E;e'\neq e}(\xi-\lambda^{-2}(e'-e))^{-1}(\mathbf{1}^{e'e'}+T^{e'e'}((\xi-\lambda^{-2}(e'-e))\mathbf{1}^{e'e'}-T^{e'e'})^{-1}).$$

Hence, by (4.25) and (4.27), we get

$$\|e^{\sigma(\omega_0+iy)}(\omega_0+iy)^{-1}G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1}\| \leqslant D_2 g(y)g(y-\lambda^{-1}\,\mathrm{Im}(e'-e)) \tag{4.28}$$

for some $D_2>0$ independent of λ, where

$$\mathbb{R} \ni y \mapsto g(y) := (\omega_0^2+y^2)^{-1/2} \in \mathbb{R}.$$

By the Hölder inequality

$$\int_{|y|>R} g(y)g(y-\lambda^{-1}\,\mathrm{Im}(e'-e))\mathrm{d}y \leqslant \|g\|_{L^2(]-\infty,-R]\cup[R,\infty[,\mathrm{dx})}\|g\|_{L^2(\mathbb{R},\mathrm{dx})} \to 0. \tag{4.29}$$

Now, by (4.28) and (4.29), we get

$$\left\| \int_{|y|>R} e^{\sigma(\omega_0+iy)}(\omega_0+iy)^{-1}G_{\mathrm{off}}\mathbf{1}^{\underline{ee}}G_{\mathrm{diag}}^{-1}\psi\,\mathrm{d}y \right\| \to 0$$

independently of λ. This ends the proof of (3.10). □

Proof of Theorem 3.5: Set

$$f(s) := \sup_{|\lambda|<\lambda_0} \|Q^{v\overline{v}}e^{sL_\lambda^{\overline{vv}}}Q^{\overline{v}v}\|.$$

We know that $f(t)$ is integrable.

For any $e \in i\mathbb{R}$ and $\xi \geqslant 0$ we can dominate the integrand in the integral,

$$F_\lambda(e,\xi) := \int_0^\infty Q^{v\overline{v}}e^{sL_\lambda^{\overline{vv}}}Q^{\overline{v}v}e^{-(e+\lambda^2\xi)s}\,\mathrm{d}s = Q^{v\overline{v}}(\mathbf{1}^{\overline{vv}}(e+\lambda^2\xi)-L_\lambda^{\overline{vv}})^{-1}Q^{\overline{v}v} \tag{4.30}$$

by $f(s)$. Hence, using the dominated convergence theorem we see that $F_\lambda(e,\xi)$ is continuous at $\lambda=0$ and $\xi\geqslant 0$. But

$$\sum_{e\in\mathrm{sp}\,E}\mathbf{1}_e(E)F_0(e,0)\mathbf{1}_e(E) = \sum_{e\in\mathrm{sp}\,E}\lim_{\lambda\to 0}\mathbf{1}_e(E)Q^{v\overline{v}}(\mathbf{1}^{\overline{vv}}(e+\lambda^2\xi)-L_\lambda^{\overline{vv}})^{-1}Q^{\overline{v}v}\mathbf{1}_e(E) = \Gamma.$$

Recall (3.11), the definition of $K(\lambda,t)$,

$$K(\lambda,t) := \int_0^{\lambda^{-2}t} e^{-sE}Q^{v\overline{v}}e^{sL_\lambda^{\overline{vv}}}Q^{\overline{v}v}\,\mathrm{d}s.$$

Its integrand can also be dominated by $f(s)$. Hence, using again the dominated convergence theorem, we see that, for $\lambda\to 0$, $K(\lambda,t)$ is convergent to

$$K = \int_0^\infty e^{-sE}Q^{v\overline{v}}e^{sL_0^{\overline{vv}}}Q^{\overline{v}v}\,\mathrm{d}s.$$

Therefore,

$$K^\natural = \sum_{e\in\mathrm{sp}\,E}\mathbf{1}_e(E)\int_0^\infty e^{-es}Q^{v\overline{v}}e^{sL_0^{\overline{vv}}}Q^{\overline{v}v}\,\mathrm{d}s\,\mathbf{1}_e(E) = \sum_{e\in\mathrm{sp}\,E}1_e(E)F_0(e,0)\mathbf{1}_e(E).$$

Wigner measures dynamics in a Coulomb potential

Sahbi Keraani[a)]
IRMAR, Université de Rennes 1, Campus de Beaulieu, 35 042 Rennes Cedex, France

(Received 8 February 2005; accepted 5 April 2005; published online 8 June 2005)

In this paper, we are concerned with the propagation of the Wigner measure of a family of solutions to the semiclassical Schrödinger evolution equation with potential having Coulomb-type singularities in *three* space dimensions. We prove that after *collision* the Wigner measure is reflected by the potential singularities under the *regularized flow* as in classical mechanics. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1924705]

I. INTRODUCTION AND RESULTS

We consider the semiclassical Schrödinger evolution equation

$$i\varepsilon\partial_t v^\varepsilon = H^\varepsilon v^\varepsilon, \quad (t,x) \in \mathbb{R}\times\mathbb{R}^d,$$
$$v^\varepsilon(0,x) = v_I^\varepsilon(x) \in L^2(\mathbb{R}^d). \tag{1.1}$$

Here, ε is a small parameter and v_I^ε is a bounded family of $L^2(\mathbb{R}^d)$. The semiclassical Schrödinger operator $H^\varepsilon = -(\varepsilon^2/2)\Delta + U(x)$ is assumed to be self-adjoint on $L^2(\mathbb{R}^d)$. The self-adjointness of H^ε implies the following conservation law:

$$\int_{\mathbb{R}^d} |v^\varepsilon(t,x)|^2 \mathrm{d}x = \int_{\mathbb{R}^d} |v_I^\varepsilon(x)|^2 \mathrm{d}x, \quad \forall\, t \in \mathbb{R}.$$

A main question in the semiclassical theory is to calculate the homogenized density $\eta(t,x)$ (the limit as positive Radon measure when ε goes to 0) of the quadratic quantity

$$\eta^\varepsilon = |v^\varepsilon(t,x)|^2,$$

called *quantum position density*.

A basic tool in this context is some positive measure in the phase space called *Wigner measure*. It was developed independently by Gérard[3] and Lions and Paul.[10] Roughly speaking, and under appropriate assumptions on the family of the initial data v_I^ε, the homogenized density $\eta(t,x)$ is obtained as the moment in ξ-space of the Wigner measure associated to (v_t^ε). [Note that, throughout this paper, v_t^ε denotes the function $x \mapsto v^\varepsilon(t,x)$.]

$$\eta(t,x) = \int_{\mathbb{R}^d_\xi} \nu_t(x, \mathrm{d}\xi).$$

The main advantage of this approach is that this measure can be calculated by solving a transport equation with initial data related to v_I^ε.

In Ref. 3 (see also Refs. 6 and 10) it has been shown that if the potential is smooth then

a)Electronic mail: sahbi.keraani@univ-rennes1.fr

$$\nu_t = \phi_t(\nu_I), \tag{1.2}$$

where ϕ_t is the classical classical Hamiltonian flow $\exp(tH_p)$ of

$$p = \frac{|\xi|^2}{2} + U(x)$$

and ν_I is the Wigner measure of v_I^ε.

In the context of frequency sets (see, e.g., Ref. 12), a classical result of propagation similar to (1.2) is well known. In *three* space dimensions, an interesting extension of this result to a potential with Coulomb-type singularities has been performed by Gérard and Knauf.[2] In fact, these authors have proved that the frequency set of the solution to (1.1) with $d=3$ and $U=-1/|x|$, is reflected by the Coulomb center $x=0$ under the regularized trajectories of the classical mechanics (see Sec. III for precise definitions). Gérard and Knauf's technique is based on the idea of applying to the quantum problem a method of regularization used in the corresponding classical problem in celestial mechanics and known as *Kustaanheimo-Stiefel* transformation (see Sec. III).

The main purpose of this paper is to perform the same extension in the context of Wigner measures. More precisely, by making use of similar arguments to those carried out in Ref. 2 in the context of frequency sets, and some refined lemmas on propagation of Wigner measures, we attempt to describe the dynamics of the Wigner measure associated to the solution to the semiclassical Schrödinger evolution equation

$$\begin{aligned} i\varepsilon\partial_t v^\varepsilon &= -\frac{\varepsilon^2}{2}\Delta v^\varepsilon - \frac{v^\varepsilon}{|x|} + V(x)v^\varepsilon, \quad (t,x) \in \mathbb{R}\times\mathbb{R}^3, \\ v^\varepsilon(0,x) &= v_I^\varepsilon(x), \end{aligned} \tag{1.3}$$

where V is a smooth real potential with sufficient decay at infinity and v_I^ε is a bounded family in $L^2(\mathbb{R}^3)$. [In this paper we do not discuss the optimal assumptions on V. We assume always that V has all the needed properties (for example, we need some control of V at infinity in order to guarantee that Hamiltonian is self-adjoint).]

Before going further into details, we fix some notations.

Notation: (i) $\dot{\mathbb{R}}^d := \mathbb{R}^d\backslash\{0\}$.

(ii) If Ω *is an open subset of* $\mathbb{R}^d$ *then* $\mathbf{T}^*(\Omega) := \Omega\times\mathbb{R}^d$.

We now recall the definition and the basic properties of Wigner measures that we use in the coming analysis. For more details, the reader is referred to Refs. 3, 6, and 10.

For $a \in \mathcal{S}(\mathbb{R}^d\times\mathbb{R}^d)$ we define the ε-dependent family of pseudo-differential operators $A^\varepsilon = a(x,\varepsilon D)$ by

$$a(x,\varepsilon D)u(x) = \frac{1}{(2\pi)^d}\int_{\mathbb{R}^d_\xi}\int_{\mathbb{R}^d_y} a(x,\varepsilon\xi)e^{i(x-y)\xi}u(y)\mathrm{d}y\,\mathrm{d}\xi,$$

for every $u \in \mathcal{S}'$. Notice that for every family (u^ε) bounded in $L^2(\mathbb{R}^d)$ we have

$$\limsup_{\varepsilon\to 0}\|a(x,\varepsilon D)u^\varepsilon\|_{L^2(\mathbb{R}^d_x)} \leqslant \|a\|_{L^\infty}\limsup_{\varepsilon\to 0}\|u^\varepsilon\|_{L^2(\mathbb{R}^d_x)}.$$

The following basic result is due to Gérard[3] and Lions and Paul.[10]

Theorem 1.1 (Refs. 3 and 10): *Let* (ψ^ε) *be a bounded family in* $L^2(\mathbb{R}^d)$. *Then there are a subsequence, still denoted by* ψ^ε, *and a positive Radon measure* ν *on* $\mathbf{T}^*(\mathbb{R}^d)$, *such that*

$$\langle a(x,\varepsilon D)\psi^\varepsilon,\psi^\varepsilon\rangle \xrightarrow[\varepsilon\to 0]{} \int_{\mathbb{R}^d_x\times\mathbb{R}^d_\xi} a(x,\xi)\nu(\mathrm{d}x\,\mathrm{d}\xi) \tag{1.4}$$

for every $a \in \mathcal{S}(\mathbb{R}^d\times\mathbb{R}^d)$. *Moreover,*

$$\|\nu\|_{\mathcal{M}} \leqslant \limsup_{\varepsilon\to 0}\|\psi^{\varepsilon}\|_{L^2(\mathbb{R}^d_x)},$$

where $\|\cdot\|_{\mathcal{M}}$ *denotes the norm in the space of bounded Radon measures*.

In this context, μ is called *Wigner* measure of (ψ^{ε}). The bounded family (ψ^{ε}) is said to be *pure* if the extraction of a subsequence in (1.4) is not needed.

The proof of the existence is based essentially on an argument of separability of the space $\mathcal{S}(\mathbb{R}^d\times\mathbb{R}^d)$. The positivity can be proved in several ways; in Ref. 3 the proof uses a Gärding inequality and in Ref. 4 a more elementary proof is given, where a Bochner–Schwartz theorem is used. In Ref. 10 the proof relies on some Gaussian regularization trick.

Remark 1.2: Theorem 1 holds for every family (ψ^{ε}) *bounded in* $L^2_{\mathrm{loc}}(\Omega)$, *where* $\Omega\subset\mathbb{R}^d$ *is an open set. In this case* μ *is locally bounded on* Ω_x *and globally bounded on* $\mathbb{R}^d_{\xi}$.

To describe the relationship between Wigner measure and the weak limit of $|\psi^{\varepsilon}|^2$, we need the two following definitions.

Definition 1.3: (1) *A bounded family* (ψ^{ε}) *in* $L^2(\mathbb{R}^d)$ *is said to be* ε*-oscillatory as* ε *goes to 0 if the following property holds for every continuous, compactly supported function* φ *on* $\mathbb{R}^d$:

$$\limsup_{\varepsilon\to 0}\int_{|\xi|\geqslant R/\varepsilon}|\widehat{\varphi\psi^{\varepsilon}}(\xi)|^2\mathrm{d}\xi \xrightarrow[R\to+\infty]{} 0.$$

(2) *A bounded family* (ψ^{ε}) *in* $L^2(\mathbb{R}^d)$ *is said to be compact at infinity as* ε *goes to 0 if*

$$\limsup_{\varepsilon\to 0}\int_{|x|\geqslant R}|\psi^{\varepsilon}(x)|^2\mathrm{d}x \xrightarrow[R\to+\infty]{} 0.$$

Under the above definitions we have the following.

Proposition 1.4 (Refs. 3 and 10): *Let* (ψ^{ε}) *be a bounded family in* $L^2(\mathbb{R}^d)$ *with Wigner measure* μ. *Then*

(1) *The measure* μ *is bounded on* $\mathbb{R}^d\times\mathbb{R}^d$ *and, if* $|\psi^{\varepsilon}|^2 \rightharpoonup m$ *as measure on* $\mathbb{R}^d$, *we have, in the sense of positive measure,*

$$\int_{\mathbb{R}^d}\mu(\cdot,\mathrm{d}\xi)\leqslant m,$$

with equality if and only if (ψ^{ε}) *is* ε*-oscillatory*.

(2) *We have*

$$\mu(\mathbb{R}^d\times\mathbb{R}^d)\leqslant\limsup_{\varepsilon\to 0}\int_{\mathbb{R}^d}|\psi^{\varepsilon}(x)|^2\mathrm{d}x,$$

with equality if and only if (ψ^{ε}) *is* ε*-oscillatory and compact at infinity*.

The Wigner measure is defined independently of the coordinates.

Proposition 1.5 (Ref. 5): *Let* θ *be a* $\mathcal{C}^{\infty}$*-diffeomorphism from* Ω_1 *onto* Ω_2. *Suppose that* (ψ_2^{ε}) *is a pure bounded family in* $L^2_{\mathrm{loc}}(\Omega_2)$. *Then* $\psi_1^{\varepsilon}:=\psi_2^{\varepsilon}\circ\theta$ *is a pure bounded family in* $L^2_{\mathrm{loc}}(\Omega_1)$ *and the Wigner measure* ν_1 *of the family* (ψ_1^{ε}) *is given by*

$$\nu_1=|\det\theta'|^{-1}\Theta^{-1}(\nu_2),$$

where ν_2 *is the Wigner measure of the family* (ψ_2^{ε}) and Θ *is the canonical transformation on* $\mathbf{T}^*(\Omega_1)$ *given by*

$$(x,\xi)\mapsto(\theta(x),{}^T\theta'^{-1}(x)\xi)^3.$$

[Note that ${}^TA$ are used to denote the transposed of a matrix A.]

Consider a particle with mass 1 moving in three-dimensional space according to the laws of classical mechanics, subject to a perturbed Coulomb potential

$$U(x) = -\frac{1}{|x|} + V.$$

The classical motion of the particle is described by the Hamiltonian system

$$\dot{\mathbf{x}} = \boldsymbol{\xi}$$

$$\dot{\boldsymbol{\xi}} = -\frac{\mathbf{x}}{|\mathbf{x}|^3} - \nabla V(\mathbf{x}), \tag{1.5}$$

$$(\mathbf{x}, \xi)_{|_{t=0}} = (x_0, \xi_0) \in \dot{\mathbb{R}}^3 \times \mathbb{R}^3.$$

The standard ODE theory yields a unique maximal solution to (1.5) on some interval $[0, t^*[$. If $t^* < +\infty$, then there is *a collision*: the particle hits the singularity of the potential in finite time t^*. A natural question in such a situation is how one can extend the trajectory after the collision time.

Let us consider the one-dimension motion in the special case of purely Coulomb potential (i.e., $V \equiv 0$) and zero Kepler energy

$$h_K := \frac{1}{|x_0|} - \frac{|\xi_0|^2}{2} = 0.$$

By assuming $\mathbf{x}(t) \geqslant 0$, the equation of motion is reduced to

$$\dot{\mathbf{x}}(t) = \sqrt{\frac{2}{\mathbf{x}(t)}},$$

which yields $\mathbf{x}(t) = Ct^{2/3}$. The particle comes in from the infinity, is reflected at the central mass, and rejected to infinity. The outgoing leg of its path is symmetrical with respect to the incoming leg.

With this example in mind, we define an *extension* of the trajectory after collision as follows: take $(x_0, \xi_0) \in \mathbf{T}^*(\dot{\mathbb{R}}^3)$ and assume that the classical trajectory reaches the origin $x = 0$ at finite time t^*. Then, the extension of this trajectory after t^* is obtained by adding the branch of the trajectory of the same particle ejected from $x = 0$, with infinite velocity in the opposite of the incoming direction.

To make this definition more precise, let us first notice that the direction of collision, when it happens, is well defined. Indeed, we have the following:

Lemma 1.6: Assume that the solution of (1.5) *collides with the origin* $x = 0$ *in a finite time* t^*. *Then, there exists a unique* $v = v(x_0, \xi_0, t^*) \in \mathbb{R}^3$, *such that*

$$\frac{\boldsymbol{\xi}(t)}{|\boldsymbol{\xi}(t)|} \xrightarrow[t \to (t^*)^-]{} v.$$

See Appendix B for the proof of this fact.

With these notations the definition of the extended trajectories can be given by

Definition 1.7: The extended flow is the mapping $\tilde{\phi}: \mathbb{R}_t \times \mathbf{T}^*(\dot{\mathbb{R}}^3) \to \mathbf{T}^*(\dot{\mathbb{R}}^3)$ *defined by*

$$\tilde{\phi}_t(x_0, \xi_0) = \begin{cases} \phi_t(x_0, \xi_0) & \text{if } t < t^* \\ \hat{\phi}_t(x_0, \xi_0) & \text{if } t > t^*, \end{cases}$$

where $\phi_t(x_0, \xi_0)$ *is the usual Hamiltonian trajectory and* $\hat{\phi}_t(x_0, \xi_0)$ *is the trajectory of the same particle ejected from* $x = 0$ *at* $t = t^*$ *with infinite velocity in the direction* $-v(x_0, \xi_0, t^*)$.

The extended trajectory is formed by two legs: the incoming one, which ends up in $x = 0$ with infinite velocity in the direction $v(x_0, \xi_0, t^*)$ and the outgoing one, which starts from $x = 0$ with

infinite velocity in the opposite direction $-v(x_0,\xi_0,t^*)$. For the case of many collisions on the same trajectory we iterate the process of extension described above. For purely Coulomb potential, the extended trajectory is obtained by following backward the incoming collision trajectory. This extension corresponds physically to an elastic bounce. Note that, outside the collision, the extended flow is the same as the usual one.

In the sequel we *denote* by $\mathrm{Coll}_t=\{(x,\xi)\in \mathbf{T}^*(\dot{\mathbb{R}}^3):\Pi_x(\tilde{\phi}_s(x,\xi))\underset{s\to t}{\to}0\}$ the collisions set at time t.

The main result of this paper can be stated as follows.

Theorem 1.8: *Take v_I^ε to be a bounded pure family in $L^2(\mathbb{R}^3)$, ε-oscillatory and compact at infinity, such that ν_I is supported in $\mathbf{T}^*(\dot{\mathbb{R}}^3)$. Let v^ε be the solution of* (1.3) *with initial data v_I^ε. Then one has:*

(i) *the family v_t^ε is pure on $\dot{\mathbb{R}}^3$ and its Wigner measure ν_t satisfies*

$$\nu_{t|_{x\neq 0}}=\tilde{\phi}_t(\nu_{I|_{\mathbb{R}^3\setminus \mathrm{Coll}_t}}).$$

(ii) *If $\nu_I(\mathrm{Coll}_t)=0$, then the family v_t^ε is pure, ε-oscillatory and compact at infinity. In addition,*

$$\nu_t=\tilde{\phi}_t(\nu_I).$$

Some remarks are in order.

Remark 1.9: The proof of the main theorem is based on two essential arguments. The first one is the fundamental fact that the extended trajectory coincides with the regularized trajectory defined by Kustaanheimo–Stiefel transformation in the context of the regularization theory in celestial mechanics (see Lemma 3.4 below). The second main argument is a new result of propagation of Wigner measure through singular regions (see Lemma 2.2 below for precise statement).

Remark 1.10: Main theorem holds for a potential displaying several Coulomb-type singularities

$$\sum_{i=1}^{N}\frac{c_i}{|x-x_i|}+V,$$

where $x_i\in\mathbb{R}^3$, $c_i\in\mathbb{R}$ for $i=1,\ldots,N$ and V is a smooth real bounded potential. The definition 1.7 can be generalized in a natural way to a potential of this type.

Remark 1.11: It is an open problem to describe ν_t over $x=0$. Even the question of uniqueness of ν_t (if (v_t^ε) is pure on $\mathbb{R}^3$ or not) is not solved.

The plan of the rest of the paper is as follows. In Sec. II some lemmas related to the propagation of Wigner measures are formulated. In Sec. III we recall the definitions and some properties of the regularized flows and the KS-transformation and we prove some preliminary results needed to the proof of the main theorem of this work, which is given in Sec. III. In the Appendixes some technical lemmas are proved.

II. PROPAGATION OF WIGNER MEASURES

We consider the initial values problem

$$\begin{aligned}&\varepsilon D_t u^\varepsilon+P^\varepsilon u^\varepsilon=0,\quad (t,x)\in\mathbb{R}^{1+d},\\ &u^\varepsilon(0,x)=u_I^\varepsilon(x),\end{aligned}\tag{2.1}$$

where $P^\varepsilon=p(x,\varepsilon D_x)$ is a semiclassical differential operator and (u_I^ε) is a bounded family in $L^2(\mathbb{R}^d)$. The self-adjointness of P^ε implies the conservation of the L^2 norm of the family of solution (u^ε). Thus, the family (u_t^ε) is bounded in $L^2(\mathbb{R}^d)$ for every $t\in\mathbb{R}$ [recall that, throughout this paper, (u_t^ε) denotes the function $x\mapsto u^\varepsilon(t,x)$] and the family (u^ε) is bounded in $L^2_{\mathrm{loc}}(\mathbb{R}_t\times\mathbb{R}_x^d)$. This allows us to

define two types of Wigner measures associated to the family (u^ε) of solutions to (2.1). The first one, $\mu=\mu(\mathrm{d}x\,\mathrm{d}t\,\mathrm{d}\xi\,\mathrm{d}\tau)$, is obtained by microlocalization in the space–time variable. The second one, $\mu_t=\mu_t(\mathrm{d}x\,\mathrm{d}\xi)$, is obtained by microlocalization in the space variable at fixed time.

Proposition 2.1: Take (u_I^ε) *to be a bounded pure family in* $L^2(R^d)$, *ε-oscillatory and compact at infinity. Let* (u^ε) *be the solution of* (2.1) *with initial data* $u^\varepsilon(0,x)=u_I^\varepsilon(x)$. *Then*:

(i) *For every* $t\in R$ *the family* (u_t^ε) *is pure, ε-oscillatory and compact at infinity. In addition,* μ_t *is given by*

$$\mu_t=\phi_t(\mu_I),$$

where ϕ_t *is the classical classical Hamiltonian flow* $\exp(tH_p)$ *of* p.

(ii) $\mu=dt\otimes\delta_{(\tau+p(x,\xi))}\otimes\phi_t(\mu_I)$.

We consider a family $(u^\varepsilon)\in L^2(\mathbb{R}^d)$ of solutions to

$$P^\varepsilon u^\varepsilon=0, \tag{2.2}$$

where $P^\varepsilon=p(x,\varepsilon D_x)$ is an ε-pseudodifferential operator with smooth real symbol. It is well known (see Refs. 3 and 10) that if the family (u^ε) is bounded in $L^2_{\mathrm{loc}}(\mathbb{R}^d)$ then any Wigner measure associated to this family is transported by the bicharacteristic of p. More precisely,

$$\mathrm{supp}(\mu)\subset\{(x,\xi)\in\mathbf{T}^*(\mathbb{R}^d):p(x,\xi)=0\}\ \text{and}\ H_p\mu=0,$$

where $H_p=\nabla_\xi p.\nabla_x-\nabla_x p.\nabla_\xi$, is the Hamiltonian field associated to p. This result remains true if the (u^ε) is bounded in $L^2_{\mathrm{loc}}(\Omega)$, where Ω is an open set of $\mathbb{R}^d$ provided that all the bicharacteristics of p starting from Ω are contained in Ω. In this paragraph we consider the case where some bicharacteristic of p starting from Ω cross some "black box" F in which the measure μ is not defined. More precisely, we prove the following refined lemma on the propagation of Wigner measure.

Lemma 2.2: Let $(u^\varepsilon)\in L^2(\mathbb{R}^d)$ *be a family of solutions to* $P^\varepsilon u^\varepsilon=0$, *where* $P^\varepsilon=p(x,\varepsilon D_x)$ *is an ε-pseudodifferential operator with smooth real symbol. Assume that*

(H1) (u^ε) *is bounded in* $L^2_{\mathrm{loc}}(\Omega)$, *for some open set* $\Omega\subset\mathbb{R}^d$.

(H2) *There exists an integer* ℓ, *such that* $(\varepsilon^\ell u^\varepsilon)$ *is bounded in* $L^2_{\mathrm{loc}}(\mathbb{R}^d)$.

Let μ *denote the Wigner measure of* $(u^\varepsilon_{|\Omega})$. *Then, for every* $\omega\Subset\mathbf{T}^*(\Omega)$ *and every* $s_0\in\mathbb{R}$, *such that* $\omega_{s_0}=\phi_{s_0}(\omega)\Subset\mathbf{T}^*(\Omega)$, *we have*

$$\mu_{|\omega_{s_0}}=\phi_{s_0}(\mu_{|\omega}),$$

where ϕ_t *is the classical Hamiltonian flow* $\exp(tH_p)$ *of* p.

Proof: Take $\psi\in\mathcal{C}_0^\infty(\mathbf{T}^*(\omega_{s_0}))$ be an arbitrary fixed function. Our aim is to show that

$$\langle\psi(x,\varepsilon D)u^\varepsilon,u^\varepsilon\rangle\xrightarrow[\varepsilon\to0]{}\int_{\mathbf{T}^*(\omega)}\psi(\phi_{s_0}(x,\xi))\mu(\mathrm{d}x\,\mathrm{d}\xi). \tag{2.3}$$

We use a classical argument of propagation of singularities in microlocal analysis. We introduce a new variable $s\in\mathbb{R}$ and we consider u^ε as depending also on this new variable. The family (u^ε) is solution of the following evolution equation with respect to s:

$$\varepsilon D_s u^\varepsilon+P^\varepsilon u^\varepsilon=0.$$

One constructs an operator $\Psi^\varepsilon(s,x,\varepsilon D_x)$, so that

$$[\varepsilon D_s + P^\varepsilon, \Psi^\varepsilon(s,x,\varepsilon D_x)] = \mathcal{O}(\varepsilon^\infty) \text{ in } \mathcal{L}(L^2([-s_0,0]\times\mathbb{R}^d)),$$

$$\Psi^\varepsilon(0,x,\varepsilon D_x) = \psi(x,\varepsilon D_x).$$

To meet these conditions, the operator $\Psi^\varepsilon(s,\cdot,\cdot)$ is chosen as a formal series in the following form:

$$\Psi^\varepsilon = \sum_{j\geqslant 0} \varepsilon^j \psi_j(s,x,\varepsilon D).$$

The construction of such operator is similar to that carried out in Ref. 7 (Chap. XXIII) in the context of propagation of wave front. We will use essentially the following three facts:

(i) For every $s\in\mathbb{R}$, one has

$$\psi_0(s,x,\xi) = \psi(\phi_{-s}(x,\xi)). \tag{2.4}$$

(ii) For every $j\geqslant 0$ and every $s\in\mathbb{R}$,

$$\text{supp}(\psi_j(s,\cdot)) \subset \phi_s(\text{supp}(\psi)).$$

(iii) The partial sum $\Psi_k^\varepsilon = \Sigma_{j=0}^k \varepsilon^j \psi_j$ verifies

$$\|[\varepsilon D_s + P^\varepsilon, \Psi_k^\varepsilon(s,x,\varepsilon D)]\|_{\mathcal{L}(L^2([-s_0,0]\times\mathbb{R}^d))} = \mathcal{O}(\varepsilon^{k+1}).$$

Under the above notations, we have

$$(\varepsilon D_s + P^\varepsilon)\Psi_k^\varepsilon u^\varepsilon = f_k^\varepsilon, \tag{2.5}$$

where $f_k^\varepsilon = [\varepsilon D_s + P^\varepsilon, \Psi_k^\varepsilon]u^\varepsilon$. By construction and (H2), it follows that

$$\|f_k^\varepsilon\|_{L^2([-s_0,0]\times\mathbb{R}^d)} \leqslant \|[\varepsilon D_s + P^\varepsilon, \Psi_k^\varepsilon]\|_{\mathcal{L}(L^2([-s_0,0]\times\mathbb{R}^d))} \|u^\varepsilon\|_{L^2([-s_0,0]\times\mathbb{R}^d)} \lesssim \varepsilon^{k+1-\ell}. \tag{2.6}$$

However, from (2.5), it ensues

$$\frac{\mathrm{d}}{\mathrm{d}s}\langle \Psi_k^\varepsilon(s,x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle = \frac{i}{\varepsilon}\langle f_k^\varepsilon, u^\varepsilon\rangle.$$

Since the family of s-dependent operators $\Psi_k^\varepsilon(s,x,\varepsilon D_x)$ is bounded in $\mathcal{L}(L^2(\mathbb{R}^d))$ uniformly in $(s,\varepsilon)\in[-s_0,0]\times]0,1]$, and by using (2.6) and (H2), we get

$$\left|\frac{\mathrm{d}}{\mathrm{d}s}\langle \Psi_k^\varepsilon(s,x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle\right| = \mathcal{O}(\varepsilon)$$

uniformly in $s\in[-s_0,0]$ for $k>2\ell$. This yields, in particular,

$$|\langle \Psi_k^\varepsilon(-s_0,x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle - \langle \Psi_k^\varepsilon(0,x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle| = \mathcal{O}(\varepsilon),$$

that is

$$\lim_{\varepsilon\to 0}\langle \Psi_k^\varepsilon(-s_0,x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle = \lim_{\varepsilon\to 0}\langle \Psi_k^\varepsilon(0,x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle.$$

Since $\Psi_k^\varepsilon(0,\cdot) = \psi$, this gives

$$\lim_{\varepsilon\to 0}\langle \Psi_k^\varepsilon(-s_0,x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle = \lim_{\varepsilon\to 0}\langle \psi(x,\varepsilon D_x)u^\varepsilon, u^\varepsilon\rangle. \tag{2.7}$$

On the other hand, since, for every $j\in\{1,\ldots,k\}$, $\text{supp}(\psi_j(-s_0,\cdot,\cdot))\subset\mathbf{T}^*(\omega)$ and (u^ε) is bounded in $L^2_{\text{loc}}(\Omega)$, the family $(\psi_j(-s_0,x,\varepsilon D_x)u^\varepsilon)$ is bounded in $L^2(\mathbb{R}^d)$. [Recall that

$\mathrm{supp}(\psi_j(-s_0,\cdot,\cdot,\cdot)) \subset \phi_{-s_0}(\mathrm{supp}(\psi))$ and $\mathrm{supp}(\psi) \subset \phi_{s_0}(\mathbf{T}^*(\omega))$.] Thus, we infer

$$\lim_{\varepsilon\to 0}\langle \Psi_k^\varepsilon(-s_0,x,\varepsilon D_x)u^\varepsilon,u^\varepsilon\rangle = \lim_{\varepsilon\to 0}\langle \psi_0(-s_0,x,\varepsilon D_x)u^\varepsilon,u^\varepsilon\rangle. \tag{2.8}$$

This fact and (2.7) imply

$$\lim_{\varepsilon\to 0}\langle \psi(x,\varepsilon D_x)u^\varepsilon,u^\varepsilon\rangle = \lim_{\varepsilon\to 0}\langle \psi(-s_0,x,\varepsilon D_x)u^\varepsilon,u^\varepsilon\rangle. \tag{2.9}$$

Since $\psi_0(-s_0,x,\xi)=\psi(\phi_{s_0}(x,\xi))$ is supported in $\mathbf{T}^*(\omega)$, then by definition of the Wigner measure it follows that

$$\lim_{\varepsilon\to 0}\langle \psi(-s_0,x,\varepsilon D_x)u^\varepsilon,u^\varepsilon\rangle = \int_{\mathbf{T}^*(\omega)} \psi_0(-s_0,x,\xi))\,\nu(\mathrm{d}x\,\mathrm{d}\xi). \tag{2.10}$$

Putting together (2.4), (2.9), and (2.10), one obtains

$$\lim_{\varepsilon\to 0}\langle \psi^\varepsilon(x,\varepsilon D_x)u^\varepsilon,u^\varepsilon\rangle = \int_{\mathbf{T}^*(\omega)} \psi(\phi_{s_0}(x,\xi))\,\nu(\mathrm{d}x\,\mathrm{d}\xi),$$

which is (2.3). □

III. REGULARIZED FLOWS AND KS-TRANSFORMATION

The classical motion of a particle subject to a Coulomb potential

$$-\frac{1}{|x|}+V(x)$$

is described by the following Hamiltonian system:

$$\begin{aligned}\dot{x}(t)&=\xi(t),\\ \dot{\xi}(t)&=-\frac{x(t)}{|x(t)|^3}-\nabla V(x(t)).\end{aligned} \tag{3.1}$$

This system is singular at the origin since the attraction force of the central mass is infinite at this point. It is a very unpleasant fact, namely from the numerical point of view. It is thus interesting to transform the singular system (3.1) into a regular one. This procedure is called *regularization*. It is an old theory in celestial mechanics starting with the paper of Euler[1] in 1767. The principle of this theory is to eliminate, by an appropriate change of space–time coordinates, the singularities of the vectors fields solutions of (3.1) and to obtain an equation of motion which is regular for the considered collision. [Note that the purpose of the regularization theory is to obtain a regular differential equation of motion and not regular solutions.] The planar perturbed problem was regularized by Levi-Civita[9] and the spatial case by Kustaanheimo.[8] The *Kustaanheimo–Stiefel* transformation (abbreviated to KS-transformation) is the basic idea in the spatial case. In Secs. III A and III B we recall the regularized flows and the KS transformation (see Ref. 13 for more details).

A. Regularized flows

Without details we single out the explicit construction of the regularized flows provided by Kustaanheimo–Stiefel transformation. For more details the reader is referred to Ref. 13 (Chaps. II, X). For $z\in\dot{\mathbb{R}}^4$ one sets

$$L(z)=\begin{pmatrix} z_1 & -z_2 & -z_3 & z_4 \\ z_2 & z_1 & -z_4 & -z_3 \\ z_3 & z_4 & z_1 & z_2 \\ z_4 & -z_3 & z_2 & -z_1 \end{pmatrix}, \quad \Lambda(z)=\begin{pmatrix} z_1 & -z_2 & -z_3 & z_4 \\ z_2 & z_1 & -z_4 & -z_3 \\ z_3 & z_4 & z_1 & z_2 \end{pmatrix}. \tag{3.2}$$

The matrix L, called KS-matrix, satisfies

$$L^T(z)L(z)=|z|^2 I.$$

The KS-transformation is the mapping of $\mathbb{R}^4$ onto the physical space $\mathbb{R}^3$ of Cartesian coordinates x_1,x_2,x_3, given by $x=\Lambda(z)z$. This may be written explicitly

$$x_1=z_1^2-z_2^2-z_3^2+z_4^2, \quad x_2=2(z_1z_2-z_3z_4), \quad x_3=2(z_1z_3+z_2z_4).$$

From this it follows that

$$|x|=|\Lambda(z)z|=|z|^2. \tag{3.3}$$

To construct the regularized trajectory starting from the point $(x_0,\xi_0)\in \mathbf{T}^*(\dot{\mathbb{R}}^3)$, one proceeds as follows. First, one chooses $(z_0,\zeta_0)\in \mathbf{T}^*(\dot{\mathbb{R}}^4)$ satisfying

$$x_0=\Lambda(z_0)z_0, \quad \xi_0=\frac{1}{2|z_0|^2}\Lambda(z_0)\zeta_0. \tag{3.4}$$

One denotes

$$\Lambda^*(z_0,\zeta_0):=\left(\Lambda(z_0)z_0,\frac{1}{2|z_0|^2}\Lambda(z_0)\zeta_0\right). \tag{3.5}$$

The pair $(z_0,\zeta_0)\in \mathbf{T}^*(\dot{\mathbb{R}}^4)$ satisfying (3.4) is not unique, but the regularized flow defined below does not depend on the choice of (z_0,ζ_0) (see Ref. 13 Lemma 2, p. 236). [In order to apply this lemma we have to check that (z_0,ζ_0) belongs to the zero level of the bilinear form: $\ell(z,\zeta)=\langle\overline{z},\zeta\rangle$, where $\overline{z}:=(z_4,-z_3,z_2,-z_1)$. Since $L(z_0)\overline{z_0}=(0,0,0,|z_0|^2)$, then the expression of ζ_0 (3.6) yields $\ell(z_0,\zeta_0)=\langle 2L^T(z_0)(\xi_0,0),\overline{z_0}\rangle=2\langle(\xi_0,0),L(z_0)\overline{z_0}\rangle=0$.] Note that, after having chosen z_0, ζ_0 is uniquely determined by

$$\zeta_0=2L^T(z_0)(\xi_0,0), \tag{3.6}$$

where $(\xi_0,0)$ is the four-vector obtained from ξ_0 by adding the fourth component of value zero and L is as in (3.2). Second, one constructs the integral curves $(\mathbf{t}(s),\mathbf{z}(s),\boldsymbol{\tau}(s),\boldsymbol{\zeta}(s))$ of the Hamiltonian

$$\tilde{p}(t,z,\tau,\zeta)=\tau|z|^2+\tfrac{1}{8}|\zeta|^2-1+W(z) \tag{3.7}$$

starting from $(0,z_0,-p(x_0,\xi_0),\zeta_0)$, where

$$p=\frac{1}{2}|\xi|^2-\frac{1}{|x|}+V(x)$$

is the classical Hamiltonian and $W(z):=|z|^2V(\Lambda(z)z)$. One easily verifies that $\tilde{p}(t_0,z_0,\tau_0,\zeta_0)=0$. The proof of the following lemma is given in Appendix A.

Lemma 3.1: The t-component of every bicharacteristic of $\tilde{p}$ is a bijection from $\mathbb{R}$ onto $\mathbb{R}$.

The regularized flow is defined by

Definition 3.2: The regularized flow is the mapping $\tilde{\phi}:\mathbb{R}_t\times\mathbf{T}^*(\dot{\mathbb{R}}^3)\to\mathbf{T}^*(\dot{\mathbb{R}}^3)$ defined by

$$\tilde{\phi}_t(x_0,\xi_0):=\Lambda^*(\mathbf{z}(s),\boldsymbol{\zeta}(s)) \tag{3.8}$$

where s satisfies $\mathbf{t}(s)=t$. [The existence and uniqueness of s is assured by Lemma 3.1.]

Remark 3.3: Note that Λ^* *is not defined for* $z=0$*; and then* $\tilde{\phi}_t(x_0,\xi_0)$ *exists only if* $\mathbf{z}(s)\neq 0$ [*with* $s=\mathbf{t}^{-1}(t)$]. *Thus, every* (x_0,ξ_0,t) *where* (x_0,ξ_0) *is on a collision orbit and t the collision time are implicitly excluded from the definition* [*for them no such* $\tilde{\phi}_t(x_0,\xi_0)$ *exist*].

For a seek of notations we decompose ϕ_t (and $\tilde{\phi}_t$) as

$$\phi_t(x,\xi)=(\phi_t^1(x,\xi),\phi_t^2(x,\xi)),\quad \phi_t^1=\prod_x(\phi_t),\quad \phi_t^2=\prod_\xi(\phi_t). \tag{3.9}$$

In the proof of the main theorem we use the following

Lemma 3.4: The extended trajectories coincide with the regularized ones.

The proof of this lemma is given in Appendix B.

B. KS-transformation

We begin this section by recalling (see also Ref. 13, p. 32) the explicit construction of the local "inverse" of the KS-transformation. One adds a dummy variable $\theta\in S^1:=[0,2\pi[$. One denotes

$$\Omega=\mathbb{R}^3\setminus\{x\in\mathbb{R}^3: x_2=x_3=0, x_1<0\}. \tag{3.10}$$

Over Ω we consider $\chi: S^1\times\Omega\to\mathbb{R}^4$ defined by

$$z_1=\frac{1}{\sqrt{2}}(x_1+|x|)^{1/2}\cos\theta,$$

$$z_2=\frac{1}{\sqrt{2}}(x_1+|x|)^{-1/2}(x_2\cos\theta+x_3\sin\theta),$$

$$z_3=\frac{1}{\sqrt{2}}(x_1+|x|)^{-1/2}(x_3\cos\theta-x_2\sin\theta),$$

$$z_4=\frac{1}{\sqrt{2}}(x_1+|x|)^{1/2}\sin\theta.$$

Remark that, for a fixed $x\in\dot{\mathbb{R}}^3$, the set $\{\chi(x,\theta),\theta\in S^1\}$ is a curve in $\dot{\mathbb{R}}^4$. Such a curve, which is called the *fiber* in $\mathbb{R}^4$ over x, is mapped by the KS-transform onto the single point x.

Remark 3.5: One denotes

$$\tilde{\Omega}=\mathbb{R}^3\setminus\{x\in\mathbb{R}^3: x_2=x_3=0, x_1>0\}.$$

There exists a "local inverse" $\tilde{\chi}$ *of the KS-transformation defined over* $\tilde{\Omega}$*. In our proof we use these two "local inverses" and a partition of unity to cover* $\dot{\mathbb{R}}^3$*. Since the discussion is the same for* χ *and* $\tilde{\chi}$ *we will work only with* χ*.*

One can check easily that

$$\det(\chi'(\theta,x))=\frac{1}{8|x|}, \tag{3.11}$$

for every $(\theta,x)\in S^1\times\dot{\mathbb{R}}^3$.

One defines the mapping $\Gamma: S^1\times\mathbf{T}^*(\Omega)\mapsto\mathbf{T}^*(\mathbb{R}^4)$ by

$$\Gamma(x,\xi,\theta) = (\chi(x,\theta), 2L^T(\chi(x,\theta))(\xi,0)), \tag{3.12}$$

where L is defined by (3.2) and $(\xi,0)$ is the four-vector obtained from ξ by adding the fourth component of value zero. Under the notations (3.5) and (3.12), we have

$$\Lambda^*(\Gamma(x,\xi,\theta)) = (x,\xi)$$

for every $\theta \in S^1$. Also it is not hard to see that

$$^T(\chi'(x,\theta))^{-1}(\xi,0) = 2L^T(\chi(x,\theta))(\xi,0) \tag{3.13}$$

for every $(\theta,x,\xi) \in S^1 \times \mathbf{T}^*(\dot{\mathbb{R}}^3)$.

The following lemmas will be useful in the proof of the main theorem.

Lemma 3.6: Take $(x,\xi) \in \mathbf{T}^*(\Omega)$ *and* $\theta \in [0,2\pi[$ *to be fixed. Let* $\Phi_s^\theta(x,\xi)$ *denote the classical flow associated to* $\tilde{p}$ *defined by* (3.7) *starting from the point* $(0,-p(x,\xi),\Gamma(x,\xi,\theta))$. [Note that for greater convenience, we will sometimes denote the point in phase space by (t,τ,z,ζ) instead of (t,z,τ,ζ).] *Then there exists* $\kappa > 0$, *such that*

$$\Phi_s^\theta(x,\xi) = (\mathbf{t}(s), -p(x,\xi), \Gamma(\phi_{\mathbf{t}(s)}(x,\xi), \theta + \alpha(x,\xi,\mathbf{t}(s)))), \tag{3.14}$$

for every $s \in]-\kappa,\kappa[$. *Here,* $\mathbf{t}(s)$ *is the inverse of the function* $\mathbf{t}^{-1}$ *given by*

$$\mathbf{t}^{-1}(t) = \int_0^t \frac{1}{|\phi_s^1(x,\xi)|} \mathrm{d}s \tag{3.15}$$

and

$$\alpha(x,\xi,t) := \int_0^t G(\phi_{t'}(x,\xi))\mathrm{d}t',$$

where

$$G(x,\xi) = \frac{x_2\xi_3 - x_3\xi_2}{2(x_1 + |x|)|x|}.$$

Proof: The number κ is chosen sufficiently small, such that (3.14) makes sense. More precisely, we take κ, such that $\phi_{\mathbf{t}(s)}(x,\xi)$ belongs to $\mathbf{T}^*(\Omega)$ for every $s \in]-\kappa,\kappa[$. Since $\phi_{\mathbf{t}(0)}(x,\xi) = \phi_0(x,\xi) = (x,\xi) \in \mathbf{T}^*(\Omega)$ then κ_0 is well defined. By a straightforward computation we can check that (3.14) defines a solution to the Hamiltonian system of $\tilde{p}$ with initial data $\Phi_0^\theta(x,\xi) = (0, -p(x,\xi),\Gamma(x,\xi,\theta))$. Let us remark finally that the application $(x,\xi) \mapsto \kappa(x,\xi)$ is continuous from $\mathbf{T}^*(\Omega)$ onto $]0,+\infty[$. □

Remark 3.7: For large times the expression of $\Phi_s^\theta(x,\xi)$ *is not explicit. Nevertheless, since* $\mathrm{d}\tilde{p}/\mathrm{d}t = 0$, *the* τ*-component is always equal to* $-p(x,\xi)$.

Lemma 3.8: Let Θ *be the canonical transformation*

$$\Theta(t,\tau,x,\theta,\xi,\beta) = (t,\tau,\chi(x,\theta), {}^T(\chi'(x,\theta))^{-1}(\xi,\beta)) \tag{3.16}$$

and $\Phi_s^\theta(x,\xi)$ *the classical flow associated to* $\tilde{p}$ *defined by* (3.7) *starting from the point* $(0, -p(x,\xi),\Gamma(x,\xi,\theta))$. *Then, for every* $\theta \in S^1$ *and every* $s \in \mathbb{R}$, *we have*

$$\prod_{(x,\xi)} [\Theta^{-1}(\Phi_s^\theta(x,\xi))] = \Lambda^*\left(\prod_{(z,\zeta)} (\Phi_s^\theta(x,\xi))\right),$$

where Λ^* *is defined by* (3.5).

See Appendix C for the proof of this lemma.

IV. PROOF OF THE MAIN THEOREM

On $\mathbb{R}_t \times \mathbb{R}^4_z$ we define the transformed function u by

$$u^\varepsilon(t,z) = v^\varepsilon(t, \Lambda(z)z). \tag{4.1}$$

It is easy to check that the mapping $f \mapsto \widetilde{f}$ defined by $\widetilde{f}(z) = f(\Lambda(z)z)$ is isometric from $L^2(\mathbb{R}^3)$ onto $L^2(\mathbb{R}^4, 8|z|^2 \mathrm{d}z)$. An explicit computation yields

Lemma 4.1: (cf. Ref. 2): If v^ε is a solution to (1.3)*, then the function u^ε defined by* (4.1) *satisfies the following equation in $\mathcal{D}'(\mathbb{R}_t \times \mathbb{R}^4_z)$:*

$$i\varepsilon |z|^2 \partial_t u^\varepsilon = -\frac{\varepsilon^2}{8} \Delta_z u^\varepsilon - u^\varepsilon + W(z) u^\varepsilon, \tag{4.2}$$

where $W(z) := |z|^2 V(\Lambda(z)z)$.

The change of variable $x = \Lambda(z)z$ and conservation laws of Eq. (1.3) give

$$\int_{\mathbb{R}^4} |z u^\varepsilon(t,\cdot)|^2 \mathrm{d}z = \frac{1}{8} \int_{\mathbb{R}^3} |v^\varepsilon(t,\cdot)|^2 \mathrm{d}x = \frac{1}{8} \int_{\mathbb{R}^3} |v_I^\varepsilon(x)|^2 \mathrm{d}x.$$

Thus, the family (u^ε) is bounded in $L^2_{\mathrm{loc}}(\mathbb{R}_t \times \dot{\mathbb{R}}^4)$, and we may define a locally bounded Wigner measure on $\mathbf{T}^*(\mathbb{R}_t \times \dot{\mathbb{R}}^4)$ associated to the family $(u^\varepsilon_{|z\neq 0})$. This measure will be denoted by μ. The strategy of the proof is to give a complete description of μ and use the transformation rule of the Wigner measure by the diffeomorphism χ to determine ν_t above $x \neq 0$. Over $x = 0$, we use the principle of conservation of the total mass.

Step 0: In order to use the KS-transform and its local inverse we have to make some extra hypotheses on ν_I. These hypotheses do not break the generality. More precisely, without any loss of generality *we may take v_I^ε to be a bounded pure family in $L^2(\mathbb{R}^d)$, ε-oscillatory and compact at infinity, such that*

$$\|v_I^\varepsilon\|_{H^2(\mathbb{R}^3)} = \mathcal{O}(\varepsilon^{-2}), \tag{4.3}$$

and ν_I is compactly supported in $\mathbf{T}^*(\Omega)$, where Ω is defined by (3.10). Indeed, since $\nu_I(\{0\} \times \mathbb{R}^3_\xi) = 0$ there exists [since $\dot{\mathbb{R}}^3 \times \mathbb{R}^3 = \cup_{v \in S^2} \{sv, s > 0\} \times \mathbb{R}^3_\xi$ is a noncountable disjoint union,] a half line $D^+ = \{sv_0, s \geqslant 0\}$, such that $\nu_I(D^+ \times \mathbb{R}^3_\xi) = 0$. By rotation we may take $D^+ = \{x, x_2 = x_3 = 0, x_1 < 0\} = \mathbb{R}^3 \backslash \Omega$. We introduce the following family of bump functions ψ_k,

$$|\psi_k| \leqslant 1,$$

$$\psi_k(\xi) = 1, \quad |\xi| \leqslant k,$$

$$\psi_k(\xi) = 0, \quad |\xi| \geqslant 2k.$$

Also, we introduce the family ϕ_k,

$$|\phi_k| \leqslant 1,$$

$$\phi_k(x) = 1, \quad \{|x| \leqslant k\} \cap \left\{ -\frac{1}{k} \leqslant x_1, \sqrt{|x_2|^2 + |x_3|^2} \geqslant \frac{1}{k} \right\},$$

$$\phi_k(x) = 0, \quad \{|x| \geqslant 2k\} \cup \left\{ -\frac{1}{2k} \leqslant x_1, \sqrt{|x_2|^2 + |x_3|^2} \leqslant \frac{1}{2k} \right\}.$$

We take

$$v_{I(k)}^{\varepsilon} = \psi_k(\varepsilon D)\phi_k(x)v_I^{\varepsilon}.$$

Under these notations, we have

$$\lim_{\varepsilon\to 0}\|v_{I(k)}^{\varepsilon} - v_I^{\varepsilon}\|_{L^2(\mathbb{R}^3)}^2 = \int (1-\psi_k(\xi)\phi(x))^2 \nu_I(\mathrm{d}x\,\mathrm{d}\xi) \underset{k\to\infty}{\to} 0. \tag{4.4}$$

In the last line we have used the dominated convergence theorem and the fact that $\nu_I(D^+\times\mathbb{R}^3_\xi)=0$.

Let v_k^{ε} be the solution of the Cauchy problem (1.3) with initial data $v_{I(k)}^{\varepsilon}$. From L^2-conservation law and (4.4) it follows that

$$\lim_{\varepsilon\to 0}\|v_k^{\varepsilon}(t,\cdot) - v^{\varepsilon}(t,\cdot)\|_{L^2(\mathbb{R}^3)} = \lim_{\varepsilon\to 0}\|v_{I(k)}^{\varepsilon} - v_I{}^{\varepsilon}\|_{L^2(\mathbb{R}^3)} \underset{k\to\infty}{\to} 0.$$

So, it holds that, for every $t\in\mathbb{R}$,

$$\|\nu_k(t) - \nu_t\|_{\mathcal{M}} \underset{k\to\infty}{\to} 0, \tag{4.5}$$

where $\nu_k(t)$ denotes the Wigner measure associated to $(v_k)^{\varepsilon}(t,\cdot))$ and $\|\cdot\|_{\mathcal{M}}$ the norm in the space of bounded Radon measures. Once the main theorem is proved for the families v_k^{ε}, $k=1,2,\ldots$, it follows for the family v_I^{ε} by (4.5).

Observe finally that since $\psi_k\in\mathcal{C}_0^{\infty}(\mathbb{R}^3)$ then the family (v_k^{ε}) of initial data belongs to $H^2(\mathbb{R}^3)$, for every $k=1,2,\ldots$. Furthermore, it satisfies

$$\|v_{I(k)}^{\varepsilon}\|_{H^2(\mathbb{R}^3)} = \mathcal{O}(\varepsilon^{-2}).$$

The rest of our proof will proceed in three steps.

Step 1: In this short paragraph we give a description of ν_t for small times (before the collision). We choose κ_0 as the minimum over $\mathrm{supp}(\nu_I)$ of the $\kappa(x,\xi)$ defined by Lemma 3.6. Notice that κ_0 is strictly positive because the mapping $(x,\xi)\mapsto\kappa(x,\xi)$ is continuous and the support of ν_I is assumed to be compact. It is evident that

$$\nu_t = \phi_t(\nu_I), \quad t\in\,]-\kappa_0,\kappa_0[,$$

and, thanks to Proposition 2.1,

$$\nu = \mathrm{d}t\otimes\delta_{\tau+p(x,\xi)}\otimes\phi_t(\nu_I), \quad t\in\,]-\kappa_0,\kappa_0[,$$

with ϕ_t denoting the classical Hamiltonian flow of

$$p = \frac{1}{2}|\xi|^2 - \frac{1}{|x|} + V.$$

In order to use the transform χ we consider v^{ε} as a function depending also on the variable θ. The associated Wigner measure becomes

$$\nu_t(\mathrm{d}\theta\,\mathrm{d}\beta\,\mathrm{d}x\,\mathrm{d}\xi) = \mathrm{d}\theta\otimes\delta_{\beta=0}\otimes\nu_t(\mathrm{d}x\,\mathrm{d}\xi), \quad t\in\,]-\kappa_0,\kappa_0[,$$

where $\mathrm{d}\theta$ denotes the Lebesgue measure on $[0,2\pi[$ and $\delta_{\beta=0}$ is the Dirac mass in β the dual variable of θ. In particular,

$$\nu_t(\mathrm{d}\theta\,\mathrm{d}\beta\,\mathrm{d}x\,\mathrm{d}\xi) = \mathrm{d}\theta\otimes\delta_{\beta=0}\otimes\phi_t(\nu_I), \quad t\in\,]-\kappa_0,\kappa_0[,$$

and

$$\nu(\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}\theta\,\mathrm{d}\tau\,\mathrm{d}\xi\,\mathrm{d}\beta) = \mathrm{d}\theta\otimes\delta_{\beta=0}\otimes\mathrm{d}t\otimes\delta_{\tau+p(x,\xi)}\otimes\phi_t(\nu_I), \quad t\in\,]-\kappa_0,\kappa_0[. \tag{4.6}$$

Step 2: This step is devoted to the description of the Wigner measure μ associated to (u^ε). The main result is the following

Proposition 4.2: Under the notation (3.12), *we have*

$$\mu(\mathrm{d}z\,\mathrm{d}t\,\mathrm{d}\zeta\,\mathrm{d}\tau)=\frac{1}{8}\int_0^{2\pi}(\Phi_t^\theta(\nu_I)\otimes \mathrm{d}t)\mathrm{d}\theta, \tag{4.7}$$

where $\Phi_s^\theta(x,\xi)$ *denotes the classical trajectory of the Hamiltonian* $\tilde{p}$ *starting from the point* $(0, -p(x,\xi),\Gamma(x,\xi,\theta))$

Proof: The idea is simple: we use the explicit expression (4.6) and the transformation rule of the Wigner measure by the diffeomorphism χ to determine μ for a small time, and then use Lemma 2.2 to propagate the local explicit information to all the time. We start with the following

Lemma 4.3: The identity (4.7) *holds for* $t\in\,]-\kappa_0,\kappa_0[$.

Proof: We have to prove that

$$\int a(t,\tau,z,\zeta)\mu(\mathrm{d}t\,\mathrm{d}\tau\,\mathrm{d}z\,\mathrm{d}\zeta)=\frac{1}{8}\int_0^{2\pi}\int_{\mathbb{R}_t}\int a(\Phi_t^\theta(x,\xi))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}t\,\mathrm{d}\theta \tag{4.8}$$

for every $a\in\mathcal{C}_0^\infty(\mathbf{T}^*(]-\kappa_0,\kappa_0[\times\dot{\mathbb{R}}^4))$.

Since $\nu_{|_{]-\kappa_0,\kappa_0[}}$ is supported in $\mathbf{T}^*(]-\kappa_0,\kappa_0[\times S^1\times\Omega)$ we may use transformation rule of the Wigner measure by the diffeomorphism $(t,x,\theta)\mapsto(t,\chi(x,\theta))$. This transformation yields

$$\mu=\Theta(|\det(\chi'(x,\theta))|\nu),\quad t\in\,]-\kappa_0,\kappa_0[\tag{4.9}$$

where Θ is the canonical transformation given by (3.16). From (3.11) it follows that

$$\mu=\Theta\left(\frac{1}{8|x|}\nu\right),\quad t\in\,]-\kappa_0,\kappa_0[. \tag{4.10}$$

Since ν is supported in $\beta=0$ then we have to deal only with the values of Θ on $\beta=0$. Using (3.13), one obtains

$$\Theta(t,\tau,x,\theta,\xi,0)=(t,\tau,\chi(x,\theta),2L^T(\chi(x,\theta))(\xi,0))=(t,\tau,\Gamma(x,\xi,\theta)). \tag{4.11}$$

Putting together (4.6) and (4.9)–(4.11), it follows that

$$\int a(t,\tau,z,\zeta)\mu(\mathrm{d}t\,\mathrm{d}\tau\,\mathrm{d}z\,\mathrm{d}\zeta)=\int\frac{1}{8|\phi_t^1(x,\xi)|}a(t,-p(x,\xi),\Gamma(\phi_t(x,\xi),\theta))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}t\,\mathrm{d}\theta, \tag{4.12}$$

where $\phi_t^1(x,\xi)=\Pi_x\phi_t(x,\xi)$. Since Γ is periodic in the variable θ, the right-hand side (RHS) of (4.12) does not change if we replace θ by $\theta+\alpha(x,\xi,t)$, where $\alpha(x,\xi,t)$ is defined in Lemma 3.6 (α is well defined because $t\in\,]-\kappa_0,\kappa_0[$). This implies

$$(4.12)=\int\frac{1}{8|\phi_t^1(x,\xi)|}a(t,-p(x,\xi),\Gamma(\phi_t(x,\xi),\theta+\alpha(x,\xi,t)))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}t\,\mathrm{d}\theta.$$

For every fixed $(x,\xi)\in\mathrm{supp}(\nu_I)$ we make the change of variables $s=\mathbf{t}^{-1}(t)$ [defined by (3.15)] in the last integral. This gives

$$(4.12)=\int\frac{1}{8}a(\mathbf{t}(s),-p(x,\xi),\Gamma(\phi_{\mathbf{t}(s)}(x,\xi),\theta+\alpha(x,\xi),\mathbf{t}(s)))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}s\,\mathrm{d}\theta.$$

Recall that the number κ_0 is chosen so that the conditions of Lemma 3.6 are satisfied for all $(x,\xi)\in\mathrm{supp}(\nu_I)$. In particular, one has

$$(\mathbf{t}(s), -p(x,\xi), \Gamma(\phi_{\mathbf{t}(s)}(x,\xi), \theta + \alpha(x,\xi,\mathbf{t}(s)))) = \Phi_s^\theta(x,\xi),$$

which yields

$$\int a(t,\tau,z,\zeta)\mu(\mathrm{d}t\,\mathrm{d}\tau\,\mathrm{d}z\,\mathrm{d}\zeta) = \frac{1}{8}\int_0^{2\pi}\int\int a(\Phi_s^\theta(x,\xi))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}s\,\mathrm{d}\theta$$

as claimed. This concludes the proof of Lemma 4.3 □

Our next task is to use Lemma 2.2 to extend the local result provided by (4.7) to all $\mathbf{T}^*(\mathbb{R}_t \times \dot{\mathbb{R}}^4)$. The family (u^ε) is solution of

$$\tilde{p}(t,x,\varepsilon D_t, \varepsilon D_x)u^\varepsilon = 0,$$

where $\tilde{p}$ is the smooth symbol given by (3.7). Also, (u^ε) is bounded in $L^2_{\mathrm{loc}}(\mathbb{R}_t \times \mathbb{R}^d \backslash F)$ where $F = \mathbb{R}_t \times \{0\}$. Thus, the hypothesis (H1) of Lemma 2.2 is satisfied. In the next lemma we prove that (u^ε) satisfies the hypothesis (H2) with $l=6$.

Lemma 4.4: The family (u^ε) *defined by* (4.1) *satisfies*

$$\|u^\varepsilon\|_{L^\infty(\mathbb{R}_t, L^2(\mathbb{R}^4_z))} = \mathcal{O}(\varepsilon^{-6}). \tag{4.13}$$

Proof: Recall that, as explained in the beginning of this section, the initial family v_I^ε is bounded in $L^2(\mathbb{R}^d)$ and belongs to $H^2(\mathbb{R}^3)$, with

$$\|v_I^\varepsilon\|_{H^2(\mathbb{R}^3)} = \mathcal{O}(\varepsilon^{-2}).$$

By change of variable and conservation laws of the equation (1.3), we have

$$\int_{\mathbb{R}^4} |z u^\varepsilon(t,\cdot)|^2 \mathrm{d}z = \frac{1}{8}\int_{\mathbb{R}^3} |v^\varepsilon(t,\cdot)|^2 \mathrm{d}x = \frac{1}{8}\int_{\mathbb{R}^3} |v_I^\varepsilon(x)|^2 \mathrm{d}x,$$

for every $t \in \mathbb{R}$. Thereby, we estimate

$$\int_{\mathbb{R}^4} |u^\varepsilon(t,\cdot)|^2 \mathrm{d}z \leqslant \int_{|z|\leqslant 1} |u^\varepsilon(t,\cdot)|^2 \mathrm{d}z + \int_{|z|\geqslant 1} |z|^2 |u^\varepsilon(t,\cdot)|^2 \mathrm{d}z \lesssim \|u^\varepsilon(t,\cdot)\|^2_{L^\infty(\mathbb{R}^3)} + \|v_I^\varepsilon\|^2_{L^2(\mathbb{R}^3)}$$

for every $t \in \mathbb{R}$. From the explicit formula (4.1), it follows that

$$\|u^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}^4)} = \|v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}^3)} \tag{4.14}$$

for every $t \in \mathbb{R}$. However, via Sobolev embedding, we obtain

$$\|v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}^3)} \lesssim \|v^\varepsilon(t,\cdot)\|_{H^2(\mathbb{R}^3)}$$

for every $t \in \mathbb{R}$. Hence, in order to prove (4.13), it suffices to prove

$$\|v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t, H^2(\mathbb{R}^3))} \lesssim \varepsilon^{-4}\|v_I^\varepsilon\|_{H^2}. \tag{4.15}$$

Observe that v^ε is solution to

$$i\partial_t v^\varepsilon = A_\varepsilon v^\varepsilon, \quad v^\varepsilon_{|t=0} = v_I^\varepsilon, \tag{4.16}$$

where

$$A_\varepsilon = \left(\frac{\varepsilon}{2}\Delta - \frac{1}{\varepsilon|x|} + V(x)\right).$$

Since the domain of A_ε is $H^2(\mathbb{R}^3)$ (see for example Ref. 11), it ensues

$$\|v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}+\|A_\varepsilon v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}\leqslant\|v_I^\varepsilon\|_{H^2}. \tag{4.17}$$

However, since

$$\Delta=\frac{2}{\varepsilon}A_\varepsilon+\frac{2}{\varepsilon^2}\frac{1}{|x|}-\frac{2}{\varepsilon^2}V(x),$$

we have

$$\|v^\varepsilon(t,\cdot)\|_{L^\infty_t(H^2(\mathbb{R}^3))}\lesssim\|v^\varepsilon(t,\cdot)\|_{L^\infty_t(L^2(\mathbb{R}^3))}+\frac{1}{\varepsilon}\|A_\varepsilon v^\varepsilon(t,\cdot)\|_{L^\infty_t(L^2(\mathbb{R}^3))}+\frac{1}{\varepsilon^2}\left\|\frac{v^\varepsilon(t,\cdot)}{|x|}\right\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}$$
$$+\frac{1}{\varepsilon^2}\|Vv^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}. \tag{4.18}$$

Since V is bounded, we get

$$\|Vv^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}\leqslant\|v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}. \tag{4.19}$$

Also, Hardy inequality gives

$$\left\|\frac{v^\varepsilon(t,\cdot)}{|x|}\right\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}\lesssim\|\nabla v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}\lesssim\delta\varepsilon^2\|v^\varepsilon\|_{L^\infty(\mathbb{R}_t,H^2(\mathbb{R}^3))}+\frac{C_\delta}{\varepsilon^2}\|v^\varepsilon\|_{L^\infty(\mathbb{R}_t,L^2(\mathbb{R}^3))}. \tag{4.20}$$

Choosing δ small and combining (4.18) and (4.20), we infer

$$\|v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R}_t,H^2(\mathbb{R}^3))}\lesssim\varepsilon^{-4}(\|v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R},L^2)}+\|A_\varepsilon v^\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R},L^2)}). \tag{4.21}$$

The statement (4.15) is then the combination of (4.17) and (4.21). □

To close the proof of Proposition 4.2, it remains to be proven that the small interval $]-\kappa_0,\kappa_0[$ contains all the information on μ. In other words, we have to check that the union of the Hamiltonian curves of $\tilde{p}$ starting from $\mathbf{T}^*(]-\kappa_0,\kappa_0[\times\dot{\mathbb{R}}^4)$ contains $\mathrm{supp}(\mu)$. This follows from the fact that $\mathrm{supp}(\mu)$ is contained in the characteristic set of $\tilde{p}$ and that the t-component of every bicharacteristic of $\tilde{p}$ is a bijection from $\mathbb{R}$ onto $\mathbb{R}$ (remember Lemma 3.1). □

Step 3: In this final step we give the description of the measure ν_t over $x\neq 0$. In order to use the "local inverse" of KS-transformation we write any test function $a\in\mathcal{C}_0^\infty(\mathbf{T}^*(S^1\times\mathbb{R}_t\times\dot{\mathbb{R}}^3))$ as $a=a_1+a_2$, such that $a_1\in\mathcal{C}_0^\infty(\mathbf{T}^*(S^1\times\mathbb{R}_t\times\Omega))$ and $a_2\in\mathcal{C}_0^\infty(\mathbf{T}^*(S^1\times\mathbb{R}_t\times\tilde{\Omega}))$. Since the functions a_1 and a_2 are treated in the same manner, we assume that $a_2=0$ and we will treat a_1 only. By using the explicit formula (4.7) and the inverse of the transformation Θ given by (3.16), we get

$$\int a(t,\tau,x,\xi,\theta,\beta)\,\nu(\mathrm{d}\tau\,\mathrm{d}x\,\mathrm{d}\xi\,\mathrm{d}\theta\,\mathrm{d}\beta)=\;=\int\left|\prod_z(\Phi_t^\theta(x,\xi))\right|^2 a(\Theta^{-1}(\Phi_t^\theta(x,\xi)))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}t\,\mathrm{d}\theta. \tag{4.22}$$

Let $\mathbf{t}(s)$ denote the t-component of $\Phi_t^\theta(x,\xi)$. The Hamiltonian system yields

$$\dot{\mathbf{t}}(s)=\left|\prod_z(\Phi_t^\theta(x,\xi))\right|^2.$$

By making the change of variables $\mathbf{t}(s)=t$ on the RHS of (4.22), one obtains

$$\int a(t,\tau,x,\xi,\theta,\beta)\,\nu(\mathrm{d}\tau\,\mathrm{d}x\,\mathrm{d}\xi\,\mathrm{d}\theta\,\mathrm{d}\beta) = \int a(\Theta^{-1}(\Phi^{\theta}_{\mathbf{t}^{-1}(t)}(x,\xi)))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}t\,\mathrm{d}\theta. \tag{4.23}$$

We do not need to calculate all the expression $\Theta^{-1}(\Phi^{\theta}_{\mathbf{t}^{-1}(t)}(x,\xi)))$. In fact, since v^{ε} does not depend on θ, the (θ,β)-component of ν is $d\theta\otimes\delta_{\beta=0}$. We take then a test function a which does not depend on (θ,β). Remark 3.7 says that

$$\prod_{t,\tau}\Theta^{-1}(\Phi^{\theta}_{\mathbf{t}^{-1}(t)}(x,\xi)) = (t,-p(x,\xi)).$$

Finally, Lemma 3.8 yields

$$\prod_{x,\xi}\Theta^{-1}(\Phi^{\theta}_{\mathbf{t}^{-1}(t)}(x,\xi)) = \Lambda^{*}\Bigg(\prod_{(z,\zeta)}(\Phi^{\theta}_{\mathbf{t}^{-1}(t)}(x,\xi))\quad.$$

Thus, the identity (4.23) becomes

$$2\pi\int a(t,\tau,x,\xi)\,\nu(\mathrm{d}t\,\mathrm{d}\tau\,\mathrm{d}x\,\mathrm{d}\xi) = \int_0^{2\pi}\int\int a\Big(t,-p(x,\xi),\ \Lambda^{*}\Big(\prod_{(z,\zeta)}(\Phi^{\theta}_{\mathbf{t}^{-1}(t)}(x,\xi))\Big)\Big)\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}t\,\mathrm{d}\theta. \tag{4.24}$$

However, by definition 3.2, we have

$$\Lambda^{*}\Big(\prod_{(z,\zeta)}(\Phi^{\theta}_{\mathbf{t}^{-1}(t)}(x,\xi))\Big) = \tilde{\phi}_t(x,\xi), \tag{4.25}$$

for *every* $\theta\in S^1$. Thus, (4.24) becomes

$$\int a(t,\tau,x,\xi)\,\nu(\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}\tau\,\mathrm{d}\xi) = \int\int a(t,-p(x,\xi),\tilde{\phi}_t(x,\xi))\,\nu_I(\mathrm{d}x\,\mathrm{d}\xi)\mathrm{d}t,$$

for every $a\in\mathcal{C}_0^{\infty}(\mathbf{T}^{*}(\mathbb{R}\times\dot{\mathbb{R}}^3))$. From this, one concludes that, as a function of (t,x)-variable, (v^{ε}) is pure on $\mathbb{R}\times\dot{\mathbb{R}}^3$. Furthermore, the Wigner measure is given by

$$\nu(\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}\tau\,\mathrm{d}\xi) = \mathrm{d}t\otimes\delta_{\tau+p(x,\xi)}\otimes\tilde{\phi}_t(\nu_I)_{|_{x\neq 0}}. \tag{4.26}$$

Let $\tilde{\nu}_t$ be a Wigner measure [we do not know if there exists only one—the uniqueness (and then the fact that (v^{ε}) is pure over $\dot{\mathbb{R}}^3$) will follow from the explicit formula (4.27)] associated to (v^{ε}) over $\dot{\mathbb{R}}^3$. According to (4.26), one obtains easily

$$\tilde{\nu}_t = \tilde{\phi}_t(\nu_I)_{|_{x\neq 0}}.$$

But

$$\tilde{\phi}_t(\nu_I)_{|_{x\neq 0}} = \tilde{\phi}_t(\nu_{I_{|_{\mathbb{R}^3\setminus\mathrm{Coll}_t}}}),$$

which yields

$$\tilde{\nu}_t = \tilde{\phi}_t(\nu_{I_{|_{\mathbb{R}^3\setminus\mathrm{Coll}_t}}}). \tag{4.27}$$

If ν_t is a Wigner measure associated to (v^{ε}) on $\mathbb{R}^3$ then

$$\nu_{t|_{x\neq 0}} = \tilde{\nu}_t = \tilde{\phi}_t(\nu_{I_{|_{\mathbb{R}^3\setminus\mathrm{Coll}_t}}}).$$

Nevertheless we do not know if ν_t is unique [if (v^{ε}) is pure on $\mathbb{R}^3$ or not]. This achieves the proof of the statement (i) of the main theorem.

The statement (ii) of the main theorem is a direct application of the conservation of the total mass. Indeed, if $\nu_I(\mathrm{Coll}_t(\nu_I))=0$ then the statement (i) of the main theorem yields

$$\nu_{t|_{x\neq 0}} = \tilde{\phi}_t(\nu_I). \tag{4.28}$$

Then it remains to prove that $\nu_{t|_{x=0}}=0$. First, one has

$$\|\nu_{t|_{x\neq 0}}\|_{\mathcal{M}} \leqslant \|\nu_t\|_{\mathcal{M}}.$$

second from (4.28), it ensues

$$\|\nu_{t|_{x\neq 0}}\|_{\mathcal{M}} = \|\tilde{\phi}_t(\nu_I)\|_{\mathcal{M}} = \|\nu_I\|_{\mathcal{M}} = \limsup_{\varepsilon\to 0}\|v_I^\varepsilon\|_{L^2(\mathbb{R}^3)}.$$

The latter equality follows from Proposition 1.4 and the assumptions on the family of initial data v_I^ε. Using again Proposition 1.4 and the conservation of the L^2-norm, one gets

$$\|\nu_t\|_{\mathcal{M}} \leqslant \limsup_{\varepsilon\to 0}\|v^\varepsilon(t,\cdot)\|_{L^2(\mathbb{R}^3)} = \limsup_{\varepsilon\to 0}\|v_I^\varepsilon\|_{L^2(\mathbb{R}^3)}.$$

This yields

$$\|\nu_{t|_{x\neq 0}}\|_{\mathcal{M}} = \|\nu_t\|_{\mathcal{M}},$$

which means that $\nu_{t|_{x=0}}\equiv 0$ and so

$$\nu_t = \nu_{t|_{x\neq 0}} = \tilde{\phi}_t(\nu_I).$$

The purity, ε-oscillation, and compactness at infinity of the family v_t^ε follows directly from the explicit expression of ν_t, and the conservation of the total mass (remember Proposition 1.4). This concludes the proof of Theorem 1.8. ■

APPENDIX A: PROOF OF LEMMA 3.1

Let $(t_0,z_0,\tau_0,\zeta_0)\in \mathbf{T}^*(\mathbb{R}\times\dot{\mathbb{R}}^4)$ satisfying $\tilde{p}(t_0,z_0,\tau_0,\zeta_0)=0$ and $(\mathbf{t}(s),\mathbf{z}(s),\boldsymbol{\tau}(s),\boldsymbol{\zeta}(s))$ be the classical trajectory of the Hamiltonian $\tilde{p}$ starting from (t_0,z_0,τ_0,ζ_0):

$$\dot{\mathbf{z}} = \frac{1}{4}\boldsymbol{\zeta}(s),$$

$$\dot{\boldsymbol{\zeta}}(s) = -2\boldsymbol{\tau}(s)\mathbf{z}(s) - \nabla W(\mathbf{z}(s)),$$

$$\dot{\mathbf{t}}(s) = |\mathbf{z}(s)|^2,$$

$$\dot{\boldsymbol{\tau}}(s) = 0,$$

$$(\mathbf{t},\mathbf{z},\boldsymbol{\tau},\boldsymbol{\zeta})_{|_{s=0}} = (t_0,z_0,\tau_0,\zeta_0). \tag{A1}$$

We have to prove that

$$\mathbf{t}(s) \underset{s\to\pm\infty}{\to} \pm\infty \tag{A2}$$

and that $s\mapsto\mathbf{t}(s)$ is an injection. Since $\dot{\mathbf{t}}(s)=|\mathbf{z}(s)|^2$ then the failure of (A2) means that $\mathbf{z}\in\mathbf{L}^2(]-\infty,0])$ or $\mathbf{z}\in\mathbf{L}^2([0,+\infty[)$. Assume, for example, that $\mathbf{z}\in\mathbf{L}^2([0,+\infty[)$, and let w a smooth real valued function, so that

$$w(s) = 0, \quad s \leqslant -1, \quad w(s) = 1, \quad s \geqslant 0.$$

We set

$$\mathbf{y}(s) = w(s)\mathbf{z}(s)$$

First, since $\mathbf{z} \in \mathbf{L}^2([0,+\infty[)$ then $y \in \mathbf{L}^2(\mathbb{R})$. Second, the equation of motion yields

$$\ddot{\mathbf{z}}(s) = -\frac{\tau_0}{2}\mathbf{z}(s) - \frac{1}{4}\nabla W(\mathbf{z}(s)), \tag{A3}$$

which implies that $\ddot{\mathbf{z}} \in \mathbf{L}^2([0,+\infty[)$. Thus, $\ddot{\mathbf{y}} \in \mathbf{L}^2(\mathbb{R})$ and so $\mathbf{y} \in \mathbf{H}^2$. This implies, in particular, that

$$|\dot{\mathbf{y}}(s)| + |\mathbf{y}(s)| \underset{s\to+\infty}{\to} 0,$$

and then

$$|\dot{\mathbf{z}}(s)| + |\mathbf{z}(s)| \underset{s\to+\infty}{\to} 0, \tag{A4}$$

However, (A1) and the conservation of the classical Hamiltonian give

$$\tau_0|\mathbf{z}(s)|^2 + 2|\dot{\mathbf{z}}(s)|^2 + W(\mathbf{z}(s)) = 1,$$

which contradicts (A4) (remember that $W(0)=0$) and proves (A2). On the other hand, since $\dot{\mathbf{t}}(s) = |\mathbf{z}(s)|^2$, if $s \mapsto \mathbf{t}(s)$ is not injective then there exists a nontrivial interval $[s_1, s_2]$, such that $z(s) = 0$, for every $s \in [s_1, s_2]$. This implies, also, that $\boldsymbol{\zeta}(s) = 4\dot{\mathbf{z}}(s) = 0$ and yields a contradiction with the conservation of the classical Hamiltonian as above. Hence, $s \mapsto \mathbf{t}(s)$ is an injection, as claimed. This concludes the proof of Lemma 3.1. □

APPENDIX B: PROOF OF LEMMA 3.4

It is easy to check (see Ref. 13, Chap. X) that outside the set $\{s \in \mathbb{R} : \mathbf{z}(s) = 0\}$ the transformation (3.8) defines a solution to the system

$$\begin{aligned} \dot{\mathbf{x}}(t) &= \boldsymbol{\xi}(t), \\ \dot{\boldsymbol{\xi}}(t) &= -\frac{\mathbf{x}(t)}{|\mathbf{x}(t)|^3} - \nabla V(\mathbf{x}(t)). \end{aligned} \tag{B1}$$

More precisely, if one writes

$$\{s \in \mathbb{R} : \mathbf{z}(s) \neq 0\} = \underbrace{[0, s_1^*[}_{I_*^1} \cup \underbrace{]s_1^*, s_2^*[}_{I_*^2} \cup \underbrace{]s_2^*, s_3^*[}_{I_*^3} \cup \ldots$$

then the transformation (3.8) is well defined on every I_*^i and $\tilde{\phi}_t(x_0, \xi_0)$ is a solution to the system (B1). [Let us note here that collision times cannot accumulate. In fact, the collision orbits are either periodic or go to spacial infinity in both time directions.] Furthermore, in I_*^1 the transformed $\tilde{\phi}_t(x_0, \xi_0)$ coincides with the regular solution of (B1) with initial data (x_0, ξ_0). Also, we have

$$s_1^* = \int_0^{t_1^*} \frac{1}{|\phi_t^1(x_0, \xi_0)|} \mathrm{d}t,$$

where t_1^* is the first collision time of the classical trajectory $\phi_t(x_0, \xi_0)$ starting from (x_0, ξ_0) with the potential center $x=0$. Let $(\tilde{\mathbf{x}}(t), \tilde{\boldsymbol{\xi}}(t)) := \tilde{\phi}_t(x_0, \xi_0)$ denotes the regularized trajectory starting from (x_0, ξ_0). The proof of Lemma 3.4 and Lemma 1.6 [Since $\tilde{\boldsymbol{\xi}}(t) = \boldsymbol{\xi}(t)$ for $t < t_1^*$ then the existence of the limit

$$\lim_{t\to(t_1^*)^-}\frac{\tilde{\boldsymbol{\xi}}(t)}{|\tilde{\boldsymbol{\xi}}(t)|}$$

proves Lemma 1.6] is equivalent to the existence of both limits

$$\lim_{t\to(t_1^*)^-}\frac{\tilde{\boldsymbol{\xi}}(t)}{|\tilde{\boldsymbol{\xi}}(t)|} \quad \text{and } \lim_{t\to(t_1^*)^+}\frac{\tilde{\boldsymbol{\xi}}(t)}{|\tilde{\boldsymbol{\xi}}(t)|},$$

and the equality

$$\lim_{t\to(t_1^*)^+}\frac{\tilde{\boldsymbol{\xi}}(t)}{|\tilde{\boldsymbol{\xi}}(t)|} = -\lim_{t\to(t_1^*)^-}\frac{\tilde{\boldsymbol{\xi}}(t)}{|\tilde{\boldsymbol{\xi}}(t)|}.$$

Since $\mathbf{t}(s)$ is a continuous and increasing function, then

$$\mathbf{t}(s)\to(t_1^*)^{\pm} \Leftrightarrow s\to(s_1^*)^{\pm}.$$

Thus, by definition, we have

$$\lim_{t\to(t_1^*)^{\pm}}\frac{\tilde{\boldsymbol{\xi}}(t)}{|\tilde{\boldsymbol{\xi}}(t)|} = \lim_{s\to(s_1^*)^{\pm}}\frac{\Lambda(\mathbf{z}(s))\boldsymbol{\zeta}(s)}{|\Lambda(\mathbf{z}(s))\boldsymbol{\zeta}(s)|}.$$

Then, to conclude the proof of the lemma, it suffices to prove that the function $s\mapsto\Lambda(\mathbf{z}(s))\boldsymbol{\zeta}(s)$ has a nonzero derivative in $s=s_1^*$. A direct computation yields

$$\frac{\mathrm{d}}{\mathrm{d}s}(\Lambda(\mathbf{z}(s))\boldsymbol{\zeta}(s))_{|s=s_1^*} = \Lambda(\dot{\mathbf{z}}(s_1^*))\boldsymbol{\zeta}(s_1^*) + \Lambda(\mathbf{z}(s_1^*))\dot{\boldsymbol{\zeta}}(s_1^*) = \frac{1}{4}\Lambda(\boldsymbol{\zeta}(s_1^*))\boldsymbol{\zeta}(s_1^*).$$

In the last line we have used $\mathbf{z}(s_1^*)=0$. Thus, we have only to check that $\Lambda(\boldsymbol{\zeta}(s_1^*))\boldsymbol{\zeta}(s_1^*)\neq 0$. On the one hand, in view of (3.3), we have

$$|\Lambda(\boldsymbol{\zeta}(s_1^*))\boldsymbol{\zeta}(s_1^*)| = |\boldsymbol{\zeta}(s_1^*)|^2.$$

On the other hand, the conservation of Hamiltonian implies

$$\tilde{p}(\mathbf{z}(s_1^*),\mathbf{t}(s_1^*),\boldsymbol{\zeta}(s_1^*),\boldsymbol{\tau}(s_1^*)) = \tilde{p}(\mathbf{z}(0),\mathbf{t}(0),\boldsymbol{\zeta}(0),\boldsymbol{\tau}(0)) = 0.$$

Since $\mathbf{z}(s_1^*)=0$ we get $\frac{1}{8}|\boldsymbol{\zeta}(s_1^*)|^2=1$ as desired. Finally, we obtain

$$\lim_{t\to(t_1^*)^{\pm}}\frac{\tilde{\boldsymbol{\xi}}(t)}{|\tilde{\boldsymbol{\xi}}(t)|} = \pm\frac{\Lambda(\boldsymbol{\zeta}(s_1^*))\boldsymbol{\zeta}(s_1^*)}{8}.$$

where $\mathbf{t}(s_1^*)=t_1^*$. Further collisions $(t_2^*,t_3^*,\ldots)$ are treated in the same way. This closes the proof of Lemma 3.4.

APPENDIX C: PROOF OF LEMMA 3.8

One denotes $\Pi_{(z,\zeta)}\Phi_s^{\theta}(x,\xi)=(\mathbf{z}(s),\boldsymbol{\zeta}(s))$. Recall that Θ^{-1} is given by

$$\Theta^{-1}(t,\tau,z,\zeta) = (t,\tau,\chi^{-1}(z),{}^{\mathrm{T}}[(\chi^{-1})'(z)]^{-1}(\zeta)).$$

It is clear that $\Pi_x(\chi^{-1}(\mathbf{z}(s)))=\Lambda(\mathbf{z}(s))\mathbf{z}(s)$. Hence, we have to prove that

$$^{T}[(\chi^{-1})'(\mathbf{z}(s))]^{-1}(\boldsymbol{\zeta}(s)) = \frac{1}{2|\mathbf{z}(s)|^2}(\Lambda(\mathbf{z}(s))\boldsymbol{\zeta}(s),0). \tag{C1}$$

By a straightforward computation we get

$$^{T}[(\chi^{-1})'(z)]^{-1} = \frac{1}{2|z|^2}\begin{pmatrix} z_1 & -z_2 & -z_3 & z_4 \\ z_2 & z_1 & -z_4 & -z_3 \\ z_3 & z_4 & z_1 & z_2 \\ 0 & 0 & 0 & 0 \end{pmatrix} + A(z), \tag{C2}$$

where $A(z)$ is a matrix with lines of the form

$$L_i = a_i(z)(z_4 \ -z_3 \ -z_2 \ z_1). \tag{C3}$$

Here $a_i:\mathbb{R}^4\to\mathbb{R}$, $i=1,2,3,4$ are given functions. Thus, in order to prove (C1), it suffices to show that the bilinear quantity

$$l(z,\zeta) = z_4\zeta_1 - z_3\zeta_2 + z_2\zeta_3 - z_1\zeta_4 \tag{C4}$$

is a first integral of the Hamiltonian $\tilde{p}$, and $l(\Gamma(x,\xi,\theta))=0$ for every $(\theta,x,\xi)\in S^1\times\mathbf{T}^*(\dot{\mathbb{R}}^3)$. This is a well-known fact (see Ref. 13 Lemma 2, p. 236). This achieves the proof of lemma 3.8.

Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto 606-8502, Japan

(Received 30 March 2005; accepted 15 April 2005; published online 9 June 2005)

We show that the equilibrium positions of the Ruijsenaars–Schneider–van Diejen systems with the trigonometric potential are given by the zeros of the Askey–Wilson polynomials with five parameters. The corresponding single particle quantum version, which is a typical example of "discrete" quantum mechanical systems with a q-shift type kinetic term, is shape invariant and the eigenfunctions are the Askey–Wilson polynomials. This is an extension of our previous study, which established the "discrete analogue" of the well-known fact; the equilibrium positions of the Calogero systems are described by the Hermite and Laguerre polynomials, whereas the corresponding single particle quantum versions are shape invariant and the eigenfunctions are the Hermite and Laguerre polynomials. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1927080]

I. INTRODUCTION

The Calogero–Sutherland systems[1] and their integrable deformation called the Ruijsenaars–Schneider–van Diejen systems[2,3] have many attractive features at both classical and quantum mechanical levels. In our recent papers,[4,5] the equilibrium positions of the classical Ruijsenaars–Schneider–van Diejen systems were studied. The equilibrium positions of the Calogero–Sutherland systems are described by the zeros of the classical orthogonal polynomials, the Hermite, Laguerre, Chebyshev, Legendre, Gegenbauer, and Jacobi polynomials.[6–8] Since the Ruijsenaars–Schneider–van Diejen systems are deformation of the Calogero–Sutherland systems, it is expected that the equilibrium positions of the Ruijsenaars–Schneider–van Diejen systems are described by some deformation of these classical orthogonal polynomials. This is indeed the case and we obtained the deformed Hermite, Laguerre, and Jacobi polynomials.[5] These deformed orthogonal polynomials fit in the Askey-scheme of the hypergeometric orthogonal polynomials;[9,10] (i) rational potential cases, one and two parameter deformation of the Hermite polynomials are a special case of the Meixner–Pollaczek polynomial and a special case of the continuous Hahn polynomial, and two and three parameter deformation of the Laguerre polynomials are the continuous dual Hahn polynomial and the Wilson polynomial, (ii) trigonometric potential cases, several one parameter deformation of the Jacobi polynomials are special cases of the Askey–Wilson polynomial. The Askey–Wilson polynomial has five parameters,[11] but the deformed Jacobi polynomials obtained in Ref. 5 have only three parameters. A natural question arises; find (integrable) multiparticle systems whose equilibrium positions are described by the Askey–Wilson polynomials with five parameters.

Shape invariance is an important ingredient of many exactly solvable quantum mechanics.[12–14] In another recent paper of ours,[15] the shape invariance of "discrete" quantum mechanical single particle systems, whose kinetic term causes a shift of the coordinate in the imaginary direction, are discussed. The eigenfunctions of these shape invariant systems are a special case of the Meixner–Pollaczek polynomial, a special case of the continuous Hahn polynomial, the continuous dual Hahn polynomial and the Wilson polynomial. These polynomials have all appeared in the above discussion about the equilibrium positions, in which we have one more

polynomial, the Askey–Wilson polynomial. This gives the second question; are the quantum mechanical single particle systems, whose eigenstates are the Askey–Wilson polynomial, shape invariant or not?

We will answer the above two questions in this paper. The answer to the first question is found by the same method given in Ref. 5, i.e., numerical analysis, functional equation, and three-term recurrence. The second question is answered affirmatively by using the properties of the Askey–Wilson polynomials and similar discussion in Ref. 15 with replacement of a shift operator by a q-shift operator.

This paper is organized as follows. In Sec. II, the classical equilibria of the Ruijsenaars–Schneider–van Diejen system are studied. For a suitable choice of the elementary potential functions, the equilibrium positions are given by the zeros of the Askey–Wilson polynomials with five parameters. In Sec. III we discuss the shape invariance of "discrete" quantum mechanical single particle systems with a q-shift type kinetic term. After discussing general theory, we present an explicit example of such shape invariant systems, in which eigenstates are described by the Askey–Wilson polynomials. The final section is for a summary and comments.

II. MULTIPARTICLE SYSTEMS: EQUILIBRIUM POSITIONS

Let us consider the equilibrium positions of the classical Ruijsenaars–Schneider–van Diejen systems with the trigonometric potential,[2,3] which are integrable deformation of the celebrated Calogero–Sutherland systems of exactly solvable multiparticle quantum mechanics. Its classical Hamiltonian corresponding to the BC root system is the following:[3]

$$H(p,q)=\sum_{j=1}^{n}\left(\cosh p_j\sqrt{V_j(q)V_j^*(q)}-\frac{1}{2}(V_j(q)+V_j^*(q))\right), \tag{1}$$

$$V_j(q)=w(q_j)\prod_{\substack{k=1\\k\neq j}}^{n}v(q_j-q_k)v(q_j+q_k)\quad(j=1,\ldots,n), \tag{2}$$

$$v(x)=\frac{\sin(x-ig_0)}{\sin x}, \tag{3}$$

$$w(x)=\frac{\sin(x-ig_1)}{\sin x}\frac{\sin(x-ig_2)}{\sin x}\frac{\cos(x-ig_3)}{\cos x}\frac{\cos(x-ig_4)}{\cos x}, \tag{4}$$

where $q={}^t(q_1,\ldots,q_n)$ and $p={}^t(p_1,\ldots,p_n)$ are the coordinates and conjugate momenta, and g_j $(j=0,\ldots,4)$ are the real positive coupling constants. The potentials V_j and V_j^* are complex conjugate of each other. Our convention of a complex conjugate function is the following: for an arbitrary function $f(x)=\Sigma_n a_n x^n$ $(a_n\in\mathbb{C})$, we define $f^*(x)=\Sigma_n a_n^* x^n$. Here c^* is the complex conjugation of a number $c\in\mathbb{C}$. Note that $f^*(x)$ is not the complex conjugation of $f(x)$, $(f(x))^*=f^*(x^*)$. This is relevant for considering complex variables in Sec. III. The equilibrium positions $p=0$, $q=\overline{q}$ are determined by the condition[4]

$$V_j(\overline{q})=V_j^*(\overline{q})>0\quad(j=1,2,\ldots,n). \tag{5}$$

This equation *without inequality* is rewritten in the Bethe ansatz type equation

$$\prod_{\substack{k=1\\k\neq j}}^{n}\frac{v(\overline{q_j}-\overline{q_k})v(\overline{q_j}+\overline{q_k})}{v^*(\overline{q_j}-\overline{q_k})v^*(\overline{q_j}+\overline{q_k})}=\frac{w^*(\overline{q_j})}{w(\overline{q_j})}. \tag{6}$$

Note that $\overline{q_j}=0,\pi/2$ is excluded in (5) but allowed in (6).

By the same method given in Ref. 5 (numerical analysis, functional equation, and three-term recurrence), we can show that the equilibrium positions $\{\overline{q_j}\}$ are given by the zeros of the Askey–Wilson polynomial[11] (we follow the notation of Koekoek and Swarttouw[10]) $p_n(x;a,b,c,d|q) \propto \Pi_{j=1}^{n}(x-\cos 2\overline{q_j})$ with the following parameters (while preparing the paper, the authors became aware of a paper by van Diejen,[16] in which the same result was presented):

$$q = e^{-2g_0}, \quad (a,b,c,d) = (e^{-2g_1}, e^{-2g_2}, -e^{-2g_3}, -e^{-2g_4}). \tag{7}$$

The outline of derivation is as follows. The functional equation for $f(x)=\Pi_{j=1}^{n}(x-\cos 2\overline{q_j})$ is the same as Eq. (A.4) ($\epsilon=-1$) in Ref. 5 with [this form of $g(x)$ is obtained by using some empirical knowledge based on numerical analysis]

$$\begin{aligned} h(x) = {} & \left(\frac{q^{-1}-q}{2}x - i\left(1+\frac{q^{-1}+q}{2}\right)\sqrt{1-x^2}\right)\left(\frac{a^{-1}-a}{2}(1+x) + i\left(1+\frac{a^{-1}+a}{2}\right)\sqrt{1-x^2}\right) \\ & \times \left(\frac{b^{-1}-b}{2}(1+x) + i\left(1+\frac{b^{-1}+b}{2}\right)\sqrt{1-x^2}\right)\left(\frac{c-c^{-1}}{2}(1-x) - i\left(1-\frac{c+c^{-1}}{2}\right)\sqrt{1-x^2}\right) \\ & \times \left(\frac{d-d^{-1}}{2}(1-x) - i\left(1-\frac{d+d^{-1}}{2}\right)\sqrt{1-x^2}\right), \end{aligned} \tag{8}$$

$$\begin{aligned} g_n(x) = {} & \frac{(1+a)(1+b)(1-c)(1-d)(1+q)(1-x^2)}{8abcdq^{n+1}}(4q(1+abcdq^{2n-1})x^2 \\ & - 2q^n(abc+abd+acd+bcd+(a+b+c+d)q)x - (1+q) \\ & \times (1+q-q^{n+1}-(ab+ac+ad+bc+bd+cd)q^n - q^{n-1}(1-q^n-q^{n+1})abcd)), \end{aligned} \tag{9}$$

and $\sqrt{\delta}=(1-q)/(1+q)$. The three-term recurrence $f_{n+1}(x)=(x-a_n)f_n(x)-b_nf_{n-1}(x)$ for the monic Askey–Wilson polynomial can be found in the literature, for example, Eq. (3.1.5) in Ref. 10. Then Eq. (A.7) in Ref. 5 holds because the functions $X_n(x), Y_n(x)$ of (A.13), (A.14) in Ref. 5 vanish for these a_n, b_n, and $g_n(x)$. Therefore we obtain Proposition A.3, A.4 in Ref. 5.

Remark 1: The models studied in Ref. 5 are special cases of this model. For example,

$$B, \quad \text{Eq. (2.75) in Ref. 5,} \quad (g_0,g_1,g_2,g_3,g_4) = \left(g_L, \tfrac{1}{2}g_S, \tfrac{1}{2}g_S, 0, 0\right),$$

$$C', \quad \text{Eq. (2.78) in Ref. 5,} \quad (g_0,g_1,g_2,g_3,g_4) = \left(g_S, \tfrac{1}{2}g_L, \tfrac{1}{2}g_L, \tfrac{1}{2}g_L, \tfrac{1}{2}g_L\right),$$

$$B'C, \quad \text{Eq. (2.79) in Ref. 5,} \quad (g_0,g_1,g_2,g_3,g_4) = (g_M, g_S, g_L, g_L, 0),$$

due to the following trigonometic formulas:

$$\frac{\sin(x-ig)}{\sin x} = \cosh g(1 - i\tanh g \cot x), \quad \frac{\cos(x-ig)}{\cos x} = \cosh g(1 + i\tanh g \tan x),$$

$$\cosh 2g(1 - i\tanh 2g \cot 2x) = \frac{\sin(2x-i2g)}{\sin 2x} = \frac{\sin(x-ig)}{\sin x}\frac{\cos(x-ig)}{\cos x}.$$

Remark 2: Ismail *et al.* studied the q-Strum Liouville problems and the Bethe ansatz equation of the *XXZ* model.[17] A special case of their results states that the zeros of Askey–Wilson polynomial $p_n(x;a,b,c,d|q) \propto \Pi_{j=1}^{n}(x-\cos 2\overline{q_j})$ with the parameters

$$q = e^{-2g_0}, \quad (a,b,c,d) = (e^{-2g_1}, e^{-2g_2}, e^{-2g_3}, e^{-2g_4}), \tag{10}$$

satisfies the Bethe ansatz type equation (6) with ($g_j > 0$)

$$v(x)=\frac{\sin(x-ig_0)}{\sin x},\quad w(x)=\frac{\sin(x-ig_1)}{\sin x}\frac{\sin(x-ig_2)}{\sin x}\frac{\sin(x-ig_3)}{\sin x}\frac{\sin(x-ig_4)}{\sin x}. \tag{11}$$

However this does not mean that $\{\overline{q_j}\}$ are equilibrium positions of the system (1) with (11), because $V_j(\overline{q})$ is not positive in this case. Moreover the $\cot^4 x$ term in $w(x)$ (11) appears too singular to give a satisfactory quantum Hamiltonian.

III. SINGLE PARTICLE SYSTEMS: SHAPE INVARIANCE

Next let us consider the shape invariance of the "discrete" quantum mechanical single particle systems with a q-shift type kinetic term. The argument is parallel to that given in Ref. 15, in which discrete quantum systems with a shift-type kinetic term are discussed.

In this section we use variables θ, x, and z, which are related as

$$0\leqslant\theta\leqslant\pi,\quad x=\cos\theta,\quad z=e^{i\theta}. \tag{12}$$

The dynamical variable is 2θ and the inner product is $(f(\theta),g(\theta))=\int_0^\pi d\theta\, f(\theta)^* g(\theta)$. We denote $D=D_z\stackrel{\text{def}}{=}z(d/dz)$. Then q^D is a q-shift operator, $q^D f(z)=f(qz)$. Note that

$$\int_0^\pi d\theta=\int_{-1}^1\frac{dx}{\sqrt{1-x^2}},\quad -i\frac{d}{d\theta}=z\frac{d}{dz}=D,\quad f(z)^*=f^*(z^{-1}). \tag{13}$$

For a real constant q $(0<q<1)$ and a function $V(z)=V(z;\boldsymbol{\lambda},q)$ with a set of real parameters $\boldsymbol{\lambda}$, let us consider the following Hamiltonian $H=H(z;\boldsymbol{\lambda},q)$:

$$H\stackrel{\text{def}}{=}\tfrac{1}{2}\sqrt{V(z)}q^D\sqrt{V^*(z^{-1})}+\tfrac{1}{2}\sqrt{V^*(z^{-1})}q^{-D}\sqrt{V(z)}-\tfrac{1}{2}(V(z)+V^*(z^{-1})). \tag{14}$$

The eigenvalue equation reads

$$H\phi_n=\mathcal{E}_n\phi_n, \tag{15}$$

with eigenfunctions $\phi_n(z)=\phi_n(z;\boldsymbol{\lambda},q)$ and eigenvalues $\mathcal{E}_n=\mathcal{E}_n(\boldsymbol{\lambda},q)$ $(n=0,1,\ldots)$ (we assume non-degeneracy $\mathcal{E}_0<\mathcal{E}_1<\cdots$). The kinetic term causes a q-shift in the variable z. This Hamiltonian is factorized and consequently positive semidefinite,

$$H=A^\dagger A, \tag{16}$$

$$A=A(z;\boldsymbol{\lambda},q)\stackrel{\text{def}}{=}\frac{1}{\sqrt{2}}(q^{D/2}\sqrt{V^*(z^{-1})}-q^{-D/2}\sqrt{V(z)}), \tag{17}$$

$$A^\dagger=A(z;\boldsymbol{\lambda},q)^\dagger\stackrel{\text{def}}{=}\frac{1}{\sqrt{2}}(\sqrt{V(z)}q^{D/2}-\sqrt{V^*(z^{-1})}q^{-D/2}), \tag{18}$$

where † denotes the Hermitian conjugation with respect to the above inner product. The ground state ϕ_0 is the function annihilated by A,

$$A\phi_0=0\quad(\Rightarrow H\phi_0=0,\ \mathcal{E}_0=0). \tag{19}$$

Explicitly this equation reads

$$\sqrt{V^*(q^{-1/2}z^{-1})}\phi_0(q^{1/2}z)=\sqrt{V(q^{-1/2}z)}\phi_0(q^{-1/2}z). \tag{20}$$

The other eigenfunctions can be obtained in the form

$$\phi_n(z)\propto P_n(z)\phi_0(z), \tag{21}$$

where $P_n(z)=P_n^{(\boldsymbol{\lambda},q)}(z)$ is a Laurent polynomial in z (for the explicit example below, it is the Askey–Wilson polynomial in x). This $P_n(z)$ satisfies

$$\widetilde{H}P_n = \mathcal{E}_n P_n. \tag{22}$$

Here $\widetilde{H}=\widetilde{H}(z;\boldsymbol{\lambda},q)$ is a similarity transformed Hamiltonian in terms of the ground state wave function ϕ_0,

$$\widetilde{H} \stackrel{\text{def}}{=} \phi_0^{-1} \circ H \circ \phi_0 = \tfrac{1}{2}V(z)q^D + \tfrac{1}{2}V^*(z^{-1})q^{-D} - \tfrac{1}{2}(V(z) + V^*(z^{-1})). \tag{23}$$

Corresponding to the factorization of H (16), $\widetilde{H}$ is also factorized,

$$\widetilde{H} = BC, \tag{24}$$

$$C = C(z,q) = \tfrac{1}{2}(q^{D/2} - q^{-D/2}), \tag{25}$$

$$B = B(z;\boldsymbol{\lambda},q) = V(z)q^{D/2} - V^*(z^{-1})q^{-D/2}. \tag{26}$$

Let us define a new set of wave functions $\phi_{1,n}(z)=\phi_{1,n}(z;\boldsymbol{\lambda},q)$,

$$\phi_{1,n} \stackrel{\text{def}}{=} A\phi_n \quad (n = 1,2,\dots). \tag{27}$$

As a consequence of the factorization, they form eigenfunctions of a new Hamiltonian $H_1 = H_1(z;\boldsymbol{\lambda},q)$,

$$H_1 = AA^\dagger \tag{28}$$

with the same eigenvalues $\{\mathcal{E}_n\}$,

$$H_1\phi_{1,n} = AA^\dagger A\phi_n = A\mathcal{E}_n\phi_n = \mathcal{E}_n\phi_{1,n} \quad (n = 1,2,\dots). \tag{29}$$

To consider the shape invariance of H, we try to find the operators A_1, $A_1^\dagger$ and a real constant $\mathcal{E}_1$ satisfying

$$H_1 = AA^\dagger = A_1^\dagger A_1 + \mathcal{E}_1, \tag{30}$$

$$A_1 = A_1(z;\boldsymbol{\lambda},q) \stackrel{\text{def}}{=} \frac{1}{\sqrt{2}}(q^{D/2}\sqrt{V_1^*(z^{-1})} - q^{-D/2}\sqrt{V_1(z)}), \tag{31}$$

$$A_1^\dagger = A_1(x;\boldsymbol{\lambda},q)^\dagger \stackrel{\text{def}}{=} \frac{1}{\sqrt{2}}(\sqrt{V_1(z)}q^{D/2} - \sqrt{V_1^*(z^{-1})}q^{-D/2}). \tag{32}$$

In other words, given $V(z)=V(z;\boldsymbol{\lambda},q)$, find a new potential $V_1(z)=V_1(z;\boldsymbol{\lambda},q)$ satisfying

$$V_1(z)V_1^*(q^{-1}z^{-1}) = V(q^{1/2}z)V^*(q^{-1/2}z^{-1}), \tag{33}$$

$$V_1(z) + V_1^*(z^{-1}) = V(q^{-1/2}z) + V^*(q^{-1/2}z^{-1}) + 2\mathcal{E}_1. \tag{34}$$

If V_1 has the same functional form as V with another set of parameters $\boldsymbol{\lambda}'$ (e.g, q-shifted $\boldsymbol{\lambda}$),

$$V_1(z;\boldsymbol{\lambda},q) \propto V(z;\boldsymbol{\lambda}',q), \tag{35}$$

then it is shape invariant. Suppose V_1 has the form

$$V_1(z) = V(q^{1/2}z)g(z), \tag{36}$$

with an as yet unspecified function $g(z)$, the above conditions (33) and (34) get slightly simplified,

$$g(z)g^*(q^{-1}z^{-1}) = 1, \tag{37}$$

$$V(q^{1/2}z)g(z) + V^*(q^{1/2}z^{-1})g^*(z^{-1}) = V(q^{-1/2}z) + V^*(q^{-1/2}z^{-1}) + 2\mathcal{E}_1. \tag{38}$$

If the desired V_1 is found, we can construct $H_2, H_3, \ldots$ by repeating the same step. We illustrate this procedure by taking the Askey–Wilson polynomial as an example.

Let us take V as

$$V(z) = V(z;\boldsymbol{\lambda},q) = \frac{(1-az)(1-bz)(1-cz)(1-dz)}{(1-z^2)(1-qz^2)}, \tag{39}$$

where $\boldsymbol{\lambda}=(a,b,c,d)$. For simplicity we assume $-1<a,b,c,d<1$. Note that $V^*(z)=V(z)$. The ground state (19) is given by[10]

$$\phi_0(z) = \phi_0(z;\boldsymbol{\lambda},q) \propto \sqrt{w(z;\boldsymbol{\lambda},q)} \stackrel{\text{def}}{=} \left| \frac{(z^2;q)_\infty}{(az,bz,cz,dz;q)_\infty} \right| \tag{40}$$

$$= \sqrt{\frac{(z^2,z^{-2};q)_\infty}{(az,az^{-1},bz,bz^{-1},cz,cz^{-1},dz,dz^{-1};q)_\infty}}, \tag{41}$$

where $(a_1,\ldots,a_m;q)_\infty = \prod_{j=1}^m \prod_{n=0}^\infty (1-a_jq^n)$. Excited states have the form (21) $\phi_n(z) \propto P_n(z)\phi_0(z)$, and (22) implies that $P_n(z)$ is proportional to the Askey–Wilson polynomial,[10]

$$P_n(z) = P_n^{(\boldsymbol{\lambda},q)}(z) \propto p_n(x;a,b,c,d;q), \tag{42}$$

$$\mathcal{E}_n = \mathcal{E}_n(\boldsymbol{\lambda},q) = \tfrac{1}{2}q^{-n}(1-q^n)(1-abcdq^{n-1}), \tag{43}$$

which is an orthogonal polynomial,

$$\int_{-1}^{1} \frac{\mathrm{d}x}{\sqrt{1-x^2}} w(z;\boldsymbol{\lambda},q) p_n(x;a,b,c,d|q) p_m(x;a,b,c,d|q) \propto \delta_{nm}, \tag{44}$$

namely $(\phi_n,\phi_m) \propto \delta_{nm}$. By denoting $p_n(x;a,b,c,d|q) = P_n(z;\boldsymbol{\lambda},q)$, the factorization (24) gives the forward and backward shift relations [(3.1.8) and (3.1.10) in Ref. 10],

$$C(z;q)P_n(z;\boldsymbol{\lambda},q) = -\mathcal{E}_n(\boldsymbol{\lambda},q)q^{n/2}(z-z^{-1})P_{n-1}(z;q^{1/2}\boldsymbol{\lambda},q), \tag{45}$$

$$-B(z;\boldsymbol{\lambda},q)q^{n/2}(z-z^{-1})P_{n-1}(z;q^{1/2}\boldsymbol{\lambda},q) = P_n(z;\boldsymbol{\lambda},q). \tag{46}$$

It is easy to check that V_1 in the form (36) with

$$g(z) = q^{-1}\frac{1-q^2z^2}{1-z^2} \tag{47}$$

satisfies (37) and (38), and it becomes

$$V_1(z;\boldsymbol{\lambda},q) = V(q^{1/2}z)g(z) = q^{-1}V(z;q^{1/2}\boldsymbol{\lambda},q), \tag{48}$$

and $\mathcal{E}_1$ is

$$\mathcal{E}_1(\boldsymbol{\lambda},q) = \tfrac{1}{2}q^{-1}(1-q)(1-abcd). \tag{49}$$

Therefore we have shape invariance, (48) and

$$A_1(z;\boldsymbol{\lambda},q) = q^{-1/2}A(z;q^{1/2}\boldsymbol{\lambda},q), \tag{50}$$

$$H_1(z;\boldsymbol{\lambda},q) = q^{-1}H(z;q^{1/2}\boldsymbol{\lambda},q) + \mathcal{E}_1(\boldsymbol{\lambda},q). \tag{51}$$

We write down important formulas once again,

$$A(z;\boldsymbol{\lambda},q)\phi_0(z;\boldsymbol{\lambda},q)=0, \tag{52}$$

$$A(z;\boldsymbol{\lambda},q)A(z;\boldsymbol{\lambda},q)^\dagger = q^{-1}A(z;q^{1/2}\boldsymbol{\lambda},q)^\dagger A(z;q^{1/2}\boldsymbol{\lambda},q)+\mathcal{E}_1(\boldsymbol{\lambda},q). \tag{53}$$

Starting from $V_0=V$, $H_0=H$, $\phi_{0,n}=\phi_n$, let us define V_s, H_s, $\phi_{s,n}$ $(n\geqslant s\geqslant 0)$ step by step,

$$V_{s+1}(z;\boldsymbol{\lambda},q)\stackrel{\text{def}}{=}q^{-1}V_s(z;q^{1/2}\boldsymbol{\lambda},q), \tag{54}$$

$$H_{s+1}(z;\boldsymbol{\lambda},q)\stackrel{\text{def}}{=}A_s(z;\boldsymbol{\lambda},q)A_s(z;\boldsymbol{\lambda},q)^\dagger+\mathcal{E}_s(\boldsymbol{\lambda},q), \tag{55}$$

$$\phi_{s+1,n}(z;\boldsymbol{\lambda},q)\stackrel{\text{def}}{=}A_s(z;\boldsymbol{\lambda},q)\phi_{s,n}(z;\boldsymbol{\lambda},q). \tag{56}$$

Here A_s and $A_s^\dagger$ are defined by

$$A_s(z;\boldsymbol{\lambda},q)\stackrel{\text{def}}{=}\frac{1}{\sqrt{2}}\left(q^{D/2}\sqrt{V_s^*(z^{-1};\boldsymbol{\lambda},q)}-q^{-D/2}\sqrt{V_s(z;\boldsymbol{\lambda},q)}\right), \tag{57}$$

$$A_s(z;\boldsymbol{\lambda},q)^\dagger\stackrel{\text{def}}{=}\frac{1}{\sqrt{2}}\left(\sqrt{V_s(z;\boldsymbol{\lambda},q)}q^{D/2}-\sqrt{V_s^*(z^{-1};\boldsymbol{\lambda},q)}q^{-D/2}\right). \tag{58}$$

As a consequence of the shape invariance (53), we obtain for $n\geqslant s\geqslant 0$,

$$V_s(z;\boldsymbol{\lambda},q)=q^{-s}V(z;q^{s/2}\boldsymbol{\lambda},q), \tag{59}$$

$$A_s(z;\boldsymbol{\lambda},q)=q^{-s/2}A(z;q^{s/2}\boldsymbol{\lambda},q),\quad A_s(z;\boldsymbol{\lambda},q)^\dagger=q^{-s/2}A(z;q^{s/2}\boldsymbol{\lambda},q)^\dagger, \tag{60}$$

$$H_s(z;\boldsymbol{\lambda},q)=A_s(z;\boldsymbol{\lambda},q)^\dagger A_s(z;\boldsymbol{\lambda},q)+\mathcal{E}_s(\boldsymbol{\lambda},q)=q^{-s}H(z;q^{s/2}\boldsymbol{\lambda},q)+\mathcal{E}_s(\boldsymbol{\lambda},q), \tag{61}$$

$$\mathcal{E}_{s+1}(\boldsymbol{\lambda},q)=\mathcal{E}_s(\boldsymbol{\lambda},q)+q^{-s}\mathcal{E}_1(q^{s/2}\boldsymbol{\lambda},q), \tag{62}$$

$$H_s(z;\boldsymbol{\lambda},q)\phi_{s,n}(z;\boldsymbol{\lambda},q)=\mathcal{E}_n(\boldsymbol{\lambda},q)\phi_{s,n}(z;\boldsymbol{\lambda},q), \tag{63}$$

$$A_s(z;\boldsymbol{\lambda},q)\phi_{s,s}(z;\boldsymbol{\lambda},q)=0, \tag{64}$$

$$A_s(z;\boldsymbol{\lambda},q)^\dagger\phi_{s+1,n}(z;\boldsymbol{\lambda},q)=(\mathcal{E}_n(\boldsymbol{\lambda},q)-\mathcal{E}_s(\boldsymbol{\lambda},q))\phi_{s,n}(z;\boldsymbol{\lambda},q). \tag{65}$$

The relation (62) means that $\{\mathcal{E}_n\}$ is calculable from $\mathcal{E}_1$ (49). In other words, the spectrum is determined by the shape invariance.

From (56) and (65) we obtain the formulas,

$$\phi_{s,n}(z;\boldsymbol{\lambda},q)=A_{s-1}(z;\boldsymbol{\lambda},q)\cdots A_1(z;\boldsymbol{\lambda},q)A_0(z;\boldsymbol{\lambda},q)\phi_n(z;\boldsymbol{\lambda},q), \tag{66}$$

$$\phi_n(z;\boldsymbol{\lambda},q)=\frac{A_0(z;\boldsymbol{\lambda},q)^\dagger}{\mathcal{E}_n(\boldsymbol{\lambda},q)-\mathcal{E}_0(\boldsymbol{\lambda},q)}\frac{A_1(z;\boldsymbol{\lambda},q)^\dagger}{\mathcal{E}_n(\boldsymbol{\lambda},q)-\mathcal{E}_1(\boldsymbol{\lambda},q)}\cdots\frac{A_{n-1}(z;\boldsymbol{\lambda},q)^\dagger}{\mathcal{E}_n(\boldsymbol{\lambda},q)-\mathcal{E}_{n-1}(\boldsymbol{\lambda},q)}\phi_{n,n}(z;\boldsymbol{\lambda},q). \tag{67}$$

The former (66) gives the eigenfunction $\phi_{s,n}$ of the sth Hamiltonian H_s along the isospectral line with energy $\mathcal{E}_n$, starting from ϕ_n of the original Hamiltonian H by repeated application of the A operators. The latter (67), on the other hand, expresses the nth eigenfunction ϕ_n of the original Hamiltonian, starting from the explicitly known ground state $\phi_{n,n}$ of the nth Hamiltonian H_n by repeated application of the $A^\dagger$ operators. Since (61) implies $\phi_{n,n}(z;\boldsymbol{\lambda},q)\propto\phi_0(z;q^{n/2}\boldsymbol{\lambda},q)$, ϕ_n is expressed in terms of ϕ_0 and V. The latter formula (67) could also be understood as the generic form of the Rodrigue's formula for the orthogonal polynomials. The situation is depicted in Fig. 1.

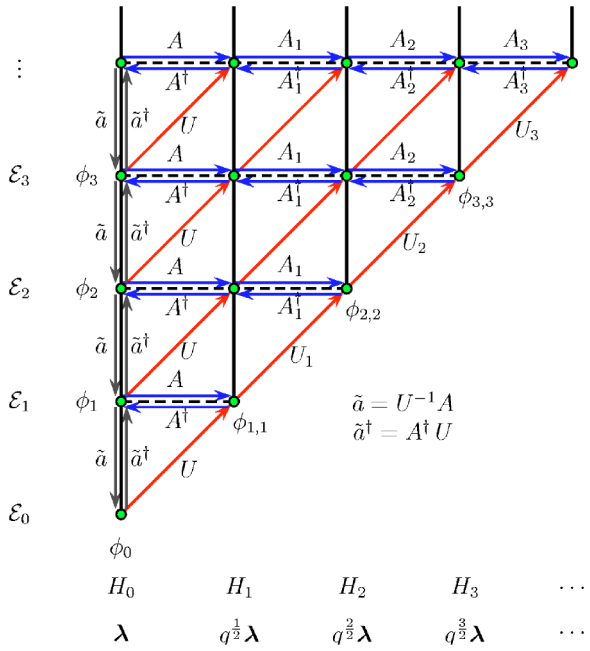

FIG. 1. A schematic diagram of the energy levels and the associated Hamiltonian systems together with the definition of the A and $A^\dagger$ operators and the creation ($\tilde{a}^\dagger$) and annihilation ($\tilde{a}$) operators. The parameter set is indicated below each Hamiltonian.

The operator A acts to the right and $A^\dagger$ to the left along the horizontal (*isospectral*) line. They should not be confused with the *annihilation* and *creation* operators, which act along the vertical line of a given Hamiltonian H_s going from one energy level $\mathcal{E}_n$ to another $\mathcal{E}_{n\pm1}$.

In order to define the annihilation and creation operators, let us introduce normalized basis $\{\hat{\phi}_{s,n}\}_{n\geqslant s}$ for each Hamiltonian H_s. Ordinarily, the phase of each element of an orthonormal basis could be completely arbitrary. In the present case, however, the eigenfunctions are orthogonal polynomials. That is, they are real and the relations among different degree members are governed by the three-term recurrence relations. So the phases of $\{\hat{\phi}_{s,n}\}_{n\geqslant s}$ are fixed. Let us introduce a unitary (in fact an orthogonal) operator U_s mapping the sth orthonormal basis $\{\hat{\phi}_{s,n}\}_{n\geqslant s}$ to the $(s+1)$th $\{\hat{\phi}_{s+1,n}\}_{n\geqslant s+1}$ (see Fig. 1 and, for example, Refs. 14 and 18),

$$U_s\hat{\phi}_{s,n} = \hat{\phi}_{s+1,n+1}, \quad U_s^\dagger\hat{\phi}_{s+1,n+1} = \hat{\phi}_{s,n}. \tag{68}$$

We denote that $U_0 = U$. Roughly speaking U changes the parameters from $\boldsymbol{\lambda}$ to $q^{1/2}\boldsymbol{\lambda}$. Let us introduce an annihilation $\tilde{a}$ and a creation operator $\tilde{a}^\dagger$ for the Hamiltonian H as follows:

$$\tilde{a} = \tilde{a}(z;\boldsymbol{\lambda},q) \stackrel{\text{def}}{=} U^\dagger A(z;\boldsymbol{\lambda},q), \quad \tilde{a}^\dagger = \tilde{a}(z;\boldsymbol{\lambda},q)^\dagger \stackrel{\text{def}}{=} A(z;\boldsymbol{\lambda},q)^\dagger U. \tag{69}$$

It is straightforward to derive

$$H = \tilde{a}^\dagger\tilde{a}, \tag{70}$$

$$[\tilde{a},\tilde{a}^\dagger]\hat{\phi}_n(z;\boldsymbol{\lambda},q) = (\mathcal{E}_{n+1}(\boldsymbol{\lambda},q) - \mathcal{E}_n(\boldsymbol{\lambda},q))\hat{\phi}_n(z;\boldsymbol{\lambda},q). \tag{71}$$

IV. SUMMARY AND COMMENTS

In this paper we have studied the equilibrium positions of the Ruijsenaars–Schneider–van Diejen systems with the trigonometric potential and shown that for a suitable choice of the

elementary potential functions they are given by the zeros of the Askey–Wilson polynomials with five parameters (see Sec. II). The equation for the equilibrium positions (5) (without the positivity condition) can be written in the Bethe ansatz type equation (6). The Bethe ansatz is a powerful method for solvable models, and solving the Bethe ansatz equation or clarifying the properties of its solutions are very important. Ismail *et al.* studied Bethe ansatz equations for spin *s XXZ* models from the *q*-Sturm–Liouville problem point of view.[17] This kind of approach would shed light on the Bethe ansatz(-type) equations.

We have also studied the shape invariance of "discrete" quantum mechanical single particle systems with a *q*-shift type kinetic term. As an example of this shape invariance, we present such a system whose eigenfunctions are the Askey–Wilson polynomials. In this example $V(z)$ is a rational function of z (trigonometric function of θ), but the method works for a wider class of functions. In ordinary quantum mechanics there is the Crum's theorem,[13] which states a construction of the associated isospectral Hamiltonians H_s and their eigenfunctions $\phi_{s,n}$ (Fig. 1) even if the system has no shape invariance. The construction of H_s and $\phi_{s,n}$ given in this paper and Ref. 15 needs shape invariance. A "discrete" analogue of the Crum's theorem, namely similar construction without shape invariance, would be very helpful, if it exists.

We comment on the shape invariance of the Askey–Wilson polynomials with a small number of parameters, $p_n(x;a,b,1,-1)$. In this case $V(z)$ in (14) is

$$V(z;\boldsymbol{\lambda},q)=\frac{(1-az)(1-bz)}{1-qz^2},\quad \boldsymbol{\lambda}=(a,b). \tag{72}$$

By taking a form (36) with the same $g(z)$ (47), the conditions (37) and (38) are satisfied, and we have

$$V_1(z;\boldsymbol{\lambda},q)=q^{-1}V(q^{-1/2}z;q\boldsymbol{\lambda},q),\quad \mathcal{E}_1(\boldsymbol{\lambda},q)=\tfrac{1}{2}(q^{-1}-1)(1+ab). \tag{73}$$

Since $D_z=z(d/dz)$ is invariant under the rescaling of z, $D_z=D_{\alpha z}$, the Hamiltonian is shape invariant,

$$H_1(z,\boldsymbol{\lambda},q)=q^{-1}H(q^{-1/2}z;q\boldsymbol{\lambda},q)+\mathcal{E}_1(\boldsymbol{\lambda},q). \tag{74}$$

The sth Hamiltonian and the spectrum are given by

$$H_s(z;\boldsymbol{\lambda},q)=q^{-s}H(q^{-s/2}z;q^s\boldsymbol{\lambda},q)+\mathcal{E}_s(\boldsymbol{\lambda},q), \tag{75}$$

$$\mathcal{E}_s(\boldsymbol{\lambda},q)=\mathcal{E}_{s-1}(\boldsymbol{\lambda},q)+q^{-(s-1)}\mathcal{E}_1(q^{s-1}\boldsymbol{\lambda},q)=\tfrac{1}{2}q^{-s}(1-q^s)(1+abq^{s-1}). \tag{76}$$

The following corrections should be made on p. 1444 of Appendix A.

(1) After the displayed equation for $\|f\|_{1,A}$ in the second paragraph, insert the definition: $H_0^1(A)$ denotes the completion of the complex space $C_0^\infty(A)$ in the norm $\|\cdot\|_{1,A}$.

(2) The first line of the third paragraph should begin with the definition: Let $A(r)=\{x\in A:\|x\|_A<r\}$.

(3) In the second line of the third paragraph, "$\partial f/\partial x_i|A(R)\in L^2(A(r))$" should read "$\Delta f|A(r)\in L^2(A(r))$."

(4) In the fourth line of the third paragraph, "$\|\cdot\|_{1,A(r)}$" should read "$\|\cdot\|_{\Delta,A(r)}$."

(5) In the sixth line of the third paragraph, "$\partial f/\partial x_i|A(r)\in L^2(A(r))$" should read "$\partial f/\partial x_i|A(r)\in L^2(A(r))(i=1,\ldots,\nu)$."

Hybrid states of two and three level atoms

Claude Billionnet[a)]
Centre de Physique Théorique, Ecole Polytechnique, 91128 Palaiseau Cedex, France

(Received 5 January 2005; accepted 25 April 2005; published online 17 June 2005)

We calculate atom-photon resonances in the Wigner-Weisskopf model, admitting two photons and choosing a particular coupling function. We also present a rough description of the set of resonances in a model for a three-level atom coupled to a scalar-photon field. We give a general picture of matter-field resonances that these results fit into. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1935428]

I. INTRODUCTION

In recent years there has been a renewed interest for atom-radiation states in nonrelativistic quantum electrodynamics. After the rigorous proof[1] of the existence, for small coupling constants, of resonances (singularities of an analytic continuation of the Hamiltonian resolvent), resonances coming from the naked-atom-Hamiltonian eigenvalues, many studies have been concentrated on the study of the Hamiltonian spectrum and more particularly on the existence of the fundamental state in various models,[2–7] for arbitrary coupling constants. This latter question is a nontrivial problem since it has long been known that negative Hamiltonian eigenvalues may appear when the coupling constant increases.[8,9] In preceding works (see Ref. 10, and references therein), for our part, we were interested in a method for calculating resonances for arbitrary values of the coupling constant. It is a way of catching the above-mentioned particular eigenvalues. The result we obtained can be generally stated as follows. The coupling of a discrete-level system S to a zero-mass field does not only shift the level energies into the complex plane. Certainly these energies become resonances. But the coupling also creates other poles of the resolvent (or of its continuations), which have to be placed on the same footing as the preceding ones. For certain values of physical parameters of S, or certain values of the $(S+field)$ coupling constant, these latter poles may be eigenvalues of the coupled-system Hamiltonian. (In this article, the word resonance will refer to such a pole or, by extension, to an eigenvalue, when there is an obvious possible continuous transition from the one to the other.)

The presence of these poles is well-known for an atom or a molecule in an environment in which the only emitted or absorbed photons are monochromatic (lasers or cavities). Indeed, for a two-level atom with energies e_0 and e_1, and photons with energy e_1-e_0, the upper level is split into two levels by the coupling, when at most one photon is considered[9] (vacuum-field Rabi splitting). The coupling increases the number of Hamiltonian eigenvalues because it splits the degeneracy of each of the eigenvalues $e_1, 2e_1-e_0, \cdots, e_1+n(e_1-e_0), \cdots$ of the uncoupled atom-photon system. This phenomenon occurs in different but analogous situations: for instance the coupling of an exciton to the mode of a cavity,[11,12] and it can be detected by spectroscopic means. It is also present in electron-phonon interactions.[13,14] Let us note that the final number of atom-photon states is simply a consequence of the combination of discrete atom states with discrete photon states.

Many papers have studied the coupling of a two-level system to another system which has either discrete levels or a continuum of levels, often focusing on the continuous transition from the

a)Electronic mail: billionnet@cpht.polytechnique.fr

vacuum Rabi splitting to the Fermi's golden rule.[15,16] In the present work, a splitting is exhibited also in the continuum case. The eigenstates of the naked atom we are used to are thus but a small part of all the possible states.

In fact, the appearance of new resonances when the system S is coupled to a field is a general phenomenon whose explanation is given in Sec. II. It is, of course, not due to the smallness of the photon-state width. A numerical method, explained and illustrated in previous publications, enabled us to study and calculate these resonances in various simple models: S was either a harmonic oscillator[17] or a two-level atom. But in this latter case, we almost always limited ourselves to considering physical states with at most one photon.

A reason to carry on with the study is that the new resonances appearing with the coupling might play a role for systems having a large spatial extension: for instance Rydberg atoms or, a case maybe more important, molecular orbitals of big molecules. Indeed, in a very simplified model for an interaction of S with the field, a model in which the spatial extension δ of S may be varied (S is a charged harmonic oscillator whose mass and spring constant may be varied), we noted that some among the poles we speak about come to the negative real axis when δ gets large enough,[18] in comparison with the length scale of the problem, namely the wavelength of the transition from the first excited state to the fundamental one. These poles then correspond to stable states and are therefore important states. Their wave function can be written: it is a mixing of electron and photon states. Analogous phenomena may be expected for more complex extended systems. Besides, the treatment of strong coupling is also interesting for applications in nuclear physics.

From the theoretical point of view, it is thus important to be able to start the study of the resonances in the two following situations: a system with more than two levels and, in the case of two levels, a system with several (non monochromatic) photons. Section III deals with this second question. To the best of our knowledge, it is tackled in the literature only when the fundamental state question is discussed.[4] Here we calculate some mixed (or hybrid) states with several photons, or the resonances which correspond to them. Section IV tackles the same problem for three-level atoms, but since the situation is more complicated, we limit ourselves to a qualitative description of the numerous resonances. Both studies lead to the reasonable conjecture that the number of resonances should be roughly the product of the number of atom states by the number of independent radiation states actually coupled to the atom.

II. NOTATION OF THE RESONANCES

We need a precise notation for the different poles.

It will follow from a very general argument, which also explains why every atomic level should give rise to a double infinity of resonances. Let us consider a material quantum system S whose Hamiltonian, H_S, has eigenstates $|0\rangle$, $|1\rangle$, $|2\rangle$,..., with energies $e_0, e_1, e_2, \ldots$. Let us suppose that this system is coupled to the field of a massless boson, here the photon. We denote the state-space of the ($S+$*field*)-system by $\mathcal{E}$.

Let us consider a very general form for the Hamiltonian of the coupled system:

$$H(\lambda) = H_S \otimes 1 + 1 \otimes H_{\mathrm{rad}} + \lambda V, \tag{2.1}$$

where H_{rad} is the energy operator for the photon field and $\lambda\ V$ represents the coupling of S to the field. Let us introduce the auxiliary Hamiltonian.

$$H(\lambda, \mu) = H_S \otimes 1 + \mu 1 \otimes H_{\mathrm{rad}} + \lambda V, \tag{2.2}$$

where μ is a parameter which may be zero or positive.

If $\mu = 0$ and $\lambda = 0$, the energy levels $e_0, e_1, \ldots$ are infinitely degenerated (in $\mathcal{E}$), as the number of photons accompanying state $|m\rangle$ may be any integer and, moreover, the dimension of the space of possible photon states is infinite. Thus the dimension of the eigenspace $\mathcal{H}_i$ associated with the eigenvalue e_i of $H(0,0)$ is infinite. Let us underline the fact that the degeneracy we speak about here is different from the one we mentioned in the second paragraph of the introduction.

The idea underlying our present study, as well as the preceding ones, is to perturb $H(0,0)$ with respect to λ and μ successively. *A priori*, the perturbation with respect to λ removes the degeneracy, although it may be only partially, in some particular cases. This leads to the following notation.

Notation 1: $\zeta_{i,1}(\lambda), \zeta_{i,2}(\lambda), \ldots$ *denote the* $\mathbb{N}^2(=\mathbb{N})$ *eigenvalues of* $H(\lambda,0)$ *which tend to* e_i *when* λ *tends to* 0.

The choice of the second index, or an equivalent choice, will be described in the different contexts.

The perturbation with respect to μ then leads us to the following notation for the resonances we are interested in.

Notation 2: When we have selected, in a way which remains to be defined, one pole among those of the resolvent of $H(\lambda,\mu)$ *which tend to* $\zeta_{i,j}(\lambda)$ *when* μ *tends to* 0, *we denote it by* $z_{i,j}(\lambda,\mu)$.

There are two reasons for having to make a selection. The first one is that if the $\zeta_{i,j}$'s remain degenerated, and this will be the case in the model of Sec. III (see Proposition 3.2), then the degeneracy may be removed for $\mu \neq 0$; in other words, for $\mu \neq 0$, there may be several resonances (or eigenvalues) going to the same $\zeta_{i,j}$ when μ goes to 0. (See a more precise description at the beginning of Sec. III D 2.) The one we call $z_{i,j}(\lambda,\mu)$ will be a particular one, selected in a way which will be made precise in the context. The second reason is that the matrix elements of $[z - H(\lambda,\mu)]^{-1}$ are multivalued functions of z for $\mu \neq 0$. Therefore, two poles of two different determinations may have the same limit when μ goes to 0. However, we assume that there is only one pole tending to $\zeta_{i,j}$ for a given determination, once the first choice has been made. This will enable us to get the $z_{i,j}(\lambda,\mu)$'s by numerical calculus, starting from their germs $\zeta_{i,j}(\lambda)$'s. The notations of the poles of the different branches of the resolvent matrix elements will be made precise later on, by adding an upper index which refers to the determination (see Sec. III D 2 c).

III. HYBRID STATES FOR A TWO-LEVEL ATOM IN THE WIGNER-WEISSKOPF MODEL

Two resonances (distinct or not, see below) are well-known in the Wigner–Weisskopf model (recalled in Sec. III A), or in the Friedrichs model, which describe a two-level atom coupled to the field of a massless scalar boson.[4,8,9] These resonances can be seen without considering two-photon states. One can be associated, for small coupling constants, to the excited state of the atom; the other one is an eigenvalue corresponding to a stable state which differs from the unperturbed fundamental state. This eigenvalue appears when the coupling constant gets large enough. (Up to recently, it was not clear whether these two resonances were two occurrences of the same resonance or not. In fact this depends on the parameters of the physical system, but in any case it can be shown that there are actually two different resonances,[10] for a given value of the coupling constant.) In this section we want to study other resonances by taking into account several photons. The existence of such states is already alluded to in Ref. 4, where Theorem 2.2 shows that the ground state of the coupled system must take several-photon states into account. In a particular coupling, we will construct two of these states or resonances. It is the subject of Sec. III D 2. In accordance with the general notations introduced in Sec. II, they will be denoted by $z_{0,2}(\lambda,1)$ and $z_{1,2}(\lambda,1)$, tending, respectively, to the energies 0 and 1 of the naked atom. The index 2 will be explained later on.

A. The model and some notations

The atom state space is $\mathbb{C}^2$. The fundamental state is $|0\rangle := (1,0)$, with energy $e_0 = 0$ and the excited state is $|1\rangle := (0,1)$, with energy $e_1 = 1$. In the $\{|0\rangle, |1\rangle\}$ basis, the annihilation operator is $a = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. The field state space is $\mathcal{F} := \oplus_{n=0}^{\infty} \mathcal{F}_n$, as usual, with $\mathcal{F}_0 := \mathbf{C}$ and $\mathcal{F}_n := L^2(\mathbb{R})^{\vee n}$. Let g be in $L^2(\mathbb{R})$ with $\|g\|_2 = 1$ and $c(\overline{g})$, $c^*(g)$ be the operators annihilating and creating a (scalar) photon in state g. If $\hat{\omega}$ denotes the multiplication operator by the function $|k|$, acting in $L^2(\mathbb{R})$, the energy operator in $\mathcal{F}, d\Gamma(\hat{\omega})$, is denoted by H_{rad}.

The Hamiltonian of the model is

$$H(\lambda) := a^*a \otimes 1 + 1 \otimes H_{\mathrm{rad}} + \lambda(a^* \otimes c(\overline{g}) + a \otimes c^*(g)). \tag{3.1}$$

In order to have the mixed states appear readily, we introduce

$$H(\lambda,\mu) := a^*a \otimes 1 + \mu 1 \otimes H_{\mathrm{rad}} + \lambda(a^* \otimes c(\overline{g}) + a \otimes c^*(g)). \tag{3.2}$$

Note that $H(\lambda,\mu)$ is unitarily equivalent to the Hamiltonian obtained through replacing g in (3.1) by its unitarily scale transformed $g_\mu(p) := \mu^{-1/2} g(\mu^{-1}p)$. Introducing the parameter μ is thus not so arbitrary as it may seem since μ is in some way related to the width of the coupling function. But note that the position of the peak of g is also moved. This is a departure from a study which would start with monochromatic photons and enlarge the width of their spectrum little by little, without changing the position of the peak.

This Hamiltonian has invariant subspaces. To describe them and, in the same way, prepare the notations for Sec. IV, let us set $\mathcal{H}^{(1)}_{\mathrm{rad}}$, the space spanned by g; $\mathcal{F}^{(1)}_n := (\mathcal{H}^{(1)}_{\mathrm{rad}})^{\vee n}$, the space of n photon states, but each photon being in state g; $\mathcal{E}_0 := |0\rangle \otimes \mathcal{F}_0$, and for $n \geqslant 1$, $\mathcal{E}_n := |0\rangle \otimes \mathcal{F}_n \oplus |1\rangle \otimes \mathcal{F}_{n-1}$, a space we call the "$n$-excitation space"; $\mathcal{E}^{(1)}_n := |0\rangle \otimes \mathcal{F}^{(1)}_n \oplus |1\rangle \otimes \mathcal{F}^{(1)}_{n-1}$, $n \geqslant 1$, $\mathcal{E}^{(1)}_0 = \mathcal{E}_0$; $\mathcal{E}^{(1)} := \oplus_0^\infty \mathcal{E}^{(1)}_n$, $\mathcal{E} := \oplus_0^\infty \mathcal{E}_n$.

We will often use the notation $|n,\varphi\rangle$ for $|n\rangle \otimes \varphi$, if $|n\rangle$ is an atom state and $\varphi \in \mathcal{F}$.

Lemma: $\mathcal{E}_n$ is invariant by $H(\lambda,\mu)$, for all $n \geqslant 0$ and all $\mu \geqslant 0$; $\mathcal{E}^{(1)}_n \subset \mathcal{E}_n$ is invariant by $H(\lambda,0)$, for all $n \geqslant 0$.

As we said when we introduced Notations 1 and 2 in Sec. II, the method for studying the resonances of $H(\lambda,\mu)$ is a numerical method in which μ takes greater and greater values, starting from 0. So we begin with giving some properties of $H(\lambda,0)$.

B. Construction of resonances of $H(\lambda,\mu)$ from eigenvalues of $H(\lambda,0)$: Setting up

Proposition 3.1: $H(\lambda,0)\downarrow_{\mathcal{E}^{(1)}}$, the restriction of $H(\lambda,0)$ to $\mathcal{E}^{(1)}$, has a double infinity of eigenvalues

$$\zeta_{0,n}(\lambda) = 2^{-1}(1 - \sqrt{1 + 4n\lambda^2}), \quad \zeta_{1,n}(\lambda) = 2^{-1}(1 + \sqrt{1 + 4n\lambda^2}). \tag{3.3}$$

For each n, an eigenvector of $H(\lambda,0)\downarrow_{\mathcal{E}^{(1)}}$ associated with $\zeta_{i,n}(\lambda)$ is

$$\phi^{(0)}_{i,n} := (1 + n\lambda^2 \zeta^{-2}_{i,n}(\lambda))^{-1}(|1, g^{\otimes(n-1)}\rangle + \sqrt{n}\lambda\zeta^{-1}_{i,n}(\lambda)|0, g^{\otimes n}\rangle) \in \mathcal{E}^{(1)}_n. \tag{3.4}$$

Proof: $\mathcal{E}^{(1)}_n$, two dimensional, is invariant by $H(\lambda,0)$. (3.3) is thus obtained through diagonalizing a two-by-two matrix. ■

The choice of the first index in the notation of the eigenvalues is in accordance with the principle stated at the end of Sec. II. By the choice of the second index, we indicate that the eigenvector belongs to $\mathcal{E}^{(1)}_n$.

