Substituting (73) into Eqs. (69) and minimizing with respect to φ we obtain again three thermodynamically stable phases of Fig. 37 for corresponding equilibrium values of φ. The difference is that now the left-hand side of the diagram describes the switch between the symmetric (ϕ_1) and the broken-symmetry ($\phi_2+\phi_3$) phases, while the BS phase on the right-hand side of the diagram corresponds to $\phi_1+\phi_2+\phi_3$.

(2) If the first or the second relation for irreps becomes equality then $c_1=c_1'\cos\varphi$, $c_2=c_2'$, $c_3=c_1'\sin\varphi$, or $c_1=c_1'\cos\varphi$, $c_2=c_1'\sin\varphi$, $c_3=c_2'$, respectively. Therefore for $\eta<1$ we can only have a symmetry-changing transition from ϕ_1 to ϕ_2 (or ϕ_3). However for $\eta>1$, at φ corresponding to thermodynamically stable BS phase $\phi_1+\phi_2+\phi_3$, the lowest boundary line in Fig. 37 separates this phase from the metastable one $\phi_1+\phi_3$ (or $\phi_1+\phi_2$). Therefore the phase transition from ϕ_1 will take place along the line which lies somewhere higher (dashed line in Fig. 37), i.e., it is of the first order. This type of transition is associated with a small jump of c_1, hence it is close to second order.

TABLE II. Possible transitions from a symmetric vortex phase.

Type[a]	η	n_1	n_2	n_f[b]	Order (symmetry)
1	<1	1	1	1	I (S)
2	>1	1	$\geqslant 1$	n_2+1	II (BS)
3	<1	1	>1	n_2	I (BS)
4	>1	>1	$\geqslant 1$	n_2+n_1	I (BS)

[a]Numbers used in Fig. 36.
[b]Number of irreps in the final state.

Considering higher numbers of mixing irreps will not result in qualitatively new phase transitions which are thus of four types (Table II).

The diagram of the lowest transitions from symmetric phases in a thin square was evaluated within the above approach, which compares well with an accurate Monte Carlo calculation[70] shown in the upper panel of Fig. 36. The critical values of ξ calculated by the two approaches differ by only several percents. One finds indeed that only a few states effectively admix to the order parameter. The described region in the phase diagram becomes relatively large with decreasing a. For small enough samples some phase boundary lines pass above $(a/\xi(0))^2$ and the nucleated symmetric phases remain thermodynamically stable down to $T=0$. Thus the transition from the phase with an antivortex in the center ($\Phi/\Phi_0=5.5\leftrightarrow 6.5$) to a BS phase with the same vorticity but without antivortex is suppressed for $a<(7\leftrightarrow 8)\xi(0)$ (≈ 1 μm for Al).

It follows from Fig. 36 that the phase boundary lines separating the areas with different vorticity have positive slopes and correspond to transitions of type 1 (Table II) in the lower part of the diagram.[71] The reason is the increase of Abrikosov parameters β_A in the lowest group of LGL states (Fig. 36) when passing through the corresponding avoided crossings towards increased fields. Indeed, it was shown[24] that the lowest Landau level of each irrep maps into cylindrical states with rotational numbers L to the left and $L+n$ to the right of the avoided crossing, respectively. Therefore for two lowest LGL states the Abrikosov parameter is smaller for the ground state to the left and for the excited one to the right of their intersection, so that the condition (71) can only be obeyed in the latter case.

On the other hand, the obtained transitions to broken-symmetry phases are always of the second order and go mostly via a two-state mixing scenario (in the phases E_-+A+B in Fig. 36 the admixture of B states is relatively small). The direct analogy for this in molecular physics is the pseudo-Jahn-Teller (PJT) instability of symmetric geometry of a molecule with respect to a low symmetry nuclear distortion (q). Usually such an instability results from a strong interaction of the ground electronic state (ϕ_1) with an excited state (ϕ_2), induced by q, which is described by the Hamiltonian,[67]

$$H_{\mathrm{PJT}}=\frac{1}{2}Kq^2+\begin{pmatrix}-\Delta & V_q\\ V_q & \Delta\end{pmatrix}, \tag{74}$$

where 2Δ is the energy gap between the ground and the excited states in the symmetric nuclear configuration, V is the vibronic constant, and K is the force constant. The instability occurs when $V^2/K>\Delta$ and it results in an equilibrium distortion $q^{(0)}$ (Fig. 38) and a broken-symmetry electronic ground state.

The PJT instability can be described by considering a functional depending on electronic variables only.[72] To obtain such a functional, we average H_{PJT} over $\Psi=c_1\phi_1+c_2\phi_2$, find the equilibrium value of q as function of c_1 and c_2 and substitute it back into the average,

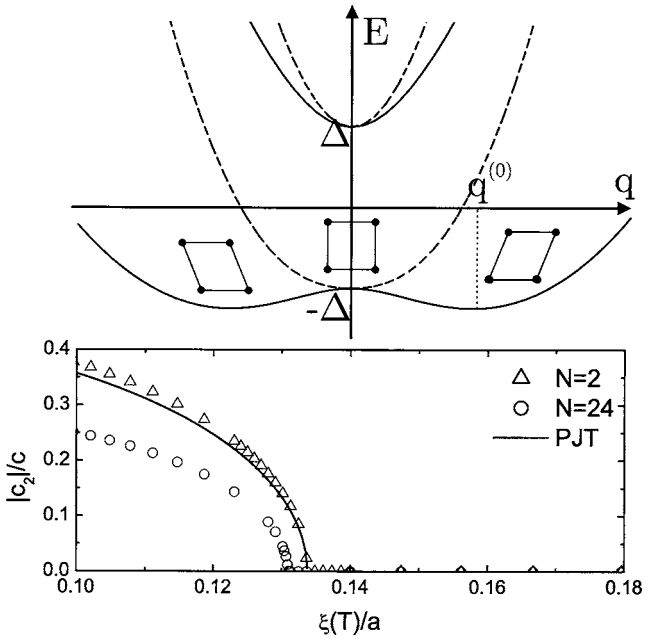

FIG. 38. Upper panel, adiabatic potential for two nondegenerate electronic terms of a square molecule in the case of weak (dashed lines) and strong (solid lines) pseudo-Jahn-Teller effect. Lower panel, temperature dependence of the normalized coefficient of admixture of the excited (A) state close to the $B \rightarrow B+A$ transition at $\Phi=4.5\Phi_0$ (Fig. 36) evaluated by Monte Carlo calculations and the pseudo-Jahn-Teller effect using the correspondence relations (77). The numbers in the inset denote the dimension of the basis set in the Monte Carlo calculations.

$$\langle \Psi | H_{\mathrm{PJT}} | \Psi \rangle^0 = -\frac{2V^2}{K} c_1^2 c_2^2 + \Delta(-c_1^2 + c_2^2). \tag{75}$$

Next we introduce polar coordinates, $c_1=c\cos\varphi$, $c_2=c\sin\varphi$ for the PJT functional (75) and $c_1=A_{11}^{-1/4}c\cos\varphi$, $c_2=A_{22}^{-1/4}c\sin\varphi$ for the functional (68), where φ plays now the role of the order parameter for the BS state. The φ-dependent part of both functionals has now the following common form:

$$\Delta E(\varphi) = -Ac^4 \sin^2 2\varphi - Bc^2 \cos^2\varphi, \tag{76}$$

where $A=V^2/2K$, $B=\Delta$ for the PJT problem and $A=(\beta/4a^2)(1-\eta^{-1/2})$, $B=(\alpha_2 A_{22}^{-1/2}-\alpha_1 A_{11}^{-1/2})/2$ for the case of superconductor. The main difference between them is that $c=1$ in the former and $c\neq 1$ in the second case. Therefore the correspondence between PJT and GL parameters is the following:

$$V^2/K \rightarrow \frac{|\alpha_1|}{2\sqrt{A_{11}}}\left(1-\frac{1}{\sqrt{\eta}}\right),$$

$$2\Delta \rightarrow \frac{\alpha_2}{\sqrt{A_{22}}} - \frac{\alpha_1}{\sqrt{A_{11}}}. \tag{77}$$

Lower panel in Fig. 38 shows how the broken symmetry phase appears for vortex molecules. We can see that the evolution of the order parameter with temperature is reproduced by the pseudo-Jahn-Teller effect. In the case $N=2$, only the ground B and the first excited A LGL states are taken into account. The accurate calculation involving $N=24$ LGL states shifts the transition point obtained in the $N=2$ calculation only by $\approx 2\%$. This shift mainly arises due to the renormalization of the effective parameters in Eq. (68) when more LGL states are taken into account.

As a result of this renormalization the nucleated phase becomes optimized so that the transition takes place at a lower temperature compared to the two-state approximation.

As the analysis shows the specific structural similarity between the pseudo-Jahn-Teller and GL symmetry breaking mechanisms is due to the presence of a quartic dependence on the expansion coefficients. A different mechanism of symmetry breaking was described by Berger for the case of the Schrödinger equation for a cylinder.[73] In this case breaking of axial symmetry was obtained through the induced magnetic field and the quadratic term in the GL potential was not considered.

The symmetric order parameters are found to be remarkably stable below the nucleation temperature, which is a pure mesoscopic effect. Besides, the mesoscopic samples show a rich variety of vortex phases compared to bulk type II superconductors where only the Abrikosov vortex lattice occurs. By using an effective two-state model the nature of the transition to these phases has been revealed and four distinct types of transitions have been found. The symmetry-breaking phase transition has the same structure as the pseudo-Jahn-Teller instability of high symmetry nuclear configurations in molecules. This analogy provides an interesting connection between real and vortex molecules.

The existence of phases can be experimentally verified by using various local probe techniques such as Hall probe microscopy, STM and AFM. The phase diagram is found to be strongly dependent on the samples size. In particular, the region on the phase diagram corresponding to the nucleated (symmetric) order parameter enlarges with reducing the size of the sample. The critical size corresponding to the complete disappearance of the BS phase (the nucleated *S*-phase persists until $T=0$) is predicted to be of the order of micrometers for conventional superconductors, such as Al, Pb. These predictions can be checked experimentally on different mesoscopic superconducting systems.

VII. CONCLUSIONS

An analytical gauge transformation for the vector potential is derived with a vanishing normal component at the boundary line of any regular polygon. With this vector potential gauge, the linearized Ginzburg–Landau problem reduces to an eigenvalue equation in a basis set of functions obeying Neumann boundary conditions, which can be found for different regular polygons. The proposed approach allows for accurate evaluations of the order parameter distributions and proves to be especially efficient at moderate values of applied magnetic fields. For low values of applied magnetic fluxes the order parameter for superconducting square and equilateral triangle contains an antivortex in the center. These solutions are found to be stable with respect to small deviations from the phase boundary line and can be probed by techniques which are sensible to the superfluid density, for example, by using scanning tunnelling microscopy. The calculated lowest energy levels $E_{\mathrm{LLL}}(H)$ show a very good agreement with the measured phase boundaries $T_c(H)$ for a variety of different geometries (triangles, squares, disks, rectangles, loops). By using full GL equations symmetry-breaking transitions deeper in the superconducting state have been studied. A remarkable similarity of these transitions for vortex molecules with pseudo-Jahn-Teller effect for real molecules has been revealed.

Numerical approximations of the Ginzburg–Landau models for superconductivity

Qiang Du[a)]
Department of Mathematics, Pennsylvania State University, University Park, Pennsylvania 16802

(Received 16 May 2005; accepted 17 May 2005; published online 29 September 2005)

In this paper, we review various methods for the numerical approximations of the Ginzburg–Landau models of superconductivity. Particular attention is given to the different treatment of gauge invariance in both the finite element, finite difference, and finite volume settings. Representative theoretical results, typical numerical simulations, and computational challenges are presented. Generalizations to other relevant models are also discussed. © *2005 American Institute of Physics.*

I. INTRODUCTION

The macroscopic model of Ginzburg and Landau[43,91] has been widely used to study both low-temperature and high-temperature superconductors. Due to its highly nonlinear nature, the complex energy landscape and the exotic dynamic responses of its solution to external conditions, its numerical simulations have become valuable tools in order to better understand the properties of the Ginzburg–Landau (GL) models and to provide further theoretical insight into the intriguing superconductivity phenomena.

The development of approximation methods of the Ginzburg–Landau model goes back to the 1950s shortly after the inception of the model.[58] Particularly notable works include the seminal paper by Abrikosov[2] on the vortex state in type-II superconductors based on the linearization of GL equations near the upper critical field. The systematic studies of the GL models from the numerical analysis point of view, to our knowledge, have not been seriously developed until the publication of Ref. 43. In Ref. 43, both rigorous mathematical theory on the well-posedness of the equilibrium GL models and their physical background were presented, along with the systematic development of finite element approximation methods. The work in Ref. 43 was partly motivated by Refs. 3 and 29 of casting the equilibrium models into a variational framework. Extensions to the dynamic models, i.e., the time-dependent Ginzburg–Landau (TDGL) equations were subsequently made.[32,31] Since then, many other works have appeared in the literature, including the development of different types of numerical approximations of Ginzburg–Landau-type models, their rigorous theoretical analysis as well as extensive simulations. By now, almost all aspects of modern numerical analysis have been utilized by people working on the numerical solutions of the GL models, ranging from the design and applications of various discretization methods and fast algorithms, domain decomposition and parallelization techniques, and adaptive computation strategies. In this paper, we briefly review some of the works concerning the numerical approximations of the Ginzburg–Landau models. In terms of spatial discretization methods, we consider, in particular, the finite difference methods, finite element methods and finite volume methods. We also discuss various time-stepping schemes for time dependent models. As there have been a large amount of works on the numerical simulations of the GL models in the last few decades, we make no attempt to provide a comprehensive survey on all existing works on the subject due to limited

[a)]Electronic mail: qdu@math.psu.edu

space. In particular, our review of the vast physics literature is very much limited to those that have also received much attention in the numerical analysis community or have been examined more rigorously in the mathematics literature.

The rest of the paper is organized as follows: in Sec. II, we briefly recall the GL models and their basic features. In Sec. III, various numerical schemes are discussed, and in Sec. IV, some sample simulation results are presented and some concluding remarks are given in Sec. V.

We end the introduction by stating that much of the research works discussed in the paper are aimed at the development and refinement of mezoscale and macroscale models for superconductivity so to enlarge the range of physical problems for which such models are valid; the analysis of these models in order to gain further understanding of their properties and of their solutions, and for the most part of the paper, the development, analysis, and the implementation of algorithms for the numerical simulation of the superconductivity models.

II. GINZBURG–LANDAU MODELS

Let $\Omega \subset R^d$ $(d=2, 3)$ be the region occupied by the superconducting sample. The primary variables used in the GL models are the complex scalar-valued *order parameter* ψ, the real vector-valued *magnetic potential* $\mathbf{A}$, and the real scalar-valued electric potential $\overline{\Phi}$. In a nondimensional form, these variables are related to the physical variables by

$$\text{density of superconducting charge carriers,} \quad |\psi|^2,$$

$$\text{induced magnetic field,} \quad \text{curl } \mathbf{A},$$

$$\text{current,} \quad \mathbf{J} = \mathbf{curl}\ \text{curl } \mathbf{A},$$

$$\text{electric field,} \quad \frac{\partial}{\partial t}\mathbf{A} + \nabla\overline{\Phi}.$$

A. Ginzburg–Landau free energy

Given a constant applied magnetic field H, the conventional Ginzburg–Landau free energy, below the critical transition temperature, is

$$\mathcal{G}(\psi,\mathbf{A}) = \int_\Omega \left(\frac{1}{2}\left| \left(\frac{i}{\kappa}\nabla + \mathbf{A} \right)\psi \right|^2 + \frac{1}{4}(1-|\psi|^2)^2 + \frac{1}{2}|\text{curl } \mathbf{A} - H|^2 \right) \mathrm{d}\Omega,$$

where κ, the Ginzburg–Landau parameter, is a material constant representing the ratio of the penetration depth and the coherence length.

Note that for the general three-dimensional (3D) problems, the interactions between the fields inside the superconducting sample and the external field are important. Various measurement of critical fields are also affected by the geometrical shape of the sample.[72,69,78,85] To apply the Ginzburg–Landau theory in such situations, a coupled system of equations must be solved in both the sample and its exterior. Energetically speaking, in the case where Ω is a bounded domain in 3D, it may be necessary to reformulate the free energy as follows:

$$\mathcal{G}(\psi,\mathbf{A}) = \int_\Omega \left(\frac{1}{2}\left| \left(\frac{i}{\kappa}\nabla + \mathbf{A} \right)\psi \right|^2 + \frac{1}{4}(1-|\psi|^2)^2 \right) \mathrm{d}\Omega + \frac{1}{2}\int_{R^3} |\text{curl } \mathbf{A} - H|^2 \, \mathrm{d}R^3.$$

The minimizers of the GL energy functional satisfy the Euler-Lagrange equations, also called the GL equations, of the form

$$\left(\frac{i}{\kappa}\nabla + \mathbf{A}\right)^2 \psi - \psi + |\psi|^2\psi = 0, \tag{2.1}$$

$$\mathbf{curl}\ \mathrm{curl}\ \mathbf{A} + \frac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + |\psi|^2\mathbf{A} = 0. \tag{2.2}$$

Here, ψ^* is the complex conjugate of ψ. With the present nondimensionalization, $|\psi|=1$ and $|\psi|=0$ correspond to the perfectly superconducting state and the normal state.

This set of nonlinear Ginzburg–Landau equations in the (bounded) interior of Ω is coupled with the linear Maxwell equations in the (unbounded) exterior $\Omega^e = R^3 \backslash \overline{\Omega}$ with far field conditions at infinity and interface conditions on $\Gamma = \partial\Omega$. If we only consider the interior problem (typically valid for a two-dimensional cross section of a long 3D cylinder with the applied magnetic field perpendicular to the cross section), then on Γ, it is customary to use the natural boundary conditions

$$\left(\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi\right)\cdot\mathbf{n} = 0, \tag{2.3}$$

$$\mathrm{curl}\ \mathbf{A} = H. \tag{2.4}$$

More general boundary conditions have also been studied. For instance, to study the proximity effect, one may use

$$\left(\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi\right)\cdot\mathbf{n} = -i\gamma\psi.$$

We refer to Refs. 14, 43, and 91 for more discussions.

B. Time-dependent Ginzburg–Landau equations

Let η_1 and η_2 be given relaxation parameters, the conventional time-dependent Ginzburg–Landau (TDGL) model is given by

$$\eta_1\left(\frac{\partial\psi}{\partial t} + i\kappa\overline{\Phi}\psi\right) + \left(\frac{i}{\kappa}\nabla + \mathbf{A}\right)^2\psi - \psi + |\psi|^2\psi = 0, \tag{2.5}$$

$$\eta_2\left(\frac{\partial\mathbf{A}}{\partial t} + \nabla\overline{\Phi}\right) + \mathbf{curl}\ \mathrm{curl}\ \mathbf{A} + \frac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + |\psi|^2\mathbf{A} = 0, \tag{2.6}$$

with boundary conditions

$$\left(\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi\right)\cdot\mathbf{n} = 0, \tag{2.7}$$

$$\mathrm{curl}\ \mathbf{A} = H, \tag{2.8}$$

$$\eta_2\left(\frac{\partial\mathbf{A}}{\partial t} + \nabla\overline{\Phi}\right)\cdot\mathbf{n} = \mathbf{J}_a\cdot\mathbf{n}, \tag{2.9}$$

where $\mathbf{J}_a$ is an applied current. The initial conditions are

$$\psi(\mathbf{x},0)=\psi_0(\mathbf{x}) \quad \text{and} \quad \mathbf{A}(\mathbf{x},0)=\mathbf{A}_0(\mathbf{x}) \quad \text{in } \Omega.$$

Note that we only focus on the interior problem for now and we assume that η_1 and η_2 are both positive real numbers (dynamics with complex valued η_1 have been studied[30]).

First, it is convenient to introduce an auxiliary variable $\Phi_a(\mathbf{x},t)=(\mathbf{J}_a\cdot\mathbf{x})/\eta_2$ and define $\Phi=\overline{\Phi}-\Phi_a$. The triple $(\psi,\mathbf{A},\Phi)$ is often used as the primary variables for the TDGL equations which are related to the energy functional by

$$\eta_1\left(\frac{\partial\psi}{\partial t}+i\kappa\overline{\Phi}\psi\right)=-\frac{\partial\mathcal{G}}{\partial\psi}(\psi,\mathbf{A}), \tag{2.10}$$

$$\eta_2\left(\frac{\partial\mathbf{A}}{\partial t}+\nabla\Phi\right)=-\frac{\partial\mathcal{G}}{\partial\mathbf{A}}(\psi,\mathbf{A}). \tag{2.11}$$

C. Gauge invariance

Both the GL and the TDGL equations enjoy the *gauge invariance* property, see Refs. 32 and 72 for more detailed discussions.

Numerical minimization of the free energy functional is made difficult due to the gauge invariance. However, a nice remedy has been developed to avoid such pitfalls.[43] Define

$$\mathcal{F}(\psi,\mathbf{A})=\mathcal{G}(\psi,\mathbf{A})+\int_\Omega |\text{div }\mathbf{A}|^2\,d\mathbf{x}. \tag{2.12}$$

By choosing proper gauge transformation, the following can be shown.

Theorem 2.1: *The following minimization problems are equivalent*:

$$\begin{array}{lll} \textbf{Min} & \mathcal{G}(\psi,\mathbf{A}) & \\ s.t. & \psi\in\mathcal{H}^1(\Omega), & \Leftrightarrow \\ & \mathbf{A}\in\mathbf{H}^1(\Omega) & \end{array} \quad \begin{array}{lll} \textbf{Min} & \mathcal{G}(\psi,\mathbf{A}) & \\ s.t. & \psi\in\mathcal{H}^1(\Omega), & \Leftrightarrow \\ & \mathbf{A}\in\mathbf{H}^1_n(\text{div},\Omega) & \end{array} \quad \begin{array}{lll} \textbf{Min} & \mathcal{F}(\psi,\mathbf{A}) & \\ s.t. & \psi\in\mathcal{H}^1(\Omega), & \\ & \mathbf{A}\in\mathbf{H}^1_n(\Omega). & \end{array}$$

where $\mathbf{H}^1_n(\Omega)$ *is a subspace of* $\mathbf{H}^1(\Omega)$ *with vanishing normal component on the boundary while* $\mathbf{H}^1_n(\text{div},\Omega)$ *is a subspace of divergence free vector valued functions in* $\mathbf{H}^1_n(\Omega)$.

With the equivalent formulation, one can simply enforce the Coulomb gauge implicitly by solving for the variational problems with respect to $\mathcal{F}$ in $\mathcal{H}^1(\Omega)\times\mathbf{H}^1_n(\Omega)$. The penalty term $\|\text{div }\mathbf{A}\|^2$ serves as a null Lagrangian which vanishes at the energy minimizer.

The TDGL equations (2.10) and (2.11) may be viewed as the gauge invariant gradient flow of the free energy. By examining the various choices of the gauge, the well posedness of the system was first reported in 1992 at the first world congress of nonlinear analysts.[33,32] Sharper results based on some better energy estimates and the long time solution behavior have later been studied, for instance, in Refs. 72, 90, and 56.

III. NUMERICAL APPROXIMATIONS

Due to the complexity stemming from the full nonlinearity of the GL models, analytical studies have been limited to special cases. Numerical approximations, on the other hand, have provided researchers useful tools to understand the models and to simulate the physical properties of the superconductors. The systematic study of the GL models from the numerical analysis point of view was first made in Ref. 43. Later, many works on the numerical approximations of Ginzburg–Landau type models and their rigorous theoretical analysis have appeared. Here, we briefly discuss the finite difference,[3,21,26,29,35,55,57,59,61] finite element,[4,17,20,18,40,43–45,62,93,95] and finite volume methods[46–48] for spatial discretizations. We also discuss various time-stepping schemes for time-dependent models[31,79,80] and some parallel and adaptive algorithms.

A. Finite element approximations

The basic theory of conforming finite element approximations for the steady state GL equations in a bounded domain has been presented in Ref. 43. Let us choose a pair of conforming finite element spaces $\mathcal{V}_k^h \times \mathbf{V}_k^h \subset \mathcal{H}^1(\Omega) \times \mathbf{H}_n^1(\Omega)$ where h being a mesh parameter, and assume that they satisfy the approximation properties

$$\inf_{g^h \in \mathcal{V}_k^h} \|\psi - g^h\|_1 \leqslant ch^r \|\psi\|_{r+1},$$

$$\inf_{\mathbf{B^h} \in \mathbf{V_k^h}} \|\mathbf{A} - \mathbf{B^h}\|_1 \leqslant \mathbf{ch^r} \|\mathbf{A}\|_{\mathbf{r+1}}$$

for functions ψ and $\mathbf{A}$ of sufficient regularity.

Then, the discrete Galerkin finite element approximation can be formulated as follows:[43]

$$\mathbf{Min}\ \mathcal{F}(\psi^h, \mathbf{A}^h),$$

$$\text{s.t.}\ (\psi^h, \mathbf{A}^h) \in \mathcal{V}_k^h \times \mathbf{V}_k^h.$$

It has been shown that the above problems generate a sequence of convergent approximate solutions as $h \to 0$ under the minimal regularity condition. Moreover, optimal order of error estimates of the following type have been derived for nonsingular solution branches:

$$\|\psi - \psi^h\|_1 + \|\mathbf{A} - \mathbf{A}^h\|_1 \leqslant ch^k \{\|\psi\|_{k+1} + \|\mathbf{A}\|_{k+1}\}.$$

It is worthwhile to note that no inf-sup condition is required for the finite element spaces. The gauge condition is not strictly imposed for finite mesh parameter h, but it is shown to be valid in the limit as $h \to 0$.

The finite element methods have later been generalized to other related models, such as the d-wave GL equations,[93] optimal control of GL models[60] and the Lawrence-Doniach models for layered superconductors.[41,62] In Refs. 44 and 45, various numerical simulations have been conducted based on the finite element approximations.

The application of finite element method to TDGL has been considered in Ref. 31. Besides the basic convergence results for semidiscrete scheme, both first order and second in time discretization schemes have also been presented. Let Δt_n be the step size and $(\psi_n^h, \mathbf{A}_n^h)$ the numerical solution at time t_n. When the applied current is absent, the first order backward Euler scheme can be given a variational form, find $(\psi_{n+1}^h, \mathbf{A}_{n+1}^h)$ such that it solves the problem

$$\mathbf{Min}\ \mathcal{G}_{\Delta t_n}(\psi, \mathbf{A}) = \mathcal{G}(\psi, \mathbf{A}) + \frac{1}{\Delta t_n} \int_\Omega [\eta_1 |\psi - \psi_n^h|^2 + \eta_2 |\mathbf{A} - \mathbf{A}_n^h|^2] \mathrm{d}\Omega.$$

It turns out that a second order in time scheme can also be similarly formulated, first find $(\psi_*^h, \mathbf{A}_*^h)$ that minimizes

$$\mathcal{G}(\psi, \mathbf{A}) + \frac{1}{2\Delta t_n} \int_\Omega [\eta_1 |\psi - \psi_n^h|^2 + \eta_2 |\mathbf{A} - \mathbf{A}_n^h|^2] \mathrm{d}\Omega,$$

then we let $(\psi_{n+1}^h, \mathbf{A}_{n+1}^h) = 2(\psi_*^h, \mathbf{A}_*^h) - (\psi_n^h, \mathbf{A}_n^h)$. We note that the derivation of error estimates of the fully discrete scheme was, however, not rigorously provided there. By using a mixed formulation, Ref. 17 has presented a more complete theory for the approximation of the TDGL along with optimal order error estimates in two space dimension. Later, Ref. 20 considered approximations to a related optimal control problem. Generalizations to the time-dependent Lawrence-Doniach model have been presented in Ref. 62.

B. Finite difference approximations

Same as in the approximations of many other physical problems, the finite difference approximations of the GL models have been the most widely used approach. Though conventional difference schemes have been studied in Refs. 55 and 67, much of the focus has been on the gauge invariant difference approximation. The motivation has come from the fact that the underlying physical model enjoys the gauge invariance property. In Ref. 3, a gauge invariant finite difference scheme was proposed for the steady-state GL equations on a uniform rectangular grid, in the spirit of discrete gauge field theory. Many subsequent works have followed up on such an approach via an introduction of the so-called link and bond variables, and various extensions have also been made.[21,22,55,57,59,61,66,68] For the approximation of the magnetic vector potential, such an approach is naturally related to the idea of staggered grid (marker-and-cell) used in computational electromagnetics and fluid dynamics.

For simplicity, let us consider the two-dimensional setting with a uniform rectangular mesh of grid size h. Following the notation in Ref. 35, the discrete gauge invariant energy functional is given by

$$\mathcal{G}^h(\vec{\psi},\vec{A}) = \frac{1}{2}\sum_{jk}\frac{1}{\kappa^2}|\psi_k \exp(-i\kappa a_{jk}h) - \psi_j|^2 + \sum_j \frac{h^2}{4}(1-|\psi_j|^2)^2 + \frac{1}{2}\sum_{jklm}(a_{jk}+a_{kl}+a_{lm}+a_{mj}-Hh)^2, \tag{3.1}$$

where the first sum is over all neighboring edges, the second over all vertices and the third over all square cells. $\vec{\psi}=\{\psi_j\}$ are the approximations of the order parameter at the cell vertices and $\vec{A}=\{a_{jk}\}$ are the approximations of the signed tangential component of the magnetic vector potential at the midpoint of the cell edges.

The gauge invariant backward Euler scheme is given by[35]

$$\eta_1\frac{\psi_j^n - \psi_j^{n-1}\exp(-i\kappa\overline{\Phi}_j^n\Delta t)}{\Delta t} = -\frac{1}{h^2}\frac{\partial \mathcal{G}^h}{\partial \psi_j^n}(\vec{\psi}^n,\vec{A}^n)$$

and

$$\eta_2\left(\frac{a_{jk}^n - a_{jk}^{n-1}}{\Delta t} + \frac{\Phi_k^n - \Phi_j^n}{h}\right) = -\frac{1}{h^2}\frac{\partial \mathcal{G}^h}{\partial a_{jk}^n}(\vec{\psi}^n,\vec{A}^n)$$

for $n=1,2,\ldots,N=T/\Delta t$. Here, $\{\overline{\Phi}_j^n\}$ are the approximations of the scalar electric potential. Note that the equations at the nodes on the boundary may require slight modifications. A complete and rigorous analysis for such a discretization has been provided in Ref. 35, including the proof of the discrete maximum principle, discrete energy law, and optimal order error estimates.

It remains to be seen if a higher order in time fully discrete gauge invariant scheme can be developed for the TDGL equations.

We note here also that, in practical numerical simulations, explicit or semi-implicit in time difference schemes have been mostly employed. In general, these schemes are only conditionally stable at best.

C. Finite volume approximations

As more and more attention is being paid to the study of the effect of the sample geometry and topology on the superconductivity phenomena, methods based on unstructured grids become more competitive in such cases. Besides the finite element methods we have discussed, finite volume methods have also been developed which have the combined advantage of being able to work with an unstructured grid while preserving the discrete gauge invariance.[48,46,47]

A standard extension to the staggered grid used in the gauge invariant difference approximation is the Voronoi-Delaunay pair. Given a set of distinct points $\{x_j\}_{j=1}^n \subset R^2$, we can define for each point $x_j, j=1,\ldots,n$, the corresponding Voronoi region $V_j, j=1,\ldots,n$, by

$$V_j = \{\mathbf{y} \in R^2 || x_j - y| < |x_k - y| \quad \text{for } 1 \leqslant k \leqslant n \quad \text{and} \quad k \neq j\}.$$

We refer to $\{V_j\}_{j=1}^n$ as the *Voronoi tessellation* corresponding to the generators $\{x_j\}_{j=1}^n$. The dual tessellation to a Voronoi tessellation consisting of triangles is referred to as a *Delaunay triangulation*. Given a discrete vector field $\vec{A}$ tangentially defined at the midpoints of the triangle edges of a Delaunay triangulation, it is easily seen that such vectors are normal to the edges of the Voronoi regions. Thus, discrete calculus can be defined for the curl operator on the Delaunay triangles and for the div operator on the Voronoi cells.

Then, the central idea for finding a suitable discretization of the GL energy functional is to construct a gauge invariant approximation to $|\nabla\psi - i\kappa\mathbf{A}\psi|$. It was noticed in Ref. 48 that one may first project the vector $v = \nabla\psi - i\kappa\mathbf{A}\psi$ into the tangential components along the triangle edges and obtain the following simple identity

$$|\tau_{ijk}||v|^2 = \sum \cot\,\theta_i |v \cdot (x_j - x_k)|^2,$$

where the sum is over all three edges and θ_i is the opposite angle. Notice that if we let θ_{i1} and θ_{i2} be the two opposing angles corresponding to the same edge $x_j x_k$, then

$$\cot\,\theta_{i1} + \cot\,\theta_{i2} = \frac{|\Gamma_{jk}|}{|x_j - x_k|},$$

where Γ_{jk} is the common edge between the two adjacent Voronoi regions V_{i1} and V_{i2}. Now, $|v \cdot (x_j - x_k)|$ can be approximated by $|\psi_k \exp(-i\kappa a_{jk}|x_j - x_k|) - \psi_j|$.

Thus, the Ginzburg–Landau functional is discretized as follows:[48]

$$\mathcal{F}^h(\vec{\psi}^h, \vec{A}^h) = \sum_{j=1}^n \frac{1}{4|V_j|}(1 - |\psi_j|^2)^2 + \sum_{j=1}^n \left\{ \sum_{k \in \chi_j} \frac{|\Gamma_{jk}|}{2\kappa^2 |x_j - x_k|} |\psi_k \exp(-i\kappa a_{jk}|x_j - x_k|) - \psi_j|^2 \right\}$$
$$+ \sum_{\tau_{jkl}} \frac{1}{2\tau_{jkl}}(a_{jk}h_{jk} + a_{kl}h_{kl} + a_{lj}h_{lj} - H\tau_{jkl})^2, \tag{3.2}$$

where for any j, the index set χ_j denotes the indices of all vertices which are adjacent to the vertex $\mathbf{x}_j$. The discrete gauge invariance is understood in the sense that

$$\mathcal{G}^h(\vec{\psi}^h, \vec{A}^h) = \mathcal{G}^h(T^h_\phi(\vec{\psi}^h, \vec{A}^h)),$$

where the transformation T^h is defined by the map

$$\psi_j \to \psi_j e^{i\kappa\phi_j}, \quad a_{jk} \to a_{jk} + \frac{\phi_k - \phi_j}{|x_j - x_k|},$$

corresponding to any scale field $\vec{\phi}^h$.

The gauge invariant difference approximation on a rectangular grid discussed earlier is in fact a special case of the above finite volume scheme. This can be seen by making the equivalence of the rectangular cells with the Voronoi cells and the equivalence of the dual cells with pairs of right Delaunay triangles sharing a common edge opposing the right angles.

Similar to the technique introduced in Ref. 43 and in the finite difference setting, a modified functional can be defined to enforce the gauge choice implicitly. Let us define

$$\mathcal{F}^h(\vec{\psi}^h, \vec{A}^h) = \mathcal{G}^h(\vec{\psi}^h, \vec{A}^h) + \sum_j \frac{1}{|V_j|}\left(\sum_{k \in \chi_j} a_{kj}|\Gamma_{kj}| \right)^2.$$

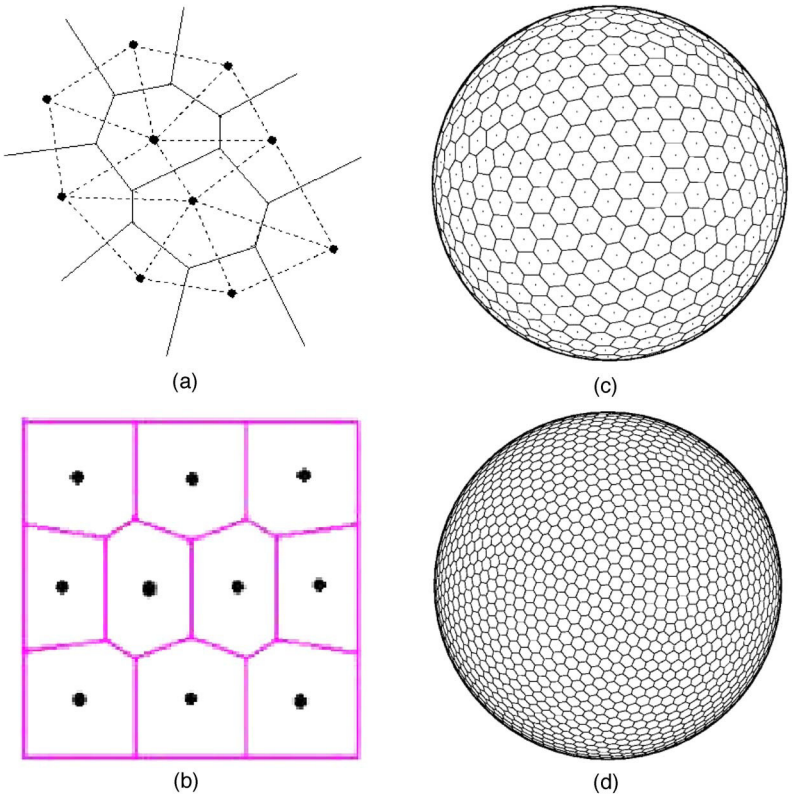

FIG. 1. (Color online) A planar Voronoi-Delaunay pair, a CVT in a square and two SCVTs of different resolution.

Then, it is easy to show that the minimizer of $\mathcal{F}^h$ is also a minimizer of $\mathcal{G}^h$ and it is also divergence free in the discrete sense:

$$\sum_{k\in\chi_j} a_{kj}|\Gamma_{kj}| = 0, \quad \forall\, j.$$

Moreover, it has been shown that the minimizer of $\mathcal{F}^h$ satisfies the discrete maximum principle, $|\psi_j| \leqslant 1$ for all j. This, coupled with suitable energy estimates, leads to the convergence of the discrete approximations as the mesh size goes to zero.[48]

In Refs. 46 and 47, such finite volume scheme was extended to solve a reduced set of TDGL models defined on a thin spherical shell. In addition to the basic convergence properties, a feature of the discussions in Refs. 46 and 47 is the consideration of a special Voronoi-Delaunay pair, namely, the spherical centroidal Voronoi tessellations and the corresponding Delaunay triangulations,[42] see Fig 1. The SCVTs are natural extensions of the centroidal Voronoi tessellations in Euclidean spaces.[39] It has been shown that by using the SCVTs, the discrete approximations exhibit a higher order convergence comparing with the conventional Voronoi-Delaunay pair.

Detailed numerical simulations have also been performed in Refs. 46 and 47 using the SCVT based gauge invariant finite volume scheme. Both static vortex configurations and vortex dynamics under applied current have been studied.

D. Artificial boundary conditions

For a full three-dimensional simulation of the GL model, taking into account the effect of the induced magnetic field of the superconducting sample on the field exterior to the sample, the numerical solution of the Ginzburg–Landau equations in the superconducting sample needs to be solved in conjunction with the solution of the Maxwell equations in the exterior.

To overcome the unboundedness of the exterior domain, approximations must be introduced or alternative formulations must be considered. The crudest but often very effective approximation is simply to ignore the effect in the exterior completely. Such approximations are particularly valid for high-kappa materials (in such cases, some reduced GL models have been proposed and used in numerical simulations of vortex lines.[15,25,40]

As an alternative, a rigorous theory based on artificial boundary conditions has been presented in Ref. 51 to transform the computation domain to a finite ball enclosing the superconducting sample.

The key step is to note that the magnetic energy $\|\mathrm{curl}\,\mathbf{A}\|^2_{L^2(R^3)}$, coupled with the null-Lagrangian term $\|\mathrm{div}\,\mathbf{A}\|^2_{L^2(R^3)}$ used to enforce the Coulomb gauge, is equivalent to $\|\nabla\mathbf{A}\|^2_{L^2(R^3)}$ which can be decomposed as $\|\nabla\mathbf{A}\|^2_{L^2(B_r)}+\|\nabla\mathbf{A}\|^2_{L^2(B_r^e)}$. Here B_r denotes a ball of radius r and $B_r^e = R^3\backslash B_r$ denotes its exterior.

For $\mathbf{A}$'s that are harmonic in B_r^e, we have

$$\|\nabla\mathbf{A}\|^2_{B_r^e} = \int_{S_r} \mathbf{A}\frac{\partial\mathbf{A}}{\partial\mathbf{n}}\mathrm{d}S = \int_{S_r} \mathbf{A}J(\mathbf{A})\mathrm{d}S,$$

where S_r denotes the sphere of radius r, J is the Stekelov-Poincaré operator (or the Dirichlet to Neumann map). Since J can be explicitly expressed with the help of Legendre functions, various orders of approximations can be constructed.

Briefly, let the Legendre polynomial and Legendre function be given by

$$P_n^0(t) = P_n(t) = \frac{1}{2^n n!}\frac{d^n(t^2-1)^n}{\mathrm{d}t^n}, \quad P_n^m(t) = (1-t^2)^{m/2}\frac{d^m}{\mathrm{d}t^m}P_n(t),$$

and let

$$G(\gamma) = -\frac{1}{4\pi R^3} - \sum_{n=1}^{\infty}\frac{(n+1)(2n+1)}{4\pi R^3}P_n(\cos\,\gamma),$$

for γ defined by $\cos\,\gamma = \cos\,\theta\cos\,\theta' + \sin\,\theta\sin\,\theta'\cos(\varphi-\varphi')$ for a pair of points $x=(r,\theta,\varphi)$ and $y=(r,\theta',\varphi')$. Then, with $\mathbf{A}_0$ satisfying $\mathrm{curl}\,\mathbf{A}_0 = H$, we have the following equivalent form of the energy functional[51]

$$\mathcal{F}(\psi,\mathbf{A}) = \int_\Omega \frac{1}{4}(1-|\psi|^2)^2\,\mathrm{d}\Omega + \frac{1}{2}\int_\Omega \left|\left(\frac{i}{\kappa}\nabla + \mathbf{A} + \mathbf{A}_0\right)\psi\right|^2\mathrm{d}\Omega + \frac{1}{2}\int_{B_r}|\nabla\mathbf{A}|^2\,\mathrm{d}x$$
$$+ \int_{S_r}\int_{S_r}\mathbf{A}(x)\cdot G(\gamma)I\cdot\mathbf{A}(y)\mathrm{d}x\,\mathrm{d}y.$$

In a nut-shell, the exterior energy is now effectively transformed into an energy defined on the boundary of the ball.

Various approximations of the boundary energy can be made, for instance, using a finite element discretization in the interior of B_r, the following discrete problem has been considered in Ref. 51:

$$\mathcal{F}(\psi^h,\mathbf{A}^h) = \frac{1}{2}\int_\Omega \left|\left(\frac{i}{\kappa}\nabla + \mathbf{A}^h + \mathbf{A}_0\right)\psi^h\right|^2\mathrm{d}\Omega + \int_\Omega \frac{1}{4}(1-|\psi^h|^2)^2\,\mathrm{d}\Omega + \frac{1}{2}\int_{B_r}|\nabla\mathbf{A}^h|^2\,\mathrm{d}x$$
$$+ \sum_{n=1}^{N}\frac{(n+1)(2n+1)}{4\pi r^3}\int_{S_r}\int_{S_r}\mathbf{A}^h(x)P_n(\cos\,\gamma)\mathbf{A}^h(y)\mathrm{d}x\,\mathrm{d}y.$$

Let $r_1=\mathrm{diam}(\Omega)$, under the approximation assumptions on the finite element spaces made earlier, the following has been proved.

Theorem 3.1: *For a smooth exact solution on a nonsingular solution branch, the approximate solutions satisfy the following error estimates: for h small and* $r>r_1$,

$$\|\psi-\psi^h\|_{1,\Omega}+\|\mathbf{A}-\mathbf{A}^h\|_{1,B_r}\leqslant c_1h^k(\|\psi\|_{k+1,\Omega}+\|\mathbf{A}\|_{k+1,B_r})+c_2(\Omega,r)(r_1/r)^N\|\mathbf{A}\|_{1,B_r},$$

for some constants c_1 *and* $c_2=c_2(\Omega,r)$ *independent of h and N.*

It has been seen in numerical computation that in practice with $N=6$, it is sufficient to choose the computational domain with r no more than twice the diameter of Ω in order to obtain good accuracy of the approximation in the exterior domain.[51]

E. More on time discretization

For TDGL models, while most of the rigorous mathematical analysis have been focused on the fully implicit in time discretizations, explicit marching schemes and semi-implicit marching schemes[94] have also been frequently used in numerical simulations due to their simplicity in implementation.

Theoretically, to make the time-marching more efficient, other useful ideas have also been considered in the literature. For example, a linearized crank-Nicolson scheme has been considered in Ref. 79, similar to the semi-implicit approach. Analytical studies of an alternating marching scheme have also been made in Ref. 80 where for the order parameter and magnetic potential are solved in alternating steps and thus reducing the size of the implicit nonlinear system by half.

To effectively solve the nonlinear and linear systems employed in the implicit schemes, constructions of suitable preconditioners can be very helpful. In this regard, the Sobolev gradient methods studied in Refs. 82 and 83 fit into such a framework. Essentially, the gradient flows in the H^{-1} space considered there are equivalent to employing the inverse of Laplace operator Δ^{-1} as the preconditioner for the standard gradient flow in the L^2 space.

For high values of κ, the Ginzburg–Landau parameter, the original GL models can often be simplified. A particular simplification corresponding to high applied magnetic field has been considered in Refs. 15 and 40. The reduced equations are very much similar to the so-called Gross-Pitaevskii equations used to model the BEC superfluid.[5] In Ref. 9, a class of efficient splitting schemes for computing the ground state solutions of the BEC condensate based on the normalized gradient flow has been studied which may be readily applied to the solution of the reduced GL models.

F. Multilevel, adaptive and parallel algorithms

The numerical simulations of the vortex state in type-II superconductors based on the GL models become computationally challenging when there is a need to resolve a large number of vortices. More efficient implementations of the numerical schemes thus become necessary. There have been a lot of interesting attempts made along this direction. For example, multilevel finite element methods have been analyzed in Ref. 63 for a *d*-wave GL model, following earlier works of Refs. 36 and 93. Posterior error estimates and adaptive finite element methods have been studied in Refs. 18 and 64 with both rigorous analysis and numerical examples.

Parallelization is naturally another important avenue for greater computational efficiency. In Ref. 59, parallelized MPI-based implementation of the explicit finite difference discretization schemes has been presented along with many large scale simulations. Using a natural domain decomposition strategy, a number of parallel algorithms for the simulation of layered superconductors based on the Lawrence Doniach model have been studied in Ref. 41. The implementation has been made first using PVM, with an MPI version developed subsequently. Numerical results indicated significant speed-ups and good scalability. Moreover, interesting numerical simulations of three-dimensional vortex tubes, their dynamics and pinning effect have been made there as well.

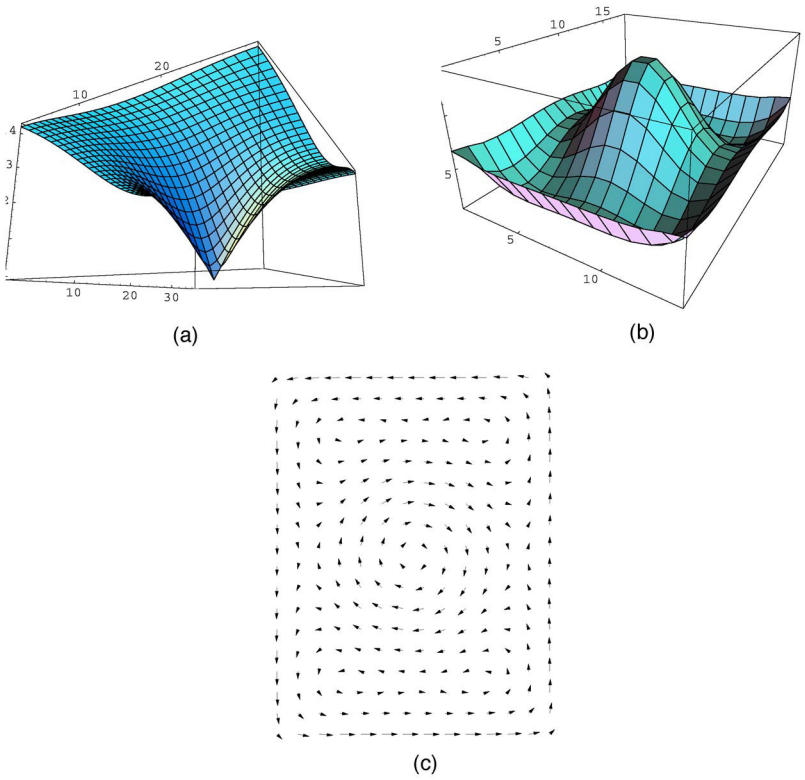

FIG. 2. (Color online) Magnitude of the order parameter, induced field and supercurrent in a 2D rectangular domain.

IV. NUMERICAL SIMULATIONS AND OTHER COMPUTATIONAL ISSUES

We now briefly describe some results of numerical simulations conducted throughout the last decade. These are based on either the finite element codes or the finite volume codes discussed earlier. We refer to Refs. 4, 23–25, 38, 46, and 47 for additional simulations.

A. Vortex solutions

A well-known feature of superconductivity is the phenomena of quantized vortices. For type-II superconductors, the study of Abrikosov on the vortex lattices based on the GL models has become a seminal work that exhibits the great predictive power of the GL theory.

In Fig. 2, we present a few typical plots for the numerical solutions of the steady state GL equations which include a surface plot of the magnitude of the order parameter, a surface plot of the induced magnetic field given by curl **A** and a vector plot of the superconducting current. The solution corresponds to one with a single vortex at the center of a rectangular superconducting sample.[4]

More systematic analysis and simulations of the phase transitions, vortex nucleation, and critical fields can be found in, for instance, Refs. 4, 7, 8, 11, 12, 65, 72, 85, 89, and 88, and the references cited therein.

B. Pinning of vortices in superconducting sample

One of the more intriguing features of superconductivity is the effect of vortex pinning which preserves the superconducting properties in a superconductor despite the penetration of the applied magnetic field.

The GL models have been used to study the pinning effect from many different angles, for instance, pinning due to variable thickness in thin films,[13,27,28,72] spatial inhomogeneities and

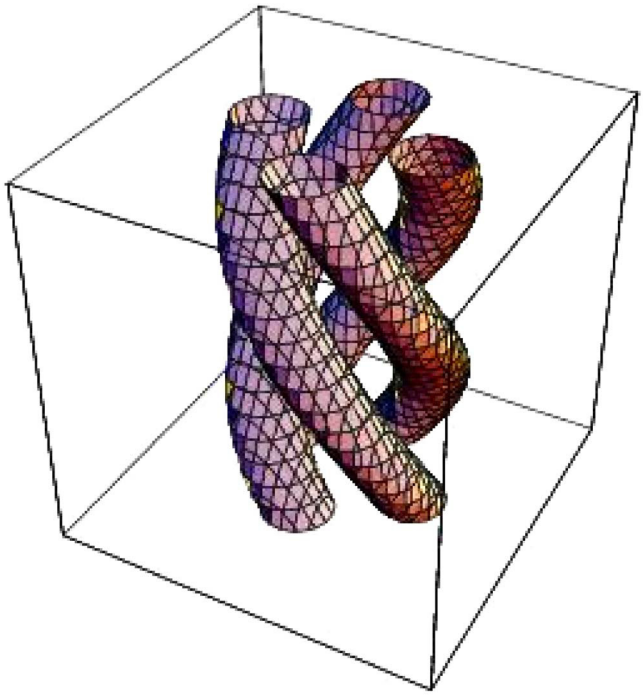

FIG. 3. (Color online) Isosurface plot of vortex tubes pinned in a 3D sample.

normal inclusions and anisotropy.[14,25,49,50] In Fig. 3, three-dimensional vortex tubes pinned by normal inclusions are shown which were computed via the Lawrence-Doniach variant of the GL model in Ref. 41. Due to the collective pinning force, the vortex tubes are no longer strictly aligned in the direction of the applied magnetic field.

C. Vortex state in a thin superconducting spherical shell

The geometry of spherical shell is not only used in superconductivity applications, but also provides an ideal setting for one to examine the vortex state.

With increasing values of the applied magnetic field, some of the energy minimizing superconducting and vortex solutions are given in Fig. 4. We refer to Ref. 46 for more detailed descriptions of the corresponding parameter values.

In Fig. 5, minimum energy values $\mathcal{G}(H)$ corresponding to different external magnetic field strengths H are plotted, along with the magnetization curve given by the derivatives of minimum energy $\mathcal{G}(H)$.

The spatially homogeneous applied magnetic field naturally produces vortices of opposite signs on the two hemispherical shells, thus providing a window for us to see the details of vortex nucleation and vortex annihilation (see Ref. 10 for some analysis in a simpler setting). In Fig. 6, with the applied magnetic field aligned along the poles, the density plots of order parameter show that a pair of vortices of opposite signs first nucleate near the equator, then later split and move into the interior of the hemispheres.[46]

Other simulations on vortex annihilation can be found in Ref. 40 in the planar domain, aided by an applied current.

D. Vortex motion driven by an applied current

An applied current J generally exerts a Lorentz force $F=J\times B$ on each vortex core such that the motion of vortices would induce an electric field, and thus produces electrical resistance. Thus,

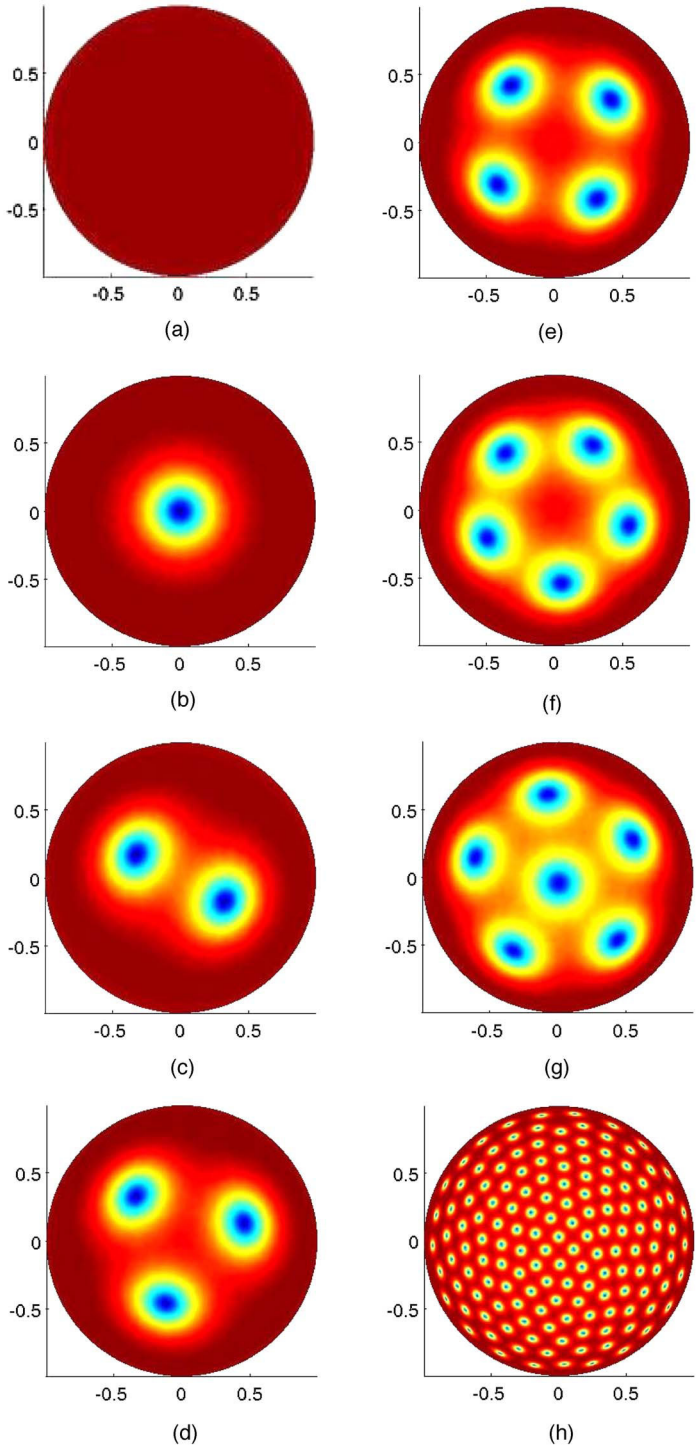

FIG. 4. (Color online) Energy minimizing vortex configurations on the upper hemisphere.

in superconductivity, it is important to understand the interaction of the vortices with the applied current and study the critical values of the applied current which will dislodge the vortices from their equilibrium positions.

In Fig. 7, contour plots of the order parameter are given, corresponding to solution of the

TDGL in a two-dimensional square with a constant applied current imposed along the vertical direction. A single vortex starts to move from the left to the right due to the Lorentz force.

E. Effect of thermal fluctuation

The effect of thermal fluctuations play a central role on the pinning of vortices in type-II superconductors. In Refs. 23 and 24, such effects have been examined through stochastic variants of a time-dependent Ginzburg–Landau model valid for high values of the Ginzburg–Landau parameter. Both additive and multiplicative noise variants have been considered. Many numerical computations have been presented that illustrate the effects that noise has on the dynamics of vortex nucleation and vortex motion. In Fig. 8, isosurface plots of vortex tubes are presented corresponding to different values of variance of the additive noise term using for the simulation of Langevin dynamics. The snapshots are taken at the same time instant and the vortex lattice melting effect can be observed in the process.

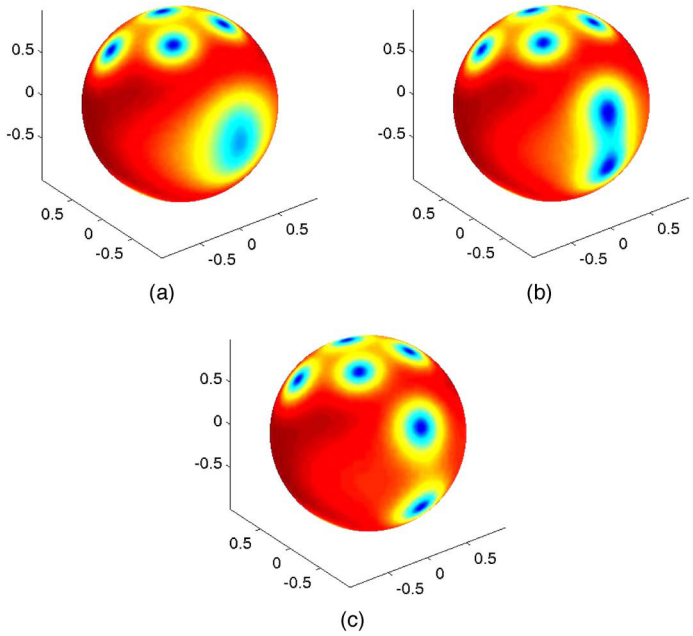

FIG. 6. (Color online) The nucleation and the splitting of vortex pairs near the equator.

F. Variants of Ginzburg–Landau models

The great success of the Ginzburg–Landau models for low T_c superconductivity generated tremendous interests in extending them to other settings including layered materials and high T_c superconductors. For example, in Ref. 36, simulations of a d-wave GL model have been carried out, the vortex solutions there typically display a fourfold symmetry. In certain parameter regimes, the basic stability properties of single and multiple vortices deviated significantly from the single component counterpart, see Fig. 9 for an illustration of a stable double vortex profile.

More analytical and numerical studies of d-wave GL models can be found in Refs. 73, 86, and 93. Numerical studies of other extensions of the GL models have also been performed, for instance, see Ref. 6 for simulations based on the SO(5) model.

Related to the vortex state in superconductors, the 1995 experimental confirmation of Bose-Einstein condensation (BEC) in alkali-metal gases provides another avenue to study the phenomena of quantized vortices. In recent BEC experiments, vortices have been nucleated with the help of laser stirring and rotating magnetic traps. Remarkably, many of the phenomenological properties of quantized vortices have been well captured by mathematical models such as the Gross-Pitaevskii (GP) equations. In the case of rotating magnetic traps, the mathematical form of the GP

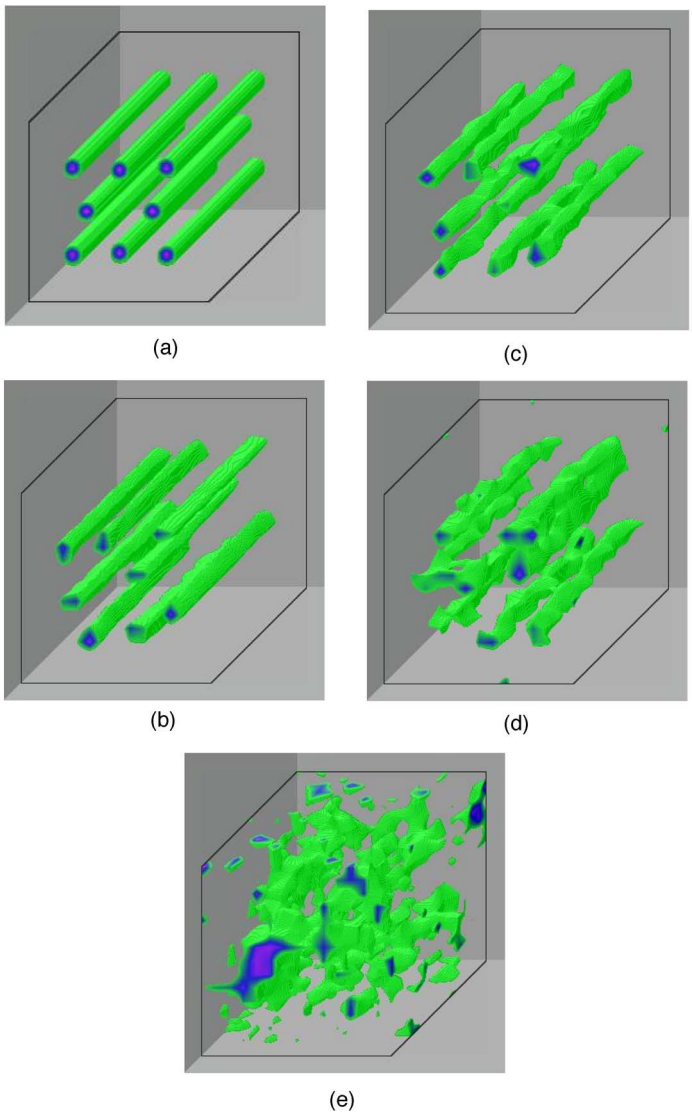

FIG. 8. (Color online) Snapshots of the vortex tubes in a cubic sample with increasing additive noises.

equations have close resemblance with the high-kappa Ginzburg–Landau (GL) model.[40] Utilizing the mathematical theory and the numerical codes developed for the GL,[5] presented a similar mathematical framework for rigorously characterizing the critical velocities for the vortex nucleation in a BEC cloud subject to a rotating magnetic trap. A class of splitting schemes for com-

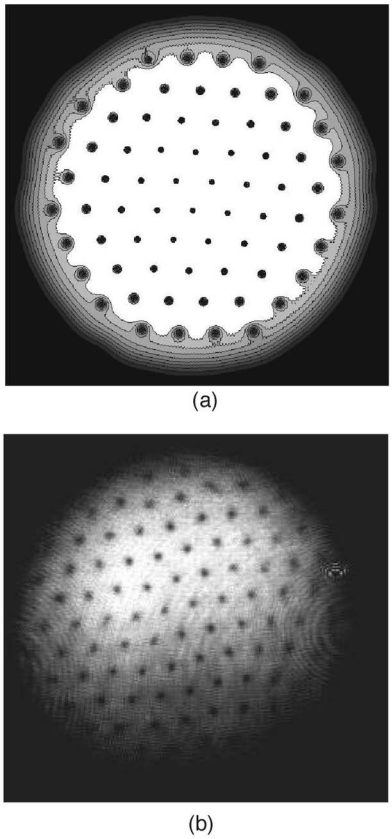

FIG. 10. Vortices in BEC: our numerical simulation (left) vs the MIT experiment (right) (Ref. 1).

puting the ground state solutions of the BEC condensate based on the normalized gradient flow has also been presented.[9] In Fig. 10, we provide a particular comparison of experimental pictures and the result of numerical simulations of the vortex solution with parameters taken from the experimental values based on the code developed in Ref. 5.

G. Computational challenges

The interests of the vortex state not only lie in the study of the vortex structures for a few isolated vortices, but also in the study of the collective effect of a large number of vortices and vortex lattices and their interactions with material structure and defects as well as the impact of sample topology and geometry. Simulations of GL models have been performed recently on structures like buckyballs and for MgB2 thin films. (See Fig. 11.)

In practice, numerical simulations of exceedingly large numbers of vortices based on the GL models remain computationally challenging, partly due to the intriguing properties associated with the vortex quantization effect. More specifically, for a square sample with n vortices in the interior, the phase angle of the complex order parameter will endure a change of $2n\pi$ around the boundary of the sample. If m points are needed to resolve a single period of phase winding, then $mn/4$ points will roughly be needed on each edge of the square. Thus, a uniform mesh will require up to $m^2n^2/16$ grid points. For large n and even moderate values of m, this can become very demanding computationally even for two-dimensional problems, not to mention the more challenging three-dimensional cases.

Naturally, adaptive schemes may save the computational cost significant, but with densely packed vortices, refinement may be required almost everywhere, and their efficiency are thus reduced. In particular, we note that it is not sufficient to only refine near the vortex cores as the

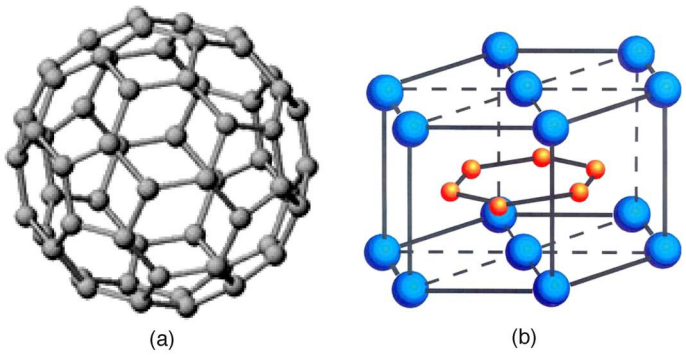

FIG. 11. (Color online) A buckyball and the atomic structure of MgB2.

correct resolution of the highly oscillatory phase change is also very important, see Fig. 12 for an interesting illustration on how the real and imaginary parts of the order parameter behave in comparison with the magnitude for a solution with 22 pairs of vortices in a spherical shell simulation.[47] Resolving the highly oscillatory phase for the Ginzburg–Landau simulation is a challenge that can be compared with resolving the solution of the Hemholtz equation with high frequency. In addition, it is easy to see that the variation in the phase variable starts to become increasingly dramatic when getting closer to the boundary (equator). How to effectively tackle such solution behavior remains to be investigated.

On the other hand, for high-T_c superconductors, codes for mezoscale GL models cannot hope to be of direct use in the design of devices due to the presence of a large number of vortices. Whenever computational or analytical results are used in such an environment, they are based on simple homogenized or macroscopic models.

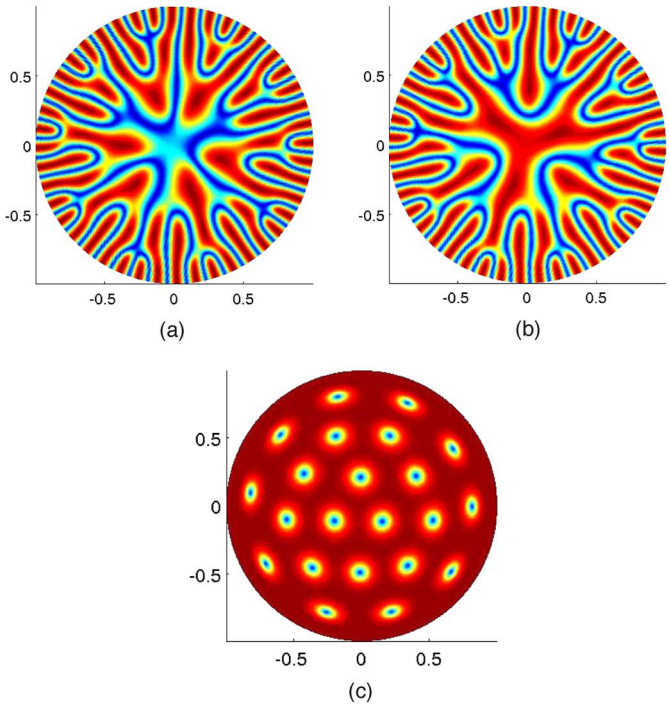

FIG. 12. (Color online) The absolute value of the real (left) and imaginary (center) parts of ψ and the magnitude $|\psi|$.

Recently, mean field models have been derived to describe the vortex state using a vortex density ω. These models are closely related to the GL models as one normally first derives a discrete set of motion laws for individual vortices based on the GL dynamics and a vortex density model is then derived when the number of vortices becomes large.[16,53,71,81,87] Let u denote the averaged magnetic field, a simplest two-dimensional version of such a model is given by

$$u - \lambda^2 \Delta u = \omega \quad \text{in } \Omega \times (0,T),$$

$$\omega_t - \nabla \cdot (\omega \nabla u) = 0 \quad \text{in } \Omega \times (0,T),$$

with suitable initial and boundary conditions. There have been a lot of studies made both from analytical and computational aspects[19,37,38,52,54,74] in recent years. It is perceivable that more efficient simulation schemes on the vortex state can be developed with a multiscale approach that combines GL model or vortex dynamic laws and the mean field models together. (Also see Refs. 34, 70, 75–77, 84, and 92.)

V. CONCLUSION

Superconductivity is one of the grand challenges identified as being crucial to future economic prosperity and scientific leadership. In this paper, various methods for the numerical approximations of the Ginzburg–Landau models of superconductivity are discussed, with an emphasis on the application to the study of vortex dynamics.

From a practical point of view, large-scale numerical simulations of the magnetic vortices complement physical experiments due to the complex three-dimensional, time-dependent, stochastic and multiscale nature of the phenomena. Thus, the development and analysis of efficient and reliable numerical algorithms remain important tasks. These algorithms and codes may ultimately prove to be useful to physicists and engineers in their study of superconducting phenomena and other related problems such as the BEC superfluidity.

I. INTRODUCTION

The analogy between certain liquid crystals and superconductivity has been recognized and explored by a number of scientists. In particular, mathematical techniques first developed within the Ginzburg–Landau theory of superconductivity have proved useful when adapted to the setting of liquid crystals (see e.g., Ref. 1). Here we pursue nontrivial stable liquid crystal configurations, motivated by the approach in the paper[2] where the authors use the Ginzburg–Landau model to produce persistent currents in topologically nontrivial domains. Our starting point is the Oseen-Frank energy for a nematic.[3,4] We add to the standard model a term that penalizes deviation of the director from a given plane. Therefore, the energy takes the form

$$F_\alpha(\mathbf{n}) = \int_\Omega \{k_1|\mathrm{div}\ \mathbf{n}|^2 + k_2|\mathbf{n}\cdot\mathrm{curl}\ \mathbf{n}|^2 + k_3|\mathbf{n}\times\mathrm{curl}\ \mathbf{n}|^2 + (k_2+k_4)[\mathrm{tr}(\nabla\mathbf{n})^2 - (\mathrm{div}\ \mathbf{n})^2] + \alpha|\mathbf{n}\cdot\mathbf{e}_3|^2\}\mathrm{d}x.$$

Here $\Omega\subset\mathbb{R}^3$ is a bounded, smooth domain occupied by the liquid crystal sample, $\mathbf{n}$ is a Frank director $\mathbf{n}:\Omega\to S^2$, the factors k_i are material constants, and $\mathbf{e}_3$ is the standard unit vector in the z direction in $\mathbb{R}^3$. The constants $\{k_i\}_{i=1}^4$ are generally assumed to satisfy

$$k_1,k_2,k_3>0, \quad k_2>|k_4|, \quad 2k_1\geqslant k_2+k_4. \tag{1}$$

We have included the last term with positive α to describe the interaction with an external electric or magnetic field.[3,5] The fact that α is positive means that the model is only relevant to certain materials.[3,5] We take the field to be uniform in the $\mathbf{e}_3$ direction, and in the case of an electric field we neglect the dipole contribution of the director. In this article we will explore the asymptotic regime $\alpha\gg 1$ so that alignment of the director perpendicular to $\mathbf{e}_3$ is heavily favored, whence we are led to consider the functional

[a]Electronic mail: yunhkim@indiana.edu
[b]Electronic mail: jrubinst@indiana.edu
[c]Electronic mail: sternber@indiana.edu

$$F_\infty(\mathbf{n}) := \int_\Omega [k_1|\text{div } \mathbf{n}|^2 + k_2|\mathbf{n}\cdot\text{curl } \mathbf{n}|^2 + k_3|\mathbf{n}\times\text{curl } \mathbf{n}|^2] + (k_2+k_4)[\text{tr}(\nabla\mathbf{n})^2 - (\text{div } \mathbf{n})^2]\text{d}x.$$

One should view F_∞ as arising formally in the limit $\alpha\to\infty$ where the extreme cost of out-of-plane alignment for the director leads to consideration of this functional over directors $\mathbf{n}$ taking values on the unit circle S^1 in the xy plane rather than on S^2.

Our main result is the assertion that, under certain conditions on Ω, there exist nontrivial local minimizers of the energy F_α for α sufficiently large. We wish to emphasize that these stable critical points locally minimize the energy among all nearby competitors in a suitable topology, without the imposition of Dirichlet boundary conditions as is often the case in the literature. As such, wherever these solutions are smooth, they will satisfy the so-called "natural boundary conditions" for the problem associated with setting the first variation of energy to zero and integrating by parts.

The technique, which we borrow from Ref. 2, involves looking for local minimizers for F_α near local minimizers of F_∞. The fact that one can find nontrivial local minimizers of F_∞ is not obvious given that one is not forcing the director into a non-constant configuration through a Dirichlet condition. It relies crucially on the assumption that the sample Ω occupies a region of nontrivial topology. We now make this hypothesis explicit:
Henceforth we assume that Ω *has the topology of a one-holed torus in* $\mathbb{R}^3$.

We should note that more exotic local minimizers can be found by the same methods if one takes Ω to be a many-holed torus but we will not pursue that here. The effect of this topological assumption is to allow us to introduce a notion of winding number for S^1-valued functions defined on Ω. We will make this notion precise in the next section. We can then minimize F_∞ among S^1-valued competitors of a given winding number m to obtain interesting solutions. Through a perturbative variational calculus, for each m we will then find local minimizers of the full energy F_α for large values of α near these local minimizers of F_∞.

In the final section we include some further observations about the limiting energy F_∞ in the case where $\Omega\subset\mathbb{R}^2$ is an annulus and the director $\mathbf{n}:\Omega\to S^1$.

II. EXISTENCE OF LOCAL MINIMIZERS

We begin by recalling the notion of winding number appropriate to our setting, namely the 1-homotopy type of an S^1-valued map. For smooth functions mapping Ω into S^1, one can simply consider the restriction of such a map to any oriented simple closed loop encircling the hole in Ω and measure the classical winding number. By a standard continuity argument, this number will not depend on the particular loop chosen. However, the natural space of competitors for both F_α and more crucially for F_∞ is not smooth maps but rather maps whose first derivatives are all square integrable, namely the Sobolev spaces $H^1(\Omega;S^2)$ and $H^1(\Omega;S^1)$ respectively, cf. Ref. 6.

Let us then recall the definition of the H^1-norm of a function $\mathbf{n}:\Omega\to\mathbb{R}^k$, $k\geqslant 1$:

$$\|\mathbf{n}\|^2_{H^1(\Omega;\mathbb{R}^m)} = \sum_{j=1}^k \|n^{(j)}\|^2_{L^2(\Omega)} + \sum_{j=1}^k \|\nabla n^{(j)}\|^2_{L^2(\Omega)} = \sum_{j=1}^k \left\{ \int_\Omega |n^{(j)}|^2 dx + \int_\Omega |\nabla n^{(j)}|^2 \text{d}x \right\}$$

where $n^{(j)}$ denotes the j^{th} component of the vector-valued function $\mathbf{n}$.

It is well-known that H^1 functions defined on a set $\Omega\subset\mathbb{R}^3$ need not be continuous so some care must be taken to define the 1-homotopy type of such a Sobolev map. This difficulty was overcome in Ref. 7, where the author studies the harmonic map problem for functions of a given 1-homotopy type. A key tool is the following lemma.

Lemma 1: (Ref. 7) *For each* $K>0$ *there is an* $\epsilon>0$ *such that if* f_1 *and* f_2 *are Lipschitz continuous mappings from* Ω *into* S^1 *satisfying the conditions*

$$\|f_1 - f_2\|_{L^2(\Omega)} < \varepsilon, \quad \|\nabla f_i\|_{L^2(\Omega)} \leqslant K \quad \text{for } i = 1,2, \tag{2}$$

then f_1 *and* f_2 *have the same 1-homotopy type.*

Armed with this information one can for instance appeal to the density of smooth maps taking Ω into S^1 (see, e.g., Ref. 8) to partition the space $H^1(\Omega;S^1)$ according to 1-homotopy type by defining for each integer m the set $H^1_m(\Omega;S^1)\subset H^1(\Omega;S^1)$ as the closure under the H^1-norm of smooth maps of 1-homotopy type m. Equally important from the standpoint of invoking the direct method in the calculus of variations, one has the following consequence of Lemma 1 and the weak compactness of bounded sets in H^1 (cf. Ref. 6): Suppose a sequence $\{\mathbf{n}_j\}\subset H^1_m(\Omega;S^1)$ satisfies the uniform bound

$$\|\mathbf{n}_j\| \leqslant M$$

for some positive constant M. Then there exists a subsequence $\{\mathbf{n}_{jk}\}$ and a function $\mathbf{n} \in H^1_m(\Omega;S^1)$ such that

$$\mathbf{n}_{j_k} \rightharpoonup \mathbf{n} \text{ in } H^1 \text{ as } k\to\infty.$$

In particular, the set $H^1_m(\Omega;S^1)$ is closed under weak H^1 convergence.

With these preliminaries in hand, we now establish the existence of minimizers for the limiting functional F_∞ within each 1-homotopy class. To this end, for each integer m we introduce the notation

$$\mu_m := \inf_{\mathbf{n}\in H^1_m(\Omega;S^1)} F_\infty(\mathbf{n}) \tag{3}$$

and

$$\mathcal{A}_m := \{\mathbf{n} \in H^1_m(\Omega;S^1): F_\infty(\mathbf{n}) = \mu_m\} \tag{4}$$

and establish:

Proposition 1: For every integer m, the set of minimizers $\mathcal{A}_m$ is nonempty.

Proof: Existence will follow from the direct method. Indeed, if $\{\mathbf{n}_j\}$ denotes a minimizing sequence for the problem (3), then the identity

$$|\nabla\mathbf{n}|^2 = \mathrm{tr}(\nabla\mathbf{n})^2 + |\mathrm{curl}\,\mathbf{n}|^2 \tag{5}$$

(cf. Ref. 4, Lemma 3.3) and our assumptions (1) readily imply the bound

$$\bar{k}\int_\Omega |\nabla\mathbf{n}_j|^2 \mathrm{d}x \leqslant 2\mu_m, \tag{6}$$

where $\bar{k} := \min\{k_2, k_3, k_2+k_4\} > 0$. Hence by Lemma 1 and the discussion following it, there exists a subsequence $\{\mathbf{n}_{jk}\}$ and a function $\mathbf{n}\in H^1_m(\Omega;S^1)$ such that

$$\mathbf{n}_{j_k} \rightharpoonup \mathbf{n} \text{ in } H^1, \quad \mathbf{n}_{j_k} \to \mathbf{n} \text{ in } L^2 \text{ as } k\to\infty. \tag{7}$$

Rearranging the terms in F_∞ as

$$F_\infty(\mathbf{n}_{j_k}) = \int_\Omega [(k_1-k_2-k_4)|\mathrm{div}\,\mathbf{n}_{j_k}|^2 + k_2|\mathbf{n}_{j_k}\cdot\mathrm{curl}\,\mathbf{n}_{j_k}|^2 + k_3|\mathbf{n}_{j_k}\times\mathrm{curl}\,\mathbf{n}_{j_k}|^2 + (k_2+k_4)\mathrm{tr}(\nabla\mathbf{n}_{j_k})^2]\mathrm{d}x,$$

we observe that the integrand is a convex function of the partial derivatives of $\mathbf{n}_{jk}$ and so (7) implies that the energy is lower-semi-continuous (cf. Ref. 9):

$$\liminf_{k\to\infty} F_\infty(\mathbf{n}_{j_k}) \geqslant F_\infty(\mathbf{n}).$$

Hence $\mathbf{n}\in\mathcal{A}_m$. □

Remark: We leave open the question as to whether the minimizer of F_∞ in $H^1_m(\Omega;S^1)$ is

unique. Resolving this does not seem to be easy but in any event, it will not be needed for the main result.

Before proceeding to the main result we require a few simple consequences of Lemma 1. For these we introduce notation for the H^1 distance to the set $\mathcal{A}_m$:

$$d(\mathbf{n},\mathcal{A}_m) := \inf_{\tilde{\mathbf{n}}\in\mathcal{A}_m} \|\mathbf{n}-\tilde{\mathbf{n}}\|_{H^1}. \tag{8}$$

First we note some compactness properties of the set $\mathcal{A}_m$:

Lemma 2: Let m be any integer.

(i) *For any sequence $\{\tilde{\mathbf{n}}_j\}\subset\mathcal{A}_m$ there exists a subsequence $\{\tilde{\mathbf{n}}_{jk}\}$ and a function $\tilde{\mathbf{n}}\in\mathcal{A}_m$ such that $\tilde{\mathbf{n}}_{jk}\to\tilde{\mathbf{n}}$ strongly in H^1.*

(ii) *For any $\mathbf{n}\in H^1(\Omega;S^2)$ and any positive constant C, the condition $d(\mathbf{n},\mathcal{A}_m)\leqslant C$ implies that there exists a function $\tilde{\mathbf{n}}\in\mathcal{A}_m$ such that*

$$\|\mathbf{n}-\tilde{\mathbf{n}}\|_{H^1(\Omega;\mathbb{R}^3)} \leqslant C.$$

Proof: To prove (i), we apply the bound (6) to the sequence $\{\tilde{\mathbf{n}}_j\}$ to obtain a weak H^1-limit $\tilde{\mathbf{n}}$ of a subsequence $\{\tilde{\mathbf{n}}_{jk}\}$. As was noted in the proof of Proposition 1, the energy F_∞ is lower-semi-continuous under weak H^1 convergence so with the aid of Lemma 1 we immediately conclude that $\tilde{\mathbf{n}}\in\mathcal{A}_m$. However, using that in fact each term in F_∞ is weakly-lower-semicontinuous we can further assert that

$$\lim_{k\to\infty}\int_\Omega |\tilde{\mathbf{n}}_{j_k}\cdot\operatorname{curl}\tilde{\mathbf{n}}_{j_k}|^2 dx = \int_\Omega |\tilde{\mathbf{n}}\cdot\operatorname{curl}\tilde{\mathbf{n}}|^2 dx,$$

$$\lim_{k\to\infty}\int_\Omega |\tilde{\mathbf{n}}_{j_k}\times\operatorname{curl}\tilde{\mathbf{n}}_{j_k}|^2 dx = \int_\Omega |\tilde{\mathbf{n}}\times\operatorname{curl}\tilde{\mathbf{n}}|^2 dx,$$

and

$$\lim_{k\to\infty}\int_\Omega \operatorname{tr}(\nabla\tilde{\mathbf{n}}_{j_k})^2 dx = \int_\Omega \operatorname{tr}(\nabla\tilde{\mathbf{n}})^2 dx,$$

for otherwise $F_\infty(\tilde{\mathbf{n}})<\mu_m$, a contradiction. Hence, via (5) we see that $\|\nabla\tilde{\mathbf{n}}jk\|_{L^2}\to\|\nabla\tilde{\mathbf{n}}\|_{L^2}$ and the convergence of the subsequence is indeed strong in H^1.

The proof of (ii) follows immediately from the definition (8) and property (i). □

The next lemma says that functions H^1 close to the set $\mathcal{A}_m$ must lie in $H^1_m(\Omega;S^1)$.

Lemma 3: For each m there is a positive number γ_m such that if $\mathbf{n}\in H^1(\Omega;S^1)$ satisfies $d(\mathbf{n},\mathcal{A}_m)<\gamma_m$, then $\mathbf{n}$ belongs to $H^1_m(\Omega;S^1)$.

Proof: First note that if $\tilde{\mathbf{n}}\in\mathcal{A}_m$ then using (6) we have

$$\int_\Omega |\nabla\tilde{\mathbf{n}}|^2 \leqslant \frac{2\mu_m}{\bar{k}}.$$

Now let $K=4\mu_m/\bar{k}+1$ and let $\varepsilon=\varepsilon(K)$ be the value guaranteed by Lemma 1. Set $\gamma_m=\min\{1/\sqrt{2},(1/2)\sqrt{\varepsilon}\}$.

Then suppose

$$d(\mathbf{n},\mathcal{A}_m) < \gamma_m, \tag{9}$$

and pick an element $\tilde{\mathbf{n}}$ in $\mathcal{A}_m$ such that $\|\mathbf{n}-\tilde{\mathbf{n}}\|_{H^1(\Omega;\mathbb{R}^3}<\gamma_m$. It follows that

$$\|\nabla \mathbf{n}\|^2_{L^2(\Omega;S^1)} \leqslant 2(\|\nabla \tilde{\mathbf{n}}\|^2_{L^2(\Omega;S^1)} + \gamma_m^2) < K.$$

Similarly, (9) implies that $\|\mathbf{n}-\tilde{\mathbf{n}}\|_{L^2(\Omega;S^1)} < \varepsilon/4$. Taking smooth sequences $\{f_j\}$ and $\{\tilde{f}_j\}$ in $H^1(\Omega;S^1)$ satisfying $f_j \to \mathbf{n}$ and $\tilde{f}_j \to \tilde{\mathbf{n}}$ in H^1, we see from Lemma 1 that both sequences lie in $H^1_m(\Omega;S^1)$ for j large. Hence $\mathbf{n}$ does as well. □

We can now state our main result:

Theorem 1: For each m there exists a positive number α_m such that for all $\alpha > \alpha_m$, the functional F_α possesses an H^1-local minimizer $\mathbf{n}^m_\alpha$. Further, $d(\{\mathbf{n}^m_\alpha\}, \mathcal{A}_m) \to 0$ as $\alpha \to \infty$.

Remark: By an H^1-local minimizer we mean a function $\mathbf{n}^m_\alpha \in H^1(\Omega;\mathbb{R}^3)$ such that

$$F_\alpha(\mathbf{n}^m_\alpha) \leqslant F_\alpha(\mathbf{n}) \quad \text{whenever} \quad \|\mathbf{n}^m_\alpha - \mathbf{n}\|_{H^1(\Omega;S^2)} < \delta$$

for some $\delta > 0$. Such a function will in particular be a critical point of the functional F_α and so will weakly satisfy the associated Euler-Lagrange equation and natural boundary conditions. The regularity theory for F_α originally developed in[11] for Dirichlet boundary conditions says that minimizers with be smooth off of a set of finite zero-dimensional Hausdorff measure. We have not checked but we suspect that such a theory would apply to this present setting of natural boundary conditions as well. The technical issue would be handling the last (null-Lagragian) term carrying coefficient k_2+k_4 which in this non-Dirichlet setting cannot be equated to a constant.

Remark: In modeling a nematic liquid crystal, the "head" and "tail" of the director are indistinguishable. One way to capture this is to pose the minimization of F_α over unit vectors taking values in $\mathbb{P}^2$, two-dimensional projective space where antipodal points on S^2 are associated. The previous theorem can readily be phrased with $\mathbb{P}^2$ replacing $\mathbb{S}^2$. In fact, if one takes this tack, then local minimizers can be found corresponding to all of the half-integer winding numbers as well. The proof below is unchanged by the substitution of $\mathbb{P}^2$ for S^2 and the consideration of the limiting energy F_∞ for mappings $\mathbf{n}:\Omega \to \mathbb{P}^1$.

Proof: Fix an integer m and consider the variational problem

$$\inf_{\{\mathbf{n} \in H^1(\Omega;S^2):\, d(\mathbf{n},\mathcal{A}_m) \leqslant (1/2)\gamma_m\}} F_\alpha(\mathbf{n}), \tag{10}$$

where γ_m is the value from Lemma 3. Exploiting the convexity of the various terms in F_α as well as the uniform H^1-bound valid for any minimizing sequence $\{\mathbf{n}_j\}$, the direct method succeeds here in a manner similar to that used in solving (3). The only new issue is that one must invoke Lemma 2 and the lower-semi-continuity of the H^1-norm under weak convergence to assure that the weak limit $\mathbf{n}^m_\alpha$ of a subsequence $\{\mathbf{n}_{j_k}\}$ will satisfy the admissibility condition $d(\mathbf{n}^m_\alpha, \mathcal{A}_m) \leqslant \frac{1}{2}\gamma_m$. We would like to argue that the minimizer $\mathbf{n}^m_\alpha$ to the constrained problem (10) is in fact an H^1-local minimizer of F_α. This would follow if one could show that the constraint is not exhausted, that is, if one could demonstrate that $d(\mathbf{n}^m_\alpha, \mathcal{A}_m) < \frac{1}{2}\gamma_m$. We will achieve this for α sufficiently large by in fact arguing that

$$d(\mathbf{n}^m_\alpha, \mathcal{A}_m) \to 0 \text{ as } \alpha \to \infty. \tag{11}$$

We proceed by contradiction and suppose that for some subsequence $\{\alpha_j\} \to \infty$ there exists a positive number η such that

$$d(\mathbf{n}^m_{\alpha_j}, \mathcal{A}_m) \geqslant \eta \text{ for all } j. \tag{12}$$

Note that necessarily, $\eta \leqslant \frac{1}{2}\gamma_m$.

Since all elements of $\mathcal{A}_m$ are uniformly bounded in H^1 by some constant depending on m, the condition $d(\mathbf{n}^m_\alpha, \mathcal{A}_m) \leqslant \frac{1}{2}\gamma_m$ implies an H^1 bound on the sequence $\{\mathbf{n}^m_\alpha\}$ that is independent of α. Hence, after passing to another subsequence (whose notation we suppress), we can conclude that there exists a function $\mathbf{\Phi} \in H^1(\Omega;S^2)$ satisfying

$$\mathbf{n}_{\alpha_j}^m \rightharpoonup \mathbf{\Phi} \quad \text{in} \quad H^1(\Omega;S^2) \quad \text{as} \quad \alpha_j \to \infty. \tag{13}$$

Now observe that for any element $\tilde{\mathbf{n}} \in \mathcal{A}_m$ one has

$$F_{\alpha_j}(\mathbf{n}_{\alpha_j}^m) \leqslant F_{\alpha_j}(\tilde{\mathbf{n}}) = F_\infty(\tilde{\mathbf{n}}) = \mu_m,$$

so that

$$\int_\Omega (\mathbf{n}_{\alpha_j}^m \cdot \mathbf{e}_3)^2 \mathrm{d}x \leqslant \frac{1}{\alpha_j}\mu_m \to 0 \text{ as } \alpha_j \to \infty.$$

Hence, $\int_\Omega(\mathbf{\Phi}\cdot\mathbf{e}_3)^2\mathrm{d}x=0$ and $\mathbf{\Phi} \in H^1(\Omega;S^1)$.

Next we apply Lemma 2 (ii) and note that for each j there exists an element $\tilde{\mathbf{n}}_j \in \mathcal{A}_m$ such that $\|\mathbf{n}_{\alpha_j}^m - \tilde{\mathbf{n}}_j\|_{H^1(\Omega;\mathbb{R}^3)} \leqslant \frac{1}{2}\gamma_m$. Then by Lemma 2 (i), there exists a strong limit $\tilde{\mathbf{n}} \in \mathcal{A}_m$ of a subsequence of $\{\tilde{\mathbf{n}}_j\}$ and the lower-semi-continuity of the H^1-norm under weak convergence implies that $\|\Phi - \tilde{\mathbf{n}}\|_{H^1(\Omega;\mathbb{R}^3)} \leqslant \frac{1}{2}\gamma_m$ as well. Applying Lemma 3, we conclude that $\Phi \in H_m^1(\Omega;S^1)$.

Finally, we once again exploit the convexity of the integrand of F_α and (13) to see that for any element $\tilde{\mathbf{n}} \in \mathcal{A}_m$ one has

$$F_\infty(\mathbf{\Phi}) \leqslant \liminf_{\alpha_j\to\infty} F_\infty(\mathbf{n}_{\alpha_j}^m) \leqslant \limsup_{\alpha_j\to\infty} F_\infty(\mathbf{n}_{\alpha_j}^m) \leqslant \limsup_{\alpha_j\to\infty} F_{\alpha_j}(\mathbf{n}_{\alpha_j}^m) \leqslant \limsup_{\alpha_j\to\infty} F_{\alpha_j}(\tilde{\mathbf{n}}) = F_\infty(\tilde{\mathbf{n}}) = \mu_m. \tag{14}$$

Consequently, $F_\infty(\mathbf{\Phi})=\mu_m$ since $\mathbf{\Phi}$ is admissible in (3) so that $\mathbf{\Phi} \in \mathcal{A}_m$ and all of the inequalities in (14) are in fact equalities. In particular, we have

$$\lim_{\alpha_j\to\infty} F_\infty(\mathbf{n}_{\alpha_j}^m) = F_\infty(\mathbf{\Phi})$$

and the lower-semi-continuity of each term of F_∞ separately under the convergence (13), along with the identity (5) implies that $\mathbf{n}_{\alpha_j}^m \to \mathbf{\Phi}$ strongly in H^1. Hence, $d(\mathbf{\Phi},\mathcal{A}_m) \geqslant \eta$ by (12), which is impossible since $\mathbf{\Phi} \in \mathcal{A}_m$. □

III. REMARKS ON THE TWO-DIMENSIONAL CASE

The entire analysis above is valid also for the case where Ω is an annulus in $\mathbb{R}^2$, or any other smooth planar domain with nontrivial topology. In this section we discuss aspects of the limiting problem of minimizing F_∞ in this 2D setting. When Ω is planar, the limit functional F_∞ takes a rather simple form

$$F_\infty(\mathbf{n}) = \int_\Omega [k_1|\mathrm{div}\ \mathbf{n}|^2 + k_3|\mathrm{curl}\ \mathbf{n}|^2]\mathrm{d}x \tag{15}$$

for $\mathbf{n}:\Omega\to S^1$. In particular, a calculation shows that the null-Lagrangian term involving $(\nabla\mathbf{n})^2 - (\mathrm{div}\ \mathbf{n})^2$ integrates to zero in this setting. We note that F_∞ in the form (15) has also arisen in the literature[10] as a simplification of the Oseen-Frank energy even without an external field under the special geometric assumption that Ω lies in $\mathbb{R}^2$ and the assumption that the director has zero third component.

One immediate conclusion is that in the one-constant case, i.e., when $k_1=k_3$, the phase φ of any critical point is a harmonic function. Moreover, the second variation is positive there and one can show that such a critical point is an isolated local minimizer (up to a constant phase shift). Of course, this is not surprising, since in such a special case the functional F_∞ is proportional to $\int_\Omega|\nabla\mathbf{n}|^2\mathrm{d}x$, which was considered in Refs. 2 and 7. The only novelty in the liquid crystal problem is the existence of extra solutions since $\mathbf{n}$ actually takes values in one-dimensional projective space, $\mathbb{P}^1$ (see the second Remark following Theorem 1). We point out though that unlike the

one-constant case, in the general case $k_1 \neq k_3$, the energy is *not* invariant to a constant shift of the phase.

Returning to the general case $k_1 \neq k_3$, we ask whether particular solutions can be found in the special geometry where Ω is a symmetric annulus (i.e. a domain bounded by concentric circles). Using polar coordinates (r, θ), we claim:

Proposition 2: Assume that Ω *is a symmetric annulus. Then the minimizer of (15) in the class of homotopy type* $m=1$ *is* $\mathbf{n}=(\cos\theta, \sin\theta)$ *if* $k_3 > k_1$, *or* $\mathbf{n}=(-\sin\theta, \cos\theta)$ *if* $k_1 > k_3$.

Proof: Assume that $k_3 > k_1$. Then for every $\mathbf{n}$

$$F_\infty(\mathbf{n}) = \int_\Omega k_1 |\nabla \mathbf{n}|^2 \mathrm{d}x + (k_3 - k_1) \int_\Omega |\mathrm{curl}\, \mathbf{n}|^2 \mathrm{d}x.$$

It is well known that $\mathbf{n}=(\cos\theta, \sin\theta)$ minimizes $\int_\Omega k_1 |\nabla \mathbf{n}|^2 \mathrm{d}x$ in the class of homotopy class 1. It also follows from a simple calculation that curl $(\cos\theta, \sin\theta)=0$. This establishes the proposition for $k_3 > k_1$, and the other case follows similarly. □

The success in finding a simple solution for the case $m=1$, motivates the search for solutions of the form $\mathbf{n}=\mathbf{n}(\theta)$ for other homotopy types as well. Indeed Landau and Lifshitz (Ref. 10, Chap. VI) propose such a solution in the entire plane. They introduce the notation ψ to denote the angle between the director $\mathbf{n}$ with the radius vector to the point $(\cos\theta, \sin\theta)$. Assuming an ansatz $\psi = \psi(\theta)$, they look for a minimizer $\mathbf{n}$ of F_∞ in the restricted family

$$\mathbf{n} = (\cos(\theta + \psi(\theta)), \sin(\theta + \psi(\theta))). \tag{16}$$

Under this restriction, the functional F_∞ can be written as

$$\frac{1}{4}(k_1 + k_3) \int (1 - \gamma \cos 2\psi)(1 + (\psi')^2) \frac{1}{r} \mathrm{d}\theta\, \mathrm{d}r, \tag{17}$$

where $\gamma=(k_3-k_1)/(k_3+k_1)$, and primes mean differentiation with respect to θ. The problem of minimizing the functional $\int_0^{2\pi}(1-\gamma\cos 2\psi)(1+(\psi')^2)\mathrm{d}\theta$ leads to the Euler Lagrange equation

$$(1 - \gamma \cos 2\psi)\psi'' = \gamma \sin 2\psi (1 - (\psi')^2). \tag{18}$$

Since the special case $m=1$ was already previously established, one can assume $m \neq 1$. A short calculation shows that the Euler-Lagrange equation (18) can be integrated in the form

$$\theta = \int_0^\psi q \left(\frac{1 - \gamma \cos 2\phi}{1 - \gamma q^2 \cos 2\phi} \right)^{1/2} \mathrm{d}\varphi, \tag{19}$$

where the integration constant q is determined by the condition

$$(m-1)q \int_0^\pi \left(\frac{1 - \gamma \cos 2\psi}{1 - \gamma q^2 \cos 2\psi} \right)^{1/2} \mathrm{d}\psi = \pi. \tag{20}$$

However, if the solution of Ref. 10 is considered over the infinite plane, as proposed by the authors, the energy density has a nonintegrable singularity at the origin. Landau and Lishitz propose to remedy the problem by introducing a small cutoff radius. Instead of using an artificial cutoff radius, one may ask whether the symmetric solution can be used in an annulus, where the origin is kept well outside the domain. Unfortunately, it turns out that the case $m=1$ is special–it is the only homotopy class in which a minimizer can have the symmetry $\mathbf{n}=\mathbf{n}(\theta)$ when $k_1 \neq k_3$. One can see this by calculating the natural boundary conditions for the functional (15). A short computation gives

$$k_1 \nabla \mathbf{n} \cdot \nu + (k_1 - k_3)(\nabla \times \mathbf{n}) \times \nu = \lambda \mathbf{n}, \tag{21}$$

where ν is the unit normal to the boundary and λ is a proportionality constant. Substituting the ansatz (16), and using the symmetry of the annulus, the condition (21) becomes

$$(k_1 - k_3)(1 + \psi')\sin(\psi)(\sin\theta, -\cos\theta) = \lambda(\cos(\theta + \psi), \sin(\theta + \psi)).$$

Clearly, the only solutions to the previous equation are $\psi = 0$, $\lambda = 0$ and $\psi = \pi/2$, $\lambda = k_3 - k_1$. Both solutions correspond to a degree 1 director field.

Finally, we make some observations regarding the functional F_∞ of (15) for a general two-dimensional domain having the topology of an annulus. For this purpose we express the director $\mathbf{n}$ as $\mathbf{n} = (\cos\varphi, \sin\varphi)$ for some phase function $\varphi(x, y)$. The functional can be written explicitly in terms of φ in the form

$$F_\infty(\phi) = \int L(\phi, \nabla\phi) = \int k_1(\varphi_y \cos\varphi - \varphi_x \sin\varphi)^2 + k_3(\varphi_x \cos\varphi + \varphi_y \sin\varphi)^2$$

Varying the phase φ by a function $\beta(x, y) \in H^1(\Omega)$, one can compute the first and second variations:

$$\delta F_\infty = \int (k_3 - k_1)\beta\left\{(\varphi_y^2 - \varphi_x^2)\frac{\sin 2\varphi}{2} + \varphi_x\varphi_y \cos 2\varphi\right\} + (k_1 \cos\varphi^2 + k_3 \sin\varphi^2)\beta_y\varphi_y$$
$$+ (k_3 - k_1)\beta_y\varphi_x \sin\varphi\cos\varphi + (k_3 - k_1)\beta_x\varphi_y \sin\varphi\cos\varphi + (k_1 \sin\varphi^2 + k_3 \cos\varphi^2)\beta_x\varphi_x,$$

and

$$\delta^2 F_\infty = \int k_1(\beta_x \sin\varphi - \beta_y \cos\varphi)^2 + k_3(\beta_x \cos\varphi + \beta_y \sin\varphi)^2 + 2(k_3 - k_1)$$
$$\times \beta_x\beta(\varphi_y \cos 2\varphi - \varphi_x \sin 2\varphi) + 2(k_3 - k_1)\beta_y\beta(\varphi_x \cos 2\varphi + \varphi_y \sin 2\varphi)$$
$$+ (k_3 - k_1)\beta^2\{(\varphi_y^2 - \varphi_x^2)\cos 2\varphi - 2\varphi_x\varphi_y \sin 2\varphi\}.$$

Consider the special case where the variation β is constant. Since the second variation must be nonnegative at a minimum, we conclude that

$$(k_3 - k_1)\int_\Omega \{(\varphi_y^2 - \varphi_x^2)\cos 2\varphi - 2\varphi_x\varphi_y \sin 2\varphi\} = (k_3 - k_1)\int_\Omega (|\mathrm{div}\,\mathbf{n}|^2 - |\mathrm{curl}\,\mathbf{n}|^2)\mathrm{d}x \geq 0. \tag{22}$$

Fix now a positive k, and set $k_3 = k + \delta$, $k_1 = k - \delta$, for some $|\delta| < k$. For each δ define $E(\delta) = \min F_\infty$ in the homotopy class m (we suppress the m dependency of E).

Proposition 3: The function E is even, i.e. $E = E(|\delta|)$, and moreover, E decreases as a function of $|\delta|$.

Proof: To prove the evenness of E, observe that a shift of $\pi/2$ in the phase φ swaps (up to a sign) the div and curl of a director $\mathbf{n}$. Hence, if $\mathbf{n}_\delta = (\cos\psi_\delta, \sin\psi_\delta)$ is a minimizer achieving $E(\delta)$ and we let $\mathbf{n}_\delta^\perp = (-\sin\psi_\delta, \cos\psi_\delta)$ then we have

$$E(\delta) = F_\infty^\delta(\mathbf{n}_\delta) = F_\infty^{-\delta}(\mathbf{n}_\delta^\perp) \geq E(-\delta)$$

and the reverse inequality follows by similar reasoning.

To see the monotonicity of E, we introduce the notation $\mathbf{n}_i$ for a minimizer of F_∞ when $\delta = \delta_i$ (we fix k and m). Assume without loss of generality that $\delta_1 > 0$. Then, the inequality (22) implies $\int_\Omega (|\mathrm{div}\,\mathbf{n}_1|^2 - |\mathrm{curl}\,\mathbf{n}_1|^2)\mathrm{d}x \geq 0$. Thus, for $\delta_2 > \delta_1$:

$$F_{\infty}^{\delta_2}(\mathbf{n}_1) = E(\delta_1) - (\delta_2 - \delta_1)\int_{\Omega}(|\text{div } \mathbf{n}_1|^2 - |\text{curl } \mathbf{n}_1|^2)\text{d}x.$$

Therefore $E(\delta_2) \leqslant F_{\infty}^{\delta_2}(\mathbf{n}_1) \leqslant E(\delta_1)$. □

Finally, inspecting the first variation for the case of constant variation β, we observe that at a minimizer $\mathbf{n}$ the quantities curl $\mathbf{n}$ and div $\mathbf{n}$ are orthogonal:

$$\int_{\Omega} \text{div } \mathbf{n} \text{ curl } \mathbf{n}\, \text{d}x = 0.$$

We hope to study the minimization of F_{∞} over a given 1-homotopy type further since much remains to be understood. In particular, the limiting cases where either k_1 or k_2 vanish look intriguing and we suspect that for $m \neq 1$, the infimum may not even be attained.

IV. SUMMARY

We proved that liquid crystal samples that occupy a topologically nontrivial domain can exhibit nontrivial local minimizers when they are subjected to a strong external field penalizing deviation from a given plane. These patterns are the liquid crystal analogue of the well-known persistent current phenomenon in superconductivity.

There are several differences between the homotopy solutions derived here and the persistent current solutions in superconductivity. First, the set of homotopy types in the liquid crystal problem is twice as large as the corresponding set in superconductivity, since the director is a headless vector. Another difference is in the way in which the local minimizers are generated. To generate a persistent current, one subjects the superconducting toroidal sample to a large magnetic field. After a supercurrent circulates in the sample, the external field is abruptly shut down trapping the supercurrent. In the liquid crystal setup, a way to generate the local minimizers is to apply boundary conditions that force a director distribution with a given degree, and then to eliminate abruptly these boundary conditions. A third difference is that the limit problem (where the director $\mathbf{n}$ in liquid crystals, or the wave function in superconductivity, are confined to the unit circle S^1) is more general and more difficult in the liquid crystal setup. In fact, we are able to say very little on this limit problem. Finally, we point out that while the phenomenon of persistent currents has been extensively observed experimentally, we are not aware of an experimental demonstration of the patterns we predict here in the liquid crystal problem.

(Received 29 April 2005; accepted 29 April 2005; published online 29 September 2005)

We consider an equation of a simplified Ginzburg–Landau model of superconductivity in a one-dimensional ring. The equation for a complex order parameter ψ has two real parameters μ and λ related to the magnitude of an applied magnetic field and the Ginzburg–Landau parameter, respectively. The purpose of this paper is to reveal a global bifurcation structure for the equation in the parameter space (μ,λ). In particular we show that there exist modulating amplitude solutions which bifurcate from constant amplitude solutions, and how the bifurcation branches of such solutions continue or disappear as μ varies. We also determine the minimizer of the energy functional. © *2005 American Institute of Physics.*

I. INTRODUCTION

There are many studies on the Ginzburg–Landau equation in phase transition problems of hydrodynamics, chemical reactions, and superconductivity. In the theory of superconductivity the Ginzburg–Landau equation is a model describing a macroscopic superconducting state (Refs. 4 and 11) and it is widely accepted as an established model describing various superconducting phenomena near the critical temperature. In the last two decades the Ginzburg–Landau equation has been extensively studied by mathematicians. We still have many interesting and unsolved mathematical problems in relevance to the superconductivity.

In this paper we are dealing with a simplified model of the superconductivity in a thin uniform superconducting ring. The energy functional in a one-dimensional form of such a model is given by

$$E(\psi;\lambda,h) := \int_0^{2\pi} \frac{1}{2}|D_h\psi|^2 + \frac{\lambda}{4}(1-|\psi|^2)^2 \mathrm{d}x, \quad D_h := \frac{d}{\mathrm{d}x} - ih(x), \tag{1.1}$$

where ψ is a complex-valued order parameter ($|\psi|^2$ expresses the density of superconducting electrons), λ is a positive parameter, and $h(x)$ is a periodic C^1 function. Note that $h(x)$ is the projection of magnetic potential of an applied magnetic field to the tangent direction of a parametrized ring (see Ref. 10 for the derivation of the above model). We consider this functional on the space of 2π-periodic functions in $H^1_{\mathrm{loc}}(\mathbb{R})$. Then the Euler-Lagrange equation of this functional is given by

$$\begin{aligned} &D_h^2\psi + \lambda(1-|\psi|^2)\psi = 0, \quad x \in \mathbb{R}, \\ &\psi(x+2\pi) = \psi(x), \quad x \in \mathbb{R}, \end{aligned} \tag{1.2}$$

which is the Ginzburg–Landau equation of this model. One feature of (1.2) is that (1.2) is transformed into the equation

$$u_{xx} + \lambda(1 - |u|^2)u = 0, \quad x \in \mathbb{R},$$
$$u(x + 2\pi)\exp(2\pi\mu i) = u(x), \quad x \in \mathbb{R}, \tag{1.3}$$

by the change of variable

$$\psi = u \exp\left(i \int_0^x h(s)\mathrm{d}s \right), \tag{1.4}$$

where

$$\mu := \frac{1}{2\pi}\int_0^{2\pi} h(s)\mathrm{d}s. \tag{1.5}$$

It is clear that (1.3) with (1.5) is equivalent to (1.2).

We give a remark on (1.3). For each $\tilde{\mu} \in \mathbb{R}$, let $\tilde{\mu}_0$ be a constant such that $\tilde{\mu}_0 \in [-1/2, 1/2]$ and $\tilde{\mu} - \tilde{\mu}_0 \in \mathbb{Z}$. Since $\exp(2\pi\tilde{\mu}_0 i) = \exp(2\pi\tilde{\mu} i)$, a solution to (1.3) for $\mu = \tilde{\mu}_0$ gives a solution to (1.3) for $\mu = \tilde{\mu}$ and vice versa. Thus it suffices to solve (1.3) for $\mu \in [-1/2, 1/2]$. However we assume $\mu \in \mathbb{R}$ throughout the paper for a simple expression of each solution to (1.2), which is given by (1.4). We also note that if $u(x)$ is a solution of (1.3), the symmetry of the equation allows solutions $u(x)e^{ic}$ and $u(x+c)$ for any constant $c \in \mathbb{R}$. However we will not mention this fact explicitly unless we need to state it clearly.

In Refs. 2 and 12 primary bifurcations from the trivial solution $\psi = 0$ (or $u = 0$) are shown together with secondary bifurcations around higher degenerate bifurcation points. Since their analysis on the secondary bifurcations only works in neighborhoods of the singular points, we are interested in a global structure of the secondary bifurcating solutions. Moreover our goal is to solve (1.3) for every $\mu \in \mathbb{R}$ and $\lambda > 0$ completely and to show how the configuration of the solutions changes as the parameters vary. As for a specific case $\mu \in \mathbb{Z}$, we have already obtained a complete global bifurcation diagram for λ in Ref. 7. We will extend that study to the present case (see also Refs. 5 and 8). However the bifurcation structure exhibits more complex pattern for $2\mu \notin \mathbb{Z}$. In fact the symmetry with respect to the reflection $x \to -x$ is lost if $2\mu \notin \mathbb{Z}$. Nonetheless the approach developed in Ref. 7 fortunately works in the present situation so that a modification of the argument can provide an explicit expression of every solution. With some additional investigation we can observe how the secondary bifurcating solution deforms as μ varies until it disappears through other bifurcation.

To obtain every solution, we first classify all the solutions to (1.3) [or (1.2)] except for the trivial solution $u = 0$ into three types (according to their configuration) as follows:

(I) Solutions with zero.

(IIa) Solutions with constant amplitude.

(IIb) Solutions with modulating but nonvanishing amplitude.

The idea of this classification is quite simple but crucial for our argument. We here made a little modification of the classification found in Ref. 7 for convenience of dealing with the present problem.

Before going to our result, we will explain some known results for these solutions in brief. Every type (I) solution is written in the form

$$u(x) = \exp(ic)\phi(x),$$

where c is a constant of $\mathbb{R}$ and ϕ is a real-valued function (see Sec. II). Moreover a type (I) solution with n zeros exists if and only if $\lambda > n^2/4$ and $\mu - n/2 \in \mathbb{Z}$. In fact, for such a fixed μ, the type (I) solution bifurcates from the trivial solution $u = 0$ at $\lambda = n^2/4$ as λ increases. We denote the type (I) solution with n zeros by $u^{\mathrm{s}}_{\lambda,n}(x)$.

As for type (IIa) solutions of (1.3) it is easy to obtain

$$u^{c}_{\lambda,\mu,m} := \sqrt{1-(m-\mu)^2/\lambda}\,\exp\left(i(m-\mu)x\right), \tag{1.6}$$

for each $m \in \mathbb{Z}$. This solution exists if and only if (μ,λ) satisfies

$$\lambda > \lambda_{\mu,m} := (m-\mu)^2.$$

Then a type (IIa) solution of (1.2) is given by

$$\psi = u^{c}_{\lambda,\mu,m}(x)\exp\left(i\int_0^x h(s)\mathrm{d}s\right),$$

which has the winding number m in the complex plane around the origin.

Next consider type (IIb) solutions. They do not bifurcate from the trivial solution as λ increases. Along the branch of $u^{c}_{\lambda,\mu,m}$, we can find bifurcation points

$$\lambda = \lambda_{\mu,m,n} := 3(m-\mu)^2 - n^2/2 \quad (n \in \mathbb{N}, \lambda_{\mu,m,n} > \lambda_{\mu,m}), \tag{1.7}$$

by investigating the linearized stability of the solution $u^{c}_{\lambda,\mu,m}$. This suggests that a type (IIb) solution bifurcates from the type (IIa) solution at $\lambda=\lambda_{\mu,m,n}$. As a matter of fact there is an intersection point

$$(\mu,\lambda) = ((m_1+m_2)/2, (m_1-m_2)^2/4), \tag{1.8}$$

of two bifurcation curves $\lambda=\lambda_{\mu,m_1}$ and $\lambda=\lambda_{\mu,m_2}$ of type (IIa) solutions. A standard local bifurcation analysis around this critical point does work to reveal that a type (IIb) solution certainly bifurcates in a neighborhood of $u=0$ around the above critical values of (μ,λ) (Ref. 12, see also Refs. 2 and 9 for bifurcations under small perturbation due to nonuniform thickness of the ring).

Besides the local bifurcation structure, as mentioned before, we are interested in a global one of (1.3), consequently (1.2). Moreover we desire to see how the configuration of the secondary bifurcating solution changes as the parameter μ varies.

Now we are going to our results. We notice that a type (IIb) solution is written as $u = w(x)\exp(i\theta(x))$ where $w(x)$ is 2π-periodic and $\theta(x)$ satisfies $\theta(x+2\pi)-\theta(x)=2(m-\mu)\pi$ for an integer m. We let n be the number of local minima of $w(x)$ in the interval $[0,2\pi)$. Since $w(x)$ is not constant, n is a positive integer. We call n the number of modulations for the solution. We denote the solution with such numbers m and n by $u^{o}_{\lambda,\mu,m,n}(x)$ and let

$$D^{-}_{m,n} := \{(\mu,\lambda): \mu < m - n/2, \lambda > \lambda_{\mu,m,n}\}, \tag{1.9}$$

$$D^{+}_{m,n} := \{(\mu,\lambda): \mu > m + n/2, \lambda > \lambda_{\mu,m,n}\}. \tag{1.10}$$

Then we can prove that there exists a solution $u^{o}_{\lambda,\mu,m,n}(x)$ if and only if $(\mu,\lambda) \in D^{-}_{m,n} \cup D^{+}_{m,n}$. This solution is unique up to rotation and translation. Moreover this solution bifurcates from the type (IIa) solution $u^{c}_{\lambda,\mu,m}$ as (μ,λ) pass through the part of $\partial D^{\pm}_{m,n}$

$$\{(\mu,\lambda): \mu < m - n/2, m + n/2 < \mu, \lambda = \lambda_{\mu,m,n}\}$$

(see Proposition 3.1 in Sec. III). We note that $w(x)$ can be expressed by the Jacobi elliptic function.

We are now in a position to propose the main theorem of this paper.

Theorem 1.1: *Let $\lambda>0$. Given 2π-periodic C^1-function h, define μ by (1.5). Then any nontrivial solution to (1.2) is one of the following:*

(I) $\psi^{s}_{\lambda,\mu,n,\omega}(x)e^{ic} = u^{s}_{\lambda,n}(x+\omega)\exp(i\int_0^x h(s)\mathrm{d}s + ic)$ for $n \in \mathbb{N}$ satisfying $n^2/4 < \lambda, \mu - n/2 \in \mathbb{Z}$,

(IIa) $\psi^{c}_{\lambda,\mu,m}(x)e^{ic} = u^{c}_{\lambda,\mu,m}(x)\exp(i\int_0^x h(s)\mathrm{d}s + ic)$ for $m \in \mathbb{Z}$ satisfying $\lambda_{\mu,m} < \lambda$,

(IIb) $\psi^{o}_{\lambda,\mu,m,n,\omega}(x)e^{ic} = u^{o}_{\lambda,\mu,m,n}(x+\omega)\exp(i\int_0^x h(s)\mathrm{d}s + ic)$ for $(m,n) \in \mathbb{Z}\times\mathbb{N}$ satisfying $n^2/4 < \lambda_{\mu,m,n} < \lambda$,

where c and ω are real numbers. Moreover if $h(x)$ is given as

$$h(x) = \mu h_e(x), \quad \frac{1}{2\pi}\int_0^{2\pi} h_e(x)\mathrm{d}x = 1, \tag{1.11}$$

and if $m \in \mathbb{Z}, n \in \mathbb{N}$, *and* $\lambda > n^2/4$ *are fixed, then the set* $\{\psi(\cdot;\mu): \mu^-_{\lambda,m,n} < \mu < \mu^+_{\lambda,m-n,n}\}$ *which is defined as*

$$\psi(x;\mu) := \begin{cases} \psi^o_{\lambda,\mu,m,n,\omega}(x), & \mu^-_{\lambda,m,n} < \mu < m - n/2, \\ i\psi^s_{\lambda,\mu,n,\omega}(x), & \mu = m - n/2, \\ -\psi^o_{\lambda,\mu,m-n,n,\omega}(x), & m - n/2 < /\mu < /\mu^+_{\lambda,m-n,n} \end{cases} \tag{1.12}$$

is a continuous curve in $C(\mathbb{R};\mathbb{C})$, *where*

$$\mu^{\pm}_{\lambda,m,n} := m \pm \sqrt{\lambda/3 + n^2/6}. \tag{1.13}$$

We note that any sectorial region $D^-_{m,n}$ is adjacent to $D^+_{m-n,n}$. The last assertion implies that a solution in one of these adjacent regions is continuously deformed up to a solution in the other region in the way of the statement. Since the two solutions are topologically different, the branch contains a solution with zeros at $\mu = m - n/2$. Then the number of modulations turns to be the number of zeros at this critical value of μ (for the configuration of solutions see figures in Sec. IV).

We next give a remark on the stability of solutions. As seen in Ref. 12, it is known that a type (IIa) solution $\psi^c_{\lambda,\mu,m}$ is stable (or unstable) if $\lambda > \lambda_{\mu,m,1}$ (or $\lambda < \lambda_{\mu,m,1}$). On the other hand, the stability (or instability) region for a type (IIb) solution is not clear. Our result tells the following: as λ increases, a type (IIb) solution $\psi^o_{\lambda,\mu,m,n,\omega}$ bifurcates from the type (IIa) solution $\psi^c_{\lambda,\mu,m}$ that is unstable up to $\lambda = \lambda_{\mu,m,1} > \lambda_{\mu,m,n} (n > 1)$, and no bifurcation takes places from $\psi^o_{\lambda,\mu,m,n,\omega}$. We thereby infer that every type (IIb) solution is unstable globally. To prove it rigorously, we need some stability analysis for $\psi^o_{\lambda,\mu,m,n,\omega}$, which would be a future work.

Nonetheless by explicit computations of the energy (1.1) for the solutions, we obtain the minimizer for given $\lambda > 0$ and $\mu \in \mathbb{R}$ as follows.

Theorem 1.2: *Assume* $\lambda > 0$ *and* $h(x)$ *satisfy (1.11). Given* $m \in \mathbb{Z}$, *let*

$$\mathcal{D}_m := \{(\mu,\lambda): m - 1/2 \leqslant \mu \leqslant m + 1/2,\ (\mu - m)^2 < \lambda\}. \tag{1.14}$$

Then the type (IIa) solution $\psi^c_{\lambda,\mu,m}$ *is a minimizer of (1.1) if* $(\lambda,\mu) \in \mathcal{D}_m$, *while the trivial solution* $\psi = 0$ *is a minimizer if* $(\mu,\lambda) \notin (\cup_{m=1}^{\infty} \mathcal{D}_m)$. *Moreover for* $(\mu,\lambda) \in \mathrm{Int}\, \mathcal{D}_m$, $\psi^c_{\lambda,\mu,m}$ *is a unique minimizer up to the rotation.*

We note that for $\mu = m - 1/2$ (or $m + 1/2$) both $\psi^c_{\lambda,\mu,m}$ and $\psi^c_{\lambda,\mu,m-1}$ (or $\psi^c_{\lambda,\mu,m+1}$) are the minimizer if $\lambda > 1/4$.

In the next section we derive type (I) solutions. Though the result is known (for instance, see Ref. 2), we give a proof for the reader's convenience. In fact the argument of the proof would be helpful when we consider a more difficult case of type (IIb) solutions. In Sec. III we are dealing with type (IIb) solutions and provide a proposition which guarantees the existence of the solution. The proof of the proposition will be postponed until Sec. V, where some lemma is only stated because it is essentially proved in Ref. 7. In Sec. IV we give various figures for existence regions of solutions in (μ,λ) space, bifurcation diagrams and configurations of type (IIb) solutions. In Sec. VI we will prove Theorem 1.2 and give a remark in the final section on the computations arising in Sec. VI.

II. TYPE (I) SOLUTIONS

In this section we treat type (I) solutions to (1.3). We will show that, given $n \in \mathbb{N}$, there exists a solution to (1.3) which has n zero points on $[0, 2\pi)$ if and only if

$$\lambda > n^2/4, \quad \mu = m + n/2 \quad (\forall m \in \mathbb{Z}), \tag{2.1}$$

and each solution is written in the form

$$u = u^s_{\lambda,n}(x+\omega)\exp(ic), \quad u^s_{\lambda,n} := k\sqrt{2/(1+k^2)}\,\mathrm{sn}(nK(k)x/\pi,k),$$

where c and ω are arbitrary constants of $\mathbb{R}$, $k \in (0,1)$ is a unique solution to

$$\sqrt{1+k^2}K(k) = \pi\sqrt{\lambda}/n, \tag{2.2}$$

$\mathrm{sn}(x,k)$ is the Jacobi elliptic function whose inverse is given by

$$\mathrm{sn}^{-1}(u,k) = \int_0^u \frac{1}{\sqrt{1-\tau^2}\sqrt{1-k^2\tau^2}}\mathrm{d}\tau,$$

and $K(k)$ is a complete elliptic integral

$$K(k) := \int_0^1 \frac{1}{\sqrt{1-\tau^2}\sqrt{1-k^2\tau^2}}\mathrm{d}\tau.$$

Recall that $\mathrm{sn}(x,k)$ is extended to $\mathbb{R}$ with period $4K(k)$ and it is not difficult to show $\phi = u^s_{\lambda,n}$ is a solution to the real-valued equation

$$\phi_{xx} + \lambda(1-\phi^2)\phi = 0. \tag{2.3}$$

To achieve the above result, we first show that if a nontrivial solution to (1.3) has a zero point, then 2μ is an integer and the solution is a real-valued function multiplied by a complex constant. The argument below is essentially due to Ref. 3. Consider a nontrivial solution $u(x)$ which vanishes at $x = x_0$. Denote $u(x) = u_1(x) + iu_2(x)$. Then (1.3) allows the expression

$$\begin{aligned} &(u_1)_{xx} + Q(x)u_1 = 0, \qquad x \in \mathbb{R}, \\ &(u_2)_{xx} + Q(x)u_2 = 0, \qquad x \in \mathbb{R}, \end{aligned} \quad Q(x) := \lambda(1 - |u(x)|^2).$$

Since $u_j(x_0) = u_j(x_0 + 2\pi) = 0 (j = 1,2)$, each u_j is an eigenfunction of the operator

$$L := \frac{d^2}{\mathrm{d}x^2} + Q(x), \quad D(L) = \{u \in H^2(x_0, x_0+2\pi) : u(x_0) = u(x_0+2\pi) = 0\}$$

corresponding to zero eigenvalue if $u_j \not\equiv 0$. It thus follows that $c_1u_1 = c_2u_2$ for some constants $c_1, c_2 \in \mathbb{R}[(c1, c2) \neq (0,0)]$ from the Sturm-Liouville theorem, which tells that the dimension of each eigenspace is one. Set $\phi := \sqrt{1 + c_1^2/c_2^2}u_1$ (or $\sqrt{1 + c_2^2/c_1^2}u_2$). Then the solution u is written in

$$u(x) = \phi(x)\exp(ic)$$

for a constant $c \in \mathbb{R}$. Thus the second condition of (1.3) implies

$$\phi(x + 2\pi)\exp(2\pi\mu i) = \phi(x). \tag{2.4}$$

Since $\phi(x)$ is real valued, 2μ must be an integer.

We next verify that any solution ϕ of (2.3) with (2.4) is written in the form $\phi = u^s_{\lambda,n}$ up to translation and (2.1) is a necessary and sufficient condition of existence. As seen below, it follows from an elementary argument of ordinary differential equations.

Let ϕ be a nontrivial solution having zeros to (2.3) with (2.4). Without loss of generality we may assume $\phi(0) = \phi(2\pi) = 0$ and $\phi_x(0) > 0$. Thus there exists a point $x_1 \in (0, 2\pi)$ such that

$$\phi_x(x_1) = 0, \quad \phi_x(x) > 0 \quad \forall\, x \in [0, x_1).$$

Set $\alpha = \phi(x_1)$. Then the equation (2.3) implies

$$\frac{d\phi}{dx} = \sqrt{\lambda(\alpha^2 - \phi^2)(\beta^2 - \phi^2)/2} \quad \forall\, x \in [0, x_1], \tag{2.5}$$

where

$$\alpha^2 + \beta^2 = 2, \quad 0 < \alpha < \beta. \tag{2.6}$$

Changing variable $\xi(x) := \phi(x)/\alpha$, we have

$$x = \frac{\sqrt{2}}{\beta\sqrt{\lambda}} \int_0^{\phi(x)/\alpha} \frac{1}{\sqrt{(1-\xi^2)(1-(\alpha/\beta)^2\xi^2)}} d\xi, \quad \forall\, x \in [0, x_1]$$

and hence

$$x_1 = \sqrt{2}K(k)/\beta\sqrt{\lambda}, \quad k := \alpha/\beta. \tag{2.7}$$

As a consequence ϕ is written in the form

$$\phi(x) = \alpha\, \mathrm{sn}(K(k)x/x_1, k) \tag{2.8}$$

and this equality is satisfied on the whole $\mathbb{R}$. By the condition (2.4) and

$$\mathrm{sn}(x + 2K(k)n, k) = (-1)^n \mathrm{sn}(x, k), \quad x \in \mathbb{R}, \quad n \in \mathbb{N},$$

there exist $n \in \mathbb{N}$ and $m \in \mathbb{Z}$ such that

$$x_1 = \pi/n, \quad \mu = m + n/2. \tag{2.9}$$

On the other hand, with the aid of (2.6) and the definition of k we obtain

$$\alpha = k\sqrt{2/(1+k^2)}, \quad \beta = \sqrt{2/(1+k^2)}. \tag{2.10}$$

Thus (2.8) and (2.7) yield the expression of $u^{\mathrm{s}}_{\lambda,n}$ and

$$x_1 = \sqrt{1+k^2}K(k)/\sqrt{\lambda}, \tag{2.11}$$

respectively. By (2.9) and (2.11), k must satisfy (2.2).

Consequently the equation (2.3) with (2.4) has a nontrivial solution with n zeros in $[0, 2\pi)$ which is uniquely given by $u^{\mathrm{s}}_{\lambda,n}$ (up to translation) with $k \in (0,1)$ satisfying (2.2) and $\mu = m + n/2 (m \in \mathbb{Z})$.

Now let us consider (2.2). Since

$$K(0) = \frac{\pi}{2}, \quad \frac{dK}{dk} > 0, \quad \lim_{k \to 1} K(k) = \infty, \tag{2.12}$$

(2.2) has a unique solution if and only if $n^2 < 4\lambda$. In conclusion we can assert that any type (I) solution ϕ of (2.3) with (2.4) is written in the form $\phi = u^{\mathrm{s}}_{\lambda,n}$ and the solution exists if and only if (2.1) is satisfied.

III. TYPE (IIb) SOLUTIONS: SECONDARY BIFURCATING SOLUTIONS

In this section we consider a solution with modulating amplitude but nonvanishing everywhere. It is not so simple to obtain globally in the parameters λ and μ, since the solution bifurcates from not a trivial solution but a type (IIa) solution. Namely this solution is a secondary bifurcating solution from the zero solution. Fortunately the method developed in the previous paper[7] still works in this present two-parameters case.

Since $|u(x)| > 0$, we can write $u = w(x) \exp(i\theta(x))$ where $w(x) > 0$. Setting it into Eq. (1.3) yields

$$w_{xx} - \theta_x^2 w + \lambda(1 - w^2)w = 0 \quad (x \in \mathbb{R}), \quad (w^2\theta_x)_x = 0 \quad (x \in \mathbb{R}). \tag{3.1}$$

Then the periodic condition in (1.3) is reduced to $w(x+2\pi)=w(x)$ and

$$\theta(x + 2\pi) + 2\pi\mu = \theta(x) + 2m\pi, \tag{3.2}$$

for an integer m. Integrating the equation $(w^2\theta_x)_x=0$, we have that

$$\theta_x = b/w^2 \tag{3.3}$$

for a constant $b \in \mathbb{R}$. Integrating this equality again and using (3.2), we obtain

$$2(m - \mu)\pi = b\int_0^{2\pi} \frac{1}{w(x)^2}\mathrm{d}x.$$

Thus the equation (3.1) is reduced to

$$\begin{gathered} w_{xx} - b^2/w^3 + \lambda(1 - w^2)w = 0, \quad x \in \mathbb{R}, \\ b = 2(m - \mu)\pi \Big/ \int_0^{2\pi} \frac{\mathrm{d}x}{w(x)^2}, \\ w(x + 2\pi) = w(x), \quad x \in \mathbb{R}, \\ w(x) > 0, \quad x \in \mathbb{R}. \end{gathered} \tag{3.4}$$

Then a solution ψ of (1.2) is obtained by solving the above equation and it is written in the form

$$\psi = w(x)\exp\left\{2(m - \mu)\pi i\int_0^x \frac{1}{w(s)^2}\mathrm{d}s \Big/ \int_0^{2\pi} \frac{1}{w(s)^2}\mathrm{d}s + i\int_0^x h(s)\mathrm{d}s\right\}.$$

We note that (3.4) has a constant solution

$$w = \sqrt{1 - (m - \mu)^2/\lambda}$$

if $\lambda > (m-\mu)^2$. This gives a type (IIa) solution. Since w stands for the amplitude of a solution ψ, we exclude this constant solution. To find all the solutions of (3.4), we also give attention to a solution with n modulating amplitude, that is, a $2\pi/n$-periodic solution of (3.4) for $n \in \mathbb{N}$.

Consequently all type (IIb) solutions are obtained by solving the following system of equations for $w(x)$ and b:

$$\begin{gathered} w_{xx} - b^2/w^3 + \lambda(1 - w^2)w = 0, \quad x \in \mathbb{R}, \\ w(x) > 0, \quad x \in \mathbb{R}, \\ T_w = 2\pi/n, \end{gathered} \tag{3.5}$$

and

$$b = 2(m - \mu)\pi \Big/ \int_0^{2\pi} \frac{1}{w(x)^2}\mathrm{d}x, \tag{3.6}$$

for each $m \in \mathbb{Z}, n \in \mathbb{N}, \mu \in \mathbb{R}$, and $\lambda > 0$, where T_w denotes the fundamental period of $w(x)$.

We here introduce some notations which will be used in our argument. Define

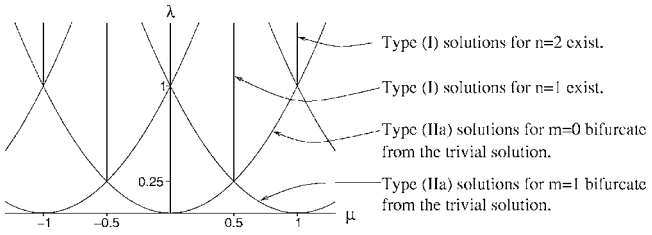

FIG. 1. Bifurcation curves and existence regions of types (I) and (IIa) solutions.

$$\Pi(\nu,k) := \int_0^1 \frac{1}{(1+\nu\tau^2)\sqrt{1-\tau^2}\sqrt{1-k^2\tau^2}}\mathrm{d}\tau, \tag{3.7}$$

$$\alpha(k) := 2/3 - 2n^2K(k)^2(k^2+1)/3\lambda\pi^2, \tag{3.8}$$

$$\beta(k) := 2/3 - 2n^2K(k)^2(1-2k^2)/3\lambda\pi^2, \tag{3.9}$$

$$\gamma(k) := 2/3 - 2n^2K(k)^2(k^2-2)/3\lambda\pi^2. \tag{3.10}$$

The following result establishes not only the existence but also the configuration of every secondary bifurcating solution.

Proposition 3.1: Given $m \in \mathbb{Z}$ *and* $n \in \mathbb{N}$, *let* $D^{\pm}_{m,n}$ *be as in (1.9) and (1.10). For* $(\mu,\lambda) \in D^{+}_{m,n} \cup D^{-}_{m,n}$, *there exists a solution*

$$u^{\mathrm{o}}_{\lambda,\mu,m,n} := w(x)\exp(i\theta(x)),$$

$$w(x) := \sqrt{\frac{2}{3} + \frac{2n^2K(k)^2}{\lambda\pi^2}\left\{k^2\,\mathrm{sn}^2\left(\frac{nK(k)}{\pi}x,k\right) - \frac{k^2+1}{3}\right\}}, \tag{3.11}$$

$$\theta(x) := 2(m-\mu)\pi\left(\int_0^{2\pi}\frac{\mathrm{d}y}{w(y)^2}\right)^{-1}\int_0^x \frac{\mathrm{d}y}{w(y)^2},$$

where $k \in (0,1)$ *is a unique solution of*

$$2(m-\mu)^2K(k)^2 - \lambda\gamma(k)\Pi(\beta(k)/\alpha(k)-1,k)^2\beta(k)/\alpha(k) = 0, \quad \alpha(k) > 0.$$

If $(\mu,\lambda) \notin D^{+}_{m,n} \cup D^{-}_{m,n}$, *there is no solution written as (3.11). Moreover for* $(\mu,\lambda) \in D^{+}_{m,n} \cup D^{-}_{m,n}$, *the solution* $u^{\mathrm{o}}_{\lambda,\mu,m,n}$ *satisfies*

$$u^{\mathrm{o}}_{\lambda,\mu,m,n} - u^{\mathrm{c}}_{\lambda,\mu,m} \to 0 \quad \text{uniformly on } \mathbb{R} \quad \text{as } \lambda \to \lambda_{\mu,m,n}, \tag{3.12}$$

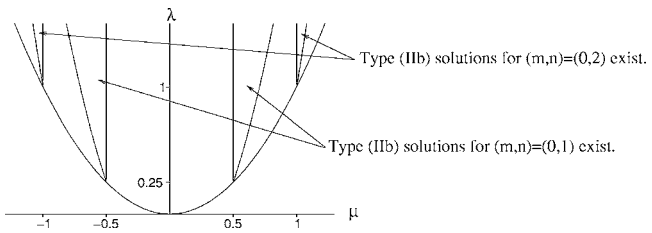

FIG. 2. Existence regions of type (IIb) solutions with $m=0$.

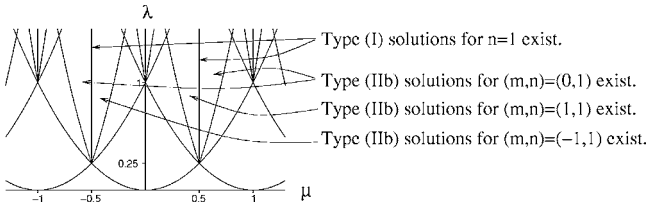

FIG. 3. Existence regions of types (I), (IIa), and (IIb) solutions with $m=-1$, 0, 1.

$$u^{o}_{\lambda,\mu,m,n} - u^{c}_{\lambda,\mu,m} \to 0 \quad \text{uniformly on } \mathbb{R} \text{ as } \mu \to m \pm \sqrt{\lambda/3 + n^2/6}, \tag{3.13}$$

$$u^{o}_{\lambda,\mu,m,n} \pm i u^{s}_{\lambda,n} \to 0 \quad \text{uniformly on } \mathbb{R} \text{ as } \mu \to m \pm n/2. \tag{3.14}$$

Proposition 3.1 implies that the secondary bifurcations take place on

$$\cup_{m\in\mathbb{Z},n\in\mathbb{N}}\{(\mu,\lambda):\mu < m - n/2, m + n/2 < \mu, \lambda = \lambda_{\mu,m,n}\}.$$

Moreover we easily see that any sectorial region $D^{-}_{m,n}$ is adjacent to $D^{+}_{m-n,n}$. Thus we obtain the following corollary.

Corollary 3.1: Let $\lambda > n^2/4$ *and fix it. Define*

$$u(x;\mu) := \begin{cases} u^{o}_{\lambda,\mu,m,n}(x), & \mu^{-}_{\lambda,m,n} < \mu < m - n/2, \\ i u^{s}_{\lambda,n}(x), & \mu = m - n/2, \\ -u^{o}_{\lambda,\mu,m-n,n}(x), & m - n/2 < \mu < \mu^{+}_{\lambda,m-n,n}. \end{cases}$$

Then $\{u(\cdot;\mu):\mu^{-}_{\lambda,m,n} < \mu < \mu^{+}_{\lambda,m-n,n}\}$ *is a continuous curve in* $C(\mathbb{R};\mathbb{C})$.

IV. BIFURCATION DIAGRAMS

In this section we observe bifurcation diagrams for the solutions of Theorem 1.1. These bifurcation diagrams are drawn by using the explicit form of the solutions obtained in Proposition 3.1. We can also exhibit the configuration of type (IIb) solutions for various values of μ.

From Figs. 1–3 we fix the parameter space $(\mu,\lambda) \in \mathbb{R}\times\mathbb{R}^{+}$. Figure 1 shows three bifurcation curves of type (IIa) for $m=-1$, 0, 1 and the straight lines on which type (I) solutions exist.

We see in Fig. 2 existence regions of type (IIb) solutions for $(m,n)=(0,1)$, (0,2) and in Fig. 3 existence regions for $(m,n)=(-2,1),(-2,2),(-1,1),(-1,2)$, (0,1), (0,2), (1,1), (1,2), (2,1), and (2,2).

In Fig. 4 a bifurcation diagram of solutions as λ increases for fixed $\mu=1/4$ is shown. We can observe four branches of type (IIa) solutions and branches of type (IIb) bifurcating from the type

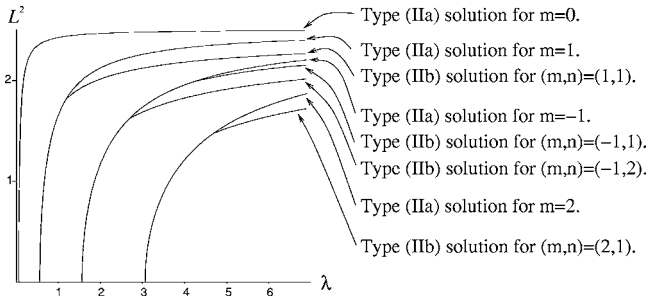

FIG. 4. Bifurcation diagram for λ at $\mu=1/4$. Vertical axis stands for L^2 amplitude.

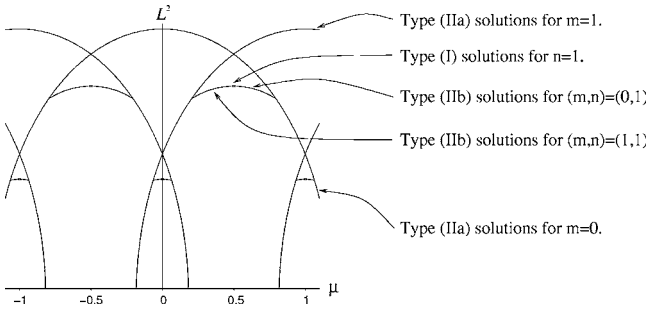

FIG. 5. Bifurcation diagram for μ at $\lambda=1.4$. Vertical axis stands for L^2 amplitude.

(IIa) solutions. On the other hand, Fig. 5 shows a bifurcation diagram as μ varies for fixed $\lambda=1.4$. Three branches of type (IIa) and 10 branches of type (IIb). Small circles separating two branches of type (IIb) indicate type (I) solutions.

Figures 6 and 7 show bifurcation sheets. In Fig. 6 we can observe the bifurcation sheets of types (IIa) and (IIb) solutions on (μ,λ) plane. The vertical axis stands for L^∞ amplitude. In Fig. 7 we also provide bifurcation sheets having cross sections on $\lambda=0.20$, 0.60, 0.85, and 1.40, respectively. The vertical axis stands for L^2 amplitude.

We display the change of configuration in the complex plane of type (IIb) solutions to (1.2) as μ increases. We set $h=$constant (i.e., $\mu=h$) in Figs. 8–10. In Figs. 8 and 9 we fix $\lambda=1.4$ (as in Fig. 5) and plot the solutions on the curves defined by (1.12) for $(m,n)=(0,1)-(-1,1)$ and $(m,n)=(1,2)-(-1,2)$ respectively. We chose six values of μ in the intervals $[-0.795\,822, -0.204\,178]$ and $[-0.064\,5813, 0.064\,5813]$ for Figs. 8 and 9 respectively. Note that the fourth shot (in the left of the second column) of each figure shows type (I) solution. The first shot and the last shot are type (IIa) solutions. We see in Fig. 8 that a solution with $(m,n)=(0,1)$ in the second shot (the winding number 0 and 1 modulation of amplitude) is changed into a solution with

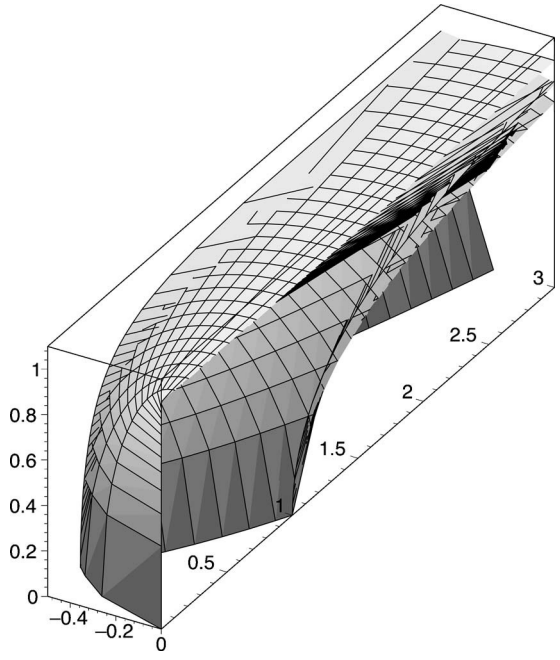

FIG. 6. Bifurcation sheets for (μ,λ). Vertical axis stands for L^∞ amplitude.

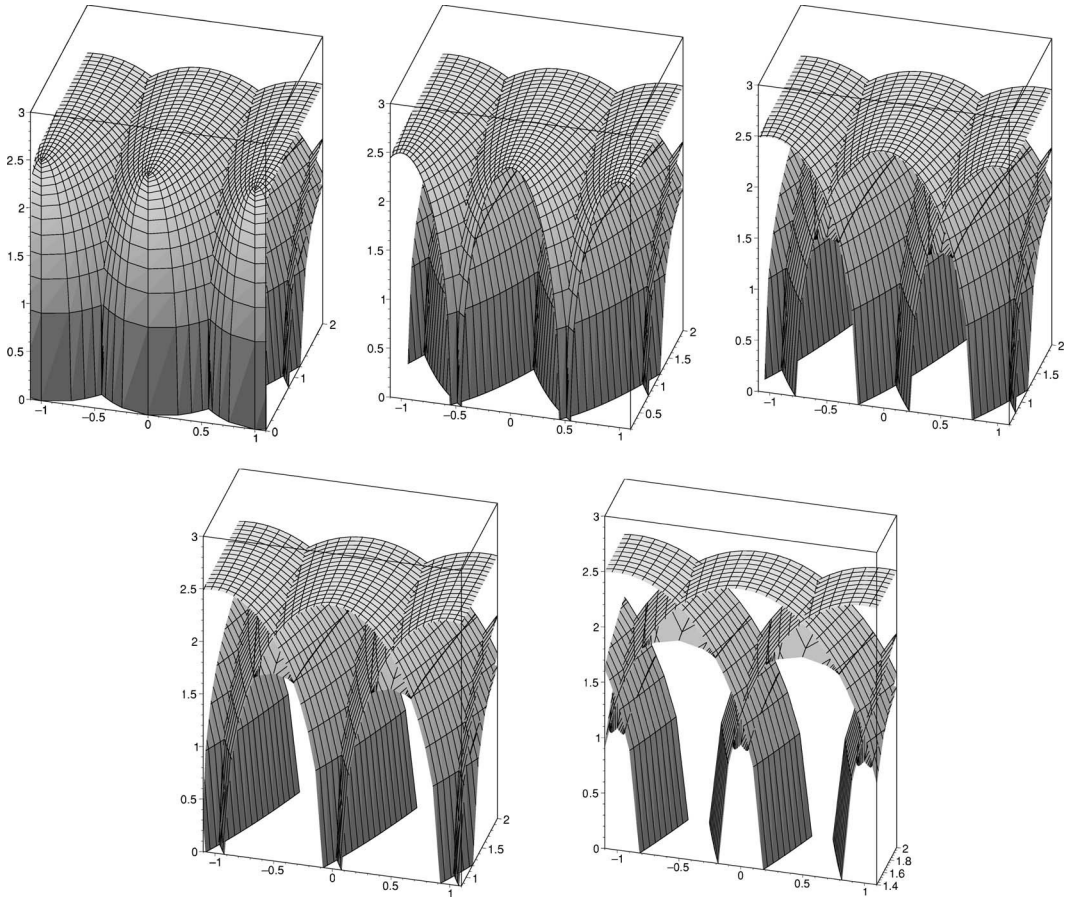

FIG. 7. Bifurcation sheets for (μ,λ). Vertical axis stands for L^2 amplitude.

$(m,n)=(-1,1)$ in the fifth shot. On the other hand, we do not see the change of the winding number of the solutions in Fig. 9, since we are not able to distinguish the sign of the winding number in this figure.

In Fig. 10 for fixed $\lambda=25/2$ we plot the solutions for μ in the interval $[2-5/\sqrt{3},-3+5/\sqrt{3}]$. A solution with $(m,n)=(2,5)$ of the first shot is changed into a solution with $(m,n)=(-3,5)$ in the sixth shot. The fifth shot shows the type (I) solution for $\mu=-1/2$.

V. PROOF OF THEOREM 1.1

We will give the proof of Theorem 1.1. It suffices to prove Proposition 3.1 by (1.4) and Corollary 3.1. Except for the argument related to the continuity of the branch of type (IIa) up to a type (I) solution as $\mu\to m\pm n/2$, the proof is substantially owing to Ref. 7. Therefore we will avoid repeating lengthy arguments in this paper, for example, the proof of Lemma 5.1 below. For the complete proof, the readers can refer to Ref. 7 complementarily.

We first solve (3.5) [without considering (3.6)]. Since w is a nonconstant periodic function in C^2, there exist $x_1,x_2\in\mathbb{R}$ such that $x_1<x_2$ and

$$w_x(x_1)=w_x(x_2)=0,\quad w_x(x)>0\quad(\forall x\in(x_1,x_2)). \tag{5.1}$$

Multiplying $2w_x$ to the equation in (3.5), we have

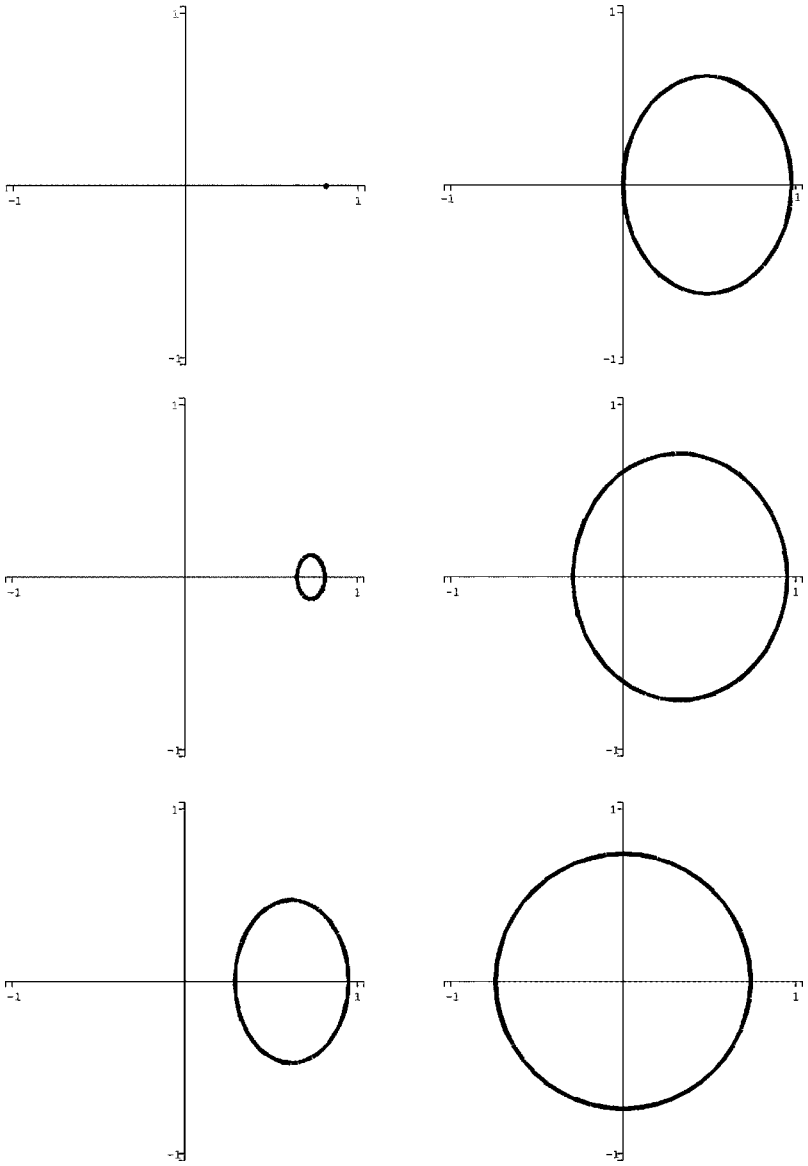

FIG. 8. Type (IIb) $[(m,n)=(0,1),(-1,1)]$ and type (I) solutions in $\mathbb{C}$.

$$\frac{d}{dx}\left((w_x)^2+\frac{b^2}{w^2}+\frac{\lambda}{2}(2w^2-w^4)\right)=0.$$

Thus

$$w_x(x)^2=\frac{\lambda\{w(x)^2-w(x_1)^2\}}{2w(x)^2w(x_1)^2}\left(\{w(x)^2+w(x_1)^2-2\}w(x)^2w(x_1)^2+\frac{2b^2}{\lambda}\right). \tag{5.2}$$

Set $x=x_2$ in (5.2) and

$$\alpha=w(x_1)^2, \quad \beta=w(x_2)^2.$$

Then we obtain $(\beta+\alpha-2)\alpha\beta+2b^2/\lambda=0$, which implies

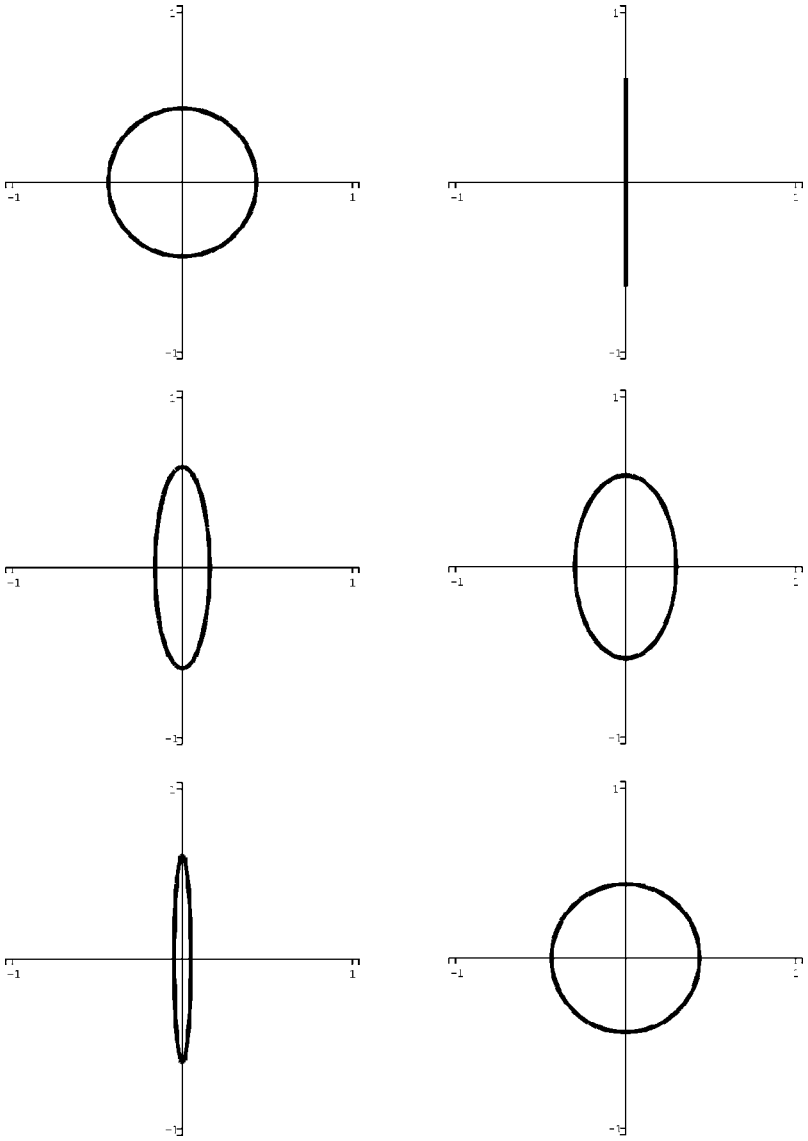

FIG. 9. Type (IIb) $[(m,n)=(1,2),(-1,2)]$ and type (I) solutions in $\mathbb{C}$.

$$2b^2/\lambda = \alpha\beta\gamma, \quad \gamma := 2-\alpha-\beta. \tag{5.3}$$

Introducing the variable

$$v(x) := w(x)^2,$$

and substituting (5.3) into (5.2), we can easily verify

$$(v_x(x))^2 = 2\lambda(v(x)-\alpha)(v(x)-\beta)(v(x)-\gamma), \quad \forall\, x \in \mathbb{R}.$$

Since

$$0 < \alpha < v(x) < \beta, \quad v_x(x) > 0 \quad (\forall x \in (x_1,x_2)),$$

the ordering $\gamma \geqslant \beta$ holds. In the sequel

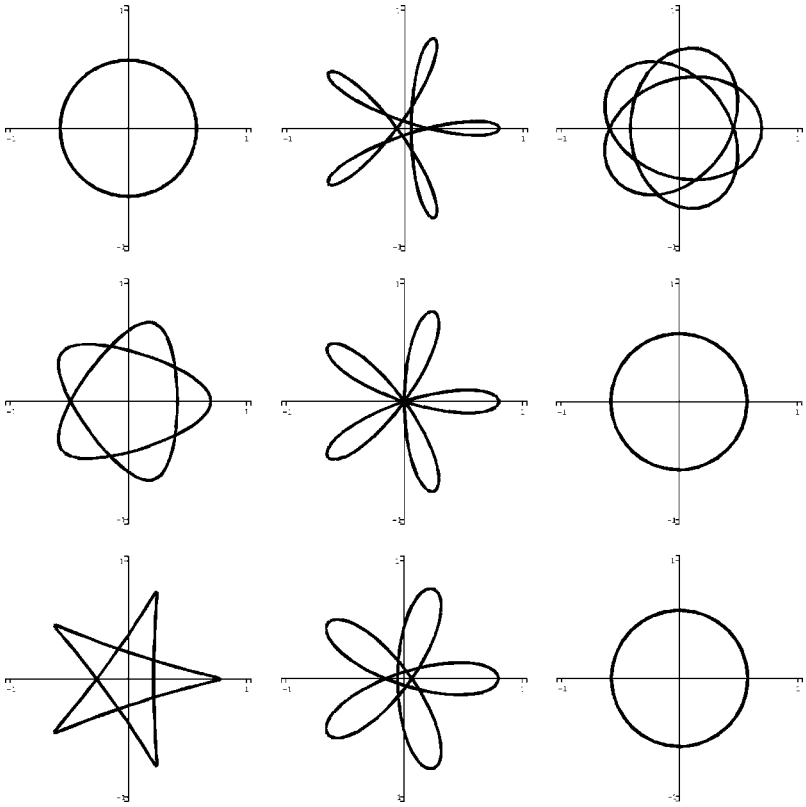

FIG. 10. Type (IIb) $[(m,n)=(2,5),(-3,5)]$ and type (I) solutions in $\mathbb{C}$.

$$v_x(x) = \sqrt{2\lambda(v(x)-\alpha)(v(x)-\beta)(v(x)-\gamma)}, \quad \forall\, x \in [x_1,x_2],$$
$$0 < \alpha < \beta \leqslant \gamma, \quad \alpha+\beta+\gamma = 2. \tag{5.4}$$

Next we solve (5.4). By integration of (5.4),

$$x - x_1 = \frac{1}{\sqrt{2\lambda}} \int_\alpha^{v(x)} \frac{\mathrm{d}y}{\sqrt{(y-\alpha)(y-\beta)(y-\gamma)}}, \quad \forall\, x \in [x_1,x_2]. \tag{5.5}$$

Changing the variable $y=\alpha+(\beta-\alpha)\tau^2$ in (5.5) and setting

$$k := \sqrt{(\beta-\alpha)/(\gamma-\alpha)}, \tag{5.6}$$

we see

$$\frac{\mathrm{d}y}{\sqrt{(y-\alpha)(y-\beta)(y-\gamma)}} = \frac{2\,\mathrm{d}\tau}{\sqrt{(\gamma-\alpha)(1-\tau^2)(1-k^2\tau^2)}}.$$

Applying this to (5.5) yields

$$x - x_1 = \sqrt{\frac{2}{\lambda(\gamma-\alpha)}}\,\mathrm{sn}^{-1}\left(\sqrt{\frac{v(x)-\alpha}{\beta-\alpha}}, k\right), \quad \forall\, x \in [x_1,x_2]. \tag{5.7}$$

Thus on the interval $[x_1,x_2]$ we obtain

$$w(x)=\sqrt{v(x)}=\sqrt{\alpha+(\beta-\alpha)\mathrm{sn}^2\left(\sqrt{\frac{\lambda(\gamma-\alpha)}{2}}(x-x_1),k\right)}. \tag{5.8}$$

Since this $w(x)$ is defined over $\mathbb{R}$ and periodic with period $2K(k)\sqrt{2/\lambda(\gamma-\alpha)}$ [$\mathrm{sn}^2(x,k)$ has a period $2K(k)$], $T_w=2\pi/n$ implies

$$2K(k)\sqrt{2/\lambda(\gamma-\alpha)}=2\pi/n. \tag{5.9}$$

Combining (5.3), (5.6), and (5.9), we obtain the expressions (3.8), (3.9), and (3.10). In the sequel we obtained solutions of (3.5). In fact let $n\in\mathbb{N}$ and $\lambda>0$. Then $(w(x),\lambda,b)$ satisfies (3.5) if and only if there exist $x_1\in\mathbb{R}$ and $k\in(0,1)$ such that $\alpha=\alpha(k)>0$ and

$$w(x+x_1)=\sqrt{\alpha+(\beta-\alpha)\mathrm{sn}^2\left(\frac{nK(k)}{\pi}x,k\right)},$$
$$b^2=\frac{\lambda\alpha\beta\gamma}{2}. \tag{5.10}$$

Now we take the condition (3.6) into account. Since $T_w=2\pi/n$ and a symmetry,

$$\int_0^{2\pi}\frac{dx}{w(x)^2}=\int_0^{2\pi}\frac{dx}{w(x+x_1)^2}=2n\int_0^{\pi/n}\frac{dx}{w(x+x_1)^2}.$$

The similar argument used in the derivation of (5.5) and (5.7) leads us to

$$\int_0^{\pi/n}\frac{dx}{w(x+x_1)^2}=\frac{1}{\sqrt{2\lambda}}\int_\alpha^\beta\frac{dy}{y\sqrt{(y-\alpha)(y-\beta)(y-\gamma)}}=\sqrt{\frac{2}{\lambda}}\frac{\Pi(\beta/\alpha-1,k)}{\alpha\sqrt{\gamma-\alpha}}, \tag{5.11}$$

where Π is the complete elliptic integral defined by (3.7). Since $\alpha>0$ and $\gamma-\alpha=2n^2K(k)^2/\lambda\pi^2$, the equation (3.6) is written as

$$b=(m-\mu)\alpha K(k)/\Pi(\beta/\alpha-1,k).$$

Substituting this into the second equation in (5.10), we can reduce our problem to solving the equation

$$2(m-\mu)^2K(k)^2-\lambda\gamma\Pi(\beta/\alpha-1,k)^2\beta/\alpha=0 \tag{5.12}$$

under the constraint $\alpha>0$. To simplify the notation in the rest of this paper, we denote the left-hand side of Eq. (5.12) by $\rho(k,\lambda,\mu)$ for each $n\in\mathbb{N}$ and $m\in\mathbb{Z}$, that is, we set

$$\rho(k,\lambda,\mu):=2(m-\mu)^2K(k)^2-\lambda\gamma\Pi(\beta/\alpha-1,k)^2\beta/\alpha. \tag{5.13}$$

Summarizing the above argument, we can assert that for each given $n\in\mathbb{N}$, $m\in\mathbb{Z}$, $\mu\in\mathbb{R}$, $\lambda>0$, and $x_1\in\mathbb{R}$, every nonconstant solution of (3.5) with (3.6) is written as

$$w(x+x_1)=\sqrt{\alpha+(\beta-\alpha)\mathrm{sn}^2\left(\frac{nK(k)}{\pi}x,k\right)},\quad b=\mathrm{sgn}(m-\mu)\sqrt{\frac{\lambda\alpha\beta\gamma}{2}}, \tag{5.14}$$

if $(k,\lambda)\in\Sigma$ is a solution of $\rho(k,\lambda,\mu)=0$, where

$$\Sigma:=\{(k,\lambda)\in(0,1)\times\mathbb{R}^+:\alpha(k)>0\}. \tag{5.15}$$

The following proposition guarantees the unique existence of a solution to $\rho=0$.

Proposition 5.1: Let $n\in\mathbb{N}$, $m\in\mathbb{Z}$ and let $D^{\pm}_{m,n}$ be the ones defined in (1.9) and (1.10).

(i) *The equation (5.12) has a solution $(k,\lambda)=(k(\lambda,\mu),\lambda)\in\Sigma$ if*

$$(\mu,\lambda) \in D^-_{m,n} \cup D^+_{m,n}, \tag{5.16}$$

where Σ *is defined by (5.15). Moreover* $k(\lambda,\mu)$ *is unique for each* $(\mu,\lambda) \in D^-_{m,n} \cup D^+_{m,n}$.

(ii) *Let* $(\mu,\lambda) \in D^-_{m,n} \cup D^+_{m,n}$. *Then*

$$k(\lambda,\mu) \to 0 \quad \text{as } \lambda \to 3(\mu-m)^2 - n^2/2, \tag{5.17}$$

$$k(\lambda,\mu) \to 0 \quad \text{as } \mu \to m \pm \sqrt{\lambda/3 + n^2/6}, \tag{5.18}$$

$$\alpha(k(\lambda,\mu)) \to 0 \quad \text{as } \mu \to m \pm n/2. \tag{5.19}$$

(iii) *There is no solution to (5.12) in* Σ *if*

$$(\mu,\lambda) \notin \bigcup_{m\in\mathbb{Z},n\in\mathbb{N}} (D^-_{m,n} \cup D^+_{m,n}).$$

Proof of Proposition 5.1 (i): Let $k=k_\alpha(\lambda) \in (0,1)$ satisfy $\alpha(k)=0$. It is easy to verify that $k=k_\alpha(\lambda)$ is uniquely determined for each $\lambda > n^2/4$ and Σ is written in the form

$$\Sigma = \{(k,\lambda): 0 < k < k_\alpha(\lambda), \lambda > n^2/4\}.$$

We here remark that $\Sigma=\emptyset$ if $\lambda \leqslant n^2/4$. Using the same computation as in the proof of Proposition 3.1 (i) of Ref. 7, we can see

$$\rho(0,\lambda,\mu) = \frac{\pi^2}{6}\left(\frac{6(m-\mu)^2 - n^2}{2} - \lambda\right) \tag{5.20}$$

and

$$\lim_{k\uparrow k_\alpha(\lambda)} \rho(k,\lambda,\mu) = (4(m-\mu)^2 - n^2)\frac{K(k_\alpha(\lambda))^2}{2}. \tag{5.21}$$

Indeed the latter limit is obtained by verifying

$$\sqrt{\beta/\alpha}\Pi(\beta/\alpha - 1, k) \to \pi/2 \quad (k\uparrow k_\alpha(\lambda)). \tag{5.22}$$

Thus the function $\rho(\cdot,\cdot,\mu)$ is extended as a continuous function on $\bar{\Sigma}\backslash\{\lambda=n^2/4\}$. Consequently $\rho(0,\lambda,\mu)\rho(k_\alpha(\lambda),\lambda,\mu) < 0$ is satisfied if and only if

$$\frac{6(m-\mu)^2 - n^2}{2} < \lambda, \quad 0 < 4(m-\mu)^2 - n^2, \tag{5.23}$$

because the inequality $\lambda > n^2/4$ implies

$$\frac{6(m-\mu)^2 - n^2}{2} - \lambda < \frac{3(4(m-\mu)^2 - n^2)}{4}.$$

Therefore it follows from the continuity of $\rho(k,\lambda,\mu)$ that (5.12) has a solution $k=k(\lambda,\mu)$ if (μ,λ) satisfies (5.16) for each $n \in \mathbb{N}$ and $m \in \mathbb{Z}$.

The following lemma implies that a solution $k=k(\lambda,\mu)$ to (5.12) is unique for each (μ,λ) if it exists in $(0,k_\alpha(\lambda))$. By this lemma we can conclude the proof of Proposition 5.1 (i). □

Lemma 5.1: If $k \in (0,k_\alpha(\lambda))$ *satisfies* $\rho(k,\lambda,\mu)=0$, *then*

$$\frac{\partial\rho}{\partial k}(k,\lambda,\mu) > 0.$$

The proof of Lemma 5.1 is performed literally in the same way as in Ref. 7; we omit it (see the proof of Lemma 3.5 in Ref. 7).

Proof of Proposition 5.1 (ii): We first show (5.17). It is clear that, for fixed μ which satisfies $(\mu-m)^2>n^2/4$, both $\rho(0,\lambda,\mu)$ and $\rho(k_\alpha(\lambda),\lambda,\mu)$ are strictly positive if $\lambda\in(n^2/4,\lambda_{\mu,m,n})$. From Lemma 5.1, it follows that

$$\rho(k,\lambda,\mu)>0,\quad \forall\, k\in[0,k_\alpha(\lambda)],\quad \forall\,\lambda\in(n^2/4,\lambda_{\mu,m,n}) \tag{5.24}$$

and hence

$$\rho(k,\lambda_{\mu,m,n},\mu)=\lim_{\lambda\uparrow\lambda_{\mu,m,n}}\rho(k,\lambda,\mu)\geqslant 0,\quad \forall\, k\in[0,k_\alpha(\lambda_{\mu,m,n})].$$

Using, (5.20) and (5.21), and Lemma 5.1 again, we can assert that

$$\begin{gathered}\rho(k,\lambda_{\mu,m,n},\mu)>0,\quad \forall\, k\in(0,k_\alpha(\lambda_{\mu,m,n})],\\ \rho(0,\lambda_{\mu,m,n},\mu)=0.\end{gathered} \tag{5.25}$$

Let $\{\lambda_\sigma\}$ be any sequence satisfying $\lambda_\sigma\downarrow\lambda_{\mu,m,n}$ as $\sigma\to\infty$. Since $k(\lambda,\mu)$ is bounded and ρ is continuous, there exists a subsequence $\{\lambda_{\sigma'}\}\subset\{\lambda_\sigma\}$ such that a limit k_* of $k(\lambda_{\sigma'},\mu)$ as $\sigma'\to\infty$ exists in $[0,k_\alpha(\lambda_{\mu,m,n})]$ and $\rho(k_*,\lambda_{\mu,m,n},\mu)=0$. Thus the limit k_* must be 0 by (5.25). This concludes the proof of (5.17).

As for the proof of (5.18), we can prove it similarly as right above, so omit it.

Now we prove (5.19), that is,

$$\lim_{\mu\to m\pm n/2}k(\lambda,\mu)=k_\alpha(\lambda) \tag{5.26}$$

for $(\mu,\lambda)\in D^+_{m,n}\cup D^-_{m,n}$. Let $\lambda>n^2/4$ be fixed. Both $\rho(0,\lambda,\mu)$ and $\rho(k_\alpha(\lambda),\lambda,\mu)$ are strictly negative if μ satisfies

$$m-n/2<\mu<m+n/2.$$

Lemma 5.1 implies

$$\rho(k,\lambda,\mu)<0,\quad \forall\, k\in[0,k_\alpha(\lambda)],\quad \forall\,\mu\in(m-n/2,m+n/2). \tag{5.27}$$

Thus

$$\rho(k,\lambda,m\pm n/2)\leqslant 0,\quad \forall\, k\in[0,k_\alpha(\lambda)]. \tag{5.28}$$

Combining (5.20), (5.21), and (5.28), and Lemma 5.1, we obtain

$$\begin{gathered}\rho(k,\lambda,m\pm n/2)<0,\quad \forall\, k\in[0,k_\alpha(\lambda)),\\ \rho(k_\alpha(\lambda),\lambda,m\pm n/2)=0.\end{gathered} \tag{5.29}$$

Therefore it follows that $k(\lambda,\mu)\to k_\alpha(\lambda)$ as $\mu\to m\pm n/2$ from the similar argument in the proof of (5.17). □

Proof of Proposition 5.1 (iii): Let $m\in\mathbb{Z}$ and $n\in\mathbb{N}$ be fixed. As mentioned in the proof of (i), $\Sigma=\emptyset$ if $\lambda\leqslant n^2/4$. Thus it suffices to prove $\rho(k,\lambda,\mu)\neq 0$ for $\forall k\in(0,k_\alpha(\lambda))$ if $(\mu,\lambda)\in\{(\mu,\lambda):\lambda>n^2/4\}\setminus(D^+_{m,n}\cup D^-_{m,n})$. By virtue of (5.24) and (5.25), it is clear that $\rho(k,\lambda,\mu)>0$ for $\forall k\in(0,k_\alpha(\lambda))$ if $n^2/4<\lambda\leqslant\lambda_{\mu,m,n}$. On the other hand, it follows from (5.27) and (5.29) that $\rho(k,\lambda,\mu)<0$ for $\forall k\in(0,k_\alpha(\lambda))$ if $m-n/2\leqslant\mu\leqslant m+n/2$ and $\lambda>n^2/4$. Therefore (iii) was proved. □

Using Proposition 5.1, we will complete the proof of Proposition 3.1, thus Theorem 1.1.

Proof of Proposition 3.1: As observed above, we proved that the type (IIa) solution is written in the form (5.14). On the other hand, Proposition 5.1 directly leads to existence and nonexistence conditions of the type (IIb) solutions which are stated in Proposition 3.1. Substituting (3.8) and (3.9) into (5.14) with $x_1=0$, we obtain (3.11). Thus the former part of the proposition was proved.

For the proof of the latter part of Proposition 3.1 it suffices to prove, (3.12), (3.13), and (3.14). In the rest of the proof, $w=w(x)$ denotes (5.14) with $x_1=0$ for simplicity of notation.

We first prove (3.12). It follows from (5.17) that if $(\mu,\lambda)\in D^-_{m,n}\cup D^+_{m,n}$ and $\lambda\to\lambda_{\mu,m,n}$, then $k(\lambda,\mu)\to 0$. Thus

$$\alpha\to 2/3-n^2/6\lambda_{\mu,m,n}=1-(\mu-m)^2/\lambda_{\mu,m,n}\quad\text{as }\lambda\to\lambda_{\mu,m,n},\tag{5.30}$$

$$\beta-\alpha\to 0\quad\text{as }\lambda\to\lambda_{\mu,m,n}.\tag{5.31}$$

For each $\ell\in\mathbb{Z}$, if $x\in[2\pi\ell,2\pi(\ell+1)]$ then

$$\begin{aligned}\theta(x)-(m-\mu)x&=(m-\mu)\left\{2\pi\int_0^x\frac{1}{w(y)^2}\mathrm{d}y\Big/\int_0^{2\pi}\frac{1}{w(y)^2}dy-x\right\}\\&=(m-\mu)\left\{2\pi\int_0^{x-2\pi\ell}\frac{1}{w(y)^2}\mathrm{d}y\Big/\int_0^{2\pi}\frac{1}{w(y)^2}\mathrm{d}y+2\pi\ell-x\right\}.\end{aligned}$$

Since

$$\sqrt{\alpha(k(\lambda,\mu))}\leqslant w(x)\leqslant\sqrt{\beta(k(\lambda,\mu))},$$

a simple calculation yields

$$\frac{\alpha-\beta}{\beta}(x-2\pi\ell)\leqslant 2\pi\int_0^{x-2\pi\ell}\frac{1}{w(y)^2}\mathrm{d}y\Big/\int_0^{2\pi}\frac{1}{w(y)^2}\mathrm{d}y+2\pi\ell-x\leqslant\frac{\beta-\alpha}{\alpha}(x-2\pi\ell)$$

and hence we obtain

$$\sup_{x\in[2\pi\ell,2\pi(\ell+1)]}\left|\theta(x)-(m-\mu)x\right|\leqslant\frac{2\pi|m-\mu|(\beta-\alpha)}{\alpha},\quad\forall\,\ell\in\mathbb{Z}.$$

It is clear that

$$\begin{aligned}|u^{\mathrm{o}}_{\lambda,\mu,m,n}(x)-u^{\mathrm{c}}_{\lambda,\mu,m}(x)|&=\left|w(x)\exp(i\theta(x)-i(m-\mu)x)-\sqrt{1-(m-\mu)^2/\lambda}\right|\leqslant|w(x)||\exp(i\theta(x)\\&\quad-i(m-\mu)x)-1|+\left|w(x)-\sqrt{1-(m-\mu)^2/\lambda}\right|,\end{aligned}$$

and

$$\sup_{x\in\mathbb{R}}\left|w(x)-\sqrt{1-(m-\mu)^2/\lambda}\right|\to 0\quad\text{as }\lambda\to\lambda_{\mu,m,n}$$

in terms of (5.30) and (5.31). It is also clear that

$$\begin{aligned}|\exp(i\theta(x)-i(m-\mu)x)-1|^2&=\{\cos(\theta(x)-(m-\mu)x)-1\}^2+\sin^2(\theta(x)-(m-\mu)x)\\&\leqslant 4\sin^4(\pi|m-\mu|(\beta-\alpha)/\alpha)+\sin^2(2\pi|m-\mu|(\beta-\alpha)/\alpha)\end{aligned}$$

and hence

$$\sup_{x\in\mathbb{R}}\left|\exp(i\theta(x)-i(m-\mu)x)-1\right|\to 0\quad\text{as }\lambda\to\lambda_{\mu,m,n},$$

by (5.31). Therefore (3.12) follows.

Similarly, (3.13) follows from (5.18).

Next we prove (3.14). We only consider $\mu\to m-n/2$ because the other case is easily done with a little modification of the argument. Let $(\mu,\lambda)\in D^-_{m,n}$ and λ be fixed. We first consider the limit of $w=w(x)$ as $\mu\to m-n/2$. Since $\alpha(k_\alpha(\lambda))=0$ holds and (5.19) implies $k(\lambda,\mu)\to k_\alpha(\lambda)$ as $\mu\to m-n/2$, we obtain

$$\beta-\alpha\to 2k_\alpha(\lambda)^2/(k_\alpha(\lambda)^2+1)\quad(\mu\to m-n/2).$$

Hence

$$w(x)\to k_\alpha(\lambda)\sqrt{2/(k_\alpha(\lambda)^2+1)}\left|\mathrm{sn}(nK(k_\alpha(\lambda))x/\pi,k_\alpha(\lambda))\right|, \tag{5.32}$$

uniformly for x as $\mu\to m-n/2$. On the other hand, noticing that $k=k_\alpha(\lambda)$ satisfies (2.2), we can write $u^{\mathrm{s}}_{\lambda,n}$ as

$$u^{\mathrm{s}}_{\lambda,n}(x)=k_\alpha(\lambda)\sqrt{2/(1+k_\alpha(\lambda)^2)}\,\mathrm{sn}(nK(k_\alpha(\lambda))x/\pi,k_\alpha(\lambda)).$$

We thereby obtain the following: For any $\varepsilon>0$, there exists $\delta_1=\delta_1(\varepsilon)>0$ such that

$$\sup_{x\in\mathbb{R}}\left|w(x)-\left|u^{\mathrm{s}}_{\lambda,n}(x)\right|\right|\leqslant\varepsilon \tag{5.33}$$

for $\forall\mu\in(m-n/2-\delta_1,m-n/2)$. We here remark that $u^{\mathrm{s}}_{\lambda,n}(x)$ is defined independently of μ, although it is not a solution to (1.3) if $2\mu\notin\mathbb{Z}$. Since $u^{\mathrm{s}}_{\lambda,n}(x)$ vanishes at $x=2\ell\pi/n(\ell\in\mathbb{Z})$, we can verify that, for any $\varepsilon>0$, there exists $d_1=d_1(\varepsilon)$ such that

$$\max_{\ell\in\mathbb{Z}}\sup_{|x-2\ell\pi/n|\leqslant d_1}\left|u^{\mathrm{s}}_{\lambda,n}(x)\right|\leqslant\varepsilon \tag{5.34}$$

thus

$$\max_{\ell\in\mathbb{Z}}\sup_{|x-2\ell\pi/n|\leqslant d_1}\left|w(x)\right|\leqslant 2\varepsilon, \tag{5.35}$$

for $\forall\mu\in(m-n/2-\delta_1,m-n/2)$.

We next deal with θ. Combining (3.8), (3.10), and (5.11), we have

$$\int_0^{2\pi}\frac{1}{w(x)^2}\mathrm{d}x=\frac{2\pi\Pi(\beta/\alpha-1,k)}{\alpha K(k)}.$$

Arbitrarily given $\ell\in\mathbb{Z}$, if $x\in(2\pi\ell/n,2\pi(\ell+1)/n)$, then

$$\int_0^x\frac{1}{w(s)^2}\mathrm{d}s=\frac{(2\ell+1)\pi\Pi(\beta/\alpha-1,k)}{n\alpha K(k)}+\int_{(2\ell+1)\pi/n}^x\frac{1}{w(s)^2}\mathrm{d}s,$$

while

$$\int_0^{2\pi\ell/n}\frac{1}{w(s)^2}\mathrm{d}s=\frac{2\ell\pi\Pi(\beta/\alpha-1,k)}{n\alpha K(k)},$$

where $(2\ell+1)\pi/n$ is the middle point of the interval $(2\pi\ell/n,2\pi(\ell+1)/n)$. Thus

$$\theta(x)=\begin{cases}\dfrac{(m-\mu)(2\ell+1)\pi}{n}+\dfrac{(m-\mu)\alpha K(k)}{\Pi(\beta/\alpha-1,k)}\displaystyle\int_{(2\ell+1)\pi/n}^x\frac{1}{w(s)^2}\mathrm{d}s\\ \text{if } x\in(2\pi\ell/n,2\pi(\ell+1)/n)\quad(\ell\in\mathbb{Z}),\\ \dfrac{2(m-\mu)\ell\pi}{n}\quad\text{if } x=2\pi\ell/n\quad(\ell\in\mathbb{Z}).\end{cases} \tag{5.36}$$

The limit of θ as $\mu\to m-n/2$ is achieved as follows. Recalling (5.22), we see

$$\alpha/\Pi(\beta/\alpha-1,k)\to 0\quad(\mu\uparrow m-n/2). \tag{5.37}$$

It is also clear that

$$\left| \int_{(2\ell+1)\pi/n}^{x} \frac{1}{w(s)^2} \mathrm{d}s \right| \leqslant \frac{\pi}{n} \frac{1}{w(d_1)^2}, \quad \forall\, x \in [2\pi\ell/n + d_1, 2\pi(\ell+1)/n - d_1],$$

where $d_1 = d_1(\varepsilon)$ is as in (5.34) and (5.35). Thus it follows from (5.32), (5.36), and (5.37), and the above inequality that for any $\varepsilon > 0$ there exists $\delta_2 = \delta_2(\varepsilon, d_1(\varepsilon)) > 0$ such that

$$\sup_{x \in (2\pi\ell/n + d_1, 2\pi(\ell+1)/n - d_1)} |\theta(x) - (2\ell+1)\pi/2| \leqslant \varepsilon, \ \ \forall\, \mu \in (m - n/2 - \delta_2, m - n/2). \tag{5.38}$$

Now we estimate

$$|u^{\mathrm{o}}_{\lambda,\mu,m,n}(x) - i u^{\mathrm{s}}_{\lambda,n}(x)|^2 = w(x)^2 \cos^2\theta(x) + \{w(x)\sin\theta(x) - u^{\mathrm{s}}_{\lambda,n}(x)\}^2. \tag{5.39}$$

For $\varepsilon > 0$, set

$$\delta = \delta(\varepsilon) := \min\{\delta_1(\varepsilon), \delta_2(\varepsilon, d_1(\varepsilon))\}. \tag{5.40}$$

Then it is clear that, if $\mu \in (m - n/2 - \delta, m - n/2)$,

$$\begin{aligned} \sup_{x \in \mathbb{R}} w(x)^2 \cos^2\theta(x) &\leqslant \max_{\ell \in \mathbb{Z}} \sup_{|x - 2\ell\pi/n| \leqslant d_1} w(x)^2 \cos^2\theta(x) + \max_{\ell \in \mathbb{Z}} \sup_{x \in (2\pi\ell/n + d_1, 2\pi(\ell+1)/n - d_1)} w(x)^2 \cos^2\theta(x) \\ &\leqslant 4\varepsilon^2 + \max_{\ell \in \mathbb{Z}} \cos^2((2\ell+1)\pi/2 + \varepsilon) \leqslant 4\varepsilon^2 + \sin^2\varepsilon, \end{aligned} \tag{5.41}$$

where we used $0 < w(x) < 1$. We estimate the second term on the right-hand side of (5.39). Since (5.35) and (5.34), we have an estimate in the neighborhoods of zero points of $u^{\mathrm{s}}_{\lambda,n}$ as

$$\max_{\ell \in \mathbb{Z}} \sup_{|x - 2\ell\pi/n| \leqslant d_1} \{w(x)\sin\theta(x) - u^{\mathrm{s}}_{\lambda,n}(x)\}^2 \leqslant 9\varepsilon^2$$

for $\mu \in (m - n/2 - \delta, m - n/2)$. In the complement to the neighborhoods of the zero points of $u^{\mathrm{s}}_{\lambda,n}$, the second term of the right-hand side of (5.39) is estimated as follows: Let $\mu \in (m - n/2 - \delta, m - n/2)$ and $x \in (2\pi\ell/n + d_1, 2\pi(\ell+1)/n - d_1)$. Then

$$\begin{aligned} |w(x)\sin\theta(x) - u^{\mathrm{s}}_{\lambda,n}(x)| &= |w(x)\sin\theta(x) - |u^{\mathrm{s}}_{\lambda,n}(x)|(-1)^{\ell}| \\ &\leqslant \big|w(x) - |u^{\mathrm{s}}_{\lambda,n}(x)|\big||\sin\theta(x)| + |u^{\mathrm{s}}_{\lambda,n}(x)||\sin\theta(x) - (-1)^{\ell}| \leqslant \varepsilon \\ &\quad + k_{\alpha}(\lambda)\sqrt{2/(1 + k_{\alpha}(\lambda)^2)}\,|\sin\theta(x) - (-1)^{\ell}| \leqslant \varepsilon + \sqrt{2}\,|\sin\theta(x) - (-1)^{\ell}|. \end{aligned}$$

Using (5.38) and

$$\begin{aligned} |\sin\theta(x) - (-1)^{\ell}| &= |(-1)^{\ell}\{\cos(\theta(x) - (2\ell+1)\pi/2) - 1\}| \\ &= 2\sin^2\{(\theta(x) - (2\ell+1)\pi/2)/2\} \leqslant 2\sin^2(\varepsilon/2), \end{aligned}$$

we obtain

$$\sup_{x \in (2\pi\ell/n + d_1, 2\pi(\ell+1)/n - d_1)} |w(x)\sin\theta(x) - u^{\mathrm{s}}_{\lambda,n}(x)| \leqslant \varepsilon + 2\sqrt{2}\sin^2(\varepsilon/2). \tag{5.42}$$

In consequence, combining (5.41) and (5.42), we obtain that there exists $C > 0$ such that for any $\varepsilon > 0$,

$$\sup_{x \in \mathbb{R}} |u^{\mathrm{o}}_{\lambda,\mu,m,n}(x) - i u^{\mathrm{s}}_{\lambda,n}(x)| \leqslant C\varepsilon, \quad \forall\, \mu \in (m - n/2 - \delta, m - n/2).$$

Therefore it completes the proof of (3.14). In conclusion we obtained Proposition 3.1. □

VI. PROOF OF THEOREM 1.2

It is clear that for $\lambda \in (0,1/4]$ the assertion of the theorem is true. Throughout the section we assume $\lambda > 1/4$. Recall the assumption of Theorem 1.2. We denote the energies for the solutions as

$$E^{\mathrm{s}}_{\lambda,n}(\mu) := E(\psi^{\mathrm{s}}_{\lambda,\mu,n};\lambda,\mu h_e),$$

$$E^{\mathrm{c}}_{\lambda,m}(\mu) := E(\psi^{\mathrm{c}}_{\lambda,\mu,m};\lambda,\mu h_e),$$

$$E^{\mathrm{o}}_{\lambda,m,n}(\mu) := E(\psi^{\mathrm{o}}_{\lambda,\mu,m,n};\lambda,\mu h_e).$$

For simplicity of notation we drop ω in the expression of the solutions in the statement of the theorem.

Fix arbitrary $m \in \mathbb{Z}$. We let $(\mu_0,\lambda) \in \operatorname{Int} \mathcal{D}_m$. For the proof of the theorem it suffices to show the following facts:

(i) Given $(\mu,\lambda) \in \mathcal{D}_m$, it holds that

$$\begin{gathered}(\mu - m)(\mathrm{d}E^{\mathrm{c}}_{\lambda,m}(\mu)/\mathrm{d}\mu) > 0,\\ E^{\mathrm{c}}_{\lambda,m}(\mu_0) < E^{\mathrm{c}}_{\lambda,m}(m \pm 1/2) \leqslant E^{\mathrm{c}}_{\lambda,\ell}(m \pm 1/2) \leqslant E^{\mathrm{c}}_{\lambda,\ell}(\mu), \quad \ell \neq m.\end{gathered} \tag{6.1}$$

(ii) Given $\ell \in \mathbb{Z}$ and $(\mu,\lambda) \in D^{-}_{\ell,n} \cup D^{+}_{\ell,n}$, it holds that

$$E^{\mathrm{o}}_{\lambda,\ell,n}(\mu) > E^{\mathrm{s}}_{\lambda,n}(\ell \pm n/2). \tag{6.2}$$

(iii) Given $\ell \in \mathbb{Z}, n, n' \in \mathbb{N}$, and $\lambda > n^2/4$, it holds that

$$E^{\mathrm{s}}_{\lambda,n}(\ell \pm n/2) = \begin{cases} E^{\mathrm{s}}_{\lambda,n}(m \pm 1/2) & \text{if } n \text{ is odd},\\ E^{\mathrm{s}}_{\lambda,n}(m \pm 1) & \text{if } n \text{ is even}, \end{cases} \tag{6.3}$$

$$E^{\mathrm{s}}_{\lambda,n}(\ell \pm n/2) > E^{\mathrm{s}}_{\lambda,n'}(\ell \pm n'/2), \quad (n > n'). \tag{6.4}$$

(iv) Given a pair $(m,n) \in \mathbb{Z} \times \mathbb{N}$, $\psi^{\mathrm{s}}_{\lambda,m\pm n/2,n}$ is unstable.

Indeed from (ii) and (iii) it follows that if $\ell \neq m$ and $(\mu,\lambda) \in \mathcal{D}_m \cap (D^{-}_{\ell,n} \cup D^{+}_{\ell,n})$,

$$E^{\mathrm{o}}_{\lambda,\ell,n}(\mu) > E^{\mathrm{s}}_{\lambda,n}(\ell \pm n/2) \geqslant E^{\mathrm{s}}_{\lambda,1}(m \pm 1/2).$$

Thus any type (IIb) solution cannot be a minimizer at $\mu = m \pm 1/2$. [Note that $\psi^{\mathrm{o}}_{\lambda,\mu,m,n}$ does not exist if $(\mu,\lambda) \in \mathcal{D}_m$.] The assertion of (iv) assures that the minimizer at $\mu = m \pm 1/2$ must be the type (IIa) solution with the least energy. Thus from (i) it follows that

$$E^{\mathrm{o}}_{\lambda,\ell,n}(\mu) > E^{\mathrm{c}}_{\lambda,m}(\mu) \quad (\ell \neq m, (\mu,\lambda) \in \mathcal{D}_m \cap (D^{-}_{\ell,n} \cup D^{+}_{\ell,n})),$$

which implies $\psi^{\mathrm{c}}_{\lambda,\mu,m}$ is the minimizer.

Now we prove (i)–(iv). From

$$E^{\mathrm{c}}_{\lambda,m}(\mu) = \pi(m-\mu)^2\{1 - (m-\mu)^2/2\lambda\}, \quad \lambda > (m-\mu)^2,$$

we can see the conclusion of (i). Since the verification is simple, we omit the proof of (i).

The inequality of (ii) immediately follows from Proposition 5.1 and the next lemma.

Lemma 6.1: Let $k = k(\mu,\lambda)$ be the unique solution of $\rho(k,\lambda,\mu) = 0$ in (5.12). Then $E^{\mathrm{o}}_{\lambda,m,n}(\mu)$ is written as

$$E^{\mathrm{o}}_{\lambda,m,n}(\mu) = I(k(\mu,\lambda)),$$

$$I(k) := -2n^4(1-k^2+k^4)K(k)^4/9\lambda\pi^3 + 4n^2(-2+k^2)K(k)^2/9\pi + 4n^2E(k)K(k)/3\pi + 5\lambda\pi/18, \tag{6.5}$$

where $E(k)$ is an elliptic integral

$$E(k) := \int_0^1 \sqrt{(1-k^2\xi^2)/(1-\xi^2)}\,\mathrm{d}\xi.$$

In the parameter region $D^-_{\ell,n}$ (or $D^+_{\ell,n}$) the inequality

$$\frac{d}{\mathrm{d}\mu}E^{\mathrm{o}}_{\lambda,m,n}(\mu) < 0 \quad (\text{or} > 0) \tag{6.6}$$

holds.

From this lemma and Theorem 1.1 it follows that

$$E^{\mathrm{o}}_{\lambda,\ell,n}(\mu) > \lim_{\mu\to\ell\pm n/2} E^{\mathrm{o}}_{\lambda,\ell,n}(\mu) = E^{\mathrm{s}}_{\lambda,n}(\ell \pm n/2), \quad (\mu,\lambda) \in D^-_{\ell,n} \cup D^+_{\ell,n}.$$

The proof of Lemma 6.1 will be done in the last part of this section.

Next consider (iii). We can verify the following.

Lemma 6.2: Let $k=k^{\mathrm{s}}(n,\lambda)$ be the unique solution to (2.2). Then $E^{\mathrm{s}}_{\lambda,n}(\mu)$ is written as

$$E^{\mathrm{s}}_{\lambda,n}(\mu) = I^{\mathrm{s}}(k^{\mathrm{s}}(n,\lambda)),$$

$$I^{\mathrm{s}}(k) := \lambda\pi(k^2-1)(3k^2+5)/6(k^2+1)^2 + 4\lambda\pi E(k)/3(k^2+1)K(k),$$

and it holds that

$$\frac{\mathrm{d}I^{\mathrm{s}}}{\mathrm{d}k}(k) < 0. \tag{6.7}$$

By this lemma we can prove (iii) as follows: For fixed $n \in \mathbb{N}$, $E^{\mathrm{s}}_{\lambda,n}(\mu)$ is defined if $\lambda > n^2/4$ and $\mu - n/2 \in \mathbb{Z}$. Since (2.2) and $I^{\mathrm{s}}(k)$ are independent of μ, $E^{\mathrm{s}}_{\lambda,n}(\mu) = E^{\mathrm{s}}_{\lambda,n}(\mu\pm 1)$ if $\mu - n/2 \in \mathbb{Z}$. Hence (6.3) follows. On the other hand, (6.4) holds by (6.7), because (2.12) implies $k^{\mathrm{s}}(n,\lambda) > k^{\mathrm{s}}(n',\lambda)$ if $n < n'$.

The proof of Lemma 6.2 will be done in the similar way to that of Lemma 6.1. We leave it to the readers because it is a straightforward computation and simpler than that of Lemma 6.1.

The proof of (iv) can be carried out by applying the arguments in Ref. 1 and Sec. 3.3 of Ref. 6 in the following way: Since the equation has the invariance under the rotation, the linearized operator at $\psi^{\mathrm{s}}_{\lambda,\mu,n}$ has zero eigenvalue with the corresponding eigenfunction $i\psi^{\mathrm{s}}_{\lambda,\mu,n}$. By virtue of the special form of the solution we can show that this eigenvalue problem is reduced to decoupled real-valued scalar equations of the Sturm-Liouville type. One of those scalar eigenvalue problems allows the zero eigenvalue coming from the invariance under the rotation. Since the corresponding eigenfunction has a vanishing point, Sturm-Liouville theorem tells it cannot be that of the least eigenvalue. As a consequence the solution is unstable (see Ref. 1 for the detail of the argument).

Now we present a proof of Lemma 6.1.

Proof of Lemma 6.1: The key computation is to verify (6.5). Once we establish, (6.5) we have

$$\frac{\mathrm{d}E^{\mathrm{o}}_{\lambda,m,n}}{\mathrm{d}\mu}(\mu) = -\frac{\mathrm{d}I}{\mathrm{d}k}\frac{\partial\rho}{\partial\mu} \Big/ \frac{\partial\rho}{\partial k}.$$

By virtue of the formulas

$$\frac{\mathrm{d}K}{\mathrm{d}k}(k)=\frac{E(k)}{(1-k^2)k}-\frac{K(k)}{k},\quad \frac{\mathrm{d}E}{\mathrm{d}k}(k)=\frac{E(k)}{k}-\frac{K(k)}{k},$$

a direct computation leads us to

$$\frac{\mathrm{d}I}{\mathrm{d}k}(k)=\frac{4n^4K(k)^3\{(2-k^2)(1-k^2)K(k)-2(1-k^2+k^4)E(k)\}}{9\lambda\pi^3k(1-k^2)}+\frac{4n^2\{K(k)^2(1-k^2)+2(k^2-2)E(k)K(k)+3E(k)^2\}}{9k\pi(1-k^2)}.$$

By Lemma 5.1 and a simple computation (see Lemma 3.6 and the proof of Lemma 3.5 in Ref. 7) we obtain

$$\frac{\mathrm{d}I}{\mathrm{d}k}(k)<0,\quad \frac{\partial\rho}{\partial\mu}=-4(m-\mu)K(k)^2,\quad \frac{\partial\rho}{\partial k}>0.$$

This implies (6.6).

Now we show (6.5). Let $u^{\mathrm{o}}_{\lambda,\mu,m,n}=w(x)\exp(i\theta(x)), v(x)=w(x)^2$, and let k be the unique solution of (5.12). In the next computation α,β, and γ are the parameters defined in, (3.8), (3.9), and (3.10), respectively. It is obvious from, (3.3), (5.3), and (5.4) that

$$\begin{aligned}E^{\mathrm{o}}_{\lambda,m,n}(\mu)&=\frac{1}{2}\int_0^{2\pi}(w_x)^2+w^2(\theta_x)^2+\frac{\lambda}{2}(1-w^2)^2\,\mathrm{d}x\\&=\frac{1}{2}\int_0^{2\pi}\frac{\lambda(v-\alpha)(v-\beta)(v-\gamma)}{2v}+\frac{\lambda\alpha\beta\gamma}{2v}+\frac{\lambda}{2}(1-v)^2\,\mathrm{d}x\\&=n\lambda\int_0^{\pi/n}(v^2-2v)\mathrm{d}x+\frac{\lambda\pi}{2}(\alpha\beta+\beta\gamma+\gamma\alpha+1).\end{aligned}\tag{6.8}$$

Using (5.4) and the change of variable $v=(\beta-\alpha)\tau^2+\alpha$, we have

$$\begin{aligned}n\lambda\int_0^{\pi/n}(v^2-2v)\mathrm{d}x&=n\sqrt{\frac{\lambda}{2}}\int_\alpha^\beta\frac{v^2-2v}{\sqrt{(v-\alpha)(v-\beta)(v-\gamma)}}\mathrm{d}v\\&=\frac{n\sqrt{2\lambda}}{\sqrt{\gamma-\alpha}}\int_0^1\frac{(\beta-\alpha)^2\tau^4+2(\alpha-1)(\beta-\alpha)\tau^2+(\alpha-2)\alpha}{\sqrt{(1-\tau^2)(1-k^2\tau^2)}}\mathrm{d}\tau.\end{aligned}\tag{6.9}$$

Notice that from

$$\frac{d}{\mathrm{d}\tau}\left(\tau\sqrt{(1-\tau^2)(1-k^2\tau^2)}\right)=\frac{3k^2\tau^4-2(k^2+1)\tau^2+1}{\sqrt{(1-\tau^2)(1-k^2\tau^2)}},$$

it follows

$$\int_0^1\frac{\tau^4}{\sqrt{(1-\tau^2)(1-k^2\tau^2)}}\mathrm{d}\tau=\int_0^1\frac{2(k^2+1)\tau^2-1}{3k^2\sqrt{(1-\tau^2)(1-k^2\tau^2)}}\mathrm{d}\tau.$$

Thus by

$$\int_0^1\frac{\tau^2}{\sqrt{(1-\tau^2)(1-k^2\tau^2)}}\mathrm{d}\tau=\frac{1}{k^2}(K(k)-E(k)),\tag{6.10}$$

we have the formula

$$\int_0^1 \frac{\tau^4}{\sqrt{(1-\tau^2)(1-k^2\tau^2)}}\mathrm{d}\tau = \frac{1}{3k^4}\{(k^2+2)K(k) - 2(k^2+1)E(k)\}. \tag{6.11}$$

Substituting (3.8), (3.9), (3.10), (6.10), and (6.11) into (6.8) and (6.9), we obtain the desired equality (6.5). □

VII. A CONCLUDING REMARK

As pointed out in the Introduction, we do not have the rigorous instability result for the solutions with modulating amplitude. If we could verify it, the proof of Theorem 1.2 would be greatly simplified. However, the computations in Sec. VI help us to see how the energy of the solution can be expressed. In addition to the result in Sec. VI we can prove

$$E^{\mathrm{c}}_{\lambda,m}(\mu) < E^{\mathrm{s}}_{\lambda,n}(\mu) \quad (\mu = m \pm n/2, \lambda > n^2/4),$$

though we need a lengthy computation. By using this inequality, instead of (iv) in Sec. VI, we can also obtain the same conclusion of Theorem 1.2.

In this article, we present a bifurcation and stability analysis on time-dependent Ginzburg–Landau model of superconductivity. It is proved in particular that there are two different phase transitions from the normal state to superconducting states or vice versa: one is continuous, and the other is jump. These two transitions are precisely determined by a simple nondimensional parameter, which links the superconducting behavior with the geometry of the material, the applied field and the physical parameters. The rigorous analysis is conducted using a bifurcation theory newly developed by the authors, and provides some interesting physical predictions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2012128]

I. INTRODUCTION

The main objective of this article is to study the nature of the phase transition from normal to superconducting states, which occurs when the temperature of a sample decreases. The rigorous analysis is conducted using a new bifurcation theory developed recently by the authors.

Superconductivity was first discovered in 1911 by H. Kamerlingh Onnes, who found that Mercury had zero electric resistance when the temperature decreases below some critical value T_c. Since then, one has found that large number of metals and alloys possess the superconducting property. In the superconducting state once a current is set up in a metal ring, it is expected that no change in this current occurs in times more that 10^{10} years (see Ref. 1). In 1933, the other important superconducting property, called the diamagnetism or the Meissner effect, was discovered by W. Meissner and R. Ochsenfield. They found that not only a magnetic field is excluded from entering a superconductor, but also that a field in an originally normal sample is expelled as it is cooled below T_c.

One central problem in the theory of superconductivity is the nature of the phase transition between a normal state, characterized by an order parameter that vanishes identically, and a superconducting state, characterized by the order parameter that is not identically zero. In this article, we address this problem by conducting rigorous bifurcation and stability analysis for the time dependent Ginzburg–Landau (TDGL) model of superconductivity.

The TDGL model of superconductivity involves an order parameter ψ, and the magnetic potential A. The problem is forced by an applied field H_a [see (2.1)–(2.3)]. The associated Ginzburg–Landau free energy is given by (see Ref. 1)

[a)]*Dedicated to Professor Louis Nirenberg on the occasion of his eightieth birthday with great affection and admiration.*
[b)]Electronic mail: showang@indiana.edu

$$f = f_{n0} + a|\psi|^2 + \frac{b}{2}|\psi|^4 + \frac{1}{2m_s}\left|\left(\frac{h}{i}\nabla - \frac{e_s}{c}A\right)\psi\right|^2 + \frac{h^2}{8\pi}, \tag{1.1}$$

where h is the Planck constant, c the speed of light, e_s and m_s the charge and mass of a Cooper pair, and the parameters $a=a(T)$ and $b=b(T)$ are coefficients satisfying the following conditions (see, among others, Ref. 2):

$$a = a(T)\begin{cases} >0 & \text{for } T > T_c \\ <0 & \text{for } T < T_c, \end{cases}$$

$$b = b(T) > 0.$$

Here T the temperature of the sample, and T_c the critical temperature where incipient superconductivity property can be observed.

With proper scaling, a nondimensional parameter α plays a key role in the phase transition (or bifurcation), which is given in terms of dimensional quantities by

$$\alpha = \alpha(T) = -\frac{2a\sqrt{b}m_s D}{e_s^3 h} = \frac{2\sqrt{b}m_s D N_0}{e_s^3 h}\frac{T_c - T}{T_c}, \tag{1.2}$$

where D is the diffusion coefficient, and the last equality was derived using (2.4) based on the Bardeen-Cooper-Schrieffer (BCS) theory.

The main objectives of this article is to establish a nonlinear bifurcation and stability theory for the Ginzburg–Landau equations. It is clear that such a nonlinear bifurcation and stability theory should at least include

(1) a bifurcation theorem when the parameter α crosses some critical numbers for all physically sound boundary conditions and geometry of the domain,
(2) asymptotic stability of bifurcated solutions, and
(3) the vortex structure and its stability and transitions in the physical space.

This bifurcation and stability analysis uses a new bifurcation theory for partial differential equations (PDEs) developed recently by the authors. This bifurcation theory is based on a new notion of bifurcation, called attractor bifurcation, and its corresponding theory introduced in Refs. 3 and 4. With the bifurcation theory, many bifurcation problems in science and engineering are becoming more accessible. In particular, applications are made for variety of PDEs from science and engineering, including, in particular, the Kuramoto-Sivashinshy equation, the Cahn-Hillard equation, the complex Ginzburg–Landau equation, Reaction-diffusion equations in biology and chemistry, the Rayleigh-Bénard convection problem, and the Taylor problem.

We now address different aspects of such a nonlinear bifurcation and stability theory for the TDGL model of superconductivity obtained in this article.

First, we proceed with the reduction of the infinite dimensional dynamical system governed by the TDGL equations to a finite dimensional system defined on the center manifold. One important ingredient of the analysis is the approximation of the center manifold function, which is part of the new bifurcation theory. With this reduction in our disposal, a general bifurcation theorem follows from the general strategy of attractor bifurcations, as required in part (1) mentioned previously. We prove in particular that there are two different phase transitions from the normal state to superconducting states or vice versa: one is continuous shown schematically in Fig. 1, and the other is jump shown in Figs. 2 and 3. These two transitions are precisely determined by a simple parameter R defined by (4.22) for transitions near a complex simple eigenvalue of the linearized problem [respectively, by two parameters R_1 and R_2 defined by (4.44) for transitions near an eigenvalues with higher multiplicity]. The parameter R links the superconducting behavior with the geometry of the material, the applied field and the physical parameters.

Second, as an attractor, the bifurcated attractor has asymptotic stability in the sense that it attracts all solutions with initial data in the phase space outside of the stable manifold of the trivial

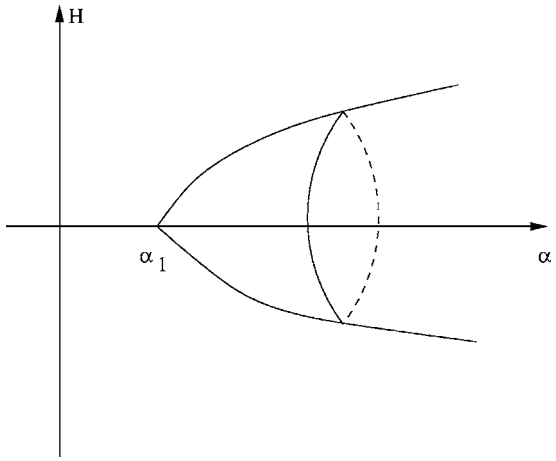

FIG. 1. For each $\alpha \leqslant \alpha_1$, the normal state is stable. For $\alpha > \alpha_1$, the normal state is unstable, the TDGL bifurcates to an S^1 attractor, representing stable superconducting state.

solution. Therefore bifurcation analysis for steady state problems provides in general only partial answers to the problem, and is not enough for solving the stability problem. Hence it appears that the right notion of asymptotic stability after the first bifurcation should be best described by the attractor near, but excluding, the trivial state. It is one of our main motivation for introducing attractor bifurcation.

Consider the TDGL model for the case where the first eigenvalue of the linearized problem is complex simple (i.e., has real multiplicity 2). When $R<0$, we obtain a continuous transition from the normal state to superconducting states. In particular, we prove in Theorem 4.1 that (a) the bifurcated attractor is a circle S^1, consisting of only steady states, (b) the solutions in the bifurcated attractor are in superconducting states, and (c) the bifurcated attractor attracts bounded open sets $U\backslash\Gamma$ in the phase space, where Γ is the stable manifold of the trivial solution. Consequently we prove in particular that under a fluctuation deviating both the normal and superconducting states, the sample will soon be restored to the superconducting states.

When $R>0$, we obtain a jump transition from the normal state to superconducting states or vice versa. In particular, from Theorems 4.2 and 4.3, as shown in Figs. 2 and 3, there are two

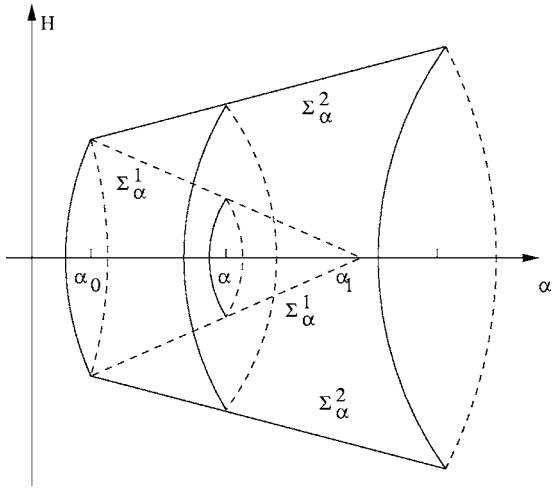

FIG. 2. For each $\alpha \in (\alpha_0, \alpha_1)$, Σ^1_α is a repeller, containing *unstable* superconducting states. For each $\alpha_0 < \alpha$, Σ^2_α is an attractor, containing *stable* superconductivity states.

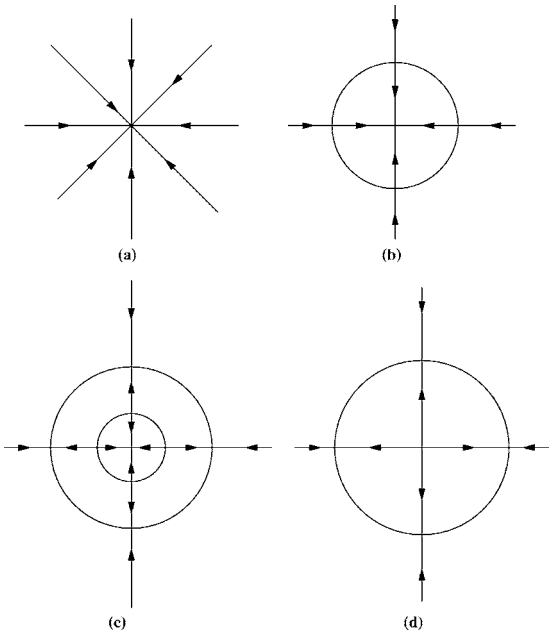

FIG. 3. Phase diagrams on the center manifold for various α: (a) case $\alpha<\alpha_0$, (b) case $\alpha=\alpha_0$, (c) case $\alpha_0<\alpha<\alpha_1$, and (d) case $\alpha_1\leqslant\alpha$

critical temperatures T_c^0 and T_c^1 ($T_c^0>T_c^1$) such that when $T_c^1<T$ (or $\alpha<\alpha_1$), physically observable states consists of the normal state, and the superconducting states in Σ_α^2, and when $T_c^1>T$ (or $\alpha>\alpha_1$), physically observable states are in Σ_α^2. In addition, the transitions at T_c^1 and T_c^0 are jump transitions.

Third, one important aspect of studies in superconductivity is the existence (appearance) and structure of vortices of the supercurrent. The associated mathematical question is to link the solutions of the PDEs (the TDGL model in this article) to the structure of the solutions in the "physical space." In fluid mechanics context, this corresponds to linking the kinematics to dynamics, and an attempt by the authors is summarized in Ref. 5. For the TDGL model, the existence of vortices and the structure of the supercurrent is analyzed using this philosophy.

Fourth, it is noteworthy to mention that although we used the steady state equations to derive the existence of one of the steady state bifurcation branches, the dynamic properties (the basin attraction, stability, introduction of the parameters R, R_1 and R_2, etc) and the branch Σ_α^2 are of a truly dynamical nature.

There have been extensive studies on bifurcation and stability analysis for superconductivity; see among others.[6–10] In particular, we point out recent work by Berger and Rubinstein[11] and Chapman,[12] where similar questions on different phase transitions of the Ginzburg–Landau model were addressed. In Ref. 11, the study is based on evaluating the second variation of the Ginzburg–Landau functional, whereas in Ref. 12, an asymptotic method traced back to Ref. 13 is used.

This article is organized as follows. Section II introduces the TDGL model. In Sec. III, after a brief introduction of the attractor bifurcation theory and center manifold functions, we prove a special case of the attractor bifurcation called S^1 attractor bifurcation. Section IV states and proves the main theorems on stability and bifurcation of the TGDL equations. Conclusions and physical remarks are given in Sec. V.

II. TDGL MODEL

A. The equations

Let $\Omega\subset\mathbb{R}^n$ ($n=2$ or 3) be a bounded open set. We consider the attractor bifurcation of the TDGL equations of superconductivity defined on Ω. The following three unknown functions are

involved in the mathematical formulation: a complex valued function $\psi:\Omega\to\mathbb{C}$ for the order parameter, a vector valued function $A:\Omega\to\mathbb{R}^3$ for the magnetic potential and a scalar function $\phi:\Omega\to\mathbb{R}^1$ for the electric potential. The TDGL model reads

$$\frac{h^2}{2m_sD}\left(\frac{\partial}{\partial t}+\frac{ie_s}{h}\phi\right)\psi+a\psi+b|\psi|^2\psi+\frac{1}{2m_s}\left(hi\nabla+\frac{e_s}{c}A\right)^2\psi=0, \tag{2.1}$$

$$J=-\sigma\left(\frac{1}{c}A_t+\nabla\phi\right)-\frac{e_s^2}{m_sc}|\psi|^2A-\frac{e_shi}{2m_s}(\psi^*\nabla\psi-\psi\nabla\psi^*), \tag{2.2}$$

$$\frac{4\pi}{c}J=\mathrm{curl}^2A-\mathrm{curl}\,H_a, \tag{2.3}$$

where σ the conductivity of the normal phase, J the supercurrent, and ψ^* the complex conjugate of ψ. In the BCS theory, the parameters $a=a(T)$ and $b=b(T)$ are given (see Ref. 2) by

$$\begin{aligned} a(T)&=N(0)\frac{T-T_c}{T_c},\\ b(T)&=0.098\frac{N(0)}{(k_bT_c)^2}. \end{aligned} \tag{2.4}$$

Equations (2.1) and (2.2) are the TDGL equations generalized by P. L. Gor'kov and G. M. Éliashberg,[1,14] and (2.3) is the classical Maxwell equation. The order parameter ψ describes the local density n_s of superconducting electrons: $|\psi|^2=n_s$. In addition, ψ is proportional to the energy gap parameter Δ near T_c, which appears in the BCS theory.

B. Scaling

From both the mathematical and physical points of view, we introduce here two nondimensional forms of the TDGL equations: one of which is used often in the literature, and the other is more suitable for the bifurcation and stability analysis presented in this article.

For convenience, we start with the dimensions of various physical quantities. Let m be the mass, L the typical length scale, t the time, and E the energy. Then we have

$$E:L^2m/t,\quad h:Et,\quad D:L^2/t,\quad e_s^2:EL,$$

$$\sigma:1/t,\quad c:L/t,\quad a:E,\quad b:EL^3,$$

$$\psi:1/L^{3/2},\quad A:(E/L)^{1/2},\quad H:(E/L^3)^{1/2}.$$

Then we introduce some physical parameters:

$$|\psi_0|^2=|a|/b,$$

$$H_c=(4\pi|a|^2/b)^{1/2},$$

$$\lambda=\lambda(T)=(m_sc^2b/4\pi e_s^2|a|)^{1/2},$$

$$\xi=\xi(T)=h/(2m_s|a|)^{1/2},$$

$$\kappa=\lambda/\xi,$$

$$\eta = 4\pi\sigma D/c^2,$$

$$\tau = \lambda^2/D.$$

Physically, $|\psi_0|^2$ stands for the equilibrium density, H_c for the thermodynamic critical field, $\lambda = \lambda(T)$ for the penetration depth, $\xi(T)$ for the coherence length, and τ for the relaxation time. The ratio of the two characteristic lengths $\kappa = \lambda/\xi$ is called the Ginzburg–Landau parameter of the substance. When $0 < \kappa < 1/\sqrt{2}$, the material is of the first type, and when $\kappa > 1/\sqrt{2}$, the material is of the second type.

We now introduce the nondimensional variables (those with a prime):

$$x = \lambda x', \quad t = \tau t', \quad \psi = \psi_0 \psi',$$

$$A = \frac{\sqrt{2}H_c\lambda}{\kappa}A', \quad \phi = \frac{D\sqrt{2}H_c}{\kappa}\phi', \quad H_a = \frac{\sqrt{2}H_c}{\kappa}H_a'.$$

Then we have the following traditional nondimensional TDGL equations (we henceforth drop the primes)

$$\psi_t + i\kappa\phi\psi + \kappa^2(|\psi|^2 - 1)\psi + (i\nabla + A)^2\psi = 0,$$

$$\eta(A_t + \nabla\phi) + \frac{i}{2}(\psi^*\nabla\psi - \psi\nabla\psi^*) + |\psi|^2 A + \operatorname{curl}^2 A - \operatorname{curl} H_a = 0,$$

for the case where $a < 0$, or equivalently $T < T_c$.

As mentioned before, we need to introduce another non-dimensional form for the stability and bifurcation study. To this end, we set

$$l = \frac{\sqrt{b}}{e_s}, \quad \tau_0 = \frac{hl}{e_s^2}, \quad \phi_0 = \frac{e_s^2}{\sqrt{b}},$$

$$A_0 = \left(\frac{e_s h c^2}{D\sqrt{b}}\right)^{1/2}, \quad \alpha = -\frac{2a\sqrt{b}m_s D}{e_s^3 h}, \quad \mu = \frac{hD}{\sqrt{b}e_s},$$

$$\beta = \frac{2m_s D}{h}, \quad \zeta = \frac{4\pi\sigma l e_s^2}{c^2 h}, \quad \gamma = \frac{4\pi e_s^2}{m_s c^2 l},$$

and

$$x = lx', \quad t = \tau_0 t', \quad \psi = l^{-3/2}\psi',$$

$$A = A_0 A', \quad \phi = \phi_0\phi', \quad H_a = l^{-1}A_0 H_a'.$$

Then we have the second type of non-dimensional TDGL equations (we drop the primes also):

$$\begin{aligned} &\psi_t + i\phi\psi = -(i\mu\nabla + A)^2\psi + \alpha\psi - \beta|\psi|^2\psi, \\ &\zeta(A_t + \mu\nabla\phi) = -\operatorname{curl}^2 A + \operatorname{curl} H_a - \gamma|\psi|^2 A - \frac{\gamma\mu i}{2}(\psi^*\nabla\psi - \psi\nabla\psi^*). \end{aligned} \tag{2.5}$$

We shall see in later discussions that the parameter α plays a key role in the phase transition (or bifurcation), which is given in terms of dimensional quantities by

$$\alpha = \alpha(T) = \frac{2\sqrt{b}m_s D N_0}{e_s^3 h}\frac{T_c - T}{T_c}.$$

C. Boundary conditions

A physically sound boundary condition for the order parameter is given by

$$C_1\left(ih\nabla + \frac{e_s}{c}A\right)\psi \cdot n = -C_2 ih\psi \quad \text{on } \partial\Omega, \tag{2.6}$$

which means that no current passes through the boundary, where n is the unit outward normal vector at $\partial\Omega$, and $C_1, C_2 \geqslant 0$ are constants depending on the material to which the contact is made. Physically, they satisfy[1,2]

$$C_2 = 0, \quad C_1 \neq 0 \quad \text{for an insulator on } \partial\Omega,$$

$$C_1 = 0, \quad C_2 \neq 0 \quad \text{for a magnetic material}, \tag{2.7}$$

$$0 < C_2/C_1 < \infty \quad \text{for a normal metal}.$$

We note that Eqs. (2.1)–(2.3) with (2.6) is invariant under the following gauge transformation

$$(\psi, A, \phi) \to \left(\psi e^{i\theta}, A - \frac{hc}{e_s}\nabla\theta, \phi - \frac{h}{e_s}\theta_t\right),$$

where θ is an arbitrary function. If we take θ such that

$$\frac{hc}{e_s}\Delta\theta = \operatorname{div} A \quad \text{in } \Omega,$$

$$\frac{hc}{e_s}\frac{\partial\theta}{\partial n} = A \cdot n \quad \text{on } \partial\Omega,$$

then we obtain an additional equation and a boundary condition; see also Refs. 2 and 15:

$$\operatorname{div} A = 0, \tag{2.8}$$

$$A_n = A \cdot n = 0 \quad \text{on } \partial\Omega. \tag{2.9}$$

Another boundary condition often imposed for A is as follows:

$$\operatorname{curl} A \times n = H_a \times n \quad \text{on } \partial\Omega. \tag{2.10}$$

D. Nondimensional TDGL model

In summary, with the gauge taken such that (2.8) and (2.9) hold true, the nondimensional TDGL equations are

$$\psi_t + i\phi\psi = -(i\mu\nabla + A)^2\psi + \alpha\psi - \beta|\psi|^2\psi,$$

$$\zeta(A_t + \mu\nabla\phi) = -\operatorname{curl}^2 A + \operatorname{curl} H_a - \gamma|\psi|^2 A - \frac{\gamma\mu i}{2}(\psi^*\nabla\psi - \psi\nabla\psi^*), \tag{2.11}$$

$$\operatorname{div} A = 0.$$

The initial conditions are given by

$$\psi(0) = \psi_0, \quad A(0) = A_0. \tag{2.12}$$

The boundary conditions are one of the following:

Neumann boundary condition: For the case where Ω is enclosed by an insulator:

$$\frac{\partial \psi}{\partial n} = 0, \quad A_n = 0, \quad \operatorname{curl} A \times n = H_a \times n \quad \text{on } \partial\Omega. \tag{2.13}$$

Dirichlet boundary condition: For the case where Ω is enclosed by a magnetic material:

$$\psi = 0, \quad A_n = 0, \quad \operatorname{curl} A \times n = H_a \times n \text{ on } \partial\Omega. \tag{2.14}$$

Robin boundary condition: For the case where Ω is enclosed by a normal metal:

$$\frac{\partial \psi}{\partial n} + C\psi = 0, \quad A_n = 0, \quad \operatorname{curl} A \times n = H_a \times n \text{ on } \partial\Omega. \tag{2.15}$$

Remark 2.1: If the material is a loop, or a plate $\Omega = \tilde{\Omega} \times (0,h)$ with the height h being small in comparison to the diameter of $\tilde{\Omega}$, then it is reasonable to consider the boundary condition with periodicity either in x direction or in (x,y) directions.

III. DYNAMIC BIFURCATION THEORY

A. Attractor bifurcation

We recall in this section a general theory on attractor bifurcation developed by the authors.[3,4,16]

Let H and H_1 be two Hilbert spaces, and $H_1 \hookrightarrow H$ be a dense and compact inclusion. We consider the following nonlinear evolution equations:

$$\begin{aligned} \frac{du}{dt} &= L_\lambda u + G(u,\lambda), \\ u(0) &= u_0, \end{aligned} \tag{3.1}$$

where $u:[0,\infty) \to H$ is the unknown function, $\lambda \in \mathbb{R}$ is the system parameter, and $L_\lambda : H_1 \to H$ are parameterized linear completely continuous fields depending continuously on $\lambda \in \mathbb{R}^1$, which satisfy

$$\begin{aligned} &L_\lambda = -A + B_\lambda \quad \text{a sectorial operator}, \\ &A: H_1 \to H \quad \text{a linear homeomorphism}, \\ &B_\lambda: H_1 \to H \quad \text{parameterized linear compact operators}. \end{aligned} \tag{3.2}$$

It is easy to see[17] that L_λ generates an analytic semigroup $\{e^{-tL_\lambda}\}_{t \geqslant 0}$. Then we can define fractional power operators L_λ^α for any $0 \leqslant \alpha \leqslant 1$ with domain $H_\alpha = D(L_\lambda^\alpha)$ such that $H_{\alpha_1} \subset H_{\alpha_2}$ if $\alpha_1 > \alpha_2$, and $H_0 = H$.

Further, we assume that the nonlinear terms $G(\cdot,\lambda): H_\alpha \to H$ for some $0 \leqslant \alpha < 1$ are a family of parameterized C^r bounded operators $(r \geqslant 1)$ depending continuously on the parameter $\lambda \in \mathbb{R}^1$, such that

$$G(u,\lambda) = o(\|u\|_{H_\alpha}), \quad \forall\, \lambda \in \mathbb{R}^1. \tag{3.3}$$

In this paper, we are interested in the sectorial operator $L_\lambda = -A + B_\lambda$ such that there exist an eigenvalue sequence $\{\rho_k\} \subset \mathbb{C}^1$ and an eigenvector sequence $\{e_k, h_k\} \subset H_1$ of A:

$$Az_k = \rho_k z_k, \quad z_k = e_k + ih_k,$$

$$\text{Re } \rho_k \to \infty (k \to \infty), \tag{3.4}$$

$$|\text{Im } \rho_k / (\text{Re } \rho_k)| \leqslant C,$$

for some $C > 0$, and such that $\{e_k, h_k\}$ is a basis of H.

Condition (3.4) implies that A is a sectorial operator. For the operator $B_\lambda : H_1 \to H$, we also assume that there is a constant $0 < \theta < 1$ such that

$$B_\lambda : H_\theta \to H \text{ bounded}, \quad \forall\, \lambda \in \mathbb{R}^1. \tag{3.5}$$

Under conditions (3.4) and (3.5), the operator $L_\lambda = -A + B_\lambda$ is a sectorial operator.

Let $\{S_\lambda(t)\}_{t \geqslant 0}$ be an operator semi-group generated by Eq. (3.1), then the solution of (3.1) can be expressed as

$$u(t) = S_\lambda(t) u_0, \quad t \geqslant 0.$$

Definition 3.1: *A set $\Sigma \subset H$ is called an invariant set of* (3.1) *if $S(t)\Sigma = \Sigma$ for any $t \geqslant 0$. An invariant set $\Sigma \subset H$ of* (3.1) *is said to be an attractor if Σ is compact, and there exists a neighborhood $U \subset H$ of Σ such that for any $\varphi \in U$ we have*

$$\lim_{t \to \infty} \text{dist}_H (u(t, \varphi), \Sigma) = 0.$$

The set U is called a basin of attraction of Σ.

Definition 3.2: (1) *We say that Eq. (3.1) bifurcates from $(u, \lambda) = (0, \lambda_0)$ an invariant set Ω_λ, if there exists a sequence of invariant sets $\{\Omega_{\lambda_n}\}$ of* (3.1) *such that $0 \notin \Omega_{\lambda_n}$, and*

$$\lim_{n \to \infty} \lambda_n = \lambda_0,$$

$$\lim_{n \to \infty} \max_{x \in \Omega_{\lambda_n}} |x| = 0.$$

(2) *If the invariant sets Ω_λ are attractors of* (3.1), *then the bifurcation is called attractor bifurcation.*

A complex number $\beta = \alpha_1 + i\alpha_2 \in \mathbb{C}$ is called an eigenvalue of L_λ if there are $x, y \in H_1$ such that

$$L_\lambda x = \alpha_1 x - \alpha_2 y,$$

$$L_\lambda y = \alpha_2 x + \alpha_1 y.$$

Now let the eigenvalues (counting the multiplicity) of L_λ be given by

$$\beta_1(\lambda), \beta_2(\lambda), \ldots, \quad \beta_k(\lambda) \in \mathbb{C},$$

where $\mathbb{C}$ is the complex space. Suppose that

$$Re\beta_i(\lambda) \begin{cases} < 0 & \text{if } \lambda < \lambda_0, \\ = 0 & \text{if } \lambda = \lambda_0, \\ > 0 & \text{if } \lambda > \lambda_0, \end{cases} \qquad \forall\, 1 \leqslant i \leqslant m, \tag{3.6}$$

$$Re\beta_j(\lambda_0) < 0 \quad \forall\, m+1 \leqslant j. \tag{3.7}$$

Let the eigenspace of L_λ at λ_0 be

$$E_0 = \bigcup_{k\in\mathbb{N}} \bigcup_{1\leqslant i\leqslant m} \{u,v \in H_1 | (L_{\lambda_0} - \beta_i(\lambda_0))^k w = 0, w = u + iv\}.$$

It is known that $\dim E_0 = m$.

Theorem 3.3: (attractor bifurcation).[3,4] *Assume that the conditions* (3.3)–(3.7) *hold true, and* $u=0$ *is a locally asymptotically stable equilibrium point of* (3.1) *at* $\lambda=\lambda_0$. *Then the following assertions hold true.*

(1) (3.1) *bifurcates from* $(u,\lambda)=(0,\lambda_0)$ *to an attractor* $\mathcal{A}_\lambda$ *for* $\lambda>\lambda_0$, *with* $m-1\leqslant \dim \mathcal{A}_\lambda \leqslant m$, *which is connected when* $m>1$;
(2) *The attractor* $\mathcal{A}_\lambda$ *is a limit of a sequence of m-dimensional annulus* M_k *with* $M_{k+1}\subset M_k$; *especially if* $\mathcal{A}_\lambda$ *is a finite simplicial complex, then* $\mathcal{A}_\lambda$ *has the homotopy type of* S^{m-1};
(3) *For any* $u_\lambda \in \mathcal{A}_\lambda$, u_λ *can be expressed as*

$$u_\lambda = v_\lambda + o(\|v_\lambda\|_{H_1}), \quad v_\lambda \in E_0;$$

(4) *There is an open set* $U\subset H$ *with* $0\in U$ *such that the attractor* $\mathcal{A}_\lambda$ *bifurcated from* $(0,\lambda_0)$ *attracts* $U\backslash\Gamma$ *in H, where* Γ *is the stable manifold of* $u=0$ *with co-dimension m.*

B. Center manifold functions

In this section, we introduce a method to derive the first order approximation of the central manifold functions, which was used in Ref. 4. For convenience, we first introduce the center manifold theorem in infinite dimensional spaces.

Let H_1 and H be decomposed into

$$\begin{aligned} H_1 &= E_1^\lambda \oplus E_2^\lambda, \\ H &= \widetilde{E}_1^\lambda \oplus \widetilde{E}_2^\lambda, \end{aligned} \tag{3.8}$$

for λ near $\lambda_0 \in \mathbb{R}^1$, where E_1^λ, E_2^λ are invariant subspaces of L_λ, such that

$$\dim E_1^\lambda < \infty,$$

$$\widetilde{E}_1^\lambda = E_1^\lambda,$$

$$\widetilde{E}_2^\lambda = \text{closure of } E_2^\lambda \text{ in } H.$$

In addition, L_λ can be decomposed into $L_\lambda = \mathcal{L}_1^\lambda \oplus \mathcal{L}_2^\lambda$ such that for any λ near λ_0,

$$\begin{aligned} \mathcal{L}_1^\lambda &= L_{\lambda E_1^\lambda}: E_1^\lambda \to \widetilde{E}_1^\lambda, \\ \mathcal{L}_2^\lambda &= L_{\lambda E_2^\lambda}: E_2^\lambda \to \widetilde{E}_2^\lambda, \end{aligned} \tag{3.9}$$

where the eigenvalues of $\mathcal{L}_2^\lambda$ possess negative real parts, and the eigenvalues of $\mathcal{L}_1^\lambda$ possess nonnegative real parts at $\lambda=\lambda_0$.

Thus, for λ near λ_0, Eq. (3.1) can be written as

$$\frac{dx}{dt} = \mathcal{L}_1^\lambda x + G_1(x,y,\lambda),$$
$$\frac{dy}{dt} = \mathcal{L}_2^\lambda y + G_2(x,y,\lambda), \tag{3.10}$$

where $u=x+y \in H_1$, $x \in E_1^\lambda$, $y \in E_2^\lambda$, $G_i(x,y,\lambda)=P_iG(u,\lambda)$, and $P_i: H \to \tilde{E}_i^\lambda$ are canonical projections. Further, let

$$E_2^\lambda(\alpha) = \text{closure of } E_2^\lambda \text{ in } H_\alpha,$$

with $\alpha<1$ given in (3.3).

The following center manifold theorem is classical.[17]

Theorem 3.4: *Assume* (3.2), (3.3), (3.8), and (3.9). *Then there exists a neighborhood of* λ_0 *given by* $|\lambda-\lambda_0|<\delta$ *for some* $\delta>0$, *a neighborhood* $U_\lambda \subset E_1^\lambda$ *of* $x=0$, *and a* C^1 *function* $\Phi(\cdot,\lambda): U_\lambda \to E_2^\lambda(\theta)$ *depending continuously on* λ, *such that*

(1) $\Phi(0,\lambda)=0$, $\Phi_x'(0,\lambda)=0$,
(2) *the set*

$$M_\lambda = \{(x,y) \in H | x \in U_\lambda, y = \Phi(x,\lambda) \in E_2^\lambda(\theta)\},$$

called the center manifolds, are locally invariant for (3.1), *i.e., for each* $u_0 \in M_\lambda$

$$u_\lambda(t,u_0) \in M_\lambda, \quad \forall\, 0 \leqslant t < t(u_0)$$

for some $t(u_0)>0$, *where* $u_\lambda(t,u_0)$ *is the solution of* (3.1);
(3) *if* $(x_\lambda(t), y_\lambda(t))$ *is a solution of* (3.10), *then there is a* $\beta_\lambda>0$ *and* $k_\lambda>0$ *with* k_λ *depending on* $(x_\lambda(0), y_\lambda(0))$ *such that*

$$\|y_\lambda(t) - \Phi(x_\lambda(t),\lambda)\|_H \leqslant k_\lambda e^{-\beta_\lambda t}.$$

Now we give a formula to calculate the center manifold function. Let the nonlinear operator G be given by

$$G(u,\lambda) = G_k(u,\lambda) + o(|u|^k), \tag{3.11}$$

for $k \geqslant 2$, where $G_k(u,\lambda)$ is a k-multilinear operator:

$$G_k: H_1 \times \cdots \times H_1 \to H,$$

$$G_k(u,\lambda) = G_k(u,\ldots,u,\lambda).$$

The following theorem gives an approximation of the center manifold function; see Ref. 4.

Theorem 3.5: *Under the conditions of Theorem 3.4, the center manifold function* $\Phi(x,\lambda)$ *can be expressed as*

$$\Phi(x,\lambda) = (-\mathcal{L}_2^\lambda)^{-1} P_2 G_k(x,\lambda) + O(|\mathrm{Re}\,\beta(\lambda)| \cdot \|x\|^k) + o(\|x\|^k), \tag{3.12}$$

where $\mathcal{L}_2^\lambda$ *is given by* (3.9), $P_2: H \to \tilde{E}_2$ *the canonical projection*, $x \in E_1^\lambda$, *and* $\beta(\lambda) = (\beta_1(\lambda),\ldots,\beta_m(\lambda))$ *the eigenvalues of* $\mathcal{L}_1^\lambda$.

C. S^1 attractor bifurcation

In this section, we prove that the bifurcated attractor Ω_λ of (3.1) from an eigenvalue with multiplicity two is homeomorphic to a circle S^1.

Let v be a two-dimensional $C^r (r \geqslant 1)$ vector field given by

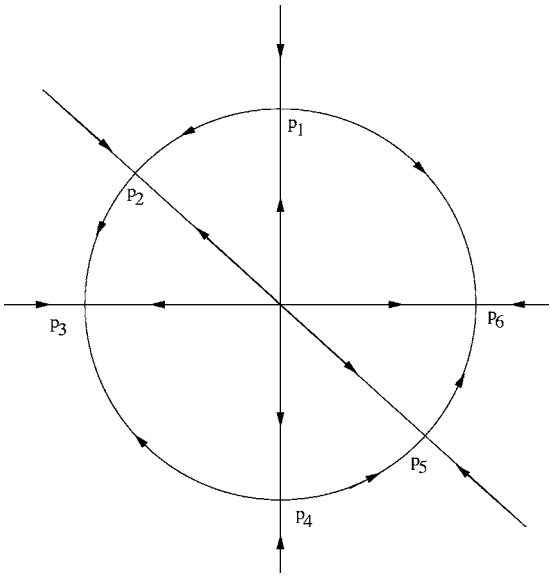

FIG. 4. Ω_λ has $4N+n$ ($N=1$ and $n=2$ shown here) singular points, where p_1,p_4 are saddles, p_3,p_6 are nodes, and p_2,p_5 are singular points with index zero.

$$v_\lambda(x) = \lambda x - G(x,\lambda), \tag{3.13}$$

for $x \in \mathbb{R}^2$. Here

$$G(x,\lambda) = G_k(x,\lambda) + o(|x|^k),$$

where G_k is a k-multilinear field, which satisfies that

$$C_1|x|^{k+1} \leqslant (G_k(x,\lambda),x) \leqslant C_2|x|^{k+1}, \tag{3.14}$$

for some constants $C_2 > C_1 > 0$, $k=2m+1$, and $m \geqslant 1$.

Theorem 3.6: *Under condition* (3.14), *vector field (3.13) bifurcates from* $(x,\lambda)=(0,0)$ *on* $\lambda > 0$ *to an attractor* Ω_λ, *which is homeomorphic to* S^1. *Moreover, one and only one of the following is true*.

(1) Ω_λ *is a periodic orbit*,
(2) Ω_λ *consists of only singular points, or*
(3) Ω_λ *contains at most* $2(k+1)=4(m+1)$ *singular points, and has* $4N+n(N+n \geqslant 1)$ *singular points*, $2N$ *of which are saddle points*, $2N$ *of which are stable node points (possibly degenerate), and* n *of which have index zero, as shown in Fig. 4 for* $N=1$ *and* $n=2$.

Proof: We proceed in the following five steps.

(1) Obviously (3.14) implies that $x=0$ is asymptotically stable for (3.13) at $\lambda=0$. Hence, by Theorem 3.3, the vector field v_λ bifurcates from $(x,\lambda)=(0,0)$ to an attractor Ω_λ on $\lambda>0$, which has the homology type of a circle S^1.

(2) Let Ω_λ have no singular points. Then, Ω_λ must contain at least a periodic orbit. We need to show that Ω_λ contains only one periodic orbit.

Take the polar coordinate system $(x_1,x_2)=(r\cos\theta, r\sin\theta)$. Then the vector field v_λ becomes

$$\frac{dr}{d\theta} = r\frac{\cos\theta v_1 + \sin\theta v_2}{\cos\theta v_2 - \sin\theta v_1}. \tag{3.15}$$

We see that

$$\cos\theta v_1 = \lambda r\cos^2\theta - \cos\theta g_1(r\cos\theta, r\sin\theta, \lambda),$$

$$\sin\theta v_2 = \lambda r\sin^2\theta - \sin\theta g_2(r\cos\theta, r\sin\theta, \lambda),$$

$$\cos\theta v_2 = \lambda r\cos\theta\sin\theta - \cos\theta\, g_2(r\cos\theta, r\sin\theta, \lambda),$$

$$\sin\theta v_1 = \lambda r\sin\theta\cos\theta - \sin\theta\, g_1(r\cos\theta, r\sin\theta, \lambda),$$

where $G(x,\lambda)=(g_1(x,\lambda), g_2(x,\lambda))$. Let

$$g_i(x,\lambda) = g_{ki}(x,\lambda) + o(|x|^k), \quad i = 1,2.$$

By (3.14) and (3.15) is rewritten as

$$\frac{dr}{d\theta} = \frac{\lambda - r^{2m}(\cos\theta\, g_{k1} + \sin\theta\, g_{k2}) + o(r^{2m})}{r^{2m-1}(\sin\theta\, g_{k1} - \cos\theta\, g_{k2} + O(r))}. \tag{3.16}$$

Based on (3.14), we have

$$C_1 \leqslant \cos\theta\, g_{k1}(\cos\theta, \sin\theta, \lambda) + \sin\theta\, g_{k2}(\cos\theta, \sin\theta, \lambda) \leqslant C_2. \tag{3.17}$$

On the other hand, by assumption, Ω_λ contains a periodic orbit for any $\lambda > 0$ sufficiently small. Hence

$$0 < C \leqslant \sin\theta\, g_{k1}(\cos\theta, \sin\theta, \lambda) - \cos\theta\, g_{k2}(\cos\theta, \sin\theta, \lambda) + O(r), \tag{3.18}$$

for any $0 \leqslant \theta \leqslant 2\pi$ and some constant $C > 0$. Condition (3.18) amounts to saying that the orbits of v_λ are circular around $x=0$.

Let $r(\theta, r_0)$ be the solution of (3.16) with initial value $r(0, r_0) = r_0$. Then we have the following Taylor expansion:

$$r^{2m}(\theta, r_0) = r_0^{2m} + R(\theta)\cdot o(|r_0|^{2m}), \quad R(0) = 0. \tag{3.19}$$

It follows from (3.16) and (3.19) that

$$\frac{1}{2m}[r^{2m}(2\pi, r_0) - r^{2m}(0, r_0)] = \int_0^{2\pi} \frac{\lambda - r^{2m}\alpha(\theta) + o(r^{2m})}{\beta(\theta) + O(r)} d\theta = 2\pi(a\lambda - b r_0^{2m}) + o(r_0^{2m}), \tag{3.20}$$

where

$$a = \int_0^{2\pi} \frac{1}{\beta(\theta) + O(r)} d\theta,$$

$$b = \int_0^{2\pi} \frac{\alpha(\theta)}{\beta(\theta) + O(r)} d\theta,$$

$$\alpha(\theta) = \cos\theta\, g_{k1} + \sin\theta\, g_{k2},$$

$$\beta(\theta) = \sin\theta\, g_{k1} - \cos\theta\, g_{k2}.$$

From (3.20) we see that the periodic solutions of v_λ near $x=0$ correspond to positive solutions of

$$2\pi(a\lambda - br_0^{2m}) + o(r_0^{2m}) = 0. \tag{3.21}$$

By (3.17) and (3.18), $a>0$ and $b>0$. Therefore, (3.21) has a unique positive solution near $r=0$:

$$r_0 = \left(\frac{a\lambda}{b}\right)^{1/2m} + o(\lambda^{1/2m}),$$

for any $\lambda>0$ sufficiently small. Thus, Ω_λ has a unique periodic orbit.

(3) We claim that if Ω_λ contains either finite number of singular points or a cycle of singular points, and if it contains finite number of singular points, then there are at most $2(k+1)$ of them near $x=0$.

In fact, if

$$\frac{g_1(x,\lambda)}{g_2(x,\lambda)} = \frac{x_1}{x_2},$$

then Ω_λ has a cycle of singular points. Otherwise, by (3.14), the number of singular points of v_λ is finite. The maximal number of singular points for v_λ is determined by the following equation

$$\lambda x - G_k(x,\lambda) = 0. \tag{3.22}$$

Since G_k is a k-multilinear vector field, the singular points of (3.22) must be on the straight lines $x_2=zx_1$, where z satisfies

$$z = \frac{g_{k2}(x_1,x_2,\lambda)}{g_{k1}(x_1,x_2,\lambda)} = \frac{g_{k2}(1,z,\lambda)}{g_{k1}(1,z,\lambda)}. \tag{3.23}$$

The number of solutions of (3.23) is at most $k+1$. Since $k=$odd, the number of solutions of (3.22) is at most $2(k+1)$.

(4) Let Ω_λ contain a circle S^1 of singular points, then we shall see that $\Omega_\lambda=S^1$.

Under the polar coordinate system, we have

$$v_r(\theta,r) = (v_x,x) = \lambda r^2 - r^{k+1}\alpha(\theta) + o(r^{k+1}),$$

where $\alpha(\theta)$ is defined by (3.20). By (3.17),

$$0 < C_1 \leqslant \alpha(\theta) \leqslant C_2, \quad \forall\, 0 \leqslant \theta \leqslant 2\pi.$$

It is clear that for each $\theta\,(0\leqslant\theta\leqslant 2\pi)$, v_r has a unique zero point $r_\lambda(\theta)>0$ near $r=0$. Hence the set

$$\widetilde{\Omega}_\lambda = \{(\theta, r_\lambda(\theta)) | v_r(\theta, r_\lambda(\theta)) = 0, \quad 0 \leqslant \theta \leqslant 2\pi\}$$

is homeomorphic to a cycle S^1, and all singular points of v near $x=0$ are on $\widetilde{\Omega}_\lambda$. It implies that $\widetilde{\Omega}_\lambda \subset \Omega_\lambda$. Let

$$g_{kl} = \sum_{i+j=k} \alpha_{ij}^l x_1^i x_2^j, \quad l=1,2. \tag{3.24}$$

By Step 3, we know that $x_2 g_{k1} = x_1 g_{k2}$. Then we infer from (3.14) that

$$0 < \alpha_{k0}^1 = \alpha_{k-11}^2. \tag{3.25}$$

For the singular point $(\tilde{x}_1,0) \in \widetilde{\Omega}_\lambda$ of v_λ, we have

$$\begin{aligned} \operatorname{div} v_\lambda(\tilde{x}_1,0) &= 2\lambda - k\alpha_{k0}^1 \tilde{x}_1^{k-1} - \alpha_{k-11}^2 \tilde{x}_1^{k-1} + o(\tilde{x}_1^{k-1}) \\ &= (\text{by } \alpha_{k0}^1 \tilde{x}_1^{k-1} = \lambda \text{ and } (3.25)) = -(k-1)\lambda + o(\lambda) < 0, \end{aligned}$$

for any $\lambda>0$ sufficiently small.

In the same fashion, for any point $\tilde{x} \in \tilde{\Omega}_\lambda$, we take an orthogonal system transformation such that $\tilde{x}$ is on the $\tilde{x}_1$ axis, then we can prove that

$$\operatorname{div} v_\lambda(x) < 0, \quad \forall\, x \in \tilde{\Omega}_\lambda,$$

which implies that $\Omega_\lambda = \tilde{\Omega}_\lambda = S^1$.

(5) Ω_λ contains finite number of singular points. We show that $\Omega_\lambda = S^1$.

By the Brouwer degree theory, it follows from (3.14) that

$$\deg(v_\lambda, \Omega, 0) = 1, \quad |\lambda| \geqslant 0 \text{ sufficiently small},$$

in some neighborhood $\Omega \subset \mathbb{R}^2$ of $x=0$. It is known that

$$\operatorname{ind}(v_\lambda, 0) = 1, \quad |\lambda| \neq 0.$$

Hence we have

$$\sum_{z_i \in \Omega_\lambda} \operatorname{ind}(v_\lambda, z_i) = 0. \tag{3.26}$$

Let $z \in \Omega_\lambda$ be a singular point of v_λ. Without loss of generality, we take the orthogonal coordinate system such that $z=(x_1, 0)$. Then by (3.14) and (3.24), the Jacobian matrix of v_λ at z is given by

$$Dv_\lambda(z) = \begin{pmatrix} -(k-1)\lambda + o(\lambda) & * \\ 0 & (1 - \alpha^2_{k-11}/\alpha^1_{k0})\lambda \end{pmatrix}, \tag{3.27}$$

where $\alpha^1_{k0} > 0$. Obviously, $Dv_\lambda(z)$ has an eigenvalue $\beta = -(k-1)\lambda + o(\lambda) \neq 0$. Hence for any singular point $z \in \Omega_\lambda$ of v_λ, the index of v_λ at z can only be either 1, -1 or 0. It is easy to see that if the index is 1, then z is a stable node point.

Let the index of v_λ at z be -1:

$$\operatorname{index}(v_\lambda, z) = -1. \tag{3.28}$$

When $\alpha^2_{k-11} \neq \alpha^1_{k0}$, z is nondegenerate. Therefore, v_λ has a unique unstable manifold at z. When $\alpha^2_{k-11} = \alpha^1_{k0}$,

$$\operatorname{div} u_\lambda(z) = -(k-1)\lambda + o(\lambda) < 0. \tag{3.29}$$

If the unstable manifold of v_λ at z is not unique, then the local structure of v_λ at z is topologically equivalent to that as shown in Fig. 5.

On the other hand, (3.29) means that there is a neighborhood $\mathcal{O} \subset \mathbb{R}^2$ of $x=0$, such that

$$\operatorname{div} u_\lambda(x) < 0, \quad \forall\, x \in \mathcal{O},$$

which implies that for any open set $\tilde{\mathcal{O}} \subset \mathcal{O}$,

$$|\tilde{\mathcal{O}}| > |\tilde{\mathcal{O}}_t|, \quad 0 < t < t_0, \tag{3.30}$$

where $t_0 > 0$ depends on $\tilde{\mathcal{O}}$, $\tilde{\mathcal{O}}_t = S(t)\tilde{\mathcal{O}}$ and $S(t)$ is the flow semigroup generated by v_λ.

However, it is clear that for any open set $\tilde{\mathcal{O}} \subset \mathcal{O}$ in domain P as shown in Fig. 5, the property (3.30) is not true. Therefore, the unstable manifold of v_λ at z must be unique.

We can prove in the same fashion that if the index of v_λ at z is 0, then the unstable manifold of v_λ at z is also unique.

By the Poincaré-Bendixson theorem, all unstable manifolds of the singular points of v_λ at z with index -1 and 0 are connected to the singular points with index 1 and 0, as shown in Fig. 4.

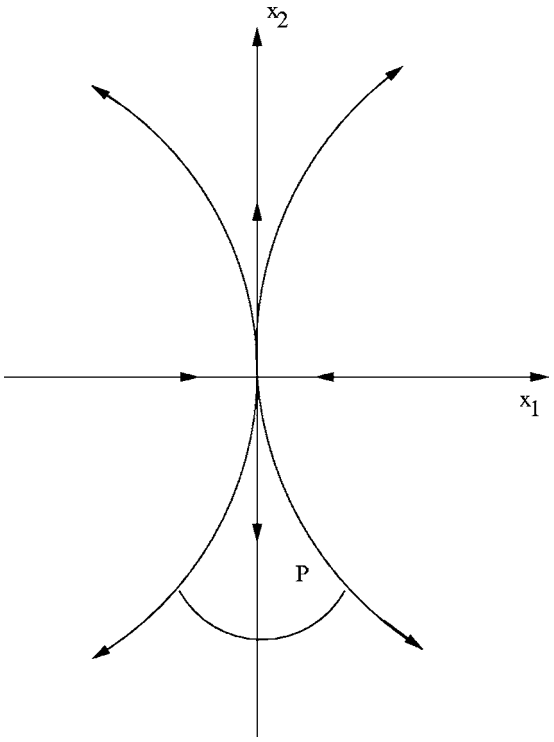

FIG. 5. Schematic illustrating the proof of Theorem 3.6.

Thus by the uniqueness of unstable manifolds for each singular point with either index -1 or index 0, the set of all singular points and unstable manifolds is a circle S^1, and $\Omega_\lambda = S^1$.

The proof is complete. □

IV. ATTRACTOR BIFURCATION FOR TDGL EQUATIONS

A. Mathematical setting

It is known that for a given applied field H_a with $\operatorname{div} H_a = 0$, there exists a field A_a such that

$$\begin{aligned} &\operatorname{curl} A_a = H_a \quad \text{in } \Omega, \\ &\operatorname{div} A_a = 0 \quad \text{in } \Omega, \\ &A_a \cdot n = 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{4.1}$$

Let $A = \mathcal{A} + A_a$. Then (2.11) are rewritten as

$$\psi_t + i\phi\psi = -(i\mu\nabla + A_a)^2\psi + \alpha\psi - 2A_a \cdot \mathcal{A}\psi - 2i\mu\mathcal{A} \cdot \nabla\psi - |\mathcal{A}|^2\psi - \beta|\psi|^2\psi,$$

$$\zeta(\mathcal{A}_t + \mu\nabla\phi) = -\operatorname{curl}^2 \mathcal{A} - \gamma A_a|\psi|^2 - \gamma\mathcal{A}|\psi|^2 - \frac{\gamma\mu i}{2}(\psi^*\nabla\psi - \psi\nabla\psi^*), \tag{4.2}$$

$$\operatorname{div} \mathcal{A} = 0,$$

with the following initial and boundary conditions

$$\psi(0) = \psi_0, \quad A(0) = A_0, \tag{4.3}$$

$$\mathcal{A}_n = 0, \quad \text{curl}\, \mathcal{A} \times n = 0 \quad \text{on } \partial\Omega, \tag{4.4}$$

together with one of the following three boundary conditions for ψ:

Neumann boundary condition:

$$\frac{\partial \psi}{\partial n} = 0 \quad \text{on } \partial\Omega, \tag{4.5}$$

Dirichlet boundary condition:

$$\psi = 0 \quad \text{on } \partial\Omega, \tag{4.6}$$

Robin boundary condition:

$$\frac{\partial \psi}{\partial n} + C\psi = 0 \quad \text{on } \partial\Omega. \tag{4.7}$$

Hereafter we use $H^k(\Omega, \mathbb{C})$ for the Sobolev spaces of complex valued functions defined on Ω, and $H^k(\Omega, \mathbb{R}^3)$ for the Sobolev spaces of vector valued functions. Let

$$H_B^2(\Omega, \mathbb{C}) = \{\psi \in H^2(\Omega, \mathbb{C}) | \psi \text{ satisfy one of (4.5) - (4.7)}\},$$

$$D^2(\Omega, \mathbb{R}^3) = \{\mathcal{A} \in H^2(\Omega, \mathbb{R}^3) | \text{div}\, \mathcal{A} = 0, \quad \mathcal{A} \text{ satisfy (4.4)}\},$$

$$\mathcal{L}^2(\Omega, \mathbb{R}^3) = \{\mathcal{A} \in L^2(\Omega, \mathbb{R}^3) | \text{div}\, \mathcal{A} = 0, \quad \mathcal{A}_n|_{\partial\Omega} = 0\}.$$

We set

$$H = L^2(\Omega, \mathbb{C}) \times \mathcal{L}^2(\Omega, \mathbb{R}^3),$$

$$H_1 = H_B^2(\Omega, \mathbb{C}) \times D^2(\Omega, \mathbb{R}^3).$$

Let

$$P: L^2(\Omega, \mathbb{R}^3) \to \mathcal{L}^2(\Omega, \mathbb{R}^3)$$

be the Leray projection. Then it is known that the function ϕ in (4.2) is determined uniquely up to constants by

$$\zeta\mu \nabla \phi = (I - P)\left[\frac{\gamma\mu}{2} i(\psi \nabla \psi^* - \psi^* \nabla \psi) - \gamma|\psi|^2(\mathcal{A} + A_a)\right], \tag{4.8}$$

where I is the identity on $L^2(\Omega, \mathbb{R}^3)$. Namely, for every $u = (\psi, \mathcal{A}) \in H_1$, there is a unique solution of (4.8) up to constants. Therefore, we define a nonlinear operator $\Phi: H_1 \to L^2(\Omega)$ by

$$\Phi(u) = \phi = \text{the solution of (4.8) with} \int_\Omega \phi \mathrm{d}x = 0. \tag{4.9}$$

B. Eigenvalue problems

In order to describe the dynamic bifurcation of the Ginzburg–Landau equations, it is necessary to consider the eigenvalue problems of the linearized equations.

Let α_1 be the first eigenvalue of the following equation

$$(i\mu\nabla + A_a)^2\psi = \alpha\psi, \quad \forall\, x \in \Omega, \tag{4.10}$$

with one of the boundary conditions (4.5)–(4.7). It is clear that (4.10) can be equivalently expressed as

$$\begin{aligned} -\mu^2\Delta\psi_1 + |A_a|^2\psi_1 - 2\mu A_a\cdot\nabla\psi_2 &= \alpha\psi_1, \\ -\mu^2\Delta\psi_2 + |A_a|^2\psi_2 + 2\mu A_a\cdot\nabla\psi_1 &= \alpha\psi_2, \end{aligned} \tag{4.11}$$

where $\psi = \psi_1 + i\psi_2$.

It is not difficult to check that (4.11) with one of the boundary conditions (4.5)–(4.7) are symmetric. Therefore, there are an infinite real eigenvalue sequence of (4.10):

$$\begin{aligned} &\alpha_1 < \alpha_2 < \cdots, \\ &\lim_{k\to\infty}\alpha_k = \infty, \end{aligned} \tag{4.12}$$

and an eigenvector sequence

$$\{e_n \in H_B^2(\Omega,\mathbb{C}) | n = 1,2,\ldots\}, \tag{4.13}$$

which is an orthogonal basis of $L^2(\Omega,\mathbb{C})$.

The eigenvalues of (4.10) always have even multiplicity, i.e. if ψ is an eigenvector of (4.10), then $e^{i\theta}\psi(\theta\in\mathbb{R}^1)$ are also eigenvectors corresponding to the same eigenvalue. Let the first eigenvalue α_1 have multiplicity $2m(m\geqslant 1)$ with eigenvectors

$$e_{2k-1} = \psi_{k1} + i\psi_{k2}, \quad e_{2k} = -\psi_{k2} + i\psi_{k1}, \quad 1 \leqslant k \leqslant m. \tag{4.14}$$

We know that α_1 enjoys the following properties:

$$\begin{aligned} &\alpha_1 = \alpha_1(A_a) \quad \text{depends continuously on } A_a, \\ &\alpha_1(A_a) > 0 \quad \text{for } A_a \neq 0, \\ &\alpha_1(0) = 0 \quad \text{for the boundary condition (4.5)}, \\ &\alpha_1(0) > 0 \quad \text{for either (4.6) or (4.7)}. \end{aligned} \tag{4.15}$$

Now, we consider another eigenvalue problem, which is also crucial for the attractor bifurcation of (4.2). The problem reads

$$\begin{aligned} &\operatorname{curl}^2 A + \nabla\phi = \rho A, \\ &\operatorname{div} A = 0, \\ &A_n|_{\partial\Omega} = 0, \quad \operatorname{curl} A\times n|_{\partial\Omega} = 0. \end{aligned} \tag{4.16}$$

We remark that the boundary condition in (4.16), i.e., (4.4), is the free boundary condition, which can be expressed as

$$A_n|_{\partial\Omega} = 0, \qquad \left.\frac{\partial A_\tau}{\partial n}\right|_{\partial\Omega} = 0, \tag{4.17}$$

where τ is the tangent vector on $\partial\Omega$.

To see this, for a given point $x_0 \in \partial\Omega$, we take (τ_1, τ_2, n) as an orthogonal coordinate system, where τ_1, τ_2 are unit tangent vectors and n the outward unit vector at $x_0 \in \partial\Omega$. We infer then from the condition $A_n|_{\partial\Omega}=0$ that

$$\operatorname{curl} A(x_0) = -\frac{\partial A_{\tau_2}}{\partial n}\tau_1 + \frac{\partial A_{\tau_1}}{\partial n}\tau_2 + \left(\frac{\partial A_{\tau_2}}{\partial \tau_1} - \frac{\partial A_{\tau_1}}{\partial \tau_2}\right) n \Bigg|_{x=x_0}.$$

Hence we have

$$\operatorname{curl} A(x_0) \times n = \frac{\partial A_{\tau_1}}{\partial n}\tau_1 + \frac{\partial A_{\tau_2}}{\partial n}\tau_2 \Bigg|_{x=x_0},$$

which implies that (4.4) is equivalent to (4.17).

It is known that there are a real eigenvalue sequence

$$0 < \rho_1 < \rho_2 < \cdots,$$
$$\lim_{k\to\infty} \rho_k = \infty, \tag{4.18}$$

and an eigenvector sequence

$$\{a_k \in D^2(\Omega, \mathbb{R}^3) | k = 1,2,\ldots\}, \tag{4.19}$$

which constitutes an orthogonal basis of $\mathcal{L}^2(\Omega, \mathbb{R}^3)$.

C. Main theorems

In superconductivity, the parameter α cannot exceed a maximal value $\alpha(T) \leqslant \alpha(0)$. Hence, we have to impose a basic hypothesis:

$$\alpha_1 < \alpha(0) = \frac{2\sqrt{b} m_s D N_0}{e_s^3 h}, \tag{4.20}$$

where α_1 is the first eigenvalue of (4.10), and N_0 the density of states at the Fermi level.

In this subsection, we consider the case where the first eigenvalue α_1 of (4.10) has multiplicity two. We start with the introduction of a physical parameter, which determines completely the dynamic properties of the bifurcation behavior of the TDGL equations.

Let $e \in H^2(\Omega, \mathbb{C})$ be a first eigenvector of (4.10). Then there is a unique solution for

$$\operatorname{curl}^2 \mathcal{A}_0 + \nabla\phi = |e|^2 A_a + \frac{\mu}{2} i(e^* \nabla e - e \nabla e^*),$$
$$\operatorname{div} \mathcal{A}_0 = 0, \tag{4.21}$$
$$\mathcal{A}_0 \cdot n|_{\partial\Omega} = 0, \quad \operatorname{curl} \mathcal{A}_0 \times n|_{\partial\Omega} = 0.$$

We define a physical parameter R as follows

$$R = -\frac{\beta}{\gamma} + \frac{2\int_\Omega |\operatorname{curl} \mathcal{A}_0|^2 dx}{\int_\Omega |e|^4 dx}. \tag{4.22}$$

It is clear that the parameter R is independent of the choice of the first eigenvectors of (4.10). Since the first eigenvector e of (4.10) and $h_0=\operatorname{curl} A_0$ given by (4.21) depend on the applied magnetic potential A_a and the geometric properties of Ω, the parameter R is essentially a function of A_a,Ω and physical parameters β,γ,μ.

The parameter R defined by (4.22) can be equivalently expressed as follows

$$R=-\frac{\beta}{\gamma}+\frac{2\sum_{k=1}^{\infty}\frac{1}{\rho_k}\left[\int_\Omega(|e|^2A_a+2\mu e_2\nabla e_1)\cdot a_k\right]^2}{\int_\Omega|e|^4\mathrm{d}x}, \tag{4.23}$$

where $e=e_1+ie_2,\rho_k$ are the eigenvalue of (4.16) given by (4.18), and $\{a_k\}$ are the normalized eigenvectors given by (4.19).

The main results in this section are the following theorems. Here, we always assume that the first eigenvalue α_1 of (4.10) with one of the boundary conditions (4.5)–(4.7) is complex simple, and the condition (4.20) holds true.

Theorem 4.1: *If the number R defined by* (4.22) *satisfies $R<0$, then for the problem* (4.2)–(4.4) *with one of* (4.5)–(4.7), *the following assertions hold true.*

(1) *If $\alpha\leqslant\alpha_1$, the steady state $(\psi,\mathcal{A})=0$ is locally asymptotically stable for the problem.*
(2) *The equations bifurcate from $((\psi,\mathcal{A}),\alpha)=(0,\alpha_1)$ to an attractor Σ_α for $\alpha>\alpha_1$, which is homeomorphic to S^1, and consists of steady state solutions of the problem.*
(3) *There is a neighborhood $U\subset H$ of $(\psi,\mathcal{A})=0$ such that the attractor Σ_α attracts $U\backslash\Gamma$ in H, where Γ is the stable manifold of $(\psi,\mathcal{A})=0$ with co-dimension two in H.*
(4) *Each $(\psi,\mathcal{A})\in\Sigma_\alpha$ can be expressed as*

$$\psi=\left|\frac{\alpha-\alpha_1}{R_1}\right|^{1/2}e+o\left(\left|\frac{\alpha-\alpha_1}{R_1}\right|^{1/2}\right),$$

$$\operatorname{curl}^2\mathcal{A}=-\gamma\left|\frac{\alpha-\alpha_1}{R_1}\right|\cdot[|e|^2A_a+\mu\operatorname{Im}(e\nabla e^*)]+o\left(\frac{\alpha-\alpha_1}{R_1}\right), \tag{4.24}$$

$$R_1=\frac{\gamma R\int_\Omega|e|^4\mathrm{d}x}{\int_\Omega|e|^2\mathrm{d}x},$$

where e is the first eigenvector of (4.10).

Theorem 4.2: *If $R>0$, then for the problem* (4.2)–(4.4) *with one of* (4.5)–(4.7), *we have the following assertions:*

(1) *The steady state $(\psi,\mathcal{A})=0$ is locally asymptotically stable at $\alpha<\alpha_1$, and unstable at $\alpha\geqslant\alpha_1$.*
(2) *The equations bifurcate from $((\psi,\mathcal{A}),\alpha)=(0,\alpha_1)$ to an invariant set Σ_α on $\alpha<\alpha_1$, and have no bifurcation on $\alpha>\alpha_1$.*
(3) *$\Sigma_\alpha=S^1$ is a circle consisting of steady states, and has a two-dimensional unstable manifold.*

Theorems 4.1 and 4.2 show that the two cases with $R<0$ and $R>0$ have completely different superconducting transition characteristics; see Sec. V for further discussion.

It is easy to check that if $\alpha=0$, $(\Psi,\mathcal{A})=0$ is globally asymptotically stable for (4.2)–(4.4) with one of (4.5)–(4.7); see Ref. 15. The following theorem is a direct consequence of the existence of global attractor for the TDGL model and Theorem 4.2.