We note that only some part of the double degeneracy mentioned in Sec. II is removed here. Indeed, each $\zeta_{i,n}(\lambda)$ is still degenerated, since adding an arbitrary number of photons whose states are orthogonal to g to some state does not change the energy of this state. This follows from $[H(\lambda,0), 1 \otimes c^*(h)] = 0$, when the scalar product (g,h) vanishes. Let us develop this in order to introduce some notations.

Let $g_1, g_2, \ldots$ be a basis of functions orthogonal to g. For $p \geqslant 1$, let $\mathcal{G}_{0,p}$ be the subspace of $\mathcal{E}$ spanned by

$$\phi^{(n_1,n_2,\ldots)}_{0,n} := \prod_{i=1}^{\infty} (1 \otimes c^*(g_i))^{n_i} \phi^{(0)}_{0,p} \in \mathcal{E}_n \tag{3.5}$$

when n varies from p to infinity; n_i are k non-negative integers, k being arbitrary and

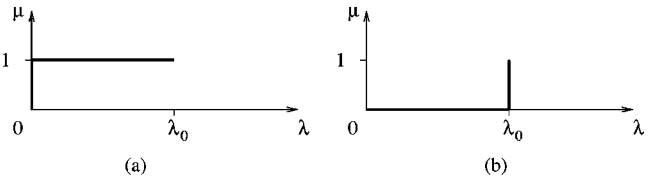

FIG. 1. Two paths enabling to construct two unnecessarily identical resonances.

$$\sum_{i=1}^{k} n_i = n - p.$$

In the same way, let $\mathcal{G}_{1,p}$ be the subspace spanned by

$$\phi_{1,n}^{(n_1,n_2,\ldots)} := \prod_{i=1}^{\infty} (1 \otimes c^*(g_i))^{n_i} \phi_{1,p}^{(0)} \in \mathcal{E}_n. \tag{3.6}$$

Proposition 3.2: For generic λ *values,* $\mathcal{G}_{i,p}$ *is the eigenspace of* $H(\lambda,0)$ *associated with the eigenvalue* $\zeta_{i,p}$*, for* $i=0,1$ *and* $p \geqslant 1$.

See hints for the proof in Appendix B 1, which is devoted to the proof of an analogous property.

Let us thus note that eigenstates of $H(\lambda,0)$ associated with $\zeta_{i,n}$ not only are not n-photon states but are neither necessarily n-excitation states. This complicates the picture of these eigenvalues and of the resonances $z_{i,n}(\lambda,\mu)$ they give rise to.

To be complete, let us still mention that 0 is an eigenvalue of $H(\lambda,0)$, with, if $\Sigma n_i = n$, n arbitrary, the associated eigenvectors

$$\phi_{0,0}^{(n_1,n_2,\ldots)} := \prod_{i=1}^{\infty} (1 \otimes c^*(g_i))^{n_i} |0\rangle \otimes \Omega \in \mathcal{E}_n. \tag{3.7}$$

where Ω denotes the vacuum state in $\mathcal{F}$.

Let us now turn to the μ variation, in order to define and construct resonances $z_{0,1}(\lambda,\mu)$, $z_{0,2}(\lambda,\mu),\ldots$ and $z_{1,1}(\lambda,\mu)$, $z_{1,2}(\lambda,\mu),\ldots$, from their germs $\zeta_{i,j}(\lambda)$ (for the notation, see Notation 2 in Sec. II).

This construction, as we said, is purely numerical for the moment. It goes step-by-step, starting from $\mu=0$. We do not look for any existence theorem nor for a complete description, difficult to get because of the complicated structure of the set of resonances. We just want to obtain numerical values for resonances which have not been considered up to now, and might be important.

This requires a particular choice for g. Before that, let us nevertheless give some general indications.

C. General remarks about the poles of the resolvent of $H(\lambda,\mu)$

In front of so many resonances, it is natural to ask oneself the question: when we consider $H(\lambda,1)$, which resonance is the one we are used to, that is to say is there any which could be "associated" with the excited state $|1\rangle$? Without going into detail here, let us explain shortly why the issue is not simple. In particular, given a value λ_0 of the coupling constant, even a small one, why $z_{1,1}(\lambda_0,\mu)$ is not necessarily the resonance we are used to. The resonance we are used to is obtained through restricting $H(\lambda,\mu)$ to $\mathcal{E}_1$ and following the resonance which sits at 1 for $\mu=1$ and $\lambda=0$. We follow it as λ increases from 0 to λ_0. Since its position at $\lambda=0$ does not depend on μ, it amounts to following the resonance along the path of Fig. 1(a), from its value 1 at the origin of the path.

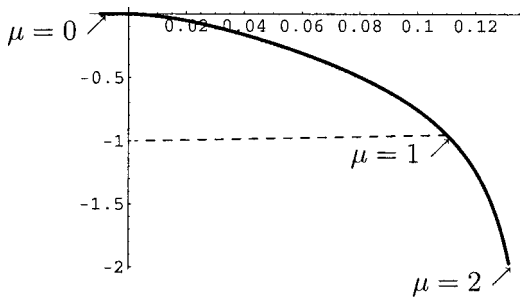

FIG. 2. The resonance $z_{0,1}(0.1,\mu)$, for $\mu \in [0,2]$, first in $\mathbb{R}^-$, then in the second sheet of the complex plane.

It is the usual perturbative approach, in which there is no need to introduce μ. On the contrary, $z_{1,1}(\lambda_0,1)$, also defined with $\mathcal{E}_1$ (see Sec. III D 1 b), is the limit of $z_{1,1}(\lambda_0,\mu)$, when μ increases from 0 (then $z_{1,1}(\lambda_0,0)=\zeta_{1,1}(\lambda_0)$) to 1. Since $\zeta_{1,1}(\lambda_0)$, by definition, tends to 1 when λ_0 tends to 0, $z_{1,1}(\lambda_0,1)$ is the resonance obtained through following the resonance along the path of Fig. 1(b), from the value 1 at the origin of this path. Now, in some examples, functions $z_{0,1}(\lambda,\mu)$ and $z_{1,1}(\lambda,\mu)$ are two branches of a unique analytic 2-variable function, which, even when restricted to $\mathbb{R}^2$, has branch points. These real branch points may lie inside the rectangle $[0,\lambda_0]\times[0,1]$ of the (λ,μ) plane, so that the two previous values of the resonances at the common end $(\lambda_0,1)$ of the two previous paths may be different. The λ and μ variations do not necessarily commute.[10] (Let us note here that it is thus dangerous to move λ and μ simultaneously without caution, as we did it for instance in the second paragraph of Sec. III of Ref. 17.) This phenomenon is at the origin of the remark in parentheses in the first paragraph of the present Sec. III.

This seems to be a drawback of the introduction of parameter μ. But this introduction enables us to see resonances for the physical Hamiltonian ($\mu=1$) which the perturbative approach does not give so easily. Indeed, when λ is the only parameter and when it is varied from λ_0 to 0, the continuous variation of the resonance siting at $z_{i,1}(\lambda_0,\mu)$ for $\lambda=\lambda_0$ may lead to 1, but also to infinity, or to a pole of g (see Fig. 2, where the pole is $-i$). The result depends on μ and g. But these two latter limits are too singular points to start a calculation in their neighborhood.

Since the difficulties of a general study are due to branch points whose positions depend on g, we choose a particular g. We now come back to the study of the announced particular case.

D. Construction of resonances of $H(\lambda,\mu)$ from eigenvalues of $H(\lambda,0)$. Calculations for a particular g

We fix the coupling constant at 0.1 and take the particular function we already used:[10]

$$g(p) = \sqrt{\frac{2}{\pi}}\frac{p}{1+p^2}. \tag{3.8}$$

This is a simple rational function which exhibits the type of singularity that actual coupling functions may have. (See, for instance, matrix elements of the interaction Hamiltonian for hydrogenic atoms in the electromagnetic field.[19])

In Sec. III D 1, we recall the definition of $z_{0,1}(\lambda,\mu)$ and $z_{1,1}(\lambda,\mu)$ and the known formulas through which they are obtained. We give their values for various μ and λ. We use them later on. Then, in Sec. III D 2, we define resonances $z_{0,2}(\lambda,\mu)$ and $z_{1,2}(\lambda,\mu)$ and give some approximate values. An evaluation of the errors is given in Appendix A.

1. Brief review about two resonances obtained with only one photon: $z_{0,1}(0.1,\mu)$ and $z_{1,1}(0.1,\mu)$

They are poles of $\langle 1\otimes\Omega|[z-H\downarrow_{\mathcal{E}_1}]^{-1}|1\otimes\Omega\rangle$ or of its analytic continuation.

TABLE I. Values of $z_{0,1}(0.1,\mu)$, for some values of μ below $\mu_c(0.1)$.

$10^3\,\mu$	0	0.1	1	3	6	6.2	6.36	6.366
$10^4\,z_{0,1}(0.1,\mu)$	−99	−94	−68	−34	−2.5	−1.1	0.04	0.001

Resonance $z_{0,1}(0.1,\mu)$.

For $\Im z>0$, the above mentioned matrix element is[20] $[f(\lambda,\mu,z)]^{-1}$, where

$$f(\lambda,\mu,z) := z-1-2\lambda^2\int_0^\infty \frac{g(p)^2}{z-\mu p}\mathrm{d}p. \tag{3.9}$$

Therefore, $z_{i,1}(0.1,\mu)$ are zeros of $f(\lambda,\mu,.)$, a function defined in the cut plane $\mathbb{C}/\mathbb{R}^+$, or of its analytic continuation through the cut, clockwise.[9,20,21] For $\mu\leqslant\mu_c(\lambda):=2\lambda^2\int_0^\infty g(p)^2/p\mathrm{d}p$, $f(\lambda,\mu,.)$ has only one zero; it is on the negative real axis and is 0 if and only if $\mu=\mu_c(\lambda)$. When μ tends to 0, it tends to $\zeta_{0,1}(0.1)$ and therefore we denote it by $z_{0,1}(0.1,\mu)$. We recall that the corresponding normalized eigenvector, which we denote by $\phi^{(0)}_{0,1}(\lambda,\mu)$, is proportional to

$$\psi^{(0)}_{0,1}(\lambda,\mu) := |1,\Omega\rangle+\lambda\left|0,\frac{g}{z_{0,1}(\lambda,\mu)-\mu|p|}\right\rangle. \tag{3.10}$$

For $\mu>\mu_c(\lambda)$, $z_{0,1}(\lambda,.)$ is defined as a zero of the analytic continuation

$$f_+(\lambda,\mu,z) := z-1-2\lambda^2\int_0^\infty \frac{g(p)^2}{z-\mu p}\mathrm{d}p+4i\pi\frac{\lambda^2}{\mu}g\left(\frac{z}{\mu}\right)^2 \tag{3.11}$$

of $f(\lambda,\mu,.)$, clockwise through the cut. When $\mu\to\mu_c(\lambda)$, it connects to the values for $\mu<\mu_c(\lambda)$. For μ varying from 0 to 2, some values of $z_{0,1}(0.1,\mu)$ are given in Table I and Fig. 2.

The physical value for $\mu=1$ is $0.11-0.95\,i$. For $\mu=0$, $z_{0,1}(0.1,0)=\zeta_{0,1}(0.1)\simeq-0.0099$; the graph goes through 0 for $\mu\simeq 6.36\ 10^{-3}$ and $z_{0,1}(0.1,2)=0.13-1.97\,i$.

In order to connect these results to the usual perturbative treatment, we drew a dashed line in Fig. 2. It describes the continuous move of the resonance which sits at the point $z_{0,1}(0.1,1)$ for $\lambda=0.1$, when λ decreases from this value to 0. One can see that the limit is not 1, the energy of the naked excited state, but $-i$, a pole of g. This makes a difference with what occurs for $z_{1,1}(\lambda,1)$, as we will see it just below. To distinguish the two behaviors, we called a resonance which, as a function of the only λ variable, does not tend to the excited state energy when λ tends to 0 a "nonstandard" resonance.[10] Be careful that a resonance may be standard for some μ's and nonstandard for others.

Resonance $z_{1,1}(0.1,\mu)$

It is another zero of $f_+(\lambda,\mu,.)$, which tends to $\zeta_{1,1}(0.1)$, when $\mu\to 0$. Its displacement when μ varies is given by the full line of Fig. 3.

We have $z_{1,1}(0.1,0)=1.0099$, $z_{1,1}(0.1,1)=0.997-0.010\,i$, $z_{1,1}(0.1,2)=0.995-0.0032\,i$. It can

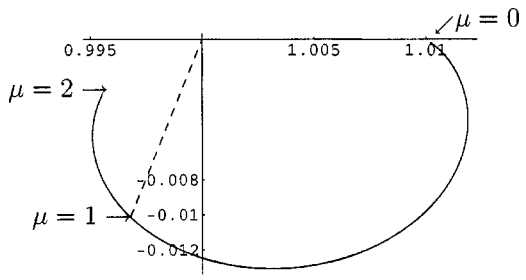

FIG. 3. $z_{1,1}(0.1,\mu)$, in the second sheet, for $\mu\in[0,2]$ (full line).

be shown that the resonance which sits at point $z_{1,1}(\lambda,1)$ for $\lambda=0.1$ moves continuously to 1 along the dashed line of Fig. 3 when λ goes to 0. Therefore, referring to the discussion of Sec. III C, we can say that $z_{1,1}(0.1,1)$ is the resonance usually associated with the excited state of the naked atom.

We now come to the original part of this Sec. III.

2. Two other resonances, obtained with two photons

Among the various resonances tending to $\zeta_{i,2}(\lambda)$ when μ goes to 0, we select poles of matrix elements of $[z-H(\lambda,\mu)\downarrow_{\mathcal{E}_2}]^{-1}$, or of one of their analytic continuation. Note that another choice among those mentioned after Notation 2 would have been to look for poles of matrix elements of $[z-H(\lambda,\mu)\downarrow_{\mathcal{E}_3}]^{-1}$, since we have eigenvectors of $H(\lambda,0)$ in $\mathcal{E}_3$ associated with the same eigenvalue $\zeta_{i,2}(\lambda)$: for instance $(1\otimes c^*(g_1))\phi_{i,2}$. But we make no claim to being complete. We just want to give an example of two resonances which are not considered usually.

Two new difficulties now appear. The first one is that, contrary to the $\mathcal{E}_1$-sector case, resonances in the $\mathcal{E}_2$ sector are given by zeros of a function $D(\lambda,\mu,.)$ which is no longer explicit, since we will see that it is the sum of a series. Up to now, we can only calculate these zeros approximately, through cutting the series after the first non trivial term. The zeros of this truncated function are the approximate values we consider, for the resonances in this sector.

The second difficulty is that this truncated function has several branch points; as a consequence, it has several analytic continuations. There is no reason why it should not be the same for $D(\lambda,\mu,.)$ itself, although it is possible. Therefore, when considering a zero, one must tell which branch is in question; we give a notation for the zeros of the various branches later on.

a. These resonances as zeros of a function $D(\lambda,\mu,.)$.

In $\mathcal{E}_2$, looking for the eigenvalues leads to the following proposition.

Proposition 3.3: (Eigenvalues of $H(\lambda,\mu)\downarrow_{\mathcal{E}_2}$ as zeros of a multivalued function) λ *being fixed and* μ *and* z *being two parameters satisfying* $\mu>0$ *and* $z\in\mathbb{R}^-$, *let* $\mathcal{D}_{\mu,z}$ *be the Fredholm function (see Ref. 22, p. 68) associated with the integral equation*

$$\varphi_{\lambda,\mu}(p)-\lambda^2\int K_{\mu,z}(p,q)\varphi_{\lambda,\mu}(q)\mathrm{d}q=0, \tag{3.12}$$

with

$$K_{\mu,z}(p,q)=\frac{g(p)\overline{g}(q)}{(z-1-\mu|p|-\lambda^2(T_{\mu,z}g)(p))(z-\mu(|p|+|q|))}, \tag{3.13}$$

where

$$(T_{\mu,z}f)(p)=\int\frac{\overline{g}(q')f(q')}{z-\mu(|p|+|q'|)}\mathrm{d}q'. \tag{3.14}$$

Let $z\to D(\lambda,\mu,z)$ *be the multivalued function which, for* $z\in\mathbb{R}^-$, *equals* $\mathcal{D}_{\mu,z}(\lambda^2)$.

In the case where one of the zeros of $D(\lambda,\mu,.)$ *is real negative, this zero is an eigenvalue of* $H(\lambda,\mu)$. *Let us denote it by* $\xi_{0,2}(\lambda,\mu)$. *The associated eigenvector is in* $\mathcal{E}_2$, *proportional to*

$$\psi_{0,2}^{(0)}(\lambda,\mu):=|1,\varphi_{\lambda,\mu}\rangle+\sqrt{2}\lambda\left|0,\frac{g\vee\varphi_{\lambda,\mu}}{\xi_{0,2}(\lambda,\mu)-\mu(|p_1|+|p_2|)}\right\rangle, \tag{3.15}$$

where $\varphi_{\lambda,\mu}$ *is a solution of*

$$\varphi_{\lambda,\mu}(p)-\lambda^2\int K_{\mu,\xi_{0,2}(\lambda,\mu)}(p,q)\varphi_{\lambda,\mu}(q)\mathrm{d}q=0. \tag{3.16}$$

Proof: $|1,\varphi_{\lambda,\mu}\rangle+|0,\chi_{\lambda,\mu}\rangle$ is an eigenvector of $H(\lambda,\mu)\downarrow_{\mathcal{E}_2}$ associated with the eigenvalue z if and only if (3.12) holds and $\chi_{\lambda,\mu}=\sqrt{2}\lambda(z-\mu(|p_1|+|p_2|))^{-1}g\vee\varphi_{\lambda,\mu}$. According to Fredholm's theory,

TABLE II. Four resonances (approximate values for two of them), for $\lambda = 0.1$ and $\mu = 1$.

$z_{0,1}$	$0.13 - 1.97i$
$z^1_{0,2}$	$0.216 - 1.9i$
$z_{1,1}$	$0.997 - 0.010i$
$z^1_{1,2}$	$1.043 - 1.127i$

(3.12) has a nontrivial solution only if $D_{\mu,z}(\lambda^2)=0$. The proposition follows from the fact that (3.14) and (3.13) are defined if z is a negative number. ■

Remark: If μ is set to 0 in (3.12)–(3.14), one finds that (3.12) implies $z=\zeta_{i,2}(\lambda)$. If the continuity with respect to μ could be proved, we would get that the limit of $\xi_{0,2}(\lambda,\mu)$ when μ goes to 0 is $\zeta_{0,2}(\lambda)$. We do not know how to prove this at the moment, since we do not know all the zeros of $D(\lambda,\mu,.)$. Nevertheless, the result of the approximate calculation of Sec. III D 2 d is along this line. That is why we eventually change notation $\xi_{0,2}(\lambda,\mu)$ for $z^1_{0,2}(\lambda,\mu)$, according to Notation 2. (The upper index is explained later on.)

To switch from eigenvalues to resonances, let us take $h \in L^2(\mathbb{R}^2)$, z s.t. $\Im z > 0$ and $\psi := |1,h\rangle$. Let us introduce $H_{\mu,z}(p,q,\lambda^2)$, the resolvent kernel of Eq. (3.12) (see Ref. 22, p. 63). It can be shown that

$$(\psi,[z - H(\lambda,\mu)]^{-1}\psi) = 1 - \lambda^2 \int H_{\mu,z}(p,q,\lambda^2)\overline{h}(p)h(q)\mathrm{d}p\mathrm{d}q. \tag{3.17}$$

We know (Ref. 22, pp. 58 and 63) that the only singular points of $H_{\mu,z}(p,q,.)$ are the solutions of $\mathcal{D}_{\mu,z}(\lambda)=0$. The zeros of analytic continuations of function $D(\lambda,\mu,.)$ of Proposition 3.3 will thus give us poles of the left-hand side of (3.17), that is to say resonances.

The calculation will be an approximate one. The result for $\mu=1$ is given by lines two and four of Table II.

b. Zeros of $D(\lambda,\mu,.)$ approached by zeros of a function $D^{(1)}(\lambda,\mu,.)$

Proposition 3.4: For

$$z < 0, \quad D(\lambda,\mu,z) = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} C_n(\lambda,\mu,z)$$

with $C_0=1$

$$C_n(\lambda,\mu,z) = \lambda^{2n} \int D_n(\mu,z,p_1,\ldots,p_n)\mathrm{d}p_1\cdots\mathrm{d}p_n \tag{3.18}$$

and, for $1 \leqslant n \leqslant 3$,

$$D_n(\mu,z,p_1,\ldots,p_n) = \mu^{-n} \prod_{i=1}^{i=n} \frac{|g(p_i)|^2}{f(\lambda,\mu,z-\mu|p_i|)\left(\dfrac{z}{\mu} - 2|p_i|\right)} \prod_{i<j} \frac{(|p_i| - |p_j|)^2}{\left(\dfrac{z}{\mu} - (|p_i| + |p_j|)\right)^2}. \tag{3.19}$$

Proof: The D_n's are determinants given by Fredholm's theory. We calculated them for $n \leqslant 3$; the result is given in (3.19). ■

The analytic structure (poles, branch points) of $D(\lambda,\mu,.)$ is difficult to determine. Indeed, $D(\lambda,\mu,.)$ is a series of terms each of which has a different analytic structure. Moreover, this structure is not simple. Therefore we will limit ourselves with replacing the search for zeros of $D(\lambda,\mu,z)$ by the search for the zeros of the sum of the first two terms of the series:

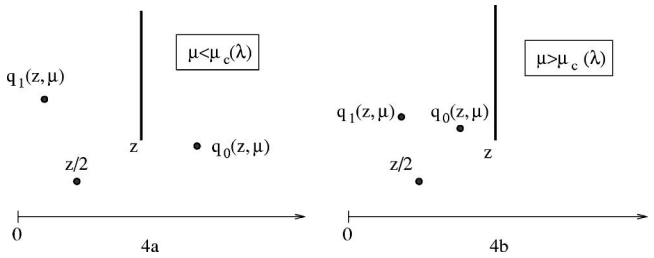

FIG. 4. Branch point and poles of $\psi(\lambda,\mu,z,.)$, defined by (3.21′).

$$D^{(1)}(\lambda,\mu,z) := 1 - C_1(\lambda,\mu,z). \tag{3.20}$$

The first corrections to this approximation are discussed in Appendix A. From Proposition 3.3, we get, if $\mu \neq 0$,

$$D^{(1)}(\lambda,\mu,z) = 1 - \frac{2\lambda^2}{\mu}\int_0^\infty \psi(\lambda,\mu,z,q)\mathrm{d}q, \tag{3.21}$$

where

$$\psi(\lambda,\mu,z,q) := \frac{g(\mu^{-1}q)^2}{(z-2|q|)f(\lambda,\mu,z-|q|)} \tag{3.21′}$$

and $D^{(1)}(\lambda,0,z)=(z(z-1)-\lambda^2)^{-1}(z(z-1)-2\lambda^2)$.

c. Analytic properties of $D^{(1)}$.

Proposition 3.5: For $\mu\neq 0$, $D^{(1)}(\lambda,\mu,.)$ *has at least three branch points:* 0, $z_{0,1}(\lambda,\mu)$ *and* $z_{1,1}(\lambda,\mu)$.

Proof: Let us recall that $f(\lambda,\mu,.)$ is analytic in the complex plane cut along $\mathbb{R}^+$, with a branch point at 0. The analytic continuation from the upper half-plane has a pole at $-i\mu$. An explicit expression of f in the upper half-plane is, for $z\neq i\mu$,

$$f(\lambda,\mu,z) = z - 1 + \lambda^2\frac{2\mu^3+\mu^2\pi z+2\mu z^2-\pi z^3+4\mu z^2(\log\mu-\log(-z))}{\pi(\mu^2+z^2)^2}. \tag{3.22}$$

The continuation clockwise across the cut, which we denote by $f_+(\lambda,\mu,z)$, is obtained through adding $4i\pi(\lambda^2/\mu)g(\mu^{-1}z)^2$ to the above expression. It is convenient to rather introduce the function $\hat{f}(\lambda,\mu,z)$ which coincides with $f(\lambda,\mu,z)$ in the upper half-plane and has a cut along $i\mathbb{R}^-$.

For $\Im z>0$, the poles of $\psi(\lambda,\mu,z,.)$ [see (3.21′)] in the complex plane cut along $z+i\mathbb{R}^+$ are $\pm i\mu$, $z/2$ and $q_i(z,\mu,\lambda):=z-z_{i,1}(\lambda,\mu)$. Depending on whether μ is smaller or greater than $\mu_c(\lambda)$, the z-dependent poles sit at places schematically shown in Fig. 4.

This follows from the position of $z_{i,1}(\lambda,\mu)$, given by the curves in Figs. 2 and 3. If $\mu=\mu_c(\lambda)$, the pole $q_0(z,\mu)$ coincides with z. (In Fig. 4, z has a positive real part, but it could be negative, as well.)

When z enters the lower half-plane along a path γ (for instance the dotted lines in Figs. 7 and 8), the integration path in (3.21) may have to be deformed in order to be kept away from some of the three poles or from the branch point z of $\psi(\lambda,\mu,z,.)$. Two different paths γ and γ' will not necessarily yield the same result. For instance, if γ crosses $z_{i,1}(\lambda,\mu)+\mathbb{R}^+$, $q_i(z,\mu)$ crosses $\mathbb{R}^+$; the integration path has thus to be deformed, whereas it is not the case if γ crosses $z_{i,1}(\lambda,\mu)-\mathbb{R}^+$. As a consequence, $z_{0,1}(\lambda,\mu)$ and $z_{1,1}(\lambda,\mu)$ are branch points.

If z comes to $z_{0,1}(\lambda,\mu)$ [respectively, $z_{1,1}(\lambda,\mu)$], then the pole $q_0(z,\mu)$ (respectively, $q_1(z,\mu)$) comes to 0 and the integral in (3.21) is singular.

To describe the various branches of $D^{(1)}$ readily, we need a notation for the homotopy classes of paths in $X_{\lambda,\mu}:=\mathbb{C}\backslash\{0,z_{0,1}(\lambda,\mu),z_{1,1}(\lambda,\mu)\}$. (Two paths are homotopic if they can be continu-

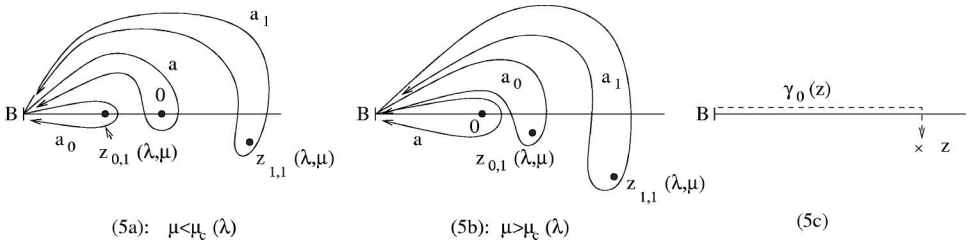

FIG. 5. Fundamental paths in the z plane.

ously deformed into one another, in $X_{\lambda,\mu}$.) Depending on whether μ is smaller or greater than $\mu_c(\lambda)$, the relative position of the three branch points is different. We refer to Fig. 5 for the definition of the fundamental class of paths a, a_0, a_1. The base point B is chosen real and smaller than $\zeta_{0,2}(\lambda)$.

The path $\gamma_0(z)$ is defined as the polyline going through points B, $B+i\epsilon$, $\Re(z)+i\epsilon$ and ending at z, for an arbitrary $\epsilon>0$. Every path γ from B to z can be expressed by means of a, a_0, a_1, and $\gamma_0(z)$. It defines a homotopy class $[\gamma_0(z)^{-1}\gamma] \in \pi_1(X_{\lambda,\mu})$. Conversely, with each class $[l]$ of $\pi_1(X_{\lambda,\mu})$, we can associate the homotopy class of paths $\gamma_0(z)l$ going from B to z. With each pair consisting of $[l]$ in $\pi_1(X_{\lambda,\mu})$ and z, we can associate the analytic continuation in z of $D^{(1)}(\mu,.)$ along the path $\gamma_0(z)l$. We denote the value at the end of the path by $D^{(1)}_{[l]}(\mu,z)$. From now on, we will omit to mention the λ variable (which has been fixed to 0.1.) We denote by $z^{[l]}(\mu)$ a point such that $D^{(1)}_{[l]}(\mu, z^{[l]}(\mu))=0$. When μ varies, we assume that this point varies continuously. It is denoted by $z^{[l]}_{i,2}(\mu)$ if its limit when μ goes to 0 is ζ_i.

These $z^{[l]}_{i,2}(\mu)$ are approximate values for the resonances we are considering. Regarding their physical meaning, we refer to the short comment in Sec. III E.

We now give some values of these functions for various μ values.

d. Values of resonance $z^{[l]}_{0,2}(\mu)$.

(i) $\mu < 6.3662\times 10^{-3}$

(a) $[l]=1$. For μ close to 0, we look for a zero of $D^{(1)}(\mu,.)$ in the neighborhood of $\zeta_{0,2}=-1.96\times 10^{-2}$. $D^{(1)}(\mu,.)$ is well defined by (3.21) in the neighborhood of every negative real number. A calculation on a computer yields negative real zeros of this expression, for μ small (see Table III, first column). When μ increases up to a certain value $\mu^a_{c,2}$, close to $\mu_c := \mu_c(10^{-1})$, the same formula still gives a negative real zero. The first column of Table III gives its values for $0 \leqslant \mu \leqslant 6.3662\times 10^{-3} \simeq \mu_c$.

Through comparing Table III with Table I, one sees that this zero is smaller than $z_{0,1}(\mu)$. In accordance with the notations of the end of Sec. III D 2 c, and with the upper index 1

TABLE III. Values of $z^1_{0,2}(\mu)$, for some values of μ below μ_c.

$10^3\ \mu$	$10^4\, z^1_{0,2}(\mu)$	$\frac{C_2}{2}(\mu, z^1_{0,2}(\mu))$	$\frac{M_3}{6}(\mu, z^1_{0,2}(\mu))$	$\frac{M_4}{24}(\mu, z^1_{0,2}(\mu))$	$\partial_z C_1(\mu, z^1_{0,2}(\mu))$
0	−196	0	0	0	103.9
0.1	−185.5	1.65×10^{-3}	3.95×10^{-6}	1.04×10^{-8}	105.3
1	−135.7	13.14×10^{-3}	10^{-4}	6.26×10^{-7}	116
3	−69.8	0.038	7.93×10^{-4}	10^{-5}	143.8
6	−9.3	0.099	7.7×10^{-3}	3.68×10^{-4}	247.1
6.2	−6.6	0.106	9.3×10^{-3}	5.2×10^{-4}	265.3
6.36	−4.4	0.111	1.09×10^{-2}	7.1×10^{-4}	284.2
6.3662	−4.328	0.112	1.10×10^{-2}	7.17×10^{-4}	285

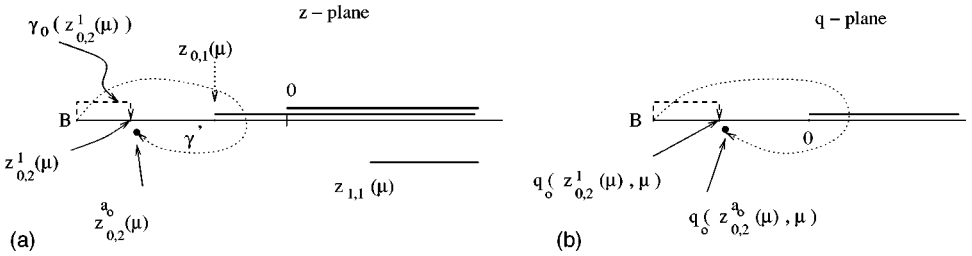

FIG. 6. Paths defining resonances $z^{[l]}_{0,2}(\mu)$ for $\mu<6\times10^{-3}$.

denoting the unity element in $\pi_1(X_\mu)$, this zero may then be denoted by $z^1_{0,2}(\mu)$, since the branch point $z_{0,1}(\mu)$ does not belong to the interval $Bz^1_{0,2}(\mu)$. Figure 6(a) shows the three cuts of $D^{(1)}(\mu,.)$ for $\mu<6.3662\times10^{-3}$ and this zero $z^1_{0,2}(\mu)$.

It has not been possible to determine the place of $\mu^a_{c,2}$ with respect to $\mu_c(10^{-1})$. We will come back to this point in Appendix A when we estimate the errors made in the approximation.

(b) $[l]=a_0$: *a zero associated with another branch*. Figure 6(a) also schematically shows another zero: $z^{[a_0]}_{0,2}(\mu)$. The notation indicates that this value is now the zero of the continuation of $D^{(1)}(\mu,.)$ along the path $\gamma':=\gamma_0(z^{[a_0]}_{0,2}(\mu))a_0$, a path which goes around the branch point $z_{0,1}(\mu)$. Figure 6(b) shows the two paths followed by $q_0(z,\mu)$ when z goes along $\gamma_0(z^{(1)}_{0,2}(\mu))$ or γ'.

This $z^{a_0}_{0,2}(\mu)$, also close to $\zeta_{0,2}$ for $\mu\simeq0$, is a zero of $D^{(1)}_{a_0}(\mu,.)$ which, for $\Re(z)<0$ (and also for $\Re(z)>0,\Im(z)>0$), reads

$$D^{(1)}_{a_0}(\mu,z)=1-\frac{2\lambda^2}{\mu}\int_0^\infty\frac{g(\mu^{-1}q)^2}{(z-2|q|)f(\mu,z-|q|)}dq+4i\pi\frac{\lambda^2}{\mu}\frac{g(q_0(z,\mu)/\mu)^2}{(z-2q_0(z,\mu))\partial_z f(z_{0,1}(\mu,\lambda),\mu,\lambda)} \tag{3.23}$$

with $\lambda=0.1$. This zero is no longer real.

(ii) For $\mu\simeq\mu_c$, things are not clear.

(iii) For $\mu>7\times10^{-3}$, the branch point $z_{0,1}$ of $D^{(1)}$ is in $\{z;\Re(z)>0,\Im(z)<0\}$ (see Fig. 2); it is shown in Fig. 7. Among the various analytic continuations of $D^{(1)}$ across $\mathbb{R}^+$, we consider $D^{(1)}_1$. Expressions are given in the following [formula (3.24) and the two last lines of the section]. The zero of $D^{(1)}_1$, denoted by $z^1_{0,2}(\mu)$, follows the curve of Fig. 7 when μ varies from 7×10^{-3} to 1. For $\mu=1$, the way $D^{(1)}$ is analytically continued to the zero of $D^{(1)}_1$ is shown by the dotted line.

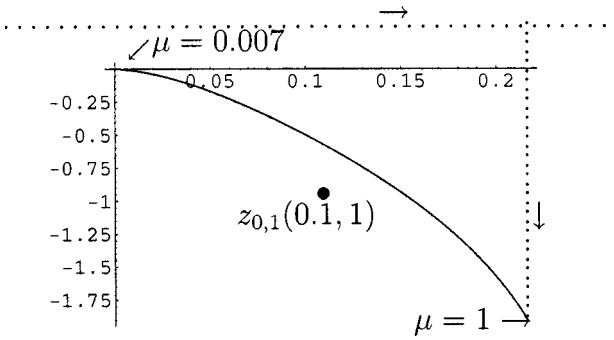

FIG. 7. $z^1_{0,2}(\mu)$ in the complex plane, for $\mu\in[0.007,1]$.

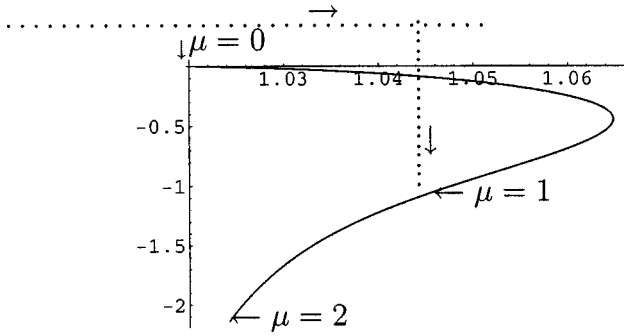

FIG. 8. $z^1_{0,2}(\mu)$, in the complex plane, for $\mu \in [310^{-4}, 2]$.

For $\mu = 7\times10^{-3}$, $z^1_{0,2}(\mu) = 2.8\times10^{-4} - 2.4\times10^{-5}i$, close to 0. Values of $z^1_{0,2}(\mu)$ for μ between 6.37×10^{-3} and 7×10^{-3} are difficult to get. Actually, their determination is not useful since $z^1_{0,2}(\mu)$ is only an approximate value of the exact resonance. We have $z^1_{0,2}(0.1,1) = 0.216 - 1.9i$. For $\Im z < 0$, $\Re(z) > 0$ and $\mu > 7.35\times10^{-3}$, still with $\lambda = 0.1$,

$$D^{(1)}_1(\mu,z) = 1 - \frac{2\lambda^2}{\mu}\left(\int_{[0,\Re(z)]\cup[\Re(z),z]} \frac{g^2(\mu^{-1}q)}{(z-2q)f_+(\mu,z-q)} + \int_{[0,\Re(z)]\cup[\Re(z),z]} \frac{g^2(\mu^{-1}q)}{(z-2q)f(\mu,z-q)}\right.$$
$$\left. + i\pi g^2\left(\frac{z}{2\mu}\right) f_+(\mu,z/2)^{-1} + 2i\pi g^2\left(\frac{z-z_{0,1}(\mu)}{\mu}\right)(2z_{0,1}(\mu)-z)^{-1}\partial_z f_+(\mu,z_{0,1}(\mu))^{-1}\right). \tag{3.24}$$

This formula is derived from (3.21) in the following way: when z enters the quadrant $\{z;\Re(z) > 0, \Im(z) < 0\}$, the cut in Fig. 4(b) drags the integration contour along, which yields the first two terms. The last two terms come from the residues of the poles $z/2$ and $q_0(z,\mu)$ which cross $\mathbb{R}^+$ [$q_1(z,\mu)$ does not cross $\mathbb{R}^+$]. For 10^3 $\mu \in [7, 7.3]$, the expression of $D^{(1)}_1(\mu,z)$ does not contain the residue term at q_0 since $\gamma_0(z^1_{0,2}(\mu))$ does not cross $z_{0,1}(\mu)+\mathbb{R}^+$.

e. Values of resonance $z^1_{1,2}(\mu)$.

It can be shown numerically that the zero of $D^{(1)}_1(\mu,.)$ which tends to $\zeta_{1,2}$ when μ tends to 0, denoted by $z^1_{1,2}(\mu)$, is a zero in $\{z;\Re(z) > 0, \Im(z) < 0\}$ of $\Delta(\mu,.)$, where

$$\Delta(\mu,z) := 1 - \frac{2\lambda^2}{\mu}\left(\int_{[0,\Re(z)]\cup[\Re(z),z]} \frac{g^2(\mu^{-1}q)}{(z-2q)f_+(\mu,z-q)} + \int_{[0,\Re(z)]\cup[\Re(z),z]} \frac{g^2(\mu^{-1}q)}{(z-2q)f(\mu,z-q)}\right.$$
$$+ i\pi g^2\left(\frac{z}{2\mu}\right) f_+(\mu,z/2)^{-1} + 2i\pi g^2\left(\frac{z-z_{0,1}(\mu)}{\mu}\right)(2z_{0,1}(\mu)-z)^{-1}\partial_z f_+(\mu,z_{0,1}(\mu))^{-1}$$
$$\left. + 2i\pi g^2\left(\frac{z-z_{1,1}(\mu)}{\mu}\right)(2z_{1,1}(\mu)-z)^{-1}\partial_z f_+(\mu,z_{1,1}(\mu))^{-1}\right). \tag{3.25}$$

$\Delta(\mu,z)$ is the expression of $D^{(1)}_1(\mu,z)$ in the neighborhood of the considered zero, but not everywhere in the lower half-plane; for example, these two functions differ at a point z such that $\Im(z) < \Im(z_{0,1}(\mu))$. The variation of $z^1_{1,2}(\mu)$ with μ is given by Fig. 8.

This resonance starts from $2^{-1}(1+\sqrt{1+8\lambda^2}) = 1.019\,62$ for $\mu = 0$ and goes through 1.043–1.127 i for $\mu = 1$. We note that this value is much farther from the real axis than the resonance $z_{1,1}(0.1,1)$ of sector $\mathcal{E}_1$. As in Fig. 7, the dotted line in Fig. 8 indicates the path of the analytic continuation of $D^{(1)}$ to the zero (of $D^{(1)}_1$), for $\mu = 1$. The origin is a branch point. The other two branch points, $z_{0,1}(0.1,1)$ and $z_{1,1}(0.1,1)$, whose values are recalled in Table II, cannot be drawn at the scale on the figure.

E. Conclusion of Sec. III

Table II gathers the four results we obtained for $\lambda=0.1$ and $\mu=1$. It gives four resonances among all those of the physical (i.e., $\mu=1$) Hamiltonian, when the function g is given by (3.8).

We see that the usual resonance $z_{1,1}$ is the only one near the real axis. This resonance represents what the excited state of the naked atom has become, due to the coupling of the atom with the field. The state is now unstable and its lifetime is in inverse proportion to $\Im z_{1,1}$. Other resonances are more than a hundred times farther from the real axis. However, for small values of μ, they approach the real axis, as it can be seen from Figs. 2, 7, and 8, or Table III. Therefore, resonances for small μ may play an important role. Now, in the harmonic-oscillator example mentioned in the introduction, what plays the role of parameter μ is δ^{-1}, the inverse of the spatial extension of the states, measured relatively to the wavelength of the transition from the excited state to the fundamental state of the naked atom. Thus, for extended states, μ is small, and we recover our motivation for the study of all the resonances of atom-field Hamiltonians.

One should of course discuss which of these resonances have a physical meaning and make this meaning precise, through finding actual situations in which these resonances or eigenvalues can be seen readily. We mean situations in which the photons are not monochromatic. The physical meaning should appear quite easily in the case of eigenvectors of the Hamiltonian. In $\mathcal{E}_1$ [see (3.10), Table I, and Fig. 2], we have an example of such a state. Regarding the restriction of $H(\lambda,\mu)$ to $\mathcal{E}_2$, we found approximate real values for the resonances. But we have not shown that (real) eigenvalues do exist. The study has to be carried on. Now, as pure resonances are concerned, we think that their study cannot simply be an academic question, since eigenvectors change continuously into resonances when parameters of the physical system are varied.

In any case, the two-level model is perhaps too simple to find a concrete application. The next section is a step toward more realistic models.

IV. HYBRID STATES FOR A THREE-LEVEL ATOM COUPLED TO PHOTONS

To be in a position to describe mixed states in more realistic models, we not only must be able to consider several photons (or bosons, in a more general setting), as in Sec. III, but we must also be able to consider several atomic or molecular levels. The present section is a preliminary study devoted to mixed states when S is a three-level atom coupled to the radiation by a Hamiltonian of type (2.2).

The reason why the study is only a preliminary one is that there comes some additional difficulty, together with those already mentioned in Sec. III: for $\mu \geqslant 0$, none of the spaces with a bounded excitation number is stable by the evolution operator, contrary to the two-level case. This is due to the possibility of the transition from the state consisting of the atom in state $|0\rangle$ and one photon to the state $|2\rangle$, the photon being absorbed ($|2\rangle$ is the second excited state). In this transition the excitation number (defined in Sec. III A) increases. For this reason, the determination of the Hamiltonian eigenvalues is already not simple for $\mu=0$. Since we assume that the structure of the resonance set will roughly be conserved when μ takes nonzero values, we must study the ($\mu=0$)-problem first. This is the subject of this Sec. IV. The displacement of these resonances when μ becomes nonzero will not be examined in the paper. (A typical result is illustrated by Fig. 12.)

A. Notations and Hamiltonian

The atom has three levels with energies $e_0=0$, e_1, and e_2, corresponding to states $|0\rangle$, $|1\rangle$, and $|2\rangle$. f_{01}, f_{12}, and f_{02} being three normalized functions in $L^2(\mathbb{R})$, the Hamiltonian is

$$H(\lambda,\mu) := H_0(\lambda,\mu) + \lambda_{02}V \tag{4.1}$$

with

$$\begin{aligned} H_0(\lambda,\mu) := {} & (e_1|1\rangle\langle 1| + e_2|2\rangle\langle 2|) \otimes 1 + \mu 1 \otimes H_{\mathrm{rad}} + \lambda_{01}(|1\rangle\langle 0| \otimes c(\overline{f_{01}}) + |0\rangle\langle 1| \otimes c^*(f_{01})) \\ & + \lambda_{12}(|2\rangle\langle 1| \otimes c(\overline{f_{12}}) + |1\rangle\langle 2| \otimes c^*(f_{12})) \end{aligned} \tag{4.2}$$

$$V := |2\rangle\langle 0| \otimes c(\overline{f_{02}}) + |0\rangle\langle 2| \otimes c^*(f_{02}), \tag{4.3}$$

where H_{rad} is as in Sec. III A. Transition $|0\rangle \to |2\rangle$ is distinguished from $|0\rangle \to |1\rangle$ and $|1\rangle \to |2\rangle$ for a physical reason and also to prepare a perturbative calculus.

We use the following notations, modeled on those of Sec. III A. Regarding the photons, we denote the Fock space by $\mathcal{F}$, the n-photon space by $\mathcal{F}_n$, the vacuum state by Ω, and we set

$\mathcal{H}^{(2)}_{\mathrm{rad}}$: the space spanned by f_{01}, f_{12}, $\mathcal{F}^{(2)}_n := (\mathcal{H}^{(2)}_{\mathrm{rad}})^{\vee n}$: the n photon-state space, but each photon being restricted to be in $\mathcal{H}^{(2)}_{\mathrm{rad}}$ and $\mathcal{F}^{(2)} := \oplus_n \mathcal{F}^{(2)}_n$.

$\mathcal{H}^{(3)}_{\mathrm{rad}}$: the space spanned by f_{01}, f_{12}, f_{02}, $\mathcal{F}^{(3)}_n := (\mathcal{H}^{(3)}_{\mathrm{rad}})^{\vee n}$ (each photon is restricted to be in $\mathcal{H}^{(3)}_{\mathrm{rad}}$) and $\mathcal{F}^{(3)} := \oplus_n \mathcal{F}^{(3)}_n$.

Regarding the atom-photon system, $\mathcal{E}_n$ and $\mathcal{E}$ have been defined in Sec. III A. We set

$$\mathcal{E}^{(k)}_1 := |0\rangle \otimes \mathcal{F}^{(k)}_1 \oplus |1\rangle \otimes \mathcal{F}^{(k)}_0, \quad k = 2,3$$

$$\mathcal{E}^{(k)}_n := |0\rangle \otimes \mathcal{F}^{(k)}_n \oplus |1\rangle \otimes \mathcal{F}^{(k)}_{n-1} \oplus |2\rangle \otimes \mathcal{F}^{(k)}_{n-2}, \quad k = 2,3, \quad n \geqslant 2$$

$$\mathcal{E}^{(k)} := \bigoplus_{n=0}^{\infty} \mathcal{E}^{(k)}_n$$

$$\lambda := (\lambda_{01}, \lambda_{12}, \lambda_{02}).$$

We also introduce $s_0 := (f_{01}, f_{02})$, $s_1 := (f_{01}, f_{12})$, $s_2 := (f_{02}, f_{12})$.

We will use the letter ϕ to indicate eigenvectors of $H_0(\lambda, 0)$; *a priori*, they depend on λ_{01} and λ_{12}. We will use χ to indicate eigenvectors of $H(\lambda, 0)$; they also depend on λ_{02}.

We aim at getting the eigenvalues of $H(\lambda, 0)$, an operator which we simply write $H(\lambda)$, from now on. When the variable μ is not mentioned, it will be assumed to be 0.

To this end, we take up the idea mentioned in Sec. II consisting in perturbing $H(0)$ through introducing the interaction step by step. The doubly infinite degeneracy of the eigenvalues e_0, e_1, and e_2 of $H(0)$, due to the arbitrariness of the number of photons and the arbitrariness of the state of each photon in the corresponding eigenvectors, is partially removed at each step. The first perturbation will be the addition of the λ_{01} and λ_{12} terms of (4.2) to $H(0)$. It is described in Sec. IV B. The second perturbation will be the supplementary addition of λ_{02} V. It is described in Sec. IV C.

B. Perturbation with respect to λ_{01} and λ_{12}: First splitting of e_0, e_1, and e_2

Here we are interested in $H_0(\lambda) := H_0(\lambda, 0)$; the interaction $\lambda_{02} V$ is switched off. First, in $\mathcal{E}_0$, $|0, \Omega\rangle$, is an eigenvector associated with the eigenvalue 0.

1. Three eigenvectors of $H_0(\lambda)$ in the 1-excitation space $\mathcal{E}^{(2)}_1$ and the three associated eigenvalues

The space $\mathcal{E}^{(2)}_1$, three-dimensional, is invariant by $H_0(\lambda)$. It is the direct sum of the eigensubspaces $|1\rangle \otimes \mathcal{F}^{(2)}_0$ and $|0\rangle \otimes \mathcal{F}^{(2)}_1$ of $H_0(0)$, associated with the eigenvalues e_1 and e_0, respectively, and dim. $\mathcal{F}^{(2)}_0 = 1$ and dim. $\mathcal{F}^{(2)}_1 = 2$. The first perturbation will shift e_1 and split e_0 into two eigenvalues, as it is represented in the first two columns of Fig. 9.

The eigenvalues obtained through the first perturbation and the associated eigenvectors are given by the following proposition.

Proposition 4.1: In $\mathcal{E}^{(2)}_1$, if $f_{01} \neq f_{12}$, $H_0(\lambda)$ has three eigenvalues:

$$(\zeta_{0,1})_1(\lambda_{01}, \lambda_{12}) = 2^{-1}(e_1 - \sqrt{e_1^2 + 4\lambda_{01}^2}), \tag{4.4}$$

$$(\zeta_{0,1})_2(\lambda_{01}, \lambda_{12}) = 0, \tag{4.5}$$

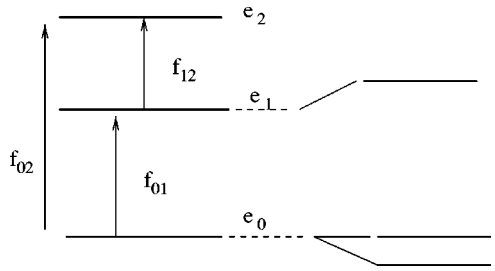

FIG. 9. Levels associated with eigenvectors of $H_0(\lambda)$ in $\mathcal{E}_1^{(2)}$, therefore without any spectator photon.

$$\zeta_{1,1}(\lambda_{01},\lambda_{12}) = 2^{-1}(e_1 + \sqrt{e_1^2 + 4\lambda_{01}^2}). \tag{4.6}$$

The associated normalized eigenvectors are

$$(\phi_{0,1}^{(0)})_1(\lambda_{01},\lambda_{12}) = (1 + (\zeta_{0,1})_1^{-2}\lambda_{01}^2)^{-1/2}(|1,\Omega\rangle + (\zeta_{0,1})_1^{-1}\lambda_{01}|0,f_{01}\rangle), \tag{4.7}$$

$$(\phi_{0,1}^{(0)})_2(\lambda_{01},\lambda_{12}) = (1 - |s_1|^2)^{-1/2}|0,f_{12} - s_1 f_{01}\rangle, \tag{4.8}$$

$$\phi_{1,1}^{(0)}(\lambda_{01},\lambda_{12}) = (1 + (\zeta_{1,1})^{-2}\lambda_{01}^2)^{-1/2}(|1,\Omega\rangle + (\zeta_{1,1})^{-1}\lambda_{01}|0,f_{01}\rangle). \tag{4.9}$$

The calculus is straightforward since the dimension of $\mathcal{E}_1^{(2)}$ is three. ■

To the second order with respect to λ, we get $(\zeta_{0,1})_1 = -(1/e_1)\lambda_{01}^2$ and $\zeta_{1,1} = e_1 + (1/e_1)\lambda_{01}^2$. Note that the perturbed eigenvalues (4.4)–(4.6) do not depend on λ_{12}. They tend to 0, 0, and e_1, respectively, if λ_{01} tends to 0. The notation $\zeta_{i,p}$ is thus in accordance with the rules stated in Sec. II, as far as the first index is concerned; index i refers to the unperturbed level in the following way: $\lim_{\lambda_{01}\to 0}(\zeta_{0,1})_j = 0$, $\lim_{\lambda_{01}\to 0}\zeta_{1,1} = e_1$. To distinguish perturbed eigenvalues which tend to the same e_i if $(\lambda_{01},\lambda_{12}) \to (0,0)$, we chose to put the index p, indicating that the eigenvectors are in $\mathcal{E}_p$ (as in Sec. III B). Since several eigenvalues with the same indices i and p may still have the same limit when $(\lambda_{01},\lambda_{12})$ tends to (0,0), an additional index j is used to number them.

We have $(\phi_{0,1}^{(0)})_1(\lambda_{01},\lambda_{12}) \to -|0,f_{01}\rangle$ and $\phi_{1,1}^{(0)}(\lambda_{01},\lambda_{12}) \to |1,\Omega\rangle$, if λ_{01} tends to 0.

If $f_{01} = f_{12}$, the dimension of $\mathcal{E}_1^{(2)}$ is two and the eigenvector $(\phi_{0,1}^{(0)})_2$ disappears.

As we said before, these eigenvalues are actually infinitely degenerated; indeed, adding photons whose states are orthogonal to $\{f_{01},f_{12}\}$ gives an eigenstate with the same energy, since the energy of the photons is not taken into account in $H_0(\lambda)$. Let us state this fact precisely, with some notations which will be useful later on.

2. Other eigenvectors of $H_0(\lambda)$ in the $(n+1)$-excitation space $\mathcal{E}_{n+1}$, $n>0$, associated with the same eigenvalues

Proposition 4.2: Let $g_1,g_2,\ldots$ be an orthonormal basis of functions orthogonal to f_{01} and f_{12}.
(i) Let $\mathcal{G}_{0,1,1}$ be the subspace of $\mathcal{E}$ spanned by the normalized vectors

$$(\phi_{0,n+1}^{(n_1,n_2,\ldots)})_1 := \prod_{i=1}^{\infty}(n_i!)^{-1/2}(1\otimes c^*(g_i))^{n_i}(\phi_{0,1}^{(0)})_1, \tag{4.10}$$

where the n_i's are k nonnegative integers and k is arbitrary. These vectors are in $\mathcal{E}_{n+1}$ if $n = \sum_{i=1}^{k} n_i$. For generic values of λ_{01} and λ_{12}, $\mathcal{G}_{0,1,1}$ is the eigenspace of $H_0(\lambda)$ associated with eigenvalue $(\zeta_{0,1})_1$

(ii) If $f_{01} \neq f_{12}$, let us set $g_0 := (1-|s_1|^2)^{-1/2}$ $(f_{12} - s_1 f_{01})$ and let $f_{01}^{\perp}$ be the subspace of $\mathcal{H}_{\mathrm{rad}}$ orthogonal to f_{01}, spanned by the g_i's, $i = 0,1,\cdots$. The eigenspace of $H_0(\lambda)$ associated with eigenvalue $(\zeta_{0,1})_2$ is $|0\rangle \otimes \mathcal{F}(f_{01}^{\perp})$, where $\mathcal{F}(f_{01}^{\perp})$ is the Fock space built with $f_{01}^{\perp}$. We set

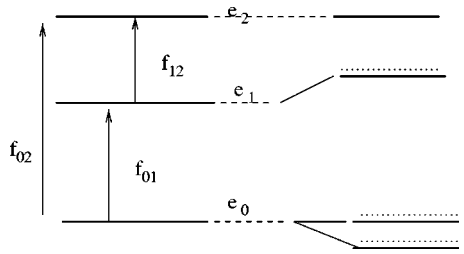

FIG. 10. Levels of Fig. 9, with eigenvectors of $H_0(\lambda)$ in $\mathcal{E}_2$; at most one spectator photon.

$$(\phi_{0,n+1}^{(n_0,n_1,\ldots)})_2 := \prod_{i=0}^{\infty} (n_i!)^{-1/2} (1 \otimes c^*(g_i))^{n_i} (\phi_{0,1}^{(0)})_2. \tag{4.11}$$

(iii) Last, let $\mathcal{G}_{1,1}$ be the subspace of $\mathcal{E}$ spanned by the normalized vectors

$$\phi_{1,n+1}^{(n_1,n_2,\ldots)} := \prod_{i=1}^{\infty} (n_i!)^{-1/2} (1 \otimes c^*(g_i))^{n_i} \phi_{1,1}^{(0)}. \tag{4.12}$$

For generic values of λ_{01} and λ_{12}, $\mathcal{G}_{1,1}$ is the eigenspace of $H_0(\lambda)$ associated with eigenvalue $\zeta_{1,1}$.

That $\Pi_{i=1}^{\infty}(1 \otimes c^*(g_i))^{n_i}$ $(\phi_{0,1}^{(0)})_1$, $\Pi_{i=0}^{\infty}(1 \otimes c^*(g_i))^{n_i}$ $(\phi_{0,1}^{(0)})_2$ and $\Pi_{i=1}^{\infty}(1 \otimes c^*(g_i))^{n_i}$ $\phi_{1,1}^{(0)}$ are eigenvectors follows from the fact that $[1 \otimes c^*(g), H_0(\lambda)] = 0$ if g is orthogonal to $\mathcal{H}_{\text{rad}}^{(2)}$. In Appendix B 1, we explain how the whole eigenspace can be determined, for each of the three eigenvalues.■

Let g [which is no longer function (3.8)] be a linear combination of the g_i's. A photon in such a state will be called a spectator photon. Proposition 4.2 may be stated in the following terms: the three eigenvalues are twice infinitely degenerated; first through the number of spectator photons (the n variable), and second through the infinity of possible states for each spectator photon (the g variable). In the level diagrams, if we symbolize the degeneracy of an eigenvalue (due to the possibility of one spectator photon in the eigenvector) by a dotted line, then in the case where at most one spectator photon is present, the degeneracy of the levels may be represented in Fig. 10 (dotted lines are slightly shifted from the level for reading purpose).

The degeneracy of the eigenvalue is greater if we admit eigenvectors with a greater number of spectator-photons, with all their possible states.

But considering a total number of photons greater than one yields other eigenvalues. For instance, we claim that eigenvectors in $\mathcal{E}_2$ different from $|2,0\rangle$ are not necessarily built with eigenvectors in $\mathcal{E}_1$ and a spectator photon. We are going to see that the set of perturbed eigenvalues coming from one given unperturbed energy e_i changes when the number of photons coupled to the atom changes. This was already the case for the two-level atom of Sec. III (see for instance Proposition 3.1 of Sec. III B, for $\mu = 0$, where the eigenvalue depended on the space in which the eigenvector was looked for).

3. Other eigenvectors of $H_0(\lambda)$ in $\mathcal{E}_{n+1}$ and other eigenvalues

In this section, we assume $f_{01} \neq f_{12}$.

Proposition 4.3: $H_0(\lambda)$ has an infinity of eigenvalues different from $(\zeta_{0,1})_1$, $(\zeta_{0,1})_2$, and $\zeta_{1,1}$.

PROOF: $\mathcal{E}_n$ is invariant by $H_0(\lambda)$. The subspace $\mathcal{E}_n^{(2)}$ of $\mathcal{E}_n$ is also invariant. Let us first consider $\mathcal{E}_2^{(2)}$, six dimensional. If the coupling constants are small, there are six eigenvalues: when λ_{01} and λ_{12} tend to 0, one of them tends to e_2 (it is denoted by $\zeta_{2,2}$), two tend to e_1 [denoted by $(\zeta_{1,2})_1$ and $(\zeta_{1,2})_2$] and three, one of which is zero, tend to 0 [denoted by $(\zeta_{0,2})_1 = 0$, $(\zeta_{0,2})_2$ and $(\zeta_{0,2})_3$]. They are obtained through diagonalizing a six by six matrix (see Appendix B 2). The calculation is straightforward although the result has not a simple expression. In this two-excitation space, that two eigenvalues tend to e_1 is due to the fact that there are two possible photon states, and that three eigenvalues tend to 0 is due to the fact that there are three possible independent states for the two

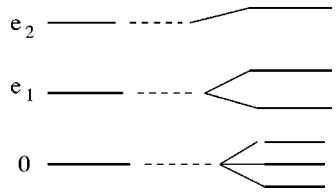

FIG. 11. Levels associated with eigenvectors of $H_0(\lambda)$ in $\mathcal{E}_2^{(2)}$, without any spectator photon.

photons. The eigenvector associated with $(\zeta_{0,2})_1=0$ is $|0,g_0\vee g_0\rangle$; we met it under the form $(\phi_{0,1}^{(1,0,\ldots)})_2$ [see (4.11)].

We already found other eigenvectors in the same space $\mathcal{E}_2$. They were built from eigenvectors in $\mathcal{E}_1^{(2)}$. They are for instance $(\phi_{0,1}^{(1,0,\ldots)})_1$ and $\phi_{1,1}^{(1,0,\ldots)}$, with notations of Proposition 4.2; they are in $\mathcal{E}_2^{(3)}$ if $g_1\in\mathcal{H}_{\mathrm{rad}}^{(3)}$. The corresponding eigenvalues, $(\zeta_{0,1})_1$ and $\zeta_{1,1}$, are different from the six we just saw (see Appendix B 2), except possibly for particular values of λ.

Since the notations are a bit heavy, we again represent the levels in Fig. 11.

The changes in the levels e_0, e_1, and e_2 of Figs. 10 and 11 cannot be superimposed on one another, in general. Both are to be considered in describing the levels of $H_0(\lambda)$.

To complete the study, we have to take an arbitrary number of photons into account. The study of the spectrum of $H_0(\lambda)$ is completed when one has also considered eigenvectors in $\mathcal{E}_3^{(2)}$, $\mathcal{E}_4^{(2)}$, etc.; They give new levels. Eventually, there is a very great number of levels. Let $S(n,p)$ be the number of independent symmetric states that can be formed with n photons, each photon being in p possible states. Let us consider $1,2,\ldots,n$ photons successively. The fundamental state is split into a doublet, a triplet, …, a $S(n,2)$ multiplet. If we look for all possible states, all these levels must be considered. As regards level 1, a shift, then a doublet, a triplet, …, a $S(n-1,2)$ multiplet. Lastly, for level 2, we get no change, then a shift, a doublet, …, a $S(n-2,2)$ multiplet. To be complete, let us recall level $e_0=0$, with eigenvector $|0,\Omega\rangle$. ■

The doubly infinite degeneracy due to spectator-photons still remains. With the six eigenvalues $\zeta_{2,2}$, $(\zeta_{1,2})_1$, and $(\zeta_{1,2})_2$, and last $(\zeta_{0,2})_1$, $(\zeta_{0,2})_2$, and $(\zeta_{0,2})_3$, are associated eigenvectors $\phi_{2,2}^{(0)}$, $(\phi_{1,2}^{(0)})_1$, and $(\phi_{1,2}^{(0)})_2$), and last $(\phi_{0,2}^{(0)})_1$, $(\phi_{0,2}^{(0)})_2$, and $(\phi_{0,2}^{(0)})_3$. As previously, through application of $(1\otimes c^*(g))^n$ with g orthogonal to $\{f_{01},f_{12}\}$, or more generally application of $\Pi(1\otimes c^*(g_i))^{n_i}$, one gets other eigenvectors associated with the same eigenvalues. In the same way that we built Fig. 10 from Fig. 9, we could illustrate this degeneracy graphically through adding dotted lines in Fig. 11.

Let us come back to our initial problem, which is to determine the spectrum of $H(\lambda)$, at least roughly. It may be expected that the perturbation $\lambda_{02}V$ partially removes the degeneracy of each of the six above-mentioned eigenvalues, as well as degeneracies of the same type, for instance those of the three eigenvalues $(\zeta_{0,1})_1$, $(\zeta_{0,1})_2$, and $\zeta_{1,1}$ that we obtained previously. It is this simpler question that we now examine. We are going to show that the coupling $\lambda_{02}\,V$ splits the first three levels of Fig. 10, eigenvalues $(\zeta_{0,1})_1$, $(\zeta_{0,1})_2$, and $\zeta_{1,1}$ of Proposition 4.2, into an infinity of levels and calculate the splittings of $(\zeta_{0,1})_1$ and $\zeta_{1,1}$, at the lowest order in λ_{02}.

C. Perturbation with respect to λ_{02}: Second removal of degeneracy

We are now interested in $H(\lambda)$. The function f_{02} comes into play. Hence we assume that the first vector of the basis $g_1,g_2,\ldots$ of Proposition 4.2 is in $\mathcal{H}_{\mathrm{rad}}^{(3)}$. The g_i's, $i>1$ are thus orthogonal to $\mathcal{H}_{\mathrm{rad}}^{(3)}$. We saw that the $(\phi_{i,p}^{(q,0,\ldots)})_k$, $q=0,1,\ldots$, which are in $\mathcal{E}^{(3)}$, are associated with a unique eigenvalue $(\zeta_{i,p})_k$. In the simple cases $(i,p)=(1,1)$ and $(i,p,k)=(0,1,1)$, we are going to show that the degeneracy is removed. We calculate the approximations of order two in λ_{02} of those eigenvalues of $H(\lambda)$ which tend to $(\zeta_{i,p})_k$ when λ_{02} tends to 0. These eigenvalues depend on q. The approximations are denoted by $(z_{i,p}^{(q)})_k^{(\leqslant 2)}$. The corresponding eigenvectors are denoted by $(\chi_{i,p}^{(q)})_k$ and their second-order approximations by $(\chi_{i,p}^{(q)})_k^{(\leqslant 2)}$. We will have

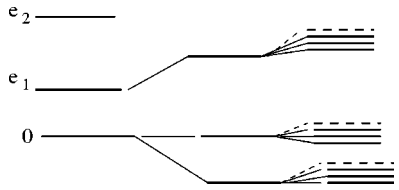

FIG. 12. Qualitative description of the perturbation of Fig. 10 first levels, due to the $\lambda_{02}\,V$ term: ($g_{i_1}=g_1$). (In the last columns, the additional degeneracy is not mentioned.)

$$\lim_{\lambda_{02}\to 0}(\chi_{i,p}^{(q)})_k^{(\leqslant 2)}=(\phi_{i,p}^{(q,0,\ldots)})_k=(1\otimes c^*(g_1))^q(\phi_{i,p}^{(0)})_k. \tag{4.13}$$

(Here, z does not have the same meaning as in Sec. III; μ remains zero.)

Note that, if $\chi\in\mathcal{H}^{(3)}$ is an eigenvector of $H(\lambda)$, then for every g orthogonal to $\mathcal{H}_{\mathrm{rad}}^{(3)}$, $(1\otimes(c^*(g))^n)\chi$ is still an eigenvector, associated with the same eigenvalue. This second degeneracy removal is thus only very partial.

We assume that $p=1$ and we limit ourselves to perturbing $(\zeta_{0,1})_1$, $(\zeta_{0,1})_2$ if $f_{01}\neq f_{12}$, and $\zeta_{1,1}$. If $f_{01}\neq f_{12}$, the diagram in Fig. 10 transforms into the one of Fig. 12. The case of $(\zeta_{0,1})_2$ is particular as we will see later on. Note that the exact eigenvector $(\chi_{i,p}^{(q)})_k$ is no longer in $\mathcal{E}_{q+1}^{(3)}$ but in $\oplus_{r=0}^{\infty}\mathcal{E}_{r+1}^{(3)}$. More precisely, we have

Proposition 4.4: Through the perturbation $\lambda_{02}\,V$*, each of the eigenvalues* $(\zeta_{0,1})_1(\lambda_{01},\lambda_{12})$ *and* $\zeta_{1,1}(\lambda_{01},\lambda_{12})$ *is at least split into an infinity of eigenvalues* $(z_{0,1}^{(n)})_1(\lambda)$ *and* $z_{1,1}^{(n)}(\lambda)$*, given at second order in* λ_{02} *by the following formulas:*

$$(i)\ (z_{0,1}^{(n)})_1^{\leqslant 2}(\lambda)=(\zeta_{0,1})_1(\lambda_{01},\lambda_{12})+\lambda_{02}^2\left(1+n!\frac{\lambda_{01}^2}{(\zeta_{0,1})_1^2}\right)^{-1}A_{0,1,1}^{(n)}(\lambda_{01},\lambda_{12}) \tag{4.14}$$

with, if $f_{01}\neq f_{12}$,

$$A_{0,1,1}^{(n)}(\lambda_{01},\lambda_{12}):=n\frac{\lambda_{01}^4|(f_{02},g_1)|^2}{((\zeta_{0,1})_1)^2(\lambda_{12}^2(\zeta_{0,1})_1+\lambda_{01}^2((\zeta_{0,1})_1-e_2))}, \tag{4.15}$$

where $|(f_{02},g_1)|$ *can be expressed with the* s_i*'s, and, if* $f_{01}=f_{12}$*, and thus* $g_1=(1+|s_0|^2)^{-\frac{1}{2}}(f_{02}-s_0f_{01})$,

$$A_{0,1,1}^{(n)}(\lambda_{01},\lambda_{12}):=\frac{\lambda_{01}^4}{((\zeta_{0,1})_1)^2(\lambda_{12}^2(\zeta_{0,1})_1+\lambda_{01}^2((\zeta_{0,1})_1-e_2))}(n|(f_{02},g_1)|^2+|s_0|^2). \tag{4.16}$$

(ii) $(z_{1,1}^{(n)})^{\leqslant 2}$ *is obtained through replacing* $(\zeta_{0,1})_1$ *by* $\zeta_{1,1}$ *in expressions giving* $(z_{0,1}^{(n)})_1^{\leqslant 2}$.

(iii) $(\zeta_{0,1})_2$*, which is more degenerated than the two previous eigenvalues, is also split. The second-order approximations of the perturbed eigenvalues,* $(z_{0,1}^{(n,m}\,)_2^{\leqslant 2}$*, now depending on two indices, are obtained through the vanishing of an infinite order determinant.*

The broad lines of the proof are given in Appendix B 3, together with the method for calculating the corresponding eigenvectors $(\chi_{0,1}^{(n)})_1^{\leqslant 2}(\lambda)$, $(\chi_{0,1}^{(n,m)})_2^{\leqslant 2}(\lambda)$, and $(\chi_{1,1}^{(n)})^{\leqslant 2}(\lambda)$.

D. Conclusion of Sec. IV

Section IV C described the splitting of the eigenvalues $(\zeta_{0,1})_1$, $(\zeta_{0,1})_2$, and $\zeta_{1,1}$ of Proposition 4.2. It gave a small part of the spectrum of $H(\lambda,0)$, described in the second column of Fig. 12. In view of these results one may reasonably surmise the following points.

This splitting of the levels of the second column of Fig. 9 (or 10) will reproduce for those of the second column of Fig. 11, which are different. In other terms, the degeneracy of the latter levels, due to spectator photons, will also be removed by the coupling $\lambda_{02}V$. More generally, each level multiplet which was mentioned at the end of the proof of Proposition 4.3 is also split when

the interaction is totally switched on. This rough description of the two level splittings we get by successively taking the two parts of the interaction Hamiltonian into account eventually yields quite a complicated spectrum for $H(\lambda,0)$. But the reason of the great number of levels is simple; it is recalled in Sec. V.

When μ increases from 0, we expect that the eigenvalues we found move into eigenvalues or resonances of $H(\lambda,\mu)$. The set of these eigenvalues or resonances thus likely has the same rich structure.

V. GENERAL CONCLUSION

Results of Secs. III and IV fit into the same frame. They lead us to expect that the number of eigenstates or resonances of the atom-photon system is formally, apart from accidental degeneracy or boundary-condition effects, the product of the dimensions of the atom state space and the field state space. The description is complicated because of the multivaluedness of the resolvent matrix elements, as functions of the λ and μ parameters. This picture may be illustrated through the following argument: if the energy of each level of the isolated atom is considered as an eigenvalue of $H_{\text{atom}}\otimes 1_{\text{field}}$, this level is twice infinitely degenerated (number of photons and state of each photon). This degeneracy is removed with the actual Hamiltonian which describes the coupling of the atom to the field. The shift of the naked-atom levels by the coupling of the atom to the photon field is thus not the main feature in the change in the Hamiltonian "spectrum." The main feature is more the emergence of numerous resonances, as in the monochromatic-photon case.

For a two-level atom and Hamiltonian (3.1) (Sec. III), only one photon state comes into play. The subspace of $\mathcal{H}_{\text{rad}}$ to be considered is $\mathcal{H}_{\text{rad}}^{(1)}$ and the two degeneracies which are removed, same energy for states $|0,0\rangle$, $|0,g\rangle,\ldots$, $|0,g^{\vee n}\rangle,\ldots$ on the one hand and $|1,0\rangle$, $|1,g\rangle,\ldots$, $|1,g^{\vee n}\rangle,\ldots$ on the other hand, only concern the number of photons. A great degeneracy remains since adding photons in states orthogonal to the distinguished g state do not change the energies.

For a three-level atom, the number of coupling functions in the Hamiltonian is greater and this forced us to start to pay attention to different photon states. As a consequence, the just mentioned degeneracy now starts being removed.

For a real atom, with its infinity of levels, the splitting will still be greater. Our perturbative treatment illustrates how the different photon states may be taken into account successively. Calculations will of course be impossible if some physically justified simplifications are not made.

The present limits of the study are the following.

Section III described resonances for a realistic Hamiltonian ($\mu\neq 0$), but for a system with only two levels. However, even in that simplified case, we are far from having found all the resonances since we considered only one or two excitation spaces, $\mathcal{E}_1$ or $\mathcal{E}_2$. It would be necessary to take more than two photons into account. But the resonances are then given by more and more complicated equations.

In Sec. IV, to be able to present a qualitative description of resonances in a three-level system, we had to work in the limit $\mu=0$. This first stage seems unavoidable to us if one wants to solve the question completely. Doing this, we were able to take an infinity of photons into account. But the calculations are only carried to the second order in λ_{02} and also the displacement of the resonances when μ becomes non-zero is just qualitatively mentioned.

However, we have seen that these partial results give new information about hybrid states which are present in matter-field interactions such as the interaction to which we borrowed our terminology: the interaction of atoms (or molecules) with the electromagnetic field. We hope that concrete problems will justify approximations making calculations possible.

APPENDIX A. ESTIMATION OF CORRECTIVE TERMS IN THE FREDHOLM EXPANSION OF PROPOSITION 3.4

Proposition: Set $\varphi_2(\mu,z,p,q):=\mu^2 D_2(\mu,z,p,q)$ *and*

$$\varphi_3(\mu,z,p,q):=\frac{|g(p)||g(q)|(1+|p|)^{1/4}(1+|q|)^{1/4}(|p|-|q|)^2}{|f(z-\mu|p|)|^{1/2}|f(z-\mu|q|)|^{1/2}\left|\frac{z}{\mu}-2|p|\right|^{1/2}\left|\frac{z}{\mu}-2|q|\right|^{1/2}\left|\frac{z}{\mu}-|p|-|q|\right|^{2}}$$

$$\varphi_4(\mu,z,p,q) := \frac{|g(p)|^{2/3}|g(q)|^{2/3}(1+|p|)^{1/4}(1+|q|)^{1/4}(|p|-|q|)^2}{|f(z-\mu|p|)|^{1/3}|f(z-\mu|q|)|^{1/3}\left|\frac{z}{\mu}-2|p|\right|^{1/3}\left|\frac{z}{\mu}-2|q|\right|^{1/3}\left|\frac{z}{\mu}-|p|-|q|\right|^2}$$

defined for $z<0$. *we have*

$$C_2(\lambda,\mu,z) = (\lambda^2/\mu)^2\|\varphi_2(\mu,z,.,.)\|_1, \tag{A1}$$

$$|C_3(\lambda,\mu,z)| < M_3(\lambda,\mu,z) := 4(\lambda^2/\mu)^3\|\varphi_3(\mu,z,.,.)\|_3^3. \tag{A2}$$

Assuming that (3.19) also holds for $n=4$, *we also have*

$$|C_4(\lambda,\mu,z)| < M_4(\lambda,\mu,z) := 4^2(\lambda^2/\mu)^4\|\varphi_4(\mu,z,.,.)\|_6^6. \tag{A3}$$

Proof: Use (3.19) and Hölder's inequalities. ■

We omit λ, which is fixed to 0.1. Table III gives values for $C_2(\mu,z_{0,2}^1(\mu))$, $M_3(\mu,z_{0,2}^1(\mu))$, $M_4(\mu,z_{0,2}^1(\mu))$, and $\partial_z C_1(\mu,z_a^{(2)}(\mu))$, from

$$\partial_z C_1(\mu,z) = -\lambda^2\int\frac{|g(p)|^2}{f(\mu,z-\mu|p|)(z-2\mu|p|)}\left(\frac{1}{f(\mu,z-\mu|p|)}-\frac{1}{z-2\mu|p|}\right)dp$$
$$-\lambda^2\int\int\frac{|g(p)|^2|g(q)|^2dpdq}{f^2(\mu,z-\mu|p|)(z-2\mu|p|)(z-\mu(p+q))^2}.$$

By definition $C_1(\mu,z_{0,1}^1(\mu))=1$. We see how the terms of the Fredholm expansion decrease with the order.

For $\mu=\mu_c$, $D(\mu_c,0)$ is close to 0. Let us recall that we have $f(\lambda,\mu_c(\lambda),0)=0$. It would be interesting to see whether $D(\mu_c,0)$ vanishes or not. To try and answer this question, let us estimate the error we made in calculating the zero of $D(\mu,.)$ by the truncated series. Let us consider the following expansion of $D(\mu,.)$ near $z_{0,2}^1(\mu)$:

$$1-C_1(\mu,z_{0,2}^1(\mu))-(z-z_{0,2}^1(\mu))\partial_z C_1(\mu,z_{0,2}^1(\mu))+\frac{1}{2}C_2(\mu,z_{0,2}^1(\mu))+\frac{1}{2}(z-z_{0,2}^1(\mu))\partial_z C_2(\mu,z_{0,2}^1(\mu))$$
$$-\frac{1}{6}(C_3(\mu,z_{0,2}^1(\mu))+(z-z_{0,2}^1(\mu))\partial_z C_3(\mu,z_{0,2}^1(\mu))).$$

Let us assume that terms $(z-z_{0,2}^1(\mu))\partial_z C_2(\mu,z_{0,2}^1(\mu))$ and $(z-z_{0,2}^1(\mu))\partial_z C_3(\mu,z_{0,2}^1(\mu))$ can be neglected. Then the correction to the zero is

$$\frac{1}{\partial_z C_1(\mu,z_{0,2}^1(\mu))}\left(-\frac{1}{2}C_2(\mu,z_{0,2}^1(\mu))+\frac{1}{6}C_3(\mu,z_{0,2}^1(\mu))\right)$$

whose principal term is of the order of 4×10^{-4}. Since it is precisely the order of $z_{0,2}^1(\mu_c)$, it is not possible to answer the question.

APPENDIX B: SKETCHES OF PROOFS OF RESULTS IN THE THIRD-LEVEL CASE

1. Sketch of the proof of Proposition 4.2

Let $\Phi := |2,F_n\rangle+|1,F_{n+1}\rangle+|0,F_{n+2}\rangle$ be an eigenvector of $H_0(\lambda)$ in $\mathcal{E}_{n+2}$ associated with z, one of the two eigenvalues $(\zeta_{0,1})_1$ or $\zeta_{1,1}$. It can be shown that

$$(z-e_2)^{-1}\lambda_{12}^2(f_{12},F_{n+1})\vee f_{12} = z^{-1}\lambda_{01}^2(f_{01},F_{n+1})\vee f_{01}, \tag{B1.1}$$

where

$$(f_{12},F_{n+1})(p_1,p_2,\ldots,p_n)=\int \overline{f}_{12}(p)F_{n+1}(p,p_1,p_2,\ldots,p_n)\mathrm{d}p,$$

$$(f^{\vee n}\vee h)(p_1,p_2,\ldots,p_{n+1})=\frac{1}{n+1}\sum_{i=1}^{n+1}\left(\prod_{j\neq i}^{n+1}f(p_j)\right)h(p_i).$$

From (B1.1), through decomposing F_{n+1} on a basis of the $(n+1)$-photon space built with f_{01},f_{12}, and the g_i's, we get that F_{n+1} is a sum of states $\Pi_{i=1}^{\infty}(c^*(g_i))^{n_i}\Omega$ with $\Sigma_i n_i=n+1$. From relations expressing that Φ is an eigenvector, we derive $F_n=0$ and, if $z\neq 0$, $F_{n+2}=z^{-1}\sqrt{n+2}\lambda_{01}F_{n+1}\vee f_{01}$; this implies that Φ is in $\mathcal{G}_{0,1,1}$ if $z=(\zeta_{0,1})_1$ or in $\mathcal{G}_{1,1}$ if $z=\zeta_{1,1}$. Hence (i) and (iii).

If $z=(\zeta_{0,1})_2=0$, then Φ is an eigenvector if and only if $F_n=0$, $F_{n+1}=0$ and $(f_{01},F_{n+2})=0$. Hence (ii).

2. The six eigenvalues $\zeta_{2,2}$, $(\zeta_{1,2})_1$, $(\zeta_{1,2})_2$, $(\zeta_{0,2})_1$, $(\zeta_{0,2})_2$ and $(\zeta_{0,2})_3$, with eigenvectors in $\mathcal{E}_2^{(2)}$

The space spanned by vectors

$$|2,\Omega\rangle,\quad |1,f_{12}\rangle,\quad |1,f_{01}\rangle,\quad |0,f_{12}\vee f_{01}\rangle,\quad |0,f_{01}\vee f_{01}\rangle$$

is invariant. Through adding $|0,f_{12}\vee f_{12}\rangle$, we get a basis of $\mathcal{E}_2^{(2)}$, in which the matrix of H_0 is

$$\begin{pmatrix} e_2 & \lambda_{12} & s_1\lambda_{12} & 0 & 0 & 0 \\ \lambda_{12} & e_1 & 0 & \frac{\lambda_{01}}{\sqrt{2}} & 0 & \sqrt{2}s_1\lambda_{01} \\ 0 & 0 & e_1 & s_1\frac{\lambda_{01}}{\sqrt{2}} & \sqrt{2}\lambda_{01} & 0 \\ 0 & \sqrt{2}\lambda_{01} & 0 & 0 & 0 & 0 \\ 0 & 0 & \sqrt{2}\lambda_{01} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

One of the eigenvalues is 0 and the eigenvector is the one mentioned in the text. The other eigenvalues are the ζ's for which

$$\zeta(\zeta-e_1)(\zeta(\zeta-e_1)(\zeta-e_2)-3\lambda_{01}^2(\zeta-e_2)-\lambda_{12}^2\zeta)+\zeta\lambda_{01}^2(2\lambda_{01}^2+(2-|s_1|^2)\lambda_{12}^2)-2e_2\lambda_{01}^4$$

vanishes. Neglecting fourth-order terms, we get the following solutions at second order in λ:

$$(\zeta_{0,2}^0)_2=0,\quad (\zeta_{0,2}^0)_3=-\frac{3}{e_1}\lambda_{01}^2,\quad (\zeta_{1,2}^0)_1=e_1,\quad (\zeta_{1,2}^0)_2=e_1+\frac{3}{e_1}\lambda_{01}^2+\frac{1}{e_1-e_2}\lambda_{12}^2,$$

$$\zeta_{2,2}^0=e_2+\frac{1}{e_2-e_1}\lambda_{12}^2.$$

This proves that these eigenvalues are different from those found in $\mathcal{E}_1^{(2)}$.

3. Sketch of the proof of Proposition 4.4.

Let us use Kato's method[23] to determine the three (infinite) sets of perturbed eigenvalues which tend to each of the unperturbed eigenvalues. (See a short account in Ref. 24.)

(i) Let us first consider $(\zeta_{0,1})_1$. The unperturbed eigenspace is $\mathcal{G}_{0,1,1}$ (Proposition 4.2). Let $P_0^{0,1,1}$ be the projector on this space and $Q_0^{0,1,1}=1-P_0^{0,1,1}$. We need operator $\tilde{Q}_0^{0,1,1}$ which is sometimes written as $Q_0^{0,1,1}[(\zeta_{0,1})_1-H_0]^{-1}Q_0^{0,1,1}$; for $x\in\mathcal{E}$, it is defined by $\tilde{Q}_0^{0,1,1}x=Q_0^{0,1,1}z$, where z is

any vector in $\mathcal{E}$ satisfying $[(\zeta_{0,1})_1 - H_0]z = Q_0^{0,1,1}x$. Let $\mathcal{H}_{0,1,1}$ be the direct sum of the eigenspaces associated with eigenvalues of $H(\lambda)$ which tend to $(\zeta_{0,1})_1$ when λ_{02} tends to 0. Let $P^{0,1,1}(\lambda_{02})$ be the projector on $\mathcal{H}_{0,1,1}$. Therefore $\lim_{\lambda_{02}\to 0} P^{0,1,1}(\lambda_{02}) = P_0^{0,1,1}$. We assume that $P_0^{0,1,1}$ and $P^{0,1,1}(\lambda_{02})$ establish one-to-one correspondences $\mathcal{H}_{0,1,1} \to \mathcal{G}_{0,1,1}$ and $\mathcal{G}_{0,1,1} \to \mathcal{H}_{0,1,1}$. Set

$$L_{0,1,1} = P_0^{0,1,1} H P^{0,1,1} P_0^{0,1,1} \text{ and } K_{0,1,1} = P_0^{0,1,1} P^{0,1,1} P_0^{0,1,1}. \tag{B3.1}$$

We recall[24] the expansion of $P^{0,1,1}$: with $S^{(0)} := -P_0^{0,1,1}$ and $S^{(k)} := (\tilde{Q}_0^{0,1,1})^k$,

$$P^{0,1,1} = P_0^{0,1,1} - \sum_n \lambda_{02}^n \sum_{k_i \geqslant 0,\ k_0+\cdots+k_n=n} S^{(k_0)} V S^{(k_1)} \cdots V S^{(k_n)}. \tag{B3.2}$$

A necessary and sufficient condition for $\chi \in \mathcal{H}_{0,1,1}$ to be an eigenvector of $H(\lambda)$ associated with the eigenvalue z is that there exists $\phi \in \mathcal{G}_{0,1,1}$ satisfying $\chi = P^{0,1,1}\phi$ and

$$L_{0,1,1}\phi = z K_{0,1,1}\phi. \tag{B3.3}$$

$L_{0,1,1}$ and $K_{0,1,1}$ are operators in $\mathcal{G}_{0,1,1}$ and the problem of the perturbation of $(\zeta_{0,1})_1$ is turned into finding such z. We still have a degeneracy due to photon-states in $(\mathcal{H}_{\text{rad}}^{(3)})^{\perp}$; indeed, if ϕ is a solution for (B3.3), then $\Pi_{i\geqslant 2}(1 \otimes c^*(g_i))^{n_i}\phi$ is still a solution. Thus we are not going to look for all ϕ's, but only for those in an invariant subspace of $\mathcal{G}_{0,1,1}$. Lemmas B3.1 to B3.6 prepare the calculation of eigenvalues into which $(\zeta_{0,1})_1$ splits. The result for $\zeta_{1,1}$ will be obtained through a simple change in the notations. The splitting of $(\zeta_{0,1})_2$ is just outlined.

Let g_1 be the function of $\mathcal{H}_{\text{rad}}^{(3)}$ orthogonal to $\mathcal{H}_{\text{rad}}^{(2)}$ and let $\mathcal{G}_{0,1,1}^{(1)}$ be the subspace of $\mathcal{G}_{0,1,1}$ spanned by $(1 \otimes c^*(g_1))^n\ (\phi_{0,1}^{(0)})_1$, $n \geqslant 0$. Let us denote the approximations of $K_{0,1,1}$ and $L_{0,1,1}$ to order q in λ_{02} by $K_{0,1,1}^{\leqslant q}$ and $L_{0,1,1}^{\leqslant q}$.

Lemma B3.1: For all q, $\mathcal{G}_{0,1,1}^{(1)}$ is invariant by $K_{0,1,1}^{\leqslant q}$ and $L_{0,1,1}^{\leqslant q}$.

PROOF: Operators $1 \otimes c^*(g_1)$ and V sent $\mathcal{E}^{(3)}$ into $\mathcal{E}^{(3)}$, since functions orthogonal to $\mathcal{H}_{\text{rad}}^{(3)}$ do not play any part. Now, $P_0^{0,1,1}$ sends $\mathcal{E}^{(3)}$ into $\mathcal{G}_{0,1,1}^{(1)} \subset \mathcal{E}^{(3)}$. Thus, if X is any endomorphism of $\mathcal{E}^{(3)}$, $P_0^{0,1,1} X P_0^{0,1,1}$ is an endomorphism of $\mathcal{G}_{0,1,1}^{(1)}$. $Q_0^{0,1,1}$ also leaves $\mathcal{E}^{(3)}$ invariant. The same is true for $\tilde{Q}_0^{0,1,1}$ and therefore for $P^{0,1,1}$. Hence the lemma. ■

Expressions to the second order in λ_{02} of $L_{0,1,1}$ and $K_{0,1,1}$ are

$$K_{0,1,1}^{\leqslant 2} = P_0^{0,1,1} - \lambda_{02}^2 P_0^{0,1,1} V (\tilde{Q}_0^{0,1,1})^2 V P_0^{0,1,1}, \tag{B3.4}$$

$$L_{0,1,1}^{\leqslant 2} = (\zeta_{0,1})_1 K_1^{\leqslant 2} + \lambda_{0,2}^2 P_0^{0,1,1} V \tilde{Q}_0^{0,1,1} V P_0^{0,1,1}. \tag{B3.5}$$

To calculate $K_{0,1,1}^{\leqslant 2}(\phi_{0,n+1}^{(n)})_1$ and $L_{0,1,1}^{\leqslant 2}(\phi_{0,n+1}^{(n)})_1$, we need the following lemma.

Lemma B3.2:

$$V(\phi_{0,n+1}^{(n)})_1 = |2, (\varphi_{0,1}^{(n)})_1\rangle \tag{B3.6}$$

with $(\varphi_{0,1}^{(0)})_1 = N_1 \lambda_{01}/(\zeta_{0,1})_1 \overline{s_0}$ *and, for* $n \geqslant 1$,

$$(\varphi_{0,1}^{(n)})_1 = N_1 \frac{\lambda_{01}}{(\zeta_{0,1})_1} (\overline{s_0} g_1^{\vee n} + n(f_{02}, g_1) f_{01} \vee g_1^{\vee n-1}), \tag{B3.7}$$

where $N_1 = (1 + (\zeta_{0,1})_1^{-2}\lambda_{01}^2)^{-1/2}$.

Lemma B3.3: $K_{0,1,1}^{\leqslant 2}$ and $L_{0,1,1}^{\leqslant 2}$ are diagonal in the basis $(\phi_{0,n+1}^{(n)})_1$ of $\mathcal{G}_{0,1,1}^{(1)}$.

Proof: $V(\phi_{0,n+1}^{(n)})_1 \in \mathcal{E}_{n+2}$, since $(\phi_{0,n+1}^{(0)})_1$ has no component on $|2\rangle \otimes \mathcal{F}$. Through using $\tilde{Q}_0^{0,1,1}\mathcal{E}_{n+2}^{(3)} \subset \mathcal{E}_{n+2}^{(3)}$, we then get

$$(\tilde{Q}_0^{0,1,1} V P_0^{0,1,1} (\phi_{0,n+1}^{(n)})_1, \tilde{Q}_0^{0,1,1} V P_0^{0,1,1} (\phi_{0,m+1}^{(m)})_1) = 0, \quad \text{if } m \neq n$$

and $K_{0,1,1}^{\leqslant 2}$ is diagonal. The same is true for $L_{0,1,1}^{\leqslant 2}$. ■

Lemma B3.4: Let us set $u_{1,n} := \tilde{Q}_0^{0,1,1} V(\phi_{0,n+1}^{(n)})_1$ *and define* $\kappa_{1,n}$, $\theta_{1,n+1}$ *and* $h_{1,n+2}$ *by* $u_{1,n} = |2,\kappa_{1,n}\rangle + |1,\theta_{1,n+1}\rangle + |0,h_{1,n+2}\rangle$. *We denote the expression of* z *to the second order in* λ_{02} *by* $(z_{0,1}^{(n)})_1^{\leqslant 2}$. *We have*

$$(z_{0,1}^{(n)})_1^{\leqslant 2} = (\zeta_{0,1})_1 + \lambda_{02}^2((\varphi_{0,1}^{(n)})_1, \kappa_{1,n}). \tag{B3.8}$$

Proof: From Lemma B3.3, it follows that $(\phi_{0,n+1}^{(n)})_1$ are eigenvectors of $L_{0,1,1}^{\leqslant 2}$ and $K_{0,1,1}^{\leqslant 2}$, associated with eigenvalues which we denote by $(l_0^{(n)})_1^{\leqslant 2}$ and $(k_0^{(n)})_1^{\leqslant 2}$ respectively. Vectors ϕ in $\mathcal{G}_{0,1,1}^{(1)}$ satisfying $(L_{0,1,1}^{\leqslant 2} - zK_{0,1,1}^{\leqslant 2})\phi = 0$ are necessarily these $(\phi_{0,n+1}^{(n)})_1$; the corresponding z-value, for each n, is $((k_{0,1}^{(n)})_1^{\leqslant 2})^{-1}(l_{0,1}^{(n)})_1^{\leqslant 2}$. Through using (B3.4) and (B3.6), we get

$$(k_{0,1}^{(n)})_1^{\leqslant 2} = ((\phi_{0,n+1}^{(n)})_1, K_{0,1,1}^{\leqslant 2}(\phi_{0,n+1}^{(n)})_1) = 1 - \lambda_{02}^2 \|u_{1,n}\|^2,$$

$$(l_{0,1}^{(n)})_1^{\leqslant 2} = (\zeta_{0,1})_1(1 - \lambda_{02}^2\|u_{1,n}\|^2) + \lambda_{02}^2(V(\phi_{0,n+1}^{(n)})_1, u_{1,n}). \tag{B3.9}$$

As a consequence,

$$(l_{0,1}^{(n)})_1^{\leqslant 2} = (\zeta_{0,1})_1(1 - \lambda_{02}^2\|u_{1,n}\|^2) + \lambda_{02}^2((\varphi_{0,1}^{(n)})_1, \kappa_{1,n}). \tag{B3.10}$$

Hence (B3.8) holds since $1 - \|u_{1,n}\|^2$ is to be replaced by 1, to the considered approximation. ■

Lemma B3.5:

(a) Let us set

$$M_1 := \left(\frac{\lambda_{12}^2}{(\zeta_{0,1})_1 - e_2} + \frac{\lambda_{01}^2}{(\zeta_{0,1})_1} \right)^{-1}.$$

For $n \geqslant 0$, *a vector* v *satisfying* $[(\zeta_{0,1})_1 - H_0]v = |2,(\sigma_{0,1}^{(n)})_1\rangle$ *is* $v_{1,n} = |2,\kappa'_{1,n}\rangle + |1,\theta'_{1,n+1}\rangle + |0,h'_{1,n+2}\rangle$ *with*

$$\kappa'_{1,n} = \frac{(\varphi_{0,1}^{(n)})_1}{(\zeta_{0,1})_1 - e_2} + \sqrt{n+1}\lambda_{12}\frac{(f_{12},\theta'_{1,n+1})}{(\zeta_{0,1})_1 - e_2}. \tag{B3.11}$$

$$h'_{1,n+2} = \sqrt{n+2}\lambda_{01}\frac{\theta'_{1,n+1} \vee f_{01}}{(\zeta_{0,1})_1}, \tag{B3.12}$$

$$\theta'_{1,n+1} = N_1\sqrt{n+1}\frac{\lambda_{01}\lambda_{12}}{((\zeta_{0,1})_1 - e_2)(\zeta_{0,1})_1}(s_0(\theta'_{1,n+1})^{(1)} + n(f_{02},g_1)(\theta'_{1,n+1})^{(2)}), \tag{B3.13}$$

where, if $f_{01} \neq f_{12}$,

$$(\theta'_{1,n+1})^{(1)} = \frac{(\zeta_{0,1})_1 - e_2}{\lambda_{12}^2}\frac{1}{1-|s_1|^2}(s_1 f_{01} - f_{12}) \vee g_1^{\vee n}, \tag{B3.14}$$

$$(\theta'_{1,1})^{(2)} = 0, \quad (\theta'_{1,n+1})^{(2)} = \frac{M_1}{2(1-|s_1|^2)}(s_1 f_{01} \vee f_{01} - 2f_{01} \vee f_{12}) + \overline{s_1} f_{12} \vee f_{12}) \vee g_1^{\vee n-1}. \tag{B3.15}$$

If $f_{01} = f_{12}$,

$$(\theta'_{1,n+1})^{(1)} = -M_1 f_{01} \vee g_1^{\vee n}, \tag{B3.16}$$

$$(\theta'_{1,1})^{(2)} = 0, \quad (\theta'_{1,n+1})^{(2)} = -\tfrac{1}{2}M_1 f_{01} \vee f_{01} \vee g_1^{\vee(n-1)}. \tag{B3.17}$$

(b) $u_{1,n}$ *of Lemma* B3.4 *is equal to* $v_{1,n}$

Proof: Relations (B3.11) and (B3.12) are obtained through projecting the equality defining v on $|2\rangle\otimes\mathcal{H}_{\rm rad}$ and $|0\rangle\otimes\mathcal{H}_{\rm rad}$, respectively. The projection on $|1\rangle\otimes\mathcal{H}_{\rm rad}$ implies that $\theta'_{1,n+1}$ satisfies

$$\mathcal{L}_{1,n+1}\theta'_{1,n+1}=\frac{\sqrt{n+1}\lambda_{12}}{(\zeta_{0,1})_1-e_2}(\varphi^{(n)}_{0,1})_1\vee f_{12}, \tag{B3.18}$$

where

$$\mathcal{L}_{1,n+1}\theta'_{1,n+1}:=-\frac{(n+1)\lambda_{12}^2}{(\zeta_{0,1})_1-e_2}f_{12}\vee(f_{12},\theta'_{1,n+1})-\frac{(n+1)\lambda_{0,1}^2}{(\zeta_{0,1})_1}f_{01}\vee(f_{01},\theta'_{1,n+1}). \tag{B3.19}$$

For $n\geqslant 1$, $(\varphi^{(n)}_{0,1})_1$, given by (B3.7) is decomposed into two parts. Hence we introduce two functions $(\theta'_{1,n+1})^{(1)}$ and $(\theta'_{1,n+1})^{(2)}$ satisfying

$$\mathcal{L}_{1,n+1}(\theta'_{1,n+1})^{(1)}=g_1^{\vee n}\vee f_{12}, \tag{B3.20}$$

$$\mathcal{L}_{1,n+1}(\theta'_{1,n+1})^{(2)}=g_1^{\vee(n-1)}\vee f_{01}\vee f_{12}, \tag{B3.21}$$

so that a solution of (B3.18) will be given by (B3.13). To prove (a) if $f_{01}\neq f_{12}$, we check that (B3.14) satisfies (B3.20) and that (B3.15) satisfies (B3.21). We proceed in the same way with (B3.16) and (B3.17), if $f_{01}=f_{12}$, (B3.18) and (B3.19) being still true. Only $(\theta_{1,n+1})^{(1)}$ plays a part if $n=0$.

To prove (b), we note that vectors in $\mathcal{G}_{0,1,1}$ are linear combinations of $|1,g_{i_1}\vee\cdots\vee g_{i_n}\rangle$ and $|0,f_{01}\vee g_{i_1}\vee\cdots\vee g_{i_n}\rangle$. Since (a) implies that $\theta'_{1,n+1}$ is a sum of symmetric products of terms one of which at least is in $\mathcal{H}^{(2)}_{\rm rad}$, we have $(\theta'_{1,n+1},g_{i_1}\vee\cdots\vee g_{i_{n+1}})=0$ and $(h'_{1,n+2},f_{01}\vee g_{i_1}\vee\cdots\vee g_{i_{n+1}})=0$. As a consequence, $|2,\kappa'_{1,n}\rangle$, $|1,\theta'_{1,n+1}\rangle$, and $|0,h'_{1,n+2}\rangle$ are orthogonal to $\mathcal{G}_{0,1,1}$ and $u_{1,n}=Q_0^{0,1,1}v_{1,n}=v_{1,n}$. ■

Lemma B3.6: Take $n\geqslant 0$. *For* $f_{01}\neq f_{12}$,

$$((\varphi^{(n)}_{0,1})_1,\kappa_{1,n})=nN_1^2\frac{\lambda_{01}^4|(f_{02},g_1)|^2}{((\zeta_{0,1})_1)^2(\lambda_{12}^2(\zeta_{0,1})_1+\lambda_{01}^2((\zeta_{0,1})_1-e_2))}. \tag{B3.22}$$

For $f_{01}=f_{12}$,

$$((\varphi^{(n)}_{0,1})_1,\kappa_{1,n})=N_1^2\frac{\lambda_{01}^4}{((\zeta_{0,1})_1)^2(\lambda_{12}^2(\zeta_{0,1})_1+\lambda_{01}^2((\zeta_{0,1})_1-e_2))}(n|(f_{02},g_1)|^2+|s_0|^2). \tag{B3.22$'$}$$

Proof: Use (B3.7) and Lemma (B3.5). ■

Formulas (4.14) and (4.15) then follow from (B3.10) and (B3.22). In the same way, (4.16) follows from (B3.22′).

(ii) All that has been written up to now can be transposed from $(\zeta_{0,1})_1$ to $\zeta_{1,1}$, with the following changes

$$P_0^{0,1,1}\to P_0^{1,1},\quad P^{0,1,1}\to P^{1,1},\quad Q_0^{0,1,1}\to Q_0^{1,1},\quad \tilde{Q}_0^{0,1,1}\to\tilde{Q}_0^{1,1},\quad \mathcal{H}_{0,1,1}\to\mathcal{H}_{1,1},$$

$$(\phi^{(n)}_{0,n+1})_1\to\phi^{(n)}_{1,n+1},\quad \mathcal{G}_{0,1,1}\to\mathcal{G}_{1,1},\quad \mathcal{G}^{(1)}_{0,1,1}\to\mathcal{G}^{(1)}_{1,1},\quad (\varphi^{(n)}_{0,1})_1\to\varphi^{(n)}_{1,1},$$

$$(k^{(n)}_{0,1})_1\to k^{(n)}_{1,1},\quad (l^{(n)}_{0,1})_1\to l^{(n)}_{1,1},\quad (z^{(n)}_{0,1})_1^{\leqslant 2}\to(z^{(n)}_{1,1})^{\leqslant 2}.$$

N_1, M_1, $(\varphi^{(n)}_{0,1})_1$ are thus also changed, as well as $\mathcal{L}_{1,n+1}$ and the solutions $\theta_{1,n+1}$ $h_{1,n+2}$ and $\kappa_{1,n}$.

One then get (ii) of Proposition 4.4.

(iii) Let us come on now to the splitting of $(\zeta_{0,1})_2$, an eigenvalue which is zero and exists only if $f_{01}\neq f_{12}$. The issue is more complicated due to the fact that the unperturbed eigenspace of

interest is no longer just spanned by the $\Pi(1\otimes c^*(g_1))^n(\phi^{(0)}_{0,1})_2$. It is spanned by the $|0,\Pi(c^*(g_i))^{n_i}\Omega\rangle$, with $i=0$ or 1. Let us denote this space by $\mathcal{G}$. Let $P_0^{0,1,2}$ be the projector on $\mathcal{G}$. With $K^{\leqslant 2}_{0,1,2}$ and $L^{\leqslant 2}_{0,1,2}$ defined as in (B3.4) and (B3.5), we can see that $L^{\leqslant 2}_{0,1,2}$ has nonvanishing matrix elements between say $g_0^{\vee p}\vee g_1^{\vee(p+2)}$ and $g_0^{\vee(p+1)}\vee g_1^{\vee(p+1)}$, or between $g_0^{\vee(p+1)}\vee g_1^{\vee(p+1)}$ and $g_0^{\vee(p+2)}\vee g_1^{\vee(p)}$ or also between $g_0^{\vee(p+2)}\vee g_1^{\vee(p)}$ and $g_0^{\vee(p+3)}\vee g_1^{\vee(p-1)}$. This makes the computation of the z's satisfying $\det(L^{\leqslant 2}_{0,1,2}-zK^{\leqslant 2}_{0,1,2})=0$ more intricate and we don't calculate them here.

This completes the proof of Proposition 4.4. ■

Eigenvectors $(\chi^{(n)}_{0,1})^{(2)}_1$, $(\chi^{(n)}_{1,1})^{(2)}$ are obtained from the correspondences $\mathcal{G}_{0,1,1}\to\mathcal{H}_{0,1,1}$, and $\mathcal{G}_{1,1}\to\mathcal{H}_{1,1}$, through the second order expansion of operators $P^{0,1,1}(\lambda_{02})$ and $P^{1,1}(\lambda_{02})$ which perform these correspondences. For example, we get (see Ref. 24, p. 614)

$$(\chi^{(n)}_{0,1})^{(2)}_1=(\phi^{(n)}_{0,n+1})_1+\lambda_{02}^2(-P_0^{0,1,1}V(\tilde{Q}_0^{0,1,1})^2V+\tilde{Q}_0^{0,1,1}V\tilde{Q}_0^{0,1,1}V)(\phi^{(n)}_{0,n+1})_1.$$

(Received 15 November 2004; accepted 28 April 2005; published online 21 June 2005)

A geometric model is proposed to describe the Berry phase phenomenon when the geometric phase does not commute with the dynamical phase. The structure used is a principal composite bundle in which the adiabatic transport appears as a horizontal lift. The formulation is applied to a simple quantum dynamical system controlled by two lasers. © *2005 American Institute of Physics.*

I. INTRODUCTION

Principal bundle theory is a classic tool of modern theoretical physics. The notation (P,M,G,π) will be used throughout this paper to designate a principal bundle on the right-hand side with base space M, total space P, structure group G, and projection π. First we quote an important result of principal bundle theory. Suppose that P is endowed with a connection described by the gauge potential A^σ associated to the local section $\sigma \in \Gamma(M,P)$. Let $\mathcal{C}$ be a curve in M, parametrized by the function $[0,1] \ni t \mapsto \gamma(t) \in M$. Then the horizontal lift of $\mathcal{C}$ at the point $\sigma(\gamma(0))$ is given by

$$P \ni p(t) = \sigma(\gamma(t))\mathbb{P}e^{-\int_0^t A^\sigma(\gamma(t))}, \tag{1}$$

where $\mathbb{P}$ is the path-ordering operator and $\mathbb{P}e^{-\int_0^t A^\sigma(\gamma(t))} \in G$ acts on P by the group canonical right action.

In 1984, Berry[1] proved, in the context of the standard adiabatic approximation, that the wave function of a quantum dynamical system takes the form

$$\psi(t) = e^{-\imath\hbar^{-1}\int_0^t E_a(\vec{R}(t'))\mathrm{d}t' - \int_0^t \langle a,\vec{R}(t')|\partial_{t'}|a,\vec{R}(t')\rangle \mathrm{d}t'}|a,\vec{R}(t)\rangle, \tag{2}$$

where E_a is a nondegenerate instantaneous eigenvalue isolated from the rest of the Hamiltonian spectrum with instantaneous eigenvector $|a,\vec{R}(t)\rangle$ and $\vec{R}$ is a set of classical control parameters used to model the time-dependent environment of the system. The set of all configurations of $\vec{R}$ is supposed to form a $\mathcal{C}^\infty$-manifold $\mathcal{M}$. The important result is the presence of the extra phase term, called the Berry phase $e^{-\int_0^t \langle a,\vec{R}(t')|\partial_{t'}|a,\vec{R}(t')\rangle \mathrm{d}t'}$. Simon[2] later found the mathematical structure which models the Berry phase phenomenon, namely a principal bundle with base space $\mathcal{M}$ and with structure group U(1). If we eliminate the dynamical phase by a gauge transformation which involves redefining the eigenvector at each time, then the expression (2) is the horizontal lift of the curve $\mathcal{C}$ described by $t \mapsto \vec{R}(t)$ with the gauge potential $A = \langle a,\vec{R}|\mathrm{d}_{\mathcal{M}}|a,\vec{R}\rangle$. If $\mathcal{C}$ is closed then the Berry phase $e^{-\oint_{\mathcal{C}} A} \in \mathrm{U}(1)$ is the holonomy of the horizontal lift.

In 1987, Aharonov and Anandan[3] proved that geometric phases such as the Berry phase are not solely attached to the adiabatic approximation but appear in a more general context. Let

[a)]Electronic mail: viennot@obs-besancon.fr

$t \mapsto \psi(t)$ be a wave function such that $\psi(T)=e^{\imath\phi}\psi(0)$ and $H(t)$ be the Hamiltonian of the system. Suppose that the Hilbert space is n-dimensional (the case $n=+\infty$ is not excluded); then the wave function defines a closed curve $\mathcal{C}$ in the complex projective space $\mathbb{C}P^{n-1}$. If one redefines the wave function such that $\tilde{\psi}(T)=\tilde{\psi}(0)$ then

$$\psi(t) = e^{-\imath\hbar^{-1}\int_0^t \langle\tilde{\psi}(t')|H(t')|\tilde{\psi}(t')\rangle \mathrm{d}t' - \int_0^t \langle\tilde{\psi}(t')|\partial_{t'}|\tilde{\psi}(t')\rangle \mathrm{d}t'} \tilde{\psi}(t). \tag{3}$$

The extra phase in addition to the dynamical phase is called the Aharonov-Anandan phase (or nonadiabatic Berry phase). We can eliminate the dynamical phase by a gauge transformation; then the Aharonov-Anandan phase appears as the horizontal lift of $\mathcal{C}$ in the principal bundle with base space $\mathbb{C}P^{n-1}$, the structure group U(1) and with the $(2n-1)$-dimensional sphere S^{2n-1} as total space. The Berry-Simon model and the Aharonov-Anandan model are related by the universal classifying theorem of principal bundles;[4,5] more precisely, the Aharonov-Anandan principal bundle is a universal bundle for the Berry-Simon principal bundle.

The two geometric phases described above are called Abelian because they are related to the Abelian group U(1). In 1984, Wilczek and Zee[6] produced a non-Abelian Berry phase phenomenom in the context of the adiabatic approximation. Let $E_a(\vec{R}(t))$ be an M-fold degenerate instantaneous eigenvalue isolated from the rest of the spectrum and $\{|a,i,\vec{R}(t)\rangle\}_{i=1,\ldots,M}$ be an orthonormal basis for the associated eigensubspace. Suppose that the initial state is $\psi(0)=|a,i,\vec{R}(0)\rangle$; then the wave function is

$$\psi(t) = \sum_{j=1}^{M} e^{-\imath\hbar^{-1}\int_0^t E_a(\vec{R}(t'))\mathrm{d}t'} \left[\mathbb{T} e^{-\int_0^t A(\vec{R}(t'))}\right]_{ji} |a,j,\vec{R}(t)\rangle, \tag{4}$$

where the matricial 1-form A has the elements $A_{ij}=\langle a,i,\vec{R}|\mathrm{d}_{\mathcal{M}}|a,j,\vec{R}\rangle$ and $\mathbb{T}$ is the time-ordering operator. By elimination of the dynamical phase, this expression becomes a horizontal lift of the curve $\mathcal{C}$ described by $t \mapsto \vec{R}(t)$ into a principal bundle with base space $\mathcal{M}$ and structure group U(M). If $\mathcal{C}$ is closed then $\mathbb{P}e^{-\oint_{\mathcal{C}} A(\vec{R})} \in U(M)$ is the holonomy of the horizontal lift.

In 1994, Bohm and Mostafazadeh[7] constructed a non-Abelian Aharonov-Anandan phase as the universal bundle of the preceding one. Let $P(t)$ be an M-fold degenerate projector such that $P(T)=P(0)$. $t \mapsto P(t)$ defines a closed curve $\mathcal{C}$ in the Grassmanian manifold $G_M(\mathbb{C}^n)$. If one chooses a local section of the bundle $[V_M(\mathbb{C}^n), G_M(\mathbb{C}^n), \mathrm{U}(M), \pi_{V_M(\mathbb{C}^n)}]$ [where $V_M(\mathbb{C}^n)$ is the Stiefel manifold] $s(P)=\{\phi_1(P),\ldots,\phi_M(P)\}$, then the evolution of the wave function for which $\psi(0)=\phi_i(0)$ is given by

$$\psi(t) = \sum_{j,k=1}^{M} \left[\mathbb{T} e^{-\imath\hbar^{-1}\int_0^t E(t')\mathrm{d}t'}\right]_{jk} \left[\mathbb{T} e^{-\int_0^t A(t')}\right]_{ki} \phi_j(t), \tag{5}$$

where $A_{ij}=\langle\phi_i|\mathrm{d}_{G_M(\mathbb{C}^n)}|\phi_j\rangle$, $E_{ij}(t)=\langle\phi_i(t)|H(t)|\phi_j(t)\rangle$, and where we suppose that $\forall t$ $\left[\int_0^t E(t')\mathrm{d}t', \int_0^t A(t')\right]=0$. By eliminating the dynamical phase, we obtain a horizontal lift in the universal bundle.

The gauge potentials defined in the four previous cases have the particular form $A=U^{\dagger}\mathrm{d}U$ where U is a $M\times n$ matrix († denotes the transconjugation). A connection with such a gauge potential is called a Stiefel connection. It is in fact the form of the universal connection in the universal bundle, a form which is unique, since Narasimhan and Ramaman[8] proved that all universal connections can be written in this form. Then the above four examples of geometric phase each have an explicit Stiefel structure.

In the previous example, the dynamical phase commutes with the geometric phase, but this is not the case in general. More usually we have $\mathbb{T}e^{-\imath\hbar^{-1}\int_0^t E(t')\mathrm{d}t' - \int_0^t A(t')} \neq \mathbb{T}e^{-\imath\hbar^{-1}\int_0^t E(t')\mathrm{d}t'} \mathbb{T}e^{-\int_0^t A(t')}$ and it is then impossible to eliminate the dynamical phase and to obtain a simple geometric structure which reduces the phenomenom to a horizontal lift in a principal bundle.

Sardanashvily introduced[9,10] a model based on a vector composite bundle, so as to obtain a geometric structure which can describe both the dynamical and the geometric phases when they do not commute. His formulation defines the covariant derivative

$$\nabla_h \psi = (\partial_t + \mathcal{A}_\mu(h(t),t)(\partial_t h^\mu(t)) + \imath\hbar^{-1}\mathcal{H}(h(t),t))\psi, \tag{6}$$

where h is a map from $\mathbb{R}$ to $\mathcal{M}$ (the manifold of classical parameters), and $\mathcal{A}$ and $\mathcal{H}$ are bounded operators. This leads to the result that if a section ψ is an integral section of the connection (i.e., $\nabla_h \psi = 0$) then

$$\psi(t) = \mathbb{T} e^{-\int_0^t (\mathcal{A}_\mu \partial_{t'} h^\mu + \imath\hbar^{-1}\mathcal{H}) \mathrm{d}t'} \psi(0). \tag{7}$$

Sardanashvily finally claims that if one can think of the equation $\nabla_h \psi = 0$ as being the Schrödinger equation of a quantum system depending on the parameter $h(t)$, then $\mathcal{A}$ generates the Berry phase and $\mathcal{H}$ generates the dynamical phase. We now explain why we are not in agreement with this claim. First his whole analysis is made in the framework of a vector bundle. This is basically not incorrect; however the Berry phase is usually described in the framework of a principal bundle and its associated vector bundle, giving a principal structure which is more rich. Also, the definition of the covariant derivative used by Saradanashvily is only indirectly justified by noting that it gives a correct final result. More precisely, Sardanashvily does not explicitly define $\mathcal{A}$ and $\mathcal{H}$, whereas the adiabatic potential and the dynamical phase have well-defined matricial expressions. Finally, Eq. (7) is not the expression of a dynamical phase added to a geometric phase, because the expression of Sardanashvily is of the form $\psi(t) = U_{\mathrm{Sar}}(t)\psi(\mathbf{0})$, whereas the expression of a parallel transport with geometric phase is of the form $\psi(t) = U_{\mathrm{phase}}(t)\tilde{\psi}(\mathbf{t})$ where $\tilde{\psi}(\mathbf{t})$ is a known function or a known basis set dependent on the time (in the case of the Berry phase it is the instantaneous eigenvector basis set). This known function (or basis set) defines the local section used to describe the horizontal lift. Then U_{Sar} is not a non-Abelian phase but is the evolution operator. Consequently we have $\imath\hbar\mathcal{A}_\mu \partial_t h^\mu + H = H$, where H is the Hamiltonian of the system, which is split into two parts $\mathcal{A}$ and $\mathcal{H}$. Since Sardanashvily does not define $\mathcal{A}$, this spliting is totally arbitrary. Moreover, if A is the generator of the Berry phase and E is the generator of the dynamical phase, we have $\imath\hbar A + E \neq H$. Thus the affirmation of Sardanashvily in Ref. 9, namely "$\mathcal{A}$ is responsible for the Berry phase phenomenon" appears to be unjustified.

In this paper we construct a geometric structure to give a correct description of the transport when the Berry phase does not commute with the dynamical phase. We apply Sardanashvily's idea of using a composite bundle, but we take a principal structure in place of the vector structure. We thus construct a connection consistent with the geometric model of the adiabatic transport and with the bundle formulation of nonrelativistic quantum dynamics. Our approach reveals that the noncommutativity of A and E introduces a modified gauge structure. Similar modifications of the gauge have been used by Attal in Ref. 11 in a treatment of the non-Abelian gerbes connection. (We note that in the literature of fiber bundle theory the words "gerbe" and "sheaf" are used by various authors to name the same mathematical entity.) He introduced a gauge theory with generalized Cartan structure equations $F = \mathrm{d}A + \frac{1}{2}[A,A] + B$ and $G = \mathrm{d}B + [A,B]$, and a Bianchi identity $\mathrm{d}G + [A,G] = [F,B]$ where A is a 1-form, B and F are 2-forms, and G is a 3-form. In the same way, Larsson,[12] in his treatment of the Yang-Baxter equation with non-Abelian gerbes, found a gauge theory with the usual Cartan equation and the usual Bianchi identity, but limited by restrictions concerning the possible gauge transformations. It should be stressed that the modified gauge theory induced by the noncommutativity of A and E in our approach is similar to the modified gauge theories of Attal and Larsson which are induced by noncommutativity in the gerbes.

This paper is organized as follows. Section II introduces the generalized adiabatic theorem with a Berry phase which does not commute with the dynamical phase. Section III is devoted to some remarks about the principal composite bundles constituting the fundamental structure of our model. Section IV presents the geometric model used for the description of quantum adiabatic dynamics. Finally, Sec. V presents an application to a simple quantum dynamical system. Different quantum dynamical aspects of this system are presented in our geometric representation.

A note about some of the notation used here: the symbol "≃" between two manifolds denotes that the two manifolds are diffeomorphic, the symbol "↪" denotes an inclusion between two sets and "$\Omega^n M$" denotes the set of the n-differential forms of the manifold M.

II. GENERALIZED ADIABATIC TRANSPORT

Theorem 1: *Let $U(t,0)$ be an evolution operator of a quantum dynamical system governed by the self-adjoint Hamiltonian $H(t)$. Let $\{E_a(t)\}_a$ and $\{|a,t\rangle\}_a$ be the instantaneous eigenvalues and eigenvectors of $H(t)$. We suppose that there exists a set of indices I such that the projector $P_m(t)=\Sigma_{a\in I}|a,t\rangle\langle a,t|$ satisfies the adiabatic condition*

$$\mathrm{U}(t,0)P_m(0) = P_m(t)\mathrm{U}(t,0) \tag{8}$$

(to satisfy this assumption, see for example, Nenciu's adiabatic theorem[13]). If at $t=0$ the wave function is $\psi(0)=|a,0\rangle$ (with $a\in I$) then at time t we have

$$\psi(t) = \sum_{b\in I} U_{ba}(t)|b,t\rangle \tag{9}$$

with the matrix

$$U(t) = \mathbb{T}e^{-\imath\hbar^{-1}\int_0^t E(t')\mathrm{d}t' - \int_0^t A(t')}. \tag{10}$$

Here $A_{ab}(t)=\langle a,t|\partial_t|b,t\rangle \mathrm{d}t$ and we also have $\forall a,b\in I\ E_{ab}(t)=E_a(t)\delta_{a,b}$.

Proof: The condition (8) states that the evolution is inside Ran P_m so that for all t the wave function can be expanded on the basis set $(|a,t\rangle)_{a\in I}$. This justifies the use of Eq. (9), in which U is a unitary matrix (the unitarity of U results from the normalization of the wave function). The use of Eq. (9) in the Schrödinger equation leads to the result

$$\sum_b \imath\hbar\dot{U}_{ba}(t)|b,t\rangle + \sum_b \imath\hbar U_{ba}(t)\partial_t|b,t\rangle = \sum_b U_{ba}(t)E_b(t)|b,t\rangle. \tag{11}$$

By projecting this expression on $\langle c,t|$ we obtain

$$\imath\hbar\dot{U}_{ca} + \sum_b \imath\hbar U_{ba}\langle c,t|\partial_t|b,t\rangle = U_{ca}E_c \tag{12}$$

which leads to the result

$$(\dot{U}U^{-1})_{cd} = \sum_a \dot{U}_{ca}U^{-1}_{ad} \tag{13}$$

$$= -\sum_a \imath\hbar^{-1}E_c U_{ca}U^{-1}_{ad} - \sum_{a,b}\langle c,t|\partial_t|b,t\rangle U_{ba}U^{-1}_{ad} \tag{14}$$

$$= -\imath\hbar^{-1}E_c(UU^{-1})_{cd} - \sum_b \langle c,t|\partial_t|b,t\rangle (UU^{-1})_{bd} \tag{15}$$

$$= -\imath\hbar^{-1}E_c\delta_{cd} - \langle c,t|\partial_t|d,t\rangle. \tag{16}$$

■

This expression manifestly displays a matrix dynamical phase and a matrix geometric phase, in other words a non-Abelian dynamical phase and a non-Abelian geometric phase. In general $[E,A]\neq 0$. If the Hamiltonian is time-dependent with respect to some classical control parameters $\vec{R}$ which describe a $\mathcal{C}^\infty$-differentiable manifold $\mathcal{M}$, then we can rewrite the non-Abelian phase (10). For a dynamics $H(\vec{R}(t))$ described by a path $\mathcal{C}$ in $\mathcal{M}$ we can set

$$U(\mathcal{C}) = \mathbb{T}e^{-\imath\hbar^{-1}\int_0^t E(\vec{R}(t'))\mathrm{d}t' - \oint_{\mathcal{C}} A(\vec{R})} \tag{17}$$

with $A(\vec{R})_{ab} = \langle a, \vec{R} | \mathrm{d}_{\mathcal{M}} | b, \vec{R} \rangle$, where $d_{\mathcal{M}}$ is the exterior differential of $\mathcal{M}$.

III. PRINCIPAL COMPOSITE BUNDLES

A. Definition of a composite bundle

A composite bundle is defined by five kinds of data, three manifolds (P^+, S, and R) and two surjective maps $\pi_+ : P^+ \to S$ and $\pi_S : S \to R$. We denote the composite bundle by $P^+ \to S \to R$. We assert that a composite bundle is a principal composite bundle if $S \to R$ is a locally trivial fiber bundle with as typical fiber a manifold $M : (S, R, M, \pi_S)$, and if $P^+ \to S$ is a principal bundle with as structure group a Lie group $G : (P^+, S, G, \pi_+)$. $\forall y \in R$, we have $\pi_S^{-1}(y) \simeq M$ and we denote by χ_y^S the associated fiber diffeomorphism. We suppose that S has a structure of a cell complex; then $\pi_S^{-1}(y)$ and M are cell complexes. The theorem of universal classification of principal bundles (see Refs. 4 and 5) is used to define the universal bundle (U, B, G, π_U) where B is the classifying space of M, ϱ_U the universal map from M to B, and $\varrho_U \circ \chi_y^S$ the universal map from $\pi_S^{-1}(y)$ to B. We finally define the principal bundle (P, M, G, π_P) such that the following diagram commutes:

$$\begin{array}{ccccccc}
P^+ & \xleftarrow{\ \hookrightarrow\ } & \chi_y^{S*}P & \xleftarrow{\chi_y^{S*}} & P & \xleftarrow{\varrho_U^*} & U \\
\downarrow{\scriptstyle \pi_+} & & \downarrow{\scriptstyle \pi_{P_y}} & & \downarrow{\scriptstyle \pi_P} & & \downarrow{\scriptstyle \pi_U} \\
S & \xleftarrow{\ \hookrightarrow\ } & \pi_S^{-1}(y) & \xrightarrow{\chi_y^S} & M & \xrightarrow{\varrho_U} & B
\end{array}$$

where $P = \varrho_U^* U$ and $\chi_y^{S^*} P = (\varrho_U \circ \chi_y^S)^* U$. We know that U is independent of $\chi_y^{S^*} P$ and thus independent of y. Moreover, since χ_y^S is a diffeomorphism then $\chi_y^{S^*}$ is a principal bundle isomorphism, so that $\chi_y^{S^*} P = \pi_+^{-1}(\pi_S^{-1}(y))$ and $\pi_{P_y} = \pi_{+1\chi_y^{S^*}P}$. Let U^i be an open local chart on M. We consider the local trivialization of (P, M, G, π_P) over U^i, $\phi_P^i : U^i \times G \to \pi_P^{-1}(U^i)$; then the local trivialization of $(\chi_y^{S^*} P, \pi_S^{-1}(y), G, \pi_{P_y})$ is $\phi_P^i[y] = \chi_y^{S^*} \phi_P^i : \chi_y^{S^{-1}}(U^i) \times G \to \pi_+^{-1}(\chi_y^{S^{-1}}(U^i))$. Let V^j be an open local chart of R, ϕ_S^j be the local trivialization of (S, R, M, π_S) over V^j, and ϕ_+^j be the local trivialization of (P^+, S, G, π_+) over $\pi_S^{-1}(V^j)$. It is clear that the local trivializations are related by

$$\phi_+^j : \begin{array}{l} \pi_S^{-1}(V^j) \times G \to \pi_+^{-1}(\pi_S^{-1}(V^j)) \\ (s, g) \mapsto \phi_P^i[\mathrm{Pr}_1\, \phi_S^{j-1}(s)](\mathrm{Pr}_2\, \phi_S^{j-1}(s), g), \end{array}$$

where we have supposed that $\mathrm{Pr}_2\, \phi_S^{j^{-1}}(s) \in U^i$. Pr_1 and Pr_2 are the canonical projections of $R \times M$ over R and M. We call (P, M, G, π_P) the structure bundle of the composite bundle.

Finally one can define a principal bundle related to the principal composite bundle. Consider the map

$$\phi_{++}^{ij} : \begin{array}{l} U^i \times V^j \times G \to P^+ \\ (x, y, g) \mapsto \phi_+^j(\phi_S^j(y, x), g) = \phi_P^i[y](x, g). \end{array}$$

This map is a local trivialization of a principal bundle $(P^+, M \times R, G, \pi_{++})$ with $\pi_{++} = \phi_S^{-1} \circ \pi_+$. It is called the total bundle of the principal composite bundle.

Let $x \in U^i$ be a fixed point of M. Define the map

$$\phi_Q^j[x] : \begin{array}{l} V^j \times G \to P^+ \\ (y, g) \mapsto \phi_{++}^{ij}(x, y, g). \end{array}$$

If we consider this map as a local trivialization, it defines a principal bundle (Q_x, R, G, π_{G_x}) with $\pi_{Q_x} = \mathrm{Pr}_1 \circ \phi_Q^j[x]^{-1}$. We call it the transversal bundle of the principal composite bundle. The situation is schematically summarized in Fig. 1.

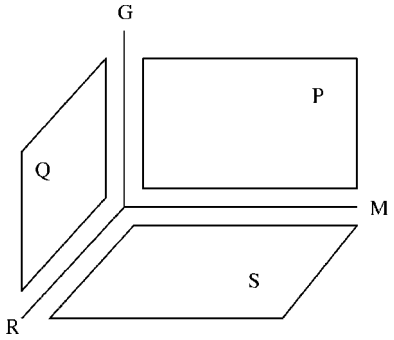

FIG. 1. Scheme of a composite bundle. P^+ is the three-dimensional space delimited by the three planes.

B. Connection on a principal composite bundle

Consider a principal composite bundle $P^+ \to S \to R$. (P^+, S, G, π_+) and $(P^+, M\times R, G, \pi_{++})$ have the structures of principal bundles. We can then define a common connection for these bundles. Let $\omega \in \Omega^1(P^+, \mathfrak{g})$ be the connection 1-form ($\mathfrak{g}$ denotes the Lie algebra of the group G). Let $\sigma^{ij}_{M\times R} \in \Gamma(U^i \times V^i, P^+)$ be a local section of the principal bundle $(P^+, M\times R, G, \pi_{++})$. The gauge potential of this bundle is by definition $A^{ij}_{M\times R} = \omega \circ \sigma^{ij}_{M\times R_*} \in \Omega^1(M\times R, \mathfrak{g})$. Let $\sigma^j_S \in \Gamma(\pi^{-1}(V^j), P^+)$ be a local section of the bundle (P^+, S, G, π_+). In order to simplify the passage from one bundle to another one, the two sections are chosen to be compatible, i.e., $\forall s \in \pi_S^{-1}(V^j)$, $\sigma^j_S(s) = \sigma^{ij}_{M\times R}(\phi^{j^{-1}}_S(s))$ [we suppose that $\mathrm{Pr}_1\, \phi^{j^{-1}}_S(s) \in U^i$], and $\forall (x,y) \in U^i \times V^j$, $\sigma^{ij}_{M\times R}(x,y) = \sigma^j_S(\phi^j_S(x,y))$. Using these relations the gauge potential of the bundle (P^+, S, G, π_+) is $A^j_S = \sigma^{j^*}_{S_*}\omega = \phi^{j^{-1}*}_S\, \sigma^{ij}_{M\times R}{}^*\omega = \phi^{j^{-1}*}_S A^{ij}_{M\times R} \in \Omega^1(S, \mathfrak{g})$.

$\chi^S_y : P \to \pi_+^{-1}(\pi_S^{-1}(y))$ is a diffeomorphism, then [remark about the notation: the first star $\chi^{S^*}_y$ denotes the map induced by χ^S_y in the principal bundles over $\pi_S^{-1}(y)$ and M, the second star $\chi^{S^{**}}_y$ denotes the map induced by $\chi^{S^*}_y$ in the cotangent bundles of P and $\chi^{S^*}_y P$] $\chi^{S^{**}}_y : \Omega^*(\pi_+^{-1}(\pi_S^{-1}(y))) \to \Omega^* P$. Let $i_y : \pi_+^{-1}(\pi_S^{-1}(y)) \hookrightarrow P^+$ be the canonical injection. We define a family of connections of (P, M, G, π_P) by $\omega_y = \chi^{S^{**}}_y\, i^*_y \omega \in \Omega^1(P, \mathfrak{g})$, for $y \in R$. Let $\sigma^i_M \in \Gamma(U^i, P)$ be a local section which is supposed to be compatible with the section of P^+: $\forall x \in M$, $\sigma^i_M(x) = \chi^{S^{*-1}}_y \sigma^{ij}_{M\times R}(x,y)$ (this section depends on y). The gauge potential is $A^i_y(x) = \sigma^i_M{}^*\omega_y = \sigma^{ij}_{M\times R}{}^* \chi^{S^{*-1}}_y\, \chi^{S^{**}}_y\, i^*_y \omega = j^*_y A^{ij}_{M\times R}(x,y) \in \Omega^1(M, \mathfrak{g})$, where $j_y : \begin{smallmatrix} M \to M\times R \\ x \mapsto (x,y) \end{smallmatrix}$.

Finally, let $i_x : \pi_{++}^{-1}(x,R) \hookrightarrow P^+$ be the canonical injection. $\omega_x = i^*_x \omega$ is a connection of the transversal bundle (Q_x, R, G, π_{Q_x}). Let $j_x : \begin{smallmatrix} R \to M\times R \\ y \mapsto (x,y) \end{smallmatrix}$, so that $A_x = j^*_x A_{M\times R} \in \Omega^1(R, \mathfrak{g})$ is the gauge potential of this bundle.

C. Horizontal lift in a principal composite bundle

In the theory of principal bundles, the notion of a horizontal lift of a curve of the base space is fundamental. In a principal composite bundle $P^+ \to S \to R$, there exists a natural generalization of this notion, but the horizontal lift concerns a section of the base bundle (S, R, M, π_S). Let $h \in \Gamma(\ell_R, S)$ be a section, where ℓ_R is a curve in R. h defines a curve $\mathcal{C}$ in $M\times R$ parametrized by $y \in R$ with the function $\phi^{j^{-1}}_S(h(y))$ (to simplify the discussion we suppose that $\ell_R \subset V^j$). Let $i_h : h(\ell_R) \hookrightarrow S$ be the canonical injection. We consider the local section $\sigma^h \in \Gamma(\mathcal{C}, P^+)$ of the bundle $(P^+, M\times R, G, \pi_{++})$ defined by $\sigma^h = \sigma^j_S \circ \phi^j_S$, $\forall y \in R$, $\sigma^h(\phi^{j^{-1}}_S(h(y))) = \sigma^j_S(h(y))$. Then the horizontal lift of h is defined as the usual horizontal lift of $\mathcal{C}$ in the total bundle of the composite bundle,

$$g_h = \mathbb{P} e^{-\int_{\mathcal{C}} A^{\sigma^h}_{M\times R}} = \mathbb{P} e^{-\int_{h(\ell_R)} i_h^* A^j_S} = \mathbb{P} e^{-\int_{\ell_R} h^* A^j_S} \tag{18}$$

IV. GEOMETRIC STRUCTURES OF GENERALIZED ADIABATIC TRANSPORT

Consider again the generalized adiabatic transport characterized by the non-Abelian phase (17) in the framework of our quantum mechanical study. The quantum dynamical system is described by a self-adjoint Hamiltonian $t \mapsto H(\vec{R}(t),t)$ in a separable Hilbert space $\mathcal{H}$ where $\vec{R}$ is a set of classical parameters which evolve adiabatically with respect to the quantum proper time. These parameters form a $\mathcal{C}^\infty$-differential manifold $\mathcal{M}$. $t \mapsto \vec{R}(t)$ represents a particular dynamics described by a curve $\mathcal{C}$ in $\mathcal{M}$. To have a more general description, we assume that the dynamics possesses a part which changes rapidly and which cannot be modeled by a classical parameter. The Hamiltonian then has an explicit dependence on t besides having the adiabatic parameters $\vec{R}(t)$.

To control the physical processes it is necessary to model numerous different dynamics, without fixing any particular path in the classical parameter manifold and without fixing the duration of the evolution. Hence we must consider the generic Hamiltonian

$$H: \begin{array}{c} \mathcal{M} \times \mathbb{R} \to \mathcal{L}(\mathcal{H}) \\ (\vec{R},t) \mapsto H(\vec{R},t) \end{array} \tag{19}$$

To study this dynamical system, we should separate the dynamical and the geometric contributions to the dynamics. To do this we fix $t \in \mathbb{R}$ in a first step and obtain a purely adiabatic (geometric) evolution $\vec{R} \mapsto H(\vec{R},t)$. Next we fix $\vec{R} \in \mathcal{M}$ and obtain a purely quantum dynamical evolution $t \mapsto H(\vec{R},t)$. These two steps are analyzed successively in the next sections A and B.

A. The fiber bundle of the geometry

Let $t_0 \in \mathbb{R}$ be fixed. $\vec{R} \mapsto H(\vec{R},t_0)$ is the Hamiltonian of an adiabatic system. We suppose that $\{E_a(\vec{R},t_0)\}_{a \in I}$ are M point eigenvalues of $H(\vec{R},t_0)$ which form a group which is isolated from the rest of the H spectrum, and we denote by $\{|a,\vec{R},t_0\rangle\}_{a \in I}$ the corresponding eigenvectors [the case of a globally degenerate eigenvalue is not excluded, but in this case $\exists a,b \in I$ such that $\forall \vec{R} E_a(\vec{R},t_0) = E_b(\vec{R},t_0)$ where $(|a,\vec{R},t_0\rangle, |b,\vec{R},t_0\rangle)$ is an orthonormal basis of the eigensubspace]. The case of an isolated degeneracy (an eigenvalue crossing) for which $\exists \vec{R}$ such that $E_a(\vec{R},t_0) = E_b(\vec{R},t_0)$ can also be included. The works of Berry,[1] Simon,[2] Wilczek and Zee[6] assert that the adiabatic evolution is described mathematically by using a principal bundle $(P,\mathcal{M},U(M),\pi_P)$ where the connection is represented by the gauge potential $A \in \Omega^1(\mathcal{M},\mathfrak{u}(M))$,

$$A_{ab}(\vec{R},t_0) = \langle a,\vec{R},t_0|\mathrm{d}_{\mathcal{M}}|b,\vec{R},t_0\rangle. \tag{20}$$

Here $\mathrm{d}_{\mathcal{M}}$ is the exterior differential of $\mathcal{M}$. This expression is associated with the section of the associated vector bundle $\vec{R} \mapsto (|a,\vec{R},t_0\rangle)_{a \in I}$.

By introducing the eigenvector-matrix $T(\vec{R},t_0) \in \mathcal{M}_{\dim \mathcal{H} \times M}(\mathbb{C})$, we can write $A = T^\dagger \mathrm{d}T$, giving a Stiefel connection in agreement with the Narasimhan-Ramaman theorem (see Refs. 14 and 8). It is evident that after a change of section $(\forall a\ |a,\vec{R},t_0\rangle \rightsquigarrow g(\vec{R})|a,\vec{R},t_0\rangle$ with $g(\vec{R}) \in U(M))$ the gauge potential satisfies the usual relation

$$\tilde{A}(\vec{R},t_0) = g(\vec{R})^{-1} A(\vec{R},t_0) g(\vec{R}) + g(\vec{R})^{-1} \mathrm{d}_{\mathcal{M}} g(\vec{R}). \tag{21}$$

Note that a family of connections $\{A(\vec{R},t) \in \Omega^1(\mathcal{M},\mathfrak{u}(M))\}_{t \in \mathbb{R}}$ is generated if t is continuously modified. If $\mathcal{C}$ is a closed curve in $\mathcal{M}$, then its horizontal lift is characterized by a Wilson loop,

$$W(\mathcal{C},t_0) = \mathbb{P} e^{-\oint_{\mathcal{C}} A_\mu(\vec{R},t_0)\mathrm{d}R^\mu}. \tag{22}$$

If the adiabatic bundle is not trivial then $W(\mathcal{C},t_0) \neq 1$ is the holonomy of the horizontal lift which is called the Berry phase.

B. The fiber bundle of the dynamics

Consider now a fixed point $\vec{R}_0 \in \mathcal{M}$. $t \mapsto H(\vec{R}_0, t)$ is the Hamiltonian describing the quantum dynamics in a static environment which is characterized by the fixed parameters $\vec{R}_0$. Let $t_0, t_1 \in \mathbb{R}$; the evolution of the system between t_0 and t_1 which is described by the evolution operator $U(\vec{R}_0, t_0, t_1)P_m(t_0) \in \mathcal{U}(\mathrm{Ran}\, P_m) \simeq U(M)$ which is assumed to satisfy the adiabatic condition (8), while also being the solution of the Schrödinger equation

$$\imath\hbar \frac{\partial}{\partial t} U(\vec{R}_0, t_0, t) = H(\vec{R}_0, t) U(\vec{R}_0, t_0, t) \tag{23}$$

with $U(\vec{R}_0, t_0, t_0) = 1$. It is well known that the solution of this equation is

$$U(\vec{R}_0, t_0, t_1) = \mathbb{T} e^{-\imath\hbar^{-1} \int_{t_0}^{t_1} H(\vec{R}_0, t)\mathrm{d}t}. \tag{24}$$

Expressions (22) and (24) are very similar, and an interpretation of the quantum dynamics as a parallel transport has been developed by Asorey *et al.*[15] in the general framework of infinite-dimensional Hilbert space and by Iliev[16] in the context of a general fiber bundle model of non-relativistic quantum mechanics. In the context of the adiabatic condition (8) the evolution is condensed into an M-dimensional space, leading to a description which involves a principal bundle $(Q_{\vec{R}_0}, \mathbb{R}, U(M), \pi_{Q_{\vec{R}_0}})$ and its associated vector bundle $(E_{\vec{R}_0}, \mathbb{R}, \mathbb{C}^M, \pi_{E_{\vec{R}_0}})$, with a state appearing as a section of the vector bundle $\psi \in \Gamma(\mathbb{R}, E_{\vec{R}_0})$.