Theorem 4.3: *For the case where* $R>0$, *there exists a saddle-node bifurcation point* $\alpha_0(0<\alpha_0<\alpha_1)$ *for the TDGL equations, such that the following statements hold true, which are described schematically by Figures 2 and 3:*

(1) *At* $\alpha=\alpha_0$, *there is an invariant set* $\Sigma_0=\Sigma_{\alpha_0}$ *with* $0\notin\Sigma_0$.
(2) *For* $\alpha<\alpha_0$, *there is no invariant set near* Σ_0.
(3) *For* $\alpha_0<\alpha<\alpha_1$, *there are two connected branches of invariant sets* Σ_α^1 *and* Σ_α^2, *and* Σ_α^2 *extends to* $\alpha\geqslant\alpha_1$ *and near* α_1 *as well*.
(4) *For each* $\alpha>\alpha_0$,
   (a) Σ_α^2 *is an attractor with* $\mathrm{dist}(\Sigma_\alpha^2,0)>0$ *at* $\alpha=\alpha_1$,
   (b) Σ_α^2 *consists of steady state solutions and orbits connecting them, and*
   (c) Σ_α^2 *contains at least one cycle of steady states*.
(5) *For* $\alpha_0<\alpha<\alpha_1$,
   (a) Σ_α^1 *is a repeller with* $0\notin\Sigma_\alpha^1$,
   (b) Σ_α^1 *consists of steady state solutions and orbits connecting them*,
   (c) Σ_α^1 *contains at least one cycle of steady states, and*
   (d) *when* α *is near* α_1, Σ_α^1 *is exactly the* $\Sigma_\alpha=S^1$ *given in Theorem 4.2, consisting exactly of steady states*.

D. Proof of Theorems 4.1 and 4.2

We proceed in several steps as follows.

(1) We set the mappings $L_\alpha=-K+B_\alpha$ and $G:H_1\to H$ by

$$Ku=\begin{pmatrix}(i\mu\nabla+A_a)^2\psi\\ \zeta^{-1}\mathrm{curl}^2\mathcal{A}\end{pmatrix},$$

$$B_\alpha u=\begin{pmatrix}\alpha\psi\\ 0\end{pmatrix},$$

$$G(u)=\begin{pmatrix}i\psi\Phi(u)+2A_a\cdot\mathcal{A}\psi+2i\mu\mathcal{A}\cdot\nabla\psi+|\mathcal{A}|^2\psi+\beta|\psi|^2\psi\\ P\left[\gamma\zeta^{-1}A_a|\psi|^2+\gamma\zeta^{-1}\mathcal{A}|\psi|^2+\frac{\gamma\mu i}{2\zeta}(\psi^*\nabla\psi-\psi\nabla\psi^*)\right]\end{pmatrix},$$

where $u=(\psi,\mathcal{A})$, $\Phi(u)$ is defined by (4.9), and P the Leray projection. Thus, the problem (4.2)–(4.4) with one of the boundary conditions (4.5)–(4.7) can be rewritten in the following operator form

$$\frac{\mathrm{d}u}{\mathrm{d}t}=L_\alpha u+G(u),\quad u=(\psi,\mathcal{A})\in H_1,$$
$$u(0)=u_0. \tag{4.25}$$

We see that $L_\alpha:H_1\to H$ is a sectorial operator, and the eigenvalues of L_α satisfy that

$$\beta_1(\alpha)=\beta_2(\alpha)=\alpha-\alpha_1\begin{cases}<0 & \text{if } \alpha<\alpha_1\\ =0 & \text{if } \alpha=\alpha_1\\ >0 & \text{if } \alpha>\alpha_1,\end{cases} \tag{4.26}$$

and for $j\geqslant 3$,

$$\beta_j(\alpha_1) = \alpha_1 - \alpha_k \text{ or } -\zeta^{-1}\rho_l,$$
$$\beta_j(\alpha_1) < 0, \tag{4.27}$$

for some $k>1$, $l\geqslant 1$.

It is clear that the operator $\Phi: H_1 \to L^2(\Omega, \mathbb{C})$ defined by (4.9) is C^∞, and by the estimates proved in Ref. 15 for Φ, we have

$$\int_\Omega |\Phi(u)\psi|^2 \mathrm{d}x \leqslant \left[\int_\Omega |\Phi(u)|^3 \mathrm{d}x\right]^{2/3}\left[\int_\Omega |\psi|^6 \mathrm{d}x\right]^{1/3} \leqslant C(\|u\|^2_{H_{1/2}} + \|u\|_{H_{1/2}}\|\psi\|^2_{L^4})^2\|\psi\|^2_{L^6},$$

where $H_{1/2}$ is the closure of H_1 for the H^{-1}-norm. Hence, it is not difficult to check that there is a number $1/2<\sigma<1$ such that $G: H_\sigma \to H$ is C^∞.

(2) It is known that the dynamic bifurcation of (4.25) is determined by its reduced equation to the center manifold.

Let

$$\psi_0 \in E_1 = \{ze | z \in \mathbb{C} \text{ and } e \text{ the first eigenvector of (4.10)}\}.$$

Then the reduced equation of (4.25) is given by

$$\frac{\mathrm{d}\psi_0}{\mathrm{d}t} = \beta_1(\alpha)\psi_0 - P_1 G(\psi_0 + \tilde{\psi}(\psi_0), \tilde{\mathcal{A}}(\psi_0)), \tag{4.28}$$

where $P_1: H \to E_1$ is the canonical projection, and $\tilde{\Phi}(\psi_0) = (\tilde{\psi}(\psi_0), \tilde{\mathcal{A}}(\psi_0)) \in H_1$ the center manifold function.

The k multilinear operators ($k=2,3$) in G are given by

$$G_2(u) = -\begin{pmatrix} 2A_a \cdot \mathcal{A}\psi + 2i\mu\mathcal{A}\cdot\nabla\psi \\ \zeta^{-1}\gamma A_a|\psi|^2 + \dfrac{\gamma\mu}{2\zeta} i(\psi^*\nabla\psi - \psi\nabla\psi^*) \end{pmatrix},$$

$$G_3(u) = -\begin{pmatrix} i\psi\Phi_2(u) + |\mathcal{A}|^2\psi + \beta|\psi|^2\psi \\ \gamma\zeta^{-1}\mathcal{A}|\psi|^2 \end{pmatrix},$$

where $\Phi_2(u)$ is the bilinear operator in $\Phi(u)$.

By the first approximation of the center manifold reduction, the center manifold function $\tilde{\Phi} = (\tilde{\psi}(\psi_0), \tilde{\mathcal{A}}(\psi_0))$ satisfies that

$$\mathrm{curl}^2\,\tilde{\mathcal{A}} + \mu\nabla\phi = -\gamma A_a|\psi_0|^2 - \frac{\gamma\mu}{2} i(\psi_0^*\nabla\psi_0 - \psi_0\nabla\psi_0^*) + o(\|\psi_0\|^2, |\beta_1(\alpha)|\cdot\|\psi_0\|), \tag{4.29}$$

$$\tilde{\psi}(\psi_0) = O(\|\tilde{\mathcal{A}}(\psi_0)\|\cdot\|\psi_0\|) = O(\|\psi_0\|^3). \tag{4.30}$$

Based on (4.28) and (4.30), (4.28)can be expressed as

$$\frac{\mathrm{d}\psi_0}{\mathrm{d}t} = \beta_1(\alpha)\psi_0 - g_3(\psi_0) + o(\|\psi_0\|^3) + O(\|\psi_0\|^3|\beta_1(\alpha)|), \tag{4.31}$$

where

$$g_3(\psi_0) = P_1[\beta|\psi_0|^2\psi_0 + 2A_a\cdot\tilde{\mathcal{A}}_2\psi_0 + 2i\mu\tilde{\mathcal{A}}_2\cdot\nabla\psi_0 + i\Phi_2\psi_0], \tag{4.32}$$

$$\operatorname{curl}^2 \tilde{\mathcal{A}}_2 + \nabla\phi = -\gamma A_a|\psi_0|^2 - \frac{\gamma\mu}{2} i(\psi_0^* \nabla \psi_0 - \psi_0 \nabla \psi_0^*),$$

$$\operatorname{div} \tilde{\mathcal{A}}_2 = 0,$$

$$\tilde{\mathcal{A}}_2 \cdot n|_{\partial\Omega} = 0, \quad \operatorname{curl} \tilde{\mathcal{A}}_2 \times n|_{\partial\Omega} = 0. \tag{4.33}$$

Equations (4.31) and (4.32) are the third-order expression of the reduction of (4.27) to the center manifold.

(3) From (4.32), we obtain

$$\langle g_3(\psi_0), \psi_0\rangle = \operatorname{Re}\int_\Omega g_3(\psi_0)\psi_0^* dx = \int_\Omega [\beta|\psi_0|^4 + 2|\psi_0|^2 A_a \cdot \tilde{\mathcal{A}}_2 + 2\mu\tilde{\mathcal{A}}_2 \cdot (\psi_2^0 \nabla \psi_1^0 - \psi_1^0 \nabla \psi_2^0)]dx$$

$$= \int_\Omega [\beta|\psi_0|^4 + 2|\psi_0|^2 A_a \cdot \tilde{\mathcal{A}}_2 + 4\mu\psi_2^0 \tilde{\mathcal{A}}_2 \cdot \nabla\psi_1^0]dx, \tag{4.34}$$

where $\psi_0 = \psi_1^0 + i\psi_2^0$.

Let $\tilde{\mathcal{A}}_2$ have the Fourier expansion for the basis (4.19) of $\mathcal{L}^2(\Omega, \mathbb{R}^3)$ as follows:

$$\tilde{\mathcal{A}}_2 = \sum_{k=1}^{\infty} y_k a_k.$$

Then, for (4.33) we can derive the solution y_k:

$$y_k = -\frac{\gamma}{\rho_k}\int_\Omega [|\psi_0|^2 A_a \cdot a_k + 2\mu\psi_2^0 a_k \cdot \nabla\psi_1^0]dx. \tag{4.35}$$

Inserting (4.35) into (4.34) we find

$$\langle g_3(\psi_0), \psi_0\rangle = \beta\int_\Omega |\psi_0|^4 dx - 2\gamma\sum_{k=1}^{\infty}\frac{1}{\rho_k}\left[\left(\int_\Omega |\psi_0|^2 A_a \cdot a_k dx\right)^2 + 4\mu\left(\int_\Omega |\psi_0|^2 A_a \cdot a_k dx\right)\right.$$
$$\left.\times\left(\int_\Omega \psi_2^0 a_k \cdot \nabla\psi_1^0 dx\right) + 4\mu^2\left(\int_\Omega \psi_2^0 a_k \cdot \nabla\psi_1^0 dx\right)^2\right]. \tag{4.36}$$

Let $\psi_0 = x_1 e_1 + x_2 e_2$, where $(x_1, x_2) \in \mathbb{R}^2$, and e_1 and e_2 are as in (4.14). Then we have

$$\psi_0 = \psi_1^0 + i\psi_2^0,$$

$$\psi_1^0 = x_1\psi_{11} - x_2\psi_{12},$$

$$\psi_2^0 = x_1\psi_{12} + x_2\psi_{11}.$$

Thus, we see that

$$\int_\Omega |\psi_0|^4 dx = \int_\Omega (|\psi_1^0|^2 + |\psi_2^0|^2)^2 dx = (x_1^2 + x_2^2)\int_\Omega |e_1|^4 dx, \tag{4.37}$$

$$\int_\Omega |\psi_0|^2 A_a \cdot a_k dx = (x_1^2 + x_2^2)\int_\Omega |e_1|^2 A_a \cdot a_k dx, \tag{4.38}$$

$$\int_\Omega \psi_2^0 a_k \cdot \nabla \psi_1^0 \mathrm{d}x = (x_1^2 + x_2^2) \int_\Omega \psi_{12} a_k \cdot \nabla \psi_{11} \mathrm{d}x. \tag{4.39}$$

Here, in (4.39) we use the following equality:

$$\int_\Omega \psi a_k \cdot \nabla \psi \mathrm{d}x = -\frac{1}{2} \int_\Omega \psi^2 \operatorname{div} a_k \, \mathrm{d}x = 0,$$

for any real function ψ.

Putting (4.37)–(4.39) into (4.36) we find

$$\langle g_3(\psi_0), \psi_0 \rangle = -\gamma R (x_1^2 + x_2^2)^2 \int_\Omega |e_1|^4 \mathrm{d}x, \tag{4.40}$$

where R is as in (4.23). It is easy to see that both numbers in (4.22) and (4.23) are the same.

(4) We shall prove that the Ginzburg–Landau equations bifurcate from $((\psi, \mathcal{A}), \alpha) = (0, \alpha_1)$ to at least one steady state solution.

Formally, there are two steady state Ginzburg–Landau systems, i.e. the stationary equations obtained directly from (4.2) which read

$$\begin{aligned} (i\mu + A_a)^2 \psi + i\Phi\psi &= \alpha\psi - 2A_a \cdot A\psi - 2i\mu\mathcal{A} \cdot \nabla\psi - \mathcal{A}^2\psi - \beta|\psi|^2\psi, \\ \operatorname{curl}^2 \mathcal{A} + \zeta\mu \nabla \Phi &= -\gamma(\mathcal{A} + A_a)|\psi|^2 - \frac{\gamma\mu}{2} i(\psi^* \nabla \psi - \psi \nabla \psi^*), \end{aligned} \tag{4.41}$$

and the other one given by

$$\begin{aligned} (i\mu \nabla + A_a)^2 &= \lambda\psi - 2A_a \cdot \mathcal{A}\psi - 2i\mu\mathcal{A} \nabla \psi - \mathcal{A}^2\psi - \beta|\psi|^2\psi, \\ \operatorname{curl}^2 \mathcal{A} &= -\gamma(\mathcal{A} + A_a)|\psi|^2 - \frac{\gamma\mu i}{2}(\psi^* \nabla \psi - \psi \nabla \psi^*). \end{aligned} \tag{4.42}$$

The form (4.42) was derived by Ginzburg and Landau in 1950 as the Euler-Lagrange equations of the free energy. In Ref. 15, it is proved that if $u = (\psi, \mathcal{A}) \in H_1$ and $\Phi \in H^1(\Omega)$ is a solution of (4.41) with (4.4) and (4.5), then we have that $\Phi = 0$. It is easy to prove in the same fashion that this assertion also holds true for the boundary conditions (4.6) and (4.7). Therefore, both steady state equations (4.41) and (4.42) are exactly the same.

The Ginzburg–Landau energy for Eq. (4.42) read

$$\begin{aligned} E = \frac{1}{2} \int_\Omega \left[|(i\mu \nabla + \mathcal{A} + A_a)\psi|^2 + \frac{\beta}{2}|\psi|^4 - \alpha|\psi|^2 + \gamma^{-1}|\operatorname{curl}\mathcal{A}|^2 \right] \\ \times \mathrm{d}x \left(+ \frac{1}{2}\mu^2 c \int_{\partial\Omega} |\psi|^2 \mathrm{d}s \quad \text{for boundary condition (4.7)} \right). \end{aligned}$$

Therefore, by the classical bifurcation theorem for potential operators (see Refs. 18–20), the steady state equations (4.42) with (4.4) and one of the boundary conditions (4.5)–(4.7) must bifurcate to at least one solution from $((\psi, \mathcal{A}), \alpha) = (0, \alpha_1)$.

(5) Proof of Theorem 4.1: When $R < 0$, by (4.31) and (4.40), we can obtain assertion (1), and we infer from Theorem 3.6 that the Ginzburg–Landau equations bifurcate from $((\psi, \mathcal{A}), \alpha) = (0, \alpha_1)$ a cycle Σ_α of attractor for $\alpha > \alpha_1$. By Step 4, the attractor Σ_α contains a singular point. Because of the invariance of the Ginzburg–Landau equations for the gauge transformation

$$\psi \to \psi e^{i\theta}, \quad \theta \in \mathbb{R}^1,$$

the steady state solutions of the Ginzburg–Landau equations appear as a circle S^1. Hence the attractor $\Sigma_\alpha = S^1$ consists of steady state solutions. Assertion (2) is proved.

Assertion (3) follows from Theorem 3.3, and Assertion (4) can be directly derived from Eqs. (4.31) and (4.40). Thus, Theorem 4.1 is proved.

(6) Proof of Theorem 4.2: When $R > 0$, the the time-reversed semigroup $S_\alpha(-t)$ generated by (4.31) has the same dynamic properties as the following equation

$$\frac{d\psi_0}{dt} = (\alpha_1 - \alpha)\psi_0 + g_3(\psi_0) + o(\|\psi_0\|^3, |\alpha - \alpha_1|\|\psi_0\|^2). \tag{4.43}$$

In the same fashion as used in Step 5, from (4.40) we infer that the semi-group $\widetilde{S}_\alpha(t)$ generated by (4.43) bifurcates from $(\psi_0, \alpha) = (0, \alpha_1)$ to an S^1 attractor Σ_α for $\alpha < \alpha_1$, which consists of singular points of (4.43). Hence, for the semi-group $S_\lambda(t)(=\widetilde{S}_\lambda(-t))$ generated by (4.31) with $R > 0$, the Assertions (1)–(3) hold true.

Thus, Theorem 4.2 is proved.

E. Bifurcation from general eigenvalues

Although the bifurcation from general eigenvalues of (4.10) has less physical interest, we consider this problem partially for the mathematical completeness.

Before our discussion, we remark that one can prove[21] that the first eigenvalue λ_1 with complex simplicity is generic. Namely, if we set

$$\mathcal{H}^1 = \{A \in H^1(\Omega, \mathbb{R}^3) | A \cdot n|_{\partial\Omega} = 0, \quad \operatorname{div} A = 0\},$$

then, there is an open and dense set $U \subset \mathcal{H}^1$ such that for any $A_a \in U$, the first eigenvalue $\lambda_1(A_a)$ of (4.10) is complex simple. However, we cannot exclude the existence of a bounded domain $\Omega \subset \mathbb{R}^3$ and a vector $A_a \in \mathcal{H}^1$ such that the first eigenvalue $\lambda_1(\Omega, A_a)$ of (4.10) has higher complex multiplicity.

Let α_k be an eigenvalue of (4.10) with complex multiplicity $m \geqslant 1$, and E_k be the eigenspace of α_k, i.e.

$$E_k = \{\psi \in H_B^2(\Omega, \mathbb{C}) | (i\mu\nabla + A_a)^2 \psi = \alpha_k \psi\}.$$

It is clear that $\dim E_k = 2 \dim_{\mathbb{C}} E_k = 2m$.

Let F be function defined on E_k:

$$F(\psi) = 2\sum_{n=1}^{\infty} \frac{1}{\rho_n}\left[\int_\Omega (|\psi|^2 A_a + 2\mu\psi_2 \nabla \psi_1) a_n dx\right]^2,$$

where $\psi = \psi_1 + i\psi_2 \in E_k$, and ρ_n, a_n are as in (4.18) and (4.19).

Set

$$R_1 = \sup_{\psi \in E_k, \psi \neq 0} \frac{F(\psi)}{\int_\Omega |\psi|^4 dx},$$
$$R_2 = \inf_{\psi \in E_k, \psi \neq 0} \frac{F(\psi)}{\int_\Omega |\psi|^4 dx}. \tag{4.44}$$

Then, we have the following theorem.

Theorem 4.4: *For the problem* (4.2)–(4.4) *with one of* (4.5)–(4.7), *we have the following assertions*.

(1) *If the physical parameter* $\beta/\gamma > R_1$, *then this problem bifurcates from* $((\psi,\mathcal{A}),\alpha)=(0,\alpha_k)$ *to an invariant set* Σ_α *for* $\alpha>\alpha_k$.
(2) *If* $\beta/\gamma < R_2$, *then this problem bifurcates from* $((\psi,\mathcal{A}),\alpha)=(0,\alpha_k)$ *to an invariant set* Σ_α *for* $\alpha<\alpha_k$.
(3) *The invariant set* Σ_α *is a* $(2m-1)$*-dimensional homological sphere, i.e.* $2m-1 \leqslant \dim \Sigma_\alpha \leqslant 2m$, *and* Σ_α *has the same homology as a* $(2m-1)$*-dimensional sphere*.
(4) Σ_α *contains at least a circle of singular points of the equations*.
(5) *When* $m=1$, Σ_α *is a circle* S^1.
(6) *When* $\alpha_k=\alpha_1$ *and* $\beta/\gamma > R_1$, Σ_α *is an attractor, which attracts an open set* $U\backslash\Gamma$, *where* $U\subset H$ *is a neighborhood of* $(\psi,\mathcal{A})=0$, *and* Γ *is the stable manifold of* $(\psi,\mathcal{A})=0$ *with co-dimension* $2m$ *in* H.

Remark 4.5: We conjecture that the bifurcated invariant set Σ_α in Theorem 4.4 is homeomorphic to a $(2m-1)$-dimensional sphere S^{2m-1}, and Σ_α contains at least m circles consisting of singular points.

When $m=1$, these two numbers R_1 and R_2 are the same: $R_1=R_2$, and $R=R_1-\beta/\gamma$ is as in (4.22).

The proof of Theorem 4.4 is the same as that of Theorems 4.1 and 4.2; we omit the details.

V. CONCLUSIONS AND REMARKS

A. General remarks

The permanent current, called supercurrent, is expressed in the Ginzburg–Landau equations by (2.2). In the steady state case, the supercurrent in the second type of nondimensional form is written as

$$J_s = J_s(\psi,\mathcal{A}) = -\gamma(A_a+\mathcal{A})|\psi|^2 - \frac{\gamma\mu}{2} i(\psi^*\nabla\psi - \psi\nabla\psi^*). \tag{5.1}$$

To take the Meissner effect into account in the Ginzburg–Landau equation. Mathematically speaking, in the normal state, the magnetic field H in a sample should be $H=H_a+\mathcal{H}$, $H_a=\operatorname{curl} A_a$ is the applied field and $\mathcal{H}=\operatorname{curl}\mathcal{A}$ the nonequilibrium fluctuation, and in the superconducting state $H=\operatorname{curl}\mathcal{A}$. In the both cases, $\mathcal{A}$ satisfy the Ginzburg–Landau equation (4.2) and boundary condition (4.4). Namely, we can express the magnetic field H in a sample Ω in the following form

$$\begin{gathered} H=\operatorname{curl} A, \quad \forall\, x\in\Omega, \\ A=\begin{cases} A_a+\mathcal{A} & \text{in the normal state,} \\ \mathcal{A} & \text{in the superconducting state,} \end{cases} \end{gathered} \tag{5.2}$$

and the supercurrent J_s in the nondimensional form also is given by

$$J_s = \operatorname{curl}^2 \mathcal{A}. \tag{5.3}$$

Here $\mathcal{A}$ satisfies (4.2) and (4.4).

An equilibrium state $(\tilde{\psi},\tilde{\mathcal{A}})$ of the TDGL equations (4.2) is called in the normal state if $\tilde{\psi}=0$, and $(\tilde{\psi},\tilde{\mathcal{A}})$ is called in the superconducting state if $\tilde{\psi}\neq 0$. A solution $(\psi,\mathcal{A})$ of (4.2) is said in the normal state if $(\psi,\mathcal{A})$ is in a domain of attraction of a normal equilibrium state, otherwise $(\psi,\mathcal{A})$ is said in the superconducting state.

We consider the simplest case where the applied field vanishes $A_a=0$. In this case, the eigenvalue equation (4.10) becomes

$$-\mu\Delta\psi = \alpha\psi. \tag{5.4}$$

The first eigenvalue α_1 of (5.4) with one of the boundary conditions (4.5)–(4.7) is simple, and the eigenvector is real. Therefore, the parameter R defined by (4.22) reads

$$R = -\frac{\beta}{\gamma} < 0.$$

By Theorem 4.1, when the parameter $\alpha(T) \leqslant \alpha_1$ the solutions $(\psi, \mathcal{A})$ of (4.2) is in the normal state, and when $\alpha(T) > \alpha_1$, $(\psi, \mathcal{A})$ with the initial $(\psi_0, \mathcal{A}_0)$ in $U\backslash\Gamma$ is in the superconducting states.

When $A_a = 0$, the steady state solutions $(\tilde{\psi}, \tilde{\mathcal{A}})$ of (4.2) are real, i.e. $\tilde{\psi} = e^{i\theta}\psi$, $I_m\psi = 0$. Hence

$$\tilde{\psi}^* \nabla \tilde{\psi} - \psi \nabla \psi^* = 0,$$

which implies that $\tilde{A} = 0$. Thus, the supercurrent (5.3) (or (5.1)) vanishes

$$J_s = 0.$$

This shows that with zero applied field $H_a = 0$, there is no current in a superconductor.

Implications of (4.20): For the Neumann boundary condition (4.5), i.e. the sample is enclosed by an insulator, the first eigenvalue $\alpha_1 = 0$ for (5.4), which is independent of Ω, the geometry of sample. Therefore, the condition (4.20) always holds true.

However, for the Dirichlet and the Robin boundary conditions (4.6) and (4.7), the situation is different. It is known that the first eigenvalue α_1 of (5.4) depends on Ω. In particular,

$$\alpha_1 = \alpha_1(\Omega) \to \infty \quad \text{if} |\Omega| \to 0$$

The condition (4.20) implies that for the cases where the samples are enclosed by a magnetic material or a normal metal, the volume of a sample must be greater than some critical value $|\Omega| > V_c > 0$. Otherwise no superconducting state occurs at any temperature. This property also holds true for the case where there is an applied magnetic field H_a present. Of course, in this case, the critical volume V_c depends on H_a as well.

B. Transitions in the case with $R < 0$

As mentioned earlier, there are two transitions determined by a simple parameter R defined by (4.22) for transitions near a complex simple eigenvalue of the linearized problem (respectively by two parameters R_1 and R_2 defined by (4.44) for transitions near an eigenvalues with higher multiplicity). The parameter R links the superconducting behavior with the geometry of the material, the applied field and the physical parameters. For simplicity, we address here only the case near a complex simple eigenvalue of the linearized problem, and physical conclusions can be derived in the same fashion.

Let a magnetic field $H_a = \text{curl}\, A_a$ be applied. By the bifurcation theorems, the critical temperature T_c^1 of superconducting transition satisfies then $T_c^1 < T_c$, where T_c is given in (2.4) and T_c^1 satisfies that

$$\alpha(T_c^1) = \alpha_1 > 0, \tag{5.5}$$

where $\alpha_1 = \alpha_1(A_a)$ is the first eigenvalue of (4.10). It is known that

$$\alpha_1(A_a) \to \infty \quad \text{if} \quad |A_a| \to \infty.$$

It implies that the applied magnetic field H_a can not be very strong for superconductivity as required by the condition (4.20).

From Theorems 4.1 and 4.2, we see that the number R defined by (4.22) is an important parameter to distinguish two different types of superconducting transitions. We first examine the case where $R < 0$.

By Theorem 4.1, when $\alpha > \alpha_1$, Eq. (4.2) bifurcate from $((\psi, \mathcal{A}, \alpha) = (0, \alpha_1)$ to a steady state solution $(\psi_\alpha, \mathcal{A}_\alpha)$ which is an attractor attracting an open set $U \backslash \Gamma \subset H$. Physically speaking, this theorem leads to the following properties of superconducting transitions in the case where $R < 0$; see Fig. 1.

Theorem 5.1: *Let $R < 0$ and $m = 1$ as in Theorem 4.1, and T_c^1 be given by* (5.5). *Then the following physical properties hold true*

(1) *When the control temperature decreases (resp. increases) and crosses the critical temperature T_c^1, there will be a phase transition of the sample from the normal to superconducting states (respectively from superconducting to normal state).*
(2) (Stability) *When the control temperature $T \geqslant T_c^1$, under a fluctuation deviating the normal state, the sample will soon be restored to the normal state. In addition, when $T < T_c^1$, under a fluctuation deviating both the normal and superconducting states, the sample will soon be restored to the superconducting states.*
(3) *In general, the supercurrent given by*

$$J_s(\alpha) = -\gamma(A_a + \mathcal{A}_\alpha)|\psi_\alpha|^2 - \frac{\gamma\mu}{2} i(\psi_\alpha^* \nabla \psi_\alpha - \psi_\alpha \nabla \psi_\alpha^*)$$

is nonzero, i.e., $J_s \neq 0$ for $\alpha_1 < \alpha (T < T_c^1)$.
(4) (Continuity) *The order parameter Ψ_α and supercurrent $J_s(\alpha)$ depend continuously on the parameter α (or the control temperature T), namely*

$$\psi_\alpha \to 0, \quad J_s(\alpha) \to 0, \quad \text{if } \alpha \to \alpha_1 + 0 \ (\text{or}, T \to T_c^1 - 0). \tag{5.6}$$

(5) *The superconducting state of the system is dominated by the lowest-energy eigenfunction of* (4.10) *in the sense given by* (4.24).

C. Transitions with $R > 0$

Transitions in this case are precisely described by Theorems 4.2 and 4.3, as shown in Figs. 2 and 3. In particular, we have the following theorem, which recapitulates some phase transition properties obtained in Theorems 4.2 and 4.3 in physical terms.

Theorem 5.2: *Consider a material described by the TDGL with $R > 0$. There are two critical temperatures T_c^0 and T_c^1 $(T_c^0 > T_c^1)$ such that*

$$\alpha(T_c^i) = \alpha_i \quad (i = 0, 1),$$

and the following phase transition properties hold true:

(1) *When the control temperature T decreases and crosses T_c^1, or equivalently α increases and crosses α_1, the stability of the normal state changes from stable to unstable.*
(2) *When $T_c^1 < T$ (or $\alpha < \alpha_1$), physically observable states consists of the normal state, and the superconducting states in Σ_α^2. When $T_c^1 > T$ (or $\alpha > \alpha_1$), physically observable states are in Σ_α^2.*
(3) (Instability) *When the control temperature T is in the interval: $T_c^1 < T < T_c^0$ (or $\alpha_0 < \alpha < \alpha_1$), the superconducting states given Σ_α^1 are unstable, i.e., with a fluctuation deviating a superconducting state in Σ_α^1, transition to either the normal state or a superconducting state in Σ_α^2 will occur.*
(4) (Discontinuity) *At the critical temperature T_c^0 (respectively at T_c^1) of the phase transitions, there is a jump from the superconducting states to the normal state (respectively from the normal state to superconducting states).*
(5) *The other lower-energy eigenfunctions possibly have a stronger influence for the superconducting states.*

It is noteworthy to remark that the phase transitions in the case where $R > 0$ is very different from the transitions for the case where $R < 0$ as described.

Physical significance of R: We note that the parameter β/γ can be characterized by the Ginzburg–Landau parameter κ and the parameter μ:

$$\frac{\beta}{\gamma} = \kappa^2\mu^2, \quad \kappa^2 = \frac{m_s^2c^2}{2\pi e_s^2h^2}b, \quad \mu^2 = \frac{h}{e_s}\frac{D}{\sqrt{b}}. \tag{5.7}$$

In the Ginzburg–Landau energy, the term

$$E_0 = \int_\Omega |e|^4 \mathrm{d}x \tag{5.8}$$

represents the nonlinear part of the energy of the superconducting electrons in the lowest-energy state, and the term

$$E_m = \int_\Omega H_0^2 \mathrm{d}x, \quad h_0 \text{ satisfies (4.21)}, \tag{5.9}$$

is the energy contributed by the magnetic field associated with the supercurrent

$$\operatorname{curl} h_0 = |e|^2 A_a + \frac{\mu}{2} i(e^* \nabla e - e \nabla e^*),$$

which is generated by the applied magnetic potential A_0 and the superconducting electrons in the lowest-energy states.

By (4.2) and (4.22), we obtain from (5.7)–(5.9) that

$$R = -\kappa^2\mu^2 + \frac{2E_m}{E_0}. \tag{5.10}$$

Hence, the type of superconducting phase transitions among the two described above for a given material depends on the "competition" between the two energies E_0 and E_m:

$$R\begin{cases} <0 \quad \text{if and only if } \dfrac{\kappa^2}{2}E_0 > \dfrac{1}{\mu^2}E_m, \\ >0 \quad \text{if and only if } \dfrac{\kappa^2}{2}E_0 < \dfrac{1}{\mu^2}E_m. \end{cases} \tag{5.11}$$

According to the Abrikosov theory, the materials with $\kappa^2<2$ and $\kappa^2>2$ are of types I and II, respectively. From (5.11), we infer that for given geometrical shape of sample and applied magnetic field, a type I material favors more to the jumped phase transition (i.e., the case $(R>0)$), and a type II material favors the continuous phase transition (i.e the case $(R<0)$).

D. Topological structure of supercurrents

In 1957, Abrikosov predicted that in the mixed state of type II superconductors, there is a square array of vortices of supercurrents, and this vortex array was confirmed by experiments later.

In the two-dimensional case, by Theorems 4.1 and 4.2, the bifurcated attractor contains superconducting states $(\psi, \mathcal{A})$ such that the supercurrent $J_s = J_s(\psi, \mathcal{A})$ given by (5.1) is in general not identically zero and

$$\operatorname{div} J_s = 0, \quad J_s \cdot n\big|_{\partial\Omega} = 0. \tag{5.12}$$

Thanks to (5.12), the geometric theory for two-dimensional incompressible flows developed recently by the authors[5] can be applied to study the structure of the supercurrent J_s in the physical space. For this purpose, we first recall briefly some basic results and concepts directly related to the study of the structure of J_s.

Structure of 2D Incompressible flows: First, let $C^r(\Omega,\mathbb{R}^2)$ be the space of all C^r vector fields on Ω, and

$$D^r(\Omega)=\{v\in C^r(\Omega,\mathbb{R}^2)|v\cdot n|_{\partial\Omega}=0,\ \mathrm{div}\ v=0\}.$$

Let $v\in D^r(\Omega)$. A point $p\in\Omega$ is called a singular point of v if $v(p)=0$; a singular point p of v is called nondegenerate if the Jacobian matrix $Dv(p)$ is invertible; v is called regular if all singular points of v are non-degenerate. An interior nondegenerate singular point of v can be either a center or a saddle, and a nondegenerate boundary singularity must be a saddle. Saddles of v must be connected to saddles. An interior saddle $p\in\Omega$ is called self-connected if p is connected only to itself, i.e., p occurs in a graph whose topological form is that of the number 8.

Second, let $v\in D^r(\Omega)$ be regular, and Ω be a connected domain with k holes. Let C be the number of centers of v, S the number of interior saddles, and B the number of boundary saddles. Then[5,22]

$$C-S-\frac{B}{2}=1-k. \tag{5.13}$$

Third, again, let $v\in D^r(\Omega)$, and $p\in M$ be a center. Then there is an open neighborhood C of p, such that for any $x\in C(x\neq p)$, the orbit $\{\Phi(x,t)\}_{t\in\mathbb{R}}$ is closed. The largest such neighborhood C of p is called a circle cell of v. Let $B\subset M$ be an open set, such that for any $x\in B$, the orbit $\{\Phi(x,t)\}_{t\in\mathbb{R}}$ is closed, and each connected component Σ of ∂B is not a single point. Then B is called a circle band of v.

Then it is proved that[5,23] for a regular divergence-free vector field $v\in D^r(\Omega)(r\geqslant 1)$, the topological structure of v consists of finite number of circle cells, circle bands, and saddle connections.

Fourth, two vector fields $u,v\in D^r(\Omega,\mathbb{R}^2)$ are called topologically equivalent if there exists a homeomorphism of $\varphi:\Omega\to\Omega$, which takes the orbits of u to orbits of v and preserves their orientation. A vector field $v\in D^r(\Omega,\mathbb{R}^2)$ is called structurally stable in $D^r(\Omega,\mathbb{R}^2)$ if there exists a neighborhood $U\subset D^r(\Omega,\mathbb{R}^2)$ of v such that for any $u\in U$, u and v are topologically equivalent.

Then it is proved that $v\in D^r(\Omega,\mathbb{R}^2)(r\geqslant 1)$ is structurally stable in $D^r(\Omega,\mathbb{R}^2)$ if and only if a) v is regular, b) all interior saddles of v are self-connected, and c) each boundary saddle point is connected to boundary saddle points on the same connected component of the boundary. Moreover, the set of all structurally stable vector fields is open and dense in $D^r(\Omega,\mathbb{R}^2)$.

Structure of J_s: Now we are in position to study the structure of the supercurrent J_s in the physical space. First observe that in the context of superconductivity, the centers of the supercurrent correspond to vortices. Hence the following is a direct consequence of (5.13), which predicts the existence of vortices.

Theorem 5.3. *Let the domain be simply connected. If the supercurrent J_s for a given superconducting state is regular, then there is at least one vortex for this superconducting state.*

When $R<0$, the superconducting states in the bifurcated attractor is dictated by the first eigenfunction e of (4.10). By Theorem 4.1 and the structural stability theorem mentioned above, the structure of the supercurrent J_s for the superconducting states in the bifurcated attractor is determined by the structure of the following vector field:

$$J_0=-A_a|e|^2-\frac{\mu}{2}i(e^*\nabla e-e\nabla e^*)+\nabla\phi, \tag{5.14}$$

which satisfies that $\mathrm{div}\ J_0=0$ and $J_0\cdot n|_{\partial\Omega}=0$. Then it is easy to obtain the following result.

Theorem 5.4: *Assume that the vector field J_0 given by* (5.14) *is structurally stable in $D^r(\Omega,\mathbb{R}^2)(r\geqslant 1)$. Then there are an $\epsilon>0$ and a time $t_0>0$ such that if $\alpha_1<\alpha<\alpha_1+\epsilon$ and $t>t_0$, then for any initial data $(\psi_0,\mathcal{A}_0)\in U\backslash\Gamma$ where $U\backslash\Gamma\subset H$ is the open set given in Theorem 4.1, the supercurrent*

$$J_s(\psi_\alpha, \mathcal{A}_\alpha) = -\gamma(A_a + \mathcal{A}_\alpha)|\psi_\alpha|^2 - \frac{\gamma\mu}{2} i(\psi^* \nabla_\alpha \psi_\alpha - \psi_\alpha \nabla \psi_\alpha^*),$$

corresponding to the solution $(\psi_\alpha, \mathcal{A}_\alpha)$ *is structurally stable, and is topologically equivalent to* J_0.

Inequalities for experimental tests of the Kochen-Specker theorem

Koji Nagata
National Institute of Information and Communications Technology, 4-2-1 Nukuikita, Koganei, Tokyo 184-8795, Japan

(Received 16 September 2004; accepted 26 August 2005; published online 12 October 2005)

We derive inequalities for n-partite states under the assumption that the hidden-variable theoretical joint probability distribution for any pair of commuting observables is equal to the quantum mechanical one. Fine showed that this assumption is connected to the no-hidden-variables theorem of Kochen and Specker (KS theorem). These inequalities give a way to experimentally test the KS theorem. The fidelity to the Bell states which is larger than $1/2$ is sufficient for the experimental confirmation of the KS theorem. Hence, the Werner state is enough to test experimentally the KS theorem. Furthermore, it is possible to test the KS theorem experimentally using uncorrelated states. An n-partite uncorrelated state violates the n-partite inequality derived here by an amount that grows exponentially with n. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2081115]

I. INTRODUCTION

From the incompleteness argument of the EPR paper,[1] hidden-variable interpretation of quantum mechanics (QM) has been an attractive topic of research.[2,3] There are two main approaches to study this conceptual foundation of QM. One is the Bell-EPR theorem.[4] This theorem says that the statistical prediction of QM violates the inequality following from the EPR-locality principle. The EPR-locality principle tells that a result of measurement pertaining to one system is independent of any measurement performed simultaneously at a distance on another system.

The other is the no-hidden-variables theorem of Kochen and Specker (KS theorem).[5] The original KS theorem says the nonexistence of a real-valued function which is multiplicative and linear on commuting operators so that QM cannot be imbedded into the KS type of hidden-variable theory. The proof of the KS theorem relies on intricate geometric argument. Fine connected[6,7] the KS theorem to the assumption, to be called Fine's assumption, that the hidden-variable theoretical joint probability distribution for any commuting pair of observables is equal to a quantum mechanical one. Greenberger, Horne, and Zeilinger discovered[8] the so-called GHZ theorem for four-partite GHZ states and the KS theorem has taken very simple form since then (see also Refs. 9–12).

In 1990, Mermin considered the Bell-EPR theorem of multipartite systems and derived multipartite Bell's inequality.[13] It has shown that the n-partite GHZ state violates the Bell-Mermin inequality by an amount that grows exponentially with n. After this work, several multipartite Bell's inequalities have been derived.[14,15] They also exhibit that QM violates local hidden-variable theory by a similar way.

As for the KS theorem, most researches are related to "all versus nothing" demolition of the KS type of hidden-variable theory.[16] (Of course, Bell's inequalities are available for a test of the KS theorem.) Recently, it has begun to research the KS theorem using inequalities (see Refs. 17). To find such inequalities to test the KS theorem is particularly useful for experimental investigation.[18] Since the KS theorem was purely related to the algebraic structure of quantum operators and was independent of states, it might be possible to find an inequality that is violated by QM when the system is in an uncorrelated state.[19] If so, we ask what an amount of a violation is like.

In this paper, we shall derive two inequalities following from the assumption pointed out[6,7] by Fine as a test for the KS theorem for n spin-1/2 states. A violation of Fine's assumption implies that there exists a pair of commuting observables such that the hidden-variable theoretical joint distribution of them does not agree with QM, or hidden-variables cannot exist in the sense that the KS theorem holds.

One of the inequalities says that the fidelity to the Bell states, which is larger than 1/2, allows a proof of the KS theorem. This says the Werner state[19] which admits local hidden-variable theory is enough to test experimentally the KS theorem. And we reveal possible modification of the Bell-Mermin inequality on combining Mermin's geometric idea[13] and a commutative operator group presented by Nagata *et al.*[20] We show that when n exceeds 2, not only n-partite GHZ states but also n-partite uncorrelated states violate the modified inequality derived here. The amount of a violation grows exponentially with n, which is a factor of $O(2^{n/2})$ at the macroscopic level.

Our result says that QM exhibits an exponentially stronger refutation of the KS type of hidden-variable theory, as the number of parties constituting the state increases linearly. The feature is independent of the requirement that the system be prepared in an entangled state. In other words, we can say that the KS theorem is more serious in high-dimensional settings than in low-dimensional ones. Further, we can see the local hidden-variable theory violates the KS type of hidden-variable theory.

This paper is organized as follows. In Sec. II, we fix several notations and prepare for arguments of this paper. In Sec. III, we review the statistical KS theorem and mention that its inequality version is necessary for an experimental test. In Sec. IV, we present an inequality which follows from Fine's assumption for two-spin-1/2 states and derive a sufficient condition to allow a proof of the KS theorem, which states that the fidelity to the Bell states is larger than 1/2. Since the fidelity to the Bell states is 5/8, the two-spin-1/2 Werner state violates the inequality. In Sec. V, we modify the Bell-Mermin inequality. It follows from Fine's assumption. And we show that not only n-partite GHZ states but also n-partite uncorrelated states violate the inequality by an amount that grows exponentially with n. Section VI summarizes this paper.

II. NOTATION AND PREPARATIONS

Throughout this paper, we assume von Neumann's projective measurements and we confine ourselves to the finite-dimensional and the discrete spectrum case. Let $\mathbf{R}$ denote the reals where $\pm\infty \notin \mathbf{R}$. We assume every eigenvalue in this paper lies in $\mathbf{R}$. Further, we assume that every Hermitian operator is associated with a unique observable because we do not need to distinguish between them in this paper.

We assume the validity of QM and we would like to investigate if the KS type of hidden-variable interpretation of QM is possible. Let $\mathcal{O}$ be the space of Hermitian operators described in a finite-dimensional Hilbert space, and $\mathcal{T}$ be the space of density operators described in the Hilbert space. Namely, $\mathcal{T}=\{\psi \mid \psi \in \mathcal{O} \wedge \psi \geqslant 0 \wedge \mathrm{Tr}[\psi]=1\}$. Now we define the notation θ which represents one result of quantum measurement. Suppose that the measurement of a Hermitian operator A for a system in the state ψ yields a value $\theta(A) \in \mathbf{R}$. We assume that the following two propositions (BSF and QDJ) hold. Here, $\chi_{\Delta}(x), (x \in \mathbf{R})$ represents the characteristic function. Δ is any subset of the reals $\mathbf{R}$.

Proposition: BSF (*the Born statistical formula*),

$$\mathrm{Prob}(\Delta)^{\psi}_{\theta(A)} = \mathrm{Tr}[\psi \chi_{\Delta}(A)]. \tag{2.1}$$

The whole symbol $(\Delta)^{\psi}_{\theta(A)}$ is used to denote the proposition that $\theta(A)$ lies in Δ if the system is in the state ψ. And Prob denotes the probability that the proposition holds.

Proposition: QDJ (*the quantum-mechanical joint probability distribution for commuting observables*),

$$\mathrm{Prob}(\Delta,\Delta')^{\psi}_{\theta(A),\theta(B)} = \mathrm{Tr}[\psi\chi_{\Delta}(A)\chi_{\Delta'}(B)] \tag{2.2}$$

for every commuting pair A,B in $\mathcal{O}$. The notation on the LHS of (2.2) is a generalization of the symbol $(\Delta)^{\psi}_{\theta(A)}$ to express the proposition that $\theta(A)$ and $\theta(B)$ lie in Δ and in Δ', respectively, if the system is in the state ψ.

Let us consider a classical probability space $(\Omega,\Sigma,\mu_{\psi})$, where Ω is a nonempty sample space, Σ is a σ-algebra of subsets of Ω, and μ_{ψ} is a σ-additive normalized measure on Σ such that $\mu_{\psi}(\Omega)=1$. The subscript ψ expresses that the probability measure is determined uniquely when the state ψ is specified.

Let us introduce measurable functions (classical random variables) onto $\Omega(f:\Omega\mapsto\mathbf{R})$, which is written as $f_A(\omega)$ for an operator $A\in\mathcal{O}$. Here $\omega\in\Omega$ is a hidden variable. We introduce appropriate notation. $P(\omega)\simeq Q(\omega)$ means $P(\omega)=Q(\omega)$ holds almost everywhere with respect to μ_{ψ} in Ω. One may assume the probability measure μ_{ψ} is chosen such that the following relation is valid:

$$\mathrm{Tr}[\psi A] = \int_{\omega\in\Omega} \mu_{\psi}(\mathrm{d}\omega) f_A(\omega) \tag{2.3}$$

for every Hermitian operator A in $\mathcal{O}$. Please notice the assumption for the probability measure μ_{ψ} does not disturb the KS theorem. See the lemma (B1) in Appendix B.

Proposition: HV (*the deterministic hidden-variable interpretation of QM*).

Measurable function $f_A(\omega)$ exists for every Hermitian operator A in $\mathcal{O}$.

Proposition: D (*the probability distribution rule*),

$$\mu_{\psi}(f_A^{-1}(\Delta)) = \mathrm{Prob}(\Delta)^{\psi}_{\theta(A)}. \tag{2.4}$$

Proposition: JD (*the joint probability distribution rule*),

$$\mu_{\psi}(f_A^{-1}(\Delta)\cap f_B^{-1}(\Delta')) = \mathrm{Prob}(\Delta,\Delta')^{\psi}_{\theta(A),\theta(B)} \tag{2.5}$$

for every commuting pair A,B in $\mathcal{O}$.

Proposition: FUNC A.E. (*the functional rule holding almost everywhere*),

$$f_{g(A)}(\omega) \simeq g(f_A(\omega)) \tag{2.6}$$

for every function $g:\mathbf{R}\mapsto\mathbf{R}$.

Proposition: PROD A.E. (*the product rule holding almost everywhere*).

If Hermitian operators A and B commute, then

$$f_{AB}(\omega) \simeq f_A(\omega)\cdot f_B(\omega). \tag{2.7}$$

Theorem:[6]

$$\mathrm{HV}\wedge\mathrm{JD}\Rightarrow\mathrm{HV}\wedge\mathrm{D}\wedge\mathrm{FUNC\ A.E.} \tag{2.8}$$

Proof: See (B6) in Appendix B.

Theorem:[6]

$$\mathrm{HV}\wedge\mathrm{FUNC\ A.E.}\Rightarrow\mathrm{HV}\wedge\mathrm{PROD\ A.E.} \tag{2.9}$$

Proof: See (B14) in Appendix B.

III. THE STATISTICAL KOCHEN-SPECKER THEOREM

In this section, we want to review the statistical KS theorem (see also Ref. 17). In what follows, we assume HV and JD hold. This implies that we can use D, FUNC A.E., and PROD A.E.. We follow the statistical version of the KS theorem proposed by Peres[11] and refined by Mermin[12] for two-spin-1/2 states. One then can see that

$$X(\omega) := f_{\sigma_x^1\sigma_x^2}(\omega) f_{\sigma_y^1\sigma_y^2}(\omega) f_{\sigma_z^1\sigma_z^2}(\omega) \simeq f_{\sigma_x^1\sigma_x^2\sigma_y^1\sigma_y^2\sigma_z^1\sigma_z^2}(\omega) = f_{-I}(\omega)$$
$$\Rightarrow \int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) X(\omega) = \mathrm{Tr}[\psi(-I)] = -1, \tag{3.1}$$

where I represents the identity operator for the four-dimensional space. By the way we can factorize two of the terms as $f_{\sigma_x^1\sigma_x^2} \simeq f_{\sigma_x^1} f_{\sigma_x^2}$ and $f_{\sigma_y^1\sigma_y^2} \simeq f_{\sigma_y^1} f_{\sigma_y^2}$. Further, we have $f_{\sigma_x^1\sigma_y^2} \simeq f_{\sigma_x^1} f_{\sigma_y^2}$ and $f_{\sigma_y^1\sigma_x^2} \simeq f_{\sigma_y^1} f_{\sigma_x^2}$. Hence we get $f_{\sigma_x^1\sigma_x^2} f_{\sigma_y^1\sigma_y^2} \simeq f_{\sigma_x^1\sigma_y^2} f_{\sigma_y^1\sigma_x^2}$ and

$$X(\omega) \simeq f_{\sigma_x^1\sigma_y^2}(\omega) f_{\sigma_y^1\sigma_x^2}(\omega) f_{\sigma_z^1\sigma_z^2}(\omega) \simeq f_{\sigma_x^1\sigma_y^2\sigma_y^1\sigma_x^2\sigma_z^1\sigma_z^2}(\omega) = f_I(\omega) \Rightarrow \int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) X(\omega) = \mathrm{Tr}[\psi I] = 1 \tag{3.2}$$

in contradiction to (3.1). Thereby, we see that HV does not hold if we accept JD.

We follow the statistical version of the KS theorem proposed in Refs. 9 and 12 for three-spin-1/2 states. Then, one can see that

$$Y(\omega) := f_{\sigma_x^1\sigma_y^2\sigma_y^3}(\omega) f_{\sigma_y^1\sigma_x^2\sigma_y^3}(\omega) f_{\sigma_y^1\sigma_y^2\sigma_x^3}(\omega) f_{\sigma_x^1\sigma_x^2\sigma_x^3}(\omega) \simeq f_{\sigma_x^1\sigma_y^2\sigma_y^3\sigma_y^1\sigma_x^2\sigma_y^3\sigma_y^1\sigma_y^2\sigma_x^3\sigma_x^1\sigma_x^2\sigma_x^3}(\omega)$$
$$= f_{-I}(\omega) \Rightarrow \int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) Y(\omega) = \mathrm{Tr}[\psi(-I)] = -1, \tag{3.3}$$

where I represents the identity operator for the eight-dimensional space. By the way, we can factorize each of the four terms as

$$f_{\sigma_x^1\sigma_y^2\sigma_y^3}(\omega) \simeq f_{\sigma_x^1}(\omega) f_{\sigma_y^2}(\omega) f_{\sigma_y^3}(\omega) \tag{3.4}$$

and so on to get

$$Y(\omega) \simeq (f_{\sigma_x^1}(\omega))^2 (f_{\sigma_y^1}(\omega))^2 (f_{\sigma_x^2}(\omega))^2 (f_{\sigma_y^2}(\omega))^2 (f_{\sigma_x^3}(\omega))^2 (f_{\sigma_y^3}(\omega))^2 \simeq f_I(\omega) f_I(\omega) f_I(\omega) f_I(\omega) f_I(\omega) f_I(\omega)$$
$$\simeq f_I(\omega) \Rightarrow \int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) Y(\omega) = \mathrm{Tr}[\psi I] = 1 \tag{3.5}$$

in contradiction to (3.3).

These two examples provide the statistical KS theorem, which says demolition of HV or of JD. We have the following result.

Theorem: (*The statistical Kochen-Specker theorem.*)

For every quantum state described in a Hilbert space $\mathcal{H}_1 \otimes \mathcal{H}_2$ or $\mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \mathcal{H}_3$, $(\mathrm{Dim}(\mathcal{H}_j) = 2, (j = 1, 2, 3))$,

$$\mathrm{HV} \wedge \mathrm{JD} \Rightarrow \perp. \tag{3.6}$$

That is, these two propositions do not hold at the same time.

These examples are sufficient to show that HV cannot be possible in any state if we accept JD. However, they are not of suitable form to test experimentally the KS theorem. Because, in a real experiment, we cannot claim a sharp value as an expectation with arbitrary precision. Therefore, its inequality version is necessary for an experimental test of the KS theorem.

IV. INEQUALITY FOR TWO-PARTITE STATES

In this section, we shall derive the inequality version statistical KS theorem for two-spin-1/2 states. Then, we show that the two-spin-1/2 Werner state[19] violates the inequality. Since the Werner state satisfies all Bell's inequalities, the inequality derived in this section does not belong

to the category of Bell's inequalities. The inequality is just the inequality concerned with the KS theorem. In the following, we assume that HV and JD hold. Let x,y be real numbers with $x,y \in \{-1,+1\}$, then we have

$$(1+x+y-xy) = \pm 2. \tag{4.1}$$

Theorem:[21] For every state ψ described in a Hilbert space $\mathcal{H}_1 \otimes \mathcal{H}_2$, $(\mathrm{Dim}(\mathcal{H}_j)=2,(j=1,2))$,

$$\mathrm{HV} \wedge \mathrm{JD}(\wedge \sigma_x^1\sigma_y^2\sigma_y^1\sigma_x^2 = \sigma_z^1\sigma_z^2) \Rightarrow 1 + \mathrm{Tr}[\psi\sigma_x^1\sigma_x^2] + \mathrm{Tr}[\psi\sigma_y^1\sigma_y^2] - \mathrm{Tr}[\psi\sigma_z^1\sigma_z^2] \leqslant 2. \tag{4.2}$$

Proof: From PROD A.E., we have

$$(f_{\sigma_k^1\sigma_k^2}(\omega))^2 \simeq f_I(\omega) \simeq +1 \Leftrightarrow f_{\sigma_k^1\sigma_k^2}(\omega) \simeq \pm 1, (k=x,y). \tag{4.3}$$

Hence, the (4.1) says

$$U(\omega) := 1 + f_{\sigma_x^1\sigma_x^2}(\omega) + f_{\sigma_y^1\sigma_y^2}(\omega) - f_{\sigma_x^1\sigma_x^2}(\omega) f_{\sigma_y^1\sigma_y^2}(\omega) \Rightarrow U(\omega) \simeq \pm 2 \tag{4.4}$$

and

$$\int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) U(\omega) \leqslant 2. \tag{4.5}$$

On using $f_{\sigma_x^1\sigma_x^2} f_{\sigma_y^1\sigma_y^2} \simeq f_{\sigma_x^1\sigma_y^2} f_{\sigma_y^1\sigma_x^2} \simeq f_{\sigma_z^1\sigma_z^2}$ we get

$$\int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) f_{\sigma_x^1\sigma_x^2}(\omega) f_{\sigma_y^1\sigma_y^2}(\omega) = \int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) f_{\sigma_x^1\sigma_y^2}(\omega) f_{\sigma_y^1\sigma_x^2}(\omega) = \int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) f_{\sigma_z^1\sigma_z^2}(\omega), \tag{4.6}$$

where we have used the quantum mechanical rule $\sigma_x^1\sigma_y^2\sigma_y^1\sigma_x^2 = \sigma_z^1\sigma_z^2$. Hence we conclude

$$\int_{\omega\in\Omega} \mu_\psi(\mathrm{d}\omega) U(\omega) \leqslant 2 \Leftrightarrow 1 + \mathrm{Tr}[\psi\sigma_x^1\sigma_x^2] + \mathrm{Tr}[\psi\sigma_y^1\sigma_y^2] - \mathrm{Tr}[\psi\sigma_z^1\sigma_z^2] \leqslant 2. \tag{4.7}$$

QED

A violation of the inequality (4.7) implies demolition of HV or of JD in the state ψ. Note the following quantum mechanical relation:

$$1 + \mathrm{Tr}[\psi\sigma_x^1\sigma_x^2] + \mathrm{Tr}[\psi\sigma_y^1\sigma_y^2] - \mathrm{Tr}[\psi\sigma_z^1\sigma_z^2] \leqslant 2 \Leftrightarrow \mathrm{Tr}[\psi|\pi\rangle\langle\pi|] \leqslant 1/2, \tag{4.8}$$

where

$$|\pi\rangle := \frac{|+_1,-_2\rangle + |-_1,+_2\rangle}{\sqrt{2}}. \tag{4.9}$$

Therefore the statistical KS theorem holds if the fidelity to the Bell state $|\pi\rangle$ is larger than $1/2$. Note the fidelity to the Bell states of the two-spin-$1/2$ Werner state[19] is $5/8(>1/2)$. The Werner state W is

$$W = (1/2)|\pi\rangle\langle\pi| + (1/8)I, \tag{4.10}$$

where I is the identity operator on the four-dimensional space. Hence, this quantum state which admits local hidden-variable theory allows a proof of the KS theorem.

V. INEQUALITY FOR MULTIPARTITE STATES

In what follows, we shall modify the Bell-Mermin inequality.[13] We derive an n-partite inequality which is satisfied if both HV and JD hold. We show n-partite uncorrelated states violate

the inequality when $n \geqslant 3$, by an amount that grows exponentially with n. Please note that any uncorrelated states satisfy all Bell's inequalities.[19] Hence, the modified inequality does not belong to the category of Bell's inequalities. In this section, we assume $n \geqslant 2$. Let us denote $\{1,2,\ldots,n\}$ by $\mathbf{N}_n$.

Definition: [*commutative group* (Λ_n) *of Hermitian operators*]

$O_p^n (p \in \{0,1,\ldots,2^n-1\}, n \geqslant 2)$ are Hermitian operators defined by

$$O_p^n := \prod_{j=1}^{n} (\sigma_z^j)^{b_j} (\sigma_x^j)^{b_0} = (\sigma_z^1)^{b_1} (\sigma_z^2)^{b_2} (\sigma_z^3)^{b_3} (\sigma_z^4)^{b_4} \cdots (\sigma_z^{n-1})^{b_{n-1}} (\sigma_z^n)^{b_n} \times (\sigma_x^1)^{b_0} (\sigma_x^2)^{b_0} (\sigma_x^3)^{b_0} \cdots (\sigma_x^{n-1})^{b_0} (\sigma_x^n)^{b_0}, \tag{5.1}$$

where the superscript j of the Pauli operators denotes the party j and the n-bit sequence $b_0 b_1 \cdots b_{n-1}$ is the binary representation of p, and $b_n \in \{0,1\} \wedge b_n \equiv \Sigma_{j=1}^{n-1} b_j (\mathrm{mod}\ 2)$. Thus, the parity of $b_1 b_2 \cdots b_n$ is even. (Here, σ_k^1 means $\sigma_k^1 \otimes_{j=2}^{n} I^j$ and so on. Omitting the identity operator, we abbreviate those as above.)

The operator O_0^n is the identity operator on the 2^n-dimensional space, and the other operators $O_1^n, \ldots, O_{2^n-1}^n$ have two eigenvalues, ± 1. In the following, there are the cases where we abbreviate O_0^n as I.

Example: If $p \in \{0,1,\ldots,2^{n-1}-1\}$, then $b_0 = 0$ and $(\sigma_x^j)^{b_0} = \otimes_{k=1}^{n} I^k = O_0^n$ for all j. That is, the binary representation of p takes, for example, the following form:

$$p_1 := \overbrace{01001\cdots01}^{B_1} (= b_0 b_1 \cdots b_{n-1}), \tag{5.2}$$

where B_1 represents the sum of the number of 1. Then, $b_n \in \{0,1\} \wedge b_n \equiv B_1 (\mathrm{mod}\ 2)$ holds. Suppose $b_n = 1$ holds, then $(\sigma_z^n)^{b_n} = \sigma_z^n$. Then, the corresponding Hermitian operator $O_{p_1}^n$ is as follows:

$$O_{p_1}^n = \sigma_z^1 I^2 I^3 \sigma_z^4 \cdots I^{n-2} \sigma_z^{n-1} \sigma_z^n \times I^1 I^2 I^3 I^4 \cdots I^{n-1} I^n = (\sigma_z^1 I^1) I^2 I^3 (\sigma_z^4 I^4) \cdots I^{n-2} (\sigma_z^{n-1} I^{n-1}) (\sigma_z^n I^n) = \sigma_z^1 I^2 I^3 \sigma_z^4 \cdots I^{n-2} \sigma_z^{n-1} \sigma_z^n, \tag{5.3}$$

where the number of $(\sigma_z I) = \sigma_z$ is even because of the definition of b_n.

Example: If $p \in \{2^{n-1}, 2^{n-1}+1, \ldots, 2^n-1\}$, then $b_0 = 1$ and $(\sigma_x^j)^{b_0} = \sigma_x^j$ for all j. That is, the binary representation of p takes, for example, the following form:

$$p_2 := \overbrace{11001\cdots01}^{B_2}, \tag{5.4}$$

where B_2 represents the sum of the number of 1. Then, $b_n \in \{0,1\} \wedge b_n \equiv B_2 (\mathrm{mod}\ 2)$ holds. Suppose $b_n = 0$ holds, then $(\sigma_z^n)^{b_n} = O_0^n$. Then the corresponding Hermitian operator $O_{p_2}^n$ is as follows:

$$O_{p_2}^n = \sigma_z^1 I^2 I^3 \sigma_z^4 \cdots I^{n-2} \sigma_z^{n-1} I^n \times \sigma_x^1 \sigma_x^2 \sigma_x^3 \cdots \sigma_x^{n-1} \sigma_x^n = (\sigma_z^1 \sigma_x^1) \sigma_x^2 \sigma_x^3 (\sigma_z^4 \sigma_x^4) \cdots \sigma_x^{n-2} (\sigma_z^{n-1} \sigma_x^{n-1}) \sigma_x^n = (i\sigma_y^1) \sigma_x^2 \sigma_x^3 (i\sigma_y^4) \cdots \sigma_x^{n-2} (i\sigma_y^{n-1}) \sigma_x^n, \tag{5.5}$$

where the number of $(\sigma_z \sigma_x) = i\sigma_y$ is even.

Example: The binary representation of 2^{n-1} takes the following form:

$$2^{n-1} = 1\overbrace{0000\cdots00}^{n-1}. \tag{5.6}$$

Then the corresponding Hermitian operator $O_{2^{n-1}}^n$ is as follows:

$$O_{2^{n-1}}^n = I^1 I^2 I^3 I^4 \cdots I^{n-1} I^n \times \sigma_x^1 \sigma_x^2 \sigma_x^3 \cdots \sigma_x^{n-1} \sigma_x^n = \sigma_x^1 \sigma_x^2 \sigma_x^3 \cdots \sigma_x^{n-1} \sigma_x^n. \tag{5.7}$$

Lemma: If $O_p^n, O_q^n \in \Lambda_n$, then

$$O_p^n O_q^n = O_{p\oplus q}^n (\in \Lambda_n), \tag{5.8}$$

where $p \oplus q$ is the bitwise XOR (exclusive OR) of p and q.

Proof: See (A1) in Appendix A.

From the lemma (5.8), the set of 2^n operators $\{O_p^n\}$ forms a commutative group isomorphic to $(Z_2)^n$. We have denoted this commutative group as Λ_n. Let us define another set of operators.

Definition: $R_p^n (p \in \{0,1,\ldots,2^n-1\}, n \geqslant 2)$ are operators defined by

$$R_p^n := \prod_{j=1}^{n} (\sigma_z^j)^{e_j} (\sigma_x^j)^{e_0}, \tag{5.9}$$

where the superscript j of the Pauli operators denotes the party j and the n-bit sequence $e_0 e_1 \cdots e_{n-1}$ is the binary representation of p, and $e_n \in \{0,1\} \wedge e_n \equiv \Sigma_{j=1}^{n-1} e_j + 1 (\mathrm{mod}\ 2)$. Thus, unlike O_p^n, the parity of $e_1 e_2 \cdots e_n$ is odd.

Example: If $p \in \{0,1,\ldots,2^{n-1}-1\}$, then $e_0 = 0$ and $(\sigma_x^j)^{e_0} = \otimes_{k=1}^n I^k = O_0^n$ for all j. That is, the binary representation of p takes, for example, the following form:

$$p_3 := 0\overbrace{1001\cdots01}^{B_3} (= e_0 e_1 \cdots e_{n-1}), \tag{5.10}$$

where B_3 represents the sum of the number of 1. Then, $e_n \in \{0,1\} \wedge e_n \equiv B_3 + 1 (\mathrm{mod}\ 2)$ holds. Suppose $e_n = 1$ holds, then $(\sigma_z^n)^{e_n} = \sigma_z^n$. Then, the corresponding Hermitian operator $R_{p_3}^n$ is as follows:

$$\begin{aligned} R_{p_3}^n &= \sigma_z^1 I^2 I^3 \sigma_z^4 \cdots I^{n-2} \sigma_z^{n-1} \sigma_z^n \times I^1 I^2 I^3 I^4 \cdots I^{n-1} I^n = (\sigma_z^1 I^1) I^2 I^3 (\sigma_z^4 I^4) \cdots I^{n-2} (\sigma_z^{n-1} I^{n-1}) (\sigma_z^n I^n) \\ &= \sigma_z^1 I^2 I^3 \sigma_z^4 \cdots I^{n-2} \sigma_z^{n-1} \sigma_z^n, \end{aligned} \tag{5.11}$$

where the number of $(\sigma_z I) = \sigma_z$ is odd because of the definition of e_n.

Example: If $p \in \{2^{n-1}, 2^{n-1}+1, \ldots, 2^n-1\}$, then $e_0 = 1$ and $(\sigma_x^j)^{e_0} = \sigma_x^j$ for all j. That is, the binary representation of p takes, for example, the following form:

$$p_4 := 1\overbrace{1001\cdots01}^{B_4}, \tag{5.12}$$

where B_4 represents the sum of the number of 1. Then, $e_n \in \{0,1\} \wedge e_n \equiv B_4 + 1 (\mathrm{mod}\ 2)$ holds. Suppose $e_n = 0$ holds, then $(\sigma_z^n)^{e_n} = O_0^n$. Then the corresponding non-Hermitian operator $R_{p_4}^n$ is as follows:

$$\begin{aligned} R_{p_4}^n &= \sigma_z^1 I^2 I^3 \sigma_z^4 \cdots I^{n-2} \sigma_z^{n-2} I^n \times \sigma_x^1 \sigma_x^2 \sigma_x^3 \cdots \sigma_x^{n-1} \sigma_x^n = (\sigma_z^1 \sigma_x^1) \sigma_x^2 \sigma_x^3 (\sigma_z^4 \sigma_x^4) \cdots \sigma_x^{n-2} (\sigma_z^{n-1} \sigma_x^{n-1}) \sigma_x^n \\ &= (i\sigma_y^1) \sigma_x^2 \sigma_x^3 (i\sigma_y^4) \cdots \sigma_x^{n-2} (i\sigma_y^{n-1}) \sigma_x^n, \end{aligned} \tag{5.13}$$

where the number of $(\sigma_z \sigma_x) = i\sigma_y$ is odd. R_p^n / i and $i R_p^n$ are Hermitian operators if $p \in \{2^{n-1}, 2^{n-1}+1, \ldots, 2^n-1\}$.

Lemma:

$$\frac{1}{2}\left(\prod_{j=1}^{n} (I^j + \sigma_z^j) + \prod_{j=1}^{n} (I^j - \sigma_z^j) \right) = \sum_{p=0}^{2^{n-1}-1} O_p^n,$$

$$\frac{1}{2}\left(\prod_{j=1}^{n} (I^j + \sigma_z^j) - \prod_{j=1}^{n} (I^j - \sigma_z^j) \right) = \sum_{p=0}^{2^{n-1}-1} R_p^n,$$

$$\frac{1}{2}\left(\prod_{j=1}^{n}(\sigma_x^j+i\sigma_y^j)+\prod_{j=1}^{n}(\sigma_x^j-i\sigma_y^j)\right)=\sum_{p=2^{n-1}}^{2^n-1}O_p^n,$$

$$\frac{1}{2}\left(\prod_{j=1}^{n}(\sigma_x^j+i\sigma_y^j)-\prod_{j=1}^{n}(\sigma_x^j-i\sigma_y^j)\right)=\sum_{p=2^{n-1}}^{2^n-1}R_p^n. \tag{5.14}$$

Proof: See (A7) and (A14) in Appendix A.

Lemma:

$$\mathrm{HV}\wedge\mathrm{FUNC\ A.E.}\Rightarrow \mathrm{Re}\left(\prod_{j=1}^{n}(f_{\sigma_x^j}(\omega)+if_{\sigma_y^j}(\omega))\right)\simeq\sum_{p=2^{n-1}}^{2^n-1}f_{O_p^n}(\omega),$$

$$\mathrm{Im}\left(\prod_{j=1}^{n}(f_{\sigma_x^j}(\omega)+if_{\sigma_y^j}(\omega))\right)\simeq\sum_{p=2^{n-1}}^{2^n-1}f_{R_p^n/i}(\omega). \tag{5.15}$$

Proof: See (A21) in Appendix A.

Theorem:[21] For every state ψ described in a Hilbert space $\otimes_{j=1}^{n}\mathcal{H}_j$, $(\mathrm{Dim}(\mathcal{H}_j)=2,(j\in\mathbf{N}_n,n\geqslant 2))$,

$$\mathrm{HV}\wedge\mathrm{JD}(\wedge(i\sigma_y^j)(i\sigma_y^j)\sigma_x^j\sigma_x^j=\sigma_z^j\sigma_z^j)\Rightarrow\sum_{p=0}^{2^{n-1}-1}\mathrm{Tr}[\psi O_p^n]\leqslant\begin{cases}2^{n/2} & n=\text{even},\\ 2^{(n-1)/2} & n=\text{odd}.\end{cases} \tag{5.16}$$

Proof: From PROD A.E., we have

$$(f_{\sigma_k^j}(\omega))^2\simeq f_{O_0^n}(\omega)\simeq+1\Leftrightarrow f_{\sigma_k^j}(\omega)\simeq\pm 1,\quad(j\in\mathbf{N}_n,k=x,y). \tag{5.17}$$

Now, we define F^ψ by

$$F^\psi:=\int_{\omega\in\Omega}\mu_\psi(\mathrm{d}\omega)G(\omega), \tag{5.18}$$

where $G(\omega)$ is defined by

$$G(\omega):=\mathrm{Re}\left(\prod_{j=1}^{n}(f_{\sigma_x^j}(\omega)+if_{\sigma_y^j}(\omega))\right)\prod_{j=1}^{n}f_{\sigma_x^j}(\omega). \tag{5.19}$$

From the geometric argument by Mermin in Ref. 13 and (5.17), we have

$$G(\omega)\leqslant\begin{cases}2^{n/2} & n=\text{even}\\ 2^{(n-1)/2} & n=\text{odd}\end{cases}\qquad(\mu_\psi-\text{a.e.}). \tag{5.20}$$

In more detail, almost everywhere with respect to μ_ψ in Ω, the maximum of $G(\omega)$ is equal to the real part of a product of complex numbers each of which has magnitude of $\sqrt{2}$ and a phase of $\pm\pi/4$ or $\pm 3\pi/4$ since absolute value of $\Pi_{j=1}^{n}f_{\sigma_x^j}(\omega)$ is unity almost everywhere with respect to μ_ψ. When n is even the product can lie along the real axis and can attain a maximum value of $2^{n/2}$, when n is odd the product must lie along an axis at 45° to the real axis and its real part can only attain the maximum value $2^{(n-1)/2}$. Therefore, the value $G(\omega)$ is bounded as (5.20) almost everywhere in Ω, and hence F^ψ is bounded as

$$F^{\psi} \leqslant \begin{cases} 2^{n/2} & n = \text{even}, \\ 2^{(n-1)/2} & n = \text{odd}. \end{cases} \tag{5.21}$$

From (5.7), it is easy to see that

$$\prod_{j=1}^{n} f_{\sigma_x^j}(\omega) \simeq f_{O^n_{2^{n-1}}}(\omega). \tag{5.22}$$

Therefore, from (5.19) and the lemma (5.15), we have

$$G(\omega) \simeq \left(\sum_{p=2^{n-1}}^{2^n-1} f_{O^n_p}(\omega) \right) f_{O^n_{2^{n-1}}}(\omega). \tag{5.23}$$

Noting $[O_p^n, O_q^n] = \mathbf{0}, \forall O_p^n, O_q^n \in \Lambda_n$ [see the lemma (5.8)], PROD A.E. tells the following relations:

$$f_{O^n_p}(\omega) f_{O^n_q}(\omega) \simeq f_{O^n_{p\oplus q}}(\omega), \quad (\forall O_p^n, O_q^n \in \Lambda_n). \tag{5.24}$$

It is easy to see that

$$\{O_p^n O^n_{2^{n-1}} | p \in \{2^{n-1}, 2^{n-1}+1, \ldots, 2^n - 1\}\} = \{O_p^n | p \in \{0, 1, \ldots, 2^{n-1} - 1\}\}. \tag{5.25}$$

Here, we have used the quantum mechanical rule $(i\sigma_y^i)(i\sigma_y^j)\sigma_x^i\sigma_x^j = \sigma_z^i\sigma_z^j (i, j \in \mathbf{N}_n, i \neq j)$. [Equation (5.25) is also obvious from the expression (5.1) and (5.7)]. Therefore, we get

$$G(\omega) \simeq \sum_{p=0}^{2^{n-1}-1} f_{O^n_p}(\omega). \tag{5.26}$$

Thus from (5.18) we conclude

$$F^{\psi} = \int_{\omega \in \Omega} \mu_{\psi}(\mathrm{d}\omega) \left(\sum_{p=0}^{2^{n-1}-1} f_{O^n_p}(\omega) \right) = \sum_{p=0}^{2^{n-1}-1} \mathrm{Tr}[\psi O_p^n]. \tag{5.27}$$

QED

Now, it follows from the lemma (5.14) that

$$|+_1;+_2;\cdots;+_n\rangle\langle+_1;+_2;\cdots;+_n| + |-_1;-_2;\cdots;-_n\rangle\langle-_1;-_2;\cdots;-_n| = \frac{1}{2^n}\left(\prod_{j=1}^{n} (I^j + \sigma_z^j) + \prod_{j=1}^{n} (I^j - \sigma_z^j) \right)$$

$$= \frac{1}{2^{n-1}} \left(\sum_{p=0}^{2^{n-1}-1} O_p^n \right), \tag{5.28}$$

where $O_p^n = \Pi_{j=1}^n (\sigma_x^j)^{b_0} (\sigma_z^j)^{b_j}$ and $\sigma_z^j |\pm_j\rangle = \pm |\pm_j\rangle$. Hence we have

$$F^{\psi} = \sum_{p=0}^{2^{n-1}-1} \mathrm{Tr}[\psi O_p^n] = \mathrm{Tr}[\psi H_n], \tag{5.29}$$

where [see (5.28)]

$$H_n := 2^{n-1}(|+_1;+_2;\cdots;+_n\rangle\langle+_1;+_2;\cdots;+_n| + |-_1;-_2;\cdots;-_n\rangle\langle-_1;-_2;\cdots;-_n|). \tag{5.30}$$

Now, let ψ be $|\Psi\rangle\langle\Psi|$ where

$$|\Psi\rangle := \alpha|+_1;+_2;\cdots;+_n\rangle + \beta|-_1;-_2;\cdots;-_n\rangle, (|\alpha|^2 + |\beta|^2 = 1). \tag{5.31}$$

This state $|\Psi\rangle$ is an n-partite uncorrelated state if α or β is zero and $|\Psi\rangle$ is an n-partite GHZ state if $\alpha=\beta=1/\sqrt{2}$.

The quantum theoretical prediction says the expectation value $\mathrm{Tr}[|\Psi\rangle\langle\Psi|H_n]$ should take a value of 2^{n-1} for the state $|\Psi\rangle$ in spite of any value of α and of β, and we get

$$F^{|\Psi\rangle} = 2^{n-1}. \tag{5.32}$$

When n exceeds 2, this value $F^{|\Psi\rangle}$ is larger than the bound (5.21), which exceeds (5.21) by the exponentially larger factor of $2^{(n-2)/2}$ (for n even) or $2^{(n-1)/2}$ (for n odd). This implies demolition of HV or of JD in the state $|\Psi\rangle$. Thus, we have derived the exponentially stronger violation of HV$\wedge$JD, irrespective of quantum entanglement effects.

VI. SUMMARY

In summary, we showed that the fidelity to the Bell states which is larger than $1/2$ is sufficient to allow a proof of the KS theorem. Thus, the Werner state is enough to test experimentally the KS theorem. We also have derived an n-partite inequality following from HV$\wedge$JD. We have shown that an n-partite uncorrelated state violates the inequality by a factor of $O(2^{n/2})$ at the macroscopic level. Hence, it turns out that QM exhibits an exponentially stronger violation of HV$\wedge$JD, as the number of parties constituting the state increases, irrespective of entanglement effects.

ACKNOWLEDGMENTS

The author thanks Masahide Sasaki for very important and helpful discussions. Masato Koashi gave the author the expression of (5.1) in Ref. 20. The author acknowledges e-mail from Marek Żukowski and Anning Zhang. Their comments were very helpful for improving this presentation. The author thanks Shin Takagi. Finally, the author wishes to dedicate this paper to his wife, Miki. This work could not have been finished without her support.

APPENDIX A

Lemma: If $O_p^n, O_q^n \in \Lambda_n$, then

$$O_p^n O_q^n = O_{p\oplus q}^n (\in \Lambda_n), \tag{A1}$$

where $p\oplus q$ is the bitwise XOR (exclusive OR) of p and q.

Proof: Suppose that the binary representations of p and q are $b_0 b_1 \cdots b_{n-1}$ and $c_0 c_1 \cdots c_{n-1}$, respectively. Suppose that $b_n \in \{0,1\} \wedge b_n \equiv \Sigma_{j=1}^{n-1} b_j (\mathrm{mod}\ 2)$ and $c_n \in \{0,1\} \wedge c_n \equiv \Sigma_{j=1}^{n-1} c_j (\mathrm{mod}\ 2)$ hold. This means that

$$c_j \in \{0,1\}\ \forall\, j \wedge \sum_{j=1}^{n} c_j \equiv 0 (\mathrm{mod}\ 2). \tag{A2}$$

This yields ($b_0 \in \{1,0\}$)

$$\left[\prod_{j=1}^{n} (\sigma_x^j)^{b_0}, \prod_{j=1}^{n} (\sigma_z^j)^{c_j}\right] = \mathbf{0}. \tag{A3}$$

Then from (5.1) we have

$$O_p^n = \prod_{j=1}^{n} (\sigma_z^j)^{b_j} (\sigma_x^j)^{b_0}, \quad O_q^n = \prod_{j=1}^{n} (\sigma_z^j)^{c_j} (\sigma_x^j)^{c_0} \Rightarrow O_p^n O_q^n = \prod_{j=1}^{n} (\sigma_z^j)^{b_j} (\sigma_x^j)^{b_0} (\sigma_z^j)^{c_j} (\sigma_x^j)^{c_0}$$
$$= \prod_{j=1}^{n} (\sigma_z^j)^{b_j} (\sigma_z^j)^{c_j} (\sigma_x^j)^{b_0} (\sigma_x^j)^{c_0} = \prod_{j=1}^{n} (\sigma_z^j)^{d_j} (\sigma_x^j)^{d_0} = O_{p\oplus q}^n, \tag{A4}$$

where

$$d_j \in \{0,1\} \wedge d_j \equiv b_j + c_j (\mathrm{mod}\, 2). \tag{A5}$$

Here,

$$d_n \equiv \sum_{j=1}^{n-1} b_j + \sum_{j=1}^{n-1} c_j (\mathrm{mod}\, 2) \equiv \sum_{j=1}^{n-1} (b_j + c_j) (\mathrm{mod}\, 2) \equiv \sum_{j=1}^{n-1} d_j (\mathrm{mod}\, 2). \tag{A6}$$

Hence, d_n can be assumed such that $d_n \in \{0,1\}$ and $d_n \equiv \Sigma_{j=1}^{n-1} d_j (\mathrm{mod}\, 2)$ hold. QED

Lemma:

$$\frac{1}{2}\left(\prod_{j=1}^{n} (I^j + \sigma_z^j) + \prod_{j=1}^{n} (I^j - \sigma_z^j) \right) = \sum_{p=0}^{2^{n-1}-1} O_p^n,$$
$$\frac{1}{2}\left(\prod_{j=1}^{n} (I^j + \sigma_z^j) - \prod_{j=1}^{n} (I^j - \sigma_z^j) \right) = \sum_{p=0}^{2^{n-1}-1} R_p^n. \tag{A7}$$

Proof: If the following relations hold for all $m, (2 \leqslant m \leqslant n)$,

$$\frac{1}{2}\left(\prod_{j=1}^{m} (I^j + \sigma_z^j) + \prod_{j=1}^{m} (I^j - \sigma_z^j) \right) = \sum_{p=0}^{2^{m-1}-1} O_p^m, \tag{A8}$$

$$\frac{1}{2}\left(\prod_{j=1}^{m} (I^j + \sigma_z^j) - \prod_{j=1}^{m} (I^j - \sigma_z^j) \right) = \sum_{p=0}^{2^{m-1}-1} R_p^m, \tag{A9}$$

then the theorem holds. Here, O_p^m means $O_p^m \otimes_{j=m+1}^{n} I^j$ and so on. Omitting the identity operator, we abbreviate those as above. Remember, σ_k^1 means $\sigma_k^1 \otimes_{j=2}^{n} I^j$ and so on.

In the case where $m=2$: The left-hand side (LHS) of (A8) is $(I^1 I^2 + \sigma_z^1 \sigma_z^2) \otimes_{j=3}^{n} I^j$ and right-hand side (RHS) of (A8) is also $(I^1 I^2 + \sigma_z^1 \sigma_z^2) \otimes_{j=3}^{n} I^j$. LHS of (A9) is $(I^1 \sigma_z^2 + \sigma_z^1 I^2) \otimes_{j=3}^{n} I^j$ and RHS of (A9) is also $(I^1 \sigma_z^2 + \sigma_z^1 I^2) \otimes_{j=3}^{n} I^j$. Therefore (A8) and (A9) hold when $m=2$. In the following, if possible, we omit the identity operator.

Suppose that (A8) and (A9) hold for $m=k-1$. Then we have

$$\prod_{j=1}^{k-1} (I^j + \sigma_z^j) = \sum_{p=0}^{2^{k-2}-1} O_p^{k-1} + \sum_{p=0}^{2^{k-2}-1} R_p^{k-1},$$
$$\prod_{j=1}^{k-1} (I^j - \sigma_z^j) = \sum_{p=0}^{2^{k-2}-1} O_p^{k-1} - \sum_{p=0}^{2^{k-2}-1} R_p^{k-1}, \tag{A10}$$

On the other hand, we have

$$
\begin{aligned}
&(I^k+\sigma_z^k)\left(\sum_{p=0}^{2^{k-2}-1}O_p^{k-1}+\sum_{p=0}^{2^{k-2}-1}R_p^{k-1}\right)\\
&=\left(\sum_{p=0}^{2^{k-2}-1}O_p^{k-1}I^k+\sum_{p=0}^{2^{k-2}-1}R_p^{k-1}\sigma_z^k\right)+\left(\sum_{p=0}^{2^{k-2}-1}O_p^{k-1}\sigma_z^k+\sum_{p=0}^{2^{k-2}-1}R_p^{k-1}I^k\right)\\
&=\sum_{p=0}^{2^{k-1}-1}O_p^k+\sum_{p=0}^{2^{k-1}-1}R_p^k
\end{aligned}
\tag{A11}
$$

and

$$
\begin{aligned}
&(I^k-\sigma_z^k)\left(\sum_{p=0}^{2^{k-2}-1}O_p^{k-1}-\sum_{p=0}^{2^{k-2}-1}R_p^{k-1}\right)\\
&=\left(\sum_{p=0}^{2^{k-2}-1}O_p^{k-1}I^k+\sum_{p=0}^{2^{k-2}-1}R_p^{k-1}\sigma_z^k\right)-\left(\sum_{p=0}^{2^{k-2}-1}O_p^{k-1}\sigma_z^k+\sum_{p=0}^{2^{k-2}-1}R_p^{k-1}I^k\right)\\
&=\sum_{p=0}^{2^{k-1}-1}O_p^k-\sum_{p=0}^{2^{k-1}-1}R_p^k.
\end{aligned}
\tag{A12}
$$

Therefore we have

$$
\begin{aligned}
\prod_{j=1}^{k}(I^j+\sigma_z^j)&=\sum_{p=0}^{2^{k-1}-1}O_p^k+\sum_{p=0}^{2^{k-1}-1}R_p^k,\\
\prod_{j=1}^{k}(I^j-\sigma_z^j)&=\sum_{p=0}^{2^{k-1}-1}O_p^k-\sum_{p=0}^{2^{k-1}-1}R_p^k.
\end{aligned}
\tag{A13}
$$

This implies that (A8) and (A9) hold for $m=k$. QED

Lemma:

$$
\begin{aligned}
\frac{1}{2}\left(\prod_{j=1}^{n}(\sigma_x^j+i\sigma_y^j)+\prod_{j=1}^{n}(\sigma_x^j-i\sigma_y^j)\right)&=\sum_{p=2^{n-1}}^{2^n-1}O_p^n,\\
\frac{1}{2}\left(\prod_{j=1}^{n}(\sigma_x^j+i\sigma_y^j)-\prod_{j=1}^{n}(\sigma_x^j-i\sigma_y^j)\right)&=\sum_{p=2^{n-1}}^{2^n-1}R_p^n.
\end{aligned}
\tag{A14}
$$

Proof: If the following relations hold for all $m,(2\leqslant m\leqslant n)$,

$$
\frac{1}{2}\left(\prod_{j=1}^{m}(\sigma_x^j+i\sigma_y^j)+\prod_{j=1}^{m}(\sigma_x^j-i\sigma_y^j)\right)=\sum_{p=2^{m-1}}^{2^m-1}O_p^m,
\tag{A15}
$$

$$
\frac{1}{2}\left(\prod_{j=1}^{m}(\sigma_x^j+i\sigma_y^j)-\prod_{j=1}^{m}(\sigma_x^j-i\sigma_y^j)\right)=\sum_{p=2^{m-1}}^{2^m-1}R_p^m,
\tag{A16}
$$

then the theorem holds. Here, O_p^m means $O_p^m \otimes_{j=m+1}^{n} I^j$ and so on.

In the case where $m=2$: LHS of (A15) is $(\sigma_x^1\sigma_x^2+i\sigma_y^1 i\sigma_y^2)\otimes_{j=3}^{n} I^j$ and RHS of (A15) is also $(\sigma_x^1\sigma_x^2+i\sigma_y^1 i\sigma_y^2)\otimes_{j=3}^{n} I^j$. LHS of (A16) is $(\sigma_x^1 i\sigma_y^2+i\sigma_y^1\sigma_x^2)\otimes_{j=3}^{n} I^j$ and RHS of (A16) is also $(\sigma_x^1 i\sigma_y^2 + i\sigma_y^1\sigma_x^2)\otimes_{j=3}^{n} I^j$. Therefore (A15) and (A16) hold when $m=2$. In the following, if possible, we omit the identity operator.

Suppose that (A15) and (A16) hold for $m=k-1$. Then we have

$$\prod_{j=1}^{k-1}(\sigma_x^j + i\sigma_y^j) = \sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1} + \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1},$$
$$\prod_{j=1}^{k-1}(\sigma_x^j - i\sigma_y^j) = \sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1} - \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1}. \tag{A17}$$

On the other hand, we have

$$\begin{aligned}(\sigma_x^k + i\sigma_y^k)&\left(\sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1} + \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1}\right)\\ &= \left(\sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1}\sigma_x^k + \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1} i\sigma_y^k\right) + \left(\sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1} i\sigma_y^k + \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1}\sigma_x^k\right)\\ &= \sum_{p=2^{k-1}}^{2^k-1} O_p^k + \sum_{p=2^{k-1}}^{2^k-1} R_p^k\end{aligned} \tag{A18}$$

and

$$\begin{aligned}(\sigma_x^k - i\sigma_y^k)&\left(\sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1} - \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1}\right)\\ &= \left(\sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1}\sigma_x^k + \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1} i\sigma_y^k\right) - \left(\sum_{p=2^{k-2}}^{2^{k-1}-1} O_p^{k-1} i\sigma_y^k + \sum_{p=2^{k-2}}^{2^{k-1}-1} R_p^{k-1}\sigma_x^k\right)\\ &= \sum_{p=2^{k-1}}^{2^k-1} O_p^k - \sum_{p=2^{k-1}}^{2^k-1} R_p^k.\end{aligned} \tag{A19}$$

Therefore we have

$$\prod_{j=1}^{k}(\sigma_x^j + i\sigma_y^j) = \sum_{p=2^{k-1}}^{2^k-1} O_p^k + \sum_{p=2^{k-1}}^{2^k-1} R_p^k,$$
$$\prod_{j=1}^{k}(\sigma_x^j - i\sigma_y^j) = \sum_{p=2^{k-1}}^{2^k-1} O_p^k - \sum_{p=2^{k-1}}^{2^k-1} R_p^k. \tag{A20}$$

This implies that (A15) and (A16) hold for $m=k$. QED

Lemma:

$$\mathrm{HV} \wedge \mathrm{FUNC\ A.E.} \Rightarrow \mathrm{Re}\left(\prod_{j=1}^{n}(f_{\sigma_x^j}(\omega)+if_{\sigma_y^j}(\omega))\right) \simeq \sum_{p=2^{n-1}}^{2^n-1} f_{O_p^n}(\omega),$$
$$\mathrm{Im}\left(\prod_{j=1}^{n}(f_{\sigma_x^j}(\omega)+if_{\sigma_y^j}(\omega))\right) \simeq \sum_{p=2^{n-1}}^{2^n-1} f_{R_p^n/i}(\omega). \tag{A21}$$

Proof: If the following relations hold for all $m, (2 \leqslant m \leqslant n)$,

$$\mathrm{Re}\left(\prod_{j=1}^{m}(f_{\sigma_x^j}(\omega)+if_{\sigma_y^j}(\omega))\right) \simeq \sum_{p=2^{m-1}}^{2^m-1} f_{O_p^m}(\omega), \tag{A22}$$

$$\mathrm{Im}\left(\prod_{j=1}^{m}(f_{\sigma_x^j}(\omega)+if_{\sigma_y^j}(\omega))\right) \simeq \sum_{p=2^{m-1}}^{2^m-1} f_{R_p^m/i}(\omega), \tag{A23}$$

then the theorem holds. Here, $f_{O_p^m}$ means $f_{O_p^m \otimes_{j=m+1}^{n} I^j}$ and so on.

In the case where $m=2$: LHS of (A22) is $f_{(\sigma_x^1\sigma_x^2)\otimes_{j=3}^{n} I^j}+f_{(i\sigma_y^1 i\sigma_y^2)\otimes_{j=3}^{n} I^j}$ almost everywhere and RHS of (A22) is $f_{(\sigma_x^1\sigma_x^2)\otimes_{j=3}^{n} I^j}+f_{(i\sigma_y^1 i\sigma_y^2)\otimes_{j=3}^{n} I^j}$. LHS of (A23) is $f_{(\sigma_x^1\sigma_y^2)\otimes_{j=3}^{n} I^j}+f_{(\sigma_y^1\sigma_x^2)\otimes_{j=3}^{n} I^j}$ almost everywhere and RHS of (A23) is $f_{(\sigma_x^1\sigma_y^2)\otimes_{j=3}^{n} I^j}+f_{(\sigma_y^1\sigma_x^2)\otimes_{j=3}^{n} I^j}$. Therefore (A22) and (A23) hold when $m=2$. Here, we have used PROD A.E.. In the following, if possible, we omit the identity operator.

Suppose that (A22) and (A23) hold for $m=k-1$. Then we have

$$\prod_{j=1}^{k-1}(f_{\sigma_x^j}+if_{\sigma_y^j}) \simeq \sum_{p=2^{k-2}}^{2^{k-1}-1} f_{O_p^{k-1}} + \sum_{p=2^{k-2}}^{2^{k-1}-1} if_{R_p^{k-1}/i},$$
$$\prod_{j=1}^{k-1}(f_{\sigma_x^j}-if_{\sigma_y^j}) \simeq \sum_{p=2^{k-2}}^{2^{k-1}-1} f_{O_p^{k-1}} - \sum_{p=2^{k-2}}^{2^{k-1}-1} if_{R_p^{k-1}/i}. \tag{A24}$$

FUNC A.E. says

$$(-1)f_A(\omega) \simeq f_{(-1)A}(\omega). \tag{A25}$$

PROD A.E. says

$$f_{O_p^{k-1}} f_{\sigma_x^k} \simeq f_{O_p^{k-1}\sigma_x^k} \tag{A26}$$

and so on. Hence, we have

$$
\begin{aligned}
&(f_{\sigma_x^k}+if_{\sigma_y^k})\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}}+\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}/i}\right)\\
&\quad=\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}}f_{\sigma_x^k}+\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}/i}if_{\sigma_y^k}\right)+\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}}if_{\sigma_y^k}+\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}/i}f_{\sigma_x^k}\right)\\
&\quad\simeq\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}\sigma_x^k}+\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{R_p^{k-1}i\sigma_y^k}\right)+\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{O_p^{k-1}i\sigma_y^k/i}+\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}\sigma_x^k/i}\right)\\
&\quad=\sum_{p=2^{k-1}}^{2^k-1}f_{O_p^k}+\sum_{p=2^{k-1}}^{2^k-1}if_{R_p^k/i}
\end{aligned}
\tag{A27}
$$

and

$$
\begin{aligned}
&(f_{\sigma_x^k}-if_{\sigma_y^k})\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}}-\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}/i}\right)\\
&\quad=\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}}f_{\sigma_x^k}+\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}/i}if_{\sigma_y^k}\right)-\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}}if_{\sigma_y^k}+\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}/i}f_{\sigma_x^k}\right)\\
&\quad\simeq\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{O_p^{k-1}\sigma_x^k}+\sum_{p=2^{k-2}}^{2^{k-1}-1}f_{R_p^{k-1}i\sigma_y^k}\right)-\left(\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{O_p^{k-1}i\sigma_y^k/i}+\sum_{p=2^{k-2}}^{2^{k-1}-1}if_{R_p^{k-1}\sigma_x^k/i}\right)\\
&\quad=\sum_{p=2^{k-1}}^{2^k-1}f_{O_p^k}-\sum_{p=2^{k-1}}^{2^k-1}if_{R_p^k/i}.
\end{aligned}
\tag{A28}
$$

Therefore we have

$$
\begin{aligned}
\prod_{j=1}^{k}(f_{\sigma_x^j}+if_{\sigma_y^j})&\simeq\sum_{p=2^{k-1}}^{2^k-1}f_{O_p^k}+\sum_{p=2^{k-1}}^{2^k-1}if_{R_p^k/i},\\
\prod_{j=1}^{k}(f_{\sigma_x^j}-if_{\sigma_y^j})&\simeq\sum_{p=2^{k-1}}^{2^k-1}f_{O_p^k}-\sum_{p=2^{k-1}}^{2^k-1}if_{R_p^k/i}.
\end{aligned}
\tag{A29}
$$

This implies that (A22) and (A23) hold for $m=k$. QED

APPENDIX B

Lemma: Let S_A stand for the spectrum of the Hermitian operator A. If

$$
\mathrm{Tr}[\psi A]=\sum_{y\in S_A}\mathrm{Prob}(\{y\})^{\psi}_{\theta(A)}y,
$$

$$
E_{\psi}(A):=\int_{\omega\in\Omega}\mu_{\psi}(\mathrm{d}\omega)f_A(\omega),
$$

then

$$\mathrm{HV} \wedge \mathrm{D} \Rightarrow \mathrm{Tr}[\psi A] = E_{\psi}(A). \tag{B1}$$

Proof: Note

$$\omega \in f_A^{-1}(\{y\}) \Leftrightarrow f_A(\omega) \in \{y\} \Leftrightarrow y = f_A(\omega),$$

$$\int_{\omega \in f_A^{-1}(\{y\})} \frac{\mu_{\psi}(\mathrm{d}\omega)}{\mu_{\psi}(f_A^{-1}(\{y\}))} = 1,$$

$$y \neq y' \Rightarrow f_A^{-1}(\{y\}) \cap f_A^{-1}(\{y'\}) = \phi. \tag{B2}$$

Hence we have

$$\begin{aligned}
\mathrm{Tr}[\psi A] &= \sum_{y \in S_A} \mathrm{Prob}(\{y\})^{\psi}_{\theta(A)} y = \sum_{y \in \mathbf{R}} \mathrm{Prob}(\{y\})^{\psi}_{\theta(A)} y = \sum_{y \in \mathbf{R}} \mu_{\psi}(f_A^{-1}(\{y\}))y \\
&= \sum_{y \in \mathbf{R}} \mu_{\psi}(f_A^{-1}(\{y\}))y \int_{\omega \in f_A^{-1}(\{y\})} \frac{\mu_{\psi}(\mathrm{d}\omega)}{\mu_{\psi}(f_A^{-1}(\{y\}))} \\
&= \sum_{y \in \mathbf{R}} \int_{\omega \in f_A^{-1}(\{y\})} \mu_{\psi}(f_A^{-1}(\{y\})) \frac{\mu_{\psi}(\mathrm{d}\omega)}{\mu_{\psi}(f_A^{-1}(\{y\}))} f_A(\omega) = \int_{\omega \in \Omega} \mu_{\psi}(\mathrm{d}\omega) f_A(\omega) = E_{\psi}(A).
\end{aligned} \tag{B3}$$

QED

Lemma:

$$\chi_{\Delta}(g(x)) = \chi_{g^{-1}(\Delta)}(x), (x \in \mathbf{R})$$

and

$$\mathrm{Prob}(\Delta)^{\psi}_{\theta(g(A))} = \mathrm{Tr}[\psi \chi_{\Delta}(g(A))] = \mathrm{Tr}[\psi \chi_{g^{-1}(\Delta)}(A)] = \mathrm{Prob}(g^{-1}(\Delta))^{\psi}_{\theta(A)}. \tag{B4}$$

Proof: Obvious.
Lemma:

$$\mathrm{QJD} \Rightarrow \mathrm{BSF},$$

$$\mathrm{HV} \wedge \mathrm{JD} \Rightarrow \mathrm{HV} \wedge \mathrm{D} \tag{B5}$$

Proof: Obvious.
Theorem:[6]

$$\mathrm{HV} \wedge \mathrm{JD} \Rightarrow \mathrm{HV} \wedge \mathrm{D} \wedge \mathrm{FUNC\ A.E.} \tag{B6}$$

Proof: Suppose JD holds. Let y be any real number, and let $S := \{\omega | f_{g(A)}(\omega) = y\}$ and $T := \{\omega | g(f_A(\omega)) = y\}$. We want $\mu_{\psi}(\bar{S} \cap T) = \mu_{\psi}(S \cap \bar{T}) = 0$. This is valid if we have $\mu_{\psi}(S) = \mu_{\psi}(T) = \mu_{\psi}(S \cap T)$ since

$$\begin{aligned}
\mu_{\psi}(S \cap \bar{T}) + \mu_{\psi}(S \cap T) &= \mu_{\psi}(S), \\
\mu_{\psi}(\bar{S} \cap T) + \mu_{\psi}(S \cap T) &= \mu_{\psi}(T).
\end{aligned} \tag{B7}$$

Note

$$\omega \in f_{g(A)}^{-1}(\{y\}) \Leftrightarrow f_{g(A)}(\omega) \in \{y\} \Leftrightarrow y = f_{g(A)}(\omega) \tag{B8}$$

and

$$\omega \in f_A^{-1}(g^{-1}(\{y\})) \Leftrightarrow f_A(\omega) \in g^{-1}(\{y\}) \Leftrightarrow g(f_A(\omega)) \in \{y\} \Leftrightarrow y = g(f_A(\omega)). \tag{B9}$$

The lemma (B5) says that JD yields D. Then, from the lemma (B4), we have

$$\begin{aligned}\mu_\psi(T) &= \mu_\psi(\{\omega | \omega \in f_A^{-1}(g^{-1}(\{y\}))\}) \\ &= \mathrm{Prob}(g^{-1}(\{y\}))_{\theta(A)}^{\psi} = \mathrm{Prob}(\{y\})_{\theta(g(A))}^{\psi} = \mu_\psi(\{\omega | \omega \in f_{g(A)}^{-1}(\{y\})\}) = \mu_\omega(S).\end{aligned} \tag{B10}$$

Using the spectral representation of A, it follows that $\chi_\Delta(A)\chi_{g(\Delta)}(g(A)) = \chi_\Delta(A)$ for any set Δ, where $g(\Delta) = \{g(x) | x \in \Delta\}$. Because, $\chi_\Delta(z) = 1 \Leftrightarrow z \in \Delta \Rightarrow g(z) \in g(\Delta) \Leftrightarrow \chi_{g(\Delta)}(g(z)) = 1$ holds ($z \in \mathbf{R}$). Hence,

$$\mathrm{Prob}(\Delta, g(\Delta))_{\theta(A),\theta(g(A))}^{\psi} = \mathrm{Tr}[\psi\chi_\Delta(A)\chi_{g(\Delta)}(g(A))] = \mathrm{Tr}[\psi\chi_\Delta(A)] = \mathrm{Prob}(\Delta)_{\theta(A)}^{\psi}. \tag{B11}$$

On the other hand, we have $g(g^{-1}(\Delta)) = \Delta$ because $g(g^{-1}(\Delta)) = \{g(x) | x \in g^{-1}(\Delta)\} = \{g(x) | g(x) \in \Delta\} = \Delta$. Therefore, on substituting $g^{-1}(\{y\})$ into Δ, we have

$$\mathrm{Prob}(g^{-1}(\{y\}), \{y\})_{\theta(A),\theta(g(A))}^{\psi} = \mathrm{Prob}(g^{-1}(\{y\}))_{\theta(A)}^{\psi} = \mu_\psi(T). \tag{B12}$$

But, from JD we have

$$\mathrm{Prob}(g^{-1}(\{y\}), \{y\})_{\theta(A),\theta(g(A))}^{\psi} = \mu_\psi(f_A^{-1}(g^{-1}(\{y\})) \cap f_{g(A)}^{-1}(\{y\})) = \mu_\psi(T \cap S). \tag{B13}$$

QED

Theorem:[6]

$$\mathrm{HV} \wedge \mathrm{FUNC\ A.E.} \Rightarrow \mathrm{HV} \wedge \mathrm{PROD\ A.E.} \tag{B14}$$

Proof: Suppose that A and B are two commuting Hermitian operators. This means that there exists a basis $\{P_i\}$ by which we can expand $A = \Sigma_i a_i P_i$, and such that B can also be expanded in the form $B = \Sigma_i b_i P_i$. Now construct a Hermitian operator $O := \Sigma_i o_i P_i$ with real numbers o_i. None of them is equal. Namely, O is assumed to be nondegenerate by construction. Let us define functions j and k by $j(o_i) := a_i$ and $k(o_i) := b_i$, respectively. Then we can see that if A and B commute, there exists a nondegenerate Hermitian operator O such that $A = j(O)$ and $B = k(O)$. Therefore, we can introduce a function h such that $AB = h(O)$ where $h := j \cdot k$. So we have the following:

$$f_{AB}(\omega) = f_{h(O)}(\omega) \simeq h(f_O(\omega)) = j(f_O(\omega)) \cdot k(f_O(\omega)) \simeq f_{j(O)}(\omega) \cdot f_{k(O)}(\omega) = f_A(\omega) \cdot f_B(\omega), \tag{B15}$$

where FUNC A.E. has been used. QED

Lemma:[7] If

$$\mu_\psi(\bar{S} \cap S') = \mu_\psi(\overline{S'} \cap S) = \mu_\psi(\bar{T} \cap T') = \mu_\psi(\overline{T'} \cap T) = 0,$$

then

$$\mu_\psi(S \cap T) = \mu_\psi(S' \cap T'). \tag{B16}$$

Proof: Note

$$\mu_\psi(\bar{S} \cap S' \cap T) + \mu_\psi(S \cap S' \cap T) = \mu_\psi(S' \cap T), \tag{B17}$$

$$\mu_\psi(\overline{S'} \cap S \cap T) + \mu_\psi(S \cap S' \cap T) = \mu_\psi(S \cap T).$$

If the following relation holds

$$\mu_\psi(\bar{S} \cap S') = \mu_\psi(\overline{S'} \cap S) = 0, \tag{B18}$$

then

$$\mu_\psi(\bar{S} \cap S' \cap T) = \mu_\psi(\overline{S'} \cap S \cap T) = 0. \tag{B19}$$

Therefore, from (B17), we have

$$\mu_\psi(S \cap S' \cap T) = \mu_\psi(S' \cap T) = \mu_\psi(S \cap T). \tag{B20}$$

Similar to the argument by changing S to T, S' to T', and T to S', we get

$$\mu_\psi(T \cap T' \cap S') = \mu_\psi(T' \cap S') = \mu_\psi(T \cap S'). \tag{B21}$$

From the relations (B20) and (B21), we conclude

$$\mu_\psi(T \cap S) = \mu_\psi(T' \cap S'). \tag{B22}$$

QED

Lemma:

$$\text{HV} \wedge \text{PROD A.E.} \Rightarrow f_{\chi_\Delta(A)}(\omega) \in \{0,1\}, \quad (\mu_\psi - \text{a.e.}). \tag{B23}$$

Proof: Obvious.

Theorem:[7]

$$\text{HV} \wedge \text{D} \wedge \text{PROD A.E.} \Rightarrow \text{HV} \wedge \text{JD} \tag{B24}$$

Proof: Suppose $[A,B]=\mathbf{0}$ holds. It follows from QJD, BSF, and D that

$$\begin{aligned}\text{Prob}(\Delta,\Delta')^{\psi}_{\theta(A),\theta(B)} &= \text{Tr}[\psi\chi_\Delta(A)\chi_{\Delta'}(B)] = \text{Tr}[\psi\chi_{\{1\}}(\chi_\Delta(A)\chi_{\Delta'}(B))] = \text{Prob}(\{1\})^{\psi}_{\theta(\chi_\Delta(A)\chi_{\Delta'}(B))} \\ &= \mu_\psi(f^{-1}_{\chi_\Delta(A)\chi_{\Delta'}(B)}(\{1\})).\end{aligned} \tag{B25}$$

PROD A.E. and the lemma (B23) say that

$$\begin{aligned}(\text{B25}) &= \mu_\psi(\{\omega|\omega \in f^{-1}_{\chi_\Delta(A)\chi_{\Delta'}(B)}(\{1\})\}) = \mu_\psi(\{\omega|f_{\chi_\Delta(A)\chi_{\Delta'}(B)}(\omega)=1\}) = \mu_\psi(\{\omega|f_{\chi_\Delta(A)}(\omega)\cdot f_{\chi_{\Delta'}(B)}(\omega) \\ &= 1\}) = \mu_\psi(\{\omega|f_{\chi_\Delta(A)}(\omega) = f_{\chi_{\Delta'}(B)}(\omega)=1\}) = \mu_\psi(f^{-1}_{\chi_\Delta(A)}(\{1\}) \cap f^{-1}_{\chi_{\Delta'}(B)}(\{1\})).\end{aligned} \tag{B26}$$

On the other hand, we have

$$\begin{aligned}\mu_\psi(f^{-1}_{\chi_\Delta(A)}(\{1\}) \cap f_A^{-1}(\Delta)) &= \mu_\psi(\{\omega|f_{\chi_\Delta(A)}(\omega) = 1 \wedge f_A(\omega) \in \Delta\}) = \mu_\psi(\{\omega|f_{\chi_\Delta(A)}(\omega)\cdot f_A(\omega) \in \Delta\}) \\ &= \mu_\psi(\{\omega|f_{\chi_\Delta(A)\cdot A}(\omega) \in \Delta\}) = \mu_\psi(f^{-1}_{\chi_\Delta(A)\cdot A}(\Delta)) = \text{Prob}(\Delta)^{\psi}_{\theta(\chi_\Delta(A)\cdot A)} \\ &= \text{Tr}[\psi\chi_\Delta(\chi_\Delta(A)\cdot A)] = \text{Tr}[\psi\chi_\Delta(A)].\end{aligned} \tag{B27}$$

We also obtain

$$\mu_\psi(f^{-1}_{\chi_\Delta(A)}(\{1\})) = \text{Tr}[\psi\chi_{\{1\}}(\chi_\Delta(A))] = \text{Tr}[\psi\chi_\Delta(A)] = \mu_\psi(f_A^{-1}(\Delta)). \tag{B28}$$

Note [see (B7)]

$$\mu_\psi(S \cap T) = \mu_\psi(S) = \mu_\psi(T) \Leftrightarrow \mu_\psi(S \cap \bar{T}) = \mu_\psi(\bar{S} \cap T) = 0. \tag{B29}$$

Therefore, from Eq. (B27) and Eq. (B28), we have

$$\mu_\psi(f^{-1}_{\chi_\Delta(A)}(\{1\}) \cap \overline{f_A^{-1}(\Delta)}) = \mu_\psi(\overline{f^{-1}_{\chi_\Delta(A)}(\{1\})} \cap f_A^{-1}(\Delta)) = 0. \tag{B30}$$

Similarly we can get

$$\mu_\psi(f^{-1}_{\chi_{\Delta'}(B)}(\{1\}) \cap f_B^{-1}(\Delta')) = \mathrm{Tr}[\psi\chi_{\Delta'}(B)], \quad \mu_\psi(f^{-1}_{\chi_{\Delta'}(B)}(\{1\})) = \mu_\psi(f_B^{-1}(\Delta')) = \mathrm{Tr}[\psi\chi_{\Delta'}(B)], \tag{B31}$$

and we have

$$\mu_\psi(f^{-1}_{\chi_{\Delta'}(B)}(\{1\}) \cap \overline{f_B^{-1}(\Delta')}) = \mu_\psi(\overline{f^{-1}_{\chi_{\Delta'}(B)}(\{1\})} \cap f_B^{-1}(\Delta')) = 0. \tag{B32}$$

Hence, from the lemma (B16), we have

$$\mu_\psi(f^{-1}_{\chi_\Delta(A)}(\{1\}) \cap f^{-1}_{\chi_{\Delta'}(B)}(\{1\})) = \mu_\psi(f_A^{-1}(\Delta) \cap f_B^{-1}(\Delta')). \tag{B33}$$

Therefore, from (B26), we conclude

$$\mathrm{Prob}(\Delta,\Delta')^{\psi}_{\theta(A),\theta(B)} = \mu_\psi(f_A^{-1}(\Delta) \cap f_B^{-1}(\Delta')), \tag{B34}$$

which is JD. QED

Theorem:[6]

$$\mathrm{HV} \wedge \mathrm{D} \wedge \mathrm{FUNC\ A.E.} \Rightarrow \mathrm{HV} \wedge \mathrm{JD} \tag{B35}$$

Proof: Suppose $[A,B]=\mathbf{0}$ holds. It follows from BSF, QJD, D, FUNC A.E., and PROD A.E. that

$$\begin{aligned}
\mathrm{Prob}(\Delta,\Delta')^{\psi}_{\theta(A),\theta(B)} &= \mathrm{Tr}[\psi\chi_\Delta(A)\chi_{\Delta'}(B)] = \mathrm{Tr}[\psi\chi_{\{1\}}(\chi_\Delta(A)\chi_{\Delta'}(B))] = \mathrm{Prob}(\{1\})^{\psi}_{\theta(\chi_\Delta(A)\chi_{\Delta'}(B))} \\
&= \mu_\psi(f^{-1}_{\chi_\Delta(A)\chi_{\Delta'}(B)}(\{1\})) = \mu_\psi(\{\omega|\omega \in f^{-1}_{\chi_\Delta(A)\chi_{\Delta'}}(\{1\})\}) = \mu_\psi(\{\omega|f_{\chi_\Delta(A)\chi_{\Delta'}(B)}(\omega) \\
&= 1\}) = \mu_\psi(\{\omega|f_{\chi_\Delta(A)}(\omega) \cdot f_{\chi_{\Delta'}(B)}(\omega) = 1\}) = \mu_\psi(\{\omega|\chi_\Delta(f_A(\omega)) \cdot \chi_{\Delta'}(f_B(\omega)) = 1\}) \\
&= \mu_\psi(\{\omega|\chi_\Delta(f_A(\omega)) = \chi_{\Delta'}(f_B(\omega)) = 1\}) = \mu_\psi(\{\omega|f_A(\omega) \in \Delta \wedge f_B(\omega) \in \Delta'\}) \\
&= \mu_\psi(f_A^{-1}(\Delta) \cap f_B^{-1}(\Delta')).
\end{aligned} \tag{B36}$$

QED

Now we summarize the inclusion relation as follows:

$$\mathrm{HV} \wedge \mathrm{JD} \Leftrightarrow \mathrm{HV} \wedge \mathrm{D} \wedge \mathrm{FUNC\ A.E.} \Leftrightarrow \mathrm{HV} \wedge \mathrm{D} \wedge \mathrm{PROD\ A.E.} \tag{B37}$$

[21] We know that every proposition is true if the presupposition is false [see Eq. (3.6)]. Therefore, one might think that theorem (4.2) and theorem (5.16) are trivial. However, this is not the matter of our argument. We have used a quantum mechanical rule $\sigma_x^1\sigma_x^2\sigma_y^1\sigma_y^2\sigma_z^1\sigma_z^2=-I$ in the proof of the theorem (3.6). But, we have not used the quantum mechanical rule in the proof of the theorem (4.2). Likewise, a quantum mechanical rule $\sigma_x^i\sigma_y^j\sigma_y^i\sigma_x^j\sigma_z^i\sigma_z^j=I$, $(i,j\in\mathbf{N}_n, i\neq j)$ is needless to prove the theorem (5.16), while we have used the quantum mechanical rule in the proof of the theorem (3.6). Obviously, $\sigma_x^i\sigma_y^j\sigma_y^k\sigma_y^i\sigma_x^j\sigma_y^k\sigma_y^i\sigma_y^j\sigma_x^k\sigma_x^i\sigma_x^j\sigma_x^k=-I$, $(i,j,k\in\mathbf{N}_n, i\neq j\neq k\neq i)$ is needless to prove the theorem (5.16). Of course, Gleason's theorem is needless. Therefore, we can derive these inequalities (4.2) and (5.16) from more precise and weaker presupposition which should not be necessarily false.

Real trajectories in the semiclassical coherent state propagator

Marcel Novaes[a)]

(Received 13 July 2005; accepted 26 July 2005; published online 12 October 2005)

The semiclassical approximation to the coherent state propagator requires complex classical trajectories in order to satisfy the associated boundary conditions, but finding these trajectories in practice is a difficult task that may compromise the applicability of the approximation. In this work several approximations to the coherent state propagator are derived that make use only of real trajectories, which are easier to handle and have a more direct physical interpretation. It is verified in a particular example that these real trajectories approximations may have excellent accuracy. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2038608]

I. INTRODUCTION

The path integral representation of the coherent state propagator $K(z_1,z_2,T)=\langle z_2|e^{-iHT/\hbar}|z_1\rangle$, where the $|z_i\rangle$ are the usual harmonic oscillator coherent states, appeared in the works of Klauder and collaborators[1,2] and of Weissman.[3] A semiclassical, or stationary phase, approximation leads to classical trajectories satisfying Hamilton equations of motion but subject to special boundary conditions that can only be satisfied in a complex phase space. Aguiar and Baranger also considered this problem[4] and discovered an extra term, which they called $\mathcal{I}$, in the semiclassical approximation that had been overlooked in previous studies and that turns out to be essential for a correct theory[5] (the semiclassical spin propagator has a similar term,[6] known as the Solari-Kochetov correction). Numerical calculations involving complex trajectories in the semiclassical coherent state propagator have been done for a variety of systems: Adachi considered a one-dimensional (1D) and time-dependent problem with chaotic dynamics;[7] Rubin and Klauder,[2] as well as Xavier and Aguiar,[8] have treated 1D bound systems; 1D tunneling was considered in Ref. 9 and also in Ref. 10; Van Voorhis and Heller presented calculations for one and two dimensions[11] and for the N-dimensional Henon-Heiles potential;[12] Ribeiro *et al.* have worked with the two-dimensional chaotic Nelson potential[13] (numerical applications involving the spin coherent states have also appeared[14]). Semiclassical approximations based on complex trajectories for the coordinate wave function, i.e., for the mixed representation $K(x,z,T)=\langle x|e^{-iHT/\hbar}|z\rangle$, were also developed, initially for the one-dimensional case[15–17] and then generalized to many dimensions.[18] The actual calculation of complex trajectories involves two difficulties: first, the effective dimensionality of the phase space is doubled, since both real and imaginary parts of position and momentum must be computed; second, the boundary conditions are defined part at initial time and part at final time, and finding the appropriate classical trajectory becomes a difficult problem known as "root search." Therefore approximations that make use only of real trajectories are certainly desirable.

Since the propagator $K(z_1,z_2,T)$ is a function of time, any complex trajectory that satisfies the boundary conditions at time T must belong to a whole "branch" of trajectories, parametrized by T. In general, for a given system and for fixed values of z_1 and z_2 there are several such branches. In practice, once a solution is found for a particular value of T, one may obtain all elements of the same branch by making small steps forward or backward in time and using appropriate iteractive

[a)]Electronic mail: mnovaes@ifi.unicamp.br

procedures. It may happen that for a certain value of time a relevant complex trajectory has a small (or even null) imaginary part, and in that case its branch was called "nearly real" by Van Voorhis and Heller.[11,12] It is possible that more than one "nearly real" branch contribute to the semiclassical propagator for a given time, and thus one may consider only these branches and still accurately reproduce interference effects.

A similar analysis can be made for the mixed propagator $K(x,z,T)$, but in this case one usually holds T fixed and considers x as a parameter. Varying x thus produces a "family" of trajectories, and again there may exist several such families. However, there is always a value of x for which the involved trajectory is real, and its family was called the "main family" by Aguiar *et al.*[16] Using the main contribution alone is sometimes a very good approximation, but it cannot reproduce interference because only one trajectory enters the calculation at a time. On the other hand, as already noted, finding all the necessary complex trajectories (i.e., performing the "root search") is usually a difficult problem, especially in more than one dimension. Therefore the possibility was considered[16,18] of employing only real trajectories in the semiclassical approximation to $K(x,z,T)$. This was done by approximating the complex trajectories by real ones, that are compatible with the quantum uncertainties and satisfy less restrictive boundary conditions. The final real trajectories approximations are in principle less accurate than the original complex one, but they are much simpler and sometimes have practically the same accuracy.[16,18]

The purpose of the present work is to present semiclassical approximations to $K(z_1,z_2,T)$ that are based only on real classical trajectories, thus making the calculation much more tractable. One method that accomplishes exactly this is the "cellular dynamics," initially developed by Heller[19] (see also Ref. 20) and later generalized and applied to the stadium billiard with great success.[21] This technique has shown to be accurate even for long times,[21,22] and it is actually very close in spirit to the present work, in the sense that the contribution of a complex classical trajectory is expanded to second order in the vicinity of a real one. However, Heller's starting point is the Van-Vleck-Gutzwiller formula for the semiclassical propagator,[23] while we start from the formulation of Baranger *et al.*,[5] and our results are slightly different from those of Heller. We also consider a variety of boundary conditions that the real trajectories may satisfy, something not discussed at length in Ref. 21.

Another approach to the semiclassical coherent state propagator that is based on real trajectories is the so-called initial value representations, such as that of Herman and Kluk.[24] Recent reviews of this method can be found in Ref. 25. Initial value methods are usually easy to apply and reasonably accurate for long times, but they require a numerical integration over all possible initial conditions. Since the present method requires only a few trajectories, at least for short times, it provides a much clearer physical picture.

This article is divided as follows. In the next section we give a brief account of the semiclassical approximation to the coherent state propagator $K(z_1,z_2,T)$ and the complex trajectories. In Sec. III we present the approximations that are based on the real trajectories defined by z_1 or by z_2. Real trajectories that satisfy mixed boundary conditions are investigated in Sec. IV. We present an application to a nonlinear oscillator in Secs. V and VI and we conclude in Sec. VII.

II. THE SEMICLASSICAL COHERENT STATE PROPAGATOR

The coherent states of a harmonic oscillator of mass m and angular frequency ω are defined by

$$|z\rangle = \exp\{za^\dagger - z^* a\}|0\rangle, \tag{2.1}$$

where $|0\rangle$ is the oscillator ground state. The operators $a^\dagger$ and a are, respectively, creation and annihilation operators, related to position Q and momentum P by

$$a = \frac{1}{\sqrt{2}}\left(\frac{Q}{b} + i\frac{P}{c}\right), \quad a^\dagger = \frac{1}{\sqrt{2}}\left(\frac{Q}{b} - i\frac{P}{c}\right). \tag{2.2}$$

The parameters b and c define natural scales of the problem, and are such that $bc=\hbar$ and $c/b=m\omega$. It is easy to see that if we write

$$z = \frac{1}{\sqrt{2}}\left(\frac{q}{b} + i\frac{p}{c}\right) \tag{2.3}$$

then q and p are average values,

$$\langle z|Q|z\rangle = q, \quad \langle z|P|z\rangle = p. \tag{2.4}$$

The parameters b and c are related to quantum uncertainties,

$$\Delta Q = \frac{b}{\sqrt{2}}, \quad \Delta P = \frac{c}{\sqrt{2}}, \tag{2.5}$$

and we see that coherent states are minimum uncertainty states.

These coherent states are never orthogonal,

$$\langle z_2|z_1\rangle = \exp\left\{-\tfrac{1}{2}|z_1|^2 - \tfrac{1}{2}|z_2|^2 + z_1 z_2^*\right\}, \tag{2.6}$$

and in the position representation they are Gaussians,

$$\langle x|z\rangle = \pi^{-1/4} b^{-1/2} \exp\left\{-\frac{(x-q)^2}{2b^2} + \frac{i}{\hbar}p(x-q)\right\}. \tag{2.7}$$

In terms of the usual basis of number states $|n\rangle$, defined such that $a^\dagger a|n\rangle = n|n\rangle$, the coherent states may be written as

$$|z\rangle = e^{-|z|^2/2} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{n!}}|n\rangle. \tag{2.8}$$

It is easy to see that they are eigenstates of the annihilation operator, $a|z\rangle = z|z\rangle$.

In order to write the semiclassical approximation to the quantum coherent state propagator

$$K(z_1, z_2, T) = \langle z_2|e^{-iHT/\hbar}|z_1\rangle, \tag{2.9}$$

we must consider a complex version of the phase space, i.e., we must make use of a coordinate $q(t)$ and a momentum $p(t)$ that are complex numbers. Following the approach of Ref. 5 we define

$$u(t) = \frac{1}{\sqrt{2}}\left(\frac{q(t)}{b} + i\frac{p(t)}{c}\right), \quad v(t) = \frac{1}{\sqrt{2}}\left(\frac{q(t)}{b} - i\frac{p(t)}{c}\right). \tag{2.10}$$

It is of fundamental importance to realize that $v(t)$ is not the complex conjugate of $u(t)$. In terms of these variables the boundary conditions become

$$u(0) = u' = z_1, \quad v(T) = v'' = z_2^*. \tag{2.11}$$

There is nothing special about the values $u(T) = u''$ and $v(0) = v'$, they are to be determined dynamically. We use hereafter a prime (double prime) to denote initial (final) values, in order to simplify the formulas and stay close to the notation of Ref. 5.

The canonical semiclassical coherent state propagator is

$$K_{\mathrm{sc}}(z_1, z_2, T) = \mathcal{N} \sum_{\mathrm{c.t.}} \sqrt{\frac{i}{\hbar}\frac{\partial^2 S}{\partial u' \, \partial v''}} \exp\left\{\frac{i}{\hbar}(S + \mathcal{I})\right\}, \tag{2.12}$$

where $\mathcal{N} = \exp\left\{-\frac{1}{2}|z_1|^2 - \frac{1}{2}|z_2|^2\right\}$ is a normalization factor, the summation is over all classical trajectories satisfying the boundary conditions, and the complex action is given by

$$S(u',v'',T)=\int_0^T dt\left[\frac{i\hbar}{2}(\dot{u}v-\dot{v}u)-\mathcal{H}\right]-\frac{i\hbar}{2}(u'v'-u''v''). \tag{2.13}$$

This is related to the usual Hamilton action

$$S_H=\int_0^T (p\dot{q}-\mathcal{H})dt \tag{2.14}$$

by

$$S=S_H-\frac{q'p'-q''p''}{2}-\frac{i\hbar}{2}(u'v'-u''v''). \tag{2.15}$$

The Hamiltonian that governs the classical movement according to the usual Hamilton equations

$$\dot{q}=\frac{\partial\mathcal{H}}{\partial p},\quad \dot{p}=-\frac{\partial\mathcal{H}}{\partial q}, \tag{2.16}$$

is the average value of the quantum Hamiltonian in coherent states,

$$\mathcal{H}=\langle z|H|z\rangle, \tag{2.17}$$

which is sometimes called the smoothed Hamiltonian. The quantity $\mathcal{I}$ is related to its second derivative,

$$\mathcal{I}=\frac{1}{2}\int_0^T \frac{\partial^2\mathcal{H}}{\partial u\,\partial v}\mathrm{d}t. \tag{2.18}$$

The prefactor in (2.12) can be written only in terms of the complex tangent matrix. The classical tangent matrix of a certain trajectory is the linear application that relates initial and final displacements about it. We take into account the quantum uncertainties to define it as follows:

$$\begin{pmatrix}\delta q''/b\\ \delta p''/c\end{pmatrix}=\begin{pmatrix}m_{qq} & m_{qp}\\ m_{pq} & m_{pp}\end{pmatrix}\begin{pmatrix}\delta q'/b\\ \delta p'/c\end{pmatrix}. \tag{2.19}$$

The complex tangent matrix, on the other hand, is defined as

$$\begin{pmatrix}\delta u''\\ \delta v''\end{pmatrix}=\begin{pmatrix}M_{uu} & M_{uv}\\ M_{vu} & M_{vv}\end{pmatrix}\begin{pmatrix}\delta u'\\ \delta v'\end{pmatrix}. \tag{2.20}$$

The relation between the matrix elements of these different representations is as follows:

$$2M_{uu}=m_{qq}+m_{pp}+im_{pq}-im_{qp}, \tag{2.21}$$

$$2M_{uv}=m_{qq}-m_{pp}+im_{pq}+im_{qp}, \tag{2.22}$$

$$2M_{vu}=m_{qq}-m_{pp}-im_{pq}-im_{qp}, \tag{2.23}$$

$$2M_{vv}=m_{qq}+m_{pp}-im_{pq}+im_{qp}. \tag{2.24}$$

It is possible to show that the second derivative of the complex action is given by

$$\frac{i}{\hbar}\frac{\partial^2 S}{\partial u'\,\partial v''}=\frac{1}{M_{vv}}, \tag{2.25}$$

and therefore the semiclassical coherent state propagator becomes

$$K_{\mathrm{sc}}(z_1,z_2,T)=\sum_{\mathrm{c.t.}}\frac{\mathcal{N}}{\sqrt{M_{vv}}}\exp\left\{\frac{i}{\hbar}(\mathcal{I}+S)\right\}. \tag{2.26}$$

Upon fixing z_1 and z_2, the squared modulus of this propagator may be interpreted as a time dependent transition probability. On the other hand, if we fix z_1 and T and consider z_2 as a variable then $|K(z_1,z_2,T)|^2$ is a phase space representation, a Husimi function, of the evolved state $e^{-iHT/\hbar}|z_1\rangle$.

If it happens that M_{vv} tends to zero for a certain combination of (z_1,z_2,T), then we see that the semiclassical approximation (2.26) diverges. This is called a phase space caustic[2,7,12,16] and the quadratic approximation used in the derivation of (2.26) is not valid in its vicinity. In order to obtain an uniform approximation that remains valid at caustics it is necessary to employ a conjugate application of the Bargmann representation, as discussed in Ref. 26. We shall not be concerned with caustics in this work.

III. THE "LEAVING" AND THE "ARRIVING" TRAJECTORIES

We have seen that the classical trajectories entering the semiclassical propagator are determined by mixed boundary conditions. The initial position and momentum q' and p' are not the real numbers q_1 and p_1, but rather some complex numbers such that $u'=z_1$. Conversely, the final values q'',p'' are not q_2,p_2 but are such that $v''=z_2^*$. It is in general not an easy task to find such trajectories in practice, even for simple systems. However, it may happen that the complex trajectory is close enough to a real one so that we may still obtain a reasonable result by expanding the propagator to second order in the vicinity of this real trajectory.[16,18] We investigate this problem with some detail in the next sections.

A. Leaving

Let us suppose a certain complex classical trajectory that is to be used in the calculation of the semiclassical propagator, and let us assume it is not very different from the real trajectory that starts at the point (q_1,p_1). We call this the "leaving" trajectory because it leaves the phase space point corresponding to the initial coherent state. After a time T the position and the momentum will be some real numbers (q_f,p_f), generally different from the pair (q_2,p_2). We will expand the complex action up to second order around this trajectory. If q' is the initial complex position and p' is the initial complex momentum, we may write

$$q'=q_1+\Delta q_1,\quad p'=p_1+\Delta p_1, \tag{3.1}$$

where Δq_1 and Δp_1 are assumed to be small (complex) quantities. Moreover, if q'' is the final complex position and p'' is the final complex momentum, we may write in a similar way

$$q''=q_f+\Delta q_f,\quad p''=p_f+\Delta p_f. \tag{3.2}$$

Therefore we have the approximation

$$\begin{aligned}S(u',v'',T)\approx S(z_1,v_r,T)+&\left.\frac{\partial S}{\partial q'}\right|_r\Delta q_1+\left.\frac{\partial S}{\partial p'}\right|_r\Delta p_1+\frac{1}{2}\left.\frac{\partial^2 S}{\partial q'^2}\right|_r\Delta q_1^2+\left.\frac{\partial^2 S}{\partial q'\,\partial p'}\right|_r\Delta q_1\Delta p_1\\&+\frac{1}{2}\left.\frac{\partial^2 S}{\partial p'^2}\right|_r\Delta p_1^2,\end{aligned} \tag{3.3}$$

where the subscript r means that the quantity must be evaluated at the real trajectory (therefore $v_r'=b^{-1}q_1-ic^{-1}p_1$ and $u_r''=b^{-1}q_f+ic^{-1}p_f$). In order to obtain the derivatives of the action, we resort to Eqs. (2.10) and (2.15). Noticing that

$$\left.\frac{\partial S_H}{\partial q'}\right|_r = -p_i + \frac{\partial S_H}{\partial q''}\frac{\partial q''}{\partial q'}, \qquad \left.\frac{\partial S_H}{\partial p'}\right|_r = \frac{\partial S_H}{\partial q''}\frac{\partial q''}{\partial p'}, \tag{3.4}$$

one can obtain the derivatives of the total action, which are given by

$$\left.\frac{\partial S}{\partial q'}\right|_r = -\frac{ic}{\sqrt{2}}[v_r' + (m_{qq} - im_{pq})u_r''], \qquad \left.\frac{\partial S}{\partial p'}\right|_r = \frac{b}{\sqrt{2}}[v_r' - (m_{pp} + im_{qp})u_r'']. \tag{3.5}$$

From the definition of the tangent matrix we have

$$\frac{\partial q''}{\partial q'} = m_{qq}, \quad \frac{\partial q''}{\partial p'} = \frac{b}{c}m_{qp}, \quad \frac{\partial p''}{\partial q'} = \frac{c}{b}m_{pq}, \quad \frac{\partial p''}{\partial p'} = m_{pp}, \tag{3.6}$$

which determines, to first order, the final differences in terms of the initial ones:

$$\Delta q_2 = m_{qq}\Delta q_1 + \frac{b}{c}m_{qp}\Delta p_1, \quad \Delta p_2 = \frac{c}{b}m_{pq}\Delta q_1 + m_{pp}\Delta p_1. \tag{3.7}$$

On the other hand, the boundary conditions

$$\frac{q'}{b} + i\frac{p'}{c} = \frac{q_1}{b} + i\frac{p_1}{c}, \quad \frac{q''}{b} - i\frac{p''}{c} = \frac{q_2}{b} - i\frac{p_2}{c}, \tag{3.8}$$

provide the secondary relations

$$b^{-1}[\Delta q_2 + (q_f - q_2)] = ic^{-1}[\Delta p_2 + (p_f - p_2)], \quad b^{-1}\Delta q_1 = -ic^{-1}\Delta p_1. \tag{3.9}$$

Solving for Δq_1 and Δp_1 in terms of $(q_f - q_2)$ and $(p_f - p_2)$ we have

$$\Delta q_1 = -M_{vv}^{-1}[(q_f - q_2) - ib(p_f - p_2)/c], \quad \Delta p_1 = ic\Delta q_1/b. \tag{3.10}$$

Substituting this in (3.3) one can see that the first-order terms give

$$\left.\frac{\partial S}{\partial q'}\right|_r \Delta q_1 + \left.\frac{\partial S}{\partial p'}\right|_r \Delta p_1 = -\frac{i\hbar}{\sqrt{2}}u_r''\left[\frac{q_f - q_2}{b} - i\frac{p_f - p_2}{c}\right] = -i\hbar u_r''(v_r'' - z_2^*). \tag{3.11}$$

It is easy to take derivatives of Eq. (3.5) in order to calculate the quadratic terms. In so doing we neglect derivatives of the tangent matrix elements, because this would be a higher order correction. Adding up all quadratic terms and making the proper identifications, we see that it can be related to the difference $(v_r'' - z_2^*)$ as

$$\text{quadratic terms} = -\frac{i\hbar}{2}M_{uv}M_{vv}^{-1}(v_r'' - z_2^*)^2. \tag{3.12}$$

Therefore the final result is the following:

$$K_{q_1p_1}(z_1, z_2, T) = \frac{\mathcal{N}}{\sqrt{(M_{vv})_r}}\exp\left\{\frac{i}{\hbar}(\mathcal{I}_r + S_r) + u_r''(v_r'' - z_2^*) + \frac{1}{2}\frac{M_{uv}}{M_{vv}}(v_r'' - z_2^*)^2\right\}. \tag{3.13}$$

The subscript in $K_{q_1p_1}$ denotes that this formula was obtained using the "leaving" trajectory. Notice that the prefactor and the extra term were not expanded but simply evaluated at the real trajectory, which is consistent with the original quadratic derivation of the semiclassical approximation. It is also important to remember that even though the action S_r is evaluated at a real trajectory, it continues to be a complex number.

The expression (3.13) depends quadratically on the difference between the final value of the variable v along the real trajectory and the value that it would have in the complex trajectory. If by

some reason the situation is such that v_r'' and z_2^* coincide, then this formula and the original one (2.12) will give the same result. One may argue that it is possible to obtain the same expression by expanding the action as

$$S \approx S_r + \left.\frac{\partial S}{\partial v''}\right|_r (v_r'' - z_2^*) + \frac{1}{2}\left.\frac{\partial^2 S}{\partial v''^2}\right|_r (v_r'' - z_2^*)^2. \tag{3.14}$$

This is certainly true and actually an easy calculation. We have chosen the long way of using the position/momentum variables because this will be the only possibility in the next section.

B. Arriving

What we call the "arriving" trajectory is the real trajectory that starts in a certain initial point (q_i, p_i) and after a time T arrives at the point (q_2, p_2). We can use this trajectory to approximate the semiclassical propagator in the very same way that we did with the "leaving" trajectory. Similar to the previous arguments, we write

$$q' = q_i + \Delta q_1, \quad p' = p_i + \Delta p_1, \quad q'' = q_2 + \Delta q_2, \quad p'' = p_2 + \Delta p_2. \tag{3.15}$$

Inverting Eq. (2.19) we see that

$$\frac{\partial q'}{\partial q''} = m_{pp}, \quad \frac{\partial q'}{\partial p''} = -\frac{b}{c} m_{qp}, \quad \frac{\partial p'}{\partial q''} = -\frac{c}{b} m_{pq}, \quad \frac{\partial p'}{\partial p''} = m_{qq}. \tag{3.16}$$

Using these relations we can write the initial differences in terms of the final ones, analogous to what we did in (3.7). Using the boundary conditions it is possible to show that

$$\Delta q_2 = -M_{vv}^{-1}[(q_i - q_1) + ib(p_i - p_1)/c], \quad \Delta p_2 = -ic\Delta q_2/b. \tag{3.17}$$

The first derivatives of the action are in this case given by

$$\left.\frac{\partial S}{\partial q''}\right|_r = -\frac{ic}{\sqrt{2}}[u_r'' + (m_{pp} - im_{pq})v_r'], \qquad \left.\frac{\partial S}{\partial p''}\right|_r = -\frac{b}{\sqrt{2}}[u_r'' - (m_{qq} + im_{qp})v_r']. \tag{3.18}$$

We now expand the complex action to second order around this real trajectory. After simplifications, we obtain

$$K_{q_2 p_2}(z_1, z_2, T) = \frac{\mathcal{N}}{\sqrt{(M_{vv})_r}} \exp\left\{\frac{i}{\hbar}(\mathcal{I}_r + S_r) + v_r'(u_r' - z_1) + \frac{1}{2}\frac{M_{vu}}{M_{vv}}(u_r' - z_1)^2\right\}, \tag{3.19}$$

where the meaning of the subscript is evident. This time the expression depends on the difference between the initial value of the variable u in the real trajectory and the value that it would have in the complex one. Its interpretation is quite close to that of (3.13).

IV. OTHER POSSIBLE REAL TRAJECTORIES

In the previous section we saw that we may expand the semiclassical propagator in the vicinity of the real trajectories determined by the initial or by the final labels, (q_1, p_1) and (q_2, p_2), which we called the "leaving" and the "arriving" trajectories, respectively. Although these are probably the most natural real trajectories approximations, we can devise four more possibilities that are also interesting. Of course one may use any real trajectory to build an approximation—in fact, in principle it should be possible to find the "best" choice by a variational approach, but this seems to be a highly nontrivial problem—but the idea here is to obtain explicit formulas for the most natural cases. These are the four trajectories that are determined by pairwise combination of the coherent state labels.

We shall present a detailed calculation for the case when the trajectories determined by the pair (q_1, q_2) are used. All other cases can be treated in a very similar way, and for them we shall be less explicit.

A. From q_1 to q_2

Let us consider a trajectory which satisfies the following boundary conditions: it leaves q_1 at time zero and arrives at q_2 at time T. Its initial and final momenta, p_i and p_f, remain unknown, but are real numbers. Different from the previous section, now there may be more than one trajectory satisfying these requirements. We write

$$q' = q_1 + \Delta q_1, \quad q'' = q_2 + \Delta q_2, \quad p' = p_i + \Delta p_i, \quad p'' = p_f + \Delta p_f. \tag{4.1}$$

The initial and final momenta are regarded as functions of the initial and final positions. Therefore we may write

$$\Delta p_i = \left.\frac{\partial p'}{\partial q'}\right|_r \Delta q_1 + \left.\frac{\partial p'}{\partial q''}\right|_r \Delta q_2, \quad \Delta p_f = \left.\frac{\partial p''}{\partial q'}\right|_r \Delta q_1 + \left.\frac{\partial p''}{\partial q''}\right|_r \Delta q_2, \tag{4.2}$$

where again the subscript r means that the quantity must be evaluated at the real trajectory. On the other hand the boundary conditions $u' = z_1$ and $v'' = z_2^*$ imply that

$$\Delta p_i = \frac{ic}{b}\Delta q_1 - (p_i - p_1), \quad \Delta p_f = -\frac{ic}{b}\Delta q_2 - (p_f - p_2). \tag{4.3}$$

Since we are considering q' and q'' as independent variables, the partial derivatives in (4.2) are given by

$$\frac{\partial p'}{\partial q'} = -\frac{c}{b}\frac{m_{qq}}{m_{qp}}, \quad \frac{\partial p'}{\partial q''} = \frac{c}{b}\frac{1}{m_{qp}}, \quad \frac{\partial p''}{\partial q'} = -\frac{c}{b}\frac{1}{m_{qp}}, \quad \frac{\partial p''}{\partial q''} = \frac{c}{b}\frac{m_{pp}}{m_{qp}}, \tag{4.4}$$

where we have used that $m_{qq}m_{pp} - m_{qp}m_{pq} = 1$. Substituting this in (4.2) and using (4.3) we have

$$\frac{\Delta q_1}{b} = \frac{m_{qp}}{c}\frac{[(p_f - p_2) - M_2(p_i - p_1)]}{1 - M_1 M_2}, \quad \frac{\Delta q_2}{b} = \frac{m_{qp}}{c}\frac{[M_1(p_f - p_2) - (p_i - p_1)]}{1 - M_1 M_2}, \tag{4.5}$$

where we have defined the complex numbers

$$M_1 = m_{qq} + i m_{qp}, \quad M_2 = m_{pp} + i m_{qp}. \tag{4.6}$$

We now expand the complex action around this real trajectory up to second order,

$$S \approx S_r + \left.\frac{\partial S}{\partial q'}\right|_r \Delta q_1 + \left.\frac{\partial S}{\partial q''}\right|_r \Delta q_2 + \frac{1}{2}\left.\frac{\partial^2 S}{\partial q'^2}\right|_r \Delta q_1^2 + \left.\frac{\partial^2 S}{\partial q'\,\partial q''}\right|_r \Delta q_1 \Delta q_2 + \frac{1}{2}\left.\frac{\partial^2 S}{\partial q''^2}\right|_r \Delta q_2^2. \tag{4.7}$$

Noticing that

$$\left.\frac{\partial S_H}{\partial q'}\right|_r = -p_i, \qquad \left.\frac{\partial S_H}{\partial q''}\right|_r = p_f, \tag{4.8}$$

we can obtain the derivatives of the total action,

$$\left.\frac{\partial S}{\partial q'}\right|_r = \frac{c}{\sqrt{2}m_{qp}}[u_r'' - v_r'(m_{qq} + i m_{qp})], \qquad \left.\frac{\partial S}{\partial q''}\right|_r = \frac{c}{\sqrt{2}m_{qp}}[v_r' - u_r''(m_{pp} + i m_{qp})]. \tag{4.9}$$

After simplifications, the linear terms can be written as

$$\text{linear terms} = -\frac{b}{\sqrt{2}}[v'(p_i - p_1) - u''(p_f - p_2)]. \tag{4.10}$$

We now calculate the second derivatives and substitute (4.5) in (4.7). After many simplifications, the final result can be shown to be

$$K_{q_1 q_2}(z_1, z_2, T) = \sum_{\text{c.t}} \frac{\mathcal{N}}{\sqrt{(M_{vv})_r}} \exp\left\{ \frac{i}{\hbar}(\mathcal{I}_r + S_r) + \frac{iz_2}{\sqrt{2}c}(p_f - p_2) - \frac{iz_1^*}{\sqrt{2}c}(p_i - p_1) \right\}$$
$$\times \exp\left\{ -\frac{A_1}{2c^2}(p_i - p_1)^2 - \frac{A_2}{2c^2}(p_f - p_2)^2 - \frac{A_{12}}{2c^2}(p_i - p_1)(p_f - p_2) \right\}, \tag{4.11}$$

where

$$A_1 = 1 - \frac{1}{2}\left(\frac{1 - M_1^* M_2}{1 - M_1 M_2}\right), \quad A_2 = 1 - \frac{1}{2}\left(\frac{1 - M_2^* M_1}{1 - M_1 M_2}\right), \quad A_{12} = \frac{2im_{qp}}{1 - M_1 M_2}. \tag{4.12}$$

This expression is more complicated than the ones we obtained in Sec. III. This is so because the classical trajectories involved are determined by mixed boundary conditions, i.e., their initial and final positions. Its structure is nevertheless still the same: it depends on differences between the values of the variables in the real trajectories and the corresponding coherent state labels. The most important property of this formula is that the initial momentum p_i is not known *a priori*. It must be determined as a function of the given parameters, and in fact there may be more than one possible value for it. Notice that since p_i and also p_f depend nontrivially on z_1, z_2 and T this formula is not a simple Gaussian as it may seem at first. Once again, even though the function S_r is evaluated at a real classical trajectory, it will in general be a complex number.

Notice that the differences $p_i - p_1$ and $p_f - p_2$ are always divided by the momentum uncertainty c. Therefore only classical trajectories whose initial momentum is within a distance c from p_1 may be important for the semiclassical propagator. The same reasoning applies to the final momentum. We see that the real trajectories to be used in this formalism must be compatible with the quantum uncertainty principle.

As a simple illustration of this formula, let us consider a harmonic oscillator of unit mass and angular frequency $\omega = c/b$. An initial condition (q', p') leads, after a time T, to the final values

$$q'' = q' \cos(\omega T) + \frac{p'}{\omega} \sin(\omega T), \quad p'' = -\omega q' \sin(\omega T) + p' \cos(\omega T). \tag{4.13}$$

If we impose that the trajectory must start in q_1 and end in q_2 then it is easy to see that there is only one possibility that satisfies these boundary conditions, for which

$$p_i = \frac{\omega(q_2 - q_1 \cos(\omega T))}{\sin(\omega T)}, \quad p_f = \frac{\omega(q_2 \cos(\omega T) - q_1)}{\sin(\omega T)}. \tag{4.14}$$

In this case we have $m_{qp} = \sin(\omega T)$ and $M_1 = M_2 = e^{i\omega T}$, which leads to $A_1 = A_2 = 1$ and $A_{12} = -e^{-i\omega T}$. The $e^{i\mathcal{I}_r/\hbar}$ term cancels the prefactor. Finally, using that $S_r = e^{-i\omega T}(q_1/b + ip_i/c)(q_2/b - ip_f/c)/2i$ we obtain

$$K_{q_1 q_2}(z_1, z_2, T) = \exp\left\{ -\tfrac{1}{2}(|z_1|^2 + |z_2|^2) + e^{-i\omega T} z_1 z_2^* \right\}, \tag{4.15}$$

which is precisely the exact result. This comes as no surprise since the exact action in this case is of second order to begin with and thus all semiclassical approximations we consider in this work will be exact.

B. From q_1 to p_2

We now consider the real trajectory that starts in $q'=q_1$ with a certain momentum $p'=p_i$ and, after a time T, is in a final point $q''=q_f$ with the momentum $p''=p_2$. We therefore treat q' and p'' as independent variables, in which case we have the following partial derivatives:

$$\frac{\partial p'}{\partial q'}=-\frac{c}{b}\frac{m_{pq}}{m_{pp}},\quad \frac{\partial p'}{\partial p''}=\frac{\partial q''}{\partial q'}=\frac{1}{m_{pp}},\quad \frac{\partial q''}{\partial p''}=\frac{b}{c}\frac{m_{qp}}{m_{pp}}. \tag{4.16}$$

We may calculate the action's first derivatives,

$$\left.\frac{\partial S}{\partial q'}\right|_r=-\frac{ic}{\sqrt{2}m_{pp}}[u_r''+v_r'(m_{pp}-im_{pq})],\qquad \left.\frac{\partial S}{\partial p''}\right|_r=\frac{b}{\sqrt{2}m_{pp}}[v_r'-u_r''(m_{pp}+im_{qp})], \tag{4.17}$$

and after writing

$$q'=q_1+\Delta q_1,\quad q''=q_f+\Delta q_f,\quad p'=p_i+\Delta p_i,\quad p''=p_2+\Delta p_2, \tag{4.18}$$

we may also obtain, using an expansion analogous to (4.2) and the boundary conditions, the relations

$$\frac{\Delta q_1}{b}=-\frac{im_{pp}}{c}\frac{[M_2(p_i-p_1)-ic(q_f-q_2)/b]}{1+M_2M_3^*}, \tag{4.19}$$

$$\frac{\Delta p_2}{c}=-\frac{im_{pp}}{b}\frac{[M_3(q_f-q_2)-ib/c(p_i-p_1)]}{1+M_2M_3^*}, \tag{4.20}$$

where M_2 has already been defined and $M_3=m_{pp}+im_{pq}$.

After calculating the action's second derivatives, the final result is

$$K_{q_1p_2}(z_1,z_2,T)=\sum_{\text{c.t}}\frac{\mathcal{N}}{\sqrt{(M_{vv})_r}}\exp\left\{\frac{i}{\hbar}(\mathcal{I}_r+S_r)-\frac{z_2}{\sqrt{2}b}(q_f-q_2)-\frac{iz_1^*}{\sqrt{2}c}(p_i-p_1)\right\}$$
$$\times\exp\left\{-\frac{B_1}{2c^2}(p_i-p_1)^2-\frac{B_2}{2b^2}(q_f-q_2)^2+\frac{B_{12}}{\hbar}(p_i-p_1)(q_f-q_2)\right\}, \tag{4.21}$$

where the coefficients are given by

$$B_1=1-\frac{1}{2}\left(\frac{1-M_2M_3}{1+M_2M_3^*}\right),\quad B_2=1-\frac{1}{2}\left(\frac{1-M_2^*M_3^*}{1+M_2M_3^*}\right),\quad B_{12}=\frac{im_{pp}}{1+M_2M_3^*}. \tag{4.22}$$

We see that the semiclassical propagator obtained is quite similar in structure to the one presented in Sec. IV A. Only this time we have position and momentum in a more equal footing. As p_i-p_1 is always divided by c and q_f-q_2 is always divided by b, we see that again the quantum uncertainties play a fundamental role in selecting the relevant classical trajectories.

C. From p_1 to q_2

It is also possible to fix the initial momentum as p_1 and then search for an initial position q_i such that the final position is q_2. In that case the final momentum will be some p_f. Proceeding in complete analogy with the previous cases, we take p' and q'' to be independent variables and calculate derivatives of q', p'' and S with respect to them. After obtaining the values of Δp_1 and Δq_2 in terms of (q_i-q_1) and (p_f-p_2) and expanding the action to second order, the final result will be

$$K_{p_1q_2}(z_1,z_2,T)=\sum_{\text{c.t}}\frac{\mathcal{N}}{\sqrt{(M_{vv})_r}}\exp\left\{\frac{i}{\hbar}(\mathcal{I}_r+S_r)+\frac{iz_2}{\sqrt{2}c}(p_f-p_2)-\frac{z_1^*}{\sqrt{2}b}(q_i-q_1)\right\}$$
$$\times\exp\left\{-\frac{C_1}{2b^2}(q_i-q_1)^2-\frac{C_2}{2c^2}(p_f-p_2)^2-\frac{C_{12}}{\hbar}(q_i-q_1)(p_f-p_2)\right\},\quad(4.23)$$

where the coefficients are given by

$$C_1=1-\frac{1}{2}\left(\frac{1-M_1^*M_4^*}{1+M_1M_4^*}\right),\quad C_2=1-\frac{1}{2}\left(\frac{1-M_1M_4}{1+M_1M_4^*}\right),\quad C_{12}=\frac{im_{qq}}{1+M_1M_4^*},\qquad(4.24)$$

with $M_4=m_{qq}+im_{pq}$.

D. From p_1 to p_2

Finally, we consider the trajectory determined by the pair (p_1,p_2). This has initial and final positions q_i and q_f, respectively. The procedure to obtain the semiclassical approximation is certainly clear by now, so it will not be repeated in any detail. The final result in this case will be

$$K_{p_1p_2}(z_1,z_2,T)=\sum_{\text{c.t}}\frac{\mathcal{N}}{\sqrt{(M_{vv})_r}}\exp\left\{\frac{i}{\hbar}(\mathcal{I}_r+S_r)-\frac{z_1^*}{\sqrt{2}b}(q_i-q_1)-\frac{z_2}{\sqrt{2}b}(q_f-q_2)\right\}$$
$$\times\exp\left\{-\frac{D_1}{2b^2}(q_i-q_1)^2-\frac{D_2}{2b^2}(q_f-q_2)^2-\frac{D_{12}}{b^2}(q_i-q_1)(q_f-q_2)\right\},\quad(4.25)$$

where the coefficients are given by

$$D_1=1-\frac{1}{2}\left(\frac{1-M_3M_4^*}{1-M_3^*M_4^*}\right),\quad D_2=1-\frac{1}{2}\left(\frac{1-M_3^*M_4}{1-M_3^*M_4^*}\right),\quad D_{12}=\frac{im_{pq}}{1-M_3^*M_4^*}.\qquad(4.26)$$

E. Summary of Sec. IV

In this section we have obtained four different semiclassical approximations to the quantum coherent state propagator that are based only on real trajectories. The trajectories considered share the property that they are not determined by initial or final values, but satisfy mixed boundary conditions. Therefore finding them in practice is not trivial, but is certainly easier than finding the original complex ones. All the semiclassical propagators obtained are in principle able to reproduce quantum effects such as interference, since there may be more than one classical trajectory involved. They will be affected by caustics just like the original formula (2.26), but the location of such caustics will change because $(M_{vv})_r$ is different for each one of them.

Which one of the several formulas obtained here and in Sec. III is more accurate will depend on the particular problem at hand. We have considered only initial and final coherent states with the same value of the parameter b, but a generalization of the semiclassical propagator was presented[27] for more general b's, and the calculations presented here may be adapted to that case with no essential difficulty. Let us suppose for a moment that the initial coherent state $|z_1\rangle$ has a position uncertainty b_1 while $|z_2\rangle$ has a position uncertainty b_2. If these numbers are small that means the states are very narrow in the position representation, while having a large uncertainty in momentum. In that case we conjecture that an approximation in the spirit of $K_{q_1q_2}$ would be the most effective one. If b_1 is small but b_2 is large, than $K_{q_1p_2}$ would be a better candidate, and so on. Of course for the free particle and the harmonic oscillator they are all exact, regardless of the values of b_1 and b_2.

In Sec. V, we present an application of the formalism just presented to a nonlinear system. The purpose is not to attempt an exhaustive investigation of the several possibilities, but rather to

illustrate the method in a simple case. We have chosen a system for which many analytical results are possible so that the main properties of the theory do not disappear under numerical calculations.

V. APPLICATION TO A NONLINEAR OSCILLATOR: SHORT TIME

We consider the nonlinear Hamiltonian

$$H = \hbar\omega(a^\dagger a)^2 = \frac{1}{\hbar\omega}\frac{(p^2+\omega^2q^2-\hbar\omega)^2}{4}, \tag{5.1}$$

which is diagonal in the usual number basis,

$$H|n\rangle = E_n|n\rangle = \hbar\omega n^2|n\rangle. \tag{5.2}$$

The quantum propagator in this case is quite simple:

$$K(z_1,z_2,T) = \langle z_2|e^{-iHT/\hbar}|z_1\rangle = \mathcal{N}\sum_{n=0}^{\infty}\frac{(z_1z_2^*)^n}{n!}e^{-in^2\omega T}. \tag{5.3}$$

We shall be interested, for simplicity, only in the diagonal case

$$K(z_1,z_1,T) = e^{-|z_1|^2}\sum_{n=0}^{\infty}\frac{|z_1|^{2n}}{n!}e^{-in^2\omega T}, \tag{5.4}$$

whose squared modulus is the return probability,

$$P(z_1,T) = |K(z_1,z_1,T)|^2. \tag{5.5}$$

This function is periodic with period $T_r=2\pi/\omega$. In the semiclassical limit the term that is responsible for the largest contribution to the sum in (5.4) is $n_0\approx|z_1|^2$. If we linearize the exponent in the vicinity of this term we have

$$P(z_1,T) \approx e^{-2|z_1|^2}\left|\sum_{n\approx n_0}\frac{|z_1|^{2n}}{n!}e^{2in_0n\omega T}\right|^2. \tag{5.6}$$

Notice that expression (5.6) has a distinct time scale,

$$T_c = \frac{\pi}{n_0\omega}. \tag{5.7}$$

The quantities T_r and T_c are usually called revival time and classical time.[28]

For short times, we can approximate $|K(z_1,T)|^2\approx 1-(\langle H^2\rangle-\langle H\rangle^2)T^2/\hbar^2$, where $\langle\cdot\rangle$ denotes an average value in the state $|z_1\rangle$. For the system in question, this gives

$$P(z_1,T) \approx 1-(4|z_1|^6+6|z_1|^4+|z_1|^2)\omega^2T^2. \tag{5.8}$$

Let us write $z_1=(q+ip)/\sqrt{2}$ and take for simplicity the value $q=0$. Since the movement in phase space has circular symmetry, this choice is of no fundamental importance. The short-time expansion (5.8) becomes simply

$$P(z_1,T) \approx 1-\tfrac{1}{2}(p^6+3p^4+p^2)T^2. \tag{5.9}$$

Let us now turn to the semiclassical approximation. From now on we set $\hbar=\omega=1$, which implies $b=c=1$. The smoothed Hamiltonian associated with (5.1) is

$$\mathcal{H} = \frac{(p^2+q^2)(p^2+q^2+2)}{4} = uv(uv+1), \tag{5.10}$$

and the corresponding Hamilton equations are

$$\dot{q} = \frac{\partial \mathcal{H}}{\partial p} = \sigma p, \quad \dot{p} = -\frac{\partial \mathcal{H}}{\partial q} = -\sigma q, \tag{5.11}$$

where we have defined $\sigma = p^2+q^2+1$. If we note that $\{\sigma, \mathcal{H}\}=0$, and thus that σ is a constant of the motion, then it is clear that

$$q'' = q'\cos(\sigma t) + p'\sin(\sigma t), \quad p'' = p'\cos(\sigma t) - q'\sin(\sigma t). \tag{5.12}$$

We see that the classical trajectories have a period of motion that is energy-dependent and given by $2\pi/\sigma$. If we remember that $n_0+1/2=(q^2+p^2)/2$ we see that in the semiclassical limit this time scale becomes precisely T_c.

The tangent matrix that is associated with the classical trajectory that starts in (q',p') can be obtained by simply differentiating the equations of motion. We must remember that the angular frequency σ is not uniform. The result is

$$\begin{pmatrix} m_{qq} & m_{qp} \\ m_{pq} & m_{pp} \end{pmatrix} = \begin{pmatrix} \cos(\sigma t) & \sin(\sigma t) \\ -\sin(\sigma t) & \cos(\sigma t) \end{pmatrix} \begin{pmatrix} 1+2q'p't & 2p'^2 t \\ -2q'^2 t & 1-2q'p't \end{pmatrix}. \tag{5.13}$$

The action of such a trajectory is easily seen to be

$$S = \frac{(\sigma-1)^2 T}{4} - i\frac{(\sigma-1)}{2}, \tag{5.14}$$

while the extra term is

$$\mathcal{I} = (\sigma - 1/2)T. \tag{5.15}$$

The result of this semiclassical approximation based on complex trajectories will be given in Sec. VI.

A. The "leaving" and the "arriving" trajectories

The first possibility we consider is to approximate the return probability by using only the real trajectory that leaves the position $q=0$ with momentum p. The tangent matrix for that trajectory is

$$\begin{pmatrix} m_{qq} & m_{qp} \\ m_{pq} & m_{pp} \end{pmatrix} = \begin{pmatrix} \cos(\sigma t) & \sin(\sigma t) \\ -\sin(\sigma t) & \cos(\sigma t) \end{pmatrix} \begin{pmatrix} 1 & 2p^2 T \\ 0 & 1 \end{pmatrix}, \tag{5.16}$$

which gives the values

$$M_{uv} = -ip^2 T e^{-i\sigma T}, \quad M_{vv} = (1+ip^2 T)e^{i\sigma T}. \tag{5.17}$$

The angular frequency is $\sigma = p^2+1$ and the final points in phase space are $q_f = p\sin(\sigma T)$ and $p_f = p\cos(\sigma T)$. This corresponds to

$$u_r'' = (v_r'')^* = \frac{ip}{\sqrt{2}} e^{-i\sigma T}. \tag{5.18}$$

Inserting all this information, together with (5.14) and (5.15), into the formula (3.13) we have

$$K_{q_1p_1}(z_1,T)=\frac{1}{\sqrt{1+ip^2T}}\exp\left\{\frac{iT}{4}(p^4+2p^2)-ip^2e^{-i\sigma T/2}\sin(\sigma T/2)\right\}$$
$$\times\exp\left\{\frac{ip^4T}{(1+ip^2T)}e^{-i\sigma T}\sin^2(\sigma T/2)\right\}. \tag{5.19}$$

The first thing we note is that for $p=0$ we obtain the exact result $K=1$. Moreover, in the short time regime we can expand (5.19) and obtain

$$|K_{q_1p_1}(z_1,T)|^2\approx 1-\frac{1}{2}(p^6+3p^4+p^2)T^2 \quad \text{(short times)}, \tag{5.20}$$

which again reproduces the exact calculation. For later times we should not expect exact agreement.

Let us now turn to the "arriving" trajectory, the one that starts in q_i,p_i and arrives at the position $q=0$ with momentum p after a time T. The tangent matrix is less trivial than in the previous case, but in the end we get

$$M_{vu}=-ip^2Te^{-i\sigma T}, \quad M_{vv}=(1+ip^2T)e^{i\sigma T}. \tag{5.21}$$

Since q^2+p^2 is a conserved quantity, we have $\sigma=q_i^2+p_i^2+1=p^2+1$. After the whole calculation is done, we find out that $K_{q_2p_2}=K_{q_1p_1}$. This indicates that perhaps these two approximations will always have the same content of information, something that is not completely unexpected because of the dual role of $|z_1\rangle$ and $|z_2\rangle$ in the quantum propagator.

B. The $q_1\to q_2$ possibility

In that case the trajectories that enter the approximation have initial momentum given by

$$p_i\sin[(p_i^2+1)T]=0. \tag{5.22}$$

Of course one solution to this equation is

$$p_i(=p_f)=0, \tag{5.23}$$

in which case the particle simply stays still and $\sigma=1$. It is easy to see that for this trajectory the tangent matrix is very simple,

$$\begin{pmatrix} m_{qq} & m_{qp} \\ m_{pq} & m_{pp} \end{pmatrix}=\begin{pmatrix} \cos(T) & \sin(T) \\ -\sin(T) & \cos(T) \end{pmatrix}, \tag{5.24}$$

and therefore $M_1=M_2=M_{vv}=e^{iT}$. The contribution of this trajectory to the propagator is

$$K_0=\exp\{-ip^2\sin(T/2)e^{-iT/2}\}, \tag{5.25}$$

where we have used $S_r+\mathcal{I}_r=T/2$. Notice that for $p=0$ we again have the exact result $K_0=1$. We also note that the function $|K_0|^2$ has a period of 2π, which of course corresponds to the quantum revival time.

We now turn to the other solutions of Eq. (5.22). They are of the form

$$p_i^2(n)=\frac{2n\pi}{T}-1, \tag{5.26}$$

where n is an integer, which leads to $\sigma_n=2n\pi/T$. In this case we have less trivial trajectories, for which the tangent matrix is given by

$$\begin{pmatrix} m_{qq} & m_{qp} \\ m_{pq} & m_{pp} \end{pmatrix} = \begin{pmatrix} 1 & 2p_i^2 T \\ 0 & 1 \end{pmatrix}, \tag{5.27}$$

and we see that the prefactor is $M_{vv}=(1+ip_i^2T)$, while $M_1=M_2=-4p_i^4T^2$. The action and the extra term are given by $S_r=(p_i^4T-2ip_i^2)/4$ and $\mathcal{I}_r=(p_i^2+1/2)T$. The coefficients in (4.11) are

$$A_1 = A_2 = 1 + \frac{ip_i^2 T}{2(1+ip_i^2 T)}, \quad A_{12} = -\frac{1}{1+ip_i^2 T}. \tag{5.28}$$

After many simplifications, we obtain

$$K_{q_1 q_2} = \sum_{n=0}^{\infty} K_n, \tag{5.29}$$

where the contribution of the trajectory with label n (different from zero) is given by

$$K_n = \frac{1}{\sqrt{1+ip_i^2 T}} \exp\left\{ -\frac{ip_i^2 T}{1+ip_i^2 T}(p_i - p)^2 + \frac{iT}{4}(p_i^4 + 4p_i^2 + 2) \right\}. \tag{5.30}$$

Note that for short times $p_i(n)$ is very large, so K_n becomes negligible and K_0 gives the only contribution. However, it predicts the initial decay $|K_0|^2 \approx 1-2p^2T^2$, which is very slow compared to the exact calculation (5.9). The two results agree only for very small values of the momentum p.

Concerning the contributions K_n, we see that for a given instant of time the value of n that will contribute the most is that for which $p_i(n)$ is as close as possible to p, because of the Gaussian decay in (5.30). If we impose $p_i^2(n) \approx p^2$ we have $T \approx 2n\pi/(p^2+1)$, which means that the return probability has a maximum at the classical period, in agreement with the exact result.

C. The $q_1 \to p_2$ possibility

If we impose that the classical trajectory starts in $q=0$ with momentum p_i and ends at q_f with momentum p, we have

$$q_f = p_i \sin(\sigma T), \quad p = p_i \cos(\sigma T), \quad \sigma = p_i^2 + 1. \tag{5.31}$$

These transcendental equations have no explicit solution. If we confine ourselves to the short time regime, then we can write $p_i \approx p$ and $q_f \approx p(p^2+1)T$. The tangent matrix is given by

$$\begin{pmatrix} m_{qq} & m_{qp} \\ m_{pq} & m_{pp} \end{pmatrix} = \begin{pmatrix} \cos(\sigma t) & \sin(\sigma t) \\ -\sin(\sigma t) & \cos(\sigma t) \end{pmatrix} \begin{pmatrix} 1 & 2p_i^2 T \\ 0 & 1 \end{pmatrix}, \tag{5.32}$$

and we obtain $M_2=e^{i\sigma T}(1+2ip_i^2T)$ and $M_3=e^{-i\sigma T}-2p_i^2T$. Substituting this in (4.21), we obtain

$$|K_{q_1 p_2}|^2 \approx 1 - \left(p^6 + \frac{5}{2}p^4 + p^2 \right) T^2 \quad \text{(short times)}, \tag{5.33}$$

which decays faster than the exact result but is a better approximation than the one obtained using the $q_1 \to q_2$ trajectory. We see that the different approximations may lead to very different results.

D. The $p_1 \to q_2$ possibility

The equations of motion in this case are

$$0 = q_i \cos(\sigma T) + p \sin(\sigma T), \quad p_f = -q_i \sin(\sigma T) + p \cos(\sigma T), \quad \sigma = q_i^2 + p^2 + 1, \tag{5.34}$$

while the tangent matrix is

$$\begin{pmatrix} m_{qq} & m_{qp} \\ m_{pq} & m_{pp} \end{pmatrix} = \begin{pmatrix} \cos(\sigma t) & \sin(\sigma t) \\ -\sin(\sigma t) & \cos(\sigma t) \end{pmatrix} \begin{pmatrix} 1+2q_i pT & 2p^2 T \\ -2q_i^2 T & 1-2q_i pT \end{pmatrix}. \tag{5.35}$$

The situation here regarding solubility of the equations is even worse than in the previous case. Once again we restrict the analysis to the short time regime. Then it is possible to write the first equation as $q_i \approx -p\sigma T/2$ and find

$$q_i \approx -\frac{1}{2pT}(1-\sqrt{1-4p^2T^2(p^2+1)}), \tag{5.36}$$

which we substitute in the first equation to find p_f. Carrying out the whole calculation will give in the end

$$|K_{p_1 q_2}|^2 \approx 1-\frac{1}{2}(p^6+3p^4+p^2)T^2 \quad \text{(short times)}, \tag{5.37}$$

which agress with the exact result.

E. The $p_1 \to p_2$ possibility

Finally, in the last possibility we have

$$q_f = q_i \cos(\sigma T) + p \sin(\sigma T), \quad p = -q_i \sin(\sigma T) + p \cos(\sigma T), \quad \sigma = q_i^2 + p^2 + 1. \tag{5.38}$$

In the short time limit we have again

$$q_i \approx -\frac{1}{2pT}(1-\sqrt{1-4p^2T^2(p^2+1)}), \tag{5.39}$$

and the final result is

$$|K_{p_1 p_2}|^2 \approx 1-\frac{p^4}{2}T^2 \quad \text{(short times)}. \tag{5.40}$$

This is kind of intermediate between the result we found in Sec. V B and that of Secs. V C and V D.

VI. APPLICATION TO A NONLINEAR OSCILLATOR: NUMERICAL RESULTS

Before we consider the semiclassical approximations based on real trajectories for longer times, let us see how well the original one (2.26) compares to the exact result. This has been considered in detail in Ref. 29, so we just present the result. Given the initial condition $u'=z_1$, for each time T we must find a value for v' such that $v''=z_2^*=z_1^*$. This problem usually has more than one solution, and we must add their contributions coherently. In Fig. 1 we see the return probability as a function of time (in units of T_c) for the case $p=10$, which we have chosen to ensure that we are in the semiclassical limit. The corresponding classical period is $T_c \approx 0.062$. The exact and the semiclassical results are indistinguishable in this scale.

In Sec. V we saw how the different approximations based on real trajectories performed in the short time regime. The exact result was reproduced only by the "leaving" and the "arriving" formulas and by $K_{p_1 q_2}$. We now turn to the less simple case of arbitrary T, when the classical trajectories and the associated propagators must be computed numerically.

Let us start with the propagator $K_{q_1 p_1}$, which is based on a real periodic orbit. Its initial decay is exact, and we can see how well it does for later times in Fig. 2. It is able to reproduce the height of the peaks with great accuracy, but not their widths. Since there is never more than one contribution for each time, it never displays any interference effects.

This is not the case for $K_{q_1 q_2}$. We see from (5.29) and (5.30) that it consists in the sum of many contributions. We focus on the values $n=1, 2, 3$. Their individual contributions are depicted in Fig.

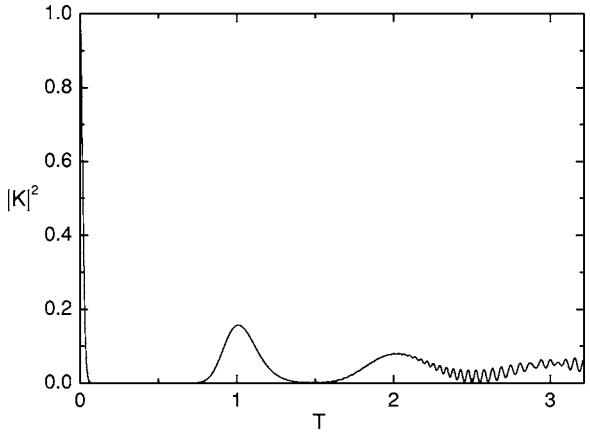

FIG. 1. Squared modulus of the exact propagator for $q=0$ and $p=10$. The semiclassical approximation based on complex trajectories is indistinguishable from it in this scale. Time is in units of the classical period.

3. Notice that the second and third peaks overlap. When we calculate the total propagator, this gives rise to interference. The final result is indistinguishable from the exact one (for $T>T_c/2$, because we have ignored K_0 which gives a bad initial decay).

So far the propagators could be obtained analytically. Since the calculation of $K_{q_1p_2}$ depends on the solution of the transcendental equation (5.31), we must resort to numerical routines. Let us try to find solutions to the second equation in (5.31) in the vicinity of the first period, $T\approx T_c$. In Fig. 4(a) we see that there are two solutions (solid lines) for $T<T_c$ and no solution at all for $T>T_c$. This is because the cosine function with a real argument is always less than unity, and thus p_i must always be greater than p. The complex solutions do not have this obstruction, as we can also see in Fig. 4(a) (dashed line), where we plot the real part of the complex momentum that satisfies the boundary conditions (2.11). Therefore the semiclassical approximation based on the complex trajectory can reproduce the whole peak, while $K_{q_1p_2}$ is discontinuous.

In Fig. 4(b) we see the squared modulus of the exact propagator and the values of $|K_{q_1p_2}|^2$ obtained using the two available real trajectories. Note that one should not add these results. They are independent and we may choose any of them, because both real trajectories are good approximations to the actual complex one (the real trajectories do not come from a saddle point approxi-

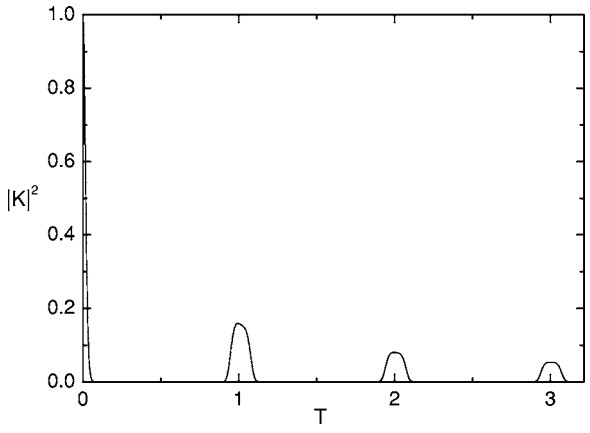

FIG. 2. The function $|K_{q_1p_1}|^2$ as a function of time. It reproduces well the height of the peaks, but not their widths, and shows no interference.

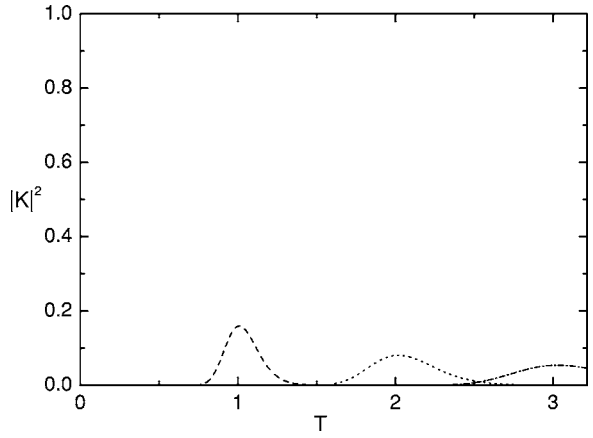

FIG. 3. The individual contributions $|K_n|^2$ for the approximation $K_{q_1q_2}$. We show the cases $n=1$, 2, and 3. When they are added there is interference, and the exact result of Fig. 1 is reproduced with extraordinary accuracy for $T>T_c/2$ (we have not included K_0 in the calculation).

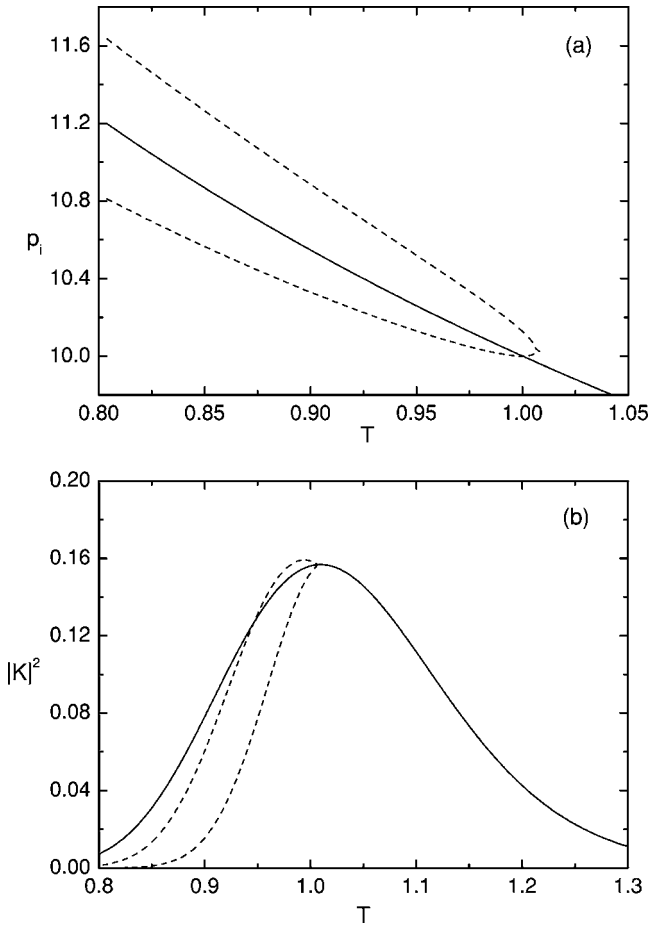

FIG. 4. Top panel: real solutions to the equation $p=p_i\cos((p_i^2+1)T)$ in the vicinity of the classical period (dashed lines). We also show the real part of the momentum for the complex trajectory (solid line). Bottom panel: approximation $|K_{q_1p_2}|^2$ (dashed lines) compared to the exact result (solid line). Since there are no real trajectories for $T>T_c$, the propagator becomes truncated. For $T<T_c$ there are two possibilities.

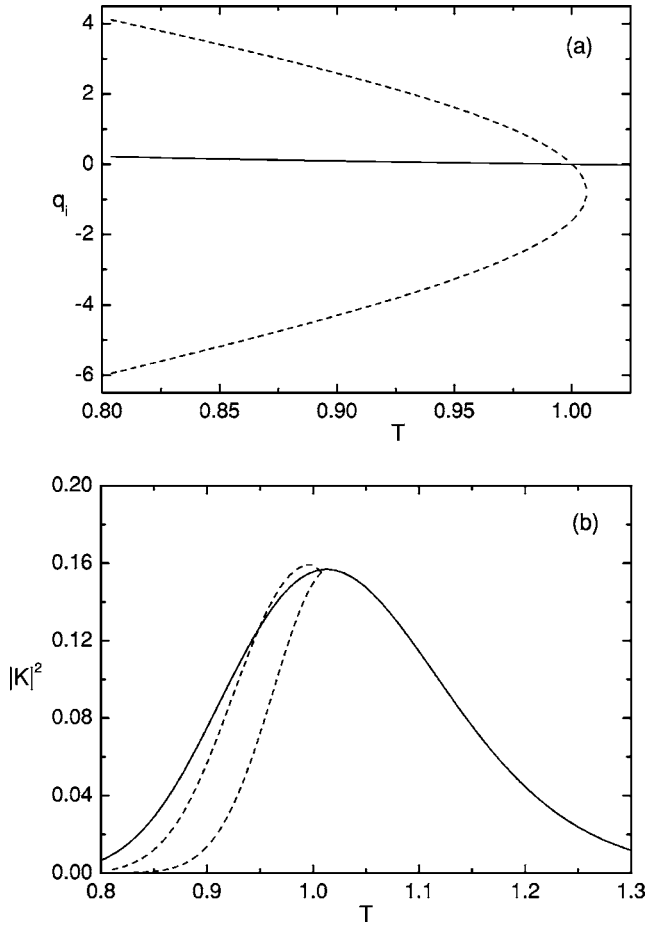

FIG. 5. Top panel: real solutions to the equation $0=q_i\cos(\sigma T)+p\cos(\sigma T)$, where $\sigma=q_i^2+p^2+1$, in the vicinity of the classical period (dashed lines). We also show the real part of the position for the complex trajectory (solid line). Bottom panel: approximation $|K_{p_1q_2}|^2$ (dashed lines) compared to the exact result (solid line). The situation is analogous to Fig. 4.

mation). As observed in Refs. 16 and 18, the mixed propagator $\langle \mathbf{x}|e^{-iHT/\hbar}|\mathbf{z}\rangle$ can also be discontinuous when calculated using real trajectories. But in that case there are caustics involved, while here we have an algebraic obstruction.

The discussion of the approximation $K_{p_1q_2}$ is quite similar to the above. The solutions to the first equation in (5.34) are shown in Fig. 5(a), where we also show the real part of the complex position that satisfies the boundary conditions (2.11). Again there is no solution for $T>T_c$ and the semiclassical propagator is discontinuous, as we appreciate in Fig. 5(b). The results are practically the same as in Fig. 4(b).

Finally, the propagator $K_{p_1p_2}$. This time we solve numerically the conditions (5.38) and find that there is a single real trajectory for $T<T_c$ and no one for $T>T_c$. The final result is in Fig. 6.

VII. CONCLUSIONS

Several approximations to the semiclassical coherent state propagator $\langle z_2|e^{-iHT/\hbar}|z_1\rangle$ were presented that are based solely on real classical trajectories. Two of these approximations do not involve mixed boundary conditions and thus are not hindered by the associated "root search" problem. The remaining four possibilities are based on trajectories that are determined by initial and final data, but since they are real for all times they are simpler to determine than the original complex ones.

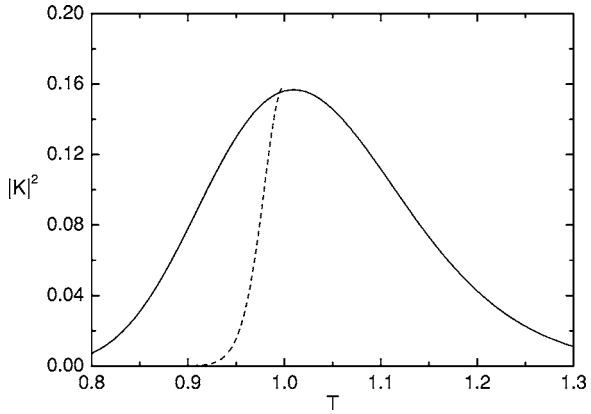

FIG. 6. Approximation $|K_{p_1p_2}|^2$ (dashed line) compared to the exact result (solid line). This time only one real trajectory exists for $T<T_c$, but again the propagator is truncated.

As a testing ground we have used the nonlinear system $H=(a^\dagger a)^2$. Only one of the approximations, namely $K_{q_1q_2}$, reproduced the exact result to the fine details. This is certainly due to the particular initial coherent state that was chosen, one corresponding to $q=0$ and $p=10$. Had we chosen for example $q=10$ and $p=0$ and then $K_{p_1p_2}$ would give excellent results. We could also consider a nondiagonal propagator, and in that case we would expect $K_{q_1p_2}$, for example, to improve its performance.

Straightforward extensions of this work include the already mentioned case of different position uncertainties (squeezed states) and also higher dimensional systems. It is also possible to fix the time T and the initial state $|z_1\rangle$ and to regard $|K(z_1,z_2,T)|^2$ as a Husimi function defined in the z_2 plane. This is technically more difficult than what we have presented here, because it involves finding classical trajectories—usually more than one—parametrized by points in the plane.

Similar results can be obtained for the semiclassical $SU(2)$, or spin, coherent state propagator, even though the introduction of position and momentum variables in that case is not as natural. The associated phase space is also two-dimensional, but since it has curvature the calculations may be a little more involved. The same may be said about the semiclassical $SU(1,1)$ coherent state propagator. Since these groups have wide applications, it would be interesting to also have the corresponding approximations based on real trajectories.

The success of quantum mechanics is due to the discovery that nature is described in infinite dimension Hilbert spaces, so that it is desirable to demonstrate the quantum teleportation process in a certain infinite dimensional Hilbert space. We describe the teleportation process in an infinite dimensional Hilbert space by giving simple examples. © *2005 American Institute of Physics.*

I. INTRODUCTION

In quantum communication theory, we code information by quantum states and send it through a quantum device that is properly designed. If one can send any quantum state from an input system to an output system as it is, that is, if one can find such a method sending an input state without changing it, then it will be an ultimate way for information transmission. It is in quantum teleportation that we can discuss such an ultimate communication system.

The problem of quantum teleportation is whether there exists a physical device and a key (or a set of keys) by which a quantum state attached to a sender (Alice) is completely transmitted and a receiver (Bob) can reconstruct the state sent. Bennett *et al.*[1] showed that such teleportation is possible through a device (channel) made from proper (EPR) entangled states of Bell basis. The basic idea behind their discussion is to divide the information encoded in the state into two parts, classical and quantum, and send them through different channels, a classical channel and an EPR channel. The classical channel is nothing but a simple correspondence between sender and receiver, and the EPR channel is constructed by using a certain entangled state. However the EPR channel is not so stable due to quick decoherence. Fichtner and Ohya[2,3] studied the quantum teleportation by means of general beam splitting processes in Bose Fock space so that it contains the EPR channel as a special case, and they constructed a stable teleportation process with coherent entangled states.

However, all these discussions have been based on finite dimensionality of the Hilbert spaces, attached to Alice and Bob. As is well known, success of quantum mechanics is due to the discovery that nature is described in infinite dimension Hilbert spaces, so that it is desirable to demonstrate the quantum teleportation process in a certain infinite dimensional Hilbert space. This paper is a trial to describe the teleportation process in an infinite dimensional Hilbert space by

giving simple examples. In Sec. II, we fix the notations based on Fock space discussion of the series of papers.[2–4] In Sec. III, the channel expression of the teleportation is reviewed and the entanglement between Alice and Bob is constructed by an isometry operator, on which an operator expression of the teleportation channel is given, and some extreme cases of the teleportation are considered. To be closer to usual teleportation schemes and to get simple and explicit results we consider in Sec. IV the case of product states. In Sec. V, the existence of unitary keys is discussed.

II. BASIC NOTIONS AND NOTATIONS

We consider three complex Hilbert spaces $\mathcal{H}_1$, $\mathcal{H}_2$, and $\mathcal{H}_3$. To Alice there are attached the Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$. Alice wants to teleportate a state ρ on $\mathcal{H}_1$ to Bob to whom there is attached the Hilbert space $\mathcal{H}_3$. Usually it is assumed that all three Hilbert spaces are finite-dimensional ones. This is also necessary for obtaining perfect teleportation. In the present article we will consider the case of Hilbert spaces being separable but not necessarily finite dimensional. We assume that all three spaces are either infinite-dimensional separable Hilbert spaces or finite-dimensional ones with same finite dimension. The paper continues and generalizes results obtained in Refs. 2–4.

Let us be given orthonormal bases,

$$(\xi_k^1)_{k\in G}, \quad (\xi_k^2)_{k\in G}, \quad (\xi_k^3)_{k\in G}, \tag{1}$$

in $\mathcal{H}_1$, $\mathcal{H}_2$, and $\mathcal{H}_3$ where the at most countable index set G is an abelian (additive) group with operation $\oplus$. An important case is that G is the set of integers $\mathbb{Z}$ where the group operation $\oplus$ will be usual addition. Since we need the structure of a group it is more convenient for our purposes to choose only orthonormal bases consisting of two-sided infinite sequences. To include usual teleportation models (with finite index space G) we consider also the case $G=\{1,\ldots,N\}$ with N belonging to the set $\mathbb{N}$ of natural numbers. In this case the operation $\oplus: G\times G\to G$ is defined by $k\oplus l := (k+l) \bmod N$. The operation inverse to $\oplus$ we denote by $\ominus$. In the latter case $k\ominus l=k-l$ if $k>l$ and $k\ominus l=k-l+N$ if $k\leqslant l$.

The algebra of all bounded linear operators on a Hilbert space $\mathcal{H}$ we will denote by $\mathcal{B}(\mathcal{H})$. Throughout this article we will assume that all states on a Hilbert space $\mathcal{H}$ are normal states (on $\mathcal{B}(\mathcal{H})$). The set of all normal states we denote by $\mathcal{S}(\mathcal{H})$.

Let $V\in\mathcal{B}(\mathcal{H}_2)$ be an arbitrary unitary operator. Consequently, the sequence $(\eta_n)_{n\in G}$ with $\eta_n := V\xi_n^2, n\in G$ is a second orthonormal basis in $\mathcal{H}_2$. Thus there exists a sequence $(b_{kl})_{k,l\in G}$ such that

$$\eta_k = \sum_{l\in G} b_{kl}\xi_l^2 \quad (k\in G). \tag{2}$$

Obviously, the sequence $(b_{kl})_{k,l\in G}$ has to fulfill

$$\sum_{l\in G} \overline{b_{kl}} b_{ml} = \delta_{k,m} \quad (k,m\in G), \tag{3}$$

where $\delta_{k,m}$ denotes the Kronecker symbol. Observe that for all $m,k\in G$ it holds $\langle \eta_m, \xi_k^2\rangle = \overline{b_{mk}}$. Consequently, we obtain

$$\xi_k^2 = \sum_{m\in G} \overline{b_{mk}}\eta_m \quad (k\in G). \tag{4}$$

Since V^* is again unitary and $\xi_n^2 = V^*\eta_n$ we also have

$$\sum_{l\in G} \overline{b_{lk}} b_{lm} = \delta_{k,m} \quad (k,m\in G). \tag{5}$$

Remark: To simplify notations only if there appear ambiguities we will separate multiple indices by "commas," i.e., usually we write b_{kl} instead of $b_{k,l}$.

Further, we consider a sequence $(U_m)_{m\in G}$ of unitary operators on $\mathcal{H}_2$ acting as shift operators on the elements of the (original) basis:

$$U_m\xi_k^2 = \xi_{k\oplus m}^2 \quad (m,k \in G). \tag{6}$$

The Hilbert space $\mathcal{H}_2$ is connected by simple isometries S_1 to $\mathcal{H}_1$ and S_3 to $\mathcal{H}_3$:

$$S_1{:}\mathcal{H}_2 \to \mathcal{H}_1 \otimes \mathcal{H}_2, \quad S_1(\xi_k^2) = \xi_k^1 \otimes \xi_k^2 \quad (k \in G), \tag{7}$$

$$S_3{:}\mathcal{H}_2 \to \mathcal{H}_2 \otimes \mathcal{H}_3, \quad S_3(\xi_k^2) = \xi_k^2 \otimes \xi_k^3 \quad (k \in G). \tag{8}$$

Finally, we construct a new basis in $\mathcal{H}_1 \otimes \mathcal{H}_2$ by setting

$$\xi_{km} = (\mathbb{1} \otimes U_m)S_1\eta_k = (\mathbb{1} \otimes U_m)S_1V\xi_k^2 \quad (k,m \in G), \tag{9}$$

where $\mathbb{1}$ denotes the identical operator (from the context it always will be clear on which space $\mathbb{1}$ operates). Observe that for $k,m \in G$

$$\xi_{km} = (\mathbb{1} \otimes U_m)\sum_{l\in G} b_{kl}(\xi_l^1 \otimes \xi_l^2) = \sum_{l\in G} b_{kl}(\xi_l^1 \otimes \xi_{l\oplus m}^2). \tag{10}$$

Proposition 1: The sequence $(\xi_{km})_{k,m\in G}$ is an orthonormal basis in $\mathcal{H}_1 \otimes \mathcal{H}_2$.

Proof: For $n,m,r,s \in G$ we get using (10) and (3)

$$\begin{aligned}\langle \xi_{nm}, \xi_{rs}\rangle &= \sum_{k,l\in G} \overline{b_{nk}} b_{rl}\langle \xi_k^1 \otimes \xi_{k\oplus m}^2, \xi_l^1 \otimes \xi_{l\oplus s}^2\rangle = \sum_{k,l\in G} \overline{b_{nk}} b_{rl}\langle \xi_k^1, \xi_l^1\rangle\langle \xi_{k\oplus m}^2, \xi_{l\oplus s}^2\rangle \\ &= \sum_{k\in G} \overline{b_{nk}} b_{rk}\langle \xi_{k\oplus m}^2, \xi_{k\oplus s}^2\rangle = \delta_{n,r}\cdot\delta_{m,s}.\end{aligned}$$

Thus $(\xi_{km})_{k,m\in G}$ is an orthonormal system in $\mathcal{H}_1 \otimes \mathcal{H}_2$.

To prove completeness we check whether the Parseval equality

$$\|\Phi\|^2 = \sum_{n,m\in G} |\langle \Phi, \xi_{nm}\rangle|^2$$

holds for all $\Phi \in \mathcal{H}_1 \otimes \mathcal{H}_2$. Let

$$\Phi = \sum_{r,s\in G} \alpha_{rs}\xi_r^1 \otimes \xi_s^2. \tag{11}$$

Then

$$\langle \Phi, \xi_{nm}\rangle = \sum_{r,s,k\in G} \overline{\alpha_{rs}} b_{nk}\langle \xi_r^1 \otimes \xi_s^2, \xi_k^1 \otimes \xi_{k\oplus m}^2\rangle = \sum_{r,s\in G} \overline{\alpha_{rs}} b_{nr}\langle \xi_s^2, \xi_{r\oplus m}^2\rangle = \sum_{r\in G} \overline{\alpha_{r,r\oplus m}} b_{nr}.$$

Using (5) this implies

$$\begin{aligned}\sum_{n,m\in G} |\langle \Phi, \xi_{nm}\rangle|^2 &= \sum_{n,m,r,s\in G} \overline{\alpha_{s,s\oplus m}}\alpha_{r,r\oplus m}\overline{b_{nr}} b_{ns} = \sum_{m,r,s\in G} \overline{\alpha_{s,s\oplus m}}\alpha_{r,r\oplus m}\sum_{n\in G} \overline{b_{nr}} b_{ns} \\ &= \sum_{m,r,s\in G} \overline{\alpha_{s,s\oplus m}}\alpha_{r,r\oplus m}\delta_{r,s} = \sum_{m,r\in G} |\alpha_{r,r\oplus m}|^2 = \sum_{m,r\in G} |\alpha_{r,m}|^2 = \|\Phi\|^2.\end{aligned}$$

This ends the proof. □

We denote by $F_{nm} \in \mathcal{B}(\mathcal{H}_1 \otimes \mathcal{H}_2)$ the projection onto ξ_{nm}, i.e.,

$$F_{nm} := |\xi_{nm}\rangle\langle \xi_{nm}| = \langle \xi_{nm}, \cdot\rangle\xi_{nm} \quad (n,m \in G). \tag{12}$$

Remark: We will use as well the "scalar product" notation as also the "bra and ket" symbols.

However, using the symbol $|\Phi\rangle$ let us make the convention that the symbol has to denote the normalization of the vector Φ, i.e.,

$$|\Phi\rangle := \frac{\Phi}{\|\Phi\|}. \tag{13}$$

Observe that for $\Phi \in \mathcal{H}_1 \otimes \mathcal{H}_2$ given by (11) and for all $n,m \in G$ one obtains

$$\begin{aligned} F_{nm}\Phi &= \langle \xi_{nm}, \Phi\rangle \xi_{nm} = \sum_{k\in G} \overline{b_{nk}} \langle \xi_k^1 \otimes \xi_{k\oplus m}^2, \Phi\rangle \xi_{nm} = \sum_{k,r,s\in G} \overline{b_{nk}} \alpha_{rs} \langle \xi_k^1 \otimes \xi_{k\oplus m}^2, \xi_r^1 \otimes \xi_s^2\rangle \xi_{nm} \\ &= \left(\sum_{k\in G} \overline{b_{nk}} \alpha_{k,k\oplus m} \right) \xi_{nm}. \end{aligned} \tag{14}$$

Especially,

$$F_{nm}(\xi_r^1 \otimes \xi_s^2) = \delta_{s,r\oplus m} \cdot \overline{b_{nr}} \xi_{nm}. \tag{15}$$

In the subsequent sections we investigate concrete teleportation channels. For this we need an explicit expression for $(F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)$ which maps $\mathcal{H}_1 \otimes \mathcal{H}_2$ into $\mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \mathcal{H}_3$.

Proposition 2: Let $\Phi \in \mathcal{H}_1 \otimes \mathcal{H}_2$ be given by (11). For all $n,m \in G$ it holds

$$(F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)\Phi = \xi_{nm} \otimes \sum_{r\in G} \overline{b_{nr}} \alpha_{r,r\oplus m} \xi_{r\oplus m}^3. \tag{16}$$

Proof: Using definition (8) of the imbedding operator S_3 and (15) we obtain for all $n,m \in G$

$$\begin{aligned} (F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)\Phi &= \sum_{r,s\in G} \alpha_{rs} (F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3) \xi_r^1 \otimes \xi_s^2 = \sum_{r,s\in G} \alpha_{rs} (F_{nm} \otimes \mathbb{1}) \xi_r^1 \otimes \xi_s^2 \otimes \xi_s^3 \\ &= \sum_{r,s\in G} \alpha_{rs} \overline{b_{nr}} \xi_{nm} \otimes \xi_s^3 \cdot \delta_{s,r\oplus m} = \sum_{r\in G} \alpha_{r,r\oplus m} \overline{b_{nr}} \xi_{nm} \otimes \xi_{r\oplus m}^3. \end{aligned}$$

This proves (16). □

Corollary 3: Let $\Phi \in \mathcal{H}_1 \otimes \mathcal{H}_2$ be given by (11) and assume $\|\Phi\| = 1$. For all $n,m \in G$ it holds

$$(F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)|\Phi\rangle\langle\Phi|(\mathbb{1} \otimes S_3^*)(F_{nm} \otimes \mathbb{1}) = F_{nm} \otimes \langle \Psi_{nm}, \cdot \rangle \Psi_{nm} \tag{17}$$

with

$$\Psi_{nm} = \sum_{r\in G} \overline{b_{nr}} \alpha_{r,r\oplus m} \xi_{r\oplus m}^3. \tag{18}$$

Proof: Immediately from Proposition 2 we obtain

$$\begin{aligned} (F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)|\Phi\rangle\langle\Phi|(\mathbb{1} \otimes S_3^*)(F_{nm} \otimes \mathbb{1}) &= \left\langle \sum_{r\in G} \alpha_{r,r\oplus m} \overline{b_{nr}} \xi_{nm} \otimes \xi_{r\oplus m}^3, \cdot \right\rangle \sum_{s\in G} \alpha_{s,s\oplus m} \overline{b_{ns}} \xi_{nm} \\ &\otimes \xi_{s\oplus m}^3 = |\xi_{nm}\rangle\langle\xi_{nm}| \\ &\otimes \left\langle \sum_{r\in G} \alpha_{r,r\oplus m} \overline{b_{nr}} \xi_{r\oplus m}^3, \cdot \right\rangle \sum_{s\in G} \alpha_{s,s\oplus m} \overline{b_{ns}} \xi_{s\oplus m}^3. \end{aligned}$$

This proves (17). □

Corollary 3 allows us to get explicit formulas for

$$(F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)\varkappa(\mathbb{1} \otimes S_3^*)(F_{nm} \otimes \mathbb{1}),$$

where $\varkappa$ is a normal state on $\mathcal{B}(\mathcal{H}_1 \otimes \mathcal{H}_2)$.

Let $\varkappa$ be given in the form

$$\varkappa = \sum_{u,v \in G} \lambda_{uv} |\Phi_{uv}\rangle\langle\Phi_{uv}| \tag{19}$$

with $(\Phi_{uv})_{u,v \in G}$ being an orthonormal sequence in $\mathcal{H}_1 \otimes \mathcal{H}_2$,

$$\Phi_{uv} = \sum_{r,s \in G} \alpha_{uvrs} \xi^1_r \otimes \xi^2_s \tag{20}$$

and $(\lambda_{uv})_{u,v \in G}$ fulfilling

$$\sum_{u,v \in G} \lambda_{uv} = 1, \quad \lambda_{uv} \geqslant 0. \tag{21}$$

Of course, we have for all $u, \tilde{u}, v, \tilde{v} \in G$

$$\sum_{r,s \in G} \overline{\alpha_{uvrs}} \alpha_{\tilde{u}\tilde{v}rs} = \delta_{u,\tilde{u}} \cdot \delta_{v,\tilde{v}}. \tag{22}$$

As an immediate consequence of Corollary 3 we obtain the following result.

Proposition 4: Let $\varkappa$ be given by (19). For all $n, m \in G$ it holds

$$\begin{aligned}(F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)\varkappa(\mathbb{1} \otimes S_3^*)(F_{nm} \otimes \mathbb{1}) &= F_{nm} \otimes \sum_{u,v \in G} \lambda_{uv} \langle \Psi_{uvnm}, \cdot \rangle \Psi_{uvnm} \\ &= F_{nm} \otimes \sum_{u,v \in G} \lambda_{uv} \|\Psi_{uvnm}\|^2 \cdot |\Psi_{uvnm}\rangle\langle\Psi_{uvnm}| \end{aligned} \tag{23}$$

with

$$\Psi_{uvnm} = \sum_{r \in G} \overline{b_{nr}} \alpha_{uvr,r\oplus m} \xi^3_{r\oplus m}. \tag{24}$$

Remark: Observe that the vectors Ψ_{uvnm} usually are not normalized. Further, in general the sequence $(\Psi_{uvnm})_{u,v \in G}$ is not an orthogonal one.

III. THE TELEPORTATION CHANNEL

A. The measurement

Now we apply the model which was used in several papers[2,3,5] for the description of a teleportation scheme. The measurement will be done with the operator

$$F = \sum_{n,m \in G} z_{nm} F_{nm}, \tag{25}$$

where $(z_{nm})_{n,m \in G}$ is a sequence of real numbers and $(F_{nm})_{n,m \in G}$ is the family of orthogonal projections on $\mathcal{H}_1 \otimes \mathcal{H}_2$ introduced in Sec. II (cf. (12) and (10)). In the above-mentioned articles one considers the case of a given state ρ on $\mathcal{H}_1$ (that has to be teleportated to Bob) and an entangled state σ on $\mathcal{H}_2 \otimes \mathcal{H}_3$. Thus the whole system is prepared in the state $\rho \otimes \sigma$. Alice makes a measurement (restricted to $\mathcal{H}_1 \otimes \mathcal{H}_2$) with the operator F given by (25), i.e., the operator $F \otimes \mathbb{1}$ is applied to the system being in the state $\rho \otimes \sigma$. As the result of the measurement Alice obtains a value z_{nm} for some $n, m \in G$. Consequently, after the measurement the whole system will be in the state θ_{nm} on $\mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \mathcal{H}_3$ given by

$$\theta_{nm} := \frac{(F_{nm} \otimes \mathbb{1})\rho \otimes \sigma(F_{nm} \otimes \mathbb{1})}{\mathrm{tr}((F_{nm} \otimes \mathbb{1})\rho \otimes \sigma(F_{nm} \otimes \mathbb{1}))}, \tag{26}$$

where tr denotes the full trace with respect to $\mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \mathcal{H}_3$. Bob who is informed about the result of the measurement controls the state $\tilde{\Lambda}_{nm}(\rho)$ on $\mathcal{H}_3$ being the partial trace of θ_{nm} with respect to $\mathcal{H}_1 \otimes \mathcal{H}_2$:

$$\tilde{\Lambda}_{nm}(\rho) := \mathrm{tr}_{12}(\theta_{nm}) = \frac{\mathrm{tr}_{12}((F_{nm}\otimes \mathbb{1})\rho\otimes\sigma(F_{nm}\otimes\mathbb{1}))}{\mathrm{tr}((F_{nm}\otimes\mathbb{1})\rho\otimes\sigma(F_{nm}\otimes\mathbb{1}))}, \tag{27}$$

where tr_{12} denotes the partial trace on $\mathcal{H}_1\otimes\mathcal{H}_2$. Of course we have to assume that the denominator in (26), respectively, in (27) is nonzero. Otherwise, the left-hand side has to be set equal to zero. The mapping $\tilde{\Lambda}_{nm}:\mathcal{S}(\mathcal{H}_1)\to\mathcal{S}(\mathcal{H}_3)$ is called a *teleportation channel*.

The teleportation works perfectly if Bob is able to reconstruct the initial state ρ from $\tilde{\Lambda}_{nm}(\rho)$. We will return to this question in the subsequent sections. Teleportation channels $\tilde{\Lambda}_{nm}$ of the above-mentioned type might be useful also for modeling other transformations of states. For instance in Ref. 4 we proposed an extremely simplified model of certain recognition processes based on a teleportation channel. In this model the spaces $\mathcal{H}_1$, $\mathcal{H}_2$, and $\mathcal{H}_3$ represent the processing part (brain), the memory before and after recognition.

B. The entanglement

Instead of the state $\rho\otimes\sigma$ on $\mathcal{H}_1\otimes\mathcal{H}_2\otimes\mathcal{H}_3$ we will consider now states of the form

$$(\mathbb{1}\otimes S_3)\varkappa(\mathbb{1}\otimes S_3^*) \tag{28}$$

with $\varkappa$ being a state on $\mathcal{H}_1\otimes\mathcal{H}_2$ and S_3 isometry (8) coupling $\mathcal{H}_1$ to $\mathcal{H}_3$. The simple entanglement between $\mathcal{H}_2$ and $\mathcal{H}_3$ is achieved just by applying S_3. Especially, if $\varkappa$ has the form $\varkappa=\rho^1\otimes\rho^2$ with ρ^j being a state on $\mathcal{H}_j$, $j=1,2$ then using the above cited notations from Refs. 2 and 3 we get $\rho=\rho^1$ and $\sigma=S_3\rho^2S_3^*$. This case of $\varkappa$ being a product state we will discuss in Sec. IV.

We will consider now the channel $\Lambda_{nm}:\mathcal{S}(\mathcal{H}_1\otimes\mathcal{H}_2)\to\mathcal{S}(\mathcal{H}_3)$ given by

$$\Lambda_{nm}(\varkappa) = \frac{\mathrm{tr}_{1,2}((F_{nm}\otimes\mathbb{1})(\mathbb{1}\otimes S_3)\varkappa(\mathbb{1}\otimes S_3^*)(F_{nm}\otimes\mathbb{1}))}{\mathrm{tr}((F_{nm}\otimes\mathbb{1})(\mathbb{1}\otimes S_3)\varkappa(\mathbb{1}\otimes S_3^*)(F_{nm}\otimes\mathbb{1}))}, \tag{29}$$

where as in (27) tr_{12} denotes the partial trace with respect to $\mathcal{H}_1\otimes\mathcal{H}_2$ and tr the full trace on $\mathcal{H}_1\otimes\mathcal{H}_2\otimes\mathcal{H}_3$. Again we have to assume that the denominator in (29) is greater than zero. Otherwise we set $\Lambda_{nm}(\varkappa)=0$. Observe that for product states $\varkappa=\rho\otimes\sigma$ one has the relation $\tilde{\Lambda}_{nm}(\rho)=\Lambda_{nm}(\rho\otimes\sigma)$.

Remark: Since $\mathrm{tr}_{1,2}((F_{nm}\otimes\mathbb{1})(\mathbb{1}\otimes S_3)\varkappa(\mathbb{1}\otimes S_3^*)(F_{nm}\otimes\mathbb{1}))$ is a positive linear functional on $\mathcal{H}_3$ the denominator in (29) can be equal to zero only if this functional is zero. In other words, in this case no information about the measured value z_{nm} can be transmitted to Bob (in a brain model this would mean that no information about the input signal will be stored in the memory). The following result is an immediate consequence of Proposition 4.

Theorem 5: *Let $\varkappa$ be a state on $\mathcal{H}_1\otimes\mathcal{H}_2$ given by (19)–(21). Then for all $n,m\in G$*

$$\Lambda_{nm}(\varkappa) = \frac{\sum_{u,v\in G}\lambda_{uv}\langle\Psi_{uvnm},\cdot\rangle\Psi_{uvnm}}{\mathrm{tr}_3\left(\sum_{u,v\in G}\lambda_{uv}\langle\Psi_{uvnm},\cdot\rangle\Psi_{uvnm}\right)} \tag{30}$$

where $\Psi_{uvnm}\in\mathcal{H}_3$ is given by (24), and $\Lambda_{nm}(\varkappa)$ has to be set equal to zero if the denominator in (30) is equal to zero (tr_3 denotes the trace in $\mathcal{H}_3$).

Sometimes it is more convenient (cf. the second remark in this article) to write (30) in the form

$$\Lambda_{nm}(\varkappa) = \frac{\sum_{u,v\in G}\lambda_{uv}\|\Psi_{uvnm}\|^2|\Psi_{uvnm}\rangle\langle\Psi_{uvnm}|}{\mathrm{tr}\left(\sum_{u,v\in G}\lambda_{uv}\|\Psi_{uvnm}\|^2|\Psi_{uvnm}\rangle\langle\Psi_{uvnm}|\right)}. \tag{31}$$

Of course, mixed states are not necessarily transformed into mixed ones—possibly there is only one pair u,v such that $\|\Psi_{uvnm}\|>0$. However, immediately from (30) we may conclude the following proposition.

Proposition 6: If $\varkappa$ is a pure state on $\mathcal{H}_1 \otimes \mathcal{H}_2$ then $\Lambda_{nm}(\varkappa)$ is a pure state on $\mathcal{H}_3$ or equal to zero.

C. Examples

Example 1: Let $\varkappa = |\Phi\rangle\langle\Phi|$ be a pure state on $\mathcal{H}_1 \otimes \mathcal{H}_2$, $\|\Phi\| = 1$, $\Phi = \Sigma_{r,s \in G} \alpha_{rs} \xi_r^1 \otimes \xi_s^2$. Then we obtain

$$\Lambda_{nm}(\varkappa) = \frac{1}{\|\Psi_{nm}\|^2} \langle \Psi_{nm}, \cdot \rangle \Psi_{nm} = |\Psi_{nm}\rangle\langle\Psi_{nm}|$$

with

$$\Psi_{nm} = \sum_{r \in G} \overline{b_{nr}} \alpha_{r,r \oplus m} \xi_{r \oplus m}^3,$$

provided $\|\Psi_{nm}\| > 0$. Especially, for $\varkappa = |\Phi\rangle\langle\Phi|$ with $\Phi = \xi_r^1 \otimes \xi_s^2$ we get

$$\Lambda_{nm}(\varkappa) = |\xi_{r \oplus m}^3\rangle\langle\xi_{r \oplus m}^3|$$

provided $b_{n,s \ominus m} \neq 0$.

Let us discuss this result. Measuring the value z_{nm} means that there was made the projection onto $\xi_{nm} = \Sigma_{r \in G} b_{nr} (\xi_r^1 \otimes \xi_{r \oplus m}^2)$. Observe that $\Sigma_{r \in G} |b_{nr}|^2 |\alpha_{r,r \oplus m}|^2 = \|\Psi_{nm}\|^2 > 0$ if and only if there exists at least one $r \in G$ such that $b_{nr} \neq 0$ and $\alpha_{r,r \oplus m} \neq 0$. Obviously, there exists $r \in G$ such that $b_{nr} \neq 0$. The number $\alpha_{r,r \oplus m}$ is the coefficient of the basis element $\xi_r^1 \otimes \xi_{r \oplus m}^2$ in the expansion of $\varkappa = |\Phi\rangle\langle\Phi|$. So only if $\varkappa$ is receptive for the signal $\xi_r^1 \otimes \xi_{r \oplus m}^2$ for at least one admissible r there will be an output transmitted to Bob.

Example 2: We consider the case $G = \mathbb{Z}$ and fix an $N \in \mathbb{N}$. Let the state $\varkappa$ be a finite mixture of basis elements with equal weights:

$$\varkappa = \sum_{u,v=-N}^{N} \frac{1}{(2N+1)^2} |\xi_u^1 \otimes \xi_v^2\rangle\langle\xi_u^1 \otimes \xi_v^2|. \tag{32}$$

Since in this case $\alpha_{uvrs} = \delta_{u,r} \cdot \delta_{v,s}$ we get from (24)

$$\Psi_{uvnm} = \begin{cases} \delta_{v,u+m} \cdot \overline{b_{nu}} \xi_{u+m}^3, & u,v \in \{-N, \ldots, N\} \\ 0 & \text{elsewhere}. \end{cases}$$

Especially,

$$\|\Psi_{uvnm}\|^2 = \begin{cases} |b_{nu}|^2, & u,v \in \{-N, \ldots, N\}, v - u = m \\ 0 & \text{elsewhere}. \end{cases}$$

The conditions $u, v \in \{-N, \ldots, N\}$ and $v - u = m$ imply $m \leqslant 2N$. So we finally get for $n \in G$ and $m \leqslant 2N$

$$\Lambda_{nm}(\varkappa) = \frac{1}{C} \sum_{u=-N}^{N-m} |b_{nu}|^2 |\xi_{u+m}^3\rangle\langle\xi_{u+m}^3|$$

provided

$$C = \sum_{u=-N}^{N-m} |b_{nu}|^2 > 0.$$

For $m > 2N$ the numerator in (30) is equal to zero. That means that measuring the value z_{nm} with $m > 2N$ it is not possible to send any information to Bob.

In further investigations one should consider more refined measurements than simple projections onto one-dimensional subspaces which are obtained just by a change of the basis and a shifting procedure. The next examples elucidates that the whole procedure becomes trivial if we even do not change the basis.

Example 3: Let us consider the (extreme) case that the second basis in $\mathcal{H}_2$ is the old one, i.e., $\eta_n=\xi_n^2$ for all $n\in G$. This implies $b_{nk}=\delta_{n,k}$, and the projection operator F_{nm} is the projection onto $\xi_{nm}=\xi_n^1\otimes\xi_{n\oplus m}^2$. Let $\varkappa$ be an arbitrary normal state on $\mathcal{H}_1\otimes\mathcal{H}_2$ given in the forms (19)–(21). If $\Sigma_{u,v}\lambda_{uv}|\alpha_{uvn,n\oplus m}|^2=0$ there will be no output, i.e., $\Lambda_{nm}(\varkappa)=0$. If $\Sigma_{u,v}\lambda_{uv}|\alpha_{uvn,n\oplus m}|^2>0$ we obtain $\Lambda_{nm}(\varkappa)=|\xi_{n\oplus m}^3\rangle\langle\xi_{n\oplus m}^3|$. Only if the vector $\xi_n^1\otimes\xi_{n\oplus m}^3$ appears in at least one nonzero component Φ_{uv} of the state $\varkappa$ some information will be transmitted and the final state $\Lambda_{nm}(\varkappa)$ will be the pure state $|\xi_{n\oplus m}^3\rangle\langle\xi_{n\oplus m}^3|$.

IV. TRANSFORMATION OF PRODUCT STATES

To be closer to usual teleportation schemes and to get simple and explicit results we want to consider in the sequel the case that the state $\varkappa$ on $\mathcal{H}_1\otimes\mathcal{H}_2$ is a product state:

$$\varkappa=\rho^1\otimes\rho^2 \tag{33}$$

where $\rho^1\in\mathcal{S}(\mathcal{H}_1)$ and $\rho^2\in\mathcal{S}(\mathcal{H}_2)$. Assume $(\Phi_u^1)_{u\in G}$, $(\Phi_u^2)_{u\in G}$ are orthonormal sequences in $\mathcal{H}_1$, respectively, $\mathcal{H}_2$ such that

$$\rho^j=\sum_{u\in G}\lambda_u^j|\Phi_u^j\rangle\langle\Phi_u^j| \quad (j=1,2) \tag{34}$$

with

$$\sum_{u\in G}\lambda_u^j=1, \quad \lambda_v^j\geqslant 0 \quad (j=1,2,v\in G) \tag{35}$$

and Φ_u^j having the representation

$$\Phi_u^j=\sum_{r\in G}\alpha_{ur}^j\xi_r^j \quad (j=1,2,u\in G). \tag{36}$$

Using the notations from (19)–(21) we thus get in that case

$$\lambda_{uv}=\lambda_u^1\cdot\lambda_v^2, \quad \alpha_{uvrs}=\alpha_{ur}^1\cdot\alpha_{vs}^2 \quad (u,v,r,s\in G).$$

Obviously, we have

$$\sum_{r\in G}\bar{\alpha}_{ur}^j\alpha_{vr}^j=\delta_{u,v} \quad (j=1,2,u,v\in G).$$

From (24) we conclude

$$\Psi_{uvnm}=\sum_{r\in G}\overline{b_{nr}}\alpha_{ur}^1\cdot\alpha_{v,r\oplus m}^2\xi_{r\oplus m}^3 \quad (u,v,n,m\in G) \tag{37}$$

and Theorem 5 can be written in the following form.

Theorem 7: *Let $\varkappa=\rho^1\otimes\rho^2$ be a state on $\mathcal{H}_1\otimes\mathcal{H}_2$ given by* (34)–(36). *Then for all $n,m\in G$*

$$\Lambda_{nm}(\rho^1\otimes\rho^2)=\frac{\sum_{u,v\in G}\lambda_u^1\cdot\lambda_v^2\langle\Psi_{uvnm},\cdot\rangle\Psi_{uvnm}}{\mathrm{tr}_3\left(\sum_{u,v\in G}\lambda_u^1\cdot\lambda_v^2\langle\Psi_{uvnm},\cdot\rangle\Psi_{uvnm}\right)} \tag{38}$$

where $\Psi_{uvnm}\in\mathcal{H}_3$ is given by (37) *and where we have to assume that the denominator in* (30) *is greater than zero* (tr_3 *again denotes the trace in* $\mathcal{H}_3$).

We want to express the channel Λ_{nm} acting from $\mathcal{S}(\mathcal{H}_1 \otimes \mathcal{H}_2)$ to $\mathcal{S}(\mathcal{H}_3)$ by a consecutive application of single channels having an intuitive meaning.

First for each $h \in \mathcal{H}_2$ we introduce an operator $A_h : \mathcal{H}_3 \to \mathcal{H}_3$ by

$$A_h f = \sum_{r \in G} \langle \xi_r^2, h \rangle \langle \xi_r^3, f \rangle \xi_r^3 \quad (f \in \mathcal{H}_3). \tag{39}$$

Especially, for all $r \in G$ we have

$$A_h \xi_r^3 = \langle \xi_r^2, h \rangle \xi_r^3 \tag{40}$$

and

$$A_{\xi_r^2} = |\xi_r^3\rangle\langle\xi_r^3|. \tag{41}$$

Obviously,

$$\|A_h f\|^2 = \sum_{r \in G} |\langle \xi_r^2, h \rangle \langle \xi_r^3, f \rangle|^2 \leqslant \|h\|^2 \|f\|^2,$$

so, for each $h \in \mathcal{H}_2$ it holds $A_h \in \mathcal{B}(\mathcal{H}_3)$.

For each $h \in \mathcal{H}_2$ the adjoint of A_h is given by

$$A_h^* f = \sum_{r \in G} \overline{\langle \xi_r^2, h \rangle} \langle \xi_r^3, f \rangle \xi_r^3 \quad (f \in \mathcal{H}_3). \tag{42}$$

On $\mathcal{H}_3$ we define for all $m \in G$ (in the same way as on $\mathcal{H}_2$—cf. (6)) the shift operator $V_m : \mathcal{H}_3 \to \mathcal{H}_3$ characterized by

$$V_m \xi_r^3 = \xi_{r \oplus m}^3 \quad (r \in G) \tag{43}$$

being a unitary operator on $\mathcal{H}_3$.

Finally, let $J_1 : \mathcal{H}_1 \to \mathcal{H}_3$ and $J_2 : \mathcal{H}_2 \to \mathcal{H}_3$ be the isomorphisms exchanging the corresponding basis elements, i.e.,

$$J_1 \xi_r^1 = \xi_r^3, \quad J_2 \xi_r^2 = \xi_r^3 \quad (r \in G). \tag{44}$$

Lemma 8: For all $u, v, n, m \in G$ it holds

$$\Psi_{uvnm} = A_{\Phi_v^2}(V_m A_{\overline{\eta}_n}(J_1 \Phi_u^1)), \tag{45}$$

where $\Psi_{uvnm} \in \mathcal{H}_3$ is given by (37), *the vectors Φ_v^j by* (36) *and $\overline{\eta}_n$ by*

$$\overline{\eta_n} = \sum_{l \in G} \overline{b_{nl}} \xi_l^2 \tag{46}$$

(*cf. definition* (2) *of* η_n).

Proof: From

$$J_1 \Phi_u^1 = \sum_{r \in G} \alpha_{ur}^1 \xi_r^3$$

we conclude

$$V_m A_{\bar{\eta}_n}(J_1\Phi_u^1) = V_m\left(\sum_{r\in G}\alpha_{ur}^1\langle\xi_r^2,\bar{\eta}_n\rangle\xi_r^3\right) = V_m\left(\sum_{r\in G}\alpha_{ur}^1\overline{b_{nr}}\xi_r^3\right) = \sum_{r\in G}\alpha_{ur}^1\overline{b_{nr}}\xi_{r\oplus m}^3$$

$$A_{\Phi_v^2}V_m A_{\bar{\eta}_n}(J_1\Phi_u^1) = \sum_{r\in G}\alpha_{ur}^1\overline{b_{nr}}A_{\Phi_v^2}\xi_{r\oplus m}^3 = \sum_{r\in G}\alpha_{ur}^1\overline{b_{nr}}\alpha_{v,r\oplus m}^2\xi_{r\oplus m}^3$$

what proves because of (37) Lemma 8. □

Observe that for all $h\in\mathcal{H}_2$, $f\in\mathcal{H}_3$ and $r\in G$

$$\langle\xi_r^2,h\rangle\langle\xi_r^3,f\rangle = \langle\xi_r^2,J_2^*f\rangle\langle\xi_r^3,J_2h\rangle.$$

From definition (39) of the operator A_h we thus immediately conclude

Lemma 9: For all $h\in\mathcal{H}_2$, $f\in\mathcal{H}_3$

$$A_h f = A_{J_2^*f}(J_2h). \tag{47}$$

The following property of the operators A_h will be basic for our description of the channel Λ_{nm}.

Lemma 10: Let τ be a positive trace-class operator on $\mathcal{H}_2$ (possibly also the operator being identically zero) and let us be given two different representations of τ

$$\tau = \sum_{k\in G}\gamma_k^1|h_k^1\rangle\langle h_k^1| = \sum_{k\in G}\gamma_k^2|h_k^2\rangle\langle h_k^2| \tag{48}$$

with $\gamma_k^j\geqslant 0$ and $(h_k^j)_{k\in G}$, $j=1,2$ being orthonormal bases in $\mathcal{H}_2$. Then for each positive trace-class operator α on $\mathcal{H}_3$ we have

$$\sum_{k\in G}\gamma_k^1 A_{h_k^1}\alpha A_{h_k^1}^* = \sum_{k\in G}\gamma_k^2 A_{h_k^2}\alpha A_{h_k^2}^*. \tag{49}$$

Proof: It is sufficient to consider the case

$$\alpha = |f\rangle\langle f| \quad (f\in\mathcal{H}_3, \|f\|=1).$$

Using Lemma 9 we get for all $g\in\mathcal{H}_3$ and $j=1,2$

$$\sum_{k\in G}\gamma_k^j A_{h_k^j}|f\rangle\langle f|A_{h_k^j}^* g = \sum_{k\in G}\gamma_k^j A_{h_k^j}f\langle A_{h_k^j}f,g\rangle = \sum_{k\in G}\gamma_k^j A_{J_2^*f}J_2h_k^j\langle A_{J_2^*f}h_k^j,g\rangle = \sum_{k\in G}\gamma_k^j A_{J_2^*f}J_2|h_k^j\rangle\langle h_k^j|J_2^*A_{J_2^*f}^* g$$
$$= A_{J_2^*f}J_2\sum_{k\in G}\gamma_k^j|h_k^j\rangle\langle h_k^j|J_2^*A_{J_2^*f}^* g = A_{J_2^*f}J_2\tau J_2^*A_{J_2^*f}^* g.$$

Consequently, left- and right-hand sides of (49) coincide—the expression in (49) does not depend on the special representation of τ in some basis in $\mathcal{H}_2$.

□

Let us remark that τ may be a finite rank operator since we did not exclude $\gamma_k^j=0$.

Denote by $\mathcal{T}_j$ the set of all positive trace-class operators on $\mathcal{H}_j$, $j=1,2,3$. For each $\tau\in\mathcal{T}_2$ we define a mapping $K_\tau:\mathcal{T}_3\to\mathcal{T}_3$ by the ansatz

$$K_\tau(\alpha) = \sum_{k\in G}\gamma_k A_{h_k}\alpha A_{h_k}^* \quad (\alpha\in\mathcal{T}_3), \tag{50}$$

where

$$\tau = \sum_{k\in G}\gamma_k|h_k\rangle\langle h_k| \quad (j=1,2) \tag{51}$$

with $\gamma_k\geqslant 0$ and $(h_k)_{k\in G}$ being an orthonormal basis in $\mathcal{H}_2$. Lemma 10 guarantees that the mapping K_τ is well defined, i.e., the definition (50) does not depend on the special representation of τ in some basis of $\mathcal{H}_2$.

In the sequel let us make the convention to denote the normalization of a positive trace-class operator $\varkappa$ by $\hat{\varkappa}$, i.e.,

$$\hat{\varkappa} = \frac{\varkappa}{\mathrm{tr}\varkappa} \tag{52}$$

provided $\mathrm{tr}\,\varkappa > 0$.

Now, we are able to express the channel $\Lambda_{nm}(\varkappa)$ as a consecutive application of single channels. This explicit construction will be done only for product states $\varkappa = \rho^1 \otimes \rho^2$. Besides the channel K_τ defined by (50) we still need two other channels—one lifting the state from $\mathcal{H}_1$ to $\mathcal{H}_3$ by the isomorphism J_1 given by (44) and one shifting the states on $\mathcal{H}_3$ with the shift operator V_m defined by (43). We define $K: \mathcal{T}_1 \to \mathcal{T}_3$ by

$$K(\alpha) = J_1 \alpha J_1^* \quad (\alpha \in \mathcal{T}_1) \tag{53}$$

and for $m \in G$ the mapping $K_m: \mathcal{T}_3 \to \mathcal{T}_3$ by

$$K_m(\alpha) = V_m \alpha V_m^* \quad (\alpha \in \mathcal{T}_3). \tag{54}$$

Theorem 11: *For all* $\rho^1 \in \mathcal{S}(\mathcal{H}_1)$, $\rho^2 \in \mathcal{S}(\mathcal{H}_2)$ *and* $n, m \in G$ *it holds*

$$\Lambda_{nm}(\rho^1 \otimes \rho^2) = \hat{K}_{\rho^2} \circ K_m \circ K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|} \circ K(\rho^1) \tag{55}$$

provided $\mathrm{tr}\, K_{\rho^2} \circ K_m \circ K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|} \circ K(\rho^1) > 0$. *Hereby,* $\overline{\eta_n}$ *is given by* (46).

Proof: Let $\rho^1 \otimes \rho^2$ be given by (34)–(36).

Using (38) in Theorem 7 and the representation (45) of Ψ_{uvnm} we obtain for all $u, v, n, m \in G$

$$\begin{aligned}
\sum_{u,v \in G} \lambda_u^1 \cdot \lambda_v^2 \langle \Psi_{uvnm}, \cdot \rangle \Psi_{uvnm} &= \sum_{u,v \in G} \lambda_u^1 \cdot \lambda_v^2 A_{\Phi_v^2} V_m A_{\overline{\eta}_n} J_1 |\Phi_u^1\rangle\langle\Phi_u^1| J_1^* A_{\overline{\eta}_n}^* V_m^* A_{\Phi_v^2}^* \\
&= \sum_{v \in G} \lambda_v^2 A_{\Phi_v^2} V_m A_{\overline{\eta}_n} J_1(\rho^1) J_1^* A_{\overline{\eta}_n}^* V_m^* A_{\Phi_v^2}^* \\
&= \sum_{v \in G} \lambda_v^2 A_{\Phi_v^2} V_m A_{\overline{\eta}_n} K(\rho^1) A_{\overline{\eta}_n}^* V_m^* A_{\Phi_v^2}^* \\
&= \sum_{v \in G} \lambda_v^2 A_{\Phi_v^2} V_m (K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|} \circ K(\rho^1)) V_m^* A_{\Phi_v^2}^* \\
&= \sum_{v \in G} \lambda_v^2 A_{\Phi_v^2} (K_m \circ K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|} \circ K(\rho^1)) A_{\Phi_v^2}^* \\
&= K_{\rho^2} \circ K_m \circ K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|} \circ K(\rho^1).
\end{aligned}$$

Since $\Lambda_{nm}(\rho^1 \otimes \rho^2)$ is just the normalization of the previous expression using the notation (52) we finally obtain (55). □

The aim of teleportation models is to find methods of transmission of states on $\mathcal{H}_1$ to states on $\mathcal{H}_3$ in such a way that Bob is able to reconstruct perfectly or in a nearly perfect way the emitted state—having only knowledge about the result of a certain measurement. In Sec. III we already gave some examples illustrating the model. For the states considered in these examples it will be impossible to reconstruct all original states. However, one is not interested only in perfect teleportations but also in the deformation of the state, the degree of destruction of the input signal, etc. In Ref. 4 we considered the special case of all spaces being equal and finite dimensional. For examples in this case we refer to this article. Further, one can ask for subsets of $\mathcal{S}(\mathcal{H}_1)$ for which perfect teleportation can be achieved. We continue to illustrate the channels and operations previously introduced by simple examples connected with product states. The aim of the examples below is just to illustrate the mechanism of the procedure.

In what follows, summands for which $\|\Psi_{uvnm}\|=0$ just have to be cancelled. If it is equal to zero no information about the input signal (the measurement of the value z_{nm}) will pass to Bob. Such cases of non-perfect teleportation were considered in Ref. 3.

Example 4: Let us consider the extreme case that $\rho^1=|\xi_k^1\rangle\langle\xi_k^1|$ *for some* $k\in G$. *Then* $K(\rho^1)=|\xi_k^3\rangle\langle\xi_k^3|$, *which implies*

$$K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|}\circ K(\rho^1)=|b_{nk}|^2|\xi_k^3\rangle\langle\xi_k^3|.$$

Consequently,

$$K_m\circ K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|}\circ K(\rho^1)=|b_{nk}|^2|\xi_{k\oplus m}^3\rangle\langle\xi_{k\oplus m}^3|.$$

From (40) *we know that for each* $h\in\mathcal{H}_2$ *it holds*

$$A_h|\xi_{k\oplus m}^3\rangle\langle\xi_{k\oplus m}^3|A_h^*=|\langle\xi_{k\oplus m}^2,h\rangle|^2|\xi_{k\oplus m}^3\rangle\langle\xi_{k\oplus m}^3|.$$

For arbitrary state ρ^2 *on* $\mathcal{H}_2$ *this leads to*

$$K_{\rho^2}\circ K_m\circ K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|}\circ K(\rho^1)=|b_{nk}|^2\mathrm{tr}_2(\rho^2|\xi_{k\oplus m}^2\rangle\langle\xi_{k\oplus m}^2|)\cdot|\xi_{k\oplus m}^3\rangle\langle\xi_{k\oplus m}^3|.$$

Finally, if $|b_{nk}|^2\mathrm{tr}_2(\rho^2|\xi_{k\oplus m}^2\rangle\langle\xi_{k\oplus m}^2|)>0$ *we obtain*

$$\Lambda_{nm}(\rho^1\otimes\rho^2)=|\xi_{k\oplus m}^3\rangle\langle\xi_{k\oplus m}^3|.$$

□

We try to give again a possible interpretation of the result. Measuring z_{nm} we made a projection onto $\xi_{nm}=\Sigma_{r\in G}b_{nr}(\xi_r^1\otimes\xi_{r\oplus m}^2)$. At least one of the coefficients $b_{nr}, r\in G$ has to be different from zero. The state Alice wants to teleportate consists only of the elementary signal ξ_k^1 since $\rho^1=|\xi_k^1\rangle\langle\xi_k^1|$. This implies that only the signal $\xi_k^1\otimes\xi_{k\oplus m}^2$ is able to pass. So it is necessary that $b_{nk}\neq 0$. The information about the index n is not contained in the elementary signal $\xi_k^1\otimes\xi_{k\oplus m}^2$ and will not be contained in the output sent to Bob. However, $b_{nk}\neq 0$ is necessary to get an output at all. Further, for the state ρ^2 given by (34)–(36) one easily checks

$$\mathrm{tr}_2(\rho^2|\xi_{k\oplus m}^2\rangle\langle\xi_{k\oplus m}^2|)=\sum_{u\in G}\lambda_u^2|\alpha_{u,k\oplus m}^2|^2.$$

Consequently, to obtain the output $|\xi_{k\oplus m}^3\rangle\langle\xi_{k\oplus m}^3|$ at least for one Φ_u^2 with $\lambda_u^2>0$ it must hold $\alpha_{u,k\oplus m}^2\neq 0$. If Bob would know that only states of the form $\rho^1=|\xi_k^1\rangle\langle\xi_k^1|$ for some $k\in G$ are sent by Alice he obviously has unitary keys to reconstruct the original state. This of course requires that all $b_{nk}\neq 0$ and that the state ρ^2 is such that for all $k\in G$ there exists at least one $u\in G$ such that $\lambda_u^2>0$ and $\alpha_{uk}^2\neq 0$.

Example 5: Now we consider the other extreme case that ρ^2 *is just an elementary signal, i.e., there exists an* $k\in G$ *such that* $\rho^2=|\xi_k^2\rangle\langle\xi_k^2|$. *Analogous calculation as in Example 4 shows that*

$$\Lambda_{nm}(\rho^1\otimes\rho^2)=|\xi_k^3\rangle\langle\xi_k^3|,$$

where we have to assume that $\mathrm{tr}_1(\rho^1|\xi_{k\ominus m}^1\rangle\langle\xi_{k\ominus m}^1|)>0$. *We already observed in the example above that* ρ^2 *should contain as much information as possible. In the case* $\rho^2=|\xi_k^2\rangle\langle\xi_k^2|$ *Bob obtains no information at all abut the state* ρ^1. *Independently of the result* z_{nm} *of the measurement performed by Alice either* $\Lambda_{nm}(\rho^1\otimes\rho^2)=0$ *or equal to* $|\xi_k^3\rangle\langle\xi_k^3|$. *So we have the most extreme case of loss of information*.

V. EXISTENCE OF UNITARY KEYS

We will consider again the case of product states $\varkappa=\rho^1\otimes\rho^2$ on $\mathcal{H}_1\otimes\mathcal{H}_2$ where $\rho^1\in\mathcal{S}(\mathcal{H}_1)$ and $\rho^2\in\mathcal{S}(\mathcal{H}_2)$. That means that the entangled state σ considered in Refs. 2 and 3 has the form $\sigma=S_3\rho^2S_3^*$. For fixed state ρ^2 on $\mathcal{H}_2$ we consider the channel $\tilde{\Lambda}_{nm}:\mathcal{S}(\mathcal{H}_1)\to\mathcal{S}(\mathcal{H}_3)$ given by

$$\tilde{\Lambda}_{nm} := \Lambda_{nm}(\cdot \otimes \rho^2),$$

i.e., (cf. (27) and (29))

$$\tilde{\Lambda}_{nm}(\rho^1) = \frac{\mathrm{tr}_{1,2}((F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)\rho^1 \otimes \lambda(\mathbb{1} \otimes S_3^*)(F_{nm} \otimes \mathbb{1}))}{\mathrm{tr}((F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)\rho^1 \otimes \lambda(\mathbb{1} \otimes S_3^*)(F_{nm} \otimes \mathbb{1}))}. \tag{56}$$

Let $\mathcal{G} \subseteq \mathcal{S}(\mathcal{H}_1)$ be a fixed set of states on $\mathcal{H}_1$.

Definition 12: We say that the teleportation scheme is perfect if for each $n,m \in G$ there exists a unitary operator $V_{nm}: \mathcal{H}_1 \to \mathcal{H}_3$ such that

$$\tilde{\Lambda}_{nm}(\rho^1) = V_{nm}\rho^1 V_{nm}^* \quad (\rho^1 \in \mathcal{G}) \tag{57}$$

and

$$\sum_{n,m \in G} \mathrm{tr}((F_{nm} \otimes \mathbb{1})(\mathbb{1} \otimes S_3)\rho^1 \otimes \rho^2(\mathbb{1} \otimes S_3^*)(F_{nm} \otimes \mathbb{1})) = 1 \quad (\rho^1 \in \mathcal{G}). \tag{58}$$

The unitary operators V_{nm} are called unitary keys.

Usually, perfect teleportation means that the above-mentioned conditions hold for all $\rho^1 \in \mathcal{S}(\mathcal{H}_1)$ (cf. Refs. 2, 3, and 5). The restriction of the set of states that have to be teleportated enlarges the possibilities for perfect or "nearly" perfect models. Condition (57) means that Bob can reconstruct the original state ρ^1 from the knowledge of the result z_{nm} of the measurement and of the received state $\tilde{\Lambda}_{nm}(\rho^1)$ where it is assumed that Bob possesses for each $n,m \in G$ the appropriate key V_{nm}. This follows obviously form $\rho^1 = V_{nm}^* \tilde{\Lambda}_{nm}(\rho^1) V_{nm}$. Finally, (58) means that with probability one Bob will find the proper key, i.e., with certainty there will be a result z_{nm} of measurement for which he has unitary keys.

Let us have a closer look to formula (55). The channel K_m is built with the help of the unitary V_m. The same is true for K since $J_1 J_1^* = J_1^* J_1 = \mathbb{1}$. The channel $K_{|\overline{\eta_n}\rangle\langle\overline{\eta_n}|}$ destroys any hope for unitary keys. An easy calculation shows that for each $f \in \mathcal{H}_3$ it holds

$$A_{\overline{\eta_n}}^* A_{\overline{\eta_n}} f = A_{\overline{\eta_n}} A_{\overline{\eta_n}}^* f = \sum_{r \in G} |b_{nr}|^2 \langle \xi_r^3, f \rangle \xi_r^3. \tag{59}$$

We see that only if G is finite and all $|b_{nk}|$ are equal A will be unitary (up to a constant that vanishes after normalization). This is in accordance with (and another proof of) the fact that perfect teleportation requires finite dimensional spaces and maximal entanglement.

VI. CONCLUDING REMARKS

The aim of this article is to touch the problem of teleportation schemes in infinite-dimensional spaces. The previous results still have to be supplemented by calculations of fidelity and other characteristics. Just to achieve simple explicit expressions we illustrated the model on the most simple sequence of elementary signals (ξ_k^j). To obtain more interesting models one has to refine the above-mentioned models:

(1) consider more complex measurements than simple one-dimensional projections F_{nm},
(2) if the Hilbert space is a symmetric Fock space take *truncated* coherent vectors (exponential vectors with "removed" vacuum part) as basis and beam splittings for the entanglement,
(3) replace the isomorphisms J_1, J_2 and the trivial isometries S_1, S_3 by more complex ones.[6–11]

The quantum relative entropy is frequently used as a distance, or distinguishability measure between two quantum states. In this article we study the relation between this measure and a number of other measures used for that purpose, including the trace norm distance. More specifically, we derive lower and upper bounds on the relative entropy in terms of various distance measures for the difference of the states based on unitarily invariant norms. The upper bounds can be considered as statements of continuity of the relative entropy distance in the sense of Fannes. We employ methods from optimisation theory to obtain bounds that are as sharp as possible. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2044667]

I. INTRODUCTION

The relative entropy of states of quantum systems is a measure of how well one quantum state can be operationally distinguished from another. Defined as

$$S(\rho\|\sigma) = \mathrm{Tr}[\rho(\log\rho - \log\sigma)]$$

for states ρ and σ, it quantifies the extent to which one hypothesis ρ differs from an alternative hypothesis σ in the sense of quantum hypothesis testing.[1–5] Dating back to work by Umegaki,[6] the relative entropy is a quantum generalization of the Kullback–Leibler relative entropy for probability distributions in mathematical statistics.[7] The quantum relative entropy plays an important role in quantum statistical mechanics[5] and in quantum information theory, where it appears as a central notion in the study of capacities of quantum channels[8–11] and in entanglement theory.[11–13]

In *finite-dimensional Hilbert spaces*, the relative entropy functional is manifestly continuous.[5] For states on infinite-dimensional Hilbert spaces the relative entropy functional is not trace norm continuous any more, but-as the von-Neumann entropy—lower semi-continuous. That is, for sequences of states $\{\sigma_n\}_n$ and $\{\rho_n\}_n$ converging in trace norm to states σ and ρ, i.e., $\lim_{n\to\infty}\|\sigma_n - \sigma\|_1 = 0$ and $\lim_{n\to\infty}\|\rho_n - \rho\|_1 = 0$, we merely have $S(\rho\|\sigma) \leqslant \liminf_{n\to\infty} S(\rho_n\|\rho_n)$. However, for systems for which the Gibbs state exists, these discontinuities can be tamed[5] when considering compact subsets of state space with finite mean energy. In a similar manner, entropic measures of entanglement can become trace norm continuous on subsets with bounded energy.[14] For considerations of the continuity of the relative entropy in classical contexts, see Ref. 15. In particular, if $\{\sigma_n\}_n$ is a sequence of states of fixed finite dimension satisfying

$$\lim_{n\to\infty}\|\sigma_n - \sigma\|_1 = \lim_{n\to\infty}\mathrm{Tr}|\sigma_n - \sigma| = 0 \tag{1}$$

for a given state σ, then

[a]Electronic address: k.audenaert@imperial.ac.uk
[b]Electronic address: jense@imperial.ac.uk

$$\lim_{n\to\infty} S(\sigma_n\|\sigma) = 0.$$

In practical contexts, however, more precise estimates can be necessary, in particular in an asymptotic setting. Consider a state ρ on a Hilbert space $\mathcal{H}$, and a sequence $\{\sigma_n\}_n$, where σ_n is a state on $\mathcal{H}^{\otimes n}$, the n-fold tensor product of $\mathcal{H}$. The sequence is said to asymptotically approximate ρ if σ_n tends to $\rho^{\otimes n}$ for $n\to\infty$. More precisely, one typically requires that

$$\lim_{n\to\infty} \|\sigma_n - \rho^{\otimes n}\|_1 = 0. \tag{2}$$

Now, as an alternative to the trace norm distance, one can consider the use of the Bures distance. The Bures distance D is defined as

$$D(\rho_1,\rho_2) = 2(1 - F(\rho_1,\rho_2))^{1/2},$$

in terms of the Uhlmann fidelity

$$F(\rho_1,\rho_2) = \mathrm{Tr}(\rho_1^{1/2}\rho_2\rho_1^{1/2})^{1/2}.$$

Because of the inequalities[16]

$$1 - F(\rho_1,\rho_2) \leqslant \mathrm{Tr}|\rho_1 - \rho_2| \leqslant (1 - F^2(\rho_1,\rho_2))^{1/2}, \tag{3}$$

the trace norm distance tends to zero if and only if the Bures distance tends to zero, which shows that, for the purpose of state discrimination, both distances are essentially equivalent and one can use whichever is most convenient.

A natural question that now immediately arises is whether the same statement is true for the relative entropy. To find an answer to that one would need inequalities like (3) connecting the quantum relative entropy, used as a distance measure, to the trace norm distance, or similar distance measures.

In this article, we do just that: we find upper bounds on the relative entropy functional in terms of various norm differences of the two states. As such, the presented bounds are very much in the same spirit as Fannes' inequality, sharpening the notion of continuity for the von Neumann entropy.[17] It has already to be noted here that one of the main stumbling blocks in this undertaking is the well-known fact that the relative entropy is not a very good distance measure, as it gives infinite distance between nonidentical pure states. However, we will present a satisfactory solution, based on using the minimal eigenvalue of the state that is the second argument of the relative entropy. Apart from the topic of upper bounds, we also study lower bounds on the relative entropy, giving a complete picture of the relation between norm based distances and relative entropy.

We start in Sec. II with presenting a short motivation of how this article came about. Section III contains the relevant notations, definitions, and basic results that will be used in the rest of the paper. In Sec. IV we discuss some properties of unitarily invariant (UI) norms that will allow us to consider all UI norms in one go. The first upper bounds on the relative entropy $S(\rho\|\sigma)$ are presented in Sec. V, one bound being quadratic in the trace norm distance of ρ and σ and the other logarithmic in the minimal eigenvalue of σ. Both bounds separately capture an essential behavior of the relative entropy, and it is argued that finding a single bound that captures both behaviors at once is not a trivial undertaking. Nevertheless, we will succeed in doing this in Sec. VII by constructing upper bounds that are as sharp as possible for given trace norm distance *and* minimal eigenvalue of σ. In Sec. VI we use similar techniques to derive lower bounds that are as sharp as possible. Finally, in Sec. IX, we come back to the issue of state discrimination mentioned at the beginning.

II. BACKGROUND

In Ref. 18 (Example 6.2.31, p. 279) we find the following upper bound on the relative entropy, valid for all ρ and for nonsingular σ:

$$S(\rho\|\sigma) \leqslant \frac{\|\rho-\sigma\|_\infty}{\lambda_{\min}(\sigma)}. \tag{4}$$

This bound is linear in the operator norm distance between ρ and σ and has a $1/x$ dependence on $\lambda_{\min}(\sigma)$. For several purposes, such a bound is not necessarily sharp enough. The impetus for the present article was given by the observation that sharper upper bounds on the relative entropy should be possible than (4). Specifically, there should exist bounds that are

1. *quadratic* in $\rho-\sigma$, and/or
2. depend on $\lambda_{\min}(\sigma)$ in a *logarithmic* way.

A simple argument shows that a logarithmic dependence on $\lambda_{\min}(\sigma)$ can be achieved instead of an $1/x$ dependence. Note that $0 \geqslant \log \sigma \geqslant \mathbb{1}\cdot\log \lambda_{\min}(\sigma)$. Thus,

$$S(\rho\|\sigma) = \mathrm{Tr}[\rho(\log\rho - \log\sigma)] \leqslant -S(\rho) - \log\lambda_{\min}(\sigma) \leqslant -\log\lambda_{\min}(\sigma). \tag{5}$$

Concerning the quadratic dependence on $\rho-\sigma$, we can put $\rho=\sigma+\varepsilon\Delta$, with $\mathrm{Tr}[\Delta]=0$, and calculate the derivative

$$\lim_{\varepsilon\to 0} S(\sigma+\varepsilon\Delta\|\sigma)/\varepsilon$$

and find that this turns out to be zero for any nonsingular σ. Indeed, the gradient of the relative entropy $S(\rho\|\sigma)$ with respect to ρ is, $\mathbb{1}+\log\rho-\log\sigma$ (see Lemma 1). Hence, for $\rho=\sigma$ and $\mathrm{Tr}[\Delta]=0$,

$$\lim_{\varepsilon\to 0} S(\sigma+\varepsilon\Delta\|\sigma)/\varepsilon = \mathrm{Tr}[\Delta(\mathbb{1}+\log\sigma-\log\sigma)] = 0.$$

This seems to imply that for small ε, $S(\sigma+\varepsilon\Delta\|\sigma)$ must at least be quadratic in ε, and, therefore, upper bounds might exist that indeed are quadratic in ε. Further, Ref. 4 contains the following quadratic lower bound (Theorem 1.15)

$$S(\rho\|\sigma) \geqslant \tfrac{1}{2}\|\rho-\sigma\|_1^2. \tag{6}$$

The rest of the article will be devoted to finding firm evidence for these intuitions, by exploring the relation between relative entropy and norm based distances, culminating in a number of bounds that are the sharpest possible.

III. NOTATION

In this article, we will use the following notations. We will use the standard vector and matrix bases: e^i is the vector with the ith element equal to 1, and all other elements being equal to 0. $e^{i,j}$ is the matrix with i,j element equal to 1 and all other elements 0. For any diagonal matrix A, we write A_i as a shorthand for $A_{i,i}$, and $\mathrm{Diag}(a_1,a_2,\ldots)$ is the diagonal matrix with a_i as diagonal elements. We reserve two symbols for the following special matrices:

$$E := \mathrm{Diag}(1,0,\ldots,0) = e^{1,1}, \tag{7}$$

and

$$F := \mathrm{Diag}(1,-1,0,\ldots,0) = e^{1,1} - e^{2,2}. \tag{8}$$

The positive semidefinite order is denoted using the $\geqslant$ sign: $A \geqslant B$ iff $A-B \geqslant 0$ (positive semidefinite).

The (quantum) relative entropy is denoted as $S(\rho\|\sigma)=\mathrm{Tr}[\rho(\log\rho-\log\sigma)]$. All logarithms in this article are natural logarithms. When ρ and σ are both diagonal (i.e., when we encounter the commutative, classical case) we use the shorthand

$$S((r_1,r_2,\ldots)\|(s_1,s_2,\ldots)) := S(\mathrm{Diag}(r_1,r_2,\ldots)\|\mathrm{Diag}(s_1,s_2,\ldots)).$$

Lemma 1: The gradient of the relative entropy $S(\rho\|\sigma)$ with respect to its first argument ρ, being nonsingular, is given by $\mathbb{1}+\log\rho-\log\sigma$.

Proof: The calculation of this derivative is straightforward. Since the classical entropy function $x\mapsto h(x):=-x\log x$ is continuously differentiable on (0,1), and therefore,

$$\left.\frac{\partial}{\partial\varepsilon}\right|_{\varepsilon=0} S(\rho+\varepsilon\Delta)=\mathrm{Tr}[\Delta h'(\rho)],$$

we can write

$$\lim_{\varepsilon\to 0} S(\rho+\varepsilon\Delta\|\sigma)/\varepsilon=\mathrm{Tr}[\Delta(\mathbb{1}+\log\rho-\log\sigma)].$$

□

Finally, we recall a number of series expansions related to the logarithm, which are valid for $-1<y<1$,

$$\log(1-y)=-\sum_{k=1}^{\infty}\frac{y^k}{k},$$

$$\log(1+y)+\log(1-y)=-\sum_{k=1}^{\infty}\frac{y^{2k}}{k},$$

$$\log(1+y)-\log(1-y)=2\sum_{k=0}^{\infty}\frac{y^{2k+1}}{2k+1}.$$

These expansions will be made extensive use of.

IV. UNITARILY INVARIANT NORMS

In this section we collect the main definitions and known results about unitarily invariant norms along with a number of refinements that will prove to be very useful for the rest of the article.

A *unitarily invariant norm* (UI norm), denoted with $|||.|||$, is a norm on square matrices that satisfies the property

$$|||UAV|||=|||A|||\tag{9}$$

for all A and for unitary U, V ([1], Sec. IV B). Perhaps the most important property of UI norms is that they only depend on the singular values of the matrix A. If A is positive semidefinite, then $|||A|||$ depends only on the eigenvalues of A.

A very important class of UI norms are the *Ky Fan norms* $\|.\|_{(k)}$, which are defined as follows: for any given square $n\times n$ matrix A, with singular values $s_j^{\downarrow}(A)$ (sorted in nonincreasing order) and $1\leqslant k\leqslant n$, the k-Ky Fan norm is the sum of the k largest singular values of A:

$$\|A\|_{(k)}=\sum_{j=1}^{k} s_j^{\downarrow}(A).$$

Two special Ky Fan norms are the *operator norm* and the *trace norm*,

$$\|A\|_{\infty}=\|A\|_{(1)},\quad \|A\|_{\mathbf{Tr}}=\|A\|_1=\|A\|_{(n)}.\tag{10}$$

The importance of the Ky Fan norms derives from their leading role in Ky Fan's *Dominance Theorem* (Ref. 19, Theorem IV.2.2):

Theorem 1 (Ky Fan Dominance): *Let A and B be any two $n\times n$ matrices. If B majorizes A*

in all the Ky Fan norms,

$$\|A\|_{(k)} \leqslant \|B\|_{(k)},$$

for all $k=1,2,\ldots$, *then it does so in all other UI norms as well*,

$$|||A||| \leqslant |||B|||.$$

From Ky Fan's Dominance Theorem follows the following well-known norm dominance statement.

Lemma 2: For any matrix A, and any unitarily invariant norm $|||.|||$,

$$\|A\|_\infty \leqslant \frac{|||A|||}{|||E|||} \leqslant \|A\|_1.$$

Proof: We need to show that, for every A,

$$|||(\|A\|_\infty)E||| \leqslant |||A||| \leqslant |||(\|A\|_1)E|||,$$

holds for every unitarily invariant norm. By Ky Fan's dominance theorem, we only need to show this for the Ky Fan norms. All the Ky Fan norms of E are 1, and

$$\|A\|_\infty = \|A\|_{(1)} \leqslant \|A\|_{(k)} \leqslant \|A\|_{(d)} = \|A\|_1$$

follows from the definition of the Ky Fan norms. □

The main mathematical object featuring in this article is not the state, but rather the difference Δ of two states, $\Delta := \rho - \sigma$, and for that object a stronger dominance result obtains. We first show that the largest norm difference between two states occurs for orthogonal pure states. Indeed, by convexity of norms, $|||\rho-\sigma|||$ is maximal in pure ρ and σ. A simple calculation then reveals that, for any unitarily invariant norm,

$$||| \, |\psi\rangle\langle\psi| - |\phi\rangle\langle\phi| \, ||| = (1 - |\langle\psi|\phi\rangle|^2)^{1/2} |||F|||.$$

This achieves its maximal value $|||F|||$ for ψ orthogonal to ϕ, showing that it makes sense to normalise a norm distance $|||\rho-\sigma|||$ by division by $|||F|||$. We will call this a *rescaled* norm. We now have the following dominance result for rescaled norms of differences of states:

Lemma 3: For any Hermitian A, with $\mathrm{Tr}[A]=0$,

$$\frac{\|A\|_\infty}{\|F\|_\infty} \leqslant \frac{|||A|||}{|||F|||} \leqslant \frac{\|A\|_1}{\|F\|_1}.$$

Note that equality can be obtained for any value of $|||A|||$, by setting $A=cF$.

Proof: We need to show, for all traceless Hermitian A, that

$$|||(\|A\|_\infty)F||| \leqslant |||A||| \leqslant |||(\|A\|_1/2)F||| \tag{11}$$

holds for every unitarily invariant norm. Again by Ky Fan's dominance theorem, we only need to do this for the Ky Fan norms $\|.\|_{(k)}$. Since

$$\|F\|_{(k)} = \begin{cases} 1, & k=1 \\ 2, & k>1, \end{cases}$$

and

$$\|X\|_\infty = \|X\|_{(1)} \leqslant \|X\|_{(k)} \leqslant \|X\|_{(d)} = \|X\|_1,$$

the inequalities (11) follow trivially for $k>1$. The case $k=1$ is covered by Lemma 4. □

Lemma 4: For any Hermitian A, with $\mathrm{Tr}[A]=0$,

$$\|A\|_1 \geqslant 2\|A\|_\infty.$$

Proof: Let the Jordan decomposition of A be

$$A = A_+ - A_-, \tag{12}$$

with $A_+, A_- \geqslant 0$. Since $\mathrm{Tr}[A]=0$, clearly $\mathrm{Tr}[A_+]=\mathrm{Tr}[A_-]$ holds. Thus, $\|A\|_1=\mathrm{Tr}|A|=\mathrm{Tr}[A_+]+\mathrm{Tr}[A_-]=2\mathrm{Tr}[A_+]$. Also,

$$\|A\|_\infty = \max(\|A_+\|_\infty, \|A_-\|_\infty). \tag{13}$$

Hence, $\|A\|_\infty \leqslant \max(\|A_+\|_1, \|A_-\|_1)=\mathrm{Tr}[A_+]=\|A\|_1/2$. □

In this article, we will also be dealing with $\Delta=\rho-\sigma$ under the constraint $\sigma \geqslant \beta\mathbb{1}$. Obviously we have

$$\beta \leqslant 1/d.$$

We now show that under this constraint, any rescaled norm of Δ is upper bounded by $1-\beta$.

Lemma 5: For any state ρ, and states σ such that $\sigma \geqslant \beta\mathbb{1}$,

$$T := |||\rho - \sigma|||/|||F||| \leqslant 1 - \beta. \tag{14}$$

Proof: We proceed by maximizing T under the constraint $\sigma \geqslant \beta\mathbb{1}$. Convexity of norms yields that T is maximal when ρ and σ are extremal,[20] hence in ρ being a pure state $|\phi\rangle\langle\phi|$ and σ being of the form

$$\sigma = \beta\mathbb{1} + (1 - \beta d)|\psi\rangle\langle\psi|. \tag{15}$$

Fixing $\phi=e^1$, we need to maximize

$$|||e^{1,1} - \beta\mathbb{1} - (1 - \beta d)|\psi\rangle\langle\psi|||$$

over all ψ. Put $\psi=(\cos\alpha, \sin\alpha, 0, \ldots, 0)^T$, then the eigenvalues of the matrix are

$$\lambda_\pm = ((d-2)\beta \pm ((\beta d)^2 + 4(1-\beta d)\sin^2\alpha)^{1/2})/2$$

and $-\beta$ (with multiplicity $d-2$). One finds that, for $d>2$, $\lambda_+, |\lambda_-| \geqslant \beta$, for any value of α, and both λ_+ and $|\lambda_-|$ are maximal for $\alpha=\pi/2$, as would be expected. The maximal Ky Fan norms of this matrix are therefore

$$\|\,.\,\|_{(1)} = \lambda_+ = 1 - \beta,$$

$$\|\,.\,\|_{(k)} = \lambda_+ + |\lambda_-| + (k-2)\beta = (2 - \beta d) + (k-2)\beta,$$

for $k>1$. Hence, for every Ky Fan norm, the maximum norm value is obtained for orthogonal ϕ and ψ. By the Ky Fan dominance theorem, this must then hold for any UI norm. In case of the trace norm, as well as of the operator norm, the rescaled value of the maximum is $1-\beta$. By Lemma 3, this must then be the maximal value for any rescaled norm. □

Remark: For the Schatten q-norm, $|||F|||=2^{1/q}$. The largest value of $|||F|||$ is 2, obtained for the trace norm, and the smallest value is 1, for the operator norm.

V. SOME SIMPLE UPPER BOUNDS

In this section we present our first attempts at finding upper bounds that capture the essential features of relative entropy. In Sec. III A we present a bound that is indeed quadratic in the trace norm distance, the existence of which was already hinted at in Sec. II. Likewise, in Sec. III B, we find a bound that is logarithmic in the minimal eigenvalue of σ, again in accordance with previous intuition. Combining the two bounds into one that has both of these features turns out to be not so

easy. In fact, in Sec. III C a number of arguments are given that initially hinted at the impossibility of realising sich a combined bound. Nevertheless, we will succeed in finding a combined bound later on in the article, by using techniques from optimisation theory.[20]

A. A quadratic upper bound

Lemma 6: For any positive definite matrix A and Hermitian Δ such that $A+\Delta$ is positive definite,

$$\log(A+\Delta)-\log(A) \leqslant \int_0^\infty \mathrm{d}x (A+x)^{-1}\Delta(A+x)^{-1}.$$

Proof: Since the logarithm is strictly matrix concave,[21] for all $t\in[0,1]$:

$$\log((1-t)A+tB) \geqslant (1-t)\log(A)+t\log(B).$$

Setting $B=A+\Delta$ and rearranging terms then gives

$$\frac{\log(A+t\Delta)-\log(A)}{t} \geqslant \log(A+\Delta)-\log(A),$$

for all $t\in[0,1]$. A fortiori, this holds in the limit for t going to zero, and then the left-hand side is just the Fréchet derivative of log at A in the direction Δ. □

This Lemma allows us to give a simple upper bound on $S(\sigma+\Delta\|\sigma)$. Note that if $A\geqslant B$ then $\mathrm{Tr}[CA]\geqslant\mathrm{Tr}[CB]$ for any $C\geqslant 0$. Therefore, we arrive at

$$S(\rho\|\sigma)=\mathrm{Tr}[(\sigma+\Delta)(\log(\sigma+\Delta)-\log(\sigma))] \leqslant \int_0^\infty \mathrm{d}x\,\mathrm{Tr}[(\sigma+\Delta)(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}]$$

$$=\int_0^\infty \mathrm{d}x\,\mathrm{Tr}[(\sigma+x)^{-1}\sigma(\sigma+x)^{-1}\Delta]+\int_0^\infty \mathrm{d}x\,\mathrm{Tr}[\Delta(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}].$$

The first integral evaluates to $\mathrm{Tr}[\Delta]$, because

$$\int_0^\infty \mathrm{d}x \frac{s}{(s+x)^2}=1$$

for any $s>0$, and therefore gives the value 0. The second integral can be evaluated most easily in a basis in which σ is diagonal. Denoting by s_i the eigenvalues of σ, we get

$$\int_0^\infty \mathrm{d}x\,\mathrm{Tr}[\Delta(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}]=\sum_{i,j}\Delta_{i,j}\Delta_{j,i}\int_0^\infty \mathrm{d}x (s_i+x)^{-1}(s_j+x)^{-1}$$

$$=\sum_{i\neq j}\Delta_{i,j}\Delta_{j,i}\frac{\log s_i-\log s_j}{s_i-s_j}+\sum_i(\Delta_{i,i})^2\frac{1}{s_i}. \tag{16}$$

The coefficients of $\Delta_{i,j}\Delta_{j,i}$ are easily seen to be always positive, and furthermore, bounded from above by $1/\lambda_{\min}(\sigma)$. Hence we get the upper bound

$$\int_0^\infty \mathrm{d}x\,\mathrm{Tr}[\Delta(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}] \leqslant \frac{\mathrm{Tr}[\Delta^2]}{\lambda_{\min}(\sigma)},$$

yielding an upper bound on the relative entropy which is, indeed, quadratic in Δ:

Theorem 2: *For states ρ and σ with $\Delta=\rho-\sigma$, $T=\|\Delta\|_2$ and $\beta=\lambda_{\min}(\sigma)$,*

$$S(\rho\|\sigma) \leqslant \frac{T^2}{\beta}. \tag{17}$$

B. An upper bound that is logarithmic in the minimum eigenvalue of σ

We have already found a sharper bound than (4) concerning its dependence on $\lambda_{\min}(\sigma)$. However, the bound (5) is not sharp at all concerning its dependence on $\rho-\sigma$. A slight modification can greatly improve this. First note

$$|\mathrm{Tr}[\Delta \log \sigma]| \leqslant \|\Delta\|_1 \cdot \|\log \sigma\|_\infty = \mathrm{Tr}|\Delta| \cdot |\log \lambda_{\min}(\sigma)|.$$

This inequality can be sharpened, since $\mathrm{Tr}[\Delta]=0$ and σ is a state. Let $\Delta=\Delta_+-\Delta_-$ be the Jordan decomposition of Δ, then

$$|\mathrm{Tr}[\Delta \log \sigma]| \leqslant \|\Delta_+\|_1 \cdot |\log \lambda_{\min}(\sigma)|, \tag{18}$$

and hence

$$|\mathrm{Tr}[\Delta \log \sigma]| \leqslant \mathrm{Tr}|\Delta|/2 \cdot |\log \lambda_{\min}(\sigma)|.$$

Further, we have Fannes' continuity of the von Neumann entropy,[15]

$$|S(\sigma+\Delta) - S(\sigma)| \leqslant T \log d + \min\left(-T \log T, \frac{1}{e}\right),$$

where d is the dimension of the underlying Hilbert space and $T := \mathrm{Tr}|\Delta|$. Combining all this with

$$S(\sigma+\Delta\|\sigma) = -(S(\sigma+\Delta) - S(\sigma)) - \mathrm{Tr}[\Delta \log \sigma]$$

gives rise to the subsequent upper bound, logarithmic in the smallest eigenvalue of σ.

Theorem 3: *For all states ρ and σ on a d-dimensional Hilbert space, with $T=\|\rho-\sigma\|_1$ and $\beta=\lambda_{\min}(\sigma)$,*

$$S(\rho\|\sigma) \leqslant T \log d + \min\left(-T \log T, \frac{1}{e}\right) - \frac{T \log \beta}{2}. \tag{19}$$

C. A combination of two bounds?

The following question comes to mind almost automatically: can we combine the two bounds (17) and (19) into a single bound that is both quadratic in Δ and logarithmic in $\lambda_{\min}(\sigma)$? This would certainly be a very desirable feature for a good upper bound. For instance, could it be true that

$$S(\rho\|\sigma) \leqslant C \cdot \mathrm{Tr}[(\rho-\sigma)^2] \cdot |\log \lambda_{\min}(\sigma)|,$$

for some constant $C>0$? Unfortunately, the answer to this first attempt is negative. In fact, the proposed inequality is violated no matter how large the value of C.

Proposition 1: For any $r>0$ there exist states σ and ρ such that

$$S(\rho\|\sigma) > r \cdot \mathrm{Tr}[(\rho-\sigma)^2] \cdot |\log \lambda_{\min}(\sigma)|. \tag{20}$$

Proof: It suffices to consider the case that σ, ρ are states acting on the Hilbert space $\mathbb{C}^2$, and that σ and ρ commute. Hence, the statement must only be shown for two probability distributions

$$P = (p, 1-p), \quad Q = (q, 1-q).$$

Without loss of generality we can require q to be in $[0, 1/2]$. Then, one has to show that for any $r>0$ there exist p, q such that the C^∞ function f, defined as

$$f(p,q,r) = r((p-q)^2 + (2-p-q)^2)|\log(q)| - (p\log(p/q) + (1-p)\log[(1-p)/(1-q)]),$$

assumes a negative value. Now, for any $r>1$, fix a $q \in (0,1/2)$ such that $-4r(q\log q)<1$. Clearly,

$$f(q,q,r) = 0, \qquad \frac{\partial}{\partial p}\bigg|_{p=q} f(p,q,r) = 0.$$

Then

$$\frac{\partial^2}{\partial p^2}\bigg|_{p=q} f(p,q,r) = -\frac{1}{1-q} - \frac{1}{q} - 4r\log(q) < -\frac{1}{q} - 4r\log(q) < 0.$$

This means that there exists an $\varepsilon>0$ such that $f(p,q,r)<0$ for $p \in [q, q+\varepsilon]$, which in turn proves the validity of (20). □

The underlying reason for this failure is that the two bounds (19) and (17) are incompatible, in the sense that there are two different regimes where either one or the other dominates. To see when the logarithmic dependence dominates, let us again take the basis where σ is diagonal, with s_i being the main diagonal elements. When keeping $\Delta=\rho-\sigma$ fixed and $s_1=\lambda_{\min}(\sigma)$ tends to zero, then

$$\lim_{s_1\to 0} S(\sigma+\Delta\|\sigma)/|\log s_1| = \Delta_{1,1} < \infty.$$

Hence, in the regime where $\lambda_{\min}(\sigma)$ tends to zero and $\rho-\sigma$ is fixed, the bound (19) is the appropriate one.

The other regime is the one where σ is fixed and $\rho-\sigma$ tends to zero. This can be intuitively seen by considering the case where the states ρ and σ commute (the classical case). Let p_i and q_i be the diagonal elements of ρ and σ, respectively, in a diagonalizing basis, and $r_i=p_i-q_i$. Then

$$S(\rho\|\sigma) = \sum_i (q_i + r_i)\log(1 + r_i/q_i).$$

We can develop $S(\rho\|\sigma)$ as a Taylor series in the r_i, giving

$$S(\rho\|\sigma) = \sum_i \frac{r_i^2}{2q_i} + O(r_i^3).$$

Hence, in the regime where $\rho-\sigma$ tends to zero and σ is otherwise fixed, the relative entropy exhibits the behaviour of bound (17).