Suppose that $\psi \in \Gamma(\mathbb{R}, E_{\vec{R}_0})$ is a solution of the Schrödinger equation. Let $\tilde{\psi}(t) = U(t)\psi(t)$ be a change of section such that

$$\imath\hbar \frac{\partial}{\partial t} \tilde{\psi}(t) = \tilde{H}(\vec{R}_0, t)\tilde{\psi}(t). \tag{25}$$

Inserting $\tilde{\psi}(t) = U(t)\psi$ into Eq. (25) leads to the result

$$\imath\hbar \frac{\partial}{\partial t} \psi(t) = (U(t)^{-1} \tilde{H}(\vec{R}_0, t) U(t) - \imath\hbar U(t)^{-1} \dot{U}(t))\psi \tag{26}$$

so that

$$\imath\hbar^{-1} \tilde{H}(\vec{R}_0, t) = U(t)\imath\hbar^{-1} H(\vec{R}_0, t) U(t)^{-1} + \dot{U}(t) U(t)^{-1} \tag{27}$$

and, finally,

$$\imath\hbar^{-1} \tilde{H}(\vec{R}_0, t)\mathrm{d}t = U(t)\imath\hbar^{-1} H(\vec{R}_0, t)\mathrm{d}t U(t)^{-1} + (\mathrm{d}_t U(t)) U(t)^{-1}, \tag{28}$$

where d_t is the exterior differential of $\mathbb{R}$: $\mathrm{d}_t f(t) = (\partial f / \partial t)\mathrm{d}t$. Equation (28) is the familiar formula of gauge transformation theory, and $\imath\hbar^{-1} H(\vec{R}_0, t)\mathrm{d}t \in \Omega^1(\mathbb{R}, \mathfrak{u}(M))$ is the gauge potential of $(Q_{\vec{R}_0}, \mathbb{R}, U(M), \pi_{Q_{\vec{R}_0}})$. $\psi \in \Gamma(\mathbb{R}, E_{\vec{R}_0})$ is horizontal if the covariant differential $D\psi = \mathrm{d}_t\psi + \imath\hbar^{-1} H(\vec{R}_0, t)\psi\, \mathrm{d}t$ is zero, i.e., if ψ obeys the Schrödinger equation. A horizontal lift of the curve $[t_0, t_1] \subset \mathbb{R}$ is well characterized by the expression (24).

Let $U_{\mathrm{dyn}}(M)$ be the set of maps from $\mathbb{R}$ to $U(M)$ which satisfies the Schrödinger-von Neumann equation [we note that this equation is the analogue for unitary operators of the equation associated to the Hermitian dynamical invariants (see Ref. 17), which are used by Mostafazadeh in Ref. 18 to define the non-Abelian nonadiabatic geometric phases]

$$\imath\hbar \dot{U}(t) = [U(t), H(\vec{R}_0, t)]. \tag{29}$$

In the framework of the adiabatic condition (8), the previous gauge potential is not used, because (24) is not the expression for the dynamical phase factor appearing in Ref. 19. Let $\{E_a(\vec{R}_0, t)\}_{a \in I}$

be the M isolated eigenvalues of $H(\vec{R}_0,t)$ and $\{|a,\vec{R}_0,t\rangle\}_{a\in I}$ be the corresponding eigenvectors. Let $E(\vec{R}_0,t)$ be the matrix such that $E(\vec{R}_0,t)_{ab}=E_a(\vec{R}_0,t)\delta_{ab}$. It is clear that $E(\vec{R}_0,t)_{ab}=\langle a,\vec{R}_0,t|H(\vec{R}_0,t)|b,\vec{R}_0,t\rangle$. A gauge transformation: $\forall a\in I$, $|\alpha,\vec{R}_0,t\rangle=U(t)|a,\vec{R}_0,t\rangle$, leads to

$$\tilde{E}_{\alpha\beta}(\vec{R}_0,t)=\langle\alpha,\vec{R}_0,t|H(\vec{R}_0,t)|\beta,\vec{R}_0,t\rangle \tag{30}$$

$$=\langle a,\vec{R}_0,t|U(t)^{-1}H(\vec{R}_0,t)U(t)|b,\vec{R}_0,t\rangle \tag{31}$$

$$=\langle a,\vec{R}_0,t|U(t)^{-1}U(t)H(\vec{R}_0,t)|b,\vec{R}_0,t\rangle+\langle a,\vec{R}_0,t|U(t)^{-1}[H(\vec{R}_0,t),U(t)]|b,\vec{R}_0,t\rangle \tag{32}$$

$$=\langle a,\vec{R}_0,t|H(\vec{R}_0,t)|b,\vec{R}_0,t\rangle+\langle a,\vec{R}_0,t|U(t)^{-1}[H(\vec{R}_0,t),U(t)]|b,\vec{R}_0,t\rangle \tag{33}$$

$$=\langle\alpha,\vec{R}_0,t|U(t)H(\vec{R}_0,t)U(t)^{-1}|\beta,\vec{R}_0,t\rangle+\langle\alpha,\vec{R}_0,t|[H(\vec{R}_0,t),U(t)]U(t)^{-1}|\beta,\vec{R}_0,t\rangle \tag{34}$$

$$=(U(t)H(\vec{R}_0,t)U(t)^{-1})_{\alpha\beta}+([H(\vec{R}_0,t),U(t)]U(t)^{-1})_{\alpha\beta}. \tag{35}$$

Thus we have

$$\tilde{E}=UEU^{-1}+[H,U]U^{-1}. \tag{36}$$

E does not satisfy the usual gauge transformation formula. But if we take $U\in U_{\mathrm{dyn}}(M)$ we obtain

$$\imath\hbar^{-1}\tilde{E}(\vec{R}_0,t)\mathrm{d}t=U(t)\imath\hbar^{-1}E(\vec{R}_0,t)\mathrm{d}tU(t)^{-1}+(\mathrm{d}_tU(t))U(t)^{-1} \tag{37}$$

we see that $\imath\hbar^{-1}E(\vec{R}_0,t)\mathrm{d}t\in\Omega^1(\mathbb{R},\mathfrak{u}(M))$ is a gauge potential of the principal bundle $(Q_{\vec{R}_0},\mathbb{R},U(M),\pi_{\vec{Q}_{\vec{R}_0}})$ but with a restriction of the gauge transformations to the set $U_{\mathrm{dyn}}(M)$ of the sections of $(Q_{\vec{R}_0},\mathbb{R},U(M),\pi_{\vec{Q}_{\vec{R}_0}})$ which are horizontal for the connection $\imath\hbar^{-1}H(\vec{R}_0,t)\mathrm{d}t$. The horizontal lift of $[t_0,t_1]\subset\mathbb{R}$ is then

$$D(\vec{R}_0,t_0,t_1)=\mathbb{T}e^{-\imath\hbar^{-1}\int_{t_0}^{t_1}E(\vec{R}_0,t)\mathrm{d}t} \tag{38}$$

which is effectively the dynamical term of (17).

The expression for the gauge potential is associated with the section of the associated vector bundle $t\mapsto(|a,\vec{R}_0,t\rangle)_{a\in I}$.

C. The composite bundle of the geodynamics and its connection

The discussion in the two preceding sections A and B suggests that the appropriate entities to give a correct description of the geometric structure of the geodynamical evolution characterized by the expression (17) would be the principal composite bundle $P^+\to S\to\mathbb{R}$ with structure bundle $(P,\mathcal{M},U(M),\pi_P)$, base bundle $(S,\mathbb{R},\mathcal{M},\pi_S)$, transversal bundles $(Q_{\vec{R}},\mathbb{R},U(M),\pi_{Q_{\vec{R}}})$ and total bundle $(P^+,\mathcal{M}\times\mathbb{R},U(M),\pi_{++})$. Note that, following the treatment of Sec. II, the structures of $(P,\mathcal{M},U(M),\pi_P)$, $(Q_{\vec{R}},\mathbb{R},U(M),\pi_{Q_{\vec{R}}})$ and of $(S,\mathbb{R},\mathcal{M},\pi_S)$ completely determine $(P^+,\mathcal{M}\times\mathbb{R},U(M),\pi_{++})$. P and $Q_{\vec{R}}$ have been introduced in the preceding paragraph. By fixing $t_0\in\mathbb{R}$ arbitrarily, the transition functions (to define a principal bundle, there are three equivalent ways, by invoking the local trivializations, by invoking the transition functions or by invoking the fiber diffeomorphisms) $g^{ij}(\vec{R},t_0)\in U(M)$ of P are obtained by setting $g^{ij}_{ab}(\vec{R})=\langle a,\vec{R},t_0,i|b,\vec{R},t_0,j\rangle$ where i and j represent two possible conventions in the matrix representation of the eigenvectors (see the example of Berry phase in Ref. 19). The topology of the bundle S is determined by the

map χ_t^S, for which P_t as defined by the transition functions $T(\vec{R},t,i)^\dagger T(\vec{R},t,j)$ is such that $\chi_t^{S^*} P = \chi_t^{S^*} P_{t_0} = P_t$. Clearly, if we consider $|a,\vec{R},t\rangle$ as a section of $\mathcal{M}$ with values in the associated vector bundle of P_t, then we have

$$\chi_{t*}^S |a,\vec{R},t_0\rangle = |a,\vec{R},t\rangle \Leftrightarrow \chi_{t*}^S = U(\vec{R},t_0,t), \tag{39}$$

$U(\vec{R},t_0,t)$ is defined by Eq. (24), and χ_{t*}^S is the map induced by χ_t^S in the sections.

This naturally leads us to take as the gauge potential of $(P_+,\mathcal{M}\times\mathbb{R},U(M),\pi_{++})$ the quantity

$$A_{\mathcal{M}\times\mathbb{R}}(\vec{R},t) = A(\vec{R},t) + \imath\hbar^{-1}E(\vec{R},t)\mathrm{d}t \in \Omega^1(\mathcal{M}\times\mathbb{R},\mathfrak{u}(M)) \tag{40}$$

with A being defined by Eq. (20). Note that we can use this expression because the two local sections used to express the gauge potentials are compatible. Introducing $j_t: \overset{\mathcal{M}\to\mathcal{M}\times\mathbb{R}}{\vec{R}\mapsto(\vec{R},t)}$ and $j_{\vec{R}}: \overset{\mathbb{R}\to\mathcal{M}\times\mathbb{R}}{t\mapsto(\vec{R},t)}$ we have $A(\vec{R},t_0)=j_{t_0}^* A_{\mathcal{M}\times\mathbb{R}}(\vec{R},t_0)$ and $\imath\hbar^{-1}E(\vec{R}_0,t)\mathrm{d}t = j_{\vec{R}_0}^* A_{\mathcal{M}\times\mathbb{R}}(\vec{R}_0,t)$.

As a gauge potential is locally defined, and as S is locally diffeomorphic to $\mathcal{M}\times\mathbb{R}$, we can write $A_S(\vec{R},t)=A_\mu(\vec{R},t)\mathrm{d}R^\mu + \imath\hbar^{-1}E(\vec{R},t)\mathrm{d}t \in \Omega^1(S,\mathfrak{u}(M))$. Let $h\in\Gamma([0,t_1],S)$ be a section. h defines a curve $\mathcal{C}$ in $\mathcal{M}\times\mathbb{R}$, where $\mathcal{L}=h([0,t_1])$ is a closed path described in $\mathcal{M}$ by $R^\mu(t)=h^\mu(t)$. Consider the pullback of h,

$$\Omega^* S \to \Omega^* \mathbb{R}$$

$$h^*: \mathrm{d}R^\mu \mapsto \frac{\partial h^\mu}{\partial t}\mathrm{d}t.$$

$$\mathrm{d}t \mapsto \mathrm{d}t$$

Then we have

$$(h^* A_S)(t) = A_\mu(h(t),t)\frac{\partial h^\mu}{\partial t}\mathrm{d}t + \imath\hbar^{-1}E(h(t),t)\mathrm{d}t. \tag{41}$$

Using expression (18), the horizontal lift of h is characterized by [with the notation $h(t)=\vec{R}(t)$]

$$g_h = \mathbb{P}e^{-\int_{\mathcal{C}} A_{\mathcal{M}\times\mathbb{R}}(\vec{R},t)} = \mathbb{T}e^{-\int_0^{t_1} A_\mu(\vec{R}(t),t)[\partial R^\mu(t)/\partial t]\mathrm{d}t - \imath\hbar^{-1}\int_0^{t_1} E(\vec{R}(t),t)\mathrm{d}t}. \tag{42}$$

Suppose now that we do not have a fast evolution in addition to the adiabatic evolution, in such a way that $H(\vec{R},t)$ has no explicit time dependence; then we have

$$g_h = \mathbb{T}e^{-\oint_{\mathcal{L}} A_\mu(\vec{R})\mathrm{d}R^\mu - \imath\hbar^{-1}\int_0^{t_1} E(\vec{R}(t))\mathrm{d}t} \tag{43}$$

which is the expression for the non-Abelian phase in (17).

Note that the connection A_S of $(P^+,S,U(M),\pi_+)$ is restricted to the gauge transformations of the form $U(M)\ni g(\vec{R},t)=g(\vec{R})U(t)$, where $g(\vec{R})$ is a map from $\mathcal{M}$ to $U(M)$ without restrictive conditions and where $U(t)\in U_{\mathrm{dyn}}(M)$. We thus have a principal structure but with a restricted choice of gauges.

It should be stressed that in $Q_{\vec{R}}$ we introduce the local fiberd coordinates (t,γ^j) where (γ^j) is a system of coordinates of $U(M)$. In the same way we introduce the fiberd coordinates of P (R^μ,γ^j) and the fiberd coordinates of P^+ (R^μ,t,γ^j). By calling on the theorem of Ehresmann (see Ref. 19), it is possible to construct a connection 1-form with gauge potential $A_{\mathcal{M}\times\mathbb{R}}$. Let $\sigma \in \Gamma(\mathcal{M}\times\mathbb{R},P^+)$ be the section used to express the gauge potential $A_{\mathcal{M}\times\mathbb{R}}$. $\forall(\vec{R},t,\gamma)\in P^+$, let $g(\vec{R},t,\gamma)$ such that $(\vec{R},t,\gamma)=\sigma(\vec{R},t)g(\vec{R},t,\gamma)$. The connection 1-form of P^+ is

$$\omega_+(\vec{R},t,\gamma) = g(\vec{R},t,\gamma)^{-1}A_\mu(\vec{R},t)g(\vec{R},t,\gamma)\mathrm{d}R^\mu + \imath\hbar^{-1}g(\vec{R},t,\gamma)^{-1}E(\vec{R},t)g(\vec{R},t,\gamma)\mathrm{d}t$$
$$+ g(\vec{R},t,\gamma)^{-1}\frac{\partial}{\partial R^\mu}g(\vec{R},t,\gamma)\mathrm{d}R^\mu + g(\vec{R},t,\gamma)^{-1}\frac{\partial}{\partial t}g(\vec{R},t,\gamma)\mathrm{d}t + g(\vec{R},t,\gamma)^{-1}\frac{\partial}{\partial \gamma^j}g(\vec{R},t,\gamma)\mathrm{d}\gamma^j$$

the connection 1-form of P for a fixed t_0 is

$$\omega_P(\vec{R},\gamma) = g(\vec{R},t_0,\gamma)^{-1}A_\mu(\vec{R},t_0)g(\vec{R},t_0,\gamma)\mathrm{d}R^\mu + g(\vec{R},t_0,\gamma)^{-1}\frac{\partial}{\partial R^\mu}g(\vec{R},t_0,\gamma)\mathrm{d}R^\mu$$
$$+ g(\vec{R},t_0,\gamma)^{-1}\frac{\partial}{\partial \gamma^j}g(\vec{R},t_0,\gamma)\mathrm{d}\gamma^j$$

and the connection 1-form of $Q_{\vec{R}_0}$ for a fixed $\vec{R}_0$ is

$$\omega_{Q_{\vec{R}_0}}(t,\gamma) = \imath\hbar^{-1}g(\vec{R}_0,t,\gamma)^{-1}E(\vec{R}_0,t)g(\vec{R}_0,t,\gamma)\mathrm{d}t + g(\vec{R}_0,t,\gamma)^{-1}\frac{\partial}{\partial t}g(\vec{R}_0,t,\gamma)\mathrm{d}t$$
$$+ g(\vec{R}_0,t,\gamma)^{-1}\frac{\partial}{\partial \gamma^j}g(\vec{R}_0,t,\gamma)\mathrm{d}\gamma^j$$

we can see then that $\omega_{P^+} \neq \omega_P + \omega_{Q_{\vec{R}}}$.

D. A pseudo-Stiefel structure

In the preceding section C we considered a fiber bundle with a restriction concerning the allowed gauge transformations. If we give up this restriction we must deal with the nonstandard equation (36) of gauge tranformation theory, $\tilde{E} = UEU^{-1} + [H,U]U^{-1}$. In order to find a structure associated with this formula we first consider the bundle $(Q_{\vec{R}_0}, \mathbb{R}, U(M), \pi_{Q_{\vec{R}_0}})$ endowed with the gauge potential $\imath\hbar^{-1}H(\vec{R}_0,t)\mathrm{d}t$. This gauge potential satisfies the correct gauge transformation formula and it is then possible to define a covariant differential $D_{Q_{\vec{R}_0}}$. Let $\psi \in \Gamma(\mathbb{R}, E_{\vec{R}_0})$ be a section of the associated vector bundle. We have

$$D_{Q_{\vec{R}_0}}\psi = \partial_t\psi\,\mathrm{d}t + \imath\hbar^{-1}H\psi\,\mathrm{d}t. \tag{44}$$

Let $U \in \Gamma(\mathbb{R}, Q_{\vec{R}_0})$ be a section from $\mathbb{R}$ to $Q_{\vec{R}_0}$ considered as the space of the operators of $E_{\vec{R}_0}$; then we have

$$D_{Q_{\vec{R}_0}}U = \partial_t U\,\mathrm{d}t + \imath\hbar^{-1}[H,U]\mathrm{d}t. \tag{45}$$

With $D_{Q_{\vec{R}_0}}$ we define a differential in $\mathcal{M}\times\mathbb{R}$,

$$\tilde{D}\eta(\vec{R},t) = \mathrm{d}_{\mathcal{M}}\eta(\vec{R},t) + D_{Q_{\vec{R}}}\eta(\vec{R},t). \tag{46}$$

We can then define a gauge potential in the style of Stiefel but with the differential $\tilde{D}$ in place of $\mathrm{d}_{\mathcal{M}\times\mathbb{R}}$. We set

$$A_+ = T^\dagger \tilde{D} T, \tag{47}$$

where T is the matrix of the eigenvectors of H. Note that $\tilde{D}^2 \neq 0$ so that the connection is not rigourously a Stiefel one. $|b,\vec{R},t\rangle \in \Gamma(\mathcal{M}\times\mathbb{R}, E_+)$ is a section of the associated vector bundle of P^+, so that

$$\tilde{D}|b,\vec{R},t\rangle = d_{\mathcal{M}}|b,\vec{R},t\rangle + d_t|b,\vec{R},t\rangle + \imath\hbar^{-1}H(\vec{R},t)|b,\vec{R},t\rangle \mathrm{d}t \tag{48}$$

and

$$A_{+ab} = \langle a,\vec{R},t|d_{\mathcal{M}}|b,\vec{R},t\rangle + \langle a,\vec{R},t|\partial_t|b,\vec{R},t\rangle \mathrm{d}t + \imath\hbar^{-1}\langle a,\vec{R},t|H(\vec{R},t)|b,\vec{R},t\rangle \mathrm{d}t \tag{49}$$

so that we have

$$A_+ = A + A_0 + \imath\hbar^{-1}E\mathrm{d}t, \tag{50}$$

where A is the adiabatic gauge potential defined by Eq. (20) and A_0 is the matrix with elements $\langle a,\vec{R},t|\partial_t|b,\vec{R},t\rangle \mathrm{d}t$, namely the expression of a Berry gauge potential for the variable t when $\vec{R}$ is fixed. Considering A_+ as a gauge potential of $(P^+,\mathcal{M}\times\mathbb{R},U(M),\pi_{++})$, the horizontal lift of $h \in \Gamma(\mathbb{R},\mathcal{M})$ is characterized by

$$g_h = \mathbb{T}e^{-\int_0^{t_1} A_\mu(\vec{R}(t),t)[\partial h^\mu(t)/\partial t]-\int_0^{t_1} A_0(\vec{R}(t),t)\mathrm{d}t-\imath\hbar^{-1}\int_0^{t_1} E(\vec{R}(t),t)\mathrm{d}t}. \tag{51}$$

Note that this equation is identical to (10) if one considers the change of variable $t\to(\vec{R}(t),t)$.

Consider a gauge transformation, it is clear that

$$\hat{A}_+ = \hat{A} + \hat{A}_0 + \imath\hbar^{-1}\hat{E}\,\mathrm{d}t \tag{52}$$

$$= UAU^{-1} + (\mathrm{d}_{\mathcal{M}}U)U^{-1} + UA_0U^{-1} + (\mathrm{d}_tU)U^{-1} + U\imath\hbar^{-1}E\,\mathrm{d}t\,U^{-1} + \imath\hbar^{-1}[H,U]U^{-1} \tag{53}$$

$$= UA_+U^{-1} + (\mathrm{d}_{\mathcal{M}}U + \mathrm{d}_tU + \imath\hbar^{-1}[H,U])U^{-1} \tag{54}$$

$$= UA_+U^{-1} + (\tilde{D}U)U^{-1}. \tag{55}$$

A_+ satisfies a gauge transformation formula analogous to the usual one but with the replacement of $\mathrm{d}_{\mathcal{M}\times\mathbb{R}}$ by $\tilde{D}$. The use of the pseudodifferential $\tilde{D}$ modifies the gauge field theory. Let the curvature F_+ be

$$F_+ = \tilde{D}A_+ + A_+\wedge A_+ \tag{56}$$

$$= \mathrm{d}_{\mathcal{M}\times\mathbb{R}}A_+ + A_+\wedge A_+ + \imath\hbar^{-1}[E\,\mathrm{d}t,A_+] \tag{57}$$

$$= \mathrm{d}_{\mathcal{M}\times\mathbb{R}}A_+ + A_+\wedge A_+ + \imath\hbar^{-1}[E\,\mathrm{d}t,A]. \tag{58}$$

Let $B=\imath\hbar^{-1}[E\,\mathrm{d}t,A]\in\Omega^2(\mathcal{M}\times\mathbb{R},\mathfrak{g})$ be the curving. B is the field which characterizes the noncommutativity between the dynamical and the geometric phases. Note that F_+-B is a standard curvature which satisfies the usual Bianchi identity and the usual Cartan structure equation. Using the standard covariant differential associated with A_+ we obtain the generalized Cartan equations

$$F_+ = \mathrm{d}_{\mathcal{M}\times\mathbb{R}}A_+ + A_+\wedge A_+ + B, \tag{59}$$

$$G = \mathrm{d}_{\mathcal{M}\times\mathbb{R}}B + [A_+,B]. \tag{60}$$

$G\in\Omega^3(\mathcal{M}\times\mathbb{R},\mathfrak{g})$ is called the fake curvature.

The fake-curvature satisfies a pseudo-Bianchi identity.

Property 1: Let G be a fake-curvature defined by generalized Cartan structure equations; then

$$\mathrm{d}_{\mathcal{M}\times\mathbb{R}}G + [G,A_+] = [F_+,B]. \tag{61}$$

Proof:

$$\mathrm{d}G = \mathrm{d}A_+ \wedge B - A_+ \wedge \mathrm{d}B - \mathrm{d}B \wedge A_+ - B \wedge \mathrm{d}A_+, \tag{62}$$

$$[F,B] - [G,A_+] = F_+ \wedge B - B \wedge F_+ - G \wedge A_+ - A_+ \wedge G \tag{63}$$

$$= \mathrm{d}A_+ \wedge B + A_+ \wedge A_+ \wedge B + B \wedge B - B \wedge \mathrm{d}A_+ - B \wedge A_+ \wedge A_+ - B \wedge B - \mathrm{d}B \wedge A_+ - A_+ \wedge B \wedge A_+ + B \wedge A_+ \wedge A_+ - A_+ \wedge \mathrm{d}B - A_+ \wedge A_+ \wedge B + A_+ \wedge B \wedge A_+ \tag{64}$$

$$= \mathrm{d}A_+ \wedge B - B \wedge \mathrm{d}A_+ - \mathrm{d}B \wedge A_+ - A_+ \wedge \mathrm{d}B. \tag{65}$$

■

V. ILLUSTRATION: THE EXAMPLE OF A SIMPLE QUANTUM DYNAMICAL SYSTEM

This final section illustrates the formal concepts introduced in the preceding sections by using a concrete physical example taken from atomic physics. We consider a particular three-level atom interacting with two lasers. Before explaining how the model illustrates the formal theory of the preceding sections we give a brief description of three-level systems.

A. Preliminary discussion

We consider a three-level quantum system, described by the Hilbert space $\mathcal{H} = \mathbb{C}^3$. The generic form of a three-level Hamiltonians is

$$H = x^i \lambda_i, \quad i = 0, \ldots, 8, \tag{66}$$

where λ_0 is the identity matrix of $\mathcal{H} = \mathbb{C}^3$ and $\{\lambda_i\}_{i=1,\ldots,8}$ are the Gell-Mann matrices,

$$\lambda_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda_2 = \begin{pmatrix} 0 & -\imath & 0 \\ \imath & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda_4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix},$$

$$\lambda_5 = \begin{pmatrix} 0 & 0 & -\imath \\ 0 & 0 & 0 \\ \imath & 0 & 0 \end{pmatrix}, \quad \lambda_6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad \lambda_7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -\imath \\ 0 & \imath & 0 \end{pmatrix}, \quad \lambda_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}.$$

The Gell-Mann matrices can be considered as the generators of the Lie algebra $\mathfrak{su}(3)$. Moreover we introduce the following matrices:

$$\mu_1 = \lambda_3 + \frac{1}{\sqrt{3}}\lambda_8 + \frac{2}{3}\lambda_0, \tag{67}$$

$$\mu_2 = -\lambda_3 + \frac{1}{\sqrt{3}}\lambda_8 + \frac{2}{3}\lambda_0, \tag{68}$$

$$\mu_3 = -\frac{1}{\sqrt{3}}\lambda_8 + \frac{2}{3}\lambda_0. \tag{69}$$

It is clear that $\{\lambda_i, \mu_j\}_{i=1,2,4,5,6,7;j=1,2,3}$ generate the Lie algebra $\mathfrak{u}(3)$. We are interested in particular Hamiltonians of the form

$$H = x^1\lambda_1 + x^2\lambda_2 + x^6\lambda_6 + x^7\lambda_7 + \tilde{x}\mu_2. \tag{70}$$

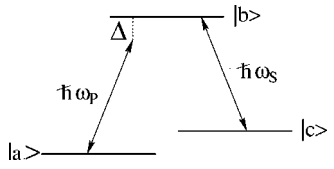

FIG. 2. Scheme of the three-level atom.

Since $\{\lambda_4, \lambda_5, \mu_1, \mu_2\}$ are the generators of the Lie algebra $\mathfrak{u}(2)$ as a subalgebra of $\mathfrak{u}(3)$, then the Hamiltonian (70) is an element of $\mathfrak{u}(3)/\mathfrak{u}(2)$ [this is a vector space quotient; $\mathfrak{u}(2)$ is not an ideal of $\mathfrak{u}(3)$ and so $\mathfrak{u}(3)/\mathfrak{u}(2)$ is a vector space without the Lie algebra structure]. In other words the Hamiltonian (70) characterized by $(x^1, x^2, x^6, x^7, \tilde{x})$ is determined by a point of the manifold $\mathrm{U}(3)/\mathrm{U}(2)$, and we know (see Ref. 4) that

$$\mathrm{U}(3)/\mathrm{U}(2) = \mathrm{SU}(3)/\mathrm{SU}(2) = S^5. \tag{71}$$

Thus, the control parameter space associated with a Hamiltonian of the form (70) can always be chosen as a submanifold of the 5-sphere S^5.

B. A concrete example: a three-level atom interacting with lasers

We consider a three-level atom in the Λ configuration interacting with two lasers, denoted by P (for pump) and S (for Stokes). The three bare states of the atom are labelled by $|a\rangle$, $|b\rangle$, and $|c\rangle$. The control parameters of the system are the amplitudes and the phases of the lasers S and P. We denote by ω_P the frequency of the laser P which is quasiresonant with the transition $|a\rangle \to |b\rangle$, with the detuning Δ. The laser S of frequency ω_S is supposed to be in perfect resonance with the transition $|b\rangle \to |c\rangle$, see Fig. 2.

The dressed Hamiltonian of the system in the rotating wave approximation (RWA) is (see, for example Ref. 20)

$$H = \frac{\hbar}{2}\begin{pmatrix} 0 & We^{\iota\beta} & 0 \\ We^{-\iota\beta} & 2\Delta & Ve^{\iota\alpha} \\ 0 & Ve^{-\iota\alpha} & 0 \end{pmatrix}, \tag{72}$$

where $W = |\langle a|\vec{\mu}\cdot\vec{E}_P|b\rangle|$ and $V = |\langle b|\vec{\mu}\cdot\vec{E}_S|c\rangle|$, $\vec{E}_P$ and $\vec{E}_S$ being the laser amplitudes and $\vec{\mu}$ being the electric dipole moment of the atom. To simplify the notation, we set $\Delta = 1$. The Hamiltonian H is of the form (70) and we can compute the three eigenvalues of H,

$$E_1 = 0, \tag{73}$$

$$E_2 = \frac{\hbar}{2}(1 - \sqrt{1 + V^2 + W^2}), \tag{74}$$

$$E_3 = \frac{\hbar}{2}(1 + \sqrt{1 + V^2 + W^2}). \tag{75}$$

We see that $E_1 = E_2$ if $V = 0$ and $W = 0$, and moreover

$$\inf_{V,W} \mathrm{dist}(\{E_1, E_2(V,W)\}; E_3(V,W)) = \hbar. \tag{76}$$

Let $P_1(W,V,\alpha,\beta)$, $P_2(W,V,\alpha,\beta)$, and $P_3(W,V,\alpha,\beta)$ be the eigenprojectors associated with E_1, E_2, and E_3. It is evident that for all particular dynamics $t \mapsto (W(t), V(t), \alpha(t), \beta(t))$ the Hamiltonian $H(t)$ and the decomposition $\mathrm{Spe}(H(t)) = \sigma_0(t) \cup \sigma_\perp(t)$ satisfy the assumptions of Nenciu's adiabatic theorem (see Ref. 13), where $\sigma_0(t) = \{E_1, E_2(t)\}$ and $\sigma_\perp(t) = \{E_3(t)\}$ and with

$\inf_t \mathrm{dist}(\sigma_0(t),\sigma_\perp(t)) \geqslant \hbar$. In accordance with Nenciu's theorem, we have at the adiabatic limit [this limit is approximately obtained if the variations of $(W(t),V(t))$ are slow with respect to the proper quantum time $\inf_t[\hbar/E_3(t)-E_1]$; for classical parameters such as W or V this hypothesis is consistent]

$$U(t,0)P_m(0) = P_m(t)U(t,0), \tag{77}$$

where $U(t,0)$ is the evolution operator associated with $H(t)$ and $P_m(t)=P_1(t)+P_2(t)$. We can apply the formalism of the previous part with Ran P_m ($\dim \mathrm{Ran}\, P_m=2$), for all particular dynamics.

The eigenvectors of H can be chosen as follows for $V\neq 0$ and $W\neq 0$:

$$|1,(\alpha,\beta,W,V)\rangle = \frac{1}{\sqrt{1+\frac{V^2}{W^2}}}\begin{pmatrix} -e^{\imath(\alpha+\beta)}\frac{V}{W} \\ 0 \\ 1 \end{pmatrix}, \tag{78}$$

$$|2,(\alpha,\beta,W,V)\rangle = \frac{1}{\sqrt{1+\frac{W^2}{V^2}+\frac{(1-\sqrt{1+V^2+W^2})^2}{V^2}}}\begin{pmatrix} e^{\imath(\alpha+\beta)}\frac{W}{V} \\ e^{\imath\alpha}\frac{(1-\sqrt{1+V^2+W^2})}{V} \\ 1 \end{pmatrix}, \tag{79}$$

$$|3,(\alpha,\beta,W,V)\rangle = \frac{1}{\sqrt{1+\frac{W^2}{V^2}+\frac{(1+\sqrt{1+V^2+W^2})^2}{V^2}}}\begin{pmatrix} e^{\imath(\alpha+\beta)}\frac{W}{V} \\ e^{\imath\alpha}\frac{(1+\sqrt{1+V^2+W^2})}{V} \\ 1 \end{pmatrix}. \tag{80}$$

Let $r=\sqrt{1+V^2+W^2}$ and (θ,φ) be such that $W=r\sin\varphi\cos\theta$, $V=r\sin\varphi\sin\theta$ and $r\cos\varphi=1$ ($\theta\in\,]0,\pi/2[$ and $\varphi\in\,]0,\pi/2[$). With these variables we can write

$$|1,(\alpha,\beta,\theta,\varphi)\rangle = \begin{pmatrix} -e^{\imath(\alpha+\beta)}\sin\theta \\ 0 \\ \cos\theta \end{pmatrix}, \tag{81}$$

$$|2,(\alpha,\beta,\theta,\varphi)\rangle = \begin{pmatrix} e^{\imath(\alpha+\beta)}\frac{\sin\varphi\cos\theta}{\sqrt{1-\cos\varphi}} \\ e^{\imath\alpha}\sqrt{1-\cos\varphi} \\ \frac{\sin\varphi\sin\theta}{\sqrt{1-\cos\varphi}} \end{pmatrix}. \tag{82}$$

Let $(\alpha,\beta,\gamma,\theta,\varphi)$ be the angles which generate S^5. The submanifold of S^5 defined by

$$0<\varphi<\frac{\pi}{2},$$

$$0<\theta<\frac{\pi}{2},$$

$$\gamma = 0,$$

is the control manifold; in the following we denote it by S^4_+.

C. The composite bundle modelling the quantum dynamical system

We will now apply the theoretical construction introduced in the preceding sections. First we note that the choice of the eigenvectors (81) and (82) is not unique. They can be

$$|i\rangle^{NE} = \begin{pmatrix} e^{\iota(\alpha+\beta)}* \\ e^{\iota\alpha}* \\ * \end{pmatrix}, \tag{83}$$

where $*$ replace the functions of (θ,φ) in the expressions of $|1\rangle$ (81) or $|2\rangle$ (82). By another choice of phase convention we can choose the following eigenvectors:

$$|i\rangle^{NW} = \begin{pmatrix} e^{\iota\alpha}* \\ e^{\iota(\alpha-\beta)}* \\ e^{-\iota\beta}* \end{pmatrix}, \quad |i\rangle^{SE} = \begin{pmatrix} e^{\iota\beta}* \\ * \\ e^{-\iota\alpha}* \end{pmatrix}, \quad |i\rangle^{SW} = \begin{pmatrix} * \\ e^{-\iota\beta}* \\ e^{-\iota(\alpha+\beta)}* \end{pmatrix}. \tag{84}$$

These different conventions are associated with four open local charts of S^4_+, $U^{NE} = \{(\alpha,\beta,\theta,\varphi) \in S^4_+ \,|\, \alpha \in]-\pi/2-\epsilon, \pi/2+\epsilon[, \beta \in]-\pi/2-\epsilon, \pi/2+\epsilon[$, $U^{NW} = \{(\alpha,\beta,\theta,\varphi) \in S^4_+ \,|\, \alpha \in]-\pi/2-\epsilon, \pi/2+\epsilon[, \beta \in]\pi/2-\epsilon, 3\pi/2+\epsilon[$, $U^{SE} = \{(\alpha,\beta,\theta,\varphi) \in S^4_+ \,|\, \alpha \in]\pi/2-\epsilon, 3\pi/2+\epsilon[, \beta \in]-\pi/2-\epsilon, \pi/2+\epsilon[$, and $U^{SW} = \{(\alpha,\beta,\theta,\varphi) \in S^4_+ \,|\, \alpha \in]\pi/2-\epsilon, 3\pi/2+\epsilon[, \beta \in]\pi/2-\epsilon, 3\pi/2+\epsilon[$, where ϵ is a small parameter. The set $\{U^i\}_{i=NE,NW,SE,SW}$ is an atlas of S^4_+. We want to construct the principal bundle of the geometric phase. Let $T^i = (|1\rangle^i, |2\rangle^i) \in \mathcal{M}_{3\times 2}(\mathbb{C})$ be the matrix of eigenvectors selected by the adiabatic theorem ($i = NE, NW, SE, SW$). We set $\vec{R} = (\alpha,\beta,\theta,\varphi) \in S^4_+$,

$$\forall i,j, \forall \vec{R} \in U^i \cap U^j, \quad g^{ij}(\vec{R}) = T^i(\vec{R})^\dagger T^j(\vec{R}) \in \mathrm{U}(2). \tag{85}$$

The functions g^{ij} are the transition functions of the principal bundle of the geometry $(P, S^4_+, \mathrm{U}(2), \pi_P)$. More precisely we have

$$g^{NE,NW} = g^{SE,SW} = e^{\iota\beta}, \quad g^{NE,SE} = g^{NW,SW} = e^{\iota\alpha}, \quad g^{NE,SW} = e^{\iota(\alpha+\beta)}. \tag{86}$$

Note that $\forall i,j\ g^{ij} \in \mathrm{U}(1) \subset \mathrm{U}(2)$, because the two eigenvectors are never globally degenerate in $U^i \cap U^j$. These functions define completely the total space P of the principal bundle of the geometry. Indeed let $\sim$ be the equivalence relation on $S^4_+ \times \mathrm{U}(2)$ defined by

$$(x,k) \sim (y,h) \text{ if } x = y \text{ and if } \exists\, i,j \text{ such that } x \in U^i \cap U^j \text{ and } k = hg^{ij}.$$

The total space is the quotient manifold $P = S^4_+ \times \mathrm{U}(2)/\sim$. Let $\pi_\sim : S^4_+ \times \mathrm{U}(2) \to P$ be the projection associated to $\sim$, then π_P is defined by the commutative diagram

$$\begin{array}{ccc} S^4_+ \times U(2) & \xrightarrow{\pi_\sim} & P \\ & {\scriptstyle \mathrm{Pr}_1} \searrow \quad \swarrow {\scriptstyle \pi_P} & \\ & S^4_+ & \end{array}$$

The principal bundle of the geometry $(P, S^4_+, \mathrm{U}(2), \pi_P)$ is then completely defined. Moreover it is the structure bundle of the principal composite bundle of the geodynamics. The connection on P is obtained by the gauge potential

$$\forall \vec{R} \in U^i, \quad A^i = T^i(\vec{R})^\dagger \mathrm{d}_{S^4} T^i(\vec{R}) \in \Omega^1(S^4_+, \mathfrak{u}(2)) \tag{87}$$

with $A^j = (g^{ij})^{-1} A^i g^{ij} + (g^{ij})^{-1} \mathrm{d}_{S^4} g^{ij}$ in $U^i \cap U^j$. Let $\{\sigma_i\}_{i=1,2,3}$ be the Pauli matrices [generators of $\mathfrak{su}(2)$] and σ_0 be the identity of $\mathbb{C}^2$, with

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -\imath \\ \imath & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The calculus of the gauge potential shows that

$$A^{NE} = \imath \frac{\sin\varphi}{\sqrt{1-\cos\varphi}} \sigma_2 \, \mathrm{d}\theta - \frac{\imath}{2\sqrt{2}} \frac{\sin(2\theta)\sin\varphi}{\sqrt{1-\cos\varphi}} \sigma_1 (\mathrm{d}\alpha + \mathrm{d}\beta) + \imath \sin\theta \frac{\sigma_3 + \sigma_0}{2} (\mathrm{d}\alpha + \mathrm{d}\beta)$$
$$+ \frac{\imath}{2} \frac{\cos^2\theta \sin^2\varphi}{1-\cos\varphi} \frac{\sigma_0 - \sigma_3}{2} (\mathrm{d}\alpha + \mathrm{d}\beta) + \frac{\imath}{2}(1-\cos\varphi) \frac{\sigma_0 - \sigma_3}{2} \mathrm{d}\alpha. \tag{88}$$

The transversal bundle for $\vec{R} = (\alpha, \beta, \theta, \varphi) \in S^4_+$ fixed is the trivial bundle of the dynamics $(\mathbb{R} \times \mathrm{U}(2), \mathbb{R}, \mathrm{U}(2), \mathrm{Pr}_1)$ endowed with the connection

$$\forall t \in \mathbb{R}, E(\vec{R}, t) = \frac{\imath}{2} \begin{pmatrix} 0 & 0 \\ 0 & 1 - \dfrac{1}{\cos\varphi} \end{pmatrix} \mathrm{d}t. \tag{89}$$

Let χ^S_t be the fiber diffeomorphism of the base bundle $(S, \mathbb{R}, S^4_+, \pi_S)$. By definition we have $P_t = \chi_t^{S^*} P$, but the Hamiltonian H does not have an explicit dependence on t. Then it is clear that $\forall t \in \mathbb{R}$, $P_t = P$ and then χ^S_t is the identity map. We conclude that $\pi_S^{-1}(t) = S^4_+$ and then $S = S^4_+ \times \mathbb{R}$. The base bundle is the trivial bundle $(S^4_+ \times \mathbb{R}, \mathbb{R}, S^4_+, \mathrm{Pr}_2)$. The local trivializations of the total bundle are

$$\phi^{ij}_{++}(\vec{R}, t, g) = \phi^i_P[t](\vec{R}, g) = \phi^i_P(\vec{R}, g) \tag{90}$$

because P_t is independent of t. Let $\{U^i \times \mathbb{R}\}_{i=NE,NW,SE,SW}$ be the atlas of $S^4_+ \times \mathbb{R}$, $\forall (\vec{R}, t) \in (U^i \cap U^j) \times \mathbb{R}$ we have the transition functions of the total space P^+ of the total bundle by $g^{ij}_{++}(\vec{R}, t) = g^{ij}(\vec{R})$. Then it is clear that $P^+ = P \times \mathbb{R}$, the total bundle of the geodynamics is then $(P \times \mathbb{R}, S^4_+ \times \mathbb{R}, \mathrm{U}(2), (\pi_P \circ \mathrm{Pr}_1) \times \mathrm{Pr}_2)$. Note that the triviality of the fibration on the time is due to the nonexplicit dependence of H on t. When this is not the case, then the base bundle is not trivial.

D. Different aspects of the quantum dynamical system in our formalism

All the ingredients of the composite bundle formalism have now been explicitly identified for our example. We now want to consider a particular dynamics in order to complete the description of the quantum dynamical system in our composite bundle representation. In order to simplify and to clarify the discussion, we consider a dynamics such that $\forall t \ \alpha = \beta = 0$ (chart U^{NE}) and we use the orginal variables (W, V) in place of (θ, φ); this restricted manifold is denoted by $\mathcal{M}$ in this paragraph. In the sequel $\mu = 1, 2$, $R^1 = W$, $R^2 = V$ and $R^0 = t$. In these conditions, the gauge potential of the total bundle P^+ over $\mathcal{M}$ is

$$A_+ = \imath\hbar^{-1} E(W, V)\mathrm{d}t + A(W, V) = \frac{\imath}{2}(1 - \sqrt{1 + V^2 + W^2})(\sigma_0 - \sigma_3)\mathrm{d}t$$
$$+ \frac{\imath\sigma_2}{\sqrt{2}\sqrt{1 + \dfrac{V^2}{W^2}}\sqrt{\dfrac{1 + V^2 + W^2 - \sqrt{1 + V^2 + W^2}}{V^2}}} \left(\frac{\mathrm{d}W}{W} - \frac{\mathrm{d}V}{V} \right). \tag{91}$$

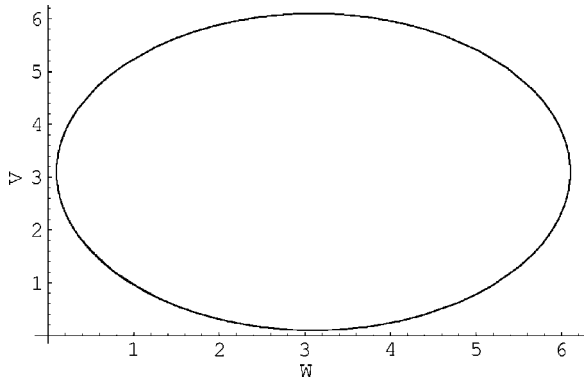

FIG. 3. The path induced by γ in $\mathcal{M}$.

We consider the dynamics described by $\gamma \in \Gamma([t_0=-25, T=90], \mathcal{M}\times\mathbb{R})$ defined by $\gamma(t) = (3\cos(2\pi(t-25)/90)+3.1, 3\sin(2\pi(t-25)/90)+3.1)$ (the units are arbitrary). γ induces a path $\mathcal{C}$ in $\mathcal{M}\times\mathbb{R}$. (See Fig. 3.)

The horizontal lift of $\mathcal{C}$ defines the holonomy operator

$$\forall t \in [t_0, T], \quad J^{\gamma,t_0,t} = \mathbb{P}e^{-\imath\hbar^{-1}\int_{t_0}^{t} E(\gamma(t'))\mathrm{d}t' - \int_0^t A_\mu(\gamma(t'))\mathrm{d}\gamma^\mu(t')/\mathrm{d}t'\mathrm{d}t'} \in \Gamma(\mathcal{M}\times\mathbb{R}, P^+). \tag{92}$$

Let $(E^+, \mathcal{M}\times\mathbb{R}, \mathbb{C}^2, \pi_{E^+})$ be the associated vector bundle of P^+ by the action of U(2) on $\mathbb{C}^2$ defined by the matrix product. The states of the system are described by the $\mathcal{C}^\infty(\mathcal{M}\times\mathbb{R}, \mathbb{C})$-module $\Gamma(\mathcal{M}\times\mathbb{R}, E^+)$, which is the space of the sections of E^+. At $t=0$ we suppose that $\psi(0) = (1/\sqrt{2}) \times (|1, \gamma(0)\rangle + |2, \gamma(0)\rangle)$; then for all $t \geqslant t_0$

$$\psi(t) = \sum_{b=1,2} \frac{1}{\sqrt{2}} ([J^{\gamma,t_0,t}]_{b,1} + [J^{\gamma,t_0,t}]_{b,2}) |b, \gamma(t)\rangle \in \Gamma(C, E^+). \tag{93}$$

The state space $\Gamma(\mathcal{M}\times\mathbb{R}, E^+)$ is endowed with the $\mathcal{C}^\infty(\mathcal{M}\times\mathbb{R}, \mathbb{C})$-valued inner product

$$\forall \chi, \phi \in \Gamma(\mathcal{M}\times\mathbb{R}, E^+), \quad \langle\chi|\phi\rangle_{E^+}(\vec{R}, t) = \langle\chi(\vec{R}, t)|\phi(\vec{R}, t)\rangle_{\mathbb{C}^2} \tag{94}$$

$\forall i = 1, 2$ $|i, \vec{R}\rangle \in \Gamma(\mathcal{M}\times\mathbb{R}, E^+)$ [in the composite bundle representation it is the canonical basis $|1\rangle = \binom{1}{0}$ and $|2\rangle = \binom{0}{1}$]. With the scalar product we obtain the instantaneous occupation probabilities of the eigenlevel E_1 and $E_2(V, W)$,

$$P_i(t) = |\langle i|\psi\rangle_{E^+}(\gamma(t), t)|^2. \tag{95}$$

These probabilities are drawn in Fig. 4.

In Sec. IV, we have introduced some fields F_+, B and G in $\mathcal{M}\times\mathbb{R}$ associated with the structure of the composite bundle. An illustration of these fields are shown in Fig. 5.

Let $(V^+, \mathcal{M}\times\mathbb{R}, u(2), \pi_{V^+})$ be the associated vector bundle of P^+ by the adjoint action Ad of U(2) on u(2) ($\mathrm{Ad}(U)X = U^{-1}XU$, $\forall U \in U(2)$, $\forall X \in \mathfrak{u}(2)$). The algebra $\Gamma(\mathcal{M}\times\mathbb{R}, V^+)$ endowed with the Lie bracket

$$\forall A, B \in \Gamma(\mathcal{M}\times\mathbb{R}, V^+), \quad [A, B]_{V^+}(\vec{R}, t) = [A(\vec{R}, t), B(\vec{R}, t)]_{u(2)} \tag{96}$$

is the observables space. In our example of a three level system, a set of observables has a particular importance. Let $S_i = \frac{1}{2}\lambda_i$ for $i = 1, \ldots, 8$, and let $S_i(t) = U(t, t_0) S_i U(t, t_0)^\dagger$, where $U(t, t_0)$ is the evolution operator associated with the Schrödinger equation. The role of the set of operators $S_i(t)$ for a three level system has been extensively studied by Ho, Chu *et al.*[21–23] Let ρ_0 be the density matrix of the initial condition of the system. We introduce the vector $\vec{\mathcal{S}}(t) \in \mathbb{R}^8$ such that

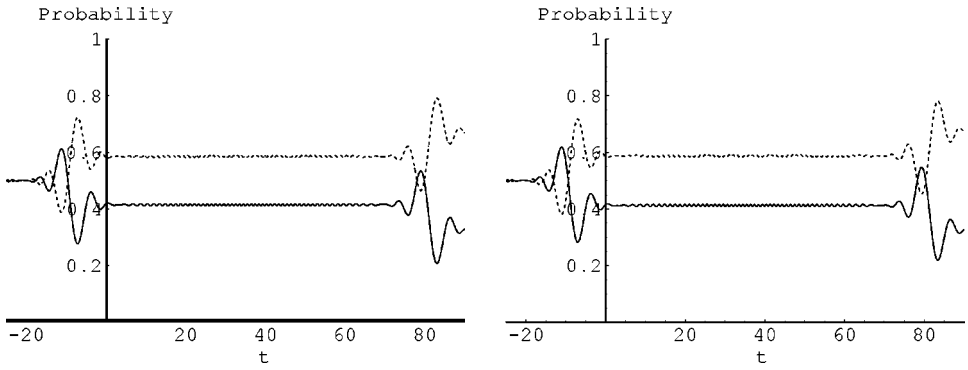

FIG. 4. Left, occupation probabilities of the state $|1\rangle$ (plain line), $|2\rangle$ (dash line), and $|3\rangle$ (strong line) computed by direct integration of the Schrödinger equation in $\mathbb{C}^3$. Right; occupation probabilities of the state $|1\rangle$ (full line), and $|2\rangle$ (dashed line) computed with the formula (93) based on the holonomy operator of the composite bundle. We see that the results obtained by the use of the holonomy operator are in perfect agreement with the direct integration. Moreover the left figure reveals that the level 3 is never occupied, in agreement with its adiabatic elimination in the bundle representation.

$S_i(t)=\mathrm{tr}(\rho_0 S_i(t))$ [the average value of the observable $S_i(t)$]. $\vec{\mathcal{S}}(t)$ is called a coherent vector. From the trajectory of this vector we can obtain information about the dynamical system (for a complete exposition of this subject see Refs. 21–23). Within an approach using our bundle formalism the analogues of the observables $S_i(t)$ are

$$S_i(\vec{R}) = T(\vec{R})^{\dagger} S_i T(\vec{R}) \in \Gamma(\mathcal{M}\times\mathbb{R}, u(2)), \tag{97}$$

and the coherent vector $\vec{\mathcal{S}}(t)$ is obtained by (in our quantum system $\rho_0=|\psi(0)\rangle\langle\psi(0)|$

$$S_i(t) = \langle\psi|S_i\psi\rangle_{E^+}(\gamma(t),t). \tag{98}$$

Figure 6 illustrates the computation of $\mathcal{S}$ in the composite bundle formalism.

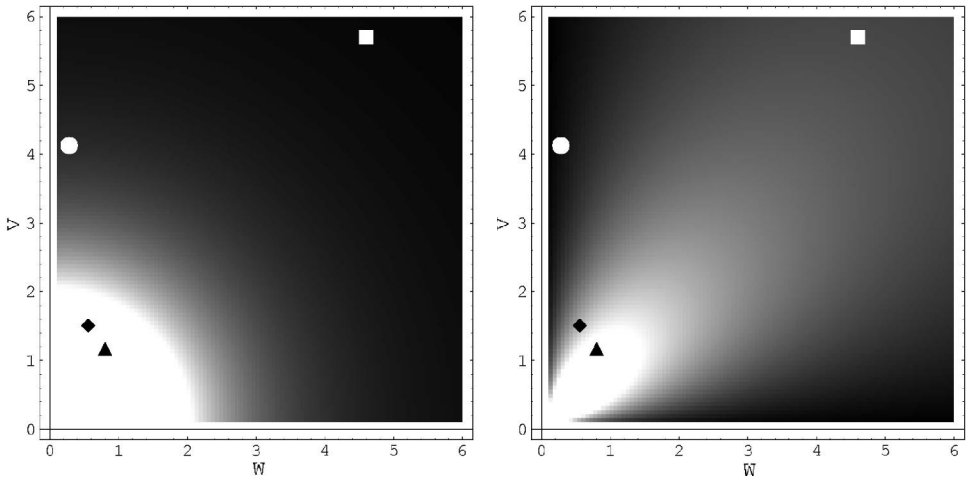

FIG. 5. Left, the (1, 2)-matrix element of $(F_+)_{12}$ with respect to $\mathcal{M}$. Right, the (1, 1)-matrix element of G_{012} with respect to $\mathcal{M}$. The white area is characterized by a strong field intensity whereas the black area corresponds to vanishing fields (arbitrary units). We have moreover indicated some points of the path $\mathcal{C}$, ○, $t=-25$; ◇, $t=-12$; □, $t=40$; and △, $t=80$. By comparison with Fig. 4 we see that the wave function changes significantly only when the control parameters are localized in the strong field area. This shows that these fields are related to the dynamical properties of the quantum system.

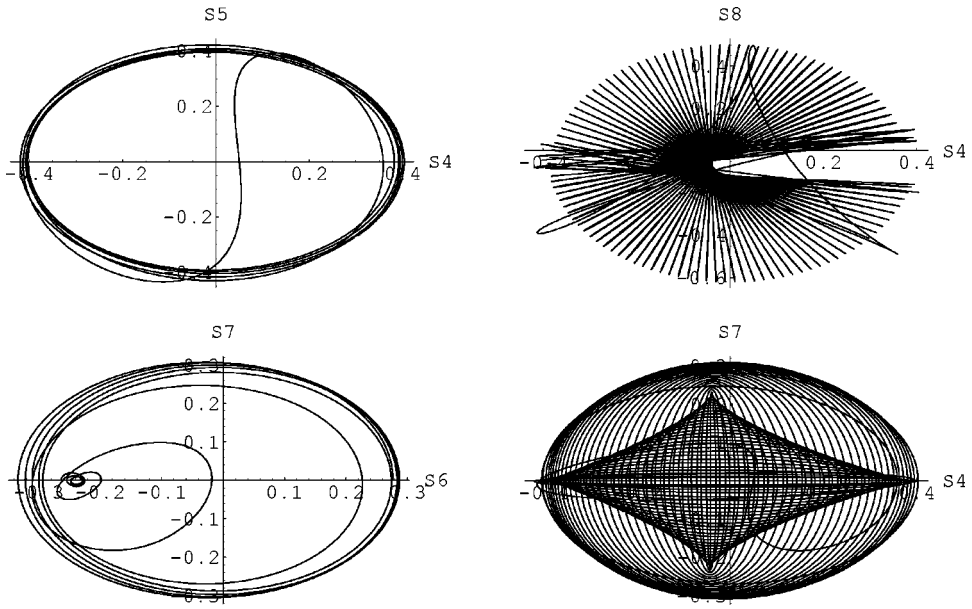

FIG. 6. Trajectories of the coherent vector $\vec{\mathcal{S}}(t)$ projected in different planes, for different time intervals, computed in the composite bundle representation.

The example of the three-level system shows that we can use the composite principal bundle representation to obtain all the physical ingredients of the quantum dynamics. This formalism, coupled with a numerical procedure to compute the holonomy operator, could be used as a powerful method to study a more complex quantum dynamical system.

VI. CONCLUSION

The principal composite bundle appears as a highly appropriate structure to describe the adiabatic transport with a Berry phase which does not commute with the dynamical phase. Nevertheless the use of the standard gauge theory requires us to restrict the gauge transformations to the sections which satisfy the Schrödinger-Von Neumann equation. This feature reveals that it is impossible to describe quantum dynamics with a purely geometric model without a dynamical postulate. If one does not accept any restriction on the gauge transformations, the price to pay is the implementation of an unusual gauge theory which introduces, in addition to the curvature, a field, the curving B, which is precisely the commutator of A with H. It is remarkable that such a situation is very similar to the gauge fields of non-Abelian gerbes, but with the important difference that in the non-Abelian gerbe theory, B does not have values in the Lie algebra g (see Ref. 11). (See Refs. 24–26.)

One can easily generalize this description to the problem of the non-Abelian Aharonov-Anandan phase which does not commute with the dynamical phase; this is done by replacing the principal bundle $(P,\mathcal{M},U(M),\pi_P)$ by the universal principal bundle $(V_M(\mathbb{C}^n),G_M(\mathbb{C}^n),U(M),\pi_U)$. The analysis of Bohm and Mostatazadeh[7] has effectively showed that $(V_M(\mathbb{C}^n),G_M(\mathbb{C}^n),U(M),\pi_U)$ is the universal bundle of $(P,\mathcal{M},U(M),\pi_P)$, and our work demonstrates that the same relationship exists between the adiabatic composite bundle and the universal composite bundle.

(Received 15 April 2005; accepted 28 April 2005; published online 22 June 2005)

A complete canonical quantization of the SU(3) Skyrme model performed in the collective coordinate formalism in general irreducible representations. In the case of SU(3) the model differs qualitatively in different representations. The Wess-Zumino-Witten term vanishes in all self-adjoint representations in the collective coordinate method for separation of space and time variables. The canonical quantization generates representation dependent quantum mass corrections, which can stabilize the soliton solution. The standard symmetry breaking mass, which in general leads to representation mixing, degenerates to the SU(2) form in all self-adjoint representations. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1940548]

I. INTRODUCTION

The Skyrme model is a nonlinear field theory, with localized finite energy soliton solutions, which may be quantized as fermions.[1,2] The semiclassically quantized Skyrme model has proven useful for baryon phenomenology as a realization of the large color limit of QCD.[3] The original model was defined for a unitary field $\mathrm{U}(\mathbf{x},t)$ that belongs to fundamental representation of SU(2). The boundary condition $\mathrm{U}\to\mathbb{1}$ as $|\mathbf{x}|\to\infty$ implies that the unitary field represents a mapping from $S^3\to S^3$, the integer valued winding number of which classifies the solitonic sectors of the model and may be interpreted as the baryon number. The model has subsequently been directly generalized the SU(3) and SU(N),[4] in which case the field $\mathrm{U}(\mathbf{x},t)$ is described by group valued functions with semiclassical quantization.

Both the SU(2) and SU(3) Skyrme versions of the model have been quantized canonically in Refs. 5 and 6 in the collective coordinate formalism. The canonical quantization procedure leads to quantum corrections to the skyrmion mass, which restore the stability of the soliton solutions that is lost in the semiclassical quantization. This method has subsequently been generalized to unitary fields $\mathrm{U}(\mathbf{x},t)$ that belong to general representations of the SU(2),[7–9] along with a demonstration that the quantum corrections, which stabilize the soliton solutions, are representation dependent.

The aim of the present paper is to extend the canonically quantized Skyrme model to general irreducible representations (irrep) of SU(3). The motivation is the absence of any *a priori* reason to restrict collective chiral models to the fundamental representation of the group. The focus here is on the mathematical aspects of the model, and on the derivation of both the Hamiltonian density and the Hamiltonian, in order to elucidate their representation dependence. The possible phenom-

enological applications both in hyperon and hypernuclear phenomenology as well as in the Skyrme model description of the quantum Hall effect[10] and Bose-Einstein condensates,[11] are not elaborated.

In contrast to the case of SU(2), the solutions to the SU(3) Skyrme model depend in an essential way on the dimension. Remarkably the Wess–Zumino–Witten (WZW) term vanishes in all self-adjoint irreps of SU(3), as it is proportional to the cubic Casimir operator $C_3^{\mathrm{SU}(3)}$ in the collective coordinate method for separation of the dependence on space and time variables. In the self-adjoint irreps the symmetry breaking mass term in the model reduces to the SU(2) form.

After some preliminary definitions in Sec. II below, the main part of this paper is organized as follows. In Sec. III, the classical treatment of the Skyrme model in a general irrep of SU(3) is reviewed. In Sec. IV, the quantum Skyrme model is constructed *ab initio* in the collective coordinates framework. In Sec. V, the WZW term is taken into account and the left and right transformation generators are derived from the Lagrangian. The Lagrangian and Hamiltonian density operators are given explicitly in terms of generators. In Sec. VI, the symmetry breaking terms are considered in the collective coordinates framework. Section VII contains a summarizing discussion. A number of relevant mathematical details are given in the Appendix.

II. DEFINITIONS FOR THE UNITARY SU(3) SOLITON FIELD

The unitary field $\mathrm{U}(\mathbf{x},t)$ is defined for general irreps (λ,μ) of SU(3) in addition to the fundamental representation (1, 0). The related Young tableaux are denoted $[\lambda_1,\lambda_2,\lambda_3]$, where $\lambda=\lambda_1-\lambda_2$, $\mu=\lambda_2-\lambda_3$. A group element is specified by the eight real parameters $\alpha^i(\mathbf{x},t)$. The unitary field is expressed in the form of Wigner D matrices for SU(3) in (λ,μ) irrep as

$$\mathrm{U}(\mathbf{x},t)=D^{(\lambda,\mu)}(\alpha^i(\mathbf{x},t)). \tag{2.1}$$

The one-form of the unitary field belongs to the Lie algebra of SU(3). The one-forms may be determined by the functions $C_i^{(Z,I,M)}(\alpha)$ and $C_i'^{(Z,I,M)}(\alpha)$, the explicit expressions for which depend on the specific group parametrization,

$$\begin{aligned}\partial_i U U^\dagger &= \left(\frac{\partial}{\partial\alpha^i}U\right)U^\dagger = C_i^{(Z,I,M)}(\alpha)\langle|J^{(1,1)}_{(Z,I,M)}|\rangle,\\ U^\dagger\partial_i U &= U^\dagger\frac{\partial}{\partial\alpha^i}U = C_i'^{(Z,I,M)}(\alpha)\langle|J^{(1,1)}_{(Z,I,M)}|\rangle.\end{aligned} \tag{2.2}$$

The parameters spin I, and its projections M and Z, which is related to hypercharge as $Y=-2Z$, specify the basis states of irrep (1,1).

The parameterization for the SU(3) model, and the expressions of the differential Casimir operator in terms of the Euler angles, has been proposed by Yabu and Ando.[12] The SU(3) generators are defined as components of irreducible tensors (1, 1) and may be expanded in terms of the Gell-Man generators Λ_k,

$$J^{(1,1)}_{(0,0,0)}=-\tfrac{1}{2}\Lambda_8,\quad J^{(1,1)}_{(0,1,0)}=\tfrac{1}{2}\Lambda_3,$$

$$J^{(1,1)}_{(0,1,1)}=-\frac{1}{2\sqrt{2}}(\Lambda_1+i\Lambda_2),\quad J^{(1,1)}_{(0,1,-1)}=\frac{1}{2\sqrt{2}}(\Lambda_1-i\Lambda_2),$$

$$J^{(1,1)}_{\left(-\frac{1}{2},\frac{1}{2},\frac{1}{2}\right)}=\frac{1}{2\sqrt{2}}(\Lambda_4+i\Lambda_5),\quad J^{(1,1)}_{\left(-\frac{1}{2},\frac{1}{2},-\frac{1}{2}\right)}=\frac{1}{2\sqrt{2}}(\Lambda_6+i\Lambda_7),$$

$$J^{(1,1)}_{\left(\frac{1}{2},\frac{1}{2},\frac{1}{2}\right)} = -\frac{1}{2\sqrt{2}}(\Lambda_6 - i\Lambda_7), \quad J^{(1,1)}_{\left(\frac{1}{2},\frac{1}{2},-\frac{1}{2}\right)} = \frac{1}{2\sqrt{2}}(\Lambda_4 - i\Lambda_5). \tag{2.3}$$

In the case of the fundamental representation the Λ_k matrices generators reduce to the standard Gell-Mann matrices λ_i. Although the generators (2.3) are non-Hermitian, $(J^{(1,1)}_{(Z,I,M)})^\dagger = (-1)^{Z+M} J^{(1,1)}_{(-Z,I,-M)}$, the commutation relations nevertheless have the simple form,

$$\left[J^{(1,1)}_{(Z',I',M')}, J^{(1,1)}_{(Z'',I'',M'')}\right] = \sum_{(Z,I,M)} -\sqrt{3}\begin{bmatrix} (1,1) & (1,1) & (1,1)_a \\ (Z',I',M') & (Z'',I'',M'') & (Z,I,M) \end{bmatrix} J^{(1,1)}_{(Z,I,M)}. \tag{2.4}$$

Here the coefficient on the right-hand side (rhs) of Eq. (2.4) is a Clebsch-Gordan coefficient of SU(3), the explicit expressions for which are given in Ref. 13. The index a in the Clebsch-Gordan coefficient denotes that only antisymmetric irrep couplings are included.

For the specification of the basis states in a general irrep (λ,μ) the parameters (z,j,m), where the hypercharge is $y=\frac{2}{3}(\mu-\lambda)-2z$, are employed. The basis state parameters satisfy the inequalities,

$$\begin{gathered} j-m \geqslant 0, \quad j-z \geqslant 0, \\ j+m \geqslant 0, \quad j+z \geqslant 0, \\ \lambda+z-j \geqslant 0, \quad \mu-z-j \geqslant 0, \end{gathered} \tag{2.5}$$

where the left-hand sides are integers. The generators (2.3) act on the basis states as follows:

$$J^{(1,1)}_{(0,0,0)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = -\frac{\sqrt{3}}{2}y\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle, \quad J^{(1,1)}_{(0,1,-1)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = \sqrt{\tfrac{1}{2}(j+m)(j-m+1)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m-1\end{matrix}\right\rangle,$$

$$J^{(1,1)}_{(0,1,0)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = m\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle, \quad J^{(1,1)}_{(0,1,1)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = -\sqrt{\tfrac{1}{2}(j-m)(j+m+1)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m+1\end{matrix}\right\rangle,$$

$$\begin{aligned} J^{(1,1)}_{\left(-\frac{1}{2},\frac{1}{2},\frac{1}{2}\right)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = &\sqrt{\frac{(\lambda+z-j)(\mu-z+j+2)(j-z+1)(j+m+1)}{2(2j+1)(2j+2)}}\left|\begin{matrix}(\lambda,\mu)\\ z-\frac{1}{2},j+\frac{1}{2},m+\frac{1}{2}\end{matrix}\right\rangle \\ &-\sqrt{\frac{(\lambda+z+j+1)(\mu-z-j+1)(j+z)(j-m)}{4j(2j+1)}}\left|\begin{matrix}(\lambda,\mu)\\ z-\frac{1}{2},j-\frac{1}{2},m+\frac{1}{2}\end{matrix}\right\rangle, \end{aligned}$$

$$\begin{aligned} J^{(1,1)}_{\left(\frac{1}{2},\frac{1}{2},-\frac{1}{2}\right)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = &-\sqrt{\frac{(\lambda+z+j+2)(\mu-z-j)(z+j+1)(j-m+1)}{2(2j+1)(2j+2)}}\left|\begin{matrix}(\lambda,\mu)\\ z+\frac{1}{2},j+\frac{1}{2},m-\frac{1}{2}\end{matrix}\right\rangle \\ &+\sqrt{\frac{(\lambda+z-j+1)(\mu-z+j+1)(j-z)(j+m)}{4j(2j+1)}}\left|\begin{matrix}(\lambda,\mu)\\ z+\frac{1}{2},j-\frac{1}{2},m-\frac{1}{2}\end{matrix}\right\rangle, \end{aligned}$$

$$\begin{aligned} J^{(1,1)}_{\left(-\frac{1}{2},\frac{1}{2},-\frac{1}{2}\right)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = &\sqrt{\frac{(\lambda+z-j)(\mu-z+j+2)(j-z+1)(j-m+1)}{2(2j+1)(2j+2)}}\left|\begin{matrix}(\lambda,\mu)\\ z-\frac{1}{2},j+\frac{1}{2},m-\frac{1}{2}\end{matrix}\right\rangle \\ &+\sqrt{\frac{(\lambda+z+j+1)(\mu-z-j+1)(j+z)(j+m)}{4j(2j+1)}}\left|\begin{matrix}(\lambda,\mu)\\ z-\frac{1}{2},j-\frac{1}{2},m-\frac{1}{2}\end{matrix}\right\rangle, \end{aligned}$$

$$J^{(1,1)}_{(\frac{1}{2},\frac{1}{2},\frac{1}{2})}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = -\sqrt{\frac{(\lambda+z+j+2)(\mu-z-j)(j+z+1)(j+m+1)}{2(2j+1)(2j+2)}}\left|\begin{matrix}(\lambda,\mu)\\ z+\frac{1}{2},j+\frac{1}{2},m+\frac{1}{2}\end{matrix}\right\rangle - \sqrt{\frac{(\lambda+z-j+1)(\mu-z+j+1)(j-z)(j-m)}{4j(2j+1)}}\left|\begin{matrix}(\lambda,\mu)\\ z+\frac{1}{2},j-\frac{1}{2},m+\frac{1}{2}\end{matrix}\right\rangle. \tag{2.6}$$

The basis states are chosen such that the generators $J^{(1,1)}_{(0,1,0)}$ and $J^{(1,1)}_{(0,0,0)}$, as well as the Casimir operator of the SU(2) subgroup $\hat{C}^{\mathrm{SU}(2)}=\Sigma(-1)^M J^{(1,1)}_{(0,1,M)}J^{(1,1)}_{(0,1,-M)}$, are diagonal and thus provide a labelling of the basis states,

$$\hat{C}^{\mathrm{SU}(2)}\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle = j(j+1)\left|\begin{matrix}(\lambda,\mu)\\ z,j,m\end{matrix}\right\rangle. \tag{2.7}$$

III. THE CLASSICAL SU(3) SKYRME MODEL

The action of the Skyrme model in SU (3) is taken to have the form

$$S=\int \mathrm{d}^4x(\mathcal{L}_{\mathrm{Sk}}+\mathcal{L}_{\mathrm{SB}})+S_{\mathrm{WZ}}, \tag{3.1}$$

where the chirally symmetric Lagrangian density is[1]

$$\mathcal{L}_{\mathrm{Sk}}=-\frac{f_\pi^2}{4}\mathrm{Tr}\{\mathbf{R}_\mu\mathbf{R}^\mu\}+\frac{1}{32e^2}\mathrm{Tr}\{[\mathbf{R}_\mu,\mathbf{R}_\nu][\mathbf{R}^\mu,\mathbf{R}^\nu]\}. \tag{3.2}$$

Here the right chiral current is defined as

$$\mathbf{R}_\mu=(\partial_\mu U)U^\dagger=\partial_\mu\alpha^i C_i^{(A)}(\alpha)\langle|J^{(1,1)}_{(A)}|\rangle. \tag{3.3}$$

The greek characters indicate differentiation with respect to space-time variables $\partial_\mu=\partial/\partial x^\mu$ in the metric $\mathrm{diag}(\eta_{\alpha\beta})=(1,-1,-1,-1)$. The only parameters of the model are f_π and e. The symmetry breaking term $\mathcal{L}_{\mathrm{SB}}$ and Wess-Zumino-Witten action S_{WZ} are specified below.

Upon substitution of (3.3) into (3.2) the classical Lagrangian density may be expressed in terms of the group parameters α^i as

$$\mathcal{L}_{\mathrm{Sk}}=\frac{3}{32N}\dim(\lambda,\mu)C_2^{\mathrm{SU}(3)}(\lambda,\mu)\Bigg\{-f_\pi^2(-1)^A\partial_\mu\alpha^i C_i^{(A)}(\alpha)\partial^\mu\alpha^{i'}C_{i'}^{(-A)}(\alpha) + \frac{3}{8e^2}\cdot(-1)^A\partial_\mu\alpha^i C_i^{(A^1)}(\alpha)\partial_\nu\alpha^{i'}C_{i'}^{(A^2)}(\alpha)\partial^\mu\alpha^{i''}C_{i''}^{(A^3)}(\alpha)\partial^\nu\alpha^{i'''}C_{i'''}^{(A^4)}(\alpha)\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (A^1) & (A^2) & (A)\end{bmatrix} \times\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (A^3) & (A^4) & (-A)\end{bmatrix}\Bigg\}. \tag{3.4}$$

In the last SU(3) Clebsch-Gordan coefficients only the antisymmetric irrep coupling is included and there is no summation over irrep multiplicity. The capital italic character indices (A) denote the state label (Z,I,M), $(-A)$ denotes $(-Z,I,-M)$ and $(-1)^A=(-1)^{Z+M}$. The dependence on group irrep appear as an overall factor because

$$\mathrm{Tr}\langle(\lambda,\mu)|J^{(1,1)}_{(A)}J^{(1,1)}_{(B)}|(\lambda,\mu)\rangle=(-1)^A\tfrac{1}{8}\dim(\lambda,\mu)C_2^{\mathrm{SU}(3)}(\lambda,\mu)\,\delta_{(A),(-B)}, \tag{3.5}$$

where $\dim(\lambda,\mu)=\frac{1}{2}(\lambda+1)(\mu+1)(\lambda+\mu+2)$ is a dimension of irrep. Above $C_2^{\mathrm{SU}(3)}(\lambda,\mu)=\frac{1}{3}(\lambda^2+\mu^2+\lambda\mu+3\lambda+3\mu)$ is an eigenvalue of the quadratic Casimir operator of SU(3),

$$\hat{C}_2^{\mathrm{SU}(3)}(\lambda,\mu) = (-1)^{Z+M} J^{(1,1)}_{(Z,I,M)} J^{(1,1)}_{(-Z,I,-M)}. \tag{3.6}$$

The time component of the conserved topological current in the Skyrme model represents the baryon number density which in terms of the variables $\alpha^i(x,t)$ takes the form

$$\begin{aligned} B^0(x) &= \frac{1}{24\pi^2 N}\epsilon^{0ikl}\,\mathrm{Tr}\,(\partial_i U)U^\dagger(\partial_k U)U^\dagger(\partial_l U)U^\dagger \\ &= \frac{(-1)^A}{2^7\sqrt{3}\pi^2 N}\dim(\lambda,\mu)C_2^{\mathrm{SU}(3)}(\lambda,\mu)\varepsilon^{abc}\partial_a\alpha^i C_i^{(A)}(\alpha) \\ &\quad\times \partial_b\alpha^{i'} C_{i'}^{(A')}(\alpha)\partial_c\alpha^{i''} C_{i''}^{(A'')}(\alpha)\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (A') & (A'') & (-A)\end{bmatrix}. \end{aligned} \tag{3.7}$$

For the classical chiral symmetric Skyrme model the dependence on the irrep is contained in the overall factor N. The normalization factor,

$$N = \tfrac{1}{4}\dim(\lambda,\mu)C_2^{\mathrm{SU}(3)}(\lambda,\mu), \tag{3.8}$$

is chosen so that the smallest nontrivial baryon number equals unity, $B=\int \mathrm{d}^3x\, B^0(x)=1$. The dynamics of the system are independent of the overall factor in the Lagrangian. Therefore in the classical case the Skyrme model defined in arbitrary irrep is equivalent to the Skyrme model in the fundamental representation (1, 0), for which $N=1$.

The classical soliton solution of the hedgehog type for (λ,μ) irrep of the SU(3) group may be expressed as direct sum of hedgehog ansätze in SU(2) irreps.[8] The SU(2) representations embedded in the (λ,μ) irrep are defined by the canonical $\mathrm{SU}(3)\supset\mathrm{SU}(2)$ chain. The hedgehog generalization takes the form

$$\exp i(\sigma\cdot\hat{x})F(r) \to U_0(\hat{x},F(r)) = \exp i2(J^{(1,1)}_{(0,1,\cdot)}\cdot\hat{x})F(r) = \sum_{z,j}^{(\lambda,\mu)} \oplus D^j(\varkappa), \tag{3.9}$$

where σ are Pauli matrices and $\hat{x}$ is the unit vector. The Euler angles of the SU(2) subgroup in terms of polar angles φ ,θ and the chiral angle function $F(r)$ are

$$\begin{aligned} \varkappa^1 &= \varphi - \arctan(\cos\theta\tan F(r)) - \pi/2, \\ \varkappa^2 &= -2\arcsin(\sin\theta\sin F(r)), \\ \varkappa^3 &= -\varphi - \arctan(\cos\theta\tan F(r)) + \pi/2. \end{aligned} \tag{3.10}$$

The normalization factor (3.8) ensures that the baryon number density for the hedgehog skyrmion in a general irrep has the usual form,

$$B^0(x) = \frac{1}{24\pi^2 N}\epsilon^{0ikl}\,\mathrm{Tr}(\partial_i U_0)U_0^\dagger(\partial_k U_0)U_0^\dagger(\partial_l U_0)U_0^\dagger = -\frac{1}{2\pi^2}\frac{\sin^2 F(r)}{r^2}F'(r). \tag{3.11}$$

With the hedgehog ansatz (3.9), and after renormalization with the factor (3.8), the Lagrangian density (3.2) reduces to the following simple form:

$$\mathcal{L}_{\mathrm{cl}}[F(r)] = -\mathcal{M}_{\mathrm{cl}}(F(r)) = -\left\{\frac{f_\pi^2}{2}\left(F'^2 + \frac{2}{r^2}\sin^2 F\right) + \frac{1}{8e^2}\frac{\sin^2 F}{r^2}\left(2F'^2 + \frac{\sin^2 F}{r^2}\right)\right\}. \tag{3.12}$$

Variation of the classical hedgehog soliton mass leads to standard differential equation for the chiral angle $F(r)$.

The SU(3) chiral symmetry breaking term of Lagrangian density is defined here as

$$\mathcal{L}_{\mathrm{SB}} = -\mathcal{M}_{\mathrm{SB}} = -\frac{1}{N}\frac{f_\pi^2}{4}[m_0^2\,\mathrm{Tr}\{U+U^\dagger-2\mathbb{1}\} - 2m_8^2\,\mathrm{Tr}\{(U+U^\dagger)J^{(1,1)}_{(0,0,0)}\}]. \tag{3.13}$$

This form is chosen so that it reduces to the mass term of the π, K, η mesons when the unitary field $\mathrm{U}(\mathbf{x},t)=\exp[(i/f_\pi)\varphi_k\Lambda_k]$ is expanded around the classical vacuum $U=\mathbb{1}$,

$$\mathcal{L}_{\mathrm{SB}} = -\tfrac{1}{2}m_\pi^2(\varphi_1^2+\varphi_2^2+\varphi_3^2) - \tfrac{1}{2}m_K^2(\varphi_4^2+\varphi_5^2+\varphi_6^2+\varphi_7^2) - \tfrac{1}{2}m_\eta^2\varphi_8^2 + \cdots . \tag{3.14}$$

For arbitrary irrep the coefficients in the symmetry breaking term can be readily obtained as

$$m_0^2 = \tfrac{1}{3}(m_\pi^2+2m_K^2), \quad m_8^2 = \frac{10}{3\sqrt{3}}\frac{C_2^{\mathrm{SU(3)}}(\lambda,\mu)}{C_3^{\mathrm{SU(3)}}(\lambda,\mu)}(m_\pi^2-m_K^2), \tag{3.15}$$

where

$$C_3^{\mathrm{SU(3)}}(\lambda,\mu) = \tfrac{1}{9}(\lambda-\mu)(2\lambda+\mu+3)(2\mu+\lambda+3), \tag{3.16}$$

is the eigenvalue of the cubic Casimir operator of SU(3).

For the self-adjoint irreps $\lambda=\mu$ the symmetry breaking part of Lagrangian (3.13) is proportional to $m_0^2=\frac{1}{4}m_\pi^2$ only. The Gell-Mann-Okubo mass formula,

$$m_\pi^2 + 3m_\eta^2 - 4m_K^2 = 0, \tag{3.17}$$

is satisfied in all but the self-adjoint irreps.

IV. QUANTIZATION OF THE SKYRMION

The direct quantization of the Skyrme model even in the case of SU(2) leads to rather complicated equations.[7] Here the collective coordinates[3] for the unitary field U in (λ,μ) irrep are employed for the separation of the variables, which depend on the temporal and spatial coordinates:

$$\mathrm{U}(\hat{x},F(r),\mathbf{q}(t)) = A(\mathbf{q}(t))U_0(\hat{x},F(r))A^\dagger(\mathbf{q}(t)). \tag{4.1}$$

Because of form of the ansatz U_0 (3.9), the unitary field U is invariant under right U(1) transformation of the $A(\mathbf{q}(t))=D^{(\lambda,\mu)}(\mathbf{q}(t))$ matrix, defined as

$$A(\mathbf{q}(t)) \to A(\mathbf{q}(t))\exp\beta J^{(1,1)}_{(0,0,0)}. \tag{4.2}$$

Thus the seven-dimensional homogeneous space SU(3)/U(1), which is specified by the seven real, independent parameters $q^k(t)$, must be considered. The mathematical structure of the Skyrme model and its quantization problems on the coset space SU(3)/U(1) have been examined by several authors.[14,16] The canonical quantization procedure for the SU(3) Skyrme model in the fundamental representation has been considered by Fujii *et al.*[6] Here the attention is on the representation dependence of the model. The Lagrangian (3.2) is considered quantum mechanically *ab initio*. The generalized coordinates $q^k(t)$ and velocities $(\mathrm{d}/\mathrm{d}t)q^k(t)=\dot{q}^k(t)$ satisfy the commutation relations

$$[\dot{q}^k,q^l] = -if^{kl}(q), \tag{4.3}$$

where $f^{kl}(q)$ are functions only of q^k, and the form of which will be determined below. The commutation relation between a velocity component $\dot{q}^k$ and arbitrary function $G(q)$ is given by

$$[\dot{q}^k,G(q)] = -i\sum_r f^{kr}(q)\partial_r G(q). \tag{4.4}$$

For the time derivative the usual Weyl ordering is adopted,

$$\partial_0 G(q) = \frac{1}{2}\left\{ \dot{q}^k, \frac{\partial}{\partial q^k} G(q) \right\}. \tag{4.5}$$

The operator ordering is fixed by the form of the Lagrangian (3.2), without further ordering ambiguity. The curly brackets denote an anticommutator.

The ansatz (4.1) is then substituted in the Skyrme Lagrangian (3.2) followed by an integration over the spatial coordinates. The Lagrangian is then obtained in terms of collective coordinates and velocities. For the derivation of the canonical momenta it is sufficient to restrict the consideration to terms of second order in the velocities here (the terms of first order vanish). This leads to

$$\begin{aligned} L_{\mathrm{Sk}} \approx & -\int \mathrm{d}r\, r^2 \Bigg[\sum_M (-1)^M \{\dot{q}^i, C_i'^{(0,1,M)}(q)\}\{\dot{q}^{i'}, C_{i'}'^{(0,1,-M)}(q)\} \\ & \times \frac{\pi}{3}\sin^2 F\left(f_\pi^2 + \frac{1}{e^2}\left(F'^2 + \frac{1}{r^2}\sin^2 F \right)\right) + \sum_{Z,M} (-1)^{Z+M} \left\{ \dot{q}^i, C_i'\left(Z,\tfrac{1}{2},M\right)(q)\right\}\left\{ \dot{q}^{i'}, C_{i'}'\left(-Z,\tfrac{1}{2},-M\right)(q)\right\} \\ & \times \frac{\pi}{4}(1-\cos F)\left(f_\pi^2 + \frac{1}{4e^2}\left(F'^2 + \frac{2}{r^2}\sin^2 F\right)\right)\Bigg] \\ \approx & \frac{1}{2}\dot{q}^\alpha g_{\alpha\beta}(q,F)\dot{q}^\beta + [(\dot{q})^0\text{-order term}] \\ \approx & \frac{1}{8}\{\dot{q}^\alpha, C_\alpha'^{(A)}(q)\} E_{(A)(B)}(F)\{\dot{q}^\beta, C_\beta'^{(B)}(q)\} + [(\dot{q})^0\text{-order term}]. \end{aligned} \tag{4.6}$$

The Lagrangian (4.6) is normalized by the factor (3.8). The metric tensor takes the form

$$g_{\alpha\beta}(q,F) = C_\alpha'^{(A)}(q) E_{(A)(B)}(F) C_\beta'^{(B)}(q), \tag{4.7}$$

where

$$E_{(Z,I,M)(Z',I',M')}(F) = -(-1)^{Z+M} a_I(F)\, \delta_{Z,-Z'}\, \delta_{I,I'}\, \delta_{M,-M'}. \tag{4.8}$$

Here the soliton moments of inertia are given as integrals over the dimensionless variable $\tilde{r} = e f_\pi r$,

$$a_0(F) = 0, \tag{4.9a}$$

$$a_{\frac{1}{2}}(F) = \frac{1}{e^3 f_\pi}\tilde{a}_{\frac{1}{2}}(F) = \frac{1}{e^3 f_\pi} 2\pi \int \mathrm{d}\tilde{r}\, \tilde{r}^2 (1-\cos F)\left[1 + \frac{1}{4}F'^2 + \frac{1}{2\tilde{r}^2}\sin^2 F\right], \tag{4.9b}$$

$$a_1(F) = \frac{1}{e^3 f_\pi}\tilde{a}_1(F) = \frac{1}{e^3 f_\pi}\frac{8\pi}{3}\int \mathrm{d}\tilde{r}\, \tilde{r}^2 \sin^2 F\left[1 + F'^2 + \frac{1}{r^2}\sin^2 F\right]. \tag{4.9c}$$

The canonical momentum, which is conjugate to q^β, is defined as

$$p_\beta^{(0)} = \frac{\partial L_{\mathrm{Sk}}}{\partial \dot{q}^\beta} = \frac{1}{2}\{\dot{q}^\alpha, g_{\alpha\beta}\}. \tag{4.10}$$

The canonical commutation relations

$$[q^\alpha, q^\beta] = [p_\alpha^{(0)}, p_\beta^{(0)}] = 0, \tag{4.11}$$

$$[p_\beta^{(0)}, q^\alpha] = -i\delta_{\alpha\beta},$$

then yield the following explicit form for the functions $f^{\alpha\beta}(q)$:

$$f^{\alpha\beta}(q) = (g_{\alpha\beta})^{-1} = C'^{\alpha}_{\overline{(A)}}(q) E^{\overline{(A)}\overline{(B)}}(F) C'^{\beta}_{\overline{(B)}}(q), \tag{4.12}$$

where

$$E^{\overline{(Z,I,M)}\overline{(Z',I',M')}}(F) = -(-1)^{Z+M} \frac{1}{a_I(F)} \delta_{Z,-Z'} \delta_{I,I'} \delta_{M,-M'}. \tag{4.13}$$

Note that here $E^{(0)(0)}(F)$ is left undefined. The summation over the indices $\overline{(A)}$ denotes summation over the basis states (Z,I,M) of irrep (1, 1), excluding the state (0, 0, 0). It proves convenient to introduce the reciprocal function matrix $C'^{\alpha}_{\overline{(A)}}(q)$, the properties of which are described in the Appendix. The commutation relations of the momenta (4.11) ensure the choice of parameters q^α on the manifold SU(3)/U(1) (see Ref. 5). Here there is no need for explicit parametrization of q^α.

After determination of function $f^{\alpha\beta}(q)$ the following explicit expression $A^\dagger \dot{A}$ obtains

$$\begin{aligned} A^\dagger \dot{A} &= \frac{1}{2} D^{(\lambda,\mu)}(-q)\{\dot{q}^\alpha, \partial_\alpha D^{(\lambda,\mu)}(q)\} \\ &= \frac{1}{2}\{\dot{q}^\alpha, C'^{(A)}_\alpha(q)\}\langle |J^{(1,1)}_{(A)}| \rangle - \frac{1}{2} i E^{\overline{(A)}\overline{(B)}}(F) C'^{\beta}_{\overline{(B)}}(q) C'^{(0)}_\beta(q) (\langle |J^{(1,1)}_{(0)} J^{(1,1)}_{\overline{(A)}}| \rangle + \langle |J^{(1,1)}_{\overline{(A)}} J^{(1,1)}_{(0)}| \rangle) \\ &\quad - \frac{3}{8} i E^{\overline{(A)}\overline{(B)}}(F) C'^{\alpha}_{\overline{(A)}}(q) C'^{(0)}_\alpha(q) C'^{\beta}_{\overline{(B)}}(q) C'^{(0)}_\beta(q) \sum_{z,j}^{(\lambda,\mu)} \oplus\, y^2 \mathbb{1}_{z,j} \\ &\quad + \frac{i}{2a_{\frac{1}{2}}(F)} C_2^{\mathrm{SU}(3)}(\lambda,\mu)\mathbb{1} + i \sum_{z,j}^{(\lambda,\mu)} \oplus \left(\frac{C^{\mathrm{SU}(2)}(j)}{2a_1(F)} - \frac{C^{\mathrm{SU}(2)}(j) + \frac{3}{4}y^2}{2a_{\frac{1}{2}}(F)} \right) \mathbb{1}_{z,j}. \end{aligned} \tag{4.14}$$

Here $\mathbb{1}$ is the unit matrix in the (λ,μ) irrep of SU(3) and $\mathbb{1}_{z,j}$ are unit matrices in the SU(2) irreps. Note that the inverse of the rotation represented by $D^{(\lambda,\mu)}(q)$ is denoted $D^{(\lambda,\mu)}(-q)$.

The field expression (4.1) is substituted in the Lagrangian density (3.2) in order to obtain the explicit expression in terms of collective coordinates and space coordinates. Some expressions with SU(3) group generators, that are useful for this purpose, are presented in the Appendix. After some lengthy manipulation the complete expression of the Skyrme model Lagrangian density is obtained as

$$\begin{aligned} \mathcal{L}_{\mathrm{Sk}} &= \frac{1}{4}\dim(\lambda,\mu) C_2^{\mathrm{SU}(3)}(\lambda,\mu) \Bigg\{ -\frac{(1-\cos F)}{16}\left[f_\pi^2 + \frac{1}{4e^2}\left(F'^2 + \frac{2}{r^2}\sin^2 F \right)\right] \\ &\quad \times \sum_{Z,M} (-1)^{Z+M} \left\{ \dot{q}^\alpha, C'^{\left(Z,\frac{1}{2},M\right)}_\alpha(q) \right\} \left\{ \dot{q}^\beta, C'^{\left(Z,\frac{1}{2},M\right)}_\beta(q) \right\} - \frac{\sin^2 F}{8}\left[f_\pi^2 + \frac{1}{e^2}\left(F'^2 + \frac{1}{r^2}\sin^2 F \right)\right] \\ &\quad \times \sum_{Z,M} [(-1)^M \{\dot{q}^\alpha, C'^{(0,1,M)}_\alpha(q)\}\{\dot{q}^{\alpha'}, C'^{(0,1,M)}_{\alpha'}(q)\} - (\{\dot{q}^\alpha, C'^{(0,1,\cdot)}_\alpha(q)\}\cdot\hat{x})(\{\dot{q}^{\alpha'}, C'^{(0,1,\cdot)}_{\alpha'}(q)\}\cdot\hat{x})] \\ &\quad - \mathcal{M}_{\mathrm{cl}} - \Delta\mathcal{M}_1 - \Delta\mathcal{M}_2 - \Delta\mathcal{M}_3 - \Delta\mathcal{M}'(q) \Bigg\}. \end{aligned} \tag{4.15}$$

Here the following notation has been introduced:

$$\Delta\mathcal{M}_1(F) = -\frac{\sin^2 F}{30a_1^2(F)}\left[f_\pi^2(12\sin^2 F\cdot C_2^{\mathrm{SU}(3)}(\lambda,\mu) - 16\sin^2 F + 15) + \frac{1}{2e^2}\left(2F'^2(12\cos^2 F\cdot \right.\right.$$
$$\left.\left.\times C_2^{\mathrm{SU}(3)}(\lambda,\mu) + 16\sin^2 F - 1) + \frac{\sin^2 F}{r^2}(6C_2^{\mathrm{SU}(3)}(\lambda,\mu) + 7)\right)\right], \tag{4.16a}$$

$$\Delta\mathcal{M}_2(F) = -\frac{(1-\cos F)}{20a_{\frac{1}{2}}^2(F)}\left[f_\pi^2(6(1-\cos F)\cdot C_2^{\mathrm{SU}(3)}(\lambda,\mu) + 3\cos F + 2)\right.$$
$$\left. + \frac{1}{4e^2}\left(F'^2(6(1+\cos F)\cdot C_2^{\mathrm{SU}(3)}(\lambda,\mu) - 3\cos F + 2) + 10\frac{\sin^2 F}{r^2}\right)\right], \tag{4.16b}$$

$$\Delta\mathcal{M}_3(F) = -\frac{\sin^2 F}{30a_1(F)a_{\frac{1}{2}}(F)}\left[f_\pi^2(12(1-\cos F)\cdot C_2^{\mathrm{SU}(3)}(\lambda,\mu) + 16\cos F - 1)\right.$$
$$\left. + \frac{1}{2e^2}\left(F'^2(4\cos F\cdot(3C_2^{\mathrm{SU}(3)}(\lambda,\mu) - 4) + 15) + 15\frac{\sin^2 F}{r^2}\right)\right], \tag{4.16c}$$

$$\Delta\mathcal{M}'(F,q) = -\frac{3(1-\cos F)}{16a_{\frac{1}{2}}^2(F)}\left[f_\pi^2 + \frac{1}{4e^2}\left(F'^2 + \frac{2}{r^2}\sin^2 F\right)\right]$$
$$\times((-1)^{\bar{\bar{A}}}C'^{\alpha}_{(\bar{\bar{A}})}(q)C'^{(0)}_{\alpha}(q)C'^{\beta}_{(-\bar{\bar{A}})}(q)C'^{(0)}_{\beta}(q) + 4). \tag{4.16d}$$

[The "4" in the last bracket on the last row is missing in the corresponding expression in Ref. 6, the consequence of which is the appearance of a spurious term $-3/8a_{1/2}(F)$ in Eq. (69b) of that paper (there are some minor misprints in that equation as well).] The notation $(\bar{\bar{A}})$ indicates that only the states for which $I=\frac{1}{2}$ and $Z=\pm\frac{1}{2}$ are included. The $\Delta\mathcal{M}_k(F)$ terms may be interpreted as quantum mass corrections to the Lagrangian density. The $\Delta\mathcal{M}'(F,q)$ term depends on the quantum variables q^i and is an operator on the configuration space.

The integration (4.17) over the space variables and normalization by factor (3.8) gives the Lagrangian,

$$L_{\mathrm{Sk}} = \int \mathcal{L}_{\mathrm{Sk}}\mathrm{d}^3x = \frac{1}{8}\{\dot{q}^i, C_i'^{(\bar{A})}(q)\}E_{(\bar{A})(\bar{B})}\{\dot{q}^{i'}, C_{i'}'^{(\bar{B})}(q)\} - M_{\mathrm{cl}} - \Delta M_1 - \Delta M_2 - \Delta M_3 - \Delta M'(q)$$
$$= -\frac{1}{8a_{\frac{1}{2}}(F)}(-1)^{\bar{A}}\{\dot{q}^i, C_i'^{(\bar{A})}(q)\}\{\dot{q}^{i'}, C_{i'}'^{(-\bar{A})}(q)\} - \frac{1}{8}\left(\frac{1}{a_1(F)} - \frac{1}{a_{\frac{1}{2}}(F)}\right)(-1)^M$$
$$\times\{\dot{q}^i, C_i'^{(0,1,M)}(q)\}\{\dot{q}^{i'}, C_{i'}'^{(0,1,-M)}(q)\} - M_{\mathrm{cl}} - \Delta M_1 - \Delta M_2 - \Delta M_3 - \Delta M'(q). \tag{4.17}$$

Here $M_{\mathrm{cl}} = (f_\pi/e)\tilde{M}_{\mathrm{cl}} = \int \mathrm{d}^3x\, \mathcal{M}_{\mathrm{cl}}(F)$, $\Delta M_k = e^3 f_\pi \Delta\tilde{M}_k = \int \mathrm{d}^3x\, \Delta\mathcal{M}_k(F)$, and $\Delta M'(q) = \int \mathrm{d}^3x\, \Delta\mathcal{M}'(q)$, where $\tilde{M}_{\mathrm{cl}}$ and $\tilde{M}_k$ are integrals over the dimensionless variable.

V. STRUCTURE OF THE LAGRANGIAN AND THE HAMILTONIAN

The Wess-Zumino-Witten (WZW) action is given as an integral over the five dimensional manifold M^5, the boundary of which is the compactified space-time, $\partial M^5 = M^4 = S^3 \times S^1$. This term is necessary to account for the anomalies in QCD.[14] The standard form for this term is

$$S_{\mathrm{WZ}}(U) = -\frac{iN_c}{240\pi^2 N'}\int_{M^5} \mathrm{d}^5x\, \epsilon^{\mu\nu\lambda\rho\sigma}\,\mathrm{Tr}\, R_\mu R_\nu R_\lambda R_\rho R_\sigma, \tag{5.1}$$

where N_c is the number of colors and N' is a normalization factor. The derivation of the contribution of the Wess-Zumino-Witten term to the effective Lagrangian in the framework of the collective coordinate formalism is given in Ref. 15. By application of Stoke's theorem it takes the following form in a general dimension:

$$\begin{aligned} L_{\mathrm{WZ}}(q,\dot{q}) &= -\frac{iN_c}{24\pi^2 N'}\int_{M^3} \mathrm{d}^3x\, \epsilon^{mjk}\,\mathrm{Tr}[(\partial_m U_0)U_0^\dagger(\partial_j U_0)U_0^\dagger(\partial_k U_0)U_0^\dagger J^{(1,1)}_{(0,0,0)}]\frac{1}{2}\{\dot{q}^\alpha, C'^{(0)}_\alpha(q)\} \\ &= -\frac{iN_c}{2\sqrt{3}\pi^2 N'}\int_{M^3} \mathrm{d}^3x \frac{\sin^2 F(r)}{r^2}F'(r)\sum_{z,j}^{(\lambda,\mu)} yj(j+1)(2j+1)\frac{1}{2}\{\dot{q}^\alpha, C'^{(0)}_\alpha(q)\} \\ &= -\lambda'\frac{i}{2}\{\dot{q}^\alpha, C'^{(0)}_\alpha(q)\}. \end{aligned} \tag{5.2}$$

Here

$$\lambda' = \frac{\sqrt{3}N_c B}{40N'}\dim(\lambda,\mu)C_3^{\mathrm{SU(3)}}(\lambda,\mu). \tag{5.3}$$

The coefficient λ' depends on the representation (λ,μ). For all self-adjoint irreps $\lambda=\mu$ the WZW term vanishes. Following Witten[14] the normalization factor is chosen to be $N'=\dim(\lambda,\mu)\times C_3^{\mathrm{SU(3)}}(\lambda,\mu)/20$ so that $\lambda'=N_cB/2\sqrt{3}$. In the fundamental representation $N'=1$. Here the coefficient λ' only serves to constrain the states of the system. Because the cubic Casimir operator $C_3^{\mathrm{SU(3)}}$ (3.16) vanishes in the self-adjoint representations, it follows that the WZW term (5.2) also vanishes in those representations.

The Lagrangian of the system, with inclusion of the WZW term is

$$L' = L_{\mathrm{Sk}} + L_{\mathrm{WZ}}. \tag{5.4}$$

There are seven collective coordinates. The momenta p_α that are canonically conjugate to q^α are defined as

$$p_\alpha = \frac{\partial L'}{\partial \dot{q}^\alpha} = \frac{1}{2}\{\dot{q}^\beta, g_{\beta\alpha}) - i\lambda' C'^{(0)}_\alpha(q). \tag{5.5}$$

These satisfy the canonical commutation relations (4.11). The WZW term may be considered as an external potential in the system.[16] The seven right transformation generators may be defined as

$$\hat{R}_{\overline{(A)}} = \frac{i}{2}\{p_\alpha + \lambda' i C'^{(0)}_\alpha(q), C'^{\alpha}_{\overline{(A)}}(q)\} = \frac{i}{2}\{\dot{q}^\beta, C'^{(\overline{B})}_\beta(q)\}E_{\overline{(B)}\overline{(A)}}. \tag{5.6}$$

The commutation rules for the generators (5.6) and their action on the $D^{(\lambda,\mu)}$ matrices are given in the Appendix. It is convenient to define an eighth transformation generator formally as[6]

$$\hat{R}_{(0)} = -\lambda'. \tag{5.7}$$

The SU(2) subalgebra of the operators $\hat{R}_{(0,1,M)}$ satisfies the standard SU(2) commutation conditions and may be interpreted as spin generators (Appendix). The eight left transformation generators may be defined as

$$\hat{L}_{(B)} = \tfrac{1}{2}\{\hat{R}_{(A)}, D^{(1,1)}_{(A)(B)}(-q)\}. \tag{5.8}$$

The transformation properties and commutation relations for the left and right transformation generators are given in the Appendix.

The effective Lagrangian, which includes the WZW term takes the form,

$$\begin{aligned} L_{\text{eff}} &= \frac{1}{2a^{\frac{1}{2}}_{\frac{1}{2}}(F)}(-1)^{\bar{A}}\hat{R}_{(A)}\hat{R}_{(-\bar{A})} + \left(\frac{1}{2a_1(F)} - \frac{1}{2a^{\frac{1}{2}}_{\frac{1}{2}}(F)}\right)(\hat{R}_{(0,1,\cdot)}\cdot\hat{R}_{(0,1,\cdot)}) - \lambda'\frac{i}{2}\{\dot{q}^{\alpha}, C'^{(0)}_{\alpha}(q)\} \\ &\quad - M_{\text{cl}} - \Delta M_1 - \Delta M_2 - \Delta M_3 - \Delta M'(q) \\ &= \frac{1}{2a^{\frac{1}{2}}_{\frac{1}{2}}(F)}((-1)^{A}\hat{L}_{(A)}\hat{L}_{(-A)} - \lambda'^2) + \left(\frac{1}{2a_1(F)} - \frac{1}{2a^{\frac{1}{2}}_{\frac{1}{2}}(F)}\right) \\ &\quad \times(\hat{R}_{(0,1,\cdot)}\cdot\hat{R}_{(0,1,\cdot)}) - \lambda'\frac{i}{2}\{\dot{q}^{\alpha}, C'^{(0)}_{\alpha}(q)\} - \Delta M_1 - \Delta M_2 - \Delta M_3 - M_{\text{cl}}. \end{aligned} \tag{5.9}$$

Note that the $\Delta M'(q)$ term which depends on quantum variables due to introducing left translation generators [see (A13)] in the Lagrangian expression (5.9) vanishes.

For the purpose of obtaining Euler-Lagrange equations that are consistent with the canonical equation of motion of the Hamiltonian, the general method of quantization on a curved space developed by Sugano *et al.*[17] is employed, in which the following auxiliary function is introduced:

$$\begin{aligned} Z(q) &= -\frac{1}{16}f^{ab}f^{cd}f^{ek}(\partial_a g_{cd})(\partial_b g_{ek}) - \frac{1}{4}\partial_a(f^{ab}f^{cd}\partial_b g_{cd}) - \frac{1}{4}\partial_a\partial_b f^{ab} \\ &= -\frac{1}{4}\partial_b C'^{\,a}_{(A)}(q)E^{(\bar{A})(\bar{B})}\partial_a C'^{\,b}_{(B)}(q) + \frac{3}{16a^{\frac{1}{2}}_{\frac{1}{2}}(F)}((-1)^{\bar{A}}C'^{(0)}_{a}(q)C'^{\,a}_{(\bar{A})}(q)C'^{\,b}_{(-\bar{A})}(q)C'^{(0)}_{b}(q) + 4). \end{aligned} \tag{5.10}$$

With this the covariant kinetic term may be defined as

$$\begin{aligned} 2K &= \frac{1}{2}\{p_{\alpha} + i\lambda C'^{(0)}_{\alpha}(q), \dot{q}^{\alpha}\} - Z(q) \\ &= \frac{1}{a^{\frac{1}{2}}_{\frac{1}{2}}(F)}((-1)^{A}\hat{L}_{(A)}\hat{L}_{(-A)} - \lambda'^2) + \left(\frac{1}{a_1(F)} - \frac{1}{a^{\frac{1}{2}}_{\frac{1}{2}}(F)}\right)(\hat{R}_{(0,1,\cdot)}\cdot\hat{R}_{(0,1,\cdot)}). \end{aligned} \tag{5.11}$$

According to the prescription[17] the effective Hamiltonian [with the constraint (5.7)] is constructed in the standard form as

$$H = \tfrac{1}{2}\{p_{\alpha}, \dot{q}^{\alpha}\} - L_{\text{eff}} - Z(q) = K + \Delta M_1 + \Delta M_2 + \Delta M_3 + M_{\text{cl}}. \tag{5.12}$$

Upon renormalization the Lagrangian density (4.15) may be reexpressed in terms of left and right transformation generators. The effective Hamiltonian density without the symmetry breaking term in turn takes the form

$$\begin{aligned} \mathcal{H}_{\text{Sk}} &= \frac{(1-\cos F)}{4a^{2}_{\frac{1}{2}}(F)}\left[f_{\pi}^2 + \frac{1}{4e^2}\left(F'^2 + \frac{2}{r^2}\sin^2 F\right)\right][(-1)^{A}\hat{L}_{(A)}\hat{L}_{(-A)} - (\hat{R}_{(0,1,\cdot)}\cdot\hat{R}_{(0,1,\cdot)}) - \lambda'^2] \\ &\quad + \frac{\sin^2 F}{2a_1^2(F)}\left[f_{\pi}^2 + \frac{1}{e^2}\left(F'^2 + \frac{1}{r^2}\sin^2 F\right)\right][(\hat{R}_{(0,1,\cdot)}\cdot\hat{R}_{(0,1,\cdot)}) - (\hat{R}_{(0,1,\cdot)}\cdot\hat{x})(\hat{R}_{(0,1,\cdot)}\cdot\hat{x})] \\ &\quad + \Delta\mathcal{M}_1 + \Delta\mathcal{M}_2 + \Delta\mathcal{M}_3 + \mathcal{M}_{\text{cl}}. \end{aligned} \tag{5.13}$$

The products of spin operators $\hat{R}_{(0,1,M)}$ may be separated into scalar and tensorial terms as

$$(\hat{R}_{(0,1,\cdot)}\cdot\hat{R}_{(0,1,\cdot)})-(\hat{R}_{(0,1,\cdot)}\cdot\hat{x})(\hat{R}_{(0,1,\cdot)}\cdot\hat{x})=\frac{2}{3}(\hat{R}_{(0,1,\cdot)}\cdot\hat{R}_{(0,1,\cdot)})-\frac{4\pi}{3}Y^{*}_{2,M+M'}(\vartheta,\varphi)\times\begin{bmatrix}1 & 1 & 2\\ M & M' & M+M'\end{bmatrix}\hat{R}_{(0,1,M)}\hat{R}_{(0,1,M')},\quad(5.14)$$

where $Y_{l,M}(\vartheta,\varphi)$ is a spherical harmonic and the factor in the square brackets on the right-hand side is an SU(2) Clebsch-Gordan coefficient.

The covariant kinetic term (5.11) is a differential operator constructed from SU(3) left and SU(2) right transformation generators. The eigenstates of the Hamiltonian (5.12) are

$$\left|\begin{matrix}(\Lambda,M)\\ Y,T,M_T;Y',S,M_S\end{matrix}\right\rangle=\sqrt{\dim(\Lambda,M)}D^{*(\Lambda,M)}_{(Y,T,M_T)(Y',S,M_S)}(q)|0\rangle.\quad(5.15)$$

Here the quantity D on the right-hand side is the complex conjugate Wigner matrix elements of (Λ,M) irrep of SU(3) in terms of quantum variables q^k. The topology of the eigenstates can be nontrivial and the quantum states contain an eighth "unphysical" quantum variable q^0.

The matrix elements of the Hamiltonian density (5.13) for states with spin $S>\frac{1}{2}$ are not spherical and those states consequently have quadrupole moments. In the case $S=\frac{1}{2}$ the matrix element of the second rank operator on the right-hand side of (5.14) vanishes.

VI. THE SYMMETRY BREAKING MASS TERM

The chiral symmetry breaking mass term for the SU(3) soliton was defined (3.13). With the ansatz (4.1) in (3.13) the symmetry breaking density operator for the general irrep (λ,μ) obtains

$$\mathcal{L}_{\mathrm{SB}}=-\mathcal{M}_{\mathrm{SB}}=-\frac{1}{N}\frac{f_\pi^2}{4}[m_0^2\,\mathrm{Tr}\{U_0+U_0^\dagger-2\mathbb{1}\}-2m_8^2\,\mathrm{Tr}\{(U_0+U_0^\dagger)J^{(1,1)}_{(0,0,0)}\}D^{(1,1)}_{(0)(0)}(-q)].\quad(6.1)$$

The operator (6.1) contains the matrix elements $D^{(1,1)}$, which depend on the quantum variables q^α. In this form this operator mixes the representations (Λ,M) of the eigenstates of the Hamiltonian.[18] The physical states of the system with symmetry breaking term therefore in principle must be calculated by diagonalization of the Hamiltonian. Since the mass term is a minor part of the Lagrangian it may be considered as a perturbation in the SU(3) representation (Λ,M).

For a given irrep (λ,μ), in which the Lagrangian is defined, the symmetry breaking term depends on the chiral angle $F(r)$ as

$$\begin{aligned}\mathrm{Tr}\{U_0+U_0^\dagger-2\mathbb{1}\}&=2\sum_{z,j}^{(\lambda,\mu)}\left(\sum_{m=-j}^{j}\cos 2mF(r)\right)-2\dim(\lambda,\mu)\\&=2\,\frac{\sin(1+\lambda)F(r)+\sin(1+\mu)F(r)-\sin(\lambda+\mu+2)F(r)}{2\sin F(r)-\sin 2F(r)}-2\dim(\lambda,\mu).\end{aligned}\quad(6.2)$$

Further development of the expression (6.1) leads to

$$\mathrm{Tr}\{(U_0+U_0^\dagger)J^{(1,1)}_{(0,0,0)}\} = 2\sum_{z,j}^{(\lambda,\mu)} 2\sqrt{3}\left[\frac{1}{3}(\lambda-\mu)+z\right]\left(\sum_{m=-j}^{j}\cos 2mF(r)\right)$$

$$= \frac{2\sqrt{3}}{2\sin F(r)-\sin 2F(r)}\times\left\{\frac{1}{2}(1+\mu)(\sin(1+\mu)F(r)-\sin(\lambda+\mu+2)F(r))\right.$$

$$+\frac{1}{3}(\lambda-\mu)(\sin(1+\lambda)F(r)+\sin(1+\mu)F(r)-\sin(\lambda+\mu+2)F(r))$$

$$+\frac{1}{2}(1+\lambda)[(\sin F(r)-\sin(2+\mu)F(r))\cos\lambda F(r)$$

$$\left.-(\cos F(r)-\cos(2+\mu)F(r))\sin\lambda F(r)]\right\}. \tag{6.3}$$

For high irrep (λ,μ) the dependence of the symmetry breaking term on the chiral angle $F(r)$ differs significantly from that in the fundamental representation (1, 0). In that representation the symmetry breaking term takes the standard form

$$\mathcal{M}_{\mathrm{SB}} = f_\pi^2(1-\cos F)\left[m_0^2+\frac{1}{\sqrt{3}}m_8^2 D^{(1,1)}_{(0)(0)}(-q)\right]. \tag{6.4}$$

In the case of (2, 0) representation the expression is

$$\mathcal{M}_{\mathrm{SB}} = \frac{1}{5}f_\pi^2\left[(1-\cos F+2\sin^2 F)m_0^2-(1-\cos F-4\sin^2 F)\frac{m_8^2}{\sqrt{3}}D^{(1,1)}_{(0)(0)}(-q)\right]. \tag{6.5}$$

Note that in both cases the asymptotical behavior at large distance of the symmetry breaking terms are different.

VII. DISCUSSION

Above the SU(3) Skyrme model was quantized canonically in the framework of the collective coordinate formalism for representations of arbitrary dimension. This leads to the complete quantum mechanical structure of the model on the homogeneous space SU(3)/U(1). The results extend those obtained earlier in the fundamental representation for SU(2) and SU(3) (Refs. 5 and 6) and those obtained in general representations of SU(2).[7–9] The explicit representation dependence of the quantum corrections to the Skyrme model Lagrangian was derived. This dependence is nontrivial, especially for the Wess-Zumino-Witten and the symmetry breaking terms. The operators that form the Hamiltonian were shown to have well-defined group-theoretical properties.

The choice of the irrep that is used for the unitary field depends on the phenomenological aspects of the physical system to which the model is applied. Formally the variation of the irrep can be interpreted as modification of the Skyrme model. The representation dependence of the Wess-Zumino-Witten term was shown to be absorbable into a normalization factor, with exception of the self-adjoint irreps in which this term vanishes. The symmetry breaking term has different functional dependence on chiral angle $F(r)$ in different irreps. In case of self-adjoint representations the symmetry breaking term, which is proportional to the m_8^2 coefficient also vanishes.

The effective Hamiltonian (5.12) commutes with the left transformation generators $\hat{L}_{(A)}$ and the right transformation (spin) generators $\hat{R}_{(0,1,M)}$,

$$[\hat{L}_{(A)},H]=[\hat{R}_{(0,1,M)},H]=0, \tag{7.1}$$

which ensures that the states (5.15) are the eigenstates of the effective Hamiltonian.

The symmetry breaking term does, however, not commute with the left generators,

$$[\hat{L}_{\left(Z,\frac{1}{2},M\right)}, M_{\mathrm{SB}}] \neq 0, \tag{7.2}$$

and therefore this term mix the states in different representations (Λ, M).

A result of this investigation is the tensor term (5.15) in the Hamiltonian density operator (5.14). Because of the tensor operator the states with spin $S > \frac{1}{2}$ have quadrupole moments.

Consider finally the energy functional of the quantum skyrmion in the states of (Λ, M) irrep. The problem is simplified if the symmetry breaking term that leads to representation mixing is dropped,

$$E(F) = \frac{C_2^{\mathrm{SU}(3)}(\Lambda, M) - \lambda'^2}{a_{\frac{1}{2}}(F)} + \left(\frac{1}{a_1(F)} - \frac{1}{a_{\frac{1}{2}}(F)}\right) S(S+1) + \Delta M_1 + \Delta M_2 + \Delta M_3 + M_{\mathrm{cl}}. \tag{7.3}$$

The variational condition for the energy is

$$\frac{\delta E(F)}{\delta F} = 0, \tag{7.4}$$

with the usual boundary conditions $F(0) = \pi$, $F(\infty) = 0$. At large distances this equation reduces to the asymptotic form

$$\tilde{r}^2 F'' + 2\tilde{r}F' - (2 + \tilde{m}^2\tilde{r}^2)F = 0, \tag{7.5}$$

where the quantity $\tilde{m}^2$ is defined as

$$\tilde{m}^2 = -e^4 \left(\frac{1}{4\tilde{a}^2_{\frac{1}{2}}(F)} (C_2^{\mathrm{SU}(3)}(\Lambda, M) - S(S+1) - \lambda'^2 + 1) + \frac{2\,S(S+1)+3}{3\tilde{a}_1^2(F)} + \frac{8\Delta\tilde{M}_1 + 4\Delta\tilde{M}_3}{3\tilde{a}_1(F)} \right.$$
$$\left. + \frac{\Delta\tilde{M}_3 + 2\Delta\tilde{M}_2}{2\tilde{a}_{\frac{1}{2}}(F)} + \frac{1}{\tilde{a}_1(F)\tilde{a}_{\frac{1}{2}}(F)} \right). \tag{7.6}$$

The corresponding asymptotic solution takes the form

$$F(\tilde{r}) = k\left(\frac{\tilde{m}^2}{\tilde{r}} + \frac{1}{\tilde{r}^2}\right) \exp(-\tilde{m}\tilde{r}). \tag{7.7}$$

The quantum corrections depends on the irrep (λ, μ) to which the unitary field $\mathrm{U}(\mathbf{x}, t)$ belongs as well as on the state irrep (Λ, M) and spin S. This bears on the stability of quantum skyrmion, the requirement of stability of which the integrals (4.9b) and (4.9c) and ΔM_k converge. This requirement is satisfied only if $\tilde{m}^2 > 0$. That condition is only satisfied in the presence of the negative quantum mass corrections ΔM_k. It is the absence of this term, which leads to the instability of the skyrmion in the semiclassical approach[9] in the SU(2) case. Note that in the quantum treatment the chiral angle $F(\tilde{r})$ has the asymptotic exponential behavior (7.7) even in the chiral limit.

APPENDIX A

The functions $C'^{(\bar{A})}_{\alpha}(q)$ defined in (2.2) are siebenbeins which constitute nonsingular 7×7 matrices. We can introduce the reciprocal functions $C'^{\alpha}_{(\bar{B})}(q)$ by

$$\sum_{\overline{A}} C'^{(\overline{A})}_{\alpha}(q)\cdot C'^{\beta}_{\underline{(A)}}(q)=\delta_{\alpha\beta}, \tag{A1a}$$

$$\sum_{\alpha} C'^{(\overline{A})}_{\alpha}(q)\cdot C'^{\alpha}_{\underline{(B)}}(q)=\delta_{\overline{(A)}\overline{(B)}}. \tag{A1b}$$

Here $(\overline{A})$ and $(\overline{B})$ denote the basis of the irrep (1, 1), with exception for the state (0, 0, 0). The $C'^{\alpha}_{(0)}(q)$ are not defined.

The properties of the functions $C'^{(K)}_{\alpha}(q)$ follow from $\partial_\alpha\partial_\beta D^{(\lambda,\mu)}=\partial_\beta\partial_\alpha D^{(\lambda,\mu)}$:

$$\partial_\beta C'^{(K)}_{\alpha}(q)-\partial_\alpha C'^{(K)}_{\beta}(q)-\sqrt{3}\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (K') & (K'') & (K)\end{bmatrix}C'^{(K')}_{\beta}(q)C'^{(K'')}_{\alpha}(q)=0, \tag{A2}$$

and are correct for all states (K) including (0, 0, 0). The following properties of the functions $C'^{\alpha}_{\underline{(K)}}(q)$ are useful:

$$\begin{aligned}&C'^{\alpha}_{\underline{(K')}}(q)\partial_\alpha C'^{\beta}_{\underline{(K'')}}(q)-C'^{\alpha}_{\underline{(K'')}}(q)\partial_\alpha C'^{\beta}_{\underline{(K')}}(q)+\sqrt{3}\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ \overline{(K')} & \overline{(K'')} & \overline{(K)}\end{bmatrix}C'^{\beta}_{\underline{(K)}}(q)\\ &\quad=\sqrt{3}z''C'^{(0)}_{\alpha}(q)C'^{\alpha}_{\underline{(K')}}(q)C'^{\beta}_{\underline{(K'')}}(q)-\sqrt{3}z'C'^{(0)}_{\alpha}(q)C'^{\alpha}_{\underline{(K'')}}(q)C'^{\beta}_{\underline{(K')}}(q).\end{aligned} \tag{A3}$$

In Sec. V the right transformation generators (5.6) are defined with the following commutation relations:

$$\begin{aligned}[\hat{R}_{\overline{(A')}},\hat{R}_{\overline{(A'')}}]=&-\sqrt{3}\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ \overline{(A')} & \overline{(A'')} & \overline{(A)}\end{bmatrix}\hat{R}_{\overline{(A)}}+\sqrt{3}z''\{C'^{\alpha}_{\underline{(A')}}(q)C'^{(0)}_{\alpha}(q),\hat{R}_{\overline{(A'')}}\}\\ &-\sqrt{3}z'\{C'^{\alpha}_{\underline{(A'')}}(q)C'^{(0)}_{\alpha}(q),\hat{R}_{\overline{(A')}}\}.\end{aligned} \tag{A4}$$

The SU(2) subalgebra of the generators $\hat{R}_{(0,1,M)}$ satisfies the standard SU(2) commutation relations. These may be interpreted as spin operators because its acting on unitary field (4.1) can be realized as a spatial rotation of skyrmion only,

$$[\hat{R}_{(0,1,M)},A(q)U_0(x)A(q)^{\dagger}]=A(q)[J^{(1,1)}_{(0,1,M)},U_0(x)]A^{\dagger}(q). \tag{A5}$$

The transformation rule for irrep matrices is

$$[\hat{R}_{\overline{(K)}},D^{(\lambda,\mu)}_{(A)(A')}(q)]=D^{(\lambda,\mu)}_{(A)(A'')}(q)\left\langle\begin{matrix}(\lambda,\mu)\\ A''\end{matrix}\middle|J^{\underline{(1,1)}}_{(K)}\middle|\begin{matrix}(\lambda,\mu)\\ A'\end{matrix}\right\rangle-\frac{\sqrt{3}}{2}y'C'^{\alpha}_{\underline{(K)}}(q)C'^{(0)}_{\alpha}(q)D^{(\lambda,\mu)}_{(A)(A')}(q). \tag{A6}$$

The eight left transformation generators are defined as

$$\hat{L}_{(B)}=\frac{1}{2}\{\hat{R}_{(A)},D^{(1,1)}_{(A)(B)}(-q)\}=\frac{i}{2}\{p_\beta+\lambda iC'^{(0)}_{\beta}(q),K^{\beta}_{(B)}(q)\}+\lambda D^{(1,1)}_{(0)(B)}(-q), \tag{A7}$$

where

$$K^{\beta}_{(B)}(q)=C'^{\beta}_{\underline{(A)}}(q)D^{\underline{(1,1)}}_{(A)(B)}(-q), \tag{A8}$$

the properties of which follows from (A3):

$$K^{\beta''}_{(B'')}(q)\partial_{\beta''}K^{\beta'}_{(B')}(q)-K^{\beta''}_{(B')}(q)\partial_{\beta''}K^{\beta'}_{(B'')}(q)=\sqrt{3}\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (B'') & (B') & (B)\end{bmatrix}K^{\beta'}_{(B)}(q). \tag{A9}$$

By making use of (A4) it may be proven that

$$[\hat{L}_{(B')},\hat{L}_{(B'')}]=\sqrt{3}\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (B') & (B'') & (B)\end{bmatrix}\hat{L}_{(B)}. \tag{A10}$$

The three right transformation generators or spin operators $\hat{R}_{(0,1,M)}$ commute with the left transformation generators,

$$[\hat{R}_{(0,1,M)},\hat{L}_{(B)}]=0. \tag{A11}$$

The left transformation rules for the irrep matrices are

$$\begin{aligned}[\hat{L}_{(B)},D^{(\lambda,\mu)}_{(A')(A)}(q)] &= \langle A'|J^{(1,1)}_{(B)}|A''\rangle D^{(\lambda,\mu)}_{(A'')(A)}(q)\\ &-\frac{\sqrt{3}}{2}y_A\cdot D^{(1,1)}_{(0)(B)}(-q)D^{(\lambda,\mu)}_{(A')(A)}(q)-\frac{\sqrt{3}}{2}y_A\cdot C'^{(0)}_{\alpha}(q)C'^{\alpha}_{(B')}(q)D^{(1,1)}_{(B')(B)}(-q)D^{(\lambda,\mu)}_{(A')(A)}(q).\end{aligned} \tag{A12}$$

It is straightforward to derive the following result:

$$(-1)^B\hat{L}_{(B)}\hat{L}_{(-B)}=(-1)^{\bar{A}}\hat{R}_{(A)}\hat{R}_{(-\bar{A})}+\lambda'^2-\tfrac{3}{4}-\tfrac{3}{16}(-1)^{\bar{A}}C'^{(0)}_{\alpha}(q)C'^{\alpha}_{(\bar{A})}(q)C'^{(0)}_{\beta}(q)C'^{\beta}_{(-\bar{A})}(q). \tag{A13}$$

For the derivation of the Lagrangian density the following expressions are needed:

$$E^{(\bar{A})(\bar{B})}(F)J^{(1,1)}_{(A)}J^{(1,1)}_{(B)}=-\frac{1}{a_{\frac{1}{2}}(F)}\hat{C}^{\mathrm{SU}(3)}_2+\left(\frac{1}{a_{\frac{1}{2}}(F)}-\frac{1}{a_1(F)}\right)\hat{C}^{\mathrm{SU}(2)}+\frac{1}{a_{\frac{1}{2}}(F)}(J^{(1,1)}_{(0,0,0)})^2, \tag{A14}$$

$$\begin{aligned}E^{(\bar{A})(\bar{B})}(F)D^{I}_{(\bar{B'})(\bar{B})}(\hat{x},F(r))J^{(1,1)}_{(A)}J^{(1,1)}_{(B')} &= -\frac{\cos F}{a_{\frac{1}{2}}(F)}\hat{C}^{\mathrm{SU}(3)}_2+\left(\frac{\cos F}{a_{\frac{1}{2}}(F)}-\frac{\cos 2F}{a_1(F)}\right)\hat{C}^{\mathrm{SU}(2)}+\frac{\cos F}{a_{\frac{1}{2}}(F)}(J^{(1,1)}_{(0,0,0)})^2\\ &+i\left(\frac{\sin 2F}{a_1(F)}+\frac{\sin F}{a_{\frac{1}{2}}(F)}\right)(J^{(1,1)}_{(0,1,\cdot)}\cdot\hat{x})-2\frac{\sin^2 F}{a_1(F)}(J^{(1,1)}_{(0,1,\cdot)}\cdot\hat{x})\\ &\times(J^{(1,1)}_{(0,1,\cdot)}\cdot\hat{x}).\end{aligned} \tag{A15}$$

Here $D^{I}_{(\bar{B'})(\bar{B})}(\hat{x},F(r))$ is a Wigner matrix of the SU(2). The summation is over SU(2) representations $I=\frac{1}{2}$, 1 and the corresponding bases,

$$E^{(\bar{A})(\bar{B})}(F)\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (\bar{A}) & (0,1,u) & (\bar{C})\end{bmatrix}J^{(1,1)}_{(B)}J^{(1,1)}_{(\bar{C})}=\frac{1}{\sqrt{3}}\left(\frac{1}{2a_{\frac{1}{2}}(F)}+\frac{1}{a_1(F)}\right)J^{(1,1)}_{(0,1,u)}, \tag{A16}$$

$$\begin{aligned}&E^{(\bar{A})(\bar{B})}(F)\begin{bmatrix}(1,1) & (1,1) & (1,1)_a\\ (\bar{A}) & (0,1,u) & (\bar{C})\end{bmatrix}D^{I}_{(\bar{C'})(\bar{C})}(\hat{x},F(r))J^{(1,1)}_{(B)}J^{(1,1)}_{(C')}\\ &=\frac{1}{\sqrt{3}}\Bigg\{-[J^{(1,1)}_{(0,1,\cdot)}\times\hat{x}]_u\left(\frac{\sin F}{2a_{\frac{1}{2}}(F)}+i\frac{2\sin^2 F}{a_1(F)}(J^{(1,1)}_{(0,1,\cdot)}\cdot\hat{x})\right)\\ &-i\left(\frac{\sin F}{2a_{\frac{1}{2}}(F)}\hat{C}^{\mathrm{SU}(3)}_2-\left(\frac{\sin F}{2a_{\frac{1}{2}}(F)}-\frac{\sin 2F}{a_1(F)}\right)\hat{C}^{\mathrm{SU}(2)}-\frac{\sin F}{2a_{\frac{1}{2}}(F)}(J^{(1,1)}_{(0,0,0)})^2\right)\hat{x}_u\end{aligned}$$

$$+\left(\frac{\cos 2F}{a_1(F)}+\frac{\cos F}{2a_{\frac{1}{2}}(F)}+i\frac{\sin 2F}{a_1(F)}(J^{(1,1)}_{(0,1,\cdot)}\cdot\hat{x})\right)J^{(1,1)}_{(0,1,u)}\Bigg\}. \tag{A17}$$

(Received 22 February 2005; accepted 13 May 2005; published online 29 June 2005)

Recent work has shown the essential equivalence of stopping power, force-force correlation function, and phase-shift analysis for nonlinear potential scattering in a three-dimensional electron gas. In the present study, we first demonstrate that the above situation is markedly different when the scattering occurs from a localized potential in a two-dimensional (2D) electron gas. Only to second order in the potential do the three methods referred to above precisely agree. However, all these methods can still be applied in 2D, some fully nonlinear evaluation proving possible. The one-dimensional case is also discussed, albeit more briefly. Scattering from a two-center modeling of the localized potential is also calculated, but now only in the Born approximation, due to the added complication of a noncentral potential. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1947118]

I. INTRODUCTION

Following a vast body of experimental and theoretical studies on three-dimensional metals and alloys,[1,2] attention more recently has focused on two-dimensional systems of itinerant electrons. As an immediate example, on the (111) surfaces of noble metals, e.g., Au, Ag, and Cu, quasiparticles form a two-dimensional electron gas. This has been investigated experimentally by cold scanning tunneling microscopy.[3,4] Turning to physical properties associated with such two-dimensional electron gases (2DEG), the present paper will have as its focus the scattering in such assemblies of the itinerant electrons from localized impurity centers. Then, it is natural enough to proceed with the discussion for spin-compensated impurity systems. However, it is highly relevant to note that both theoretical[5] and experimental[6] studies have appeared recently. In the former, the 2DEG was considered in the presence of a single magnetic impurity (e.g., Co) and the additional scattering phase shift induced by the charge of the Co ion and its specially extended displaced electronic density distribution.[5] Subsequently, scanning tunneling microscopy was employed[6] to measure the phase shift that surface-state electrons suffer when scattering from a single magnetic impurity, which forms a Kondo state.

This is the context then which has motivated the present theoretical study. This follows the earlier discussions,[7,8] of a few aspects of the stopping power of a 2DEG for heavy particles. Two

results utilized there form a valuable starting point for the present study of such a two-dimensional system. First, the transport (tr) cross section is given in the partial wave representation as

$$\sigma_{tr}(k_F) = \frac{4}{k_F} \sum_{m=0}^{\infty} \sin^2[\delta_m(k_F) - \delta_{m+1}(k_F)], \tag{1.1}$$

where k_F denotes the Fermi wave number of the electron gas, related to the Fermi energy E_F by

$$E_F = k_F^2/2. \tag{1.2}$$

In Eq. (1.1), the scattering phase shifts at the Fermi level are denoted by $\delta(k_F)$ for the different partial waves ($m=0,1,\ldots$, etc.). We are interested further in the stopping power $\mathrm{d}E/\mathrm{d}x$ say, at $T=0$, to which the present treatment is restricted, for a heavy ion moving with velocity $\mathbf{v}$. This is related in a direct fashion, as set out in Ref. 7 for slow ions, to the transport cross section σ_{tr} in Eq. (1.1) above

$$\frac{\mathrm{d}E}{\mathrm{d}x} = n_0 v v_F \sigma_{tr}(k_F), \tag{1.3}$$

in which n_0 and v_F are, respectively, the areal density and Fermi velocity of the 2DEG.

The outline of the present investigation is then as follows. In Sec. II below, a force-force correlation function formula, due to Rousseau, Stoddart, and March (RSM),[2,9] in three dimensions, is first adapted to two dimensions. We comment here on the three-dimensional (3D) result. There, the total potential which scatters the electrons is denoted by $V(\mathbf{r})$, and this generates a Dirac density matrix $\gamma(\mathbf{r}_1,\mathbf{r}_2,E)$, which is such that its diagonal element, say $\gamma(\mathbf{r},\mathbf{r},E)$, denotes the integrated local density of electronic states. Correlating the force $-\partial V(\mathbf{r})/\partial \mathbf{r}$ at points $\mathbf{r}_1$ and $\mathbf{r}_2$ via $\partial\gamma(\mathbf{r}_1,\mathbf{r}_2,E)/\partial E$, which is then a generalized density of states, it can readily be shown, when $V(\mathbf{r})$ is assumed to be a central potential $V(r) \equiv V(|\mathbf{r}|)$, to be related to the phase shifts $\delta_l(E)$ for scattering off $V(r)$, via the radial wave functions $R_l(r,E)$ from which the density matrix is constructed. The 3D force-force correlation function formula of RSM is then exactly equivalent to the phase-shift scattering cross section for impurity resistivity of Huang,[10] as shown by one of us.[11] In Sec. II, this 3D situation will be contrasted with that in 2D. Adapting the RSM formula in 3D then leads to the 2D analog set out in Eq. (2.1) below, where account is taken of the Fermi statistics of electrons by considering, as in 3D, that scattering is on the Fermi surface, corresponding to Fermi energy E_F. The 2D phase shift result derived in Eq. (2.15) below for the force-force correlation function is demonstrated here to be distinct from the stopping power in 2D already set out in Eqs. (1.1) and (1.3). This is in contrast to the equivalence of the force-force correlation function and the scattering cross section in 3D which we have discussed above.

Section III is then devoted to studying at some length the Born approximation to this force-force correlation function. In this section, contact is then made with Eqs. (1.1) and (1.3) above. In Sec. IV further illustrations are given by using linear-response formalism for the induced density in 2D. The one-dimensional case of scattering is outlined in Sec. V. Finally, additional and more technical details are summarized in four Appendixes at the end of the paper.

II. FORCE-FORCE CORRELATION FUNCTION IN A TWO-DIMENSIONAL ELECTRON GAS

As indicated above, let us take as starting point a definition of the force-force correlation function in two dimensions as

$$\langle \mathbf{F}\cdot\mathbf{F}\rangle = \int d\mathbf{r}_1 d\mathbf{r}_2 \frac{\partial V(\mathbf{r}_1)}{\partial \mathbf{r}_1}\cdot\frac{\partial V(\mathbf{r}_2)}{\partial \mathbf{r}_2}\left[\frac{\partial \gamma(\mathbf{r}_1,\mathbf{r}_2,E)}{\partial E}\right]^2_{E=E_F}. \tag{2.1}$$

Evidently the two forces $-\partial V(\mathbf{r})/\partial \mathbf{r}$ at two-dimensional position vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ are correlated via the off-diagonal local density of states $N(E,\mathbf{r}_1,\mathbf{r}_2)\equiv \partial\gamma/\partial E$ evaluated at the Fermi level E_F, γ as defined above being the off-diagonal integrated density of states.

As emphasized in three dimensions by Rousseau *et al.*,[9] the merit of the corresponding two-dimensional form in Eq. (2.1) is that it is defined for potentials $V(\mathbf{r})$ of lower than circular symmetry. However, it is a valuable starting point in calculating the force-force correlation function $\langle \mathbf{F}\cdot\mathbf{F}\rangle$ in Eq. (2.1) to treat the case of circular symmetry, i.e., $V(\mathbf{r})=V(|\mathbf{r}|)=V(r)$. This is the objective of the present section. For this limiting case of $V(r)$ with circular symmetry, we shall draw also on the treatments by Adhikari[12] and by Tang and Thouless.[13]

Beginning then with the wave function $\psi(r,\theta)$ in polar coordinates defined by $x=r\cos\theta$ and $y=r\sin\theta$, one can write in the asymptotic region, far from the origin of the scattering potential energy $V(r)$, that $\psi(r,\theta)$ consists of a plane wave, propagating say along the x axis, plus a scattered outgoing wave. Both Refs. 12 and 13 adopt the form

$$\psi(r,\theta)_{r\to\infty} \to \exp(ikx) + \sqrt{i/k} f_k(\theta)\frac{\exp(ikr)}{\sqrt{r}}, \tag{2.2}$$

where $f_k(\theta)$ denotes the scattering amplitude. This result (2.2) follows asymptotically from the Schrödinger equation

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial \psi}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2\psi}{\partial\theta^2} + k^2\psi = U\psi, \tag{2.3}$$

where $k^2=2mE/\hbar^2$ and $U(r)=2mV(r)/\hbar^2$. In this case of circular symmetry $V(r)$, one can separate the variables r and θ by writing

$$\psi(r,\theta) = R(r)\Theta(\theta), \tag{2.4}$$

to find

$$\frac{d^2\Theta}{d\theta^2} + m^2\Theta = 0. \tag{2.5}$$

Hence, we have now wave functions of the form following from Eq. (2.4) plus the physically significant solution of Eq. (2.5) as

$$\psi_m(\mathbf{r}_1) = \exp(im\theta_1)R(k_F r_1). \tag{2.6}$$

Returning to the definition (2.1), we can write the energy derivative of the Dirac matrix γ in terms of $\psi_m(\mathbf{r}_1)$ and the energies E_i generated by the one-body Hamiltonian H given by

$$H = -\frac{1}{2}\nabla^2 + V(r), \tag{2.7}$$

as

$$\frac{\partial\gamma}{\partial E} = \sum_i \psi_i^*(\mathbf{r}_1)\psi_i(\mathbf{r}_2)\delta(E-E_i), \tag{2.8}$$

with the complex conjugate satisfying

$$\frac{\partial \gamma^*}{\partial E} = \sum_j \psi_j(\mathbf{r}_1)\psi_j^*(\mathbf{r}_2)\delta(E-E_j). \tag{2.9}$$

Thus, from Eqs. (2.8) and (2.9) it follows that

$$\left|\frac{\partial \gamma}{\partial E}\right|^2_{E=E_F} = \sum_{i,j} \psi_i^*(k_F\mathbf{r}_1)\psi_j(k_F\mathbf{r}_1)\psi_i(k_F\mathbf{r}_2)\psi_j^*(k_F\mathbf{r}_2). \tag{2.10}$$

Replacing i, j by m, m', it follows from Eq. (2.1) for isotropic scattering potentials that

$$\langle \mathbf{F}\cdot\mathbf{F}\rangle = \int r_1 r_2 \frac{\partial V(r_1)}{\partial r_1}\frac{\partial V(r_2)}{\partial r_2}\cos(\theta_2-\theta_1)\left|\frac{\partial \gamma}{\partial E}\right|^2_{E=E_F} \mathrm{d}r_1\,\mathrm{d}r_2\,\mathrm{d}\theta_1\,\mathrm{d}\theta_2. \tag{2.11}$$

Using the wave functions (2.6), the angular integration in Eq. (2.11) becomes, after some manipulation

$$\begin{aligned}&\frac{1}{2}\sum_{m,m'}\int_0^{2\pi}\int_0^{2\pi}[\exp(i(\theta_2-\theta_1))+\exp(-i(\theta_2-\theta_1))][\exp(i(m-m')\theta_2)\exp(-i(m-m')\theta_1)]\mathrm{d}\theta_1\,\mathrm{d}\theta_2\\ &\quad = 2\pi^2\sum_{m,m'}[\delta(m'=m+1)+\delta(m'=m-1)].\end{aligned} \tag{2.12}$$

Using Eqs. (2.12) and (2.6) in Eq. (2.11), and performing the summation over m' then yields

$$\begin{aligned}\langle \mathbf{F}\cdot\mathbf{F}\rangle = 2\pi^2\sum_m \int_{r_1} r_1\frac{\partial V(r_1)}{\partial r_1}R_m^*(k_Fr_1)[R_{m+1}(k_Fr_1)+R_{m-1}(k_Fr_1)]\mathrm{d}r_1\int_{r_2} r_2\frac{\partial V(r_2)}{\partial r_2}R_m(k_Fr_2)\\ \times[R_{m+1}^*(k_Fr_2)+R_{m-1}^*(k_Fr_2)]\mathrm{d}r_2.\end{aligned} \tag{2.13}$$

Using the result of Tang and Thouless[13] that

$$\int rR_{m+1}^*(kr)\frac{\partial V(r)}{\partial r}R_m(kr)\mathrm{d}r = -\frac{k}{\pi}\exp(\delta_m-\delta_{m+1})\sin(\delta_{m+1}-\delta_m) \tag{2.14}$$

then gives

$$\begin{aligned}\langle \mathbf{F}\cdot\mathbf{F}\rangle &= \frac{(2\pi)^2}{2}\left(\frac{k}{\pi}\right)^2\sum_m[\exp(-i(\delta_m-\delta_{m+1}))\sin(\delta_{m+1}-\delta_m)+\exp(i(\delta_{m-1}-\delta_m))\sin(\delta_m-\delta_{m-1})]\\ &\quad\times[\exp(i(\delta_m-\delta_{m+1}))\sin(\delta_{m+1}-\delta_m)+\exp(-i(\delta_{m-1}-\delta_m))\sin(\delta_m-\delta_{m-1})]\\ &= k^2\sum_m[1-\cos(2(\delta_{m+1}-\delta_{m-1}))].\end{aligned} \tag{2.15}$$

The above analysis is analogous to that of Huang[10] in terms of partial waves of orbital angular momentum quantum number l in 3D; there, only the phase shifts δ_l with $k=k_F$ are required, where k_F is the Fermi wave number (independent of l). This two-dimensional result for the force-force correlation function with $V(\mathbf{r})=V(|\mathbf{r}|)$ appears to be new. It must be stressed that this phase-shift result (2.15) for $\langle \mathbf{F}\cdot\mathbf{F}\rangle$ is distinct from the stopping power in Eqs. (1.1) and (1.3).