In terms of the matrix derivatives, this notion can be made more precise as follows. Denote the bound (19) as

$$g(\rho\|\sigma) = \frac{\mathrm{Tr}[(\rho-\sigma)^2]}{\lambda_{\min}(\sigma)}$$

for states ρ,σ, then clearly

$$\lim_{\varepsilon\to 0} g(\sigma+\varepsilon\Delta\|\sigma)/\varepsilon = 0.$$

On using the integral representation of the second Fréchet derivative of the matrix logarithm,[4]

$$\frac{\partial^2}{\partial\varepsilon^2}\bigg|_{\varepsilon=0} \log(\sigma+\varepsilon\Delta) = -2\int_0^\infty \mathrm{d}x(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}\Delta(\sigma+x)^{-1},$$

one obtains

$$\left.\frac{\partial^2}{\partial\varepsilon^2}\right|_{\varepsilon=0} S(\sigma+\varepsilon\Delta\|\sigma) = -2\,\mathrm{Tr}\left[\sigma\int_0^\infty \mathrm{d}x(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}\right] + 2\,\mathrm{Tr}\left[\Delta\int_0^\infty \mathrm{d}x(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}\right].$$

The right-hand side is bounded from above by

$$\left.\frac{\partial^2}{\partial\varepsilon^2}\right|_{\varepsilon=0} S(\sigma+\varepsilon\Delta\|\sigma) \leqslant \int_0^\infty \mathrm{d}x\,\mathrm{Tr}[\Delta(\sigma+x)^{-1}\Delta(\sigma+x)^{-1}],$$

see Refs. 4 and 22. This bound can be written as in Eq. (16). Therefore, one can conclude that

$$\left.\frac{\partial^2}{\partial\varepsilon^2}\right|_{\varepsilon=0} S(\sigma+\varepsilon\Delta\|\sigma) = \left.\frac{\partial^2}{\partial\varepsilon^2}\right|_{\varepsilon=0} g(\sigma+\varepsilon\Delta\|\sigma)$$

holds for all Δ satisfying $\mathrm{Tr}[\Delta]=0$ if and only if $\sigma=\mathbb{1}/d$, where d is the dimension of the underlying Hilbert space. These considerations seem to spell doom for any attempt at "unifying" the two kinds of upper bounds. However, below we will see how a certain change of perspective will allow us to get out of the dilemma.

VI. A SHARP LOWER BOUND IN TERMS OF NORM DISTANCE

We define $S_{\min}(T)$ with respect to a norm to be the smallest relative entropy between two states that have a distance of exactly T in that norm, that is

$$S_{\min}(T) = \min_{\rho,\sigma}\{S(\rho\|\sigma):|||\rho-\sigma||| = T\}. \tag{21}$$

When one agrees to assign $S(\rho\|\sigma)=+\infty$ for nonpositive ρ, the definition of $S_{\min}$ can be rephrased as

$$S_{\min}(T) = \min_{\Delta,\sigma}\{S(\sigma+\Delta\|\sigma):|||\Delta||| = T,\mathrm{Tr}[\Delta]=0\}. \tag{22}$$

Intuitively one would guess that $S_{\min}$ is monotonously increasing with T. The following lemma shows that this is true, but some care is required in proving it.

Lemma 7: For $T_1\leqslant T_2$, $S_{\min}(T_1)\leqslant S_{\min}(T_2)$.

Proof: Keep σ fixed and define

$$f_\sigma(T) = \min_{\Delta}\{S(\sigma+\Delta\|\sigma):|||\Delta||| = T,\mathrm{Tr}[\Delta]=0\},$$

so that $S_{\min}(T)=\min_\sigma f_\sigma(T)$. Considering $S(\sigma+\Delta\|\sigma)$ as a function of Δ, it is convex and minimal in the origin $\Delta=0$. Further, for the norm balls

$$\mathcal{B}(T) := \{\Delta:|||\Delta||| \leqslant T,\mathrm{Tr}[\Delta]=0\} \tag{23}$$

we have

$$\{0\} = \mathcal{B}(0) \subseteq \mathcal{B}(T_1) \subseteq \mathcal{B}(T_2). \tag{24}$$

This is sufficient to prove that $0=f_\sigma(0)\leqslant f_\sigma(T_1)\leqslant f_\sigma(T_2)$. Now, since this holds for any σ, it also holds when minimising over σ, and that is just the statement of the lemma. □

As a direct consequence, a third equivalent definition of $S_{\min}(T)$ is

$$S_{\min}(T) = \min_{\Delta,\sigma}\{S(\sigma+\Delta\|\sigma):|||\Delta||| \geqslant T,\mathrm{Tr}[\Delta]=0\}. \tag{25}$$

We now show that one can restrict oneself to the commutative case.

Lemma 8: The minimum in Eq. (22) is obtained for σ and Δ commuting.

Proof: Fix Δ and consider a basis in which Δ is diagonal. Let $\rho \mapsto \mathrm{Diag}(\rho)$ be the completely positive trace-preserving map which, in that basis, sets all off-diagonal elements of ρ equal to zero. Thus $\mathrm{Diag}(\Delta)=\Delta$. By monotonicity of the relative entropy,

$$S(\sigma+\Delta\|\sigma) \geqslant S(\mathrm{Diag}(\sigma)+\Delta\|\mathrm{Diag}(\sigma)).$$

Minimizing over all states σ then gives

$$\min_{\sigma} S(\sigma+\Delta\|\sigma) \geqslant \min_{\sigma} S(\mathrm{Diag}(\sigma)+\Delta\|\mathrm{Diag}(\sigma)) = \min_{\sigma}\{S(\sigma+\Delta\|\sigma):[\sigma,\Delta]=0\}.$$

On the other hand, the states σ that commute with Δ are included in the domain of minimization of the left-hand side, hence equality holds. □

For later reference we define the auxiliary function

$$s(x) := \min_{0<r<1-x} S((r+x,1-r-x)\|(r,1-r)), \tag{26}$$

for $0 \leqslant x < 1$. An equivalent expression for this function is given by

$$s(x) := \min_{x<r<1} S((r-x,1-r+x)\|(r,1-r)). \tag{27}$$

The first three nonzero terms in its series expansion around $x=0$ are given by

$$s(x) = 2x^2 + \frac{4}{9}x^4 + \frac{32}{135}x^6 + O(x^8) \tag{28}$$

(obtained using a computer algebra package). Further calculations reveal that some of the higher-order coefficients are negative, the first one being the coefficient of x^{62}. One can easily prove[23] that the lowest order expansion $2x^2$ is actually a lower bound. It is, therefore, the sharpest quadratic lower bound. For values of x up to $1/2$, the error incurred by considering only the lowest order term in (28) is at most 6.5%. For larger values of x, the error increases rapidly. In fact, when x tends to its maximal value of 1, $s(x)$ tends to infinity, as can easily be seen from the minimisation expression (r tends to 0); accordingly, the series expansion diverges. For values of $x > 4/5$, $s(x)$ is well approximated by its upper bound

$$s(x) \leqslant \lim_{r\to 1-x} S((r+x,1-r-x)\|(r,1-r)) = -\log(1-x).$$

This is illustrated in Fig. 1.

Let us now come back to Eq. (22), with σ and Δ diagonal, and $|||.|||$ any unitarily invariant norm. Let σ and Δ have diagonal elements σ_k and Δ_k, respectively. Fixing Δ, we minimize first over σ. This is a convex problem and any local minimum is automatically a global minimum.[20] The corresponding Lagrangian is

$$\mathcal{L} = \sum_k \sigma_k(1+\Delta_k/\sigma_k)\log(1+\Delta_k/\sigma_k) - \nu\left(\sum_k \sigma_k - 1\right). \tag{29}$$

The derivative of the Lagrangian with respect to σ_k is

$$\frac{\partial \mathcal{L}}{\partial \sigma_k} = \log(1+\Delta_k/\sigma_k) - \Delta_k/\sigma_k - \nu. \tag{30}$$

This must vanish in a critical point, giving the expression

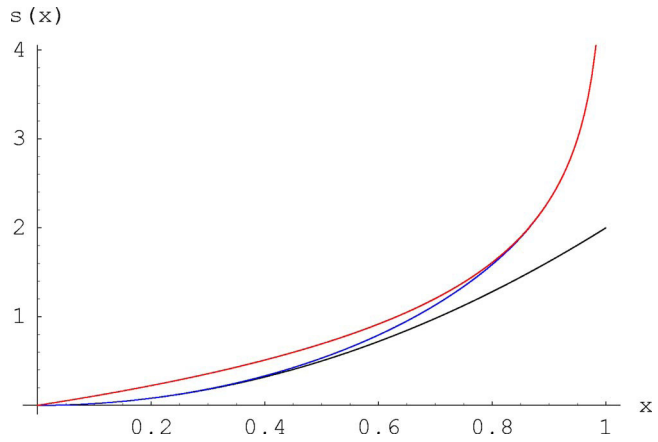

FIG. 1. (Color online) Function s defined in Eq. (26) (middle curve), the lower bound $2x^2$ (lower curve), and the upper bound $-\log(1-x)$ (upper curve).

$$\log(1+\Delta_k/\sigma_k) = \Delta_k/\sigma_k + \nu. \tag{31}$$

Now note that the equation $\log(1+x)-x=b$, for $b<0$ has only two real solutions, one positive and one negative, and none for $b>0$. Therefore, for any $k\Delta_k/\sigma_k$ can assume only one of these two possible values. Let K be an integer between 1 and $d-1$. Without loss of generality we can set

$$\Delta_k/\sigma_k = \begin{cases} c_p, & 1 \leqslant k \leqslant K \\ -c_m, & K < k \leqslant d, \end{cases} \tag{32}$$

where c_p and c_m are positive numbers, to be determined along with K. The requirement $\Sigma_k\Delta_k = 0$ imposes

$$c_p \sum_{k=1}^{K} \sigma_k - c_m \sum_{k=K+1}^{d} \sigma_k = 0,$$

which upon defining

$$r := \sum_{k=1}^{K} \sigma_k, \tag{33}$$

turns into

$$c_p r = c_m(1-r) =: c. \tag{34}$$

Substituting Eqs. (32) and (33), the function to be minimized becomes

$$r(1+c_p)\log(1+c_p) + (1-r)(1-c_m)\log(1-c_m),$$

which, given Eq. (34), can be rewritten as

$$S((r+c, 1-r-c)\|(r, 1-r)).$$

The one remaining constraint $|||\Delta||| = T$ likewise becomes

$$|||(c_p\sigma_1, \ldots, c_p\sigma_K, -c_m\sigma_{K+1}, \ldots, -c_m\sigma_d)||| = T.$$

Defining

$$\tau' := (\sigma_1, \ldots, \sigma_K)/r,$$

$$\tau'' := (\sigma_{K+1}, \ldots, \sigma_d)/(1-r),$$

this turns into

$$T = |||(c_p r\tau'; -c_m(1-r)\tau'')||| = c|||(\tau';\tau'')|||,$$

where we have exploited the homogeneity of a norm. Note that by their definition, τ' and τ'' are vectors consisting of positive numbers adding up to 1.

The minimization itself thus turns into

$$S_{\min}(T) = \min_{r,\tau',\tau''} S((r+c,1-r-c)\|(r,1-r)),$$

where $c := T/|||(\tau';\tau'')|||$. Quite obviously, the minimum over c is obtained for the smallest possible c, hence

$$S_{\min}(T) = \min_{r} S((r+T/\gamma,1-r-T/\gamma)\|(r,1-r)) = s(T/\gamma),$$

with

$$\gamma = \max_{\tau',\tau''} |||(\tau';\tau'')|||.$$

By convexity of a norm, this maximum is obtained in an extreme point, so

$$\gamma = |||F|||.$$

Incidentally, by Lemma 5, this value is also the maximum

$$\max_{\rho,\sigma} |||\rho-\sigma|||,$$

over all possible states ρ and σ, i.e., γ is the largest possible value of T for the given norm. We have thus proven

Theorem 4: *For any unitarily invariant norm* $|||.|||$, *we have the sharp lower bound*

$$S(\rho\|\sigma) \geqslant s(|||\rho-\sigma|||/|||F|||). \tag{35}$$

A few remarks are in order at this point:

(1) Within the setting of finite-dimensional systems, this theorem generalizes a result of Refs. 4 and 24 for the trace norm to all unitarily invariant norms. This article also uses the technique of getting lower bounds by projecting on an abelian subalgebra and then exploiting the case of a two-dimensional support as the worst case scenario.

(2) If we take the results of Refs. 4 and 24 for granted and combine it with Lemma 3, we immediately get

$$S(\rho\|\sigma) \geqslant s(\|\rho-\sigma\|_1/\|F\|_1) \geqslant s(|||\rho-\sigma|||/|||F|||).$$

(3) The divergence of s at $x=1$ is easily understood. The largest norm difference between two states occurs for orthogonal pure states, in which case their relative entropy is infinite.

VII. SHARP UPPER BOUNDS IN TERMS OF NORM DISTANCE

Let now $S_{\max}(T,\beta)$ be the largest relative entropy between ρ and σ that have a normalized distance of exactly T and $\lambda_{\min}(\sigma)=\beta$, so let

$$S_{\max}(T,\beta) := \max_{\rho,\sigma}\left\{ S\left(\rho||\sigma\right): \frac{|||\rho-\sigma|||}{|||F|||} = T, \lambda_{\min}(\sigma) = \beta \right\}. \tag{36}$$

The need for the extra parameter β arises because for $\beta=0$, $S_{\max}$ is infinite, as can be seen by taking different pure states for ρ and σ. We can rephrase this definition as

$$S_{\max}(T,\beta) = \max_{\Delta,\sigma}\left\{ S(\sigma+\Delta\|\sigma): \frac{|||\Delta|||}{|||F|||} = T, \mathrm{Tr}[\Delta]=0, \sigma+\Delta \geqslant 0, \lambda_{\min}(\sigma)=\beta \right\}. \tag{37}$$

Because Δ commutes with the identity matrix, there is a unique common least upper bound on $\beta\mathbb{1}$ and $-\Delta$, which we will denote by $\max(\beta\mathbb{1},-\Delta)$. In the eigenbasis of Δ, this is a diagonal matrix with diagonal elements $\max(\beta,-\Delta_i)$. The constraints $\sigma\geqslant\beta$ and $\sigma+\Delta\geqslant 0$ can therefore be combined into the single constraint

$$\sigma \geqslant \max(\beta\mathbb{1},-\Delta). \tag{38}$$

The extremal σ obeying this constraint are

$$\sigma = \max(\beta\mathbb{1},-\Delta) + \eta|\psi\rangle\langle\psi|, \tag{39}$$

where ψ is any state vector, and

$$\eta := 1 - \mathrm{Tr}[\max(\beta\mathbb{1},-\Delta)]. \tag{40}$$

Therefore, the constrained maximisation over σ can be replaced by an unconstrained maximisation over all pure states of the function

$$S(\Delta + \max(\beta\mathbb{1},-\Delta) + \eta|\psi\rangle\langle\psi| \,\|\max(\beta\mathbb{1},-\Delta) + \eta|\psi\rangle\langle\psi|). \tag{41}$$

Of course, all of this puts constraints on Δ as well. Indeed, in order that states σ obeying (38) exist, $\max(\beta\mathbb{1},-\Delta)$ must obey the condition

$$\mathrm{Tr}[\max(\beta\mathbb{1},-\Delta)] \leqslant 1. \tag{42}$$

We now have to distinguish between two cases: the case $d=2$, and the case $d>2$.

A. The case $d=2$

For the $d=2$ case, the maximization over Δ is trivial. In its eigenbasis, Δ is a multiple of $\mathrm{Diag}(1,-1)=F$. Hence, fixing the eigenbasis of Δ (which we can do because of unitary invariance of the relative entropy), and fixing

$$|||\Delta|||/|||F||| = T, \tag{43}$$

actually leaves just one possibility for Δ, namely $\Delta=TF$. The term $\max(\beta\mathbb{1},-\Delta)$ leads to two cases: $T\leqslant\beta$ and $T>\beta$.

The condition $T\leqslant\beta$ implies, by Lemma 3, that $\|\Delta\|_\infty\leqslant\beta$ and, hence,

$$\max(\beta\mathbb{1},-\Delta) = \mathrm{Diag}(\beta,\beta),$$

$$\eta = 1-2\beta.$$

The remaining maximization of (41) is therefore given by

$$\max_{\psi} S(\mathrm{Diag}(\beta+T,\beta-T)+(1-2\beta)|\psi\rangle\langle\psi|\,\|\mathrm{Diag}(\beta,\beta)+(1-2\beta)|\psi\rangle\langle\psi|). \tag{44}$$

Positivity of η requires $\beta\leqslant 1/2$. By unitary invariance of the relative entropy, and invariance of diagonal states under diagonal unitaries (phase factors), we can restrict ourselves to vectors ψ of the form $\psi=(\cos\alpha,\sin\alpha)^T$.

Lemma 9: For a state vector $\psi=(\cos\alpha,\sin\alpha)^T$, *the function to be maximized in (44) is convex in* $\cos(2\alpha)$.

Proof: Let D_1 be the determinant of the first argument. It is linear in $t:=\cos(2\alpha)$:

$$D_1=\beta^2-T^2+(1-2\beta)(\beta-Tt).$$

After some basic algebra involving eigensystem decompositions of the states, the function to be maximized in (44) is found to be given by

$$f(x):=((1-x)\log(1-x)+(1+x)\log(1+x))/2+(-1+2\beta-2Tt)(\log(1-\beta)-\log\beta)/2$$
$$-(\log(4-4\beta)+\log\beta)/2,$$

where $x=(1-4D_1)^{1/2}$. We will now show that this function is convex in t. Since the second and third terms are linear in t, we only need to show convexity for the first term. The series expansion of the first term is

$$((1-x)\log(1-x)+(1+x)\log(1+x))/2=\sum_{k=1}^{\infty}\frac{x^{2k}}{2k(2k-1)}.$$

Every term in the expansion is a positive power of x^2 with positive coefficient and is therefore convex in x^2, which itself is linear in t.The sum is therefore also convex in t. □

By the previous lemma, the maximum of the maximization over ψ is obtained for extremal values of t, that is: either $\psi=(1,0)^T$ or $\psi=(0,1)^T$. Evaluation of the maximum is now straightforward and it can be checked that the choice $\psi=(1,0)^T$ always yields the largest value of the relative entropy.

We will now more specifically look at the case where $T>\beta$. In this case, we get

$$\max(\beta\mathbb{1},-\Delta)=\mathrm{Diag}(\beta,T),$$

$$\eta=1-\beta-T,$$

and the remaining maximization of (41) is given by

$$\max_{\psi} S(\mathrm{Diag}(\beta+T,0)+(1-\beta-T)|\psi\rangle\langle\psi|\,\|\mathrm{Diag}(\beta,T)+(1-\beta-T)|\psi\rangle\langle\psi|). \tag{45}$$

Positivity of η requires $\beta\leqslant 1/2$ and $T\leqslant 1-\beta$. Again, we can restrict ourselves to states $\psi=(\cos\alpha,\sin\alpha)^T$. We also have the equivalent of Lemma 9, which needs more work in this case.

Lemma 10: For a state vector $\psi=(\cos\alpha,\sin\alpha)^T$, *the function to be maximised in (45) is convex in* $\cos(2\alpha)$.

Proof: Let D_1 and D_2 be the determinant of the first and second argument, respectively. Both are linear in $t:=\cos(2\alpha)$:

$$D_1=(1-\beta-T)(\beta+T)(1-t)/2,$$

$$D_2=((\beta+T-\beta^2-T^2)+(1-\beta-T)(T-\beta)t)/2.$$

In the (D_1,D_2) plane, this describes a line segment with gradient

$$K := -\frac{T-\beta}{T+\beta},$$

which lies in the interval $[-1,0]$.

Again, after some basic algebra, the function to be maximized in (45) is identified to be $f((1-4D_1)^{1/2},(1-4D_2)^{1/2})$, where

$$f(x,y) := ((1-x)\log(1-x)+(1+x)\log(1+x))/2 + ((x^2+y^2-2y-4T^2)\log(1-y) - (x^2+y^2+2y-4T^2)\log(1+y))/4y.$$

We will now show that $f((1-4D_1)^{1/2},(1-4D_2)^{1/2})$ is convex in t. First, note that

$$f(x,y) = f_0(x,y) + T^2 f_1(y).$$

The term $f_1(y)$ is itself convex in t: its series expansion is

$$f_1(y) = (\log(1+y)-\log(1-y))/y = 2\sum_{k=0}^{\infty}\frac{y^{2k}}{2k+1},$$

which by the positivity of all its coefficients is convex in y^2, and y^2 is linear in t.

The other term, $f_0(x,y)$ is given by a sum of three terms

$$f_0(x,y) = \frac{1}{2}((1-x)\log(1-x)+(1+x)\log(1+x)) + \frac{1}{4}((y-2)\log(1-y)-(y+2)\log(1+y)) - \frac{x^2}{4}(\log(1+y)-\log(1-y))/y.$$

Replacing each of the three terms by its series expansion yields

$$f_0(x,y) = \sum_{k=1}^{\infty}\frac{x^{2k}}{2k(2k-1)} + \sum_{k=1}^{\infty}(k-1)\frac{y^{2k}}{2k(2k-1)} - \frac{x^2}{2}\sum_{k=0}^{\infty}\frac{y^{2k}}{2k+1}.$$

To show that this function is convex in t, we will evaluate it along the curve

$$x^2 = u+p,$$

$$y^2 = v+Kp,$$

with gradient K between 0 and -1, and u and v lying in the interval $[0,1]$, and check positivity of its second derivative with respect to p at $p=0$:

$$\left.\frac{\partial^2}{\partial p^2}\right|_{p=0} f_0(x,y) = \sum_{k=2}^{\infty}\frac{k-1}{2k-1}u^{k-2} + (k-1)\left(K\frac{(k-1)K-2}{2k-1} - K^2\frac{k}{2k+1}u\right)v^{k-2}.$$

The coefficient of u^{k-2} is clearly positive, hence the derivative is positive if the coefficient of v^{k-2} is positive for all allowed values of u and K. The worst case occurs for $u=1$, yielding a coefficient

$$K\frac{(k-1)K-2}{2k-1} - K^2\frac{k}{2k+1} = \frac{-K(2+4k+K)}{(2k-1)(2k+1)}.$$

For values of K between 0 and -1, this is indeed positive. □

By the previous lemma, the maximum of the maximization over ψ is obtained for extremal values of t, that is: either $\psi=(1,0)^T$ or $\psi=(0,1)^T$. Evaluation of the maximum is again straightforward, and calculations show that sometimes $\psi=(1,0)^T$ yields the larger value, and sometimes $\psi=(0,1)^T$. In this way we have obtained the upper bounds.

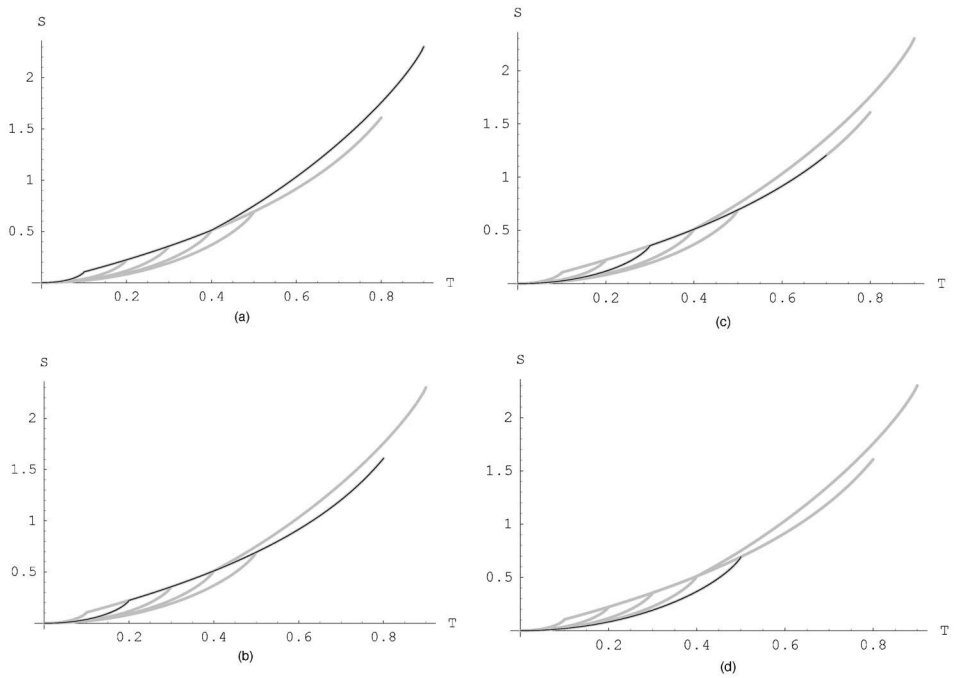

FIG. 2. Upper bounds of Theorem 5 on $S=S(\rho\|\sigma)$ vs. the rescaled norm distance $T=|||\rho-\sigma|||/|||F|||$, for $d=2$, and for values of smallest eigenvalue of σ (a) $\beta=0.1$, (b) 0.2, (c) 0.3, and (d) 0.5. The two regimes $T\leqslant\beta$ and $\beta\leqslant T\leqslant 1-\beta$ can be clearly identified. For ease of comparison, each curve is shown superimposed on the curves for $\beta=0.1$, 0.2, 0.3, 0.4, and 0.5 shaded line.

Theorem 5: *Let* $\Delta=\rho-\sigma$, $T=|||\Delta|||/|||F|||$ *and* $\beta=\lambda_{\min}(\sigma)$. *For* $d=2$, *and* $T\leqslant\beta$,

$$S(\rho\|\sigma)\leqslant(T+1-\beta)\log\frac{T+1-\beta}{1-\beta}+(\beta-T)\log(1-T/\beta). \tag{46}$$

For $d=2$, *and* $T>\beta$,

$$S(\rho\|\sigma)\leqslant\max(-\log(1-T)\ ,$$

$$(\beta+T)\log(1+T/\beta)+\ (1-\beta-T)\log(1-T/(1-\beta))). \tag{47}$$

It is interesting to study the behavior of the bound in the case of large β. More specifically, an approximation for bound (46), valid for $T\ll\beta$, is

$$S(\rho\|\sigma)\leqslant\sum_{k=2}^{\infty}\frac{T^k}{k(k-1)}\left(\frac{1}{\beta^k}-\frac{(-1)^k}{(1-\beta)^k}\right)\approx\frac{T^2}{2\beta(1-\beta)}, \tag{48}$$

Figure 2 illustrates the combined upper bounds of Theorem 5 ($d=2$) for various values of β.

B. The case $d>2$

In case d is larger than 2, it is not clear how to proceed in the most general setting, for general UI norms, as the maximization over Δ must explicitly be performed. In the following, we will restrict ourselves to using the trace norm, which is in some sense the most important one anyway. That is, the requirements on Δ are

$$\|\Delta\|_1=2T, \tag{49}$$

$$\mathrm{Tr}[\Delta] = 0, \tag{50}$$

$$\mathrm{Tr}[\max(\beta\mathbb{1}, -\Delta)] \leqslant 1. \tag{51}$$

The following very simple lemma will prove to be a powerful tool.

Lemma 11: For all A, B, and C, *positive semidefinite operators*,

$$S(A + C\|B + C) \leqslant S(A\|B).$$

Proof: First note that for any $a > 0$,

$$S(aA\|aB) = \mathrm{Tr}[aA(\log(aA) - \log(aB))] = aS(A\|B).$$

This, together with joint convexity of the relative entropy in its arguments (which need not be normalized to trace 1), leads to

$$S(A + C\|B + C) = 2S\left(\frac{A + C}{2}\middle\|\frac{B + C}{2}\right) \leqslant S(A\|B) + S(C\|C) = S(A\|B).$$

□

The Lemma immediately yields an upper bound on (41): letting

$$\sigma := \max(\beta\mathbb{1}, -\Delta) + \eta|\psi\rangle\langle\psi|,$$

such that we obtain

$$S(\Delta + \sigma\|\sigma) \leqslant S(\Delta + \max(\beta\mathbb{1}, -\Delta)\|\max(\beta\mathbb{1}, -\Delta)) = S((\Delta + \beta\mathbb{1})_+\|\beta\mathbb{1} + (\Delta + \beta\mathbb{1})_-). \tag{52}$$

To continue, we consider two cases.

Case 1: When $T \leqslant \beta$, requirement (51) is automatically satisfied, and $\max(\beta\mathbb{1}, -\Delta) = \beta\mathbb{1}$. Let Δ_+ and Δ_- be the positive and negative part of Δ, respectively. That is, $\Delta = \Delta_+ - \Delta_-$, with Δ_+ and Δ_- nonnegative and orthogonal. Because we are using the trace norm we can rewrite the conditions on Δ as

$$\|\Delta\|_1 = \mathrm{Tr}[\Delta_+] + \mathrm{Tr}[\Delta_-] = 2T,$$

$$\mathrm{Tr}[\Delta] = \mathrm{Tr}[\Delta_+] - \mathrm{Tr}[\Delta_-] = 0,$$

hence

$$\mathrm{Tr}[\Delta_+] = \mathrm{Tr}[\Delta_-] = T.$$

By Lemma 11, (41) is upper bounded by $S(\Delta + \beta\mathbb{1}\|\beta\mathbb{1})$. By convexity, its maximum over Δ_+, $\Delta_- \geqslant 0$, with $\mathrm{Tr}[\Delta_+] = \mathrm{Tr}[\Delta_-] = T$, is obtained in Δ_+ and Δ_- of rank 1, giving as upper bound

$$S(\Delta + \sigma\|\sigma) \leqslant (\beta + T)\log\frac{\beta + T}{\beta} + (\beta - T)\log\frac{\beta - T}{\beta}.$$

The upper bound can be achieved in dimensions $d \geqslant 3$ for all values of $T \leqslant \beta$ by setting $\Delta = TF$ and $\psi = e^3$.

Case 2: In the other case, when $T > \beta$, we have to deal with condition (51). To do that we split Δ into three nonnegative parts,

$$\Delta = \Delta_+ - \Delta_0 - \Delta_-, \tag{53}$$

with Δ_+, Δ_0 and Δ_-, operating on orthogonal subspaces V_+, V_0 and V_-, respectively, with

$$\Delta_+ \geqslant 0,$$

$$0 \geqslant -\Delta_0 \geqslant -\beta\mathbb{1}_0,$$

$$-\beta\mathbb{1}_- \geqslant -\Delta_-.$$

We denote the projectors on these subspaces by $\mathbb{1}_+$, $\mathbb{1}_0$, and $\mathbb{1}_-$. Then

$$(\Delta+\beta)_+ = \Delta_+ - \Delta_0 + \beta\mathbb{1}_{+0},$$

where $\mathbb{1}_{+0} := \mathbb{1}_+ + \mathbb{1}_0$. The conditions on Δ, $\mathrm{Tr}[\Delta]=0$ and $\mathrm{Tr}[|\Delta|]=2T$ translate to

$$\mathrm{Tr}[\Delta_+] = \mathrm{Tr}[\Delta_0] + \mathrm{Tr}[\Delta_-] = T.$$

Due to the orthogonality of positive and negative part, (52) can be simplified to $S((\Delta+\beta\mathbb{1})_+ \| \beta\mathbb{1}_{+0})$. After subtracting $\beta\mathbb{1}_0 - \Delta_0$ from both arguments, we get

$$S(\Delta_+ + \beta\mathbb{1}_+ \| \beta\mathbb{1}_+ + \Delta_0),$$

which is an upper bound on (52), by Lemma 11. Ignoring condition (51) on Δ, we get

$$S_{\max} \leqslant \max_{\substack{\Delta_+ \geqslant 0 \\ \mathrm{Tr}[\Delta_+]=T}} S(\Delta_+ + \beta\mathbb{1}_+ \| \beta\mathbb{1}_+).$$

By convexity, the maximum is obtained for Δ_+ rank 1, giving the upper bound

$$S_{\max} \leqslant (T+\beta)\log((T+\beta)/\beta).$$

To see that this bound is sharp for (almost) any value of T, consider the two states

$$\rho = \mathrm{Diag}(T+\beta, 0, 0^{\times J}, \beta^{\times K}, \beta+\eta),$$

$$\sigma = \mathrm{Diag}(\beta, T-J\beta, \beta^{\times J}, \beta^{\times K}, \beta+\eta),$$

$$\eta := 1 - T - (d-1-J)\beta.$$

Here, J is an integer between 0 and $d-3$ and $k=d-3-J$. Conditions on J are $J\beta \leqslant T$ (so that $\sigma \geqslant 0$) and $T \leqslant 1-(d-1-J)\beta$ (so that $\eta \geqslant 0$). This choice of states can thus be obtained for $\beta \leqslant T \leqslant 1-2\beta$. It can be seen that $\|\rho-\sigma\|_1 = 2T$ and

$$S(\rho\|\sigma) = (T+\beta)\log((T+\beta)/\beta). \tag{54}$$

The result of the foregoing can be subsumed into the following theorem.

Theorem 6: *Let* $\Delta=\rho-\sigma$, $T=\|\Delta\|_1/2$ *and* $\beta=\lambda_{\min}(\sigma)$. *If* $T \leqslant \beta$ *then*

$$S(\rho\|\sigma) \leqslant (\beta+T)\log\frac{\beta+T}{\beta} + (\beta-T)\log\frac{\beta-T}{\beta}, \tag{55}$$

and this upper bound is sharp when $d>2$. *If* $\beta \leqslant T \leqslant 1-\beta$ *then*

$$S(\rho\|\sigma) \leqslant (\beta+T)\log\frac{\beta+T}{\beta}. \tag{56}$$

When $d>2$, *this bound is sharp for (at least)* $\beta \leqslant T \leqslant 1-2\beta$.

Figure 3 illustrates these bounds and shows their superiority to the previously obtained bound (19).

Again, it is interesting to look at the bound for large β. An approximation for bound (55), valid for $T \ll \beta$, is given by

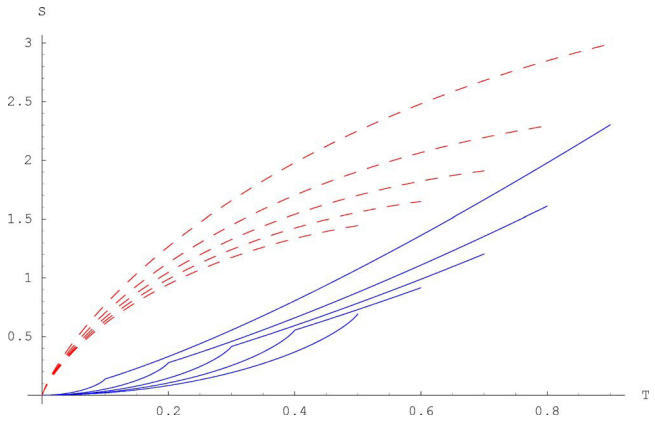

FIG. 3. (Color online) Comparison between upper bounds (19), (55), and (56) on $S=S(\rho\|\sigma)$ vs. the trace norm distance $T=\|\rho-\sigma\|_1/2$, for various values of β, the smallest eigenvalue of σ. The upper set of dashed curves depict bound (19) (with $d=3$) for $\beta=0.1$ (lower curve), 0.2, 0.3, 0.4, and 0.5 (upper curve). The lower set of full line curves depict bounds (55) and (56) for $\beta=0.1$ (upper curve), 0.2, 0.3, 0.4, and 0.5 (lower curve). The two regimes $T\leqslant\beta$ and $\beta\leqslant T\leqslant 1-\beta$ can be clearly seen.

$$S(\rho\|\sigma)\leqslant\sum_{k=1}^{\infty}\frac{T^{2k}}{k(2k-1)\beta^{2k-1}}\approx\frac{T^2}{\beta}. \tag{57}$$

VIII. APPLICATION TO STATE APPROXIMATION

In the following paragraph we will give an application of our bounds to state approximation. Consider a state ρ on a Hilbert space $\mathcal{H}$, and a sequence $\{\sigma_n\}_n$ where σ_n is a state on $\mathcal{H}^{\otimes n}$. As before, the sequence is said to asymptotically approximate ρ if for n tending to infinity, $\|\sigma_n-\rho^{\otimes n}\|_1=\mathrm{Tr}|\sigma_n-\rho^{\otimes n}|$ tends to zero. Let us define T_n as

$$T_n:=\mathrm{Tr}|\rho^{\otimes n}-\sigma_n|/2.$$

Because of the lower bound (6), we get

$$S_n:=S(\rho^{\otimes n}\|\sigma_n)\geqslant 2T_n^2,$$

and this bound is sharp. Hence, T_n goes to zero if S_n does.

On the other hand, T_n going to zero does not necessarily imply S_n going to zero. Indeed, S_n can be infinite for any finite value of n when $\rho^{\otimes n}$ is not restricted to the range of σ_n. In particular, the relative entropy distance between two pure states is infinite unless the states are identical. At first sight, this seems to render the relative entropy useless as a distance measure. Nevertheless, sense can be made of it by imposing an additional requirement that the range of σ_n must contain the range of $\rho^{\otimes n}$. Let us then restrict σ_n to the range of $\rho^{\otimes n}$, as the relative entropy only depends on that part of σ_n. Letting d be the rank of ρ, the dimension of the range of $\rho^{\otimes n}$ is d^n. Let β_n be the smallest nonzero eigenvalue of σ_n on that range; β_n is at most $1/d^n$.

The behavior of the relative entropy then very much depends on the relation between β_n and T_n. Since β_n decreases at least exponentially, we only need to consider the case $T_n\geqslant\beta_n$, and use the bound (56)

$$S_n\leqslant(\beta_n+T_n)\log\left(1+\frac{T_n}{\beta_n}\right).$$

In the worst-case behavior of T_n (T_n/β_n tending to infinity) the bound can be approximated by

$$S_n \leqslant T_n \log \frac{T_n}{\beta_n} = T_n(\log T_n - \log \beta_n) \approx T_n |\log \beta_n|.$$

To guarantee convergence of S_n we therefore need T_n to converge to 0 at least as fast as $1/|\log \beta_n|$, which in the best case goes as $1/n$. Note that bound (19) yields the same requirement, but as this bound is not a sharp one it could have been too strong a requirement. This gives us the subsequent theorem.

Theorem 7: *Consider a state ρ on a finite-dimensional Hilbert space $\mathcal{H}$ and a sequence $\{\sigma_n\}_n$ of states σ_n on $\mathcal{H}^{\otimes n}$. The sequence $\{\sigma_n\}_n$ asymptotically approximates ρ in the trace norm, if*

$$\lim_{n\to\infty} S(\rho^{\otimes n} \| \sigma_n) = 0. \tag{58}$$

Conversely, if the range of σ_n includes the range of $\rho^{\otimes n}$ and $\|\rho^{\otimes n} - \sigma_n\|_1$ *converges to zero faster than $1/|\log \beta_n|$, where β_n is the minimal eigenvalue of σ_n restricted to the range of $\rho^{\otimes n}$, then* $\lim_{n\to\infty} S(\rho^{\otimes n} \| \sigma_n) = 0$.

IX. SUMMARY

In this article, we have discussed several lower and upper bounds on the relative entropy functional, thereby sharpening the notion of continuity of the relative entropy for states which are close to each other in the trace norm sense.

The main results are the sharp lower bound from Theorem 4, and the sharp upper bounds of Theorems 5 ($d=2$) and 6 ($d>2$). Theorems 4 and 5 give the relation between relative entropy and norm distances based on any unitarily invariant norm, while Theorem 6 holds only for the trace norm distance. These results have been obtained employing methods from optimization theory.

The frequency spectrum of the Casimir effect

Andrew S. I. D. Lang[a)]
Computer Science and Mathematics Department, Oral Roberts University, Tulsa, Oklahoma 74171

(Received 18 March 2005; accepted 29 July 2005; published online 17 October 2005)

The frequency spectrum of the Casimir effect between parallel plates is studied. Calculations are performed for both the massless scalar field and the electromagnetic field cases, first using a spectral weight function, and then via the Fourier transform of the renormalized expectation of the Casimir energy-momentum operator. The Casimir force is calculated using the spectrum for two plates which are perfectly transparent in a frequency band. The result of this calculation suggests a way to detect the frequency spectrum of the Casimir effect. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2046529]

I. INTRODUCTION

The Casimir effect[1] is a force between two physical objects, classically a pair of perfectly conducting parallel plates, resulting from quantum vacuum fluctuations of the electromagnetic field between them. In recent years, this relatively small effect has been detected in the laboratory.[2] It has also been extensively studied, see Bordag *et al.*[3] for a comprehensive review, and Milton[4] for a more recent one.

Between two perfectly conducting parallel plates, the Casimir effect can be calculated by subtracting the infinite regularized vacuum zero-point energy per unit area of the electromagnetic field

$$E_v(l) = \hbar c \lim_{\Omega\to\infty} \frac{3l}{\pi^2}\Omega^4, \tag{1}$$

from the again infinite regularized zero-point energy per unit area for the electromagnetic field between the two plates

$$E_p(l) = \hbar c \lim_{\Omega\to\infty} \left(\frac{3l}{\pi^2}\Omega^4 - \frac{1}{720}\frac{\pi^2}{l^3} + O\left(\frac{1}{\Omega}\right)\right), \tag{2}$$

to obtain a renormalized energy between the two plates of

$$E(l) = \hbar c \lim_{\Omega\to\infty} \left(-\frac{1}{720}\frac{\pi^2}{l^3} + O\left(\frac{1}{\Omega}\right)\right) = -\frac{\pi^2\hbar c}{720 l^3}. \tag{3}$$

Even though the zero-point energies given by (1) and (2) are infinite, for which as yet there is no complete understanding, most physics only involves differences in energies. So by renormalizing, taking the limit only after we have performed the subtraction, we obtain a finite negative energy between the plates. It is this renormalized energy that results in an attractive Casimir force between the two plates of

[a)]Electronic mail: alang@oru.edu

$$F(l) = -\frac{\partial E}{\partial l} = -\frac{\pi^2 \hbar c}{240 l^4}. \tag{4}$$

See Ref. 5 for further details. The method used previously for calculating the vacuum energy, though rather elegant, does not show the immense cancelation between the frequency modes which renders the renormalized energy finite. To make this cancelation more explicit, a spectral function $\sigma(\omega)$ can be introduced.

Work begun by Ford[6] for the scalar fields case, followed by Hacyan *et al.*[7] for the electromagnetic field case, shows that such a spectral function can be defined in at least two ways. Ford[6] introduces a spectral weight function which samples the frequency spectrum, and Hacyan *et al.*[7] take the Fourier transform of the renormalized expectation of the Casimir energy-momentum operator. The spectral weight function method is used to assign a frequency spectrum for the energy density between the two plates, whose integral over all frequencies gives the net energy per unit area (3), whereas the Fourier transform method defines a spectrum for the Casimir force, whose integral over all frequencies gives the net force per unit area (4).

This article reviews and extends previous work in this area and proposes an experimental test for the validity of assigning frequency spectra by using frequency band-gap materials.

II. ASSIGNING A FREQUENCY SPECTRUM USING A SPECTRAL WEIGHT FUNCTION

Following Ford,[6] we may use the Plana summation formula

$$\sum_{n=1}^{\infty} f(n) + \frac{1}{2} f(0) = \int_0^{\infty} f(x)\mathrm{d}x + \mathrm{i}\int_0^{\infty} \frac{f(\mathrm{i}t) - f(-\mathrm{i}t)}{\exp(2\pi t) - 1}\mathrm{d}t, \tag{5}$$

instead of the standard regularization and renormalization technique outlined previously, to rewrite the zero-point energy between the plates as an integral

$$E_p(l) = {\sum_{n=0}^{\infty}}' \hbar\omega_n = \int_0^{\infty} \hbar\omega(n)\mathrm{d}n + \mathrm{i}\hbar\int_0^{\infty} \frac{\omega(\mathrm{i}t) - \omega(-\mathrm{i}t)}{\exp(2\pi t) - 1}\mathrm{d}t, \tag{6}$$

where the prime indicates a factor of $\frac{1}{2}$ should be introduced when $n=0$, and the particular form of the frequency modes ω_n depends on the type of field between the plates and the number of spatial dimensions. Subtracting from (6) the zero-point energy of the vacuum

$$E_v(l) = \int_0^{\infty} \hbar\omega(n)\mathrm{d}n, \tag{7}$$

we obtain the *convergent* integral for the renormalized energy

$$E(l) = \mathrm{i}\hbar\int_0^{\infty} \frac{\omega(\mathrm{i}t) - \omega(-\mathrm{i}t)}{\exp(2\pi t) - 1}\mathrm{d}t. \tag{8}$$

To measure the contribution that each mode, ω_0 say, gives to the total energy, we introduce a spectral weight function

$$W_m(\omega) = \left(\frac{2m}{\omega_0}\right)^{2m+1} \frac{\omega^{2m}}{(2m)!} e^{-m\omega/\omega_0}, \tag{9}$$

which has the following properties:

$$\int_0^{\infty} W(\omega)\mathrm{d}\omega = 1, \tag{10}$$

$$\int_0^\infty W(\omega)\mathrm{d}\omega_0 = 1, \tag{11}$$

$$\lim_{m\to\infty} W(\omega) = \delta(\omega - \omega_0). \tag{12}$$

For $m \gg 1$, the spectral weight function (9) is sharply peaked about ω_0, so by substituting it into the equation for the energy density (8), we reproduce Ford's expression for the contribution that ω_0 gives to the total vacuum energy between the plates[6]

$$\sigma(\omega_0) = \mathrm{i}\hbar \int_0^\infty \frac{\omega(\mathrm{i}t)W(\mathrm{i}t) - \omega(-\mathrm{i}t)W(-\mathrm{i}t)}{\exp(2\pi t) - 1}\mathrm{d}t. \tag{13}$$

By integrating this expression over all frequencies we recover the energy density, i.e.,

$$E(l) = \int_0^\infty \sigma(\omega)\mathrm{d}\omega. \tag{14}$$

Thus $\sigma(\omega)$ is a **spectrum for the Casimir energy**.

A. Energy spectrum for the massless scalar field

The massless scalar field in two dimensions with periodic boundary conditions $\mathbb{S}^1 \times \mathbb{R}$ gives rise to normal modes[6]

$$\omega_n = \frac{2n\pi c}{l}, \quad n = 0, \pm 1, \pm 2, \ldots . \tag{15}$$

These modes give a rise to a formally divergent vacuum energy

$$E_p(l) = \sum_{n=0}^{\infty}{}' \frac{2n\pi\hbar c}{l^2} \tag{16}$$

which has a renormalized value

$$E(l) = -\frac{\pi\hbar c}{6l^2}. \tag{17}$$

Substituting the normal modes (15) into (13) and integrating gives

$$\sigma(\omega_0) = (-1)^{m+1}\frac{(2m+1)\hbar c}{\pi^{2m+1}l^2}\left(\frac{m}{\omega_0}\right)^{2m+1}\left[\zeta\left(2m+2, 1 - \frac{\mathrm{i}m}{\pi\omega_0}\right) + \zeta\left(2m+2, 1 + \frac{\mathrm{i}m}{\pi\omega_0}\right)\right], \tag{18}$$

where $\zeta(s,a)$ is the Hurwitz zeta function defined by

$$\zeta(s,a) = \sum_{k=0}^{\infty} \frac{1}{(k+a)^s}. \tag{19}$$

Plotting the energy spectrum for the massless scalar field in $\mathbb{S}^1 \times \mathbb{R}$ we see that it is an oscillatory function of decaying amplitude with maxima at integer values of ω_0, see Fig. 1. It is easy to verify that for all m, the integral over all frequencies is, as required, the energy density, i.e.,

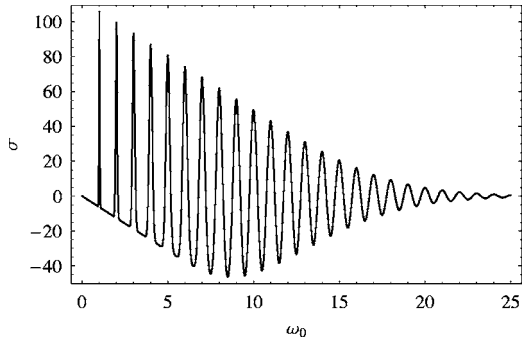

FIG. 1. Energy spectrum $\sigma(\omega_0)$ for the massless scalar field in $\mathbb{S}^1\times\mathbb{R}$ plotted using $m=1000$, $\hbar=c=l=1$.

$$E(l)=\int_0^\infty \sigma(\omega)\mathrm{d}\omega=-\frac{\pi\hbar c}{6l^2}. \tag{20}$$

Thus $\sigma(\omega)$, given by (18), is the energy spectrum for the massless scalar field in $\mathbb{S}^1\times\mathbb{R}$. Comparing the energy spectrum (18) with Ford's[6] equations [(2.13)–(2.15)], it can be shown that (18) is equivalent to Ford's expression for $\sigma(\omega)$.

The energy spectrum for the four-dimensional massless scalar field can be calculated similarly. The massless scalar field in four-dimensions with periodic boundary conditions $\mathbb{S}^1\times\mathbb{R}^3$ gives rise to normal modes[6]

$$\omega_n=c\sqrt{k^2+\left(\frac{2n\pi}{l}\right)^2},\quad n=0,\pm 1,\pm 2,\ldots\ . \tag{21}$$

These modes give a rise to a formally divergent vacuum energy

$$E_p(l)=\frac{\hbar c}{2\pi l}\int_0^\infty {\sum_{n=0}^{\infty}}' k\sqrt{k^2+\left(\frac{2n\pi}{l}\right)^2}\,\mathrm{d}k. \tag{22}$$

Using the change of variables $x^2=k^2+4n^2\pi^2/l^2$ and regularizing, by introducing the convergence factor $e^{-\alpha x}$ yields

$$E_p(l)=\lim_{\alpha\to 0}\frac{\hbar c}{2\pi l}{\sum_{n=0}^{\infty}}'\int_{2n\pi/l}^\infty x^2e^{-\alpha x}\mathrm{d}k.$$

$$=\lim_{\alpha\to 0}\frac{\hbar c}{2\pi l}{\sum_{n=0}^{\infty}}'\left(\frac{2}{\alpha^3}+\frac{4n\pi}{\alpha^2 l}+\frac{4n^2\pi^2}{\alpha l^2}\right)e^{-2n\pi\alpha/l}. \tag{23}$$

As mentioned in Sec. I, we can renormalize this expression by subtracting the zero-point energy of the vacuum to obtain the energy between the plates. Instead we proceed here to derive an expression for the energy spectrum. Substituting

$$\omega(n)=\frac{c}{2\pi l}\left(\frac{2}{\alpha^3}+\frac{4n\pi}{\alpha^2 l}+\frac{4n^2\pi^2}{\alpha l^2}\right)e^{-2n\pi\alpha/l} \tag{24}$$

into (13), where $W_m(\omega)$ is as before, we obtain (after some algebra)

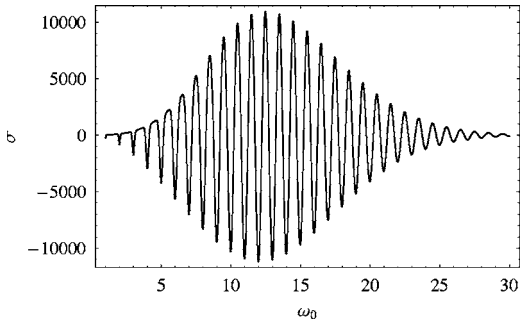

FIG. 2. Energy spectrum $\sigma(\omega_0)$ for the massless scalar field in $\mathbb{S}^1\times\mathbb{R}^3$ plotted using $m=1000$, $\hbar=c=l=1$.

$$\sigma(\omega_0)=\frac{i\hbar c}{\pi\omega_0 l^3\alpha^3}\frac{(-1)^m(2m)^{2m+1}}{(2m)!}\int_0^\infty dt\left(\frac{t}{\omega_0}\right)^{2m}(\coth(\pi t)-1)$$
$$\times\left[(l^2-2\alpha^2\pi^2t^2)\sin\left[2t\left(\frac{\alpha\pi}{l}+\frac{m}{\omega_0}\right)\right]-2\alpha l\pi t\cos\left[2t\left(\frac{\alpha\pi}{l}+\frac{m}{\omega_0}\right)\right]\right]. \tag{25}$$

Integrating and taking the limit as $\alpha\to 0$ gives

$$\sigma(\omega_0)=(-1)^{m+1}\frac{(2m+1)(2m+2)(2m+3)\hbar c}{6\pi^{2m+2}l^4}\left(\frac{m}{\omega_0}\right)^{2m+1}$$
$$\times\left[\zeta\left(2m+4,1-\frac{im}{\pi\omega_0}\right)+\zeta\left(2m+4,1+\frac{im}{\pi\omega_0}\right)\right]. \tag{26}$$

Plotting the energy spectrum for the massless scalar field in $\mathbb{S}^1\times\mathbb{R}^3$ we see a slightly different shaped oscillatory function than before, the amplitude initially increasing before it decays to zero. Again, the maxima are at integer values of ω_0, see Fig. 2. It is again easy to verify that for all m, the integral over all frequencies is, as required, the energy density, i.e.,

$$E(l)=\int_0^\infty\sigma(\omega)d\omega=-\frac{\pi^2\hbar c}{90l^4}. \tag{27}$$

Thus $\sigma(\omega)$, given by (26), is the energy spectrum for the massless scalar field in $\mathbb{S}^1\times\mathbb{R}^3$. Comparing the energy spectrum (26) with Ford's[6] equation (3.18) it can be shown that (26) is equivalent to Ford's expression for $\sigma(\omega)$ but is given here in a more compact form.

B. Energy spectrum for the electromagnetic field

For two perfectly conducting parallel plates, the frequency modes for the electromagnetic field are given by[5]

$$\omega_n=c\sqrt{k_x^2+k_y^2+\left(\frac{n^2\pi^2}{l^2}\right)^2},\quad n=0,\pm1,\pm2,\ldots\ . \tag{28}$$

These modes give rise to a formally divergent vacuum energy

$$E_p(l)=\frac{\hbar c}{4\pi^2}{\sum_{n=0}^{\infty}}'\int_0^\infty\int_0^\infty\sqrt{k_x^2+k_y^2+(n^2\pi^2/l^2)^2}dk_xdk_y=\frac{\hbar c}{4\pi^2}{\sum_{n=0}^{\infty}}'\int_0^\infty 2\pi k\sqrt{k^2+(n^2\pi^2/l^2)^2}dk_x. \tag{29}$$

Using the change of variables $x^2=k^2+n^2\pi^2/l^2$ and regularizing, by introducing the convergence factor $e^{-\alpha x}$, yields

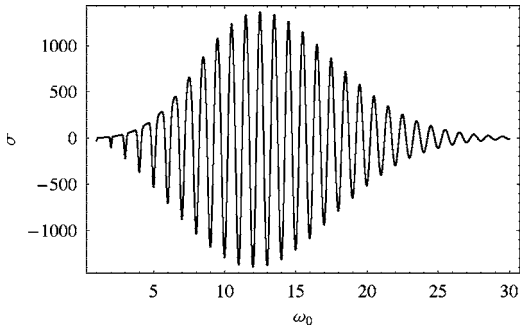

FIG. 3. Energy spectrum $\sigma(\omega_0)$ for the electromagnetic field in between parallel plates plotted using $m=1000$, $\hbar=c=l=1$.

$$E_p(l) = \lim_{\alpha\to 0} \frac{\hbar c}{2\pi} {\sum_{n=0}^{\infty}}' \int_{n\pi/l}^{\infty} x^2 e^{-\alpha x} \mathrm{d}x = \lim_{\alpha\to 0} \frac{\hbar c}{2\pi} {\sum_{n=0}^{\infty}}' \left(\frac{1}{\pi\alpha^3} + \frac{n}{l\alpha^2} + \frac{n^2\pi}{2l^2\alpha} \right) e^{-n\pi\alpha/l}. \tag{30}$$

We can renormalize this expression by subtracting the zero-point energy of the vacuum to obtain the energy between the plates (3). Instead we proceed here to derive an expression for the energy spectrum. Substituting

$$\omega(n) = \frac{c}{2\pi} \left(\frac{1}{\pi\alpha^3} + \frac{n}{l\alpha^2} + \frac{n^2\pi}{2l^2\alpha} \right) e^{-n\pi\alpha/l} \tag{31}$$

into (13), where $W_m(\omega)$ is as before, we obtain (after some algebra)

$$\sigma(\omega_0) = \frac{\mathrm{i}\hbar c}{2\pi\omega_0 l^2\alpha^3} \frac{(-1)^m m}{(2m)!} \int_0^{\infty} \left(\frac{2mt}{\omega_0} \right)^{2m} (\coth(\pi t) - 1) \times \left[\exp\left[\mathrm{i}t \left(\frac{2m}{\omega_0} + \frac{\pi\alpha}{l} \right) \right] ((\mathrm{i}+1)l + \pi t\alpha)((\mathrm{i}-1)l + \pi t\alpha) - c.c. \right] \mathrm{d}t. \tag{32}$$

Integrating and taking the limit as $\alpha\to 0$ gives

$$\sigma(\omega_0) = (-1)^m \frac{(2m+1)(2m+2)(2m+3)\hbar c}{48\pi^{2m+2} l^3} \left(\frac{m}{\omega_0} \right)^{2m+1} \times \left[\zeta\left(2m+4, 1 - \frac{\mathrm{i}m}{\pi\omega_0} \right) + \zeta\left(2m+4, 1 + \frac{\mathrm{i}m}{\pi\omega_0} \right) \right]. \tag{33}$$

Plotting the energy spectrum for the electromagnetic field, see Fig. 3, we see that it is, up to scaling, identical to the plot of energy spectrum for the massless scalar field in $\mathbb{S}^1\times\mathbb{R}^3$, see Fig. 2. This is not surprising as the equations for σ are nearly identical, see Eq. (26). As before, the amplitude initially increases before it decays to zero and the maxima are at integer values of ω_0. Integrating over all frequencies for any m gives, as required, the energy density, i.e.,

$$E(l) = \int_0^{\infty} \sigma(\omega)\mathrm{d}\omega = -\frac{\pi^2\hbar c}{720 l^3}. \tag{34}$$

Thus $\sigma(\omega)$, given by (33), is the energy spectrum for the electromagnetic field between two perfectly conducting parallel plates in vacuum.

III. ASSIGNING A FREQUENCY SPECTRUM USING FOURIER TRANSFORMS

An alternative definition of a frequency spectrum for the Casimir effect has been proposed by Hacyan *et al.*[7] They define the spectrum as the Fourier transform of the renormalized expectation value of the energy-momentum stress operator for a quantized field, i.e.,

$$\varsigma(\omega) = \frac{1}{\pi}\int_{-\infty}^{\infty} \langle T^{zz}(\tau)\rangle_{\mathrm{R}} e^{-\mathrm{i}\omega\tau}\mathrm{d}\tau, \tag{35}$$

where z is the direction normal to the plates. Integrating this expression over all frequencies we recover, not the energy density, but the Casimir force itself. That is

$$F(l) = \int_0^{\infty} \varsigma(\omega)\mathrm{d}\omega. \tag{36}$$

Thus $\varsigma(\omega)$ given by (35) is a **spectrum for the Casimir force**.

The renormalized stress tensor for the electromagnetic field between two perfectly conducting parallel plates in vacuum in given by[7]

$$\langle T^{zz}(\tau)\rangle_{\mathrm{R}} = \frac{2\hbar c}{\pi^2}\sum_{n=1}^{\infty} \frac{\tau^2 + 3(2ln)^2}{(\tau^2 - (2ln)^2)^3}. \tag{37}$$

Substituting this expression into (35) gives the spectrum

$$\varsigma(\omega) = \frac{\hbar c}{\pi^2 l^3}\sum_{n=1}^{\infty}\left(\frac{l\omega}{2n^2}\cos(2ln\omega) + \frac{2l^2\omega^2n^2 - 1}{4n^3}\sin(2ln\omega)\right). \tag{38}$$

By introducing a convergence term $e^{-\alpha\omega}$, and integrating over all frequencies, we recover the Casimir force as follows:

$$\begin{aligned} F(l) &= \lim_{\alpha\to 0}\frac{\hbar c}{\pi^2 l^3}\sum_{n=1}^{\infty}\int_0^{\infty}\left(\frac{l\omega}{2n^2}\cos(2ln\omega) + \frac{2l^2\omega^2n^2 - 1}{4n^3}\sin(2ln\omega)\right)e^{-\alpha\omega}\mathrm{d}\omega \\ &= \lim_{\alpha\to 0}\frac{\hbar c}{\pi^2}\sum_{n=1}^{\infty}\frac{-24l^2n^2 + 2\alpha^2}{(4l^2n^2 + \alpha^2)^3} = \lim_{\alpha\to 0}\frac{\hbar c}{\pi^2}\left(\frac{\pi^3\coth(\pi\alpha/2l)\mathrm{csch}^2(\pi\alpha/2l)}{8l^3\alpha} - \frac{1}{\alpha^4}\right) \\ &= \lim_{\alpha\to 0}\hbar c\left(\frac{-\pi^2}{240l^4} + \frac{\pi^2\alpha^2}{3024l^6} + O(\alpha)^3\right) = -\frac{\pi^2\hbar c}{240l^4}. \end{aligned} \tag{39}$$

Thus $\varsigma(\omega)$, given by (38), is the force spectrum for the electromagnetic field between two perfectly conducting parallel plates in vacuum. Ford[8] has shown that this force spectrum may also be derived directly from Lifshitz theory.[9]

The force spectrum (38) may be expressed in the following form, useful for evaluating and plotting

$$\begin{aligned} \varsigma(\omega) = \frac{\hbar c}{\pi^2}\Bigg\{ &\frac{\mathrm{i}\omega^2}{4l}[\ln(1 - e^{2\mathrm{i}l\omega}) - \ln(1 - e^{-2\mathrm{i}l\omega})] + \frac{\omega}{4l^2}[\mathrm{Li}_2(e^{2\mathrm{i}l\omega}) - \mathrm{Li}_2(e^{-2\mathrm{i}l\omega})] + \frac{\mathrm{i}}{8l^3}[\mathrm{Li}_3(e^{2\mathrm{i}l\omega}) \\ &- \mathrm{Li}_3(e^{-2\mathrm{i}l\omega})]\Bigg\}, \end{aligned} \tag{40}$$

where $\mathrm{Li}_2(z)$ and $\mathrm{Li}_3(z)$ are the dilogarithm and trilogarithm functions, respectively, defined in general by

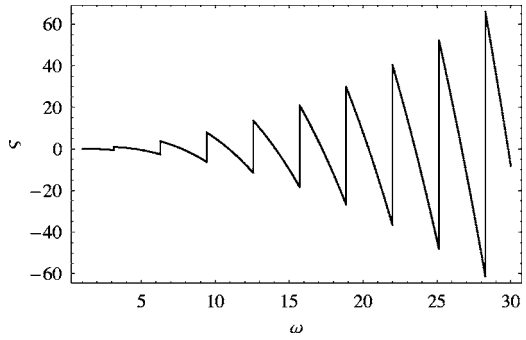

FIG. 4. Force spectrum $\varsigma(\omega)$ for the electromagnetic field plotted using $\hbar=c=l=1$.

$$\mathrm{Li}_n(z)=\sum_{k=1}^{\infty}\frac{z^k}{k^n}. \tag{41}$$

Plotting the force spectrum for fixed l, see Fig. 4, we see that it has a different form than the energy spectra. First, the location of the extrema depends explicitly on l, the separation between the plates. Specifically, the extrema occur for $\omega=n\pi/l$; $n=1,2,\ldots$ instead of integer values of ω as we saw for the energy spectra. Second, the amplitude of the force spectrum does not decay to zero as $\omega\to 0$, as it does for the energy spectra, but instead it increases without bound. Since integrating the force spectrum over all ω gives the Casimir force, we clearly see here the almost total cancelation that must occur between all the modes to render the Casimir force finite. These two properties suggest that for certain physical materials (and by varying l), the frequency mode cancelation may be disturbed to produce designer Casimir forces of almost any magnitude, both attractive and repulsive.

IV. CASIMIR FORCE BETWEEN IDEAL FREQUENCY BAND AND FREQUENCY BAND-GAP MATERIALS

In this section, the term **frequency band** material is used to mean a physical material that is perfectly reflecting in a narrow frequency interval and perfectly transparent outside of that interval. Similarly, the term **frequency band-gap** material is used to mean a physical material that is perfectly reflecting for all frequencies except for a narrow frequency interval, for which it is perfectly transparent. Such ideal materials, of course, do not exist. In fact, a spatially homogeneous dielectric material is restricted by the Kramers–Kronig relations from having the type of discontinuous response I assume[10] and the results of Lifshitz[9] restrict the Casimir force between two homogeneous dielectric half-spaces to be always attractive and no greater than the Casimir

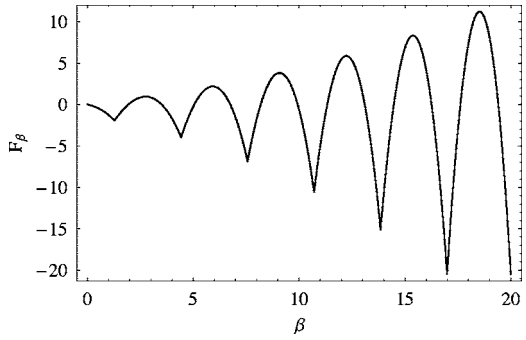

FIG. 5. Casimir force for a frequency band material with fixed ω_0 and varying band width β plotted using $\hbar=c=l=1$ and $\omega_0=5$.

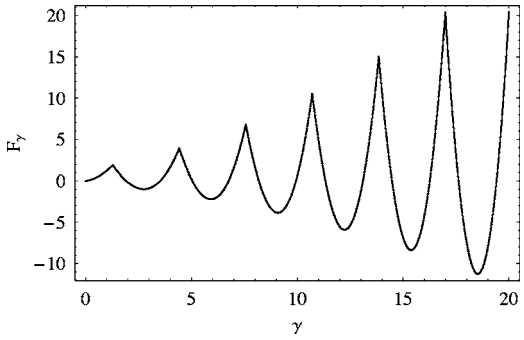

FIG. 6. Casimir force for a frequency band-gap material with fixed ω_0 and varying band-gap width γ plotted using $\hbar=c=l=1$ and $\omega_0=5$.

force between two perfectly reflecting parallel plates. It is possible however to do better with inhomogeneous materials such as photonic crystals which are regular arrays of materials with different refractive indices.[11] Photonic crystals have been made which are essentially perfectly reflecting over a finite frequency band, and partially reflecting (having rather complicated transmission spectra) outside this band.[12–14]

In the preceeding section, we explicitly saw the cancelation, alluded to in Sec. I, between the frequency modes which gives a finite Casimir force. It was Ford and Sopova[8,15,16] who first speculated that "one might be able to upset this cancelation in some way," and alter the magnitude and even direction of the Casimir force. For frequency band material plates, which are perfectly reflecting in the interval $(\omega_0, \omega_0+\beta)$ say, the Casimir force is given by[8]

$$F_\beta(l,\omega_0) = \int_{\omega_0}^{\omega_0+\beta} \varsigma(\omega)\mathrm{d}\omega. \tag{42}$$

Similarly, for frequency band-gap material plates, which are perfectly reflecting everywhere except in the interval $(\omega_0, \omega_0+\gamma)$ say, the Casimir force is given by

$$F_\gamma(l,\omega_0) = F(l) - F_\beta(l,\omega_0). \tag{43}$$

Substituting the force spectrum (40) into (42), we obtain

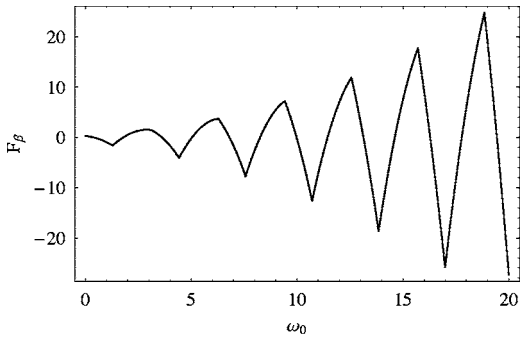

FIG. 7. Casimir force for a frequency band material with fixed β and varying band width ω_0 plotted using $\hbar=c=l=1$ and $\beta=5$.

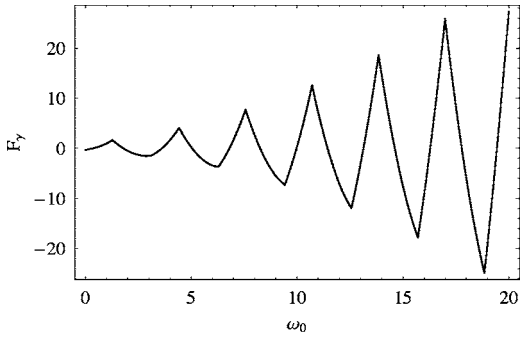

FIG. 8. Casimir force for a frequency band-gap material with fixed γ and varying band-gap width ω_0 plotted using $\hbar = c = l = 1$ and $\gamma = 5$.

$$F_\beta(l,\omega_0) = -\frac{\hbar c}{16\pi^2 l^4}\{2l^2(\omega_0+\beta)^2[\mathrm{Li}_2(e^{2il(\omega_0+\beta)}) + \mathrm{Li}_2(e^{-2il(\omega_0+\beta)})] - 2l^2\omega_0^2[\mathrm{Li}_2(e^{2il\omega_0}) + \mathrm{Li}_2(e^{-2il\omega_0})] + 4il\beta[\mathrm{Li}_3(e^{2il(\omega_0+\beta)}) + \mathrm{Li}_3(e^{-2il(\omega_0+\beta)})] - 4il\omega[\mathrm{Li}_3(e^{2il\omega_0}) + \mathrm{Li}_3(e^{-2il\omega_0})] - 3[\mathrm{Li}_4(e^{2il(\omega_0+\beta)}) + \mathrm{Li}_4(e^{-2il(\omega_0+\beta)})] + 3[\mathrm{Li}_4(e^{2il\omega_0}) + \mathrm{Li}_4(e^{-2il\omega_0})]\}. \quad (44)$$

Plotting the Casimir band force and the Casimir band-gap force for constant ω_0 and l, we see that the force oscillates with the amplitude increasing as the frequency band (or band gap) increases, see Figs. 5 and 6. Also we have an infinite number of equilibria points where the force between the plates equals zero. Since l is constant here, the two plots are reflections of each other about the line $F = F(l)/2$.

Plotting the Casimir band force and the Casimir band-gap force for constant β, γ and l, we see that the force again oscillates with the amplitude increasing as the frequency ω_0 increases, see Figs. 7 and 8. We again have an infinite number of equilibria points where the force between the plates equals zero, and since l is constant, the graphs are reflections of each other about the line $F = F(l)/2$. One thing to note here is that as $\beta \to 0^+$, the graph of $F_\beta(l,\omega_0)$ tends to the graph of $\varsigma(\omega)$. Thus one way to test the theoretical frequency spectra is to use a narrow frequency band material to sample the contribution that each frequency mode contributes to the total force. This can also be done using a narrow frequency band-gap materials via Eq. (43). Ideally one would like to have a material in which you could control where the frequency band (or band-gap) began and its width. Plotting the Casimir band force and the Casimir band-gap force for constant β, γ, and ω_0 and for varying l, we see that the force again oscillates but this time the amplitude decreases as the separation l increases, see Figs. 9 and 10. This is clearly what we would expect from physical principles. We have an infinite number of equilibria points where the force between the plates equals zero. These equilibria points alternate between being unstable $F' > 0$ and stable $F' < 0$ for

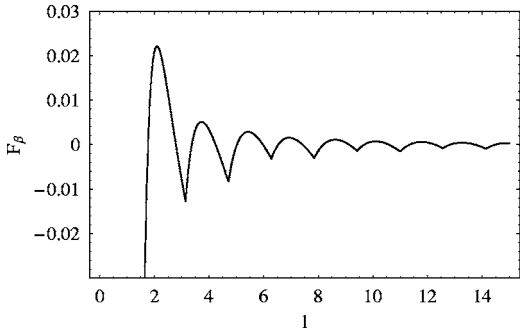

FIG. 9. Casimir force for a frequency band material with fixed β and ω_0 with varying l plotted using $\hbar = c = \beta = \omega_0 = 1$.

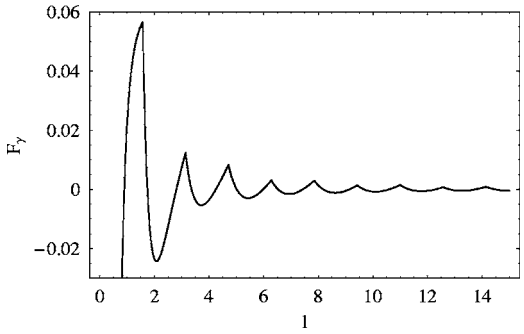

FIG. 10. Casimir force for a frequency band-gap material with fixed γ and ω_0 with varying l plotted using $\hbar=c=\gamma=\omega_0=1$.

both the band and band-gap cases. Unlike the previous two sets of plots, the Casimir force $F(l)$ is not constant, this is why the two plots are not merely reflections of each other about the line $F=F(l)/2$. We have here another possible experimental test for the force spectrum. By taking a frequency band (or band-gap) material and measuring the Casimir force at varying distances, we should be able to detect the oscillation in the force that comes from the spectrum. If at all possible, care should be taken to produce a material where the width of the band (or band gap) corresponds to an ω_0, for which the magnitude of the force is a maximum. This occurs when

$$\gamma = \frac{n\pi}{l} - \omega_0. \tag{45}$$

Plotting the Casimir band-gap force in two dimensions for constant γ, see Fig. 11, with lighter gray levels corresponding to repulsive forces and darker levels corresponding to attractive forces, and with the zero force equilibria indicated with the black curves. We see that oscillations die out as l increases for all ω_0, even though the amplitude increases as ω_0 increases. Plotting the Casimir band-gap force in two dimensions for constant l, see Fig. 12, again with lighter gray levels corresponding to repulsive forces and darker gray levels corresponding to attractive forces, and with the zero force equilibria indicated with the black curves. We see the amplitude of the force oscillations increases as both ω_0 and γ increase.

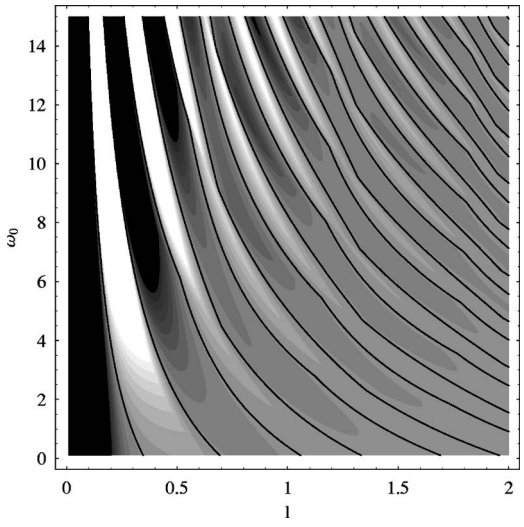

FIG. 11. Casimir force for a frequency band-gap material with fixed γ plotted using $\hbar=c=1$ and $\gamma=5$.

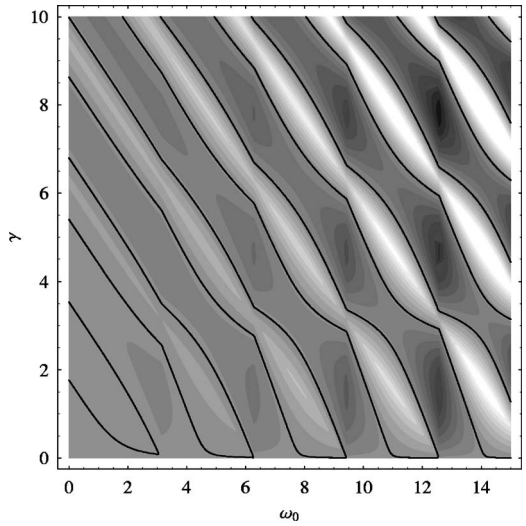

FIG. 12. Casimir force for a frequency band-gap material with fixed l plotted using $\hbar=c=l=1$.

V. DISCUSSION AND CONCLUSION

In the previous sections, we have reviewed the two main ways of assigning a frequency spectrum for the Casimir effect. First by using a spectral weight function to assign an energy spectrum and second by using the Fourier transform of the energy density to assign a force spectrum. Calculations were performed for both the massless scalar field and the electromagnetic field. New exact forms for the various spectra were presented in all cases.

There is some doubt to the validity of assigning a spectrum to the Casimir effect, as a theoretical understanding of how exactly the individual modes contribute to the total force will not be complete until the individual infinite zero-point energies are themselves better understood. Possible experiments were proposed to test the validity of the models. Such experimental tests may be done using either frequency band or frequency band-gap materials. Some limitations to this are the physical restrictions of any plasma frequency of the material and also the smoothness of the interface, where we would like to keep the variations in l small compared to $1/\omega_0$.[6] Also, as already mentioned, there may be restrictions imposed by causality and passivity considerations.[10] Another possible way to detect such a frequency spectrum is via a Casimir-Polder spectrum, whereby an experiment to detect the force between a dielectric wall and small metal sphere is conducted.[15,16]

For possible future work, the Casimir force between photonic band gap materials with a more realistic band gap structure needs to be calculated. Also, other geometries need to be considered, especially the cases of a sphere and a cylinder. Assigning a spectrum to these geometries now seems accessible via a generalized Plana summation formula.[17]

(Received 9 March 2005; accepted 10 August 2005; published online 18 October 2005)

The group of local unitary transformations partitions the space of n-qubit quantum states into orbits, each of which is a differentiable manifold of some dimension. We prove that all orbits of the n-qubit quantum state space have dimension greater than or equal to $3n/2$ for n even and greater than or equal to $(3n+1)/2$ for n odd. This lower bound on orbit dimension is sharp, since n-qubit states composed of products of singlets achieve these lowest orbit dimensions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2048327]

I. INTRODUCTION

Quantum entanglement theory can be regarded as the branch of nonrelativistic quantum mechanics that seeks to understand the states and dynamics of composite quantum systems with a fixed number of subsystems. Composite quantum systems can exhibit correlations among subsystems in ways that classically describable composite systems cannot. A (pure) state of a composite quantum system is called entangled if it cannot be described by specifying (pure) states for each of the subsystems.

Quantum entanglement plays a particularly important role in quantum information, where the subsystems are quantum bits or qubits (a spin-1/2 particle is a physical realization of a qubit). An n-qubit system is the quantum analog of an n-bit computer or communications channel. Because quantum computing algorithms and quantum communications protocols utilize entanglement as an essential resource, potential applications of quantum information theory provide motivation for a more complete description of entanglement (see Refs. 1 and 2 for surveys of a broad range of topics in this area).

A fundamental problem in the theory of quantum entanglement is to describe the types of entanglement that are achievable for a composite quantum system. We regard two states of a composite quantum system as having the same type of entanglement if unitary operations on the subsystems, called local unitary or LU transformations, can transform one quantum state into the other. Local unitary transformations form a Lie group which acts on the manifold of quantum states, partitioning it into orbits. Each orbit is a differentiable manifold that represents a type of quantum entanglement. The *orbit space*—the set of orbits made into a topological space by the quotient topology—is the collection of entanglement types.

A theory of quantum entanglement based on local unitary transformations seeks to describe the orbit spaces and the orbits themselves for composite quantum systems. Much of the progress toward understanding the orbit spaces of quantum systems comes from invariant theory—the study of functions which are constant along orbits.[3–12] One hopes to use these invariants, which are usually polynomial functions of state vector coefficients, to distinguish and classify orbits. Rains[3] and Grassl *et al.*[4] laid the groundwork for a systematic approach using this philosophy. The

[a)]Electronic mail: lyons@lvc.edu
[b)]Electronic mail: walck@lvc.edu

success in choosing particular, finite sets of invariants to label points in the orbit space has so far been limited to small numbers of qubits. Makhlin[6] gave a set of 18 polynomial invariants that separate orbits for two-qubit mixed states. Sudbery[5] gave a set of six polynomial invariants that separate orbits for 3-qubit pure states. Acín *et al.*[13,14] gave a convenient set of nonpolynomial invariants and a classification of 3-qubit pure states based on it.

In this paper we pursue a strategy inspired by Linden and Popescu,[15,16] who approached entanglement properties of quantum states working on the Lie algebra level to study the orbits themselves. We develop a general technique for calculating the orbit dimension of a state and use this to prove a lower bound on orbit dimension. We have also used our methods to provide a proof[17] of the authors' claim in Refs. 15 and 16 that almost all states have orbit dimension $3n$ [we take the manifold of pure n-qubit states to be the projective space $\mathbb{P}((\mathbb{C}^2)^{\otimes n})$ and the group of local unitary transformations to be $G=\mathrm{SU}(2)^n$].

Most of the progress in understanding orbits and orbit dimensions has been for systems of only two or three qubits. Carteret and Sudbery[18] described the nongeneric orbits (including orbit dimensions) for pure 3-qubit states. Życzkowski *et al.*[19,20] analyze orbits for bipartite states. Few general results are known about those orbits which are the most interesting from the quantum information point of view, namely the nongeneric or exceptional orbits of n-qubit states (basic examples are the singlet state of two qubits and the GHZ state of three qubits). The main result in the present paper is at least a small step towards the larger goal of orbit classification for general n.

A. Physical significance of the result

In this paper, we identify the minimum orbit dimension of n-qubit quantum states. States that have the minimum orbit dimension are, in some sense, the "rarest" quantum states. Until now, it has been known that singlet states have minimum orbit dimension for two qubits, and one could conjecture that some n-qubit generalization of the singlet state would have minimum orbit dimension for n qubits, but it was not clear how the singlet should be generalized to maintain the minimum orbit dimension as n increases. For example, one generalization of the singlet is the so-called n-cat state, $1/\sqrt{2}|00\cdots00\rangle+1/\sqrt{2}|11\cdots11\rangle$, of which the GHZ state is an example for three qubits. But the n-cat generalization of the singlet does not maintain the minimum orbit dimension for higher qubit numbers. As we show in this paper, it is the product of singlet states (for even qubit numbers) or the product of singlets and one unentangled qubit (for odd qubit numbers) that is the generalization of singlets that achieves minimum orbit dimension. This suggests a special role for the 2-qubit singlet state in the theory of n-qubit quantum entanglement.

B. Proof strategy and outline

To establish the minimum orbit dimension, we show that the orbit dimension of a given state is (one less than) the rank of a real matrix M associated to that state. The matrix M arises naturally via consideration of the action of the local unitary group on an infinitesimal level, that is, the action of the Lie algebra of the local unitary group. The column vectors of M can be identified with complex vectors. We then establish lower bounds on the rank of M by showing that a sufficient number of real dot products of columns of M can be arranged, possibly after local unitary operations, to vanish. Instead of working directly with real dot products, it is convenient to calculate complex inner products; the vanishing of the real part of a complex inner product guarantees that the real dot product is zero [see (15) below].

In Sec. III we introduce the matrix M. To establish the necessary cancellations among terms of complex inner products of columns of M requires careful bookkeeping and a technical lemma; we present this machinery in Sec. IV. Next we establish orthogonality among columns of M in Sec. V and Sec. VI. We then use these results to prove minimum orbit dimension in Sec. VII.

II. CONVENTIONS AND NOTATION

A. Hilbert space, state space and the local unitary group

Let $H=(\mathbb{C}^2)^{\otimes n}$ denote the Hilbert space of pure states of a system of n qubits and let $\mathbb{P}(H)$ denote the projectivization of H which is the state space of the system. We take the local unitary group to be $G=\mathrm{SU}(2)^n$. These definitions constitute a minor departure, made for the sake of clarity and compactness of exposition, from the widespread practice of taking state space to be the set of normalized state vectors and resolving phase ambiguity by including an extra U(1) factor in the local unitary group.

B. Multi-index notation for Hilbert space basis vectors

Let $|0\rangle,|1\rangle$ denote the standard basis for $\mathbb{C}^2$ and write $|i_1 i_2 \cdots i_n\rangle$ for $|i_1\rangle\otimes|i_2\rangle\otimes\cdots\otimes|i_n\rangle$ in $(\mathbb{C}^2)^{\otimes n}$. For a multi-index $I=(i_1 i_2 \cdots i_n)$ with $i_k=0,\ 1$ for $1\leqslant k\leqslant n$, we will write $|I\rangle$ to denote $|i_1 i_2 \cdots i_n\rangle$. Let i_k^c denote the bit complement

$$i_k^c=\begin{cases}0 & \text{if } i_k=1,\\ 1 & \text{if } i_k=0,\end{cases}$$

and let I_k denote the multi-index

$$I_k := (i_1 i_2 \cdots i_{k-1} i_k^c i_{k+1} \cdots i_n)$$

obtained from I by taking the complement of the kth bit for $1\leqslant k\leqslant n$. Similarly, let I_{kl} denote the multi-index

$$I_{kl} := (i_1 i_2 \cdots i_{k-1} i_k^c i_{k+1} \cdots i_{l-1} i_l^c i_{l+1} \cdots i_n)$$

obtained from I by taking the complement of the kth and lth bits for $1\leqslant k<l\leqslant n$.

C. Standard identification of $\mathbb{C}^N$ with $\mathbb{R}^{2N}$

We identify the complex vectors in $\mathbb{C}^N$ with real vectors in $\mathbb{R}^{2N}$ via

$$\mathbb{C}^N \leftrightarrow \mathbb{R}^{2N},$$

$$(z_1,z_2,\ldots,z_N) \leftrightarrow (a_1,b_1,a_2,b_2,\ldots,a_N,b_N), \tag{1}$$

where $z_j=a_j+ib_j$ for $1\leqslant j\leqslant N$.

III. LIE ALGEBRA ACTION

The Lie algebra su(2) of SU(2) is the set of traceless skew Hermitian matrices,

$$\mathrm{su}(2)=\left\{\begin{bmatrix} it & u \\ -\bar{u} & -it\end{bmatrix} : t\in\mathbb{R}, u\in\mathbb{C}\right\}$$

and the Lie algebra $LG=(\mathrm{su}(2))^n$ of the local unitary group $G=(\mathrm{SU}(2))^n$ is the set of n-tuples of matrices of this form.

A local unitary operator $g=(g_1,g_2,\ldots,g_n)$ in G acts on a product state vector $|v\rangle=|v_1\rangle\otimes|v_2\rangle\otimes\cdot\otimes|v_n\rangle$ in Hilbert space $H=(\mathbb{C}^2)^{\otimes n}$ by

$$g\cdot|v\rangle = g_1|v_1\rangle\otimes g_2|v_2\rangle\otimes\cdots\otimes g_n|v_n\rangle. \tag{2}$$

The induced action on $|v\rangle$ by $X=(X_1,X_2,\ldots,X_n)$ in LG is given by

$$X \cdot |v\rangle = \sum_{i=1}^{n} |v_1\rangle \otimes \cdots \otimes |v_{i-1}\rangle \otimes X_i |v_i\rangle \otimes |v_{i+1}\rangle \otimes \cdots \otimes |v_n\rangle. \tag{3}$$

This action extends linearly to all of Hilbert space as follows. Let $|\psi\rangle = \Sigma_I c_I |I\rangle$ be an element in Hilbert space H, and let $X = (X_1, X_2, \ldots, X_n)$ be an element of LG with

$$X_k = \begin{bmatrix} it_k & u_k \\ -\overline{u_k} & -it_k \end{bmatrix} \quad \text{for } 1 \leqslant k \leqslant n.$$

A straightforward calculation shows that the action of X on $|\psi\rangle$ is given by

$$X \cdot |\psi\rangle = \sum_I \left(\sum_{k=1}^{n} (-1)^{i_k} [c_I i t_k + c_{I_k} \mathrm{conj}^{i_k}(u_k)] \right) |I\rangle, \tag{4}$$

where $\mathrm{conj}^1(z) = \overline{z}$ and $\mathrm{conj}^0(z) = z$. Let a_I, b_I denote the real and imaginary parts of the coefficient c_I in the expression for $|\psi\rangle$, and let r_k, s_k denote the real and imaginary parts of the entry u_k in X_k. The real and imaginary parts of the Ith coefficient on the right-hand side of Eq. (4) are the following:

$$\mathrm{Re}\langle I|X|\psi\rangle = \sum_{k=1}^{n} [(-1)^{i_k}(-b_I t_k) + (-1)^{i_k} a_{I_k} r_k - b_{I_k} s_k], \tag{5}$$

$$\mathrm{Im}\langle I|X|\psi\rangle = \sum_{k=1}^{n} [(-1)^{i_k}(a_I t_k) + (-1)^{i_k} b_{I_k} r_k + a_{I_k} s_k]. \tag{6}$$

Given a state x in $\mathbb{P}(H)$, the isotropy Lie subalgebra LI_x of the isotropy subgroup I_x is determined by the following condition.

Proposition 3.1: Isotropy Lie algebra condition: Let $x \in \mathbb{P}(H)$ be a state and let $|\psi\rangle$ be a Hilbert space representative for x. The element $X \in LG$ is in the Lie algebra LI_x of the isotropy subgroup I_x of x if and only if

$$X \cdot |\psi\rangle = i\theta |\psi\rangle$$

for some real θ.

Together with (5) and (6), Proposition 3.1 implies the following.

Corollary 3.2: Let X, x and $|\psi\rangle$ be as above. Suppose that X is in LI_x. Then for each multi-index I, we have the following pair of equations:

$$\sum_{k=1}^{n} [(-1)^{i_k}(-b_I t_k) + (-1)^{i_k} a_{I_k} r_k - b_{I_k} s_k] = -b_I \theta, \tag{7}$$

$$\sum_{k=1}^{n} [(-1)^{i_k}(a_I t_k) + (-1)^{i_k} b_{I_k} r_k + a_{I_k} s_k] = a_I \theta, \tag{8}$$

for some real number θ.

By adding $b_I\theta$, respectively $a_I\theta$, to both sides of Eq. (7), respectively (8), the corollary shows that calculating the Lie algebra LI_x is a matter of solving a homogeneous real linear system of 2^{n+1} equations (two for each of the 2^n multi-indices) in the $3n+1$ unknowns t_k, r_k, s_k, θ. Let

$$M(t_1, r_1, s_1, t_2, r_2, s_2, \ldots, t_n, r_n, s_n, \theta) = 0 \tag{9}$$

denote the linear system of 2^{n+1} equations given by (7) and (8), so that the $2^{n+1} \times (3n+1)$ matrix for M has all entries of the form $\pm a_I, \pm b_I$.

Here is the fundamental observation which reduces the problem of orbit dimension to finding the rank of M.

Proposition 3.3: Orbit dimension as rank of M: Let x be a state, let $|\psi\rangle$ be a Hilbert space representative for x, and let M be the associated matrix constructed from the coordinates of $|\psi\rangle$ as described above. Then we have

$$\operatorname{rank} M = \dim \mathcal{O}_x + 1.$$

Proof: We can think of M as the matrix of a linear map $M: LG \times \mathbb{R} \to \mathbb{R}^{2^{n+1}}$ via the identification

$$\mathbb{R}^{3n} \leftrightarrow LG,$$

$$(t_1, r_1, s_1, t_2, r_2, s_2, \ldots, t_n, r_n, s_n) \leftrightarrow (X_1, X_2, \ldots, X_n),$$

where

$$X_k = \begin{bmatrix} it_k & r_k + is_k \\ -r_k + is_k & -it_k \end{bmatrix}.$$

Consider a solution (X, θ) of $M(X, \theta) = 0$. Proposition 3.1 says that $|\psi\rangle$ is an eigenvector for X with eigenvalue $i\theta$, so θ is determined by X. Since $X \in LI_x$ if and only if $M(X, \theta) = 0$ for some θ, it follows that $\dim LI_x = \dim \ker M$. From this we have

$$\dim LI_x = \dim \ker M = \text{number of columns of } M - \operatorname{rank} M = 3n + 1 - \operatorname{rank} M.$$

Thus we have $\dim \mathcal{O}_x = \dim G - \dim LI_x = 3n - (3n + 1 - \operatorname{rank} M) = \operatorname{rank} M - 1$. □

Next we introduce three operators on H whose purpose is to simplify calculations (specifically, inner products of column vectors) to establish the rank of M,

$$\text{Let } A = \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \quad \text{and } C = \begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix}$$

denote the standard basis for su(2), so that the element

$$X = \begin{bmatrix} it & r + is \\ -r + is & -it \end{bmatrix}$$

is written $X = tA + rB + sC$ with respect to this basis.

[This basis is standard in the sense that A, B, C correspond to the truly standard basis vectors $\mathbf{i} = (0,1,0,0)$, $\mathbf{j} = (0,0,1,0)$, $\mathbf{k} = (0,0,0,1)$ of the pure quaternions, under the natural identification $\begin{bmatrix} a & b \\ -\bar{b} & \bar{a} \end{bmatrix} \leftrightarrow a + b\mathbf{j}$. In terms of the Pauli spin matrices, we have $A = i\sigma_z$, $B = i\sigma_y$, and $C = i\sigma_x$ where $\sigma_x = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, $\sigma_y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}$, and $\sigma_z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$.]

Define elements A_k, B_k, C_k of LG for $1 \leqslant k \leqslant n$ to have A, B, C, respectively, in the kth coordinate and zero elsewhere.

$$A_k = \left(0, \ldots, 0, \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix}, 0, \ldots, 0\right),$$

$$B_k = \left(0, \ldots, 0, \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, 0, \ldots, 0\right),$$

$$C_k = \left(0,\ldots,0,\begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix},0,\ldots,0\right).$$

Applying (4), we have the following:

$$A_k|\psi\rangle = \sum_I i(-1)^{i_k} c_I |I\rangle, \tag{10}$$

$$B_k|\psi\rangle = \sum_I (-1)^{i_k} c_{I_k} |I\rangle, \tag{11}$$

$$C_k|\psi\rangle = \sum_I i c_{I_k} |I\rangle. \tag{12}$$

Simple checking shows that the complex vectors on the right-hand sides of the above three equations identify with columns of M via the standard identification (1). The rightmost column of M identifies with $-i|\psi\rangle$. Thus we may view M as the $(3n+1)$-tuple of complex vectors,

$$M = (A_1|\psi\rangle, B_1|\psi\rangle, C_1|\psi\rangle, \ldots, A_n|\psi\rangle, B_n|\psi\rangle, C_n|\psi\rangle, -i|\psi\rangle). \tag{13}$$

It is convenient to gather the columns of M into 3-tuples. We define the *triple* T_k to be the set of vectors

$$T_k = \{A_k|\psi\rangle, B_k|\psi\rangle, C_k|\psi\rangle\} \tag{14}$$

for $1 \leqslant k \leqslant n$. We view the vectors both as real and also as complex via (1).

IV. TECHNICAL LEMMAS

In this section we present combinatorial machinery that will be used to establish orthogonality among columns of the matrix M described in the preceding section.

Lemma 4.1: Let $L=(i_{jk})$ be an $\ell \times m$ matrix with entries in $\mathbb{Z}_2=\{0,1\}$, and let $E=((-1)^{i_{jk}})$. We view L as the matrix of a $\mathbb{Z}_2$-linear map $\mathbb{Z}_2^m \to \mathbb{Z}_2^\ell$ and we view E as the matrix of an $\mathbb{R}$-linear map. Suppose that E has a nontrivial kernel. Then either L has a nontrivial kernel or there is some $v \in \mathbb{Z}_2^m$ such that $Lv=(1,1,\ldots,1)$.

Proof: Assume the hypotheses of the lemma. Let N be the $\ell \times m$ matrix whose entries are all ones. As matrices over $\mathbb{R}$, observe that $E=N-2L$.

Since E has integer coefficients, there is a nonzero kernel vector v with integer coordinates. Dividing by a power of 2, if necessary, we may rescale v so that the integer coordinates are not all even. We have $0=Ev=(N-2L)v$, so $Lv=(N/2)v=(s/2)c$, where c is the column vector of all ones and s is the sum of the entries in v. Since Lv is a vector with integer entries, $Lv=(s/2)c$ implies s is even. Now we can read the equation $Lv=(s/2)c \bmod 2$. If $s/2=0 \bmod 2$, then $v \bmod 2$ is a nonzero kernel vector for L since not all coordinates of v are even. If $s/2=1 \bmod 2$, then $c=(1,1,\ldots,1)$ is in the image of L. □

Corollary 4.2: Let $\xi_1,\xi_2,\ldots,\xi_m$ be real numbers, not necessarily distinct, and not all of which are zero. Let D_m be the $2^m \times 2^m$ diagonal matrix whose r,r entry is

$$\sum_{i=1}^m (-1)^{r_i}\xi_i,$$

where $r=(r_m r_{m-1}\cdots r_2 r_1)$ is the binary expansion of the integer r in the range $0 \leqslant r \leqslant 2^m-1$. Suppose that D_m has at least one zero eigenvalue. Let $r^1,r^2,\ldots,r^\ell$ be the row numbers of the zero eigenvalues of D_m. Then there is a nonempty set $\mathcal{K}=\{k_1,k_2,\ldots,k_{m'}\}$ with $1 \leqslant k_1 < k_2 < \cdots < k_{m'} \leqslant m$ and m' even so that

$$\sum_{k\in\mathcal{K}} r_k^1 = \sum_{k\in\mathcal{K}} r_k^2 = \cdots = \sum_{k\in\mathcal{K}} r_k^\ell,$$

where the sums are taken mod 2.

Proof: Let $L=(r_j^i)$ and let $E=((-1)^{r_j^i})$. Since E kills the nonzero vector $(\xi_1,\xi_2,\ldots,\xi_m)$, Lemma 4.1 applies. If L is not injective, let $v=(v_1,v_2,\ldots,v_m)$ be a nonzero kernel vector and let $k_1,k_2,\ldots,k_{m'}$ be the indices i in the range from 1 to m inclusive for which $v_i=1$. Then the mod 2 equation $Lv=0$ yields

$$0 = \sum_{k\in\mathcal{K}} r_k^1 = \sum_{k\in\mathcal{K}} r_k^2 = \cdots = \sum_{k\in\mathcal{K}} r_k^\ell.$$

If there is a $v=(v_1,v_2,\ldots,v_m)$ such that $Lv=(1,1,\ldots,1)$, then setting $k_1,k_2,\ldots,k_{m'}$ to be the indices i for which $v_i=1$, then we have

$$1 = \sum_{k\in\mathcal{K}} r_k^1 = \sum_{k\in\mathcal{K}} r_k^2 = \cdots = \sum_{k\in\mathcal{K}} r_k^\ell.$$

To see that m' must be even, note that if

$$0 = \sum_{i=1}^{m} (-1)^{r_i}\xi_i$$

then we also have

$$0 = -\sum_{i=1}^{m} (-1)^{r_i}\xi_i = \sum_{i=1}^{m} (-1)^{r_i^c}\xi_i.$$

So if $r^1=r$ is a row number for a zero entry in D_m, so is $r^2=r^c$, where r^c is the binary string obtained from r by complementing each bit. Since these two rows have opposite parity in each bit, m' cannot be odd. This completes the proof. □

Definition 4.3: For the set $\mathcal{K}=\{k_1,k_2,\ldots,k_{m'}\}$ arising from zero entries in D_m in row numbers $r^1,r^2,\ldots,r^J$ as in 4.2 above, we define the *parity of* $\mathcal{K}$ to be the common value in $\mathbb{Z}_2$ of the sums

$$\sum_{k\in\mathcal{K}} r_k^1 = \sum_{k\in\mathcal{K}} r_k^2 = \cdots = \sum_{k\in\mathcal{K}} r_k^\ell.$$

Now we are ready to establish lower bounds on the rank of M by showing that inner products of certain pairs of columns can be arranged (via local unitary equivalence operations) to vanish.

V. ORTHOGONALITY RESULTS

Throughout this section, let $|\psi\rangle=\Sigma_I c_I|I\rangle\in H$ be a Hilbert space vector, and let M be the associated matrix as defined in Sec. III.

We make repeated use of the following elementary observation about the relationship between complex and real inner products. Let u,v be vectors in $\mathbb{C}^N$ and let u',v' be the corresponding vectors in $\mathbb{R}^{2N}$ given by the standard identification (1). The complex inner product $\langle u|v\rangle$ and the real dot product $u'\cdot v'$ are related by

$$\mathrm{Re}(\langle u|v\rangle = u'\cdot v'. \tag{15}$$

We shall consider complex inner products given in Table I among the column vectors of M given in (13). For the sake of compactness we have omitted a factor of $-i$ in the inner products (A), (E), and (I). With or without the factor $-i$, their vanishing guarantees the orthogonality of the rightmost column vector $-i|\psi\rangle$ of M to $A_k|\psi\rangle, B_k|\psi\rangle$, and $C_k|\psi\rangle$.

Our first proposition is that each triple spans three real dimensions.

Proposition 5.1: Triples span three dimensions: Let $T_k=\{A_k|\psi\rangle, B_k|\psi\rangle, C_k|\psi\rangle\}$ *be a triple of*

TABLE I. Inner products of pairs of columns of M.

$\langle\psi\|A_k\|\psi\rangle=\Sigma_I i(-1)^{i_k}\|c_I\|^2$	(A)
$\langle\psi\|A_j^\dagger A_k\|\psi\rangle=\Sigma_I(-1)^{i_j+i_k}\|c_I\|^2$	(B)
$\langle\psi\|B_j^\dagger A_k\|\psi\rangle=\Sigma_I i(-1)^{i_j+i_k}\overline{c_{I_j}}c_I$	(C)
$\langle\psi\|C_j^\dagger A_k\|\psi\rangle=\Sigma_I(-1)^{i_k}\overline{c_{I_j}}c_I$	(D)
$\langle\psi\|B_k\|\psi\rangle=\Sigma_I(-1)^{i_k}\overline{c_I}c_{I_k}$	(E)
$\langle\psi\|A_j^\dagger B_k\|\psi\rangle=\Sigma_I-i(-1)^{i_j+i_k}\overline{c_I}c_{I_k}$	(F)
$\langle\psi\|B_j^\dagger B_k\|\psi\rangle=\Sigma_I(-1)^{i_j+i_k}\overline{c_{I_j}}c_{I_k}$	(G)
$\langle\psi\|C_j^\dagger B_k\|\psi\rangle=\Sigma_I-i(-1)^{i_j}\overline{c_{I_j}}c_{I_k}$	(H)
$\langle\psi\|C_k\|\psi\rangle=\Sigma_I i\overline{c_I}c_{I_k}$	(I)
$\langle\psi\|A_j^\dagger C_k\|\psi\rangle=\Sigma_I(-1)^{i_j}\overline{c_I}c_{I_k}$	(J)
$\langle\psi\|B_j^\dagger C_k\|\psi\rangle=\Sigma_I i(-1)^{i_j}\overline{c_{I_j}}c_{I_k}$	(K)
$\langle\psi\|C_j^\dagger C_k\|\psi\rangle=\Sigma_I\overline{c_{I_j}}c_{I_k}$	(L)

columns of M. The three vectors in the triple are orthogonal when viewed as real vectors.

Proof: To prove the proposition, we show that inner products (F), (J), and (K) in Table I are pure imaginary for the case $j=k$. First, for (F), the Ith summand is

$$-i(-1)^{i_k+i_k}\overline{c_I}c_{I_k}=-i\overline{c_I}c_{I_k}$$

and the I_kth summand is

$$-i(-1)^{i_k+1+i_k+1}\overline{c_{I_k}}c_I=-i\overline{c_{I_k}}c_I.$$

The sum of the Ith and the I_kth summands is therefore $-2i\,\mathrm{Re}(\overline{c_I}c_{I_k})$. By pairing the summands in this way, we see that $\langle\psi|A_k^\dagger B_k|\psi\rangle$ is pure imaginary. Thus it follows from (15) that $A_k|\psi\rangle, B_k|\psi\rangle$ are orthogonal as real vectors.

Next we consider (J) with $j=k$. The Ith summand is $(-1)^{i_k}\overline{c_I}c_{I_k}$, while the I_kth summand is $(-1)^{i_k+1}\overline{c_{I_k}}c_I$. Thus the sum of the Ith and I_kth summands is $(-1)^{i_k}2i\,\mathrm{Im}(\overline{c_I}c_{I_k})$, which is pure imaginary, so $A_k|\psi\rangle, C_k|\psi\rangle$ are orthogonal as real vectors.

Finally we check (K) for $j=k$. In this case the Ith summand is $i(-1)^{i_k}|c_{I_k}|^2$ so the inner product is pure imaginary. Therefore $B_k|\psi\rangle, C_k|\psi\rangle$ are orthogonal as real vectors. This establishes the proposition. □

Next we show that a nontrivial linear dependence among the columns $A_k|\psi\rangle$ as real vectors guarantees that certain columns among the $B_k|\psi\rangle, C_k|\psi\rangle$ are orthogonal to spans of certain sets of triples.

Proposition 5.2: Main orthogonality proposition: Suppose that

$$\sum_{k=1}^{m}\xi_k A_{j_k}|\psi\rangle=0$$

for some $1\leqslant j_1<j_2<\cdots<j_m\leqslant n$, ξ_j *real and not all zero. Then there is a nonempty subset* $K\subseteq\{j_1,j_2,\ldots,j_m\}$ *containing an even number of elements such that* $B_k|\psi\rangle$ *and* $C_k|\psi\rangle$ *are orthogonal to* $-i|\psi\rangle$ *and to* $A_j|\psi\rangle, B_j|\psi\rangle, C_j|\psi\rangle$ *for all* $k\in K$, $j\notin K$.

Proof: Let D_m be the matrix constructed from $\xi_1,\ldots,\xi_m$ as described in the technical lemmas section. Let c_I be a nonzero state vector coefficient. By (10), the Ith coordinate of $\Sigma_{k=1}^m\xi_k A_{j_k}|\psi\rangle$ is $ic_I\Sigma_k(-1)^{i_{j_k}}\xi_k$, so the hypothesis $\Sigma_{k=1}^m\xi_k A_{j_k}|\psi\rangle=0$ guarantees that D_m has at least one zero eigenvalue, namely $\Sigma_k(-1)^{i_{j_k}}\xi_k$ where I is any multi-index for which $c_I\neq 0$. Therefore $\xi_1,\xi_2,\ldots,\xi_m$ and D_m meet the hypothesis of corollary 4.2.

Let $\mathcal{K}=\{k_1,k_2,\ldots,k_{m'}\}$ be the subset of $\{1,2,\ldots,m\}$ whose existence is guaranteed by 4.2 with corresponding parity b as defined in 4.3, and let $K=\{j_{k_1},j_{k_2},\ldots,j_{k_{m'}}\}$. The set of multi-indices of state basis vectors $|I\rangle$ is partitioned by K into two equal-sized equivalence classes by the following equivalence relation.

$$(i_1,i_2,\ldots,i_n)\sim(i'_1,i'_2,\ldots,i'_n)\Leftrightarrow\sum_{k\in K}i_k=\sum_{k\in K}i'_k \bmod 2 \tag{16}$$

In words, $I\sim I'$ if the parity of the sum of bits in columns in K is the same for I and I'. Let $\mathcal{P}$ be the set of multi-indices of parity class b and let $\mathcal{P}'$ be the opposite parity class.

We claim that all complex inner products of the form (E)–(L) in Table I vanish for $k\in K$ and $j\notin K$. From this it follows from (15) that the corresponding real dot products also vanish. Observe that for any I for which $c_I\neq 0$ we have $\Sigma_k(-1)^{i_{j_k}}\xi_k=0$, so I is in parity class $\mathcal{P}$. So if I,J are multi-indices in opposite parity classes, at least one of c_I,c_J must be zero. If $k\in K$ and $j\notin K$ then multi-indices I,I_k are in opposite parity classes, and also I_j,I_k are in opposite parity classes. Since every summand in each of the inner products (E)–(L) has a factor either of the form $\overline{c_I}c_{I_k}$ or of the form $\overline{c_{I_j}}c_{I_k}$ with $k\in K$ and $j\notin K$, all of the inner products vanish.

This completes the proof. □

Proposition 5.3: Suppose that for some $1\leq l<l'\leq n$ *we have* $A_l|\psi\rangle=A_{l'}|\psi\rangle$ *and* $C_l|\psi\rangle=C_{l'}|\psi\rangle$. *Then* $A_k|\psi\rangle,B_k|\psi\rangle$, *and* $C_k|\psi\rangle$ *are each orthogonal to* $-i|\psi\rangle$ *and to* $A_j|\psi\rangle,B_j|\psi\rangle,C_j|\psi\rangle$ *for all* $k\in\{l,l'\}$, $j\notin\{l,l'\}$.

Proof: We claim that all of the complex [and hence also real, by (15)] inner products (A)–(L) vanish for $k\in\{l,l'\}$ and $j\notin\{l,l'\}$. We begin by applying Proposition 5.2 to the hypothesis $A_l|\psi\rangle=A_{l'}|\psi\rangle$. In the notation of 5.2 we have $m=2$ and therefore also $m'=2$ since m' is an even number in the range $0<m'\leq m$, so $K=\{l,l'\}$. Thus we have from 5.2 that $B_k|\psi\rangle$ and $C_k|\psi\rangle$ are orthogonal to $-i|\psi\rangle$ and to $A_j|\psi\rangle,B_j|\psi\rangle,C_j|\psi\rangle$ for all $k\in\{l,l'\}$, $j\notin\{l,l'\}$.

It remains to be shown that $A_l|\psi\rangle,A_{l'}|\psi\rangle$ are also orthogonal to $-i|\psi\rangle$ and to $A_j|\psi\rangle,B_j|\psi\rangle,C_j|\psi\rangle$ for all $j\notin\{l,l'\}$.

The hypothesis $C_l|\psi\rangle=C_{l'}|\psi\rangle$ implies that $c_{I_l}=c_{I_{l'}}$, or equivalently, that $c_I=c_{I_{ll'}}$ for all I. This implies that summands of the inner products (A)–(D) cancel in pairs for $k\in\{l,l'\}$, $j\notin\{l,l'\}$, as follows. The Ith summand of (A) is $i(-1)^{i_k}|c_I|^2$ and the $I_{ll'}$th summand is $i(-1)^{i_k+1}|c_I|^2$. The Ith summand of (B) is $(-1)^{i_j+i_k}|c_I|^2$ and the $I_{ll'}$th summand is $(-1)^{i_j+i_k+1}|c_I|^2$. The Ith summand of (C) is $i(-1)^{i_j+i_k}\overline{c_{I_j}}c_I$ and the $I_{ll'}$th summand is $i(-1)^{i_j+i_k+1}\overline{c_{I_j}}c_I$. The Ith summand of (D) is $(-1)^{i_k}\overline{c_{I_j}}c_I$ and the $I_{ll'}$th summand is $(-1)^{i_k+1}\overline{c_{I_j}}c_I$.

This completes the proof. □

VI. LOCAL UNITARY ADJUSTMENT

In this section we adapt the orthogonality results of the preceding section to hypotheses involving more general linear dependencies.

Let us write $\langle T_{i_1},T_{i_2},\ldots,T_{i_r}\rangle$ to denote the subspace of the (real) column space of M spanned by the vectors in the triples $T_{i_1},\ldots,T_{i_r}$ viewed as real vectors.

Proposition 6.1: Main orthogonality proposition generalized: Suppose that

$$\dim\langle T_{j_1},T_{j_2},\ldots,T_{j_m}\rangle<3m$$

for some $1\leq j_1<j_2<\cdots<j_m\leq n$. *Then there is a nonempty subset* $K\subseteq\{j_1,j_2,\ldots,j_m\}$ *containing an even number of elements such that there are two orthogonal vectors* $|\zeta_k\rangle,|\eta_k\rangle$ *in* $\langle T_k\rangle$, *both of which are orthogonal to* $-i|\psi\rangle,A_j|\psi\rangle,B_j|\psi\rangle$ *and to* $C_j|\psi\rangle$ *for all* $k\in K$, $j\notin K$.

Proof: Let us write the linear dependency as a relation

$$\sum_{i=1}^{m} \xi_i |\phi_i\rangle = 0,$$

where ξ_i is real, $|\phi_i\rangle$ lies in $\langle T_{j_i}\rangle$, $\langle \phi_i|\phi_i\rangle = \langle \psi|\psi\rangle$ for $1 \leqslant i \leqslant m$, and not all the ξ_i are zero. Write each $|\phi_i\rangle$ as a linear combination

$$|\phi_i\rangle = \alpha_i A_{j_i}|\psi\rangle + \beta_i B_{j_i}|\psi\rangle + \gamma_i C_{j_i}|\psi\rangle$$

with α_i, β_i, and γ_i real. Let $R_i \in \mathrm{SO}(\mathrm{su}(2))$ be such that

$$R_i(A) = \alpha_i A + \beta_i B + \gamma_i C.$$

Since the adjoint representation $\mathrm{Ad}: \mathrm{SU}(2) \to \mathrm{SO}(\mathrm{su}(2))$ is surjective, we can choose $U_{j_i} \in \mathrm{SU}(2)$ such that $\mathrm{Ad}(U_{j_i}^{\dagger}) = R_i$, that is, $U_{j_i}^{\dagger} X U_{j_i} = R_i X$ for all $X \in \mathrm{su}(2)$. For $j \notin \{j_1, j_2, \ldots, j_m\}$, set U_j equal to the identity. Finally, let $U \in G = \mathrm{SU}(2)^n$ be $U = \prod_{i=1}^{n} U_i$.

Now observe that

$$\sum_{i=1}^{m} \xi_i (U^{\dagger} A_{j_i} U)|\psi\rangle = \sum_{i=1}^{m} \xi_i |\phi_i\rangle = 0.$$

Applying U to both sides, we get

$$\sum_{i=1}^{m} \xi_i A_{j_i} (U|\psi\rangle) = 0.$$

Let M' be the matrix for the state vector $U|\psi\rangle$. Applying the main orthogonality proposition 5.2 to M', we get that $B_k(U|\psi\rangle), C_k(U|\psi\rangle)$ are orthogonal to $U|\psi\rangle$ and to $A_j U|\psi\rangle, B_j U|\psi\rangle, C_j U|\psi\rangle$ for $k \in K$, $j \notin K$. Now set

$$|\zeta_k\rangle = U^{\dagger} B_k U|\psi\rangle,$$

$$|\eta_k\rangle = U^{\dagger} C_k U|\psi\rangle$$

for $k \in K$. Since U is unitary, we have that $|\zeta_k\rangle, |\eta_k\rangle$ are orthogonal to $U^{\dagger}U|\psi\rangle = |\psi\rangle$ and to $U^{\dagger}A_j U|\psi\rangle, U^{\dagger}B_j U|\psi\rangle, U^{\dagger}C_j U|\psi\rangle$ for $k \in K$, $j \notin K$. Since the three vectors $U^{\dagger}A_j U|\psi\rangle, U^{\dagger}B_j U|\psi\rangle, U^{\dagger}C_j U|\psi\rangle$ have the same span as $A_j|\psi\rangle, B_j|\psi\rangle, C_j|\psi\rangle$ for all j, the proposition is established. □

Proposition 6.2: Generalization of 5.3: Suppose that $\dim\langle T_l, T_{l'}\rangle \leqslant 4$ *for some* $1 \leqslant l < l' \leqslant n$. *Then* $A_k|\psi\rangle, B_k|\psi\rangle$, *and* $C_k|\psi\rangle$ *are each orthogonal to* $-i|\psi\rangle$ *and to* $A_j|\psi\rangle, B_j|\psi\rangle, C_j|\psi\rangle$ *for all* $k \in \{l, l'\}$, $j \notin \{l, l'\}$.

Proof: The proof is very similar to the proof of 6.1.

Since $\dim\langle T_l, T_{l'}\rangle \leqslant 4$, the dimension of the intersection $\langle T_l\rangle \cap \langle T_{l'}\rangle$ is at least two. Choose orthogonal vectors $|\phi\rangle, |\phi'\rangle$ in $\langle T_l\rangle \cap \langle T_{l'}\rangle$ with $\langle \phi|\phi\rangle = \langle \phi'|\phi'\rangle = \langle \psi|\psi\rangle$. Write linear combinations,

$$|\phi\rangle = \alpha_k A_k|\psi\rangle + \beta_k B_k|\psi\rangle + \gamma_k C_k|\psi\rangle,$$

$$|\phi'\rangle = \alpha'_k A_k|\psi\rangle + \beta'_k B_k|\psi\rangle + \gamma'_k C_k|\psi\rangle,$$

and let $R_k \in \mathrm{SO}(\mathrm{su}(2))$ be such that

$$R_k(A) = \alpha_k A + \beta_k B + \gamma_k C,$$

$$R_k(C) = \alpha'_k A + \beta'_k B + \gamma'_k C,$$

for $k \in \{l, l'\}$.

Since the adjoint representation $\mathrm{Ad}:\mathrm{SU}(2)\to\mathrm{SO}(\mathrm{su}(2))$ is surjective, we can choose $U_k \in \mathrm{SU}(2)$ such that $\mathrm{Ad}(U_k^\dagger)=R_k$, that is, $U_k^\dagger X U_k = R_k X$ for all $X\in\mathrm{su}(2)$. For $j\notin\{l,l'\}$, set U_j equal to the identity. Finally, let $U\in G=\mathrm{SU}(2)^n$ be $U=\prod_{i=1}^n U_i$.

Now observe that

$$U^\dagger A_l U|\psi\rangle = |\phi\rangle = U^\dagger A_{l'} U|\psi\rangle,$$

$$U^\dagger C_l U|\psi\rangle = |\phi'\rangle = U^\dagger C_{l'} U|\psi\rangle.$$

Applying U to both sides, we get

$$A_l U|\psi\rangle = A_{l'} U|\psi\rangle,$$

$$C_l U|\psi\rangle = C_{l'} U|\psi\rangle.$$

Let M' be the matrix for the state vector $U|\psi\rangle$. Applying 5.3 M', we get that $A_k(U|\psi\rangle), B_k(U|\psi\rangle), C_k(U|\psi\rangle)$ are orthogonal to $U|\psi\rangle$ and to $A_jU|\psi\rangle, B_jU|\psi\rangle, C_jU|\psi\rangle$ for $k\in\{l,l'\}$, $j\notin\{l,l'\}$. Since U is unitary, we have that $U^\dagger A_k U|\psi\rangle, U^\dagger B_k U|\psi\rangle, U^\dagger C_k U|\psi\rangle$ are orthogonal to $U^\dagger U|\psi\rangle=|\psi\rangle$ and to $U^\dagger A_j U|\psi\rangle, U^\dagger B_j U|\psi\rangle, U^\dagger C_j U|\psi\rangle$ for $k\in\{l,l'\}$, $j\notin\{l,l'\}$. Since the three vectors $U^\dagger A_j U|\psi\rangle, U^\dagger B_j U|\psi\rangle, U^\dagger C_j U|\psi\rangle$ have the same span as $A_j|\psi\rangle, B_j|\psi\rangle, C_j|\psi\rangle$ for all j, the proposition is established. □

VII. MINIMUM ORBIT THEOREM

Theorem 7.1: *Minimum orbit dimension: For the local unitary group action on state space for n qubits, the smallest orbit dimension is*

$$\min\{\dim \mathcal{O}_x : x\in\mathbb{P}(H)\} = \begin{cases} \frac{3n}{2}, & n \text{ even}, \\ \frac{3n+1}{2}, & n \text{ odd}. \end{cases}$$

We begin the proof by exhibiting a state for which the claimed minimum dimension is realized.

Let $|s\rangle=|01\rangle-|10\rangle$ be a Hilbert space representative of the singlet state, let $X=\begin{bmatrix} it & u \\ -\bar{u} & -it \end{bmatrix}$ be an element of su(2). We have

$$(X,X)\cdot|s\rangle = 0$$

so (X,X) is in the isotropy Lie algebra of the state represented by $|s\rangle$.

From this it follows that $(X_1,X_1,X_2,X_2,\ldots,X_k,X_k)$ stabilizes the $2k$-qubit state x represented by

$$\underbrace{|s\rangle\otimes|s\rangle\otimes\cdots\otimes|s\rangle}_{k \text{ copies}}$$

for all $X_1,X_2,\ldots,X_k$ in su(2). Therefore LI_x has dimension at least $3k=3n/2$ for $n=2k$, and therefore $\dim \mathcal{O}_x \leqslant 3n-3n/2=3n/2$ for n even.

Observe that $\left(X_1,X_1,X_2,X_2,\ldots,X_k,X_k,\begin{bmatrix} it & 0 \\ 0 & -it \end{bmatrix}\right)$ stabilizes the $(2k+1)$-qubit state x represented by $|s\rangle\otimes|s\rangle\otimes\cdots\otimes|s\rangle\otimes|0\rangle$ (by a phase factor), so the dimension of LI_x is at least $3k+1=(3n-1)/2$ for $n=2k+1$, and therefore $\dim \mathcal{O}_x \leqslant 3n-(3n-1)/2=(3n+1)/2$ for n odd.

These calculations establish that

$$\min\{\dim \mathcal{O}_x : x \in \mathbb{P}(H)\} \leqslant \begin{cases} \frac{3n}{2}, & n \text{ even}, \\ \frac{3n+1}{2}, & n \text{ odd}. \end{cases} \tag{17}$$

Next we show that this bound on orbit dimension is sharp by establishing a lower bound for the rank of M. From 3.3 the desired lower bound for the minimum orbit dimension follows immediately from 7.2 below.

Proposition 7.2: Minimum rank of M: Let x be a state for a system of n qubits, let $|\psi\rangle$ be a Hilbert space representative for x, and let M be the real matrix associated to $|\psi\rangle$ as defined in Sec. III. *We have*

$$\operatorname{rank} M \geqslant \begin{cases} \frac{3n}{2} + 1, & n \textit{ even}, \\ \frac{3n+1}{2} + 1, & n \textit{ odd}. \end{cases}$$

Proof: Let $\mathcal{C} = \{A_1|\psi\rangle, B_1|\psi\rangle, C_1|\psi\rangle, \ldots, A_n|\psi\rangle, B_n|\psi\rangle, C_n|\psi\rangle, -i|\psi\rangle\}$ denote the set of columns of M. For a subset $\mathcal{S} \subseteq \mathcal{C}$, let $\langle \mathcal{S} \rangle$ denote the real span of the column vectors contained in $\mathcal{S}$. Let $\mathcal{S}_0$ be a subset of $\mathcal{C}$ which is the union of some number p of triples, and is maximal with respect to the property that $\langle \mathcal{S}_0 \rangle$ contains a subspace W for which

(i)

$$\dim W \geqslant \begin{cases} \frac{3p}{2}, & p \text{ even}, \\ \frac{3p+1}{2}, & p \text{ odd}, \end{cases}$$

(ii)

$$W \perp \langle \mathcal{C} \setminus \mathcal{S}_0 \rangle.$$

We separate the argument into cases. We show that in every case, either 7.2 holds or we can derive a contradiction by constructing a superset $\mathcal{S}_1$ of $\mathcal{S}_0$ which is the union of some number $p' > p$ of triples and which contains a subspace W' satisfying properties (i) and (ii) with p' in place of p. The construction of $\mathcal{S}_1$ violates the maximality of $\mathcal{S}_0$ and therefore rules out the case in question.

Case 1: Suppose that $p = n$, so that $\mathcal{C} \setminus \mathcal{S}_0 = \{-i|\psi\rangle\}$. Then property (ii) guarantees that $\operatorname{rank} M \geqslant \dim W + 1$, so property (i) guarantees that 7.2 holds.

Case 2: Suppose that $p < n$ and that the remaining triples $T_{j_1}, T_{j_2}, \ldots, T_{j_{n-p}}$ in $\mathcal{C} \setminus \mathcal{S}_0$ have the maximum possible span, that is,

$$\dim\langle T_{j_1}, T_{j_2}, \ldots, T_{j_{n-p}} \rangle = 3(n-p).$$

Properties (i) and (ii) imply that

$$\operatorname{rank} M \geqslant \dim W + \dim\langle \mathcal{C} \setminus \mathcal{S}_0 \rangle \geqslant \frac{3p}{2} + 3(n-p) = \frac{6n-3p}{2}$$

$$\geqslant \frac{6n-(3n-3)}{2} \quad (\text{since } p \leqslant n-1) = \frac{3n+3}{2} = \frac{3n+1}{2} + 1$$

and so 7.2 holds. Note that if $p = n-1$, the hypothesis of full span is met by 5.1. Therefore in the remaining cases we need only consider $p \leqslant n-2$.

Case 3: Suppose $p \leqslant n-2$ and that there is a pair of triples $T_l, T_{l'}$ in $\mathcal{C} \setminus \mathcal{S}_0$ with $1 \leqslant l < l' \leqslant n$ such that $\dim\langle T_l, T_{l'} \rangle \leqslant 4$. Let $\mathcal{S}_1 = \mathcal{S}_0 \cup T_l \cup T_{l'}$, let $p' = p+2$, and let $W' = W \oplus \langle T_l \cup T_{l'} \rangle$, where "$\oplus$" denotes the orthogonal direct sum. That the sum is orthogonal is guaranteed by property (ii) for W. Proposition 6.2 implies that property (ii) also holds for the pair $(\mathcal{S}_1, W')$ and that $\dim W' \geqslant \dim W + 3$. It follows that if p is even, so is p' and we have

$$\dim W' \geqslant \frac{3p}{2} + 3 = \frac{3p+6}{2} = \frac{3(p+2)}{2} = \frac{3p'}{2}$$

and similarly if p and p' are odd we have

$$\dim W' \geqslant \frac{3p+1}{2} + 3 = \frac{3p'+1}{2}$$

so $(\mathcal{S}_1, W')$ satisfies property (i). Thus $\mathcal{S}_1$ violates the maximality of $\mathcal{S}_0$, so we conclude that the hypothesis of case 3 is impossible.

Case 4: Suppose $p \leqslant n-2$ and that there is a pair of triples $T_l, T_{l'}$ in $\mathcal{C}\backslash\mathcal{S}_0$ with $1 \leqslant l < l' \leqslant n$ such that $\dim\langle T_l, T_{l'}\rangle = 5$. Applying 6.1 we have four vectors

$$|\zeta_l\rangle, |\eta_l\rangle \in \langle T_l\rangle, \quad |\zeta_{l'}\rangle, |\eta_{l'}\rangle \in \langle T_{l'}\rangle$$

which must span at least three dimensions, so once again $\mathcal{S}_1 = \mathcal{S}_0 \cup T_l \cup T_{l'}$ with the subspace

$$W' = W \oplus \langle |\zeta_l\rangle, |\eta_l\rangle, |\zeta_{l'}\rangle, |\eta_{l'}\rangle\rangle$$

violates the maximality of $\mathcal{S}_0$. We conclude that the hypothesis of case 4 is impossible.

Case 5: The only remaining possibility is that $p \leqslant n-3$. Let $\mathcal{T} = \{T_{j_1}, T_{j_2}, \ldots, T_{j_m}\}$ be a set of triples in $\mathcal{C}\backslash\mathcal{S}_0$ with $m \geqslant 3$ minimal with respect to the property

$$\dim\langle T_{j_1}, T_{j_2}, \ldots, T_{j_m}\rangle < 3m.$$

Applying 6.1 we have two vectors

$$|\zeta_k\rangle, |\eta_k\rangle \in \langle T_k\rangle$$

for each of the $m' \geqslant 2$ elements $k \in K$. Let

$$\mathcal{S}_1 = \mathcal{S}_0 \cup \left(\bigcup_{k\in K} T_k\right),$$

let $p' = p + m'$, and let

$$W' = W \oplus \langle \{|\zeta_k\rangle, |\eta_k\rangle\}_{k\in K}\rangle.$$

Note that property (ii) holds for $(\mathcal{S}_1, W')$. If $m' < m$, then the $2m'$ vectors in $\{|\zeta_k\rangle, |\eta_k\rangle\}_{k\in K}$ are independent by the minimality of $\mathcal{T}$, so we have

$$\dim W' \geqslant \dim W + 2m' \geqslant \frac{3p}{2} + 2m' = \frac{3p' + m'}{2} \geqslant \frac{3p'+1}{2}$$

so property (i) holds for $(\mathcal{S}_1, W')$, but this contradicts the maximality of $\mathcal{S}_0$. Finally, if $m' = m$, then $m \geqslant 4$ (since m' is even) and at least $2(m-1)$ of the vectors in $\{|\zeta_k\rangle, |\eta_k\rangle\}_{k\in K}$ must be independent, again by the minimality of $\mathcal{T}$. If p is even, then $p' = p + m$ is also even and we have

$$\dim W' \geqslant \dim W + 2(m-1) \geqslant \frac{3p}{2} + 2(m-1) = \frac{3p' + m - 4}{2} \geqslant \frac{3p'}{2}.$$

If p is odd, then $p' = p + m$ is odd and we have

$$\dim W' \geqslant \dim W + 2(m-1) \geqslant \frac{3p+1}{2} + 2(m-1) = \frac{3p' + m - 3}{2} \geqslant \frac{3p'+1}{2}.$$

Thus $\mathcal{S}_1$ with the subspace W' violates the maximality of $\mathcal{S}_0$. We conclude that the hypothesis of case 5 is impossible.

Having exhausted all possible cases, this completes the proof of 7.2, and hence of Theorem 7.1. □

We consider a model of a particle coupled to a massless scalar field (the massless Nelson model) in a non-Fock representation. We prove the existence of a ground state of the system, applying the method of Griesemer, Lieb, and Loss. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2050507]

I. INTRODUCTION

The Nelson model is a quantum mechanical model which describes an interaction between some quantum mechanical particles and a Bose field.[8] In this article, we present a criterion for a Nelson model to have a ground state.

We consider one particle under the influence of an external potential V and coupled to a scalar Bose field. The Hilbert space of the system is given by

$$\mathcal{F} := L^2(\mathbb{R}^3) \otimes \mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3)), \tag{1}$$

where $\mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3))$ is the Boson Fock space over $L^2(\mathbb{R}^3)$. The standard Nelson Hamiltonian is of the form

$$H_m^V := (-\Delta + V) \otimes \mathbb{1} + \mathbb{1} \otimes H_f(m) + \lambda \phi^{\oplus}(v), \quad \text{on } \mathcal{F},$$

where $\mathbb{1}$ denotes identity, Δ is the generalized Laplacian on $L^2(\mathbb{R}^3)$, $\lambda \in \mathbb{R}$ is a coupling constant, and $H_f(m)$ and $\phi^{\oplus}(v)$ are defined by

$$H_f(m) := \int_{\mathbb{R}^3} \omega_m(k) a(k)^* a(k) \mathrm{d}k,$$

$$\phi^{\oplus}(v) := \frac{1}{\sqrt{2}} \int_{\mathbb{R}^3} (v(x,k) \otimes a(k)^* + v(x,k)^* \otimes a(k)) \mathrm{d}k,$$

with

$$\omega_m(k) := \sqrt{k^2 + m^2}, \quad v(x,k) := \frac{1}{\sqrt{(2\pi)^3}} \frac{\hat{\rho}(k)}{|k|^{1/2}} e^{-ikx},$$

where $|k|^{-1/2}\hat{\rho} \in \mathrm{Dom}(\omega_m^{-1/2})$ and $a(k)^*, a(k)$ are the distribution kernels of the creation and annihilation operators on $\mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3))$ ($\mathrm{Dom}(A)$ means the domain of operator A). The problem on the ground state of H_m^V can be classified as follows:

(i) the massive case: $m > 0$

[a)]Electronic mail: i-sasaki@math.sci.hokudai.ac.jp

$$\text{(ii) the massless case: } m=0 \begin{cases} |k|^{-1/2}\hat{\rho} \in \mathrm{Dom}(\omega_0^{-1}) \text{: infrared regular} \\ |k|^{-1/2}\hat{\rho} \notin \mathrm{Dom}(\omega_0^{-1}) \text{: infrared singular.} \end{cases}$$

In almost all cases, to prove existence of a ground state for the massive case is easy. The first result on the ground state problem, to our knowledge, is due to Spohn.[12] In Ref. 12 he proved existence of a ground state in the case where the infrared regular (I.R.) condition holds and $(-\Delta+V+i)^{-1}$ is compact. If $(-\Delta+V+i)^{-1}$ is not compact, this theorem shows that a ground state exists if the I.R. condition holds and the coupling constant λ is small enough. After the work of Spohn,[12] C. Gérard proved existence of a ground state of an extended model of the Nelson model in the case where an abstract particle Hamiltonian K (which corresponds to $-\Delta+V$ in the previous context) has compact resolvent and an I.R. like condition holds.[3] On the other hand, Lörinczi *et al.*[7] showed that H_0^V has *no* ground state if the infrared singular (I.S.) condition holds in spite of the condition $V(x) > C|x|^{\alpha}(C, \alpha > 0)$ (also refer to Ref. 2 about the absence of ground states). Recently, Hirokawa *et al.*[5] proved existence of a ground state for the renormalized Nelson model.

In the case where the I.S. condition holds, H_0^V may not have a ground state,[7] but Arai[1] showed that a massless Nelson model in *a non-Fock representation* has a ground state.

We work with the non-Fock representation introduced in Ref. 1. In this representation the massless Nelson model we consider is of the form:

$$\tilde{H}^V := (-\Delta + V) \otimes \mathbb{1} + \mathbb{1} \otimes H_f(0) + \lambda \phi^{\oplus}(G) - \lambda^2 \mathcal{V}(\hat{x}) \otimes \mathbb{1} + \lambda^2 \mathcal{W} \mathbb{1},$$

where $\mathcal{V}(\hat{x})$ is the multiplication operator by $\mathcal{V}(x) := \mathrm{Re}\langle |k|^{-1/2} v(0), |k|^{-1/2} v(x) \rangle$, $\mathcal{W} := \| |k|^{-1/2} v(0) \|^2$ is a constant, and $G(x,k) := v(x,k) - v(0,k)$. If $m=0$ and the I.R. condition holds, $\tilde{H}^V$ is unitarily equivalent to H_0^V (Proposition 2.1). But if the I.S. condition holds, $\tilde{H}^V$ may not be unitarily equivalent to H_0^V. If the I.S. condition holds, to consider $\tilde{H}^V$ means to choose a non-Fock representation of the canonical commutation relations of a, a^* (see Ref. 1). Note that, in the massless case $m=0$, the Hamiltonian we consider is $\tilde{H}^V$, not H_0^V.

For the non-Fock Hamiltonian $\tilde{H}^V$, we present a criterion for $\tilde{H}^V$ to have a ground state. The criterion is essentially the same condition as in Ref. 4, and we prove existence of a ground state without assuming the I.R. condition. Our strategy is the same as that of Ref. 4. We, however, improved the proof of the photon derivative bound. In the proof of photon derivative bound in Ref. 4, it is difficult to prove that the integer-valued k-dependent sequence $h_l(k)$ is measurable. In our new proof of the photon derivative bound, such uncertain sequence does not appear.

This article is organized as follows. In Sec. II we describe rigorous definitions of our system and state main results. In Sec. III, we prove the main theorem. In the Appendix, we establish a formula which expresses a second quantization operator by the annihilation operators.

II. NOTATION AND MAIN RESULTS

We consider a model of one particle interacting with a scalar Bose field, and in an external potential $V: \mathbb{R}^3_x \to \mathbb{R}$ satisfying $V \in L^1_{\mathrm{loc}}(\mathbb{R}^3_x)$. The Hilbert space for the model is given by $\mathcal{F} := L^2(\mathbb{R}^3_x) \otimes \mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3_k))$, where $\mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3_k))$ is the Boson Fock space over $L^2(\mathbb{R}^3_k)$ (see Ref. 9). For $m \geqslant 0$ we define a function $\omega_m: \mathbb{R}^3_k \to \mathbb{R}$ by $\omega_m(k) := \sqrt{k^2+m^2}$. The multiplication operator by ω_m is denoted by the same symbol. The free Hamiltonian of the scalar Bose field is the second quantization of ω_m (Ref. 9):

$$H_f(m) := \mathrm{d}\Gamma_{\mathrm{b}}(\omega_m). \tag{2}$$

We set $V_{\pm}(x) := \max\{0, \pm V(x)\}$. Throughout this article, we assume that the potential V has the following properties:

[N.1] There exist constants $a < 1$ and $b \in \mathbb{R}$ such that

$$\|V_-^{1/2}\psi\|^2 \leqslant a\|(-\Delta)\psi\|^2 + b\|\psi\|^2, \quad \psi \in C_0^\infty(\mathbb{R}_x^3).$$

The particle Hamiltonian H_p is a self-adjoint operator defined by

$$H_\mathrm{p} := -\Delta \dot{+} V, \quad \text{on } L^2(\mathbb{R}_x^3),$$

where $\dot{+}$ means the form sum. For $f \in L^2(\mathbb{R}_k^3)$ we denote by $a(f)^*$, $a(f)$, the creation and annihilation operators respectively, by $\Phi_\mathrm{S}(f) := \overline{[a(f)+a(f)^*]}/\sqrt{2}$ the Segal field operators ("$-$" means closure). It is well known that $\Phi_\mathrm{S}(f)$ is a self-adjoint operator on $\mathcal{F}_\mathrm{b}(L^2(\mathbb{R}_k^3))$ (see Ref. 10). For $x \in \mathbb{R}_x^3$ and $\hat{\rho} \in L^2(\mathbb{R}_k^3) \cap \mathrm{Dom}(|k|^{-1/2})$ we define $v(x) \in L^2(\mathbb{R}_k^3)$ by

$$v(x)(k) := v(x,k) := \frac{1}{(2\pi)^{3/2}} \frac{\hat{\rho}(k)}{|k|^{1/2}} e^{-ikx}, \quad k \in \mathbb{R}_k^3.$$

The Hilbert space $\mathcal{F}$ can be identified with the fibre direct integral of $\mathcal{F}_\mathrm{b}(L^2(\mathbb{R}_k^3))$ (see Ref. 11):

$$\mathcal{F} = \int_{\mathbb{R}_x^3}^{\oplus} \mathcal{F}_\mathrm{b}(L^2(\mathbb{R}_k^3))\mathrm{d}x.$$

In this identification the operator

$$\phi^\oplus(v) := \int_{\mathbb{R}_x^3}^{\oplus} \Phi_\mathrm{S}(v(x))\mathrm{d}x$$

gives a self-adjoint operator on $\mathcal{F}$.[11]

The Hamiltonian of the standard Nelson model is defined by

$$H_m^V := H_\mathrm{p} \otimes \mathbb{1} + \mathbb{1} \otimes H_f(m) + \lambda\phi^\oplus(v).$$

Here $\lambda \in \mathbb{R}$ is a coupling constant. We set

$$H_0 := H_\mathrm{p} \otimes \mathbb{1} + \mathbb{1} \otimes H_f(m),$$

the free Hamiltonian of the Nelson model. By [N.1], H_p is bounded below. Therefore H_0 is self-adjoint on $D(H_0) = D(H_\mathrm{p} \otimes \mathbb{1}) \cap D(\mathbb{1} \otimes H_f(m))$ and bounded below.

The following fact is well known:

Proposition 2.1: Assume $|k|^{-1/2}\hat{\rho} \in \mathrm{Dom}(\omega_m^{1/2})$ *and (N.1). Then* H_m^V *is self-adjoint on* $\mathrm{Dom}(H_0)$ *and bounded below. Moreover* H_m^V *is essentially self-adjoint on each core for* H_0.

Under the assumption of Proposition 2.1, we set

$$E^V(m) := \inf \sigma(H_m^V),$$

the ground state energy of H_m^V. Where $\sigma(H_m^V)$ means the spectrum of H_m^V. If $E^V(m)$ is an eigenvalue of H_m^V, we say that H_m^V has a ground state and a eigenvector $\Phi_m \in \ker(H_m^V - E^V(m)) \backslash \{0\}$ is called a ground state of H_m^V.

Let $\theta \in C_0^\infty(\mathbb{R}_x^3)$, $\tilde{\theta} \in C^\infty(\mathbb{R}_x^3)$ be functions which satisfy the following properties (i), (ii):

$$\text{(i) } 0 \leqslant \theta(x), \tilde{\theta}(x) \leqslant 1, \quad \theta(x)^2 + \tilde{\theta}(x)^2 = 1, \ (x \in \mathbb{R}_x^3).$$

$$\text{(ii) } \theta(x) = \begin{cases} 1, & |x| \leqslant 1 \\ 0, & |x| \geqslant 2. \end{cases}$$

For $R > 0$ we define particle cutoff functions $\theta_R, \tilde{\theta}_R$ as follows:

$$\theta_R(x) := \theta(x/R), \quad \widetilde{\theta}_R(x) := \widetilde{\theta}(x/R).$$

We abbreviate $\theta_R \otimes \mathbb{1}, \widetilde{\theta}_R \otimes \mathbb{1}$ to $\theta_R, \widetilde{\theta}_R$, respectively if there is no danger of confusion. For a self-adjoint operator T, we denote by $Q(T)$ the form domain of T, and for $\Psi, \Phi \in Q(T)$, we write simply $\langle \Psi, T\Phi \rangle = \int_{\mathbb{R}} \mu \mathrm{d}\langle \Psi, E_T(\mu)\Phi \rangle$, where E_T means the spectral measure of T.

We define a quantity which physically means the minimal energy in the states where the particle is separated more than R away from the origin:

Definition 2.2:

$$E_\infty(R,m) := \inf_{\substack{\Psi \in Q(H_m^V) \\ \|\widetilde{\theta}_R \Psi\| \neq 0}} \frac{\langle \widetilde{\theta}_R \Psi, H_m^V \widetilde{\theta}_R \Psi \rangle}{\langle \Psi, \widetilde{\theta}_R^2 \Psi \rangle}.$$

Remark: For all $R > 0$, it is easy to see that $E^V(m) - E_\infty(R,m) \leqslant 0$.

The following condition is based on Ref. 4.

Hypothesis I (binding condition for $m > 0$):

$$E^V(m) < \limsup_{R \to \infty} E_\infty(R,m).$$

Theorem 2.3: *(Existence of ground state ($m > 0$)). Let $m > 0$. Assume [N.1] and Hypothesis I. Then H_m^V has a ground state.*

Proof: This is done in the same method as in the proof of (Ref. 4, Theorem 4.1). Therefore we omit the proof. ■

In the case $m = 0$, we need more assumptions:

[N.2] $\hat{\rho}/|k| \in L^2(\mathbb{R}_k^3)$.

Under conditions [N.1] and [N.2], the Hamiltonian of the massless Nelson model we consider is:

$$\widetilde{H}^V := H_{\mathrm{p}} \otimes \mathbb{1} + \mathbb{1} \otimes H_f(0) + \lambda \phi^{\oplus}(G) - \lambda^2 \mathcal{V}(\hat{x}) \otimes \mathbb{1} + \lambda^2 \mathcal{W} \mathbb{1},$$

where $\mathcal{W} := \|\omega_0^{-1/2} v(0)\|^2$ is a constant and $\mathcal{V}(\hat{x})$ is the multiplication operator by the function $\mathcal{V}(x) := \mathrm{Re}\langle \omega_0^{-1/2} v(0), \omega_0^{-1/2} v(x) \rangle$.

By [N.2], $\mathcal{V}(x)$ is uniformly continuous and $\lim_{|x| \to 0} \mathcal{V}(x) = 0$. The relation between $\widetilde{H}^V$ and H_0^V is given by the following proposition.

Proposition 2.4: Suppose that the infrared regular condition $\hat{\rho}/|k|^{3/2} \in L^2(\mathbb{R}_k^3)$ holds. Then $\widetilde{H}^V$ is unitarily equivalent to H_0^V.

Proof: By the assumption, the operator $T := \exp[-i\lambda \mathbb{1} \otimes \Phi_{\mathrm{S}}(i|k|^{-1} v(0))]$ is a unitary operator on $\mathcal{F}$ and H_m^V is unitarily equivalent to $\widetilde{H}^V = T H_m^V T^*$. ■

If the infrared singular condition $\hat{\rho}/|k|^{3/2} \notin L^2(\mathbb{R}_k^3)$ holds, this Hamiltonian $\widetilde{H}^V$ gives a Nelson Hamiltonian in a non-Fock representation (see Ref. 1).

For the existence of ground states of $\widetilde{H}^V$, we impose some conditions on $\hat{\rho}$:

[N.3] There exists an open set $S \subset \mathbb{R}^3$, such that $\mathrm{supp}\, \hat{\rho} = \overline{S}$. Moreover, for all $n \in \mathbb{N}$

$$S_n := \{k \in S \,|\, |k| < n\}$$

has the cone-property (see Ref. 6).

[N.4] There exists a function $\eta \in H^1(\mathbb{R}_k^3)$, such that $\hat{\rho} = \chi_S \eta$, where χ_S is the characteristic function of S.

[N.5] $\hat{\rho}$ is continuously differentiable in $S \backslash \{0\}$.

[N.6] $|k|^{-3/2} \hat{\rho}, |k|^{-1/2} |\nabla \hat{\rho}| \in L^p(S)$ for all $p, 1 < p < 2$.

Under the condition [N.1] and [N.2], it is easy to see that $E^V(0) = \inf \sigma(\widetilde{H}^V)$. One of the most important conditions for the existence of ground states of $\widetilde{H}^V$ is

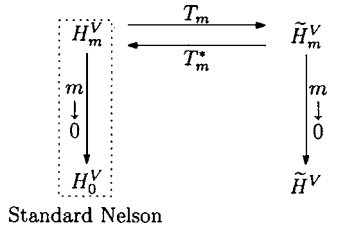

FIG. 1. Author—please provide caption.

Hypothesis II (binding condition for $m=0$):

$$E^V(0) < \limsup_{R\to\infty} E_\infty(R,0). \tag{3}$$

Now we state the main result of this article.

Theorem 2.5. *(Existence of ground state $(m=0)$): Assume [N.1]–[N.6] and Hypothesis II. Then the massless Nelson Hamiltonian $\tilde{H}^V$ has a ground state.*

Remark: In the case $\lim_{|x|\to\infty} V(x)=\infty$, it is easy to see that $\lim_{R\to\infty} E_\infty(R,m)=\infty$. Therefore Hypothesis II holds. On the other hand, if $\lim_{|x|\to\infty} V(x)\to 0$ and the particle Hamiltonian H_{p} has negative energy ground states, then Hypotheses I and II hold (see Ref. 4 Theorem 3.1).

Remark: Let $\Lambda>0$. Then $\hat{\rho}=\chi_\Lambda$ (the characteristic function of the region $|k|<\Lambda$) satisfies the above conditions [N.2]–[N.6]. Note that the function $\hat{\rho}=\chi_\Lambda$ is infrared singular, because $|k|^{-3/2}\hat{\rho}$ is not in $L^2(\mathbb{R}^3)$.

III. PROOF OF THEOREM 2.5

Throughout this section we assume [N.1]–[N.6] and Hypothesis II. In this section, we set $\lambda=1$, because Theorem 2.5 does not depend on λ explicitly (to restore λ, it is enough to replace $\hat{\rho}$ by $\lambda\hat{\rho}$).

For $m>0, T_m := \exp[-i\mathbb{1}\otimes\Phi_{\mathrm{S}}(iv(0/\omega_m))]$ is a unitary operator on $\mathcal{F}$, and we have

$$\tilde{H}_m^V := T_m H_m^V T_m^* = H_{\mathrm{p}}\otimes\mathbb{1} + \mathbb{1}\otimes H_f(m) + \phi^{\oplus}(G) - \mathcal{V}_m(\hat{x})\otimes\mathbb{1} + \mathcal{W}_m\mathbb{1},$$

where $\mathcal{V}_m(\hat{x})$ is the multiplication operator by the function $\mathcal{V}_m(x) := \mathrm{Re}\langle\omega_m^{-1}v(0), v(x)\rangle$ and $\mathcal{W}_m := \|\omega_m^{-1/2}v(0)\|^2$ is a constant. In Fig. 1, we show the relation to the original model.

The ground state energy $E^V(m)$ is monotone increasing in $m\geqslant 0$, and $\lim_{m\to 0} E^V(m)=E^V(0)$ (see Ref. 4, Sec. 5). Therefore, by Hypothesis II, for all sufficiently small $m\geqslant 0$ we have $E^V(m) < \limsup_{R\to\infty} E_\infty(R,0)$. Since $E_\infty(R,m)$ is monotone increasing in $m\geqslant 0$, there exists a constant m such that

$$E^V(m) < \limsup_{R\to\infty} E_\infty(R,m) \quad (0\leqslant m<\mathsf{m}).$$

In what follows, we consider only the case $0<m<\mathsf{m}$. Hence, by Theorem 2.3, H_m^V has a ground state Φ_m. We set $\tilde{\Phi}_m := T_m\Phi_m$ a ground state of $\tilde{H}_m^V$.

Lemma 3.1. (Exponential decay): Let $\beta>0$ be a constant such that

$$\beta^2 < \limsup_{R\to\infty} E_\infty(R,m) - E^V(m) \quad (0<m<\mathsf{m}).$$

Then, for all large $R>0$,

$$\|\exp(\beta|x|)\tilde{\Phi}_m\|^2 \leqslant C\left(1+\frac{1}{E_\infty(R,m)-E^V(m)-\beta^2+o(1/R^0)}\right)\|\tilde{\Phi}_m\|^2,$$

where the constant $C>0$ does not depend on m with $C\leqslant\frac{3}{2}e^{4\beta R}$.

Proof: See Ref. 4. ■

Let $f \in \mathrm{Dom}(\omega_m)$. Since $\mathrm{Dom}(\tilde{H}_m^V) = \mathrm{Dom}(H_\mathrm{p} \otimes \mathbb{1}) \cap \mathrm{Dom}(\mathbb{1} \otimes H_f(m))$, $a(f)\tilde{\Phi}_m \in Q(\tilde{H}_m^V)$. Hence, for all $\Psi \in \mathrm{Dom}(H_m^V)$, we have

$$\langle (\tilde{H}_m^V - E^V(m))\Psi, a(f)\tilde{\Phi}_m \rangle = -\langle \Psi, a(\omega_m f)\tilde{\Phi}_m \rangle - \frac{1}{\sqrt{2}} \langle \Psi, \langle f, G(\hat{x}) \rangle \tilde{\Phi}_m \rangle.$$

Here we use the canonical commutation relations of a, a^*, and $\langle f, G(\hat{x}) \rangle$ is the multiplication operator by the function $\langle f, G(x) \rangle$. Since $\Psi \in \mathrm{Dom}(\tilde{H}_m^V)$ is arbitrary, $a(f)\tilde{\Phi}_m \in \mathrm{Dom}(\tilde{H}_m^V)$, and hence,

$$\langle a(f)\tilde{\Phi}_m, a(\omega_m f)\tilde{\Phi}_m \rangle + \frac{1}{\sqrt{2}} \langle a(f)\tilde{\Phi}_m, \langle f, G(\hat{x}) \rangle \tilde{\Phi}_m \rangle \leqslant 0. \tag{4}$$

Lemma 3.2 (Photon number bound): For all $0 < m < \mathsf{m}$, *we have*

$$\| a(k)\tilde{\Phi}_m \|^2 \leqslant \frac{1}{2(2\pi)^3} \frac{|k|}{\omega_m(k)^2} |\hat{\rho}(k)|^2 \| |x| \tilde{\Phi}_m \|^2, \quad \text{a.e. } k \in \mathbb{R}^3. \tag{5}$$

Proof: Let $q(k)$ be a bounded real-valued measurable function. We choose some complete orthonormal system $\{f_i\}_{i=1}^\infty \subset \mathrm{Dom}(\omega_m)$. By (4), we have

$$\sum_{i=1}^\infty \langle a(\omega_m^{-1/2} q f_i)\tilde{\Phi}_m, a(\omega_m^{1/2} q f_i)\tilde{\Phi}_m \rangle + \frac{1}{\sqrt{2}} \sum_{i=1}^\infty \langle a(\langle \omega_m^{-1/2} q f_i, G(\hat{x}) \rangle \omega_m^{-1/2} q f_i)\tilde{\Phi}_m, \tilde{\Phi}_m \rangle \leqslant 0.$$

By Lemma A.1 in the Appendix, we have

$$\langle \tilde{\Phi}_m, \mathrm{d}\Gamma(q^2)\tilde{\Phi}_m \rangle \leqslant -\frac{1}{\sqrt{2}} \langle a(\omega_m^{-1} q^2 G(\hat{x}))\tilde{\Phi}_m, \tilde{\Phi}_m \rangle \leqslant \frac{1}{\sqrt{2}} \int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)} |\langle G(\hat{x}, k)^* a(k)\tilde{\Phi}_m, \tilde{\Phi}_m \rangle|.$$

Note that q is arbitrary. Hence, we obtain

$$\| a(k)\tilde{\Phi}_m \|^2 \leqslant \frac{1}{\sqrt{2}} \frac{1}{\omega_m(k)} \| a(k)\tilde{\Phi}_m \| \, \| G(\hat{x}; k)\tilde{\Phi}_m \|, \quad \text{a.e. } k.$$

By the definition of G, we have $|G(x, k)|^2 \leqslant |\hat{\rho}(k)|^2 |k| |x|^2 / (2\pi)^3$. Therefore, (5) holds. ■

We write $\tilde{\Phi}_m = (\tilde{\Phi}_m^{(n)})_{n=0}^\infty$ with $\tilde{\Phi}_m^{(n)} \in L^2(\mathbb{R}_x^3) \otimes (\otimes_s^n L^2(\mathbb{R}_k^3))$, $n \geqslant 0$, where $\otimes_s^n L^2(\mathbb{R}_k^3)$ is the n-fold symmetric tensor product of $L^2(\mathbb{R}_k^3)$.

Lemma 3.3 (Photon derivative bound): Let $0 < m < \mathsf{m}$. *Then, for all* $\tilde{\Phi}_m^{(n)}$ *is in the Sobolev space* $H^1(\mathbb{R}_x^3 \times S^{3n})$, *and* $\mathcal{F}$*-valued function* $a(k)\tilde{\Phi}_m$ *is strongly differentiable in* $k \in S \backslash \{0\}$ *for all directions with*

$$\partial_j a(k)\tilde{\Phi}_m = (\partial_j \tilde{\Phi}_m^{(1)}(k), \sqrt{2}\partial_j \tilde{\Phi}_m^{(2)}(k, \cdot), \ldots, \sqrt{n}\partial_j \tilde{\Phi}_m^{(n)}(k, \cdot), \ldots), \quad j = 1, 2, 3,$$

$$\| \nabla_k a(k)\tilde{\Phi}_m \|^2 \leqslant \frac{1}{(2\pi)^3} \frac{1}{\omega_m(k)^2} \left[3\frac{|\hat{\rho}(k)|^2}{|k|} + |k| |\nabla \hat{\rho}(k)|^2 \right] \| |\hat{x}| \tilde{\Phi}_m \|^2,$$

where ∂_j *and* ∇_k *means the differential operator for j-th component of k and the nabla operator for the coordinate k.*

Proof: For $h \in \mathbb{R}^3$ and a function $f(k)$, we define

$$(\Delta_h f)(k) := f(k+h) - f(k).$$

We consider (4) with f replaced by $\Delta_{-h}\omega_m^{-1/2} q f_i$. Here q and f_i are the same function as in the proof of the above Lemma. By Lemma A.1, we have

$$\sum_{i=1}^{\infty} \langle a(\Delta_{-h}\omega_m^{-1/2} q f_i)\tilde{\Phi}_m, a(\omega_m \Delta_{-h}\omega_m^{-1/2} q f_i)\tilde{\Phi}_m\rangle = \langle \tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{-h}\omega_m^{-1} q^2 \Delta_h \omega_m)\tilde{\Phi}_m\rangle. \tag{6}$$

We introduce an operator $(T_h f)(k) := f(k+h)$. It is easy to see that $\Delta_h \omega_m = (\Delta_h \omega_m) T_h + \omega_m \Delta_h$. Therefore, we have

$$(6) = \langle \tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{-h} q^2 \Delta_h)\tilde{\Phi}_m\rangle + \langle \tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{-h} q^2 \omega_m^{-1}(\Delta_h \omega_m) T_h)\tilde{\Phi}_m\rangle.$$

On the other hand,

$$\sum_{i=1}^{\infty} \langle a(\Delta_{-h}\omega_m^{-1/2} q f_i)\tilde{\Phi}_m, \langle \Delta_{-h}\omega_m^{-1/2} q f_i, G(\hat{x})\rangle \tilde{\Phi}_m\rangle = \langle a(\Delta_{-h}\omega_m^{-1} q^2 \Delta_h G(\hat{x}))\tilde{\Phi}_m, \tilde{\Phi}_m\rangle.$$

Therefore, we obtain

$$\langle \tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{-h} q^2 \Delta_h)\tilde{\Phi}_m\rangle \leqslant -\langle \tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{-h} q^2 \omega_m^{-1}(\Delta_h \omega_m) T_{-h})\tilde{\Phi}_m\rangle - \frac{1}{\sqrt{2}}\langle a(\Delta_{-h}\omega_m^{-1} q^2 \Delta_h G(\hat{x}))\tilde{\Phi}_m, \tilde{\Phi}_m\rangle. \tag{7}$$

By the Schwarz inequality, we have

$$|\langle a(\Delta_{-h}\omega_m^{-1} q^2 \Delta_h G(\hat{x}))\tilde{\Phi}_m, \tilde{\Phi}_m\rangle| = \langle \Phi, \mathrm{d}\Gamma(\Delta_{-h} q^2 \Delta_h)\Phi\rangle^{1/2} \left[\int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} \|(\Delta_h G(\hat{x}))(k)\tilde{\Phi}_m\|^2\right]^{1/2}.$$

By using the general inequality $|\langle \Phi, \mathrm{d}\Gamma(S^* T)\Psi\rangle| \leqslant \langle \Phi, \mathrm{d}\Gamma(S^* S)\Phi\rangle^{1/2} \langle \Psi, \mathrm{d}\Gamma(T^* T)\Psi\rangle^{1/2}$, we have

$$\begin{aligned} |\langle \tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{-h} q^2 \omega_m^{-1}(\Delta_h \omega_m) T_h)\tilde{\Phi}_m\rangle| &\leqslant \langle \tilde{\Phi}_m, \mathrm{d}\Gamma((\Delta_{-h} q)(\Delta_{-h} q)^*)\tilde{\Phi}_m\rangle^{1/2} \\ &\quad \times \langle \tilde{\Phi}_m, \mathrm{d}\Gamma(T_{-h}(\Delta_h \omega_m) q^2 \omega_m^{-2}(\Delta_h \omega_m) T_h)\tilde{\Phi}_m\rangle^{1/2}. \end{aligned}$$

Hence, we obtain

$$\begin{aligned} \langle \tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{-h} q^2 \Delta_h)\tilde{\Phi}_m\rangle &\leqslant \int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} \|(\Delta_h G(\hat{x}))(k)\tilde{\Phi}_m\|^2 \\ &\quad + 2\langle \tilde{\Phi}_m, \mathrm{d}\Gamma(T_{-h}(\Delta_h \omega_m) q^2 \omega_m^{-2}(\Delta_h \omega_m) T_h)\tilde{\Phi}_m\rangle \\ &= \int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} \|(\Delta_h G(\hat{x}))(k)\tilde{\Phi}_m\|^2 + 2 \\ &\quad \times \int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k-h)^2}{\omega_m(k-h)^2} |(\Delta_h \omega_m)(k-h)|^2 \|a(k)\tilde{\Phi}_m\|^2. \end{aligned}$$

By (5), this is dominated by

$$\int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} \|(\Delta_h G(\hat{x}))(k)\tilde{\Phi}_m\|^2 + \frac{1}{(2\pi)^3} \int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} |(\Delta_h \omega_m)(k)|^2 \frac{|k+h|\hat{\rho}(k+h)^2}{\omega_m(k+h)^2} \||x|\tilde{\Phi}_m\|^2.$$

Since the function q is arbitrary, we have

$$\|\Delta_h a(k)\tilde{\Phi}_m\|^2 \leqslant \frac{\|(\Delta_h G(\hat{x}))(k)\tilde{\Phi}_m\|^2}{\omega_m(k)^2} + \frac{|k+h|\hat{\rho}(k+h)^2|(\Delta_h\omega_m)(k)|^2}{(2\pi)^3\omega_m(k+h)^2\omega_m(k)^2}\||x|\tilde{\Phi}_m\|^2,$$

for a.e. $k \in \mathbb{R}^3$. By using the definition of $G(x,k)$, we have

$$\sqrt{(2\pi)^3}|\Delta_h G(x,k)| \leqslant \frac{|h||k+h||x|}{|k+h|^{1/2}|k|}|\hat{\rho}(k+h)| + \frac{|h||x|}{|k|^{1/2}}|\hat{\rho}(k+h)| + |k|^{1/2}|x||\hat{\rho}(k+h)-\hat{\rho}(k)|,$$

and it is easy to see that $|(\Delta_h\omega_m)(k)| \leqslant |h|$. Therefore we obtain

$$\|\Delta_h a(k)\tilde{\Phi}_m\|^2 \leqslant \frac{1}{(2\pi)^3}\frac{1}{\omega_m(k)^2}\left[3\frac{|h|^2}{|k|^2}|k+h||\hat{\rho}(k+h)|^2 + 3\frac{|h|^2}{|k|}|\hat{\rho}(k+h)|^2 + 3|k||\hat{\rho}(k+h)-\hat{\rho}(k)|^2 + \frac{|k+h||\hat{\rho}(k+h)|^2|h|^2}{\omega_m(k+h)^2}\right]\||x|\tilde{\Phi}_m\|^2. \tag{8}$$

By this inequality with [N.5], we see that $\mathcal{F}$-valued function $a(k)\tilde{\Phi}_m$ is strongly continuous in $k \in S\backslash\{0\}$. Next, we show that $a(k)\tilde{\Phi}_m$ is strongly differentiable. For this purpose, we introduce the operator $\Delta_{h,\ell}$ by

$$(\Delta_{h,\ell}f)(k) = \frac{f(k+h)-f(k)}{|h|} - \frac{f(k+\ell)-f(k)}{|\ell|}, \quad k,\ell \in \mathbb{R}^3.$$

We define $\Delta^*_{h,\ell} := \Delta_{-h,-\ell}$. Returning to (4) with f replaced by $\Delta^*_{h,\ell}\omega_m^{-1/2}qf_i$ and summing over $i = 1,\ldots,\infty$ we have

$$\langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\omega_m^{-1}\Delta_{h,\ell}\omega_m)\tilde{\Phi}_m\rangle + \frac{1}{\sqrt{2}}\langle a(\Delta^*_{h,\ell}\omega_m^{-1}q^2\Delta_{h,\ell}G(\hat{x}))\tilde{\Phi}_m, \tilde{\Phi}_m\rangle \leqslant 0.$$

It is easy to see that $\Delta_{h,\ell}\omega_m = \omega_m\Delta_{h,\ell} + F_h - F_\ell$, where $F_h := (\Delta_h\omega_m)|h|^{-1}T_h$. Hence, we have

$$\langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\Delta_{h,\ell})\tilde{\Phi}_m\rangle \leqslant -\frac{1}{\sqrt{2}}\langle a(\Delta^*_{h,\ell}\omega_m^{-1}q^2\Delta_{h,\ell}G(\hat{x}))\tilde{\Phi}_m, \tilde{\Phi}_m\rangle \tag{9}$$

$$+ \langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\omega_m^{-1}F_h)\tilde{\Phi}_m\rangle + \langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\omega_m^{-1}F_\ell)\tilde{\Phi}_m\rangle. \tag{10}$$

By the Schwarz inequality, we have

$$|\text{r.h.s. of (9)}| \leqslant \langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\Delta_{h,\ell})\tilde{\Phi}_m\rangle^{1/2}\left[\int_{\mathbb{R}^3}\mathrm{d}k\frac{q(k)^2}{\omega_m(k)^2}\|(\Delta_{h,\ell}G(\hat{x}))(k)\tilde{\Phi}_m\|^2\right]^{1/2},$$

$$|(10)| \leqslant |\langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\omega_m^{-1}[\Delta^*_{h,\ell}\omega_m]T_h)\tilde{\Phi}_m\rangle| \tag{11}$$

$$+ \left|\left\langle\tilde{\Phi}_m, \mathrm{d}\Gamma\left(\Delta^*_{h,\ell}q^2\omega_m^{-1}\left[\frac{\Delta_\ell}{|\ell|}\omega_m\right](T_h - T_\ell)\right)\tilde{\Phi}_m\right\rangle\right|. \tag{12}$$

Moreover,

$$\begin{aligned}\text{r.h.s. of (11)} &\leqslant \langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\Delta_{h,\ell})\tilde{\Phi}_m\rangle^{1/2}\langle\tilde{\Phi}_m, \mathrm{d}\Gamma(T_{-h}q^2\omega_m^{-2}[\Delta^*_{h,\ell}\omega_m]^2T_h)\tilde{\Phi}_m\rangle^{1/2} \\ &= \langle\tilde{\Phi}_m, \mathrm{d}\Gamma(\Delta^*_{h,\ell}q^2\Delta_{h,\ell})\tilde{\Phi}_m\rangle^{1/2}\left[\int_{\mathbb{R}^3}\mathrm{d}kq(k)^2\omega_m^{-2}(k)[\Delta^*_{h,\ell}\omega_m]^2(k)\|a(k+h)\tilde{\Phi}_m\|^2\right]^{1/2},\end{aligned}$$

and

$$\text{r.h.s. of (12)} \leqslant \langle\widetilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{h,\ell}^* q^2 \Delta_{h,\ell})\widetilde{\Phi}_m\rangle^{1/2} \left\langle \widetilde{\Phi}_m, \mathrm{d}\Gamma\left((T_{-h} - T_{-\ell}) \left[\frac{\Delta_\ell}{|\ell|}\omega_m \right]^2 q^2 \omega_m^{-2} (T_h - T_\ell) \right) \right\rangle^{1/2}$$
$$\leqslant \langle\widetilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{h,\ell}^* q^2 \Delta_{h,\ell})\widetilde{\Phi}_m\rangle^{1/2} \left[\int_{\mathbb{R}^3} \mathrm{d}k q(k)^2 \omega_m(k)^{-2} \| a(k+h)\widetilde{\Phi}_m - a(k+\ell)\widetilde{\Phi}_m \|^2 \right]^{1/2}.$$

This inequality yields

$$\begin{aligned}\langle\widetilde{\Phi}_m, \mathrm{d}\Gamma(\Delta_{h,\ell}^* q^2 \Delta_{h,\ell})\widetilde{\Phi}_m\rangle \leqslant{}& \frac{3}{2}\int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} \| (\Delta_{h,\ell} G(\hat{x}))(k)\widetilde{\Phi}_m \|^2 \\ &+ 3\int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} |\Delta_{h,\ell}^* \omega_m|^2(k) \| a(k+h)\widetilde{\Phi}_m \|^2 \\ &+ 3\int_{\mathbb{R}^3} \mathrm{d}k \frac{q(k)^2}{\omega_m(k)^2} \| a(k+h)\widetilde{\Phi}_m - a(k+\ell)\widetilde{\Phi}_m \|^2.\end{aligned}$$

Since the function q is arbitrary, we have

$$\begin{aligned}\| \Delta_{h,\ell} a(k)\widetilde{\Phi}_m \|^2 \leqslant \frac{3}{\omega_m(k)^2} \Bigg[& \frac{1}{2} \| (\Delta_{h,\ell} G(\hat{x}))(k)\widetilde{\Phi}_m \|^2 + |\Delta_{h,\ell}^* \omega_m|^2(k) \| a(k+h)\widetilde{\Phi}_m \|^2 \\ & + \| a(k+h)\widetilde{\Phi}_m - a(k+\ell) \|^2 \Bigg], \quad \text{a.e. } k \in \mathbb{R}^3. \end{aligned} \tag{13}$$

Remembering the condition [N.5] and that $a(k)\widetilde{\Phi}_m$ is continuous, we get,

$$\lim_{h,\ell\to\infty} \| \Delta_{|h|e,|\ell|e} a(k)\widetilde{\Phi}_m \|^2 = 0, \quad \text{a.e. } k \in S\setminus\{0\},$$

for all $e \in \mathbb{R}^3$. Therefore the $\mathcal{F}$-valued function $\Delta_{|h|e} a(k)\widetilde{\Phi}_m/|h|$ is a Cauchy sequence in $|h|$ as $|h| \to 0$. Namely, for all directions, $a(k)\widetilde{\Phi}_m$ is strongly differentiable in $k \in S\setminus\{0\}$. Let $e_j (j = 1,2,3)$ be the unit vectors of the jth direction, and let

$$v_j(k) := \text{s-lim}_{|h|\to 0} \frac{1}{|h|} \Delta_{|h|e_j} a(k)\widetilde{\Phi}_m, \quad \text{a.e. } k \in S.$$

Next, we show that $\widetilde{\Phi}_m^{(n)} \in H^1(\mathbb{R}_x^3 \times S^{3n})$ for all $n \in \mathbb{N}$. Let $\psi \in C_0^\infty(\mathbb{R}_x^3) \times S^{3n}$. Then, we have

$$\begin{aligned}&\int_{\mathbb{R}^{3(n+1)}} (\partial_j \psi)(x,k,K)\widetilde{\Phi}_m^{(n)}(x,k,K)\mathrm{d}x\mathrm{d}k\mathrm{d}K \\ &= \lim_{h\to 0} \frac{1}{|h|} \int_{\mathbb{R}^{3(n+1)}} [\psi(x,k,K) - \psi(x,k,-|h|e_j,K)]\widetilde{\Phi}_m^{(n)}(x,k,K)\mathrm{d}x\mathrm{d}k\mathrm{d}K \\ &= -\lim_{h\to 0} \frac{1}{|h|} \int_{\mathbb{R}^3} \mathrm{d}k \left[\int_{\mathbb{R}^{3(n+1)}} \psi(x,k,K)[\widetilde{\Phi}_m^{(n)}(x,k+|h|e_j,K) - \widetilde{\Phi}_m^{(n)}(x,k,K)]\mathrm{d}x\mathrm{d}K \right],\end{aligned}$$

where $K = (k_1, k_2, \ldots, k_{n-1}) \in \mathbb{R}^{3(n-1)}$. On the other hand,

$$\left| \int_{\mathbb{R}^3} \mathrm{d}k \left[\int_{\mathbb{R}^{3n}} \mathrm{d}x\mathrm{d}K \psi(x,k,K) \left\{ \frac{1}{|h|} [\tilde{\Phi}_m^{(n)}(x,k+|h|e_j,K) + \tilde{\Phi}_m^{(n)}(x,k,K)] - v_j^{(n)}(x,k,K) \right\} \right] \right|$$
$$\leqslant \int_{\mathbb{R}^3} \mathrm{d}k \|\psi(k,\cdot)\|_{L^2(\mathbb{R}^{3n})} \left\| \frac{1}{|h|} (\Delta_{|h|e_j} a(k) \tilde{\Phi}_m)^{(n)} - v_j^{(n)}(k) \right\|$$
$$\leqslant \int_{\mathbb{R}^3} \mathrm{d}k \|\psi(k,\cdot)\|_{L^2(\mathbb{R}^{3n})} \left\| \frac{1}{|h|} \Delta_{|h|e_j} a(k) \tilde{\Phi}_m - v_j(k) \right\|. \tag{14}$$

Returning to (13) with $h \to |h|e_j$, $\ell \to |\ell|e_j$ and $\lim_{|\ell|\to 0}$, we have

$$\left\| \frac{1}{|h|} \Delta_h a(k) \tilde{\Phi}_m - v_j(k) \right\|^2 \leqslant \frac{3}{\omega_m(k)^2} \left[\frac{1}{2} \left\| \left(\frac{1}{h} (\Delta_{he_j} G)(\hat{x},k) - \partial_j G(\hat{x},k) \right) \tilde{\Phi}_m \right\|^2 + \frac{2|h|}{\omega_m(k)} \|a(k+h)\tilde{\Phi}_m\|^2 \right.$$
$$\left. + \|a(k+h)\tilde{\Phi}_m - a(k)\tilde{\Phi}_m\|^2 \right], \quad \text{a.e. } k \in \mathbb{R}^3,$$

where we use the elementary inequality $|(1/h)\Delta_{he_j}\omega_m(k) - \partial_j\omega_m(k)| \leqslant 2|h|/\omega_m(k)$. Since the set $S_\psi := \mathrm{supp}\|\psi(k,\cdot)\|$ is a subset of S, $k+h \in S$ for all h and $k \in S_\psi$ with $|h| < \mathrm{dist}\{S_\psi, S\}$. Using this fact and (8), we obtain

$$\lim_{|h|\to 0} \int_{\mathbb{R}^3} \mathrm{d}k \|\psi(k,\cdot)\|_{L^2(\mathbb{R}^{3n})} \left[|h| \frac{\|a(k+h)\tilde{\Phi}_m\|}{\omega_m(k)^2} + \frac{\|a(k+h)\tilde{\Phi}_m - a(k)\tilde{\Phi}_m\|}{\omega_m(k)} \right] = 0.$$

By condition [N.4] and the dominated convergence theorem, we have

$$\|\chi_{S_\psi}|h|^{-1}\Delta_h\hat{\rho} - \partial_j\hat{\rho}\|^2 \leqslant \||h|^{-1}\Delta_h\eta - \partial_j\eta\|^2_{L^2(\mathbb{R}^3)} \leqslant \int_{\mathbb{R}^3_y} \left| \frac{e^{-i|h|y_j} - 1}{|h|y_j} + i \right|^2 y_j^2 |(\mathsf{F}\eta)(y)|^2 \mathrm{d}y \to 0, (|h| \to 0),$$

where F means Fourier transformation. By this formula and simple but tedious estimates, we can show that

$$\lim_{|h|\to 0} \int_{\mathbb{R}^3} \mathrm{d}k \|\psi(k,\cdot)\|_{L^2(\mathbb{R}^{3n})} \cdot \frac{1}{\omega_m} \left\| \left(\frac{1}{h} (\Delta_{he_j} G)(\hat{x},k) - \partial_j G(\hat{x},k) \right) \tilde{\Phi}_m \right\| = 0.$$

These facts mean that

$$\lim_{h\to 0} (14) = 0.$$

Therefore, $\tilde{\Phi}_m^{(n)} \in H^1(\mathbb{R}^3_x \times S^{3n})$. ■

Pick a sequence $m_1 > m_2 > \cdots$ tending to zero and we set

$$\tilde{\Phi}_j := \tilde{\Phi}_{m_j}, \quad j = 1,2, \ldots .$$

Since $\tilde{\Phi}_j$'s are normalized, a subsequence of $\{\tilde{\Phi}_j\}_j$ has a weak limit $\tilde{\Phi}$ (the subsequence denoted by the same symbol).

Lemma 3.4: $\tilde{\Phi} \in \mathrm{Dom}(\tilde{H}^V)$ *and*,

$$\tilde{H}^V\tilde{\Phi} = E^V(0)\tilde{\Phi}. \tag{15}$$

Proof: First, we show that $\tilde{\Phi} \in Q(\tilde{H}^V) = \mathrm{Dom}(H_f(0)^{1/2}) \cap Q(H_\mathrm{p})$. For all $\Psi \in \mathrm{Dom}(H_f(0)^{1/2})$, we have

$$|\langle\tilde{\Phi},H_f(0)^{1/2}\Psi\rangle| = \lim_{j\to\infty}|\langle H_f(0)^{1/2}\tilde{\Phi}_j,\Psi\rangle| = \limsup_{j\to\infty}\|H_f(0)^{1/2}\tilde{\Phi}_j\|\,\|\Psi\|.$$

Since H_{p} is bounded below, we have

$$\|H_f(0)^{1/2}\tilde{\Phi}_j\|^2 \leqslant \text{const.}\langle\tilde{\Phi}_j,(\tilde{H}^V(m_j)-E^V(m_j)+1)\tilde{\Phi}_j\rangle \leqslant \text{const.},$$

where const. is a constant independent of j. Hence $\tilde{\Phi}\in\mathrm{Dom}(H_f(0)^{1/2})$. Similarly we have $\tilde{\Phi}\in Q(H_{\mathrm{p}})$. Since $E^V(m_j)\to E^V(0)(j\to\infty)$, we have

$$\|(\tilde{H}^V-E^V(0))^{1/2}\tilde{\Phi}_j\|^2 \leqslant \|(\tilde{H}^V(m_j)-E^V(0))^{1/2}\tilde{\Phi}_j\|^2 \leqslant (E^V(m_j)-E^V(0))\|\tilde{\Phi}_j\|^2 \to 0,$$

as $j\to\infty$. Therefore $(\tilde{H}^V-E^V(0))^{1/2}\tilde{\Phi}=0$. This means $\tilde{\Phi}\in\mathrm{Dom}(\tilde{H}^V)$ and $\tilde{H}^V\tilde{\Phi}=E^V(0)\tilde{\Phi}$. ■

By this lemma, if $\tilde{\Phi}\neq 0$ then $\tilde{\Phi}$ is a ground state of $\tilde{H}^V$. This proof is essentially same as (Ref. 4 and 7 Proof of Theorem 2.1), so we omit it (notice that the condition [N.3] and [N.6] were used there).

APPENDIX: PARSEVAL's EQUALITY FOR THE ANNIHILATION OPERATORS

Let $\mathcal{K}$ be a complex separable Hilbert space, and let $\mathcal{F}_{\mathrm{b}}(\mathcal{K})$ be the Boson Fock space over $\mathcal{K}$. We denote by N_{b} the number operator on $\mathcal{F}_{\mathrm{b}}(\mathcal{K})$. Let S and T be densely defined closed linear operators on $\mathcal{K}$, such that $\mathrm{Dom}(S)\cap\mathrm{Dom}(T)$ is dense.

Lemma A.1 (Parseval's equality for the annihilation operators): Assume that, for vectors $\Psi,\Phi\in\mathrm{Dom}(N_{\mathrm{b}}^{1/2})$, *there exist constants* $\alpha,\beta(\alpha+\beta=1,\alpha,\beta\geqslant 0)$ *such that*,

$$N_{\mathrm{b}}^{\alpha-1}\Phi\in\mathrm{Dom}(\mathrm{d}\Gamma(T^*)),\quad N_{\mathrm{b}}^{\beta-1}\Psi\in\mathrm{Dom}(\mathrm{d}\Gamma(S^*)).$$

Then, for all complete orthonormal basis $\{f_j\}_{j=1}^{\infty}\subset\mathrm{Dom}(S)\cap\mathrm{Dom}(T)$, *the following equality holds:*

$$\sum_{j=1}^{\infty}\langle a(Sf_j)\Psi,a(Tf_j)\Phi\rangle = \sum_{n=1}^{\infty} n\langle S^*\otimes\mathbb{1}_{n-1}\Psi^{(n)},T^*\otimes\mathbb{1}_{n-1}\Phi^{(n)}\rangle_{\otimes^n\mathcal{K}}. \tag{A1}$$

In particular, if $\Phi\in\mathrm{Dom}(\mathrm{d}\Gamma(ST^*))$, *then*

$$\sum_{j=1}^{\infty}\langle a(Sf_j)\Psi,a(Tf_j)\Phi\rangle = \langle\Psi,\mathrm{d}\Gamma(ST^*)\Phi\rangle. \tag{A2}$$

Proof: It is enough to show in the case that $\mathcal{K}$ is L^2-space on a measurable space. For simplicity, we prove (A1) only in the case $\mathcal{K}=L^2(\mathbb{R}^3)$. Using the definition of $a(f)$, we have

$$\begin{aligned}\langle a(Sf_j)\Psi,a(Tf_j)\Phi\rangle &= \int \mathrm{d}k\int \mathrm{d}k'(Sf_j)(k)(Tf_j)^*(k')\langle a(k)\Psi,a(k')\Phi\rangle\\ &= \int \mathrm{d}k\int \mathrm{d}k'\sum_{n=1}^{\infty} n\int \mathrm{d}K(Sf_j)(k)(Tf_j)^*(k')\Psi^{(n)}(k,K)^*\Phi^{(n)}(k',K),\end{aligned}$$

where $K=(k_2,\ldots,k_n)$, $\mathrm{d}K=\mathrm{d}k_2\cdots\mathrm{d}k_n$. In the above equation, the integral and the summation commute, because

$$\int \mathrm{d}k \int \mathrm{d}k' \sum_{n=1}^{\infty} n \int \mathrm{d}K |(Sf_j)(k)(Tf_j)^*(k')\Psi^{(n)}(k,K)^*\Phi^{(n)}(k',K)|$$

$$\leqslant \int \mathrm{d}k\mathrm{d}k' |(Sf_j)(k)(Tf_j)(k')| \left[\sum_{n=1}^{\infty} n \int \mathrm{d}K |\Psi^{(n)}(k,K)|^2\right]^{1/2} \left[\sum_{n=1}^{\infty} n \int \mathrm{d}K |\Phi^{(n)}(k',K)|^2\right]^{1/2}$$

$$= \int \mathrm{d}k\mathrm{d}k' |(Sf_j)(k)| \cdot |(Tf_j)(k')| \cdot \|a(k)\Psi\| \, \|a(k')\Phi\|$$

$$\leqslant \|Sf_j\| \, \|Tf_j\| \left[\int \mathrm{d}k \|a(k)\Psi\|^2\right]^{1/2} \left[\int \mathrm{d}k \|a(k')\Phi\|^2\right]^{1/2}$$

$$= \|Sf_j\| \, \|Tf_j\| \, \|N_{\mathrm{b}}^{1/2}\psi\| \, \|N_{\mathrm{b}}^{1/2}\Phi\| < \infty,$$

and hence one can apply Fubini's theorem. Hence,

$$\sum_{j=1}^{\infty} \langle a(Sf_j)\Psi, a(Tf_j)\Phi\rangle = \sum_{j=1}^{\infty} \sum_{n=0}^{\infty} n \int \mathrm{d}K \langle (T^* \otimes \mathbb{1}\Phi^{(n)})(\cdot,K), f_j(\cdot)\rangle \langle f_j(\cdot), (S^* \otimes \mathbb{1}\Psi^{(n)})(\cdot,K)\rangle.$$

Using Bessel's inequality, we have

$$\left| \sum_{j=1}^{N} \langle (T^* \otimes \mathbb{1}\Phi^{(n)})(\cdot,K), f_j(\cdot)\rangle \langle f_j(\cdot), (S^* \otimes \mathbb{1}\Psi^{(n)})(\cdot,K)\rangle \right| \leqslant \|(T^* \otimes \mathbb{1}\Phi^{(n)})(\cdot,K)\| \, \|(S^* \otimes \mathbb{1}\Psi^{(n)})(\cdot,K)\|$$

$$\leqslant \frac{1}{2n}\{n^{2\alpha}\|(T^* \otimes \mathbb{1}\Phi^{(n)})(\cdot,K)\|^2 + n^{2\beta}\|(S^* \otimes \mathbb{1}\Psi^{(n)})(\cdot,K)\|^2\}, \quad \text{a.e. } K \in \mathbb{R}^{3(n-1)}. \tag{A3}$$

By assumption for Ψ, Φ, we have

$$\sum_{n=1}^{\infty} n \int \mathrm{d}K (\text{r.h.s. of (A3)}) = \frac{1}{2}\sum_{n=1}^{\infty} \|n^{\alpha}T^* \otimes \mathbb{1}\Phi^{(n)}\|^2 + \frac{1}{2}\sum_{n=1}^{\infty} \|n^{\beta}S^* \otimes \mathbb{1}\Psi^{(n)}\|^2 < \infty.$$

Hence, by applying the dominated convergence theorem and the standard parseval equality, we obtain (A1). ■

Application of pseudo-Hermitian quantum mechanics to a $\mathcal{PT}$-symmetric Hamiltonian with a continuum of scattering states

Ali Mostafazadeh[a)]

(Received 20 May 2005; accepted 23 August 2005; published online 21 October 2005)

We extend the application of the techniques developed within the framework of the pseudo-Hermitian quantum mechanics to study a unitary quantum system described by an imaginary $\mathcal{PT}$-symmetric potential $v(x)$ having a continuous real spectrum. For this potential that has recently been used, in the context of optical potentials, for modeling the propagation of electromagnetic waves traveling in a waveguide half and half filled with gain and absorbing media, we give a perturbative construction of the physical Hilbert space, observables, localized states, and the equivalent Hermitian Hamiltonian. Ignoring terms of order three or higher in the non-Hermiticity parameter ζ, we show that the equivalent Hermitian Hamiltonian has the form $p^2/2m+(\zeta^2/2)\Sigma_{n=0}^{\infty}\{\alpha_n(x),p^{2n}\}$ with $\alpha_n(x)$ vanishing outside an interval that is three times larger than the support of $v(x)$, i.e., in 2/3 of the physical interaction region the potential $v(x)$ vanishes identically. We provide a physical interpretation for this unusual behavior and comment on the classical limit of the system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2063168]

I. INTRODUCTION

During the past seven years there have appeared over 200 research papers on $\mathcal{PT}$-symmetric quantum systems. This was initially triggered by the surprising observation of Bessis and Zinn-Justin and its subsequent numerical verification by Bender and his co-workers[1] that certain non-Hermitian but $\mathcal{PT}$-symmetric Hamiltonians, such as

$$H=p^2+x^2+i\epsilon x^3 \text{ with } \epsilon\in\mathbb{R}^+, \tag{1}$$

have a purely real spectrum. This observation suggested the possibility to use these Hamiltonians in the description of certain quantum systems. Since the $\mathcal{PT}$-symmetry of a non-Hermitian Hamiltonian H, i.e., the condition $[H,\mathcal{PT}]=0$, did not ensure the reality of its spectrum, a crucial task was to seek the necessary and sufficient conditions for the reality of the spectrum of a given non-Hermitian Hamiltonian H. This was achieved in Ref. 2 where it was shown, under the assumptions of the diagonalizability of H and discreteness of its spectrum, that the reality of the spectrum was equivalent to the existence of a positive-definite inner product $\langle\cdot,\cdot\rangle_+$ that rendered the Hamiltonian self-adjoint, i.e., for any pair (ψ,ϕ) of state vectors $\langle\psi,H\phi\rangle_+=\langle H\psi,\phi\rangle_+$.

Another condition that is equivalent to the reality of the spectrum of H is that it can be mapped to a Hermitian Hamiltonian h via a similarity transformation;[2,3] there is an invertible Hermitian operator ρ such that

$$H=\rho^{-1}h\rho. \tag{2}$$

The positive-definite inner product $\langle\cdot,\cdot\rangle_+$ and the operator ρ entering (2) are determined by a positive-definite operator η_+ according to[2,3]

[a)]Electronic mail: amostafazadeh@ku.edu.tr

$$\langle \cdot, \cdot \rangle_+ := \langle \cdot | \eta_+ \cdot \rangle, \tag{3}$$

$$\rho = \sqrt{\eta_+}, \tag{4}$$

and the Hamiltonian satisfies the η_+-pseudo-Hermiticity condition:[4]

$$H^\dagger = \eta_+ H \eta_+^{-1}. \tag{5}$$

Here $\langle \cdot | \cdot \rangle$ stands for the standard (L^2) inner product that determines the (reference) Hilbert space $\mathcal{H}$ as well as the adjoint $H^\dagger$ of H.[5] (The adjoint $A^\dagger$ of an operator A is the unique operator satisfying, for all $\psi, \phi \in \mathcal{H}$, $\langle \psi | A^\dagger \phi \rangle = \langle A\psi | \phi \rangle$. A is called Hermitian if $A^\dagger = A$.)

It is this, so-called metric operator, η_+ that determines the kinematic structure (the physical Hilbert space and the observables) of the desired quantum system. Note however that η_+ is not unique[6–8] (it is only unique up to symmetries of the Hamiltonian[7]). In Ref. 2 we have not only established the existence of a positive definite metric operator η_+ and the corresponding positive-definite inner product $\langle \cdot, \cdot \rangle_+$ for a diagonalizable Hamiltonian with a discrete real spectrum, but we have also explained the role of antilinear symmetries such as $\mathcal{PT}$ and offered a method for computing the most general η_+. [For a treatment of nondiagonalizable pseudo-Hermitian Hamiltonians see Refs. 9–11. Note that diagonalizability of the Hamiltonian is a necessary condition for applicability of the standard quantum measurement theory.[5] It is also necessary for the unitarity of the time-evolution, for a nondiagonalizable Hamiltonian is never Hermitian (its evolution operator is never unitary[11]) with respect to a positive-definite inner product.[9,10]] An alternative approach that yields a positive-definite inner product for a class of $\mathcal{PT}$-symmetric models is that of Ref. 12. As shown in Refs. 7 and 13, the $\mathcal{CPT}$-inner product proposed in Ref. 12 is identical to the inner product $\langle \cdot, \cdot \rangle_+ = \langle \cdot | \eta_+ \cdot \rangle$ for a particular choice of η_+.

Under the above-mentioned conditions every Hamiltonian having a real spectrum determines a set $\mathcal{U}_{H+}$ of positive-definite metric operators. To formulate a consistent unitary quantum theory having H as its Hamiltonian, one needs to choose an element η_+ of $\mathcal{U}_{H+}$. (Alternatively one may choose sufficiently many operators with real spectrum to construct a so-called irreducible set of observables which subsequently fixes a metric operator η_+.[14]) Each choice fixes a positive-definite inner product $\langle \cdot, \cdot \rangle_+$ and defines the physical Hilbert space $\mathcal{H}_{\text{phys}}$ and the observables. The latter are by definition[15] the operators O that are self-adjoint with respect to $\langle \cdot, \cdot \rangle_+$, alternatively they are η_+-pseudo-Hermitian. These can be constructed from Hermitian operators o acting in $\mathcal{H}$ according to[5]

$$O = \rho^{-1} o \rho. \tag{6}$$

In particular, one can define η_+-pseudo-Hermitian position X and momentum P operators,[5,15] express H as a function of X and P, and determine the underlying classical Hamiltonian for the system by letting $\hbar \to 0$ in the latter expression.[5,16] Alternatively, one may calculate the equivalent Hermitian Hamiltonian h and obtain its classical limit (again by letting $\hbar \to 0$).

Another application of the η_+-pseudo-Hermitian position operator X is in the construction of the physical localized states:

$$|\xi^{(x)}\rangle := \rho^{-1} |x\rangle. \tag{7}$$

These in turn define the physical position wave function, $\Psi(x) := \langle \xi^{(x)}, \psi \rangle_+ = \langle x | \rho | \psi \rangle$, and the invariant probability density,

$$\varrho(x) := \frac{|\Psi(x)|^2}{\int_{-\infty}^{\infty} |\Psi(x)|^2 \mathrm{d}x} = \frac{|\langle x|\rho|\psi\rangle|^2}{\langle \psi, \psi \rangle_+}, \tag{8}$$

for a given state vector $|\psi\rangle$.[5,16]

The above-mentioned prescription for treating $\mathcal{PT}$-symmetric and more generally pseudo-Hermitian Hamiltonians with a real spectrum has been successfully applied in the study of the $\mathcal{PT}$-symmetric square well in Ref. 5 and the cubic anharmonic oscillator (1) in Ref. 16—See also Ref. 17. Both these systems have a discrete nondegenerate energy spectrum, and the results of Refs. 4 and 2 are known to apply to them. The aim of the present paper is to seek whether these results (in particular the construction method for η_+) may be used for treating a system with a continuous spectrum. (The question whether the theory of pseudo-Hermitian operators as outlined in Refs. 4 and 2 is capable of treating a system having scattering states was posed to the author by Zafar Ahmed during the second International Workshop on Pseudo-Hermitian Hamiltonians in Quantum Physics, held in Prague, 14–16 June, 2004.) This question is motivated by the desire to understand field-theoretical analogues of $\mathcal{PT}$-symmetric systems which should admit an S-matrix formulation. Furthermore, there are some basic questions related to the nonlocal nature of the Hermitian Hamiltonian h and the pseudo-Hermitian observables such as X and P especially for $\mathcal{PT}$-symmetric potentials with a compact support (i.e., potentials vanishing outside a compact region).

To achieve this aim we will focus our attention on a simple toy model recently considered as an effective model arising in the treatment of the electromagnetic waves traveling in a planar slab waveguide that is half and half filled with gain and absorbing media.[18] This model has a standard Hamiltonian,

$$H=\frac{p^2}{2m}+v(x), \tag{9}$$

and a $\mathcal{PT}$-symmetric imaginary potential,

$$v(x):=i\zeta\left[\theta\left(x+\frac{L}{2}\right)+\theta\left(x-\frac{L}{2}\right)-2\theta(x)\right]=\begin{cases}0 & \text{for } |x|\geqslant\frac{L}{2} \text{ or } x=0\\ i\zeta & \text{for } x\in\left(-\frac{L}{2},0\right)\\ -i\zeta & \text{for } x\in\left(0,\frac{L}{2}\right),\end{cases} \tag{10}$$

where $L\in(0,\infty)$ is a length scale, $\zeta\in[0,\infty)$ determines the degree of non-Hermiticity of the system, and θ is the step function:

$$\theta(x):=\begin{cases}0 & \text{for } x<0\\ \frac{1}{2} & \text{for } x=0\\ 1 & \text{for } x>0.\end{cases} \tag{11}$$

The Hamiltonian (9) differs from a free particle Hamiltonian only within $(-L/2,L/2)$ where it coincides with the Hamiltonian for the $\mathcal{PT}$-symmetric square well.[5,19]

It is important to note that unlike in Ref. 18 we will consider the potential (10) as defining a fundamental (noneffective) quantum system having a unitary time-evolution (and S-matrix). Therefore our approach will be completely different from that pursued in Ref. 18 and the earlier studies of effective (optical) non-Hermitian Hamiltonians.[20]

Among the main reasons for our consideration of the potential (10) is that its eigenvalue problem can be solved exactly and analytically. However, the computation of the metric operator and consequently that of physical observables, localized states, associated Hermitian Hamiltonian, etc., are extremely involved, and we could only carry them out using first-order perturbation theory.

To the best of the author's knowledge, the only other non-Hermitian Hamiltonian with a continuous (and doubly degenerate) spectrum that is shown to admit a similar treatment is the one

arising in the two-component formulation of the free Klein-Gordon equation.[21,22] Compared to (9), this Hamiltonian defines a technically much simpler system to handle, because it is essentially a tensor product of an ordinary Hermitian Hamiltonian and a 2×2 matrix pseudo-Hermitian Hamiltonian.

II. METRIC OPERATOR

The essential ingredient of our approach is the metric operator η_+. For a diagonalizable Hamiltonian with a discrete spectrum it can be expressed as

$$\eta_+ = \sum_n \sum_{a=1}^{d_a} |\phi_n,a\rangle\langle\phi_n,a|, \tag{12}$$

where n, a, and d_n are a spectral label, a degeneracy label, and the multiplicity (degree of degeneracy) for the eigenvalue E_n of H, respectively, and $\{|\phi_n,a\rangle\}$ is a complete set of eigenvectors of $H^\dagger$ that together with the eigenvectors $|\psi_n,a\rangle$ of H form a biorthonormal system.[4,2]

Now, consider a diagonalizable Hamiltonian with a purely continuous doubly degenerate real spectrum $\{E_k\}$, where $k\in(0,\infty)$. We will extend the application of (12) to this Hamiltonian by changing $\Sigma_n\cdots$ to $\int dk\cdots$. This yields

$$\eta_+ = \int_0^\infty dk(|\phi_k,+\rangle\langle\phi_k,+| + |\phi_k,-\rangle\langle\phi_k,-|), \tag{13}$$

where we have used $\pm$ as the values of the degeneracy label a.[22] The biorthonormal system $\{|\psi_k,a\rangle,|\phi_k,a\rangle\}$ satisfies

$$H|\psi_k,a\rangle = E_k|\psi_k,a\rangle, \quad H^\dagger|\phi_k,a\rangle = E_k|\phi_k,a\rangle, \tag{14}$$

$$\langle\phi_k,a|\psi_\ell,b\rangle = \delta_{ab}\delta(k-\ell), \quad \int_0^\infty (|\psi_k,+\rangle\langle\phi_k,+| + |\psi_k,-\rangle\langle\phi_k,-|)\mathrm{d}k = 1, \tag{15}$$

where δ_{ab} and $\delta(k)$ stand for the Kronecker and Dirac delta functions, respectively, $k\in(0,\infty)$, and $a,b\in\{-,+\}$,

We define the eigenvalue problem for the Hamiltonian (9) using the oscillating (plane wave) boundary conditions at $x=\pm\infty$ similar to the free particle case which corresponds to $\zeta=0$. To simplify the calculation of the eigenvectors we first introduce the following dimensionless quantities:

$$\mathrm{x} := \left(\frac{2}{L}\right)x, \quad \mathrm{p} := \left(\frac{L}{2\hbar}\right)p, \quad Z := \left(\frac{mL^2}{2\hbar^2}\right)\zeta, \quad \mathrm{H} := \left(\frac{mL^2}{2\hbar^2}\right)H = \mathrm{p}^2 + \mathrm{v}(\mathrm{x}), \tag{16}$$

$$\mathrm{v}(\mathrm{x}) := iZ[\theta(\mathrm{x}+1) + \theta(\mathrm{x}-1) - 2\theta(\mathrm{x})] = \begin{cases} 0 & \text{for } |\mathrm{x}|\geqslant 1 \text{ or } \mathrm{x}=0 \\ iZ & \text{for } \mathrm{x}\in(-1,0) \\ -iZ & \text{for } \mathrm{x}\in(0,1). \end{cases} \tag{17}$$

The eigenvalue problem for the scaled Hamiltonian H corresponds to the solution of the differential equation

$$\left[-\frac{\mathrm{d}^2}{\mathrm{dx}^2} + \mathrm{v}(\mathrm{x}) - \mathrm{E}_k\right]\psi(\mathrm{x}) = 0, \tag{18}$$

that is subject to the condition that ψ is a differentiable function at the discontinuities $\mathrm{x}=-1,0,1$ of v. Introducing $\psi_1:(-\infty,-1]\to\mathbb{C}$, $\psi_-:[-1,0]\to\mathbb{C}$, $\psi_+:[0,1]\to\mathbb{C}$, and $\psi_2:[1,\infty)\to\mathbb{C}$ according to

$$\psi(\mathrm{x}) =: \begin{cases} \psi_1(\mathrm{x}) & \text{for } \mathrm{x} \in (-\infty,-1] \\ \psi_-(\mathrm{x}) & \text{for } \mathrm{x} \in [-1,0] \\ \psi_+(\mathrm{x}) & \text{for } \mathrm{x} \in [0,1] \\ \psi_2(\mathrm{x}) & \text{for } \mathrm{x} \in [1,\infty), \end{cases} \tag{19}$$

we have

$$\psi_1(-1) = \psi_-(-1), \quad \psi_1'(-1) = \psi_-'(-1), \tag{20}$$

$$\psi_-(0) = \psi_+(0), \quad \psi_-'(0) = \psi_+'(0), \tag{21}$$

$$\psi_+(1) = \psi_2(1), \quad \psi_+'(1) = \psi_2'(1). \tag{22}$$

Now, imposing the plane-wave boundary condition at $\mathrm{x}=\pm\infty$ and demanding that the eigenfunctions ψ be $\mathcal{PT}$-invariant, which implies

$$\psi_-(0) = \psi_+(0)^*, \quad \psi_-'(0) = -\psi_+'(0)^*, \tag{23}$$

we find $E_k=k^2$, i.e., the spectrum is real positive and continuous, and

$$\psi_1(\mathrm{x}) = A_1 e^{ik\mathrm{x}} + B_1 e^{-ik\mathrm{x}}, \quad \psi_2(\mathrm{x}) = A_2 e^{ik\mathrm{x}} + B_2 e^{-ik\mathrm{x}}, \quad \psi_\pm(\mathrm{x}) = A_\pm e^{ik_\pm \mathrm{x}} + B_\pm e^{-ik_\pm \mathrm{x}}, \tag{24}$$

where

$$k_\pm := \sqrt{k^2 \pm iZ}, \tag{25}$$

$$A_1 = A_2^* = \frac{e^{ik}}{\sqrt{2\pi}}[L_-(k)u + K_-(k)v], \quad B_1 = B_2^* = \frac{e^{-ik}}{\sqrt{2\pi}}[L_-(-k)u + K_-(-k)v], \tag{26}$$

$$L_-(k) := \frac{1}{2}\left(\cos k_- - \frac{ik_- \sin k_-}{k}\right), \quad K_-(k) := \frac{1}{2}\sqrt{\frac{k_+}{k_-}}\left(\frac{k_- \cos k_-}{k} - i \sin k_-\right), \tag{27}$$

$$A_\pm = \frac{1}{\sqrt{8\pi}}\left[u + \left(\frac{k_+}{k_-}\right)^{\mp 1/2} v\right], \quad B_\pm = \frac{1}{\sqrt{8\pi}}\left[u - \left(\frac{k_+}{k_-}\right)^{\mp 1/2} v\right], \tag{28}$$

and $u,v \in \mathbb{R}$ are arbitrary constants (possibly depending on k and/or Z and not both vanishing).

The presence of the free parameters u and v is an indication of a double degeneracy of the eigenvalues $E_k=k^2$. We will select u and v in such a way as to ensure that in the limit $Z\to 0$ we recover the plane-wave solutions of the free particle Hamiltonian, i.e., we demand $\lim_{Z\to 0} \psi(x) = e^{\pm ikx}/\sqrt{2\pi}$. This condition is satisfied if we set

$$u = 1, \quad v = \pm 1. \tag{29}$$

In the following we use the superscript $\pm$ to identify the value of a quantity obtained by setting $u=1$ and $v=\pm 1$. In this way we introduce $A_1^\pm$, $B_1^\pm$, $A_2^\pm$, $B_2^\pm$, $A_\pm^\pm$, $B_\pm^\pm$, and $\psi^\pm$. The latter define the basis (generalized[23]) eigenvectors $|\psi_k,\pm\rangle$ by $\langle \mathrm{x}|\psi_k,\pm\rangle := \psi^\pm(\mathrm{x})$.

The next step is to obtain $|\phi_k,\pm\rangle$. In view of the identity $\mathrm{H}^\dagger = \mathrm{H}|_{Z\to -Z}$, we can easily obtain the expression for the eigenfunctions ϕ of $H^\dagger$. Introducing

$$\phi(\mathrm{x}) =: \begin{cases} \phi_1(\mathrm{x}) & \text{for } \mathrm{x} \in (-\infty,-1] \\ \phi_-(\mathrm{x}) & \text{for } \mathrm{x} \in [-1,0] \\ \phi_+(\mathrm{x}) & \text{for } \mathrm{x} \in [0,1] \\ \phi_2(\mathrm{x}) & \text{for } \mathrm{x} \in [1,\infty), \end{cases} \tag{30}$$

we have

$$\phi_1(\mathrm{x}) = C_1 e^{ik\mathrm{x}} + D_1 e^{-ik\mathrm{x}}, \quad \phi_2(\mathrm{x}) = C_2 e^{ik\mathrm{x}} + D_2 e^{-ik\mathrm{x}}, \quad \phi_\pm(\mathrm{x}) = C_\pm e^{ik_\mp \mathrm{x}} + D_\pm e^{-ik_\mp \mathrm{x}}, \tag{31}$$

where

$$C_1 = C_2^* = \frac{e^{ik}}{\sqrt{2\pi}}[L_+(k)r + K_+(k)s], \quad D_1 = D_2^* = \frac{e^{-ik}}{\sqrt{2\pi}}[L_+(-k)r + K_+(-k)s], \tag{32}$$

$$L_+(k) := L_-(-k)^*, \quad K_+(k) := -K_-(-k)^*, \tag{33}$$

$$C_\pm = \frac{1}{\sqrt{8\pi}}\left[r + \left(\frac{k_+}{k_-}\right)^{\pm 1/2} s\right], \quad D_\pm = \frac{1}{\sqrt{8\pi}}\left[r - \left(\frac{k_+}{k_-}\right)^{\pm 1/2} s\right], \tag{34}$$

and $r,s \in \mathbb{R}$ are (possibly k- and/or Z-dependent) parameters that are to be fixed by imposing the biorthonormality condition (15). The latter is equivalent to a set of four (complex) equations [corresponding to the four possible choices for the pair of indices (a,b) in the first equation in (15)] which are to be solved for the two real unknowns r and s. This together with the presence of the delta function in two of these equations make the existence of a solution quite nontrivial.

We checked these equations by expanding all the quantities in powers of the non-Hermiticity parameter Z up to (but not including) terms of order two and found after a long and tedious calculation (partly done using MATHEMATICA) that indeed all four of these equations are satisfied, if we set $r=u=1$ and $s=v=\pm 1$. Again we will refer to this choice using superscript $\pm$. In particular, we have $\phi^\pm = \psi^\pm|_{Z\to -Z}$ and $\langle \mathrm{x}\,|\,\phi_k,\pm\rangle := \phi^\pm(\mathrm{x})$.

Having obtained $|\phi_k,\pm\rangle$ we are in a position to calculate the metric operator (13). We carried out this calculation using first-order perturbation theory in Z. It involved expanding the $\phi_1^\pm(\mathrm{x})$, $\psi_2^\pm(\mathrm{x})$, and $\psi_\pm^\pm(\mathrm{x})$ in powers of Z, substituting the result in

$$\langle \mathrm{x}|\,\eta_+\,|\mathrm{y}\rangle = \int_0^\infty [\phi^+(\mathrm{y})^*\phi^+(\mathrm{x}) + \phi^-(\mathrm{y})^*\phi^-(\mathrm{x})]dk \tag{35}$$

which follows from (13), and using the identities:

$$\int_{-\infty}^{\infty} e^{iak}dk = 2\pi\delta(a), \quad \int_{-\infty}^{\infty} \frac{e^{iak}}{k}dk = i\pi\,\mathrm{sign}(a), \quad \int_{-\infty}^{\infty} \frac{e^{iak}-e^{ibk}}{k^2}dk = \pi(|b|-|a|) \tag{36}$$

[where $a,b \in \mathbb{R}$ and $\mathrm{sign}(a) := \theta(a) - \theta(-a)$] to perform the integral over k for all 16 possibilities for the range of values of the pair of independent variables (x,y) in (35). This is an extremely lengthy calculation whose detail we will not include here. It is absolutely remarkable that the expressions for $\langle \mathrm{x}|\,\eta_+\,|\mathrm{y}\rangle$ that we obtain for these 16 possibilities may be combined to yield a single formula that is valid for all $\mathrm{x},\mathrm{y} \in \mathbb{R}$, namely

$$\langle \mathrm{x}|\,\eta_+\,|\mathrm{y}\rangle = \delta(\mathrm{x}-\mathrm{y}) + \frac{i}{8}(4 + 2|\mathrm{x}+\mathrm{y}| - |\mathrm{x}+\mathrm{y}+2| - |\mathrm{x}+\mathrm{y}-2|)\mathrm{sign}(\mathrm{x}-\mathrm{y})Z + \mathcal{O}(Z^2), \tag{37}$$

where $\mathcal{O}(Z^2)$ stands for terms of order two and higher in powers of Z. Note that $\langle \mathrm{x}|\,\eta_+\,|\mathrm{y}\rangle^* = \langle \mathrm{y}|\,\eta_+\,|\mathrm{x}\rangle$, which is consistent with the Hermiticity of η_+.

III. PHYSICAL OBSERVABLES AND LOCALIZED STATES

The physical observables of the system described by the Hamiltonian (9) are obtained from the Hermitian operators acting in $\mathcal{H}=L^2(\mathbb{R})$ by the similarity transformation (6). This equation involves the positive square root ρ of η_+ which takes the form[16]

$$\rho^{\pm 1} = e^{\mp Q/2}, \tag{38}$$

if we express η in the exponential form

$$\eta_+ = e^{-Q}. \tag{39}$$

In view of (38) and the Backer-Campbell-Hausdorff identity,

$$e^{-A}Be^{A} = B + [B,A] + \frac{1}{2!}[[B,A],A] + \ldots \tag{40}$$

(where A and B are linear operators), physical observables (6) satisfy[16]

$$O = o - \tfrac{1}{2}[o,Q] + \tfrac{1}{8}[[o,Q],Q] + \ldots . \tag{41}$$

If we expand η_+ and Q in powers of Z,

$$\eta_+ = 1 + \sum_{\ell=1}^{\infty} \eta_{+_\ell} Z^\ell, \quad Q = \sum_{\ell=1}^{\infty} Q_\ell Z^\ell, \tag{42}$$

where η_{+_ℓ} and Q_ℓ are Z-independent Hermitian operators, we find using (39) that

$$Q_1 = -\eta_{+_1}, \quad Q_2 = -\eta_{+_2} + \tfrac{1}{2}\eta_{+_1}^2. \tag{43}$$

Combining this relation with (41), we have

$$O = o - \tfrac{1}{2}[o,Q_1]Z + \tfrac{1}{8}(-4[o,Q_2] + [[o,Q_1],Q_1])Z^2 + \mathcal{O}(Z^3). \tag{44}$$

In the following we calculate the η_+-pseudo-Hermitian position (X) and momentum (P) operators,[16] up to (but not including) terms of order Z^2. This is because so far we have only calculated η_{+_1} which in view of (37) satisfies

$$\langle \mathrm{x}|\eta_{+_1}|\mathrm{y}\rangle = \tfrac{i}{8}(4 + 2|\mathrm{x}+\mathrm{y}| - |\mathrm{x}+\mathrm{y}+2| - |\mathrm{x}+\mathrm{y}-2|)\mathrm{sign}(\mathrm{x}-\mathrm{y}), \quad \forall\, \mathrm{x},\mathrm{y} \in \mathbb{R}. \tag{45}$$

Substituting the scaled position (x) and momentum (p) operator for o in (44), using (45), and doing the necessary algebra, we find

$$\langle \mathrm{x}|\mathrm{X}|\mathrm{y}\rangle = \mathrm{x}\,\delta(\mathrm{x}-\mathrm{y}) + \frac{i}{16}(4 + 2|\mathrm{x}+\mathrm{y}| - |\mathrm{x}+\mathrm{y}+2| - |\mathrm{x}+\mathrm{y}-2|)|\mathrm{x}-\mathrm{y}|Z + \mathcal{O}(Z^2), \tag{46}$$

$$\langle \mathrm{x}|\mathrm{P}|\mathrm{y}\rangle = -i\partial_{\mathrm{x}}\delta(\mathrm{x}-\mathrm{y}) + \tfrac{1}{8}[2\,\mathrm{sign}(\mathrm{x}+\mathrm{y}) - \mathrm{sign}(\mathrm{x}+\mathrm{y}+2) - \mathrm{sign}(\mathrm{x}+\mathrm{y}-2)]\mathrm{sign}(\mathrm{x}-\mathrm{x})Z + \mathcal{O}(Z^2), \tag{47}$$

where $\mathrm{X} := 2X/L$ and $\mathrm{P} := LP/(2\hbar)$ are dimensionless η_+-pseudo-Hermitian position and momentum operators, respectively.

As seen from (46), both X and P are manifestly nonlocal and non-Hermitian (but pseudo-Hermitian) operators. If we scale back the relevant quantities in (46) and (47) according to (16), we find

$$\langle x|X|y\rangle = x\,\delta(x-y) + \frac{im}{4\hbar^2}(2L + 2|x+y| - |x+y+L| - |x+y-L|)|x-y|\zeta + \mathcal{O}(\zeta^2), \tag{48}$$

$$\langle x|P|y\rangle = -i\hbar\partial_x\delta(x-y) + \frac{m}{4\hbar}[2\,\mathrm{sign}(x+y) - \mathrm{sign}(x+y+L) - \mathrm{sign}(x+y-L)]\mathrm{sign}(x-y)\zeta + \mathcal{O}(\zeta^2). \tag{49}$$

Note that the contributions of order ζ to P vanish, if both x and y take values outside $[-L/2, L/2]$.

Next, we compute the localized states $\xi^{(x)}$ of the system. The corresponding state vectors are defined by (7). Using this equation as well as (38), (42), (43), (45), and (16) we have the following expression for the x-representation of a localized state $\xi^{(y)}$ centered at $y \in \mathbb{R}$:

$$\langle x|\xi^{(y)}\rangle = \delta(x-y) - \frac{im\zeta}{8\hbar^2}(2L + 2|x+y| - |x+y+L| - |x+y-1|)\mathrm{sign}(x-y) + \mathcal{O}(\zeta^2). \tag{50}$$

Because the linear term in ζ is imaginary, the presence of a weak non-Hermiticity only modifies the usual (Hermitian) localized states by making them complex (nonreal) while keeping their real part intact. Note however that for a fixed y the imaginary part of $\langle x|\xi^{(y)}\rangle$ does not tend to zero as $|x-y| \to \infty$. This observation which seems to be in conflict with the usual notion of localizability has a simple explanation. Because the usual x operator is no longer an observable, it does not describe the position of the particle. This is done by the pseudo-Hermitian position operator X; it is the physical position wave function $\Psi(x) := \langle \xi^{(x)}, \psi\rangle_+$ that defines the probability density of localization in space (8). The physical position wave function for the localized state $\xi^{(y)}$ is given by $\langle \xi^{(x)}, \xi^{(y)}\rangle_+ = \langle x|y\rangle = \delta(x-y)$ which is the expected result.

IV. EQUIVALENT HERMITIAN HAMILTONIAN AND CLASSICAL LIMIT

The calculation of the equivalent Hermitian Hamiltonian h for the Hamiltonian (9) is similar to that of the physical observables. In view of (2), (38), (40), and (42), and the last equation in (16) which we express as

$$\mathrm{H} = \mathrm{p}^2 + i\nu(\mathrm{x})Z \text{ with } \nu(\mathrm{x}) := \theta(\mathrm{x}+1) + \theta(\mathrm{x}-1) - 2\theta(\mathrm{x}), \tag{51}$$

we have

$$\mathrm{h} = \mathrm{p}^2 + h_1 Z + h_2 Z^2 + \mathcal{O}(Z^3), \tag{52}$$

$$\mathrm{h}_1 := i\nu(\mathrm{x}) + \tfrac{1}{2}[\mathrm{p}^2, Q_1], \tag{53}$$

$$\mathrm{h}_2 := \tfrac{1}{8}\{4[\mathrm{p}^2, Q_2] + 4i[\nu(\mathrm{x}), Q_1] + [[\mathrm{p}^2, Q_1], Q_1]\}. \tag{54}$$

where

$$\mathrm{h} := \rho\mathrm{H}\rho^{-1} = mL^2 h/(2\hbar^2) \tag{55}$$

is the dimensionless Hermitian Hamiltonian associated with H.

Next, we substitute (43) and (45) in the identity $\langle \mathrm{x}|[\mathrm{p}^2, Q_1]|\mathrm{v}\rangle = (\partial_\mathrm{y}^2 - \partial_\mathrm{x}^2)\langle \mathrm{x}|Q_1|\mathrm{y}\rangle$, and perform the necessary algebra. We then find $\langle \mathrm{x}|[\mathrm{p}^2, Q_1]|\mathrm{v}\rangle = -2i\nu(\mathrm{x})\delta(\mathrm{x}-\mathrm{y})$. Therefore,

$$[\mathrm{p}^2, Q_1] = -2i\nu(\mathrm{x}), \tag{56}$$

and in view of (53)

$$\mathrm{h}_1 = 0. \tag{57}$$

This was actually to be expected, for both the operators appearing on the right-hand side of (53) are anti-Hermitian, while its left-hand side is Hermitian. The fact that an explicit calculation of the right-hand side of (53) yields the desired result, namely (57), is an important check on the validity

of our calculation of η_{+_1}. It may also be viewed as an indication of the consistency and general applicability of our method, that was initially formulated for systems with a discrete spectrum.[5,16]

According to (57),

$$\mathrm{h} = \mathrm{p}^2 + \mathrm{h}_2 Z^2 + \mathcal{O}(Z^3). \tag{58}$$

Hence, in order to obtain a better understanding of the nature of the system described by the Hamiltonian H, we need to calculate h_2. As we will next show, the knowledge of $\langle \mathrm{x}|\eta_{+_1}|\mathrm{y}\rangle$ turns out to be sufficient for the calculation of h_2. To see this we first employ (56) to express h_2 in the form

$$\mathrm{h}_2 = \tfrac{1}{4}(2[\mathrm{p}^2, Q_2] + i[\nu(\mathrm{x}), Q_1]). \tag{59}$$

Now, we recall that p^2, Q_2, $\nu(\mathrm{x})$, and Q_1 are all Hermitian operators. Therefore $[\mathrm{p}^2, Q_2]$ and $i[\nu(\mathrm{x}), Q_1]$ are, respectively, anti-Hermitian and Hermitian. In view of (59) and the Hermiticity of h_2, this implies that

$$[\mathrm{p}^2, Q_2] = 0. \tag{60}$$

Hence,

$$\mathrm{h}_2 = \frac{i}{4}[\nu(\mathrm{x}), Q_1] = \frac{i}{4}[\eta_{+1}, \nu(\mathrm{x})], \tag{61}$$

where we have also made use of the first equation in (43). We should also mention that the identities (56) and (60) can be directly obtained from the pseudo-Hermiticity condition (5) by substituting (39) in (5) and using (40) and (42).

We can easily use (45) and (61) to yield the expression for the integral kernel of h_2, namely

$$\langle \mathrm{x}|\mathrm{h}_2|\mathrm{y}\rangle = \tfrac{1}{32}(4 + 2|\mathrm{x}+\mathrm{y}| - |\mathrm{x}+\mathrm{y}+2| - |\mathrm{x}+\mathrm{y}-2|)\mathrm{sign}(\mathrm{x}-\mathrm{y})[\nu(\mathrm{x}) - \nu(\mathrm{y})], \quad \forall\, \mathrm{x},\mathrm{y} \in \mathbb{R}. \tag{62}$$

As seen from this equation, $\langle \mathrm{x}|\mathrm{h}_2|\mathrm{y}\rangle = 0$, if $\mathrm{x} \notin [-1,1]$ and $\mathrm{y} \notin [-1,1]$.

We can express h_2 as a function of x and p by performing a Fourier transformation on the y variable appearing in (62), i.e., computing

$$\langle \mathrm{x}|\mathrm{h}_2|\mathrm{p}\rangle := (2\pi)^{-1/2} \int_{-\infty}^{\infty} \langle \mathrm{x}|\mathrm{h}_2|\mathrm{y}\rangle e^{i\mathrm{p}\mathrm{y}} d\mathrm{y}. \tag{63}$$

This yields h_2 as a function of x and p, if we order the factors by placing x's to the left of p's. We can easily do this by expanding $\langle \mathrm{x}|\mathrm{h}_2|\mathrm{p}\rangle$ in powers of p. Denoting the x-dependent coefficients by ω_n, we then have

$$\mathrm{h}_2 = \sum_{n=0}^{\infty} \omega_n(\mathrm{x})\mathrm{p}^n, \tag{64}$$

where we have made the implicit assumption that $\langle \mathrm{x}|\mathrm{h}_2|\mathrm{p}\rangle$ is a real-analytic function of p.

The Fourier transform of $\langle \mathrm{x}|\mathrm{h}_2|\mathrm{y}\rangle$ can be performed explicitly. [One way of doing this is to use the integral representations of the absolute value and sign function, as given in (36), to perform the y-integrations in (63) and use the identities

$$\int_{-\infty}^{\infty} \frac{e^{iau} du}{u(u-k)} = \frac{i\pi}{k}(e^{iak} - 1)\mathrm{sign}(a),$$

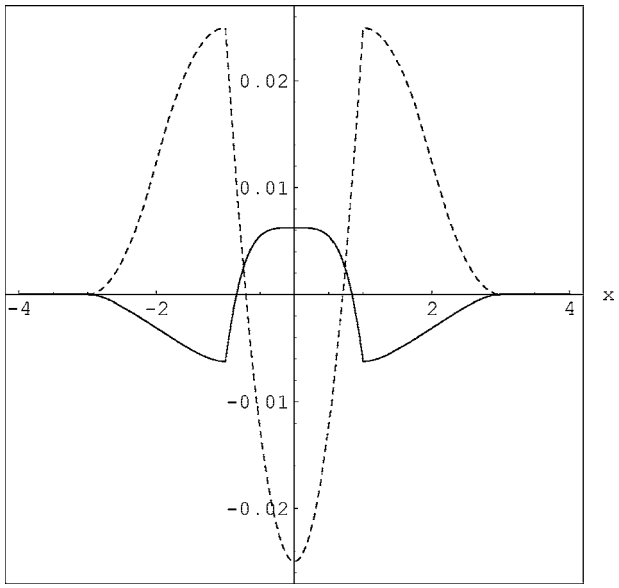

FIG. 1. Graph of the real part of ω_0 (dashed curve) and ω_2 (full curve).

$$\int_{-\infty}^{\infty} \frac{e^{iau}du}{u(u-k)^2} = \frac{i\pi}{k^2}[1+(iak-1)e^{iak}]\text{sign}(a), \quad \forall\, a,k \in \mathbb{R},$$

to evaluate the remaining two integrals. The resulting expression is too lengthy and complicated to be presented here.] We have instead used MATHEMATICA to calculate $\langle x|h_2|p\rangle$ and found the coefficients ω_n for $n \leqslant 5$. It turns out that indeed $\langle x|h_2|p\rangle$ does not have a singularity at $p=0$, and that $\omega_0, \omega_2, \omega_4$ are real and vanish outside $(-3,3)$ while $\omega_1, \omega_3, \omega_5$ are imaginary and proportional to $\theta(x)-1/2$ outside $(-3,3)$. As we will explain momentarily these properties are necessary to ensure the Hermiticity of h.

Figures 1, 2, and 3 show the plots of real part of ω_n for $n=0,2,4$ and the imaginary part of ω_n

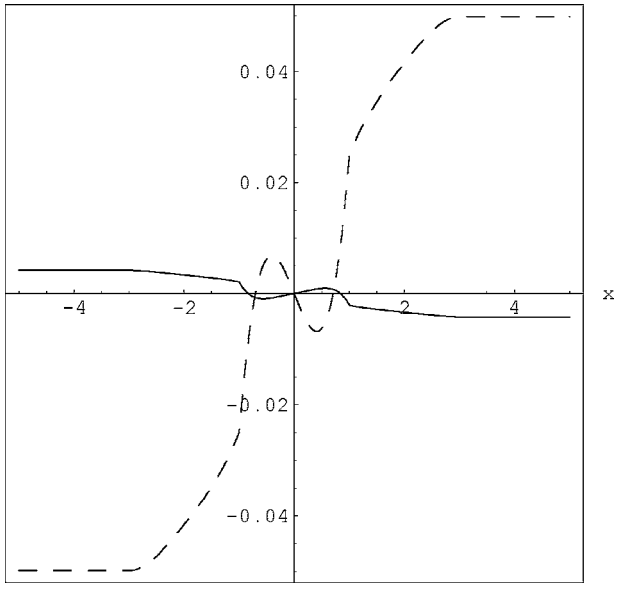

FIG. 2. Graph of the imaginary part of ω_1 (dashed curve) and ω_3 (full curve).

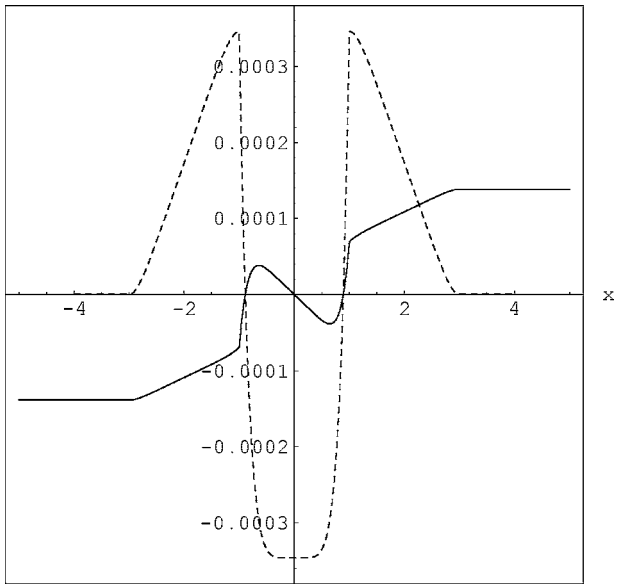

FIG. 3. Graph of the real part of ω_4 (dashed curve) and the imaginary part of ω_5 (full curve).

for $n=1,3,5$. As seen from these figures (the absolute value of) ω_n sharply decreases with n, which suggests that a truncation of (64) yields a good approximation for the action of h_2 on the wave functions with bounded and sufficiently small x-derivatives.

If we use $\langle \mathrm{p}|\mathrm{h}_2|\mathrm{x}\rangle=\langle \mathrm{x}|\mathrm{h}_2|\mathrm{p}\rangle^*$ to determine the form of h_2 and suppose that $\omega_{2n}(\mathrm{x})$ are real and $\omega_{2n+1}(\mathrm{x})$ are imaginary for all $n=0,1,2,3,\ldots$, we find

$$\mathrm{h}_2=\sum_{n=0}^{\infty}\mathrm{p}^n\omega_n(\mathrm{x})^*=\sum_{n=0}^{\infty}[\mathrm{p}^{2n}\omega_{2n}(\mathrm{x})-\mathrm{p}^{2n+1}\omega_{2n+1}(\mathrm{x})].$$

Adding both sides of this relation to those of (64) and diving by two, we obtain

$$\mathrm{h}_2=\frac{1}{2}\sum_{n=0}^{\infty}\{a_n(\mathrm{x}),\mathrm{p}^{2n}\},\quad a_n(\mathrm{x}):=\omega_{2n}(\mathrm{x})+i\omega'_{2n+1}(\mathrm{x}),\tag{65}$$

where $\{\cdot,\cdot\}$ stands for the anticommutator, a prime denotes a derivative, and we have made use of the identity: $[f(\mathrm{x}),\mathrm{p}^m]=\{if'(\mathrm{x}),\mathrm{p}^{m-1}\}$. It is important to note that because $\omega_{2n}(\mathrm{x})$ are real and $\omega_{2n+1}(\mathrm{x})$ are imaginary, $a_n(\mathrm{x})$ are real. Moreover, outside $(-3,3)$, $\omega_{2n}(\mathrm{x})$, $\omega'_{2n+1}(\mathrm{x})$, and consequently a_n vanish. Therefore, we can express h_2 in the manifestly Hermitian form (65) with all the x-dependent coefficient functions vanishing outside $(-3,3)$. Figure 4 shows the plots of a_n for $n=0,1,2$. They are all even functions of x with an amplitude of variations that decreases rapidly as n increases.

Next, we scale back the relevant quantities and use (16), (55), (58), and (65) to obtain

$$h=\frac{p^2}{2m}+\frac{\zeta^2}{2}\sum_{n=0}^{\infty}\{\alpha_n(x),p^{2n}\}+\mathcal{O}(\zeta^3),\quad \alpha_n(x):=2m\left(\frac{L}{2\hbar}\right)^{2(n+1)}a_n\left(\frac{2x}{L}\right).\tag{66}$$

In view of the fact that a_n and α_n are real-valued even functions, h is a manifestly Hermitian $\mathcal{P}$- and $\mathcal{T}$-symmetric Hamiltonian. We can also express it in the form

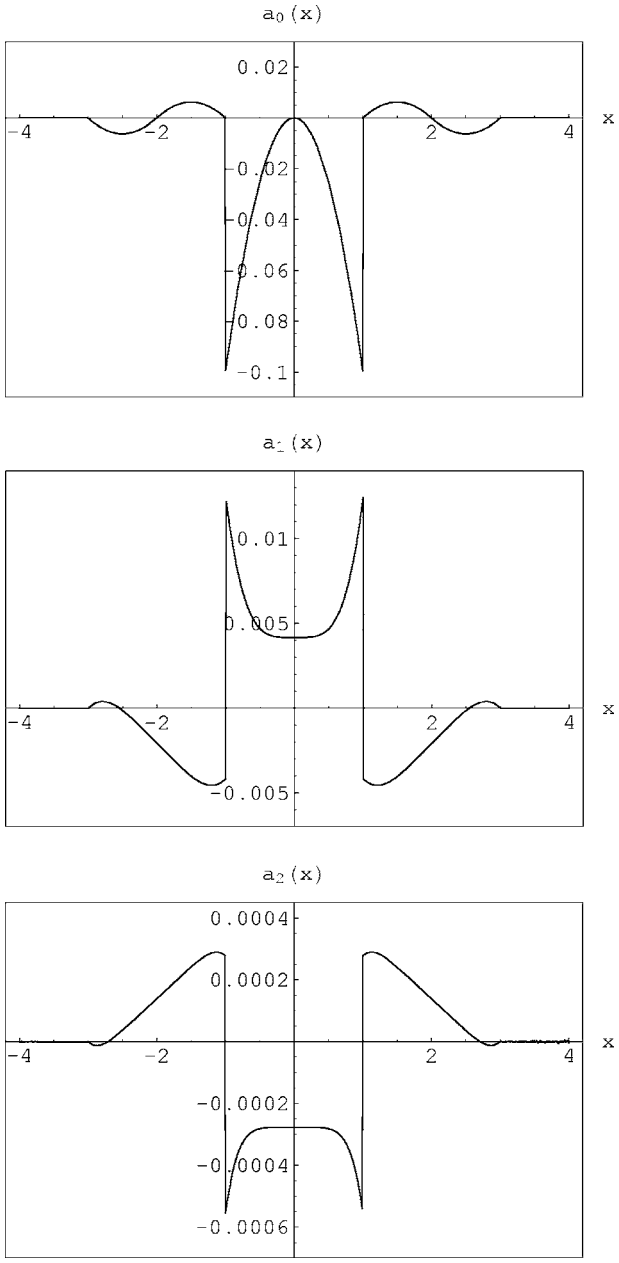

FIG. 4. Graph of a_0, a_1, and a_2.

$$h = \frac{1}{4}\{m_{\text{eff}}^{-1}(x), p^2\} + w(x) + \frac{\zeta^2}{2}\sum_{n=2}^{\infty}\{\alpha_n(x), p^{2n}\} + \mathcal{O}(\zeta^3), \tag{67}$$

where

$$m_{\text{eff}}(x) := \frac{m}{1 + 2m\zeta^2\alpha_1(x)}, \quad w(x) := \zeta^2\alpha_0(x).$$

Therefore, for low energy particles where one may neglect terms involving fourth and higher powers of p, the Hamiltonian h and consequently H describe motion of a particle with an effective position dependent mass $m_{\text{eff}}(x)$ that interacts with the potential $w(x)$. Figure 5 shows a graph of

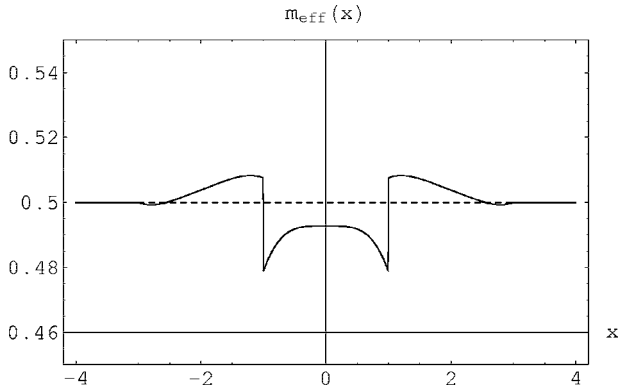

FIG. 5. Graph of the effective mass m_{eff} (full curve) for $m=\frac{1}{2}$, $\hbar=1$, $L=2$, and $\zeta=\frac{1}{3}$. The dashed curve represents $m=\frac{1}{2}$.

$m_{\text{eff}}(x)$ for $m=1/2$, $\hbar=1$, $L=2$, and $\zeta=1/3$. For the same values of these parameters, $w(x)=a_0(x)/9$. See Fig. 4 for a graph of a_0.

If we replace (x,p) of (66) and (67) with their classical counterparts (x_c,p_c), we obtain the "classical" Hamiltonian:

$$\widetilde{H}_c=\frac{p_c^2}{2m}+\frac{\zeta^2}{2}\sum_{n=0}^{\infty}\alpha_n(x_c)p_c^{2n}+\mathcal{O}(\zeta^3)=\frac{p_c^2}{2m_{\text{eff}}(x_c)}+w(x_c)+\frac{\zeta^2}{2}\sum_{n=2}^{\infty}\alpha_n(x_c)p_c^{2n}+\mathcal{O}(\zeta^3), \tag{68}$$

which coincides with the free particle Hamiltonian outside the *physical interaction region*, i.e., $(-3L/2,3L/2)$. The fact that this region is three times larger than the support $(-L/2,L/2)$ of the potential $v(x)$ is quite surprising. Note also that $\widetilde{H}_c$ is an even function of both the position x_c and momentum p_c variables.

Figure 6 shows the phase space trajectories associated with the Hamiltonian $\widetilde{H}_c$ for $L=2$, $\hbar=1$, $m=1/2$, $\zeta=Z=1/3$. For large values of the momentum the trajectories are open curves describing the scattering of a particle due to an interaction that takes place within the physical interaction region, $(-3,3)$. For sufficiently small values of the momentum closed trajectories are

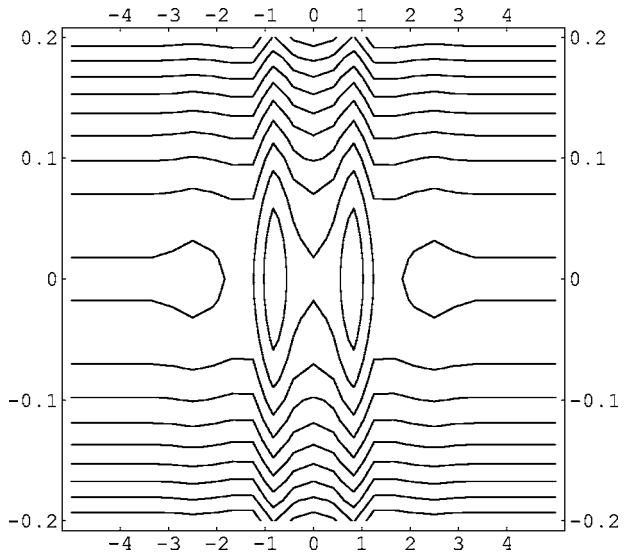

FIG. 6. Phase space trajectories of the Hamiltonian $\widetilde{H}_c(x_c,p_c)$ for $m=\frac{1}{2}$, $\hbar=1$, $L=2$, and $\zeta=\frac{1}{3}$. The horizontal and vertical axes are, respectively, those of x_c and p_c.

generated. These describe a particle that is trapped inside the physical interaction region. This is consistent with the fact that for small p_c, $\widetilde{H}_c$ is dominated by the potential term $w(x_c)$ which in view of its relation to $a_0(x)$ and Fig. 4 can trap the particle.

We wish to emphasize that because we have not yet taken the $\hbar \to 0$ limit of $\widetilde{H}_c$, we cannot identify it with the the true classical Hamiltonian H_c for the quantum Hamiltonian h and consequently H. Given the limitations of our perturbative calculation of $\widetilde{H}_c$, we are unable to determine this limit. (This is in contrast with both the $\mathcal{PT}$-symmetric square well and the $\mathcal{PT}$-symmetric cubic anharmonic oscillator studied in Refs. 5 and 16, respectively. In the former system the presence of an exceptional spectral point imposes the condition that ζ must be of order $\hbar^2$ or higher and consequently the classical system is the same as that of the Hermitian infinite square well.[5] In the latter system, the $\hbar \to 0$ limit of the associated Hermitian Hamiltonian can be easily evaluated and classical Hamiltonian obtained.[16]) Therefore, we cannot view the presence of closed phase space trajectories for $\widetilde{H}_c$ as evidence for the existence of bound states of h and H. This is especially because these trajectories are associated with very low momentum values where the quantum effects are expected to be dominant.

V. CONCLUSION

In this paper we explored for the first time the utility of the methods of pseudo-Hermitian quantum mechanics in dealing with a non-Hermitian $\mathcal{PT}$-symmetric potential $v(x)$ that has a continuous spectrum. We were able to solve the eigenvalue problem for this potential exactly and obtain the explicit form of the metric operator, the pseudo-Hermitian position and momentum operators, the localized states, and the equivalent Hermitian Hamiltonian perturbatively.

Our analysis revealed the surprising fact that the physical interaction region for this model is three times larger than the support of the potential, i.e., there is a region of the configuration space in which $v(x)$ vanishes but the interaction does not seize.

A simple interpretation for this peculiar property is that the argument x of the potential $v(x)$ is not a physical observable and the support $(-L/2, L/2)$ of $v(x)$ being a range of eigenvalues of x does not have a direct physical meaning. This observation underlines the importance of the Hermitian representation of non-Hermitian (inparticular $\mathcal{PT}$-symmetric) Hamiltonians having a real spectrum.

The Hermitian representation involves a nonlocal Hamiltonian that is not suitable for the computation of the energy spectrum or the S-matrix of the theory. Yet it provides invaluable insight in the physical meaning and potential applications of pseudo-Hermitian and $\mathcal{PT}$-symmetric Hamiltonians and is indispensable for the determination of the other observables of the corresponding quantum systems.

On the semigroup decomposition of the time evolution of quantum mechanical resonances

Y. Strauss[a)]
Einstein Institute of Mathematics, The Hebrew University of Jerusalem, Jerusalem 91904, Israel

(Received 28 June 2005; accepted 24 August 2005; published online 24 October 2005)

A way of utilizing Lax-Phillips type semigroups for the description of time evolution of resonances for scattering problems involving Hamiltonians with a semibounded spectrum was recently introduced by Strauss. In the proposed framework the evolution is decomposed into a background term and an exponentially decaying resonance term evolving according to a semigroup law given by a Lax-Phillips-type semigroup; this is called the semigroup decomposition. However, the proposed framework assumes that the *S*-matrix in the energy representation is the boundary value on the positive real axis of a bounded analytic function in the upper half-plane. This condition puts strong restrictions on possible applications of this formalism. In this paper it is shown that there is a simple way of weakening the assumptions on the *S*-matrix analyticity while still obtaining the semigroup decomposition of the evolution of a resonance. © *2005 American Institute of Physics.*

I. INTRODUCTION

There has been a recent effort to adapt the formalism of the scattering theory developed by Lax and Phillips[1] into the framework of quantum mechanics. An initial effort in this direction[2–4] was followed by the introduction of a more general formalism by Strauss, Eisenberg, and Horwitz[5] which was subsequently applied to certain Lee-Friedrichs-type models in relativistic quantum field theory[6,7] and, more recently, to the analysis of the Stark effect.[8] In a parallel work Baumgartel[9] has used a modification of the Lax-Phillips scattering theory in order to deal with quantum mechanical resonances. In particular, he has shown the relevancy of this modified structure for the construction of appropriate Gamow vectors for resonances of certain scattering problems.

It is readily observed that the class of problems which can be analyzed within the framework introduced in Ref. 5 is limited by the very fact that it essentially maintains the original structure of the Lax-Phillips theory. In this formalism the generator of evolution is required to have an unbounded spectrum from below as well as from above, thus a large class of quantum mechanical scattering problems is excluded from its range of applicability. A way of overcoming this difficulty, when dealing with scattering problems for which the generator of evolution has a semibounded absolutely continuous spectrum, was recently proposed in Ref. 10.

The basic setting analyzed in Ref. 10 is a scattering problem involving a "free" unperturbed Hamiltonian $\mathbf{H}_0$ and a perturbed Hamiltonian $\mathbf{H}$ defined on a Hilbert space $\mathcal{H}$ where we assume that the absolutely continuous spectrum of both $\mathbf{H}_0$ and $\mathbf{H}$ satisfies $\text{ess Supp}\,\sigma_{\text{ac}}(\mathbf{H}_0) = \text{ess Supp}\,\sigma_{\text{ac}}(\mathbf{H}) = \mathbb{R}^+$ and that the Møller wave operators $\Omega^{\pm}(\mathbf{H}_0, \mathbf{H})$ exist and are complete. In order to obtain the desired result, described below, it is assumed further that the *S*-matrix in the energy representation, denoted by $\tilde{S}$, is a boundary value on $\mathbb{R}^+$ of an $\mathcal{H}^{\infty}(\Pi)$ function where, denoting by Π the upper half of the complex plane, $\mathcal{H}^{\infty}(\Pi)$ is the class of functions which are bounded analytic in Π.

[a)]Electronic mail: ystrauss@math.huji.ac.il

Suppose that under the assumptions mentioned above $\tilde{S}$, as an analytic function in Π, has a simple zero in the upper half-plane at a point $\bar{\mu}$ with $\mathrm{Im}\,\mu<0$ and $\mathrm{Re}\,\mu>0$. It is then easy to show that there exists an analytic continuation of $\tilde{S}$ across the positive real axis and that this analytic continuation has a simple pole below the real axis at the point $z=\mu$ which is considered to be associated with a scattering resonance (this is usually referred to as a second sheet pole of the S-matrix). Denote by $\mathbf{U}(t)$ the unitary evolution generated by the full scattering Hamiltonian $\mathbf{H}$ and by $\mathcal{H}_{\mathrm{ac}}$ the subspace of $\mathcal{H}$ corresponding to the ac spectrum of $\mathbf{H}$. It is shown in Ref. 10 that the pole of $\tilde{S}$ at $z=\mu$ (or rather the zero at $\bar{\mu}$) induces a decomposition of any matrix element $(g,\mathbf{U}(t)f)_{\mathcal{H}_{\mathrm{ac}}}$, for $t\geqslant 0$ and f and g belonging to a certain dense set in $\mathcal{H}_{\mathrm{ac}}$, into a term evolving according to a semigroup law and a background term. In a sense to be made precise in the next section the semigroup term is of Lax-Phillips type and the eigenvalue of the generator of the semigroup is exactly μ, i.e., the location of the pole of the S-matrix $\tilde{S}$. One may say that the semigroup part of the evolution is driven by the pole of the S-matrix. The identification of the eigenvalue of the generator of the semigroup with the location of the S-matrix pole is made through a mechanism originating from the Sz.-Nagy–Foias theory of contractions on Hilbert space.[11] The decomposition of the matrix element $(g,\mathbf{U}(t)f)_{\mathcal{H}_{\mathrm{ac}}}$ in the form

$$(g,\mathbf{U}(t)f)_{\mathcal{H}_{\mathrm{ac}}}=R^{sg}(g,f;t)+\alpha(g,f)e^{-i\mu t},\quad t\geqslant 0 \tag{1}$$

induced via the Sz.-Nagy–Foias mechanism by a pole of the scattering matrix $\tilde{S}$ at $z=\mu$ will be called the *semigroup decomposition* of the time evolution of a resonance. The second term in Eq. (1) is the semigroup contribution and the first term is the background term.

One important drawback of the framework developed in Ref. 10 is the strong assumption made on the analyticity properties of the S-matrix. While the assumption that $\tilde{S}$ is the boundary value of an $\mathcal{H}^{\infty}(\Pi)$ function allows for the application of the proposed framework in certain situations including, for example, certain Friedrichs-type models or compactly supported perturbations of the Laplacian, it excludes large classes of quantum mechanical scattering problems for which the scattering matrix does not have the necessary analyticity properties. The main focus of the present paper is on an attempt to overcome this obstacle.

The paper is organized as follows: A short summary of the framework for the description of the time evolution of resonances developed in Ref. 10 is given in Sec. II. As mentioned above this framework assumes certain strong analyticity properties for the S-matrix in the upper half-plane. The weakening of these strong assumptions is dealt with in Sec. III. Section IV contains a few comments which are included in order to elucidate some important points in the formalism introduced in the preceding two sections. Final remarks are made in Sec. V.

II. THE SEMIGROUP DECOMPOSITION FOR RESONANCE EVOLUTION

This section provides a short summary of the formalism introduced in Ref. 10. As mentioned in Sec. I, the result, Eq. (1), is obtained under the assumption that $\tilde{S}$, the S-matrix in the energy representation, is the boundary value on $\mathbb{R}^{+}$ of a function in $\mathcal{H}^{\infty}(\Pi)$. In the next section it is shown that it is possible to obtain the same results with a weaker assumption on the analyticity of the S-matrix.

We start the discussion in this section with the definition of a Lax-Phillips-type semigroup. Consider a Hilbert space $\mathcal{H}$ and an evolution group of unitary operators $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ on $\mathcal{H}$. The starting point for the Lax-Phillips scattering theory is the assumption that there exist in $\mathcal{H}$ two distinguished subspaces $\mathcal{D}_{-}$ and $\mathcal{D}_{+}$ with the properties

$$\mathcal{D}_{-}\perp\mathcal{D}_{+},$$

$$\mathbf{U}(t)\mathcal{D}_{-}\subset\mathcal{D}_{-},\quad t\leqslant 0,$$

$$\mathbf{U}(t)\mathcal{D}_+ \subset \mathcal{D}_+, \quad t \geqslant 0,$$

$$\cap_t \mathbf{U}(t)\mathcal{D}_\pm = \{0\},$$

$$\overline{\cup_t \mathbf{U}(t)\mathcal{D}_\pm} = \mathcal{H}. \tag{2}$$

The subspaces $\mathcal{D}_-$ and $\mathcal{D}_+$ are called, respectively, the *incoming subspace* and *outgoing subspace* for the evolution $\mathbf{U}(t)$. The main object investigated in the Lax-Phillips theory is the Lax-Phillips semigroup which is defined to be the family $\{\mathbf{Z}(t)\}_{t\geqslant 0}$ of operators on $\mathcal{H}$ given by

$$\mathbf{Z}(t) = \mathbf{P}_+\mathbf{U}(t)\mathbf{P}_-, \quad t \geqslant 0. \tag{3}$$

Here $\mathbf{P}_-$ is the orthogonal projection of $\mathcal{H}$ onto the orthogonal complement of $\mathcal{D}_-$ and $\mathbf{P}_+$ is the orthogonal projection of $\mathcal{H}$ onto the orthogonal complement of $\mathcal{D}_+$. The family $\{\mathbf{Z}(t)\}_{t\geqslant 0}$ forms a strongly continuous contractive semigroup on $\mathcal{K}=\mathcal{H}\ominus(\mathcal{D}_-\oplus\mathcal{D}_+)$ with $s-\lim_{t\to\infty}\mathbf{Z}(t)x=0$ for every $x\in\mathcal{K}$.

Under the assumptions in Eq. (2) Lax and Phillips prove the existence of two *translation representations* for $\mathcal{H}$. In the *incoming translation representation* $\mathcal{H}$ is mapped onto the Hilbert space $L^2_{\mathcal{N}}(\mathbb{R})$ of functions taking their values in a Hilbert space $\mathcal{N}$ (called auxiliary space), $\mathcal{D}_-$ is mapped onto $L^2_{\mathcal{N}}(\mathbb{R}^-)$ and the evolution $\mathbf{U}(t)$ is represented as translation to the right by t units. Analogously, in the *outgoing translation representation* $\mathcal{H}$ is mapped onto $L^2_{\mathcal{N}}(\mathbb{R})$, $\mathcal{D}_+$ is mapped onto $L^2_{\mathcal{N}}(\mathbb{R}^+)$ and the evolution $\mathbf{U}(t)$ is again represented by translation to the right. The mapping S^{LP} of the incoming translation representation onto the outgoing translation representation is the *Lax-Phillips S-matrix*. One usually does not work with the translation representations but rather with their Fourier transforms called, respectively, the *incoming spectral representation and outgoing spectral representation*. According to the Paley-Wiener theorem[12] in the incoming spectral representation $\mathcal{D}_-$ is represented by $\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})$ where $\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})$ is the space of boundary values on $\mathbb{R}$ of functions in $\mathcal{H}^2_{\mathcal{N}}(\Pi)$, the space of (vector valued) Hardy class functions on the upper half-plane. By the same theorem $\mathcal{D}_+$ is represented in the outgoing spectral representation by the function space $\mathcal{H}^-_{\mathcal{N}}(\mathbb{R})$ containing boundary values of functions in $\mathcal{H}^2_{\mathcal{N}}(\bar{\Pi})$ where $\bar{\Pi}$ is the lower half-plane. The Lax-Phillips S-matrix in the spectral representation, i.e., the Fourier transform of the Lax-Phillips S-matrix, will be denoted by $\mathcal{S}^{\mathrm{LP}}$. The operator $\mathcal{S}^{\mathrm{LP}}: L^2_{\mathcal{N}}(\mathbb{R})\mapsto L^2_{\mathcal{N}}(\mathbb{R})$ is realized as a multiplicative, operator valued function $\Theta(\cdot)$, such that $\Theta(\sigma)$ maps $\mathcal{N}$ onto $\mathcal{N}$ for each $\sigma\in R$. The operator valued function $\Theta(\cdot)$ is characterized by its action on $\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})$ as being as *inner function*[13–15] [the notation in this paper does not distinguish between an operator defined on the space $\mathcal{H}^2_{\mathcal{N}}(\Pi)$ and the corresponding operator defined on the space of boundary value functions $\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})$; since the two spaces are isomorphic the same notation is being used for both].

As mentioned above the main object of interest in the Lax-Phillips theory is the Lax-Phillips semigroup. In the outgoing spectral representation an element $\mathbf{Z}(t):\mathcal{K}\mapsto\mathcal{K}$ of the Lax-Phillips semigroup is represented by $\hat{Z}(t)$, $\hat{\mathcal{K}}\mapsto\hat{\mathcal{K}}$ defined by

$$\hat{Z}(t) = T_{u(t)}|\hat{\mathcal{K}}, \quad t \geqslant 0, \tag{4}$$

where

$$\hat{\mathcal{K}} = L^2_{\mathcal{N}}(\mathbb{R}) \ominus (\mathcal{H}^-_{\mathcal{N}}(\mathbb{R}) \oplus \mathcal{S}^{\mathrm{LP}}\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})) = L^2_{\mathcal{N}}(\mathbb{R}) \ominus (\mathcal{H}^-_{\mathcal{N}}(\mathbb{R}) \oplus \Theta(\cdot)\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})) \tag{5}$$

and where $T_{u(t)}:\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})\mapsto\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})$ is a *Toeplitz operator*[13,16,17] with symbol $u(t)$ define by

$$[u(t)f](\sigma) = e^{-i\sigma t}f(\sigma), \quad f\in L^2_{\mathcal{N}}(\mathbb{R}), \quad \sigma\in\mathbb{R}. \tag{6}$$

The structure of the semigroup $\hat{Z}(t)$, representing $\mathbf{Z}(t)$ in the outgoing spectral representation, can be understood in the context of the construction of *functional models* for continuous contractive semigroups on Hilbert space, a part of the Sz.-Nagy–Foias theory of contraction operators on

Hilbert space.[11] We call an operator a *model operator* for a class of operators if every operator in that class is similar to a multiple of a part of it (a part of an operator is defined to be the restriction of the operator to one of its invariant subspaces). By a functional model we mean that the model operator is defined on suitable function spaces. In fact, Eq. (4) provides a functional model for a Lax-Phillips type semigroup. From this point of view the semigroup is a fundamental object, the Lax-Phillips Hilbert space and incoming and outgoing subspaces are obtained in the process of a *unitary dilation* of the semigroup and there always exits a similarity, in fact a unitary, transformation of $\mathbf{Z}(t)$ into its functional model representation in terms of $\hat{Z}(t)$.

We notice that Eq. (5) can be written in the form

$$\hat{\mathcal{K}} = \mathcal{H}^+_{\mathcal{N}}(\mathbb{R}) \ominus \Theta(\cdot)\mathcal{H}^+_{\mathcal{N}}(\mathbb{R}). \tag{7}$$

In fact, Eq. (4) together with Eq. (7) are considered to be the canonical functional model for a Lax-Phillips-type semigroup. Here we consider an *isometric dilation* of the semigroup and we end up with a functional model defined on the Hardy space $\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})$.[10,11] We are interested in this canonical functional model for the Lax-Phillips semigroup and accordingly, for $\Theta(\cdot)$ an inner function, we call a semigroup of the form

$$\hat{Z}(t) = T_{u(t)}|(\mathcal{H}^+_{\mathcal{N}}(\mathbb{R}) \ominus \Theta(\cdot)\mathcal{H}^+_{\mathcal{N}}(\mathbb{R})), \quad t \geqslant 0 \tag{8}$$

a semigroup of *Lax-Phillips type* [in the mathematical literature a functional model for $\mathbf{Z}(t)$ in the form of Eq. (8) follows from the observation that the contractive semigroup $\{\mathbf{Z}^*(t)\}_{t\geqslant 0}$ belongs to the class C_0].

A semigroup of the form given in Eq. (8) is one ingredient entering into the formalism developed in Ref. 10. Another important ingredient is the notion of Hilbert space nesting introduced into the study of quantum mechanical resonances by Grossman.[18] A nesting map of a Hilbert space $\mathcal{H}_1$ into a Hilbert space $\mathcal{H}_0$ is a linear mapping $\theta: \mathcal{H}_1 \to \mathcal{H}_0$ such that

(1) the domain of θ is $\mathcal{H}_1$ and θ is continuous on $\mathcal{H}_1$,
(2) the range $\theta\mathcal{H}_1 \subset \mathcal{H}_0$ is dense in $\mathcal{H}_0$,
(3) θ is injective.

A map with the properties (1)–(3) is also known as a *quasi affine map* (for interesting properties of such maps see, for example, Ref. 11). The adjoint of a nesting map θ, defined by

$$(f, \theta g)_{\mathcal{H}_0} = (\theta^* f, g)_{\mathcal{H}_1},$$

is a nesting of $\mathcal{H}_0$ into $\mathcal{H}_1$. A slightly more extended version of the following theorem was proved in Ref. 10.

Theorem 1 (outgoing\incoming contractive nesting): *Let* $\mathbf{H}_0$ *and* $\mathbf{H}$ *be self-adjoint operators on a Hilbert space* $\mathcal{H}$. *Let* $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ *be the unitary evolution group on* $\mathcal{H}$ *generated by* $\mathbf{H}$ [i.e., $\mathbf{U}(t) = \exp(-i\mathbf{H}t)$]. *Denote by* $\mathcal{H}^0_{\mathrm{ac}}$ *and* $\mathcal{H}_{\mathrm{ac}}$, *respectively, the absolutely continuous subspaces of* $\mathbf{H}_0$ *and* $\mathbf{H}$. *Assume that the absolutely continuous spectrum of* $\mathbf{H}_0$ *and* $\mathbf{H}$ *has multiplicity one and that* ess Supp $\sigma_{\mathrm{ac}}(\mathbf{H}_0) =$ ess Supp $\sigma_{\mathrm{ac}}(\mathbf{H}) = \mathbb{R}^+$. *Assume furthermore that the Møller wave operators* $\mathbf{\Omega}^{\pm}(\mathbf{H}_0, \mathbf{H}): \mathcal{H}^0_{\mathrm{ac}} \mapsto \mathcal{H}_{\mathrm{ac}}$ *exist and are complete. Then there are mappings* $\hat{\mathbf{\Omega}}_{\pm}: \mathcal{H}_{\mathrm{ac}} \mapsto \mathcal{H}^+(\mathbb{R})$ *such that*

(i) $(\mathcal{H}_{\mathrm{ac}}, \mathcal{H}^+(\mathbb{R}), \hat{\mathbf{\Omega}}_{\pm})$ *are contractive Hilbert space nestings of* $\mathcal{H}_{\mathrm{ac}}$ *into* $\mathcal{H}^+(\mathbb{R})$,
(ii) *for every* $t \geqslant 0$ *and every* $f \in \mathcal{H}_{\mathrm{ac}}$ *we have*

$$\hat{\mathbf{\Omega}}_{\pm}\mathbf{U}(t)f = T_{u(t)}\hat{\mathbf{\Omega}}_{\pm}f, \tag{9}$$

where $T_{u(t)}$ *is the Toeplitz operator with symbol* $u(t)$. ■

The nesting $(\mathcal{H}_{\mathrm{ac}}, \mathcal{H}^+(\mathbb{R}), \hat{\mathbf{\Omega}}_-)$ is called below the *incoming contractive nesting* of $\mathcal{H}_{\mathrm{ac}}$ and we

denote $f_{\text{in}}=\hat{\mathbf{\Omega}}_{-}f$. Similarly $(\mathcal{H}_{\text{ac}},\mathcal{H}^{+}(\mathbb{R}),\hat{\mathbf{\Omega}}_{+})$ is called the *outgoing contractive nesting* and we denote $f_{\text{out}}=\hat{\mathbf{\Omega}}_{+}f$. The natural definition of the *nested S-matrix* is then $S_{\text{nest}}\equiv\hat{\mathbf{\Omega}}_{+}\hat{\mathbf{\Omega}}_{-}^{-1}$ and we have

$$f_{\text{out}}=\hat{\mathbf{\Omega}}_{+}\hat{\mathbf{\Omega}}_{-}^{-1}f_{\text{in}}=S_{\text{nest}}f_{\text{in}}.$$

Let $U:\mathcal{H}_{\text{ac}}^{0}\mapsto L^{2}(\mathbb{R}^{+})$ be the unitary transformation of $\mathcal{H}_{\text{ac}}^{0}$ into the spectral representation for $\mathbf{H}_{0}$ (the energy representation). If $\mathbf{S}=(\mathbf{\Omega}^{-})^{*}\mathbf{\Omega}^{+}$ is the scattering operator associated with $\mathbf{H}_{0}$ and $\mathbf{H}$ then $\tilde{S}:L^{2}(\mathbb{R}^{+})\mapsto L^{2}(\mathbb{R}^{+})$ defined by

$$\tilde{S}\equiv U\mathbf{S}U^{*}$$

is the energy representation of the S-matrix. Define a map $\theta:\mathcal{H}^{+}(\mathbb{R})\mapsto L^{2}(\mathbb{R}^{+})$ by taking, for each function $f\in\mathcal{H}^{2}(\Pi)$ the restriction on $\mathbb{R}^{+}$ of the boundary value of f on $\mathbb{R}$. Then, by a theorem of Van Winter,[19] θ is a nesting of $\mathcal{H}^{+}(\mathbb{R})$ into $L^{2}(\mathbb{R}^{+})$. The map $\theta^{*}:L^{2}(\mathbb{R}^{+})\mapsto\mathcal{H}^{+}(\mathbb{R})$ is well defined and is a nesting of $L^{2}(\mathbb{R}^{+})$ into $\mathcal{H}^{+}(\mathbb{R})$. It is shown in Ref. 10 that

$$S_{\text{nest}}=\theta^{*}\tilde{\mathbf{S}}(\theta^{*})^{-1} \tag{10}$$

[in fact Eq. (10) is taken in Ref. 10 to be the definition of S_{nest}].

In Sec. III we will need an explicit form for the map θ^{*}. The following Lemma provides the needed expression.[10]

Lemma 1: Define the inclusion map $I:L^{2}(\mathbb{R}^{+})\mapsto L^{2}(\mathbb{R})$ by

$$(If)(\sigma)=\begin{cases}f(\sigma), & \sigma\geqslant 0,\\ 0, & \sigma<0.\end{cases} \tag{11}$$

Let P_{+} be the orthogonal projection of $L^{2}(\mathbb{R})$ onto $\mathcal{H}^{+}(\mathbb{R})$. Then for any $f\in L^{2}(\mathbb{R}^{+})$ we have

$$\theta^{*}f=P_{+}If. \tag{12}$$

■

We are now able to state the semigroup decomposition result following from the $\mathcal{H}^{\infty}(\Pi)$ assumption on the S-matrix mentioned in Sec. I. Assume therefore that $\tilde{S}$, the S-matrix in the energy representation, is the boundary value on $\mathbb{R}^{+}$ of an $\mathcal{H}^{\infty}(\Pi)$ function which will be denoted by $\mathcal{S}$. If $\mathcal{S}$ has only a simple zero in the upper half-plane then, according to the canonical factorization theorems for $\mathcal{H}^{p}$ functions,[14,15] we can write $\mathcal{S}$ in the form

$$\mathcal{S}(z)=\mathcal{B}_{\mu}(z)\mathcal{G}(z), \tag{13}$$

where $\mathcal{B}_{\mu}$ is a simple *Blaschke* factor of the form (for the definition of Blaschke products see, for example, Refs. 14 and 15)

$$\mathcal{B}_{\mu}(z)=\frac{z-\bar{\mu}}{z-\mu} \tag{14}$$

and $\mathcal{G}\in\mathcal{H}^{\infty}(\Pi)$ has no zeros in Π. Under the above assumptions we have the following result on the semigroup decomposition for the $\mathcal{H}^{\infty}$ case.[10]

Proposition 1 ($\mathcal{H}^{\infty}$ case): Assume that the S-matrix $\tilde{S}:L^{2}(\mathbb{R}^{+})\mapsto L^{2}(\mathbb{R}^{+})$ is the boundary value on $\mathbb{R}^{+}$ of some function $\mathcal{S}\in\mathcal{H}^{\infty}(\Pi)$. Suppose, furthermore that $\mathcal{S}$ has a single, simple zero at the point $z=\bar{\mu}$, $\operatorname{Im}\mu<0$ in Π. For any $f\in\mathcal{H}_{\text{ac}}$ let $f_{\text{in}}=\hat{\mathbf{\Omega}}_{-}f$ and $f_{\text{out}}=\hat{\mathbf{\Omega}}_{+}f$. We have

$$f_{\text{out}}=S_{\text{nest}}f_{\text{in}}=\mathcal{B}_{\mu}\theta^{*}\tilde{\mathcal{G}}(\theta^{*})^{-1}f_{\text{in}}-i2\operatorname{Im}\mu[P_{-}\mathcal{G}\bar{f}_{\text{in}}](\mu)x_{\mu}, \tag{15}$$

where P_{-} is the orthogonal projection of $L^{2}(\mathbb{R})$ on $\mathcal{H}^{-}(\mathbb{R})$, $\bar{f}_{\text{in}}\in\mathcal{H}^{-}(\mathbb{R})$ is such that $P_{\mathbb{R}^{-}}(f_{\text{in}}+\bar{f}_{\text{in}})=0$, $\tilde{\mathcal{G}}$ is the boundary value on $\mathbb{R}^{+}$ of a function $\mathcal{G}\in\mathcal{H}^{\infty}(\Pi)$ and $\mathcal{G}$ has no zeros in Π. The vector

$x_\mu \in \mathcal{H}^+(\mathbb{R})$ is given by $x_\mu(\sigma)=(\sigma-\mu)^{-1}$ ($[P_-\mathcal{G}f_{\rm in}^-](\mu)$ is the value of the function $[P_-\mathcal{G}f_{\rm in}^-] \in \mathcal{H}^-(\mathbb{R})$ at $\mu \in \bar{\Pi}$). ■

Define

$$\hat{\mathcal{K}}_\mu \equiv \mathcal{H}^+(\mathbb{R}) \ominus \mathcal{B}_\mu \mathcal{H}^+(\mathbb{R}), \tag{16}$$

then $\hat{\mathcal{K}}_\mu$ is a one-dimensional subspace of $\mathcal{H}^+(\mathbb{R})$ and $x_\mu \in \hat{\mathcal{K}}_\mu$. Since $\mathcal{B}_\mu$ is an inner function for $\mathcal{H}^+(\mathbb{R})$ we can define the Lax-Phillips type semigroup $\{\hat{Z}(t)\}_{t\geqslant 0}$ by

$$\hat{Z}(t) \equiv T_{u(t)}|\hat{\mathcal{K}}_\mu, \quad t \geqslant 0. \tag{17}$$

Then x_μ is an eigenvector of the generator of $\{\hat{Z}(t)\}_{t\geqslant 0}$ and

$$\hat{Z}(t)x_\mu = e^{-i\mu t}x_\mu, \quad t \geqslant 0.$$

Thus, for any $f \in \mathcal{H}_{\rm ac}$ we find that

$$\begin{aligned}\hat{\mathbf{\Omega}}_+\mathbf{U}(t)f = T_{u(t)}f_{\rm out} &= T_{u(t)}\mathcal{B}_\mu\theta^*\tilde{\mathcal{G}}(\theta^*)^{-1}f_{\rm in} - i(2\ \mathrm{Im}\ \mu[P_-\mathcal{G}f_{\rm in}^-](\mu))\hat{Z}(t)x_\mu \\ &= T_{u(t)}\mathcal{B}_\mu\theta^*\tilde{\mathcal{G}}(\theta^*)^{-1}f_{\rm in} - i(2\ \mathrm{Im}\ \mu[P_-\mathcal{G}f_{\rm in}^-](\mu))e^{-i\mu t}x_\mu, \quad t \geqslant 0. \end{aligned} \tag{18}$$

Define

$$\Lambda_{\hat{\mathbf{\Omega}}_+} = \hat{\mathbf{\Omega}}_+^*\hat{\mathbf{\Omega}}_+\mathcal{H}_{\rm ac}. \tag{19}$$

The linear space $\Lambda_{\hat{\mathbf{\Omega}}_+} \subset \mathcal{H}_{\rm ac}$ is dense in $\mathcal{H}_{\rm ac}$. By the injective property of both $\hat{\mathbf{\Omega}}_+$ and $\hat{\mathbf{\Omega}}_+^*$, for any element $g \in \Lambda_{\hat{\mathbf{\Omega}}_+}$ we can find a unique $h_g \in \mathcal{H}_{\rm ac}$ such that $g=\hat{\mathbf{\Omega}}_+^*\hat{\mathbf{\Omega}}_+h_g$. For any $g \in \Lambda_{\hat{\mathbf{\Omega}}_+}$, $f \in \mathcal{H}_{\rm ac}$ and for $t \geqslant 0$ we have

$$\begin{aligned}(g,\mathbf{U}(t)f)_{\mathcal{H}_{\rm ac}} &= (\hat{\mathbf{\Omega}}_+^*\hat{\mathbf{\Omega}}_+h_g,\mathbf{U}(t)f)_{\mathcal{H}_{\rm ac}} = (\hat{\mathbf{\Omega}}_+h_g,\hat{\mathbf{\Omega}}_+\mathbf{U}(t)f)_{\mathcal{H}^+(\mathbb{R})} = (h_{g,\rm out},T_{u(t)}f_{\rm out})_{\mathcal{H}^+(\mathbb{R})} \\ &= (h_{g,\rm out},u(t)\mathcal{B}_\mu\theta^*\tilde{\mathcal{G}}(\theta^*)^{-1}f_{\rm in})_{\mathcal{H}^+(\mathbb{R})} - i(2\ \mathrm{Im}\ \mu[P_-\mathcal{G}f_{\rm in}^-](\mu))e^{-i\mu t}(h_{g,\rm out},x_\mu)_{\mathcal{H}^+(\mathbb{R})}. \end{aligned} \tag{20}$$

Equation (20) is of the form given in Eq. (1) and its rhs provides (for $t \geqslant 0$) the semigroup decomposition of the matrix element $(g,\mathbf{U}(t)f)_{\mathcal{H}_{\rm ac}}$. The zero of the S-matrix at $z=\bar{\mu}$ in Π is related, via the Sz.-Nagy–Foias mechanism described in Ref. 10, to the Lax-Phillips-type semigroup structure leading to the exponential decay of the second term on the rhs of Eq. (20).

As discussed in detail in Ref. 10, Eq. (20) is a direct result of the assumption on the analyticity properties of the S-matrix. In particular, this result is a consequence of the fact that the $\mathcal{H}^\infty$ assumption imply the canonical factorization in Eq. (13). As mentioned in Sec. I above, the assumption that the S-matrix $\tilde{S}$ is a boundary value of a bounded analytic function in the upper half-plane is stronger than what one would consider as desirable. Large classes of models for quantum mechanical scattering phenomena do not possess the assumed analyticity properties and hence cannot be analyzed within the framework developed in Ref. 10. A way of resolving this difficulty is suggested in the next section.

III. MODIFIED ASSUMPTIONS ON *S*-MATRIX ANALYTICITY

In this section it is shown that weaker assumptions on the analyticity of the S-matrix lead to a result very similar to the semigroup decomposition of Eq. (20). Thus, we assume that the S-matrix is analytic in a certain region above the real axis, that it can be analytically continued

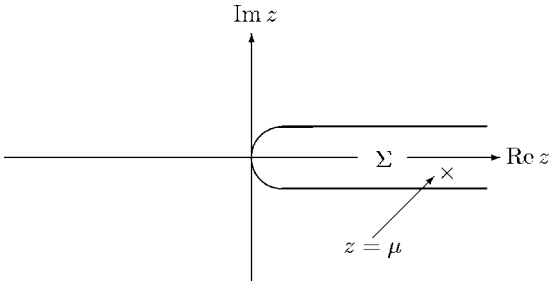

FIG. 1. *S*-matrix analyticity properties. We assume that $\tilde{\mathcal{S}}$ has a meromorphic extension to the region Σ with a simple pole at $z=\mu$.

across $\mathbb{R}^+$ and that the resulting function is meromorphic in an open region Σ containing $\mathbb{R}^+$ with a single, simple pole at $z=\mu$, $\mathrm{Im}\,\mu<0$ inside Σ as depicted in Fig. 1. We have the following theorem.

Theorem 2: *Under the assumptions of Theorem 1, let* **S** *be the scattering operator associated with* $\mathbf{H}_0$ *and* **H** *and let* $\tilde{\mathcal{S}}:L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R}^+)$ *be the S-matrix in the energy representation (i.e.,* $\tilde{\mathcal{S}} \equiv U\mathbf{S}U^*$ *as above). Assume that* $\tilde{\mathcal{S}}$ *has an extension to a meromorphic function* $\mathcal{S}$ *defined in the region* Σ *with a single, simple, pole at* $z=\mu$, $\mathrm{Im}\,\mu<0$, *and no other pole in* $\bar{\Sigma}$, *the closure of* Σ, *as in Fig. 1.*

For any $f\in\mathcal{H}_{\mathrm{ac}}$ *use the nesting maps* $\hat{\mathbf{\Omega}}_\pm$ *to define* $f_{\mathrm{out}}=\hat{\mathbf{\Omega}}_+f$ *and* $f_{\mathrm{in}}=\hat{\mathbf{\Omega}}_-f$. *Then there exists a unique element* $\psi_\mu\in\mathcal{H}_{\mathrm{ac}}$, *such that*

$$f_{\mathrm{out}} = S_{\mathrm{nest}}f_{\mathrm{in}} = \mathcal{B}_\mu\theta^*\tilde{\mathcal{G}}(\theta^*)^{-1}f_{\mathrm{in}} + i2\,\mathrm{Im}\,\mu(\psi_\mu,f)_{\mathcal{H}_{\mathrm{ac}}}x_\mu, \tag{21}$$

where θ^* *is the map given in Lemma 1,* $x_\mu\in\mathcal{H}^+(\mathbb{R})$ *is given by* $x_\mu(\sigma)=(\sigma-\mu)^{-1}$, $\mathcal{B}_\mu$ *is the Blaschke factor defined in Eq. (14) and the complex valued function* $\tilde{\mathcal{G}}$ *is defined on* $\mathbb{R}^+$ *and is the restriction to* $\mathbb{R}^+$ *of a function* $\mathcal{G}$ *holomorphic in* Σ *and having no zeros on* $\bar{\Sigma}$. ■

Proof: Let $\tilde{\mathcal{S}}$ be the *S*-matrix in the energy representation and assume that it has a meromorphic extension $\mathcal{S}$ in Σ with a simple pole at μ. Then $\mathcal{S}$ has in Σ the representation

$$\mathcal{S}(z) = (z-\mu)^{-1}\mathcal{G}'(z), \tag{22}$$

where $\mathcal{G}'$ is analytic in Σ and has no zero at $z=\mu$. Now, if $\mathcal{S}$ is expressed by Eq. (22) below the real axis then, by the unitarity of $\tilde{\mathcal{S}}$, the restriction of $\mathcal{S}$ to $\mathbb{R}^+$, we find that in the region $\Sigma\cap\Pi$ we can write $\mathcal{S}$ in the form

$$\mathcal{S}(z) = (\bar{\mathcal{S}}(\bar{z}))^{-1} = (z-\bar{\mu})(\overline{\mathcal{G}'}(\bar{z}))^{-1}, \quad \mathrm{Im}\,z>0.$$

Since $\mathcal{G}'$ has no zero at $z=\mu$ then $(\overline{\mathcal{G}'}(\bar{z}))^{-1}$ does not have a pole at $z=\bar{\mu}$ and we conclude that $\mathcal{S}$ has a representation in Σ expressed by

$$\mathcal{S}(z) = \frac{z-\bar{\mu}}{z-\mu}\mathcal{G}(z) = \mathcal{B}_\mu(z)\mathcal{G}(z), \quad z\in\Sigma, \tag{23}$$

where $\mathcal{G}(z)$ has no zero or pole in Σ. We see that $\mathcal{S}$ has in Σ a representation similar to Eq. (13) with the difference being in the fact that this representation is limited to the region Σ.

The *S*-matrix $\tilde{S}$ is given by the restriction of $\mathcal{S}$ in Eq. (23) to $\mathbb{R}^+$, i.e., $\tilde{S}(\lambda)=\mathcal{B}_\mu(\lambda)\tilde{\mathcal{G}}(\lambda)$, $\lambda\in\mathbb{R}^+$. Plugging this form of the *S*-matrix into the expression of the nested *S*-matrix S_{nest} in Eq. (10), we cannot use the methods of Ref. 10 to obtain the desired results since we no longer assume that $\mathcal{S}$ is an $\mathcal{H}^\infty(\Pi)$ function. However, we can avoid the need for this assumption by writing

$$f_{\text{out}} = S_{\text{nest}} f_{\text{in}} = \theta^* \tilde{S}(\theta^*)^{-1} f_{\text{in}} = \theta^* \mathcal{B}_\mu \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}} = P_+ I \mathcal{B}_\mu \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}}$$
$$= P_+ \mathcal{B}_\mu (P_+ + P_-) I \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}} = \mathcal{B}_\mu \theta^* \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}} + P_+ \mathcal{B}_\mu P_- \bar{\theta}^* \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}}, \tag{24}$$

where $\bar{\theta}^* = P_- I$. We see that the first term on the rhs of Eq. (24) is identical in form to the first term on the rhs of Eq. (15). In the second term on the rhs of Eq. (24) the operator $P_+ \mathcal{B}_\mu P_- : \mathcal{H}^-(\mathbb{R}) \mapsto \mathcal{H}^+(\mathbb{R})$ is a *Hankel operator* with a one-dimensional range. In fact, for any $g \in \mathcal{H}^+(\mathbb{R})$ and $f \in \mathcal{H}^-(\mathbb{R})$ we have

$$(\mathcal{B}_\mu g, P_+ \mathcal{B}_\mu P_- f)_{\mathcal{H}^+(\mathbb{R})} = (\mathcal{B}_\mu g, \mathcal{B}_\mu f)_{L^2(\mathbb{R})} = 0.$$

Hence Ran $(P_+ \mathcal{B}_\mu P_-) = \hat{\mathcal{K}}_\mu$, where $\hat{\mathcal{K}}_\mu$ is given in Eq. (16). Define the subspace $\hat{\mathcal{K}}_{\bar{\mu}} \subset \mathcal{H}^-(\mathbb{R})$ by

$$\hat{\mathcal{K}}_{\bar{\mu}} \equiv \mathcal{H}^-(\mathbb{R}) \ominus \mathcal{B}_{\bar{\mu}} \mathcal{H}^-(\mathbb{R}).$$

with $\mathcal{B}_{\bar{\mu}}(z) = (z-\mu)/(z-\bar{\mu})$ [$\mathcal{B}_{\bar{\mu}}$ is an inner function for $\mathcal{H}^-(\mathbb{R})$] and denote by $P_{\hat{\mathcal{K}}_{\bar{\mu}}}$ the orthogonal projection on this subspace. Then we also have $P_+ \mathcal{B}_\mu P_- = P_+ \mathcal{B}_\mu P_- P_{\hat{\mathcal{K}}_{\bar{\mu}}}$ since

$$P_+ \mathcal{B}_\mu P_- (\mathcal{B}_{\bar{\mu}} \mathcal{H}^-(\mathbb{R})) = 0.$$

We conclude that

$$P_+ \mathcal{B}_\mu P_- = P_{\hat{\mathcal{K}}_\mu} P_+ \mathcal{B}_\mu P_- P_{\hat{\mathcal{K}}_{\bar{\mu}}}. \tag{25}$$

Using Eq. (25) in Eq. (24) we obtain

$$f_{\text{out}} = \mathcal{B}_\mu \theta^* \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}} + P_{\hat{\mathcal{K}}_\mu} P_+ \mathcal{B}_\mu P_- P_{\hat{\mathcal{K}}_{\bar{\mu}}} \bar{\theta}^* \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}}. \tag{26}$$

According to Eq. (16) and Eq. (26) we expect that the second term on the rhs of Eq. (26) is proportional to the vector $x_\mu \in \mathcal{H}^+(\mathbb{R})$. Indeed this is verified by explicit calculation. For the projection operators $P_\pm$ we have the standard expressions

$$[P_\pm f](\sigma') = \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{1}{\sigma' \pm i\epsilon - \sigma} f(\sigma) \mathrm{d}\sigma, \quad f \in L^2(\mathbb{R}).$$

Hence, for $f \in \mathcal{H}^-(\mathbb{R})$ we have

$$[P_+ \mathcal{B}_\mu P_- f](\sigma) = [P_+ \mathcal{B}_\mu f](\sigma) = \frac{1}{2\pi i} \int_{\mathbb{R}} \frac{1}{\sigma + i\epsilon - \sigma'} \frac{\sigma' - \bar{\mu}}{\sigma' - \mu} f(\sigma') = \frac{1}{\sigma - \mu} i 2 \,\mathrm{Im}\, \mu f(\mu). \tag{27}$$

If the S-matrix $\tilde{S}$ has a meromorphic extension $\mathcal{S}$ in Σ with a simple pole at $z = \mu$ then the holomorphic factor of $\mathcal{S}$ in Σ can be found from Eq. (23) and is given by $\mathcal{G} = \mathcal{B}_{\bar{\mu}} \mathcal{S}$. Hence we have

$$[\bar{\theta}^* \mathcal{G}(\theta^*)^{-1} f_{\text{in}}](\mu) = [P_- I \mathcal{B}_{\bar{\mu}} \tilde{\mathcal{S}}(\theta^*)^{-1} f_{\text{in}}](\mu)$$
$$= \frac{1}{2\pi i} \int_{\mathbb{R}^+} \frac{1}{\lambda - \mu} (\mathcal{B}_{\bar{\mu}} \tilde{\mathcal{S}}(\theta^*)^{-1} f_{\text{in}})(\lambda)$$
$$= \frac{1}{2\pi i} \int_{\mathbb{R}^+} \frac{1}{\lambda - \bar{\mu}} (\tilde{\mathcal{S}}(\theta^*)^{-1} f_{\text{in}})(\lambda) = [\theta^* \tilde{\mathcal{S}}(\theta^*)^{-1} f_{\text{in}}](\bar{\mu}) = f_{\text{out}}(\bar{\mu}). \tag{28}$$

Furthermore, it was shown in Ref. 10 that the nesting maps $\hat{\mathbf{\Omega}}_\pm$ are given by $\hat{\mathbf{\Omega}}_\pm = \theta^* U(\mathbf{\Omega}^\mp)^*$ [where, as above, $U : \mathcal{H}_{\text{ac}}^0 \mapsto L^2(\mathbb{R}^+)$ is the mapping onto the $\mathbf{H}_0$ spectral representation] so that, for every $f \in \mathcal{H}_{\text{ac}}$, we have

$$f_{\text{out}}(\bar{\mu}) = \frac{1}{2\pi i}\int_{\mathbb{R}^+} \frac{1}{\lambda - \bar{\mu}}(U(\mathbf{\Omega}^-)^* f)(\lambda) = (\psi_\mu, f)_{\mathcal{H}_{\text{ac}}}, \tag{29}$$

where we define $\psi_\mu = \mathbf{\Omega}^- U^* \tilde{\psi}_\mu$ with $\tilde{\psi}_\mu \in L^2(\mathbb{R}^+)$, $\tilde{\psi}_\mu(\lambda) = (2\pi i)^{-1}(\lambda - \mu)^{-1}$. Combining Eqs. (26)–(29) we obtain the result Eq. (21). ■

In order to see how Theorem 2 is used we go back to Eq. (20). From this equation, together with Eq. (26) and Eq. (21) we find, for any $f \in \mathcal{H}_{\text{ac}}$ and any $g \in \Lambda_{\hat{\mathbf{\Omega}}_+}$,

$$\begin{aligned}(g, \mathbf{U}(t)f)_{\mathcal{H}_{\text{ac}}} &= (h_{g,\text{out}}, T_{u(t)} f_{\text{out}})_{\mathcal{H}^+(\mathbb{R})} = (h_{g,\text{out}}, u(t)\mathcal{B}_\mu \theta^* \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}})_{\mathcal{H}^+(\mathbb{R})} \\ &\quad + (h_{g,\text{out}}, \hat{Z}(t) P_{\hat{\mathcal{K}}_\mu} P_+ \mathcal{B}_\mu P_- P_{\hat{\mathcal{K}}_{\bar{\mu}}} \overline{\theta}^* \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}})_{\mathcal{H}^+(\mathbb{R})} \\ &= (h_{g,\text{out}}, u(t)\mathcal{B}_\mu \theta^* \tilde{\mathcal{G}}(\theta^*)^{-1} f_{\text{in}})_{\mathcal{H}^+(\mathbb{R})} + e^{-i\mu t}(h_{g,\text{out}}, x_\mu)_{\mathcal{H}^+(\mathbb{R})}(\psi_\mu, f)_{\mathcal{H}_{\text{ac}}}. \end{aligned} \tag{30}$$

Equation (30) has the general form of Eq. (1) and provides the semigroup decomposition in the case that the S-matrix $\tilde{S}$ has a meromorphic extension to the region Σ in Fig. 1. It can be easily shown that Eq. (30) reduces to Eq. (20) if $\tilde{S}$ is in fact the boundary value on $\mathbb{R}^+$ of a function belonging to $\mathcal{H}^\infty(\Pi)$.

We observe that if in Eq. (30) the state $f \in \mathcal{H}_{\text{ac}}$ is chosen to be orthogonal to ψ_μ then the exponentially decaying term on the rhs of Eq. (30), originating from the Lax-Phillips-type semigroup evolution associated with the pole of the S-matrix, does not appear. This enables us to make a direct correspondence between the state ψ_μ and the resonance contribution to the time evolution. Since, as is seen in Sec. IV below, no state in $\mathcal{H}_{\text{ac}}$ can be mapped into an exact resonance state in the Hardy space $\mathcal{H}^+(\mathbb{R})$ and there always exists some nonzero background contribution, the vector $\psi_\mu \in \mathcal{H}_{\text{ac}}$ will be called an *approximate resonance state*. Using Dirac's notation, let us denote by $\{|E^-\rangle\}_{E\in\mathbb{R}^+}$ the set of outgoing scattering states, i.e., outgoing solutions of the Lipmann-Schwinger equation. It is then easy to see that for $f \in \mathcal{H}_{\text{ac}}$ we have

$$(U(\mathbf{\Omega}^-)^* f)(E) = \langle E^- | f \rangle, \quad E \in \mathbb{R}^+$$

and the definition of the state ψ_μ [see Eq. (29)] implies that it is given by the simple expression

$$|\psi_\mu\rangle = \frac{1}{2\pi i}\int_{\mathbb{R}^+} dE \frac{1}{E - \mu}|E^-\rangle. \tag{31}$$

IV. COMMENTS

This section contains some comments on the framework described in Sec. II and further extended in Sec. III. The discussion below is presented in a slightly more general form than is strictly necessary in order to relate it to the formalism of Secs. II and III. The more general form of the statements made below places the remarks at the end of the present section, on the Bohm-Gadella rigged Hardy space formalism for the resonance problem,[20] into their natural context.

Let $\mathcal{S}$ denote the *Schwartz class* of rapidly decreasing functions in $C^\infty(\mathbb{R})$. Let $\mathcal{S}'$ denote the space of *tempered distributions* on $\mathcal{S}$. We shall need the following definition.[21]

Definition 1 (*the space* $\mathcal{H}^p(\mathbb{C}\backslash\mathbb{R})$)*: For any fixed* $p \in (0,\infty)$ *let* $\mathcal{H}^p(\mathbb{C}\backslash\mathbb{R})$ *denote the space of analytic functions on* $\mathbb{C}\backslash\mathbb{R}$ *for which*

$$\|f\| = \sup_{y\neq 0}\left\{\int_{\mathbb{R}} |f(x+iy)|^p \, dx\right\}^{1/p} < \infty.$$

It can be shown[21] that every function $F \in \mathcal{H}^p(\mathbb{C}\backslash\mathbb{R})$ is associated with a unique tempered distribution $\ell_F \in \mathcal{S}'$ defined by

$$\ell_F(\psi) = \lim_{y\to 0^+} \int \{F(x+iy) - F(x-iy)\}\psi(x)\mathrm{d}x, \quad \psi \in \mathcal{S}. \tag{32}$$

Denote the set of all distributions arising in this way by $H^p(\mathbb{R})$. Then, conversly, for any $p \in (0,\infty)$ and for any distribution $\ell \in H^p(\mathbb{R})$, one can find the unique function $F_\ell \in \mathcal{H}^p(\mathbb{C}\backslash\mathbb{R})$ that defines the distribution ℓ through Eq. (32) via the formula[21]

$$F_\ell(z) = \frac{1}{2\pi i}\ell\left(\frac{1}{\cdot - z}\right). \tag{33}$$

Equation (33) can be thought of as a generalization of the Cauchy integral formula for the recovery of an $\mathcal{H}^p$ function from its boundary value on $\mathbb{R}$.

Even though Eq. (32) and Eq. (33) are valid for any $p \in (0,\infty)$, for $p \in (1,\infty)$ we have the further identification of the space $H^p(\mathbb{R})$ with the space $L^p(\mathbb{R})$ in the sense that any function $f \in L^p(\mathbb{R})$ defines a tempered distribution on $\mathcal{S}$ by

$$\ell_f(\psi) = \int_{\mathbb{R}} f(x)\psi(x)\mathrm{d}x, \quad \psi \in \mathcal{S} \tag{34}$$

and that for any $f \in L^p(\mathbb{R})$ there exists a unique $F_f \in \mathcal{H}^p(\mathbb{C}\backslash\mathbb{R})$ such that $\ell_{F_f} = \ell_f$, i.e., Eqs. (32) and (34) define the same tempered distribution on $\mathcal{S}$.

Finally, we will also need the following result.[21]

Proposition 2: A distribution $\ell \in H^p(\mathbb{R})$ has support which omits an open interval $I \in \mathbb{R}$ if and only if the corresponding function $F_\ell \in \mathcal{H}^p(\mathbb{C}\backslash\mathbb{R})$ given by Eq. (33) has an analytic continuation across the interval I.

Consider now the map $\theta^*: L^2(\mathbb{R}^+) \mapsto \mathcal{H}^+(\mathbb{R})$ and its inverse $(\theta^*)^{-1}: \theta^* L^2(\mathbb{R}^+) \mapsto L^2(\mathbb{R}^+)$. An explicit expression for θ^* is given in Eq. (12). Breaking the action of θ^* into two steps we first have, for any $f \in L^2(\mathbb{R}^+)$,

$$If = P_+ If + P_- If = \theta^* f + \bar{\theta}^* f = f_+ + f_-, \quad f_+ \in \mathcal{H}^+(\mathbb{R}), \quad f_- \in \mathcal{H}^-(\mathbb{R}), \tag{35}$$

where $f_+ = P_+ If$, $f_- = P_- If$. In the second step we take the $\mathcal{H}^+(\mathbb{R})$ piece, i.e.,

$$\theta^* f = P_+ If = f_+.$$

On the other hand, the discussion preceding Proposition 2 implies that if we apply the inclusion map $I: L^2(\mathbb{R}^+) \mapsto L^2(\mathbb{R})$ then, for any element $f \in L^2(\mathbb{R}^+)$, the element $If \in L^2(\mathbb{R})$ is associated with a unique function $F_f \in \mathcal{H}^2(\mathbb{C}\backslash\mathbb{R})$ such that

$$(If)(\sigma) = \lim_{\epsilon\to 0^+} \{F_f(\sigma + i\epsilon) - F_f(\sigma - i\epsilon)\}. \tag{36}$$

In fact, the function $F_f \in \mathcal{H}^2(\mathbb{C}\backslash\mathbb{R})$ is easily found from Eq. (35). We first use the isomorphism of $\mathcal{H}^+(\mathbb{R})$ and $\mathcal{H}^2(\Pi)$ to extend the map θ^* to a mapping $\theta_\pi^*: L^2(\mathbb{R}^+) \mapsto \mathcal{H}^2(\Pi)$. Subsequently we simply define

$$F_f(z) = \begin{cases} f_+(z) = (\theta_\pi^* f)(z), & \mathrm{Im}\, z > 0, \\ -f_-(z) = -(\bar{\theta}_\pi^* f)(z), & \mathrm{Im}\, z < 0. \end{cases} \tag{37}$$

Moreover, Proposition 2 shows that F_f defined in Eq. (37) is in fact analytic on $\mathbb{C}\backslash\mathbb{R}^+$. Denoting the subspace of $\mathcal{H}^2(\mathbb{C}\backslash\mathbb{R})$ of functions analytic on $\mathbb{R}^-$ by $\mathcal{H}^2(\mathbb{C}\backslash\mathbb{R}^+)$ we conclude that there exists a surjective map $A: L^2(\mathbb{R}^+) \mapsto \mathcal{H}^2(\mathbb{C}\backslash\mathbb{R}^+)$ with $Af = F_f$ for $f \in L^2(\mathbb{R}^+)$, $F_f \in \mathcal{H}^2(\mathbb{C}\backslash\mathbb{R}^+)$. Note that

$$(Af)(z) = F_f(z) = (\theta_\pi^* f)(z), \quad \text{Im } z > 0. \tag{38}$$

In addition, we note that Eqs. (36)–(38) provide us with a procedure for the construction of the map $(\theta^*)^{-1}$. Given $f_+ \in \theta^* L^2(\mathbb{R}^+) \subset \mathcal{H}^+(\mathbb{R})$ we use the Cauchy integral formula to obtain the function $f_+ \in \mathcal{H}^2(\Pi)$. We know from Eq. (38) and Eq. (37) that there is a unique function $f \in L^2(\mathbb{R}^+)$ such that $f_+ \in \mathcal{H}^2(\Pi)$ is the restriction to Π of a function $F_f = Af \in \mathcal{H}^2(\mathbb{C}\backslash\mathbb{R}^+)$. Hence we can analytically continue f_+ across $\mathbb{R}^-$ into the lower half-plane and obtain the full function F_f. The reconstruction of the corresponding function $f \in L^2(\mathbb{R}^+)$ is then obtained by using Eq. (36). The process of analytically continuing f_+ across $\mathbb{R}^-$ is done in Ref. 10 essentially by using the Van Winter theorem and explicit integral expressions for the map $(\theta^*)^{-1}$ are obtained.

Next we turn to a discussion of the resonance states. Let

$$R_s \equiv \{x_\mu | x_\mu \in \mathcal{H}^+(\mathbb{R}),\ x_\mu(\sigma) = (\sigma - \mu)^{-1},\ \sigma \in \mathbb{R},\ \text{Im } \mu < 0\}. \tag{39}$$

Obviously, it is not possible to analytically continue any element $x_\mu \in R_s$ across $\mathbb{R}^-$ in order to obtain a function in $\mathcal{H}^2(\mathbb{C}\backslash\mathbb{R}^+)$. By Eq. (38) we obtain the following.

Lemma 2: Define the set $R_s \subset \mathcal{H}^+(\mathbb{R})$ according to Eq. (39). Then $R_s \subset \mathcal{H}^+(\mathbb{R})\backslash\hat{\mathbf{\Omega}}_\pm \mathcal{H}_{\text{ac}}$.

Now, for any given S-matrix $\widetilde{S}$ the eigenvector of the Lax-Phillips-type semigroup in the second term on the rhs of Eq. (30) is proportional to some $x_\mu \in R_s$. Identifying the Hardy space state $x_\mu \in \mathcal{H}^+(\mathbb{R})$ as a pure, exponentially decaying, resonance state, Lemma 2 provides a formal verification for the impossibility of the association of any unique state in the original Hilbert space $\mathcal{H}_{\text{ac}}$ with a pure resonance. For this reason the time evolution (e.g., the survival amplitude) of any state in $\mathcal{H}_{\text{ac}}$ always contains some background contribution and is never purely exponentially decaying.

The final remark in this section is concerned with the Bohm-Gadella rigged Hilbert space formalism for the problem of resonances.[20] The main tool in this formalism is a Gelfand triplet $\Delta_+ \subset \mathcal{H}^+(\mathbb{R}) \subset \Delta_+^*$ constructed by a rigging of the Hardy space $\mathcal{H}^+(\mathbb{R})$. The smaller sector Δ_+ of the Gelfand triple is taken to be $\Delta_+ \equiv \mathcal{H}^+(\mathbb{R}) \cap \mathcal{S}$ where $\mathcal{S}$ again denotes the Schwartz space. The larger sector Δ_+^* contains all the continuous linear functionals on Δ_+. One then uses a pullback procedure in order to obtain a rigged Hilbert space $\Phi \subset L^2(\mathbb{R}^+) \subset \Phi^*$ centered around the Hilbert space $L^2(\mathbb{R}^+)$. The procedure of pull back uses the map θ. We first define $\Phi \equiv \theta\Delta_+$ and then the pull back procedure is used in order to define the set Φ^* of functionals on Φ. Denoting the evaluation of the functional F on a test function f in the rigged Hilbert spaces $\Phi \subset L^2(\mathbb{R}^+) \subset \Phi^*$ or $\Delta_+ \subset \mathcal{H}^+(\mathbb{R}) \subset \Delta_+^*$ by $\langle f, F\rangle_{L^2}$ and $\langle f, F\rangle_{\mathcal{H}^+}$, respectively, the pull back of a functional $F \in \Delta_+^*$ is defined to be

$$\langle f, \widehat{(\theta^{-1})^*} F\rangle_{L^2} \equiv \langle \theta^{-1} f, F\rangle_{\mathcal{H}^+}, \quad f \in \Phi, \quad F \in \Delta_+^*. \tag{40}$$

The map $\widehat{(\theta^{-1})^*}: \Delta_+^* \mapsto \Phi^*$ on the lhs of Eq. (40) is an extension to Δ_+^* of the map $(\theta^{-1})^*$. But on its domain of definition in $\mathcal{H}^+(\mathbb{R})$ we have $(\theta^{-1})^* = (\theta^*)^{-1}$. Hence Eq. (40) can serve just as well to define an extension of the map $(\theta^*)^{-1}$, i.e., we have

$$\langle f, \widehat{(\theta^*)^{-1}} F\rangle_{L^2} \equiv \langle \theta^{-1} f, F\rangle_{\mathcal{H}^+}, \quad f \in \Phi, \quad F \in \Delta_+^*. \tag{41}$$

For any function $F \in \theta^* L^2(\mathbb{R}^+) \subset \mathcal{H}^+(\mathbb{R}) \subset \Delta_+^*$ we have $(f, \widehat{(\theta^*)^{-1}} F\rangle_{L^2} = (f, (\theta^*)^{-1} F)_{L^2(\mathbb{R}^+)}$ and $\widehat{(\theta^*)^{-1}} F$ is then identified with a function in $L^2(\mathbb{R}^+)$ by the procedure for the construction of $(\theta^*)^{-1}$ described above. Here $F \in \theta^* L^2(\mathbb{R}^+)$ is a function in $\mathcal{H}^2(\mathbb{C}\backslash\mathbb{R}^+)$. However, the map $\widehat{(\theta^*)^{-1}}$, defined on Δ_+^*, is certainly well defined for the whole Hardy space $\mathcal{H}^+(\mathbb{R})$ and, in particular, it is well defined in the distributional sense for any resonance state $x_\mu \in R_s \subset \mathcal{H}^+(\mathbb{R})$. Indeed, a resonance in the Bohm-Gadella theory has the form $\widehat{(\theta^*)^{-1}} x_\mu$ for some $x_\mu \in R_s$. Moreover, since the elements of R_s cannot be analytically continued into functions in $\mathcal{H}^2(\mathbb{C}\backslash\mathbb{R}^+)$, they belong to $\Delta_+^* \backslash \theta^* L^2(\mathbb{R}^+)$.

V. CONCLUSIONS

A way of utilizing Lax-Phillips-type semigroups for the description of the time evolution of quantum mechanical resonances was suggested in Ref. 10. The present paper addresses the main difficulty with the framework introduced in Ref. 10 and described in Sec. II above, i.e., the assumption that the S-matrix is the boundary value on $\mathbb{R}^+$ of a function in $\mathcal{H}^\infty(\Pi)$. Such a requirement is not satisfied by large classes of quantum mechanical scattering problems. It is shown in Sec. III above that this condition can be weakened to the assumption that the given S-matrix is analytic in a region Σ as in Fig. 1. In addition, it is shown in Sec. IV that, if we regard a resonance as a quantum object and we look for a Hilbert space state describing it, our expectation that no such state can be found in the Hilbert space $\mathcal{H}$ for the scattering problem is valid. In fact a resonance, identified as an eigenvector of the Lax-Phillips-type semigroup responsible for the exponential decay of the second term on the rhs of the semigroup decomposition in Eq. (30), exists as an element of the Hilbert space $\mathcal{H}^+(\mathbb{R})$, but cannot be associated with any element in $\mathcal{H}_{\mathrm{ac}}$ in the sense that it is outside of the range of the nesting map $\hat{\mathbf{\Omega}}_+$. This implies that the background term, i.e., the first term on the rhs of Eq. (30), exists for any choice of the vectors $g, f \in \mathcal{H}_{\mathrm{ac}}$ and is never zero. However, the formalism developed above does provide a clear identification of a well-defined approximate resonance state $\psi_\mu \in \mathcal{H}_{\mathrm{ac}}$ associated with the resonance contribution to the time evolution (i.e., the semigroup term).

ACKNOWLEDGMENTS

The author wishes to thank Professors L. P. Horwitz and Hellmut Baumgartel for useful discussions. In particular, L. P. Horwitz's advice concerning the definition of an approximate resonance state is greatly appreciated. A notion of effective gauge fields which does not involve a background metric is introduced. The role of scale is played by cellular decompositions of the base manifold. Once a cellular decomposition is chosen, the corresponding space of effective gauge fields is the space of flat connections with singularities on its codimension two skeleton, $\mathcal{A}_{C\text{-flat}}/\bar{\mathcal{G}}_{M,\star} \subset \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$. If cellular decomposition C_2 is finer than cellular decomposition C_1, there is a coarse graining map $\pi_{C_2\to C_1}: \mathcal{A}_{C_2\text{-flat}}/\bar{\mathcal{G}}_{M,\star} \to \mathcal{A}_{C_1\text{-flat}}/\bar{\mathcal{G}}_{M,\star}$. We prove that the triple $(\mathcal{A}_{C_2\text{-flat}}/\bar{\mathcal{G}}_{M,\star}, \pi_{C_2\to C_1}, \mathcal{A}_{C_1\text{-flat}}/\bar{\mathcal{G}}_{M,\star})$ is a principal fiber bundle with a preferred global section given by the natural inclusion map $i_{C_1\to C_2}: \mathcal{A}_{C_1\text{-flat}}/\bar{\mathcal{G}}_{M,\star} \to \mathcal{A}_{C_2\text{-flat}}/\bar{\mathcal{G}}_{M,\star}$. Since the spaces $\mathcal{A}_{C\text{-flat}}/\bar{\mathcal{G}}_{M,\star}$ are partially ordered (by inclusion) and this order is directed in the direction of refinement, we can define a continuum limit, $C \to M$. We prove that, in an appropriate sense, $\lim_{C\to M} \mathcal{A}_{C\text{-flat}}/\bar{\mathcal{G}}_{M,\star} = \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$. We also define a construction of measures in $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ as the continuum limit (not a projective limit) of effective measures. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2037527]

I. MOTIVATION

The Wilsonian renormalization group is fundamental in standard constructions of quantum field theories. The notions of *effective theories at given scales, coarse graining and the ultraviolet/continuum limit* are essential for that scheme.

There are important physical systems for which there is no natural concept of scale which can be used to describe an effective theory as needed by standard renormalization group ideas. Any system that includes gravitational phenomena is in this category of systems because a scale is defined through a metric which in these cases is a dynamical variable. Thus, a definition of effective theories and coarse graining calls for an "extension of the concept of scale."

It is of course possible to introduce a fiducial metric and use its induced notion of scale to define effective theories and coarse graining. In fact this alternative has been developed in recent years.[1]

We will study a proposal of effective theories and coarse graining for gauge theories which emulates structures from lattice gauge theory to situations that are free of a background metric. In standard lattice gauge theory one works with a family of effective theories (labeled by increasingly finer lattices) describing the same system. The key ingredient that fine-tunes all these theories with observation and with each other is a renormalization procedure.

General relativity can be formulated as a gauge theory, but if one wishes to represent the diffeomorphism symmetry it is impossible to use a single embedded lattice to host the theory. A

solution to this problem is given by the kinematics of loop quantization "which is a lattice gauge theory for a lattice that is infinitely refined" (for a precise statement see Ref. 2). Since there was a single lattice—even if infinitely refined—there was no sequence of effective theories that let one implement Wilson's renormalization group and that in a continuum limit selected a dynamics for the loop quantized theory.

A goal of our research program[2] is to provide a family of effective theories connected to each other by coarse graining maps that average away fluctuations and whose infinite refinement limit takes us to a loop quantized theory. The dynamics of the continuum limit will be defined only after fine-tuning all the effective theories by a renormalization procedure. The proposal is simple and natural in the context of loop quantization. However, there is no claim of uniqueness; we know other families of effective theories with similar structure. Physical applications are still being developed. The most illustrative result at the moment is that when the same ideas are applied to the Ising model one recovers the standard renormalization by blocking. In addition, an extension to irregular lattices of the the blocking and bond-moving procedure of Migdal and Kadanoff is natural in our framework.[3]

A regularization procedure is included in our framework because the configuration spaces of the effective theories lie inside the space of generalized connections, $\mathcal{A}_{\text{"scale"}} \subset \bar{\mathcal{A}}_M$. Thus any observable in the continuum (cylindrical function) is automatically regularized to an observable of the effective theory. This same feature lets us define the continuum limit of the effective theories. For example, the vacuum expectation value of a cylindrical function in the continuum $\langle f \rangle_M$ is defined as the continuum limit of the vacuum expectation value of the same function evaluated in the effective theory defined at a given "scale," "$\langle f \rangle_M = \lim_{\text{"scale"}\to 0} \langle f|_{\mathcal{A}_{\text{"scale"}}} \rangle_{\text{"scale"}}$." Our structure should be compared with others using the restriction of the space of connections to a fixed graph (embedded lattice) $\mathcal{A}_\gamma$ as the home for an effective theory. In that case one would have to provide a separate regularization of observables from $\bar{\mathcal{A}}_M$ to act on each of the spaces $\mathcal{A}_\gamma$ contained in the sequence used to define the continuum limit. Moreover, this family of regularization procedures would have to satisfy compatibility conditions to define a continuum theory.

The specific goal of this paper is to present a geometrical study of a family of configuration spaces of effective theories and of the coarse graining maps that relate them to each other and to the space of generalized connections of loop quantization. The aim is to provide a solid ground for implementing a Wilsonian renormalization in a framework that is independent of a background metric. Eventually, this will serve to define the dynamics (physical measure) of loop quantized theories as the continuum limit of the dynamics of our effective theories.

This paper has the following organization. The next section introduces C-flat connections as effective gauge fields. It also studies the geometry of a C-flat connection and of the space of C-flat connections, as well defines the continuum limit $C \to M$. Section III defines coarse graining maps, studies the resulting geometry, and writes an "exact renormalization prescription" that links different effective measures. Section IV is about the action of diffeomorphisms on the spaces of C-flat connections; it also defines a space of diffeomorphism invariant effective configurations. Finally, the Appendix contains detailed definitions of some preliminary material.

II. A MODEL OF EFFECTIVE GAUGE FIELDS

The access to only finitely many measurement devices implies that only partial knowledge of the system is available. In order to have a presumed state of the system in the continuum for each set of measurements, one complements this partial knowledge with regularity assumptions. A set of measuring devices and complementary regularity assumptions "turn on" some degrees of freedom at a given "measuring scale." This intuitive idea of "measuring scale" is behind all our definitions.

In this paper, the role of scale is played by cellular decompositions of the base manifold. Once a cellular decomposition is chosen, there are regularity assumptions tailored to it. The idea is that inside each cell of the cellular decomposition the connection will be as regular as possible. Ironically these regularity assumptions take us to distributional configurations, configurations that

are not smooth connections but generalized connections. The particular kind of generalized connections (see the Appendix for a definition) that we work with are flat everywhere except for the codimension two cells of the cellular decomposition. The available observables at this "measuring scale" are holonomies along the links of a lattice constructed from the cellular decomposition.

Definition 1 (C-flat connections): A generalized connection is considered to be C-flat, $A \in \mathcal{A}_{C\text{-}flat} \subset \bar{\mathcal{A}}_M$, *if and only if its restriction to each cell of C is flat.*

Notice first that the cells of a cellular decomposition are disjoint, $c_\alpha \cap c_\beta = \emptyset$ if $\alpha \neq \beta$. Thus, there are many nonflat connections which are *C*-flat.

Also notice that in the context of generalized connections the concept of flatness is phrased in terms of the path independence of parallel transport. With this in mind our definition may be clear as it stands, but the following characterization in terms of the holonomy maps induced by *C*-flat connections is most useful in the rest of the paper.

The presence of a cellular decomposition *C* induces a natural equivalence relation among directed paths. Two oriented paths γ_1, γ_2 are defined to be *C-equivalent*, $\gamma_1 \sim_C \gamma_2$, if the two sequences of cells (of any dimension) induced by traversing the curves coincide.

Lemma 1: $\mathcal{A}_{C\text{-}flat}/\bar{\mathcal{G}}_{M,\star}$ *can be characterized as the subset of generalized connections modulo gauge transformations,* $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$, *whose elements are those and only those which satisfy*

$$[A](\gamma_1) = [A](\gamma_2)$$

for any two closed oriented paths based at $\star \in M$ *which are C-equivalent,*

$$\gamma_1 \sim_C \gamma_2.$$

The proof of this lemma is a simple application of the reconstruction theorems[4] to our context.

In the rest of this section we will talk about three different subjects in the corresponding sections. In the first section we will describe the geometry of single flat connections; in the second we will elaborate on the space $\mathcal{A}_{C\text{-flat}}$, and in the third we will present configuration spaces that are relevant for the continuum limit in our framework.

A. Geometry of a *C*-flat connection

A good starting point for studying the geometry of *C*-flat connections is the previous lemma; by using it, it is easy to see that the "regularity" assumptions yield generalized connections that may not even be continuous. Consider, for example, a smooth deformation of a given closed curve. According to our lemma, once a *C*-flat connection is chosen, the holonomy of the curve would be independent of the deformation unless its *C*-equivalence class changes. At that point of the deformation process the holonomy may experience a drastic change.

Moreover, since $\bar{\mathcal{G}}_{M,\star}(\mathcal{A}_{C\text{-flat}}) = \mathcal{A}_{C\text{-flat}}$ and $\bar{\mathcal{G}}_{M,\star}$ includes discontinuous gauge transformations, we see that even the gauge equivalence class of an everywhere flat connection has representatives which are not continuous.

However, the distributional nature of our connections modulo gauge is of a very tame type. Essentially they are the familiar spaces of flat connections with "conical" singularities along the codimension two skeleton of *C*. To see that this is the case consider a small loop contained in a single cell of maximum dimension and deform it continuously until it crosses one codimension one cell. The holonomy along the loop before the deformation was the identity and after the deformation it is still the identity because the loop is *C*-equivalent to another loop constructed as $l = c^{-1} \circ c$ (where *c* is an open curve starting in one maximal dimension cell, crossing a codimension one cell, and ending at another maximal dimension cell). Then the codimension one cells cannot host curvature singularities. However, drastic changes in the holonomy during continuous deformations may result from crossing (or hitting) cells of codimension greater or equal to two. (In our framework also the holonomies along curves that pass through singularities are defined. In some contexts these nongeneric curves may be regarded as not important.) This observation is formally stated as a direct corollary of Lemma 1 and the reconstruction theorems.[4]

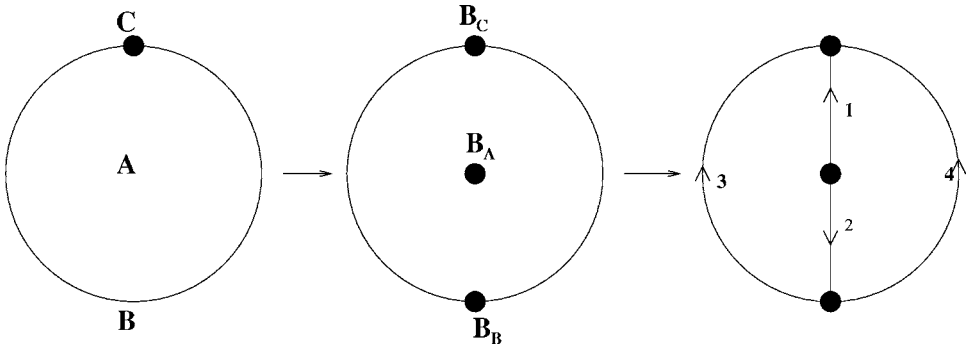

FIG. 1. Construction of $L(C)$.

Corollary 1: For any $[A]\in\mathcal{A}_{C\text{-}flat}/\bar{\mathcal{G}}_{M,\star}$ *there is a unique (up to fiber bundle equivalence) smooth bundle* Φ *over* $M-C^{(n-2)}$ *and a representative* $A\in[A]$ *such that*

$$A|_{M-C^{(n-2)}}\in\mathcal{A}^{\infty}_{M-C^{(n-2)},\Phi}.$$

Moreover, in this domain its curvature is defined and vanishes.

One can expect that the topological charges that characterize the topology and geometry of such singularities will play an important role when investigating the dynamical properties of certain types of fields. Within our framework it would be natural to choose stronger regularity assumptions to make the space of effective configurations at scale C the space of C-flat connections with a restricted type of topological charges at the singularities.

B. Geometry of the space of *C*-flat connections

The space $\mathcal{A}_{C\text{-flat}}$ is infinite dimensional, but we can expect $\mathcal{A}_{C\text{-flat}}/\bar{\mathcal{G}}_{M,\star}$ to be finite dimensional because flat connections modulo gauge do not have any local degrees of freedom. We will show that this is indeed the case by conveniently characterizing gauge equivalence classes of C-flat connections in terms of lattice gauge theory connections.

The starting point is again Lemma 1. Observe that the lattice dual to C contains representatives of the C-equivalence classes of "most" curves, but not all. Hence the space of connections on a lattice dual to C has almost all the holonomy information in $\mathcal{A}_{C\text{-flat}}/\bar{\mathcal{G}}_{M,\star}$, but some is missing. Then we complete the dual lattice to include curves C-equivalent to curves passing through cells of codimension bigger than one; call the resulting lattice $L(C)$. By definition oriented paths in $L(C)$ label C-equivalence classes of oriented paths in M. In the case of simplicial cellular decompositions $L(C)$ is the one skeleton of their barycentric subdivision, $L(C)=\mathrm{Sd}(C)^{(1)}$ (see the Appendix for a definition). In Fig. 1 we present another simple example.

An embedding $\mathrm{Emb}_{L(C)}:L(C)\to M$ can be used to define a fiber bundle with (one-dimensional) base $L(C)$ starting from the fiber bundle (E,φ,M). The total space would be $\varphi^{-1}(\mathrm{Emb}_{L(C)}[L(C)])$, and projection $\varphi|_{\mathrm{Emb}_{L(C)}[L(C)]}$. Apart from pulling back the bundle, $\mathrm{Emb}_{L(C)}$ pulls back connections from $\bar{\mathcal{A}}_M$ to the space of connections on the bundle, $\mathrm{Emb}^{\star}_{L(C)}:\bar{\mathcal{A}}_M\to\mathcal{A}_{L(C)}$.

Clearly not all embeddings are of our interest. To maintain the meaning of directed paths in $L(C)$ as representatives of C-equivalence classes of directed paths in M we restrict ourselves to *representative embeddings*. These are embeddings $\mathrm{Emb}_{L(C)}:L(C)\to M$ such that the inverse image of any oriented path γ in M is a path in $L(C)$ which labels the C-equivalence class of γ.

We denote the group of $\star$-based oriented loops on M by $\mathcal{P}_{M,\star}$; we also denote the induced group of C-equivalent classes of loops by $\mathcal{P}_{C,\star}$ and by $\mathcal{P}_{L(C),b}[\mathrm{Emb}_{L(C)}(b)=\star]$ the analogous object in $L(C)$.

Note that for any representative embedding

$$\mathrm{Emb}_{L(C)}:\mathcal{P}_{L(C),b}\to\mathcal{P}_{C,\star}$$

is an isomorphism independent of the choice of representative embedding [with $\mathrm{Emb}_{L(C)}(b)=\star$]. Thus we also have the natural isomorphism

$$\mathrm{Emb}^{\star}_{L(C)}:\mathrm{Hom}(\mathcal{P}_{C,\star},G)\to\mathrm{Hom}(\mathcal{P}_{L(C),b},G),$$

where $\mathrm{Hom}(\mathcal{P}_{C,\star},G)$ is naturally embedded in $\mathrm{Hom}(\mathcal{P}_{M,\star},G)$.

Using the reconstruction theorems[4] this can be stated in a more familiar language as follows: there is a natural isomorphism

$$\mathrm{Emb}^{\star}_{L(C)}:\mathcal{A}_{C\text{-flat}}/\bar{\mathcal{G}}_{M,\star}\to\mathcal{A}_{L(C)}/\mathcal{G}_{L(C),b}$$

which is independent of the choice of representative embedding $\mathrm{Emb}_{L(C)}:L(C)\to M$ [with $\mathrm{Emb}_{L(C)}(b)=\star$].

It is important to remark that simplicity appears only at the gauge invariant level; for example, since the space $\mathcal{A}_{C\text{-flat}}$ is infinite dimensional it is not isomorphic to a lattice gauge theory configuration space. Working on infinite dimensional quotient spaces is difficult, but we know that the complications must be inessential. This motivates us to study the same spaces in a partially gauge fixed context. It can be thought of as a strengthening of our previous regularity assumptions with extra gauge fixing conditions.

Once a local trivialization is chosen, we can assign group elements to holonomy mappings of open paths. Using this fact, a partially gauge fixed version of the space of C-flat connections is easily characterized as follows: we say that $A\in\mathcal{A}_{C\text{-flat},A_0}$ if and only if the generalized connection $A\in\bar{\mathcal{A}}_M$ is such that the holonomies along any (possibly open) oriented paths are equal, $A(\gamma_1)=A(\gamma_2)\in G$, whenever $\gamma_1\sim_C\gamma_2$. The space $\mathcal{A}_{C\text{-flat},A_0}$ depends on the local trivialization. It is more convenient to say that it depends on an auxiliary flat connection A_0 (the one induced by the local trivialization). Using this notation it is clear that generic gauge transformations do not leave it invariant, but $g(\mathcal{A}_{C\text{-flat},A_0})=\mathcal{A}_{C\text{-flat},g(A_0)}$. The gauge transformations that do leave it invariant form a finite dimensional subgroup of the group of gauge transformations denoted by $\mathcal{G}_{C,A_0,\star}\subset\bar{\mathcal{G}}_{M,\star}$. We can also define this space of residual gauge transformations in terms of the local trivialization as composed by gauge transformations such that $g(p)=g(q)\in G$ whenever p and q are in the same cell.

It is clear that, after the partial gauge fixing $P_{A_0}:\mathcal{A}_{L(C)}\to\mathcal{A}_{L(C),A_0}$, these spaces of connections can be parametrized by the assignment of group elements to C-equivalence classes of paths, or more conveniently to paths in $L(C)$. Then the local trivialization induces isomorphisms $\mathcal{A}_{L(C),A_0}\sim G^{N_1}$ and $\mathcal{G}_{L(C),A_0}\sim G^{N_0-1}$ where N_1 and N_0 are, respectively, the number of edges and vertices in $L(C)$. In this way a local trivialization sets $\mathcal{A}_{C\text{-flat}}/\mathcal{G}_{M,\star}$ in correspondence with G^{N_1}/G^{N_0-1}, where G^{N_0-1} acts by the relevant adjoint action as in the gauge transformations of lattice gauge theory.

We remark that in principle our parametrizations of $\mathcal{A}_{C\text{-flat},A_0}$ and $\mathcal{G}_{C,A_0,\star}$ hold only inside the open set U where A_0 is defined. We can choose an open cover of M in which each open set is a union of cells in C, and proceed as above for each open set. Then we paste all the local parametrizations with the aid of some transition functions. This strategy leads to definitions of partial gauge fixing of $\mathcal{A}_{C\text{-flat}}$ and $\mathcal{G}_{C,\star}$ that hold in all of M. For any choice of transition functions we have a true partial gauge fixing; in the sense that the resulting space contains elements of all the gauge equivalence classes. Thus all the choices of transition functions are equivalent. This radical difference with the theory of smooth bundles is due to working with $\bar{\mathcal{G}}_{M,\star}$. Since this fact makes all the topological considerations almost trivial we will not be concerned about them in the rest of this paper.

Let us summarize the results stated above in the form of a lemma.

Lemma 2: The following spaces are naturally isomorphic:

$$\frac{\mathcal{A}_{C\text{-}flat}}{\bar{\mathcal{G}}_{M,\star}} \sim \frac{\mathcal{A}_{C\text{-}flat,A_0}}{\mathcal{G}_{C,A_0,\star}} \text{ and } \frac{\mathcal{A}_{L(C)}}{\mathcal{G}_{L(C),b}} \sim \frac{\mathcal{A}_{L(C),A_0}}{\mathcal{G}_{L(C),A_0,b}}.$$

Additionally

$$\mathrm{Emb}^{\star}_{L(C)}: \frac{\mathcal{A}_{C\text{-}flat}}{\bar{\mathcal{G}}_{M,\star}} \to \frac{\mathcal{A}_{L(C)}}{\mathcal{G}_{L(C),b}} \text{ and } \mathrm{Emb}^{\star}_{L(C)}: \mathcal{A}_{C\text{-}flat,A_0} \to \mathcal{A}_{L(C),A_0}$$

are natural isomorphisms which are independent of the choice of representative embedding $\mathrm{Emb}_{L(C)}: L(C) \to M$ [*with* $\mathrm{Emb}_{L(C)}(b) = \star$].

Thus,

$$\mathcal{A}_{C\text{-}flat}/\bar{\mathcal{G}}_{M,\star} \sim G^{N_1(L(C))}/G^{N_0(L(C))-1}.$$

Our intuition about the lack of local degrees of freedom in C-flat connections is realized in the form of an identification between the space of C-flat connections modulo gauge transformations and a finite dimensional quotient space.

Within the partially gauge fixed construction both gauge invariance and diffeomorphism invariance are broken by the regularity assumptions. However, note that the original construction does not break gauge invariance, but still breaks diffeomorphism invariance. In a separate presentation we will construct an "extended" space of effective configurations which admits a nontrivial action of the diffeomorphism group, and that after a partial gauge fixation yields our space $\mathcal{A}_{C\text{-flat}}$.[5]

C. Configuration spaces relevant for the continuum limit

A most important element in renormalization is the change to a coarser or finer scale, and a limit in which the scale is the smallest possible (the continuum limit). Thus, in any extended notion of scale used to formulate effective theories there must be a relation that lets us know if a measuring "scale" is finer than another one, and the limit of the smallest "scale" must make sense.

Recall that the set of cellular decompositions of a manifold admits a partial order relation that tells us if a cellular decomposition C_2 is finer than cellular decomposition $C_1 (C_1 \leqslant C_2)$, and that this partial order is directed in the direction of refinement towards "the finest cellular decomposition" $(C \to M)$. [We remark that the directionality of the set of cellular decompositions holds in the piecewise linear and piecewise analytic categories, but not in the smooth category.] This partial order is preserved by our assignment of effective theories to cellular decompositions in the sense of "being contained in" as subsets of $\bar{\mathcal{A}}_M$ or subsets of $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$. (Later on we will use the notation $i_C: \mathcal{A}_{C\text{-flat}} \to \bar{\mathcal{A}}_M$ and $i_C: \mathcal{A}_{C_1\text{-flat}}/\bar{\mathcal{G}}_{M,\star} \to \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ for the inclusion maps.)

Lemma 3: Our assignment of effective gauge fields to cellular decompositions respects the partial order relation. Namely, $C_1 \leqslant C_2$ *implies*

$$\mathcal{A}_{C_1\text{-}flat} \subseteq \mathcal{A}_{C_2\text{-}flat}, \quad \mathcal{A}_{C_1\text{-}flat,A_0} \subseteq \mathcal{A}_{C_2\text{-}flat,A_0},$$

$$\mathcal{A}_{C_1\text{-}flat}/\bar{\mathcal{G}}_{M,\star} \subseteq \mathcal{A}_{C_2\text{-}flat}/\bar{\mathcal{G}}_{M,\star},$$

and $i_{C_1 \to C_2}$ *will denote all the respective refining maps.*

[The injective map $\mathrm{Emb}^{\star}_{L(C_2)} \circ i_{C_1 \to C_2} \circ (\mathrm{Emb}^{\star}_{L(C_1)} | \mathcal{A}_{C_1\text{-flat},A_0})^{-1}: \mathcal{A}_{L(C_1),A_0} \to \mathcal{A}_{L(C_2),A_0}$, which is not really an inclusion, will also be denoted by $i_{C_1 \to C_2}$. Similarly, at the partially gauge fixed level we will use the same notation for the maps induced by the refining. The ambiguity should be resolved by the context.]

Now let us introduce some configuration spaces that will be the kinematical basis of the continuum limit. First we present the space of connections that are eventually C-flat (given the directed partial order of the cellular decompositions). This space can also be seen as the space of connections that are C-flat according to some cellular decomposition.

Definition 2:

$$\tilde{\mathcal{A}}_M = \cup_C \mathcal{A}_{C\text{-}flat}.$$

There are smaller configuration spaces labeled by a given triangulation Δ of M that are also relevant for the continuum limit. These are constructed iterating the refining operation called barycentric subdivision (see the Appendix).

Definition 3:

$$\tilde{\mathcal{A}}_{M,\Delta} = \cup_n \mathcal{A}_{\mathrm{Sd}^n(\Delta)\text{-}flat}.$$

We will see in the next section that $\tilde{\mathcal{A}}_{M,\Delta}$ can also be constructed as a projective limit, while $\tilde{\mathcal{A}}_M$ cannot.

The interesting property is that while each $\mathcal{A}_{C\text{-flat}}$ captures very little of the information stored in $\bar{\mathcal{A}}_M$, both $\tilde{\mathcal{A}}_M$ and $\tilde{\mathcal{A}}_{M,\Delta}$ can be used to approximate any generalized connection arbitrarily well.

Theorem 1:

$$\lim_{C\to M} \mathcal{A}_{C\text{-}flat} = \lim_{n\to\infty} \mathcal{A}_{\mathrm{Sd}^n(\Delta)\text{-}flat} = \bar{\mathcal{A}}_M$$

in the sense that the subset of generalized connections composed by elements that are eventually in $\mathcal{A}_{C\text{-}flat}$ ($\mathcal{A}_{\mathrm{Sd}^n(\Delta)\text{-}flat}$) *is* $\tilde{\mathcal{A}}_M$ ($\tilde{\mathcal{A}}_{M,\Delta}$) *which is dense in* $\bar{\mathcal{A}}_M$.

Proof: While the restriction of two distinct cylindrical functions $f, g \in \mathrm{Cyl}(\mathcal{A}_M)$ to some $\mathcal{A}_{C\text{-flat}}$ may agree, it is a clear fact that if $f|_{\tilde{\mathcal{A}}_{M,\Delta}} = g|_{\tilde{\mathcal{A}}_{M,\Delta}}$ then $f=g$. In particular, if $f|_{\tilde{\mathcal{A}}_{M,\Delta}}=0$ then f is the zero of the algebra $\mathrm{Cyl}(\mathcal{A}_M)$.

Now suppose that $\tilde{\mathcal{A}}_M$ is not dense in $\bar{\mathcal{A}}_M$. Then there is $A \in \bar{\mathcal{A}}_M$ and a whole neighborhood of it $\mathcal{N}_A$ such that $\mathcal{N}_A \subset \bar{\mathcal{A}}_M - \tilde{\mathcal{A}}_M$. Thus, there is a nonzero continuous function $f \in \mathrm{Cyl}(\mathcal{A}_M)$ such that $f|_{\bar{\mathcal{A}}_M - \mathcal{N}_A}=0$. In particular our assumption implies that there is a $f \in \mathrm{Cyl}(\mathcal{A}_M)$ which $f|_{\tilde{\mathcal{A}}_M}=0$ while it is not the zero of $\mathrm{Cyl}(\mathcal{A}_M)$. The contradiction implies that $\tilde{\mathcal{A}}_M$ is indeed dense in $\bar{\mathcal{A}}_M$.□

Although $\tilde{\mathcal{A}}_M$ and its subset $\tilde{\mathcal{A}}_{M,\Delta}$ are both dense inside $\bar{\mathcal{A}}_M$, in the measure theoretical sense they are both small subsets of $\bar{\mathcal{A}}_M$. The formal statement at the gauge invariant level is the following.

Theorem 2: *As subsets of the space* $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ *equipped with the measure* μ_{AL}, $\tilde{\mathcal{A}}_{M,\Delta}/\bar{\mathcal{G}}_{M,\star}$ *and* $\tilde{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ *are thin sets.*

Proof: The proof is a simple adaptation of a theorem by Mourao, Thiemann, and Velhinho on the support of the Ashtekar-Lewandowski measure[6] (Theorem I.212).

We will construct a map

$$h^s : \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star} \to G^{[0,1]}$$

that will let us study "a piece of $\bar{\mathcal{A}}_M$." To make this possible we consider $G^{[0,1]}$ equipped with a different topology and measure theoretical structure than the usual ones. For the moment consider $G^{[0,1]}$ as a set; its structure will be defined below to be compatible with the structure of $\bar{\mathcal{A}}_M$ through the map h^s.

Consider a one parameter family of loops based at $\star \in M$, $s(t) \in \mathcal{P}_\star$, $t \in [0,1]$, such that $s(0)=\mathrm{id}_\star$ and $s(1)$ is a holonomicaly nontrivial loop. Generalized connections assign group elements to loops, $A(s(t)) \in G$. The latter can be seen as a function from $[0, 1]$ to G, or equivalently an element of $G^{[0,1]}$. Thus, a one parameter family of loops $s(t)$ induces a map from $\bar{\mathcal{A}}_M$ to $G^{[0,1]}$. This is our map $h^s : \bar{\mathcal{A}}_M \to G^{[0,1]}$.

Given a choice of finitely many points $t_i \in [0,1]$ consider it as an assignment from $G^{[0,1]}$ to some G^n. Thus continuous functions from $f : G^n \to \mathbb{C}$ induce *cylindrical functions* $f_{\{t_i\}} : G^{[0,1]} \to \mathbb{C}$. Clearly the pull back of these functions by h^s are cylindrical functions of $\bar{\mathcal{A}}_M$. We endow $G^{[0,1]}$

with the weakest topology that makes cylindrical functions continuous and also consider these cylinder functions the basis of its measure theoretical structure. Additionally, the push forward of the Ashtekar-Lewandowski measure is the natural homogeneous measure on $G^{[0,1]}$ endowed with this structure.

Consider the subset $D \subset G^{[0,1]}$ defined by those functions $h:[0,1] \to G$ that are nowhere continuous *according to the usual topologies* of $[0, 1]$ and G.

Thiemann proves that $G^{[0,1]} - D$ is contained in a measure zero set of $G^{[0,1]}$ with respect to the homogeneous measure.[6]

Our result follows from the fact that $h^s(\tilde{\mathcal{A}}_{M,\Delta}/\bar{\mathcal{G}}_{M,\star}) \subset G^{[0,1]} - D$ and $h^s(\tilde{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}) \subset G^{[0,1]} - D$. □

Given that our spaces of effective configurations are nested in the sense of Lemma 3, each $\mathcal{A}_{C\text{-flat}}$ can be used to regularize (approximate) any cylindrical function from the continuum or from a finer cellular decomposition. This regularization is naturally performed by the pull back of the inclusion maps $i_C: \mathcal{A}_{C_1\text{-flat}}/\bar{\mathcal{G}}_{M,\star} \to \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ or $i_{C_1 \to C_2}: \mathcal{A}_{C_1\text{-flat}}/\bar{\mathcal{G}}_{M,\star} \to \mathcal{A}_{C_2\text{-flat}}/\bar{\mathcal{G}}_{M,\star}$.

Now we will define measures in $\bar{\mathcal{A}}_M$ as the continuum limit of effective measures.

Definition 4 (continuum limit of effective theories): Consider a collection of measures $\{\mu_C\}$ [*or* $\{\mu_n\}$], *one measure in each of the spaces of effective configurations* $\{\mathcal{A}_{C\text{-}flat}\}$ [*or* $\{\mathcal{A}_{\mathrm{Sd}^n(\Delta)\text{-}flat}\}$].

When the measures converge, the continuum limit measure μ_M, *will be a measure in* $\bar{\mathcal{A}}_M$ *defined by its action on cylindrical functions as follows:*

$$\mu_M(f) \doteq \lim_{C \to M} \mu_C(i_C^\star f)$$

or

$$\mu_M(f) \doteq \lim_{n \to \infty} \mu_n(i_C^\star f)$$

for any cylindrical function $f \in Cyl(\mathcal{A}_M)$.

Clearly the continuum limit of effective measures as $C \to M$ is a much stronger condition than the limit using a sequence of refinements of a given triangulation. The limit $C \to M$ needs that an effective measure be defined for any C and that different refinement sequences of effective measures have the same limit. If our objective is to define measures in the continuum, we should use the limit $n \to \infty$ because it is more economical, but the limit $C \to M$ has the advantage of being manifestly independent of any choice of "discretization" (refining sequence).

The measures in finer and coarser effective theories should be related if they describe the same physical system. In Sec. III C we will show how a finer measure is coarse grained to produce a measure for a coarser effective theory. If in a given refining sequence the measures at coarser scales are constructed by coarse graining finer measures, we say that the measures are projectively compatible. In all these cases the limit $n \to \infty$ of our previous definition exists, but it is trivial in the sense that starting from a high enough n_0 for any $n \geqslant n_0 \mu_n(i_C^\star f)$ is independent of n. The known examples of measures that can be constructed in this way include the Ashtekar-Lewandowski measure (the homogeneous measure) and distributional measures peaked on flat connections.

Our objective is to emulate the lattice gauge theory procedure to find a theory in the continuum, which is much more powerful. There are many examples of collections $\{\mu_n\}$ which are not projectively compatible, but as n increases they become more and more compatible in the sense of the definition given above. It is easy to exhibit examples of nontrivial convergence for sigma models, and one can also construct them for gauge fields.

When the continuum limit exist, the measure μ_M can be coarse grained to define measures in all the spaces $\mathcal{A}_{\mathrm{Sd}^n(\Delta)\text{-flat}}$. Clearly this sequence of measures will be projectively compatible. These measures should be considered as "completely renormalized." In general they differ from the original effective measure used to construct the continuum limit measure, but in the sense of the limit defined above they differ less and less as we approach the continuum limit.

In a restricted version of our framework where we consider only regular cellular decomposi-

tions we can simply declare that the effective measures are the ones used in lattice gauge theory (by a renormalization group procedure). From this point of view there is a whole body of evidence supporting the existence of nontrivial physically interesting measures. A more detailed study of the relation between our framework and standard lattice gauge theory is needed.

The question arises of which measures on $\bar{\mathcal{A}}_M$ can be constructed as a continuum limit. This question and many others are outside of the scope of this paper. A detailed measure theoretical study of this continuum limit is certainly needed.

III. COARSE GRAINING AND FIBER BUNDLE STRUCTURE

Consider a situation in which we have two effective theories, one of which is based on finer knowledge of the system. The coarser and the finer effective theories should be related by a renormalization procedure which adjusts the coupling constants to account for the bulk effect of averaging out the degrees of freedom of the finer theory which are considered as fluctuations over the degrees of freedom relevant for the coarser theory.

In the preceding section we defined spaces of effective connections. The space of connections related to a finer theory contains that of a coarser theory. Physically this will let us treat the degrees of freedom used to describe coarser configurations as background degrees of freedom.

In this section we define a coarse graining procedure based on a choice of fibration which organizes the remaining degrees of freedom of the finer theory as fluctuations over each of the coarser (background) configurations. This fibration and Fubini's theorem tell us how to integrate out the fluctuations; a measure for the coarser theory is induced by coarse graining the measure for the finer theory.

Definition 5 (coarse graining maps): A natural coarse graining in our setting is induced by a choice of representative embedding $\mathrm{Emb}_{L(C)}: L(C) \to M$,

$$\pi_C \doteq (\,\mathrm{Emb}^{\star}_{L(C)}|_{\mathcal{A}_{C\text{-}flat}/\bar{\mathcal{G}}_{M,\star}})^{-1} \circ \mathrm{Emb}^{\star}_{L(C)}: \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star} \to \mathcal{A}_{C\text{-}flat}/\bar{\mathcal{G}}_{M,\star},$$

where $\mathrm{Emb}^{\star}_{L(C)}: \mathcal{A}_{C\text{-}flat}/\bar{\mathcal{G}}_{M,\star} \to \mathcal{A}_{L(C)}/\mathcal{G}_{L(C),b}$ *is an isomorphism*,

$$\pi_C \doteq (\,\mathrm{Emb}^{\star}_{L(C)}|_{\mathcal{A}_{C\text{-}flat,A_0}})^{-1} \circ P_{A_0} \circ \mathrm{Emb}^{\star}_{L(C)}: \bar{\mathcal{A}}_M \to \mathcal{A}_{C\text{-}flat,A_0},$$

where $P_{A_0}: \mathcal{A}_{L(C)} \to \mathcal{A}_{L(C),A_0}$ *is the partial gauge fixing and* $\mathrm{Emb}^{\star}_{L(C)}: \mathcal{A}_{C\text{-}flat,A_0} \to \mathcal{A}_{L(C),A_0}$ *is an isomorphism. Given* $C_1 \leqslant C_2$,

$$\pi_{C_2 \to C_1} \doteq \pi_{C_1}|_{\mathcal{A}_{C_2\text{-}flat}/\bar{\mathcal{G}}_{M,\star}}: \mathcal{A}_{C_2\text{-}flat}/\bar{\mathcal{G}}_{M,\star} \to \mathcal{A}_{C_1\text{-}flat}/\bar{\mathcal{G}}_{M,\star},$$

$$\pi_{C_2 \to C_1} \doteq \pi_{C_1}|_{\mathcal{A}_{C_2\text{-}flat,A_0}}: \mathcal{A}_{C_2\text{-}flat,A_0} \to \mathcal{A}_{C_1\text{-}flat,A_0}.$$

[When working on the spaces $\mathcal{A}_{L(C_i)}$ the relevant coarse graining map is $\pi_{C_2 \to C_1} = \mathrm{Emb}^{\star}_{1,2}$, where $\mathrm{Emb}_{1,2}: L(C_1) \to L(C_2)$ represents a C_2-equivalence class of representative embeddings $\mathrm{Emb}_{L(C_1)}$. Note that this map is not a projection. The ambiguity in our notation should be resolved by the context.]

In the rest of this section we will treat three different subjects in corresponding sections. In the first section we will give a minimal example of our spaces of effective configurations and coarse graining maps; in addition we use the example to motivate the general result of the following section. In the second section we present a theorem describing the fiber bundle structure induced by our coarse graining maps. In the final section we then study the effect of coarse graining on measures; in particular we treat the issue of renormalization prescriptions, conditions that relate the measures on different effective theories "asking them to describe the same physical system."

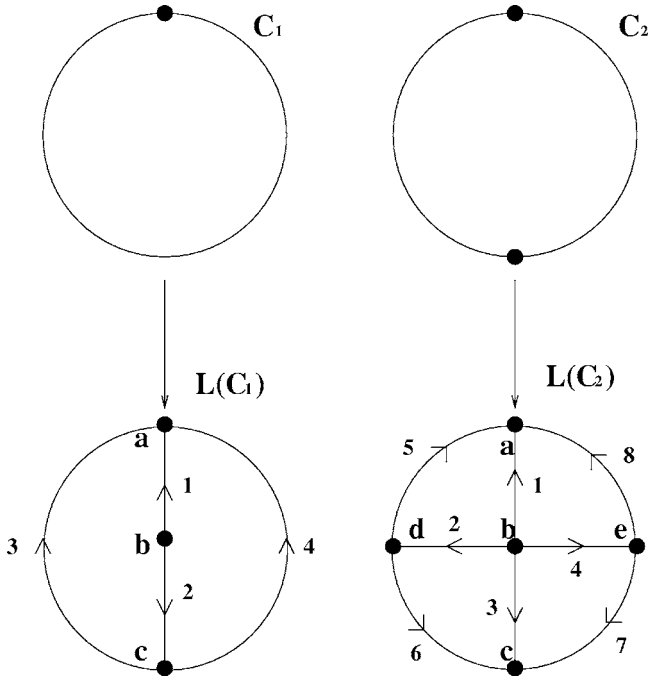

FIG. 2. Two cellular decompositions of the disc, $C_1 \leqslant C_2$.

A. A minimal example

Here we present a minimal example and use it to begin our exploration of the general properties of the coarse graining map. For concreteness we present it at the partially gauge fixed level.

Consider a closed disc (a two-dimensional closed ball) with the cellular decompositions C_1, C_2 described in Fig. 2. These cellular decompositions induce the auxiliary lattices $L(C_1)$, $L(C_2)$ also depicted in the figure. In the parametrizations described in the preceding section we can write

$$A \in \mathcal{A}_{L(C_1),A_0} \quad \text{as } A = (g_1, g_2, g_3, g_4) \in G^4,$$

$$g \in \mathcal{G}_{L(C_1),A_0} \quad \text{as } g = (g_a, g_b, g_c) \in G^3,$$

$$A' \in \mathcal{A}_{L(C_2),A_0} \quad \text{as } A' = (g'_1, g'_2, g'_3, g'_4, g'_5, g'_6, g'_7, g'_8) \in G^8,$$

and

$$g' \in \mathcal{G}_{L(C_2),A_0} \quad \text{as } g' = (g'_a, g'_b, g'_c, g'_d, g'_e) \in G^5.$$

We will also use the subgroup of gauge transformations that are the identity at a vertex, our notation will be

$$g \in \mathcal{G}_{L(C_1),A_0,b} \quad \text{as } g = (g_a, g_c) \in G^2$$

and

$$g' \in \mathcal{G}_{L(C_2),A_0,b} \quad \text{as } g' = (g'_a, g'_c, g'_d, g'_e) \in G^4.$$

The corresponding connections modulo gauge can be written as

$$[A] \in \mathcal{A}_{L(C_1),A_0}/\mathcal{G}_{L(C_1),A_0,b} \quad \text{as } A=(g_{l1},g_{l2}) \in G^2$$

and

$$[A'] \in \mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0,b} \quad \text{as } [A']=(g'_{l'1},g'_{l'2},g'_{l'3},g'_{l'4}) \in G^4,$$

where $l1=2^{-1}\circ 3^{-1}\circ 1$ and $l2=1^{-1}\circ 4\circ 2$ are loops in $L(C_1)$ based at b, and $l'1=2^{-1}\circ 5^{-1}\circ 1$, $l'2=3^{-1}\circ 6\circ 2$, $l'3=4^{-1}\circ 7^{-1}\circ 3$ and $l'4=1^{-1}\circ 8\circ 4$ are loops in $L(C_2)$ based at b.

The maps induced by refining (the inclusion of C-flat connections) on connections $i_{C_1\to C_2}:\mathcal{A}_{L(C_1),A_0}\to\mathcal{A}_{L(C_2),A_0}$ and gauge transformations $i_{C_1\to C_2}:\mathcal{G}_{L(C_1),A_0}\to\mathcal{G}_{L(C_2),A_0}$ are

$$i_{C_1\to C_2}(A)=(g_1,g_2,g_2,g_2,g_3,\mathrm{id},\mathrm{id},g_4),$$

$$i_{C_1\to C_2}(g)=(g_a,g_b,g_c,g_c,g_c).$$

In addition, the three different coarse graining maps depending on the choice of embedding $\mathrm{Emb}_{1,2}:L(C_1)\to L(C_2)$ are

$$\pi_1(A')=(g'_1,g'_2,g'_5,g'_8(g'_7)^{-1}g'_6),$$

$$\pi_1(g')=(g'_a,g'_b,g'_d),$$

$$\pi_2(A')=(g'_1,g'_3,g'_5(g'_6)^{-1},g'_8(g'_7)^{-1}),$$

$$\pi_2(g')=(g'_a,g'_b,g'_c),$$

$$\pi_3(A')=(g'_1,g'_4,g'_5(g'_6)^{-1}g'_7,g'_8),$$

$$\pi_3(g')=(g'_a,g'_b,g'_e).$$

It is easy to verify that the maps $i_{C_1\to C_2}$ and π_i descend to the quotient by gauge transformations since $i_{C_1\to C_2}(g(A))=i_{C_1\to C_2}(g)(i_{C_1\to C_2}(A))$ and $\pi_i(g'(A'))=\pi_i(g')(\pi_i(A'))$.

We will work out the example using the projection π_1. The other projections π_i yield the same structures. Our study will show that in this example $(\mathcal{A}_{L(C_2),A_0},\pi_1,\mathcal{A}_{L(C_1),A_0})$ and $(\mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0,b},\pi_1,\mathcal{A}_{L(C_1),A_0}/\mathcal{G}_{L(C_2),A_0,b})$ are principal fiber bundles with structure group G^4 and G^2, respectively. In addition, they have a preferred global section induced by the refining maps (inclusion of C-flat connections).

On the other hand, $(\mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0},\pi_1,\mathcal{A}_{L(C_1),A_0}/\mathcal{G}_{L(C_2),A_0})$ has the structure of a bundle where neither the total space nor the base are manifolds and where most fibers are homeomorphic to G^2, the only exceptions being the fibers over nongeneric connections modulo gauge, which are not typical. For example, the fiber over the flat connection is the quotient space generated by two copies of the gauge group modulo the adjoint action, $G^2/\mathrm{Ad}\,G$. We will not study this space directly; the most illuminating fact about it is that it is the quotient of the principal fiber bundle, $(\mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0,b},\pi_1,\mathcal{A}_{L(C_1),A_0}/\mathcal{A}_{L(C_2),A_0,b})$ by G, that is a finite-dimensional Lie group.

Now we start with the study of the typical fiber of

$$(\mathcal{A}_{L(C_2),A_0},\pi_1,\mathcal{A}_{L(C_1),A_0}).$$

Given any $A_0=(g_1^\circ,g_2^\circ,g_3^\circ,g_4^\circ)\in\mathcal{A}_{L(C_1),A_0}$ the fiber over it can be parametrized as

$$\pi_1^{-1}(A_0)=\{(g_1^\circ,g_2^\circ,g_3,g_4,g_3^\circ,g_7(g_8)^{-1}g_4^\circ,g_7,g_8)\}.$$

Then all the fibers of $(\mathcal{A}_{L(C_2),A_0},\pi_1,\mathcal{A}_{L(C_1),A_0})$ are homeomorphic to G^4.

A bit of graphical thinking will let us understand this example and generalize the result. At the nongauge invariant level G^4 appears because we have eight unknowns [the number of edges in $L(C_2)$] and four restrictions [the number of edges in $L(C_1)$]. Once we have found one solution to the conditions, we can generate more solutions in two ways, (i) modifying only holonomies along edges in the graph $L(C_2)-\mathrm{Emb}_{1,2}(L(C_1))$, (ii) modifying holonomies along edges of $L(C_2)$ covered by $\mathrm{Emb}_{1,2}(L(C_1))$ without modifying the induced holonomies in the edges of $L(C_1)$.

In our example (i) corresponds to modifying the components of A' assigned to edges 3,4 of $L(C_2)$. Whereas (ii) must be achieved by modifications that involve the components of A' assigned to edges 6,7,8 of $L(C_2)$ without modifying the holonomy along the image by $\mathrm{Emb}_{1,2}$ of edge 4 of $L(C_1)$. Of course, these modifications can be of the form of "gauge transformations" acting on vertices c, e of $L(C_2)$. Moreover, these transformations of the "gauge transformation" style together with type (i) transformations generate all the possible modifications of solutions to the restrictions.

Then, consider the following $G^2\times G^2$ left action on $\mathcal{A}_{L(C_2),A_0}$,

$$\mathcal{F}_{\nu_3,\nu_4;\nu_c,\nu_e}(g_1^\circ,\ldots,g_8^\circ)=(g_1^\circ,g_2^\circ,\nu_c g_3^\circ\nu_3^{-1},\nu_e g_4^\circ\nu_4^{-1},g_5^\circ,\nu_c g_6^\circ,\nu_c g_7^\circ\nu_e^{-1},g_8^\circ\nu_e^{-1}).$$

In our notation type (i) transformations are parametrized by $(\nu_3,\nu_4)\in G^2$ and type (ii) transformations are parametrized by $(\nu_c,\nu_e)\in G^2$.

Our argument in the preceding paragraph implies that the map $\mathcal{F}_\nu$ preserves fibers, $\pi_1(A_0')=\pi_1(\mathcal{F}_\nu(A_0'))$. Furthermore, it gives a bijection between each fiber and G^4. Then $(\mathcal{A}_{L(C_2),A_0},\pi_1,\mathcal{A}_{L(C_2),A_0})$ is a G^4 principal fiber bundle.

Now we would like to describe the typical fiber of

$$(\mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0,b},\pi_1,\mathcal{A}_{L(C_1),A_0}/\mathcal{G}_{L(C_1),A_0,b});$$

the procedure will follow our previous analysis closely. Given any $[A_0]=(g_{l1}^\circ,g_{l2}^\circ)\in\mathcal{A}_{L(C_1),A_0}/\mathcal{G}_{L(C_1),A_0,b}$ the fiber over it can be parametrized as

$$\pi_1^{-1}([A_0])=\{(g_{l1}^\circ,g'_{l'2},g'_{l'3},g_2^\circ g'^{-1}_{l'3}g'^{-1}_{l'2})\}.$$

Then all the fibers of $(\mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0,b},\pi_1,\mathcal{A}_{L(C_1),A_0}/\mathcal{G}_{L(C_1),A_0,b})$ are homeomorphic to G^2.

Consider the following G^2 left action on $\mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0,b}$:

$$\widetilde{\mathcal{F}}_{\nu_1,\nu_2}(g'_{l'1},g'_{l'2},g'_{l'3},g'_{l'4}) \tag{1}$$

$$=(g'_{l'1},\nu_1 g'_{l'2},\nu_2 g'_{l'3}\nu_1^{-1},g'_{l'4}\nu_2^{-1}).$$

Note that it is the action induced by $\mathcal{F}_\nu$ at the gauge invariant level.

Clearly the map $\widetilde{\mathcal{F}}_\nu$ preserves fibers, $\pi_1([A_0'])=\pi_1(\widetilde{\mathcal{F}}_\nu([A_0']))$. Furthermore, it gives a bijection between each fiber and G^2. Then $(\mathcal{A}_{L(C_2),A_0}/\mathcal{G}_{L(C_2),A_0,b},\pi_1,\mathcal{A}_{L(C_1),A_0}/\mathcal{G}_{L(C_1),A_0,b})$ is a G^2 principal fiber bundle.

B. Fiber bundle structure

Theorem 3: *Given a cellular decomposition and a refinement of it, $C_1\leqslant C_2$, the triples $(\mathcal{A}_{C_2\text{-}flat}/\mathcal{G}_{C_2,\star},\pi_{C_2\to C_1},\mathcal{A}_{C_1\text{-}flat}/\mathcal{G}_{C_1,\star})$ and $(\mathcal{A}_{C_2\text{-}flat,A_0},\pi_{C_2\to C_1},\mathcal{A}_{C_1\text{-}flat,A_0})$ are principal fiber bundles with a preferred global section induced by the refining maps (inclusion of C-flat connections).*

Proof: The proof of the general case is entirely analogous to our treatment of the example. Here we present it only at the gauge invariant level.

$\mathcal{A}_{C_2\text{-flat}}/\mathcal{G}_{C_2,\star}$—or equivalently, $\mathcal{A}_{L(C_2)}/\mathcal{G}_{L(C_2),b}$—is parametrized by $G^{N_1(L(C_2))-(N_0(L(C_2))-1)}$.

Once the base space point is fixed in the parametrization of $\mathcal{A}_{C_1\text{-flat}}/\mathcal{G}_{C_1,\star}$ as $G^{N_1(L(C_1))-(N_0(L(C_1))-1)}$, the locus of the fiber over it is found by solving $N_1(L(C_1))-(N_0(L(C_1))-1)$ conditions on the variables $G^{N_1(L(C_2))-(N_0(L(C_2))-1)}$.

When a solution has been found for these equations, one can find all the other solutions through a $G^{[N_1(L(C_2))-(N_0(L(C_2))-1)]-[N_1(L(C_1))-(N_0(L(C_1))-1)]}$ action, $\tilde{\mathcal{F}}_\nu$, of the "gauge transformation type" (1).

Clearly the map $\tilde{\mathcal{F}}_\nu$ preserves fibers and gives a bijection between each fiber and $G^{[N_1(L(C_2))-(N_0(L(C_2))-1)]-[N_1(L(C_1))-(N_0(L(C_1))-1)]}$. □

Since the C-effective theory is isomorphic to a lattice gauge theory, it is clear that configuration observables correspond to holonomies and momentum observables correspond to left invariant vector fields. The set of these observables is an algebra under a Poisson bracket product and is called the holonomy flux algebra, H-F(C).

The pull back of the coarse graining map takes holonomies from H-F(C_1) to H-F(C_2) and the left invariant push forward of the refining map can be used to bring fluxes from H-F(C_1) to H-F(C_2). We call this map $\widehat{\pi^\star_{C_2\to C_1}}$. It turns out that

Corollary 2: If $C_1 \leqslant C_2$,

$$\widehat{\pi^\star_{C_2\to C_1}}\text{:H-}F(C_1) \to \text{H-}F(C_2)$$

is a $\star$*-algebra embedding.*

The proof of this statement, a detailed study of coarse graining within the algebraic approach and phase space effective theories will be treated elsewhere.

C. Coarse graining effective measures

In Sec. III C we defined a construction of measures in $\bar{\mathcal{A}}_M$ as a continuum limit of effective measures on the spaces $\mathcal{A}_{C\text{-flat}}$. If $C_1 \leqslant C_2$, the effective measures μ_{C_1} and μ_{C_2} must be related by coarse graining (at least approximately) because they define effective theories for the same physical system. Assume that we have chosen a projection map $\pi_{C_2\to C_1}$, which amounts to having chosen certain degrees of freedom on $\mathcal{A}_{C_2\text{-flat}}$ as fluctuations over the background configurations $i_{C_1\to C_2}\mathcal{A}_{C_1\text{-flat}}$.

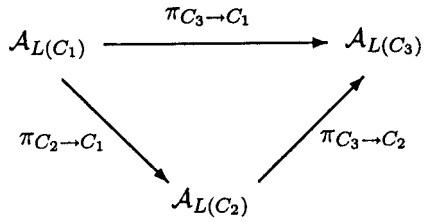
Definition 6 (exact renormalization prescription):

$$(\pi_{C_2\to C_1})_\star \mu_{C_2} = \mu_{C_1}.$$

The definition means that for any cylindrical function f of $\mathcal{A}_{C_1\text{-flat}}$ we have $\int_{\mathcal{A}_{C_1\text{-flat}}} f\, \mathrm{d}\mu_{C_1} = \int_{\mathcal{A}_{C_2\text{-flat}}} \pi^\star_{C_2\to C_1} f\, \mathrm{d}\mu_{C_2}$. Its physical interpretation is that any scale C_1 observable can either be measured by μ_{C_1} on the space $\mathcal{A}_{C_1\text{-flat}}$ or be "observed at scale C_2" as a rather coarse function and measured by μ_{C_2} on the space $\mathcal{A}_{C_2\text{-flat}}$ *producing exactly the same results.*

Given any refining sequence $C1 \leqslant C_2 \leqslant \cdots \leqslant C_n \leqslant \cdots$ there are choices of projections that make the corresponding exact renormalization prescriptions *compatible*. This is because the following lemma holds.

Lemma 4: Given any three cellular decompositions related by refinement $C_1 \leqslant C_2 \leqslant C_3$ *there are choices of embeddings* $\mathrm{Emb}_{i,j}: L(C_i) \to L(C_j)$ *which induce projections* $\pi_{C_j\to C_i} = \mathrm{Emb}^\star_{i,j}: \mathcal{A}_{L(C_j)} \to \mathcal{A}_{L(C_i)}$ *that make the following triangle diagram commute:*



Proof: Fix $\mathrm{Emb}_{1,2}: L(C_1)\to L(C_2)$ and $\mathrm{Emb}_{2,3}: L(C_2)\to L(C_3)$. Clearly $\mathrm{Emb}_{2,3}\circ\mathrm{Emb}_{1,2}: L(C_1)\to L(C_3)$ sends holonomicaly independent paths into holonomicaly independent paths, and it also represents a C_3-equivalence class of embeddings $\mathrm{Emb}_{L(C_1)}: L(C_1)\to M$ as required. □

In particular one can choose compatible exact renormalization prescriptions for the refining sequence $\Delta\leqslant \mathrm{Sd}(\Delta)\leqslant\cdots\leqslant \mathrm{Sd}^n(\Delta)\leqslant\cdots$. In this case a solution of such chain of conditions would yield a sequence of projectively compatible measures $\{\mu_n\}$. Thus, the continuum limit of definition (4) would exist and define a measure μ_M on $\bar{\mathcal{A}}_M$.

It is important to remark that a collection of compatible embeddings that makes the exact renormalization prescriptions compatible can also be used to define the projective limit more commonly used in loop quantization and that the results are compatible in the following sense.

Theorem 4: *Given a family of compatible projections* $\{\pi_{n+1\to n}: \mathcal{A}_{\mathrm{Sd}^{n+1}(\Delta)\text{-}flat}\to\mathcal{A}_{\mathrm{Sd}^{n}(\Delta)\text{-}flat}\}$ *the projective limit of the spaces* $\mathcal{A}_{\mathrm{Sd}^{n}(\Delta)\text{-}flat}$ *is* $\tilde{\mathcal{A}}_{M,\Delta}$.

In addition, the collection of projectively compatible measures $\{\mu_n\}$ *defines a measure* $\tilde{\mu}_M$ *on* $\tilde{\mathcal{A}}_{M,\Delta}$ *which is compatible with our continuum limit measure in the sense that*

$$i_\star\tilde{\mu}_M=\mu_M,$$

where $i:\tilde{\mathcal{A}}_{M,\Delta}\to\bar{\mathcal{A}}_M$ *is the inclusion map.*

The proof of this theorem is a simple corollary of definitions. Of course the continuum limit in these cases is trivial in the sense that starting from a high enough n_0 for any $n\geqslant n_0\mu_n(i_C^\star f)$ is independent of n.

Our continuum limit of measures significantly extends the projective limit and this extension is of interest for physical applications. We say that because there are many examples of collections $\{\mu_n\}$ which are not projectively compatible, but as n increases they become more and more compatible in a way that makes the continuum limit exist. More significantly, the construction of measures by standard lattice gauge theory can be imported to a restricted version of our framework where we consider only regular cellular decompositions. From this point of view there is a whole body of evidence supporting the existence of nontrivial physically interesting measures.

In standard lattice gauge theory the used renormalization prescriptions are much weaker than our exact renormalization prescription: they ask only that some correlation functions chosen by their physical importance be preserved by coarse graining. Also, the allowed measures in LGT are of a very constrained type; only a few coupling constants completely specify their measures. With a smaller space of allowed measures and weaker renormalization prescriptions they are able to generate a flow in the space of coupling constants, which flows in the direction of refinement. We have followed and implemented their ideas in a few examples of our framework.[3]

What about compatible renormalization prescriptions relating the effective theories assigned to all the cellular decompositions? Consider two refining sequences that share a cellular decomposition C. A choice of compatible projections for a refining sequence completely determines the embedding map $\mathrm{Emb}_{L(C)}: L(C)\to M$. Thus, if one chooses independently the two families of compatible projections, it could happen that the induced embedding $\mathrm{Emb}_{L(C)}: L(C)\to M$ may be different for the two sequences. This would mean that the projection from $\bar{\mathcal{A}}_M$ to $\mathcal{A}_{C\text{-flat}}$ would depend on the coarse graining route. If the coarse graining between two effective theories depends on the coarse graining route, there would be one exact renormalization prescription per path and they would not be compatible with each other.

Again we stress that the lattice gauge theory experience tells us that nonexact renormalization

prescriptions are more interesting than exact ones. Then, the more relevant question would be about compatibility of (nonexact) renormalization prescriptions. In this context it is known that coarse graining does depend on the coarse graining route. A familiar example is performing Migdal-Kadanoff blocking in two dimensions first in the x direction and then in the y direction, or reversing the order of the blocking.

IV. ACTION OF "DIFFEOMORPHISMS"

Clearly general fiber bundle maps do not leave the spaces of C-flat connections invariant, but their action is very simple.

Theorem 5: *$\mathcal{A}_{C\text{-}flat} \subset \bar{\mathcal{A}}_M$ is not left invariant by the pull back of fiber bundle automorphisms. Instead*

$$f^\star(\mathcal{A}_{C\text{-}flat}) = \mathcal{A}_{\tilde{f}^{-1}C\text{-}flat},$$

where $\tilde{f}$ is the map induced by f in the base space.

We leave the simple proof of this theorem to the reader.

In this work the relevant fiber bundle maps are the ones that preserve the space of cellular decompositions of the base space that we are considering. Thus, we should focus either on piecewise analytic (also called stratified analytic) or on piecewise linear maps. However, we loosely refer to them as "diffeomorphisms."

For convenience we write $\mathcal{A}_{C\text{-flat}}/\bar{\mathcal{G}}_{M,\star}$ as $(\mathcal{A}/\mathcal{G})_C$.

If the theory under study has diffeomorphism symmetry our construction of spaces of effective configurations breaks that symmetry. However, we can define a space of "diffeomorphism" invariant configurations by injecting $(\mathcal{A}/\mathcal{G})_C$ into $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ and using the notion of "diffeomorphism" equivalence there.

Definition 7: Two connections modulo gauge $[A_1],[A_2] \in (\mathcal{A}/\mathcal{G})_C$ are said to be "diffeomorphism" equivalent,

$$[A_1] \sim_d [A_2],$$

if and only if there is a "diffeomorphism" $\tilde{f}$ of M (that has $\star \in M$ as a fixed point and) such that $\tilde{f}^\star[A_1]=[A_2]$. (We are considering the action $\tilde{f}^\star$ defined by $f^\star: \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star} \to \bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ for any bundle map f that induces $\tilde{f}$ on the base space and whose restriction to the fiber over $\star \in M$ is the identity.)

Consider two cellular decompositions C_1 and $C_2=\tilde{f}(C_1)$ [with $\tilde{f}(\star)=\star$]. Clearly the quotient spaces $(\mathcal{A}/\mathcal{G})_{C_1}/\sim_d$ and $(\mathcal{A}/\mathcal{G})_{C_2}/\sim_d$ are identified by $\tilde{f}^\star$. Moreover, the identification would be the same for any other "diffeomorphism" which relates the two cellular decompositions and has $\star \in M$ as a fixed point.

Thus, we define the space of "diffeomorphism" invariant effective configurations at scale $[C]$ as

$$\left(\frac{\mathcal{A}}{\mathcal{G}\times\mathcal{D}}\right)_{[C]} \doteq \frac{\left(\frac{\mathcal{A}}{\mathcal{G}}\right)_C}{\sim_d},$$

for any C in the "diffeomorphism" equivalence class $[C]$ (relative to the subgroup of "diffeomorphisms" that fixes $\star \in M$).

It is important to remark that the equivalence relation $\sim_d$ is not induced by the space of automorphisms of the abstract cellular complex underlying C. Even for a regular cellular decomposition whose automorphism group is large, $\sim_d$ is larger than the equivalence relation induced by automorphisms of C.

There is a construction of effective configurations—$\mathcal{A}_{K\text{-flat}} \subset \bar{\mathcal{A}}_M$ (where K is an abstract cellular complex)—which does not break the "diffeomorphism" symmetry. One can take quotient by the "diffeomorphism" group of $\mathcal{A}_{K\text{-flat}}$ to find a space of "diffeomorphism" invariant configurations finding the same space that we just defined.[5]

From the point of view of the framework mentioned above, the framework presented in this paper is *partially gauge fixed with respect to the "diffeomorphism" group*. The complex nature of the equivalence relation $\sim_d$ in $(\mathcal{A}/\mathcal{G})_C$ as compared to the transparent action of the "diffeomorphism" group in $\bar{\mathcal{A}}_M$ means that this partial gauge fixation would not help if we want to analyze the "diffeomorphism" symmetry. However, many other aspects (including those presented in this paper) are much simpler to study in the gauge fixed framework.

ACKNOWLEDGMENTS

The authors would like to thank Elisa Manrique, Robert Oeckl, and Axel Weber for the many hours of discussion about this subject. The authors also acknowledge exchange of ideas and constructive criticism from Michael Reisenberger, Abhay Ashtekar, Hanno Sahlmann, Danielle Perini, Fotini Markopoulou, and Lee Smolin during different stages of the development of this work. This work was partially supported by Grant Nos. CONACyT 40035-F, DGAPA IN108803-3, and SNI 21286.

APPENDIX

For the convenience of the reader we give a minimal recollection of definitions and properties needed in the main body of the paper. The subjects covered are

(1) generalized connections,
(2) cellular decompositions of a manifold and the limit $C \to M$.

Generalized connections

Generalized connections lie at the core of loop quantized theories.

Consider a G-principal fiber bundle (E, φ, M). In the physics literature it is customary to denote the space of smooth G-connections on that fiber bundle simply by $\mathcal{A}_M$. However, topologically different G-bundles over M lead to different spaces of smooth connections.

A *generalized connection* $A \in \bar{\mathcal{A}}_M$ is an assignment (a semigroup morphism) of holonomies to oriented paths in M,

$$A(\gamma): \varphi^{-1}(s(\gamma)) \to \varphi^{-1}(t(\gamma)),$$

where $s(\gamma)$ and $t(\gamma)$ denote the source and target points of γ. A holonomy must be compatible with the right G-action on the fiber bundle, $A(\gamma)[xg] = A(\gamma)[x]g$ for any $g \in G$ and any $x \in \varphi^{-1}(s(\gamma))$. Holonomies can be composed when the corresponding paths can. Asking that the assignment be a morphism means that $A(\gamma_2 \circ \gamma_1) = A(\gamma_2) \circ A(\gamma_1)$. We remark that paths of the form $c^{-1} \circ c$ are regarded as equivalent to the path that stays at the single point $s(c)$; thus $A(c^{-1}) = A(c)^{-1}$.

It is important to emphasize that there are no requirements of smoothness or even continuity for the holonomy assignments with respect to deformations of the path. Analogously the group of gauge transformations acts on holonomy assignments without any continuity restrictions. If one imposes restrictions of this type on the space of connections and the space of gauge transformations, one can recover the space of smooth connections modulo gauge.

At the gauge invariant level the focus changes to group homomorphisms from the group of $\star \in M$-based oriented loops (modulo an equivalence relation that prevents holonomical triviality), $\mathcal{P}_{M,\star}$, to G. The space of such homomorphisms is the space of gauge equivalence classes of generalized connections

$$\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star} = \mathrm{Hom}(\mathcal{P}_{M,\star}, G).$$

Again no continuity restrictions are imposed. If one imposes this type of conditions one can reconstruct the space of smooth connections modulo gauge. In fact, it is in exactly these terms these the reconstruction theorems are enounced and proven.[4]

Instead of placing continuity restrictions from classical considerations, one defines a different topology for $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$. By definition this is the weakest topology for which cylindrical functions, $\mathrm{Cyl}(\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star})$, are continuous. Cylindrical functions are functions on $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ induced by continuous functions on finitely many copies of G by the choice of a based loop for each copy of G. With respect to this topology, the space $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$ is independent of the topology of the total space of the fiber bundle. This finishes with our definition of $\bar{\mathcal{A}}_M/\bar{\mathcal{G}}_{M,\star}$.

Cellular decompositions and the limit $C \to M$

A typical example of a cellular decomposition is a triangulation of the sphere whose cells are four triangles, six edges, and four vertices.

A *cellular decomposition* C of a manifold M is a presentation of it as a union of disjoint cells,

$$M = \cup_{c_\alpha \in C} c_\alpha,$$

$$c_\alpha \cup c_\beta = \emptyset \quad \text{if } \alpha \neq \beta.$$

Each cell c_α is the image of an open convex polyhedron in $\mathbb{R}^{n(\alpha)}$ with $n(\alpha)$ between zero and $\dim M$. Then, we can specify a cell by a pair consisting of an open convex polyhedron in $\mathbb{R}^n$ and a map that takes the polyhedron to M,

$$c_\alpha = (p_\alpha, \phi_\alpha).$$

To be precise we must identify the types of maps we consider. In this work we consider maps $\phi_\alpha: \mathbb{R}^{n(\alpha)} \to M$ which are either piecewise analytic or piecewise linear.

The n-skeleton of a cellular decomposition $C^{(n)}$ is the collection of cells of dimension smaller or equal to n. For example, $C^{(\dim M)}$ is C and $C^{(0)}$ is the set of vertices of C. In our work we use the one-dimensional complex $C^{(1)}$ because it is a lattice.

Notice that the set of cellular decompositions of a manifold admits a partial order relation that tells us if a cellular decomposition C_2 is finer than another one C_1. We write

$$C_1 \leqslant C_2$$

if any cell in the coarser decomposition is a finite union of cells of the finer decomposition.

Triangulations (or simplicial decompositions) are particular examples of cellular decompositions where the polyhedra used are only simplices. In this category of cellular decompositions one can easily define the *barycentric subdivision* operation that produces a finer cellular decomposition, $\Delta \leqslant \mathrm{Sd}(\Delta)$. The triangulation $\mathrm{Sd}(\Delta)$ is easily constructed inductively.

(1) To each simplicial cell $\delta_\alpha \in \Delta$ one assigns a zero-dimensional cell in $\mathrm{Sd}(\Delta)$ called the barycenter of δ_α. (For zero-dimensional cells the barycenter coincides with the original cell.)
(2) For one-dimensional simplicial cells the cone over their boundary with vertex in their barycenter is a simplicial subdivision of δ_α. We call it the barycentric subdivision of δ_α, $\mathrm{Sd}(\delta_\alpha)$.
(3) The barycentric subdivision of the union of cells is by definition the union of the barycentric subdivision of the cells, $\mathrm{Sd}(\delta_\alpha \cup \delta_\beta) = \mathrm{Sd}(\delta_\alpha) \cup \mathrm{Sd}(\delta_\beta)$.
(4) Assume that Sd is defined for cells of dimension $n-1$.
(5) The boundary of an n-dimensional simplicial cell $\partial(\delta_\alpha)$ is the union of $(n-1)$-dimensional simplicial cells. The cone over $\mathrm{Sd}(\partial(\delta_\alpha))$ with vertex in the barycenter of δ_α is defined as $\mathrm{Sd}(\delta_\alpha)$.

The partial order of cellular decompositions is *directed* in the direction of refinement. This means that given any two cellular decompositions C_1, C_2 there is third one such that $C_1 \leqslant C_3$ and $C_2 \leqslant C_3$. With this property in mind, we restrict to piecewise analytic or piecewise linear cellular decompositions; the directionality property would not hold if we allowed any smooth map.

The directionality property is the one that will let us talk about the continuum limit as a limit towards "the finest cellular decomposition." For example, if there is any physically meaningful number calculated in an effective theory associated to a cellular decomposition $N(C)$, we would like it to have a finite limit when we remove the cutoff. Our notation is $N(M)=\lim_{C\to M} N(C)$, where the directionality property of the partial order gives a meaning to the limit "in terms of epsilons and deltas as in ordinary calculus." When one is talking about objects different than numbers one must specify the meaning of $\lim_{C\to M}$; here we simply remark that the directionality of the partial order makes it possible to define a variety of such limits.

Function group approach to unconstrained Hamiltonian Yang–Mills theory

Antti Salmela[a)]
Theoretical Physics Division, Department of Physical Sciences, University of Helsinki, P.O. Box 64, FIN-00014 Helsinki, Finland

(Received 26 May 2005; accepted 29 July 2005; published online 12 October 2005)

Starting from the temporal gauge Hamiltonian for classical pure Yang–Mills theory with the gauge group SU(2) a canonical transformation is initiated by parametrizing the Gauss law generators with three new canonical variables. The construction of the remaining variables of the new set proceeds through a number of intermediate variables in several steps, which are suggested by the Poisson bracket relations and the gauge transformation properties of these variables. The unconstrained Hamiltonian is obtained from the original one by expressing it in the new variables and then setting the Gauss law generators to zero. This Hamiltonian turns out to be local and it decomposes into a finite Laurent series in powers of the coupling constant. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2040327]

I. INTRODUCTION

An important and still open problem of quantum chromodynamics is to work out analytical predictions for the low-energy states of the theory. In order to make these predictions we need a proper quantum Yang–Mills theory which is valid in the low-energy regime. However, for many reasons it has turned out to be a difficult task to construct a useful physical Hamiltonian. One of the problems encountered is the implementation of Gauss's law in the Hamiltonian formalism. Up to this date, several methods have been developed to tackle it,[1–13] and this paper aims to provide a method, which is motivated by Lie's theory of function groups and their canonical representations.

Usually one starts with an extended quantum Hamiltonian where the physical subspace consists of states that are annihilated by the Gauss law generators. In this paper, by contrast, the order of quantization and constraining is reversed and Gauss's law is incorporated into the Hamiltonian formalism already at the classical level with the help of a suitable canonical transformation. Whenever one performs canonical transformations in a classical Hamiltonian gauge theory, one must choose the new variables in a way that makes their fundamental Poisson bracket relations compatible with the gauge algebra satisfied by the Gauss law generators. This is often done by the method of Abelianization, where the Gauss law generators are multiplied by suitable matrices that transform them into mutually involutive canonical momenta. In this paper, however, the opposite strategy is followed and the generator algebra is taken as given. The generators are then parametrized with the minimum number of canonical variables in such a way that the gauge algebra is satisfied as a consequence of the fundamental Poisson brackets of the new variables. The remaining variables of the new set are finally constructed by following the logical steps implied by this parametrization. The procedure is carried through for pure SU(2) Yang–Mills theory, but a generalization to other Lie groups is discussed in the end.

The actual construction of the canonical transformation is done in several steps in Sec. II. The procedure is a bit lengthy, but it may be worthwhile to give a presentation where the underlying logic is made clear and where possibilities for modifications and generalizations are also offered.

[a)]Electronic mail: antti.salmela@helsinki.fi

The final transformation is then used in the third section, where the unconstrained Hamiltonian is derived and expanded in a finite series involving both positive and negative powers of the coupling constant. The last section is devoted to conclusions. Throughout the paper Einstein's summation convention will be used with spatial and Lie algebra metrics normalized to positive unity. The generators of the SU(2) algebra are, as usual, taken to be $T_a=\frac{1}{2}\sigma_a$, where the σ_a's stand for the Pauli matrices.

II. CONSTRUCTION OF THE CANONICAL TRANSFORMATION

A. Parametrization of the Gauss law generators

We start with the temporal gauge ($A_0^a=0$) Hamiltonian

$$H=\int\left(\frac{1}{2}\Pi_{ka}\Pi^{ka}+\frac{1}{4}F_{kl}^{a}F_{a}^{kl}\right)\mathrm{d}^3\mathbf{x}, \tag{1}$$

where the field tensor F_{kl}^a is defined by

$$F_{kl}^{a}=\partial_l A_k^a-\partial_k A_l^a+g\varepsilon_{bc}{}^{a}A_k^b A_l^c.$$

The variables $A_k^a(\mathbf{x})$ and $\Pi_{ka}(\mathbf{x})$ are canonically conjugate, i.e., they satisfy the fundamental Poisson bracket relations

$$\{A_k^a(\mathbf{x}),\Pi_{lb}(\mathbf{y})\}=\delta_{kl}\delta^a{}_b\delta(\mathbf{x}-\mathbf{y}).$$

From these relations it follows that the Gauss law generators

$$G_a=\partial^k\Pi_{ka}-g\varepsilon_b{}^c{}_a A^{kb}\Pi_{kc} \tag{2}$$

obey the SU(2) algebra

$$\{G_a(\mathbf{x}),G_b(\mathbf{y})\}=-g\varepsilon_{ab}{}^{c}G_c(\mathbf{y})\delta(\mathbf{x}-\mathbf{y}). \tag{3}$$

They also generate time-independent gauge transformations of the canonical variables as follows:

$$\begin{aligned}\{G_a(\mathbf{x}),A_k^b(\mathbf{y})\}&=-\delta_a{}^b\partial_k^{(x)}\delta(\mathbf{x}-\mathbf{y})-g\varepsilon_{ca}{}^{b}A_k^c(\mathbf{y})\delta(\mathbf{x}-\mathbf{y}),\\ \{G_a(\mathbf{x}),\Pi_{kb}(\mathbf{y})\}&=-g\varepsilon^{c}{}_{ab}\Pi_{kc}(\mathbf{y})\delta(\mathbf{x}-\mathbf{y}).\end{aligned} \tag{4}$$

The canonical equations of motion

$$\dot{A}_k^a(\mathbf{x})=\frac{\delta H}{\delta\Pi_a^k(\mathbf{x})},\quad \dot{\Pi}_{ka}(\mathbf{x})=-\frac{\delta H}{\delta A^{ka}(\mathbf{x})} \tag{5}$$

reproduce the dynamical Yang–Mills equations

$$\ddot{A}_k^a(\mathbf{x})-\left[\delta^a{}_c\partial^l-g\varepsilon_{bc}{}^{a}A^{lb}(\mathbf{x})\right]F_{kl}^{c}(\mathbf{x})=0,$$

but not Gauss's law

$$G_a(\mathbf{x})=0.$$

However, the Gauss law generators are constants of motion, i.e.,

$$\dot{G}_a(\mathbf{x})=0$$

in the dynamics described by the equations (5). This property ensures that the implementation of Gauss's law can be done consistently with the Hamiltonian equations of motion. Unfortunately we cannot just use (2) to eliminate redundant coordinates in the limit $G_a\to 0$, because we do not know

which coordinates to eliminate or how to deal with the canonical conjugates of these redundant variables.

The first stage in the function group approach consists of replacing the Gauss law generators with such canonical variables that will vanish in the limit when Gauss's law is put into force. At this point we recall that in Lie's work a function group is defined as a set of variables equipped with Poisson brackets that close on the set.[14] According to Lie, every function group can be transformed into a form where every variable either has a canonically conjugate counterpart in the set or its Poisson brackets with the remaining variables vanish. Applying this idea to the function group formed by the G_a's, we parametrize it with three canonical variables p_1, p_2, and q_2 as follows:

$$\begin{aligned} G_1 &= \sqrt{p_1^2 - p_2^2}\cos(gq_2), \\ G_2 &= -\sqrt{p_1^2 - p_2^2}\sin(gq_2), \\ G_3 &= p_2. \end{aligned} \tag{6}$$

It is easy to check that the SU(2) algebra relations (3) are satisfied if the Poisson brackets of the new variables are canonical, i.e., if

$$\{q_2(\mathbf{x}), p_2(\mathbf{y})\} = \delta(\mathbf{x} - \mathbf{y})$$

and all the other brackets vanish. Conversely, we can invert this transformation and check that the variables

$$\begin{aligned} p_1 &= \sqrt{G_1^2 + G_2^2 + G_3^2}, \\ p_2 &= G_3, \\ q_2 &= -\frac{2}{g}\arctan\left(\frac{\sqrt{G_1^2 + G_2^2} - G_1}{G_2}\right) \end{aligned} \tag{7}$$

satisfy the fundamental Poisson bracket relations by virtue of the algebra (3).

The parametrization (6) is by no means the only possibility of defining a canonical representation, but it is one of the simplest with respect to the properties of the SU(2) algebra. Namely, Eq. (3) allows us to identify the G_a's with the basis vectors of the SU(2) algebra and the Poisson bracket with the commutator. We can now make use of the fact that for all semisimple Lie groups the Casimir operators together with the basis of the Cartan subalgebra span an Abelian subspace of the enveloping algebra. With higher-dimensional Lie groups this Abelian subspace can be augmented by Casimir operators of some lower-dimensional subalgebras. Since all canonical momenta must have vanishing Poisson brackets with each other, we see that the maximal set of momenta can be obtained from the maximal Abelian subspace of the enveloping algebra. This is the idea behind the transformation (7), where we now recognize p_1^2 as the Casimir operator of SU(2) and p_2 as the usual basis vector for the Cartan subalgebra. Once this choice has been made, the form of q_2 follows from the consistency of the canonical Poisson brackets with the algebra (3). However, the fundamental Poisson bracket relations do not determine the canonical conjugate of p_1 uniquely and we can thus leave the specific form of q_1 open at this stage. The next step is to extend the transformation (7) to the remaining variables.

B. Gauge-invariant variables

Let ξ_i stand for any new canonical variable not equal to those already fixed. By the requirement that the Poisson brackets between ξ_i and the members of the set $\{q_1, p_1, q_2, p_2\}$ vanish and with the help of the parametrization (6) we see that

$$\{G_a(\mathbf{x}),\xi_i(\mathbf{y})\}=0, \quad a=1,2,3, \tag{8a}$$

$$\frac{\delta\xi_i(\mathbf{y})}{\delta p_1(\mathbf{x})}=0. \tag{8b}$$

In particular, Eq. (8a) means that all the remaining variables must be invariant under topologically trivial gauge transformations. Since we have already defined three non-gauge-invariant variables (q_1,q_2,p_2), they completely fix the gauge angles (modulo constant gauge transformations) in the new set of variables. The gauge-invariant fields must therefore be constructed by transforming the old variables into a gauge where q_1, q_2, and p_2 are absent. Note that the term "gauge" does not imply neglecting any dynamical degrees of freedom at this stage, it only describes the way that the gauge-invariant variables of the new set are formed. In other words, the new variables consist of both gauge-dependent and gauge-invariant degrees of freedom. Although it may sound a little paradoxical, the gauge-invariant variables also satisfy a gauge condition due to the fact that, by construction, the gauge-dependent degrees of freedom have been transformed away. (This procedure is discussed in a more general context in Ref. 4.)

Let us begin with the elimination of q_2 and p_2. When these variables tend to zero, Eq. (6) shows that the components G_a tend to $\delta_{a1}p_1$. The intermediate variables $\hat{A}_k^a$ and $\hat{\Pi}_{ka}$ are then determined by the requirement that this property holds exactly, i.e.,

$$\begin{aligned}\hat{A}_k^a &= (O_1)^a{}_b A_k^b - \frac{1}{2g}\varepsilon_{bc}{}^a\left(O_1\partial_k O_1^T\right)^{cb},\\ \hat{\Pi}_{ka} &= (O_1)_a{}^b \Pi_{kb},\end{aligned} \tag{9}$$

where the orthogonal matrix O_1 satisfies the relation

$$\hat{G}_a=(O_1)_a{}^b G_b=\delta_{a1}p_1. \tag{10}$$

This is clearly fulfilled if we take

$$O_1=\begin{pmatrix} \sqrt{1-\left(\frac{p_2}{p_1}\right)^2}\cos(gq_2) & -\sqrt{1-\left(\frac{p_2}{p_1}\right)^2}\sin(gq_2) & \frac{p_2}{p_1} \\ \frac{p_2}{p_1}\cos(gq_2) & -\frac{p_2}{p_1}\sin(gq_2) & -\sqrt{1-\left(\frac{p_2}{p_1}\right)^2} \\ \sin(gq_2) & \cos(gq_2) & 0 \end{pmatrix} \tag{11a}$$

$$=\begin{pmatrix} \frac{G_1}{\sqrt{G_1^2+G_2^2+G_3^2}} & \frac{G_2}{\sqrt{G_1^2+G_2^2+G_3^2}} & \frac{G_3}{\sqrt{G_1^2+G_2^2+G_3^2}} \\ \frac{G_1G_3}{\sqrt{G_1^2+G_2^2}\sqrt{G_1^2+G_2^2+G_3^2}} & \frac{G_2G_3}{\sqrt{G_1^2+G_2^2}\sqrt{G_1^2+G_2^2+G_3^2}} & -\frac{\sqrt{G_1^2+G_2^2}}{\sqrt{G_1^2+G_2^2+G_3^2}} \\ -\frac{G_2}{\sqrt{G_1^2+G_2^2}} & \frac{G_1}{\sqrt{G_1^2+G_2^2}} & 0 \end{pmatrix}. \tag{11b}$$

It is interesting to note that the condition (10) falls in the category of Abelian gauges,[15] where the gauge is partially fixed by diagonalizing some homogeneously transforming object. In our case this object is the Gauss law generator $G=G^aT_a$, which is transformed into the direction of T_1. The residual U(1) gauge transformations are generated by T_1, and Eq. (10) then suggests that q_1 and p_1 are associated with this gauge freedom. More precisely, using the inverse formula (7) together with the properties (4) we can calculate the brackets

$$\{p_1(\mathbf{x}),\widehat{A}^a_k(\mathbf{y})\} = -\,\delta^a{}_1\partial^{(x)}_k\delta(\mathbf{x}-\mathbf{y}) - g\varepsilon_{b1}{}^a\widehat{A}^b_k(\mathbf{y})\,\delta(\mathbf{x}-\mathbf{y}),$$
$$\{p_1(\mathbf{x}),\widehat{\Pi}_{ka}(\mathbf{y})\} = -\,g\varepsilon^b{}_{1a}\widehat{\Pi}_{kb}(\mathbf{y})\,\delta(\mathbf{x}-\mathbf{y}), \tag{12}$$

which prove that p_1 indeed generates U(1) rotations in the direction of T_1. On the other hand,

$$\{p_1(\mathbf{x}),\widehat{A}^a_k(\mathbf{y})\} = -\,\frac{\delta\widehat{A}^a_k(\mathbf{y})}{\delta q_1(\mathbf{x})}, \quad \{p_1(\mathbf{x}),\widehat{\Pi}_{ka}(\mathbf{y})\} = -\,\frac{\delta\widehat{\Pi}_{ka}(\mathbf{y})}{\delta q_1(\mathbf{x})},$$

and combining these equations with the brackets (12) we get the following functional differential equations for the fields $\widehat{A}^a_k$ and $\widehat{\Pi}_{ka}$:

$$\frac{\delta\widehat{A}^a_k(\mathbf{y})}{\delta q_1(\mathbf{x})} = \delta^a{}_1\partial^{(x)}_k\delta(\mathbf{x}-\mathbf{y}) + g\varepsilon_{b1}{}^a\widehat{A}^b_k(\mathbf{y})\,\delta(\mathbf{x}-\mathbf{y}),$$

$$\frac{\delta\widehat{\Pi}_{ka}(\mathbf{y})}{\delta q_1(\mathbf{x})} = g\varepsilon^b{}_{1a}\widehat{\Pi}_{kb}(\mathbf{y})\,\delta(\mathbf{x}-\mathbf{y}).$$

Given that these equations hold, it is then easy to see that new fields $\mathcal{A}^a_k$ and π_{ka} defined by

$$\mathcal{A}^a_k = (O_2)^a{}_b\widehat{A}^b_k - \frac{1}{2g}\varepsilon_{bc}{}^a\left(O_2\partial_k O_2^T\right)^{cb},$$
$$\pi_{ka} = (O_2)_a{}^b\widehat{\Pi}_{kb}, \tag{13}$$

$$O_2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(gq_1) & -\sin(gq_1) \\ 0 & \sin(gq_1) & \cos(gq_1) \end{pmatrix} \tag{14}$$

are independent of q_1, i.e.,

$$\frac{\delta\mathcal{A}^a_k(\mathbf{y})}{\delta q_1(\mathbf{x})} = 0, \quad \frac{\delta\pi_{ka}(\mathbf{y})}{\delta q_1(\mathbf{x})} = 0. \tag{15}$$

Combining the transformations (9) and (13) we can express the new variables in terms of the original fields A^a_k, Π_{ka} and the variables $\{q_1,p_1,q_2,p_2\}$. Employing formulas (4) and (6) together with the identity

$$\{G_a(\mathbf{x}),q_1(\mathbf{y})\} = -\,\frac{\delta G_a(\mathbf{x})}{\delta p_1(\mathbf{y})}$$

it is then a straightforward albeit rather lengthy exercise to check that the new variables are really gauge invariant,

$$\{G_a(\mathbf{x}),\mathcal{A}^b_k(\mathbf{y})\} = 0, \quad \{G_a(\mathbf{x}),\pi_{kb}(\mathbf{y})\} = 0.$$

The requirement (8a) is thus satisfied, but this is not yet sufficient to make $\mathcal{A}^a_k$ and π_{ka} independent of p_1. Moreover, the new fields are redundant in number, because they satisfy the relation

$$\mathcal{G}_a = \partial^k\pi_{ka} - g\varepsilon_b{}^c{}_a\mathcal{A}^{kb}\pi_{kc} = \delta_{a1}p_1, \tag{16}$$

which is actually more like a functional identity rather than a constraint, because it follows immediately from the transformations (9) and (13). Finally, $\mathcal{A}^a_k$ and π_{ka} are not canonical variables

due to the fact that the gauge transformation matrices (11) and (14) depend on the original fields. Employing the fundamental Poisson brackets of the original variables and the gauge transformation properties (4) it is relatively straightforward to work out the brackets of $\mathcal{A}_k^a$ and π_{ka}, but the calculations are lengthy. In fact, it becomes almost inevitable to use computer software capable of symbolic manipulations to perform these extensive calculations. Eventually we obtain the following result:

$$\begin{aligned}\{\mathcal{A}_k^a(\mathbf{x}),\pi_{lb}(\mathbf{y})\} &= \frac{1}{p_1(\mathbf{y})}\left[\delta^a{}_b\pi_{l1}(\mathbf{y})-\delta_{b1}\pi_l^a(\mathbf{y})\right]\partial_k^{(x)}\delta(\mathbf{x}-\mathbf{y})\\ &\quad+\left[\frac{g}{2p_1(\mathbf{y})}\left(\delta^a{}_1\varepsilon_{bc}{}^d+\delta_{b1}\varepsilon^a{}_c{}^d+\delta^d{}_1\varepsilon^a{}_{bc}+\delta_{c1}\varepsilon^a{}_b{}^d\right)\mathcal{A}_k^c(\mathbf{y})\pi_{ld}(\mathbf{y})+\delta_{kl}\delta^a{}_b\right]\delta(\mathbf{x}-\mathbf{y})\\ &\quad+\left[\delta^a{}_1\partial_k^{(x)}-g\varepsilon_{c1}{}^a\mathcal{A}_k^c(\mathbf{x})\right]\frac{\delta\pi_{lb}(\mathbf{y})}{\delta p_1(\mathbf{x})}+g\varepsilon^c{}_{1b}\pi_{lc}(\mathbf{y})\frac{\delta\mathcal{A}_k^a(\mathbf{x})}{\delta p_1(\mathbf{y})},\end{aligned}\tag{17a}$$

$$\begin{aligned}\{\mathcal{A}_k^a(\mathbf{x}),\mathcal{A}_l^b(\mathbf{y})\} &= \frac{1}{g}\varepsilon_1{}^{ab}\partial_l^{(y)}\left[\frac{1}{p_1(\mathbf{y})}\partial_k^{(x)}\delta(\mathbf{x}-\mathbf{y})\right]+\frac{1}{p_1(\mathbf{y})}\left[\delta^{ab}\mathcal{A}_{l1}(\mathbf{y})-\delta^b{}_1\mathcal{A}_l^a(\mathbf{y})\right]\partial_k^{(x)}\delta(\mathbf{x}-\mathbf{y})\\ &\quad-\partial_l^{(y)}\left[\frac{1}{p_1(\mathbf{y})}\left(\delta^{ab}\mathcal{A}_{k1}(\mathbf{y})-\delta^a{}_1\mathcal{A}_k^b(\mathbf{y})\right)\delta(\mathbf{x}-\mathbf{y})\right]\\ &\quad+\frac{g}{2p_1(\mathbf{y})}\left(\delta^a{}_1\varepsilon^b{}_{cd}+\delta^b{}_1\varepsilon^a{}_{cd}+\delta_{d1}\varepsilon^{ab}{}_c+\delta_{c1}\varepsilon^{ab}{}_d\right)\mathcal{A}_k^c(\mathbf{y})\mathcal{A}_l^d(\mathbf{y})\delta(\mathbf{x}-\mathbf{y})\\ &\quad+\left[\delta^a{}_1\partial_k^{(x)}-g\varepsilon_{c1}{}^a\mathcal{A}_k^c(\mathbf{x})\right]\frac{\delta\mathcal{A}_l^b(\mathbf{y})}{\delta p_1(\mathbf{x})}-\left[\delta^b{}_1\partial_l^{(y)}-g\varepsilon_{c1}{}^b\mathcal{A}_l^c(\mathbf{y})\right]\frac{\delta\mathcal{A}_k^a(\mathbf{x})}{\delta p_1(\mathbf{y})},\end{aligned}\tag{17b}$$

$$\begin{aligned}\{\pi_{ka}(\mathbf{x}),\pi_{lb}(\mathbf{y})\} &= \frac{g}{2p_1(\mathbf{y})}\left(\delta_{a1}\varepsilon_b{}^{cd}+\delta_{b1}\varepsilon_a{}^{cd}+\delta^d{}_1\varepsilon_{ab}{}^c+\delta^c{}_1\varepsilon_{ab}{}^d\right)\pi_{kc}(\mathbf{y})\pi_{ld}(\mathbf{y})\delta(\mathbf{x}-\mathbf{y})\\ &\quad-g\varepsilon^c{}_{1a}\pi_{kc}(\mathbf{x})\frac{\delta\pi_{lb}(\mathbf{y})}{\delta p_1(\mathbf{x})}+g\varepsilon^c{}_{1b}\pi_{lc}(\mathbf{y})\frac{\delta\pi_{ka}(\mathbf{x})}{\delta p_1(\mathbf{y})}.\end{aligned}\tag{17c}$$

As there are redundant coordinates in this set of variables, we should verify that these brackets are compatible with (16). Indeed, starting from the brackets (17) it is possible to derive the result

$$\{\mathcal{G}_a(\mathbf{x}),\mathcal{A}_k^b(\mathbf{y})\}=0,\quad \{\mathcal{G}_a(\mathbf{x}),\pi_{kb}(\mathbf{y})\}=0,$$

which is consistent with (15) and (16). Our next task is to parametrize $\mathcal{A}_k^a$ and π_{ka} with new canonical variables in such a way that the relations (16) and (17) are satisfied.

C. Canonical variables

The elimination of the residual U(1) gauge degree of freedom with the transformation (13) was rather symbolic by nature, because the form of q_1 was not specified. The advantage of doing so is the fact that the Poisson brackets (17) now hold for all possible U(1) gauges and we can thus experiment with different gauge choices. Once a choice is made, its consistency with the brackets (17) then yields equations that determine the p_1 dependence of $\mathcal{A}_k^a$ and π_{ka}. The ingredients for choosing the gauge can be read off from the transformation formula (13). It is seen that the available objects fall in three categories, where the pairs $(\hat{A}_k^2,\hat{A}_k^3)$ and $(\hat{\Pi}_{k2},\hat{\Pi}_{k3})$ form SO(2) doublets, the components $\hat{\Pi}_{k1}$ are invariant and $\hat{A}_k^1$ transforms as a photon. Although every gauge is possible from the physical point of view, yet in practice some gauges are not manifestly compatible with the brackets (17). For example, in the Coulomb gauge we should choose q_1 in such a way that the equation $\partial^k\mathcal{A}_k^1=0$ would hold as a functional identity, as indicated by (15).

Therefore the Poisson brackets $\{\partial^k \mathcal{A}_k^1(\mathbf{x}), \partial^l \mathcal{A}_l^1(\mathbf{y})\}$ should also vanish identically, but according to the relations (17b) this is not the case. Probably this contradiction stems from the canonical structure of the variables already fixed, and the problem could possibly be circumvented by adjusting q_1 and the definitions (7) suitably.

In the following calculations the unitary gauge

$$\pi_{12}(\mathbf{x}) = 0$$

will be employed. Its consistency with the resulting identity $\{\pi_{12}(\mathbf{x}), \pi_{12}(\mathbf{y})\}=0$ is obvious and it corresponds to defining q_1 by

$$q_1 = \frac{2}{g} \arctan\left(\frac{\sqrt{\widehat{\Pi}_{12}^2 + \widehat{\Pi}_{13}^2} - \widehat{\Pi}_{13}}{\widehat{\Pi}_{12}} \right). \tag{18}$$

Using formulas (4), (7), and (11b) it is a straightforward but lengthy calculation to verify that the fundamental Poisson bracket relations between q_1 and the variables $\{p_1, q_2, p_2\}$ indeed hold. Now the functional identities

$$\{\mathcal{A}_k^a(\mathbf{x}), \pi_{12}(\mathbf{y})\} = 0, \quad \{\pi_{ka}(\mathbf{x}), \pi_{12}(\mathbf{y})\} = 0$$

combined with the brackets (17) give the following equations:

$$\frac{\delta \mathcal{A}_k^a(\mathbf{x})}{\delta p_1(\mathbf{y})} = -\frac{1}{g p_1(\mathbf{y})} \frac{\pi_{11}(\mathbf{y})}{\pi_{13}(\mathbf{y})} \delta^a{}_2 \partial_k^{(x)} \delta(\mathbf{x}-\mathbf{y}) + \frac{1}{\pi_{13}(\mathbf{y})} \left(\frac{\pi_{11}(\mathbf{y})}{p_1(\mathbf{y})} \varepsilon_{b2}{}^a \mathcal{A}_k^b(\mathbf{y}) - \frac{1}{g} \delta_{k1} \delta^a{}_2 \right) \delta(\mathbf{x}-\mathbf{y}),$$

$$\frac{\delta \pi_{ka}(\mathbf{x})}{\delta p_1(\mathbf{y})} = \frac{1}{p_1(\mathbf{y})} \frac{\pi_{11}(\mathbf{y})}{\pi_{13}(\mathbf{y})} \varepsilon^b{}_{2a} \pi_{kb}(\mathbf{y}) \delta(\mathbf{x}-\mathbf{y}).$$

At first sight these equations look a bit frightening, but they turn out to be solvable with a reasonable effort. The solution can be written as a gauge transformation in the direction of T_2,

$$\mathcal{A}_k^a = (O_3)^a{}_b \left(\mathcal{Q}_k^b - \frac{1}{g} \delta_{k1} \delta^b{}_2 \frac{p_1}{\mathcal{P}_{11}} \cos\phi \right) - \frac{1}{2g} \varepsilon_{bc}{}^a \left(O_3 \partial_k O_3^T \right)^{cb},$$
$$\pi_{ka} = (O_3)_a{}^b \mathcal{P}_{kb}, \tag{19}$$

with

$$O_3 = \begin{pmatrix} \sin\phi & 0 & -\cos\phi \\ 0 & -1 & 0 \\ -\cos\phi & 0 & -\sin\phi \end{pmatrix},$$
$$\sin\phi = \frac{\beta}{p_1}, \tag{20}$$

where $\mathcal{Q}_k^a$, $\mathcal{P}_{ka}$, and β are constants of integration, i.e.,

$$\frac{\delta \mathcal{Q}_k^a(\mathbf{x})}{\delta p_1(\mathbf{y})} = 0, \quad \frac{\delta \mathcal{P}_{ka}(\mathbf{x})}{\delta p_1(\mathbf{y})} = 0, \quad \frac{\delta \beta(\mathbf{x})}{\delta p_1(\mathbf{y})} = 0,$$

and

$$\mathcal{P}_{12}(\mathbf{x}) = \mathcal{P}_{13}(\mathbf{x}) = 0. \tag{21}$$

These constant fields fulfill both of the requirements (8), and therefore they should be adopted as new variables. The transformation formula is the inverse of (19), that is,

$$\begin{gathered}\mathcal{Q}_k^a = (O_3)^a{}_b\left(\mathcal{A}_k^b + \frac{1}{g}\delta_{k1}\delta^b{}_2 p_1 \frac{\pi_{13}}{\pi_{11}^2 + \pi_{13}^2}\right) - \frac{1}{2g}\varepsilon_{bc}{}^a\left(O_3\partial_k O_3^T\right)^{cb}, \\ \mathcal{P}_{ka} = (O_3)_a{}^b\pi_{kb},\end{gathered} \tag{22}$$

where we now write the gauge angle as

$$\sin\phi = \frac{\pi_{11}}{\sqrt{\pi_{11}^2 + \pi_{13}^2}}, \quad \cos\phi = -\frac{\pi_{13}}{\sqrt{\pi_{11}^2 + \pi_{13}^2}}. \tag{23}$$

Note that the matrix O_3 is both orthogonal and symmetric.

In order to proceed towards our final canonical transformation we must now find out whether the newest set of variables can be made canonical in accordance with the relation (16). Using (19) it is easy to see that the corresponding relation in the new variables reads

$$\partial^k\mathcal{P}_{ka} - g\varepsilon_b{}^c{}_a\mathcal{Q}^{kb}\mathcal{P}_{kc} = \delta_{a1}\beta. \tag{24}$$

The Poisson brackets are evaluated by inserting expressions (22) into the relations (17). Again this is a formidable calculation which requires extensive use of computer software. Here is the result,

$$\begin{gathered}\{\mathcal{Q}_k^a(\mathbf{x}), \mathcal{P}_{lb}(\mathbf{y})\} = \delta_{kl}\delta^a{}_b\delta(\mathbf{x}-\mathbf{y}), \quad k \neq 1, \\ \{\mathcal{Q}_1^a(\mathbf{x}), \mathcal{P}_{11}(\mathbf{y})\} = \delta^a{}_1\delta(\mathbf{x}-\mathbf{y}), \\ \{\mathcal{Q}_1^a(\mathbf{x}), \mathcal{P}_{lb}(\mathbf{y})\} = -\frac{1}{\mathcal{P}_{11}(\mathbf{y})}\left[\delta^a{}_b\mathcal{P}_{l1}(\mathbf{y}) - \delta_{b1}\mathcal{P}_l^a(\mathbf{y})\right]\delta(\mathbf{x}-\mathbf{y}), \quad l \neq 1, \\ \{\mathcal{Q}_k^a(\mathbf{x}), \mathcal{Q}_l^b(\mathbf{y})\} = 0, \quad k \neq 1, \quad l \neq 1, \\ \{\mathcal{Q}_k^a(\mathbf{x}), \mathcal{Q}_1^b(\mathbf{y})\} = -\frac{1}{g}\varepsilon_1{}^{ab}\frac{1}{\mathcal{P}_{11}(\mathbf{y})}\partial_k^{(x)}\delta(\mathbf{x}-\mathbf{y}) + \frac{1}{\mathcal{P}_{11}(\mathbf{y})}\left[\delta^{ab}\mathcal{Q}_{k1}(\mathbf{y}) - \delta^a{}_1\mathcal{Q}_k^b(\mathbf{y})\right]\delta(\mathbf{x}-\mathbf{y}), \quad k \neq 1,\end{gathered} \tag{25}$$

$$\begin{gathered}\{\mathcal{Q}_1^a(\mathbf{x}), \mathcal{Q}_1^b(\mathbf{y})\} = -\frac{1}{\mathcal{P}_{11}(\mathbf{y})}\left[\delta^a{}_1\mathcal{Q}_1^b(\mathbf{y}) - \delta^b{}_1\mathcal{Q}_1^a(\mathbf{y}) + \frac{1}{g}\varepsilon_1{}^{ab}\frac{\beta(\mathbf{y}) - \partial_1^{(y)}\mathcal{P}_{11}(\mathbf{y})}{\mathcal{P}_{11}(\mathbf{y})}\right]\delta(\mathbf{x}-\mathbf{y}), \\ \{\mathcal{P}_{ka}(\mathbf{x}), \mathcal{P}_{lb}(\mathbf{y})\} = 0, \\ \{\beta(\mathbf{x}), \mathcal{Q}_k^a(\mathbf{y})\} = -\delta^a{}_1\partial_k^{(x)}\delta(\mathbf{x}-\mathbf{y}) - g\varepsilon_{b1}{}^a\mathcal{Q}_k^b(\mathbf{y})\,\delta(\mathbf{x}-\mathbf{y}), \\ \{\beta(\mathbf{x}), \mathcal{P}_{ka}(\mathbf{y})\} = -g(1-\delta_{k1})\varepsilon^b{}_{1a}\mathcal{P}_{kb}(\mathbf{y})\,\delta(\mathbf{x}-\mathbf{y}).\end{gathered}$$

Remember that $\mathcal{P}_{12}=\mathcal{P}_{13}=0$ in these relations. It is now easy to construct the desired canonical fields. The brackets (25) suggest that we choose the pairs

$$(\mathcal{Q}_1^1, \mathcal{P}_{11}), \quad (\mathcal{Q}_k^a, \mathcal{P}_{ka}), \quad k \neq 1 \tag{26}$$

as canonically conjugate variables. If we then solve the remaining variables from Eq. (24),

$$\beta = \partial_1 \mathcal{P}_{11} + \sum_{k=2}^{3} \left(\partial_k \mathcal{P}_{k1} - g\varepsilon_b{}^c{}_1 \mathcal{Q}_k^b \mathcal{P}_{kc} \right), \tag{27a}$$

$$\mathcal{Q}_1^2 = -\frac{1}{g\mathcal{P}_{11}} \sum_{k=2}^{3} \left(\partial_k \mathcal{P}_{k3} - g\varepsilon_b{}^c{}_3 \mathcal{Q}_k^b \mathcal{P}_{kc} \right), \tag{27b}$$

$$\mathcal{Q}_1^3 = \frac{1}{g\mathcal{P}_{11}} \sum_{k=2}^{3} \left(\partial_k \mathcal{P}_{k2} - g\varepsilon_b{}^c{}_2 \mathcal{Q}_k^b \mathcal{P}_{kc} \right), \tag{27c}$$

it turns out that all the Poisson brackets in the set (25) involving these variables follow from the fundamental brackets of the pairs (26). Unfortunately the variables (26), although gauge-invariant and canonical, are still not useful for implementing the Gauss law. The reason is Eq. (20), which shows that β tends to zero in the limit when p_1 vanishes. Looking at expression (27a), we see that it would be difficult to implement the requirement $\beta \to 0$ using the variables (26). A suitable canonical transformation is needed.

D. Canonical U(1) transformation

Passing to the variables (26), we have replaced the original SU(2) fields with a set of gauge-invariant canonical fields. However, the Poisson brackets (25) show that these variables have an inner U(1) symmetry, which is generated by β. Note that this symmetry has nothing to do with the original SU(2) symmetry since all the variables (26) and the generator β, defined by Eq. (27a), are gauge invariant with respect to the generators G_a. Even so, we can apply the procedures of Secs. II A–II C also to this U(1) symmetry and choose β as a new canonical momentum variable, i.e.,

$$p_3 = \partial_1 \mathcal{P}_{11} + \sum_{k=2}^{3} \left(\partial_k \mathcal{P}_{k1} - g\varepsilon_b{}^c{}_1 \mathcal{Q}_k^b \mathcal{P}_{kc} \right). \tag{28}$$

The canonical conjugate of p_3 then determines the gauge angle associated with transformations generated by p_3, but again we leave the specific form of q_3 open at this stage. Since both q_3 and p_3 must have vanishing Poisson brackets with the remaining variables of the final canonical set, we conclude that the remaining variables must be functionally independent of q_3 and p_3. The elimination of q_3 can be done, as before, with a gauge transformation in the T_1 direction,

$$\begin{aligned} \widehat{\mathcal{Q}}_k^a &= (O_4)^a{}_b \mathcal{Q}_k^b - \frac{1}{2g} \varepsilon_{bc}{}^a \left(O_4 \partial_k O_4^T \right)^{cb}, \\ \widehat{P}_{ka} &= (O_4)_a{}^b \mathcal{P}_{kb}, \end{aligned} \tag{29}$$

where

$$O_4 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(gq_3) & -\sin(gq_3) \\ 0 & \sin(gq_3) & \cos(gq_3) \end{pmatrix}.$$

The Poisson brackets of the new variables follow from the algebra (25), the result being

$$\{\widehat{Q}_k^a(\mathbf{x}),\widehat{P}_{lb}(\mathbf{y})\}=\delta_{kl}\delta^a{}_b\delta(\mathbf{x}-\mathbf{y})+\left[\delta^a{}_1\partial_k^{(x)}-g\varepsilon_{c1}{}^a\widehat{Q}_k^c(\mathbf{x})\right]\frac{\delta\widehat{P}_{lb}(\mathbf{y})}{\delta p_3(\mathbf{x})}+g\varepsilon^c{}_{1b}\widehat{P}_{lc}(\mathbf{y})\frac{\delta\widehat{Q}_k^a(\mathbf{x})}{\delta p_3(\mathbf{y})},$$

$$\{\widehat{Q}_k^a(\mathbf{x}),\widehat{Q}_l^b(\mathbf{y})\}=\left[\delta^a{}_1\partial_k^{(x)}-g\varepsilon_{c1}{}^a\widehat{Q}_k^c(\mathbf{x})\right]\frac{\delta\widehat{Q}_l^b(\mathbf{y})}{\delta p_3(\mathbf{x})}-\left[\delta^b{}_1\partial_l^{(y)}-g\varepsilon_{c1}{}^b\widehat{Q}_l^c(\mathbf{y})\right]\frac{\delta\widehat{Q}_k^a(\mathbf{x})}{\delta p_3(\mathbf{y})},\tag{30}$$

$$\{\widehat{P}_{ka}(\mathbf{x}),\widehat{P}_{lb}(\mathbf{y})\}=-g\varepsilon^c{}_{1a}\widehat{P}_{kc}(\mathbf{x})\frac{\delta\widehat{P}_{lb}(\mathbf{y})}{\delta p_3(\mathbf{x})}+g\varepsilon^c{}_{1b}\widehat{P}_{lc}(\mathbf{y})\frac{\delta\widehat{P}_{ka}(\mathbf{x})}{\delta p_3(\mathbf{y})}.$$

For the sake of clarity only those brackets have been written down that hold for the actual variables

$$(\widehat{Q}_1^1,\widehat{P}_{11}),\quad(\widehat{Q}_k^a,\widehat{P}_{ka}),\quad k\neq 1.$$

In order to define variables independent of p_3 we must now specify the U(1) gauge by fixing q_3. In the following we choose

$$q_3=\frac{2}{g}\arctan\left(\frac{\sqrt{\mathcal{P}_{22}^2+\mathcal{P}_{23}^2}-\mathcal{P}_{23}}{\mathcal{P}_{22}}\right),\tag{31}$$

which corresponds to the identity

$$\widehat{P}_{22}(\mathbf{x})=0.\tag{32}$$

Making use of the brackets (25) it is possible to verify that q_3 and p_3 indeed satisfy

$$\{q_3(\mathbf{x}),p_3(\mathbf{y})\}=\delta(\mathbf{x}-\mathbf{y}),$$

while their brackets with the variables $\{q_1,p_1,q_2,p_2\}$ vanish due to the fact that both $\mathcal{Q}_k^a$ and $\mathcal{P}_{ka}$ meet the requirements (8). As before, the functional identities

$$\{\widehat{Q}_k^a(\mathbf{x}),\widehat{P}_{22}(\mathbf{y})\}=0,\quad\{\widehat{P}_{ka}(\mathbf{x}),\widehat{P}_{22}(\mathbf{y})\}=0$$

lead to the equations

$$\frac{\delta\widehat{Q}_k^a(\mathbf{x})}{\delta p_3(\mathbf{y})}=-\frac{1}{g\widehat{P}_{23}(\mathbf{y})}\delta_{k2}\delta^a{}_2\delta(\mathbf{x}-\mathbf{y}),$$

$$\frac{\delta\widehat{P}_{ka}(\mathbf{x})}{\delta p_3(\mathbf{y})}=0,$$

whose solutions read

$$\widehat{Q}_k^a=Q_k^a-\frac{1}{g}\delta_{k2}\delta^a{}_2\frac{p_3}{P_{23}},$$
$$\widehat{P}_{ka}=P_{ka},\tag{33}$$

where Q_k^a and P_{ka} are constants of integration, i.e.,

$$\frac{\delta Q_k^a(\mathbf{x})}{\delta p_3(\mathbf{y})} = 0, \quad \frac{\delta P_{ka}(\mathbf{x})}{\delta p_3(\mathbf{y})} = 0.$$

Now we choose these constants as new variables. Equation (28) then leads to the relation

$$\partial_1 P_{11} + \sum_{k=2}^{3} \left(\partial_k P_{k1} - g\varepsilon_b{}^c{}_1 Q_k^b P_{kc} \right) = 0, \tag{34}$$

which holds as a functional identity, implying that the new variables contain one redundant coordinate. The Poisson brackets of Q_k^a and P_{ka} are easily evaluated with the help of the relations (30). The result reads

$$\{Q_k^a(\mathbf{x}), P_{lb}(\mathbf{y})\} = \delta_{kl}\delta^a{}_b \delta(\mathbf{x}-\mathbf{y}) - \delta_{k2}\delta^a{}_2 \varepsilon^c{}_{1b} \frac{1}{P_{23}(\mathbf{y})} P_{lc}(\mathbf{y})\, \delta(\mathbf{x}-\mathbf{y}),$$

$$\{Q_k^a(\mathbf{x}), Q_l^b(\mathbf{y})\} = 0, \quad (k,a) \neq (2,2), \quad (l,b) \neq (2,2),$$

$$\{Q_k^a(\mathbf{x}), Q_2^2(\mathbf{y})\} = -\frac{1}{gP_{23}(\mathbf{y})} \left[\delta^a{}_1 \partial_k^{(x)} - g\varepsilon_{c1}{}^a Q_k^c(\mathbf{x}) \right] \delta(\mathbf{x}-\mathbf{y}), \quad (k,a) \neq (2,2), \tag{35}$$

$$\{Q_2^2(\mathbf{x}), Q_2^2(\mathbf{y})\} = 0,$$

$$\{P_{ka}(\mathbf{x}), P_{lb}(\mathbf{y})\} = 0,$$

showing that the pairs

$$(Q_1^1, P_{11}), \quad (Q_2^a, P_{2a}), \quad a = 1,3, \quad (Q_3^a, P_{3a}), \quad a = 1,2,3$$

are the most natural choice for final canonical variables. Solving (34) for the redundant coordinate,

$$Q_2^2 = \frac{1}{gP_{23}} \left(\partial^k P_{k1} - g\varepsilon_b{}^c{}_1 Q_3^b P_{3c} \right), \tag{36}$$

it is easy to see that all of the Poisson bracket relations (35) hold true. Our search for suitable canonical variables is now over.

E. Results

Starting from the original canonical fields (A_k^a, Π_{ka}) and passing through four sets of intermediate variables we have found the final canonical pairs

$$\begin{gathered} (q_i, p_i), \quad i = 1,2,3, \\ (Q_1^1, P_{11}), \\ (Q_2^a, P_{2a}), \quad a = 1,3, \\ (Q_3^a, P_{3a}), \quad a = 1,2,3. \end{gathered} \tag{37}$$

Equation (7) relates p_1, q_2, and p_2 to the original variables, and a formula for q_1 is obtained by combining Eqs. (18), (9), and (11b). The momentum p_3 is most easily calculated by combining Eqs. (20), (23), (13), and (9), while it takes successive applications of Eqs. (31), (22), (13), and (9) to work out a formula for q_3. The remaining variables of the set (37) are then obtained by performing the transformations (33), (29), (22), (13), and (9) one after the other. Again the

manipulations are so lengthy that computer assistance is required. Introducing the notation

$$\|X\| := \sqrt{X_a X^a}$$

for the Lie algebra norm, the results can be written as follows:

$$q_1 = \frac{2}{g}\arctan\left(\frac{\sqrt{\widehat{\Pi}_{12}^2+\widehat{\Pi}_{13}^2}-\widehat{\Pi}_{13}}{\widehat{\Pi}_{12}}\right), \tag{38a}$$

$$\widehat{\Pi}_{12} = \frac{1}{\|G\|}\left[\frac{G_3}{\sqrt{G_1^2+G_2^2}}\left(G_1\Pi_{11}+G_2\Pi_{12}\right)-\sqrt{G_1^2+G_2^2}\Pi_{13}\right],$$

$$\widehat{\Pi}_{13} = \frac{1}{\sqrt{G_1^2+G_2^2}}\left(-G_2\Pi_{11}+G_1\Pi_{12}\right),$$

$$q_2 = -\frac{2}{g}\arctan\left(\frac{\sqrt{G_1^2+G_2^2}-G_1}{G_2}\right), \tag{38b}$$

$$q_3 = \frac{2}{g}\arctan\left(\frac{\sqrt{\mathcal{P}_{22}^2+\mathcal{P}_{23}^2}-\mathcal{P}_{23}}{\mathcal{P}_{22}}\right), \tag{38c}$$

$$\mathcal{P}_{22} = \frac{1}{\|\mathcal{N}\|}\varepsilon^{abc}G_a\Pi_{1b}\Pi_{2c},$$

$$\mathcal{P}_{23} = \frac{1}{\|\mathcal{N}\|}\frac{1}{\|\Pi_1\|}\left(\delta^{ad}\delta^{bc}-\delta^{ab}\delta^{cd}\right)G_a\Pi_{1b}\Pi_{1c}\Pi_{2d},$$

$$\mathcal{N}_a = \varepsilon_a{}^{bc}G_b\Pi_{1c},$$

$$p_1 = \|G\|, \tag{38d}$$

$$p_2 = G_3, \tag{38e}$$

$$p_3 = \frac{G^a\Pi_{1a}}{\|\Pi_1\|}, \tag{38f}$$

$$Q_k^a = \Omega^a{}_b A_k^b - \frac{1}{2g}\varepsilon_{bc}{}^a\left(\Omega\partial_k\Omega^T\right)^{cb}, \tag{38g}$$

$$P_{ka} = \Omega_a{}^b\Pi_{kb}, \tag{38h}$$

where

$$\Omega_a{}^b = \left(O_4O_3O_2O_1\right)_a{}^b$$

$$= \delta_{a1}\frac{1}{\|\Pi_1\|}\Pi_1^b + \delta_{a2}\frac{1}{\|N\|}\varepsilon^{bcd}\Pi_{2c}\Pi_{1d} + \delta_{a3}\frac{1}{\|\Pi_1\|}\frac{1}{\|N\|}\left(\delta^{be}\delta^{cd} - \delta^{bc}\delta^{de}\right)\Pi_{1c}\Pi_{1d}\Pi_{2e}, \tag{39}$$

$$N_a = \varepsilon_a{}^{bc}\Pi_{1b}\Pi_{2c}.$$

This transformation is singular when $||\Pi_1||$ or $||N||$ vanishes, corresponding to points where the gauge angles (23) and (38c) become ambiguous. These singularities are Gribov ambiguities[16] peculiar to unitary gauges, and it is well known that such ambiguities appear in almost every gauge.[17]

When inverting the transformation (38), it should be noted that formula (38g) holds for variables of the set (37) only. The general expression reads

$$Q_k^a + \frac{1}{g}\delta_{k1}(O_4)^a{}_2\frac{p_1}{P_{11}}\sqrt{1-\left(\frac{p_3}{p_1}\right)^2} - \frac{1}{g}\delta_{k2}\delta^a{}_2\frac{p_3}{P_{23}}$$

$$= \Omega^a{}_b A_k^b - \frac{1}{2g}\varepsilon_{bc}{}^a\left(\Omega\partial_k\Omega^T\right)^{cb}.$$

This equation determines the original gauge potential A_k^a as a function of the variables (37), provided that we use Eqs. (27), (36), (29), and (33) to define those components Q_k^a that are not regarded as free variables. In the same way we can invert the momentum transformation equation (38h), taking into account the definitions (21) and (32). The result is

$$A_k^a = \left(\Omega^T\right)^a{}_b\left(Q_k^b + \frac{1}{g}\delta_{k1}(O_4)^b{}_2\frac{p_1}{P_{11}}\sqrt{1-\left(\frac{p_3}{p_1}\right)^2} - \frac{1}{g}\delta_{k2}\delta^b{}_2\frac{p_3}{P_{23}}\right) - \frac{1}{2g}\varepsilon_{bc}{}^a\left(\Omega^T\partial_k\Omega\right)^{cb}, \tag{40a}$$

$$\Pi_{ka} = \left(\Omega^T\right)_a{}^b P_{kb}, \tag{40b}$$

where

$$Q_1^2 = -\frac{1}{gP_{11}}\sum_{k=2}^{3}\left(\partial_k P_{k3} - g\varepsilon_b{}^c{}_3 Q_k^b P_{kc}\right) + \frac{1}{g}p_3\frac{P_{21}}{P_{11}P_{23}},$$

$$Q_1^3 = \frac{1}{gP_{11}}\left(\partial_3 P_{32} - \sum_{k=2}^{3} g\varepsilon_b{}^c{}_2 Q_k^b P_{kc}\right),$$

$$Q_2^2 = \frac{1}{gP_{23}}\left(\partial^k P_{k1} - g\varepsilon_b{}^c{}_1 Q_3^b P_{3c}\right), \tag{41}$$

$$P_{12} = P_{13} = P_{22} = 0,$$

and Ω^T is expressed in the variables (q_i, p_i), i.e.,

$$\Omega^T = \begin{pmatrix} \sqrt{1-\left(\frac{p_2}{p_1}\right)^2}\cos(gq_2) & \frac{p_2}{p_1}\cos(gq_2) & \sin(gq_2) \\ -\sqrt{1-\left(\frac{p_2}{p_1}\right)^2}\sin(gq_2) & -\frac{p_2}{p_1}\sin(gq_2) & \cos(gq_2) \\ \frac{p_2}{p_1} & -\sqrt{1-\left(\frac{p_2}{p_1}\right)^2} & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(gq_1) & \sin(gq_1) \\ 0 & -\sin(gq_1) & \cos(gq_1) \end{pmatrix}$$
$$\times \begin{pmatrix} \frac{p_3}{p_1} & 0 & \sqrt{1-\left(\frac{p_3}{p_1}\right)^2} \\ 0 & -1 & 0 \\ \sqrt{1-\left(\frac{p_3}{p_1}\right)^2} & 0 & -\frac{p_3}{p_1} \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(gq_3) & \sin(gq_3) \\ 0 & -\sin(gq_3) & \cos(gq_3) \end{pmatrix}.$$

The transformation equations can also be obtained from a generating functional of the form

$$F\left[p_1, q_2, p_3, \{Q_k^{a'}\}, \{\Pi_{ka}\}\right] = \int \mathcal{F}(\mathbf{x}) \mathrm{d}^3\mathbf{x}, \tag{42}$$

where

$$\mathcal{F} = \frac{2}{g}\eta p_1 \arctan\left(\frac{\sqrt{1-\left(\frac{p_3}{p_1}\right)^2}\|\Pi_1\| - \left[\Pi_{11}\sin(gq_2) + \Pi_{12}\cos(gq_2)\right]}{\sqrt{\Pi_{13}^2 - \left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2 + \left[\Pi_{11}\cos(gq_2) - \Pi_{12}\sin(gq_2)\right]^2}} \right)$$
$$+ \frac{2}{g}p_3 \arctan\left(\left[\|\Pi_1\|\left[N_1\sin(gq_2) + N_2\cos(gq_2)\right]\sqrt{1-(p_3/p_1)^2} \right.\right.$$
$$\left. + \eta\|N\|\left[\Pi_{13}^2 - \left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2 + \left[\Pi_{11}\cos(gq_2) - \Pi_{12}\sin(gq_2)\right]^2 \right]^{1/2} \right]$$
$$\times \left[\left(\sqrt{1-(p_3/p_1)^2}K_1 - \frac{p_3}{p_1}\|N\|\Pi_{11} \right)\sin(gq_2) \right.$$
$$\left. + \left(\sqrt{1-(p_3/p_1)^2}K_2 - \frac{p_3}{p_1}\|N\|\Pi_{12} \right)\cos(gq_2) \right] \Bigg/ \left[-(K_1^2 + K_2^2) + \left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2 N_3^2 \right.$$
$$\left. + \left[K_1\cos(gq_2) - K_2\sin(gq_2)\right]^2 + \left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2\left[N_1\cos(gq_2) - N_2\sin(gq_2)\right]^2 \right] \Bigg)$$
$$- Q^{ka'}\Omega_{a'}{}^{b}\Pi_{kb} + \frac{1}{2g}\varepsilon_{bc}{}^{a}\left(\Omega^T\partial_3\Omega\right)^{cb}\Pi_{3a} - \frac{1}{2g}\Pi_{11}N_1\partial_2\left(\frac{1}{\Pi_{12}^2 + \Pi_{13}^2}\right)$$
$$+ \frac{1}{g}\frac{\Pi_{21}(\Pi_{13}\partial_2\Pi_{12} - \Pi_{12}\partial_2\Pi_{13}) + \Pi_{11}(\Pi_{13}\partial_1\Pi_{12} - \Pi_{12}\partial_1\Pi_{13})}{\Pi_{12}^2 + \Pi_{13}^2}$$
$$- \frac{1}{g}\left[\partial_1\|\Pi_1\| + \partial_2\left(\|\Pi_1\|\frac{\Pi_{12}\Pi_{22} + \Pi_{13}\Pi_{23}}{\Pi_{12}^2 + \Pi_{13}^2} \right) \right]\arctan\left(\frac{K_1}{\|\Pi_1\|N_1} \right)$$

$$+\frac{1}{2g}\left[\partial_2\left(\frac{\Pi_{11}N_1}{\Pi_{12}^2+\Pi_{13}^2}\right)\right]\ln\left(\frac{\|N\|^2}{M^8}\right)$$

and

$$K_a=\varepsilon_a{}^{bc}\Pi_{1b}N_c=\left(\delta_a{}^c\delta^{bd}-\delta_a{}^d\delta^{bc}\right)\Pi_{1b}\Pi_{1c}\Pi_{2d}.$$

The components N_a are those defined in (39) and M denotes a constant with the dimension of energy. There is also a real phase η which can take the values ± 1. Expression (39) is used for the matrix Ω, and the primed index a' stands as a reminder of the fact that only independent components $Q_k^{a'}$, i.e., those included in the list (37) should be summed over. Now the transformation equations read

$$q_1(\mathbf{x})=\frac{\delta F}{\delta p_1(\mathbf{x})}, \tag{43a}$$

$$p_2(\mathbf{x})=-\frac{\delta F}{\delta q_2(\mathbf{x})}, \tag{43b}$$

$$q_3(\mathbf{x})=\frac{\delta F}{\delta p_3(\mathbf{x})}, \tag{43c}$$

$$P_{ka'}(\mathbf{x})=-\frac{\delta F}{\delta Q^{ka'}(\mathbf{x})}, \tag{43d}$$

$$A_k^a(\mathbf{x})=-\frac{\delta F}{\delta \Pi_a^k(\mathbf{x})}. \tag{43e}$$

Equations (43a)–(43c) reproduce Eqs. (38a), (38e), and (38c) in a form where the components G_a are expressed in the variables $\{p_1,q_2,p_3,\Pi_{1a}\}$ by inverting Eqs. (38d), (38b), and (38f), i.e.,

$$\begin{aligned}G_1=&\left(\frac{p_3}{p_1}\|\Pi_1\|\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]\right.\\&\left.-\eta\Pi_{13}\sqrt{\Pi_{13}^2-\left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2+\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]^2}\right)\\&\times\frac{p_1\cos(gq_2)}{\Pi_{13}^2+\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]^2},\end{aligned}$$

$$\begin{aligned}G_2=&-\left(\frac{p_3}{p_1}\|\Pi_1\|\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]\right.\\&\left.-\eta\Pi_{13}\sqrt{\Pi_{13}^2-\left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2+\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]^2}\right)\\&\times\frac{p_1\sin(gq_2)}{\Pi_{13}^2+\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]^2},\end{aligned} \tag{44}$$

$$\begin{aligned}G_3=&\left(\frac{p_3}{p_1}\|\Pi_1\|\Pi_{13}+\eta\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]\right.\\&\left.\times\sqrt{\Pi_{13}^2-\left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2+\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]^2}\right)\\&\times\frac{p_1}{\Pi_{13}^2+\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]^2},\end{aligned}$$

where the sign η must be chosen so that

$$\left(\frac{p_3}{p_1}\|\Pi_1\|\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]\right.$$

$$\left.-\eta\Pi_{13}\sqrt{\Pi_{13}^2-\left(\frac{p_3}{p_1}\right)^2\|\Pi_1\|^2+\left[\Pi_{11}\cos(gq_2)-\Pi_{12}\sin(gq_2)\right]^2}\right)\geqslant 0.$$

Equations (43d) and (38h) are equivalent, and with the help of Eqs. (38c), (38h), and (44) it is also possible to see the equivalence of Eqs. (43e) and (40a). Although the generating functional looks rather complicated, its mere existence is sufficient to confirm that the transformation (38) is canonical. We have now all the necessary tools at hand for constructing the physical Hamiltonian.

III. PHYSICAL VARIABLES

The greatest advantage in passing to the new variables (37) is the fact that their behavior in the limit $G_a\to 0$ is relatively simple to analyze. Of course, if we were to be exact, we would have to specify this limit precisely by starting from Eq. (2) and then defining suitable norms and function spaces for the fields A_k^a and Π_{ka}. Instead of doing so let us adopt a physicist's point of view and assume that it does not matter much which particular function spaces we use if our fields are sufficiently smooth and vanish rapidly enough at infinity. Looking at Eqs. (38d)–(38f) we see then that Gauss's law is implemented in the new variables by setting

$$p_1=p_2=p_3=0. \tag{45}$$

That these constraints are preserved in time in the dynamics described by the Hamiltonian (1) is evident because p_1 and p_2 are constants of motion and $\dot{p}_3$ is proportional to the Gauss law generators. Equations (38a)–(38c) reveal similarly that the angles q_1, q_2, and q_3 become ambiguous when $G_a\to 0$ and therefore we must discard these variables as nonphysical. The physical variables are then the pairs $(Q_k^{a'},P_{ka'})$, as their defining equations (38g) and (38h) are independent of G_a. Since the generating functional (42) does not contain explicit time dependence, the dynamics of $Q_k^{a'}$ and $P_{ka'}$ is governed by the Hamiltonian (1) under the constraint (45), i.e.,

$$H_{\text{phys}}=H_{|p_1=p_2=p_3=0}.$$

A formula for the Hamiltonian (1) in the variables (37) is most easily obtained with the help of Eq. (40). Since the Hamiltonian is invariant under gauge transformations of this form, we immediately get the result

$$H=\int\left(\frac{1}{2}P_{ka}P^{ka}+\frac{1}{4}\widetilde{\Phi}_{kl}^a\widetilde{\Phi}_a^{kl}\right)d^3\mathbf{x},$$

where

$$\widetilde{\Phi}_{kl}^a=\partial_l\widetilde{Q}_k^a-\partial_k\widetilde{Q}_l^a+g\varepsilon_{bc}{}^a\widetilde{Q}_k^b\widetilde{Q}_l^c,$$

$$\widetilde{Q}_k^a=Q_k^a+\frac{1}{g}\delta_{k1}(O_4)^a{}_2\frac{p_1}{P_{11}}\sqrt{1-\left(\frac{p_3}{p_1}\right)^2}-\frac{1}{g}\delta_{k2}\delta^a{}_2\frac{p_3}{P_{23}},$$

and the definitions (41) are implied. Imposing the constraint (45), it is then easy to see that

$$H_{\text{phys}} = \int \left(\frac{1}{2} P_{ka} P^{ka} + \frac{1}{4} \Phi^a_{kl} \Phi^{kl}_a \right) d^3\mathbf{x}, \tag{46}$$

where

$$\Phi^a_{kl} = \partial_l Q^a_k - \partial_k Q^a_l + g \varepsilon_{bc}{}^a Q^b_k Q^c_l$$

and

$$\begin{aligned} Q^2_1 &= -\frac{1}{g P_{11}} \sum_{k=2}^{3} \left(\partial_k P_{k3} - g \varepsilon_b{}^c{}_3 Q^b_k P_{kc} \right), \\ Q^3_1 &= \frac{1}{g P_{11}} \left(\partial_3 P_{32} - \sum_{k=2}^{3} g \varepsilon_b{}^c{}_2 Q^b_k P_{kc} \right), \\ Q^2_2 &= \frac{1}{g P_{23}} \left(\partial^k P_{k1} - g \varepsilon_b{}^c{}_1 Q^b_3 P_{3c} \right), \end{aligned} \tag{47}$$

$$P_{12} = P_{13} = P_{22} = 0.$$

Equations (38h) and (39) also show that

$$P_{11} \geqslant 0, \quad P_{23} \geqslant 0.$$

It may be a little surprising that the Hamiltonian (46) is local, because one would expect the Gauss law to produce nonlocal terms. However, the locality of H_{phys} becomes easy to understand if we look at the definitions (47). Our gauge choices have annihilated three momentum components, and when we solve Gauss's law for the coordinates conjugate to these momenta, the result is local. One should also note that the Hamiltonian density is singular at points where P_{11} or P_{23} vanishes. These are exactly the same points where the gauge transformation matrix (39) becomes ambiguous.

Now we would like to examine what the Hamiltonian (46) looks like at small and large values of the coupling constant g. For that purpose we note that every component Q^a_k consists of terms proportional to g^{-1} and terms independent of g. Therefore the field tensor components Φ^a_{kl} range from g^{-1} to g^1 and as a result, the Hamiltonian density takes the form

$$\mathcal{H}_{\text{phys}} = \frac{1}{2g^2} \mathcal{H}^{(0)} + \frac{1}{g} \mathcal{H}^{(1)} + \mathcal{H}^{(2)} + g \mathcal{H}^{(3)} + \frac{g^2}{2} \mathcal{H}^{(4)}. \tag{48}$$

At small values of g the dominant term is $\mathcal{H}^{(0)}$, and it is rather straightforward to work out that

$$\begin{aligned}\mathcal{H}^{(0)} = &\left[-\partial_2\left(\frac{1}{P_{11}}\sum_{k=2}^{3}\partial_k P_{k3}+\frac{P_{21}}{P_{11}P_{23}}\sum_{k=1}^{3}\partial_k P_{k1}\right)-\partial_1\left(\frac{1}{P_{23}}\sum_{k=1}^{3}\partial_k P_{k1}\right)\right]^2\\ &+\left[-\partial_3\left(\frac{1}{P_{11}}\sum_{k=2}^{3}\partial_k P_{k3}+\frac{P_{21}}{P_{11}P_{23}}\sum_{k=1}^{3}\partial_k P_{k1}\right)\right]^2+\left[\partial_2\left(\frac{\partial_3 P_{32}}{P_{11}}\right)\right]^2+\left[\partial_3\left(\frac{\partial_3 P_{32}}{P_{11}}\right)\right]^2\\ &+\left[-\frac{\partial_3 P_{32}}{P_{11}P_{23}}\sum_{k=1}^{3}\partial_k P_{k1}\right]^2+\left[\partial_3\left(\frac{1}{P_{23}}\sum_{k=1}^{3}\partial_k P_{k1}\right)\right]^2. \qquad (49)\end{aligned}$$

This expression looks a bit complicated, but it is noteworthy that $\mathcal{H}^{(0)}$ does not depend on the coordinates Q_k^a. At large values of g we similarly find the dominant term to be

$$\begin{aligned}\mathcal{H}^{(4)} = &\{[\left(P_{33}Q_3^1-P_{31}Q_3^3\right)\left(P_{33}Q_3^2-P_{32}Q_3^3\right)+P_{23}Q_3^2\left(P_{33}Q_2^1-P_{31}Q_2^3\right)+P_{23}P_{32}\left(Q_2^3Q_3^1-Q_2^1Q_3^3\right)]^2\\ &+P_{23}^2[-P_{11}Q_1^1Q_2^3+Q_2^1\left(P_{23}Q_2^1-P_{21}Q_2^3+P_{33}Q_3^1-P_{31}Q_3^3\right)]^2+[P_{23}Q_2^1\left(-P_{32}Q_3^1+P_{31}Q_3^2\right)\\ &-\left(P_{11}Q_1^1+P_{21}Q_2^1\right)\left(P_{33}Q_3^2-P_{32}Q_3^3\right)]^2+[-P_{23}Q_3^2\left(P_{23}Q_2^1-P_{21}Q_2^3+P_{33}Q_3^1\right)+Q_3^3\left(P_{23}P_{32}Q_3^1\\ &+P_{21}P_{33}Q_3^2\right)-P_{21}P_{32}\left(Q_3^3\right)^2]^2+P_{23}^2[Q_3^1\left(P_{23}Q_2^1-P_{21}Q_2^3+P_{33}Q_3^1\right)-Q_3^3\left(P_{11}Q_1^1+P_{31}Q_3^1\right)]^2\\ &+[-P_{23}P_{32}\left(Q_3^1\right)^2+P_{23}Q_3^2\left(P_{11}Q_1^1+P_{31}Q_3^1\right)+P_{21}Q_3^1\left(-P_{33}Q_3^2+P_{32}Q_3^3\right)]^2+P_{11}^2[-P_{23}Q_2^3Q_3^2\\ &-Q_3^3\left(P_{33}Q_3^2-P_{32}Q_3^3\right)]^2+\left(P_{11}P_{23}\right)^2\left(Q_2^3Q_3^1-Q_2^1Q_3^3\right)^2+P_{11}^2[P_{23}Q_2^1Q_3^2+Q_3^1\left(P_{33}Q_3^2\right.\\ &\left.-P_{32}Q_3^3\right)]^2\}/\left(P_{11}P_{23}\right)^2. \qquad (50)\end{aligned}$$

This is also a rather complicated expression, being fourth order in the coordinates Q_k^a and fractional in the momenta P_{ka}. Finally we should note that the form of the decomposition (48) is actually a matter of choice, since it is always possible to scale the variables by

$$(Q_k^a, P_{ka}) \to (g^{\alpha_{ka}}Q_k^a, g^{-\alpha_{ka}}P_{ka}),$$

where the α_{ka}'s are arbitrary constants. However, scalings like this would alter the g dependence of the field tensor Φ_{kl}^a and the covariant derivative. As a result, the interpretation of g would also change. In the present form g is defined so that the limit $g \to 0$ corresponds to an Abelian theory. The singular behavior of $\mathcal{H}_{\text{phys}}$ in this limit then stems from an obvious qualitative difference between Abelian and non-Abelian theories in the function group method. Namely, the algebra (3) shows that for a non-Abelian theory ($g \neq 0$) the Gauss law generators must be parametrized with variables that contain one canonically conjugate pair, whereas in the Abelian case ($g=0$) this parametrization cannot contain canonical pairs at all. Also the solution of Gauss's law given in (47) is genuinely non-Abelian and impossible to extend to the Abelian case.

When quantizing the Hamiltonian (46), we could try to quantize one of the limiting cases (49) or (50) first and then develop a perturbation expansion in appropriate powers of g. At least the weak coupling Hamiltonian (49), despite its complicated appearance, looks easy to quantize as its eigenstates would consist of common eigenstates of the momentum operators. The strong coupling Hamiltonian (50) is considerably more difficult to quantize in the canonical approach because we would have to solve problems connected with the ordering of operators and with the regularization of higher order functional derivatives defined at the same point in space. Moreover, it is not clear whether large values of the bare coupling constant are physically relevant. As a general feature of quantization one should also take into account that two classical systems connected by a canonical transformation do not necessarily yield unitarily equivalent quantum systems. For example, in quantum mechanics it is often difficult to find a unitary transformation corresponding to action-angle variables in classical mechanics.[18] The fact that the transformation (38) is nonlinear might thus have an effect on the quantization of the Hamiltonian (46). Finding a suitable quantization procedure remains a problem to study.

IV. CONCLUSIONS

The unconstrained Hamiltonian (46) lies at the end of a long journey which started from the temporal gauge Hamiltonian (1) and passed through the transformation (38), making it finally possible to implement Gauss's law in the new variables (37). The canonical pairs (q_i, p_i) turned out to be nonphysical, which led to the conclusion that the physical degrees of freedom are described by the gauge-invariant fields $(Q_k^{a'}, P_{ka'})$. Equation (47) then defined those components that are not free variables. The actual construction of the variables (37) relied on the parametrization (6) and the complementary choices (18), (28), and (31). One could also easily experiment with different choices and derive alternative Hamiltonians corresponding to them by applying the general principles stated in Sec. II. In particular, the Poisson bracket relations (17) allow for a large variety of possible U(1) gauges, given only that the initial choice (7) is made.

An extension of this construction to more general Lie groups is relatively straightforward to outline. One should begin by deriving a parametrization of the Gauss law generators similar to (6). Identifying the G_a's with elements of the corresponding Lie algebra, one should select the maximum number of new canonical momenta from the maximal Abelian subspace of the enveloping algebra. The remaining variables needed for the parametrization should then be chosen so that the Lie algebra relations

$$\{G_a(\mathbf{x}), G_b(\mathbf{y})\} = -gf_{ab}{}^c G_c(\mathbf{y})\delta(\mathbf{x}-\mathbf{y})$$

would hold as a consequence of the canonical Poisson brackets. After identifying which variables are gauge-dependent one should define gauge-invariant variables by transforming the gauge-dependent degrees of freedom away. The details of the construction would then depend on the Poisson brackets of the gauge-invariant variables and the way of defining those gauge degrees of freedom that are not fixed by the parametrization of the Gauss law generators. No doubt that the calculations would be much more complicated than in the SU(2) case. In addition to generalizing the Lie group, one could also extend the method by adding matter fields, in particular fermions, into the theory. However, it seems that the question of quantization deserves the most attention in the future because it is crucial for the physical applicability of the Hamiltonian (46).

A note on BRST quantization of SU(2) Yang-Mills mechanics

A. Fuster[a] and J. W. van Holten[b]
NIKHEF, Amsterdam, the Netherlands

(Received 9 May 2005; accepted 1 August 2005; published online 13 October 2005)

The quantization of SU(2) Yang-Mills theory reduced to 0+1 space-time dimensions is performed in the BRST framework. We show that in the unitary gauge $A_0=0$ the BRST procedure has difficulties which can be solved by introduction of additional singlet ghost variables. In the Lorenz gauge $\dot{A}_0=0$ one has additional unphysical degrees of freedom, but the BRST quantization is free of the problems of the unitary gauge. © *2005 American Institute of Physics.*

I. SU(2) YANG-MILLS MECHANICS

We consider SU(2) Yang-Mills mechanics obtained by the reduction of SU(2) Yang-Mills field theory in $(D+1)$-dimensional space-time to a finite-dimensional quantum system, by taking the dynamical variables to depend on the time coordinate t only. The Lagrangian of such a theory is

$$L_{\mathrm{YMQM}} = \tfrac{1}{2}(F^a_{0i})^2 - \tfrac{1}{4}(F^a_{ij})^2, \tag{1}$$

where $i,j=(1,\ldots,D)$, and

$$F^a_{0i} = \dot{A}^a_i - g\epsilon^{abc}A^b_0A^c_i, \quad F^a_{ij} = -g\epsilon^{abc}A^b_iA^c_j. \tag{2}$$

Such a system has been widely studied in the context of nonperturbative aspects of (super) Yang-Mills theories,[1,2] and as a first step in the regularized dynamics of membrane theory.[3–5]

The Lagrangian is invariant under time-dependent gauge transformations with parameters $\Lambda^a(t)$, taking the infinitesimal form

$$\delta A^a_0 = \dot{\Lambda}^a - g\epsilon^{abc}A^b_0\Lambda^c, \quad \delta A^a_i = -g\epsilon^{abc}A^b_i\Lambda^c. \tag{3}$$

This invariance allows us to impose a gauge condition leaving the physical dynamics unchanged. The simplest choice is

$$A^a_0 = 0. \tag{4}$$

With this condition the effective Lagrangian for the remaining D-dimensional vector potentials $\mathbf{A}_a$ becomes [we do not distinguish between upper and lower adjoint indices $(a,b,c,\ldots)$ for SU(2)]

$$L_{\mathrm{eff}} = \tfrac{1}{2}\dot{\mathbf{A}}^2_a - V[\mathbf{A}], \tag{5}$$

with the potential

[a]Electronic mail: fuster@nikhef.nl
[b]Electronic mail: v.holten@nikhef.nl

$$V[\mathbf{A}] = \frac{g^2}{4}(\mathbf{A}_a^2\mathbf{A}_b^2 - (\mathbf{A}_a \cdot \mathbf{A}_b)^2). \tag{6}$$

In addition, we must impose a set of (first-class) constraints corresponding to the previous equations of motion for A_0^a,

$$G^a \equiv g\ \epsilon^{abc}A_i^b F_{0i}^c \simeq g\ \epsilon_{abc}\mathbf{A}_b \cdot \dot{\mathbf{A}}_c = 0. \tag{7}$$

Thus, the physical trajectories in configuration space in the gauge (4) are the solutions of the Euler-Lagrange equations derived from (5) subject to the additional constraints (7).

In addition to the pure Yang-Mills theory described by the action (1), one can also construct various supersymmetric extensions, based on the reduction of supersymmetric Yang-Mills field theory in $D=1$, 3, 5, 9. The spectra of these theories differ in certain aspects,[1,6,3,4,7–9] but for the problem addressed in this paper those differences are not relevant.

To keep track of the constraints, especially in the context of the Yang-Mills quantum theory, we follow the BRST procedure. (For reviews, see Refs. 10 and 11.) Thus we introduce anticommuting ghost degrees of freedom (b^a, c^a) as well as commuting auxiliary scalars N^a in such a way, that the total gauge-fixed action becomes invariant under a set of special ghost-dependent gauge transformations, the rigid BRST invariance. The anticommuting BRST differentials δ_Ω are defined before gauge fixing as follows:

$$\begin{gathered}\delta_\Omega A_0^a = (D_0 c)^a = \dot{c}^a - g\epsilon^{abc}A_0^b c^c, \quad \delta_\Omega A_i^a = (D_i c)^a = -g\epsilon^{abc}A_i^b c^c, \\ \delta_\Omega c^a = \frac{g}{2}\epsilon^{abc}c^b c^c, \\ \delta_\Omega b^a = iN^a, \quad \delta_\Omega N^a = 0.\end{gathered} \tag{8}$$

The gauge invariance of the classical action (1) implies its invariance under the BRST transformations by construction. The BRST differential has the standard property that $\delta_\Omega^2 = 0$. The implementation of the BRST construction for the gauge $A_0 = 0$ is, to impose this gauge condition using the Nakanishi-Lautrup fields N^a as Lagrange multipliers, and complete the effective Lagrangian so as to make it fully BRST invariant. For the case at hand this results in the effective Lagrangian,

$$L_{\text{eff}} = L_{\text{YMQM}} + N^a A_0^a + ib^a(\dot{c}^a - g\epsilon^{abc}A_0^b c^c). \tag{9}$$

We can use the gauge condition implied by the Nakanishi-Lautrup fields to eliminate A_0^a and N^a simultaneously; in a path-integral formulation, this implies integrating out a δ-functional $\delta(A_0)$. The result is

$$L_{\text{eff}} = \tfrac{1}{2}\dot{\mathbf{A}}_a^2 - \tfrac{1}{4}(F_{ij}^a)^2 + ib_a\dot{c}_a. \tag{10}$$

Note that for $D=3$ we can construct a magnetic field by $1/2\ \epsilon_{ijk}F_{jk}^a = B_i^a$, but this does not hold for general D. The effective Lagrangian (10) is invariant under the reduced form of the BRST variations (8) obtained by taking $A_0^a = 0$, and using the equation of motion for N^a,

$$\delta b^a = iN^a \simeq ig\epsilon^{abc}(A_i^b F_{0i}^c - ic^b b^c). \tag{11}$$

The BRST invariance of the effective Lagrangian implies an anticommuting conserved charge by Noether's theorem. The BRST charge takes the form

$$\Omega = c^a G^a - \frac{ig}{2}\epsilon^{abc}c^a c^b b^c. \tag{12}$$

The first-class constraints of the classical theory are summarized effectively by the statement that $\Omega = 0$; more precisely, in the phase-space formulation, all brackets of physical quantities with Ω

must vanish, physical quantities must be BRST invariant; this is discussed in more detail in the next section.

II. QUANTUM THEORY

In the quantum theory the dynamical variables A_i^a and their conjugate momenta $P_i^a = \dot{A}_i^a$, as well as the Faddeev-Popov ghosts are operators satisfying (anti-)commutation relations

$$[A_i^a, P_j^b] = i\ \delta^{ab}\delta_{ij}, \quad [c^a, b^b]_+ = \delta^{ab}. \tag{13}$$

The Hamiltonian is given by

$$H_{\text{eff}} = \tfrac{1}{2}\mathbf{P}_a^2 + \tfrac{1}{4}F_{ij}^{a\,2}, \tag{14}$$

as for pure Yang-Mills theory, in fact. The Hamiltonian determines the time evolution of any quantity X constructed from the Yang-Mills or ghost operators by the Schrödinger equation

$$\dot{X} = i[H, X]. \tag{15}$$

Gauge transformations on $(\mathbf{A}_a, \mathbf{P}_a)$ are generated by the SU(2) charges

$$G_a = g\ \epsilon_{abc}\mathbf{A}_b \cdot \mathbf{P}_c, \tag{16}$$

such that

$$\delta_a X = i[G_a, X], \quad \delta_a G_b = i[G_a, G_b] = -\,g\ \epsilon_{abc}G_c, \tag{17}$$

while more generally the BRST transformations are given by

$$\delta_\Omega X = i[\Omega, X]_\pm, \tag{18}$$

where the sign depends on the fermionic parity of the quantity X, + (anticommutator) for fermionic X and − (commutator) for bosonic X. In particular, the commutation relation (17) for the gauge charges together with the ghost anticommutator (13) implies the nilpotency of the BRST charge,

$$\Omega^2 = 0. \tag{19}$$

To complete the theory we must define an inner product on the extended state space, such that zero-norm states decouple and physical states have positive norm. For this to happen, it is necessary that the BRST operator is self-adjoint with respect to this inner product. In the coordinate representation, with states being represented by wave functions $\Psi[\mathbf{A}, c]$, such an inner product is defined by the integral[12]

$$(\Phi, \Psi) = i \int \mathrm{d}c^1 \mathrm{d}c^2 \mathrm{d}c^3 \int \prod_{i,a} \mathrm{d}A_i^a \Phi^\dagger[\mathbf{A}, c]\Psi[\mathbf{A}, c]. \tag{20}$$

It is easily seen that with this definition the ghost operators (b, c) are self-adjoint themselves. It follows directly that, indeed,

$$(\Omega\Phi, \Psi) = (\Phi, \Omega\Psi). \tag{21}$$

III. PHYSICAL STATES

The physical states of Yang-Mills quantum mechanics are constructed by solving for the eigenstates and eigenvalues of the Hamiltonian (14) subject to the constraint of BRST invariance.

One useful way to construct states is by the Fock-space approach,[7] in which one starts with an oscillator basis for the dynamical degrees of freedom defined by

$$\mathbf{a}_a = \frac{1}{\sqrt{2}}(\mathbf{A}_a + i\mathbf{P}_a), \quad \mathbf{a}_a^\dagger = \frac{1}{\sqrt{2}}(\mathbf{A}_a - i\mathbf{P}_a). \tag{22}$$

These creation and annihilation operators satisfy the standard commutation relations

$$[\mathbf{a}_a, \mathbf{a}_b^\dagger] = \delta_{ab} 1_D, \tag{23}$$

where 1_D is the D-dimensional unit matrix. As implied by Eq. (13) the ghost operators already behave like fermionic ladder operators. One is free to consider either c^a or b^a as creation operator; we choose c^a. Fock states are now constructed as polynomials in $\mathbf{a}_a^\dagger$ and c^a acting on an empty state Ψ_0 defined by

$$\mathbf{a}_a \Psi_0 = b^a \Psi_0 = 0. \tag{24}$$

Such a construction differs from the standard (bosonic or fermionic) creation and annihilation operators in that c^a and b^a are self-adjoint with respect to the inner product (20) rather than adjoint to each other. A similar treatment of ghost ladder operators can be found in Ref. 13.

The Hamiltonian can be represented as a matrix in a basis of Fock states. Subsequent diagonalization would give the spectrum of the theory. [Note one can only construct a basis of finite dimension and therefore any results would be approximate (see Ref. 7).]

In the context of the coordinate representation this construction is realized by taking

$$\mathbf{a}_a = \frac{1}{\sqrt{2}}\left(\mathbf{A}_a + \frac{\partial}{\partial \mathbf{A}_a}\right), \quad b^a = \frac{\partial}{\partial c^a}, \tag{25}$$

and

$$\Psi_0 = N e^{-\frac{1}{2}\mathbf{A}_a \cdot \mathbf{A}_a}, \tag{26}$$

with N a normalization factor. In this representation the gauge generators are of the form

$$G_a = -ig\ \epsilon_{abc} \mathbf{a}_b^\dagger \cdot \mathbf{a}_c. \tag{27}$$

We analyze next the restrictions imposed by the BRST symmetry on states in order to be physical. In the BRST formalism physical states are identified with the cohomology classes of the nilpotent BRST charge Ω,

$$\mathcal{H}^{\text{phys}} \simeq \frac{\text{Ker}\,\Omega}{\text{Im}\,\Omega}. \tag{28}$$

This implies that physical states Ψ are BRST invariant,

$$\Omega\Psi = 0, \quad (\Psi, \Psi) = 1, \tag{29}$$

and state vectors differing by a BRST-exact state are identified,

$$\Psi \sim \Psi' = \Psi + \Omega\Lambda. \tag{30}$$

Therefore matrix elements of physical operators between physical states must be invariant under the BRST transformations (30):

$$(\Phi, X\Psi) = (\Phi, X\Psi'), \quad \text{if } [\Omega, X]_\pm = 0. \tag{31}$$

These properties are guaranteed if BRST-exact states of the form $\Omega\Lambda$ decouple from the physical state space and have zero norm,

$$(\Psi,\Omega\Lambda)=(\Omega\Psi,\Lambda)=0,\quad (\Omega\Lambda,\Omega\Lambda)=(\Lambda,\Omega^2\Lambda)=0. \tag{32}$$

Observe that it is crucial for these results that the BRST charge is self-adjoint with respect to the physical inner product.

To do any practical calculation one needs an explicit expression for the physical state vectors; this can be achieved by selecting one element from each equivalence class, using the nilpotent co-BRST operator

$$^*\Omega = G^a b^a - \frac{ig}{2}\epsilon^{abc}c^a b^b b^c,\quad {}^*\Omega^2 = 0. \tag{33}$$

Indeed, the co-BRST condition

$$^*\Omega\Psi = 0, \tag{34}$$

acts as a gauge fixing condition for the BRST transformations (30), reducing the state space as required.[12] States satisfying both $\Omega\Psi = {}^*\Omega\Psi = 0$ are called BRST harmonic. Physical states are defined as BRST harmonic states of finite norm. We build first Fock states which are BRST harmonic.

Define the (total) ghost number as the operator

$$N_g = c^a b^a. \tag{35}$$

Splitting the Fock space in four sectors corresponding to the eigenvalues n_g of N_g, 0,…,3, we construct states in each ghost sector as follows:

$$\Psi^{(0)}[M] = M[\mathbf{a}^\dagger]\Psi_0,$$

$$\Psi^{(1)}_a[M] = c_a M[\mathbf{a}^\dagger]\Psi_0,$$

$$\tilde{\Psi}^{(2)}_a[M] = \tfrac{1}{2}\epsilon_{abc}c^a c^b M[\mathbf{a}^\dagger]\Psi_0,$$

$$\tilde{\Psi}^{(3)}[M] = \frac{1}{3!}\epsilon_{abc}c^a c^b c^c M[\mathbf{a}^\dagger]\Psi_0.$$

Here $M[\mathbf{a}^\dagger]$ is some gauge-invariant polynomial in the operators $\mathbf{a}^\dagger$,

$$M[\mathbf{a}^\dagger] = \sum_n \mu_{a_1\cdots a_n}\mathbf{a}^\dagger_{a_1}\cdots\mathbf{a}^\dagger_{a_n}, \tag{36}$$

and the coefficients $\mu_{a_1\cdots a_n}$ are invariant SU(2) tensors.

The complete set of solutions consists of two distinct classes, the states at ghost number $n_g=0$, $\Psi^{(0)}_M$, and those at ghost number $n_g=3$, $\tilde{\Psi}^{(3)}[M]$. We discuss next the possibility for these states to have finite norm (see also Refs. 14 and 15). The spectrum of the Hamiltonian in such a basis would be guaranteed to be physical.

IV. INNER PRODUCT AND GHOST VACUUM

The existence of two classes of BRST-harmonic states at different ghost number is of crucial importance for the construction of a nontrivial physical inner product.[11,14] Indeed, if we would only have the states at $n_g=0$ it is quite obvious from the definition (20) that the vacuum state Ψ_0 would have zero norm,

$$(\Psi_0,\Psi_0)=0, \tag{37}$$

while the BRST-invariant 3-ghost operator has a nonzero vacuum expectation value,

$$\frac{i}{3!}\epsilon^{abc}\langle c^a c^b c^c\rangle = \frac{i}{3!}(\Psi_0, \epsilon^{abc} c^a c^b c^c \Psi_0) = 1. \tag{38}$$

The problem clearly is in the definition of the ghost vacuum, in combination with the fact that the ghosts are self-conjugate. Therefore the ghost creation operators c^a do not act as annihilation operators on the conjugate (bra) vectors; if they would, the BRST charge would not be self-adjoint. In particular, it is not an option to replace the space of bra states by the BRST-dual states

$$\tilde{\Psi}^\dagger[M] = \frac{i}{3!}\Psi^\dagger[M]\epsilon^{abc} c^a c^b c^c, \tag{39}$$

as proposed in Refs. 14 and 16, which is equivalent to the replacement of the inner product (20) by

$$(\Phi, \Psi) \to \langle \Phi, \Psi\rangle = \frac{i}{3!}\epsilon^{abc}(\Phi, c^a c^b c^c \Psi). \tag{40}$$

In fact, it is clear that the ghost variables have vanishing matrix elements between any of the states (physical or unphysical):

$$\langle \Phi, c^a \Psi\rangle = 0, \quad \forall\, \Psi, \Phi, \tag{41}$$

i.e., the ghosts would effectively vanish as operators, and the same is true for the BRST charge Ω.

Part of the solution of this problem, also along the lines suggested in Ref. 16, is to use the existence of the second set of solutions of the BRST and co-BRST constraints with $n_g = 3$ to change the definition of the ghost vacuum. If we define a new vacuum state,

$$\Psi_+ = \frac{1}{\sqrt{2}}\left(1 + \frac{i}{3!}\epsilon^{abc} c^a c^b c^c\right)\Psi_0, \tag{42}$$

with corresponding physical excited states $\Psi_+[M] = M[\mathbf{a}^\dagger]\Psi_+$, the ghost operators remain self-adjoint and the vacuum is normalizable,

$$(\Psi_+, \Psi_+) = 1. \tag{43}$$

A drawback is, that the vacuum Ψ_+ has no well-defined ghost number, and not even a well-defined Grassmann parity, being a sum of an even and odd ghost number state. Moreover, the vacuum expectation value of the ghosts (38) is changed, but still nonvanishing; actually we now have

$$\frac{i}{3!}\epsilon^{abc}\langle c^a c^b c^c\rangle_+ = \frac{i}{3!}(\Psi_+, \epsilon^{abc} c^a c^b c^c \Psi_+) = \frac{1}{2}, \tag{44}$$

and similarly

$$\frac{i}{3!}\epsilon^{abc}\langle b^a b^b b^c\rangle_+ = \frac{1}{2}. \tag{45}$$

Although these expectation values are BRST invariant, they carry a nonzero ghost number, a manifestation of the noninvariance of both the vacuum and the inner product itself under ghost rescaling.

Both problems can be solved by introducing a fourth ghost θ, with conjugate antighost ζ,

$$[\theta, \zeta]_+ = 1. \tag{46}$$

The new ghost θ is taken to be a BRST singlet and has ghost number $n_g(\theta) = -3$; thus it has the same quantum numbers as the invariant antighost operator, while ζ has the quantum numbers of the corresponding ghost operator,

$$\theta \sim \frac{i}{3!}\epsilon^{abc}b^a b^b b^c, \quad \zeta \sim \frac{i}{3!}\epsilon^{abc}c^a c^b c^c. \tag{47}$$

We then define the physical vacuum state

$$\Phi_0 = \frac{1}{\sqrt{2}}\left(1 + \frac{1}{3!}\theta\ \epsilon^{abc}c^a c^b c^c\right)\Psi_0, \tag{48}$$

and the physical excited states

$$\Phi[M] = M[\mathbf{a}^\dagger]\Phi_0. \tag{49}$$

These physical states have a well-defined ghost number $n_g(\Phi_M)=0$ and Grassmann parity (even). This is especially important in the supersymmetric extensions of the theory, as the action of the gaugino operators would otherwise cause problems with sign changes for odd ghost number terms.

Simultaneously we also redefine the inner product (20) in the coordinate representation the full state space to

$$(\Phi,\Psi) = \int \mathrm{d}\theta \int \mathrm{d}c^1\mathrm{d}c^2\mathrm{d}c^3 \int \prod_{i,a} \mathrm{d}A_i^a \Phi^\dagger[\mathbf{A},c]\Psi[\mathbf{A},c]. \tag{50}$$

With respect to this inner product, all ghosts, including the new singlet ghost, are self-adjoint, and so is the BRST charge Ω. Observe that the ghost integration measure now has vanishing ghost number as well. Finally, the 3-ghost operator vacuum expectation value vanishes trivially,

$$\frac{i}{3!}\epsilon^{abc}\langle c^a c^b c^c\rangle_\theta = \frac{i}{3!}(\Phi_0, \epsilon^{abc}c^a c^b c^c \Phi_0) = 0. \tag{51}$$

Of course, there arise new vacuum expectation values

$$\frac{1}{3!}\langle \theta\ \epsilon^{abc}c^a c^b c^c\rangle_\theta = \frac{1}{3!}\langle \zeta\ \epsilon^{abc}b^a b^b b^c\rangle_\theta = \frac{1}{2}, \tag{52}$$

but these expectation values are both BRST invariant and have vanishing ghost number.

In passing, let us point out a further result of some interest, it is possible to define new antighost operators β^a and η by

$$\beta^a = b^a + \tfrac{1}{2}\epsilon^{abc}\theta c^b c^c, \quad \eta = \zeta - \frac{1}{3!}\epsilon^{abc}c^a c^b c^c. \tag{53}$$

These redefinitions preserve the ghost number. Moreover, one easily establishes the anticommutation relations

$$[c^a,\beta^b]_+ = \delta^{ab}, \quad [\theta,\eta]_+ = 1, \quad [\eta,\beta^a]_+ = [\theta,c^a]_+ = 0, \tag{54}$$

with all other anticommutators vanishing as well. In addition

$$\beta^a\Phi_0 = \eta\ \Phi_0 = 0, \tag{55}$$

suggesting that Φ_0 is the actual Fock vacuum for the new antighosts (η,β^a). Unfortunately, it is to be noted that these antighosts are no longer self-adjoint with respect to the inner product (50),

$$\beta_a^\dagger = b^a - \tfrac{1}{2}\epsilon^{abc}\theta c^b c^c, \quad \eta^\dagger = \zeta + \frac{1}{3!}\epsilon^{abc}c^a c^b c^c. \tag{56}$$

Hence these operators do not annihilate the conjugate vacuum, for a general state vector Ψ,

$$(\Phi_0, \beta^a \Psi) = (\beta_a^\dagger \Phi_0, \Psi) \neq 0. \tag{57}$$

Moreover, the conjugate ghosts have nontrivial anticommutation relations with the original antighosts, e.g.,

$$[\beta_a^\dagger, \eta]_+ = -\epsilon^{abc} c^b c^c, \quad [\beta_a^\dagger, \beta^b]_+ = -\epsilon^{abc} \theta c^c. \tag{58}$$

Therefore the ghost variables (β^a, η) are not of much use in the construction of states. Nevertheless, they do provide a good way to characterize the ghost dependence of the physical states by the conditions (55).

V. LORENZ GAUGE

We will now show, that the problems with the definition of physical states and inner products sketched in Sec. IV do not exist in the Lorenz gauge quantization. The starting point for our analysis is again the classical theory defined in Eqs. (1)–(3), and the representation of the nilpotent BRST algebra defined in Eq. (8). In the $(0+1)$-dimensional reduction of the Yang-Mills theory, the Lorenz gauge takes the form

$$\dot{A}_0 = 0. \tag{59}$$

A convenient BRST-invariant extension of the classical Lagrangian for this gauge is

$$L_{\text{Lorenz}} = L_{\text{YMQM}} + N^a \dot{A}_0^a - \tfrac{1}{2} N_a^2 - i\dot{b}^a (D_0 c)^a \simeq \tfrac{1}{2}(D_0 \mathbf{A}^a)^2 + \tfrac{1}{2}(\dot{A}_0^a)^2 - \tfrac{1}{4}(F_{ij}^a)^2 - i\dot{b}^a (D_0 c)^a, \tag{60}$$

where the last line results from elimination of the auxiliary fields N^a. The corresponding Hamiltonian is

$$H_{\text{Lorenz}} = \frac{1}{2}(\mathbf{P}^a + g\epsilon^{abc} A_0^b \mathbf{A}^c)^2 + \frac{1}{2}(P_0^a)^2 + \frac{1}{4}(F_{ij}^a)^2 - \frac{g^2}{2}(\epsilon^{abc} A_0^b \mathbf{A}^c)^2 + i(u^a - ig\epsilon^{abc} A_0^b c^c) v^a, \tag{61}$$

where the canonical momenta are defined by

$$\mathbf{P}_a = (D_0 \mathbf{A})^a, \quad P_0^a = \dot{A}_0^a,$$

$$u^a = -(D_0 c)^a, \quad v^a = \dot{b}^a. \tag{62}$$

The conserved BRST charge takes the form

$$\Omega = G^a c^a - \frac{ig}{2}\epsilon^{abc} c^a c^b v^c + P_0^a u^a, \tag{63}$$

with the gauge charges G^a as in Eq. (16). As neither of the expressions (61) and (63) suffer from ordering ambiguities, they can be interpreted directly as quantum operators, with the fundamental commutation relations given by

$$[\mathbf{A}_a, \mathbf{P}_b] = i\delta_{ab} 1_D, \quad [A_0^a, P_0^b] = i\delta^{ab},$$
$$[c^a, v^b]_+ = \delta^{ab}, \quad [b^a, u^b]_+ = \delta^{ab}. \tag{64}$$

The quantum equations of motion and the BRST transformations then again take the form (15) and (18). In the coordinate representation, the BRST-invariant inner product of two wave functions in the full ghost-extended Hilbert space now takes the form

$$(\Phi,\Psi)=i\int\prod_a \mathrm{d}b^a\mathrm{d}c^a\int\prod_a \mathrm{d}A_0^a\int\prod_{i,a}\mathrm{d}A_i^a\Phi^\dagger[\mathbf{A},A_0,c,b]\Psi[\mathbf{A},A_0,c,b]. \tag{65}$$

To fix the BRST gauge, we introduce the co-BRST operator

$${}^*\Omega=G^a v^a+\frac{ig}{2}\epsilon^{abc}c^a v^b v^c+P_0^a b^a. \tag{66}$$

Requiring states to be simultaneously BRST and co-BRST invariant leads to the conditions

$$G^a\Psi=0,\quad \Sigma^a\Psi=0,\quad P_0^a\Psi=0, \tag{67}$$

where

$$\Sigma^a=ig\epsilon^{abc}c^b v^c, \tag{68}$$

is the generator of the rigid SU(2) transformations, which is still an invariance of the theory, on the conjugate ghosts variables (c^a,v^a). In contrast to the unitary gauge $A_0^a=0$, in the Lorenz gauge the BRST conditions do not fix the physical states complelety. We can still impose a further constraint fixing the dependence of physical states on the antighost variables (b^a,u^a), by requiring states to be rigid SU(2) singlets with respect to all variables,

$$\tilde{\Sigma}^a\Psi=0,\quad \tilde{\Sigma}^a=ig\epsilon^{abc}b^b u^c. \tag{69}$$

Indeed, it is easily checked that $\tilde{\Sigma}^a$ is a BRST and co-BRST invariant operator; therefore the constraint can be imposed consistently on all physical states.

The full set of solutions of conditions (67) and (69) are wave functions which are SU(2) singlets (i.e., gauge invariant), which do not depend on A_0^a, and whose ghost dependence is a constraint to the form

$$\Psi_{\mathrm{phys}}[\mathbf{A},c,b]=\Psi_1[\mathbf{A}]+\frac{i}{3!}\epsilon^{abc}c^a c^b c^c\Psi_2[\mathbf{A}]+\frac{i}{3!}\epsilon^{abc}b^a b^b b^c\Psi_3[\mathbf{A}]+\frac{i}{(3!)^2}(\epsilon^{abc}c^a c^b c^c)\times(\epsilon^{def}b^d b^e b^f)\Psi_4[\mathbf{A}]. \tag{70}$$

With the standard assignment of the ghost number +1 for c^a and −1 for b^a, requiring the states to have vanishing ghost number and definite Grassmann parity imposes the further constraint

$$\Psi_2[\mathbf{A}]=\Psi_3[\mathbf{A}]=0. \tag{71}$$

Finally, requiring the inner product (65) to be positive definite in the subspace of physical states, we must fix the space of physical states to be represented by factorized wave functions,

$$\Psi_{\mathrm{phys}}=\frac{1}{\sqrt{2}}\left[1+\frac{i}{(3!)^2}(\epsilon^{abc}c^a c^b c^c)(\epsilon^{def}b^d b^e b^f)\right]\Psi_M=\frac{1}{\sqrt{2}}\left(1-i\prod_a(c^a b^a)\right)\Psi_M, \tag{72}$$

where Ψ_M can be taken as a physical Fock state of the form (36). Observe that the operator $(i/3!)\epsilon^{abc}b^a b^b b^c$ plays the same role here as the extra ghost θ in our construction of the states in the unitary gauge. Obviously, as in the unitary gauge, we can define a ghost operator with nonzero vacuum expectation value

$$\frac{i}{(3!)^2}\left\langle\prod_a(c^a b^a)\right\rangle=\frac{1}{2}, \tag{73}$$

but like (52) it is BRST invariant and has vanishing ghost number. Finally, defining the vacuum state of the physical subspace as

$$\Phi_0 = \frac{1}{\sqrt{2}}\left(1 - i\prod_a (c^a b^a)\right)\Psi_0, \tag{74}$$

where Ψ_0 is the Fock vacuum of the Yang-Mills system, one can again define ghost operators anihilating Φ_0 by taking

$$\gamma^a = c^a + \frac{i}{2\cdot 3!}\epsilon^{abc}v^b v^c \epsilon^{def}u^d u^d u^f, \quad \beta^a = b^a - \frac{i}{2\cdot 3!}\epsilon^{abc}u^b u^c \epsilon^{def}v^d v^d v^f. \tag{75}$$

As might be expected from our previous analysis, these operators are not self-adjoint and do not define a good basis for a complete Fock-space construction in the ghost sector. Nevertheless, the conditions

$$\gamma^a \Phi_0 = \beta^a \Phi_0 = 0 \tag{76}$$

provide a convenient way to characterize the physical ghost vacuum.

Finally we should remark, that in the physical subspace the integration over A_0^a is of course divergent in the absence of damping, as the physical wave functions are A_0 independent. This divergence can be absorbed in a wave-function renormalization factor

$$N = \frac{1}{\sqrt{\int \Pi_a \mathrm{d}A_0^a}}. \tag{77}$$

Knowing this, we can remove the A_0^a from the physical inner product and effectively set $N=1$; we observe, that N is BRST invariant, and the procedure does not jeopardize the BRST invariance of the integration measure.

VI. DISCUSSION

In this paper we have shown, that although the physical content of the $(0+1)$-dimensional Yang-Mills theory is clearest in the unitary gauge $A_0^a=0$, the BRST quantization works in a more straightforward way in the Lorenz gauge $\dot{A}_0^a=0$. An important part of the discussion and analysis was based on the construction of a BRST-invariant inner product with respect to which the BRST charge Ω is self-adjoint.

To get a little more algebraic and geometric insight into the constructions, consider again the unitary gauge, in which a general state is represented by a wave function

$$\Psi[c] = \psi + c^a \psi_a + \frac{i}{2!}c^a c^b \psi_{ab} + \frac{i}{3!}c^a c^b c^c \psi_{abc}. \tag{78}$$

Defining the dual wave function

$$\tilde{\Psi}[c] = \tilde{\psi} + c^a \tilde{\psi}_a + \frac{i}{2!}c^a c^b \tilde{\psi}_{ab} + \frac{i}{3!}c^a c^b c^c \tilde{\psi}_{abc} \tag{79}$$

with components

$$\tilde{\psi} = \frac{1}{3!}\epsilon_{abc}\psi_{abc}, \quad \tilde{\psi}_a = \frac{1}{2!}\epsilon_{abc}\psi_{bc},$$
$$\tilde{\psi}_{ab} = \epsilon_{abc}\psi_c, \quad \tilde{\psi}_{abc} = \epsilon_{abc}\psi, \tag{80}$$

we recognize that the physical states (42) are characterized as the self-dual states $\tilde{\Psi}=\Psi$, such that the inner product (20) becomes

$$i\int \mathrm{d}c^1\mathrm{d}c^2\mathrm{d}c^3\Psi^\dagger\Psi = \frac{1}{3!}\epsilon_{abc}(\psi^\dagger_{abc}\psi + \psi^\dagger\psi_{abc} + 3\psi^\dagger_a\psi_{bc} + 3\psi^\dagger_{ab}\psi_c) = 2\psi^\dagger\psi + 2\psi^\dagger_a\psi_a. \tag{81}$$

In particular, with $\tilde{\psi}=\psi=\sqrt{2}\psi_M$ and $\psi_a=\tilde{\psi}_a=0$, this reduces to

$$i\int \mathrm{d}c^1\mathrm{d}c^2\mathrm{d}c^3\Psi^\dagger[M]\Psi[M] = \psi^\dagger_M\psi_M. \tag{82}$$

Hence this inner product is positive definite for physical states. Of course, one can also consider the anti-self-dual states $\tilde{\Psi}=-\Psi$, which than have a negative definite norm. This should not surprise us, as the existence of a self-adjoint nilpotent BRST operator $\Omega^2=0$ is possible only in a space with indefinite norm. The important point is, that the space of physical states should have positive norm, and that is realized in the subspace of self-dual states.

Generalization of this discussion to the Lorenz gauge is simple. Each component in the wave-function expansion (78) now is a function of the additional ghost variables b_a, and we can again distinguish between components which are self-dual or anti-self-dual with respect to the expansion in b_a. In this formulation the physical states are then identified with the wave functions for which the components of zero ghost number are completely self-dual, i.e., self-dual both with respect to the c-ghost duality and with respect to the b-ghost duality.

We have discussed in particular the case of SU(2) Yang-Mills theory. The generalization to SU(N) is straightforward; with $r=N^2-1$ generators, and the same number of ghost and antighost variables, the self-dual physical states in the unitary gauge are of the form

$$\Psi[c] = \frac{1}{\sqrt{2}}\left(1 + \frac{i^{[r/2]}}{r!}\epsilon^{a_1\cdots a_r}c^{a_1}\cdots c^{a_r}\right)\psi_M. \tag{83}$$

For odd r (even N), both ghost number and Grassmann parity of the wave functions are ill defined; for even r (odd N), it is only the ghost number which is violated. In both cases, introduction of a singlet ghost θ with ghost number $n_g(\theta)=-r$ solves the problems. On the other hand, in the Lorenz gauge this is taken care of automatically by the antighost variables, as the operator

$$\frac{i^{[r/2]}}{r!}\epsilon^{a_1\cdots a_r}b^{a_1}\cdots b^{a_r} \tag{84}$$

has the same quantum numbers and plays the same role.

Finally we note, that as we have constructed precisely one BRST-invariant wave function for each physical state, in the supersymmetric extension the computation of the Witten index[17,9] is not affected by including the ghost degrees of freedom in the appropriate way (also see Refs. 18–20).

(Received 13 June 2005; accepted 10 August 2005; published online 17 October 2005)

Coset methods are used to construct the action describing the dynamics of the (massive) Nambu-Goldstone scalar degree of freedom associated with the spontaneous breaking of the isometry group of AdS_{d+1} space to that of an AdS_d subspace. The resulting action is an $SO(2,d)$ invariant AdS generalization of the Nambu-Goto action. The vector field theory equivalent action is also determined. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2048307]

I. INTRODUCTION

The AdS/CFT correspondence originally proposed by Maldecena[1] has sparked an enormous amount of theoretical investigation and speculation.[2] The nature of this connection has been recently considered[3,4] for the case of an AdS_d defect (brane) embedded in an underlying AdS_{d+1} space so that the $SO(2,d)$ isometry group of the AdS_{d+1} metric is spontaneously broken to the $SO(2,d-1)$ isometry group of the AdS_d space. It turns out that this case also provides a surprising example of a localized $D=4$ gravity in which the metric differs drastically from the Minkowski metric only far from the brane.[3] Moreover, when a CFT is coupled to AdS gravity, it has been shown that the AdS graviton obtains a mass by means of the AdS Higgs mechanism with the graviton absorbing a massive AdS vector[5] Nambu-Goldstone field.[3,6,7]

As a consequence of the embedding of the AdS_d brane in AdS_{d+1} space, it follows that $(d+1)$ of the pseudotranslations and Lorentz transformations of the AdS_{d+1} space are spontaneously broken. As is typical of spontaneous space-time symmetry breaking,[8] however, not all of the broken symmetries give rise to independent Nambu-Goldstone degrees of freedom. In fact, there is only a single Nambu-Goldstone boson, denoted $\phi(x)$, associated with a broken pseudotranslation generator which is independent. Here x^μ, $\mu=0,1,\ldots,d-1$, are coordinates parametrizing the AdS_d space. In this paper, we construct the action governing the dynamics of this Nambu-Goldstone boson. This mode has a natural interpretation as describing the coordinate oscillations of the brane into the target space covolume. As such we obtain the AdS space generalization of the Nambu-Goto action.

AdS_{d+1} space can be simply described as the $SO(2,d)$ invariant hyperboloidal hypersurface

$$\frac{1}{m^2} = X_0^2 - X_1^2 - X_2^2 - \cdots - X_d^2 + X_{d+1}^2 = X^{\mathcal{M}} \hat{\eta}_{\mathcal{M}\mathcal{N}} X^{\mathcal{N}}, \tag{1.1}$$

embedded in a $(d+2)$-dimensional pseudo-Euclidean space defined with invariant interval

$$\mathrm{d}s^2 = \mathrm{d}X^{\mathcal{M}} \hat{\eta}_{\mathcal{M}\mathcal{N}} \mathrm{d}X^{\mathcal{N}} \tag{1.2}$$

characterized by the metric tensor $\hat{\eta}_{\mathcal{M}\mathcal{N}}$ of signature $(+1,-1,-1,\ldots,-1,+1)$, where $\mathcal{M},\mathcal{N} = 0,1,\ldots,d,d+1$. Here $X^{\mathcal{M}}$ are the pseudo-Euclidean space homogeneous coordinates and m is a constant inverse length scale characterizing the AdS_{d+1} space.

AdS_{d+1} space containing an AdS_d brane, which is a d-dimensional world volume with an AdS metric embedded as a $X^d=0$ hypersurface, can be described by the coordinates $X^{\mathcal{M}} = (X^\mu, X^d, X^{d+1})$ with

$$X^\mu = a(x^2) x^\mu \cosh(mr), \quad \mu = 0,1,\ldots,d-1,$$

$$X^d = \frac{1}{m}\sinh(mr), \tag{1.3}$$

$$X^{d+1} = \frac{1}{m} b(x^2)\cosh(mr).$$

Here x^μ are the intrinsic coordinates of the AdS_d world volume and $-\infty < r < \infty$ is the covolume coordinate. To satisfy Eq. (1.1) of the AdS_{d+1} hyperbola, $a(x^2)$ and $b(x^2)$ are related as

$$1 = m^2 x^2 a^2(x^2) + b^2(x^2). \tag{1.4}$$

Hence the $\mathrm{SO}(2,d)$ invariant interval, Eq. (1.2), becomes

$$\mathrm{d}s^2 = e^{2A(r)} \mathrm{d}\overline{s^2} - \mathrm{d}r^2, \tag{1.5}$$

where the warp factor is $A(r) = \ln\cosh(mr)$ and $\mathrm{d}\overline{s^2} = \mathrm{d}x^\mu \overline{g}_{\mu\nu}(x) \mathrm{d}x^\nu$ is the AdS_d invariant interval with $\overline{g}_{\mu\nu}$ the AdS_d metric tensor.

The AdS_d subspace has the isotropic coordinates x^μ of an $\mathrm{SO}(2,d-1)$ invariant hyperboloid, $1/m^2 = X_0^2 - X_1^2 - \cdots - X_{d-1}^2 + X_{d+1}^2$, embedded at $r=0=X^d$. This subsurface maintains the coordinate relation Eq. (1.4). This in turn leads to a form for the AdS_d metric tensor given by

$$\begin{aligned}\overline{g}_{\mu\nu}(x) &= a^2(x^2) P_{T\mu\nu}(x) + \left[\left(a(x^2) + 2x^2 \frac{\mathrm{d}a(x^2)}{\mathrm{d}x^2} \right)^2 + 4\frac{x^2}{m^2} \left(\frac{\mathrm{d}b(x^2)}{\mathrm{d}x^2} \right)^2 \right] P_{L\mu\nu}(x) \\ &= a^2(x^2) P_{T\mu\nu}(x) + \frac{\left(a(x^2) + 2x^2 \frac{\mathrm{d}a(x^2)}{\mathrm{d}x^2} \right)^2}{\left(1 - m^2 x^2 a^2(x^2)\right)} P_{L\mu\nu}.\end{aligned} \tag{1.6}$$

Here the transverse and longitudinal projectors for x^μ are defined as

$$P_{T\mu\nu}(x) = \eta_{\mu\nu} - \frac{x_\mu x_\nu}{x^2},$$

$$P_{L\mu\nu}(x) = \frac{x_\mu x_\nu}{x^2}, \tag{1.7}$$

and $\eta_{\mu\nu}$ is the metric tensor for d-dimensional Minkowski space having signature $(+1,-1,\ldots,-1)$. Throughout this paper, indices are raised, lowered, and contracted using $\eta_{\mu\nu}$ so that,

for instance $x^2 \equiv x^\mu \eta_{\mu\nu} x^\nu$. Any use of a curved metric will be noted explicitly. Further discussion of AdS coordinates and some specfic choices for $a(x^2)$ and $b(x^2)$ are found in Appendix A.

Since the embedding of the AdS_d brane breaks the AdS_{d+1} space-time symmetries to those of AdS_d, the associated Nambu-Goldstone bosons act as coordinates of the coset manifold corresponding to the $SO(2,d) \to SO(2,d-1)$ breakdown. In this paper, we show, using coset methods,[9–11] that the $SO(2,d)$ invariant action governing the dynamics of the Nambu-Goldstone boson degree of freedom takes the form

$$\Gamma = -\sigma \int d^d x \det \overline{e}(x) \cosh^d(m\phi(x)) \sqrt{1 - \frac{\mathcal{D}_\ell \phi(x)\, \eta^{\ell n} \mathcal{D}_n \phi(x)}{\cosh^2(m\phi(x))}}. \tag{1.8}$$

Here $\mathcal{D}_n = \overline{e}_n^{-1\mu}(x)\partial_\mu$ is the $SO(2,d-1)$ covariant derivative with $n = 0,1,\ldots,d-1$. The AdS_d vielbein, $\overline{e}_\mu^{\ n}$, corresponding to the metric tensor $\overline{g}_{\mu\nu} = \overline{e}_\mu^{\ \ell} \eta_{\ell n} \overline{e}_\nu^{\ n}$ is given by

$$\begin{aligned} \overline{e}_\mu^{\ n}(x) &= a(x^2) P_{T\mu}^{\ \ n}(x) + \sqrt{\left[\left(a(x^2) + 2x^2 \frac{da(x^2)}{dx^2}\right)^2 + 4\frac{x^2}{m^2}\left(\frac{db(x^2)}{dx^2}\right)^2\right]} P_{L\mu}^{\ \ n}(x) \\ &= a^2(x^2) P_{T\mu}^{\ \ n}(x) + \frac{a(x^2) + 2x^2 \frac{da(x^2)}{dx^2}}{\sqrt{1 - m^2 x^2 a^2(x^2)}} P_{L\mu}^{\ \ n}. \end{aligned} \tag{1.9}$$

The overall positive constant σ (brane tension) carries mass dimension d. Note that the overall sign of the action is fixed so that the ϕ kinetic energy term is positive. Equation (1.8) is the AdS generalization of the Nambu-Goto action for an AdS_d brane embedded in AdS_{d+1} space. We see that the Nambu-Goldtone mode is massive and has nonderivative self-interactions.

The outline of the paper is as follows. The coset method construction is presented in Sec. II along with the explicit form of the nonlinear realizations of the $SO(2,d)$ transformations of the Nambu-Goldstone fields. The action building blocks secured from the Maurer-Cartan one-form also appear in this section. Section III includes the transformation properties of the Maurer-Cartan one form along with the construction of the $SO(2,d)$ invariant AdS_d action. In addition, this section contains the general AdS_d coordinate transformations. The form of the AdS_d action is shown to remain invariant under these coordinate transformations. Finally in Sec. III, the vector field theory equivalent of this action is also secured. In this construction, it is the longitudnal component of the vector field which plays the role of the massive Nambu-Goldstone degree of freedom. In the Poincaré limit, $m \to 0$, the usual equivalence of this action to a tensor gauge theory[12] action is obtained.[13] There are two appendixes. Appendix A contains a discussion of the various AdS coordinate systems used in the paper, while the AdS isometry charge algebra is reviewed in Appendix B.

II. THE COSET CONSTRUCTION

The isometry group of the AdS_{d+1} hyperboloid [cf. Eq. (1.1)] is $SO(2,d)$ while that of the AdS_d subspace is $SO(2,d-1)$. The action governing the dynamics of the Nambu-Goldstone modes associated with the symmetry breakdown $SO(2,d) \to SO(2,d-1)$ can be constructed by means of the coset method. This technique begins by introducing the coset element $\Omega \in SO(2,d)/SO(1,d-1)$ where $SO(1,d-1)$ corresponds to the Lorentz (stability) group of transformations in AdS_d. The $AdS_d = SO(2,d-1)/SO(1,d-1)$ coordinates, y^μ, act as parameters for pseudotranslations in the world volume and are part of the coset so that

$$\Omega(y) = e^{iy^\mu P_\mu} e^{i\phi(y) Z} e^{iv^\mu(y) K_\mu}. \tag{2.1}$$

Here the symmetry generators P_μ, Z, and K_μ, as well as the Lorentz transformations generators $M_{\mu\nu}$, are defined in Appendix B. The coset so defined corresponds to a particular choice of coordinates, specifically denoted as y^μ, for the AdS_d world volume. The fields are also defined as functions of y^μ. Other coordinate choices, generically denoted by x^μ, can and will be used. In

order to transform to these coordinates, the y^μ will be defined as a function of the x^μ coordinates, $y^\mu = y^\mu(x)$. Likewise in this case, the fields will also be relabeled as functions of x^μ. That is, $\phi(y) = \phi(y(x)) \to \phi(x)$ and $v^m(y) = v^m(y(x)) \to v^m(x)$. Hence the coset element has the same operator structure as in Eq. (2.1) but now the fields and y are functions of x so that $\Omega(y) = \Omega(y(x)) \to \Omega(x) = e^{iy^\mu(x)P_\mu} e^{i\phi(x)Z} e^{iv^\mu(x)K_\mu}$. For the present, we use the y^μ coordinates and the fields are considered functions of y^μ. The Nambu-Goldstone field $\phi(y)$ along with $v^\mu(y)$ act as the remaining coordinates needed to parametrize the coset manifold $\mathrm{SO}(2,d)/\mathrm{SO}(2,d-1)$.

Left multiplication of the coset elements Ω by an $\mathrm{SO}(2,d)$ group element

$$g = e^{i\epsilon^\mu P_\mu} e^{izZ} e^{ib^\mu K_\mu} e^{(i/2)\lambda^{\mu\nu} M_{\mu\nu}}, \tag{2.2}$$

which is specified by the (space-time independent) infinitesimal parameters $\epsilon^\mu, z, b^\mu, \lambda^{\mu\nu}$, results in transformations of the space-time coordinates and the Nambu-Goldstone fields according to the general form[9]

$$g\Omega = \Omega' h. \tag{2.3}$$

The transformed coset element, Ω', is a function of the transformed world volume coordinates and the total variations of the fields,

$$\Omega' = e^{iy'^\mu P_\mu} e^{i\phi'(y')Z} e^{iv'^\mu(y')K_\mu}, \tag{2.4}$$

while h is a field dependent element of the stability group $\mathrm{SO}(1,d-1)$,

$$h = e^{(i/2)\theta^{\mu\nu}(y) M_{\mu\nu}}. \tag{2.5}$$

Exploiting the algebra of the $\mathrm{SO}(2,d)$ charges displayed in Appendix B, along with extensive use of the Baker-Campbell-Hausdorf formulas, the AdS transformations are obtained as

$$\begin{aligned} y'^\mu = {} & \left[1 - z\sqrt{m^2}\tanh\sqrt{m^2\phi^2}\frac{\sin\sqrt{m^2y^2}}{\sqrt{m^2y^2}} \right] y^\mu - \lambda^{\mu\nu} y_\nu + [P_L^{\mu\nu}(y) + \sqrt{m^2y^2}\cot\sqrt{m^2y^2} P_T^{\mu\nu}(y)]\epsilon_\nu \\ & + \frac{\tanh\sqrt{m^2\phi^2}}{\sqrt{m^2}} \left[\cos\sqrt{m^2y^2} P_L^{\mu\nu}(y) + \frac{\sqrt{m^2y^2}}{\sin\sqrt{m^2y^2}} P_T^{\mu\nu}(y) \right] b_\nu, \end{aligned}$$

$$\phi'(y') = \phi(y) + z\cos\sqrt{m^2y^2} + b_\mu y^\mu \frac{\sin\sqrt{m^2y^2}}{\sqrt{m^2y^2}},$$

$$\begin{aligned} v'^\mu(y') = {} & v^\mu(y) - \lambda^{\mu\nu} v_\nu - \frac{m^2}{2}\frac{\tan\sqrt{m^2y^2/4}}{\sqrt{m^2y^2/4}}(\epsilon^\mu y^\nu - \epsilon^\nu y^\mu) v_\nu \\ & - z\frac{m^2}{\cosh\sqrt{m^2\phi^2}}\frac{\sin\sqrt{m^2y^2}}{\sqrt{m^2y^2}}[P_L^{\mu\nu}(v) + \sqrt{v^2}\coth\sqrt{v^2} P_T^{\mu\nu}(v)] y_\nu \\ & + \sqrt{m^2/4}\frac{\tan\sqrt{m^2y^2/4}}{\sqrt{m^2y^2/4}}\tanh\sqrt{m^2\phi^2}(b^\mu y^\nu - b^\nu y^\mu) v_\nu \\ & + \frac{1}{\cosh\sqrt{m^2\phi^2}}[P_L^{\mu\nu}(v) + \sqrt{v^2}\coth\sqrt{v^2} P_T^{\mu\nu}(v)][\cos\sqrt{m^2y^2} P_{L\nu\rho}(y) + P_{T\nu\rho}(y)] b^\rho, \end{aligned}$$

$$\theta^{\mu\nu}(y)=\lambda^{\mu\nu}+\frac{m^2}{2}\frac{\tan\sqrt{m^2y^2/4}}{\sqrt{m^2y^2/4}}(\epsilon^\mu y^\nu-\epsilon^\nu y^\mu)-z\frac{m^2}{\cosh\sqrt{m^2\phi^2}}\frac{\sin\sqrt{m^2y^2}}{\sqrt{m^2y^2}}(v^\mu y^\nu-v^\nu y^\mu)\frac{\tanh\sqrt{v^2/2}}{\sqrt{v^2}}$$
$$-\sqrt{m^2/4}\frac{\tan\sqrt{m^2y^2/4}}{\sqrt{m^2y^2/4}}\tanh\sqrt{m^2\phi^2}(b^\mu y^\nu-b^\nu y^\mu)-\frac{1}{\cosh\sqrt{m^2\phi^2}}\frac{\tanh\sqrt{v^2/2}}{\sqrt{v^2}}$$
$$\times[\cos\sqrt{m^2y^2}P_L^{\mu\rho}(y)b_\rho v^\nu+P_T^{\mu\rho}(y)b_\rho v^\nu-(\mu\leftrightarrow\nu)]. \tag{2.6}$$

The nonlinearly realized $SO(2,d)$ transformations induce a field dependent general coordinate transformation of the world volume space-time coordinates. Using the y^μ coordinate transformation given above, the AdS_{d+1} general coordinate transformation for the world volume space-time coordinate differentials is given by

$$dy'^\mu=dy^\nu\overline{G}_\nu{}^\mu, \tag{2.7}$$

with $\overline{G}_\nu{}^\mu=\partial y'^\mu/\partial y^\nu$. The $SO(2,d)$ invariant interval can be formed using the metric tensor $g_{\mu\nu}(y)$ so that $ds^2=dy^\mu g_{\mu\nu}(y)dy^\nu=ds'^2=dy'^\mu g'_{\mu\nu}(y')dy'^\nu$ where the metric tensor transforms as

$$g'_{\mu\nu}(y')=\overline{G}^{-1\rho}_\mu g_{\rho\sigma}(y)\overline{G}^{-1\sigma}_\nu. \tag{2.8}$$

The form of the vielbein (and hence the metric tensor) as well as the $SO(2,d)$ covariant derivatives of the Nambu-Goldstone boson fields and the spin connection can be extracted from the Maurer-Cartan one-form, $\Omega^{-1}d\Omega$, which can be expanded in terms of the generators as

$$\Omega^{-1}d\Omega=i\left[\omega^m P_m+\omega_Z Z+\omega_K^m K_m+\tfrac{1}{2}\omega_M^{mn}M_{mn}\right]. \tag{2.9}$$

Italic indices $m,n=0,1,\ldots,d-1$, are used to distinguish tangent space (italic indices) transformation properties from world volume (greek indices) transformation properties. Recall all contracted indices (italic or greek) are summed using the d-dimensional Minkowski metric tensor. Applying the Feynman formula for the variation of an exponential operator in conjunction with the Baker-Campell-Hausdorff formulas, the individual world volume one-forms appearing in the above decomposition of the Maurer-Cartan one-form are secured as

$$\omega^m=-\frac{\sinh\sqrt{v^2}}{\sqrt{v^2}}v^m d\phi+\cosh\sqrt{m^2\phi^2}[P_T^{mn}(v)+\cosh\sqrt{v^2}P_L^{mn}(v)]\overline{\omega}_n,$$

$$\omega_Z=\cosh\sqrt{v^2}\left[d\phi-\cosh\sqrt{m^2\phi^2}\overline{\omega}_m v^m\frac{\tanh\sqrt{v^2}}{\sqrt{v^2}}\right],$$

$$\omega_K^m=dv^m-\left(\frac{\sinh\sqrt{v^2}}{\sqrt{v^2}}-1\right)\frac{[v^m v_n dv^n-v^2dv^m]}{v^2}-\overline{\omega}_M^{mn}v_n\frac{\sinh\sqrt{v^2}}{\sqrt{v^2}}$$
$$+\sqrt{m^2}\sinh\sqrt{m^2\phi^2}[P_L^{mn}(v)+\cosh\sqrt{v^2}P_T^{mn}(v)]\overline{\omega}_n,$$

$$\omega_M^{mn}=\overline{\omega}_M^{mn}+[\cosh\sqrt{v^2}-1]\frac{v^m dv^n-v^n dv^m}{v^2}-(\cosh\sqrt{v^2}-1)[P_{Lr}^m(v)\overline{\omega}_M^{nr}-P_{Lr}^n(v)\overline{\omega}_M^{mr}]$$
$$+\sqrt{m^2}\sinh\sqrt{m^2\phi^2}\frac{\sinh\sqrt{v^2}}{\sqrt{v^2}}\overline{\omega}_r[v^m P_T^{rn}(v)-v^n P_T^{rm}(v)]. \tag{2.10}$$

In these expressions, the AdS_d covariant coordinate differential, $\overline{\omega}^m$, and spin connection, $\overline{\omega}_M^{mn}$, are obtained from the AdS_d coordinate one-form $(e^{-iy^m P_m})d(e^{iy^n P_n})=i\left[\overline{\omega}^m P_m+\frac{1}{2}\overline{\omega}_M^{mn}M_{mn}\right]$ as

$$\overline{\omega}^m = \frac{\sin\sqrt{m^2y^2}}{\sqrt{m^2y^2}} P_T^{mn}(y)\mathrm{d}y_n + P_L^{mn}(y)\mathrm{d}y_n,$$
$$\overline{\omega}_M^{mn} = [\cos\sqrt{m^2y^2} - 1]\frac{(y^m\mathrm{d}y^n - y^n\mathrm{d}y^m)}{y^2}. \tag{2.11}$$

The differential $\overline{\omega}^m$ is related to the y^μ world volume coordinate differential via the vielbein $\overline{e}_\mu{}^m(y)$ as

$$\overline{\omega}^m = \mathrm{d}y^\mu \overline{e}_\mu{}^m(y). \tag{2.12}$$

Using Eq. (2.11) along with $d=\mathrm{d}y^\mu\partial_\mu^y$, this vielbein is obtained as

$$\overline{e}_\mu{}^m(y) = \frac{\sin\sqrt{m^2y^2}}{\sqrt{m^2y^2}} P_{T\mu}{}^m(y) + P_{L\mu}{}^m(y). \tag{2.13}$$

Thus it is seen that the y coordinates correspond to the choice of embedding coordinates [cf. Eq. (1.3)]

$$a(y^2) = \frac{\sin\sqrt{m^2y^2}}{\sqrt{m^2y^2}},$$
$$b(y^2) = \cos(\sqrt{m^2y^2}). \tag{2.14}$$

The two sets of bases for coordinate differentials, $\mathrm{d}y^\mu$ and the AdS_{d+1} covariant one-form ω^m, are related to each other through the vielbein $e_\mu{}^m(y)$,

$$\omega^m(y) = \mathrm{d}y^\mu e_\mu{}^m(y). \tag{2.15}$$

Again using that $d=\mathrm{d}y^\mu\partial_\mu^y$, it follows from the first equality in Eq. (2.10) that the vielbein $e_\mu{}^m$ can be factorized as

$$e_\mu{}^m(y) = \overline{e}_\mu{}^n(y) N_n{}^m(y), \tag{2.16}$$

where the Nambu-Goto vielbein, $N_n{}^m(y)$, is

$$N_n{}^m(y) = -v^m\frac{\sinh\sqrt{v^2}}{\sqrt{v^2}}\mathcal{D}_n\phi + \cosh\sqrt{m^2\phi^2}[P_{Tn}^m(v) + \cosh\sqrt{v^2}P_{Ln}^m(v)], \tag{2.17}$$

and the AdS_d covariant derivative is defined as $\mathcal{D}_n=\overline{e}_n^{-1\mu}(y)\partial_\mu^y$.

III. THE INVARIANT ACTION

To construct an $\mathrm{SO}(2,d)$ invariant action, we begin by using [cf. Eqs. (2.3) and (2.5)]

$$\Omega'(y') = g\Omega(y)e^{-(i/2)\theta^{mn}(y)M_{mn}} \tag{3.1}$$

and isolating the coefficient of P_m in the decomposition of $(\Omega^{-1}\mathrm{d}\Omega)'(y')$ giving

$$\omega'^m(y')P_m = \omega^m(y)e^{(i/2)\theta^{lr}(y)M_{lr}}P_m e^{-(i/2)\theta^{st}(y)M_{st}}. \tag{3.2}$$

Next, from the $\mathrm{SO}(2,d)$ algebra (see Appendix B) it follows that

$$e^{(i/2)\theta^{lr}M_{lr}}P_m e^{-(i/2)\theta^{st}M_{st}} = \Lambda_m{}^n(\theta)P_n, \tag{3.3}$$

where $\Lambda_m{}^n(\theta)$ is an AdS_d (local) Lorentz transformation with parameter $\theta^{rs}(y)$ so that $\det\Lambda=1$.

Thus

$$\omega'^{m}(y') = dy'^{\nu} e'^{m}_{\nu}(y') = \omega^{n}(y)\Lambda_{n}{}^{m} = dy^{\rho} e_{\rho}{}^{n}(y)\Lambda_{n}{}^{m}, \tag{3.4}$$

where $dy'^{\mu} = dy^{\rho}\overline{G}_{\rho}{}^{\mu}$, Eq. (2.7). Consequently the vielbeins are related as

$$e_{\rho}{}^{n}(y)\Lambda_{n}{}^{m} = \overline{G}_{\rho}{}^{\nu} e'^{m}_{\nu}(y'). \tag{3.5}$$

Taking the determinant (using $\det \Lambda = 1$) then yields $\det e' = (\det \overline{G})^{-1} \det e$. Since the Jacobian of the $y^{\mu} \to y'^{\mu}$ transformation is simply

$$d^{d}y' = d^{d}y \det \overline{G}, \tag{3.6}$$

it follows that $d^{d}y' \det e'(y') = d^{d}y \det e(y)$. Thus an $SO(2,d)$ invariant action is constructed as

$$\Gamma = -\sigma \int d^{d}y \det e(y), \tag{3.7}$$

with the vacuum energy denoted by σ. Note that the action is simply the negative of the brane tension integrated over the invariant AdS volume.

An additional general coordinate transformation can be made taking the y^{μ} coordinates to the x^{μ} coordinates, $y^{\mu} = y^{\mu}(x)$, so that the $SO(2,d)$ invariant interval will assume the form $ds^2 = dx^{\mu} g_{\mu\nu}(x) dx^{\nu}$ with the metric tensor given by

$$g_{\mu\nu}(x) = \frac{\partial y^{\rho}(x)}{\partial x^{\mu}} g_{\rho\sigma}(y(x)) \frac{\partial y^{\sigma}(x)}{\partial x^{\nu}} = a_{\mu}{}^{\rho}(x) g_{\rho\sigma}(y(x)) a_{\nu}{}^{\sigma}(x). \tag{3.8}$$

The transformation matrix associated with this change of variables is defined to be $a_{\mu}{}^{\rho}(x) = \partial y^{\rho}(x)/\partial x^{\mu}$. Consequently the $SO(2,d)$ transformations similarly induce a field dependent general coordinate transformation of these new world volume coordinates

$$x'^{\mu} = x^{\mu} + a^{-1\mu}_{\nu}(x)\, \delta y^{\nu}(x), \tag{3.9}$$

where the corresponding $SO(2,d)$ variation of y^{μ} is given in Eq. (2.6), $\delta y^{\mu} = y'^{\mu} - y^{\mu}$. From Eq. (3.9), the new coordinate differentials transform as

$$dx'^{\mu} = dx^{\nu} G_{\nu}{}^{\mu}, \tag{3.10}$$

with $G_{\nu}{}^{\mu} = \partial x'^{\mu}/\partial x^{\nu}$. Relating the coordinate differentials through the transformation matrix, $dy^{\mu} = dx^{\nu}(\partial y^{\mu}/\partial x^{\nu}) = dx^{\nu} a_{\nu}{}^{\mu}$ and likewise for the $SO(2,d)$ transformed coordinates, $dy'^{\mu} = dx'^{\nu}(\partial y'^{\mu}/\partial x'^{\nu}) = dx'^{\nu} a'^{\mu}_{\nu}$, the variation of the transformation matrix is obtained,

$$a'^{\mu}_{\nu} = \frac{\partial y'^{\mu}}{\partial x'^{\nu}} = \frac{\partial y'^{\mu}}{\partial y^{\sigma}} \frac{\partial y^{\sigma}}{\partial x^{\rho}} \frac{\partial x^{\rho}}{\partial x'^{\nu}} = G^{-1\rho}_{\nu} a_{\rho}{}^{\sigma} \overline{G}_{\sigma}{}^{\mu}. \tag{3.11}$$

Hence the invariance of the interval in terms of the new x^{μ} coordinates is secured since $g'_{\mu\nu}(x') = G^{-1\rho}_{\mu} g_{\rho\sigma}(x) G^{-1\sigma}_{\nu}$.

The covariant coordinate differential one-forms are related to the new coordinate differentials dx^{μ} through the vielbein $e_{\mu}{}^{m}(x)$ as

$$\omega^{m}(x) = dx^{\mu} e_{\mu}{}^{m}(x). \tag{3.12}$$

Thus the y^{μ} and the x^{μ} coordinate vielbein are related by the transformation matrix

$$e_{\mu}{}^{m}(x) = a_{\mu}{}^{\nu} e_{\nu}{}^{m}(y). \tag{3.13}$$

In a similar fashion, the $\overline{\omega}^{m}$ one-form can also be expanded in terms of dx^{μ} as $\overline{\omega}^{m} = dx^{\mu}\, \overline{e}_{\mu}{}^{m}(x) = dy^{\mu}\, \overline{e}_{\mu}{}^{m}(y)$ thus giving

$$\overline{e}_{\mu}{}^{m}(x) = a_{\mu}{}^{\nu}\overline{e}_{\nu}{}^{m}(y). \tag{3.14}$$

The AdS_d covariant derivative has the same form in either coordinate system,

$$\mathcal{D}_m = \overline{e}{}^{-1\mu}_{m}(y)\partial^{y}_{\mu} = \overline{e}{}^{-1\mu}_{m}(y)a^{-1\nu}_{\mu}\partial^{x}_{\nu} = \overline{e}{}^{-1\mu}_{m}(x)\partial^{x}_{\mu} \tag{3.15}$$

as does the Nambu-Goto vielbein $N_n{}^m$. Thus Eq. (2.17), after making the replacements $\phi(y) = \phi(y(x)) \to \phi(x)$ and $v^m(y) = v^m(y(x)) \to v^m(x)$, reads

$$N_n{}^m(x) = -v^m\frac{\sinh(\sqrt{v^2})}{\sqrt{v^2}}\mathcal{D}_n\phi + \cosh\sqrt{m^2\phi^2}\left[P^m_{Tn}(v) + \cosh(\sqrt{v^2})P^m_{Ln}(v)\right]. \tag{3.16}$$

It follows that the x coordinate vielbein also has the factorized form

$$e_{\mu}{}^{m}(x) = a_{\mu}{}^{\nu}e_{\nu}{}^{m}(y) = a_{\mu}{}^{\nu}\overline{e}_{\nu}{}^{n}(y)N_n{}^m(y) = \overline{e}_{\mu}{}^{n}(x)N_n{}^m(x). \tag{3.17}$$

Using Eq. (3.13), the $\mathrm{SO}(2,d)$ invariant action in the x coordinate system then becomes

$$\begin{aligned}\Gamma &= -\sigma\int \mathrm{d}^d y \det e(y) = -\sigma\int \mathrm{d}^d x \det a \det a^{-1}\det e(x)\\ &= -\sigma\int \mathrm{d}^d x \det e(x) = -\sigma\int \mathrm{d}^d x \det \overline{e}(x)\det N(x).\end{aligned} \tag{3.18}$$

Finally, the determinant of the Nambu-Goto vielbein is evaluated as

$$\det N = \cosh^d(m\phi)\cosh(\sqrt{v^2})\left[1 - \left(v^n\frac{\tanh(\sqrt{v^2})}{\sqrt{v^2}}\right)\left(\frac{\mathcal{D}_n\phi}{\cosh(m\phi)}\right)\right], \tag{3.19}$$

so that the action (3.18) reads

$$\Gamma = -\sigma\int \mathrm{d}^d x \det \overline{e}(x)\cosh^d(m\phi)\cosh(\sqrt{v^2})\left[1 - \left(v^n\frac{\tanh(\sqrt{v^2})}{\sqrt{v^2}}\right)\left(\frac{\mathcal{D}_n\phi}{\cosh(m\phi)}\right)\right]. \tag{3.20}$$

Note that the v^n field is not an independent dynamical degree of freedom since it enters the action with no derivative. Hence it can be expressed in terms of the Nambu-Goldstone boson ϕ through its field equation as

$$v_n\frac{\tanh\sqrt{v^2}}{\sqrt{v^2}} = \frac{\mathcal{D}_n\phi}{\cosh\sqrt{m^2\phi^2}}. \tag{3.21}$$

This relation is identical to that obtained by setting to zero the $\mathrm{SO}(2,d)$ invariant second equality in Eq. (2.10) from the expansion of the Maurer-Cartan one-form, $\omega_Z = 0$. This is referred to as the "inverse Higgs mechanism."[8] Exploiting this relation, the final form of the Nambu-Goto action for an AdS_d brane embedded in AdS_{d+1} target space is secured,

$$\Gamma = -\sigma\int \mathrm{d}^d x \det e = -\sigma\int \mathrm{d}^d x \det \overline{e}\cosh^d(m\phi)\sqrt{1 - \frac{\mathcal{D}_\ell\phi\eta^{\ell n}\mathcal{D}_n\phi}{\cosh^2(m\phi)}}. \tag{3.22}$$

This is the AdS space generalization of the Nambu-Goto action for the Nambu-Goldstone mode. Expanding the action through terms bilinear in ϕ gives

$$\Gamma = -\sigma \int d^d x \det \overline{e} \left\{ 1 + \frac{1}{2}(d\ m^2)\phi^2 - \frac{1}{2}\partial_\mu \phi \overline{g}^{\mu\nu}\partial_\nu \phi + \cdots \right\}. \tag{3.23}$$

It is seen that the Nambu-Goldstone boson carries the $(E,s)=(d,0)$ representation[5] of $SO(2,d-1)$. That is, it has mass squared equal to $d\ m^2$ and hence energy d in units of m while being spin zero.

Note that the form of the action, Eq. (3.22), also follows from the invariant interval of the AdS_{d+1} space, Eq. (1.5), provided one identifies the covolume coordinate r with the Nambu-Goldstone field $\phi(x), r\to\phi(x)$. Using this identification, the interval can be written as $ds^2 = dx^\mu g_{\mu\nu}(x) dx^\nu$, with

$$g_{\mu\nu}(x) = \overline{g}_{\mu\nu}(x)\cosh^2(m\phi) - \partial_\mu\phi\partial_\nu\phi. \tag{3.24}$$

The $SO(2,d)$ invariant AdS_d brane action, Γ, can then be constructed from $g_{\mu\nu}$ as

$$\Gamma = -\sigma \int d^d x \sqrt{-(-1)^d \det g_{\mu\nu}}. \tag{3.25}$$

Introducing the AdS_d vielbein, $\overline{e}_\mu{}^m(x)$, via $\overline{g}_{\mu\nu} = \overline{e}_\mu{}^m \eta_{mn} \overline{e}_\nu{}^n$, as in Eq. (1.9), and likewise the AdS_{d+1} vielbein, $e_\mu{}^m(x)$ as $g_{\mu\nu} = e_\mu{}^m \eta_{mn} e_\nu{}^n$, it then follows that $e_\mu{}^m$ has the factorized form

$$e_\mu{}^n(x) = \overline{e}_\mu{}^\ell(x) N_\ell{}^n(x), \tag{3.26}$$

where the Nambu-Goto vielbein, $N_n{}^m$ is given by

$$N_\ell{}^n(x) = \delta_\ell{}^n \cosh(m\phi(x)) + \left[\sqrt{(\cosh^2(m\phi(x)) - \mathcal{D}_r\phi(x)\,\eta^{rs}\mathcal{D}_s\phi(x))} - \cosh(m\phi(x))\right] \frac{\mathcal{D}_\ell\phi(x)\mathcal{D}^n\phi(x)}{(\mathcal{D}\phi)^2(x)}. \tag{3.27}$$

The action can then be expressed in terms of the vielbein as

$$\begin{aligned}\Gamma &= -\sigma \int d^d x \det e(x) = -\sigma \int d^d x \det \overline{e}(x) \det N(x) \\ &= -\sigma \int d^d x \det \overline{e}(x) \cosh^d(m\phi(x)) \sqrt{1 - \frac{\mathcal{D}_\ell\phi(x)\,\eta^{\ell n}\mathcal{D}_n\phi(x)}{\cosh^2(m\phi(x))}},\end{aligned} \tag{3.28}$$

which is precisely Eq. (3.22).

Next reconsider the action with both Nambu-Goldstone fields ϕ and v^m present and independent as given in Eq. (3.20),

$$\Gamma = -\sigma \int d^d x \det \overline{e} \left[\cosh^d(\sqrt{m^2\phi^2}) \cosh(\sqrt{v^2}) - \cosh^{d-1}\sqrt{(m^2\phi^2)} \frac{\sinh(\sqrt{v^2})}{\sqrt{v^2}} v^m \mathcal{D}_m\phi \right]. \tag{3.29}$$

Defining the (ϕ independent) vector density field F^μ as

$$F^\mu \equiv \det \overline{e} \frac{\sinh(\sqrt{v^2})}{\sqrt{v^2}} v^n \overline{e}_n^{-1\mu}, \tag{3.30}$$

the v^n dependent terms can be expressed as F^μ and

$$\det \overline{e} \cosh(\sqrt{v^2}) = \sqrt{(\det \overline{e})^2 + F^\mu \overline{g}_{\mu\nu} F^\nu} = \sqrt{-(-1)^d \det \overline{g}_{\mu\nu} + F^\mu \overline{g}_{\mu\nu} F^\nu} = \sqrt{-(-1)^d \det(\overline{g}_{\mu\nu} + F_\mu F_\nu)}, \tag{3.31}$$

where the covariant vector field is

$$F_\mu = \frac{1}{\det \overline{e}} \overline{g}_{\mu\nu} F^\nu. \tag{3.32}$$

The action can then be written as

$$\Gamma = -\sigma \int \mathrm{d}^d x [\sqrt{-(-1)^d \det(\overline{g}_{\mu\nu} + F_\mu F_\nu)} \cosh^d(m\phi) - F^\mu \partial_\mu \phi \cosh^{d-1}(m\phi)]. \tag{3.33}$$

Expressing the second term on the right-hand side as

$$\partial_\mu \phi \cosh^{d-1}(m\phi) = \partial_\mu f(\phi) \tag{3.34}$$

so that $\mathrm{d}f/\mathrm{d}\phi = \cosh^{d-1}(m\phi)$, the action, after integrating the second term by parts, can be written as

$$\Gamma = -\sigma \int d^d x [\sqrt{-(-1)^d \det(\overline{g}_{\mu\nu} + F_\mu F_\nu)} \cosh^d(m\phi) + f(\phi) \partial_\mu F^\mu]. \tag{3.35}$$

Note that in the Poincaré limit, $m \to 0$, the action reduces to $\Gamma \to -\sigma \int \mathrm{d}^d x [\sqrt{1+F^2} + \phi \partial_\mu F^\mu]$. In that case, the ϕ field equation, $\delta\Gamma/\delta\phi = 0 = \partial_\mu F^\mu$, is just the Bianchi identity for F^μ. That is, the dual of F^μ is closed. Hence F^μ can be (locally) expressed as $F^\mu = \epsilon^{\mu\nu(\rho)} \partial_\nu B_{(\rho)}$, where the $(d-2)$-form $B_{(\rho)}$ is a tensor gauge potential. Eliminating the ϕ term from the action by integration by parts, the tensor gauge theory action dual to the bosonic Poincaré brane Nambu-Goto action is obtained.[13] The situation for $m \neq 0$ is quite different.

Now the ϕ field equation

$$\frac{\delta\Gamma}{\delta\phi} = 0 = -\sigma \frac{\mathrm{d}f(\phi)}{\mathrm{d}\phi} [\partial_\mu F^\mu + \mathrm{d}\ m \sinh(m\phi) \det \overline{e} \cosh(\sqrt{v^2})] \tag{3.36}$$

can be used to eliminate it from the action. Introducing a Lagrange multiplier field L to enforce this equality, the action becomes

$$\Gamma = -\sigma \int \mathrm{d}^d x [\sqrt{-(-1)^d \det(\overline{g}_{\mu\nu} + F_\mu F_\nu)} (T(\phi) + L\ \mathrm{d}\ m \sinh(m\phi)) + L \partial_\mu F^\mu], \tag{3.37}$$

where

$$T(\phi) = \cosh^d(m\phi) - \mathrm{d}\ m\ f(\phi) \sinh(m\phi). \tag{3.38}$$

After employing Eq. (3.36) to eliminate the ϕ and L fields, the action takes the form

$$\Gamma = -\sigma \int \mathrm{d}^d x \sqrt{(-1)^{d-1} \det(\overline{g}_{\mu\nu} + F_\mu F_\nu)} T(F). \tag{3.39}$$

Here $T(\phi) = T(\phi(F)) \to T(F)$ where the implicit dependence of ϕ on F^μ is given by

$$\sinh m\phi = -\frac{\partial_\mu F^\mu}{\mathrm{d}\ m \sqrt{-(-1)^d \det(\overline{g}_{\mu\nu} + F_\mu F_\nu)}}, \tag{3.40}$$

which follows from the equation of motion (3.36).

Expanding T through terms bilinear in the field gives

$$T(F) = 1 - \frac{1}{2} \mathrm{d}\ m^2 \phi^2 + \mathcal{O}(\phi^3) = 1 - \left(\frac{1}{\mathrm{d}\ m^2 \det^2 \overline{e}} \right) (\partial_\mu F^\mu)^2 + \cdots. \tag{3.41}$$

Substituting this into Eq. (3.39) and expanding the square root, the bilinear in the field F^μ form of the action becomes

$$\Gamma = -\sigma \int d^d x \det \overline{e} \left\{ 1 + \left(\frac{1}{m^2 d \det^2 \overline{e}} \right) \left[\frac{1}{2}(m^2 d) F^\mu \overline{g}_{\mu\nu} F^\nu - \frac{1}{2} \partial_\mu F^\mu \partial_\nu F^\nu + \cdots \right] \right\}. \quad (3.42)$$

The ellipses refer to the F^μ field self-interactions.

The F_μ field equation then gives

$$\det \overline{e}\, \overline{g}^{\mu\nu} \partial_\nu \left(\frac{1}{\det \overline{e}} \partial_\lambda F^\lambda \right) - \mathrm{d}\, m^2 F^\mu = J^\mu, \quad (3.43)$$

where J_μ contains the F field self-interactions contained in the ellipses. Taking the divergence of Eq. (3.43), it follows that the longitudnal projection $F_L \equiv (1/\det \overline{e}) \partial_\mu F^\mu$ satisfies the equation

$$\left[\overline{g}^{\mu\nu} \partial_\mu \partial_\nu - \mathrm{d}\, m^2 + \frac{1}{\det \overline{e}} \partial_\mu (\det \overline{e}\, \overline{g}^{\mu\nu}) \partial_\nu \right] F_L = \frac{1}{\det \overline{e}} \partial_\mu J^\mu. \quad (3.44)$$

The differential operator on the left-hand side acting on F_L is identical to the differential operator acting on ϕ which appears in the ϕ field equation resulting from the AdS Nambu-Goto action. Thus the longitudinal mode F_L describes a propagating scalar degree of freedom with mass $\mathrm{d}\, m^2$ and Eq. (3.39) is the vector field action equivalent to the Nambu-Goto action in AdS space. On the other hand, using the field equation (3.43), the transverse component of F is constrained to satisfy

$$\mathrm{d}\, m^2 \epsilon^{\mu_1 \mu_2 \cdots \mu_d} \partial_{\mu_1} \left[\frac{1}{\det \overline{e}} \overline{g}_{\mu_2 \nu} F^\nu \right] = -\epsilon^{\mu_1 \mu_2 \cdots \mu_d} \partial_{\mu_1} \left[\frac{1}{\det \overline{e}} \overline{g}_{\mu_2 \nu} J^\nu \right]. \quad (3.45)$$

Indeed this equivalence can be run in reverse. Starting with Eq. (3.39), the Lagrange multiplier field L can be reintroduced to give Eq. (3.37) [recall that $T(\phi) = \cosh^d(m\phi) - \mathrm{d}\, m\, g(\phi) \sinh(m\phi)$]. The fields ϕ, F^μ, and L are all independent. Hence the ϕ field equation, $\delta\Gamma/\delta\phi = 0$ implies that $L = g(\phi)$. Substituting this into the action along with the definition of F^μ in terms of v^n, Eq. (3.30), and integrating by parts, the Nambu-Goto action equation (3.29) is once again obtained.

APPENDIX A: AdS COORDINATES

An AdS_d brane embedded as a $r=0$ hypersurface in an AdS_{d+1} target space has intrinsic coordinates x^μ with the pseudo-Euclidean $(d+2)$-dimensional homogeneous coordinates given as in Eq. (1.3),

$$X^\mu = a(x^2) x^\mu \cosh(mr),$$

$$X^d = \frac{1}{m} \sinh(mr), \quad (A1)$$

$$X^{d+1} = \frac{1}{m} b(x^2) \cosh(mr).$$

The AdS_{d+1} target space and the embedded AdS_d brane hyperbolic equations require the coordinate relation $1 = m^2 x^2 a^2 + b^2$. This leads to a form of the AdS_d metric tensor, Eq. (1.6),

$$\overline{g}_{\mu\nu}(x) = a^2(x^2)P_{T\mu\nu}(x) + \left[\left(a(x^2) + 2x^2\frac{da(x^2)}{dx^2}\right)^2 + 4\frac{x^2}{m^2}\left(\frac{db(x^2)}{dx^2}\right)^2\right]P_{L\mu\nu}(x)$$
$$= a^2(x^2)P_{T\mu\nu}(x) + \frac{\left(a(x^2) + 2x^2\frac{da(x^2)}{dx^2}\right)^2}{1 - m^2x^2a^2(x^2)}P_{L\mu\nu} \tag{A2}$$

and the AdS_d vielbein, Eq. (1.9),

$$\overline{e}_\mu{}^m(x) = a(x^2)P_{T\mu}{}^m(x) + \sqrt{\left[\left(a(x^2) + 2x^2\frac{da(x^2)}{dx^2}\right)^2 + 4\frac{x^2}{m^2}\left(\frac{db(x^2)}{dx^2}\right)^2\right]}P_{L\mu}{}^m(x)$$
$$= a(x^2)P_{T\mu}{}^m(x) + \frac{\left(a(x^2) + 2x^2\frac{da(x^2)}{dx^2}\right)}{\sqrt{1 - m^2x^2a^2(x^2)}}P_{L\mu}{}^m(x). \tag{A3}$$

Only the case where a and b are functions of x^2 are considered.

The coset construction setup naturally led to a specific choice of intrinsic coordinates denoted by y^μ for which the functions a and b were given by Eq. (2.14),

$$a(y^2) = \frac{\sin(\sqrt{m^2y^2})}{\sqrt{m^2y^2}},$$
$$b(y^2) = \cos\sqrt{m^2y^2}. \tag{A4}$$

Hence the embedding relations for these homogeneous coordinates are

$$X^\mu = y^\mu\frac{\sin(\sqrt{m^2y^2})}{\sqrt{m^2y^2}}\cosh(mr),$$
$$X^d = \frac{1}{m}\sinh(mr), \tag{A5}$$
$$X^{d+1} = \frac{1}{m}\cos(\sqrt{m^2y^2})\cosh(mr).$$

The metric on the AdS_d brane was then given by the vielbein, Eq. (2.13),

$$\overline{e}_\mu{}^n(y) = \frac{\sin(\sqrt{m^2y^2})}{\sqrt{m^2y^2}}P_{T\mu}{}^n(y) + P_{L\mu}{}^n(y). \tag{A6}$$

A different choice of intrinsic coordinates x^μ that leaves the AdS_d vielbein $\overline{e}_\mu{}^n$ diagonal is given by

$$a(x^2) = \frac{4}{4 + m^2x^2},$$
$$b(x^2) = \left(\frac{4 - m^2x^2}{4 + m^2x^2}\right), \tag{A7}$$

hence the embedding relations for the homogeneous coordinates become

$$X^\mu = a(x^2)x^\mu \cosh(mr),$$

$$X^d = \frac{1}{m}\sinh(mr), \tag{A8}$$

$$X^{d+1} = a(x^2)\frac{1}{m}\left(\frac{4-m^2x^2}{4}\right)\cosh(mr).$$

The metric on the AdS_d brane is then given by the vielbein,

$$\overline{e_\mu}^n(x) = a(x^2)\delta_\mu{}^n = \left(\frac{4}{4+m^2x^2}\right)\delta_\mu{}^m. \tag{A9}$$

Note that in the Poincaré limit, $m \to 0$, this reduces to the Minkowski metric and vielbein.

The transformation between the x and y coordinates is found by substituting the transformation $y^\mu = x^\mu f(x^2)$ into the expression for $\overline{\omega}^m$ in Eq. (2.11) and requiring a diagonal vielbein. In the process, the function $a(x^2)$ is also determined. The resulting differential equation for f,

$$2x^2 f'(x^2) = -f(x^2)\left(1 - \frac{\sin\sqrt{m^2x^2f(x^2)}}{\sqrt{m^2x^2f(x^2)}}\right), \tag{A10}$$

has the solution

$$f(x^2) = \frac{2\tan^{-1}\sqrt{m^2x^2/4}}{\sqrt{m^2x^2}}. \tag{A11}$$

Hence the coordinate transformation is given by

$$y^\mu = x^\mu \frac{\tan^{-1}\sqrt{m^2x^2/4}}{\sqrt{m^2x^2/4}}, \tag{A12}$$

while the inverse relation is

$$x^\mu = y^\mu \frac{\tan\sqrt{m^2y^2/4}}{\sqrt{m^2y^2/4}}. \tag{A13}$$

In the Poincaré limit, the x and y coordinates are identical, $y^\mu = x^\mu$. In AdS space the transformation matrix between these coordinates is

$$a_\mu{}^\nu(x) = \partial^x_\mu y^\nu(x) = \frac{\tan^{-1}\sqrt{m^2x^2/4}}{\sqrt{m^2x^2/4}}P_{T\mu}{}^\nu(x) + a(x^2)P_{L\mu}{}^\nu(x). \tag{A14}$$

This choice of coordinates has the advantage of simplifying the variations of the fields as well as the transformations of the coordinates themselves. Transforming Eq. (2.6) from y to x coordinates yields

$$x'^\mu = x^\mu + \frac{1}{4}(4-m^2x^2)\epsilon^\mu + \frac{m^2}{2}(\epsilon_\nu x^\nu)x^\mu - \lambda^{\mu\nu}x_\nu - zx^\mu\sqrt{m^2}\tanh\sqrt{m^2\phi^2}$$
$$+ \frac{1}{4}\frac{\tanh\sqrt{m^2\phi^2}}{\sqrt{m^2}}[(4-m^2x^2)P_L^{\mu\nu}(x) + (4+m^2x^2)P_T^{\mu\nu}(x)]b_\nu,$$

$$\phi'(x') = \phi(x) + z\left[\frac{4-m^2x^2}{4+m^2x^2}\right] + a(x^2)x^\mu b_\mu,$$

$$v'^{\mu}(x') = v^{\mu}(x) - \lambda^{\mu\nu}v_{\nu} - \frac{m^2}{2}(\epsilon^{\mu}x^{\nu} - \epsilon^{\nu}x^{\mu})v_{\nu} - za(x^2)\frac{m^2}{\cosh\sqrt{m^2\phi^2}}[P_L^{\mu\nu}(v) + \sqrt{v^2}\coth\sqrt{v^2}P_T^{\mu\nu}(v)]x_{\nu}$$
$$+ \frac{\sqrt{m^2}}{2}\tanh\sqrt{m^2\phi^2}(b^{\mu}x^{\nu} - b^{\nu}x^{\mu})v_{\nu} + \frac{1}{\cosh\sqrt{m^2\phi^2}}[P_L^{\mu\nu}(v) + \sqrt{v^2}\coth\sqrt{v^2}P_T^{\mu\nu}(v)]$$
$$\times\left[P_{T\nu\rho}(x) + \left(\frac{4-m^2x^2}{4+m^2x^2}\right)P_{L\nu\rho}(x)\right]b^{\rho},$$

$$\theta^{\mu\nu} = \lambda^{\mu\nu} + \frac{m^2}{2}(\epsilon^{\mu}x^{\nu} - \epsilon^{\nu}x^{\mu}) - za(x^2)\frac{m^2}{\cosh\sqrt{m^2\phi^2}}\frac{\tanh\sqrt{v^2/2}}{\sqrt{v^2}}(v^{\mu}x^{\nu} - v^{\nu}x^{\mu})$$
$$- \frac{\sqrt{m^2}}{2}\tanh\sqrt{m^2\phi^2}(b^{\mu}x^{\nu} - b^{\nu}x^{\mu}) - \frac{1}{\cosh\sqrt{m^2\phi^2}}\frac{\tanh\sqrt{v^2/2}}{\sqrt{v^2}}$$
$$\times\left[P_T^{\mu\rho}(x)b_{\rho}v^{\nu} + \left(\frac{4-m^2x^2}{4+m^2x^2}\right)P_L^{\mu\rho}(x)b_{\rho}v^{\nu} + -(\mu\leftrightarrow\nu)\right]. \tag{A15}$$

APPENDIX B: AdS SYMMETRY CHARGE ALGEBRA

AdS_{d+1} space can be viewed as a hyperboloid embedded in a $(d+2)$-dimensional pseudo-Euclidean space. The equation of such a hypersurface is given in Eq. (1.1),

$$\frac{1}{m^2} = X_0^2 - X_1^2 - X_2^2 - \cdots - X_d^2 + X_{d+1}^2 = X^{\mathcal{M}}\hat{\eta}_{\mathcal{M}\mathcal{N}}X^{\mathcal{N}}. \tag{B1}$$

Here the pseudo-Euclidean metric tensor $\hat{\eta}_{\mu\nu}$ has signature $(+1,-1,-1,\cdots,-1,+1)$ and $\mathcal{M},\mathcal{N} = 0,1,\cdots,d,d+1$. It follows that the isometry group of this AdS_{d+1} space is $\mathrm{SO}(2,d)$. Denoting the symmetry generators as $M^{\mathcal{M}\mathcal{N}}$, they obey the algebra

$$[M^{\mathcal{M}\mathcal{N}},M^{\mathcal{R}\mathcal{S}}] = -i(\hat{\eta}^{\mathcal{M}\mathcal{R}}M^{\mathcal{N}\mathcal{S}} - \hat{\eta}^{\mathcal{M}\mathcal{S}}M^{\mathcal{N}\mathcal{R}} + \hat{\eta}^{\mathcal{N}\mathcal{S}}M^{\mathcal{M}\mathcal{R}} - \hat{\eta}^{\mathcal{N}\mathcal{R}}M^{\mathcal{M}\mathcal{S}}). \tag{B2}$$

The $\mathrm{SO}(1,d)$ subgroup of Lorentz transformations in AdS_{d+1} space is generated by the charges M^{MN}, where $M,N=0,1,\ldots,d$. The remaining $\mathrm{SO}(2,d)$ generators are the pseudotranslations in AdS_{d+1} space and are given by the Lorentz group vectors $P^M = mM^{d+1,M}$. In terms of P^M and M^{MN}, the $\mathrm{SO}(2,d)$ algebra (B2) reads

$$[M^{MN},M^{RS}] = -i(\eta^{MR}M^{NS} - \eta^{MS}M^{NR} + \eta^{NS}M^{MR} - \eta^{NR}M^{MS}),$$

$$[M^{MN},P^L] = i(P^M\eta^{NL} - P^N\eta^{ML}), \tag{B3}$$

$$[P^M,P^N] = -im^2M^{MN},$$

where the $(d+1)$-dimensional Minkowski metric $\eta_{MN}=(+1,-1,-1,\ldots,-1)$.

An AdS_d brane embedded in the AdS_{d+1} space as a $X^d=0$ hypersurface is described by the hyperboloidal hypersurface

$$\frac{1}{m^2} = X_0^2 - X_1^2 - \cdots - X_{d-1}^2 + X_{d+1}^2. \tag{B4}$$

The brane spontaneously breaks the isometry group of the AdS_{d+1} space from $\mathrm{SO}(2,d)$ to $\mathrm{SO}(2,d-1)$, which is the isometry group of the AdS_d space. The $\mathrm{SO}(2,d)$ generators can be expressed in terms of the unbroken $\mathrm{SO}(1,d-1)$ Lorentz subgroup representation content of the $\mathrm{SO}(2,d-1)$ symmetry group of the brane. The unbroken $\mathrm{SO}(2,d-1)$ symmetry group is generated

by the subgroup Lorentz transformation generators $M^{\mu\nu}$, where $\mu,\nu=0,1,2,\ldots,d-1$ and the pseudotranslations in AdS_d space with charges P^μ. The remaining charges are the generating elements of the $SO(2,d)/SO(2,d-1)$ coset. They are the broken $SO(2,d)$ symmetry transformation charges. $Z=P_d$ generates the broken $SO(2,d)$ pseudotranslations in the X_d direction, while $K^\mu=M^{d\mu}$ generates the broken AdS_{d+1} Lorentz transformations. Thus the $SO(2,d)$ algebra, Eqs. (B2) and (B3), can be written in terms of the $P^\mu, M^{\mu\nu}, Z$, and K^μ charges as

$$
\begin{aligned}
[M^{\mu\nu},M^{\rho\sigma}] &= -i(\eta^{\mu\rho}M^{\nu\sigma}-\eta^{\mu\sigma}M^{\nu\rho}+\eta^{\nu\sigma}M^{\mu\rho}-\eta^{\nu\rho}M^{\mu\sigma}),\\
[M^{\mu\nu},P^\lambda] &= i(P^\mu\eta^{\nu\lambda}-P^\nu\eta^{\mu\lambda}),\\
[M^{\mu\nu},K^\lambda] &= i(K^\mu\eta^{\nu\lambda}-K^\nu\eta^{\mu\lambda}),\\
[M^{\mu\nu},Z] &= 0,\\
[P^\mu,P^\nu] &= -im^2M^{\mu\nu},\\
[K^\mu,K^\nu] &= iM^{\mu\nu},\\
[P^\mu,K^\nu] &= i\eta^{\mu\nu}Z,\\
[P^\mu,Z] &= -im^2K^\mu,\\
[Z,K^\mu] &= iP^\mu.
\end{aligned}
\tag{B5}

The present paper is devoted to the detailed study of quantization and evolution of the point limit of the Pauli-Fierz model for a charged oscillator interacting with the electromagnetic field in dipole approximation. In particular, a well defined dynamics is constructed for the classical model, which is subsequently quantized according to the Segal scheme. To this end, the classical model in the point limit, already obtained by Noja and Posilicano [Ann. I.H.P. Phys. Theor. **71**, 425 (1999)], is reformulated as a second order abstract wave equation, and a consistent quantum evolution is given. This allows a study of the behavior of the survival and transition amplitudes for the process of decay of the excited states of the charged particle, and the emission of photons in the decay process. In particular, for the survival amplitude the exact time behavior is found. This is completely determined by the resonances of the systems plus a tail term prevailing in the asymptotic, long time regime. Moreover, the survival amplitude exhibits in a fairly clear way the Lamb shift correction to the unperturbed frequencies of the oscillator. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2009607]

I. INTRODUCTION

In recent years a considerable effort was tributed by the mathematical physics community to the problem of a rigorous formulation of the dynamics of the main models in nonrelativistic quantum field theory. In particular, a comprehensive study of the Pauli-Fierz model, the model which describes the low energy interaction of nonrelativistic matter and electromagnetic radiation, was undertaken by various authors, both in its full form, or making resort to different approximations, such as rotating wave approximation, dipole approximation, or others. Correspondingly, a wealth of results concerning various aspects of the model have been obtained, concerning self-adjointness of the Hamiltonian, existence, multiplicity or also nonexistence of the ground state and related infrared behavior, and detailed study of the spectral properties of the model and of its resonances. In the present paper we give a comprehensive analysis of some of the previous problems in the special case of a point charged oscillator interacting with the electromagnetic field in dipole approximation. While this model is unrealistically simple compared to the case, to give an example, of the hydrogen atom interacting with the full (not dipole) radiation field, (about which a lot is known thanks to the work of Lieb *et al.*[10,14] and Frölich *et al.*,[3,4] the original

[c)]Electronic mail: posilicano@uninsubria.it

contribution of the present work resides in the fact that we are able to cope with the point limit of the model. The removal of the ultraviolet cutoff in the interaction between matter and radiation is in its generality, a difficult and unsolved problem, and in particular one not faced off in the quoted rigorous literature. In some previous papers of the last two authors (Refs. 16 and 17 and references therein) the renormalized dynamics of the classical Pauli-Fierz model in dipole approximation (Ref. 18) and for fairly general external potentials, was rigorously constructed and analyzed. In particular, it was shown that the evolution of the Pauli-Fierz model in the point limit is given by an abstract wave equation generated by a family of operators related to the so-called point interactions (see Ref. 1 and references therein). Given the classical model in the ultraviolet limit, a second step would be to construct the quantized model. The harmonic potential has the unique feature of giving rise to linear equations of motion, so that the classical equations for the system take the form of an abstract linear wave equation. This allows a plain quantization *à la* Segal of the model, which seems otherwise quite problematic (in contrast with the case of the regularized Pauli-Fierz model, where canonical quantization works; a detailed study of the canonically quantized regularized dipole Pauli-Fierz model with an external harmonic potential was given by Arai in Ref. 2). So we confine ourself to this case, about which we give in the next section a self-contained treatment independent and different in spirit from Ref. 17, to clarify some of the themes discussed above. We outline briefly our main results. The classical evolution of the system is given by the abstract wave equation

$$(\partial_{tt}^2 + L_{\mathrm{e}})\xi = 0$$

for the couple $\xi=(A,p)$ where A is the vector potential of the electromagnetic field in Coulomb gauge and p is the particle momentum variable (see Sec. II for the explanation of this choice). Here L_{e} is a self-adjoint operator in $L^2_*(\mathbb{R}^3)\oplus\mathbb{R}^3$ ($*$ stands for "divergenceless") such that its resolvent can be explicitly calculated (see Lemma 2.2 and Theorem 2.3).