Though we do not have an analog of Eq. (2.15) for $\langle \mathbf{F}\cdot\mathbf{F}\rangle$ when the isotropy of $V(\mathbf{r})$ is relaxed, it is of immediate interest to treat this more general case in the Born approximation, and this is the essential content of the following section.

III. FORCE-FORCE CORRELATION FUNCTION IN TWO DIMENSIONS IN THE BORN APPROXIMATION

To calculate $\langle \mathbf{F}\cdot\mathbf{F}\rangle$ in Eq. (2.1) to $\mathcal{O}(V^2)$ for a potential $V(\mathbf{r})$ without circular symmetry, we can make the crucial simplifying approximation that the Dirac density matrix γ in Eq. (2.1) is replaced by its two-dimensional free-electron counterpart $\gamma_0(\mathbf{r}_1,\mathbf{r}_2,E)$. This we obtain following the approach of March and Murray[14,15] in their three-dimensional density matrix perturbation theory, based on the scattering potential $V(r)$ above embedded in an initially uniform free-electron gas. Their main achievement was to start from the canonical, or Bloch density matrix $C(\mathbf{r}_1,\mathbf{r}_2,\beta)$, defined for the one-body Hamiltonian (2.7) having eigenfunctions $\psi_i(\mathbf{r})$ and corresponding eigenvalues ϵ_i as

$$C(\mathbf{r}_1,\mathbf{r}_2,\beta)=\sum_{\text{all}i}\psi_i^*(\mathbf{r}_1)\psi_i(\mathbf{r}_2)\exp(-\beta\epsilon_i):\ \beta=(k_BT)^{-1}. \tag{3.1}$$

The (zero-temperature) Dirac density matrix appearing in Eq. (2.1) is then related to the C matrix in Eq. (3.1) by

$$C(\mathbf{r}_1,\mathbf{r}_2,\beta)=\beta\int_0^\infty \gamma(\mathbf{r}_1,\mathbf{r}_2,E)\exp(-\beta E)\mathrm{d}E. \tag{3.2}$$

A. Free-electron results in two dimensions

It is well known that in D dimensions the free-electron canonical density matrix is given by

$$C_0(\mathbf{r}_1,\mathbf{r}_2,\beta,D)=\frac{1}{(2\pi\beta)^{D/2}}\exp\left(-\frac{|\mathbf{r}_1-\mathbf{r}_2|^2}{2\beta}\right). \tag{3.3}$$

March and Murray were concerned with the three-dimensional case, for which they obtained the Dirac matrix as

$$\gamma_0(\mathbf{r}_1,\mathbf{r}_2,E)_{D=3}=\frac{k_F^3}{2\pi^2}\frac{j_1(k|\mathbf{r}_1-\mathbf{r}_2|)}{k|\mathbf{r}_1-\mathbf{r}_2|}, \tag{3.4}$$

where $j_1(x)$ is the first-order spherical Bessel function $(\sin x - x\cos x)/x^2$, and we have written Eq. (3.4) for single occupied levels.

To obtain the two-dimensional analog, we need the inverse Laplace transform of C_0/β, according to Eq. (3.2), where C_0 is given by Eq. (4.4) with $D=2$. This can be found from Ref. 16 as

$$\gamma_0(\mathbf{r}_1,\mathbf{r}_2,E)=\frac{1}{2\pi}\frac{\sqrt{2E}}{|\mathbf{r}_1-\mathbf{r}_2|}J_1(\sqrt{2E}|\mathbf{r}_1-\mathbf{r}_2|). \tag{3.5}$$

Fortunately, the energy derivative $\partial\gamma/\partial E$ appearing in the force-force formula (2.1) is more compact, and follows after a short calculation using properties of Bessel functions as

$$\frac{\partial\gamma_0(\mathbf{r}_1,\mathbf{r}_2,E)}{\partial E}=\frac{1}{2\pi}J_0(\sqrt{2E}|\mathbf{r}_1-\mathbf{r}_2|). \tag{3.6}$$

An immediate check on the result (3.6) is the density of states $N(E)$ obtained by setting $\mathbf{r}_2=\mathbf{r}_1$ in Eq. (3.6), the result being simply the constant $1/2\pi$ since $J_0(0)=1$. This result (3.6), in conjunction with Eq. (4.7) below, is used in Appendix A to derive the linear response function in two dimensions.

Returning to Eq. (2.1), the force-force correlation function, B denoting the Born approximation, is given, apart from a multiplicative factor, explicitly in terms of the scattering potential $V(\mathbf{r})$ by making use of Eq. (3.6) as

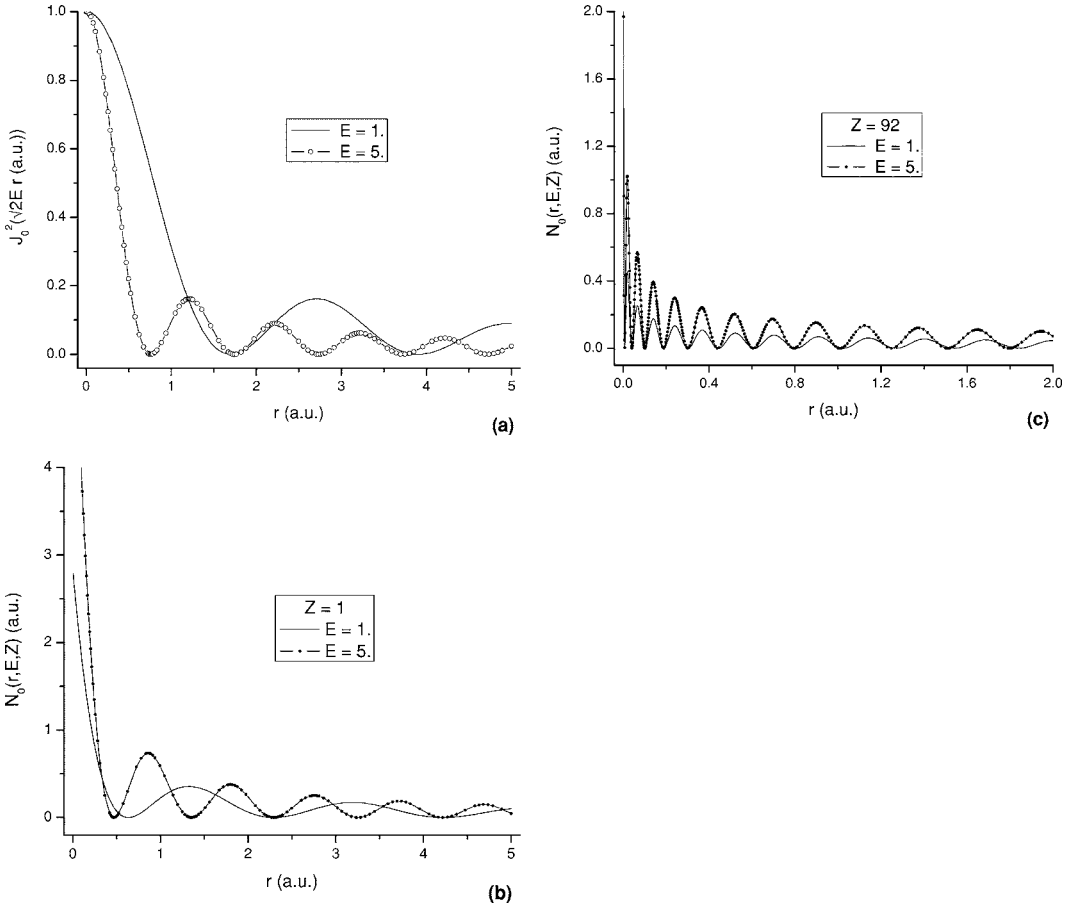

FIG. 1. (a) Plot of $J_0^2(\sqrt{2E}r)$ appearing in force-force correlation function set out in Eq. (3.7), versus r, for two values of E [compare also Eq. (D4)]. Other curves shown are (b) and (c) the s-state ($m=0$) component of the local density of states $N_0(r,E,Z)$ generated by a bare Coulomb potential ($-Z/r$) embedded in a two-dimensional electron gas, for $Z=1$ and 92 and the same two values of energy E as in the plot of J_0^2. Apart from an unimportant normalization factor, J_0^2 is the limit of $N_0(r,E,Z)$ as Z tends to zero.

$$\langle \mathbf{F}\cdot\mathbf{F}\rangle_B \propto \int d\mathbf{r}_1\, d\mathbf{r}_2 \frac{\partial V(\mathbf{r}_1)}{\partial \mathbf{r}_1}\cdot\frac{\partial V(\mathbf{r}_2)}{\partial \mathbf{r}_2} J_0^2(\sqrt{2E}|\mathbf{r}_1-\mathbf{r}_2|). \tag{3.7}$$

Some examples relating to Eq. (3.7) are set out in Appendixes C and D below. By way of illustration, we show in Fig. 1 a plot of $J_0^2(\sqrt{2E}r)$ versus r for two values of E. For comparison, we show the local density of states $N_0(r,E,Z)$ for the bare Coulomb potential energy $-Ze^2/r$ given in Eq. (C3), which reduces to $J_0^2(\sqrt{2E}r)$ when $Z=0$, apart from an unimportant normalization factor.

B. Scattering from a model two-center potential in two dimensions and in Born approximation

Dimers of impurities on nonmagnetic substrates provide a very active research field in scanning tunneling spectroscopy at the atomic scale.[17] This activity motivates the present subsection on the role of reduced dimensionality in associated scattering processes.

Consider the case of two equivalent scattering centers in a 2D electron gas. Let $\mathbf{R}$ be the vector joining the centers, $\mathbf{n}_0$ a unit vector in the direction of incidence, $\mathbf{n}_1$ a unit vector in the direction of scattering, and $\mathbf{k}$ the scattering wave vector of electrons. Due to the Fermi statistics $\mathbf{k}=\mathbf{k}_F$ is, in fact, the practically important value. As a first approximation we regard the two centers as scattering independently but coherently. Therefore, the result obtained will be generally

valid (even for strong scattering by the single center) if $kR \gg 1$. Following closely the standard[18,19] derivation in the 3D case, one obtains for the 2D differential cross section the following expression, in this so-called independent-atom approximation:

$$d\sigma(k,\theta)d\theta = 2|f_k(\theta)|^2(1+\cos[k(\mathbf{n}_0-\mathbf{n}_1)\cdot\mathbf{R}])d\theta, \tag{3.8}$$

where $\cos\theta = \mathbf{n}_0\cdot\mathbf{n}_1$. The function $f_k(\theta)$ is given in Eq. (2.2).

Practically, due to the random orientations of dimers (diclusters), the averaged cross section $d\sigma_{av}(k,\theta)$ is required. Therefore, we average over all orientations of the vector $\mathbf{R}$ in 2D by using Eqs. (3.715.18) of Ref. 20 and obtain

$$d\sigma_{av}(k,\theta)d\theta = 2|f_k(\theta)|^2[1+J_0(qR)]d\theta, \tag{3.9}$$

in which $q=2k\sin(\theta/2)$, the momentum transfer. In the first-order Born approximation the scattering amplitude $f_k^B(\theta)$ is related simply to the Fourier transform of the single-atom screened potential $V(q)$. Thus, in this case we have

$$|f_k^B(\theta)|^2 = \frac{1}{2\pi k}|V(q)|^2. \tag{3.10}$$

For the $kR \gg 1$ condition, Eq. (3.9) is applicable also for stronger scattering using partial-wave expansion.[12,13] In the so-called leading ($m=0$) phase-shift approximation, one gets the usual expression

$$|f_k(\theta)|^2 = \frac{2}{\pi k}\sin^2(\delta_0(k)). \tag{3.11}$$

If the unitary limit, as prescribed by the 2D Friedel sum rule,[8] is a valid approximation, one may use $\delta_0=\pi/2$ in Eqs. (3.11) and (3.9).

Various angular integrals of $d\sigma_{av}(k,\theta)$ need, in the leading phase-shift method, only a simple averaging of the $J_0[2k\sin(\theta/2)R]$ factor. Applying the standard expansion

$$J_0(qR) = \sum_{m=-\infty}^{\infty} J_m^2(kR)\exp(im\theta), \tag{3.12}$$

in Eq. (3.9), the total (t) cross section becomes

$$\sigma_{av}^t(k) = \frac{8}{k}\sin^2(\delta_0(k))(1+[J_0(kR)]^2), \tag{3.13}$$

for this case. This quantity may prove useful in estimating the dephasing time due to elastic scattering of surface-state electrons by dimer impurities.

Other angle-weighted cross sections (transport, diffusion) require more detailed, but feasible, calculations for the important 2D case.

IV. LINEAR RESPONSE FUNCTION GIVING THE DISPLACED FERMION DENSITY AROUND A "PERTURBING POTENTIAL" $V(\mathbf{r})$ IN A TWO-DIMENSIONAL UNIFORM ELECTRON GAS

Though our main purpose has been to evaluate the force-force correlation function defined in Eq. (2.1) to all orders in the scattering potential $V(|\mathbf{r}|)$ in Eq. (2.13), and to illustrate this by presenting numerical results at the Born level, it seemed of interest, in view of the usefulness of the March-Murray result[14,15] for the density $\rho(\mathbf{r})$ in three dimensions, namely

$$\rho_{3d}(\mathbf{r}) - \rho_0 = \text{const.} \times \int d\mathbf{r}' V(\mathbf{r}') \frac{j_1(2k_F|\mathbf{r}-\mathbf{r}'|)}{|\mathbf{r}-\mathbf{r}'|^2}, \tag{4.1}$$

where $\rho_0 = k_F^3/6\pi^2$, and the constant is given in Eq. (A2), to obtain the corresponding two-dimensional result. This then is the purpose of the present section. We shall take as starting point the work of Stoddart, March, and Stott,[21] who write Eq. (4.1) more generally as

$$\Delta\rho(\mathbf{r}) = \int d\mathbf{r}' V(\mathbf{r}') F(|\mathbf{r}-\mathbf{r}'|, E), \tag{4.2}$$

where

$$\frac{\partial F}{\partial E} = 2\,\mathrm{Re}\left[G(\mathbf{r},\mathbf{r}',E) \frac{\partial \gamma(\mathbf{r},\mathbf{r}',E)}{\partial E} \right]. \tag{4.3}$$

Thus, to obtain the two-dimensional counterpart of Eq. (4.1), we shall write, for the uniform gas, that

$$\frac{\partial F_0(\mathbf{r},\mathbf{r}',E)}{\partial E} = 2 \frac{\partial \gamma_0(\mathbf{r},\mathbf{r}',E)}{\partial E}\,\mathrm{Re}[G_0(\mathbf{r},\mathbf{r}',E)]. \tag{4.4}$$

Here, G_0 is the free-particle Green function in two dimensions. This is related to the canonical density matrix $C_0(\mathbf{r},\mathbf{r}',\beta)$ discussed above by

$$\mathcal{L} C_0(\mathbf{r},\mathbf{r}',\beta) = G_0(\mathbf{r},\mathbf{r}',-E). \tag{4.5}$$

With C_0 again given by Eq. (3.3) with $D=2$, the Laplace transform $\mathcal{L}$ above can be obtained as

$$\mathcal{L} C_0(\mathbf{r},\mathbf{r}',\beta) = \frac{K_0(\sqrt{2E}|\mathbf{r}-\mathbf{r}'|)}{\pi} \tag{4.6}$$

where $K_0(x)$ is the modified Bessel function.[16] Using Eqs. (4.5) and (4.6), we thus find

$$G_0(\mathbf{r},\mathbf{r}',E) = \frac{K_0(i\sqrt{2E}|\mathbf{r}-\mathbf{r}'|)}{\pi}. \tag{4.7}$$

Since $\partial\gamma_0/\partial E$ is known in terms of J_0 from Eq. (3.6), we have $\partial F_0/\partial E$ by appealing to Eq. (4.4). We note that Zhang[22] has obtained a more compact form in **k**-space, although he then invokes the Meijer function in the **r**-space representation we focus on in the present study. The above theory is extended somewhat in Appendix A.

V. ONE-DIMENSIONAL SCATTERING

Having contrasted nonlinear scattering in 2D and 3D electron gases from a localized potential, we turn, albeit briefly, to consider what further changes are introduced by dimensionality reduction to the case of 1D. We follow March and Murray,[14,15] who dealt completely with 3D plane wave perturbation theory, by starting from the integral equation derived from the well-known Bloch equation[23] for the canonical density matrix $C(x,x_0,\beta)$, where

$$C(x,x_0,\beta) = \sum_{\text{all}\,i} \psi_i(x)\psi_i^*(x_0)\exp(-\beta\epsilon_i). \tag{5.1}$$

In Eq. (5.1), $\psi_i(x)$ and the corresponding eigenvalues ϵ_i satisfy

$$H\psi_i = \epsilon_i \psi_i, \tag{5.2}$$

where the one-dimensional Hamiltonian is simply

$$H = -\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2} + V(x). \tag{5.3}$$

Evidently, completeness yields from Eq. (5.1) at $\beta=0$

$$C(x,x_0,0) = \delta(x-x_0), \tag{5.4}$$

and this is built in the integral form of the Bloch equation, namely

$$C(x,x_0,\beta) = C_0(x,x_0,\beta) - \int_0^\beta d\beta_1 \int dx_1 C_0(x,x_1,\beta-\beta_1)V(x_1)C(x_1,x_0,\beta_1). \tag{5.5}$$

In Eq. (5.5), C_0 is the free-particle density matrix[23]

$$C_0(x,x_0,\beta) = \frac{1}{\sqrt{2\pi\beta}}\exp\left(-\frac{(x-x_0)^2}{2\beta}\right). \tag{5.6}$$

The β_1 integration can be removed by a Laplace transform on β ($\rightarrow E$) to yield ($C\rightarrow\tilde{C}$)

$$\tilde{C}(x,x_0,E) = \tilde{C}_0(x,x_0,E) - \int \mathrm{d}x_1\, \tilde{C}_0(x,x_1,E)V(x_1)\tilde{C}(x_1,x_0,E). \tag{5.7}$$

The Laplace transform of Eq. (5.6) is readily obtained as[24]

$$\tilde{C}_0(x,x_0,E) \equiv \mathcal{L}C_0(x,x_0,\beta) = \frac{1}{\sqrt{2E}}\exp(-\sqrt{2E}|x-x_0|). \tag{5.8}$$

If in Eq. (5.7) we then work to first order in the "perturbing" potential $V(x)$, we find

$$\tilde{C}(x,x_0,E) = \frac{1}{\sqrt{2E}}\exp(-\sqrt{2E}|x-x_0|) - \frac{1}{2E}\int \mathrm{d}x_1\, V(x_1)\exp(-\sqrt{2E}\{|x-x_1|+|x_1-x_0|\}). \tag{5.9}$$

Inverting the Laplace transform ($E\rightarrow\beta$) in Eq. (5.9) readily yields

$$C(x,x_0,\beta) = \frac{1}{\sqrt{2\pi\beta}}\exp\left(-\frac{(x-x_0)^2}{2\beta}\right) - \frac{1}{2}\int \mathrm{d}x_1\, V(x_1)\mathrm{erfc}\left(\sqrt{\frac{2}{\beta}}\frac{\{|x-x_1|+|x_1-x_0|\}}{2}\right). \tag{5.10}$$

The Dirac density matrix $\gamma(x,x_0,E)$ then follows as the inverse Laplace transform of $C(x,x_0,\beta)/\beta$, and is given by

$$\gamma(x,x_0,E) = \frac{\sin(\sqrt{2E}|x-x_0|)}{\pi|x-x_0|} - \int \mathrm{d}x_1\, V(x_1)\left[\frac{1}{2} - \frac{\mathrm{Si}(\sqrt{2E}\{|x-x_1|+|x_1-x_0|\})}{\pi}\right], \tag{5.11}$$

which is the 1D analog of the first-order 3D result of March and Murray.[14,15]

Of course, one obvious difference between 2D and 3D scattering and the 1D case to be discussed further below is that in the 1D system there are only two discrete directions for scattering: forward and backward along a line. Below, we restrict our discussion to symmetric localized potentials $V(x)$ satisfying

$$V(x) = V(-x). \tag{5.12}$$

The 1D analog of the customary Lippmann-Schwinger equation takes the form

$$\psi_k(x) = \phi_k(x) + \int_{-\infty}^{\infty} G_0(x,x')V(x')\psi_k(x')\mathrm{d}x', \tag{5.13}$$

where $\phi_k(x)$ is the free-particle wave function $\exp(ikx)$. The one-dimensional Green function $G_0(x,x')$ is given by

$$G_0(x,x') = -\frac{i}{2k}\exp(ik|x-x'|), \tag{5.14}$$

which is readily verified to be the Laplace transform ($\mathcal{L}$) of the canonical density matrix (3.3) with respect to β for the case $D=1$, since

$$\mathcal{L}C = G_0(x,x'):E = k^2. \tag{5.15}$$

Using Eq. (5.14) in (5.13), the following asymptotic form of $\psi_k(x)$ results:

$$\psi_k(x) \to \exp(ikx) + \frac{i}{k}f_k(\epsilon)\exp(ikx), \tag{5.16}$$

where $f_k(\epsilon)$ is the analog of the scattering amplitude in higher dimensions. However, as discussed above, there are but two scattering directions in 1D, corresponding to $\epsilon=\pm 1$. This is to be contrasted with the continuum of scattering angles in both 2D and 3D. The differential cross sections in these two directions in the 1D case are given by

$$\sigma_\epsilon = \frac{1}{k^2}|f_k(\epsilon)|^2, \tag{5.17}$$

while the total cross section σ takes the form

$$\sigma = \frac{1}{k^2}[|f_k(+1)|^2 + |f_k(-1)|^2]. \tag{5.18}$$

To press the analogy with higher dimensions, we have now just two partial waves. For potentials satisfying Eq. (5.12), these two partial waves are distinct, with even and odd parity. It is to be noted that the cross section σ, in principle an observable, has units of length L squared in 3D, L in 2D, and is dimensionless according to Eq. (5.18) in 1D.

Analogs of the optical theorem and the unitarity relation again exist, paralleling here the 2D and 3D scattering, but we shall not go into further detail. It is worth adding, in concluding this brief discussion of 1D scattering, that the above can be usefully illustrated for a potential $V(x)$ which is the Dirac delta function (see the discussion in 3D in Ref. 25), but we shall not go into further detail since the 3D example was treated fully for a similar, completely localized, scattering center.

VI. DISCUSSION AND FUTURE DIRECTIONS

Our principal aim has been to demonstrate the effect of dimensionality reduction on the 3D results given earlier[25] for nonlinear scattering by a localized potential. For the 2D case, which is the main focus of the present study, it is striking that the stopping power problem summarized in Eqs. (1.1) and (1.3) turns out, beyond the Born approximation, to be distinct from the force-force correlation function $\langle \mathbf{F}\cdot\mathbf{F}\rangle$ defined in Eq. (2.1) in 2D. These are essentially identical to all orders in the localized scattering potential V in 3D. It is possible in 2D that there are "frictional effects" in surfaces, the theory of which has been discussed by d'Agliano and co-workers,[26] which may mirror $\langle \mathbf{F}\cdot\mathbf{F}\rangle$, but it remains to be proved that this latter correlation function is indeed an observable in 2D, whereas it is established that this is the case, though not distinct from stopping power or transport cross section, in 3D. Here, we believe for the first time, $\langle \mathbf{F}\cdot\mathbf{F}\rangle$ in Eq. (2.1) has been

calculated analytically in terms of phase shifts at the Fermi level, and is given for 2D in Eq. (2.13). This is evidently closely related to, but nevertheless distinct from, Eq. (1.1) in terms of the same input information, for the transport cross section.

Further directions of interest for the future, which were already touched on in the Introduction, are scattering in essentially two dimensions from a single magnetic impurity. Here, the spin-dependent theoretical approach of Stoddart and March[27] may well find application, and the two-dimensional version should prove of considerable interest for the future.

APPENDIX A: r-SPACE LINEAR RESPONSE FUNCTION $F(|\mathbf{r}-\mathbf{r}'|,E)$ IN TWO DIMENSIONS

The object of this appendix is to give the two-dimensional form of the result of March and Murray[14]

$$\Delta\rho(\mathbf{r},E)=\int F_{3d}(|\mathbf{r}-\mathbf{r}'|,E)V(\mathbf{r}')\mathrm{d}\mathbf{r}', \tag{A1}$$

for the displaced charge below energy E created by a perturbing potential $V(\mathbf{r})$ inserted into an initially uniform electron gas. The result of Ref. 14 was explicitly [compare Eq. (4.1)]

$$F_{3d}(R,E)=-\frac{mE}{\pi^3\hbar^2}\frac{j_1(2\sqrt{2E}R)}{R^2}. \tag{A2}$$

Below, we derive an analogous form to Eq. (A2) in two dimensions. As shown by Stoddart, March, and Stott,[21] for the uniform Fermi gas as the unperturbed system, $\partial F(R,E)/\partial E$ is given by Eq. (4.3) of the main text, where the free-electron 2D Green function has been given in Eq. (4.7) in terms of the Bessel function K_0. Likewise, $\partial\gamma/\partial E$ is known in 2D in terms of J_0 from Eq. (3.6), and inserting these results into Eq. (4.3) and forming the energy derivative yields, after using the identity

$$\mathrm{Re}[K_0(ikR)]=-Y_0(kR)/2\pi, \tag{A3}$$

the result

$$F(R,E)=-\frac{1}{2\pi}\int^E J_0(\sqrt{2E}R)Y_0(\sqrt{2E}R)\mathrm{d}E. \tag{A4}$$

Performing the integration, one finds

$$F(R,E)=-\frac{E}{2\pi}[J_0(\sqrt{2E}R)Y_0(\sqrt{2E}R)+J_1(\sqrt{2E}R)Y_1(\sqrt{2E}R)]+f(R). \tag{A5}$$

But, the energy-independent function $f(R)$ must be zero since $\Delta\rho(R,E=0)=0$, and thus, for the displaced charge at the origin $\Delta\rho(0,E)$, one obtains

$$\Delta\rho(0,E)=-ZE\int_0^\infty [J_0(\sqrt{2E}r)Y_0(\sqrt{2E}r)+J_1(\sqrt{2E}r)Y_1(\sqrt{2E}r)]\mathrm{d}r, \tag{A6}$$

for the case of the bare Coulomb potential, by way of illustration. From Ref. 20, we have

$$\int_0^\infty J_\nu(ax)Y_\nu(ax)\mathrm{d}x=-\frac{1}{2a},\quad [\nu>-1/2,a>0], \tag{A7}$$

and hence

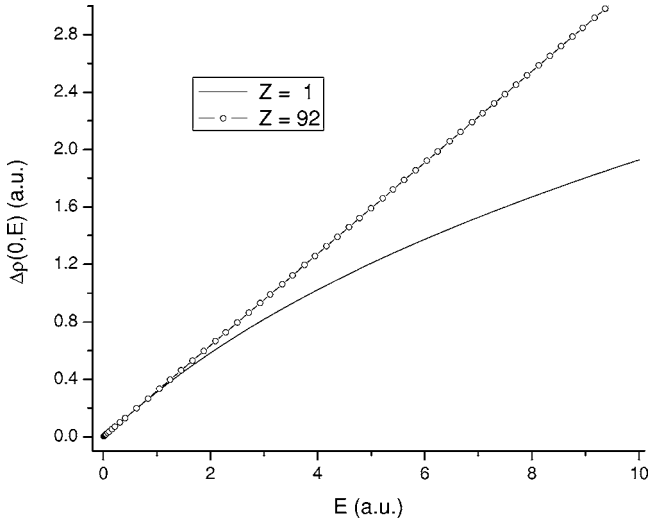

FIG. 2. Displaced charge $\Delta\rho(0,E)$ at nucleus, resulting from a bare Coulomb potential $(-Z/r)$ embedded in a two-dimensional electron gas, for $Z=1$ and 92, versus energy E, as given in Eq. (A9).

$$\Delta\rho(0,E) = \frac{ZE}{\sqrt{2E}} = Z\sqrt{\frac{E}{2}}, \quad E \neq 0. \tag{A8}$$

In fact, for $V=-Z/r$, this result (A8) has the fully nonlinear generalization

$$\Delta\rho(0,E) = \frac{E}{\pi}\tanh\left(\frac{Z\pi}{\sqrt{2E}}\right), \tag{A9}$$

which is equivalent to Eq. (A8) to first order in Z. Equation (A9) is plotted as a function of energy E for $Z=1$ and $Z=92$ in Fig. 2. The following appendix adds some further nonlinear results associated still with the unscreened Coulomb potential.

APPENDIX B: SOME FURTHER PROPERTIES GENERATED BY THE BARE COULOMB POTENTIAL IN TWO DIMENSIONS

The real-space Schrödinger equation in plane polar coordinates (r,θ) reads

$$\left[-\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) - \frac{1}{r^2}\frac{\partial^2}{\partial\theta^2} + V(\mathbf{r})\right]\psi(\mathbf{r}) = E\psi(\mathbf{r}), \tag{B1}$$

where, writing

$$\psi(\mathbf{r}) = R(r)\Theta(\theta), \tag{B2}$$

we have

$$\Theta(\theta) = \frac{1}{\sqrt{2\pi}}\exp(im\theta). \tag{B3}$$

The corresponding radial equation, with $E=-k_0^2$, say, is

$$\frac{d^2R}{dr^2} + \frac{1}{r}\frac{dR}{dr} + \left[\frac{2}{r} - k_0^2 - \frac{m^2}{r^2}\right]R = 0. \tag{B4}$$

The normalized wave functions are then

$$\psi_{nm}(\mathbf{r}) = \sqrt{\frac{k_0^3(n-|m|)!}{\pi(n+|m|)!}}(2k_0r)^{|m|}\exp(-k_0r)L_{n-|m|}^{2|m|}(2k_0r)\exp(im\theta), \tag{B5}$$

where L as usual denotes the associated Laguerre polynomial.

In three dimensions, Heilmann and Lieb[28] (HL) calculated the total density of the entire spectrum of bound states of the hydrogen atom. Below, we note one property for the two-dimensional case that is much simpler than for the three-dimensional case, namely the density $\rho_\infty(r)$ at $r=0$. Using the definition in two dimensions that

$$\rho_\infty(r) = \sum_{n=0}^{\infty}\sum_{m\leqslant n}\psi^*(\mathbf{r})\psi(\mathbf{r}), \tag{B6}$$

one has from Eq. (B5) the result

$$\rho_\infty(r) = \sum_{n=0}^{\infty}\sum_{m\leqslant n}\frac{k_0^3(n-|m|)!}{\pi(n+|m|)!}(2k_0r)^{2|m|}\exp(-2k_0r)[L_{n-|m|}^{2|m|}(2k_0r)]^2. \tag{B7}$$

At $r=0$, the above summation simplifies (because only $m=0$ terms contribute) to

$$\rho_\infty(0) = \sum_{n=0}^{\infty}\frac{k_0^3}{\pi}, \tag{B8}$$

where the bound-state energy levels are given by

$$E = -k_0^2 = -\frac{1}{(n+1/2)^2}. \tag{B9}$$

Using the summation in Ref. 16, namely

$$(1-2^{-n})\zeta(n) = \sum_{k=0}^{\infty}(2k+1)^{-n}, \tag{B10}$$

with $n=3$ yields the closed result

$$\rho_\infty(0) = \frac{7}{\pi}\zeta(3), \tag{B11}$$

where ζ denotes the Riemann zeta function. This result can be further generalized to N closed shells as

$$\rho_N(0) = \frac{7}{\pi}\zeta(3) + \frac{\Psi(2,N+3/2)}{2\pi}, \tag{B12}$$

and Fig. 3 shows a plot of this equation as a function of N. The value $\rho_\infty(0)$ is solely due to the spherically symmetric wave functions corresponding to $m=0$ (s states) and hence $\rho_\infty(0)=\rho_{\infty s}(0)$.

Kato's theorem, discussed by one of us in Ref. 29, has then the generalization to D dimensions for nuclear charge Ze given by

$$\left.\frac{\partial\rho(r)}{\partial r}\right|_{r=0} = \left. -\frac{4Z}{(D-1)}\rho_s(r)\right|_{r=0}, \tag{B13}$$

and means that, for $Z=1$ and $D=2$

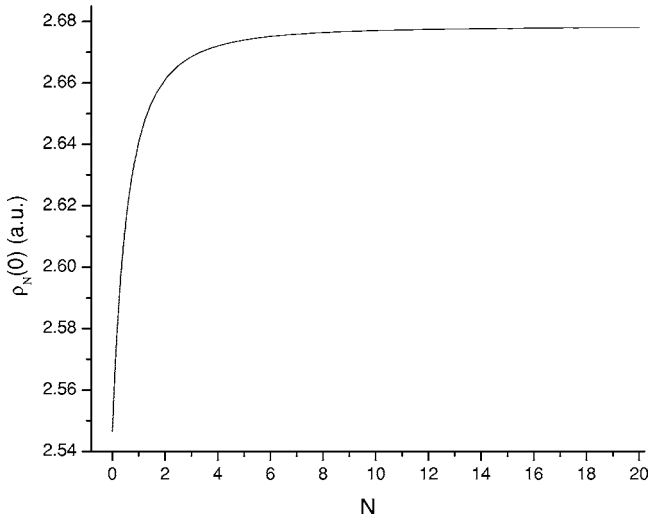

FIG. 3. Plot of electron density $\rho_N(0)$ at the nucleus given by Eq. (B12) for a two-dimensional hydrogen-like atom, versus the number of closed shells N.

$$\left.\frac{\partial\rho(r)}{\partial r}\right|_{r=0} = -\frac{28}{\pi}\zeta(3). \tag{B14}$$

This implies, in particular, that after differentiating $\rho_\infty(r)$ in Eq. (B7) with respect to r, the summation over m can be performed and the result then relates to the s-like ($m=0$) density according to Eq. (B13).

APPENDIX C: DIFFERENTIAL EQUATION SATISFIED BY THE DIAGONAL LOCAL DENSITY OF STATES $N(r,E)$ FOR THE $m=0$ COMPONENT

Denoting the $m=0$ component of the local density of states by $N_0(r,E,Z)$, we have the differential equation, with primes denoting derivatives with respect to r, as

$$\frac{r^2}{2E}N_0''' + \frac{3r}{2E}N_0'' + \left[4r\left(r+\frac{1}{E}\right)+\frac{1}{2E}\right]N_0' + \left[4\left(r+\frac{1}{2E}\right)+\frac{1}{2E}\left(4+\frac{1}{r}\right)\right]N_0 = 0. \tag{C1}$$

Dropping the "potential energy" term $1/r$, one can readily verify that Eq. (C1) is satisfied by the free-electron result

$$N_0(r,E,Z=0) = \text{const.} \times [J_0(\sqrt{2E}r)]^2. \tag{C2}$$

The physical solution (with $V(r)=-Z/r$ now the 2D Coulomb potential) of Eq. (C1) is

$$N_0(r,E,Z) = \text{const.} \times \frac{\mathcal{M}(-iZ/k,0,i2kr)^2}{r}, \tag{C3}$$

where $\mathcal{M}$ denotes the Whittaker function (see also Fig. 1 of the main text).

APPENDIX D: COULOMB LOCAL DENSITY OF STATES AND FREE-ELECTRON LIMIT

In the main text we proved that

$$\frac{\partial\gamma_0}{\partial E} = \frac{1}{2\pi}J_0(\sqrt{2E}|\mathbf{r}-\mathbf{r}'|), \tag{D1}$$

which we now expand in terms of angular functions $\exp(im\phi)$, where $\cos(\phi)=\mathbf{r}\cdot\mathbf{r}'/rr'$, to write

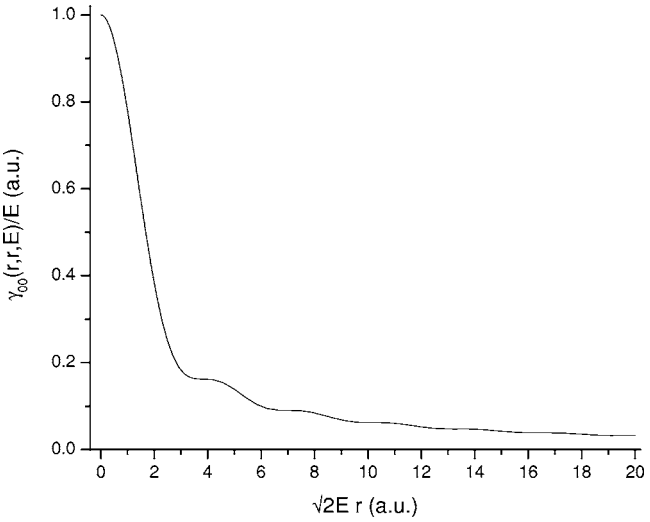

FIG. 4. s-state ($m=0$) electron density $\gamma_{00}(r,r,E)$ for a two-dimensional free electron gas, as given by Eq. (D6). Actual plot is $\gamma_{00}(r,r,E)/E$ versus $\sqrt{2E}r$.

$$\frac{\partial\gamma_0}{\partial E}=\sum_{m=-\infty}^{\infty}\frac{\partial\gamma_{0m}(r,r')}{\partial E}\exp(im\phi). \tag{D2}$$

Then, it follows directly from Eqs. (D1) and (D2) above that

$$\frac{\partial\gamma_{00}(r,r')}{\partial E}=\frac{1}{2\pi}\int_0^{2\pi}J_0(\sqrt{2E}|\mathbf{r}-\mathbf{r}'|)d\phi. \tag{D3}$$

From Ref. 20, Eq. 6.684.1, we have that the integral on the right-hand side of Eq. (D3) is a product of Bessel functions of order zero, and hence we obtain explicitly

$$\frac{\partial\gamma_{00}(r,r')}{\partial E}=J_0(\sqrt{2E}r)J_0(\sqrt{2E}r'). \tag{D4}$$

Performing the energy integration, and using the physical boundary condition that $\partial\gamma_{00}/\partial E\to 0$ as $E\to 0$, we find the $m=0$ component of the Dirac density matrix for the free-electron gas in 2D as

$$\gamma_{00}(r,r',E)=\frac{\sqrt{2E}}{(r'^2-r^2)}[r'J_0(\sqrt{2E}r)J_1(\sqrt{2E}r')-rJ_0(\sqrt{2E}r')J_1(\sqrt{2E}r)]. \tag{D5}$$

Taking the limit of Eq. (D5) as $r'\to r$ yields

$$\gamma_{00}(r,r,E)=E[J_0^2(\sqrt{2E}r)+J_1^2(\sqrt{2E}r)]. \tag{D6}$$

This result (D6) is plotted in Fig. 4 as a function of r for two different values of the energy E.

1. Coulomb analogue

For the continuous spectrum of the hydrogen-like atom with $V(r)=-Z/r$ in two dimensions, the radial wave function corresponding to $m=0$ is

$$R_0(kr) = C_{k0} \exp(-ikr)\,{}_1F_1(iZ/k + 1/2, 1, i2kr), \tag{D7}$$

where ${}_1F_1$ denotes the confluent hypergeometric function, and hence, apart from a multiplying factor which can depend on energy and Z, we can write the analog of Eq. (D4) in the limit $r \to r'$ as

$$\left.\frac{\partial \gamma_{m=0}(r,r',Z)}{\partial E}\right|_{r'=r} = \left|{}_1F_1(iZ/k + 1/2, 1, i2kr)\right|^2 : k = \sqrt{2E}. \tag{D8}$$

Allowing $Z \to 0$ in Eq. (D8), we can make use of the identity (Ref. 20, Eq. 9.215.3)

$${}_1F_1(b + 1/2, 2p + 1, i2z) = \Gamma(p+1)\left(\frac{Z}{2}\right)^{-p} \exp(iz) J_p(z), \tag{D9}$$

for the case $p=0$ to verify that, apart from a factor already referred to, Eq. (D8) correctly leads back to the free-electron result (D4) in the limit $Z \to 0$ and $r'=r$.

The force-force correlation function formula can then be written explicitly as a quadrature involving $(\partial V(r_1)/\partial \mathbf{r}_1)\cdot(\partial V(r_2)/\partial \mathbf{r}_2)$ multiplied by $(\partial \gamma_{m=0}/\partial E)^2 = R_0(kr_1)R_0(kr_2)$, the analog if the higher terms for $m \neq 0$ in Eq. (D2) are assumed small for the Coulomb case. However, the detail proliferates and we shall therefore not give it.

ACKNOWLEDGMENTS

N.H.M. and I.A.H. would like to acknowlege the hospitality of the DIPC during a period of 2003 when some of this work was started. N.H.M. wishes to acknowledge financial support for work on density functional theory from the ONR. Dr. P. Schmidt of that Office is especially thanked for much motivation and continuing support. Spectral and localization properties for the one-dimensional Bernoulli discrete Dirac operator

César R. de Oliveira[a] and Roberto A. Prado[b]
Departamento de Matemática–UFSCar, São Carlos, SP, 13560-970 Brazil

(Received 21 February 2005; accepted 17 May 2005; published online 5 July 2005)

An one-dimensional (1D) Dirac tight-binding model is considered and it is shown that its nonrelativistic limit is the 1D discrete Schrödinger model. For random Bernoulli potentials taking two values (without correlations), for typical realizations and for all values of the mass, it is shown that its spectrum is pure point, whereas the zero mass case presents dynamical delocalization for specific values of the energy. The massive case presents dynamical localization (excluding some particular values of the energy). Finally, for general potentials the dynamical moments for distinct masses are compared, especially the massless and massive Bernoulli cases. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1948328]

I. INTRODUCTION

Besides the huge amount of mathematical works on spectral problems related to the one-dimensional (1D) Dirac model,[4,26] in physics it has also been used in comparative studies of relativistic and nonrelativistic electron-localization phenomena,[2] in relativistic investigations of electrical conduction in disordered systems,[21] in the construction of supertransparent models with supersymmetric structures[25] and in relativistic tunnelling problems.[20]

In this paper a discrete version of the 1D Dirac model is discussed, which can be interpreted as a relativistic version of the well-known tight-binding Schrödinger Hamiltonian (with $\hbar=1$),

$$(H\psi)_n = -\frac{1}{2m}(\Delta\psi)_n + V_n\psi_n = \frac{1}{2m}(-\psi_{n+1} - \psi_{n-1} + 2\psi_n) + V_n\psi_n. \tag{1}$$

The model was first reported in Ref. 11 and this work is its very expanded and mathematical detailed version. Consider a particle of mass $m \geqslant 0$ in the one-dimensional lattice $\mathbb{Z}$ under the real site potential $\tilde{V}=(V_n)$. The proposed 1D Dirac tight-binding operator is

$$\mathbb{D}(m,c) = \mathbb{D}_0(m,c) + \tilde{V}\,\mathrm{Id}_2 = c\mathcal{B} + mc^2\sigma_3 + \tilde{V}\,\mathrm{Id}_2, \tag{2}$$

with $c>0$ representing the speed of light,

$$\mathcal{B} = \begin{pmatrix} 0 & d^* \\ d & 0 \end{pmatrix},$$

σ_3 the usual Pauli matrix, Id_2 the 2×2 identity matrix and d the finite difference operator (a discrete counterpart of the first derivative) defined by

$$(d\psi)_n = \psi_{n+1} - \psi_n.$$

$(d^*\psi)_n = \psi_{n-1} - \psi_n$ is the adjoint of d so that $\mathbb{D}_0(m,c) = c\mathcal{B} + mc^2\sigma_3$ is a bounded self-adjoint operator acting on $\ell^2(\mathbb{Z};\mathbb{C}^2)$ and its square is

[a]Electronic mail: oliveira@dm.ufscar.br
[b]Electronic mail: rap@dm.ufscar.br

$$\mathbb{D}_0(m,c)^2 = \begin{pmatrix} c^2 dd^* + m^2c^4 & 0 \\ 0 & c^2 dd^* + m^2c^4 \end{pmatrix}.$$

This equality is reminiscent of the relation between momentum $\vec{p}$ and energy E in relativistic quantum mechanics,[4] given by $E^2 = c^2\vec{p}^2 + m^2c^4$. Denoting by $\sigma(A)$ the spectrum of a self-adjoint operator A, it is well known that $\sigma(-\Delta) = [0,4]$, and since $d^*d = dd^* = -\Delta$,

$$\sigma(\mathbb{D}_0(m,c)) = [-c\sqrt{4 + m^2c^2}, -mc^2] \cup [mc^2, c\sqrt{4 + m^2c^2}].$$

In case the potential $\tilde{V}$ is a bounded sequence, $\mathbb{D}(m,c)$ is also a bounded self-adjoint operator acting on $\ell^2(\mathbb{Z};\mathbb{C}^2)$.

It will be shown that the nonrelativistic limit of the resolvent of the discrete Dirac operator (2) is the resolvent of discrete Schrödinger operator (1) (when projected on a proper subspace; see Sec. II). This is an important support for such Dirac model.

The study of quantum transport depends, of course, on the admitted definitions. In the physics literature terms like "extended states" and "zero Lyapunov exponents" have been used to crudely designate quantum transport. For instance, in Ref. 27 it was claimed that "extended states" were found in one-dimensional Schrödinger systems with off-diagonal randomness, but in Ref. 24 it was argued that although the localization length diverges the "transmission coefficient" vanishes as the system size goes to infinity. Up to recently, in the mathematical literature pure point spectrum (sometimes with exponentially decaying eigenfunctions) was considered synonymous of absence of transport. Currently the transport has been probed via the time behavior of the moments of the position operator, and in this work this idea will be followed. See ahead for precise definitions and related comments.

One of the goals of this paper is to study the phenomenon called dynamical localization (in the sense of time-boundedness of all moments of the position operator) for the Bernoulli-Dirac model, that is, the model (2) with the site potentials V_n, $n \in \mathbb{Z}$, being independent identically distributed Bernoulli random variables taking the values $\pm V$, $V > 0$. In this case it will be shown that almost surely the spectrum of $\mathbb{D}(m,c)$ is pure point for all values of the mass, the massive case has dynamical localization (excluding some particular values of the energy for which a more careful analysis is needed) and the zero mass case presents dynamical delocalization (that is, absence of localization) for specific values of the energy.

The problem of dynamical localization has been intensively studied during the last years, especially in the case of random discrete and continuous Schrödinger operators (in particular for the Bernoulli-Anderson model, that is, the Schrödinger model with Bernoulli potentials); see Refs. 10, 14, and 16 and references therein. What one usually proves is the so-called exponential localization,[1,6,28] i.e., pure point spectrum and exponentially decaying eigenfunctions. On the other hand, it is also known that exponential localization does not imply dynamical localization;[12] it is usually needed a precise control of the decay of the eigenfunctions, called SULE,[12,16] that can be obtained through the method of multiscale analysis, a technique set out by Fröhlich and Spencer.[14,15]

One motivation for studying dynamical localization for the Bernoulli-Dirac operator comes from the random dimer model,[10,13] i.e., the Bernoulli-Anderson model with the site energies V_n assigned for pairs of lattices, $V_{2n} = V_{2n+1} = \pm V$ for all n. This model almost surely presents pure point spectrum for all values of $V \neq 0$.[10] It was also numerically found in Ref. 13 and rigorously shown in Refs. 10 and 18 the existence of *critical energies* (in the sense of Ref. 18; see ahead) at which the Lyapunov exponent vanishes; dynamical localization was obtained in Ref. 10 only after projecting onto closed energy intervals not containing such critical energies. Despite the similarity between the transfer matrices of the two models, it is not immediate the adaptation of the localization (delocalization) results to the Bernoulli-Dirac model and each step needs to be verified; here, many points will not be detailed when they follow exactly the same lines of their Schrödinger counterpart.

With respect to nontrivial quantum transport, probed via dynamical delocalization (unbounded moments of the position operator), it was found in random polymer models[18] and in random

palindrome models[7] (both including the important random dimer model), due to existence of critical energies.[18] Recently, for 1D discrete Schrödinger operators, Damanik, Sütő, and Tcheremchantsev[9] have developed a general method which allows one to derive quantum dynamical lower bounds from upper bounds on the growth of norms of transfer matrices, and they applied this method to some substitution, Sturmian and prime models, among others. Damanik, Lenz, and Stolz[8] presented an extension of this method to 1D continuous Schrödinger operators, with application to the continuous Bernoulli-Anderson model. Another method to obtain quantum transport from upper bounds on transfer matrix was lately developed by Germinet, Kiselev, and Tcheremchantsev,[17] with application to Schrödinger operators with random decaying potentials, providing examples of Schrödinger operator with point spectrum and nontrivial quantum transport.

In the zero mass case, the one-dimensional Bernoulli-Dirac model presented here has pure point spectrum and nontrivial quantum transport for potentials with no correlations nor decaying properties (see Sec. III). This phenomenon does not take place in the corresponding Schrödinger tight-binding model,[16] and this also motivates the interest to better understanding the Dirac case. Presumably, this tight-binding model is the simplest one presenting such phenomenon.

Now the localization results for the Bernoulli-Dirac model will be briefly summarized. By using as the main tool a particular form of Furstenberg theorem (Lemma 2 ahead), it is shown (see Theorems 2, 3, and 4) that the Lyapunov exponent $\gamma_m(E)$ is strictly positive for the energies $E \in \sigma(\mathbb{D}(m,c))$, except for $E=\pm V$, $V\in(0,c]$, $V\neq c/\sqrt{2}$, in the case $m=0$; and if $m\geqslant 0$ for $(E_V=0, V=c\sqrt{2+m^2c^2})$ and the four energy-potential pairs $(E_V=\pm c\sqrt{2+m^2c^2}\pm c/\sqrt{2}, V=c/\sqrt{2})$.

For all energies E for which $\gamma_m(E)>0$, an initial estimate for localization (Lemma 4) and the Wegner's estimate (Lemma 3) will be checked; by adapting the method multiscale analysis[14,16,28] to this model, it will be shown (see Theorems 2 and 3) that for typical realizations the spectrum of $\mathbb{D}(m,c)$ is pure point and the corresponding eigenfunctions are semiuniformly exponentially localized (SULE).[12,16] This and the results of Ref. 16 [properly adapted to $\mathbb{D}(m,c)$] imply dynamical localization.

In the massless ($m=0$) case, the values $E=\pm V$ with $V\in(0,c]$, $V\neq c/\sqrt{2}$, are critical energies for the operator $\mathbb{D}(0,c)$ and this implies (almost surely) upper boundedness for the transfer matrices in the vicinity of these energies (see Lemmas 5 and 6). By adapting the ideas of Ref. 18 (see also Ref. 9) to $\mathbb{D}(0,c)$ it will follow (see Theorem 5) that for an initial spinor Ψ well localized in space, there is $0<C_q<\infty$ such that

$$\int_0^\infty \frac{1}{T} e^{-2t/T} M_\Psi^{(q)}(0,t)\mathrm{d}t \geqslant C_q T^{q-1/2},$$

for almost all realization of the potential (or exponent $q-1$ instead of $q-1/2$ for every realization), where (X is the usual position operator)

$$M_\Psi^{(q)}(m,t) := \langle e^{-i\mathbb{D}(m,c)t}\Psi, |X|^q e^{-i\mathbb{D}(m,c)t}\Psi\rangle,$$

i.e., there is nontrivial quantum transport despite the absence of a continuous component in the spectrum of $\mathbb{D}(0,c)$.

In the case of the set of pairs $(E_V=\pm c\sqrt{2+m^2c^2}\pm c/\sqrt{2}, V=c/\sqrt{2})$ and $(E_V=0, V=c\sqrt{2+m^2c^2})$ it is shown (see Theorem 4) that the Lyapunov exponent γ_m vanishes, but it was not possible to give an answer about dynamical localization for them. Nevertheless, for these cases there is a general dynamical upper bound (in fact valid for all potentials $\widetilde{V}$) established in Theorem 6.

For distinct masses $m,m'\geqslant 0$, but m close to m', it is expected that the moments $M_\Psi^{(q)}(m,t)$ follow closely the moments $M_\Psi^{(q)}(m',t)$ (both with the same potential), at least for a small period of time. The final result to be reported is an inequality confirming such expectative; by making use of DuHamel's formula, it will be shown (see Theorem 7) that, for the initial state Ψ with only one nonzero component, there exists $K_q>0$ so that, for all $t>0$,

$$|M_\Psi^{(q)}(m,t) - M_\Psi^{(q)}(m',t)| \leqslant K_q|m-m'|c^2t^{q+2}.$$

In particular, for the Bernoulli-Dirac model this relation with $m'=0$ gives quantitatively an estimate of how, for small times, the dynamics of the localized regime follows the delocalized one (see also Corollary 1 in Sec. VI).

This paper is organized as follows: In Sec. II the nonrelativistic limit for the discrete Dirac model (2) is discussed. In Sec. III the results about spectral properties of such model, dynamical localization (delocalization) and a dynamical upper bound for moments are presented, whose proofs appear in Sec. V. In Sec. IV some tools used in those proofs are collected. Finally, in the Sec. VI the dynamical moments with different masses are compared; in particular the dynamics of the massless and massive Dirac-Bernoulli cases.

II. NONRELATIVISTIC LIMIT

In this section consider $\mathbb{D}(m,c)$ with $m>0$ fixed and c as a parameter. For simplicity, $\mathbb{D}(c)$ will denote $\mathbb{D}(m,c)$, which is supposed to be self-adjoint with (real) potential $\tilde{V}$.

The nonrelativistic limit means c going to infinity, and since the rest energy mc^2 is a purely relativistic quantity, (as usual) it must be subtracted before taking this limit. The norm convergence of the resolvent operators $(\mathbb{D}(c)-mc^2-z)^{-1}$, for $z\in\mathbb{C}\backslash\mathbb{R}$ will be considered. Λ below is the projector onto the subspace of "positive energies," and so ΛH_∞ corresponds to the Schrödinger operator (1). It is interesting to compare the approach presented here with the one in Ref. 11.

Theorem 1: *If* $z\in\mathbb{C}\backslash\mathbb{R}$, *then*

$$\lim_{c\to\infty}(\mathbb{D}(c)-mc^2-z)^{-1} = \Lambda(H_\infty - z)^{-1},$$

where $\Lambda=\frac{1}{2}(Id_2+\sigma_3)$ *and* $H_\infty=(\mathcal{B}^2/2m)+\tilde{V}\Lambda$, *and the limit is in the norm of bounded operators.*

Lemma 1: If $z\in\mathbb{C}\backslash\mathbb{R}$, *then*

$$(\mathbb{D}(c)-mc^2-z)^{-1} = \left(\Lambda+\frac{c\mathcal{B}+z}{2mc^2}\right)S(c)\left(\mathrm{Id}+\tilde{V}\frac{c\mathcal{B}+z}{2mc^2}S(c)\right)^{-1}, \tag{3}$$

where Id is the identity operator and

$$S(c) = \left(H_\infty - z - \frac{z^2}{2mc^2}\right)^{-1} = \left(\mathrm{Id}-\frac{z^2}{2mc^2}(H_\infty-z)^{-1}\right)^{-1}(H_\infty-z)^{-1}. \tag{4}$$

Proof: Note that

$$(\mathbb{D}_0(c)+mc^2+z)(\mathbb{D}_0(c)-mc^2-z) = c^2\mathcal{B}^2 - 2mc^2z - z^2.$$

Hence

$$(\mathbb{D}_0(c)-mc^2-z)^{-1} = \frac{\mathbb{D}_0(c)+mc^2+z}{2mc^2}\left(\frac{\mathcal{B}^2}{2m}-z-\frac{z^2}{2mc^2}\right)^{-1} = \left(\Lambda+\frac{c\mathcal{B}+z}{2mc^2}\right)S_0 \tag{5}$$

with $S_0=[(\mathcal{B}^2/2m)-z-(z^2/2mc^2)]^{-1}$. On the other hand, by using the operator relation

$$(A+B)^{-1} = (\mathrm{Id}-A^{-1}B)^{-1}A^{-1}$$

with $A=(\mathcal{B}^2/2m)-z-(z^2/2m)$ and $B=\tilde{V}\Lambda$, one obtains

$$S(c) = S_0(\mathrm{Id}+\tilde{V}\Lambda S_0)^{-1}. \tag{6}$$

Therefore, by (5) and (6) it is found that

$$(\mathbb{D}(c)-mc^2-z)^{-1}=(\mathbb{D}_0(c)-mc^2-z)^{-1}(\mathrm{Id}+\tilde{V}(\mathbb{D}_0(c)-mc^2-z)^{-1})^{-1}$$
$$=\left(\Lambda+\frac{c\mathcal{B}+z}{2mc^2}\right)S_0\left(\mathrm{Id}+\tilde{V}\Lambda S_0+\tilde{V}\frac{c\mathcal{B}+z}{2mc^2}S_0\right)^{-1}$$
$$=\left(\Lambda+\frac{c\mathcal{B}+z}{2mc^2}\right)S(c)\left(\mathrm{Id}+\tilde{V}\frac{c\mathcal{B}+z}{2mc^2}S(c)\right)^{-1}.$$

□

Proof (Theorem 1): Since $(H_\infty-z)^{-1}$ is bounded for $z\in\mathbb{C}\backslash\mathbb{R}$ and

$$\left\|\frac{z^2}{2mc^2}(H_\infty-z)^{-1}\right\|<1$$

for c sufficiently large, one can expand

$$S(c)=\sum_{n=0}^{\infty}\left(\frac{z^2}{2mc^2}(H_\infty-z)^{-1}\right)^n(H_\infty-z)^{-1}, \tag{7}$$

where the sum is convergent in the operator norm.

For any fixed $z\in\mathbb{C}\backslash\mathbb{R}$ and c sufficiently large,

$$\left\|T(c):=\tilde{V}\frac{c\mathcal{B}+z}{2mc^2}S(c)\right\|<1$$

and so

$$(\mathrm{Id}+T(c))^{-1}=\sum_{n=0}^{\infty}(-T(c))^n. \tag{8}$$

Replacing (7) and (8) into (3) one obtains the expansion

$$(\mathbb{D}(c)-mc^2-z)^{-1}=\sum_{n=0}^{\infty}\frac{R_n(z)}{c^n}$$

with

$$R_0(z)=\Lambda(H_\infty-z)^{-1},$$

$$R_1(z)=\Lambda(H_\infty-z)^{-1}\frac{\mathcal{B}}{2m}+\frac{\mathcal{B}}{2m}(H_\infty-z)^{-1}\Lambda,$$

and so on, and the sum is convergent in the operator norm. The result then follows. □

III. LOCALIZATION RESULTS

Consider the family of Dirac operators,

$$\mathbb{D}_\omega(m,c)=\begin{pmatrix}mc^2 & cd^*\\ cd & -mc^2\end{pmatrix}+V_\omega\,\mathrm{Id}_2,\quad \omega\in\Omega=\{-V,V\}^{\mathbb{Z}}, \tag{9}$$

on $\ell^2(\mathbb{Z};\mathbb{C}^2)$, where $V_\omega(n)$, $n\in\mathbb{Z}$, are i.i.d. Bernoulli random variables taking the values $\pm V$, $V>0$, with common (nontrivial) probability measure μ and product measure $\boldsymbol{P}=\Pi_{n\in\mathbb{Z}}\mu(V_\omega(n))$. Let $P^\omega_{I,m}$ be the spectral projector of $\mathbb{D}_\omega(m,c)$ onto the interval $I\subset\mathbb{R}$.

Denote by $\delta_n^{\pm}$ the elements of the canonical position basis of $\ell^2(\mathbb{Z};\mathbb{C}^2)$, for which all entries are $\binom{0}{0}$ except at the nth entry, which is given by $\binom{1}{0}$ and $\binom{0}{1}$ for the superscript indices $+$ and $-$, respectively. If $\Psi=\binom{\psi^+}{\psi^-}$ is a solution of the eigenvalue equation

$$(\mathbb{D}_\omega(m,c)-E)\Psi=0,$$

then it is simple to check that

$$\begin{pmatrix}\psi^+(n+1)\\ \psi^-(n)\end{pmatrix}=T_m^{V_\omega(n)}(E)\begin{pmatrix}\psi^+(n)\\ \psi^-(n-1)\end{pmatrix},$$

with

$$T_m^V(E)=\begin{pmatrix}1+\dfrac{m^2c^4-(E-V)^2}{c^2} & \dfrac{mc^2+E-V}{c}\\ \dfrac{mc^2-E+V}{c} & 1\end{pmatrix}.$$

The transfer matrix from site k to site n is introduced by

$$T_m^{\omega}(E;n,k)=T_m^{V_\omega(n-1)}(E)T_m^{V_\omega(n-2)}(E)\cdots T_m^{V_\omega(k)}(E),\quad n>k$$

and $T_m^{\omega}(E;n,n)=\mathrm{Id}_2$. For $q>0$, let $|X|^q$ be the moment of order q of the position operator on $\ell^2(\mathbb{Z};\mathbb{C}^2)$, i.e.,

$$|X|^q\Psi=\sum_n |n|^q(\langle\delta_n^+,\Psi\rangle\delta_n^+ + \langle\delta_n^-,\Psi\rangle\delta_n^-).$$

Definition 1: The operator $\mathbb{D}_\omega(m,c)$ is dynamically localized on a spectral interval I if for all $q>0$ and for all exponentially decaying initial state $\Psi\in\ell^2(\mathbb{Z};\mathbb{C}^2)$,

$$\sup_t M_{\Psi,I,\omega}^{(q)}(m,t):=\sup_t\langle P_{I,m}^{\omega}e^{-i\mathbb{D}_\omega(m,c)t}\Psi,|X|^qP_{I,m}^{\omega}e^{-i\mathbb{D}_\omega(m,c)t}\Psi\rangle<\infty,$$

***P** almost surely (**P**-a.s.). Otherwise $\mathbb{D}_\omega(m,c)$ is dynamically delocalized on I. If $I=\sigma(\mathbb{D}_\omega(m,c))$, then $M_{\Psi,I,\omega}^{(q)}(m,t)$ will be denoted by $M_{\Psi,\omega}^{(q)}(m,t)$.*

It is important to notice that although the Dirac operator acts on spinors, its eigenvalue equation, in the transfer matrix form, looks exactly like the equation for a one-dimensional Schrödinger operator acting on scalar valued functions, with the transfer matrix being in $\mathrm{SL}(2,\mathbb{R})$. Hence the methods used in studies of the usual one-dimensional Anderson model, as Furstenberg's theorem, can be applied for this Dirac model; see Secs. IV and V.

The localization results are gathered in the following set of theorems.

Theorem 2: *Let $(\mathbb{D}_\omega(m,c))_{\omega\in\Omega}$ be as in (9) and $V\in(0,c],V\neq c/\sqrt{2}$. Then, **P** almost surely, the Lyapunov exponent,*

$$\gamma_m(E)=\lim_{n\to\infty}\frac{1}{|n|}\ln\|T_m^{\omega}(E;n,1)\|$$

exists, is independent of ω, and

(i) (i.1) $\gamma_m(E\neq\pm V)>0$ for $m\geqslant 0$,
(i.2) $\gamma_m(E=\pm V)>0$ for $m>0$,
(i.3) $\gamma_0(E=\pm V)=0$.

(ii) *Let $m\geqslant 0$; then **P**-a.s. $\sigma(\mathbb{D}_\omega(m,c))$ is pure point.*

(iii) (iii.1) *Let $m>0$. Then **P**-a.s. the operator $\mathbb{D}_\omega(m,c)$ is dynamically localized on its spectrum.*

(iii.2) *For any closed interval* $I \subset \sigma(\mathbb{D}_\omega(0,c))$, *with* $\pm V \notin I$, *the operator* $\mathbb{D}_\omega(0,c)$ *is dynamically localized on* I.

Theorem 3: *Let* $(\mathbb{D}_\omega(m,c))_{\omega\in\Omega}$ *be as in (9),* $m \geqslant 0$ *and* $V > c, V \neq c\sqrt{2+m^2c^2}$. *Then,* ***P****a.s. the spectrum of* $\mathbb{D}_\omega(m,c)$ *is pure point and this operator is dynamically localized on its spectrum.*

Theorem 4: *Let* $(\mathbb{D}_\omega(m,c))_{\omega\in\Omega}$ *be as in (9),* $m \geqslant 0$ *and* $V = c/\sqrt{2}$ (*respectively*, $V = c\sqrt{2+m^2c^2}$). *Then the same conclusions of Theorem 2 (respectively, Theorem 3) hold except at the four possibilities of energies* $E_V = \pm c\sqrt{2+m^2c^2} \pm c/\sqrt{2}$ (*respectively*, $E_V = 0$). [*The point is that* $E_V = \pm c\sqrt{2+m^2c^2} \pm c/\sqrt{2}$ (*respectively*, $E_V = 0$) *are energies so that* $\gamma_m(E_V) = 0$.]

For the next result it is convenient to use the average dynamical moments

$$A^{(q)}_{\Psi,\omega}(m,T) := \int_0^\infty \frac{1}{T} e^{-2t/T} M^{(q)}_{\Psi,\omega}(m,t)\mathrm{d}t, \tag{10}$$

defined for $m \geqslant 0$ and $T > 0$. The main reason for working with this kind of Laplace transform average is relation (14) ahead.

Theorem 5 (massless case): *Let* $(\mathbb{D}_\omega(0,c))_{\omega\in\Omega}$ *be as in (9) and* $V \in (0,c]$, $V \neq c/\sqrt{2}$. *Then, for* $q > 0$ *and* Ψ *with only one nonzero component, there exists* $0 < C_q(\omega) < \infty$ *such that, for* $T > 0$,

(i) $A^{(q)}_{\Psi,\omega}(0,T) \geqslant C_q(\omega) T^{q-1/2}$ ***P****-a.s.*,
(ii) $A^{(q)}_{\Psi,\omega}(0,T) \geqslant C_q(\omega) T^{q-1}$ *for every* ω,

i.e., $\mathbb{D}_\omega(0,c)$ *is not dynamically localized on its spectrum.*

The following theorem establishes very general upper bounds for the dynamical moments of the position operator; notice that it holds for any potential sequence $\widetilde{V}$ and is not restricted to the Bernoulli case.

Theorem 6: *Let* $\mathbb{D}(m,c)$ *be as in (2),* $m \geqslant 0$ *and* Ψ *with only one nonzero component (so in the domain of* $|X|^q$ *for all* $q > 0$). *Then for any* $q \in \mathbb{N}$ *there exists* $0 < K_q(\widetilde{V},m,c) < \infty$ *such that*

$$M^{(q)}_\Psi(m,t) \leqslant K_q(\widetilde{V},m,c) t^q, \quad t \geqslant 1.$$

Remark: It is possible to adjust the constant K_q so that the above upper bound holds for $t \geqslant \varepsilon$ for any given $\varepsilon > 0$, instead of just $t \geqslant 1$. Since $M^{(q)}_\Psi(m,t) \geqslant M^{(q')}_\Psi(m,t)$ for $q \geqslant q'$, it is evident that $M^{(q)}_\Psi(m,t) \leqslant K_{\lceil q \rceil}(\widetilde{V},m,c) t^{\lceil q \rceil}$ for real q.

IV. TOOLS

In this section some tools and notations that will be used in the proofs of the results presented in Sec. III are collected. For studying the positivity of the Lyapunov exponent γ_m, $m \geqslant 0$, the following particular form of Furstenberg theorem[5] will be used.

Lemma 2: Let $\mathcal{G}_m(E)$ *be the smallest closed subgroup of* $SL(2,\mathbb{R})$ *generated by the matrices* $T^V_m(E)$ *and* $T^{-V}_m(E)$. *Then* $\gamma_m(E) > 0$ *if*

(i) $\mathcal{G}_m(E)$ *is not compact, and*
(ii) *there is no probability measure on* $P(\mathbb{R}^2)$ *(the set of all the directions of* $\mathbb{R}^2$*) that is invariant under the action of* $\mathcal{G}_m(E)$, *which is equivalent to the statement, the orbit* $\mathcal{G}_m(E)\cdot\tilde{x} := \{T\cdot\tilde{x}, T \in \mathcal{G}_m(E)\}$ *of each direction* $\tilde{x} \in P(\mathbb{R}^2)$ *contains at least three elements.*

If $L > 0$, $n \in \mathbb{Z}$, consider the finite subset of $\mathbb{Z}$,

$$\Lambda_L(n) = \left\{ k \in \mathbb{Z} : |k-n| \leqslant \frac{L}{2} \right\}$$

with boundary

$$\partial\Lambda_L(n)=\{(k,k'):k\in\Lambda_L(n),k'\notin\Lambda_L(n),|k-k'|=1\}.$$

Denote by $\mathbb{D}_\omega^{\Lambda_L(n)}(m,c)$ the operator $\mathbb{D}_\omega(m,c)$ restricted to $\ell^2(\Lambda_L(n);\mathbb{C}^2)$ with zero boundary conditions outside $\Lambda_L(n)$.

The matrix elements of an operator $\mathcal{O}$ on $\ell^2(\mathbb{Z};\mathbb{C}^2)$ are given by

$$\mathcal{O}_{nk}=\begin{pmatrix}\langle\delta_n^+,\mathcal{O}\delta_k^+\rangle & \langle\delta_n^+,\mathcal{O}\delta_k^-\rangle\\ \langle\delta_n^-,\mathcal{O}\delta_k^+\rangle & \langle\delta_n^-,\mathcal{O}\delta_k^-\rangle\end{pmatrix}$$

with "norm"

$$\|\mathcal{O}_{nk}\|^2=|\langle\delta_n^+,\mathcal{O}\delta_k^+\rangle|^2+|\langle\delta_n^+,\mathcal{O}\delta_k^-\rangle|^2+|\langle\delta_n^-,\mathcal{O}\delta_k^+\rangle|^2+|\langle\delta_n^-,\mathcal{O}\delta_k^-\rangle|^2.$$

Now two important results required for the multiscale analysis are described. The first one is the Wegner's estimate, adapted from Ref. 6 to the discrete Dirac operator (details will be omitted, since they are long and very similar to the Schrödinger case).

Lemma 3: Let $\mathbb{D}_\omega(m,c)$ *be as in (9) and I a compact energy interval. For any* $\theta\in(0,1)$ *and* $\tau>0$ *there exist* $L_0=L_0(I,\theta,\tau,m)>0$ *and* $a=a(I,\theta,\tau,m)>0$ *such that*

$$\boldsymbol{P}\{\omega:\mathrm{dist}(E,\sigma(\mathbb{D}_\omega^{\Lambda_L(0)}(m,c)))\leqslant e^{-\tau L^\theta}\}\leqslant e^{-aL^\theta}$$

for all $E\in I$ *and* $L\geqslant L_0$.

The second result is the initial estimate for localization, adapted from Ref. 28 (details omitted).

Lemma 4: Let $\mathbb{D}_\omega(m,c)$ *be as in (9),* $\epsilon>0$ *and* $\theta\in(0,1)$. *For each* $E_0\in\mathbb{R}$, $E_0\notin\sigma(\mathbb{D}_\omega^{\Lambda_L(0)}(m,c))$ *with* $\gamma_m(E_0)>\epsilon$, *there exist* $L_0=L_0(E_0,\epsilon,\theta,m)>0$ *and* $r=r(E_0,\epsilon,\theta,m)>0$ *such that*

$$\boldsymbol{P}\{\omega:\|(\mathbb{D}_\omega^{\Lambda_L(0)}(m,c)-E_0)_{0k}^{-1}\|\leqslant e^{-(\gamma_m(E_0)-\epsilon)L/2}\ \forall\ k\in\partial\Lambda_L(0)\}\geqslant 1-e^{-rL^\theta}$$

for all $L\geqslant L_0$.

In order to obtain dynamical localization from the multiscale analysis, the following properties of $\mathbb{D}_\omega(m,c)$ are useful.

(P1) With respect to the spectral measure of $\mathbb{D}_\omega(m,c)$, almost every energy is a generalized eigenvalue, i.e., with polynomially bounded eigenvector (see Ref. 3 and 22).

(P2) If $E\notin\sigma(\mathbb{D}_\omega^{\Lambda_L(n)}(m,c))$ and $\Psi\in\ell^2(\mathbb{Z};\mathbb{C}^2)$ so that $\mathbb{D}_\omega(m,c)\Psi=E\Psi$, then

$$\Psi(n)=-(\mathbb{D}_\omega^{\Lambda_L(n)}(m,c)-E)_{nl_1}^{-1}\begin{pmatrix}0 & c\\ 0 & 0\end{pmatrix}\Psi(l_1-1)-(\mathbb{D}_\omega^{\Lambda_L(n)}(m,c)-E)_{nl_2}^{-1}\begin{pmatrix}0 & 0\\ c & 0\end{pmatrix}\Psi(l_2+1),$$

with $\{(l_1,l_1-1),(l_2,l_2+1)\}=\partial\Lambda_L(n)$.

Property (P2) follows after defining the *boundary operator* $\mathcal{F}_{\Lambda_L(n)}$ by its matrix elements

$$(\mathcal{F}_{\Lambda_L(n)})_{jk}=\begin{cases}-\begin{pmatrix}0 & c\\ 0 & 0\end{pmatrix} & \text{if } j-1=k,\quad j\in\Lambda_L(n),\quad k\notin\Lambda_L(n),\\ -\begin{pmatrix}0 & 0\\ c & 0\end{pmatrix} & \text{if } j+1=k,\quad j\in\Lambda_L(n),\quad k\notin\Lambda_L(n),\\ \begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix} & \text{otherwise},\end{cases}$$

noting that $l^2(\mathbb{Z};\mathbb{C}^2)=l^2(\Lambda_L(n);\mathbb{C}^2)\oplus l^2(\mathbb{Z}\setminus\Lambda_L(n);\mathbb{C}^2)$ and

$$\mathbb{D}_\omega(m,c)=\mathbb{D}_\omega^{\Lambda_L(n)}(m,c)+\mathbb{D}_\omega^{\mathbb{Z}\setminus\Lambda_L(n)}(m,c)-\mathcal{F}_{\Lambda_L(n)}.$$

In the zero mass case ($m=0$) the operators $\mathbb{D}_\omega(0,c)$, $\omega\in\Omega$, presents critical energies $E_V=\pm V$ for $V\in(0,c]$, $V\neq c/\sqrt{2}$, as defined in Ref. 18, since either $T_0^V(V)=\mathrm{Id}_2$ and $T_0^{-V}(V)$ is elliptic [that is, $|\mathrm{trace}\ T_0^{-V}(V)|<2$] or $T_0^{-V}(-V)=\mathrm{Id}_2$ and $T_0^V(-V)$ is elliptic. Thus there exists a real invertible matrix Q such that

$$QT_0^{\pm V}(E_V)Q^{-1}=\begin{pmatrix}\cos(\eta_\pm) & -\sin(\eta_\pm)\\ \sin(\eta_\pm) & \cos(\eta_\pm)\end{pmatrix}.$$

Since the eigenvalues of this matrix are $e^{i\eta_\pm}$ and $e^{-i\eta_\pm}$, for both of the above cases one has $\eta_+-\eta_-\neq k\pi$, $k\in\mathbb{Z}$ (a condition required in Ref. 18). By using the modified Prüfer variables, phase shifts, oscillatory sums, large deviation estimates as in Ref. 18, one obtains the following result.

Lemma 5 (massless case): Let $\lambda>0$ be arbitrary. Then there are $b>0$ and $C<\infty$ such that for every $N\in\mathbb{N}$, there exists a set $\Omega_N(\lambda)\subset\Omega$ with $\mathbf{P}(\Omega_N(\lambda))\leqslant Ce^{-bN^\lambda}$ and

$$\|T_0^\omega(E;n,k)\|\leqslant C$$

for all $\omega\in\Omega\backslash\Omega_N(\lambda)$, $0\leqslant k\leqslant n\leqslant N$, and $E\in[E_V-N^{-\lambda-1/2},E_V+N^{-\lambda-1/2}]$.

On the other hand, since $\|QT_0^{\pm V}(E_V)Q^{-1}\|=1$, expanding $T_0^{\pm V}(E_V+\epsilon)$ into powers of ϵ one obtains

$$\|QT_0^{\pm V}(E_V+\epsilon)Q^{-1}\|\leqslant 1+a|\epsilon|$$

for $|\epsilon|\leqslant\delta$, $0<a<\infty$, and one deduces the following.

Lemma 6 (massless case): For $\delta>0$ there exists $C<\infty$ such that for all $n,k\in\mathbb{Z}$ and $E\in[E_V-\delta,E_V+\delta]$,

$$\|T_0^\omega(E;n,k)\|\leqslant Ce^{C\delta|n-k|}.$$

An inductive argument shows that, for $\zeta\in\mathbb{C}$ and $m\geqslant 0$,

$$T_m^\omega(E+\zeta;n,k)=T_m^\omega(E;n,k)-\zeta\sum_{l=k}^{n-1}T_m^\omega(E+\zeta;n,l+1)S_\zeta^\omega(E;l)T_m^\omega(E;l,k),\tag{11}$$

where

$$S_\zeta^\omega(E;l)=\frac{\zeta}{c^2}\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}+\frac{1}{c}\begin{pmatrix}\frac{2}{c}(E-V_\omega(l)) & -1\\ 1 & 0\end{pmatrix}.$$

Now, for $z\in\mathbb{C}\backslash\mathbb{R}$ and $m\geqslant 0$, introduce the two-components Green's function

$$\begin{pmatrix}G_{m,\omega}^+(z;n)\\ G_{m,\omega}^-(z;n)\end{pmatrix}=\begin{pmatrix}\langle\delta_n^+,(\mathbb{D}_\omega(m,c)-z)^{-1}\delta_0^+\rangle\\ \langle\delta_n^-,(\mathbb{D}_\omega(m,c)-z)^{-1}\delta_0^+\rangle\end{pmatrix},$$

so that

$$(\mathbb{D}_\omega(m,c)-z)\begin{pmatrix}G_{m,\omega}^+(z;n)\\ G_{m,\omega}^-(z;n)\end{pmatrix}=\delta_0^+(n).$$

By using transfer matrices, one obtains for $n\leqslant 0$,

$$\begin{pmatrix}G_{m,\omega}^+(z;n)\\ G_{m,\omega}^-(z;n-1)\end{pmatrix}=T_m^\omega(z;n,0)\begin{pmatrix}G_{m,\omega}^+(z;0)\\ G_{m,\omega}^-(z;-1)\end{pmatrix}\tag{12}$$

and for $n\geqslant 1$,

$$\begin{pmatrix} G^{+}_{m,\omega}(z;n) \\ G^{-}_{m,\omega}(z;n-1) \end{pmatrix} = T^{\omega}_{m}(z;n,1)\begin{pmatrix} G^{+}_{m,\omega}(z;1) \\ G^{-}_{m,\omega}(z;0) \end{pmatrix}. \tag{13}$$

For $z=E+i/T(T>0)$ and $m\geqslant 0$, it is also valid the following identity (adapted from Lemma 3.2 in Ref. 19):

$$A^{(q)}_{\delta^{+}_{0},\omega}(m,T) = \frac{1}{2\pi T}\sum_{n\in\mathbb{Z}}|n|^{q}\int_{\mathbb{R}}(|G^{+}_{m,\omega}(z;n)|^{2}+|G^{-}_{m,\omega}(z;n)|^{2})\mathrm{d}E. \tag{14}$$

V. LOCALIZATION PROOFS

In this section the proofs of Theorems 2–6 are presented.

Proof (Theorems 2 and 3): The strategy of the proof is based on Ref. 10, where the random dimer Schrödinger operator was studied. Since for the discrete Dirac operator there are the particular role played by the mass and some different possibilities for the transfer matrices, a rather detailed proof will be presented. The idea is to show that given $\epsilon>0$, $I\subset\sigma(\mathbb{D}_{\omega}(m,c))$ a compact energy interval not containing the excluded V values, then for each $0<\gamma<\gamma_{m}(I):=\inf\{\gamma_{m}(E):E\in I\}$ there exist a constant $C(\omega,\epsilon,\gamma)$ and, for each eigenfunction $\varphi_{j,\omega}=\binom{\varphi^{+}_{j,\omega}}{\varphi^{-}_{j,\omega}}$ with energy $E_{j,\omega}\in I$, a "center" $z_{j,\omega}\in\mathbb{Z}$, such that

$$\|\varphi_{j,\omega}(n)\|\leqslant C(\omega,\epsilon,\gamma)e^{\gamma|z_{j,\omega}|^{\epsilon}}e^{-\gamma|n-z_{j,\omega}|},\quad \forall\, n\in\mathbb{Z}. \tag{15}$$

If Ψ decays exponentially with rate $\theta_{0}>0$ and if $q>0$, it is known that (15) (that is, SULE condition) implies the existence of a constant $C_{\Psi}(m,I,\omega)$ so that

$$\sup_{t} M^{(q)}_{\Psi,I,\omega}(m,t)\leqslant C_{\Psi}(m,I,\omega),\quad \boldsymbol{P}\text{-}a.s.,$$

i.e., $\mathbb{D}_{\omega}(m,c)$ is dynamically localized on I (see Sec. II in Ref. 16).

To prove (ii) and (15), it is sufficient to show strict positivity of the Lyapunov exponent, because in this case Lemmas 3 and 4 hold. By using the multiscale analysis[28] together with (P1) and (P2), one can then follow the proof of Theorem 3.1 in Ref. 16 [properly adapted to $\mathbb{D}_{\omega}(m,c)$] to obtain (ii) and (15) (details will be omitted).

Now the proof of (i). It follows from Furstenberg and Kesten theorem[5] that, $\boldsymbol{P}$-*a.s.* the Lyapunov exponent γ_{m} exists and is independent of ω.

Consider first the energies $E\neq\pm V$ and it will be proven that $\gamma_{m}(E\neq\pm V)>0$ for all $m\geqslant 0$ and for all $E\in\sigma(\mathbb{D}_{\omega}(m,c))$. Let $\mathcal{G}_{m}(E)$ be as in the Lemma 2. Set $\alpha=E-V$, $\beta=E+V$ and rename $T^{V}_{m}(E)=T^{(\alpha)}_{m}$, $T^{-V}_{m}(E)=T^{(\beta)}_{m}$. In the present case $\alpha\neq 0$ and $\beta\neq 0$.

Since the problem is symmetric in α and β, the proof is reduced to the study of three cases,

(a) $T^{(\alpha)}_{m}$ and $T^{(\beta)}_{m}$ are elliptic ($|\mathrm{trace}\ T^{(\alpha)}_{m}|<2, |\mathrm{trace}\ T^{(\beta)}_{m}|<2$),
(b) $T^{(\alpha)}_{m}$ is parabolic ($|\mathrm{trace}\ T^{(\alpha)}_{m}|=2$),
(c) $T^{(\alpha)}_{m}$ is hyperbolic ($|\mathrm{trace}\ T^{(\alpha)}_{m}|>2$).

Note that in cases (b) and (c) the group $\mathcal{G}_{m}(E)$ is not compact.

Case (a): Since $T^{(\alpha)}_{m}$ and $T^{(\beta)}_{m}$ are both elliptic, then $|\alpha|,|\beta|\in(mc^{2},c\sqrt{4+m^{2}c^{2}})$. In this case such matrices do not commute. Since the operator

$$T^{(\alpha)}_{m}T^{(\beta)}_{m}(T^{(\alpha)}_{m})^{-1}(T^{(\beta)}_{m})^{-1}$$

built from two noncommuting elliptic elements is hyperbolic, it follows that $\mathcal{G}_{m}(E)$ is not compact. Moreover, note that

$$\operatorname{trace}(T_m^{(\alpha)})^2 = \frac{\alpha^4}{c^4} - \left(2m^2 + \frac{4}{c^2}\right)\alpha^2 + m^2c^2(4 + m^2c^2) + 2$$

(analogous for $T_m^{(\beta)}$). Hence, if $\alpha^2 \neq 2c^2 + m^2c^4$ or $\beta^2 \neq 2c^2 + m^2c^4$, then $T_m^{(\alpha)}$ and $(T_m^{(\alpha)})^2$ or $T_m^{(\beta)}$ and $(T_m^{(\beta)})^2$ are elliptic. Since elliptic elements have no fixed points in $P(\mathbb{R}^2)$, it follows that for any $\tilde{x} \in P(\mathbb{R}^2)$, $\mathcal{G}_m(E)\cdot\tilde{x}$ contains at least the three elements $\tilde{x}$, $T_m^{(\alpha)}\cdot\tilde{x}$, $(T_m^{(\alpha)})^2\cdot\tilde{x}$ or $\tilde{x}$, $T_m^{(\beta)}\cdot\tilde{x}$, $(T_m^{(\beta)})^2\cdot\tilde{x}$. Therefore, by Lemma 2, $\gamma_m(E) > 0$. If, on the other hand, $\alpha^2 = 2c^2 + m^2c^4$ and $\beta^2 = 2c^2 + m^2c^4$, then $E = 0$ and $V = c\sqrt{2 + m^2c^2}$, which is one of the excluded pairs described in Theorem 4.

Case (b): Suppose $T_m^{(\alpha)}$ is parabolic, that is, $|\alpha| = mc^2$ or $|\alpha| = c\sqrt{4 + m^2c^2}$. First the possibility $\alpha = mc^2$ will be discussed (the case $\alpha = -mc^2$ is similar). In this case

$$T_m^{(\alpha)} = \begin{pmatrix} 1 & 2mc \\ 0 & 1 \end{pmatrix}, \quad \text{and so } (T_m^{(\alpha)})^n = \begin{pmatrix} 1 & 2nmc \\ 0 & 1 \end{pmatrix}.$$

Denote by $\{e_1, e_2\}$ the canonical basis of $\mathbb{R}^2$. By taking a vector $x = x_1e_1 + x_2e_2$, and setting $\tilde{x}$ for its direction, one concludes that $\lim_{n\to\infty}(T_m^{(\alpha)})^n\cdot\tilde{x} = \tilde{e}_1$. If ν is a probability measure that is invariant under the action of $\mathcal{G}_m(E)$, and if $f \in C_0^\infty(P(\mathbb{R}^2))$, by Lebesgue's dominated convergence theorem one has

$$f(\tilde{e}_1) = \lim_{n\to\infty} \int f((T_m^{(\alpha)})^n \cdot \tilde{x}) \mathrm{d}\nu(\tilde{x}).$$

This means that $\nu = \delta_{\tilde{e}_1}$. But the matrix $T_m^{(\beta)}$ does not leave invariant the direction $\tilde{e}_1$ since

$$T_m^{(\beta)}e_1 = \left(1 + \frac{m^2c^4 - \beta^2}{c^2}\right)e_1 + \frac{-\beta + mc^2}{c}e_2 \quad \text{and } \beta \neq mc^2.$$

Thus it is proven that there is no invariant measure under the action of $\mathcal{G}_m(E)$. Therefore, by Lemma 2 one gets $\gamma_m(E) > 0$.

Consider now the possibility $\alpha = c\sqrt{4 + m^2c^2}$ (the case $\alpha = -c\sqrt{4 + m^2c^2}$ is similar). In this case an eigenvector of

$$T_m^{(\alpha)} = \begin{pmatrix} -3 & mc + \sqrt{4 + m^2c^2} \\ mc - \sqrt{4 + m^2c^2} & 1 \end{pmatrix}$$

is given by $v_1 = (mc + \sqrt{4 + m^2c^2}/2, 1)$. Picking $v_2 = (-mc + \sqrt{4 + m^2c^2}/2, -1)$ a vector orthogonal to v_1, the matrix $T_m^{(\alpha)}$ in the basis $\{v_1, v_2\}$ is

$$\begin{pmatrix} -1 & -4 - m^2c^2 + mc\sqrt{4 + m^2c^2} \\ 0 & -1 \end{pmatrix}.$$

Repeating the previous calculation for this case, one obtains $\nu = \delta_{\tilde{v}_1}$. But $T_m^{(\beta)}$ does not leave invariant the direction $\tilde{v}_1$ except for $\beta = 0$ or $\beta = c\sqrt{4 + m^2c^2} = \alpha$, which are excluded since the first condition yields $E = -V$ and the second one $V = 0$. Thus it is proven that there is no invariant measure and, by Lemma 2, $\gamma_m(E) > 0$.

Case (c): Suppose now that $T_m^{(\alpha)}$ is hyperbolic (so $|\alpha| < mc^2$ or $|\alpha| > c\sqrt{4 + m^2c^2}$). It is sufficient to study the orbit of the eigendirections of $T_m^{(\alpha)}$, namely

$$e_m^\epsilon = \begin{pmatrix} \alpha^2 - m^2c^4 + \epsilon\sqrt{(\alpha^2 - m^2c^4)(\alpha^2 - m^2c^4 - 4c^2)} \\ 2c(\alpha - mc^2) \end{pmatrix}, \quad \epsilon = \pm 1.$$

If $T_m^{(\beta)}$ is hyperbolic then the orbit of e_m^ϵ is infinite. Hence $\gamma_m(E) > 0$ by Lemma 2. If $T_m^{(\beta)}$ is parabolic, it is again case (b). Finally, suppose that $T_m^{(\beta)}$ is elliptic. If $T_m^{(\beta)}\tilde{e}_m^{\ \epsilon} \neq \tilde{e}_m^{\ -\epsilon}$, then $T_m^{(\beta)}\tilde{e}_m^{\epsilon}$ cannot belong to the eigendirections of $T_m^{(\alpha)}$ and its orbit is infinite. Hence $\gamma_m(E) > 0$ by Lemma 2. If $T_m^{(\beta)}\tilde{e}_m^{\ \epsilon} = \tilde{e}_m^{\ -\epsilon}$, then simple calculations lead to the equations

$$\left(1+m^2c^2-\frac{\beta^2}{c^2}\right)(\alpha^2-m^2c^4+\epsilon u)=4(m^2c^4-\beta\alpha)+(\alpha^2-m^2c^4-\epsilon u)$$

with $\epsilon=\pm 1$ and $u=\sqrt{(\alpha^2-m^2c^4)(\alpha^2-m^2c^4-4c^2)}\neq 0$. It implies $\beta^2=2c^2+m^2c^4$ and $\alpha=\beta\pm c\sqrt{2}$, which means $V=c/\sqrt{2}$ and $E=\pm c\sqrt{2+m^2c^2}-c/\sqrt{2}$. The symmetric case where one assumes that $T_m^{(\beta)}$ is hyperbolic leads naturally to $\alpha^2=2c^2+m^2c^4$ and $\beta=\alpha\pm c\sqrt{2}$, which means $V=c/\sqrt{2}$ and $E=\pm c\sqrt{2+m^2c^2}+c/\sqrt{2}$. Those are excluded pairs that will be discussed in the proof of Theorem 4.

Consider now the energy $E=V$ (the case $E=-V$ is analogous). Note that $\alpha=0$ and $\beta=2V$. First the case $m>0$ will be discussed. The two possible transfer matrices are

$$T_m^{(\alpha)}=\begin{pmatrix}1+m^2c^2 & mc\\ mc & 1\end{pmatrix} \quad \text{and} \quad T_m^{(\beta)}=\begin{pmatrix}1+\dfrac{m^2c^4-4V^2}{c^2} & \dfrac{mc^2+2V}{c}\\ \dfrac{mc^2-2V}{c} & 1\end{pmatrix}.$$

Observe that $T_m^{(\alpha)}$ and $T_m^{(\beta)}$ do not commute, and that $T_m^{(\alpha)}$ is hyperbolic. It is enough to study this case for $\beta=c\sqrt{4+m^2c^2}$ ($T_m^{(\beta)}$ is parabolic). The eigendirections of $T_m^{(\alpha)}$ are

$$e_m^{\delta}=\begin{pmatrix}\dfrac{mc+\delta\sqrt{4+m^2c^2}}{2}\\ 1\end{pmatrix}, \quad \delta=\pm 1.$$

The matrices $T_m^{(\alpha)}$ and $T_m^{(\beta)}$ in the basis $\{e_m^1,e_m^{-1}\}$ are given, respectively, by

$$\begin{pmatrix}\lambda_1 & 0\\ 0 & \lambda_{-1}\end{pmatrix} \quad \text{and} \quad \begin{pmatrix}-1 & 4+m^2c^2-mc\sqrt{4+m^2c^2}\\ 0 & -1\end{pmatrix},$$

with

$$\lambda_1\lambda_{-1}=\left(1+\frac{m^2c^2}{2}+\frac{mc\sqrt{4+m^2c^2}}{2}\right)\left(1+\frac{m^2c^2}{2}-\frac{mc\sqrt{4+m^2c^2}}{2}\right)=1.$$

Suppose that $T_m^{(\alpha)}$ occurs with probability $0<p<1$ and $T_m^{(\beta)}$ occurs with probability $1-p$. Denote by n_α (respectively, n_β) the number of times that $T_m^{(\alpha)}$ (respectively, $T_m^{(\beta)}$) occurs in the product $T_m^{\omega}(E;n,1)$. Supposing, without loss of generality, that $T_m^{V_\omega(1)}(E)=T_m^{(\alpha)}$, one has

$$T_m^{\omega}(E;n,1)=\begin{pmatrix}\lambda_1^{n_\alpha} & C_nP(\lambda_1,\lambda_{-1})\\ 0 & \lambda_{-1}^{n_\alpha}\end{pmatrix},$$

***P**-a.s.*, where C_n is a constant and $P(\lambda_1,\lambda_{-1})$ is a polynomial in λ_1 and λ_{-1}. Thus,

$$\|T_m^{\omega}(E;n,1)\|\geqslant\left\|\begin{pmatrix}\lambda_1^{n_\alpha}\\ 0\end{pmatrix}\right\|=\lambda_1^{n_\alpha}, \quad \lambda_1>1,$$

and therefore ***P**-a.s.*

$$\gamma_m(E=V)=\lim_{n\to\infty}\frac{1}{|n|}\ln\|T_m^{\omega}(E;n,1)\|\geqslant(\ln\lambda_1)\lim_{n\to\infty}\frac{n_\alpha}{|n|}=(\ln\lambda_1)p>0.$$

Now the case $m=0$ will be treated. In this case

$$T_0^{(\alpha)}=\mathrm{Id}_2 \quad \text{and} \quad T_0^{(\beta)}=\begin{pmatrix}1-4V^2/c^2 & 2V/c\\ -2V/c & 1\end{pmatrix}.$$

One then finds

$$\lim_{n\to\infty} \|(T_0^{(\beta)})^n\|^{1/n} = 1$$

if $V \in (0,c]$ and

$$\lim_{n\to\infty} \|(T_0^{(\beta)})^n\|^{1/n} > 1$$

if $V > c$. Hence, if $V \in (0,c]$, $V \neq c/\sqrt{2}$,

$$\gamma_0(E=V) = \lim_{n\to\infty} \frac{n_\beta}{|n|} \ln\|(T_0^{(\beta)})^{n_\beta}\|^{1/n_\beta} = (1-p)\ln 1 = 0,$$

and $\gamma_0(E=V) > 0$ if $V > c$. □

Proof (Theorem 4): By analyzing the proof of Theorems 2 and 3 observe that for $V=c/\sqrt{2}$ (respectively, $V=c\sqrt{2+m^2c^2}$) one has $\gamma_m(E_V \neq \pm c\sqrt{2+m^2c^2} \pm c/\sqrt{2}) > 0$ [respectively, $\gamma_m(E_V \neq 0) > 0$] and then the same conclusions of Theorem 2 (respectively, Theorem 3) hold. It remains to show that γ_m vanishes at the pairs $(V=c\sqrt{2+m^2c^2}, E_V=0)$ and $(V=c/\sqrt{2}, E_V = \pm c\sqrt{2+m^2c^2} \pm c/\sqrt{2})$. Note that in all cases $E_V \in \sigma(\mathbb{D}_\omega(m,c))$ $\boldsymbol{P}$-*a.s.*.

First it will be treated the case $(V=c/\sqrt{2}, E_V=-c\sqrt{2+m^2c^2}-c/\sqrt{2})$ (the others three excluded cases with $V=c/\sqrt{2}$ are similar). In this case one has $\beta=-c\sqrt{2+m^2c^2}$ and $\alpha=\beta-c\sqrt{2}$. The eigenvectors of $T_m^{(\alpha)}$ are given by

$$\begin{pmatrix} \dfrac{2c-\sqrt{2}\beta+\epsilon\sqrt{4c^2+2m^2c^4-2\sqrt{2}c\beta}}{\beta-c\sqrt{2}-mc^2} \\ 1 \end{pmatrix}, \quad \epsilon = \pm 1,$$

and by looking at the matrices in the basis given by these two vectors, the study is reduced to products of matrices of the following two types:

$$\begin{pmatrix} \lambda_+ & 0 \\ 0 & \lambda_- \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & \kappa_- \\ \kappa_+ & 0 \end{pmatrix}$$

with $\lambda_+\lambda_- = 1$ and $\kappa_+\kappa_- = -1$, where

$$\lambda_\pm = -1 + \frac{\sqrt{2}\beta}{c} \pm \frac{\sqrt{4c^2+2m^2c^4-2\sqrt{2}c\beta}}{c}$$

and

$$\kappa_\pm = \left(-\frac{\beta}{c}+mc\right)\left(\frac{2c-\sqrt{2}\beta \pm \sqrt{4c^2+2m^2c^4-2\sqrt{2}c\beta}}{\beta-c\sqrt{2}-mc^2}\right)+1.$$

Moreover,

$$(T_m^{(\beta)})^2 = \begin{pmatrix} -1 & mc+\beta/c \\ mc-\beta/c & 1 \end{pmatrix}^2 = -\mathrm{Id}_2.$$

Therefore the proof that $\gamma_m(E_V=-c\sqrt{2+m^2c^2}-c/\sqrt{2}, V=c/\sqrt{2})=0$ is analogous to the Schrödinger case (see the proof of Theorem 2.4 in Ref. 10).

Now consider the excluded case $(V=c\sqrt{2+m^2c^2}, E_V=0)$. In this case $\alpha^2=\beta^2=2c^2+m^2c^4$. Since $\alpha \neq \beta$ (otherwise $V=0$), then $\alpha=-\beta=\pm c\sqrt{2+m^2c^2}$. Noting that $(T_m^{(\alpha)})^2=(T_m^{(\beta)})^2=-\mathrm{Id}_2$ and $T_m^{(\alpha)}T_m^{(\beta)}$ is hyperbolic, the proof that $\gamma_m(E_V=0, V=c\sqrt{2+m^2c^2})=0$ is again similar to the corresponding Schrödinger case (see the proof of Theorem 2.4 in Ref. 10). □

Proof (Theorem 5): (i) It is sufficient to prove the theorem for $\Psi=\delta_0^+$. Given $\lambda>0$, there exists $b'>0$ and by Lemma 5 there are $b>0$ and $C<\infty$ such that, by applying Lemma 5 for N

$=[b'T]$, together with the relation (11) for $m=0$ and $\zeta=i/T$, one concludes that there exists a set $\Omega_N(\lambda)\subset\Omega$ with $\boldsymbol{P}(\Omega_N(\lambda))\leqslant Ce^{-bN^{\lambda}}$ and

$$\|T_0^{\omega}(E+i/T;n,1)\|\leqslant C \tag{16}$$

for all $\omega\in\Omega\backslash\Omega_N(\lambda)$, $1\leqslant n\leqslant N$, and $E\in I_V=[E_V-N^{-\lambda-1/2},E_V+N^{-\lambda-1/2}]$.

Supposing that

$$|G^+_{0,\omega}(E+i/T;1)|^2+|G^-_{0,\omega}(E+i/T;0)|^2\geqslant B_1(\omega)>0,$$

it follows from (13) and

$$\|T_0^{\omega}(E+i/T;n,1)^{-1}\|=\|T_0^{\omega}(E+i/T;n,1)\|$$

that

$$\max\{|G^+_{0,\omega}(E+i/T;n)|^2,|G^-_{0,\omega}(E+i/T;n-1)|^2\}\geqslant\frac{B_1(\omega)}{2\|T_0^{\omega}(E+i/T;n,1)\|^2}. \tag{17}$$

Thus, replacing (16) and (17) into (14), $\boldsymbol{P}$-*a.s.* one has

$$A^{(q)}_{\delta_0^+,\omega}(0,T)\geqslant\frac{1}{2\pi T}\sum_{0\leqslant n\leqslant[b'T]}n^q\int_{I_V}\frac{B_1(\omega)}{2C^2}\mathrm{d}E\geqslant B_q(\omega)T^qN^{-\lambda-1/2}\geqslant C_q(\omega)T^{q-1/2-\lambda}$$

for some constant $C_q(\omega)>0$.

If, on the other hand,

$$|G^+_{0,\omega}(E+i/T;0)|^2+|G^-_{0,\omega}(E+i/T;-1)|^2\geqslant B_2(\omega)>0,$$

then one gets this estimate in the same way, but based on (12) instead of (13). Since $\lambda>0$ is arbitrary, this finishes the proof.

(ii) It follows from the above arguments by using Lemma 6. □

Proof (Theorem 6): The arguments will be a variation of Ref. 23. Define the operator

$$p:=i[\mathbb{D}(m,c),X]=ci\begin{pmatrix}0 & -d^*-1\\ d+1 & 0\end{pmatrix}$$

with $[\cdot,\cdot]$ denoting the commutator. Note that p is self-adjoint and bounded. Set

$$X(t)=e^{i\mathbb{D}(m,c)t}Xe^{-i\mathbb{D}(m,c)t}\quad\text{and}\quad p(t)=e^{i\mathbb{D}(m,c)t}pe^{-i\mathbb{D}(m,c)t},$$

so that

$$\frac{d}{\mathrm{d}t}X(t)=i[\mathbb{D}(m,c),X(t)]=e^{i\mathbb{D}(m,c)t}i[\mathbb{D}(m,c),X]e^{-i\mathbb{D}(m,c)t}=p(t).$$

Hence

$$X(t)=X+\int_0^t p(s)\mathrm{d}s.$$

Using this relation, the boundedness $\|p(t)\|=\|p\|<\infty$ for all t, Cauchy-Schwarz inequality, and keeping only the dominant terms for large t, it follows that for $t\geqslant 1$ and $q\in\mathbb{N}$, there exists $C_q(\tilde{V},m,c)>0$ so that

$$M_{\Psi}^{(q)}(m,t) = \langle \Psi, |X(t)|^q \Psi \rangle \leqslant C_q(\tilde{V},m,c) \int_0^t \cdots \int_0^t \langle \Psi, p(s_1)\cdots p(s_q)\Psi \rangle \mathrm{d}s_1 \cdots \mathrm{d}s_q \leqslant C_q(\tilde{V},m,c)$$
$$\times \|p\|^q t^q = K_q(\tilde{V},m,c) t^q.$$

□

VI. DYNAMICAL COMPARISON

The aim of this section is to compare the dynamical moments $M_{\Psi}^{(q)}(m,t)$, as in Definition 1, for different masses and general potentials, in particular for the massless and massive Bernoulli cases.

Theorem 7: *Let $\mathbb{D}(m,c)$ and $\mathbb{D}(m',c)$ be Dirac operators on $l^2(\mathbb{Z},\mathbb{C}^2)$ defined as in (2) with the same potential $\tilde{V}$, and let Ψ be with only one nonzero component. Given $T>0$, there exists a constant $B_q>0$ so that*

$$\sup_{0\leqslant t\leqslant T} |M_{\Psi}^{(q)}(m,t) - M_{\Psi}^{(q)}(m',t)| \leqslant B_q |m-m'| c^2 T^{q+2}. \tag{18}$$

Proof: Observe that for $m=m'$ the result is immediate. Suppose $m \neq m'$. For the proof it will be assumed that $m>0$, $m'=0$ and $\Psi = \delta_0^+$ (the case $m>0$, $m'>0$ and Ψ as in the hypotheses is similar).

For fixed $\alpha>0$ consider the Banach space

$$B_\alpha := \{\Phi \in l^2(\mathbb{Z},\mathbb{C}^2) : \|\Phi\|_\alpha = \sup_{k\in\mathbb{Z}} e^{\alpha|k|}(|\langle \delta_k^+, \Phi\rangle| + |\langle \delta_k^-, \Phi\rangle|) < \infty\}.$$

Since $\mathbb{D}(m,c)$ is a bounded operator on B_α, it follows that

$$|\langle \delta_n^+, e^{-i\mathbb{D}(m,c)t}\delta_0^+\rangle| + |\langle \delta_n^-, e^{-i\mathbb{D}(m,c)t}\delta_0^+\rangle| \leqslant \|e^{-i\mathbb{D}(m,c)t}\delta_0^+\|_\alpha e^{-n\alpha} \leqslant e^{-n\alpha + t\|\mathbb{D}(m,c)\|_\alpha}. \tag{19}$$

For $k\in\mathbb{N}$ denote by X^k the restriction of the position operator X to the set $\{n\in\mathbb{Z}: |n|\leqslant k\}$ and by $M_{\delta_0^+}^{(q),k}(m,t)$ the corresponding dynamical moments. Then, for all times $t \leqslant \alpha k/2\|\mathbb{D}(m,c)\|_\alpha$, using (19) one has

$$|M_{\delta_0^+}^{(q)}(m,t) - M_{\delta_0^+}^{(q),k}(m,t)| = \sum_{|n|>k} |n|^q (|\langle \delta_n^+, e^{-i\mathbb{D}(m,c)t}\delta_0^+\rangle|^2 + |\langle \delta_n^-, e^{-i\mathbb{D}(m,c)t}\delta_0^+\rangle|^2)$$
$$\leqslant C_1(q) k^q e^{-k\alpha + 2t\|\mathbb{D}(m,c)\|_\alpha} \leqslant C_1(q) k^q. \tag{20}$$

Furthermore, it follows by DuHamel's formula that

$$M_{\delta_0^+}^{(q),k}(m,t) - M_{\delta_0^+}^{(q),k}(0,t) = -i\int_0^t \langle \delta_0^+, e^{i\mathbb{D}(m,c)t}|X^k|^q e^{-i\mathbb{D}(m,c)(t-s)}(\mathbb{D}(m,c)-\mathbb{D}(0,c))e^{-i\mathbb{D}(0,c)s}\delta_0^+\rangle \mathrm{d}s$$
$$+ i\int_0^t \langle \delta_0^+, e^{i\mathbb{D}(m,c)(t-s)}(\mathbb{D}(m,c)-\mathbb{D}(0,c))e^{i\mathbb{D}(0,c)s}|X^k|^q e^{-i\mathbb{D}(0,c)t}\delta_0^+\rangle \mathrm{d}s.$$

Hence, for $t\leqslant \alpha k/2\|\mathbb{D}(m,c)\|_\alpha$, using (19), the fact of the operator $e^{i\mathbb{D}(m,c)t}$ on $\ell^2(\mathbb{Z};\mathbb{C}^2)$ be unitary and Cauchy-Schwarz, it is found that

$$|M_{\delta_0^+}^{(q),k}(m,t) - M_{\delta_0^+}^{(q),k}(0,t)| \leqslant C_2(q) mc^2 k^{q+1} t e^{-k\alpha + t\|\mathbb{D}(m,c)\|_\alpha} \leqslant C_2(q) mc^2 \frac{\alpha}{2\|\mathbb{D}(m,c)\|_\alpha} k^{q+2}. \tag{21}$$

Thus, by (20) and (21),

$$|M^{(q)}_{\delta_0^+}(m,t) - M^{(q)}_{\delta_0^+}(0,t)| \leqslant B_q mc^2 \frac{\alpha}{2\|\mathbb{D}(m,c)\|_\alpha} k^{q+2},$$

for all times $t \leqslant \alpha k/2\|\mathbb{D}(m,c)\|_\alpha$.

Now, for each $T>0$ choose k to be the smallest integer such that

$$k \geqslant \frac{2\|\mathbb{D}(m,c)\|_\alpha}{\alpha} T.$$

Therefore, for all $t \leqslant T$,

$$|M^{(q)}_{\delta_0^+}(m,t) - M^{(q)}_{\delta_0^+}(0,t)| \leqslant B_q mc^2 T^{q+2}.$$

□

With respect to the Bernoulli-Dirac model (9), the relation (18) with $m>0$ and $m'=0$ gives an estimate of how, for small times and/or sufficiently small mass, the dynamics of the localized regime follows the delocalized one. In terms of the average dynamical moments $A^{(q)}_{\Psi,\omega}(m,T)$ defined in (10) one has the following.

Corollary 1: Let $(\mathbb{D}_\omega(m,c))_{\omega\in\Omega}$ *be as in (9),* $m \geqslant 0$ *and* $V \in (0,c]$, $V \neq c/\sqrt{2}$, *and let* Ψ *be with only one nonzero component. Then, for each* $q>0$, ***P****-a.s. there is* $\widetilde{C}_{q,\omega}>0$ *so that*

$$\left| 1 - \frac{A^{(q)}_{\Psi,\omega}(m,t)}{A^{(q)}_{\Psi,\omega}(0,t)} \right| \leqslant \widetilde{C}_{q,\omega} mc^2 t^{5/2}, \quad t>0.$$

Notice that the power exponent on the right-hand side of this expression does not depend on q.

Proof: By Theorem 7 with $m>0$ and $m'=0$, it follows that for all $t>0$,

$$|A^{(q)}_{\Psi,\omega}(m,t) - A^{(q)}_{\Psi,\omega}(0,t)| \leqslant \Gamma(q+3) C_{q,\omega} mc^2 t^{q+2},$$

with Γ the usual gamma function. By Theorem 5(i) there is $0<B_q(\omega)<\infty$ such that

$$A^{(q)}_{\Psi,\omega}(0,t) \geqslant B_q(\omega) t^{q-1/2}, \quad \textbf{\textit{P}}\text{-}a.s.,$$

and the result follows with $\widetilde{C}_{q,\omega}=\Gamma(q+3)C_{q,\omega}/B_q(\omega)$. □

Remark: By using Theorem 6 one gets (for $q \in \mathbb{N}$),

$$|M^{(q)}_{\Psi}(m,t) - M^{(q)}_{\Psi}(m',t)| \leqslant \widetilde{K}_q(\omega,m,m',c) t^q,$$

but with no expression for the constant $\widetilde{K}_q(\omega,m,m',c)$. The price paid for the explicit dependence on the masses and light speed c in Theorem 7 is the larger exponent $q+2$ instead of just q. In the same way, the exponent $5/2$ in Corollary 1 could be replaced by $3/2$, but with no precise dependence of the resulting multiplicative constant on m and c.

(Received 23 April 2005; accepted 23 May 2005; published online 6 July 2005)

k-component *q*-deformed charge coherent states are constructed, their (over)completeness proved and their generation explored. The *q*-deformed charge coherent states and the even (odd) *q*-deformed charge coherent states are the two special cases of them as *k* becomes 1 and 2, respectively. A *D*-algebra realization of the $SU_q(1,1)$ generators is given in terms of them. Their nonclassical properties are studied and it is shown that for $k \geqslant 3$, they exhibit two-mode *q*-antibunching, but neither $SU_q(1,1)$ squeezing, nor one- or two-mode *q*-squeezing. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1951607]

I. INTRODUCTION

The coherent states introduced by Schrödinger[1] and Glauber[2] are the eigenstates of the boson annihilation operator, and have widespread applications in the fields of physics.[3–7] However, in all the cases the quanta involved are uncharged. In 1976, Bhaumik *et al.*[4,8,9] constructed the boson coherent states which, carrying definite charge, are the eigenstates of both the pair boson annihilation operator and the charge operator. These kind of states are the so-called charge coherent states. Based on this work, the charge coherent states for SU(2),[10] SU(3),[11] and arbitrary compact Lie groups[12] were also put forward.

The concept of charge coherent states has proved to be very useful in many areas, such as elementary particle physics,[9,13–17] quantum field theory,[12,18,19] nuclear physics,[20] thermodynamics,[21–23] quantum mechanics,[24] and quantum optics.[25–27] Moreover, some schemes for generating charge coherent states in quantum optics were proposed.[25,26,28,29]

As is well known, the even and odd coherent states,[30] which are the two orthonormalized eigenstates of the square of the boson annihilation operator, play an important role in quantum optics.[31–33] An extension of the even and odd coherent states is to define the *k*-component coherent states,[34,35] which are the k ($k \geqslant 1$) orthonormalized eigenstates of the kth power of the boson annihilation operator. The coherent states and the even (odd) ones are the two special cases of the *k*-component coherent states as *k* becomes 1 and 2, respectively. Inspired by the above idea, in Ref. 36 one of the authors (X.-M.L.) has generalized the charge coherent states to the even and odd charge coherent states, defined as the two orthonormalized eigenstates of both the square of the pair boson annihilation operator and the charge operator; in Ref. 37 he has further extended the

even and odd charge coherent states to the k-component charge coherent states, defined as the k orthonormalized eigenstates of both the kth power of the pair boson annihilation operator and the charge operator. The charge coherent states and the even (odd) ones are the two special cases of the k-component charge coherent states as k becomes 1 and 2, respectively.

On the other hand, quantum groups,[38,39] introduced as a mathematical description of deformed Lie algebras, have given the possibility of generalizing the notion of coherent states to the case of q-deformations.[40–44] A q-deformed harmonic oscillator[40,45] was defined in terms of q-boson annihilation and creation operators, the latter satisfying the quantum Heisenberg-Weyl algebra,[40,45,46] which plays an important role in quantum groups. The q-deformed coherent states introduced by Biedenharn[40] are the eigenstates of the q-boson annihilation operator. Such states have been well studied,[41,42,47,48] and widely applied to quantum optics and mathematical physics.[44,49–53] Furthermore, the q-deformed charge coherent states[54,55] were constructed as the eigenstates of both the pair q-boson annihilation operator and the charge operator.

A natural extension of the q-deformed coherent states is provided by the even and odd q-deformed coherent states,[56] which are the two orthonormalized eigenstates of the square of the q-boson annihilation operator. In a previous paper,[57] motivated by the above idea, the authors (X.-M.L. and C.Q.) have generalized the q-deformed charge coherent states to the even and odd q-deformed charge coherent states, defined as the two orthonormalized eigenstates of both the square of the pair q-boson annihilation operator and the charge operator. A further extension of the even and odd q-deformed coherent states is given by the k-component q-deformed coherent states,[58,59] which are the k orthonormalized eigenstates of the kth power of the q-boson annihilation operator. The q-deformed coherent states and the even (odd) ones are the two special cases of the k-component q-deformed coherent states as k becomes 1 and 2, respectively. In a parallel way, it is very desirable to generalize the even and odd q-deformed charge coherent states to the k-component q-deformed charge coherent states, defined as the k orthonormalized eigenstates of both the kth power of the pair q-boson annihilation operator and the charge operator. The q-deformed charge coherent states and the even (odd) ones are the two special cases of the k-component q-deformed charge coherent states as k becomes 1 and 2, respectively.

This paper is arranged as follows. In Sec. II, the k-component q-deformed charge coherent states are constructed. Their completeness is proved in Sec. III. Section IV is devoted to generating them. In Sec. V, they are used to provide a D-algebra realization of the $\mathrm{SU}_q(1,1)$ generators. Their nonclassical properties, such as $\mathrm{SU}_q(1,1)$ squeezing, single- or two-mode q-squeezing, and two-mode q-antibunching, are studied in Sec. VI. Section VII contains a summary of the results.

II. k-COMPONENT q-DEFORMED CHARGE COHERENT STATES

Two mutually commuting q-deformed harmonic oscillators are defined in terms of two pairs of independent q-boson annihilation and creation operators a_i, a_i^+ $(i=1,2)$, together with corresponding number operators N_i, satisfying the quantum Heisenberg-Weyl algebra

$$a_i a_i^+ - q a_i^+ a_i = q^{-N_i}, \tag{1}$$

$$[N_i, a_i^+] = a_i^+, \quad [N_i, a_i] = -a_i, \tag{2}$$

where q is a positive real deformation parameter. The operators a_i, a_i^+, and N_i act in the Fock space with basis $|n\rangle_i$, $(n=0, 1, 2, \ldots)$, such that

$$a_i|0\rangle_i = 0, \quad |n\rangle_i = \frac{(a_i^+)^n}{\sqrt{[n]!}}|0\rangle_i, \tag{3}$$

where

$$[n]! \equiv [n]_q! = [n]_q[n-1]_q \cdots [1]_q, \quad [0]! = 1, \tag{4}$$

$$[n]_q = \frac{q^n - q^{-n}}{q - q^{-1}} \equiv [n]. \tag{5}$$

Their action on the basis states is given by

$$a_i|n\rangle_i = \sqrt{[n]}|n-1\rangle_i, \quad a_i^+|n\rangle_i = \sqrt{[n+1]}|n+1\rangle_i, \quad N_i|n\rangle_i = n|n\rangle_i. \tag{6}$$

Note that $[n]$ is invariant under $q \leftrightarrow 1/q$. In the following, $[n]$ will refer to the q-deformed n defined by (5) corresponding to the base q. If the base is different, then it will be indicated explicitly.

The q-boson operators a_i and a_i^+ can be constructed from the conventional boson annihilation and creation operators b_i, b_i^+ in the following way:[60]

$$a_i = \sqrt{\frac{[N_i+1]}{N_i+1}}\, b_i, \quad a_i^+ = b_i^+ \sqrt{\frac{[N_i+1]}{N_i+1}}, \tag{7}$$

where $N_i = b_i^+ b_i$. It is worth noticing that $[N_i] = a_i^+ a_i$.

The operators $a_1(a_1^+)$ and $a_2(a_2^+)$ are assigned the "charge" quanta 1 and -1, respectively. Thus the charge operator is given by

$$Q = N_1 - N_2. \tag{8}$$

In view of the fact that

$$[Q, (a_1 a_2)^k] = 0, \tag{9}$$

where k is a positive integer ($k=1, 2, 3, \ldots$), we may seek the k-component q-deformed charge coherent states, which are the k orthonormalized eigenstates of both the kth power $(a_1 a_2)^k$ of the pair q-boson annihilation operator $a_1 a_2$ and the charge operator Q.

Let $|m,n\rangle = |m\rangle_1 |n\rangle_2$ denote the basis states of two-mode Fock space, where $|m\rangle_1$ and $|n\rangle_2$ are the eigenstates of N_1 and N_2 corresponding to the eigenvalues m and n, respectively. They satisfy the completeness relation

$$\sum_{m=0}^{\infty} \sum_{n=0}^{\infty} |m,n\rangle\langle m,n| = I. \tag{10}$$

We now consider the following states:

$$\begin{aligned} |\xi, \underline{q}, k\rangle_j &= N_{k\underline{q}}^j \sum_{p=\max(0,-\underline{q}/k)}^{\infty} \frac{\xi^{kp+j+\min(0,\underline{q})}}{\{[kp+j]\,![kp+j+\underline{q}]\,!\}^{1/2}} |kp+j+\underline{q}, kp+j\rangle \\ &= \begin{cases} N_{k\underline{q}}^j \sum_{n=0}^{\infty} \dfrac{\xi^{kn+j}}{\{[kn+j]\,![kn+j+\underline{q}]\,!\}^{1/2}} |kn+j+\underline{q}, kn+j\rangle, & \underline{q} \geqslant 0, \\ N_{k\underline{q}}^j \sum_{n=0}^{\infty} \dfrac{\xi^{kn+j}}{\{[kn+j]\,![kn+j-\underline{q}]\,!\}^{1/2}} |kn+j, kn+j-\underline{q}\rangle, & \underline{q} \leqslant 0, \end{cases} \end{aligned} \tag{11}$$

where $j = 0, 1, \ldots, k-1$, ξ is a complex number, $\underline{q}$ is a fixed integer, and $N_{k\underline{q}}^j$ are normalization factors given by

$$N_{k\underline{q}}^j \equiv N_{k\underline{q}}^j(|\xi|^2) = \left\{ \sum_{n=0}^{\infty} \frac{(|\xi|^2)^{kn+j}}{[kn+j]\,![kn+j+|\underline{q}|]!} \right\}^{-1/2}. \tag{12}$$

As can be verified by explicit calculations, these states satisfy the relations

$$(a_1a_2)^k|\xi,\underline{q},k\rangle_j=\xi^k|\xi,\underline{q},k\rangle_j,\quad Q|\xi,\underline{q},k\rangle_j=\underline{q}|\xi,\underline{q},k\rangle_j,\quad {}_j\langle\xi,\underline{q},k|\xi,\underline{q},k\rangle_{j'}=\delta_{jj'}. \tag{13}$$

It indicates that $|\xi,\underline{q},k\rangle_j$ $(j=0,1,\ldots,k-1)$ in (11) are exactly the k orthonormalized eigenstates of both the operator $(a_1a_2)^k$ and Q corresponding to the eigenvalues ξ^k and $\underline{q}$, respectively. Obviously, $\underline{q}$ is the charge number which the states $|\xi,\underline{q},k\rangle_j$ carry.

Therefore, the k states of (11) are just what we want, that is to say, they are the k-component q-deformed charge coherent states. In the limit $q\to 1$, they reduce to the usual k-component charge coherent states constructed by the author (X.-M.L.).[37]

According to (11), for $k=1$, we obtain

$$\begin{aligned}|\xi,\underline{q},1\rangle_0&=N_{\underline{q}}\sum_{p=\max(0,-\underline{q})}^{\infty}\frac{\xi^{p+\min(0,\underline{q})}}{\{[p]!\,[p+\underline{q}]!\,\}^{1/2}}|p+\underline{q},p\rangle\\&=\begin{cases}N_{\underline{q}}\sum_{n=0}^{\infty}\dfrac{\xi^n}{\{[n]!\,[n+\underline{q}]!\,\}^{1/2}}|n+\underline{q},n\rangle, & \underline{q}\geqslant 0,\\ N_{\underline{q}}\sum_{n=0}^{\infty}\dfrac{\xi^n}{\{[n]!\,[n-\underline{q}]!\,\}^{1/2}}|n,n-\underline{q}\rangle, & \underline{q}\leqslant 0,\end{cases}\\&\equiv|\xi,\underline{q}\rangle\end{aligned} \tag{14}$$

where

$$N_{\underline{q}}\equiv N^0_{1\underline{q}}(|\xi|^2)=\left\{\sum_{n=0}^{\infty}\frac{(|\xi|^2)^n}{[n]!\,[n+|\underline{q}|]!}\right\}^{-1/2}. \tag{15}$$

It is evident that $|\xi,\underline{q},1\rangle_0(\equiv|\xi,\underline{q}\rangle)$ are exactly the so-called q-deformed charge coherent states given in Ref. 54.

According to (11), for $k=2$, we obtain

$$\begin{aligned}|\xi,\underline{q},2\rangle_j&=N^j_{2\underline{q}}\sum_{p=\max(0,-\underline{q}/2)}^{\infty}\frac{\xi^{2p+j+\min(0,\underline{q})}}{\{[2p+j]!\,[2p+j+\underline{q}]!\,\}^{1/2}}|2p+j+\underline{q},2p+j\rangle\\&=\begin{cases}N^j_{2\underline{q}}\sum_{n=0}^{\infty}\dfrac{\xi^{2n+j}}{\{[2n+j]!\,[2n+j+\underline{q}]!\,\}^{1/2}}|2n+j+\underline{q},2n+j\rangle, & \underline{q}\geqslant 0,\\ N^j_{2\underline{q}}\sum_{n=0}^{\infty}\dfrac{\xi^{2n+j}}{\{[2n+j]!\,[2n+j-\underline{q}]!\,\}^{1/2}}|2n+j,2n+j-\underline{q}\rangle, & \underline{q}\leqslant 0,\end{cases}\end{aligned} \tag{16}$$

where $j=0$, 1. It is evident that $|\xi,\underline{q},2\rangle_0$ $(|\xi,\underline{q},2\rangle_1)$ are exactly the so-called even (odd) q-deformed charge coherent states obtained by the authors (X.-M.L. and C.Q.).[57]

From (11), it follows that

$${}_j\langle\xi,\underline{q},k|\xi',\underline{q}',k\rangle_{j'}=N^j_{k\underline{q}}(|\xi|^2)N^j_{k\underline{q}}(|\xi'|^2)[N^j_{k\underline{q}}(\xi^*\xi')]^{-2}\delta_{\underline{q}\underline{q}'}\delta_{jj'}. \tag{17}$$

This further shows that, for the same value of k, the states $|\xi,\underline{q},k\rangle_j$ are orthogonal to one another with respect to both the subscript j and the charge number $\underline{q}$. However, they are nonorthogonal with respect to the parameter ξ.

For the mean values of the operators N_1 and N_2, there exists the relation

$${}_j\langle\xi,\underline{q},k|N_1|\xi,\underline{q},k\rangle_j=\underline{q}+{}_j\langle\xi,\underline{q},k|N_2|\xi,\underline{q},k\rangle_j. \tag{18}$$

In terms of the k-component q-deformed charge coherent states, the q-deformed charge coherent states can be expanded as

$$|\xi,\underline{q}\rangle = N_{\underline{q}}\left[\sum_{j=0}^{k-1}(N_{k\underline{q}}^{j})^{-1}|\xi,\underline{q},k\rangle_j\right], \tag{19}$$

where the normalization factors are such that

$$N_{\underline{q}}^{-2} = \sum_{j=0}^{k-1}(N_{k\underline{q}}^{j})^{-2}. \tag{20}$$

III. COMPLETENESS OF *k*-COMPONENT *q*-DEFORMED CHARGE COHERENT STATES

Let us begin with some q-deformed formulas which are useful in the proof of completeness of the k-component q-deformed charge coherent states. The q-deformed Bessel function of (integer) order ν may be defined by[61]

$$J_\nu(q,x) = \sum_{k=0}^{\infty}\frac{(-1)^k}{[k]\,![\nu+k]!}\left(\frac{x}{\sqrt{q}[2]_{\sqrt{q}}}\right)^{\nu+2k}, \tag{21}$$

where $[n]_{\sqrt{q}}$ is defined as in Eq. (5) except for replacing q by $\sqrt{q}$. An integral representation of the q-deformed modified Bessel function of order ν is given by[62]

$$K_\nu(q,x) = \frac{1}{[2]_{\sqrt{q}}}\left(\frac{x}{[2]_{\sqrt{q}}}\right)^{\nu}\int_0^{\infty} d_q t\,\frac{1}{t^{\nu+1}}e_q(-t)e_q\left(-\frac{x^2}{([2]_{\sqrt{q}})^2 t}\right), \tag{22}$$

where $d_q t$ is a standard q-integration,[47,63,64] and $e_q(x)$ is a q-exponential function[47]

$$e_q(x) = \begin{cases}\displaystyle\sum_{n=0}^{\infty}\frac{x^n}{[n]!} & \text{for } x > -\zeta,\\ 0 & \text{otherwise},\end{cases} \tag{23}$$

with $-\zeta$ being the largest zero of $e_q(x)$. Then, it follows that[62]

$$\int_0^{\infty} d_{\sqrt{q}}u\, u^{2p+\nu+1}K_\nu(q,[2]_{\sqrt{q}}u) = \frac{[\nu+p]\,![p]!}{([2]_{\sqrt{q}})^2}. \tag{24}$$

We now prove that the k-component q-deformed charge coherent states form an (over)complete set, that is to say

$$\sum_{\underline{q}=-\infty}^{\infty}\int\frac{d_q^2\xi}{\pi}\phi_{\underline{q}}(\xi)N_{\underline{q}}^2\left[\sum_{j=0}^{k-1}(N_{k\underline{q}}^{j})^{-2}|\xi,\underline{q},k\rangle_{j\,j}\langle\xi,\underline{q},k|\right] \equiv \sum_{\underline{q}=-\infty}^{\infty} I_{\underline{q}} = I, \tag{25}$$

where

$$d_q^2\xi = |\xi|d_{\sqrt{q}}|\xi|\mathrm{d}\theta, \quad \xi = |\xi|e^{i\theta}, \tag{26}$$

and

$$\phi_{\underline{q}}(\xi) = \frac{([2]_{\sqrt{q}})^2}{2}(-\mathrm{i})^{\underline{q}}J_{\underline{q}}(q,\mathrm{i}\sqrt{q}[2]_{\sqrt{q}}|\xi|)K_{\underline{q}}(q,[2]_{\sqrt{q}}|\xi|). \tag{27}$$

Note that the integral over θ is a standard integration while that over $|\xi|$ is a q-integration.

In fact, for $\underline{q}\geqslant 0$, we have

$$
\begin{aligned}
I_{\underline{q}} &= \int \frac{d_{\underline{q}}^2\xi}{\pi}\phi_{\underline{q}}(\xi)N_{\underline{q}}^2\sum_{j=0}^{k-1}\sum_{n,m}\frac{\xi^{kn+j}\xi^{*km+j}|kn+j+\underline{q},kn+j\rangle\langle km+j+\underline{q},km+j|}{\{[kn+j]![kn+j+\underline{q}]![km+j]![km+j+\underline{q}]!\}^{1/2}} \\
&= \int_0^\infty \frac{d_{\sqrt{\bar{q}}}|\xi|}{\pi}\frac{([2]_{\sqrt{\bar{q}}})^2}{2}|\xi|^{\underline{q}+1}K_{\underline{q}}(q,[2]_{\sqrt{\bar{q}}}|\xi|)\sum_{j=0}^{k-1}\sum_{n,m}|\xi|^{k(n+m)+2j}\int_{-\pi}^{\pi}\mathrm{d}\theta\, e^{\mathrm{i}k(n-m)\theta} \\
&\quad\times\frac{|kn+j+\underline{q},kn+j\rangle\langle km+j+\underline{q},km+j|}{\{[kn+j]![kn+j+\underline{q}]![km+j]![km+j+\underline{q}]!\}^{1/2}} \\
&= \int_0^\infty d_{\sqrt{\bar{q}}}|\xi|([2]_{\sqrt{\bar{q}}})^2|\xi|^{\underline{q}+1}K_{\underline{q}}(q,[2]_{\sqrt{\bar{q}}}|\xi|)\times\sum_{j=0}^{k-1}\sum_{n=0}^{\infty}\frac{(|\xi|^2)^{kn+j}|kn+j+\underline{q},kn+j\rangle\langle kn+j+\underline{q},kn+j|}{[kn+j]![kn+j+\underline{q}]!} \\
&= \sum_{n=0}^{\infty}\frac{([2]_{\sqrt{\bar{q}}})^2}{[n]![n+\underline{q}]!}|n+\underline{q},n\rangle\langle n+\underline{q},n|\int_0^\infty d_{\sqrt{\bar{q}}}|\xi||\xi|^{2n+\underline{q}+1}K_{\underline{q}}(q,[2]_{\sqrt{\bar{q}}}|\xi|) \\
&= \sum_{n=0}^{\infty}|n+\underline{q},n\rangle\langle n+\underline{q},n|. \qquad (28)
\end{aligned}
$$

Similarly, for $\underline{q}\leqslant 0$, we get

$$
I_{\underline{q}} = \sum_{n=0}^{\infty}|n,n-\underline{q}\rangle\langle n,n-\underline{q}|. \qquad (29)
$$

Consequently, we derive

$$
\begin{aligned}
\sum_{\underline{q}=-\infty}^{\infty} I_{\underline{q}} &= \sum_{n=0}^{\infty}\left(\sum_{\underline{q}=-\infty}^{-1}|n,n-\underline{q}\rangle\langle n,n-\underline{q}| + \sum_{\underline{q}=0}^{\infty}|n+\underline{q},n\rangle\langle n+\underline{q},n|\right) \\
&= \sum_{m=0}^{\infty}\sum_{n=0}^{\infty}|m,n\rangle\langle m,n| = I. \qquad (30)
\end{aligned}
$$

Hence, the k-component q-deformed charge coherent states are qualified to make up an (over) complete representation. It should be mentioned that $I_{\underline{q}}$ represents the resolution of unity in the subspace where $Q=\underline{q}$.

In the two special cases of $k=1$ and $k=2$, the above demonstration gives the proof of completeness of the q-deformed charge coherent states[65] and the even (odd) q-deformed charge coherent states,[57] respectively.

IV. GENERATION OF *k*-COMPONENT *q*-DEFORMED CHARGE COHERENT STATES

The k-component q-deformed coherent states, defined as the k orthonormalized eigenstates of the kth power of the q-boson annihilation operator, can be expanded in the single-mode Fock space as[58,59]

$$
|\xi,k\rangle_j = N_k^j\sum_{n=0}^{\infty}\frac{\xi^{kn+j}}{\sqrt{[kn+j]!}}|kn+j\rangle, \qquad (31)
$$

where $j=0,1,\ldots,k-1$ and

$$
N_k^j \equiv N_k^j(|\xi|^2) = \left\{\sum_{n=0}^{\infty}\frac{(|\xi|^2)^{kn+j}}{[kn+j]!}\right\}^{-1/2}. \qquad (32)
$$

As a special case, for $k=1$, $|\xi,1\rangle_0$ are exactly the q-deformed coherent states, i.e.,

$$|\xi,1\rangle_0 = e_q^{-1/2}(|\xi|^2)\sum_{n=0}^{\infty}\frac{\xi^n}{\sqrt{[n]!}}|n\rangle \equiv |\xi\rangle. \tag{33}$$

The *k*-component *q*-deformed charge coherent states can also be obtained from the states (31) and (33) according to the following expression:

$$|\xi,\underline{q},k\rangle_j = \begin{cases} N_{k\underline{q}}^j e_q^{1/2}(|\xi_1|^2)[N_k^j(|\xi_2|^2)]^{-1}\xi_1^{-\underline{q}}\displaystyle\int_{-\pi}^{\pi}\frac{d\alpha}{2\pi}e^{+i\underline{q}\alpha}|e^{-i\alpha}\xi_1\rangle\otimes|e^{i\alpha}\xi_2,k\rangle_j, & \underline{q}\geqslant 0, \\ N_{k\underline{q}}^j e_q^{1/2}(|\xi_1|^2)[N_k^j(|\xi_2|^2)]^{-1}\xi_1^{+\underline{q}}\displaystyle\int_{-\pi}^{\pi}\frac{d\alpha}{2\pi}e^{-i\underline{q}\alpha}|e^{i\alpha}\xi_2,k\rangle_j\otimes|e^{-i\alpha}\xi_1\rangle, & \underline{q}\leqslant 0, \end{cases} \tag{34}$$

where $\xi=\xi_1\xi_2$. Such a representation is very useful since the properties of *q*-deformed coherent states and *k*-component *q*-deformed coherent states can now be employed in a study of the properties of *k*-component *q*-deformed charge coherent states. The expression for the latter given in (34) has a very simple group-theoretical interpretation, in (34) one suitably averages over the U(1)-group (caused by the charge operator Q) action on the product of *q*-deformed coherent states and *k*-component *q*-deformed coherent states, which then projects out the $Q=\underline{q}$ charge subspace contribution.

It is easy to see that in the limit $q\to 1$, the above discussion gives back the corresponding results for the usual *k*-component charge coherent states obtained in Ref. 37, and that in the two special cases of $k=1$ and $k=2$, it gives the corresponding results for the *q*-deformed charge coherent states[54] and the even (odd) *q*-deformed charge coherent states,[57] respectively.

V. *D*-ALGEBRA REALIZATION OF $SU_q(1,1)$ GENERATORS

As is well known, the coherent state *D*-algebra[6,66] is a mapping of quantum observables onto a differential form that acts on the parameter space of coherent states, and has a beautiful application in the reformulation of the entire laser theory in terms of *C*-number differential equations.[67] We shall construct the *D*-algebra realization of the *q*-deformed $SU_q(1,1)$ generators corresponding to the unnormalized *k*-component *q*-deformed charge coherent states, defined by

$$\|\underline{q}\rangle_j \equiv \|\xi,\underline{q},k\rangle_j = (N_{k\underline{q}}^j)^{-1}|\xi,\underline{q},k\rangle_j. \tag{35}$$

Let $\|\underline{q}\rangle$ denote a column vector composed of $\|\underline{q}\rangle_j$ $(j=0,1,\ldots,k-1)$, i.e.,

$$\|\underline{q}\rangle \equiv \begin{bmatrix} \|\underline{q}\rangle_0 \\ \|\underline{q}\rangle_1 \\ \vdots \\ \|\underline{q}\rangle_{k-1} \end{bmatrix}. \tag{36}$$

The action of the operators a_i, a_i^+ and N_i on this column vector can be written in the matrix form,

$$
\begin{array}{ll}
\text{Positive } Q & \text{Negative } Q \\
a_1\|\underline{q}\rangle = \|\underline{q}-1\rangle & a_1\|\underline{q}\rangle = \xi M\|\underline{q}-1\rangle \\
a_2\|\underline{q}\rangle = \xi M\|\underline{q}+1\rangle & a_2\|\underline{q}\rangle = \|\underline{q}+1\rangle \\
a_1^+\|\underline{q}\rangle = \xi^{-\underline{q}}\dfrac{d}{d_q\xi}\xi^{\underline{q}+1}\|\underline{q}+1\rangle & a_1^+\|\underline{q}\rangle = \dfrac{d}{d_q\xi}N\|\underline{q}+1\rangle \\
a_2^+\|\underline{q}\rangle = \dfrac{d}{d_q\xi}N\|\underline{q}-1\rangle & a_2^+\|\underline{q}\rangle = \xi^{\underline{q}}\dfrac{d}{d_q\xi}\xi^{-\underline{q}+1}\|\underline{q}-1\rangle \\
N_1\|\underline{q}\rangle = \left(\xi\dfrac{d}{\mathrm{d}\xi}+\underline{q}\right)\|\underline{q}\rangle & N_1\|\underline{q}\rangle = \xi\dfrac{d}{\mathrm{d}\xi}\|\underline{q}\rangle \\
N_2\|\underline{q}\rangle = \xi\dfrac{d}{\mathrm{d}\xi}\|\underline{q}\rangle & N_2\|\underline{q}\rangle = \left(\xi\dfrac{d}{\mathrm{d}\xi}-\underline{\mathrm{q}}\right)\|\underline{q}\rangle,
\end{array}
\tag{37}
$$

where $d/\mathrm{d}\xi$ is a standard differential operator, whereas $d/d_q\xi$ is a q-differential one,[42,47,64] defined by

$$
\frac{d}{d_q\xi}f(\xi) = \frac{f(q\xi)-f(q^{-1}\xi)}{q\xi-q^{-1}\xi}, \tag{38}
$$

and

$$
M = \begin{bmatrix} 0 & 0 & \cdots & 0 & 1 \\ 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & 0 \end{bmatrix}, \quad N = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 1 & 0 & 0 & \cdots & 0 \end{bmatrix}. \tag{39}
$$

Obviously, N is both the inverse and the transpose of M. It is worth noticing that $M^k=N^k=I$, and $M^\alpha N^\beta=N^\beta M^\alpha$ for integers α,β.

The q-deformed $\mathrm{SU}_q(1,1)$ algebra consists of three generators K_0, K_+, and K_-, satisfying the commutation relations

$$
[K_+,K_-] = -[2K_0], \quad [K_0,K_\pm] = \pm K_\pm, \tag{40}
$$

and is realized in terms of the two-mode q-boson operators as

$$
K_- = a_1a_2, \quad K_+ = a_1^+a_2^+, \quad K_0 = \tfrac{1}{2}(N_1+N_2+1). \tag{41}
$$

Actually, the k-component q-deformed charge coherent states are also the k orthonormalized eigenstates of the kth power of K_-.