The operator L_{e} has a single negative eigenvalue and the rest of its spectrum is purely absolutely continuous and coincides with $[0,+\infty)$. Thus, to quantize the abstract wave equation above according to the Segal method, one must take L_{e}^+, i.e., L_{e} projected onto the spectral subspace corresponding to $\sigma_{\mathrm{ac}}(L_{\mathrm{e}})$. The (first) quantized dynamics of the system is defined through the Schrödinger-type equation $i\dot{\psi}=(L_{\mathrm{e}}^+)^{1/2}\psi$, defined on the complex Hilbert space $L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3$ and the Hamiltonian of the quantized system of particle and field is given by the second quantization $\mathrm{d}\Gamma((L_{\mathrm{e}}^+)^{1/2})$, on the Fock space over $L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3$.

A preliminary but essential step in the description of the properties of the system is to write the first quantized evolution in terms of the resolvent of the original classical operator L_{e}^+. By Stone formula, spectral theorem and after some work, one gets (see Lemma 2.5) a representation (perhaps new or at least not known to us) for the transition amplitudes $\langle\psi_1, e^{-it(L_{\mathrm{e}}^+)^{1/2}}\psi_2\rangle$ between one particle states in terms of the resolvent of L_{e}. Correspondingly, one has an expression for the survival and transition amplitudes for the second quantized model on the Fock space, just using functoriality of Γ. Our main concern here is in the calculation of two relevant characteristics of the evolution. The first is the survival amplitude $\mathcal{S}(t)$ of the unperturbed first excited bound state of the oscillator. The second is the amplitude transition $\mathcal{A}(t)$ between states with the photon field in the vacuum state and the oscillator in the first excited state, and states with one photon and the oscillator in the ground state. The survival and transition amplitudes relative to more general states factorize in a sum of product of these two simpler types. The survival amplitude $\mathcal{S}(t)$ has a particularly neat form (see Theorem 3.3),

$$\mathcal{S}(t) = c_1 e^{-\lambda_{\mathrm{e}}|t|} + c_2 e^{-\gamma_{\mathrm{e}}|t|}e^{-i\omega_{\mathrm{e}}t} + c_3 e^{-\lambda_{\mathrm{e}}|t|}\mathrm{Ei}(\lambda_{\mathrm{e}}|t|).$$

In this formula, the complex numbers

$$z_k := (-1)^k\omega_{\mathrm{e}} - i\gamma_{\mathrm{e}}, \quad k=1,2$$

coincide with the complex poles of the analytically continued resolvent of L_{e}^+; $-\lambda_{\mathrm{e}}^2$ is the unique negative eigenvalue of L_{e}, and by Ei we mean the exponential integral function. The complex

numbers c_1, c_2, and c_3 depend on the physical parameters. So, in the time evolution of the survival amplitude for the bound states of the oscillator it is possible to distinguish three different time behaviors. The first term, depends on a resonance on the imaginary axis originated from the projection onto the positive spectral subspace; it is a pure exponentially decaying term (for positive times) and the characteristic time of the decay, for realistic values of mass and charge of the electron, has an order of 10^{-23} s, an exceedingly small time. The second term is an exponentially damped oscillation described in terms of the complex resonance poles. In particular, the imaginary part of the resonance γ_{e} gives as usual a measure of the lifetime of the excited unperturbed states, or, equivalently, the breadth of the spectral lines of the spontaneous decay of the excited states (according to the Breit-Wigner law, see Ref. 7); while the real part gives the position of the maximum in the emission of the spectral line. In terms of given physical parameters of the systems, the behavior of these quantities is the following:

$$\omega_{\mathsf{e}} = \omega_0 + \frac{28\omega_0^3}{3m^2c^6}\mathsf{e}^4 + O(\mathsf{e}^5), \quad \gamma_{\mathsf{e}} = \frac{2\omega_0^2}{3mc^3}\mathsf{e}^2 + O(\mathsf{e}^5)$$

Here the symbols m, c, and e denote the (renormalized) phenomenological mass, the velocity of light and the electric charge, respectively. The noteworthy fact is the Lamb shift in the expression of ω_{e}. The maximum in the emission does not appear in correspondence of the unperturbed frequency of the oscillator, but at a displaced frequency. The last term, taking into account the asymptotic behavior of the exponential integral, is of the order $1/t$ for $t \gg 1$. The appearance of a slowly decaying tail implies a departure from the purely exponential decay given by the Breit-Wigner law, and is well known both in theoretical models and experimental studies. See Lemma 2.5 and the following remarks for an interpretation of its origin.

The transition amplitudes $\mathcal{A}(t)$ have a form very similar to the one for $\mathcal{S}(t)$ (see Theorem 3.5), and to them apply the same remarks and comments concerning their time behavior.

II. AN EXACTLY SOLUBLE MODEL IN CLASSICAL AND QUANTUM ELECTRODYNAMICS

A. Classical theory

The classical Pauli-Fierz model for a particle with charge e, charge density $\mathsf{e}\rho_r$ and bare mass m_r interacting with the electromagnetic field in dipole approximation and subjected to a restoring harmonic force, is described by the Hamiltonian

$$H = 2\pi c^2\langle E,E\rangle + \frac{1}{8\pi}\langle A,\Delta A\rangle + \frac{1}{2m_r}\left|p - \frac{\mathsf{e}}{c}\langle \rho_r,A\rangle\right|^2 + \frac{1}{2}\alpha|q|^2,$$

where $E = \dot{A}/(4\pi c^2)$ is the canonical variable conjugated to A and p is the canonical momentum conjugated to the particle position q. The model is written in the Coulomb gauge, so the fields are divergenceless. A suitable phase space for this dynamical system is $H^1_*(\mathbb{R}^3) \oplus L^2_*(\mathbb{R}^3) \oplus \mathbb{R}^3 \oplus \mathbb{R}^3$ where $H^1_*(\mathbb{R}^3)$ denotes the space of divergenceless locally square integrable vector fields with square integrable first derivatives. A point electron should have a Dirac measure as charge distribution, and the regular form factor ρ_r is introduced to give meaning to the equations of motion. So r must be interpreted as a measure of the particle radius. In the point limit, as $r \downarrow 0$, the charge distribution ρ_r weakly converges to δ_0, and the Hamilton equations corresponding to the Pauli-Fierz Hamiltonian lose their original meaning. A well-defined dynamical system is recovered only at the expense of renormalizing the bare mass m_r. This procedure is analyzed in detail in Ref. 16 and we content ourself to say here that the correct prescription is given by the well-known relation between the bare, electromagnetic (m_{em}) and renormalized (m) masses,

$$m = m_r + m_{\mathrm{em}} = m_r + \frac{8\pi}{3}\frac{\mathsf{e}^2}{c^2}\langle(-\Delta)^{-1}\rho_r, \rho_r\rangle.$$

Keeping m fixed to the physical value, this is the only choice for the bare mass which allows to obtain a nontrivial limit for the Pauli-Fierz model. From now on, with the symbol m_r we mean precisely the function $m_r(\mathsf{e}, m)$ given by the above relation.

The rigorous deduction of the limit dynamics is carried out in Ref. 17 for a general external potential; specializing the result to the case of the harmonic potential one obtains the equations

$$\dot{A} = 4\pi c^2 E,$$

$$\dot{E} = -\frac{1}{4\pi} H_m^p A,$$

$$\dot{q} = Q_A,$$

$$\dot{p} = -\alpha q.$$

The p-dependent operator H_m^p is an affine deformation of a linear self-adjoint operator in the class of point interactions (see Ref. 1 and references therein for the use of point interactions in quantum mechanics), H_m^p is linear if and only if $p=0$ and H_m^0 is the vector-valued version of one of such linear operators; Q_A is a certain linear functional which in some sense extract the singular part of the vector potential.

While obtaining a well-defined dynamics in the point limit it is an interesting and not obvious result, it remains unclear how to quantize such a system. So, according to the point of view we adopt in this paper, and in view of the Segal quantization of the system, we would like to work with (abstract) second order wave equations of the form

$$\ddot{\xi}(t) = -L\xi(t),$$

with a suitable self-adjoint operator L. This is not the case of the previous system of equation, due to the presence of a tight relation between the dynamical variables contained in the definition of the operator H_m^p. Going back to the regularized system, the second order equations corresponding to the Hamiltonian given above are not better from this point of view; they are

$$\frac{1}{c^2}\ddot{A} = \Delta A + \frac{4\pi\mathsf{e}}{c} M\dot{q}\rho,$$

$$m_r\ddot{q} = -\frac{\mathsf{e}}{c}\langle\rho_r, \dot{A}\rangle - \alpha q,$$

and the presence of $\dot{q}$ and $\dot{A}$ on the right-hand side make them not of the desired form. So we prefer to give a construction of the limit dynamics independent of the one given in Ref. 17. In fact, making resort to the Hamiltonian regularized equations above, it is simple to overcome this problem. Deriving with respect to time the equation which gives $\dot{p}$ and using the other equations, one obtains that the couple $\xi=(A, p)$ satisfies the abstract second-order wave equation

$$\ddot{\xi} = -L_{\mathsf{e}}^r \xi,$$

where the operator L_{e}^r is given by

$$L_{\mathrm{e}}^r(A,p)=\left(-c^2\Delta A-\frac{4\pi \mathrm{e}c}{m_r}M\left(p-\frac{\mathrm{e}}{c}\langle\rho_r,A\rangle\right)\rho_r,\frac{\alpha}{m_r}\left(p-\frac{\mathrm{e}}{c}\langle\rho_r,A\rangle\right)\right).$$

The analogous result is obtained by means of the canonical transformation which exchanges the particle position and momentum (see also Ref. 22),

$$q=-P,\quad p=Q.$$

The change of dynamical variable from q to p in the second order (or Lagrangian) formalism is not particularly relevant to the analysis of the problems we are interested in, and the interpretation of the results we get. For example, the time behavior of the classical position q, which is important in the calculation of the survival amplitude of the bound states of the oscillator, is quite simply related to the time behavior of the variable p, up to a constant, the derivative of the momentum gives the position, and this relation is preserved in the limit dynamics.

Another important point to note, is that the operator L_{e}^r is a finite rank perturbation of the noninteracting operator $L_0=(-c^2\Delta,0)$. This simple structure suggests the possibility that the operator L_{e}^r has a limit for $r\downarrow 0$, and being an unbounded operator such a limit, if existing, should be sought in the resolvent sense. The calculation of the resolvent of the operator L_{e}^r is lenghty but elementary. We omit the proof and give the result in the following.

Lemma 2.1: For every $z\in\mathbb{C}_{\pm}$, the resolvent of L_{e}^r is given by

$$(L_{\mathrm{e}}^r-z^2)^{-1}(A,p)=(\mathcal{G}_z^{\pm}*A,0)-\Lambda^r(z)R_{\mathrm{e}}^r(z)(A,p),$$

where

$$\Lambda^r(z)=\frac{-1}{m_r k_1^r k_2^r},\quad \mathcal{G}_z^{\pm}(x)=\frac{1}{c^2}\frac{e^{\pm iz|x|/c}}{4\pi|x|},\quad \pm\operatorname{Im} z>0,$$

$$R_{\mathrm{e}}^r(z)(A,p)=(R_{\mathrm{e}}^{1r}(z)(A,p),R_{\mathrm{e}}^{2r}(z)(A,p)),$$

$$R_{\mathrm{e}}^{1r}(z)(A,p)=\frac{4\pi\mathrm{e}}{c}M\left(\left(z^2c\mathrm{e}\langle(-c^2\Delta-z^2)^{-1}A,\rho_r\rangle+c^2\frac{m_rk_1^r}{\alpha}(z^2+k_2^r)p\right)(-c^2\Delta-z^2)^{-1}\rho_r\right),$$

$$R_{\mathrm{e}}^{2r}(z)(A,p)=\alpha\frac{\mathrm{e}}{c}\langle(-c^2\Delta-z^2)^{-1}A,\rho_r\rangle+m_rk_1^rp,$$

$$k_1^r=1+\tfrac{8}{3}\pi\mathrm{e}^2\langle(-c^2\Delta-z^2)^{-1}\rho_r,\rho_r\rangle,$$

$$k_2^r=\frac{\alpha}{m_r}-z^2-\frac{8}{3}\frac{\alpha\pi\mathrm{e}^2}{m_r^2k_1^r}\langle(-c^2\Delta-z^2)^{-1}\rho_r,\rho_r\rangle.$$

The next step is the point limit $r\downarrow 0$. The result is analogous to the corresponding result given in Ref. 16 for the case of a free particle, and the proof is modelled on one of the well known ways of defining point interactions (see Ref. 1). We give only an outline of the proof.

Lemma 2.2: Let $\rho_r\to\delta_0$ weakly as $r\downarrow 0$. For every fixed $z\in\mathbb{C}_{\pm}$, $(L_{\mathrm{e}}^r-z^2)^{-1}$ converges as $r\downarrow 0$ in the norm resolvent sense to the operator

$$(\mathcal{G}_z^{\pm}*A,0)-\Lambda_{\pm}(z)R_{\mathrm{e}}^{\pm}(z)(A,p),$$

where, setting $\omega_0^2:=\alpha/m$,

$$R_{\mathrm{e}}^{\pm}(z)(A,p)=\left(\frac{4\pi\mathrm{e}}{c}M(z^2c\mathrm{e}\langle\mathcal{G}_{z^*}^{\mp},A\rangle+c^2p)\mathcal{G}_z^{\pm},m\omega_0^2\frac{\mathrm{e}}{c}\langle\mathcal{G}_{z^*}^{\mp},A\rangle+\left(m\pm i\frac{2\mathrm{e}^2}{3c^3}z\right)p\right),$$

$$\Lambda_{\pm}(z) = \frac{1}{\pm i\dfrac{2\mathsf{e}^2}{3c^3}z^3 - m(\omega_0^2 - z^2)}.$$

Such an operator is the resolvent of a self-adjoint operator L_{e} *on* $L^2_*(\mathbb{R}^3)\oplus\mathbb{R}^3$ *when on the component* $\mathbb{R}^3$ *one considers the scalar product* $\langle p_1,p_2\rangle := \kappa_0 p_1\cdot p_2$, *with* $\kappa_0 := 4\pi c^2/m\omega_0^2$.

Proof: The proof of the convergence of the regularized resolvent is a direct consequence of the following limiting relations:

$$\lim_{r\downarrow 0}(-c^2\Delta - z^2)^{-1}\rho_r = \mathcal{G}_z^{\pm},$$

$$\lim_{r\downarrow 0} k_1^r = 0, \quad \lim_{r\downarrow 0} k_1^r m_r = m \pm i\frac{2\mathsf{e}^2}{3c^3}z,$$

$$\lim_{r\downarrow 0} k_2^r = -\frac{\pm i\dfrac{2\mathsf{e}^2}{3c^3}z^3 - m(\omega_0^2 - z^2)}{m \pm i\dfrac{2\mathsf{e}^2}{3c^3}z}.$$

Checking that the limit operator is the resolvent of a self-adjoint operator is routine. See Ref. 16 for a similar verification. □

By the resolvent just constructed it is straightforward to derive the actions of L_{e} itself and of its spectral properties.

Theorem 2.3: *The action and domain of the self-adjoint operator*

$$L_{\mathsf{e}}: D(L_{\mathsf{e}}) \subseteq L^2_*(\mathbb{R}^3)\oplus\mathbb{R}^3 \to L^2_*(\mathbb{R}^3)\oplus\mathbb{R}^3$$

are given by

$$L_{\mathsf{e}}(A,p) = \left(-c^2\Delta A_0, \omega_0^2\left(p - \frac{\mathsf{e}}{c}A_0(0)\right)\right),$$

$$D(L_{\mathsf{e}}) = \left\{(A,p)\in L^2_*(\mathbb{R}^3)\oplus\mathbb{R}^3 : A = A_0 + \frac{4\pi\mathsf{e}}{c}Mv\mathcal{G}, \sqrt{-\Delta}A_0, \Delta A_0 \in L^2_*(\mathbb{R}^3), v\in\mathbb{R}^3, mv = p - \frac{\mathsf{e}}{c}A_0(0)\right\},$$

where

$$\mathcal{G}(x) = \frac{1}{4\pi|x|}.$$

Moreover,

$$\sigma_p(L_{\mathsf{e}}) = \{-\lambda_{\mathsf{e}}^2\}, \quad \sigma_{\mathrm{ess}}(L_{\mathsf{e}}) = \sigma_{\mathrm{ac}}(L_{\mathsf{e}}) = [0,+\infty), \quad \sigma_{\mathrm{sc}}(L_{\mathsf{e}}) = \varnothing,$$

where

$$\lambda_{\mathsf{e}} = \frac{3mc^3}{2\mathsf{e}^2} + O(\mathsf{e}^2)$$

is the unique real (and positive) solution of the third order equation

$$\frac{2e^2}{3c^3}\lambda^3 - m(\omega_0^2 + \lambda^2) = 0.$$

We emphasize that, due to the fact that the operator L_e has been constructed as a norm resolvent limit of the operator L_e^r, the flow generated by the limit operator coincides with the limit of the regularized flow, in the relevant norms of the phase space and uniformly in time. This allows to consider L_e as the generator of the limit dynamics. As a second remark, note that the algebraic equation $\Lambda_\pm(z)^{-1}=0$ is nothing but the characteristic equation of the Abraham-Lorentz (AL) equation (see, e.g., Ref. 15) in the particular case of an harmonic external force, i.e.,

$$-\tau_0 \dddot{q} + \ddot{q} + \omega_0 q = 0, \quad \tau_0 = \frac{2e^2}{3mc^3},$$

the equation which classically describes the behavior of the particle position in the nonrelativistic regime (the classical relativistic equation was obtained by Dirac in Ref. 9). In particular, the negative eigenvalue of L_e corresponds to the so-called runaway solution of the AL equation. In the traditional approaches, this solution is discarded due to its unphysical character. From the present point of view, we give up the (important) interpretative problem related to the presence of these instabilities, and take the attitude according to which the suppression of runaway behavior corresponds to reduction of the dynamics on the stable subspace, or equivalently, restriction to the absolutely continuous component of the spectrum. This should correspond, in ordinary scattering theory for Schrödinger operators, to the elimination of bound states. The procedure to obtain this reduction can be explicitly performed as follows. Let us consider, from now on, L_e as acting on the complex Hilbert space $L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3$. It is self-adjoint when on the component $\mathbb{C}^3$ one considers the scalar product $\langle\zeta_1,\zeta_2\rangle := \kappa_0 \zeta_1^* \cdot \zeta_2$.

Given ζ_1,ζ_2,ζ_3, an orthonormal base in $\mathbb{C}^3$, and defining

$$\mathcal{G}_{\lambda_e}(x) := \frac{1}{c^2}\frac{e^{-\lambda_e|x|/c}}{4\pi|x|}, \quad \kappa := \left(\frac{2\pi e^2\lambda_0^3}{m^2\omega_0^4 c} + \kappa_0\right)^{1/2}, \quad \kappa_1 := \frac{e}{c}\lambda_e^2\kappa_0,$$

let

$$\psi_i^0 = \frac{1}{\kappa}(-\kappa_1 M\zeta_i \mathcal{G}_{\lambda_e}, \zeta_i), \quad i=1,2,3$$

be the normalized eigenvectors corresponding to the eigenvalue $-\lambda_e^2$. Then the projection P_e onto the absolutely continuous subspace of the operator L_e is given by

$$P_e\psi \equiv \psi^+ = \psi - \sum_{i=1,2,3}\langle\psi,\psi_i^0\rangle\psi_i^0.$$

In particular

$$P_e(0,\zeta) = \frac{\kappa_2}{\kappa^2}\left(\frac{12\pi c^4}{e}M\zeta\mathcal{G}_{\lambda_e},\lambda_e\zeta\right), \quad \kappa_2 := \frac{4\pi e^2\lambda_e^2}{m^2\omega_0^4 c}.$$

We define the positive self-adjoint operator L_e^+ by $L_e^+ := P_e L_e$, and from now on we consider this reduced operator as the generator of the physical limit dynamics.

B. Quantum theory

The operator L_e^+ generates the classical evolution, whereas, according to the results summarized in the appendix, the corresponding quantum evolution is given in terms of its square root $(L_e^+)^{1/2}$. More explicitly, denoting by $\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3)$ the bosonic Fock space over $L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3$, i.e.,

$$\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3) := \bigoplus_{n\geqslant 0} S_n (L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3)^{\otimes n},$$

where S_n denotes the symmetrization operator on the nth sector, the quantum Hamiltonian on $\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3)$ corresponding to the second quantization of the classical wave equation

$$(\partial^2_{tt} + L^+_{\mathsf{e}})(A,p) = 0$$

is given by

$$\mathsf{H}_{\mathsf{e}} := \hbar\, \mathrm{d}\Gamma((L^+_{\mathsf{e}})^{1/2}).$$

Note that the noninteracting Hamiltonian

$$\mathsf{H}_0 := \hbar\, \mathrm{d}\Gamma(L_0^{1/2}) \equiv \hbar\, \mathrm{d}\Gamma(\sqrt{-\Delta}\oplus\omega_0)$$

is unitarily equivalent to

$$\hbar\, \mathrm{d}\Gamma(\sqrt{-\Delta})\otimes 1 + 1\otimes \hbar\, \mathrm{d}\Gamma(\omega_0),$$

defined on the Hilbert space

$$\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3))\otimes\mathcal{F}(\mathbb{C}^3) := \bigoplus_{n\geqslant 0} S_n L^2_*(\mathbb{R}^3;\mathbb{C}^3)^{\otimes n} \otimes \bigoplus_{n\geqslant 0} S_n(\mathbb{C}^3)^{\otimes n}.$$

The unitary operator

$$\mathsf{U}:\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3) \to \mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3))\otimes\mathcal{F}(\mathbb{C}^3) \tag{1}$$

giving the stated equivalence is defined by

$$\mathsf{U}\Omega := \Omega\otimes\Omega, \quad \mathsf{U}\mathsf{C}(\psi)\mathsf{U}^{-1} = \mathsf{C}(\varphi)\otimes 1 + 1\otimes \mathsf{C}(\zeta),$$

where Ω denotes the vacuum, $\psi=(\varphi,\zeta)$ and C is the usual creation operator. Moreover $\hbar\, \mathrm{d}\Gamma(\omega_0)$ is unitarily equivalent to the usual harmonic oscillator Hamiltonian on $L^2(\mathbb{R}^3;\mathbb{C})$ given by the self-adjoint operator

$$-\frac{\hbar^2}{2m}\Delta + \frac{m\omega_0^2}{2}q^2.$$

Concerning the interacting Hamiltonian H_{e}, the present one is its first *explicit* construction in the ultraviolet limit and the problem arises if other representations more directly confrontable with usual canonical formulation could be given. We emphasize the fact that in our description, already at the classical level, the point limit produces an intimate interlacing between field singularities and particle variables, through the definition of the domain of the operator L_{e} itself, and this fact introduces essential difficulties in tracing the relation with the canonical formalism based on the usual regularized Pauli-Fierz Hamiltonian, where this constraint disappears. Nevertheless, in the quoted Arai paper (Ref. 2), a reconstruction theorem based on the limit of the Wightman functions of the regularized model is outlined. It could be interesting to analyze the relations between two approaches.

Since the resolvent of L_{e} is quite explicit, making use of the Birman-Kato invariance principle to deal with the group generated by the square root, and of the Birman-Kuroda completeness theorem (see Ref. 6) which is applicable because $(L_{\mathsf{e}}+z)^{-1}-(L_0+z)^{-1}$ is a finite rank operator, one immediately obtains the following.

Theorem 2.4: *Let P_0 and P_{e} be the orthogonal projections onto the absolutely continuous subspaces of L_0 and L_{e}, respectively. Then the Möller wave operators exist, they are complete and,*

$$\Omega_{\pm}(\mathsf{H}_{\mathsf{e}},\mathsf{H}_0) := \text{s-}\lim_{t\to\pm\infty} e^{-it\mathsf{H}_{\mathsf{e}}/\hbar} e^{-it\mathsf{H}_0/\hbar}\Gamma(P_0) = \Gamma(\Omega_{\pm}(L_{\mathsf{e}},L_0)),$$

$$\Omega_{\pm}(\mathsf{H}_0,\mathsf{H}_e) := \text{s-}\lim_{t\to\pm\infty} e^{-it\mathsf{H}_0/\hbar}e^{-it\mathsf{H}_e/\hbar}\Gamma(P_e) = \Gamma(\Omega_{\pm}(L_0,L_e)).$$

A final result of this paragraph is a formula for the evaluation of transition amplitudes of the Schrödinger-type propagator $e^{-it(L_e^+)^{1/2}}$, that is the scalar product of the type $\langle\psi_1, e^{-it(L_e^+)^{1/2}}\psi_2\rangle$, in terms of boundary values of the resolvent of the classical operator L_e. In the formula the special form of the operator L_e plays no rule, and it holds true for a positive generator A whatsoever. By linearity it will be sufficient to suppose that ψ_1 and ψ_2 are real valued. Since (see the Appendix for the definition of $W_{L_e^+}$)

$$((iW_{L_e^+} - z)^{-1})(\psi,0) = (z(L_e^+ - z^2)^{-1}\psi, -i\psi - iz^2(L_e^+ - z^2)^{-1}\psi),$$

by Lemma A.2 and Lemma A.3 one obtains

$$\begin{aligned}\langle\psi_1, e^{-it(L_e^+)^{1/2}}\psi_2\rangle = &\lim_{a\uparrow\infty}\lim_{\epsilon\downarrow 0}\frac{1}{2\pi i}\int_{-a}^{a} d\lambda\, e^{-it\lambda}(\langle\psi_1,((\lambda+i\epsilon)(L_e-(\lambda+i\epsilon)^2)^{-1}\\ &-(\lambda-i\epsilon)(L_e-(\lambda-i\epsilon)^2)^{-1})\psi_2^+\rangle)\\ &+\lim_{a\uparrow\infty}\lim_{\epsilon\downarrow 0}\frac{1}{2\pi i}\int_{-a}^{a} d\lambda\, e^{-it\lambda}(\langle\psi_1,((\lambda+i\epsilon)^2(L_e-(\lambda+i\epsilon)^2)^{-1}\\ &-(\lambda-i\epsilon)^2(L_e-(\lambda-i\epsilon)^2)^{-1})(L_e^+)^{-1/2}\psi_2^+\rangle).\end{aligned}$$

Moreover, using first resolvent identity and

$$(L_e^+)^{-1/2} = \frac{1}{\pi}\int_{\mathbb{R}} ds(L_e^+ + s^2)^{-1}$$

it turns that

$$\langle\psi_1,(L_e-z^2)^{-1}(L_e^+)^{-1/2}\psi_2^+\rangle = \frac{1}{\pi}\int_{\mathbb{R}}\frac{ds}{s^2+z^2}\langle\psi_1,(L_e-z^2)^{-1}\psi_2^+\rangle - \frac{1}{\pi}\int_{\mathbb{R}}\frac{ds}{s^2+z^2}\langle\psi_1,(L_e+s^2)^{-1}\psi_2^+\rangle.$$

Thus for any couple ψ_1,ψ_2 for which the limits

$$\langle\psi_1,(L_e-\lambda_{\pm}^2)^{-1}\psi_2^+\rangle := \lim_{\epsilon\downarrow 0}\langle\psi_1,(L_e-(\lambda\pm i\epsilon)^2)^{-1}\psi_2^+\rangle$$

exist, one obtains the following.

Lemma 2.5:

$$\begin{aligned}\langle\psi_1, e^{-it(L_e^+)^{1/2}}\psi_2\rangle = &\lim_{a\uparrow\infty}\frac{1}{2\pi i}\int_{-a}^{a} d\lambda\, e^{-it\lambda}\lambda(\langle\psi_1,((L_e-\lambda_+^2)^{-1}-(L_e-\lambda_-^2)^{-1})\psi_2^+\rangle)\\ &+\frac{1}{\pi}\int_{\mathbb{R}}\frac{ds}{2\pi i}\int_{\mathbb{R}} d\lambda\,\frac{e^{-it\lambda}\lambda^2}{s^2+\lambda^2}\langle\psi_1,((L_e-\lambda_+^2)^{-1}-(L_e-\lambda_-^2)^{-1})\psi_2^+\rangle.\end{aligned}$$

Note that the second contribution in the previous formula comes from the nonlocal relation between the real phase space classical variables and the complexified ones, described in Lemma A.3. Performing however the s integral one obtains, under the same condition of the previous result, the following alternative representation:

$$\langle \psi_1, e^{-it(L_e^+)^{1/2}}\psi_2\rangle = \lim_{a\uparrow\infty}\frac{1}{2\pi i}\int_0^a d\lambda\, e^{-it\lambda}\lambda(\langle\psi_1,((L_e-\lambda_+^2)^{-1}-(L_e-\lambda_-^2)^{-1})\psi_2^+\rangle).$$

This last representation has a more direct meaning, in that it is an integral extended over the spectrum of the operator $(L_e^+)^{1/2}$. Moreover, it presents the evolution generated by $(L_e^+)^{1/2}$ as a Fourier transform of a function (for every fixed couple of states ψ_1 and ψ_2) supported on a half-line. As a consequence of the Paley-Wiener theorem, the evolution of the amplitude transition cannot have a leading large time contribution of exponential type, but a slower one should appear (see Refs. 11 and 12 for an early application of this remark to the time decay of amplitude transition). The exact time behavior cannot be precised without the knowledge of further details about the generator. To this end it more practical to use the formula given in Lemma 2.5, as we see in the following section.

III. RADIATION THEORY

A. Generalities

In this section we want to give some details of the quantum dynamics of the model we are studying. In particular, we want to estimate, under the dynamics generated by H_e, the survival amplitudes of the bound states of H_0 and the probability amplitudes of the transitions between two of such states with emission of photons. We begin with some preliminaries on the general structure of the amplitude transitions in our model.

In the space $\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3))\otimes\mathcal{F}(\mathbb{C}^3)$ a bound state (n level) for the Hamiltonian operator H_0 is represented by a vector of the kind

$$\Omega\otimes S_n(\zeta_1\otimes\cdots\otimes\zeta_n).$$

According to (1) this state is represented in $\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3)$ by the vector

$$S_n((0,\zeta_1)\otimes\cdots\otimes(0,\zeta_n)).$$

By (1) again, a more general state with m photons, of the kind

$$S_m(\varphi_1\otimes\cdots\otimes\varphi_m)\otimes S_n(\zeta_1\otimes\cdots\otimes\zeta_n),$$

is represented in $\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3)$ by the vector

$$S_{m+n}((\varphi_1,0)\otimes\cdots\otimes(\varphi_m,0)\otimes(0,\zeta_1)\otimes\cdots\otimes(0,\zeta_n)).$$

Note that, being $\mathsf{H}_e=\hbar\,d\Gamma((L_e^+)^{1/2})$, any sector in $\mathcal{F}(L^2_*(\mathbb{R}^3;\mathbb{C}^3)\oplus\mathbb{C}^3)$ is preserved under $e^{-it\mathsf{H}_e}$. Thus only the transitions from a n level to a m level with the emission of $n-m$ photons are allowed.

On the other hand, as we shall see, asymptotically the particle part of the wave function of the state relaxes to the ground state, and this yelds to the asymptotic conservation of the photon number in the scattering process. This property was devised by Arai in Ref. 2 for the regularized Pauli-Fierz model with quadratic potential, as a consequence of the factorization properties of the scattering matrix, and we find it again in the point model.

Since

$$\begin{aligned}e^{-it\mathsf{H}_e/\hbar}S_n(\psi_1\otimes\cdots\otimes\psi_n)&=\Gamma(e^{-it(L_e^+)^{1/2}})S_n(\psi_1\otimes\cdots\otimes\psi_n)\\&=\frac{1}{n!}\sum_\sigma e^{-it(L_e^+)^{1/2}}\psi_{\sigma_1}\otimes\cdots\otimes e^{-it(L_e^+)^{1/2}}\psi_{\sigma_n},\end{aligned}$$

the survival amplitude of the bound state $\Omega\otimes S_n(\zeta_1\otimes\cdots\otimes\zeta_n)$ is given by

$$\frac{1}{n!}\sum_{\sigma}\prod_{j=1}^{n}\langle(0,\zeta_{\sigma_j}),e^{-it(L_{\mathrm{e}}^{+})^{1/2}}(0,\zeta_j)\rangle,$$

whereas the the probability amplitude of the transition

$$\Omega\otimes S_n(\zeta_1\otimes\cdots\otimes\zeta_n)\leftrightarrow S_m(\varphi_1\otimes\cdots\otimes\varphi_m)\otimes S_{n-m}(\xi_{m+1}\otimes\cdots\otimes\xi_{n-m})$$

is given by

$$\frac{1}{n!}\sum_{\sigma}\prod_{\sigma_j\leqslant m}\langle(\varphi_{\sigma_j},0),e^{-it(L_{\mathrm{e}}^{+})^{1/2}}(0,\zeta_j)\rangle\prod_{\sigma_k>m}\langle(0,\xi_{\sigma_k}),e^{-it(L_{\mathrm{e}}^{+})^{1/2}}(0,\zeta_k)\rangle.$$

B. Survival amplitudes

After these general remarks, we evaluate the survival amplitudes for the bound states of the unperturbed dynamics along the perturbed evolution. To simplify the exposition we break the analysis in a number of lemmata.

Lemma 3.1: For any $\zeta_1,\zeta_2\in\mathbb{C}^3$ *one has*

$$\langle(0,\zeta_1),e^{-it(L_{\mathrm{e}}^{+})^{1/2}}(0,\zeta_2)\rangle=\mathcal{S}(t)\bar{\zeta}_1\cdot\zeta_2,$$

where

$$\mathcal{S}(t)=-\frac{2\kappa_0\kappa_2}{\kappa^2}I(t)$$

and, with $\pm t>0$,

$$I(t)=\mp e^{\mp\lambda_{\mathrm{e}}t}i\lambda_{\mathrm{e}}\frac{p(-i\lambda_{\mathrm{e}})}{q(-i\lambda_{\mathrm{e}})}\pm e^{\mp\gamma_{\mathrm{e}}t}\frac{e^{-i\omega_{\mathrm{e}}t}2z_{\pm}}{z_{\pm}+i\lambda_{\mathrm{e}}}\frac{p(z_{\pm})}{q'(z_{\pm})}+J_1(t)+J_2(t),$$

$$J_1(t)=\frac{1}{\pi}\int_{\mathbb{R}}\mathrm{d}s\frac{e^{\mp|s|t}|s|}{2(|s|+\lambda_{\mathrm{e}})}\frac{p(i|s|)}{q(i|s|)},$$

$$J_2(t)=\frac{1}{\pi}\int_{\mathbb{R}}\mathrm{d}s\left(\frac{e^{\mp|s|t}|s|}{2(|s|-\lambda_{\mathrm{e}})}\frac{p(-i|s|)}{q(-i|s|)}-\frac{e^{\mp\lambda_{\mathrm{e}}t}\lambda_{\mathrm{e}}^2}{s^2-\lambda_{\mathrm{e}}^2}\frac{p(-i\lambda_{\mathrm{e}})}{q(-i\lambda_{\mathrm{e}})}\right),$$

$$p(z)=\frac{\mathrm{e}^2\lambda_{\mathrm{e}}}{3c^3}z+i\frac{m}{\lambda_{\mathrm{e}}}\left(\omega_0^2+\frac{\lambda_{\mathrm{e}}^2}{2}\right),$$

$$q(z)=\frac{2\mathrm{e}^2}{3c^3}z^2+i\frac{m\omega_0^2}{\lambda_{\mathrm{e}}^2}(z+i\lambda_{\mathrm{e}}),$$

where

$$z_{\pm}:=\pm\omega_{\mathrm{e}}-i\gamma_{\mathrm{e}},$$

$$\omega_{\mathrm{e}}=\omega_0+\frac{28\omega_0^3}{3m^2c^6}\mathrm{e}^4+O(\mathrm{e}^5),\quad \gamma_{\mathrm{e}}=\frac{2\omega_0^2}{3mc^3}\mathrm{e}^2+O(\mathrm{e}^5)$$

are the two roots of $q(z)$.

Proof: Let $z\in\mathbb{C}_{\pm}$. Taking in account the algebraic equation satisfied by λ_{e} and the identity

$$\langle \mathcal{G}_{z^*}^{\mp}, \mathcal{G}_{\lambda_e} \rangle = \frac{1}{4\pi c^3} \frac{1}{\lambda_e \mp iz}$$

we have, for the projected resolvent,

$$\begin{aligned}\langle (0,\zeta_1), (L_e - z^2)^{-1}(0,\zeta_2)^+ \rangle &= -\kappa_0 \frac{\kappa_2}{\kappa^2} \Lambda_\pm(z) \left(m\omega_0^2 8\pi c^3 \langle \mathcal{G}_{z^*}^{\mp}, \mathcal{G}_{\lambda_e} \rangle + \left(m \pm i \frac{2e^2}{3c^3} z \right) \lambda_e \right) \zeta_1^* \cdot \zeta_2 \\ &= \frac{-2\kappa_0\kappa_2}{\kappa^2(\pm iz - \lambda_e)} \frac{\left(\pm i \frac{e^2 \lambda_e}{3c^3} z - \frac{m}{\lambda_e} \left(\omega_0^2 + \frac{\lambda_e^2}{2} \right) \right) (\pm iz + \lambda_e)}{\left(\frac{2e^2}{3c^3} z^2 + \frac{m\omega_0^2}{\lambda_e^2} (\pm iz - \lambda_e) \right) (\pm iz + \lambda_e)} \zeta_1^* \cdot \zeta_2 .\end{aligned}$$

Thus using the representation formula given in Lemma 2.5, we get

$$\langle (0,\zeta_1), e^{-it(L_e^+)^{1/2}} (0,\zeta_2) \rangle = -\frac{2\kappa_0\kappa_2}{\kappa^2} \left(I_1(t) + \frac{1}{\pi} \int_{\mathbb{R}} ds\, I_2(t,s) \right) \zeta_1^* \cdot \zeta_2,$$

where

$$I_1(t) := \frac{1}{2\pi i} \lim_{a \uparrow \infty} \int_{-a}^{a} d\lambda\, e^{-it\lambda} \lambda (f(\lambda) - f(-\lambda)),$$

$$I_2(t,s) := \frac{1}{2\pi i} \int_{\mathbb{R}} d\lambda\, e^{-it\lambda} \lambda^2 \frac{f(\lambda) - f(-\lambda)}{s^2 + \lambda^2},$$

$$f(\lambda) := \frac{1}{\lambda + i\lambda_e} \frac{\frac{e^2 \lambda_e}{3c^3} \lambda + i \frac{m}{\lambda_e} \left(\omega_0^2 + \frac{\lambda_e^2}{2} \right)}{\frac{2e^2}{3c^3} \lambda^2 + i \frac{m\omega_0^2}{\lambda_e^2} (\lambda + i\lambda_e)} \equiv \frac{1}{\lambda + i\lambda_e} \frac{p(\lambda)}{q(\lambda)}.$$

Then, by residue theorem and Jordan's lemma, when $\pm t > 0$, one obtains

$$I_1(t) = \mp e^{\mp \lambda_e t} i\lambda_e \frac{p(-i\lambda_e)}{q(-i\lambda_e)} \pm e^{\mp \gamma_e t} \sum_{k=1,2} \frac{e^{\mp (-1)^k i \omega_e t} z_k}{z_k + i\lambda_e} \frac{p(z_k)}{q'(z_k)},$$

where $z_k := (-1)^k \omega_e - \gamma_e$, and

$$\begin{aligned}I_2(t,s) = &-\frac{e^{\mp \lambda_e t} \lambda_e^2}{s^2 - \lambda_e^2} \frac{p(-i\lambda_e)}{q(-i\lambda_e)} + e^{\mp t\gamma_e} \sum_{k=1,2} \frac{z_k}{s^2 + z_k^2} \frac{e^{\mp (-1)^k i\omega_e t} z_k}{z_k + i\lambda_e} \frac{p(z_k)}{q'(z_k)} \\ &+ e^{\mp |s| t} \frac{|s|}{2} \left(\frac{1}{|s| \mp \lambda_e} \frac{p(\mp i|s|)}{q(\mp i|s|)} + \frac{1}{|s| \pm \lambda_e} \frac{p(\pm i|s|)}{q(\pm i|s|)} \right).\end{aligned}$$

Since

$$\frac{1}{\pi} \int_{\mathbb{R}} ds \frac{z_k}{s^2 + z_k^2} = (-1)^k,$$

one has

$$I_1(t)+\frac{1}{\pi}\int_{\mathbb{R}}\mathrm{d}s\, I_2(t,s)= \mp e^{\mp\lambda_e t}i\lambda_e\frac{p(-i\lambda_e)}{q(-i\lambda_e)}\pm e^{\mp\gamma_e t}\frac{e^{-i\omega_e t}2z_k}{z_k+i\lambda_e}\frac{p(z_k)}{q'(z_k)}+\frac{1}{\pi}\int_{\mathbb{R}}\mathrm{d}s\left(\frac{e^{\mp|s|t}|s|}{2(|s|-\lambda_e)}\frac{p(-i|s|)}{q(-i|s|)}\right.$$
$$\left.-\frac{e^{\mp\lambda_e t}\lambda_e^2}{s^2-\lambda_e^2}\frac{p(-i\lambda_e)}{q(-i\lambda_e)}\right)+\frac{1}{\pi}\int_{\mathbb{R}}\mathrm{d}s\frac{e^{\mp|s|t}|s|}{2(|s|+\lambda_e)}\frac{p(i|s|)}{q(i|s|)},$$

where $k=2$ if $t>0$ and $k=1$ if $t<0$. □

We distinguish three contributions in the previous formula for $I(t)$. The one on the first line is due to the resonances of the system. In particular, we have a purely exponential term with lifetime λ_e, coming from the projection on the stable subspace of the system, which dies out very quickly; and terms exponentially damped, due to the complex resonances. These last resonances are typical of the Breit-Wigner distribution, and they are the only terms which survive to the usual single pole approximation for the resolvent. They give both the breadth of emission lines in the spectrum (or equivalently the lifetime of the process) and the Lamb shift, as recalled in the introduction. The other contributions to the survival amplitude need more direct analysis. To simplify the exposition we confine to the case of $t>0$, the case $t<0$ being completely analogous. The term $J_1(t)$ is nothing more than the Laplace transform (which we denote by the symbol $\mathcal{L}$), a rational function. It is a tedious but standard calculation to verify that such a Laplace transform is in fact the sum of a pure exponential and a damped oscillation with the same characteristic exponents as the ones coming from the first group of terms. So, the term $J_1(t)$ corresponds to a further resonance contribution.

Concerning $J_2(t)$ the following result holds true.

Lemma 3.2: There exist complex constants c_1, c_2, c_3 such that, for $t>0$,

$$J_2(t)=\frac{1}{\pi}\mathcal{L}\left(\frac{c_1 s+c_2}{(s-\gamma_e)^2+\omega_e^2}\right)+\frac{c_3}{\pi}PV\int_0^\infty\frac{e^{-st}}{s-\lambda_e}\mathrm{d}s.$$

Proof: Introducing a parameter ϵ to isolate the singularity in λ_e, one can write

$$J_2(t)=\frac{2}{\pi}\int_0^{+\infty}\mathrm{d}s\left(\frac{e^{-|s|t}|s|}{2(|s|-\lambda_e)}\frac{p(-i|s|)}{q(-i|s|)}-\frac{e^{-\lambda_e t}\lambda_e^2}{s^2-\lambda_e^2}\frac{p(-i\lambda_e)}{q(-i\lambda_e)}\right)$$
$$=\lim_{\epsilon\downarrow 0}\left(\frac{2}{\pi}\left(\int_0^{\lambda_e-\epsilon}\mathrm{d}s\frac{e^{-|s|t}|s|}{2(|s|-\lambda_e)}\frac{p(-i|s|)}{q(-i|s|)}+\int_{\lambda_e+\epsilon}^{+\infty}\mathrm{d}s\frac{e^{-|s|t}|s|}{2(|s|-\lambda_e)}\frac{p(-i|s|)}{q(-i|s|)}\right)\right.$$
$$\left.-\frac{2}{\pi}\left(\int_0^{\lambda_e-\epsilon}\mathrm{d}s\frac{e^{-\lambda_e t}\lambda_e^2}{s^2-\lambda_e^2}\frac{p(-i\lambda_e)}{q(-i\lambda_e)}+\int_{\lambda_e+\epsilon}^{+\infty}\frac{e^{-\lambda_e t}\lambda_e^2}{s^2-\lambda_e^2}\frac{p(-i\lambda_e)}{q(-i\lambda_e)}\mathrm{d}s\right)\right),$$

and the integrals in the second braces is vanishing for every ϵ. So, one remains with

$$J_2(t)=\frac{2}{\pi}PV\int_0^\infty\frac{e^{-st}s}{2(s-\lambda_e)}\frac{p(-is)}{q(-is)}.$$

Finally, the rational function in the above integral can be decomposed in a singular (not integrable) part and an integrable one, obtaining

$$J_2(t)=\frac{1}{\pi}\mathcal{L}\left(\frac{c_1 s+c_2}{(s-\gamma_e)^2+\omega_e^2)}\right)+\frac{c_3}{\pi}PV\int_0^\infty\frac{e^{-st}}{s-\lambda_e}\mathrm{d}s,$$

where c_1, c_2, and c_3 are constants depending on the parameters. □

The first integral has the time behavior of the other already studied contributions, and the last one is related to the exponential integral function

$$\frac{c_3}{\pi} PV \int_0^\infty \frac{e^{-st}}{s-\lambda_e} ds = -\frac{c_3}{\pi} e^{-\lambda_e t} \mathrm{Ei}(\lambda_e t).$$

From the well-known asymptotic behavior for large arguments of the exponential integral function, one can deduce that the leading contribution for large times to the survival amplitude is of the order $1/t$ when $t \gg 1$. In summary, collecting the previous calculations, we end with the following result.

Theorem 3.3: *There exist complex constants c_1, c_2, c_3 depending on the physical parameters e, m, c, ω_0 such that the survival amplitude is given by*

$$\mathcal{S}(t) = c_1 e^{-\lambda_e |t|} + c_2 e^{-\gamma_e |t|} e^{-i\omega_e t} + c_3 e^{-\lambda_e |t|} \mathrm{Ei}(\lambda_e |t|).$$

C. Transition amplitudes

Now we turn to the evaluation of the transition amplitudes. As we see in the previous theorem, the unperturbed excited states of the oscillator decay. The transition to a lower energy state takes place with the emission of electromagnetic radiation, photons in the Fock space. To give a quantitative estimate of the probability of emission of photons one must decide which functions describe the one particle states of the electromagnetic field one is interested in. We choose to calculate the transition amplitudes in the case of a regularized plane wave of (approximatively) given momentum.

Classically, a natural choice for the functions φ representing the photons of energy $\hbar\nu$ should be the divergence-free plane waves of the kind

$$\varphi(x) := k \wedge \zeta e^{-i\nu k \cdot x/c}, \quad |k| = 1.$$

Of course such functions are not square integrable and so we consider the divergence-free regularization defined by

$$\varphi^\epsilon(x) := \left(k - \frac{i\epsilon}{\nu} \frac{x}{|x|} \right) \wedge \zeta e^{-i\alpha k \cdot x/c - \epsilon |x|/c}, \quad \nu > 0, \quad \epsilon > 0, \quad |k| = 1.$$

We choose this one as the one-particle wave functions describing photons. Eventually, we are interested in removing the cutoff ϵ from the amplitude transitions.

We anticipate the definitions of some quantities appearing in the statement and proof of the following result. To evaluate the resolvent between states relevant to the transitions, one needs the scalar product $\langle \varphi^\epsilon, \mathcal{G}_z^\pm \rangle$. Assuming that k is along the z axis and ζ is along the y axis, by elementary calculations one obtains

$$\chi^\epsilon(\pm z) := \langle \varphi^\epsilon, \mathcal{G}_z^\pm \rangle \equiv k \wedge \zeta^* \frac{1}{\alpha} \left(\frac{\alpha^2 - \epsilon(\epsilon \mp iz)}{\alpha^2 + (\epsilon \mp iz)^2} - \frac{i\epsilon}{2\alpha^2} \ln \frac{\alpha + i\epsilon \pm z}{\alpha - i\epsilon \mp z} \right) \equiv (k \wedge \zeta^*)(\chi_r^\epsilon(\pm z) + \chi_l^\epsilon(\pm z)).$$

We have written the function $\chi^\epsilon(\pm z)$ just defined, as the sum $\chi_r^\epsilon(\pm z) + \chi_l^\epsilon(\pm z)$ with two summands, a rational one and a logarithmic one. The first, $\chi_r^\epsilon(\pm z)$ has poles at the points $\pm\alpha \pm i\epsilon$, and at the same points the logaritmic part $\chi_l^\epsilon(\pm z)$ has branching points. Due to this fact, some cautions are needed in the use of the residue theorem to evaluate transition amplitudes. Note, moreover, that these branching points of χ are to be thought of as artificial byproducts of the regularization of the plane wave, and that the poles of the function χ_r correspond to the frequencies of the plane wave. These poles depend on the particular wave function representing the photon, at variance with the poles of the function $1/q(z)$, which are determined by the physical parameters of the system. We indicate with $\mathcal{C}$ the logarithmic cut in the complex plane, and we distinguish the components of the cut with real part of a fixed sign $(\pm)$, with $\mathcal{C}^\pm$. With these premises, we state the following.

Lemma 3.4: For any $\zeta_1, \zeta_2 \in \mathbb{C}^3$ one has

$$\langle (\varphi_1^\epsilon, 0), e^{-it(L_e^+)^{1/2}} (0, \zeta_2) \rangle = \mathcal{A}^\epsilon(t) k \cdot (\zeta_1^* \wedge \zeta_2),$$

where

$$\mathcal{A}^{\epsilon}(t) = -\frac{4\pi e}{c}\frac{\kappa_2}{\kappa^2} I^{\epsilon}(t)$$

and, with $\pm t > 0$,

$$\begin{aligned} I^{\epsilon}(t) = {} & \mp e^{\mp \lambda_e t}\lambda_e^2 \frac{\chi(-i\lambda_e)}{q(-i\lambda_e)} \pm e^{\mp \gamma_e t}\frac{e^{-i\omega_e t} 2z_{\pm}}{z_{\pm}+i\lambda_e}\frac{2z_{\pm}+i\lambda_e}{q'(z_{\pm})}\chi(z_{\pm}) \\ & \pm e^{\mp \epsilon t}\frac{e^{\mp i\nu t}2(\pm\nu - i\epsilon)}{\pm\nu + i(\lambda_e - \epsilon)}\frac{2\nu + i(\lambda_e - 2\epsilon)}{q(\pm\nu - i\epsilon)}\frac{\mp\nu - i\epsilon}{2\nu} \\ & + \frac{i}{\pi}\int_{\mathbb{R}} ds \left(\frac{e^{\mp\lambda_e t}\lambda_e^3}{s^2-\lambda_e^2}\frac{\chi(-i\lambda_e)}{q(-i\lambda_e)} + \frac{e^{\mp|s|t}|s|(-2|s|+\lambda_e)}{2(|s|-\lambda_e)}\frac{\chi(-i|s|)}{q(-i|s|)}, \right) \\ & + \frac{i}{\pi}\int_{\mathbb{R}} ds \frac{e^{\mp|s|t}|s|(2|s|+\lambda_e)}{2(|s|+\lambda_e)}\frac{\chi(i|s|)}{q(i|s|)} + \frac{\epsilon}{\nu^3}\int_{\mathcal{C}} dz\, e^{-itz}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{1}{q(z)} \\ & + \pi\frac{\epsilon}{\nu^3}\left(\int_{\mathcal{C}^+} dz\, e^{-itz}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{z}{q(z)} - \int_{\mathcal{C}^-} dz\, e^{-itz}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{z}{q(z)} \right), \end{aligned}$$

Proof: One has, proceeding as in the proof of Lemma 3.1,

$$\langle (\varphi_1^{\epsilon},0), (L_e - z^2)^{-1}(0,\zeta_2)^{+}\rangle = \frac{4\pi c e \kappa_2}{\kappa^2(\mp iz+\lambda_e)}\frac{(\pm 2iz-\lambda_e)(\pm iz+\lambda_e)}{\left(\frac{2e^2}{3c^3}z^2 - \frac{m\omega_0^2}{\lambda_e^2}(\mp iz+\lambda_e)\right)(\pm iz+\lambda_e)}\chi^{\epsilon}(\pm z)(k\wedge\zeta_1^*)\cdot\zeta_2.$$

Therefore,

$$\langle (\varphi_1^{\epsilon},0), e^{-it(L_e^+)^{1/2}}(0,\zeta_2)\rangle = -\frac{4\pi e}{c}\frac{\kappa_2}{\kappa^2}\left(I_1(t) + \frac{1}{\pi}\int_{\mathbb{R}} ds\, I_2(t,s)\right)(k\wedge\zeta_1^*)\cdot\zeta_2,$$

where (we omit the dependence on ϵ)

$$I_1(t) := \frac{1}{2\pi i}\lim_{a\uparrow\infty}\int_{-a}^{a} d\lambda\, e^{-it\lambda}\lambda(g(\lambda)-g(-\lambda)),$$

$$I_2(t,s) := \frac{1}{2\pi i}\int_{\mathbb{R}} d\lambda\, e^{-it\lambda}\lambda^2\frac{g(\lambda)-g(-\lambda)}{s^2+\lambda^2},$$

$$g(\lambda) := \frac{2\lambda+i\lambda_e}{\lambda+i\lambda_e}\frac{\chi(\lambda)}{q(\lambda)}.$$

Now, let us choose a path in the complex lower half-plane which has the real axis as the upper side, avoids the cuts of the function χ_l (say, the straight half lines parametrized as $z=\pm\nu+u-i\epsilon$, $\pm u>0$), and close itself at ∞ along a great circle, as in the previous lemma. There will be contributions due to the residues of the function $1/q(z)$, the residues of the function $\chi_r(z)$, and to the discontinuity of the logarithmic part of $\chi_l(z)$ along the cut. In the end, one obtains, when $\pm t > 0$,

$$I_1(t) = \mp e^{\mp\lambda_e t}\lambda_e^2\frac{\chi(-i\lambda_e)}{q(-i\lambda_e)} \pm e^{\mp\gamma_e t}\sum_{k=1,2}\frac{e^{\mp(-1)^k i\omega_e t}z_k}{z_k+i\lambda_e}\frac{2z_k+i\lambda_e}{q'(z_k)}\chi(z_k) \pm e^{\mp\epsilon t}\sum_{k=1,2}\frac{e^{\mp i\nu t}w_k}{w_k+i\lambda_e}\frac{2w_k+i\lambda_e}{q(w_k)}r_k + \int_{\mathcal{C}}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{e^{-itz}}{q(z)},$$

where $z_\pm$ are the poles of q, $w_k := (-1)^k\nu - i\epsilon$ are the two poles of $\chi_r(z)$ and r_k the residues of χ_r, and finally $\mathcal{C}$ is the path along the cut of the logarithmic term.

Moreover, we have

$$I_2(t,s) = i\frac{e^{\mp\lambda_e t}\lambda_e^3}{s^2-\lambda_e^2}\frac{\chi(-i\lambda_e)}{q(-i\lambda_e)} + e^{\mp\gamma_e t}\sum_{k=1,2}\frac{z_k}{s^2+z_k^2}\frac{e^{\mp(-1)^k i\omega_e t}z_k}{z_k+i\lambda_e}\frac{2z_k+i\lambda_e}{q'(z_k)}\chi(z_k) + e^{\mp\epsilon t}\sum_{k=1,2}\frac{w_k}{s^2+w_k^2}\frac{e^{\mp i\nu t}w_k}{w_k+i\lambda_e}\frac{2w_k+i\lambda_e}{q(w_k)}r_k + ie^{\mp|s|t}\frac{|s|}{2}\left(\frac{\mp 2|s|+\lambda_e}{|s|\mp\lambda_e}\frac{\chi(\mp i|s|)}{q(\mp i|s|)} + \frac{\pm 2|s|+\lambda_e}{|s|\pm\lambda_e}\frac{\chi(\pm i|s|)}{q(\pm i|s|)}\right) + \int_{\mathcal{C}}e^{-itz}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{z^2}{q(z)}\frac{1}{s^2+z^2}.$$

Therefore one obtains

$$\begin{aligned} I_1(t) + \frac{1}{\pi}\int_{\mathbb{R}} ds\, I_2(t,s) = {} & \mp e^{\mp\lambda_e t}\lambda_e^2\frac{\chi(-i\lambda_e)}{q(-i\lambda_e)} \pm e^{\mp\gamma_e t}\frac{e^{-i\omega_e t}2z_k}{z_k+i\lambda_e}\frac{2z_k+i\lambda_e}{q'(z_k)}\chi(z_k) \\ & \pm e^{\mp\epsilon t}\frac{e^{\mp i\nu t}2w_k}{w_k+i\lambda_e}\frac{2w_k+i\lambda_e}{q(w_k)}r_k \\ & + \frac{i}{\pi}\int_{\mathbb{R}} ds\left(\frac{e^{\mp\lambda_e t}\lambda_e^3}{s^2-\lambda_e^2}\frac{\chi(-i\lambda_e)}{q(-i\lambda_e)} + \frac{e^{\mp|s|t}|s|(-2|s|+\lambda_e)}{2(|s|-\lambda_e)}\frac{\chi(-i|s|)}{q(-i|s|)}\right) \\ & + \frac{i}{\pi}\int_{\mathbb{R}} ds\frac{e^{\mp|s|t}|s|(2|s|+\lambda_e)}{2(|s|+\lambda_e)}\frac{\chi(i|s|)}{q(i|s|)} + \frac{\epsilon}{\nu^3}\int_{\mathcal{C}} dz\, e^{-itz}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{1}{q(z)} \\ & + \pi\frac{\epsilon}{\nu^3}\left(\int_{\mathcal{C}^+} dz\, e^{-itz}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{z}{q(z)} - \int_{\mathcal{C}^-} dz\, e^{-itz}\frac{2z+i\lambda_e}{z+i\lambda_e}\frac{z}{q(z)}\right), \end{aligned}$$

where $k=2$ if $t>0$ and $k=1$ if $t<0$ and $\mathcal{C}^\pm$ are the components of $\mathcal{C}$ with $\pm\mathrm{Sign}(\mathrm{Re}(z))>0$, respectively.

□

Now we can give the time behavior of the various terms, as in the previous theorem. A first group of terms is composed by the resonant contributions. One can distinguish natural resonances, depending on the structural parameters only (the physical constants e,m,c), and the resonance due to the incident photon. For $\epsilon\downarrow 0$ this last contribution reduces to a strictly oscillating term, as expected. A second group of terms is given by the s integrals. We give their behavior for vanishing ϵ only. The calculation is similar to the one already given for the survival amplitude, and one has in the end Laplace transforms of rational functions with poles at the resonances, producing other exponentials of the type already seen, and an exponential integral function. So the leading behavior of the type t^{-1} survives to the $\epsilon\downarrow 0$ limit.

The last group of terms are the contour complex integrals. These could be analyzed asymptotically as Fourier integrals of rational functions, but they vanish as $\epsilon\downarrow 0$. Summarizing we can state the following.

Theorem 3.5: *There exist complex constants C_1,C_2,C_3 depending on the physical parameters m, e, c, ω_0, ν, and a function $R(t)$ such that*

$$\lim_{\epsilon \downarrow 0} \mathcal{A}^{\epsilon}(t) = C_1 e^{-\lambda_{\mathrm{e}}|t|} + C_2 e^{-\gamma_{\mathrm{e}}|t|} e^{-i\omega_{\mathrm{e}} t} + C_3 e^{-i\nu t} + R(t)$$

with

$$R(t) = O(1/t), \quad |t| \gg 1.$$

APPENDIX: QUANTIZATION OF ABSTRACT WAVE EQUATIONS

In this appendix we give a brief and self-contained introduction to the quantization of second order abstract wave equations, along the lines traced by Segal in the 1950s and 1960s and with an emphasis on the aspects of direct concern with our work. We refer for details and different approaches to Refs. 23 and 13 as regards abstract wave equations and to Refs. 21 and 5 as regards quantization.

Let $B: D(B) \subseteq \mathcal{H} \to \mathcal{H}$ be an injective self-adjoint operator on the real Hilbert space $(\mathcal{H}, \langle \cdot, \cdot \rangle)$. We denote by $\mathcal{H}^1$, the Hilbert space given by the domain of B with the scalar product $\langle \cdot, \cdot \rangle_1$ leading to the graph norm, i.e.,

$$\langle \phi_1, \phi_2 \rangle_1 := \langle B\phi_1, B\phi_2 \rangle + \langle \phi_1, \phi_2 \rangle.$$

We then define the Hilbert space $\bar{\mathcal{H}}^1$ by completing the pre-Hilbert space $D(B)$ endowed with the scalar product

$$[\phi_1, \phi_2]_1 := \langle B\phi_1, B\phi_2 \rangle.$$

We extend the self-adjoint operator B to $\bar{\mathcal{H}}^1$ by considering $\bar{B}: \bar{\mathcal{H}}^1 \to \mathcal{H}$, the closed bounded extension of the densely defined linear operator

$$B: \mathcal{H}^1 \subseteq \bar{\mathcal{H}}^1 \to \mathcal{H}.$$

Since B is self-adjoint one has $\mathrm{Ran}(B)^{\perp} = \mathrm{Ker}(B)$, so that, being B injective, $\mathrm{Ran}(B)$ is dense in $\mathcal{H}$. Therefore we can define $\bar{B}^{-1}: \mathcal{H} \to \bar{\mathcal{H}}^1$ as the closed bounded extension of the densely defined linear operator

$$B^{-1}: \mathrm{Ran}(B) \subseteq \mathcal{H} \to \mathcal{H}^1.$$

One can then verify that $\bar{B}$ is boundedly invertible with inverse given by $\bar{B}^{-1}$.

Given $\bar{B}$ we can now introduce the space $\bar{\mathcal{H}}^2$ defined by

$$\bar{H}^2 := \{\phi \in \bar{\mathcal{H}}_1 : \bar{B}\phi \in \mathcal{H}_1\}.$$

On the Hilbert space $\bar{\mathcal{H}}^1 \oplus \mathcal{H}$ with scalar product

$$\langle\langle (\phi_1, \dot{\phi}_1), (\phi_2, \dot{\phi}_2) \rangle\rangle := \langle \bar{B}\phi_1, \bar{B}\phi_2 \rangle + \langle \dot{\phi}_1, \dot{\phi}_2 \rangle$$

we define the linear operator

$$W_B: \bar{\mathcal{H}}_2 \oplus \mathcal{H}^1 \subseteq \bar{\mathcal{H}}^2 \oplus \mathcal{H} \to \bar{\mathcal{H}}^1 \oplus \mathcal{H}, \quad W_B(\phi, \dot{\phi}) := (\dot{\phi}, -B\bar{B}\phi).$$

Theorem A.1: *The linear operator W_B is skew-adjoint.*

Being W_B skew-adjoint, by the Stone theorem it generates the strongly continuous one-parameter group of isometric operators e^{tW_B}. By defining $(\phi(t), \dot{\phi}(t)) := e^{tW_B}(\phi, \dot{\phi})$, one has that, in the case $\phi \in \bar{\mathcal{H}}^2$, $\dot{\phi} \in \mathcal{H}^1$, $\phi(t)$ is the unique strong solution of the Cauchy problem

$$\ddot{\phi}(t) = -B\bar{B}\phi(t),$$

$$\phi(0) = \phi, \quad \dot{\phi}(0) = \dot{\phi}.$$

Given an arbitrary real Hilbert space $(\mathcal{K}, \langle\cdot,\cdot\rangle_{\mathcal{K}})$ we will denote by $(\mathcal{K}_c, \langle\cdot,\cdot\rangle_c)$ its standard complexification, i.e., $\mathcal{K}_c = \mathcal{K}\oplus\mathcal{K}$, the multiplication by the complex unity being defined by $i\psi := J\psi$, $J(\varphi_1,\varphi_2) := (-\varphi_2,\varphi_1)$, and

$$\langle\psi_1,\psi_2\rangle_c := \langle\psi_1,\psi_2\rangle_{\mathsf{K}\oplus\mathsf{K}} - i\langle\psi_1, J\psi_2\rangle_{\mathsf{K}\oplus\mathsf{K}}.$$

Given any linear operator $A: D(A)\subseteq\mathcal{K}\to\mathcal{K}$ on $\mathcal{K}$, we define $A_c: D(A_c)\subset\mathcal{K}_c\to\mathcal{K}_c$ by $D(A_c) := D(A)\times D(A)$, $A_c(\varphi_1,\varphi_2) := (A\varphi_1, A\varphi_2)$. Conversely, given any linear operator $L: D(L)\subset\mathcal{K}_c \to\mathcal{K}_c$, $L(\varphi_1,\varphi_2)\equiv(L_1(\varphi_1,\varphi_2), L_2(\varphi_1,\varphi_2))$, we define $L_r: D(L_r)\subseteq\mathcal{K}\to\mathcal{K}$ by $D(L_r) := \{\phi \in \mathsf{K}: (\phi,0)\in D(L)\}$, $L_r := L_1(\varphi,0)$.

By the above definitions B_c is self-adjoint and $(W_B)_c = W_{B_c}$, where

$$W_{B_c}: \bar{\mathcal{H}}^2_c \oplus \mathcal{H}^1_c \subseteq \bar{\mathcal{H}}^2_c \oplus \mathcal{H}_c \to \bar{\mathcal{H}}^1_c \oplus \mathcal{H}_c, \quad W_{B_c}(\psi,\dot{\psi}) := (\dot{\psi}, -B_c\bar{B}_c\psi).$$

By the Stone formula one has the following.

Lemma A.2:

$$e^{tW_B} = \lim_{a\uparrow\infty}\lim_{\epsilon\downarrow 0}\frac{1}{2\pi i}\int_{-a}^{a} \mathrm{d}\lambda\, e^{-it\lambda}((iW_{B_c} - (\lambda + i\epsilon))^{-1} - (iW_{B_c} - (\lambda - i\epsilon))^{-1})_r.$$

The following lemma translates the wave flow in a Schrödinger-type one.

Lemma A.3: The map

$$C_B: \bar{\mathcal{H}}^1 \oplus \mathcal{H} \to \mathcal{H}_c, \quad C_B(\phi,\dot{\phi}) := (\bar{B}\phi, \dot{\phi})$$

is unitary once one makes $\bar{\mathcal{H}}^1\oplus\mathcal{H}$ a complex Hilbert space by introducing the complex structure $J_B(\phi,\dot{\phi}) := (-\bar{B}^{-1}\dot{\phi}, \bar{B}\phi)$ and by defining $i(\phi,\dot{\phi}) := J_B(\phi,\dot{\phi})$ and the scalar product

$$\langle\langle(\phi_1,\dot{\phi}_1),(\phi_2,\dot{\phi}_2)\rangle\rangle_B := \langle\langle(\phi_1,\dot{\phi}_1),(\phi_2,\dot{\phi}_2)\rangle\rangle - i\langle\langle(\phi_1,\dot{\phi}_1), J_B(\phi_2,\dot{\phi}_2)\rangle\rangle.$$

Moreover

$$e^{tW_B} = C_B^* e^{-itB_c} C_B.$$

Once we have transformed the abstract wave equation $\ddot{\phi}(t) = -B\bar{B}\phi(t)$, defined on the real Hilbert space $\bar{\mathcal{H}}^1\oplus\mathcal{H}$, into the Schrödinger equation $i\dot{\psi} = B_c\psi$, defined on the complex Hilbert space $\mathcal{H}_c$, we can then (second) quantize it in the standard way. Let us define K to be the bosonic Fock space over $\mathcal{H}_c$ (see Ref. 19, Sec. II.4, for the definition). For any $\psi\in\mathcal{H}$ we define the self-adjoint operator on K given by the Segal field $\mathsf{S}(\psi) := (1/\sqrt{2})(\mathsf{C}(\psi) + \mathsf{C}^*(\psi))$, were C and C^* denote the usual creation and destruction operators (see Ref. 20, Sec. X.7, for the definition). Given the Segal field S we can then define the Weyl system $\mathsf{W}(\psi) := e^{i\mathsf{S}}\psi$, so that

$$\mathsf{W}(\psi_1+\psi_2) = e^{(i/2)\langle\psi_1,\psi_2\rangle_c}\mathsf{W}(\psi_1)\mathsf{W}(\psi_2).$$

The unitary strongly continuous one-parameter group of evolution on K defined by $\mathsf{U}(t) := \Gamma(e^{-itB_c})$ satisfies the relations

$$\mathsf{W}(e^{-itB_c}\psi) = \mathsf{U}(t)\mathsf{W}(\psi)\mathsf{U}(t)^*$$

and we denote by $\mathrm{d}\Gamma(B_c)$ the self-adjoint operator on K which generates $\mathsf{U}(t)$ (we refer to Ref. 20, Sec. II.4, and Ref. 8 for the definitions of Γ and $\mathrm{d}\Gamma$). The quantum Hamiltonian corresponding to the (second) quantization of the abstract wave equation $\ddot{\phi}(t) = -B\bar{B}\phi(t)$ is defined by $\mathsf{H} := \hbar\,\mathrm{d}\Gamma(B_c)$. Suppose now that we start with a self-adjoint operator A on the real Hilbert space $\mathcal{K}$. Denoting by A^+ the positive part of A and by $\mathcal{K}^+$ the projection of $\mathcal{K}$ onto the positive spectral subspace. Then

we can apply the previous construction to $B:=(A^+)^{1/2}$, considered as an injective self-adjoint operator on $\mathcal{H}:=\mathcal{K}^+$. However, since

$$\langle \psi_1, e^{-it(A^+)_c^{1/2}} \psi_2 \rangle = \langle \psi_1^+, e^{-it(A^+)_c^{1/2}} \psi_2^+ \rangle,$$

where ψ^+ denotes the projection of ϕ on $\mathcal{K}^+$, we will work with $\mathrm{d}\Gamma((A^+)_c^{1/2})$ on the bosonic Fock space over $\mathcal{K}$.

We consider classical static solutions of the pure massive SU(N) Yang–Mills field equations in (3+1)-dimensional space–time. By applying harmonic map ansatz, constructed from the harmonic maps $S^2 \to CP^{N-1}$, we construct some bounded spherically symmetric solutions having finite energies for $N=2$, 3, and 4 cases.
 [DOI: 10.1063/1.1857063]

I. INTRODUCTION

It is well known that the pure massless (3+1)-dimensional SU(N) Yang–Mills theories do not admit static classical finite-energy solutions.[1,2] This fact is related to the conformal invariance of the action which implies that the corresponding stress-energy tensor is traceless. As mass terms in the action break this conformal invariance, this raises the expectation that finite-energy solutions might exist in the pure massive SU(N) Yang–Mills theories. This expectation is our main concern in this paper.

The pure massive case is of course pathological, as its action is nongauge invariant. In order to get rid of this nongauge invariance, in Sec. II we consider a Stückelberg-type gauge invariant formalism,[3] where SU(N) chiral currents $\tilde{U}^{-1}\partial_\mu \tilde{U}$ with $\tilde{U} \in \mathrm{SU}(N)$ are added to render the massive terms gauge invariant. The pure massive case now corresponds to choosing the special gauge $\tilde{U}=I$. We then observe that if, within this special gauge, we choose the massive gauge potential to be of *almost* pure gauge form, we recover the SU(N) Skyrme models action,[4] which adds strong support to our previous expectation.

Armed with this observation, in Sec. III we turn to consider a static magnetic type case where we show that the corresponding energy satisfies a Hobart–Derrick-type stability condition[5,6] for the existence of finite energy solutions. By performing a Bogomolnyi-type analysis to the energy, we found that the energy has a lower bound that is proportional to a metric independent integral we call B-integral, which is analogous to the topological charge of the SU(N) Skyrme models.[4]

To construct these solutions, in Sec. IV we consider the spherically symmetric case where we apply harmonic map ansatz for the gauge potentials that were introduced by Ioannidou and Sutcliffe in their study of non-Bogomolnyi BPS monopoles.[7] The ansatz is constructed by using $(N-1)$ rank-1 projectors of the harmonic maps $S^2 \to CP^{N-1}$ as formulated in Ref. 8. Here, the two-dimensional (2D) harmonic map construction, which is a generalization of geodesic concept in differential geometry,[9] is used to describe the angular dependence of the field configurations. This has the advantage of reducing the complicated matrix field equations into simpler sets of nonlinear ordinary differential equations (ODEs) for the profile functions $g_l(r)$, $l=0,1,\ldots,(N-1)$, i.e., the radial dependence part of the fields.

In Sec. V, we study spherically symmetric solutions of the equations (numerically) for lower N cases (2, 3, and 4), where we found that by letting the profile functions $g_l(r)$ vanish at $r \to \infty$ and appropriately choosing the boundary conditions to be imposed at the origin $r=0$, some bounded solutions with finite energies can be constructed.

II. MASSIVE SU(*N*) YANG–MILLS THEORIES AND SKYRME MODELS

Let $\tilde{U}(x)$ be an SU(N) group valued function of space–time coordinates. Then a Stückelberg-type formalism of massive SU(N) Yang–Mills theories is given by the action[3]

$$S = \int \mathrm{d}^4x \, \mathrm{Tr}\Big[-\tfrac{1}{2}F^{\mu\nu}F_{\mu\nu} + M^2(A^\mu - \tilde{L}^\mu)(A_\mu - \tilde{L}_\mu)\Big], \tag{1}$$

where Tr is for trace and where

$$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu + i[A_\mu, A_\nu], \tag{2}$$

$$\tilde{L}_\mu = -i\tilde{U}^{-1}\partial_\mu \tilde{U}, \tag{3}$$

with M as a mass parameter and where we have chosen arbitrarily the gauge coupling $e=1$. The gauge potential A_μ and the left chiral current $\tilde{L}_\mu$ have values in the Lie algebra Su(N) and here we have chosen them to be Hermitian, i.e., $A_\mu^\dagger = A_\mu$ and $\tilde{L}_\mu^\dagger = \tilde{L}_\mu$, respectively.

We note that the action (1) is *invariant* under the gauge transformations,

$$A'_\mu = \Omega^{-1}A_\mu\Omega - i\Omega^{-1}\partial_\mu\Omega, \tag{4}$$

$$\tilde{U}' = \tilde{U}\Omega, \tag{5}$$

where $\Omega \in \mathrm{SU}(N)$. On the other hand, as under the scale transformation $x^\mu \to \lambda x^\mu$, the gauge potential and the chiral current scale as $\lambda A_\mu(\lambda x)$ and $\lambda\tilde{L}_\mu(\lambda x)$, respectively, we see that the mass term breaks the scale invariancy of the action (1).

The corresponding Euler–Lagrange equations are

$$D_\mu F^{\mu\nu} - M^2(A^\nu - \tilde{L}^\nu) = 0, \tag{6}$$

$$\partial_\mu A^\mu - D_\mu \tilde{L}^\mu = 0, \tag{7}$$

where for any $G \in \mathrm{Su}(N)$,

$$D_\mu G \equiv \partial_\mu G + i[A_\mu, G]. \tag{8}$$

Taking $\Omega = \tilde{U}^{-1}$ in (4) and (5), $\tilde{U}$ becomes the unit element I and the action (1) reduces to

$$S = \int \mathrm{d}^4x \, \mathrm{Tr}\Big[-\tfrac{1}{2}F^{\mu\nu}F_{\mu\nu} + M^2A^\mu A_\mu\Big], \tag{9}$$

i.e., it is the *pure massive* SU(N) Yang–Mills action. The field equations (6) and (7) then reduce to

$$D_\mu F^{\mu\nu} - M^2A^\nu = 0, \tag{10}$$

$$\partial_\mu A^\mu = 0, \tag{11}$$

respectively.

Equation (11) means that the gauge potential A_μ satisfies the *Lorentz condition*. Thus, we may interpret the action (9) as a gauge fixed version of the gauge invariant action (1). As the field equations (10) and (11) imply 3 degrees of freedom (polarization states) for each vector field A_μ^a where a is the Lie algebra index, we call the gauge $\tilde{U}=I$ the *physical* or *unitary gauge*. In the following, by massive SU(N) Yang–Mills theories we mean the pure case (9).

Now, let us make the following observation by choosing the gauge potential A_μ in the action

(9) to be of *almost* pure-gauge form, i.e.,

$$A_\mu = iqU^{-1}\partial_\mu U, \tag{12}$$

where U takes value in the group SU(N), and q is a space–time independent free parameter. In terms of U, the gauge field strength $F_{\mu\nu}$, according to (2), becomes

$$F_{\mu\nu} = -iq(1+q)[L_\mu, L_\nu], \tag{13}$$

where

$$L_\mu = U^{-1}\partial_\mu U. \tag{14}$$

Thus we see that, if we choose $q=-1$ then $F_{\mu\nu}=0$ and so the corresponding gauge potential A_μ is a pure gauge.

Setting (12) and (13) into the action (9) yields a new action

$$S = \int \mathrm{d}^4x \, \mathrm{Tr}\left(\tfrac{1}{2}q^2(1+q)^2[L^\mu, L^\nu][L_\mu, L_\nu] - q^2M^2L^\mu L_\mu\right), \tag{15}$$

which coincides with the SU(N) Skyrme models action,[4] with the parameters identification,

$$F = 4qM, \quad a = \frac{1}{4q(1+q)}, \tag{16}$$

where F is the pion decay constant, and a the Skyrme models dimensionless constant.

As the SU(N) Skyrme models have finite (or solitonic) solutions called skyrmions, this coincidence gives us a strong basis to expect that massive SU(N) Yang–Mills theories might admit finite energy solutions as well. To check this further, in the following sections, III–V, we choose to study the static magnetic type case.

III. STATIC MAGNETIC TYPE ENERGY AND *B*-INTEGRAL

As we are interested in the static magnetic type case, we exclude the electric type fields by imposing

$$A_0 = 0, \quad \partial_0 A_a = 0, \tag{17}$$

from which it follows that

$$F_{0a} = 0, \tag{18}$$

where $a=1, 2, 3$. Then, from the action (9), the static magnetic type energy of the massive SU(N) Yang–Mills fields is

$$E = \int \mathrm{d}^3x \, \mathrm{Tr}\left[\tfrac{1}{2}F_{ab}^2 + M^2A_a^2\right]. \tag{19}$$

In Ref. 10, Sheng had shown that the static magnetic type massive SU(N) Yang–Mills fields in $(n+1)-D$ space–time with $n\neq 3$ do not allow for the existence of finite-energy static solutions. Thus, the $n=3$ case that we are considering here evades Sheng nonexistence theorems which was left as an open problem in Ref. 10.

To examine this $n=3$ case explicitly, let us study the scale stability of the energy integral (19) under the scale transformation, $\vec{x}\to\lambda\vec{x}$. As the gauge potentials A_μ scale as

$$A_\mu(\vec{x}) \to \lambda A_\mu(\lambda\vec{x}), \tag{20}$$

from which

$$F_{\mu\nu}(\vec{x}) \to \lambda^2 F_{\mu\nu}(\lambda\vec{x}), \tag{21}$$

the energy integral (19) scales as

$$E \to E[\lambda] = \int \frac{\mathrm{d}^3(\lambda x)}{\lambda^3} \mathrm{Tr}\left[\tfrac{1}{2}\lambda^4 F_{ab}(\lambda\vec{x})^2 + M^2\lambda^2 A_a(\lambda\vec{x})^2\right]$$

$$= \lambda E_F + \frac{1}{\lambda} E_M, \tag{22}$$

where E_F and E_M are the F-term and the massive term, respectively. Thus we see that the pure massive SU(N) Yang–Mills static energy (19) scales in the same fashion as the static energy of the SU(N) Skyrme models.[4] As

$$\left.\frac{\mathrm{d}E[\lambda]}{\mathrm{d}\lambda}\right|_{\lambda=1} = E_F - E_M, \tag{23}$$

$$\left.\frac{\mathrm{d}^2E[\lambda]}{\mathrm{d}\lambda^2}\right|_{\lambda=1} = 2E_M, \tag{24}$$

the extremum condition guarantees that $E_M = E_F$. Thus we see that the Hobart–Derrick-type stability condition[5,6] could be satisfied, and so we conclude that static massive SU(N) Yang–Mills field theories admit the existence of finite-energy solutions as we expected.

Next, we note that the energy integral (19) can be expressed in the form of a perfect square term plus "something" as follows:

$$E = \int \mathrm{d}^3x\, \mathrm{Tr}\left[\left(\tfrac{1}{2}\epsilon_{abc}F_{ab} - MA_c\right)^2 + M\epsilon_{abc}F_{ab}A_c\right]. \tag{25}$$

The second term in (25) has structure which is independent of the metric tensor, which raises the expectation that it is a topological quantity. As it is proportional to the baryon number B of the SU(N) Skyrme models if A_μ is of almost pure gauge form, so for convenience we keep the same letter B for it, and define

$$B = \frac{1}{16\pi}\int \mathrm{d}^3x\, \mathrm{Tr}[\epsilon_{abc}F_{ab}A_c]. \tag{26}$$

For later reference, we call it by the name *B-integral*. From (25) it is obvious that, for finite B,

$$E \geqslant 16\pi MB, \tag{27}$$

and so the lower bound of the energy would be saturated if

$$\epsilon_{abc}F_{ab} - 2MA_c = 0, \tag{28}$$

which is analogous to Bogomolnyi's bound in Yang–Mills–Higgs monopole theories.[7] Note that (28) is consistent with the Lorentz condition (11) in this static magnetic type case.

In terms of the spherical polar coordinates (r, θ, ϕ), the energy (19) becomes

$$E = \int \mathrm{d}r(\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi)\mathrm{Tr}\left[F_{r\theta}^2 + \frac{1}{\sin^2\theta}F_{r\phi}^2 + \frac{1}{r^2\sin^2\theta}F_{\theta\phi}^2 + M^2r^2A_r^2 + M^2A_\theta^2 + \frac{M^2}{\sin^2\theta}A_\phi^2\right]. \tag{29}$$

As we are going to apply the harmonic maps $S^2 \to CP^{N-1}$ to this problem, in the following we choose to use the stereographic (holomorphic) coordinates $(\xi, \bar{\xi})$ for S^2 where ξ is related to the θ, φ, via $\xi = \tan(\theta/2)e^{i\varphi}$. The angular derivatives ∂_θ and ∂_ϕ then read

$$\partial_\theta = \frac{(1+|\xi|^2)}{2|\xi|}(\xi\partial_\xi + \bar{\xi}\partial_{\bar{\xi}}), \tag{30}$$

$$\partial_\phi = i(\xi\partial_\xi - \bar{\xi}\partial_{\bar{\xi}}), \tag{31}$$

respectively, where $|\xi| = \sqrt{|\xi|^2}$, whereas for the volume element,

$$\mathrm{d}^3x = r^2\,\mathrm{d}r[\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi] = r^2\,\mathrm{d}r\left[\frac{2i\,\mathrm{d}\bar{\xi}\,\mathrm{d}\xi}{(1+|\xi|^2)^2}\right]. \tag{32}$$

The transformation relations between the angular components of the gauge potential and field strength in the spherical polar and holomorphic coordinates are

$$A_\theta = \frac{(1+|\xi|^2)}{2|\xi|}(\xi A_\xi + \bar{\xi}A_{\bar{\xi}}), \tag{33}$$

$$A_\phi = i(\xi A_\xi - \bar{\xi}A_{\bar{\xi}}), \tag{34}$$

$$F_{r\theta} = \frac{(1+|\xi|^2)}{2|\xi|}(\xi F_{r\xi} + \bar{\xi}F_{r\bar{\xi}}), \tag{35}$$

$$F_{r\phi} = i(\xi F_{r\xi} - \bar{\xi}F_{r\bar{\xi}}), \tag{36}$$

$$F_{\theta\phi} = i|\xi|(1+|\xi|^2)F_{\bar{\xi}\xi}. \tag{37}$$

In terms of the complex quantities on the right-hand side of (33)–(37), the energy (29) in the spherical holomorphic coordinates $(r,\xi,\bar{\xi})$ is

$$E = 2i\int \mathrm{d}r\,\mathrm{d}\xi\,\mathrm{d}\bar{\xi}\,\mathrm{Tr}\left[F_{r\bar{\xi}}F_{r\xi} - \frac{(1+|\xi|^2)^2}{4r^2}F_{\bar{\xi}\xi}F_{\bar{\xi}\xi} + \frac{M^2r^2}{(1+|\xi|^2)^2}A_rA_r + M^2A_{\bar{\xi}}A_\xi\right], \tag{38}$$

and the field equations (10) become

$$D_{\bar{\xi}}F_{\xi r} + D_\xi F_{\bar{\xi}r} - \frac{2Mr^2}{(1+|\xi|^2)^2}A_r = 0, \tag{39}$$

$$D_rF_{r\bar{\xi}} - D_{\bar{\xi}}\left[\frac{(1+|\xi|^2)^2}{2r^2}F_{\bar{\xi}\xi}\right] - M^2A_{\bar{\xi}} = 0, \tag{40}$$

while the Lorentz condition (11) becomes

$$\partial_r(r^2A_r) + \frac{(1+|\xi|^2)^2}{2}[\partial_\xi A_{\bar{\xi}} + \partial_{\bar{\xi}}A_\xi] = 0. \tag{41}$$

IV. SU(*N*) HARMONIC MAP ANSATZ

In this section, we solve the massive SU(N) Yang–Mills field equations (39) and (40) together with the constraint (41), numerically, by using harmonic maps $S^2 \to CP^{N-1}$. Our harmonic map ansatz for the gauge potentials, following Ioannidou and Sutcliffe,[7] are given by

$$A_r = 0, \quad A_{\bar{\xi}} = i\sum_{k=0}^{N-2} g_k[P_k, \partial_{\bar{\xi}} P_k], \tag{42}$$

where $P_k = P_k(\xi, \bar{\xi})$ are rank-1 projector fields of the $CP^{N-1}\sigma$ model,[8] and where g_k, the profile functions, are dependent on the radial coordinate r only.

Following the construction in Ref. 8, the projectors P_k are given by

$$P_k = M_k |M_k|^{-2} M_k^\dagger \quad (k = 0, 1, \ldots, N-1), \tag{43}$$

where M_k are a set of N mutually orthogonal N-component vector fields that are constructed by the Gram–Schmidt procedure from the holomorphic vector fields, M_0, $\partial_\xi M_0, \ldots, \partial_\xi^{(N-1)} M_0$.

Note that, in (43) and the rest of our discussion, summation convention on repeated indices are no longer held. Notice also that the upper sum in (42) is $(N-2)$ as the projectors P_k satisfy the completeness relation, $P_0 + P_1 + \cdots + P_{N-1} = I_N$ where I_N is the $(N \times N)$ unit matrix.

As M_0 is holomorphic, i.e., $\partial_{\bar{\xi}} M_0 = 0$, the following properties of the constructed matrices M_k in (43) hold:[8]

$$\partial_{\bar{\xi}} M_k = -M_{k-1} |M_{k-1}|^{-2} |M_k|^2, \tag{44}$$

$$\partial_\xi (M_k |M_k|^{-2}) = M_{k+1} |M_k|^{-2}. \tag{45}$$

Now, from the construction (43) we see that $A_{\bar{\xi}} = (A_\xi)^\dagger$ and that, as the projectors P_k satisfy the $CP^{N-1}\sigma$ model equation,[8] $[P_k, \partial_{\bar{\xi}\bar{\xi}} P_k] = 0$, it follows from the ansatz (42) that the gauge potentials A_ξ and $A_{\bar{\xi}}$ satisfy the identity

$$\partial_\xi A_{\bar{\xi}} + \partial_{\bar{\xi}} A_\xi = 0, \tag{46}$$

and so (41) is solved by this ansatz automatically.

Furthermore, we find that with the ansatz (42), Eq. (39) is also satisfied identically. Thus, the only nontrivial equation left is (40). To derive the explicit equations for the profile functions g_k from (40), we need to extract out the angular dependence in a consistent way. To carry out this manipulation directly is a formidable task due to the complexities in evaluating the derivatives of the projectors. In order to get rid of it, we reduce the dependencies on the holomorphic coordinates $(\xi, \bar{\xi})$ by multiplying (40) from the right by the mutually orthogonal vector fields $M_l[l = 0, \ldots, (N-1)]$, i.e.,

$$\left(D_r F_{r\bar{\xi}} - D_{\bar{\xi}} \left[\frac{(1 + |\xi|^2)^2}{2r^2} F_{\bar{\xi}\bar{\xi}} \right] - M^2 A_{\bar{\xi}} \right) M_l = 0, \tag{47}$$

and then use the following properties of the projector operators $P_k = M_k |M_k|^{-2} M_k^\dagger$ and its derivatives applied to M_l:

$$P_k M_l = \delta_{kl} M_l, \tag{48}$$

$$(\partial_\xi P_k) M_l = (\delta_{kl} - \delta_{k,l+1}) M_{l+1}, \tag{49}$$

$$(\partial_{\bar{\xi}} P_k) M_l = \kappa_{l-1} (\delta_{k,l-1} - \delta_{kl}) M_{l-1}, \tag{50}$$

where

$$\kappa_l = |M_l|^{-2} |M_{l+1}|^2. \tag{51}$$

In deriving the above results we have taken M_0 to be holomorphic and we have used the derivative properties of M_l as given by Eqs. (44) and (45). Note that, by definition, $\kappa_{-1} = 0$. For example, in deriving (50) we first write

$$(\partial_{\bar{\xi}} P_k) M_l = \partial_{\bar{\xi}}(P_k M_l) - P_k \partial_{\bar{\xi}} M_l. \tag{52}$$

Then, using (44) and (48), i.e., $\partial_{\bar{\xi}} M_l = -\kappa_{l-1} M_{l-1}$, gives (50).

Hence, the action of the gauge potential, as given by the ansatz (42), on the vectors M_l are

$$A_{\xi} M_l = -iG_l M_{l+1}, \tag{53}$$

$$A_{\bar{\xi}} M_l = iG_{l-1}\kappa_{l-1} M_{l-1}, \tag{54}$$

where

$$G_l = (g_l + g_{l+1}), \tag{55}$$

from which we derive that

$$F_{r\xi} M_l = -i\dot{G}_l M_{l+1}, \tag{56}$$

$$F_{r\bar{\xi}} M_l = i\dot{G}_{l-1}\kappa_{l-1} M_{l-1}, \tag{57}$$

$$F_{\bar{\xi}\xi} M_l = i(\tilde{Q}_l \kappa_l - \tilde{Q}_{l-1}\kappa_{l-1}) M_l, \tag{58}$$

where

$$\tilde{Q}_l = G_l(2 - G_l). \tag{59}$$

Note that, by definition, $g_l = 0$ if $l \notin [0, 1, \ldots, (N-2)]$.

Let us now return to Eq. (47). We observe that, in order to have a compatible set of equations for the profile functions g_l, we must choose the vectors M_l in such a way that each factor $(1+|\xi|^2)^2\kappa_l$ is equal to a constant, i.e.,

$$\kappa_l = \frac{\mathcal{K}_l}{(1+|\xi|^2)^2}, \tag{60}$$

where $\mathcal{K}_l$ are some constants depending on the index l. In fact, we found that the condition (60) is satisfied if we choose the initial vector M_0 to be given by the *Veronese map*,[11]

$$M_0 = [1, \sqrt{C_1^{N-1}}\xi, \ldots, \sqrt{C_k^{N-1}}\xi^k, \ldots, \xi^{N-1}]^T, \tag{61}$$

where C_k^{N-1} are binomial coefficients.

With this choice then from the construction of the vectors M_l we obtain[4]

$$\mathcal{K}_l = (l+1)(N-l-1) = \mathcal{N}_l. \tag{62}$$

Using (53)–(57) and (60) for κ_l then for the first two terms of Eq. (40), we obtain

$$\left(D_r F_{r\bar{\xi}} - D_{\bar{\xi}}\left[\frac{(1+|\xi|^2)^2}{2r^2} F_{\bar{\xi}\xi}\right]\right) M_l$$
$$= i\left(\ddot{G}_{l-1} + \frac{1}{2r^2}[\mathcal{N}_l \tilde{Q}_l - 2\mathcal{N}_{l-1}\tilde{Q}_{l-1} + \mathcal{N}_{l-2}\tilde{Q}_{l-2}](1 - G_{l-1})\right)\kappa_{l-1} M_{l-1}. \tag{63}$$

Substituting (54) and (63) in Eq. (40), and noticing that M_l are independent vector fields, we find that the profile functions g_l satisfy the following second order nonlinear ordinary differential equations:

$$\ddot{G}_l + \frac{1}{2r^2}[\mathcal{N}_{l+1}\widetilde{Q}_{l+1} - 2\mathcal{N}_l\widetilde{Q}_l + \mathcal{N}_{l-1}\widetilde{Q}_{l-1}](1-G_l) - M^2 G_l = 0. \tag{64}$$

Thus we see that the harmonic map ansatz (42) with the initial vector M_0 given by the Veronese map (61) is an exact spherically symmetric solution of the massive Yang–Mills field equations (39)–(41).

Next, we want to express the static magnetic type energy (19) in terms of the profile functions g_l. To simplify the evaluation of the traces in (19), we choose to use the formula

$$\mathrm{Tr}[R] = \sum_{k=0}^{N-1} \frac{1}{|M_k|^2} M_k^{\dagger}[R]M_k, \tag{65}$$

where R is a $(N\times N)$ nonsingular complex matrix which is diagonal in each basis vector $M_k (k=0,1,\ldots,N-1)$. Note that the upper sum in (65) is $(N-1)$, instead of $(N-2)$, because here we must sum over the whole *complete set* of basis vectors M_k in C^N.

Using (53)–(57) and (60) we obtain

$$\mathrm{Tr}(F_{r\bar{\xi}}F_{r\xi}) = \frac{1}{(1+|\xi|^2)^2}\sum_{k=0}^{N-2} \mathcal{N}_l \dot{G}_l^2, \tag{66}$$

$$\mathrm{Tr}(F_{\xi\bar{\xi}}F_{\bar{\xi}\xi}) = -\frac{1}{(1+|\xi|^2)^4}\sum_{k=0}^{N-1} (\mathcal{N}_l\widetilde{Q}_l - \mathcal{N}_{l-1}\widetilde{Q}_{l-1})^2, \tag{67}$$

$$\mathrm{Tr}(A_{\bar{\xi}}A_{\xi}) = \frac{1}{(1+|\xi|^2)^2}\sum_{k=0}^{N-2} \mathcal{N}_l G_l^2, \tag{68}$$

where, by definition, $G_{N-1}=0$ and $\mathcal{N}_{-1}=0$.

With the above results for the traces, the static energy (38), written in a symmetrical form, becomes

$$E = 4\pi\int_0^{\infty} \mathrm{d}r \sum_{l=0}^{N-1}\left[\mathcal{N}_l\dot{G}_l^2 + \frac{1}{4r^2}(\mathcal{N}_l\widetilde{Q}_l - \mathcal{N}_{l-1}\widetilde{Q}_{l-1})^2 + M^2\mathcal{N}_l G_l^2\right]. \tag{69}$$

We note that equations for the critical points of the energy (69) coincide with the equations for the profile functions g_l in (64) as we expected. From this expression we see that the energy is finite provided the profile functions G_l, for all $l=0,1\ldots,(N-2)$, are bounded and that they approach zero at infinity as re^{-Mr} and at the origin the boundary conditions, $G_l=0$ or 2, are imposed.

The B-integral in this coordinate system is

$$B = -\frac{2i}{16\pi}\int \mathrm{d}r\,\mathrm{d}\xi\,\mathrm{d}\bar{\xi}\,\mathrm{Tr}[F_{r\bar{\xi}}A_{\bar{\xi}} + F_{\bar{\xi}r}A_{\xi}], \tag{70}$$

and so using the formula (65) to express the traces, we obtain

$$B = -\frac{1}{2}\sum_{l=0}^{N-2}\mathcal{N}_l\int_0^{\infty}\mathrm{d}r(\dot{G}_l G_l) = -\frac{1}{4}\sum_{l=0}^{N-2}\mathcal{N}_l[G_l^2(r)]_{r=0}^{\infty}, \tag{71}$$

where $\mathcal{N}_l$ is given by (62). Thus, by taking the boundary conditions $G_l(\infty)=0$, we see that the B-integral is determined solely by the boundary conditions at the origin.

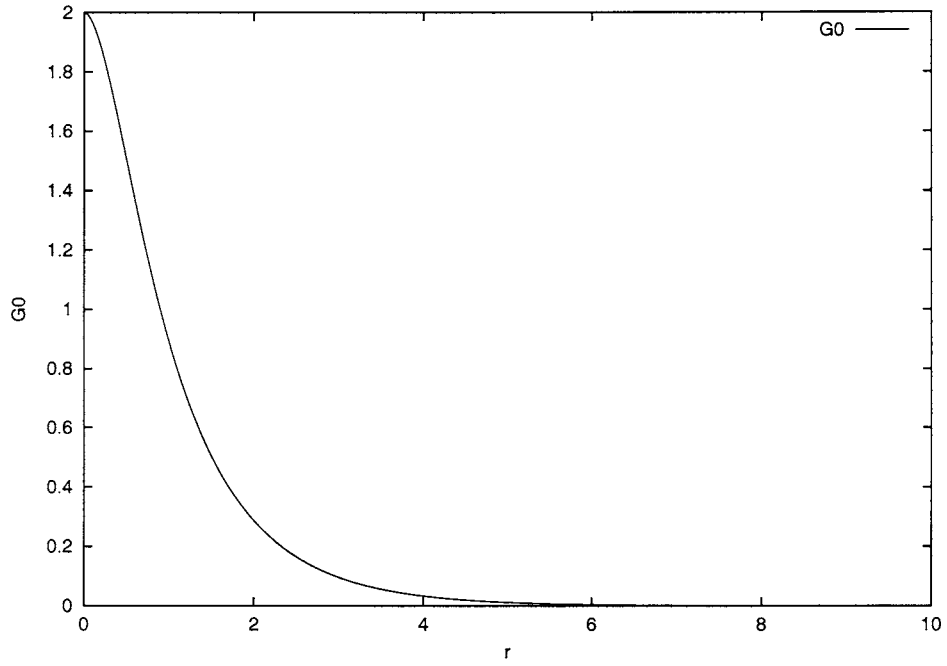

FIG. 1. Profile function of the massive SU(2) YM field for $M=1$.

V. SPHERICALLY SYMMETRIC SOLUTIONS

In this section, we have a look at the numerical solutions of the profile equations (64) for some different values of the mass M by imposing the boundary conditions, $G_l(\infty)=0$ and $G_l(0)=0$ or 2, as required for having finite-energy solutions. In fact, we only consider the cases $N=2$, 3, and 4.

A. SU(2)

Here we have only one profile function G_0, with $\mathcal{N}_0=1$, so the profile equations (64) reduce to a single equation,

$$\ddot{G}_0 - \frac{1}{r^2}\tilde{Q}_0(1-G_0) - M^2 G_0 = 0. \tag{72}$$

Solving (72) for some different values of the mass M with the boundary condition $G_0(0)=2$ at the origin, we have found that each solution G_0 is bounded. In Fig. 1 we show the solution for $M=1$.

We have also computed the corresponding energy from (69), i.e.,

$$E = 4\pi \int_0^\infty \mathrm{d}r \left[\dot{G}_0^2 + \frac{1}{2r^2}\tilde{Q}_0^2 + M^2 G_0^2 \right], \tag{73}$$

and the results for four different mass parameters, i.e., $M=1$, 5, 10, and 50, are summarized in Table I.

TABLE I. Energies of the massive SU(2) YM fields.

$G_0(0)$	B	$E_{M=1}/4\pi$	$E_{M=5}/4\pi$	$E_{M=10}/4\pi$	$E_{M=50}/4\pi$
2	1	4.946 29e+00	2.473 20e+01	4.946 70e+01	2.477 55e+02

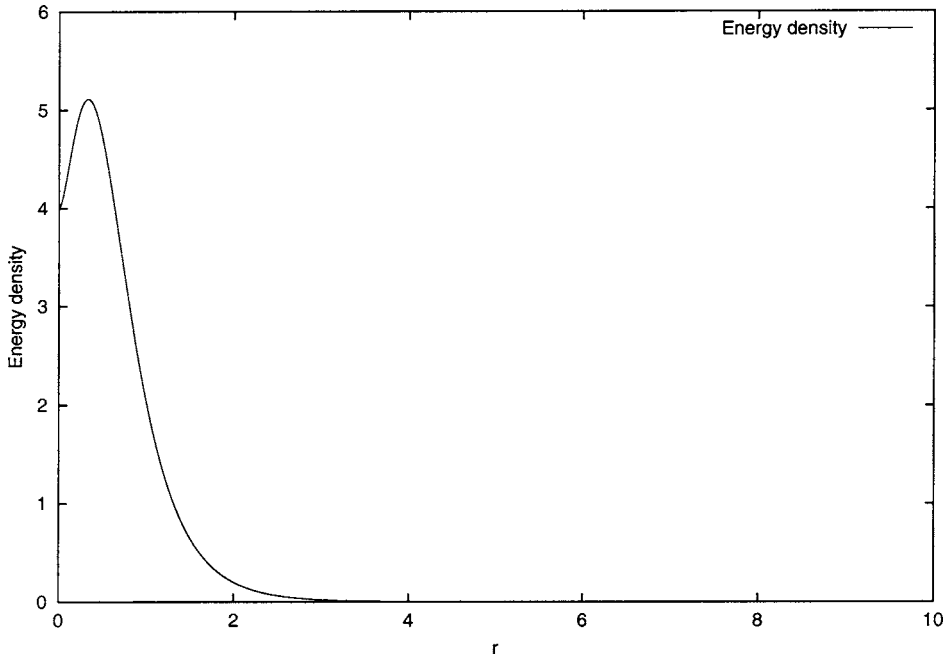

FIG. 2. Energy density of the massive SU(2) YM field for $M=1$.

In Fig. 2 we show the radial energy density for $M=1$ and we see that it looks like a trough ball.

These solutions has B-integral equal to 1 and so, according to (27), the lower bound of the energy is $E/(4\pi)=4M$. We see that each energy is about 25% higher than the corresponding lower bound value.

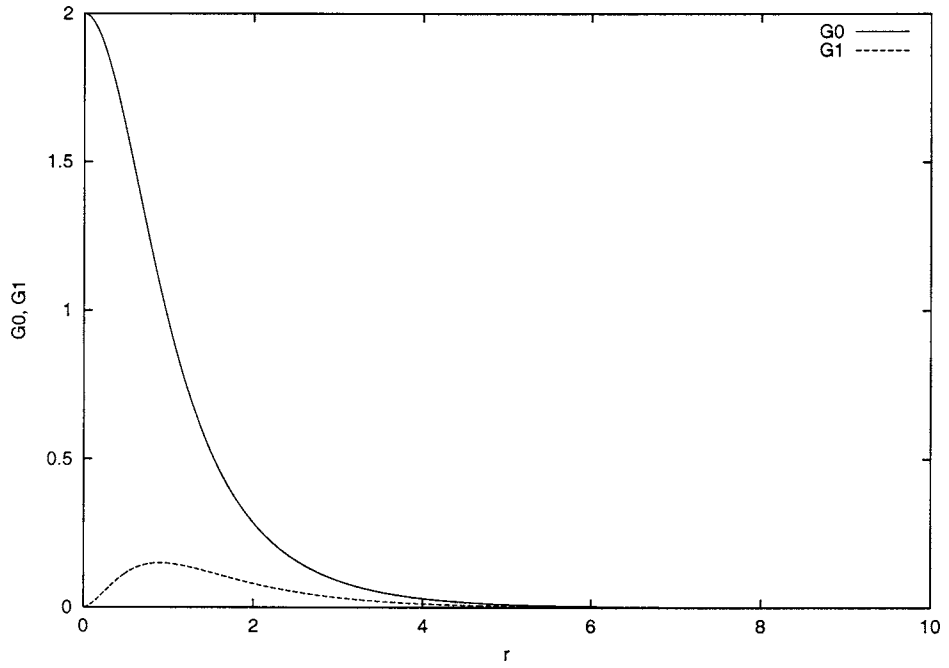

FIG. 3. Profile functions of the massive SU(3) YM fields for $M=1$, $G_0(0)=2$, and $G_1(0)=0$.

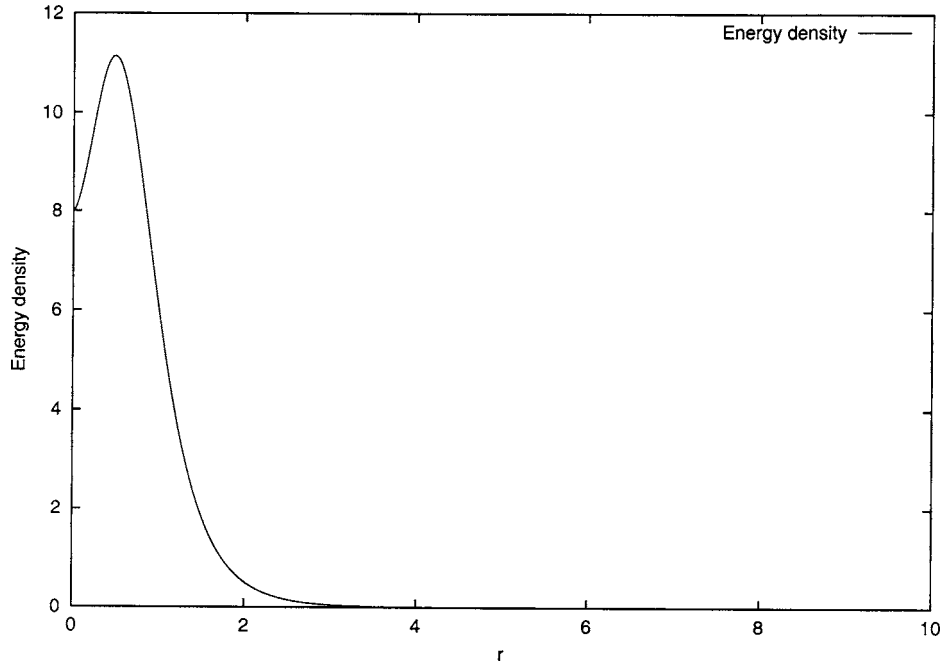

FIG. 4. Energy density of the massive SU(3) YM fields for $M=1$, $G_0(0)=2$, and $G_1(0)=0$.

For the boundary condition $G_0(0)=0$, we have found that Eq. (72) has trivial solution $G_0(r)=0$.

B. SU(3)

For $N=3$, we have two profile functions G_0 and G_1 which satisfy

$$\ddot{G}_0 - \frac{1}{r^2}[2\tilde{Q}_0 - \tilde{Q}_1](1-G_0) - M^2 G_0 = 0, \tag{74}$$

$$\ddot{G}_1 - \frac{1}{r^2}[-\tilde{Q}_0 + 2\tilde{Q}_1](1-G_1) - M^2 G_1 = 0, \tag{75}$$

as $\mathcal{N}_0=\mathcal{N}_1=2$.

We have solved these equations for each of the following two different choices of boundary conditions imposing at the origin $(G_0(0), G_1(0))=(2,0)$ and (2, 2), and we have also found that the corresponding solutions are bounded. In Fig. 3, we show the graphs of these solutions for $M=1$, and the corresponding radial energy distribution is presented in Fig. 4. In Table II we have summarized the result of energies computed from (69), i.e.,

TABLE II. Energies of the massive SU(3) YM fields.

$G_0(0)$	$G_1(0)$	B	$E_{M=1}/4\pi$	$E_{M=5}/4\pi$	$E_{M=10}/4\pi$	$E_{M=50}/4\pi$
2	0	2	1.190 80*e*+01	5.954 09*e*+01	1.190 87*e*+02	5.962 17*e*+02
2	2	4	2.164 98*e*+01	1.082 51*e*+02	2.165 16*e*+02	1.084 40*e*+03

TABLE III. Energies of the massive SU(4) YM fields (reduced case).

$G(0)$	$G_1(0)$	B	$E_{M=1}/4\pi$	$E_{M=5}/4\pi$	$E_{M=10}/4\pi$	$E_{M=50}/4\pi$
0	2	4	2.690 92e+01	1.345 50e+02	2.691 20e+02	1.348 17e+03
2	0	6	3.665 47e+01	1.832 76e+02	3.665 67e+02	1.834 96e+03

$$E = 4\pi(2)\int_0^\infty \mathrm{d}r\left(\dot{G}_0^2 + \dot{G}_1^2 + \frac{1}{r^2}[\tilde{Q}_0^2 - \tilde{Q}_0\tilde{Q}_1 + \tilde{Q}_1^2] + M^2G_0^2 + M^2G_1^2\right), \tag{76}$$

for different values of mass M.

We notice that Eqs. (74) and (75) are symmetric with respect to the interchange $G_0 \leftrightarrow G_1$. This allows us to set $G_0 = G_1$ which reduces the system to a single SU(2) profile equation (72). This configuration has $B=4$ [taking $G_0(0)=2$] and having energy 4 times the energy of a SU(2) configuration.

C. SU(4)

Here we have three profile functions G_0, G_1, and G_2, with $\mathcal{N}_0=\mathcal{N}_2=3$ and $\mathcal{N}_1=4$, so the profile equations (64) reduce to

$$\ddot{G}_0 - \frac{1}{r^2}[3\tilde{Q}_0 - 2\tilde{Q}_1](1-G_0) - M^2G_0 = 0, \tag{77}$$

$$\ddot{G}_1 - \frac{1}{2r^2}[-3\tilde{Q}_0 + 8\tilde{Q}_1 - 3\tilde{Q}_2](1-G_1) - M^2G_1 = 0, \tag{78}$$

$$\ddot{G}_2 - \frac{1}{r^2}[-2\tilde{Q}_1 + 3\tilde{Q}_2](1-G_2) - M^2G_2 = 0, \tag{79}$$

The corresponding energy (69) is

$$E = 4\pi\int_0^\infty \mathrm{d}r\left(3\dot{G}_0^2 + 4\dot{G}_1^2 + 3\dot{G}_2^2 + \frac{1}{2r^2}[9\tilde{Q}_0^2 - 12\tilde{Q}_0\tilde{Q}_1 + 16\tilde{Q}_1^2 - 12\tilde{Q}_1\tilde{Q}_2 + 9\tilde{Q}_2^2]\right.$$
$$\left. + 3M^2G_0^2 + 4M^2G_1^2 + 3M^2G_2^2\right). \tag{80}$$

We observe that the system (77)–(79) has symmetry $G_0 \leftrightarrow G_2$, which allows us to set $G_0 = G_2 = G$ by keeping G_1 arbitrary. The energies for this configuration are summarized in Table III.

In addition, letting $G_0=G_1=G_2=G$, the above system of equations reduces to the SU(2) profile equation (72). This configuration has $B=10$ [taking $G(0)=2$] and has energy 10 times the energy of one SU(2) configuration.

TABLE IV. Energies of the massive SU(4) YM fields.

$G_0(0)$	$G_1(0)$	$G_2(0)$	B	$E_{M=1}/4\pi$	$E_{M=5}/4\pi$	$E_{M=10}/4\pi$	$E_{M=50}/4\pi$
0	0	2	3	1.917 95e+01	9.589 85e+01	1.918 04e+02	9.601 04e+02

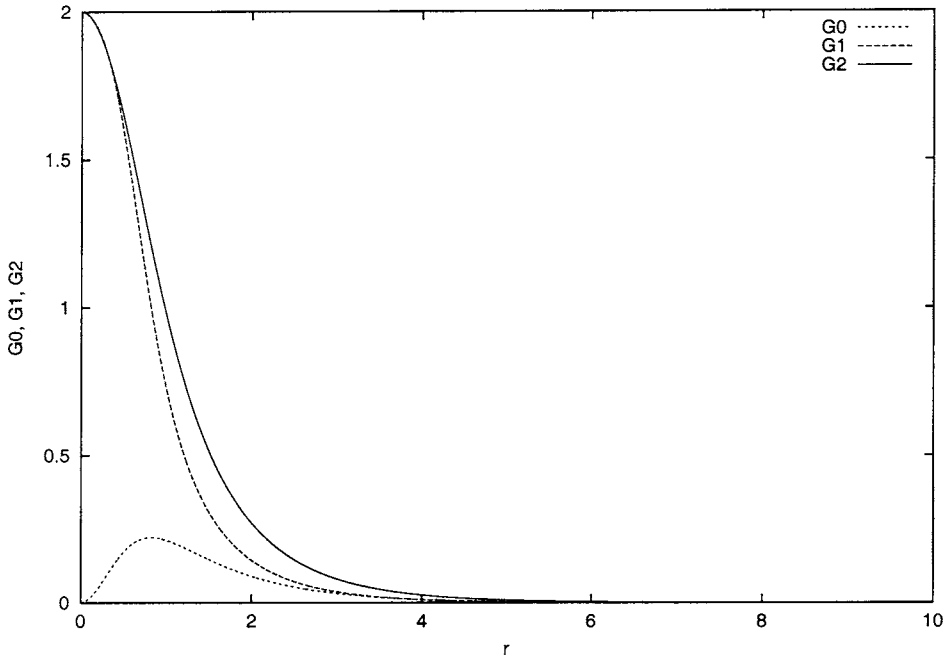

FIG. 5. Profile functions of the massive SU(4) YM fields for $M=1$, $G_0(0)=0$, $G_1(0)=2$, and $G_2(0)=2$.

In Table IV, we have summarized the values of energies for general configurations $G_0 \neq G_1 \neq G_2$ for four different combinations of boundary conditions at the origin. In Fig. 5, we show the graphs of the solutions for $M=1$, $G_0(0)=0$, $G_1(0)=2$, and $G_2(0)=2$. The corresponding radial energy distribution is presented in Fig. 6.

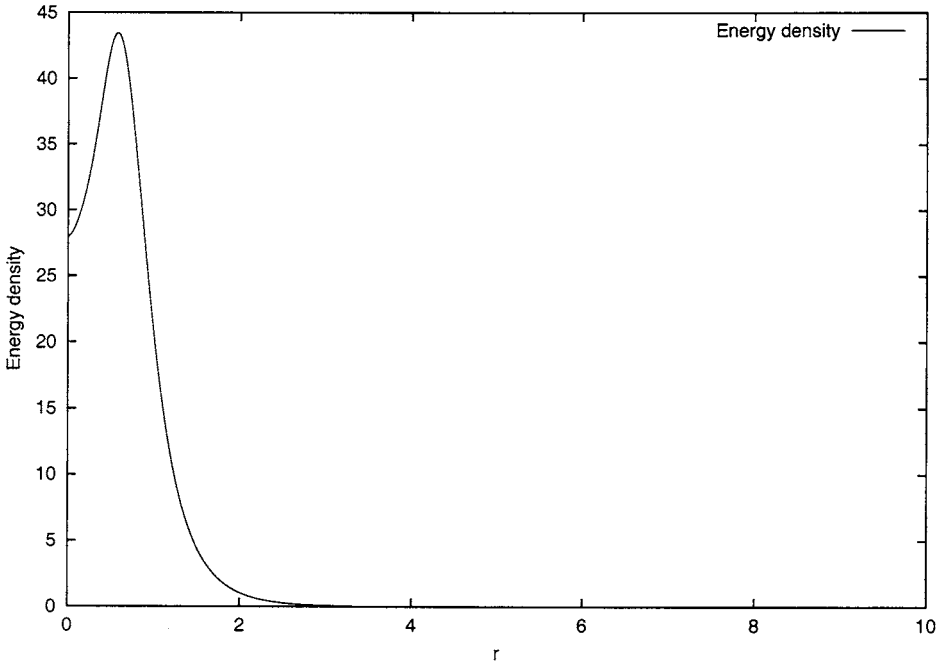

FIG. 6. Energy density of the massive SU(4) YM fields for $M=1$, $G_0(0)=0$, $G_1(0)=2$, and $G_2(0)=2$.

VI. CONCLUSIONS

In this paper we considered the pure massive SU(N) Yang–Mills theories where we first showed that for the case when the gauge potential is chosen to be of almost pure gauge form, the theories reduce to the SU(N) Skyrme models. When we studied the static magnetic type case we found that the energy is bounded from below by a topological chargelike quantity that we called by the name B-integral.

To solve the corresponding static equations, we used Ioannidou–Sutcliffe harmonic map ansatz that they introduced in their study of non-Bogomolnyi BPS monopoles.[7] This ansatz enabled us to construct some bounded solutions having finite energies for $N=2$, 3, and 4 cases. These solutions are very special in the sense that they depend very much on the chosen boundary conditions to be imposed on the profile functions g_k, i.e., $g_k=-2$, 0 or 2 at the origin and zero at infinity. We also showed that each solution is classified by the B-integral which is an integer number.

(Received 2 August 2005; accepted 1 September 2005; published online 31 October 2005)

We consider the polaron model in the relativistic quantum electrodynamics. We prove that the ground state energy of the model is finite for all values of the fine-structure constant and the ultraviolet cutoff Λ. Moreover we give an upper bound and a lower bound of the ground state energy. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2084749]

I. INTRODUCTION AND MAIN RESULTS

We consider the relativistic quantum electrodynamics (QED) for a fixed total momentum—the polaron model of the relativistic QED. The Hamiltonian, which describes a Dirac particle minimally coupled to the quantized radiation field, commutes with the total momentum operator, and has a direct integral decomposition with respect to the total momentum operator.[1,2] Each fiber in this direct integral decomposition is just the Hamiltonian of the polaron we consider. The Hilbert space of the polaron model is defined by

$$\mathcal{F} := \mathbb{C}^4 \otimes \mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3 \times \{1,2\})), \tag{1}$$

where

$$\mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3 \times \{1,2\})) := \bigotimes_{n=0}^{\infty} \left[\bigotimes_{s}^{n} (L^2(\mathbb{R}^3 \times \{1,2\})) \right] \tag{2}$$

is the photon Fock space ($\otimes_s^n$ denotes n-fold symmetric tensor product). For a closable operator T on $L^2(\mathbb{R}^3 \times \{1,2\})$ we denote by $\mathrm{d}\Gamma_{\mathrm{b}}(T)$, the second quantization operator of T (see Ref. 3). Let $a(f)$, $f \in L^2(\mathbb{R}^3 \times \{1,2\})$ be the annihilation operator on the photon Fock space. For a function $g_j \in L^2(\mathbb{R}^3 \times \{1,2\})$, $j=1,2,3$, we set

$$A_j := a(g_j) + a(g_j)^*, \quad j = 1,2,3. \tag{3}$$

Let $\{\alpha_1, \alpha_2, \alpha_3, \beta\}$ be the 4×4-Dirac matrices, i.e., $\{\alpha_i, \alpha_j\} = 2\delta_{i,j}$, $\{\alpha_i, \beta\} = 0$, $\beta^2 = 1$, $i,j = 1,2,3$. Here $\{A,B\} := AB + BA$. For three objects a_1, a_2, a_3 we set $\mathbf{a} = (a_1, a_2, a_3)$, and write $\mathbf{a} \cdot \mathbf{b} := \Sigma_{j=1}^3 a_j b_j$, provided that $a_j b_j$ and $\Sigma_{j=1}^3 a_j b_j$ are defined.

The Hamiltonian of the polaron model we consider is

$$H(\mathbf{p}) := \boldsymbol{\alpha} \cdot \mathbf{p} + M\beta + \mathrm{d}\Gamma_{\mathrm{b}}(\omega) - \boldsymbol{\alpha} \cdot \mathrm{d}\Gamma_{\mathrm{b}}(\mathbf{k}) - q\boldsymbol{\alpha} \cdot \mathbf{A}, \tag{4}$$

where $\mathbf{p} \in \mathbb{R}^3$ is the fixed total momentum, $M \geqslant 0$ is the mass of the Dirac particle, $q \in \mathbb{R}$ is a constant proportional to the fine-structure constant, and $\omega = |\mathbf{k}|$ is the one-photon Hamiltonian ($\mathbf{k} \in \mathbb{R}^3$). Note that we omit the symbol $\otimes$ between the Hilbert space for the Dirac matrices $\mathbb{C}^4$ and the photon Fock space $\mathcal{F}_{\mathrm{b}}(L^2(\mathbb{R}^3 \times \{1,2\}))$. The most important example of $\{g_j\}_{j=1}^3$ is of the form

[a)]Electronic mail: i-sasaki@math.sci.hokudai.ac.jp

$$f_j(\mathbf{k},r) := \frac{\chi_\Lambda(\mathbf{k})}{|\mathbf{k}|^{1/2}} e_j^{(r)}(\mathbf{k}), \tag{5}$$

where the measurable functions $\mathbf{e}^{(1)}(\mathbf{k}), \mathbf{e}^{(2)}(\mathbf{k})$ are the polarization vectors:

$$\mathbf{k}\cdot\mathbf{e}^{(r)}(\mathbf{k}) = 0, \quad \mathbf{e}^{(r)}(\mathbf{k})\cdot\mathbf{e}^{(s)}(\mathbf{k}) = \delta_{r,s}, \quad \text{a.e.}\mathbf{k} \in \mathbb{R}^3, \quad r,s = 1,2, \tag{6}$$

and $\chi_\Lambda(\mathbf{k})$ is the characteristic function of the ball $\{\mathbf{k}\in\mathbb{R}^3 | |\mathbf{k}| < \Lambda\}$, $\Lambda > 0$.

We define

$$E_0(\mathbf{p}) := \inf_{\substack{\Psi\in \mathrm{Dom}(H(\mathbf{p})) \\ \|\Psi\|=1}} \langle \Psi, H(\mathbf{p})\Psi\rangle \tag{7}$$

the ground state energy of $H(\mathbf{p})$, where "Dom" means operator domain. We assume the following.

Hypothesis I: $g_j \in \mathrm{Dom}(\omega^{-1/2}) \cap \mathrm{Dom}(\omega)$, $\langle g_j, g_\ell\rangle \in \mathbb{R}$, $j,\ell = 1,2,3$.

It should be noted that it is highly nontrivial whether or not $E_0(\mathbf{p})$ is finite, because $H(\mathbf{p})$ contains the term $-\boldsymbol{\alpha}\cdot \mathrm{d}\Gamma_b(\mathbf{k})$. This is the main problem discussed in the present paper.

We prove that the ground state energy $E_0(\mathbf{p})$ is finite under suitable conditions:

Theorem 1.1: *Assume Hypothesis I, and*

$$G(\mathbf{g}) := \sup_{\mathbf{k}\in\mathbb{R}^3\setminus\{0\}} \frac{1}{|\mathbf{k}|} \sum_{r=1,2} \int_{\mathbb{R}^3} \frac{|\mathbf{k}\cdot\mathbf{g}(\mathbf{k}',r)|^2}{|\mathbf{k}||\mathbf{k}'| - \mathbf{k}\cdot\mathbf{k}'} \mathrm{d}\mathbf{k}' < \infty. \tag{8}$$

Then, the ground state energy $E_0(\mathbf{p})$ is finite:

$$E_0(\mathbf{p}) > -\infty. \tag{9}$$

In particular, if $g_j = f_j$, $j=1,2,3$, the ground state energy $E_0(\mathbf{p})$ is finite.

For a vector $u \in \mathbb{C}^4$, we set $a_j := \langle u, \alpha_j u\rangle_{\mathbb{C}^4}$, and

$$\mathcal{E}(\Lambda_1, u) := \mathbf{p}\cdot\mathbf{a} + M\langle u, \beta u\rangle + 4\pi\Lambda q^2 \frac{1-|\mathbf{a}|^2}{|\mathbf{a}|} \log\left(\frac{1+|\mathbf{a}|}{1-|\mathbf{a}|}\right) - 4\pi\Lambda q^2.$$

In the physical case (i.e., the function g_j's are given by (5)), the lower bound of $E_0(\mathbf{p}) + \sqrt{|\mathbf{p}|^2 + M^2}$ are proportional to Λ.

Theorem 1.2: *Let $g_j = f_j$, $j=1,2,3$. Then*

$$C_1\Lambda - \sqrt{|\mathbf{p}|^2 + M^2} \leqslant E_0(\mathbf{p}), \tag{10}$$

$$E_0(\mathbf{p}) \leqslant C_2(\Lambda), \tag{11}$$

where

$$C_1 := \inf_{\epsilon,\epsilon'>0} \left\{ \epsilon|q| + 16\pi q^2 + \left(\epsilon' + \frac{1}{\epsilon'}\right) 4\pi q^2, \sqrt{\frac{4\pi|q|}{3\epsilon} + \left(1 + \frac{1}{\epsilon'}\right) 4\pi q^2} \right\}, \tag{12}$$

$$C_2(\Lambda) := \inf_{\substack{u\in\mathbb{C}^4 \\ \|u\|_{\mathbb{C}^4}=1}} \mathcal{E}(\Lambda, u). \tag{13}$$

II. PROOF OF THEOREM 1.1 AND 1.2

Lemma 2.1: Let A be a positive self-adjoint operator on a Hilbert space $\mathcal{H}$. Let B be a symmetric operator with $\mathrm{Dom}(A) \subset \mathrm{Dom}(B)$ *and*

$$\|B\Psi\| \leqslant \|A\Psi\|, \quad \Psi \in \mathrm{Dom}(A). \tag{14}$$

Then, for all $\Psi \in D(A)$, $\langle \Psi, (A+B)\Psi \rangle \geqslant 0$.

Proof: By the Kato–Rellich theorem,[4] for all $\epsilon \in (-1,1)$, $A+\epsilon B$ is self-adjoint and $A+\epsilon B \geqslant 0$. Therefore $\langle \Psi, (A+B)\Psi \rangle \geqslant 0$ for all $\Psi \in \mathrm{Dom}(A)$. ■

By this lemma, it suffices to show that there exists a constant $E \geqslant 0$ such that

$$\|(\mathrm{d}\Gamma_b(\omega)+E)\Psi\|^2 \geqslant \|\boldsymbol{\alpha}\cdot(\mathrm{d}\Gamma_b(\mathbf{k})+q\mathbf{A})\Psi\|^2, \quad \Psi \in \mathrm{Dom}(\mathrm{d}\Gamma_b(\omega)). \tag{15}$$

We use the following representation for $\boldsymbol{\alpha}$ matrices:

$$\alpha_j = \begin{bmatrix} \sigma_j & 0 \\ 0 & -\sigma_j \end{bmatrix}, \quad j=1,2,3,$$

with $(\sigma_1,\sigma_2,\sigma_3)$ being the Pauli matrices. Using the anticommutation relation of α_1, α_2, and α_3, we have

$$\|\boldsymbol{\alpha}\cdot(\mathrm{d}\Gamma_b(\mathbf{k})+q\mathbf{A})\Psi\|^2 = \sum_{j=1}^{3}\|(\mathrm{d}\Gamma_b(k_j)+qA_j)\Psi\|^2 - q\langle \Psi, \mathbf{S}\cdot[a(i\mathbf{k}\times\mathbf{g})+a(i\mathbf{k}\times\mathbf{g})^*]\Psi\rangle, \tag{16}$$

where $S_j=\sigma_j\oplus\sigma_j$, $j=1,2,3$. The Hilbert space $\mathbb{C}^4\otimes[\otimes_s^n L^2(\mathbb{R}^3\times\{1,2\})]$ is naturally embedded in $L^2(\mathbb{R}^3\times\{1,2\};\mathbb{C}^4\otimes[\otimes_s^{(n-1)}L^2(\mathbb{R}^3\times\{1,2\})])$. For a vector $\Psi\in\mathbb{C}^4\otimes[\otimes_s^n L^2(\mathbb{R}^3\times\{1,2\})]$, we denote its value at point $(\mathbf{k},r)\in\mathbb{R}^3\times\{1,2\}$ by $\Psi(\mathbf{k},r,\cdot)$.

For $\Psi=(\Psi^{(n)})_{n=0}^{\infty}\in\mathrm{Dom}(\mathrm{d}\Gamma_b(\omega))$, we define

$$a^{(r)}(\mathbf{k})\Psi := (\Psi^{(1)}(\mathbf{k},r), \sqrt{2}\Psi^{(2)}(\mathbf{k},r,\cdot), \ldots, \sqrt{n}\Psi^{(n)}(\mathbf{k},r,\cdot), \ldots) \in \mathcal{F}, \quad \mathbf{k}\in\mathbb{R}^3, \quad r=1,2, \tag{17}$$

a Fock space valued function. This operator $a^{(r)}(\mathbf{k})$ is the distributional kernel of the annihilation operator.

Lemma 2.2: For all $\Psi\in\mathrm{Dom}(\mathrm{d}\Gamma_b(\omega))$ *and* $\epsilon>0$, *the following inequality holds:*

$$|q\langle \Psi, \mathbf{S}\cdot[a(i\mathbf{k}\times\mathbf{g})+a(i\mathbf{k}\times\mathbf{g})^*]\Psi\rangle| \leqslant |q|\epsilon\langle\Psi,\mathrm{d}\Gamma_b(\omega)\Psi\rangle + \frac{|q|}{\epsilon}\langle\mathbf{g},\omega\mathbf{g}\rangle\|\Psi\|^2, \tag{18}$$

where $\langle\mathbf{g},\omega\mathbf{g}\rangle := \Sigma_{j=1}^3\langle g_j,\omega g_j\rangle$.

Proof:

$$\begin{aligned}
\text{left-hand side of (18)} &= 2|q|\left|\mathrm{Re}\sum\!\!\!\!\!\!\int_{\mathbb{R}^3}\langle\Psi, -i\mathbf{S}\cdot(\mathbf{k}\times\mathbf{g}(\mathbf{k},r))a^{(r)}(\mathbf{k})\Psi\rangle\mathrm{d}\mathbf{k}\right| \\
&\leqslant 2|q|\sum\!\!\!\!\!\!\int_{\mathbb{R}^3}\|\mathbf{S}\cdot(\mathbf{k}\times\mathbf{g}(\mathbf{k},r))\Psi\|\,\|a^{(r)}(\mathbf{k})\Psi\|\mathrm{d}\mathbf{k} \\
&= 2|q|\sum\!\!\!\!\!\!\int_{\mathbb{R}^3}|\mathbf{k}|^{1/2}|\mathbf{g}(\mathbf{k},r)|\cdot\|\,|\mathbf{k}|^{1/2}a^{(r)}(\mathbf{k})\Psi\|\cdot\|\Psi\|\mathrm{d}\mathbf{k} \leqslant 2|q| \\
&\quad\times\langle\mathbf{g},\omega\mathbf{g}\rangle^{1/2}\left[\sum\!\!\!\!\!\!\int_{\mathbb{R}^3}\|\,|\mathbf{k}|^{1/2}a^{(r)}(\mathbf{k})\Psi\|^2\right]^{1/2}\|\Psi\| \\
&\leqslant |q|\epsilon\langle\Psi,\mathrm{d}\Gamma_b(\omega)\Psi\rangle + \frac{|q|}{\epsilon}\langle\mathbf{g},\omega\mathbf{g}\rangle\|\Psi\|^2,
\end{aligned}$$

where $\sum\!\!\!\!\!\!\int := \Sigma_{r=1,2}\int$. ■

Lemma 2.3: For all $\Psi\in\mathrm{Dom}(\mathrm{d}\Gamma_b(\omega))$ *and* $\epsilon>0$, *the following inequality holds*:

$$\langle \Psi, \mathbf{A}^2 \Psi \rangle \leqslant \left(2 + \epsilon + \frac{1}{\epsilon}\right) \langle \omega^{-1/2}\mathbf{g}, \omega^{-1/2}\mathbf{g} \rangle \langle \Psi, \mathrm{d}\Gamma_{\mathrm{b}}(\omega)\Psi \rangle + \left(1 + \frac{1}{\epsilon}\right) \langle \mathbf{g}, \mathbf{g} \rangle \|\Psi\|^2. \tag{19}$$

Proof:

$$\begin{aligned}
\langle \Psi, \mathbf{A}^2 \Psi \rangle &\leqslant \sum_{j=1}^{3} \left[(1+\epsilon) \|a(g_j)\Psi\|^2 + \left(1 + \frac{1}{\epsilon}\right) \|a(g_j)^* \Psi\|^2 \right] \\
&\leqslant \sum_{j=1}^{3} \left[(1+\epsilon) \| \, |\mathbf{k}|^{-1/2} g_j \|^2 \cdot \|\mathrm{d}\Gamma_{\mathrm{b}}(\omega)^{1/2}\Psi\|^2 + \left(1 + \frac{1}{\epsilon}\right) \| |\mathbf{k}|^{-1/2} g_j \|^2 \cdot \|\mathrm{d}\Gamma_{\mathrm{b}}(\omega)^{1/2}\Psi\|^2 \right. \\
&\quad \left. + \left(1 + \frac{1}{\epsilon}\right) \|g_j\|^2 \cdot \|\Psi\|^2 \right].
\end{aligned}$$

■

The following Lemma is the most important fact in the proof of Theorem 1.1.

Lemma 2.4: For all $\Psi \in \mathrm{Dom}(\mathrm{d}\Gamma_{\mathrm{b}}(\omega))$, *the following inequality holds*:

$$\begin{aligned}
&\|\mathrm{d}\Gamma_{\mathrm{b}}(\omega)\Psi\|^2 - \sum_{j=1}^{3} \|\mathrm{d}\Gamma_{\mathrm{b}}(k_j)\Psi\|^2 - q\langle \mathrm{d}\Gamma_{\mathrm{b}}(\mathbf{k})\Psi, \mathbf{A}\Psi \rangle - q\langle \mathbf{A}\Psi, \mathrm{d}\Gamma_{\mathrm{b}}(\mathbf{k})\Psi \rangle \\
&\quad \geqslant -4q^2 G(\mathbf{g}) \langle \Psi, \mathrm{d}\Gamma_{\mathrm{b}}(\omega)\Psi \rangle - q\langle \Psi, (a(\mathbf{k}\cdot\mathbf{g})^* + a(\mathbf{k}\cdot\mathbf{g}))\Psi \rangle.
\end{aligned} \tag{20}$$

Proof: We define

$$F := \frac{\mathbf{k}\cdot\mathbf{g}(\mathbf{k}', \mu)}{|\mathbf{k}|\cdot|\mathbf{k}| - \mathbf{k}\cdot\mathbf{k}'}. \tag{21}$$

For all $\Psi \in \mathrm{Dom}(\mathrm{d}\Gamma_{\mathrm{b}}(\omega))$, we have

$$\begin{aligned}
\text{left-hand side of (20)} = \int_{\mathbb{R}^3} \mathrm{d}\mathbf{k} \int'_{\mathbb{R}^3} \mathrm{d}\mathbf{k}' (|\mathbf{k}|\cdot|\mathbf{k}'| - \mathbf{k}\cdot\mathbf{k}') \|(b - 2qF)a\Psi\|^2 - q\langle \Psi, [a(\mathbf{k}\cdot\mathbf{g}) \\
+ a(\mathbf{k}\cdot\mathbf{g})^*]\Psi \rangle - 4q^2 \int_{\mathbb{R}^3} \mathrm{d}\mathbf{k} \left[\int'_{\mathbb{R}^3} \mathrm{d}\mathbf{k}' (|\mathbf{k}|\cdot|\mathbf{k}'| - \mathbf{k}\cdot\mathbf{k}')^{-1} |\mathbf{k}\cdot\mathbf{g}(\mathbf{k}', \mu)|^2 \right] \\
\times \|a\Psi\|^2,
\end{aligned}$$

where $a := a^{(r)}(\mathbf{k})$, $b := a^{(\mu)}(\mathbf{k}')$, and $\int' := \Sigma_{\mu=1,2} \int$. Since $|\mathbf{k}|\cdot|\mathbf{k}'| - \mathbf{k}\cdot\mathbf{k}' \geqslant 0$, inequality (20) holds. ■

Proof of Theorem 1.1: Using Lemmas 2.2–2.4, we get

$$\begin{aligned}
(\mathrm{d}\Gamma_{\mathrm{b}}(\omega) + E)^2 - \sum_{j=1}^{3} (\mathrm{d}\Gamma_{\mathrm{b}}(k_j) + qA_j)^2 - q\mathbf{S}\cdot[a(i\mathbf{k}\times\mathbf{g}) + a(i\mathbf{k}\times\mathbf{g})^*] &\geqslant 2E\mathrm{d}\Gamma_{\mathrm{b}}(\omega) + E^2 \\
- 4q^2 G(\mathbf{g})\mathrm{d}\Gamma_{\mathrm{b}}(\omega) - q[a(\mathbf{k}\cdot\mathbf{g})^* + a(\mathbf{k}\cdot\mathbf{g})] - |q|\mathrm{d}\Gamma(\omega) - |q|\langle \mathbf{g}, \omega\mathbf{g} \rangle - 4\langle \omega^{-1/2}\mathbf{g}, \omega^{-1/2}\mathbf{g} \rangle \mathrm{d}\Gamma_{\mathrm{b}}(\omega) \\
- 2\langle \mathbf{g}, \mathbf{g} \rangle,
\end{aligned}$$

in the sense of quadratic form on $\mathrm{Dom}(\mathrm{d}\Gamma_{\mathrm{b}}(\omega))$. Since $a(\mathbf{k}\cdot\mathbf{g}) + a(\mathbf{k}\cdot\mathbf{g})^*$ is $\mathrm{d}\Gamma_{\mathrm{b}}(\omega)^{1/2}$ bounded, for a large $E > 0$ we have

$$(\mathrm{d}\Gamma_{\mathrm{b}}(\omega) + E)^2 - \sum_{j=1}^{3} (\mathrm{d}\Gamma_{\mathrm{b}}(k_j) + qA_j)^2 - q\mathbf{S}\cdot[a(i\mathbf{k}\times\mathbf{g}) + a(i\mathbf{k}\times\mathbf{g})] \geqslant 0.$$

By Lemma 2.1, for a large $E \geqslant 0$, we obtain

$$\mathrm{d}\Gamma_{\mathrm{b}}(\omega)-\boldsymbol{\alpha}\cdot\mathrm{d}\Gamma_{\mathrm{b}}(\mathbf{k})-q\boldsymbol{\alpha}\cdot\mathbf{A}\geqslant -E, \tag{22}$$

in the sense of quadratic form on $\mathrm{Dom}(\mathrm{d}\Gamma_{\mathrm{b}}(\omega))$. This inequality implies that $E_0(\mathbf{p})$ is finite.

Next we show that $G(\mathbf{f})<\infty$ if $g_j=f_j(j=1,2,3)$. By the definitions of $\mathbf{e}^{(r)}(\mathbf{k})$, the vectors $\mathbf{k}/|\mathbf{k}|$, $\mathbf{e}^{(1)}(\mathbf{k})$, $\mathbf{e}^{(2)}(\mathbf{k})$ are the orthonormal basis of $\mathbb{C}^3$. Therefore

$$G(\mathbf{f})=\sup_{\mathbf{k}\in\mathbb{R}^3\setminus\{0\}}\frac{1}{|\mathbf{k}|}\int_{\mathbb{R}^3}\frac{\chi_\Lambda(\mathbf{k}')\mathrm{d}\mathbf{k}'}{|\mathbf{k}||\mathbf{k}'|-\mathbf{k}\cdot\mathbf{k}'}\cdot\frac{1}{|\mathbf{k}'|}\left[|\mathbf{k}|^2-\frac{(\mathbf{k}\cdot\mathbf{k}')^2}{|\mathbf{k}'|^2}\right]=\int_{\mathbb{R}^3}\frac{\chi_\Lambda(\mathbf{k}')}{|\mathbf{k}'|^2}\mathrm{d}\mathbf{k}'=4\pi\Lambda.$$

■

Proof of Theorem 1.2: First we show (10). We set $g_j=f_j(j=1,2,3)$. It is easy to see that

$$H(\mathbf{p})\geqslant-\sqrt{|\mathbf{p}|^2+M^2}+\mathrm{d}\Gamma_{\mathrm{b}}(\omega)-\boldsymbol{\alpha}\cdot\mathrm{d}\Gamma_{\mathrm{b}}(\mathbf{k})-q\boldsymbol{\alpha}\cdot\mathbf{A}. \tag{23}$$

By the definition of $\mathbf{e}^{(r)}(\mathbf{k})$, we have $\mathbf{k}\cdot\mathbf{f}(\mathbf{k},r)=0(\mathbf{k}\in\mathbb{R}^3,r=1,2)$. Therefore, using Lemmas 2.2–2.4, we have

$$\begin{aligned}&(\mathrm{d}\Gamma_{\mathrm{b}}(\omega)+C_1\Lambda)^2-(\mathrm{d}\Gamma_{\mathrm{b}}(\mathbf{k})+q\mathbf{A})^2-q\mathbf{S}\cdot[a(i\mathbf{k}\times\mathbf{f})+a(i\mathbf{k}\times\mathbf{f})^*]\\&\quad\geqslant\left(2C_1\Lambda-2|q|\epsilon\Lambda-4q^2G(\mathbf{f})-\left(2+\epsilon'+\frac{1}{\epsilon'}\right)\langle\omega^{-1/2}\mathbf{f},\omega^{-1/2}\mathbf{f}\rangle\right)\mathrm{d}\Gamma_{\mathrm{b}}(\omega)\\&\qquad+C_1^2\Lambda^2-\frac{|q|}{2\epsilon\Lambda}\langle\mathbf{f},\omega\mathbf{f}\rangle-\left(1+\frac{1}{\epsilon'}\right)q^2\langle\mathbf{f},\mathbf{f}\rangle,\quad\epsilon,\epsilon'>0.\end{aligned} \tag{24}$$

It is easy to see that $\langle\omega^{-1/2}\mathbf{f},\omega^{-1/2}\mathbf{f}\rangle=8\pi\Lambda$, $\langle\mathbf{f},\omega\mathbf{f}\rangle=8\pi\Lambda^3/3$, $\langle\mathbf{f},\mathbf{f}\rangle=4\pi\Lambda^2$. Hence, by the definition of C_1, the left-hand side of (24) is positive for suitable $\epsilon,\epsilon'>0$. Thus, using Lemma 2.1 (and (16)), we have

$$H(\mathbf{p})\geqslant-\sqrt{|\mathbf{p}|^2+M^2}-C_1\Lambda. \tag{25}$$

For normalized vectors $u\in\mathbb{C}^4$, $\psi\in\mathrm{Dom}(\mathrm{d}\Gamma_{\mathrm{b}}(\omega))$ we define

$$a_j:=\langle u,\alpha_j u\rangle,\quad h(\mathbf{a}):=\mathrm{d}\Gamma_{\mathrm{b}}(\omega-\mathbf{a}\cdot\mathbf{k})-q\mathbf{a}\cdot\mathbf{A},$$

$$\Psi:=u\otimes\psi\in\mathcal{F}.$$

Note that $\omega-\mathbf{a}\cdot\mathbf{k}\geqslant0$ and $\omega-\mathbf{a}\cdot\mathbf{k}$ is injective as a multiplication operator. We have

$$\langle\Psi,H(\mathbf{p})\Psi\rangle=\mathbf{a}\cdot\mathbf{p}+M\langle u,\beta u\rangle+\langle\psi,h(\mathbf{a})\psi\rangle. \tag{26}$$

Since $h(\mathbf{a})$ is a van Hove type Hamiltonian, we have

$$\begin{aligned}\inf\sigma(h(\mathbf{a}))&=-q^2\|(|\mathbf{k}|-\mathbf{a}\cdot\mathbf{k})^{-1/2}\mathbf{a}\cdot\mathbf{f}\|^2=-4\pi\Lambda q^2+q^2(1-|\mathbf{a}|^2)\int_{\mathbb{R}^3}\mathrm{d}\mathbf{k}\frac{\chi_\Lambda(\mathbf{k})}{|\mathbf{k}|^2-(\mathbf{a}\cdot\mathbf{k})^2}\\&=-4\pi\Lambda q^2+2\pi\Lambda q^2(1-|\mathbf{a}|^2)\frac{1}{|\mathbf{a}|}\log\left(\frac{1-|\mathbf{a}|}{1+|\mathbf{a}|}\right),\end{aligned}$$

where σ means the spectrum (e.g., Ref. 3). Thus we have

$$E_0(\mathbf{p})\leqslant\inf_{u\in\mathbb{C}^4;\|u\|=1}\inf_{\psi\in\mathrm{Dom}(\mathrm{d}\Gamma_{\mathrm{b}}(\omega))}\langle\Psi,H(\mathbf{p})\Psi\rangle=\inf_{u\in\mathbb{C}^4;\|u\|=1}\mathcal{E}(u).$$

Induced matter: Curved *N*-manifolds encapsulated in Riemann-flat *N*+1 dimensional space

(Received 22 July 2005; accepted 4 August 2005; published online 13 October 2005)

Liko and Wesson have recently introduced a new five-dimensional induced matter solution of the Einstein equations, a negative curvature Robertson-Walker space embedded in a Riemann-flat five-dimensional manifold. We show that this solution is a special case of a more general theorem prescribing the structure of certain $N+1$ dimensional Riemann-flat spaces which are all solutions of the Einstein equations. These solutions encapsulate N-dimensional curved manifolds. Such spaces are said to "induce matter" in the submanifolds by virtue of their geometric structure alone. We prove that the N-manifold can be any maximally symmetric space. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2042968]

The concept of "induced matter," was originally introduced by Wesson.[1,2] While investigating five-dimensional (5D) Kaluza-Klein theory, he recognized that a curved 4-space could be embedded in a Ricci-flat ($R_{AB}=0$; $A,B,\ldots\in\{0,1,2,3,4\}$) 5-space. This is a reflection of the Campbell-Magaard theorem[3] which, applied to 5D, states that it is always possible to embed a curved four-dimensional (4D) manifold in a 5D Ricci-flat space. Seahra and Wesson[4] provide an overview and rigorous proof of the Campbell-Magaard theorem with applications to higher dimensions. Wesson takes "induced matter" to mean that the left-hand geometric side extra terms of the flat 5D Ricci-tensor provide the source terms in the 4D curved Ricci-tensor of the embedded space. A "weak" version of this concept utilizing an embedding of the Friedmann-Roberston-Walker (FRW) 4-space in a Minkowski 5-space has been used to visualize the big bang sectionally.[5] Here, the 5-space is Riemann-flat ($R_{ABCD}=0$) since it is Minkowski. There is no physics in the 4D subspace, except with reference to the original FRW coordinates. This simply provides a Euclidean embedding diagram.

More recently, Liko and Wesson have introduced a new 5D, Riemann-flat solution[6] which they found could "encapsulate" a 4D curved FRW space. We use the term "encapsulate" as distinct from embed since in this 5-space, the coordinates are not Minkowski. The 4D subspace is itself curved in the same 5D coordinates. It is true that a flattening transformation can be found to a 5D Minkowski space. However, this would simply produce another embedding diagram. The physics seems to lie in the encapsulating 5D metric. We shall use the term "induced matter" to include a Riemann-flat 5D manifold encapsulating a curved 4D subspace. The Liko-Wesson induced matter solution goes on to describe an apparently inflationary universe as a negative curvature FRW space embedded in a special 5D universe. The RW space undergoes accelerated expansion subject to a repulsive "dark energy" ($P=-\rho$). We will show in this paper that the Liko-Wesson solution is a special case of a more general class of maximally symmetric submanifolds embedded in Riemann-

[a)]Author to whom correspondence should be addressed. Electronic mail: lawrence.mead@usm.edu

flat space. A detailed discussion of maximally symmetric submanifolds based on Poincarè metrics and their consequences can be found in Ref. 7. For convenience, we repeat some critical definitions and calculations.

Consider the Riemann manifold defined by

$$\mathrm{d}S^2 = \tilde{g}_{ij}\,\mathrm{d}x^i\,\mathrm{d}x^j. \tag{1}$$

This space is said to be maximally symmetric if and only if it has constant sectional curvature $\kappa=\kappa(i,j)$, for any $1\leqslant i\neq j\leqslant N$. In the plane spanned by the basis vectors $(\hat{e}_i,\hat{e}_j)$ the sectional curvature is defined by

$$\kappa(i,j) = \tilde{g}^{ii}R^j_{iji} \quad (i,j \text{ not summed}). \tag{2}$$

For a maximally symmetric space $R^j_{iji}=\kappa\tilde{g}_{ii}$, $j\neq i$. For such a space,

$$R_{ii} = -\kappa(N-1)\tilde{g}_{ii}. \tag{3}$$

Theorem: Let $\tilde{g}_{ij}$ represent a maximally symmetric space of sectional curvature κ. *The metric*

$$\mathrm{d}S^2 = \mathrm{d}\tau^2 - D\tau^2\tilde{g}_{ij}\,\mathrm{d}x^i\,\mathrm{d}x^j, \quad i,j\ldots,\in\{1,2,\ldots,N\}, \tag{4}$$

is Riemann-flat whenever $D=-\kappa$.

Proof: Consider the metric

$$\mathrm{d}S^2 = \mathrm{d}\tau^2 - f(\tau)^2\tilde{g}_{ij}\,\mathrm{d}x^i\,\mathrm{d}x^j, \tag{5}$$

where $\tilde{g}_{ij}$ denotes a maximally symmetric space. We compute the independent components of the curvature tensor (the overtilde denotes differentiation in τ):

$$R^i_{0j0} = -\frac{f''}{f}\delta^i_j,$$

$$R^0_{i0j} = -ff''\tilde{g}_{ij},$$

$$R^k_{ikj} = \tilde{R}_{ij} - (N-1)f'^2\tilde{g}_{ij} = -\kappa(N-1)\tilde{g}_{ij} - (N-1)f'^2\tilde{g}_{ij} = -(N-1)(f'^2+\kappa)\tilde{g}_{ij}, \tag{6}$$

where we have made use of the result (3). It is evident from (6) that the space will be Riemann-flat if and only if $f''=0$ and $f'^2+\kappa=0$. Let $f(\tau)=\sqrt{D}\tau$. Then $f''=0$ and $f'^2-D=0$. It follows that $D=-\kappa$ and the proof is complete.

Liko and Wesson[6] introduce the line element (with overall sign of $\mathrm{d}S^2$ reversed from ours),

$$\mathrm{d}S^2 = \mathrm{d}\tau^2 - \frac{\tau^2}{L^2}\left[\mathrm{d}t^2 - L^2\sinh^2\left(\frac{t}{L}\right)\mathrm{d}\sigma_3^2\right], \tag{7}$$

where

$$\mathrm{d}\sigma_3^2 = \left(1+\frac{kr^2}{4}\right)^{-2}(\mathrm{d}r^2 + r^2\,\mathrm{d}\theta^2 + r^2\sin^2\theta\,\mathrm{d}\phi^2), \tag{8}$$

is the Robertson-Walker 3-space with $k=-1$.

Define coordinates $x^A=\{\tau,r,\theta,\phi,t\}$, $A\in\{0,1,2,3,4\}$.

We can then identify in (4),

$$\tilde{g}_{ii} = \{-f, -fr^2, -fr^2 \sin^2\theta, 1\}, \quad f = L^2 \sinh^2(t/L)\left(1 + \frac{kr^2}{4}\right)^{-2}, \tag{9}$$

and $D = 1/L^2$. Equation (7) is thus of the form (4) and will satisfy the theorem provided that the sectional curvature of the 4-space is $\kappa = -1/L^2$. Direct evaluation of the sectional curvature for two typical cases (by symmetry, the remaining cases are identical) results in

$$\kappa(1,2) = \tilde{g}^{11} R^2_{121} = -\frac{1}{L^2},$$

$$\kappa(4,2) = \tilde{g}^{44} R^2_{424} = -\frac{1}{L^2}$$

which show that the conditions (6) are met. That is, the 4-space has constant sectional curvature which then results in a Riemann-flat 5-space. We have thus shown that the new metric solution, (7), introduced by Liko and Wesson is a special case of our more general theorem (4) which allows the N-space to be any maximally symmetric manifold.

Tetrads in geometrodynamics

Alcides Garat[a)]
Instituto de Física, Facultad de Ciencias, Iguá 4225, esq. Mataojo, Montevideo, Uruguay

(Received 14 July 2005; accepted 4 August 2005; published online 18 October 2005)

A new tetrad is introduced within the framework of geometrodynamics for non-null electromagnetic fields. This tetrad diagonalizes the electromagnetic stress-energy tensor and allows for maximum simplification of the expression of the electromagnetic field. The Einstein-Maxwell equations will also be simplified. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2049167]

I. INTRODUCTION

The theory of geometrodynamics[1] tried to account for the classical problem of the charged particle. It is a point of view where there is nothing except curved spacetime. Electromagnetism is only a manifestation of the curvature. The electric charge was described as the flux of lines of force that emerges from the mouth of a small wormhole in a multiply connected space. An observer with poor resolving power would see the emerging flux as coming from an elementary electric charge.[1] Therefore, it was concluded that if elementary charge can be associated with a geometrical property of the multiply connected spacetime, there should not be a source term in Maxwell's equations. Geometrodynamics is not in agreement with the idea that particles and fields live in a geometrical background as imported entities. However, it presented difficulties, since it was not possible to find a variational principle for this theory. If $F_{\mu\nu}$ is the electromagnetic field and $f_{\mu\nu}=(G^{1/2}/c^2)F_{\mu\nu}$ is the geometrized electromagnetic field, then the Einstein-Maxwell equations can be written,

$$f^{\mu\nu}{}_{;\nu}=0, \tag{1}$$

$$*f^{\mu\nu}{}_{;\nu}=0, \tag{2}$$

$$R_{\mu\nu}=f_{\mu\lambda}f_{\nu}{}^{\lambda}+*f_{\mu\lambda}*f_{\nu}{}^{\lambda}, \tag{3}$$

where $*f_{\mu\nu}=\frac{1}{2}\epsilon_{\mu\nu\sigma\tau}f^{\sigma\tau}$ is the dual tensor of $f_{\mu\nu}$ (Appendix A). The symbol ";" stands for covariant derivative with respect to the metric tensor $g_{\mu\nu}$. The quadratic right-hand side in Eq. (3) is solved in terms of the left-hand side. Then the "square root of the left-hand side" written in terms of the metric tensor is replaced in Eqs. (1) and (2) and two sets of equations have to be satisfied by the metric tensor. On the one hand, the Bianchi identities. They are identically satisfied by the metric tensor, so they were not a problem. On the other hand, a set of integrability conditions that could not be derived from a variational principle. In this work, it is not our goal to solve the problem of the variational principle in geometrodynamics. It is our purpose to introduce a new tetrad, specifically adapted to the geometry of electromagnetic fields in geometrodynamics. This new tetrad could simplify the understanding of the geometry associated with non-null electromagnetic fields. A tetrad is a set of four linearly independent vectors $V^{\alpha}_{(j)}$ that could be defined at every point in a spacetime.[2,3] The index j is the tetrad index and runs from one to four, naming the vectors. It is

[a)]Electronic mail: garat@fisica.edu.uy

possible then, to write at every point in a spacetime, the components of a tensor in terms of the tetrad vectors,

$$Z^{\alpha\beta\ldots}{}_{\mu\nu\ldots} = Z^{rs\ldots}{}_{pq\ldots} V^{\alpha}_{(r)} V^{\beta}_{(s)} V^{(p)}_{\mu} V^{(q)}_{\nu} \ldots , \tag{4}$$

where the quantities $Z^{rs\ldots}{}_{pq\ldots}$ are the tetrad components of the tensor. Our purpose is to find a tetrad in geometrodynamics that diagonalizes the stress-energy tensor and simplifies the expression of the electromagnetic field. We need to understand first the concept of duality rotations. A duality rotation of the electromagnetic field is defined as[1]

$$e^{*\alpha} f_{\mu\nu} = f_{\mu\nu} \cos\alpha + {*f}_{\mu\nu} \sin\alpha, \tag{5}$$

where α is a scalar called the complexion. At every point in spacetime there is a duality rotation by an angle $-\alpha$ that transforms a non-null electromagnetic field into an extremal field,

$$\xi_{\mu\nu} = e^{-*\alpha} f_{\mu\nu}. \tag{6}$$

Extremal fields are essentially electric fields and they satisfy,

$$\xi_{\mu\nu} * \xi^{\mu\nu} = 0. \tag{7}$$

The tetrad that diagonalizes the stress-energy tensor will be written in terms of the extremal field $\xi_{\mu\nu}$, and two other vector fields X^{α} and Y^{α}. It will be proved that these two extra vector fields are available freedom that we have in the construction of a general tetrad for non-null electromagnetic fields. The fact that in geometrodynamics Maxwell's equations (1) and (2) have zero source terms, introduces the existence of two potential vector fields, A^{α} and ${*A}^{\alpha}$, natural candidates for a particular and explicit choice or example of X^{α} and Y^{α}. In this particular example, an unexpected question will arise at this point. If our tetrad involves in its construction the potential vectors A^{α} and ${*A}^{\alpha}$, how is the tetrad going to be affected by electromagnetic gauge transformations? The geometry of electromagnetic fields defines at every point in spacetime two planes related to the symmetries of the stress-energy tensor.[4] Gauge transformations $A^{\alpha} \rightarrow A^{\alpha} + \Lambda^{\cdot\alpha}$, with Λ a scalar function, that leave invariant the electromagnetic field, will generate proper and improper Lorentz transformations on one of the planes. Gauge transformations ${*A}^{\alpha} \rightarrow {*A}^{\alpha} + {*\Lambda}^{\cdot\alpha}$, with ${*\Lambda}$ a scalar function, that leave invariant the dual of the electromagnetic field will generate spatial rotations on the other plane. The possibility of introducing null tetrads in geometrodynamics will also be explored. Finally, the general tetrad will be studied for non-null electromagnetic fields where X^{α} and Y^{α} are considered as generic fields, and the Einstein-Maxwell equations in this general tetrad will be discussed. The explicit example introduced and all its properties will be useful in understanding the general case. The remainder of this paper will be organized as follows. The tetrad that diagonalizes the stress-energy tensor will be introduced in Sec. II. The available freedom that we have in building this tetrad will be analyzed in Sec. III. The geometrical implications of gauge transformations will be discussed in Sec. IV. An isomorphism between the local gauge group and local Lorentz transformations on blades one and two will be included in Sec. V. The normalized tetrad will be studied in Sec. VI. In this last section a new null tetrad will also be introduced. The general case and the Einstein-Maxwell equations written in terms of the general tetrad will be discussed in Sec. VII. Throughout the paper we use the conventions of Ref. 1. In particular we use a metric with sign conventions $-+++$. The only difference in notation with Ref. 1 will be that we will call our geometrized electromagnetic potential A^{α}, where $f_{\mu\nu} = A_{\nu;\mu} - A_{\mu;\nu}$ is the geometrized electromagnetic field $f_{\mu\nu} = (G^{1/2}/c^2) F_{\mu\nu}$.

II. DIAGONALIZATION OF THE STRESS-ENERGY TENSOR

The stress-energy tensor according to Eq. (14a) in Ref. 1, can be written as

$$T_{\mu\nu} = f_{\mu\lambda} f_{\nu}^{\ \lambda} + {}^{*}f_{\mu\lambda}\, {}^{*}f_{\nu}^{\ \lambda}, \tag{8}$$

where ${}^{*}f_{\mu\nu} = \frac{1}{2}\epsilon_{\mu\nu\sigma\tau} f^{\sigma\tau}$ is the dual tensor of $f_{\mu\nu}$. The tensor $\epsilon_{\mu\nu\sigma\tau}$ is studied in Appendix A. The duality rotation given by Eq. (59) in Ref. 1,

$$f_{\mu\nu} = \xi_{\mu\nu} \cos\alpha + {}^{*}\xi_{\mu\nu} \sin\alpha, \tag{9}$$

allows us to express the stress-energy tensor in terms of the extremal field,

$$T_{\mu\nu} = \xi_{\mu\lambda} \xi_{\nu}^{\ \lambda} + {}^{*}\xi_{\mu\lambda}\, {}^{*}\xi_{\nu}^{\ \lambda}. \tag{10}$$

The extremal field $\xi_{\mu\nu}$ and the scalar complexion α are defined through Eqs. (22)–(25) in Ref. 1. It is our purpose to find a tetrad in which the stress-energy tensor is diagonal. This tetrad would simplify the analysis of the geometrical properties of the electromagnetic field. There are four tetrad vectors that at every point in spacetime diagonalize the stress-energy tensor in geometrodynamics,

$$V_{(1)}^{\alpha} = \xi^{\alpha\lambda} \xi_{\rho\lambda} X^{\rho}, \tag{11}$$

$$V_{(2)}^{\alpha} = \sqrt{-Q/2}\, \xi^{\alpha\lambda} X_{\lambda}, \tag{12}$$

$$V_{(3)}^{\alpha} = \sqrt{-Q/2}\, {}^{*}\xi^{\alpha\lambda} Y_{\lambda}, \tag{13}$$

$$V_{(4)}^{\alpha} = {}^{*}\xi^{\alpha\lambda}\, {}^{*}\xi_{\rho\lambda} Y^{\rho}, \tag{14}$$

where $Q = \xi_{\mu\nu}\xi^{\mu\nu} = -\sqrt{T_{\mu\nu}T^{\mu\nu}}$ according to Eq. (39) in Ref. 1. Q is assumed not to be zero, because we are dealing with non-null electromagnetic fields. We are free to choose the vector fields X^{α} and Y^{α}, as long as the four vector fields (11)–(14) are not trivial. Two identities in the extremal field are going to be used extensively in this work, in particular, to prove that tetrads (11)–(14) diagonalizes the stress-energy tensor. The first identity is given by Eq. (64) in Ref. 1,

$$\xi_{\alpha\mu}\, {}^{*}\xi^{\mu\nu} = 0. \tag{15}$$

In order to find the second identity we need Eq. (15) in Ref. 1,

$$f_{\mu\alpha} f^{\nu\alpha} - {}^{*}f_{\mu\alpha}\, {}^{*}f^{\nu\alpha} = \tfrac{1}{2}\delta_{\mu}^{\ \nu} f_{\alpha\beta} f^{\alpha\beta}. \tag{16}$$

When we replace (9) in (16) and make use of (15), the second identity is found,

$$\xi_{\mu\alpha}\xi^{\nu\alpha} - {}^{*}\xi_{\mu\alpha}\, {}^{*}\xi^{\nu\alpha} = \tfrac{1}{2}\delta_{\mu}^{\ \nu} Q. \tag{17}$$

When we make iterative use of (15) and (17) we find,

$$V_{(1)}^{\alpha} T_{\alpha}^{\ \beta} = \frac{Q}{2} V_{(1)}^{\beta}, \tag{18}$$

$$V_{(2)}^{\alpha} T_{\alpha}^{\ \beta} = \frac{Q}{2} V_{(2)}^{\beta}, \tag{19}$$

$$V_{(3)}^{\alpha} T_{\alpha}^{\ \beta} = -\frac{Q}{2} V_{(3)}^{\beta}, \tag{20}$$

$$V_{(4)}^{\alpha} T_{\alpha}^{\ \beta} = -\frac{Q}{2} V_{(4)}^{\beta}. \tag{21}$$

In Ref. 1 the stress-energy tensor was diagonalized through the use of a Minkowskian frame in which the equation for this tensor was given in (34) and (38). In this work, we give the explicit expression for the tetrad in which the stress-energy tensor is diagonal. The freedom we have to choose the vector fields X^α and Y^α represents available freedom that we have to choose the tetrad. If we make use of Eqs. (15) and (17), it is straightforward to prove that (11)–(14) is a set of orthogonal vectors.

III. ELECTROMAGNETIC POTENTIALS IN GEOMETRODYNAMICS

Our goal is to simplify as much as we can the expression of the electromagnetic field through the use of an orthonormal tetrad, so its geometrical properties can be understood in an easier way. As was mentioned earlier we would like to show this simplification through an explicit example by making a convenient and particular choice of the vector fields X^α and Y^α. In geometrodynamics, the Maxwell equations,

$$f^{\mu\nu}{}_{;\nu}=0,$$

$$*f^{\mu\nu}{}_{;\nu}=0, \tag{22}$$

are telling us that two potential vector fields exist,

$$f_{\mu\nu}=A_{\nu;\mu}-A_{\mu;\nu},$$

$$*f_{\mu\nu}=*A_{\nu;\mu}-*A_{\mu;\nu}. \tag{23}$$

For instance, in the Reissner-Nordstrom geometry the only nonzero electromagnetic tensor component is $f_{tr}=A_{r;t}-A_{t;r}$ and its dual $*f_{\theta\phi}=*A_{\phi;\theta}-*A_{\theta;\phi}$. The vector fields A^α and $*A^\alpha$ represent a possible choice in geometrodynamics for the vectors X^α and Y^α. It is not meant that the two vector fields have independence from each other, it is just a convenient choice for a particular example. This choice allows us to write the new tetrad as

$$V^\alpha_{(1)}=\xi^{\alpha\lambda}\xi_{\rho\lambda}A^\rho, \tag{24}$$

$$V^\alpha_{(2)}=\sqrt{-Q/2}\,\xi^{\alpha\lambda}A_\lambda, \tag{25}$$

$$V^\alpha_{(3)}=\sqrt{-Q/2}\,*\xi^{\alpha\lambda}*A_\lambda, \tag{26}$$

$$V^\alpha_{(4)}=*\xi^{\alpha\lambda}*\xi_{\rho\lambda}*A^\rho. \tag{27}$$

A further justification for the choice $X^\alpha=A^\alpha$ and $Y^\alpha=*A^\alpha$ could be illustrated through the Reissner-Nordstrom geometry. In this particular geometry, $f_{tr}=\xi_{tr}$ and $*f_{\theta\phi}=*\xi_{\theta\phi}$, therefore, $A_\theta=0$ and $A_\phi=0$. Then, for the last two tetrad vectors (26) and (27), the choice $Y^\alpha=*A^\alpha$ becomes meaningful under the light of this particular extreme case, when basically there is no magnetic field. However, we have to be careful about the choice we made for X^α and Y^α. The normalization of the tetrad vectors (24)–(27) requires one to know the values of the invariant quantities,

$$V^\alpha_{(1)}V_{(1)\alpha}=(Q/2)A_\mu\xi^{\mu\sigma}\xi_{\nu\sigma}A^\nu, \tag{28}$$

$$V^\alpha_{(2)}V_{(2)\alpha}=(-Q/2)A_\mu\xi^{\mu\sigma}\xi_{\nu\sigma}A^\nu, \tag{29}$$

$$V^\alpha_{(3)}V_{(3)\alpha}=(-Q/2)*A_\mu*\xi^{\mu\sigma}*\xi_{\nu\sigma}*A^\nu \tag{30}$$

$$V^{\alpha}_{(4)}V_{(4)\alpha} = (-Q/2) * A_{\mu} * \xi^{\mu\sigma} * \xi_{\nu\sigma} * A^{\nu}. \tag{31}$$

Then, it is convenient to calculate the invariants (28)–(31) in the Minkowski reference frame given by Eqs. (38) and (39) in Ref. 1,

$$V^{\alpha}_{(1)}V_{(1)\alpha} = (\xi_{01})^4(A^0A_0 + A^1A_1), \tag{32}$$

$$V^{\alpha}_{(2)}V_{(2)\alpha} = -(\xi_{01})^4(A^0A_0 + A^1A_1), \tag{33}$$

$$V^{\alpha}_{(3)}V_{(3)\alpha} = (\xi_{01})^4(*A^2 * A_2 + *A^3 * A_3), \tag{34}$$

$$V^{\alpha}_{(4)}V_{(4)\alpha} = (\xi_{01})^4(*A^2 * A_2 + *A^3 * A_3). \tag{35}$$

Several cases arise. Since $\xi_{01} \neq 0$ because the electromagnetic field is non-null ($Q \neq 0$), the two vector components A_0 and A_1 cannot be simultaneously zero. If in a region of spacetime or in the whole spacetime $A^0A_0 + A^1A_1 > 0$, it would be necessary to switch the first two tetrad vectors, $V^{\alpha}_{(1)} = \sqrt{-Q/2}\xi^{\alpha\lambda}A_{\lambda}$ and $V^{\alpha}_{(2)} = \xi^{\alpha\lambda}\xi_{\rho\lambda}A^{\rho}$. If $A^0A_0 + A^1A_1 = 0$, then we have $V^{\alpha}_{(1)}T_{\alpha}{}^{\beta}V_{(1)\beta} = 0$ and $V^{\alpha}_{(2)}T_{\alpha}{}^{\beta}V_{(2)\beta} = 0$. We are not dealing with this kind of situation in this work. Another choice of X^{α} would be necessary at the points where $A^0A_0 + A^1A_1 = 0$. It is clear that if $A^0A_0 + A^1A_1 < 0$, the following equations hold:

$$-V^{\alpha}_{(1)}V_{(1)\alpha} = V^{\alpha}_{(2)}V_{(2)\alpha} > 0, \tag{36}$$

$$V^{\alpha}_{(3)}V_{(3)\alpha} = V^{\alpha}_{(4)}V_{(4)\alpha} > 0. \tag{37}$$

The treatment of the problem of building tetrad vectors in geometrodynamics, studying their gauge transformation properties and building null tetrads would be analogous for the two cases when $A^0A_0 + A^1A_1 > 0$ or $A^0A_0 + A^1A_1 < 0$. The treatment of just one of the these two possible cases would automatically provide the framework and the ideas to solve the other one. That is why we choose to analyze in detail $A^0A_0 + A^1A_1 < 0$.

IV. GAUGE GEOMETRY

Once we make the choice $X^{\alpha} = A^{\alpha}$ and $Y^{\alpha} = *A^{\alpha}$ the question about the geometrical implications of electromagnetic gauge transformations arises. When we make the transformation,

$$A_{\alpha} \rightarrow A_{\alpha} + \Lambda_{,\alpha}, \tag{38}$$

$f_{\mu\nu}$ remains invariant, and the transformation,

$$*A_{\alpha} \rightarrow *A_{\alpha} + *\Lambda_{,\alpha}, \tag{39}$$

leaves $*f_{\mu\nu}$ invariant, as long as the functions Λ and $*\Lambda$ are scalars. It is valid to ask how the tetrad vectors (24) and (25) are going to transform under (38), (26), and (27) under (39). Schouten defined what he called a two-bladed structure in a spacetime.[4] These blades are the planes determined by the pairs $(V^{\alpha}_{(1)}, V^{\alpha}_{(2)})$ and $(V^{\alpha}_{(3)}, V^{\alpha}_{(4)})$. For simplicity we will study first what we call gauge transformations associated with blade one, the blade generated by the pair $(V^{\alpha}_{(1)}, V^{\alpha}_{(2)})$. Later we will study similar transformations on blade two, the blade generated by $(V^{\alpha}_{(3)}, V^{\alpha}_{(4)})$.

A. Gauge transformations on blade one

In order to simplify the notation we are going to write $\Lambda_{,\alpha} = \Lambda_{\alpha}$. First we study the change in (24) and (25) under (38),

$$\tilde{V}^{\alpha}_{(1)} = V^{\alpha}_{(1)} + \xi^{\alpha\lambda}\xi_{\rho\lambda}\Lambda^{\rho}, \tag{40}$$

$$\tilde{V}^{\alpha}_{(2)} = V^{\alpha}_{(2)} + \sqrt{-Q/2}\xi^{\alpha\lambda}\Lambda_{\lambda}, \tag{41}$$

The second term on the right-hand side of (40) has the orthogonality properties,

$$\xi^{\alpha\lambda}\xi_{\rho\lambda}\Lambda^{\rho}V_{(3)\alpha} = \xi^{\alpha\lambda}\xi_{\rho\lambda}\Lambda^{\rho}V_{(4)\alpha} = 0. \tag{42}$$

The second term on the right-hand side of (41) has similar orthogonality properties,

$$\sqrt{-Q/2}\xi^{\alpha\lambda}\Lambda_{\lambda}V_{(3)\alpha} = \sqrt{-Q/2}\xi^{\alpha\lambda}\Lambda_{\lambda}V_{(4)\alpha} = 0. \tag{43}$$

Since the four vectors (24)–(27) are independent and orthogonal, Eqs. (42) and (43) imply that the second terms on the right-hand sides of (40) and (41) must be a linear combination of the vectors (24) and (25). We proceed then to write Eqs. (40) and (41) as

$$\tilde{V}^{\alpha}_{(1)} = V^{\alpha}_{(1)} + CV^{\alpha}_{(1)} + DV^{\alpha}_{(2)}, \tag{44}$$

$$\tilde{V}^{\alpha}_{(2)} = V^{\alpha}_{(2)} + EV^{\alpha}_{(1)} + FV^{\alpha}_{(2)}. \tag{45}$$

From Eqs. (40) and (44) we know that

$$\xi^{\alpha\lambda}\xi_{\rho\lambda}\Lambda^{\rho} = CV^{\alpha}_{(1)} + DV^{\alpha}_{(2)}, \tag{46}$$

and from Eqs. (41) and (45) we have

$$\sqrt{-Q/2}\xi^{\alpha\lambda}\Lambda_{\lambda} = EV^{\alpha}_{(1)} + FV^{\alpha}_{(2)}. \tag{47}$$

Making use of identities (15)–(17) it can be proved that

$$\xi_{\alpha\sigma}V^{\alpha}_{(1)} = \sqrt{-Q/2}V_{(2)\sigma}, \tag{48}$$

$$\xi_{\alpha\sigma}V^{\alpha}_{(2)} = \sqrt{-Q/2}V_{(1)\sigma}. \tag{49}$$

If we contract Eq. (46) with $\xi_{\alpha\sigma}$ and make use of identities (15)–(17) and Eqs. (48) and (49) we get

$$\sqrt{-Q/2}\xi_{\sigma\lambda}\Lambda^{\lambda} = CV_{(2)\sigma} + DV_{(1)\sigma}. \tag{50}$$

This last equation means that

$$\tilde{V}^{\alpha}_{(2)} = V^{\alpha}_{(2)} + CV^{\alpha}_{(2)} + DV^{\alpha}_{(1)}. \tag{51}$$

Then, from (45) and (51) we have the following relations between coefficients:

$$E = D, \tag{52}$$

$$F = C. \tag{53}$$

Contracting Eq. (50) with $V^{\sigma}_{(1)}$ and $V^{\sigma}_{(2)}$ it can be found that

$$C = (-Q/2)V_{(1)\sigma}\Lambda^{\sigma}/(V_{(2)\beta}V^{\beta}_{(2)}), \tag{54}$$

$$D = (-Q/2)V_{(2)\sigma}\Lambda^{\sigma}/(V_{(1)\beta}V^{\beta}_{(1)}). \tag{55}$$

We would like to calculate the norm of the transformed vectors $\tilde{V}^{\alpha}_{(1)}$ and $\tilde{V}^{\alpha}_{(2)}$,

$$\tilde{V}^{\alpha}_{(1)}\tilde{V}_{(1)\alpha}=[(1+C)^2-D^2]V^{\alpha}_{(1)}V_{(1)\alpha}, \tag{56}$$

$$\tilde{V}^{\alpha}_{(2)}\tilde{V}_{(2)\alpha}=[(1+C)^2-D^2]V^{\alpha}_{(2)}V_{(2)\alpha}, \tag{57}$$

where the relation $V^{\alpha}_{(1)}V_{(1)\alpha}=-V^{\alpha}_{(2)}V_{(2)\alpha}$ has been used. In order for these transformations to keep the timelike or spacelike character of $V^{\alpha}_{(1)}$ and $V^{\alpha}_{(2)}$ the condition $[(1+C)^2-D^2]>0$ must be satisfied. If this condition is fulfilled, then we can normalize the transformed vectors $\tilde{V}^{\alpha}_{(1)}$ and $\tilde{V}^{\alpha}_{(2)}$ as follows:

$$\frac{\tilde{V}^{\alpha}_{(1)}}{\sqrt{-\tilde{V}^{\beta}_{(1)}\tilde{V}_{(1)\beta}}}=\frac{(1+C)}{\sqrt{(1+C)^2-D^2}}\frac{V^{\alpha}_{(1)}}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{D}{\sqrt{(1+C)^2-D^2}}\frac{V^{\alpha}_{(2)}}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}, \tag{58}$$

$$\frac{\tilde{V}^{\alpha}_{(2)}}{\sqrt{\tilde{V}^{\beta}_{(2)}\tilde{V}_{(2)\beta}}}=\frac{D}{\sqrt{(1+C)^2-D^2}}\frac{V^{\alpha}_{(1)}}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{(1+C)}{\sqrt{(1+C)^2-D^2}}\frac{V^{\alpha}_{(2)}}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}. \tag{59}$$

The condition $[(1+C)^2-D^2]>0$ allows for two possible situations, $1+C>0$ or $1+C<0$. For the particular case when $1+C>0$, the transformations (58) and (59) are telling us that an electromagnetic gauge transformation on the vector field A^{α}, that leaves invariant the electromagnetic field $f_{\mu\nu}$, generates a boost transformation on the normalized tetrad vector fields

$$\left(\frac{V^{\alpha}_{(1)}}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}},\frac{V^{\alpha}_{(2)}}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}\right).$$

For the case $1+C<0$, Eqs. (58) and (59) can be rewritten,

$$\frac{\tilde{V}^{\alpha}_{(1)}}{\sqrt{-\tilde{V}^{\beta}_{(1)}\tilde{V}_{(1)\beta}}}=\frac{[-(1+C)]}{\sqrt{(1+C)^2-D^2}}\frac{(-V^{\alpha}_{(1)})}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{[-D]}{\sqrt{(1+C)^2-D^2}}\frac{(-V^{\alpha}_{(2)})}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}, \tag{60}$$

$$\frac{\tilde{V}^{\alpha}_{(2)}}{\sqrt{\tilde{V}^{\beta}_{(2)}\tilde{V}_{(2)\beta}}}=\frac{[-D]}{\sqrt{(1+C)^2-D^2}}\frac{(-V^{\alpha}_{(1)})}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{[-(1+C)]}{\sqrt{(1+C)^2-D^2}}\frac{(-V^{\alpha}_{(2)})}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}. \tag{61}$$

Equations (60) and (61) represent the composition of two transformations—an inversion of the normalized tetrad vector fields

$$\left(\frac{V^{\alpha}_{(1)}}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}},\frac{V^{\alpha}_{(2)}}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}\right),$$

and a boost. If the case is that $[(1+C)^2-D^2]<0$, the vectors $V^{\alpha}_{(1)}$ and $V^{\alpha}_{(2)}$ are going to change their timelike or spacelike character,

$$\tilde{V}^{\alpha}_{(1)}\tilde{V}_{(1)\alpha}=[-(1+C)^2+D^2](-V^{\alpha}_{(1)}V_{(1)\alpha}), \tag{62}$$

$$(-\tilde{V}^{\alpha}_{(2)}\tilde{V}_{(2)\alpha})=[-(1+C)^2+D^2]V^{\alpha}_{(2)}V_{(2)\alpha}. \tag{63}$$

These are improper transformations on blade one. The normalized tetrad vectors $V^{\alpha}_{(1)}$ and $V^{\alpha}_{(2)}$ transform as

$$\frac{\tilde{V}^{\alpha}_{(1)}}{\sqrt{\tilde{V}^{\beta}_{(1)}\tilde{V}_{(1)\beta}}}=\frac{(1+C)}{\sqrt{-(1+C)^2+D^2}}\frac{V^{\alpha}_{(1)}}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{D}{\sqrt{-(1+C)^2+D^2}}\frac{V^{\alpha}_{(2)}}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}, \tag{64}$$

$$\frac{\tilde{V}^{\alpha}_{(2)}}{\sqrt{-\tilde{V}^{\beta}_{(2)}\tilde{V}_{(2)\beta}}}=\frac{D}{\sqrt{-(1+C)^2+D^2}}\frac{V^{\alpha}_{(1)}}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{(1+C)}{\sqrt{-(1+C)^2+D^2}}\frac{V^{\alpha}_{(2)}}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}. \tag{65}$$

For $D>0$ and $1+C>0$ these transformations (64) and (65) represent improper space inversions on blade one. If $D>0$ and $1+C<0$, Eqs. (64) and (65) are improper time reversal transformations on blade one.[5] If the case is that $D<0$, we can proceed to analyze in analogy to (60) and (61). Then, the normalized tetrad vectors transform as

$$\frac{\tilde{V}^{\alpha}_{(1)}}{\sqrt{\tilde{V}^{\beta}_{(1)}\tilde{V}_{(1)\beta}}}=\frac{[-(1+C)]}{\sqrt{-(1+C)^2+D^2}}\frac{(-V^{\alpha}_{(1)})}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{[-D]}{\sqrt{-(1+C)^2+D^2}}\frac{(-V^{\alpha}_{(2)})}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}, \tag{66}$$

$$\frac{\tilde{V}^{\alpha}_{(2)}}{\sqrt{-\tilde{V}^{\beta}_{(2)}\tilde{V}_{(2)\beta}}}=\frac{[-D]}{\sqrt{-(1+C)^2+D^2}}\frac{(-V^{\alpha}_{(1)})}{\sqrt{-V^{\beta}_{(1)}V_{(1)\beta}}}+\frac{[-(1+C)]}{\sqrt{-(1+C)^2+D^2}}\frac{(-V^{\alpha}_{(2)})}{\sqrt{V^{\beta}_{(2)}V_{(2)\beta}}}. \tag{67}$$

For $D<0$ and $1+C<0$ these transformations (66) and (67) represent the composition of inversions, and improper space inversions on blade one. If $D<0$ and $1+C>0$, Eqs. (66) and (67) are inversions composed with improper time reversal transformations on blade one.[5] For $D=1+C$ we can see using Eqs. (44) and (51) that

$$\tilde{V}^{\alpha}_{(1)}=(1+C)V^{\alpha}_{(1)}+(1+C)V^{\alpha}_{(2)}, \tag{68}$$

$$\tilde{V}^{\alpha}_{(2)}=(1+C)V^{\alpha}_{(2)}+(1+C)V^{\alpha}_{(1)}. \tag{69}$$

Equations (68) and (69) show that any vector on blade one transforms as

$$AV^{\alpha}_{(1)}+BV^{\alpha}_{(2)}\rightarrow A\tilde{V}^{\alpha}_{(1)}+B\tilde{V}^{\alpha}_{(2)}=(1+C)(A+B)(V^{\alpha}_{(1)}+V^{\alpha}_{(2)}). \tag{70}$$

This is clearly a noninjective transformation. At the same time we know that there is an inverse transformation,

$$\tilde{\tilde{V}}^{\alpha}_{(1)}=\tilde{V}^{\alpha}_{(1)}-\xi^{\alpha\lambda}\xi_{\rho\lambda}\Lambda^{\rho}=V^{\alpha}_{(1)}, \tag{71}$$

$$\tilde{\tilde{V}}^{\alpha}_{(2)}=\tilde{V}^{\alpha}_{(2)}-\sqrt{-Q/2}\xi^{\alpha\lambda}\Lambda_{\lambda}=V^{\alpha}_{(2)}. \tag{72}$$

Then, the conclusion must be that there could not exist a scalar function that satisfies the initial assumption $D=1+C$. Analogous for $D=-(1+C)$.

B. Gauge transformations on blade two

The change in notation $*\Lambda_{,\alpha}=*\Lambda_{\alpha}$ is going to be adopted. In this section we are interested in the study of the change in (26) and (27) under (39),

$$\tilde{V}^{\alpha}_{(3)}=V^{\alpha}_{(3)}+\sqrt{-Q/2}*\xi^{\alpha\lambda}\Lambda_{\lambda}, \tag{73}$$

$$\tilde{V}^{\alpha}_{(4)} = V^{\alpha}_{(4)} + {}^{*}\xi^{\alpha\lambda} {}^{*}\xi_{\rho\lambda} {}^{*}\Lambda^{\rho}. \tag{74}$$

The second term on the right-hand side of (73) has the orthogonality properties,

$$\sqrt{-Q/2}\, {}^{*}\xi^{\alpha\lambda} {}^{*}\Lambda_{\lambda} V_{(1)\alpha} = \sqrt{-Q/2}\, {}^{*}\xi^{\alpha\lambda} {}^{*}\Lambda_{\lambda} V_{(2)\alpha} = 0. \tag{75}$$

The second term on the right-hand side of (74) has similar orthogonality properties,

$${}^{*}\xi^{\alpha\lambda} {}^{*}\xi_{\rho\lambda} {}^{*}\Lambda^{\rho} V_{(1)\alpha} = {}^{*}\xi^{\alpha\lambda} {}^{*}\xi_{\rho\lambda} {}^{*}\Lambda^{\rho} V_{(2)\alpha} = 0. \tag{76}$$

Since the four vectors (24)–(27) are independent and orthogonal, Eqs. (75) and (76) imply that the second terms on the right-hand sides of (73) and (74) must be a linear combination of the vectors (26) and (27). We proceed then to write equations (73) and (74) as

$$\tilde{V}^{\alpha}_{(3)} = V^{\alpha}_{(3)} + KV^{\alpha}_{(3)} + LV^{\alpha}_{(4)}, \tag{77}$$

$$\tilde{V}^{\alpha}_{(4)} = V^{\alpha}_{(4)} + MV^{\alpha}_{(3)} + NV^{\alpha}_{(4)}. \tag{78}$$

From Eqs. (73) and (77) we know that

$$\sqrt{-Q/2}\, {}^{*}\xi^{\alpha\lambda} {}^{*}\Lambda_{\lambda} = KV^{\alpha}_{(3)} + LV^{\alpha}_{(4)}, \tag{79}$$

and from Eqs. (74) and (78) we have

$${}^{*}\xi^{\alpha\lambda} {}^{*}\xi_{\rho\lambda} {}^{*}\Lambda^{\rho} = MV^{\alpha}_{(3)} + NV^{\alpha}_{(4)}. \tag{80}$$

Making use of identities (15)–(17) it can be proved that

$${}^{*}\xi_{\alpha\sigma} V^{\alpha}_{(3)} = \sqrt{-Q/2} V_{(4)\sigma}, \tag{81}$$

$${}^{*}\xi_{\alpha\sigma} V^{\alpha}_{(4)} = -\sqrt{-Q/2} V_{(3)\sigma}. \tag{82}$$

If we contract Eq. (80) with ${}^{*}\xi_{\alpha\sigma}$ and make use of identities (15)–(17) and Eqs. (81) and (82) we get

$$-\sqrt{-Q/2}\, {}^{*}\xi_{\sigma\lambda} {}^{*}\Lambda^{\lambda} = MV_{(4)\sigma} - NV_{(3)\sigma}. \tag{83}$$

This last equation means that

$$\tilde{V}^{\alpha}_{(3)} = V^{\alpha}_{(3)} + NV^{\alpha}_{(3)} - MV^{\alpha}_{(4)}. \tag{84}$$

Then, from (77) and (84) we have the following relations between coefficients:

$$K = N, \tag{85}$$

$$L = -M. \tag{86}$$

Contracting Eq. (83) with $V^{\sigma}_{(3)}$ and $V^{\sigma}_{(4)}$ it can be found that

$$M = (-Q/2) V_{(3)\sigma} {}^{*}\Lambda^{\sigma} / (V_{(4)\beta} V^{\beta}_{(4)}), \tag{87}$$

$$N = (-Q/2) V_{(4)\sigma} {}^{*}\Lambda^{\sigma} / (V_{(3)\beta} V^{\beta}_{(3)}). \tag{88}$$

We would like to calculate the norm of the transformed vectors $\tilde{V}^{\alpha}_{(3)}$ and $\tilde{V}^{\alpha}_{(4)}$,

$$\tilde{V}^{\alpha}_{(3)}\tilde{V}_{(3)\alpha}=[(1+N)^2+M^2]V^{\alpha}_{(3)}V_{(3)\alpha}, \tag{89}$$

$$\tilde{V}^{\alpha}_{(4)}\tilde{V}_{(4)\alpha}=[(1+N)^2+M^2]V^{\alpha}_{(4)}V_{(4)\alpha}, \tag{90}$$

where the relation $V^{\alpha}_{(3)}V_{(3)\alpha}=V^{\alpha}_{(4)}V_{(4)\alpha}$ has been used. Now, we see that the gauge transformations of the invariants given by (89) and (90) cannot change the spacelike character of vectors $V^{\alpha}_{(3)}$ and $V^{\alpha}_{(4)}$, unless $1+N=M=0$. Apart from that exception, the factor $[(1+N)^2+M^2]$ is always positive, so we would have no problems normalizing the transformed vectors $\tilde{V}^{\alpha}_{(3)}$ and $\tilde{V}^{\alpha}_{(4)}$,

$$\frac{\tilde{V}^{\alpha}_{(3)}}{\sqrt{\tilde{V}^{\beta}_{(3)}\tilde{V}_{(3)\beta}}}=\frac{(1+N)}{\sqrt{(1+N)^2+M^2}}\frac{V^{\alpha}_{(3)}}{\sqrt{V^{\beta}_{(3)}V_{(3)\beta}}}-\frac{M}{\sqrt{(1+N)^2+M^2}}\frac{V^{\alpha}_{(4)}}{\sqrt{V^{\beta}_{(4)}V_{(4)\beta}}}, \tag{91}$$

$$\frac{\tilde{V}^{\alpha}_{(4)}}{\sqrt{\tilde{V}^{\beta}_{(4)}\tilde{V}_{(4)\beta}}}=\frac{M}{\sqrt{(1+N)^2+M^2}}\frac{V^{\alpha}_{(3)}}{\sqrt{V^{\beta}_{(3)}V_{(3)\beta}}}+\frac{(1+N)}{\sqrt{(1+N)^2+M^2}}\frac{V^{\alpha}_{(4)}}{\sqrt{V^{\beta}_{(4)}V_{(4)\beta}}}. \tag{92}$$

As long as $[(1+N)^2+M^2]>0$ the transformations (91) and (92) are telling us that an electromagnetic gauge transformation on the vector field $*A^{\alpha}$ that leaves invariant the dual electromagnetic field $*f_{\mu\nu}$, generates a rotation on the normalized tetrad vector fields

$$\left(\frac{V^{\alpha}_{(3)}}{\sqrt{V^{\beta}_{(3)}V_{(3)\beta}}},\frac{V^{\alpha}_{(4)}}{\sqrt{V^{\beta}_{(4)}V_{(4)\beta}}}\right).$$

V. GROUP ISOMORPHISM

In Secs. IV A and IV B the gauge transformation properties of the tetrad vectors were analyzed. But we can take advantage of the expressions we found for both the transformations on blade one and blade two to prove an important result involving the mappings between the local gauge group and the local Lorentz transformations on both blades. We are going to name LB1 the group of Lorentz transformations on blade one. Analogously we name the group of rotations on blade two, LB2. Making use of expressions (58) and (59), (60) and (61), (64) and (65), (66) and (67), and (91) and (92) we can prove the transformation properties of the local gauge group. We proceed first to study the transformation properties of the elements of the local gauge group on blade one.

A. Isomorphism on blade one

We can readily verify that the identity is given by $\Lambda=0$ or any other constant. Since all the gauge transformations only involve gradients of scalar functions, then the results we are going to find are going to be true, except for additional constants that have no physical or geometrical meaning. If the scalar function Λ generates a Lorentz transformation, then $(-\Lambda)$ generates the inverse Lorentz transformation. It is necessary at this point to understand several details about inverse transformations. Following the notation of the proceeding sections we can introduce on blade one, for instance, the inverse of the direct transformation as

$$\tilde{\tilde{V}}^{\alpha}_{(1)}=\tilde{V}^{\alpha}_{(1)}-\xi^{\alpha\lambda}\xi_{\rho\lambda}\Lambda^{\rho}=V^{\alpha}_{(1)}, \tag{93}$$

$$\tilde{\tilde{V}}^{\alpha}_{(2)}=V^{\alpha}_{(2)}-\sqrt{-Q/2}\xi^{\alpha\lambda}\Lambda_{\lambda}=V^{\alpha}_{(2)}, \tag{94}$$

$$\tilde{C} = (-Q/2)\tilde{V}_{(1)\sigma}(-\Lambda^{\sigma})/(\tilde{V}_{(2)\beta}\tilde{V}^{\beta}_{(2)}), \tag{95}$$

$$\tilde{D} = (-Q/2)\tilde{V}_{(2)\sigma}(-\Lambda^{\sigma})/(\tilde{V}_{(1)\beta}V^{\beta}_{(1)}). \tag{96}$$

We can see that in expressions (95) and (96) the change in sign of the scalar function Λ is not the only change. Therefore, we can also notice that for transformations (58) and (59),

$$\frac{(1+C)}{\sqrt{(1+C)^2 - D^2}} = \frac{(1+\tilde{C})}{\sqrt{(1+\tilde{C})^2 - \tilde{D}^2}}, \tag{97}$$

$$\frac{D}{\sqrt{(1+C)^2 - D^2}} = -\frac{\tilde{D}}{\sqrt{(1+\tilde{C})^2 - \tilde{D}^2}}, \tag{98}$$

while for transformations (64) and (65),

$$\frac{(1+C)}{\sqrt{-(1+C)^2 + D^2}} = -\frac{(1+\tilde{C})}{\sqrt{-(1+\tilde{C})^2 + \tilde{D}^2}}, \tag{99}$$

$$\frac{D}{\sqrt{-(1+C)^2 + D^2}} = \frac{\tilde{D}}{\sqrt{-(1+\tilde{C})^2 + \tilde{D}^2}}. \tag{100}$$

In order to get a better geometrical insight into the results that follow, we are introducing the angle ϕ. For proper transformations on blade one,

$$\cosh\phi = \frac{|1+C|}{\sqrt{(1+C)^2 - D^2}}, \tag{101}$$

while for improper transformations,

$$\cosh\phi = \frac{|D|}{\sqrt{-(1+C)^2 + D^2}}. \tag{102}$$

For instance, if the scalar function Λ_1 generates a boost ϕ_1, and the scalar function Λ_2 generates a boost ϕ_2, then it is straightforward to see that the subsequent transformation, first by Λ_1 and then by Λ_2 generates a boost $\phi_1 + \phi_2$. In general, if the scalar function Λ_1 generates a Lorentz transformation on blade one, and the scalar function Λ_2 generates another Lorentz transformation on blade one, then it is straightforward to see that the subsequent transformation, first by Λ_1 and then by Λ_2, generates the composition of the two Lorentz transformations.

Therefore, we proved that the transformations (58) and (59), (60) and (61), (64) and (65), and (66) and (67), represent a mapping between the local gauge group and the group LB1. Both groups are Abelian and have the same dimension. If in addition we manage to prove that this mapping is injective, and the image is not a subgroup of LB1, then the mapping would be an isomorphism. To this end, using equations (54) and (55), (87) and (88) we can write

$$(-Q/2)\Lambda^{\alpha} = -CV^{\alpha}_{(1)} - DV^{\alpha}_{(2)} + MV^{\alpha}_{(3)} + NV^{\alpha}_{(4)}, \tag{103}$$

such that

$$D = (1+C)\tanh\phi \quad \text{for proper transformations}, \tag{104}$$

$$D = (1+C)/\tanh\phi \quad \text{for improper transformations}. \tag{105}$$

It is simple to check that Eq. (104) is valid for $1+C>0$ or $1+C<0$, and Eq. (105) is also valid for $D>0$ or $D<0$. Once we are given a ϕ, the functions C, M, and N should be found through the use of the integrability conditions $\Lambda_{\alpha;\beta}=\Lambda_{\beta;\alpha}$. We know that if $\phi_1\neq\phi_2$, then $\tanh\phi_1\neq\tanh\phi_2$ and $\tanh\phi_1\neq 1/\tanh\phi_2$. Then, accordingly, the corresponding scalar functions Λ_1 and Λ_2 are not going to be the same. Conversely, we can ask if it is possible to map two different scalar functions Λ_1 and Λ_2 into the same Lorentz transformation. If this is possible, then we can first generate a Lorentz transformation by Λ_1 and then another one by $-\Lambda_2$. The result should be the identity, because $-\Lambda_2$ generates the inverse Lorentz transformation of Λ_1. Therefore $\Lambda_1-\Lambda_2$ must be a constant. Summarizing, the injectivity remains proved. The last point to make clear is related to the image of this mapping. The question to answer is if the image of this mapping is a subgroup of LB1. Let us suppose that there is a certain local gauge transformation Λ, such that $1+C>0$, with $-1<C<0$. Then, there is always the transformation $n\Lambda$ with n a natural number, $C_n=nC$. $1+C_n=1+nC=1-n|C|$. For n sufficiently large $1+C_n$ is going to become negative. If $C>0$, there is the transformation $-n\Lambda$ with n a natural number, $C_n=-nC$. $1+C_n=1-nC=1-n|C|$. Once more for n sufficiently large $1+C_n$ is going to become negative. Following similar ideas, but now if $1+C>D>0$ we can prove for instance, that if $-1<C<0$, for n sufficiently large, $D_n>0>1+C_n$, and analogous for $C>0$. Then, the mapping image obviously cannot be a subgroup of LB1. Therefore the mapping is surjective.

Theorem 1: *The mapping between the local gauge group of transformations is isomorphic to the group LB1 defined above*.

B. Isomorphism on blade two

The proof for the mapping between the local gauge group and the rotations on blade two is analogous to the previous one. For rotations all the considerations about inverse transformations and composition of transformations apply in a similar fashion as for the ones on blade one. The precisions we have to make on blade two regard fundamentally the injectivity. We can introduce the angle φ as

$$\cos\varphi=\frac{(1+N)}{\sqrt{(1+N)^2+M^2}}. \tag{106}$$

Then, we can use again Eq. (103), along with

$$M=(1+N)\tan\varphi. \tag{107}$$

Once we are given a φ, the functions C, D, and N should be found through the use of the integrability conditions $\Lambda_{\alpha;\beta}=\Lambda_{\beta;\alpha}$. For rotations, we know that $\tan(\varphi)=\tan(\varphi-\pi)$, but simultaneously we have that $\mathrm{sg}(M_\varphi)=-\mathrm{sg}(M_{(\varphi-\pi)})$ and $\mathrm{sg}(1+N_\varphi)=-\mathrm{sg}(1+N_{(\varphi-\pi)})$. The last sign equalities arise from the fact that under a change $\varphi\rightarrow\varphi-\pi$, the sine and cosine change their signs. All these results put together mean that given a pair of different angles φ_1 and φ_2, the corresponding scalar functions Λ_1 and Λ_2 are not going to be the same. Conversely, we can ask if it is possible to transform two different scalar functions Λ_1 and Λ_2 into the same φ. If this is possible, then we can proceed exactly as for the blade one case, we can first generate a rotation transformation by Λ_1 and then another one by $-\Lambda_2$. The result should be the identity, because $-\Lambda_2$ generates a rotation transformation by $-\varphi$. Therefore $\Lambda_1-\Lambda_2$ must be a constant, and the injectivity remains proved.

Theorem 2: *The mapping between the local gauge group of transformations is isomorphic to the group LB2 defined above*.

VI. TETRADS

A. Orthonormal tetrad

It was found in Sec. III that for an electromagnetic vector potential A^α, with $A^0A_0+A^1A_1<0$ in the Minkowski reference frame given by Eqs. (38) and (39) in Ref. 1, it was possible to normalize the tetrad vectors fields (24)–(27). Then, at the points in spacetime where the set of four vectors (24)–(27) is not trivial, we can proceed to normalize,

$$U^\alpha = \xi^{\alpha\lambda}\xi_{\rho\lambda}A^\rho/(\sqrt{-Q/2}\sqrt{A_\mu\xi^{\mu\sigma}\xi_{\nu\sigma}A^\nu}), \tag{108}$$

$$V^\alpha = \xi^{\alpha\lambda}A_\lambda/(\sqrt{A_\mu\xi^{\mu\sigma}\xi_{\nu\sigma}A^\nu}), \tag{109}$$

$$Z^\alpha = *\,\xi^{\alpha\lambda} * A_\lambda/(\sqrt{*A_\mu * \xi^{\mu\sigma} * \xi_{\nu\sigma} * A^\nu}), \tag{110}$$

$$W^\alpha = *\,\xi^{\alpha\lambda} * \xi_{\rho\lambda} * A^\rho/(\sqrt{-Q/2}\sqrt{*A_\mu * \xi^{\mu\sigma} * \xi_{\nu\sigma} * A^\nu}). \tag{111}$$

The notation we are using to name the four tetrad vectors (108)–(111) is the same notation used in Ref. 2, even though the geometrical meaning is different. The four vectors (108)–(111) have the following algebraic properties:

$$-U^\sigma U_\alpha = V^\alpha V_\alpha = Z^\alpha Z_\alpha = W^\alpha W_\alpha = 1. \tag{112}$$

Any other scalar product is zero. It is possible to find expressions for the metric tensor and the stress-energy tensor in the new tetrad (108)–(111). The new expression for the metric tensor is

$$g_{\alpha\beta} = -U_\alpha U_\beta + V_\alpha V_\beta + Z_\alpha Z_\beta + W_\alpha W_\beta. \tag{113}$$

The stress-energy tensor can be written,

$$T_{\alpha\beta} = (Q/2)[-U_\alpha U_\beta + V_\alpha V_\beta - Z_\alpha Z_\beta - W_\alpha W_\beta]. \tag{114}$$

In order to find the expression for the electromagnetic field in terms of the tetrad (108)–(111), it is necessary to find some previous results. Using Eqs. (15) and (17) it is possible to prove that

$$U^\alpha\xi_{\alpha\beta} = \sqrt{-Q/2}V_\beta, \tag{115}$$

$$V^\alpha\xi_{\alpha\beta} = \sqrt{-Q/2}U_\beta, \tag{116}$$

$$Z^\alpha * \xi_{\alpha\beta} = \sqrt{-Q/2}W_\beta, \tag{117}$$

$$W^\alpha * \xi_{\alpha\beta} = -\sqrt{-Q/2}Z_\beta. \tag{118}$$

Equations (112) and (115)–(118) allow us to find the expressions for the extremal field in terms of the new tetrad,

$$U^\alpha\xi_{\alpha\beta}V^\beta = \sqrt{-Q/2}, \tag{119}$$

$$Z^\alpha * \xi_{\alpha\beta}W^\beta = \sqrt{-Q/2}. \tag{120}$$

The extremal field tensor and its dual can then be written,

$$\xi_{\alpha\beta} = -2\sqrt{-Q/2}U_{[\alpha}V_{\beta]}, \tag{121}$$

$$*\xi_{\alpha\beta} = 2\sqrt{-Q/2}Z_{[\alpha}W_{\beta]}. \tag{122}$$

Equations (121) and (122) are providing the necessary information to express the electromagnetic field in terms of the new tetrad,

$$f_{\alpha\beta} = -2\sqrt{-Q/2}\cos\alpha U_{[\alpha}V_{\beta]} + 2\sqrt{-Q/2}\sin\alpha Z_{[\alpha}W_{\beta]}. \tag{123}$$

B. Null tetrad

We are ready now to introduce a new null tetrad. It will be defined as

$$K_\alpha = \frac{1}{\sqrt{2}}(U_\alpha + V_\alpha), \tag{124}$$

$$L_\alpha = \frac{1}{\sqrt{2}}(U_\alpha - V_\alpha), \tag{125}$$

$$T_\alpha = \frac{1}{\sqrt{2}}(Z_\alpha + \imath W_\alpha), \tag{126}$$

$$\bar{T}_\alpha = \frac{1}{\sqrt{2}}(Z_\alpha - \imath W_\alpha), \tag{127}$$

where $\imath$ is the imaginary complex unit, $\imath^2=-1$. The notation we are using to name the null tetrad vectors (124)–(127) is the same as in Ref. 2. Again it should be noticed that even though the null tetrad notation is the same as in Ref. 2, the geometrical meaning is not the same. This new null tetrad (124)–(127) satisfies the following algebraic relations;

$$K^\alpha K_\alpha = K^\alpha T_\alpha = L^\alpha L_\alpha = L^\alpha T_\alpha = T^\alpha T_\alpha = 0, \tag{128}$$

and

$$K^\alpha L_\alpha = -1, \tag{129}$$

$$T^\alpha \bar{T}_\alpha = 1. \tag{130}$$

It can also be proved in the Minkowskian reference frame given by Eqs. (38) and (39) in Ref. 1, and through the use of the results found in Appendices A and B that the identity,

$$\epsilon_{\alpha\beta\mu\nu}K^\alpha L^\beta T^\alpha \bar{T}^\nu = -\imath, \tag{131}$$

is satisfied. Then, the metric tensor can be written in terms of the new null tetrad,

$$g_{\alpha\beta} = T_\alpha \bar{T}_\beta + \bar{T}_\alpha T_\beta - K_\alpha L_\beta - K_\beta L_\alpha. \tag{132}$$

Using (124)–(127) it is straightforward to prove that (132) is equivalent to (113). In terms of the new null tetrad the stress-energy tensor can be expressed,

$$T_{\alpha\beta} = (-Q/2)[K_\alpha L_\beta + K_\beta L_\alpha + T_\alpha \bar{T}_\beta + T_\beta \bar{T}_\alpha]. \tag{133}$$

It is not difficult to prove that (133) and (114) are equivalent. We would like to find the expression for the electromagnetic field in terms of the new null tetrad. It is necessary to find first the components of the external tensor and its dual in terms of the new null tetrad. Making use of (119) and (120) we find,

$$K^\alpha \xi_{\alpha\beta} L^\beta = -\sqrt{-Q/2}, \tag{134}$$

$$T^{\alpha} * \xi_{\alpha\beta}\bar{T}^{\beta} = -\iota\sqrt{-Q/2}. \tag{135}$$

Now, we have the expressions for the extremal field tensor and its dual in terms of the new null tetrad,

$$\xi_{\alpha\beta} = 2\sqrt{-Q/2}K_{[\alpha}L_{\beta]}, \tag{136}$$

$$*\xi_{\alpha\beta} = 2\iota\sqrt{-Q/2}T_{[\alpha}\bar{T}_{\beta]}. \tag{137}$$

Equations (136) and (137) allow us to find the electromagnetic field expressed in terms of the new null tetrad,

$$f_{\alpha\beta} = 2\sqrt{-Q/2}\cos\alpha K_{[\alpha}L_{\beta]} + 2\iota\sqrt{-Q/2}\sin\alpha T_{[\alpha}\bar{T}_{\beta]}. \tag{138}$$

C. Bivectors

It is possible to express any antisymmetric second-rank tensor, as a linear combination of the following bivectors:

$$U_{\alpha\beta} = \bar{T}_{\alpha}L_{\beta} - \bar{T}_{\beta}L_{\alpha}, \tag{139}$$

$$V_{\alpha\beta} = K_{\alpha}T_{\beta} - K_{\beta}T_{a}, \tag{140}$$

$$W_{\alpha\beta} = T_{\alpha}\bar{T}_{\beta} - T_{\beta}\bar{T}_{\alpha} - K_{\alpha}L_{\beta} + K_{\beta}L_{\alpha}. \tag{141}$$

These bivectors are combinations of the null tetrad vectors (124)–(127), and making use of (131) it can be proved that they are also self-dual,

$$\tilde{U}_{\alpha\beta} = \tfrac{1}{2}\epsilon_{\alpha\beta\mu\nu}U^{\mu\nu} = -\iota U_{\alpha\beta}, \tag{142}$$

$$\bar{V}_{\alpha\beta} = -\iota V_{\alpha\beta}, \tag{143}$$

$$\tilde{W}_{\alpha\beta} = -\iota W_{\alpha\beta}. \tag{144}$$

One more time, the notation for (139)–(141) is analogous to the one in Ref. 2 but the geometrical meaning is different. The self-dual bivectors (139)–(141) have the following associated scalar products:

$$W_{\alpha\beta}V^{\alpha\beta} = W_{\alpha\beta}U^{\alpha\beta} = V_{\alpha\beta}V^{\alpha\beta} = U_{\alpha\beta}U^{\alpha\beta} = 0, \tag{145}$$

$$W_{\alpha\beta}W^{\alpha\beta} = -4, \tag{146}$$

$$U_{\alpha\beta}V^{\alpha\beta} = 2. \tag{147}$$

It was our purpose since the beginning of this work to find the simplest possible expression for the electromagnetic field through the use of null tetrads in geometrodynamics. Now, we would like to see what is the expression in the new bivectors (139)–(141) for the self-dual electromagnetic bivector,

$$\Phi_{\alpha\beta} = f_{\alpha\beta} + \iota * f_{\alpha\beta}. \tag{148}$$

Making use of expressions (136), (137), and (141) it is possible to write

$$\Phi_{\alpha\beta} = -\sqrt{-Q/2}e^{(-\iota\alpha)}W_{\alpha\beta}. \tag{149}$$

The standard way of expressing the bivector (148) is through an expansion in the three standard bivectors given by Eq. (18.9) in Ref. 2, which in turn are built in terms of the familiar NP tetrads.[3] The new null tetrad (124)–(127) has the advantage that in the particular problem of geometrodynamics the expression of the bivector (148) given by (149) is the simplest possible one, since we can write it only in terms of one of the three independent new bivectors, expression (141). The two scalar functions associated with the electromagnetic field are included in the complex factor $-\sqrt{-Q/2}e^{(-\iota\alpha)}$. This example shows the simplifying power of the new tetrad built specifically for the problem of geometrodynamics.

VII. GENERAL TETRAD

In Sec. III a particular example of an explicit choice of the vector fields X_α and Y_α was introduced ($X_\alpha = A_\alpha$ and $Y_\alpha = *A_\alpha$) within the framework of geometrodynamics. Through this example several properties of these new tetrads were discussed. The transformation properties induced by usual gauge transformations $A^\alpha \to A^\alpha + \Lambda'^\alpha$ and $*A^\alpha \to *A^\alpha + *\Lambda'^\alpha$ were analyzed in Sec. IV. Let us assume that it is possible to normalize the general tetrad (11)–(14). For generic fields X_α and Y_α, we can proceed to study the transformation properties of the normalized version of (11) and (12) under the transformation $X_\alpha \to X_\alpha + V_\alpha$, where V_α is any well-behaved vector field in spacetime. The necessary steps to study these tetrad transformations are a replica of the ones taken in Sec. IV A. The conclusions are analogous. In a similar way, the normalized version of (13) and (14) can be transformed under $Y_\alpha \to Y_\alpha + W_\alpha$, where W_α is any well-behaved vector field. Again, the steps and conclusions involved in the study of these tetrad transformations are a replica of the ones taken in Sec. IV B. Once we introduced these new tetrad transformations for the general case, we can easily prove that $X_\alpha \to X_\alpha + V_\alpha$ and $Y_\alpha \to Y_\alpha + W_\alpha$ leave invariant two tensors, $g_{\alpha\beta}$ and $f_{\alpha\beta}$. The fact that these tetrad transformations leave invariant the metric tensor means that they are symmetries of the geometry. They also leave invariant the electromagnetic tensor, which means that they represent symmetries of the electromagnetic geometry. But the important issue is that they do not alter the tensors that carry the physical information. The new tetrads (11)–(14) when normalized can be used to simplify the Einstein-Maxwell equations in the Newman-Penrose tetrad formalism. It is worth noticing the substantial simplification that the new tetrads would introduce in the Einstein-Maxwell equations. As an example, the vacuum Maxwell equations using the notation given in Ref. 7 are given by

$$D\phi_1 = 2\rho\phi_1, \tag{150}$$

$$\delta\phi_1 = -2\tau\phi_1, \tag{151}$$

$$\bar{\delta}\phi_1 = -2\pi\phi_1, \tag{152}$$

$$\Delta\phi_1 = -2\mu\phi_1. \tag{153}$$

It is important to notice that the tetrads will be independent variables. For a non-null solution to the set of Einstein-Maxwell equations we can find the scalars α and Q from $\phi_1 = -\sqrt{-Q/2}e^{(-\iota\alpha)}$. Expression (136) will provide the relation between the extremal field and the new tetrads. The electromagnetic field will be available through expression (138) and the metric tensor will be given by (132) once a tetrad is known for a particular solution. The overall effect of the new tetrads is to reallocate or reorganize algebraic information in the Einstein-Maxwell equations making it easier to find new possible solutions.

VIII. CONCLUSIONS

A new tetrad that diagonalizes the electromagnetic stress-energy tensor for non-null electromagnetic fields was introduced. However, this tetrad has an inherent freedom in the choice of two vector fields. Geometrodynamics is an arena in which an explicit example or choice can be given for these two vector fields, because Maxwell's equations are providing two vector potentials. The simplicity of the expression for the electromagnetic field in this new tetrad and the associated null tetrad becomes evident. It was also proved that the local gauge group is related to the group LB1, and also to the group LB2 through an isomorphism. In the last section the tetrad is also considered without making any specific choice for these two vector fields. It is found that there are transformations that leave invariant the metric and electromagnetic tensors simultaneously. It was also proved that when written in terms of the new tetrad, the Einstein-Maxwell equations are substantially simplified.

ACKNOWLEDGMENTS

I am grateful to R. Gambini and J. Pullin for reading this manuscript and for many fruitful discussions. This work was partially funded by PEDECIBA.

APPENDIX A

The Levi-Civita pseudotensor can be transformed into a tensor through the use of factors $\sqrt{-g}$, where g is the determinant of the metric tensor. We use the notation $e_{\alpha\beta\mu\nu}=[\alpha\beta\mu\nu]$ for the covariant components of the Levi-Civita pseudotensor in the Minkowskian frame given in Ref. 1,

$$e_{\alpha\beta\mu\nu}=\begin{cases}1 \text{ if } \alpha\beta\mu\nu \text{ is an even permutation of } 0123\\ -1 \text{ if } \alpha\beta\mu\nu \text{ is an odd permutation of } 0123\\ 0 \text{ if } \alpha\beta\mu\nu \text{ are not all different.}\end{cases}$$

It can be noticed that the signs in $e^{\alpha\beta\mu\nu}$ are going to be opposite to the standard notation.[5] The reason for this is that we want to keep the compatibility with Ref. 1 where the definition $e_{0123}=[0123]=1$ was adopted. With these definitions we see that in a spacetime with a metric $g_{\alpha\beta}$,

$$e^{\alpha\beta\mu\nu}=\frac{e^{\alpha\beta\mu\nu}}{\sqrt{-g}}=-\frac{[\alpha\beta\mu\nu]}{\sqrt{-g}} \tag{A1}$$

are the components of a contravariant tensor.[5–7] The covariant components of (A1) are

$$\epsilon_{\alpha\beta\mu\nu}=e_{\alpha\beta\mu\nu}\sqrt{-g}=[\alpha\beta\mu\nu]\sqrt{-g}, \tag{A2}$$

where

$$g_{\alpha\sigma}g_{\beta\rho}g_{\mu\kappa}g_{\nu\lambda}e^{\sigma\rho\kappa\lambda}=-ge_{\alpha\beta\mu\nu} \tag{A3}$$

is satisfied.

APPENDIX B

The tetrad vectors $(U^\alpha,V^\alpha,Z^\alpha,W^\alpha)$ have the following expressions in the Minkowski reference frame given by Eqs. (38) and (39) in Ref. 1,

$$U^0=-A^0/\sqrt{-(A^0A_0+A^1A_1)}, \tag{B1}$$

$$U^1=-A^1/\sqrt{-(A^0A_0+A^1A_1)}, \tag{B2}$$

$$V^0=-\xi_{01}A^1/(|\xi_{01}|\sqrt{-(A^0A_0+A^1A_1)}), \tag{B3}$$

$$V^1 = -\xi_{01}A^0/(|\xi_{01}|\sqrt{-(A^0A_0 + A^1A_1)}), \tag{B4}$$

$$Z^2 = -\xi_{01} * A^3/(|\xi_{01}|\sqrt{*A^2 * A_2 + *A^3 * A_3}), \tag{B5}$$

$$Z^3 = \xi_{01} * A^2/(|\xi_{01}|\sqrt{*A^2 * A_2 + *A^3 * A_3}), \tag{B6}$$

$$W^2 = *A^2/\sqrt{*A^2 * A_2 + *A^3 * A_3}, \tag{B7}$$

$$W^3 = *A^3/\sqrt{*A^2 * A_2 + *A^3 * A_3}, \tag{B8}$$

where $|\xi_{01}| = \sqrt{(\xi_{01})^2}$.

(Received 12 August 2005; accepted 24 August 2005; published online 25 October 2005)

Exact outer boundary conditions for gravitational perturbations of the Schwarzschild metric feature integral convolution between a time-domain boundary kernel and each radiative mode of the perturbation. For both axial (Regge–Wheeler) and polar (Zerilli) perturbations, we study the Laplace transform of such kernels as an analytic function of (dimensionless) Laplace frequency. We present numerical evidence indicating that each such frequency-domain boundary kernel admits a "sum-of-poles" representation. Our work has been inspired by Alpert, Greengard, and Hagstrom's analysis of nonreflecting boundary conditions for the ordinary scalar wave equation. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2073287]

I. INTRODUCTION

Now 50 years old, the perturbation theory of Schwarzschild blackholes remains a timely subject with fundamental applications. The covariant d'Alembertian (or wave equation) associated with the Schwarzschild line-element describes scalar "perturbations." Classical Schwarzschild blackholes are spherically symmetric and static in time, and these symmetries allow for combined multipole and Fourier (or Laplace) decompositions. As a result, perturbations may be described via a denumerable collection of ODE rather than the d'Alembertian PDE. Similar ODE describe electromagnetic "perturbations"[1] and gravitational perturbations (small genuine fluctuations in the background geometry),[2,3] although their derivation is more complicated since the multipole decomposition involves either vector or tensor spherical harmonics. Remarkably, via the technique of "despinning" based on the eth operator,[4] such ODEs can be related to scalar wave equations.

Wheeler considered the case of electromagnetic perturbations in 1955,[1] showing for a given multipole that each of the two electromagnetic polarization states are described by a copy of a single ODE. Regge and Wheeler then derived a similar ODE describing odd-parity (or axial) gravitational perturbations in 1957,[2] and Zerilli introduced an ODE describing even-parity (or polar) gravitational perturbations in 1970.[3] In the 1970s Chandrasekhar and Detweiler demonstrated that the Zerilli equation can be derived from the Regge–Wheeler equation, although the derivation involves differential operations (see Ref. 5, and references therein). In their treatment[6] of *intertwining operators*, Anderson and Price clarified the relationship between solutions to the Regge–Wheeler and Zerilli ODEs. Application of a first-order differential operator transforms smooth solutions of one equation into solutions of the other.

Schwarzschild perturbation theory has played a central role in several modern areas of classical and quantum gravity. Although the following is by no means an exhaustive list, we mention four salient applications: the "close-limit" approximation for blackhole collisions, a time-domain approach to the radiation reaction problem, the asymptotic form of high frequency quasinormal modes, and quantum uncertainty in blackhole horizons. Price and Pullin, assuming that the colliding blackholes are initially cloaked in a common horizon, have used first-order perturbation

[a)]Present address: Department of Mathematics and Statistics, MSC03 2150, 1 University of New Mexico, Albuquerque, New Mexico 87131-0001; electronic mail: srlau@math.unm.edu

theory and the Zerilli equation to compute the energy radiated away by gravitational waves.[7] They initially applied their close-limit approximation to time-symmetric initial data. More general data were subsequently considered,[8] and the accuracy of the approximation studied via second-order perturbation theory.[9,10] Lousto has studied the binary radiation reaction problem in the extreme mass ratio limit via time-domain calculations.[11] His approach relies on numerical simulation of Schwarzschild perturbations, and he has developed a fourth-order convergent algorithm for such simulations.[12] Interest in the quasinormal mode spectrum of classical Schwarzschild blackholes has been renewed by possible connections with the Barbero-Immirzi parameter in loop quantum gravity.[13–15] While these issues are beyond us, we note that they have focused attention on the asymptotic form of high frequency quasinormal modes[16,17] (a purely classical issue). Most recently, York and Schmekel have considered a truncated superspace of blackhole fluctuations, using path integral quantization to derive a Schrödinger equation and estimate the quantum uncertainty in the horizon.[18] York and Schmekel's analysis constitutes an improved derivation of results already found by York via semiclassical arguments.[19]

This paper addresses the mathematical issue of *exact* radiation outer boundary conditions (ROBC) for Schwarzschild blackhole perturbations. Our work is based on an approach[20] developed by Alpert, Greengard, and Hagstrom (AGH) for nonreflecting boundary conditions and time-domain wave propagation on flat spacetime. Beyond being of theoretical interest, such boundary conditions are relevant for numerical simulations. Indeed, long-time simulations require some form of domain reduction, that is specification of appropriate boundary conditions at the "edge" of the computational domain. Exact outer boundary conditions for gravitational perturbations of Schwarzschild blackholes feature integral convolution between a time-domain boundary kernel and each angular mode of the perturbation. For both axial (Regge–Wheeler) and polar (Zerilli) perturbations, we study the Laplace transform of the such kernels as an analytic function of (dimensionless) Laplace frequency σ. We present numerical evidence indicating that each such gravitational boundary kernel admits a "sum-of-poles" representation. These representations are similar to those considered by AGH for wave propagation on flat $3+1$ and $2+1$ spacetimes. We hope to interest analysts in our conjectured sum-of-poles representation and the theorems we believe are lurking behind it.

We have considered such boundary conditions in detail before[21,22] (hereafter referred to as Papers I and II). However, this paper goes beyond these references in the following ways. First, we consider the Zerilli equation, not considered at all in Papers I and II. Second, we focus here on the analytic structure of gravitational kernels (both Regge–Wheeler and Zerilli cases), whereas Paper I almost exclusively considered kernels for scalar wave propagation. Although the theory and methods in Papers I and II were also spelled out for the gravitational (spin 2) Regge–Wheeler equation, we consider these results in more detail here. We also discuss the asymptotic agreement between Schwarzschild ROBC and flatspace nonreflecting boundary conditions, remarking on some fine points unmentioned in our earlier work. Part of this paper roughly parallels Sec. III from Paper I, which documented several numerical tests of the sum-of-poles representation for scalar (spin 0) kernels. Here we run through those same tests for the gravitational kernels, and also carry out another test based on the Argument principle. A longer paper on numerical implementation of these ideas, complete with extensive numerical tables, is forthcoming,[23] and in part this paper is meant to lay more groundwork for that longer work.

II. PRELIMINARIES

A. Wave equations for gravitational perturbations

In terms of dimensionless time τ and radius $\rho > 1$, the standard Schwarzschild line-element reads

$$\mathrm{d}s^2 = -F\mathrm{d}\tau^2 + F^{-1}\mathrm{d}\rho^2 + \rho^2(\mathrm{d}\theta^2 + \sin^2\theta\mathrm{d}\phi^2), \tag{1}$$

where $F(\rho) = 1 - \rho^{-1}$. With M the mass parameter of the solution, standard physical coordinates are then $t = 2M\tau$ and $r = 2M\rho$. We also consider a dimensionless Laplace frequency σ related to the

physical frequency s via $\sigma=2Ms$. As is well known (see, for example, Ref. 24), radiative perturbations of the Schwarzschild metric are ultimately described by wave equations for angular modes $\rho^{-1}\Psi_{\ell m}(\tau,\rho)$. From now on, we drop the "azimuthal" index m and write $\Psi_\ell(\tau,\rho)$, since all equations depend only on the "orbital" index ℓ. In terms of the Regge–Wheeler tortoise coordinate $\rho_*=\rho+\log(\rho-1)$, the perturbation Ψ_ℓ obeys the wave equation

$$\frac{\partial^2\Psi_\ell}{\partial\tau^2}-\frac{\partial^2\Psi_\ell}{\partial\rho_*^2}+V(\rho)\Psi_\ell=0. \tag{2}$$

For axial perturbations $V(\rho)$ is the Regge–Wheeler potential

$$V^{RW}(\rho)=\left(1-\frac{1}{\rho}\right)\left[\frac{\ell(\ell+1)}{\rho^2}+\frac{1-j^2}{\rho^3}\right], \tag{3}$$

where $j=2$. Scalar and electromagnetic perturbations correspond to $j=0$ and 1, respectively.

Equation (2) also describes polar perturbations, although in this case $V(\rho)$ is the Zerilli potential

$$V^{Z}(\rho)=\left(1-\frac{1}{\rho}\right)\left[\frac{8n^2(n+1)\rho^3+12n^2\rho^2+18n\rho+9}{\rho^3(2n\rho+3)^2}\right], \tag{4}$$

where $n=\frac{1}{2}(\ell-1)(\ell+2)$. Throughout this paper we consider the same objects for the Regge–Wheeler and Zerilli cases, and we shall make use of the following convention. An object without a superscript letter, say $V(\rho)$, will refer to the generic object, and could correspond to either of the two cases (actually four cases, since the Regge–Wheeler scenario is three cases in itself). Superscript letters will denote the specific cases. For example, we have $V^{RW}(\rho)$ and $V^{Z}(\rho)$ as above. We will also sometimes use a superscript F to denote corresponding flatspace objects, for example

$$V^{F}(\rho)=\frac{\ell(\ell+1)}{\rho^2} \tag{5}$$

as the flatspace potential.

Formal Laplace transformation of the Regge–Wheeler wave equation (2) yields a second-order ODE

$$L^{RW}\hat{\Psi}_\ell=0,\quad L^{RW}=\frac{\mathrm{d}^2}{\mathrm{d}\rho_*^2}-V^{RW}(\rho)-\sigma^2, \tag{6}$$

where σ is Laplace frequency. This equation is—apart from a transformation on the dependent variable—a special case of the *confluent Heun equation*.[25,26] Therefore, implementation of ROBC for the Regge–Wheeler equation involves confluent Heun functions, whereas the flatspace implementation of AGH[20] involves Bessel functions (closely related to *confluent* hypergeometric functions).

Likewise, we may consider formal Laplace transformation of the Zerilli wave equation (2),

$$L^{Z}\hat{\Psi}_\ell=0,\quad L^{Z}=\frac{\mathrm{d}^2}{\mathrm{d}\rho_*^2}-V^{Z}(\rho)-\sigma^2. \tag{7}$$

Solutions of (6) with $j=2$ are related to solutions of (7) and *vice versa* by the intertwining relations[6]

$$D_+L^{RW}=L^{Z}D_+,\quad D_-L^{Z}=L^{\mathrm{RW}}D_-, \tag{8}$$

with

$$D_{\pm} = \frac{\mathrm{d}}{\mathrm{d}\rho_*} \pm \left[\frac{2}{3} n(n+1) + \frac{3(\rho-1)}{\rho^2(3+2n\rho)} \right]. \tag{9}$$

We have mentioned that Papers I and II examined the exact ROBC for the Regge–Wheeler equation, although mostly focusing on the $j=0$ case. A natural question then is whether or not these boundary conditions can be easily carried over to the Zerilli case via use of intertwining relations. It would seem the answer is "no," and we have been unable to make direct use of our previous work on ROBC via the intertwining relations. Although we believe the issue may merit further study, in this paper we develop and describe Zerilli ROBC from scratch.

B. Radiation outer boundary conditions

Let us assume initial data of compact support, and that the radial location ρ_B of the outer boundary B lies beyond the support of the data. Then the exact nonlocal ROBC is the following differential-integral identity:[21]

$$\left(\frac{\partial \Psi_\ell}{\partial \tau} + \frac{\partial \Psi_\ell}{\partial \rho_*} \right) \Bigg|_{\rho=\rho_B} = \frac{F(\rho_B)}{\rho_B} \int_0^\tau \omega_\ell(\tau-\tau';\rho_B) \Psi_\ell(\tau',\rho_B) \mathrm{d}\tau'. \tag{10}$$

The ROBC equates an outgoing characteristic derivative of the field with an integral convolution of the field history. Although the conditions (10) are equally valid for the Regge–Wheeler and Zerilli cases, we must consider two separate kernels: $\omega_\ell^{RW}(\tau;\rho_B)$ and $\omega_\ell^{Z}(\tau;\rho_B)$. As a function of complex Laplace frequency σ, Paper I has considered the Laplace transform $\hat{\omega}_\ell^{RW}(\sigma;\rho_B)$ of the integral kernel $\omega_\ell^{RW}(\tau;\rho_B)$, in particular arguing that it admits a "sum-of-poles" representation quite similar to the representation of frequency-domain kernels for flatspace wave propagation in $2+1$ dimensions. Such representations involve both a finite pole sum as well as a continuous sector.[20] The analysis in Paper I mostly concentrated on the $\hat{\omega}_\ell^{RW}(\sigma;\rho_B)$ relevant for scalar wave propagation (that is for $j=0$), and did not consider the Zerilli equation at all. In the following we consider the analytic structure of both $\hat{\omega}_\ell^{RW}(\sigma;\rho_B)$ for $j=2$ and $\hat{\omega}_\ell^{Z}(\sigma;\rho_B)$ in some detail.

Paper I has developed numerical methods for evaluating $\hat{\omega}_\ell(\sigma;\rho_B)$ along the axis of imaginary Laplace frequency, precisely the contour over which the inverse Laplace transform is taken to obtain the time-domain kernel. We further touch upon these methods in the following, but mention here that they rely on stable numerical integration over various paths in both the complex ρ and complex $z=\sigma\rho$ planes. All of our work in this paper is based upon these methods, and we have used them to plot in Fig. 1 the $j=2$ Regge–Wheeler profiles Re $\hat{\omega}_2^{RW}(\mathrm{i}y;15)$ and Im $\hat{\omega}_2^{RW}(\mathrm{i}y;15)$ for real y. Although different, the corresponding Zerilli profiles would be indistinguishable to the eye, were they also plotted in Fig. 1.

C. Kernel compression

With the ability to generate such numerical profiles for exact frequency-domain kernels, we have employed the technique of kernel compression in order to construct highly accurate numerical kernels which allow for efficient evaluation of the convolution appearing in (10). Introduced by AGH[20] and described further in both Ref. 27 and Paper II, compression is vital both for high-ℓ kernels as well as low-ℓ kernels which are dominated by costly continuous sectors (such sectors are further described in the following). The technique produces a rational function,

$$\hat{\xi}_\ell(\sigma;\rho_B) = \sum_{k=1}^{d} \frac{\gamma_{\ell,k}(\rho_B)}{\sigma - \beta_{\ell,k}(\rho_B)}, \tag{11}$$

which approximates $\hat{\omega}_\ell(\sigma;\rho_B)$ and is in fact a sum of d simple poles. The pole locations $\beta_{\ell,k}(\rho_B)$ and strengths $\gamma_{\ell,k}(\rho_B)$—output from the compression algorithm—lie in the left-half plane. The approximation is rigged to satisfy

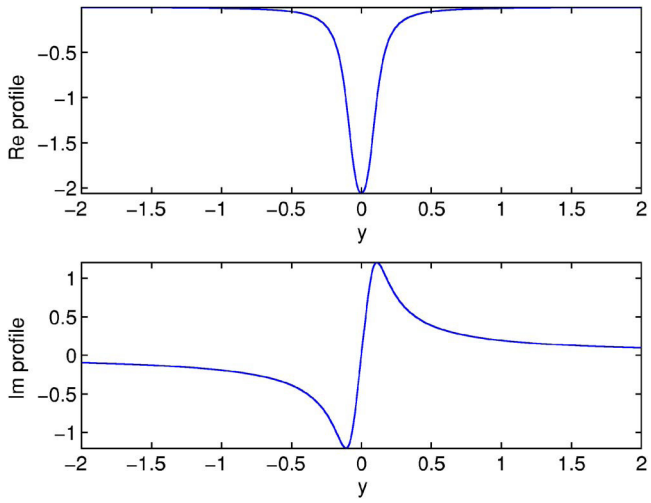

FIG. 1. (Color online) Re $\hat{\omega}_2^{RW}(\mathrm{iy};15)$ and Im $\hat{\omega}_2^{RW}(\mathrm{iy};15)$ profiles for the $j=2$ frequency domain kernel $\hat{\omega}_2^{RW}(\mathrm{iy};15)$. As indicated, $\ell=2$ and $\rho_B=15$.

$$\sup_{y\in R}\frac{|\hat{\xi}_\ell(\mathrm{iy};\rho_B)-\hat{\omega}_\ell(\mathrm{iy};\rho_B)|}{|\hat{\omega}_\ell(\mathrm{iy};\rho_B)|}<\varepsilon, \tag{12}$$

where ε is a chosen numerical tolerance. Theoretically, this bound on the relative supremum error in the frequency domain ensures a long-time bound on the relative convolution error associated with (10), as discussed in Ref. 20 and Paper II. This convolution error arises when using the approximate time-domain kernel

$$\xi_\ell(\tau;\rho_B)=\sum_{k=1}^{d}\gamma_{\ell,k}(\rho_B)\exp[\beta_{\ell,k}(\rho_B)\tau] \tag{13}$$

in place of the true kernel $\omega_\ell(\tau;\rho_B)$. Since $\xi_\ell(\tau;\rho_B)$ is a sum of exponentials, due to recursive identities an approximation of the convolution (10) based on $\xi_\ell(\tau;\rho_B)$ is not memory intensive. We list representative compressed kernels for Regge–Wheeler and Zerilli kernels in Tables I and II. The two kernels are strikingly similar, although they differ by a relative supremum error of about 3.03×10^{-2}, well below their stated $\varepsilon=10^{-10}$ tolerances. Extensive numerical tables of compressed kernels are being prepared and will appear in Ref. 23.

D. Quasinormal ringing and decay tail

Providing little detail, we now carry out a simple experiment meant only to indicate that the described ROBC work well for long-time simulations. More careful experiments were considered in Paper II (for Regge–Wheeler cases only) and will be considered in Ref. 23. In terms of retarded time $\mu=\tau-\rho_*$ and the pulse function

$$g(\mu)=\begin{cases}[\mu(\mu+4)]^4/256 & \text{for } -4\leqslant\mu\leqslant0\\ 0 & \text{otherwise,}\end{cases} \tag{14}$$

we construct the $\ell=2$ wave packet

$$\Psi_2(0,\rho)=g(-\rho_*) \tag{15}$$

as initial data for the Zerilli equation. The initial packet is then of unit height and compactly supported on $0\leqslant\rho_*\leqslant4$. To complete the data, we assume that

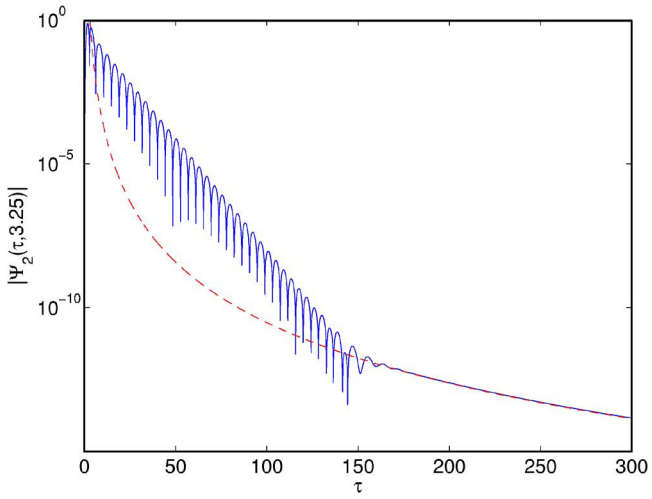

FIG. 2. (Color online) Quasinormal ringing and decay tail.

$$\left[\frac{\partial\Psi_2}{\partial\tau}+\frac{\partial\Psi_2}{\partial\rho_*}\right]\Bigg|_{\tau=0}=0, \tag{16}$$

so that the pulse starts as essentially outgoing. We place the inner boundary at $\rho_*=-175$, and adopt (10) as the boundary condition at $\rho=\rho_B=15$, with an approximation of the exact ROBC based on the compressed kernel listed in Table II.

We evolve the data until $\tau=300$, using the MacCormack predictor-corrector algorithm. (A scheme in consistent conservation form[28] when applied to a hyperbolic conservation law.) Throughout the evolution, we record the value $\Psi_2(\tau,3.25)$ of the field, that is to say, we record the history of the field in time at the fixed location $\rho=3.25$ (actually at the grid point nearest this location). Notice that the total run time is not long enough for the history $\Psi_2(\tau,3.25)$ to be influenced by reflection off of the inner boundary. The absolute value of the history is depicted as a linear-log plot in Fig. 2. It exhibits *quasinormal ringing*[24] until about $\tau=150$, and afterward a *Price tail* with the field decaying as $t^{-(2\ell+3)}=t^{-7}$.[24] This late-time behavior stems from backscatter of the outgoing packet off of the long-range potential $V^Z(\rho)$. The dashed curve $3000t^{-7}$ has been eyeballed to fit the late-time decay tail.

III. SUM-OF-POLES REPRESENTATION

A. Flatspace frequency-domain nonreflecting kernel and outgoing solution

AGH have considered nonreflecting boundary conditions (NRBC) for both 3+1 and 2+1 flatspace wave propagation, thoroughly treating both theoretical description and numerical approximation of NRBC for both scenarios.[20] For later comparison with the two gravitational scenarios, let us briefly recall the principal theoretical aspects of their work for the 3+1 scenario. To facilitate the comparison, we will use the same letters ρ, τ, and σ used for our dimensionless Schwarzschild coordinates, although for the flatspace case r, t, and s would be more standard notations. Their boundary condition for a flatspace order-ℓ multipole $\rho^{-1}\Psi_\ell$ is

$$\left(\frac{\partial\Psi_\ell}{\partial\tau}+\frac{\partial\Psi_\ell}{\partial\rho}\right)\Bigg|_{\rho=\rho_B}=\frac{1}{\rho_B}\int_0^\tau \omega_\ell^F(\tau-\tau';\rho_B)\Psi_\ell(\tau',\rho_B)\mathrm{d}\tau', \tag{17}$$

comparable with (10). The exact TDRK $\omega_\ell^F(\tau;\rho_B)$ appearing in (17) is now also a time-domain nonreflecting kernel (TDNK), and it is the inverse Laplace transform of an exact frequency-domain nonreflecting kernel (FDNK) admitting the following representation:[20]

$$\hat{\omega}_\ell^F(\sigma;\rho_B) = \sum_{k=1}^{\ell} \frac{b_{\ell,k}/\rho_B}{\sigma - b_{\ell,k}/\rho_B}, \tag{18}$$

where the $b_{\ell,k}$ are the zeros of the classical MacDonald function $K_{\ell+1/2}(z)$, a modified cylindrical Bessel function. Here the Bessel order is a half-integer, since we are considering the radial wave equation stemming from ordinary wave propagation on $3+1$ flat spacetime, and these functions have the form[29]

$$\begin{aligned}
K_{1/2}(z) &= \sqrt{\frac{\pi}{2z}} e^{-z}, \\
K_{3/2}(z) &= \sqrt{\frac{\pi}{2z}} e^{-z}\left(1 + \frac{1}{z}\right), \\
K_{5/2}(z) &= \sqrt{\frac{\pi}{2z}} e^{-z}\left(1 + \frac{3}{z} + \frac{3}{z^2}\right), \\
K_{7/2}(z) &= \sqrt{\frac{\pi}{2z}} e^{-z}\left(1 + \frac{6}{z} + \frac{15}{z^2} + \frac{15}{z^3}\right), \\
&\vdots \\
K_{\ell+1/2}(z) &= \sqrt{\frac{\pi z}{2}} (-1)^\ell z^\ell \left(\frac{1}{z}\frac{\mathrm{d}}{\mathrm{d}z}\right)^\ell \frac{e^{-z}}{z}.
\end{aligned} \tag{19}$$

The function $K_{\ell+1/2}(z)$ has ℓ simple zeros $\{b_{\ell,k}: k=1,\ldots,\ell\}$. When scaled by order, these zeros $(\ell+1/2)^{-1} b_{\ell,k}$ are known to accumulate on a fixed transcendental curve $\mathcal{C}$ in the left-half plane[20,30] (the numerical methods developed in Paper I take advantage of this fact). Although this accumulation is asymptotic with large order $\ell+1/2 \to \infty$, Fig. 3 shows that the agreement holds even for the lowest ℓ, at least to the eye. The curve $\mathcal{C}$ shown in Fig. 3 has parametric form[30,27]

$$z(\lambda) = -\sqrt{\lambda^2 - \lambda \tanh\lambda} \pm \mathrm{i}\sqrt{\lambda \coth\lambda - \lambda^2}, \tag{20}$$

for λ in the domain $[0,\lambda_0]$ with $\lambda_0 \simeq 1.1997$ such that $\tanh\lambda_0 = 1/\lambda_0$. In terms of the "normalized-at-infinity" outgoing solution [in the introduction of Paper II, the correspondence between $W_\ell(z)$ and $K_{\ell+1/2}(z)$ is off by a factor of $\pi/2$]

$$W_\ell(z) = \sqrt{\frac{2z}{\pi}} \exp(z) K_{\ell+1/2}(z), \tag{21}$$

we have

$$\hat{\omega}_\ell^F(\sigma;\rho_B) = \sigma\rho_B \frac{W_\ell'(\sigma\rho_B)}{W_\ell(\sigma\rho_B)} \tag{22}$$

as another expression for the flatspace frequency-domain kernel.[20] In passing, we remark that although the exact FDNK (18) is already a rational function, the technique of kernel compression still proves useful for high-ℓ FDNK, since for a given tolerance ε compression of (18) yields a numerical kernel with far fewer poles.[20]

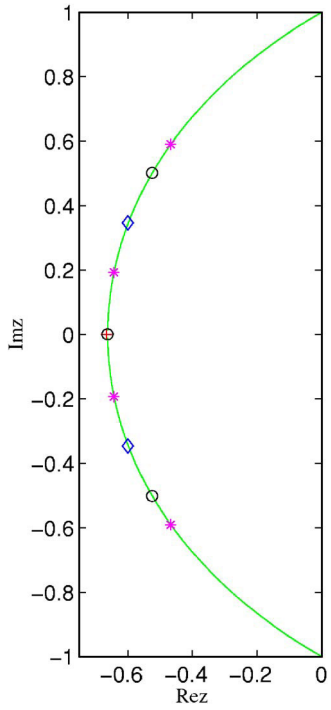

FIG. 3. (Color online) Scaled zeros of MacDonald functions. Here we plot scaled zeros $(\ell+1/2)^{-1}b_{\ell,k}$ for $\ell=1,2,3,4$. The cross is the scaled zero of $K_{1/2}(z)$, the diamonds are the scaled zeros of $K_{3/2}(z)$, the circles are the scaled zeros of $K_{5/2}(z)$, and the stars are the scaled zeros of $K_{7/2}(z)$.

B. Gravitational FDRK and outgoing solution

Let us first consider the relationship between a gravitational FDRK $\hat{\omega}_\ell(\sigma;\rho_B)$ described earlier and solutions to the formal Laplace transform

$$\frac{\mathrm{d}^2\hat{\Psi}_\ell}{\mathrm{d}\rho_*^2} - V(\rho)\hat{\Psi}_\ell = \sigma^2\hat{\Psi}_\ell \tag{23}$$

of the generic equation (2). Here we mostly just collect relevant formulas. These formulas are derived in the first section of Paper I, and the derivation presented there goes through for Regge–Wheeler case ($j=0,1,2$ considered there) as well as the Zerilli case (not considered there). Whence the formulas we consider now are valid for all cases.

We "peel off" the exponential behavior of the field by setting $\hat{\Psi}_\ell=\exp(-\sigma\rho_*)\hat{\Phi}_\ell$, whereupon finding

$$\frac{\mathrm{d}^2\hat{\Phi}_\ell}{\mathrm{d}\rho^2} + \left(-2\sigma - \frac{1}{\rho} + \frac{1-2\sigma}{\rho-1}\right)\frac{\mathrm{d}\hat{\Phi}_\ell}{\mathrm{d}\rho} - \frac{\rho^2 V(\rho)}{(\rho-1)^2}\hat{\Phi}_\ell = 0 \tag{24}$$

as the ODE satisfied by $\hat{\Phi}_\ell$. When numerically integrating (24) in various contexts, we have found it useful to work instead with $z=\sigma\rho$, re-expressing the equation as follows:

$$\frac{\mathrm{d}^2\hat{\Phi}_\ell}{\mathrm{dz}^2} + \left(-2 - \frac{1}{z} + \frac{1-2\sigma}{z-\sigma}\right)\frac{\mathrm{d}\hat{\Phi}_\ell}{\mathrm{dz}} - \frac{z^2 V(z/\sigma)}{\sigma^2(z-\sigma)^2}\hat{\Phi}_\ell = 0. \tag{25}$$

Let $W_\ell(z;\sigma)$ denote the outgoing solution to (25). This solution obeys[30]

$$W_\ell(z;\sigma) \sim \sum_{k=0}^{\infty} d_k(\sigma) z^{-k} \tag{26}$$

as $z \to \infty$, and we describe it as "normalized at infinity." Appendix B considers the recursion relations defining the $d_k^{RW}(\sigma)$ and $d_k^{Z}(\sigma)$. As described in Paper I, the flatspace solution $W_\ell(z)$ in (21) is formally $W_\ell(z) = W_\ell^{RW}(z;0)$ in terms of the Regge–Wheeler case $W_\ell^{RW}(z;\sigma)$.

In our notation $W_\ell(\sigma\rho;\sigma)$ is the outgoing solution to (24), and Paper I expresses the FDRK in terms of it as

$$\hat{\omega}_\ell(\sigma;\rho_B) = \sigma\rho_B \frac{W_\ell'(\sigma\rho_B;\sigma)}{W_\ell(\sigma\rho_B;\sigma)}, \tag{27}$$

where the prime denotes differentiation in the first slot of $W_\ell(z;\sigma)$. Since we have peeled off the exponential factor $\exp(-\sigma\rho_*)$ earlier and now work with an outgoing solution $W_\ell(\sigma\rho,\sigma)$ which is normalized at infinity, the FDRK (27) is more apt to have a well-defined inverse Laplace transform.

Paper I has described a collection of numerical methods which allow us to (i) evaluate $W_\ell(\sigma\rho_B;\sigma)$ for σ in the left-half plane and (ii) evaluate $\hat{\omega}_\ell(\mathrm{i}y;\rho_B)$ for real y. We remark that Leaver has analytically represented a solution, say the outgoing one $W_\ell^{RW}(\sigma\rho_B;\sigma)\exp(-\sigma\rho_*)$, to the frequency-domain Regge–Wheeler equation as an infinite series in Coulomb wave functions, where the expansion coefficients obey a three-term recursion relation. In fact, such series expansions hold more generally for the generalized spheroidal wave equation (essentially the confluent Heun equation).[31] The methods described in Paper I are not based on the appropriate Leaver series, rather they rely on direct integration of (25). As such they can and have now been carried over to the Zerilli case. We note that the Zerilli equation is not directly related to the confluent Heun equation; whence it is not immediately evident how to evaluate $W_\ell^{Z}(\sigma\rho_B;\sigma)$ via a Leaver series.

Roughly, our method for evaluating $W_\ell(\sigma\rho_B;\sigma)$ is as follows. For a fixed frequency σ, initial data at a large radius are obtained for (25) using the asymptotic expansion (26). Then (25) is integrated over a suitable path in the complex $z=\sigma\rho$ plane to a terminal point $z_B=\sigma\rho_B$. To convey the basic idea behind our numerical evaluation of the FDRK $\hat{\omega}_\ell(\mathrm{i}y;\rho_B)$ itself, we introduce

$$w_\ell(z;\sigma) = z\frac{W_\ell'(z;\sigma)}{W_\ell(z;\sigma)}. \tag{28}$$

Then the FDRK is $\hat{\omega}_\ell(\sigma;\rho_B) = w_\ell(\sigma\rho_B;\sigma)$, and we have from (25) that $w_\ell(z;\sigma)$ obeys the first-order nonlinear equation

$$\frac{\mathrm{d}w_\ell}{\mathrm{d}z} + \frac{w_\ell^2}{z} + \left(-2 - \frac{2}{z} + \frac{1-2\sigma}{z-\sigma}\right) w_\ell - \frac{z^3 V(z/\sigma)}{\sigma^2 (z-\sigma)^2} = 0. \tag{29}$$

We calculate values $\hat{\omega}_\ell(\mathrm{i}y;\rho_B) = w_\ell(\mathrm{i}y\rho_B;\mathrm{i}y)$ via direct numerical integration of (29). To achieve stability and high accuracy, the methods associated with both (i) and (ii) evaluations require integration over nontrivial paths in the z plane. Moreover, for technical reasons the integration employed for kernel evaluation (ii) is sometimes carried out in the complex ρ plane rather than complex z plane. Finally, we remark that to produce the origin value $\hat{\omega}_\ell(0;\rho_B)$ of the kernel, we do not integrate (29). Rather, we make use of an exact series expression, one given for the Regge–Wheeler cases in Paper I and for the Zerilli case in Appendix A.

C. Gravitational sum-of-poles representation

For the case of $j=0$ scalar perturbations Paper I has documented compelling numerical evidence indicating that the FDRK (27) admits an explicit "sum-of-poles" representation,

$$\hat{\omega}_\ell(\sigma;\rho_B)=\sum_{k=1}^{N_\ell}\frac{\alpha_{\ell,k}(\rho_B)}{\sigma-\sigma_{\ell,k}(\rho_B)}-\frac{1}{\pi}\int_0^\infty\frac{f_\ell(\chi;\rho_B)}{\sigma+\chi}\mathrm{d}\chi, \tag{30}$$

in terms of complex frequency σ. When we discussed compressed kernels before, we introduced approximate pole locations $\beta_{\ell,k}(\rho_B)$ and strengths $\gamma_{\ell,k}(\rho_B)$. We now consider N_ℓ (an integer) *physical pole locations* $\sigma_{\ell,k}(\rho_B)$ and *physical pole strengths* $\alpha_{\ell,k}(\rho_B)$, all of which lie in the left-half plane. Also appearing in (30) is a *cut profile* $f_\ell(\chi;\rho_B)$, and like the pole locations and strengths it depends on the value of ρ_B. [It may or may not be the case that an approximate location $\beta_{\ell,k}(\rho_B)$, for example, approximates a physical one $\sigma_{\ell,k}(\rho_B)$. It is the compressed kernel $\hat{\xi}_\ell(\mathrm{i}y;\rho_B)$ in whole which approximates the physical FDRK $\hat{\omega}_\ell(\mathrm{i}y;\rho_B)$ uniformly in $y\in\mathbb{R}$.] In principle the integer N_ℓ also depends on ρ_B, but turns out to be constant over sizable regions of the relevant parameter space (more comments on this point to follow). The kth pole strength and cut profile are given, respectively, by

$$\alpha_{\ell,k}(\rho_B)=-\rho_B\sigma'_{\ell,k}(\rho_B),\quad f_\ell(\chi;\rho_B)=\mathrm{Im}\;\hat{\omega}_\ell(\chi e^{i\pi};\rho_B), \tag{31}$$

with $\chi\geqslant 0$ and the prime here standing for $\partial/\partial\rho_B$ differentiation.

We will argue that the representation (30) is also valid for both $j=2$ Regge–Wheeler and Zerilli gravitational cases, and this conjecture is the main result of our paper. Note that (30) is not really a "sum of poles." Indeed, recall that in the sense of complex analysis a pole is an *isolated* singularity. Strictly speaking then, the cut integral in (30) does not correspond to a "continuous distribution of poles" (an oxymoron). Nevertheless, we shall continue to describe the representation (30) as a "sum of poles."

We stress that (30) is a representation for a *boundary* integral kernel. Its inverse Laplace transform, the TDRK $\omega_\ell(\tau;\rho_B)$, lives on the history of the spatial boundary B. Indeed, (10) makes no reference to the details of the initial data and is certainly not a spatial convolution over initial data. Moreover, the pole locations $\sigma_{\ell,k}(\rho_B)$ are not quasinormal modes. An infinite number of quasinormal modes belong to each ℓ value, and these characteristic frequencies do not depend on any particular choice of outer boundary radius ρ_B. Quasinormal modes are associated with a boundary value problem specifying that $\hat{\Psi}_\ell$ is downgoing at the horizon and outgoing at infinity. The locations $\sigma_{\ell,k}(\rho_B)$ are finite in number, and they do depend on ρ_B. They can be associated with a boundary value problem specifying that $\hat{\Psi}_\ell$ is outgoing at infinity and vanishes at ρ_B. [As such, the locations $\sigma_{\ell,k}(\rho_B)$ are analogous to the "flatspace quasinormal modes" considered in Ref. 32, a misleading terminology for our paper.] Likewise, the cut integral appearing in (30) is not the branch-cut contribution to the usual Green's function studied in the quasinormal mode problem.[33]

IV. NUMERICAL STUDY

In this section we both provide further qualitative description of the key representation (30) and justify it numerically. To argue that the representation (30) is valid for both $j=2$ Regge–Wheeler and Zerilli gravitational cases, we offer nearly the same evidence as that offered in Paper I for the case of scalar perturbations. However, here we also consider one extra numerical experiment based on the Argument principle. Our main numerical justification is to compare values $\hat{\omega}_\ell(\mathrm{i}y;\rho_B)$ of the kernel obtained via two independent approaches. These are the following:

(1) Direct integration of (29) as alluded to earlier [a process which makes no use whatsoever of the conjecture representation (30)].
(2) Approximation of the sum-of-poles representation itself (by this we do *not* mean kernel compression).

In the second approach, we "build" the kernel as

$$\hat{\omega}_\ell(\mathrm{i}y;\rho_B) \simeq \sum_{k=1}^{N_\ell} \frac{\alpha_{\ell,k}(\rho_B)+\delta\alpha_{\ell,k}(\rho_B)}{\mathrm{i}y-\sigma_{\ell,k}(\rho_B)-\delta\sigma_{\ell,k}(\rho_B)} - \frac{1}{\pi}\int_{\chi_{\min}}^{\chi_{\max}} \frac{f_\ell(\chi;\rho_B)+\delta f_\ell(\chi;\rho_B)}{\mathrm{i}y+\chi}\mathrm{d}\chi, \tag{32}$$

where the δ terms represent numerical errors and the integral over the chosen window $[\chi_{\min},\chi_{\max}]$ must be handled via numerical quadrature. We have used Simpson's rule, respectively, with 2048, 2048, 1024, 2048, 1024, 2048, 1024, 2048, 512 subintervals for $\ell=2,3,4,5,6,7,8,9,10$ (odd ℓ requires more subintervals). We stress that this latter approach to evaluation, quite unlike the first approach, requires that we numerically compute all pole locations and strengths and well as the cut profile. To locate poles, zeros in σ of $W_\ell(\sigma\rho_B;\sigma)$, we have used the secant algorithm. The $\partial/\partial\rho_B$ derivatives of the $\sigma_{\ell,k}(\rho_B)$ needed to compute the strengths $\alpha_{\ell,k}(\rho_B)$ are obtained by first building a high-order interpolating polynomial $T_{\ell,k}(1/\rho_B)$ for each $\sigma_{\ell,k}(\rho_B)$ based on Chebyshev nodes in $1/\rho_B$. Derivatives are then found via differentiation of the Chebyshev polynomial. This procedure is described in more detail in Paper I where it was used for the $j=0$ Regge–Wheeler case.

We remark that this direct approximation (32) to the sum-of-poles representation (30) is certainly not a compressed kernel. Indeed, as mentioned, this brute-force approximation of (30) typically requires thousands of poles (stemming from the numerical quadrature of the cut integral) to achieve the same error tolerance achieved by a compressed kernel comprised of ten or so poles.

Besides making the comparison outlined in the last paragraph, we also wish to provide further qualitative description of the sum-of-poles representation (30). We describe both the poles and the cut profile in more detail, and also compare the representation to the strikingly similar representation (18) of the FDNK $\hat{\omega}_\ell^F(\sigma;\rho_B)$ for a flatspace order-ℓ multipole. We have found that both gravitational kernels, $\hat{\omega}_\ell^{RW}(\sigma;\rho_B)$ and $\hat{\omega}_\ell^Z(\sigma;\rho_B)$, indeed agree with $\hat{\omega}_\ell^F(\sigma;\rho_B)$ in the $\rho_B\to\infty$ limit, although here we will focus on the Zerilli case. One certainly expects such agreement, since the Schwarzschild solution is asymptotically flat. However, the nature of this asymptotic agreement is rather interesting, and we point out some subtleties not mentioned in Paper I.

A. Pole locations and strengths

For the most part, here we give what amounts to a qualitative description. Using our method for evaluating the outgoing solution $W_\ell(\sigma\rho_B;\sigma)$, we may plot the modulus $|W_\ell(\sigma\rho_B;\sigma)|$ in order to suggest rough values for zeros (that is, roots) of the function. Provided such a zero is simple, it will correspond to a pole appearing in the representation (30). Over the parameter space $\rho_B\geqslant 15$ and $\ell=2,3,\ldots,10$, and for both Zerilli and $j=2$ Regge–Wheeler cases, we have found that the number N_ℓ of zeros $\sigma_{\ell,k}(\rho_B)$ is as follows: $N_2=2$, $N_3=4=N_4$, $N_5=6=N_6$, $N_7=8=N_8$, $N_9=10=N_{10}$. For a fixed choice of ℓ and ρ_B, these zeros form a crescent pattern in the left-half σ plane.

For example, Fig. 4 depicts the modulus $|W_3^Z(\sigma 15;\sigma)|$ in the indicated region of the left-half σ plane. Four zeros appear to be evident in the figure, and in order to further explore whether or not they are indeed zeros, we appeal to the Argument principle. We focus on the two upper locations shown closer up in Fig. 5. Let $h(\sigma)=W_3^Z(\sigma 15;\sigma)$ represent our numerically computed function. [Due to small errors in the asymptotic expansion (26) used to generate initial data for an evaluation based on integrating (25), $h(\sigma)$ will actually represent the product of $W_3^Z(\sigma 15;\sigma)$ and an analytic function of σ which slowly varies over the region of interest. However, Paper I showed that the choice of integration path in the $z=\sigma\rho$ plane results in exponential suppression of the second solution to (25), and absolute differences in the zero *locations* of $h(\sigma)$ and those of $W_3^Z(\sigma 15;\sigma)$ are of size 10^{-13} in modulus.] We numerically compute

$$\frac{1}{2\pi\mathrm{i}}\oint_{\text{square}} \frac{h'(\sigma)}{h(\sigma)}\mathrm{d}\sigma \simeq 1.999\,732 - \mathrm{i}4.185\,506\times 10^{-5} \tag{33}$$

over the square (running in the counterclockwise sense) shown in Fig. 5. On each side of the square we have introduced 1024 subintervals, and used the trapezoid rule. Since we are unable to numerically evaluate $h'(\sigma)$ directly, we approximate this derivative using difference quotients (this requires two extra function evaluations beyond the corners). Using a sequence of discretizations, we have confirmed that the integral convergences to 2 at a second-order rate, suggesting that the

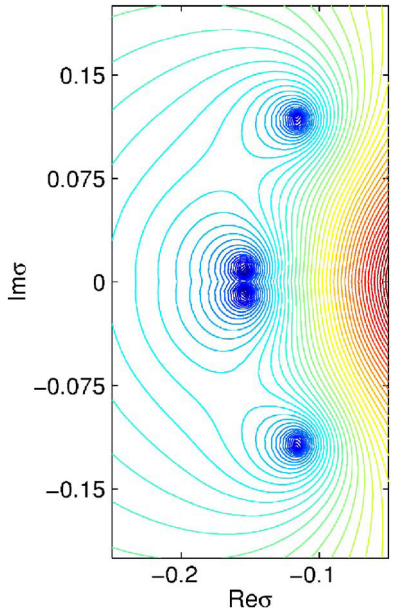

FIG. 4. (Color online) Zeros $\{\sigma^Z_{3,k}(15):1\leqslant k\leqslant 4\}$ in frequency of $W^Z_3(\sigma 15;\sigma)$. The contour lines are of $\log_{10}|W^Z_3(\sigma 15;\sigma)|$, with the logarithm distributing contour lines more evenly.

square indeed encloses two simple zeros. As a second example, consider the modulus $|W^Z_8(\sigma 25;\sigma)|$ plotted in Fig. 6 over the indicated region (four other zeros, conjugate to those shown, are located in the third quadrant). For the analogous line integral over the square shown (and using 2048 cells on each side for the trapezoidal integration), we find a value of $3.999\,975-\mathrm{i}5.169\,761\times 10^{-5}$, suggesting four simple zeros.

As with the scalar case, we find for the Zerilli and $j=2$ Regge–Wheeler cases that the zeros $\sigma_{\ell,k}(\rho_B)$ in frequency of $W_\ell(\sigma\rho_B;\sigma)$ behave asymptotically as

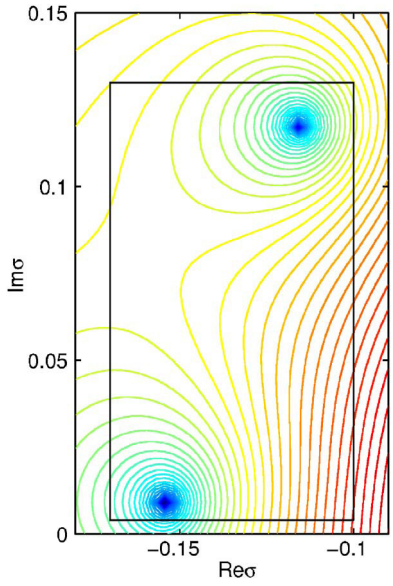

FIG. 5. (Color online) Zeros in frequency of $W^Z_3(\sigma 15;\sigma)$. The plot here is a blow-up of the one shown in Fig. 4.

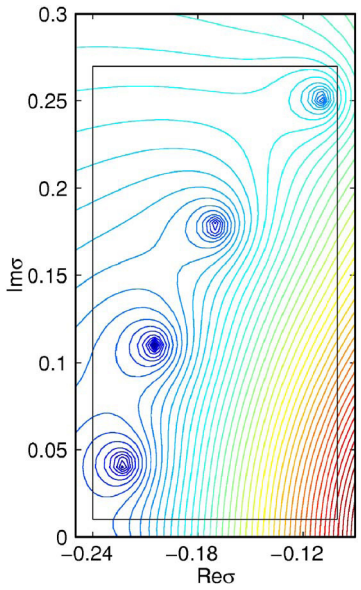

FIG. 6. (Color online) Zeros in frequency of $W_8^Z(\sigma 25;\sigma)$. The contour lines are of $\log_{10}|W_8^Z(\sigma 25;\sigma)|$, with the logarithm distributing contour lines more evenly.

$$\sigma_{\ell,k}(\rho_B) \sim b_{\ell,k}/\rho_B \tag{34}$$

in the $\rho_B \to \infty$ limit. However, let us offer several important observations in order to sharpen the precise nature of this asymptotic agreement. First, in the opposite limit as $\rho_B \to 1^+$, we do not believe N_ℓ remains constant. Indeed, we expect the phenomenon of "zero pair creation" in this limit, as described in Paper I for the scalar $j=0$ Regge–Wheeler FDRK. Although we believe that the sum-of-poles representation remains valid for ρ_B close (but not equal) to unity, description of the FDRK and implementation of ROBC both become more difficult in this limit. For these reasons, we have required $\rho_B \geqslant 15$. Second, for odd ℓ there is an "extra" zero. That is to say, for odd ℓ the number $N_\ell = \ell + 1$ of zeros $\sigma_{\ell,k}(\rho_B)$ is greater by one than the number ℓ of MacDonald zeros (provided ρ_B is large enough, otherwise N_ℓ could be a larger integer still). We will argue that this curious feature is not at odds with the asymptotic result (34). Let us focus on the Zerilli case, with the understanding that similar statements apply to the $j=2$ Regge–Wheeler case.

For even $\ell = 2,4,6,8,10$ and $\rho_B \geqslant 15$, the number of zeros $\sigma_{\ell,k}^Z(\rho_B)$ is $N_\ell = \ell$, the same as the number of $b_{\ell,k}/\rho_B$. As an illustration, Fig. 7 depicts the six zeros $\sigma_{6,k}^Z(\rho_B)$ of $W_6^Z(\sigma\rho_B;\sigma)$ as diamonds for $\rho_B = 15,16,\ldots,30$. We also plot the corresponding MacDonald–Bessel zeros $b_{6,k}/\rho_B$ as crosses. The collection $\sigma_{6,k}^Z(15)$ of zeros is the outermost crescent of diamonds, while the collection $\sigma_{6,k}^Z(30)$ is the innermost (and similarly for the crescents of Bessel crosses). The plot is clearly not at odds with the asymptotic formula (34) above.

As mentioned, for odd $\ell = 1,3,5,7,9$ and $\rho_B \geqslant 15$, the number of zeros $\sigma_{\ell,k}^Z(\rho_B)$ is $N_\ell = \ell + 1$, that is one more than the corresponding number of MacDonald–Bessel zeros. For odd ℓ there is a single MacDonald–Bessel zero which lies on the negative real axis. As with the $j=0$ Regge–Wheeler case, we find for odd ℓ that two zeros of $W_\ell^Z(\sigma\rho_B;\sigma)$ correspond to this single real MacDonald–Bessel zero. Moreover, as ρ_B gets large each of these two zeros is asymptotic to the single MacDonald–Bessel zero. This phenomenon is evident in Fig. 8, and corresponding plots for other odd ℓ are similar. The existence of an "extra" zero is at first sight troubling in light of the expected asymptotic agreement between $\hat{\omega}_\ell^Z(\mathrm{i}y;\rho_B)$ and $\hat{\omega}_\ell^F(\mathrm{i}y;\rho_B)$. However, we argue in the following that the pole and cut contributions to the gravitational FDRK in tandem do yield the correct asymptotic agreement.

So far we have only considered locations $\sigma_{\ell,k}^Z(\rho_B)$ associated with Zerilli kernels. To the eye, both Figs. 7 and 8 would be the same had we instead plotted the corresponding locations $\sigma_{\ell,k}^{RW}(\rho_B)$

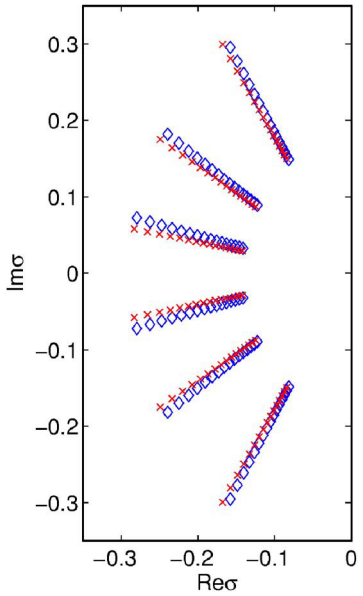

FIG. 7. (Color online) Zeros $\{\sigma^{Z}_{6,k}(\rho_B): 1 \leqslant k \leqslant 6\}$ in frequency of $W^{Z}_{6}(\sigma\rho_B;\sigma)$. Diamonds represent the zeros $\sigma_{6,k}(\rho_B)$, while the crosses represent the $b_{6,k}/\rho_B$. All zeros for $\rho_B=15,16,\ldots,30$ are shown. The outermost crescent of locations corresponds to $\rho_B=15$ and the innermost to $\rho_B=30$.

associated with $j=2$ Regge–Wheeler kernels. For the examples we have considered, $|\sigma^{Z}_{\ell,k}(\rho_B) - \sigma^{RW}_{\ell,k}(\rho_B)|$ is typically on the order of 10^{-5} to 10^{-3}. However, from Paper I results we know that this difference is seven to ten orders of magnitude larger than our knowledge of these locations. As an example, we list the two conjugate locations $\sigma_{2,k}(15)$ for $j=0$ Regge–Wheeler, $j=2$ Regge–Wheeler, and Zerilli cases. Respectively, these are

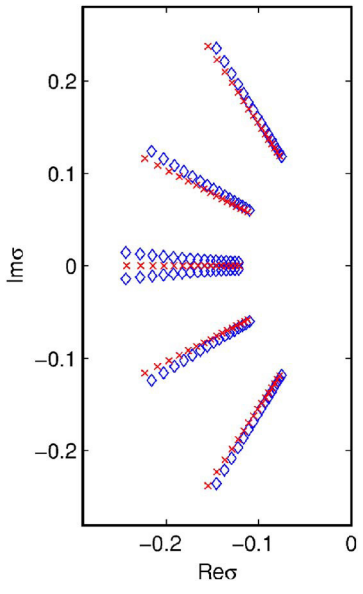

FIG. 8. (Color online) Zeros $\{\sigma^{Z}_{5,k}(\rho_B): 1 \leqslant k \leqslant 6\}$ in frequency of $W^{Z}_{5}(\sigma\rho_B;\sigma)$. Diamonds represent the zeros $\sigma^{Z}_{5,k}(\rho_B)$, while the crosses represent $b_{5,k}/\rho_B$. All zeros for $\rho_B=15,16,\ldots,30$ are shown. The outermost crescent of locations corresponds to $\rho_B=15$ and the innermost to $\rho_B=30$. For each ρ_B two diamonds correspond to the single cross lying on the negative real axis.

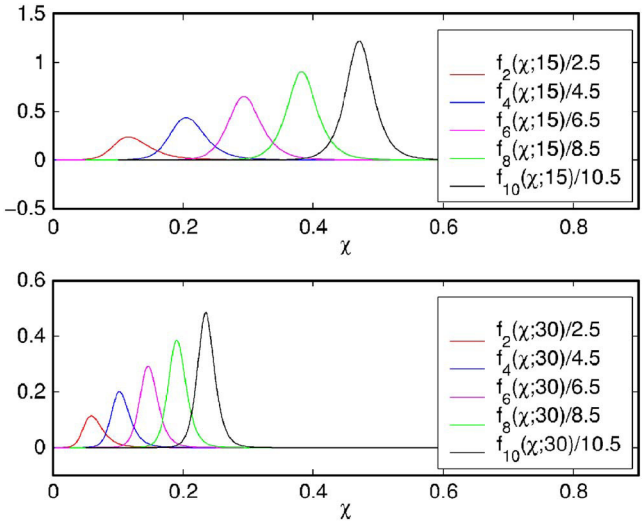

FIG. 9. (Color online) Scaled even cut profiles for Zerilli kernels. In each plot the leftmost profile is $f_2^Z(\chi;\rho_B)/2.5$ and the rightmost $f_{10}^Z(\chi;\rho_B)/10.5$.

$$-0.096\,885\,391\,711\,329 \pm i0.061\,245\,961\,499\,841.$$

$$-0.094\,779\,501\,145\,744 \pm i0.059\,927\,941\,363\,806,$$

$$-0.093\,406\,539\,086\,840 \pm i0.058\,977\,077\,340\,679.$$

These locations are all quite similar, and they may be compared to the roots $b_{2,k}/15$: $-(3/2 \pm i\sqrt{3}/2)/15 = -0.1 \pm i0.057\,735\,026\,918\,96$. In this short list the last location, say, clearly corresponds in some sense to the ninth pole location in the compressed kernel in Table II, but note that the absolute difference between the value here and the table value is more than the stated $\varepsilon = 10^{-10}$ tolerance for the compressed kernel. See the information in square brackets just after Eq. (30).

B. Cut profile

Using the type (i) numerical method from Paper I described earlier [which also returns derivative information for $W'_\ell(\sigma\rho_B;\sigma)$], we have generated Zerilli cut profiles $f_\ell^Z(\chi;\rho_B)$ for various ℓ and ρ_B. Figure 9 depicts profiles for even ℓ. To the eye the cut profiles shown match $j=2$ Regge–Wheeler profiles $f_\ell^{RW}(\chi;\rho_B)$ corresponding to the same parameter choices. However, the Zerilli and Regge–Wheeler even profiles are indeed different, as is shown by an example plot in Fig. 11. Near the peak of this plotted difference, the accuracy to which we know the Zerilli and Regge–Wheeler profiles is some ten orders of magnitude greater than the difference. Notice that these even cut profiles *weaken* as ρ_B gets larger, and we believe that the cut contribution to an even-ℓ gravitational FDRK "dies out" as ρ_B gets large. Based on our earlier claim that for an even-ℓ gravitational FDRK we have the same number $N_\ell = \ell$ of zeros $\sigma_{\ell,k}(\rho_B)$ as Bessel zeros $b_{\ell,k}/\rho_B$, and that these zeros lock on to the latter as ρ_B gets large, we conjecture that the even-ℓ kernels $\hat{\omega}_\ell^Z(iy;\rho_B)$ and $\hat{\omega}_\ell^{RW}(iy;\rho_B)$ both approach $\hat{\omega}_\ell^F(iy;\rho_B)$ uniformly in y as $\rho_B \to \infty$.

We plot odd-ℓ Zerilli cut profiles in Fig. 10. Like before with the even-ℓ profiles, to the eye these could be either Zerilli or $j=2$ Regge–Wheeler profiles. However, as is evident in the bottom plot shown in Fig. 11, these cases are different. Notice that for odd ℓ the cut profiles *strengthen* as ρ_B increases. We believe that such a strengthening profile in tandem with the two zeros closest to the real axis as a whole combine to asymptotically agree with the single MacDonald–Bessel zero $b_{\ell,0}/\rho_B$ located on the negative real axis. [For notational simplicity we have now labeled this zero

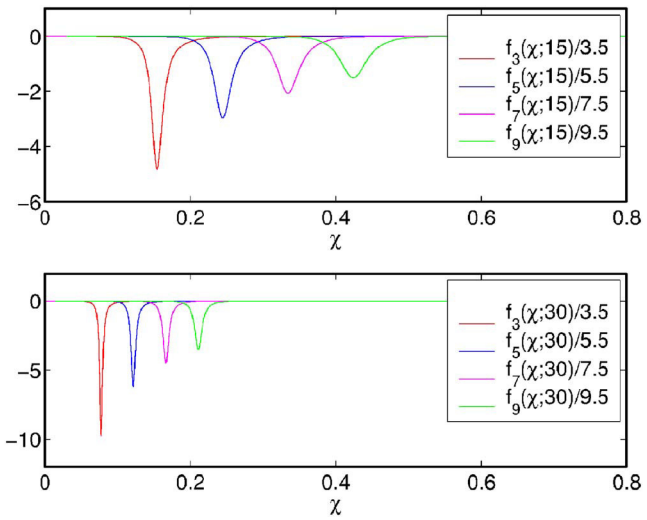

FIG. 10. (Color online) Scaled odd cut profiles for Zerilli kernels. In each plot the leftmost profile is $f_3^Z(\chi;\rho_B)/3.5$ and the rightmost $f_9^Z(\chi;\rho_B)/9.5$.

by $k=0$. Before it would have corresponded to $k=\frac{1}{2}(\ell+1)$ for odd ℓ, if $k=1,\ldots,\ell$ for the zeros $b_{\ell,k}$ of $K_{\ell+1/2}(z)$.] In other words, for odd ℓ the cut profile in effect cancels one of the zeros $\sigma_{\ell,k}^Z(\rho_B)$, so that again we have agreement between the gravitational FDRK $\hat{\omega}_\ell^Z(\mathrm{i}y;\rho_B)$ and flatspace FDNK $\hat{\omega}_\ell^F(\mathrm{i}y;\rho_B)$ uniformly in y as $\rho_B\to\infty$. While we cannot precisely describe how this cancellation of the extra zero occurs, we believe that it stems from the following two conjectures, claimed to hold as $\rho_B\to\infty$. First, the cut profile becomes sharply concentrated for χ near $-b_{\ell,0}/\rho_B$. Second,

$$-\frac{1}{\pi}\int_0^\infty f_\ell^Z(\chi;\rho_B)\mathrm{d}\chi\sim -b_{\ell,0}/\rho_B. \tag{35}$$

Preliminary numerical investigations indicate that both claims are in fact valid, but the issue deserves further study (preferably theoretical). All statements made in this paragraph also pertain to $\hat{\omega}_\ell^{RW}(\mathrm{i}y;\rho_B)$.

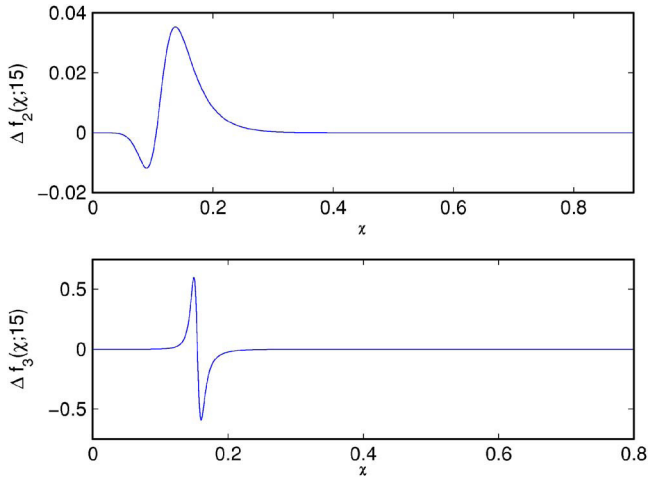

FIG. 11. (Color online) Difference between Regge–Wheeler and Zerilli cut profiles. Here we plot example differences with the notation $\Delta f_\ell(\chi;15)=f_\ell^{RW}(\chi;15)-f_\ell^Z(\chi;15)$.

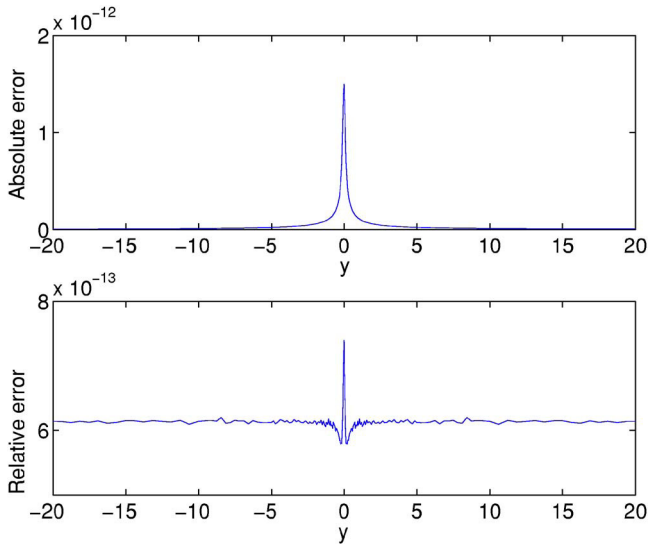

FIG. 12. (Color online) Relative and absolute numerical errors. Here we plot numerical errors corresponding to $|\Delta\hat{\omega}_2^Z(\mathrm{i}y;15)|$ and $|\Delta\hat{\omega}_2^Z(\mathrm{i}y;15)|/|\hat{\omega}_2^Z(\mathrm{i}y;15)|$ for the Zerilli case with $\ell=2$ and $\rho_B=15$.

C. Numerical validation of the sum-of-pole representation

Up to this point we have mainly given a qualitative description of what we believe are the main features of the sum-of-poles representation (30). In order to quantitatively test our representation (30), we compare the two numerical approaches for evaluating either $\hat{\omega}_\ell^Z(\mathrm{i}y;\rho_B)$ or $\hat{\omega}_\ell^{RW}(\mathrm{i}y;\rho_B)$ outlined at the beginning of this section. Figure 12 depicts such a comparison for the Zerilli case with $\ell=2$ and $\rho_B=15$. To make the plots in the figure, we have used a y grid with 5 adaptive levels, each with 32 grid points. The adaptive grid provides more resolution near the origin where we expect the largest errors. We have then generated two separate numerical arrays of values $\hat{\omega}_2^Z(\mathrm{i}y;15)$ on the y grid, the first obtained by integrating the ODE (29) and the second via the direct construction (32). Both arrays of numerical values are obtained in double precision arithmetic. Over the y grid, the plots depict the absolute error $|\Delta\hat{\omega}_2^Z(\mathrm{i}y;15)|$ and relative error $|\Delta\hat{\omega}_2^Z(\mathrm{i}y;15)|/|\hat{\omega}_2^Z(\mathrm{i}y;15)|$, and they indicate striking agreement between the two methods. We note that the maximum value of the absolute error in the top plot is 1.49×10^{-12}, and the maximum value of the relative error in the bottom plot is 7.35×10^{-13}. We can now perform the same experiment over a range of ρ_B values, say $\rho_B=15,16,\ldots,30$. For each choice of ρ_B we compute maximum values of absolute and relative error over the y grid. It turns out that the same values above corresponding to $\rho_B=15$ are the largest errors encountered.

We now perform the same experiment for each $\ell\leqslant10$ and for both $j=2$ Regge–Wheeler and Zerilli cases. That is to say, for each ℓ we compute the maximum absolute error $|\Delta\hat{\omega}_\ell(\mathrm{i}y;\rho_B)|$ and maximum relative error $|\Delta\hat{\omega}_\ell(\mathrm{i}y;\rho_B)|/|\hat{\omega}_\ell(\mathrm{i}y;\rho_B)|$ uniformly over the described y grid and all $\rho_B=15,16,\ldots,30$. For the Zerilli case we list these errors in the Table III. Errors for the $j=2$ Regge–Wheeler case are comparable.

V. CONCLUSION

For both flatspace 3+1 and flatspace 2+1 wave propagation and nonreflecting boundary conditions, AGH proved several theorems related to both the exact sum-of-poles representation for a FDNK (also a FDRK, but we have used FDNK for the special flatspace case) and its numerical approximation.[20] In particular, they proved that a FDNK admits a rational approximation as a compressed kernel, and for a given large Bessel order ν (for the 3+1 case $\nu=\ell+1/2$) and choice of ε tolerance they estimated the required number d of poles appearing in the compressed kernel. In addition to some techniques stemming from the fast multipole method, their proofs rely heavily

on the well-understood theory of Bessel functions. In particular, AGH made extensive use of integral representations, order recursion relations, and detailed understanding of the scaling behavior for both the poles and (for the 2+1 case) the cut profile. [The 2+1 case, associated with integer-order Bessel functions, is analytically richer than the 3+1 case, as for the 2+1 case there is a continuous sector associated with the sum-of-poles representation for the FDNK. This sector is at least qualitatively similar to the one in (30).]

While the numerical evidence amassed here is extremely convincing, it does not constitute a mathematical proof that a gravitational FDRK admits the representation (30), and we hope that our numerical investigation spurs the interest of analysts capable of theoretically investigating our conjectured representation. Were (30) established theoretically, we believe approximation theorems—similar to those proved by AGH but pertaining to our gravitational ROBC—would follow. One might prove that a gravitational FDRK also admits a rational approximation as a compressed kernel, and determine the asymptotic growth of the number d of approximating poles as $\ell\to\infty, \varepsilon\to0^+$. Since numerically constructed compressed kernels have performed spectacularly in implementations of ROBC (see Paper II), we have good reason to believe that approximation theorems must hold. Such theorems are bound to involve the details of the underlying special functions. Unfortunately, relative to Bessel functions, significantly less is known about the special functions considered here, confluent Heun functions for the Regge–Wheeler cases and seemingly more exotic functions for the Zerilli case. Indeed, we are unaware of useful integral representations, and while appropriate Leaver series are certainly of formal interest, they would not seem a good platform for carrying out the requisite asymptotic analysis. While our own knowledge of modern analysis would seem not up to such theoretical investigation, we believe our results offer fertile new ground for more capable analysts.

APPENDIX A: ORIGIN VALUE OF THE FDRK

For the $j=0,1,2$ Regge–Wheeler cases Paper I has expressed the origin value $\hat{\omega}_\ell^{RW}(0;\rho_B)$ of the FDRK in terms of an infinite series in ρ_B^{-1}, where the expansion coefficients obey a two-term recursion relation (see Sec. 3.2.3 of that reference). All expansion coefficients are positive, and the value $\hat{\omega}_\ell^{RW}(0;\rho_B)$ can be accurately approximated in terms of two partial sums. This series was used numerically to evaluate the kernel at the origin $\sigma=0$, a frequency value for which direct integration of (29) proved problematic.

To express $\hat{\omega}_\ell^{Z}(0;\rho_B)$ for the Zerilli case of polar perturbations, we have used a similar series expression, although now the series coefficients obey a four-term rather than two-term recursion relation. We have obtained this series via the following recipe. First, we set $\sigma=0$ in (24) and use (4), thereby reaching

$$\frac{d^2\hat{\Phi}_\ell}{d\rho^2}+\left(-\frac{1}{\rho}+\frac{1}{\rho-1}\right)\frac{d\hat{\Phi}_\ell}{d\rho}-\left[\frac{8n^2(n+1)\rho^3+12n^2+18n\rho+9}{\rho^2(\rho-1)(2n\rho+3)^2}\right]\hat{\Phi}_\ell=0. \tag{A1}$$

Next, plugging the expansion

$$\hat{\Phi}_\ell=\sum_{k=0}^{\infty}a_k\rho^{-(\ell+k)} \tag{A2}$$

into (A1), assuming $a_0=1$, and balancing terms, we find the recursion relation

$$\beta_k a_{k+3}+\gamma_k a_{k+2}+\delta_k a_{k+1}+\epsilon_k a_k=0, \tag{A3}$$

where

$$\begin{aligned}\beta_k&=4n^2[(\ell+k+3)(\ell+k+4)-2(n+1)],\\ \gamma_k&=4n(\ell+k+2)[(3-n)(\ell+k+3)-n]-12n^2,\\ \delta_k&=(\ell+k+1)[(9-12n)(\ell+k+2)-12n]-18n,\\ \epsilon_k&=-9(\ell+k+1)^2.\end{aligned} \tag{A4}$$

Again $n=\frac{1}{2}(\ell-1)(\ell+2)$, and in the start-up, $\delta_{-2}=0=\epsilon_{-2}$, and $\epsilon_{-1}=0$. The origin value of the FDRK is

$$\hat{\omega}_\ell^Z(0;\rho_B)=-\sum_{k=0}^{\infty}(\ell+k)a_k\rho_B^{-(\ell+k)}\Bigg/\sum_{k=0}^{\infty}a_k\rho_B^{-(\ell+k)}. \tag{A5}$$

Despite the four-term recursion relation used to generate the series and its ρ derivative, in using (A5) we have encountered no numerical instabilities.

APPENDIX B: ASYMPTOTIC EXPANSION FOR OUTGOING SOLUTION

To generate initial data for our numerical methods based on path integration in the complex z plane (or sometimes the complex ρ plane), we use the asymptotic expansion (26) about the irregular singular point at infinity. Paper I describes this expansion for all the Regge–Wheeler cases, showing that the $d_k^{RW}(\sigma)$ obey a three-term recursion relation. For the Zerilli case, we write the expansion coefficients as $d_k^Z(\sigma)=g_k(\sigma)\sigma^k$, then finding that the $g_k(\sigma)$ obey the five-term recursion relation

$$A_k g_{k+4}+B_k g_{k+3}+C_k g_{k+2}+D_k g_{k+1}+E_k g_k=0, \tag{B1}$$

where

$$\begin{aligned}A_k&=8\sigma n^2(k+4),\\ B_k&=4n(k+3)[6\sigma+n(k+4)]-8n^2(n+1),\\ C_k&=(k+2)[18\sigma-4n^2+(12n-4n^2)(k+3)]-12n^2,\\ D_k&=(k+1)[(9-12n)(k+2)-12n]-18n,\end{aligned} \tag{B2}$$

$$E_k = -9(k+1)^2.$$

Here again $n=\frac{1}{2}(\ell-1)(\ell+2)$, and in the start-up $C_{-3}=D_{-3}=E_{-3}=0$, $D_{-2}=E_{-2}=0$, and $E_{-1}=0$. Typically, we have used fewer than ten terms in the expansion (26) to generate initial data for numerical integration, and have encountered no problems in using this expansion (despite potentially tricky issues associated with high-order recursions). We have used dimensionless coordinates and Laplace rather than Fourier transform. Adjusting for these choices, (B1) and (B2) agree with an expansion given by Chandrasekhar and Detweiler in Ref. 34.

(Received 8 June 2005; accepted 6 July 2005; published online 27 October 2005)

This paper deals thoroughly with the scalar and electromagnetic fields of uniformly accelerated charges in de Sitter space–time. It gives details and makes various extensions of our Physical Review Letter from 2002. The basic properties of the classical Born solutions representing two uniformly accelerated charges in flat space–time are first summarized. The worldlines of uniformly accelerated particles in de Sitter universe are defined and described in a number of coordinate frames, some of them being of cosmological significance, the others are tied naturally to the particles. The scalar and electromagnetic fields due to the accelerated charges are constructed by using conformal relations between Minkowski and de Sitter space. The properties of the generalized "cosmological" Born solutions are analyzed and elucidated in various coordinate systems. In particular, a limiting procedure is demonstrated which brings the cosmological Born fields in de Sitter space back to the classical Born solutions in Minkowski space. In an extensive Appendix, which can be used independently of the main text, nine families of coordinate systems in de Sitter space–time are described analytically and illustrated graphically in a number of conformal diagrams. © *2005 American Institute of Physics.*

I. INTRODUCTION

In 1969, on the 60th anniversary of Max Born's[1] first analysis of the field of a uniformly accelerated charge, Ginzburg, Nobelist in 2003, reanalyzed[2–4] this—what he called—"perpetual problem of classical physics," with the conclusion that the problem "is already clear enough not to be regarded as perpetual." Ginzburg confirmed the presence of radiation and emphasized that the vanishing of the radiation reaction force during the uniformly accelerated motion of the charge "is in no way paradoxical, in spite of the presence of radiation," since "a nonzero total energy flux through a surface surrounding a charge at a zero radiation force is exactly equal to the decrease of the field energy in the volume enclosed by this surface." Despite Ginzburg's view, however, the problem does not seem to lose its "perpetuity." A number of distinguished physicists who dealt with it before Ginzburg like Sommerfeld, Schott, von Laue, Pauli and others have, after Ginzburg, been followed by such authors as, for example, Bondi,[5] Boulware,[6] Peierls,[7] Thirring[8] and others.[9–12]

The fields and radiation patterns from uniformly accelerated general multipole particles were also studied.[13] The December 2000 issue of Annals of Physics contains three papers by Eriksen and Grøn[14–16] with numerous references on "electrodynamics of hyperbolically accelerated charges." (Yet, except for Refs. 1 and 6, the explicit citations above are not contained in Refs. 14–16.)

Space–times describing "uniformly accelerated particles or black holes" play fundamental role in general relativity. They are the only explicit solutions of Einstein's field equations known which

[a]Electronic mail: bicak@mbox.troja.mff.cuni.cz
[b]Electronic mail: pavel.krtous@mff.cuni.cz

are radiative and represent the fields of finite sources. Born fields in electrodynamics are produced by two charges moving along an "axis of symmetry" in opposite directions with uniform accelerations of the same magnitude. They have two symmetries: they are axially symmetric and symmetric with respect to the boosts along the axis of symmetry. Their general-relativistic counterparts, the boost-rotation symmetric space–times, are unique because of a theorem which roughly states that in axially symmetric, locally asymptotically flat space–times the only additional symmetry that does not exclude radiation is the boost symmetry. The boost-rotation symmetric space–times have been used in gravitational radiation theory, quantum gravity, and as test beds in numerical relativity; their general structure is described in Ref. 17, their applications and new references are given in the reviews.[18–20] One of the best known examples, the so-called C-metric, describing uniformly accelerated black holes, is the only boost-rotation symmetric solution known also for a nonvanishing cosmological constant Λ. Asymptotically this "generalized" C-metric approaches de Sitter space–time if $\Lambda>0$. It is well known from the classical work of Penrose[21] on the asymptotic properties of fields and space–times that, in contrast to asymptotically Minkowskian space–times with null (lightlike) conformal infinities $\mathcal{I}^{\pm}$, asymptotically de Sitter vacuum space–times have two disjoint conformal infinities, past and future, which are both *spacelike*. When $\Lambda<0$, as in anti-de Sitter space, the conformal infinity is timelike, and it is not disjoint. (In the analytically extended C-metrics, there is an infinite number of such infinities which can be reached by going "through" black holes like with a Reissner-Nordtröm black hole, but this is not pertinent to the present work.)

The importance of de Sitter space–time in the history of modern cosmology seems to grow steadily. The "flat" de Sitter universe became the standard cosmological model in steady state theory, more recently, as the "first approximation" of inflationary models, and today, with indications that $\Lambda>0$ in our Universe, it is an asymptote of all indefinitely expanding Friedmann-Robertson-Walker models with $\Lambda>0$. In fact much more general cosmological models with $\Lambda>0$ approach de Sitter model asymptotically in time. This manifestation of the validity of the "cosmic no-hair conjecture,"[22,23] will also be noticed in the properties of the fields analyzed in this work.

Motivated by the role of the Born solution in classical electrodynamics, by the importance of the boost-rotation symmetric space–times in general relativity, and by the relevance of de Sitter space in contemporary cosmology, we have recently generalized the Born solution for scalar and electromagnetic fields to the case of two charges uniformly accelerated in de Sitter universe.[24] In the present paper we give calculations and detailed proofs of the results and statements briefly sketched in our paper.[25] In addition, we investigate the character of the field in a number of various coordinate systems which are relevant either in a general-relativistic context or from a cosmological perspective.

The appropriate coordinates and corresponding tetrad fields were important in finding our recent results on a general asymptotic behavior of fields in the neighborhood of future infinity $\mathcal{I}^{+}$ in asymptotically de Sitter space–times.[26] In obtaining these results we were inspired by the inspection of the electromagnetic fields from uniformly accelerated charges in de Sitter universe.

It was known from the work of Penrose since late 1960s that the radiation field is "less invariantly" defined when $\mathcal{I}^{+}$ is spacelike—that it depends on the direction in which $\mathcal{I}^{+}$ is approached. However, no explicit models were available. The investigation of the test fields of accelerated charges in de Sitter universe has served as a useful example; it was then generalized also to the study of asymptotic and radiative properties of the C-metric with $\Lambda>0$ (Ref. 27), as well as to the case of the C-metric with $\Lambda<0$ when infinity is timelike.[28] (For other recent works on the "cosmological" C-metric, see, e.g., Refs. 29 and 30.) These studies led to a more general conclusion[26] that the directional pattern of gravitational and electromagnetic radiation near de Sitter-like conformal infinity has a universal character, determined by the algebraic (Petrov) type of a solution of the Maxwell/Einstein equations considered. In particular, the radiation field vanishes along directions opposite to principal null directions. Very recently analogous conclusions have been obtained for space–times with anti-de Sitter asymptotics.[31]

Since past and future infinities are spacelike in de Sitter space–time, there exist particle and

event horizons. Under the presence of the horizons, purely retarded fields (appropriately defined) become singular or even cannot be constructed at the "creation light cones," i.e., at future light cones of the "points" at $\mathcal{I}^-$ at which the sources "enter" the universe. In Ref. 24 we analyzed this phenomenon in detail and constructed smooth (outside the sources) fields involving both retarded and advanced effects. As demonstrated in Ref. 24, to be "born in de Sitter" is quite a different matter than to be "born in Minkowski." This reveals the double meaning of the second—perhaps somewhat enigmatic—part of the title of this paper.

Its plan is as follows. In order to gain an understanding of the generalized Born solution in de Sitter space it is advantageous to be familiar with some details of the classical Born solution in Minkowski space. Hence, its properties most relevant for our purpose are summarized in Sec. II. Here we also discuss why in Minkowski space problems with purely retarded fields of uniformly accelerated particles do not arise.

There exists vast literature on de Sitter space in which various types of coordinates are employed. We shall construct fields in de Sitter space by using its conformal relations to Minkowski space. For our aim coordinate systems on conformally compactified spaces and their properties will be particularly useful. These, together with several "cosmological" and "static" coordinate systems, will be described and graphically illustrated in conformal diagrams in Sec. III. What is meant by "uniformly accelerated particles in de Sitter space" is defined and the properties of the corresponding worldlines are studied in Sec. IV. For technical reasons it is more advantageous to consider particles which asymptotically start and end at the poles of coordinates covering de Sitter space, i.e., particles "born at the poles" (Sec. IV A). In order to find a direct relation between the standard form of the Born solution produced by two charges at each time located symmetrically with respect to the origin of Minkowski space and the generalized Born solution in de Sitter space, it is necessary to construct also worldlines of uniformly accelerated particles which are "born at the equator" (Sec. IV B).

With the worldlines of accelerated particles available, it is advantageous to consider coordinates in de Sitter space which are centered on these worldlines. These "accelerated coordinates" and "Robinson-Trautman coordinates" are obtained, in a constructive manner, in Sec. V.

Section VI is devoted to the fields from particles "born at the poles." Here we also study in detail their properties in various coordinate systems introduced before. The fields of particles "born at the equator" are found in Sec. VII by a simple rotation. Starting from these fields we demonstrate by means of which limiting procedure the standard Born field in Minkowski space can be regained. Finally, we conclude by few remarks in Sec. VIII.

The paper contains a rather extensive Appendix in which nine families of coordinate systems employed in the main text are described in detail, illustrated graphically, their relations are given, and corresponding metric forms as well as orthonormal tetrads are presented. We believe the Appendix can be used as a general-purpose catalogue in other studies of physics in de Sitter space–time.

II. BORN IN MINKOWSKI

It was Einstein in 1908, inspired by a letter from Planck, who first defined a uniformly accelerated motion in special relativity.[32,33] A particle is in uniformly accelerated motion if its acceleration has a fixed constant value in instantaneous rest frames of the particle. This can be stated in a covariant form (see, e.g., Ref. 34) as

$$P^{\alpha}_{\mu}\dot{a}^{\mu} = \dot{a}^{\alpha} - (a^{\mu}a_{\mu})u^{\alpha} = 0, \tag{2.1}$$

u^{α} being four-velocity, $\dot{} \equiv u^{\mu}\nabla_{\mu}$ covariant derivative with respect to proper time, $a^{\alpha}=\dot{u}^{\alpha}$ four-acceleration, and $P^{\alpha}_{\mu}=\delta^{\alpha}_{\mu}+u^{\alpha}u_{\mu}$ is the projection tensor into the hypersurface orthogonal to u^{α}. Equation (2.1) implies $\dot{a}^{\mu}a_{\mu}=0$ so that the condition of uniform acceleration guarantees that the magnitude of the four-acceleration is constant,

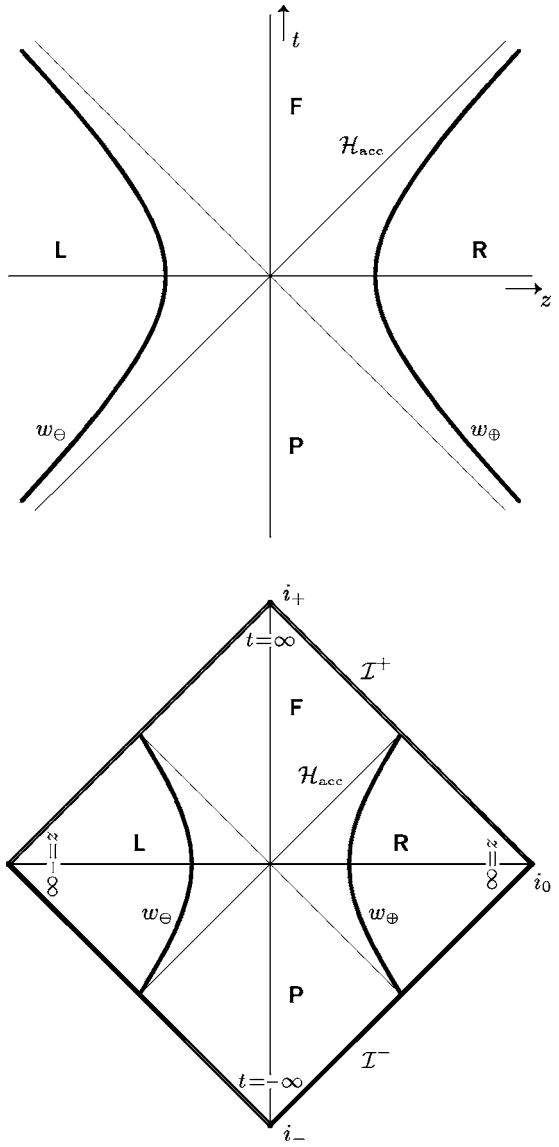

FIG. 1. A pair of uniformly accelerated charges in Minkowski space–time (with the conformal diagram below). The boost Killing vector is timelike in regions **L** and **R**; it is spacelike in **F** and **P**. The charges are causally disconnected by null hypersurfaces ("the roof") $-t^2+z^2=0$. These hypersurfaces represent the acceleration horizon for uniformly accelerated observers with respect to which the charges are at rest.

$$a_{\mathrm{M}} = \sqrt{\mathrm{a}^\mu \mathrm{a}_\mu} = \text{constant}, \tag{2.2}$$

although $\dot{\mathrm{a}}^\mu \neq 0$. Integrating Eq. (2.1) in Minkowski space–time, one finds that the worldline of a uniformly accelerated particle is a hyperbola.[35,36] One can then choose an inertial frame, in which the initial three-velocity and three-acceleration are parallel; in such frames the motion is spatially one-dimensional. It can be produced by placing a test charged particle into a homogeneous electric field with initial velocity aligned with the field. The motion along the z axis is illustrated in Fig. 1. There, in fact, *two* particles uniformly accelerated in opposite directions are shown, the one moving along the positive ($\varepsilon=+1$ for particle $w_\oplus$ in the figure) and the second one along the negative z axis ($\varepsilon=-1$ for particle $w_\ominus$); their worldlines parametrized by proper time λ_{M} are

$$z = \varepsilon b_{\mathrm{o}} \cosh\frac{\lambda_{\mathrm{M}}}{b_{\mathrm{o}}}, \quad t = b_{\mathrm{o}} \sinh\frac{\lambda_{\mathrm{M}}}{b_{\mathrm{o}}}, \quad x = y = 0, \tag{2.3}$$

or

$$z = \varepsilon\sqrt{t^2 + b_{\mathrm{o}}^2}. \tag{2.4}$$

Here we have chosen the particles to be at rest at $z=\varepsilon b_{\mathrm{o}}$ at $t=0$. Then their three-acceleration at initial moment $t=0$ is $a_{\mathrm{M}}=|\mathrm{d}^2z/\mathrm{d}t^2|=1/b_{\mathrm{o}}$. As $t\to\infty$, the three-velocity $v_{\mathrm{M}}=|\mathrm{d}z/\mathrm{d}t|=t/\sqrt{t^2+b_{\mathrm{o}}^2}$ approaches the velocity of light. This is the well-known hyperbolic motion.

The worldlines of the particles coincide with the orbits of the boost Killing vector in the t–z plane,

$$\xi_{\mathrm{boost}} = z\frac{\partial}{\partial t} + t\frac{\partial}{\partial z}. \tag{2.5}$$

These orbits, given by $-t^2+z^2=$constant, $x,y=$constant, are timelike at $-t^2+z^2>0$, but they are spacelike at $-t^2+z^2<0$. The fields (scalar, electromagnetic, higher-spin) produced by charged particles in the hyperbolic motion will have boost-rotational symmetry. They are thus static in the region $-t^2+z^2>0$—"below the roof" as introduced in Ref. 17, however, we can expect them to be radiative in the region $-t^2+z^2<0$—"above the roof."

Consider a massless scalar field Φ with the scalar charge source S satisfying, in a general four-dimensional space–time, the wave equation

$$\left[\Box - \tfrac{1}{6}R\right]\Phi = S, \tag{2.6}$$

in which $\Box \equiv g^{\mu\nu}\nabla_\mu\nabla_\nu$ is the curved-space d'Alambertian, and R is the scalar curvature (of course, in Minkowski space $R=0$). We are interested in a field due to two monopole particles with the same constant scalar charge of magnitude s moving along hyperbolae (2.3). The source at a space–time point x is thus given by

$$S = S_{\oplus} + S_{\ominus}, \quad S_{\varepsilon} = s\int \delta(x - w_{\varepsilon}(\lambda_{\mathrm{M}}))\mathrm{d}\lambda_{\mathrm{M}}, \tag{2.7}$$

where $w_{\varepsilon}(\lambda_{\mathrm{M}})$ denotes the worldlines of the particles. The resulting fields may be written as

$$\Phi = \Phi_{\oplus} + \Phi_{\ominus}, \tag{2.8}$$

where Φ_{ε} is produced by S_{ε}. The retarded and advanced fields of these sources are constructed and analyzed in detail in Ref. 17. It can be demonstrated that the retarded and advanced fields due to the particle $w_{\oplus}$ or $w_{\ominus}$ are all given by exactly *identical* expression

$$\Phi_{\mathrm{BM}} = \frac{s}{4\pi}\frac{1}{\mathcal{R}}, \tag{2.9}$$

which, however, occurs in different regions of space–time. Namely,

$$\Phi_{\mathrm{ret/adv}\ \varepsilon} = \frac{s}{4\pi}\frac{1}{\mathcal{R}}\theta\,(\varepsilon z \pm t), \tag{2.10}$$

θ being the step function and upper/lower sign is valid for retarded/advanced case. The quantity $\mathcal{R}$ in the denominator is given by

$$\mathcal{R} = \frac{1}{2b_o}((b_o^2 + t^2 - r^2)^2 + 4b_o^2 r^2 \sin^2 \vartheta)^{1/2}. \tag{2.11}$$

It has the meaning of a retarded or advanced distance—it is a spatial distance of the "observation" (field) point from the position of the source at retarded or advanced time. Here, as usual, $x=r\sin\vartheta\cos\varphi$, $y=r\sin\vartheta\sin\varphi$, $z=r\cos\vartheta$. The fields (2.9), as well as (2.10), are, at first glance, axially (rotationally) symmetric. They are also unchanged under the boost along the z axis.

The field Φ_{BM} can, in fact, be viewed as the field due to both accelerated particles, i.e., as the field corresponding to the source (2.7). Inspecting regions at which the retarded and advanced fields (2.10) are nonvanishing we discover that Φ_{BM} admits the interpretation as arising from 1-parametric combination of retarded and advanced effects from both particles,

$$\Phi_{\mathrm{BM}} = \xi\,\Phi_{\mathrm{ret}\oplus} + (1-\xi)\,\Phi_{\mathrm{adv}\oplus} + (1-\xi)\,\Phi_{\mathrm{ret}\ominus} + \xi\,\Phi_{\mathrm{adv}\ominus}, \tag{2.12}$$

where $\xi\in\mathbb{R}$ is an arbitrary constant parameter. In particular, choosing $\xi=\frac{1}{2}$, the field Φ_{BM} arises from $\frac{1}{2}(\Phi_{\mathrm{ret}}+\Phi_{\mathrm{adv}})$ from both particles. With $\xi=1$, the field can be interpreted as being caused by purely retarded effects from particle $w_\oplus$ in region $z+t>0$, and by purely advanced effects from particle $w_\ominus$ in region $z+t<0$.

The case of electrodynamics is very similar. The solution corresponding to the scalar field (2.9) was found by Born in 1909.[1] It is customarily given in cylindrical coordinates (see, e.g., Refs. 34, 37, and 14), however, in order to compare it with its generalization to de Sitter universe, it is more convenient to write it down in spherical coordinates,

$$\begin{aligned}\mathrm{F}_{\mathrm{BM}} = -\frac{e}{4\pi}\frac{1}{2b_o}\frac{1}{\mathcal{R}^3}(&-(b_o^2+t^2-r^2)\cos\vartheta\,\mathrm{d}t\wedge\mathrm{d}r + (b_o^2+t^2+r^2)r\sin\vartheta\,\mathrm{d}t\wedge\mathrm{d}\vartheta.\\ &-2tr^2\sin\vartheta\,\mathrm{d}r\wedge\mathrm{d}\vartheta\end{aligned} \tag{2.13}$$

The field can be obtained from the Liénard-Wiechert retarded and advanced potentials of two charged particles moving along hyperbolae (2.3), however, in contrast to the scalar case when charges are exactly the same, the electric charges have opposite signs. Similarly to the scalar case, the field is smooth everywhere, except for the places where the particles occur. F_{BM} can be interpreted in the precisely same way as the scalar field (2.9), i.e., as the 1-parametric combination of retarded and advanced effects from both charges, analogously to Eq. (2.12). However, in the electromagnetic case an exact form of retarded and advanced fields from a single particle is a more subtle issue. Considering that the field in the region $z+t>0$ may be interpreted as the retarded effect emitted from the charge which moves along $z>0$, it is natural to try to exclude advanced effects of the other particle by requiring the field to vanish in the region $z+t<0$ (cf. Fig. 1). The field is then not smooth at the null hypersurface $z=-t$. In the scalar case such a field does represent the pure retarded field of the single particle, cf. Eq. (2.10). However, in the electromagnetic case the field $\mathrm{F}_{\mathrm{BM}}\theta(z+t)$ corresponds to sources consisting not only of the particle but also of a "charged wall" moving along hypersurface $z+t=0$ with velocity of light.[38,5] Nevertheless, it is possible to obtain[6,39,40] a pure retarded field of the only single particle by modifying the field with a delta function valued term localized on $z+t=0$.

In de Sitter space such a modification is not feasible because the advanced fields cannot be excluded. The underlying cause is the null character of the past conformal infinity in Minkowski space–time, whereas in de Sitter space–time both future and past conformal infinities are spacelike. As a consequence, the Gauss constraint restricts the data at the spacelike past infinity, and it can be shown that a purely retarded field of a pointlike charge cannot satisfy this constraint.[24] The absence of purely retarded fields is also related to a different character of the past horizon of a particle. Since the worldline of a particle "enters" the universe through the past spacelike infinity, there exists the past particle horizon, called also the creation light cone. In de Sitter space a purely retarded electromagnetic field of a pointlike charge cannot be constructed on the whole cone. In Minkowski space–time the creation light cone of a particle moving asymptotically in the past

freely, coincides with the whole past null infinity, and thus it does not belong to the physical space–time. Eternally accelerated particles can "enter" the Minkowski space–time at a point of the past null infinity—as, for example, uniformly accelerated particles do. Like in de Sitter case, in conformal space–time the past horizon of such particles forms the null cone but, in contrast to de Sitter space, it has one generator in common with the null infinity. In physical space–time this horizon thus corresponds to a null hyperplane—for the particle $w_{\oplus}$ it is just the hyperplane $z+t=0$ (cf. Fig. 1)—and so its spatial sections are not compact. Thanks to this noncompactness the "bad" behavior of the retarded field on the horizon can be "pushed out of sight" to the infinity. We analyzed this issue in detail in Ref. 24.

III. MANY FACES OF DE SITTER

The fields due to various types of uniformly accelerated sources in de Sitter space–time found in Ref. 24, as well as those described briefly in Ref. 25, were constructed by employing the conformal relation between Minkowski and de Sitter space–times. When analyzing the worldlines of the sources in de Sitter space–time and their relation to the corresponding worldlines in Minkowski space–time we need to introduce appropriate coordinate systems. Suitable coordinates will later be used to exhibit various properties of the fields. An extensive literature exists on various types of coordinates in de Sitter space (e.g., Refs. 41 and 42); we will survey some of them in this section. In particular, we relate them to the corresponding coordinates on conformally related Minkowski spaces since this does not appear to be given elsewhere. In the next section, after identifying the worldlines of uniformly accelerated particles in de Sitter space, we shall construct coordinate systems tied to such particles, such as Rindler-type "accelerated" coordinates, or Robinson-Trautman-type coordinates in which the null cones emanating from the particles have especially simple forms. These coordinate systems will turn out to be very useful in analyzing the fields. Here, in the main text, however, only a brief description of relevant coordinates will be given. More details, including both formulas and illustrations, are relegated to the Appendix.

As it is well known from textbooks on general relativity (for a recent pedagogical exposition, see Ref. 43), de Sitter space–time, which is the solution of Einstein vacuum equations with a cosmological term $\Lambda>0$, is best visualized as the four-dimensional hyperboloid imbedded in flat five-dimensional Minkowski space. It is the homogeneous space of constant curvature equal to 4Λ. Hereafter, we use the quantity

$$\ell_\Lambda = \sqrt{\frac{3}{\Lambda}} \tag{3.1}$$

(with the dimension of length) to parametrize the radius of the curvature.

The entire de Sitter space–time can be covered by a single coordinate system—which we call standard coordinates—$\tau\in\mathbb{R}$, $\chi\in(0,\pi)$, $\vartheta\in(0,\pi)$, $\varphi\in(-\pi,\pi)$ in which the metric reads

$$g_{\mathrm{dS}} = -\,\mathrm{d}\tau^2 + \ell_\Lambda^2 \cosh^2\frac{\tau}{\ell_\Lambda}(\mathrm{d}\chi^2 + \sin^2\chi\,\mathrm{d}\omega^2), \tag{3.2}$$

$$\mathrm{d}\omega^2 = \mathrm{d}\vartheta^2 + \sin^2\vartheta\,\mathrm{d}\varphi^2. \tag{3.3}$$

Clearly, we can imagine the space–time as the time evolution of a 3-sphere which shrinks from infinite extension at $\tau\to-\infty$ to a radius ℓ_Λ, and then expands again in a time-symmetric way. Hence, we also call τ,χ the spherical cosmological coordinates. The coordinate lines are shown in the conformal diagram, Fig. 2.

In cosmology the most popular "flat" de Sitter universe is obtained by considering only a half of de Sitter hyperboloid foliated by flat three-dimensional spacelike hypersurfaces labeled by timelike coordinate $\check{\tau}\in\mathbb{R}$, cf. Fig. 3. Together with appropriate radial coordinate $\check{r}\in\mathbb{R}^+$, the coordinates, which we call flat cosmological coordinates, are given in terms of τ,χ by

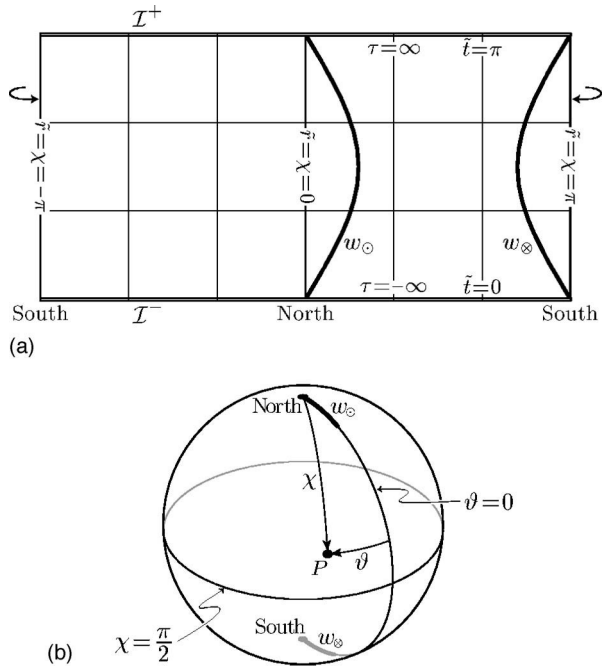

FIG. 2. The spherical cosmological coordinates and a pair of uniformly accelerated particles $w_\odot$ and $w_\otimes$ in de Sitter universe: the conformal diagram (above) and projection on the spacelike cut τ=constant in the standard cosmological spherical coordinates (angle φ suppressed). The whole de Sitter space–time could be represented by just the "right half" of the conformal diagram. For convenience, we admit negative values of radial coordinates and identify $\tilde{r}=\chi=-\pi$ and $\tilde{r}=\chi=\pi$ [see the text below Eq. (3.12) and the Appendix].

$$\check{\tau}=\ell_\Lambda \log\left(\sinh\frac{\tau}{\ell_\Lambda}+\cosh\frac{\tau}{\ell_\Lambda}\cos\chi\right), \quad \check{r}=\ell_\Lambda\frac{\sin\chi}{\cos\chi+\tanh(\tau/\ell_\Lambda)}, \tag{3.4}$$

implying the well-known "inflationary" metric

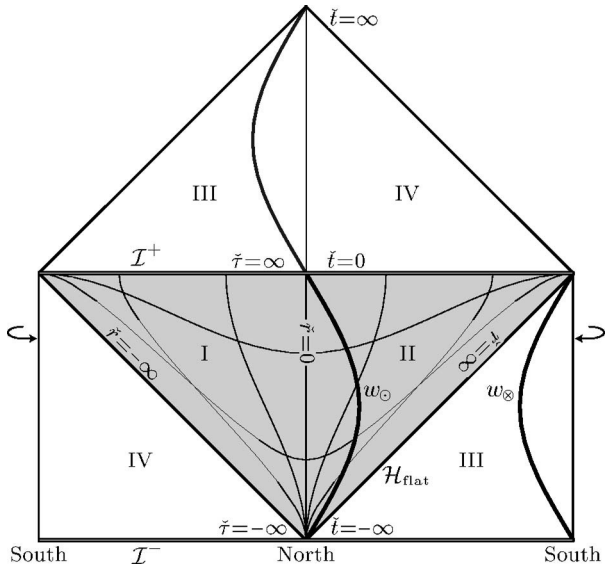

FIG. 3. The flat cosmological coordinates and particles $w_\odot, w_\otimes$ in de Sitter space and in conformally related Minkowski space. The flat cosmological coordinates cover shaded region. Its boundary, $\check{r}=\pm\infty$, represents the horizon for observers at rest in these coordinates.

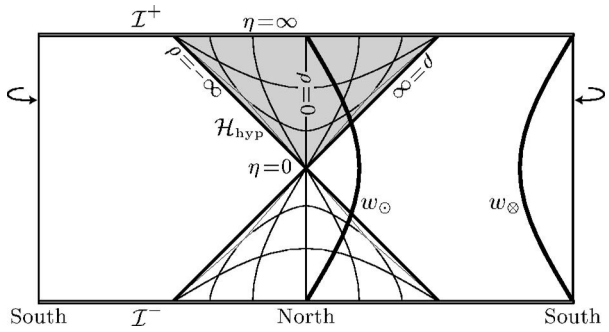

FIG. 4. The hyperbolic cosmological coordinates. They cover only the shaded region and, therefore, only a part of the worldline $w_\odot$. The horizon $\mathcal{H}_{\rm hyp}$ arises for the observers who are at rest in the hyperbolic cosmological coordinates.

$$g_{\rm dS} = -\,\mathrm{d}\check{\tau}^2 + \exp\frac{2\check{\tau}}{\ell_\Lambda}(\mathrm{d}\check{r}^2 + \check{r}^2\,\mathrm{d}\omega^2). \tag{3.5}$$

These coordinates cover only "one-half" of de Sitter space as indicated by shading in Fig. 3.

de Sitter introduced his model in what we call hyperbolic cosmological coordinates $\eta\in\mathbb{R}$, $\rho\in\mathbb{R}^+$ (see Fig. 4) related to τ,χ by

$$\cosh\frac{\eta}{\ell_\Lambda} = \cosh\frac{\tau}{\ell_\Lambda}\cos\chi, \quad \tanh\frac{\rho}{\ell_\Lambda} = \coth\frac{\tau}{\ell_\Lambda}\sin\chi. \tag{3.6}$$

The metric

$$g_{\rm dS} = -\,\mathrm{d}\eta^2 + \sinh^2\frac{\eta}{\ell_\Lambda}\left(\mathrm{d}\rho^2 + \ell_\Lambda^2\sinh^2\frac{\rho}{\ell_\Lambda}\mathrm{d}\omega^2\right) \tag{3.7}$$

shows that the time slices η=constant have the geometry of constant negative curvature, i.e., as the standard time slices in an open FRW universe.

The last commonly used coordinates in de Sitter space–time are static coordinates $T\in\mathbb{R}$, $R\in(0,\ell\Lambda)$,

$$T = \frac{\ell_\Lambda}{2}\log\left|\frac{\cos\chi+\tanh(\tau/\ell_\Lambda)}{\cos\chi-\tanh(\tau/\ell_\Lambda)}\right|, \quad R = \ell_\Lambda\cosh\frac{\tau}{\ell_\Lambda}\sin\chi, \tag{3.8}$$

covering also only a part of the universe. The metric in these coordinates reads

$$g_{\rm dS} = -\left(1-\frac{R^2}{\ell_\Lambda^2}\right)\mathrm{d}T^2 + \left(1-\frac{R^2}{\ell_\Lambda^2}\right)^{-1}\mathrm{d}R^2 + R^2\,\mathrm{d}\omega^2, \tag{3.9}$$

revealing that $\partial/\partial T$ is a timelike Killing vector in the region $0<R<\ell_\Lambda$.

Among the coordinates introduced until now only the standard coordinates $\tau,\chi,\vartheta,\varphi$ cover the whole de Sitter space–time globally. One can easily extend flat cosmological coordinates to cover (though not smoothly) the whole de Sitter hyperboloid, which will be useful in discussion of the conformally related Minkowski space–time, cf. Eq. (3.13). We shall also use extensions of the static coordinates into the whole space–time, using definitions (3.8), but allowing $R\in\mathbb{R}^+$. In regions where $R>\ell_\Lambda$ coordinates T and R interchange their character, $\partial/\partial T$ becomes a spacelike Killing vector (analogously to $\partial/\partial t$ inside a Schwarzschild black hole). However, the static coordinates T,R are not globally smooth and uniquely valued. Namely, $T\to\infty$ at the cosmological horizons $R=\ell_\Lambda$. The static coordinates, extended to the whole de Sitter space, are illustrated in Fig. 5. Here we also indicate the regions in which $\partial/\partial T$ is spacelike by bold **F** ("future") and **P** ("past"), whereas the regions in which it is timelike are denoted by **N** (containing the "north pole" $\chi=0$) and **S** (containing the "south pole" $\chi=\pi$). Hereafter, this notation will be used repeatedly.

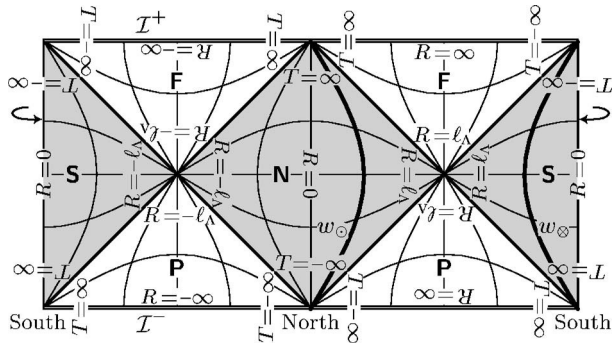

FIG. 5. The static coordinates and the worldlines of particles $w_\odot$ and $w_\otimes$. These coordinates can be defined in the whole space–time, however several coordinate patches, in diagram indicated by shaded and nonshaded regions, have to be used (cf. sections 5 and 6 of the Appendix). These regions are separated by the cosmological horizons at $R=\ell_\Lambda$, where $T=\pm\infty$. The vector $\partial/\partial T$ is a Killing vector of de Sitter space–time. It is timelike in the domains **N** and **S** (shaded regions) and spacelike in the domains **F** and **P**. The histories of both particles $w_\odot$ and $w_\otimes$ belong to the domains **N** and **S**.

The conformal structure of Minkowski and de Sitter space–times, their conformal relation, and their conformal relation to various regions of the Einstein static universe have been discussed extensively in literature (see, e.g., Refs. 44–47). The complete compactified picture of these space–times, in particular the three-dimensional diagram of the compactified Minkowski and de Sitter spaces $M^{\#}$ as parts of the Einstein universe represented by *a solid* cylinder can be found in Ref. 24. We refer the reader especially to Sec. III of Ref. 24 where we explain and illustrate the compactification in detail. In the present paper we shall confine ourselves to the two-dimensional Penrose diagrams.

The basic standard rescaled coordinates covering globally de Sitter space–time including the conformal infinity are simply related to the standard coordinates as follows:

$$\tan\frac{\tilde{t}}{2}=\exp\frac{\tau}{\ell_\Lambda},\quad \tilde{r}=\chi, \tag{3.10}$$

$\tilde{t}\in(0,\pi),\tilde{r}\in(0,\pi)$. The metric (3.2) becomes

$$g_{\mathrm{dS}}=\ell_\Lambda^2\sin^{-2}\tilde{t}\,(-\mathrm{d}\tilde{t}^2+\mathrm{d}\,\tilde{r}^2+\sin^2\tilde{r}\,\mathrm{d}\omega^2), \tag{3.11}$$

demonstrating explicitly the conformal relations of de Sitter space–time to the Einstein universe,

$$g_{\mathrm{E}}=\Omega_{\mathrm{dS}}^2\,g_{\mathrm{dS}},\quad \Omega_{\mathrm{dS}}=\sin\tilde{t}. \tag{3.12}$$

Therefore, we also call coordinates $\tilde{t},\tilde{r}$ the conformally Einstein coordinates. The conformal diagram of de Sitter space–time is illustrated in Fig. 2. The past and future infinities, $\tilde{t}=0$ and $\tilde{t}=\pi$ are spacelike, the worldlines of the north and south poles (given by the choice of the origin of the coordinates) are described by $\tilde{r}=\chi=0$ and $\tilde{r}=\chi=\pi$.

The whole de Sitter space–time could be represented by just the "right half" of Fig. 2. Indeed, it is customary to draw this half only and to consider any point in the figure as a 2-sphere, except for the poles $\tilde{r}=0,\pi$. As we shall see, the formulas relating coordinates on the conformally related de Sitter and Minkowski space–times have simpler forms if we admit negative values of the radial coordinate $\tilde{r}\in(-\pi,0)$ covering the left half of the diagram. We shall thus consider the two-dimensional diagrams as in Fig. 2 to represent the cuts of de Sitter space–time along the axis going through the origins (through north and south poles—analogously to the cuts along the z axis in E^3). The axis, i.e., the main circle of the spatial spherical section of de Sitter space–time, is typically chosen as $\vartheta=0,\pi$. Thus, in the diagram the point with $\tilde{r}=-\tilde{r}_{\mathrm{o}}<0$, $\vartheta=\vartheta_{\mathrm{o}}$, $\varphi=\varphi_{\mathrm{o}}$ is identical to that with $\tilde{r}=\tilde{r}_{\mathrm{o}}$, $\vartheta=\pi-\vartheta_{\mathrm{o}}$, and $\varphi=\varphi_{\mathrm{o}}+\pi$. We use the same convention also for other radial coordinates appearing later, as explicitly stated in the Appendix (cf. also Appendix in

Ref. 24). We admit negative radial coordinates only when describing various relations between the coordinate systems. In the expressions for the fields in the following sections only positive radial coordinates are considered.

As mentioned above, in Ref. 24 we constructed fields on de Sitter space–time by conformally transforming the fields from Minkowski space–time. Now "different Minkowski spaces" can be used in the conformal relation to de Sitter space, depending on which region of a Minkowski space is mapped onto which region of de Sitter space. Consider, for example, Minkowski space with metric g_{M} given in spherical coordinates $\check{t},\check{r},\vartheta,\varphi$. Identify it with de Sitter space by relations

$$\check{t}=\frac{\ell_\Lambda \sin\tilde{t}}{\cos\tilde{t}-\cos\tilde{r}}, \quad \check{r}=\frac{\ell_\Lambda \sin\tilde{r}}{\cos\tilde{r}-\cos\tilde{t}}, \tag{3.13}$$

the inverse relation (A11) is given in the Appendix. In the coordinates $\check{t}$, $\check{r}$, ϑ, φ the de Sitter metric (3.11) becomes

$$g_{\mathrm{dS}}=\frac{\ell_\Lambda^2}{\check{t}^2}\,(-\,\mathrm{d}\check{t}^2+\mathrm{d}\check{r}^2+\check{r}^2\,\mathrm{d}\omega^2), \tag{3.14}$$

so that

$$g_{\mathrm{dS}}=\Omega_{\check{\mathrm{M}}}^2 g_{\check{\mathrm{M}}}, \quad \Omega_{\check{\mathrm{M}}}=\frac{\ell_\Lambda}{\check{t}}. \tag{3.15}$$

The coordinates $\check{t}$, $\check{r}$, ϑ, φ can, of course, be used in both de Sitter and Minkowski spaces. Figure 3 illustrates the coordinate lines. It also shows how four regions I, II, III, and IV of Minkowski space are mapped onto four regions of de Sitter space by relations (3.13). We call $\check{t}$, $\check{r}$ rescaled flat cosmological coordinates since their radial coordinate $\check{r}$ coincides with that of the flat cosmological coordinates (3.4) and the time coordinate is simply related to $\check{\tau}$ as

$$\check{t}=-\,\ell_\Lambda \exp(-\,\check{\tau}/\ell_\Lambda). \tag{3.16}$$

The caron or the check (still better "háček") "$\vee$" formed by cosmological horizon at $\check{t}=\pm\infty$ in de Sitter space (cf. Fig. 3) inspired our notation of these coordinates. It is possible to introduce analogously the coordinates $\hat{t}$, $\hat{r}$ given in the Appendix, Eqs. (A39) and (A40), that cover nicely the past conformal infinity but are not smooth at the cosmological horizon $\hat{t}=\pm\infty$; in this case they form the hat "$\wedge$" in the conformal diagram (see Fig. 16 in the Appendix).

From relations (3.13) it is explicitly seen why, when writing down mappings between de Sitter and Minkowski spaces and drawing the corresponding two-dimensional conformal diagrams, it is advantageous to admit negative radial coordinates. If we would restrict all radial coordinates to be non-negative, we would have to consider the second relation in Eq. (3.13) with different signs for regions III and II in de Sitter space: in III $\check{r}=\ell_\Lambda \sin\tilde{r}/(\cos\tilde{r}-\cos\tilde{t})$, but in III we would have $\check{r}=-\ell_\Lambda \sin\tilde{r}/(\cos\tilde{r}-\cos\tilde{t})$.

Another mapping of Minkowski on de Sitter space will be used to advantage in the explicit manifestation that the generalized Born solution in de Sitter space goes over to the classical solution (2.13). Instead of the mapping (3.13), consider the relations

$$t=-\,\frac{\ell_\Lambda \cos\tilde{t}}{\cos\tilde{r}+\sin\tilde{t}}, \quad r=\frac{\ell_\Lambda \sin\tilde{r}}{\cos\tilde{r}+\sin\tilde{t}} \tag{3.17}$$

[see Eq. (A17) for the inverse mapping], which turn the metric (3.11) into

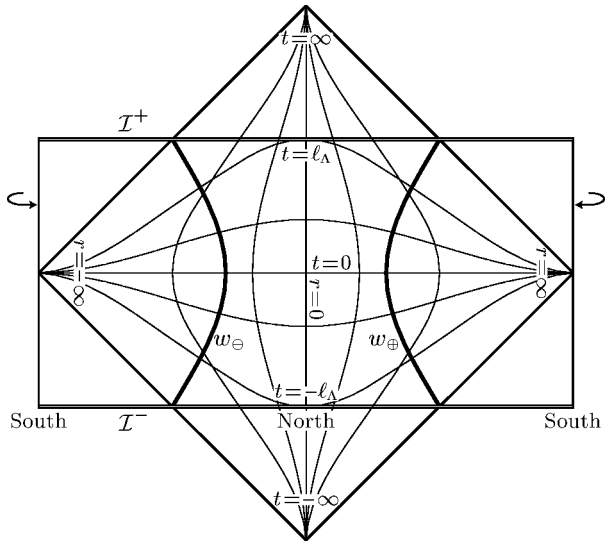

FIG. 6. The conformally Minkowski coordinates. They cover the whole conformally related Minkowski space but only a part of corresponding de Sitter space. This Minkowski space is related to that in Fig. 3 by a shift "downwards" by $\pi/2$ in the direction of the conformally Einstein coordinate $\tilde{\tau}$.

$$g_{\mathrm{dS}} = \left(\frac{2\ell_\Lambda^2}{\ell_\Lambda^2 - t^2 + r^2}\right)^2 (-\,\mathrm{d}t^2 + \mathrm{d}r^2 + r^2\,\mathrm{d}\omega^2). \tag{3.18}$$

We again obtain the de Sitter metric in the form explicitly conformal to the Minkowski metric with, however, a different conformal factor from that in Eq. (3.15),

$$g_{\mathrm{dS}} = \Omega_{\mathrm{M}}^2 g_{\mathrm{M}}, \quad \Omega_{\mathrm{M}} = \frac{2\ell_\Lambda^2}{\ell_\Lambda^2 - t^2 + r^2}. \tag{3.19}$$

[For the use of the de Sitter metric in "atypical" form (3.18) in the work on the domain wall space–times, see Ref. 48). The relation of Minkowski space to de Sitter space based on the mapping (3.17) is illustrated in Fig. 6. Clearly, the Minkowski space in this figure is shifted "downwards" by $\pi/2$ in $\tilde{\tau}$ coordinate, as compared with Minkowski space in Fig. 3. Indeed, replacing $\tilde{\tau}$ by $\tilde{\tau}+\pi/2$ in Eq. (3.13), we get $\check{t}=t$, $\check{r}=r$ with t, r given by Eq. (3.17). Since coordinates t, r, ϑ, φ are not connected directly with any cosmological model and correspond to Minkowski space "centered" on de Sitter space (Fig. 6), we just call them conformally Minkowski coordinates.

In Ref. 24 still another Minkowski space is related to de Sitter space—one which is shifted "downward" in $\tilde{\tau}$ coordinate by another $\pi/2$. As mentioned below Eq. (3.16), the cosmological horizon forms hat "$\wedge$" in this case and the corresponding coordinates are accordingly denoted as $\hat{t}$, $\hat{r}$. They are given explicitly in section 3 of the Appendix and Fig. 16.

The three sets of coordinates $\check{t}$, $\check{r}$, t, r, and $\hat{t}$, $\hat{r}$ (with the same ϑ, φ) relating naturally "three" Minkowski spaces to de Sitter space are suitable for different purposes. The third set describes conveniently the past infinity of de Sitter space—that is why it was used extensively in Ref. 24 where we were interested in how the sources enter (are "born in") de Sitter universe. The second set will be needed in Sec. VII for exhibiting the flat-space limit of the generalized Born solution. The first set describes nicely the future infinity and will be employed when analyzing radiative properties of the fields.

With all the coordinates discussed above, corresponding double null coordinates can be associated; some of them will also be used in the following. Their more detailed description and illustration is presented in section 10 of the Appendix.

Before concluding this section let us notice that the observers which are at rest in cosmological coordinate systems τ, χ, $\check{\tau}$, $\check{r}$, and η, ρ move along the geodesics with proper time τ, $\check{\tau}$, and η respectively. These geodesics are also the orbits of the conformal Killing vectors. Indeed, the symmetries of Minkowski space–time and of the Einstein universe become conformal symmetries in conformally related de Sitter space–time. In particular, we shall employ the fact that since $\partial/\partial\check{t}$ and $\partial/\partial t$ are timelike Killing vectors in Minkowski space–time and $\partial/\partial\tilde{t}$ is a timelike Killing vector in the Einstein universe, the vectors

$$\frac{\partial}{\partial\tilde{t}}, \quad \frac{\partial}{\partial\check{t}}, \quad \text{and} \quad \frac{\partial}{\partial t} \tag{3.20}$$

are timelike conformal Killing vectors in de Sitter space–time. As mentioned below Eq. (3.9), $\partial/\partial T$ is a Killing vector which is timelike for $|R|<\ell_\Lambda$.

IV. UNIFORMLY ACCELERATED PARTICLES IN DE SITTER

A. Particles born at the poles

In Sec. II we defined uniformly accelerated motion in Minkowski space–time. However, the formulas given there, being in covariant forms, remain valid in de Sitter space–time. As explained in Ref. 24 in detail, a simple way of obtaining a worldline of a uniformly accelerated particle in de Sitter space–time is to consider a suitable particle moving with a *uniform velocity* in Minkowski space–time and use the conformal relation between the spaces.

Consider a particle moving with a constant velocity of magnitude

$$v_{\check{M}} = \tanh\alpha_o = \text{constant}, \tag{4.1}$$

such that for $\alpha_o>0$ it moves in a negative direction along the $\check{z}$ axis of the inertial frame in Minkowski space $\check{M}$ with coordinates $\check{t}$, $\check{r}$, ϑ, φ and passes through $\check{r}=0$ at $\check{t}=0$,

$$\check{t} = \lambda_{\check{M}}\cosh\alpha_o, \quad \check{r} = -\lambda_{\check{M}}\sinh\alpha_o, \quad \vartheta = 0. \tag{4.2}$$

Substituting into transformation (A11), we find

$$\tilde{t} = \arctan\left(-2\ell_\Lambda\frac{\lambda_{\check{M}}\cosh\alpha_o}{\lambda_{\check{M}}^2-\ell_\Lambda^2}\right), \quad \tilde{r} = \arctan\left(-2\ell_\Lambda\frac{\lambda_{\check{M}}\sinh\alpha_o}{\lambda_{\check{M}}^2+\ell_\Lambda^2}\right), \tag{4.3}$$

or expressing Minkowski proper time $\lambda_{\check{M}}$ in terms of the proper time of de Sitter space–time,

$$\lambda_{\check{M}} = \mp\,\ell_\Lambda\exp(\mp(\cosh\alpha_o)\lambda_{dS}/\ell_\Lambda), \tag{4.4}$$

we obtain

$$\tilde{t} = \operatorname{arccot}\left(-\frac{\sinh((\cosh\alpha_o)\lambda_{dS}/\ell_\Lambda)}{\cosh\alpha_o}\right), \quad \tilde{r} = \operatorname{arccot}\left(\pm\frac{\cosh((\cosh\alpha_o)\lambda_{dS}/\ell_\Lambda)}{\sinh\alpha_o}\right), \quad \vartheta = 0. \tag{4.5}$$

Here $\lambda_{dS}\in\mathbb{R}$, arccot takes values such that $\tilde{t}\in(0,\pi)$ and $\tilde{r}\in(0,\pi)$ for $\alpha_o>0$, or $\tilde{r}\in(-\pi,0)$ for $\alpha_o<0$. Upper sign is valid for the particle starting and ending with $\tilde{r}=0$ (particle $w_\odot$ in Fig. 7), lower sign for the particle starting and ending at $\tilde{r}=\pi$ (particle $w_\otimes$ in Fig. 7).

One can make sure by direct calculations of the four-acceleration (for its simplest form in the static coordinates, see below) that these worldlines describe the uniformly accelerated motion as defined in Sec. II, the magnitude of the acceleration being

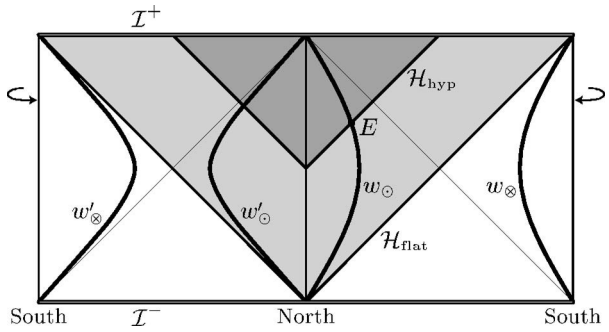

FIG. 7. The worldlines of uniformly accelerated charges. The particles $w_\odot$ and $w'_\odot$ start and end at the "north pole," $w_\otimes, w'_\otimes$ start and end at the south pole. Particles $w'_\odot, w'_\otimes$ have a higher magnitude of acceleration $a_{\rm dS}$ than particles $w_\odot, w_\otimes$. They are characterized by a negative parameter $\alpha_{\rm o}$, whereas particles $w_\odot, w_\otimes$ have a positive $\alpha_{\rm o}$.

$$a_{\rm dS} = \sqrt{\mathrm{a}^\mu \mathrm{a}_\mu} = |\ell_\Lambda^{-1} \sinh \alpha_{\rm o}|. \tag{4.6}$$

Since de Sitter universe represents the asymptotic state of all three types of indefinitely expanding FRW models with $\Lambda > 0$, it is of interest to find out the form of these worldlines in the three types of cosmological frames—spherical, flat, and hyperbolic—introduced in Sec. II.

In terms of cosmological spherical coordinates the worldlines are given by

$$\tau = \ell_\Lambda \,\mathrm{arcsinh}\left(\frac{\sinh((\cosh \alpha_{\rm o})\lambda_{\rm dS}/\ell_\Lambda)}{\cosh \alpha_{\rm o}}\right), \quad \chi = \mathrm{arccot}\left(\pm\frac{\cosh((\cosh \alpha_{\rm o})\lambda_{\rm dS}/\ell_\Lambda)}{\sinh \alpha_{\rm o}}\right), \quad \vartheta = 0. \tag{4.7}$$

In flat cosmological coordinates, which cover only half of de Sitter space, we obtain just particle $w_\odot$ described by the worldline

$$\check{\tau} = \lambda_{\rm dS} \cosh \alpha_{\rm o} - \ell_\Lambda \log \cosh \alpha_{\rm o}, \quad \check{r} = \ell_\Lambda \sinh \alpha_{\rm o} \exp(-(\cosh \alpha_{\rm o})\lambda_{\rm dS}/\ell_\Lambda). \tag{4.8}$$

Finally, in hyperbolic cosmological coordinates, which are also not global, we obtain again one particle's worldline only given in terms of its proper time as

$$\eta = \ell_\Lambda \,\mathrm{arccosh}\,\frac{\cosh((\cosh \alpha_{\rm o})\lambda_{\rm dS}/\ell_\Lambda)}{\cosh \alpha_{\rm o}}, \quad \rho = \ell_\Lambda \,\mathrm{arccoth}\frac{\sinh((\cosh \alpha_{\rm o})\lambda_{\rm dS}/\ell_\Lambda)}{\sinh \alpha_{\rm o}}. \tag{4.9}$$

These formulas have no meaning for $|\lambda_{\rm dS}/\ell_\Lambda \cosh \alpha_{\rm o}| < |\alpha_{\rm o}|$ where the inverse hyperbolic functions are not defined. This corresponds to the fact that for such $\lambda_{\rm dS}$ the particle occurs in the region where the hyperbolic cosmological coordinates are not defined (cf. Fig. 4). Excluding the proper time we find the worldlines to be given by remarkably simple formulas in the three systems of the cosmological coordinates,

(a) spherical,

$$\sin \chi = \pm \tanh \alpha_{\rm o} / \cosh \frac{\tau}{\ell_\Lambda}; \tag{4.10}$$

(b) flat,

$$\frac{\check{r}}{\ell_\Lambda} = \tanh \alpha_{\rm o} / \exp \frac{\check{\tau}}{\ell_\Lambda}; \tag{4.11}$$

(c) hyperbolic,

$$\sinh\frac{\rho}{\ell_\Lambda}=\tanh\alpha_o\big/\sinh\frac{\eta}{\ell_\Lambda}. \tag{4.12}$$

It is of interest to see what are the physical radial velocities which will be observed by three types of the fundamental cosmological observers, i.e., those with fixed χ, $\check{r}$, and ρ, respectively, whose proper times are τ, $\check{\tau}$, and η, respectively. Such velocities can be defined by the covariant expression

$$v_{\text{obs}}=\mathrm{u}_\alpha\,\mathrm{e}_1^\alpha\frac{\mathrm{d}\lambda_{\text{dS}}}{\mathrm{d}\lambda_{\text{obs}}}, \tag{4.13}$$

where u^α is the particle's four-velocity, λ_{dS} its proper time, e_1^α is the unit spacelike vector in the direction of the radial coordinate $x^1=\chi$, $\check{r}$, and ρ, respectively, i.e., in directions $\partial/\partial\chi$, $\partial/\partial\check{r}$, and $\partial/\partial\rho$, and λ_{obs} is the proper time of an observer, i.e., τ, $\check{\tau}$, or η, respectively. Since all three cosmological metrics are diagonal the expression (4.13) takes on the form

$$v_{\text{obs}}=\sqrt{g_{\text{dS}11}}\frac{dx^1}{d\lambda_{\text{obs}}}. \tag{4.14}$$

The results are of interest,

$$v_{\text{obs}(\chi)}=\mp\frac{\operatorname{sign}\tau\sinh\alpha_o}{\sqrt{\sinh^2\alpha_o+\coth^2(\tau/\ell_\Lambda)}}, \tag{4.15}$$

$$v_{\text{obs}(\check{r})}=-\tanh\alpha_o, \tag{4.16}$$

$$v_{\text{obs}(\rho)}=-\frac{\sinh\alpha_o}{\sqrt{\sinh^2\alpha_o+\tanh^2(\eta/\ell_\Lambda)}}. \tag{4.17}$$

Consider first the picture in spherical cosmological coordinates, Eqs. (4.7) and (4.10). Only in this frame both particles are present. They start asymptotically at antipodes of the spatial section of de Sitter space at $\mathcal{I}^-(\tau\to-\infty)$ and move one towards the other until $\tau=0$, the moment of maximal contraction of de Sitter space ("the neck" of de Sitter hyperboloid), when they stop, $v_{\text{obs}(\chi)}=0$. Then they move, in a time-symmetric manner, apart from each other until they reach future infinity asymptotically at the antipodes from which they started. In contrast to the flat space case, the particles do not approach the velocity of light in this global spherical cosmological coordinate system, the asymptotical magnitude of their velocity being equal to $|\tanh\alpha_o|$ [cf. Eq. (4.15)]. Hence, curiously enough, the particles approach the antipodes asymptotically with a finite nonvanishing velocity (for an intuitive insight into this effect, see below).

Although the particles $w_\odot$ and $w_\otimes$ do not approach infinities with velocity of light, they *are* causally disconnected as the analogous pair of particles in Minkowski space (cf. Fig. 1 and Fig. 7). No retarded or advanced effects from the particle $w_\odot$ can reach the particle $w_\otimes$ and vice versa.

Next, consider flat and hyperbolic observers. As seen from Eq. (4.16), with respect to the flat cosmological coordinates the particle $w_\odot$ moves with the same velocity $|\tanh\alpha_o|$ all the time. And the same velocity is asymptotically, at $\eta\to\infty$, reached by this particle in the hyperbolic cosmological coordinates. The magnitude of the asymptotic values of the velocity at $\mathcal{I}^+$ is, in fact, equal to the velocity (4.1) of the particle in Minkowski space from which we constructed uniformly accelerated worldlines by a conformal transformation. The identity of all these velocities is understandable, the magnitude of the velocity with respect to an observer can be determined by projecting the particle's four-velocity on the observer's four-velocity, i.e., by the angle between these directions. In de Sitter space all three types of cosmological observers reach $\mathcal{I}^+$ with the same four-velocity; moreover, this four-velocity is at $\mathcal{I}^+$ identical to the four-velocity of observers

at rest in conformally related Minkowski space. But a conformal transformation preserves the angles and thus, the velocities with respect to the three types of cosmological observers in de Sitter space and the velocity in the conformally related Minkowski space must all be equal—given by the "Lorentzian" angle α_o.

It is worth noticing yet what is the *initial* velocity of the particle $w_\odot$ in hyperbolic cosmological coordinates. Regarding Fig. 4 we have $\eta\to-\infty$, $\rho\to 0$ at the "starting point" of the particle at $\mathcal{I}^-$. From Eq. (4.17) we get $v_{\mathrm{obs}(\rho)}\to-\tanh\alpha_o$ which in the magnitude is the same as in spherical cosmological coordinates but has opposite sign since the particle moves in the direction of increasing negative ρ. More interesting is how the particle enters the upper region of the hyperbolic coordinates. Figure 4 suggests that its velocity must approach the velocity of light since at this boundary the fundamental observers of the hyperbolic cosmological frame themselves approach the velocity of light. Indeed, at this boundary $\eta=0,\rho=\infty$, and the expression (4.17) implies $v_{\mathrm{obs}(\rho)}\to-1$.

By far the simplest description of the particles is obtained in the static coordinates T,R. Using, for example, the relation $R=\ell_\Lambda\sin\tilde{r}/\sin\tilde{t}$ [cf. Eqs. (A64) and (A77)], and substituting from Eq. (4.5), we find that the worldlines of both particles $w_\odot$ and $w_\otimes$ are given by remarkably lucid forms

$$T=\lambda_{\mathrm{dS}}\cosh\alpha_o=\frac{\lambda_{\mathrm{dS}}}{\sqrt{1-R_o^2/\ell_\Lambda^2}},\quad R=\ell_\Lambda\tanh\alpha_o\equiv R_o. \tag{4.18}$$

These expressions imply that the four-acceleration $\mathrm{a}^\alpha=\mathrm{u}^\mu\nabla_\mu\mathrm{u}^\alpha$ is simply

$$\mathrm{a}=-\frac{R_o}{\ell_\Lambda^2}\frac{\partial}{\partial R}=-\frac{1}{\ell_\Lambda}\tanh\alpha_o\frac{\partial}{\partial R}=a_o\mathrm{e}_R, \tag{4.19}$$

where e_R is a unit spatial vector in the direction $\partial/\partial R$ of the static radial coordinate R, and we introduced constant

$$a_o=-\ell_\Lambda^{-1}\sinh\alpha_o=-\frac{R_o/\ell_\Lambda^2}{\sqrt{1-R_o^2/\ell_\Lambda^2}} \tag{4.20}$$

which represents the "oriented" value of the acceleration of the particles.

We thus find the uniformly accelerated particles in de Sitter space–time to be at rest in the static coordinates at fixed values $R=R_o$ of the radial coordinate. Two charges moving along the orbits of the boost Killing vector (2.5) in Minkowski space are at rest in the Rindler coordinate system and have a constant distance from the space–time origin, as measured along the slices orthogonal to the Killing vector. Similarly, we see that the worldlines $w_\odot$ and $w_\otimes$ are the orbits of the static Killing vector $\partial/\partial T$ of de Sitter space. The particle $w_\odot$ (respectively, $w_\otimes$) has, as measured at fixed T, a constant proper distance from the origin $\tilde{t}=\pi/2$ $(\tau=0)$, $\tilde{r}=\chi=0$ (respectively, $\tilde{r}=\chi=\pi$). As with Rindler coordinates in Minkowski space, the static coordinates cover only a "half" of de Sitter space. In the other half the Killing vector becomes spacelike. Owing to "cosmic repulsion" caused by the presence of Λ, fundamental cosmological observes moving along geodesics χ,ϑ,φ constant are "repelled" one from the others. Their initial implosion starting at $\tau\to-\infty$ is stopped at $\tau=0$ and changes into expansion. Clearly, a particle with constant $R=R_o$—hence a constant proper distance from the particle at $R=0=\chi$—must be accelerated towards that "central" particle.

In Eq. (4.20) we have denoted the radial tetrad component of the acceleration in the static coordinates by a_o; notice that, in contrast to the magnitude of the acceleration $a_{\mathrm{dS}}=|a_o|$ [cf. Eq. (4.6)], a_o can be negative as, in fact, it is the case with both particles $w_\odot$ and $w_\otimes$, assuming that the static radial coordinate of the particles is positive, $R=R_o>0$. Geometrically, the four-vectors of the acceleration of the particles point in opposite directions—towards $\chi=0$, the other towards $\chi=\pi$. Since, however, one needs two sets of the static coordinates to cover both particles, and the radial coordinate R increases from both $\chi=0$ and $\chi=\pi$ worldlines (cf. Fig. 5), the accelerations of both particles point in the direction of decreasing R's and is thus negative. All the particles we are

considering perform one-dimensional motion only, hence we use for the description of their worldlines the same convention as for the two-dimensional diagrams with time and radial coordinates—we allow the radial coordinate to take negative values. Thus, for example, consider a particle with worldline $w'_\odot$ which is a "reflection" of the worldline $w_\odot$ with respect to $\tilde{r}=\chi=0$ (see Fig. 7). The particle $w'_\odot$ moves in the region of negative $\tilde{r}$, respectively R, it has an acceleration positive, $a_o=-\ell_\Lambda^{-1}\sinh\alpha_o>0$ (i.e., $\alpha_o<0$), and its four-acceleration vector is pointing in the direction of increasing R. With our convention, the particle $w'_\odot$ is just that which moves from $\chi=0$ along the $\vartheta=\pi$ direction. This convention will be particularly useful when we shall construct worldlines of uniformly accelerated particles which start and end at the equator. Those which move in the region $\chi>\pi/2$ will have negative a_o, those moving with $\chi<\pi/2$ will have positive a_o—see Sec. IV B.

An intuitive geometrical understanding of the worldlines of uniformly accelerated particles in de Sitter space–time can be gained by considering de Sitter space as a four-dimensional hyperboloid $-Z_0^2+Z_1^2+Z_2^2+Z_3^2+Z_4^2=\ell_\Lambda^2$ in five-dimensional Minkowski space. The spherical cosmological coordinates $\tau,\chi,\vartheta,\varphi$ are then identical to the hyperspherical coordinates on this hyperboloid. The worldlines of the north and south poles, $\chi=0,\pi$, can be obtained by cutting the hyperboloid by a timelike 2-plane $\mathcal{T}_2$, given by $Z_2=Z_3=Z_4=0$. The worldlines of our uniformly accelerated particles $w_\odot$ and $w_\otimes$ then arise when the hyperboloid is cut by a timelike 2-plane $\mathcal{T}_2^*$ parallel to $\mathcal{T}_2$ at a distance $R_o=\ell_\Lambda\tanh(\alpha_o/\ell_\Lambda)$ from the origin.[43] $\mathcal{T}_2^*$ is thus given by $Z_2=R_o$, $Z_3=Z_4=0$. From the definition of the hyperspherical coordinates it follows $\vartheta=0,\pi$ and $Z_2=\ell_\Lambda\cosh(\tau/\ell_\Lambda)\sin\chi\cos\vartheta=R_o$, i.e., $\sin\chi=\pm\tanh\alpha_o/\cosh(\tau/\ell_\Lambda)$, which is just Eq. (4.10) describing $w_\odot$ and $w_\otimes$.

From this construction, the curious result mentioned above—that $w_\odot$ and $w_\otimes$ approach antipodes $\chi=0$ and $\chi=\pi$ asymptotically with a fixed speed $|\tanh\alpha_o|$ in spherical cosmological coordinates—is not so surprising: thanks to the expansion of de Sitter space–time fundamental cosmological observers with arbitrarily small $\chi=\text{constant}>0$ will, in the limit $\tau\to\infty$, eventually cross the plane $\mathcal{T}_2^*$, and thus the particle $w_\odot$; however at any finite but arbitrarily large τ there will be observers with $\chi=\text{constant}$ which are still moving towards the particle $w_\odot$. The same, of course, is true with the symmetrically located particle $w_\otimes$ and corresponding observers close to $\chi=\pi$.

B. Particles born at the equator

In the classical Born solutions both charges are, at all times, located symmetrically with respect to the origin of the Minkowski coordinates (see Fig. 1). In order to demonstrate explicitly that a limiting procedure exists in which our generalized Born's solution goes over to its classical counterpart, we shall now construct the pair of uniformly accelerated particles which are, at all times, symmetrically located with respect to the origin of the standard spherical coordinates in de Sitter space, i.e., with respect to the "north pole" at $\chi=0$. Asymptotically at $\tau\to-\infty$ these two particles both start ("are born") with the same speed at the equator, $\chi=\pi/2$, at the antipodal points $\vartheta=0$ and $\vartheta=\pi$. As the universe contracts, they both move symmetrically along the axis $\vartheta=0,\pi$, reach some limiting value χ_o at the moment of time symmetry, and accelerate back towards the equator, reaching the initial positions asymptotically at $\tau\to+\infty$. These two particles are illustrated in Fig. 8, with their worldlines denoted by $w_\oplus$ and $w_\ominus$. In Fig. 9, a snapshot at $\tau=\text{constant}$ is depicted. Comparing Fig. 8 with Fig. 7, it is evident that the particles $w_\oplus$ and $w_\ominus$ are located with respect to the point $\chi=\pi/2$, $\vartheta=0$ in exactly the same manner as the particles $w_\odot$ and $w_\otimes$ are located with respect to the pole $\chi=0$ (or, rather, as the particles $w'_\odot$, $w'_\otimes$, since we chose $w_\oplus$, $w_\ominus$ to have positive a_o in Fig. 8).

Owing to the global homogeneity of de Sitter space and the spherical geometry of its slices $\tau=\text{constant}$, the worldlines of the particles $w_\oplus$ and $w_\ominus$ can be constructed by a suitable rotation of the worldlines of the particles $w_\odot$ and $w_\otimes$. In Sec. VII the same rotation will be applied to obtain

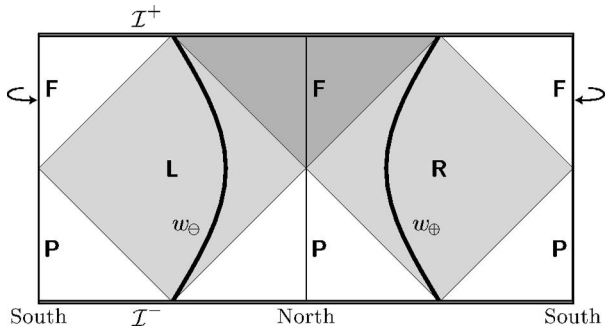

FIG. 8. The worldlines of uniformly accelerated charges located symmetrically with respect to the origin (north pole) of the standard spherical coordinates in de Sitter space. The particles "start" and "end" at the equator. They are causally disconnected as a corresponding pair in Minkowski space (cf. Fig. 1). The "oriented" value a_o of the acceleration of these particles is positive [cf. the "rotated" version of Eq. (4.20)].

the fields of these particles "born at the equator." We rotate the coordinates χ, ϑ, φ into coordinates $\bar{\chi}$, $\bar{\vartheta}$, $\bar{\varphi}$ which, as a pole, have the point $\chi=\pi/2$, $\vartheta=0$ (see Fig. 9). The relations between these coordinates follow from the spherical geometry:

$$\cos\bar{\chi}=\sin\chi\cos\vartheta,\quad \tan\bar{\vartheta}=-\tan\chi\sin\vartheta,\quad \bar{\varphi}=\varphi. \tag{4.21}$$

The new worldlines, $w_\oplus$ and $w_\ominus$, will then be given by Eqs. (4.7) in which χ, ϑ, φ are replaced by rotated coordinates $\bar{\chi}$, $\bar{\vartheta}$, $\bar{\varphi}$. Substituting for these by using relations (4.21), we find the worldlines $w_\oplus$, $w_\ominus$ in the original coordinates to be described by the expressions

$$\tau=\ell_\Lambda\,\mathrm{arcsinh}\left(\frac{\sinh((\cosh\alpha_o)\lambda_{dS}/\ell_\Lambda)}{\cosh\alpha_o}\right),\quad \chi=\pm\arctan\left(-\frac{\cosh((\cosh\alpha_o)\lambda_{dS}/\ell_\Lambda)}{\sinh\alpha_o}\right),\quad \vartheta=0, \tag{4.22}$$

with the values of arctan from $(0,\pi)$ and upper (lower) sign corresponding to the particle starting at the positive (negative) value of χ, i.e., to the particle $w_\oplus$ (or $w_\ominus$, respectively).

Excluding the proper time λ_{dS}, we arrive at simple result [cf. Eq. (4.10)]

$$\cos\chi=-\frac{\tanh\alpha_o}{\cosh(\pi/\ell_\Lambda)}. \tag{4.23}$$

As $\tau\to\pm\infty$, then indeed $|\chi|\to\pi/2$; at $\tau=0$, $|\chi|=\arccos(-\tanh\alpha_o)=\arccos(-R_o/\ell_\Lambda)$, in agreement with the "deviation" of the "original" particles $w_\odot$, $w_\otimes$ from $\chi=0$ at $\tau=0$. In the spherical rescaled coordinates, Eqs. (4.22) read

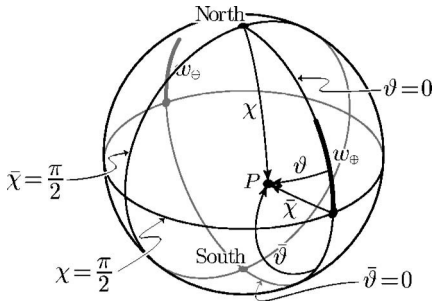

FIG. 9. The rotated spherical coordinates $\bar{\chi},\bar{\vartheta}$ on 3-sphere (the cut φ=constant). The relation between the coordinates is given in Eq. (4.21).

$$\tilde{t} = \operatorname{arccot}\left(- \frac{\sinh((\cosh \alpha_o)\lambda_{dS}/\ell_\Lambda)}{\cosh \alpha_o} \right),$$

$$\tilde{r} = \pm \operatorname{arccot}\left(- \frac{\cosh((\cosh \alpha_o)\lambda_{dS}/\ell_\Lambda)}{\sinh \alpha_o} \right), \tag{4.24}$$

$$\vartheta = 0,$$

again with the values of arctan and arccot from $(0, \pi)$. Equation (4.23) becomes

$$\cos \tilde{r} = - \tanh \alpha_o \sin \tilde{t}. \tag{4.25}$$

Although the flat (rescaled) cosmological coordinates cover only parts of the worldlines $w_\oplus$, $w_\ominus$ (see Figs. 8 and 3), we transcribe the equations above also into these frames in which the particles "emerge" at $\check{\tau}$, $\check{t} \to -\infty$ at the cosmological horizon at $\check{r} = \pm\infty$. We find

$$\frac{\check{\tau}}{\ell_\Lambda} = - \log\left(\frac{- \cosh \alpha_o}{- \sinh((\cosh \alpha_o)\lambda_{dS}/\ell_\Lambda) + \sinh \alpha_o} \right),$$

$$\frac{\check{t}}{\ell_\Lambda} = \frac{\cosh \alpha_o}{- \sinh((\cosh \alpha_o)\lambda_{dS}/\ell_\Lambda) + \sinh \alpha_o}, \tag{4.26}$$

$$\frac{\check{r}}{\ell_\Lambda} = \mp \frac{\cosh((\cosh \alpha_o)\lambda_{dS}/\ell_\Lambda)}{- \sinh((\cosh \alpha_o)\lambda_{dS}/\ell_\Lambda) + \sinh \alpha_o},$$

so that Eq. (4.25) translates into the relations

$$\begin{aligned} \check{r} &= \pm \sqrt{\ell_\Lambda^2 + \check{t}^2 - 2\ell_\Lambda \check{t} \tanh \alpha_o}, \\ \check{r} &= \pm \ell_\Lambda \sqrt{1 + 2 \tanh \alpha_o \exp(- \check{\pi}/\ell_\Lambda) + \exp(- 2\check{\pi}/\ell_\Lambda)}. \end{aligned} \tag{4.27}$$

As $\check{\tau} \to +\infty$, we have $\check{r} \to \pm \ell_\Lambda$, as it corresponds to $\chi \to \pm \pi/2$; at $\check{\tau} \to -\infty$, we get $\check{r} \to \pm\infty$—here the particles enter flat cosmological frame at the horizon (cf. Fig. 8).

The worldlines $w_\oplus$, $w_\ominus$ are situated outside the regions covered by our choice of the hyperbolic cosmological coordinates. Similarly, we get only finite parts of $w_\oplus$, $w_\ominus$ in our static coordinates. Of course, we could rotate the static coordinates to cover both particles but then we arrive at exactly the same picture as with the particles $w_\odot$, $w_\otimes$ considered above.

Our primary reason to discuss the pair $w_\oplus$, $w_\ominus$ is to demonstrate explicitly how our fields go over into the classical Born solution in the limit of vanishing Λ. For this purpose, it will be important to have available also the description of the worldlines $w_\oplus$, $w_\ominus$ in the Minkowski coordinates introduced in Eqs. (3.17). As it is obvious from Fig. 6, these coordinates cover both worldlines $w_\oplus$ and $w_\ominus$ completely. Using the relations inverse to Eqs. (3.17) given in the Appendix, Eq. (A17), we find Eqs. (4.24) to imply

$$t = b_o \sinh \frac{\lambda_M}{b_o}, \quad r = \pm b_o \cosh \frac{\lambda_M}{b_o}, \quad \vartheta = 0, \tag{4.28}$$

where

$$\frac{b_o}{\ell_\Lambda} = \exp \alpha_o = \sqrt{1 + a_o^2 \ell_\Lambda^{-2}} - a_o \ell_\Lambda = \sqrt{\frac{\ell_\Lambda + R_o}{\ell_\Lambda - R_o}}, \tag{4.29}$$

and λ_M is the proper time measured in Minkowski space M related to de Sitter space by conformal mapping (3.18) and (3.19),

$$\lambda_M = \exp \alpha_o \cosh \alpha_o \, \lambda_{dS}. \tag{4.30}$$

Consequently,

$$r = \pm \sqrt{t^2 + b_o^2}, \quad \vartheta = 0, \tag{4.31}$$

which is the simplest form of the hyperbolic motion with the uniform acceleration $1/b_o$ as measured in Minkowski space [cf. Eqs. (2.3)].

V. FRAMES CENTERED ON ACCELERATED PARTICLES

For the investigation of the radiative properties and other physical aspects of the fields, the use of (physically equivalent) particles $w_\odot, w_\otimes$, i.e., those "born at the poles" of spherical coordinates is technically more advantageous. We shall now return back and construct frames with the origins located directly on these particles. In such frames, various properties of the fields will become more transparent than in the coordinates introduced so far.

As we have seen in the preceding section, the uniformly accelerated particles $w_\odot$ and $w_\otimes$ are at rest in static coordinates T, R at given $R = R_o = -a_o \ell_\Lambda^2 / \sqrt{1 + a_o^2 \ell_\Lambda^2}$, where $|a_o|$ is the magnitude of the acceleration. In order to investigate the properties of the fields, in particular, in order to see what is the structure of the field along the null cones with vertices at the particle's position, i.e., what is the field "emitted" by the particle at a given time, it is useful to construct coordinate frames centered on the accelerated particles. Such systems of coordinates are used to describe accelerating black holes in general relativity (like C-metrics, known also for $\Lambda \neq 0$, cf. Refs. 27 and 28), so that their properties on de Sitter background may indicate what is their meaning in more general cases—in situations when they are centered on gravitating objects rather than on test particles.

We shall now describe three coordinate systems of this type: the accelerated coordinates, the C-metric-like coordinates, and the Robinson-Trautman coordinates, all centered on the worldlines $w_\odot$ and $w_\otimes$. Instead of writing down just the transformation formulas, we wish to indicate some steps how these coordinates can be obtained naturally. We list only the main transformation relations here, many other formulas and forms of the metrics can be found in the Appendix. Let us also note that in this section we assume $R_o, \alpha_o > 0$, i.e., $a_o < 0$, and we use only static radial coordinate with positive values, i.e., $R > 0$.

A. Accelerated coordinates

We begin with the construction of accelerated coordinates $T', R', \vartheta', \varphi$. This type of coordinates was recently introduced[49] by another method in the context of the C-metric with $\Lambda > 0$. In the preceding section we obtained the worldlines $w_\odot, w_\otimes$ of uniformly accelerated particles in de Sitter space by starting from a particle moving with a uniform velocity $v_{\breve{M}} = \tanh \alpha_o$ in a negative direction of the $\breve{z}$ axis in the inertial frame $\breve{t}, \breve{r}, \vartheta, \varphi$ in Minkowski space $\breve{M}$ which passes through $\breve{r} = 0$ at $\breve{t} = 0$ [see Eqs. (4.1) and (4.2)]; and we used then the conformal relation between Minkowski and de Sitter spaces to find $w_\odot, w_\otimes$. Therefore, let us first construct a frame centered on the uniformly moving particle in $\breve{M}$. Using spherical coordinates again, this boosted frame denoted by primes is related to the original one simply by

$$\begin{aligned} \breve{t}' &= \breve{t} \cosh \alpha_o + \breve{r} \cos \vartheta \sinh \alpha_o, \\ \breve{r}' \cos \vartheta' &= \breve{t} \sinh \alpha_o + \breve{r} \cos \vartheta \cosh \alpha_o, \end{aligned} \tag{5.1}$$

$$\check{r}' \sin \vartheta' = r \sin \vartheta,$$

the φ-coordinate does not change and will be suppressed in the following. From here

$$\begin{aligned} -\check{t}'^2 + \check{r}'^2 &= -\check{t}^2 + \check{r}^2, \\ \tan \vartheta' &= \frac{\sin \vartheta}{(\check{t}/\check{r})\sinh \alpha_o + \cos \vartheta \cosh \alpha_o}. \end{aligned} \tag{5.2}$$

The original frame $\check{t}, \check{r}, \vartheta$ in Minkowski space $\check{M}$ is related to the static coordinates T, R, ϑ in de Sitter space by [cf. Eqs. (A67) and (A80)]

$$T = -\frac{\ell_\Lambda}{2} \log \left| \frac{\check{t}^2 - \check{r}^2}{\ell_\Lambda^2} \right|, \quad R = -\ell_\Lambda \frac{\check{r}}{\check{t}}, \quad \vartheta = \vartheta. \tag{5.3}$$

The metrics of the two spaces are related by $g_{\mathrm{dS}} = (\ell_\Lambda^2/\check{t}^2) g_{\check{M}}$, g_{dS} being given by Eq. (3.9)—cf. Eq. (3.14). Now, let us introduce coordinates T', R', ϑ' given in terms of $\check{t}', \check{r}', \vartheta'$ by exactly the same formulas as coordinates T, R, ϑ are given in terms of $\check{t}, \check{r}, \vartheta$ in Eq. (5.3). In this way we obtain $g_{\mathrm{dS}'} = (\ell_\Lambda^2/\check{t}'^2) g_{\check{M}}$. Combining the last relation with $g_{\mathrm{dS}} = (\ell_\Lambda^2/\check{t}^2) g_{\check{M}}$, we find the metric of the original de Sitter space in the new coordinates T', R', ϑ' in the form

$$g_{\mathrm{dS}} = \frac{\check{t}'^2}{\check{t}^2} g_{\mathrm{dS}'}, \tag{5.4}$$

$g_{\mathrm{dS}'}$ is given by the "primed" version of Eq. (3.9). Expressing then the factor $(\check{t}'/\check{t})^2$ by using Eqs. (5.1) and (5.2), and "primed" relations (5.3), we arrive at the de Sitter metric in the accelerated coordinates in the form

$$g_{\mathrm{dS}} = \frac{1 - R_o^2/\ell_\Lambda^2}{[1 + (R' R_o/\ell_\Lambda^2)\cos \vartheta']^2} \left(-\left(1 - \frac{R'^2}{\ell_\Lambda^2}\right) \mathrm{d}T'^2 + \left(1 - \frac{R'^2}{\ell_\Lambda^2}\right)^{-1} \mathrm{d}R'^2 + R'^2 (\mathrm{d}\vartheta'^2 + \sin^2 \vartheta' \, \mathrm{d}\varphi^2) \right). \tag{5.5}$$

Here the accelerated coordinates $T', R', \vartheta', \varphi$ are given in terms of static coordinates by the relation obtained by the procedure described above as follows:

$$\begin{aligned} R' &= \ell_\Lambda \sqrt{1 - \frac{(1 - R^2/\ell_\Lambda^2)(1 - R_o^2/\ell_\Lambda^2)}{[1 - (R R_o/\ell_\Lambda^2)\cos \vartheta]^2}}, \\ T' &= T, \quad \tan \vartheta' = \frac{\sqrt{1 - R_o^2/\ell_\Lambda^2} R \sin \vartheta}{R \cos \vartheta - R_o}. \end{aligned} \tag{5.6}$$

Notice that the time coordinate of static and accelerated frames coincide. Technically, this is easy to see from the first relation in Eqs. (5.2) and (5.3). Intuitively, this is evident since the uniformly accelerated particles are at rest in the static coordinates, as well as in the accelerated coordinates, the only difference being that they are located at the origin of the accelerated frame. Setting $R_o = 0$ in Eq. (5.6), we get $R' = R$, $\vartheta' = \vartheta$, as expected. The static coordinates are centered on the poles $\chi = 0, \pi$, hence, on the *un*accelerated worldlines. The name accelerated coordinates *is* thus inspired by the fact that their origin is accelerated, and the value of this acceleration enters the form of the metric (5.5) explicitly through the quantity R_o.

The two-dimensional conformal diagram of de Sitter space with coordinate lines $T' = \text{constant}$, $R' = \text{constant}$ of the accelerated frame is given in Fig. 10. For details, see the figure caption. Here let us just notice that the cosmological horizons are still described by $R'^2 = \ell_\Lambda^2$.

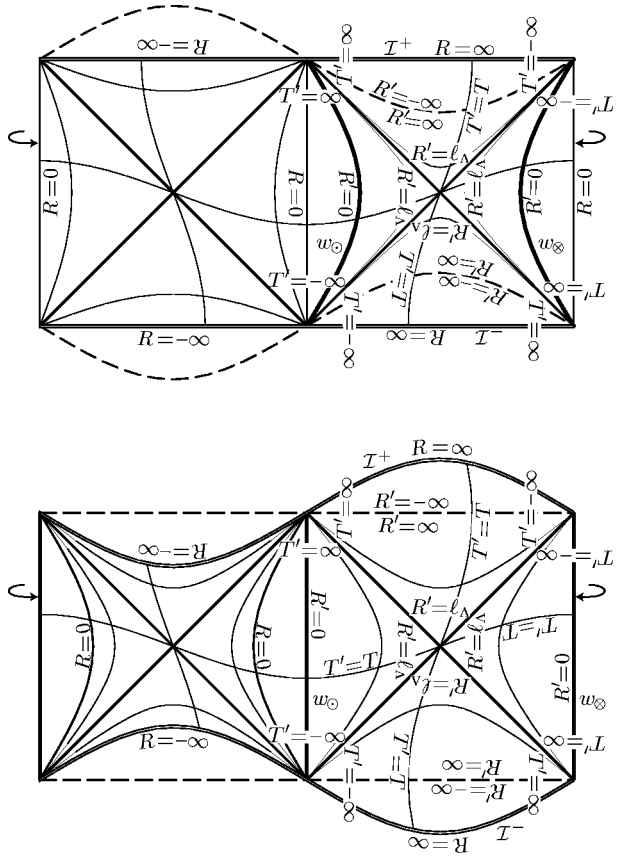

FIG. 10. The two-dimensional conformal diagrams of de Sitter space based on the static, nonaccelerated coordinates (upper diagram), and on the accelerated coordinates (lower diagram). Starting from static coordinates T,R,ϑ,φ, one can draw the conformal diagram of the axis $\vartheta=0,\pi$ in which the conformal past and future infinities, $\mathcal{I}^\pm(R=\pm\infty)$, are horizontal (double) lines. In addition to static coordinates T,R, also accelerated coordinates T',R' are indicated in both diagrams. These have a coordinate singularity for $R'=\infty$ (drawn as a dashed line). The origins of the accelerated coordinates, $R'=0$ (thick lines), are worldlines of uniformly accelerated particles. In the conformal diagram of the axis $\vartheta'=0,\pi$ based on accelerated coordinates, the origins $R'=0$ and the coordinate singularity $R'=\infty$ of the accelerated frame are straight lines; the true infinities $\mathcal{I}^\pm$ have a "bulge" upwards or "downwards," depending on the angle ϑ'. The hypersurface $R'=\infty$ corresponds to the boosted hyperplane $\check{t}'=0$, whereas the conformal infinity corresponds to $\check{t}=0$ (the relation of both hyperplanes can be well understood in the diagram of the conformally related Minkowski space $\check{M}$). The diagrams in which the conformal infinities $\mathcal{I}^\pm$ are not straight naturally arise in the studies of the C-metric with $\Lambda>0$ [de Sitter space being a special case of this class of the metrics (Ref. 27)]. In general, outside the axis $\vartheta=\vartheta'=0,\pi$, the transformations between the static and accelerated coordinates mix radial and angular coordinates R, ϑ and R',ϑ', as is seen also in the following Fig. 11. The sections $\vartheta'=$constant (for some general ϑ') are also shown in Fig. 21 in the Appendix.

Infinite values of R' can, however, be encountered "before" the conformal infinities $\mathcal{I}^\pm$ are reached. This depends on the angle ϑ'. Indeed, $R'=\infty$ corresponds to $\check{t}'=0$, whereas $\mathcal{I}^\pm$ is given by $\check{t}=0$, i.e.,

$$R'=-\frac{\ell_\Lambda^2}{R_\mathrm{o}}\frac{1}{\cos\vartheta'}, \tag{5.7}$$

[cf. metric (5.5)]. Relation of these two surfaces is best viewed in Minkowski space $\check{M}$. We see that for $\vartheta,\vartheta'<\pi/2$, the conformal infinity $\mathcal{I}^+$ ($\mathcal{I}^-$) lies "above" ("below") the surface $R'=\pm\infty$. Thus the infinity $R'=\pm\infty$ is just a coordinate singularity, which can be removed using, for example, the C-metric-like coordinate v introduced below.

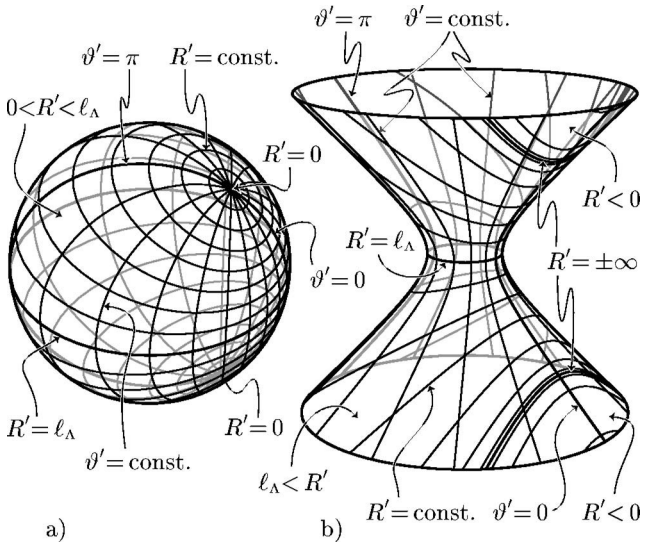

FIG. 11. The accelerated coordinates R', ϑ' on the sections $T'=$constant of de Sitter space (coordinate φ suppressed). In the region where $\partial/\partial T'$ is timelike ($0<R'<\ell_\Lambda$), the cut $T'=$constant is a spacelike sphere [diagram (a)]. In the region where $\partial/\partial T'$ is spacelike ($\ell_\Lambda<R'$ and $R'<0$), it is a timelike hyperboloid [diagram (b)]. The diagrams are not in the same scale—the radius of the sphere and of the neck of the hyperboloid should be the same. The axis $\vartheta'=0,\pi$ corresponds to the lines $T'=$constant of Fig. 10. The coordinate singularity $R'=\pm\infty$ is also indicated. For more details see the text.

Figure 11(a) shows the cut $T=T'=$constant located in the region of de Sitter space where the Killing vector $\partial/\partial T=\partial/\partial T'$ is timelike ($R,R'<\ell_\Lambda$); φ-direction is suppressed. The cut is a spacelike sphere S^3 with homogeneous spherical metric. The coordinate lines $R'=$constant and $\vartheta'=$constant are plotted, with two origins $R'=0$ indicated, here the accelerated particles occur. The coordinate R' grows from $R'=0$ at the origins to the equator where $R'=\ell_\Lambda$. In Fig. 11(b) the cut $T=T'=$constant located in the regions where $\partial/\partial T=\partial/\partial T'$ is spacelike ($R,R'>\ell_\Lambda$) is illustrated, again with φ-direction suppressed. Here the cut is timelike with the geometry of three-dimensional de Sitter space. The coordinate lines $R'=$constant and $\vartheta'=$constant are also shown.

As we have just seen, the points with $R'=\infty$ can be "nice" points in de Sitter manifold. It may thus be convenient to introduce the inverse of R' as a new coordinate. Also, we consider $-\cos\vartheta'$ as a coordinate, and make the time coordinate dimensionless. We thus arrive at the C-metric-like coordinates $\tau, \upsilon, \xi, \varphi$,

$$\tau=\frac{T'}{\ell_\Lambda},\quad \upsilon=\frac{\ell_\Lambda}{R'},\quad \xi=-\cos\vartheta'. \tag{5.8}$$

The metric (5.5) becomes

$$g_{\mathrm{dS}}=\mathfrak{r}^2\left(-(\upsilon^2-1)\mathrm{d}\tau^2+\frac{1}{\upsilon^2-1}\mathrm{d}\upsilon^2+\frac{1}{1-\xi^2}\mathrm{d}\xi^2+(1-\xi^2)\mathrm{d}\varphi^2\right), \tag{5.9}$$

with the conformal factor $\mathfrak{r}$ given by

$$\mathfrak{r}=\frac{\ell_\Lambda}{\upsilon\cosh\alpha_{\mathrm{o}}-\xi\sinh\alpha_{\mathrm{o}}}. \tag{5.10}$$

This is de Sitter space–time in the "C-metric form:" setting the mass and charge parameters, m and e, equal to zero in the the C-metric with a positive cosmological constant [written in the form (2.8) of Ref. 27], and choosing the acceleration parameter equal to $A=\ell_\Lambda^{-1}|\sinh\alpha_{\mathrm{o}}|=|a_{\mathrm{o}}|$, we obtain the metric (5.9).

B. Robinson-Trautman coordinates

In order to arrive naturally to the Robinson-Trautman form of the metric, notice that the coefficients in the metric (5.9) become singular at $v \to \pm 1$, similarly as they do on the horizon of the Schwarzschild space–time in the standard Schwarzschild coordinates. Analogously to that case, we choose a "tortoise-type" coordinate $v_\star$ by

$$v_\star = \frac{1}{2} \log \left| \frac{1-v}{1+v} \right| . \tag{5.11}$$

Similarly to the Schwarzschild case again, we introduce a suitable *null* coordinate $\mathfrak{u}$ in terms of the radial and time coordinates τ and $v_\star$ as follows:

$$\mathfrak{u} = (\ell_\Lambda \tanh \alpha_\mathrm{o})(\tau + v_\star). \tag{5.12}$$

Together with the conformal factor $\mathfrak{r}$ defined in Eq. (5.10), we arrive at the de Sitter metric in coordinates $\mathfrak{u}, \mathfrak{r}, \xi, \varphi$ [cf. Eq. (A109)] which is very near to being in the Robinson-Trautman form. However, there is a nonvanishing mixed metric coefficient at $\mathrm{d}\mathfrak{u} \vee \mathrm{d}\xi$ which is absent in the Robinson-Trautman metric. Such a term can be made to vanish by introducing a new angular coordinate ψ by

$$\psi = \operatorname{arctanh} \xi + \frac{\mathfrak{u}}{\ell_\Lambda} \sinh \alpha_\mathrm{o}. \tag{5.13}$$

The de Sitter metric then becomes

$$g_{\mathrm{dS}} = -H\, \mathrm{d}\mathfrak{u}^2 - \mathrm{d}\mathfrak{u} \vee \mathrm{d}\mathfrak{r} + \frac{\mathfrak{r}^2}{P^2}(\mathrm{d}\psi^2 + \mathrm{d}\varphi^2), \tag{5.14}$$

where

$$\begin{gathered} H = -\frac{\mathfrak{r}^2}{\ell_\Lambda^2} + 2\frac{\mathfrak{r}}{\ell_\Lambda} \sinh \alpha_\mathrm{o} \tanh\left(\psi - \frac{\mathfrak{u}}{\ell_\Lambda} \sinh \alpha_\mathrm{o} \right) + 1, \\ P = \cosh\left(\psi - \frac{\mathfrak{u}}{\ell_\Lambda} \sinh \alpha_\mathrm{o} \right). \end{gathered} \tag{5.15}$$

This is precisely the form of the Robinson-Trautman metric—see, e.g., Ref. 50. Tracking back the transformations leading to the metric (5.14), the connection between the Robinson-Trautman coordinates and the static coordinates T, R, ϑ, φ turns out to be not as complicated as our procedure might have indicated, in particular, for the radial coordinate. We find a nice formula for $\mathfrak{r}$,

$$\mathfrak{r} = \frac{\ell_\Lambda}{\sqrt{1 - \dfrac{R_\mathrm{o}^2}{\ell_\Lambda^2}}} \left(\left(1 - \frac{R R_\mathrm{o}}{\ell_\Lambda^2} \cos \vartheta \right)^2 - \left(1 - \frac{R^2}{\ell_\Lambda^2} \right) \left(1 - \frac{R_\mathrm{o}^2}{\ell_\Lambda^2} \right) \right)^{1/2}, \tag{5.16}$$

whereas the other two coordinates are simply expressed only in terms of accelerated coordinates $T' = T, R', \vartheta', \varphi$,

$$\mathfrak{u} = \sqrt{1 - \frac{R_\mathrm{o}^2}{\ell_\Lambda^2}} \left(T' + \frac{\ell_\Lambda}{2} \log \left| \frac{R' - \ell_\Lambda}{R' + \ell_\Lambda} \right| \right), \quad \psi = \frac{R_\mathrm{o}}{\ell_\Lambda} \left(\frac{T'}{\ell_\Lambda} + \frac{1}{2} \log \left| \frac{R' - \ell_\Lambda}{R' + \ell_\Lambda} \right| \right) + \log \left| \tan \frac{\vartheta'}{2} \right| . \tag{5.17}$$

Coordinates R', ϑ' can then be obtained in terms of the original static coordinates by using Eqs. (5.6).

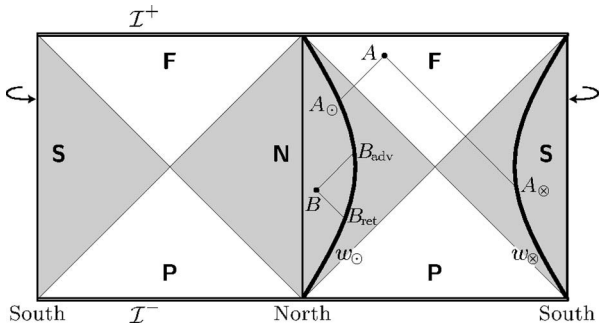

FIG. 12. The field at an event A can be interpreted as $1/2$ of the sum of the retarded fields produced by particle $w_\odot$ at $A_\odot$ and particle $w_\otimes$ at $A_\otimes$. The field at B can be interpreted as $1/2$ of the sum of the retarded and advanced effects from particle $w_\odot$. The affine parameter distances $BB_{\rm ret}$ and $BB_{\rm adv}$ are equal, the same being true for the distances $AA_\odot$ and $AA_\otimes$.

The Robinson-Trautman coordinates with metric (5.14) are centered on the accelerated particles. As with static or accelerated frames, we need two sets of such coordinates to cover both $w_\odot$ and $w_\otimes$. The relations to the static coordinates become, of course, much simpler if the particles are not accelerated, $R_{\rm o}=0$, and when both the Robinson-Trautman and static coordinates are centered on the pole $\chi=0$,

$$\mathfrak{r}=R, \quad \psi=\log\tan\frac{\vartheta}{2}, \quad \mathfrak{u}=T+\frac{\ell_\Lambda}{2}\log\left|\frac{R-\ell_\Lambda}{R+\ell_\Lambda}\right|. \tag{5.18}$$

However, even "accelerated" Robinson-Trautman coordinates possess some very convenient features. The radial coordinate $\mathfrak{r}$ is an affine parameter along null rays $\mathfrak{u},\psi,\varphi=$constants, normalized at the particle's worldline by the condition

$$\frac{\partial^\mu}{\partial\mathfrak{r}}g_{{\rm dS}\mu\nu}\mathfrak{u}^\nu=-1, \tag{5.19}$$

where $\mathfrak{u}$ is the particle's four-velocity. These null rays form a diverging but nonshearing and nonrotating congruence of geodesics. The null vector $\partial/\partial\mathfrak{r}$, tangent to the rays, is parallelly propagated along them. Its divergence is given by $\nabla_\mu(\partial^\mu/\partial\mathfrak{r})=2/\mathfrak{r}$ so that $\mathfrak{r}$ is both the affine parameter and the luminosity distance (see, e.g., Ref. 51). With Robinson-Trautman coordinates, one can also associate a null tetrad [explicitly written down in the Appendix, Eq. (A114)] which is parallelly transported along the null rays from the particle ($\mathfrak{r}=0$) up to infinity ($\mathfrak{r}=\infty$).

Owing to the boost symmetry of both the worldlines and de Sitter space, an interesting feature arises, which is analogous to the situation in Minkowski space. Consider a point B in region **N** (Fig. 12). There are two generators of the null cone with the origin at B which cross the worldline $w_\odot$ at two points, $B_{\rm ret}$ and $B_{\rm adv}$. Then the affine parameter distance $BB_{\rm ret}$ is the same as $BB_{\rm adv}$. (In order to go towards the past from $B_{\rm adv}$ to B, the "advanced" Robinson-Trautman coordinates built on the past null cones with origins on $w_\odot$ can easily be introduced.) This is evident because B lies on one orbit of the boost Killing vector $\partial/\partial T$ and a boost can be applied which leaves the worldline $w_\odot$ invariant but moves B into event B' on the slice of time symmetry, $\tau=0$ (also $T=T'=0$), where the particle is at rest. Then $B_{\rm adv}$ and $B_{\rm ret}$ move to the new points $B'_{\rm adv},B'_{\rm ret}$, which are located symmetrically with respect to $\tau=0$. The equality of the affine parameter distances then follows from the symmetry immediately. Similarly, for an event A in region **F** one can show that the affine parameter distance $AA_\odot$ is equal to the distance $AA_\otimes$ (see Fig. 12). The point A lies on a boost orbit (which now has a spatial character) along which it can be brought, by an appropriate boost, to the point located symmetrically between the worldlines $w_\odot$ and $w_\otimes$ (lying so on the equator, $\chi=\pi/2$). The same consideration can, of course, be applied to an event in the "past" region **P**—showing that the affine distances along future-oriented null rays from an event to the particles are equal.

Although the symmetries just described are common to the worldlines of uniformly accelerated particles in Minkowski and de Sitter space–times, an important difference exists. In Minkowski space, the affine parameter distance along the null ray from an event on particle's worldline, such as $A_\odot$, to an "observation" point A is equal to the proper distance between $A_\perp$ and $A_\odot$ where $A_\perp$ is the orthogonal projection of A onto the spacelike slice $T=T(A_\odot)$. This is not the case in de Sitter space if, as it appears natural, under an orthogonal projection we understand the projection of the observation point A onto the spacelike slice $T=$constant containing $A_\odot$ performed along a timelike geodesic orthogonal to such a slice. Nevertheless, the proper distance s between $A_\odot$ and $A_\perp$ is still related to the affine parameter distance $\mathfrak{r}$ by a simple expression

$$\frac{\mathfrak{r}}{\ell_\Lambda} = \tan \frac{s}{\ell_\Lambda}. \tag{5.20}$$

This relation can be derived as follows. Consider, without loss of generality, $A_\odot$ located at the turning point of the particle $w_\odot$ at $T=0$. The condition that the events A and $A_\odot$ are connected by a null ray implies that the distance s between $A_\odot$ and $A_\perp$ is the same as the time interval between $A_\perp$ and A as measured by the metric (3.12) of the conformally related static Einstein universe. Since A occurs at some time $\tilde{t}$ whereas $A_\odot$ and $A_\perp$ at $\tilde{t}=\pi/2$ (i.e., at static time $T=0$), this time interval is equal to $\ell_\Lambda(\tilde{t}-\pi/2)$, cf. Eq. (3.11). The static radial coordinate R of A thus reads [cf. Eqs. (A64) and (A77)]

$$R = \frac{\sin \tilde{r}}{\sin \tilde{t}} = \frac{\sin \tilde{r}}{\cos(s/\ell_\Lambda)}. \tag{5.21}$$

The slice $T=0$ has a geometry of the 3-sphere of radius ℓ_Λ. Using the standard law of cosines in spherical trigonometry for the sides of the triangle spanned by $A_\odot, A_\perp$, and the north pole, we can eliminate $\tilde{r}$. Finally, employing Eq. (5.16), we obtain the result (5.20). Clearly, near the particle $w_\odot$ we have $s \ll \ell_\Lambda$, and Eq. (5.20) then gives $\mathfrak{r} \approx s$, as in Minkowski space.

In the following section we shall explore the character of the fields of the particles $w_\odot$ and $w_\otimes$. We shall see that the affine parameter distance $\mathfrak{r}$ will play most important role, simplifying their description enormously. Namely, as we will see in Sec. VI B, Eq. (6.28), the affine parameter $\mathfrak{r}$ is identical to the factor $\mathcal{Q}$ which will be introduced in the following and will appear in all expressions for the fields.

VI. FIELDS OF UNIFORMLY ACCELERATED SOURCES AND THEIR MANY FACES

In this section we wish to construct the scalar and electromagnetic fields of uniformly accelerated (scalar and electric) charges in de Sitter universe. A general procedure, suitable in case of any—not necessarily uniform—acceleration would be to seek for appropriate Green's functions. Alternatively, in particular for sources moving along uniformly accelerated worldlines, we can make use of the conformal relations between Minkowski and de Sitter spaces, and of the properties of scalar and electromagnetic fields under conformal mappings. This method is advantageous not only for finding the fields in de Sitter space–time, but also for understanding their relationships to the known fields of corresponding sources in special relativity. The only delicate issue is the fact that there are no conformal mappings between Minkowski and de Sitter space which are globally smooth. We discussed, in Sec. III, how various regions of one space can be mapped onto the regions of the other space. In Ref. 24 we carefully treated the fields at the hypersurfaces where the conformal transformation fails to be regular. In order to obtain well-behaved fields, one must continue analytically across such a hypersurface the field obtained in one region into the whole de Sitter space. In Sec. II in Ref. 24, we also analyzed in detail the behavior of the scalar field wave equation with sources and of Maxwell's equations with sources under (general) conformal transformations.

In Ref. 24 we primarily concentrated on the absence of purely retarded fields at the past infinity $\mathcal{I}^-$ of de Sitter space–time—in fact, in any space–time in which $\mathcal{I}^-$ is spacelike. In order

to analyze this problem we also considered, in addition to monopole charges, more complicated sources like rigid and geodesic dipoles; and we constructed some retarded solutions to show their patological features. However, we confined ourselves to the sources the worldlines of which start and end at the poles; we did not employ coordinates best suited for exhibiting the properties of the fields at future infinity $\mathcal{I}^+$, and the frames corresponding to cosmological models like flat ($k=0$) or hyperbolic ($k=-1$) cosmological coordinates; and we did not give the physical components of the fields. In the following we shall find the fields and discuss their properties in various physically important coordinate systems, in particular those significant at $\mathcal{I}^+$ or in a cosmological context. In the next section, we also obtain the fields due to the uniformly accelerated scalar and electric charges starting at $\mathcal{I}^-$ at $\chi=\pi/2$ ("born at the equator"). This, among others, will be important when we wish to regain the classical Born fields in the limit $\Lambda\to 0$.

We start by using the analysis of the conformal behavior of the fields and sources given in Sec. II in Ref. 24, and we also take over from Ref. 24 the resulting forms of the fields due to the sources starting and ending at the poles of de Sitter space, as described in standard coordinates.

A. Fields in coordinates centered on the poles

Consider two uniformly accelerated point sources starting at $\mathcal{I}^-$ (i.e., at $\tau\to-\infty$, $\tilde{t}\to 0$) at the poles $\chi=\tilde{r}=0$ and $\chi=\tilde{r}=\pi$ (Fig. 7). Their worldlines $w_\odot, w_\otimes$ are given by Eqs. (4.7) [or (4.24)] in these standard (rescaled) coordinates, by Eqs. (4.8) and (4.9) in the flat and hyperbolic cosmological coordinates, and by Eqs. (4.18) in the static coordinates. Their simplest description is, of course, given by $R'=0$ and $\mathfrak{r}=0$ in the accelerated and Robinson-Trautman coordinates since these frames are centered exactly on their worldlines. In Sec. IV we discussed physical velocities and other properties of these particles.

Now, as noticed at the beginning of Sec. IV, these two worldlines can be obtained by conformally mapping the worldline of one uniformly moving particle in Minkowski space into de Sitter space. The fields of uniformly moving sources in Minkowski space are just boosted Coulomb fields. Under a conformal rescaling of the metric, $g_{\alpha\beta}\to\hat{g}_{\alpha\beta}=\Omega^2 g_{\alpha\beta}$, the fields behave as follows: $\Phi\to\hat{\Phi}=\Omega^{-1}\Phi$, $\mathrm{F}_{\alpha\beta}\to\hat{\mathrm{F}}_{\alpha\beta}=\mathrm{F}_{\alpha\beta}$ (see Ref. 24, Sec. II, where the behavior of the source terms is also analyzed). Hence, the fields due to two uniformly accelerated sources in de Sitter space–time can be obtained by conformally transforming the boosted Coulomb fields in Minkowski space–time. Employing the conformal mapping (3.13)–(3.15), we arrive at the following results.[52] The scalar field is given by the expression

$$\Phi=\frac{s}{4\pi}\frac{1}{\mathcal{Q}}, \tag{6.1}$$

where

$$\mathcal{Q}=\ell_\Lambda\left[\left(\sqrt{1+a_\mathrm{o}^2\ell_\Lambda^2}+a_\mathrm{o}\ell_\Lambda\cosh\frac{\tau}{\ell_\Lambda}\sin\chi\cos\vartheta\right)^2-\left(1-\cosh^2\frac{\tau}{\ell_\Lambda}\sin^2\chi\right)\right]^{1/2}, \tag{6.2}$$

or, written in the standard rescaled coordinates,

$$\mathcal{Q}=\ell_\Lambda\left[\left(\sqrt{1+a_\mathrm{o}^2\ell_\Lambda^2}+a_\mathrm{o}\ell_\Lambda\frac{\sin\tilde{r}}{\sin\tilde{t}}\cos\vartheta\right)^2-1+\frac{\sin^2\tilde{r}}{\sin^2\tilde{t}}\right]^{1/2}. \tag{6.3}$$

This field is produced by two identical charges of magnitude s moving along worldlines $w_\odot$ and $w_\otimes$. It is smooth everywhere outside the charges and it can be written as a symmetric combination of retarded and advanced effects from both charges [cf. Eq. (6.6) in Ref. 24].

Similarly to the scalar-field case, by using conformal technique the electromagnetic field produced by two uniformly accelerated charges moving along $w_\odot$ and $w_\otimes$ can be obtained in the form

$$\mathrm{F}=\frac{e}{4\pi}\frac{\ell_\Lambda^2}{\mathcal{Q}^3}\cosh\frac{\tau}{\ell_\Lambda}\Bigg[a_\mathrm{o}\ell_\Lambda\sin\chi\cos\chi\sin\vartheta\,\mathrm{d}\tau\wedge\mathrm{d}\vartheta$$
$$-\left(\sqrt{1+a_\mathrm{o}^2\ell_\Lambda^2}\cosh\frac{\tau}{\ell_\Lambda}\sin\chi+a_\mathrm{o}\ell_\Lambda\cos\vartheta\right)\mathrm{d}\tau\wedge\mathrm{d}\chi$$
$$+a_\mathrm{o}\ell_\Lambda^2\sinh\frac{\tau}{\ell_\Lambda}\cosh\frac{\tau}{\ell_\Lambda}\sin^2\chi\sin\vartheta\,\mathrm{d}\chi\wedge\mathrm{d}\vartheta \tag{6.4}$$

where $\mathcal{Q}$ is again given by Eq. (6.2). As in the scalar-field case, the field is smooth, nonvanishing in the whole de Sitter space–time and involving thus both retarded and advanced effects (cf. Sec. VII A in Ref. 24). However, an important difference between the scalar and electromagnetic case exists: the magnitude of the scalar charges is the same, whereas the electromagnetic charges producing the fields (6.4) have opposite signs. This is analogous to the situation in Minkowski space–time described in Sec. II [see the discussion below Eq. (2.13)]. At the root of this fact appears to be CPT theorem—cf. Ref. 53 for the analogous gravitational case where the masses of the particles uniformly accelerated in the opposite direction are the same. In de Sitter space–time, as in any space–time with compact spacelike sections, a simpler argument exists: the total charge in a compact space must vanish as a consequence of the Gauss theorem.[24]

To gain a better physical insight into the electromagnetic fields, we shall introduce the orthonormal tetrad $\{\mathrm{e}_\mu\}$ and the dual tetrad $\{\mathrm{e}^\mu\}$ tied to each coordinate frame used, and we shall decompose the electromagnetic field F into the electric and magnetic parts. Such a decomposition, of course, depends on the choice of the tetrad. For example, in the standard spherical coordinates τ, χ, ϑ, φ the electromagnetic field (2-form) F can be written as

$$\mathrm{F}=\mathrm{E}^\chi\mathrm{e}^\chi\wedge\mathrm{e}^\tau+\mathrm{E}^\vartheta\mathrm{e}^\vartheta\wedge\mathrm{e}^\tau+\mathrm{E}^\varphi\mathrm{e}^\varphi\wedge\mathrm{e}^\tau+\mathrm{B}^\chi\mathrm{e}^\vartheta\wedge\mathrm{e}^\varphi+\mathrm{B}^\vartheta\mathrm{e}^\varphi\wedge\mathrm{e}^\chi+\mathrm{B}^\varphi\mathrm{e}^\chi\wedge\mathrm{e}^\vartheta, \tag{6.5}$$

and the electric and magnetic field spatial vectors are given in terms of their frame components as follows:

$$\mathrm{E}=\mathrm{E}^\chi\mathrm{e}_\chi+\mathrm{E}^\vartheta\mathrm{e}_\vartheta+\mathrm{E}^\varphi\mathrm{e}_\varphi,$$
$$\mathrm{B}=\mathrm{B}^\chi\mathrm{e}_\chi+\mathrm{B}^\vartheta\mathrm{e}_\vartheta+\mathrm{B}^\varphi\mathrm{e}_\varphi. \tag{6.6}$$

In the present case of the standard spherical coordinates, using the explicit forms of the tetrad given in Appendix [Eqs. (A10)], we find

$$\mathrm{E}_\mathrm{sph}=\frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{Q}^3}\left[-a_\mathrm{o}\ell_\Lambda\cos\chi\sin\vartheta\,\mathrm{e}_\vartheta+\left(\sqrt{1+a_\mathrm{o}^2\ell_\Lambda^2}\cosh\frac{\tau}{\ell_\Lambda}\sin\chi+a_\mathrm{o}\ell_\Lambda\cos\vartheta\right)\mathrm{e}_\chi\right],$$
$$\mathrm{B}_\mathrm{sph}=\frac{e}{4\pi}\frac{a_\mathrm{o}\ell_\Lambda^2}{\mathcal{Q}^3}\sinh\frac{\tau}{\ell_\Lambda}\sin\chi\sin\vartheta\,\mathrm{e}_\varphi. \tag{6.7}$$

In Appendix the orthonormal tetrads tied to the coordinate systems considered in this paper are all listed explicitly. The only exception is the Robinson-Trautman coordinate system with one coordinate null and thus with a nondiagonal metric; in this case the null tetrad is given in which the Newman-Penrose-type components are more telling.

The tetrad components of the electric intensity and the magnetic induction vectors are physically meaningful objects, they can be measured by observers who move with the four-velocities given by the timelike vector of the tetrad (as, e.g., e_τ for spherical cosmological observers), and are equipped with an orthonormal triad of the spacelike vectors (e.g., e_χ, e_ϑ, e_φ).

We first list the resulting electromagnetic field tensor and its electric and magnetic parts in the coordinate systems centered on the poles $\chi=0,\pi$. The scalar field is always given by expression

(6.1), the explicit form of the scalar factor $\mathcal{Q}$ changes according to the coordinates used. Since this factor enters all the electromagnetic quantities as well, we always give $\mathcal{Q}$ first and then write the electromagnetic field quantities.

In the flat cosmological coordinates [see Eqs. (3.4) and (3.5)] we find

$$\mathcal{Q}=\ell_\Lambda\left[\left(\cosh\alpha_o-\sinh\alpha_o\frac{\check r}{\ell_\Lambda}\exp\frac{\check\tau}{\ell_\Lambda}\cos\vartheta\right)^2-\left(1-\frac{\check r^2}{\ell_\Lambda^2}\exp\left(2\frac{\check\tau}{\ell_\Lambda}\right)\right)\right]^{1/2}, \tag{6.8}$$

$$\begin{aligned}F=&-\frac{e}{4\pi}\frac{1}{\mathcal{Q}^3}\exp\frac{\check\tau}{\ell_\Lambda}\left[\ell_\Lambda\check r\sinh\alpha_o\sin\vartheta\,d\check\tau\wedge d\vartheta+\left(\check r\cosh\alpha_o\exp\frac{\check\tau}{\ell_\Lambda}-\ell_\Lambda\sinh\alpha_o\cos\vartheta\right)d\check\tau\wedge d\check r\right.\\&\left.+\check r^2\sinh\alpha_o\exp\left(2\frac{\check\tau}{\ell_\Lambda}\right)\sin\vartheta\,d\check r\wedge d\vartheta\right],\end{aligned} \tag{6.9}$$

$$\begin{aligned}E_{flat}=&\frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{Q}^3}\left[\sinh\alpha_o\sin\vartheta\,e_{\vartheta}-\left(\cosh\alpha_o\frac{\check r}{\ell_\Lambda}\exp\frac{\check\tau}{\ell_\Lambda}-\sinh\alpha_o\cos\vartheta\right)e_{\check r}\right],\\B_{flat}=&-\frac{e}{4\pi}\frac{\ell_\Lambda\sinh\alpha_o}{\mathcal{Q}^3}\frac{\check r}{\ell_\Lambda}\exp\frac{\check\tau}{\ell_\Lambda}\sin\vartheta\,e_\varphi.\end{aligned} \tag{6.10}$$

In the hyperbolic cosmological coordinates [see Eqs. (3.6) and (3.7)], the results are slightly lengthier,

$$\mathcal{Q}=\ell_\Lambda\left[\left(\cosh\alpha_o-\sinh\alpha_o\sinh\frac{\eta}{\ell_\Lambda}\sinh\frac{\rho}{\ell_\Lambda}\cos\vartheta\right)^2-\left(1-\sinh^2\frac{\eta}{\ell_\Lambda}\sinh^2\frac{\rho}{\ell_\Lambda}\right)\right]^{1/2}, \tag{6.11}$$

$$\begin{aligned}F=&-\frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{Q}^3}\left[\sinh\frac{\eta}{\ell_\Lambda}\left(\cosh\alpha_o\sinh\frac{\eta}{\ell_\Lambda}\sinh\frac{\rho}{\ell_\Lambda}-\sinh\alpha_o\cos\vartheta\right)d\eta\wedge d\rho\right.\\&+\sinh\alpha_o\sinh\frac{\eta}{\ell_\Lambda}\sinh\frac{\rho}{\ell_\Lambda}\cosh\frac{\rho}{\ell_\Lambda}\sin\vartheta\,\ell_\Lambda d\eta\wedge d\vartheta\\&\left.+\sinh\alpha_o\sinh^2\frac{\eta}{\ell_\Lambda}\cosh\frac{\eta}{\ell_\Lambda}\sinh^2\frac{\rho}{\ell_\Lambda}\sin\vartheta\,\ell_\Lambda\,d\rho\wedge d\vartheta\right]\end{aligned} \tag{6.12}$$

$$\begin{aligned}E_{hyp}=&\frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{Q}^3}\left[\sinh\alpha_o\cosh\frac{\rho}{\ell_\Lambda}\sin\vartheta\,e_{\vartheta}+\left(\cosh\alpha_o\sinh\frac{\eta}{\ell_\Lambda}\sinh\frac{\rho}{\ell_\Lambda}-\sinh\alpha_o\cos\vartheta\right)e_\rho\right],\\B_{hyp}=&-\frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{Q}^3}\sinh\alpha_o\cosh\frac{\eta}{\ell_\Lambda}\sinh\frac{\rho}{\ell_\Lambda}\sin\vartheta\,e_\varphi.\end{aligned} \tag{6.13}$$

Much simpler expressions for the fields arise in the static coordinates [see Eqs. (3.8) and (3.9)]. We obtain

$$\mathcal{Q}^2=\frac{(\ell_\Lambda^2-RR_o\cos\vartheta)^2}{(\ell_\Lambda^2-R_o^2)}-(\ell_\Lambda^2-R^2), \tag{6.14}$$

$$\mathrm{F} = -\frac{e}{4\pi}\frac{\ell_\Lambda}{\sqrt{\ell_\Lambda^2 - R_\mathrm{o}^2}}\frac{1}{\mathcal{Q}^3}\left[(R - R_\mathrm{o}\cos\vartheta)\,\mathrm{d}T\wedge\mathrm{d}R + \left(1 - \frac{R^2}{\ell_\Lambda^2}\right)RR_\mathrm{o}\sin\vartheta\,\mathrm{d}T\wedge\mathrm{d}\vartheta\right], \quad (6.15)$$

$$\mathrm{E}_{\mathrm{stat}} = \frac{e}{4\pi}\frac{1}{\mathcal{Q}^3}\left[\frac{\ell_\Lambda(R - R_\mathrm{o}\cos\vartheta)}{\sqrt{\ell_\Lambda^2 - R_\mathrm{o}^2}}\mathrm{e}_R + R_\mathrm{o}\sin\vartheta\,\mathrm{e}_\vartheta\right], \quad \mathrm{B}_{\mathrm{stat}} = 0. \quad (6.16)$$

Since for practical calculations and for an understanding of the conformal relations between Minkowski and de Sitter spaces the rescaled coordinates are very useful, we also give the fields in these coordinates. The rescaled coordinates are tied with the same orthonormal tetrad as nonrescaled ones, and they define the same splitting into electric and magnetic parts (E and B are the same spatial vectors); the functional dependence on the coordinates, however, is different. In the standard rescaled (conformally Einstein) coordinates [see Eqs. (3.10)–(3.12)], which cover the whole de Sitter space–time including its conformal infinities globally, we get Eq. (6.3) for $\mathcal{Q}$ and

$$\mathrm{F} = -\frac{e}{4\pi}\frac{1}{\mathcal{Q}^3}\frac{\ell_\Lambda^3}{\sin^3\tilde{t}}\Big[a_\mathrm{o}\ell_\Lambda\cos\tilde{t}\sin^2\tilde{r}\sin\vartheta\,\mathrm{d}\tilde{r}\wedge\mathrm{d}\vartheta + \Big(\sqrt{1 + a_\mathrm{o}^2\ell_\Lambda^2}\sin\tilde{r} + a_\mathrm{o}\ell_\Lambda\sin\tilde{t}\cos\vartheta\Big)\mathrm{d}\tilde{t}\wedge\mathrm{d}\tilde{r}$$
$$- a_\mathrm{o}\ell_\Lambda\sin\tilde{t}\cos\tilde{r}\sin\tilde{r}\sin\vartheta\,\mathrm{d}\tilde{t}\wedge\mathrm{d}\vartheta\Big], \quad (6.17)$$

$$\mathrm{E}_{\mathrm{sph}} = \frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{Q}^3}\left[-a_\mathrm{o}\ell_\Lambda\cos\tilde{r}\sin\vartheta\,\mathrm{e}_\vartheta + \left(\sqrt{1 + a_\mathrm{o}^2\ell_\Lambda^2}\,\frac{\sin\tilde{r}}{\sin\tilde{t}} + a_\mathrm{o}\ell_\Lambda\cos\vartheta\right)\mathrm{e}_\chi\right],$$
$$\mathrm{B}_{\mathrm{sph}} = -\frac{e}{4\pi}\frac{a_\mathrm{o}\ell_\Lambda^2}{\mathcal{Q}^3}\cot\tilde{t}\sin\tilde{r}\sin\vartheta\,\mathrm{e}_\varphi, \quad (6.18)$$

whereas in the flat rescaled cosmological coordinates (3.13)–(3.15), which cover globally the conformally related Minkowski space (see also Fig. 3), we arrive at

$$\mathcal{Q} = \ell_\Lambda\left[\left(\cosh\alpha_\mathrm{o} + \sinh\alpha_\mathrm{o}\frac{\check{r}}{\check{t}}\cos\vartheta\right)^2 - \left(1 - \frac{\check{r}^2}{\check{t}^2}\right)\right]^{1/2}, \quad (6.19)$$

$$\mathrm{F} = \frac{e}{4\pi}\frac{1}{\mathcal{Q}^3}\frac{\ell_\Lambda^3}{\check{t}^3}\Big[\sinh\alpha_\mathrm{o}\,\check{r}^2\sin\vartheta\,\mathrm{d}\check{r}\wedge\mathrm{d}\vartheta + (\cosh\alpha_\mathrm{o}\,\check{r} + \sinh\alpha_\mathrm{o}\,\check{t}\cos\vartheta)\mathrm{d}\check{t}\wedge\mathrm{d}\check{r}$$
$$- \sinh\alpha_\mathrm{o}\,\check{t}\check{r}\sin\vartheta\,\mathrm{d}\check{t}\wedge\mathrm{d}\vartheta\Big], \quad (6.20)$$

$$\mathrm{E}_{\mathrm{flat}} = \frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{Q}^3}\left[\sinh\alpha_\mathrm{o}\sin\vartheta\,\mathrm{e}_\vartheta - \left(\cosh\alpha_\mathrm{o}\frac{\check{r}}{\check{t}} + \sinh\alpha_\mathrm{o}\cos\vartheta\right)\mathrm{e}_{\check{r}}\right],$$
$$\mathrm{B}_{\mathrm{flat}} = \frac{e}{4\pi}\frac{\ell_\Lambda\sinh\alpha_\mathrm{o}}{\mathcal{Q}^3}\frac{\check{r}}{\check{t}}\sin\vartheta\,\mathrm{e}_\varphi. \quad (6.21)$$

In various contexts the electromagnetic field four-potential form A, implying the field F=dA, may be needed. In the standard rescaled (conformally Einstein) coordinates the potential reads

$$\mathrm{A} = -\frac{e}{4\pi}\frac{1}{\mathcal{Q}}\frac{\ell_\Lambda}{\sin\tilde{t}}\frac{\sqrt{1+a_\mathrm{o}^2\ell_\Lambda^2}\sin\tilde{t}+a_\mathrm{o}\ell_\Lambda\sin\tilde{r}\cos\vartheta}{\sin^2\tilde{t}-\sin^2\tilde{r}}(\sin\tilde{t}\cos\tilde{r}\,\mathrm{d}\tilde{t}-\cos\tilde{t}\sin\tilde{r}\,\mathrm{d}\tilde{r}). \tag{6.22}$$

From this expression the frame components can easily be obtained and the four-potential form can be transformed directly to any coordinate system of interest. The four-potential acquires a particularly simple form in static coordinates,

$$A = -\frac{e}{4\pi}\frac{1}{\mathcal{Q}}\frac{\ell_\Lambda^2 - RR_\mathrm{o}\cos\vartheta}{\ell_\Lambda\sqrt{\ell_\Lambda^2 - R_\mathrm{o}^2}}\mathrm{d}T. \tag{6.23}$$

Inspecting now the expressions (6.4)–(6.21), we first notice few basic features of the fields. As a consequence of the axisymmetry, the azimuthal φ component of the electric field vanishes. On the other hand, only the azimuthal φ component of the magnetic field is nonzero. At the axis of symmetry, $\vartheta=0,\pi$, the latitudinal ϑ component of the electric field and magnetic field vanish as $\sim\sin\vartheta$. The electric field points along the axis.

In the classical Born solution in Minkowski space, both charges are, at any time, located symmetrically with respect to the equatorial plane $\vartheta=\pi/2$. Consequently, the radial part of the electric field vanishes for $\vartheta=\pi/2$ [cf. Eq. (2.13)]. In de Sitter space–time the charges outgoing from the poles are, at all times, symmetrically located with respect to the sphere $\chi=\pi/2$ (illustrated as the circle in Fig. 2). We thus expect the ϑ component of the electric field to vanish for $\chi=\pi/2$. This, indeed, follows from Eq. (6.7). This symmetry can be seen only in the standard spherical coordinates since the sphere $\chi=\pi/2$ is not covered by the hyperbolic cosmological coordinates and in the flat cosmological coordinates only one particle occurs.

Another typical feature of the Born solution in Minkowski space is its time symmetry. As a consequence, the magnetic field vanishes at $t=0$ [cf. Eq. (2.13)]. In the past, it was this fact which led some investigators, Pauli[54] among them, to the conclusion that there is "no formation of a wave zone nor any corresponding radiation" since $\mathrm{B}=0$ at $t=0$. However, it is not at a spacelike hypersurface $t=$constant but at $\mathcal{I}^+$, which is reached by taking $u=t-r$ constant, $t,r\to\infty$, where the Born field has typical radiative features, i.e., $|\mathrm{E}|=|\mathrm{B}|\sim r^{-1}$ (see Refs. 37, 53, and 25). In our generalized Born solution, the time symmetry of the fields is clearly demonstrated in the global standard coordinates, under inversion $\tau\to-\tau$ the electric field in Eq. (6.7) is invariant, whereas the magnetic field changes the sign; $\mathrm{B}_\varphi=0$ at $\tau=0$. The field also exhibits radiative character when we approach $\mathcal{I}^+$ in an appropriate way, as it is briefly indicated in Ref. 25. A detailed analysis of the radiative properties of the generalized Born field will be given elsewhere.

The fields take the simplest form in the static coordinates, Eq. (6.15). In these coordinates the particles are at rest, and they both have a constant distance from the poles; their world lines are the orbits of the "static" Killing vector $\partial/\partial T$ of de Sitter space. The electric field is time independent, the magnetic field vanishes. This is fully analogous to the Born field in Minkowski space–time, it is static, and purely electric in the Rindler coordinates, the time coordinate of which is aligned along the orbit of the boost Killing vectors (see, e.g., Ref. 6). However, as we discussed in Sec. III, the static coordinates cover only a "half" of de Sitter space. In the other half, the Killing vector $\partial/\partial T$ becomes spacelike. It is in this nonstatic domain (regions **F** and **P** in Fig. 12) where we expect, in analogy with the results in Minkowski space–time, to find fields which have radiative properties. $\partial/\partial T$ is the Killing vector also in the nonstatic regions, however, it is spacelike here, as it is typical for a boost Killing vector in Minkowski space. The fields of uniformly accelerated charges in de Sitter space–time are invariant under the boosts along $\partial/\partial T$ everywhere. They are thus boost-rotation symmetric as the Born fields in Minkowski space–time.

In the cosmological coordinates, respectively, in their rescaled versions, the fields are, of course, time dependent. Here we expect the effects of the expansion/contraction of de Sitter universe to be manifested. Indeed, considering in any of the cosmological frames the spatial coordinates fixed, and examining the fields along the timelike geodesics, we discover that the fields exponentially decay at large times, i.e., as $\mathcal{I}^+$ is approached. More specifically, with the

spherical coordinates χ, ϑ, φ fixed, the factor $\mathcal{Q}$ behaves as $\exp(\tau/\ell_\Lambda)$ at large times τ, and hence, we obtain $\mathrm{E}_{\mathrm{sph}} \approx c_1 \exp(-2\tau/\ell_\Lambda)\mathrm{e}_\chi + c_2 \exp(-3\tau/\ell_\Lambda)\mathrm{e}_\vartheta$, $\mathrm{B}_{\mathrm{sph}} \approx b_1 \exp(-2\tau/\ell_\Lambda)\mathrm{e}_\varphi, c_1, c_2, b_1$ being constants. The electric field thus becomes radial at large τ. Similarly, in flat cosmological coordinates we find $\mathrm{E}_{\mathrm{flat}} \approx c_1 \exp(-2\check{\tau}/\ell_\Lambda)\mathrm{e}_{\check{r}}$, $\mathrm{B}_{\mathrm{flat}} \approx b_1 \exp(-2\check{\tau}/\ell_\Lambda)\mathrm{e}_\varphi$. In the hyperbolic cosmological coordinates the proper time η appears instead of $\check{\tau}$. The rapid decay of the fields along timelike worldlines at large times is caused by the exponential expansion (at large times) of the spatial slices τ=constant (respectively, $\check{\tau}, \eta$=constant). Although our fields are just test fields, their exponential decay is another manifestation of the "cosmic no-hair phenomenon:" geodesic observers in space–times with $\Lambda > 0$ see at large times these space–times to approach the de Sitter universe exponentially fast—the universe becomes "bald" (see, e.g., Refs. 22 and 23). Clearly, as one approaches past infinity $\mathcal{I}^-$ ($\tau \to -\infty$), the fields also decay exponentially.

It is interesting to notice the character of the field as it would be seen by the observers at rest with respect to the hyperbolic cosmological coordinates in the limit at which the particles "enter" the region covered by these observers across the horizon $\tilde{t} = \tilde{r}$ (cf. Fig. 4), given in the hyperbolic coordinates by $\eta \to 0$, $\rho \to \infty$. As discussed in Sec. IV, the observed velocity (4.17) of the charges at this boundary is (in the limit) equal to the velocity of light. Employing the transformation formulas (A86), it is easy to see that at this boundary $|\sinh(\eta/\ell_\Lambda)\sinh(\rho/\ell_\Lambda)| \to 1$. Hence, the factor $\mathcal{Q}$ is finite here (as it is evident from its scalar character and its finiteness in the global standard coordinates). Also, the radial part of the electric field remains finite. However, E^ϑ diverges as $\exp(\rho/\ell_\Lambda)$ here, indicating that the field has a character of an impulse, in fact, rather of an impulsive wave—indeed, Eq. (6.10) implies $|\mathrm{E}^\vartheta| = |\mathrm{B}^\varphi|$. The situation appears to be analogous to the field of a static charge viewed from an inertial frame boosted to the velocity of light in Minkowski space–time (see, e.g., Ref. 55).

B. Fields in coordinates centered on the particles

As expected, a remarkable simplification occurs when the fields are evaluated in the coordinates at the origin of which the charges are situated at all times. Since the accelerated coordinates T', R', ϑ' and the C-metric-like coordinates are simply related by Eqs. (5.8), the discussion of the field properties is the same in both these frames. Namely, notice that both coordinate systems are tied with the same orthonormal tetrad, and they thus define the same splitting of the field into the electric and magnetic parts. In these coordinates, we find the factor $\mathcal{Q}$ to read

$$\mathcal{Q} = \cosh\alpha_{\mathrm{o}} \frac{1}{R'} + \sinh\alpha_{\mathrm{o}} \frac{1}{\ell_\Lambda} \cos\vartheta' = \frac{1}{\ell_\Lambda}(v\cosh\alpha_{\mathrm{o}} - \xi\sinh\alpha_{\mathrm{o}}). \tag{6.24}$$

The scalar field is again given by $\Phi = (s/4\pi)\mathcal{Q}^{-1}$, and the electromagnetic field also acquires now an extremely simple form,

$$\mathrm{F} = \frac{e}{4\pi}\frac{1}{R'^2}\mathrm{d}R' \wedge \mathrm{d}T' = \frac{e}{4\pi}\mathrm{d}\tau \wedge \mathrm{d}v, \tag{6.25}$$

$$\mathrm{E}_{\mathrm{acc}} = \frac{e}{4\pi}\frac{1}{\mathcal{Q}^2}e_{R'}, \quad \mathrm{B}_{\mathrm{acc}} = 0. \tag{6.26}$$

The magnetic field vanishes in the frame tied to the accelerated and C-metric coordinates, the electric field has precisely the Coulomb form, with the factor $\mathcal{Q}$ playing the role of a distance.

As signalized above already, the factor $\mathcal{Q}$ turns out to be the Robinson-Trautman radial coordinate [see Eq. (6.28) below], i.e., the affine parameter distance along null geodesics. The geometrical role of $\mathcal{Q}$ was elucidated in Sec. V B. Considering a fixed point in de Sitter universe and a light cone emanating from this point, three typical situations can arise as illustrated in Fig. 12. For a point B from the regions **N** or **S**, there are two null geodesics, one past-pointing, the other future-pointing, each of which crosses the worldline of the same particle, say $w_\odot$ (in case of B from **N**), at points B_{ret} and B_{adv} (see Fig. 12). Since $\mathcal{Q}$ is equal to the (specific) affine parameter

distance which is the same from B_{ret} as from B_{adv} (see Sec. V B), we can interpret the field (6.26) as arising from purely retarded, respectively, advanced effects from B_{ret}, respectively B_{adv}; or, equivalently, as a combination of retarded and advanced effects from these points. In the second situation, when the fixed point, say A, is located "above the roof" (in the region **F**), there are two past-oriented null geodesics emanating from it which cross now both particles $w_{\odot}$ and $w_{\otimes}$ at points $A_{\odot}$ and $A_{\otimes}$ (see Fig. 12). The field can be interpreted as arising from retarded effects only, either as a combination from both particles $w_{\odot}$ and $w_{\otimes}$, or as the retarded field from just one of them. Finally, for a point from the region **P** the field can analogously be interpreted in terms of advanced effects.

As we discussed in Sec. V A and illustrate in detail in Appendix, the accelerated coordinates (similarly as the static coordinates to which they go over for a vanishing acceleration) are static, i.e., the vector $\partial/\partial T'$ tangent to the orbits of the Killing vector is timelike, only in the regions **N** and **S** (cf. Figs. 10 and 12). Observers following the orbits of the Killing vector are thus confined to the regions **N** and **S**, and they cannot detect the fields in the region **F** (respectively, **P**). Nevertheless, notice that although the time coordinate T' diverges at the horizon $R=\ell_{\Lambda}$, the radial coordinate R' is perfectly finite there, $R'=\ell_{\Lambda}$ [cf. Eq. (5.6) with $R=\ell_{\Lambda}$], and the field (6.25) is meaningful in the region **F** (or **P**) as well. Since here the roles of the coordinates R' and T' are interchanged, R' becoming a time coordinate, the field becomes time dependent. As mentioned above, we do not expect to find radiative properties in the regions **N** and **S**. Indeed, in accelerated coordinates the field (6.26) is static Coulomb field, with $\mathcal{Q}$ playing the role of a distance. However, the radiative properties of the whole field in the wave zone in the region **F** are not evident from the time-dependent, purely electric field in the accelerated coordinates with R' as a time coordinate.

It is worthwhile to recall that with finite sources in Minkowski space–time the field at any event is of a general algebraic type; only asymptotically, at large distances, its features approach those of a null field ($\mathrm{E}^2-\mathrm{B}^2=0$, $\mathrm{E}\cdot\mathrm{B}=0$), if there is a radiation (see, e.g., Refs. 56 and 45). In case of a non-null field, one can always introduce a frame in which the electric and magnetic fields are collinear, or, in the language of the Newman-Penrose formalism, to choose such a null tetrad k, l, m, $\bar{\mathrm{m}}$, corresponding to the orthonormal tetrad, that the only nonvanishing null-tetrad component is $\Phi_1=1/(2\sqrt{2})\ (\mathrm{E}-i\mathrm{B})\cdot(\mathrm{k}-\mathrm{l})$ [see Eqs. (A114) for the explicit expressions of the null tetrad and Eqs. (A4) for the null-tetrad components of the electromagnetic field]. Such a situation arises precisely for the null tetrad associated with the accelerated coordinates: the null-tetrad components are simply

$$\Phi_1^{\mathrm{acc}}=-\frac{1}{2}\frac{e}{4\pi}\frac{1}{\mathcal{Q}^2},\quad \Phi_0^{\mathrm{acc}}=\Phi_2^{\mathrm{acc}}=0. \tag{6.27}$$

The vanishing of the other two null-tetrad components, Φ_0^{acc} and Φ_2^{acc}, has a deeper algebraic explanation: the null tetrad tied to the accelerated coordinates is special in the sense that it contains both principal null directions of the electromagnetic field. Inspecting the form of the null tetrad constructed from the orthonormal tetrad (A95), we observe that both these principal null directions are tangent to the "radial" surfaces ϑ', $\varphi=$constant in the accelerated coordinates.

The radiative properties are well exhibited in the Robinson-Trautman coordinates. As we discussed in Sec. V B, these coordinates are tied to the future null cones centered on the worldline of a particle. We consider the null cones with vertices on the particle $w_{\odot}$. Let us recall that the radial coordinate $\mathfrak{r}$ is the affine parameter along the generators of the null cones, each of which is given by $\mathfrak{u}$, ψ, φ fixed. Now, as mentioned above, it turns out that the factor $\mathcal{Q}$ is precisely equal to this affine parameter $\mathfrak{r}$,

$$\mathcal{Q}=\mathfrak{r}. \tag{6.28}$$

The scalar field is then simply given by

$$\Phi = \frac{s}{4\pi}\frac{1}{\mathfrak{r}}. \tag{6.29}$$

A remarkably nice form also acquires the electromagnetic field,

$$F = \frac{e}{4\pi}\left(\frac{1}{\mathfrak{r}^2}\mathrm{d}\mathfrak{u}\wedge\mathrm{d}\mathfrak{r} + a_{\mathrm{o}}\sin^2\vartheta'\mathrm{d}\mathfrak{u}\wedge\mathrm{d}\vartheta'\right) = \frac{e}{4\pi}\left(\frac{1}{\mathfrak{r}^2}\mathrm{d}\mathfrak{u}\wedge\mathrm{d}\mathfrak{r} + a_{\mathrm{o}}\sin^2\vartheta'\mathrm{d}\mathfrak{u}\wedge\mathrm{d}\psi\right). \tag{6.30}$$

The Newman-Penrose scalars are defined in terms of the null tetrad (A114), which is parallelly propagated from the source to the "observation point" along the rays $\mathfrak{u}$, ψ, φ=constant. They look as follows:

$$\Phi_0^{\mathrm{RT}} = 0, \quad \Phi_1^{\mathrm{RT}} = -\frac{1}{2}\frac{e}{4\pi}\frac{1}{\mathfrak{r}^2}, \quad \Phi_2^{\mathrm{RT}} = \frac{1}{\sqrt{2}}\frac{e}{4\pi}\frac{1}{\mathfrak{r}}a_{\mathrm{o}}\sin\vartheta'. \tag{6.31}$$

Now the radiative character of the field is transparent: the first term entering the peeling behavior, the scalar Φ_2, decays indeed as $\mathfrak{r}^{-1}$, and it is nonvanishing for a nonzero acceleration a_{o}. In the expressions (6.30) and (6.31), the de Sitter background is completely "hidden." The same form of the fields are obtained in case of uniformly accelerated charges in Minkowski space if the coordinates built on the null cones emanating from the particles are employed. A difference between both cases reveals itself only in the explicit dependence of the affine parameter $\mathfrak{r}$ on the coordinates of space–time points.

VII. BORN IN DE SITTER

Finally, we turn to the fields from the particles symmetrically located with respect to the origin $\chi=0$ (the "north pole") of the standard spherical coordinates. The particles are thus "born" asymptotically at the equator, $\chi=\pi/2$, at $\tau\to-\infty$, and return back at $\tau\to\infty$ with the opposite speeds (Fig. 8). Their fields, of course, are intrinsically the same as those considered in the preceding section but only now they represent the direct generalization of the classical Born solutions due to uniformly accelerated charges symmetrically located with respect to the origin of Minkowski space.

We shall find the generalized Born fields easily by using the transformation (4.21) which we applied to obtain the worldlines of the particles born at the equator from those born at the poles. The scalar field due to two equal scalar charges s moving along the worldlines $w_{\oplus}$ and $w_{\ominus}$ reads

$$\Phi = \frac{s}{4\pi}\Omega_{\mathrm{M}}^{-1}\frac{1}{\mathcal{R}}, \tag{7.1}$$

where the factor $\mathcal{R}$ is determined by

$$\mathcal{R} = \frac{\ell_\Lambda}{1+\cosh\dfrac{\tau}{\ell_\Lambda}\cos\chi}\left[\cosh^2\frac{\tau}{\ell_\Lambda}\sin^2\chi\sin^2\vartheta + \left(\sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2}\cosh\frac{\tau}{\ell_\Lambda}\cos\chi - a_{\mathrm{o}}\ell_\Lambda\right)^2\right]^{1/2}, \tag{7.2}$$

and the conformal factor Ω_{M} is given by [cf. Eq. (3.19)]

$$\Omega_{\mathrm{M}} = 1+\cosh\frac{\tau}{\ell_\Lambda}\cos\chi. \tag{7.3}$$

This factor is left in the explicit form here, in contrast to the preceding section, since it explicitly exhibits conformal relation of the scalar field under conformal mappings (3.19) between de Sitter space and Minkowski space M. This relation will be used in the following to perform the limit from the Born field in de Sitter to the Born field in Minkowski space–time.

The electromagnetic field produced by charge e moving along the worldline $w_{\oplus}$ and by symmetrically located charge $-e$ moving along $w_{\ominus}$ has the following form:

$$\mathrm{F}_{\mathrm{BdS}} = \frac{e}{4\pi}\frac{\ell_\Lambda^2}{\mathcal{R}^3}\frac{\cosh\dfrac{\tau}{\ell_\Lambda}\sin\vartheta}{\left(1+\cosh\dfrac{\tau}{\ell_\Lambda}\cos\chi\right)^3}\Bigg[a_{\mathrm{o}}\ell_\Lambda^2\sinh\frac{\tau}{\ell_\Lambda}\cosh\frac{\tau}{\ell_\Lambda}\sin^2\chi\,\mathrm{d}\chi\wedge\mathrm{d}\vartheta$$

$$+\left(\sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2}\cosh\frac{\tau}{\ell_\Lambda}\cos\chi - a_{\mathrm{o}}\ell_\Lambda\right)\cot\vartheta\,\mathrm{d}\tau\wedge\mathrm{d}\chi \tag{7.4}$$

$$-\left(\sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2}\cosh\frac{\tau}{\ell_\Lambda} - a_{\mathrm{o}}\ell_\Lambda\cos\chi\right)\sin\chi\,\mathrm{d}\tau\wedge\mathrm{d}\vartheta\Bigg].$$

with factor $\mathcal{R}$ given by (7.2). In the tetrad tied to the standard spherical coordinates the electric and magnetic fields become

$$\mathrm{E}^{\mathrm{BdS}}_{\mathrm{sph}} = -\frac{e}{4\pi}\frac{\ell_\Lambda}{\mathcal{R}^3}\frac{1}{\left(1+\cosh\dfrac{\tau}{\ell_\Lambda}\cos\chi\right)^3}\Bigg[\left(\sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2}\cosh\frac{\tau}{\ell_\Lambda}\cos\chi - a_{\mathrm{o}}\ell_\Lambda\right)\cot\vartheta\,\mathrm{e}_\chi$$

$$-\left(\sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2}\cosh\frac{\tau}{\ell_\Lambda} - a_{\mathrm{o}}\ell_\Lambda\cos\chi\right)\sin\chi\,\mathrm{e}_\vartheta\Bigg], \tag{7.5}$$

$$\mathrm{B}^{\mathrm{BdS}}_{\mathrm{sph}} = \frac{e}{4\pi}\frac{a_{\mathrm{o}}\ell_\Lambda^2}{\mathcal{R}^3}\frac{\sinh\dfrac{\tau}{\ell_\Lambda}\sin\chi\sin\vartheta}{\left(1+\cosh\dfrac{\tau}{\ell_\Lambda}\cos\chi\right)^3}\,\mathrm{e}_\varphi.$$

In the standard rescaled (conformally Einstein) coordinates the expressions (7.4) and (7.5) slightly simplify

$$\frac{\mathcal{R}}{\ell_\Lambda} = \frac{\left[\left(a_{\mathrm{o}}\ell_\Lambda\sin\tilde{t} - \sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2}\cos\tilde{r}\right)^2 + \sin^2\tilde{r}\sin^2\vartheta\right]^{1/2}}{\sin\tilde{t}+\cos\tilde{r}}, \tag{7.6}$$

$$\Omega_{\mathrm{M}} = \frac{\cos\tilde{r}+\sin\tilde{t}}{\sin\tilde{t}}, \tag{7.7}$$

$$\mathrm{F}_{\mathrm{BdS}} = -\frac{e}{4\pi}\frac{\ell_\Lambda^3}{\mathcal{R}^3}\frac{\sin\vartheta}{(\sin\tilde{t}+\cos\tilde{r})^3}\Big[a_{\mathrm{o}}\ell_\Lambda\sin^2\tilde{r}\cos\tilde{t}\,\mathrm{d}\tilde{r}\wedge\mathrm{d}\vartheta$$

$$-\left(\sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2}\cos\tilde{r} - a_{\mathrm{o}}\ell_\Lambda\sin\tilde{t}\right)\cot\vartheta\,\mathrm{d}\tilde{t}\wedge\mathrm{d}\tilde{r} \tag{7.8}$$

$$+\left(\sqrt{1+a_{\mathrm{o}}^2\ell_\Lambda^2} - a_{\mathrm{o}}\ell_\Lambda\cos\tilde{r}\sin\tilde{t}\right)\sin\tilde{r}\,\mathrm{d}\tilde{t}\wedge\mathrm{d}\vartheta$$

$$\mathrm{E}^{\mathrm{BdS}}_{\mathrm{CE}} = \frac{e}{4\pi}\frac{\ell_\Lambda \sin^2\tilde{t}}{\mathcal{R}^3(\sin\tilde{t}+\cos\tilde{r})^3}\Big[-\Big(\sqrt{1+a_\mathrm{o}^2\ell_\Lambda^2}\cos\tilde{r}-a_\mathrm{o}\ell_\Lambda\sin\tilde{t}\Big)\cos\vartheta\,\mathrm{e}_{\tilde{r}} + \Big(\sqrt{1+a_\mathrm{o}^2\ell_\Lambda^2}-a_\mathrm{o}\ell_\Lambda\sin\tilde{t}\cos\tilde{r}\Big)\sin\vartheta\,\mathrm{e}_\vartheta\Big], \tag{7.9}$$

$$\mathrm{B}^{\mathrm{BdS}}_{\mathrm{CE}} = -\frac{e}{4\pi}\frac{a_\mathrm{o}\ell_\Lambda^2\sin^2\tilde{t}}{\mathcal{R}^3(\sin\tilde{t}+\cos\tilde{r})^3}\cos\tilde{t}\sin\tilde{r}\sin\vartheta\,\mathrm{e}_\varphi.$$

The character of these fields was discussed in the preceding section for the particles $w_\odot$ and $w_\otimes$. One must only rotate all the structures by $\pi/2$ in the χ direction; hence, for example, the sphere of symmetry changes from $\chi=\pi/2$ to $\vartheta=\pi/2$.

There is some interest in having the fields available also in the hyperbolic cosmological coordinates. They cover only those regions of the fields in which we assume the radiative properties will be manifested. The sources producing the fields are not covered by these coordinates (cf. Fig. 8). The fields in the hyperbolic cosmological coordinates look as follows:

$$\mathcal{R} = \frac{1}{2b_\mathrm{o}}\left[\left(b_\mathrm{o}^2+\ell_\Lambda^2\tanh^2\frac{\eta}{2\ell_\Lambda}\right)^2+4b_\mathrm{o}^2\tanh^2\frac{\eta}{2\ell_\Lambda}\sinh^2\frac{\rho}{\ell_\Lambda}\sin^2\vartheta\right]^{1/2}, \tag{7.10}$$

$$\Omega_\mathrm{M} = 1+\cosh\frac{\eta}{\ell_\Lambda} = 2\cosh^2\frac{\eta}{2\ell_\Lambda}, \tag{7.11}$$

$$\mathrm{F}_{\mathrm{BdS}} = \frac{e}{4\pi}\frac{\ell_\Lambda^3}{\mathcal{R}^3}\frac{1}{2b_\mathrm{o}\Omega_\mathrm{M}^2} \times\left[\left(\frac{b_\mathrm{o}^2}{\ell_\Lambda^2}+\tanh^2\frac{\eta}{2\ell_\Lambda}\right)\sinh\frac{\eta}{\ell_\Lambda}\left(\frac{1}{\ell_\Lambda}\cos\vartheta\,\mathrm{d}\eta\wedge\mathrm{d}\rho-\sinh\frac{\rho}{\ell_\Lambda}\cosh\frac{\rho}{\ell_\Lambda}\sin\vartheta\,\mathrm{d}\eta\wedge\mathrm{d}\vartheta\right) -\left(\frac{b_\mathrm{o}^2}{\ell_\Lambda^2}-\tanh^2\frac{\eta}{2\ell_\Lambda}\right)\sinh^2\frac{\eta}{\ell_\Lambda}\sinh^2\frac{\rho}{\ell_\Lambda}\sin\vartheta\,\mathrm{d}\rho\wedge\mathrm{d}\vartheta\right], \tag{7.12}$$

$$\mathrm{E}^{\mathrm{BdS}}_{\mathrm{hyp}} = \frac{e}{4\pi}\frac{\ell_\Lambda^2}{\mathcal{R}^3}\frac{1}{2b_\mathrm{o}\Omega_\mathrm{M}^2}\left(\frac{b_\mathrm{o}^2}{\ell_\Lambda^2}+\tanh^2\frac{\eta}{2\ell_\Lambda}\right)\left(-\cos\vartheta\,\mathrm{e}_\rho+\cosh\frac{\rho}{\ell_\Lambda}\sin\vartheta\,\mathrm{e}_\vartheta\right), \tag{7.13}$$

$$\mathrm{B}^{\mathrm{BdS}}_{\mathrm{hyp}} = -\frac{e}{4\pi}\frac{\ell_\Lambda^2}{\mathcal{R}^3}\frac{\sinh\dfrac{\rho}{\ell_\Lambda}}{2b_\mathrm{o}\Omega_\mathrm{M}^2}\left(\frac{b_\mathrm{o}^2}{\ell_\Lambda^2}-\tanh^2\frac{\eta}{2\ell_\Lambda}\right)\sin\vartheta\,\mathrm{e}_\varphi.$$

Finally, we wish to describe the limiting procedure which leads from the generalized Born solutions directly to their counterparts in Minkowski space–time. For this purpose it is natural to employ the conformally Minkowski coordinates t,r,ϑ,φ introduced in Eq. (3.17), with the inverse transformation given in Appendix, Eq. (A17). Transforming the fields of the particles $w_\oplus$, $w_\ominus$ from the conformally Einstein coordinates to the conformally Minkowski coordinates, we arrive at the following intriguing forms. The scalar field is given by Eq. (7.1) where now the factors $\mathcal{R}$ and Ω_M are determined by

$$\mathcal{R} = \frac{1}{2b_\mathrm{o}}\sqrt{(b_\mathrm{o}^2+t^2-r^2)^2+4b_\mathrm{o}^2r^2\sin^2\vartheta}, \tag{7.14}$$

$$\Omega_{\mathrm{M}} = \frac{2\ell_\Lambda^2}{\ell_\Lambda^2 - t^2 + r^2}. \tag{7.15}$$

Notice that factor $\mathcal{R}$ coincides with the expression (2.11) in Minkowski space. The electromagnetic field reads

$$\begin{aligned} \mathrm{F}_{\mathrm{BdS}} = &- \frac{e}{4\pi}\frac{1}{2b_{\mathrm{o}}}\frac{1}{\mathcal{R}^3}[-2tr^2 \sin\vartheta\, \mathrm{d}r\wedge \mathrm{d}\vartheta - (b_{\mathrm{o}}^2 + t^2 - r^2)\cos\vartheta\, \mathrm{d}t\wedge \mathrm{d}r \\ &+ r(b_{\mathrm{o}}^2 + t^2 + r^2)\sin\vartheta\, \mathrm{d}t\wedge \mathrm{d}\vartheta], \end{aligned} \tag{7.16}$$

and the electric and magnetic parts of the field turn out to be

$$\begin{aligned} \mathrm{E}_{\mathrm{CM}}^{\mathrm{BdS}} &= \frac{e}{4\pi}\frac{1}{\mathcal{R}^3}\frac{1}{2b_{\mathrm{o}}\Omega_{\mathrm{M}}^2}[(b_{\mathrm{o}}^2 + t^2 - r^2)\cos\vartheta\, \mathrm{e}_r - (b_{\mathrm{o}}^2 + t^2 + r^2)\sin\vartheta\, \mathrm{e}_\vartheta], \\ \mathrm{B}_{\mathrm{CM}}^{\mathrm{BdS}} &= \frac{e}{4\pi}\frac{1}{\mathcal{R}^3}\frac{1}{b_{\mathrm{o}}\Omega_{\mathrm{M}}^2} tr\sin\vartheta\, \mathrm{e}_\varphi. \end{aligned} \tag{7.17}$$

To connect these fields with their counterparts in flat space, note first that they are conformally related by the conformal transformation (3.19). Under the conformal mapping, the field Φ_{BdS} must be multiplied by factor Ω_{M}, which gives $\Phi_{\mathrm{M}} = (s/4\pi)\mathcal{R}^{-1}$, and $\mathrm{F}_{\mathrm{BdS}}$ in (7.16) remains unchanged. The transformed fields then coincide with the classical Born fields (2.9), (2.11), and (2.13).

In order to see the limit for $\Lambda \to 0$, we parametrize the sequence of de Sitter spaces by Λ, and identify them in terms of coordinates t, r, ϑ, φ. As $\Lambda = 3/\ell_\Lambda^2 \to 0$, Eq. (3.19) implies $(\Omega_{\mathrm{M}})_\Lambda \to 2$, $(g_{\mathrm{dS}})_\Lambda \to 4g_{\mathrm{M}}$. After the trivial rescaling of t, r by factor 2, the standard Minkowski metric is obtained. The limit of the scalar and electromagnetic fields (7.1) and (7.16), in which b_{o} is kept constant [with $a_{\mathrm{o}} = (1 - b_{\mathrm{o}}^2\ell_\Lambda^{-2})/(2b_{\mathrm{o}})$—cf. Eq. (4.29)], leads precisely to the scalar and electromagnetic Born fields (2.9) and (2.13) in flat space. Because of the rescaling of the coordinates by factor 2, we get the physical acceleration equal to $1/b_{\mathrm{o}} = 2a_{\mathrm{o}}$, and the scalar field rescaled by $1/2$. The explicit limiting procedure carrying the generalized Born fields in de Sitter universe back into the classical Born solution in Minkowski space has thus been demonstrated.

VIII. CONCLUDING REMARKS

Since 1998 the observations of high-redshift supernovae indicate, with an increasing evidence, that we live in an accelerating universe with a positive cosmological constant (for most recent observations see, e.g., Ref. 57). Vacuum energy seems to dominate in the universe and it is thus of interest to understand fundamental physics in the vacuum dominated de Sitter space–time.

In the present work, we constructed the fields of uniformly accelerated charges in this universe. They go over to the classical Born fields in Minkowski space in the limit of a vanishing cosmological constant. Aside from some similarities found, the generalized fields provide the models showing how a positive cosmological constant implies essential differences from physics in flat space–time. For example, advanced effects occur inevitably due to the spacelike character of the past infinity $\mathcal{I}^-$ and its consequence—the existence of the past particles' horizons, respectively, of the "creation light cones" of the particles' worldlines.

Since de Sitter space–time, according to our present understanding, appears to be not only an appropriate basic model for studying future cosmological epochs, but it is commonly used also for exploring the inflationary era, various physical processes have been investigated in de Sitter space from the perspective of the early universe, among them, the effects of quantum field theory. Also in quantum contexts, however, problems arise from combining the causal structure of the full de Sitter space–time with the constraint equations (see Ref. 58 for a recent review). These problems are associated with the "insufficiency of purely retarded fields" in space–times with a spacelike $\mathcal{I}^-$. We analyzed this issue in detail for the classical electromagnetic and scalar fields with sources in Ref. 24.

Another intriguing implication of the rapid expansion of de Sitter universe due to a positive cosmological constant is manifested in the exponential decay of the fields at large times. We noticed this "cosmic no-hair phenomenon" explicitly on the late-time behavior of the fields due to accelerated charges.

In the present paper we wished to give all details on the construction of the fields and on coordinate frames useful in understanding their various aspects, including their relation to their counterparts in flat space–time. We did not here analyze the radiative characteristics of the fields. In the Introduction we indicated that radiative properties depend on the way in which a given point of infinity is approached. This is briefly described at the end of our paper.[25]

In de Sitter space–time it is not *a priori* clear, as it is in special relativity, how to define global physical quantities like energy or energy flux. Such issues connected with the question of radiation from "Born in de Sitter" will be considered in a future presentation.

APPENDIX A: THE PALETTE OF COORDINATE SYSTEMS IN DE SITTER SPACE–TIME

Nine families of coordinate systems are here introduced, described analytically and illustrated graphically. The corresponding forms of de Sitter metric, orthonormal tetrads and interrelations between the systems are given. All these systems are suitable for exhibiting various features of de Sitter space; two families are directly associated with uniformly accelerated particles. Although the majority (though not all) of these coordinate systems undoubtedly appeared in literature in some form already, they are scattered and, as far as we know, not summarized as comprehensively as in the following. In the main text we refer frequently to this Appendix, but the Appendix can be read independently. We hope it can serve as a catalogue useful for analyzing various aspects of physics in de Sitter universe.

By a family of coordinate systems we mean the systems with the same coordinate lines; e.g., $\{x^\mu\}$ and $\{y^\mu\}$ where $x^1=x^1(y^1)$, $x^2=x^2(y^2)$, etc. Seven of our families have the same spherical angular coordinates ϑ,φ, accelerated and Robinson-Trautman coordinates mix three coordinates, only azimuthal coordinate φ remains unchanged.

The homogeneous normalized metric on two-spheres (the metric "in angular direction") is denoted by

$$\mathrm{d}\omega^2 = \mathrm{d}\vartheta^2 + \sin^2\vartheta\,\mathrm{d}\varphi^2. \tag{A1}$$

The radial coordinates label directions pointing out from the pole and acquire only positive values. However, transformations among coordinates take simpler forms if we allow radial coordinates to take on negative values as well. This causes no problems if, denoting by t and r the prototypes of time and radial coordinates, we adopt the convention that the following two values of coordinates describe the same point:

$$\{t,r,\vartheta,\varphi\} \leftrightarrow \{t,-r,\pi-\vartheta,\varphi+\pi\}. \tag{A2}$$

Hence, intuitively we may consider a point with $-r<0$ and ϑ,φ fixed to lie on diametrically opposite side of the pole $r=0$ with respect to the point $r>0,\vartheta,\varphi$.

The orthonormal tetrad $\mathrm{e}_t,\mathrm{e}_r,\mathrm{e}_\vartheta,\mathrm{e}_\varphi$ associated with a coordinate system is tangent to the coordinate lines and oriented (with few exceptions) in the directions of growing coordinates. It is chosen in such a way that the external product $\mathrm{e}^t\wedge\mathrm{e}^r\wedge\mathrm{e}^\vartheta\wedge\mathrm{e}^\varphi$ of 1-forms of the dual tetrad has

always the same orientation. Since all forms of the metric contain the term (A1) the only component $(e_\varphi)^\varphi$ of the tetrad vector e_φ in coordinate frame $\{\partial/\partial x^\mu\}$ is related to the ϑ-component of e_ϑ as

$$(e_\varphi)^\varphi = \frac{1}{\sin\vartheta}(e_\vartheta)^\vartheta, \tag{A3}$$

and we thus omit e_φ henceforth.

In the standard Newman-Penrose null complex tetrad $k, l, m, \bar{m}$ with only nonvanishing inner products $k\cdot l=-1$, $m\cdot\bar{m}=1$, the electromagnetic field F is represented by three complex components:

$$\Phi_0 = F_{\alpha\beta}\, k^\alpha m^\beta, \quad \Phi_2 = F_{\alpha\beta}\, \bar{m}^\alpha l^\beta, \quad \Phi_1 = \tfrac{1}{2}\, F_{\alpha\beta}\,(k^\alpha l^\beta - m^\alpha \bar{m}^\beta). \tag{A4}$$

The null tetrad can be specified directly [as it will be done in the case of Robinson-Trautman coordinates in Eq. (A114)], or it can be associated with any orthonormal tetrad, say t, q, r, s, by relations

$$k = \frac{1}{\sqrt{2}}(t+q), \quad l = \frac{1}{\sqrt{2}}(t-q), \quad m = \frac{1}{\sqrt{2}}(r - i\,s), \quad \bar{m} = \frac{1}{\sqrt{2}}(r + i\,s). \tag{A5}$$

Here, t and q are timelike and spacelike unit vectors, respectively, typically in a direction of "time" and "radial" coordinate, and r, s are spacelike unit vectors in angular directions, $r=e_\vartheta$, $s=e_\varphi$.

For each coordinate family we give the diagram illustrating section ϑ, φ=constant with the radial coordinate taking on both positive and negative values. The diagrams thus represent the history of the entire main circle of the spatial spherical section of de Sitter universe. The left and right edges of the diagrams represent the south pole and should be considered as identified; the central vertical line describes the history of the north pole. Recalling the meaning of the negative radial coordinate we could eliminate the left half of each of the diagrams by transforming it into the right one by replacements $\{\vartheta,\varphi\}\to\{\pi-\vartheta,\varphi+\pi\}$. However, it is instructive to keep both halves for better understanding of the spatial topology of the sections. All diagrams are compactified—they are adapted to the standard rescaled coordinates $\tilde{t}$, $\tilde{r}$ (see below). The past and future conformal infinites are drawn as double lines. The ranges of time and radial coordinates are shown, the orientation of coordinate labels indicates the directions of the growth of corresponding coordinates.

We will also introduce several sign factors. The values of these factors in different domains of space–time are indicated in Fig. 13.

1. The spherical cosmological family:

The first family consists of the standard or spherical cosmological coordinates τ, χ, ϑ, φ, and of the standard rescaled or conformally Einstein coordinates $\tilde{t}$, $\tilde{r}$, ϑ, φ (where $\tilde{r}\equiv\chi$). These coordinates cover de Sitter space–time globally. They are associated with cosmological observers with homogeneous spatial sections of positive spatial curvature. The coordinates are adjusted to the spherical symmetry of the spatial sections, χ, ϑ, and φ are standard angular coordinates. The coordinate τ is a proper time along the worldlines of the cosmological observers given by χ, ϑ, φ=constant. The vector $\partial/\partial\tau$ is a conformal Killing vector which is everywhere timelike. The rescaled coordinates $\tilde{t}$, $\tilde{r}$, ϑ, φ can also be viewed as the standard coordinates of the conformally related Einstein universe; they cover smoothly both conformal infinities $\mathcal{I}^\pm$ of de Sitter space–time. (See Fig. 14.)

Metric and relation between coordinates

$$g = -\,d\tau^2 + \ell_\Lambda^2 \cosh^2(\tau/\ell_\Lambda)(d\chi^2 + \sin^2\chi\, d\omega^2), \tag{A6}$$

$$g = \ell_\Lambda^2 \sin^{-2}\tilde{t}\,(-\,d\tilde{t}^2 + d\tilde{r}^2 + \sin^2\tilde{r}\, d\omega^2), \tag{A7}$$

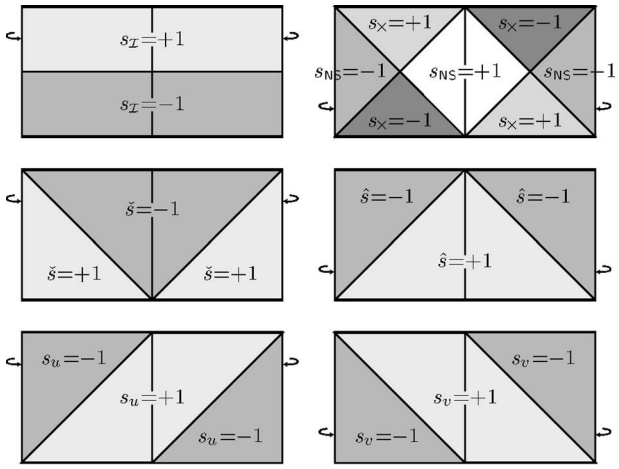

FIG. 13. The values of the factors $s_{\mathcal{I}}$, s_{NS}, $s_\times$, $\check{s}$, $\hat{s}$, s_u, and s_v in various regions of de Sitter space. The factors are defined in Eqs. (A21), (A36), (A61), (A73), (A74), and (A128), respectively. The factor $s_\times$ is used only in the expressions for static coordinates in the region where the Killing vector is spacelike. Therefore, we indicated the values of $s_\times$ only in those regions, although Eq. (A74) defines $s_\times$ everywhere. The factors $s_\times$, s_u, and s_v are defined only for any given section ϑ=constant, but not as unique functions on the whole space–time (they are not symmetric with respect to the pole). This is related to our convention using negative radial coordinates, cf. the text below Eq. (A1).

$$\tan\frac{\tilde{t}}{2}=\exp\frac{\tau}{\ell_\Lambda},\quad \cot\tilde{t}=-\sinh\frac{\tau}{\ell_\Lambda},\quad \sin\tilde{t}=\cosh^{-1}\frac{\tau}{\ell_\Lambda},\quad \cos\tilde{t}=-\tanh\frac{\tau}{\ell_\Lambda}, \tag{A8a}$$

$$\tilde{r}=\chi. \tag{A8b}$$

The ranges of coordinates are

$$\tau\in\mathbb{R},\quad \chi\in(-\pi,\pi),\quad \tilde{t}\in(0,\pi),\quad \tilde{r}\in(-\pi,\pi), \tag{A9}$$

with negative values of radial coordinates χ, $\tilde{r}$ interpreted in accordance with Eq. (A2).

Orthonormal tetrad,

$$\mathrm{e}_\tau=\frac{\partial}{\partial\tau}=\frac{1}{\ell_\Lambda}\sin\tilde{t}\,\frac{\partial}{\partial\tilde{t}},$$

$$\mathrm{e}_\chi=\frac{1}{\ell_\Lambda}\cosh^{-1}\frac{\tau}{\ell_\Lambda}\frac{\partial}{\partial_\chi}=\frac{1}{\ell_\Lambda}\sin\tilde{t}\,\frac{\partial}{\partial\tilde{r}}, \tag{A10}$$

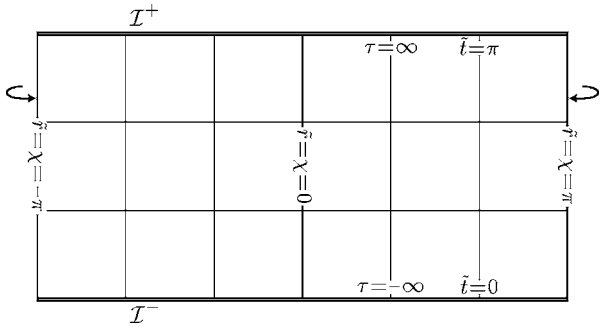

FIG. 14. The spherical cosmological family of coordinates.

$$\mathrm{e}_\vartheta = \frac{1}{\ell_\Lambda}\frac{1}{\cosh(\pi/\ell_\Lambda)\sin\chi}\frac{\partial}{\partial\vartheta} = \frac{1}{\ell_\Lambda}\frac{\sin\tilde{t}}{\sin\tilde{r}}\frac{\partial}{\partial\vartheta}\,.$$

Relation to flat cosmological family,

$$\tan\tilde{t} = \frac{2\ell_\Lambda\hat{t}}{\ell_\Lambda^2 - \hat{t}^2 + \hat{r}^2} = \frac{2\ell_\Lambda\check{t}}{\ell_\Lambda^2 - \check{t}^2 + \check{r}^2}\,, \quad \tan\tilde{r} = \frac{2\ell_\Lambda\hat{r}}{\ell_\Lambda^2 + \hat{t}^2 - \hat{r}^2} = \frac{2\ell_\Lambda\check{r}}{\ell_\Lambda^2 + \check{t}^2 - \check{r}^2}\,. \tag{A11}$$

Relation to hyperbolic cosmological coordinates,

$$\cot\tilde{t} = -\sinh\frac{\eta}{\ell_\Lambda}\cosh\frac{\rho}{\ell_\Lambda}\,, \quad \tan\tilde{r} = \tanh\frac{\eta}{\ell_\Lambda}\sinh\frac{\rho}{\ell_\Lambda}\,. \tag{A12}$$

Relation to static family in timelike domains **N**, **S**,

$$\tan\tilde{t} = -s_{\mathbf{NS}}\frac{\ell_\Lambda}{\sqrt{\ell_\Lambda^2 - R^2}}\sinh^{-1}\frac{T}{\ell_\Lambda}, \quad \tan\tilde{r} = s_{\mathbf{NS}}\frac{R}{\sqrt{\ell_\Lambda^2 - R^2}}\cosh^{-1}\frac{T}{\ell_\Lambda}, \tag{A13}$$

$$\tan\tilde{t} = -s_{\mathbf{NS}}\frac{\cosh\dfrac{\bar{r}}{\ell_\Lambda}}{\sinh\dfrac{\bar{t}}{\ell_\Lambda}}\,, \quad \tan\tilde{r} = s_{\mathbf{NS}}\frac{\sinh\dfrac{\bar{r}}{\ell_\Lambda}}{\cosh\dfrac{\bar{t}}{\ell_\Lambda}}\,, \tag{A14}$$

where $s_{\mathbf{NS}} = +1(-1)$ in domain **N** (**S**), cf. Eq. (A61).

Relation to static family in spacelike domains **F**, **P**,

$$\tan\tilde{t} = \frac{-s_{\mathcal{I}}\ell_\Lambda}{\sqrt{R^2 - \ell_\Lambda^2}}\cosh^{-1}\frac{T}{\ell_\Lambda}, \quad \tan\tilde{r} = \frac{s_{\mathcal{I}}R}{\sqrt{R^2 - \ell_\Lambda^2}}\sinh^{-1}\frac{T}{\ell_\Lambda}, \tag{A15}$$

$$\tan\tilde{t} = s_\times\frac{\sinh\dfrac{\bar{r}}{\ell_\Lambda}}{\cosh\dfrac{\bar{t}}{\ell_\Lambda}}\,, \quad \tan\tilde{r} = s_\times\frac{\cosh\dfrac{\bar{r}}{\ell_\Lambda}}{\sinh\dfrac{\bar{t}}{\ell_\Lambda}}\,, \tag{A16}$$

where $s_{\mathcal{I}} = -\mathrm{sign}\cos\tilde{t}$ and $s_\times = -s_{\mathcal{I}}\,\mathrm{sign}\,\tilde{r}$, cf. Eqs. (A73) and (A74).

Relation to conformally Minkowski coordinates,

$$\cot\tilde{t} = \frac{2\ell_\Lambda t}{t^2 - r^2 - \ell_\Lambda^2}\,, \quad \tan\tilde{r} = \frac{2\ell_\Lambda r}{t^2 - r^2 + \ell_\Lambda^2}\,. \tag{A17}$$

2. The flat cosmological family, type "$\vee$":

The first flat cosmological coordinate family (Fig. 15) consists of the flat cosmological coordinates $\check{\tau}$, $\check{r}$, ϑ, φ and of the rescaled flat cosmological coordinates $\check{t}$, $\check{r}$, ϑ, φ. Hypersurfaces $\check{\tau}$ =constant are homogeneous flat spaces and coordinate lines $\check{r}$, ϑ, φ=constant are worldlines of cosmological observers orthogonal to these hypersurfaces. They are geodesic with proper time $\check{\tau}$, the vector $\partial/\partial\check{\tau}$ is a conformal Killing vector. The coordinates cover de Sitter space–time smoothly, except for the past cosmological horizon, $\tilde{r}=\tilde{t}$, of the north pole where $\check{r}$, $\check{t}\to\pm\infty$. The coordinates thus split into two coordinate patches—"above" and "below" the horizon. The domain above the horizon has a cosmological interpretation of an exponentially expanding flat three-space. The rescaled coordinates can be viewed as inertial coordinates in the conformally related Minkowski space $\check{M}$, cf. Fig. 3; the domain above the horizon corresponds to the "lower half," $\check{t}<0$, of $\check{M}$, the domain below corresponds to the "upper half," $\check{t}>0$.

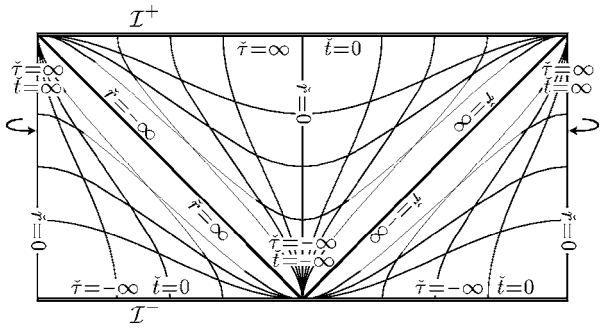

FIG. 15. The flat cosmological family, type "∨."

Metric and relation between coordinates,

$$g=\frac{\ell_\Lambda^2}{\check{t}^2}(-\,\mathrm{d}\check{t}^2+\mathrm{d}\check{r}^2+\check{r}^2\,\mathrm{d}\omega^2), \tag{A18}$$

$$g=-\,\mathrm{d}\check{\tau}^2+\exp(-\check{s}2\check{\tau}/\ell_\Lambda)(\mathrm{d}\check{r}^2+\check{r}^2\,\mathrm{d}\omega^2). \tag{A19}$$

$$\check{t}=\check{s}\,\ell_\Lambda\exp\left(\check{s}\frac{\check{\tau}}{\ell_\Lambda}\right), \tag{A20}$$

$$\check{s}=\operatorname{sign}\check{t}. \tag{A21}$$

The ranges of coordinates are

$$\begin{aligned}&\check{\tau}\in\mathbb{R},\quad \check{t}\in\mathbb{R}^-,\quad \check{r}\in\mathbb{R}\ \text{above the horizon},\\ &\check{\tau}\in\mathbb{R},\quad \check{t}\in\mathbb{R}^+,\quad \check{r}\in\mathbb{R}\ \text{below the horizon},\end{aligned} \tag{A22}$$

with negative values of radial coordinate $\check{r}$ interpreted as described in Eq. (A2).

Orthonormal tetrad,

$$\begin{aligned}&\mathrm{e}_{\check{t}}=\frac{\partial}{\partial\check{\tau}}=\frac{\check{s}\check{t}}{\ell_\Lambda}\frac{\partial}{\partial\check{t}},\quad \mathrm{e}_{\check{r}}=\exp\frac{\check{s}\check{\tau}}{\ell_\Lambda}\frac{\partial}{\partial\check{r}}=\frac{\check{s}\check{t}}{\ell_\Lambda}\frac{\partial}{\partial\check{r}},\\ &\mathrm{e}_{\vartheta}=-\frac{\check{s}}{\check{r}}\exp\frac{\check{s}\check{\tau}}{\ell_\Lambda}\frac{\partial}{\partial\vartheta}=-\frac{1}{\ell_\Lambda}\frac{\check{t}}{\check{r}}\frac{\partial}{\partial\vartheta}.\end{aligned} \tag{A23}$$

Relation to spherical cosmological family,

$$\check{t}=\frac{-\,\ell_\Lambda\cosh^{-1}(\tau/\ell_\Lambda)}{\cos\chi+\tanh(\tau/\ell_\Lambda)},\quad \check{r}=\frac{\ell_\Lambda\cosh^{-1}(\tau/\ell_\Lambda)}{\cos\chi+\tanh(\tau/\ell_\Lambda)}, \tag{A24}$$

$$\check{t}=\frac{\ell_\Lambda\sin\tilde{t}}{\cos\tilde{t}-\cos\tilde{r}},\quad \check{r}=\frac{\ell_\Lambda\sin\tilde{r}}{\cos\tilde{r}-\cos\tilde{t}}. \tag{A25}$$

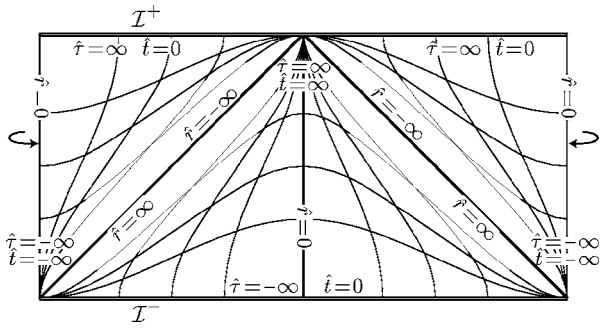

FIG. 16. The flat cosmological family, type "∧."

Relation to flat cosmological family, type "∧",

$$\check t=-\frac{\hat t\ell_\Lambda^2}{\hat t^2-\hat r^2}\,,\quad \check r=\frac{\hat r\ell_\Lambda^2}{\hat t^2-\hat r^2}\,, \tag{A26}$$

$$\begin{gathered}\check t\hat r+\hat t\check r=0\,,\quad \hat t\check t+\hat r\check r=-\ell_\Lambda^2\,,\\ (-\hat t^2+\hat r^2)(-\check t^2+\check r^2)=\ell_\Lambda^4\,,\quad (\hat t+\hat r)(\check t+\check r)=(\hat t-\hat r)(\check t-\check r)=-\ell_\Lambda^2\,.\end{gathered} \tag{A27}$$

Relation to static family in timelike domains $\mathbf{N},\mathbf{S}$,

$$\frac{\check t}{\ell_\Lambda}=-s_{\mathbf{NS}}\frac{\ell_\Lambda}{\sqrt{\ell_\Lambda^2-R^2}}\exp\!\left(-\frac{T}{\ell_\Lambda}\right),\quad \frac{\check r}{\ell_\Lambda}=s_{\mathbf{NS}}\frac{R}{\sqrt{\ell_\Lambda^2-R^2}}\exp\!\left(-\frac{T}{\ell_\Lambda}\right), \tag{A28}$$

$$\check t=-s_{\mathbf{NS}}\ell_\Lambda\exp\!\left(-\frac{\overline t}{\ell_\Lambda}\right)\cosh\frac{\overline r}{\ell_\Lambda}\,,\quad \check r=s_{\mathbf{NS}}\ell_\Lambda\exp\!\left(-\frac{\overline t}{\ell_\Lambda}\right)\sinh\frac{\overline r}{\ell_\Lambda}\,, \tag{A29}$$

where $s_{\mathbf{NS}}=+1(-1)$ in domain $\mathbf{N}(\mathbf{S})$, cf. Eq. (A61).

Relation to static family in spacelike domains $\mathbf{F},\mathbf{P}$,

$$\frac{\check t}{\ell_\Lambda}=s_\times\frac{\ell_\Lambda}{\sqrt{R^2-\ell_\Lambda^2}}\exp\!\left(-\frac{T}{\ell_\Lambda}\right),\quad \frac{\check r}{\ell_\Lambda}=-s_\times\frac{R}{\sqrt{R^2-\ell_\Lambda^2}}\exp\!\left(-\frac{T}{\ell_\Lambda}\right), \tag{A30}$$

$$\check t=s_\times\ell_\Lambda\exp\!\left(-\frac{\overline t}{\ell_\Lambda}\right)\sinh\frac{\overline r}{\ell_\Lambda}\,,\quad \check r=-s_\times\ell_\Lambda\exp\!\left(-\frac{\overline t}{\ell_\Lambda}\right)\cosh\frac{\overline r}{\ell_\Lambda}\,, \tag{A31}$$

where $s_\times=\operatorname{sign}\widetilde r\,\operatorname{sign}\cos\widetilde t$, cf. Eqs. (A73) and (A74).

Relation to conformally Minkowski coordinates,

$$\frac{\check t}{\ell_\Lambda}=-\frac{\ell_\Lambda^2-t^2+r^2}{(\ell_\Lambda+t)^2-r^2}\,,\quad \frac{\check r}{\ell_\Lambda}=\frac{2\ell_\Lambda r}{(\ell_\Lambda+t)^2-r^2}\,. \tag{A32}$$

3. The flat cosmological family, type "∧":

The second flat cosmological coordinate family (Fig. 16) consists of the flat cosmological coordinates $\hat\tau,\hat r,\vartheta,\varphi$ and of the rescaled flat cosmological coordinates $\hat t,\hat r,\vartheta,\varphi$. They can be built analogously to the flat coordinates introduced above, with north and south poles interchanged only. They thus have similar properties. Hypersurfaces $\hat t=$constant are homogeneous flat three-spaces, coordinate lines $\hat r,\vartheta,\varphi=$constant are geodesics with proper time $\hat\tau$, and $\partial/\partial\hat\tau$ is a conformal Killing vector. The coordinates cover de Sitter space–time everywhere except the future

cosmological horizon, $\tilde{r}=\pi-\tilde{t}$, of the north pole (i.e., the past horizon of the south pole), and the rescaled coordinates can be viewed as inertial coordinates in the conformally related Minkowski space $\hat{M}$.

Metric and relation between coordinates,

$$g=\frac{\ell_\Lambda^2}{\hat{t}^2}(-\,\mathrm{d}\hat{t}^2+\mathrm{d}\hat{r}^2+\hat{r}^2\,\mathrm{d}\omega^2), \tag{A33}$$

$$g=-\,\mathrm{d}\hat{\tau}^2+\exp(-\hat{s}2\hat{\tau}/\ell_\Lambda)(\mathrm{d}\hat{r}^2+\hat{r}^2\,\mathrm{d}\omega^2), \tag{A34}$$

$$\hat{t}=\hat{s}\ell_\Lambda\exp\left(\hat{s}\frac{\hat{\tau}}{\ell_\Lambda}\right), \tag{A35}$$

where

$$\hat{s}=\operatorname{sign}\hat{t}. \tag{A36}$$

The ranges of coordinates are

$$\begin{gathered}\hat{\tau}\in\mathbb{R},\quad \hat{t}\in\mathbb{R}^-,\quad \hat{r}\in\mathbb{R}\ \text{above the horizon},\\ \hat{\tau}\in\mathbb{R},\quad \hat{t}\in\mathbb{R}^+,\quad \hat{r}\in\mathbb{R}\ \text{below the horizon},\end{gathered} \tag{A37}$$

with negative values of radial coordinate $\hat{r}$ interpreted as described in Eq. (A2).

Orthonormal tetrad,

$$\begin{gathered}\mathrm{e}_{\hat{t}}=\frac{\partial}{\partial\hat{\tau}}=\frac{\hat{s}\hat{t}}{\ell_\Lambda}\frac{\partial}{\partial\hat{t}},\quad \mathrm{e}_{\hat{r}}=\exp\frac{\hat{s}\hat{\tau}}{\ell_\Lambda}\frac{\partial}{\partial\hat{r}}=\frac{\hat{s}\hat{t}}{\ell_\Lambda}\frac{\partial}{\partial\hat{r}},\\ \mathrm{e}_{\vartheta}=\frac{\hat{s}}{\hat{r}}\exp\frac{\hat{s}\hat{\tau}}{\ell_\Lambda}\frac{\partial}{\partial\vartheta}=\frac{1}{\ell_\Lambda}\frac{\hat{t}}{\hat{r}}\frac{\partial}{\partial\vartheta}.\end{gathered} \tag{A38}$$

Relation to spherical cosmological family,

$$\hat{t}=\frac{\ell_\Lambda\cosh^{-1}(\tau/\ell_\Lambda)}{\cos\chi-\tanh(\tau/\ell_\Lambda)},\quad \hat{r}=\frac{\ell_\Lambda\cosh^{-1}(\tau/\ell_\Lambda)}{\cos\chi-\tanh(\tau/\ell_\Lambda)}, \tag{A39}$$

$$\hat{t}=\frac{\ell_\Lambda\sin\tilde{t}}{\cos\tilde{t}+\cos\tilde{r}},\quad \hat{r}=\frac{\ell_\Lambda\sin\tilde{r}}{\cos\tilde{r}+\cos\tilde{t}}. \tag{A40}$$

Relation to flat cosmological family, type "$\wedge$",

$$\hat{t}=-\frac{\check{t}\ell_\Lambda^2}{\check{t}^2-\check{r}^2},\quad \hat{r}=\frac{\check{r}\ell_\Lambda^2}{\check{t}^2-\check{r}^2}, \tag{A41}$$

$$\begin{gathered}\check{t}\hat{r}+\hat{t}\check{r}=0,\quad \hat{t}\check{t}+\hat{r}\check{r}=-\,\ell_\Lambda^2,\\ (-\,\hat{t}^2+\hat{r}^2)(-\,\check{t}^2+\check{r}^2)=\ell_\Lambda^4,\quad (\hat{t}+\hat{r})(\check{t}+\check{r})=(\hat{t}-\hat{r})(\check{t}-\check{r})=-\,\ell_\Lambda^2.\end{gathered} \tag{A42}$$

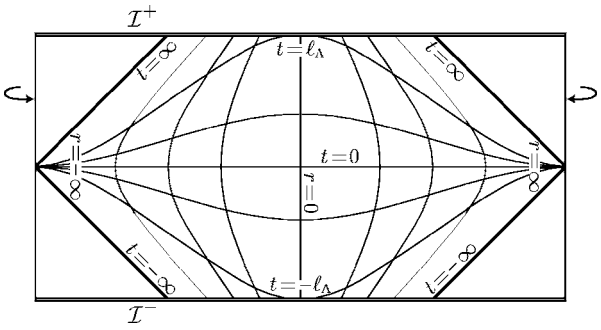

FIG. 17. The conformally Minkowski family of coordinates.

Relation to static family in timelike domains **N**, **S**,

$$\frac{\hat{t}}{\ell_\Lambda} = s_{\mathbf{NS}} \frac{\ell_\Lambda}{\sqrt{\ell_\Lambda^2 - R^2}} \exp \frac{T}{\ell_\Lambda}, \quad \frac{\hat{r}}{\ell_\Lambda} = s_{\mathbf{NS}} \frac{R}{\sqrt{\ell_\Lambda^2 - R^2}} \exp \frac{T}{\ell_\Lambda}, \tag{A43}$$

$$\hat{t} = s_{\mathbf{NS}} \ell_\Lambda \exp \frac{\overline{t}}{\ell_\Lambda} \cosh \frac{\overline{r}}{\ell_\Lambda}, \quad \hat{r} = s_{\mathbf{NS}} \ell_\Lambda \exp \frac{\overline{t}}{\ell_\Lambda} \sinh \frac{\overline{r}}{\ell_\Lambda}, \tag{A44}$$

where $s_{\mathbf{NS}} = +1(-1)$ in domain **N** (**S**), cf. Eq. (A61).

Relation to static family in spacelike domains **F**, **P**,

$$\frac{\hat{t}}{\ell_\Lambda} = s_\times \frac{\ell_\Lambda}{\sqrt{R^2 - \ell_\Lambda^2}} \exp \frac{T}{\ell_\Lambda}, \quad \frac{\hat{r}}{\ell_\Lambda} = s_\times \frac{R}{\sqrt{R^2 - \ell_\Lambda^2}} \exp \frac{T}{\ell_\Lambda}, \tag{A45}$$

$$\hat{t} = s_\times \ell_\Lambda \exp \frac{\overline{t}}{\ell_\Lambda} \sinh \frac{\overline{r}}{\ell_\Lambda}, \quad \hat{r} = s_\times \ell_\Lambda \exp \frac{\overline{t}}{\ell_\Lambda} \cosh \frac{\overline{r}}{\ell_\Lambda}, \tag{A46}$$

where $s_\times = \operatorname{sign} \tilde{r} \operatorname{sign} \cos \tilde{t}$, cf. Eqs. (A73) and (A74).

Relation to conformally Minkowski coordinates,

$$\frac{\hat{t}}{\ell_\Lambda} = \frac{\ell_\Lambda^2 - t^2 + r^2}{(\ell_\Lambda - t)^2 - r^2}, \quad \frac{\hat{r}}{\ell_\Lambda} = \frac{2\ell_\Lambda r}{(\ell_\Lambda - t)^2 - r^2}. \tag{A47}$$

4. The conformally Minkowski family:

The conformally Minkowski coordinates t, r, ϑ, φ can be understood as spherical coordinates in the conformally related Minkowski space M. The coordinates do not cover de Sitter space–time globally—they cover only a region around north pole, see Fig. 17. The boundary of this region is given by the conformal infinity of the Minkowski space–time. These coordinates are useful for studying the limit $\Lambda \to 0$.

The metric,

$$g = \left(\frac{2\ell_\Lambda^2}{\ell_\Lambda^2 - t^2 + r^2} \right)^2 (-\mathrm{d}t^2 + \mathrm{d}r^2 + r^2 \, \mathrm{d}\omega^2), \tag{A48}$$

the ranges of coordinates

$$t \in \mathbb{R}, \quad r \in \mathbb{R}, \quad \text{such that } t^2 - r^2 < \ell_\Lambda^2, \tag{A49}$$

with negative values of radial coordinate r interpreted as described in Eq. (A2).

Orthonormal tetrad,

$$\mathrm{e}_t = \frac{\ell_\Lambda^2 - t^2 + r^2}{2\ell_\Lambda^2}\frac{\partial}{\partial t}, \quad \mathrm{e}_r = \frac{\ell_\Lambda^2 - t^2 + r^2}{2\ell_\Lambda^2}\frac{\partial}{\partial r}, \quad \mathrm{e}_\vartheta = \frac{\ell_\Lambda^2 - t^2 + r^2}{2\ell_\Lambda^2}\frac{1}{r}\frac{\partial}{\partial t}. \tag{A50}$$

Relation to spherical cosmological family,

$$t = -\frac{\ell_\Lambda \cos\tilde{t}}{\cos\tilde{r} + \sin\tilde{t}}, \quad r = \frac{\ell_\Lambda \sin\tilde{r}}{\cos\tilde{r} + \sin\tilde{t}}. \tag{A51}$$

Relation to flat cosmological family,

$$\begin{aligned} \frac{t}{\ell_\Lambda} &= -\frac{\ell_\Lambda^2 - \hat{t}^2 + \hat{r}^2}{(\ell_\Lambda + \hat{t})^2 - \hat{r}^2} = \frac{\ell_\Lambda^2 - \check{t}^2 + \check{r}^2}{(\ell_\Lambda - \check{t})^2 - \check{r}^2}, \\ \frac{r}{\ell_\Lambda} &= \frac{2\ell_\Lambda \hat{r}}{(\ell_\Lambda + \hat{t})^2 - \hat{r}^2} = \frac{2\ell_\Lambda \check{r}}{(\ell_\Lambda - \check{t})^2 - \check{r}^2}. \end{aligned} \tag{A52}$$

Relation to hyperbolic cosmological coordinates,

$$\frac{t}{\ell_\Lambda} = \tanh\frac{\eta}{2\ell_\Lambda}\cosh\frac{\beta}{\ell_\Lambda}, \quad \frac{r}{\ell_\Lambda} = \tanh\frac{\eta}{2\ell_\Lambda}\sinh\frac{\beta}{\ell_\Lambda}. \tag{A53}$$

Relation to static family in timelike domains **N**, **S**,

$$\frac{t}{\ell_\Lambda} = \frac{\sinh\dfrac{\bar{t}}{\ell_\Lambda}}{\cosh\dfrac{\bar{t}}{\ell_\Lambda} + s_{\mathbf{NS}}\cosh\dfrac{\bar{r}}{\ell_\Lambda}}, \quad \frac{r}{\ell_\Lambda} = \frac{\sinh\dfrac{\bar{r}}{\ell_\Lambda}}{\cosh\dfrac{\bar{r}}{\ell_\Lambda} + s_{\mathbf{NS}}\cosh\dfrac{\bar{t}}{\ell_\Lambda}}, \tag{A54}$$

$$\frac{t}{\ell_\Lambda} = \frac{\sqrt{\ell_\Lambda^2 - R^2}\sinh\dfrac{T}{\ell_\Lambda}}{s_{\mathbf{NS}}\ell_\Lambda + \sqrt{\ell_\Lambda^2 - R^2}\cosh\dfrac{T}{\ell_\Lambda}}, \quad \frac{r}{\ell_\Lambda} = \frac{R}{\ell_\Lambda + s_{\mathbf{NS}}\sqrt{\ell_\Lambda^2 - R^2}\cosh\dfrac{T}{\ell_\Lambda}}, \tag{A55}$$

where $s_{\mathbf{NS}} = +1(-1)$ in domain **N** (**S**), cf. Eq. (A61).

Relation to static family in spacelike domains **F**, **P**,

$$\frac{t}{\ell_\Lambda} = \frac{\cosh\dfrac{\bar{t}}{\ell_\Lambda}}{\sinh\dfrac{\bar{t}}{\ell_\Lambda} - s_\times\sinh\dfrac{\bar{r}}{\ell_\Lambda}}, \quad \frac{r}{\ell_\Lambda} = \frac{\cosh\dfrac{\bar{r}}{\ell_\Lambda}}{\sinh\dfrac{\bar{r}}{\ell_\Lambda} - s_\times\cosh\dfrac{\bar{t}}{\ell_\Lambda}}, \tag{A56}$$

$$\frac{t}{\ell_\Lambda} = \frac{\sqrt{R^2 - \ell_\Lambda^2}\cosh\dfrac{T}{\ell_\Lambda}}{-s_\times\ell_\Lambda + \sqrt{R^2 - \ell_\Lambda^2}\sinh\dfrac{T}{\ell_\Lambda}}, \quad \frac{r}{\ell_\Lambda} = \frac{R}{\ell_\Lambda - s_\times\sqrt{R^2 - \ell_\Lambda^2}\sinh\dfrac{T}{\ell_\Lambda}}, \tag{A57}$$

with $s_\times = \mathrm{sign}\,\tilde{r}\,\mathrm{sign}\cos\tilde{t}$, cf. Eqs. (A73) and (A74).

***5. The static family in timelike domains* N *and* S:** This family consists of the static coordinates T, R, ϑ, φ and the "tortoise" static coordinates $\bar{t}$, $\bar{r}$, ϑ, φ. The metric does not depend on time coordinate $T = \bar{t}$—the coordinates are associated with a Killing vector. Since the Killing vector

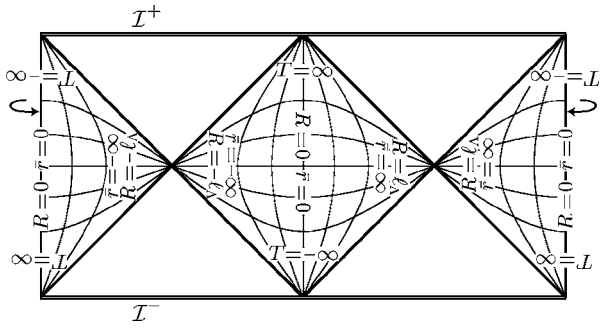

FIG. 18. The static family of coordinates, timelike domains.

changes its character, the coordinates do not cover the space–time smoothly. We first describe the static coordinates in domains **N** and **S**, where the Killing vector is timelike. In domain **N** the orbits of the Killing vector (corresponding to the worldlines of static observers) start and end at the north pole, in domain **S**—at the south pole. They are orthogonal to slices $T=$constant, each of which consists of two hemispheres (one in domain **N**, the other in **S**) with homogeneous spherical 3-metric. The distances between static observers (measured within these slices) do not change. Since the static observers must overcome first the cosmological contraction and then the expansion, they move with a (uniform) acceleration. (See Fig. 18.)

Metric and relation between coordinates,

$$g=\cosh^{-2}\frac{\bar{r}}{\ell_\Lambda}\left(-\mathrm{d}\bar{t}^{\,2}+\mathrm{d}\bar{r}^2+\ell_\Lambda^2\sinh^2\frac{\bar{r}}{\ell_\Lambda}\mathrm{d}\omega^2\right), \tag{A58}$$

$$g=-\left(1-\frac{R^2}{\ell_\Lambda^2}\right)\mathrm{d}T^2+\left(1-\frac{R^2}{\ell_\Lambda^2}\right)^{-1}\mathrm{d}R^2+R^2\,\mathrm{d}\omega^2, \tag{A59}$$

$$T=\bar{t}, \tag{A60a}$$

$$\exp\frac{\bar{r}}{\ell_\Lambda}=\sqrt{\frac{\ell_\Lambda+R}{\ell_\Lambda-R}}\,,\quad \sinh\frac{\bar{r}}{\ell_\Lambda}=\frac{R}{\sqrt{\ell_\Lambda^2-R^2}}\,,$$
$$\tanh\frac{\bar{r}}{\ell_\Lambda}=\frac{R}{\ell_\Lambda},\quad \cosh\frac{\bar{r}}{\ell_\Lambda}=\frac{\ell_\Lambda}{\sqrt{\ell_\Lambda^2-R^2}}, \tag{A60b}$$

$$s_{\mathbf{NS}}=\begin{cases}+1 & \text{in domain } \mathbf{N},\\ -1 & \text{in domain } \mathbf{S}.\end{cases} \tag{A61}$$

The ranges of coordinates are

$$T\in\mathbb{R},\quad R\in(-\ell_\Lambda,\ell_\Lambda),\quad \bar{t}\in\mathbb{R},\quad \bar{r}\in\mathbb{R}, \tag{A62}$$

with negative values of coordinates R and $\bar{r}$ interpreted as described in Eq. (A2).

Orthonormal tetrad,

$$\mathrm{e}_T=\left(1-\frac{R^2}{\ell_\Lambda^2}\right)^{-1/2}\frac{\partial}{\partial T}=\cosh\frac{\bar{r}}{\ell_\Lambda}\frac{\partial}{\partial\bar{t}},\quad \mathrm{e}_R=\left(1-\frac{R^2}{\ell_\Lambda^2}\right)^{1/2}\frac{\partial}{\partial R}=\cosh^{-1}\frac{\bar{r}}{\ell_\Lambda}\frac{\partial}{\partial\bar{r}}\,, \tag{A63}$$

$$\mathrm{e}_\vartheta = \frac{1}{R}\frac{\partial}{\partial\vartheta} = \frac{1}{\ell_\Lambda}\coth\frac{\bar r}{\ell_\Lambda}\frac{\partial}{\partial\vartheta}\,.$$

Relation to spherical cosmological family,

$$T = \frac{\ell_\Lambda}{2}\log\frac{\cos\tilde r-\cos\tilde t}{\cos\tilde r+\cos\tilde t}, \quad R = \ell_\Lambda\frac{\sin\tilde r}{\sin\tilde t}\,, \tag{A64}$$

$$\bar t = \frac{\ell_\Lambda}{2}\log\left(\tan\frac{\tilde t+\tilde r}{2}\tan\frac{\tilde t-\tilde r}{2}\right), \quad \bar r = \frac{\ell_\Lambda}{2}\log\left(\tan\frac{\tilde t+\tilde r}{2}\cot\frac{\tilde t-\tilde r}{2}\right),$$

$$\exp\frac{\bar t}{\ell_\Lambda} = \sqrt{\frac{\cos\tilde r-\cos\tilde t}{\cos\tilde r+\cos\tilde t}}, \quad \sinh\frac{\bar t}{\ell_\Lambda} = \frac{-s_{\mathbf{NS}}\cos\tilde t}{\sqrt{\cos^2\tilde r-\cos^2\tilde t}}\,,$$

$$\tanh\frac{\bar t}{\ell_\Lambda} = -\frac{\cos\tilde t}{\cos\tilde r}, \quad \cosh\frac{\bar t}{\ell_\Lambda} = \frac{s_{\mathbf{NS}}\cos\tilde r}{\sqrt{\cos^2\tilde r-\cos^2\tilde t}}\,, \tag{A65}$$

$$\exp\frac{\bar r}{\ell_\Lambda} = \sqrt{\frac{\sin\tilde t+\sin\tilde r}{\sin\tilde t-\sin\tilde r}}, \quad \sinh\frac{\bar r}{\ell_\Lambda} = \frac{\sin\tilde r}{\sqrt{\sin^2\tilde t-\sin^2\tilde r}}\,,$$

$$\tanh\frac{\bar r}{\ell_\Lambda} = \frac{\sin\tilde r}{\sin\tilde t}, \quad \cosh\frac{\bar r}{\ell_\Lambda} = \frac{\sin\tilde t}{\sqrt{\sin^2\tilde t-\sin^2\tilde r}}.$$

Relation to flat cosmological family,

$$\bar t = \frac{\ell_\Lambda}{2}\log\frac{\hat t^2-\hat r^2}{\ell_\Lambda^2} = -\frac{\ell_\Lambda}{2}\log\frac{\check t^2-\check r^2}{\ell_\Lambda^2}, \quad \bar r = \frac{\ell_\Lambda}{2}\log\frac{\hat t+\hat r}{\hat t-\hat r} = \frac{\ell_\Lambda}{2}\log\frac{\check t-\check r}{\check t+\check r}\,, \tag{A66}$$

$$\frac{T}{\ell_\Lambda} = \frac{1}{2}\log\frac{\hat t^2-\hat r^2}{\ell_\Lambda^2} = -\frac{1}{2}\log\frac{\check t^2-\check r^2}{\ell_\Lambda^2}, \quad \frac{R}{\ell_\Lambda} = \frac{\hat r}{\hat t} = -\frac{\check r}{\check t}\,. \tag{A67}$$

Relation to conformally Minkowski coordinates,

$$\tanh\frac{T}{\ell_\Lambda} = \frac{2\ell_\Lambda t}{\ell_\Lambda^2+t^2-r^2}\,, \quad \frac{R}{\ell_\Lambda} = \frac{2\ell_\Lambda r}{\ell_\Lambda^2+r^2-t^2}\,, \tag{A68}$$

$$\bar t = \frac{\ell_\Lambda}{2}\log\frac{(\ell_\Lambda+t)^2-r^2}{(\ell_\Lambda-t)^2-r^2}\,, \quad \bar r = \frac{\ell_\Lambda}{2}\log\frac{(\ell_\Lambda+r)^2-t^2}{(\ell_\Lambda-r)^2-t^2}\,. \tag{A69}$$

***6. The static family in spacelike domains* F *and* P**:

Here we describe the static coordinates T, R, ϑ, φ and the "tortoise" static coordinates $\bar t, \bar r, \vartheta, \varphi$ from the preceding section in domains **F** and **S** where the Killing vector is spacelike. These "nonstatic" domains extend up to infinity, namely, domain **F** up to $\mathcal{I}^+$, domain **P** up to $\mathcal{I}^-$. The orbits of the Killing vector start at the south pole and end at the north pole in **F**, and they point in opposite direction in **P**. The motion along them could thus be characterized as a "translation" from one pole to the other. The Lorentzian hypersurfaces $T=$constant are homogeneous spaces with positive curvature, i.e., three-dimensional de Sitter space–times. (See Fig. 19.)

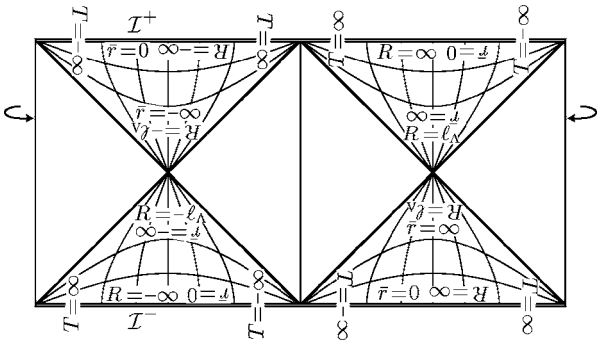

FIG. 19. The static family of coordinates, spacelike domains.

Metric and relation between coordinates,

$$g = \sinh^{-2}\frac{\bar{r}}{\ell_\Lambda}\left(-\mathrm{d}\bar{r}^2 + \mathrm{d}\bar{t}^2 + \ell_\Lambda^2 \cosh^2\frac{\bar{r}}{\ell_\Lambda}\mathrm{d}\omega^2\right), \tag{A70}$$

$$g = -\left(1 - \frac{R^2}{\ell_\Lambda^2}\right)\mathrm{d}T^2 + \left(1 - \frac{R^2}{\ell_\Lambda^2}\right)^{-1}\mathrm{d}R^2 + R^2\,\mathrm{d}\omega^2, \tag{A71}$$

$$T = \bar{t}, \tag{A72a}$$

$$\exp\frac{\bar{r}}{\ell_\Lambda} = \sqrt{\frac{R+\ell_\Lambda}{R-\ell_\Lambda}}, \quad \left|\sinh\frac{\bar{r}}{\ell_\Lambda}\right| = \frac{\ell_\Lambda}{\sqrt{R^2-\ell_\Lambda^2}}, \qquad \tanh\frac{\bar{r}}{\ell_\Lambda} = \frac{\ell_\Lambda}{R}, \quad \cosh\frac{\bar{r}}{\ell_\Lambda} = \frac{|R|}{\sqrt{R^2-\ell_\Lambda^2}}. \tag{A72b}$$

The signature factors $s_\mathcal{I}$ and $s_\times$ are defined as

$$s_\mathcal{I} = \begin{cases} +1 & \text{in domain } \mathbf{F}, \\ -1 & \text{in domain } \mathbf{P}, \end{cases} \tag{A73}$$

$$s_\times = -\,s_\mathcal{I}\,\mathrm{sign}\,\tilde{r}. \tag{A74}$$

The coordinates ranges are

$$T \in \mathbb{R}, \quad |R| \in (\ell_\Lambda, \infty), \quad \bar{t} \in \mathbb{R}, \quad \bar{r} \in \mathbb{R}, \tag{A75}$$

with negative values of coordinates R and $\bar{r}$ interpreted as described in Eq. (A2).

Orthonormal tetrad,

$$\mathrm{e}_T = \left(\frac{R^2}{\ell_\Lambda^2} - 1\right)^{-1/2}\frac{\partial}{\partial T} = \left|\sinh\frac{\bar{r}}{\ell_\Lambda}\right|\frac{\partial}{\partial \bar{t}}, \qquad \mathrm{e}_R = \left(\frac{R^2}{\ell_\Lambda^2} - 1\right)^{1/2}\frac{\partial}{\partial R} = -\left|\sinh^{-1}\frac{\bar{r}}{\ell_\Lambda}\right|\frac{\partial}{\partial \bar{r}}, \quad \mathrm{e}_\vartheta = \frac{1}{R}\frac{\partial}{\partial \vartheta} = \frac{1}{\ell_\Lambda}\left|\tanh\frac{\bar{r}}{\ell_\Lambda}\right|\frac{\partial}{\partial \vartheta}. \tag{A76}$$

Relation to spherical cosmological family,

$$T=\frac{\ell_\Lambda}{2}\log\frac{\cos\tilde{t}-\cos\tilde{r}}{\cos\tilde{t}+\cos\tilde{r}}\,,\quad R=\ell_\Lambda\frac{\sin\tilde{r}}{\sin\tilde{t}}\,,\tag{A77}$$

$$\bar{t}=\frac{\ell_\Lambda}{2}\log\left(-\tan\frac{\tilde{t}+\tilde{r}}{2}\tan\frac{\tilde{t}-\tilde{r}}{2}\right),\quad \bar{r}=\frac{\ell_\Lambda}{2}\log\left(-\tan\frac{\tilde{t}+\tilde{r}}{2}\cot\frac{\tilde{t}-\tilde{r}}{2}\right),$$

$$\exp\frac{\bar{t}}{\ell_\Lambda}=\sqrt{\frac{\cos\tilde{t}-\cos\tilde{r}}{\cos\tilde{t}+\cos\tilde{r}}}\,,\quad \sinh\frac{\bar{t}}{\ell_\Lambda}=\frac{s_{\mathcal{I}}\cos\tilde{r}}{\sqrt{\cos^2\tilde{t}-\cos^2\tilde{r}}}\,,$$

$$\tanh\frac{\bar{t}}{\ell_\Lambda}=-\frac{\cos\tilde{r}}{\cos\tilde{t}}\,,\quad \cosh\frac{\bar{t}}{\ell_\Lambda}=\frac{-s_{\mathcal{I}}\cos\tilde{t}}{\sqrt{\cos^2\tilde{t}-\cos^2\tilde{r}}}\,,\tag{A78}$$

$$\exp\frac{\bar{r}}{\ell_\Lambda}=\sqrt{\frac{\sin\tilde{r}+\sin\tilde{t}}{\sin\tilde{r}-\sin\tilde{t}}}\,,\quad \left|\sinh\frac{\bar{r}}{\ell_\Lambda}\right|=\frac{\sin\tilde{t}}{\sqrt{\sin^2\tilde{r}-\sin^2\tilde{t}}}\,,$$

$$\tanh\frac{\bar{r}}{\ell_\Lambda}=\frac{\sin\tilde{t}}{\sin\tilde{r}}\,,\quad \cosh\frac{\bar{r}}{\ell_\Lambda}=\frac{|\sin\tilde{r}|}{\sqrt{\sin^2\tilde{r}-\sin^2\tilde{t}}}\,.$$

Relation to flat cosmological family,

$$\bar{t}=\frac{\ell_\Lambda}{2}\log\frac{-\hat{t}^2+\hat{r}^2}{\ell_\Lambda^2}=-\frac{\ell_\Lambda}{2}\log\frac{-\check{t}^2+\check{r}^2}{\ell_\Lambda^2}\,,\quad \bar{r}=\frac{\ell_\Lambda}{2}\log\frac{\hat{r}+\hat{t}}{\hat{r}-\hat{t}}=\frac{\ell_\Lambda}{2}\log\frac{\check{r}-\check{t}}{\check{r}+\check{t}}\,,\tag{A79}$$

$$\frac{T}{\ell_\Lambda}=\frac{1}{2}\log\frac{-\hat{t}^2+\hat{r}^2}{\ell_\Lambda^2}=-\frac{1}{2}\log\frac{-\check{t}^2+\check{r}^2}{\ell_\Lambda^2}\,,\quad \frac{R}{\ell_\Lambda}=\frac{\hat{r}}{\hat{t}}=-\frac{\check{r}}{\check{t}}\,.\tag{A80}$$

Relation to conformally Minkowski coordinates,

$$\coth\frac{T}{\ell_\Lambda}=\frac{2\ell_\Lambda t}{\ell_\Lambda^2+t^2-r^2}\,,\quad \frac{R}{\ell_\Lambda}=\frac{2\ell_\Lambda r}{\ell_\Lambda^2+r^2-t^2}\,,\tag{A81}$$

$$\bar{t}=\frac{\ell_\Lambda}{2}\log\left(-\frac{(\ell_\Lambda+t)^2-r^2}{(\ell_\Lambda-t)^2-r^2}\right),\quad \bar{r}=\frac{\ell_\Lambda}{2}\log\left(-\frac{(\ell_\Lambda+r)^2-t^2}{(\ell_\Lambda-r)^2-t^2}\right).\tag{A82}$$

7. The hyperbolic cosmological family:

The third type of cosmological coordinates are the hyperbolic cosmological coordinates η, ρ, ϑ, φ. The hypersurfaces η=constant are homogeneous spaces with negative curvature, coordinate lines ρ,ϑ,φ=constant correspond to the worldlines of cosmological observers orthogonal to these slices, and the vector $\partial/\partial\eta$ is a timelike conformal Killing vector. The coordinates cover space–time only partially—they can be introduced in two disconnected domains near the north pole, namely, in the past of the event $\tilde{t}=\pi/2$, $\tilde{r}=0$ (where $\eta<0$), and in the future of this event (where $\eta>0$). (see. Fig. 20.)

The metric,

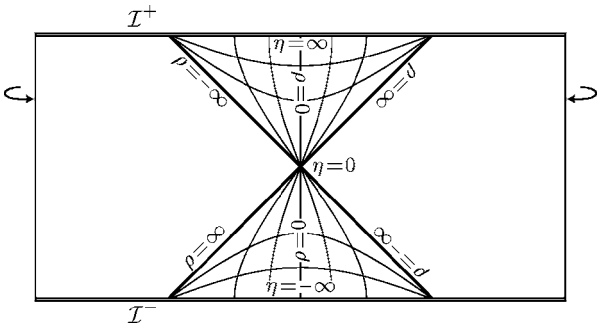

FIG. 20. The hyperbolic cosmological family of coordinates.

$$g=-\,\mathrm{d}\eta^2+\sinh^2\frac{\eta}{\ell_\Lambda}\left(\mathrm{d}\rho^2+\ell_\Lambda^2\sinh^2\frac{\rho}{\ell_\Lambda}\mathrm{d}\omega^2\right). \tag{A83}$$

The ranges of coordinates and the signature factor $s_\mathcal{I}$ are

$$\begin{aligned}&\eta\in\mathbb{R}^+,\quad \rho\in\mathbb{R},\quad s_\mathcal{I}=+1\quad \text{in the future patch},\\ &\eta\in\mathbb{R}^-,\quad \rho\in\mathbb{R},\quad s_\mathcal{I}=-1\quad \text{in the past patch},\end{aligned} \tag{A84}$$

with negative values of radial coordinate ρ interpreted as described in Eq. (A2).

Orthonormal tetrad,

$$\mathrm{e}_\eta=\frac{\partial}{\partial\eta},\quad \mathrm{e}_\rho=\sinh^{-1}\frac{\eta}{\ell_\Lambda}\frac{\partial}{\partial\rho},\quad \mathrm{e}_\vartheta=\sinh^{-1}\frac{\eta}{\ell_\Lambda}\sinh^{-1}\frac{\rho}{\ell_\Lambda}\frac{\partial}{\partial\rho}. \tag{A85}$$

Relation to spherical cosmological family,

$$\tanh\frac{\eta}{2\ell_\Lambda}=s_\mathcal{I}\sqrt{\frac{\cos\tilde{r}-\sin\tilde{t}}{\cos\tilde{r}+\sin\tilde{t}}},\quad \tanh\frac{\rho}{\ell_\Lambda}=-\frac{\sin\tilde{r}}{\cos\tilde{t}}. \tag{A86}$$

Relation to conformally Minkowski coordinates,

$$\tanh\frac{\eta}{2\ell_\Lambda}=s_\mathcal{I}\frac{\sqrt{t^2-r^2}}{\ell_\Lambda},\quad \tanh\frac{\rho}{\ell_\Lambda}=\frac{r}{t}. \tag{A87}$$

8. The accelerated coordinate family:

This family consists of the accelerated coordinates T',R',ϑ',φ, and the C-metric-like coordinates $\tau,\upsilon,\xi,\varphi$ (τ being different from τ of the standard coordinates). Contrary to the previous cases the accelerated coordinates are centered on uniformly accelerated origins, $R'=0$ corresponds to two worldlines with acceleration $|a_\mathrm{o}|$. The transformation relations to the systems introduced above mix these three coordinates in general.

The accelerated coordinates are closely related to the static system. Their time coordinates coincide, $T'=T$, and coordinate lines R',ϑ',φ=constant are the same as those with R,ϑ,φ=constant. Both coordinate systems are identical for $a_\mathrm{o}=0$. Sections T,T',φ=constant with $R,R'<\ell_\Lambda$ have geometry of 2-sphere with parallels and meridians given by the coordinate lines of the static coordinates R,ϑ. The lines of coordinates R',ϑ' are the deformed version of static ones, their poles are shifted along meridian $\vartheta=0$ towards each other, cf. Fig. 11.

Two conformal diagrams of sections ϑ',φ=constant ($\vartheta'<\pi/2$ on the right, $\vartheta'>\pi/2$ on the left), adapted to the accelerated coordinates, are depicted in Fig. 21. The shape of the diagram varies with different values of ϑ'; indeed, the position of infinity is given by $R'=-\ell_\Lambda^2/R_\mathrm{o}\cos^{-1}\vartheta'$. See also Fig. 10 for sections $\vartheta'=0,\pi$.

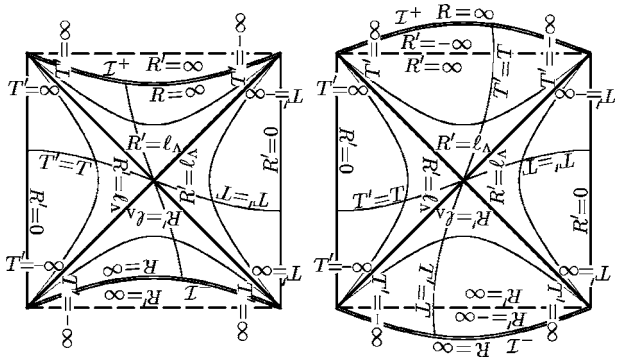

FIG. 21. The accelerated family of coordinates.

The C-metric-like coordinates rescale only the values of the accelerated coordinates and regularize the coordinate singularity $R'=\pm\infty$. de Sitter metric in these coordinates is a zero-mass limit of the C-metric (the metric describing accelerated black holes; see, e.g., Refs. 28 and 29, cf. also Ref. 59).

Finally, we use four parameters a_o,α_o,R_o,b_o to parametrize the acceleration. They are related as follows:

$$\begin{aligned}
\sinh\alpha_o &= \frac{R_o}{\sqrt{\ell_\Lambda^2-R_o^2}} = \frac{b_o^2-\ell_\Lambda^2}{2\ell_\Lambda b_o} = -a_o\ell_\Lambda,\\
\cosh\alpha_o &= \frac{\ell_\Lambda}{\sqrt{\ell_\Lambda^2-R_o^2}} = \frac{b_o^2+\ell_\Lambda^2}{2\ell_\Lambda b_o} = \sqrt{1+a_o^2\ell_\Lambda^2},\\
\tanh\alpha_o &= \frac{R_o}{\ell_\Lambda} = \frac{b_o^2-\ell_\Lambda^2}{b_o^2+\ell_\Lambda^2} = -\frac{a_o\ell_\Lambda}{\sqrt{1+a_o^2\ell_\Lambda^2}},\\
\exp\alpha_o &= \sqrt{\frac{\ell_\Lambda+R_o}{\ell_\Lambda-R_o}} = \frac{b_o}{\ell_\Lambda} = \sqrt{1+a_o^2\ell_\Lambda^2}-a_o\ell_\Lambda.
\end{aligned} \tag{A88}$$

Metric and relation between coordinates,

$$g=\Omega^2\left[-\left(1-\frac{R'^2}{\ell_\Lambda^2}\right)\mathrm{d}T'^2+\left(1-\frac{R'^2}{\ell_\Lambda^2}\right)^{-1}\mathrm{d}R'^2+R'^2\,\mathrm{d}\omega^{2\prime}\right], \tag{A89}$$

$$g=\mathfrak{r}^2\left[-(v^2-1)\mathrm{d}\tau^2+\frac{1}{v^2-1}\mathrm{d}v^2+\frac{1}{1-\xi^2}\mathrm{d}\xi^2+(1-\xi^2)\mathrm{d}\varphi^2\right], \tag{A90}$$

where

$$\mathrm{d}\omega^{2\prime}=(\mathrm{d}\vartheta'^2+\sin^2\vartheta'\,\mathrm{d}\varphi^2), \tag{A91}$$

$$\Omega=\frac{\sqrt{1-R_o^2/\ell_\Lambda^2}}{1+(R'R_o/\ell_\Lambda^2)\cos\vartheta'}=\frac{\mathfrak{r}}{R'}=\frac{\mathfrak{r}v}{\ell_\Lambda}, \tag{A92}$$

$$\mathfrak{r}=\frac{\ell_\Lambda}{v\cosh\alpha_o-\xi\sinh\alpha_o}=\Omega R'=\Omega\frac{\ell_\Lambda}{v}, \tag{A93}$$

$$\tau = \frac{T'}{\ell_\Lambda}, \quad \upsilon = \frac{\ell_\Lambda}{R'}, \quad \xi = -\cos\vartheta', \tag{A94}$$

Orthonormal tetrad:

$$\mathrm{e}_{T'} = |\Omega|^{-1}\left(1 - \frac{R'^2}{\ell_\Lambda^2}\right)^{-1/2}\frac{\partial}{\partial T'} = \frac{1}{\mathfrak{r}\sqrt{\upsilon^2 - 1}}\frac{\partial}{\partial T'},$$

$$\mathrm{e}_{R'} = |\Omega|^{-1}\left(1 - \frac{R'^2}{\ell_\Lambda^2}\right)^{1/2}\frac{\partial}{\partial R'} = \frac{1}{\mathfrak{r}}\sqrt{\upsilon^2 - 1}\frac{\partial}{\partial R'}, \tag{A95}$$

$$\mathrm{e}_{\vartheta'} = \frac{1}{\Omega R'}\frac{\partial}{\partial\vartheta'} = \frac{1}{\mathfrak{r}}\frac{\partial}{\partial\vartheta'}.$$

Relation to static coordinates,

$$T = T',$$

$$R\cos\vartheta = \frac{R'\cos\vartheta' + R_\mathrm{o}}{1 + (R'R_\mathrm{o}/\ell_\Lambda^2)\cos\vartheta'}, \quad R\sin\vartheta = \frac{R'\sin\vartheta'\sqrt{1 - \dfrac{R_\mathrm{o}^2}{\ell_\Lambda^2}}}{1 + (R'R_\mathrm{o}/\ell_\Lambda^2)\cos\vartheta'},$$

$$\frac{R^2}{\ell_\Lambda^2} = 1 - \frac{(1 - R'^2/\ell_\Lambda^2)(1 - R_\mathrm{o}^2/\ell_\Lambda^2)}{(1 + (R'R_\mathrm{o}/\ell_\Lambda^2)\cos\vartheta')^2}, \quad \tan\vartheta = \frac{R'\sin\vartheta'\sqrt{1 - \dfrac{R_\mathrm{o}^2}{\ell_\Lambda^2}}}{R'\cos\vartheta' + R_\mathrm{o}}. \tag{A96}$$

The inverse relations have the same form with T, R, ϑ and T', R', ϑ' interchanged only and α_o replaced by $-\alpha_\mathrm{o}$,

$$\Omega = \frac{\sqrt{1 - R_\mathrm{o}^2/\ell_\Lambda^2}}{1 + (R'R_\mathrm{o}/\ell_\Lambda^2)\cos\vartheta'} = \frac{1 - (RR_\mathrm{o}/\ell_\Lambda^2)\cos\vartheta}{\sqrt{1 - R_\mathrm{o}^2/\ell_\Lambda^2}}, \tag{A97}$$

$$\left(1 + \frac{R'R_\mathrm{o}}{\ell_\Lambda^2}\cos\vartheta'\right)\left(1 - \frac{RR_\mathrm{o}}{\ell_\Lambda^2}\cos\vartheta\right) = 1 - \frac{R_\mathrm{o}^2}{\ell_\Lambda^2}, \tag{A98}$$

$$\frac{1 - R'^2/\ell_\Lambda^2}{1 + (R'R_\mathrm{o}/\ell_\Lambda^2)\cos\vartheta'} = \frac{1 - R^2/\ell_\Lambda^2}{1 - (RR_\mathrm{o}/\ell_\Lambda^2)\cos\vartheta}. \tag{A99}$$

Relation to Robinson-Trautman coordinates,

$$T' = \mathfrak{u}\cosh\alpha_\mathrm{o} - \frac{\ell_\Lambda}{2}\log\left|\frac{\ell_\Lambda - \mathfrak{r}(\sinh\alpha_\mathrm{o}\cos\vartheta' + \cosh\alpha_\mathrm{o})}{\ell_\Lambda - \mathfrak{r}(\sinh\alpha_\mathrm{o}\cos\vartheta' - \cosh\alpha_\mathrm{o})}\right|,$$

$$R' = \frac{\mathfrak{r}\cosh\alpha_\mathrm{o}}{1 - (\mathfrak{r}/\ell_\Lambda)\sinh\alpha_\mathrm{o}\cos\vartheta'}, \quad \left|\tan\frac{\vartheta'}{2}\right| = \exp\left(\psi - \frac{\mathfrak{u}}{\ell_\Lambda}\sinh\alpha_\mathrm{o}\right), \tag{A100}$$

$$\tau = \frac{\mathfrak{u}}{\ell_\Lambda}\cosh\alpha_\mathrm{o} - \frac{1}{2}\log\left|\frac{\ell_\Lambda - \mathfrak{r}(\sinh\alpha_\mathrm{o}\cos\vartheta' + \cosh\alpha_\mathrm{o})}{\ell_\Lambda - \mathfrak{r}(\sinh\alpha_\mathrm{o}\cos\vartheta' - \cosh\alpha_\mathrm{o})}\right|, \tag{A101}$$

$$v=\frac{\ell_\Lambda}{\mathfrak{r}\cosh\alpha_o}-\tanh\alpha_o\cos\vartheta',\quad \xi=\tanh\left(\psi-\frac{\mathfrak{u}}{\ell_\Lambda}\sinh\alpha_o\right),$$

where $\cos\vartheta'=-\xi$ is given in terms of the Robinson-Trautman coordinates by the last equation.

Relation to flat cosmological family: If we introduce the spherical coordinates $\check{t}'$, $\check{r}'$, ϑ', φ boosted with respect to the flat cosmological coordinates $\check{t}$, $\check{r}$, ϑ, φ by a boost α_o (in the sense of Minkowski space $\check{M}$), we find that the accelerated coordinates T', R' are related to $\hat{t}'$, $\hat{r}'$ in exactly the same way as the static coordinates T, R are related to the coordinates $\check{t}$, $\check{r}$. The boost $\check{t}'=\check{t}\cosh\alpha_o+\check{z}\sinh\alpha_o$, $\check{x}'=\check{x}$, $\check{y}'=\check{y}$, $\check{z}'=\check{t}\sinh\alpha_o+\check{z}\cosh\alpha_o$, rewritten in the spherical coordinates $\check{r}'\cos\vartheta'=\check{z}'$, $\check{r}'\sin\vartheta'=\sqrt{\check{x}'^2+\check{y}'^2}$, reads

$$\begin{aligned}\check{t}'&=\check{t}\cosh\alpha_o+\check{r}\cos\vartheta\sinh\alpha_o,\\ \check{r}'\cos\vartheta'&=\check{t}\sinh\alpha_o+\check{r}\cos\vartheta\cosh\alpha_o,\\ \check{r}'\sin\vartheta'&=\check{r}\sin\vartheta,\end{aligned}\tag{A102}$$

and relations analogous to Eqs. (A67) and (A80) are

$$T'=-\frac{\ell_\Lambda}{2}\log\left|\frac{\check{t}'^2-\check{r}'^2}{\ell_\Lambda^2}\right|,\quad R'=-\ell_\Lambda\frac{\check{r}'}{\check{t}'}\,.\tag{A103}$$

Similarly, the formulas relating the accelerated coordinates to the coordinates $\hat{t}$, $\hat{r}$, ϑ are

$$\begin{aligned}\hat{t}'&=\hat{t}\cosh\alpha_o-\hat{r}\cos\vartheta\sinh\alpha_o,\\ \hat{r}'\cos\vartheta'&=-\hat{t}\sinh\alpha_o+\hat{r}\cos\vartheta\cosh\alpha_o,\\ \hat{r}'\sin\vartheta'&=\hat{r}\sin\vartheta,\end{aligned}\tag{A104}$$

$$T'=\frac{\ell_\Lambda}{2}\log\left|\frac{\hat{t}'^2-\hat{r}'^2}{\ell_\Lambda^2}\right|,\quad R'=\ell_\Lambda\frac{\hat{r}'}{\hat{t}'}\,.\tag{A105}$$

The conformal factor takes the form

$$\Omega=\frac{\check{t}'}{\check{t}}=\frac{\hat{t}'}{\hat{t}}=\cosh\alpha_o-\frac{R}{\ell_\Lambda}\sinh\alpha_o\cos\vartheta.\tag{A106}$$

9. The Robinson-Trautman coordinates:

In the Robinson-Trautman coordinates $\mathfrak{u},\mathfrak{r},\psi,\varphi$ (or in their complex version $\mathfrak{u},\mathfrak{r},\zeta,\bar{\zeta}$), de Sitter metric takes the standard Robinson-Trautman form (see Fig. 22).[50] The coordinate $\mathfrak{u}$ is null, the "radial" coordinate $\mathfrak{r}$ is an affine parameter along coordinate lines $\mathfrak{u},\psi,\varphi=$constant. These lines are null geodesics generating light cones with vertices at the origin $\mathfrak{r}=0$. The coordinates ψ,φ (or $\zeta,\bar{\zeta}$) are angular coordinates, however, they are not functions of the accelerated angular coordinates ϑ',φ only [cf. Eq. (A112)]. Because ϑ',φ have a clearer geometrical meaning, we list some formulas also in the mixed coordinate system $\mathfrak{u},\mathfrak{r},\vartheta',\varphi$.

The origin $\mathfrak{r}=0$ of the Robinson-Trautman coordinates is centered on the worldline of the uniformly accelerated observer moving with the acceleration $|a_o|=|\ell_\Lambda^{-1}\sinh\alpha_o|$. The coordinates are thus closely related to the accelerated coordinates.

The coordinates $\mathfrak{u},\mathfrak{r},\psi,\varphi$ do not cover the whole space–time smoothly. They can be introduced smoothly in the future of the north pole, or in the past of the south pole. At the boundary of these two domains, $\mathfrak{u}\to\pm\infty$.

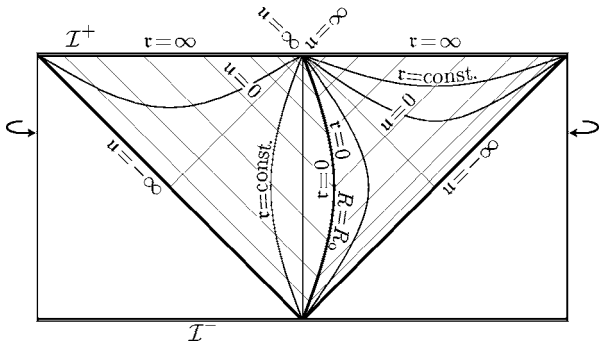

FIG. 22. The Robinson-Trautman coordinates.

Metric and relation between coordinates,

$$g = -H\,\mathrm{d}\mathfrak{u}^2 - \mathrm{d}\mathfrak{u}\vee\mathrm{d}\mathfrak{r} + \frac{\mathfrak{r}^2}{P^2}(\mathrm{d}\psi^2+\mathrm{d}\varphi^2), \tag{A107}$$

$$g = -H\,\mathrm{d}\mathfrak{u}^2 - \mathrm{d}\mathfrak{u}\vee\mathrm{d}\mathfrak{r} + \frac{\mathfrak{r}^2}{P^2}\mathrm{d}\zeta\vee\mathrm{d}\bar{\zeta}, \tag{A108}$$

$$g = -\cosh^2\alpha_0\frac{\mathfrak{r}^2}{\ell_\Lambda^2}(v^2-1)\mathrm{d}\mathfrak{u}^2 - \mathrm{d}\mathfrak{u}\vee\mathrm{d}\mathfrak{r} + \cosh\alpha_0\frac{\mathfrak{r}^2}{\ell_\Lambda}\sin\vartheta'\,\mathrm{d}\mathfrak{u}\vee\mathrm{d}\vartheta' + \mathfrak{r}^2(\mathrm{d}\vartheta'^2+\sin^2\vartheta'\,\mathrm{d}\varphi^2), \tag{A109}$$

$$H = -\frac{\mathfrak{r}^2}{\ell_\Lambda^2} + 2\frac{\mathfrak{r}}{\ell_\Lambda}\sinh\alpha_0\tanh\left(\psi - \frac{\mathfrak{u}}{\ell_\Lambda}\sinh\alpha_0\right) + 1 = -\frac{\mathfrak{r}^2}{\ell_\Lambda^2} - 2\frac{\mathfrak{r}}{\ell_\Lambda}\sinh\alpha_0\cos\vartheta' + 1, \tag{A110}$$

$$P = \cosh\left(\psi - \frac{\mathfrak{u}}{\ell_\Lambda}\sinh\alpha_0\right) = \frac{1}{\sin\vartheta'}, \tag{A111}$$

$$\begin{aligned}\psi &= \frac{\mathfrak{u}}{\ell_\Lambda}\sinh\alpha_0 + \log\left|\tan\frac{\vartheta'}{2}\right|,\\ \left|\tan\frac{\vartheta'}{2}\right| &= \exp\left(\psi - \frac{\mathfrak{u}}{\ell_\Lambda}\sinh\alpha_0\right),\end{aligned} \tag{A112}$$

$$\begin{aligned}\zeta &= \frac{1}{\sqrt{2}}(\psi - i\varphi), \quad \psi = \frac{1}{\sqrt{2}}(\zeta+\bar{\zeta}),\\ \bar{\zeta} &= \frac{1}{\sqrt{2}}(\psi + i\varphi), \quad \varphi = \frac{i}{\sqrt{2}}(\zeta-\bar{\zeta}).\end{aligned} \tag{A113}$$

Null tetrad: Since the Robinson-Trautman coordinates are closely related to the congruence of null geodesics, it is convenient to introduce the null tetrad which is parallelly transported along these geodesics $\mathfrak{u}, \psi, \varphi$=constant,

$$\mathrm{k}_{\mathrm{RT}}=\frac{1}{\sqrt{2}}\frac{\partial}{\partial\mathfrak{r}},\quad \mathrm{l}_{\mathrm{RT}}=-\frac{1}{\sqrt{2}}H\frac{\partial}{\partial\mathfrak{r}}+\sqrt{2}\frac{\partial}{\partial\mathfrak{u}},$$

$$\mathrm{m}_{\mathrm{RT}}=\frac{1}{\sqrt{2}}\frac{P}{\mathfrak{r}}\left(\frac{\partial}{\partial\psi}-i\frac{\partial}{\partial\varphi}\right),\quad \bar{\mathrm{m}}_{\mathrm{RT}}=\frac{1}{\sqrt{2}}\frac{P}{\mathfrak{r}}\left(\frac{\partial}{\partial\psi}+i\frac{\partial}{\partial\varphi}\right). \tag{A114}$$

Relation to accelerated coordinate family,

$$\mathfrak{r}=\frac{R'\sqrt{1-R_{\mathrm{o}}^2/\ell_\Lambda^2}}{1+(R'R_{\mathrm{o}}/\ell_\Lambda^2)\cos\vartheta'},$$

$$\mathfrak{u}=\sqrt{1-\frac{R_{\mathrm{o}}^2}{\ell_\Lambda^2}}\left(T'+\frac{\ell_\Lambda}{2}\log\left|\frac{R'-\ell_\Lambda}{R'+\ell_\Lambda}\right|\right), \tag{A115}$$

$$\psi=\frac{R_{\mathrm{o}}}{\ell_\Lambda}\left(\frac{T'}{\ell_\Lambda}+\frac{1}{2}\log\left|\frac{R'-\ell_\Lambda}{R'+\ell_\Lambda}\right|\right)+\log\left|\tan\frac{\vartheta'}{2}\right|,$$

$$\mathfrak{r}=\frac{\ell_\Lambda}{v\cosh\alpha_{\mathrm{o}}-\xi\sinh\alpha_{\mathrm{o}}},$$

$$\mathfrak{u}=\frac{\ell_\Lambda}{\cosh\alpha_{\mathrm{o}}}\left(\tau+\frac{1}{2}\log\left|\frac{1-v}{1+v}\right|\right), \tag{A116}$$

$$\psi=\tanh\alpha_{\mathrm{o}}\left(\tau+\frac{1}{2}\log\left|\frac{1-v}{1+v}\right|\right)+\frac{1}{2}\log\left|\frac{1+\xi}{1-\xi}\right|.$$

Relation to static family,

$$\mathfrak{r}=\frac{\ell_\Lambda}{\sqrt{1-R_{\mathrm{o}}^2/\ell_\Lambda^2}}\left[\left(1-\frac{RR_{\mathrm{o}}}{\ell_\Lambda^2}\cos\vartheta\right)^2-\left(1-\frac{R^2}{\ell_\Lambda^2}\right)\left(1-\frac{R_{\mathrm{o}}^2}{\ell_\Lambda^2}\right)\right]^{1/2}, \tag{A117}$$

$$\mathfrak{r}\sin\vartheta'=R\sin\vartheta,\quad \mathfrak{r}\cos\vartheta'=\frac{R\cos\vartheta-R_{\mathrm{o}}}{\sqrt{1-R_{\mathrm{o}}^2/\ell_\Lambda^2}}, \tag{A118}$$

$$R\sin\vartheta=\mathfrak{r}\sin\vartheta',\quad R\cos\vartheta=\mathfrak{r}\cos\vartheta'\sqrt{1-R_{\mathrm{o}}^2/\ell_\Lambda^2}+R_{\mathrm{o}}. \tag{A119}$$

10. The null family:

Finally, we return back to the coordinate systems which employ standard coordinates ϑ, φ. Time and radial coordinates can be transformed into two null coordinates. Such null coordinates can be associated with most coordinate families introduced above. Coordinates $\tilde{u}$, $\tilde{v}$ are related to the standard coordinates; $\check{u}$, $\check{v}$ and $\hat{u}$, $\hat{v}$ to the flat cosmological coordinates; u, v to the conformally Minkowski; and $\bar{u}$, $\bar{v}$ to the static coordinates. Coordinate vectors $\{\partial/\partial\tilde{u},\partial/\partial\tilde{v}\}$, $\{\partial/\partial\check{u},\partial/\partial\check{v}\}$, etc., are the pairs of independent null vectors in the radial 2-slices ϑ, φ=constant. We do not allow the radial coordinate to be negative in the definitions of null coordinates because this would interchange the meaning of u and v. The null coordinates are thus drawn in the right half of Fig. 23 only.

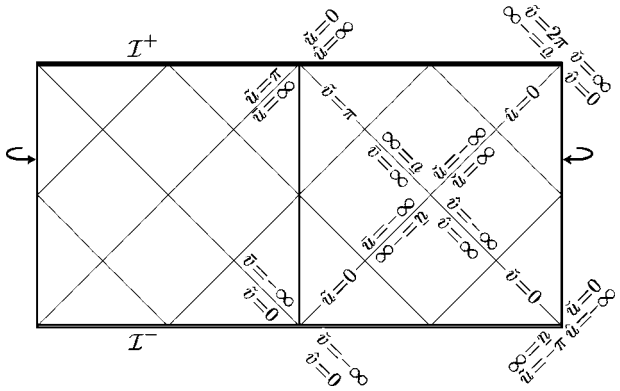

FIG. 23. The null family of coordinates

Metric and relation to other coordinates,

$$g = \frac{\ell_\Lambda^2}{1-\cos(\tilde{u}+\tilde{v})}(-\,\mathrm{d}\tilde{u}\vee\mathrm{d}\tilde{v} + (1-\cos(\tilde{u}-\tilde{v}))\mathrm{d}\omega^2), \tag{A120}$$

$$g = \frac{\ell_\Lambda^2}{(\hat{u}+\hat{v})^2}(-\,2\,\mathrm{d}\hat{u}\vee\mathrm{d}\hat{v} + (\hat{u}-\hat{v})^2\,\mathrm{d}\omega^2), \tag{A121}$$

$$g = \frac{\ell_\Lambda^2}{(\check{u}+\check{v})^2}(-\,2\,\mathrm{d}\check{u}\vee\mathrm{d}\check{v} + (\check{u}-\check{v})^2\,\mathrm{d}\omega^2), \tag{A122}$$

$$g = \left(\frac{\ell_\Lambda^2}{\ell_\Lambda^2 - uv}\right)^2(-\,2\,\mathrm{d}u\vee\mathrm{d}v + (u-v)^2\,\mathrm{d}\omega^2), \tag{A123}$$

$$g = \left(\exp\frac{\bar{u}}{\ell_\Lambda} + \exp\frac{\bar{v}}{\ell_\Lambda}\right)^{-2}\left(-\,2\exp\frac{\bar{u}+\bar{v}}{\ell_\Lambda}\mathrm{d}\bar{u}\vee\mathrm{d}\bar{v} + \ell_\Lambda^2\left(\exp\frac{\bar{u}}{\ell_\Lambda} - \exp\frac{\bar{v}}{\ell_\Lambda}\right)^2\mathrm{d}\omega^2\right). \tag{A124}$$

The relation of time and radial coordinates $\overset{*}{t}$, $\overset{*}{r}$ to the corresponding null coordinates $\overset{*}{u}$, $\overset{*}{v}$ is given by the usual formulas,

$$\begin{aligned} \overset{*}{t} &= \tfrac{1}{2}(\overset{*}{v}+\overset{*}{u}), \quad \overset{*}{u} = \overset{*}{t} - \overset{*}{r}, \\ \overset{*}{r} &= \tfrac{1}{2}(\overset{*}{v}-\overset{*}{u}), \quad \overset{*}{v} = \overset{*}{t} + \overset{*}{r}. \end{aligned} \tag{A125}$$

Here $\{\overset{*}{t},\overset{*}{r}\}$ stands for $\{\tilde{t},\tilde{r}\}$, $\{\check{t},\check{r}\}$, $\{\hat{t},\hat{r}\}$, $\{t,r\}$, and $\{\bar{t},\bar{r}\}$, respectively; similarly with $\{\overset{*}{u},\overset{*}{v}\}$.