The D-algebra of the $\mathrm{SU}_q(1,1)$ generators A may be defined for the action on the ket coherent states (36) or for that on the corresponding bras as

$$
A\|\underline{q}\rangle = D^k(A)\|\underline{q}\rangle, \tag{42}
$$

$$
\langle\underline{q}\|A = D^b(A)\langle\underline{q}\|, \tag{43}
$$

respectively. Using (37) and (41), we get for the former

$$
D^k(K_-) = \xi M, \tag{44}
$$

$$
D^k(K_+) = \xi^{-|\underline{q}|}\frac{d}{d_q\xi}\xi^{|\underline{q}|+1}\frac{d}{d_q\xi}N, \tag{45}
$$

$$D^k(K_0) = \frac{1}{2}\left(2\xi\frac{d}{d\xi} + |\underline{q}| + 1\right)I, \tag{46}$$

while the latter can be obtained from the adjoint relation

$$D^b(A) = [D^k(A^+)]^*. \tag{47}$$

Thus, the D-algebra of the $SU_q(1,1)$ generators corresponding to the unnormalized k-component q-deformed charge coherent states has been realized in a q-differential-operator matrix form.

From (36), (39), (42), and (44), we clearly see that by the successive actions of the operator a_1a_2, each component of the k-component q-deformed charge coherent states, apart from normalization, can be transformed into another in this way, $|\xi,\underline{q},k\rangle_0 \to |\xi,\underline{q},k\rangle_{k-1} \to |\xi,\underline{q},k\rangle_{k-2} \to \cdots \to |\xi,\underline{q},k\rangle_1 \to |\xi,\underline{q},k\rangle_0$. Actually, a_1a_2 plays the role of a rotating operator among these k-component states.

It is easy to check that in the limit $q \to 1$, the above discussion gives back the corresponding results for the usual k-component charge coherent states obtained in Ref. 37, and that in the two special cases of $k=1$ and $k=2$, it gives the corresponding results for the q-deformed charge coherent states[65] and the even (odd) q-deformed charge coherent states,[57] respectively.

VI. NONCLASSICAL PROPERTIES OF *k*-COMPONENT *q*-DEFORMED CHARGE COHERENT STATES

In Ref. 57, the authors (X.-M.L. and C.Q.) have examined the even and odd q-deformed charge coherent states for some nonclassical properties, such as $SU_q(1,1)$ squeezing, single- or two-mode q-squeezing, and two-mode q-antibunching. In this section, we will study the nonclassical properties of the k-component q-deformed charge coherent states with $k \geqslant 3$.

A. $SU_q(1,1)$ squeezing

In analogy with the definition of SU(1,1) squeezing,[68] we have introduced $SU_q(1,1)$ squeezing[57] in terms of the Hermitian q-deformed quadrature operators

$$X_1 = \frac{K_+ + K_-}{2}, \quad X_2 = \frac{i(K_+ - K_-)}{2}, \tag{48}$$

which satisfy the commutation relation

$$[X_1, X_2] = \frac{i}{2}[2K_0] \tag{49}$$

and the uncertainty relation

$$\langle(\Delta X_1)^2\rangle\langle(\Delta X_2)^2\rangle \geqslant \tfrac{1}{16}|\langle[2K_0]\rangle|^2. \tag{50}$$

A state is said to be $SU_q(1,1)$ squeezed if

$$\langle(\Delta X_i)^2\rangle < \tfrac{1}{4}|\langle[2K_0]\rangle| \quad (i = 1 \text{ or } 2). \tag{51}$$

Let us now calculate the fluctuations (variances) of X_1 and X_2 with respect to the k-component q-deformed charge coherent states. Using (41)–(44) and (47), we get

$${}_0\langle\xi,\underline{q},k|K_+K_-|\xi,\underline{q},k\rangle_0 = |\xi|^2(N^0_{k\underline{q}})^2/(N^{k-1}_{k\underline{q}})^2, \tag{52}$$

$${}_m\langle\xi,\underline{q},k|K_+K_-|\xi,\underline{q},k\rangle_m = |\xi|^2(N^m_{k\underline{q}})^2/(N^{m-1}_{k\underline{q}})^2, \quad m = 1,2,\ldots,k-1. \tag{53}$$

In the meantime, for the states $|\xi,\underline{q},k\rangle_j$ $(k \geqslant 3)$, it always follows that

$$ {}_j\langle \xi,\underline{q},k|K_-|\xi,\underline{q},k\rangle_j = {}_j\langle \xi,\underline{q},k|K_-^2|\xi,\underline{q},k\rangle_j = 0, \quad j=0,1,\ldots,k-1. \tag{54} $$

Therefore, for $|\xi,\underline{q},k\rangle_0$ and $|\xi,\underline{q},k\rangle_m$ $(m=1,2,\ldots,k-1)$, the fluctuations are given by

$$ \begin{aligned} {}_0\langle \xi,\underline{q},k|(\Delta X_1)^2|\xi,\underline{q},k\rangle_0 &= {}_0\langle \xi,\underline{q},k|(\Delta X_2)^2|\xi,\underline{q},k\rangle_0 \\ &= \tfrac{1}{4}{}_0\langle \xi,\underline{q},k|[2K_0]|\xi,\underline{q},k\rangle_0 + \tfrac{1}{2}|\xi|^2(N_{k\underline{q}}^0)^2/(N_{k\underline{q}}^{k-1})^2, \end{aligned} \tag{55} $$

$$ \begin{aligned} {}_m\langle \xi,\underline{q},k|(\Delta X_1)^2|\xi,\underline{q},k\rangle_m &= {}_m\langle \xi,\underline{q},k|(\Delta X_2)^2|\xi,\underline{q},k\rangle_m \\ &= \tfrac{1}{4}{}_m\langle \xi,\underline{q},k|[2K_0]|\xi,\underline{q},k\rangle_m + \tfrac{1}{2}|\xi|^2(N_{k\underline{q}}^m)^2/(N_{k\underline{q}}^{m-1})^2. \end{aligned} \tag{56} $$

Consequently, for $k\geqslant 3$, we find

$$ \begin{aligned} {}_j\langle \xi,\underline{q},k|(\Delta X_1)^2|\xi,\underline{q},k\rangle_j &= {}_j\langle \xi,\underline{q},k|(\Delta X_2)^2|\xi,\underline{q},k\rangle_j \\ &\geqslant \tfrac{1}{4}{}_j\langle \xi,\underline{q},k|[2K_0]|\xi,\underline{q},k\rangle_j, \quad j=0,1,\ldots,k-1. \end{aligned} \tag{57} $$

The inequalities in (57) say that there is no $\mathrm{SU}_q(1,1)$ squeezing in the k-component q-deformed charge coherent states with $k\geqslant 3$. However, there is such squeezing in the even and odd q-deformed charge coherent states.[57]

It is easy to verify that the q-deformed charge coherent states satisfy the equality in (50) and that $\langle(\Delta X_1)^2\rangle=\langle(\Delta X_2)^2\rangle$. This point has been observed in Ref. 57. Therefore, the q-deformed charge coherent states are not $\mathrm{SU}_q(1,1)$ squeezed.

B. Single-mode *q*-squeezing

In analogy with the definition of single-mode squeezing,[27] we have introduced single-mode q-squeezing[57] in terms of the Hermitian q-deformed quadrature operators for the individual modes

$$ Y_1 = \frac{a_1^+ + a_1}{2}, \quad Y_2 = \frac{i(a_1^+ - a_1)}{2}, $$

$$ Z_1 = \frac{a_2^+ + a_2}{2}, \quad Z_2 = \frac{i(a_2^+ - a_2)}{2}, \tag{58} $$

which satisfy the commutation relations

$$ [Y_1,Y_2] = \frac{i}{2}[a_1,a_1^+], \quad [Z_1,Z_2] = \frac{i}{2}[a_2,a_2^+], \tag{59} $$

and the uncertainty relations

$$ \langle(\Delta Y_1)^2\rangle\langle(\Delta Y_2)^2\rangle \geqslant \tfrac{1}{16}|\langle[a_1,a_1^+]\rangle|^2, \quad \langle(\Delta Z_1)^2\rangle\langle(\Delta Z_2)^2\rangle \geqslant \tfrac{1}{16}|\langle[a_2,a_2^+]\rangle|^2. \tag{60} $$

A state is said to be single-mode q-squeezed if

$$ \langle(\Delta Y_i)^2\rangle < \tfrac{1}{4}|\langle[a_1,a_1^+]\rangle|, \quad \langle(\Delta Z_i)^2\rangle < \tfrac{1}{4}|\langle[a_2,a_2^+]\rangle| \quad (i=1 \text{ or } 2). \tag{61} $$

For the states $|\xi,\underline{q},k\rangle_j$ $(k\geqslant 1)$, it always follows that

$$ {}_j\langle a_1\rangle_j = {}_j\langle a_2\rangle_j = {}_j\langle a_1^2\rangle_j = {}_j\langle a_2^2\rangle_j = {}_j\langle a_1^+a_2\rangle_j = 0, \quad j=0,1,\ldots,k-1. \tag{62} $$

Thus, the fluctuations are given by

$$
\begin{aligned}
{}_j\langle \xi,\underline{q},k|(\Delta Y_1)^2|\xi,\underline{q},k\rangle_j &= {}_j\langle \xi,\underline{q},k|(\Delta Y_2)^2|\xi,\underline{q},k\rangle_j \\
&= \tfrac{1}{4}\{{}_j\langle \xi,\underline{q},k|[a_1,a_1^+]|\xi,\underline{q},k\rangle_j + 2{}_j\langle \xi,\underline{q},k|a_1^+a_1|\xi,\underline{q},k\rangle_j\} \\
&> \tfrac{1}{4}{}_j\langle \xi,\underline{q},k|[a_1,a_1^+]|\xi,\underline{q},k\rangle_j, \qquad (63)
\end{aligned}
$$

$$
\begin{aligned}
{}_j\langle \xi,\underline{q},k|(\Delta Z_1)^2|\xi,\underline{q},k\rangle_j &= {}_j\langle \xi,\underline{q},k|(\Delta Z_2)^2|\xi,\underline{q},k\rangle_j \\
&= \tfrac{1}{4}\{{}_j\langle \xi,\underline{q},k|[a_2,a_2^+]|\xi,\underline{q},k\rangle_j + 2{}_j\langle \xi,\underline{q},k|a_2^+a_2|\xi,\underline{q},k\rangle_j\} \\
&> \tfrac{1}{4}{}_j\langle \xi,\underline{q},k|[a_2,a_2^+]|\xi,\underline{q},k\rangle_j. \qquad (64)
\end{aligned}
$$

This shows that there is no single-mode q-squeezing in the k-component q-deformed charge coherent states with $k \geqslant 1$. As two special cases, there is no such q-squeezing in the q-deformed charge coherent states[65] and the even (odd) q-deformed charge coherent states[57] as k becomes 1 and 2, respectively.

C. Two-mode q-squeezing

In analogy with the definition of two-mode squeezing,[69] we have introduced two-mode q-squeezing[57] in terms of the Hermitian q-deformed quadrature operators for the two modes

$$
W_1 = \frac{Y_1 + Z_1}{\sqrt{2}} = \frac{1}{\sqrt{8}}(a_1^+ + a_2^+ + a_1 + a_2), \quad W_2 = \frac{Y_2 + Z_2}{\sqrt{2}} = \frac{i}{\sqrt{8}}(a_1^+ + a_2^+ - a_1 - a_2), \qquad (65)
$$

which satisfy the commutation relation

$$
[W_1, W_2] = \tfrac{1}{4}i\{[a_1,a_1^+] + [a_2,a_2^+]\} \qquad (66)
$$

and the uncertainty relation

$$
\langle(\Delta W_1)^2\rangle\langle(\Delta W_2)^2\rangle \geqslant \tfrac{1}{64}|\langle[a_1,a_1^+]\rangle + \langle[a_2,a_2^+]\rangle|^2. \qquad (67)
$$

A state is said to be two-mode q-squeezed if

$$
\langle(\Delta W_i)^2\rangle < \tfrac{1}{8}|\langle[a_1,a_1^+]\rangle + \langle[a_2,a_2^+]\rangle| \quad (i = 1 \text{ or } 2). \qquad (68)
$$

For the states $|\xi,\underline{q},k\rangle_j$ $(k \geqslant 2)$, the fluctuations are given by

$$
\begin{aligned}
{}_j\langle \xi,\underline{q},k|(\Delta W_1)^2|\xi,\underline{q},k\rangle_j &= {}_j\langle \xi,\underline{q},k|(\Delta W_2)^2|\xi,\underline{q},k\rangle_j \\
&= \tfrac{1}{2}\{{}_j\langle \xi,\underline{q},k|(\Delta Y_1)^2|\xi,\underline{q},k\rangle_j + {}_j\langle \xi,\underline{q},k|(\Delta Z_1)^2|\xi,\underline{q},k\rangle_j\} = \tfrac{1}{2}\{{}_j\langle \xi,\underline{q},k| \\
&\quad \times(\Delta Y_2)^2|\xi,\underline{q},k\rangle_j + {}_j\langle \xi,\underline{q},k|(\Delta Z_2)^2|\xi,\underline{q},k\rangle_j\} \\
&= \tfrac{1}{8}\{{}_j\langle \xi,\underline{q},k|[a_1,a_1^+]|\xi,\underline{q},k\rangle_j + {}_j\langle \xi,\underline{q},k|[a_2,a_2^+]|\xi,\underline{q},k\rangle_j \\
&\quad + 2{}_j\langle \xi,\underline{q},k|a_1^+a_1|\xi,\underline{q},k\rangle_j + 2{}_j\langle \xi,\underline{q},k|a_2^+a_2|\xi,\underline{q},k\rangle_j\} \\
&> \tfrac{1}{8}\{{}_j\langle \xi,\underline{q},k|[a_1,a_1^+]|\xi,\underline{q},k\rangle_j + {}_j\langle \xi,\underline{q},k|[a_2,a_2^+]|\xi,\underline{q},k\rangle_j\}. \qquad (69)
\end{aligned}
$$

This shows that there is no two-mode q-squeezing in the k-component q-deformed charge coherent states with $k \geqslant 2$. As a special case, there is no such q-squeezing in the even and odd q-deformed charge coherent states[57] as k becomes 2. However, there is such q-squeezing in the q-deformed charge coherent states.[65]

D. Two-mode q-antibunching

In analogy with the definition of two-mode antibunching,[36] we have introduced a two-mode q-correlation function as[57]

$$g^{(2)}(0) \equiv \frac{\langle (a_1^+ a_2^+)^2 (a_1 a_2)^2 \rangle}{\langle a_1^+ a_2^+ a_1 a_2 \rangle^2} = \frac{\langle :([N_1][N_2])^2: \rangle}{\langle [N_1][N_2] \rangle^2} = \frac{\langle K_+^2 K_-^2 \rangle}{\langle K_+ K_- \rangle^2}, \tag{70}$$

where a_i and a_i^+ represent the annihilation and creation operators of q-deformed photons of a deformed light field and $::$ denotes normal ordering. We call $g^{(2)}(0)$ the two-mode q-correlation degree. Physically, $g^{(2)}(0)$ is a measure of q-deformed two-photon correlations in the q-deformed two-mode field and is related to the q-deformed two-photon number distributions. A state is said to be two-mode q-antibunched if

$$g^{(2)}(0) < 1. \tag{71}$$

Let us now study the two-mode q-antibunching effect for the k-component q-deformed charge coherent states with $k \geqslant 3$. First, for $k \geqslant 3$, one can easily obtain the following relations:

$${}_0\langle \xi, \underline{q}, k | K_+^2 K_-^2 | \xi, \underline{q}, k \rangle_0 = |\xi|^4 (N_{k\underline{q}}^0)^2 / (N_{k\underline{q}}^{k-2})^2, \tag{72}$$

$${}_1\langle \xi, \underline{q}, k | K_+^2 K_-^2 | \xi, \underline{q}, k \rangle_1 = |\xi|^4 (N_{k\underline{q}}^1)^2 / (N_{k\underline{q}}^{k-1})^2, \tag{73}$$

$${}_l\langle \xi, \underline{q}, k | K_+^2 K_-^2 | \xi, \underline{q}, k \rangle_l = |\xi|^4 (N_{k\underline{q}}^l)^2 / (N_{k\ \underline{q}}^{l-2})^2, \quad l = 2,3,\ldots,k-1. \tag{74}$$

According to (52), (53), and (72)–(74), the two-mode q-correlation degrees of the k-component q-deformed charge coherent states can be obtained as follows:

$$g_0^{(2)}(0) = \frac{{}_0\langle \xi, \underline{q}, k | K_+^2 K_-^2 | \xi, \underline{q}, k \rangle_0}{({}_0\langle \xi, \underline{q}, k | K_+ K_- | \xi, \underline{q}, k \rangle_0)^2} = \frac{(N_{k\underline{q}}^{k-1})^4}{(N_{k\underline{q}}^0)^2 (N_{k\underline{q}}^{k-2})^2}, \tag{75}$$

$$g_1^{(2)}(0) = \frac{{}_1\langle \xi, \underline{q}, k | K_+^2 K_-^2 | \xi, \underline{q}, k \rangle_1}{({}_1\langle \xi, \underline{q}, k | K_+ K_- | \xi, \underline{q}, k \rangle_1)^2} = \frac{(N_{k\underline{q}}^0)^4}{(N_{k\underline{q}}^1)^2 (N_{k\underline{q}}^{k-1})^2}, \tag{76}$$

$$g_l^{(2)}(0) = \frac{{}_l\langle \xi, \underline{q}, k | K_+^2 K_-^2 | \xi, \underline{q}, k \rangle_l}{({}_l\langle \xi, \underline{q}, k | K_+ K_- | \xi, \underline{q}, k \rangle_l)^2} = \frac{(N_{k\underline{q}}^{l-1})^4}{(N_{k\underline{q}}^{l-2})^2 (N_{k\underline{q}}^l)^2}, \quad l = 2,3,\ldots,k-1. \tag{77}$$

Evidently, the following relation exists:

$$\prod_{j=0}^{k-1} g_j^{(2)}(0) = 1. \tag{78}$$

We shall prove that for $k \geqslant 3$, the k-component q-deformed charge coherent states show two-mode q-antibunching.

From (12) and (75), it follows that

$$g_0^{(2)}(0) = \frac{f(x)}{x^k \varphi(x)},$$

where

$$f(x) = \sum_{m=0}^{\infty} \left\{ \sum_{n=0}^{m} \frac{1}{[kn]\,![kn + |\underline{q}|]\,![km - kn + k - 2]\,![km - kn + k - 2 + |\underline{q}|]!} \right\} x^{km},$$

$$\varphi(x)=\sum_{m=0}^{\infty}\left\{\sum_{n=0}^{m}\frac{1}{[kn+k-1]![kn+k-1+|\underline{q}|]![km-kn+k-1]![km-kn+k-1+|\underline{q}|]!}\right\}x^{km}$$

and $x=|\xi|^2$. For $k\geqslant 3$, we have

$$\sum_{n=0}^{m}\frac{1}{[kn]![kn+|\underline{q}|]![km-kn+k-2]![km-kn+k-2+|\underline{q}|]!}$$
$$>\sum_{n=0}^{m}\frac{1}{[kn+k-1]![kn+k-1+|\underline{q}|]![km-kn+k-1]![km-kn+k-1+|\underline{q}|]!},$$

and thus $f(x)>\varphi(x)$ when $x>0$. Hence, $g_0^{(2)}(0)>1$ when $0<x\leqslant 1$. However, when $x>1$, the following inequality,

$$\frac{f(x)}{x^k\varphi(x)}<1,\quad \text{i.e.}, x^k>\frac{f(x)}{\varphi(x)},$$

may have real roots. Consequently, in the region of $x>1$, for arbitrary fixed values of $\underline{q}$ and q, there surely exists some range of x values such that

$$g_0^{(2)}(0)=\frac{f(x)}{x^k\varphi(x)}<1.$$

To make the above statement clear, we plot $g_0^{(2)}(0)$ against x for various k, $\underline{q}$, and q in Fig. 1.

From (12) and (76), it follows that

$$g_1^{(2)}(0)=\frac{x^k f_1(x)}{\varphi_1(x)},$$

where

$$f_1(x)=\sum_{m=0}^{\infty}\left\{\sum_{n=0}^{m}\frac{1}{[kn+1]![kn+1+|\underline{q}|]![km-kn+k-1]![km-kn+k-1+|\underline{q}|]!}\right\}x^{km},$$

$$\varphi_1(x)=\sum_{m=0}^{\infty}\left\{\sum_{n=0}^{m}\frac{1}{[kn]![kn+|\underline{q}|]![km-kn]![km-kn+|\underline{q}|]!}\right\}x^{km}.$$

Apparently,

$$\sum_{n=0}^{m}\frac{1}{[kn+1]![kn+1+|\underline{q}|]![km-kn+k-1]![km-kn+k-1+|\underline{q}|]!}$$
$$<\sum_{n=0}^{m}\frac{1}{[kn]![kn+|\underline{q}|]![km-kn]![km-kn+|\underline{q}|]!},$$

so that $f_1(x)<\varphi_1(x)$. Therefore, $g_1^{(2)}(0)<x^k$, namely, $g_1^{(2)}(0)<1$ as $x\leqslant 1$.

From (12) and (77), it follows that

$$g_l^{(2)}(0)=\frac{f_2(x)}{\varphi_2(x)},$$

where

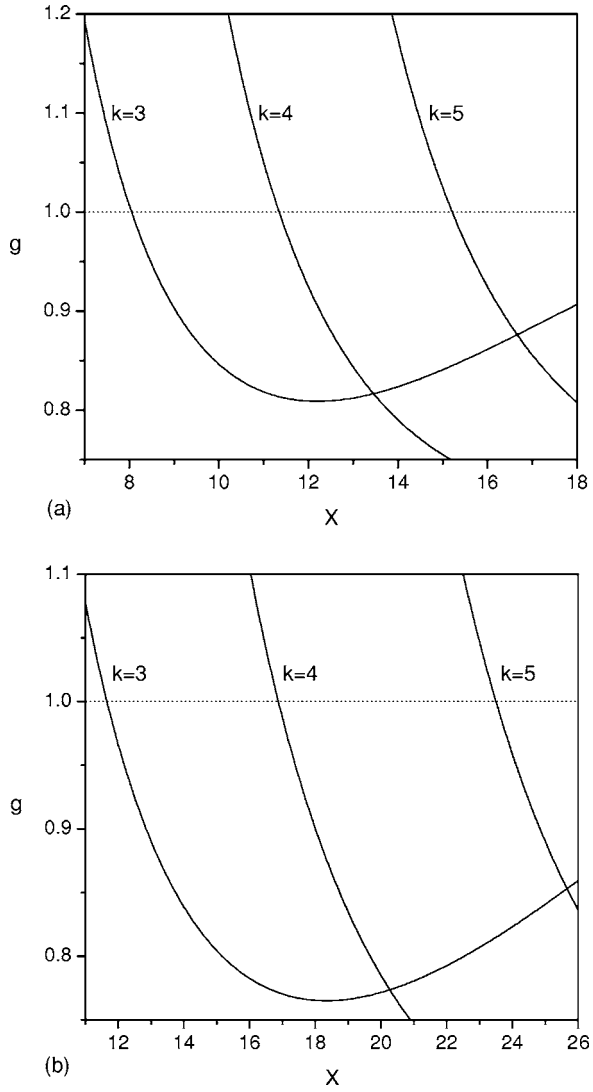

FIG. 1. $g\,[\equiv g_0^{(2)}(0)]$ against x for $k=3$, 4, 5, with (a) $\underline{q}=\pm 2$, $q=0.9$ and (b) $\underline{q}=\pm 3$, $q=0.8$.

$$f_2(x)=\sum_{m=0}^{\infty}\left\{\sum_{n=0}^{m}\frac{1}{[kn+l-2]\,![kn+l-2+|\underline{q}|]\,![km-kn+l]\,![km-kn+l+|\underline{q}|]!}\right\}x^{km},$$

$$\varphi_2(x)=\sum_{m=0}^{\infty}\left\{\sum_{n=0}^{m}\frac{1}{[kn+l-1]\,![kn+l-1+|\underline{q}|]\,![km-kn+l-1]\,![km-kn+l-1+|\underline{q}|]!}\right\}x^{km}.$$

Obviously,

$$f_2(x)<\frac{1}{[l-2]\,![l-2+|\underline{q}|]\,![l]\,![l+|\underline{q}|]!}\sum_{m=0}^{\infty}(m+1)x^{km},$$

$$\varphi_2(x) > \sum_{m=0}^{\infty} \frac{(m+1)x^{km}}{\{[km+l-1]![km+l-1+|\underline{q}|]!\}^2} > \frac{1}{\{[l-1]![l-1+|\underline{q}|]!\}^2}.$$

Thus, we obtain

$$g_l^{(2)}(0) < \frac{\{[l-1]![l-1+|\underline{q}|]!\}^2}{[l-2]![l-2+|\underline{q}|]![l]![l+|\underline{q}|]!} \sum_{m=0}^{\infty} (m+1)x^{km}.$$

For $x<1$, it reads

$$\sum_{m=0}^{\infty} (m+1)x^{km} = \frac{1}{(1-x^k)^2}.$$

Therefore, as $x<1$, we get

$$g_l^{(2)}(0) < \frac{[l-1][l-1+|\underline{q}|]}{[l][l+|\underline{q}|]} \frac{1}{(1-x^k)^2}.$$

As a result, if $x^k \leqslant 1-\{[l-1][l-1+|\underline{q}|]/[l][l+|\underline{q}|]\}^{1/2}$, then

$$g_l^{(2)}(0) < 1, \quad l=2,3,\ldots,k-1.$$

From the above discussion, we see that for $k \geqslant 3$, the two-mode q-correlation degrees $g_j^{(2)}(0)$ $(j=0,1,\ldots,k-1)$ can be less than 1 over some particular range of x values. This indicates that two-mode q-antibunching exists for the k-component q-deformed charge coherent states with $k \geqslant 3$. The same situation occurs for the even and odd q-deformed charge coherent states.[57] However, for the q-deformed charge coherent states we have $g^{(2)}(0)=1$ so that no two-mode q-antibunching exists.

It can be shown that in the limit $q \to 1$, the nonclassical properties of the usual k-component charge coherent states, studied in Ref. 37, are retrieved as expected.

VII. SUMMARY

Let us sum up the results obtained in the present paper.

(1) The k-component q-deformed charge coherent states, defined as the k $(k \geqslant 1)$ orthonormalized eigenstates of both the kth power of the pair q-boson annihilation operator and the charge operator, have been constructed and their (over)completeness proved. Such q-deformed states become the usual k-component charge coherent states in the limit $q \to 1$. They become the q-deformed charge coherent states and the even (odd) q-deformed charge coherent states in the two special cases of $k=1$ and $k=2$, respectively.

(2) The k-component q-deformed charge coherent states have been shown to be generated by a suitable average over the U (1)-group (caused by the charge operator) action on the product of q-deformed coherent states and k-component q-deformed coherent states.

(3) The D-algebra of the $SU_q(1,1)$ generators corresponding to the k-component q-deformed charge coherent states has been realized in a q-differential-operator matrix form.

(4) For $k \geqslant 3$, the k-component q-deformed charge coherent states have been shown to exhibit two-mode q-antibunching, but neither $SU_q(1,1)$ squeezing, nor single- or two-mode q-squeezing.

Stargenfunctions, generally parametrized systems and a causal formulation of phase space quantum mechanics

Nuno Costa Dias[a] and João Nuno Prata[b]
Departamento de Matemática, Universidade Lusófona de Humanidades e Tecnologias, Av. Campo Grande, 376, 1749-024 Lisboa, Portugal

(Received 14 January 2005; accepted 11 May 2005; published online 13 July 2005)

We address the deformation quantization of generally parametrized systems displaying a natural time variable. The purpose of this exercise is twofold: first, to illustrate through a pedagogical example the potential of quantum phase space methods in the context of constrained systems and particularly of generally covariant systems. Second, to show that a causal representation for quantum phase space quasidistributions can be easily achieved through general parametrization. This result is succinctly discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1948327]

I. INTRODUCTION

Generally covariant systems are a particular kind of dynamical systems in which time is included among the canonical variables.[1] The state of the system evolves along orbits parametrized by an unphysical scalar parameter. The formalism is invariant under reparametrizations of this parameter (for this reason these systems are also called general parametrized systems) leading to a gauge symmetry, which in the Hamiltonian formulation is implemented by a first class (Hamiltonian) constraint. One of the most striking properties of generally covariant theories is that the Hamiltonian is identically zero on the constraint hypersurface. Consequently there is no standard Hamiltonian time evolution (which coincides exactly with the gauge transformation). Instead, dynamics is to be found among the relations between the canonical variables that are determined by the Hamiltonian constraint.[2–4] In other words, dynamics is the unfolding of the gauge transformation. The most famous example of a generally covariant theory is, of course, general relativity.[5–7]

Upon quantization these systems display a number of technical and conceptual problems which, motivated by the quest to quantize general relativity, have been intensively studied in the literature. Since the publication of Dirac's seminal work on the quantization of constrained systems,[8] several quantization programs have been developed with the aim of refining Dirac's approach and making it suitable to address the generally covariant case.[1,6,9–11] In spite of this, several important problems concerning the quantization of these systems (the problem of time, the observables' problem and the measurement problem, just to mention a few) are still lacking a definitive answer.[3,4,10]

One quantization program that has only been scarcely explored in this context is the deformation approach.[12–22] And this regardless of the fact that the deformation quantization method displays some remarkable features that make it especially suitable to address the generally covariant case.[23–25] On the one hand, the deformation approach leads to a formulation of quantum mechanics in terms of classical-like objects. The theory lives in phase space and mimics the structure of classical statistical mechanics. The state of the system is described by a phase space

[a]Electronic mail: ncdias@mail.telepac.pt
[b]Electronic mail: joao.prata@ulusofona.pt

quasidistribution and observables are also functionals on the phase space. From the deformation point of view quantization amounts to the substitution of the standard product of functions by a noncommutative star product.[21,22] The theory has been proved useful when addressing a wide range of fields of research ranging from topics in nonrelativistic quantum mechanics[16,26–29] to some current developments in M-theory.[30–32] In the context of generally covariant systems it has been advocated that the relation between classical statistical and standard operator quantum mechanics should be emphasized when approaching the quantization of these systems.[33] The point of view is that the problems besetting their quantization, being to a large extent conceptual ones, may receive key physical insights from the more intuitive classical statistical analysis. From this perspective the deformation methods seem to be especially suited.

On the technical side the deformation approach acquired the status of a powerful mathematical theory not displaying any of the subtleties of the path integral or canonical quantization prescriptions. Most remarkable is the fact that the theory is able to generate the quantum version of a classical system living on a generic (possibly curved) Poisson or sympletic manifold.[34–37] Of special relevance for generally covariant systems is that the deformation approach displays some powerful tools to address the quantum eigenvalue problem, the most meaningful of which being a covariant formalism unifying all distinct phase space representations of the eigenvalue problem,[21,38,39] a formal solution of a generic stargenvalue equation[19,40] and a set of efficient methods to determine the semiclassical expansion of the stargenfunctions.[41,42]

In this paper we aim at providing a pedagogical incursion into some of these methods by studying the deformation quantization of a special simple kind of generally covariant systems, those obtained by parametrizing an originally noncovariant version of the system. The parametrization procedure leads to a formulation of the dynamics living on an enlarged phase space where the physical time is incorporated as a canonical variable.[1] The existence of such a natural time variable considerably simplifies the (technical and conceptual) analysis of the dynamical structure of the system. For this reason these models have been used[1,3,4] to test a set of quantization techniques and interpretative prescriptions aiming at addressing the far more difficult problem of quantizing "already parametrized systems" of which the most significant example is general relativity.

The Hamiltonians of these models (as in the general case) are identically zero on the constraint hypersurface. At the quantum level the imposition of this constraint determines the physical states of the system. In the deformation context the imposition of first class constraints yields a stargenvalue equation[19,43] and so the physical states are the zero stargenfunctions of the Hamiltonian symbol. We are then able to apply the powerful tools of the deformation approach to study the quantum eigenvalue problem. A complete characterization of the physical states will be provided in three different phase space representations. In particular, we obtain a representation where the dynamics of the quasidistribution (with respect to the physical time variable) is dictated by the classical Liouville equation. This is an interesting side result that shows that through general parametrization a causal formulation for the distributional sector of quantum mechanics is made possible. More generally we find that the remarkable parallelism between classical statistical mechanics and phase space quantum mechanics carries on intact to the generally covariant setting, a property that establishes a promising starting point for the future research on the deformation quantization of generally covariant systems.

II. COVARIANT WIGNER QUANTUM MECHANICS

The aim of this section is to review the main structures of the covariant formulation of the deformation quantization procedure. Our analysis will be restricted to the case of flat phase space as we will be dealing only with systems of this sort. The reader should refer to Refs. 36 and 38 for a more detailed presentation of these results and to Refs. 35 and 37 for the generalization of the formalism to the nonflat case. An important part of this section [Eqs. (9)–(15)] focuses on the covariant generalization of the $*$-genvalue equation, once again, just for the flat case. This is a topic that will play an important role latter on.

Before proceeding and to avoid future misunderstandings let us make the following remark:

Throughout the paper the word *covariant* will be used in two different contexts, to designate the invariance under time reparametrizations of the original classical system and to designate the invariance under general coordinate transformations of the Moyal plane. The aim of this paper is to present the deformation quantization of a generally covariant (parametrized) classical system. We use the covariant version of the deformation quantization procedure (a subject where this paper makes no original contribution) because this leads to a larger set of possible quantum phase space representations, among which we will find the causal representation presented in Sec. IV.

Let us then settle down the preliminaries. We consider a N-dimensional dynamical system, its classical formulation living on the flat phase space T^*M. A set of global canonical coordinates $(\{q_i,p_i,i=1,\ldots,N\})$ can then be defined on T^*M in terms of which the sympletic structure reads $w=\mathrm{d}q_i\wedge\mathrm{d}p_i$. Upon quantization the set $\{\hat{q}_i\}$ constitutes a complete set of commuting observables. Let us introduce the vector notation $\hat{\vec{q}}=(\hat{q}_1,\ldots,\hat{q}_N)$ and designate by $|\vec{q}\rangle$ the general eigenstate of $\hat{\vec{q}}$ associated to the array of eigenvalues $\vec{q}$ and spanning the Hilbert space $\mathcal{H}$ of the system. Let also $\mathcal{A}(\mathcal{H})$ be the algebra of quantum observables over $\mathcal{H}$ and $\mathcal{A}(T^*M)$ the algebra of classical functions over the classical phase space T^*M. Let $(\vec{Q},\vec{P})$ be a second set of phase space coordinates, related to $(\vec{q},\vec{p})$ by a generic phase space diffeomorphism (not necessarily canonical), $\vec{q}=\vec{q}(\vec{Q},\vec{P})$ and $\vec{p}=\vec{p}(\vec{Q},\vec{P})$. The covariant Weyl transform,[38]

$$
\begin{aligned}
&W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}:\mathcal{A}(\mathcal{H})\to\mathcal{A}(T^*M),\\
&\hat{A}\to W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{A})=\hbar^N\int \mathrm{d}^N\vec{x}\int \mathrm{d}^N\vec{y}\,e^{-i\vec{p}(\vec{Q},\vec{P})\cdot\vec{y}}\delta(\vec{x}-\vec{q}(\vec{Q},\vec{P}))\left\langle \vec{x}+\frac{\hbar}{2}\vec{y}|\hat{A}|\vec{x}-\frac{\hbar}{2}\vec{y}\right\rangle,
\end{aligned}
\tag{1}
$$

where $|\vec{x}\pm(\hbar/2)\vec{y}\rangle$ are eigenstates of $\hat{\vec{q}}$, yields the entire structure of covariant phase space quantum mechanics. The map $W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}$ can be applied both to an observable $\hat{A}$ as well as to the density matrix $|\psi(t)\rangle\langle\psi(t)|$. In the first case it yields the $^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}$-Weyl symbol $A'(\vec{Q},\vec{P})=W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{A})$ of the original quantum operator and, in the second case, the celebrated Wigner function $f'_W(\vec{Q},\vec{P},t)=[1/(2\pi\hbar)^N]W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(|\psi(t)\rangle\langle\psi(t)|)$. Notice that if $(\vec{Q},\vec{P})=(\vec{q},\vec{p})$ then the covariant map $W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}$ reduces to the standard Weyl transform in the variables $(\vec{q},\vec{p})$. In this case we will use the notation $W_{(\vec{q},\vec{p})}$ to designate $W^{(\vec{q},\vec{p})}_{(\vec{q},\vec{p})}$. Notice also that $A'(\vec{Q},\vec{P})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))$ where $A(\vec{q},\vec{p})=W_{(\vec{q},\vec{p})}(\hat{A})$ and the same relation is valid for the Wigner function. The covariant Weyl map implements the transformation $(\vec{q},\vec{p})\to(\vec{Q},\vec{P})$ as a coordinate transformation in quantum phase space and defines a covariant star-product $*'_{(\vec{Q},\vec{P})}$ and Moyal bracket $[,]_{M'_{(\vec{Q},\vec{P})}}$ (Refs. 21 and 38) $(\hat{A},\hat{B}\in\mathcal{A}(H))$,

$$
\begin{aligned}
&W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{A}\hat{B})=W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{A})*'_{(\vec{Q},\vec{P})}W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{B}),\\
&W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}\left(\frac{1}{i\hbar}[\hat{A},\hat{B}]\right)=[W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{A}),W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{B})]_{M'_{(\vec{Q},\vec{P})}},
\end{aligned}
\tag{2}
$$

which display the functional form

$$
A'(\vec{Q},\vec{P})*'_{(\vec{Q},\vec{P})}B'(\vec{Q},\vec{P})=A'(\vec{Q},\vec{P})e^{(i\hbar/2)\overleftarrow{\nabla}'_i J'^{ij}_{(\vec{Q},\vec{P})}\overrightarrow{\nabla}'_j}B'(\vec{Q},\vec{P}),
$$

$$[A'(\vec{Q},\vec{P}),B'(\vec{Q},\vec{P})]_{M'_{(\vec{Q},\vec{P})}}=\frac{2}{\hbar}A'(\vec{Q},\vec{P})\sin\left(\frac{\hbar}{2}\overleftarrow{\nabla}'_i J'^{ij}_{(\vec{Q},\vec{P})}\overrightarrow{\nabla}'_j\right)B'(\vec{Q},\vec{P}), \tag{3}$$

where the covariant derivative is given by (let $O'^i=P_i$, $O^i=p_i$, $i=1,\ldots,N$; $O'^i=Q_{i-N}$, $O^i=q_{i-N}$, $i=N+1,\ldots,2N$)

$$\nabla'_i A'=\partial'_i A', \quad \nabla'_i\nabla'_j A'=\partial'_i\partial'_j A'-\Gamma'^k_{ij}\partial'_k A', \quad \partial'_i=\partial/\partial O'^i, \quad i,j,k=1,\ldots,2N, \tag{4}$$

and

$$J'^{ij}_{(\vec{Q},\vec{P})}(\vec{Q},\vec{P})=\frac{\partial O'^i}{\partial O^k}\frac{\partial O'^j}{\partial O^l}J^{kl}_{(\vec{q},\vec{p})}, \quad \Gamma'^i_{jk}(\vec{Q},\vec{P})=\frac{\partial O'^i}{\partial O^b}\frac{\partial^2 O^b}{\partial O'^j\,\partial O'^k}, \tag{5}$$

are the symplectic structure and Poisson connection associated with the coordinates $(\vec{Q},\vec{P})$, respectively. Finally, notice that in Eq. (5) we explicitly took into account the phase space flat structure.

When formulated in terms of these structures Wigner mechanics becomes fully invariant under the action of general phase space diffeomorphisms,

$$A'(\vec{Q},\vec{P})*'_{(\vec{Q},\vec{P})}B'(\vec{Q},\vec{P})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))*_{(\vec{q},\vec{p})}B(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})) \quad \forall_{A,B\in\mathcal{A}(T^*M)}, \tag{6}$$

the covariant generalization of the Moyal and stargenvalue equations reading

$$\frac{\partial f'_W}{\partial t}=[H',f'_W]_{M'_{(\vec{Q},\vec{P})}},$$

$$A'(\vec{Q},\vec{P})*'_{(\vec{Q},\vec{P})}\rho'_{a;b}(\vec{Q},\vec{P})=a\rho'_{a;b}(\vec{Q},\vec{P}), \tag{7}$$

$$\rho'_{a;b}(\vec{Q},\vec{P})*'_{(\vec{Q},\vec{P})}A'(\vec{Q},\vec{P})=b\rho'_{a;b}(\vec{Q},\vec{P}),$$

where $\rho'_{a;b}(\vec{Q},\vec{P})$ is the a-left and b-right $*'_{(\vec{Q},\vec{P})}$-genfunction of $A'(\vec{Q},\vec{P})$. These equations transform covariantly under arbitrary phase space diffeomorphisms yielding, in any coordinates, identical mathematical solutions and thus identical physical predictions,

$$P(A'(\vec{Q},\vec{P};t)=a)=\int \mathrm{d}^N\vec{Q}\int \mathrm{d}^N\vec{P}(\det J'^{ij}_{(\vec{Q},\vec{P})})^{-1/2}\rho'_{a;a}(\vec{Q},\vec{P})f'_W(\vec{Q},\vec{P};t). \tag{8}$$

Let us consider the stargenvalue equation (7) in more detail. Let $\{\hat{A}_1,\ldots,\hat{A}_N\}$ and $\{\hat{B}_1,\ldots,\hat{B}_N\}$ be two sets of commuting observables satisfying $[\hat{A}_i,\hat{B}_j]=i\hbar\,\delta_{ij}$. Let $A'_i(\vec{Q},\vec{P})=W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{A}_i)$ and $B'_i(\vec{Q},\vec{P})=W^{(\vec{q},\vec{p})}_{(\vec{Q},\vec{P})}(\hat{B}_i)$. Then the simultaneous solution of

$$\begin{aligned}A'_i(\vec{Q},\vec{P})*'_{(\vec{Q},\vec{P})}\rho'_{a_1,\ldots,a_N;b_1,\ldots,b_N}(\vec{Q},\vec{P})&=a_i\rho_{a_1,\cdots,a_N;b_1,\ldots,b_N}(\vec{Q},\vec{P}),\\ \rho'_{a_1,\ldots,a_N;b_1,\ldots,b_N}(\vec{Q},\vec{P})*'_{(\vec{Q},\vec{P})}A'_i(\vec{Q},\vec{P})&=b_i\rho_{a_1,\ldots,a_N;b_1,\ldots,b_N}(\vec{Q},\vec{P}), \quad i=1,\ldots,N\end{aligned} \tag{9}$$

is given by[19]

$$\rho'_{a_1,\ldots,a_N;b_1,\ldots,b_N}(\vec{Q},\vec{P})\equiv\Delta_{*'_{(\vec{Q},\vec{P})}}(A'_1,\ldots,A'_N;a_1,\ldots,a_N;b_1,\ldots,b_N)=\prod_{i=1}^{N}*'_{(\vec{Q},\vec{P})}\rho'_{a_i;b_i}(\vec{Q},\vec{P}), \tag{10}$$

$$\rho'_{a_i;b_i}(\vec{Q},\vec{P}) \equiv \Delta_{*'_{(\vec{Q},\vec{P})}}(A'_i;a_i;b_i) = \frac{1}{2\pi} e^{(i/\hbar)(b_i-a_i)B'_i(\vec{Q},\vec{P})} *'_{(\vec{Q},\vec{P})} \int \mathrm{d}k\, e^{ik(A'_i(\vec{Q},\vec{P})-b_i)}_{*'_{(\vec{Q},\vec{P})}}, \tag{11}$$

where $\Pi^N_{i=i*'_{(\vec{Q},\vec{P})}}$ is the N-fold star-product and the star-exponential $e^{ikA'_i(\vec{Q},\vec{P})}_{*'_{(\vec{Q},\vec{P})}} \equiv E_{*'_{(\vec{Q},\vec{P})}}(k,\vec{Q},\vec{P})$ is defined as the solution of the differential problem, $(\partial/\partial k)E_{*'_{(\vec{Q},\vec{P})}}(k,\vec{Q},\vec{P}) = iA'_i(\vec{Q},\vec{P}) *'_{(\vec{Q},\vec{P})} E_{*'_{(\vec{Q},\vec{P})}}(k,\vec{Q},\vec{P})$ and $E_{*'_{(\vec{Q},\vec{P})}}(0,\vec{Q},\vec{P}) = 1$, which is unique for the Weyl symbol $A'_i(\vec{Q},\vec{P})$ of a generic self-adjoint operator $\hat{A}_i$ (a result that is just the Weyl-Wigner translation of an equivalent result in operator quantum mechanics[44]). Furthermore $E_{*'_{(\vec{Q},\vec{P})}}(k,\vec{Q},\vec{P}) = \Sigma^{+\infty}_{n=1}[(ik)^n/n!]\Pi^n_{j=1*'_{(\vec{Q},\vec{P})}} A'_i(\vec{Q},\vec{P})$ whenever k is in the radius of convergence of the series, which justifies the notation used in Eq. (11). We also introduced the $*$-delta notation $\Delta_{*'_{(\vec{Q},\vec{P})}}(A'_1,\ldots,A'_N;a_1,\ldots,a_N;b_1,\ldots,b_N)$ that will be extensively used later on. Notice that the stargenfunctions $\rho'_{a_1,\ldots,a_N;b_1,\ldots,b_N}(\vec{Q},\vec{P})$ are the $\frac{(\vec{q},\vec{p})}{(\vec{Q},\vec{P})}$-Weyl transform of the projectors $|a_1,\ldots,a_N\rangle\langle b_1,\ldots,b_N|$ where $|a_1,\ldots,a_N\rangle$ and $|b_1,\ldots,b_N\rangle$ are simultaneous eigenvectors of $\hat{A}_i, i=1,\ldots,N$. Moreover the stargenfunctions $\rho'_{a_i;b_i}(\vec{Q},\vec{P})$ are the $\frac{(\vec{q},\vec{p})}{(\vec{Q},\vec{P})}$-Weyl transform of the projector

$$|a_i\rangle\langle b_i| = \int \mathrm{d}\vec{z}\,|a_i,\vec{z}\rangle\langle b_i,\vec{z}| = \frac{1}{2\pi}\int \mathrm{d}k\, e^{(i/\hbar)(b_i-a_i)\hat{B}_i} e^{ik(\hat{A}_i-b_i)}, \tag{12}$$

where $\vec{z}=(a_1,\ldots,a_{i-1},a_{i+1},\ldots,a_N)$ is the $N-1$ array of degeneracy indices. The Weyl transform of the first identity in Eq. (12) yields the inverse relation of Eq. (10),

$$\rho'_{a_i;b_i}(\vec{Q},\vec{P}) = \int \mathrm{d}a_1 \cdots \mathrm{d}a_{i-1}\,\mathrm{d}a_{i+1} \cdots \mathrm{d}a_N\, \rho'_{a_1,\ldots,a_i,\ldots,a_N;a_1,\ldots,b_i,\ldots,a_N}(\vec{Q},\vec{P}). \tag{13}$$

Finally, the diagonal elements $\rho'_{a_i;a_i}(\vec{Q},\vec{P})$ are given by

$$\rho'_{a_i;a_i}(\vec{Q},\vec{P}) = \frac{1}{2\pi}\int \mathrm{d}k\, e^{ik(A'_i(\vec{Q},\vec{P})-a_i)}_{*'_{(\vec{Q},\vec{P})}} = \Delta_{*'_{(\vec{Q},\vec{P})}}(A'_i;a_i;a_i) \equiv \Delta_{*'_{(\vec{Q},\vec{P})}}(A'_i-a_i), \tag{14}$$

this being the object that enters the probability functional (8). The stargenfunctions (10) and (11) transform as scalars under arbitrary phase space coordinate transformations. For instance $\rho'_{a_i;a_i}(\vec{Q},\vec{P})$ satisfies

$$\rho'_{a_i;a_i}(\vec{Q},\vec{P}) = \Delta_{*'_{(\vec{Q},\vec{P})}}(A'_i(\vec{Q},\vec{P})-a_i) = \Delta_{*_{(\vec{q},\vec{p})}}(A_i(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))-a_i) = \rho_{a_i;a_i}(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})), \tag{15}$$

where $\rho_{a_i;a_i}(\vec{q},\vec{p})$ is the diagonal solution of the stargenvalue equation in the $(\vec{q},\vec{p})$-representation.

Last, we should point out that the former results (in the presented form) are valid whenever we are able to provide the complete sets of commuting observables $\{\hat{A}_i\}$ and $\{\hat{B}_i\}$. In fact this restriction can be considerably weakened. It is crucial to the overall approach that the complete set $\{\hat{A}_i\}$ exists, but the requirement on the existence of the set $\{\hat{B}_i\}$ can be discarded, while preserving the validity of Eqs. (8), (10), (13), and (14) exactly and that of Eqs. (11) and (12) under slight modifications. This is the case, for instance, when $\hat{A}_i$ displays a discrete spectrum. The reader should refer to Ref. 19 for a detailed presentation of these results.

III. DEFORMATION QUANTIZATION OF A PARAMETRIZED NONRELATIVISTIC SYSTEM

Let us consider an arbitrary N-dimensional dynamical system with configuration variables $\vec{q}=(q_1,\ldots,q_N)$, described by the Lagrangian $L_0(\vec{q},\mathrm{d}\vec{q}/\mathrm{d}t)$. Starting from the standard action $S=\int \mathrm{d}t\, L_0(\vec{q},\mathrm{d}\vec{q}/\mathrm{d}t)$ we impose the time reparametrization invariance by introducing an unphysical time τ and promoting t to a configuration variable. The action is now rewritten as[1]

$$S=\int \mathrm{d}\tau\, \dot{t} L_0\left(\vec{q},\frac{\dot{\vec{q}}}{\dot{t}}\right), \tag{16}$$

where the overdot represents the derivative with respect to τ. The Legendre transform yields the Hamiltonian formulation living in a $(2N+2)$-dimensional phase space spanned by the canonical variables $t,P_t,\vec{q},\vec{p}$ where $P_t=\partial L/\partial \dot{t}$, $p_i=\partial L/\partial \dot{q}_i$, $i=1,\ldots,N$ and $L(t,\dot{t},\vec{q},\dot{\vec{q}})=\dot{t}L_0(\vec{q},\dot{\vec{q}}/\dot{t})$. This, as expected, is a "zero-Hamiltonian" system,

$$H=\lambda\phi, \quad \phi=P_t+H_0(\vec{q},\vec{p}), \tag{17}$$

where ϕ is a first class constraint, λ is a Lagrange multiplier, and H_0 is the Hamiltonian associated to the original Lagrangian L_0.

Dirac's quantization procedure imposes the constraint as a restriction on the space of physical states, $\hat{\phi}|\psi\rangle=0$. In the density matrix formulation this equation reads

$$\hat{\phi}|\psi\rangle\langle\psi|=|\psi\rangle\langle\psi|\hat{\phi}=0. \tag{18}$$

To find the complete specification of its solutions, and according to the general method of Sec. II, the first step is to introduce the complete set of observables $\{\hat{\phi},\hat{\vec{A}}=(\hat{A}_1,\ldots,\hat{A}_N)\}$ and the set of operators $\hat{\vec{B}}=(\hat{B}_1,\ldots,\hat{B}_N)$, generators of translations in the spectrum of $\hat{\vec{A}}$, satisfying $[\hat{A}_j,\hat{B}_k]=i\hbar\delta_{jk}$ and $[\hat{\phi},\hat{B}_k]=0, j,k=1,\ldots,N$. We easily find that

$$\hat{A}_j=\hat{F}_j(\hat{\vec{q}},\hat{\vec{p}},-\hat{t}), \quad \hat{B}_k=\hat{G}_k(\hat{\vec{q}},\hat{\vec{p}},-\hat{t}), \tag{19}$$

where $\hat{F}_j(\hat{\vec{q}},\hat{\vec{p}},t)$ and $\hat{G}_k(\hat{\vec{q}},\hat{\vec{p}},t)$ are the solutions of the original Heisenberg equations,

$$\frac{\partial \hat{F}_j}{\partial t}=[\hat{F}_j,\hat{H}_0], \quad \frac{\partial \hat{G}_k}{\partial t}=[\hat{G}_k,\hat{H}_0], \quad j,k=1,\ldots,N \tag{20}$$

together with the initial conditions $\hat{F}_j(\hat{\vec{q}},\hat{\vec{p}},0)=\hat{q}_j$ and $\hat{G}_k(\hat{\vec{q}},\hat{\vec{p}},0)=\hat{p}_k$, satisfy the aforementioned requirements. $\hat{\vec{A}}$ and $\hat{\vec{B}}$ are the quantum histories of the system.

The phase space representation of Eq. (18) is determined by the Weyl transform. We may write

$$\phi *_{(t,\phi,\vec{A},\vec{B})} f_W(t,\phi,\vec{A},\vec{B})=f_W(t,\phi,\vec{A},\vec{B})*_{(t,\phi,\vec{A},\vec{B})}\phi=0 \tag{21}$$

by using the map $W_{(t,\phi,\vec{A},\vec{B})}$ or equivalently

$$\phi(t,P_t,\vec{q},\vec{p})*_{(t,P_t,\vec{q},\vec{p})} f_W(t,P_t,\vec{q},\vec{p})=f_W(t,P_t,\vec{q},\vec{p})*_{(t,P_t,\vec{q},\vec{p})}\phi(t,P_t,\vec{q},\vec{p})=0 \tag{22}$$

by using the map $W_{(t,P_t,\vec{q},\vec{p})}$. We start by considering the simplest representation, which is provided by Eq. (21). In this case the Wigner function is a left and right zero $(t,\phi,\vec{A},\vec{B})$-stargenfunction of the constraint symbol ϕ. To determine f_W explicitly we will follow the procedure described in Sec. II. From Eqs. (10), (11), and (14), the fundamental zero stargenfunctions of the Hamiltonian constraint (which will be designated by $\rho_{\vec{a},\vec{b}}$) are given by

$$\rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}) = \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(\phi,\vec{A};h=0,\vec{a};h=0,\vec{b})$$

$$= \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(\phi) *_{(t,\phi,\vec{A},\vec{B})} \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(\vec{A};\vec{a};\vec{b}) = \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(\phi) \prod_{j=1}^{N} {}_{*_{(t,\phi,\vec{A},\vec{B})}}$$

$$\{e^{(i/\hbar)(b_j-a_j)B_j}_{*_{(t,\phi,A,B)}} *_{(t,\phi,\vec{A},\vec{B})} \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(A_j - b_j)\}$$

$$= \delta(\phi) *_{(t,\phi,\vec{A},\vec{B})} \prod_{j=1}^{N} \{e^{(i/\hbar)(b_j-a_j)B_j} *_{(t,\phi,\vec{A},\vec{B})} \delta(A_j - b_j)\}$$

$$= \delta(\phi) \prod_{j=1}^{N} \left\{ \frac{1}{2\pi} \sum_{n=0}^{+\infty} \frac{1}{n!} \left(\frac{-i\hbar}{2} \right)^n e^{(i/\hbar)(b_j-a_j)B_j} \left[\frac{i}{\hbar}(b_j - a_j) \frac{\partial}{\partial A_j} \right]^n \int \mathrm{d}k \, e^{ik(A_j-b_j)} \right\}$$

$$= \frac{\delta(\phi)}{(2\pi)^N} \prod_{j=1}^{N} \left\{ e^{(i/\hbar)(b_j-a_j)B_j} \int \mathrm{d}k \sum_{n=0}^{+\infty} \frac{1}{n!} \left[\frac{i}{2} k(b_j - a_j) \right]^n e^{ik(A_j-b_j)} \right\}$$

$$= \delta(\phi) \prod_{j=1}^{N} \left\{ e^{(i/\hbar)(b_j-a_j)B_j} \frac{1}{2\pi} \int \mathrm{d}k \, e^{ik[A_j-b_j+(b_j/2)-(a_j/2)]} \right\}$$

$$= \delta(\phi) \prod_{j=1}^{N} \left\{ e^{(i/\hbar)(b_j-a_j)B_j} \delta\left(A_j - \frac{a_j}{2} - \frac{b_j}{2} \right) \right\} = \delta(\phi) e^{(i/\hbar)(\vec{b}-\vec{a})\cdot\vec{B}} \delta\left(\vec{A} - \frac{\vec{a}+\vec{b}}{2} \right), \quad (23)$$

where $\Pi_{j=1*_{(t,\phi,\vec{A},\vec{B})}}^{N}$ stands for the N-fold star-product and $\Pi_{j=1}^{N}$ for the standard N-fold product of functions. The stargenfunctions $\rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B})$ are simultaneously solutions of Eq. (21) and

$$A_j *_{(t,\phi,\vec{A},\vec{B})} \rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}) = a_j \rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}),$$

$$\rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}) *_{(t,\phi,\vec{A},\vec{B})} A_j = b_j \rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}), \quad j = 1,\ldots,N. \quad (24)$$

Notice that the diagonal elements $\vec{a}=\vec{b}$ fully identify a history of the system, $\rho_{\vec{a},\vec{a}}(t,\phi,\vec{A},\vec{B}) = \delta(\phi)\Pi_{j=1}^{N}\delta(A_j - a_j)$. It is also straightforward to realize that the fundamental stargenfunctions (23) are the $(t,\phi,\vec{A},\vec{B})$-Weyl transform of the projectors,

$$|h=0,\vec{a}\rangle\langle h=0,\vec{b}| = \hat{\Delta}(\hat{\phi}) \prod_{j=1}^{N} \{e^{(i/\hbar)(b_j-a_j)\hat{B}_j} \hat{\Delta}(\hat{A}_j - b_j)\}, \quad (25)$$

where the general ket satisfies

$$\hat{\phi}|h,\vec{x}\rangle = h|h,\vec{x}\rangle \quad \text{and } \hat{A}_j|h,\vec{x}\rangle = x_j|h,\vec{x}\rangle \quad (26)$$

and

$$\hat{\Delta}(\hat{\phi}) = \int \mathrm{d}\vec{x}|h=0,\vec{x}\rangle\langle h=0,\vec{x}| = \frac{1}{2\pi} \int \mathrm{d}k \, e^{ik\hat{\phi}}, \quad (27)$$

is the operator analogue of (14). The most general solution of Eq. (21) is a linear combination of the fundamental solutions (23):

$$f_W(t,\phi,\vec{A},\vec{B}) = \frac{1}{(2\pi\hbar)^N} \int \mathrm{d}\vec{a} \int \mathrm{d}\vec{b} \, C(\vec{a}) C^*(\vec{b}) \rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}), \quad (28)$$

where $C(\vec{a})$ obeys the normalization condition that is induced by the normalization of the Wigner function. Let us then calculate its norm,

$$\iiint \mathrm{d}t\,\mathrm{d}\phi\,\mathrm{d}\vec{A}\,\mathrm{d}\vec{B}\,f_W(t,\phi,\vec{A},\vec{B}) = \frac{1}{(2\pi\hbar)^N}\iiint \mathrm{d}t\,\mathrm{d}\vec{A}\,\mathrm{d}\vec{B}\int \mathrm{d}\vec{a}\int \mathrm{d}\vec{b}\,C(\vec{a})C^*(\vec{b})\prod_{j=1}^{N} e^{(i/\hbar)(b_j-a_j)B_j}\delta$$

$$\left(A_j - \frac{a_j+b_j}{2}\right) = \int \mathrm{d}t\int \mathrm{d}\vec{a}\int \mathrm{d}\vec{b}\,C(\vec{a})C^*(\vec{b})\delta(\vec{b}-\vec{a})$$

$$= \int \mathrm{d}t\int \mathrm{d}\vec{a}\,C(\vec{a})C^*(\vec{a}). \tag{29}$$

The divergence of the previous integral indicates that we are integrating over the gauge orbits thus spoiling the normalization of the Wigner function. In this case this is quite simple to correct. In fact we just have to introduce the phase space measure $\mathrm{d}\mu = \mathrm{d}\phi\,\mathrm{d}\vec{A}\,\mathrm{d}\vec{B}$ and use it from now on whenever we must integrate the Wigner function. The procedure corresponds to cutting the gauge orbits through a single time hypersurface. With this measure the Wigner function satisfies

$$\int \mathrm{d}\mu\, f_W = 1, \quad \forall\, t \tag{30}$$

provided the parameters $C(\vec{a})$ satisfy $\int \mathrm{d}\vec{a}|C(\vec{a})|^2 = 1$. The proper normalization of the Wigner function determines a phase space measure and a restriction on the factors $C(\vec{a})$. These parameters display a natural physical interpretation. To see this explicitly let us calculate the probabilities for the output of a measurement of $\vec{A}$. The general $\vec{x} = (x_1, \ldots, x_N)$ left and right stargenfunction of $\vec{A}$ (and simultaneously y left and right stargenfunction of the constraint) is

$$\rho_{y,\vec{x};y,\vec{x}} = \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(\phi,\vec{A};y,\vec{x};y,\vec{x}) = \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(\phi - y)\prod_{j=1}^{N} {}_{*_{(t,\phi,\vec{A},\vec{B})}}\Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(A_j - x_j)$$

$$= \delta(\phi - y)\prod_{j=1}^{N}\delta(A_j - x_j) = \delta(\phi - y)\,\delta(\vec{A} - \vec{x}). \tag{31}$$

Therefore, the probability density for $\vec{A} = \vec{x}$ and $\phi = y$ is given by

$$\mathcal{P}(\phi = y, \vec{A} = \vec{x}) = \int \mathrm{d}\mu\, f_W(t,\phi,\vec{A},\vec{B})\,\delta(\phi - y)\,\delta(\vec{A} - \vec{x}) = \int \mathrm{d}\vec{B}\, f_W(t,y,\vec{x},\vec{B})$$

$$= \frac{1}{(2\pi\hbar)^N}\int \mathrm{d}\vec{B}\iint \mathrm{d}\vec{a}\,\mathrm{d}\vec{b}\,C(\vec{a})C^*(\vec{b})\,\delta(y)\prod_{j=1}^{N}\left\{e^{(i/\hbar)(b_j-a_j)B_j}\delta\left(x_j - \frac{a_j+b_j}{2}\right)\right\}$$

$$= \iint \mathrm{d}\vec{a}\,\mathrm{d}\vec{b}\,C(\vec{a})C^*(\vec{b})\,\delta(\vec{b}-\vec{a})\,\delta\left(\vec{x} - \frac{\vec{a}+\vec{b}}{2}\right)\delta(y) = |C(\vec{x})|^2\delta(y) \tag{32}$$

from where it follows:

$$P(\phi = y, \vec{A} = \vec{x}) = \lim_{\epsilon\to 0^+}\int_{y-\epsilon}^{y+\epsilon}\mathrm{d}y'\,\mathcal{P}(\phi = y', \vec{A} = \vec{x}) = |C(\vec{x})|^2\delta_{y,0}. \tag{33}$$

It is clear from the previous equation that the term $|C(\vec{x})|^2$ represents the probability for the system to be found in the history $\vec{A} = \vec{x}$. Under the measurement of $\vec{A}$ with output $\vec{x}$ the Wigner function will indeed collapse to the state,

$$\rho_{0,\vec{x};0,\vec{x}} = \delta(\phi)\,\delta(\vec{A}-\vec{x}). \tag{34}$$

Let us also point out that in the $(t,\phi,\vec{A},\vec{B})$ representation the Wigner function is static both with respect to the external time τ and to the physical time t. In fact from Eqs. (23) and (28) we see that $(\partial/\partial t)f_W=0$.

The former results can now be easily translated to the $(t,P_t,\vec{q},\vec{p})$ representation where the intention is to solve Eq. (22). The two representations are related by the unitary transformation:

$$t(t,P_t,\vec{q},\vec{p}) = U^{-1}*_{(t,P_t,\vec{q},\vec{p})}t*_{(t,P_t,\vec{q},\vec{p})}U = t,$$

$$\begin{aligned}
\phi(t,P_t,\vec{q},\vec{p}) &= W_{(t,P_t,\vec{q},\vec{p})}(\hat{\phi}) = U^{-1}*_{(t,P_t,\vec{q},\vec{p})}P_t*_{(t,P_t,\vec{q},\vec{p})}U = P_t + H_0(\vec{q},\vec{p}),\\
A_j(t,\vec{q},\vec{p}) &= W_{(t,P_t,\vec{q},\vec{p})}(\hat{A}_j) = U^{-1}*_{(t,P_t,\vec{q},\vec{p})}q_j*_{(t,P_t,\vec{q},\vec{p})}U, \quad j=1,\ldots,N,\\
B_j(t,\vec{q},\vec{p}) &= W_{(t,P_t,\vec{q},\vec{p})}(\hat{B}_j) = U^{-1}*_{(t,P_t,\vec{q},\vec{p})}p_j*_{(t,P_t,\vec{q},\vec{p})}U, \quad j=1,\ldots,N,
\end{aligned} \tag{35}$$

where $U=e^{(i/\hbar)H_0(\vec{q},\vec{p})t}_{*_{(t,P_t,\vec{q},\vec{p})}}$. The fundamental stargenfunctions are

$$\begin{aligned}
\rho_{\vec{a},\vec{b}}(t,P_t,\vec{q},\vec{p}) &= \Delta_{*_{(t,P_t,\vec{q},\vec{p})}}(\phi,\vec{A};h=0,\vec{a};h=0,\vec{b}) = \Delta_{*_{(t,P_t,\vec{q},\vec{p})}}(P_t+H_0(\vec{q},\vec{p}))\prod_{j=1}^{N}{}_{*_{(t,P_t,\vec{q},\vec{p})}}\\
&\{e^{(i/\hbar)(b_j-a_j)B_j(t,\vec{q},\vec{p})}_{*_{(t,P_t,\vec{q},\vec{p})}}*_{(t,P_t,\vec{q},\vec{p})}\Delta_{*_{(t,P_t,\vec{q},\vec{p})}}(A_j(t,\vec{q},\vec{p})-b_j)\},
\end{aligned} \tag{36}$$

which in general do not simplify any further as in Eq. (23). These stargenfunctions are the $(t,P_t,\vec{q},\vec{p})$-Weyl transform of the projector (25). The most general solution of (22) is then

$$f_W(t,P_t,\vec{q},\vec{p}) = \frac{1}{(2\pi\hbar)^N}\int \mathrm{d}\vec{a}\,\mathrm{d}\vec{b}\,C(\vec{a})C^*(\vec{b})\rho_{\vec{a},\vec{b}}(t,P_t,\vec{q},\vec{p}) \tag{37}$$

and can be obtained directly from the Wigner function (28) by applying the unitary transformation (35). Hence, $f_W(t,P_t,\vec{q},\vec{p})$ is properly normalized for the phase space measure $\mathrm{d}\mu=\mathrm{d}P_t\,\mathrm{d}\vec{q}\,\mathrm{d}\vec{p}$ provided the coefficients $C(\vec{a})$ satisfy the normalization $\int \mathrm{d}\vec{a}\,C(\vec{a})C^*(\vec{a})=1$. Notice that in general the Wigner function does not have support exclusively on the classical constraint hypersurface. This is due to the nonlocal character of the $*$-delta functions in Eq. (36). Notice also that f_W does not evolve with respect to the external time τ but it displays the standard time evolution with respect to the canonical time t,

$$\begin{aligned}
\frac{\partial f_W(t,P_t,\vec{q},\vec{p})}{\partial\tau} &= [H(t,P_t,\vec{q},\vec{p}),f_W(t,P_t,\vec{q},\vec{p})]_{M_{(t,P_t,\vec{q},\vec{p})}} = 0 \Leftrightarrow \frac{\partial f_W(t,P_t,\vec{q},\vec{p})}{\partial t}\\
&= [H_0(\vec{q},\vec{p}),f_W(t,P_t,\vec{q},\vec{p})]_{M_{(\vec{q},\vec{p})}}.
\end{aligned} \tag{38}$$

We conclude that the $(t,P_t,\vec{q},\vec{p})$ representation yields the extended phase space Schrödinger picture for the quantum generally covariant system. Likewise the $(t,\phi,\vec{A},\vec{B})$ representation provides the phase space Heisenberg picture.

IV. CAUSAL REPRESENTATION

We now study another possible phase space representation of the system. The first step is to specify a set of classical phase space coordinates $(t,P_t,\vec{Q},\vec{P})$. Let us define the phase space diffeomorphism by

$$t = t, \quad P_t = \phi - H_0(\vec{A},\vec{B}), \quad \vec{Q} = \vec{Q}(t,\vec{A},\vec{B}), \quad \vec{P} = \vec{P}(t,\vec{A},\vec{B}), \tag{39}$$

where $H_0(\vec{A},\vec{B}) = W_{(\vec{A},\vec{B})}(\hat{H}_0) = W_{(\vec{q},\vec{p})}(\hat{H}_0)|_{\vec{q}=\vec{A}\wedge\vec{p}=\vec{B}}$ and $\vec{Q}(t,\vec{A},\vec{B}), \vec{P}(t,\vec{A},\vec{B})$ satisfy

$$\frac{\partial \vec{Q}(t,\vec{A},\vec{B})}{\partial t} = \{\vec{Q}(t,\vec{A},\vec{B}), H_0(\vec{A},\vec{B})\}_{(\vec{A},\vec{B})}, \quad \frac{\partial \vec{P}(t,\vec{A},\vec{B})}{\partial t} = \{\vec{P}(t,\vec{A},\vec{B}), H_0(\vec{A},\vec{B})\}_{(\vec{A},\vec{B})} \tag{40}$$

together with the initial conditions $\vec{Q}(0,\vec{A},\vec{B}) = \vec{A}$ and $\vec{P}(0,\vec{A},\vec{B}) = \vec{B}$. That is $\vec{Q}(t,\vec{A},\vec{B})$ and $\vec{P}(t,\vec{A},\vec{B})$ constitute the *classical* time evolution of the deparametrized system. The transformation (39) is canonical and can be easily inverted. It yields

$$t = t, \quad \phi = \phi'(t,P_t,\vec{Q},\vec{P}) = P_t + H_0(\vec{Q},\vec{P}), \quad \vec{A} = \vec{A}'(t,\vec{Q},\vec{P}), \quad \vec{B} = \vec{B}'(t,\vec{Q},\vec{P}), \tag{41}$$

where this time $H_0(\vec{Q},\vec{P}) = W_{(\vec{q},\vec{p})}(\hat{H}_0)|_{\vec{q}=\vec{Q}\wedge\vec{p}=\vec{P}}$ and $\vec{A}'(t,\vec{Q},\vec{P}), \vec{B}'(t,\vec{Q},\vec{P})$ satisfy

$$\frac{\partial \vec{A}'(t,\vec{Q},\vec{P})}{\partial t} = \{H_0(\vec{Q},\vec{P}), \vec{A}'(t,\vec{Q},\vec{P})\}_{(\vec{Q},\vec{P})}, \quad \frac{\partial \vec{B}'(t,\vec{Q},\vec{P})}{\partial t} = \{H_0(\vec{Q},\vec{P}), B'(t,\vec{Q},\vec{P})\}_{(\vec{Q},\vec{P})} \tag{42}$$

together with the initial conditions $\vec{A}'(0,\vec{Q},\vec{P}) = \vec{Q}$ and $\vec{B}'(0,\vec{Q},\vec{P}) = \vec{P}$. This means that the *functions* $\vec{A}'(t,\vec{Q},\vec{P})$ and $\vec{B}'(t,\vec{Q},\vec{P})$ are the classical histories of the system. We should point out that in general the two functions $\vec{A}'(t,\vec{Q},\vec{P})$ and $\vec{A}(t,\vec{q},\vec{p})$ given by Eqs. (41) and (35), respectively, as well as $\vec{B}'(t,\vec{Q},\vec{P})$ and $\vec{B}(t,\vec{q},\vec{p})$, display different functional forms (they are, respectively, the classical and the quantum Weyl-Wigner histories of the system). To make this point explicit, we introduced the prime notation which is in agreement with the fact that $\vec{A}'(t,\vec{Q},\vec{P}) = W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{Q},\vec{P})}(\hat{\vec{A}})$, $\vec{B}'(t,\vec{Q},\vec{P}) = W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{Q},\vec{P})}(\hat{\vec{B}})$, and $\phi'(t,P_t,\vec{Q},\vec{P}) = W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{Q},\vec{P})}(\hat{\phi})$. Finally, let us concisely designate the transformation (41) by $\vec{T}: \mathbb{R}^{(2N+2)} \to \mathbb{R}^{(2N+2)}$; $(t,P_t,\vec{Q},\vec{P}) \to (t,\phi,\vec{A},\vec{B}) = \vec{T}(t,P_t,\vec{Q},\vec{P})$.

The transformation $\vec{T}$ is canonical but in general it does not preserve either the star-product or the Moyal bracket. Using the generalized Weyl transform $W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t\vec{Q},\vec{P})}$ we find a phase space representation of the eigenvalue equation (18),

$$\phi'(t,P_t,\vec{Q},\vec{P}) *'_{(t,P_t,\vec{Q},\vec{P})} f'_W(t,P_t,\vec{Q},\vec{P}) = f'_W(t,P_t,\vec{Q},\vec{P}) *'_{(t,P_t,\vec{Q},\vec{P})} \phi'(t,P_t,\vec{Q},\vec{P}) = 0, \tag{43}$$

where the $*'_{(t,P_t,\vec{Q},\vec{P})}$ is the covariant star-product given by (3) with

$$J'^{ij}_{(t,P_t,\vec{Q},\vec{P})} = J^{ij}_{(t,\phi,\vec{A},\vec{B})} \quad \text{and } \Gamma'^{i}_{jk} = \frac{\partial O'^{i}}{\partial O^{b}} \frac{\partial^2 O^{b}}{\partial O'^{j}\, \partial O'^{k}}, \tag{44}$$

where $O^b \in \{t,\phi,\vec{A},\vec{B}\}$ and $O'^i \in \{t,P_t,\vec{Q},\vec{P}\}$. The solutions of Eq. (43) can be read from Eqs. (23) and (28),

$$f'_W(t,P_t,\vec{Q},\vec{P}) = \frac{1}{(2\pi\hbar)^N} W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{Q},\vec{P})}(|\psi\rangle\langle\psi|) = \frac{1}{(2\pi\hbar)^N} \int \mathrm{d}\vec{a} \int \mathrm{d}\vec{b}\; C(\vec{a}) C^*(\vec{b}) \rho'_{\vec{a},\vec{b}}(t,P_t,\vec{Q},\vec{P}), \tag{45}$$

where

$$\rho'_{\vec{a},\vec{b}}(t,P_t,\vec{Q},\vec{P}) = \Delta_{*'_{(t,P_t,\vec{Q},\vec{P})}}(\phi'(t,P_t,\vec{Q},\vec{P}),\vec{A}'(t,\vec{Q},\vec{P});h=0,\vec{a};h=0,\vec{b})$$

$$= \Delta_{*'_{(t,P_t,\vec{Q},\vec{P})}}(\phi'(t,P_t,\vec{Q},\vec{P}))\prod_{j=1}^{N} {}_{*'_{(t,P_t,\vec{Q},\vec{P})}}\Delta_{*'_{(t,P_t,\vec{Q},\vec{P})}}(A'_j(t,\vec{Q},\vec{P}),a_j,b_j) = \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}$$

$$(\phi'(t,P_t,\vec{Q},\vec{P}))\prod_{j=1}^{N} {}_{*_{(t,\phi,\vec{A},\vec{B})}}\{e^{(i/\hbar)(b_j-a_j)B'_j(t,\vec{Q},\vec{P})}_{*_{(t,\phi,\vec{A},\vec{B})}} *_{(t,\phi,\vec{A},\vec{B})}\Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(A'_j(t,\vec{Q},\vec{P})-b_j)\}$$

$$= \delta(\phi'(t,P_t,\vec{Q},\vec{P}))\prod_{j=1}^{N}\left\{e^{(i/\hbar)(b_j-a_j)B'_j(t,\vec{Q},\vec{P})}\delta\left(A'_j(t,\vec{Q},\vec{P})-\frac{a_j+b_j}{2}\right)\right\}$$

$$= \delta(\phi'(t,P_t,\vec{Q},\vec{P}))e^{i/\hbar(\vec{b}-\vec{a})\cdot\vec{B}'(t,\vec{Q}\vec{P})}\delta\left(\vec{A}'(t,\vec{Q},\vec{P})-\frac{\vec{a}+\vec{b}}{2}\right). \tag{46}$$

The Wigner function satisfies

$$f'_W(t,P_t,\vec{Q},\vec{P}) = f_W(t,\phi'(t,P_t,\vec{Q},\vec{P}),\vec{A}'(t,\vec{Q},\vec{P}),\vec{B}'(t,\vec{Q},\vec{P})), \tag{47}$$

where f_W is given by Eq. (28). Furthermore and since the coordinate transformation is canonical we have

$$\mathrm{d}\mu = \mathrm{d}\phi\,\mathrm{d}\vec{A}\,\mathrm{d}\vec{B} = \delta(t)\mathrm{d}t\,\mathrm{d}\phi\,\mathrm{d}\vec{A}\,\mathrm{d}\vec{B} = \delta(t)\mathrm{d}t\,\mathrm{d}P_t\,\mathrm{d}\vec{Q}\,\mathrm{d}\vec{P} = \mathrm{d}P_t\,\mathrm{d}\vec{Q}\,\mathrm{d}\vec{P}, \tag{48}$$

and the Wigner function obeys the proper normalization, $\int \mathrm{d}\mu\, f'_W = 1$. Also notice that both the diagonal and the nondiagonal stargenfunctions (and thus also the Wigner function) have support only on the classical constraint hypersurface, a property that it is not shared by the previous representation (36) and (37).

Finally, let us briefly elaborate on the dynamical structure of the system in this representation. It is clear from Eq. (43) that the Wigner function is static,

$$\frac{\partial}{\partial\tau}f'_W(t,P_t,\vec{Q},\vec{P};\tau) = [H'(t,P_t,\vec{Q},\vec{P}),f'_W(t,P_t,\vec{Q},\vec{P};\tau)]_{M'_{(t,P_t,\vec{Q},\vec{P})}}$$

$$= \lambda[\phi'(t,P_t,\vec{Q},\vec{P}),f'_W(t,P_t,\vec{Q},\vec{P};\tau)]_{M'_{(t,P_t,\vec{Q},\vec{P})}} = 0, \tag{49}$$

confirming the typical picture of frozen dynamics. However, the Wigner function does evolve with respect to the physical time t. From Eqs. (42) and (47) we have

$$\frac{\partial}{\partial t}f'_W(t,P_t,\vec{Q},\vec{P}) = \frac{\partial f_W}{\partial\phi}(\vec{T}(t,P_t,\vec{Q},\vec{P}))\frac{\partial\phi'}{\partial t} + \sum_{j=1}^{N}\frac{\partial f_W}{\partial A_j}(\vec{T}(t,P_t,\vec{Q},\vec{P}))\frac{\partial A'_j}{\partial t} + \sum_{j=1}^{N}\frac{\partial f_W}{\partial B_j}(\vec{T}(t,P_t,\vec{Q},\vec{P}))\frac{\partial B'_j}{\partial t}$$

$$= \sum_{j=1}^{N}\frac{\partial f_W}{\partial A_j}(\vec{T}(t,P_t,\vec{Q},\vec{P}))\{H_0,A'_j\}_{(t,P_t,\vec{Q},\vec{P})} + \sum_{j=1}^{N}\frac{\partial f_W}{\partial B_j}(\vec{T}(t,P_t,\vec{Q},\vec{P}))\{H_0,B'_j\}_{(t,P_t,\vec{Q},\vec{P})}$$

$$= \{H_0,f'_W\}_{(t,P_t,\vec{Q},\vec{P})}, \tag{50}$$

reproducing the classical Liouville equation $\{H',f'_W\}_{(t,P_t,\vec{Q},\vec{P})}=0$.

We see that the $\frac{(t,\phi,\vec{A},\vec{B})}{(t,P_t,\vec{Q},\vec{P})}$-representation of the system leads to an interesting mathematical picture; the Hamiltonian vector field lives on the extended phase space and is given by

$$\xi_H = \lambda \left\{ \frac{\partial}{\partial t} + \sum_{j=1}^{N} \frac{\partial H_0}{\partial P_j}\frac{\partial}{\partial Q_j} - \sum_{j=1}^{N} \frac{\partial H_0}{\partial Q_j}\frac{\partial}{\partial P_j} \right\}. \tag{51}$$

The flows of this vector field define lines in phase space. These lines cross each time hypersurface once and only once; they are the histories of the system. These histories are one-dimensional hypersurfaces that can be identified by the values of the $1+2N$ constants of motion, $\phi, \vec{A}, \vec{B}$. Along these lines the Wigner distribution function is constant. However, the correlations between the canonical variables, namely between $\vec{Q}$ and t, do change and time evolution is imprinted on these correlations. The interesting point is that this picture is not of the classical description but of the quantum mechanical instead.

A natural question is what happened to the quantum content of the theory? What happened to the interfering trajectories and to the nonlocal behavior? The answer is that the quantum features have been completely removed from the distributional sector and are now exclusively placed in the observables' sector of the theory. This can be checked explicitly by applying the proper generalized Weyl transform to one of the fundamental operators of the system. We have for instance,

$$W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{Q},\vec{P})}(\hat{q}_1) = q_1(t,\phi,\vec{A},\vec{B})|_{(t,\phi,\vec{A},\vec{B})=\vec{T}(t,P_t,\vec{Q},\vec{P})} = q_1(t,\phi'(t,P_t,\vec{Q},\vec{P}),A'(t,\vec{Q},\vec{P}),B'(t,\vec{Q},\vec{P})), \tag{52}$$

leading to the time evolution

$$\begin{aligned} \frac{\mathrm{d}q_1}{\mathrm{d}t} &= \frac{\partial q_1}{\partial t} + \frac{\partial q_1}{\partial \phi}\frac{\partial \phi'}{\partial t} + \sum_{j=1}^{N} \frac{\partial q_1}{\partial A_j}\frac{\partial A'_j}{\partial t} + \sum_{j=1}^{N} \frac{\partial q_1}{\partial B_j}\frac{\partial B'_j}{\partial t} = [q_1, H_0]_{M_{(\vec{A},\vec{B})}} - \sum_{j=1}^{N} \frac{\partial q_1}{\partial A_j}\{A'_j, H_0\}_{(\vec{Q},\vec{P})} \\ &\quad - \sum_{j=1}^{N} \frac{\partial q_1}{\partial B_j}\{B'_j, H_0\}_{(\vec{Q},\vec{P})} = [q_1, H_0]_{M_{(\vec{A},\vec{B})}} - \{q_1, H_0\}_{(\vec{A},\vec{B})}, \end{aligned} \tag{53}$$

where the identity $\partial q_1/\partial t = [q_1, H_0]_{M_{(\vec{A},\vec{B})}}$ follows from Eq. (20) [or alternatively from Eq. (35)], we used the fact that ϕ' is time independent and that the transformation $(\vec{Q},\vec{P}) \to (\vec{A},\vec{B})$ is canonical. Equation (53) does in fact constitute a quantum correction to the classical statistical description where we have

$$\frac{\partial \rho}{\partial t} = \{H_0, \rho\} \quad \text{and} \quad \frac{\mathrm{d}q_1}{\mathrm{d}t} = 0. \tag{54}$$

Notice that in the classical description $\vec{Q} = \vec{q}, \vec{P}, = \vec{p}$ and $\vec{q}(t,\phi'(t,P_t,\vec{q},\vec{p}),\vec{A}'(t,\vec{q},\vec{p}),\vec{B}'(t,\vec{q},\vec{p})) = \vec{q}$.

We finally conclude by pointing out that a causal representation can also be obtained for deparametrized systems by using an explicit "time dependent phase space representation" where the star-product and Moyal bracket are themselves (scalar) time dependent.[39] In this approach we apply a time dependent generalization of the Weyl map to the density matrix formulation of the deparametrized system and obtain a phase space causal representation of the Wigner function, which is formally identical to the one described by Eqs. (45), (46), and (52), although t is a canonical variable in the former equations and an external scalar parameter in the approach of Ref. 39. Accordingly, the two resulting quasidistributions live on different phase spaces. In spite of this the two formulations are consistent with each other leading to the single conclusion that a phase space formulation of quantum mechanics where the distributional sector displays a fully classical causal structure is made possible through a suitable choice of representation. This may either be a (scalar) time dependent representation in the deparametrized phase space or a history representation in the generally covariant setting.

V. EXAMPLE

To illustrate our previous results let us consider the simple system composed by two coupled particles and described by the Hamiltonian

$$H_0 = \frac{p_1^2}{2M} + \frac{p_2^2}{2m} + kq_1p_2^2, \tag{55}$$

where (q_1,p_1) are the canonical variables of the particle of mass M, (q_2,p_2) those of the particle of mass m and k is a coupling constant.

The generally covariant version of this system is obtained by promoting t to a canonical variable and imposing the time reparametrization invariance. The extended Hamiltonian formulation of the system lives on a six-dimensional phase space spanned by the canonical variables $t,P_t,\vec{q}=(q_1,q_2),\vec{p}=(p_1,p_2)$ which satisfy the commutation relations $\{t,P_t\}=1,\{q_i,p_j\}=\delta_{ij},i,j=1,2$, all others being zero. Upon quantization the system is described by the "zero Hamiltonian,"

$$\hat{H} = \lambda\hat{\phi}, \quad \hat{\phi} = \hat{P}_t + \hat{H}_0 = \hat{P}_t + \frac{\hat{p}_1^2}{2M} + \frac{\hat{p}_2^2}{2m} + k\hat{q}_1\hat{p}_2^2, \tag{56}$$

where $\hat{\phi}$ is the first class Hamiltonian constraint and λ is a Lagrange multiplier. In standard the Dirac formulation the physical states of this system are the wave functions ψ solutions of the constraint equation

$$\hat{\phi}|\psi\rangle = 0. \tag{57}$$

We now address the deformation quantization of the system. As in the main text, three distinct quantum phase space representations will be presented.

(1) *The map $W_{(t,P_t,\vec{q},\vec{p})}$ and the generally covariant Schrödinger picture*. The Weyl map $W_{(t,P_t,\vec{q},\vec{p})}$ yields the $(t,P_t,\vec{q},\vec{p})$-constraint symbol

$$\phi = W_{(t,P_t,\vec{q},\vec{p})}(\hat{\phi}) = P_t + \frac{p_1^2}{2M} + \frac{p_2^2}{2m} + kq_1p_2^2 \tag{58}$$

and the quantum phase space version of the Hamiltonian constraint (57) is given by

$$\phi(t,P_t,\vec{q},\vec{p}) *_{(t,P_t,\vec{q},\vec{p})} f_W(t,P_t,\vec{q},\vec{p}) = f_W(t,P_t,\vec{q},\vec{p}) *_{(t,P_t,\vec{q},\vec{p})} \phi(t,P_t,\vec{q},\vec{p}) = 0. \tag{59}$$

The solutions of this right and left stargenvalue equation are given by Eqs. (36) and (37) and they do not easily simplify any further. It is worth noticing that due to the nonlocal character of the $*$-product the phase space quasidistribution f_W will have support on phase-space regions which are not classically allowed. One can easily calculate the evolution of f_W with respect to the physical time t. From Eq. (59) we have

$$\begin{aligned}\frac{\partial f_W}{\partial\tau} = \lambda[\phi,f_W]_{M_{(t,P_t,\vec{q},\vec{p})}} = 0 \Leftrightarrow \frac{\partial f_W}{\partial t} = [H_0,f_W]_{M_{(\vec{q},\vec{p})}} \Leftrightarrow \frac{\partial f_W}{\partial t} \\ = \{H_0,f_W\}_{(\vec{q},\vec{p})} + \frac{\hbar^2}{24}\left[2\left\{2kp_2,\frac{\partial^2 f_W}{\partial q_2\,\partial p_1}\right\}_{(\vec{q},\vec{p})} - \left\{2kq_1,\frac{\partial^2 f_W}{\partial q_2^2}\right\}_{(\vec{q},\vec{p})}\right]\end{aligned} \tag{60}$$

which is obviously not of the form of the Liouville equation. Consequently, the Wigner function does not display a classical causal structure.

(2) *The map $W_{(t,\phi,\vec{A},\vec{B})}$ and the generally covariant Heisenberg picture*. Following the approach of Sec. III our first step is to determine the quantum histories associated to $\hat{H}$. We easily find that [check Eqs. (19) and (20)]

$$\hat{A}_1 = \hat{q}_1 - \frac{\hat{p}_1}{M}\hat{t} - \frac{k}{2M}\hat{p}_2^2\hat{t}^2,$$

$$\hat{B}_1 = \hat{p}_1 + k\hat{p}_2^2\hat{t},$$

$$\hat{A}_2 = \hat{q}_2 - \left\{\frac{\hat{p}_2}{m} + 2k\hat{q}_1\hat{p}_2\right\}\hat{t} + \frac{k}{M}\hat{p}_1\hat{p}_2\hat{t}^2 + \frac{k^2}{3M}\hat{p}_2^3\hat{t}^3,$$

$$\hat{B}_2 = \hat{p}_2 \tag{61}$$

satisfy the requisites following Eq. (18), i.e., $\hat{A}_j, \hat{B}_j, j=1, 2$ commute with the constraint $\hat{\phi}$ and with $\hat{t}$ and furthermore they satisfy the Heisenberg algebra $[\hat{A}_1, \hat{B}_1]=[\hat{A}_2, \hat{B}_2]=i\hbar$, all other commutators being zero. Since $[\hat{t}, \hat{\phi}]=i\hbar$ the set $\{\hat{t}, \hat{\phi}, \hat{\vec{A}}=(\hat{A}_1, \hat{A}_2), \hat{\vec{B}}=(\hat{B}_1, \hat{B}_2)\}$ is a complete set of fundamental operators for this system.

Using the Weyl map $W_{(t,\phi,\vec{A},\vec{B})}$ we find the Heisenberg phase space representation of the constraint equation (57),

$$\phi *_{(t,\phi,\vec{A},\vec{B})} f_W(t,\phi,\vec{A},\vec{B}) = f_W(t,\phi,\vec{A},\vec{B}) *_{(t,\phi,\vec{A},\vec{B})} \phi = 0. \tag{62}$$

The fundamental solutions of this equation $\rho_{\vec{a},\vec{b}}$ [where $\vec{a}=(a_1, a_2)$ and $\vec{b}=(b_1, b_2)$], and also satisfying

$$A_j *_{(t,\phi,\vec{A},\vec{B})} \rho_{\vec{a},\vec{b}} = a_j \rho_{\vec{a},\vec{b}}, \quad \rho_{\vec{a},\vec{b}} *_{(t,\phi,\vec{A},\vec{B})} A_j = b_j \rho_{\vec{a},\vec{b}}, \quad j = 1,2 \tag{63}$$

are given by

$$\rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}) = \delta(\phi) e^{(i/\hbar)\{(b_1-a_1)B_1+(b_2-a_2)B_2\}} \delta\left(A_1 - \frac{a_1+b_1}{2}\right)\delta\left(A_2 - \frac{a_2+b_2}{2}\right). \tag{64}$$

And the Wigner function, solution of (62), is just a Hermitian combination of the fundamental solutions. We have

$$f_W(t,\phi,\vec{A},\vec{B}) = \frac{1}{2\pi\hbar}\int \mathrm{d}\vec{a} \int \mathrm{d}\vec{b}\, C(\vec{a}) C^*(\vec{b}) \rho_{\vec{a},\vec{b}}(t,\phi,\vec{A},\vec{B}), \tag{65}$$

where $C(\vec{a})$ obeys to the normalization condition that is induced by the normalization of the Wigner function, $\int \mathrm{d}\vec{a}|C(\vec{a})|^2=1$. The Wigner function satisfies Eq. (62) which implies that $\partial f_W/\partial\tau=0$. We also have from Eq. (64) that $\partial f_W/\partial t=0$. That is, the Wigner function is static both with respect to the unphysical scalar parameter as well as to the physical time. This is an expected result since, in this representation, the Wigner quasidistribution is an exclusive function of observables of the system (the histories), i.e., of quantities that commute with the Hamiltonian constraint.

On the other hand, in this representation, the stargenfunctions of the fundamental variables $\hat{t}$, $\hat{\vec{q}}$, and $\hat{\vec{p}}$ do evolve with respect to the physical time. For instance (let $|x\rangle$ be the general eigenket of $\hat{q}_1$ with associated eigenvalue x),

$$g_x(t,\phi,\vec{A},\vec{B}) = W_{(t,\phi,\vec{A},\vec{B})}(|x\rangle\langle x|) = \Delta_{*_{(t,\phi,\vec{A},\vec{B})}}(q_1(t,\vec{A},\vec{B}) - x) = \frac{1}{2\pi}\int \mathrm{d}k\, e^{ik(q_1(t,\vec{A},\vec{B})-x)}_{*_{(t,\phi,\vec{A},\vec{B})}}$$

$$= \frac{1}{2\pi}\int \mathrm{d}k\, e^{ik(q_1(t,\vec{A},\vec{B})-x)} = \delta(q_1(t,\vec{A},\vec{B}) - x), \tag{66}$$

where $q_1(t,\vec{A},\vec{B})$ can be easily derived from Eq. (61), $q_1(t,\vec{A},\vec{B}) = W_{(t,\phi,\vec{A},\vec{B})}(\hat{q}_1(\hat{t},\hat{\vec{A}},\hat{\vec{B}})) = A_1 + (B_1/M)t - (k/2M)B_2^2t^2$. Hence, $g_x(t,\phi,\vec{A},\vec{B})$ satisfies

$$\frac{\partial}{\partial t}g_x(t,\phi,\vec{A},\vec{B}) = [g_x(t,\phi,\vec{A},\vec{B}), H_0(\vec{A},\vec{B})]_{M_{(\vec{A},\vec{B})}} = \{g_x(t,\phi,\vec{A},\vec{B}), H_0(\vec{A},\vec{B})\}_{(\vec{A},\vec{B})}, \tag{67}$$

where $H_0(\vec{A},\vec{B}) = W_{(\vec{A},\vec{B})}(\hat{H}_0) = (B_1^2/2M) + (B_2^2/2m) + kA_1B_2^2$. We conclude that the Weyl transform $W_{(t,\phi,\vec{A},\vec{B})}$ casts the phase space dynamics in the Heisenberg picture. Accordingly, the time dependence is exclusively displayed by the observable (stargenfunction) sector of the theory.

(3) *The map* $W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{q},\vec{p})}$ *and the generally covariant causal picture*. Following the prescription of Sec. IV let us introduce a set of phase space coordinates $[t, P_t, \vec{Q}=(Q_1,Q_2), \vec{P}=(P_1,P_2)]$ defined by Eqs. (39) and (40). We get $t=t$, $P_t = \phi - H_0(\vec{A},\vec{B})$, and

$$\begin{cases} Q_1 = A_1 + \dfrac{B_1}{M}t - \dfrac{k}{2M}B_2^2t^2 \\ P_1 = B_1 - kB_2^2t \\ Q_2 = A_2 + \left\{\dfrac{B_2}{m} + 2kA_1B_2\right\}t \\ \quad + \dfrac{k}{M}B_1B_2t^2 - \dfrac{k^2}{3M}B_2^3t^3 \\ P_2 = B_2 \end{cases} \Leftrightarrow \begin{cases} A_1 = Q_1 - \dfrac{P_1}{M}t - \dfrac{k}{2M}P_2^2t^2, \\ B_1 = P_1 + kP_2^2t, \\ A_2 = Q_2 - \left\{\dfrac{P_2}{m} + 2kQ_1P_2\right\}t \\ \quad + \dfrac{k}{M}P_1P_2t^2 + \dfrac{k^2}{3M}P_2^3t^3, \\ B_2 = P_2. \end{cases} \tag{68}$$

We notice that $\vec{Q}(t,\vec{A},\vec{B})$ and $\vec{P}(t,\vec{A},\vec{B})$ coincide with $W_{(t,\phi,\vec{A},\vec{B})}(\hat{\vec{q}}), W_{(t,\phi,\vec{A},\vec{B})}(\hat{\vec{p}})$, respectively [this is an easy result that follows from Eq. (61)], i.e., the classical and the quantum histories of this system are exactly the same. Indeed, Eq. (68) solves both the Moyal and the Hamiltonian equations of motion. In the notation of Sec. IV we have $\vec{A}' = \vec{A}$ and $\vec{B}' = \vec{B}$ (one should notice that this result is not valid in general). Hence, for this system, we are not required to introduce a second set of "classical coordinates" and can simplify the notation by making $Q_j = q_j$ and $P_j = p_j$, $j=1, 2$.

We now consider the action of the generalized Weyl map $W^{(t,\phi,A,B)}_{(t,P_t,\vec{q},\vec{p})}$. The associated covariant star-product $*'_{(t,P_t,\vec{q},\vec{p})}$ and Moyal bracket $[,]_{M_{(t,P_t,\vec{q},\vec{p})}}$ are characterized by (let $O'^1 = P_t$, $O'^2 = p_1$, $O'^3 = p_2$, $O'^4 = t$, $O'^5 = q_1$, $O'^6 = q_2$, $O^1 = \phi$, $O^2 = B_1$, $O^3 = B_2$, $O^4 = t$, $O^5 = A_1$, $O^6 = A_2$ and $i,j = 1,\ldots,6$) [check Eq. (5)]

$$J'^{ij}_{(\vec{q},\vec{p})} = J^{ij}_{(\vec{q},\vec{p})},$$

$$\Gamma'^1_{22} = -\Gamma'^5_{24} = -\Gamma'^5_{42} = \frac{1}{M}, \quad \Gamma'^1_{24} = \Gamma'^1_{42} = -\Gamma'^5_{44} = \frac{k}{M}p_2^2, \quad \Gamma'^1_{33} = 2kA_1(t,\vec{q},\vec{p}),$$

$$\Gamma'^1_{34} = \Gamma'^1_{43} = -\Gamma'^6_{44} = -\frac{2k}{M}p_1p_2, \quad \Gamma'^1_{35} = \Gamma'^1_{53} = \Gamma'^2_{34} = \Gamma'^2_{43} = -\Gamma'^6_{45} = -\Gamma'^6_{54} = 2kp_2, \tag{69}$$

$$\Gamma'^{1}_{44}=\frac{k^2}{M}p_2^4,\quad \Gamma'^{2}_{33}=-\Gamma'^{6}_{35}=-\Gamma'^{6}_{53}=2kt,\quad \Gamma'^{5}_{33}=\Gamma'^{6}_{23}=\Gamma'^{6}_{32}=\frac{k}{M}t^2,$$

$$\Gamma'^{5}_{34}=\Gamma'^{5}_{43}=\frac{k}{M}p_2t,\quad \Gamma'^{6}_{33}=\frac{2k^2}{M}p_2t^3,\quad \Gamma'^{6}_{34}=\Gamma'^{6}_{43}=-\frac{1}{m}-2kA_1(t,\vec{q},\vec{p})$$

all other Christoffel symbols being zero.

In this representation the constraint equation reads

$$(P_t+H_0(\vec{q},\vec{p}))*'_{(t,P_t,\vec{q},\vec{p})}f'_W(t,P_t,\vec{q},\vec{p})=f'_W(t,P_t,\vec{q},\vec{p})*'_{(t,P_t,\vec{q},\vec{p})}(P_t+H_0(\vec{q},\vec{p}))=0, \tag{70}$$

where $H_0(\vec{q},\vec{p})=W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{q},\vec{p})}(\hat{H}_0)$ is given by Eq. (54). The fundamental solutions of Eq. (70) are given by

$$\begin{aligned}\rho'_{\vec{a},\vec{b}}(t,P_t,\vec{q},\vec{p})&=\Delta_{*'_{(t,P_t,\vec{q},\vec{p})}}(\phi(t,P_t,\vec{q},\vec{p}),\vec{A}(t,\vec{q},\vec{p});h=0,\vec{a};h=0,\vec{b})\\&=\delta(\phi(t,P_t,\vec{q},\vec{p}))e^{(i/\hbar)(\vec{b}-\vec{a})\cdot\vec{B}(t,\vec{q},\vec{p})}\delta\left(\vec{A}(t,\vec{q},\vec{p})-\frac{\vec{a}+\vec{b}}{2}\right).\\&=\delta(P_t+H_0(\vec{q},\vec{p}))e^{(i/\hbar)\{(b_1-a_1)(p_1+kp_2^2t)+(b_2-a_2)p_2\}}\delta\left(q_1-\frac{p_1}{M}t-\frac{k}{2M}p_2^2t^2-\frac{a_1+b_1}{2}\right)\\&\quad\times\delta\left(q_2-\left\{\frac{p_2}{m}+2kq_1p_2\right\}t+\frac{k}{M}p_1p_2t^2+\frac{k^2}{3M}p_2^3t^3-\frac{a_2+b_2}{2}\right)\end{aligned} \tag{71}$$

and the Wigner function is once again a Hermitian combination of the fundamental solutions $\rho'_{\vec{a},\vec{b}}$,

$$f'_W(t,P_t,\vec{q},\vec{p})=\frac{1}{(2\pi\hbar)^N}W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{q},\vec{p})}(|\psi\rangle\langle\psi|)=\frac{1}{(2\pi\hbar)^N}\int \mathrm{d}\vec{a}\int \mathrm{d}\vec{b}\; C(\vec{a})C^*(\vec{b})\rho'_{\vec{a},\vec{b}}(t,P_t,\vec{q},\vec{p}). \tag{72}$$

It is related with the $(t,\phi,\vec{A},\vec{B})$ representation by

$$f'_W(t,P_t,\vec{q},\vec{p})=f_W(0,\phi(t,P_t,\vec{q},\vec{p}),\vec{A}(t,\vec{q},\vec{p}),\vec{B}(t,\vec{q},\vec{p})), \tag{73}$$

where f_W is given by Eqs. (64) and (65). We conclude that (1) The support of f'_W is confined to the classically allowed regions [check Eq. (71)] and (2) its evolution with respect to the physical time satisfies the Liouville equation

$$\frac{\partial f'_W}{\partial t}=\sum_{j=1}^{2}\frac{\partial f_W}{\partial A_j}\frac{\partial A_j}{\partial t}+\sum_{j=1}^{2}\frac{\partial f_W}{\partial B_j}\frac{\partial B_j}{\partial t}=\sum_{j=1}^{2}\frac{\partial f_W}{\partial A_j}\{H_0,A_j\}_{(\vec{q},\vec{p})}+\sum_{j=1}^{2}\frac{\partial f_W}{\partial B_j}\{H_0,B_j\}_{(\vec{q},\vec{p})}=\{H_0,f'_W\}_{(\vec{q},\vec{p})}. \tag{74}$$

Hence, in this representation the quantum behavior is displayed by the stargenfunction sector alone. However, for this system, we also have (let $z=q_1,p_1\vee p_2$ and $|z_0\rangle$ be a generic eigenket of $\hat{z}$ with associated eigenvalue z_0)

$$\begin{aligned}W^{(t,\phi,\vec{A},\vec{B})}_{(t,P_t,\vec{q},\vec{p})}(|z_0\rangle\langle z_0|)&=\Delta_{*'(t,P_t,\vec{q},\vec{p})}(z-z_0)=\Delta_{*(t,\phi,\vec{A},\vec{B})}(z(t,\vec{A},\vec{B})-z_0)|_{\vec{A}=\vec{A}(t,\vec{q},\vec{p})\wedge\vec{B}=\vec{B}(t,\vec{q},\vec{p})}\\&=\delta(z(t,\vec{A},\vec{B})-z_0)|_{\vec{A}=\vec{A}(t,\vec{q},\vec{p})\wedge\vec{B}=\vec{B}(t,\vec{q},\vec{p})}=\delta(z-z_0),\end{aligned} \tag{75}$$

where in the third step we used the fact that $e^{ik(z(t,\vec{A},\vec{B})-z_0)}_{*_{(t,\phi,A,B)}}=e^{ik(z(t,\vec{A},\vec{B})-z_0)}$ for $z=q_1,p_1\vee p_2$ [a simple result that follows from Eq. (61)]. Hence, the former three fundamental stargenfunctions display a

classical structure and satisfy $(\partial/\partial t)\Delta_{*'(t,P_t,q,p)}(z-z_0)=0$. We conclude that for this system, in this representation, the nontrivial (quantum) behavior is displayed by the stargenfunction $z=q_2$ alone.

VI. CONCLUSIONS

We addressed the deformation quantization of the nonrelativistic particle in the generally parametrized form and provided the complete specification of its physical quantum states in three different phase space representations. We proved that in one of these representations the distributional sector of the system displays a classical causal structure. This result confirms a similar conclusion that has been recently obtained for a generic nonrelativistic deparametrized system and reinforces the point of view that the De Broglie-Bohm formulation is not the unique possible causal formulation of quantum mechanics. In the De Broglie-Bohm theory[45–47] the source of quantum behavior is the quantum potential determining a causal (although not fully classical) dynamics for the quasidistribution. Furthermore, the theory also displays a nontrivial quantum correction to the momentum stargenfunction. On the other hand, in the "causal covariant formulation" presented here the quantum effects have been completely removed from the distributional sector (which now displays a fully classical causal structure) and the price to pay was the appearance of some further (quantum) corrections on the observable's sector of the theory.

We finish by recalling the point of view according to which the relation between the classical statistical and the quantum mechanical formulations of generally covariant systems should be further explored as it may provide key physical insights into some of the conceptual problems displayed by the quantum version of these systems. From this perspective the deformation methods seem to be especially suited. We proved that (at least for the simplest case of the parametrized nonrelativistic particle) the formal similarities between classical statistical and phase space quantum mechanics carry on intact to the generally covariant context. This close analogy is obviously superior to the one displayed by the standard operator formulation, and supports the point of view that the deformation methods should be further explored as an alternative, conceptually simpler approach to the quantization of generally covariant systems.

(Received 3 April 2005; accepted 9 May 2005; published online 19 July 2005)

We obtain the solution of the one-dimensional hydrogen atom on the hyperbola by transforming its Schrödinger equation into the modified Pöschl-Teller equation. We write explicitly the wave functions both in configuration and momentum space, and check the contraction limit of the system to the flat space model. Finally, we find the closed form of the Wigner function for the states of this system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1945767]

I. INTRODUCTION

One-dimensional hydrogen atom is customarily called the quantum system described by the Hamiltonian

$$H = -\frac{1}{2}\frac{\mathrm{d}^2}{\mathrm{d}x^2} - \frac{1}{|x|} \tag{1}$$

(using units so that $e=m=\hbar=1$), and the point $x=0$ is *excluded* from the range of the operator. This is the so-called regularization, at the limit $\alpha \to 0$, of the Coulomb-type potentials

$$V(x,\alpha) = -\frac{1}{|x|+\alpha}, \quad \alpha > 0. \tag{2}$$

At first sight it may seem that a system with the Hamiltonian (1) is physically unremarkable and technically easy to solve. But this is not true. The one-dimensional hydrogen atom models a real hydrogen atom present in an extremely strong magnetic field, for instance in astrophysics, where the field of a pulsar is $B \approx 10^{12}$. In such situations, the atomic sizes perpendicular to the field are much smaller than the longitudial sizes.[1,2] In contrast to the real three-dimensional hydrogen atom, the one-dimensional system (1) demands more delicacy in the mathematical methods needed to understand the spectrum and complete eigenfunction set of the corresponding Schrödinger equation.[3]

The one-dimensional hydrogen atom was first investigated in 1959 by Loudon.[4] He proved that the spectrum of the one-dimensional hydrogen atom contains a ground state $E_0=-\infty$ and an infinite number of doubly degenerate excited states, even and odd solutions, defined over the

[a)]Electronic mail: vicent@fis.unam.mx
[b)]Electronic mail: bwolf@fis.unam.mx

whole x axis. This degeneracy is very strange since it contradicts one of the basic principles of (one-dimensional) quantum mechanics.[1] In Ref. 5, Andrews explained the double degeneracy observing that the strong singularity at $x=0$ absolutely isolates the two regions of the system, $x<0$ and $x>0$. The "Andrews mechanism" states that the probability for the particle in the left side to penetrate the right side or *vice versa* is zero. (See Refs. 6 and 7 where this *space-spliting effect* is studied further.) For all finite values of the energy Loudon found two independent solutions; the degeneracy of the eigenvalues has been explained in terms of hidden symmetry group $O(2)$,[6,8,9] and even in terms supersymmetry.[10–12] These papers contain three noncontradicting models to explain the same phenomenon. Indeed, during the last three decades this model has been the subject of intensive discussion and study, but there is still controversy in the interpretation of some of its features (see the literature contained in Ref. 13).

Analogs of the hydrogen atom on the spaces with constant positive or negative curvature were introduced by Schrödinger[14] and Infeld[15] in three and more dimensions. In this article we analyze the one-dimensional hydrogen atom analog on the upper branch of a hyperbola of pseudoradius R, defined by

$$\mathcal{H}^1 := \{s_1, s_2 \in \Re | s_2^2 - s_1^2 = R^2 > 0, s_2 \geqslant R\}, \tag{3}$$

where $\boldsymbol{s}=(s_2, s_1)$ are Cartesian coordinates in the ambient pseudo-Euclidean space. We have seen in a recent work[16] that spaces of constant curvature $1/R$ provide parametrized families of models which properly contract to the previously known ones as $R \to \infty$. The one-dimensional hydrogen atom on the sphere was recently analyzed for the circle $\mathcal{S}^1$ in the work of Mardoyan *et al.*[17] The hyperbolic case is studied here; it is connected by a transformation of coordinates to the Pöschl-Teller potential;[18] it participates thus in the representation theory of the three-dimensional Lorentz group (Ref. 19, Sec. 6.5); and has served as a model for scattering phenomena in systems with mixed (discrete and continuous) spectra.[20] Finally, it is an exactly solvable problem, so its eigenfunctions are expected (and confirmed) to be expressible in terms of special functions, particularly Gauss hypergeometrics ${}_2F_1$.

Physical interest leads us to extend the analysis of this one-dimensional system to phase space by means of the Wigner distribution function.[21] The phase space model that contains a hyperbolic position subspace was introduced in Ref. 16 for $N \geqslant 1$ dimensions. (See also Ref. 22 where phase space and the Wigner distribution are defined for N-sphere position spaces.) It is constructed from a complete set of solutions of the Schrödinger equations in configuration and momentum spaces. And it turns out that also the Wigner function can be expressed in terms of hypergeometric and other elementary special functions.

The Coulomb potential of the one-dimensional hydrogen atom on the hyperbola $\mathcal{H}^1$ in (3) is

$$V(\boldsymbol{s}) = -\frac{\kappa}{R}\frac{s_2}{|s_1|} \leqslant \frac{\kappa}{R}, \tag{4}$$

where κ is the coupling constant. This system belongs to the well-known class with superintegrable potentials on constant curvature spaces,[23,24] which is here restricted to one spatial dimension.

The organization of this paper is as follow: In sec. II we detail the method used to find the wave functions of this system in configuration space, and the corresponding wave functions in momentum space are obtained in Sec. III; in Sec. IV we verify the flat-space contraction limit. Section V is devoted to the calculation of the Wigner functions of the eigenstates of this system.

II. SOLUTIONS ON THE HYPERBOLA

Following Ref. 25, we shall use the map from the space $s=\{(s_1, s_2) \in \Re^2\}$ to the space $u=\{(u_1, u_2) \in \Re^2\}$ given by

$$s_1 = (\text{sign } u_1)\sqrt{u_2^2 - u_1^2}\frac{u_1^2}{2u_2}, \quad s_2 = \sqrt{u_2^2 - u_1^2}\left(u_2 - \frac{u_1^2}{2u_2}\right), \tag{5}$$

which satisfies

$$s_2^2 - s_1^2 = (u_2^2 - u_1^2)^2. \tag{6}$$

The relation between the distance elements in s- and u-spaces through the map (5) is

$$\mathrm{d}\boldsymbol{s} \,.\, \mathrm{d}\boldsymbol{s} = (u_2^2 - u_1^2)\left[\frac{(\boldsymbol{u}\cdot\mathrm{d}\boldsymbol{u})^2}{u_2^2} - \frac{u_1^2}{u_2^2}\mathrm{d}\boldsymbol{u}\cdot\boldsymbol{u}\right] + 3(\boldsymbol{u}\cdot\mathrm{d}\boldsymbol{u})^2. \tag{7}$$

From (6) we see that when the point $\boldsymbol{s}=(s_1,s_2)$ lies on the upper branch of the hyperbola of pseudoradius R, then $\boldsymbol{u}=(u_1,u_2)$ belongs to the upper branch of another hyperbola in u-space: $u_2^2-u_1^2=D^2$, with the pseudoradius $D=\sqrt{R}$. Thus in particular (5) corresponds to a transformation between the one-dimensional s- and u-hyperbolic spaces $\mathcal{H}^1$. From (7), for the points on the hyperbolas, the line elements are then related through

$$\frac{\mathrm{d}\boldsymbol{s}\cdot\mathrm{d}\boldsymbol{s}}{R} = -\frac{u_1^2}{u_2^2}\mathrm{d}\boldsymbol{u}\cdot\mathrm{d}\boldsymbol{u}. \tag{8}$$

This mapping is conformal, i.e., it conserves angles between lines.

Choosing the ordinary hyperbolic coordinates on s-space, their transformation (5) to u-space is

$$s_1 = R\sinh\tau, \quad s_2 = R\cosh\tau, \tag{9}$$

$$u_1 = \pm D\sqrt{e^{2\tau}-1}, \quad u_2 = De^{\tau}, \quad 0 \leqslant \tau < \infty. \tag{10}$$

This transformation is one-to-one between the points of the two $\mathcal{H}^1$ spaces, and a trivial case of the series of Hurwitz-type quadratic transformations between oscillator systems in two, four, and eight dimensions, and Coulomb systems in two, three, and five dimensions, respectively.[25,26] The line elements in the s- and u-hyperbolas are then

$$\mathrm{d}s = R\,\mathrm{d}\tau, \quad \mathrm{d}u = \frac{De^{\tau}}{\sqrt{e^{2\tau}-1}}\mathrm{d}\tau, \tag{11}$$

and so they are related by

$$\frac{\mathrm{d}s}{R} = \mathrm{d}\tau = \frac{u_1}{u_2}\frac{\mathrm{d}u}{D}. \tag{12}$$

Taking into account that $R=D^2$, the relation between the inner products defining the Hilbert space on the s- and u-hyperbolas is

$$(\Psi_1,\Psi_2)_{\mathcal{H}^1} \coloneqq \int_{\mathcal{H}^1}\mathrm{d}s\Psi_1^*(s)\Psi_2^*(s) = D\int_{\mathcal{H}^1}\frac{u_1}{u_2}\mathrm{d}u\Psi_1^*(s(u))\Psi_2^*(s(u)) =: (\Phi_1,\Phi_2)_{\mathcal{H}^1}, \tag{13}$$

for the renormalized functions

$$\Phi(u) \coloneqq \sqrt{D|u_2/u_1|}\Psi(s(u)). \tag{14}$$

In order to compare the dynamics in the two hyperbolic spaces, we write the one-dimensional Laplace-Beltrami operators on the s-hyperbola in the coordinates (9),

$$\Delta_{\mathrm{LB}}^{(s)} = \frac{1}{R^2}\left(s_1\frac{\partial}{\partial s_2} + s_2\frac{\partial}{\partial s_1}\right)^2 = \frac{1}{R^2}\frac{\mathrm{d}^2}{\mathrm{d}\tau^2}, \tag{15}$$

while on the u-hyperbola this operator is

$$\Delta_{\mathrm{LB}}^{(u)} = \frac{1}{D^2}\left(u_1\frac{\partial}{\partial u_2} + u_2\frac{\partial}{\partial u_1}\right)^2 = \frac{2}{D^2}\sqrt{\sinh\,\tau}e^{-\pi/2}\frac{\mathrm{d}}{\mathrm{d}\tau}\sqrt{\sinh\,\tau}e^{-\pi/2}\frac{\mathrm{d}}{\mathrm{d}\tau}. \tag{16}$$

With the identification (14) we find that the operators $\Delta_{\mathrm{LB}}^{(s)}$ and $\Delta_{\mathrm{LB}}^{(u)}$ are related by

$$\Delta_{\mathrm{LB}}^{(s)} = \left(\left|\frac{u_1}{u_2}\right|\right)^{1/2}\left\{\frac{u_2^2}{u_1^2}\frac{1}{D^2}\left[\Delta_{\mathrm{LB}}^{(u)} - \frac{3/4}{u_1^2} + \frac{1/4}{u_2^2}\right]\right\}\left(\left|\frac{u_1}{u_2}\right|\right)^{-1/2}. \tag{17}$$

The Schrödinger equation describing the nonrelativistic motion on the one-dimensional hyperbolic space $\mathcal{H}^1$ under the potential (4), written in terms of the Laplace-Beltrami operator $\Delta_{\mathrm{LB}}^{(s)}$, has the form

$$-\frac{1}{2}\Delta_{\mathrm{LB}}^{(s)}\Psi(\boldsymbol{s}) - \frac{\kappa}{R}\left(\frac{s_2}{|s_1|} - 1\right)\Psi(\boldsymbol{s}) = E\Psi(\boldsymbol{s}), \tag{18}$$

where E is the total energy of the system, and we have added the constant κ/R to the Coulomb potential in order to have bound states with negative energy. The transformation (5) and the substitutions (14) and (17) convert the Schrödinger equation (18) of the one-dimensional hydrogen atom into that of the singular oscillator whose parameters depend on the pseudoradius $R=D^2$ and the energy E,

$$-\frac{1}{2}\Delta_{\mathrm{LB}}^{(u)}\Phi(\boldsymbol{u}) + \left(\frac{\kappa_1^2 - \frac{1}{4}}{u_2^2} - \frac{\kappa_2^2 - \frac{1}{4}}{u_1^2}\right)\Phi(\boldsymbol{u}) = \lambda^2\Phi(\boldsymbol{u}), \tag{19}$$

$$\lambda^2 = -R(RE + \kappa), \quad k_1^2 = -2R(RE - \kappa), \quad k_2^2 = 1. \tag{20}$$

As in the case of the flat space where the corresponding transformation establishes the connection between the one-dimensional Coulomb system and an oscillator system with a centrifugal barrier,[6] in the case of the hyperbola (5) with the coordinates (9) and (10), the change of variables

$$e^{\tau} = \cosh\,\alpha, \tag{21}$$

transforms Eq. (19) into the *modified Pöschl-Teller* equation,

$$-\frac{1}{2}\frac{d^2\Phi}{d\alpha^2} + \left(-\frac{\kappa_1^2 - \frac{1}{4}}{\cosh^2\,\alpha} + \frac{\kappa_2^2 - \frac{1}{4}}{\sinh^2\,\alpha}\right)\Phi = \lambda^2\Phi, \tag{22}$$

where $u_1>0$ and $u_1<0$ correspond to $\alpha>0$ and $\alpha<0$ respectively. In Fig. 1 we show the one-dimensional hydrogen atom potential with five bound states shown as energy levels [see $E_n^{R,\kappa}$ in Eq. (30) ahead], and the Pöschl-Teller potentials that correspond to them through the parameters in Eq. (20). We remark this *duality* where for each energy level of the hydrogen atom one has a different Pöschl-Teller potential, whose coupling constant k_1 is thus quantized. These Schrödinger equations exhibit singularities in the potentials $\sim u_1^{-2} = 1/R\,\sinh^2\,\tau$ which disconnect the $u_1<0$ and $u_1>0$ halves of the plane (u_1, u_2).[5–7] In the two half-planes there are two potential wells which are mirror images of each other and separated by an impenetrable barrier, as shown in the figure. Correspondingly, the singularity of the potential (4) at $s_1=0$ splits the physical s-space in such a way that the particle on the upper branch of the hyperbola can be located either on the left-hand side $s_1<0$, or on the right-hand side $s_1>0$. Correspondingly, the motion in u-space takes place in only one of the two wells, so we must consider separately the Schrödinger equation (19) in each of these two regions, that we indicate by right (R) and left (L), as

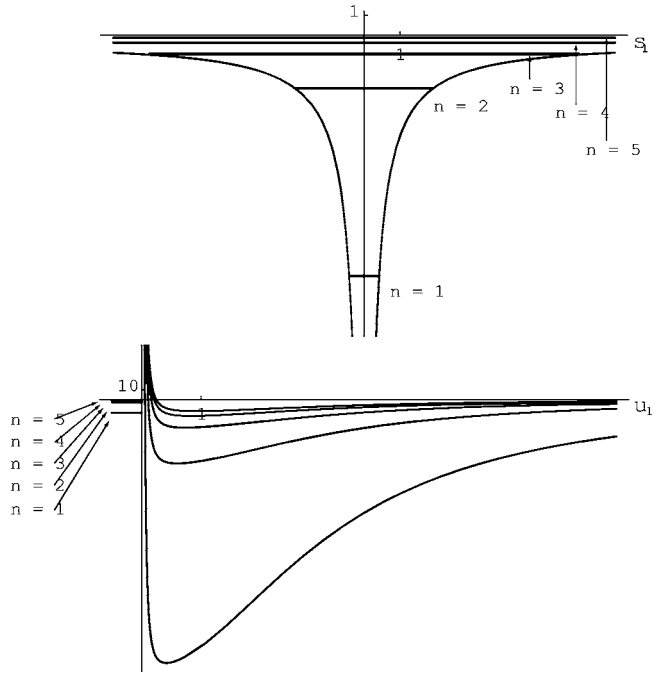

FIG. 1. Top: Panel The one-dimensional hydrogen atom potential (4) for $R=10$ and $\kappa=5$, showing all the energy levels, $n=1$, 2, 3, 4, and 5. The *physical* coordinate s_1 is related to the ensuing variable τ through $s_1=R\sinh\tau$. Bottom panel: The Pöschl-Teller potentials corresponding to the energy levels of the top figure (for $n=1$, 2, 3, 4, 5, $R=10$ and $\kappa=5$). The deeper potentials correspond to lower n's. The energy levels of the corresponding eigenstates are shown by horizontal lines to the left of the vertical axis. The coordinate u_1 is related to the variable τ by $u_1(\tau)=\sqrt{R(e^{2\tau}-1)}$.

$$\Phi^{\mathrm{R}}(u_1,u_2)=\Theta(u_1)f(u_1,u_2),\quad \Phi^{\mathrm{L}}(u_1,u_2)=\Theta(-u_1)g(u_1,u_2), \tag{23}$$

where $g(u_1,u_2)=f(-u_1,u_2)$ and $\Theta(x)=0,\frac{1}{2}$ and 1, for $x<0,x=0$ and $x>0$, respectively, is the Heaviside Θ-function.

The solutions of the Pöschl-Teller equation (22) are a well-known set of functions, one of whose outstanding properties is to serve as coupling (Clebsch-Gordan or Wigner) coefficients for the three-dimensional Lorentz group in the parabolic subgroup reduction,[19] between its discrete and continuous representation series. The coefficients k_1,k_2 in (22) are the Bargmann indices of the Lorentz group, which are determined by the two representations being coupled, and the energy eigenvalues determine the coupled representation, which can belong to the discrete or to the continuous series. In the present case $k_1>k_2+1$, the full spectrum of the one-dimensional hydrogen atom corresponds to the coupling of a discrete lower-bound and a discrete upper-bound representations: $D^+_{k_1}\otimes D^-_{k_2}=\Sigma_{k=0}^{K}D^+_k\oplus\int_0^\infty \mathrm{d}\kappa C_q$. The Clebsch-Gordan series yields here a finite number $K=\lfloor\frac{1}{2}(k_1-k_2-1)\rfloor$ of discrete representations ($\lfloor x\rfloor$ denotes the integer part of x), and a generalized integral over the continuous series representations $q=k(1-k),k=-\frac{1}{2}+ir$ and $r\in\Re$.

For $\alpha>0$, the wave functions that solve (22) are[19,23,24]

$$\Phi_n(\alpha)=A_n(\sinh\alpha)^{1/2+k_2}(\cosh\alpha)^{2n-k_1+1/2}\times {}_2F_1(-n,-n+k_1;1+k_2;\tanh^2\alpha), \tag{24}$$

$$A_n=\sqrt{\frac{2k_1(k_1-2n-k_2-1)\Gamma(k_1-n)\Gamma(n+1+k_2)}{D^2(2n+1+k_2)n\,!\,[\Gamma(1+k_2)]^2\Gamma(k_1-n-k_2)}}. \tag{25}$$

For these bound states, the eigenvalues λ are quantized as

$$\lambda = k_2 - k_1 + 2n + 1 > 0, \quad n = 0,1,\ldots,\left\lfloor \tfrac{1}{2}(k_1 - k_2 - 1)\right\rfloor, \tag{26}$$

and so bound state solutions exist only for $k_1 - k_2 > 1$. The normalization constant A_n in (25) is computed from the requirement of square integrability of the wave functions for $\alpha > 0$ under the inner product (13). We are reminded by (23) that there are right and left solutions for $\alpha \in \Re$, namely

$$\Phi^R(\alpha) = \Theta(\alpha)\Phi_n(|\alpha|), \quad \Phi^L(\alpha) = \Theta(-\alpha)\Phi_n(|\alpha|). \tag{27}$$

So, after replacement of $d\tau = \tanh\alpha\, d\alpha$ and $u_1/u_2 = \tanh\alpha$, the normalization condition can be expressed as

$$R\int_0^\infty d\tau |\Psi_n^R(\tau)|^2 = D\int_0^\infty d\alpha |\Psi_n^R(\alpha)|^2 \tanh^2\alpha = 1. \tag{28}$$

Finally, we note that the wave functions (24) can be written in terms of Jacobi polynomials of degree n, indices (k_2, k_1), and argument $\cosh 2\alpha$, including other factors of powers $\frac{1}{2} - k_1$ and $\frac{1}{2} + k_2$ of $\cosh\alpha$ and $\sinh\alpha$, respectively.[19]

Now we are ready to construct the eigenfunctions and energy eigenvalues of the one-dimensional hydrogen atom. Comparing (20) and (26), and replacing $n \mapsto n-1$, we find that for

$$k_1 = n + \rho_n, \quad \rho_n := \kappa R/n = \rho/n, \tag{29}$$

with $\rho := \kappa R$, the energy spectrum is

$$E_n^{R,\kappa} = -\frac{n^2}{2R^2} - \frac{\kappa^2}{2n^2} + \frac{\kappa}{R}, \quad n = 1,2,\ldots,\lfloor\sqrt{\rho}\rfloor. \tag{30}$$

Returning to the variable $\tau = \ln\cosh\alpha$ of (21), we express the bound state wave functions $\Psi^{\mathrm{R}}_{n\rho_n}(\tau)$ which describe the particle in the right ($\tau > 0$) and left ($\tau < 0$) regions, in the form

$$\Psi^{\mathrm{R,L}}_{n\rho_n}(\tau) = \Theta(\pm\tau)\sqrt{\frac{\rho_n(\rho_n^2 - n^2)}{R}}\, 2\sinh|\tau| e^{(n-1-\rho_n)|\tau|}\, {}_2F_1\left(-n+1, 1+\rho_n; 2; 1-e^{-2|\tau|}\right), \tag{31}$$

$$= \Theta(\pm\tau)\frac{2^n}{n}\sqrt{\frac{\rho_n(\rho_n^2 - n^2)}{R}}(\sinh|\tau|)^n e^{-\rho_n|\tau|} P_{n-1}^{(-n-\rho_n, -n+\rho_n)}\left(-\coth|\tau|\right), \tag{32}$$

where $P_{n-1}^{(\alpha,\beta)}(x)$ is a Jacobi polynomial and we have added ρ_n as an explicit parameter in the functions. Thus we find that all excited bound states ($n \geqslant 1$) of the one-dimensional hydrogen atom are doubly degenerate—as in the model on flat space. To find the ground state of this $\mathcal{H}^1$-system one must solve the Schrödinger equation for an "inoculating" potential,[4] but this boundary case lies outside our present scope. In Fig. 2 we show on configuration space the five bound wave functions of the system in the previous figure.

III. SOLUTIONS IN MOMENTUM SPACE

From the wave functions on the τ-space for the R- and L-regions, we introduce the two wave functions on momentum space $p \in \Re$, $\tilde{\Psi}^{\mathrm{R}}_{n,\rho_n}(p)$ and $\tilde{\Psi}^{L}_{n,\rho_n}(p)$ [see (23)] by means of the Fourier integral transform

$$\tilde{\Psi}^{\mathrm{R,L}}_{n,\rho_n}(p) = \sqrt{\frac{R}{2\pi}}\int_{-\infty}^{+\infty} d\tau\, e^{-ipR\tau}\Psi^{\mathrm{R,L}}_{n,\rho_n}(\tau). \tag{33}$$

For the positive-τ region, replacing the explicit form (31) of the wave function $\tilde{\Psi}^{\mathrm{R}}_{n,\rho n}(\tau)$ into Eq. (33), we obtain

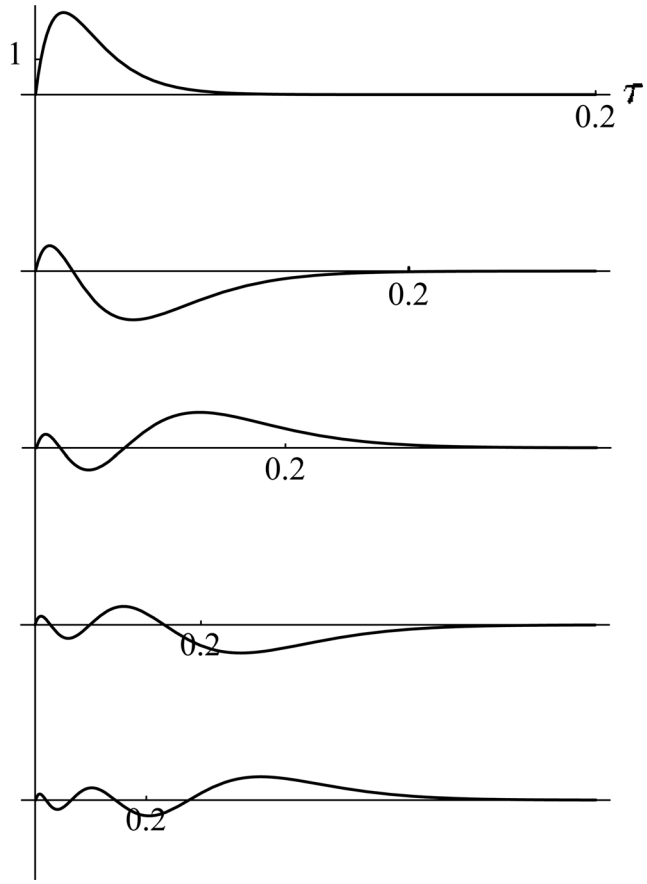

FIG. 2. Wave functions of the one-dimensional hydrogen atom on the right half of hyperbolic configuration space, for the levels $n=1$, 2, 3, 4, and 5 (from top to bottom). The horizontal axis is the variable $\tau>0$ (related to the physical coordinate through $s_1=R\sinh\tau$); for visibility, it has been rescaled by a factor of 3/2 between successive levels. The plots were generated from Eq. (31).

$$\tilde{\Psi}^{\mathrm{R}}_{n,\rho n}(p)=\sqrt{\frac{2\rho n(\rho_n^2-n^2)}{\pi}}\int_0^\infty \mathrm{d}\tau\sinh\tau e^{(n-1-\rho n-ipR)\tau}\times {}_2F_1(-n+1,1+\rho n;2;1-e^{-2\tau}), \tag{34}$$

$$=\sqrt{\frac{\rho_n(\rho_n^2-n^2)}{8\pi}}\frac{\Gamma\left(\frac{1}{2}[\rho_n-n+ipR]\right)}{\Gamma\left(\frac{1}{2}[\rho_n-n+ipR]+2\right)}$$
$$\times {}_2F_1\left(-n+1,1+\rho_n;\tfrac{1}{2}(\rho_n-n+ipR)+2;1\right), \tag{35}$$

where we have used the formula [Ref. 27, Eq. (10) on p. 110]

$$\int_0^\infty \mathrm{d}t\, e^{-\alpha t}(\sinh t)^\gamma=\frac{\Gamma\left(\frac{1}{2}[\alpha-\gamma]\right)\Gamma(\gamma+1)}{2^{\gamma+1}\Gamma\left(\frac{1}{2}[\alpha+\gamma]+1\right)}. \tag{36}$$

Finally, with the help of the Gauss identity for the ${}_2F_1(a,b;c;1)$ and using

$$\frac{\Gamma(z)}{\Gamma(z-n)}=(-1)^n\frac{\Gamma(1+n-z)}{\Gamma(1-z)}, \tag{37}$$

the result (35) can be written in the form

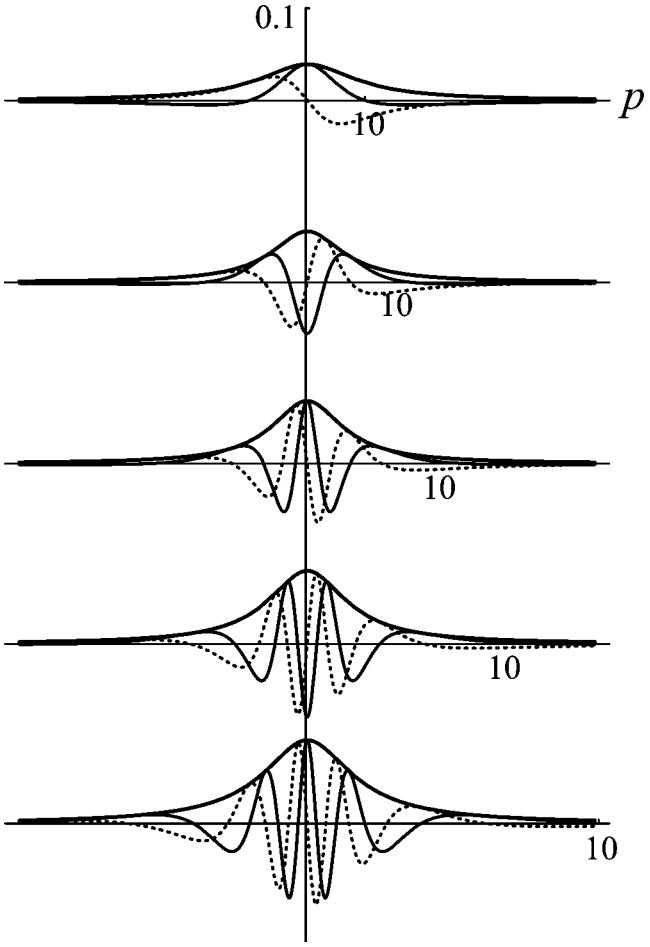

FIG. 3. Wave functions in momentum space of the one-dimensional hydrogen atom on the hyperbola, for $n=1$, 2, 3, 4, and 5 (from top to bottom, corresponding to those on configuration space in the previous figure). Real and imaginary parts of the function are indicated by thin continuous and dashed lines; the modulus by thick continuous lines. For visibility, the axes have been rescaled by 2/3 between successive levels—the proportion inverse to that of the previous figure. The plots were generated from Eq. (38).

$$\tilde{\Psi}^{\mathrm{R,L}}_{n,\rho_n}(p)=[\tilde{\Psi}^{\mathrm{L,R}}_{n,\rho_n}(p)]^*=\frac{(-1)^{n+1}}{4}\sqrt{\frac{\rho_n(\rho_n^2-n^2)}{2\pi}}\frac{\Gamma\left(\frac{1}{2}[\rho_n-n\pm ipR]\right)}{\Gamma\left(\frac{1}{2}[\rho_n-n\mp ipR]+1\right)}\frac{\Gamma\left(\frac{1}{2}[\rho_n+n\mp ipR]\right)}{\Gamma\left(\frac{1}{2}[\rho_n+n\pm ipR]+1\right)}. \tag{38}$$

For the particular case $n=1$, the preceding expression simplifies to

$$\tilde{\Psi}^{\mathrm{R,L}}_{1,\rho}(p)=\sqrt{\frac{\rho(\rho^2-1)}{2\pi}}\frac{1}{(\rho-1\pm ipR)(\rho+1\pm ipR)}. \tag{39}$$

In Fig. 3 we show the wave functions of the hyperbolic hydrogen atom in momentum space, for the levels $n=1$, 2, 3, 4, and 5, of the previous figure.

IV. CONTRACTION TO FLAT SPACE

The contraction of the hyperbola $\mathcal{H}^1$ to flat space $\mathfrak{R}$ is obtained considering the limit $R\to\infty$. In this case, the energy spectrum (30) for finite n becomes the energy spectrum of the one-dimensional standard hydrogen atom:[4]

$$E_n^{\kappa} = \lim_{R\to\infty} E_n^{R,\kappa} = -\frac{\kappa^2}{2n^2}, \quad n = 1,2,\ldots . \tag{40}$$

The bound-state wave functions of the one-dimensional hydrogen atom on the hyperbola given by (31) in the limit $R\to\infty$ converge to the well-known Coulomb wave functions different from zero on of the region $x>0$ or $x<0$. Their contraction is

$$\lim_{R\to\infty} \Psi_{n,\rho_n}^{\mathrm{R,L}}\left(\frac{x}{R}\right) = \Theta(\pm x)\frac{2\kappa^{3/2}}{n^{3/2}}|x|e^{-\kappa|x|/n}{}_1F_1\left(-n+1;2;\frac{2\kappa|x|}{n}\right) \tag{41}$$

$$= \Theta(\pm x)\frac{2\kappa^{3/2}}{n^{5/2}}|x|e^{-\kappa|x|/n}L_{n-1}^1\left(\frac{2\kappa|x|}{n}\right), \tag{42}$$

where $L_n^{\alpha}(x)$ is a generalized Laguerre polynomials.[27]

The bound-state wave functions in momentum representation, in (38) will contract to functions on the circle (which is the Hopf sphere for the one-dimensional case). In order to compute the contraction limit $R\to\infty$ for these functions we use the Stirling asymptotic formula for the gamma functions to prove that

$$\begin{aligned}\lim_{R\to\infty} \sqrt{R}\tilde{\psi}_{n,\rho_n}^{\mathrm{R,L}}(p) &= \frac{(-1)^{n+1}}{\sqrt{2\pi}}\frac{p_n^{3/2}}{p_n^2+p^2}\left(\frac{p_n \mp ip}{p_n \pm ip}\right)^n \\ &= \frac{(-1)^{n+1}}{\sqrt{2\pi}}\frac{p_n^{3/2}}{p_n^2+p^2}\exp\left(\mp 2in\arctan\frac{p}{p_n}\right) = \frac{(-1)^{n+1}}{\sqrt{2\pi p_n}}(1+\cos\theta_n)e^{\mp in\theta_n},\end{aligned} \tag{43}$$

where $n=1, 2,\ldots$, and

$$p_n := \sqrt{-2E_n^{\kappa}} = \frac{\kappa}{n}, \quad \tan\frac{1}{2}\theta_n = \frac{p}{p_n} = \frac{n}{\kappa}p. \tag{44}$$

The limit in Eq. (43) coincides with the momentum wave functions found in Ref. 8.

V. WIGNER DISTRIBUTION FUNCTION

We now construct the Wigner distribution function for the states of the one-dimensional hydrogen atom in hyperbolic space. According to the definition of the Wigner function on momentum space,[16] we have

$$W(\Psi_{n,p_n}^{\mathrm{R,L}}|\tau,p) = \frac{R}{2\pi}\int_{-\infty}^{\infty} dp'\,\tilde{\Psi}_{n,p_n}^{\mathrm{L,R}}\left(p-\tfrac{1}{2}p'\right)^* e^{iRp'\tau}\tilde{\Psi}_{n,p_n}^{\mathrm{R,L}}\left(p+\tfrac{1}{2}p'\right) \tag{45}$$

$$= W(\Psi_{n,p_n}^{\mathrm{L,R}}|-\tau,p), \tag{46}$$

where the last equality follows from (38).