Relation between null coordinates: The coordinates $\hat{u}$, $\hat{v}$, u, v, and $\check{u}$, $\check{v}$ can be viewed as null coordinates in the conformally related Minkowski spaces $\hat{M}$, M, and $\check{M}$; these are shifted with respect to each other by $\pi/2$ in the direction of the conformally Einstein time coordinate $\tilde{t}$, or associated null coordinates,

$$\frac{\hat{u}}{\ell_\Lambda} = \tan\frac{\tilde{u}}{2}, \quad \frac{\hat{v}}{\ell_\Lambda} = \tan\frac{\tilde{v}}{2},$$

$$\frac{u}{\ell_\Lambda}=\tan\left(\frac{\tilde{u}}{2}-\frac{\pi}{4}\right),\quad \frac{v}{\ell_\Lambda}=\tan\left(\frac{\tilde{v}}{2}-\frac{\pi}{4}\right), \tag{A126}$$

$$\frac{\check{u}}{\ell_\Lambda}=\tan\left(\frac{\bar{u}}{2}-\frac{\pi}{2}\right),\quad \frac{\check{v}}{\ell_\Lambda}=\tan\left(\frac{\bar{v}}{2}-\frac{\pi}{2}\right).$$

The remaining coordinates $\bar{u}$, $\bar{v}$ are related to the conformally Einstein null coordinates $\tilde{u}$, $\tilde{v}$ by the "compactification transformation,"

$$\tan\frac{\tilde{u}}{2}=s_u\exp\frac{\bar{u}}{\ell_\Lambda},\quad \tan\frac{\tilde{v}}{2}=s_v\exp\frac{\bar{v}}{\ell_\Lambda}. \tag{A127}$$

Here the sign factors s_u and s_v are given by

$$s_u=\operatorname{sign}\tan\frac{\tilde{u}}{2},\quad s_v=\operatorname{sign}\tan\frac{\tilde{v}}{2}. \tag{A128}$$

Relations (A126) and (A127) between null coordinates can also be rewritten as follows:

$$\tan\frac{\tilde{u}}{2}=s_u\exp\frac{\bar{u}}{\ell_\Lambda}=\frac{\hat{u}}{\ell_\Lambda}=-\frac{\ell_\Lambda}{\check{u}}=\frac{\ell_\Lambda+u}{\ell_\Lambda-u},$$

$$\tan\tilde{u}=-s_u\sinh^{-1}\frac{\bar{u}}{\ell_\Lambda}=\frac{2\hat{u}\ell_\Lambda}{\ell_\Lambda^2-\hat{u}^2}=\frac{2\check{u}\ell_\Lambda}{\ell_\Lambda^2-\check{u}^2}=\frac{u^2-\ell_\Lambda^2}{2u\ell_\Lambda},$$

$$\sin\tilde{u}=s_u\cosh^{-1}\frac{\bar{u}}{\ell_\Lambda}=\frac{2\hat{u}\ell_\Lambda}{\ell_\Lambda^2+\hat{u}^2}=\frac{-2\check{u}\ell_\Lambda}{\ell_\Lambda^2+\check{u}^2}=\frac{\ell_\Lambda^2-u^2}{\ell_\Lambda^2+u^2}, \tag{A129}$$

$$\cos\tilde{u}=-\tanh\frac{\bar{u}}{\ell_\Lambda}=\frac{\ell_\Lambda^2-\hat{u}^2}{\ell_\Lambda^2+\hat{u}^2}=\frac{\hat{u}^2-\ell_\Lambda^2}{\hat{u}^2+\ell_\Lambda^2}=\frac{-2u\ell_\Lambda}{\ell_\Lambda^2+u^2},$$

$$\frac{\hat{u}}{\ell_\Lambda}=\tan\frac{\tilde{u}}{2}=s_u\exp\frac{\bar{u}}{\ell_\Lambda}=-\frac{\ell_\Lambda}{\check{u}}=\frac{\ell_\Lambda+u}{\ell_\Lambda-u}, \tag{A130}$$

$$-\frac{\check{u}}{\ell_\Lambda}=\cot\frac{\tilde{u}}{2}=s_u\exp\left(-\frac{\bar{u}}{\ell_\Lambda}\right)=\frac{\ell_\Lambda}{\hat{u}}=\frac{\ell_\Lambda-u}{\ell_\Lambda+u}, \tag{A131}$$

$$\frac{u}{\ell_\Lambda}=-\frac{1-\sin\tilde{u}}{\cos\tilde{u}}=-\frac{\cos\tilde{u}}{1+\sin\tilde{u}}=\left(\tanh\frac{\bar{u}}{2\ell_\Lambda}\right)^{s_u}=\frac{\hat{u}-\ell_\Lambda}{\hat{u}+\ell_\Lambda}=\frac{\ell_\Lambda+\check{u}}{\ell_\Lambda-\check{u}}, \tag{A132}$$

$$\frac{\bar{u}}{\ell_\Lambda}=\log\left|\tan\frac{\tilde{u}}{2}\right|=\log\left|\frac{\hat{u}}{\ell_\Lambda}\right|=\log\left|\frac{\ell_\Lambda}{\check{u}}\right|=\log\left|\frac{\ell_\Lambda+u}{\ell_\Lambda-u}\right|=2\operatorname{arctanh}\left(\frac{u}{\ell_\Lambda}\right)^{s_u}, \tag{A133}$$

$$\hat{u}\check{u}=-\ell_\Lambda^2,\quad \frac{\hat{u}}{\ell_\Lambda}+\frac{\ell_\Lambda}{\check{u}}=0. \tag{A134}$$

The same relations hold for coordinates v, $\tilde{v}$, $\hat{v}$, $\check{v}$ and $\bar{v}$.

[52] For the detailed derivation, see Ref. 24, Sec. V. The field (6.1), with $\mathcal{Q}$ given by (6.3), is the field (5.2) in Ref. 24. Notice, however, the following changes in notation: the quantities α, β_o, and $\mathcal{X}$ in Ref. 24 are, in the present paper, denoted by ℓ_Λ, α_o, and $\sqrt{\ell_\Lambda^2 - R_o^2}\mathcal{Q}$ with R_o again given by Eq. (4.20). Since the field (6.1) [as well as the electromagnetic field (6.4)] can be written as a symmetric combination of retarded and advanced effects from both charges, we called it "symmetric" in Ref. 24 and used a subscript "sym." Such a notation was necessary in Ref. 24, but is not used here.

(Received 20 June 2005; accepted 13 July 2005; published online 10 October 2005)

$\mathfrak{sl}_2$ Gaudin model with jordanian twist is studied. This system can be obtained as the semiclassical limit of the *XXX* spin chain deformed by the jordanian twist. The appropriate creation operators that yield the Bethe states of the Gaudin model and consequently its spectrum are defined. Their commutation relations with the generators of the corresponding loop algebra as well as with the generating function of integrals of motion are given. The inner products and norms of Bethe states and the relation to the solutions of the Knizhnik-Zamolodchikov equations are discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2036932]

I. INTRODUCTION

The quantum inverse scattering method (QISM) was largely created by Faddeev and his school at St. Petersburg as a quantum counterpart of the classical inverse scattering method.[1–4] Classifying quantum solvable systems with respect to the underlying dynamical symmetry algebras, one could say that the Gaudin models[5,6] can be seen as the simplest ones being based on loop algebras. Their Hamiltonians are related to classical r-matrices,

$$H^{(a)} = \sum_{b \neq a}^{N} r_{ab}(z_a - z_b). \tag{1.1}$$

The condition of their commutativity $[H^{(a)}, H^{(b)}]=0$ is nothing else but the classical Yang-Baxter equation

$$[r_{ab}(z_a - z_b), r_{ac}(z_a - z_c) + r_{bc}(z_b - z_c)] + [r_{ac}(z_a - z_c), r_{bc}(z_b - z_c)] = 0, \tag{1.2}$$

where r is antisymmetric and belongs to the tensor product $\mathfrak{g} \otimes \mathfrak{g}$ of a Lie algebra $\mathfrak{g}$, or its representations and the indices fix the corresponding factors in the N-fold tensor product of this algebra. The Gaudin models based on the classical r-matrices of simple Lie algebras attracted a lot of attention.[7–11] Their spectrum and corresponding eigenfunctions were obtained using different methods such as coordinate and algebraic Bethe ansatz, separated variables, etc. The correlation functions of the $\mathfrak{sl}_2$ Gaudin system were calculated by means of the Gauss factorization.[8] A connection between the Bethe vectors of the Gaudin models for simple Lie algebras to the solutions of the Knizhnik-Zamolodchikov equation was established in Refs. 9–11. An explanation of this connection based on Wakimoto modules at critical level of the underlying affine algebra was given in Ref. 10.

The algebraic Bethe Ansatz for the Gaudin model based on the $\mathfrak{sl}_2$ invariant classical r-matrix deformed by the constant jordanian r-matrix was postulated in Ref. 12. Following the ideas used

[a)]Electronic mail: nantonio@math.ist.utl.pt
[b)]Electronic mail: nmanoj@ualg.pt

in the case of the $\mathfrak{osp}(1|2)$ trigonometric Gaudin model,[13] Kulish noticed that the similarity transformation by $\exp(\alpha X^+)\otimes\exp(\alpha X^+)$ on the $\mathfrak{sl}_2$ trigonometrical classical r-matrix,

$$r_{\mathrm{trig}}(\lambda)=\frac{e^{-\lambda}}{\sinh(\lambda)}r^{(+)}+\frac{e^{\lambda}}{\sinh(\lambda)}r^{(-)}=\frac{e^{-\lambda}}{\sinh(\lambda)}\left(\frac{1}{2}h\otimes h+2X^+\otimes X^-\right)+\frac{e^{\lambda}}{\sinh(\lambda)}\left(\frac{1}{2}h\otimes h+2X^-\otimes X^+\right),$$

setting $\lambda\to\epsilon\lambda$, $\alpha\to\xi/2\epsilon$ and after the scaling limit

$$\lim_{\epsilon\to 0}\epsilon r_{\mathrm{trig}}(\epsilon\lambda)=\frac{1}{\lambda}(h\otimes h+2(X^+\otimes X^-+X^-\otimes X^+))+\xi(h\otimes X^+-X^+\otimes h),$$

yields the $\mathfrak{sl}_2$-invariant classical r-matrix deformed by the jordanian r-matrix. Moreover the highest weight vector of the corresponding Gaudin model is preserved. Based on these arguments Kulish postulated the Bethe vectors, the spectrum, and the Bethe equations of the system.

Alternatively, the jordanian twist[14–16]

$$\mathcal{F}^J=e^{h\otimes\sigma}=\exp\left(h\otimes\tfrac{1}{2}\ln(1+2\theta X^+)\right) \tag{1.3}$$

can be applied to the $\mathfrak{sl}_2$-invariant spin system based on the Yang quantum R-matrix,

$$R(\lambda;\eta)=I+\frac{\eta}{\lambda}\mathcal{P}, \tag{1.4}$$

where $\mathcal{P}$ is the permutation matrix in the tensor product $\mathbb{C}^2\otimes\mathbb{C}^2$, to obtain the twisted $\mathfrak{sl}_2$ spin system.[14,17] The semiclassical limit $\eta\to 0$ of this system yields the same Gaudin model discussed by Kulish.[12] The twisted XXX spin chain related to the quantum R-matrix,

$$R(\lambda;\eta;\theta)=R^J(\theta)+\frac{\eta}{\lambda}\mathcal{P}, \tag{1.5}$$

where $R^J(\theta)=\mathcal{F}^J_{21}(\mathcal{F}^J_{12})^{-1}$ is the $\mathfrak{sl}_2$ jordanian quantum R-matrix studied in Refs. 18–20, whose homogeneous case was analyzed in Ref. 14, will be discussed elsewhere,[17] here will only be presented the aspects relevant to the study of the corresponding Gaudin model.

The $\mathfrak{L}$-operator of the quantum spin system on a one-dimensional lattice with N sites coincides with R-matrix acting on a tensor product $V_0\otimes V_a$ of auxiliary space $V_0=\mathbb{C}^2$ and the space of states at site $a=1,2,\ldots,N$,

$$\mathfrak{L}_{0a}(\lambda-z_a)=\begin{pmatrix}e^{-\sigma_a} & \theta h_a e^{\sigma_a}\\ 0 & e^{\sigma_a}\end{pmatrix}+\frac{\eta}{\lambda-z_a}\begin{pmatrix}\frac{h_a}{2} & X_a^-\\ X_a^+ & -\frac{h_a}{2}\end{pmatrix}, \tag{1.6}$$

where z_a is a parameter of inhomogeneity (site dependence). Corresponding monodromy matrix $\mathfrak{T}$ is an ordered product of the $\mathfrak{L}$ operators,

$$\mathfrak{T}(\lambda;\{z_a\}_1^N)=\mathfrak{L}_{0N}(\lambda-z_N)\cdots\mathfrak{L}_{01}(\lambda-z_1)=\prod_{a=1}^{\overleftarrow{N}}\mathfrak{L}_{0a}(\lambda-z_a)=\begin{pmatrix}A(\lambda) & B(\lambda)\\ C(\lambda) & D(\lambda)\end{pmatrix}. \tag{1.7}$$

The commutation relations of the $\mathfrak{T}$-matrix entries follow form the FRT relation

$$R_{12}(\lambda-\mu;\eta;\theta)\mathfrak{T}_1(\lambda)\mathfrak{T}_2(\mu)=\mathfrak{T}_2(\mu)\mathfrak{T}_1(\lambda)R_{12}(\lambda-\mu;\eta;\theta). \tag{1.8}$$

Multiplying (1.8) by R_{12}^{-1} and taking the trace over $\mathbb{C}^2\otimes\mathbb{C}^2$, one gets commutativity of the transfer matrix

$$\mathfrak{t}(\lambda)=\operatorname{tr}\mathfrak{T}(\lambda)=A(\lambda)+D(\lambda) \tag{1.9}$$

for different values of the spectral parameter $\mathfrak{t}(\lambda)\mathfrak{t}(\mu)=\mathfrak{t}(\mu)\mathfrak{t}(\lambda)$.

It is of interest to choose different spins l_a at different sites of the lattice, hence the following space of states:

$$\mathcal{H}=\bigotimes_{a=1}^{N}V_a^{(l_a)},$$

with the highest spin vector $\Omega_+=\otimes_{a=1}^{N}\omega_a$. It is straightforward to show that

$$C(\lambda)\Omega_+=0, \tag{1.10}$$

and

$$A(\lambda)\Omega_+=a(\lambda)\Omega_+=\prod_{a=1}^{N}\left(\frac{\lambda-z_a+\ell_a\eta/2}{\lambda-z_a}\right)\Omega_+, \tag{1.11}$$

$$D(\lambda)\Omega_+=d(\lambda)\Omega_+=\prod_{a=1}^{N}\left(\frac{\lambda-z_a-\ell_a\eta/2}{\lambda-z_a}\right)\Omega_+. \tag{1.12}$$

As the first step in the application of the algebraic Bethe Ansatz to the twisted *XXX* spin chain one can confirm that the highest spin vector Ω_+ is an eigenvector of the transfer matrix (1.9),

$$\mathfrak{t}(\lambda)\Omega_+=\Lambda_0(\lambda)\Omega_+, \tag{1.13}$$

with $\Lambda_0(\lambda)=a(\lambda)+d(\lambda)$. The next step is to show that $\Psi_1(\mu)=B(\mu)\Omega_+$ is also an eigenvector of the transfer matrix

$$\begin{aligned}\mathfrak{t}(\lambda)\Psi_1(\mu)=\mathfrak{t}(\lambda)B(\mu)\Omega_+=\Lambda_1(\lambda,\mu)\Psi_1(\mu)+\frac{\eta}{\lambda-\mu}(a(\mu)-d(\mu))\Psi_1(\lambda)\\ -\theta(a(\mu)-d(\mu))(a(\lambda)-d(\lambda))\Omega_+,\end{aligned} \tag{1.14}$$

where the eigenvalue $\Lambda_1(\lambda,\mu)$ and the Bethe equations are given by

$$\Lambda_1(\lambda,\mu)=\Lambda_0(\lambda)-\frac{\eta}{\lambda-\mu}(a(\lambda)-d(\lambda)), \tag{1.15}$$

$$a(\mu)-d(\mu)=0. \tag{1.16}$$

The following steps of the algebraic Bethe Ansatz are analogous having the same eigenvalues and Bethe equations as in the invariant case,[14] the details will be presented elsewhere.[17]

The corresponding Gaudin model can be obtained from the spin system via the semiclassical limit[7,21] by setting $\theta=-(\eta/2)\xi$ and using the expansion in powers of η of the monodromy matrix

$$\mathfrak{T}(\lambda)=\mathrm{I}+\frac{\eta}{2}L(\lambda)+\mathcal{O}(\eta^2), \tag{1.17}$$

where

$$L(\lambda)=\begin{pmatrix} h(\lambda) & 2X^{-}(\lambda) \\ 2X^{+}(\lambda) & -h(\lambda) \end{pmatrix} \tag{1.18}$$

and

$$h(\lambda)=\sum_{a=1}^{N}\left(\frac{h_a}{\lambda-z_a}+\xi X_a^{+}\right),\quad X^{-}(\lambda)=\sum_{a=1}^{N}\left(\frac{X_a^{-}}{\lambda-z_a}-\frac{\xi}{2}h_a\right),\quad X^{+}(\lambda)=\sum_{a=1}^{N}\frac{X_a^{+}}{\lambda-z_a}. \tag{1.19}$$

Substituting the expansion of the monodromy matrix (1.17) and

$$R(\lambda;\eta;\theta)\big|_{\theta=-(\eta/2)\xi}=\mathrm{I}+\frac{\eta}{2}r_{\xi}(\lambda)+\mathcal{O}(\eta^2), \tag{1.20}$$

with

$$r_{\xi}(\lambda)=\begin{pmatrix} \frac{1}{\lambda} & \xi & -\xi & 0 \\ 0 & -\frac{1}{\lambda} & \frac{2}{\lambda} & \xi \\ 0 & \frac{2}{\lambda} & -\frac{1}{\lambda} & -\xi \\ 0 & 0 & 0 & \frac{1}{\lambda} \end{pmatrix}, \tag{1.21}$$

into the FRT relations (1.8), the first nontrivial term, the coeficient of η^2, is the so-called Sklyanin bracket[7]

$$[L_1(\lambda),L_2(\mu)]=-[r_{\xi}(\lambda-\mu),L_1(\lambda)+L_2(\mu)]. \tag{1.22}$$

Moreover the central element $\Delta(\lambda)$,[2] of the algebra (1.8), admits the expansion in η such that the second order term of $\mathfrak{t}(\lambda)-\Delta(\lambda)$ is the generating function of the integrals of motion of the corresponding Gaudin model,[7]

$$t(\lambda)=\tfrac{1}{2}\mathrm{Tr}\,L^2(\lambda). \tag{1.23}$$

The first step in the application of the algebraic Bethe Ansatz, to the Gaudin models, is to define appropriate creation operators that yield the Bethe states and consequently the spectrum of the generating function $t(\lambda)$. The creation operators used in the $\mathfrak{sl}_2$-invariant Gaudin model coincide with one of the L-matrix entry.[5,7] However, in the present case these operators are not homogeneous polynomials of the generator $X^{-}(\lambda)$ and can be defined by the recursive relation as proposed by Kulish.[12] It is convenient to define $B_M^{(k)}(\mu_1,\ldots,\mu_M)$, a more general set of operators, in order to simplify the calculation of the commutators between the creation operators and the generating function of the integrals of motion $t(\lambda)$. These operators are symmetric functions of their arguments and they satisfy certain recursive relations. Their commutation relations with the generators of the loop algebra are straightforward to calculate and they are essential in the main step of the algebraic Bethe Ansatz. The creation operators of the $\mathfrak{sl}_2$ Gaudin model with jordanian twist are the particular case $B_M(\mu_1,\ldots,\mu_M)=B_M^{(0)}(\mu_1,\ldots,\mu_M)$. Thus the commutation relations between the creation operators and $t(\lambda)$ are easily calculated. Therefore the corresponding Bethe vectors can be defined by the action of the creation operators on the highest spin vector Ω_+ and thus the spectrum of the system is determined. In this way the algebraic Bethe Ansatz is fully implemented confirming the result of Kulish[12] that the spectrum of the system coincides with the one of the $\mathfrak{sl}_2$-invariant model and consequently the twisted Gaudin Hamiltonians have the same spectrum as in the $\mathfrak{sl}_2$-invariant case, although the Bethe vectors of the two systems are different. However the Bethe vectors, in this case, are not eigenstates of the global Cartan generator h_{gl}.

Besides the problem of determining the spectrum of the system, via algebraic Bethe Ansatz, some properties of the creation operators are fundamental in calculating the inner products and the norms of the Bethe states. In particular, it turns out that the relation between the creation operators of the system and the ones in the untwisted case is essential in determining the inner products of the Bethe vectors. In addition, it is necessary to consider the dual creation operators $B_M^*(\mu_1,\ldots,\mu_M)$ obtained by using the dual Gaudin model based on the following classical r-matrix:

$$r^*(\lambda)=\frac{1}{\lambda}(h\otimes h+2(X^+\otimes X^-+X^-\otimes X^+))+\xi(h\otimes X^--X^-\otimes h). \tag{1.24}$$

As opposed to the $\mathfrak{sl}_2$-invariant case, the Bethe vectors $\Psi_M(\mu_1,\ldots,\mu_M)$ are not orthogonal for different M's. It should also be mentioned that, due to the jordanian twist, the dual generating function of integrals of motion $t^*(\lambda)$ is not equal to $t(\lambda)$, the generating function of integrals of motion of the original model, contrary to the $\mathfrak{sl}_2$-invariant case, thus these operators are not Hermitian.

A connection between the Bethe vectors, when the Bethe equations are not imposed on their parameters, of the twisted Gaudin model to the solutions of the corresponding Knizhnik-Zamolodchikov equation, similarly to the $\mathfrak{sl}_2$-invariant model, is based on some analytical properties of the creation operators $B_M(\mu_1,\ldots,\mu_M)$.

The paper is organized as follows. In Sec. II we discuss the Gaudin model based on the $\mathfrak{sl}_2$ invariant r-matrix with jordanian twist emphasizing the creation operators B_M. Using the previously established properties of the creation operators B_M, in Sec. III the spectrum and the Bethe vectors of the system are given. The dual creation operators are used to obtain the expressions for inner products and norms of Bethe states. In conclusion a relation between the Bethe vectors and the solutions to the Knizhnik-Zamolodchikov equation are discussed. In the appendix the proofs of the lemmas are given.

II. $_2$ TWISTED GAUDIN MODEL

The $\mathfrak{sl}_2$-invariant classical r-matrix with jordanian twist[22,18,19] is the following element of $\mathfrak{sl}_2\otimes\mathfrak{sl}_2$:

$$r_\xi(\lambda)=\frac{c_2^\otimes}{\lambda}+\xi r^J=\frac{1}{\lambda}(h\otimes h+2(X^+\otimes X^-+X^-\otimes X^+))+\xi(h\otimes X^+-X^+\otimes h). \tag{2.1}$$

The matrix form of $r_\xi(\lambda)$ in the fundamental representation of $\mathfrak{sl}_2$ follows from (2.1) by replacing the appropriate matrices for the generators of $\mathfrak{sl}_2$ given explicitly by

$$r_\xi(\lambda)=\begin{pmatrix}\frac{1}{\lambda} & \xi & -\xi & 0\\ 0 & -\frac{1}{\lambda} & \frac{2}{\lambda} & \xi\\ 0 & \frac{2}{\lambda} & -\frac{1}{\lambda} & -\xi\\ 0 & 0 & 0 & \frac{1}{\lambda}\end{pmatrix}, \tag{2.2}$$

here $\lambda\in\mathbb{C}$ is the spectral and $\xi\in\mathbb{C}$ is the twisting parameter. Definition of the Gaudin model requires not only the classical r-matrix but also the L operator

$$L(\lambda)=\begin{pmatrix} h(\lambda) & 2X^{-}(\lambda) \\ 2X^{+}(\lambda) & -h(\lambda) \end{pmatrix}, \tag{2.3}$$

whose entries $(h(\lambda),X^{\pm}(\lambda))$ are generators of the loop algebra $\mathcal{L}_{\xi}(\mathfrak{sl}_2)$ defined by the Sklyanin linear bracket

$$[L_1(\lambda),L_2(\mu)]=-[r_{12}(\lambda-\mu),L_1(\lambda)+L_2(\mu)]. \tag{2.4}$$

The corresponding commutation relations between the generators are explicitly given by

$$\begin{aligned}
&[h(\lambda),h(\mu)]=2\xi(X^{+}(\lambda)-X^{+}(\mu)),\\
&[X^{-}(\lambda),X^{-}(\mu)]=-\xi(X^{-}(\lambda)-X^{-}(\mu)),\\
&[X^{+}(\lambda),X^{-}(\mu)]=-\frac{h(\lambda)-h(\mu)}{\lambda-\mu}+\xi X^{+}(\lambda),\\
&[X^{+}(\lambda),X^{+}(\mu)]=0,\\
&[h(\lambda),X^{-}(\mu)]=2\frac{X^{-}(\lambda)-X^{-}(\mu)}{\lambda-\mu}+\xi h(\mu),\\
&[h(\lambda),X^{+}(\mu)]=-2\frac{X^{+}(\lambda)-X^{+}(\mu)}{\lambda-\mu}.
\end{aligned} \tag{2.5}$$

The usual $\mathfrak{sl}_2$ loop algebra is recovered be setting $\xi=0$.

In order to define a dynamical system besides the algebra of observables $\mathcal{L}_{\xi}(\mathfrak{sl}_2)$ a Hamiltonian should be specified. Due to the Sklyanin linear bracket (2.4) the elements

$$t(\lambda)=\tfrac{1}{2}\mathrm{Tr}\,L^2(\lambda)=h^2(\lambda)+2(X^{+}(\lambda)X^{-}(\lambda)+X^{-}(\lambda)X^{+}(\lambda))=h^2(\lambda)-2h'(\lambda)+2(2X^{-}(\lambda)+\xi)X^{+}(\lambda) \tag{2.6}$$

generate an Abelian subalgebra

$$t(\lambda)t(\mu)=t(\mu)t(\lambda). \tag{2.7}$$

One way to show (2.7) is to notice that the commutation relation between $t(\lambda)$ and $L(\mu)$ can be written in the form

$$[t(\lambda),L(\mu)]=[M(\lambda,\mu),L(\mu)], \tag{2.8}$$

using (2.4)–(2.6) it is straightforward to calculate $M(\lambda,\mu)$,

$$\begin{aligned}
M(\lambda,\mu)&=-\mathrm{Tr}_1(r_{12}(\lambda-\mu)L_1(\lambda))-\frac{1}{2}\mathrm{Tr}_1(r_{12}^2(\lambda-\mu))\\
&=\begin{pmatrix} -2\dfrac{h(\lambda)}{\lambda-\mu}+2\xi X^{+}(\lambda) & -4\dfrac{X^{-}(\lambda)}{\lambda-\mu}-2\xi h(\lambda) \\ -4\dfrac{X^{+}(\lambda)}{\lambda-\mu} & 2\dfrac{h(\lambda)}{\lambda-\mu}-2\xi X^{+}(\lambda) \end{pmatrix}-\frac{3}{(\lambda-\mu)^2}I_2.
\end{aligned} \tag{2.9}$$

Thus the commutators between the generating function $t(\lambda)$ and the generators of the loop algebra follow from (2.8) and (2.9):

$$[t(\lambda),X^+(\mu)]=4\frac{X^+(\mu)h(\lambda)-X^+(\lambda)h(\mu)}{\lambda-\mu}-4\xi X^+(\lambda)X^+(\mu), \tag{2.10}$$

$$[t(\lambda),h(\mu)]=8\frac{X^-(\mu)X^+(\lambda)-X^-(\lambda)X^+(\mu)}{\lambda-\mu}-4\xi h(\lambda)X^+(\mu), \tag{2.11}$$

$$[t(\lambda),X^-(\mu)]=4\frac{X^-(\lambda)h(\mu)-X^-(\mu)h(\lambda)}{\lambda-\mu}+2\xi h(\lambda)h(\mu)+4\xi X^-(\mu)X^+(\lambda)+2\xi^2X^+(\mu). \tag{2.12}$$

Preserving some generality, the representation space $\mathcal{H}$ of the Sklyanin algebra (2.4) and (2.5) can be a highest spin $\rho(\lambda)$ representation with the highest spin vector Ω_+,

$$X^+(\lambda)\Omega_+=0,\quad h(\lambda)\Omega_+=\rho(\lambda)\Omega_+. \tag{2.13}$$

The spectrum and the eigenstates of $t(\lambda)$ can be studied in this general setting. However to have a physical interpretation a local realization

$$\mathcal{H}=V_1\otimes\cdots\otimes V_N \tag{2.14}$$

as tensor product of $\mathfrak{sl}_2$-modules is needed. Then the L operator is given by

$$L(\lambda)=\sum_{a=1}^{N}\left(\frac{1}{\lambda-z_a}\begin{pmatrix}h_a & 2X_a^-\\ 2X_a^+ & -h_a\end{pmatrix}+\xi\begin{pmatrix}X_a^+ & -h_a\\ 0 & -X_a^+\end{pmatrix}\right), \tag{2.15}$$

where $Y_a=(h_a,X_a^\pm)\in\mathrm{End}(V_a)$ are $\mathfrak{sl}_2$ generators in representation V_a, associated with each site a. For convenience, the generators $Y(\lambda)=(h(\lambda),X^\pm(\lambda))$ are written down explicitly,

$$h(\lambda)=\sum_{a=1}^{N}\left(\frac{h_a}{\lambda-z_a}+\xi X_a^+\right),\quad X^-(\lambda)=\sum_{a=1}^{N}\left(\frac{X_a^-}{\lambda-z_a}-\frac{\xi}{2}h_a\right),\quad X^+(\lambda)=\sum_{a=1}^{N}\frac{X_a^+}{\lambda-z_a}. \tag{2.16}$$

In this realization it is useful to consider the expressions of the generators of the global $\mathfrak{sl}_2$ Lie algebra in terms of the local ones,

$$Y_{\mathrm{gl}}=\sum_{a=1}^{N}Y_a, \tag{2.17}$$

where $Y=(h,X^\pm)$. Also, the following notation is useful:

$$Y(\lambda)_0=\left.Y(\lambda)\right|_{\xi=0}, \tag{2.18}$$

then $h(\lambda)=h(\lambda)_0+\xi X_{\mathrm{gl}}^+$.

A representation of the model with the above Gaudin realization is obtained by considering at each site a an irreducible representation $V_a^{(\ell_a)}$ of $\mathfrak{sl}_2$ with highest weight ℓ_a corresponding to a singular vector $\omega_a\in V_a^{(\ell_a)}$ such that $X_a^+\omega_a=0$ and $h_a\omega_a=\ell_a\omega_a$. Thus the space of states is

$$\mathcal{H}=V_1^{(\ell_1)}\otimes\cdots\otimes V_N^{(\ell_N)}, \tag{2.19}$$

with the highest spin vector (2.13),

$$\Omega_+=\omega_1\otimes\cdots\otimes\omega_N \tag{2.20}$$

and the corresponding highest spin

$$\rho(\lambda)=\sum_{a=1}^{N}\frac{\ell_a}{\lambda-z_a}. \tag{2.21}$$

The Gaudin Hamiltonians,

$$H^{(a)}=\sum_{b\neq a}^{N} r_{ab}(z_a-z_b)=\sum_{b\neq a}^{N}\left(\frac{c_2^{\otimes}(a,b)}{z_a-z_b}+\xi(h_aX_b^{+}-X_a^{+}h_b)\right), \tag{2.22}$$

where $c_2^{\otimes}(a,b)=h_a\otimes h_b+2(X_a^{+}\otimes X_b^{-}+X_a^{-}\otimes X_b^{+})$, can be obtained as the residues of the generating function $t(\lambda)$ at the points $\lambda=z_a$, $a=1,\ldots,N$ using the expansion

$$t(\lambda)=\sum_{a=1}^{N}\left(\frac{c_2(a)}{(\lambda-z_a)^2}+\frac{2H^{(a)}}{\lambda-z_a}\right)+\xi^2\sum_{a,b=1}^{N}X_a^{+}X_b^{+}, \tag{2.23}$$

here $c_2(a)=h_a^2+2h_a+4X_a^{-}X_a^{+}$ is the $\mathfrak{sl}_2$ Casimir at site a. As opposed to the $\mathfrak{sl}_2$-invariant case, the generating function (2.23) commutes only with the generator X_{gl}^{+}.

The first step in the algebraic Bethe Ansatz is to define appropriate creation operators that yield the Bethe states and consequently the spectrum of the generating function $t(\lambda)$. The creation operators used in the $\mathfrak{sl}_2$-invariant Gaudin model coincide with one of the L-matrix entries.[5,7] However, in the present case these operators are not homogeneous polynomials of the generator $X^{-}(\lambda)$. It is convenient to define a more general set of operators in order to simplify the presentation.

Definition 2.1: Given two integers M and $k\geqslant 0$ consider the operators

$$\begin{aligned}B_M^{(k)}(\mu_1,\ldots,\mu_M)&=(X^{-}(\mu_1)+k\xi)(X^{-}(\mu_2)+(k+1)\xi)\cdots(X^{-}(\mu_M)+(M+k-1)\xi)\\&=\prod_{n=k}^{M+k-1}{}^{\rightarrow}(X^{-}(\mu_{n-k+1})+n\xi),\end{aligned} \tag{2.24}$$

with $B_0^{(k)}=1$ and $B_M^{(k)}=0$ for $M<0$.

The following lemma describes some properties of the $B_M^{(k)}(\mu_1,\ldots,\mu_M)$ operators which will be used later on.

Lemma 2.1: Some useful properties of $B_M^{(k)}(\mu_1,\ldots,\mu_M)$ operators are the following:

(i) *The operators $B_M^{(k)}(\mu_1,\ldots,\mu_M)$ are symmetric functions of their arguments.*

(ii) $B_M^{(k)}(\mu_1,\ldots,\mu_M)=B_{M-1}^{(k)}(\mu_1,\ldots,\mu_{M-1})(B_1^{(0)}(\mu_M)+(M+k-1)\xi)$.

(iii) $B_M^{(k)}(\boldsymbol{\mu})=B_M^{(k-1)}(\boldsymbol{\mu})+\xi\sum_{i=1}^{M}B_{M-1}^{(k)}(\boldsymbol{\mu}^{(i)})$, *here $\boldsymbol{\mu}$ is a set of $M=|\boldsymbol{\mu}|$ complex scalars with a particular ordering $\boldsymbol{\mu}=\{\mu_1,\ldots,\mu_M\}$ assumed for convenience and the notation*

$$\boldsymbol{\mu}^{(i_1,\ldots,i_k)}=\boldsymbol{\mu}\setminus\{\mu_{i_1},\ldots,\mu_{i_k}\}$$

for any distinct $i_1,\ldots,i_k\in\{1,\ldots,M\}$.

(iv) $B_M^{(k)}(\boldsymbol{\mu})=B_1^{(k)}(\mu_1)B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(1)})$.

Implementation of the algebraic Bethe Ansatz requires the commutation relations between the generators of the loop algebra $\mathcal{L}_{\xi}(\mathfrak{sl}_2)$ and the $B_M^{(k)}(\mu_1,\ldots,\mu_M)$ operators. To this end we first introduce the notation for the Bethe operators

$$\hat{\beta}_M(\lambda;\boldsymbol{\mu})=h(\lambda)+\sum_{\mu\in\boldsymbol{\mu}}\frac{2}{\mu-\lambda}, \tag{2.25}$$

where $\boldsymbol{\mu}=\{\mu_1,\ldots,\mu_{M-1}\}$ and $\lambda\in\mathbb{C}\setminus\boldsymbol{\mu}$. In the particular case $M=1$, $\hat{\beta}_1(\lambda;\varnothing)=h(\lambda)$ and will be denoted by $\hat{\beta}_1(\lambda)$. The required commutators are given in the following lemma.

Lemma 2.2: The commutation relation between the generators $h(\lambda)$, $X^{\pm}(\lambda)$, *and the* $B_M^{(k)}(\mu_1,\ldots,\mu_M)$ *operators are given by*

$$h(\lambda)B_M^{(k)}(\boldsymbol{\mu}) = B_M^{(k)}(\boldsymbol{\mu})h(\lambda) + 2\sum_{i=1}^{M}\frac{B_M^{(k)}(\lambda\cup\boldsymbol{\mu}^{(i)}) - B_M^{(k)}(\boldsymbol{\mu})}{\lambda-\mu_i} + \xi\sum_{i=1}^{M} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)}), \tag{2.26}$$

$$X^{+}(\lambda)B_M^{(k)}(\boldsymbol{\mu}) = B_M^{(k)}(\boldsymbol{\mu})X^{+}(\lambda) - \sum_{i=1}^{M} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})\frac{\hat{\beta}_M(\lambda;\boldsymbol{\mu}^{(i)}) - \hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i} - 2\sum_{\substack{i,j=1\\ i<j}}^{M}\frac{B_{M-1}^{(k+1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)}$$
$$+ \xi\sum_{i=1}^{M} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})X^{+}(\lambda), \tag{2.27}$$

$$X^{-}(\lambda)B_M^{(k)}(\boldsymbol{\mu}) = B_M^{(k)}(\boldsymbol{\mu})(X^{-}(\lambda)+M\xi) - \xi\sum_{i=1}^{M} B_M^{(k)}(\lambda\cup\boldsymbol{\mu}^{(i)}) = B_{M+1}^{(k)}(\lambda\cup\boldsymbol{\mu}) - \xi\sum_{i=1}^{M} B_M^{(k)}(\lambda\cup\boldsymbol{\mu}^{(i)}). \tag{2.28}$$

The B operators that define the Bethe states of the system were proposed by Kulish.[12] These operators are the particular case $k=0$ of (2.24) and will be denoted by $B_M(\mu_1,\ldots,\mu_M)=B_M^{(0)}(\mu_1,\ldots,\mu_M)$. A recursive relation of the B operators follows from (ii) of Lemma 2.1,

$$B_M(\boldsymbol{\mu}) = B_{M-1}(\boldsymbol{\mu}^{(M)})(X^{-}(\mu_M)+(M-1)\xi). \tag{2.29}$$

It may be useful to write down explicitly the first few B operators,

$$B_0 = 1, \quad B_1(\mu) = X^{-}(\mu), \quad B_2(\mu_1,\mu_2) = X^{-}(\mu_1)X^{-}(\mu_2) + \xi X^{-}(\mu_1),$$

$$B_3(\mu_1,\mu_2,\mu_3) = X^{-}(\mu_1)X^{-}(\mu_2)X^{-}(\mu_3) + 2\xi X^{-}(\mu_1)X^{-}(\mu_2) + \xi X^{-}(\mu_1)X^{-}(\mu_3) + 2\xi^2 X^{-}(\mu_1).$$

As a particular case of Lemma 2.2 the commutation relation between loop algebra generators $h(\lambda)$, $X^{\pm}(\lambda)$ and the B operators are given by setting $k=0$ in (2.26)–(2.28),

$$h(\lambda)B_M(\boldsymbol{\mu}) = B_M(\boldsymbol{\mu})h(\lambda) + \sum_{i=1}^{M}\left(2\frac{B_M(\lambda\cup\boldsymbol{\mu}^{(i)}) - B_M(\boldsymbol{\mu})}{\lambda-\mu_i} + \xi B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})\right), \tag{2.30}$$

$$X^{+}(\lambda)B_M(\boldsymbol{\mu}) = B_M(\boldsymbol{\mu})X^{+}(\lambda) - \sum_{i=1}^{M} B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})\left(\frac{\hat{\beta}_M(\lambda;\boldsymbol{\mu}^{(i)}) - \hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i} - \xi X^{+}(\lambda)\right)$$
$$- 2\sum_{\substack{i,j=1\\ i<j}}^{M}\frac{B_{M-1}^{(1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)}, \tag{2.31}$$

$$X^{-}(\lambda)B_M(\boldsymbol{\mu}) = B_M(\boldsymbol{\mu})(X^{-}(\lambda)+M\xi) - \xi\sum_{i=1}^{M} B_M(\lambda\cup\boldsymbol{\mu}^{(i)}). \tag{2.32}$$

The crucial step in the algebraic Bethe Ansatz is to determine the commutation relations between the creation operators, in this case the B operators, and the generating function $t(\lambda)$. The main lemma, based on the results established previously in this section, will given a complete expression for the required commutator.

Lemma 2.3: The generating function $t(\lambda)$ has the following commutation relation with the B operators:

$$
\begin{aligned}
t(\lambda)B_M(\boldsymbol{\mu}) = B_M(\boldsymbol{\mu})&\left(t(\lambda) - \sum_{i=1}^{M}\frac{4h(\lambda)}{\lambda-\mu_i} + \sum_{i<j}^{M}\frac{8}{(\lambda-\mu_i)(\lambda-\mu_j)}\right) + 4\sum_{i=1}^{M}\frac{B_M(\lambda\cup\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})\\
&+ 2\xi\sum_{i=1}^{M}B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})h(\lambda)\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)}) + 4\xi\sum_{\substack{i,j=1\\ i\neq j}}^{M}\frac{B_{M-1}^{(1)}(\lambda\cup\boldsymbol{\mu}^{(i,j)}) - B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})}{\lambda-\mu_j}\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})\\
&+ \xi^2\sum_{\substack{i,j=1\\ i\neq j}}^{M}B_{M-2}^{(2)}(\boldsymbol{\mu}^{(i,j)})\hat{\beta}_{M-1}(\mu_j;\boldsymbol{\mu}^{(i,j)})\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)}) + 4M\xi B_M(\boldsymbol{\mu})X^{+}(\lambda)\\
&+ 2\xi^2\sum_{i=1}^{M}B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})X^{+}(\mu_i).
\end{aligned}
\tag{2.33}
$$

Proof: The case $M=1$ can be obtained directly from the M matrix (2.9) and is given by (2.12). For $M>1$ the commutator between the operator $t(\lambda)$ and the corresponding B operator is to be calculated directly using expression (2.6),

$$
\begin{aligned}
[t(\lambda),B_M(\boldsymbol{\mu})] = [h(\lambda),[h(\lambda),B_M(\boldsymbol{\mu})]] &+ 2[h(\lambda),B_M(\boldsymbol{\mu})]h(\lambda) - 2\frac{d}{d\lambda}[h(\lambda),B_M(\boldsymbol{\mu})]\\
&+ 2(2X^{-}(\lambda)+\xi)[X^{+}(\lambda),B_M(\boldsymbol{\mu})] + 4[X^{-}(\lambda),B_M(\boldsymbol{\mu})]X^{+}(\lambda).
\end{aligned}
$$

The terms in the preceding expression only involve the commutators between the generators of the loop algebra and the B operators. Each term in the above equation will be calculated separately. Using the commutators (2.26) and (2.30)–(2.32) the first term is given by

$$
\begin{aligned}
[h(\lambda),[h(\lambda),B_M(\boldsymbol{\mu})]] = B_M(\boldsymbol{\mu})&\sum_{i<j}^{M}\frac{8}{(\lambda-\mu_i)(\lambda-\mu_j)}\\
&- 4\sum_{i=1}^{M}\left(\frac{B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)}) - B_M(\boldsymbol{\mu})}{(\lambda-\mu_i)^2} - \frac{\frac{d}{d\lambda}B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}\right)\\
&+ 8\sum_{i<j}^{M}\frac{X^{-}(\lambda)B_{M-1}^{(1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)} - 4\sum_{i=1}^{M}\frac{B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}\sum_{j\neq i}^{M}\frac{2}{\lambda-\mu_j}\\
&+ 4\xi\sum_{i<j}^{M}\frac{B_{M-1}^{(1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)} + 2\xi\sum_{i=1}^{M}B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})\frac{\hat{\beta}_M(\lambda;\boldsymbol{\mu}^{(i)}) - \hat{\beta}_M(\mu_i\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}\\
&+ \xi\sum_{i\neq j}^{M}\left(4\frac{B_{M-1}^{(1)}(\lambda\cup\boldsymbol{\mu}^{(i,j)}) - B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})}{\lambda-\mu_j} + \xi B_{M-2}^{(2)}(\boldsymbol{\mu}^{(i,j)})\hat{\beta}_{M-1}(\mu_j;\boldsymbol{\mu}^{(i,j)})\right)\\
&\times\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)}) + 2\xi^2\sum_{i=1}^{M}B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})(X^{+}(\lambda)-X^{+}(\mu_i)).
\end{aligned}
$$

The commutator between the generator $h(\lambda)$ and $B_M(\boldsymbol{\mu})$ is also used to determine the next two terms

$$2[h(\lambda),B_M(\boldsymbol{\mu})]h(\lambda)=B_M(\boldsymbol{\mu})\sum_{i=1}^{M}\frac{-4h(\lambda)}{\lambda-\mu_i}+4\sum_{i=1}^{M}\frac{B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}h(\lambda)+2\xi\sum_{i=1}^{M}B_{M-1}^{(1)}$$
$$\times(\boldsymbol{\mu}^{(i)})h(\lambda)\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})-4\xi^2\sum_{i=1}^{M}B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})(X^+(\lambda)-X^+(\mu_i)),$$

and after differentiating (2.30),

$$-2\frac{d}{d\lambda}[h(\lambda),B_M(\boldsymbol{\mu})]=4\sum_{i=1}^{M}\frac{B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})-B_M(\boldsymbol{\mu})}{(\lambda-\mu_i)^2}-\frac{\frac{d}{d\lambda}B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}.$$

The next term follows directly from (2.31),

$$2(2X^-(\lambda)+\xi)[X^+(\lambda),B_M(\boldsymbol{\mu})]=-4\sum_{i=1}^{M}B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})\frac{\hat{\beta}_M(\lambda;\boldsymbol{\mu}^{(i)})-\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}$$
$$-8\sum_{i<j}^{M}\frac{X^-(\lambda)B_{M-1}^{(1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)}-2\xi\sum_{i=1}^{M}B_{M-1}^{(1)}$$
$$\times(\boldsymbol{\mu}^{(i)})\frac{\hat{\beta}_M(\lambda;\boldsymbol{\mu}^{(i)})-\hat{\beta}_M(\mu_i;\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}-4\xi\sum_{i<j}^{M}\frac{B_{M-1}^{(1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)}$$
$$+4\xi\sum_{i=1}^{M}B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})X^+(\lambda)+2\xi^2\sum_{i=1}^{M}B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})X^+(\lambda).$$

The last term is obtained from (2.32),

$$4[X^-(\lambda),B_M(\boldsymbol{\mu})]X^+(\lambda)=4M\xi B_M(\boldsymbol{\mu})X^+(\lambda)-4\xi\sum_{i=1}^{M}B_M(\{\lambda\}\cup\boldsymbol{\mu}^{(i)})X^+(\lambda).$$

When all terms in $[t(\lambda),B_M(\boldsymbol{\mu})]$ are put together it is straightforward to obtain the formula (2.33) □

Besides the problem of determining the spectrum of the system, via algebraic Bethe Ansatz, some properties of the B operators are fundamental in calculating the inner products and the norms of the Bethe states. To this end the relation between the B operators and the untwisted ones is established using the Gaudin realization (2.16),

$$B_M(\boldsymbol{\mu})=\sum_{k=0}^{M-1}\xi^k\sum_{j_1<\cdots<j_{M-k}}^{M}B_{M-k}(\mu_{j_1},\ldots,\mu_{j_{M-k}})_0\hat{p}_k^{(M-k)}+\xi^M\hat{p}_M,\tag{2.34}$$

where

$$B_{M-k}(\mu_{j_1},\ldots,\mu_{j_{M-k}})_0=B_{M-k}(\mu_{j_1},\ldots,\mu_{j_{M-k}})|_{\xi=0}$$

and also

$$\hat{p}_i^{(j)}=\left(-\frac{h_{\mathrm{gl}}}{2}+j\right)\cdots\left(-\frac{h_{\mathrm{gl}}}{2}+i+j-1\right)\quad\text{with }\hat{p}_i=\hat{p}_i^{(0)}\tag{2.35}$$

are operators defined for any integers i and j.

Moreover, some analytical properties of the B operators are important when solving the corresponding Knizhnik-Zamolodchikov equation.

Lemma 2.4: The B operators satisfy the following identity:

$$\frac{\partial}{\partial z_a} B_M(\boldsymbol{\mu}) = -\sum_{i=1}^{M} \frac{\partial}{\partial \mu_i} (X_a^-(\mu_i) B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})), \tag{2.36}$$

where $X_a^-(\mu_i) = [X_a^-/(\mu_i - z_a)] - (\xi/2)h_a$ *for site* $a = 1, \ldots, N$.

Using the relevant properties of the B operators established in this section, the fundamental description of the $\mathfrak{sl}_2$ Gaudin model with jordanian twist can be obtained.

III. SPECTRUM AND BETHE VECTORS OF THE TWISTED $_2$ GAUDIN MODEL

In this section the spectrum and the Bethe vectors of the twisted $\mathfrak{sl}_2$ Gaudin model as well as their inner products and norms will be determined by applying the algebraic Bethe Ansatz. The first step is to define the Bethe vectors $\Psi_M(\boldsymbol{\mu}) = B_M(\boldsymbol{\mu})\Omega_+$ by the action of the B operators on the highest spin vector Ω_+. Then the key observation is that highest spin vector Ω_+ is an eigenvector of the generating function of integrals of motion $t(\lambda)$. Finally the spectrum of the system is obtained as a consequence of the commutation relations between $t(\lambda)$ and $B_M(\boldsymbol{\mu})$ Lemma 2.3 (2.33). The unwanted terms coming from the commutator are annihilated by the Bethe equations on the parameters $\boldsymbol{\mu} = \{\mu_1, \ldots, \mu_M\}$ as well as by the condition $X^+(\lambda)\Omega_+ = 0$. Hence the algebraic Bethe Ansatz can be resumed in the following theorem.

Theorem 3.1: *The highest weight vector* Ω_+ *is an eigenvector of* $t(\lambda)$,

$$t(\lambda)\Omega_+ = \Lambda_0(\lambda)\Omega_+ \tag{3.1}$$

with the corresponding eigenvalue,

$$\Lambda_0(\lambda) = \rho^2(\lambda) - 2\rho'(\lambda) = \sum_{a=1}^{N} \frac{2}{\lambda - z_a} \left(\sum_{b \neq a}^{N} \frac{\ell_a \ell_b}{z_a - z_b} \right) + \sum_{a=1}^{N} \frac{\ell_a(\ell_a + 2)}{(\lambda - z_a)^2}. \tag{3.2}$$

Furthermore, the action of the B operators on the highest spin vector Ω_+ *yields the Bethe vectors*,

$$\Psi_M(\boldsymbol{\mu}) = B_M(\boldsymbol{\mu})\Omega_+, \tag{3.3}$$

such that

$$t(\lambda)\Psi_M(\boldsymbol{\mu}) = \Lambda_M(\lambda; \boldsymbol{\mu})\Psi_M(\boldsymbol{\mu}), \tag{3.4}$$

with the eigenvalues

$$\Lambda_M(\lambda; \boldsymbol{\mu}) = \rho_M^2(\lambda; \boldsymbol{\mu}) - 2\frac{\partial \rho_M}{\partial \lambda}(\lambda; \boldsymbol{\mu}) \quad \textit{and} \quad \rho_M(\lambda; \boldsymbol{\mu}) = \rho(\lambda) - \sum_{i=1}^{M} \frac{2}{\lambda - \mu_i}, \tag{3.5}$$

provided that the Bethe equations are imposed on the parameters $\boldsymbol{\mu} = \{\mu_1, \ldots, \mu_M\}$,

$$\sum_{a=1}^{N} \frac{\ell_a}{\mu_i - z_a} - \sum_{j \neq i}^{M} \frac{2}{\mu_i - \mu_j} = 0, \quad i = 1, \ldots, M. \tag{3.6}$$

Proof: A consequence of (2.6), (2.13), (2.20), and (2.21) is

$$t(\lambda)\Omega_+ = (h^2(\lambda) - 2h'(\lambda))\Omega_+ = (\rho^2(\lambda) - 2\rho'(\lambda))\Omega_+ = \Lambda_0(\lambda)\Omega_+.$$

The action of $t(\lambda)$ on the Bethe vectors $\Psi_M(\boldsymbol{\mu})$ (3.3) is evident from Lemma 2.3,

$$
\begin{aligned}
t(\lambda)\Psi_M(\boldsymbol{\mu}) &= t(\lambda)B_M(\boldsymbol{\mu})\Omega_+ = \Lambda_0(\lambda)\Psi_M(\boldsymbol{\mu}) + [t(\lambda), B_M(\boldsymbol{\mu})]\Omega_+ \\
&= \left(\Lambda_0(\lambda) - \sum_{i=1}^{M}\frac{4\rho(\lambda)}{\lambda-\mu_i} + \sum_{i<j}^{M}\frac{8}{(\lambda-\mu_i)(\lambda-\mu_j)}\right)\Psi_M(\boldsymbol{\mu}) \\
&\quad + 4\sum_{i=1}^{M}\frac{\Psi_M(\lambda\cup\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}\rho_M(\mu_i;\boldsymbol{\mu}^{(i)}) + 2\xi\sum_{i=1}^{M}\left(\rho(\lambda)\Psi^{(1)}_{M-1}(\boldsymbol{\mu}^{(i)})\right. \\
&\quad \left. + 2\sum_{i\neq j}^{M}\frac{\Psi^{(1)}_{M-1}(\lambda\cup\boldsymbol{\mu}^{(i,j)}) - \Psi^{(1)}_{M-1}(\boldsymbol{\mu}^{(i)})}{\lambda-\mu_j}\right)\rho_M(\mu_i;\boldsymbol{\mu}^{(i)}) \\
&\quad + \xi^2\sum_{i=1}^{M}\left(\sum_{j\neq i}^{M}\rho_{M-1}(\mu_j;\boldsymbol{\mu}^{(i,j)})\Psi^{(2)}_{M-2}(\boldsymbol{\mu}^{(i,j)})\right)\rho_M(\mu_i;\boldsymbol{\mu}^{(i)}),
\end{aligned}
\tag{3.7}
$$

where $\Psi^{(k)}_M(\boldsymbol{\mu}) = B^{(k)}_M(\boldsymbol{\mu})\Omega_+$ and $X^+(\lambda)\Omega_+ = 0$. When the Bethe equations are imposed on the parameters $\boldsymbol{\mu} = \{\mu_1, \ldots, \mu_M\}$,

$$
\rho_M(\mu_i;\boldsymbol{\mu}^{(i)}) = \sum_{a=1}^{N}\frac{\ell_a}{\mu_i - z_a} - \sum_{j\neq i}^{M}\frac{2}{\mu_i-\mu_j} = 0, \quad i = 1, \ldots, M, \tag{3.8}
$$

the unwanted terms in (3.7) vanish and hence $t(\lambda)\Psi_M(\boldsymbol{\mu}) = \Lambda_M(\boldsymbol{\Lambda};\boldsymbol{\mu})\Psi_M(\boldsymbol{\mu})$ with

$$
\Lambda_M(\lambda;\boldsymbol{\mu}) = \Lambda_0(\lambda) - \sum_{i=1}^{M}\frac{4\rho(\lambda)}{\lambda-\mu_i} + \sum_{i<j}^{M}\frac{8}{(\lambda-\mu_i)(\lambda-\mu_j)} = \rho^2_M(\lambda;\boldsymbol{\mu}) - 2\frac{\partial\rho_M}{\partial\lambda}(\lambda;\boldsymbol{\mu}). \tag{3.9}
$$

□

Due to the pole expansion (2.23) of $t(\lambda)$ the previous theorem yields the spectrum of the Gaudin Hamiltonians.

Corollary 3.1: The Bethe vectors $\Psi_M(\boldsymbol{\mu})$ are eigenvectors of the Gaudin Hamiltonians (2.22),

$$
H^{(a)}\Psi_M(\boldsymbol{\mu}) = E^{(a)}_M\Psi_M(\boldsymbol{\mu}) \tag{3.10}
$$

with the eigenvalues

$$
E^{(a)}_M = \sum_{b\neq a}^{N}\frac{\ell_a\ell_b}{z_a - z_b} - \sum_{i=1}^{M}\frac{2\ell_a}{z_a-\mu_i}. \tag{3.11}
$$

Remark 3.1: The fact that the spectrum of the $\mathfrak{sl}_2$-invariant Gaudin model remains is not affected by the jordanian twist can also be deduced from the following expression:

$$
t(\lambda) = t(\lambda)_0 + 2\xi(h(\lambda)_0X^+_{\mathrm{gl}} + 2\hat{p}^{(1)}_1X^+(\lambda)) + \xi^2(X^+_{\mathrm{gl}})^2. \tag{3.12}
$$

Remark 3.2: From the Gaudin realization (2.16) follows that $\xi X^+_{\mathrm{gl}} = \lim_{\lambda\to\infty} h(\lambda)$ and together with (2.30) is straightforward to obtain the action of the global generator X^+_{gl} on the Bethe vectors

$$
X^+_{\mathrm{gl}}\Psi_M(\boldsymbol{\mu}) = \sum_{i=1}^{M}\beta_M(\mu_i;\boldsymbol{\mu}^{(i)})\Psi^{(1)}_{M-1}(\boldsymbol{\mu}^{(i)}). \tag{3.13}
$$

Thus the Bethe vectors are annihilated by the global generator X^+_{gl},

$$
X^+_{\mathrm{gl}}\Psi_M(\boldsymbol{\mu}) = 0 \tag{3.14}
$$

once the Bethe equations (3.5) are imposed.

Remark 3.3: Analogously from (2.16) follows that $-(\xi/2)h_{\mathrm{gl}} = \lim_{\lambda\to\infty} X^-(\lambda)$ and with (2.32) and (ii) of Lemma 2.1 shows that Bethe vectors are not eigenstates of the global generator h_{gl},

$$h_{\mathrm{gl}}\Psi_M(\boldsymbol{\mu}) = -2p_1^{(M)}\Psi_M(\boldsymbol{\mu}) + 2\xi p_1^{(M-1)}\sum_{i=1}^{M}\Psi_{M-1}(\boldsymbol{\mu}^{(i)}), \tag{3.15}$$

where $p=-\frac{1}{2}\sum_{a=1}^{N}\ell_a$ *and* $p_l^{(k)}=(p+k)_l=(p+k)\cdots(p+l+k-1)$ *is the Pochhammer symbol.*

As it was shown already, the jordanian twist of the $\mathfrak{sl}_2$-invariant Gaudin model preserves its spectrum but the Bethe vectors are different, thus their inner products and norms are changed also. In order to determine the inner products and norms of the Bethe vectors it is of interest to consider the dual B operators, obtained by using the dual

$$(X^-)^*(\lambda) = \sum_{a=1}^{N}\left(\frac{X_a^+}{\lambda - z_a} - \frac{\xi}{2}h_a\right), \tag{3.16}$$

explicitly given by

$$B_M^*(\lambda_1, \ldots, \lambda_M) = \prod_{\substack{k=1\\ \leftarrow}}^{M}((X^-)^*(\lambda_k) + (k-1)\xi). \tag{3.17}$$

As opposed to the $\mathfrak{sl}_2$-invariant case here evidently the dual B operators do not annihilate the highest spin vector Ω_+,

$$B_M^*(\boldsymbol{\mu})\Omega_+ = \xi^M p_M \Omega_+. \tag{3.18}$$

Moreover the Bethe vectors are not orthogonal and their norms depend on the twist parameter.

Lemma 3.1: Consider integers $M_1, M_2 \geqslant 0$, $M=\min\{M_1, M_2\}$ *and complex numbers* $\boldsymbol{\lambda}=\{\lambda_1, \ldots, \lambda_{M_1}\}$ *and* $\boldsymbol{\mu}=\{\mu_1, \ldots, \mu_{M_2}\}$ *such that* $\boldsymbol{\lambda}\cap\boldsymbol{\mu}=\emptyset$. *Then the inner products between Bethe vectors is given by*

$$\begin{aligned}\langle\Psi_{M_1}(\boldsymbol{\lambda})|\Psi_{M_2}(\boldsymbol{\mu})\rangle &= p_{M_1}p_{M_2}\xi^{M_1+M_2} + \sum_{k=1}^{M} p_{M_1-k}^{(k)}p_{M_2-k}^{(k)}\xi^{M_1+M_2-2k}\\ &\times \sum_{i_1<\cdots<i_k}^{M_1}\ \sum_{j_1<\cdots<j_k}^{M_2}\langle\Psi_k(\lambda_{i_1}, \ldots, \lambda_{i_k})|\Psi_k(\mu_{j_1}, \ldots, \mu_{j_k})\rangle_0,\end{aligned} \tag{3.19}$$

where $\langle\cdot|\cdot\rangle_0=\langle\cdot|\cdot\rangle|_{\xi=0}$ *denotes the corresponding inner product of the* $\mathfrak{sl}_2$*-invariant Gaudin model.*[8]

Proof: The Bethe vectors are obtained from the action of the B operators (2.34) on Ω_+,

$$\Psi_M(\boldsymbol{\mu}) = B_M(\boldsymbol{\mu})\Omega_+ = p_M\xi^M\Omega_+ + \sum_{k=0}^{M-1}p_k^{(M-k)}\xi^k\sum_{j_1<\cdots<j_{M-k}}^{M}\Psi_{M-k}(\mu_{j_1}, \ldots, \mu_{j_{M-k}})_0,$$

where $\Psi_M(\boldsymbol{\mu})_0=B_M(\boldsymbol{\mu})|_{\xi=0}\Omega_+$ are the corresponding Bethe vectors of the $\mathfrak{sl}_2$-invariant Gaudin model. Then the inner product of the Bethe vectors of the twisted model are

$$\begin{aligned}\langle\Psi_{M_1}(\boldsymbol{\lambda})|\Psi_{M_2}(\boldsymbol{\mu})\rangle &= p_{M_1}p_{M_2}\xi^{M_1+M_2} + \sum_{k=0}^{M_1-1}\sum_{l=0}^{M_2-1}p_k^{(M_1-k)}p_l^{(M_2-l)}\xi^{k+l}\\ &\times\sum_{i_1<\cdots<i_{M_1-k}}^{M_1}\ \sum_{j_1<\cdots<j_{M_2-l}}^{M_2}\langle\Psi_{M_1-k}(\lambda_{i_1}, \ldots, \lambda_{i_{M_1-k}})|\Psi_{M_2-l}(\mu_{j_1}, \ldots, \mu_{j_{M_2-l}})\rangle_0\\ &= p_{M_1}p_{M_2}\xi^{M_1+M_2} + \sum_{n=1}^{M-1}p_{M_1-n}^{(n)}p_{M_1-n}^{(n)}\xi^{M_1+M_2-2n}\end{aligned}$$

$$\times \sum_{i_1<\cdots<i_n}^{M_1} \sum_{j_1<\cdots<j_n}^{M_2} \langle \Psi_n(\lambda_{i_1}, \ldots, \lambda_{i_n}) | \Psi_n(\mu_{j_1}, \ldots, \mu_{j_n}) \rangle_0.$$

□

The norms of the Bethe vector follow from the previous lemma.

Corollary 3.2: The norms of Bethe vectors $\Psi_M(\boldsymbol{\mu})$ are given by

$$\|\Psi_M(\boldsymbol{\mu})\|^2 = \sum_{k=0}^{M} (p_{M-k}^{(k)})^2 \xi^{2(M-k)} \sum_{\substack{i_1<\cdots<i_k \\ j_1<\cdots<j_k}}^{M} \langle \Psi_k(\mu_{i_1}, \ldots, \mu_{i_k}) | \Psi_k(\mu_{j_1}, \ldots, \mu_{j_k}) \rangle_0. \tag{3.20}$$

IV. CONCLUSION

The Gaudin model based on the $\mathfrak{sl}_2$ classical r-matrix with jordanian twist is studied. This system can be obtained as the semiclassical limit of the *XXX* spin chain deformed by the jordanian twist. Alternatively, applying a certain similarity transformation on the XXZ Gaudin model and using the scaling limit, Kulish[12] was able to postulate the spectrum and the Bethe states of the system.

The result of Kulish[12] that the spectrum of the system coincides with the one of the $\mathfrak{sl}_2$-invariant model is demonstrated by full implementation of the algebraic Bethe Ansatz. In order to construct the Bethe vectors it is necessary to consider the creation operators which are not homogeneous polynomials of one of the generators of the corresponding loop algebra. However, it was convenient to consider a more general set of operators $B_M^{(k)}(\mu_1, \ldots, \mu_M)$, in order to simplify the calculation of the commutators between the creation operators and the generating function of the integrals of motion $t(\lambda)$. These operators are symmetric functions of their arguments and they satisfy certain recursive relations. Their commutation relations with the generators of the loop algebra are given and they are essential in the main step of the algebraic Bethe Ansatz. The creation operators are the particular case $B_M(\mu_1, \ldots, \mu_M) = B_M^{(0)}(\mu_1, \ldots, \mu_M)$. Thus the commutation relations between the creation operators and $t(\lambda)$ are easily calculated. The corresponding Bethe vectors are defined by the action of the creation operators on the highest spin vector Ω_+ and the spectrum of the system is determined. However, the Bethe vectors in this case, are not eigenstates of the global Cartan generator h_{gl}.

Some properties of the creation operators are fundamental in calculating the inner products and the norms of the Bethe states. It is necessary to consider the dual creation operators $B_M^*(\mu_1, \ldots, \mu_M)$ obtained by using the dual Gaudin model. The Bethe vectors $\Psi_M(\mu_1, \ldots, \mu_M)$ are not orthogonal for different M's. Moreover, contrary to the $\mathfrak{sl}_2$-invariant case, the generating function of integrals of motion is not Hermitian.

The well known relation[9,10] between the off-shell Bethe vectors of the Gaudin models related to simple Lie algebras and the solutions of Knizhnik-Zamolodchikov equation[23]

$$\kappa \frac{\partial}{\partial z_a} \psi(z_1, \ldots, z_N) = H^{(a)} \psi(z_1, \ldots, z_N), \tag{4.1}$$

where $H^{(a)}$ are the Gaudin Hamiltonians (1.1), also holds for the KZ equation related to the $\mathfrak{sl}_2$ classical r-matrix with the jordanian twist. This relation is obtained by considering a Bethe vector $\Psi(\vec{\mu}|\vec{z})$, where the corresponding Bethe equations are not imposed, and the integral representation of solutions to the Knizhnik-Zamolodchikov equation,

$$\psi(z_1, \ldots, z_N) = \oint \cdots \oint \phi(\vec{\mu}|\vec{z}) \Psi(\vec{\mu}|\vec{z}) \mathrm{d}\vec{\mu}, \tag{4.2}$$

where $\phi(\vec{\mu}|\vec{z})$ is a scalar function

$$\phi(\vec{\mu}|\vec{z}) = \prod_{i<j}^{M} (\mu_i - \mu_j)^{4/\kappa} \prod_{a<b}^{N} (z_a - z_b)^{\ell_a \ell_b/\kappa} \prod_{a=1}^{N} \prod_{k=1}^{M} (z_a - \mu_k)^{-2\ell_a/\kappa}. \tag{4.3}$$

The partial derivatives of the scalar factor (4.3) are simply written

$$\kappa \partial_{z_a}(\phi) = E_M^{(a)} \phi \quad \text{and} \quad \kappa \partial_{\mu_i}(\phi) = -2\rho_M(\mu_i; \boldsymbol{\mu}^{(i)})\phi. \tag{4.4}$$

It is a simple matter to check that ψ given by (4.2) satisfies (4.1). Due to the Leibniz rule $\partial_{z_a}(\phi\Psi) = \partial_{z_a}(\phi)\Psi + \phi\partial_{z_a}(\Psi)$ and the residue of (3.7) at $\lambda = z_a$,

$$H^{(a)}\Psi(\boldsymbol{\mu}) = E_M^{(a)}\Psi(\boldsymbol{\mu}) - 2\sum_{i=1}^{M} \Psi_M^{(i,a)}(\boldsymbol{\mu})\rho_M(\mu_i; \boldsymbol{\mu}^{(i)}), \tag{4.5}$$

where $\Psi_M^{(i,a)}(\boldsymbol{\mu}) = X_a^-(\mu_i) B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})\Omega_+$ and $X_a^-(\mu_i) = [X_a^-/(\mu_i - z_a)] - (\xi/2)h_a$, we have

$$\kappa\partial_{z_a}(\phi\Psi) = H^{(a)}(\phi\Psi) + 2\phi\sum_{i=1}^{M} \Psi_M^{(i,a)}(\boldsymbol{\mu})\rho_M(\mu_i; \boldsymbol{\mu}^{(i)}) + \kappa\phi\partial_{z_a}(\Psi) = H^{(a)}(\phi\Psi) - \kappa\sum_{i=1}^{M} \partial_{\mu_i}(\phi\Psi_M^{(i,a)}). \tag{4.6}$$

To obtain the final formula we have used the Lemma 2.4 and formulas (4.4). Moreover, a closed contour integration of $\phi\Psi$ with respect to $\mu_1, \ldots, \mu_M$ will cancel the contribution from the sum and therefore $\psi(z_1, \ldots, z_N)$ given by (4.2) will satisfy Knizhnik-Zamolodchikov equation.

APPENDIX: PROOFS OF LEMMAS

Proof of Lemma 2.1: The recurrence relations in (ii) and (iv) are evident from Definition 2.1.

(i) Given a fixed integer k, induction on M is used. Consider $M=2$ in definition (2.24),

$$B_2^{(k)}(\mu_1, \mu_2) = X^-(\mu_1)X^-(\mu_2) + (k+1)\xi X^-(\mu_1) + k\xi X^-(\mu_2) + k(k+1)\xi^2, \tag{A1}$$

then using (2.5) it is straightforward to check that $B_2^{(k)}(\mu_1, \mu_2) = B_2^{(k)}(\mu_2, \mu_1)$.

Assume $B_N^{(k)}(\mu_1, \ldots, \mu_N)$ is symmetric for $M-1 \geqslant N$. For $1 \leqslant i < j < M$ it is clear from (ii) that

$$B_M^{(k)}(\mu_1, \ldots, \mu_i, \ldots, \mu_j, \ldots, \mu_M) = B_M^{(k)}(\mu_1, \ldots, \mu_j, \ldots, \mu_i, \ldots, \mu_M).$$

The symmetry of $B_M^{(k)}(\mu_1, \ldots, \mu_M)$ with respect to μ_{M-1} and μ_M must be shown. To this end the recurrence relation in (ii) is to be iterated twice and the appropriate terms combined

$$\begin{aligned} B_M^{(k)}(\mu_1, \ldots, \mu_M) &= B_{M-2}^{(k)}(\mu_1, \ldots, \mu_{M-2})(X^-(\mu_{M-1}) + (M+k-2)\xi)(X^-(\mu_M) + (M+k-1)\xi) = B_{M-1}^{(k)} \\ &\quad \times(\mu_1, \ldots, \mu_{M-2}, \mu_M)(X^-(\mu_{M-1}) + (M+k-2)\xi) \\ &\quad + B_{M-2}^{(k)}(\mu_1, \ldots, \mu_{M-2})([X^-(\mu_{M-1}), X^-(\mu_M)] + \xi(X^-(\mu_{M-1}) + (M+k-2)\xi)) \\ &= B_{M-1}^{(k)}(\mu_1, \ldots, \mu_{M-2}, \mu_M)(X^-(\mu_{M-1}) + (M+k-2)\xi) + \xi B_{M-1}^{(k)}(\mu_1, \ldots, \mu_{M-2}, \mu_M) \\ &= B_M^{(k)}(\mu_1, \ldots, \mu_{M-2}, \mu_M, \mu_{M-1}). \end{aligned}$$

(iii) Applying the induction on M, for a fixed integer k. Set $M=2$, it is a direct consequence of (A1) that

$$B_2^{(k)}(\mu_1,\mu_2) = B_2^{(k-1)}(\mu_1,\mu_2) + \xi(B_1^{(k)}(\mu_1) + B_1^{(k)}(\mu_2)).$$

Assume (iii) is true for $M-1$ then

$$\begin{aligned} B_M^{(k)}(\boldsymbol{\mu}) &= \left(B_{M-1}^{(k-1)}(\boldsymbol{\mu}^{(M)}) + \xi \sum_{i=1}^{M-1} B_{M-2}^{(k)}(\boldsymbol{\mu}^{(i,M)}) \right)(X^-(\mu_M) + (M+k-1)\xi) \\ &= B_M^{(k-1)}(\boldsymbol{\mu}) + \xi B_{M-1}^{(k-1)}(\boldsymbol{\mu}^{(M)}) + \xi \sum_{i=1}^{M-1} (B_{M-1}^{(k)}(\boldsymbol{\mu}^{(i)}) + \xi B_{M-2}^{(k)}(\boldsymbol{\mu}^{(i,M)})) \\ &= B_M^{(k-1)}(\boldsymbol{\mu}) + \xi \sum_{i=1}^{M-1} B_{M-1}^{(k)}(\boldsymbol{\mu}^{(i)}) + \xi B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)}) = B_M^{(k-1)}(\boldsymbol{\mu}) + \xi \sum_{i=1}^{M} B_{M-1}^{(k)}(\boldsymbol{\mu}^{(i)}). \end{aligned}$$

□

Proof of Lemma 2.2: From Definition 2.1 $B_1^{(k)}(\mu) = X^-(\mu) + k\xi$, and commutators (2.5) it is clear that $M=1$ in (2.26) and (2.28) is given by

$$[h(\lambda), B_1^{(k)}(\mu)] = [h(\lambda), X^-(\mu)] = 2\frac{B_1^{(k)}(\lambda) - B_1^{(k)}(\mu)}{\lambda - \mu} + \xi\hat{\beta}_1(\mu),$$

$$[X^+(\lambda), B_1^{(k)}(\mu)] = [X^+(\lambda), X^-(\mu)] = -\frac{\hat{\beta}_1(\lambda) - \hat{\beta}_1(\mu)}{\lambda - \mu} + \xi X^+(\lambda),$$

$$[X^-(\lambda), B_1^{(k)}(\mu)] = [X^-(\lambda), X^-(\mu)] = \xi B_1^{(k)}(\mu) - \xi B_1^{(k)}(\lambda).$$

The induction method is used to demonstrate Lemma 2.2. Assume that (2.26)–(2.28) hold for $B_N^{(k)}(\boldsymbol{\mu}), M-1 \geqslant N \geqslant 1$ then, to show that these formulas are valid for M, the recurrence relation (ii) in Lemma 2.1 is used,

$$\begin{aligned} [h(\lambda), B_M^{(k)}(\boldsymbol{\mu})] &= [h(\lambda), B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})](B_1(\mu_M) + (M+k-1)\xi) + B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})[h(\lambda), X^-(\mu_M)] \\ &= \sum_{i=1}^{M-1} \left(2\frac{B_M^{(k)}(\{\lambda\} \cup \boldsymbol{\mu}^{(i)}) - B_M^{(k)}(\boldsymbol{\mu})}{\lambda - \mu_i} + \xi B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})\hat{\beta}_{M-1}(\mu_i; \boldsymbol{\mu}^{(i,M)}) \right) \\ &\quad + \xi \sum_{i=1}^{M-1} B_{M-2}^{(k+1)}(\boldsymbol{\mu}^{(i,M)})[h(\mu_i), X^-(\mu_M)] + B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)}) \left(2\frac{B_1(\lambda) - B_1(\mu_M)}{\lambda - \mu_M} + \xi h(\mu_M) \right) \\ &= 2\sum_{i=1}^{M} \frac{B_M^{(k)}(\{\lambda\} \cup \boldsymbol{\mu}^{(i)}) - B_M^{(k)}(\boldsymbol{\mu})}{\lambda - \mu_i} + \xi \sum_{i=1}^{M-1} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)}) \left(\hat{\beta}_{M-1}(\mu_i; \boldsymbol{\mu}^{(i,M)}) + \frac{2}{\mu_M - \mu_i} \right) \\ &\quad + \xi B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(M)}) \sum_{i=1}^{M-1} \frac{2}{\mu_i - \mu_M} + \xi \left(B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)}) + \xi \sum_{i=1}^{M-1} B_{M-2}^{(k+1)}(\boldsymbol{\mu}^{(i,M)}) \right) h(\mu_M) \\ &= \sum_{i=1}^{M} \left(2\frac{B_M^{(k)}(\lambda \cup \boldsymbol{\mu}^{(i)}) - B_M^{(k)}(\boldsymbol{\mu})}{\lambda - \mu_i} + \xi B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})\hat{\beta}_M(\mu_i; \boldsymbol{\mu}^{(i)}) \right), \end{aligned}$$

here we used, where appropriate, the induction hypothesis, the commutators $[h(\lambda), X^-(\mu)]$, and properties (ii) and (iv) in Lemma 2.1. Thus (2.26) is proved,

$$
\begin{aligned}
[X^+(\lambda),B_M^{(k)}(\boldsymbol{\mu})] &= [X^+(\lambda),B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})](B_1(\mu_M)+(M+k-1)\xi)+B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})[X^+(\lambda),X^-(\mu_M)]\\
&= -\sum_{i=1}^{M-1} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})\frac{\hat{\beta}_{M-1}(\lambda;\boldsymbol{\mu}^{(i,M)})-\hat{\beta}_{M-1}(\mu_i;\boldsymbol{\mu}^{(i,M)})}{\lambda-\mu_i}-2\sum_{i<j}^{M-1}\frac{B_{M-1}^{(k+1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)}\\
&\quad+\xi\sum_{i=1}^{M-1} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})X^+(\lambda)+\left(B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})+\xi\sum_{i=1}^{M-1}B_{M-2}^{(k+1)}(\boldsymbol{\mu}^{(i,M)})\right)\\
&\quad\times\left(-\frac{h(\lambda)-h(\mu_M)}{\lambda-\mu_M}+\xi X^+(\lambda)\right)-\sum_{i=1}^{M-1}B_{M-2}^{(k+1)}\\
&\quad\times(\boldsymbol{\mu}^{(i,M)})\frac{[h(\lambda),X^-(\mu_M)]-[h(\mu_i),X^-(\mu_M)]}{\lambda-\mu_i}\\
&= -\sum_{i=1}^{M-1} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})\frac{\hat{\beta}_{M}(\lambda;\boldsymbol{\mu}^{(i)})-\hat{\beta}_{M}(\mu_i;\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}-2\sum_{i<j}^{M-1}\frac{B_{M-1}^{(k+1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)}\\
&\quad+\xi\sum_{i=1}^{M} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})X^+(\lambda)-B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(M)})\frac{\hat{\beta}_{M}(\lambda;\boldsymbol{\mu}^{(M)})-\hat{\beta}_{M}(\mu_M;\boldsymbol{\mu}^{(M)})}{\lambda-\mu_M}\\
&\quad-2\sum_{i=1}^{M-1}\frac{B_{M-1}^{(k+1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,M)})}{(\lambda-\mu_i)(\lambda-\mu_M)}\\
&= -\sum_{i=1}^{M} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})\frac{\hat{\beta}_{M}(\lambda;\boldsymbol{\mu}^{(i)})-\hat{\beta}_{M}(\mu_i;\boldsymbol{\mu}^{(i)})}{\lambda-\mu_i}-2\sum_{i<j}^{M}\frac{B_{M-1}^{(k+1)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,j)})}{(\lambda-\mu_i)(\lambda-\mu_j)}\\
&\quad+\xi\sum_{i=1}^{M} B_{M-1}^{(k+1)}(\boldsymbol{\mu}^{(i)})X^+(\lambda),
\end{aligned}
$$

here we used, where appropriate, the commutators $[h(\lambda),X^-(\mu)]$ and $[X^+(\lambda),X^-(\mu)]$. Thus (2.27) is proved,

$$
\begin{aligned}
[X^-(\lambda),B_M^{(k)}(\boldsymbol{\mu})] &= [X^-(\lambda),B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})](B_1(\mu_M)+(M+k-1)\xi)+B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})[X^-(\lambda),B_1(\mu_M)]\\
&= \left((M-1)\xi B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})-\xi\sum_{i=1}^{M-1}B_{M-1}^{(k)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i,M)})\right)(B_1(\mu_M)+(M+k-1)\xi)\\
&\quad+\xi B_{M-1}^{(k)}(\boldsymbol{\mu}^{(M)})(B_1(\mu_M)-B_1(\lambda))=M\xi B_M^{(k)}(\boldsymbol{\mu})-\xi\sum_{i=1}^{M}B_M^{(k)}(\{\lambda\}\cup\boldsymbol{\mu}^{(i)}),
\end{aligned}
$$

here we used, where appropriate, the commutators $[X^-(\lambda),X^-(\mu)]$. □

Proof of Lemma 2.4: In the case for $M=1$ the proof is straightforward,

$$
\frac{\partial}{\partial z_a}B_1(\mu)=\frac{X_a^-}{(\mu-z_a)^2}=-\frac{\partial}{\partial\mu}\left(\frac{X_a^-}{\mu_i-z_a}-\frac{\xi}{2}h_a\right)=-\frac{\partial}{\partial\mu}X_a^-(\mu_i).
$$

Assume (2.36) is true for any set $\boldsymbol{\mu}$ with $|\boldsymbol{\mu}|<M$ complex numbers. Use formula (2.29) and the induction hypothesis together with (1) of Lemma 2.1 we can write

$$\frac{\partial}{\partial z_a}B_M(\boldsymbol{\mu}) = \frac{\partial}{\partial z_a}(B_{M-1}(\boldsymbol{\mu}^{(M)})(B_1(\mu_M) + (M-1)\xi))$$

$$= -\sum_{i=1}^{M-1}\frac{\partial}{\partial \mu_i}(X_a^-(\mu_i)B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})) - \frac{\partial}{\partial \mu_M}B_{M-1}(\boldsymbol{\mu}^{(M)})X_a^-(\mu_M)$$

$$= -\sum_{i=1}^{M-1}\frac{\partial}{\partial \mu_i}(X_a^-(\mu_i)B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})) - \frac{\partial}{\partial \mu_M}\left(X_a^-(\mu_M)B_{M-1}(\boldsymbol{\mu}^{(M)}) + \frac{[B_{M-1}(\boldsymbol{\mu}^{(M)}), X_a^-]}{\mu_M - z_a}\right)$$

$$= -\sum_{i=1}^{M}\frac{\partial}{\partial \mu_i}(X_a^-(\mu_i)B_{M-1}^{(1)}(\boldsymbol{\mu}^{(i)})).$$

(Received 28 April 2005; accepted 14 July 2005; published online 10 October 2005)

In a previous paper of one of us [Europhys. Lett. **59**, 330–336 (2002)] the validity of Greene's method for determining the critical constant of the standard map (SM) was questioned on the basis of some numerical findings. Here we come back to that analysis and we provide an interpretation of the numerical results, by showing that the conclusions of that paper were wrong as they relied on a plausible but untrue assumption. Hence no contradiction exists with respect to Greene's method. We show that the previous results, based on the expansion in Lindstedt series, do correspond to the critical constant but for a different map: the semi-standard map (SSM). For such a map no Greene's method analog is at disposal, so that methods based on Lindstedt series are essentially the only possible ones. Moreover, we study the expansion for two simplified models obtained from the SM and SSM by suppressing the small divisors. We call them the simplified SM and simplified SSM, respectively; the first case turns out to be related to Kepler's equation after a proper transformation of variables. In both cases we give an analytical solution for the radius of convergence, that represents the singularity in the complex plane closest to the origin. Also here, the radius of convergence of the simplified SM turns out to be lower than that of the simplified SSM. However, despite the absence of small divisors these two radii are lower than those of the true maps (i.e., of the maps with small divisors) when the winding number equals the golden mean. Finally, we study the analyticity domain and, in particular, the critical constant for the two maps without small divisors. The analyticity domain turns out to be a perfect circle for the simplified SSM (as for the SSM itself), while it is stretched along the real axis for the simplified SM, yielding a critical constant which is larger than its radius of convergence. © *2005 American Institute of Physics.*

I. INTRODUCTION

The Taylor-Chirikov map[12,23] or standard map (SM) is one of the best known nonlinear models showing the onset of chaos in Hamiltonian systems. It describes with some level of approximation many physical systems. Among these there are numerous applications to plasma physics, the field in which it was originally introduced. The SM is also exactly related to the time evolution of the "kicked rotor" and the equilibrium condition for a chain of masses superpositioned on a periodic potential. The latter model is known as the Frenkel-Kontorova (FK) model. This model is of equal importance for solid state physics as the SM is for plasma physics. It has, e.g., been applied to Josephson junctions arrays, charge density waves and surface friction.[19] More importantly, due to their simplicity and, yet, the complex behavior they show, these minimalistic

[a)]Electronic mail: gentile@mat.uniroma3.it
[b)]Electronic mail: tsvanerp@cecam.fr

models have had an enormous impact for the understanding in complex phenomena such as nonlinearity, chaos, quasi-periodicity, and commensurate-incommensurate transitions. Although now part of any textbook in nonlinear physics and studied extensively over many years, the SM and FK still bear many unsolved problems. The most intriguing one of these is the sudden transition from smooth to chaotic orbits in the SM when the coupling parameter K is increased above a critical value K_c. In the FK model this transition is connected to change from a sliding to a pinned state and bears the name of Aubry transition (or analyticity breaking transition).

The theoretical framework that characterizes this transition originates from the Kolmogorov-Arnol'd-Moser (KAM) theorem,[2] that deals with the problem of small divisors that can occur in any perturbation expansion for quasi-integrable systems. In fact, the KAM theorem can be used to prove the non-chaotic behavior of the SM for very small coupling K and sufficiently irrational winding number ω. Other arguments can then be applied to prove that a chaotic regime exists for values of K large enough giving an upper bound to K_c. For ω equal to the golden mean there exists an analytical bound by Mather, $K_c<4/3$,[34] and the computer assisted proof of MacKay and Percival $K_c<63/64\approx 0.9844$.[33] Moreover, another computer assisted analysis of Jungreis excluded the value $K=0.9718$ for possible occurrence of invariant circles (smooth orbits).[27]

There exist several methods to calculate K_c precisely, among which Greene's method[23] has shown to be one of the most effective giving the estimate $K_c=0.971\,635$. This method is based on the assumption that the dissolution of invariant curves can be associated with the sudden change from stability to instability of nearby closed orbits. The renormalization technique of MacKay (cf. Ref. 32, Sec. 4.4.1) is a further refinement of this method and has established the same value (cf. p. 199 of the quoted reference) with higher digit precision with respect to the original Greene's result. Yet, Greene's hypothesis has only been partly proven. A result by Falcolini and de la Llave[16] and, independently, by MacKay[31] yields that the critical constants for symplectic maps can never be higher than the ones obtained by Greene's method. Recently, the result has been extended to nontwist maps by Delshams and de la Llave.[14] Hence, $K_c\leqslant 0.971\,635$ for the SM with the golden mean as winding number. We mention that MacKay also showed that Greene's method does not apply to every map.[31] However, in the case of the SM, the situations for which no rigorous result can be given are considered unlikely; cf. the discussion in Refs. 16 and 31.

Another way to calculate (or, at least, to estimate) K_c is through the Lindstedt series expansion. Any smooth invariant curve in the SM can be described, for complex K small enough, say $|K|<\rho$, where ρ will depend on the winding number of the curve, by an analytic function which conjugates the dynamics to the unperturbed one. Of course ρ provides a lower bound for K_c, which is essentially the maximum real value of K for which there is an analytic invariant curve with the fixed winding number (more precise definitions will be given below). By writing down the Taylor expansion and equating the Taylor orders in the functional equation satisfied by this conjugation function, the Fourier-Taylor coefficients can, in principle, be derived from the ones of lower order. In Ref. 42 an evaluation of this expansion, always in the case of the golden mean, to high orders led the authors to infer a convergence to a value $K_c\sim 0.979\,78$, which is higher than Greene's result. [Note that the fact that ρ and K_c are different cannot be invoked to explain the discrepancy because of the direction of the inequality between the two quantities. One could also wonder what information about K_c can be inferred from ρ other than a lower bound. In general none, but one has strong numerical evidence that $\rho=K_c$ for the golden mean.] In this paper, we revisit that analysis and show that an apparent plausible assumption made in Ref. 42 is falsified beyond Taylor order $n>200$. As a result, the Lindstedt expansion does not contradict Greene's result. The value $K_c\sim 0.979\,78$, however, does correspond to the critical value for a different map, the semi-standard map (SSM); cf. also Ref. 24. We come back to this in Sec. III; though, we note straight away that this method is fundamental for the SSM, where no analog of Greene's method exists (see also the comments at the end of Sec. II).

Aubry[3] proposed another method, which is probably not very effective for high precision evaluation in a computer algorithm, but still interesting. It is based on an eigenvalue calculation of the dynamical matrix for the FK chain close to the critical point. Although this, in principle, requires the diagonalization of an infinite matrix, one can use the fact that the eigenvector of the

lowest mode tends to localize.[43] The instability of the FK chain can then be determined in successive approximants by calculating the determinants of finite matrices of increasing size.

Another effective method is the frequency analysis method proposed by Laskar, which has been applied to the standard map in Ref. 30, giving for the golden mean a critical value $K_c = 0.9718$, which is close to Greene's value. In Ref. 11 it has been used to study numerically the dependence of the critical constant on the winding number.

Finally we mention the use of Padé approximants to study numerically the entire analyticity domain. [The (L,M)-Padé approximant for a function $f(x)$ is given by the ratio of two polynomials, $f(x) \approx P_L(x)/Q_M(x)$, with $P_L = p_0 + p_1 x + \cdots + p_L x^L$ and $Q_M = 1 + q_1 x + \cdots + q_M x^M$. Hence, the simple Taylor expansion of order n can be considered as a special case of Padé approximant with $L=n$ and $M=0$.] This is a powerful numerical tool even if it is less precise than other methods for detecting the critical constant K_c and not completely under control from a rigorous point of view. It has, for instance, been employed in Ref. 4 and, very recently, in Ref. 5, where the existence of a natural boundary for the analyticity domain of the SM has been checked numerically. Always with the aim of studying the analyticity domain Falcolini and de la Llave[17] developed a variant of Greene's method working for complex values of the parameter K that gives an alternative to the Padé approximants approach. An implementation of Padé approximants is given in Sec. IV, though for a case in which the analytical solution is known.

Eventually, these approaches are assumed to converge to the same value. However, the proof of this is highly non trivial. The ultimate goal, of course, would be to gain an analytical expression for K_c. This is still far beyond our capabilities. Inspired by the desire to investigate further the influence of the small divisors in the Lindstedt series expansion, we introduce two simplified models by setting rigorously all the divisors equal to 1 both for the SSM and the SM. In the latter case, this is a very well-known model, Kepler's equation,[50] which turns out to have a very similar transition and can be solved analytically. The radii of convergence are found to be lower than those determined with the methods described above for the SM and SSM, respectively, in the case of golden mean winding numbers.

This paper is organized as follows. In Sec. II we recall the definition of the SM and SSM. In Sec. III we come back to the analysis of Ref. 42 showing that, contrary to what was asserted in that paper, the Lindstedt expansion does not violate Greene's method, and we make the comparison between the SM and SSM. In our opinion the analysis in Sec. III gives some insight onto the mechanism of break up of the invariant curves, and leaves some open problems: this will be discussed to more extent in Sec. V. In Sec. IV we present a model in which we suppress the small divisors and give an analytical expression both for the radius of convergence and the critical constant. Moreover, the analysis in Sec. IV has some consequence on the cases with small divisors in relation with the appearance of a natural boundary in the analyticity domain; this is further discussed in Sec. V. Finally we end up with the conclusions in Sec. V.

II. THE (SEMI-) STANDARD MAP

The SM and SSM can be written as

$$\begin{pmatrix} x_{i+1} \\ x_i \end{pmatrix} = \mathrm{T}\begin{pmatrix} x_i \\ x_{i-1} \end{pmatrix} = \begin{pmatrix} 2x_i + V'(x_i) - x_{i-1} \\ x_i \end{pmatrix}, \tag{1}$$

with $\{x_i\}$ defined mod 1, and

$$V'(x) = \begin{cases} \dfrac{K}{2\pi}\sin(2\pi x) & \text{for the SM,} \\ \dfrac{K}{4\pi i}\exp(i2\pi x) & \text{for the SSM.} \end{cases} \tag{2}$$

The resulting sequence $\{x_i \bmod 1\}$, for $i=2,\ldots\infty$, originating from a starting point (x_1,x_0) corresponds to a discrete trajectory on an invariant curve, when the latter exists. Such a trajectory for

the SM can be related to the equilibrium positions of an infinite FK chain where particles with harmonic nearest neighbor coupling are placed on a periodic potential $V(x)=K(2\pi)^{-2}(1-\cos(2\pi x))$. The SSM has not a similar counterpart, but is much simpler in its mathematics, and this is basically the reason why it was considered by Greene and Percival.[24] By definition, in terms of the lift of the map, the winding number or rotation number of an orbit is given by

$$\omega \equiv \langle x_{i+1} - x_i \rangle \equiv \lim_{n\to\infty} \sum_{i=0}^{n} \frac{x_{i+1} - x_i}{n} = \lim_{n\to\infty} \frac{x_n - x_0}{n}, \tag{3}$$

when the limit exists. For low coupling K and ω incommensurate to the periodicity of V', there exists a continuous function $g(x;K,\omega)$ such that the positions $\{x_i \bmod 1\}$ can be expressed as $x_i = g(i\omega+\varphi;K,\omega)$, where φ is an arbitrary phase. This function is often called the conjugating function or, in context with the FK model, the modulation or hull function. Its shape depends on the winding number ω and on the coupling parameter K.

The conjugating function satisfies the functional equation

$$2g(x;K,\omega) - g(x+\omega;K,\omega) - g(x-\omega;K,\omega) = -V'(x+g(x;K,\omega)). \tag{4}$$

For K large enough the function $g(x;K,\omega)$ becomes discontinuous. For the SM this implies that the orbits become chaotic and for the FK that the chain of particles gets pinned together with the appearance of a phonon gap.

There are several quantities of interest which one can introduce in order to study the transition from regular to chaotic dynamics. As the function $g(x;K,\omega)$ is analytic for K close to the origin one can consider its series expansion in powers of K,

$$g(x;K,\omega) = \sum_{n=1}^{\infty} K^n g^{(n)}(x;\omega), \tag{5}$$

and define the radius of convergence $\rho(\omega)$ as

$$\rho(\omega) = \inf_{x\in[0,1]} \left(\limsup_{n\to\infty} \left| g^{(n)}(x;\omega) \right|^{1/n} \right)^{-1}. \tag{6}$$

Note that the infimum appears in the definition of the radius of convergence because, as a result of the incommensurate winding number ω, each invariant curve is filled densely by any trajectory lying on it. Hence, existence of the invariant curve itself requires the latter to be defined for all $x \in [0,1]$.

The critical constant is defined as the (positive) real value $K_c(\omega)$ such that for $K > K_c(\omega)$ the conjugating function is not analytic any more. [The reason why one usually does not consider the negative critical constant, that is the negative value $K_c'(\omega)$ such that for $K < K_c'(\omega)$ there is no longer an analytic invariant curve, is that $K_c'(\omega) = -K_c(\omega)$ for the SM.] It is believed that the analyticity domain of the conjugating function has a natural boundary,[4,5,24] this means that $g(x;K,\omega)$ has a set of singularities in terms of K that form a closed curve around the origin in the complex plane. Hence, the radius of convergence $\rho(\omega)$ corresponds to the singularity closest to the origin, while the critical constant $K_c(\omega)$ corresponds to the intersection of this curve with the (positive) real axis. By definition one has $K_c(\omega) \geqslant \rho(\omega)$, so that by estimating the radius of convergence one finds a lower bound for the critical constant. Furthermore, it is generally accepted that $K_c(\tau) = \rho(\tau)$ for the golden mean [the golden mean is sometimes in other literature defined as the inverse of this value, $(\sqrt{5}+1)/2 = \tau^{-1} \approx 1.618\,034$ $\tau = (\sqrt{5}-1)/2 \approx 0.618\,034$], whereas there is strong numerical evidence that $K_c(\omega)$ can be much larger than $\rho(\omega)$ for winding numbers which have very large partial quotients in their continued fraction expansion.[9,11] [For an introduction of the continued fraction theory and a discussion of the basic properties we refer to the classical textbook by Hardy and Wright.[26] In the continued fraction expansion of a number $\omega = [a_0, a_1, a_2, \ldots] = a_0 + 1/(a_1 + 1/(a_2 + 1/(\cdots)))$, the numbers a_j are called the partial quotients,

while the rational numbers $q_j/p_j=[a_0,a_1,a_2,\ldots,a_j]$ are called the best approximants for ω.] It is also commonly believed (on the basis of numerical simulations and heuristic arguments) that $K_c(\omega)$ has the highest value for the golden mean $\omega=\tau$.

So far, the most accurate method to calculate K_c is based on Greene's method (also known as residue criterion). In this method the infinite trajectory $\{x_i \bmod 1\}$ with irrational winding number ω is approached by successive approximants which are periodic trajectories with rational winding numbers $\omega_j=p_j/q_j$ tending to ω, and $x_{i+q_j} \bmod 1=x_i$. Hence, p_j and q_j are at each level j two integer values whose ratio gives a better estimate of ω for each increment in j and $\omega=\lim_{j\to\infty}\omega_j$. These numbers can, for instance, be obtained using the best approximants in the continued fraction expansion of ω. For $\omega=\tau$ this results in the ratios of subsequent Fibonacci numbers ($\tau\approx F_{j-1}/F_j$ with $F_0=F_1=1$ and $F_j=F_{j-1}+F_{j-2}$ for $j>1$). Conclusively, Greene's method tells how to construct the periodic orbits and to measure their stability by means of a suitable quantity, called the residue, which does not tend to zero any more for $K>K_c$.

Besides being only partly proven, Greene's method has also some other limitations. For instance, this method does not work for other interesting models, as the SSM and Siegel's problem,[39] where the construction of periodic orbits fails. One can also easily check the nonexistence of smooth periodic orbit by a first orders perturbation theory. The best general alternative is the Lindstedt series expansion. This method is more generally applicable (it also works for the SSM and for any Hamiltonian systems close to an integrable one), but, in view of a numerical implementation, is less accurate than Greene's method for the SM and, in general, is more suitable for studying the radius of convergence rather than the critical constant.

III. THE LINDSTEDT SERIES EXPANSION

A. Standard map

A way to study the transition is by means of the Lindstedt series, which in this case means the expansion of the function $g(x;K,\omega)$ both in Fourier and in Taylor series. Such expansions were originally introduced by Lindstedt and Newcomb to study problems in celestial mechanics.[37] By defining the Fourier transform as

$$g(x;K,\omega)=\sum_{k=-\infty}^{+\infty}\hat{g}_k(K,\omega)e^{2\pi ikx} \quad \text{with inverse,}$$
$$\hat{g}_k(K,\omega)=\int_0^1 \mathrm{d}x\, g(x;K,\omega)e^{-2\pi ikx}, \tag{7}$$

and expanding

$$\hat{g}_k(K,\omega)=K\hat{g}_k^{(1)}(\omega)+K^2\hat{g}_k^{(2)}(\omega)+K^3\hat{g}_k^{(3)}(\omega)+\cdots, \tag{8}$$

we end up with Fourier-Taylor coefficients $\hat{g}_k^{(n)}(\omega)$, where n is the Taylor index and k is the Fourier index. Of course, $\hat{g}_k^{(n)}(\omega)$ depends on ω, but henceforth we withdraw such a dependence in order not to overwhelm the notation, whenever no ambiguity can arise.

Now, using Eq. (4) we can relate the Fourier-Taylor coefficients of order n by the ones with lower Taylor index by[42]

$$D_k^2\hat{g}_k^{(n)}=\frac{i}{4\pi}\{\delta_{1,k}-\delta_{-1,k}\}\delta_{1,n}+\frac{i}{4\pi}\sum_{m=1}^{\infty}\frac{(i2\pi)^m}{m!}\sum_{n_1+n_2+\cdots+n_m=n-1}\left\{\sum_{k_1+k_2+\ldots+k_m=k-1}\hat{g}_{k_1}^{(n_1)}\hat{g}_{k_2}^{(n_2)}\cdots\hat{g}_{k_m}^{(n_m)}-(-1)^m\sum_{k_1+k_2+\cdots+k_m=k+1}\hat{g}_{k_1}^{(n_1)}\hat{g}_{k_2}^{(n_2)}\cdots\hat{g}_{k_m}^{(n_m)}\right\}, \tag{9}$$

with

$$D_k^2 \equiv \frac{1}{\hat{g}_k(K,\omega)} \int_0^1 \mathrm{d}x (2g(x;K,\omega) - g(x+\omega;K,\omega) - g(x-\omega;K,\omega)) e^{-2\pi i k x}$$
$$= 2(1-\cos(2\pi k\omega)) = (2\sin(\pi k\omega))^2, \tag{10}$$

and where $\Sigma_{n_1+n_2+\cdots+n_m=n\pm1}$ implies a summation of all possible integers $n_1, n_2, \ldots, n_m$ with the constraint that $\sum_{i=1}^{m} n_i = n \pm 1$. There are ways to reduce the number of summations in Eq. (9). One possible way was proposed in Ref. 42 to construct an extended matrix $P(n,k,m)$ defined as

$$P(n,k,m) = \frac{(2\pi i)^m}{m!} \sum_{n_1+n_2+\cdots+n_m=n} \sum_{k_1+k_2+\cdots+k_m=k} \hat{g}_{k_1}^{(n_1)} \hat{g}_{k_2}^{(n_2)} \cdots \hat{g}_{k_m}^{(n_m)}. \tag{11}$$

One can show that $P(n,k,m)=0$ if $|k|>n$ or $m>n$. This gives rise to the following recursive relations:[42]

$$P(1,\pm 1,1) = \frac{\mp 1}{2D_1^2},$$

$$P(n,k,1) = -\frac{1}{2} D_k^{-2} \sum_{m=1}^{n-1} [P(n-1,k-1,m) - (-1)^m P(n-1,k+1,m)],$$

$$P(n,k,m) = \frac{1}{m} \sum_{n'=1}^{n-m+1} \sum_{k'=\max\{-n',k-n+n'\}}^{\min\{n',k+n-n'\}} P(n',k',1) P(n-n',k-k',m-1), \quad 1 < m \leqslant n, \tag{12}$$

from which we can distract the Fourier-Taylor coefficients by

$$\hat{g}_k^{(n)} = \frac{P(n,k,1)}{2\pi i}. \tag{13}$$

The entries of P are all real and obey the symmetry relation $P(n,k,m)=(-1)^m P(n,-k,m)$. Moreover, besides being zero for $|k|>n$ and $m>n, P(n,k,m)$ has zero values whenever $k+n$ is odd. Hence, $k=n,n-2,\ldots,-n$ are the only non-zero entries of P.

The relations of Eqs. (12) are very efficient to evaluate $\hat{g}_k^{(n)}$, and they were used in Ref. 42 to reach a Taylor order of approximately $n=200$. To go beyond this limit, sufficient computer power and time is needed as both the computation time and the number of non-zero matrix entries increase with $\sim n^3$. Hence, memory can become a severe problem as the number of entries that must be stored can easily go beyond the maximum allowed allocation limit of the computing system. Also the precision must be high enough in order to minimize numerical errors, but this problem is easily solved without requiring a precision as high as in the case of winding numbers close to rational numbers, as in Ref. 5, where the small divisors could become really small and up to 480 digits were needed. In this work, we reached the level $n=700$ (see Fig. 1) and we believe that going beyond this order is not very profitable for obtaining a more accurate evaluation of K_c. We come back to these results after addressing the small divisor problem that arises from Eq. (12).

From Eq. (10) and the second line in Eq. (12) one sees that even for irrational values of ω, the terms D_k^{-2} can become arbitrarily high for some k. This effect is a typical example of the small divisor problem (or small denominator problem), that can strongly prevent the convergence of any perturbation series. In fact, in general it requires a stronger condition than irrationality, such as a Diophantine condition.[2] [The usual Diophantine condition requires $|\omega q - p| > 1/C_0 |q|^\gamma$ for all $(p,q) \in \mathbb{Z}^2$ with $q \neq 0$ and for suitable positive constants C_0 and γ. But one can require also the Bryuno condition, which is a condition stronger than irrationality but weaker than the usual Diophantine condition; cf. for instance Refs. 8 and 21 in the case of the SM.] Among all the irrational numbers, the golden mean τ suffers the least from the small divisor problem and has

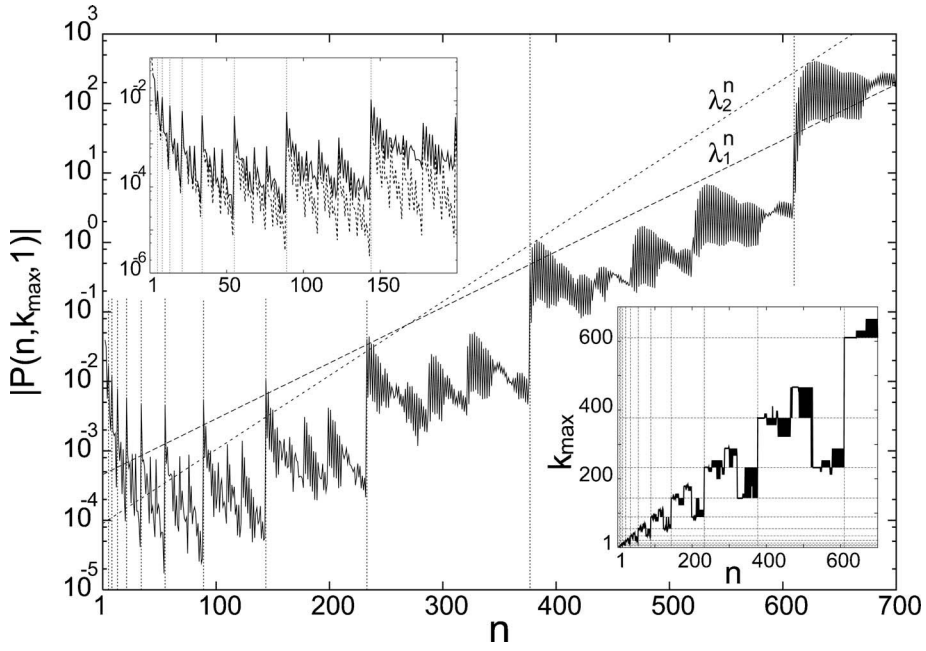

FIG. 1. $|P(n,k_{\max},1)|$ as a function of n. This is defined as the maximum value of $|P(n,k,1)|$ of all k; hence, $k_{\max}=k_{\max}(n)$ is defined as the k value where $|P(n,k,1)|$ has this maximum. The inset in the lower corner shows $k_{\max}$ as a function of n. The inset in the left upper corner is an enlargement of the first 200 terms together with $|P(n,n,1)|$ (dashed line). From these figures, one can clearly detect sudden boosts in the function $|P(n,k_{\max},1)|$ where $k_{\max}=n$ at the Fibonacci values (dashed vertical lines). However, whereas for $n<200$ the character is sharply peaked at these values, its behavior changes for higher orders. Still $k_{\max}=n$ for n a Fibonacci number, but the intersecting line described by $\alpha_1\lambda_1^n$ does no longer dominate the complete evolution of all the $|P(n,k,1)|$ terms. $\lambda_1=1.0186$ is determined by the line through $(n,k)=(F_{13},F_{13})=(377,377)$ and $(n,k)=(F_{14},F_{14})=(610,610)$. $\lambda_2=1.0248$ is set by the line through $(n,k)=(383,377)$ and $(n,k)=(622,610)$ where $|P(n,k_{\max}(n),1)|^{1/n}$ shows local maxima in n. The inversed values, $\lambda_1^{-1}\approx 0.9817$ and $\lambda_2^{-1}\approx 0.9758$ are assumed to converge for higher n to K_c for the SSM and SM, respectively.

therefore the highest convergence radius $K_c(\tau)$. The golden mean is "relatively difficult" to approximate by rational numbers as those arising, for instance, from the continued fraction expansion (one can say that it is the "most irrational number"). [A more formal statement is that τ allows the smallest values of C_0 and γ in the Diophantine condition. Hence, it is the number that is the most distant from all rational numbers.] As addressed above, the best approximants for the golden mean are given by the ratios F_j/F_{j+1}, where $\{F_j\}$ is the sequence of the Fibonacci numbers. Therefore, the small divisors will be largest for $k=F_j$. From the exact relation $F_{j-1}-F_j\tau=(-\tau)^{j+1}$, one can show that for $j\to\infty$,

$$D_{F_j}^{-2}\approx\frac{1}{4\pi^2}\left(\frac{1}{\tau^2}\right)^{j+1}\sim(2.618)^{j+1}. \tag{14}$$

However, we would like to stress that the small divisor problem is not the only mechanism causing the breakdown of the perturbative approach. This becomes evident in Sec. IV where we introduce the model that arises when we rigorously set $D_k^{-2}=1$ for all k in the series of Eq. (12). Clearly, this simplified expansion cannot be affected by the small divisors. However, it still has a radius of convergence and a critical constant, as shown by the analytical solution. As the radius of convergence ρ of this simplified model is found to be lower than $\rho(\tau)=K_c(\tau)$ for the SM, it proves that the golden mean winding number is remarkably resistant to the problem of small divisors. The full analysis of this model is given in Sec. IV.

Coming back to the results of Fig. 1, we see that indeed the evolution of $P(n,k,1)$ makes sudden jumps at the Fibonacci numbers as expected from Eq. (14). Besides, deceptively the values

$n=k=F_j$ seem to determine the whole power law behavior of $\hat{g}_k^{(n)}$, which is true until Taylor order $n\sim 200$. This assumption made in Ref. 42 allows for a further simplification of Eq. (12) by defining the reduced matrix $Q(n,m)\equiv P(n,n,m)$ obeying the relations

$$Q(1,1)=\frac{-1}{2D_1^2},$$

$$Q(n,1)=-\frac{1}{2}D_n^{-2}\sum_{m=1}^{n-1}Q(n-1,m), \tag{15}$$

$$Q(n,m)=\frac{1}{m}\sum_{n'=1}^{n-m+1}Q(n',1)Q(n-n',m-1),\quad 1<m\leqslant n.$$

This set of equations make high order ($\sim n=F_{20}=10\,946$) evaluations accessible for computer calculations. At this order the value of the radius of convergence seems to stabilize near $\rho=0.979\,78$, but this is still higher than the one obtained by Greene's method. As a consequence, validity of Greene's method was questioned in Ref. 42.

The more elaborated calculations in this work show that the assumption made in Ref. 42 was actually wrong as shown by the high order behavior in Fig. 1. Still, we find that $k=n$ gives the maximum for $|P(n,k,1)|$ whenever n is a Fibonacci number. However, the character of the evolution changes from being peaked to more smooth oscillations. Clearly, the line connecting the points $(F_j,|P(F_j,F_j,1)|)$ does no longer dominate the increment of the entries of P for $n>200$. As $|P(n,k_{\max}(n),1)|^{1/n}$ shows local maxima for $(n,k_{\max})=(383,377)$ and $(n,k_{\max})=(622,610)$ just after F_{13} and F_{14}, we fitted the line $\alpha_2\lambda_2^n$ through the corresponding points. From this fit, $\lambda_2=1.0248$, the estimate for $K_c\approx\lambda_2^{-1}=0.9758$ is obtained. Although still higher than Greene's value, it is already considerably lower than $\rho=0.979\,78$ obtained from Eqs. (15) for $n=F_{20}=10\,946$. Note that the latter approach of Ref. 42 for this lower approximant $n=F_{14}=610$, as obtained from the line λ_1^n (see Fig. 1), would result in $\rho\approx 1/\lambda_1=0.9817$, still approximately 0.002 higher than the nearly converged value of $\rho=0.979\,78$. Hence, a decay of 0.004 from 0.9758 at $n=622$ to 0.9716 at $n\to\infty$ is not unlikely. As a consequence, contrary to the results of the restricted series (15), there is no evidence at all that the full Lindstedt series (12) violates Greene's hypothesis. This also shows that a further simplification of Eqs. (12) is not easily obtained and that an accurate evaluation of K_c based on the Lindstedt perturbation is severely demanding.

B. Semi-standard map

When evaluating Eq. (1) for the SSM (2), the factors $\delta_{-1,k}$ and $-(-1)^m\Sigma\cdots$ are not present in Eq. (9). It is then straightforward to show that the only non zero entries of $P(n,k,m)$ in (11) are those with $n=k$. Hence, the assumption made in Ref. 42 that gave rise to Eqs. (15) does not correspond to the critical constant of the SM, but still gives the correct value for SSM. A result by Davie[13] shows that, for maps including the ones we are considering, the radius of convergence (6) is equal to

$$\rho(\omega)=\left(\limsup_{n\to\infty}\max_{|k|\leqslant n}\left|\hat{g}_k^{(n)}(\omega)\right|^{1/n}\right)^{-1}. \tag{16}$$

Therefore, the radius of convergence for the SM cannot be larger than the radius of convergence of the SSM, but of course it implies only a lower bound on the critical constant. Numerically by using Padé approximants in Ref. 5 it has been found that for certain values of the winding number ω, the radius of convergence of the SM is strictly smaller than the radius for the SSM. For the golden mean it is hard to improve upon simple power series using Padé, but for other numbers closer to resonant values it is possible and the phenomenon becomes much more evident.

The fact that the radius of convergence for these numbers is lower for the SM than for the SSM implies, by (16), that dominant contributions arise from terms with Taylor orders n for which $|\hat{g}_{k_{\max}}^{(n)}| > |\hat{g}_n^{(n)}|$, where $k_{\max}=k_{\max}(n)$ is defined as the value of k maximizing $|P(n,k,1)|$ at fixed n. This is exactly what emerges from the numerics as noted above and shown in Fig. 1 for $n > 200$. Clearly, this is not the case for the SSM where one can limit to $k=n$. Hence, in Ref. 42 $K_c(\tau)=\rho(\tau)$ was actually determined for the SSM to be 0.979 78 at Taylor order $n=F_{20}=10\,946$. In the calculations of this work, we went to order $n=F_{24}=75\,025$, that gave the value 0.979 37. As the root criterion saturates very slowly, the numerical results provide essentially only an (accurate) upper bound for the radius of convergence.

To summarize, we found that, also for the golden mean, the radius of convergence for the SM is strictly less than the radius of convergence for the SSM. Therefore, as a general comment we can remark that for the SM the presence of all harmonics in the Fourier expansion of the Taylor coefficients, that is $g^{(n)}(x;\omega)=\Sigma_{k\in\mathbb{Z}}\hat{g}_k^{(n)}(\omega)e^{2\pi ix}$, has a double effect. On the one hand, the radius of convergence becomes smaller with respect to that of the SSM. On the other hand, the critical constant $K_c(\omega)$ can be larger than its radius of convergence $\rho(\omega)$. For the golden mean the two values are equal as emerges numerically,[17] but for other values they can be appreciably different. One can imagine that the first phenomenon is due to the presence of contributions $\hat{g}_k^{(n)}(\omega)$ larger (in modulus) than $\hat{g}_n^{(n)}(\omega)$, while the second one is a consequence of deep cancellations between the harmonics of given perturbative order. These two effects are, in general, much more dominant for winding numbers ω close to rational values (see for instance Refs. 5, 6, and 8–10).

IV. SETTING SMALL DIVISORS TO UNITY

A. Introduction of the simplified maps

An interesting study appears if we set rigorously all possible small divisors equal to unity, $D_k=1$ for all k in Eqs. (12) and (15). Although the inspiration of this model was simply the study of the perturbation expansion when the small divisors have no effect, we can retrace from this series back to a functional relation as the one in Eq. (4) for a function $h(x;K)$,

$$h(x;K)+\frac{K}{4\pi i}\exp\left(i2\pi(x+h(x;K))\right)=0 \quad \text{for the SSM and,}$$
$$h(x;K)+\frac{K}{4\pi}\sin(2\pi(x+h(x;K)))=0 \quad \text{for the SM,} \tag{17}$$

where ω has vanished. Hence, the divergence of the simplified series corresponds to values K where the functional equations (17) have no analytical solution any more. A logical next step would be to relate Eqs. (17) to the iteration of a map similar to Eq. (1). As the relation (17) no longer contains the arguments $x\pm\omega$ this is not so evident. However, one can relate the function $h(x;K)$ to the hull function of a FK-type system. It can be shown that this corresponds to a one-dimensional Einstein solid that is interacting with an external incommensurate potential. (The Einstein model is a well-known approximation in solid physics where the vibrations of a lattice of N atoms is treated as a set of $3N$ independent harmonic oscillators in one dimension.[29]) Due to the lack of neighbor interaction, which makes each particle independent, it is highly unusual to describe for such a system the equilibrium coordinates by a collective hull function. Still, there are no restrictions not to do so and one can even give such a function a physical meaning. As known from the FK model, the continuous shape of the hull function is directly associated with the existence of a sliding mode where the FK chain can slide over the periodic potential without cost of energy.[19,43] In this case, the complete phonon spectrum is given by the sum of oscillations of the individual particles that are not zero in general. The sliding mode appears when we add an extra degree of freedom to the system as shown in Fig. 2.

Here, all particles have no interaction with their neighbors, but are connected to an upper rod. When the rod has an infinite mass compared to the particle masses, the system is basically an

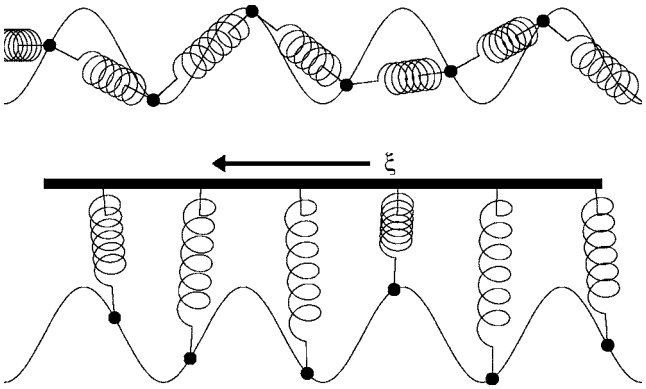

FIG. 2. Illustration of the FK model (top) and the system that obeys Eq. (17) (bottom). The latter corresponds also to the FKT model without neighbor interaction. All particles are connected to the upper rod whose position is given by ξ. A sliding mode exists when ξ can be varied without cost of energy.

Einstein solid. However, if we assume that the position of the rod may vary according to a coordinate ξ an extra phonon mode exist that is zero for $K<K_c$ in this system. Hence, the breakdown of the Lindstedt expansion (12) with $D_k=1$ for all k can be also related to a real physical sliding-pinning transition. The model as illustrated in Fig. 2 is also equal to a special case of the Frenkel-Kontorova-Tomlinson (FKT) model where each particle is connected to a rod by a spring with spring constant c_r and additionally to its neighbors with a coupling c_n. [The simple Tomlinson model[41] is not the system in Fig. 2 as this usually consists of only one single oscillator (particle). This ancient model is now often applied to simulate the "stick-slip" motion of an atomic force microscope (AFM) tip over a sample surface.] The FKT model has been proposed to study more realistically the frictional behavior between atomic surfaces.[25,45,46] The model that is described by Eq. (17) simply corresponds to the FKT system with $c_r=1$ and $c_n=0$. The nice thing is that the perturbation series of Eqs. (17) can be solved exactly. To show this, we will start with the more simple SSM case.

B. Radii of convergence for simplified maps

1. Simplified SSM

It can be convenient to use the following normalization:

$$R(n,m) = n\,!\,(-2)^n Q(n,m), \tag{18}$$

with matrix entries that are integer and positive and with $R(n,n)=1$. From Eqs. (12) and (18) with $D_n^{-2}=1$ we derive

$$\begin{aligned} R(n,1) &= n\sum_{m=1}^{n-1} R(n-1,m), \\ R(n,m) &= \frac{1}{m}\sum_{n'=1}^{n-m+1}\binom{n}{n'}R(n',1)R(n-n',m-1), \quad 1<m\leqslant n. \end{aligned} \tag{19}$$

Note that the recursive relations in Eq. (19) for $m>1$ coincide with those satisfied by the Stirling numbers of the first and second kind, $S_n^{(m)}$ and $\mathfrak{S}_n^{(m)}$, respectively. [The Stirling numbers of the first kind $S_n^{(m)}$ are defined by the requirement that $(-1)^{n-m}S_m^{(n)}$ is the number of permutations of n symbols which have exactly m cycles. The Stirling number of the second kind $\mathfrak{S}_n^{(m)}$ is equal to the way of partioning a set of n elements into m non-empty subsets. See Ref. 1, p. 824, Secs. 24.1.3 and 24.1.4, with $r=m-1$.] Of course what is different is the relation for $m=1$.

From relations (19) with $R(1,1)=1$ the following exact equality can be proven:

$$R(n,m) = n^{n-m}\binom{n-1}{m-1}. \tag{20}$$

The proof of this equation is given in the appendixes in two ways. In Appendix A we derive this proof using the argument of induction. In Appendix B we give a proof based on the tree formalism that was first introduced in Refs. 15 and 36, then extended and formalized in Ref. 20. The first proof is quite elementary, but a little elongated. The second is short, but less self-contained as it requires some knowledge of the previous publications about the tree formalism (but of course it becomes very simple for any reader acquainted with such a technique). Furthermore, the latter is most practical for the more complicated proof for the simplified SM in Eq. (17). Now, from Eqs. (18) and (20) we deduce that

$$Q(n,1) = (-1)^n \frac{n^{n-1}}{2^n n!}, \tag{21}$$

which shows a power law behavior $\sim a\lambda^n$ for large n giving the radius of convergence as $\rho = 1/\lambda$. Hence,

$$\ln|Q(n,1)| \sim (n-1)\ln(n) - n\ln(2) - \ln(n!). \tag{22}$$

Then by using (this is a refinement of the well-known Stirling's formula $\ln n! \approx n\ln n - n$)[47]

$$\ln(n!) \approx \left(n+\tfrac{1}{2}\right)\ln n - n + \tfrac{1}{2}\ln(2\pi), \tag{23}$$

we get

$$\ln|Q(n,1)| = n(1-\ln(2)) - \tfrac{3}{2}\ln(n) - \tfrac{1}{2}\ln(2\pi) \Rightarrow |Q(n,1)| \sim \frac{1}{\sqrt{2\pi n^3}}\left(\frac{1}{2}e\right)^n, \tag{24}$$

yielding a radius of convergence $\rho = 2/e \approx 0.735\,759$. This value is less than the SSM value or SM value. This can be a bit contraintuitive, as one could have expected that the possible occurrence of small divisors would give a lower ρ. Apparently, this does not happen for the golden mean. This can be understood by the following reasoning. Although the small divisor factors D_k^{-2} can become arbitrarily large for some k giving a boost to the series (12) and (15), at most values of k they will be considerable smaller than 1 resulting in an opposite effect. Hence, for the golden mean as winding number the latter effect seems to be more dominant yielding an even higher value for ρ than the case where all D_k^{-2} terms are equal to 1. We can say that, in fact, for the golden mean the small divisors "are not so bad," whereas they become really small for winding numbers much closer to rational values (that is with very large partial quotients in their continued fraction expansion).

2. Simplified SM

The simplified SM considered in Eq. (17) is well known in celestial mechanics[50] after applying the following variable transformation. Write $K/2 = -\mathfrak{e}$ and $2\pi x = \mathfrak{M}$ where $\mathfrak{e}$ is the eccentricity and $\mathfrak{M}$ is the mean anomaly. Then the eccentric anomaly $E = 2\pi(x + h(x;K))$ is related to $\mathfrak{M}$ through Kepler's equation $\mathfrak{M} = E - \mathfrak{e}\sin E$, which is exactly the second equation in Eq. (17).

The recursive relations (12) with $D_k^{-2} = 1$ have also an exact solution that we write here,

$$P(n,k,1)=\begin{cases}\dfrac{(-1)^{n+(n-k)/2}}{2^n}\dfrac{k^{n-1}}{((n-k)/2)!\,((n+k)/2)!}, & \text{for } |k|\leqslant n \text{ and } k+n \text{ is even}\\ 0 & \text{otherwise,}\end{cases} \tag{25}$$

which can be obtained by the Lagrange inversion theorem.[48,50] We present a derivation of this relation based on the tree formalism in Appendix B.

Then, by using Eq. (16) we see that we must compute the maximum over k of $|P(n,k,1)|$. It is immediate to realize that the maximum is reached for some $k>n/2$; by assuming that the maximum is reached for some k which is not too close to n (an assumption that we shall verify *a posteriori*), we can approximate the factorial appearing in Eq. (25) with Stirling's formula (23). This gives rise to

$$\begin{aligned}|P(n,k,1)| &\sim \frac{1}{2^n}\frac{k^{n-1}e^n}{\left(\frac{1}{2}(n-k)\right)^{\frac{1}{2}(n-k)}\left(\frac{1}{2}(n+k)\right)^{\frac{1}{2}(n+k)}}\frac{1}{\left(\frac{1}{4}(n^2-k^2)\right)^{\frac{1}{2}}}\\ &\sim \frac{2e^n}{n^2}\frac{1}{\sigma(1-\sigma^2)^{\frac{1}{2}}}\left(\frac{\sigma}{(1-\sigma)^{\frac{1}{2}(1-\sigma)}(1+\sigma)^{\frac{1}{2}(1+\sigma)}}\right)^n,\end{aligned} \tag{26}$$

where we have defined $\sigma=k/n\in[-1,1]$. Hence, we must compute the maximum of the function

$$E(\sigma)=\sigma\exp\left(-\frac{1-\sigma}{2}\ln(1-\sigma)-\frac{1+\sigma}{2}\ln(1+\sigma)\right). \tag{27}$$

By taking the derivative $\partial E(\sigma)/\partial\sigma=0$, we find that the maximum is reached at a value $\sigma_{\max}$ that satisfies the following relation:

$$2+\sigma_{\max}\ln(1-\sigma_{\max})-\sigma_{\max}\ln(1+\sigma_{\max})=0, \tag{28}$$

yielding $\sigma_{\max}\approx 0.833\,557$. Hence, $k_{\max}=\sigma_{\max}n\approx 0.833\,557n$. Using Eq. (28), $E(\sigma_{\max})$ simplifies to $E(\sigma_{\max})=(1/e)[\sigma_{\max}/(\sqrt{1-\sigma_{\max}^2})]$. Inserting this relation into Eq. (26) gives

$$|P(n,k_{\max},1)|\sim\frac{2}{n^2\sigma_{\max}^2}\lambda^{n+1}, \tag{29}$$

with $\lambda=[\sigma_{\max}/(\sqrt{1-\sigma_{\max}^2})]$. This yields a radius of convergence $\rho=\lambda^{-1}\approx 0.662\,743$, which is known as the Laplace limit.[18] This value is again smaller than the radius of convergence of the true SM [recall that for the golden mean the radius of convergence $\rho(\tau)$ equals $K_c(\tau)$]. Moreover, similar to the true maps, this SM-analog transition value ρ is lower than the one of the SSM.

C. The critical constant and the analyticity domain

The argument above gives only information about the location of the singularities closest to the origin. The solution of the functional equations (17) could still exist for real values of K larger than the radius ρ. This would correspond to the situation where $h(x;K)$ is still analytic for $K>\rho$ real, but at which the power series (5) and (8) are no longer defined. In particular, there could be no singularity at all on the real axis so that an analytical form of $h(x;K)$ could still exist for $K\to\infty$. To analyze the extent of the analyticity domain and the critical constants, we need to "evaluate" the summations of Eqs. (5) and (8). This means that we need to find the functional form $h(x;K)$ that corresponds to the power series, but, contrary to the summation itself, can still be perfectly defined for $|K|>\rho$.

In the following analysis, we will show that the analyticity domains for the simplified maps are, like those for the true maps, also constrained by a closed boundary. More precisely, we find that for fixed x there are only a few singularities, but the union over all $x\in[0,1]$ of such singularities reconstruct a closed curve surrounding the origin. Hence, outside this natural bound-

ary there is no function $h(x;K)$ that can be obtained by an analytic continuation of the power series around $K=0$. Although very unlikely, this does not completely exclude the existence of a very different function, say $\tilde{h}(x;K)$, that is defined outside this domain and obeys Eq. (17) and may even persist for $K\to\infty$. Recurrence phenomena, such as appearance and disappearance of an invariant curve with given winding number when varying the parameter K, are known to occur for certain maps,[49] but, for instance, this is not the case of the SM.

1. Simplified SSM

As for this model one has $\hat{h}_k(K)=\hat{h}_k^{(k)}K^k$, we can directly write down the summation of Eq. (5) for the function $h(x;K)$,

$$h(x;K)=\sum_{k=1}^{\infty}\hat{h}_k^{(k)}K^k e^{2\pi ikx}. \tag{30}$$

Inserting the expression (21) gives

$$h(x;K)=\frac{1}{2\pi i}\sum_{k=1}^{\infty}(-1)^k\frac{k^{k-1}}{2^k k!}K^k e^{2\pi ikx}=\frac{1}{2\pi i}\sum_{k=1}^{\infty}|Q(k,1)|K^k e^{\pi ik(2x+1)}. \tag{31}$$

To find the full analyticity domain of $h(x;K)$, one basically must fix a certain value for x, say $x=x'$, and search for the singularities in K of the function $h(x';K)$ by, e.g., using the Padé approximants method. Then, one must repeat, in principle, this procedure for all possible values of x and collect the set of all singularities to construct the full analyticity domain. Finally, the radius of convergence ρ is then the complex singularity closest to the origin, while K_c is the smallest (positive) real singularity, if any.

Vice versa, we could also fix the argument ϕ of the complex value K, such that $K=|K|e^{i\phi}$. The summation (31) will then be maximized for $x=-\left[(\phi/2\pi)+\frac{1}{2}\right]$, where each term in the sum turns into a positive value. For these values of K and x, by using the inclusion argument and the root criterion on the delimiting series, one can show that the radius of convergence is given by $2/e$. Hence, for each x there is one singularity at $K=-(2/e)e^{-i2\pi x}$, and the complete set over all x forms a closed curve that is a circle around the origin.

Note that this is very different from the true maps with the small divisors. Although not proven, numerical studies (for instance Ref. 5 and references quoted therein) suggest that for the true SM and SSM the function $g(x;K,\omega)$ has for each value of x, independently of its value, an infinite set of singularities forming the same (for each x) natural boundary. Numerical analysis[5] shows that the natural boundary of the true SSM, at fixed x, is a circle just as in this simplified model when the union on all x is taken. [It is easy to prove that the analyticity domain in K, that is by taking the union over all values of $x\in[0,1]$, is a circle for the true SSM, as first pointed out in Ref. 35. However, to our knowledge, there is no analytical proof that it is a circle for a fixed value of x.] This property appears to be true irrespective to the choice of ω as long as it fulfills a Diophantine condition,[2] or even a Bryuno condition. For the SM with golden mean as winding number this curve resembles close to a circle, but not very smooth and slightly elongated (about 1%) along the imaginary axis.[17]

2. Simplified SM

Taking the power series (8) for $\hat{h}_k(K)$ for the simplified SM using Eq. (25) we have

$$\hat{h}_k(K)=\sum_{n=1}^{\infty}\frac{1}{2\pi i}P(n,k,1)K^n=\frac{1}{2\pi i}\sum_{n=|k|,|k|+2,\ldots}^{\infty}K^n\frac{(-1)^{n+(n-k)/2}}{2^n}\frac{k^{n-1}}{((n-k)/2)!\,((n+k)/2)!}. \tag{32}$$

Changing variables to $j=(n-|k|)/2$ gives

$$\hat{h}_k(K) = \frac{(-1)^k}{2\pi i k} \sum_{j=0}^{\infty} \frac{(-1)^j}{2^{2j+|k|} j\,!\,(j+|k|)!} (|k|K)^{2j+|k|} = \frac{(-1)^k}{2\pi i k} J_{|k|}(K|k|), \tag{33}$$

with $J_v(z)$ the Bessel function of the first kind[22,44] defined (for integers v) as

$$J_v(z) \equiv \sum_{j=0}^{\infty} \frac{(-1)^j}{2^{2j+v} j\,!\,(j+v)!} z^{2j+v}. \tag{34}$$

As these Bessel functions $J_v(z)$ have no singularities in z, neither has $\hat{h}_k(K)$ in K. Therefore, the Fourier coefficients do not give direct information about K_c. On the other hand, one can conclude from Eqs. (33) and (34) that $|\hat{h}_k(K)|$ is maximized for pure imaginary K, so that the singularity closest to the origin is lying on the imaginary axis, on a distance ρ from the origin. Here, the individual terms in Eq. (34) can not cancel as $(-1)^j$ is then neutralized by $z^{2j} \sim K^{2j} = (-1)^j |K|^{2j}$.

We can now try to evaluate the Fourier series (7) for $h(x;K)$,

$$h(x;K) = \sum_{k=-\infty}^{+\infty} \frac{(-1)^k}{2\pi i k} J_{|k|}(|k|K) \exp(2\pi i k x) = \sum_{k=1}^{\infty} \frac{(-1)^k}{\pi k} J_k(kK) \sin(2\pi k x). \tag{35}$$

Further simplification is achieved by taking the derivative with respect to x and searching the singularities in

$$h'(x;K) = \sum_{k=1}^{\infty} 2(-1)^k J_k(kK) \cos(2\pi k x) \tag{36}$$

instead of $h(x;K)$; this is allowed as the two problems are equivalent.

From the series (36) we can guess for which values of x the singularities will be K_c and ρ respectively. As $J_k(kK)$ is positive for real values $0 < K < 1$ (see p. 534 in Ref. 44), we need to compensate the $(-1)^k$ term by $\cos(2\pi k x)$. This is achieved for $x = \frac{1}{2}$ that reduces Eq. (36) to

$$h'(1/2;K) = 2\sum_{k=1}^{\infty} J_k(kK), \tag{37}$$

which has the exact solution [see formula (1) on p. 615 in Ref. 44]

$$2\sum_{k=1}^{\infty} J_k(kK) = \frac{K}{1-K}. \tag{38}$$

Hence, $h'(1/2;K)$ has a singularity at $K=1$, yielding the critical constant $K_c = 1$, a well known result in celestial mechanics.[50]

The complete analyticity domain can be found in Ref. 50, p. 219. In Fig. 3 we represent what can be obtained by using Padé approximants for some values of x. What emerges is that the function $h(x;K)$ has for each value of x a pair of complex singularities closest to the origin symmetric with respect to the real axis. For x going from 0 to 1/2 such singularities move continuously from -1 to 1 along two (symmetric) curves which pass through the points $\pm i\rho$ at $x = 1/4$ (see Fig. 3). Hence the entire set of singularities closest to the origin lies on a curve which is smooth except at $K = \pm 1$, where it has a discontinuity in its first derivative (cf. again Ref. 50, p. 219).

An important feature is, however, that, as already noted in a similar context by Simon,[40] a natural boundary in K for fixed x seems to appear only in the presence of small divisors. In fact, the latter give rise to the occurrence of sudden peaks yielding a pattern similar to lacunary series,[28] for which natural boundaries can be proved to arise. Hence, these peaks seem to be responsible for the formation of the natural boundary as suggested by Prange (cf. again Ref. 40).

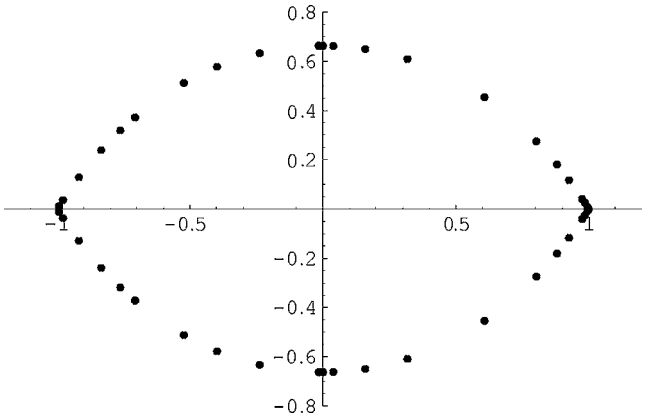

FIG. 3. Singularities in K of the function $h(x;K)$ for the SM without small divisors for x varying in [0,1]. The radius of convergence ρ corresponds to the value $x=1/4$, while the critical constant $K_c=1$ corresponds to $x=1/2$. The curve is symmetric with respect to both the real and the imaginary axes.

V. CONCLUSIONS

We showed by a numerical evaluation of the Lindstedt series up to order $n=700$ that a previously assumed violation of Greene's criterion[42] was ungrounded. The assumption that allowed the restricted series (15) was falsified for orders $n>200$. The resulting critical constant did not correspond to the SM, but is still the true one for the SSM. From our numerics, we conclude that, for the golden mean, the SSM critical constant is strictly higher than the SM. This seems to be generally true for all winding numbers, but it is specifically difficult to prove for the golden mean where both constants are very close. Still, the numerics up to order $n=700$ do not give a complete convergence. An evaluation that would compare to the accuracy of Greene's method would rely on a prohibitive computational effort.

Note that our analysis leaves some open problems. As we have seen, the small divisors introduce some sudden jumps in the coefficients $\hat{g}_k^{(n)}(\omega)$ whenever k is a Fibonacci number, or more generally (for $\omega\neq\tau$) the denominator of a best approximant for the winding number ω, and one has $|k|\leqslant n$ for the SM, hence one could think, as done in Ref. 42, that the most dominant terms in the Taylor expansion of $g(x;K,\omega)$ are those with n the denominator of a best approximant and $k=n$. In principle this conjecture could seem very plausible, but in fact, as the analysis above shows, it is wrong, even if it appears as numerically supported up to rather high Taylor orders n (up to $n\sim 200$). If one bears in mind Davie's result (16), the only possibility left is that there are Taylor orders n such that $|P(n,k,1)|$ is maximized for $k=k_{\max}(n)<n$. It would be interesting to study the dependence of $k_{\max}(n)$ on n. An interesting problem would be also to understand which are the values of n at which the peaks of $|P(n,k_{\max},1)|$ appear. They are very likely related to the best approximants, but the exact nature of such a relationship deserves further investigation. An already remarked consequence of our analysis is that also for the golden mean the SM has a radius of convergence lower than that of the SSM. Even if such a property has been numerically checked for other winding numbers,[10] it is not *a priori* obvious that it must hold for the golden mean. [To make an analogy, also the equality $\rho(\omega)=K_c(\omega)$ is certainly false for most of ω, but still it holds for $\omega=\tau$.] Our result suggests that the radius of convergence for the SM is always less than that of the SSM for all winding numbers, but we leave such a property as a conjecture.

In addition to the analysis performed in Sec. III, we have proposed a simplified model that appears when the small divisors in the SM and SSM are suppressed. We show that this model maintains many features of the SM and SSM. It has an analytical solution in both cases, and it corresponds to Kepler's equation in case of the SM. Also here, the analog of the SM has a lower value of ρ than that of the SSM. Moreover, surprisingly, the radii of convergence are lower than the true models for golden mean winding numbers. This proves that the golden mean winding number is remarkably resistant to the small divisor effect and falsifies a common misconception

that the small divisor problem is the dominant and only mechanism for the analyticity breaking transition. The fact, that the simplified model still has a transition with a value even lower than the true maps for the golden mean, shows that this is not the case.

Finally, we studied the full analyticity domain for the two models (the case of the SM was well known in literature, as it correspond to the celebrated Kepler's equation). Also here, there are striking differences between the simplified and the true maps. Similar to the true maps, the set of singularities form a natural boundary. However, whereas the SM and SSM all the singularities in K for the function $g(x;K,\omega)$ are present for any value of x (that is there is a natural boundary at fixed x), the situation is quite different for the simplified maps. The simplified SSM has only one singularity in the complex K plane for the function $h(x;\boldsymbol{K})$ at each value of x. The simplified SM has for each value of x two singularities symmetric with respect to the real axis, except for the singularities on the real axis for $x=0$ and $x=1/2$ which are single. The closed natural boundary is retained after gathering all singularities for all x.

This natural boundary is a perfect circle in case of the simplified SSM (such as it is for the true SSM), while it is a more stretched curve for the simplified SM with a discontinuity in the first derivative on the real axis at $K=\pm 1$. This shows that the radius of convergence of the simplified SSM equals its critical constant, as it was found for the true SSM. In contrast, the simplified SM has a critical constant of $K_c=1$ that is higher than its radius of convergence. In that respect, the simplified SM resembles more the true SM with winding numbers close to rational values. Also this is a bit of a surprise, as one would expect the contrary, but it is consistent with the trend mentioned above. It is almost as if the model, in which all small divisors were eliminated, still suffers more from this effect than the true SM with the golden mean, somehow the small divisors for the golden mean introduce sort of a rotational symmetry for the analyticity domain.

Therefore, we believe that the study of these kinds of simplified analytical models are a worthy prerequisite for the understanding of the SM, SSM, and FK models and, in particular, the influence of the small divisors. For instance, our results about the simplified SSM give further support that the existence of a natural boundary at a single fixed x is created by the presence of small divisors, in agreement with the general remarks at the end of Sec. IV. In particular, this shows that the circular shape of the analyticity domain of the SSM is not simply due to the fact that the corresponding conjugating function depends on K and x through the variable $\eta=K e^{2\pi i x}$ (see Appendix B). On the contrary, there is some deeper reason for this to occur as the above argument cannot explain the existence of the natural boundary, neither its circular shape, for a single fixed value of x.

ACKNOWLEDGMENTS

The authors thank Alberto Berretti for pointing out the relation between the simplified SM and Kepler's equation. One of the authors (T.S.v.E) acknowledges support from Marie Curie Intra-European fellowships (MEIF-CT-2003-501976) within the 6th European Community Framework Programme and the support through the European Network LOCNET HPRN-CT-1999-00163.

APPENDIX A: INDUCTION PROOF

Proof of Eq. (20): Assuming that relation (20) is true up to some Taylor order $n-1$, then the first relation of Eq. (19) for n yields

$$R(n,1)=n\sum_{m=1}^{n-1}\frac{(n-1)^{n-1-m}}{(m-1)!}\frac{(n-2)!}{(n-1-m)!}$$
$$=n\sum_{m=0}^{n-2}\frac{(n-1)^{m}}{(n-2-m)!}\frac{(n-2)!}{m!}=n\sum_{m=0}^{n-2}(n-1)^{m}\binom{n-2}{m}=n((n-1)+1)^{n-2}=n^{n-1}. \tag{A1}$$

The second relation of Eq. (19) is slightly more difficult. One can write

$$
\begin{aligned}
R(n,m) &= \frac{1}{m}\sum_{n'=1}^{n-m+1}\binom{n}{n'}\binom{n-n'-1}{m-2}n'^{(n'-1)}(n-n')^{(n-n'-m+1)} \\
&= \frac{1}{m}\sum_{n'=1}^{n-m+1}\frac{n!}{n'!\,(n-n')!}\frac{(n-n'-1)!}{(m-2)!\,(n-n'-m+1)!}n'^{(n'-1)}(n-n')^{(n-n'-m+1)} \\
&= \frac{1}{m}\sum_{n'=1}^{n-m+1}\frac{n!}{n'!\,(m-2)!\,(n-n'-m+1)!}n'^{(n'-1)}(n-n')^{(n-n'-m)} \\
&= \frac{1}{m}\sum_{n'=1}^{n-m+1}\frac{n!}{(m-2)!\,(n-m+1)!}\binom{n-m+1}{n'}n'^{(n'-1)}(n-n')^{(n-n'-m)} \\
&= \frac{m-1}{m}\sum_{n'=1}^{n-m+1}\binom{n}{m-1}\binom{n-m+1}{n'}n'^{(n'-1)}(n-n')^{(n-n'-m)} \\
&= \frac{m-1}{m}\binom{n}{m-1}\sum_{n'=0}^{n-m}\binom{n-m+1}{n'+1}(n'+1)^{n'}(n-n'-1)^{(n-n'-1-m)} \\
&= \frac{(m-1)(n-m+1)}{m}\binom{n}{m-1}\sum_{n'=0}^{n-m}\binom{n-m}{n'}(n'+1)^{n'-1}(n-n'-1)^{(n-n'-1-m)}. \qquad \text{(A2)}
\end{aligned}
$$

Using Abel's identity[38]

$$
(x+y)(x+y-a\tilde{n})^{\tilde{n}-1} = \sum_{k=0}^{\tilde{n}}\binom{\tilde{n}}{k}xy(x-ak)^{k-1}[y-a(\tilde{n}-k)]^{\tilde{n}-k-1}, \qquad \text{(A3)}
$$

with $k=n'$, $\tilde{n}=n-m$, $a=-1$, $x=1$, $y=m-1$ yields

$$
mn^{n-m-1} = \sum_{n'=0}^{n-m}\binom{n-m}{n'}(m-1)(1+n')^{n'-1}(n-n'-1)^{n-m-n'-1}, \qquad \text{(A4)}
$$

hence

$$
\begin{aligned}
R(n,m) &= \frac{(m-1)(n-m+1)}{m}\binom{n}{m-1}\sum_{n'=0}^{n-m}\binom{n-m}{n'}(n'+1)^{n'-1}(n-n'-1)^{(n-n'-1-m)} \\
&= (n-m+1)\binom{n}{m-1}n^{n-m-1} = \frac{n-m+1}{n}\frac{n!}{(m-1)!\,(n-m+1)!}n^{n-m} \\
&= \frac{(n-1)!}{(m-1)!\,(n-m)!}n^{n-m} = \binom{n-1}{m-1}n^{n-m}, \qquad \text{(A5)}
\end{aligned}
$$

which concludes the proof as the case $n=1$ is trivial.

APPENDIX B: TREE FORMALISM

Proof of Eq. (20) for $m=1$: First of all, by defining $\alpha=2\pi x$ and $u(\alpha)=2\pi g(x;K,\omega)$ (of course, besides α,u also depends on K and ω) one can write the functional relation that the function $u(\alpha)$ must satisfy as $u(\alpha)+(K/2i)\exp(i\alpha+iu(\alpha))=0$ for the SSM and $u(\alpha)+K\sin(\alpha+u(\alpha))=0$ for the SM. Note that in the case of the SSM the function u, which in principle depends on two parameters K and α (for a given ω), is in fact a function of the only parameter $\eta\equiv Ke^{i\alpha}$.

In terms of the function $u(\alpha)$ the functional equation (4) becomes, for the SM,

$$2u(\alpha) - u(\alpha + 2\pi\omega) - u(\alpha - 2\pi\omega) = -K \sin(\alpha + u(\alpha)), \tag{B1}$$

in which we recognize Eq. (1.4) of Ref. 6, with $\varepsilon = K$. For the SSM we have the same equation with the sine function replaced with $(2i)^{-1} \exp(i\alpha + iu(\alpha))$. Then we can envisage the same tree expansion as in Ref. 6; see formula (2.2), where, to make a relation with the notations we are using now, k and ν are what we are denoting with n and k, respectively. (In fact we need only p. 162 of the quoted reference, where the tree formalism is introduced.) Moreover $\gamma(\nu_{\ell_v}) = -D_{\nu_{\ell_v}}$, hence it is -1 in our case, and one has $\nu_v = 1$ for the SSM and $\nu_u \in \{\pm 1\}$ for the SM. At the end we find

$$\hat{h}_k^{(n)} = \frac{1}{2\pi i} \frac{(-1)^n}{2^n} \sum_{\vartheta \in \mathcal{T}_{n,k}} \mathrm{Val}(\vartheta), \quad \mathrm{Val}(\vartheta) = \prod_{u \in \vartheta} \frac{1}{m_u!} \nu_u^{m_u + 1}, \tag{B2}$$

where the trees ϑ, the branching numbers m_u and the set of trees $\mathcal{T}_{n,k}$ of order n (that is with n nodes) and with momentum k flowing through the root line (that is such that $\Sigma_{u \in \vartheta} \nu_u = k$) are defined as in Ref. 6. Extensions of notations to more general maps are easily obtained; see for instance Ref. 7.

In the case of the SSM, Eq. (B2) reduces to

$$\hat{h}_n^{(n)} = \frac{1}{2\pi i} \frac{(-1)^n}{2^n} \sum_{\vartheta \in \mathcal{T}_{n,n}} \mathrm{Val}(\vartheta), \quad \mathrm{Val}(\vartheta) = \prod_{u \in \vartheta} \frac{1}{m_u!}, \tag{B3}$$

as $\nu_u \equiv 1$, and the sum over trees of order n can be written as a sum over all possible configurations of branching numbers $\{m_u\}_{u \in \vartheta}$ with the constraint $\Sigma_{u \in \vartheta} m_u = n - 1$, indeed they are the only labels of the trees, and their values uniquely determine the elements of $\mathcal{T}_{n,n}$. Therefore we can rewrite $\hat{h}_n^{(n)}$ as

$$\hat{h}_n^{(n)} = \frac{1}{2\pi i} \frac{(-1)^n}{2^n} \sum_{m_1 + \cdots + m_n = n-1} \frac{1}{m_1 ! \cdots m_n!} = \frac{1}{2\pi i} \frac{(-1)^n}{2^n} \frac{n^{n-1}}{n!}, \tag{B4}$$

where we have used the multinomial theorem

$$\sum_{m_1 + \cdots + m_n = p} \frac{n!}{m_1 ! \ldots m_n!} x_1^{m_1} \cdots x_n^{m_n} = (x_1 + \cdots + x_n)^p, \tag{B5}$$

which extends the binomial theorem to $n > 2$; see Ref. 1, Sec 24.1.3.

Proof of Eq. (25): In the case of the SM, without small divisors, we can still use formula (B2), but now one can have $\nu_u = \pm 1$.

As $k = \Sigma_{u \in \vartheta} \nu_u$ we see that, first, k can assume only the values $-n, -n+2, -n+4, \ldots, n-4, n-2, n$ [so that, in particular, $(n \pm k)/2$ is even], and, second, in order to have a contribution to $\hat{h}_k^{(n)}$ we must set $(n-k)/2$ mode labels ν_u equal to -1 and the remaining $(n+k)/2$ mode labels equal to 1. Moreover for any tree $\vartheta \in \mathcal{T}_{n,k}$ we can write

$$\prod_{u \in \vartheta} \nu_u^{m_u + 1} = \left(\prod_{u \in \vartheta} \nu_u \right) \left(\prod_{u \in \vartheta} \nu_u^{m_u} \right) = (-1)^{(n-k)/2} \prod_{u \in \vartheta} \nu_u^{m_u}, \tag{B6}$$

which inserted into Eq. (B2) gives, by using again the multinomial theorem,

$$\begin{aligned} \hat{h}_k^{(n)} &= \frac{1}{2\pi i} \frac{(-1)^{n+(n-k)/2}}{2^n} \binom{n}{(n-k)/2} \sum_{m_1 + \cdots + m_n = n-1} \frac{\nu_1^{m_1} \cdots \nu_n^{m_n}}{m_1 ! \cdots m_n!} \\ &= \frac{1}{2\pi i} \frac{(-1)^{n+(n-k)/2}}{2^n} \frac{k^{n-1}}{((n-k)/2) ! \, ((n+k)/2)!}, \end{aligned} \tag{B7}$$

which yields Eq. (25).

(Received 20 May 2005; accepted 29 July 2005; published online 12 October 2005)

The most general Jacobi brackets in $\mathbb{R}^3$ are constructed after solving the equations imposed by the Jacobi identity. Two classes of Jacobi brackets were identified, according to the rank of the Jacobi structures. The associated Hamiltonian vector fields are also constructed. © *2005 American Institute of Physics.*

I. INTRODUCTION

Jacobi brackets have all properties of Poisson brackets, except from the fact that they are not necessarily derivations. A manifold endowed with a Jacobi bracket is called a Jacobi manifold. In this context, Jacobi manifolds are natural generalizations of Poisson, contact and locally conformal symplectic manifolds. Jacobi manifolds were introduced by Lichnerowicz[1] and, in a local Lie algebra setting, by Kirillov.[2] The general properties of Jacobi manifolds are discussed, for instance, in Refs. 3 and 4. Some recent advances on the study of Jacobi manifolds can be found in Refs. 5–16.

The present work is devoted to the explicit construction of Jacobi structures. Although contact and locally conformal symplectic manifolds are general concrete examples of Jacobi manifolds, there is a lack of knowledge of other possible classes of Jacobi brackets even for low dimensional manifolds. An exception in this regard is given by linear Jacobi structures on vector bundles.[17] This is to be compared with the Poisson manifolds case, where, in recent years, there has been much work for the explicit construction of Poisson structures, generalizing the well-known case of Lie-Poisson structures.[18–22] In particular, there have been intensive efforts in the derivation of new classes of three-dimensional Poisson structures, with application to three-dimensional dynamical systems.[23–31] More recently, Ay *et al.*[32] have found the general solution of the determining equation for Poisson structures in $\mathbb{R}^3$. The purpose of the present work is to extend this result, obtaining the general form of Jacobi structures in $\mathbb{R}^3$. Our approach is not applicable to generic three-dimensional manifolds.

The paper is organized as follows. In Sec. II, we briefly review the basic definitions about Jacobi manifolds. In Sec. III, we consider the specific case of Jacobi structures in $\mathbb{R}^3$. The determining equations for Jacobi brackets in $\mathbb{R}^3$ are obtained and solved. In Sec. IV, the associated Hamiltonian vector fields are discussed. Section V is reserved to our conclusions.

II. JACOBI MANIFOLDS

Here we review the essential results about Jacobi manifolds. More detailed accounts on the subject can be found in Refs. 1–4. By definition, a Jacobi structure on a manifold M is a 2-vector $\mathbf{\Lambda}$ and a vector field $\mathbf{E}$ on M such that

$$[\mathbf{\Lambda},\mathbf{\Lambda}] = 2\mathbf{E} \wedge \mathbf{\Lambda}, \quad [\mathbf{E},\mathbf{\Lambda}] = 0, \tag{1}$$

where $[,]$ is the Schouten-Nijenhuis bracket.[33] Let $C^\infty(M,\mathbb{R})$ be the algebra of C^∞ real-valued functions on M. If $(M,\mathbf{\Lambda},\mathbf{E})$ is a Jacobi structure, then the space $C^\infty(M,\mathbb{R})$ endowed with a

[a)]Electronic mail: ferhaas@unisinos.br

mapping $\{,\}: C^\infty(M,\mathbb{R})\times C^\infty(M,\mathbb{R})\to C^\infty(M,\mathbb{R})$ becomes a local Lie algebra in the sense of Kirillov.[2] This so-called Jacobi bracket $\{,\}$ is defined by

$$\{f,g\} = \mathbf{\Lambda}(\mathrm{d}f,\mathrm{d}g) + f\mathbf{E}(g) - g\mathbf{E}(f), \tag{2}$$

for all $f,g\in C^\infty(M,\mathbb{R})$. The Jacobi bracket is $\mathbb{R}$ bilinear, skew-symmetric, and satisfies the Jacobi identity. In other words,

$$\{c_1 f + c_2 g, h\} = c_1\{f,h\} + c_2\{g,h\},$$

$$\{f,g\} = -\{g,f\},$$

$$\{\{f,g\},h\} + \{\{g,h\},f\} + \{\{h,f\},g\} = 0, \tag{3}$$

for all $f,g,h\in C^\infty(M,\mathbb{R})$ and $c_1,c_2\in\mathbb{R}$. The local Lie algebra character of $C^\infty(M,\mathbb{R})$ is assured by

$$\text{support}\{f,g\}\subseteq \text{support } f\cap \text{support } g, \tag{4}$$

for all $f,g\in C^\infty(M,\mathbb{R})$.

In addition, the Jacobi bracket is a first-order differential operator in each of its arguments using ordinary multiplication of functions,

$$\{fg,h\} = f\{g,h\} + \{f,h\}g - fg\{1,h\}, \tag{5}$$

for all $f,g,h\in C^\infty(M,\mathbb{R})$. As apparent from (5), the Jacobi bracket is not a derivation unless the constant unit function has a vanishing Jacobi bracket with all functions in $C^\infty(M,\mathbb{R})$. It happens if and only if the vector field $\mathbf{E}$ vanish, $\mathbf{E}\equiv 0$. If $\mathbf{E}\equiv\mathbf{0}$, then $(M,\mathbf{\Lambda})$ is a Poisson manifold. In this sense, Jacobi manifolds are generalizations of Poisson manifolds. Examples of manifolds with Jacobi but not Poisson structures are contact and locally conformal symplectic manifolds.

As shown by Lichnerowicz,[1] any Jacobi structure $(M,\mathbf{\Lambda},\mathbf{E})$ can be associated to a higher-dimensional Poisson structure $(\mathbf{\Pi},M\times\mathbb{R})$, defined by

$$\mathbf{\Pi}(\mathbf{x},t) = \exp(-t)\left(\mathbf{\Lambda}(\mathbf{x}) + \frac{\partial}{\partial t}\wedge\mathbf{E}\right), \tag{6}$$

where (x,t) are local coordinates in $(\mathbf{\Pi},M\times\mathbb{R})$. While Eq. (6) provides a simple recipe to obtain a Poisson structure from a Jacobi structure in a lower-dimensional manifold, it is not trivial to construct a Jacobi structure in the manifold M itself. Hence the importance of deriving concrete examples of Jacobi structures in manifolds like $\mathbb{R}^3$, for instance.

In a local coordinate chart x^i, for $i=1,\ldots,n$ with $n=\dim M$, we have the following expressions for the tensor field $\mathbf{\Lambda}$, the vector field $\mathbf{E}$, and the Jacobi bracket of two functions f and g,

$$\mathbf{\Lambda} = \tfrac{1}{2}\Lambda^{ij}\partial_i\wedge\partial_j, \quad \mathbf{E} = E^i\partial_i,$$

$$\{f,g\} = \Lambda^{ij}\partial_i f\partial_j g + fE^i\partial_i g - gE^i\partial_i f. \tag{7}$$

The summation convention was used, as well as the notation $\partial_i = \partial/\partial x^i$. In addition, the Schouten-Nijenhuis bracket conditions (1) traduces into

$$\Lambda^{im}\partial_m\Lambda^{jk} + \Lambda^{jm}\partial_m\Lambda^{ki} + \Lambda^{km}\partial_m\Lambda^{ij} + \Lambda^{ij}E^k + \Lambda^{jk}E^i + \Lambda^{ki}E^j = 0, \tag{8}$$

$$E^k\partial_k\Lambda^{ij} - \Lambda^{ik}\partial_k E^j + \Lambda^{jk}\partial_k E^i = 0. \tag{9}$$

As can be verified, Eqs. (8) and (9) are completely equivalent to the Jacobi identity for the Jacobi bracket (2). In this context, we call (8) and (9) the Jacobi equations. The general solution for the Jacobi equations yields the general form of the Jacobi structures in $\mathbb{R}^n$. Ay *et al.* have solved the

Jacobi equations for $n=3$ and $\mathbf{E}=\mathbf{0}$, that is, the Poisson case in $\mathbb{R}^3$. In the next section we allow for nonvanishing vector fields $\mathbf{E}$, looking for the general class of Jacobi structures in $\mathbb{R}^3$.

III. JACOBI STRUCTURES IN $\mathbb{R}^3$

Consider the $\mathbb{R}^3$ case, introducing a vector field $\mathbf{A}=A^i\partial_i$ according to

$$\Lambda^{ij}=\varepsilon_{ijk}A^k, \tag{10}$$

using the Levi-Civita symbol ε_{ijk}. In other words, $\mathbf{A}=(\Lambda^{23},\Lambda^{31},\Lambda^{12})$. In terms of this vector field $\mathbf{A}$, the Jacobi equations (8) and (9) are rewritten as

$$\mathbf{A}\cdot(\nabla\times\mathbf{A}-\mathbf{E})=0, \tag{11}$$

$$\mathbf{E}\times(\nabla\times\mathbf{A})+\mathbf{A}\nabla\cdot\mathbf{E}=\nabla(\mathbf{A}\cdot\mathbf{E}), \tag{12}$$

using standard symbols of vector calculus in $\mathbb{R}^3$.

Using (11) and (12) we can proceed to construct Jacobi structures using the well-known language of vector calculus in $\mathbb{R}^3$. Before we do that, it is interesting to interpret geometrically equation (11). Consider $(M,\mathbf{\Lambda},\mathbf{E})$ a given Jacobi structure and let $\mathbf{\Lambda}^\sharp:T^*M\to TM$ be the vector bundle map associated with $\mathbf{\Lambda}$. In other words, for all $\mathbf{p}\in M,\zeta,\eta\in T_p^*M$,

$$\mathbf{\Lambda}(\zeta,\eta)=\langle\eta,\mathbf{\Lambda}^\sharp(\zeta)\rangle, \tag{13}$$

where $\langle,\rangle$ denotes the natural pairing. In terms of the vector field $\mathbf{A}$, the last equation shows that the image of the vector bundle map $\Lambda^\sharp$ is the plane orthogonal to $\mathbf{A}$. Taking into account (11), written as $\mathbf{A}\cdot\mathbf{E}=\mathbf{A}\cdot\nabla\times\mathbf{A}$, we conclude that the condition $\mathbf{A}\cdot\nabla\times\mathbf{A}\neq0$ would imply that the vector $\mathbf{E}$ does not belong to the image of $\mathbf{\Lambda}^\sharp$, or, in other words, that the rank of the Jacobi structure is everywhere 3. On the other hand, the condition $\mathbf{A}\cdot\nabla\times\mathbf{A}\equiv0$ would imply that the vector $\mathbf{E}$ takes its values in the image of $\mathbf{\Lambda}^\sharp$. Together with $\mathbf{A}\neq0$, that means that the rank of the Jacobi structure would be everywhere 2.

Now consider the calculation of Jacobi structures. For $\mathbf{A}\equiv0$, Eqs. (11) and (12) are identically satisfied for arbitrary $\mathbf{E}$, but this will not produce very interesting Jacobi structures. Disregarding the too trivial case $\mathbf{A}\equiv0$, we conclude that Eq. (11) is equivalent to

$$\mathbf{E}=\nabla\times\mathbf{A}-\mathbf{g}\times\mathbf{A}, \tag{14}$$

for some vector field $\mathbf{g}$ in $\mathbb{R}^3$, to be determined. The Poisson case $\mathbf{E}=\mathbf{0}$ is obtained for

$$\nabla\times\mathbf{A}=\mathbf{g}\times\mathbf{A}. \tag{15}$$

As shown by Ay and co-workers in a different notation,[32] the general solution for (15) is given by

$$\mathbf{A}=\mu\nabla\psi, \tag{16}$$

for $\mu,\psi\in C^\infty(\mathbb{R}^3,\mathbb{R})$. The solution (16) has shown to be valid[32] also in the neighborhood of some classes of irregular points, where $\mathbf{A}=\mathbf{0}$. The corresponding vector field $\mathbf{g}$ is given by

$$\mathbf{g}=\frac{\nabla\mu}{\mu}. \tag{17}$$

Returning to the not necessarily Poisson case and substituting the form (14) into (12), we get the following condition:

$$\nabla(\mathbf{A}\cdot\nabla\times\mathbf{A})=\mathbf{g}(\mathbf{A}\cdot\nabla\times\mathbf{A})-\mathbf{A}(\mathbf{A}\cdot\nabla\times\mathbf{g}). \tag{18}$$

In the remaining part of the section we examine the general solution for (18), thus determining the possible classes of Jacobi structures in $\mathbb{R}^3$. We consider two cases, according to the rank of the Jacobi structure.

A. Rank 3 Jacobi structures

Suppose

$$\mathbf{A}\cdot\nabla\times\mathbf{A}\neq 0. \tag{19}$$

In this situation, $(\mathbb{R}^3,\mathbf{\Lambda})$ is certainly not a Poisson structure, with 2-vector $\mathbf{\Lambda}$ specified by (10). However, we can construct Jacobi structures defining a vector field $\mathbf{h}$ such that

$$\mathbf{g}=\nabla\phi+\mathbf{h}, \tag{20}$$

for

$$\phi=\ln(\mathbf{A}\cdot\nabla\times\mathbf{A}). \tag{21}$$

Of course the function ϕ is not well defined unless $\mathbf{A}\cdot\nabla\times\mathbf{A}$ is not identically vanishing. Inserting (20) into (18), the result is

$$\mathbf{h}(\mathbf{A}\cdot\nabla\times\mathbf{A})-\mathbf{A}(\mathbf{A}\cdot\nabla\times\mathbf{h})=0. \tag{22}$$

The cross product of (22) with $\mathbf{A}$ gives

$$\mathbf{A}\times\mathbf{h}=\mathbf{0}\rightarrow\mathbf{h}=\alpha\mathbf{A}, \tag{23}$$

for an arbitrary real-valued function α on $\mathbb{R}^3$. We can take $\alpha\equiv 0$ without loss of generality, since, according to (14) and (20), this function will add nothing to the vector field $\mathbf{E}$. Hence, in the rank 3 case the determining equation (18) is solved for any vector field $\mathbf{A}$ satisfying $\mathbf{A}\cdot\nabla\times\mathbf{A}\neq 0$, taking $\mathbf{g}=\nabla\phi$ with ϕ given by (21). The corresponding vector field $\mathbf{E}$ follows from (14). After using some vector identities, the result is

$$\mathbf{E}=e^{\phi}\nabla\times(e^{-\phi}\mathbf{A}). \tag{24}$$

Using (2) and (10) and the above solution $\mathbf{E}$, we get the Jacobi bracket between any functions $f,g\in C^{\infty}(\mathbb{R}^3,\mathbb{R})$,

$$\{f,g\}=\mathbf{A}\cdot\nabla f\times\nabla g+e^{\phi}(f\nabla g-g\nabla f)\cdot\nabla\times(e^{-\phi}\mathbf{A}). \tag{25}$$

It takes a simpler form for $\phi=$constant, in which case

$$\{f,g\}=\mathbf{A}\cdot\nabla f\times\nabla g+(f\nabla g-g\nabla f)\cdot\nabla\times\mathbf{A}. \tag{26}$$

In conclusion, the Jacobi bracket (25) has three free ingredients, namely the three components of the vector field $\mathbf{A}$, as long as $\mathbf{A}\cdot\nabla\times\mathbf{A}$ is not identically null. For simplicity, we do not consider the behavior of the solution in the neighborhood of points into domains $\Omega\subset\mathbb{R}^3$ where $\mathbf{A}\cdot\nabla\times\mathbf{A}=0$.

On $\mathbb{R}^3$, rank 3 Jacobi structures are in one-to-one correspondence with contact 1-forms. Specifically, giving a contact 1-form θ on $\mathbb{R}^3$ such that $\theta\wedge\mathrm{d}\theta\neq 0$, there is a Jacobi structure $(\mathbb{R}^3,\mathbf{\Lambda},\mathbf{E})$ satisfying $\mathbf{\Lambda}\wedge\mathbf{E}\neq 0$ and $i_{\theta}(\mathbf{\Lambda})=0$, $i_{\mathbf{E}}(\theta)=1$. In the case of the rank 3 Jacobi structures of this section, using Cartesian coordinates we can show that

$$\mathbf{\Lambda}\wedge\mathbf{E}=\mathbf{A}\cdot\mathbf{E}\frac{\partial}{\partial x}\wedge\frac{\partial}{\partial y}\wedge\frac{\partial}{\partial z}=\mathbf{A}\cdot\nabla\times\mathbf{A}\frac{\partial}{\partial x}\wedge\frac{\partial}{\partial y}\wedge\frac{\partial}{\partial z}\neq 0. \tag{27}$$

Since $\mathbf{\Lambda}\wedge\mathbf{E}$ is nowhere zero, there is a contact 1-form θ associated to this Jacobi structure. It can be shown that

$$\theta=e^{-\phi}A^i\,\mathrm{d}x^i \tag{28}$$

satisfies

$$i_{\theta}(\mathbf{\Lambda})=-e^{-\phi}(\mathbf{A}\times\mathbf{A})\cdot\nabla=0, \tag{29}$$

$$i_{\mathbf{E}}(\theta) = e^{-\phi}\mathbf{A}\cdot(\nabla\times\mathbf{A}-\nabla\phi\times\mathbf{A}) = e^{-\phi}\mathbf{A}\cdot\nabla\times\mathbf{A} = 1, \tag{30}$$

the last equality following from the definition of ϕ. Moreover,

$$\theta\wedge \mathrm{d}\theta = e^{-\phi}\,\mathrm{d}x\wedge\mathrm{d}y\wedge\mathrm{d}z, \tag{31}$$

which never vanishes. Therefore, the 1-form θ given by (28) qualifies as the contact 1-form associated to rank 3 Jacobi structures in $\mathbb{R}^3$. As a corollary, we conclude that

$$\mathrm{d}\theta = e^{-\phi}(\partial_i A^j - A^j\partial_i\phi)\mathrm{d}x^i\wedge\mathrm{d}x^j \tag{32}$$

is a symplectic structure on the vector bundle $\ker\theta\to\mathbb{R}^3$ defined as the set of vector fields orthogonal to $\mathbf{A}$ at every point.

Another way to interpret the above construction is in terms of the characteristic distribution[2,3] of the Jacobi structure $(\mathbb{R}^3,\mathbf{\Lambda},\mathbf{E})$, defined as the subbundle D of $T(\mathbb{R}^3)$ spanned by the set of all Hamiltonian vector fields. In other words, $D_{\mathbf{p}}=\mathrm{Span}\{\mathbf{\Lambda}^{\sharp}(\zeta)(\mathbf{p}),\mathbf{E}(\mathbf{p}),\forall\,\zeta\in T^*(\mathbb{R}^3)\}$ is the fiber at a point $\mathbf{p}\in\mathbb{R}^3$. The characteristic distribution of a Jacobi structure is completely integrable, defining a foliation whose leaves are contact manifolds or locally conformal symplectic manifolds. The leaves of the foliation can be represented as the level sets of a function $f(x,y,z)$. In terms of the vector fields $\mathbf{A}$ and $\mathbf{E}$, the determining equations of the foliation are given by

$$\mathbf{A}\times\nabla f = 0, \tag{33}$$

$$\mathbf{E}\cdot\nabla f = 0. \tag{34}$$

For the rank 3 Jacobi structures of this section, inserting (24) into (34) and considering equation (33) gives

$$\nabla\times\mathbf{A}\cdot\nabla f = 0, \tag{35}$$

which is redundant since $\nabla\times\mathbf{A}\cdot\nabla f=\nabla\cdot(\mathbf{A}\times\nabla f)=0$ in virtue of (33). Hence, for rank 3 Jacobi structures in $\mathbb{R}^3$ the vector field $\mathbf{A}$ is always normal to the leaves of the foliation, as stated in (33).

B. Rank 2 Jacobi structures

For

$$\mathbf{A}\cdot\nabla\times\mathbf{A}\equiv 0, \tag{36}$$

the determining equation (18) simplifies to

$$\mathbf{A}\cdot\nabla\times\mathbf{g} = 0, \tag{37}$$

excluding the trivial case $\mathbf{A}=\mathbf{E}=\mathbf{0}$. As shown by Ay and co-workers,[32] the general solution for (36) is given in terms of two scalar functions μ and ψ, as in Eq. (16). Using (16), the Eq. (37) traduces into

$$\nabla\psi\cdot\nabla\times\mathbf{g} = \nabla\cdot(\mathbf{g}\times\nabla\psi) = 0, \tag{38}$$

showing that the vector field $\mathbf{g}\times\nabla\psi$ is solenoidal. Hence, there are real smooth functions ξ_1 and ξ_2 on $\mathbb{R}^3$ such that

$$\mathbf{g}\times\nabla\psi = \nabla\xi_1\times\nabla\xi_2 \tag{39}$$

in a neighborhood U of every regular point of $\mathbf{g}\times\nabla\psi$. We exclude the trivial case $\nabla\psi=0$.

Inversion of (39) gives

$$\mathbf{g} = \frac{\nabla\psi \times (\nabla\xi_1 \times \nabla\xi_2)}{|\nabla\psi|^2} + \alpha \nabla\, \psi, \tag{40}$$

where α is an arbitrary real-valued smooth function on $\mathbb{R}^3$ and

$$\nabla\psi \cdot \nabla\xi_1 \times \nabla\xi_2 = 0 \tag{41}$$

for consistency with (39). Equation (41) implies a functional dependence between ψ, ξ_1, and ξ_2,

$$\psi = \psi(\xi_1, \xi_2). \tag{42}$$

Since we have solved the determining equation (18), we can construct the vector field $\mathbf{E}$, using Eqs. (14), (16), and (40). This procedure gives

$$\mathbf{E} = \nabla\mu \times \nabla\psi - \mu \nabla\, \xi_1 \times \nabla\xi_2. \tag{43}$$

The corresponding Jacobi bracket reads

$$\{f,g\} = \mu \nabla\, \psi \cdot \nabla f \times \nabla g + (f \nabla\, g - g \nabla\, f) \cdot (\nabla\mu \times \nabla\psi - \mu \nabla\, \xi_1 \times \nabla\xi_2). \tag{44}$$

Notice that the real function α in (40) does not appear in the final form of the Jacobi bracket. Therefore, the Jacobi structure described by (44) has only four ingredients, namely μ, ξ_1, ξ_2, and $\psi(\xi_1, \xi_2)$.

The presence of the function μ in the Jacobi bracket can be eliminated by a conformal transformation. Indeed,[15] if $(M, \mathbf{\Lambda}, \mathbf{E})$ is a Jacobi structure in a manifold M, then $(M, \widetilde{\mathbf{\Lambda}}, \widetilde{\mathbf{E}})$ is also a Jacobi structure in M, where $\widetilde{\mathbf{\Lambda}}$ and $\widetilde{\mathbf{E}}$ are obtained from the conformal change

$$\widetilde{\mathbf{\Lambda}} = \lambda \mathbf{\Lambda}, \quad \widetilde{\mathbf{E}} = \lambda \mathbf{E} + \mathbf{\Lambda}^{\sharp}(\mathrm{d}\lambda), \tag{45}$$

for any $\lambda \in C^{\infty}(\mathbb{R}^3, \mathbb{R})$. Applying such a conformal transformation to everywhere rank 2 Jacobi structures in $\mathbb{R}^3$ using $\lambda = 1/\mu$ gives

$$\widetilde{\Lambda}^{ij} = \varepsilon_{ijk}\partial_k\psi, \quad \widetilde{E} = -\nabla\xi_1 \times \nabla\xi_2, \tag{46}$$

with no presence of the arbitrary function μ. However, this does not mean that μ is to be taken as irrelevant in applications for dynamical systems, for instance.

A Jacobi structure everywhere of rank 2 on $\mathbb{R}^3$ determines a foliation of $\mathbb{R}^3$ whose leaves are locally conformal symplectic surfaces.[2,3] Perhaps the simplest way to describe such a foliation is in terms of the characteristic distribution of the Jacobi structure, as follows from (33) and (34). Representing, as before, the leaves of the foliation as the level sets of a function $f(x,y,z)$ and using (16) and (43) in (34), we get

$$\mathbf{E} \cdot \nabla f = -\mu \nabla\, \xi_1 \times \nabla\xi_2 \cdot \nabla f \equiv 0, \tag{47}$$

showing that $f = f(\xi_1, \xi_2)$. When we insert this result into (33) with $\mathbf{A}$ given by (16), we conclude that

$$\frac{\partial\psi}{\partial\xi_1}\frac{\partial f}{\partial\xi_2} - \frac{\partial\psi}{\partial\xi_2}\frac{\partial f}{\partial\xi_1} = 0, \tag{48}$$

showing that f and ψ are functionally dependent. In conclusion, for rank 2 Jacobi structures in $\mathbb{R}^3$ there exists a locally conformal symplectic foliation whose leaves can be represented by the level sets of the function $\psi(x,y,z)$ entering the Jacobi bracket.

The degenerate character of rank 2 Jacobi structures in $\mathbb{R}^3$ allows to search for Casimir functions associated to the Jacobi bracket. These Casimir functions can be defined in analogy with the Casimir functions of degenerate Poisson manifolds. In other words, we define Casimir func-

tions as the nonconstant functions having a vanishing Jacobi bracket with any other function on $\mathbb{R}^3$. Let a Casimir function be denoted by $C=C(x,y,z)$. In terms of the vector fields **A** and **E**, we have

$$\{f,C\}=(\nabla C\times\mathbf{A}-C\mathbf{E})\cdot\nabla f+f\mathbf{E}(C)\equiv 0 \tag{49}$$

for an arbitrary smooth function $f\in C^{\infty}(\mathbb{R}^3,\mathbb{R})$. Since f is arbitrary, Eq. (49) is decomposed in two parts,

$$\nabla C\times\mathbf{A}=C\mathbf{E}, \tag{50}$$

$$\mathbf{E}(C)=0. \tag{51}$$

Observe that the Casimirs are preserved by the flow of the vector field **E**. In addition, notice that, for $C\neq 0$, Eq. (51) follows from (50) taking the scalar product with ∇C. Therefore, (50) is sufficient for the construction of the Casimirs.

For $C\neq 0$, scalar product of (50) with **A** implies

$$\mathbf{A}\cdot\mathbf{E}=0, \tag{52}$$

incidentally the condition for rank 2 Jacobi structures in $\mathbb{R}^3$. Therefore, nontrivial Casimirs can exist only in the case of rank 2 Jacobi structures, as expected. As will be explicitly shown in what follows, the condition (50) is not only necessary but also sufficient for the existence of nontrivial Casimirs.

Equation (50), written in terms of **A** as given in (16) and **E** as given in (43), reads, after some simple algebra considering $\mu\neq 0$,

$$\nabla\Gamma\times\nabla\psi=-\nabla\xi_1\times\nabla\xi_2, \tag{53}$$

where

$$\Gamma=\ln\left(\frac{C}{\mu}\right). \tag{54}$$

After solving (53) for Γ, the Casimirs follows trivially from (54).

Scalar product of (53) with $\nabla\Gamma$ gives

$$\nabla\Gamma\cdot\nabla\xi_1\times\nabla\xi_2=0, \tag{55}$$

showing that

$$\Gamma=\Gamma(\xi_1,\xi_2). \tag{56}$$

Inserting this information on the functional dependence of Γ in (50), we get

$$\left(\frac{\partial\Gamma}{\partial\xi_1}\frac{\partial\psi}{\partial\xi_2}-\frac{\partial\Gamma}{\partial\xi_2}\frac{\partial\psi}{\partial\xi_1}+1\right)\nabla\xi_1\times\nabla\xi_2=0. \tag{57}$$

Since this equation holds for arbitrary ξ_1, ξ_2, we conclude that

$$\frac{\partial\Gamma}{\partial\xi_1}\frac{\partial\psi}{\partial\xi_2}-\frac{\partial\Gamma}{\partial\xi_2}\frac{\partial\psi}{\partial\xi_1}=-1. \tag{58}$$

Equation (58) can be solved by the method of characteristics. The characteristic equations can be written as

$$\frac{\mathrm{d}\xi_1}{\partial\psi/\partial\xi_2} = -\frac{\mathrm{d}\xi_2}{\partial\psi/\partial\xi_1} = -\,\mathrm{d}\Gamma. \tag{59}$$

One of the characteristics is readily identified as $\psi(\xi_1,\xi_2)$. Without loss of generality, suppose $\partial\psi/\partial\xi_1 \neq 0$ in some neighborhood. Then, the inverse function theorem allows to consider $\xi_1 = \xi_1(\xi_2;\psi)$, written locally as a function of ξ_2 and ψ. This allows writing the general solution for (58) according to

$$\Gamma = \int_{\xi_1=\xi_1(\xi_2;\psi)} \frac{\mathrm{d}\xi_2}{\partial\psi/\partial\xi_1} + \bar{\Gamma}(\psi), \tag{60}$$

where $\bar{\Gamma}$ is an arbitrary function of the indicated argument.

Equation (60), together with (54), provides a recipe to compute the Casimirs of a given rank 2 Jacobi structure in $\mathbb{R}^3$. Perhaps it would be interesting to provide a concrete example of the procedure. Consider a rank 2 Jacobi structure in $\mathbb{R}^3$ defined by

$$\xi_1 = x, \quad \xi_2 = y, \quad \psi = x^2 + y^2, \quad \mu = 1. \tag{61}$$

With (60) and then (54), we obtain the Casimirs in the form

$$C = \bar{C}(r^2)e^{\theta/2}, \tag{62}$$

using cylindrical coordinates and defining

$$\bar{C}(\psi) = e^{\bar{\Gamma}(\psi)}. \tag{63}$$

In addition, we observe that in this case the leaves of the foliation of $\mathbb{R}^3$ in locally conformal symplectic surfaces are given by the cylinders defined by $\psi = x^2 + y^2 = \text{constant}$.

In the next section, we discuss the Hamiltonian vector fields associated to the two types of Jacobi structures derived.

IV. HAMILTONIAN VECTOR FIELDS ASSOCIATED TO JACOBI STRUCTURES IN $\mathbb{R}^3$

For a function $H \in C^\infty(M,\mathbb{R})$, the Hamiltonian vector field $\mathbf{v}_H$ associated with H is defined by[1]

$$\mathbf{v}_H = \mathbf{\Lambda}^\sharp(\mathrm{d}H) + H\mathbf{E}. \tag{64}$$

In this context, the function H is said to be the Hamiltonian for the vector field $\mathbf{v}_H$. In particular,

$$\mathbf{v}_1 = \mathbf{E}, \tag{65}$$

that is, the unit function $H=1$ is a Hamiltonian associated to any vector field $\mathbf{E}$. In this sense, any dynamical system in a manifold M can be viewed as a Hamiltonian system with Jacobi structure given by Hamiltonian function $H=1$, vector field $\mathbf{E}$ being the dynamical vector field itself and tensor field $\mathbf{\Lambda} \equiv 0$. In addition,

$$\mathbf{v}_{\{f,g\}} = [\mathbf{v}_f, \mathbf{v}_g], \tag{66}$$

for any $f,g \in C^\infty(M,\mathbb{R})$, so that the mapping which associates a function with the corresponding Hamiltonian vector field is a Lie algebra homomorphism. Finally, notice that the Hamiltonian is not always a constant of motion, even if time independent. In fact, for a time-independent Hamiltonian function,

$$\frac{\mathrm{d}H}{\mathrm{d}t} = H\mathbf{E}(H). \tag{67}$$

Hence, H is a constant of motion if and only if it is preserved by the flow associated to the vector field $\mathbf{E}$.

In a local coordinate chart x^i, for $i=1,\ldots,n$ with $n=\dim M$, the Hamiltonian vector field at (64) and the corresponding Hamilton equations in M are then

$$\dot{x}^i = v_H^i = \Lambda^{ij}\partial_j H + HE^i, \tag{68}$$

where $\mathbf{v}_H = v_H^i \partial_i$. For $\mathbb{R}^3$ and in terms of the vector field $\mathbf{A}$, the result is

$$\dot{\mathbf{r}} = \nabla H \times \mathbf{A} + H\mathbf{E}, \tag{69}$$

where $\mathbf{r}=(x,y,z)$. The expression (69) can be used to compute the Hamiltonian vector fields associated to the Jacobi structures of Sec. III. The two classes of Jacobi structures are treated separately.

A. Hamiltonian vector fields associated to rank 3 Jacobi structures

The class of Jacobi structures described in Sec. III A yields the following Hamilton equations, taking $\mathbf{E}$ as in (24):

$$\dot{\mathbf{r}} = \nabla \times (H\mathbf{A}) + H\mathbf{A} \times \nabla\phi, \tag{70}$$

with Hamiltonian H and ϕ as in (21).

At first sight, it appears that a simple rescaling $\mathbf{A} \to \bar{\mathbf{A}} = H\mathbf{A}$ would be sufficient to incorporate H into the new vector field $\bar{\mathbf{A}}$, eliminating one irrelevant function. However, the dependence of ϕ on $\mathbf{A}$ prevents this possibility. Indeed, consider $\bar{\mathbf{A}}$ and $\bar{\phi}$ given by

$$\bar{\mathbf{A}} = H\mathbf{A}, \quad \bar{\phi} = \ln(\bar{\mathbf{A}} \cdot \nabla \times \bar{\mathbf{A}}). \tag{71}$$

With these definitions, (70) reads

$$\dot{\mathbf{r}} = \nabla \times \bar{\mathbf{A}} + \bar{\mathbf{A}} \times \nabla\bar{\phi} + 2\frac{\nabla H}{H} \times \bar{\mathbf{A}}. \tag{72}$$

The last term in (72) is H dependent. Therefore, we are left with a dynamical system (70) determined by four functions, namely the three components of $\mathbf{A}$ and the Hamiltonian function H.

Among the whole class (70), an interesting subclass is provided by the choices

$$\nabla \times \mathbf{A} = \lambda\mathbf{A}, \quad H = 1, \tag{73}$$

where $\lambda \in C^\infty(\mathbb{R}^3, \mathbb{R})$ is an arbitrary smooth function. With the choice (73), we get

$$\dot{\mathbf{r}} = \lambda\mathbf{A} + \mathbf{A} \times \nabla\phi, \tag{74}$$

so that the Hamiltonian vector field is immediately decomposed into a parallel and a perpendicular part to the vector field $\mathbf{A}$.

As seen in (73), $\mathbf{A}$ is in the class of the force free vector fields.[34] For instance, a force free field is given by the Arnold-Beltrami-Childress (ABC) vector field,

$$\mathbf{A} = (a\sin z + c\cos y, b\sin x + a\cos z, c\sin y + b\cos x), \tag{75}$$

for a,b,c real nonnegative parameters. In this case, $\lambda=1$. The ABC flow is known to be generically nonintegrable. For instance, for $a=b=c$ there is even an analytic proof of nonintegrability.[35] Inserting (75) into (74), we would obtain a perturbed ABC flow endowed with a Jacobi bracket structure. It would be interesting to investigate the integrability properties of such a system.

To conclude, notice that the dynamical vector field v_H associated to (70) is not necessarily solenoidal, because

$$\nabla \cdot \mathbf{v}_H = \nabla\phi \cdot \nabla \times (H\mathbf{A}), \tag{76}$$

an expression which may be nonvanishing.

B. Hamiltonian vector fields associated to rank 2 Jacobi structures

The class of Jacobi structures described in Sec. III B yields the following Hamilton equations:

$$\dot{\mathbf{r}} = \nabla(\mu H) \times \nabla\psi - \mu H \nabla\, \xi_1 \times \nabla\xi_2. \tag{77}$$

Without any loss of generality, for this class of dynamical systems we can set $H=1$, thanks to the rescaling $\mu \to \mu H$. Hence, we adopt the choice $H=1$ in the following. The dynamical system (77) contains four free functions, namely μ, ξ_1, ξ_2, and $\psi(\xi_1, \xi_2)$.

Notice that ψ is a constant of motion if time independent, because

$$\frac{\mathrm{d}\psi}{\mathrm{d}t} = -\,\mu\, \nabla\, \psi \cdot \nabla\xi_1 \times \nabla\xi_2 = 0. \tag{78}$$

Therefore, to obtain a Hamiltonian description of a dynamical system in $\mathbb{R}^3$ using a Jacobi structure of the extended Poisson type, one must know a first integral. This is a most restrictive condition, in comparison with the case of the preceding section.

Using (50) and (51) and taking $H=1$, one can show that the Casimirs of the rank 2 Jacobi structures in $\mathbb{R}^3$ are preserved by the flow of the associated Hamiltonian vector field,

$$\mathbf{v}_H(C) = 0, \tag{79}$$

where C is any Casimir function. Since one can readily derive all Casimirs from the recipe described by Eqs. (54) and (60), we conclude that a constant of motion ψ plus a rank 2 Jacobi structure amounts to complete integrability, with the corresponding time-independent constants of motion being ψ and C.

To conclude, we observe that the Hamiltonian vector field $\mathbf{v}_H$ associated to (77) (with $H=1$) is not necessarily solenoidal,

$$\nabla \cdot \mathbf{v}_H = -\,\nabla\mu \cdot \nabla\xi_1 \times \nabla\xi_2, \tag{80}$$

which may be nonvanishing.

V. CONCLUSION

The two admissible classes of Jacobi structures in $\mathbb{R}^3$ were constructed. For simplicity, neighborhood of points into domains $\Omega \subset \mathbb{R}^3$ where the vector field $\mathbf{A}$ vanish were not considered. In this sense the results of the work are not completely general.

One of the reasons why Poisson structures are so ubiquitous rests in their applications for dynamical systems.[18–32] Certainly Jacobi structures have not been already applied at the same level in connection with dynamical systems. The results of Sec. IV shows the possible classes of Hamiltonian vector fields endowed with Jacobi structures in $\mathbb{R}^3$. This is a first step towards a more detailed examination of the possibilities opened by Jacobi structures for dynamical systems. For instance, one can ask about the existence of some kind of energy Casimir method for Hamiltonian systems on Jacobi manifolds. In addition, notice that the inverse problem of the construction of a nontrivial Jacobi bracket associated to a given dynamical system was not considered here. This seems to be a difficult task. For instance, due to the dependence of the ϕ function on $\mathbf{A}$, the equation (70) is a nonlinear equation for $\mathbf{A}$ for a given dynamical vector field. However, the class of Hamiltonian equations in Sec. IV A is possibly more interesting for applications, since one does not need to obtain a first integral for it. In contrast, the Hamiltonian description in Sec. IV B must be constructed in terms of a function ψ which was shown to be a first integral for the dynamical system, if $\partial\psi/\partial t = 0$. Therefore, it is more difficult to derive Jacobi structures of the type in Sec. IV B, considering nonintegrable dynamical systems in $\mathbb{R}^3$.

Recently, there has been interest on Leibniz manifolds,[36] that is, manifolds endowed with brackets satisfying the derivation property but not necessarily the Jacobi identity. These Leibniz manifolds provide another possible alternative to generalize Poisson manifolds. It would be interesting to extend the results of the present work to Leibniz structures in $\mathbb{R}^3$.

Wigner-Moyal description of free variable mass Klein-Gordon fields

J. P. Santos and L. O. Silva[a)]
GoLP/Centro de Física dos Plasmas, Instituto Superior Técnico, 1049-001 Lisboa, Portugal

(Received 4 May 2005; accepted 12 August 2005; published online 19 October 2005)

A system of coupled kinetic transport equations for the Wigner distributions of a free variable mass Klein-Gordon field is derived. This set of equations is formally equivalent to the full wave equation for electromagnetic waves in nonlinear dispersive media, thus allowing for the description of broadband radiation-matter interactions and the associated instabilities. The standard results for the classical wave action are recovered in the short wavelength limit of the generalized Wigner-Moyal formalism for the wave equation. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2049169]

I. INTRODUCTION

The Wigner-Moyal formalism provides an alternative formulation for nonrelativistic Quantum Mechanics, where the wave function is replaced by a quasiparticle distribution function, the Wigner distribution, in phase space, which evolves in time according to a transport equation for the Wigner-Moyal distribution.[1] One of the main advantages of the Wigner-Moyal formalism is the possibility to describe quantum fields with nontrivial statistical properties.[2]

Since the evolution of electromagnetic waves can be described, in the paraxial approximation, by a Schrödinger-like equation it is not surprising that the Wigner-Moyal formalism has been used to describe waves propagating in an inhomogeneous, dispersive, anisotropic and slowly varying in time medium.[3] However, the propagation of electromagnetic waves is, in general, a two mode problem as clearly stated by the second-order time derivative in the wave equation for electromagnetic waves in any medium.[4] Previous works[5] have only dealt with the single mode problem, formally equivalent to propagating a nonlinear Schrödinger-like field, but this approach clearly breaks down when backscattering of the field is an important ingredient for the full dynamics of the system, as it usually occurs in laser/radiation-matter interactions at high intensities.

In this paper, we build an alternative description for the propagation of electromagnetic waves in dispersive and nonlinear media, capable of capturing both forward and backscattering dynamics of the electromagnetic waves, by generalizing the work developed by Javanainen *et al.*[6] to a variable mass problem. In the short wavelength approximation the results regarding the classical wave action (e.g., Ref. 7) are recovered.

We first construct a 2×2 Wigner matrix[6] on the basis of the Hamiltonian form of the Klein-Gordon equation of a charged scalar particle field, introduced by Feshbach and Villars.[8] The diagonal elements describe forward and backward photon densities and off-diagonal elements correspond to cross-densities in phase space. In the corresponding quantum problem, the mass is assumed to be fixed;[6] here a further generalization is performed in order to study the variable mass problem, since the response of the medium (in our case, a cold plasma) exhibits spatial and temporal dependencies. The motivation of this approach is to develop the relativistic phase-space description of the dynamics of Klein-Gordon particles analogously to the Hamiltonian description used earlier by Bialynichi-Birula, Górnicki, and Rafelski for the Dirac particles.[9] The advantage of

[a)]Electronic mail: luis.silva@ist.utl.pt

this method, compared with the manifestly covariant descriptions of Ref. 10, is that a single time parameter is used to describe the dynamics; as a result, the phase space is a genuine dynamical system with its fully prescribed dynamics, and its conservation laws.

In order for the discussion to be self-contained, a brief outline of the Feshbach and Villars Hamiltonian formulation for the Klein-Gordon equation is given in Sec. II, along with the definition of the 2×2 Wigner matrix. In Sec. III, we present the derivation of the generalized Boltzmann-Vlasov equation of motion for the Wigner matrix, and the set of coupled equations for the four real phase-space densities, which are related to the diagonal and cross-densities of the Klein-Gordon particles and their antiparticles, are derived. A physical interpretation of the phase-space densities is provided. In Sec. IV the short wavelength approximation of the Boltzmann-Vlasov equation of motion for the Wigner matrix is performed, and the well-known results of the classical wave action (e.g., Ref. 7 and references therein) are recovered. Finally, in Sec. V, we state our conclusions.

II. THE FESHBACK-VILLARS FORMALISM FOR ELECTROMAGNETIC WAVES AND THE WIGNER MATRIX

The propagation of an electromagnetic wave in a dispersive medium is described by the Klein-Gordon equation:[4]

$$\varepsilon^2\partial_t^2\Phi - \varepsilon^2 c^2\vec{\nabla}_{\mathbf{r}}^2\Phi + \omega_p^2(\mathbf{r},t)\Phi = 0. \tag{1}$$

Here, Φ stands for one of the spatial components of the vector potential, in the Coulomb gauge, and c is the speed of light in vacuum. The CGS system of units is assumed throughout the paper, except where explicitly noted. We observe that ω_p plays the role of the mass of the Klein-Gordon field. For a cold plasma $\omega_p(\mathbf{r},t)$ is the electron plasma frequency, a function of time and space, given by $\omega_p(\mathbf{r},t)=(4\pi e^2 n_e/m_e\gamma)^{1/2}$ where e is the electron charge, m_e is the electron mass, $n_e(\Phi(\mathbf{r},t),\mathbf{r},t)$ is the electron density in the plasma, and $\gamma(\Phi(\mathbf{r},t),\mathbf{r},t)$ is the relativistic Lorentz factor of the plasma electrons. The electron plasma frequency can be an arbitrary function of both time and space, and it may be a source of nonlinearity.[11] Equivalently, Eq. (1) is also the starting point for nonlinear optics,[12] which traditionally uses the index of refraction instead of ω_p to describe the properties of the media.

A distinguishing feature of this problem is the presence of a positive dimensionless parameter ε. This parameter can be taken inversely proportional to the scale size of the spatial inhomogeneities, being small, but finite, for a slowing varying medium. We stress that our discussion is valid for $\varepsilon=1$, which corresponds to the usual wave equation. The inclusion of this small parameter will allow us to easily perform the analysis in the short-wavelength limit in Sec. IV.

To find the Hamiltonian form of Eq. (1), we follow the Feshbach-Villars[8] description, defining

$$\phi,\chi = \frac{1}{2}\left(\Phi \pm \frac{i\varepsilon}{\omega_{p0}}\partial_t\Phi\right), \tag{2}$$

where ω_{p0}^2 is the background electron plasma frequency, independent of time and space, such that $\omega_p^2(\mathbf{r},t)=\omega_{p0}^2+\tilde{\omega}_p^2(\mathbf{r},t)$. Equation (1) can then be written as

$$i\varepsilon\partial_t\phi = -\frac{\varepsilon^2 c^2}{2\omega_{p0}}\vec{\nabla}_{\mathbf{r}}^2(\phi+\chi) + \frac{\tilde{\omega}_p^2}{2\omega_{p0}}(\phi+\chi) + \omega_{p0}\phi, \tag{3a}$$

$$i\varepsilon\partial_t\chi = \frac{\varepsilon^2 c^2}{2\omega_{p0}}\vec{\nabla}_{\mathbf{r}}^2(\phi+\chi) - \frac{\tilde{\omega}_p^2}{2\omega_{p0}}(\phi+\chi) - \omega_{p0}\chi. \tag{3b}$$

There are several ways of separating Eq. (1) in two coupled equations, respecting definitions (2). Equation (3) denotes the correct expansion for the scalar potential, $\tilde{\omega}_p^2$, and guarantees, unlike the prescription proposed in Ref. 6, that the short wavelength limit leads to the standard classical wave action conservation, as shown in Sec. IV.

If we now introduce Ψ, the two-component vector potential, as

$$\Psi = \begin{bmatrix} \phi \\ \chi \end{bmatrix}, \tag{4}$$

Eq. (3) can be rewritten as

$$i\varepsilon\partial_t\Psi = \frac{(\tau_3 + i\tau_2)}{2\omega_{p0}}(-\varepsilon^2 c^2\vec{\nabla}_{\mathbf{r}}^2 + \tilde{\omega}_p^2)\Psi + \omega_{p0}\tau_3\Psi = \mathcal{H}_m\Psi, \tag{5}$$

where $\mathcal{H}_m$ is the Hamiltonian matrix. In Eq. (5), and henceforth, the notation

$$\tau_0 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad \tau_1 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

$$\tau_2 = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}, \quad \tau_3 = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \tag{6}$$

is used to represent the Pauli matrices.

Equation (5) is a Schrödinger-like equation. Thus, the usual Wigner formalism can be applied to a 2×2 igner matrix, instead of using the Wigner formalism on a scalar function. Defining the 2×2 Wigner matrix using the Feshbach-Villars representation:[6]

$$W(\mathbf{k},\mathbf{r},t) \equiv \left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} d\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}\Psi(\mathbf{r}_-,t)\overline{\Psi}(\mathbf{r}_+,t), \tag{7}$$

where $\overline{\Psi} = \Psi^\dagger\tau_3$ denotes the Feshbach-Villars adjoint of the vector potential Ψ, $\mathbf{r}_\pm = \mathbf{r} \pm \mathbf{y}/2$, and $\mathbb{R}^3$ the usual three-dimensional Cartesian space. By construction, W is an Hermitian matrix in the Feshbach-Villars sense, namely $\overline{W} \equiv \tau_3 W^\dagger \tau_3 = W$, and its explicit form can be expressed in terms of the field components ϕ and χ, yielding

$$W = \begin{bmatrix} W_{\phi\phi} & -W_{\phi\chi}^* \\ W_{\phi\chi} & -W_{\chi\chi} \end{bmatrix}, \tag{8}$$

where

$$W_{\phi\phi} = \left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} d\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}\phi^*(\mathbf{r}_+,t)\phi(\mathbf{r}_-,t), \tag{9a}$$

$$W_{\phi\chi} = \left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} d\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}\phi^*(\mathbf{r}_+,t)\chi(\mathbf{r}_-,t), \tag{9b}$$

$$W_{\chi\chi} = \left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} d\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}\chi^*(\mathbf{r}_+,t)\chi(\mathbf{r}_-,t). \tag{9c}$$

It is useful to calculate the equation governing the time evolution of $\overline{\Psi}$. Taking the conjugate transpose of Eq. (5), and multiplying on the right by τ_3, we obtain

$$i\varepsilon\partial_t\overline{\Psi} = -\overline{\Psi}\frac{(\tau_3 + i\tau_2)}{2\omega_{p0}}(-\varepsilon^2 c^2\overleftarrow{\nabla}_{\mathbf{r}}^2 + \tilde{\omega}_p^2) - \overline{\Psi}\tau_3\omega_{p0} = -\overline{\Psi}\mathcal{H}_m, \tag{10}$$

where we used $\tau_i^\dagger = \tau_i, i \in \{0,1,2,3\}$ and $\{\tau_i, \tau_j\} = 2\tau_0\delta_{ij}$, $i,j \in \{1,2,3\}$. Equation (10) demonstrates that the Hamiltonian matrix is not Hermitian. As a consequence the transport equation for the Wigner matrix will have to include both commutators and anticommutators.

III. GENERALIZED BOLTZMANN-VLASOV EQUATION OF MOTION

The equation of motion for the Wigner matrix (7), can be derived from the Schrödinger-type equations (5) and (10) for, respectively, $\Psi(\mathbf{r}_-,t)$ and $\overline{\Psi}(\mathbf{r}_+,t)$, following a standard procedure.[13]

From Eqs. (5), (7), and (10) we obtain

$$\partial_t W(\mathbf{k},\mathbf{r},t) = \mathcal{R}_1 + \mathcal{R}_2 - \frac{i}{\varepsilon}\omega_{p0}[\tau_3, W], \tag{11}$$

where

$$\partial_t W(\mathbf{k},\mathbf{r},t) = \left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} \mathrm{d}\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}[\partial_t \Psi(\mathbf{r}_-,t)\overline{\Psi}(\mathbf{r}_+,t) + \Psi(\mathbf{r}_-,t)\partial_t\overline{\Psi}(\mathbf{r}_+,t)], \tag{12a}$$

$$\mathcal{R}_1 = \frac{i\varepsilon c^2}{\omega_{p0}}\left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} \mathrm{d}\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}\left\{(\tau_3 + i\tau_2)\left[\frac{\vec{\nabla}_{\mathbf{r}}^2}{2}\Psi(\mathbf{r}_-,t)\right]\overline{\Psi}(\mathbf{r}_+,t) - \Psi(\mathbf{r}_-,t)\left[\frac{\vec{\nabla}_{\mathbf{r}}^2}{2}\overline{\Psi}(\mathbf{r}_+,t)\right](\tau_3 + i\tau_2)\right\}, \tag{12b}$$

$$\mathcal{R}_2 = \frac{i}{2\varepsilon\omega_{p0}}\left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} \mathrm{d}\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}[\Psi(\mathbf{r}_-,t)\overline{\Psi}(\mathbf{r}_+,t)(\tau_3 + i\tau_2)\widetilde{\omega}_{p_+}^2 - (\tau_3 + i\tau_2)\widetilde{\omega}_{p_-}^2\Psi(\mathbf{r}_-,t)\overline{\Psi}(\mathbf{r}_+,t)], \tag{12c}$$

where $\widetilde{\omega}_{p_\pm}^2 = \widetilde{\omega}_p^2(\mathbf{r}_\pm,t)$. Note that $[A,B]$ represents the usual commutator between operator A and B, and that we also used the following identities:

$$\vec{\nabla}_{\mathbf{r}_\pm} g(\mathbf{r}_\pm,t) = \vec{\nabla}_{\mathbf{r}} g(\mathbf{r}_\pm,t) = \pm 2\vec{\nabla}_{\mathbf{y}} g(\mathbf{r}_\pm,t), \tag{13}$$

where $g(\mathbf{r},t)$ stands for a first-order differentiable function of $\mathbf{r}$, and an arbitrary function of t.

The first term on the right-hand side of Eq. (11), $\mathcal{R}_1$, is the kinetic contribution for the equation of motion, and it is always present, independently of the potential $\widetilde{\omega}_p^2(\mathbf{r},t)$, whereas the second term, $\mathcal{R}_2$, accounts for the potential contribution. After some lengthy calculations $\mathcal{R}_1$ can also be written as

$$\mathcal{R}_1 = -\frac{c^2\mathbf{k}\cdot\vec{\nabla}_{\mathbf{r}}}{2\omega_{p0}}\{\tau_3 + i\tau_2, W\} - \frac{i}{\varepsilon}[\mathcal{H}_0(\mathbf{k})(\tau_3 + i\tau_2), W] + \mathcal{Q}, \tag{14}$$

where

$$\mathcal{H}_0(\mathbf{k}) = \frac{c^2}{\omega_{p0}}\mathbf{k}^2, \tag{15a}$$

$$\mathcal{Q} = -2\frac{i\varepsilon c^2}{\omega_{p0}}\left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} \mathrm{d}\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}[(\tau_3 + i\tau_2)\vec{\nabla}_{\mathbf{y}}\Psi(\mathbf{r}_-,t)\cdot\vec{\nabla}_{\mathbf{y}}\overline{\Psi}(\mathbf{r}_+,t) - \vec{\nabla}_{\mathbf{y}}\Psi(\mathbf{r}_-,t)\cdot\vec{\nabla}_{\mathbf{y}}\overline{\Psi}(\mathbf{r}_+,t)(\tau_3 + i\tau_2)] \tag{15b}$$

and $\{A,B\}$ represents the usual anticommutator. Consequently, the equation of motion already denotes the effects of the non-Hermiticity of the Hamiltonian $\mathcal{H}_m$, as previously noted.

The form of Eq. (15b) suggests that a second-order derivative in space, and a commutator must be involved; in fact, $\mathcal{Q}$ can be rewritten as

$$\mathcal{Q} = \frac{i\varepsilon c^2}{\omega_{p0}}\left[(\tau_3 + i\tau_2)\frac{\vec{\nabla}_{\mathbf{r}}^2}{8}, W\right] + \frac{i}{\varepsilon}\left[\frac{1}{2}\mathcal{H}_0(\hat{\mathbf{k}})(\tau_3 + i\tau_2), W\right] \tag{16}$$

leading to

$$\mathcal{R}_1 = -\frac{c^2\mathbf{k}\cdot\vec{\nabla}_{\mathbf{r}}}{2\omega_{p0}}\{\tau_3 + i\tau_2, W\} - \frac{i}{\varepsilon}\left[\frac{1}{2}\mathcal{H}_0(\hat{\mathbf{k}})(\tau_3 + i\tau_2), W\right] \tag{17}$$

with the generalized wave number $\hat{\mathbf{k}}^2 = \mathbf{k}^2 - \varepsilon^2\vec{\nabla}_{\mathbf{r}}^2/4$

To calculate $\mathcal{R}_2$, we observe first that the inverse Fourier transform of the Wigner matrix (7) yields the vector potential matrix $\Psi(\mathbf{r}_+, t)\overline{\Psi}(\mathbf{r}_-, t)$, viz.:

$$\Psi(\mathbf{r}_+, t)\overline{\Psi}(\mathbf{r}_-, t) = \int_{\mathbb{R}^3} \mathrm{d}\mathbf{k}' e^{-i(\mathbf{k}'\cdot\mathbf{y})/\varepsilon} W(\mathbf{k}', \mathbf{r}, t). \tag{18}$$

Combining Eq. (18) and Eq. (12c) leads to

$$\mathcal{R}_2 = \frac{i}{2\varepsilon\omega_{p0}}\left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3}\mathrm{d}\mathbf{k}' \int_{\mathbb{R}^3}\mathrm{d}\mathbf{y} e^{i[(\mathbf{k}-\mathbf{k}')\cdot\mathbf{y}]/\varepsilon}[W(\mathbf{k}', \mathbf{r}, t)(\tau_3 + i\tau_2)\tilde{\omega}_{p_+}^2 - (\tau_3 + i\tau_2)W(\mathbf{k}', \mathbf{r}, t)\tilde{\omega}_{p_-}^2]. \tag{19}$$

Since $\tilde{\omega}_{p_\pm}^2 = e^{\pm i\mathbf{y}/2i\cdot\vec{\nabla}_{\mathbf{r}}}\tilde{\omega}_p^2(\mathbf{r}, t)$, and in the case of a sufficient regular function g:[13]

$$\int_{-\infty}^{+\infty} e^{iyk'} g(iy)F(k')\mathrm{d}k' = \int_{-\infty}^{+\infty} e^{iyk'} g\left(-\frac{\partial}{\partial k'}\right)F(k')\mathrm{d}k'. \tag{20}$$

Thus, $\mathcal{R}_2$ can be expressed as

$$\mathcal{R}_2 = \frac{i\tilde{\omega}_p^2(\mathbf{r}, t)}{2\varepsilon\omega_{p0}}\cos\left(\frac{\varepsilon}{2}\overleftarrow{\nabla}_{\mathbf{r}}\cdot\vec{\nabla}_{\mathbf{k}}\right)[W, (\tau_3 + i\tau_2)] + \frac{\tilde{\omega}_p^2(\mathbf{r}, t)}{2\varepsilon\omega_{p0}}\sin\left(\frac{\varepsilon}{2}\overleftarrow{\nabla}_{\mathbf{r}}\cdot\vec{\nabla}_{\mathbf{k}}\right)\{W, (\tau_3 + i\tau_2)\}. \tag{21}$$

Combining Eqs. (17) and (21) in Eq. (11), the generalized Boltzmann-Vlasov equation of motion for the Wigner matrix is

$$\partial_t W(\mathbf{k}, \mathbf{r}, t) + (\hat{D} - \hat{S})\tfrac{1}{2}\{\tau_3 + i\tau_2, W(\mathbf{k}, \mathbf{r}, t)\} + \frac{i}{\varepsilon}[\mathcal{H}_0(\hat{\mathbf{k}}) + \hat{C}]\frac{1}{2}[(\tau_3 + i\tau_2), W(\mathbf{k}, \mathbf{r}, t)] + \frac{i\omega_{p0}}{\varepsilon}[\tau_3, W(\mathbf{k}, \mathbf{r}, t)] = 0, \tag{22}$$

where

$$\hat{D} = \frac{c^2}{\omega_{p0}}\mathbf{k}\cdot\vec{\nabla}_{\mathbf{r}}, \quad \hat{S} = \frac{\tilde{\omega}_p^2(\mathbf{r}, t)}{\varepsilon\omega_{p0}}\sin\left(\frac{\varepsilon}{2}\overleftarrow{\nabla}_{\mathbf{r}}\cdot\vec{\nabla}_{\mathbf{k}}\right), \quad \hat{C} = \frac{\tilde{\omega}_p^2(\mathbf{r}, t)}{\omega_{p0}}\cos\left(\frac{\varepsilon}{2}\overleftarrow{\nabla}_{\mathbf{r}}\cdot\vec{\nabla}_{\mathbf{k}}\right). \tag{23}$$

In the argument of the trigonometric functions, the operator $\overleftarrow{\nabla}_{\mathbf{r}}$ acts on the electron plasma frequency, and the operator $\vec{\nabla}_{\mathbf{k}}$ acts on the components of the Wigner matrix $W(\mathbf{k}, \mathbf{r}, t)$. The matrix operator $\mathcal{H}_0(\hat{\mathbf{k}})$ reduces, in the short wavelength approximation, to the free particle Hamiltonian $\mathcal{H}_0(\mathbf{k})$. Both $\hat{C}$ and $\hat{S}$ can be expanded in a power series, containing only even powers of ε and, therefore, $\hat{S}$ and $\hat{C}$ in Eqs. (23) have regular limits when $\varepsilon \to 0$.

The operators (23) can also be cast in an integral form, which is more useful for numerical implementations:

$$\hat{C},\hat{S}f(\mathbf{k},\mathbf{r},t) = \int_{\mathbb{R}^3} d\mathbf{k}' \mathcal{K}^{\pm}(\mathbf{k}-\mathbf{k}',\mathbf{r},t) f(\mathbf{k}',\mathbf{r},t), \tag{24}$$

where

$$\mathcal{K}^{\pm}(\mathbf{k},\mathbf{r},t) = \frac{i}{2\varepsilon\omega_{p0}}\left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} d\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}(\tilde{\omega}_{p_+}^2 - \tilde{\omega}_{p_-}^2). \tag{25}$$

Equation (22) describes the equation of motion for the Wigner matrix, and therefore it describes the transport of W in phase space. Even though it is formally equivalent to the wave equation (1), it is more useful to represent our field in terms of real Wigner distributions. Since the Pauli matrices form a basis for the 2×2 complex matrix space, W admits the expansion

$$W = \tfrac{1}{2}(\tau_0 W_0 + i\tau_1 W_1 - i\tau_2 W_2 + \tau_3 W_3), \tag{26}$$

where all the $W_i, i \in \{0,1,2,3\}$ are real distributions. Since W is not Hermitian, an expansion in the form $W=\Sigma_{i=0}^{3} W_i \tau_i$, where all the $W_i, i \in \{0,1,2,3\}$, are real functions, is not possible. Nevertheless, W is Hermitian in the Feshbach-Villars sense and the natural expansion with real coefficients is given by Eq. (26). It is easily seen that $W_0 = W_{\phi\phi} - W_{\chi\chi}$, $W_1 = 2\,\mathrm{Im}(W_{\phi\chi})$, $W_2 = 2\,\mathrm{Re}(W_{\phi\chi})$, and $W_3 = W_{\phi\phi} + W_{\chi\chi}$. The physical meaning of $W_2(\mathbf{k},\mathbf{r},t) + W_3(\mathbf{k},\mathbf{r},t)$ is of interest, because it is related to the Wigner function of the vector potential Φ. In fact, with

$$W_{\Phi\Phi}(\mathbf{k},\mathbf{r},t) = \left(\frac{1}{2\pi\varepsilon}\right)^3 \int_{\mathbb{R}^3} d\mathbf{y} e^{i(\mathbf{k}\cdot\mathbf{y})/\varepsilon} \Phi^*(\mathbf{r}_+,t)\Phi(\mathbf{r}_-,t), \tag{27}$$

where $\Phi^*(\mathbf{r},t)$ stands for the complex conjugate of $\Phi(\mathbf{r},t)$, then

$$W_{\Phi\Phi} = W_2(\mathbf{k},\mathbf{r},t) + W_3(\mathbf{k},\mathbf{r},t) = W_{\phi\phi} + W_{\chi\chi} + 2\,\mathrm{Re}(W_{\phi\chi}). \tag{28}$$

The vector potential is completely characterized by the distribution function $W_{\Phi\Phi}$, which can be calculated for different electromagnetic field configurations. Furthermore, there is a one-to-one correspondence between the distribution $W_{\Phi\Phi}$, and the vector potential Φ, apart from a constant phase shift ϕ_0. Defining the inverse Fourier transform of $W_{\Phi\Phi}$, as

$$\mathcal{F}_{\mathbf{k},\mathbf{y}}^{-1}(\mathbf{y},\mathbf{r},t) = \int_{\mathbb{R}^3} d\mathbf{k} e^{-i(\mathbf{k}\cdot\mathbf{y})/\varepsilon}[W_2(\mathbf{k},\mathbf{r},t) + W_3(\mathbf{k},\mathbf{r},t)], \tag{29}$$

$\Phi(\mathbf{r},t)$ is determined by

$$\Phi(\mathbf{r},t) = \frac{\mathcal{F}_{\mathbf{k},\mathbf{r}}^{-1}\left(\mathbf{r},\frac{\mathbf{r}}{2},t\right)}{\sqrt{\mathcal{F}_{\mathbf{k},\mathbf{r}}^{-1}(0,0,t)}} e^{i\phi_0}. \tag{30}$$

In Eq. (30) ϕ_0 is determined from the initial conditions, and the inverse Fourier transform of the Wigner function is assumed to be different from 0 at $t=0$.

The imaginary part of the cross-density $W_{\phi\chi}, W_1$, is the classical equivalent of the quantum "Zitterbewegung,"[6] and it represents the interference between forward and backward photons. For Wigner matrices of a free forward plane wave or a free backward plane wave, of momentum $\mathbf{k}_0, W_1$ is zero.

As a simple illustration, let us consider a vector potential described by the superposition of two plane waves $\Phi(\mathbf{r},t) = \Phi_0 \exp[i(\mathbf{k}_0\cdot\mathbf{r} - \omega_0 t)] + \Phi_1 \exp[i(\mathbf{k}_1\cdot\mathbf{r} - \omega_1 t)]$, propagating in an uniform medium with $\tilde{\omega}_p^2(\mathbf{r},t) = 0$. For this field:

$$\phi(\mathbf{r},t)=\frac{\Phi_0}{2}\left(\frac{\omega_{p0}+\omega_0}{\omega_{p0}}\right)e^{i(\mathbf{k}_0\cdot\mathbf{r}-\omega_0 t)}+\frac{\Phi_1}{2}\left(\frac{\omega_{p0}+\omega_1}{\omega_{p0}}\right)e^{i(\mathbf{k}_1\cdot\mathbf{r}-\omega_1 t)}, \tag{31a}$$

$$\chi(\mathbf{r},t)=\frac{\Phi_0}{2}\left(\frac{\omega_{p0}-\omega_0}{\omega_{p0}}\right)e^{i(\mathbf{k}_0\cdot\mathbf{r}-\omega_0 t)}+\frac{\Phi_1}{2}\left(\frac{\omega_{p0}-\omega_1}{\omega_{p0}}\right)e^{i(\mathbf{k}_1\cdot\mathbf{r}-\omega_1 t)}. \tag{31b}$$

The corresponding components of the Wigner matrix are

$$W_{\phi\phi}(\mathbf{k},\mathbf{r},t)=\frac{(\omega_0+\omega_{p0})^2}{4\omega_{p0}^2}\Phi_0^2\delta(\mathbf{k}-\mathbf{k}_0)+\frac{(\omega_1+\omega_{p0})^2}{4\omega_{p0}^2}\Phi_1^2\delta(\mathbf{k}-\mathbf{k}_1)+\frac{(\omega_{p0}+\omega_0)(\omega_{p0}+\omega_1)}{2\omega_{p0}^2}\Phi_0\Phi_1\cos(\eta)\delta\left(\mathbf{k}-\frac{\mathbf{k}_0+\mathbf{k}_1}{2}\right), \tag{32a}$$

$$W_{\phi\chi}(\mathbf{k},\mathbf{r},t)=-\frac{\mathbf{k}_0^2c^2}{4\omega_{p0}^2}\Phi_0^2\delta(\mathbf{k}-\mathbf{k}_0)-\frac{\mathbf{k}_1^2c^2}{4\omega_{p0}^2}\Phi_1^2\delta(\mathbf{k}-\mathbf{k}_1)+\frac{\Phi_0\Phi_1}{2}\times\left\{\left[1-\frac{\omega_0\omega_1}{\omega_{p0}^2}\right]\cos(\eta)+i\frac{\omega_0-\omega_1}{\omega_{p0}}\sin(\eta)\right\}\delta\left(\mathbf{k}-\frac{\mathbf{k}_0+\mathbf{k}_1}{2}\right), \tag{32b}$$

$$W_{\chi\chi}(\mathbf{k},\mathbf{r},t)=\frac{(\omega_0-\omega_{p0})^2}{4\omega_{p0}^2}\Phi_0^2\delta(\mathbf{k}-\mathbf{k}_0)+\frac{(\omega_1-\omega_{p0})^2}{4\omega_{p0}^2}\Phi_1^2\delta(\mathbf{k}-\mathbf{k}_1)+\frac{(\omega_{p0}-\omega_0)(\omega_{p0}-\omega_1)}{2\omega_{p0}^2}\Phi_0\Phi_1\cos(\eta)\delta\left(\mathbf{k}-\frac{\mathbf{k}_0+\mathbf{k}_1}{2}\right), \tag{32c}$$

where $\eta=\Delta_{\mathbf{k}}\cdot\mathbf{r}-\Delta_\omega t$, $\Delta_{\mathbf{k}}=\mathbf{k}_1-\mathbf{k}_0$, $\Delta_\omega=\omega_1-\omega_0$, $\delta(\mathbf{k})$ represents the Dirac delta distribution and $\omega_{0,1}=\sqrt{\mathbf{k}_{0,1}^2c^2+\omega_{p0}^2}$. The presence of two photon beams associated with the two plane waves is easily seen. Furthermore there is a "third wave" which results from the interference between the two plane waves. In this case, W_1 is different from zero, since it accounts for the interference between forward and backward photons. W_0 is associated with the effective photon density, i.e., it is positive when the forward photon density is bigger than the backward photon density.

Using the decomposition $W=\mathrm{Re}(W)+i\,\mathrm{Im}(W)$ in Eq. (22), one can derive a set of two coupled real equations:

$$\partial_t 2\,\mathrm{Re}(W)+(\hat{D}-\hat{S})\frac{1}{2}\{\tau_3+i\tau_2,2\,\mathrm{Re}(W)\}-\frac{1}{\varepsilon}[\mathcal{H}_0(\hat{\mathbf{k}})+\hat{C}]\frac{1}{2}[(\tau_3+i\tau_2),\tau_1]W_1-\frac{\omega_{p0}}{\varepsilon}[\tau_3,\tau_1]W_1=0, \tag{33a}$$

$$\partial_t(\tau_1W_1)+\frac{1}{\varepsilon}[\mathcal{H}_0(\hat{\mathbf{k}})+\hat{C}]\frac{1}{2}[(\tau_3+i\tau_2),2\,\mathrm{Re}(W)]+\frac{\omega_{p0}}{\varepsilon}[\tau_3,2\,\mathrm{Re}(W)]=0, \tag{33b}$$

where we have used $\{\tau_i,\tau_j\}=2\tau_0\delta_{ij}$, $i,j\in\{1,2,3\}$ and $2\,\mathrm{Im}(W)=\tau_1W_1$. From expansion (26) it is easily seen that $2\,\mathrm{Re}(W)=\tau_0W_0-i\tau_2W_2+\tau_3W_3$ and, therefore, the four real phase-space densities obey the set of transport equations:

$$\partial_t W_0+(\hat{D}-\hat{S})(W_2+W_3)=0, \tag{34a}$$

$$\partial_t W_1-\frac{1}{\varepsilon}[\mathcal{H}_0(\hat{\mathbf{k}})+\hat{C}](W_2+W_3)-\frac{2}{\varepsilon}\omega_{p0}W_2=0, \tag{34b}$$

$$\partial_t W_2 - (\hat{D} - \hat{S}) W_0 + \frac{1}{\varepsilon}[\mathcal{H}_0(\hat{\mathbf{k}}) + \hat{C}] W_1 + \frac{2}{\varepsilon}\omega_{p0} W_1 = 0, \tag{34c}$$

$$\partial_t W_3 + (\hat{D} - \hat{S}) W_0 - \frac{1}{\varepsilon}[\mathcal{H}_0(\hat{\mathbf{k}}) + \hat{C}] W_1 = 0. \tag{34d}$$

The set of equations (34) is the main result of this paper. With the appropriate definitions for W_i, the set of equations (34) is formally equivalent to Eq. (1), and therefore opens the way to an appropriate description of the propagation of electromagnetic waves with arbitrary spectral content in nonlinear dispersive media.[14]

IV. THE SHORT WAVELENGTH LIMIT

We now examine the short wavelength limit of the Boltzmann-Vlasov equation of motion (22) by examining the limit $\varepsilon \to 0$. In order to consider the short wavelength limit of (22) we first observe that

$$\lim_{\varepsilon\to 0} \hat{S} = \frac{\vec{\nabla}_{\mathbf{r}} \tilde{\omega}_p^2(\mathbf{r},t)}{2\omega_{p0}} \cdot \vec{\nabla}_{\mathbf{k}}, \quad \lim_{\varepsilon\to 0} \hat{C} = \frac{\tilde{\omega}_p^2(\mathbf{r},t)}{\omega_{p0}}, \quad \lim_{\varepsilon\to 0} \hat{\mathbf{k}} = \mathbf{k}. \tag{35}$$

Let the superscript (0) represent any function in the short wavelength limit. In the limit $\varepsilon \to 0$, the set of equations (33) converges to a meaningful limit only if $W_1 \to 0$ faster than $\varepsilon \to 0$; hence $W^{(0)}$ must be real, i.e., $W_1^{(0)} = 0$. The same conclusions can also be obtained using the coarse-graining technique introduced by Shin and Rafelski.[15] Using the results in (35) and the previous considerations, Eq. (33) can be written, in the $\epsilon \to 0$ limit, as

$$\partial_t W^{(0)} + \left[\frac{c^2}{\omega_{p0}} \mathbf{k} \cdot \vec{\nabla}_{\mathbf{r}} - \frac{1}{2} \frac{\vec{\nabla}_{\mathbf{r}} \tilde{\omega}_p^2(\mathbf{r},t)}{\omega_{p0}} \cdot \vec{\nabla}_{\mathbf{k}} \right] \frac{1}{2} \{ (\tau_3 + i\tau_2), W^{(0)} \} = 0, \tag{36a}$$

$$\left[(c^2\mathbf{k}^2 + \tilde{\omega}_p^2(\mathbf{r},t)) \frac{(\tau_3 + i\tau_2)}{2\omega_{p0}} + \omega_{p0}\tau_3, W^{(0)} \right] = 0. \tag{36b}$$

Our first goal now is to find a matrix operator that transforms Eq. (36b) into a necessary condition for $W' = U^{-1} W^{(0)} U$ to be diagonal. This will significantly reduce the amount of calculations needed to identify the form of the classical wave action, since the system will be reduced to two degrees of freedom. The matrix operator that performs this task is

$$U(\zeta) = e^{-\tau_1 \zeta}, \tag{37}$$

where

$$\zeta = \frac{1}{2} \log \left[\frac{\omega(\mathbf{k},\mathbf{r},t)}{\omega_{p0}} \right],$$

and with $\omega(\mathbf{k},\mathbf{r},t) = \sqrt{\mathbf{k}^2 c^2 + \omega_{p0}^2 + \tilde{\omega}_p^2(\mathbf{r},t)}$. On performing the similarity transformation induced by U in Eq. (36b), we obtain

$$\omega(\mathbf{k},\mathbf{r},t)[\tau_3, W'] = 0, \tag{38}$$

where

$$U^{-1}(\tau_3 + i\tau_2) U = \frac{\omega_{p0}}{\omega(\mathbf{k},\mathbf{r},t)} (\tau_3 + i\tau_2). \tag{39}$$

From Eq. (38) we can see that W' must be a linear combination of τ_0 and τ_3, since all the other Pauli matrices do not commute with τ_3. One can choose this linear combination to be parametrized by two real functions f and g, such that

$$W' = \frac{f-g}{2}\tau_0 + \frac{f+g}{2}\tau_3. \tag{40}$$

Performing the transformation (37) in Eq. (36a), with W' given by Eq. (40), the diagonal part leads to

$$\partial_t f(\mathbf{k},\mathbf{r},t) + \frac{c^2\mathbf{k}}{\omega(\mathbf{k},\mathbf{r},t)}\cdot\vec{\nabla}_{\mathbf{r}} f(\mathbf{k},\mathbf{r},t) - \frac{1}{2}\frac{\vec{\nabla}_{\mathbf{r}}\tilde{\omega}_p^2(\mathbf{r},t)}{\omega_{p0}}\cdot\vec{\nabla}_{\mathbf{k}} f(\mathbf{k},\mathbf{r},t) = 0, \tag{41a}$$

$$\partial_t g(\mathbf{k},\mathbf{r},t) - \frac{c^2\mathbf{k}}{\omega(\mathbf{k},\mathbf{r},t)}\cdot\vec{\nabla}_{\mathbf{r}} g(\mathbf{k},\mathbf{r},t) + \frac{1}{2}\frac{\vec{\nabla}_{\mathbf{r}}\tilde{\omega}_p^2(\mathbf{r},t)}{\omega_{p0}}\cdot\vec{\nabla}_{\mathbf{k}} g(\mathbf{k},\mathbf{r},t) = 0. \tag{41b}$$

Equations (41a) and (41b) clearly resemble the classical wave action conservation for forward and backward radiation, respectively.[7] However to confirm this fact, the relation between f, g, and $W^{(0)}_{\Phi\Phi}$ needs to be established. On one hand, we know that $\mathrm{Re}(W)$ is $1/2(\tau_0 W_0 - i\tau_2 W_2 + \tau_3 W_3)$. On the other hand, in the short wavelength limit, $\mathrm{Re}(W)$ is $W^{(0)}$. Thus, we conclude that

$$W^{(0)} = \tfrac{1}{2}(\tau_0 W_0^{(0)} - i\tau_2 W_2^{(0)} + \tau_3 W_3^{(0)}). \tag{42}$$

Performing the transformation induced by U in Eq. (42) we obtain

$$2W' = (f-g)\tau_0 + (f+g)\tau_3 = U^{-1}(\tau_0 W_0^{(0)} - i\tau_2 W_2^{(0)} + \tau_3 W_3^{(0)})U, \tag{43}$$

which after some manipulation can be reduced to the set of algebraic equations:

$$f - g = W_0^{(0)}, \tag{44a}$$

$$f + g = \frac{R^2+1}{2R}W_3^{(0)} + \frac{R^2-1}{2R}W_2^{(0)}, \tag{44b}$$

$$0 = \frac{R^2+1}{2R}W_2^{(0)} + \frac{R^2-1}{2R}W_3^{(0)}, \tag{44c}$$

where we have defined $R = \omega(\mathbf{k},\mathbf{r},t)/\omega_{p0}$. From Eq. (44), one infers

$$f + g = \frac{\omega(\mathbf{k},\mathbf{r},t)}{\omega_{p0}}W^{(0)}_{\Phi\Phi} = \frac{c^2}{2\omega_{p0}}J(\mathbf{k},\mathbf{r},t), \tag{45}$$

where $J(\mathbf{k},\mathbf{r},t)$ represents the classical wave action, as defined in Ref. 7. Thus, in the short wavelength limit, Eqs. (41a) and (41b) state that the classical wave action, $J(\mathbf{k},\mathbf{r},t)$, is conserved along the geometrical optics ray, independent of the adiabaticity condition.[16]

To conclude the discussion of the short wavelength limit, we observe that when $\varepsilon \to 0$ in Eq. (3) χ is negligible, since reflected waves are exponentially small.[17] Dropping the small component χ in Eq. (3) and eliminating the ω_{p0} term by setting $\phi(\mathbf{r},t) = \tilde{\phi}(\mathbf{r},t)\exp(-i\omega_{p0}t/\varepsilon)$, yields the paraxial wave equation:[18]

$$2i\omega_{p0}\varepsilon\partial_t\tilde{\phi} = -\varepsilon^2 c^2\vec{\nabla}_{\mathbf{r}}^2\tilde{\phi} + \tilde{\omega}_p^2\tilde{\phi}. \tag{46}$$

This equation is formally equivalent to the Schrödinger equation, and the Wigner-Moyal formalism can be followed in a straightforward way. This is the approach followed by Besieris and

Tappert.[2,3] As expected, this path also leads to classical wave action conservation in the same limit we have explored here, but fails to capture the dynamics of the backscattered component of the radiation field.

V. CONCLUSIONS

In order to establish a description of the propagation of electromagnetic waves in nonlinear dispersive media, including the two modes described by the wave equation, we have employed the Feshbach-Villars description of the Klein-Gordon field with a variable mass term, and the corresponding 2×2 Wigner matrix. The equations of motion for the Wigner matrix lead to a set of four coupled equations for four real phase-space densities, whose physical meanings are clearly identified. The general Boltzmann-Vlasov equations of motion account for the backscattered waves, and for the interference between forward and backward radiation. These equations replace the standard Wigner-Moyal description of classical fields,[3] generalizing it to the two mode problem with variable mass terms, and are formally equivalent to the full wave equation.

The short wavelength limit of the Boltzmann-Vlasov equations of motion was considered, and it was shown they reduce to uncoupled equations for the forward and backward radiation phase-space densities. In this limit, the standard results regarding wave action conservation,[7] are recovered.

The formalism introduced here provides a complete description for the electromagnetic field in nonlinear dispersive media, and opens the way to the description of broadband radiation driven parametric instabilities in nonlinear media. Applications of this formalism will be presented elsewhere.

Rigid body mechanics in Galilean spacetimes

Ajit Bhand[a] and Andrew D. Lewis
Department of Mathematics and Statistics, Queen's University, Kingston, Ontario K7L3N6, Canada

(Received 13 May 2005; accepted 19 August 2005; published online 20 October 2005)

An observer-independent formulation of rigid body dynamics is provided in the general setting of a Galilean spacetime. The equations governing the motion of a rigid body undergoing a rigid motion in a Galilean spacetime are derived on the basis of the principle of conservation of spatial momentum. The formulation of rigid body dynamics is then studied in the presence of an observer. It is seen that an observer defines a connection such that there exist rigid motions that are horizontal with respect to this connection that give the same physical motion of the rigid body, and for which the general equations of motion are exactly the usual Euler equations for a rigid body undergoing rigid motion. © *2005 American Institute of Physics.*

I. INTRODUCTION

The main aim of this paper is to understand the dynamics of a rigid body in the general framework of a Galilean spacetime. We study how the physical motion of a rigid body is related to "rigid motions"—the set of mappings belonging to the group of Galilean transformations from a Galilean spacetime to itself, called the Galilean group. We present a new formulation of rigid body dynamics that is independent of an observer. Note that the momentum associated with a particle undergoing motion in a Galilean spacetime is thought of as observer-dependent quantity in the literature (see, for example, Ref. 1). In this paper we take the view that momentum is an intrinsic property of a rigid body in motion, and that it is possible to define it without using any external structure. An observer merely affects the way the momentum is *measured*.

The problem of deriving equations of motion for a rigid body in a Newtonian setting has a rich history. Galileo (1564–1642) carried out the first systematic study of rigid bodies in motion. Newton (1643–1727) built on the foundations laid by Galileo, and came up with equations of motion for a particle in an inertial frame. Later on, Euler (1703–1783) derived the equations of motion for a rigid body fixed at a point in $\mathbb{R}^3$. A modern treatment of this subject, from a general point of view of mechanics on Lie groups, can be found in Refs. 2 and 3. The role of the Galilean structure of the Newtonian spacetime has been understood in the case of the dynamics of a particle.[1,3] A Galilean covariant formulation of the classical mechanics of a single particle has been studied in Ref. 4, and, of course, the dynamics of a rigid body in a fixed Galilean frame has been investigated quite thoroughly.[3,5] However, to our knowledge, the role played by the Galilean structure has not been explained for *rigid body* mechanics. Unlike a particle or a rigid body fixed at a point in $\mathbb{R}^3$, in the general setting of a Galilean spacetime, there does not exist an exact correspondence between rigid motions and physical motions of a rigid body. We address this issue in detail and derive the "Galilean-Euler equations" for a rigid body.

We also show that an observer in a Galilean spacetime, apart from providing a reference frame for observing Newton's laws, also provides an isomorphism from the "abstract" Galilean group to the "standard" or "canonical" Galilean group which consists of rotations, spatial translations, uniform velocity boosts, and time translations. Furthermore, an observer defines a connection such

[a]Electronic mail: ajit@mast.queensu.ca

that, for any given rigid motion, there exists a rigid motion that is horizontal with respect to this connection that gives the same physical motion of the body as the given rigid motion, and for which the generalized equations of motion reduce to the usual Euler equations for a rigid body.

It should be noted that notions of Galilean spacetimes more general than ours have also been studied in the literature. For example, the full machinery of affine differential geometry has been used in Ref. 6 (see also Ref. 7) while a notion of "inertial relations" has been used in Refs. 8–10 to characterize more general Galilean spacetimes.

It is also worth noting that Souriau's approach[11] is different from ours. In particular, he considers a symplectic formulation and his definition of momentum is based on the "Lagrange two-form." Souriau also works with the canonical Galilean group, so obscuring the role of the observer.

This paper is organized as follows. In Sec. II, we present the mathematical preliminaries relevant to our investigation. Several important concepts like affine spaces and subspaces, observers, Galilean spacetimes, and the Galilean group are introduced and their various properties are described. The notion of a rigid body, along with its attendant features, is introduced in Sec. III. In particular, the inertia tensor of a rigid body is defined and its properties are thoroughly explained. In Sec. IV, the structure of the canonical, as well as the abstract, Galilean group is investigated in detail. It is shown that an observer induces an isomorphism between the Galilean group and the canonical group. Next, "canonical velocities" are defined. These are curves in the Lie algebra of the Galilean group. With this background, we first look at rigid motions in Sec. V. Various quantities associated with a rigid motion, such as the body and spatial linear and angular velocities, are defined. Throughout this section, the treatment is observer-independent. The discussion then focuses on angular and spatial momenta, and finally the generalized equations of motion (called the Galilean-Euler equations) for a rigid body are derived. In Sec. VI, the formulation presented in Sec. V is studied in the *presence* of an observer. It is shown that, in such a case, we recover the familiar quantities associated with the classical treatment of rigid body mechanics. The Galilean-Euler equations are also studied in the presence of an observer, and the connection induced by the observer (called the Galilean connection) is defined. It is shown that, for each constant velocity boost, we recover the classical Euler equations for a rigid body.

II. GALILEAN SPACETIME

In this section, we present the mathematical background and introduce the notation to be used in the following sections. In Sec. II A, we define affine spaces and subspaces; the principle objects of interest in this paper. In Sec. II B, we introduce the notion of a Galilean spacetime and describe the affine spaces naturally associated with it. We also introduce the set of Galilean velocities. Next, we define observers in a Galilean spacetime and discuss their properties. Finally, in Sec. II E, we define the Galilean group of a Galilean spacetime and introduce the fundamental maps associated with a Galilean mapping.

A. Affine spaces

In this section, we define affine spaces and subspaces, and record some of their properties. We refer to Ref. 12 for more details.

Definition 2.1: Let V be an $\mathbb{R}$-vector space. An *affine space* modeled on V is a pair $(\mathcal{A}, \phi)$ where $\mathcal{A}$ is a set and $\phi: V \times \mathcal{A} \to \mathcal{A}$ is a map with the following properties:

(i) for every $x, y \in \mathcal{A}$, there exists $v \in V$ such that $y = \phi(v, x)$;
(ii) $\phi(v, x) = x$ for every $x \in \mathcal{A}$ implies that $v = 0$;
(iii) $\phi(0, x) = x$, for each $x \in \mathcal{A}$;
(iv) $\phi(u + v, x) = \phi(u, \phi(v, x))$.

We shall now cease to use the map ϕ and instead use the more suggestive notation $\phi(v, x) = v + x$. By definition, if $x, y \in \mathcal{A}$, there exists a unique $v \in V$ such that $y = v + x$. In this case we shall

denote $v=y-x$. By a slight abuse of notation, we shall denote an affine space $(\mathcal{A},\phi)$ simply by $\mathcal{A}$. If $\mathcal{A}$ is an affine space modeled on V and we fix a point $x\in\mathcal{A}$, then $\mathcal{A}$ is isomorphic to the vector space V. We denote this vector space by $\mathcal{A}_x$.

Definition 2.2: Let $\mathcal{A}$ and $\mathcal{B}$ be affine spaces. A map $f:\mathcal{A}\to\mathcal{B}$ is an *affine map* if, for each $x\in\mathcal{A}$, the map f is an $\mathbb{R}$-linear map between the vector spaces $\mathcal{A}_x$ and $\mathcal{B}_{f(x)}$.

A subset $\mathcal{B}$ of an affine space modeled on V is an *affine subspace* if there is a subspace U of V with the property that $y-x\in U$ for every $x,y\in\mathcal{B}$. In this case, $\mathcal{B}$ is itself an affine space modeled on U. It can be shown that if $\mathcal{B}$ is an affine subspace of $\mathcal{A}$, then there exists a subspace U of V such that, for any fixed $x\in\mathcal{B}$, we have $\mathcal{B}=\{u+x\,|\,u\in U\}$.

B. Time and distance

We begin by giving the basic definition of a Galilean spacetime and by providing meaning to the intuitive notions of time and distance.

Definition 2.3: A *Galilean spacetime* is a quadruple $\mathcal{G}=(\mathcal{E},V,g,\tau)$ where

(i) V is a four-dimensional $\mathbb{R}$-vector space,
(ii) $\tau:V\to\mathbb{R}$ is a surjective linear map called the *time map*,
(iii) g is an inner product on $\ker(\tau)$, and
(iv) $\mathcal{E}$ is an affine space modeled on V.

Points in $\mathcal{E}$ are called *events*—thus $\mathcal{E}$ is a model for the spatiotemporal world of Newtonian mechanics. With the time map, we may measure the time between two events $x_1,x_2\in\mathcal{E}$ as $\tau(x_2-x_1)$. Events $x_1,x_2\in\mathcal{E}$ are called *simultaneous* if $\tau(x_2-x_1)=0$; that is, if $x_2-x_1\in\ker(\tau)$.

We may define the *distance* between simultaneous events $x_1,x_2\in\mathcal{E}$ to be equal to $\sqrt{g(x_2-x_1,x_2-x_1)}$. Note that this method for defining distance does not allow us to measure distances between events that are *not* simultaneous. In particular, it does not make sense to talk about two nonsimultaneous events as occurring in the same place.

Simultaneity is an equivalence relation on $\mathcal{E}$ and the quotient we denote by $I_{\mathcal{G}}=\mathcal{E}/\sim$, with $\sim$ denoting the relation of simultaneity. $I_{\mathcal{G}}$ is simply the collection of equivalence classes of simultaneous events. We call it the *set of instants*. We denote by $\pi_{\mathcal{G}}:\mathcal{E}\to I_{\mathcal{G}}$ the canonical projection.

For $s\in I_{\mathcal{G}}$, we denote by $\mathcal{E}(s)$ the collection of events $x\in\mathcal{E}$ with the property that $\pi_{\mathcal{G}}(x)=s$. Thus events in $\mathcal{E}(s)$ are simultaneous. We next denote by $V_{\mathcal{G}}$ the vectors $v\in V$ for which $\tau(v)=1$. We call vectors in $V_{\mathcal{G}}$ *Galilean velocities*. The following result is easy to prove.

Proposition 2.4: The following statements hold:

(i) *for each $s\in I_{\mathcal{G}}$, $\mathcal{E}(s)$ is a three-dimensional affine space modeled on* $\ker(\tau)$*;*
(ii) *$I_{\mathcal{G}}$ is a one-dimensional affine space modeled on* $\mathbb{R}$*;*
(iii) *$V_{\mathcal{G}}$ is an affine space modeled on* $\ker(\tau)$.

C. Observers

An observer is to be thought of intuitively as someone who is present at each instant. Such an observer should be moving at a "uniform velocity." Note that, in a Galilean spacetime, the notion of "stationarity" makes no sense. We now provide our definition of an observer.

Definition 2.5: An *observer* in a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$ is a one-dimensional affine subspace $\mathcal{O}$ of $\mathcal{E}$ with the property that $\pi_{\mathcal{G}}|\mathcal{O}$ is surjective.

The definition thus requires that $\mathcal{O}$ not be comprised entirely of simultaneous events. As a consequence of the definition, we have the following result.

Proposition 2.6: If $\mathcal{O}$ is an observer in a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$, then, for each $s_0\in I_{\mathcal{G}}$, there exists a unique point $x_0\in\mathcal{O}\cap\mathcal{E}(s_0)$.

Proof: Given $s_0\in I_{\mathcal{G}}$, there exists $x_0\in\mathcal{O}$ such that $\pi_{\mathcal{G}}(x_0)=s_0$. Since $\mathcal{O}$ is a one-dimensional affine space with the property that $\pi_{\mathcal{G}}|\mathcal{O}$ is surjective, there exists a one-dimensional subspace $W\subset V$ such that

$$\mathcal{O} = (w + x_0 | w \in W),$$

where W is not contained in $\ker(\tau)$. By construction, $x_0 \in \mathcal{E}(s_0) \cap \mathcal{O}$. This means that, for each $s_0 \in I_{\mathcal{G}}$, the intersection $\mathcal{E}(s_0) \cap \mathcal{O}$ is nonempty. Next, let $y_0 \in \mathcal{E}(s_0) \cap \mathcal{O}$. Now, $y_0 \in \mathcal{E}(s_0)$ implies that $y_0 - x_0 \in \ker(\tau)$. On the other hand, $y_0 \in \mathcal{O}$ implies that $y_0 - x_0 \in W$. This means that $y_0 = x_0$ which proves the uniqueness of x_0. □

This means that an observer does exactly what it should: it resides in exactly one place at each instant. By requiring that $\mathcal{O}$ be an affine subspace, we ensure that it has a "uniform velocity" and so is an appropriate reference for observing Newton's laws. We shall denote by $\mathcal{O}_s$ the unique point in the intersection $\mathcal{O} \cap \mathcal{E}(s)$.

Since an observer $\mathcal{O}$ is a one-dimensional affine subspace, there is a unique one-dimensional subspace U of V upon which $\mathcal{O}$ is modeled. Therefore, there exists a unique vector $v_{\mathcal{O}} \in U \cap V_{\mathcal{G}}$ with the property that $\tau(v_{\mathcal{O}}) = 1$. Conversely, given $v \in V_{\mathcal{G}}$ and $x \in \mathcal{E}$, there exists a unique observer $\mathcal{O}$ such that $x \in \mathcal{O}$ and $v = v_{\mathcal{O}}$. We call $v_{\mathcal{O}}$ the *Galilean velocity* of the observer $\mathcal{O}$. It provides a reference velocity with which we can measure other velocities. Indeed, given an observer $\mathcal{O}$, we may define an associated map $P_{\mathcal{O}} : V \to \ker(\tau)$ by $P_{\mathcal{O}}(v) = v - (\tau(v))v_{\mathcal{O}}$. In particular, if $v \in V_{\mathcal{G}}$, we note that $v = v_{\mathcal{O}} + P_{\mathcal{O}}(v)$. Thus $P_{\mathcal{O}}$ can be thought of as giving the velocity of v relative to the observer's Galilean velocity $v_{\mathcal{O}}$. Note that such velocities always live in the three-dimensional vector space $\ker(\tau)$ that is to be thought of as the space of velocities that are familiar in mechanics. Such velocities are, however, only defined relative to an observer.

D. World lines

Intuitively, a world line is to be thought of as being the spatiotemporal history of something moving in the spacetime. We make the following definition.

Definition 2.7: Let $\mathcal{G} = (\mathcal{E}, V, g, \tau)$ be a Galilean spacetime. A *world line* in $\mathcal{G}$ is a section of $\pi_{\mathcal{G}} : \mathcal{E} \to I_{\mathcal{G}}$.

A world line $c : I_{\mathcal{G}} \to \mathcal{E}$ is *differentiable* at $s_0 \in I_{\mathcal{G}}$ if the limit

$$c'(s_0) := \lim_{t \to 0} \frac{c(t + s_0) - c(s_0)}{t}$$

exists. Since c is a section of $\pi_{\mathcal{G}}$, we have $\tau(c(t+s_0) - c(s_0)) = t$ and so $c'(s_0) \in V_{\mathcal{G}}$, provided it exists. Similarly, for a differentiable world line, if the limit

$$\lim_{t \to 0} \frac{c'(t + s_0) - c'(s_0)}{t}$$

exists, we denote it by $c''(s_0)$, the acceleration of the world line at the instant s_0. Since

$$\tau(c''(s_0)) = \lim_{t \to 0} \frac{\tau(c'(t + s_0) - c'(s_0))}{t} = \lim_{t \to 0} \frac{1 - 1}{t} = 0,$$

we have $c''(s_0) \in \ker(\tau)$.

E. Galilean mappings

If $\mathcal{G}_i = (\mathcal{E}_i, V_i, g_i, \tau_i)$, $i = 1, 2$, are two Galilean space-times, a *Galilean mapping* from $\mathcal{G}_1$ to $\mathcal{G}_2$ is a map $\psi : \mathcal{E}_1 \to \mathcal{E}_2$ with the following properties:

(i) ψ is an affine map;
(ii) $\tau_2(\psi(x_1) - \psi(x_2)) = \tau_1(x_1 - x_2)$ for $x_1, x_2 \in \mathcal{E}_1$;
(iii) $g_2(\psi(x_1) - \psi(x_2), \psi(x_1) - \psi(x_2)) = g_1(x_1 - x_2, x_1 - x_2)$ for simultaneous events $x_1, x_2 \in \mathcal{E}_1$.

The set of Galilean mappings from a Galilean spacetime $\mathcal{G}$ to itself is a Lie group (under composition of Galilean mappings), and we call it the *Galilean group* of the Galilean spacetime $\mathcal{G}$. We

shall denote this group by $\mathrm{Gal}(\mathcal{G})$ and its Lie algebra by $\mathfrak{gal}(\mathcal{G})$. If $\psi \in \mathrm{Gal}(\mathcal{G})$, then there are induced natural mappings of V, $I_{\mathcal{G}}$, and $\mathbb{R}$ as follows.

Lemma 2.8: Let $\mathcal{G}=(\mathcal{E},V,g,\tau)$ be a Galilean spacetime with $\psi \in \mathrm{Gal}(\mathcal{G})$. The following mappings are well defined:

(i) *the mapping $\psi_V: V \to V$ defined by $\psi_V(v)=\psi(v+x_0)-\psi(x_0)$, where $x_0 \in \mathcal{E}$;*
(ii) *the mapping $\psi_{I_{\mathcal{G}}}: I_{\mathcal{G}} \to I_{\mathcal{G}}$ defined by $\psi_{I_{\mathcal{G}}}(s)=\pi_{\mathcal{G}}(\psi(x))$, where $x \in \mathcal{E}(s)$;*
(iii) *the mapping $\psi_\tau: \mathbb{R} \to \mathbb{R}$ defined by $\psi_\tau(t)=t+\psi_{I_{\mathcal{G}}}(s)-s$, for $s \in I_{\mathcal{G}}$. Furthermore,*
(iv) *$\psi_V(v)=\psi(x_1)-\psi(x_2)$, where $x_1-x_2=v$, and*
(v) *there exists $t_\psi \in \mathbb{R}$ such that $\psi_{I_{\mathcal{G}}}(s)=s+t_\psi$ and $\psi_\tau(t)=t+t_\psi$.*

Proof: (i) Let $x_0, \bar{x}_0 \in \mathcal{E}$. We have

$$\psi(v+x_0)-\psi(x_0)=\psi((v+(x_0-\tilde{x}_0))+\tilde{x}_0)-\psi((x_0-\tilde{x}_0)+\tilde{x}_0)=\psi((x_0-\tilde{x}_0)+\tilde{x}_0)+\psi(v+\tilde{x}_0)-\psi(\tilde{x}_0)$$
$$-\psi((x_0-\tilde{x}_0)+\tilde{x}_0)=\psi(v+\tilde{x}_0)-\psi(\tilde{x}_0),$$

where we have used the property

$$\psi((v_1+v_2)+x)=(\psi(v_1+x)+\psi(v_2+x))-\psi(x),$$

since ψ is an affine map. This property is readily verified using the definition of an affine map. We will now show that $\ker(\tau)$ is an invariant subspace for ψ_V. We let $x, \tilde{x} \in \mathcal{E}$ have the property that $x-\tilde{x}=u \in \ker(\tau)$. Then

$$\tau(\psi_V(u))=\tau(\psi(x)-\psi(\tilde{x}))=\tau(u)=0,$$

where we have used property (ii) of Galilean mappings.

(ii) Let $x, \tilde{x} \in \mathcal{E}(s)$. There exists $u \in \ker(\tau)$ such that $\tilde{x}=u+x$. Now we compute

$$\pi_{\mathcal{G}}(\psi(\tilde{x}))-\pi_{\mathcal{G}}(\psi(x))=\tau(\psi(\tilde{x})-\psi(x))=\tau(\psi_V(\tilde{x}-x))=\tau(\psi_V(u))=0,$$

using the fact that $\ker(\tau)$ is an invariant subspace for ψ_V.

(iii) We must show that the definition is independent of the choice of $s \in I_{\mathcal{G}}$. For $\tilde{s} \in I_{\mathcal{G}}$, we compute

$$t+\psi_{I_{\mathcal{G}}}(\tilde{s})-\tilde{s}=t+\psi_{I_{\mathcal{G}}}(s+(\tilde{s}-s))-s+(s-\tilde{s})=t+\psi_{I_{\mathcal{G}}}(s+(\tilde{s}-s))-\psi_{I_{\mathcal{G}}}(s)+\psi_{I_{\mathcal{G}}}(s)-s+(s-\tilde{s})$$
$$=t+\psi_{I_{\mathcal{G}}}(s)-s.$$

(iv) We have

$$\psi(x_1)-\psi(x_2)=\psi((x_1-x_2)+x_2)-\psi(x_2)=\psi_V(x_1-x_2),$$

as desired.

(v) Let $x_0 \in \mathcal{E}$ and let $t_\psi=\tau(\psi(x_0)-x_0)$. For $s \in I_{\mathcal{G}}$, let $x \in \mathcal{E}(s)$. We then have

$$\psi_{I_{\mathcal{G}}}(s)-s=\psi_{I_{\mathcal{G}}}(s)-\pi_{\mathcal{G}}(x)=\pi_{\mathcal{G}}(\psi(x))-\pi_{\mathcal{G}}(x)=\tau(\psi(x)-\psi(x_0))+\tau(\psi(x_0)-x_0)+\tau(x_0-x)$$
$$=\tau(\psi(x_0)-x_0)=t_\psi,$$

where we have used the property (ii) of Galilean mappings. This shows that the definition of t_ψ is independent of x_0, and that $\psi_{I_{\mathcal{G}}}(s)=t_\psi+s$, as desired. From (iii) it also follows that $\psi_\tau(t)=t_\psi+t$. □

Remarks 2.9: (1) In the proof of the lemma we showed that, given $\psi \in \mathrm{Gal}(\mathcal{G})$, ψ_V leaves $\ker(\tau)$ invariant. We shall see in the next section that $\psi_V|_{\ker(\tau)}$ has a mechanical interpretation.

(2) Using the definition of a Galilean mapping, it is easy to see that $V_{\mathcal{G}}$ is also invariant under ψ_V.

Given a Galilean spacetime $\mathcal{G}$, we let $O(\ker(\tau))$ denote the g-orthogonal linear mappings of $\ker(\tau)$. The Lie algebra of $O(\ker(\tau))$ we denote by $\mathfrak{o}(\ker(\tau))$, recalling that it is the collection of g-skew symmetric linear mappings of $\ker(\tau)$. We identify $\ker(\tau)$ with $\mathfrak{o}(\ker(\tau))$ by the "hat" map (see Ref. 5) given by $\omega \mapsto \hat{\omega}$. This is a generalization of the map from $\mathbb{R}^3$ to $\mathfrak{o}(3)$ defined by

$$\begin{bmatrix} \omega_1 \\ \omega_2 \\ \omega_3 \end{bmatrix} \mapsto \begin{bmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & -\omega_1 \\ -\omega_2 & \omega_1 & 0 \end{bmatrix},$$

and may be explicitly defined by choosing an orthonormal basis for $\ker(\tau)$ and then applying this transformation to the components in this basis. Since the vector product in $\mathbb{R}^3$ commutes with orthogonal transformations, this definition is independent of the choice of orthonormal basis. In like manner, one can define $u_1 \times u_2$ for any $u_1, u_2 \in \ker(\tau)$ as the generalization of the $\mathbb{R}^3$ vector product.

III. RIGID BODIES

In order to talk about momenta, we need the notion of a rigid body. In this section we provide our definition for a rigid body and provide some implications of this definition. We begin by proving, in our Galilean setting, some of the basic properties of the inertia tensor of a rigid body.

A. Definitions

Let $\mathcal{G}=(\mathcal{E}, V, g, \tau)$ be a Galilean spacetime. A *rigid body* is a pair $(\mathcal{B}, \mu)$, where $\mathcal{B} \subset \mathcal{E}(s_0)$ is a compact subset of simultaneous events, and μ is a mass-distribution on $\mathcal{E}(s_0)$ with support equal to $\mathcal{B}$. Our definition thus allows such degenerate rigid bodies as point masses, and bodies whose mass distribution is contained in a line in $\mathcal{E}(s_0)$. We denote

$$\mu(\mathcal{B}) = \int_{\mathcal{B}} \mathrm{d}\mu$$

as the *mass* of the body.

The *center of mass* of the body $(\mathcal{B}, \mu)$ is the point

$$x_c = \frac{1}{\mu(\mathcal{B})} \int_{\mathcal{B}} (x - x_0) \mathrm{d}\mu + x_0.$$

Note that the integrand is in $\ker(\tau)$ and so too will be the integral. The following lemma gives some of the basic properties of this definition. If $\mathcal{S} \subset \mathcal{A}$ is a subset of an affine space $\mathcal{A}$, we let $\mathrm{conv}(\mathcal{S})$ denote the convex hull of $\mathcal{S}$ and $\mathrm{aff}(\mathcal{S})$ denote the affine hull of $\mathcal{S}$. If X is a topological space with subsets $T \subset S \subset X$, $\mathrm{int}_S(T)$ denotes the interior of T relative to the induced topology on S.

Lemma 3.1: Let $(\mathcal{B}, \mu)$ be a rigid body in a Galilean spacetime with $\mathcal{B} \subset \mathcal{E}(s_0)$. The following statements hold:

(i) *the expression*

$$x_c = \frac{1}{\mu(\mathcal{B})} \int_{\mathcal{B}} (x - x_0) \mathrm{d}\mu + x_0$$

is independent of the choice of $x_0 \in \mathcal{E}(s_0)$;

(ii) *x_c is the unique point in $\mathcal{E}(s_0)$ with the property that $\int_{\mathcal{B}} (x - x_c) \mathrm{d}\mu = 0$;*

(iii) *$x_c \in \mathrm{int}_{\mathrm{aff}(\mathcal{B})}(\mathrm{conv}(\mathcal{B}))$.*

Proof: (i) To check that the definition of x_c is independent of $x_0 \in \mathcal{E}(s_0)$, we let $\tilde{x}_0 \in \mathcal{E}(s_0)$ and compute

$$\frac{1}{\mu(\mathcal{B})}\int_{\mathcal{B}}(x-\tilde{x}_0)\mathrm{d}\mu+\tilde{x}_0=\frac{1}{\mu(\mathcal{B})}\int_{\mathcal{B}}(x-x_0)\mathrm{d}\mu+\frac{1}{\mu(\mathcal{B})}\int_{\mathcal{B}}(x_0-\tilde{x}_0)\mathrm{d}\mu$$
$$+(\tilde{x}_0-x_0)+x_0=\frac{1}{\mu(\mathcal{B})}\int_{\mathcal{B}}(x-x_0)\mathrm{d}\mu+x_0.$$

(ii) By definition of x_c and by part (i), we have

$$x_c=\frac{1}{\mu(\mathcal{B})}\int_{\mathcal{B}}(x-x_c)\mathrm{d}\mu+x_c,$$

from which it follows that

$$\int_{\mathcal{B}}(x-x_c)\mathrm{d}\mu=\mu(\mathcal{B})(x_c-x_c)=0.$$

Now suppose that $\tilde{x}_c\in\mathcal{E}(s_0)$ is an arbitrary point with the property that

$$\int_{\mathcal{B}}(x-\tilde{x}_c)\mathrm{d}\mu=0.$$

Then, by (i),

$$x_c=\frac{1}{\mu(\mathcal{B})}\int_{\mathcal{B}}(x-\tilde{x}_c)\mathrm{d}\mu+\tilde{x}_c,$$

from which we conclude that $\tilde{x}_c=x_c$.

(iii) If x_c is on the relative boundary of $\mathrm{conv}(\mathcal{B})$ or not in $\mathcal{B}$ at all, then there exists a hyperplane P in $\mathcal{E}(s_0)$ passing through x_c such that there are points in $\mathcal{B}$ which lie on one side of P, but there are no points in $\mathcal{B}$ on the opposite side. In other words, there exists $\lambda\in\ker(\tau)^\star$ such that the set

$$\{x\in\mathcal{B}|\lambda(x-x_c)>0\}$$

is nonempty, but the set

$$\{x\in\mathcal{B}|\lambda(x-x_c)<0\}$$

is empty. But this would imply that

$$\int_{\mathcal{B}}\lambda(x-x_c)\mathrm{d}\mu>0,$$

contradicting (ii). □

B. The inertia tensor

The properties of a rigid body are characterized by three things: (1) its mass, (2) its center of mass, and (3) its inertia tensor. We now define the latter. The *inertia tensor* about $x_0\in\mathcal{E}(s_0)$ of a rigid body $(\mathcal{B},\mu)$ is defined to be the linear map $\mathbb{I}_{x_0}:\ker(\tau)\to\ker(\tau)$ given by

$$\mathbb{I}_{x_0}(u)=\int_{\mathcal{B}}(x-x_0)\times(u\times(x-x_0))\mathrm{d}\mu.$$

We denote the inertia tensor about the center of mass of $(\mathcal{B},\mu)$ by $\mathbb{I}_c$. Next, we record some basic properties of the inertia tensor.

Proposition 3.2: The inertia tensor $\mathbb{I}_{x_0}$ of a rigid body $(\mathcal{B},\mu)$ is symmetric with respect to the inner product g.

Proof: Using the vector identity $g(u,v\times w)=g(w,u\times v)$, we compute

$$g(\mathbb{I}_{x_0}(u_1),u_2)=\int_{\mathcal{B}} g((x-x_0)\times(u_1\times(x-x_0)),u_2)\mathrm{d}\mu=\int_{\mathcal{B}} g(u_1\times(x-x_0)\ ,(u_2\times(x-x_0))\mathrm{d}\mu$$

$$=\int_{\mathcal{B}} g(u_1,(x-x_0)\times(u_2\times(x-x_0)))\mathrm{d}\mu=g(u_1,\mathbb{I}_{x_0}(u_2)),$$

which is what we wished to show. □

C. Eigenvalues of the inertia tensor

Since $\mathbb{I}_{x_0}$ is symmetric, its eigenvalues are real. Furthermore, they are non-negative. The following result demonstrates this, as well as other eigenvalue related assertions.

Proposition 3.3: Let $(\mathcal{B},\mu)$ be a rigid body with $\mathcal{B}\subset\mathcal{E}(s_0)$ and let $x_0\in\mathcal{E}(s_0)$. Let $\mathbb{I}_{x_0}$ denote the inertia tensor of $(\mathcal{B},\mu)$ about x_0. The following statements hold:

(i) *the eigenvalues of the inertia tensor $\mathbb{I}_{x_0}$ of the rigid body are real and non-negative;*
(ii) *if $\mathbb{I}_{x_0}$ has a zero eigenvalue, then the other two eigenvalues are equal;*
(iii) *if $\mathbb{I}_{x_0}$ has two zero eigenvalues, then $\mathbb{I}_{x_0}=0$.*

Proof: (i) Since $\mathbb{I}_{x_0}$ is symmetric, its eigenvalues will be non-negative if and only if the quadratic form $u\mapsto g(\mathbb{I}_{x_0}(u),u)$ is positive-semidefinite. For $u\in\ker(\tau)$, we compute

$$g(\mathbb{I}_{x_0}(u),u)=\int_{\mathcal{B}} g(u,(x-x_0)\times(u\times(x-x_0)))\mathrm{d}\mu=\int_{\mathcal{B}} g(u\times(x-x_0),u\times(x-x_0))\mathrm{d}\mu.$$

Since the integrand is non-negative, so too will be the integral.

(ii) Let I_1 be the zero eigenvalue with v_1 a unit eigenvector. We claim that the support of the mass distribution μ must be contained in the line

$$\ell_{v_1}=\{sv_1+x_0|s\in\mathbb{R}\}.$$

To see that this must be so, suppose that the support of μ is not contained in ℓ_{v_1}. Then there exists a Borel set $S\subset\mathcal{E}(s_0)\backslash\ell_{v_1}$ such that $\mu(S)>0$. This would imply that

$$g(\mathbb{I}_{x_0}(v_1),v_1)=\int_{\mathcal{B}} g(v_1\times(x-x_0),v_1\times(x-x_0))\mathrm{d}\mu\geqslant\int_{S} g(v_1\times(x-x_0),v_1\times(x-x_0))\mathrm{d}\mu.$$

Since $S\cap\ell_{v_1}=\varnothing$, it follows that, for all points $x\in S$, the vector $x-x_0$ is not collinear with v_1. Therefore

$$g(v_1\times(x-x_0),v_1\times(x-x_0))>0$$

for all $x\in S$, and this would imply that $g(\mathbb{I}_{x_0}(v_1),v_1)>0$. But this contradicts v_1 being an eigenvector with zero eigenvalue, and so the support of $\mathcal{B}$ must be contained in the line ℓ_{v_1}.

To see that this implies that the remaining two eigenvectors are equal, we shall show that any vector that is g-orthogonal to v_1 is an eigenvector for $\mathbb{I}_{x_0}$. First write

$$x-x_0=f^1(x)v_1+f^2(x)v_2+f^3(x)v_3$$

for functions $f^i:\mathcal{E}(s_0)\to\mathbb{R}$, $i=1,2,3$. Since the support of μ is contained in the line ℓ_{v_1}, we have

$$\int_{\mathcal{B}} (x-x_0)\times(u\times(x-x_0))\mathrm{d}\mu = v_1\times(u\times v_1)\int_{\mathcal{B}} (f^1(x))^2\mathrm{d}\mu$$

for all $u\in\ker(\tau)$. Now recall the property of the cross product that $v_1\times(u\times v_1)=u$, provided that u is orthogonal to v_1 and that v_1 has unit length. Therefore, we see that for any u that is orthogonal to v_1, we have

$$\mathbb{I}_{x_0}(u) = \left(\int_{\mathcal{B}} (f^1(x))^2\mathrm{d}\mu\right)u,$$

meaning that all such vectors u are eigenvectors with the same eigenvalue, which is what we wished to show.