Let us first consider the particular case $n=1$. Using the explicit form of the wave function $\tilde{\Psi}_{1,\rho}^{\mathrm{R}}$ given in (39), we can write

$$W(\Psi_{1,\rho}^{\mathrm{R}}|\tau,p) = \frac{\rho(\rho^2-1)}{16i\pi^2}\int_{-i\infty}^{i\infty} dz\,\frac{e^{-4y\tau}}{\left|\left(\frac{1}{2}[\rho-1+ipR]-y\right)\left(\frac{1}{2}[\rho+1+ipR]-y\right)\right|^2}. \tag{47}$$

The integrand on (47) has four poles in the upper complex half-plane, at the points $y_{1,2}=\frac{1}{2}(\rho-1\pm ipR)$ and $y_{3,4}=\frac{1}{2}(\rho+1\pm ipR)$. After complex integration, using the residue theorem, we obtain

$$W(\Psi^{\mathrm{R}}_{1,\rho}|\tau,p)=\frac{\rho(\rho^2-1)}{2\pi(pR)}e^{-2\rho\tau}\mathrm{Im}\frac{\sinh 2\tau(1+ipR)}{1+ipR}. \tag{48}$$

The Wigner function for the left-side solutions $\Psi^{\mathrm{L}}_{1,\rho}$ is obtained, according to (46), reversing the sign of τ in the exponential factor in (48), to $e^{+2\rho\tau}$. Using the last expression, it is easy to check the marginal properties for this particular case, that is

$$\int_{-\infty}^{\infty}\mathrm{d}p\ W(\Psi^{\mathrm{R}}_{1,\rho}|\tau,p)=|\Psi^{\mathrm{R}}_{1,\rho}(\tau)|^2,\quad \int_0^{\infty}\mathrm{d}\tau\ W(\Psi^{\mathrm{R}}_{1,\rho}|\tau,p)=|\tilde{\Psi}^{\mathrm{R}}_{1,\rho}(p)|^2. \tag{49}$$

We can now tackle the computation of the Wigner function for the general-n bound wave functions $\Psi^{\mathrm{R,L}}_{n,\rho_n}(\tau)$, whose momentum representation $\tilde{\Psi}^{\mathrm{R,L}}_{n,\rho_n}(p)$ is given by (38). Replacing the explicit forms in (45) with $y:=-i\frac{1}{2}p'R$, we obtain

$$\begin{aligned}W(\Psi^{\mathrm{R}}_{n,\rho_n}|\tau,p)&=\frac{\rho_n(\rho_n^2-n^2)}{16i\pi^2}\int_{-i\infty}^{i\infty}\mathrm{d}y\left|\frac{\Gamma\left(\frac{1}{2}[\rho_n-1+ipR]-y\right)\Gamma\left(\frac{1}{2}[\rho_n-1+ipR]+n+y\right)}{\Gamma\left(\frac{1}{2}[\rho_n+1+ipR]+y\right)\Gamma\left(\frac{1}{2}[\rho_n+1+ipR]+n-y\right)}\right|^2 e^{-4y\tau}\\&=(-1)^{n+1}\frac{\rho_n(\rho_n^2-n^2)\Gamma(\rho_n)}{4\pi n!\,\Gamma(\rho_n-n+1)}e^{-2(\rho_n-n)\tau}\times\mathrm{Re}\left[\frac{\Gamma(-n+ipR)\Gamma(\rho_n+ipR)e^{-2i\pi pR}}{\Gamma(1+ipR)\Gamma(\rho_n-n+1+ipR)}\right.\\&\left.\times\,{}_4F_3\left(\begin{matrix}-n,-n+ipR,\rho_n,\rho_n+ipR\\1+ipR,\rho_n-n+1,\rho_n-n+1+ipR\end{matrix}\middle|e^{-4\tau}\right)\right].\end{aligned} \tag{50}$$

The Wigner functions for the left-side wave functions $\Psi^{\mathrm{L}}_{n,\rho_n}$ are obtained from (46) through changing the sign of τ in the three exponentials of the general result (50). In Fig. 4 we show the Wigner functions of the states in the previous two figures, for $n=1$, 2, 3, 4, and 5. We note in the figure that the number of zeros of the configuration-space function on $\tau>0$ axis can be seen from the Wigner plot in Fig. 4 by counting the changes of sign of the phase space function along the $\tau>0$ axis. The absolute square of the momentum wave functions are symmetric and bell-shaped, with their width increasing with n.

VI. CONCLUSIONS

We obtained the bound-state wave functions of the one-dimensional hydrogen atom on the hyperbola $\mathcal{H}^1$ by solving the Schrödinger equation in configuration space. As in the flat case, we have shown that their double degeneracy is explained by the Andrews mechanism of space-splitting. We have found that the two independent position wave functions in the regions $u_1>0$ and $u_1<0$ are expressible in terms of Gauss hypergeometric functions ${}_2F_1$ (or Jacobi polynomials) as expected. This is in contrast with the flat one-dimensional case where the wave functions are written in terms of the associated Laguerre polynomials $L^1_{n-1}(\gamma|x|)\,\gamma>0$, i.e., ${}_1F_1(-n+1;\gamma|x|)$ confluent hypergeometric functions [see Eq. (31) and Ref. 4]. The wave functions in momentum representation were obtained through the usual Fourier transform method, and it was surprising that these could be written in the closed form also, in terms of ordinary Gamma functions. And we verified that in the $R\to\infty$ contraction limit, the hyperbolic system becomes the well-known one on flat space.

The simple form of the momentum wave functions allowed us to construct the Wigner distribution function of this model in closed analytic form, and to check its correctness through the marginal projections. We note that the above-noted expressions for the Wigner functions in the hydrogen atom model are considerably simpler than those for the one-dimensional *oscillator* on $\mathcal{H}^1$, found in Ref. 16, which have the form of two sums over Gauss hypergeometrics. As expected, Fig. 4 shows that with increasing energy the states show larger spread of probability at greater distances. The pointed-triangle shapes of the main peak of the Wigner function and its regions of negativity follow the pattern of Wigner functions for bound states of other potentials having a mixed spectra.[28]

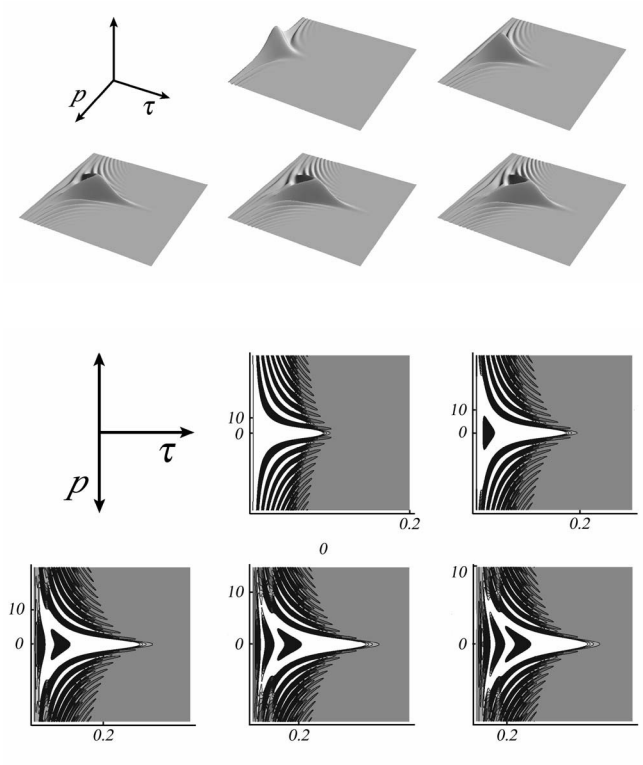

FIG. 4. Top panel: Wigner functions of the one-dimensional hydrogen atom states on phase space (τ,p), $\tau>0$, for the levels $n=1$, 2, 3, 4, and 5 of the previous two figures (left to right and top to bottom). Bottom panel: Contour plots on phase space of the previous Wigner functions, with emphasis on distinguishing their positive (white) and negative (black) regions. As in the previous two figures, the axes are rescaled by reciprocal factors to frame the oscillatory behavior of the functions.

We leave for future consideration important issues such as the hidden symmetry group and the supersymmetrization of the one-dimensional hydrogen atom on the hyperbola and on the circle.

(Received 16 April 2005; accepted 25 April 2005; published online 20 June 2005)

We propose a general method for the deformation quantization of any second-class constrained system on a symplectic manifold. The constraints determining an arbitrary constraint surface are in general defined only locally and can be components of a section of a nontrivial vector bundle over the phase-space manifold. The covariance of the construction with respect to the change of the constraint basis is provided by introducing a connection in the "constraint bundle," which becomes a key ingredient of the conversion procedure for the nonscalar constraints. Unlike in the case of scalar second-class constraints, no Abelian conversion is possible in general. Within the BRST framework, a systematic procedure is worked out for converting nonscalar second-class constraints into non-Abelian first-class ones. The BRST-extended system is quantized, yielding an explicitly covariant quantization of the original system. An important feature of second-class systems with nonscalar constraints is that the appropriately generalized Dirac bracket satisfies the Jacobi identity only on the constraint surface. At the quantum level, this results in a weakly associative star-product on the phase space. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1935430]

I. INTRODUCTION

The quantization problem is usually understood as that of constructing a quantum theory for a given classical system, at the same time preserving important properties of the system such as locality and global symmetries. This additional requirement is crucial. Indeed, formally one can always find a representation such that all the constraints are solved, gauge symmetries are just shift symmetries, and the Poisson bracket has the canonical form. But in doing so one usually destroys locality and global symmetries. It is the problem of the quantization of relativistic local field theories that initiated the development of sophisticated quantization methods applicable to systems with non-Abelian and open gauge algebras.[1–4]

From this point of view, the problem of quantizing curved phase space appears as a problem of constructing quantization in a way that is explicitly covariant with respect to the arbitrary change of phase-space coordinates. Given such a method (at the level of deformation quantization at least) one can always find quantization in each coordinate patch and then glue everything together. Similar to the curved phase-space quantization problem is the one of quantizing an arbitrary constraint surface. Any surface can be represented by independent equations (constraints) but in general only locally. In fact, one can always assume that the surface is the zero locus of a section of a vector bundle over the phase space. The quantization problem for arbitrary constrained systems can then be reformulated as the problem of constructing quantization that is explicitly covariant with respect to the basis of constraints. In this paper, we restrict ourselves to the case of second-class constraints and address the problem of constructing a quantization scheme that is explicitly covariant with respect to the change of phase-space coordinates and the constraint basis.

A general framework that allows us to quantize second-class constraints at the same footing as first-class ones is the well-known *conversion*—the procedure that converts the original second-class constraints into first-class ones by introducing extra variables known as conversion variables. At least locally in the phase space, any second-class constraints can be converted into Abelian ones, and therefore the Abelian conversion is sufficient for most applications. The situation changes drastically if one wants the quantization to be explicitly covariant with respect to the change of the constraint basis. Indeed, by changing the constraint basis one can always make the converted constraints non-Abelian. The additional price one has to pay for covariance is the appearance of a connection in the vector bundle associated with the constraints. This is reminiscent of the quantization of systems with curved phase space, where phase-space covariance requires introducing a symplectic connection on the phase space. In fact, this is more than a coincidence.

The coordinate and constraint basis covariance appear to be intimately related within the quantization methods developed in Refs. 5 and 6 (see also Refs. 7 and 8). Indeed, the key ingredient of these methods is the embedding of the system into the cotangent bundle over its phase space. In the natural coordinate system x^i, p_i, the embedding constraints $p_i=0$ are nonscalar.[7] In this example, the reparametrization covariance in the original phase space translates into the covariance with respect to the basis of constraints p_i. In Ref. 8, this approach was extended to general second-class constrained systems with constraints being scalar functions.

In this paper, we extend the method in Ref. 8 to the case where the second-class constraint surface is an arbitrary symplectic submanifold of the phase space, not necessarily defined by zero locus of the set of any independent scalar functions. Considering the quantization problem for the constrained systems whose classical dynamics evolves on the constraint surface, one has to take care of the geometry of the tubular neighborhood of the constrained submanifold. The geometry of the entire phase space is irrelevant for this problem. In its turn, any tubular neighborhood of the submanifold can be identified with the normal bundle over the submanifold. For coisotropic submanifolds (first-class constrained systems), the corresponding approach to quantization was considered in Ref. 9. It then follows that an arbitrary constrained submanifold can be considered a zero locus of a section of the appropriate vector bundle over the phase space. Moreover, in practical physical problems, the second-class constraints can appear from the outset as components of a section of some bundle over the original phase space rather than scalar functions. This leads naturally to the concept of constrained systems with nonscalar constraints.

By considering the original nonscalar constraints θ_α at the same footing with the constraints p_i determining the embedding into $T^*\mathcal{M}$, we achieve a globally defined description for general second-class systems. Using the appropriate non-Abelian conversion procedure and subsequent BRST quantization, we then arrive at the formulation of the quantum theory (at the level of deformation quantization) that is explicitly covariant under the reparametrizations of the original phase space and under the changing of the constraint basis. We note that the nonscalar first-class constraints were also considered in Ref. 10 in a different framework.

The conventional approach to second-class systems is based on the Dirac bracket—a Poisson bracket on the entire phase space, which is determined by constraints and for which the constraint surface is a symplectic leaf. This allows considering the Poisson algebra of observables as a Dirac bracket algebra of phase-space functions modulo those vanishing on the constrained submanifold. From this point of view, the quantization problem can be understood as that of quantizing a degenerate Poisson bracket. However, outside the constraint surface, the Dirac bracket is not invariant under the change of the constraint basis and therefore is not well defined in the case of nonscalar constraints. The Dirac bracket bivector can be invariantly continued from the constraint surface under certain natural conditions, although the price is that the Jacobi identity is in general satisfied only in the weak sense, i.e., on the constrained submanifold. In the non-Abelian conversion framework such a covariant generalization of the Dirac bracket is naturally determined by the Poisson bracket of observables of the converted system. We note that weak brackets were previously studied in various contexts in Refs. 11–14.

At the quantum level, the lack of Jacobi identity for the covariant Dirac bracket results in a

phase-space star product that is not associative in general. Within the non-Abelian conversion approach developed in the paper, this star product naturally originates from the quantum multiplication of BRST-invariant extensions of phase-space functions. In the BRST cohomology, we obtain an associative star product that is identified with the quantum deformation of the classical algebra of observables (functions on the constraint surface). In particular, the associativity of the phase-space star-product is violated only by the terms vanishing on the constraint surface.

The quantization method developed in this paper can be viewed as an extension of the Fedosov quantization scheme[15,6] to systems whose constrained submanifolds are defined by nonscalar constraints and whose phase spaces, as a result, carry a weak Poisson structure. We note that gauge systems with a weak Poisson structure can be alternatively quantized[14] using the Kontsevich formality theorem.

II. GEOMETRY OF CONSTRAINED SYSTEMS WITH LOCALLY DEFINED CONSTRAINTS

We consider a constrained system on a general symplectic manifold $(\omega, \mathcal{M})$. The constrained system is defined on $\mathcal{M}$ by specifying a submanifold $\Sigma \subset \mathcal{M}$ such that the restriction $\omega|_\Sigma$ of the symplectic form to the constraint surface has a constant rank. If Σ is coisotropic, the constrained system is called first class. A constrained system is called second class if the restriction $\omega|_\Sigma$ of the symplectic form is invertible on Σ.

Let us assume for a moment that Σ is determined by constraints $\theta_\alpha = 0$ that are globally defined functions on $\mathcal{M}$; then $\{\theta_\alpha, \theta_\beta\}|_\Sigma = 0$ ($\{\theta_\alpha, \theta_\beta\}|_\Sigma$ is invertible) iff the system is first (respectively, second) class. The converse is also true, but *only locally*: if a constrained system is first (respectively, second) class, then locally there exist independent functions θ_α determining the constraint surface Σ by $\theta_\alpha = 0$ and any such functions satisfy $\{\theta_\alpha, \theta_\beta\}|_\Sigma = 0$ (respectively, $\{\theta_\alpha, \theta_\beta\}|_\Sigma$ is invertible).

The dynamics of a constrained system on $\mathcal{M}$ is assumed evolving on the constraint surface $\Sigma \subset \mathcal{M}$. At the quantum level, a tubular neighborhood of Σ gets involved in describing dynamics. In its turn, it is a standard geometrical fact that any such neighborhood is diffeomorphic to a vector bundle over Σ. Indeed, in each neighborhood $U^{(i)}$ of a point of Σ one can pick a coordinate system $x^a_{(i)}$, $\theta^{(i)}_\alpha$ such that $\Sigma \cap U^{(i)}$ is singled out by $\theta^{(i)}_\alpha = 0$ and on the intersection of two such neighborhoods $U^{(i)}$ and $U^{(j)}$

$$x^a_{(i)} = X^a_{(ij)}(x_{(j)}), \quad \theta^{(i)}_\alpha = (\phi^{(ij)})^\beta_\alpha \theta^{(j)}_\beta \tag{2.1}$$

with some functions $X^a_{(ij)}(x)$ and $\phi^{(ij)}(x)$. Functions $(\phi^{ij})^\alpha_\beta$ can be identified with transition functions of a vector bundle $V^*(\Sigma)$ over Σ (we use the notation for a dual bundle to make notations convenient in what follows). Under the identification of an open neighborhood of Σ with the vector bundle $V^*(\Sigma)$, coordinates θ_α are identified with constraint functions on $\mathcal{M}$. In particular, Σ goes to the zero section of $V^*(\Sigma)$. Note that the constraints θ_α, being understood as functions on $\mathcal{M}$, are defined only locally. If there exist globally defined constraints then $V^*(\Sigma)$ is trivial.

It can be useful to pull back the vector bundle $V^*(\Sigma)$ to the vector bundle $V^*(\mathcal{M})$ over $\mathcal{M}$. Functions θ_α are then naturally identified with the components of a globally defined section θ of $V^*(\mathcal{M})$. At the same time Σ is nothing else than a submanifold of points where θ vanishes. These arguments motivate the following concept of a constrained system.

Definition 2.1: A constrained system with nonscalar constraints is a triple $(\mathcal{M}, V^*(\mathcal{M}), \theta)$ *where the* $\mathcal{M}$*-symplectic manifold with a symplectic form* ω*,* $V^*(\mathcal{M})$*-vector bundle over* $\mathcal{M}$*, and* θ *is a fixed section of* $V^*(\mathcal{M})$*. It is assumed that vanishing points of* θ *are regular and form a submanifold* $\Sigma \subset \mathcal{M}$ *(constraint surface) such that* $\omega|_\Sigma$ *has a constant rank.*

The definitions of first- and second-class constrained systems still stand because they are formulated entirely in the intrinsic terms of the constraint surface Σ, making use only of the rank of $\omega|_\Sigma$ irrespectively of the way of defining Σ.

Several comments are in order:

(i) Another possibility to consider an arbitrary constraint surface keeping at the same time constraints as globally defined functions is to use overcomplete sets of constraints (i.e., reducible constraints with different terminology). However, depending on a particular system this can be a complicated task. Moreover, even if the constraints are reducible it can also be useful to allow them to be nonscalar.

(ii) As we have seen, any submanifold $\Sigma \subset \mathcal{M}$ can be represented as a surface of regular vanishing points of a section of a vector bundle over $\mathcal{M}$. Note, however, that by taking arbitrary constraints $\theta^{(i)}_{\alpha}$ in each neighborhood $U^{(i)}$, one does not necessarily arrive at a vector bundle. Indeed, in the intersection $U^{(i)} \cap U^{(j)}$ one still has

$$\theta^{(i)}_{\alpha} = (\phi^{(ij)})^{\beta}_{\alpha}\theta^{(j)}_{\beta}. \tag{2.2}$$

But functions $(\phi^{(ij)})^{\beta}_{\alpha}$ are defined only up to terms of the form $(\chi^{(ij)})^{\beta\gamma}_{\alpha}\theta_{\gamma}$ with $(\chi^{(ij)})^{\beta\gamma}_{\alpha} = -(\chi^{(ij)})^{\gamma\beta}_{\alpha}$. As a consequence, functions $(\phi^{(ij)})^{\beta}_{\alpha}$ satisfy the cocycle condition also up to terms proportional to θ,

$$(\phi^{(ik)})^{\gamma}_{\alpha}(\phi^{(kj)})^{\beta}_{\gamma} = (\phi^{(ij)})^{\beta}_{\alpha} + \cdots . \tag{2.3}$$

This means that only appropriately chosen constraints can be identified with components of a section of a vector bundle over $\mathcal{M}$. What differential geometry tells us is that such a choice always exists.

III. CONNECTIONS AND SYMPLECTIC STRUCTURES ON VECTOR BUNDLES

In what follows we need some geometrical facts on the connections and symplectic structures on the appropriately extended cotangent bundle over a symplectic manifold. Now let $\mathcal{M}$ be a symplectic manifold and $\mathcal{W}(\mathcal{M}) \to \mathcal{M}$ be a symplectic vector bundle over $\mathcal{M}$. Also let e_A be a local frame [locally defined basic sections of $\mathcal{W}(\mathcal{M})$] and $\mathcal{D}$ be the symplectic form on the fibers of $\mathcal{W}(\mathcal{M})$. The components of $\mathcal{D}$ with respect to e_A are determined by $\mathcal{D}_{AB} = \mathcal{D}(e_A, e_B)$.

It is well known (see, e.g., Ref. 6) that any symplectic vector bundle admits a symplectic connection. Let Γ and $\boldsymbol{\nabla}$ denote a symplectic connection and the corresponding covariant differential in $\mathcal{W}(\mathcal{M})$. The compatibility condition reads as

$$\boldsymbol{\nabla}\mathcal{D} = 0, \quad \partial_i \mathcal{D}_{AB} - \Gamma^{C}_{iA}\mathcal{D}_{CB} - \Gamma^{C}_{iB}\mathcal{D}_{AC} = 0, \tag{3.1}$$

where the coefficients Γ^{C}_{iA} of Γ are determined as

$$\boldsymbol{\nabla} e_A = dx^i \, \Gamma^{C}_{iA} e_C. \tag{3.2}$$

It is useful to introduce the following connection 1-form:

$$\Gamma_{AB} = dx^i \, \Gamma_{AiB}, \quad \Gamma_{AiB} = \mathcal{D}_{AC}\Gamma^{C}_{iB}. \tag{3.3}$$

Then compatibility condition (3.1) is rewritten as

$$d\mathcal{D}_{AB} = \Gamma_{AB} - \Gamma_{BA}, \quad \partial_i \mathcal{D}_{AB} - \Gamma_{AiB} + \Gamma_{BiA} = 0. \tag{3.4}$$

As a consequence of the condition, one arrives at the following property of the connection 1-form Γ_{AB}:

$$d\Gamma_{AB} = d\Gamma_{BA}. \tag{3.5}$$

Consider the following direct sum of vector bundles:

$$\mathcal{E}_0 = \mathcal{W}(\mathcal{M}) \oplus T^*\mathcal{M}, \tag{3.6}$$

where $T^*\mathcal{M}$ denotes a cotangent bundle over $\mathcal{M}$. Let x^i, p_j and Y^A be standard local coordinates on $\mathcal{E}_0$ (x^i are local coordinates on $\mathcal{M}$, p_j are standard coordinates on the fibers of $T^*\mathcal{M}$, and Y^A are

coordinates on the fibers of $\mathcal{W}(\mathcal{M})$ corresponding to the local frame e_A). Assume in addition that $\mathcal{M}$ is equipped with a closed 2-form ω (not necessarily nondegenerate).

Considered as a manifold that $\mathcal{E}_0$ can be equipped with the following symplectic structure:

$$\omega^{\mathcal{E}_0} = \pi^* \omega + 2\, dp_i \wedge dx^i + \mathcal{D}_{AB} dY^A \wedge dY^B + d\Gamma_{AB}\, Y^A Y^B - 2\Gamma_{AB} \wedge dY^A\, Y^B, \tag{3.7}$$

where $\pi^*\omega$ is the 2-form ω on $\mathcal{M}$ pulled back by the bundle projection $\pi: \mathcal{E}_0 \to \mathcal{M}$. One can directly check that 2-form (3.7) is well defined. Indeed, it can be brought to the standard explicitly covariant form, similar to that of the supersymplectic manifolds[16]

$$\omega^{\mathcal{E}_0} = \pi^* \omega + 2\, dp_i \wedge dx^i + \mathcal{D}_{AB}\, \boldsymbol{\nabla} Y^A \wedge \boldsymbol{\nabla} Y^B + \mathcal{R}_{AB} Y^A Y^B. \tag{3.8}$$

Here, $\boldsymbol{\nabla} Y^A = dY^A + \Gamma^A_C Y^C$, and $\mathcal{R}_{AB} = \mathcal{R}_{ij;AB} dx^i \wedge dx^j$ denotes the curvature of Γ:

$$\begin{aligned} \mathcal{R}_{ij;AB} &= \mathcal{D}_{AC} \mathcal{R}^C_{ijB} = \mathcal{D}_{AC} (\partial_i \Gamma^C_{jB} - \partial_j \Gamma^C_{iB} + \Gamma^C_{iD} \Gamma^D_{jB} - \Gamma^C_{jD} \Gamma^D_{iB}) \\ &= \partial_i \Gamma_{AjB} - \partial_j \Gamma_{AiB} + \Gamma_{CiA} \mathcal{D}^{CD} \Gamma_{DjB} - \Gamma_{CjA} \mathcal{D}^{CD} \Gamma_{DiB}. \end{aligned} \tag{3.9}$$

The last equality follows from the nondegeneracy of $\mathcal{D}_{AB}$ and compatibility condition (3.4). Also, it is straightforward to show that the 2-form (3.7) is exact, besides the first term:

$$\omega^{\mathcal{E}} = \pi^* \omega + d[2p_i\, dx^i + Y^A \mathcal{D}_{AB}\, \boldsymbol{\nabla} Y^B]. \tag{3.10}$$

Analyzing the structure on the rhs of (3.10), one can see that an arbitrary (not necessarily symplectic) connection $\overset{0}{\Gamma}$ can be taken to construct the close 2-form on $\mathcal{E}$ in (3.10). It turns out that the resulting 2-form still has the structure (3.7), with Γ given by

$$\Gamma_{AB} = \frac{1}{2}(d\mathcal{D}_{AB} + \overset{0}{\Gamma}_{AB} + \overset{0}{\Gamma}_{BA}). \tag{3.11}$$

It is easy to see that connection Γ is by construction compatible with the sympletric structure $\mathcal{D}$ for any connection $\overset{0}{\Gamma}$. In addition, if $\overset{0}{\Gamma}$ was taken symplectic it would bring $\Gamma = \overset{0}{\Gamma}$.

The Poisson bracket on $\mathcal{E}_0$ corresponding to the symplectic form (3.7) is determined by the following basic relations:

$$\begin{gathered} \{p_i, x^j\}_{\mathcal{E}_0} = -\delta^j_i, \quad \{p_i, p_j\}_{\mathcal{E}_0} = \omega_{ij}(x) + \frac{1}{2}\mathcal{R}_{ij;AB}(x) Y^A Y^B, \\ \{Y^A, Y^B\}_{\mathcal{E}_0} = \mathcal{D}^{AB}(x), \quad \{p_i, Y^A\}_{\mathcal{E}_0} = \Gamma^A_{iB}(x) Y^B, \end{gathered} \tag{3.12}$$

with all the others vanishing: $\{x^i, Y^A\}_{\mathcal{E}_0} = \{x^i, x^j\}_{\mathcal{E}_0} = 0$.

IV. EMBEDDING AND CONVERSION AT THE CLASSICAL LEVEL

A. Embedding

Consider a second-class constrained system $(\mathcal{M}, V^*(\mathcal{M}), \theta)$ with locally defined constraints θ_α [i.e., θ_α are components of a section θ of $V^*(\mathcal{M})$ with respect to a local frame e^α]. Let $T^*_\omega \mathcal{M}$ be a cotangent bundle equipped with the modified symplectic structure $2\, dp_i \wedge dx^i + \pi_0^* \omega$, where ω is a symplectic form on $\mathcal{M}$ and $\pi_0: T^*_\omega \mathcal{M} \to \mathcal{M}$ is the canonical projection.

The embedding of $\mathcal{M}$ into $T^*_\omega \mathcal{M}$ as a zero section is a symplectic map, i.e., a restriction of symplectic form $2\, dp_i \wedge dx^i + \pi_0^* \omega$ to the submanifold $\mathcal{M}$ is ω. Moreover, constrained system $(\mathcal{M}, V^*(\mathcal{M}), \theta)$ is equivalent to the constrained system $(T^*_\omega \mathcal{M}, W^*(\mathcal{M}), \Theta)$, where $W^*(\mathcal{M})$ is a direct sum $W^*(\mathcal{M}) = T^*\mathcal{M} \oplus V^*(\mathcal{M})$ considered as a vector bundle over $T^*_\omega(\mathcal{M})$ and components of Θ with respect to the local frame dx^i, e^α are $-p_i, \theta_\alpha$ (in other words, locally, the constraints are

given by $-p_i=0$ and $\theta_\alpha=0$). Indeed, by solving constraints $-p_i=0$ one arrives at the starting point constrained system. At this stage the construction here repeats the one from Ref. 8, with the only difference being that constraints θ_α are now defined only locally.

B. Non-Abelian conversion

Given second-class constraints Θ_A, one can always find an appropriate extension of the phase space by introducing conversion variables Y^A whose Poisson bracket relations have the form $\{Y^A, Y^B\}=\mathcal{D}^{AB}$, with $\mathcal{D}^{AB}$ invertible. Then one can find converted constraints T_A in the extended phase space, satisfying

$$\{T_A, T_B\} = U_{AB}^C T_C, \quad T_A|_{Y=0} = \Theta_A. \tag{4.1}$$

The resulting first-class system with constraints T_A is equivalent to the original second-class one and is called converted system. For second-class constraints that are scalar functions on the phase space one can always assume the conversion to be Abelian, i.e. with vanishing functions U_{AB}^C (see Ref. 17 for a detailed discussion of the conversion and the existence theorem for the Abelian conversion).

For the nonscalar constraints one naturally wants to build converted constraints in the invariant way, i.e., independently of a particular choice of the constraint basis. As we will see momentarily this forces one to consider, in general, a non-Abelian conversion.

To see this, one first needs to introduce conversion variables in a geometrically covariant way. It is useful to take as conversion variables the coordinates on the fibers of the bundle $W(\mathcal{M})$ dual to the bundle $W^*(\mathcal{M})=T^*\mathcal{M}\oplus V^*(\mathcal{M})$ associated to constraints $\theta_\alpha, -p_i$. The phase space is then

$$\mathcal{E}_0 = T^*_\omega \mathcal{M} \oplus W(\mathcal{M}), \quad W(\mathcal{M}) = V(\mathcal{M}) \oplus T\mathcal{M}. \tag{4.2}$$

We introduce unified notation e_A and Y^A for the local frame and coordinates on the fibers of $W(\mathcal{M})$, respectively. In the adapted basis Y^A is split into Y^i and Y^α.

Given a connection $\overline{\Gamma}$ in $V(\mathcal{M})$, one can equip $W(\mathcal{M})$ with the following fiberwise symplectic structure:

$$\mathcal{D}_{ij} = \omega_{ij}, \quad \mathcal{D}_{i\alpha} = -\mathcal{D}_{\alpha i} = \overline{\nabla}_i \theta_\alpha = \partial_i \theta_\alpha - \overline{\Gamma}^\beta_{i\alpha}\theta_\beta, \quad \mathcal{D}_{\alpha\beta} = 0. \tag{4.3}$$

In what follows we also need the explicit form of its inverse $\mathcal{D}^{AC}$, $\mathcal{D}^{AC}\mathcal{D}_{CB}=\delta^A_B$

$$\begin{gathered} \mathcal{D}^{\alpha\beta} = \Delta^{\alpha\beta}, \quad \mathcal{D}^{i\beta} = -\omega^{il}\mathcal{D}_{l\gamma}\Delta^{\gamma\beta}, \\ \mathcal{D}^{ij} = \omega^{ij} - \omega^{ik}\mathcal{D}_{k\alpha}\Delta^{\alpha\beta}\mathcal{D}_{l\beta}\omega^{lj}, \end{gathered} \tag{4.4}$$

where we introduced $\Delta^{\alpha\beta}$ as follows:

$$\Delta^{\alpha\gamma}\Delta_{\gamma\beta} = \delta^\alpha_\beta, \quad \Delta_{\alpha\beta} = \mathcal{D}_{i\alpha}\omega^{ij}\mathcal{D}_{j\beta}. \tag{4.5}$$

Δ is invertible on Σ by assumption (recall that its invertibility is a part of the defining property of second-class constraints). It is then invertible in some neighborhood of Σ and we assume that it is invertible on the entire $\mathcal{M}$.

Note that $\mathcal{D}^{ij}$ determines a bivector field on $\mathcal{M}$ that coincides on Σ with the conventional Dirac bracket. The latter bracket is not well defined beyond Σ if the constraints are not scalars. The bracket determined by $\mathcal{D}^{ij}$ in (4.4) can therefore be understood as a covariant generalization of the Dirac bracket to the case of nonscalar constraints. It is straightforward to check that the covariant Dirac bracket satisfies Jacobi identity modulo terms vanishing on Σ.

Furthermore, one can equip $W(\mathcal{M})$ with the symplectic connection compatible with the fiberwise symplectic form. This is achieved as follows. First, one picks a linear symplectic connection $\overline{\Gamma}_{\mathcal{M}}$ on the symplectic manifold $\mathcal{M}$ and equips $W(\mathcal{M})$ with the direct sum connection $\overset{0}{\Gamma}$ determined by

$$\overset{0}{\nabla} e_i = (\overline{\Gamma}_{\mathcal{M}})_i^j e_j, \quad \overset{0}{\nabla} e_\alpha = (\overline{\Gamma})_\alpha^\beta e_\beta, \tag{4.6}$$

where $\overset{0}{\nabla}$ denotes the covariant differential determined by $\overset{0}{\Gamma}$. Given "bare" connection $\overset{0}{\nabla}$ in $W(\mathcal{M})$ one then arrives at the symplectic connection Γ using (3.11). In its turn the symplectic connection in $W(\mathcal{M})$ determines a symplectic structure $\omega^{\mathcal{E}_0}$ on $\mathcal{E}_0$ in accordance to the general formula (3.7). The associated Poisson bracket reads as

$$\begin{gathered}\{p_i, x^j\} = -\delta_i^j, \quad \{p_i, p_j\} = \omega_{ij}(x) + \frac{1}{2} R_{ij;AB}(x) Y^A Y^B, \\ \{Y^A, Y^B\} = \mathcal{D}^{AB}(x), \quad \{p_i, Y^A\} = \Gamma_{iB}^A(x) Y^B.\end{gathered} \tag{4.7}$$

Here and in what follows we drop the superscript of the Poisson bracket on the extended phase space whenever it cannot lead to confusions. Note that the embedding of $T^*_\omega \mathcal{M}$ into $\mathcal{E}_0$ is symplectic. This implies that coordinates Y^A can be treated as second-class constraints (they can also be understood as gauge conditions for the converted system). Considered together with constraints Θ_A they determine a constrained system on $\mathcal{E}_0$ that is equivalent to the original constrained system on $\mathcal{M}$.

Since we are interested in the non-Abelian conversion, it is preferable to work in terms of the BFV-BRST formalism from the very beginning. To this end we introduce ghost variables $\mathcal{C}^A$ and $\mathcal{P}^A$ with the transformation law determined by that of components of a section of $W(\mathcal{M})$ and $W^*(\mathcal{M})$, respectively. One can consistently assume canonical Poisson bracket relations,

$$\{\mathcal{P}_A, \mathcal{C}^B\} = -\delta_A^B, \tag{4.8}$$

and brackets between $\mathcal{C}^A$ and $\mathcal{P}^A$ and all other variables vanishing. Note that in order for Poisson brackets between ghosts and other variables to remain vanishing when passing from one neighborhood to another momenta p_i should transform inhomogeneously. This means that the extended phase space is $\mathcal{E} = T^*_\omega(\Pi W(\mathcal{M})) \oplus W(\mathcal{M})$ with $W(\mathcal{M})$ in the second summand considered as a vector bundle over $\Pi W(\mathcal{M})$. Here and below Π indicates that the Grassmann parity of the fibers of a vector bundle is reversed. Note also that the extended phase space $\mathcal{E}$ is not anymore a vector bundle over $\mathcal{M}$ because p_i transform in an inhomogeneous way.

In the BRST language the conversion problem can be formulated as follows. Given "bare" generating function $\overline{\Omega}$ whose expansion with respect to the ghosts variables starts with given second-class constraints Θ_A,

$$\overline{\Omega} = \mathcal{C}^A \Theta_A + \cdots, \quad gh(\overline{\Omega}) = 1. \tag{4.9}$$

The conversion implies finding BRST charge satisfying

$$\{\Omega, \Omega\} = 0, \quad gh(\Omega) = 1, \quad \Omega|_{Y=0} = \overline{\Omega}. \tag{4.10}$$

Note that Ω and $\overline{\Omega}$ are assumed to be globally defined functions on the entire extended phase space and its submanifold determined by $Y^A = 0$, respectively.

Now we describe conversion of the second-class constraints $\Theta_A = \{-p_i, \theta_\alpha\}$. Taking into account their transformation properties a natural anzatz for a generating function $\overline{\Omega}$ is as follows:

$$\overline{\Omega} = -\mathcal{C}^i p_i + \mathcal{C}^\alpha \theta_\alpha + \mathcal{C}^i (\overline{\Gamma})^\alpha_{i\beta} \mathcal{C}^\beta \mathcal{P}_\alpha . \tag{4.11}$$

Indeed, the nonlinear in ghosts term coming from the transformation law for p_i is compensated by the term coming from inhomogeneous contribution in the transformation law for the connection coefficients. This is exactly the point. In order for the generating function $\overline{\Omega}$ as well as BRST charge Ω to be globally defined functions, one needs to introduce the terms nonlinear in ghosts. In terms of constraints, this implies that the conversion is non-Abelian.

C. Existence and construction of the classical BRST charge

In the standard BFV-BRST formalism the BRST charge and BRST-invariant observables are constructed by expanding in homogeneity degree in ghost momenta. The existence of a nilpotent BRST charge is ensured by Homological Perturbation Theory[18] with the relevant operator being Koszul–Tate differential associated with the constraints. At the same time, within the Abelian conversion procedure the effective first-class constraints, BRST charge, and BRST-invariant observables are constructed by expanding in homogeneity degree in conversion variables, and all these quantities are to be found order by order in these variables.

In the case of non-Abelian conversion it is then natural to take as an expansion degree the total homogeneity in ghost momenta $\mathcal{P}_A$ and conversion variables Y^A:

$$\deg Y^A = \deg \mathcal{P}_A = 1, \quad \deg x^i = \deg p_i = \deg \mathcal{C}^A = 0 . \tag{4.12}$$

Accordingly, Ω decomposes as

$$\Omega = \sum_{s=0} \Omega_s, \quad \Omega_0 = \mathcal{C}^\alpha \theta_\alpha - \mathcal{C}^i p_i, \quad \Omega_1 = \mathcal{C}^i (\overline{\Gamma})^\alpha_{i\beta} \mathcal{C}^\beta \mathcal{P}_\alpha + \cdots , \tag{4.13}$$

where we have explicitly kept the term from the first-order contribution that is needed for covariance. The required BRST charge satisfying (4.10) is to be constructed order by order in the degree. To this end one first needs to satisfy the master equation to zeroth order in the degree, which implies finding Ω_1. A "minimal" form of Ω_1 that satisfies a master equation to the zeroth order can be taken as

$$\Omega_1 = \mathcal{C}^i (\overline{\Gamma})^\alpha_{i\beta} \mathcal{C}^\beta \mathcal{P}_\alpha - \mathcal{C}^A \mathcal{D}_{AB} Y^B . \tag{4.14}$$

In constructing BRST charge it is also useful to restrict ourselves to the following class of phase-space functions: let $\mathfrak{U}^0$ be the space of formal power series in Y^A, ghosts $\mathcal{C}^A$, and ghost momenta $\mathcal{P}_\alpha$ with coefficients being smooth functions in x^i. In other words we forbid dependence on p_i and $\mathcal{P}_i$. The space $\mathfrak{U}^0$ is closed under the multiplication and the Poisson bracket (both operations can be naturally defined for formal power series). Algebra $\mathfrak{U}^0$ decomposes with respect to the degree (4.12) as $\mathfrak{U}^0 = \oplus_{s \geqslant 0} \mathfrak{U}^0_s$ so that an element of $\mathfrak{U}^0_s$ has the form

$$a = \sum_{p \geqslant 0, q \geqslant 0}^{p+q=s} (a_{pq})^{\alpha_1 \cdots \alpha_q}_{A_1 \cdots A_p} Y^{A_1} \cdots Y^{A_p} \mathcal{P}_{\alpha_1} \cdots \mathcal{P}_{\alpha_q}, \quad a_{pq} = a_{pq}(x, \mathcal{C}) . \tag{4.15}$$

Since the BRST charge and BRST-invariant observables are to be constructed by expanding in the degree (4.12) the lowest degree term $-\delta$ in the expansion of $\{\Omega, \cdot\}$ plays a role of the nilpotent operator determining homological perturbation theory. Considered acting on elements from $\mathfrak{U}^0$, operator δ is completely determined by $\overline{\Omega}$ and is given by degree -1 operator

$$\delta = \mathcal{C}^A \frac{\partial}{\partial Y^A} + \theta_\alpha \frac{\partial}{\partial \mathcal{P}_\alpha}. \tag{4.16}$$

It is therefore a sum of the standard Koszul–Tate operator $\delta_K = \theta_\alpha(\partial/\partial \mathcal{P}_\alpha)$ associated with original constraints θ_α and the operator $\mathcal{C}^A(\partial/\partial Y^A)$ that determines a homological perturbation theory in the Abelian conversion framework and in the Fedosov quantization.

To proceed with the conversion we need to introduce a version of the contracting homotopy operator determined by

$$\delta^* f_{pq} = \frac{1}{p+q} Y^A \frac{\partial}{\partial \mathcal{C}^A} f_{pq}, \quad p+q \neq 0, \quad \delta^* f_{00} = 0, \quad \delta^{*2} \equiv 0, \tag{4.17}$$

for an element $f_{pq} \in \mathfrak{U}^0$ that is homogeneous in $\mathcal{C}^A$ and Y^A of orders p and q, respectively. Operators δ and δ^* satisfy

$$\delta^* \delta a + \delta \delta^* a = a - a|_{\mathcal{C}=Y=0}. \tag{4.18}$$

Proposition 4.1: There exists a classical BRST charge Ω, $\mathrm{gh}(\Omega)=1$ *satisfying master equation* $\{\Omega,\Omega\}=0$, *boundary conditions (4.13) and (4.14), and such that* $\Omega_s \in \mathfrak{U}^0_s$ *for* $s \geqslant 2$. *In addition, given* Ω_0 *and* Ω_1 *such a BRST charge is unique provided* $\delta^* \Omega_s = 0$ *for all* $s \geqslant 2$.

Proof: The Poisson bracket on $\mathcal{E}$ can also be expanded with respect to the degree as

$$\{\cdot,\cdot\} = \{\cdot,\cdot\}_{-2} + \{\cdot,\cdot\}_{-1} + \{\cdot,\cdot\}_0 + \{\cdot,\cdot\}_2 \tag{4.19}$$

(terms with other degrees vanish), where each term is a bilinear first-order differential operator of definite degree. In particular,

$$\{f,g\}_{-2} = f \frac{\overleftarrow{\partial}}{\partial Y^A} \mathcal{D}^{AB} \frac{\partial}{\partial Y^B} g. \tag{4.20}$$

The master equation at order n in degrees implies

$$\{\Omega_0, \Omega_{n+2}\}_{-2} + \{\Omega_0, \Omega_{n+1}\}_{-1} + \{\Omega_1, \Omega_{n+1}\}_{-2} + B_n = 0, \tag{4.21}$$

where B_n depends on Ω_s with $s \leqslant n$ only and is given explicitly by

$$B_n = \sum_{0 \geqslant p,q \geqslant n}^{p+q+s=n} \{\Omega_p, \Omega_q\}_s. \tag{4.22}$$

In fact, the first term in (4.21) vanishes because Ω_0 does not depend on Y and the equation takes the form

$$\delta \Omega_{n+1} = B_n. \tag{4.23}$$

This equation can always be solved by $\Omega_{n+1} = \delta^* B_n$ using (4.18), $B_n|_{\mathcal{C}=Y=0}=0$, and the consistency condition $\delta B_n = 0$. The later is fulfilled provided the master equation holds to lowest orders, i.e., that Ω_s for $s \leqslant n$ are such that

$$\{\overset{(n)}{\Omega}, \overset{(n)}{\Omega}\} \in \bigoplus_{s \geqslant n} \mathfrak{U}^0_s, \quad \overset{(n)}{\Omega} = \sum_{s=0}^{n} \Omega_s. \tag{4.24}$$

Indeed, consider the following identity:

$$\{\overset{(n)}{\Omega},\{\overset{(n)}{\Omega},\overset{(n)}{\Omega}\}\}=0. \tag{4.25}$$

Next, observe that $\{\overset{(n)}{\Omega},\overset{(n)}{\Omega}\}=B_n+\cdots$ with dots denoting terms from $\mathfrak{U}^0_{\geqslant n+1}$ and, finally, check that to order $n-1$ in the degree this identity gives $\delta B_n=0$.

This solution for Ω_{n+1} obviously belongs to $\mathfrak{U}^0$ and satisfies $\delta^*\Omega_{n+1}=0$. Conversely, Eq. (4.23) has a unique solution Ω_{n+1} satisfying $\Omega_{n+1}\in\mathfrak{U}^0_{n+1}$, $\delta^*\Omega_{n+1}=0$, and $\mathrm{gh}(\Omega_{n+1})=1$. □

D. Classical observables and weak Dirac bracket

We show that observables of the original system on $\mathcal{M}$ are isomorphic to observables of the BFV-BRST system on $\mathcal{E}$. The latter are understood as cohomology of the adjoint action,

$$Q=\{\Omega,\cdot\} \tag{4.26}$$

of the BRST charge.

Proposition 4.2: Let $f_0=f_0(x,\mathcal{C})$ be any Y and $\mathcal{P}$-independent function. Then there exists $f\in\mathfrak{U}^0$ such that

$$\{\Omega,f\}=0,\quad f|_{Y=\mathcal{P}=0}=f_0,\quad \mathrm{gh}(f)=\mathrm{gh}(f_0). \tag{4.27}$$

If, in addition, $\delta^*(f-f_0)=0$ and $\mathrm{gh}(f)\geqslant 0$, then f is a unique BRST-invariant extension of f_0. Moreover, if $f,\tilde{f}\in\mathfrak{U}^0$ both satisfy (4.27) with the same function f_0, then $f-\tilde{f}=Qh$ for some function $h\in\mathfrak{U}^0$.

Proof: The proof is standard and follows by expanding $Qf=0$ with respect to degree (4.12) and using the fact that δ cohomology is trivial in nonzero degree. The later statement obviously holds provided cohomology of the standard Koszul–Tate operator $\delta_K=\theta_\alpha(\partial/\partial\mathcal{P}_\alpha)$ vanishes in nonzero degree in $\mathcal{P}_\alpha$. Locally, operator δ_K is known to have vanishing cohomology in nonzero degree, provided constraints θ_α satisfy standard regularity assumptions. This also holds globally, as can be shown by using a suitable partition of unity. □

Let f_0 and g_0 be two inequivalent observables of the original system, i.e. $f_0|_\Sigma-g_0|_\Sigma\neq 0$. It then follows from the explicit form of Ω that their BRST-invariant extensions f and g determined by Proposition **4.2** are not equivalent, i.e., $f-g\neq\{\Omega,h\}$ for any h. This means that observables of the original system are observables of the BFV-BRST system. In fact, one can show that these systems are equivalent in the sense that the Poisson algebra of inequivalent observables of the original system (i.e., the algebra of functions on Σ equipped with the Poisson bracket) is isomorphic to the Poisson algebra of ghost number zero BRST cohomology of the BFV-BRST system. Now we restrict ourselves to a little bit weaker equivalence statement. Namely, we show that this holds for BRST cohomology evaluated in $\mathfrak{U}^0$ (Q obviously maps $\mathfrak{U}^0$ to itself).

Proposition 4.3: Let f be an arbitrary function from $\mathfrak{U}^0$ satisfying $Qf=0$. Then $f=Qh$ for some h iff $f|_\Sigma=f|_{\theta_\alpha=\mathcal{C}^A=Y^A=\mathcal{P}_\alpha=0}=0$.

Proof: Let $f_0=f|_{Y=\mathcal{P}=0}$. Condition $f|_\Sigma=f_0|_\Sigma=0$ implies that there exist $f_0^\alpha(x)$ and $f_{0A}(x,\mathcal{C})$, such that

$$f_0=\theta_\alpha f_0^\alpha+\mathcal{C}^A f_{0A}, \tag{4.28}$$

and their transformation properties can be assumed to be those of sections of $V(\mathcal{M})$ and $W^*(\mathcal{M})$, respectively. One can then check that

$$(Qh)|_{Y=\mathcal{P}=0}=f_0,\quad h=-\mathcal{P}_\alpha f_0^\alpha-Y^A f_{0A}, \tag{4.29}$$

because $f_0=-\delta h$ and $(Qh)|_{\mathfrak{U}^0_0}=-\delta h$ for $h\in\mathfrak{U}^0_1$. Proposition **4.2** then implies that there exists $h'\in\mathfrak{U}^0$ such that $f=Q(h+h')$. □

To summarize, we have the following.

Theorem 4.1: *The BRST cohomology of $Q=\{\Omega,\cdot\}$ evaluated in $\mathfrak{U}^0$ are given by*

$$H^n(Q,\mathfrak{U}^0) = C^\infty(\Sigma), \quad n = 0,$$
$$H^n(Q,\mathfrak{U}^0) = 0, \quad n \neq 0. \tag{4.30}$$

The fact that all the physical observables can be taken elements of $\mathfrak{U}^0$ suggests that we consider $\mathfrak{U}^0$ as a fundamental object replacing the algebra of functions on the entire extended phase space. This can be consistently done in spite of the fact that the BRST charge Ω and the ghost charge $\mathcal{G}=\mathcal{C}^A\mathcal{P}_A$ do not belong to $\mathfrak{U}^0$. Indeed, from a more general point of view, a classical BFV-BRST system is determined by (i) Poisson algebra with a not necessarily nondegenerate Poisson structure, which is also graded with the ghost degree, (ii) Odd nilpotent BRST differential Q of ghost number 1 that differentiates both the product of functions and the Poisson bracket, and (iii) differential V (determining evolution) of zero ghost number that differentiates both the product and the Poisson bracket and satisfies $[Q,V]=0$. The standard Hamiltonian BFV-BRST system fits this definition with $Q=\{\Omega,\cdot\}$ and $V=\{H,\cdot\}$, with H denoting a Hamiltonian. Such a generalization of the Hamiltonian BFV-BRST theory was recently studied in Ref. 14. Note also that in the Lagrangian context this corresponds to theories described by the BRST differential not necessarily generated by a master action and an antibracket. Theories of this type were recently considered in Ref. 19.

From this slightly more general point of view, the Poisson algebra $\mathfrak{U}^0$ is a BFV-BRST system because Q and the ghost number operator preserve $\mathfrak{U}^0$. The notion of a generalized BFV-BRST system can be extended to the quantum case by replacing the Poisson algebra with the star-product algebra. It can also be generalized further in the sense that the bracket can be allowed to satisfy the Jacobi identity only up to Q-exact terms as well as V can preserve the bracket only weakly.[14]

Let us give some further comments concerning the Poisson bracket of BRST observables. In the case where Ω is Abelian (see Ref. 8 for a detailed discussion of this case) Proposition **4.2** establishes an isomorphism between the algebra of functions of x^i and functions of x^i, Y^A satisfying $\{\Omega,\cdot\}=0$ and $\delta^*\cdot=0$. The later algebra (understood as a subalgebra in $\mathfrak{U}^0$) is closed under the Poisson bracket in $\mathfrak{U}^0$. The Poisson bracket in this algebra determines a Poisson bracket on $\mathcal{M}$ that can be easily seen to coincide with the Dirac bracket associated to second-class constraints θ_α.

In the present case Ω explicitly depends on $\mathcal{P}_\alpha$ and one is forced to consider δ^* and $\{\Omega,\cdot\}$-closed functions from $\mathfrak{U}^0$ that are now allowed to depend also on $\mathcal{C}^A$ and $\mathcal{P}_\alpha$. However, this algebra is not anymore closed under the Poisson bracket and therefore a direct counterpart of the Dirac bracket fails to satisfy the Jacobi identity outside Σ in this case. Indeed, finding unique lifts $f,g\in\mathfrak{U}^0$ of two phase-space functions f_0 and g_0, evaluating their Poisson bracket, and putting $Y=\mathcal{P}=0$ one finds a bracket on $\mathcal{M}$ that coincides with the standard Dirac bracket when $\theta_\alpha=0$. Explicitly, the bracket reads as

$$\{f_0,g_0\}_D = \partial_i f_0 \mathcal{D}^{ij}\,\partial_j g_0 = \partial_i f_0\,\omega^{ij}\,\partial_j g_0 - \partial_i f_0\,\omega^{il}\overline{\nabla}_l\theta_\alpha\Delta^{\alpha\beta}\overline{\nabla}_k\theta_\beta\omega^{kj}\,\partial_j g_0, \tag{4.31}$$

where

$$\overline{\nabla}_i\theta_\alpha = \partial_i\theta_\alpha - \overline{\Gamma}^\beta_{i\alpha}\theta_\beta, \quad \Delta^{\alpha\gamma}\Delta_{\gamma\beta}=\delta^\alpha_\beta, \quad \Delta_{\alpha\beta}=\overline{\nabla}_i\theta_\alpha\omega^{ij}\overline{\nabla}_j\theta_\beta. \tag{4.32}$$

This bracket can be considered as a direct generalization of the standard Dirac bracket. Unlike the later this generalized bracket does not depend on the choice of constraint basis and therefore is well defined outside Σ in the case of nonscalar constraints. The Jacobi identity for the bracket (4.31) is violated by the terms proportional to the curvature $\overline{R}^\alpha_{ij\beta}$ of the connection $\overline{\nabla}$ and to the constraints θ_α. So it is inevitably a weak bracket if the bundle $V(\mathcal{M})$ does not admit a flat connection.

E. Dirac connection

As we have seen, the construction imposes no constraints on the connection Γ^A_{iB} entering the Poisson bracket on $\mathcal{E}$ but the compatibility with the symplectic from $\mathcal{D}_{AB}$. A symplectic connection

always exists and can be obtained, starting from an arbitrary connection in $W(\mathcal{M})$, e.g., using (3.11). Let us, nevertheless, give an explicit form of the particular symplectic connection, which, as we are going to see, also has some additional properties.

To this end let us consider an explicit form of the compatibility condition $\nabla\mathcal{D}=0$,

$$\partial_i\omega_{jk}-\Gamma_{jik}+\Gamma_{kij}=0,$$

$$\partial_i\overline{\nabla}_j\theta_\alpha-\Gamma_{ji\alpha}+\Gamma_{\alpha ij}=0, \tag{4.33}$$

$$\Gamma_{\alpha i\beta}-\Gamma_{\beta i\alpha}=0.$$

A minimal solution having correct transformaion properties reads as

$$\Gamma_{\alpha i\beta}=0,\quad \Gamma_{ji\alpha}=\mathcal{D}_{j\beta}(\overline{\Gamma})^\beta_{i\alpha},$$
$$\Gamma_{ijk}=(\overline{\Gamma}_{\mathcal{M}})_{ijk},\quad \Gamma_{\alpha ij}=-\overline{\nabla}_i\overline{\nabla}_j\theta_\alpha, \tag{4.34}$$

where $\overline{\nabla}_i\overline{\nabla}_j\theta_\alpha=\overline{\nabla}_i\mathcal{D}_{j\alpha}=\partial_i\mathcal{D}_{j\alpha}-\Gamma^\beta_{i\alpha}\mathcal{D}_{j\beta}$.

It is easy to see that if $V(\mathcal{M})$ is trivial and one takes $\overline{\Gamma}=0$ then (4.34) coincides with the Dirac connection introduced in Ref. 8. In fact, connection (4.34) possesses similar properties with respect to the weak Dirac bracket. To see this let us write down this connection in terms of the coefficients with upper indices,

$$\Gamma^j_{ik}=\omega^{jl}((\overline{\Gamma}_{\mathcal{M}})_{lik}+\mathcal{D}_{l\gamma}\Delta^{\gamma\alpha}\hat{\nabla}_i\hat{\nabla}_k\theta_\alpha),\quad \Gamma^j_{i\alpha}=0,$$
$$\Gamma^\alpha_{ij}=-\Delta^{\alpha\beta}\hat{\nabla}_i\hat{\nabla}_j\theta_\beta,\quad \Gamma^\beta_{i\alpha}=\overline{\Gamma}^\beta_{i\alpha}, \tag{4.35}$$

where $\hat{\nabla}_i\theta_\alpha=\overline{\nabla}_i\theta_\alpha$ and $\hat{\nabla}_i\hat{\nabla}_j\theta_\alpha=\partial_i\mathcal{D}_{j\alpha}-\overline{\Gamma}^\beta_{i\alpha}\mathcal{D}_{j\beta}-(\overline{\Gamma}_{\mathcal{M}})^k_{ji}\mathcal{D}_{k\alpha}$. Connection Γ in $W(\mathcal{M})$ determines a connection $\Gamma_{\mathcal{D}}$ in $T\mathcal{M}$ whose coefficients are Γ^j_{ik}. It follows from $\nabla\mathcal{D}^{AB}=0$ and $\Gamma^j_{i\alpha}=0$ that

$$(\nabla_{\mathcal{D}})_i\mathcal{D}^{jk}=\partial_i\mathcal{D}^{jk}+\Gamma^j_{il}\mathcal{D}^{lk}+\Gamma^k_{il}\mathcal{D}^{jl}=0, \tag{4.36}$$

which means that the Dirac bivector is covariantly constant with respect to the connection $\Gamma_{\mathcal{D}}$. One then concludes that $\Gamma_{\mathcal{D}}$ can be considered a generalization of the Dirac connection introduced in Ref. 8.

Note that $\Gamma_{\mathcal{D}}$ is, in general, not symmetric and its torsion is proportional to the curvature of $\overline{\Gamma}$. On the constraint surface this connection coincides with the Dirac connection in Ref. 8. Similar arguments then show that $\Gamma_{\mathcal{M}}$ can be restricted to Σ and its restriction is a symplectic connection on Σ considered as a symplectic manifold.

There is an ambiguity in Γ that is described by an arbitrary 1-form with values in the symmetric tensor square of the bundle $W^*(\mathcal{M})$ (in components, a general symplectic connection has the form $\Gamma_{AiB}=\Gamma^{\text{fixed}}_{AiB}+\gamma_{AiB}$, with $\gamma_{AiB}-\gamma_{BiA}=0$). One can try to find additional conditions restricting the ambiguity in the connection. In particular, it seems natural to formulate an invariant criterion allowing to single out a symplectic connection in $W(\mathcal{M})$ that after restricting to $T\mathcal{M}\subset W(\mathcal{M})$ would respect the Dirac bracket (4.31) on $\mathcal{M}$.

Such a condition can be seen from analyzing the conversion procedure. To demostrate this, we note that the term in Ω_2 of the form $\mathcal{C}^i\gamma_{AiB}Y^AY^B$ can be absorbed into the redefinition of p_i, which, in turn, leads to the adjustment of the symplectic connection $\Gamma_{AiB}\to\Gamma_{AiB}+\gamma_{AiB}$. It is then natural to choose the connection such that the respective contribution to Ω_2 vanishes, i.e., the connection that is not modified by the conversion. For Ω satisfying conditions of the second part of Proposition **4.1**, this implies that

$$(\delta^*\{-\mathcal{C}^i p_i + \mathcal{C}^i \overline{\Gamma}^{\beta}_{i\alpha}\mathcal{C}^{\alpha}\mathcal{P}_{\beta}, C^A\mathcal{D}_{AB}Y^B\})|_{\mathcal{C}^{\alpha}=0} = 0. \tag{4.37}$$

This gives the following conditions on Γ:

$$\begin{gathered}\partial_i\omega_{jk} - \Gamma_{jik} + \partial_k\omega_{ji} - \Gamma_{jki} + \Gamma_{ijk} + \Gamma_{kji} = 0,\\ \partial_i\mathcal{D}_{j\alpha} - \mathcal{D}_{i\beta}\overline{\Gamma}^{\beta}_{j\alpha} - \Gamma_{ji\alpha} + \Gamma_{ij\alpha} + \Gamma_{\alpha ji} = 0,\\ \Gamma_{\alpha i\beta} + \Gamma_{\beta i\alpha} = 0.\end{gathered} \tag{4.38}$$

If one takes $\Gamma_{ijk}=(\overline{\Gamma}_{\mathcal{M}})_{ijk}$, where $(\overline{\Gamma}_{\mathcal{M}})_{ijk}$ are coefficients of a fixed symmetric symplectic connection on $\mathcal{M}$, then Eqs. (4.33) and (4.38) have a unique solution given by

$$\begin{gathered}\Gamma_{\alpha i\beta} = 0, \quad \Gamma_{ji\alpha} = \mathcal{D}_{j\beta}(\overline{\Gamma})^{\beta}_{i\alpha} + \frac{1}{3}\overline{R}^{\beta}_{ji\alpha}\theta_{\beta},\\ \Gamma_{ijk} = (\overline{\Gamma}_{\mathcal{M}})_{ijk}, \quad \Gamma_{\alpha ij} = -\overline{\boldsymbol{\nabla}}_i\overline{\boldsymbol{\nabla}}_j\theta_{\alpha} - \frac{1}{3}\overline{R}^{\beta}_{ij\alpha}\theta_{\beta},\end{gathered} \tag{4.39}$$

where $\overline{R}^{\beta}_{ij\alpha}\theta_{\beta}=-[\overline{\boldsymbol{\nabla}}_i,\overline{\boldsymbol{\nabla}}_j]\theta_{\alpha}$. Note that the consistency of (4.33) and (4.38) together with $d\omega=0$ requires $\Gamma_{ijk}-\Gamma_{ikj}=0$.

This connection differs from the one in (4.34) by the terms proportional to $\overline{R}^{\beta}_{ij\alpha}\theta_{\beta}$. It also determines a connection $\Gamma'_{\mathcal{D}}$ on $\mathcal{M}$, which coincides with $\Gamma_{\mathcal{D}}$ on Σ. In particular, $\Gamma'_{\mathcal{D}}$ is compatible with the Dirac bracket only weakly in general.

V. CONVERSION AT THE QUANTUM LEVEL

A. Quantization of the extended phase space

At the quantum level we concentrate on the algebra $\hat{\mathfrak{U}}^0=\mathfrak{U}^0\otimes[[\hbar]]$ and its extension $\hat{\mathfrak{U}}$ obtained by allowing the dependence on p_i and $\mathcal{P}_i$ through the following combinations (see Ref. 8 for details):

$$\mathbf{P} = \mathcal{C}^i(-p_i + \overline{\Gamma}^{\alpha}_{i\beta}\mathcal{C}^{\beta}\mathcal{P}_{\alpha}), \quad \mathbf{G} = \mathcal{C}^i\mathcal{P}_i. \tag{5.1}$$

A general element of $\hat{\mathfrak{U}}$ has the form

$$a = \mathbf{P}^r\mathbf{G}^s a_0, \quad r = 0,1, \quad s = 0,1,\ldots,\dim(\mathcal{M}), \quad a_0 \in \hat{\mathfrak{U}}^0. \tag{5.2}$$

The algebra $\hat{\mathfrak{U}}$ is closed under ordinary multiplication and the Poisson bracket. Moreover, it can be directly quantized. To this end one first quantizes $\hat{\mathfrak{U}}^0$ by introducing the Weyl star product according to

$$\begin{aligned}(a\star b)(x,Y,\mathcal{C},\mathcal{P},\hbar) = \Bigg\{&(a(x,Y_1,\mathcal{C}_1,\mathcal{P}_2,\hbar))\exp\Bigg(-\frac{i\hbar}{2}\Bigg(\mathcal{D}^{AB}\frac{\tilde{\partial}}{\partial Y_1^A}\frac{\partial}{\partial Y_2^B} - \frac{\tilde{\partial}}{\partial\mathcal{C}_1^{\alpha}}\frac{\partial}{\partial\mathcal{P}_{\alpha}^2}\\ &- \frac{\tilde{\partial}}{\partial\mathcal{P}_{\alpha}^1}\frac{\partial}{\partial\mathcal{C}_2^{\alpha}}\Bigg)\Bigg)b(x,Y_2,\mathcal{C}_2,\mathcal{P}_2,\hbar)\Bigg\}\Bigg|_{Y_1=Y_2=Y,\mathcal{C}_1=\mathcal{C}_2=\mathcal{C},\mathcal{P}_1=\mathcal{P}_2=\mathcal{P}},\end{aligned} \tag{5.3}$$

where $\mathcal{P}$ stands for $\mathcal{P}_{\alpha}$ only. This star product can then be extended from $\hat{\mathfrak{U}}^0$ to $\hat{\mathfrak{U}}$. Here we give only those formulas that we really need in what follows (we refer to Refs. 8 and 7 for further details of such an extension):

$$\frac{i}{\hbar}[\mathbf{P},a]=\mathcal{C}^i\left(\frac{\partial}{\partial x^i}-\overline{\Gamma}^{\beta}_{i\alpha}\mathcal{C}^{\alpha}\frac{\partial}{\partial\mathcal{C}^{\beta}}+\overline{\Gamma}^{\alpha}_{i\beta}\mathcal{P}_{\beta}\frac{\partial}{\partial\mathcal{P}^{\beta}}-\Gamma^{B}_{iA}Y^{B}\frac{\partial}{\partial Y^{A}}\right)a,\quad a\in\hat{\mathfrak{U}}^0,$$

$$\frac{i}{\hbar}[\mathbf{P},\mathbf{P}]=-i\hbar\mathcal{C}^i\mathcal{C}^j\left(\omega_{ij}+\overline{R}^{\beta}_{ij\alpha}\mathcal{C}^{\alpha}\mathcal{P}_{\beta}+\frac{1}{2}\mathcal{R}_{ijAB}Y^AY^B\right),\tag{5.4}$$

$$\frac{i}{\hbar}[\mathbf{G},a]=-\mathcal{C}^i\frac{\partial}{\partial\mathcal{C}^i}+\mathcal{P}_i\frac{\partial}{\partial\mathcal{P}_i},\quad a\in\hat{\mathfrak{U}}^0.$$

Note that these relations are sufficient to consistently consider $\hat{\mathfrak{U}}^0$ as a star-product algebra underlying the BFV-BRST system at the quantum level in the sense described in **4.4** after the Theorem **4.1**.

On $\hat{\mathfrak{U}}$ we introduce the following degree:

$$\deg Y^A=\deg\mathcal{P}_A=\deg p_i=1,\quad \deg\mathcal{C}^A=\deg x^i=0,\quad \deg\hbar=2.\tag{5.5}$$

One then decomposes $\hat{\mathfrak{U}}^0$ and $\hat{\mathfrak{U}}$ with respect to the degree as

$$\hat{\mathfrak{U}}^0=\bigoplus_{s=0}\hat{\mathfrak{U}}^0_s,\tag{5.6}$$

and similarly for $\hat{\mathfrak{U}}$. The star product is also decomposed into homogeneous components with respect to degree

$$\star=\star_0+\star_1+\star_2+\cdots.\tag{5.7}$$

In particular, $\star_0$ contains an ordinary product, a Weyl product in the sector of Y variables, and the component of the product that takes $\mathbf{P}$ with itself into $-\imath\hbar\mathcal{C}^i\mathcal{C}^j\omega_{ij}$.

Let us note that the choice of the degree is not unique. The one we are using is convenient for general proofs but perhaps is not the most suitable for computations because it is not preserved by the star product in $\hat{\mathfrak{U}}^0$. From this point of view one can consider another degree for which $\deg\mathcal{C}^A=1$ and gradings of other variables left unchanged.

B. Quantum BRST charge

Now we are going to show the existence of the quantum BRST charge satisfying

$$[\hat{\Omega},\hat{\Omega}]=0,\quad \mathrm{gh}(\hat{\Omega})=1,\tag{5.8}$$

together with the condition $\hat{\Omega}|_{\hbar=0}=\Omega$. Here and below $[\cdot,\cdot]$ stands for the graded commutator with respect to the star multiplication in $\hat{\mathfrak{U}}$, which is also decomposed into homogeneous component with respect to the degree. A degree s component of the commutator is denoted by $[\cdot,\cdot]_s$.

It follows from the standard deformation theory and the vanishing of Q cohomology in nonzero ghost number that quantum BRST charge exists. However, instead of deforming the classical BRST charge we construct the quantum one from scratch. To this end we show that the quantum master equation (5.8) has a solution satisfying the following boundary conditions:

$$\hat{\Omega}_0=\mathcal{C}^{\alpha}\theta_{\alpha},\quad \hat{\Omega}_1=\mathbf{P}-\mathcal{C}^A\mathcal{D}_{AB}Y^B=-\mathcal{C}^ip_i+\mathcal{C}^i\overline{\Gamma}^{\alpha}_{i\beta}\mathcal{C}^{\beta}\mathcal{P}_{\alpha}-\mathcal{C}^A\mathcal{D}_{AB}Y^B.\tag{5.9}$$

Proposition 5.1: Equation (5.8) has a solution satisfying boundary condition (5.9) and $\hat{\Omega}_s\subset\hat{\mathfrak{U}}^0_s$ for $s\geqslant 2$. *Under the additional condition* $\delta^*\hat{\Omega}_s=0$, $s\geqslant 2$ *the solution is unique.*

Proof: Proof is completely standard once degree is prescribed. The only thing to check is that with boundary conditions (5.9), the master equation holds at orders 0, 1, and 2, which is straightforward. The rest follows by induction, using that

$$[\hat{\Omega}_0, a]_0 = 0, \quad \frac{1}{i\hbar}([\hat{\Omega}_0, a]_1 + [\hat{\Omega}_1, a]_0) = \delta a, \tag{5.10}$$

for any $a \in \hat{\mathfrak{U}}^0$. Here, $[\cdot, \cdot]_s$ denotes the degree s component of the star commutator. □

C. Quantum BRST observables and weakly associative star product

Given a nilpotent quantum BRST charge one can consider the cohomology group of its adjoint action $\hat{Q} = (i/\hbar)[\hat{\Omega}, \cdot]$. It follows from the standard deformation theory and Theorem **4.1** that any classical BRST cohomology class determines a quantum one. In fact it also follows that

$$H^n(\hat{Q}, \hat{\mathfrak{U}}^0) \cong H^n(Q, \mathfrak{U}^0) \otimes [[\hbar]]. \tag{5.11}$$

It is nevertheless useful to explicitly construct representatives of the quantum BRST cohomology classes. Similarly to the classical case this is achieved by finding a lift of functions of x^i, $\mathcal{C}^A$ to BRST-invariant elements of $\hat{\mathfrak{U}}^0$. We have the following.

Proposition 5.2: For any $f_0 = f_0(x, \mathcal{C}, \hbar)$ there exists $f \in \hat{\mathfrak{U}}^0$, such that

$$[\Omega, f] = 0, \quad \mathrm{gh}(f) = \mathrm{gh}(f_0), \quad f|_{Y=\mathcal{P}=0} = f_0. \tag{5.12}$$

If in addition f is such that $\delta^*(f - f_0) = 0$ and $\mathrm{gh}(f) \geqslant 0$, then f is a unique quantum BRST-invariant extension of f_0. Moreover, if f and $\tilde{f}$ both satisfy (5.12) *with the same f_0, then $f - \tilde{f} = [\hat{\Omega}, h]$ for some $h \in \hat{\mathfrak{U}}^0$.*

Proof: The proof is standard once the degree is prescribed. That equation holds to lowest order and follows from $\delta f_0 = 0$. □

If $f, g \in \hat{\mathfrak{U}}^0$ are unique BRST-invariant extensions of functions $f_0(x)$ and $g_0(x)$ determined by Proposition **5.2**, then one can define a bilinear operation,

$$f_0 \star_D g_0 = (f \star g)|_{Y=\mathcal{P}=0}. \tag{5.13}$$

This operation is not an associative product in general. However, it determines the associative star product on Σ. Indeed, BRST cohomology can be identified with functions on Σ while quantum multiplication in $\hat{\mathfrak{U}}^0$ determines a quantum multiplication in the cohomology. By choosing different lifts from functions on $\mathcal{M}$ to $\hat{\mathfrak{U}}^0$ one can describe different extensions of the associative star products on Σ to, in general, a nonassociative product on $\mathcal{M}$.

As a final remark, we comment on the emergence of weak Poisson brackets and weak star products in the context of constrained systems. In dynamics, and especially in what concerns the deformations and quantization of classical dynamical systems, the Poisson geometry is stereotypically considered the most fundamental structure of the theory. But whenever a constrained or a gauge system is considered, the dynamics, as such, does not require a Poisson algebra to exist for all functions on the entire phase-space manifold. Only the space of physical quantities has to carry a Poisson structure, and hence the geometry of the entire manifold turns out to have a weaker structure than the Poisson one. As we have seen, this is the case with nonscalar second-class constraints. The BRST theory was originally worked out as a tool for quantizing systems with gauge symmetries defined by weakly integrable distributions. Now, as is seen, the idea of BRST cohomology allows one to quantize systems whose Poisson algebra is also weak.

A θ-local formulation of superfield Lagrangian quantization in non-Abelian hypergauges is proposed on the basis of an extension of general reducible gauge theories to special superfield models with a Grassmann parameter θ. We solve the problem of describing the quantum action and the gauge algebra of an L-stage-reducible superfield model in terms of a BRST charge for a formal dynamical system with first-class constraints of $(L+1)$-stage reducibility. Starting from θ-local functions of the quantum and gauge-fixing actions, with an essential use of Darboux coordinates on the antisymplectic manifold, we construct a superfield generating functionals of Green's functions, including the effective action. We present two superfield forms of BRST transformations, considered as θ-shifts along vector fields defined by Hamiltonian-like systems constructed in terms of the quantum and gauge-fixing actions and an arbitrary θ-local boson function, as well as in terms of corresponding fermion functionals, through Poisson brackets with opposite Grassmann parities. The gauge independence of the S-matrix is proved. The Ward identities are derived. Connection is established with the BV method, the multilevel Batalin-Tyutin formalism, as well as with the superfield quantization scheme of Lavrov, Moshin, and Reshetnyak, extended to the case of general coordinates. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1938707]

I. INTRODUCTION

The construction of superfield counterparts of the Lagrangian[1] and Hamiltonian[2,3] quantization schemes for gauge theories on the basis of BRST symmetry[4] has been covered in a number of papers.[5–7] These works are based on nontrivial (represented by the operator $D=\partial_\theta+\theta\partial_t$, $[D,D]_+=2\partial_t$) and trivial relations between the even t and odd θ components of supertime.[8] In Refs. 5–7, the geometric interpretation[9] of BRST transformations is realized by special translations in superspace, which originally provided a basis for the superspace description[10] of quantum theories of Yang–Mills type.

It should be noted that superfield quantization is closely related to generalized Poisson sigma-models,[11] described from a superfield geometric viewpoint in Ref. 12, and then developed algorithmically by Batalin and Marnelius in Ref. 13. The geometry of $D=2$ supersymmetric sigma-models[14] with an arbitrary, $N\geqslant 1$, number of Grassmann coordinates has been adapted to the classical and quantum description of $D=1$ sigma-models by Hull, and, independently, to the

construction of the partition function for $N=2$, by Gozzi *et al.*[15] Quantization with a single fermion supercharge, $Q(t,\theta)$, containing the BRST charge and the unitarizing Hamiltonian,[5] was recently extended to $N=2$ (non-space–time) supersymmetries,[16] and then, in Ref. 17, to the case of an arbitrary number of supercharges, $Q^k(t,\theta^1,\ldots,\theta^N)$, $k=1,\ldots,N$, depending on Grassmann variables θ^k. The superfield modification[18] of the procedure[5] reveals a close interplay between the quantum action of the Batalin–Vilkovisky (BV) method[1] and the BRST charge of the Batalin–Fradkin–Vilkovisky (BFV) method.[2] Finally, note that the superfield approach is used in the description of second-class constrained systems as gauge models[19] as well as in the second quantization of gauge theories.[20]

The Lagrangian superfield partition function of Ref. 5 is derived from the Hamiltonian partition function through functional integration over so-called Pfaffian ghosts and momenta. On the other hand, the quantization rules (Refs. 6 and 7) present a superfield modification of the BV formalism by including non-Abelian hypergauges.[21] The corresponding hypergauge functions enter a gauge-fixing action which obeys (following the ideas of Ref. 22) the same generating equation that holds for the quantum action,[6,7] except that the first-order operator V in this equation is replaced by the first-order operator U (these operators are crucial ingredients of Refs. 6 and 7 from the viewpoint of a superspace interpretation of BRST transformations).

The formalism (Refs. 6 and 7) provides a comparatively detailed analysis of superfield quantization (BRST invariance, S-matrix gauge-independence). This analysis is based on solutions to the generating equations; however, a detailed correspondence between these solutions and a gauge model is not established. To achieve a better understanding of the quantum properties based on solutions of the superfield generating equations, it is natural to equip the formalism (Refs. 6 and 7) with an *explicit superfield description* of gauge algebra structure functions that determine a given model. So far, this problem has remained unsolved. For instance, the definition of a classical action of superfields, $\mathcal{A}^i(\theta)=A^i+\lambda^i\theta$, on a superspace with coordinates (x^μ,θ), $\mu=0,\ldots,D-1$, as an integral of a nontrivial odd density, $\mathcal{L}(\mathcal{A}(x,\theta),\partial_\mu\mathcal{A}(x,\theta),\ldots;x,\theta)\equiv\mathcal{L}(x,\theta)$, is a problem for every given model. Here, by trivial densities $\mathcal{L}(x,\theta)$ we understand those of the form

$$\int \mathrm{d}^D x\,\mathrm{d}\theta\mathcal{L}(x,\theta)=\int \mathrm{d}\theta\theta S_0(\mathcal{A}(\theta))=S_0(A),$$

where $S_0(A)$ is a usual classical action.

A peculiar feature of the vacuum functional Z and generating functional of Green's functions $Z[\Phi^*]$ in the formalism (Refs. 6 and 7) is the dependence of the gauge fermion $\Psi[\Phi]$ and quantum action $S[\Phi,\Phi^*]$ on the components λ^A of superfields $\Phi^A(\theta)$ in the multiplet $(\Phi^A,\Phi^*_A)(\theta)=(\phi^A+\lambda^A\theta,\phi^*_A-\theta J_A)$, where $(\phi^A,\phi^*_A,\lambda^A,J_A)$ are the complete set of variables of the BV method. Another peculiarity of Refs. 6 and 7 is that, due to the manifest structure of $\Phi^*_A(\theta)$ and $Z[\Phi^*]$, an effective action Γ with the standard Ward identity $(\Gamma,\Gamma)=0$ in terms of a superantibracket[6] can be introduced by a Legendre transformation of $\ln Z[\Phi^*]$ with respect to $P_1(\theta)\Phi^*_A(\theta)$,

$$\Gamma[P_0(\Phi,\Phi^*)]=\frac{\hbar}{i}\ln Z[\Phi^*]+\partial_\theta\{[P_1(\theta)\Phi^*_A(\theta)]\Phi^A(\theta)\},\quad \Phi^A(\theta)=-\frac{\hbar}{i}\frac{\delta\ln Z[\Phi^*]}{\delta(P_1(\theta)\Phi^*_A(\theta))}. \tag{1}$$

[The objects $P_1(\theta)$ and $\delta/\delta(P_1(\theta)\Phi^*_A(\theta))$ are, respectively, an element of the system of projectors $\{P_a(\theta)=\delta_{a0}(1-\theta\partial_\theta)+\delta_{a1}\theta\partial_\theta, a=0,1\}$, acting on the supermanifold with coordinates $(\Phi^A,\Phi^*_A)(\theta)$, and a superfield variational derivative with respect to $P_1(\theta)\Phi^*_A(\theta)$.] Although noncontradictory, such an introduction of Γ violates the superfield content of the variables. By violating the superfield content, we understand the fact that the derivative of $Z[\Phi^*]$, which defines the effective action through a Legendre transformation, is taken with respect to only one superfield component, namely, the θ-component of $\Phi^*_A(\theta)$, so that the resulting effective action depends only on ϕ^A and ϕ^*_A, which can be formally expressed as $P_0(\theta)(\Phi^A,\Phi^*_A)(\theta)=(\phi^A,\phi^*_A)$.

In this paper, we propose a local formalism of superfield Lagrangian quantization in which the quantities of an initial classical theory are realized in the framework of a *θ-local superfield model* (LSM). The idea of LSM is to represent the objects of a gauge theory (classical action, generators

of gauge transformations, etc.) in terms of θ-local functions, trivially related to the space–time coordinates, in the sense that (as compared to the formalism—Ref. 5) the derivatives with respect to the even t and odd θ component of supertime are taken independently. Using an analogy with classical mechanics (or classical field theory), we reproduce the dynamics and gauge invariance (in particular, BRST transformations) of the initial theory (the one with $\theta=0$) in terms of θ-local equations, called *Lagrangian* and *Hamiltonian systems* (LS, HS) with a dynamical odd time θ, which implies that this coordinate enters a LS or HS not as a parameter but as part of a differential operator ∂_θ that describes the θ-evolution of a system.

On the basis of the suggested formalism, we circumvent the peculiarities of the functionals Z and $Z[\Phi^*]$ in Refs. 6 and 7 as well as solve the following problems:

1. We develop a *dual description* of an arbitrary reducible LSM of Ref. 18 in the case of irreducible gauge theories (with bosonic classical fields and parameters of gauge transformations), in terms of a BRST charge related to a (formal) dynamical system with first-class constraints of a higher stage of reducibility. By dual description, we understand such a treatment of a gauge model that interrelates the Lagrangian and Hamiltonian formulations (the latter understood in the sense of formal dynamical systems).

2. An HS constructed from θ-local quantities, i.e., a quantum action, a gauge-fixing action, and an arbitrary bosonic function, encodes (through a θ-local antibracket) both BRST and so-called anticanonical-like transformations, in terms of a universal set of equations underlying the gauge-independence of the S-matrix. This set of equations is generated, in terms of an even superfield Poisson bracket, by a linear combination of fermionic functionals corresponding to the mentioned θ-local quantities, e.g., the quantum and gauge-fixing actions as well as the bosonic function.

3. For the first time in the framework of superfield approach, we introduce a *superfield effective action* (also in the case of non-Abelian hypergauges).

4. We extend the superfield quantization of Refs. 6 and 7 to the case of general coordinates on the manifold of super(anti)fields and establish a relation with the proposed local quantization.

The paper is organized as follows. In Sec. II, a Lagrangian formulation of a LSM is proposed as an extension of a usual model of classical fields A^i, $i=1,\ldots,n=n_+ + n_-$, to a θ-local theory, defined on the odd tangent bundle $T_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}} \equiv \Pi T\mathcal{M}_{\mathrm{CL}} = \{\mathcal{A}^I, \partial_\theta \mathcal{A}^I\}$, $I=1,\ldots,N=N_+ + N_-$, $(n_+,n_-) \leqslant (N_+,N_-)$. [$\Pi$ denotes the exchange operation of the coordinates of a tangent fiber bundle $T\mathcal{M}_{\mathrm{CL}}$ over a configuration $\mathcal{A}^I$ into the coordinates of the opposite Grassmann parity,[23] and N_+,N_-, are the numbers of bosonic and fermionic fields, among which there may exist superfields corresponding to the ghosts of the minimal sector in the BV quantization scheme (in terms of the condensed notation[24] used in this paper).] The superfields $(\mathcal{A}^I, \partial_\theta \mathcal{A}^I)$ are defined in a superspace $\mathcal{M} = \tilde{\mathcal{M}} \times \tilde{P}$ parametrized by (z^M, θ), where the space–time coordinates $z^M \subset i \subset I$ include Lorentz vectors and spinors of the superspace $\tilde{\mathcal{M}}$. We investigate the superfield equations of motion, introduce the notions of reducible *general* and *special* superfield gauge theories, and apply Noether's first theorem to θ-translations. Section III is devoted to the Hamiltonian formulation of a LSM on the odd cotangent bundle $T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}} \equiv \Pi T^*\mathcal{M}_{\mathrm{CL}} = \{\mathcal{A}^I, \mathcal{A}^*_I\}$. Here, we establish a connection to the Lagrangian formalism and investigate the existence of a Noether integral, related to θ-translations, which leads to the validity of a θ-local master equation. The quantization rules are given in Sec. IV. In particular, we construct the dual description of a LSM and define a generating functional of Green's functions, $\mathrm{Z}(\theta)$, and an effective action, $\Gamma(\theta)$, using an invariant description of super(anti)fields on a general antisymplectic manifold. An essential feature in introducing $\mathrm{Z}(\theta)$ and $\Gamma(\theta)$ is a choice of Darboux coordinates $(\varphi,\varphi^*)(\theta)$ compatible with the properties of the quantum action. In Sec. V, on the basis of a component form of the local superfield quantization, we establish its connection with the first-level formalism,[21] with the BV method, and with an extension of the superfield scheme (Refs. 6 and 7). In Sec. VI, we discuss the results of the present work.

In addition to DeWitt's condensed notation,[24] we partially use the conventions of Refs. 6 and 7. We distinguish between two types of superfield derivatives: the right (left) variational derivative $\delta_{(l)}F/\delta\Phi^A(\theta)$ of a functional F, and the right (left) derivative $\partial_{(l)}\mathcal{F}(\theta)/\partial\Phi^A(\theta)$ of a function $\mathcal{F}(\theta)$

for a fixed θ. Derivatives with respect to super(anti)fields and their components are understood as right (left), for instance, $\delta/\delta\Phi^*_A(\theta)$ or $\delta/\delta\lambda^A$, while the corresponding left (right) derivatives are labeled by the subscript $l(r)$. For right-hand derivatives with respect to $\mathcal{A}^I(\theta)$, with a fixed θ, we use the notation $\mathcal{F}_{,I}(\theta)\equiv\partial\mathcal{F}(\theta)/\partial\mathcal{A}^I(\theta)$. The $\delta(\theta)$-function and integration over θ are given, respectively, by $\delta(\theta)=\theta$ and left-hand differentiation over θ. We refer to a function $\mathcal{F}(\theta)$, regarded as an element of the superalgebra $C^\infty(T_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}})$, as a $C^\infty(T_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}})$-function. The rank of an even θ-local supermatrix $K(\theta)$ with Z_2-grading ε is characterized by a pair of numbers $\overline{m}=(m_+,m_-)$, where m_+ (m_-) is the rank of the Bose–Bose (Fermi–Fermi) block of the θ-independent part of the supermatrix $K(\theta)$: $\mathrm{rank}\|K(\theta)\|=\mathrm{rank}\|K(0)\|$. With respect to the same Grassmann parity ε, we understand the dimension of a smooth supersurface, also characterized by a pair of numbers, in the sense of the definition (Ref. 25) of a supermanifold, so that the above pair coincides with the corresponding numbers of the Bose and Fermi components of $z^i(0)$, being the θ-independent parts of local coordinates $z^i(\theta)$ parametrizing this supersurface. On these pairs, we consider the operations of component addition, $\overline{m}+\overline{n}=(m_++n_+,m_-+n_-)$, and comparison,

$$\overline{m}=\overline{n}\Leftrightarrow m_\pm=n_\pm,\quad \overline{m}>\overline{n}\Leftrightarrow(m_+>n_+,m_-\geqslant n_-)\ \text{or}\ (m_+\geqslant n_-,m_+>n_-).$$

II. ODD-TIME LAGRANGIAN FORMULATION

The basic objects of the Lagrangian formulation of a LSM are a *Lagrangian action* S_{L}: $T_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}}\times\{\theta\}\to\Lambda_1(\theta;\mathbb{R})$, being a $C^\infty(T_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}})$-function taking values in a real Grassmann algebra $\Lambda_1(\theta;\mathbb{R})$, and (independently) a functional $Z[\mathcal{A}]$, whose θ-density is defined with accuracy up to an arbitrary function $f((\mathcal{A},\partial_\theta\mathcal{A})(\theta),\theta)\in\ker\{\partial_\theta\}$, $\vec{\varepsilon}(f)=\vec{0}$,

$$Z[\mathcal{A}]=\partial_\theta S_{\mathrm{L}}(\theta),\quad \vec{\varepsilon}(Z)=\vec{\varepsilon}(\theta)=(1,0,1),\quad \vec{\varepsilon}(S_{\mathrm{L}})=\vec{0}. \tag{2}$$

The values $\vec{\varepsilon}=(\varepsilon_P,\varepsilon_{\overline{J}},\varepsilon)$, $\varepsilon=\varepsilon_P+\varepsilon_{\overline{J}}$, of Z_2-grading, with the auxiliary components $\varepsilon_{\overline{J}}$, ε_P related to the respective coordinates (z^M,θ) of a superspace $\mathcal{M}$, are defined on superfields $\mathcal{A}^I(\theta)$ by the relation $\vec{\varepsilon}(\mathcal{A}^I)=((\varepsilon_P)_I,(\varepsilon_{\overline{J}})_I,\varepsilon_I)$. Note that $\mathcal{M}$ may be realized as the quotient of a symmetry supergroup $J=\overline{J}\times P$, $P=\exp(i\mu p_\theta)$, for the functional $Z[\mathcal{A}]$, where μ and p_θ are, respectively, a nilpotent parameter and a generator of θ-shifts, whereas $\overline{J}$ is chosen as the space–time SUSY group. The quantities $\varepsilon_{\overline{J}}$, ε_P are the respective Grassmann parities of the coordinates of representation spaces of the supergroups $\overline{J}$, P. The introduced objects allow one to achieve a correct incorporation of the spin-statistic relation into operator quantization.

Among the objects $S_{\mathrm{L}}(\theta)$ and $Z[\mathcal{A}]$, invariant under the action of a J-superfield representation T restricted to $\overline{J}$, $T|_{\overline{J}}$, it is only $S_{\mathrm{L}}(\theta)$ that transforms nontrivially (in view of the J-scalar nature of $Z[\mathcal{A}]$) with respect to the total representation T under $\mathcal{A}^I(\theta)\to\mathcal{A}'^I(\theta)=(T|_{\overline{J}}\mathcal{A})^I(\theta-\mu)$,

$$\delta S_{\mathrm{L}}(\theta)=S_{\mathrm{L}}(\mathcal{A}'(\theta),\partial_\theta\mathcal{A}'(\theta),\theta)-S_{\mathrm{L}}(\theta)=-\mu\left[\frac{\partial}{\partial\theta}+P_0(\theta)(\partial_\theta U)(\theta)\right]S_{\mathrm{L}}(\theta). \tag{3}$$

Here, we have introduced the nilpotent operator $(\partial_\theta U)(\theta)=\partial_\theta\mathcal{A}^I(\theta)\partial_l/\partial\mathcal{A}^I(\theta)=[\partial_\theta,U(\theta)]_-$, $U(\theta)=P_1\mathcal{A}^I(\theta)\partial_l/\partial\mathcal{A}^I(\theta)$.

Assuming the existence of a critical superfield configuration for $Z[\mathcal{A}]$, one presents the dynamics of an LSM in terms of superfield Euler–Lagrange equations:

$$\frac{\delta_l Z[\mathcal{A}]}{\delta\mathcal{A}^I(\theta)}=\left[\frac{\partial_l}{\partial\mathcal{A}^I(\theta)}-(-1)^{\varepsilon_I}\partial_\theta\frac{\partial_l}{\partial(\partial_\theta\mathcal{A}^I(\theta))}\right]S_{\mathrm{L}}(\theta)\equiv\mathcal{L}^l_I(\theta)S_{\mathrm{L}}(\theta)=0, \tag{4}$$

equivalent, in view of $\partial^2_\theta\mathcal{A}^I(\theta)\equiv0$, to a LS characterized by $2N$ formally second-order differential equations in θ,

$$\partial_\theta^2 \mathcal{A}^J(\theta) \frac{\partial_l^2 S_{\mathrm{L}}(\theta)}{\partial(\partial_\theta \mathcal{A}^I(\theta))\partial(\partial_\theta \mathcal{A}^J(\theta))} \equiv \partial_\theta^2 \mathcal{A}^J(\theta)(S_{\mathrm{L}}'')_{IJ}(\theta) = 0,$$

$$\Theta_I(\theta) \equiv \frac{\partial_l S_{\mathrm{L}}(\theta)}{\partial \mathcal{A}^I(\theta)} - (-1)^{\varepsilon_I}\left[\frac{\partial}{\partial\theta}\frac{\partial_l S_{\mathrm{L}}(\theta)}{\partial(\partial_\theta \mathcal{A}^I(\theta))} + (\partial_\theta U)(\theta)\frac{\partial_l S_{\mathrm{L}}(\theta)}{\partial(\partial_\theta \mathcal{A}^I(\theta))}\right] = 0. \tag{5}$$

The *Lagrangian constraints* $\Theta_I(\theta) = \Theta_I(\mathcal{A}(\theta), \partial_\theta \mathcal{A}(\theta), \theta)$ restrict the setting of the Cauchy problem for the LS and may be functionally dependent, as first-order equations in θ.

Provided that there exists (at least locally) a supersurface $\Sigma \subset \mathcal{M}_{\mathrm{CL}}$ such that

$$\Theta_I(\theta)|_\Sigma = 0, \quad \dim \Sigma = \overline{M}, \quad \operatorname{rank}\|\mathcal{L}_J^l(\theta)[\mathcal{L}_I^l(\theta)S_{\mathrm{L}}(\theta)(-1)^{\varepsilon_I}]\|_\Sigma = \overline{N} - \overline{M}, \tag{6}$$

there exist $M = M_+ + M_-$ independent identities:

$$\int \mathrm{d}\theta \frac{\delta Z[\mathcal{A}]}{\delta \mathcal{A}^I(\theta)} \hat{\mathcal{R}}^I_{\mathcal{A}_0}(\theta;\theta_0) = 0, \quad \hat{\mathcal{R}}^I_{\mathcal{A}_0}(\theta;\theta_0) = \sum_{k\geqslant 0} ((\partial_\theta)^k \delta(\theta - \theta_0)) \hat{\mathcal{R}}^I_{k\mathcal{A}_0}(\mathcal{A}(\theta), \partial_\theta \mathcal{A}(\theta), \theta). \tag{7}$$

The generators $\hat{\mathcal{R}}^I_{\mathrm{A}_0}(\theta;\theta_0)$ of *general gauge transformations*,

$$\delta_g \mathcal{A}^I(\theta) = \int \mathrm{d}\theta_0 \hat{\mathcal{R}}^I_{\mathcal{A}_0}(\theta;\theta_0)\xi^{\mathcal{A}_0}(\theta_0), \quad \vec{\varepsilon}(\xi^{\mathcal{A}_0}) = \vec{\varepsilon}_{\mathcal{A}_0}, \quad \mathcal{A}_0 = 1, \ldots, \quad M_0 = M_{0+} + M_{0-},$$

that leave $Z[\mathcal{A}]$ invariant, are functionally dependent under the assumption of locality and $\overline{J}$-covariance, provided that

$$\operatorname{rank}\left\|\sum_{k\geqslant 0} \hat{\mathcal{R}}^I_{k\mathcal{A}_0}(\theta)(\partial_\theta)^k\right\|_\Sigma = \overline{M} < \overline{M}_0.$$

The dependence of $\hat{\mathcal{R}}^I_{\mathcal{A}_0}(\theta;\theta_0)$ implies the existence (on solutions of the LS) of proper zero-eigenvalue eigenvectors, $\hat{\mathcal{Z}}^{\mathcal{A}_0}_{\mathcal{A}_1}(\mathcal{A}(\theta_0), \partial_{\theta_0}\mathcal{A}(\theta_0), \theta_0; \theta_1)$, with a structure analogous to $\hat{\mathcal{R}}^I_{\mathcal{A}_0}(\theta;\theta_0)$ in (7), which exhaust the zero-modes of the generators, and are dependent in case

$$\operatorname{rank}\left\|\sum_k \hat{\mathcal{Z}}^{\mathcal{A}_0}_{k\mathcal{A}_1}(\theta_0)(\partial_{\theta_0})^k\right\|_\Sigma = \overline{M}_0 - \overline{M} < \overline{M}_1.$$

As a result, the relations of dependence for eigenvectors that define a general L_g-stage reducible LSM are given by

$$\int \mathrm{d}\theta' \hat{\mathcal{Z}}^{\mathcal{A}_{s-2}}_{\mathcal{A}_{s-1}}(\theta_{s-2};\theta')\hat{\mathcal{Z}}^{\mathcal{A}_{s-1}}_{\mathcal{A}_s}(\theta';\theta_s) = \int \mathrm{d}\theta' \Theta_J(\theta')\mathcal{L}^{\mathcal{A}_{s-2}J}_{\mathcal{A}_s}((\mathcal{A}, \partial_\theta \mathcal{A})(\theta_{s-2}), \theta_{s-2}, \theta';\theta_s),$$

$$\overline{M}_{s-1} > \sum_{k=0}^{s-1}(-1)^k \overline{M}_{s-k-2} = \operatorname{rank}\left\|\sum_{k\geqslant 0} \hat{\mathcal{Z}}^{\mathcal{A}_{s-2}}_{\mathcal{A}_{s-1}}(\theta_{s-2})(\partial_{\theta_{s-2}})^k\right\|_\Sigma,$$

$$\overline{M}_{L_g} = \sum_{k=0}^{L_g}(-1)^k \overline{M}_{L_g - k - 1} = \operatorname{rank}\left\|\sum_{k\geqslant 0} \hat{\mathcal{Z}}^{\mathcal{A}_{L_g-1}}_{\mathcal{A}_{L_g}}(\theta_{L_g-1})(\partial_{\theta_{L_g-1}})^k\right\|_\Sigma,$$

$$\vec{\varepsilon}(\hat{\mathcal{Z}}^{\mathcal{A}_s}_{\mathcal{A}_{s+1}}) = \vec{\varepsilon}_{\mathcal{A}_s} + \vec{\varepsilon}_{\mathcal{A}_{s+1}} + (1,0,1), \quad \hat{\mathcal{Z}}^{\mathcal{A}_{-1}}_{\mathcal{A}_0}(\theta_{-1};\theta_0) \equiv \hat{\mathcal{R}}^I_{\mathcal{A}_0}(\theta_{-1};\theta_0),$$

$$\mathcal{L}^{\mathcal{A}_{-1}J}_{\mathcal{A}_1}(\theta_{-1},\theta';\theta_1) \equiv \mathcal{K}^{IJ}_{\mathcal{A}_1}(\theta_{-1},\theta';\theta_1) = -(-1)^{(\varepsilon_I+1)(\varepsilon_J+1)}\mathcal{K}^{JI}_{\mathcal{A}_1}(\theta',\theta_{-1};\theta_1), \tag{8}$$

for $s=1,\ldots,L_g$, $\mathcal{A}_s=1,\ldots,M_s=M_{s+}+M_{s-}$, $\overline{M}\equiv\overline{M}_{-1}$. For $L_g=0$, the LSM is an irreducible *general gauge theory*.

In case a LSM admits the form $S_{\mathrm{L}}(\theta)=T(\partial_\theta\mathcal{A}(\theta))-S(\mathcal{A}(\theta),\theta)$, the functions $\Theta_I(\theta)$ are given in the extended configuration space $\mathcal{M}_{\mathrm{CL}}\times\{\theta\}$ by

$$\Theta_I(\theta)=-S_{,I}(\mathcal{A}(\theta),\theta)(-1)^{\varepsilon_I}=0, \tag{9}$$

being the extremals of the functional $S_0(A)=S(\mathcal{A}(0),0)$, corresponding to $\theta=0$. Condition (6) and identities (7) take the usual form (in case $\theta=0$)

$$\mathrm{rank}\|S_{,IJ}(\mathcal{A}(\theta),\theta)\|_\Sigma=\overline{N}-\overline{M},\quad S_{,I}(\mathcal{A}(\theta),\theta)\mathcal{R}^{I}_{0\mathcal{A}_0}(\mathcal{A}(\theta),\theta)=0, \tag{10}$$

with linearly-dependent (for $\overline{M}_0>\overline{M}$) generators of *special gauge transformations*,

$$\delta\mathcal{A}^I(\theta)=\mathcal{R}^{I}_{0\mathcal{A}_0}(\mathcal{A}(\theta),\theta)\xi_0^{\mathcal{A}_0}(\theta),$$

that leave invariant only $S(\theta)$, in contrast to $T(\theta)$. The dependence of generators $\mathcal{R}_{0\mathcal{A}_0}{}^{I}(\theta)$, as well as of their zero-eigenvalue eigenvectors $\mathcal{Z}^{\mathcal{A}_0}_{\mathcal{A}_1}(\mathcal{A}(\theta),\theta)$, and so on, can also be expressed by special relations of reducibility for $s=1,\ldots,L_g$, namely,

$$\mathcal{Z}^{\mathcal{A}_{s-2}}_{\mathcal{A}_{s-1}}(\mathcal{A}(\theta),\theta)\mathcal{Z}^{\mathcal{A}_{s-1}}_{\mathcal{A}_s}(\mathcal{A}(\theta),\theta)=S_{,J}(\theta)\mathcal{L}^{\mathcal{A}_{s-2}J}_{\mathcal{A}_s}(\mathcal{A}(\theta),\theta),\quad \vec{\varepsilon}(\mathcal{Z}^{\mathcal{A}_{s-1}}_{\mathcal{A}_s})=\vec{\varepsilon}_{\mathcal{A}_{s-1}}+\vec{\varepsilon}_{\mathcal{A}_s},$$

$$\mathcal{Z}^{\mathcal{A}_{-1}}_{\mathcal{A}_0}(\theta)\equiv\mathcal{R}^{I}_{0\mathcal{A}_0}(\theta),\quad \mathcal{L}^{\mathcal{A}_{-1}J}_{\mathcal{A}_1}(\theta)\equiv\mathcal{K}^{IJ}_{\mathcal{A}_1}(\theta)=-(-1)^{\varepsilon_I\varepsilon_J}\mathcal{K}^{JI}_{\mathcal{A}_1}(\theta). \tag{11}$$

For $\overline{M}_{L_g}=\Sigma_{k=0}^{L_g}(-1)^k\overline{M}_{L_g-k-1}=\mathrm{rank}\|\mathcal{Z}^{\mathcal{A}_{L_{g-1}}}_{\mathcal{A}_{L_g}}\|_\Sigma$, relations (9)–(11) determine a *special gauge theory* of L_g-stage reducibility. The gauge algebra of such a theory is θ-locally embedded into the gauge algebra of a general gauge theory with the functional $Z[\mathcal{A}]=\partial_\theta(T(\theta)-S(\theta))$, which implies the relation between the eigenvectors

$$\hat{\mathcal{Z}}^{\mathcal{A}_{s-1}}_{\mathcal{A}_s}(\mathcal{A}(\theta_{s-1}),\theta_{s-1};\theta_s)=-\delta(\theta_{s-1}-\theta_s)\mathcal{Z}^{\mathcal{A}_{s-1}}_{\mathcal{A}_s}(\mathcal{A}(\theta_{s-1}),\theta_{s-1}) \tag{12}$$

and the fact that the structure functions of the gauge algebra of a special gauge theory may depend on $\partial_\theta\mathcal{A}^I(\theta)$ only parametrically. Note that an extended (as compared to $\{P_a(\theta)\}$, $a=0,1$) system of projectors onto $C^\infty(T_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}})\times\{\theta\}$, $\{P_0(\theta),\theta\partial/\partial\theta,U(\theta)\}$, selects from (11) two kinds of gauge algebras: one with structure equations and functions $S(\mathcal{A}(\theta))$, $\mathcal{Z}^{\mathcal{A}_{s-1}}_{\mathcal{A}_s}(\mathcal{A}(\theta))$ not depending on θ in an explicit form; another with the standard relations for the gauge algebra of a reducible model with quantities $S_0(A)$, $\mathcal{Z}^{\alpha_{s-1}}_{\alpha_s}(A)$, in case $\theta=0$, $(\varepsilon_P)_I=(\varepsilon_P)_{\mathcal{A}_s}=0$, $s=1,\ldots,L_g$, and under the assumption of completeness of the reduced generators $\mathcal{R}^{i}_{\alpha_0}(\mathcal{A}(\theta))$ and eigenvectors $\mathcal{Z}^{\alpha_{s-1}}_{\alpha_s}(\mathcal{A}(\theta))$; see Sec. IV A.

An extension of a usual field theory to a θ-local LSM permits one to apply Noether's first theorem[26] to the invariance of the density $d\theta S_{\mathrm{L}}(\theta)$ with respect to global θ-translations as symmetry transformations of the superfields $\mathcal{A}^I(\theta)$ and coordinates (z^M,θ), $(\mathcal{A}^I,z^M,\theta)\to(\mathcal{A}^I,z^M,\theta+\mu)$. By direct verification, one establishes that the function

$$S_E((\mathcal{A},\partial_\theta\mathcal{A})(\theta),\theta)\equiv\frac{\partial S_{\mathrm{L}}(\theta)}{\partial(\partial^r_\theta\mathcal{A}^I(\theta))}\partial^r_\theta\mathcal{A}^I(\theta)-S_{\mathrm{L}}(\theta) \tag{13}$$

is a LS integral of motion, i.e., a conserved quantity under the θ-evolution, in case there holds the equation

$$\frac{\partial}{\partial\theta}S_{\mathrm{L}}(\theta)+2(\partial_\theta U)(\theta)S_{\mathrm{L}}(\theta)\Big|_{\mathcal{L}^I_I S_{\mathrm{L}}=0}=0. \tag{14}$$

In contrast to its analogue in a t-local field theory, the energy $E(t)$, the function $S_E(\theta)$ is a LS integral also in the case of an explicit dependence on θ. This fact takes place in case $S_{\mathrm{L}}(\theta)$ admits the structure

$$S_{\mathrm{L}}((\mathcal{A},\partial_\theta\mathcal{A})(\theta),\theta)=S^0_{\mathrm{L}}(\mathcal{A},\partial_\theta\mathcal{A})(\theta)-2\theta(\partial_\theta U)(\theta)S^0_{\mathrm{L}}(\theta),\vec{\varepsilon}(S^0_{\mathrm{L}})=\vec{0}. \tag{15}$$

III. ODD-TIME HAMILTONIAN FORMULATION

Independently, a LSM can be formulated in terms of a *Hamiltonian action*, being a $C^\infty(T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}})$-function, S_{H}: $T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}}\times\{\theta\}\to\Lambda_1(\theta;\mathbb{R})$, depending on superantifields $\mathcal{A}^*_I(\theta)=(A^*_I-\theta J_I)$, included in the local coordinates of $T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}}$: $\Gamma^P_{\mathrm{CL}}(\theta)=(\mathcal{A}^I,\mathcal{A}^*_I)(\theta)$, $\vec{\varepsilon}(\mathcal{A}^*_I)=\vec{\varepsilon}(\mathcal{A}^I)+(1,0,1)$. The equivalence of the Lagrangian and Hamiltonian formulations is implied by the nondegeneracy of the supermatrix $\|(S''_{\mathrm{L}})_{IJ}(\theta)\|$ given by (5), in the framework of a Legendre transformation of $S_{\mathrm{L}}(\theta)$ with respect to $\partial^r_\theta\mathcal{A}^I(\theta)$,

$$S_{\mathrm{H}}(\Gamma_{\mathrm{CL}}(\theta),\theta)=\mathcal{A}^*_I(\theta)\partial^r_\theta\mathcal{A}^I(\theta)-S_{\mathrm{L}}(\theta),\ \mathcal{A}^*_I(\theta)=\frac{\partial S_{\mathrm{L}}(\theta)}{\partial(\partial^r_\theta\mathcal{A}^I(\theta))}, \tag{16}$$

where $S_{\mathrm{H}}(\Gamma_{\mathrm{CL}}(\theta),\theta)$ coincides with $S_E(\theta)$ in terms of the $T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}}$-coordinates.

The dynamics of a LSM is given by a *generalized Hamiltonian system* of $3N$ first-order equations in θ, equivalent to the LS equations in (5), and expressed through a θ-local antibracket $(\cdot,\cdot)_\theta$, namely,

$$\begin{gathered}\partial^r_\theta\Gamma^P_{\mathrm{CL}}(\theta)=(\Gamma^P_{\mathrm{CL}}(\theta),S_{\mathrm{H}}(\theta))_\theta,\quad \Theta^{\mathrm{H}}_I(\Gamma_{\mathrm{CL}}(\theta),\theta)=\Theta_I(\mathcal{A}(\theta),\partial_\theta\mathcal{A}(\Gamma_{\mathrm{CL}}(\theta),\theta),\theta)=0,\\ (\mathcal{F}_1(\theta),\mathcal{F}_2(\theta))_\theta\equiv\frac{\partial\mathcal{F}_1(\theta)}{\partial\mathcal{A}^I(\theta)}\frac{\partial\mathcal{F}_2(\theta)}{\partial\mathcal{A}^*_I(\theta)}-\frac{\partial_r\mathcal{F}_1(\theta)}{\partial\mathcal{A}^*_I(\theta)}\frac{\partial_l\mathcal{F}_2(\theta)}{\partial\mathcal{A}^I(\theta)},\ \mathcal{F}_t(\theta)\in C^\infty(\Pi T^*\mathcal{M}_{\mathrm{CL}}),\quad t=1,2\end{gathered} \tag{17}$$

with *Hamiltonian constraints* $\Theta^{\mathrm{H}}_I(\Gamma_{\mathrm{CL}}(\theta),\theta)$. The latter coincide with half of the equations of the HS proper, due to transformations (16) and their consequences:

$$\Theta^{\mathrm{H}}_I(\Gamma_{\mathrm{CL}}(\theta),\theta)=-\partial^r_\theta\mathcal{A}^*_I(\theta)-S_{\mathrm{H},I}(\theta)(-1)^{\varepsilon_I}. \tag{18}$$

Formula (18) establishes the equivalence of an HS with a generalized HS, and hence with a LS in the corresponding [formal, in view of the degeneracy conditions (6)] setting ($\theta=0$, $k=\mathrm{CL}$) of the Cauchy problem for integral curves $\hat{\mathcal{A}}^I(\theta)$, $\hat{\Gamma}^P_k(\theta)$,

$$(\hat{\mathcal{A}}^I,\partial^r_\theta\hat{\mathcal{A}}^I)(0)=(\overline{\mathcal{A}^I},\overline{\partial^r_\theta\mathcal{A}^I}),\quad \hat{\Gamma}^P_k(0)=(\overline{\mathcal{A}^I},\overline{\mathcal{A}^*_I}):\overline{\mathcal{A}^*_I}=P_0\left[\frac{\partial S_{\mathrm{L}}(\theta)}{\partial(\partial^r_\theta\mathcal{A}^I(\theta))}\right](\overline{\mathcal{A}^I},\overline{\partial^r_\theta\mathcal{A}^I}), \tag{19}$$

where we have ignored the continuous part of I. The equivalence between an HS and a generalized HS is valid due to the coincidence (mutual inclusion) of the corresponding sets of solutions. Indeed, the solutions of a generalized HS are included into those of an HS by construction, while the reverse is valid due to (18).

The HS is defined through a variational problem for a functional identical to $Z[\mathcal{A}]$,

$$Z_{\mathrm{H}}[\Gamma_k]=\int\mathrm{d}\theta\left[\frac{1}{2}\Gamma^P_k(\theta)\omega^k_{PQ}(\theta)\partial^r_\theta\Gamma^Q_k(\theta)-S_{\mathrm{H}}(\Gamma_k(\theta),\theta)\right],$$

$$\omega_k^{PQ}(\theta) \equiv (\Gamma_k^P(\theta), \Gamma_k^Q(\theta))_\theta, \quad \omega_k^{PD}(\theta)\omega_{DQ}^k(\theta) = \delta^P{}_Q. \tag{20}$$

Definitions (9)–(11) remain the same for special gauge theories, while definitions (7) and (8), in the case of general gauge theories of L_g-stage reducibility, are transformed by the rule

$$\hat{\mathcal{Z}}_{\mathrm{H}\mathcal{A}_s}^{\mathcal{A}_{s-1}}(\Gamma_k(\theta_{s-1}), \theta_{s-1}; \theta_s) = \hat{\mathcal{Z}}_{\mathcal{A}_s}^{\mathcal{A}_{s-1}}(\mathcal{A}(\theta_{s-1}), \partial_{\theta_{s-1}}\mathcal{A}(\Gamma_k(\theta_{s-1}), \theta_{s-1}), \theta_{s-1}; \theta_s), \quad s = 0, \ldots, L_g. \tag{21}$$

Equation (14), transformations (16) and their consequence $(\partial/\partial\theta)(S_\mathrm{L} + S_\mathrm{H})(\theta) = 0$ imply the invariance of $S_\mathrm{H}(\theta)$ under θ-shifts along arbitrary solutions $\hat{\Gamma}_k^P(\theta)$, or, equivalently, along an $(\varepsilon_P, \varepsilon)$-odd vector field $\mathbf{Q}(\theta) = \mathrm{ad}S_\mathrm{H}(\theta) \equiv (S_\mathrm{H}(\theta), \cdot)_\theta$. Hence,

$$\delta_\mu S_\mathrm{H}(\theta)|_{\hat{\Gamma}_k(\theta)} = \mu\left[\frac{\partial}{\partial\theta}S_\mathrm{H}(\theta) - (S_\mathrm{H}(\theta), S_\mathrm{H}(\theta))_\theta\right] = 0, \quad \delta_\mu S_\mathrm{H}(\theta) = \mu\partial_\theta S_\mathrm{H}(\theta) \tag{22}$$

holds true, provided that $S_\mathrm{H}(\theta)$ can be presented, according to (14), in the form

$$S_\mathrm{H}\big(\Gamma_k(\theta), \theta\big) = S_\mathrm{H}^0(\Gamma_k(\theta)) + \theta\big(S_\mathrm{H}^0(\Gamma_k(\theta)), S_\mathrm{H}^0(\Gamma_k(\theta))\big)_\theta, \tag{23}$$

where $(\partial_\theta U)(\theta)S_\mathrm{L}(\theta) = 1/2(S_\mathrm{H}(\theta), S_\mathrm{H}(\theta))_\theta$, and $S_\mathrm{H}^0(\Gamma_k(\theta))$ is the Legendre transform of $S_\mathrm{L}^0(\theta)$, defined by (15).

If $S_\mathrm{H}(\theta)$ or $S_\mathrm{L}(\theta)$ does not depend on θ explicitly, then Eq. (22) or (14) implies the fulfillment of the equation $(S_\mathrm{H}(\theta), S_\mathrm{H}(\theta))_\theta = 0$, or $(\partial_\theta U)(\theta)S_\mathrm{L}(\theta)|_{\hat{\mathcal{A}}(\theta)} = 0$, which has no counterpart in a *t*-local field theory, and imposes the known condition[1] that $S_\mathrm{H}(\theta)$ or $S_\mathrm{L}(\theta)$ be proper, although for a LSM at the classical level. In this case, a θ-superfield integrability (introduced by analogy with the treatment of Ref. 16) of the HS in (17) is guaranteed by the standard properties of the antibracket, including the Jacobi identity:

$$(\partial_\theta^r)^2\Gamma_k^P(\theta) = \tfrac{1}{2}(\Gamma_k^P(\theta), (S_\mathrm{H}(\Gamma_k(\theta)), S_\mathrm{H}(\Gamma_k(\theta)))_\theta)_\theta = 0. \tag{24}$$

This fact ensures the validity on $C^\infty(T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}} \times \{\theta\})$ of the θ-translation formula

$$\delta_\mu \mathcal{F}(\theta)|_{\hat{\Gamma}_k(\theta)} = \mu\left[\frac{\partial}{\partial\theta} - \mathrm{ad}\, S_\mathrm{H}(\theta)\right]\mathcal{F}(\theta) \equiv \mu\check{s}^l(\theta)\mathcal{F}(\theta), \tag{25}$$

as well as the nilpotency of a BRST-like generator of θ-shifts along $\mathbf{Q}(\theta)$, $\check{s}^l(\theta)$.

Depending on the realization of additional properties of a gauge theory (see Sec. IV), we shall henceforth assume the validity of

$$\Delta^k(\theta)S_\mathrm{H}(\theta) = 0, \quad \Delta^k(\theta) \equiv \tfrac{1}{2}(-1)^{\varepsilon(\Gamma^Q)}\omega_{QP}^k(\theta)(\Gamma_k^P(\theta), (\Gamma_k^Q(\theta), \cdot)_\theta)_\theta. \tag{26}$$

Equation (26) is equivalent to a vanishing divergence of the vector field $\mathbf{Q}(\theta)$, namely,

$$\mathrm{div}(\partial_\theta^r\Gamma_k(\theta)|_{\hat{\Gamma}_k(\theta)}) = \frac{\partial_r}{\partial\Gamma_k^P(\theta)}(\partial_\theta^r\Gamma_k^P(\theta)|_{\hat{\Gamma}_k(\theta)}) = 2\Delta^k(\theta)S_\mathrm{H}(\theta) = 0. \tag{27}$$

This condition is trivial for the symplectic counterpart of formula (27). The validity of the *Hamiltonian master equation* $(S_\mathrm{H}(\theta), S_\mathrm{H}(\theta))_\theta = 0$ in case $(\partial/\partial\theta)S_\mathrm{H}(\theta) = 0$ justifies the interpretation of the equivalent equation in (14), for $(\partial/\partial\theta)S_\mathrm{L}(\theta) = 0$, $(\partial_\theta U)(\theta)S_\mathrm{L}(\theta)|_{\mathcal{L}_I^l S_\mathrm{L} = 0} = 0$, as a *Lagrangian master equation.*

IV. LOCAL SUPERFIELD QUANTIZATION

In order to set up the rules of local superfield quantization for a gauge model, we should first extract such a model from a general LSM. Then we should consider a procedure of constructing a quantum action for the restricted LSM, and, finally, investigate the possibility (inherent in the

θ-local approach) of a *dual description* of the LSM in terms of the quantities of the BFV formalism.

A. Superfield quantum action in initial coordinates

In this section, we transform the reducibility relations of a *restricted* special LSM into a sequence of new gauge transformations for the ghost superfields of the minimal sector. Together with the gauge transformations of the classical superfields $\mathcal{A}^i(\theta)$, extracted from $\mathcal{A}^I(\theta)$, the new gauge transformations are translated into a Hamiltonian system related to the initial restricted HS. A requirement of superfield integrability for the resulting HS produces a deformation of the θ-local Hamiltonian in powers of the ghosts and superantifields of the minimal sector, and leads to a quantum action, and, independently, to a gauge-fixing action (Sec. IV C), subject to different θ-local master equations.

Given the standard distribution of ghost number[1] for $\Gamma^P_{\mathrm{CL}}(\theta)$, $\mathrm{gh}(\mathcal{A}^*_I)=-1-\mathrm{gh}(\mathcal{A}^I)=-1$, the choice $\mathrm{gh}(\theta,\partial_\theta)=(-1,1)$ implying the absence of ghosts among $\mathcal{A}^I$, and, in particular, the relations $(\varepsilon_P)_I=0$, the quantization rules consist, first, in restricting a LSM (in both Lagrangian and Hamiltonian formulations) by

$$\left(\mathrm{gh},\frac{\partial}{\partial\theta}\right)S_{\mathrm{H(L)}}(\theta)=(0,0). \tag{28}$$

Given the existence of a potential term in $S_{\mathrm{H(L)}}(\theta)$, $S(\mathcal{A}(\theta),0)=\mathcal{S}(\mathcal{A}(\theta))$, and the absence in $S_{\mathrm{H(L)}}(\theta)$ of a dimensional constants with a nonzero ghost number, solutions of Eq. (28) select from a LSM a usual gauge model with a classical action $S_0(A)$ in which the fields A^i are extended to $\mathcal{A}^i(\theta)$. Then the generalized HS in (17) is transformed into a θ-integrable system defined in $\Pi T^*\mathcal{M}_{\mathrm{cl}}=\{\Gamma^p_{\mathrm{cl}}(\theta)\}=\{(\mathcal{A}^i,\mathcal{A}^*_i)(\theta)\}$, with $\Theta^{\mathrm{H}}_i(\mathcal{A}(\theta))=\Theta_i(\mathcal{A}(\theta))$,

$$\partial^r_\theta\Gamma^p_{\mathrm{cl}}(\theta)=(\Gamma^p_{\mathrm{cl}}(\theta),S_0(\mathcal{A}(\theta)))_\theta,\quad \Theta^{\mathrm{H}}_i(\mathcal{A}(\theta))=-(-1)^{\varepsilon_i}S_{0,i}(\mathcal{A}(\theta)). \tag{29}$$

The restricted special gauge transformations $\delta\mathcal{A}^i(\theta)=\mathcal{R}^i_{0\alpha_0}(\mathcal{A}(\theta))\xi^{\alpha_0}_0(\theta)$, $\vec{\varepsilon}(\xi^{\alpha_0}_0(\theta))=\vec{\varepsilon}_{\alpha_0}$, with the condition $(\varepsilon_P)_{\alpha_0}=0$, are embedded by the substitution $\xi^{\alpha_0}_0(\theta)=d\tilde{\xi}^{\alpha_0}_0(\theta)=\mathcal{C}^{\alpha_0}(\theta)d\theta$, $\alpha_0=1,\ldots,m_0=m_{0-}+m_{0+}$, into a Hamiltonian system with $2n$ equations for unknown $\Gamma^p_{\mathrm{cl}}(\theta)$, with the Hamiltonian $S^0_1(\Gamma_{\mathrm{cl}},C_0)(\theta)=(\mathcal{A}^*_i\mathcal{R}_{0\alpha0}^{\ i}(\mathcal{A})\mathcal{C}^{\alpha_0})(\theta)$. A union of this system with the HS in (29), extended to $2(n+m_0)$ equations, has the form

$$\partial^r_\theta\Gamma^{p_{[0]}}_{[0]}(\theta)=(\Gamma^{p_{[0]}}_{[0]}(\theta),S^0_{[1]}(\theta))_\theta,\quad S^0_{[1]}(\theta)=(S_0+S^0_1)(\theta),\quad \Gamma^{p_{[0]}}_{[0]}\equiv(\Gamma^p_{\mathrm{cl}},\Gamma^{p_0}_0),\Gamma^{p_0}_0\equiv(\mathcal{C}^{\alpha_0},\mathcal{C}^*_{\alpha_0}). \tag{30}$$

By virtue of (11), the function $S^0_1(\theta)$ is invariant, modulo $S_{0,i}(\theta)$, under special gauge transformations of ghost superfields $\mathcal{C}^{\alpha_0}(\theta)$, with arbitrary functions $\xi^{\alpha_1}_1(\theta)$, $(\varepsilon_P)_{\alpha_1}=0$, on the superspace $\mathcal{M}$:

$$\delta\mathcal{C}^{\alpha_0}(\theta)=\mathcal{Z}^{\alpha_0}_{\alpha_1}(\mathcal{A}(\theta))\xi^{\alpha_1}_1(\theta),\ (\vec{\varepsilon},\mathrm{gh})\xi^{\alpha_1}_1(\theta)=(\vec{\varepsilon}_{\alpha_1}+(1,0,1),1). \tag{31}$$

Making the substitution $\xi^{\alpha_1}_1(\theta)=d\tilde{\xi}^{\alpha_1}_1(\theta)=\mathcal{C}^{\alpha_1}(\theta)d\theta$, $\alpha_1=1,\ldots,m_1$, and an enlargement of m_0 first-order equations in θ, with respect to the unknowns $\mathcal{C}^{\alpha_0}(\theta)$ in transformations (31), to an HS of $2m_0$ equations with the Hamiltonian $S^1_1(\mathcal{A},\mathcal{C}^*_0,\mathcal{C}_1)(\theta)=(\mathcal{C}^*_{\alpha_0}\mathcal{Z}^{\alpha_0}_{\alpha_1}(\mathcal{A})\mathcal{C}^{\alpha_1})(\theta)$, we obtain a system of the form (30), written for $\partial^r_\theta\Gamma^{p_0}_0(\theta)$. The enlargement of the union of the latter HS with Eq. (30) is formally identical to the system (30) under the replacement

$$(\Gamma^{p_{[0]}}_{[0]},S^0_{[1]})\to(\Gamma^{p_{[1]}}_{[1]},S^1_{[1]}):\{\Gamma^{p_{[1]}}_{[1]}=(\Gamma^{p_{[0]}}_{[0]},\Gamma^{p_1}_1),\Gamma^{p_1}_1=(\mathcal{C}^{\alpha_1},\mathcal{C}^*_{\alpha_1}),S^1_{[1]}=S^0_{[1]}+S^1_1\}.$$

The iteration sequence related to a reformulation of the special gauge transformations of ghosts $\mathcal{C}^{\alpha_0}\ldots$, $\mathcal{C}^{\alpha_{s-2}}$, obtained from (possibly) enhanced relations (11), leads, for an L-stage-reducible restricted LSM at the sth step with $0<s\leqslant L$ and $\Gamma^p_{cl}\equiv\Gamma^{p_{-1}}_{-1}$, to invariance transformations for $S_1^{s-1}(\theta)$, modulo $S_{0,i}(\theta)$, namely,

$$\delta\mathcal{C}^{\alpha_{s-1}}(\theta)=\mathcal{Z}^{\alpha_{s-1}}_{\alpha_s}(\mathcal{A}(\theta))\xi_s^{\alpha_s}(\theta),\quad (\vec{\varepsilon},\mathrm{gh})\xi_s^{\alpha_s}(\theta)=(\vec{\varepsilon}_{\alpha_s}+s(1,0,1),s),\quad (\varepsilon_P)_{\alpha_s}=0,$$

$$S_1^{s-1}(\theta)=(\mathcal{C}^*_{\alpha_{s-2}}\mathcal{Z}^{\alpha_{s-2}}_{\alpha_{s-1}}(\mathcal{A})C^{\alpha_{s-1}})(\theta),\quad \left(\mathrm{gh},\frac{\partial}{\partial\theta}\right)S_1^{s-1}(\theta)=(0,0). \tag{32}$$

[From $\mathrm{gh}(\mathcal{A}^I)=0$ in Eq. (28), with $(\varepsilon_P)_{\mathcal{A}_s}=(\varepsilon_P)_I=0$, $s=0,\ldots,L_g$, it follows that the values of $\overline{m}$, $\overline{m_s}$ may be both larger and smaller than the corresponding values $\overline{M}$, $\overline{M_s}$, in contrast to the values of $\overline{n}$, $\overline{N}$. Indeed, for a restricted LSM, the presence of additional gauge symmetries is possible; therefore, we suppose that (possibly) enhanced sets of restricted functions $\mathcal{R}^i_{0\,\alpha_0}(\theta)$, $\mathcal{Z}^{\alpha_{s-1}}_{\alpha_s}(\theta)$ exhaust, correspondingly, on the surface $S_{0,i}(\theta)=0$, the zero-modes of both the Hessian $S_{0,ij}(\theta)$ and $\mathcal{Z}^{\alpha_{s-2}}_{\alpha_{s-1}}(\theta)$. As a consequence, this implies that the final stage of reducibility for a restricted model L is different from L_g.] The substitution $\xi_s^{\alpha_s}(\theta)=d\tilde{\xi}_s^{\alpha_s}(\theta)=\mathcal{C}^{\alpha_s}(\theta)d\theta$, $\alpha_s=1,\ldots,m_s=m_{s-}+m_{s+}$, transforms special gauge transformations (32) into m_{s-1} equations for unknown $\mathcal{C}^{\alpha_{s-1}}(\theta)$, extended by the introduction of superantifields $\mathcal{C}^*_{\alpha_{s-1}}(\theta)$ to an HS:

$$\partial^r_\theta\Gamma^{p_{s-1}}_{s-1}(\theta)=(\Gamma^{p_{s-1}}_{s-1}(\theta),S_1^s(\theta))_\theta,\quad S_1^s(\theta)=(\mathcal{C}^*_{\alpha_{s-1}}\mathcal{Z}^{\alpha_{s-1}}_{\alpha_s}(\mathcal{A})\mathcal{C}^{\alpha_s})(\theta),\quad \Gamma^{p_{s-1}}_{s-1}=(\mathcal{C}^{\alpha_{s-1}},\mathcal{C}^*_{\alpha_{s-1}}). \tag{33}$$

Having combined the system (33) with an HS of the same form, although with $\partial^r_\theta\Gamma^{p_{[s-1]}}_{[s-1]}(\theta)$ and the Hamiltonian $S^{s-1}_{[1]}(\theta)=(S_0+\Sigma_{r=0}^{s-1}S_1^r)(\theta)$, and having expressed the result for $2(n+\Sigma_{r=0}^s m_r)$ equations with $S^s_{[1]}(\theta)=(S^{s-1}_{[1]}+S_1^s)(\theta)$, we obtain, by induction, the following HS:

$$\partial^r_\theta\Gamma^{p_{[L]}}_{[L]}(\theta)=(\Gamma^{p_{[L]}}_{[L]}(\theta),S^L_{[1]}(\theta))_\theta,\quad S^L_{[1]}(\theta)=S_0(\mathcal{A}(\theta))+\sum_{s=0}^{L}(\mathcal{C}^*_{\alpha_{s-1}}\mathcal{Z}^{\alpha_{s-1}}_{\alpha_s}(\mathcal{A})\mathcal{C}^{\alpha_s})(\theta). \tag{34}$$

The function $S^L_{[1]}(\theta)$, subject to the condition of a proper θ-local solution of the classical master equation,[1] with the antibracket extended in $\Pi T^*\mathcal{M}_k=\{\Gamma^{p_{[L]}}_{[L]}(\theta)\equiv\Gamma^{p_k}_k(\theta)=(\Phi^{A_k},\Phi^*_{A_k})(\theta),A_k=1,\ldots,n+\Sigma_{r=0}^L m_r,k=\min\}$, is a solution of the master equation with accuracy up to $O(C^{\alpha_s})$, modulo $S_{0,i}(\theta)$. The integrability of the HS in (34) is guaranteed by a double deformation of $S^L_{[1]}(\theta)$: first in powers of $\Phi^*_{A_k}(\theta)$ and then in powers of $\mathcal{C}^{\alpha_s}(\theta)$, in the framework of the existence theorem[27] for the classical master equation in the minimal sector:

$$(S_{\mathrm{H};k}(\Gamma_k(\theta)),S_{\mathrm{H};k}(\Gamma_k(\theta)))_\theta=0,\quad \left(\vec{\varepsilon},\mathrm{gh},\frac{\partial}{\partial\theta}\right)S_{\mathrm{H};k}(\Gamma_k(\theta))=(\vec{0},0,0),\quad k=\min. \tag{35}$$

The proposed superfield algorithm for constructing the function $S_{\mathrm{H};\min}(\theta)$ may be considered as a superfield version of the Koszul–Tate complex resolution.[28]

Let us consider an extension of $S_{\mathrm{H};\min}(\theta)$ to $S_{\mathrm{H};k}(\theta)=S_{\mathrm{H};\min}(\theta)+\Sigma_{s=0}^L\Sigma_{s'=0}^s(\mathcal{C}^*_{s'\,\alpha_s}\mathcal{B}^{\alpha_s}_{s'})(\theta)$, being a proper solution[1] in $\Pi T^*\mathcal{M}_k=\{\Gamma^{p_k}_k(\theta)\}$,

$$\Gamma^{p_k}_k(\theta)=(\Gamma^{p_{\min}}_{\min},\mathcal{C}^{\alpha_s}_{s'},\mathcal{B}^{\alpha_s}_{s'},\mathcal{C}^*_{s'\,\alpha_s},\mathcal{B}^*_{s'\,\alpha_s})(\theta),\quad s'=0,\ldots,s,\quad s=0,\ldots,L,$$

$$(\vec{\varepsilon},\mathrm{gh})\mathcal{C}^{\alpha_s}_{s'}(\theta)=(\vec{\varepsilon}_{\alpha_s}+(s+1)(1,0,1),2s'-s-1)=(\vec{\varepsilon},\mathrm{gh})\mathcal{B}^{\alpha_s}_{s'}(\theta)+((1,0,1),-1)$$

[henceforth we assume $k=\mathrm{ext}$ and take into account that $(\vec{\varepsilon},\mathrm{gh})\Phi^*_{A_k}(\theta)=-((1,0,1),1)-(\vec{\varepsilon},\mathrm{gh})\Phi^{A_k}(\theta)$], with the pyramids of ghosts and Nakanishi–Lautrup superfields, and with a

deformation in the Planck constant $\hbar$. Then $S_{\mathrm{H};k}(\theta)$ determines the quantum action $S^{\Psi}_{\mathrm{H}}(\Gamma(\theta),\hbar)$, e.g., in case of an Abelian hypergauge defined as an anticanonical phase transformation:

$$\Gamma^{p_k}_k(\theta)\to\Gamma'^{p_k}_k(\theta)=\left(\Phi^{A_k}(\theta),\Phi^*_{A_k}(\theta)-\frac{\partial\Psi(\Phi(\theta))}{\partial\Phi^{A_k}(\theta)}\right):S^{\Psi}_{\mathrm{H}}(\Gamma(\theta),\hbar)=e^{\mathrm{ad}\Psi}S_{\mathrm{H};k}(\Gamma_k(\theta),\hbar). \tag{36}$$

The functions $(S^{\Psi}_{\mathrm{H}},S_{\mathrm{H};k})(\theta,\hbar)$ obey Eqs. (26) and (35) in case the $\hbar$-deformation of $S_{\mathrm{H;min}}(\theta)$ is a solution of these equations. It is known that this choice of equations ensures the integrability of a nonequivalent HS constructed from S^{Ψ}_{H}, $S_{\mathrm{H};k}$, as well as the anticanonical [preserving the volume element $dV_k(\theta)=\Pi_{p_k}d\Gamma^{p_k}_k(\theta)$] nature of this change of variables, corresponding to a θ-shift by a constant parameter μ along the corresponding HS solutions. In its turn, the quantum master equation

$$\Delta^k(\theta)\exp\left[\frac{i}{\hbar}E(\theta,\hbar)\right]=0,\quad E\in\{S^{\Psi}_{\mathrm{H}},S_{\mathrm{H};k}\} \tag{37}$$

determines a nonintegrable HS, with the respective anticanonical change of variables preserving $d\hat{V}_k(\theta)=\exp[(i/\hbar)E(\theta,\hbar)]dV_k(\theta)$. It is the latter nonintegrable HS with the Hamiltonian $S^{\Psi}_{\mathrm{H}}(\theta,\hbar)$ that is crucial, for $\theta=0$, in the BV formalism. This HS defines in $\Pi T^*\mathcal{M}_k$ a θ-local, but not nilpotent, generator of BRST transformations, $\tilde{s}^{l(\Psi)}(\theta)$, which is associated with its θ-nonintegrable consequence:

$$\partial^r_\theta(\Phi^{A_k},\Phi^*_{A_k})(\theta)=((\Phi^{A_k}(\theta),S^{\Psi}_{\mathrm{H}}(\theta,\hbar))_\theta,0),\quad \tilde{s}^{l(\Psi)}(\theta)=\frac{\partial}{\partial\theta}+\frac{\partial_r S^{\Psi}_{\mathrm{H}}(\theta,\hbar)}{\partial\Phi^*_{A_k}(\theta)}\frac{\partial_l}{\partial\Phi^{A_k}(\theta)}. \tag{38}$$

B. Duality between the BV and BFV superfield quantities

An embedding of a restricted LSM gauge algebra, described by $S_{\mathrm{H;min}}(\theta)$ and Eq. (35), into the gauge algebra of a general gauge theory in the Lagrangian formalism, see Eqs. (7)–(12), can be effectively realized by means of dual functional counterparts, with the opposite $(\varepsilon_P,\varepsilon)$-parity, of the action and antibracket, by analogy with the approach of Refs. 12 and 18. To this end, let us consider the functional

$$Z_k[\Gamma_k]=-\partial_\theta S_{\mathrm{H};k}(\theta),\quad(\vec{\varepsilon},\mathrm{gh})Z_k=((1,0,1),1)$$

on the supermanifold $\Pi T(\Pi T^*\mathcal{M}_k)=\{(\Gamma^{p_k}_k,\partial_\theta\Gamma^{p_k}_k)(\theta),k=\min\}$ with natural $(\varepsilon_P,\varepsilon)$-even, symplectic, and $(\varepsilon_P,\varepsilon)$-odd Poisson structures. These structures define an $(\varepsilon_P,\varepsilon)$-even functional $\{\cdot,\}$ with canonical pairs $\{(\Phi^{A_k}_k,\partial_\theta\Phi^*_{A_k}),(\partial_\theta\Phi^{A_k}_k,\Phi^*_{A_k})\}(\theta)$, and $(\varepsilon_P,\varepsilon)$-odd θ-local, $(\cdot,\cdot)^{(\Gamma_k,\partial_\theta\Gamma_k)}_\theta$, Poisson brackets. The latter act on the superalgebra $C^\infty(\Pi T(\Pi T^*\mathcal{M}_k)\times\theta)$ and provide a lifting of the antibracket $(\cdot,\cdot)_\theta$ defined on $\Pi T^*\mathcal{M}_k$. For arbitrary functionals $F_t[\Gamma_k]=\partial_\theta\mathcal{F}_t((\Gamma_k,\partial_\theta\Gamma_k)(\theta),\theta)$, $t=1,2$, one has the following correspondence between the Poisson brackets of opposite Grassmann grading:

$$\{F_1,F_2\}=\int\mathrm{d}\theta\left[\frac{\delta F_1}{\delta\Phi^{A_k}(\theta)}\frac{\delta F_2}{\delta\Phi^*_{A_k}(\theta)}-\frac{\delta_r F_1}{\delta\Phi^*_{A_k}(\theta)}\frac{\delta_l F_2}{\delta\Phi^{A_k}(\theta)}\right]=\int\mathrm{d}\theta(\mathcal{F}_1(\theta),\mathcal{F}_2(\theta))^{(\Gamma_k,\partial_\theta\Gamma_k)}_\theta,$$
$$(\mathcal{F}_1(\theta),\mathcal{F}_2(\theta))^{(\Gamma_k,\partial_\theta\Gamma_k)}_\theta\equiv[(\mathcal{L}_{A_k}\mathcal{F}_1)\mathcal{L}^{*A_k}\mathcal{F}_2-(\mathcal{L}^{*A_k}_r\mathcal{F}_1)\mathcal{L}^l_{A_k}\mathcal{F}_2](\theta), \tag{39}$$

where the Euler–Lagrange superfield derivative, e.g., with respect to $\Phi^*_{A_k}(\theta)$, for a fixed θ, has the form $\mathcal{L}^{*A_k}(\theta)=\partial/\partial\Phi^*_{A_k}(\theta)-(-1)^{\varepsilon_{A_k}+1}\partial_\theta\cdot\partial/\partial(\partial_\theta\Phi^*_{A_k}(\theta))$.

By construction, the functional Z_k is nilpotent:

$$\{Z_k, Z_k\} = \int \mathrm{d}\theta (S_{\mathrm{H};k}(\theta), S_{\mathrm{H};k}(\theta))_\theta = 0, \quad k = \min, \tag{40}$$

and, due to the absence of the additional time coordinate, is formally related to the BRST charge of a dynamical system with first-class constraints.[2] Indeed, after identifying $(\Gamma_k, \partial_\theta \Gamma_k)(0)$ with the phase-space coordinates of the minimal sector, canonical with respect to the $(\varepsilon_P, \varepsilon)$-even brackets in the framework of the BFV method[2] for first-class constrained systems of $(L+1)$-stage reducibility,

$$\begin{gathered}(q^i, p_i) = (\mathcal{A}^i, \partial_\theta \mathcal{A}_i^*)(0), \quad (C^{A_s}, \mathcal{P}_{A_s}) = \left((\partial_\theta^r \mathcal{C}^{\alpha_{s-1}}, \mathcal{C}^{\alpha_s}), (\mathcal{C}^*_{\alpha_{s-1}}, \partial_\theta \mathcal{C}^*_{\alpha_s})\right)(0), \\ A_s = (\alpha_{s-1}, \alpha_s), \quad s = 0, \ldots, L, \quad (C^{A_{L+1}}, \mathcal{P}_{A_{L+1}}) = (\partial_\theta^r \mathcal{C}^{\alpha_L}, \mathcal{C}^*_{\alpha_L})(0),\end{gathered} \tag{41}$$

the functional Z_k takes the form

$$Z_k[\Gamma_k] = T_{A_0}(q,p) C^{A_0} + \sum_{s=1}^{L+1} \mathcal{P}_{A_{s-1}} Z^{A_{s-1}}_{A_s}(q) C^{A_s} + O(C^2). \tag{42}$$

With allowance for the gauge algebra structure functions of the original L-stage-reducible restricted LSM described by the enhanced Eq. (11), the constraints $T_{A_0}(q,p)$ and the set of $(L+1)$-stage-reducible eigenvectors $Z^{A_{s-1}}_{A_s}(q)$ are defined by (the symbol T below stands for transposition)

$$\begin{gathered}T_{A_0}(q,p) = (S_{0,i}(q), -p_i \mathcal{R}_{0\ \alpha_0}^{\ i}(q)), \quad Z^{A_{s-1}}_{A_s}(q) = \mathrm{diag}(\mathcal{Z}^{\alpha_{s-2}}_{\alpha_{s-1}}, \mathcal{Z}^{\alpha_{s-1}}_{\alpha_s})(q), \\ s = 1, \ldots, L, \quad (Z^{A_L}_{A_{L+1}})^T(q) = (\mathcal{Z}^{\alpha_{L-1}}_{\alpha_L}, 0)^T(q),\end{gathered} \tag{43}$$

$$\begin{gathered}Z^{A_{s-2}}_{A_{s-1}} Z^{A_{s-1}}_{A_s} = T_{B_0} L^{A_{s-2} B_0}_{A_s}(q,p), \quad s = 1, \ldots, \quad L+1, \quad Z^{A_{-1}}_{A_0} \equiv T_{A_0}, \quad L^{A_{s-2}\beta_0}_{A_s} = 0, \\ L^{A_{s-2} j}_{A_s} = \mathrm{diag}(\mathcal{L}^{\alpha_{s-3} j}_{\alpha_{s-1}}, \mathcal{L}^{\alpha_{s-2} j}_{\alpha_s}), \quad \mathcal{L}^{\alpha_{-2} j}_{\alpha_0} = \mathcal{L}^{\alpha_{L-1} j}_{\alpha_{L+1}} = 0, \quad \mathcal{L}^{\alpha_{-1} j}_{\alpha_1}(q,p) = (-1)^{\varepsilon_j + 1} p_i \mathcal{K}^{ji}_{\alpha_1}(q).\end{gathered} \tag{44}$$

Relations (39)–(44) generalize, to the case of arbitrary reducible theories, the results of Ref. 18 concerning a dual description (for $\varepsilon_i = \varepsilon_{\alpha_0} = L = 0$) of the quantum action and classical master equation in terms of a nilpotent BRST charge.

By the rule (41), the variables $(\mathcal{C}^*_{s'\alpha_s}, \mathcal{B}^*_{s'\alpha_s}, \mathcal{B}^{\alpha_s}_{s'})(\theta)$ are identical to the respective ghost momenta $\mathcal{P}_{s'A_s}$, Lagrangian multipliers $\lambda_{s'A_s}$, and their conjugate momenta $\pi^{A_s}_{s'}$ in Ref. 2. Then a comparison of the superfields $\mathcal{C}^{\alpha_s}_{s'}(\theta)$, $s' = 0, \ldots, s$, selected from the nonminimal configuration space of an L-stage-reducible LSM, with the coordinates $C^{A_s}_{s'}$ selected from the nonminimal phase space of the corresponding $(L+1)$-stage-reducible dynamical system[2] demonstrates the only possible embedding of $\Pi T(\Pi T^* \mathcal{M}_{\mathrm{ext}})$ into the phase space of the BFV method. Indeed, for the coordinates $C^{A_{L+1}}_0$, $\mathrm{gh}(C^{A_{L+1}}_0) = -L-2$, there exists no preimage among $(\mathcal{C}^{\alpha_s}_{s'}, \partial_\theta \mathcal{C}^{\alpha_s}_{s'})(0)$, because the ghost number spectrum for the latter variables is bounded from below:

$$\min \mathrm{gh}(\mathcal{C}^{\alpha_s}_{s'}, \partial_\theta \mathcal{C}^{\alpha_s}_{s'}) = \mathrm{gh}(\mathcal{C}^{\alpha_L}_0) = -L-1.$$

As a consequence, the nilpotent functional $Z_k[\Gamma_k] = -\partial_\theta S_{\mathrm{H};k}(\theta)$, $k = \mathrm{ext}$, is embedded into the total BRST charge constructed by the prescription of Ref. 2.

It should be noted that the systems constructed with respect to the Hamiltonians $S^\Psi_{\mathrm{H}}(\Gamma(\theta), \hbar)$ and $S_{\mathrm{H};k}(\theta)$, $k = \min$, ext, are equivalently described by dual fermion functionals $Z_k[\Gamma_k]$ and $Z^\Psi[\Gamma] = -\partial_\theta S^\Psi_{\mathrm{H}}(\Gamma(\theta), \hbar)$, in terms of even Poisson brackets, for instance,

$$\partial^r_\theta \Gamma^p(\theta) = (\Gamma^p(\theta), S^\Psi_{\mathrm{H}}(\Gamma(\theta),\hbar))_\theta = -\{\Gamma^p(\theta), Z^\Psi[\Gamma]\}. \tag{45}$$

Thereby, BRST transformations in the Lagrangian formalism with Abelian hypergauges can be encoded by a formal BRST charge, $Z^\Psi[\Gamma]$, related to $Z_k[\Gamma_k]$, $k=\mathrm{ext}$, by a phase canonical transformation with the $(\varepsilon_P,\varepsilon)$-even phase $F^\Psi[\Phi]=\partial_\theta\Psi(\Phi(\theta))$,

$$Z^\Psi[\Gamma] = e^{\overline{\mathrm{ad}}F^\Psi} Z_k[\Gamma_k], \quad \overline{\mathrm{ad}}F^\Psi \equiv \{F^\Psi, \cdot\}. \tag{46}$$

On the assumption that an additional gauge invariance does not appear in deriving the restricted LSM from the initial general gauge theory, i.e., $\overline{m_s} \leqslant \overline{M_s}$, and, therefore, $L \leqslant L_g$, the problem of including the restricted LSM gauge algebra into the initial gauge algebra, defined by (2), (7), and (8), is solved with the help of a nilpotent functional on $\Pi T(\Pi T^*\mathcal{M}_k)=\{(\Gamma^{P_k}_k, \partial_\theta\Gamma^{P_k}_k)(\theta), \Gamma^{P_k}_k(\theta) = (\Gamma^{P_{\mathrm{CL}}}_{\mathrm{CL}}, \mathcal{C}^{\mathcal{A}_s}, \mathcal{C}^*_{\mathcal{A}_s})(\theta), s=0,1,\ldots,L_g, k=\mathrm{MIN}\}$, namely,

$$\hat{Z}_k[\Gamma_k] = Z[\mathcal{A}] + \sum_{s=0}^{L_g}\left[\int \mathrm{d}\theta_{s-1}\mathrm{d}\theta_s \mathcal{C}^*_{\mathcal{A}_{s-1}}(\theta_{s-1})\hat{\mathcal{Z}}^{\mathcal{A}_{s-1}}_{\mathcal{A}_s}(\theta_{s-1};\theta_s)\mathcal{C}^{\mathcal{A}_s}(\theta_s)(-1)^{\varepsilon_{\mathcal{A}_{s-1}}+s} + O(C^{\mathcal{A}_s})\right]$$

$$= \int \mathrm{d}\theta S_{\mathrm{L};k}((\Gamma_k, \partial_\theta\Gamma_k)(\theta),\theta). \tag{47}$$

Given the superfields $\mathcal{C}^{\mathcal{A}_s}$ introduced as simple ghosts $\mathcal{C}^{\alpha_s}$, although used for a description of a general gauge algebra, a representation of solutions to the generating equation $\{\hat{Z}_k,\hat{Z}_k\}=0$ as expansions in powers of $\mathcal{C}^{\mathcal{A}_s}$ can be controlled by an additional *generalized ghost number*, gh_g, $\mathrm{gh}_g(\hat{Z}_k)=0$, coinciding with the standard ghost number only in the sector of $(\Phi^{A_{\mathrm{MIN}}}, \Phi^*_{A_{\mathrm{MIN}}})(0)$, for $\mathrm{gh}(\mathcal{A}^I, C^{\mathcal{A}_s})=(0,1+s)$, and having the spectrum

$$\mathrm{gh}_g(\mathcal{A}^I, C^{\mathcal{A}_s}) = (0,1+s), \quad \mathrm{gh}_g(\Phi^*_{A_{\mathrm{MIN}}}) = -1 - \mathrm{gh}_g(\Phi^{A_{\mathrm{MIN}}}), \quad \mathrm{gh}_g(\theta,\partial_\theta) = (0,0).$$

Conditions (28), applied to $S_{\mathrm{L};k}(\theta)$ in case $(\varepsilon_P)_{\mathcal{A}_s}=(\varepsilon_P)_I=0$, $s=0,\ldots,L_g$, extract from $\hat{Z}_k$ the functional Z_k in (42), so that the $(\varepsilon_P,\varepsilon)$-even θ-density $S_{\mathrm{L};k}(\theta)$ lifts the function $S_{\mathrm{H};k}(\theta) \in C^\infty(\Pi T^*\mathcal{M}_{\mathrm{min}})$ to the superalgebra $C^\infty(\Pi T(\Pi T^*\mathcal{M}_{\mathrm{MIN}})\times\theta)$. In general, $S_{\mathrm{L};k}(\theta)$ does not obey the generalized master equation (35) with the antibracket (39) acting on $C^\infty(\Pi T(\Pi T^*\mathcal{M}_{\mathrm{MIN}}) \times\theta)$,

$$(S_{\mathrm{L};k}(\theta), S_{\mathrm{L};k}(\theta))^{(\Gamma_k,\partial_\theta\Gamma_k)}_\theta = \tilde{f}((\Gamma_k,\partial_\theta\Gamma_k)(\theta),\theta), \quad \tilde{f}(\theta) \in \ker\{\partial_\theta\}, \quad k=\mathrm{MIN}. \tag{48}$$

C. Local quantization

Leaving aside the realization of a reducible LSM on $\Pi T^*\mathcal{M}_{\mathrm{ext}}$, we now suppose that the model is described by a quantum action, $W(\theta,\hbar)=W(\theta)$, defined on an arbitrary antisymplectic manifold $\mathcal{N}$ without connection, $\dim\mathcal{N}=\dim\Pi T^*\mathcal{M}_{\mathrm{ext}}=\overline{n}+(n_-,n_+) +\Sigma^L_{r=0}(2r+3)(\overline{m_r} +(m_{r-},m_{r+}))$, with local coordinates $\Gamma^p(\theta)$ and a density function $\rho(\Gamma(\theta))$. A local antibracket, an invariant volume element, $\mathrm{d}\mu(\Gamma(\theta))$, and a nilpotent second-order operator, $\Delta^{\mathcal{N}}(\theta)$, are defined in terms of an $(\varepsilon_P,\varepsilon)$-odd Poisson bivector, $\omega^{pq}(\Gamma(\theta))=(\Gamma^p(\theta),\Gamma^q(\theta))^{\mathcal{N}}_\theta$, namely,

$$\mathrm{d}\mu(\Gamma(\theta)) = \rho(\Gamma(\theta))\mathrm{d}\Gamma(\theta),\ \Delta^{\mathcal{N}}(\theta) = \tfrac{1}{2}(-1)^{\varepsilon(\Gamma^q)}\rho^{-1}\omega_{qp}(\theta)\big(\Gamma^p(\theta),\rho(\Gamma^q(\theta),\ \cdot)^{\mathcal{N}}_\theta\big)^{\mathcal{N}}_\theta. \tag{49}$$

The definition of a generating functional of Green's functions $Z((\partial_\theta\varphi^*,\varphi^*,\partial_\theta\varphi,\mathcal{I})(\theta))\equiv Z(\theta)$ as a path integral, for a fixed θ, is possible, within perturbation theory, by introducing on $\mathcal{N}$ the Darboux coordinates, $\Gamma^p(\theta)=(\varphi^a,\varphi^*_a)(\theta)$, in a vicinity of solutions of the equations $\partial W(\theta)/\partial\Gamma^p(\theta)=0$, so that $\rho=1$ and $\omega^{pq}(\theta)=\mathrm{antidiag}(-\delta^a_b,\delta^a_b)$. The function

$$Z(\theta) = \int d\mu(\tilde{\Gamma}(\theta)) d\Lambda(\theta) \exp\{(i/\hbar)[W(\tilde{\Gamma}(\theta),\hbar) + X((\tilde{\varphi},\tilde{\varphi}^* - \varphi^*,\Lambda,\Lambda^*)(\theta),\hbar)|_{\Lambda^*=0} - ((\partial_\theta \varphi_a^*)\tilde{\varphi}^a + \tilde{\varphi}_a^* \partial_\theta^r \varphi^a - \mathcal{I}_a \Lambda^a)(\theta)]\} \tag{50}$$

depends on an extended set of sources,

$$(\partial_\theta \varphi_a^*, \partial_\theta^r \varphi^a, \mathcal{I}_a)(\theta) = (-J_a, \lambda^a, I_{0a} + I_{1a}\theta),$$

$$(\vec{\varepsilon}, \mathrm{gh}) \partial_\theta \varphi_a^* = (\vec{\varepsilon}, \mathrm{gh}) \mathcal{I}_a + ((1,0,1),1) = (\vec{\varepsilon}, -\mathrm{gh}) \varphi^a,$$

to the superfields $(\varphi^a, \varphi_a^*, \Lambda^a)(\theta)$, where $\Lambda^a(\theta) = (\lambda_0^a + \lambda_1^a \theta)$ are Lagrangian multipliers to independent non-Abelian hypergauges, see Ref. 21,

$$G_a(\Gamma(\theta)), a = 1, \ldots, \quad k = n + \sum_{r=0}^{L} (2r+3) m_r, \quad k = k_+ + k_-,$$

$$\mathrm{rank} \| \partial G_a(\theta) / \partial \Gamma^p(\theta) \|_{\partial W / \partial \Gamma = G = 0} = \overline{l}, \quad l = l_+ + l_- = k.$$

The functions $G_a(\Gamma(\theta))$, $(\vec{\varepsilon}, \mathrm{gh}) G_a = (\vec{\varepsilon}, \mathrm{gh}) \mathcal{I}_a$, determine a boundary condition for the gauge-fixing action, $X(\theta) = X((\Gamma, \Lambda, \Lambda^*)(\theta), \hbar)$,

$$\partial_r X(\theta) / \partial \Lambda^a(\theta)|_{\Lambda^* = \hbar = 0} = G_a(\theta),$$

defined on the direct sum $\mathcal{N}_{\mathrm{tot}} = \mathcal{N} \oplus \Pi T^* \mathcal{K}$ of the manifolds $\mathcal{N}$ and $\Pi T^* \mathcal{K} = \{(\Lambda^a, \Lambda_a^*)(\theta)\}$. Hypergauges in involution, $(G_a(\theta), G_b(\theta))_\theta^{\mathcal{N}} = G_c(\theta) U_{ab}^c(\Gamma(\theta))$, obey different types of unimodularity relations,[21] depending on a set of equations for which $X(\theta)$ may be a solution, independent from $W(\theta)$, in terms of the antibracket $(\cdot,\cdot)_\theta = (\cdot,\cdot)_\theta^{\mathcal{N}} + (\cdot,\cdot)_\theta^{\mathcal{K}}$ and the operator $\Delta(\theta) = (\Delta^{\mathcal{N}} + \Delta^{\mathcal{K}})(\theta)$, trivially lifted from $\mathcal{N}$ to $\mathcal{N}_{\mathrm{tot}}$,

$$1)\ (E(\theta), E(\theta))_\theta = 0, \quad \Delta(\theta) E(\theta) = 0;\ 2)\ \Delta(\theta) \exp\left[\frac{i}{\hbar} E(\theta)\right] = 0, \quad E \in \{W, X\}. \tag{51}$$

The functions $G_a(\theta)$, assumed to be solvable with respect to $\varphi_a^*(\theta)$, determine a Lagrangian surface, $\mathcal{Q} = \{(\varphi^*, \Lambda)(\theta)\} \subset \mathcal{N}_{\mathrm{tot}}$, on which the restriction $X(\theta)|_{\mathcal{Q}}$ is nondegenerate. Given this, integration over $(\tilde{\varphi}^*, \Lambda)(\theta)$ in Eq. (50) determines a function, for $\partial_\theta \varphi^a = \mathcal{I}_a = 0$, whose restriction to the Lagrangian surface $\{\varphi(\theta)\} \subset \mathcal{N}$ is also nondegenerate.

In view of the properties of $(W, X)(\theta)$, one can introduce an effective action $\Gamma(\theta) \equiv \Gamma(\varphi, \varphi^*, \partial_\theta^r \varphi, \mathcal{I})(\theta)$ defined, in the usual manner, by means of a Legendre transformation of $\ln Z(\theta)$ with respect to $\partial_\theta \varphi_a^*(\theta)$,

$$\Gamma(\theta) = \frac{\hbar}{i} \ln Z(\theta) + ((\partial_\theta \varphi_a^*) \varphi^a)(\theta), \quad \varphi^a(\theta) = -\frac{\hbar}{i} \frac{\partial_l \ln Z(\theta)}{\partial(\partial_\theta \varphi_a^*(\theta))}. \tag{52}$$

The analysis of the properties of $(Z, \Gamma)(\theta)$ is based on the following θ-nonintegrable Hamiltonian-like system, which contains an arbitrary $(\varepsilon_P, \varepsilon)$-even $C^\infty(\mathcal{N}_{\mathrm{tot}})$-function, $R(\theta) = R((\tilde{\Gamma}, \Lambda, \Lambda^*) \times (\theta), \hbar)$, with a vanishing ghost number:

$$\partial_\theta^r \tilde{\Gamma}^p(\theta) = -i\hbar\, T^{-1}(\theta) (\tilde{\Gamma}^p(\theta), T(\theta) R(\theta))_\theta|_{\Lambda^* = 0},$$

$$\partial_\theta^r \Lambda^a(\theta) = -2i\hbar\, T^{-1}(\theta) (\Lambda^a(\theta), T(\theta) R(\theta))_\theta|_{\Lambda^* = 0},$$

$$\partial^r_\theta(\varphi^*_a,\Lambda^*_a)(\theta)=0, \tag{53}$$

where the function $T((\tilde{\Gamma},\Lambda,\Lambda^*)(\theta),\hbar)\equiv T(\theta)$ has the form $T(\theta)=\exp[(i/\hbar)(W-X)(\theta)]$. Let us enumerate the properties of $(\mathrm{Z},\Gamma)(\theta)$.

1. The integrand in (50) is invariant, for $\partial_\theta\varphi^*=\partial_\theta\varphi=\mathcal{I}=0$, with respect to the *superfield BRST transformations*

$$\tilde{\Gamma}_{\mathrm{tot}}(\theta)=(\tilde{\Gamma},\Lambda,\Lambda^*)(\theta)\to(\tilde{\Gamma}_{\mathrm{tot}}+\delta_\mu\tilde{\Gamma}_{\mathrm{tot}})(\theta),\ \delta_\mu\tilde{\Gamma}_{\mathrm{tot}}(\theta)=\ (\partial^r_\theta\tilde{\Gamma}_{\mathrm{tot}})|_{\check{\Gamma}_{\mathrm{tot}}}\mu, \tag{54}$$

having the form of a θ-shift by a constant parameter μ along an arbitrary solution $\check{\Gamma}_{\mathrm{tot}}(\theta)$ of the system (53), or, equivalently, along a vector field determined by the right-hand side of (53), for $R(\theta)=1$. Here, the arguments of $(W,X)(\theta)$ are the same as in definition (50). The above statement can be verified with the help of the identities

$$\partial_r X(\theta)/\partial F(\theta)|_{\Lambda^*=0}=\partial_r(\,X(\theta)|_{\Lambda^*=0})/\partial F(\theta),\quad F\in\{\Gamma^p,\Lambda^a\}.$$

Notice that the system (53), for $R(\theta)=\mathrm{const}$, admits the integral $(W+X)(\theta)$ in case W and X obey the first system in (51).

2. The vacuum function $\mathrm{Z}_X(\theta)\equiv\mathrm{Z}(0,\varphi^*,0,0)(\theta)$ is gauge-independent, namely, it does not change when $X(\theta)$ is replaced by an $(X+\Delta X)(\theta)$ subject to the same system in (51) that holds for $X(\theta)$ and conforming to nondegeneracy on the surface $\mathcal{Q}$. Indeed, this hypothesis implies that the variation $\Delta X(\theta)$ obeys a system of linearized equations with a nilpotent operator $Q_j(X)$, $j=1,2$,

$$Q_j(X)\Delta X(\theta)=0,\ \delta_{j1}\Delta(\theta)\Delta X(\theta)=0;\ Q_j(X)=\mathrm{ad}X(\theta)-\delta_{j2}(i\hbar\Delta(\theta)), \tag{55}$$

where j is identical to the number that labels that system in Eq. (51) for which $X(\theta)$ is a solution. Using the fact that solutions $X(\theta)$ of every system in (51) are proper, one can prove, by analogy with the theorems of Ref. 29, that the cohomologies of the operator $Q_j(X)$ on the functions $f(\Gamma_{\mathrm{tot}}(\theta))\in C^\infty(\mathcal{N}_{\mathrm{tot}})$ vanishing for $\Gamma_{\mathrm{tot}}(\theta)=0$ are trivial. Hence, the general solution of Eq. (55) has the form

$$\Delta X(\theta)=Q_j(X)\Delta Y(\theta),\ \left(\vec{\varepsilon},\mathrm{gh},\frac{\partial}{\partial\theta}\right)\Delta Y(\theta)=((1,0,1),-1,0),\ \ \Delta Y(\theta)|_{\Gamma_{\mathrm{tot}}=0}=0, \tag{56}$$

with a certain $\Delta Y(\theta)$. Now, making in $\mathrm{Z}_{X+\Delta X}(\theta)$ a change of variables induced by a θ-shift by a constant μ, related to the system (53), and choosing

$$2R(\theta)\mu=\Delta Y(\theta),$$

we find that $\mathrm{Z}_{X+\Delta X}(\theta)=\mathrm{Z}_X(\theta)$, and conclude that the S-matrix is gauge-independent in view of the equivalence theorem.[30] [Properties 1, 2 of $\mathrm{Z}_X(\theta)|_{\varphi^*=0}$ are valid for arbitrary $\rho(\theta)$, $\Gamma^p(\theta)$ on the manifold $\mathcal{N}$.]

The above proof shows, due to (54), that the system (53) encodes the BRST transformations for $R(\theta)=\mathrm{const}$, as well as continuous anticanonical-like transformations in an infinitesimal form, with the scalar fermionic generating function $R(\theta)\mu$, where $R(\theta)$ is arbitrary and μ is constant.

Equivalently, following the ideas of Sec. IV B, the above characteristics of the generating functional of Green's functions can be derived from a Hamiltonian-like system presented in terms of an even superfield Poisson bracket in general coordinates,

$$\partial^r_\theta\tilde{\Gamma}^p(\theta)=-\{\tilde{\Gamma}^p(\theta),Z^W[\tilde{\Gamma}]-(Z^X+i\hbar Z^R)[\tilde{\Gamma}_{\mathrm{tot}}]\}|_{\Lambda^*=0},$$

$$\partial^r_\theta\Lambda^a(\theta)=-2\{\Lambda^a(\theta),Z^W[\tilde{\Gamma}]-(Z^X+i\hbar Z^R)[\tilde{\Gamma}_{\mathrm{tot}}]\}|_{\Lambda^*=0},$$

$$\partial_\theta^r(\varphi_a^*,\Lambda_a^*)(\theta)=0 \tag{57}$$

with a linear combination of fermionic functionals related to the above actions and a bosonic function by the rule

$$Z^E[\Gamma_{\mathrm{tot}}]=-\partial_\theta E(\Gamma_{\mathrm{tot}}(\theta),\hbar),\quad E\in\{W,X,R\}. \tag{58}$$

If the actions $(W,X)(\theta)$ obey the first system in (51), then the functionals Z^W, Z^X, formally playing the role of the usual and *gauge-fixing* BRST charges, are nilpotent with respect to the even Poisson bracket $\{\cdot,\cdot\}=\{\cdot,\cdot\}^{\Pi TM}+\{\cdot,\cdot\}^{\Pi TK}$. Here, for instance, the first bracket in the sum is defined on arbitrary functionals on $\Pi TM\times\{\theta\}$, via a θ-local extension of the odd bracket $(\cdot,\cdot)_\theta^{\Pi TM}$ in (39), as follows:

$$\begin{aligned}&\{F_1,F_2\}^{\Pi TM}\equiv\int \mathrm{d}\theta\frac{\delta_r F_1}{\delta\Gamma^p(\theta)}\omega^{pq}(\Gamma(\theta))\frac{\delta_l F_2}{\delta\Gamma^q(\theta)}=\partial_\theta(\mathcal{F}_1(\theta),\mathcal{F}_2(\theta))_\theta^{\Pi TM},\\&(\mathcal{F}_1(\theta),\mathcal{F}_2(\theta))_\theta^{\Pi TM}\equiv((\mathcal{L}_p^r\mathcal{F}_1)\omega^{pq}(\Gamma(\theta))\mathcal{L}_q^l\mathcal{F}_2)(\theta),\quad F_t[\Gamma]=\partial_\theta\mathcal{F}_t((\Gamma,\partial_\theta\Gamma)(\theta),\theta),\end{aligned} \tag{59}$$

where $\mathcal{L}_q^l(\theta)$ is the left-hand Euler–Lagrange superfield derivative with respect to $\Gamma^q(\theta)$. [The antibracket $(\cdot,\cdot)_\theta^{\Pi TM}$, identical, for $\mathcal{N}=\Pi TM_k$, with $(\cdot,\cdot)_\theta^{(\Gamma_k,\partial_a\Gamma_k)}$, $k=$ext, in (39) lifts the operator $\Delta^{\mathcal{N}}$ in (49) to the nilpotent operator $\Delta^{\Pi TM}$ acting in $C^\infty(\Pi TM\times\{\theta\})$, defined exactly as $\Delta^{\mathcal{N}}(\theta)$, although in terms of the antibracket (59).]

Therefore, as in the case of the HS in (45), we arrive at an interpretation of BRST transformations, for a gauge theory with non-Abelian hypergauges in Lagrangian formalism, in terms of the formal "BRST charges" Z^W, Z^X, as well as in terms of the functional Z^R and the even Poisson bracket. [The construction of the latter bracket is different from that of Ref. 5, where an odd superfield Poisson bracket was derived from a (t,θ)-local even bracket; however, it is similar to the construction of Ref. 18; see Eq. (27).] The system (57) encodes the BRST transformations, for $Z^R=0$, as well as the BRST and continuous canonical-like transformations with the bosonic generating functional $Z^R\mu$, for an arbitrary Z^R and a constant μ.

3. The functions $(\mathrm{Z},\Gamma)(\theta)$ obey the Ward identities

$$\begin{aligned}&\left[\left\{\partial_\theta\varphi_a^*(\theta)-\left(\frac{\partial W}{\partial\tilde{\varphi}^a(\theta)}\right)\left(i\hbar\frac{\partial_l}{\partial(\partial_\theta\varphi^*)},i\hbar\frac{\partial_r}{\partial(\partial_\theta^r\varphi)}\right)\right\}\frac{\partial_l}{\partial\varphi_a^*(\theta)}+\frac{i}{\hbar}\mathcal{I}_a(\theta)\frac{\partial_l}{\partial\Lambda_a^*(\theta)}\right.\\&\left.X\left(i\hbar\frac{\partial_l}{\partial(\partial_\theta\varphi^*)},i\hbar\frac{\partial_r}{\partial(\partial_\theta^r\varphi)}-\varphi^*,\frac{\hbar}{i}\frac{\partial_l}{\partial\mathcal{I}},\Lambda^*\right)\Big|_{\Lambda_a^*=0}\right]\mathrm{Z}(\theta)=0,\end{aligned} \tag{60}$$

$$\begin{aligned}&\mathcal{I}_a(\theta)\frac{\partial_l}{\partial\Lambda_a^*(\theta)}\;X\left(\varphi^b+i\hbar(\Gamma''^{-1})^{bc}\frac{\partial_l}{\partial\varphi^c},i\hbar\frac{\partial_r}{\partial(\partial_\theta^r\varphi)}-\frac{\partial_r\Gamma}{\partial(\partial_\theta^r\varphi)}-\varphi^*,\frac{\partial_l\Gamma}{\partial\mathcal{I}}+\frac{\hbar}{i}\frac{\partial_l}{\partial\mathcal{I}},\Lambda^*\right)\Big|_{\Lambda_a^*=0}-\left[\left(\frac{\partial W}{\partial\tilde{\varphi}^a(\theta)}\right)\right.\\&\left.\times\left(\varphi^b+i\hbar(\Gamma''^{-1})^{bc}\frac{\partial_l}{\partial\varphi^c},i\hbar\frac{\partial_r}{\partial(\partial_\theta^r\varphi)}-\frac{\partial_r\Gamma}{\partial(\partial_\theta^r\varphi)}\right)\right]\frac{\partial_l\Gamma(\theta)}{\partial\varphi_a^*(\theta)}+\frac{1}{2}(\Gamma(\theta),\Gamma(\theta))_\theta^{(\Gamma)}=0,\end{aligned} \tag{61}$$

with the notation

$$\Gamma''_{ab}(\theta)\equiv\frac{\partial_l}{\partial\varphi^a(\theta)}\frac{\partial_r}{\partial\varphi^b(\theta)}\Gamma(\theta),\quad \Gamma''_{ac}(\theta)(\Gamma''^{-1})^{cb}(\theta)=\delta_a{}^b.$$

In the symmetric form of these identities, we have extended the standard set of sources $\partial_\theta\varphi_a^*(\theta)$ used in the definition of the generating functional of Green's functions in Abelian hypergauges.

The technique used in deriving the above identities is analogous to the corresponding procedure of Refs. 31 and 32 applied, in the framework of the BV[1] and Batalin–Lavrov–Tyutin[29]

methods, to the problem of gauge dependence in theories with composite fields. Thus, identities (60) and (61) follow from the corresponding system in (51) for $(W,X)(\theta)$. For instance, making the functional averaging of the second system in (51) for $X(\theta)$,

$$\int \mathrm{d}\Lambda(\theta)\mathrm{d}\mu(\tilde{\Gamma}(\theta))\exp\left[\frac{i}{\hbar}(W-(\partial_\theta\varphi_a^*)\tilde{\varphi}^a-\tilde{\varphi}_a^*\partial_\theta^r\varphi^a+\mathcal{I}_a\Lambda^a)(\theta)\right]$$
$$\times\left\{\Delta(\theta)\exp\left[\frac{i}{\hbar}X((\tilde{\varphi},\tilde{\varphi}^*-\varphi^*,\Lambda,\Lambda^*)(\theta),\hbar)\right]\right\}_{\Lambda^*=0}=0, \tag{62}$$

and integrating by parts in (62), with allowance for $(\partial/\partial\tilde{\varphi}^*+\partial/\partial\varphi^*)X(\theta)=0$, we obtain identity (60). Identities (60) and (61) take the standard form in case $\partial_\theta\varphi^a=\mathcal{I}_a(\theta)=\theta=0$, which becomes more involved due to the quantities $(\partial_\theta W(\theta)/\partial\tilde{\varphi}^a(\theta))$, in the case of non-Abelian hypergauges.

In the special case of Abelian hypergauges, $G_A((\Phi,\Phi^*)(\theta))=\Phi_A^*(\theta)-\partial\Psi(\Phi(\theta))/\partial\Phi^A(\theta)=0$, corresponding to the change of variables (36), for $(\varphi,\varphi^*,W)=(\Phi,\Phi^*,S_{\mathrm{H;ext}})$, $\partial_\theta\Phi^A=\mathcal{I}_A=0$ (locally, $\mathcal{N}=\Pi T^*\mathcal{M}_{\mathrm{ext}}$), the object $\mathrm{Z}(\partial_\theta\Phi^*,\Phi^*)(\theta)$ takes the form

$$\mathrm{Z}(\partial_\theta\Phi^*,\Phi^*)(\theta)=\int \mathrm{d}\Phi(\theta)\exp\left\{\frac{i}{\hbar}[S_{\mathrm{H}}^{\Psi}(\Gamma(\theta),\hbar)-((\partial_\theta\Phi_A^*)\Phi^A)(\theta)]\right\}. \tag{63}$$

A θ-local BRST transformation for $\mathrm{Z}(\partial_\theta\Phi^*,\Phi^*)(\theta)$ is given, for an HS defined on $\Pi T^*\mathcal{M}_{\mathrm{ext}}$, with the Hamiltonian $S_{\mathrm{H}}^{\Psi}(\theta,\hbar)$ and a solution $\check{\Gamma}(\theta)$, by the change of variables

$$\Gamma^p(\theta)\to\Gamma^{(1)p}(\theta)=\exp[\mu s^{l(\Psi)}(\theta)]\Gamma^p(\theta),\quad s^{l(\Psi)}(\theta)\equiv\frac{\partial}{\partial\theta}-\mathrm{ad}S_{\mathrm{H}}^{\Psi}(\theta,\hbar). \tag{64}$$

Transformation (64) with a constant μ is anticanonical, with

$$\mathrm{Ber}\left\|\frac{\partial\Gamma^{(1)}(\theta)}{\partial\Gamma(\theta)}\right\|=\mathrm{Ber}\left\|\frac{\partial\Phi^{(1)}(\theta)}{\partial\Phi(\theta)}\right\|=1,$$

provided that $S_{\mathrm{H}}^{\Psi}(\theta,\hbar)$ is subject to the first system in (51).

The obvious permutation rule of the functional integral, $\varepsilon(\mathrm{d}\Phi(\theta))=0$,

$$\partial_\theta\int \mathrm{d}\Phi(\theta)\mathcal{F}((\Phi,\Phi^*)(\theta),\theta)=\int \mathrm{d}\Phi(\theta)\left[\frac{\partial}{\partial\theta}+(\partial_\theta V)(\theta)\right]\mathcal{F}(\theta),\ (\partial_\theta V)(\theta)=\partial_\theta\Phi_A^*(\theta)\frac{\partial}{\partial\Phi_A^*(\theta)},$$

yields, for $i\hbar\partial_\theta^r\ln\mathrm{Z}(\theta)=(\partial_\theta\Phi_A^*\partial_\theta^r\Phi^A)(\theta)-\partial_\theta^r\Gamma(\theta)$, the following relations:

$$\partial_\theta\mathrm{Z}(\theta)|_{\check{\Gamma}(\theta)}=(\partial_\theta V)(\theta)\mathrm{Z}(\theta)=0,\qquad \partial_\theta^r\Gamma(\theta)|_{\check{\Gamma}(\theta)}=(\Gamma(\Gamma(\theta)),\Gamma(\Gamma(\theta)))_\theta=0. \tag{65}$$

When deriving Eq. (65), we have taken into account the fact that the functional averaging of the HS with respect to $\mathrm{Z}(\theta)$ and $\Gamma(\theta)$ has the form

$$\langle\partial_\theta^r\Gamma^p\rangle|_{\mathrm{Z}}=\left(\frac{\hbar}{i}\mathrm{Z}^{-1}\frac{\partial\mathrm{Z}(\theta)}{\partial\Phi_A^*(\theta)},-\partial_\theta\Phi_A^*(\theta)\right),\quad \langle\partial_\theta^r\Gamma^p\rangle=(\langle\Gamma^p(\theta)\rangle,\Gamma(\langle\Gamma(\theta)\rangle))_\theta=\partial_\theta^r\langle\Gamma^p\rangle, \tag{66}$$

without the sign of average in (65) for $\check{\Gamma}^p(\theta)$ and $\Gamma^p(\theta)$. Expressions (65) relate the explicit form of the Ward identities in a theory with Abelian hypergauges to the invariance of the generating functional of Green's functions with respect to the superfield BRST transformations.

V. CONNECTION BETWEEN LAGRANGIAN QUANTIZATIONS

The problem of establishing a correspondence between a LSM and a usual gauge theory can be solved on the basis of a component form of the local quantization in the following two ways: one is applicable to an arbitrary LSM, another applies to theories of Yang–Mills type. This makes

it possible to establish a relation of the local superfield scheme with the known formulations of Lagrangian quantization,[1,21] as well as with an extension (proposed in the following) of the superfield method[6,7] to the case of general coordinates.

A. Component formulation and its relation to Batalin–Vilkovisky, Batalin–Tyutin, and superfield methods

The objects of θ-local quantization in the Lagrangian and Hamiltonian formulations are related to the conventional description of a gauge theory by means of a component representation of the variables $\Gamma^{P_{\mathrm{MIN}}}_{\mathrm{MIN}}$, $\Gamma^{p_k}_k$, Λ^a, $\mathcal{I}_a$, $\Gamma^{p_k}_k(\theta)=\Gamma^{p_k}_{0k}+\Gamma^{p_k}_{1k}\theta$, $k=\mathrm{tot}$, under the restriction $\theta=0$, for instance, $(\mathcal{M},\mathcal{N}_k,\Lambda^a,\mathcal{I}_a)\to(\widetilde{\mathcal{M}},\ \mathcal{N}_k|_{\theta=0}=\{\Gamma^{p_k}_{0k}\},\lambda^a_0,I_{0a})$. Extracting a standard field model from a classical description of a general gauge theory can be effected, in addition to $\theta=0$, by various kinds of eliminating the functions $\partial_\theta\mathcal{A}^I(\theta)$, $\mathcal{A}^*_I(\theta)$, as well as the superfields $\mathcal{A}^I(\theta)$ that contain objects with an incorrect spin-statistics relation, $\varepsilon_P(\mathcal{A}^I)\neq 0$. A possible way of such elimination is provided by the conditions $\mathrm{gh}(\mathcal{A}^I)=-1-\mathrm{gh}(\mathcal{A}^*_I)=0$, $(\varepsilon_P)_I=0$, and $(\mathrm{gh},\partial/\partial\theta)S_{\mathrm{L(H)}}(\theta)=(0,0)$, mentioned in Sec. IV A. Another possibility is related to superfield BRST transformations for theories of Yang–Mills type,[10,33,34] in which a Lagrangian classical action $S_{\mathrm{LYM}}(\theta)=S_{\mathrm{L}}(\mathcal{A},\mathcal{D}_\theta\mathcal{A},\widetilde{\mathcal{A}},\mathcal{D}_\theta\widetilde{\mathcal{A}})(\theta)$ is defined in terms of generalized Yang–Mills superfields, $\mathcal{A}^{Bu}(z)$, $\mathcal{A}^{Bu}=(\mathcal{A}^{\mu u},\mathcal{C}^u)$, $u=1,\ldots,r$, and matter superfields, $\widetilde{\mathcal{A}}(z)=(\Psi^\varrho,\overline{\Psi}^\sigma,\varphi^f,\varphi^{+g})(z)$, where Ψ^ϱ, $\overline{\Psi}^\sigma$, ϱ, $\sigma=1,\ldots,k_1$, are spinor superfields, and φ^g, φ^{+h}, g, $h=1,\ldots,k_2$, are spinless ones. The superfields $\mathcal{A}^{Bu}(z)$ and $\widetilde{\mathcal{A}}(z)$ are defined on the superspace $\mathcal{M}=\mathbb{R}^{1,3}\times\widetilde{P}=\{z^B=(x^\mu,\theta)\}$ and take values, respectively, in the adjoint and vector representation spaces of an r-parametric Lie group. The action $S_{\mathrm{LYM}}(\theta)$ can be written as

$$S_{\mathrm{LYM}}(\theta)=\int \mathrm{d}^4x\left[\frac{1}{4}\mathcal{G}_{BC}{}^u\mathcal{G}^{CBu}(-1)^{\varepsilon_B}-i\overline{\Psi}^\sigma\gamma^B\nabla_{B\varrho}{}^\sigma\Psi^\varrho-\overline{\nabla}_{Bg}{}^h\varphi^{+g}\nabla^{Bh}{}_f\varphi^f+M(\widetilde{\mathcal{A}})\right](z), \tag{67}$$

with an $\widetilde{\mathcal{A}}(z)$-local gauge-invariant polynomial $M(\widetilde{\mathcal{A}})$, containing no derivatives over z^B. In expression (67), we have introduced the superfield strength $\mathcal{G}_{BC}{}^u=i[\mathcal{D}_B,\mathcal{D}_C]^u=\partial_B\mathcal{A}^u_C-(-1)^{\varepsilon_B\varepsilon_C}\partial_C\mathcal{A}^u_B+f^{uvw}\mathcal{A}^v_B\mathcal{A}^w_C$, $\partial_B=(\partial_\mu,\partial_\theta)$ and the following covariant derivatives, expressed through the matrix elements of the Hermitian generators $\Gamma^u=\mathrm{diag}(T^u,\overline{T^u},\tau^\mu,\overline{\tau^\mu})$ of the corresponding Lie algebra:

$$(\mathcal{D}^{uv}_B,\nabla_{B\varrho}{}^\sigma,\nabla_{Bf}{}^e,\overline{\nabla}_{Bh}{}^g)=\partial_B(\delta^{uv},\delta^\sigma_\varrho,\delta^e_f,\delta^g_h)+(f^{uwv},-i(T^w)^\sigma_\varrho,-i(\tau^w)^e_f,-i(\overline{\tau^w})^g_h)\mathcal{A}^w_B, \tag{68}$$

where the coupling constant is absorbed into the completely antisymmetric structure coefficients f^{uvw}. We have also used a generalization of Dirac's matrices, $\gamma^B=(\gamma^\mu,\gamma^\theta)$, $\gamma^\theta=(\gamma^\theta)^+=\xi\mathbb{I}_4$, with a Grassmann scalar ξ, $(\vec{\varepsilon},\mathrm{gh})\xi=((1,0,1),-1)$. The $\vec{\varepsilon}$-grading and ghost number are nonvanishing for the superfields $(\Psi,\overline{\Psi},\mathcal{C}^u)$, namely, $\vec{\varepsilon}(\Psi,\overline{\Psi})=(0,1,1)$, $\vec{\varepsilon}(\mathcal{C}^u)=(1,0,1)$, $\mathrm{gh}(\mathcal{C}^u)=1$. The functional $Z[\mathcal{A},\widetilde{\mathcal{A}}]=\partial_\theta S_{\mathrm{LYM}}(\theta)$ is invariant under the infinitesimal general gauge transformations

$$\delta_g\mathcal{A}^I(\theta)=\delta_g(\mathcal{A}^{Bu};\widetilde{\mathcal{A}})(z)=-\int \mathrm{d}^5z_0(\mathcal{D}^{Buv}(z)(-1)^{\varepsilon_B};i\Gamma^v\widetilde{\mathcal{A}}(z)(-1)^{\varepsilon(\widetilde{\mathcal{A}})})\delta(z-z_0)\xi^v(z_0), \tag{69}$$

with arbitrary bosonic $(\vec{\varepsilon}_{\mathcal{A}_0}=\vec{0})$ functions $\xi^v(z_0)$ on $\mathcal{M}$, and with functionally independent generators $\hat{\mathcal{R}}^I_{\mathcal{A}_0}(\theta,\theta_0)\equiv\hat{\mathcal{R}}^I_{A_0}(\mathcal{A}(\theta),\theta,\theta_0)$. The condensed indices I, $\mathcal{A}_0$ of the theory in question, $(I;\mathcal{A}_0)=((B,u,\delta,\epsilon,f,h,x);(v,x_0))$, conform to the relations, $\overline{N}>\overline{n}$, $\overline{M}=\overline{m}$, $(\overline{m},\overline{M})=(\overline{m}_0,\overline{M}_0)$, provided that

$$\overline{N}=(4r+2k_2,r+8k_1),\quad \overline{M}=(r,0),\quad \overline{n}=\overline{N}-(0,r),$$

which holds for a reduced theory with the action [for $\theta=0$, the functional $S_{\mathrm{YM}}(0)=S_{0\mathrm{YM}}$ coincides with the corresponding classical action of Ref. 36] $S_{\mathrm{YM}}(\theta)=-S_{\mathrm{LYM}}(\mathcal{A},0,\widetilde{\mathcal{A}},0)(\theta)$ on $\mathcal{M}_{\mathrm{cl}}$

$=\{A^{\mu u},\tilde{\mathcal{A}}\}(z)$, in view of special *horizontality conditions* for the strength $\mathcal{G}_{BC}{}^{u}$ and certain subsidiary conditions for the matter superfields $\tilde{\mathcal{A}}(z)$ in Refs. 10 and 33,

$$\mathcal{G}_{BC}{}^{u}(z)=\mathcal{G}_{\mu\nu}{}^{u}(z),\quad (\nabla_{\theta\eta}^{\delta}\Psi^{\eta},\overline{\nabla}_{\theta\varrho}^{\sigma}\overline{\Psi}^{\varrho},\nabla_{\theta e}^{f}\varphi^{e},\overline{\nabla}_{\theta g}^{h}\overline{\varphi}^{g})(z)=(0,0,0,0). \tag{70}$$

To extract a standard component model defined on $\mathcal{M}_{\mathrm{cl}}|_{\theta=0}$ from a Hamiltonian LSM, it is sufficient to eliminate, for $\theta=0$, the antifields $\mathcal{A}_I^*(\theta)$ of a theory of Yang–Mills type, by analogy with the prescription (70), i.e., by taking into account the relation between $\mathcal{A}_I^*(\theta)$ and $\partial_\theta\mathcal{A}^I(\theta)$: see Sec. III and the final remarks (item 1) of the Conclusion.

For the restricted LSM used in the Feynman rules of Sec. IV, the reduction to the model of the multilevel formalism of Ref. 21 is realized by the conditions

$$\theta=0,\quad \partial_\theta\varphi_a^*=\partial_\theta\varphi^a=\varphi_a^*=\mathcal{I}_a=0. \tag{71}$$

In this case, the identification $(\rho,\omega^{pq})(\Gamma_0)=(M,E^{pq})(\Gamma_0)$ implies the coincidence of $(\cdot,\cdot)_\theta|_{\theta=0}$ and $\Delta(0)$ with their counterparts of Ref. 21. Then the first-level functional integral $Z^{(1)}$ and its symmetry transformations[21]

$$Z^{(1)}=\int \mathrm{d}\lambda_0\mathrm{d}\Gamma_0 M(\Gamma_0)\exp\left\{\frac{i}{\hbar}(W(\Gamma_0)+G_a(\Gamma_0)\lambda_0^a)\right\},$$

$$\delta\Gamma_0^p=(\Gamma_0^p,-W+G_a\lambda_0^a)\mu,$$

$$\delta\lambda_0^a=(-U_{cb}^a\lambda_0^b\lambda_0^c(-1)^{\varepsilon_c}+2i\hbar V_b^a\lambda_0^b+2(i\hbar)^2\tilde{G}^a)\mu,$$

coincide (λ_0^a being replaced by the notation π^a of Ref. 21), respectively, with $\mathrm{Z}_X(0)|_{\varphi_0^*=0}$ and the BRST transformations $\delta_\mu\Gamma_{0\,\mathrm{tot}}$ (having the opposite signs) generated by the system (53) for $R(\theta)=1$. This coincidence is guaranteed by the choice of $X(\theta)$ in the form

$$X(\theta)=\left\{G_a(\Gamma)\Lambda^a-\Lambda_a^*\left[\tfrac{1}{2}U_{cb}^a(\Gamma)\Lambda^b\Lambda^c(-1)^{\varepsilon_c}-i\hbar V_b^a(\Gamma)\Lambda^b-(i\hbar)^2\tilde{G}^a(\Gamma)\right]\right\}(\theta)+o(\Lambda^*), \tag{72}$$

where $(V_b^a,\tilde{G}^a)(\theta)$, together with $(U_{cb}^a,G_a)(\theta)$, define the unimodularity relations.[21] The relation of the θ-local quantization to the generating functional of Green's function $Z[J,\phi^*]$ of the BV method[1] is obvious from the identification $\mathrm{Z}(\partial_\theta\Phi^*,\Phi^*)(0)=Z[J,\phi^*]$ in (63), where the action $S_H^\Psi(\Gamma_0,\hbar)$ of (36) obeys Eq. (37).

Another aspect of the restriction $\theta=0$ is that an arbitrary function $\mathcal{F}(\theta)=\mathcal{F}((\Gamma,\partial_\theta\Gamma)(\theta),\theta)\in C^\infty(\Pi T\mathcal{N}\times\{\theta\})$ is represented by a functional $F[\Gamma]$ of the superfield methods[6,7] (in case $\Gamma^p=(\Phi^A,\Phi_A^*)$, see Sec. I)

$$F[\Gamma]=\int \mathrm{d}\theta\theta\mathcal{F}(\theta)=\mathcal{F}(\Gamma(0),\partial_\theta\Gamma,0)\equiv\mathcal{F}(\Gamma_0,\Gamma_1). \tag{73}$$

In the first place, formula (73) implies the independence of $F[\Gamma]$ from $\partial_\theta^r\Gamma^p(\theta)=\Gamma_1^p$, in case $F(\theta)=F(\Gamma(\theta),\theta)$. Second, formula (73) is fundamental in establishing a relation between the θ-local antibracket $(\cdot,\cdot)_\theta^{\mathcal{N}}$ and operator $\Delta^{\mathcal{N}}(\theta)$, acting on $C^\infty(N\times\{\theta\})$, with a generalization to arbitrary $(\Gamma,\omega^{pq},\rho)(\theta)$ of the flat functional operations $(\cdot,\cdot)$, Δ of Refs. 6 and 7, identical to their counterparts of the BV method in case $\Gamma^p=(\Phi^A,\Phi_A^*)$, $\omega^{pq}(\Gamma(\theta))=\mathrm{antidiag}(-\delta_B^A,\delta_B^A)$, $\rho(\theta)=1$, and in case of a different odd Poisson bivector, $\tilde{\omega}^{pq}(\Gamma(\theta),\theta')=(1+\theta'\partial_\theta)\omega^{pq}(\theta)$. The correspondence follows from

$$(\mathcal{F}(\theta),\mathcal{G}(\theta))_\theta^{\mathcal{N}}|_{\theta=0}=\frac{\delta_r\mathcal{F}(\Gamma_0)}{\delta\Gamma_0^p}\omega^{pq}(\Gamma_0)\frac{\delta_l\mathcal{G}(\Gamma_0)}{\delta\Gamma_0^q}=(F[\Gamma],G[\Gamma])^{\mathcal{N}},$$

$$(F[\Gamma],G[\Gamma])^{\mathcal{N}}=\partial_\theta\left[\frac{\delta_r F[\Gamma]}{\delta\Gamma^p(\theta)}\partial_{\theta'}\left(\tilde{\omega}^{pq}(\Gamma(\theta),\theta')\frac{\delta_l G[\Gamma]}{\delta\Gamma^q(\theta')}\right)\right](-1)^{\varepsilon(\Gamma^p)+1}, \tag{74}$$

$$\begin{gathered}\Delta^{\mathcal{N}}(\theta)\mathcal{F}(\theta)|_{\theta=0}=\Delta^{\mathcal{N}}(0)\mathcal{F}(\Gamma_0)=\Delta^{\mathcal{N}}F[\Gamma],\\ \Delta^{\mathcal{N}}=\tfrac{1}{2}(-1)^{\varepsilon(\Gamma^q)}\partial_\theta\partial_{\theta'}[\rho^{-1}[\Gamma]\tilde{\omega}_{qp}(\theta',\theta)(\Gamma^p(\theta),\rho[\Gamma](\Gamma^q(\theta'),\cdot)^{\mathcal{N}})^{\mathcal{N}}],\end{gathered} \tag{75}$$

where $(\rho[\Gamma],\tilde{\omega}_{pq}(\theta',\theta))=(\rho(\Gamma_0),\theta'\theta\omega_{pq}(\theta))$ and

$$\int \mathrm{d}\theta''\tilde{\omega}^{pd}(\theta',\theta'')\tilde{\omega}_{dq}(\theta'',\theta)=\theta\delta^p{}_q.$$

When establishing the correspondence with the operations $(\cdot,\cdot)$ and Δ of Refs. 6 and 7 in (74) and (75), we have used a relation between the superfield and component derivatives:

$$\delta_l/\delta\Gamma^p(\theta)=(-1)^{\varepsilon(\Gamma^p)}(\theta\delta_l/\delta\Gamma^p_0-\delta_l/\delta\Gamma^p_1),\quad \Gamma^p_1=(\lambda^A,-(-1)^{\varepsilon_A}J_A).$$

In general coordinates, the action of the sum and difference $\partial_\theta(V\pm U)^{\mathcal{N}}(0)$ for $\mathcal{N}=\Pi T^*\mathcal{M}_{\mathrm{ext}}|_{\theta=0}$ reduced to

$$\partial_\theta(V\pm U)(0)=\partial_\theta\Phi^*_A(\theta)\partial/\partial\Phi^*_A(0)\pm\partial_\theta\Phi^A(\theta)\partial_l/\partial\Phi^A(0),$$

is identical to the action of the generalized sum and difference of their counterparts V, U in Ref. 6:

$$\begin{gathered}\partial_\theta(V-(-1)^tU)^{\mathcal{N}}(\theta)\mathcal{F}(\theta)|_{\theta=0}=(\mathcal{S}^t(\theta),\mathcal{F}(\theta))^{\mathcal{N}}_\theta|_{\theta=0}=(V-(-1)^tU)^{\mathcal{N}}F[\Gamma]=(S^t[\Gamma],F[\Gamma])^{\mathcal{N}},\\ t=1,2,\\ \mathcal{S}^t(\theta)=(\partial_\theta\Gamma^p)\omega^t_{pq}(\Gamma(\theta))\Gamma^q(\theta),\quad S^t[\Gamma]=\partial_\theta\{\Gamma^p(\theta)\partial_{\theta'}\partial_\theta[\tilde{\omega}^t_{pq}(\theta,\theta')\Gamma^q(\theta')]\}=\mathcal{S}^t(0),\end{gathered} \tag{76}$$

where the functions $\omega^t_{pq}(\theta),\tilde{\omega}^t_{pq}(\theta,\theta')$, identical with $\omega_{pq}(\theta)$ and $\tilde{\omega}_{pq}(\theta,\theta')$ for $t=1$, are defined by

$$\tilde{\omega}^t_{pq}(\theta,\theta')=\theta\theta'\omega^t_{pq}(\theta')=-(-1)^{t+\varepsilon(\Gamma^p)\varepsilon(\Gamma^q)}\tilde{\omega}^t_{qp}(\theta',\theta),\quad \omega^t_{pq}(\theta)=(-1)^{\varepsilon(\Gamma^p)\varepsilon(\Gamma^q)+t}\omega^t_{qp}(\theta).$$

The $\vec{\varepsilon}$-bosonic quantities $\mathcal{S}^t(\theta)$ and $S^t[\Gamma]$ with a vanishing ghost number play the role of the symmetric Sp(2)-tensor S_{ab} $(a,b=1,2)$ and anti-Hamiltonian S_0 of Ref. 35, which define (in terms of extended antibrackets) the first-order operators of the modified triplectic algebra. In this case, the additional functions $\omega^2_{pq}(\theta),\tilde{\omega}^2_{pq}(\theta,\theta')$ may be considered as quantities that define another nonantisymplectic (non-Riemannian) nondegenerate structure on $\mathcal{N}$. The θ-local functional operators $\{\Delta^{\mathcal{N}},V^{\mathcal{N}},U^{\mathcal{N}}\}(\theta)$ anticommute for a fixed θ,

$$[E^{\mathcal{N}}_i(\theta),E^{\mathcal{N}}_j(\theta)]_+=0,\ i,j=1,2,3,\quad (E_1,E_2,E_3)=(\Delta,V,U), \tag{77}$$

provided that $\mathcal{S}^t(\theta)$ or $S^t[\Gamma]$ is subject to

$$\Delta^{\mathcal{N}}(\theta)\mathcal{S}^t(\theta)=0,\quad (\mathcal{S}^u(\theta),\mathcal{S}^v(\theta))^{\mathcal{N}}_\theta=0,\quad t,u,v=1,2. \tag{78}$$

Relations (78), which hold, due to Eqs. (74)–(77), also for functional objects (those without a θ-dependence), follow from the well-known properties of the antibracket (*bilinearity, graded antisymmetry, Leibniz rule, Jacobi identity*), and from the rule of antibracket differentiation by the operator $\Delta^{\mathcal{N}}(\theta)$. The system (78) determines the geometry of $\mathcal{N}$ by restricting the choice of both quantities $\omega^t_{pq}(\theta),\tilde{\omega}^t_{pq}(\theta,\theta')$. Notice that a solution of Eq. (78) always exists, for instance, $\omega^t_{pq}(\theta)=\mathrm{antidiag}(\delta^A_B,(-1)^t\delta^A_B)$.

B. Superfield functional quantization in general coordinates

Let us consider a generalization of the vacuum functional of the superfield method,[6,7] namely,

$$Z^{\mathcal{N}}_{X'} = \int \mathrm{d}\mu[\Gamma] q^{\mathcal{N}}[\Gamma] \exp\left\{ \frac{i}{\hbar}(W' + X' + \varkappa_2 S^2)[\Gamma] \right\}, \tag{79}$$

where $\varkappa_2$ is an arbitrary real number; W', X' are the quantum and gauge-fixing actions, defined on $\mathcal{N}$ and subject to the equations

$$\tfrac{1}{2}(W', W')^{\mathcal{N}} + \mathcal{V}W' = i\hbar\Delta^{\mathcal{N}}W', \quad \tfrac{1}{2}(X', X')^{\mathcal{N}} + \mathcal{U}X' = i\hbar\Delta^{\mathcal{N}}X', \tag{80}$$

while the integration measure and the weight functional $q^{\mathcal{N}}[\Gamma]$ have the form

$$\mathrm{d}\mu[\Gamma] = \rho[\Gamma]\tilde{\mathrm{d}}\Gamma, \quad \tilde{\mathrm{d}}\Gamma = \mathrm{d}\Gamma_0 \mathrm{d}\Gamma_1, \quad q^{\mathcal{N}}[\Gamma] = \delta(G^{\mathcal{V}}_{a_1}(\Gamma(\theta))), \quad a_1 = 1, \ldots, \quad \dim_+ \mathcal{N}. \tag{81}$$

In (80), we have introduced a two-parameter set $\mathcal{U}(\varkappa_1, \varkappa_2)$, $\mathcal{V}(\varkappa_1, \varkappa_2)$ of anticommuting operators,

$$\mathcal{U} = \tfrac{1}{2}(-1)^t \varkappa_t (S^t[\Gamma], \cdot)^{\mathcal{N}}, \quad \mathcal{V} = \tfrac{1}{2}\varkappa_t (S^t[\Gamma], \cdot)^{\mathcal{N}}, \tag{82}$$

satisfying, together with $\Delta^{\mathcal{N}}$, the algebra (77), for arbitrary real numbers $\varkappa_t$, whose choice admissible for the existence of the functional integral fixes the form of $Z^{\mathcal{N}}_{X'}$. This choice also fixes Eq. (80), the admissible boundary conditions for W', X', and the form of the *additional hypergauge conditions*, $G^{\mathcal{V}}_{a_1}(\Gamma(\theta)) = 0$, which are required to retain the explicit superfield form of the vacuum functional. The independent functions $G^{\mathcal{V}}_{a_1}(\Gamma(\theta))$ are equivalent to the set of functions $\mathcal{V}\Gamma^p(\theta)$: $G^{\mathcal{V}}_{a_1}(\theta_1) = \partial_\theta[Y_{a_1 p}(\Gamma(\theta_1), \theta)\mathcal{V}\Gamma^p(\theta)]$ with certain $Y_{a_1 p}(\theta_1, \theta)$ such that

$$\mathrm{rank}\left\| P_0(\theta)\frac{\delta_l E_t(\theta_1)}{\delta\Gamma^q(\theta)} \right\|_{\delta W'/\delta\Gamma = \delta X'/\delta\Gamma = G^{\mathcal{V}} = 0} = (L^{\mathcal{V}}_t, \dim_+\mathcal{N} - L^{\mathcal{V}}_t), \quad (E_1, E_2) = (G^{\mathcal{V}}_{a_1}, \mathcal{V}\Gamma^p), \tag{83}$$

for some integers $L^{\mathcal{V}}_1$, $L^{\mathcal{V}}_2$: $0 \leqslant L^{\mathcal{V}}_1$, $L^{\mathcal{V}}_2 \leqslant \dim_+ \mathcal{N}$.

The basic properties of the functional $Z^{\mathcal{N}}_{X'}$ are analogous to properties 1, 2 of $Z(\theta)$ in (50), which are encoded by a Hamiltonian-like system with an arbitrary functional $R[\Gamma]$, $(\vec{\varepsilon}, \mathrm{gh})R = (\vec{0}, 0)$,

$$\partial^r_\theta \Gamma^p(\theta) = \frac{\hbar}{i} T^{-1}[\Gamma](\Gamma^p(\theta), T[\Gamma]R)^{\mathcal{N}}, \quad T[\Gamma] = \exp\left[\frac{i}{\hbar}(W' - X' + \varkappa_1 S^1) \right]. \tag{84}$$

For instance, the *superfield BRST transformations* $\delta_\mu \Gamma^p(\theta) = \partial^r_\theta \Gamma^p(\theta)\mu$ for $Z^{\mathcal{N}}_{X'}$ are derived from (84), with $R = 1$, and from the additional equations

$$(G^{\mathcal{V}}_{a_1}(\Gamma(\theta)), W' - X' + \varkappa_1 S^1)^{\mathcal{N}} = 0 \Leftrightarrow \delta_\mu G^{\mathcal{V}}_{a_1}(\Gamma(\theta)) = 0, \tag{85}$$

which ensure the BRST invariance of $q^{\mathcal{N}}$. In order to be valid for any gauge theory with an admissible action, Eq. (85) imposes strong restrictions on all the quantities $Y_{a_1 p}(\theta_1, \theta)$, $\tilde{\omega}^t_{pq}(\theta, \theta')$, and consequently on the geometry of $\mathcal{N}$. For example, the constant functions $Y_{a_1 p}(\theta_1, \theta)$, $\tilde{\omega}^t_{pq}(\theta, \theta')$ belong to solutions of Eq. (85). We, however, do not restrict the consideration to this special case, assuming that Eq. (85) is fulfilled for any W', X'. Some remarks are in order concerning the status of the functional $q^{\mathcal{N}}[\Gamma]$. Here, we do not consider the possibility of presenting the functions $G^{\mathcal{V}}_{a_1}(\theta)$ by an integral over new additional superfields $\Lambda^{a_1}(\theta)$, following in part the prescription of Ref. 21 that introduces so-called "unimodularity involution relations" for $G^{\mathcal{V}}_{a_1}(\theta)$ and modifies the BRST transformations for the extended set of variables $(\Gamma^p, \Lambda^{a_1})(\theta)$.

Choosing

$$(\varkappa_t,\Gamma^p,\rho,\tilde{\omega}^t_{pq}(\theta,\theta'),Y_{a_1p}(\theta_1,\theta))=(1,(\Phi^A,\Phi^*_A),1,\theta\theta'\,\mathrm{antidiag}(\delta^A_B,(-1)^t\delta^A_B),\delta(\theta_1-\theta)\delta_{Ap}), \tag{86}$$

we obtain

$$(\mathcal{V},\mathcal{U},S^2,q^{\mathcal{N}})=(V,U,\partial_\theta(\Phi^*_A\Phi^A)(\theta),\delta(J_A)), \tag{87}$$

where $(V,U)=(-1)^{\varepsilon_A}\partial_\theta(-\Phi^*_A(\theta)\partial_\theta\delta/\delta\Phi^*_A(\theta),\Phi^A(\theta)\partial_\theta\delta_l/\delta\Phi^A(\theta))$, according to Ref. 6, and hence $Z^{\mathcal{N}}_{X'}$, as well as Eq. (80), and BRST transformations, implied by (84) for $R=1$, coincide, respectively, with the vacuum functional Z,

$$Z=\int \mathrm{d}\Phi\mathrm{d}\Phi^*\delta(\partial_\theta\Phi^*(\theta))\exp\left\{\frac{i}{\hbar}(W[\Phi,\Phi^*]+X[\Phi,\Phi^*]+\partial_\theta(\Phi^*_A\Phi^A))\right\},$$

with the equations $1/2(W,W)+VW=i\hbar\Delta W$, $1/2(X,X)-UX=i\hbar\Delta X$, for $W=W'$, $X=X'$, and with the BRST symmetry transformations[7] for Z (having the opposite signs in the r.h.s.)

$$\delta\Phi^A(\theta)=\mu U\Phi^A(\theta)+(\Phi^A(\theta),X-W)\mu,\quad \delta\Phi^*_A(\theta)=\mu V\Phi^*_A(\theta)+(\Phi^*_A(\theta),X-W)\mu.$$

In particular, choosing X in terms of the gauge fermion $\Psi[\Phi]=\Psi(\phi,\lambda)$, $X[\Phi,\Phi^*]=U\Psi[\Phi]$, first realized in Ref. 6, we obtain the generating functional of Green's functions $Z[\Phi^*]$ used in Sec. I in order to determine the superfield effective action in Abelian hypergauges.

A complete correspondence between $Z^{\mathcal{N}}_{X'}$ and the functional $Z_X(0)|_{\varphi^*_0=0}$ in (50) can be established as follows: First, the functional $\varkappa_2S^2$ is represented as $(1/2)(1+(-1)^t)\varkappa_tS^t$, so that the redefined actions

$$W''=W'+\tfrac{1}{2}\varkappa_tS^t,\ X''=X'+\tfrac{1}{2}(-1)^t\varkappa_tS^t \tag{88}$$

obey Eq. (80) without the operators $\mathcal{V}$ and $\mathcal{U}$. Second, the actions $W(\theta)$ in (50) and $W''[\Gamma]$, as well as the quantities $X(\theta)|_{\Lambda^*=0}$ in (50) and $X''[\Gamma]$, are related by formula (73). Third, the solvability of the hypergauges $G_a[\Gamma]$ with respect to the fields $\varphi^*_a(\theta)$, on condition that $\Lambda^a(\theta)=\partial^r_\theta\varphi^a(\theta)$, implies, together with the previous restriction, a linear dependence of $X''[\Gamma]$ on $\Lambda^a(\theta)$ and its independence from $\partial_\theta\varphi^*_a(\theta)$. Next, one should take into account the structure of the generating equation for $X''[\Gamma]$, as well as the second system in (51) with (72) for $X(\theta)$, and the fact that the corresponding systems (84) and (53), encoding the BRST transformations, coincide with each other. The latter requires the commutativity of $G_a[\Gamma]$ and the triviality of the unimodularity relations, i.e., $\Delta^{\mathcal{N}}G_a=V^a_b=\tilde{G}^a=0$. Finally, the measure $\mathrm{d}\mu[\Gamma]q^{\mathcal{N}}$ in (79) is made identical to $\mathrm{d}\mu(\Gamma(\theta))\mathrm{d}\Lambda(\theta)|_{\theta=0}$ in (50) by the choice $q^{\mathcal{N}}=\delta(\partial_\theta\varphi^*(\theta))$. This choice can be realized by $(\varkappa_t,\tilde{\omega}^t_{pq}(\theta,\theta'),a_1,Y_{a_1p}(\theta_1,\theta))=(1,\theta\theta'\,\mathrm{antidiag}(\delta^a_b,(-1)^t\delta^a_b),a,\delta(\theta_1-\theta)\delta_{a_1p})$.

VI. CONCLUSION

Let us summarize the main results of the present work:

We have proposed a θ-local description of an arbitrary reducible superfield theory as a natural extension of a usual gauge theory, defined on a configuration space $\mathcal{M}_{\mathrm{cl}}|_{\theta=0}$ of classical fields A^i, to a superfield model defined on extended cotangent, $T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}}\times\{\theta\}$, and tangent, $T_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}}\times\{\theta\}$, odd bundles, in respective Hamiltonian and Lagrangian formulations. It is shown that the conservation under a θ-evolution (defined by a Hamiltonian or Lagrangian system providing a superfield extension of the usual extremals) of a Hamiltonian action $S_H((\mathcal{A},\mathcal{A}^*)(\theta),\theta)$, or, equivalently, of an odd counterpart of energy, $S_E((\mathcal{A},\partial_\theta\mathcal{A})(\theta),\theta)$, is equivalent, in view of Noether's first theorem, to the validity of a Hamiltonian or Lagrangian master equation, respectively.

Using non-Abelian hypergauges, we have constructed a θ-local superfield formulation of Lagrangian quantization for a reducible gauge model, extracted from a general superfield model by the conditions of a manifest θ-independence of the classical action and the vanishing of ghost number and auxiliary Grassmann parity (related to θ) for the action and $\mathcal{A}^I(\theta)$. In particular, we

have proposed a new superfield algorithm for constructing a first approximation to the quantum action in powers of ghosts of the minimal sector, on the basis of interpreting the reducibility relations as special gauge transformations of ghosts for an HS with the Hamiltonian chosen as the quantum action. To investigate the properties of BRST invariance and gauge-independence in a superfield form, for the introduced generating functionals of Green's functions (including the effective action), we have used *two equivalent* Hamiltonian-like systems. The first system is defined by a θ-local antibracket, in terms of a quantum action, a gauge-fixing action, and an arbitrary θ-local boson function, while the second (dual) system is defined by an even Poisson bracket, in terms of fermion functionals corresponding to the above functions. The two systems allow one to describe the BRST transformations and the continuous (anti)canonical-like transformations in a manner analogous to the relation between these transformations in the superfield Hamiltonian formalism.[5] We emphasize that, as a basis for the local quantization, we have intensely used the first-level formalism of Ref. 21, whose main ingredient is the vacuum functional (however, without recourse to the gauge-fixing action in a manifest form).

We have considered the problem of a *dual description* for an L-stage reducible gauge theory in terms of a BRST charge for a formal dynamical system with first-class constraints of $(L+1)$-stage reducibility. It is shown that this problem is a particular case of embedding a reducible special gauge theory into a general gauge theory of the same stage of reducibility.

We have proposed an extension of functional superfield quantization[6,7] to the case of general antisymplectic manifold without connection. It is shown that the condition of anticommutativity for all operators as well as the requirement of a correct transformation of the path integral measure impose strong restrictions on the geometry of the manifold as well as on *additional hypergauge conditions* that determine the measure.

We have established the coincidence of the first-level functional integral $Z^{(1)}$ in Ref. 21 with the local vacuum function of the proposed quantization scheme, in case $\theta=0$ and $\varphi^*(\theta)=0$, $Z_X(0)|_{\varphi_0^*=0}$. A correspondence is found between $Z_X(0)|_{\varphi_0^*=0}$ and the vacuum functional $Z_{X'}^{\mathcal{N}}$ of the proposed extension of the superfield quantization.[6,7] It is shown that the above functionals coincide only in Abelian hypergauges, with a trivial choice of the additional hypergauge conditions.

From the obtained results there follow the generating functional of Green's functions and the effective action of the first-level formalism.[21] It is observed that in case the quantum action $W'[\Gamma]$ depends on the superfields $\partial_\theta\Gamma^p(\theta)$, or the gauge-fixing action $X'[\Gamma]$ depends on the same superfields more than linearly, the functional $Z_{X'}^{\mathcal{N}}$ differs from $Z_X(0)|_{\varphi_0^*=0}$ exactly as the functional Z in Ref. 7 differs from $Z^{(1)}$ in Ref. 21.

In connection with the discussed points, the following open problems seem to be of interest:

1. One could obtain a Hamiltonian formulation of a LSM from a Lagrangian formulation in the case of a degenerate Hessian supermatrix $(S_L'')_{IJ}(\theta)$ in (5), and consider its relation to the standard component description of a model. In this case, Dirac's algorithm in terms of a θ-local antibracket, under the conservation of primary constraints in the course of θ-evolution along a vector field defined by an HS with a primary Hamiltonian in terms of antifields, would determine all antisymplectic constraints for the classical superfields $\Gamma^P_{\mathrm{CL}}(\theta)$. Among these constraints, there may exist a subsystem of second-class ones, in the case of the degeneracy of the supermatrix $\|\mathcal{L}^l_J(\theta_1)[\mathcal{L}^l_I(\theta_1)S_{\mathrm{L}}(\theta_1)(-1)^{\varepsilon_I}]\|_\Sigma$ in (6). It is interesting to apply the BFV method to construct, in terms of a θ-local Dirac's antibracket (the prescription for the first-level functional integral in terms of Dirac's antibracket was considered in Ref. 21), $(\cdot,\cdot)_{\theta D}$, a triplet of θ-local quantities $\widetilde{S}_{\mathrm{H}}(\theta)$, $\widetilde{\Omega}(\theta),\widetilde{\Psi}(\theta)$: $(\varepsilon_P,\varepsilon)$-even functions $\widetilde{S}_{\mathrm{H}}(\theta)$, $\widetilde{\Omega}(\theta)$, commuting with respect to $(\cdot,\cdot)_{\theta D}$ [by analogy with the Hamilton function and the BFV-BRST charge in a t-local field theory] and an $(\varepsilon_P,\varepsilon)$-odd function $\widetilde{\Psi}(\theta)$, which encodes the dynamics of a LSM and its first-class constraint algebra, as well as fixes the "gauge" arbitrariness in a space larger than $T^*_{\mathrm{odd}}\mathcal{M}_{\mathrm{CL}}\times\{\theta\}$. In this connection, it seems interesting to consider the question of how the construction of $\widetilde{S}_{\mathrm{H}}(\theta)$, $\widetilde{\Omega}(\theta)$ and of the "unitarizing Hamiltonian" $\widetilde{\mathcal{S}}_{\mathrm{H}}(\theta)=\widetilde{S}_{\mathrm{H}}(\theta)+(\widetilde{\Omega}(\theta),\widetilde{\Psi}(\theta))_{\theta D}$ is related to the quantum action of the BV method.

2. From the solution of the dual problem of Sec. IV B, found within the classical description,

there arise two natural questions: "How does the operator formulation of a formal dynamical system with a nilpotent BRST charge and a quantum counterpart of the even Poisson bracket correspond to the Lagrangian quantization of a gauge model?" and "What is related, in a Lagrangian formulation, to the formal supercommutator and the Hilbert space of states?" The mentioned problems appear to be related to the correspondence found in Ref. 37 between Poisson brackets and their operator counterparts of the opposite parity.

I. INTRODUCTION

A Yang-Mills-Higgs model is specified by choosing a real compact Lie group describing the gauge bosons and three unitary representations describing the left- and right-handed fermions and the Higgs scalars. Connes[1] remarks that the set of all Yang-Mills-Higgs models comes in two classes, Fig.1. The first is tiny and contains all those models that derive from gravity by generalizing Riemannian to almost commutative geometry. The intersections of this tiny class with the classes of left-right symmetric, grand unified, or supersymmetric Yang-Mills-Higgs models are all empty. However, the tiny class does contain the standard model of electromagnetic, weak, and strong forces with an arbitrary number of colors.

The first class is tiny, but still infinite and difficult to assess. We have started putting some order into this class. The criteria we apply are heteroclitic.[2]

Two criteria are simply motivated by simplicity: we take the internal algebra to be simple, or with two, three,… simple summands, we take the internal triple to be irreducible.

Two criteria are motivated from perturbative quantum field theory of the nongravitational part in flat time space: vanishing Yang-Mills anomalies and dynamical nondegeneracy. The latter imposes that the number of possible fermion mass equalities be restricted to the minimum, and that they be stable under renormalization flow. The origin of these mass equalities is the following. In almost commutative geometry, the fermionic mass matrix is the "Riemannian metric" of internal space, and as such becomes a dynamical variable. Its "Einstein equation" is the requirement that the fermionic mass matrix minimize the Higgs potential. Indeed, in almost commutative geometry, the Higgs potential is the "Einstein-Hilbert action" of internal space.

Two criteria are motivated from particle phenomenology: We want the fermion representation to be complex under the little group in each of its irreducible components, because we want to distinguish particles from antiparticles by means of unbroken charges. We want possible massless fermions to remain neutral under the little group, i.e., not to couple to massless gauge bosons.

Two criteria are motivated from the hope that, one day, we will have a unified quantum theory of all forces: vanishing mixed gravitational Yang-Mills anomalies and again dynamical nondegeneracy.

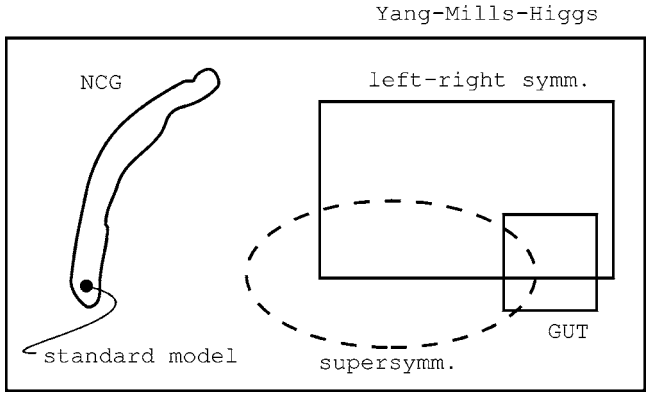

FIG. 1. Pseudoforces from noncommutative geometry.

Our analysis is based on a classification of all finite spectral triples by means of Krajewski diagrams[3] and centrally extended spin lifts of the automorphism group of their algebras.[4] The central extension serves two purposes: (i) It makes the spin lift of complex algebras $M_n(\mathbb{C})$ well defined. (ii) It allows the corresponding $U(n)$ anomalies to cancel.

Of course, we started with the case of a simple internal algebra. Here, there is only one contracted, irreducible Krajewski diagram and all induced Yang-Mills-Higgs models are dynamically degenerate.

The second case concerns algebras with two simple summands. It admits three contracted, irreducible Krajewski diagrams, one of them being a direct sum of two diagrams from the first case. The corresponding triples induce two Yang-Mills-Higgs models which are dynamically nondegenerate and anomaly free: SU(2) with a doublet of left-handed fermions and a singlet of right-handed fermions. The Higgs scalar is a doublet. Therefore, the little group is trivial, $SU(2)\rightarrow\{1_2\}$, and the fermion representation is real under the little group. The second model is the SO(2) submodel of the first.

The case of three summands has 41 contracted, irreducible diagrams plus direct sums. Its combinatorics is on the limit of what we can handle without a computer. There are only four induced models satisfying all criteria: The first is the standard model with C colors, $C\geqslant 2$, $SU(2)\times U(1)\times SU(C)$, with one generations of leptons and quarks and one colorless SU(2) doublet of scalars. The three others are submodels, $SO(2)\times U(1)\times SU(C)$, $SU(2)\times U(1)\times SO(C)$, and $SU(2)\times U(1)\times USp(C/2)$ and must have $C\geqslant 2$; the last submodel of course requires C even, $C\geqslant 4$.

In the following we push our classification to four summands. For simplicity we will only consider diagrams made of letter-changing arrows, i.e., we exclude arrows of type $a\bar{a}$ because, in the first three cases, these arrows always produced degeneracy. When the algebra is simple, of course all arrows are of this type and all models were degenerate. All direct sum diagrams in cases 2 and 3 necessarily contain such arrows. For two summands, there is only one contracted, irreducible diagram, which is not a direct sum and which is made of letter changing arrows; for three summands there are 30 such diagrams.

For four summands, a well-educated computer[5] tells us that there are 22 contracted, irreducible diagrams made of letter-changing arrows and which are not direct sums. They are shown in Fig. 2. We have two pleasant surprises: (i) the number of these diagrams is small; (ii) there are only two ladder diagrams, diagrams 18 and 19, i.e., diagrams with vertically aligned arrows, and all other diagrams have no subdiagrams of ladder form. We will see that these other diagrams are easily dealt with.

II. STATEMENT OF THE RESULT

Consider a finite, real, S^0-real, irreducible spectral triple whose algebra has four simple summands and the extended lift as described in Ref. 4. Consider the list of all Yang-Mills-Higgs models induced by these triples and lifts. Discard all models that have either

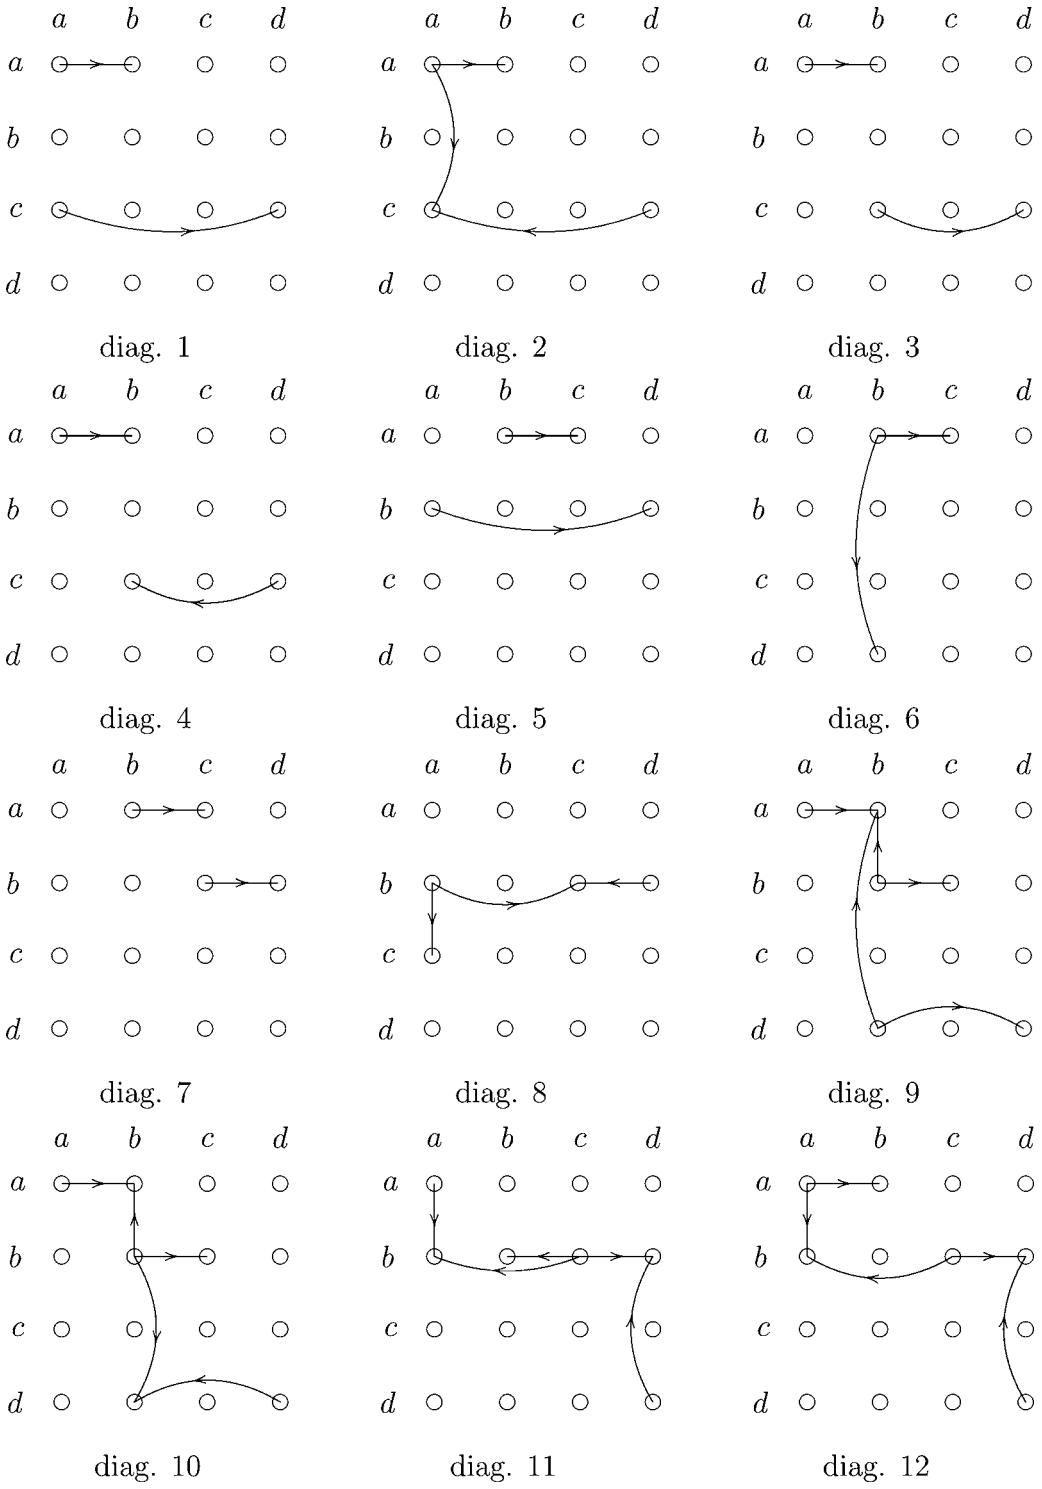

FIG. 2. Four simple summands produce 22 contracted, irreducible diagrams made of letter changing arrows and which are not direct sums.

(i) a dynamically degenerate fermionic mass spectrum;
(ii) Yang-Mills or gravitational anomalies;
(iii) a fermion multiplet whose representation under the little group is real or pseudoreal,

The remaining models are the following: C is the number of colors, the gauge group is on the left-hand side of the arrow, the little group on the right-hand side

$C=3, 5\ldots$

$$\frac{\mathrm{SU}(2)\times\mathrm{U}(1)\times\mathrm{SU}(C)}{\mathbb{Z}_2\times\mathbb{Z}_C}\to\frac{\mathrm{U}(1)\times\mathrm{SU}(C)}{\mathbb{Z}_C}.$$

The left-handed fermions transform according to a multiplet $\underline{2}\otimes\underline{C}$ with hypercharge $q/(2C)$ and a multiplet $\underline{C}$ with hypercharge $-q/2$. The right-handed fermions sit in two multiplets $\underline{C}$ with hypercharges $q(1+C)/(2C)$ and $q(1-C)/(2C)$ and one singlet with hypercharge $-q$, $q\in\mathbb{Q}$. The elements in $\mathbb{Z}_2\times\mathbb{Z}_C$ are embedded in the center of $\mathrm{SU}(2)\times\mathrm{U}(1)\times\mathrm{SU}(C)$ as

$$\left(\exp\frac{2\pi ik}{2}1_2,\exp[2\pi i(Ck-2\ell)/q],\exp\frac{2\pi i\ell}{C}1_p\right),\quad k=0,1,\quad \ell=0,1,\ldots,C-1.$$

The Higgs scalar transforms as an SU(2) doublet, SU(C) singlet and has hypercharge $-q/2$.

With the number of colors $C=3$, this is the standard model with one generation of quarks and leptons.

We also have in our list two submodels of the above model defined by the subgroups

$$\frac{\mathrm{SO}(2)\times\mathrm{U}(1)\times\mathrm{SU}(C)}{\mathbb{Z}_2\times\mathbb{Z}_C}\to\frac{\mathrm{U}(1)\times\mathrm{SU}(C)}{\mathbb{Z}_C},$$

$$\frac{\mathrm{SU}(2)\times\mathrm{U}(1)\times\mathrm{SO}(C)}{\mathbb{Z}_2}\to\mathrm{U}(1)\times\mathrm{SO}(C).$$

They have the same particle content as the standard model; in the first case only the $W^{\pm}$ bosons are missing, in the second case roughly half the gluons are lost.

$C=2, 4\ldots$

$$\frac{\mathrm{SU}(2)\times\mathrm{U}(1)\times\mathrm{SU}(C)}{\mathbb{Z}_C}\to\frac{\mathrm{U}(1)\times\mathrm{SU}(C)}{\mathbb{Z}_C},$$

with the same particle content as for odd C. But, now we have three possible submodels

$$\frac{\mathrm{SO}(2)\times\mathrm{U}(1)\times\mathrm{SU}(C)}{\mathbb{Z}_C}\to\frac{U(1)\times\mathrm{SU}(C)}{\mathbb{Z}_C},$$

$$\mathrm{SU}(2)\times\mathrm{U}(1)\times\mathrm{SO}(C)\to\mathrm{U}(1)\times\mathrm{SO}(C),$$

$$\frac{\mathrm{SU}(2)\times\mathrm{U}(1)\times\mathrm{USp}(C/2)}{\mathbb{Z}_2}\to\frac{U(1)\times\mathrm{USp}(C/2)}{\mathbb{Z}_2}.$$

electro-strong

$$\mathrm{U}(1)\times\mathrm{SU}(C)\to\mathrm{U}(1)\times\mathrm{SU}(C).$$

The fermionic content is $\underline{C}\oplus\underline{1}$, one quark and one charged lepton. The two fermion masses are arbitrary but different and nonvanishing. The number of colors is greater than or equal to 2, the two charges are arbitrary but vectorlike; of course the lepton charge must not vanish. There is no scalar and no symmetry breaking.

III. DIAGRAM BY DIAGRAM

We will use the following letters to denote algebra elements and unitaries: Let $\mathcal{A}=M_A(\mathbb{C})\oplus M_B(\mathbb{C})\oplus M_C(\mathbb{C})\oplus M_D(\mathbb{C})\ni(a,b,c,d)$. The extended lift is defined by

$$L(u,v,w,z) \coloneqq \rho(\hat{u},\hat{v},\hat{w},\hat{z})J\rho(\hat{u},\hat{v},\hat{w},\hat{z})J^{-1}, \tag{1}$$

with

$$\hat{u} \coloneqq u(\det u)^{q_{11}}(\det v)^{q_{12}}(\det w)^{q_{13}}(\det z)^{q_{14}} \in U(A), \tag{2}$$

$$\hat{v} \coloneqq v(\det u)^{q_{21}}(\det v)^{q_{22}}(\det w)^{q_{23}}(\det z)^{q_{24}} \in U(B), \tag{3}$$

$$\hat{w} \coloneqq w(\det u)^{q_{31}}(\det v)^{q_{32}}(\det w)^{q_{33}}(\det z)^{q_{34}} \in U(C), \tag{4}$$

$$\hat{z} \coloneqq z(\det u)^{q_{41}}(\det v)^{q_{42}}(\det w)^{q_{43}}(\det z)^{q_{44}} \in U(D), \tag{5}$$

and unitaries $(u,v,w,z) \in U(M_A(\mathbb{C}) \oplus M_B(\mathbb{C}) \oplus M_C(\mathbb{C}) \oplus M_D(\mathbb{C}))$. It is understood that, for instance, if $A=1$ we set $u=1$ and $q_{j1}=0$, $j=1$, 2,3,4. If $M_A(\mathbb{C})$ is replaced by $M_A(\mathbb{R})$ or $M_{A/2}(\mathbb{H})$, we set $q_{j1}=0$ and $q_{1j}=0$.

Diagram 1 yields

$$\rho_L = \begin{pmatrix} b \otimes 1_A & 0 \\ 0 & d \otimes 1_C \end{pmatrix}, \quad \rho_R = \begin{pmatrix} a \otimes 1_A & 0 \\ 0 & {}^{\alpha}a \otimes 1_C \end{pmatrix},$$

$$\rho_L^c = \begin{pmatrix} 1_B \otimes {}^{\alpha'}a & 0 \\ 0 & 1_D \otimes c \end{pmatrix}, \quad \rho_R^c = \begin{pmatrix} 1_A \otimes {}^{\alpha'}a & 0 \\ 0 & 1_A \otimes c \end{pmatrix}, \tag{6}$$

and

$$\mathcal{M} = \begin{pmatrix} M_1 \otimes 1_A & 0 \\ 0 & M_2 \otimes 1_C \end{pmatrix}, \quad M_1 \in M_{B\times A}(\mathbb{C}), \quad M_2 \in M_{D\times A}(\mathbb{C}). \tag{7}$$

The parameters α and α' take values ± 1 and distinguish between fundamental representation and its complex conjugate: ${}^{1}a \coloneqq a$, ${}^{-1}a \coloneqq \bar{a}$. The color algebras consist of a's and c's. The a's are broken and therefore we must have $A=1$. We want at most one massless Weyl fermion, which leaves us with three possibilities. The first is $B=2$, $D=1$. The fluctuations read

$$\varphi_1 = \sum_j r_j \hat{v}_j M_1 \hat{u}_j^{-1}, \quad \varphi_2 = \sum_j r_j \hat{z}_j M_2 {}^{\alpha}\hat{u}_j^{-1}. \tag{8}$$

We can decouple the two scalars φ_1 and φ_2 by means of the fluctuation: $r_1=\frac{1}{2}$, $\hat{u}_1=1$, $\hat{v}_1=1_2$, $\hat{w}_1=1_C$, $\hat{z}_1=1$, $r_2=\frac{1}{2}$, $\hat{u}_2=1$, $\hat{v}_2=-1_2$, $\hat{w}_2=1_C$, $\hat{z}_2=1$. Since the arrows M_1 and M_2 are disconnected, the Higgs potential is a sum of a potential in φ_1 and of a potential in φ_2. The minimum is $\mathring{\varphi}_1 = \mu(4\lambda)^{-1/2}\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $\mathring{\varphi}_2 = \mu(4\lambda)^{-1/2}$, and the model is dynamically degenerate.

The same accidents happen for the second possibility, $B=1$, $D=2$. We are left with the third possibility, $B=D=1$. Anomaly cancellations imply that the fermion couplings are vectorial: $q_{13}=q_{23}$, $q_{43}=\alpha q_{13}$, and there is no spontaneous symmetry breaking, $\mathrm{SU}(C)\times\mathrm{U}(1) \to \mathrm{SU}(C)\times\mathrm{U}(1)$. The model describes electro-strong forces with one charged lepton, one quark, and no scalar. The masses of both fermions are arbitrary but nonvanishing, the electric charges are arbitrary, nonvanishing for the lepton, and the number of colors C is arbitrary, $C \geqslant 2$.

Diagrams 3, 4, and **7** are treated in the same way and produce only the electro-strong model.

Diagram 2 yields

$$\rho_L = \begin{pmatrix} b \otimes 1_A & 0 \\ 0 & {}^{\alpha}a \otimes 1_C \end{pmatrix}, \quad \rho_R = \begin{pmatrix} a \otimes 1_A & 0 \\ 0 & d \otimes 1_C \end{pmatrix}, \tag{9}$$

$$\rho_L^c = \begin{pmatrix} 1_B \otimes^{\alpha'} a & 0 \\ 0 & 1_A \otimes c \end{pmatrix}, \quad \rho_R^c = \begin{pmatrix} 1_A \otimes^{\alpha'} a & 0 \\ 0 & 1_D \otimes c \end{pmatrix},$$

and

$$\mathcal{M} = \begin{pmatrix} M_1 \otimes 1_A & 0 \\ 1_A \otimes M_3 & M_2 \otimes 1_C \end{pmatrix}, \quad M_1 \in M_{B\times A}(\mathbb{C}), \quad M_2 \in M_{A\times D}(\mathbb{C}), \quad M_3 \in M_{C\times A}(\mathbb{C}). \tag{10}$$

If $M_3=0$ diagram 2 is treated as diagram 1. We consider the case $M_3 \neq 0$. Then, the first-order axiom implies $\alpha=1$. The color algebras consist of a's and c's. Both are broken and we take $A=C=1$. Then, $\mathcal{M}$ is of rank two or less. If we want at most one massless Weyl fermion, we must take $B=2$ and $D=1$ or $B=1$ and $D=2$. Anomaly cancellations then imply that the doublet of fermions does not couple to the determinant of the 2×2 unitary, "the hypercharge of the doublet is zero." On the other hand, the little group turns out either trivial or U(1). In the latter case the neutrino sitting in the doublet is charged under this U(1).

Diagram 5 has no unbroken color and fails as the first possibility of diagram 1, $B=2$, $D=1$.

Diagram 6 has color a and b; both are broken, implying $A=B=1$. Then, we must have $C=D=1$ to avoid two or more neutrinos.

Diagram 8 yields

$$\rho_L = \begin{pmatrix} a \otimes 1_C & 0 \\ 0 & c \otimes 1_B \end{pmatrix}, \quad \rho_R = \begin{pmatrix} a \otimes 1_A & 0 \\ 0 & d \otimes 1_C \end{pmatrix}, \tag{11}$$

$$\rho_L^c = \begin{pmatrix} 1_A \otimes^{\gamma} c & 0 \\ 0 & 1_C \otimes b \end{pmatrix}, \quad \rho_R^c = \begin{pmatrix} 1_A \otimes b & 0 \\ 0 & 1_D \otimes b \end{pmatrix},$$

and

$$\mathcal{M} = \begin{pmatrix} 1_A \otimes M_1 & 0 \\ M_3 \otimes 1_B & M_2 \otimes 1_B \end{pmatrix}, \quad M_1 \in M_{C\times B}(\mathbb{C}), \quad M_2 \in M_{C\times D}(\mathbb{C}), \quad M_3 \in M_{C\times A}(\mathbb{C}). \tag{12}$$

We suppose that M_3 does not vanish; otherwise, diagram 8 is treated as diagram 1. Broken color implies $A=B=1$. Neutrino counting leaves two possibilities, $C=1$ and $D=2$ or $C=D=2$. The first possibility is disposed of as in diagram 2. For the second possibility, anomaly cancellations imply that the determinants of the 2×2 unitaries w and z do not couple to the right-handed fermions.

Diagrams 14, 15, 16, and **17** share the fate of diagram 6.

Diagram 9 yields

$$\rho_L = \begin{pmatrix} b \otimes 1_A & 0 & 0 \\ 0 & c \otimes 1_B & 0 \\ 0 & 0 & d \otimes 1_D \end{pmatrix}, \quad \rho_R = \begin{pmatrix} a \otimes 1_A & 0 & 0 \\ 0 & {}^{\beta_1} b \otimes 1_B & 0 \\ 0 & 0 & {}^{\beta_2} b \otimes 1_D \end{pmatrix}, \tag{13}$$

$$\rho_L^c = \begin{pmatrix} 1_B \otimes^{\alpha'} a & 0 & 0 \\ 0 & 1_C \otimes^{\beta'} b & 0 \\ 0 & 0 & 1_D \otimes^{\delta'} d \end{pmatrix}, \quad \rho_R^c = \begin{pmatrix} 1_A \otimes^{\alpha'} a & 0 & 0 \\ 0 & 1_B \otimes^{\beta'} b & 0 \\ 0 & 0 & 1_B \otimes^{\delta'} d \end{pmatrix},$$

and

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_A & 1_B\otimes M_4 & 1_B\otimes M_5 \\ 0 & M_2\otimes 1_B & 0 \\ 0 & 0 & M_3\otimes 1_D \end{pmatrix},$$

with $M_1\in M_{B\times A}(\mathbb{C})$, $M_2\in M_{C\times D}(\mathbb{C})$, $M_3\in M_{D\times B}(\mathbb{C})$, $M_4\in M_{A\times B}(\mathbb{C})$, $M_5\in M_{A\times D}(\mathbb{C})$. If M_4 is nonzero β_1 must be 1, and if M_5 is nonzero β_2 must be 1. From broken color and neutrino counting, we have $A=B=D=1$ and $C=2$. Vanishing anomalies imply that the first and the third fermion have vectorlike hypercharges, while the hypercharges of the second fermion are zero. It is therefore neutral under the little group U(1).

Diagrams 10, 11, 12, and **13** fail in the same way.

Diagram 18 produces the following triple:

$$\rho_L=\begin{pmatrix} a\otimes 1_C & 0 \\ 0 & {}^{\alpha}a\otimes 1_D \end{pmatrix},\quad \rho_R=\begin{pmatrix} b\otimes 1_C & 0 & 0 \\ 0 & {}^{\beta_1}\bar{b}\otimes 1_C & 0 \\ 0 & 0 & {}^{\beta_2}\bar{b}\otimes 1_D \end{pmatrix},$$

$$\rho_L^c=\begin{pmatrix} 1_A\otimes c & 0 \\ 0 & 1_A\otimes d \end{pmatrix},\quad \rho_R^c=\begin{pmatrix} 1_B\otimes c & 0 & 0 \\ 0 & 1_B\otimes c & 0 \\ 0 & 0 & 1_B\otimes d \end{pmatrix},$$

and

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_C & M_2\otimes 1_C & 0 \\ 0 & 0 & M_3\otimes 1_D \end{pmatrix},\quad M_1,M_2,M_3\in M_{A\times B}(\mathbb{C}). \tag{14}$$

Counting neutrinos leaves two possibilities, $A=2$ and $B=1$, or $A=1$ and $B=1$. If the neutrino is to be neutral under the little group, we must have $D=1$ for the first possibility and $C=1$ for the second.

The first possibility has two U(1)'s if $C\geqslant 2$ and all four algebras consist of matrices with complex entries. They are parametrized by $\det u$ and by $\det w$. For $(\alpha,\beta_1,\beta_2)=+++,-++,++-$, and $-+-$, anomaly cancellations imply that the fermionic hypercharges of both U(1)'s are proportional

$$q_{11}=-\frac{1}{2},\quad q_{21}=Cp,\quad q_{31}=p,\quad q_{41}=-Cp, \tag{15}$$

$$q_{13}=0,\quad q_{23}=Cq,\quad q_{33}=q-\frac{1}{C},\quad q_{43}=-Cq, \tag{16}$$

with $p,\ q\in\mathbb{Q}$. Consequently, one linear combination of the two generators decouples from the fermions and is absent from the spectral action. This is similar to what happens to the scalar in the electro-strong model of diagram 1. The hypercharges of the remaining generator are those of the standard model with C colors. In the remaining four cases $(\alpha,\beta_1,\beta_2)=+-+,--+,+--$, and $---$, all ten fermionic hypercharges vanish and the three leptons are neutral under the little group. Finally, the cases where some of the four summands consist of matrices with real or quaternionic entries are treated as in the situation with three summands, and they produce the same submodels of the standard model.

The first possibility with $C=1$ has only one U(1). For the four sign assignments: $(\alpha,\beta_1,\beta_2)=+++,-++,++-$, and $-+-$, we find anomaly free lifts with nontrivial little group. For example,

for the first assignment, we get $q_{11}=-1/2$, $q_{21}=p$, $q_{31}=-p$, and $q_{41}=-p$, with $p\in\mathbb{Q}$. All four assignments produce the electro-weak model $(\mathrm{SU}(2)\times\mathrm{U}(1))/\mathbb{Z}_2\to\mathrm{U}(1)$ of protons, neutrons, neutrinos, and electrons.

The second possibility, $A=B=C=1$, contains at least one chiral lepton with vanishing hypercharge and therefore neutral under the little group.

Diagram 19 gives the same results as diagram 18.

In **diagrams 20, 21**, and **22**, the elements a and b must be matrices with complex entries to allow for conjugate representations. Without both the fundamental representation and its complex conjugate, these diagrams would violate the condition that every nonvanishing entry of the multiplicity matrix of a (blown-up) Krajewski diagram must have the same sign as its transposed element if the latter is not zero. Diagram 20 is treated and fails as diagram 2; diagrams 21 and 22 are treated and fail as diagram 13.

At this point we have exhausted all diagrams of Fig. 2.

IV. CONCLUSION AND OUTLOOK

For three summands there was essentially one irreducible spectral triple satisfying all items on our shopping list: the standard model with one generation of quarks and leptons and an arbitrary number of colors (greater than or equal to 2). We say "essentially" because a few submodels of the standard model can be obtained. Going to four summands adds precisely one model, the electro-strong model for one massive quark with an arbitrary number of colors and one massive, charged lepton. Note that this is the first appearance of a spectral triple without any Higgs scalar and without symmetry breaking.

We still have to prove that spectral triples in four summands involving letter-preserving arrows like $a\ \bar{a}$ do not produce any model compatible with our shopping list.

We are curious to know what happens in five (and more) summands. Here, ladder diagrams do not exist and we may speculate that our present list of models exhausts our shopping list also in any number of summands.

Anyhow, two questions remain: Who ordered three colors? Who ordered three generations?

Seiberg-Witten equations in R^4: Lie symmetries, particular solutions, integrability

Dmitriy V. Aleynikov[a)]
B.I. Stepanov Institute of Physics, National Academy of Sciences of Belarus, 68 F. Skaryna Avenue, 220072 Minsk, Belarus

(Received 25 January 2005; accepted 16 May 2005; published online 1 July 2005)

It is shown that the 11-parameter automorphism group of Lie algebra of four-dimensional Euclidean group is a maximal Lie symmetries group of the Seiberg-Witten equations in R^4. Particular explicit solutions which are invariant under SO(3) subgroups of the maximal Lie symmetries group are constructed. It is established that Seiberg-Witten equations do not possess the Painlevé property. Nevertheless, SO(3) invariant solutions obtained are turned to admit a characteristic singularity structure. © *2005 American Institute of Physics.*

I. INTRODUCTION

The Seiberg-Witten, or Abelian monopole, equations introduced in Ref. 1, following up with Ref. 2, play a significant role in the quantum gauge field theory and can be used as a powerful tool in the analysis of four manifolds.[3] These equations have arisen in the context of the *S*-duality between $N=2$ SUSY pure gauge Yang-Mills theory and $N=2$ supersymmetric Abelian theory, the latter including not only gauge fields but matter ones.[2,4] The Witten twist leads the SUSY pure gauge Yang-Mills theory to the Witten-Donaldson topological theory.[5] The weakly coupled region of field space in this theory is described by (anti)self-dual Yang-Mills instanton equations. The Seiberg-Witten equations describe the dynamics of "twisted" $N=2$ supersymmetric Abelian gauge fields with weakly coupling constant.[1,6] The more precise relationship between Donaldson theory, counting instantons, and dual Seiberg-Witten theory, counting monopoles, is explored in Ref. 7. So, the Seiberg-Witten equations, to some extent, are "dual" to Yang-Mills instanton equations. The problems of duality and topological aspects of low dimensional reduction of these theories have been studied in Refs. 8,9.

In light of these results, we note some properties of self-dual Yang-Mills equations. It was shown in Ref. 10 that the SU(2) self-dual Yang-Mills equations pass the Painlevé test for integrability.[11] Moreover, experience has shown that many well-known integrable equations are the reductions of the Yang-Mills equations.[12–15] These facts led to the famous Ward hypothesis.[13,14] The Seiberg-Witten equations have been linked to integrable systems by means of prepotentials (Refs. 16 and 17 and references therein). Some equations of the Painlevé type were obtained from the non-Abelian generalization of monopole equations.[18,19] However, the integrability of the Seiberg-Witten equations was not investigated.

Besides, the Abelian monopole equations are referred to in the context of zero-eigenvalue solutions to the Euclidean Dirac equation in external gauge field. The general ansatz of zero modes of the Abelian Dirac operator in three dimensional Euclidean space was proposed in Ref. 20. By exploiting this result, some particular solutions to the Seiberg-Witten equations in R^3 were found.[21,22] Furthermore, the Freund's equations were proposed which differ from Seiberg-Witten ones in the sign of the quadratic term.[22] It was shown in Ref. 23 that conformal group of three-

[a)]Electronic mail: aleynik@dragon.bas-net.by

dimensional Euclidean space is a maximal group of Lie symmetries of the Seiberg-Witten equations in R^3. Particular explicit solutions which are invariant under some subgroups of conformal group were constructed.

This paper deals with the Seiberg-Witten equations in four dimensional Euclidean space. The maximal group of Lie symmetries and particular solutions of this equations will be constructed. Besides, it will be shown that Seiberg-Witten equations do not possess the Painlevé property. Strictly speaking, we should define equations on compact manifolds. However, an arbitrary manifold M is defined by introducing a set of Euclidean-type neighborhoods covering M. In other words, a manifold is constructed by pasting together many pieces of Euclidean space. In turn, this paper is devoted to a study of the local properties of the Seiberg-Witten equations. Our point of view does not concern with the global topological aspects of Seiberg-Witten theory. Connections between Painlevé analysis and global aspects have been studied in Ref. 24.

II. SEIBERG-WITTEN AND FREUND'S EQUATIONS IN R^4

The Seiberg-Witten equations as well as Freund's ones are a set of coupled PDEs in four dimensions for the Abelian vector potential A_ν and the two-component spinor field $\tilde{\psi}$. Following Ref. 22, we write the Seiberg-Witten (Freund's) equations as

$$\gamma^\mu(i\partial_\mu - eA_\mu)\psi = 0,$$

$$\epsilon(ie/2)\overline{\psi}(\sigma^{\mu\nu})^+\psi = (F^{\mu\nu})^+, \tag{1}$$

$$\partial^\mu A^\nu - \partial^\nu A^\mu = F^{\mu\nu}.$$

Here the bispinor ψ is

$$\psi = \begin{pmatrix} \tilde{\psi} \\ 0 \end{pmatrix};$$

$\epsilon = \pm 1$; μ, $\nu = 0,1,2,3$; γ^ν are the Dirac matrices satisfying $\{\gamma^\mu, \gamma^\nu\} = -2g^{\mu\nu}I_4$; $\sigma^{\mu\nu} = 1/2[\gamma^\mu, \gamma^\nu]$. $\overline{\psi}$ means the Hermitian conjugate bispinor. We use the usual summation convention throughout, repeated indices are summed if one index is "up" and one is "down." For $\epsilon = 1$, these equations will be the Seiberg-Witten ones. In the case $\epsilon = -1$, we will think of the equations (1) as the Freund's equations. With the Euclidean metric $g^{\mu\nu}$ of signature $(-,-,-,-)$ the Dirac matrices can be represented in the form

$$\gamma^0 = \begin{pmatrix} 0 & \sigma^0 \\ \sigma^0 & 0 \end{pmatrix}, \quad \gamma^k = \begin{pmatrix} 0 & -i\sigma^k \\ i\sigma^k & 0 \end{pmatrix},$$

where $\sigma^0 = I_2$ and σ^k are the Pauli matrices; $k = 1,2,3$. Then

$$(\sigma_{\mu\nu})^+ = 1/2(\sigma_{\mu\nu} + (1/2)\varepsilon_{\mu\nu\rho\lambda}\sigma^{\rho\lambda}) = \frac{1}{2}(\delta_{\mu\rho}\delta_{\nu\lambda} - \delta_{\nu\rho}\delta_{\mu\lambda} + \varepsilon_{\mu\nu\rho\lambda})\begin{pmatrix} \sigma^\rho\sigma^\lambda & 0 \\ 0 & 0 \end{pmatrix}$$

and the self-dual tensor $(F^{\mu\nu})^+$ is given by

$$(F^{\mu\nu})^+ = 1/2(F^{\mu\nu} + (1/2)\varepsilon^{\mu\nu\rho\sigma}F_{\rho\sigma}),$$

where $\varepsilon^{\mu\nu\rho\sigma}$ is a totally antisymmetric tensor with $\varepsilon_{0123} = 1$ and δ is a Kronecker symbol. As has been shown in Ref. 25, the gauge vector field A^μ can be related to the spinor field ψ by

$$A^{\nu}=\frac{ie}{2\bar{\psi}\psi}[\partial_{\mu}(\bar{\psi}\gamma^{\mu}\gamma^{\nu}\psi)+2\bar{\psi}\partial^{\nu}\psi]. \tag{2}$$

This relation follows from the equations

$$\gamma^{\mu}(i\partial_{\mu}-eA_{\mu})\psi=0,$$

$$\bar{\psi}\gamma^{\mu}(i\overleftarrow{\partial}_{\mu}+eA_{\mu})=0,$$

which are equivalent to

$$i\bar{\psi}\gamma^{\nu}\gamma^{\mu}\partial_{\mu}\psi=e\bar{\psi}\gamma^{\nu}\gamma^{\mu}\psi A_{\mu},$$

$$i\partial_{\mu}(\bar{\psi})\gamma^{\mu}\gamma^{\nu}\psi=-e\bar{\psi}\gamma^{\mu}\gamma^{\nu}\psi A_{\mu}.$$

Using the property $\{\gamma^{\mu},\gamma^{\nu}\}=-2g^{\mu\nu}I_4$ leads us to the equation (2). The curvature $F^{\mu\nu}$ is

$$F^{\mu\nu}=\frac{ie}{2(\bar{\psi}\psi)}[\partial^{\mu}\partial_{\rho}(\bar{\psi}\gamma^{\rho}\gamma^{\nu}\psi)-\partial^{\nu}\partial_{\rho}(\bar{\psi}\gamma^{\rho}\gamma^{\mu}\psi)+2(\partial^{\mu}\bar{\psi})(\partial^{\nu}\psi)-2(\partial^{\nu}\bar{\psi})(\partial^{\mu}\psi)]$$
$$+\frac{ie}{2(\bar{\psi}\psi)^2}[\partial^{\nu}(\bar{\psi}\psi)(2\bar{\psi}\partial^{\mu}\psi+\partial_{\rho}(\bar{\psi}\gamma^{\rho}\gamma^{\mu}\psi))-\partial^{\mu}(\bar{\psi}\psi)(2\bar{\psi}\partial^{\nu}\psi+\partial_{\rho}(\bar{\psi}\gamma^{\rho}\gamma^{\nu}\psi))]. \tag{3}$$

The second equation of (1) defines the projection of Kustaanheimo-Stiefel bundle $R^4/\{0\}\rightarrow R^3/\{0\}$, ψ being a total space and $F^{+}_{\mu\nu}$ being a base manifold.[20,26] (The Kustaanheimo-Stiefel bundle is isomorphic to Hopf one.) Within this framework the solutions to the Seiberg-Witten equations can be represented as the local sections

$$\tilde{\psi}=\begin{cases}\tilde{\psi}_N, & f\neq -f^3,\\ \tilde{\psi}_S, & f\neq f^3,\end{cases} \tag{4}$$

where

$$\tilde{\psi}_N=\frac{1}{\sqrt{2(f+f^3)}}\begin{pmatrix}f+f^3\\ f^1+\mathrm{i}f^2\end{pmatrix},\quad \tilde{\psi}_S=\frac{1}{\sqrt{2(f-f^3)}}\begin{pmatrix}f^1-\mathrm{i}f^2\\ f-f^3\end{pmatrix},$$

and the local connections

$$A^{\nu}=\begin{cases}A^{\nu}_N, & f\neq -f^3,\\ A^{\nu}_S, & f\neq f^3.\end{cases} \tag{5}$$

Here $F^{01}+F^{23}=f^1$, $F^{02}+F^{31}=f^2$, $F^{03}+F^{12}=f^3$, and $f=\sqrt{-f^kf_k}=\sqrt{(f^1)^2+(f^2)^2+(f^3)^2}$.

It can be verified using the equations (2), (4), and (5) that

$$\psi_N=e^{i\alpha}\psi_S,\quad A^{\nu}_N=A^{\nu}_S-\partial^{\nu}\alpha,\quad \text{where}\quad \alpha=\arctan(f^2/f^1).$$

Using the equations (3) and (4) one can rewrite the second equation of (1) in the form

$$\tfrac{1}{2}(\varepsilon^{\lambda j\rho k}(\partial_{\lambda}f_j)(\partial_{\rho}f_k)+(\partial_kf^j)(\partial_jf^k)-(\partial_jf^j)(\partial_kf^k))f^i+\varepsilon^{ik\sigma j}((\partial_{\sigma}f^m)(\partial_mf_j)-(\partial_mf^m)(\partial_{\sigma}f_j)$$
$$-\varepsilon_{\sigma\lambda n\rho}(\partial^{\lambda}f^n)(\partial^{\rho}f_j))f_k+(f^kf_k)\partial_{\rho}\partial^{\rho}f^i-f_j(\partial^{\rho}f^j)(\partial_{\rho}f^i)+2\epsilon(-f^kf_k)^{3/2}f^i=0. \tag{6}$$

We note that greek indices can take the four values (0, 1, 2, 3). Italic indices take the three values (1, 2, 3). As speaking above the ε-tensor has its usual meaning.

So, we obtain the second order nonlinear differential equations in four independent and three dependent variables. The gauge ambiguity is removed.

III. LIE SYMMETRIES AND PARTICULAR SOLUTIONS

One of the most useful methods for determining particular explicit solutions to partial differential equations is to reduce them to ordinary differential equations which are invariant under some subgroups of maximal Lie symmetry group. For this purpose we need to construct the infinitesimal Lie algebra generators. Using the method described in Ref. 27 gives (see the Appendix)

$$M_{\nu\mu} = x_\nu \partial_\mu - x_\mu \partial_\nu + (\delta_{\nu i}\delta_{\mu j} - \delta_{\nu j}\delta_{\mu i} + \varepsilon_{\nu\mu ij}) f^i \frac{\partial}{\partial f_j}, \tag{7}$$

$$P_\nu = \partial_\nu, \tag{8}$$

$$D = x^\mu \partial_\mu - 2 f^i \frac{\partial}{\partial f^i}. \tag{9}$$

The commutation relations of generators (7)–(9) are

$$[M_{\nu\mu}, M_{\rho\sigma}] = g_{\nu\sigma} M_{\mu\rho} + g_{\mu\rho} M_{\nu\sigma} - g_{\nu\rho} M_{\mu\sigma} - g_{\mu\sigma} M_{\nu\rho},$$

$$[M_{\nu\mu}, P_\sigma] = g_{\mu\sigma} P_\nu - g_{\nu\sigma} P_\mu,$$

$$[M_{\nu\mu}, D] = 0,$$

$$[P_\mu, D] = P_\mu,$$

$$[P_\nu, P_\mu] = 0.$$

We note that $g_{\nu\mu} = -\delta_{\nu\mu}$. So, the generators (7)–(9) reproduce the infinitesimal transformations of $T^4 \ltimes (SO(4) \otimes D)$ automorphism group of Lie algebra of four-dimensional Euclidean group. The group obtained has the structure of a semidirect product, namely, the semidirect product of the translation group T^4 and $SO(4) \otimes D$ group, the latter being the direct product of the rotation group SO(4) and the dilatation group D. Generators $M_{\nu\mu}$, P_ν, and D determine infinitesimal rotations, shifts and dilatation, respectively. Note in particular that (7)–(9) generate fiber-preserving transformations, meaning that the transformations in x^μ do not depend on the coordinates f^i.

The symmetry group $T^4 \ltimes (SO(4) \otimes D)$ of four dimensional Seiberg-Witten equations does not include the inversions in spite of the fact that the initial fields ψ and A_ν are massless. The theorem proven in Ref. 28 states that an arbitrary Poincaré (Euclidean) invariant equation for massless fields are conformally invariant "by default." In general, the latter fact holds for linear equations such as massless Dirac and Maxwell ones.[29] Since the Seiberg-Witten equations contain the nonlinear quadratic term, the Euclidean invariance does not give rise to the conformal one. It is interesting to note that the inversions are nonlinear transformations. So, the invariance under nonlinear transformations is removed. We must note that Yang-Mills equations are conformal invariant.[30,31] Moreover, the conformal invariance is not removed by coupling of Yang-Mills fields with massless scalar fields[32] or massless Dirac fields.[33]

Consider the solutions of (6) which are invariant under SO(3) subgroups of $T^4 \ltimes (SO(4) \otimes D)$ or, more precisely, SO(4). It should be noted that subgroups are determined up to inner automorphisms of maximal symmetry group. So, a class of adjoint subgroups can be associated

with a subgroup $\mathrm{SO}(3):\widetilde{\mathrm{SO}}(3)=g\mathrm{SO}(3)g^{-1}$, where g is an arbitrary element of $\mathrm{T}^4\ltimes(\mathrm{SO}(4)\otimes\mathrm{D})$ group. There are three nonequivalent SO(3) subgroups of SO(4) group. One of them can be generated by vector fields

$$M_{ij}=x_i\partial_j-x_j\partial_i+f_i\frac{\partial}{\partial f^j}-f_j\frac{\partial}{\partial f^i}.$$

The solutions to the Witten-Seiberg equations which are invariant under the SO(3) subgroup generated by vector fields M_{ij} and the solutions which are invariant under some adjoint subgroup to this SO(3) group were constructed in Ref. 23. The SO(3) invariant solutions are turned out to be a monopolelike ones.

The second SO(3) subgroup is generated by vector fields $M^-_{\nu\mu}=M_{\nu\mu}-\frac{1}{2}\varepsilon_{\nu\mu\lambda\tau}M^{\lambda\tau}$,

$$M^-_{\nu\mu}=x_\nu\partial_\mu-x_\mu\partial_\nu-\tfrac{1}{2}\varepsilon_{\nu\mu\lambda\tau}(x^\lambda\partial^\tau-x^\tau\partial^\lambda).$$

It is evidently that f^i, $i=1,2,3$ and $r=\sqrt{-x^\mu x_\mu}$ are group invariants. By Lie's reduction method the equations (6) are reduced to the ordinary differential equations in the three dependent variables f^i and the independent variable r,

$$(-f^jf_j)\left(\frac{\mathrm{d}^2f^i}{\mathrm{d}r^2}+\frac{3}{r}\frac{\mathrm{d}f^i}{\mathrm{d}r}\right)+\frac{1}{2}\frac{\mathrm{d}(f^jf_j)}{\mathrm{d}r}\frac{\mathrm{d}f^i}{\mathrm{d}r}+2\epsilon(-f^jf_j)^{3/2}f^i=0.$$

These equations with $\epsilon=1$ admit the solution

$$f^i=\pm\frac{2\hat{u}^i}{r^2}=\mp\frac{2\hat{u}^i}{x^\nu x_\nu}, \tag{10}$$

where $\hat{u}^i$ is an arbitrary constant unit vector, $\hat{u}^i\hat{u}_i=-1$.

The finite transformations $\exp(\varphi M^-_{\nu\mu})$ of this subgroup are

$$x^\sigma\mapsto x^\sigma\cos\phi+(x^\nu g^{\mu\sigma}-x^\mu g^{\nu\sigma}+\varepsilon^{\nu\mu\sigma\lambda}x_\lambda)\sin\phi,$$

$$f^i\mapsto f^i.$$

It is evidently that

$$\widetilde{f}^i(x^\sigma)\equiv G(\exp(\varphi M^-_{\nu\mu}))f^i(x^\sigma)\equiv\exp(\varphi M^-_{\nu\mu})f^i(\exp(-\varphi M^-_{\nu\mu})x^\sigma)=f^i(\exp(-\varphi M^-_{\nu\mu})x^\sigma)=f^i(x^\sigma)$$

for the solutions (10).

The third SO(3) subgroup is generated by vector fields $M^+_{\nu\mu}=M_{\nu\mu}+\frac{1}{2}\varepsilon_{\nu\mu\lambda\tau}M^{\lambda\tau}$,

$$M^+_{\nu\mu}=x_\nu\partial_\mu-x_\mu\partial_\nu+\tfrac{1}{2}\varepsilon_{\nu\mu\lambda\tau}(x^\lambda\partial^\tau-x^\tau\partial^\lambda)+2(\delta_{\nu i}\delta_{\mu j}-\delta_{\nu j}\delta_{\mu i}+\varepsilon_{\nu\mu ij})f^i\frac{\partial}{\partial f_j}.$$

As in the previous case the variable $r=\sqrt{-x^\mu x_\mu}$ is a group invariant. The next three invariants have the form $F_i=\Omega_{ij}f^j$, where Ω_{ij} is the orthogonal matrix

$$\Omega_{ij}=\frac{1}{x^\mu x_\mu}(-\delta_{ij}x^\nu x_\nu+2\delta_{ij}x^kx_k+2x_ix_j-\varepsilon_{ijk\mu}x^kx^\mu).$$

We recall that greek indices can take the four values (0, 1, 2, 3). Italic indices take the three values (1, 2, 3). It can be verified by direct calculation that $M^+_{\nu\mu}F^i=0$. The equations (6) are reduced to the ordinary differential equations

$$(-F^jF_j)\left(\frac{\mathrm{d}^2F^i}{\mathrm{d}r^2}+\frac{1}{r}\frac{\mathrm{d}F^i}{\mathrm{d}r}-\frac{12}{r^2}F^i\right)+\frac{1}{2}\frac{\mathrm{d}(F^jF_j)}{\mathrm{d}r}\left(\frac{\mathrm{d}F^i}{\mathrm{d}r}+\frac{2F^i}{r}\right)+2\epsilon(-F^jF_j)^{3/2}F^i=0.$$

The solutions to the latter equations with $\epsilon=1$ are

$$F^i=\pm\frac{4\hat{v}^i}{r^2}=\mp\frac{4\hat{v}^i}{x^\nu x_\nu},$$

where $\hat{v}^i$ is an arbitrary constant unit vector, $\hat{v}^i\hat{v}_i=-1$. Then

$$f^i=\pm\frac{4\hat{w}^i}{r^2}=\mp\frac{4\hat{w}^i}{x^\nu x_\nu}, \tag{11}$$

where

$$\hat{w}_i=\Omega_{ij}^{-1}\hat{v}^j=\frac{1}{x^\mu x_\mu}(-\delta_{ij}x^\nu x_\nu+2\delta_{ij}x^kx_k+2x_ix_j+\varepsilon_{ijk\mu}x^kx^\mu)\hat{v}^j.$$

To avoid difficulties we write out the finite transformations $\exp(\varphi M^+_{\nu\mu})$ in component form. Thus, $\exp(\varphi M^+_{21})=\exp(\varphi M^+_{30})$ is given by

$$x^0\mapsto x^0\cos\varphi-x^3\sin\varphi,\quad x^3\mapsto x^3\cos\varphi+x^0\sin\varphi,$$

$$x^1\mapsto x^1\cos\varphi-x^2\sin\varphi,\quad x^2\mapsto x^2\cos\varphi+x^1\sin\varphi,$$

$$f^1\mapsto f^1\cos 2\varphi-f^2\sin 2\varphi,\quad f^2\mapsto f^2\cos 2\varphi+f^1\sin 2\varphi,$$

$$f^3\mapsto f^3.$$

For $\exp(\varphi M^+_{13})=\exp(\varphi M^+_{20})$ we have

$$x^0\mapsto x^0\cos\varphi-x^2\sin\varphi,\quad x^2\mapsto x^2\cos\varphi+x^0\sin\varphi,$$

$$x^1\mapsto x^1\cos\varphi+x^3\sin\varphi,\quad x^3\mapsto x^3\cos\varphi-x^1\sin\varphi,$$

$$f^1\mapsto f^1\cos 2\varphi+f^3\sin 2\varphi,\quad f^3\mapsto f^3\cos 2\varphi-f^1\sin 2\varphi,$$

$$f^2\mapsto f^2.$$

The transformation $\exp(\varphi M^+_{32})=\exp(\varphi M^+_{10})$ is defined by

$$x^0\mapsto x^0\cos\varphi-x^1\sin\varphi,\quad x^1\mapsto x^1\cos\varphi+x^0\sin\varphi,$$

$$x^2\mapsto x^2\cos\varphi-x^3\sin\varphi,\quad x^3\mapsto x^3\cos\varphi+x^2\sin\varphi,$$

$$f^2\mapsto f^2\cos 2\varphi-f^3\sin 2\varphi,\quad f^3\mapsto f^3\cos 2\varphi+f^2\sin 2\varphi,$$

$$f^1\mapsto f^1.$$

It can be verified that

$$\tilde{f}^i(x^\sigma) \equiv G(\exp(\varphi M^+_{\nu\mu}))f^i(x^\sigma) \equiv \exp(\varphi M^+_{\nu\mu})f^i(\exp(-\varphi M^+_{\nu\mu})x^\sigma) = f^i(x^\sigma)$$

for the functions (11). This implies that the solutions (11) are invariant under finite transformations $\exp(\varphi M^+_{\nu\mu})$.

The point that we wish to emphasize is that a class of solutions containing 11 parameters can be obtained from some initial particular solution by transformations of the $T^4 \ltimes (SO(4) \otimes D)$ group. In turn, both the equations (6) and group transformations are gauge independent. For this reason, none of the parameters are removable by gauge transformation. These parameters are interpreted as degrees of freedom of field configurations. In contrast, the gauge transformations of instanton solutions of self-dual Yang-Mills equations remove the degrees of freedom generated by inversion subgroup of the conformal symmetry group.[34,35]

An interesting property of Seiberg-Witten equations can be pointed out. The four dimensional Seiberg-Witten equations are reduced to the three dimensional ones through some differential constraints, namely $\partial_i f^i = 0$ and $\partial_0 f^j = 0$.[22,23] We have already mentioned that the reduced three dimensional Seiberg-Witten equations are invariant under 10-parameter conformal group of three dimensional Euclidean space as well as under shifts along x^0. So, the $T^4 \ltimes (SO(4) \otimes D)$ group goes over into the $SO(4,1) \otimes T^0$ one.

Indeed, let us copy out the generators of SO(4,1) group obtained in Ref. 23,

$$M_{ij} = x_i\partial_j - x_j\partial_i + f_i\frac{\partial}{\partial f^j} - f_j\frac{\partial}{\partial f^i},$$

$$P_i = \partial_i,$$

$$\tilde{D} = x^j\partial_j - 2f^i\frac{\partial}{\partial f^i},$$

$$K_i = -2x_i x^j\partial_j + x^j x_j\partial_i + 4x_i f^j\frac{\partial}{\partial f^j} - 2f_i x^j\frac{\partial}{\partial f^j} + 2x^j f_j\frac{\partial}{\partial f^i}.$$

It is evident that the violation of symmetry caused by dimensional reduction does not change the number of group parameters. The generators K_i of three dimensional inversions occur instead of the generators M_{0i}. We must note that although the $SO(4,1) \otimes T^0$ group is the symmetry group of the reduced equations, but there is no straightforward reduction procedure which transforms the generators of the $T^4 \ltimes (SO(4) \otimes D)$ group to the generators K_i.

IV. PAINLEVÉ ANALYSIS

The Painlevé property for partial differential equations[11] is believed to be a sufficient condition for integrability.[36] A partial differential equation has the Painlevé property when the solutions of the equation are single valued about the movable singularity manifolds. These manifolds are determined by conditions of the form $Z(x_1,\ldots,x_n)=0$, where Z is an analytic function of n complex variables. So, if Seiberg-Witten (Freund's) equations (6) had the Painlevé property, the solutions to the equations (6) would be represented by the power expansion

$$f^i = \frac{1}{Z^p}\sum_{q=0}^{\infty} a^i_q Z^q, \tag{12}$$

where p is an integer. The expansion (12) contains an arbitrary analytic function $Z=Z(x^\mu)$ determining a singularity manifold $M=\{x^\mu : Z(x^\mu)=0\}$ and five arbitrary analytic functions $a^i_q = a^i_q(x^\mu)$ for some values of q. These values are resonances.

To determine the leading power p, one can take

$$f^i = \frac{a^i}{Z^p},$$

$$\partial_\nu f^i = \frac{\partial_\nu a^i}{Z^p} - \frac{p a^i \partial_\nu Z}{Z^{p+1}},$$

$$\partial^\nu \partial_\nu f^i = \frac{\partial^\nu \partial_\nu a^i}{Z^p} - \frac{2p(\partial_\nu a^i)(\partial^\nu Z) + p a^i \partial^\nu \partial_\nu Z}{Z^{p+1}} + \frac{p(p+1) a^i (\partial_\nu Z)(\partial^\nu Z)}{Z^{p+2}}.$$

By setting the leading term of (6) equal to zero we get

$$\frac{p(a^k a_k)(\partial_\nu Z)(\partial^\nu Z) a^i}{Z^{3p+2}} = -\epsilon \frac{2(-a^k a_k)^{3/2} a^i}{Z^{4p}}.$$

As a consequence, we have

$$p = 2, \quad (-a^k a_k)^{1/2} = \epsilon (\partial^\nu Z)(\partial_\nu Z). \tag{13}$$

The vector function $\hat{a}^i = a^i/(-a_i a^i)^{1/2}$, $\hat{a}_i \hat{a}^i = -1$ is arbitrary.

We note that the Witten-Seiberg equations are equivalent to the Freund's ones up to change of variables $x^\mu \to \mathrm{i} x^\mu$. Without loss of a generality we choose $\epsilon = -1$.

Resonances can be found by setting

$$f^i = \frac{a^i + \omega^i Z^n}{Z^2},$$

$$\partial_\nu f^i = \cdots + \frac{(n-2)\omega^i Z^n - 2a^i}{Z^3} \partial_\nu Z,$$

$$\partial^\nu \partial_\nu f^i = \cdots + \frac{6a^i + (n-2)(n-3)\omega^i Z^n}{Z^4} (\partial^\nu Z)(\partial_\nu Z).$$

Collecting terms which involve ω^i leads us to the linear equations

$$-((a^k a_k)(n-1)(n-2)\omega^i + 2(n+2)a^i (a^k \omega_k))(\partial^\nu Z)(\partial_\nu Z) = (-a^k a_k)^{1/2} (6a^i (a^k \omega_k) + 2(a^k a_k)\omega^i),$$

or

$$2(n-1)a^i (a^k \omega_k) + n(n-3)\omega^i (a^k a_k) \equiv \Lambda^i_k \omega^k = 0.$$

It then follows from $\det \Lambda^i_k = 0$ that

$$\det \Lambda^i_k = (-a^k a_k)^3 (n+1) n^2 (n-2)(n-3)^2 = 0.$$

So, resonances occur at $n = 0,2,3$. This indicates that the solutions f^i do not have an algebraic movable singularity. However, a logarithmic movable singularitity can occur.

For further purpose it is sufficient to consider the four leading terms of (12),

$$f^i = \frac{a^i}{Z^2} + \frac{b^i}{Z} + c^i + d^i Z. \tag{14}$$

Substitution of (14) into (6) gives

$$6a^i(a^kb_k)(\partial_\rho Z)(\partial^\rho Z)-2(a^ka_k)(a^i\partial_\rho\partial^\rho Z+(\partial^\rho a^i)(\partial_\rho Z))+2(a^ka_k)((\partial^i Z)(\partial_j a^j)-(\partial_j Z)(\partial^i a^j)+\varepsilon^{i\nu\rho j}(\partial_\nu Z)$$
$$\times(\partial_\rho a_j))+a^i(\partial_\rho Z)\partial^\rho(a^ka_k)+a^j(\partial_j Z)\partial^i(a^ka_k)-a^j(\partial^i Z)\partial_j(a^ka_k)-\varepsilon^{ij\rho\sigma}a_j(\partial_\rho Z)\partial_\sigma(a^ka_k)$$
$$+6a^i(-a^ka_k)^{1/2}a^jb_j-2b^i(-a^ka_k)^{3/2}=0. \tag{15}$$

The vector function b^i is uniquely determined,

$$b^i=\frac{1}{(-a^ka_k)^{1/2}}\Bigg(a^i\partial^\rho\partial_\rho Z+(\partial^\rho a^i)\partial_\rho Z-\varepsilon^{i\nu\rho j}(\partial_\nu Z)(\partial_\rho a_j)-(\partial^i Z)(\partial_j a^j)+(\partial_j Z)(\partial^i a^j)$$
$$+\frac{1}{2(a^ka_k)}(2a^i(\partial^\nu Z)\partial_\nu(a^ka_k)+\varepsilon^{ij\rho\sigma}a_j(\partial_\rho Z)\partial_\sigma(a^ka_k)+a^j(\partial^i Z)\partial_j(a^ka_k)-a^j(\partial_j Z)\partial^i(a^ka_k))\Bigg). \tag{16}$$

The compatibility condition at $n=2$ is

$$-2(-a^ka_k)^{1/2}((a^ja_j)c^i-a^i(a^jc_j))=\Delta^i, \tag{17}$$

where

$$\Delta^i=(a^ka_k)(\partial^\rho\partial_\rho a^i-b^i\partial^\rho\partial_\rho Z)-(a^kb_k)(5b^i(\partial^\rho Z)(\partial_\rho Z)+4a^i\partial^\rho\partial_\rho Z)+a^i(\partial^\rho Z)(\partial_\rho Z)(b^kb_k)-3\hat{a}^i(a^kb_k)^2$$
$$-5(a^kb_k)(\partial^\rho Z)(\partial_\rho a^i)-\partial^\rho(a^ka_k)(\partial_\rho a^i)/2+b^i(\partial^\rho Z)\partial_\rho(a^ka_k)/2+2a^i(\partial^\rho Z)\partial_\rho(a^kb_k)+(\partial_j(a^ka_k)(\partial^i a^j)$$
$$-\partial^i(a^ka_k)(\partial_j a^j)-\varepsilon^{i\nu\rho j}\partial_\nu(a^ka_k)(\partial_\rho a_j))/2-3(a^kb_k)((\partial_j Z)(\partial^i a^j)-(\partial^i Z)(\partial_k a^k)-\varepsilon^{i\nu\rho j}(\partial_\nu Z)(\partial_\rho a_j))$$
$$+2(a^j(\partial_j Z)\partial^i(a^kb_k)-a^j(\partial^i Z)\partial_j(a^kb_k)-\varepsilon^{ij\nu\rho}a_j(\partial_\nu Z)\partial_\rho(a^kb_k))-(b^j(\partial_j Z)\partial^i(a^ka_k)-b^j(\partial^i Z)\partial_j(a^ka_k)$$
$$-\varepsilon^{ij\nu\rho}b_j(\partial_\nu Z)\partial_\rho(a^ka_k))/2-2(a^ka_k)((\partial_j Z)(\partial^i b^j)-(\partial^i Z)(\partial_k b^k)-\varepsilon^{i\nu\rho j}(\partial_\nu Z)(\partial_\rho b_j))$$
$$+\varepsilon_{jl\rho m}a^jb^l((\partial^i Z)(\partial^\rho a^m)-(\partial^\rho Z)(\partial^i a^m)+\varepsilon^{i\tau\sigma\rho}(\partial_\tau Z)(\partial_\sigma a^m))+\varepsilon_{kl\rho m}a^k((\partial^i a^l)(\partial^\rho a^m)-(\partial^\rho a^l)(\partial^i a^m)$$
$$+\varepsilon^{i\tau\sigma\rho}(\partial_\tau a^l)(\partial_\sigma a^m))/2.$$

The condition (17) is not compatible because $a_i\Delta^i\neq 0$ for arbitrary functions $\hat{a}^i$ and Z. For the compatible condition (17) to occur, a logarithmic term must be included into the expansion (12). So, a logarithmic movable singularity holds. For this reason, the Seiberg-Witten (Freund's) equations do not possess the Painlevé property.

It is interesting to note that the expansion (14) can be rewritten as

$$f^i=\partial^\mu(\partial_\mu(\ln Z)\hat{a}^i)-\varepsilon^{ij\mu\nu}(\partial_\mu(\ln Z)(\partial_\nu\hat{a}_j)+\varepsilon_{\mu\nu\rho\sigma}\partial^\rho(\ln Z)(\partial^\sigma\hat{a}_j))+c^i+d^iZ.$$

The latter fact follows from (13) and (16). Consider the expansion (12) with $a^i_q\equiv 0$ for $q\geqslant 2$ (so-called truncated expansion). We can think of

$$f^i=\partial^\mu(\partial_\mu(\ln Z)\hat{a}^i)-\varepsilon^{ij\mu\nu}(\partial_\mu(\ln Z)(\partial_\nu\hat{a}_j)+\varepsilon_{\mu\nu\rho\sigma}\partial^\rho(\ln Z)(\partial^\sigma\hat{a}_j)) \tag{18}$$

as a change of variables f^i in the equations (6). According to Ref. 37, the truncation (18) gives an available ansatz for particular solutions to the equations (6). Substitution of the truncation (18) into the equations (6) leads to a set of differential constraints for $\hat{a}^i$ and Z. The resulting overdetermined system requires separate analysis.

We note in conclusion that the solutions (10) correspond to (18) with $\hat{a}^i=\hat{u}^i$ and $Z=(-x^\mu x_\mu)^{\mp 1/2}$. In turn, for the solutions (11) we have $Z=(-x^\mu x_\mu)^{\mp 1}$ and $\hat{a}^i=\hat{w}^i$.

The monopolelike solutions obtained in Ref. 21 correspond to (18) with $Z=(-x^ix_i)^{\pm 1/4}$ and $\hat{a}^i=x^i/(-x^jx_j)^{1/2}$.

ACKNOWLEDGMENT

The author wishes to thank Professor E.A. Tolkachev for interesting conversations and comments on the paper.

APPENDIX

The infinitesimal Lie group transformations have the form[27]

$$L = \xi^{\nu}\partial_{\nu} + \varphi^{i}\frac{\partial}{\partial f^{i}}, \tag{A1}$$

where ξ and φ depend on x^{μ}, f^{j}.

The second prolongation $\mathrm{pr}^{2} L$ of vector field (A1) is

$$\mathrm{pr}^{2} L = L + \Phi^{i\nu}\frac{\partial}{\partial h^{i\nu}} + \Phi^{i\nu\mu}\frac{\partial}{\partial h^{i\nu\mu}},$$

where

$$\Phi^{i\nu} = D^{\nu}(\varphi^{i} - \xi_{\mu}h^{i\mu}) + \xi_{\rho}h^{i\rho\nu}$$

and

$$\Phi^{i\nu\mu} = D^{\nu\mu}(\varphi^{i} - \xi_{\sigma}h^{i\sigma}) + \xi_{\rho}h^{i\rho\nu\mu}.$$

Here $h^{i\nu}=\partial^{\nu}f^{i}$, $h^{i\nu\mu}=\partial^{\nu}\partial^{\mu}f^{i}$, D^{ν} is the total derivative operator

$$D^{\mu}P(x^{\mu},f^{i}) = \partial^{\mu}P + (\partial^{\mu}f^{i})\frac{\partial P}{\partial f^{i}}$$

for arbitrary function $P(x^{\mu},f^{i})$.

It is convenient to denote the equations (6) by $W(f^{i},h^{i\mu},h^{i\mu\nu})=0$. These equations are invariant under infinitesimal transformations (A1) if

$$\mathrm{pr}^{2} L[W(f^{i},h^{i\mu},h^{i\mu\nu})] = 0 \tag{A2}$$

for all solutions of (6). The infinitesimal condition (A2) leads to the differential constraints

$$\frac{\partial\xi^{\mu}}{\partial f^{i}} = \frac{\partial\varphi^{i}}{\partial x^{\mu}} = \frac{\partial^{2}\xi^{\rho}}{\partial x^{\nu}\,\partial x^{\mu}} = \frac{\partial\varphi^{i}}{\partial f^{k}\,\partial f^{m}} = 0, \quad \frac{\partial\varphi^{k}}{\partial f_{m}} + \frac{\partial\varphi^{m}}{\partial f_{k}} = -2\delta^{km}\frac{\varphi^{j}f_{j}}{f^{i}f_{i}},$$

$$\partial_{\mu}\xi_{\nu} + \partial_{\nu}\xi_{\mu} = -\delta_{\mu\nu}\frac{\partial\varphi^{i}}{\partial f_{i}}, \quad \frac{\partial\varphi^{i}}{\partial f_{j}} = \frac{1}{2}\varepsilon^{ijk\mu}\partial_{\mu}\xi_{k} - \partial^{i}\xi^{j} - \frac{1}{4}\delta^{ij}\partial_{\nu}\xi^{\nu}.$$

The functions which satisfy these constraints are

$$\xi^{\nu} = s^{\nu\mu}x_{\mu} + sx^{\nu} + s^{\nu}, \tag{A3}$$

$$\varphi^{i} = s^{ij}f_{j} - \varepsilon^{ij\rho\sigma}s_{\rho\sigma}f_{j}, \tag{A4}$$

where $s^{\mu\nu}=-s^{\nu\mu}$, s^{ν} and s are arbitrary constants. Substituting (A3) and (A4) into (A1) gives

$$L = s^{\mu\nu}M_{\mu\nu} + s^{\nu}P_{\nu} + sD.$$

A generalization of Connes-Kreimer Hopf algebra

Jungyoon Byun
Mathematics, University of Pennsylvania, Philadelphia, Pennsylvania 19104

(Received 21 March 2005; accepted 19 May 2005; published online 5 July 2005)

"Bonsai" Hopf algebras, introduced here, are generalizations of Connes-Kreimer Hopf algebras, which are motivated by Feynman diagrams and renormalization. We show that we can find operad structure on the set of bonsais. We introduce a differential on these bonsai Hopf algebras, which is inspired by the tree differential. The cohomologies of these are computed here, and the relationship of this differential with the appending operation $*$ of Connes-Kreimer Hopf algebras is investigated. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1951591]

I. MOTIVATION

Kreimer (1998) discovered a Hopf algebra structure on Feynman diagrams and the forest formula of perturbative quantum field theory. Connes and Kreimer (1999) suggested the representation of Feynman graphs using rooted tree diagrams and represented the Hopf algebra structure with the notion of cuts of tree diagrams. That expression is as follows: let us consider a Feynman diagram in ϕ^3 theory as in Fig. 1.

Figure 1 is a 1-loop graph. Now let us look at another loop having subloops in Fig. 2.

In Kreimer's expression of a Feynman diagram using decorated rooted trees (Connes and Kreimer, 1999), if the loop of Fig. 1 is labeled 1 (in Kreimer's context, this label indicates a specific shape of loop. So, later in this paper, if every loop in the Feynman diagram has the same shape, we do not need this label), the loop of Fig. 2 is expressed as in Fig. 3. In Fig. 2, the loops labeled 2 are immediate subloops of loop 1, and the loop 3 is an immediate subloop of the lower loop 2 and not of loop 1.

In the Connes and Kreimer context, we call a connected rooted tree, which corresponds to a connected Feynman graph, a *tree* and we call a diagram of trees having more than one connected component a *forest*.

The Connes-Kreimer Hopf algebra $\mathcal{H}_K$ is a Hopf algebra with forests of rooted trees as basis elements (see Sec. III for details).

In Fig. 2, the author observed that the biggest loop cannot include more than three immediate subloops of the shape of Fig. 1. Hence, in the tree diagram, the vertex labeled 1 cannot have more than three subsidiary vertices labeled 1, and so the rooted tree of Fig. 3 cannot have a ramification number (or arity, branch number) greater than 3 at the root.

So, in the ϕ^3 theory in which the only allowed loop is that of Fig. 1, the corresponding tree diagrams are forbidden to have ramification number greater than 3. The theory of such ramification number bounded trees is our main interest in this paper. We will call them *bonsais*.

For a more precise description of Feynman diagrams, let us consider the positions of subloops in a loop. For the loops having subloops like Fig. 2, in the context of Connes and Kreimer (unpublished), sometimes we need to indicate which subloop is shrinking and what position is available for a subloop. For that, we label each corner of the loop in Fig. 4 and change that loop into a tree as shown in Fig. 4, by expressing a subloop as a subsidiary vertex in the tree diagram and attaching the labels representing the subloop positions to the edges.

The tree diagram of Fig. 4 asssigns the numbers of the occupied corners in the big loop to edges of the tree. Note that there is no edge numbered 2. This means there is no subloop on the corner 2. We easily see that, in this expression, the left tree of Fig. 5 is allowed but the right tree of Fig. 5 is not.

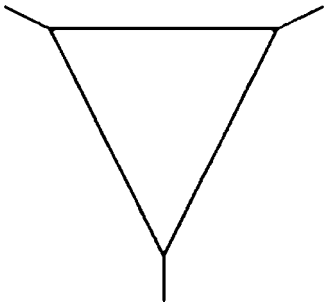

FIG. 1.

II. MAIN RESULTS

Definition 2.1: *We define a Hopf algebra which has the same operations as in the Connes-Kreimer Hopf algebra, and whose basis elements are forests of* trees having ramification numbers at each vertex smaller than or equal to m and under each vertex v, each subsidiary edge of v has labels from $1,2,\ldots,m$ without duplication. *We call this Hopf algebra the* m-bonsai Hopf algebra $\mathcal{H}_{b,m}$. In $\mathcal{H}_{b,m}$, *each tree is called a* m-bonsai.

As in Connes and Kreimer (1999), we can show the following.

Theorem 2.1: $\mathcal{H}_{b,m}$ *is a Hopf algebra*.

As in Connes and Kreimer (1999), when we define an *appending operation*,

$$T * T' = \Sigma \text{ (a bonsai obtained by connecting the root of } T \text{ to a vertex } v \text{ of } T' \text{ with one edge, where the added edge has every possible label)}.$$

(An example of the $*$ operation is in Fig. 11.)

Theorem 2.2: *The operation* $*$ *is pre-Lie, and we have* $\mathcal{H}_{b,m}=\mathcal{U}(\mathcal{L})^{\vee}$, *where* $V^{\vee}$ *is the dual of* V.

In the m-bonsai Hopf algebra, the set of m-bonsais has a structure of an operad, thus there is a natural analog of the tree differential [as in Markl, Shnider, and Stasheff (2002)]. We call it the *vertex-appending differential* ∂ (Definition 9.1).

Then, mainly using the Künneth theorem, we can calculate the cohomology groups of ∂ as follows.

Theorem 2.3: *In m-bonsai*,

$$H^i(\mathcal{H}_{b,m},\partial) = \begin{cases} k\frac{(mn)!}{((m-1)n+1)!n!} & \text{if } i=(2m-1)n+1,\ n\geqslant 0, \\ 0 & \text{otherwise}. \end{cases}$$

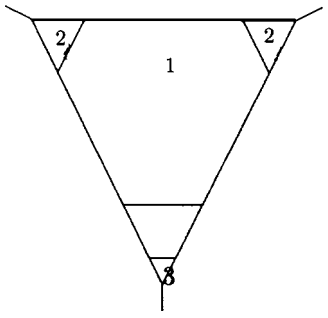

FIG. 2.

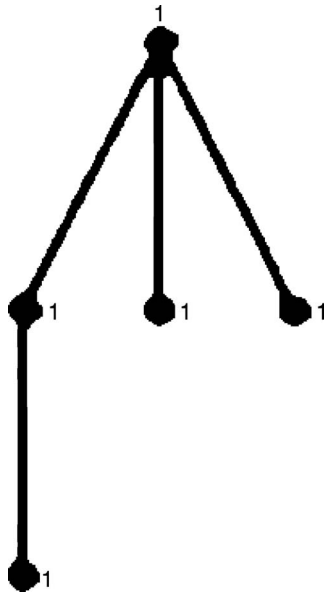

FIG. 3.

Here, $(mn)!/[(m-1)n+1]!n!$ is the number of rooted trees consisting of n of m-corollas, which is called the m-Catalan number. When $m=2$, this number is just the Catalan number. Representatives of H^i are Σ (a bonsai obtained by appending edges to all tips of a rooted tree every vertex of which except tips has ramification number m, one edge to each tip, with every possible label).

When we define $T_1 *_1 T_2$, which is the deviation from ∂ being a derivation of $*$ as

$$T_1 *_1 T_2 = (\partial T_1) * T_2 + T_1 * (\partial T_2) - \partial(T_1 * T_2),$$

we have the following.

Theorem 2.4: *With coefficients mod 2,*

$$T_1 *_1 T_2 = \Sigma \text{ (}a \text{ bonsai obtained by connecting a tip } v \text{ of } T_2 \text{ and the root of } T_1 \text{ with one--edge, and attaching an edge to } v\text{, added edge have every admissible label)} + \Sigma \text{ (}a \text{ bonsai obtained by connecting a nontip of } T_2 \text{ and the root of } T_1 \text{ with two--edge ladder, having every possible label)}$$

and

$$\partial(T_1 *_1 T_2) = (\partial T_1) *_1 T_2 + T_1 *_1 (\partial T_2).$$

We provide an example in Fig. 6.

Now, let us consider another Hopf algebra, having the same operations but the trees having ramification numbers at each vertex smaller than or equal to m but no edge labels, and call it

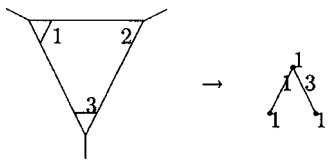

FIG. 4.

FIG. 5.

clear-edged m-bonsai Hopf algebra $\mathcal{H}_{c,m}$. (In other words, a clear-edged m-bonsai is an m-bonsai without edge labels.)

Clear-edged m-bonsai Hopf algebras still represent Feynman graphs, actually more physically relevant, and also appear in the tree diagrams of "open-closed homotopy algebra (OCHA)" [Kajiura and Stasheff (unpublished)].

Then we can define the *vertex-appending differential* similarly to the case of m-bonsai. For example, in planar clear-edged 3-bonsai, we can get an example like Fig. 7.

The cohomology groups of the vertex-appending differential in clear-edged bonsai are not as easy to calculate as in m-bonsai and we have just partial results as follows:

We first define a specific form of bonsai S called "seedling" (Definition 11.3), and then we define the complexes $(\mathbf{C}^{S,*},\partial)$. Then we can show that the cohomology of the whole bonsai complex $H^i=\oplus H^i(S)$, where the sum is over all seedlings.

By the definition of seedling, when $S_1,S_2,\ldots,S_n$ are seedlings, the new bonsai S obtained by appending the roots of each S_i's to a single new root is a seedling again. There is an example in Fig. 8.

On the way to find the relationship of $H(S)$ and $H(S_1),\ldots,H(S_n)$, we have a definition of a bonsai called *grafting seedlings* $(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n)$ (Definition 11.6), a complex $\{\mathbf{K}^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))\}$ (Definition 11.8) and the following.

Theorem 2.5: *When* $H^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))$ *is the ith cohomology group of the complex* $\mathbf{K}^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))$, *the ith cohomology group* H^i *of clear-edged m-bonsai is*

$$H^i=\bigoplus_{S\ \text{is a grafting seedling}} H^i(S),$$

and

$$H^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))=\bigoplus_{j_1+\ldots+j_n=i-m}[H^{i_1}(S_1)\otimes\cdots\otimes H^{i_n}(S_n)]^{\oplus N},$$

where N is combinatorially all determined and

$$P=\deg T_1+\cdots+\deg T_n.$$

Finally, as in the case of m-bonsai, we have again the following.

Theorem 2.6: *For any clear-edged m-bonsai* T_1 *and* T_2, $\partial(T_1*_1T_2)=(\partial T_1)*_1T_2+T_1*_1\partial T_2$ *with coefficients mod 2.*

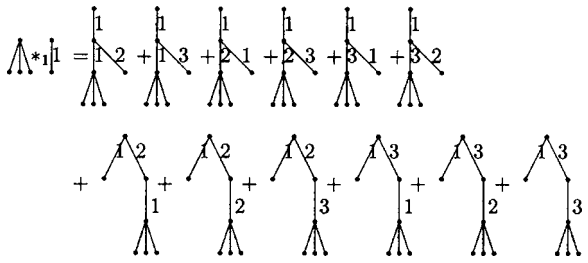

FIG. 6.

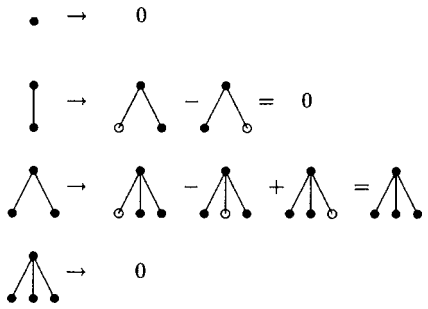

FIG. 7.

III. BONSAI HOPF ALGEBRA

As seen in the last section, loops in Feynman diagrams of a specific theory have a maximum number of immediate subloops. In the example of the preceeding section, the maximum number is 3 and each edge of the tree diagram corresponding to a Feynman diagram has label 1, 2 or 3.

From this motivation, we define the following.

Definition 3.1: A simple cut *of rooted tree is a cut of edges such that at any vertex of T, the path between it and the root has at most one cut, $P_c(T)$ is the part of T cut off by c and $R_c(T)$ is the part of T remaining after cut c.*

Definition 3.2: Let $\mathcal{H}_{b,m}$ be the vector space having as its basis the forests consisting of trees whose vertices have ramification numbers $\leqslant m$ and whose edges are labeled by numbers in $1,2,\ldots,m$.

We equip this $\mathcal{H}_{b,m}$ with operations, as in Connes and Kreimer (1999),

$$(\textit{multiplication})\ m(T_1T_2\cdots T_m,S_1S_2\cdots S_n)=T_1\cdots T_mS_1\cdots S_n \quad (T_i,S_j \textit{ are trees, } m \textit{ is commutative}), \tag{1}$$

$$(\textit{diagonal})\ \Delta(T)=T\otimes 1+\sum_c P_c(T)\otimes R_c(T)\ (T \textit{ is a tree}),$$

$$\Delta(T_1\cdots T_n)=\Delta(T_1)\cdots\Delta(T_n), \tag{2}$$

$$(\textit{antipode})\ S(T)=-\sum_c S(P_c(T))R_c(T)\ (T \textit{ is a tree}),$$

$$S(1)=1,\ S(v)=-v\ (\textit{where } v \textit{ is the one-vertex bonsai}),$$

$$S(T_1\cdots T_n)=S(T_n)\cdots S(T_1), \tag{3}$$

where c runs over simple cuts of T including $c=\emptyset$, and a counit function

$$\epsilon:\mathcal{H}_{b,m}\to\mathcal{H}_{b,m} \quad \textit{such that } \epsilon(1)=1 \quad \textit{and} \quad \epsilon(f)=0 \quad \textit{if a forest } f\neq 1. \tag{4}$$

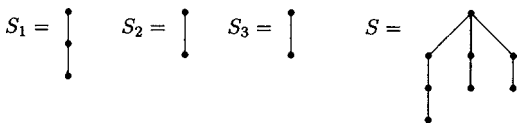

FIG. 8.

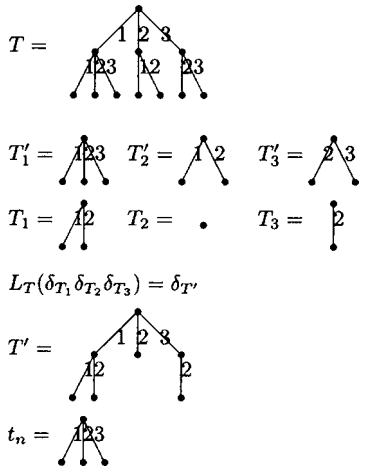

FIG. 9.

We call the rooted tree T an m-bonsai *and* $\mathcal{H}_{b,m}$ *the m*-bonsai Hopf algebra.

It will be proved in the next section that this vector space $\mathcal{H}_{b,m}$ is actually a Hopf algebra.

Definition 3.3: Sometimes we will ignore the positions of subloops in Feynman graphs and use trees without labels on edges. Then the trees in the forests corresponding to the Feynman graphs have no label on their edges. In this case, we denote the vector space having a basis consisting of forests of planar trees as $\mathcal{H}_{c,m}$*, where m is the maximum of ramification number of each vertex in the trees of the forests in* $\mathcal{H}_{c,m}$*. We equip* $\mathcal{H}_{c,m}$ *with operations* (1)–(4) *in Definition 3.2. Then we call that Hopf algebra* planar clear-edged *m*-bonsai Hopf algebra.

IV. BASIC RESULTS RELATED TO HOPF ALGEBRAS

In order to develop a basic theorem related to Lie algebras, let us adapt Connes and Kreimer (1999) to our bonsai language and get some basic results.

In order to prove that our Hopf algebras are actually Hopf algebras and derive some algebraic results, let us give another expression of bonsai Hopf algebras and their elements.

First we give the following.

Definition 4.1: For a bonsai T, deg(*T*) *is the number of vertices of T*.

For each p, we let Σ_p be the set of bonsai T such that $\deg(T) \leqslant p$ with the restriction of ramification numbers by m, and let $\mathcal{H}_p$ be the polynomial commutative algebra generated by the symbols,

$$\delta_T, \quad T \in \Sigma_p. \tag{5}$$

We define a coproduct on $\mathcal{H}_p$ by

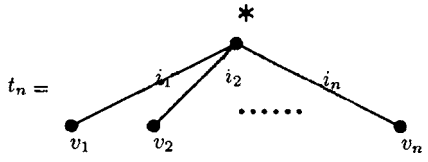

FIG. 10.

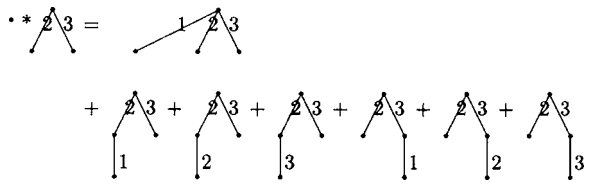

FIG. 11.

$$\Delta\delta_T = \delta_T \otimes 1 + \sum_c \left(\prod_{P_c(T)} \delta_{T_i} \right) \otimes \delta_{R_c(T)}, \tag{6}$$

where the last sum is over all simple cuts including $c=\emptyset$, while the product $\Pi_{P_c(T)}$ is over the cut branches. Sometimes $\Pi_{P_c(T)}\delta_{T_i}$ is written $\delta_{P_c(T)}$. The antipodal map S is given as

$$S(1) = 1, \tag{7}$$

$$S(\delta_T) = -\delta_T - \sum_{\text{simple cuts } c\neq\emptyset \text{ of } T} S(\delta_{P_c(T)})\delta_{R_c(T)}. \tag{8}$$

We let $\mathcal{H}_{b,m}=\cup\mathcal{H}_p$ and extend the maps on $\mathcal{H}_p$ to $\mathcal{H}_{b,m}$. Coassociativity of Δ and $m((S\otimes \mathrm{id})\Delta)=\epsilon$ can be shown just by introducing the notion of double cuts of T. But in order to emphasize the algebraic aspect of the definition, let us give another proof of the following theorem.

Theorem 4.1: Δ *is coassociative*.

Proof: It is enough to check

$$(\mathrm{id}\otimes\Delta)\Delta\delta_T = (\Delta\otimes\mathrm{id})\Delta\delta_T \quad \forall\, T\in\Sigma_p, \tag{9}$$

where T is a tree in $\mathcal{H}_{b,m}$. Define $L_T:\mathcal{H}_{b,m}\to\mathcal{H}_{b,m}$ as follows: Let $T'_1,\ldots,T'_n$ be the subsidiary branches of the root of T in T. Let T_{n_i} be a subtree of T'_{n_i} whose root is the root of T'_{n_i}. Define T' to be the tree obtained by appending T_{n_i}'s to a new root $*$ and the edge connecting $*$ and the root of T_{n_i} is labeled the same as the edge connecting the root of T and the root of T'_{n_i}. Then $L_T(\delta_{T_{n_1}}\cdots\delta_{T_{n_p}})=\delta_{T'}$. If some T_j is not a subsidiary branch of the root in T, $L_T(\delta_{T_1}\cdots\delta_{T_n})$ is 0. (An example of this notation is in Fig. 9.)

First let us show that

$$\Delta\circ L_T(a) = L_T(a)\otimes 1 + (\mathrm{id}\otimes L_T)\circ\Delta(a), \tag{10}$$

where $a=\delta_{T_1}\delta_{T_2}\cdots\delta_{T_n}$ and $T_1,\ldots,T_n$ are all subsidiary branches of the root of T in T so that $L_T(a)=\delta_T$. From (6), we get

$$\Delta(L_T(a)) - L_T(a)\otimes 1 = \sum_c \left(\prod_{P_c} \delta_{T'_i} \right) \otimes \delta_{R_c}, \tag{11}$$

where all simple cuts of T (including $c=\emptyset$) are allowed. Moreover,

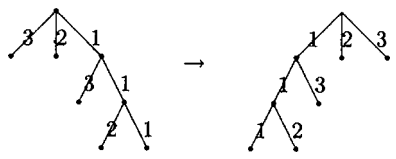

FIG. 12.

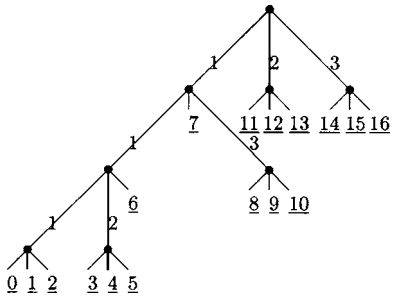

FIG. 13.

$$\Delta(a) = \prod_{i=1}^{n} \left(\delta_{T_i} \otimes 1 + \sum_{c_i} \left(\prod_{P_{c_i}} \delta_{T_{i_j}''} \right) \otimes \delta_{R_{c_i}} \right), \tag{12}$$

where again all simple cuts c_i of T_i are allowed.

Let t_n be the corolla with root $*$ and n other vertices v_i labeled by $i_1, \ldots, i_n$, where i_j is the label of the edge in T connecting the root of T and the vertex of T_j', all directly connected to the root $*$, as in Fig. 10.

We view t_n in an obvious way as a subgraph of the tree T, where $*$ is the root of T and the vertex v_i is the root of T_i, i.e., we can get T by attaching the root of T_i to the vertex v_i of t_n. Given a simple cut c of T we get by restriction to the corolla subgraph $t_n \subset T$ a cut of t_n. It is characterized by the subset $I = \{i \,|\, (*, v_i) \in c\} \subset \{1, \ldots, m\}$. The simple cut c is uniquely determined by the restriction c_i of c to each subtree T_i'. Thus the simple cuts c_i of T are in one to one correspondence with the various terms of the expression (12), namely the $\Pi_{k \in I}(\delta_{T_k} \otimes 1) \Pi_{i \in \{1,\ldots,m\}-I} \Pi_{P_{c_i}} \delta_{T_{i_j}''} \otimes \delta_{R_{c_i}}$. So, applying $\mathrm{id} \otimes L$ to (12) and comparing with (11), we get (10).

Now let us show (10) by induction. We have,

$$\Delta \delta_\bullet = \delta_\bullet \otimes 1 + 1 \otimes \delta_\bullet, \tag{13}$$

where $\bullet$ is the one-vertex bonsai, so that $\mathcal{H}_1$ is coassociative. Let us assume that $\mathcal{H}_n$ is coassociative and prove it for $\mathcal{H}_{n+1}$. It is enough to check (9) for the generators δ_T, with $\deg(T) \leqslant n+1$. We have $\delta_T = L_T(\delta_{T_1} \delta_{T_2} \cdots \delta_{T_m}) = L_T(a)$ where the degrees of all T_j are $\leqslant n$, i.e., $a \in \mathcal{H}_n$. Using (10) we can replace $\Delta \delta_T$ by

$$L_T(a) \otimes 1 + (\mathrm{id} \otimes L_T) \Delta(a), \tag{14}$$

where Δ is the coassociative coproduct in $\mathcal{H}_n$.

The first term of (9) is then

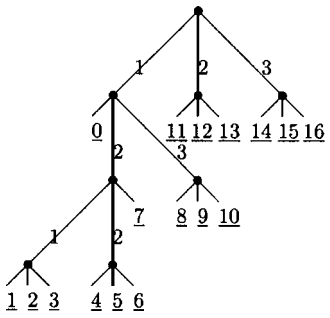

FIG. 14.

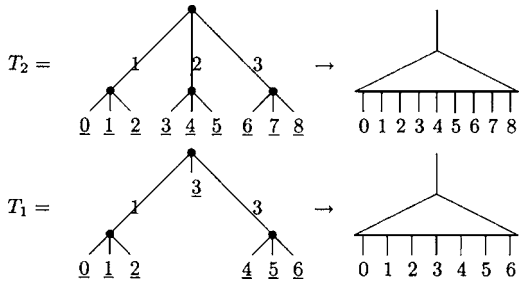

FIG. 15.

$$(\mathrm{id} \otimes \Delta)(L_T(a) \otimes 1 + (\mathrm{id} \otimes L_T)\Delta(a)) = L_T(a) \otimes 1 \otimes 1 + \Sigma a_{(1)} \otimes \Delta \circ L_T a_{(2)}, \tag{15}$$

where $\Delta(a) = \Sigma a_{(1)} \otimes a_{(2)}$, which by (10) gives

$$L_T(a) \otimes 1 \otimes 1 + \Sigma a_{(1)} \otimes L_T a_{(2)} \otimes 1 + \Sigma a'_{(1)} \otimes a'_{(2)} \otimes L_T a'_{(3)}, \tag{16}$$

where

$$(\Delta \otimes \mathrm{id})\Delta(a) = (\mathrm{id} \otimes \Delta)\Delta(a) = \Sigma a'_{(1)} \otimes a'_{(2)} \otimes a'_{(3)} \tag{17}$$

by induction hypothesis on n, since $a \in \mathcal{H}_n$.

The second term of (9) is $\Delta \circ L(a) \otimes 1 + \Sigma \Delta a_{(1)} \otimes L a_{(2)}$, which by (10) gives,

$$L(a) \otimes 1 \otimes 1 + \Sigma a_{(1)} \otimes L a_{(2)} \otimes 1 + \Sigma a'_{(1)} \otimes a'_{(2)} \otimes L a'_{(3)}. \tag{18}$$

Thus we conclude that Δ is coassociative.

Theorem 4.2: $m((S \otimes \mathrm{id})\Delta) = \epsilon$.

Proof: We have $m((S \otimes \mathrm{id})\Delta)(1) = m(S \otimes \mathrm{id})(1 \otimes 1) = S(1)1 = 1 = \epsilon(1)$. And when $\delta_T \neq 1$,

$$\begin{aligned} m((S \otimes \mathrm{id})\Delta)(\delta_T) &= m\left((S \otimes \mathrm{id})\left(\delta_T \otimes 1 + \sum_{\text{simple cuts } c} \delta_{P_c(T)} \otimes \delta_{R_c(T)}\right)\right) = S(\delta_T) \\ &\quad + m\left(\sum_{\text{simple cuts } c} S(\delta_{P_c(T)}) \otimes \delta_{R_c(T)}\right) = S(\delta_T) + \sum_{\text{simple cuts } c} S(\delta_{P_c(T)})\delta_{R_c(T)} = 0, \end{aligned} \tag{19}$$

where the last equality is by the definition of the antipodal map S.

V. LIE ALGEBRA $\mathcal{L}^1$

Let $\mathcal{L}^1 \subset \mathcal{H}^\vee_{b,m}$ be the linear space having basis $\{Z_T | T \in \mathcal{H}_{b,m}$ is a tree$\}$, where δ_T is defined as

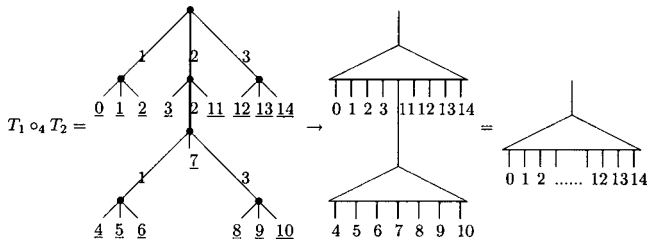

FIG. 16.

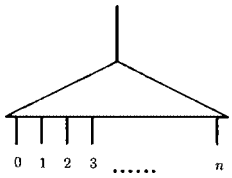

FIG. 17.

$$\langle Z_T, \delta_T \rangle = 1 \tag{20}$$

and

$$\langle Z_T, P(\delta_{T_i}) \rangle = (\partial / \partial \delta_T P)(0) \tag{21}$$

for each rooted tree T.

We introduce an operation on $\mathcal{L}^1$ by

$$Z_{T_1} * Z_{T_2} = \sum_T n(T_1, T_2; T) Z_T, \tag{22}$$

where the integer $n(T_1, T_2; T)$ is determined as the number of simple cuts c with cardinality $|c| = 1$ of bonsai T such that the cut branch is T_1 while the remaining trunk is T_2.

With a notational abuse such as $T = Z_T$, we have an example of $*$ in Fig. 11.

In this section, we will show that $\mathcal{L}^1$ is a Lie algebra and the Hopf algebra $\mathcal{H}_{b,m}$ is the dual of the enveloping algebra of $\mathcal{L}^1$.

Theorem 5.1: $\deg(T)$ defines a grading of the Lie algebra $\mathcal{L}^1$.

Proof: If we write $Z_{T_1} * Z_{T_2} = \Sigma\, Z_T$, then the number of vertices in T is the sum of numbers of vertices in T_1 and T_2.

Definition 5.1: We define the bracket $[Z_{T_1}, Z_{T_2}] = Z_{T_1} * Z_{T_2} - Z_{T_2} * Z_{T_1}$.

Theorem 5.2: *(a) The bracket of the previous definition makes* $\mathcal{L}^1$ *a Lie algebra. (b) The Hopf algebra* $\mathcal{H}_{b,m}$ *is the dual of the enveloping algebra of the Lie algebra* $\mathcal{L}^1$.

First we define the associator

$$A(T_1, T_2, T_3) := Z_{T_1} * (Z_{T_2} * Z_{T_3}) - (Z_{T_1} * Z_{T_2}) * Z_{T_3}. \tag{23}$$

and see the following.

Lemma 1: $A(T_1, T_2, T_3) = \Sigma n(T_1, T_2, T_3; T) Z_T$, where the integer $n(T_1, T_2, T_3; T)$ is the number of simple cuts c of T such that the number of elements $|c|$ of c is 2 and the two branches cut out from T_3 by c are T_1, T_2 while the remaining trunk $R_c(T) = T_3$.

Proof: When we evaluate (23) against Z_T we get the coefficient

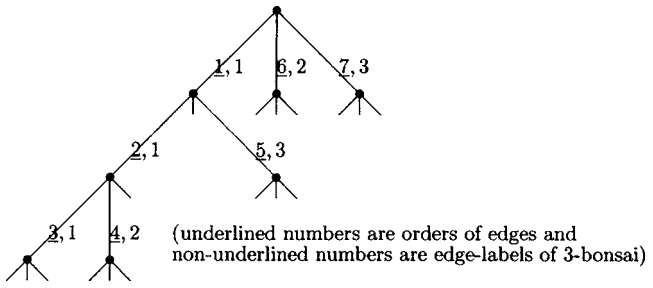

FIG. 18.

$$\sum_{T'} n(T_1,T';T)n(T_2,T_3;T') - \sum_{T''} n(T_1,T_2;T'')n(T'',T_3;T). \tag{24}$$

The first term corresponds to pairs of cuts, c, c' of T with $|c|=|c'|=1$ and where c' is a cut of $R_c(T)$. These pairs of cuts fall into two classes either $c\cup c'$ is an admissible cut or it is not. The second sum corresponds to pairs of cuts c_1, c_1' of T such that $|c_1|=|c_1'|=1$, $R_{c_1}(T)=T_3$ and c_1' is a cut of $P_{c_1}(T)$. In such a case $c_1\cup c_1'$ is never an admissible cut so the difference (24) amounts to subtracting from the first sum the pairs c, c' such that $c\cup c'$ is not an admissible cut. This gives

$$A(T_1,T_2,T_3) = \sum_T n(T_1,T_2,T_3;T)Z_T, \tag{25}$$

where $n(T_1,T_2,T_3;T)$ is the number of admissible cuts c of T of cardinality 2 such that the two cut branches are T_1 and T_2, and T_3 is the remaining trunk.

Now for the theorem, we have the following.

Proof: (a) By the lemma, it is clear that

$$A(T_1,T_2,T_3) = A(T_2,T_1,T_3). \tag{26}$$

Now compute $[[Z_{T_1},Z_{T_2}],Z_{T_3}]+[[Z_{T_2},Z_{T_3}],Z_{T_1}]+[[Z_{T_3},Z_{T_1}],Z_{T_2}]$. We can write it as a sum of 12 terms,

$$\begin{aligned}(T_1*T_2)*T_3 - (T_2*T_1)*T_3 - T_3*(T_1*T_2) + T_3*(T_2*T_1) + (T_2*T_3)*T_1 - (T_3*T_2)*T_1\\ - T_1*(T_2*T_3) + T_1*(T_3*T_2) + (T_3*T_1)*T_2 - (T_1*T_3)*T_2 - T_2*(T_3*T_1)\\ + T_2*(T_1*T_3) = -A(T_1,T_2,T_3) + A(T_2,T_1,T_3) - A(T_3,T_1,T_2) + A(T_3,T_2,T_1) - A(T_2,T_3,T_1)\\ + A(T_1,T_3,T_2) = 0.\end{aligned} \tag{27}$$

(b) Let P and Q be polynomials of δ_T's. By the definition of Z_T, Z_T vanishes when paired with any monomial $\delta_{T_1}^{n_1}\cdots\delta_{T_k}^{n_k}$ except when this monomial is δ_T. Since $P\to P(0)$ is the counit ϵ of $\mathcal{H}_{b,m}$ and since Z_T satisfies

$$\langle Z_T,PQ\rangle = (\partial/\partial\delta_T PQ)(0) = (\partial/\partial\delta_T P)(0)Q(0) + P(0)(\partial/\partial\delta_T Q)(0) = \langle Z_T,P\rangle\epsilon(Q) + \epsilon(P)\langle Z_T,Q\rangle, \tag{28}$$

it follows that the coproduct of Z_T is

$$\Delta Z_T = Z_T\otimes 1 + 1\otimes Z_T. \tag{29}$$

The product of two elements of $\mathcal{H}_{b,m}^\vee$ is defined by

$$\langle Z_1Z_2,P\rangle = \langle Z_1\otimes Z_2,\Delta P\rangle. \tag{30}$$

Since the commutator of two derivations is still a derivation, the subspace of $\mathcal{H}_{b,m}^\vee$ satisfying (36) is stable under bracket. What remains is to show that

$$Z_{T_1}Z_{T_2} - Z_{T_2}Z_{T_1} = [Z_{T_1},Z_{T_2}], \tag{31}$$

where $[Z_{T_1},Z_{T_2}]=Z_{T_1}*Z_{T_2}-Z_{T_2}*Z_{T_1}$ by definition.

Let $\mathcal{H}_0=\mathrm{Ker}\,\epsilon$ be the augmentation ideal of $\mathcal{H}_{b,m}$. By definition of Δ,

$$\Delta\delta_T = \delta_T\otimes 1 + 1\otimes\delta_T + R_T, \tag{32}$$

where $R_T\in\mathcal{H}_0\otimes\mathcal{H}_0$. In fact, we have

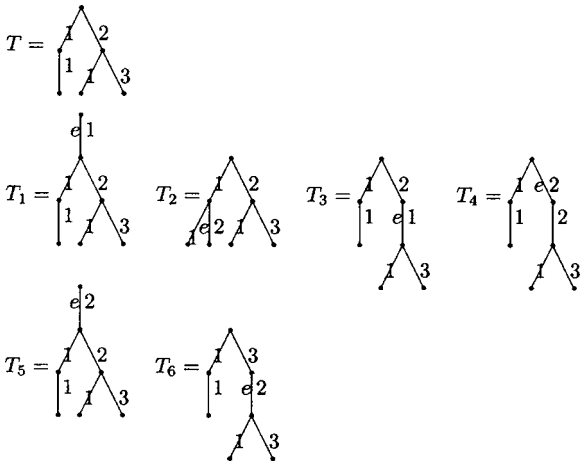

FIG. 19.

$$R_T = \sum_c \delta_{T'_c} \otimes \delta_{T_c} \tag{33}$$

modulo $(\mathcal{H}_0)^2 \otimes \mathcal{H}_0$, where c varies among single cuts of the bonsai tree T, where T_c is the trunk of T that contains the root, and T'_c is the tree which remains. When we compute

$$\langle Z_{T_1} Z_{T_2}, \delta_T \rangle = \langle Z_{T_1} \otimes Z_{T_2}, \Delta \delta_T \rangle, \tag{34}$$

the only part which contributes comes from R_T and it counts the number of ways of obtaining T from T_1 and T_2, which gives (31).

If a map f satisfies

$$\langle f, PQ \rangle = \langle f, P \rangle \epsilon(Q) + \epsilon(P) \langle f, Q \rangle, \tag{35}$$

f is determined by $f(\delta_T) = \langle f, \delta_T \rangle$'s and each of them is a scalar. Since $f(\delta_T) = \Sigma_{T'} f(\delta_{T'}) Z_{T'}(\delta_T)$, f has the form $\Sigma f(\delta_T) Z_T$. Hence $\{Z_T\}$ is a basis of the subspace of $\mathcal{H}^\vee_{b,m}$ consisting of the vectors f satisfying (35).

Since every Z_T satisfies (35) by (28) and $f \in \mathcal{H}^\vee_{b,m}$ satisfies (35) if and only if f satisfies

$$\Delta f = f \otimes 1 + 1 \otimes f, \tag{36}$$

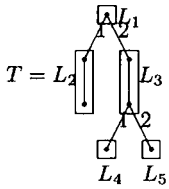
we have $\mathcal{L}^1 = Prim(\mathcal{H}^\vee_{b,m})$ and they are isomorphic as Lie algebras. Since $\mathcal{H}^\vee_{b,m}$ is connected and cocommutative, by the Milnor-Moore theorem, $\mathcal{H}^\vee_{b,m} = \mathcal{U}(Prim(\mathcal{H}^\vee_{b,m})) = \mathcal{U}(\mathcal{L}^1)$ and so $\mathcal{H}_{b,m} = \mathcal{U}(\mathcal{L}^1)^\vee$.

$$d^0(\ \cdot \otimes 1) = e' \left\lfloor 1 \otimes e_{1,1} \right. \ + \ e' \left\lfloor 2 \otimes e_{1,2} \right.$$

$$d^1(\ e' \left\lfloor 1 \otimes e_{1,1}) = \begin{matrix} e'' \\ e' \end{matrix} \left\lfloor \begin{matrix} 1 \\ 1 \end{matrix} \right. \otimes e_{1,1} \wedge e_{2,1} \ + \ \begin{matrix} e' \\ e'' \end{matrix} \left\lfloor \begin{matrix} 1 \\ 1 \end{matrix} \right. \otimes e_{2,1} \wedge e_{1,1}$$

$$+ \ \begin{matrix} e'' \\ e' \end{matrix} \left\lfloor \begin{matrix} 2 \\ 1 \end{matrix} \right. \otimes e_{1,2} \wedge e_{2,1} \ + \ \begin{matrix} e' \\ e'' \end{matrix} \left\lfloor \begin{matrix} 1 \\ 2 \end{matrix} \right. \otimes e_{2,2} \wedge e_{1,1}$$

FIG. 20.



L_1 only grows upward by ii) of Definition 7.1.

FIG. 21.

VI. OPERAD OF *m*-BONSAI

Now let us consider operad theory with respect to the m-bonsai Hopf algebra structure. As seen in the preceding section, for trees $T, T' \in \mathcal{H}_{b,m}$ we can define $T * T'$ and this is a (left) pre-Lie operation. The map $T \mapsto Z_T$ is a pre-Lie isomorphism from the space spanned by trees to $\mathcal{L}^1$. In $\mathcal{H}_{b,m}$, we denote this $\mathcal{L}^1$ as $\mathcal{L}_{b,m}$. We will sometimes allow a notational abuse such as $T = Z_T$ from now on.

Let us start from a rudimentary idea. Every bonsai in $\mathcal{H}_{b,m}$ has a unique form in which for each vertex, its subsidiary edges are arranged so that the lower edge label is on the left of the higher edge label as in Fig. 12.

We can number the possible positions in the bonsai of Fig. 12 to append other bonsais as in Fig. 13, the example in $\mathcal{L}_{b,3}$ (the orders of possible appending positions are underlined). When the labeling of Fig. 13 is changed into that of Fig. 14, then the numbering of possible appending positions is also changed.

Then, by taking the standard form of bonsai and ordering the possible positions of appending, we can get the transform of a bonsai into the broomstick diagram used in Markl, Shnider, and Stasheff (2002) like Fig. 15, again in $\mathcal{L}_{b,3}$.

So, we can define $T_1 \circ_i T_2$ as appending T_1 to T_2 at the ith appending position of T_2, and for T_2 and T_1 in Fig. 15, $T_1 \circ_4 T_2$ is given as in Fig. 16.

Then obviously, this $\circ_i$ satisfies the definition of *pre-Lie system* of Gerstenhaber (1963) [it is called *nonsymmetric pseudo-operad* in Markl, Shnider, and Stasheff (2002), but it has a difference in the convention of grading]. When we use the pseudo-operad later, we will give an extra definition, which we give here.

Definition 6.1: When $\{V_i\}$ *is a graded module over a field* k *and* $\circ_i = \circ_i(m,n) : V_m \otimes V_n \to V_{m+n}$ *is an operation satisfying; when* f^m, g^n, *and* h^p *are in* V_m, V_n, *and* V_p, *respectively*,

$$h^p \circ_j (g^n \circ_i f^m) = \begin{cases} g^n \circ_{i+p} (h^p \circ_j f^m) & \text{if } 0 \leqslant j \leqslant i-1, \\ (h^p \circ_{j-i} g^n) \circ_i f^m & \text{if } i \leqslant j \leqslant n+i, \end{cases} \tag{37}$$

then $\{\{V_i\}, \circ_i\}$ *is called a* (left) pre-Lie system.

[In Gerstenhaber (1963) the right pre-Lie system is defined, but we define and use the left pre-Lie system. This is mainly intended for the theory related to Hopf algebra we will argue later.] By the broomstick diagrams shown in Figs. 15 and 16, we have the following.

Definition 6.2: When $W_{m,n}$ *is the vector subspace of* $\mathcal{L}_{b,m}$ *generated by the trees having the number* n *of possible appending positions, and* $T_1 \circ_i T_2$ *is appending* T_1 *to* T_2 *at the appending position* i *of* T_2, *then* $\{\{W_{m,n}\}, \circ_i\}$ *is a left pre-Lie system. It is called* m-bonsai pre-Lie system. *For*

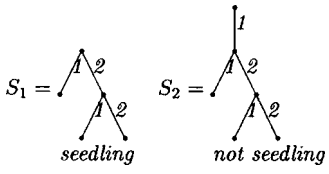


FIG. 22.

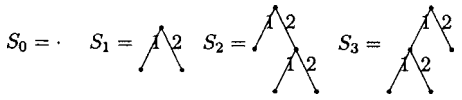

FIG. 23.

trees T which are basis elements of $W_{m,n}$, *n is called the appending degree of T, and denoted* $\deg_{ap}(T)$.

(Graphically, a basis element of $W_{m,n}$ has the broomstick representation like Fig. 17.)

VII. BRANCH-FIXED DIFFERENTIAL

In the next several sections, following the oracle of Markl, Shnider, and Stasheff (2002), we will define some complexes related to bonsais. To get the analogy of the *cobar complex* and the *tree differential* in Sec. 3.1 of Markl, Shnider, and Stasheff (2002), first let us give an order of edges of a bonsai as in Fig. 18, i.e., starting from the root, sweeping around the bonsai counterclockwise and numbering the edges. We call this order the *traversing order*. In the traversing order, e_{k,l_k} is a vector representing the kth edge of a tree T, such that $1 \leqslant l_k \leqslant m$ is the edge label of the kth edge.

Second, let us define a vector space $\mathbf{C}^n$ having basis $T \otimes e_{1,l_1} \wedge \cdots \wedge e_{k,l_k}$, where T is a m-bonsai (not forest) having n edges and the pairs k, l_k run over the labels of edges of T. (If T is a vertex, i.e., a connected bonsai without any edge, then $e_{1,l_1} \wedge \cdots \wedge e_{k,l_k}$ is the constant unit 1.) For later use, we denote this $e_{1,l_1} \wedge \cdots \wedge e_{k,l_k}$ as $\det(T)$ and call it the *determinant term* of T, and call $T \otimes \det(T)$ a *determinanted bonsai*. So the basis element corresponding to the bonsai T of Fig. 18 is $T \otimes e_{1,1} \wedge e_{2,1} \wedge e_{3,1} \wedge e_{4,2} \wedge e_{5,3} \wedge e_{6,2} \wedge e_{7,3} = T \otimes \det(T)$. Let us denote $\mathbf{C} = \oplus \mathbf{C}^m$. Once we define d, we call this complex $(\mathbf{C}, d)$ the *bonsai cobar complex* after the *cobar complex* of Markl, Shnider, and Stasheff (2002).

Third, let us define a map $d^i : \mathbf{C}^i \to \mathbf{C}^{i+1}$ and show that $d^{i+1} \circ d^i = 0$ as follows.

Definition 7.1: Let T be an m-bonsai. Let T′ be a bonsai such that we can obtain T by contracting an edge e′ from T′ and the following conditions are satisfied.

(i) *T′ does not have more branching vertices (i.e., vertices which have the ramification numbers >1) than T,*
(ii) *e′ is not attatched to a branching vertex of T so that e′ becomes a subsidiary edge of that branching vertex.*

We call this T′ a branch-fixed extension *of T.*

For example, for the 3-bonsai T in Fig. 19, T_1, T_3, T_5, and T_6 are all branch-fixed extension of T, but T_2 [violating (i)] and T_4 [violating (ii)] are not.

Then we define $d^i : C^i \to C^{i+1}$ as follows: when $T \in \mathbf{C}^i$,

$$d^i(T) = \sum T' \otimes e'_{j,l_j} \wedge e'_{1,l_1} \wedge \cdots \wedge \widehat{e'_{j,l_j}} \wedge \cdots \wedge e'_{i+1,l_{i+1}}, \tag{38}$$

where the sum runs over T', which is a branch-fixed extension of T having an edge e added to T and that e is denoted e'_{j,l_j} in the edge-ordering of T'.

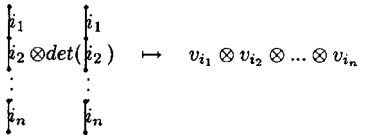

FIG. 24.

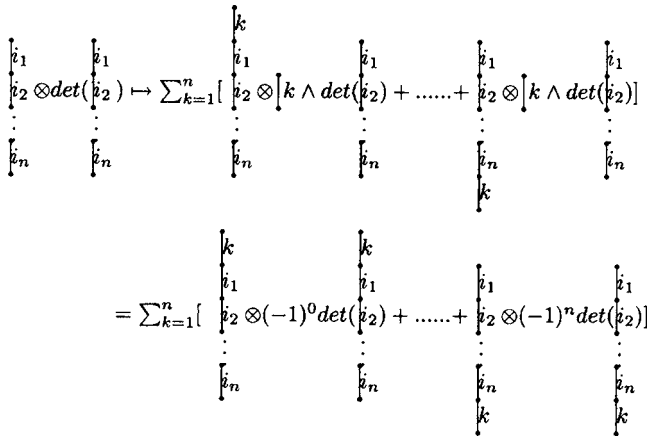

FIG. 25.

Theorem 7.1: $d^{i+1}\circ d^i=0$.

Proof: Suppose T'' is a branch-fixed extension of a bonsai T' with added edge e'', which is a branch-fixed extension of T with added edge e'. Then, when e'' is e''_{j,l_j} and e' is e''_{k,l_k} in the edge ordering of T'' and $d^{i+1}\circ d^i(T)$ is written as $\Sigma S\otimes f_{1,p_1}\wedge\cdots\wedge f_{i+2,p_{i+2}}$, where S runs over the bonsais obtained by attaching two edges as given in (i) and (ii) in Definition 7.1 and f_{i,p_i}'s are the edges of $S, T''\otimes e''_{1,l_1}\wedge\cdots\wedge e''_{i+2,l_{i+2}}$ can be obtained only in two ways.

(i) Adding e' first to T, then the component of $T''\otimes e''_{1,l_1}\wedge\cdots\wedge e''_{i+2,l_{1+2}}$ is $T''\otimes e''_{j,l_j}\wedge e''_{k,l_k}\wedge e''_{1,l_1}\wedge\cdots\wedge\widehat{e''_{j,l_j}}\wedge\cdots\wedge\widehat{e''_{k,l_k}}\wedge\cdots\wedge e''_{i+2,l_{i+2}}$.

(ii) Adding e'' first to T, then the component of $T''\otimes e''_{1,l_1}\wedge\cdots\wedge e''_{i+2,l_{1+2}}$ is $T''\otimes e''_{k,l_k}\wedge e''_{j,l_j}\wedge e''_{1,l_1}\wedge\cdots\wedge\widehat{e''_{j,l_j}}\wedge\cdots\wedge\widehat{e''_{k,l_k}}\wedge\cdots\wedge e''_{i+2,l_{i+2}}$.

Since the orders of e''_{k,l_k} and e''_{j,l_j} are different in the wedge products, the sum of two terms in (i) and (ii) is 0, and this is true for all components of $d^{i+1}\circ d^i(T)$. Hence $d^{i+1}\circ d^i=0$.

We call this boundary map d^i the *branch-fixed differential*. A simple example is given in Fig. 20. We will study the cohomology of this $\{d^i\}$, but before that, following Markl, Shnider, and Stasheff (2002), let us see an important property of this bonsai complex in the next section.

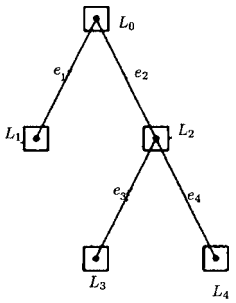

FIG. 26.

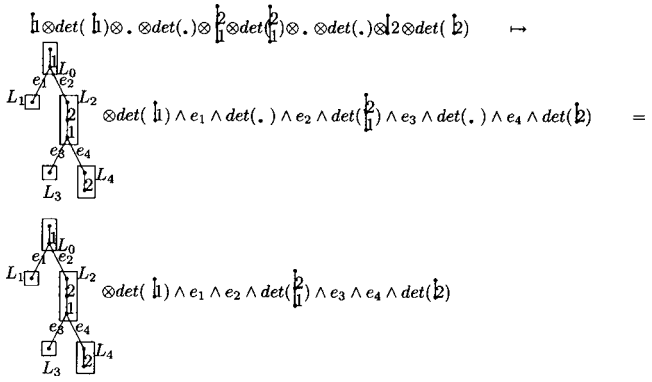

FIG. 27.

VIII. COHOMOLOGY OF BRANCH-FIXED DIFFERENTIAL

In this section, we study the cohomology theory of the cochain complex $\{C^i, d^i\}$, where C^i is the bonsai cobar complex and d^i is the branch-fixed differential. We will define a kind of bonsai called *seedling* and a complex $\{\mathbf{C}^{S,j}, d^{i+j}\}_{j\geq 0}$ called *thread* and show that the cohomology groups of $\{C^i, d^i\}$ are the direct sum of cohomology groups of threads $\{\mathbf{C}^{S,j}, d^{i+j}\}_{j\geq 0}$.

First, let us give some definitions.

Definition 8.1: A bonsai every vertex, of which has the ramification number 0 or 1, is called a ladder. *In other words, a ladder is a bonsai which has no branching vertex.*

Definition 8.2: If a bonsai T has an edge, a vertex v which is an end of only one edge and is not the root, is called a tip. *If a bonsai T is a one-vertex bonsai, the root v is a tip.*

By the definition of d^i, all terms in $d^i(T)$ are of the form $\pm T' \otimes e \wedge \det(T)$, where T' runs over bonsais obtained by adding an edge e to T so that (i) and (ii) of Definition 7.1 hold. So T' has the form of extending a subladder of T which does not contain the subsidiary edges of branching vertices, as in the example of Fig. 21, boxed subladders of which are denoted $L_1, L_2, \ldots, L_5$.

So, the action of d^i on $T \otimes \det(T)$ is by extending a ladder of T, getting an edge e and changing $\det(T)$ into $e \wedge \det(T)$. Acting by d^i's on $T \otimes \det(T)$, the possible bonsais appearing in the $d^i(T)$ are obtained by extending a subladder of T as in the example of Fig. 21.

Keeping this intuitive fact in mind, we have some definitions.

Definition 8.3: A seedling *is an m-bonsai all of whose vertices other than tips are branching vertices. For example, in 2-bonsai, S_1 of Fig. 22 is a seedling, but S_2 is not, because the root vertex is not a branching vertex. In other words, a seedling is a bonsai which cannot be obtained from another bonsai by adding an edge so that (i) and (ii) of Definition 7.1 are satisfied.*

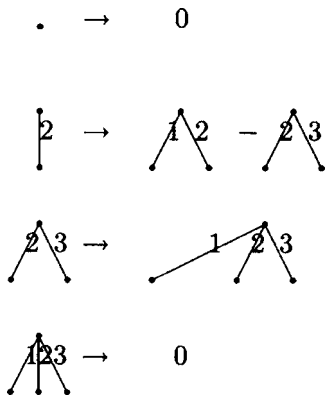

FIG. 28.

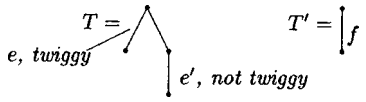

FIG. 29.

Definition 8.4: Let $\mathbf{C}^{S,0}$ *be the submodule of* $\mathcal{C}^i$, *where S is a seedling and i is the number of edges of S, generated by* $S \otimes \det(S)$. *Let* $\mathbf{C}^{S,j}(j \geqslant 0)$ *be the submodule of* $\mathcal{C}^{i+j}$ *generated by* $T \otimes \det(T)$, *where T is an m-bonsai obtained by adding j edges to S so that (i) and (ii) of Definition 7.1 are satisfied.*

Then, every $\mathcal{C}^i$ is the direct sum of some $\mathbf{C}^{S,j}$'s and $d(\mathbf{C}^{S,j}) \subset \mathbf{C}^{S,j+1}$. For example, in 2-bonsai, when S_0, S_1, S_2, and S_3 are as given in Fig. 23, we have

$$\mathcal{C}^0 = \mathbf{C}^{S_0,0},$$

$$\mathcal{C}^1 = \mathbf{C}^{S_0,1},$$

$$\mathcal{C}^2 = \mathbf{C}^{S_0,2} \oplus \mathbf{C}^{S_1,0},$$

$$\mathcal{C}^3 = \mathbf{C}^{S_0,3} \oplus \mathbf{C}^{S_1,1},$$

$$\mathcal{C}^4 = \mathbf{C}^{S_0,4} \oplus \mathbf{C}^{S_1,2} \oplus \mathbf{C}^{S_0,3} \oplus \mathbf{C}^{S_1,1},$$

$$\mathcal{C}^5 = \mathbf{C}^{S_0,5} \oplus \mathbf{C}^{S_1,3} \oplus \mathbf{C}^{S_0,3} \oplus \mathbf{C}^{S_1,1},$$

$$\cdots . \tag{39}$$

Definition 8.5: For a given seedling S, when i is the number of edges of S, $\{\mathbf{C}^{S,j}, d^{i+j}\}_{j \geqslant 0}$ *is called a* thread *of S.*

So the cohomology groups of $\{\mathcal{C}^i, d^i\}$ are the direct sum of cohomology groups of threads $\{\mathbf{C}^{S,j}, d^{i+j}\}_{j \geqslant 0}$.

Let us look into each of these threads. For $\mathbf{C}^{S_0,0}$, where S_0 is a vertex, $\mathbf{C}^{S_0,i}$ is the module with the basis $\{T \otimes \det(T)\}$, where T is a ladder with i edges and the boundary maps extend the ladders by adding an edge e and replacing $\det(T)$ with $e \wedge \det(T)$. Let us consider a chain complex which is isomorphic to the thread $\mathbf{C}^{S_0,0}$ of the ladder S_0. For any m-bonsai, consider a vector space V which has a basis $\{v_1, \ldots, v_m\}$, and let $V_n = V^{\otimes n} (n \geqslant 1)$. Then we define a map $\delta^n : V^n \to V^{n+1}$ as

$$v_{i_1} \otimes v_{i_2} \otimes \cdots \otimes v_{i_n} \mapsto \sum_{k=1}^{m} v_k \otimes v_{i_1} \otimes v_{i_2} \otimes \cdots \otimes v_{i_n} + \sum_{k=1}^{m} (-1)^1 v_{i_1} \otimes v_k \otimes v_{i_2} \otimes \cdots \otimes v_{i_n} + \cdots$$
$$+ \sum_{k=1}^{m} (-1)^n v_{i_1} \otimes \cdots \otimes v_{i_{n-1}} \otimes v_{i_n} \otimes v_k, \tag{40}$$

and it is easily seen that this δ^n is a boundary map, so we have made $\{V^n, \delta^n\}$ a cochain complex.

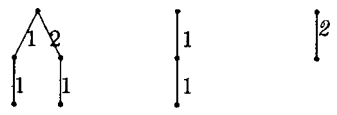

FIG. 30.

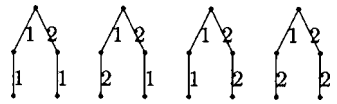

FIG. 31.

By the cochain map f as in Fig. 24, the cochain complexes $\{\mathbf{C}^{S_0,n}, d^n\}$ and $\{V^n, \delta^n\}$ are isomorphic, since d^n acts as in Fig. 25, that is, we have $f \circ \delta^n = d^n \circ f$.

In $\{V^n, \delta^n\}_{n \geqslant 1}$, by the definition of δ^n, inductively we have

$$\delta((v_1 \otimes \cdots \otimes v_i) \otimes v) = \delta(v_1 \otimes \cdots \otimes v_i) \otimes v + (-1)^{i+1}(v_1 \otimes \cdots \otimes v_i) \otimes v \otimes \sum_{k=1}^{m} v_k, \tag{41}$$

where $v_1 \otimes \cdots \otimes v_i \in V^i$ and $v \in V$. Suppose $\delta(\Sigma_{k=1}^m v_k' \otimes v_k) = 0$ where $v_k' \in V^i$, then we have

$$\sum_{k=1}^{m} \delta(v_k') \otimes v_k + (-1)^{i+1}\left(\sum_{k=1}^{m} v_k' \otimes v_k\right) \otimes \sum_{l=1}^{m} v_l = \sum_{l=1}^{m} \left\{ \delta(v_l') - (-1)^k \left(\sum_{k=1}^{m} v_k' \otimes v_k\right)\right\} \otimes v_l = 0. \tag{42}$$

Therefore, we have $(\Sigma_{k=1}^m v_k' \otimes v_k) = (-1)^k \delta(v_l')$ and it is a coboundary. So, $\{V^n, \delta^n\}$ is acyclic, and so is $\{\mathbf{C}^{S_0,n}, d^n\}$.

Here, we can directly calculate $H^0(\mathbf{C}^{S_0,*}) = 0$, since the boundary map image of a one-vertex bonsai is the sum of one-edge bonsais over all labels $1, 2, \ldots, n$. So $\{\mathbf{C}^{S_0,n}, d^n\}$ is acyclic with $H^0 = 0$.

Now for an arbitrary seedling S, when S has n edges, there are $n+1$ vertices and each vertex other than the root has one and only one edge whose branch end is that vertex. When we order the edges of a bonsai T with the shape S as in Fig. 13 and denote them as e_l's $(l = 1, 2, \ldots, n)$, we can denote the branch-end vertex of e_l as v_l and denote the root v_0. Then the bonsais which appear in the basis of $\mathbf{C}^{S,j}$ are obtained by extending the vertices of T into upward-growing ladders, and each ladder grown from v_l is denoted as L_l, as in the example of Fig. 26.

To get the cohomology of $\mathbf{C}^{S,j}$, let us consider the complexes $\mathbf{C}_k^{S_0,p}$, where $k = 0, \ldots, n$ and each of $\mathbf{C}_k^{S_0,p}$ is a copy of $\mathbf{C}^{S_0,p}$, i.e., each of $\mathbf{C}_k^{S_0,p}$ has the basis $\{L_k^p \otimes \det(L_k^p)\}$, where L_k^p is a ladder with p edges. Then we have an isomorphism F between

$$\mathbf{D}^l = \bigoplus_{p_0 + \cdots + p_n = l} \mathbf{C}_0^{S_0,p_0} \otimes \cdots \otimes \mathbf{C}_n^{S_0,p_n} \tag{43}$$

and $\mathbf{C}^{S,l}$ given by

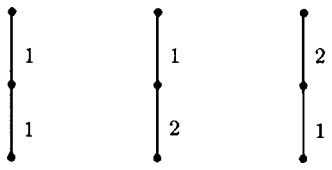

FIG. 32.

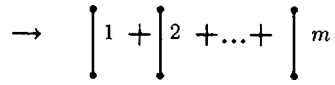

FIG. 33.

$$L_0^{p_0} \otimes \det(L_0^{p_0}) \otimes \cdots \otimes L_n^{p_n} \otimes \det(L_n^{p_n}) \mapsto \Sigma \text{ (the bonsai obtained by setting } L_i^{p_0} \text{ into the place of vertex } v_i) \otimes \det(L_0^{p_0}) \wedge e_1 \wedge \det(L_1^{p_1}) \wedge \cdots \wedge e_n \wedge \det(L_n^{p_n}) \tag{44}$$

as in the example of Fig. 27, for the seedling of Fig. 26.

From now on, we write $L_i^{p_i}$ just as L_i for convenience of writing.

In $T \otimes \det(T) \in \mathbf{C}^{S,l}$, $\det(T)$ is

$$\det(L_0) \wedge e_{1,k_1} \wedge \det(L_1) \wedge \cdots \wedge e_{n,k_n} \wedge \det(L_n), \tag{45}$$

where k_l is the label of the edge e_l, and $d^n(T \otimes \det(T))$ is

$$\Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to one of the } L_i) \otimes f \wedge \det(T)$$

and this is

$$\begin{aligned} &\Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to one of } L_i) \\ &\quad \otimes f \wedge \det(L_0) \wedge e_{1,k_1} \wedge \det(L_1) \wedge \cdots \wedge e_{n,k_n} \wedge \det(L_n) \\ &= \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to one of } L_i) \\ &\quad \otimes (-1)^{\beta} \det(L_0) \wedge e_{1,k_1} \wedge \det(L_1) \wedge \cdots \wedge e_{i,k_i} \wedge f \wedge \det(L_i) \wedge \cdots \wedge e_{n,k_n} \wedge \det(L_n), \end{aligned}$$

where $\beta = (\deg(L_0)+1)+(\deg(L_1)+1)+\cdots+(\deg(L_{i-1})+1)$.

Here, $\det(T')$ is obtained by replacing $\det(L_i)$ with $f \wedge \det(L_i)$ in (45), and we get the sign $(-1)^{\beta}$ since when f is added to L_i, in the ordering of edges of T', the edges of $L_j (j=0,1,\ldots,i-1)$ and edges $e_1, e_2, \ldots, e_i$ are prior to the edges of L_i. So we can conclude that $d(T \otimes \det(T))$ is the sum of $(-1)^{\deg(L_0)+1+\cdots+\deg(L_{i-1})+1} T' \otimes \det(T')$, where T' is the bonsai obtained by adding an edge in the subladder L_i.

Thus, when we construct a coboundary map ∂^l for $\{\mathbf{D}^l\}$, acting on $\mathbf{C}_1^{S_0,p_1} \otimes \cdots \otimes \mathbf{C}_n^{S_0,p_n}$ by

$$\begin{aligned} \partial^l(L_0 \otimes \det(L_0) \otimes \cdots \otimes L_n \otimes \det(L_n)) &= d(L_0 \otimes \det(L_0)) \otimes L_1 \otimes \det(L_1) \otimes \cdots \otimes L_n \otimes \det(L_n) \\ &+ (-1)^{\deg(L_0)+1} L_0 \otimes \det(L_0) \otimes d(L_1 \otimes \det(L_1)) \otimes \cdots \otimes L_n \otimes \det(L_n) + \cdots \\ &+ (-1)^{(\deg(L_0)+1)+\cdots+(\deg(L_{n-1})+1)} L_0 \otimes \det(L_0) \otimes L_1 \otimes \det(L_1) \otimes \cdots \otimes d(L_n \otimes \det(L_n)), \end{aligned}$$

the isomorphism F becomes a cochain isomorphism between $\{\mathbf{D}^l\}$ and $\{\mathbf{C}^{S,l}\}$, and since each $\{\mathbf{C}_k^{S_0,p_k}\}$ is acyclic and $H^0=0$, by the Künneth theorem, $\{\mathbf{D}^l\}$ is acyclic and $H^0=0$, and so is $\{\mathbf{C}^{S,l}\}$.

Then, by a Künneth argument, every thread of $\{\mathbf{C}^{S,j}, d^{i+j}\}$ (i is the number of edges of S) is acyclic with $H^0=0$, and so we have the following.

Theorem 8.1: *$\{\mathcal{C}^n, d^n\}$ is acyclic.*

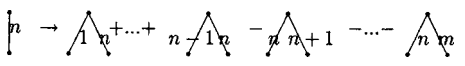

FIG. 34.

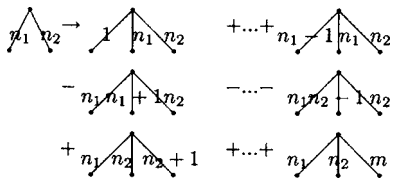

FIG. 35.

IX. VERTEX-APPENDING DIFFERENTIAL

In this section, we consider a differential, different from the ladder-extension. Again, all bonsais of this section are m-bonsais.

Definition 9.1: We define the vertex-appending differential ∂ *as follows; consider a determinanted bonsai* $T\otimes\det(T)$. *Then* $\partial(T\otimes\det(T))$ *is the sum of* $T'\otimes e\wedge\det(T)$, *where* T' *is a bonsai obtained by*

(i) *appending a vertex to* T,
(ii) *except to tips of* T,

and so, getting an edge e.

If there is no available appending position an a bonsai, the map ∂ *assigns 0 to that bonsai.*

For example, in 3-bonsai, we have an example like Fig. 28 (in bonsais, determinant terms are omitted). (Note that one vertex in the first example is also a tip and the fourth bonsai is a cocycle).

First, we have the following.

Theorem 9.1: $\partial^{i+1}\circ\partial^{i}=0$. *That is,* ∂ *is actually a differential.*

Proof: This proof is almost the same as that of Theorem 7.1. Suppose T'' is obtained by appending a vertex to T' with added edge e'' so that (i) and (ii) of Definition 9.1 are satisfied, where T' is obtained by appending a vertex to T with added edge e' so that (i) and (ii) of Definition 9.1 are satisfied. Here, if T' has no available position to append a vertex, then $\partial(T')=0$, so $T''=0$. Otherwise, when e'' is e''_{j,l_j} and e' is e''_{k,l_k} in the edge ordering of T'', in $\partial^{i+1}\circ\partial^{i}(T)$ hits the component $T''\otimes e''_{1,l_1}\wedge\cdots\wedge e''_{i+2,l_{i+2}}$ just by adding the edge e' and e'' to T, and it can be done only in two ways.

(i) Adding e' first to T, then the component of $T''\otimes e''_{1,l_1}\wedge\cdots\wedge e''_{i+2,l_{1+2}}$ is $T''\otimes e''_{j,l_j}\wedge e''_{k,l_k}\wedge e''_{1,l_1}\wedge\cdots\wedge\widehat{e''_{j,l_j}}\wedge\cdots\wedge\widehat{e''_{k,l_k}}\wedge\cdots\wedge e''_{i+2,l_{i+2}}$.
(ii) Adding e'' first to T, then the component of $T''\otimes e''_{1,l_1}\wedge\cdots\wedge e''_{i+2,l_{1+2}}$ is $T''\otimes e''_{k,l_k}\wedge e''_{j,l_j}\wedge e''_{1,l_1}\wedge\cdots\wedge\widehat{e''_{j,l_j}}\wedge\cdots\wedge\widehat{e''_{k,l_k}}\wedge\cdots\wedge e''_{i+2,l_{i+2}}$.

Since the order of e''_{k,l_k} and e''_{j,l_j} are different in the wedge products, the sum of the two terms in (i) and (ii) is 0. This is true for all components of $\partial^{i+1}\circ\partial^{i}(T)$, and so $\partial^{i+1}\circ\partial^{i}=0$. □

9.1. Definition of seedling: By the definition of ∂^{i}, all terms in $\partial^{i}(T)$ are of the form $\pm T'$

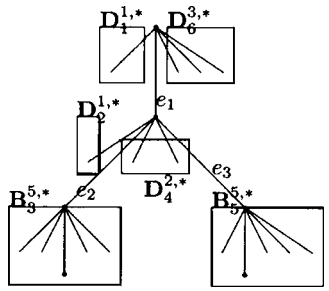

FIG. 36.

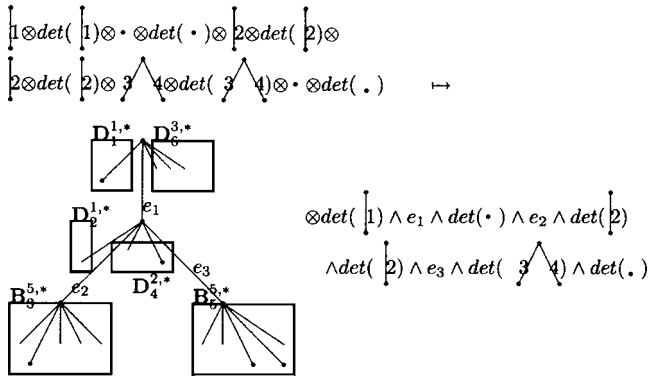

FIG. 37.

$\otimes e \wedge \det(T)$, where T' runs over bonsais obtained by adding an edge e to T so that (i) and (ii) of Definition 9.1 hold. So T' has the form of appending a vertex to a vertex of T which is not a tip. Having this intuitive fact in mind, let us present some definitions and reorganize the cochain complex of bonsais.

Definition 9.2: For a bonsai T, an edge e of T is called twiggy *if it is at the end of a branch and the opposite end of the tip is a branching vertex. In Fig. 29, e is twiggy in T and e′ is not, and f is not a twiggy edge of T′.*

Definition 9.3: A bonsai which has no twiggy edge is called a vertex-appending seedling. *In this section, we will call this just a* seedling. *The left bonsai in Fig. 35 is not a seedling, and the ones in Fig. 30 are all seedlings in 2-bonsai. Note that the one-vertex bonsai is a seedling. Intuitively, a seedling is a bonsai which cannot be obtained by adding edges like (i) and (ii) of Definition 9.1.*

Definition 9.4: For two seedlings S and S′, we define an equivalence relation $S \sim S'$ if S is obtained by changing labels of branch-end edges of S′. For example, all four seedlings in Fig. 31 are equivalent, and so are the first and second seedlings of Fig. 32, but the first and third seedlings of Fig. 32 are not equivalent.

Let us try the same trick as in the proof of acyclicity of the branch-fixed differential. When S is a seedling, let $\mathbf{C}^{[S],0}$ be the subspace of the determinanted m-bonsai space having $\{T \otimes \det(T)\}$ as the basis, where T is in the equivalence class $[S]$ of S by $\sim$. And let $\mathbf{C}^{[S],i+1}$ be the space with the basis $\{T' \otimes \det(T')\}$, where T' is obtained by adding an edge to T, where $\{T \otimes \det(T)\}$ is the basis of $\mathbf{C}^{S,i}$, as (i) and (ii) of Definition 9.1. Every bonsai is obtained by adding some edges to a seedling as given in Definition 9.1 and if S and S' are not equivalent seedlings, then the bonsais obtained by adding edges to S and S' as given in Definition 9.1 are not equivalent; the space of determinant bonsais is the direct sum of $\mathbf{C}^{[S],i}$. Then, since $\partial(\mathbf{C}^{[S],i}) \subset \mathbf{C}^{[S],i+1}$, the cohomology groups of determinant bonsais by the differential ∂ is the direct sum of cohomology groups of the threads $\{\mathbf{C}^{[S],i}\}$.

9.2. The cohomology groups of the vertex-appending differential: First let us consider a coboundary complex $\{\mathbf{D}^{m,i}\}$ consisting of corollas, such that each corolla is an m-bonsai, and the boundary map is the vertex-appending differential, but in this complex, appending to the one-vertex bonsai is allowed, so we must be careful not to be confused with the definition of the above

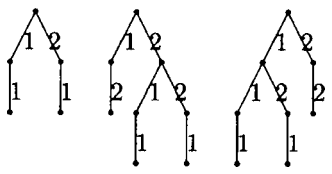

FIG. 38.

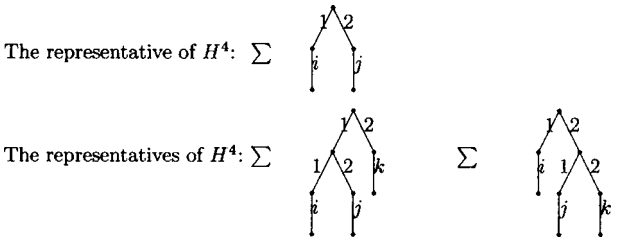

FIG. 39.

vertex-appending differential. By the definition of $\partial^i: \mathbf{D}^{m,i} \to \mathbf{D}^{m,i+1}$, all terms in $\partial^i(T)$ are of the form $\pm T' \otimes e \wedge \det(T)$, where T' runs over bonsais obtained by adding one vertex as defined in Definition 9.1. Since appending to a tip is forbidden, every ∂^i is appending a vertex to the root of a corolla. Now let us show some boundary map sequences of the thread starting from one vertex. For one vertex, ∂^0 acts as in Fig. 33.

For the one-edge corolla, ∂^1 acts as in Fig. 34, where $1 \leqslant n \leqslant m$, and for the two-edge corolla, ∂^2 acts as in Fig. 35, where $1 \leqslant n_1 < n_2 \leqslant m$, and so on.

This sequence of coboundary maps is the same as that of the reduced cohomology of the $(m-1)$-simplex with vertices $v_1, v_2, \ldots, v_m$, once we identify the corolla with labels $i_1, i_2, \ldots, i_k$ with the simplex generated by vertices $v_{i_1}, v_{i_2}, \ldots, v_{i_k}$. So the cohomology groups of this thread of boundary maps is acyclic, and the lowest degree group is trivial. Let us denote the module having the basis consisting of one vertex having m available positions of vertex appending as $\mathbf{D}^{m,0}$, and the module having the basis consisting of corollae with n edges as shown above $\mathbf{D}^{m,n}$. Also, let $\{\mathbf{B}^{m,n}\}$ be a cochain complex defined by $\mathbf{B}^{m,n} = \mathbf{D}^{m,n+1}$ for later convenience. Then $\{\mathbf{B}^{m,n}\}$ is acyclic and $H^0 = k$, where k is the base field, since the cohomology of $\{\mathbf{B}^{m,n}\}$ is isomorphic to the cohomology (not the reduced cohomology) of the $(m-1)$-simplex.

9.3. The case of general seedlings: Now let us show an example.

Lemma 2: *Any complex* $\{\mathbf{C}^{[S],i}\}$ *is isomorphic to it, which is represented as a direct sum of tensor products of* $\{\mathbf{D}^{m,i}\}$*'s and* $\{\mathbf{B}^{m,i}\}$*'s (as in the proof of acyclicity of the branch-fixed differential).*

In 5-bonsai, the seedling S in Fig. 36 can get twiggy edges at the positions of the twigs shown in the picture which are grouped as surrounded by squares.

Note that, in Fig. 36 adding an edge to each square is the same as attaching an edge to the corolla at the vertex at which the square is appended, each corolla corresponds to the module that is written on each square (in Fig. 36, $\mathbf{D}_i^{m,*}$ is isomorphic to $\mathbf{D}^{m,*}$ and $\mathbf{B}_i^{m,*}$ is isomorphic to $\mathbf{B}^{m,*}$).

Keeping this in mind, we can define modules $\{\mathbf{D}^l\}$ and an isomorphism F of them with $\{\mathbf{C}^{[S],i}\}$ like the following:

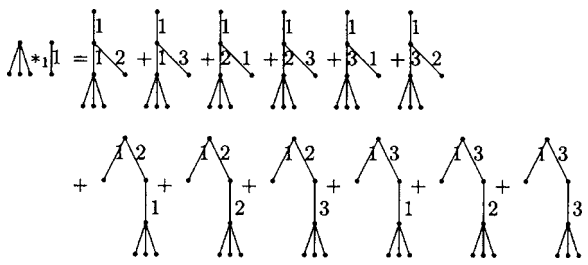

FIG. 40.

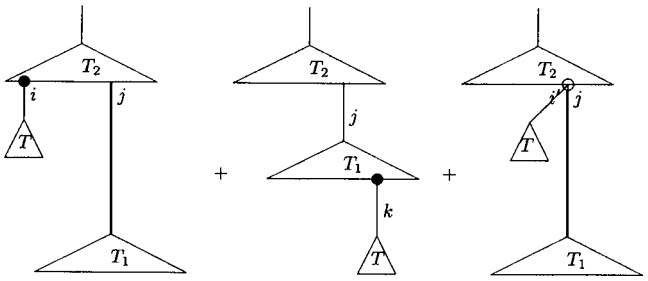

FIG. 41.

$$\mathbf{D}^l = \bigoplus_{p_1+\cdots+p_6=l} \mathbf{D}_1^{1,p_1} \otimes \mathbf{D}_2^{1,p_2} \otimes \mathbf{B}_3^{5,p_3} \otimes \mathbf{D}_4^{2,p_4} \otimes \mathbf{B}_5^{5,p_5} \otimes \mathbf{D}_6^{3,p_6} \tag{46}$$

and when $\mathbf{M}_1=\mathbf{D}_1^{1,p_1}$, $\mathbf{M}_2=\mathbf{D}_2^{1,p_2}$, $\mathbf{M}_3=\mathbf{B}_3^{5,p_3}$, $\mathbf{M}_4=\mathbf{D}_4^{2,p_4}$, $\mathbf{M}_5=\mathbf{B}_5^{5,p_5}$ and $\mathbf{M}_6=\mathbf{D}_6^{3,p_6}$, the map $F:\mathbf{D}^l \to \mathbf{C}^{[S],l}$ is defined as, when $c_i \in \mathbf{M}_i$ is a corolla,

$$\begin{aligned} &c_1 \otimes \det(c_1) \otimes \cdots \otimes c_6 \otimes \det(c_6) \mapsto \\ &\quad \Sigma \text{ (the bonsai obtained by attaching } c_i \text{ to the square corresponding to } \mathbf{M}_i) \\ &\quad \otimes \det(c_1) \wedge e_1 \wedge \det(c_2) \wedge e_2 \wedge \det(c_3) \wedge \det(c_4) \wedge e_3 \wedge \det(c_5) \wedge \det(c_6) \end{aligned} \tag{47}$$

as in the example of Fig. 37.

Then in $T \otimes \det(T) \in \mathbf{C}^{S,l}$, $\det(T)$ is

$$\det(c_1) \wedge e_{1,k_1} \wedge \det(c_2) \wedge e_{2,k_2} \wedge \det(c_3) \wedge \det(c_4) \wedge e_{3,k_3} \wedge \det(c_5) \wedge \det(c_6), \tag{48}$$

where k_l is the label of the edge e_l, and $\partial^n(T \otimes \det(T))$ is

$$\begin{aligned} &\Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to one of } c_i) \otimes f \wedge \det(T) \\ &\quad = \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to one of } c_i) \\ &\qquad \otimes f \wedge \det(c_1) \wedge e_{1,k_1} \wedge \det(c_2) \wedge e_{2,k_2} \wedge \det(c_3) \wedge \det(c_4) \wedge e_{3,k_3} \wedge \det(c_5) \wedge \det(c_6) \\ &\quad = \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to } c_1) \\ &\qquad \otimes f \wedge \det(c_1) \wedge e_{1,k_1} \wedge \det(c_2) \wedge e_{2,k_2} \wedge \det(c_3) \wedge \det(c_4) \wedge e_{3,k_3} \wedge \det(c_5) \wedge \det(c_6) \\ &\qquad + \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to } c_2) \otimes (-1)^{\deg(c_1)+1} \det(c_1) \wedge e_{1,k_1} \\ &\qquad \wedge f \wedge \det(c_2) \wedge e_{2,k_2} \wedge \det(c_3) \wedge \det(c_4) \wedge e_{3,k_3} \wedge \det(c_5) \wedge \det(c_6) \\ &\qquad + \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to } c_3) \otimes (-1)^{(\deg(c_1)+1)+(\deg(c_2)+1)} \end{aligned}$$

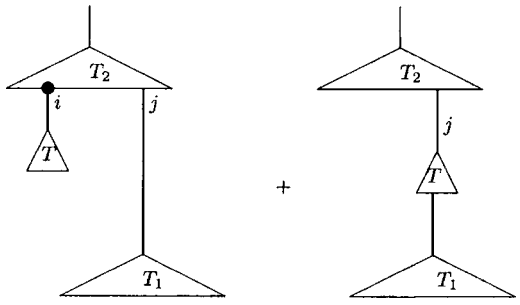

FIG. 42.

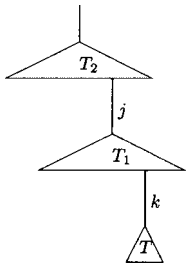

FIG. 43.

$$\det(c_1) \wedge e_{1,k_1} \wedge \det(c_2) \wedge e_{2,k_2} \wedge f \wedge \det(c_3) \wedge \det(c_4) \wedge e_{3,k_3} \wedge \det(c_5) \wedge \det(c_6)$$

$$+ \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to } c_4)$$

$$\otimes (-1)^{(\deg(c_1)+1)+(\deg(c_2)+1)+(\deg(c_3)+0)}$$

$$\times \det(c_1) \wedge e_{1,k_1} \wedge \det(c_2) \wedge e_{2,k_2} \wedge \det(c_3) \wedge f \wedge \det(c_4) \wedge e_{3,k_3} \wedge \det(c_5) \wedge \det(c_6)$$

$$+ \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to } c_5)$$

$$\otimes (-1)^{(\deg(c_1)+1)+(\deg(c_2)+1)+(\deg(c_3)+0)+(\deg(c_4)+1)}$$

$$\det(c_1) \wedge e_{1,k_1} \wedge \det(c_2) \wedge e_{2,k_2} \wedge \det(c_3) \wedge \det(c_4) \wedge e_{3,k_3} \wedge f \wedge \det(c_5)$$

$$\wedge \det(c_6) + \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to } c_6)$$

$$\otimes (-1)^{(\deg(c_1)+1)+(\deg(c_2)+1)+(\deg(c_3)+0)+(\deg(c_4)+1)+(\deg(c_5)+0)} \det(c_1) \wedge e_{1,k_1}$$

$$\wedge \det(c_2) \wedge e_{2,k_2} \wedge \det(c_3) \wedge \det(c_4) \wedge e_{3,k_3} \wedge \det(c_5) \wedge f \wedge \det(c_6). \tag{49}$$

So, when $m_1=\deg(c_1)+1$, $m_2=\deg(c_2)+1$, $m_3=\deg(c_3)+0$, $m_4=\deg(c_4)+1$, and $m_5=\deg(c_5)+0$, we can write $\partial(T\otimes\det(T))$ as

$$+ \Sigma \text{ (a bonsai } T' \text{ obtained by adding an edge } f \text{ to } c_i)$$

$$\otimes (-1)^{m_1+\cdots+m_{i-1}} \det(c_1) \wedge e_{1,k_1} \wedge \cdots \wedge (f \wedge \det(c_i)) \wedge \cdots \wedge \det(c_6).$$

Hence, when we define the coboundary map on $\{\mathbf{D}^l\}$ as

$$c_1 \otimes \cdots \otimes c_6 \mapsto \Sigma(-1)^{\beta_i} c_1 \otimes \cdots \otimes \partial(c_i) \otimes \cdots \otimes c_6, \tag{50}$$

where $\beta_i=m_1+\cdots+m_{i-1}$ and $\beta_1=0$, the map F defined in (47) becomes a cochain isomorphism of $\{\mathbf{D}^l\}$ and $\{\mathbf{C}^{[S],l}\}$. Then by the Künneth theorem, the cohomology of the cochain complex $\{\mathbf{D}^l\}$ is

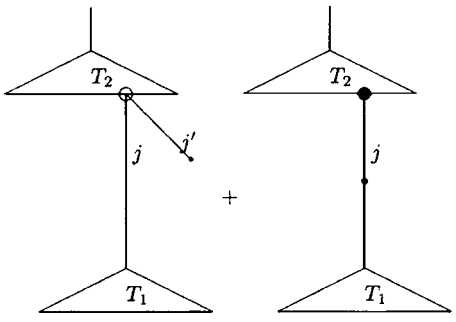

FIG. 44.

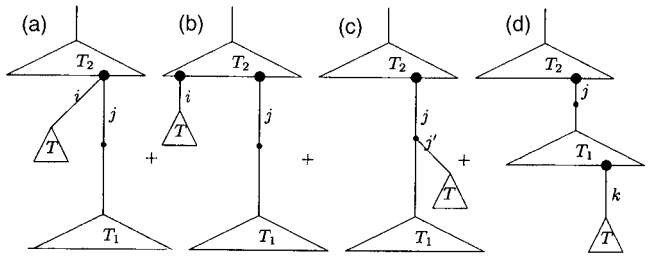

FIG. 45.

expressed as the sum of $H^{q_1}(\mathbf{M}_1)\otimes\cdots\otimes H^{q_6}(\mathbf{M}_6)$ for some q_i's, and since $H^i(\mathbf{M}_1)=H^i(\mathbf{D}^{1,*})=0$ for any i, the cohomology of $\mathbf{C}^{[S],l}$ for S of Fig. 36 is acyclic.

Definition 9.5: As shown for the example of Fig. 36, for any seedling S, we have a cochain complex as in (46) *and an isomorphism F of it with* $\mathbf{C}^{[S],l}$ *as in* (47). *We call this cochain complex as in* (46) *the* tensor product representation *of* $\mathbf{C}^{[S],l}$.

Then, whether $\{\mathbf{C}^{[S],l}\}$ is acyclic or not depends on whether its tensor product representation contains $\mathbf{D}^{m,*}$. As shown in Fig. 36, $\mathbf{B}^{m,*}$ appears only at the branch-end edges of a seedling, and $\mathbf{D}^{m,*}$ appears only at the available positions of vertex-appending other than at branch-end edges. So, the only case where $\{\mathbf{C}^{[S],l}\}$ is not acyclic is that the bonsai obtained by deleting all branch-end edges of S is a cocycle, i.e., that bonsai has no available position of vertex appending and so there is no room for $\mathbf{D}^{m,*}$ on S, like the bonsais of Fig. 38, in 2-bonsai. The only nontrivial cohomology group of $\{\mathbf{C}^{[S],l}\}$ is $H^0=k$ by Künneth theorem, where k is the base field, since all $H^0(\mathbf{B}^{m,i})=k$.

In m-bonsai, every cocycle C is a planar tree, all of whose vertices which are not branch-ends have ramification number m, so if C contains n corollas with m edges, it has $mn+1$ vertices, n of those vertices have m successors and $(mn+1)-n$ of those vertices have 0 successors, i.e., are the endpoints of edges, in the language of Stanley (1999). Then, by Theorem 5.3.10 of Stanley (1999), the number of such C is

$$\frac{1}{mn+1}\binom{mn+1}{(mn+1)-n,\ldots,n} \tag{51}$$

which is $(mn)!/((m-1)n+1)!n!$. A seedling S is obtained by adding one edge to every branch-end vertex of C and C has $(mn+1)-n$ branch-end vertices. So S has $mn+((mn+1)-n)=(2m-1)n+1$ vertices. Thus we have the following.

Theorem 9.2: *The cohomology groups* H^i *of m-bonsai Hopf algebra by the vertex-appending differential is*

$$H^i=\begin{cases} k\frac{(mn)!}{((m-1)n+1)!n!} & \text{if } i=(2m-1)n+1, n\geqslant 0,\\ 0 & \text{otherwise.}\end{cases}$$

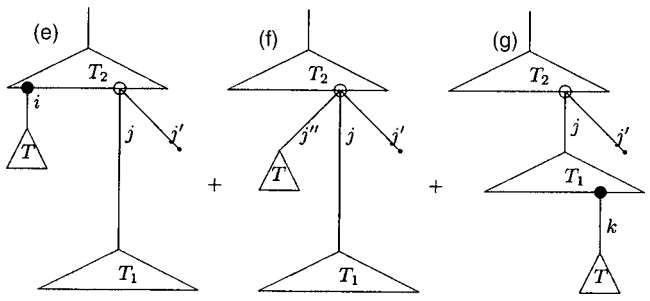

FIG. 46.

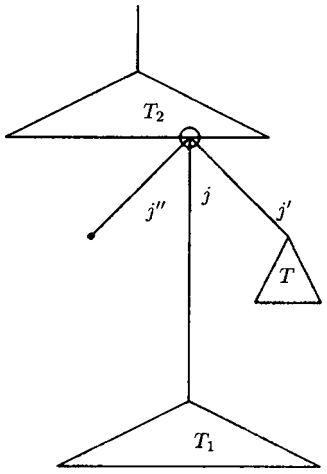

FIG. 47.

In 2-bonsai, the representatives of H^i are as in Fig. 39.

X. APPENDING OPERATION $*$ AND ITS DEVIATION

Over a general base field k for a bonsai Hopf algebra, it is not so easy to find a good algebraic relationship between $\partial(T_1 * T_2)$ and $(\partial T_1) * T_2 \pm T_1 * (\partial T_2)$ where ∂ is the vertex-appending differential, mainly because of the signs of determinant bonsais. But if k has characteristic 2, we do not need to consider signs. Moreover, the vertex-appending differential becomes just appending of a vertex, taking no consideration of determinant terms, but it is still a boundary map by the same argument as in the preceding section. Then the relation of $\partial(T_1 * T_2)$ and $(\partial T_1) * T_2 + T_1 * (\partial T_2)$ becomes much simpler. In this section, we consider only the case where the characteristic of k is 2.

Let us define the binary operation $*_1$ by

$$\partial(T_1 * T_2) = (\partial T_1) * T_2 + T_1 * (\partial T_2) + T_1 *_1 T_2 \tag{52}$$

and call this operation $*_1$ the *first deviation* of the operation $*$. We let $*_2$ be defined by

$$\partial(T_1 *_1 T_2) = (\partial T_1) *_1 T_2 + T_1 *_1 (\partial T_2) + T_1 *_2 T_2 \tag{53}$$

and call this operation the *second deviation* of the operation $*$. We define third, fourth, etc., deviations iteratively. Note that $*_2$ is the first deviation of $*_1$.

First, for the appending operation $*$, we have the following.

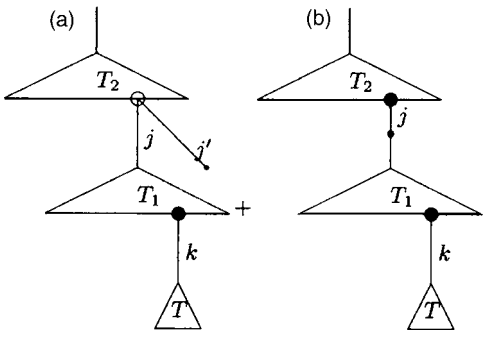

FIG. 48.

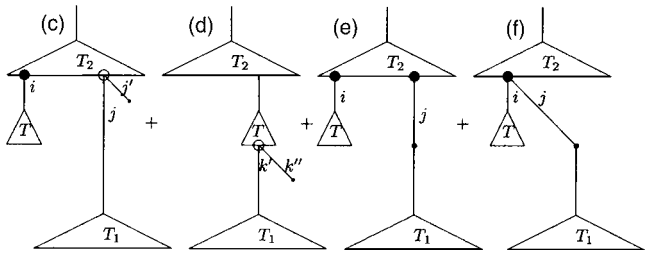

FIG. 49.

Theorem 10.1: *In bonsai Hopf algebra, with its base field of characteristic 2,* $T_1 *_1 T_2$ *is the sum of all* T' 's, *where* T' *is any bonsai obtained by connecting a tip* v *of* T_2 *and the root of* T_1 *with one edge and attatch another edge to that vertex of* T_2, *or by connecting a nontip of* T_2 *and the root of* T_1 *with a length-2 ladder. In both cases, the edges added to* T_1 *and* T_2 *are allowed to have all possible labels, as in the example in 3-bonsai of Fig. 40.*

Proof: Let us use a graphical illustration. Bonsais which are summands of $\partial(T_1 * T_2)$ are as in Fig. 41, where T_1 and T_2 and the appended vertex are drawn as broomsticks, and i, j, and k are indices of twigs and $T_1 * T_2$ is the sum of these two kinds of bonsai over i, j, and k. In this proof, the black circles in the pictures represent the twigs at nontips of bonsais, and the white circles represent the twigs at tips of bonsais. Here, i is on the vertices of T_2 which are not tips, and k is on the vertices of T_1 which are not tips and i' is on the vertices of T_2 which are tips, but not tips in $\partial(T_1 * T_2)$ since the connecting edge is attached.

The bonsais which are summands of $T_1 * \partial T_2$ are as in Fig. 42. On the right-hand bonsai of Fig. 42, the label of the edge connecting T and T_1 can be anything out of $1, 2, \ldots, m$.

The bonsais which are summands of $\partial T_1 * T_2$ are as in Fig. 43. Then the discrepancy between $\partial(T_1 * T_2)$ and $\partial T_1 * T_2 + T_1 * \partial T_2$ is the sum of the third bonsai of Fig. 41 and the second bonsai of Fig. 42, which gives the wanted formula.

Theorem 10.2: Mod 2, *for any m-bonsais* T_1 *and* T_2, *we have* $T_1 *_2 T_2 = 0$. *In other words,* $\partial(T_1 *_1 T_2) = \partial T_1 *_1 T_2 + T_1 *_1 \partial T_2$.

Proof: Bonsais which are summands of $T_1 *_1 T_2$ are those in Fig. 44, which represent the bonsais obtained by connecting T_1 and T_2 with one edge and attaching another edge and obtained by connecting T_1 and T_2 with a length-2 ladder. As in the proof of the previous theorem, a black circle represents a nontip of a bonsai and a white circle represents a tip of a bonsai.

The bonsais in $\partial(T_1 *_1 T_2)$ obtained by ∂ acting on the left-hand bonsai in Fig. 44 are those in Fig. 45, and the bonsais obtained by ∂ acting on the right-hand bonsai in Fig. 44 are those in Fig. 46. In both pictures, the broomstick lettered T is a one-vertex bonsai which is appended by the vertex-appending differential ∂.

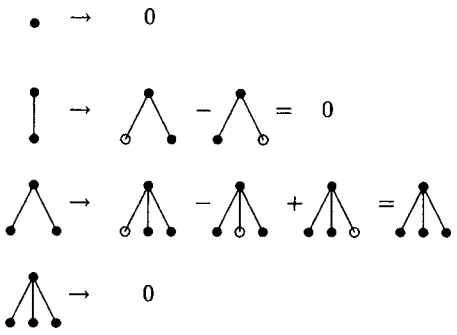

FIG. 50.

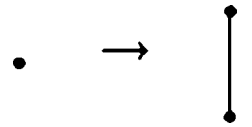

FIG. 51.

The bonsais in $\partial(T_1 *_1 T_2)$ corresponding to the left-hand bonsai in Fig. 44 are like Fig. 45, and the ones corresponding to the right-hand one are like Fig. 46. For later use, we denote those bonsais A, B,…,G as assigned in the figures. In both pictures, the broomstick lettered T is a one-vertex bonsai which is appended by the vertex-appending differential ∂.

For the bonsai F, actually we have a term like Fig. 47 also in $\partial(T_1 *_1 T_2)$, and since we are working mod 2, the bonsais looking like F are all canceled. So we have F=0.

Now, the bonsais in $\partial(T_1) *_1 T_2$ are as in Fig. 48. Let us denote them as a and b.

The bonsais in $T_1 *_1 \partial(T_2)$ are like those in Fig. 49, where we denote the bonsais as c, d, e, and f.

In Figs. 45–49, we have a=G, b=D, c=E, d=C, e=B, and f=A. We already showed that F=0, so we have $\partial(T_1 *_1 T_2) = \partial(T_1) *_1 T_2 + T_1 *_1 \partial(T_2)$. □

XI. PLANAR CLEAR-EDGED *m*-BONSAI AND ITS DERIVATIVE

In planar clear-edged m-bonsai, we can define a differential and calculate some cohomologies as for m-bonsai.

Definition 11.1: For the planar clear-edged m-bonsai, we define the vertex-appending differential ∂ *as follows. Consider a determinant planar clear-edged m-bonsai* $T \otimes \det(T)$. *Then* $\partial(T \otimes \det(T))$ *is the sum of* $T' \otimes \wedge \det(T)$, *where* T' *is a planar clear-edged m-bonsai obtained by*

(i) *appending a vertex to* T,
(ii) *except to tips of* T,

and so, getting an edge e.

If there is no available appending position on a bonsai, the map assigns 0 to that bonsai.

For example, in planar clear-edged 3-bonsai, we can get an example like Fig. 50 (in bonsais of Fig. 50, determinant terms are omitted). (Note that one vertex in the first example is also a tip and the third bonsai is a cocycle. In the picture, appended vertices are drawn as open vertices, not indicating colors.)

And by the totally same argument as for edge-numbered bonsai, we get the following.

Theorem 11.1: $\partial^{i+1} \circ \partial^i = 0$. *That is,* ∂ *is a differential.*

Now let us consider the cohomology groups of this differential. First let us consider a cochain complex $\{\mathbf{D}^i\}$ consisting of corollas, with the boundary map $\bar{\partial}$ being the vertex-appending differential, but in this complex, appending to the one-vertex bonsai is allowed. Here, let us denote as $\mathbf{D}^0$ the module having the basis consisting of one vertex, and as $\mathbf{D}^n$ the one-dimensional module having the basis consisting of the corolla with n edges as shown above. By the definition of ∂^i, all terms in $\partial^i(T)$ are of the from $\pm T' \otimes e \wedge \det(T)$, where T' runs over bonsais obtained by adding one vertex as defined in Definition 11.1. Since appending to an edge-end is forbidden, every ∂^i is appending a vertex to the root of a corolla. Now let us show some boundary map sequences of the thread starting from one vertex. For one vertex, ∂^0 acts as in Fig. 51.

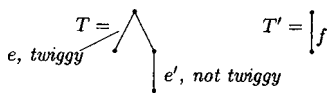

FIG. 52.

FIG. 53.

For the one-edge corolla, ∂^1 acts as in the second map of Fig. 50, for the two-edge corolla, ∂^2 acts as in the third map of Fig. 50, and so on.

This sequence of coboundary maps is

$$k \xrightarrow{id} k \xrightarrow{0} k \xrightarrow{id} k \xrightarrow{0} \cdots \tag{54}$$

where k is the base field.

So the cohomology groups of this thread of boundary maps is acyclic, and the lowest degree group is trivial.

Also, let $\{\mathbf{B}^n\}$ be a cochain complex defined by $\mathbf{B}^n=\mathbf{D}^{n+1}$ for later convenience. Then $\{\mathbf{B}^n\}$ is acyclic and $H^0=k$, where k is the base field.

Now let us consider the general case. By the definition of ∂^i, all terms in $\partial^i(T)$ are of the form $\pm T' \otimes e \wedge \det(T)$, where T' runs over bonsais obtained by adding an edge e to T so that (i) and (ii) of Definition 11.1 hold. So T' has the form of appending a vertex to a vertex of T other than a tip. Having this intuitive fact in mind, let us present some definitions and reorganize the cochain complex of bonsais.

Definition 11.2: For a bonsai T, an edge e of T is called twiggy *if it is at the end of a branch and the opposite end of the tip is a branching vertex. In Fig. 52, e is twiggy in T and e′ is not, and f is not a twiggy edge of T′.*

Definition 11.3: A bonsai which has no twiggy edge is called a vertex-appending seedling. *In this section, we will just call this* seedling. *The bonsais in Fig. 53 are all seedlings. Note that the one-vertex bonsai is a seedling. Intuitively, a seedling is a bonsai which cannot be obtained by adding edges like (i) and (ii) of Definition 9.1.*

11.1. *Cohomology groups of ∂ when m=∞:* Let us try the same trick as in the proof of acyclicity of the branch-fixed differential.

Definition 11.4: When S is a seedling, let $\mathbf{C}^{S,0}$ *be the subspace of the determinant planar clear-edged ∞-bonsai space having* $\{S \otimes \det(S)\}$ *as the basis. And let* $\mathbf{C}^{S,i+1}$ *be the space with the basis* $\{T' \otimes \det(T')\}$, *where T′ is obtained by adding an edge to T, where* $\{T \otimes \det(T)\}$ *is the basis of* $\mathbf{C}^{S,i}$, *as (i) and (ii) of Definition 11.1. Then since every bonsai is obtained by adding some edges to a seedling as given in Definition 11.1 and if S and S′ are different seedlings, then the bonsais obtained by adding edges to S and S′ as given in Definition 11.1 are different, the space of determinant bonsais is the direct sum of the* $\mathbf{C}^{S,i}$. *We call this complex* $\{\mathbf{C}^{S,i}\}$ *a* thread *starting from S.*

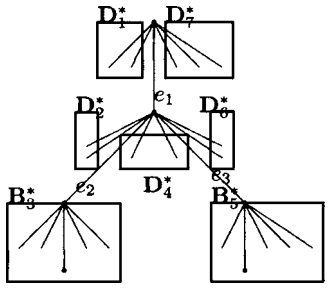

FIG. 54.

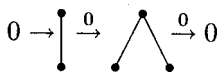

FIG. 55.

Then, since $\partial(\mathbf{C}^{S,i}) \subset \mathbf{C}^{S,i+1}$, the cohomology groups of determinant bonsais by the differential ∂ are the direct sum of cohomology groups of the threads $\{\mathbf{C}^{S,i}\}$.

Now let us show through an example that, for any thread $\{\mathbf{C}^{S,i}\}$, we can get a cochain complex which is isomorphic to it, obtained from the direct sums of tensor products of $\{\mathbf{D}^i\}$'s and $\{\mathbf{B}^i\}$'s as in the proof of acyclicity of branch-fixed differential. In 5-bonsai, the seedling S in Fig. 54 can have twiggy edges at the positions of the twigs shown in the picture, and those twigs are grouped as surrounded by squares.

Note that, in Fig. 54, adding edges to the corolla in each square is the same as attaching edges to the vertex at which the square is appended, each corolla corresponds to the module that is written on each square (in Fig. 54, $\mathbf{D}_i^{m,*}$ is isomorphic to $\mathbf{D}^{m,*}$ and $\mathbf{B}_i^{m,*}$ is isomorphic to $\mathbf{B}^{m,*}$).

Then, as in Sec. XI, we can get the cochain isomorphism of $\{\mathbf{C}^{S,i}\}$ and $\mathbf{D}_1^* \otimes \mathbf{D}_2^* \otimes \mathbf{B}_3^* \otimes \mathbf{D}_4^* \otimes \mathbf{B}_5^* \otimes \mathbf{D}_6^* \otimes \mathbf{D}_7^*$, and use Künneth's theorem. Since the cohomology of $\{\mathbf{D}^*\}$ is acyclic with trivial base degree cohomology, it is clear that any $\{\mathbf{C}^{S,*}\}$ whose tensor product representation has $\{\mathbf{D}^*\}$ is acyclic with trivial base degree cohomology. The only seedlings having no $\{\mathbf{D}^*\}$ are the first two bonsais of Fig. 50, i.e., the one-vertex bonsai v and the one-edge bonsai e. Since v is a cocycle, we have $H^0 = k$ and since $\mathbf{C}^{e,*} = \mathbf{B}^*$, we have $H^1 = H^0(\mathbf{B}^*) = k$. This illustrates a general argument. Thus we have the following.

Theorem 11.2: *The cohomology groups H^i of the planar clear-edged m-bonsai Hopf algebra by vertex-appending differential are*

$$H^i = \begin{cases} k & \text{if } i = 0 \text{ or } 1, \\ 0 & \text{otherwise}. \end{cases}$$

11.2. *Cohomology groups of ∂ when $m < \infty$: terminology*. In this section, let us consider the cohomology groups in case $m < \infty$. It is not as easy as in the preceding section to get a simple tensor product representation of a thread $\{\mathbf{C}^{S,i}\}$ when each vertex has the upper bound m of ramification number. So we need to change our strategy for the case of $m < \infty$. Since every $\{\mathbf{C}^{S,i}\}$ is finite dimensional, we can calculate the cohomology groups by considering a finite number of bonsais. So from now on, we develop an "inductive strategy" for calculating the cohomology groups of the thread $\{\mathbf{C}^{S,i}\}$ for any given S.

Let us illustrate the basic idea of the " inductive strategy" using an example. In 2-bonsai, let S_i be the ladder of length i. Then the cohomology $H^j(S_1)$ of $\{\mathbf{C}^{S_1,j}\}$ is, by a sequence as in Fig. 55, $H^1(S_1) = H^2(S_2) = k$, the base field.

Let us find an inductive step to get $H^i(S_{j+1})$'s from $H^i(S_j)$'s, so that we can get the cohomology group of every $\{\mathbf{C}^{S_i,j}\}$.

As in Fig. 56, when T is a linear combination of m-bonsais, the other two expressions of Fig. 56 represent linear combinations of bonsais obtained by attaching a bonsai to the roots of bonsais which are the components of T.

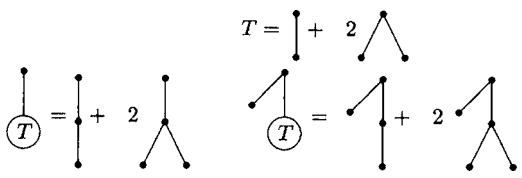

FIG. 56.

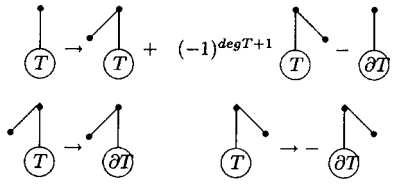

FIG. 57.

Then, when T is a linear combination of bonsais in $\{\mathbf{C}^{S_i,j}\}$ in 2-bonsai, the map ∂ on $\{\mathbf{C}^{S_{i+1},j}\}$ is expressed in Fig. 57.

From Fig. 57, we can find that the kernel of ∂ on $\{\mathbf{C}^{S_{i+1},j}\}$ is generated by the linear combinations of bonsais shown in Fig. 58 in which $T \in \ker \partial$ and $\partial T' = \partial T'' = T$, and that the image of ∂ on $\{\mathcal{C}^{S^{i+1},j}\}$ is generated by the linear combinations of bonsais shown in Fig. 59.

So we can write

$$\frac{\ker \partial}{\operatorname{im} \partial} = \frac{\langle A,B,C\rangle}{\langle a,b,c\rangle}. \tag{55}$$

In A, we have $\partial T=0$, $\partial T' = T$ and $\partial T'' = T$, so we have $A-a=(-1)^{\deg T''+1}C$. Hence we have C is generated by A and a. Also, in c, when $T' = \partial T$, we have $a-b=(-1)^{\deg T}c$. So c is generated by a and b. So we have

$$\frac{\ker \partial}{\operatorname{im} \partial} = \frac{\langle A,B\rangle}{\langle a,b\rangle}. \tag{56}$$

In Fig. 58, $\partial T'' = T$. So A in Fig. 58 can be redrawn as Fig. 60.

Since $\partial T' = \partial T'' = T$, we have $\partial(T' - T'') = 0$ and so A can be rewritten as $B+a$. Hence we have

$$\frac{\ker \partial}{\operatorname{im} \partial} = \frac{\langle B+a,B\rangle}{\langle a,b\rangle} = \frac{\langle a,B\rangle}{\langle a,b\rangle} = \frac{\langle a\rangle \oplus \langle B\rangle}{\langle a\rangle \oplus \langle b\rangle} = \frac{\langle B\rangle}{\langle b\rangle}. \tag{57}$$

Obviously, $\langle B\rangle/\langle b\rangle$ is isomorphic to the cohomology group of $\mathbf{C}^{S_i,j}$. Since B and b have two more edges than bonsais in $\mathbf{C}^{S_i,j}$, we can see the following.

Theorem 11.3: *When $H^j(S_i)$ is the jth cohomology group of the thread $\mathbf{C}^{S_i,j}$, $H^{j+2}(S_{i+1}) = H^j(S_i)$.*

As in the previous theorem, we can generalize the process of getting the cohomology of the thread starting from S' which is obtained by attaching the root of a seedling S to a tip of a corolla, when the cohomology of the thread starting from S is already known. Let us define some terminology. We first define a kind of "seedling."

Definition 11.5: We define a grafting seedling *as a bonsai defined as one of the following:*

(1) *a seedling*,
(2) *a bonsai obtained by attaching even-arity corollas to vertices of a seedling S which are more than two edges from any tip, and by replacing branch-end edges of S to even-arity corollas.*

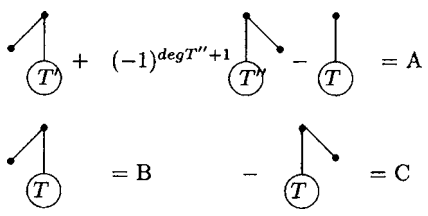

FIG. 58.

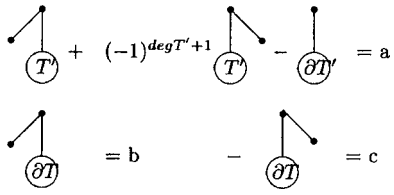

FIG. 59.

In Fig. 61, the first three bonsais are grafting seedlings and the last is not.

Definition 11.6: A grafting seedling $gs(n;T_1,T_2,\dots,T_{n+1};S_1,S_2,\dots,S_n)$, *which we call a* grafting seedling *is constructed like the following: In the corollas C with arity n, the corollas* $T_1,T_2,\dots,T_{n+1}$ *of* even *arities are attached so that the root of* T_1 *is attached to the root of C on the left of the leftmost edge of C, the root of* T_2 *is attached to the root of C between the first leftmost edge and the second leftmost edge of C,…, and so on, and the grafting seedlings* $S_1,S_2,\dots,S_n$ *are attached so that the root of* S_1 *is attached to the tip of the first leftmost edge of C, the root of* S_2 *is attached to the tip of the second leftmost edge of C, …, and so on, as in Fig. 62 in 6-bonsai.*

Note that the grafting seedling defined here is different from the seedling we used until now.

Definition 11.7: We define the relation $T_1 \to T_2$ *of clear-edged m-bonsais* T_1 *and* T_2 *as follows:*

(i) T_2 *is a nonzero component of* ∂T_1 *and* T_2 *is obtained by attaching one edge to the* root *of* T_1 *or*

(ii) T_2 *is obtained by attaching an edge to a nonroot vertex of* T_1.

In 3-bonsai, we have examples as in Fig. 63.

Definition 11.8: We define the relation $T_1 \Rightarrow T_1'$ *if there is a sequence of m-bonsais such that* $T_1 \to T_2 \to \cdots \to T_n = T_1'$ *or* $T_1 = T_1'$.

Let $\mathbf{K}(gs(n;T_1,\dots,T_{n+1};S_1,\dots,S_n))$ *be the vector space generated by the bonsais* T' *such that* $gs(n;T_1,\dots,T_{n+1};S_1,\dots,S_n) \Rightarrow T'$. *Also, when S is a grafting seedling and* $\mathbf{C}$ *is the cochain complex of m-bonsai, we define* $\mathbf{K}^i(S) := \mathbf{C}^i \cap \mathbf{K}(S)$.

Theorem 11.4: *When S is a grafting seedling and* $H^i(S)$ *is the ith cohomology group of the thread* $\{\mathbf{K}^i(S)\}$, *the ith cohomology group* H^i *of m-bonsai is*

$$H^i = \bigoplus_{S \text{ is a grafting seedling}} H^i(S).$$

Proof: We have

$$\mathbf{C} = \bigoplus_{S \text{ is a grafting seedling}} \mathbf{K}(S)$$

since (i) there is no T such that $T \Rightarrow T'$, $T \neq T'$, and T' is a grafting seedling and (ii) if two grafting seedlings S and S' are not equal, then $\mathbf{K}(S) \cap \mathbf{K}(S') = \emptyset$. Also we have $\partial \mathbf{K}^i(S) \subset \partial \mathbf{K}^{i+1}(S)$. So we get the wanted result. □

11.3. The cohomology groups for each $\{\mathbf{K}^i(gs(n;T_1,\dots,T_{n+1};S_1,\dots,S_n))\}$*:* Now we must cal-

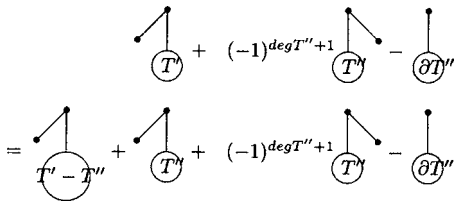

FIG. 60.

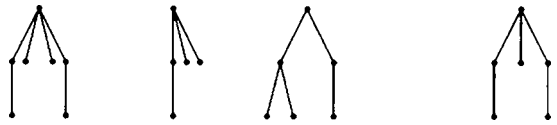

FIG. 61.

culate the cohomology groups for $\{\mathbf{K}^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))\}$. First let us define some notation.

Definition 11.9: For any integer $n\geqslant 0$, the cochain complex $\{\mathbf{D}^j_{2n}\}$ is defined as follows: when $j=2n$ or $2n+1$, $\mathbf{D}^j_{2n}$ is a one-dimensional vector space with the basis $\{C_j\}$, where C_j is the corolla of arity j (when $j=0$, C_j is the one-vertex bonsai), and otherwise, $\mathbf{D}^j_{2n}=0$. And when $j=2n$, the boundary map $\partial:\mathbf{D}^j_{2n}\to\mathbf{D}^{j+1}_{2n}$ is given by $C_j\mapsto C_{j+1}$ and otherwise, $\partial=0$.

To calculate the cohomology groups of $\{\mathbf{K}^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))\}$, we use a similar type of tensor product representation as in Sec. XI.

Definition 11.10: Let $B(n;U_1,\ldots,U_{n+1};V_1,\ldots,V_n)$ be the bonsai obtained by replacing T_i by U_i and S_i by V_i in $gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n)$, where U_i is the corolla C_k of arity $k=deg\ T_i$ or deg T_i+1 (i.e., U_i is a basis element of $\{\mathbf{D}_{deg\ T_i}\}$) and V_i is a bonsai in the thread $\{\mathbf{C}^{S_i,i}\}$ starting from S_i (see section 11.2).

Let us define the cochain complexes $\{\mathbf{D}_i\}$ and $\{\mathbf{E}_i\}$ as $\{\mathbf{D}_{\deg\ T_i}\}$ and $\{\mathbf{C}(S_i)\}$. Then we can define an isomophism P from $\mathbf{K}^i(S)$ to $\mathbf{L}^i=\mathbf{D}_1^{i_1}\otimes\mathbf{E}_1^{j_1}\otimes\cdots\otimes\mathbf{D}_n^{i_n}\otimes\mathbf{E}_n^{j_n}\otimes\mathbf{D}_{n+1}^{i_{n+1}}$ where $i_1+\cdots+i_{n+1}+j_1+\cdots+j_n+n=i$ and $i_1+\cdots+i_{n+1}+n\leqslant m$, by sending $B(n;U_1,\ldots,U_{n+1};V_1,\ldots,V_n)$ to $U_1\otimes V_1\otimes\cdots\otimes U_n\otimes V_n\otimes U_{n+1}$. The differential d in $\mathbf{L}$ is defined as, when $\deg U_1+\cdots+\deg U_{n+1}<m-n$,

$$\begin{aligned}d(U_1\otimes V_1\otimes U_2\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\otimes U_{n+1}) &= \partial U_1\otimes V_1\otimes U_2\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\\ &\otimes U_{n+1}+U_1\otimes(-1)^{p_1}\partial V_1\otimes U_2\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\otimes U_{n+1})+U_1\otimes V_1\otimes(-1)^{q_1}\partial U_2\\ &\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\otimes U_{n+1})+U_1\otimes V_1\otimes U_2\otimes(-1)^{p_2}\partial V_2\otimes\cdots\otimes U_n\otimes V_n\otimes U_{n+1})\\ &+\cdots+U_1\otimes V_1\otimes U_2\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\otimes(-1)^{q_n}\partial U_{n+1},\end{aligned}$$

where $p_i=\deg U_1+\deg V_1+\cdots+\deg U_{i-1}+\deg V_{i-1}+\deg U_i+i$ and $q_i=\deg U_1+\deg V_1+\cdots+\deg U_i+\deg V_i+i$, and if $\deg U_1+\cdots+\deg U_{n+1}=m-n$,

$$\begin{aligned}d(U_1\otimes V_1\otimes U_2\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\otimes U_{n+1}) &= \partial U_1\otimes V_1\otimes U_2\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\\ &\otimes U_{n+1}+U_1\otimes V_1\otimes(-1)^{q_1}\partial U_2\otimes V_2\otimes\cdots\otimes U_n\otimes V_n\otimes U_{n+1})+\cdots+U_1\otimes V_1\otimes U_2\otimes V_2\\ &\otimes\cdots\otimes U_n\otimes V_n\otimes(-1)^{q_n}\partial U_{n+1}).\end{aligned}$$

Then by the definition of ∂ in $\mathbf{C}$, the isomorphism P is a cochain complex isomorphism from $(\mathbf{K}^i(S),\partial)$ to $(\mathbf{L}^i,d)$.

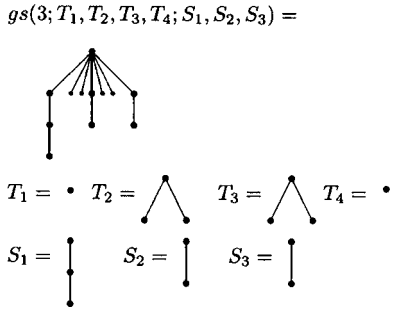

FIG. 62.

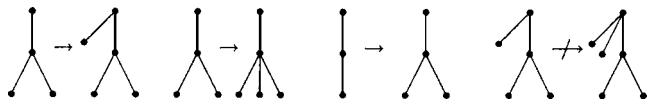

FIG. 63.

Now let us define a double complex $\{\mathbf{M}^i \otimes \mathbf{N}^j\}^{i,j}$ where $\mathbf{M}^i = \Sigma \mathbf{D}_1^{i_1} \otimes \cdots \otimes \mathbf{D}_{n+1}^{i_{n+1}}$ where $i_1, \ldots, i_{n+1}$ satisfy $i_1 + \cdots + i_{n+1} + n = i$ and $i \leqslant m$, and $\mathbf{N}^j = \Sigma_{j_1+\cdots+j_n=j} \mathbf{E}_1^{j_1} \otimes \cdots \otimes \mathbf{E}_n^{j_n}$ where $j_1, \ldots, j_n$ satisfy $j_1 + \cdots + j_n = j$, and differentials $\bar{\partial}_1$ and $\bar{\partial}_2$ are

$$\begin{aligned}\bar{\partial}_1(U_1 \otimes U_2 \otimes \cdots \otimes U_{n+1} \otimes V_1 \otimes \cdots \otimes V_n) &= \partial U_1 \otimes U_2 \otimes \cdots \otimes U_{n+1} \otimes V_1 \otimes \cdots \otimes V_n + U_1 \\ &\otimes (-1)^{q_1} \partial U_2 \otimes \cdots \otimes U_{n+1} \otimes V_1 \otimes \cdots \otimes V_n + \cdots + U_1 \otimes U_2 \otimes \ldots \otimes (-1)^{q_n} \partial U_{n+1} \otimes V_1 \\ &\otimes \ldots \otimes V_n\end{aligned}$$

where $U_1 \otimes \cdots \otimes U_{n+1} \in \mathbf{M}^j (j < m)$ (if $j \geqslant m$, since $\mathbf{M}^j = 0$, $\bar{\partial}_1 = 0$), and

$$\begin{aligned}\bar{\partial}_2(U_1 \otimes \cdots \otimes U_{n+1} \otimes V_1 \otimes V_2 \otimes \cdots \otimes V_n) &= U_1 \otimes \cdots \otimes U_{n+1} \otimes (-1)^{p_1} \partial V_1 \otimes V_2 \otimes \cdots \otimes V_n \\ &+ U_1 \otimes \cdots \otimes U_{n+1} \otimes V_1 \otimes (-1)^{p_2} \partial V_2 \otimes \cdots \otimes V_n) + \cdots + U_1 \otimes \cdots \otimes U_{n+1} \otimes V_1 \otimes V_2 \\ &\otimes \cdots \otimes (-1)^{p_n} \partial V_n.\end{aligned}$$

Then each of $\bar{\partial}_1$ and $\bar{\partial}_2$ is a differential of Künneth products of $\{\mathbf{D}_{2n}^i\}$'s and $\{\mathbf{C}^{S,j}\}$'s, respectively. Let $\bar{\partial} = \bar{\partial}_1 + \bar{\partial}_2$. When the bijection $Q: \{\mathbf{L}^i\} \to \{\mathbf{M}^i \otimes \mathbf{N}^j\}$ is given by $U_1 \otimes V_1 \otimes \cdots \otimes U_n \otimes V_n \otimes U_{n+1} \mapsto U_1 \otimes \cdots \otimes U_{n+1} \otimes V_1 \otimes \cdots \otimes V_n$, immediately by the definitions of d and $\bar{\partial}$, we have

$$\bar{\partial} \circ Q = Q \circ d. \tag{58}$$

Hence $\bar{\partial}$ satisfies $\bar{\partial} \circ \bar{\partial} = 0$. So we have $0 = \bar{\partial} \circ \bar{\partial} = \bar{\partial}_1 \circ \bar{\partial}_1 + \bar{\partial}_1 \circ \bar{\partial}_2 + \bar{\partial}_2 \circ \bar{\partial}_1 + \bar{\partial}_2 \circ \bar{\partial}_2 = \bar{\partial}_1 \circ \bar{\partial}_2 + \bar{\partial}_2 \circ \bar{\partial}_1$, therefore $\{\mathbf{M}^i \otimes \mathbf{N}^j\}$ is a double complex. Also, by (58), Q induces the cochain complex isomorphism $(\{\mathbf{L}^i\}, d) \to (\{\mathbf{M}^i \otimes \mathbf{N}^j\}, \bar{\partial})$. So by the isomorphism $Q \circ P, (\{\mathbf{K}(gs(n; T_1, \ldots T_{n+1}; S_1, \ldots, S_n))\}, \partial)$ and $(\{\mathbf{M} \otimes \mathbf{N}\}, \bar{\partial})$ are isomorphic. In order to calculate the cohomology of $(\{\mathbf{K}^i(gs(n; T_1, \ldots, T_{n+1}; S_1, \ldots, S_n))\})$, we can use the cohomology groups $(\{\mathbf{M} \otimes \mathbf{N}\}, \bar{\partial})$. Let us use the spectral sequence starting with $\bar{\partial}_1$.

Since $\bar{\partial}_1$ acts only on $\{\mathbf{M}^i\}$, we can write $E_1^{i,j} = H_{\bar{\partial}_1}(\{\mathbf{M}^i \otimes \mathbf{N}^j\}) = H_{\bar{\partial}_1}^i(\{\mathbf{M}\}) \otimes \mathbf{N}^j$, and similarly, since $\bar{\partial}_2$ acts only on $\{\mathbf{N}^j\}$, we can write $E_2^{i,j} = H_{\bar{\partial}_2}(E_1) = H_{\bar{\partial}_1}^i(\{\mathbf{M}\}) \otimes H_{\bar{\partial}_2}^j(\{\mathbf{N}\})$. Since $\bar{\partial}_2$ is a Künneth product of $\mathbf{E}_i$'s, $H_{\bar{\partial}_2}(\{\mathbf{N}\})$ is the Künneth product $H(\mathbf{E}_1) \otimes \cdots \otimes H(\mathbf{E}_n) = H(S_1) \otimes \cdots \otimes H(S_n)$. But as we can see in the definition of $\bar{\partial}_1$, it is not exactly the canonical differential of Künneth product, so the calculation of $H(\{\mathbf{M}\})$ takes some more consideration.

When $i < m$, $\mathbf{M}^i = \oplus_{i_1+\cdots+i_{n+1}=i-n} \mathbf{D}_1^{i_1} \otimes \cdots \otimes \mathbf{D}_{n+1}^{i_{n+1}}$ and $\bar{\partial}_1$ is a Künneth differential. So when $i < m, H_{\bar{\partial}_1}^i(\{\mathbf{M}\})$ is a Künneth product of $H(\{\mathbf{D}_j\})$'s, and so it is 0, since each $\{\mathbf{D}_j\}$ is acyclic.

When $i > m, \mathbf{M}^j = 0$. So when $i \geqslant m, \bar{\partial}_1 = 0$ on $\mathbf{M}^i$ and $H_{\bar{\partial}_1}^i(\{\mathbf{M}\}) = 0 (i > m)$.

Let us calculate $H_{\bar{\partial}_1}^m(\{\mathbf{M}\}) = \ker \bar{\partial}_1|_{\mathbf{M}^m} / im \bar{\partial}_1|_{\mathbf{M}^{m-1}}$.

First, if $(i_1 + 1) + \cdots + (i_{n+1} + 1) + n < m, \mathbf{M}^m = 0$. So, $H_{\bar{\partial}_1}^m(\{\mathbf{M}\}) = 0$.

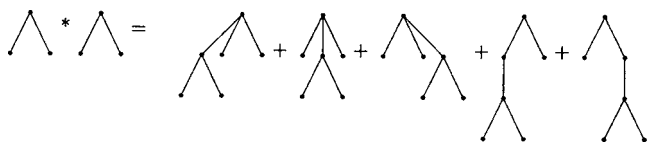

FIG. 64.

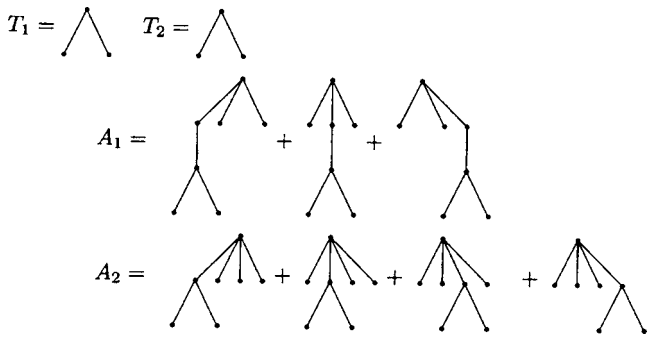

FIG. 65.

Suppose that $(i_1+1)+\cdots+(i_{n+1}+1)+n \geqslant m$. Since the clear-edged m-bonsai is a vector space over the field k, we just need to calculate the dimension of H^m. We have

$$\dim(H^m_{\bar{\partial}_1}(\{\mathbf{M}\})) = \dim\left(\ker \bar{\partial}_1\big|_{\mathbf{M}^m}\right) - \dim\left(\operatorname{im} \bar{\partial}_1\big|_{\mathbf{M}^{m-1}}\right), \tag{59}$$

$$\dim\left(\ker \bar{\partial}_1\big|_{\mathbf{M}^m}\right) = \dim(\mathbf{M}^m), \tag{60}$$

and

$$\dim\left(\operatorname{im} \bar{\partial}_1\big|_{\mathbf{M}^{m-1}}\right) = \dim(\mathbf{M}^{m-1}) - \dim\left(\ker \bar{\partial}_1\big|_{\mathbf{M}^{m-1}}\right). \tag{61}$$

Since

$$H^j_{\bar{\partial}_1}(\{\mathbf{M}\}) = 0 \text{ when } j < m, \tag{62}$$

we have

$$\dim\left(\ker \bar{\partial}_1\big|_{\mathbf{M}^{m-1}}\right) = \dim\left(\operatorname{im} \bar{\partial}_1\big|_{\mathbf{M}^{m-2}}\right) = \dim(\mathbf{M}^{m-2}) - \dim\left(\ker \bar{\partial}_1\big|_{\mathbf{M}^{m-2}}\right), \tag{63}$$

and so, by (59)–(63),

$$\begin{aligned}\dim(H^m_{\bar{\partial}_1}(\{\mathbf{M}\})) &= \dim(\mathbf{M}^m) - \left(\dim(\mathbf{M}^{m-1}) - \dim\left(\ker \bar{\partial}_1\big|_{\mathbf{M}^{m-1}}\right)\right) = \dim(\mathbf{M}^m) - \dim(\mathbf{M}^{m-1}) \\ &\quad + \dim(\mathbf{M}^{m-2}) - \dim\left(\ker \bar{\partial}_1\big|_{\mathbf{M}^{m-2}}\right).\end{aligned} \tag{64}$$

Continuing like this, we have

$$\dim(H^m_{\bar{\partial}_1}(\{\mathbf{M}\})) = \dim(\mathbf{M}^m) - \dim(\mathbf{M}^{m-1}) + \dim(\mathbf{M}^{m-2}) - \dim(\mathbf{M}^{m-3}) + \cdots \tag{65}$$

and since $\mathbf{M}^i = 0$ if $i < n+P$ where

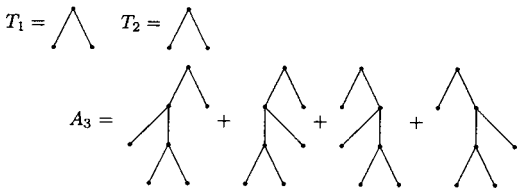

FIG. 66.

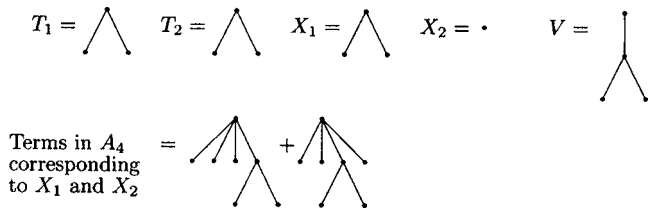

FIG. 67.

$$P = \deg T_1 + \cdots + \deg T_{n+1}, \tag{66}$$

we have

$$\dim(H^m_{\bar{\partial}_1}(\{\mathbf{M}\})) = \dim(\mathbf{M}^m) - \dim(\mathbf{M}^{m-1}) + \ldots + (-1)^{m-(n+P)} \dim(\mathbf{M}^{n+P}). \tag{67}$$

Let N be the number and let us calculate it. By the definition of $\mathbf{M}^i$, its dimension is that of

$$\bigoplus_{i_1+\cdots+i_{n+1}+n=i} \mathbf{D}_1^{i_1} \otimes \cdots \otimes \mathbf{D}_n^{i_n}. \tag{68}$$

Every $\mathbf{D}_k^{i_k}$ is one-dimensional when $p_k = i_k - \deg T_k$ is 0 or 1, and 0 otherwise. So the above direct sum is

$$\bigoplus_{p_1+\ldots+p_{n+1}+P+n=i} \mathbf{D}_1^{p_1+\deg T_1} \otimes \cdots \otimes \mathbf{D}_n^{p_n+\deg T_n}. \tag{69}$$

Hence, $\dim(\mathbf{M}^i)$ is the number of $(p_1, \ldots, p_{n+1})$'s satisfying $p_1+\cdots+p_{n+1}+P+n=i$ and each p_k is 0 or 1. Hence

$$\dim(\mathbf{M}^i) = \binom{n+1}{i-P-n} \tag{70}$$

and

$$N = \binom{n+1}{m-P-n} - \binom{n+1}{(m-1)-P-n} + \cdots + (-1)^{m-P-n}\binom{n+1}{0}.$$

Now we have

$$E_2^{i,j} = \begin{cases} \oplus_{j_1+\cdots+j_n=j} k^N \otimes H^{j_1}(S_1) \otimes \cdots \otimes H^{j_n}(S_n) & \text{if } i = m \\ 0 & \text{otherwise.} \end{cases}$$

Since $E_2^{i,j}=0$ except when $j=m$, every "knight's move map" on $E^{i,j}$'s is trivial. So the spectral sequence collapses and we have $H^n_{\bar{\partial}} = \oplus_{i+j=n} E^{i,j} = \oplus_{j_1+\cdots+j_n=n-m} k^N \otimes H^{j_1}(S_1) \otimes \cdots \otimes H^{j_n}(S_n)$, and since

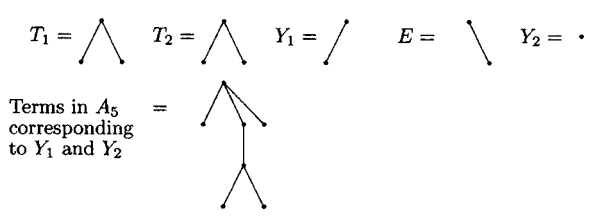

FIG. 68.

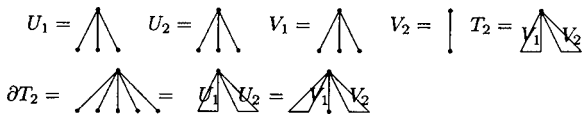

FIG. 69.

$$k^N \otimes H^{j_1}(S_1) \otimes \ldots \otimes H^{j_n}(S_n) = (H^{j_1}(S_1) \otimes \ldots \otimes H^{j_n}(S_n))^{\oplus N}, \tag{71}$$

we finally have the following.

Theorem 11.5: *When* $H^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))$ *is the ith cohomology group of the thread* $\mathbf{K}^i(gs(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))$, *the ith cohomology group* H^i *of clear-edged m-bonsai is*

$$H^i = \bigoplus_{S \text{ is a grafting seedling}} H^i(S).$$

And, if $P=\deg T_1+\cdots+\deg T_n<m-2n+1$, *then* $H^i(gr(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n))=0$. *Otherwise*,

$$H^i(gr(n;T_1,\ldots,T_{n+1};S_1,\ldots,S_n)) = \bigoplus_{j_1+\ldots+j_n=n-m} [H^{j_1}(S_1) \otimes \cdots \otimes H^{j_n}(S_n)]^{\oplus N},$$

where

$$N = \binom{n+1}{m-P-n} - \binom{n+1}{(m-1)-P-n} + \cdots + (-1)^{m-(n+P)}\binom{n+1}{0}.$$

XII. DIFFERENTIAL AND APPENDING OF CLEAR-EDGED BONSAI

Let us consider the relationship between the appending operation $*$ on the clear-edged m-bonsai Hopf algebra $\mathcal{H}_{c,m}$ and the vertex appending differential ∂. We work mod 2 again. First, the operation $T_1 * T_2$ is the sum of all m-bonsais obtained by connecting the root of T_1 and a vertex of T_2 with an edge, as illustrated for 3-bonsai in Fig. 64.

In this section, we will show that $T_1 *_2 T_2 = 0$ for every T_1 and T_2 as in Sec. X.

Temporarily in this section, we use a differential $\bar{\partial}$ of corollas which is the same as ∂ except $\bar{\partial}(v)=e$, where v is the one-vertex bonsai and e is the one-edge bonsai.

12.1 Brief table of contents: In this section, first we will describe $T_1 *_1 T_2$ for each of the following cases when T_2 is a corolla, by dividing the cases as follows;

(i) when $\partial T_2 \neq 0$ and $\deg(T_2) \leqslant m-2$,
(ii) when $\partial T_2 \neq 0$ and $\deg(T_2) = m-1$,
(iii) when $\partial T_2 = 0$ and $\deg(T_2) \leqslant m-2$,
(iv) when $\partial T_2 = 0$ and $\deg(T_2) = m-1$,

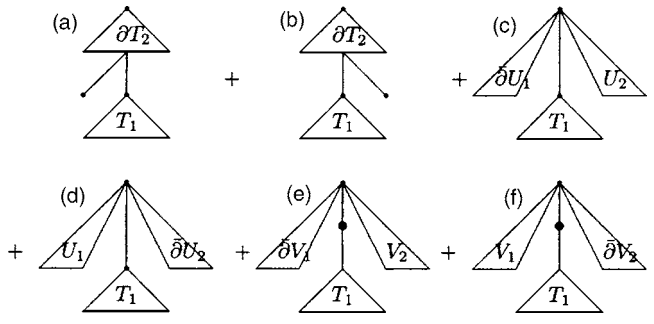

FIG. 70.

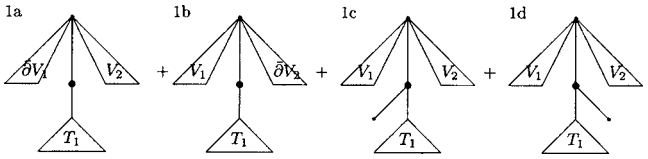

FIG. 71.

(v) when $\deg(T_2)=m$.

Second, we will show that $T_1 *_2 T_2$ for each of the following cases when T_2 is a corolla:

(i) when $\partial T_2 \neq 0$ and $\deg(T_2) \leqslant m-3$,
(ii) when $\partial T_2 \neq 0$ and $\deg(T_2)=m-2$,
(iii) when $\partial T_2 \neq 0$ and $\deg(T_2)=m-1$,
(iv) when $\partial T_2=0$ and $\deg(T_2) \leqslant m-2$,
(v) when $\partial T_2=0$ and $\deg(T_2)=m-1$,
(vi) when $\deg(T_2)=m$.

Finally, we show that $T_1 *_2 T_2$ for a general T_2.

12.2. $T_1 *_1 T_2$ when T_2 is a corolla: For clear-edged bonsai, since it is not an operad, we cannot use broomstick diagrams for graphical proof. Let us look into $T_1 *_1 T_2$ by dividing the cases of ∂T_2 and $\deg(T_2)$.

12.2.1. When $\partial T_2 \neq 0$ and $deg(T_2) \leqslant m-2$: If T_1 is not the one-vertex bonsai, then $(\partial T_1) * T_2$ is the sum of terms in $\partial(T_1 * T_2)$ obtained by attaching edges to T_1. So $T_1 *_1 T_2 = (\partial T_1) * T_2 + T_1 * (\partial T_2) - \partial(T_1 * T_2)$ ("−" in this equation is in fact "+", since we are working mod 2),

$$T_1 * (\partial T_2)$$

$+\Sigma$ [a term in $\partial(T_1 * T_2)$ which is obtained by attaching an edge to a vertex of $T_1 * T_2$ not in T_1 so that (i) and (ii) of Definition 11.1 is satisfied].

Then the first summand is the sum of (i) bonsais A_1 obtained by connecting a nonroot vertex of ∂T_2 and the root of T_1 with an edge, which is depicted as in the first equation of Fig. 65 in 3-bonsai and (ii) bonsais A_2 obtained by connecting the root of ∂T_2 and the root of T_1 with an edge, which is depicted as in the second equation in Fig. 65 in 3-bonsai.

The second summand is the sum of A_3, A_4, and A_5, where A_3, A_4, and A_5 are as follows.

A_3 is the sum of bonsais obtained by connecting a vertex v of T_2 and the root of T_1 with one edge and attaching an edge to v, as in Fig. 66 in 3-bonsai.