(iii) It follows from the above arguments that, if two eigenvalues I_1 and I_2 are zero, then the support of μ must lie in the intersection of the lines ℓ_{v_1} and ℓ_{v_2} (here v_i is an eigenvector for I_i, $i=1,2$), and this intersection is a single point that must therefore be x_0. From this and the definition of $\mathbb{I}_{x_0}$, it follows that $\mathbb{I}_{x_0}=0$. □

Note that, in proving the result, we have proved the following corollary.

Corollary 3.4: Let $(\mathcal{B},\mu)$ *be a rigid body with inertia tensor* $\mathbb{I}_{x_0}$. *The following statements are true:*

(i) $\mathbb{I}_{x_0}$ *has a zero eigenvalue if and only if* $\mathcal{B}$ *is contained in a line through* x_0;
(ii) *if* $\mathbb{I}_{x_0}$ *has two zero eigenvalues, then* $\mathcal{B}=\{x_0\}$, *i.e.,* $\mathcal{B}$ *is a particle located at* x_0;
(iii) *if there is no line through* x_0 *that contains the support of* μ, *then the inertia tensor is an isomorphism.*

In coming to an understanding of the "appearance" of a rigid body, it is most convenient to refer to its inertia tensor $\mathbb{I}_c$ about its center of mass. Let $\{I_1,I_2,I_3\}$ be the eigenvalues of $\mathbb{I}_c$ that we call the *principal inertias* of $(\mathcal{B},\mu)$. If $\{v_1,v_2,v_3\}$ are orthonormal eigenvectors associated with these eigenvalues, we call these the *principal axes* of $(\mathcal{B},\mu)$. Related to these is the *inertial ellipsoid* which is the ellipsoid in $\ker(\tau)$ given by

$$E(\mathcal{B}) = \{x^1v_1+x^2v_2+x^3v_3\in\ker(\tau)\,|\,I_1(x^1)^2+I_2(x^2)^2+I_3(x^3)^2=1\},$$

provided that none of the eigenvalues of $\mathbb{I}_{x_0}$ are zero. If one of the eigenvalues *does* vanish, then by Proposition 3.3, the other two eigenvalues are equal. If we suppose that $I_1=0$ and that $I_2=I_3=I$, then in the case of a single zero eigenvalue, the inertial ellipsoid is

$$E(\mathcal{B}) = \left\{x^1v_1+x^2v_2+x^3v_3\in\ker(\tau)\,|\,x^2=x^3=0, x^1\in\left\{-\frac{1}{\sqrt{I}},\frac{1}{\sqrt{I}}\right\}\right\}.$$

In the most degenerate case, when all eigenvalues are zero, we define $E(\mathcal{B})=\{0\}$. These latter two inertial ellipsoids correspond to cases (i) and (ii) in Corollary 3.4.

To relate these properties of the eigenvalues of $\mathbb{I}_c$ with the inertial ellipsoid $E(\mathcal{B})$, it is helpful to introduce the notion of an axis of symmetry for a rigid body. We let $\mathbb{I}_c$ be the inertia tensor about the center of mass, and denote by $\{I_1,I_2,I_3\}$ its eigenvalues and $\{v_1,v_2,v_3\}$ its orthogonal eigenvectors. A vector $v\in\ker(\tau)\backslash\{0\}$ is an *axis of symmetry* for $(\mathcal{B},\mu)$ if, for every $R\in O(\ker(\tau))$ which fixes v, we have $R(E(\mathcal{B}))=E(\mathcal{B})$. The following result gives the relationship between axes of symmetry and the eigenvalues of $\mathbb{I}_c$.

Proposition 3.5: Let $(\mathcal{B},\mu)$ *be a rigid body with inertia tensor* $\mathbb{I}_c$ *about its center of mass. Let* $\{I_1,I_2,I_3\}$ *be the eigenvalues of* $\mathbb{I}_c$ *with orthonormal eigenvectors* $\{v_1,v_2,v_3\}$. *If* $I_1=I_2$, *then* v_3 *is an axis of symmetry for* $(\mathcal{B},\mu)$.

Conversely, if $v\in\ker(\tau)$ *is an axis of symmetry, then* v *is an eigenvector of* $\mathbb{I}_c$. *If* I *is the eigenvalue for which* v *is an eigenvector, then the other two eigenvalues of* $\mathbb{I}_c$ *are equal.*

Proof: Write $I_1=I_2=I$. We then see that any vector $v\in\mathrm{span}_{\mathbb{R}}\{v_1,v_2\}$ will have the property

that $\mathbb{I}_c(v)=Iv$. Now, let $R\in O(\ker(\tau))$ fix the vector v_3. Because R is orthogonal, if we have $v\in \mathrm{span}_{\mathbb{R}}\{v_1,v_2\}$, then $R(v)\in \mathrm{span}_{\mathbb{R}}\{v_1,v_2\}$. Also, if $v=a^1v_1+a^2v_2$, then,

$$R(v)=(\cos\theta a^1+\sin\theta a^2)v_1+(-\sin\theta a^1+\cos\theta a^2)v_2 \tag{1}$$

for some $\theta\in\mathbb{R}$, since R is simply a rotation in the plane spanned by v_1,v_2. Now let $u\in E(\mathcal{B})$. We then write $u=x^1v_1+x^2v_2+x^3v_3$ and note that

$$I(x^1)^2+I(x^2)^2+I_3(x_3)^2=1.$$

It is now a straightforward calculation to verify that $R(u)\in E(\mathcal{B})$ using (1) and the fact that R fixes v_3. This shows that $R(E(\mathcal{B}))=E(\mathcal{B})$, and so v_3 is an axis of symmetry for $(\mathcal{B},\mu)$.

For the second part of the proposition, let v be an axis of symmetry for $(\mathcal{B},\mu)$. Denote the set of orthogonal mappings that fix v by $O(v)$. That is, let

$$O(v)=\{R\in O(\ker(\tau))\,|\,R(v)=v\}.$$

Now $R\in O(v)$ has the property that $R(E(\mathcal{B}))=E(\mathcal{B})$, and thus maps principal axes of $(\mathcal{B},\mu)$ to principal axes. Since $\{v_1,v_2,v_3\}$ form an orthonormal basis for $\ker(\tau)$, it is clear that, for every $R\in O(v)$, the set $\{R(v_1),R(v_2),R(v_3)\}$ is also an orthonormal basis. It can be seen that every vector orthogonal to v is a principal axis and thus, without loss of generality, we can take $v/\|v\|=v_3$. It is now clear that $\mathbb{I}_c$ acts on $v^\perp$ by scalars, and thus v is an eigenvector of $\mathbb{I}_c$. The result now follows. □

IV. THE STRUCTURE OF THE GALILEAN GROUP

As defined previously, the Galilean group of a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$ is the set of affine maps from $\mathcal{E}$ to itself that preserve simultaneity of events and the distance between simultaneous events. In this section, we shall examine the Galilean group and describe its properties. In Sec. IV A we study the canonical Galilean group and show that it consists of rotations, translations, velocity boosts, and temporal origin shifts. We also look at its subgroups and describe the various fundamental objects associated with it. In Sec. IV B, we study the abstract Galilean group $\mathrm{Gal}(\mathcal{G})$. We show that, in the presence of an observer, the Galilean group is isomorphic to the canonical Galilean group. Finally, in Sec. VI A, we introduce canonical velocities and describe their images under the isomorphism of the Lie algebras induced by the Lie group isomorphism constructed previously.

A. The canonical Galilean group

In this section, we study the Galilean group of a canonical Galilean spacetime, which is a generalization of the "standard" Galilean spacetime $\mathbb{R}^3\times\mathbb{R}$. To be precise, given a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$, the *canonical* spacetime of $\mathcal{G}$ is the Galilean spacetime $\mathcal{G}_{\mathrm{can}}:=(\mathcal{E}_{\mathrm{can}}:=\ker(\tau)\oplus\mathbb{R},V=\ker(\tau)\oplus\mathbb{R},g,\tau)$. We now investigate the structure of the canonical Galilean group $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$. The next proposition shows that $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ decomposes into rotations, spatial translations, Galilean velocity boosts, and temporal translations.

Proposition 4.1: The Galilean group $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ *of the canonical spacetime* $\mathcal{G}_{\mathrm{can}}$ *is isomorphic to* $(O(\ker(\tau))\ltimes\ker(\tau))\ltimes(\ker(\tau)\times\mathbb{R})$, *where* $\ltimes$ *denotes semidirect product of groups. The group operation on* $O(\ker(\tau))\ltimes\ker(\tau))\ltimes(\ker(\tau)\times\mathbb{R})$ *is given by*

$$(R_1,r_1,u_1,t_1)\cdot(R_2,r_2,u_2,t_2)=(R_1\circ R_2,r_1+R_1(r_2)+t_2u_1,u_1+R_1(u_2),t_1+t_2),$$

where $(R_i,r_i,u_i,t_i)\in O(\ker(\tau))\ltimes\ker(\tau))\ltimes(\ker(\tau)\times\mathbb{R}$, $i=1,2$.

Proof: We first find the form of a Galilean transformation $\phi:\mathcal{E}_{\mathrm{can}}\to\mathcal{E}_{\mathrm{can}}$. Recall that, since ϕ is an affine map, it has the form $\phi(x,t)=A(x,t)+(r,\sigma)$ where $A:\ker(\tau)\oplus\mathbb{R}\to\ker(\tau)\oplus\mathbb{R}$ is $\mathbb{R}$-linear and where $(r,\sigma)\in\ker(\tau)\oplus\mathbb{R}$. Given vector spaces U and V, we denote the set of linear maps from U to V by $L(U,V)$. Let us write $A(x,t)=(A_{11}x+A_{12}t,A_{21}x+A_{22}t)$ where $A_{11}\in L(\ker(\tau),\ker(\tau))$, $A_{12}\in L(\mathbb{R},\ker(\tau))$, $A_{21}\in L(\ker(\tau),\mathbb{R})$, and $A_{22}\in L(\mathbb{R},\mathbb{R})$. By property (iii) of

Galilean mappings, A_{11} is a g-orthogonal transformation of $\ker(\tau)$. Property (ii) of Galilean mappings implies that

$$A_{22}(t_2-t_1)+A_{21}(x_2-x_1)=t_2-t_1, \quad t_1,t_2\in\mathbb{R}, x_1x_2\in\ker(\tau).$$

Thus, taking $x_1=x_2$, we see that $A_{22}=1$. This in turn implies that $A_{21}=0$. Gathering this information shows that a Galilean transformation has the form

$$\phi:\begin{bmatrix}x\\t\end{bmatrix}\mapsto\begin{bmatrix}R & u\\0 & 1\end{bmatrix}\begin{bmatrix}x\\t\end{bmatrix}+\begin{bmatrix}r\\\sigma\end{bmatrix},$$

where $R\in O(\ker(\tau))$, $\sigma\in\mathbb{R}$, and $r,u\in\ker(\tau)$. This proves the first part of the proposition. Now, it is easy to see that, if ϕ_i, $i=1,2$, are Galilean transformations given by

$$\phi_i:\begin{bmatrix}x\\t\end{bmatrix}\mapsto\begin{bmatrix}R_i & u_i\\0 & 1\end{bmatrix}\begin{bmatrix}x\\t\end{bmatrix}+\begin{bmatrix}r_i\\\sigma_i\end{bmatrix}, \quad i=1,2,$$

then

$$\phi_1\circ\phi_2:\begin{bmatrix}x\\t\end{bmatrix}\mapsto\begin{bmatrix}R_1\circ R_2 & u_1+R_1(u_2)\\0 & 1\end{bmatrix}\begin{bmatrix}x\\t\end{bmatrix}+\begin{bmatrix}r_1+R_1(r_2)+\sigma_2u_1\\\sigma_1+\sigma_2\end{bmatrix}.$$

which gives us the desired group operation. □

Remarks 4.2: (1) It is clear from this proposition that $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ is a ten-dimensional group. This is not altogether obvious from the definition.

(2) The meaning of the appearance of two semi-direct products in the decomposition of $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ should be understood correctly. They arise because $\ker(\tau)\times\mathbb{R}$ is a normal subgroup of $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ and the quotient group itself is a semi-direct product of $O(\ker(\tau))$ and $\ker(\tau)$.

(3) A canonical Galilean transformation may now be written as a composition of one of three basic classes of transformations.

(i) *A spatiotemporal shift of origin:*

$$\begin{bmatrix}x\\t\end{bmatrix}\mapsto\begin{bmatrix}x\\t\end{bmatrix}+\begin{bmatrix}r\\\sigma\end{bmatrix},$$

for $r\in\ker(\tau)$, $\sigma\in\mathbb{R}$.

(ii) *A "rotation" of reference frame:*

$$\begin{bmatrix}x\\t\end{bmatrix}\mapsto\begin{bmatrix}R & 0\\0 & 1\end{bmatrix}\begin{bmatrix}x\\t\end{bmatrix},$$

for $R\in O(\ker(\tau))$.

(iii) *A (Galilean) velocity boost:*

$$\begin{bmatrix}x\\t\end{bmatrix}\mapsto\begin{bmatrix}\mathrm{id}_{\ker(\tau)} & u\\0 & 1\end{bmatrix}\begin{bmatrix}x\\t\end{bmatrix},$$

for $u\in\ker(\tau)$.

The names we have given these fundamental transformations are suggestive. A shift of the spatiotemporal origin should be thought of as moving the origin to a new position, and resetting the clock, but maintaining the same orientation in space. A rotation of reference frame means the origin stays in the same place, and uses the same clock but rotates the "point of view." The final basic transformation, a velocity boost, means that the origin maintains its orientation and uses the same clock, but now moves with a certain velocity with respect to the previous origin.

B. The structure of the abstract Galilean group

In the usual presentation of Galilean invariant mechanics (e.g., Ref. 11), one considers a spacetime $\mathbb{R}^3 \times \mathbb{R}$ and Galilean invariance is imposed by asking that the system admit the Galilean group as a symmetry group. In this case, the Galilean group naturally breaks down into rotations, translations, Galilean boosts (constant velocity shifts), and temporal origin shifts. In our abstract setting, the Galilean group $\mathrm{Gal}(\mathcal{G})$ does not admit such a decomposition. Note that this is similar to what one sees in an affine Euclidean space where a decomposition of an isometry into rotation and translation is not possible until one chooses an origin about which to measure rotations. However, the presence of an observer in a Galilean spacetime defines, for each instant, an isomorphism from the abstract Galilean group $\mathrm{Gal}(\mathcal{G})$ into the canonical group $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$.

Proposition 4.3: Let $\mathcal{G}=(\mathcal{E}, V, g, \tau)$ be a Galilean spacetime with $\mathcal{O}$ an observer. The following statements hold.

(i) *The mapping from V to $\ker(\tau) \oplus \mathbb{R}$ defined by $v \mapsto (P_{\mathcal{O}}(v), \tau(v))$ is an isomorphism.*

(ii) *For each $s_0 \in I_{\mathcal{G}}$, the observer at s_0, $\mathcal{O}_{s_0}$, induces a natural isomorphism $\iota_{\mathcal{O}_{s_0}}$ from $\mathrm{Gal}(\mathcal{G})$ to the group $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$. Explicitly, if $\psi \in \mathrm{Gal}(\mathcal{G})$ with t_ψ as defined in Lemma 2.8, and if $R_\psi \in O(\ker(\tau))$ and $r_{\psi,\mathcal{O}} \in \ker(\tau)$ satisfy*

$$\psi(x) = (R_\psi(x - \mathcal{O}_{s_0}) + r_{\psi,\mathcal{O}}) + \mathcal{O}_{t_\psi + s_0}, \quad x \in \mathcal{E}(s_0),$$

then

$$\iota_{\mathcal{O}_s}(\psi) = (R_\psi, r_{\psi,\mathcal{O}}, u_{\psi,\mathcal{O}}, t_\psi),$$

where $u_{\psi,\mathcal{O}} = P_{\mathcal{O}}(\psi_V(v_{\mathcal{O}}))$.

Proof: (i) It suffices to show that the mapping $v \mapsto (P_{\mathcal{O}}(v), \tau(v))$ is injective. If $\tau(v)=0$, then $v \in \ker(\tau)$. Now, if we also have

$$P_{\mathcal{O}}(v) = v - (\tau(v))v_{\mathcal{O}} = 0,$$

we must have $v=0$, thus the mapping is injective as desired.

(ii) We first assign to each $(R, r, u, t) \in \mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ a Galilean mapping ψ, and show that the construction implies that $(R, r, u, t) = (R_\psi, r_{\psi,\mathcal{O}}, u_{\psi,\mathcal{O}}, t_\psi)$, thus showing that $\iota_{\mathcal{O}_{s_0}}$ is invertible. Now, given $(R, r, u, t) \in \mathrm{Gal}_{\mathrm{can}}(\mathcal{G})$, we define a map $\psi: \mathcal{E} \to \mathcal{E}$ by

$$\psi(x) = tv_{\mathcal{O}} + (R(x - \mathcal{O}_{\pi_{\mathcal{G}}(x)}) + (\pi_{\mathcal{G}}(x) - s_0)u + r) + \mathcal{O}_{\pi_{\mathcal{G}}(x)}. \tag{2}$$

We now show that this mapping is Galilean. First we show that it is affine. For $v \in V$, we compute

$$\begin{aligned}
\psi(v + \mathcal{O}_{s_0}) - \psi(\mathcal{O}_{s_0}) &= tv_{\mathcal{O}} + (R(v + \mathcal{O}_{s_0} - \mathcal{O}_{\tau(v)+s_0}) + ((\tau(v) + s_0) - s_0)u + r) \\
&\quad + \mathcal{O}_{\tau(v)+s} - (tv_{\mathcal{O}} + r + \mathcal{O}_{s_0}) \\
&= R(v + \mathcal{O}_{s_0} - (\tau(v)v_{\mathcal{O}} + \mathcal{O}_{s_0})) + \tau(v)(u + v_{\mathcal{O}}) \\
&= R(v - \tau(v)v_{\mathcal{O}}) + \tau(v)(u + v_{\mathcal{O}}) \\
&= R(P_{\mathcal{O}}(v)) + \tau(v)(u + v_{\mathcal{O}}).
\end{aligned} \tag{3}$$

Thus the map $v \mapsto \psi(v + \mathcal{O}_{s_0}) - \psi(\mathcal{O}_{s_0})$ is linear, so ψ is affine. Similarly, we calculate

$$\tau(\psi(x_1) - \psi(x_2)) = \tau(tv_{\mathcal{O}} + \mathcal{O}_{\pi_{\mathcal{G}}(x_1)}) - \tau(tv_{\mathcal{O}} + \mathcal{O}_{\pi_{\mathcal{G}}(x_2)}) = t + \pi_{\mathcal{G}}(x_1) - (t + \pi_{\mathcal{G}}(x_2)) = \tau(x_1 - x_2).$$

So property (ii) of Galilean mappings is satisfied. Next, for $s_0 \in I_{\mathcal{G}}$, consider $y_1, y_2 \in \mathcal{E}(s_0)$. We compute

$$\psi(y_1) - \psi(y_2) = tv_{\mathcal{O}} + R(y_1 + \mathcal{O}_{s_0}) + (s_0 - s_0)u + r + \mathcal{O}_{s_0} - (tv_{\mathcal{O}} + R(y_2 - \mathcal{O}_{s_0}) + (s_0 - s_0)u + r + \mathcal{O}_{s_0})$$
$$= R(y_1 - y_2).$$

Thus ψ satisfies property (iii) of Galilean mappings. Next we show that $(R,r,u,t) = (R_\psi, r_{\psi,\mathcal{O}}, u_{\psi,\mathcal{O}}, t_\psi)$. By restricting ψ to $\mathcal{E}(s_0)$ we get

$$(\psi|\mathcal{E}(s_0))(x) = tv_{\mathcal{O}} + (R(x - \mathcal{O}_{s_0}) + r) + \mathcal{O}_{s_0} = (R(x - \mathcal{O}_{s_0}) + r) + \mathcal{O}_{t+s_0}.$$

However, the definition of R_ψ and $r_{\psi,\mathcal{O}}$ gives

$$R(x - \mathcal{O}_{s_0}) + r = R_\psi(x - \mathcal{O}_{s_0}) + r_{\psi,\mathcal{O}},$$

for each $x \in \mathcal{E}(s_0)$. Taking $x = \mathcal{O}_{s_0}$ gives $r = r_{\psi,\mathcal{O}}$, from which it follows that $R = R_\psi$. Also, for $x \in \mathcal{E}(s_0)$, we have

$$\psi_{I_{\mathcal{G}}}(s_0) = \pi_{\mathcal{G}}(\psi(x)) = t + s_0.$$

From Lemma 2.8, it follows that $t = t_\psi$. From (3) we also have

$$P_{\mathcal{O}}(\psi_V(v_{\mathcal{O}})) = R(P_{\mathcal{O}}(v_{\mathcal{O}})) + \tau(v_{\mathcal{O}})u = u,$$

using the fact that $P_{\mathcal{O}}(v_{\mathcal{O}}) = 0$. This shows that $u = u_{\psi,\mathcal{O}}$. We have now shown that, for every $(R,r,u,t) \in \mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$, there is a Galilean mapping ψ such that $\iota_{\mathcal{O}_{s_0}}(\psi) = (R,r,u,t)$. Thus we have shown that $\iota_{\mathcal{O}_{s_0}}$ is surjective. Next we show that it is injective. For this, let $\tilde{\psi} \in \mathrm{Gal}(\mathcal{G})$ be such that, for $x \in \mathcal{E}$,

$$\tilde{\psi}(x) = tv_{\mathcal{O}} + (R(x - \mathcal{O}_{s_0}) + (\pi_{\mathcal{G}}(x) - s_0)u + r) + \mathcal{O}_{\pi_{\mathcal{G}}(x)}.$$

that is, suppose that

$$\iota_{\mathcal{O}_{s_0}}(\tilde{\psi}) = (R,r,u,t) = \iota_{\mathcal{O}_{s_0}}(\psi).$$

We shall show that $\tilde{\psi} = \psi$. Since $\tilde{\psi}(\mathcal{O}_{s_0}) = \psi(\mathcal{O}_{s_0})$, using (3) this will follow if we can show that $\tilde{\psi}_V = \psi_V$. As in (i), we note that $V \simeq \ker(\tau) \oplus \mathbb{R}$ and the preimage of (u,t) under this isomorphism is $u + tv_{\mathcal{O}}$. We also write

$$\psi_V(u + tv_{\mathcal{O}}) = A_{11}(u) + A_{12}(t) + (A_{21}(u) + A_{22}(t))v_{\mathcal{O}},$$

for linear mappings $A_{11}: \ker(\tau) \to \ker(\tau)$, $A_{12}: \mathbb{R} \to \ker(\tau)$, $A_{21}: \ker(\tau) \to \mathbb{R}$, and $A_{22}: \mathbb{R} \to \mathbb{R}$. The property (ii) of Galilean mappings implies that ψ_V has $\ker(\tau)$ as an invariant subspace. Thus $A_{21} = 0$. We next calculate

$$\tau(\psi_V(tv_{\mathcal{O}})) = \tau(\psi(tv_{\mathcal{O}} + \mathcal{O}_{s_0})) - \tau(\psi(\mathcal{O}_{s_0})) = \tau(tv_{\mathcal{O}} + \mathcal{O}_{s_0}) - \tau(\mathcal{O}_{s_0}) = t.$$

This gives $A_{22}(t) = t$. With $t = 0$, property (iii) of Galilean mappings implies that $A_{11} \in O(\ker(\tau))$. Thus we have

$$\psi_V(u + tv_{\mathcal{O}}) = \tilde{R}(u) + t(\tilde{u} + v_{\mathcal{O}}), \tag{4}$$

for some $\tilde{R} \in O(\ker(\tau))$ and $\tilde{u} \in \ker(\tau)$. Since $\psi|\mathcal{E}(s) = \tilde{\psi}|\mathcal{E}(s)$ we have

$$\psi_V(u) = \tilde{\psi}(u + \mathcal{O}_{s_0}) - \tilde{\psi}(\mathcal{O}_{s_0}) = R_\psi(u),$$

giving $\tilde{R} = R$. From (3) we also have

$$P_{\mathcal{O}}(\psi_V(v_{\mathcal{O}}) = \tilde{u},$$

from which we get $u=\tilde{u}$. This shows that $\psi_V=\tilde{\psi}_V$, thus showing that, if $\psi_1,\psi_2\in\mathrm{Gal}(\mathcal{G})$ satisfy $\iota_{\mathcal{O}_{s_0}}(\psi_1)=\iota_{\mathcal{O}_{s_0}}(\psi_2)$, then $\psi_1=\psi_2$. Therefore, $\iota_{\mathcal{O}_{s_0}}$ is injective.

Finally we show that $\iota_{\mathcal{O}_{s_0}}$ is a homomorphism. We let $\psi_1,\psi_2\in\mathrm{Gal}(\mathcal{G})$ and denote $\iota_{\mathcal{O}_{s_0}}(\psi_i)=(R_i,r_i,u_i,t_i)$, $i=1,2$. We also let $\iota_{\mathcal{O}_{s_0}}(\psi_1\circ\psi_2)=(R_{12},r_{12},u_{12},t_{12})$. First, we compute

$$\begin{aligned}(\psi_1\circ\psi_2)_V(v) &= (\psi_1\circ\psi_2)(v+\mathcal{O}_{s_0})-(\psi_1\circ\psi_2)(\mathcal{O}_{s_0}) = \psi_1(\psi_2(v+\mathcal{O}_{s_0}))-\psi_1(\psi_2(\mathcal{O}_{s_0}))\\ &= \psi_1(tv_{\mathcal{O}}+R_2(v+\mathcal{O}_{s_0}-\mathcal{O}_{\tau(v)+s_0})+\tau(v)u_2+r_2+\mathcal{O}_{\tau(v)+s_0})-\psi_1(tv_{\mathcal{O}}+r+\mathcal{O}_{s_0})\\ &= \psi_1((tv_{\mathcal{O}}+r)+R_2(P_{\mathcal{O}}(v))+\tau(v)(u_2+v_{\mathcal{O}})+\mathcal{O}_{s_0})-\psi_1(tv_{\mathcal{O}}+r_2+\mathcal{O}_{s_0})\\ &= \psi_{1,V}(R_2(P_{\mathcal{O}}(v))+\tau(v)(u_2+v_{\mathcal{O}}))=\psi_{1,V}(\psi_{2,V}(v)).\end{aligned}$$

From this we deduce that

$$R_{12}(u)+t(u_{12}+v_{\mathcal{O}})=R_1\circ R_2(u)+t(u_1+R_1(u_2)+v_{\mathcal{O}}),$$

for each $(u,t)\in\ker(\tau)\oplus\mathbb{R}$. Thus we have

$$R_{12}=R_1\circ R_2,\quad u_{12}=u_1+R_1(u_2).$$

Next we have

$$\psi_1\circ\psi_2(\mathcal{O}_{s_0})=r_{12}+\mathcal{O}_{t_{12}+s_0}. \tag{5}$$

Also,

$$\psi_2(\mathcal{O}_{s_0})=r_2+\mathcal{O}_{t_2+s_0}.$$

Therefore

$$\begin{aligned}\psi_1\circ\psi_2(\mathcal{O}_{s_0}) &= \psi_1(r_2+\mathcal{O}_{t_2+s_0})=R_1(r_2+\mathcal{O}_{t_2+s_0}-\mathcal{O}_{t_2+s_0})+t_2u_1+r_1+\mathcal{O}_{s_0+t_2+t_1}\\ &= R_1r_2+t_2u_1+r_1+\mathcal{O}_{s_0+t_1+t_2}.\end{aligned}$$

Comparing this to (5) we get

$$r_{12}=R_1r_2+t_2u_1+r_1,\quad t_{12}=t_1+t_2.$$

Thus we have shown that the group action defined on $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ agrees with that on $\mathrm{Gal}(\mathcal{G})$ under the bijection $\iota_{\mathcal{O}_{s_0}}$. □

We end this section by listing some of the subgroups of $\mathrm{Gal}(\mathcal{G})$ that we shall have occasion to use in the sequel. The following result is easy to prove.

Proposition 4.4: The following statements hold:

(i) *the following are subgroups of* $\mathrm{Gal}(\mathcal{G})$*:*

- *(a)* $\mathrm{Gal}_0(\mathcal{G}):=\{\psi\in\mathrm{Gal}(\mathcal{G}):\psi_{I_{\mathcal{G}}}=\mathrm{id}_{I_{\mathcal{G}}}\}$;
- *(b)* $N:=\{\psi\in\mathrm{Gal}(\mathcal{G}):\ \psi_V|_{\ker(\tau)}=\mathrm{id}_{\ker(\tau)}\}$;
- *(c)* $N_0:=N\cap\mathrm{Gal}_0(\mathcal{G})$.

(ii) *the set* $\mathrm{Lin}(\mathcal{G}):=\{\psi_V\,|\,\psi\in\mathrm{Gal}(\mathcal{G})\}$ *is a Lie group.*

V. OBSERVER-INDEPENDENT FORMULATION OF RIGID BODY MECHANICS

In this section we formulate rigid mechanics in an observer independent manner. All of the classical concepts in Eulerian rigid body mechanics—motions, body and spatial velocities, body and spatial momenta, and the equations of motion—are given definitions independent of an observer.

A. Rigid motions

A *rigid motion* in a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$ is a smooth mapping $\Psi:\mathbb{R}\to\mathrm{Gal}(\mathcal{G})$ with the property that $(\Psi(t))_{I_\mathcal{G}}(s)=s+t$, for each $t\in\mathbb{R}$ (see Sec. II E). In other words, if we denote $\Psi_t:=\Psi(t)$, then a rigid motion Ψ has the property that $\Psi_t(x)\in\mathcal{E}(t+\pi_\mathcal{G}(x))$ for each $x\in\mathcal{E}(s)$. Thus a rigid motion maps points in $\mathcal{E}(s)$ to $\mathcal{E}(s)$ at $t=0$, and for $t\neq 0$, the points get shifted by the affine action of $\mathbb{R}$ on $I_\mathcal{G}$. Let us give some of the basic properties of rigid motions. The following result is immediate.

Lemma 5.1: Given a rigid motion Ψ, for each $x\in\mathcal{E}$ the map $I_\mathcal{G}\ni s\mapsto\Psi_{s-\pi_\mathcal{G}(x)}(x)\in\mathcal{E}$ is a world line.

The next result shows how we can extract the "rotational component" of a rigid motion for each $t\in\mathbb{R}$.

Proposition 5.2: Let Ψ be a rigid motion in a Galilean specetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$. Then, for each $t\in\mathbb{R}$, we have $\Psi_{t,V}|_{\ker(\tau)}\in O(\ker(\tau))$.

Proof: From Lemma 2.8, it is clear that $\Psi_{t,V}$ maps $\ker(\tau)$ to itself. Next for simultaneous events x_1 and x_2, we compute

$$\begin{aligned} g(\Psi_{t,V}|_{\ker(\tau)}(x_1-x_2),\Psi_{t,V}|_{\ker(\tau)}(x_1-x_2)) &= g(\Psi_{t,V}(x_1-x_2),\Psi_{t,V}(x_1-x_2)) \\ &= g(\Psi_t(x_1)-\Psi_t(x_2),\Psi(x_1)-\Psi_t(x_2)) \\ &= g(x_1-x_2,x_1-x_2), \end{aligned}$$

where we have used the properties of the rigid motion and Lemma 2.8. This shows that $\Psi_{t,V}|_{\ker(\tau)}\in O(\ker(\tau))$ as desired. □

This proposition shows that, given a rigid motion Ψ in a Galilean spacetime, we can associate to this rigid motion a unique map from $\mathbb{R}\to O(\ker(\tau))$. We denote this map by R_Ψ.

B. Spatial and body velocities

In this section we define the concepts of spatial and body velocities corresponding to a rigid motion Ψ. Intuitively, the configuration of a rigid body is given by its "orientation" and "position" (with respect to an initial orientation and position). To make this precise, let us denote $Q:=O(\ker(\tau))\times\mathcal{E}$. If we choose a reference configuration, say $q_0=(R_0,x_0)\in Q$, it is easy to see that a Galilean mapping $\phi\in\mathrm{Gal}(\mathcal{G})$ maps q_0 to another point in Q as follows:

$$\mathrm{Gal}(\mathcal{G})\times Q\to Q,$$

$$(\phi,(R_0,x_0))\mapsto(R_\phi R_0,\phi(x_0)),\quad \phi\in\mathrm{Gal}(\mathcal{G}).$$

This defines an action of $\mathrm{Gal}(\mathcal{G})$ on Q which we represent by Φ. In other words, we have $\Phi(\phi,(R_0,x_0))=(R_\phi R_0,\phi(x_0))$. For each $q\in Q$ and $g\in\mathrm{Gal}(\mathcal{G})$, we define the maps $\Phi_q:\mathrm{Gal}(\mathcal{G})\to Q$ and $\Phi_g:Q\to Q$ by $\Phi_q(g):=\Phi(g,q)=:\Phi_q(g)$. The action Φ also defines an action of $\mathrm{Gal}(\mathcal{G})$ on $O(\ker(\tau))$ and $\mathcal{E}$, respectively. The latter action is denoted by $\Psi^\mathcal{E}$. Given $\zeta\in\mathfrak{gal}(\mathcal{G})$, denote the infinitesimal generator corresponding to ζ at $(R_0,x_0)\in Q$ by $\zeta_Q(R_0,x_0)$. It is easy to see that $\zeta_Q(R_0,x_0)$ can be written as

$$\zeta_Q(R_0,x_0) = (\zeta_{O(\ker(\tau))}(R_0), \zeta_{\mathcal{E}}(x_0)),$$

where $\zeta_{O(\ker(\tau))}(R_0)$ is the infinitesimal generator at $R_0 \in O(\ker(\tau))$ corresponding to ζ of the action of $\mathrm{Gal}(\mathcal{G})$ on $O(\ker(\tau))$, and $\zeta_{\mathcal{E}}(x_0)$ is the infinitesimal generator at $x_0 \in \mathcal{E}$ corresponding to ζ of the action of $\mathrm{Gal}(\mathcal{G})$ on $\mathcal{E}$.

Now, given a rigid motion Ψ, define curves $\xi_\Psi(t)$ and $\eta_\Psi(t) \in \mathfrak{gal}(\mathcal{G})$ as follows:

$$\eta_\Psi(t) = \Psi_t^{-1}\dot{\Psi}_t, \quad \xi_\Psi(t) = \dot{\Psi}_t\Psi_t^{-1}.$$

Notice that $\xi_\Psi(t) = \mathrm{Ad}_{\Psi_t}\eta_\Psi(t)$. These curves $\xi_\Psi(t)$ and $\eta_\Psi(t)$ are called "spatial velocity" and "body velocity," respectively, in the literature (see, for example, Ref. 5) and the interpretation for defining them in this way is somewhat unintuitive. In the sequel, given a rigid motion Ψ, we think of velocities at a point $q_0 = (R_0, x_0) \in Q$ as tangent vectors defined by the infinitesimal generators corresponding to the curves $\eta_\Psi(t)$ and $\xi_\Psi(t)$, respectively, at q_0. The idea is that a rigid motion generates a curve in Q (starting at q_0) given by $\Psi_t(q_0) := (R_\Psi(t)R_0, \Psi_t(x_0))$, and the tangent vector to this curve at a point corresponds to the velocity at that point. We now give our definitions for spatial and body velocities, respectively. First, given a rigid motion Ψ, we define maps $\Omega, \omega : \mathbb{R} \to \mathfrak{o}(\ker(\tau))$ by $\hat{\Omega}_\Psi(t) := R_\Psi^{-1}(t)\dot{R}_\Psi(t)$ and $\hat{\omega}_\Psi(t) := \dot{R}_\Psi(t)R_\Psi^{-1}(t)$, respectively. We also represent by $\tau_{\mathrm{ang}} : TQ \to T(O(\ker(\tau)))$ and $\tau_{\mathrm{lin}} : TQ \to T\mathcal{E}$ the respective projections. Denote by $\Theta_{\mathrm{ang}} : T(O(\ker(\tau))) \to O(\ker(\tau)) \times \mathfrak{o}(\ker(\tau))$ the right-trivialization of $T(O(\ker(\tau)))$. Thus $\Theta_{\mathrm{ang}}(v_g) = (g, T_gR_{g^{-1}}v_g)$ for $v_g \in T_g(O(\ker(\tau)))$ and $g \in O(\ker(\tau))$. Similarly, denote by $\Theta_{\mathrm{lin}} : T\mathcal{E} \to \mathcal{E} \times V$ the natural trivialization of $T\mathcal{E}$. Let us denote by pr_2 the projection onto the second components of $O(\ker(\tau)) \times \mathfrak{o}(\ker(\tau))$ and $\mathcal{E} \times V$, respectively. With an abuse of notation, we represent the maps $\mathrm{pr}_2 \circ \Theta_{\mathrm{ang}}$ and $\mathrm{pr}_2 \circ \Theta_{\mathrm{lin}}$ by Θ_{ang} and Θ_{lin}, respectively.

Definition 5.3: Let Ψ be a rigid motion in a Galilean spacetime $\mathcal{G}$.

(i) The *body velocity* is the map $V_\Psi^b : Q \times \mathbb{R} \to TQ$ given by

$$V_\Psi^b(R,x,t) = (\eta_\Psi(t))_Q(R,x).$$

The maps $V_{\Psi,\mathrm{ang}}^b := \Theta_{\mathrm{ang}} \circ \tau_{\mathrm{ang}} \circ V_\Psi^b$ and $V_{\Psi,\mathrm{lin}}^b := \Theta_{\mathrm{lin}} \circ \tau_{\mathrm{lin}} \circ V_\Psi^b$ are called *body angular velocity* and *body linear velocity*, respectively.

(ii) The *spatial velocity* is the map $V_\Psi^s : Q \times \mathbb{R} \to TQ$ defined by

$$V_\Psi^s(R,x,t) = (\xi_\Psi(t))_Q(R,x).$$

The maps $V_{\Psi,\mathrm{ang}}^s := \Theta_{\mathrm{ang}} \circ \tau_{\mathrm{ang}} \circ V_\Psi^s$ and $V_{\Psi,\mathrm{lin}}^s := \Theta_{\mathrm{lin}} \circ \tau_{\mathrm{lin}} \circ V_\Psi^s$ are called *spatial angular velocity* and *spatial linear velocity*, respectively.

Let us make a few comments about these definitions.

Remarks 5.4: (1) We identify the TQ-valued velocities with the corresponding $Q \times (\mathfrak{o}(\ker(\tau)) \times V)$-valued trivialization. Let us provide some intuition for these definitions. Notice that, for $q \in Q$, we have

$$\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(q)) = T_q\Phi_{\Psi_t}(\xi_\Psi(t)^{-1}\dot{\xi}_\Psi(t))_Q(q) = T_q\Phi_{\Psi_t}(V_\Psi^b(q,t)).$$

Therefore, $V_\Psi^b(q,t) = T_q\Phi_{\Psi_t^{-1}}((\mathrm{d}/\mathrm{d}t)(\Psi_t(q)))$. The body velocity can therefore be thought of as the velocity of the curve $\Psi_t(q)$ at $t \in \mathbb{R}$ as seen in the "frame" fixed at q.

(2) The definition of spatial velocity is less intuitive. It will become clearer once we prove Proposition 5.6.

(3) It is not clear at this stage how our definitions are consistent with the existing ones. We shall see, in Sec. VI B, that in the presence of an observer, the body and spatial velocities correspond to "canonical" velocities.

The definitions lead to the following relationship between body and spatial velocities, which we shall have occasion to use.

Lemma 5.5: $V^s_\Psi(R_\Psi(t)R,\Psi_t(x),t)=T_{(R,x)}\Phi_{\Psi_t}V^b_\Psi(R,x,t)$.

Proof: Given an action $\Phi:G\times Q\to Q$ of a Lie group G on a manifold Q, we have, for $\zeta\in\mathfrak{g}$ and $g\in G$, $(\mathrm{Ad}_g\zeta)_Q(g\cdot q)=T_q\Phi_g\zeta_Q(q)$. The result follows directly from this equality. □

Next, we write down the expressions for linear and angular velocities.

Proposition 5.6: Let Ψ be a motion in a Galilean spacetime $\mathcal{G}$. Then

(i) $V^b_{\Psi,\mathrm{ang}}(R,x,t)=\hat{\Omega}_\Psi(t)$,
(ii) $V^b_{\Psi,\mathrm{lin}}(R,x,t)=\Psi^{-1}_{t,V}(\mathrm{d}/\mathrm{d}t\Psi_t(x))$,
(iii) $V^s_{\Psi,\mathrm{ang}}(R,x,t)=\hat{\omega}_\Psi(t)$, *and*
(iv) $V^s_{\Psi,\mathrm{lin}}(R,x,t)=-\Psi_{t,V}(\mathrm{d}/\mathrm{d}t\Psi_t^{-1}(x))$.

Proof: (i) The projection $\tau_{\mathrm{ang}}(V^b_{\Psi,\mathrm{ang}}(R,x,t))$ is actually the infinitesimal generator corresponding to $(\Psi_{t,V}|^{-1}_{\ker(\tau)}\dot{\Psi}_{t,V}|_{\ker(\tau)})=\hat{\Omega}_\Psi(t)$. We compute

$$V^b_{\Psi,\mathrm{ang}}(R,x,t)=\left.\frac{\mathrm{d}}{\mathrm{d}s}\exp(s\hat{\Omega}_\Psi(t))R\right|_{s=0}=\hat{\Omega}_\Psi(t)R.$$

Thus $V^b_{\Psi,\mathrm{ang}}(R,x,t)=\hat{\Omega}_\Psi(t)$.

(ii) The body linear velocity $V^b_{\Psi,\mathrm{lin}}(R,x,t)$ is the infinitesimal generator corresponding to $\eta_\Psi(t)$ at $x\in\mathcal{E}$ of the action of $\mathrm{Gal}(\mathcal{G})$ on $\mathcal{E}$. We compute

$$\begin{aligned}V^b_{\Psi,\mathrm{lin}}(R,x,t)&=T_e\Phi^{\mathcal{E}}_x(T_{\Psi_t}L_{\Psi_t^{-1}}\dot{\Psi}_t)=T_{\Psi_t}(\Phi_{\Psi_t^{-1}}\Phi^{\mathcal{E}}_x)(\dot{\Psi}_t)\\&=\left.\frac{\mathrm{d}}{\mathrm{d}s}\Phi_{\Psi_t^{-1}}\Phi^{\mathcal{E}}_x\circ(\Psi_{t+s})\right|_{s=0}=\left.\frac{\mathrm{d}}{\mathrm{d}s}\Phi_{\Psi_t^{-1}}(\Psi_{t+s}(x))\right|_{s=0}\\&=T_{\Psi_t(x)}\Phi_{\Psi_t^{-1}}\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(x))=\Psi^{-1}_{t,V}\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(x)).\end{aligned}$$

This is what we wanted to prove.

(iii) This is identical to the proof of part (i).

(iv) The spatial linear velocity $V^s_{\Psi,\mathrm{lin}}(R,x,t)$ is the infinitesimal generator corresponding to $\xi_\Psi(t)$ at $x\in\mathcal{E}$ of the action of $\mathrm{Gal}(\mathcal{G})$ on $\mathcal{E}$. Notice that, by differentiating $\Psi_t\Psi_t^{-1}=\mathrm{id}_{\mathcal{E}}$, we get

$$T_{\Psi_t}R_{\Psi_t^{-1}}\dot{\Psi}_t=-T_{\Psi_t^{-1}}L_{\Psi_t}\dot{\Psi}_t^{-1}.$$

We compute

$$\begin{aligned}V^s_{\Psi,\mathrm{lin}}(R,x,t)&=T_e\Phi^{\mathcal{E}}_x(T_{\Psi_t}R_{\Psi_t^{-1}}\dot{\Psi}_t)=-T_e\Phi^{\mathcal{E}}_x(T_{\Psi_t}L_{\Psi_t}\dot{\Psi}_t^{-1})\\&=-\left.\frac{\mathrm{d}}{\mathrm{d}s}\Phi_{\Psi_t}\Phi^{\mathcal{E}}_x(\Psi^{-1}_{t+s})\right|_{s=0}=-\left.\frac{\mathrm{d}}{\mathrm{d}s}\Phi_{\Psi_t}(\Psi^{-1}_{t+s}(x))\right|_{s=0}\\&=-T_{\Psi_t^{-1}(x)}\Phi_{\Psi_t}\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t^{-1}(x))=-\Psi_{t,V}\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t^{-1}(x)),\end{aligned}$$

as desired. □

Thus, the spatial velocity at $(q_0,t)\in Q\times\mathbb{R}$ is obtained by taking the tangent vector to the curve $\Psi_t^{-1}(q_0)$, and then "pushing" this vector by the map $(-T_{\Psi_t^{-1}(x)}\Phi_{\Psi_t})$. In other words, $V^s_\Psi(q_0,t)$ can be thought of as the velocity of a point in Q traveling through q_0 at time t. This is exactly the interpretation of spatial velocity given in Ref. 5

C. Spatial and body momenta

In this section we define the spatial and body momenta for a rigid body. We identify $\mathfrak{o}(\ker(\tau))$ with $\ker(\tau)$ by the inverse of the map defined earlier and denote the angular velocities thought of as taking values in $\ker(\tau)$ by $V^b_{\Psi,\mathrm{ang}}$ and $V^s_{\Psi,\mathrm{ang}}$. Given a rigid body $(\mathcal{B},\mu)$, a rigid motion Ψ, and a curve $u:\mathbb{R}\to\ker(\tau)$, we define the *instantaneous inertia tensor* $\mathbb{I}_c(t):\ker(\tau)\to\ker(\tau)$ by

$$\mathbb{I}_c(t)(u(t)) = \int_{\mathcal{B}(t)} (\Psi_t(x)-\Psi_t(x_c)) \times (u(t)\times(\Psi_t(x)-\Psi_t(x_c)))\,\mathrm{d}\mu(t),$$

where $\mathcal{B}(t)=\Psi_t(\mathcal{B})$ and $u(t)\in\ker(\tau)$. Notice that, since the integrand is in $\ker(\tau)$, so too will be the integral. The following result shows what the spatial angular momentum looks like in terms of the inertia tensor of the body about its center of mass.

Lemma 5.7: $\mathbb{I}_c(t)(\omega_\Psi(t))=R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}(t)\omega_\Psi(t))$.

Proof: We represent by $\mathcal{B}(t)$ the rigid body after it has undergone the transformation Ψ_t and the corresponding mass distribution by $\mathrm{d}\mu(t)$. We compute

$$\begin{aligned}
\mathbb{I}_c(t)(\omega_\Psi(t)) &= \int_{\mathcal{B}(t)} (\Psi_t(x)-\Psi_t(x_c)) \times (\omega_\Psi(t)\times(\Psi_t(x)-\Psi_t(x_c)))\mathrm{d}\mu(t)\\
&= \int_{\mathcal{B}(t)} (\Psi_{t,V}(x-x_c)) \times (\omega_\Psi(t)\times(\Psi_{t,V}(x-x_c)))\mathrm{d}\mu(t)\\
&= \int_{\mathcal{B}(t)} (R_\Psi(t)(x-x_c)) \times (\omega_\Psi(t)\times(R_\Psi(t)(x-x_c)))\mathrm{d}\mu(t)\\
&= R_\Psi(t)\int_{\mathcal{B}} (x-x_c)\times(R_\Psi^{-1}(t)\omega_\Psi(t)\times(x-x_c))\mathrm{d}\mu = R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}(t)\omega_\Psi(t)),
\end{aligned}$$

where we have used the fact that $x-x_c\in\ker(\tau)$, and therefore $\Psi_{t,V}(x-x_c)=R_\Psi(t)(x-x_c)$. □

We can now define spatial and body momenta.

Definition 5.8: Let $(\mathcal{B},\mu)$ be a rigid body in a Galilean spacetime $\mathcal{G}$ and let Ψ be a rigid motion.

(i) *The spatial momentum is a map* $p_{\Psi,\mathcal{B}}:\mathbb{R}\to\ker(\tau)\times V$ *given by*

$$p_{\Psi,\mathcal{B}}(t) = (\mathbb{I}_c(t)V^s_{\Psi,\mathrm{ang}},\mu(\mathcal{B})V^s_{\Psi,\mathrm{lin}})(R_\Psi(t),\Psi_t(x_c),t).$$

(ii) *The body momentum is the map* $P_{\Psi,\mathcal{B}}:\mathbb{R}\to\ker(\tau)\times V$ *given by*

$$P_{\Psi,\mathcal{B}}(t) = (\mathbb{I}_c(t)V^b_{\Psi,\mathrm{ang}},\mu(\mathcal{B})V^b_{\Psi,\mathrm{lin}})(\mathrm{id}_{\ker(\tau)},x_c,t).$$

The following result can be readily proved using Lemma 5.5.

Proposition 5.9: Let $(\mathcal{B},\mu)$ *be a rigid body in a Galilean spacetime* $\mathcal{G}$ *and let* Ψ *be a rigid motion. Then*

(i) $p_{\Psi,\mathcal{B}}(t)=(\mathbb{I}_c(t)\omega_\Psi(t),\mu(\mathcal{B})\mathrm{d}/\mathrm{d}t\Psi_t(x_c))$,
(ii) $P_{\Psi,\mathcal{B}}(t)=(R_\Psi(t)^{-1}\mathbb{I}_c(t)\omega_\Psi(t),\mu(\mathcal{B})\Psi_{t,V}^{-1}\mathrm{d}/\mathrm{d}t\Psi_t(x_c))$.

Given a rigid body $(\mathcal{B},\mu)$, define an equivalence class of Galilean mappings as follows. Two mappings ϕ and $\psi\in\mathrm{Gal}(\mathcal{G})$ are called $\mathcal{B}$-*equivalent* if $\phi(\mathcal{B})=\psi(\mathcal{B})$. It is easy to see that this is an equivalence relation. In such a case, we denote the equivalence class containing ϕ by $[\phi]_\mathcal{B}$. In other words, any two mappings in the equivalence class $[\phi]_\mathcal{B}$ map the rigid body $\mathcal{B}$ to the same set of points in $\mathcal{E}$. The following result is readily verified.

Proposition 5.10: $\phi\in[\psi]_\mathcal{B}$ *if and only if* $\phi(x_c)=\psi(x_c)$ *and* $R_\phi=R_\psi$.

Proof: If $\phi\in[\psi]_\mathcal{B}$ then, for each $x\in\mathcal{B}$, we have $\phi(x)=\psi(x)$. Since $\mathcal{B}$ is a subset of $\mathcal{E}(s_0)$

(which is an affine space modeled on $\ker(\tau)$), we can write $x \in \mathcal{B}$ as $x = x_c + w$ for some $w \in \ker(\tau)$. We thus have

$$\phi(x_c + w) = \psi(x_c + w),$$

which implies that

$$\phi(x_c + w) - \phi(x_c) = \psi(x_c + w) - \psi(x_c).$$

We thus have $\phi_V(w) = \psi_V(w)$ and thus $R_\phi w = R_\psi w$. Conversely, assume that ψ is such that $R_\psi = R_\phi$ and $\psi(x_c) = \phi(x_c)$. By reversing the argument above, it is easy to show that $\phi(x) = \psi(x)$ for all $x \in \mathcal{B}$. □

Given a rigid body $(\mathcal{B}, \mu)$ and a rigid motion Ψ, a rigid motion $\tilde{\Psi}$ is *$\mathcal{B}$-equivalent* to Ψ if $\tilde{\Psi}_t \in [\Psi_t]_{\mathcal{B}}$ for each $t \in \mathbb{R}$. The following result is immediate.

Lemma 5.11: Let $(\mathcal{B}, \mu)$ be a rigid body in a Galilean spacetime and let Ψ be a motion. If a rigid motion $\tilde{\Psi}$ is $\mathcal{B}$-equivalent to Ψ, then $p_{\tilde{\Psi},\mathcal{B}} = p_{\Psi,\mathcal{B}}$.

D. Galilean–Euler equations

In this section we derive the equations of motion for a rigid body in our general framework. As remarked in Sec. I, the problem of finding the equations of motion for rigid bodies has a rich history. The key observation of Newton and Euler is that the free motion of a rigid body is completely determined by imposing conservation of spatial linear and angular momenta. The observation that this approach generalizes to other physical settings such as hydrodynamics was first made by Arnol'd[13] (see also Ref. 2). Using his method, the Euler equations for an incompressible fluid can be written as geodesic equations on a certain infinite-dimensional Lie group. We note that the Galilean group $\mathrm{Gal}(\mathcal{G})$ of a Galilean spacetime $\mathcal{G}$ does not have a natural invariant metric, and thus we cannot use Arnol'd's method in this setup. Intuitively speaking, $\mathrm{Gal}(\mathcal{G})$ is "too big" to uniquely determine the physical motion of the body. We shall have more to say on this matter in Sec. VI E. We use the principle of conservation of spatial momentum to derive differential equations in terms of "spatial" as well as "body" quantities that describe the physical motion of the body. We also show that, if a rigid motion Ψ satisfies these equations for the body $(\mathcal{B}, \mu)$, then every rigid motion $\mathcal{B}$-equivalent to Ψ also satisfies the equations. From the definitions given in the previous section, it can be seen that $p_{\Psi,\mathcal{B}}(t) = (\ell_{\Psi,\mathcal{B}}(t), m_{\Psi,\mathcal{B}}(t)) = (R_\Psi(t) L_{\Psi,\mathcal{B}}(t), \Psi_{t,V} M_{\Psi,\mathcal{B}}(t))$.

Proposition 5.12 (Galilean-Euler equations): Let $(\mathcal{B}, \mu)$ be a rigid body in a Galilean spacetime and let Ψ be a rigid motion. The following statements are equivalent:

(i) *the spatial momentum $p_{\Psi,\mathcal{B}}$ is conserved;*

(ii) *the motion of the body satisfies the spatial Galilean–Euler equations*

$$\mathbb{I}_c(\dot{\omega}_\Psi(t)) = \mathbb{I}_c(\omega_\Psi(t)) \times \omega_\Psi(t)$$

$$\ddot{x}_c(t) = 0,$$

where $\ddot{x}_c(t) = (\mathrm{d}^2/\mathrm{d}t^2)(\Psi_t(x_c))$;

(iii) *the motion of the body satisfies the body Galilean–Euler equations*

$$\dot{L}_{\Psi,\mathcal{B}}(t) = L_{\Psi,\mathcal{B}}(t) \times \Omega_\Psi(t),$$

$$\dot{M}_{\Psi,\mathcal{B}}(t) = -(\eta_V(t))_V(M_{\Psi,\mathcal{B}}(t)),$$

where $(\eta_V(t))_V(M_{\Psi,\mathcal{B}}(t))$ is the infinitesimal generator corresponding to $\eta_V(t) = \Psi_{t,V}^{-1} \dot{\Psi}_{t,V}$ of

the action of $\mathrm{Lin}(\mathcal{G})$ *on* V.

Furthermore,

(iv) *if* $\tilde{\Psi}$ *is a rigid motion* $\mathcal{B}$*-equivalent to* Ψ*, then* Ψ *can be replaced with* $\tilde{\Psi}$ *in the above statements.*

Proof: Conservation of spatial momentum implies that $\dot{p}_{\Psi,\mathcal{B}}(t)=0$. The equation $\ddot{x}_c(t)=0$ immediately follows. To derive the first equation, we note that

$$\mathbb{I}_c(t)\omega_\Psi(t) = R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}\omega_\Psi(t)).$$

Therefore,

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}\omega_\Psi(t)) &= \dot{R}_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}\omega_\Psi(t) + R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}\dot{\omega}_\Psi(t))\\ &= \hat{\omega}_\Psi(t)R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}\omega_\Psi(t)) + R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}\dot{\omega}_\Psi(t))\\ &= \hat{\omega}_\Psi(t)\mathbb{I}_c(\omega_\Psi(t)) + \mathbb{I}_c(t)\dot{\omega}_\Psi(t) = 0,\end{aligned}$$

by conservation of spatial momentum. Therefore

$$\mathbb{I}_c(\dot{\omega}_\Psi(t)) = -\hat{\omega}_\Psi(t)\mathbb{I}_c(\omega_\Psi(t)) = \mathbb{I}_c(\omega_\Psi)\times\omega_\Psi(t)).$$

Next, we write spatial momentum in terms of the body momentum. That is,

$$p_{\Psi,\mathcal{B}}(t) = (R_\Psi(t)L_{\Psi,\mathcal{B}}, \Psi_{t,V}M_{\Psi,\mathcal{B}}(t)).$$

Conservation of spatial momentum implies that

$$\frac{\mathrm{d}}{\mathrm{d}t}(R_\Psi(t)L_{\Psi,\mathcal{B}}(t)) = 0 \text{ and } \frac{\mathrm{d}}{\mathrm{d}t}(\Psi_{t,V}M_{\Psi,\mathcal{B}}(t)) = 0.$$

The first equation gives

$$0 = (\dot{R}_\Psi(t)L_{\Psi,\mathcal{B}}(t) + (R_\Psi(t)\dot{L}_{\Psi,\mathcal{B}}(t) = R_\Psi(t)\tilde{\Omega}_\Psi(t)L_{\Psi,\mathcal{B}}(t) + R_\Psi(t)\dot{L}_{\Psi,\mathcal{B}}(t).$$

We therefore get

$$\dot{L}_{\Psi,\mathcal{B}}(t) = -\hat{\Omega}_\Psi(t)L_{\Psi,\mathcal{B}}(t) = L_{\Psi,\mathcal{B}}(t)\times\Omega_\Psi(t).$$

Next, consider the second equation. Written appropriately in terms of the action Φ^V of $\mathrm{Lin}(\mathcal{G})$ on V, the equation becomes

$$\frac{\mathrm{d}}{\mathrm{d}t}\Phi^V_{\Psi_{t,V}}(M_{\Psi,\mathcal{B}}(t)) = 0.$$

We compute

$$\frac{\mathrm{d}}{\mathrm{d}t}\Phi^V_{\Psi_{t,V}}(M_{\Psi,\mathcal{B}}(t)) = T_{M_{\Psi,\mathcal{B}(t)}}\Phi^V_{\Psi_{t,V}}\dot{M}_{\Psi,\mathcal{B}}(t) + T_{M_{\Psi,\mathcal{B}}}\Phi^V_{\Psi_{t,V}}(\eta_V(t))_V\ (M)) = 0,$$

which gives us the requisite equation. The final part of the proposition follows directly from Lemma 5.11. □

Remarks 5.13: (1) Proposition 5.12 shows that if a motion Ψ satisfies the Galilean–Euler equations for a rigid body so does every motion $\mathcal{B}$-equivalent to Ψ. In other words, the Galilean–Euler equations hold for an equivalence class of motions specified by the rigid body.

(2) The Galilean–Euler equations are very general because they have been derived in the setting of an abstract Galilean spacetime without requiring an observer. However, the generality of the treatment makes certain things less obvious. In particular, it is not clear how the classical Euler equations fit into this setup and, if they do, whether or not there is a geometrical explanation for it. We shall see, in the next section, that the presence of an observer allows us to answer these questions.

VI. DYNAMICS OF RIGID BODIES IN THE PRESENCE OF AN OBSERVER

In Sec. V we formulated rigid body dynamics in an observer-independent way. In this section, we shall explore the effect of introducing an observer in this formulation. In Sec. VI A we introduce canonical velocities associated with a rigid motion in the presence of an observer. In Sec. VI B we show that in the presence of an observer, the body and spatial velocities defined in Sec. V project to the corresponding canonical velocities. In the next section, we show that the momenta also project to the well-known quantities in the presence of the observer. Finally, in Sec. VI D, we illustrate how an observer enables us to recover the classical Euler equations for a rigid body.

A. Canonical velocities

Consider a rigid motion Ψ in a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$. In Sec. V B, we introduced the curves $\eta_\Psi(t)$ and $\xi_\Psi(t)\in\mathfrak{gal}(\mathcal{G})$ corresponding to Ψ. The following result provides a decomposition of these curves in the presence of an observer.

Proposition 6.1: Let $\mathcal{G}=(\mathcal{E},V,g,\tau)$ be a Galilean spacetime with $\mathcal{O}$ an observer and Ψ a rigid motion. For $s_0\in I_\mathcal{G}$, let

$$\iota_{\mathcal{O}_{s_0}}(\Psi_t)=(R_\Psi(t),r_{\Psi,\mathcal{O}}(t),u_{\Psi,\mathcal{O}}(t),t).$$

Then, the following statements hold:

(i) *the image of $\eta_\Psi(t)\in\mathfrak{gal}(\mathcal{G})$ under the isomorphism of the Lie algebras induced by $\iota_{\mathcal{O}_{s_0}}$ is*

$$(\hat{\Omega}_\Psi(t),V_{\Psi,\mathcal{O}}(t)-R_\Psi^{-1}(t)u_{\Psi,\mathcal{O}}(t),R_\Psi^{-1}(t)\dot{u}_{\Psi,\mathcal{O}}(t),1)\in\mathfrak{gal}(\mathcal{G}_{\mathrm{can}});$$

(ii) *the image of $\xi_\Psi(t)\in\mathfrak{gal}(\mathcal{G})$ under the isomorphism of Lie algebra induced by $\iota_{\mathcal{O}_{s_0}}$ is*

$$(\hat{\omega}_\Psi(t),v_{\Psi,\mathcal{O}}(t)-t(\dot{u}_{\Psi,\mathcal{O}}(t)+u_{\Psi,\mathcal{O}}(t)\times\omega_\Psi(t)),\dot{u}_{\Psi,\mathcal{O}}(t)+u_{\Psi,\mathcal{O}}(t)\times\omega_\Psi(t),1)\in\mathfrak{gal}(\mathcal{G}_{\mathrm{can}}),$$

where $V_{\Psi,\mathcal{O}}(t)=R_\Psi^{-1}(t)\dot{r}_{\Psi,\mathcal{O}}(t)$, and $v_{\Psi,\mathcal{O}}(t)=\dot{r}_{\Psi,\mathcal{O}}(t)+r_{\Psi,\mathcal{O}}(t)\times\omega_\Psi(t)$.

Proof: We start by faithfully representing $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ in a vector space. We let $W=\ker(\tau)\oplus\mathbb{R}\oplus\mathbb{R}$ and, for $g=(R,r,u,t)\in\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$, define an isomorphism ρ_g of W by

$$(\mu,\sigma,\xi)\mapsto(R(\mu)+\sigma u+\xi r,\sigma+\xi t,\xi).$$

One readily verifies that the map $\rho:\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})\to GL(W)$ defined by $\rho(g)=\rho_g$ is a homomorphism. To see that the representation is faithful, suppose that

$$(\mu,\sigma,\xi)\mapsto(R(\mu)+\sigma u+\xi r,\sigma+\xi t,\xi)=(\mu,\sigma,\xi)$$

for all $(\mu,\sigma,\xi)\in W$. Then we must have $\sigma+\xi t=0$, for all $\sigma,\xi\in\mathbb{R}$, implying that $t=0$. Similarly, $R(\mu)+\sigma u+\xi r=\mu$ for all $(\mu,\sigma,\xi)\in W$ implies that $r=0$, $u=0$, and $R=\mathrm{id}_{\ker(\tau)}$. Thus the representation is faithful. In block matrix form, the representation of (R,r,u,t) on W is

$$\begin{bmatrix} R & u & r \\ 0 & 1 & t \\ 0 & 0 & 1 \end{bmatrix} \in GL(W).$$

We then compute

$$\begin{bmatrix} R & u & r \\ 0 & 1 & t \\ 0 & 0 & 1 \end{bmatrix}^{-1} = \begin{bmatrix} R^{-1} & -R^{-1}u & R^{-1}(tu-r) \\ 0 & 1 & -t \\ 0 & 0 & 1 \end{bmatrix}.$$

With this expression, both parts follow from direct computation. □

We call the first two components in (i) respectively, the *canonical body angular velocity*, and the *canonical body linear velocity*, and denote them by $\Omega^{\text{can}}_{\Psi}$ and $V^{\text{can}}_{\Psi,\mathcal{O}}$, respectively. Similarly, we call the first two components in (ii) respectively, the *canonical spatial angular velocity* and the *canonical spatial linear velocity*, and represent them by $\omega^{\text{can}}_{\Psi}$ and $v^{\text{can}}_{\Psi,\mathcal{O}}$, respectively.

B. Linear and angular velocities

Recall that, given a rigid motion Ψ in a Galilean spacetime, the body linear velocity is the map $V^{b}_{\Psi,\text{lin}}: Q\times\mathbb{R}\to V$ given by

$$V^{b}_{\Psi,\text{lin}}(R,x,t) = \Psi^{-1}_{t,V}\left(\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(x\ ))\right),$$

and the spatial linear velocity is the map $V^{s}_{\Psi,\text{lin}}: Q\times\mathbb{R}\to V_{\mathcal{G}}$ given by

$$V^{s}_{\Psi,\text{lin}}(R,x,t) = -\Psi_{t,V}\left(\frac{\mathrm{d}}{\mathrm{d}t}(\Psi^{-1}_{t}(x))\right).$$

Let us see what these velocities look like in the presence of an observer. We look at body linear velocity first.

Proposition 6.2: Let Ψ be a rigid motion in a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$ and let $\mathcal{O}$ be an observer. Then $P_{\mathcal{O}}(V^{b}_{\Psi,\text{lin}}(R,x,t))=V^{\text{can}}_{\Psi,\mathcal{O}}(t)$.

Proof: We know that, for each instant $s_0\in I_{\mathcal{G}}$, there exists an isomorphism $\iota_{\mathcal{O}_{s_0}}$ such that, for a motion Ψ, we have

$$\iota_{\mathcal{O}_{s_0}}(\Psi_t) = (R_{\Psi}(t), r_{\Psi,\mathcal{O}}(t), u_{\Psi,\mathcal{O}}(t), t).$$

Also,

$$\Psi_t(x) = R_{\Psi}(t)(x-\mathcal{O}_{\pi_{\mathcal{G}}(x)}) + (\pi_{\mathcal{G}}(x)-s_0)u_{\Psi,\mathcal{O}}(t) + r_{\Psi,\mathcal{O}}(t) + \mathcal{O}_{\pi_{\mathcal{G}}(x)+t}.$$

Now, for $x\in\mathcal{O}$, we have

$$\Psi_t(x) = r_{\Psi,\mathcal{O}}(t) + \mathcal{O}_{\pi_{\mathcal{G}}(x)+t},$$

so we have

$$\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(x)) = \dot{r}_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}}.$$

Next,

$$\Psi_{t,V}^{-1}\left(\frac{\mathrm{d}}{\mathrm{d}t}\,\Psi_t(x)\right) = \Psi_{t,V}^{-1}(\dot{r}_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}}) = \Psi_t^{-1}(\dot{r}_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}} + \mathcal{O}_{s_0}) - \Psi_t^{-1}(\mathcal{O}_{s_0})$$
$$= R_\Psi^{-1}(t)(\dot{r}_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}} + \mathcal{O}_{s_0} - \mathcal{O}_{1+s_0}) - R_\Psi^{-1}(t)u_{\Psi,\mathcal{O}}(t)$$
$$+ R_\Psi^{-1}(t)(tu_{\Psi,\mathcal{O}}(t) - r_{\Psi,\mathcal{O}}(t)) + (1-t)v_{\mathcal{O}} + \mathcal{O}_{s_0} - R_\Psi^{-1}(t)(tu_{\Psi,\mathcal{O}}(t)$$
$$- r_{\Psi,\mathcal{O}}(t)) + tv_{\mathcal{O}} - \mathcal{O}_{s_0}$$
$$= R_\Psi^{-1}(t)\dot{r}_{\Psi,\mathcal{O}}(t) - R_\Psi^{-1}(t)u_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}}.$$

From this, the result follows. □

Let us look at the spatial linear velocity now.

Proposition 6.3: Let Ψ be a motion in a Galilean spacetime $\mathcal{G}=(\mathcal{E},V,g,\tau)$ and let $\mathcal{O}$ be an observer. Then $P_{\mathcal{O}}(V^s_{\Psi,\mathrm{lin}}(R,x,t))=v^{\mathrm{can}}_{\Psi,\mathcal{O}}(t)$.

Proof: For $x\in\mathcal{O}$, we compute,

$$\Psi_t^{-1}(x) = R_\Psi^{-1}(t)(tu_{\Psi,\mathcal{O}}(t) - r_{\Psi,\mathcal{O}}(t)) - tv_{\mathcal{O}} + \mathcal{O}_{s_0}.$$

Therefore,

$$\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t^{-1}(x)) = R_\Psi^{-1}(t)(u_{\Psi,\mathcal{O}}(t) + t\dot{u}_{\Psi,\mathcal{O}}(t) - \dot{r}_{\Psi,\mathcal{O}}(t)) + (-R_\Psi^{-1}(t)\dot{R}_\Psi(t)R_\Psi^{-1}(t))(tu_{\Psi,\mathcal{O}}(t) - r_{\Psi,\mathcal{O}}(t))) - v_{\mathcal{O}}$$
$$= R_\Psi^{-1}(t)(u_{\Psi,\mathcal{O}}(t) + t\dot{u}_{\Psi,\mathcal{O}}(t) - \dot{r}_{\Psi,\mathcal{O}}(t)) - R_\Psi^{-1}(t)\hat{\omega}_\Psi(t)(tu_{\Psi,\mathcal{O}}(t) - r_{\Psi,\mathcal{O}}(t)) - v_{\mathcal{O}}$$
$$= R_\Psi^{-1}(t)u_{\Psi,\mathcal{O}}(t) + R_\Psi^{-1}(t)[t(\dot{u}_{\Psi,\mathcal{O}}(t) + u_\Psi(t)\times\omega_\Psi(t))]$$
$$- R_\Psi^{-1}(t)(\dot{r}_{\Psi,\mathcal{O}}(t) + r_{\Psi,\mathcal{O}}(t)\times\omega_\Psi(t)) - v_{\mathcal{O}}$$
$$= R_\Psi^{-1}(t)u_\Psi(t) - R_\Psi^{-1}(t)(v_{\Psi,\mathcal{O}}(t) - t(\dot{u}_{\Psi,\mathcal{O}}(t) + u_{\Psi,\mathcal{O}}(t)\times\omega_\Psi(t))) - v_{\mathcal{O}}.$$

Let us call the last expression $\dot{\Psi}_t^{-1}(x)$. Now, we compute

$$-\Psi_{t,V}\left(\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t^{-1}(x))\right) = \Psi_t(-\dot{\Psi}_t^{-1}(x) + \mathcal{O}_{s_0}) - \Psi_t(\mathcal{O}_{s_0})$$
$$= R_\Psi(t)(-\dot{\Psi}_t^{-1}(x) + \mathcal{O}_{s_0} - \mathcal{O}_{1+s_0}) + u_{\Psi,\mathcal{O}}(t) + r_{\Psi,\mathcal{O}}(t) + tv_{\mathcal{O}} + \mathcal{O}_{1+s_0}$$
$$- r_{\Psi,\mathcal{O}}(t) - tv_{\mathcal{O}} - \mathcal{O}_{s_0}$$
$$= R_\Psi(t)(-\dot{\Psi}_t^{-1}(x) - v_{\mathcal{O}}) + u_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}}$$
$$= R_\Psi(t)(R_\Psi^{-1}(t)(v_{\Psi,\mathcal{O}}(t) - t(\dot{u}_{\Psi,\mathcal{O}}(t) + u_{\Psi,\mathcal{O}}(t)\times\omega_\Psi(t))) - u_{\Psi,\mathcal{O}}(t) + u_{\Psi,\mathcal{O}}(t)$$
$$+ v_{\mathcal{O}} = v_{\Psi,\mathcal{O}}(t) - t(\dot{u}_{\Psi,\mathcal{O}}(t) + u_{\Psi,\mathcal{O}}(t)\times\omega_\Psi(t)) + v_{\mathcal{O}}.$$

From this the result follows. □

We notice that, in the presence of an observer, the spatial linear and body linear velocities project onto the canonical spatial linear and canonical body linear velocities, respectively.

C. Spatial and body momenta

We let $\mathcal{G}=(\mathcal{E},V,g,\tau)$ be a Galilean spacetime with Ψ a rigid motion, $\mathcal{O}$ an observer, and $(\mathcal{B},\mu)$ a rigid body with $\mathcal{B}\in\mathcal{E}(s_0)$. We next see how our definitions of spatial and body momenta look when we have an observer $\mathcal{O}$. In such a case, we have the following result.

Proposition 6.4: Let $\mathcal{G}=(\mathcal{E},V,g,\tau)$ be a Galilean spacetime with Ψ a rigid motion, $\mathcal{O}$ an observer, and $(\mathcal{B},\mu)$ a rigid body with $\mathcal{B}\in\mathcal{E}(s_0)$, and let $m_{\Psi,\mathcal{B}}$, $\ell_{\Psi,\mathcal{B}}$, $M_{\Psi,\mathcal{B}}$, and $L_{\Psi,\mathcal{B}}$ be as defined in Sec. V C. For $s_0\in I_{\mathcal{G}}$, let

$$\iota_{\mathcal{O}_{s_0}}(\Psi_t) = (R_\Psi(t), r_{\Psi,\mathcal{O}}(t), u_{\Psi,\mathcal{O}}(t), t).$$

Then the following statements hold:

(i) $P_{\mathcal{O}}(m_{\Psi,\mathcal{B}}(t)) = \mu(\mathcal{B})\dot{r}_{\Psi,\mathcal{O}}(t)$;
(ii) $P_{\mathcal{O}}(\ell_{\Psi,\mathcal{B}}(t)) = R_\Psi(t)\mathbb{I}_c(R_\Psi^{-1}(t)\omega_\Psi(t))$;
(iii) $P_{\mathcal{O}}(M_{\Psi,\mathcal{B}}(t)) = \mu(\mathcal{B})V^{\text{can}}_{\Psi,\mathcal{O}}(t)$;
(iv) $P_{\mathcal{O}}(L_{\Psi,\mathcal{B}}(t)) = \mathbb{I}_c(R_\Psi^{-1}(t)\omega_\Psi(t))$.

Proof: (i) We compute

$$P_{\mathcal{O}}(m_{\Psi,\mathcal{B}}(t)) = \mu(\mathcal{B})P_{\mathcal{O}}\left(\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(x_c))\right) = \mu(\mathcal{B})P_{\mathcal{O}}(\dot{r}_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}}) = \mu(\mathcal{B})\dot{r}_{\Psi,\mathcal{O}}(t),$$

where we have used the computations carried out in Proposition 6.2.

Parts (ii) and (iv) are easily seen to be true since both $\ell_{\Psi,\mathcal{B}}$ and $L_{\Psi,\mathcal{B}}$ take their values in $\ker(\tau)$ and the projection $P_{\mathcal{O}}$ is the identity map on $\ker(\tau)$.

To obtain (iii), we compute

$$\begin{aligned} P_{\mathcal{O}}(M_{\Psi,\mathcal{B}}(t)) &= \mu(\mathcal{B})P_{\mathcal{O}}(\Psi_{t,V}^{-1}\left(\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(x_c))\right) = \mu(\mathcal{B})P_{\mathcal{O}}(\Psi_{t,V}^{-1}(\dot{r}_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}})) \\ &= \mu(\mathcal{B})P_{\mathcal{O}}(R_\Psi^{-1}(t)\dot{r}_{\Psi,\mathcal{O}}(t) - R_\Psi^{-1}(t)u_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}}) = \mu(\mathcal{B})V^{\text{can}}_{\Psi,\mathcal{O}}(t), \end{aligned}$$

as desired. □

It is worth pointing out that the classical definition of spatial angular momentum requires an observer, and is different from ours. Given an observer $\mathcal{O}$ and a rigid motion Ψ, the *classical spatial angular momentum* $\ell^{\text{cl}}_{\Psi,\mathcal{B}}$ for a rigid body $(\mathcal{B},\mu)$ about its center of mass x_c is defined as

$$\ell^{\text{cl}}_{\Psi,\mathcal{B}}(t) = \int_{\mathcal{B}} P_{\mathcal{O}}(\Psi_t(x) - x_c) \times P_{\mathcal{O}}\left(\frac{\mathrm{d}}{\mathrm{d}t}(\Psi_t(x) - x_c)\right)\mathrm{d}\mu.$$

One can motivate this definition of spatial angular momentum by recalling how it might be defined for a particle of mass m (see, for example, Ref. 3). If a particle is moving in $\mathbb{R}^3$ following a curve $t \mapsto x(t)$, then we would define the spatial angular momentum at time t to be $mx(t) \times \dot{x}(t)$. This is exactly the intuition behind the definition of $\ell^{\text{cl}}_{\Psi,\mathcal{O}}$. Our definition of body angular momentum agrees with the classical one, and therefore we do not need to consider it separately. We shall see in the next section that the equations of motion derived on the basis of the conservation of classical spatial angular momentum are equivalent to the general spatial Euler equations. We have the following result.

Proposition 6.5: Let $(\mathcal{B},\mu)$ *be a rigid body in a Galilean spacetime* $\mathcal{G}$ *undergoing a rigid motion* Ψ, *and let* $\mathcal{O}$ *be an observer with the property that* $x_c \in \mathcal{O}$. *Then* $\ell^{\text{cl}}_{\Psi,\mathcal{B}}(t) = R_\Psi(t)\mathbb{I}_c(R_\Psi(t)^{-1}\omega_\Psi(t)) + \mu(\mathcal{B})r_{\Psi,\mathcal{O}}(t) \times \dot{r}_{\Psi,\mathcal{O}}(t)$.

Proof: We let $s_0 = \pi_{\mathcal{G}}(x_c)$, and use the isomorphism $\iota_{\mathcal{O}_{s_0}}$ between $\mathrm{Gal}(\mathcal{G})$ and $\mathrm{Gal}(\mathcal{G}_{\text{can}})$ to get

$$\Psi_t(x) = R_\Psi(t)(x - \mathcal{O}_{\pi_{\mathcal{G}}(x)}) + r_{\Psi,\mathcal{O}}(t) + tv_{\mathcal{O}} + \mathcal{O}_{\pi_{\mathcal{G}}(x)}, \quad x \in \mathcal{B},$$

which implies that $\Psi_t(x) - x_c = R_\Psi(t)(x - x_c) + r_{\Psi,\mathcal{O}}(t)$. The result is readily verified by using part (ii) of Lemma 3.1 in the computation of the integral. □

D. Euler equations of a rigid body

In this section we look at the Galilean–Euler equations, as derived in Sec. V D in the presence of an observer. Since we consider the abstract Galilean group in our analysis, derivatives of velocity boosts also appear in the equations. We first write down the general Galilean–Euler equations in the presence of an observer.

Proposition 6.6: Let $(\mathcal{B},\mu)$ *be a rigid body,* Ψ *a rigid motion, and let* $\mathcal{O}$ *be an observer. For* $s_0 \in I_{\mathcal{G}}$, *let*

$$\iota_{\mathcal{O}_{s_0}}(\Psi_t) = (R_\Psi(t), r_{\Psi,\mathcal{O}}(t), u_{\Psi,\mathcal{O}}(t), t)$$

for each $t \in \mathbb{R}$. *The following statements hold:*

(i) the spatial Galilean–Euler equations for Ψ *are equivalent to*

$$\mathbb{I}_c(\dot{\omega}_\Psi(t)) = \mathbb{I}_c(\omega_\Psi(t)) \times \omega_\Psi(t)$$

$$\ddot{r}_{\Psi,\mathcal{O}}(t) = -\ddot{R}_\Psi(t)(x_c - \mathcal{O}_{\pi_{\mathcal{G}}(x_c)}) - (\pi_{\mathcal{G}}(x_c) - s_0)\ddot{u}_{\Psi,\mathcal{O}}(t);$$

(ii) the body Galilean–Euler equations for Ψ *are equivalent to*

$$\dot{L}_{\Psi,\mathcal{B}}(t) = L_{\Psi,\mathcal{B}}(t) \times \Omega_\Psi(t),$$

$$\dot{M}_{\Psi,\mathcal{B}}(t) = P_{\mathcal{O}}(M_{\Psi,\mathcal{B}}(t)) \times \Omega_\Psi(t) - R_\Psi^{-1}(t)\dot{u}_{\Psi,\mathcal{O}}(t).$$

Proof: (i) The first spatial Galilean–Euler equation evolves on $\ker(\tau)$ and thus remains the same under the projection $P_{\mathcal{O}}$. For the second equation, we compute

$$\begin{aligned} 0 = \ddot{x}_c(t) &= \frac{\mathrm{d}}{\mathrm{d}t}(\dot{R}_\Psi(t)(x_c - \mathcal{O}_{\pi_{\mathcal{G}}}(x_c)) + (\pi_{\mathcal{G}}(x_c) - s_0)\dot{u}_{\Psi,\mathcal{O}}(t) + \dot{r}_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}}) \\ &= \ddot{R}_\Psi(t)(x_c - \mathcal{O}_{\pi_{\mathcal{G}}}(x_c)) + \ddot{r}_{\Psi,\mathcal{O}}(t) + (\pi_{\mathcal{G}}(x_c) - s_0)\ddot{u}_{\Psi,\mathcal{O}}(t), \end{aligned}$$

from which we get the required equation.

(ii) Similarly, the first body Galilean–Euler equation remains unchanged under the projection onto $\ker(\tau)$. To get the second equation we use the definition of $M_{\Psi,\mathcal{O}}$ and the relation $\Psi_V(v) = R_\Psi P_{\mathcal{O}}(v) + \tau(v)(u_{\Psi,\mathcal{O}} + v_{\mathcal{O}})$, and compute

$$\begin{aligned} 0 = \frac{\mathrm{d}}{\mathrm{d}t} m_{\Psi,\mathcal{B}}(t) &= \frac{\mathrm{d}}{\mathrm{d}t}\Psi_{t,V}(M_{\Psi,\mathcal{O}}(t)) = \frac{\mathrm{d}}{\mathrm{d}t}(R_\Psi(t)P_{\mathcal{O}}(M_{\Psi,\mathcal{O}}(t))) + \tau(M_{\Psi,\mathcal{O}}(t))(u_{\Psi,\mathcal{O}}(t) + v_{\mathcal{O}})) \\ &= \dot{R}_\Psi(t)P_{\mathcal{O}}(M_{\Psi,\mathcal{O}}(t)) + R_\Psi(t)\frac{\mathrm{d}}{\mathrm{d}t}(P_{\mathcal{O}}(M_{\Psi,\mathcal{O}}(t))) + \dot{u}_{\Psi,\mathcal{O}}(t) \\ &= R_\Psi(t)\hat{\Omega}P_{\mathcal{O}}(M_{\Psi,\mathcal{O}}(t)) + R_\Psi(t)(\dot{M}_{\Psi,\mathcal{O}}(t))) + \dot{u}_{\Psi,\mathcal{O}}(t), \end{aligned}$$

since $M_{\Psi,\mathcal{O}}(t) \in V_{\mathcal{G}}$ and thus $\dot{M}_{\Psi,\mathcal{O}}(t) = (d/\mathrm{d}t)P_{\mathcal{O}}(M_{\Psi,\mathcal{O}}(t))$. The result now follows. □

Let us now show that we get the same equations of motion if we use the classical spatial angular momentum $\ell^{\mathrm{cl}}_{\Psi,\mathcal{B}}$ instead of $\ell_{\Psi,\mathcal{B}}$. Let us write $p^{\mathrm{cl}}_{\Psi,\mathcal{B}} = (\ell^{\mathrm{cl}}_{\Psi,\mathcal{B}}, m_{\Psi,\mathcal{B}})$ to denote the classical spatial momentum. We also call the equations of motion derived on the basis of the conservation of classical spatial momentum the *classical spatial Euler equations*. We have the following result.

Proposition 6.7: Let $(\mathcal{B},\mu)$ *be a rigid body undergoing a rigid motion* Ψ *in a Galilean spacetime* $\mathcal{G}$. *Let* $\mathcal{O}$ *be an observer with the property that* $x_c \in \mathcal{O}$. *The following statements are equivalent*:

(i) the classical spatial momentum $p^{\mathrm{cl}}_{\Psi,\mathcal{B}}$ *is conserved;*
(ii) the motion of the body satisfies the classical spatial Euler equations

$$\mathbb{I}_c(\dot{\omega}_\Psi(t)) = \mathbb{I}_c(\omega_\Psi(t)) \times \omega_\Psi(t),$$

$$\ddot{r}_{\Psi,\mathcal{O}}(t) = 0.$$

Proof: As before, we let $s_0=\pi_{\mathcal{G}}(x_c)$ and consider the isomorphism $\iota_{\mathcal{O}_{s_0}}$, using which, it is easy to see that the conservation of spatial linear momentum $m_{\Psi,\mathcal{B}}$ implies that $\ddot{r}_{\Psi,\mathcal{O}}(t)=0$. It is a simple computation to show that this also implies that

$$\frac{\mathrm{d}}{\mathrm{d}t}(\ell^{\mathrm{cl}}_{\Psi,\mathcal{B}}(t)) = \frac{\mathrm{d}}{\mathrm{d}t}(R_\Psi(t)\mathbb{I}_c(R_\Psi(t)^{-1}\omega_\Psi(t))) = \frac{\mathrm{d}}{\mathrm{d}t}(l_{\Psi,\mathcal{B}}(t)).$$

The result now follows. □

E. The Galilean connection

In Proposition 6.6, we wrote down the general form of the Galilean–Euler equations in the presence of an observer. Since we have considered the abstract Galilean group in our analysis, we have imposed no restrictions on the velocity boost (the "$u_{\Psi,\mathcal{O}}$" component) corresponding to a rigid motion. This is the reason why the derivatives of these velocity boosts appear in the equations given in Proposition 6.6. Recall that the classical Euler equations for a rigid body do not include these derivative terms because the velocity boosts are assumed to be "uniform." In this section, we explain how, in our general setting, an observer allows us to recover the classical equations of motion for a rigid body by defining a special geometric structure (namely a principal connection) on $\mathrm{Gal}(\mathcal{G})$. We refer to Ref. 14 for the definitions and properties of principal connections.

Let $Q=O(\ker(\tau))\times\mathcal{E}$ and $(\mathcal{B},\mu)$ be a rigid body. For the center of mass $x_c\in\mathcal{E}$ of the rigid body, consider the map

$$\pi_c:\mathrm{Gal}(\mathcal{G})\to Q$$

$$\psi\mapsto(R_\psi,\psi(x_c)).$$

An observer $\mathcal{O}$ defines a map $\pi_{c,\mathcal{O}}:\mathrm{Gal}(\mathcal{G})\to O(\ker(\tau))\times\ker(\tau)\times\mathbb{R}$ given by

$$\psi\mapsto(R_\psi,P_{\mathcal{O}}(\psi(x_c)-x_c),\tau(\psi(x_c)-x_c)).$$

We also know that, for $s_0\in I_{\mathcal{G}}$, there is an isomorphism $\iota_{\mathcal{O}_{s_0}}$ from $\mathrm{Gal}(\mathcal{G})$ to $O(\ker(\tau))\times\ker(\tau)\times\ker(\tau)\times\mathbb{R}$ given by

$$\psi\mapsto(R_\psi,r_{\psi,\mathcal{O}},u_{\psi,\mathcal{O}},t_\psi).$$

For $x_c\in\mathcal{O}$, we can write

$$\psi(x_c)=R_\psi(x_c-x_c)+(\pi_{\mathcal{G}}-s_0)u_{\psi,\mathcal{O}}+r_{\psi,\mathcal{O}}+t_\psi v_{\mathcal{O}}+x_c,$$

and thus we have

$$P_{\mathcal{O}}(\psi(x_c)-x_c)=(\pi_{\mathcal{G}}(x_c)-s_0)u_{\psi,\mathcal{O}}+r_{\psi,\mathcal{O}}.$$

Also, $\tau(\psi(x_c)-x_c)=t_\psi$, so the map $\pi_{c,\mathcal{O}}$ induces a map

$$\pi^{\mathrm{can}}_{c,\mathcal{O}}:\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})\to O(\ker(\tau))\times\ker(\tau)\times\mathbb{R}=\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})/\ker(\tau)$$

$$(R_\psi,r_{\psi,\mathcal{O}},u_{\psi,\mathcal{O}},t_\psi)\mapsto(R_\psi(\pi_{\mathcal{G}}-s_0)u_{\psi,\mathcal{O}}+r_{\psi,\mathcal{O}},t_\psi),$$

where the quotient $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})/\ker(\tau)$ corresponds to the following action of $\ker(\tau)$ on $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$:

$$\ker(\tau)\times\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})\to\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$$

$$(\mu,(R,r,u,s)) \mapsto (R, r-(\pi_{\mathcal{G}}(x_c)-s_0)\mu, u+\mu, s).$$

Thus, $\ker(\tau)$ acts on $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ by appropriately changing the $r_{\psi,\mathcal{O}}$ and $u_{\psi,\mathcal{O}}$ components of a given $\psi \in \mathrm{Gal}(\mathcal{G})$ such that the resulting mapping gives the same physical motion of the body as ψ, that is, it lies in $[\psi]_{\mathcal{B}}$. We also write $\pi := \pi^{\mathrm{can}}_{c,\mathcal{O}} \circ \iota_{\mathcal{O}_{s_0}} : \mathrm{Gal}(\mathcal{G}) \to \mathrm{Gal}(\mathcal{G}_{\mathrm{can}})/\ker(\tau)$. It is clear that, given $\psi \in \mathrm{Gal}(\mathcal{G})$, a Galilean mapping $\phi \in [\psi]_{\mathcal{B}}$ if and only if $\pi(\phi)=\pi(\psi)$. We have the following result.

Proposition 6.8: Let $(\mathcal{B},\mu)$ be a rigid body in a Galilean spacetime and $\mathcal{O}$ be an observer. For fixed $s_0 \in I_{\mathcal{G}}$, the map $\omega_{\mathrm{can}} : T\mathrm{Gal}(\mathcal{G}_{\mathrm{can}}) \to \ker(\tau)$ given by

$$\omega_{\mathrm{can}}(X_R,X_r,X_u,X_t) = X_u, \quad (X_R,X_r,X_u,X_t) \in T_{(R,r,u,t)}\mathrm{Gal}(\mathcal{G}_{\mathrm{can}}),$$

is a principal connection one-form in the bundle

$$\pi^{\mathrm{can}}_{c,\mathcal{O}} : \mathrm{Gal}(\mathcal{G}_{\mathrm{can}}) \to \mathrm{Gal}(\mathcal{G}_{\mathrm{can}})/\ker(\tau).$$

Proof: Given $X=(X_R,X_r,X_u,X_t) \in T_{(R,r,u,t)}\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$, it is easy to see that

$$T\pi^{\mathrm{can}}_{c,\mathcal{O}}(X_R,X_R,X_u,X_t) = (X_R, X_r + (\pi_{\mathcal{G}}(x_c)-s_0)X_u, X_t).$$

The observer $\mathcal{O}$ allows us to decompose X into its *vertical* and *horizontal* components as follows. We write

$$X = \mathrm{hor}(X) + \mathrm{ver}(X), \tag{6}$$

where

$$\mathrm{hor}(X) = (X_R, X_r + (\pi_{\mathcal{G}}(x_c)-s_0)X_u, 0, X_t),$$

$$\mathrm{ver}(X) = (0, -(\pi_{\mathcal{G}}(x_c)-s_0)X_u, X_u, 0).$$

It can be seen that $T\pi^{\mathrm{can}}_{c,\mathcal{O}}(\mathrm{ver}(X))=0$, and $\omega_{\mathrm{can}}(\mathrm{hor}(X))=0$. Thus (6) defines an Ehresmann connection in $\pi^{\mathrm{can}}_{c,\mathcal{O}} : \mathrm{Gal}(\mathcal{G}_{\mathrm{can}}) \to O(\ker(\tau)) \times \ker(\tau) \times \mathbb{R}$. Next, the infinitesimal generator $\zeta_{\mathrm{Gal}(\mathcal{G})}$ corresponding to $\zeta \in \ker(\tau)$ for the action of $\ker(\tau)$ on $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ is given by

$$\zeta_{\mathrm{Gal}(\mathcal{G})}(R,r,u,s) = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=0} (R, r-(\pi_{\mathcal{G}}(x_c)-s_0)\exp(\zeta t), u+\exp(\zeta t), s) = (0, -(\pi_{\mathcal{G}}(x_c)-s_0)\zeta, \zeta, 0),$$

and thus, by definition,

$$\omega_{\mathrm{can}}(\zeta_{\mathrm{Gal}(\mathcal{G})}(R,r,u,s)) = \zeta.$$

Next, given $h \in \ker(\tau)$ and $X=(X_R,X_r,X_u,X_t) \in T_{(R,r,u,t)}\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$, it is easy to see that $\omega_{\mathrm{can}}(T_{(R,r,u,t)}\Phi_h X) = \mathrm{ad}_h \cdot \omega_{\mathrm{can}}(X)$, where $\Phi_h : \mathrm{Gal}(\mathcal{G}_{\mathrm{can}}) \to \mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ is the action of $\ker(\tau)$ on $\mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$ and $\mathrm{ad}_h : \mathfrak{gal}(\mathcal{G}_{\mathrm{can}}) \to \mathfrak{gal}(\mathcal{G}_{\mathrm{can}})$ is defined by $\mathrm{ad}_h(\beta) = T_e L_h R_{h^{-1}}(\beta)$, $\beta \in \mathfrak{gal}(\mathcal{G}_{\mathrm{can}})$. So ω_{can} is indeed a connection one-form. □

Now, it is easy to see that $\ker(\tau)$ also acts on $\mathrm{Gal}(\mathcal{G})$ as follows:

$$\ker(\tau) \times \mathrm{Gal}(\mathcal{G}) \to \mathrm{Gal}(\mathcal{G})$$

$$(\mu, \psi) \mapsto \psi_\mu \circ \psi,$$

where ψ_μ is such that $\iota_{\mathcal{O}_{s_0}}(\psi_\mu) = (\mathrm{id}_{O(\ker(\tau))}, -(\pi_{\mathcal{G}}(x_c)-s_0)\mu, \mu, 0) \in \mathrm{Gal}(\mathcal{G}_{\mathrm{can}})$. In other words, $\ker(\tau)$ acts on $\mathrm{Gal}(\mathcal{G})$ as a subgroup of N_0 that fixes x_c. It can be seen that, for any $x \in \mathcal{E}$, we have $\psi_\mu(x) = x + (\pi_{\mathcal{G}}(x) - \pi_{\mathcal{G}}(x_c))\mu$. As a direct consequence of Proposition 6.8, we have the following corollary.

Corollary 6.9: The $\ker(\tau)$-valued one-form on $\mathrm{Gal}(\mathcal{G})$ defined by $\omega_{\mathcal{O}} = (\iota_{\mathcal{O}_{s_0}})^* \omega_{\mathrm{can}}$ is a connec-

tion one-form in the bundle $\mathrm{Gal}(\mathcal{G}) \to \mathrm{Gal}(\mathcal{G})/\ker(\tau)$. *We call* $\omega_{\mathcal{O}}$ *the* Galilean connection induced by $\mathcal{O}$.

Thus, the Galilean connection $\omega_{\mathcal{O}}$ induced by $\mathcal{O}$ is the pull-back of ω_{can} to $\mathrm{Gal}(\mathcal{G})$ by $\iota_{\mathcal{O}_{s_0}}$. It allows us to recover the classical Euler equations for a rigid body. It may be recalled that these equations do not contain derivatives of velocity boosts (that is, the "$\dot{u}_{\Psi,\mathcal{O}}$" terms) corresponding to the given rigid motion. The next proposition shows that, given a rigid motion, the Galilean connection allows us to choose a rigid motion that gives the same physical motion of the rigid body as the given rigid motion, and such that the corresponding Galilean–Euler equations do not contain the "$\dot{u}_{\Psi,\mathcal{O}}$" terms. This is made precise in the following proposition.

Proposition 6.10: Let $(\mathcal{B},\mu)$ *be a rigid body in a Galilean spacetime*, $\mathcal{O}$ *be an observer such that* $x_c \in \mathcal{O}$, *and* $s_0 \in I_{\mathcal{G}}$. *Then, for every rigid motion* Ψ, *there exists a rigid motion* Φ *with the following properties:*

(i) Φ *is* $\mathcal{B}$*-equivalent to* Ψ*;*
(ii) Φ_t *is horizontal with respect to* $\omega_{\mathcal{O}}$*;*
(iii) The Galilean-Euler equations for Φ *are equivalent to*

$$\mathbb{I}_c(t)(\dot{\omega}_\Phi(t)) = \mathbb{I}_c(t)(\omega_\Phi(t)) \times \omega_\Phi(t),$$

$$\ddot{r}_{\Phi,\mathcal{O}}(t) = 0,$$

$$\dot{L}_{\Phi,\mathcal{B}}(t) = L_{\Phi,\mathcal{B}}(t) \times \Omega_\Phi(t),$$

$$\dot{M}_{\Phi,\mathcal{B}}(t) = P_{\mathcal{O}}(M_{\Phi,\mathcal{B}}(t)) \times \Omega_\Phi(t).$$

Moreover, given $C_0 \in \ker(\tau)$, *the rigid motion* Φ *can be uniquely chosen such that* $u_{\Psi,\mathcal{O}}(t) = C_0$ *for every* $t \in \mathbb{R}$. *In particular, if* $x(t) = \pi(\Psi_t) = (R_\Psi(t), a_{\Psi,\mathcal{O}}(t), t)$, *then,* Φ_t *is the horizontal lift of* $x(t)$ *passing through* $\iota^{-1}_{\mathcal{O}_{s_0}}(R_\Psi(t_0), a_{\Psi,\mathcal{O}}(t_0) - (\pi_{\mathcal{G}}(x_c) - s_0)C_0, C_0, t_0)$ *for some (and therefore every)* $t_0 \in \mathbb{R}$.

Proof: For $x(t) = \pi(\Psi_t) = (R_\Psi(t), a_{\Psi,\mathcal{O}}(t), t) \in O(\ker(\tau)) \times \ker(\tau) \times \mathbb{R}$, we have, for each $t \in \mathbb{R}$,

$$(\pi^{\mathrm{can}}_{c,\mathcal{O}})^{-1}(R_\Psi(t), a_{\Psi,\mathcal{O}}(t), t) = \{(R_\Psi(t), a_{\Psi,\mathcal{O}}(t) - (\pi_{\mathcal{G}}(x_c) - s_0)\tilde{u}(t), \tilde{u}(t), t) \in \mathrm{Gal}(\mathcal{G}_{\mathrm{can}}) \,|\, \tilde{u}(t) \in \ker(\tau)\}.$$

Thus, all rigid motions Φ for which $\iota_{\mathcal{O}_{s_0}}(\Phi_t) \in (\pi^{\mathrm{can}}_{c,\mathcal{O}})^{-1}(R_\Psi(t), a_{\Psi,\mathcal{O}}(t), t)$ for each $t \in \mathbb{R}$, have the property that $\pi(\Psi_t) = \pi(\Phi_t), t \in \mathbb{R}$, and map the rigid body $(\mathcal{B},\mu)$ to the same set of points. Therefore, every such Φ is $\mathcal{B}$-equivalent to Ψ. Now, given $C_0 \in \ker(\tau)$, define a motion Φ by

$$\Phi_t = \iota^{-1}_{\mathcal{O}_{s_0}}(R_\Psi(t), a_{\Psi,\mathcal{O}}(t) - (\pi_{\mathcal{G}}(x_c) - s_0)C_0, C_0, t).$$

Clearly, Φ_t is horizontal and $\Phi_t \in (\pi^{\mathrm{can}}_{c,\mathcal{O}})^{-1}(R_\Psi(t), a_{\Psi,\mathcal{O}}(t), t)$, for each $t \in \mathbb{R}$. It can be directly verified that the curve Φ_t passes through the point $\iota^{-1}_{\mathcal{O}_{s_0}}(R_\Psi(t_0), a_{\Psi,\mathcal{O}}(t_0) - (\pi_{\mathcal{G}}(x_c) - s_0)C_0, C_0, t_0)$ at $t = t_0$, for each $t_0 \in \mathbb{R}$, and thus corresponds to the unique rigid motion Φ with the property that $u_{\Phi,\mathcal{O}}(t) = C_0$, for all $t \in \mathbb{R}$. From Proposition 6.6 we can see that, for $x_c \in \mathcal{O}$, the Galilean–Euler equations for the rigid motion Φ are equivalent to

$$\mathbb{I}_c(t)(\dot{\omega}_\Phi(t)) = \mathbb{I}_c(t)(\omega_\Phi(t)) \times \omega_\Phi(t),$$

$$\ddot{r}_{\Phi,\mathcal{O}}(t) = 0,$$

$$\dot{L}_{\Phi,\mathcal{B}}(t) = L_{\Phi,\mathcal{B}}(t) \times \Omega_\Phi(t),$$

$$\dot{M}_{\Phi,\mathcal{B}}(t) = P_{\mathcal{O}}(M_{\Phi,\mathcal{B}}(t)) \times \Omega_{\Phi}(t).$$

The result now follows. □

(Received 16 April 2005; accepted 13 July 2005; published online 7 October 2005)

We obtain correction terms to the large N asymptotic expansions of the eigenvalue density for the Gaussian unitary and Laguerre unitary ensembles of random $N \times N$ matrices, both in the bulk of the spectrum and near the spectral edge. This is achieved by using the well known orthogonal polynomial expression for the kernel to construct a double contour integral representation for the density, to which we apply the saddle point method. The main correction to the bulk density is oscillatory in N and depends on the distribution function of the limiting density, while the corrections to the Airy kernel at the soft edge are again expressed in terms of the Airy function and its first derivative. We demonstrate numerically that these expansions are very accurate. A matching is exhibited between the asymptotic expansion of the bulk density, expanded about the edge, and the asymptotic expansion of the edge density, expanded into the bulk. © *2005 American Institute of Physics.*

I. INTRODUCTION

We consider in this article two classical ensembles of random matrices, the Gaussian unitary ensemble (GUE), and the Laguerre unitary ensemble (LUE). These ensembles can be characterized by their joint eigenvalue probability density functions

$$P_N(x_1,\ldots,x_N) \propto \prod_{l=1}^{N} \omega_N(x_l) \prod_{1\leqslant j<k\leqslant N} (x_k - x_j)^2, \quad x_l \in \Omega, \tag{1}$$

with

$$\omega_N(x) = \begin{cases} \exp(-2Nx^2), & \text{GUE} \\ x^{\alpha}\exp(-4Nx), & \text{LUE}, \end{cases} \tag{2}$$

and

[c)]Electronic mail: n.frankel@physics.unimelb.edu.au

$$\Omega = \begin{cases} \mathbb{R}, & \text{GUE} \\ (0,\infty), & \text{LUE.} \end{cases} \tag{3}$$

The GUE consists of $N \times N$ Hermitian matrices with independent normally distributed entries on and above the diagonal. It is the cornerstone of random matrix theory.[1–3] The LUE has fundamental applications in mathematical statistics and quantum field theory since it includes Wishart matrices and the Chiral GUE as special cases (the latter after a straightforward change of variables); see, e.g., Ref. 1.

We are interested in the large N behavior of the marginal eigenvalue probability density $\rho_N(x)$, which we hereafter refer to simply as "the density," and which is defined by

$$\rho_N(x) := \int_{\Omega^{N-1}} P_N(x,x_2,\ldots,x_N)\mathrm{d}x_2 \cdots \mathrm{d}x_N. \tag{4}$$

The function $N\,\rho_N(x)$ can be interpreted as the number density of eigenvalues near the point x. We also remark that for the GUE, $N\,\rho_N(x)$ is equal to the number density of a harmonically trapped system of either non-interacting fermions or impenetrable bosons.[4] There is a similar interpretation for the LUE in terms of a Calogero-Sutherland type model.[5] For recent advances in asymptotic questions related to these interpretations, complementary to the present study, see Refs. 6–8.

As background to the present study we note that aspects of the large N form of $\rho_N(x)$ first arose in studies of field theories related to Hermitian matrix models.[9] There, for the GUE the large N asymptotic expansion of the moments

$$m_N(p) := \int_\Omega x^p \rho_N(x)\mathrm{d}x \quad (p = 1,2,\ldots)$$

was sort. By a graphical expansion of the matrix integral, involving cataloging the corresponding maps according to their genus, it was predicted that for certain coefficients $a_{2j}(p)$,

$$m_N^{\mathrm{GUE}}(p) = \sum_{j=0}^{p/2} \frac{a_{2j}(p)}{N^{2j}} \quad (p = 2,4,\ldots), \tag{5}$$

(the odd moments of course vanish). Analogous considerations in the case of the LUE[10] show that

$$m_N^{\mathrm{LUE}}(p) = \sum_{j=0}^{\lfloor (p+1)/2 \rfloor - 1} \frac{\tilde{a}_{2j}(p,\alpha)}{N^{2j}} \quad (p = 1,2,\ldots), \tag{6}$$

for certain coefficients $\tilde{a}_{2j}(p,\alpha)$. Observe in particular that both (5) and (6) contain only even inverse powers of N.

The graphical methods allow $a_0(p)$ in (5) and $\tilde{a}_0(p,\alpha)$ in (6) to be computed in terms of binomial coefficients for all $p = 0,1,\ldots$. This knowledge in turn can be used (see, e.g., Ref. 1) to prove that in the limit $N \to \infty$ with x fixed

$$\rho(x) := \lim_{N\to\infty} \rho_N(x) = \begin{cases} \frac{2}{\pi}\sqrt{1-x^2}, & x \in [-1,1], \quad \text{GUE} \\ \frac{2}{\pi}\sqrt{\frac{1}{x}-1}, & x \in (0,1], \quad \text{LUE}, \\ 0 \quad \text{otherwise}. \end{cases} \tag{7}$$

The first functional form in (7) is referred to as the Wigner semicircle law, whereas the second is sometimes named after Marčenko-Pastur. See, e.g., Refs. 1–3.

The expansions (5) and (6) provide a motivation to undertake a study of the asymptotic form of (4). In the case of the GUE such a result has been given by Kalish and Braak.[11] It states that for $|x| < 1$ and fixed

$$\rho_N(x) = \rho(x) - \frac{2\cos[2\ N\ \pi\ P(x)]}{\pi^3 \rho^2(x)} \frac{1}{N} + O\left(\frac{1}{N^2}\right), \tag{8}$$

where

$$P(x) = 1 + \frac{x}{2}\rho(x) - \frac{1}{\pi}\,\mathrm{Arccos}(x).$$

Thus, one sees that unlike the situation with the moments (5), the leading correction term is $O(1/N)$. Of course, this term is oscillatory so one might anticipate that after integration it contributes at a higher order. However inspection of (8) reveals that the situation is more complex: the oscillatory term is not integrable at the endpoints of the support, $|x|=1$. Indeed, it is well known that with the boundary of the eigenvalue support taken as the origin, a scaling regime distinct from that of the bulk becomes relevant. Explicitly, with $\mathrm{Ai}(x)$ denoting the Airy function, it has been proved that[12]

$$\lim_{N\to\infty} \frac{N^{1/3}}{2} \rho_N^{\mathrm{GUE}}\left(1 + \frac{\xi}{2N^{2/3}}\right) = \lim_{N\to\infty} \frac{(2N)^{1/3}}{2} \rho_N^{\mathrm{LUE}}\left(1 + \frac{\xi}{(2N)^{2/3}}\right) = [\mathrm{Ai}'(\xi)]^2 - \xi[\mathrm{Ai}(\xi)]^2, \tag{9}$$

where ξ is fixed. In view of the breakdown of (8) in the vicinity of the spectrum edge, (referred to as the *soft edge*, since although it defines the edge of the support of $\rho(x)$, for any finite N there is a nonzero probability of finding eigenvalues lying beyond it), we are thus led to also investigate the large N asymptotic expansion extending the limit law (9).

At a technical level, the main achievement of this paper is the derivation of the first correction terms to the limit laws (7) and (9). We do this by utilizing the well known orthogonal polynomial expression for $\rho_N(x)$ to obtain a double integral representation which is amenable to the saddle point method. In the bulk, i.e., in the interior of the support of $\rho(x)$, we show that the asymptotic series progresses in powers of $1/N$, and we obtain the explicit form of the $1/N$ correction. We find for the LUE that the coefficient of the $1/N$ term consists of a component which is oscillatory in N as well a component which is nonoscillatory in N, whereas for the GUE it consists of only an oscillatory component, as shown in (8). For the soft edge we will see that the asymptotic series progresses in powers of $N^{-1/3}$, and we obtain explicit expressions for the coefficients of the $N^{-1/3}$ and $N^{-2/3}$ terms, which again involve Airy functions.

Due to the similarity in the structure of $\rho_N(x)$ for the GUE and LUE, it is convenient to consider both cases simultaneously to avoid unnecessary repetition, and so at each step of our presentation we discuss the GUE and LUE in parallel. In Section II we discuss the double contour integral expression for $\rho_N(x)$ to which we shall apply the saddle point method. Section III contains our discussion of the asymptotics of $\rho_N(x)$ in the bulk whereas Sec. IV discusses the soft edge. In Sec. V we discuss the extent to which our expansions in the bulk match up with those for the soft edge.

Problems relating to the present study, but which remain to be investigated, are discussed in Sec. VI.

II. CONTOUR INTEGRAL EXPRESSION FOR $\rho_N(x)$

For the unitary ensembles there is a well known and very neat expression for $\rho_N(x)$ in terms of orthogonal polynomials, valid for any N and $x \in \Omega$. If we let $\{\pi_j(x)\}_{j=0}^{\infty}$ denote the monic polynomials orthogonal with respect to $\omega_N(x)$ on Ω, then

$$\rho_N(x) = \frac{\omega_N(x)}{N\|\pi_{N-1}\|^2}[\pi'_N(x)\pi_{N-1}(x) - \pi'_{N-1}(x)\pi_N(x)]. \tag{10}$$

The norm in the denominator of (10) is just the L^2 norm associated with $\omega_N(x)$ and Ω. For a derivation of (10) the reader is referred to Refs. 1–3. We remark at this point that there is no

universally agreed scale by which the GUE and LUE are defined. To match our choice of scale and notation in (2) to that employed in Ref. 1 for instance, we observe that

$$\rho_N(x) = \begin{cases} \sqrt{2}N^{-1/2}P_N(\sqrt{2N}x, \sqrt{2N}x), & \text{GUE} \\ 4\ P_N(4Nx,4Nx), & \text{LUE}, \end{cases}$$

where $P_N(x,y)$ (not to be confused with our definition (1) mentioned previously) is the kernel defined in Chap. 4 of Ref. 1 (the kernel is often also denoted $K_N(x,y)$ in the literature).

To investigate the large N behavior of $\rho_N(x)$ it is obviously advantageous to start with the expression (10) rather than with the $(N-1)$-fold integral (4). The $\pi_{N+j-1}(x)$ can be expressed in terms of the standard Hermite and Laguerre polynomials found in Szegö's classic book[13] as follows

$$\pi_{N+j-1}(x) = \begin{cases} 2^{-3(N+j-1)/2}N^{-(N+j-1)/2}H_{N+j-1}(\sqrt{2N}x), & \text{GUE} \\ (-1)^{N+j-1}(N+j-1)!\,(4N)^{-N-j+1}L_{N+j-1}^{(\alpha)}(4Nx), & \text{LUE}. \end{cases} \tag{11}$$

The required asymptotic expansions of the scaled Hermite and Laguerre polynomials appearing in (11) are known to any order both in the bulk and near the soft edge,[14,15] and such asymptotic expansions of scaled orthogonal polynomials are now generically said to be of *Plancherel-Rotach* type (Plancherel and Rotach were the first to compute such asymptotics for the Hermite polynomials). It is reasonable to assume that the most straightforward procedure to obtain the desired asymptotic corrections for $\rho_N(x)$ in each region of interest is to simply insert the corresponding asymptotic expansion for $\pi_{N+j-1}(x)$ into (10). While this is certainly legitimate in principle, and does indeed recover the leading term fairly easily, to derive the correction terms it turns out that such a procedure is rather tedious, and provides little if any insight into the resulting expressions. The source of the complication is that the asymptotic expansions for $\pi_{N+j-1}(x)$ contain a large amount of superfluous information which is canceled when the expansions are substituted into (10). To avoid this, we shall pursue a related, but more direct route.

The Plancherel-Rotach asymptotics for the Hermite and Laguerre polynomials were originally derived by first expressing the polynomials in terms of contour integrals, and then applying the saddle point method. By suitably massaging the standard results in Szegö's book[13] one finds that

$$\pi_{N+j-1}(x) = \begin{cases} c_j(N)\oint \frac{\mathrm{d}z}{2\pi i} e^{2N\,z\,x}\frac{e^{-Nz^2/2}}{z^{N+j}}, & \text{GUE} \\ (-1)^{N+j-1}c_j(N)\oint \frac{\mathrm{d}z}{2\pi i}\frac{e^{-2N\,z\,x}}{z^{N+1}}\left(1+\frac{z}{2}\right)^{N+\alpha}\left(\frac{1}{z}+\frac{1}{2}\right)^{j-1}, & \text{LUE}, \end{cases} \tag{12}$$

$$c_j(N) := \frac{(N+j-1)!}{(2N)^{N+j-1}}. \tag{13}$$

In both cases the contour of integration is a closed positively oriented contour which encircles the origin; in the Laguerre case we further demand that it not contain the point $z=-2$.

Instead of applying the saddle point method to (12) and then substituting the expansions into (10), we shall first insert the contour integrals (12) into (10) to obtain a double integral expression for $\rho_N(x)$, and then perform the saddle point method on this double integral. To highlight the similarity between the GUE and LUE it is convenient in the GUE case to substitute the contour integral for $\pi_{N+j-1}(-x)$ into (10) rather than that for $\pi_{N+j-1}(x)$; since $H_j(-x)=(-1)^jH_j(x)$ this ruse is perfectly harmless. This results in

$$\rho_N(x) = 2\frac{c_0(N)c_1(N)}{\|\pi_{N-1}\|^2}\omega_N(x)J_N(x), \tag{14}$$

where

$$J_N(x) := \oint \frac{dz_1}{2\pi i} \oint \frac{dz_2}{2\pi i} e^{NS(z_1,x)+NS(z_2,x)} G(z_1,z_2) \tag{15}$$

and

$$S(z,x) := \begin{cases} -2z\,x - \log(z) - z^2/2, & \text{GUE} \\ -2z\,x - \log(z) + \log(1+z/2), & \text{LUE}, \end{cases} \tag{16}$$

$$G(z_1,z_2) := u(z_1)u(z_2)\left(1 - \frac{z_1}{z_2}\right), \tag{17}$$

$$u(z) := \begin{cases} 1, & \text{GUE} \\ (1+z/2)^{\alpha-1}, & \text{LUE}. \end{cases} \tag{18}$$

The remainder of this paper will involve a careful asymptotic analysis of the double integral (15).

Before proceeding we note that it is straightforward to show, using standard results in the orthogonal polynomial literature,[13] that

$$\|\pi_{N-1}\|^{-2} = \begin{cases} \dfrac{2^{2N-3/2}}{\sqrt{\pi}} \dfrac{N^{N+1/2}}{N!}, & \text{GUE} \\ \dfrac{(4N)^{2N+\alpha-1}}{\Gamma(N)\Gamma(N+\alpha)}, & \text{LUE}, \end{cases} \tag{19}$$

and hence the asymptotics of the prefactors in (14) is

$$2\frac{c_0(N)c_1(N)}{\|\pi_{N-1}\|^2} = \begin{cases} \sqrt{\dfrac{2}{\pi}} N^{\frac{3}{2}-N}\Gamma(N), & \text{GUE} \\ \dfrac{4^{N+\alpha}N^{\alpha}\Gamma(1+N)}{\Gamma(N+\alpha)}, & \text{LUE}, \end{cases} \tag{20}$$

$$= \begin{cases} 2Ne^{-N}\left[1 + \dfrac{1}{12\,N} + O\left(\dfrac{1}{N^2}\right)\right], & \text{GUE} \\ 4^{N+\alpha}N\left[1 - \dfrac{(\alpha-1)\alpha}{2\,N} + O\left(\dfrac{1}{N^2}\right)\right], & \text{LUE}. \end{cases} \tag{21}$$

Saddle points: Before applying the saddle point method to (15) we need to identify and classify the saddle points of (16). The functions $S(z,x)$ in general have two saddle points at $z = z_\pm$ where

$$z_\pm := \begin{cases} -x \pm i\,\nu(x), & \text{GUE} \\ -1 \pm i\,\nu(x), & \text{LUE}, \end{cases} \tag{22}$$

and

$$\nu(x) := \begin{cases} \sqrt{1-x^2}, & \text{GUE} \\ \sqrt{\frac{1}{x}-1}, & \text{LUE}. \end{cases} \tag{23}$$

We note that for both the GUE and LUE we have

$$\nu(x) = \frac{\pi}{2}\rho(x) \quad \text{for} \quad |x| \leqslant 1, \tag{24}$$

with $\rho(x)$ as defined in (7). (Recall that, as defined in (3), when considering the LUE we always demand that $x>0$, so that (22) is indeed well defined).

Since for $|x| \leqslant 1$ we have

$$\frac{S''(z_\pm,x)}{2} = \begin{cases} \nu(x)e^{\pm i(\pi - \mathrm{Arcsin}(x))}, & \text{GUE} \\ 2x^2\nu(x)e^{\pm i\pi/2}, & \text{LUE}, \end{cases} \tag{25}$$

the saddle points $z=z_\pm$ are both simple when $|x|<1$, i.e., $S''(z_\pm,x)\neq 0$. However, when $x=1$ the two simple saddle points given in (22) coalesce to $z_\pm=-1$ and $S''(z_\pm,1)$ vanishes, so we obtain one double saddle point in this case. Thus we already see why the regions $|x|<1$ and $x\sim 1$ have qualitatively distinct asymptotic behavior. Simple saddle points generically produce Gaussian integrals whereas double saddle points generically produce Airy functions (see e.g., Ref. 16).

III. BULK ASYMPTOTICS FOR THE GUE AND LUE

In the bulk of the spectrum, i.e., for $|x|<1$, we hold x fixed and investigate the asymptotics of (15) as N becomes large. From (22) we see that there are two distinct simple saddle points of $S(z,x)$, which form a complex conjugate pair in this case. Let us define $S_\pm := S(z_\pm,x)$. Then since

$$\mathrm{Re}(S_+) = \mathrm{Re}(S_-), \tag{26}$$

both saddle points contribute to the same order and we deform our contour through both of them. Denoting by $\Omega_\pm$ a contour passing through $z_\pm$ along a path of steepest descent, the standard arguments of the saddle point method (see for e.g., Ref. 16) yield

$$J_N(x) = \left(\int_{\Omega_+}\frac{dz_1}{2\pi i} + \int_{\Omega_-}\frac{dz_1}{2\pi i}\right)\left(\int_{\Omega_+}\frac{dz_2}{2\pi i} + \int_{\Omega_-}\frac{dz_2}{2\pi i}\right) e^{N\,S(z_1,x)+N\,S(z_2,x)}G(z_1,z_2) + O(e^{2N\,\mathrm{Re}(S_+)-N\,\epsilon}), \tag{27}$$

$$= -\sum_{\sigma\in\{-,+\}^2}\int_{\Omega_{\sigma_1}}\frac{dz_1}{2\pi}\int_{\Omega_{\sigma_2}}\frac{dz_2}{2\pi} e^{N\,S(z_1,x)+N\,S(z_2,x)}G(z_1,z_2) + O(e^{2N\,\mathrm{Re}(S_+)-N\,\epsilon}), \tag{28}$$

for suitably small $\epsilon>0$.

We now need to parameterize the contours $\Omega_\pm$. From (25) we see that if we set

$$\theta = \begin{cases} \mathrm{Arcsin}(x)/2, & \text{GUE} \\ \pi/4, & \text{LUE}, \end{cases} \tag{29}$$

then a suitable parameterization of $\Omega_\pm$ is

$$z = z_\pm + e^{\pm i\theta}t, \quad t\in[-\eta,\eta], \tag{30}$$

for sufficiently small $\eta>0$. In (29) the function $\mathrm{Arcsin}:[-1,1]\to[-\pi/2,\pi/2]$ denotes the principle branch of arcsine. With the parameterization (30) the contour Ω_+ is traversed in the negative direction, so we need to compensate for this with an explicit minus sign.

By choosing η sufficiently small $S(z,x)$ is analytic on $\Omega_\pm$ and so using the parameterization (30) we see that

$$S(z,x) = S_\pm - a\,t^2 - a\,t^2\varphi_\pm(t), \quad z\in\Omega_\pm, \tag{31}$$

where

$$a := \begin{cases} \nu(x), & \text{GUE} \\ 2x^2\nu(x), & \text{LUE}, \end{cases} \tag{32}$$

and

$$\varphi_{\pm}(t) := \sum_{k=3}^{\infty} \frac{S^{(k)}(z_{\pm},x)}{S^{(2)}(z_{\pm},x)} \frac{2}{k!} e^{\pm i(k-2)\theta} t^{k-2}. \tag{33}$$

We note that $\varphi_{-}(t)=\varphi_{+}^{*}(t)$, where * denotes complex conjugation.

It is a straightforward exercise to show that $S_{-}=S_{+}^{*}$, and that

$$\mathrm{Re}(S_{+}) = \begin{cases} \frac{1}{2} + x^2, & \text{GUE} \\ 2x - \log(2), & \text{LUE}, \end{cases} \tag{34}$$

$$\mathrm{Im}(S_{+}) = -\pi\, P(x), \tag{35}$$

where

$$P(x) := \int_{x_0}^{x} \rho(t)\mathrm{d}t, \tag{36}$$

$$= \begin{cases} 1 + \frac{x}{2}\rho(x) - \frac{1}{\pi}\mathrm{Arccos}(x), & \text{GUE} \\ 1 + x\ \rho(x) - \frac{2}{\pi}\mathrm{Arccos}(\sqrt{x}), & \text{LUE}. \end{cases} \tag{37}$$

Here x_0 is the left edge of the support of $\rho(x)$ given in (7), i.e., $x_0=-1$, 0, for the GUE and LUE respectively. We note that $P(x)$ is the probability distribution function corresponding to $\rho(x)$. The limiting distribution function $P(x)$ will play a significant role in the bulk asymptotic expansion of $\rho_N(x)$.

With the results (31) and (35) for $S(z,x)$, and the definitions

$$G_{\sigma}(t) := G(z_1,z_2)\big|_{\substack{z_1\to z_{\sigma_1}+e^{i\sigma_1\theta}t_1 \\ z_2\to z_{\sigma_2}+e^{i\sigma_2\theta}t_2}}, \tag{38}$$

$$\mathbb{E}_i^{(B)} := \int_{-\eta}^{\eta} \frac{e^{-aNt_i^2}}{2\pi}\mathrm{d}t_i, \tag{39}$$

where $\mathbb{E}_i^{(B)}$ is an integral operator acting to the right, we can make the change of variables (30) in (28) to obtain

$$J_N(x) = e^{2N\,\mathrm{Re}(S_{+})}\mathbb{E}_1^{(B)}\mathbb{E}_2^{(B)} \sum_{\sigma\in\{-1,+1\}^2} -\sigma_1\sigma_2 e^{i(\sigma_1+\sigma_2)(\theta-N\ \pi\ P(x))} e^{-aNt_1^2\varphi_{\sigma_1}(t_1)-aNt_2^2\varphi_{\sigma_2}(t_2)} G_{\sigma}(t) + O(e^{2N\,\mathrm{Re}(S_{+})-\epsilon\ N}). \tag{40}$$

A small amount of massaging shows that the $(-1,+1)$ term in (40) is the complex conjugate of the $(+1,-1)$ term, and likewise the $(-1,-1)$ term is conjugate to the $(+1,+1)$ term. Suppose now that we define the function $F_{\sigma}(\lambda,t)$ by

$$F_{\sigma}(\lambda,t) := e^{\lambda_1\varphi_{\sigma_1}(t_1)} e^{\lambda_2\varphi_{\sigma_2}(t_2)} G_{\sigma}(t), \tag{41}$$

then

$$J_N(x) = 2\ e^{2N\ \mathrm{Re}(S_+)} \mathrm{Re}\ \mathbb{E}_1^{(B)} \mathbb{E}_2^{(B)} \{F_{+,-}(\lambda,t)|_{\lambda_i=-aNt_i^2} - e^{2i(\theta - N\ \pi\ P(x))} F_{+,+}(\lambda,t)|_{\lambda_i=-aNt_i^2}\} + O(e^{2N\ \mathrm{Re}(S_+)-\epsilon N}). \tag{42}$$

We shall discuss the purpose of the parameters λ_i shortly. Note that the two terms in (42) are qualitatively distinct—the second term is oscillatory in N whereas the first is not.

It is convenient to pause for a moment and multiply (42) by the the explicit forms for the prefactors required in (14) using (21) and (34) to obtain the corresponding expression for $\rho_N(x)$ Since

$$\frac{2c_0(N)c_1(N)}{\|\pi_{N-1}\|^2} \omega_N(x) e^{2N\ \mathrm{Re}(S_+)} = h_0 N \left[1 + \frac{h_1}{N} + O\left(\frac{1}{N^2}\right) \right] \tag{43}$$

with

$$h_0 = \begin{cases} 2, & \text{GUE} \\ 4^\alpha x^\alpha, & \text{LUE}, \end{cases} \tag{44}$$

$$h_1 = \begin{cases} \frac{1}{12}, & \text{GUE} \\ -\frac{\alpha(\alpha-1)}{2}, & \text{LUE}, \end{cases} \tag{45}$$

we have

$$\rho_N(x) = h_0 \left[1 + \frac{h_1}{N} + O\left(\frac{1}{N^2}\right) \right] \times 2\ \mathrm{Re}\ N\ \mathbb{E}_1^{(B)} \mathbb{E}_2^{(B)} \{F_{+,-}(\lambda,t)|_{\lambda_i=-aNt_i^2} - e^{2i(\theta - N\ \pi\ P(x))} F_{+,+}(\lambda,t)|_{\lambda_i=-aNt_i^2}\} + O(e^{-\epsilon N}). \tag{46}$$

The introduction of the auxiliary variables λ_1, λ_2 in (41) is a common ruse applied in the saddle point method (see e.g., Ref. 16) which we now discuss. Suppose that we construct the Maclaurin expansion in t_1, t_2 of $F_\sigma(\lambda, t)$ with λ considered as a fixed parameter

$$F_\sigma(\lambda,t) = \sum_{j=0}^{p} \sum_{k=0}^{j} \frac{t_1^k t_2^{j-k}}{k!\,(j-k)!} \left[\frac{\partial^k}{\partial s_1^k} \frac{\partial^{j-k}}{\partial s_2^{j-k}} F_\sigma(\lambda, s_1, s_2) \right] \Bigg|_{s_1,s_2=0} + O(t_1^{p_1} t_2^{p_2})|_{p_1+p_2=p+1}. \tag{47}$$

If we now set $\lambda_i = -aNt_i^2$ in (47) and perform the integrations required in (46) then we find that each term corresponding to a given value of j in (47) has the same resulting N dependence. This then gives a systematic way of obtaining the corrections out to any given order in N. To see why this occurs, first note that we need only consider the terms in (47) for which both j and k are even since any odd monomials are annihilated by (39), and then further note that with $\lambda_i = -aNt_i^2$ we have

$$N\ \mathbb{E}_1^{(B)} \mathbb{E}_2^{(B)} t_1^{2m_1} t_2^{2m_2} \lambda_1^{l_1} \lambda_2^{l_2} = (-1)^{l_1+l_2} \frac{\Gamma(m_1 + l_1 + 1/2)\Gamma(m_2 + l_2 + 1/2)}{4\ \pi^2 a^{m_1+m_2+1}} N^{-(m_1+m_2)} + O(e^{-a\eta^2 N}), \tag{48}$$

for any $l_1, l_2 \in \mathbb{N}$. Hence, despite the fact that various powers of λ_1 and λ_2 arise when $F_\sigma(\lambda, t)$ is differentiated, for a given value of j all terms end up with the same N dependence after setting $\lambda_i = -aNt_i^2$ and performing the integrations.

Hence, substituting (47) into (46) one can construct the asymptotic series for $\rho_N(x)$ out to any desired order. We shall explicitly construct this series out to order $1/N$ but the generalization to

higher orders is obvious. However, as we shall see the resulting asymptotic expansions obtained by keeping only the $1/N$ correction are already extremely good, and it appears that numerically optimal truncation occurs at this order.

Let us denote by $c_m^{(\sigma)}(x)$ the coefficient of $1/N^m$ in the $1/N$ expansion generated by acting with $N\,\mathbb{E}_1^{(B)}\mathbb{E}_2^{(B)}$ on (47), with λ_i set to $-aNt_i^2$. Then since the only terms which contribute are those for which j and k are even we have

$$\frac{c_m^{(\sigma)}(x)}{N^m} = \sum_{k=0}^{m} \frac{1}{(2k)!\,(2[m-k])!} N\,\mathbb{E}_1^{(B)}\mathbb{E}_2^{(B)} t_1^{2k} t_2^{2(m-k)} \left[\frac{\partial^{2k}}{\partial {s_1}^{2k}} \frac{\partial^{2(m-k)}}{\partial {s_2}^{2(m-k)}} F_\sigma(\lambda, s)\Big|_{s_i=0} \right] \Bigg|_{\lambda_i=-aNt_i^2}. \tag{49}$$

We can re-express $\rho_N(x)$ from (46) in terms of the $c_m^{(\sigma)}(x)$ as follows:

$$\begin{aligned}\rho_N(x) = {} & 2\,h_0 \mathrm{Re}\{c_0^{(1,-1)}(x)\} - 2\,h_0 \mathrm{Re}\{e^{2i(\theta - N\,\pi\,P(x))} c_0^{(1,1)}(x)\} - 2\,h_0 \mathrm{Re}\{e^{2i(\theta - N\,\pi\,P(x))}[c_1^{(1,1)}(x) \\ & + h_1 c_0^{(1,1)}(x)]\}\frac{1}{N} + 2h_0 \mathrm{Re}\{c_1^{(1,-1)}(x) + h_1 c_0^{(1,-1)}(x)\}\frac{1}{N} + O\left(\frac{1}{N^2}\right).\end{aligned} \tag{50}$$

It is not hard to show that the term $2\,h_0\mathrm{Re}\{c_0^{(1,-1)}(x)\}$ is equal to the limiting density $\rho(x)$ from (7) when $|x|<1$, as required, and also that $c_0^{(1,1)}(x)$ vanishes identically (this is actually obvious from (17) and (38)). The explicit construction of the remaining $c_m^{(\sigma)}(x)$ required in (50) is straightforward and we finally obtain the following.

Proposition 1: *Let* $\rho_N(x)$ *be as defined in* (4), *and let x be fixed, with* $|x|<1$ *for the GUE and* $x \in (0,1)$ *for the LUE. Then as* $N \to \infty$ *we have the following:*

For the GUE

$$\rho_N(x) = \rho(x) - \frac{2\cos[2\,N\,\pi\,P(x)]}{\pi^3 \rho^2(x)}\frac{1}{N} + O\left(\frac{1}{N^2}\right), \tag{51}$$

whereas for the LUE

$$\begin{aligned}\rho_N(x) &= \rho(x) - \left(\frac{\cos(2\,N\,\pi\,P(x) - \alpha\,\pi[1 + x\,\rho(x) - P(x)])}{\pi^3 x^2 \rho^2(x)} - \frac{\alpha}{\pi^2 x\,\rho(x)}\right)\frac{1}{N} + O\left(\frac{1}{N^2}\right), \\ &= \rho(x) - \left(\frac{\cos(2\,N\,\pi\,P(x) - 2\,\alpha\,\mathrm{Arccos}(\sqrt{x}))}{\pi^3 x^2 \rho^2(x)} - \frac{\alpha}{\pi^2 x\,\rho(x)}\right)\frac{1}{N} + O\left(\frac{1}{N^2}\right),\end{aligned} \tag{52}$$

where $\rho(x)$ *is given in* (7) *and* $P(x)$ *is the corresponding probability distribution function, given explicitly in* (37).

As remarked in Sec. I, the result (51) was obtained previously in[11] again by steepest descent, but starting from an integral representation derived by super-symmetric arguments rather than orthogonal polynomials.

It is interesting to note that it is the distribution function $P(x)$ of the limiting density $\rho(x)$ which controls the large N oscillations in the $1/N$ correction to $\rho_N(x)$. Note also that while the non-oscillatory correction vanishes at order $1/N$ for the GUE leaving only an oscillatory correction at this order, the LUE has both an oscillatory and a non-oscillatory component to its $1/N$ correction.

To demonstrate to the reader just how accurate the expansions given by Proposition 1 are we provide in Figs. 1 and 2 a numerical comparison of the asymptotic expansions with the exact results computed using the expression (10) in terms of orthogonal polynomials.

IV. SOFT EDGE ASYMPTOTICS FOR THE GUE AND LUE

The appropriate scaling to elucidate the behavior of $\rho_N(x)$ near the soft edge is to set $x = 1 + \xi/N^{2/3}$ for fixed ξ, as appears in (9). Substituting such a scaling into (16) we find

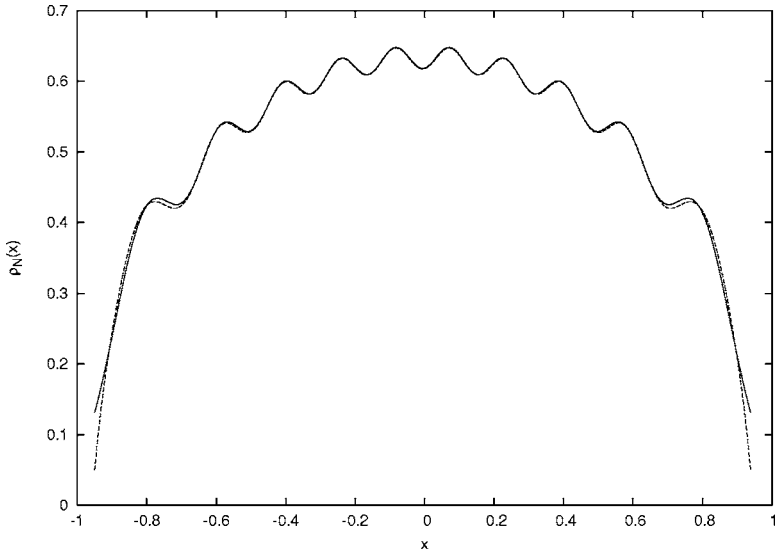

FIG. 1. Comparison of the asymptotic expansion (51), shown as the dashed line, and the exact result (10), shown as the solid line, for the eigenvalue density of the GUE with $N=10$.

$$N\,S\left(z,1+\frac{b^{1/3}}{2}\frac{\xi}{N^{2/3}}\right)=-\xi b^{1/3}N^{1/3}z+N\,S(z), \tag{53}$$

where we have introduced the shorthand $S(z):=S(z,1)$. Here $b>0$ is a free parameter that we can fix later as convenient. Defining

$$\tilde{J}_N(\xi):=J_N\left(1+\frac{b^{1/3}}{2}\frac{\xi}{N^{2/3}}\right), \tag{54}$$

we see that (53) leads to

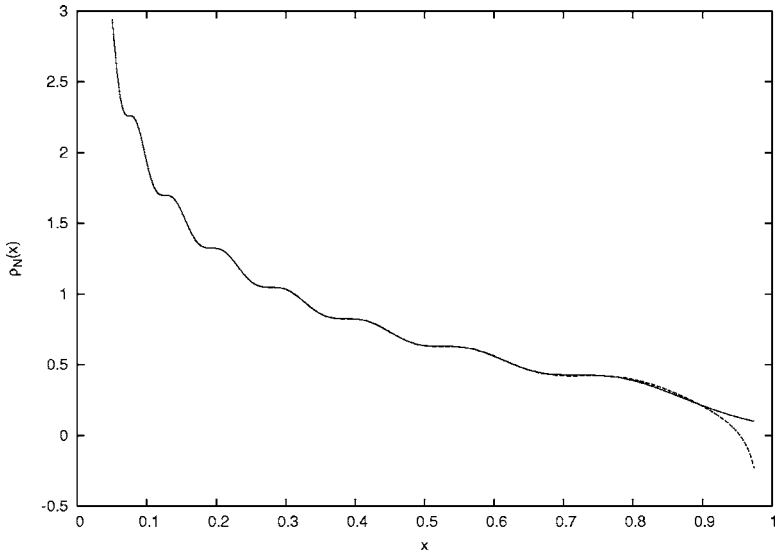

FIG. 2. Comparison of the asymptotic expansion (52), shown as the dashed line, and the exact result (10), shown as the solid line, for the eigenvalue density of the LUE with $\alpha=1/2$ and $N=10$.

$$\widetilde{J}_N(\xi) = \oint \frac{\mathrm{d}z_1}{2\pi i} \exp(N\,S(z_1) - b^{1/3}N^{1/3}z_1\xi) \oint \frac{\mathrm{d}z_2}{2\pi i} \exp(N\,S(z_2) - b^{1/3}N^{1/3}z_2\xi)G(z_1,z_2). \tag{55}$$

The reader might be concerned by the slightly unorthodox term in the exponent proportional to $N^{1/3}$, however it is subdominant to the $N\,S(z)$ term and its presence does not affect any of the usual arguments of the saddle point method; the asymptotic behavior of (55) is determined by $S(z)$. From (22), (23), and (25) we see for both the GUE and LUE that $S(z)$ has one double saddle point, located at $z=-1$. We can deform the contour of integration to a new contour which passes through $z=-1$ along paths of steepest descent. Note that although in (12) the integrals must be positively oriented, since we have two integrals in (55) we are free to orient the integrals in the negative direction since the consequent minus signs cancel. Let us denote by $\mathcal{C}$ the contour consisting of the union of two rays of unit length, the first starting at $z=e^{-i\pi/3}-1$ and ending at $z=-1$ and the second starting at $z=-1$ and ending at $z=e^{i\pi/3}-1$. If we then denote by $\mathcal{A}$ any suitable arc such that $\mathcal{C}\cup\mathcal{A}$ is a simple closed curve enclosing the origin we can write

$$\begin{aligned}\widetilde{J}_N(\xi) = &\left(\int_{\mathcal{C}} + \int_{\mathcal{A}}\right)\frac{\mathrm{d}z_1}{2\pi i} \exp(N\,S(z_1) - b^{1/3}N^{1/3}z_1\xi) \\ &\times \left(\int_{\mathcal{C}} + \int_{\mathcal{A}}\right)\frac{\mathrm{d}z_2}{2\pi i}\exp(N\,S(z_2) - b^{1/3}N^{1/3}z_2\xi)G(z_1,z_2),\end{aligned} \tag{56}$$

$$\begin{aligned}= &\int_{\mathcal{C}} \frac{\mathrm{d}z_1}{2\pi i} \exp(N\,S(z_1) - b^{1/3}N^{1/3}z_1\xi) \int_{\mathcal{C}} \frac{\mathrm{d}z_2}{2\pi i} \exp(N\,S(z_2) - b^{1/3}N^{1/3}z_2\xi)G(z_1,z_2) \\ &+ o(e^{2N\,S(-1)}N^{-p}).\end{aligned} \tag{57}$$

The error bound in (57) holds for all $p\in\mathbb{N}$, and so in what follows we consider p as arbitrarily large. The equality between (56) and (57) can be obtained by noting that we can choose $\mathcal{A}$ to consist of two rays lying along the path of steepest descent away from the endpoints of $\mathcal{C}$, which extend as far as we like into the right half plane, together with an arc to close the contour which we can choose to be as far into the right half plane as desired. With such a choice for $\mathcal{A}$ one can obtain the required bounds by a straightforward generalization of the usual argument used in the saddle point method. For a careful discussion of the saddle point method, suitable for this purpose, see, e.g., Sec. 2.5 of Ref. 16. We note that Ref. 16 refers to the saddle point method as *Perron's method*.

Now let us change variables in (57) according to $t=z+1$, so that the vertex of our contour is now at the origin. We shall denote the image of $\mathcal{C}$ under this change of variables by $\mathcal{B}$. Further, since $S(z)$ is analytic on $\mathcal{C}$ we have

$$S(t-1) = S(-1) + b\frac{t^3}{3} + b\frac{t^3}{3}\varphi(t), \tag{58}$$

where

$$\varphi(t) := \sum_{k=4}^{\infty} \frac{S^{(k)}(-1)}{S^{(3)}(-1)}\frac{3!}{k!}t^{k-3}, \tag{59}$$

and we have now chosen

$$b = \frac{S^{(3)}(-1)}{2}, \tag{60}$$

$$= \begin{cases} 1, & \text{GUE} \\ 2, & \text{LUE.} \end{cases} \tag{61}$$

We also note that by setting $x=1$ in (34) and (35) we have

$$S(-1) = \begin{cases} \frac{3}{2} - i\pi, & \text{GUE} \\ 2 - \log(2) - i\pi, & \text{LUE.} \end{cases} \tag{62}$$

Finally, defining

$$F(\lambda,t) := G(t_1 - 1, t_2 - 1) e^{\lambda_1 \varphi(t_1) + \lambda_2 \varphi(t_2)}, \tag{63}$$

and the integral operator

$$\mathbb{E}_i^{(S)} := \int_{\mathcal{B}} \exp\left(bN \frac{t_i^3}{3} - \xi b^{1/3} N^{1/3} t_i \right) \frac{dt_i}{2\pi i} \tag{64}$$

we have

$$\tilde{J}_N(\xi) = e^{2N \,\mathrm{Re}[S(-1)] + 2b^{1/3}N^{1/3}\xi} [\mathbb{E}_1^{(S)} \mathbb{E}_2^{(S)} F(\lambda,t)|_{\lambda_i = bNt_i^3/3} + o(N^{-p})]. \tag{65}$$

If we now multiply (65) by the prefactors required in (14) using (21) we obtain

$$\frac{(bN)^{1/3}}{2} \rho_N\left(1 + \frac{b^{1/3}}{2} \frac{\xi}{N^{2/3}}\right) = \left[g_0(\xi) + \frac{g_1(\xi)}{N^{1/3}} + \frac{g_2(\xi)}{N^{2/3}} + O\left(\frac{1}{N}\right) \right] \times [N^{4/3} \mathbb{E}_1^{(S)} \mathbb{E}_2^{(S)} F(\lambda,t)|_{\lambda_i = bNt_i^3/3} + o(N^{-p})], \tag{66}$$

where $g_m(\xi)$ is the coefficient of $N^{-m/3}$ in the large N fixed ξ expansion of

$$\begin{cases} e^{-\xi^2/2N^{1/3}}, & \text{GUE} \\ 2^{2\alpha - 2/3} \left(1 + \dfrac{\xi}{(2N)^{2/3}}\right)^{\alpha}, & \text{LUE.} \end{cases} \tag{67}$$

In (66) we have presented only terms $O(1/N)$ in the first factor since this will be sufficient for our purposes in what follows. Higher order terms are easily retained if desired.

Our work is now essentially done. One expands $F(\lambda,t)$ around $t=0$ for fixed λ as in (47) and then sets $\lambda_i = bNt_i^3/3$, analogous to the bulk case. Again, after integration, each value of j in the Maclaurin expansion (47) contributes to the same order in N. To see this explicitly we can use the following lemma.

Lemma 1. Let $\mathcal{B}$ be the contour consisting of the union of a ray starting at $e^{-i\pi/3}$ and ending at the origin, and a ray starting at the origin and ending at $e^{i\pi/3}$. For any $b>0$ and $0<\beta<1/3$ we have for large N that

$$\int_{\mathcal{B}} z^m \exp\left(bN \frac{z^3}{3} - \xi b^{1/3} N^{1/3} z \right) \frac{dz}{2\pi i} = (-1)^m b^{-(m+1)/3} N^{-(m+1)/3} [\mathrm{Ai}^{(m)}(\xi) + O(e^{-\beta bN})],$$

where $\mathrm{Ai}^{(m)}(\xi)$ *is the* m^{th} *derivative of the Airy function* $\mathrm{Ai}(\xi)$.

Proof: This follows from the standard entire contour integral expression for $\mathrm{Ai}(\xi)$ (see e.g., Ref. 17) by simply changing variables $z \mapsto b^{-1/3} N^{-1/3} z$, and noting that the rays defining the contour $\mathcal{B}$ can be extended to infinity at the cost of introducing exponentially subdominant corrections.

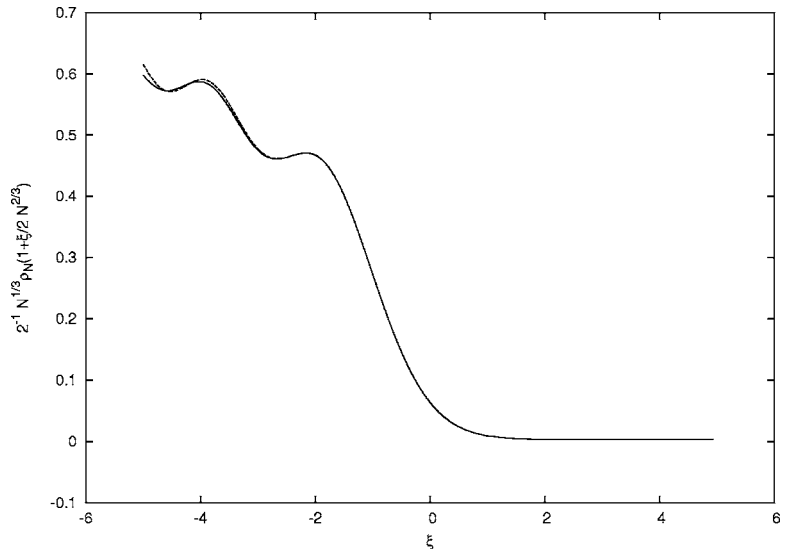

FIG. 3. Comparison of the asymptotic expansion (72), shown as the dashed line, and the exact result (10), shown as the solid line, for the eigenvalue density near the soft edge at $x=1$, for the GUE with $N=10$.

An immediate consequence of Lemma 1 is that with $\lambda_i = bNt_i^3/3$ we have

$$N^{4/3}\mathbb{E}_1^{(S)}\mathbb{E}_2^{(S)}t_1^{k_1}t_2^{k_2}\lambda_1^{l_1}\lambda_2^{l_2} = \frac{(-1)^{l_1+l_2+k_1+k_2}}{3^{l_1+l_2}b^{(k_1+k_2+2)/3}}\mathrm{Ai}^{(k_1+3l_1)}(\xi)\mathrm{Ai}^{(k_2+3l_2)}(\xi)\left(\frac{1}{N^{1/3}}\right)^{k_1+k_2-2} + O(e^{-\beta bN}). \tag{68}$$

Hence, if we construct the Maclaurin expansion of $F(\lambda,t)$ with λ fixed as in (47), and set $\lambda_i = bNt_i^3/3$ and integrate using (68), we obtain an expansion for

$$N^{4/3}\mathbb{E}_1^{(S)}\mathbb{E}_2^{(S)}F(\lambda,t)|_{\lambda_i=bNt_i^3/3} \tag{69}$$

in powers of $N^{-1/3}$. Denoting the coefficient of $N^{-m/3}$ in this expansion by $c_m(\xi)$ we have explicitly that

$$\frac{c_m(\xi)}{N^{m/3}} = \sum_{k=0}^{m+2}\frac{1}{k\,!\,(m+2-k)!}N^{4/3}\mathbb{E}_1^{(S)}\mathbb{E}_2^{(S)}t_1^k t_2^{m+2-k}\left[\frac{\partial^k}{\partial s_1^k}\frac{\partial^{m+2-k}}{\partial s_2^{m+2-k}}F(\lambda,s_1,s_2)\bigg|_{s_1,s_2=0}\right]\Bigg|_{\lambda_i=bNt_i^3/3}. \tag{70}$$

The reader might be concerned that according to (68) the $k_1+k_2=1$ and $k_1+k_2=0$ terms grow with N; however it is not hard to show from (70) that the coefficients $c_{-2}(\xi)$ and $c_{-1}(\xi)$ vanish identically.

We can now express (66) in terms of the coefficients $c_m(\xi)$ as

$$\frac{(bN)^{1/3}}{2}\rho_N\left(1+\frac{b^{1/3}}{2}\frac{\xi}{N^{2/3}}\right) = g_0(\xi)c_0(\xi) + [g_1(\xi)c_0(\xi)+g_0(\xi)c_1(\xi)]\frac{1}{N^{1/3}} + [g_2(\xi)c_0(\xi)+g_1(\xi)c_1(\xi)+g_0(\xi)c_2(\xi)]\frac{1}{N^{2/3}} + O\left(\frac{1}{N}\right). \tag{71}$$

We have explicitly displayed terms $o(1/N)$ here, but it is straightforward to retain as many terms as desired. The expansion constructed from terms $o(1/N)$ however is extremely accurate, as we demonstrate in Figs. 3 and 4, and it appears to be the numerically optimal order at which to truncate the expansions.

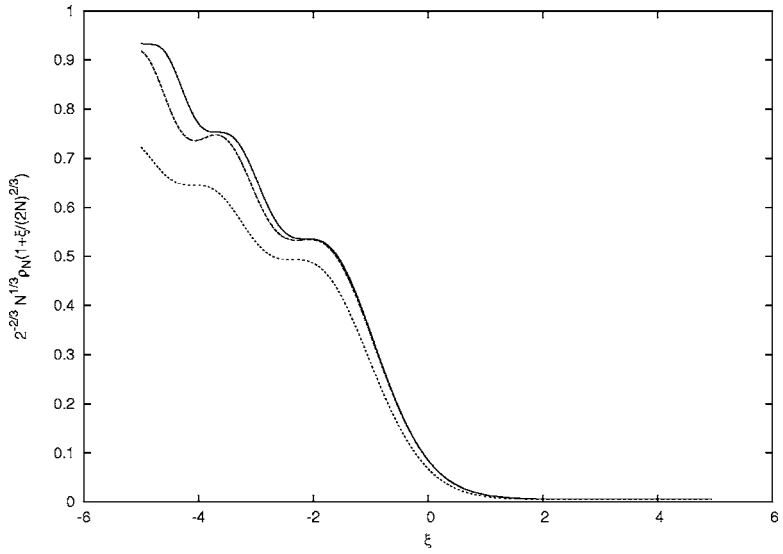

FIG. 4. Comparison of the asymptotic expansion (73), shown as the dashed line, and the exact result (10), shown as the solid line, for the eigenvalue density near the soft edge at $x=1$, for the LUE with $\alpha=1/2$ and $N=20$. Also shown is the limit as $N\to\infty$ given by the Airy kernel (9), shown as the dotted line lying below the other two curves.

The explicit forms for the coefficients $c_m(\xi)$ can be constructed from (70) and substituted into (71). We can also further simplify the Airy derivatives appearing in (68) using the Airy differential equation $\mathrm{Ai}''(\xi)=\xi\,\mathrm{Ai}(\xi)$ so that only $\mathrm{Ai}(\xi)$ and its first derivative appear. We finally obtain the following.

Proposition 2: Let $\rho_N(x)$ be as defined in (4). *Then with ξ fixed, as $N\to\infty$ we have the following:*

For the GUE

$$\frac{N^{1/3}}{2}\rho_N\left(1+\frac{\xi}{2N^{2/3}}\right)=[\mathrm{Ai}'(\xi)]^2-\xi[\mathrm{Ai}(\xi)]^2 - \frac{1}{20}(3\xi^2[\mathrm{Ai}(\xi)]^2-2\xi[\mathrm{Ai}'(\xi)]^2-3\,\mathrm{Ai}(\xi)\mathrm{Ai}'(\xi))\frac{1}{N^{2/3}} + O\left(\frac{1}{N}\right), \tag{72}$$

whereas for the LUE

$$\frac{(2N)^{1/3}}{2}\rho_N\left(1+\frac{\xi}{(2N)^{2/3}}\right)=[\mathrm{Ai}'(\xi)]^2-\xi[\mathrm{Ai}(\xi)]^2+\frac{\alpha}{2^{1/3}}[\mathrm{Ai}(\xi)]^2\frac{1}{N^{1/3}} + \frac{2^{1/3}}{10}(3\xi^2[\mathrm{Ai}(\xi)]^2-2\xi[\mathrm{Ai}'(\xi)]^2+(2-5\alpha^2)\mathrm{Ai}(\xi)\mathrm{Ai}'(\xi))\frac{1}{N^{2/3}} + O\left(\frac{1}{N}\right). \tag{73}$$

Figures 3 and 4 provide a numerical comparison of the asymptotic expansions given in Proposition 2 with the exact results computed using the expression (10) in terms of orthogonal polynomials.

Note that it appears that the GUE converges much faster than the LUE, since while the two curves in (3) are almost indistinguishable at $N=10$ for the GUE, the asymptotic expansion for the

LUE begins to diverge from the exact result in (4) already by $\xi \sim 2$, and both curves are rather different from the limiting Airy kernel expression (9). We investigated the affects of retaining more terms in the expansion for the LUE case; keeping terms $O(1/N)$ did not noticeably change the plots, while keeping terms higher than $1/N$ caused significant divergence of the asymptotic expansion from the exact result. The explanation for this is most likely that, as made precise in the next section, the edge expansions match onto the bulk expansions, and these in turn become more divergent near the edge at each order in $1/N$.

V. MATCHING OF THE BULK AND EDGE EXPANSIONS

In Figs. 1–4 plots of the bulk and edge asymptotic expansions have separately been compared against the exact density for I finite N. Although the scale of the independent variable is different, we can see from Figs. 3 and 4 that the edge asymptotic expansions are accurate approximations to the exact density at least up to the neighborhood of the first local maximum (relative to the edge $\xi=0$), and thus the edge asymptotic expansions should be used instead of the bulk asymptotic expansions in this region.

At a quantitative level, it is possible to exhibit a matching between the various asymptotic expansions. Suppose in (51) we set $x=1+\xi/2N^{2/3}$, and in (52) we set $x=1+\xi/(2N)^{2/3}$, and take $\xi<0$ and fixed. Expanding the right hand sides as an asymptotic series in N gives

$$N^{1/3}\rho_N^{\mathrm{GUE}}(1+\xi/2N^{2/3}) \dot{\sim} \left(\frac{2\sqrt{|\xi|}}{\pi} - \frac{\cos(4|\xi|^{3/2}/3)}{2\pi|\xi|}\right) - \left(\frac{|\xi|^{3/2}}{4\pi} + \frac{\cos(4|\xi|^{3/2}/3)}{8\pi} + \frac{|\xi|^{3/2}\sin(4|\xi|^{3/2}/3)}{20\pi}\right)\frac{1}{N^{2/3}} + O\left(\frac{1}{N^{4/3}}\right), \tag{74}$$

$$(2N)^{1/3}\rho_N^{\mathrm{LUE}}(1+\xi/(2N)^{2/3}) \dot{\sim} \left(\frac{2\sqrt{|\xi|}}{\pi} - \frac{\cos(4|\xi|^{3/2}/3)}{2\pi|\xi|}\right) + \frac{\alpha(1+\sin(4|\xi|^{3/2}/3))}{\pi\sqrt{|\xi|}}\frac{1}{(2N)^{1/3}} + O\left(\frac{1}{N^{2/3}}\right), \tag{75}$$

where the symbol $\dot{\sim}$ denotes that the asymptotic series have been expanded as specified. An important feature is that this procedure mixes the terms which are at different orders in N in (51) and (52).

Let us now compute the $\xi \to -\infty$ asymptotic expansions of the right hand sides of the first two terms in each of (72) and (73), multiplied by 2. Using the fact that for $x \to \infty$ (see e.g., Ref. 17)

$$\mathrm{Ai}(-x) = \frac{1}{\sqrt{\pi}x^{1/4}}\cos\left(\frac{\pi}{4} - \frac{2}{3}x^{3/2}\right) - \frac{5}{48\sqrt{\pi}x^{7/4}}\cos\left(\frac{\pi}{4} + \frac{2}{3}x^{3/2}\right) + O\left(\frac{1}{x^{13/4}}\right),$$

we obtain expansions which reproduce the N-independent terms in (74) and (75), giving furthermore, terms of higher order in $1/|\xi|$. In (75) the term proportional to $1/(2N)^{1/3}$ is reproduced, and this too is accompanied by terms of higher order in $1/|\xi|$. In (74) the term $-|\xi|^{3/2}/4\pi N^{2/3}$ is reproduced, as is the term proportional to $|\xi|^{3/2}\sin(4|\xi|^{3/2}/3)/N^{2/3}$, whereas the term proportional to $\cos(4|\xi|^{3/2}/3)/N^{2/3}$ is out by a rational factor. The explanation for the missing higher order terms in $1/|\xi|$, and incorrect rational factors is most likely due to the fact that terms of all orders in $1/N$ in (51) and (52) contribute to each distinct order in the expansions (74) and (75). Specifically, from the results exhibited above, it would seem that expanding the complete large N asymptotic series for $\rho_N^{\mathrm{GUE}}(x)$ and $\rho_N^{\mathrm{LUE}}(x)$ as in (74) and (75) would give precisely the large $\xi \to -\infty$ expansion of (72) and (73), extended to all orders in N.

VI. DISCUSSION AND QUESTIONS FOR FUTURE STUDIES

From the viewpoint of obtaining accurate numerical approximations to the density, it appears to be optimal to retain only the order $1/N$ corrections in the bulk. However, as remarked at the end

of the previous section, knowledge of higher order terms would allow us to exhibit higher order matching relating the bulk and edge expansions. Higher order non-oscillatory corrections in the bulk are also of interest because they relate to earlier work.[18,19] In particular, in Ref. 18 [Eqs. (2.6), (3.15), (3.24), (3.25)], the nonoscillatory order $1/N^2$ correction to $\rho_N(x)$ for the GUE is calculated by way of the corresponding resolvent to equal

$$\frac{1}{16\pi(1-x^2)^{5/2}}\frac{1}{N^2}.$$

On the other hand, using the method of Sec. III to extend (51) gives the order $1/N^2$ correction as

$$\left(\frac{1}{16\pi(1-x^2)^{5/2}}+\frac{x(15+2x^2)\sin[2N\pi P(x)]}{48\pi(1-x^2)^{5/2}}\right)\frac{1}{N^2},$$

exhibiting precise agreement with the earlier study.

A result of Ref. 18 as it relates to the GUE, and of Ref. 19 as it relates to the LUE in the case $\alpha=0$, is that all corrections to the bulk density which are proportional to odd powers of $1/N$ contain only oscillatory terms. Indeed, the expansions of Proposition 1 are consistent with this result, although its truth in general does not appear to be an easy corollary of the working of Sec. III.

For the LUE, in addition to the bulk and soft edge regimes, there is a distinct regime in the neighborhood of $x=0$ referred to as the hard edge.[12] The bulk expansion (52) diverges for $x\to 0$, and we are faced with the same matching issue as that between the bulk and soft edge expansions. To leading order this matching can be seen by comparing the $x\to\infty$ behavior of the hard edge density known from Ref. 12, with the $x\to 0$ form of the Marčenko-Pastur law in (7). At higher order, correction terms to the hard edge density must be computed. This we hope to address in a future study.

The studies of Refs. 18 and 19 tell us the bulk asymptotic expansion of the smoothed form of not just the density, but the two-point Green function as well. From this the bulk asymptotic expansion of the smoothed two-point correlation can be read off. On the other hand, this latter quantity, and in fact the general k-point correlations, are determined by a single quantity known as the Christoffel-Darboux kernel, generalizing (10). It would thus be of interest to apply the methods of the present study to compute the asymptotic expansion of this kernel for the GUE and LUE, both in the bulk and at the soft edge.

A field theoretic derivation of the Max Born hypothesis

Abdulmuhsen H. Ali[a)]

(Received 23 May 2005; accepted 8 August 2005; published online 14 October 2005)

It is shown in this article that the statistical character of the nonrelativistic, one particle quantum probabilities can be inferred from the function which results from the Wigner transformation on the field operator $\hat{\psi}^{\dagger}(\vec{x})$ which, in turn, must be expressed in the occupation number representation. The function which results from the Wigner transformation is shown to be the state function of a single particle which is defined in the conventional quantum mechanics. The integral of the norm squared of that function is proven to be unity which is the step that proves the Max Born hypothesis. The compatibility of the expression for the field amplitude, obtained here, with the measurability of the Bosonic and the Fermionic fields is explained. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2044668]

I. INTRODUCTION

The relation between quantum expectation values and statistical averages is a subject that has been studied very extensively. Early attempts to explore that relation includes the Bohr and the von Neumann reasonings, both of which rule out the possibility of interpreting quantum expectation values in terms of averaging over uniquely determined processes because, as was discussed by Groenewold,[1] these processes may not be well defined either on physical or mathematical grounds. On the other hand, Wigner functions[2] proved to be the main objects through which phase-space *c*-number density functions may be defined.[3] These functions have been studied very extensively, for example, Curtright and Zachos,[3,4] Bohun *et al.*,[5] and Lesche.[6] A Wigner function is the Wigner transform of the quantum density operator,[7,8] and it can be used to calculate averages of a phase space function which will give the statistical average of that particular phase space function and not the quantum expectation value. In spite of the fact that the Wigner function leaves the interpretation of the expectation value as an axiom of quantum mechanics it remains to be the superior function which bridges quantum density operators to statistical averages.

Another way to relate quantum operators to statistical averages is to identify expectation values with statistical averages through an equation which directly relates the quantum probability density to the statistical probability. The purpose of this article is to show that using quantum field theory one can connect the single particle, nonrelativistic, quantum probability density to the statistical probability which is a step that will give the Max Born hypothesis a mathematical proof. This connection is important because it presents a nonaxiomatic approach to the statistical interpretation of the state function's norm square.[9] Consequently, one will be able to study, as will be shown in a future work, the conditions under which the norm square of a one particle state function may fail to represent the probability density. To relate the quantum probability to the statistical probability one needs to apply the Wigner transformation to the field operator $\hat{\psi}^{\dagger}(\vec{x})$, an operator which is introduced in the second quantization and which represents the creation of a particle at the position $\vec{x}$. The matrix element of $\hat{\psi}^{\dagger}(\vec{x})$ should be given in the coordinate representation of N particles. The function $\Psi_{w}^{*}(x,p,\vec{x})$, which denotes the Wigner transform of $\hat{\psi}^{\dagger}(\vec{x})$, will have an N-coordinate dependence, an N-momentum dependence, and an $\vec{x}$ dependence. To eliminate the N coordinates and momenta dependencies an integration over the coordinates fol-

a)Electronic mail: aliamh@hotmail.com

lowed by an ensemble averaging is performed. The resulting function $\bar{\psi}_w^*(\vec{x})$ is proven to obey the Schrödinger equation, and thus is proven to be the state function defined in quantum mechanics. Further, the integral over the spatial coordinates of the norm square of the function $\bar{\psi}_w^*(\vec{x})$ is shown to be unity.

It is worth mentioning that the equation derived here for the field amplitude have a direct proportionality to the average occupation number per state. A consequence of that direct proportionality is the fact that Bosons will have a much stronger field amplitude than Fermions. Fermions are allowed to have an occupation number of either 1 or 0 per state. Bosons, on the other hand, can have up to the total number of particles in the system occupying a single state. With the direct proportionality between the particle field amplitude and the average occupation number per state, for a certain projection, the above-mentioned statistics will lead to a much stronger field amplitude for Bosons than for Fermions. This is consistent with the classical measurability of a field; if a field is to be measurable then the field amplitude must be strong enough to be detected on a classical scale[10] which means that particles having Bose–Einstein statistics have a physically measurable field, for example, the classical electromagnetic fields, and particles obeying the Fermi–Dirac statistics have a field amplitude which, in comparison to the Bosons, is too weak.

II. THE TRANSFORMATION FOR FERMIONS

For any operator $\hat{A}$ the Wigner transformation is defined by[5,7]

$$A_w(x,p) = \int_{R^{3N}} d^{3N}z e^{i(p\cdot z)/\hbar} \left\langle x - \frac{z}{2} \middle| \hat{A} \middle| x + \frac{z}{2} \right\rangle \tag{1}$$

where $x,z,p \in R^{3N}$, R is the real axis, N is the total number of particles, $(p\cdot z)=\Sigma_{\ell=1}^{3N} p_\ell z_\ell$, $\hbar$ is Plank's constant, $d^{3N}z=\Pi_{\ell=1}^{N} d\vec{z}_\ell$, $\vec{z}_\ell \in R^3$, and $A_w(x,p)$ is the classical function corresponding to the quantum operator $\hat{A}$, which may have a position dependence. The interest here is in the spatial integral of the Wigner transformation of the field operator $\hat{\psi}^\dagger(\vec{x})=\Sigma_{j=1}^{\infty}\hat{b}_j^\dagger \phi_j^*(\vec{x})$.[10] The Wigner transform of $\hat{\psi}^\dagger(\vec{x})$ is denoted by $\Psi_w^*(x,p,\vec{x})$, the sum in the expansion of $\hat{\psi}^\dagger(\vec{x})$ runs over single particle states, the $\phi_j(\vec{x})$ is a single particle state function which corresponds to the $N+1st$ particle, and $\vec{x}$ is the position vector of that particle. In particular, the function of interest is

$$\psi_w^*(p,\vec{x}) = \int d^{3N}x \Psi_w^*(x,p,\vec{x}) = \int d^{3N}x d^{3N}z e^{i(p\cdot z)/\hbar} \left\langle x - \frac{z}{2} \middle| \hat{\psi}^\dagger(\vec{x}) \middle| x + \frac{z}{2} \right\rangle, \tag{2}$$

where $d^{3N}x=\Pi_{\ell=1}^{N} d\vec{x}_\ell$. The general plan is to insert the unit operator[11]

$$1^{S,A} = \frac{1}{N!}\sum_{\{n_k\}} |n_1,n_2,\ldots\rangle^{S,A\ S,A}\langle n_1,n_2,\ldots|$$

in the matrix element in the integrand, multiply terms, and then integrate. The superscripts indicate, respectively, the symmetric (Bosonic) and the antisymmetric (Fermionic) state vectors.[7] The matrix element in the integrand will be

$$\begin{aligned}\left\langle x - \frac{z}{2} \middle| \psi^\dagger(\vec{x}) \middle| x + \frac{z}{2} \right\rangle &= {}^{S,A}\left\langle x - \frac{z}{2} \middle| 1^{S,A}\left(\sum_j \hat{b}_j^\dagger \phi_j^*(\vec{x})\right)1^{S,A} \middle| x + \frac{z}{2} \right\rangle^{S,A} = {}^{S,A}\left\langle x - \frac{z}{2} \right| \\ &\times \left(\frac{1}{N!}\sum_{\{n_k\}} |n_1,n_2,\ldots\rangle^{S,A\ S,A}\langle n_1,n_2,\ldots|\right)\sum_j \hat{b}_j^\dagger \phi_j^*(\vec{x}) \\ &\times \left(\frac{1}{N!}\sum_{\{n_k'\}} |n_1',n_2',\ldots\rangle^{S,A\ S,A}\langle n_1',n_2',\ldots|\right)\left| x + \frac{z}{2} \right\rangle^{S,A}\end{aligned}$$

$$= \sum_{\{n_k\}} \sum_{\{n_k'\}} \left(\frac{1}{N!}\right)^2 {}^{S,A}\left\langle x - \frac{z}{2} \,|n_1, n_2, \ldots \right\rangle^{S,A} {}^{S,A}\langle n_1, n_2, \ldots |\left(\sum_j \hat{b}_j^\dagger \phi_j^*(\vec{x})\right)$$
$$\times |n_1', n_2', \ldots\rangle^{S,A S,A}\left\langle n_1', n_2', \ldots \left| x + \frac{z}{2}\right\rangle^{S,A}. \tag{3}$$

The last term in Eq. (3) is the N-particle state function and it will be written as[12]

$${}^{S,A}\left\langle n_1', n_2', \ldots \left| x + \frac{z}{2}\right\rangle^{S,A} = {}^{S,A}\left\langle n_1', n_2', \ldots \left| \vec{x}_1 + \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N + \frac{\vec{z}_N}{2}\right\rangle^{S,A}\right.\right.$$
$$= \Phi^*_{[n_1' n_2' \cdots]}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N + \frac{\vec{z}_N}{2}\right)^{S,A}. \tag{4}$$

According to quantum mechanics[12] the square of the amplitude of the Φ function in Eq. (4) will give the simultaneous probability of finding a particle at $\vec{x}_1$, a particle at $\vec{x}_2, \ldots$, and a particle at $\vec{x}_N$ with the knowledge that the "first" state is occupied by n_1 particles, the second state by n_2 particles, the third state by n_3 particles, and so forth. With Eq. (4) the matrix elements of the field operator $\hat{\psi}^\dagger(\vec{x})$ is

$$\left\langle x - \frac{z}{2}\right| \hat{\psi}^\dagger(\vec{x}) \left| x + \frac{z}{2}\right\rangle = \sum_j \sum_{\{n_k'\}} \sum_{\{n_k\}} \left(\frac{1}{N!}\right)^2 \Phi_{[n_1 n_2 \ldots]}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N - \frac{\vec{z}_N}{2}\right)^{S,A}$$
$$\times {}^{S,A}\langle n_1, n_2, \ldots |\hat{b}_j^\dagger| n_1', n_2', \ldots\rangle^{S,A} \Phi^*_{[n_1' n_2' \cdots]}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N + \frac{\vec{z}_N}{2}\right)^{S,A} \phi_j^*(\vec{x}). \tag{5}$$

The value of the matrix ${}^{S,A}\langle n_1, n_2, \ldots |\hat{b}_j^\dagger| n_1', n_2', \ldots\rangle^{S,A}$ will depend on the type of particles being considered. For Bosons and Fermions it is respectively given by[10]

$${}^{S}\langle n_1, n_2, \ldots, n_j, \ldots |\hat{b}_j^\dagger| n_1', n_2', \ldots, n_j', \ldots\rangle^{S} = \sqrt{n_j' + 1}\, \delta_{n_1, n_1'} \cdots \delta_{n_j, n_j'+1} \cdots, \tag{6}$$

$${}^{A}\langle n_1, n_2, \ldots, n_j, \ldots |\hat{b}_j^\dagger| n_1', n_2', \ldots, n_j', \ldots\rangle^{A} = (-1)^{R_j}\sqrt{1 - n_j'}\, \delta_{n_1, n_1'} \cdots \delta_{n_j, 1 - n_j'} \cdots. \tag{7}$$

The prefactor $(-1)^{R_j}$ with $R_j = \sum_{\nu=1}^{n_{j-1}} n_\nu$ is ± 1 depending on the number of occupied states between n_1 and n_{j-1}.[10] When doing the calculations for Fermions the matrix element of the field operator $\hat{\psi}^\dagger(\vec{x})$ will be

$$\left\langle x - \frac{z}{2}\right| \hat{\psi}^\dagger(\vec{x}) \left| x + \frac{z}{2}\right\rangle = \sum_j \sum_{\{n_k'\}} \sum_{\{n_k\}} \left(\frac{1}{N!}\right)^2 \Phi_{[n_1 n_2 \cdots]}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N - \frac{\vec{z}_N}{2}\right)^{A}$$
$$\times (-1)^{R_j}\sqrt{1 - n_j'}\, \delta_{n_1, n_1'} \cdots \delta_{n_j, 1 - n_j'} \cdots \Phi^*_{[n_1' n_2' \cdots]}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N + \frac{\vec{z}_N}{2}\right)^{A}$$
$$\times \phi_j^*(\vec{x}) = \sum_j \sum_{\{n_k\}} \left(\frac{1}{N!}\right)^2 \Phi_{[n_1 n_2 \cdots]}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N - \frac{\vec{z}_N}{2}\right)^{A}$$
$$\times (-1)^{R_j}\sqrt{n_j}\, \Phi^*_{[n_1 n_2 \cdots]}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N + \frac{\vec{z}_N}{2}\right)^{A} \phi_j^*(\vec{x})$$
$$= \sum_j \left(\frac{1}{N!}\right)^2 \left[\sum_{k_1, k_2, \ldots, k_N} \Phi_{k_1, \ldots, k_N}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}, \ldots, \vec{x}_N - \frac{\vec{z}_N}{2}\right)^{A}\right.$$

$$\times \Phi^{*}_{k_1,\ldots,k_N}\left(\vec{x}_1+\frac{\vec{z}_1}{2},\ldots,\vec{x}_N+\frac{\vec{z}_N}{2}\right)^{A}\Bigg](-1)^{(j-1)}\sqrt{n_j}\phi^{*}_{j}(\vec{x}), \tag{8}$$

where the state function has been rewritten as

$$\Phi_{[n_1 n_2\cdots]}\left(\vec{x}_1-\frac{\vec{z}_1}{2},\ldots,\vec{x}_N-\frac{\vec{z}_N}{2}\right)^{S,A}\equiv\Phi_{k_1,\ldots,k_N}\left(\vec{x}_1-\frac{\vec{z}_1}{2},\ldots,\vec{x}_N-\frac{\vec{z}_N}{2}\right)^{S,A} \tag{9}$$

which makes the statement that this is an N-particle state function with particles in the levels $k_1,\ldots,k_N$. The symmetric and the antisymmetric N-particle state function are, respectively, given by[13]

$$\Phi_{k_1,\ldots,k_N}\left(\vec{x}_1-\frac{\vec{z}_1}{2},\ldots,\vec{x}_N-\frac{\vec{z}_N}{2}\right)^{S}=\frac{1}{\sqrt{N!n_1!n_2!\cdots}}\sum_{p\in S_N}\phi_{k_{p(1)}}\left(\vec{x}_1-\frac{\vec{z}_1}{2}\right)\cdots\phi_{k_{p(N)}}\left(\vec{x}_N-\frac{\vec{z}_N}{2}\right), \tag{10}$$

$$\Phi_{k_1,\ldots,k_N}\left(\vec{x}_1-\frac{\vec{z}_1}{2},\ldots,\vec{x}_N-\frac{\vec{z}_N}{2}\right)^{A}=\frac{1}{\sqrt{N!}}\sum_{p\in S_N}\mathrm{sgn}(p)\phi_{k_{p(1)}}\left(\vec{x}_1-\frac{\vec{z}_1}{2}\right)\cdots\phi_{k_{p(N)}}\left(\vec{x}_N-\frac{\vec{z}_N}{2}\right), \tag{11}$$

where $\mathrm{sgn}(p)=+1$ for even permutations, $\mathrm{sgn}(p)=-1$ for odd permutations, and where S_N is the set of all permutations of the N particles. The permutation of N elements is denoted by[13]

$$p(1,2,\ldots,N)=(p(1),p(2),\ldots,p(N)).$$

The $\phi(\vec{x})_k$'s in Eqs. (10) and (11) are single particle solutions to the Schrödinger equation and form a complete basis in Hilbert space.[13]

The expanded form of the antisymmetric state functions should now be inserted in Eq. (8):

$$\begin{aligned}\left\langle x-\frac{z}{2}\middle|\hat{\psi}^{\dagger}(\vec{x})\middle|x+\frac{z}{2}\right\rangle=\sum_j\left(\frac{1}{N!}\right)\Bigg[&\sum_{k_1,\ldots,k_N}\left(\frac{1}{N!}\right)^2\\&\times\sum_{p'\in S_N}\mathrm{sgn}(p')\sum_{p\in S_N}\mathrm{sgn}(p)\phi_{k_{p(1)}}\left(\vec{x}_1-\frac{\vec{z}_1}{2}\right)\cdots\phi_{k_{p(N)}}\left(\vec{x}_N-\frac{\vec{z}_N}{2}\right)\\&\times\phi^{*}_{k_{p'(1)}}\left(\vec{x}_1+\frac{\vec{z}_1}{2}\right)\cdots\phi^{*}_{k_{p'(N)}}\left(\vec{x}_N+\frac{\vec{z}_N}{2}\right)(-1)^{(j-1)}\sqrt{n_j}\Bigg]\phi^{*}_{j}(\vec{x}).\end{aligned} \tag{12}$$

Now one must substitute (12) into (2) but Eq. (12) is complicated and the calculations at this point will be done for $N=3$ and $j=3$ so that by induction one may obtain the general N particles result. The results below will hold only under the imposition of the ansatz

$$\phi_{k_j}\left(\vec{x}_j-\frac{\vec{z}_j}{2}\right)=\phi_{k_j}(\vec{x}_j)\phi_{k_j}\left(-\frac{\vec{z}_j}{2}\right)$$

and

$$\phi^{*}_{k_j}\left(\vec{x}_j+\frac{\vec{z}_j}{2}\right)=\phi^{*}_{k_j}(\vec{x}_j)\phi^{*}_{k_j}\left(\frac{\vec{z}_j}{2}\right).$$

Thus, according to Eq. (12) for three particles and three quantum states the Wigner transform of the field operator $\hat{\psi}^{\dagger}(\vec{x})$ will be

$$\Psi_w^*(x,p,\vec{x}) = \left(\frac{1}{3!}\right)^3 \int d^3z_1 d^3z_2 d^3z_3 e^{i(p\cdot z)/\hbar} \sum_{j=1}^{3} \sum_{k_1,k_2,k_3} (-1)^{(j-1)} \sqrt{n_j} \phi_j^*(\vec{x}) \Bigg[\sum_{p\in S_3} \prod_{\nu=1}^{3} \phi_{k_{p(\nu)}}(\vec{x}_\nu)$$
$$\times \phi_{k_{p(\nu)}}^*(\vec{x}_\nu) \phi_{k_{p(\nu)}}\left(-\frac{\vec{z}_\nu}{2}\right) \phi_{k_{p(\nu)}}^*\left(\frac{\vec{z}_\nu}{2}\right) - \sum_{p\in S_2} \sum_{m,\ell,j,r=1}^{3}{}' \phi_{k_j}(r) \phi_{k_j}^*(r) \phi_{k_{p(r)}}(\ell) \phi_{k_{p(\ell)}}^*(\ell) \phi_{k_{p(\ell)}}(m)$$
$$\times \phi_{k_{p(r)}}^*(m) - \frac{1}{2} \sum_{p\in S_2} \sum_{j,r=1}^{3}{}' \phi_{k_r}(r) \phi_{k_r}^*(r) \phi_{k_{p(j)}}(\ell) \phi_{k_{p(\ell)}}^*(\ell) \phi_{k_{p(\ell)}}(j) \phi_{k_{p(j)}}^*(j)$$
$$+ \sum_{p'\in S_2} \sum_{p\in S_2} \phi_{k_{p'(1)}}(1) \phi_{k_{p'(2)}}^*(1) \phi_{k_{p'(2)}}(p(2)) \phi_{k_3}^*(p(2)) \phi_{k_3}(p(3)) \phi_{k_{p'(1)}}^*(p(3))$$
$$+ \sum_{p'\in S_2} \sum_{p\in S_2} \phi_{k_{p'(1)}}(1) \phi_{k_{p'(3)}}^*(1) \phi_{k_2}(p(2)) \phi_{k_{p'(1)}}^*(p(2)) \phi_{k_{p'(3)}}(p(3)) \phi_{k_2}^*(p(3))$$
$$+ \sum_{p'\in S_2} \sum_{p\in S_2} \phi_{k_{p'(2)}}(1) \phi_{k_{p'(3)}}^*(1) \phi_{k_{p'(1)}}(p(2)) \phi_{k_{p'(2)}}^*(p(2)) \phi_{k_{p'(3)}}(p(3)) \phi_{k_{p'(1)}}^*(p(3)) \Bigg], \tag{13}$$

where the prime on the summation indicates a restricted sum which means that in taking the sum one should consider terms in which a subscript k_j occurs only twice, and in the last three terms the permutations are $p(m)=j, p(j)=m$. Specifically, in the last term the permutations are $p(m)=j, p(j)=m$ per $\vec{x}_\ell$, $\ell=1,2,3$. The total number of terms in Eq. (13) are 36. The first term in Eq. (13) accounts for 6 of the 36 terms, the second term in equation (13) gives 12 terms out of the 36 terms, the third term in Eq. (13) will give 6 terms out of the 36 terms, and the last three will give 12 terms out of the 36 terms. Also, in Eq. (13) the coordinate dependence of the state functions have been suppressed such that $\phi_{k_\ell}(j) \equiv \phi_{k_\ell}(\vec{x}_j - \vec{z}_j/2)$, and $\phi_{k_\ell}^*(j) \equiv \phi_{k_\ell}^*(\vec{x}_j + \vec{z}_j/2)$. Applying the above-mentioned Ansatz and the orthonormal property of the complete set $\{\phi_j(\vec{x})\}$ will make the last five terms in Eq. (13) vanish when the integrations over the $\vec{x}_j$'s are performed. Given this fact and Eqs. (2) and (13) one can write

$$\psi_w^*(p,\vec{x}) = \int d^{3N}x \Psi_w^*(x,p,\vec{x}) = \left(\frac{1}{3!}\right)^3 \int_{R^9} d^9x \int_{R^9} d^9z e^{i(p\cdot z)/\hbar} \sum_{j=1}^{3} \sum_{k_1,k_2,k_3} (-1)^{(j-1)} \sqrt{n_j} \phi_j^*(\vec{x})$$
$$\times \sum_{p\in S_3} \prod_{\nu=1}^{3} \phi_{k_{p(\nu)}}(\vec{x}_\nu) \phi_{k_{p(\nu)}}^*(\vec{x}_\nu) \phi_{k_{p(\nu)}}\left(-\frac{\vec{z}_\nu}{2}\right) \phi_{k_{p(\nu)}}^*\left(\frac{\vec{z}_\nu}{2}\right). \tag{14}$$

The orthonormal property of the complete set $\{\phi_{k_j}(\vec{x})\}$ will make all the integrals with respect to the $\vec{x}_j$'s be equal to unity

$$\psi_w^*(p,\vec{x}) = \left(\frac{1}{3!}\right)^3 \int_{R^9} d^9z e^{i(p\cdot z)/\hbar} \sum_{j=1}^{3} \sum_{k_1,k_2,k_3} (-1)^{(j-1)} \sqrt{n_j} \phi_j^*(\vec{x}) \sum_{p\in S_3} \prod_{\nu=1}^{3} \phi_{k_{p(\nu)}}\left(-\frac{\vec{z}_\nu}{2}\right) \phi_{k_{p(\nu)}}^*\left(\frac{\vec{z}_\nu}{2}\right). \tag{15}$$

In Eq. (15) employ the closure relation $\Sigma_{k_\ell} \phi_{k_\ell}(\vec{z}_m/2) \phi_{k_\ell}^*(-\vec{z}_m/2) = \delta(\vec{z}_m)$, $\forall j=1,2,3 \ni j \neq \ell$, and $m=1,2,3$. Now integrate over the z coordinate and the function $\psi_w^*(p,\vec{x})$ will reduce to

$$\psi_w^*(p,\vec{x}) = \left(\frac{1}{3!}\right)^3 (2) \sum_{j=1}^{3} \Bigg[\sum_{k_j} (-1)^{(j-1)} \sqrt{n_j} \sum_{\ell=1}^{3} \int d^3z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar} \phi_{k_j}\left(-\frac{\vec{z}_\ell}{2}\right) \phi_{k_j}^*\left(\frac{\vec{z}_\ell}{2}\right) \Bigg] \phi_j^*(\vec{x}). \tag{16}$$

The dependence on p is eliminated by taking the average $\bar{\psi}_w^*(\vec{x})=\Sigma_{\{n_k\}}\psi_w^*(p,\vec{x})P\{n_k\}$, where

$$P\{n_k\}=\frac{g\{n_k\}e^{-\beta\Sigma_{k=1}^{\infty}n_k(\epsilon_k-\mu)}}{\sum_{\{n_k\}}g\{n_k\}e^{-\beta\Sigma_{k=1}^{\infty}n_k(\epsilon_k-\mu)}}$$

is the probability of finding the set of occupation numbers $\{n_1,n_2,\ldots\}=\{n_k\}_{k=1}^{\infty}$ in the grand canonical ensemble,[7] $g\{n_k\}$ is the statistical weight of the set $\{n_k\}_{k=1}^{\infty}$, ϵ_k is the energy of the single particle state k, μ is the chemical potential, $\beta=1/k_BT$, k_B is the Boltzmann constant, and T is the absolute temperature. The statistical weight $g\{n_k\}$ equals to unity for both Fermions and Bosons. The Fermionic function $\bar{\psi}_w^*(\vec{x})$ will be obtained by virtue of the function $P\{n_k\}$

$$\bar{\psi}_w^*(\vec{x})=\sum_{\{n_k\}}\psi_w^*(p,\vec{x})P\{n_k\}=\left(\frac{1}{3!}\right)^3(2)\sum_{j=1}^{3}\left[\sum_{k_j}(-1)^{(j-1)}\left(\frac{\prod_{r=1}^{3}\sum_{n_r}e^{-\beta n_r(\epsilon_r-\mu)}\sqrt{n_j}}{\prod_{r=1}^{3}\sum_{n_r}e^{-\beta n_r(\epsilon_r-\mu)}}\right)\right.$$
$$\left.\times\sum_{\ell=1}^{3}\int d^3z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar}\phi_{k_j}\left(-\frac{\vec{z}_\ell}{2}\right)\phi_{k_j}^*\left(\frac{\vec{z}_\ell}{2}\right)\right]\phi_j^*(\vec{x}).$$

The fraction in the parentheses will simplify to the average of $\sqrt{n_j}$ denoted as $\langle\sqrt{n_j}\rangle$

$$\left(\frac{\prod_{r=1}^{3}\sum_{n_r}e^{-\beta n_r(\epsilon_r-\mu)}\sqrt{n_j}}{\prod_{r=1}^{3}\sum_{n_j}e^{-\beta n_r(\epsilon_r-\mu)}}\right)=\frac{\sum_{n_j}\sqrt{n_j}e^{-\beta n_j(\epsilon_j-\mu)}\prod_{\substack{r=1\\r\neq j}}^{3-1}\sum_{n_r}e^{-\beta n_r(\epsilon_r-\mu)}}{\sum_{n_j}e^{-\beta n_j(\epsilon_j-\mu)}\prod_{\substack{r=1\\r\neq j}}^{3-1}\sum_{n_r}e^{-\beta n_r(\epsilon_r-\mu)}}=\frac{\sum_{n_j}\sqrt{n_j}e^{-\beta n_j(\epsilon_j-\mu)}}{\sum_{n_j}e^{-\beta n_j(\epsilon_j-\mu)}}$$
$$=\sum_{n_j}\sqrt{n_j}p_j(n_j)=\langle\sqrt{n_j}\rangle,$$

where

$$p_j(n_j)=\frac{e^{-\beta n_j(\epsilon_j-\mu)}}{\sum_{n_j}e^{-\beta n_j(\epsilon_j-\mu)}}$$

is the probability of finding n_j particles in the subsystem j which has the energy ϵ_j.[7] This last result will simplify the function $\bar{\psi}^*(\vec{x})$ significantly

$$\bar{\psi}_w^*(\vec{x})=\left(\frac{1}{3!}\right)^3(2)\sum_{j=1}^{3}\left[\sum_{k_j}\sum_{\ell=1}^{3}\int d^3z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar}\phi_{k_j}\left(-\frac{\vec{z}_\ell}{2}\right)\phi_{k_j}^*\left(\frac{\vec{z}_\ell}{2}\right)\right](-1)^{(j-1)}\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x})$$
$$=\left(\frac{1}{3!}\right)^3(2)\sum_{j=1}^{3}\left[\sum_{\ell=1}^{3}\int d^3z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar}\sum_{k_j}\phi_{k_j}\left(-\frac{\vec{z}_\ell}{2}\right)\phi_{k_j}^*\left(\frac{\vec{z}_\ell}{2}\right)\right](-1)^{(j-1)}\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x})$$

a further simplification is reached by using the closure relation

$$\bar{\psi}_w^*(\vec{x})=\left(\frac{1}{3!}\right)^3(2)\sum_{j=1}^{3}\left[\sum_{\ell=1}^{3}\int d^3z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar}\delta(\vec{z}_\ell)\right](-1)^{(j-1)}\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x})=\left(\frac{1}{3!}\right)^3(2)\sum_{j=1}^{3}[3](-1)^{(j-1)}$$
$$\times\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x})=\left(\frac{1}{3!}\right)^3(3!)\sum_{j=1}^{3}(-1)^{(j-1)}\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x})$$

or

$$\bar{\psi}_w^*(\vec{x}) = \left(\frac{1}{3!}\right)\left(\frac{1}{(3-1)!\sqrt{3}}\right)\sum_{j=1}^{3}(-1)^{(j-1)}\frac{\langle\sqrt{n_j}\rangle}{\sqrt{3}}\phi_j^*(\vec{x}). \tag{17}$$

By induction the general equation for the average number of particles,[7] $N=\Sigma_j\langle n_j\rangle$, and a denumerable set of states is

$$\psi_w^*(\vec{x}) \equiv \bar{\psi}_w^*(\vec{x})(N!)((N-1)!\sqrt{N}) = \sum_{j=1}^{\infty}(-1)^{(j-1)}\frac{\langle\sqrt{n_j}\rangle}{\sqrt{N}}\phi_j^*(\vec{x}). \tag{18}$$

The following approximation[10] is valid only in the limit of a very large average number of particles N:

$$\ln(N^{1/2}N!(N-1)!) = (1/2)\ln N + \ln N! + \ln(N-1)! \approx (1/2)\ln N + N\ln N - N + (N-1)\ln(N-1)$$
$$-(N-1) = 2N\ln N - (1/2)\ln N - 2N \approx 2N\ln N, \tag{19}$$

where $N \gg 1$ leads to $N \pm 1 \approx N$. Raising both sides in Eq. (19) to the exponent will give the approximate equality, $N^{1/2}N!(N-1)! \approx (N)^{2N}$. Under the large N approximation and the assumption of negligible occupation number fluctuations[7] Eq. (18) is

$$\psi_w^*(\vec{x}) \equiv \bar{\psi}_w^*(\vec{x})(N)^{2N} = \sum_j (-1)^{(j-1)}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}\phi_j^*(\vec{x}), \tag{20}$$

where the negligible fluctuations of the occupation number leads to $\langle\sqrt{n_j}\rangle \approx \sqrt{\langle n_j\rangle}$. The function $\psi_w^*(\vec{x})$ changes sign according to the way the factor $(-1)^{(j-1)}$ contributes to the sum. With the complex conjugate of Eq. (20)

$$\psi_w(\vec{x}) = \sum_j (-1)^{(j-1)}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}\phi_j(\vec{x}) \tag{21}$$

and the integration of the product between Eqs. (20) and (21), an insight may be given into the physical meaning of the function $\psi_w(\vec{x})$

$$\int d^3x\psi_w^*(\vec{x})\psi_w(\vec{x}) = \int d^3x\sum_j\sum_k (-1)^{(j+k-2)}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}\left(\frac{\langle n_k\rangle}{N}\right)^{1/2}\phi_j^*(\vec{x})\phi_k(\vec{x}). \tag{22}$$

By the orthonormal property of the complete set of the basis states, $\int d^3x\phi_j^*(\vec{x})\phi_k(\vec{x}) = \delta_{jk}$, the above-mentioned equation simplifies to

$$\int d^3x\psi_w^*(\vec{x})\psi_w(\vec{x}) = \sum_j\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2} = \sum_j\left(\frac{\langle n_j\rangle}{N}\right) = 1, \tag{23}$$

where $(-1)^{j+k-2}=1$ when $j=k$, and $N=\Sigma_j\langle n_j\rangle$. This result makes it clear that, in relation to the statistical average, the product $\psi_w^*(\vec{x})\psi_w(\vec{x})$ may be identified with the probability density known in quantum mechanics. Given that, one can find a general explicit expression for the expansion coefficients of the series expansion of $\psi_w(\vec{x})$,

$$\psi_w(\vec{x}) = \sum_j b_j\phi_j(\vec{x}) = \sum_j (-1)^{j-1}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}\phi_j(\vec{x}), \tag{24}$$

this equality will, by linear independence, lead to $b_j=(-1)^{j-1}(\langle n_j\rangle/N)^{1/2}$.

III. THE TRANSFORMATION FOR BOSONS

The transformation for Bosons is not too different from the Fermions. In fact the steps are all similar except that in the calculations one needs to exclude the phase factor $(-1)^{(j-1)}$, and include the fact that more than one Boson may occupy the same quantum state. The matrix element for the field operator $\hat{\psi}^{\dagger}(\vec{x})$ in the case of Bosons is

$$\left\langle x-\frac{z}{2}\left|\hat{\psi}^{\dagger}(\vec{x})\right|x+\frac{z}{2}\right\rangle=\sum_{j}\left(\frac{1}{N!}\right)^{2}\left[\sum_{k_1,\ldots,k_N}\Phi_{k_1,\ldots,k_N}\left(\vec{x}_1-\frac{\vec{z}_1}{2},\ldots,\vec{x}_N-\frac{\vec{z}_N}{2}\right)^{S}\right.$$
$$\left.\times\,\Phi^{*}_{k_1,\ldots,k_N}\left(\vec{x}_1+\frac{\vec{z}_1}{2},\ldots,\vec{x}_N+\frac{\vec{z}_N}{2}\right)^{S}\right]\sqrt{n_j}\phi^{*}_{j}(\vec{x}). \tag{25}$$

The numbers $n_1,n_2,\ldots$ are not simply either 1 or 0, because of the Bosons statistics they are allowed to vary from 0 to N. Equation (12) should be written for Bosons

$$\left\langle x-\frac{z}{2}\left|\hat{\psi}^{\dagger}(\vec{x})\right|x+\frac{z}{2}\right\rangle=\sum_{j}\left(\frac{1}{N!n_1!n_2!\cdots}\right)\left[\sum_{k_1,\ldots,k_N}\left(\frac{1}{N!}\right)^{2}\sum_{p'\in S_N}\sum_{p\in S_N}\phi_{k_{p(1)}}\left(\vec{x}_1-\frac{\vec{z}_1}{2}\right)\cdots\phi_{k_{p(N)}}\right.$$
$$\left.\times\left(\vec{x}_N-\frac{\vec{z}_N}{2}\right)\phi^{*}_{k_{p'(1)}}\left(\vec{x}_1+\frac{\vec{z}_1}{2}\right)\cdots\phi^{*}_{k_{p'(N)}}\left(\vec{x}_N+\frac{\vec{z}_N}{2}\right)\sqrt{n_j}\right]\phi^{*}_{j}(\vec{x}). \tag{26}$$

Next apply the same ansatz as with Fermions and integrate with respect to x. All the terms with product of the form $\phi_{k_\ell}(j)\phi^{*}_{k_m}(j)$, $\ni \ell\neq m$, will vanish. Now one can write Eq. (15) for N Bosons

$$\psi^{*}_{w}(p,\vec{x})=\left(\frac{1}{N!}\right)^{2}\frac{1}{N!n_1!n_2!\cdots}\int_{R^{3N}}d^{3N}z e^{i(p\cdot z)/\hbar}\sum_{j=1}^{\infty}\sum_{k_1,\ldots,k_N}\sqrt{n_j}\phi^{*}_{j}(\vec{x})\sum_{p\in S_N}\prod_{\nu=1}^{N}\phi_{k_{p(\nu)}}\left(-\frac{\vec{z}_\nu}{2}\right)\phi^{*}_{k_{p(\nu)}}\left(\frac{\vec{z}_\nu}{2}\right), \tag{27}$$

which when integrated over the z coordinate will give

$$\psi^{*}_{w}(p,\vec{x})=\left(\frac{1}{N!}\right)^{2}\frac{1}{N!n_1!n_2!\cdots}(N-1)!\sum_{j=1}^{\infty}\left[\sum_{k_j}\sqrt{n_j}\sum_{\ell=1}^{N}\int d^{3}z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar}\phi_{k_j}\left(-\frac{\vec{z}_\ell}{2}\right)\phi^{*}_{k_j}\left(\frac{\vec{z}_\ell}{2}\right)\right]\phi^{*}_{j}(\vec{x}). \tag{28}$$

The Bosonic $\psi^{*}_{w}(p,\vec{x})$ will make it possible to calculate the function $\bar{\psi}^{*}_{w}(\vec{x})$ for Bosons

$$\bar{\psi}^{*}_{w}(\vec{x})=\sum_{\{n_k\}}\psi^{*}_{w}(p,\vec{x})P\{n_k\}=\left(\frac{1}{N!}\right)^{2}\frac{1}{N!n_1!n_2!\cdots}(N-1)!\sum_{j=1}^{\infty}\left[\sum_{\ell=1}^{N}\int d^{3}z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar}\right.$$
$$\left.\times\sum_{k_j}\phi_{k_j}\left(-\frac{\vec{z}_\ell}{2}\right)\phi^{*}_{k_j}\left(\frac{\vec{z}_\ell}{2}\right)\right]\langle\sqrt{n_j}\rangle\phi^{*}_{j}(\vec{x}) \tag{29}$$

and using the closure relation

$$\bar{\psi}_w^*(\vec{x}) = \left(\frac{1}{N!}\right)^2 \frac{1}{N!n_1!n_2!\cdots}(N-1)!\sum_{j=1}^{\infty}\left[\sum_{\ell=1}^{N}\int d^3z_\ell e^{i(p\cdot\vec{z}_\ell)/\hbar}\delta(\vec{z}_\ell)\right]\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x})$$
$$= \left(\frac{1}{N!}\right)^2 \frac{1}{N!n_1!n_2!\cdots}(N-1)!\sum_{j=1}^{\infty}(N)\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x}) = \left(\frac{1}{N!}\right)\frac{1}{N!n_1!n_2!\cdots}\sum_{j=1}^{\infty}\langle\sqrt{n_j}\rangle\phi_j^*(\vec{x})$$
$$= \left(\frac{1}{N!}\right)\frac{1}{(N-1)!\sqrt{N}n_1!n_2!\cdots}\sum_{j=1}^{\infty}\frac{\langle\sqrt{n_j}\rangle}{\sqrt{N}}\phi_j^*(\vec{x}). \tag{30}$$

The Bosonic $\psi_w^*(\vec{x})$ is

$$\psi_w^*(\vec{x}) \equiv \bar{\psi}_w^*(\vec{x})(N!)(N-1)!\sqrt{N}(n_1!n_2!\cdots) = \sum_{j=1}^{\infty}\frac{\langle\sqrt{n_j}\rangle}{\sqrt{N}}\phi_j^*(\vec{x}). \tag{31}$$

As in the Fermionic case $\psi_w^*(\vec{x})$ will be written for the $N\gg 1$ and the approximation in Eq. (19) will be applied

$$\ln(N^{1/2}N!(N-1)!(n_1!n_2!\cdots)) = (1/2)\ln N + \ln N! + \ln(N-1)! + \sum_{j=1}^{\infty}\ln n_j! \approx (1/2)\ln N + N\ln N$$
$$- N + (N-1)\ln(N-1) - (N-1) + \sum_{j=1}^{\infty}(n_j\ln n_j - n_j) \approx 2N\ln N$$
$$+ \sum_{j=1}^{\infty} n_j\ln n_j = \sum_{j=1}^{\infty}(2N\ln N + n_j\ln n_j) \approx \sum_{j=1}^{\infty}2N\ln N = (N)2N\ln N$$
$$= 2N^2\ln N,$$

where $n_j \ll N, \forall j$. Therefore, for $N\gg 1$ one have

$$\psi_w^*(\vec{x}) \equiv \bar{\psi}_w^*(\vec{x})(N)^{2N^2} = \sum_j\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}\phi_j^*(\vec{x}), \tag{32}$$

where the negligible fluctuation approximation has been applied. The rest of the argument following Eq. (32) will be similar to the fermionic case. Thus, for Bosons, the product $\psi_w^*(\vec{x})\psi_w(\vec{x})$ may be identified with the probability density as well.

IV. THE INCLUSION OF TIME

The time dimension may be added simply by solving the Heisenberg equation[12] for the operator $\hat{b}_j$

$$i\hbar\dot{\hat{b}}_j(t) = [\hat{b}_j(t), \hat{H}(t)] \tag{33}$$

and this will allow the definition of the time-dependent expansion coefficient

$$b_j(t) = (-1)^{(j-1)}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}e^{-i\epsilon_j t/\hbar}, \tag{34}$$

where ϵ_j is the energy of the j^{th} eigenstate. The transformed function in Eq. (24) may now be written as a field with a position, and a time dependence

$$\psi_w^*(\vec{x},t)=\sum_j(-1)^{(j-1)}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}e^{+i\epsilon_j t/\hbar}\phi_j^*(\vec{x}) \tag{35}$$

which, in turn, will allow the Wigner transformation with the time dimension

$$\begin{aligned}\psi_w^*(\vec{x},t)&=N\bar{\psi}_w^*(\vec{x},t)=N\sum_{\{n_k\}}\psi_w^*(p,\vec{x},t)P\{n_k\}=N\sum_{\{n_k\}}\int d^{3N}x\Psi_w^*(x,p,\vec{x},t)P\{n_k\}\\&=N\sum_{\{n_k\}}\int_{R^{3N}}d^{3N}xd^{3N}ze^{i(p\cdot z)/\hbar}\left\langle x-\frac{z}{2}\middle|\hat{\psi}^\dagger(\vec{x},t)\middle|x+\frac{z}{2}\right\rangle P\{n_k\}.\end{aligned} \tag{36}$$

V. IN RELATION TO THE SCHRÖDINGER EQUATION

Unless one can show a relation between $\psi_w^*(\vec{x},t)$ and a function which is defined in quantum mechanics, the function $\psi_w^*(\vec{x},t)$ remains to be only the function resulting from the Wigner transform of the operator $\hat{\psi}^\dagger(\vec{x},t)$. To this end one applies the energy operators $\hat{E}=i\hbar\partial/\partial t$, and $\hat{H}=-(\hbar^2/2m)\nabla^2+V(\vec{x})$ separately to the complex conjugate of the function $\psi_w^*(\vec{x},t)$

$$i\hbar\frac{\partial}{\partial t}\psi_w(\vec{x},t)=N\sum_{\{n_k\}}\int_{R^{3N}}d^{3N}xd^{3N}ze^{-i(p\cdot z)/\hbar}\left\langle x+\frac{z}{2}\middle|i\hbar\frac{\partial}{\partial t}\hat{\psi}(\vec{x},t)\middle|x-\frac{z}{2}\right\rangle P\{n_k\}, \tag{37}$$

$$\hat{H}\psi_w(\vec{x},t)=N\sum_{\{n_k\}}\int_{R^{3N}}d^{3N}xd^{3N}ze^{-i(p\cdot z)/\hbar}\left\langle x+\frac{z}{2}\middle|\hat{H}\hat{\psi}(\vec{x},t)\middle|x-\frac{z}{2}\right\rangle P\{n_k\}, \tag{38}$$

which by subtraction leads to

$$\begin{aligned}\hat{H}\psi_w(\vec{x},t)-i\hbar\frac{\partial}{\partial t}\psi_w(\vec{x},t)=N\sum_{\{n_k\}}\int_{R^{3N}}d^{3N}xd^{3N}ze^{-i(p\cdot z)/\hbar}&\left\langle x+\frac{z}{2}\middle|\hat{H}\hat{\psi}(\vec{x},t)\right.\\&\left.-i\hbar\frac{\partial}{\partial t}\hat{\psi}(\vec{x},t)\middle|x-\frac{z}{2}\right\rangle P\{n_k\}.\end{aligned} \tag{39}$$

However, the field equation[12]

$$-\frac{\hbar^2}{2m}\nabla^2\hat{\psi}(\vec{x},t)+V(\vec{x})\hat{\psi}(\vec{x},t)=i\hbar\frac{\partial}{\partial t}\hat{\psi}(\vec{x},t) \tag{40}$$

holds for both Fermions and Bosons, which along with Eq. (39) will give

$$-\frac{\hbar^2}{2m}\nabla^2\psi_w(\vec{x},t)+V(\vec{x})\psi_w(\vec{x},t)=i\hbar\frac{\partial}{\partial t}\psi_w(\vec{x},t). \tag{41}$$

Equation (41) leads to the fact that the function $\psi_w(\vec{x},t)$ is the solution to the Schrödinger equation, thereby proving that the functions $\psi_w^*(\vec{x})$ appearing in Eqs. (20) and (32) are the quantum mechanical wave functions from which the probability density may be calculated by taking the square of the norm for each function. With the understanding that the Fermionic wave function is $(N)^{2N}$ times the Fermionic $\bar{\psi}_w^*(\vec{x})$ and that the Bosonic wave function is $(N)^{2N^2}$ times the Bosonic $\bar{\psi}_w^*(\vec{x})$, the quantum mechanical wave function $\psi_w(\vec{x},t)\equiv\psi(\vec{x},t)$ can now be written for the both types of particles

$$\psi(\vec{x},t) = \sum_j \kappa_j \left(\frac{\langle n_j\rangle}{N}\right)^{1/2} e^{-i\epsilon_j t/\hbar}\phi_j(\vec{x}), \tag{42}$$

where

$$\kappa_j = \begin{cases} (-1)^{(j-1)} & \text{for Fermions} \\ 1 & \text{for Bosons.} \end{cases}$$

According to Eq. (42) projections of the Bosonic field amplitude can be much stronger than the same projections of the Fermionic field amplitude. This is due to the fact that both fields are directly proportional to the average occupation number. If $x \equiv \beta(\epsilon_k - \mu)$ then $x \to 0$ leads to $\langle n_j\rangle \to \infty$ for Bosons and $\langle n_j\rangle \to 1$ for Fermions (Ref. 7, p. 306). Also, for Bosons the κ_j factor is positive for all the terms in Eq. (42), but for Fermions it changes sign which means that some terms will be subtracted from the total sum. Thus, one can conclude that a certain projection of the Bosonic field amplitude can be much stronger than a similar projection of the Fermionic field amplitude for that limit. This is consistent with physical observations.[10]

APPENDIX: PRODUCT RESULTS OF ANTISYMMETRIZED (SYMMETRIZED) STATE FUNCTIONS

For a two state system $\{k_1,k_2\}$ the product of the anti-symmetrized sums in Eq. (12) is

$$\begin{aligned}
I_2 &= \sum_{k_1,k_2}\sum_{p',p} \mathrm{sgn}(p')\mathrm{sgn}(p)\phi_{k_{p_1}}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}\right)\phi_{k_{p_2}}\left(\vec{x}_2 - \frac{\vec{z}_2}{2}\right)\phi^*_{k_{p_1}}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}\right)\phi^*_{k_{p_2}}\left(\vec{x}_2 + \frac{\vec{z}_2}{2}\right) \\
&= \sum_{k_1}\phi_{k_1}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}\right)\phi^*_{k_1}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}\right)\sum_{k_2}\phi_{k_2}\left(\vec{x}_2 - \frac{\vec{z}_2}{2}\right)\phi^*_{k_2}\left(\vec{x}_2 + \frac{\vec{z}_2}{2}\right) - \sum_{k_1}\phi_{k_1}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}\right)\phi^*_{k_1}\left(\vec{x}_2 + \frac{\vec{z}_2}{2}\right) \\
&\quad \times \sum_{k_2}\phi_{k_2}\left(\vec{x}_2 - \frac{\vec{z}_2}{2}\right)\phi^*_{k_2}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}\right) - \sum_{k_1}\phi_{k_1}\left(\vec{x}_2 - \frac{\vec{z}_2}{2}\right)\phi^*_{k_1}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}\right)\sum_{k_2}\phi_{k_2}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}\right)\phi^*_{k_2}\left(\vec{x}_2 + \frac{\vec{z}_2}{2}\right) \\
&\quad + \sum_{k_1}\phi_{k_1}\left(\vec{x}_2 - \frac{\vec{z}_2}{2}\right)\phi^*_{k_1}\left(\vec{x}_2 + \frac{\vec{z}_2}{2}\right)\sum_{k_2}\phi_{k_2}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}\right)\phi^*_{k_2}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}\right) = \delta(\vec{z}_1)\delta(\vec{z}_2) - \sum_{k_1,k_2}\phi_{k_1}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}\right) \\
&\quad \times \phi^*_{k_1}\left(\vec{x}_2 + \frac{\vec{z}_2}{2}\right)\phi_{k_2}\left(\vec{x}_2 - \frac{\vec{z}_2}{2}\right)\phi^*_{k_2}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}\right) - \sum_{k_1,k_2}\phi_{k_1}\left(\vec{x}_2 - \frac{\vec{z}_2}{2}\right)\phi^*_{k_1}\left(\vec{x}_1 + \frac{\vec{z}_1}{2}\right) \\
&\quad \times \phi_{k_2}\left(\vec{x}_1 - \frac{\vec{z}_1}{2}\right)\phi^*_{k_2}\left(\vec{x}_2 + \frac{\vec{z}_2}{2}\right) + \delta(\vec{z}_2)\delta(\vec{z}_1) = 2!\,\delta(\vec{z}_1)\delta(\vec{z}_2) + \text{other terms} = 2!\prod_{\ell=1}^{2}\delta(\vec{z}_\ell) \\
&\quad + \text{other terms}.
\end{aligned} \tag{A1}$$

For a three state system the product of the anti-symmetrized sums in (12) is

$$\begin{aligned}
I_3 &= \phi_{k_1}(1)\phi_{k_2}(2)\phi_{k_3}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3) - \phi_{k_1}(1)\phi_{k_2}(2)\phi_{k_3}(3)\phi^*_{k_2}(1)\phi^*_{k_1}(2)\phi^*_{k_3}(3) \\
&\quad + \phi_{k_1}(1)\phi_{k_2}(2)\phi_{k_3}(3)\phi^*_{k_2}(1)\phi^*_{k_3}(2)\phi^*_{k_1}(3) - \phi_{k_1}(1)\phi_{k_2}(2)\phi_{k_3}(3)\phi^*_{k_3}(1)\phi^*_{k_2}(2)\phi^*_{k_1}(3) \\
&\quad + \phi_{k_1}(1)\phi_{k_2}(2)\phi_{k_3}(3)\phi^*_{k_3}(1)\phi^*_{k_1}(2)\phi^*_{k_2}(3) - \phi_{k_1}(1)\phi_{k_2}(2)\phi_{k_3}(3)\phi^*_{k_1}(1)\phi^*_{k_3}(2)\phi^*_{k_2}(3) \\
&\quad - \phi_{k_2}(1)\phi_{k_1}(2)\phi_{k_3}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3) + \phi_{k_2}(1)\phi_{k_1}(2)\phi_{k_3}(3)\phi^*_{k_2}(1)\phi^*_{k_1}(2)\phi^*_{k_3}(3)
\end{aligned}$$

$$
\begin{aligned}
&- \phi_{k_2}(1)\phi_{k_1}(2)\phi_{k_3}(3)\phi^*_{k_2}(1)\phi^*_{k_3}(2)\phi^*_{k_1}(3) + \phi_{k_2}(1)\phi_{k_1}(2)\phi_{k_3}(3)\phi^*_{k_3}(1)\phi^*_{k_2}(2)\phi^*_{k_1}(3)\\
&- \phi_{k_2}(1)\phi_{k_1}(2)\phi_{k_3}(3)\phi^*_{k_3}(1)\phi^*_{k_1}(2)\phi^*_{k_2}(3) + \phi_{k_2}(1)\phi_{k_1}(2)\phi_{k_3}(3)\phi^*_{k_1}(1)\phi^*_{k_3}(2)\phi^*_{k_2}(3)\\
&+ \phi_{k_2}(1)\phi_{k_3}(2)\phi_{k_1}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3) - \phi_{k_2}(1)\phi_{k_3}(2)\phi_{k_1}(3)\phi^*_{k_2}(1)\phi^*_{k_1}(2)\phi^*_{k_3}(3)\\
&+ \phi_{k_2}(1)\phi_{k_3}(2)\phi_{k_1}(3)\phi^*_{k_2}(1)\phi^*_{k_3}(2)\phi^*_{k_1}(3) - \phi_{k_2}(1)\phi_{k_3}(2)\phi_{k_1}(3)\phi^*_{k_3}(1)\phi^*_{k_2}(2)\phi^*_{k_1}(3)\\
&+ \phi_{k_2}(1)\phi_{k_3}(2)\phi_{k_1}(3)\phi^*_{k_3}(1)\phi^*_{k_1}(2)\phi^*_{k_2}(3) - \phi_{k_2}(1)\phi_{k_3}(2)\phi_{k_1}(3)\phi^*_{k_1}(1)\phi^*_{k_3}(2)\phi^*_{k_2}(3)\\
&- \phi_{k_3}(1)\phi_{k_2}(2)\phi_{k_1}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3) + \phi_{k_3}(1)\phi_{k_2}(2)\phi_{k_1}(3)\phi^*_{k_2}(1)\phi^*_{k_1}(2)\phi^*_{k_3}(3)\\
&- \phi_{k_3}(1)\phi_{k_2}(2)\phi_{k_1}(3)\phi^*_{k_2}(1)\phi^*_{k_3}(2)\phi^*_{k_1}(3) + \phi_{k_3}(1)\phi_{k_2}(2)\phi_{k_1}(3)\phi^*_{k_3}(1)\phi^*_{k_2}(2)\phi^*_{k_1}(3)\\
&- \phi_{k_3}(1)\phi_{k_2}(2)\phi_{k_1}(3)\phi^*_{k_1}(1)\phi^*_{k_3}(2)\phi^*_{k_2}(3) + \phi_{k_3}(1)\phi_{k_2}(2)\phi_{k_1}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3)\\
&+ \phi_{k_3}(1)\phi_{k_1}(2)\phi_{k_2}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3) - \phi_{k_3}(1)\phi_{k_1}(2)\phi_{k_2}(3)\phi^*_{k_2}(1)\phi^*_{k_1}(2)\phi^*_{k_3}(3)\\
&+ \phi_{k_3}(1)\phi_{k_1}(2)\phi_{k_2}(3)\phi^*_{k_2}(1)\phi^*_{k_3}(2)\phi^*_{k_1}(3) - \phi_{k_3}(1)\phi_{k_1}(2)\phi_{k_2}(3)\phi^*_{k_3}(1)\phi^*_{k_2}(2)\phi^*_{k_1}(3)\\
&+ \phi_{k_3}(1)\phi_{k_1}(2)\phi_{k_2}(3)\phi^*_{k_3}(1)\phi^*_{k_1}(2)\phi^*_{k_2}(3) - \phi_{k_3}(1)\phi_{k_1}(2)\phi_{k_2}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3)\\
&- \phi_{k_1}(1)\phi_{k_3}(2)\phi_{k_2}(3)\phi^*_{k_1}(1)\phi^*_{k_2}(2)\phi^*_{k_3}(3) + \phi_{k_1}(1)\phi_{k_3}(2)\phi_{k_2}(3)\phi^*_{k_2}(1)\phi^*_{k_1}(2)\phi^*_{k_3}(3)\\
&- \phi_{k_1}(1)\phi_{k_3}(2)\phi_{k_2}(3)\phi^*_{k_2}(1)\phi^*_{k_3}(2)\phi^*_{k_1}(3) + \phi_{k_1}(1)\phi_{k_3}(2)\phi_{k_2}(3)\phi^*_{k_3}(1)\phi^*_{k_2}(2)\phi^*_{k_1}(3)\\
&- \phi_{k_1}(1)\phi_{k_3}(2)\phi_{k_2}(3)\phi^*_{k_3}(1)\phi^*_{k_1}(2)\phi^*_{k_2}(3) + \phi_{k_1}(1)\phi_{k_3}(2)\phi_{k_2}(3)\phi^*_{k_1}(1)\phi^*_{k_3}(2)\phi^*_{k_2}(3)\\
&= 6\delta(\vec{z}_1)\delta(\vec{z}_2)\delta(\vec{z}_3) + \text{other terms} = 3!\prod_{\ell=1}^{3}\delta(\vec{z}_\ell) + \text{other terms}. \qquad \text{(A2)}
\end{aligned}
$$

For a symmetrized I_2 and I_3 the $\mathrm{sgn}(p')$ and $\mathrm{sgn}(p)$ need not be included.

An H-theorem for the general relativistic Ornstein-Uhlenbeck process

M. Rigotti[a] and F. Debbasch[b]
LERMA (ERGA), UMR 8112, UPMC, Site Le Raphaël, 3 rue Galilée 94200 Ivry sur Seine, France

(Received 9 June 2005; accepted 26 July 2005; published online 28 October 2005)

We construct conditional entropy four-currents for the general relativistic Ornstein-Uhlenbeck process and we prove that the four-divergences of these currents are always non-negative. This *H*-theorem is then discussed in detail. In particular, the theorem is valid in any Lorentzian space-time, even those presenting well-known chronological violations. © *2005 American Institute of Physics.*

NOTATIONS

In this article, c denotes the speed of light, and the signature of the space-time metric is $(+,-,-,-)$. Indices running from 0 to 3 are indicated by Greek letters. Latin letter indices run instead from 1 to 3. We also introduce the abbreviation $\partial_p^\mu = \partial/\partial p_\mu$ for the partial derivative with respect to an arbitrary component of the momentum p. This notation underlines the fact that this operator transforms as a contravariant vector. Similarly we will often write $\partial_\mu = \partial/\partial x^\mu$, but the latter operator naturally does *not* transform as a tensor. Finally, det g stands for the determinant of the coordinate basis components of the metric tensor g.

I. INTRODUCTION

In Galilean physics, the most common way to quantify the irreversibility of a phenomenon is to introduce an entropy, i.e., a functional of the time-dependent thermodynamical state of the system which never decreases with time. In usual Galilean continuous media theories, the total entropy $\mathcal{S}$ can be written as the integral of an entropy density s over the volume occupied by the system.[24] One also introduces an entropy current $\mathbf{j}_s$ and, since entropy is by definition not generally conserved, the relation $\partial_t s + \nabla \cdot \mathbf{j}_s \geqslant 0$ holds for every evolution of the system.

Traditional relativistic hydrodynamics and kinetic theory deal with the problem in a completely similar manner. An entropy four-current S is associated to the local thermodynamical state of the system;[5,21,14] the total entropy $\mathcal{S}(t_0)$ of the system at time-coordinate $t=t_0$ can be obtained by integrating S over the three-dimensional space-like submanifold $t=t_0$ and the entropy fluxes are obtained by integrating S over two-dimensional submanifolds of space-time. Since entropy is not generally conserved, the simple relation $\nabla \cdot S = \nabla_\mu S^\mu \geqslant 0$ holds for any evolution of the system.

Actually, given a system and its dynamics, any four-vector field S of non-negative divergence which depends on the local thermodynamical state of the system can be considered as an entropy current. In particular, nothing precludes the possibility of associating more than one entropy current to a single local state of a system.

Let us illustrate this remark by considering two special cases of great physical and mathematical interest. Historically speaking, the first statistical theory of out-of-equilibrium systems is Boltzmann's model of dilute Galilean gases.[4,24,13] The local state of the system is encoded in the so-called one particle distribution function f, which obeys the traditional Boltzmann equation. A

direct consequence of this equation is that a certain functional of the distribution function never decreases with time. Boltzmann denoted this functional by H and the result is therefore known as Boltzmann's H-theorem. To this day, H is the only-known functional of f that never decreases in time. This H-theorem has later on been extended to the relativistic generalization of Boltzmann's model of dilute gases.[14] Thus, the relativistic Boltzmann gas also admits an entropy (and an entropy current) and it seems that this entropy is unique.

The situation is drastically different for stochastic processes. Indeed, a theorem due to Voigt[26,22] states that, under very general conditions, a stochastic process admits an infinity of entropies: Let X be the variable whose time-evolution is governed by the stochastic process and let $\mathrm{d}X$ be a measure in X-space $\mathcal{X}$ (typically, $\mathrm{d}X$ is the Lebesgue measure if $\mathcal{X}\subset\mathbb{R}^n$). Now let f and g be any two probability distribution functions solutions of the transport equation associated to the stochastic process. Then, the quantity

$$\mathcal{S}_{f|g}(t) = -\int_{\mathcal{X}} f(t,X)\ln\left(\frac{f(t,X)}{g(t,X)}\right)dX \tag{1}$$

is a never decreasing function of time and is called the conditional entropy of f with respect to g. Thus, to any given $f(t,\cdot)$ representing the state of the system at time t, one can associate as many entropies as there are different solutions g of the transport equation so, typically, an infinity. Naturally, if the function g_0 defined by $g_0(t,X)=1$ for all t and X is a solution of the transport equation, the conditional entropy $\mathcal{S}_{f|g_0}$ of any distribution f with respect to g_0 coincides with the Boltzmann entropy of f.

The notion of conditional entropy corresponds to what is sometimes called the Kullback information and we refer the reader to Refs. 19, 18, and 3 for extensive discussions of this concept.

The application of Voigt's theorem to Galilean stochastic processes is of course straightforward and rather well known, but its application to relativistic stochastic processes demands discussion. To be definite, we will now particularize our treatment to the ROUP, which is the first relativistic process to have been introduced in the literature.[7,8,2,1,6]

Given a reference frame (chart) $\mathcal{R}$, the ROUP transcribes as a set of stochastic equations governing the evolution of the position and momentum of a diffusing particle as functions of the time coordinate t in $\mathcal{R}$. This set of equations is a stochastic process in the usual sense of the word, and Voigt's theorem ensures this process admits an infinity of conditional entropies. But, by construction, these entropies *a priori* depend on the reference frame $\mathcal{R}$ and the general theorem does not furnish any information about their tensorial status.

This question has been partly answered for the special relativistic Ornstein-Uhlenbeck process.[1] In flat space-time, the ROUP admits as invariant measure in p-space a Jüttner distribution J;[16] this distribution simply describes a special relativistic equilibrium at the temperature of the fluid surrounding the diffusing particle. It has been shown in Ref. 1 that this Jütnner distribution can be used to construct a four-vector field of non-negative four-divergence which can be interpreted as the conditional entropy current of f with respect to J.

The aim of the present article is to prove the existence of conditional entropy currents for the ROUP in curved space-time. The matter is organized as follows. Section II reviews some basic results pertaining to the ROUP in curved space-time with particular emphasis on the Kolmogorov equation associated to the process. It is also recalled here that, in a generic space-time, this equation does *not* admit any equilibrium stationary solution.[6] In particular, a general relativistic Jütnner distribution is not, generically, a solution of the Kolmogorov equation and, therefore, cannot be used to construct an entropy current in curved space-time. We therefore consider two arbitrary solutions f and g of the Kolmogorov equation and introduce in Sec. III A a candidate for the conditional entropy current of f with respect to g. We then prove in Sec. III B that the four-divergence of this current is always non-negative. This is our main result and it constitutes an H-theorem for the ROUP in curved space-time. Note that the flat space-time version of this H-theorem is itself a new result because our previous work[1] only proved the existence of a single

entropy current for the ROUP in flat space-time, i.e., the conditional entropy current of an arbitrary distribution f with respect to the Jüttner equilibrium distribution J. Finally, the new H-theorem and some of its possible extensions are discussed at length in Sec. IV. The Appendix recalls and, if necessary, proves some simple but important purely geometrical relations useful in deriving the H-theorem.

II. BASICS ON THE ROUP IN CURVED SPACE-TIME

A. Kolmogorov equation

The general relativistic Ornstein-Uhlenbeck process can be viewed as a toy model for the diffusion of a point particle of nonvanishing mass m interacting with both a fluid and a gravitational field. This process is best presented by its Kolmogorov equation in manifestly covariant form.[6] The extended phase-space is the eight-dimensional bundle cotangent to the space-time manifold with local coordinates, say (x^μ, p_ν), $(\mu,\nu)\in\{0,1,2,3\}^2$. At each point in space-time, the four-dimensional (4D) momentum space $\mathcal{P}$ is equipped with the 4D volume measure:

$$\mathcal{D}^4p = \theta(p_0)\,\delta(p^2 - m^2c^2)\frac{1}{\sqrt{-\det g}}d^4p, \tag{2}$$

with $d^4p = dp_0\wedge dp_1\wedge dp_2\wedge dp_3$. This measure behaves as a scalar with respect to arbitrary coordinate changes. Note that integrals over $\mathcal{P}$ defined by using (multiples of) $\mathcal{D}^4p$ as a measure are *de facto* restricted to the (generally position-dependent) mass-shell.

Let f be the probability distribution function in the extended phase-space of a particle diffusing in a surrounding fluid with normalized four-velocity U. As shown in Ref. 6, f obeys a manifestly covariant Kolmogorov equation which can be written in the following compact form:

$$\partial_\mu(p^\mu f) = -\partial_p^\mu\left\{\widetilde{\Gamma}_\mu f + \mathcal{K}_\mu(f)\right\}. \tag{3}$$

The coefficients $\widetilde{\Gamma}_\mu$, which do not constitute a tensor, are defined by

$$\widetilde{\Gamma}_\mu = \Gamma^\lambda_{\mu\nu}g^{\kappa\nu}p_\kappa p_\lambda \tag{4}$$

and

$$\mathcal{K}_\mu(f) = I_\mu f - \partial_p^\nu(J_{\mu\nu}f) \tag{5}$$

with

$$I_\mu = -DK^\alpha{}_\mu{}^\beta{}_\nu\partial_p^\nu\left(\frac{p_\alpha p_\beta}{p\cdot U}\right) + mcF_\mu, \tag{6}$$

$$J_{\mu\nu} = -DK^\alpha{}_\mu{}^\beta{}_\nu\frac{p_\alpha p_\beta}{p\cdot U}. \tag{7}$$

The tensor K is independent of p. It depends on U and on the metric g, but only through the projector Δ on the orthogonal to U, which reads:

$$\Delta^{\mu\nu} = g^{\mu\nu} - U^\mu U^\nu. \tag{8}$$

The explicit expression of K in terms of U and Δ is

$$K^{\alpha\mu\beta\nu} = U^\alpha U^\beta\Delta^{\mu\nu} + U^\mu U^\nu\Delta^{\alpha\beta} - U^\alpha U^\nu\Delta^{\mu\beta} - U^\mu U^\beta\Delta^{\alpha\nu}. \tag{9}$$

Finally, F represents the deterministic part of the force exerted by the fluid on the diffusing particle; its expression as a function of p and U reads

$$F_\mu = -\lambda_{\mu\nu} p^\nu \frac{p^2}{m^2c^2} + \lambda_{\alpha\beta} \frac{p^\alpha p^\beta}{m^2c^2} p_\mu, \tag{10}$$

with

$$\lambda_{\mu\nu} = \frac{\alpha (mc)^2}{(p \cdot U)^2} \Delta_{\mu\nu}, \tag{11}$$

$\alpha > 0$ being the friction coefficient (see Ref. 7). Note that F is by construction orthogonal to p.

It has been shown in Ref. 6 that (3) does not generically admit stationary solutions. In particular, a general relativistic Jüttner distribution cannot be used to construct in curved space-time a preferred conditional entropy current for the ROUP.

III. *H*-THEOREM FOR THE ROUP IN CURVED SPACE-TIME

A. Definition of the conditional entropy currents

Given any two probability distribution functions f and g defined over the extended phase-space, a natural definition for the conditional entropy current of f with respect to g is

$$S_{f|g}(x) = -\int_{\mathcal{P}} p f(x,p) \ln\left(\frac{f(x,p)}{g(x,p)}\right) \mathcal{D}^4 p. \tag{12}$$

This definition is clearly the simplest generalization of Eq. (37) in Ref. 1 to both an arbitrary reference distribution g and a possibly curved space-time background.

We will now prove that for all f and g solutions of the Kolmogorov equation (3), the four-divergence of $S_{f|g}$ is non-negative.

B. Proof of the *H*-theorem

The proof of the H-theorem for the general relativistic Ornstein-Uhlenbeck process will be carried out in two steps.

1. Computation of the four-divergence of the entropy current

Theorem 1: *For any f and g solutions of Kolmogorov equation*

$$\nabla \cdot S_{f|g}(x) = \int_{\mathcal{P}} J_{\mu\nu}(x,p) D^\mu[f/g] D^\nu[f/g] \mathcal{D}^4 p, \tag{13}$$

where J is defined by (7) *and the functional D is given by*

$$D^\mu[f/g] = \partial_p^\mu \ln(f/g). \tag{14}$$

Proof: The main idea behind the proof is to use Kolmogorov equation (3) to convert all the spatial derivatives into derivatives with respect to momentum components. To do this we will deal with various integrals over $\mathcal{P}$ by integrating most of them by parts. This procedure generally leads to the appearance of so-called "border terms." Some of them trivially vanish if we suppose, as is customary in statistical physics, that phase-space distribution functions tend to zero sufficiently rapidly at infinity (in 4D p-space). One is then left with border terms that are to be evaluated on the hyperplane $p \cdot U = 0$. These also vanish for the following reason. Let us choose, at each point in space-time, an orthornormal basis (tetrad) (e_a), $a = 0,1,2,3$ in the tangent space. Introducing the components p_a and U^a of p and U in this base, the normalization condition $U^2 = 1$ reads:

$$U^0 = \sqrt{1 + \sum_{i=1}^{3} (U^i)^2} \tag{15}$$

so that

$$U^0 > \sqrt{\sum_{i=1}^{3} (U^i)^2}. \tag{16}$$

The condition $p \cdot U = 0$ becomes $p_0 U^0 + \Sigma_{i=1}^3 p_i U^i = 0$; since $U^0 > 0$, this translates into

$$p_0 = - \frac{\sum_{i=1}^3 p_i U^i}{U^0}. \tag{17}$$

It follows easily from (16) and (17) that $(p_0)^2 < \Sigma_{i=1}^3 (p_i)^2$ on the hyperplane $p \cdot U = 0$. The Dirac δ distribution which enforces the on mass-shell restriction $p^2 = m^2 c^2$ therefore vanishes on the hyperplane $p \cdot U = 0$, ensuring that the corresponding border terms disappear.

Let us now proceed with the proof of Theorem 1. Direct derivation of Eq. (12) leads to

$$\begin{aligned}
\nabla_\kappa S^\kappa_{f|g} &= -\partial_\kappa \int_{\mathcal{P}} p^\kappa f \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p - \Gamma^\alpha_{\alpha\kappa} \int_{\mathcal{P}} p^\kappa f \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p \\
&= \underbrace{- \int_{\mathcal{P}} \partial_\kappa (p^\kappa f) \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p}_{=\mathcal{A}_1} \underbrace{- \int_{\mathcal{P}} p^\kappa \left[(\partial_\kappa f) - \frac{f}{g} (\partial_\kappa g) \right] \mathcal{D}^4 p}_{=\mathcal{A}_2} \\
&\underbrace{- \int_{\mathcal{P}} p^\kappa f \ln\left(\frac{f}{g}\right) \partial_\kappa (\mathcal{D}^4 p)}_{=\mathcal{A}_3} \underbrace{- \Gamma^\alpha_{\alpha\kappa} \int_{\mathcal{P}} p^\kappa f \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p}_{=\mathcal{A}_4}.
\end{aligned} \tag{18}$$

Using Kolmogorov equation (3), integrating by parts, and inserting the definition of $\mathcal{K}_\mu(f)$ Eq. (5) we obtain for $\mathcal{A}_1$:

$$\begin{aligned}
\mathcal{A}_1 &= \int_{\mathcal{P}} \partial_p^\mu \left\{ \widetilde{\Gamma}_\mu f + \mathcal{K}_\mu(f) \right\} \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p = - \int_{\mathcal{P}} \left\{ \widetilde{\Gamma}_\mu f + \left[I_\mu f - \partial_p^\nu (J_{\mu\nu} f) \right] \right\} \partial_p^\mu \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p \\
&\quad - \int_{\mathcal{P}} \left\{ \widetilde{\Gamma}_\mu f + \mathcal{K}_\mu(f) \right\} \ln\left(\frac{f}{g}\right) \partial_p^\mu (\mathcal{D}^4 p).
\end{aligned} \tag{19}$$

Let us now consider the term $\mathcal{A}_2$:

$$\begin{aligned}
\mathcal{A}_2 &= - \int_{\mathcal{P}} p^\kappa \left[(\partial_\kappa f) - \frac{f}{g} (\partial_\kappa g) \right] \mathcal{D}^4 p \\
&= \underbrace{- \int_{\mathcal{P}} \partial_\kappa (p^\kappa f) \mathcal{D}^4 p}_{=\mathcal{B}_1} + \underbrace{\int_{\mathcal{P}} \partial_\kappa (p^\kappa g) \frac{f}{g} \mathcal{D}^4 p}_{=\mathcal{B}_2}.
\end{aligned} \tag{20}$$

Using again Kolmogorov equation (3) and integrating by parts, we obtain for the term $\mathcal{B}_1$:

$$\mathcal{B}_1 = \int_{\mathcal{P}} \partial_p^\mu \left\{ \widetilde{\Gamma}_\mu f + \mathcal{K}_\mu(f) \right\} \mathcal{D}^4 p = - \int_{\mathcal{P}} \left\{ \widetilde{\Gamma}_\mu f + \mathcal{K}_\mu(f) \right\} \partial_p^\mu (\mathcal{D}^4 p), \tag{21}$$

and for the term $\mathcal{B}_2$:

$$\mathcal{B}_2 = -\int_{\mathcal{P}} \partial_p^\mu \left\{ \widetilde{\Gamma}_\mu g + \mathcal{K}_\mu(g) \right\} \frac{f}{g} \mathcal{D}^4 p = \int_{\mathcal{P}} \left\{ \widetilde{\Gamma}_\mu f + \mathcal{K}_\mu(g) \frac{f}{g} \right\} \partial_p^\mu \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p + \int_{\mathcal{P}} \left\{ \widetilde{\Gamma}_\mu f + \mathcal{K}_\mu(g) \frac{f}{g} \right\} \partial_p^\mu (\mathcal{D}^4 p). \tag{22}$$

Summing (21) and (22) and inserting the definition of $\mathcal{K}_\mu(g)$ Eq. (5) we obtain:

$$\mathcal{A}_2 = \int_{\mathcal{P}} \left\{ \widetilde{\Gamma}_\mu f + \left[I_\mu f - \partial_p^\nu (J_{\mu\nu} g) \frac{f}{g} \right] \right\} \partial_p^\mu \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p + \int_{\mathcal{P}} \left\{ \mathcal{K}_\mu(g) \frac{f}{g} - \mathcal{K}_\mu(f) \right\} \partial_p^\mu (\mathcal{D}^4 p). \tag{23}$$

Putting (19) and (23) together we get:

$$\mathcal{A}_1 + \mathcal{A}_2 = \int_{\mathcal{P}} \left\{ \partial_p^\nu (J_{\mu\nu} f) - \partial_p^\nu (J_{\mu\nu} g) \frac{f}{g} \right\} \partial_p^\mu \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p - \int_{\mathcal{P}} \widetilde{\Gamma}_\mu f \ln\left(\frac{f}{g}\right) \partial_p^\mu (\mathcal{D}^4 p) + \int_{\mathcal{P}} \left\{ \mathcal{K}_\mu(g) \frac{f}{g} - \mathcal{K}_\mu(f) \left[1 + \ln\left(\frac{f}{g}\right) \right] \right\} \partial_p^\mu (\mathcal{D}^4 p). \tag{24}$$

The third integral on the right-hand side of (24) contains two contributions and they both involve the contraction of the operator $\mathcal{K}$ with $\partial_p^\mu(\mathcal{D}^4 p)$. By Eq. (A9), this contraction is proportional to the contraction of $\mathcal{K}$ with p. By definitions (5)–(7), the action of this latter contraction on an arbitrary function h reads:

$$p^\mu \mathcal{K}_\mu(h) = p^\mu \{ I_\mu h - \partial_p^\nu (J_{\mu\nu} h) \} = D K^\alpha{}_\mu{}^\beta{}_\nu p^\mu \frac{p_\alpha p_\beta}{p \cdot U} (\partial_p^\nu h) + mc p^\mu F_\mu h. \tag{25}$$

The tensor $K^{\alpha\mu\beta\nu}$ is antisymmetric upon exchange of the indices μ and α, entailing that $K^{\alpha\mu\beta\nu} p_\alpha p_\mu p_\beta = 0$; moreover, the deterministic four-force F is orthogonal to the momentum p, i.e., $p^\mu F_\mu = 0$. Equation (25) therefore simply reduces to

$$p^\mu \mathcal{K}_\mu(h) = 0. \tag{26}$$

The last integral in (24) therefore disappears, and we can write:

$$\mathcal{A}_1 + \mathcal{A}_2 = \int_{\mathcal{P}} f \underbrace{\left\{ \frac{1}{f} \partial_p^\nu (J_{\mu\nu} f) - \frac{1}{g} \partial_p^\nu (J_{\mu\nu} g) \right\}}_{= J_{\mu\nu} D^\mu [f/g]} D^\mu [f/g] \, \mathcal{D}^4 p - \Gamma^\nu_{\mu\kappa} \int_{\mathcal{P}} p^\kappa p_\nu f \ln\left(\frac{f}{g}\right) \partial_p^\mu (\mathcal{D}^4 p), \tag{27}$$

where we used definition (14) of $D^\mu[\cdot]$ and definition (4) of $\widetilde{\Gamma}_\mu$.

Let us now address the $\mathcal{A}_3$ contribution to Eq. (18). Inserting the expression (A10) for $\partial_\kappa(\mathcal{D}^4 p)$, we have

$$\mathcal{A}_3 = -\int_{\mathcal{P}} p^\kappa f \ln\left(\frac{f}{g}\right) \partial_\kappa (\mathcal{D}^4 p) = \Gamma^\nu_{\kappa\mu} \int_{\mathcal{P}} p^\kappa p_\nu f \ln\left(\frac{f}{g}\right) \partial_p^\mu (\mathcal{D}^4 p) + \Gamma^\alpha_{\alpha\kappa} \int_{\mathcal{P}} p^\kappa f \ln\left(\frac{f}{g}\right) \mathcal{D}^4 p. \tag{28}$$

Inserting Eqs. (28) and (27) in (18), we obtain the wanted simple expression:

$$\nabla_\mu S^\mu_{f|g} = \int_{\mathcal{P}} J_{\mu\nu} D^\mu[f/g] D^\nu[f/g] \mathcal{D}^4 p. \tag{29}$$

□

2. The four-divergence of the entropy current is non-negative

We now state a second theorem, which, together with the previous one, will prove the *H*-theorem.

Theorem 2: *For any two arbitrary distributions f and g, the integrand in* Eq. (13) *of Theorem* 1 *is non-negative, that is*:

$$J_{\mu\nu} D^\mu[f/g] D^\nu[f/g] \geqslant 0. \tag{30}$$

Proof: Let us fix an arbitrary point x in space-time and choose as local reference frame ($\mathcal{R}$) at x the proper rest frame at x of the fluid surrounding the diffusing particle. By definition, in this reference frame, the components of the four-velocity $U(x)$ of the fluid at x are simply $U^\mu = (1/\sqrt{g_{00}})(1,0,0,0)$. Inserting these components into the definition (7) for J, we get

$$J^{00} = -\frac{D}{\sqrt{g_{00}} p_0} g^{ij} p_i p_j, \tag{31}$$

$$J^{0i} = -D\left(\frac{1}{g_{00}}(p_0)^2 g^{0i} - \frac{1}{g_{00}} p_0 g^{i\alpha} p_\alpha\right)\frac{\sqrt{g_{00}}}{p_0} = \frac{D}{\sqrt{g_{00}} p_0} g^{ij} p_0 p_j, \tag{32}$$

$$J^{ij} = -D\left(\frac{1}{g_{00}}(p_0)^2 g^{ij}\right)\frac{\sqrt{g_{00}}}{p_0} = -\frac{D}{\sqrt{g_{00}} p_0} g^{ij} (p_0)^2. \tag{33}$$

We thus find:

$$\begin{aligned} J^{\mu\nu} D_\mu D_\nu &= J^{00} D_0 D_0 + 2 J^{0i} D_0 D_i + J^{ij} D_i D_j \\ &= -\frac{D}{\sqrt{g_{00}} p_0}\left[g^{ij} p_i p_j (D_0)^2 - 2 g^{ij} p_0 p_j D_0 D_i + g^{ij} (p_0)^2 D_i D_j\right] \\ &= -\frac{D}{\sqrt{g_{00}} p_0} \underbrace{\left[p_i D_0 - (p_0)^2 D_i\right]}_{=v_i} g^{ij} \underbrace{\left[p_j D_0 - (p_0)^2 D_j\right]}_{=v_j} \\ &= -\frac{D}{\sqrt{g_{00}} p_0} g^{ij} v_i v_j. \end{aligned} \tag{34}$$

By Lemma 1 presented in the Appendix, the right-hand side of this equation is non-negative, which proves Theorem 2. □

IV. DISCUSSION

This article has been focused on the general relativistic Ornstein-Uhlenbeck process introduced in Ref. 6; we have constructed a conditional entropy four-current associated to any two arbitrary distributions solutions of Kolmogorov equation for the ROUP, and we have proven that the four-divergence of this current is always non-negative; this constitutes an *H*-theorem for the ROUP in curved space-time. It is a twofold generalization of the theorem introduced in Ref. 1. First, the *H*-theorem proved in Ref. 1 concerns flat space-time only. Second, Ref. 1 does not deal with a conditional entropy four-current associated to *two* arbitrary distributions, but only with the conditional entropy four-current of *one* arbitrary distribution with respect to the equilibrium dis-

tribution (invariant measure) of the ROUP in flat space-time. Let us note in this context that the ROUP does not generally admit an equilibrium distribution in curved space-time.[6]

We would like now to comment on this new *H*-theorem. Let us first remark that the theorem is valid in any Lorentzian space-time and for any time-like field U representing the velocity of the fluid in which the particles diffuse. In particular, the theorem is even valid in space-times with closed time-like curves, as the Gödel universe or the extended Kerr black hole,[12] and even if U is tangent to one of these closed time-like curves. The irreversibility measured by the local increase of the conditional entropy currents is entirely due to the Markovian character[25,11,23] of the ROUP and the remarkably general validity of the *H*-theorem proves that this irreversibility is in some sense stronger than all possible general relativistic chronological violations.

It should nevertheless be remarked that, as the Boltzmann-Gibbs entropy current associated to the relativistic Boltzmann equation, the conditional entropy four-currents introduced in Sec. III A are not necessarily time-like. And, even when they are time-like, their time-orientation in an orientable space-time generally depends on the point at which they are evaluated. Let us elaborate on this by first recalling the definition of the Boltzmann-Gibbs entropy current $S_{\mathrm{BG}}[f]$ associated to a distribution f (see Ref. 14):

$$S_{\mathrm{BG}}[f](x) = -\int_{\mathcal{P}} pf \ln f \mathcal{D}^4 p. \tag{35}$$

The normalization of f reads:

$$1 = \int_{\mathcal{T}_\Sigma} f d^3x \mathcal{D}^4 p, \tag{36}$$

where Σ is an arbitrary space-like hypersurface of the space-time $\mathcal{M}$ and where $\mathcal{T}_\Sigma \subset T^*(\mathcal{M})$ is defined by

$$\mathcal{T}_\Sigma = \{(x,p) \in T^*(\mathcal{M}), x \in \Sigma\}. \tag{37}$$

As a probability distribution, f is certainly non-negative; but f may take values both superior and inferior to unity. Therefore, nothing can be said on the sign of the function $f \ln f$ against which the time-like vector p is integrated in (35). This entails that $S_{\mathrm{BG}}[f](x)$ may be either time-like or space-like. Also note that the sign of the zeroth component of $S_{\mathrm{BG}}[f](x)$ cannot be ascertained either; thus, even when time-like, the Boltzmann-Gibbs entropy current may be past as well as future oriented (in a time-orientable space-time).

Similarly, the sign of the function $f(x,p)\ln(f(x,p)/g(x,p))$ appearing in definition (12) of the conditional entropy current $S_{f|g}(x)$ generally depends on p (and x) and $S_{f|g}(x)$ may therefore not be time-like. For the same reason, the sign of the zeroth component of $S_{f|g}(x)$ also generally depends on the point in space-time so that the conditional entropy currents, even when time-like, may not have a definite time-orientation (in a time-orientable space-time).

The Galilean limit deserves a particular discussion. The very notions of time-like and space-like vector-fields do not exist in this limit and only the time-orientation of the conditional entropy currents should be addressed. In the Galilean limit, the zeroth component of $S_{f|g}(x)$ reads

$$s_{f|g}(t,\mathbf{x}) = -\int_{\mathbb{R}^3} f(t,\mathbf{x},\mathbf{p}) \ln\left(\frac{f(t,\mathbf{x},\mathbf{p})}{g(t,\mathbf{x},\mathbf{p})}\right) d^3p; \tag{38}$$

note that this expression coincides with the conditional entropy density of the usual, non relativistic Ornstein-Uhlenbeck process.[22] A reasoning similar to the one presented in the preceding paragraph shows that this density may take positive as well as negative values. The time-orientation of the conditional entropy currents is therefore generally position-dependent, even in the Galilean regime.

However, in the Galilean limit, it surely makes sense to integrate $s_{f|g}(t,\mathbf{x})$ over the whole three-dimensional (3D) space to obtain the total (time-dependent) conditional entropy $\mathcal{S}(t)$ of f with respect to g and this quantity can be proven to be non-positive. The proof[22,3] is based on the so-called Gibbs-Klein inequality[25]

$$F \ln F \geqslant F - 1, \tag{39}$$

valid for any positive real number F and applied to $F(t,\mathbf{x},\mathbf{p})=f(t,\mathbf{x},\mathbf{p})/g(t,\mathbf{x},\mathbf{p})$ (with the hypothesis that g does not vanish anywhere in $\mathbb{R}^3$). One has indeed:

$$\int_{\mathcal{V}} s_{f|g}(t,\mathbf{x})d^3x = -\int_{\mathcal{V}\times\mathbb{R}^3} f(t,\mathbf{x},\mathbf{p})\ln\left(\frac{f(t,\mathbf{x},\mathbf{p})}{g(t,\mathbf{x},\mathbf{p})}\right)d^3x\,d^3p \leqslant \int_{\mathcal{V}\times\mathbb{R}^3}\big(f(t,\mathbf{x},\mathbf{p})-g(t,\mathbf{x},\mathbf{p})\big)d^3x\,d^3p \leqslant 0. \tag{40}$$

This calculation can be extended formally to the special and general relativistic situations, but, since conditional entropy four-currents are then not necessarily time-like, their integrals on space-like 3D submanifolds may take positive or negative values. It is therefore far from clear that the concept of *total* conditional entropy makes sense in the relativistic regime. In particular, the relativistic H-theorem proved in this article should be primarily considered as a purely local result.

Thus, the conceptual status of the entropy currents introduced in Sec. III A is in a certain sense similar to the status of the general relativistic black hole entropies.[28,29,17,15] Indeed, we have shown in this article that stochastic processes theory proves the existence of conditional entropy currents in curved space-time and permits their computation, exactly as quantum field theory and string theory both prove the existence of black-holes entropies and furnish the tools necessary for their computations. But the standard statistical interpretation of conditional entropy currents via their fluxes through 3D space-like submanifolds is certainly not straightforward in curved space-time, as the usual interpretation of entropy and temperature via Gibbs canonical ensembles does not seem to extend smoothly to black hole thermodynamics.[29]

It is our opinion that progress in interpreting the notion of entropy in curved space-time can best be achieved by studying specific examples in particular circumstances where most results can be obtained by explicit or semi-explicit calculations. The ROUP is obviously an interesting tool for such computations and diffusion in space-times exhibiting naked or unnaked singularities should certainly be studied in detail.

Finally, it would naturally be most interesting to determine if H-theorems can also be proved for the two "new" relativistic stochastic processes recently proposed as alternative models of relativistic diffusion in Refs. 10 and 9.

APPENDIX

General relations

A basic assumption of general relativity is that the connection ∇ used in space-time is the Levi-Civita connection of the space-time metric g.[27] Given a coordinate basis, this translates into the following relation between the metric components $g_{\mu\nu}$ and the connection coefficients $\Gamma^{\alpha}_{\mu\nu}$:

$$\partial_\kappa g_{\mu\nu} = \Gamma^{\alpha}_{\kappa\mu} g_{\alpha\nu} + \Gamma^{\alpha}_{\kappa\nu} g_{\mu\alpha}. \tag{A1}$$

Another equivalent form of (A1) is

$$\partial_\kappa g^{\mu\nu} = -\Gamma^{\mu}_{\kappa\alpha} g^{\alpha\nu} - \Gamma^{\nu}_{\kappa\alpha} g^{\mu\alpha}. \tag{A2}$$

A direct consequence of (A2) is that, for any vector p:

$$(\partial_\kappa g^{\mu\nu}) p_\mu p_\nu = -\Gamma^{\mu}_{\kappa\alpha} p^\alpha p_\mu - \Gamma^{\nu}_{\kappa\alpha} p^\alpha p_\nu = -2\Gamma^{\nu}_{\kappa\mu} p_\nu p^\mu. \tag{A3}$$

Another useful relation reads:[20]

$$\partial_\kappa \det g = (\det g) g^{\mu\nu} \partial_\kappa g_{\mu\nu}. \tag{A4}$$

Using (A1), this translates into

$$\partial_\kappa \det g = (\det g) g^{\mu\nu} 2\Gamma^\alpha_{\kappa\mu} g_{\alpha\nu} = 2(\det g)\Gamma^\alpha_{\kappa\alpha}. \tag{A5}$$

A useful lemma

Lemma 1: *Let* (∂_μ) *be a* (*local*) *coordinate basis of a Lorentzian space-time* (*with time-like* ∂_0). *Then*, *at any point x of space-time*, *the set of the six spatial components* $g^{ij}(x)$ *of the inverse metric tensor define a non-positive quadratic form. More precisely*,

$$g^{ij}(x) v_i v_j \leqslant 0 \quad \text{for all } (v_1, v_2, v_3) \in \mathbb{R}^3.^1 \tag{A6}$$

Proof: Let x be a point in space-time and suppose there exists a set of three real numbers (v_1, v_2, v_3) such that $g^{ij}(x) v_i v_j > 0$. Define V, cotangent to the space-time manifold at x, by its components $V_0 = 0$, $V_1 = v_1$, $V_2 = v_2$, $V_3 = v_3$. The vector V is both time-like and orthogonal to ∂_0. The space cotangent to the space-time manifold at x therefore admits a time-like subspace of dimension at least two, which is impossible for a Lorentzian space-time. This proves the lemma.□

Derivatives of the volume measure in momentum-space

Let us now evaluate the partial derivatives of the volume measure $\mathcal{D}^4 p$ with respect to both space-time coordinates and momentum components. The measure $\mathcal{D}^4 p$ is defined by an expression which involves the product of a Heaviside function and a Dirac distribution. Direct derivation of this expression would lead to a product of Dirac distributions, which is not a well-defined mathematical object. To avoid this (at least formal) problem, we introduce a class of regular functions h_ϵ, which uniformly converge towards δ as ϵ tends to zero and write:

$$\partial^\mu_p \{\theta(p_0)\delta(p^2 - m^2c^2)\} = \lim_{\epsilon \to 0} \partial^\mu_p \{\theta(p_0) h_\epsilon (g^{\alpha\beta} p_\alpha p_\beta - m^2 c^2)\}$$

$$= \lim_{\epsilon \to 0} \{\delta(p_0)\delta^\mu_0 h_\epsilon (g^{\alpha\beta} p_\alpha p_\beta - m^2 c^2) + \theta(p_0)\partial^\mu_p [h_\epsilon (g^{\alpha\beta} p_\alpha p_\beta - m^2 c^2)]\}$$

$$= \lim_{\epsilon \to 0} \{\delta(p_0)\delta^\mu_0 h_\epsilon (g^{ij} p_i p_j - m^2 c^2) + \theta(p_0) 2 g^{\mu\nu} p_\nu h'_\epsilon (g^{\alpha\beta} p_\alpha p_\beta - m^2 c^2)\}. \tag{A7}$$

By Lemma 1 (Eq. (A6)), $g^{ij} p_i p_j \leqslant 0$. The argument of h_ϵ in the last line of (A7) is therefore always strictly negative. The term involving h_ϵ thus disappears for $\epsilon \to 0$ and we are left with the result:

$$\partial^\mu_p \{\theta(p_0)\delta(p^2 - m^2c^2)\} = 2p^\mu \theta(p_0)\delta'(p^2 - m^2c^2). \tag{A8}$$

This equation leads directly to the following expression for the partial derivatives of $\mathcal{D}^4 p$ with respect to momentum components:

$$\partial^\mu_p (\mathcal{D}^4 p) = \partial^\mu_p \left\{ \theta(p_0)\delta(p^2 - m^2c^2) \frac{1}{\sqrt{-\det g}} \right\} d^4 p = 2p^\mu \theta(p_0)\delta'(p^2 - m^2c^2) \frac{1}{\sqrt{-\det g}} d^4 p. \tag{A9}$$

[1] See for example Sec. 84 of Ref. 20.

Let us now focus on the derivatives of $\mathcal{D}^4p$ with respect to space-time coordinates. Using Eqs. (A3), (A5), and (A9), we obtain

$$\partial_\kappa(\mathcal{D}^4p) = \partial_\kappa\left\{\theta(p_0)\delta(g^{\mu\nu}p_\mu p_\nu - m^2c^2)\frac{1}{\sqrt{-\det g}}\right\}d^4p = \theta(p_0)(\partial_\kappa g^{\mu\nu})p_\mu p_\nu \delta'(p^2 - m^2c^2)\frac{1}{\sqrt{-\det g}}d^4p$$
$$+ \theta(p_0)\delta(p^2 - m^2c^2)\partial_\kappa\left(\frac{1}{\sqrt{-\det g}}\right)d^4p = -2\Gamma^\nu_{\kappa\mu}p_\nu p^\mu \theta(p_0)\delta'(p^2 - m^2c^2)\frac{1}{\sqrt{-\det g}}d^4p$$
$$- \theta(p_0)\delta(p^2 - m^2c^2)\frac{1}{\sqrt{-\det g}}\frac{\partial_\kappa \det g}{2\det g}d^4p = -\Gamma^\nu_{\kappa\mu}p_\nu\partial^\mu_p(\mathcal{D}^4p) - \Gamma^\alpha_{\kappa\alpha}\mathcal{D}^4p. \quad \text{(A10)}$$

The modified intermediate long wave (MILW) equation is a (1+1)-dimensional nonlinear singular integro-differential equation that possesses soliton solutions. In an appropriate limit the MILW equation reduces to the well-known modified Korteweg-de Vries equation. In this paper we solve the initial value problem for the MILW equation through a suitable implementation of the inverse scattering transform and use of the Miura-type transformation that maps solutions of the MILW equation into solutions of a complexified version of the standard intermediate long wave (ILW) equation. The initial value used for the MILW equation is assumed to be real valued, sufficiently smooth, and decaying to zero as the absolute value of the spatial variable approaches large values. An interesting feature of the procedure we develop is that soliton solutions for the ILW and MILW equations can be derived by appropriate specializations of a master set of equations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1996830]

I. INTRODUCTION AND PRELIMINARY

In a remarkable and seminal paper[1] that appeared in 1967, Gardner, Greene, Kruskal, and Miura (GGKM) derived an exact reduction to a linear problem for the initial value problem associated with the nonlinear evolution equation,

$$u_t + 6uu_x + u_{xxx} = 0, \tag{1.1}$$

where u $(=u(x,t))$ is a real-valued function of x and t over the domain $-\infty < x < \infty$ and $t \geqslant 0$, and u_x denotes $\partial u/\partial x$, etc. Equation (1.1) is known as the "KdV equation," and derives its name from work by Korteweg and de Vries[2] that models weakly nonlinear long waves propagating on the surface of a rectangular canal. However, it was Boussinesq[3] who first derived Eq. (1.1) as a model in a hydrodynamical context.

GGKM[1] solved Eq. (1.1) by leveraging results derived by Gel'fand and Levitan[4] for the solution of the inverse problem associated with the one-dimensional time-independent Schrödinger equation,

$$\psi_{xx} = -(u + \kappa)\psi, \tag{1.2}$$

where $\psi = \psi(x,t)$, κ is the spectral parameter, and u is the potential. Their ingenious method identified the potential in Eq. (1.2) with the desired solution of Eq. (1.1), and eventually arrived at a closed system of linear integral equations from which one can construct the physical variable $u(x,t)$.

The modified Korteweg-de Vries (MKdV) equation,

[a)]Permanent address: National Australia Bank, Level 27, 255 George Street, Sydney, NSW 2000, Australia.

$$\nu_t + 6\nu^2\nu_x + \nu_{xxx} = 0, \tag{1.3}$$

where $\nu = \nu(x,t)$, was pivotal[5,6] in the development of the procedure used by GGKM to solve the initial value problem for Eq. (1.1). Equation (1.3) has important physical applications,[7] but we will focus our attention on a certain transformation that connects Eq. (1.3) to Eq. (1.1). Miura[8] has derived the explicit nonlinear transformation,

$$u = \nu^2 + i\nu_x, \tag{1.4}$$

which maps a *real-valued* solution of Eq. (1.3) into a *complex-valued* solution of Eq. (1.1). (The phrase "complex-valued" will be used throughout this paper to designate a complex-valued function of the two real variables x and t.) The appearance of the imaginary unit i in Eq. (1.4), which can obviously be removed by a complex scaling $\nu \to i\nu$, can be attributed to our selection of positive coefficients throughout Eq. (1.3). Ablowitz *et al.*[9] have shown that Eq. (1.4) maps sparsely onto the set of KdV solutions. Equation (1.4) is the x part of a pair of equations forming a Bäcklund transformation (BT),[10] and it was this particular BT that led GGKM[5] to consider the inverse problem for Eq. (1.2).

The method used by GGKM to solve the initial value problem for the KdV equation has flourished into a systematic mathematical technique known as the "inverse scattering transform" (IST).[11] Initial value problems for numerous nonlinear wave equations have been solved analytically by suitable implementations of the IST.[12–17]

The versatility of the IST is exemplified in its application to nonlinear singular integro-differential equations. The prototype equation of this type that is solvable by an application of the IST is the intermediate long wave (ILW) equation,[18–20]

$$U_t + \frac{1}{\delta}U_x + 2UU_x + \mathbf{T}(U_{xx}) = 0, \tag{1.5}$$

where $U = U(x,t)$ [or, more precisely, $U(x,t;\delta)$], δ is a *positive* parameter, and the operator $\mathbf{T}$ is defined by the Cauchy principal-value integral,

$$(\mathbf{T}f)(x) := \frac{1}{2\delta}(P)\int_{-\infty}^{\infty} \coth\left(\frac{\pi}{2\delta}(\xi - x)\right) f(\xi)\mathrm{d}\xi. \tag{1.6}$$

For convenience, we will use the notation $\mathbf{T}(f(x))$ interchangeably with $(\mathbf{T}f)(x)$. Equation (1.5) models one-dimensional propagation of weakly nonlinear long internal gravity waves in a density-stratified fluid of *finite* total depth.[21,22]

Throughout this paper we assume that any argument of $\mathbf{T}$ satisfies all the conditions necessary to guarantee the validity of our computations. In particular, a necessary condition for the existence of $(\mathbf{T}f)(x)$ is the convergence of the improper Riemann integral $\int_{-\infty}^{\infty} f(x)\mathrm{d}x$. For later purposes, we require that the convergence be absolute. We also assume that $U(x,t)$ and its first few derivatives with respect to x vanish in the limit $x \to \pm\infty$. In Appendix A of this paper the reader will find a useful summary of some relevant mathematical properties of the operator $\mathbf{T}$. An essential property that we use frequently is the fact that $\mathbf{T}$ commutes with differentiation so that, for example, $\mathbf{T}(U_{xx}) = \partial^2\mathbf{T}(U)/\partial x^2$. Appendix B contains a selection of useful $\mathbf{T}$ transforms.

Despite the obvious differences in the mathematical structure of the KdV and ILW equations, these two equations are connected by virtue of the physical systems they describe. Several researchers[18,22,23] have observed that Eq. (1.5) contracts in the shallow-water limit ($\delta \to 0^+$) to the KdV equation (1.1). To carry out the reduction, let

$$U = \tfrac{1}{4}\delta u + O(\delta^2), \quad x = 2x', \quad t = 24\delta^{-1}t'. \tag{1.7}$$

Then, with the help of Eqs. (A3) and (A5) from Appendix A to compute the shallow-water expansion of $\mathbf{T}(U_{xx})$, the left-hand side of Eq. (1.5) becomes

$$\frac{\delta^2}{96}(u_{t'}+6uu_{x'}+u_{x'x'x'})+O(\delta^3).$$

In the deep-water limit ($\delta\to\infty$), Eq. (1.5) becomes the Benjamin-Ono (BO) equation,[24]

$$q_t+2qq_x+\mathbf{H}(q_{xx})=0, \tag{1.8}$$

where $q=q(x,t)$ and $\mathbf{H}$ (the Hilbert transform) is defined by the integral operator,

$$(\mathbf{H}f)(x):=\frac{1}{\pi}(P)\int_{-\infty}^{\infty}\frac{f(\xi)}{\xi-x}\mathrm{d}\xi. \tag{1.9}$$

Transition from Eq. (1.5) to Eq. (1.8) is a direct consequence of the limit given by Eq. (A2) and the mild restriction that $U(x,t)=q(x,t)+O(1/\delta)$ as $\delta\to\infty$. Equation (1.8) was first derived by Benjamin[24] to model the propagation of unidirectional internal waves with finite amplitude in stable heterogeneous fluid systems of *infinite* total depth. Fokas and Ablowitz[25] have solved the initial value problem for Eq. (1.8) by using an implementation of the IST that is conceptually similar to the IST for nonlinear evolution equations that involve three independent variables (two spatial variables and one temporal variable).

A natural extrapolation from Eqs. (1.5) and (1.8) is to construct *modified* versions (in the sense of the MKdV equation) of the ILW and BO equations. The nomenclature that we will use to refer to the two modified-type nonlinear singular integro-differential equations is *modified intermediate long wave* (MILW) equation for the modified version of the ILW equation, and *modified Benjamin-Ono* (MBO) for the modified version of the BO equation. Desirable attributes of the MILW and MBO equations are that (i) MILW$\to$MKdV in the shallow-water limit $\delta\to 0^+$, (ii) MILW$\to$MBO in the deep-water limit $\delta\to\infty$, and (iii) a Miura transformation maps MILW to ILW such that its deep-water limit maps MBO to BO and its shallow-water limit is the classical Miura transformation mapping MKdV to KdV.

The two candidates to represent the MILW and MBO equations are the following nonlinear singular integro-differential equations:[26–29]

$$\text{MILW},\quad V_t+\beta V_x(e^V-1)+\frac{1}{\delta}V_x+V_x\mathbf{T}(V_x)+\mathbf{T}(V_{xx})=0, \tag{1.10}$$

$$\text{MBO},\quad Q_t+\alpha Q_x(e^Q-1)+Q_x\mathbf{H}(Q_x)+\mathbf{H}(Q_{xx})=0, \tag{1.11}$$

where $V=V(x,t)$, $Q=Q(x,t)$, $\mathbf{T}$ is defined by Eq. (1.6), $\mathbf{H}$ is defined by Eq. (1.9), and α and β are real parameters. Both the MILW and MBO equations are integrable soliton equations. The MILW equation in particular possesses an infinite number of conservation laws,[27] a linear scattering problem,[27] a BT,[27,28] and multisoliton solutions.[28]

Despite the important extension that the MILW equation provides to the mathematical theory for the KdV-MKdV pairing and the possible physical applications of the MILW equation (whose dispersion law is the same as the ILW equation), the initial value problem for the MILW equation has not been solved.[30] The corresponding initial value problem for the MBO equation was recently solved by Scoufis and Cosgrove.[31] The main purpose of this paper is to use the IST to derive the solution of the initial value problem for the MILW equation Eq. (1.10). The initial value $V(x,0)$ for the MILW equation is real-valued, sufficiently smooth, decays to zero as $|x|\to\infty$, and is such that $\int_{-\infty}^{\infty}V(x,0)\mathrm{d}x$ converges absolutely, but is otherwise arbitrary.

We now close this section with an outline of how the remainder of this paper is arranged. Section II is devoted to the derivation of the MILW equation and its Miura transformation to the complex-valued ILW equation. In Sec. III we present the linear scattering problem for the MILW equation. Suitable Jost functions are defined in this section, and we also derive equations that characterize the scattering data forming the continuous spectrum. Section IV examines the bound states and extends the previous results to identify the scattering data forming the discrete spec-

trum. The temporal evolution of the scattering data is presented in Sec. V. Section VI carries out the solution of the inverse problem that emerges from our efforts in Sec. III to identify the analytical properties of the scattering data. Soliton solutions for the complex-valued ILW and real-valued MILW equations are derived in Sec. VII by recourse to the results contained in the preceding sections.

II. MATHEMATICAL ORIGIN OF THE MILW EQUATION

Our primary objective in this section is to elucidate the mathematical origin of the MILW equation. The standard ILW equation provides the catalyst for our work in this section. The dependent variable transformation,

$$W(x,t) := \int_{-\infty}^{x} U(\xi,t)\mathrm{d}\xi,$$

accompanied by the boundary conditions $U(x,t)\to 0$ (uniformly in t) as $|x|\to\infty$, facilitates the conversion of Eq. (1.5) into the equation,

$$W_t + \frac{1}{\delta}W_x + (W_x)^2 + \mathbf{T}(W_{xx}) = 0. \tag{2.1}$$

Let W and W' denote two local complex-valued solutions of Eq. (2.1) that are connected by the auto-Bäcklund transformation,[23]

$$(W' + W)_x = \alpha + i\mathbf{T}(W'_x - W_x) + \beta e^{i(W'-W)}, \tag{2.2}$$

$$(W' - W)_t = -(\alpha + \delta^{-1})(W' - W)_x + i(W' + W)_{xx} - i(W' - W)_x\mathbf{T}(W'_x - W_x), \tag{2.3}$$

where α and β denote two arbitrary real nonzero constants. The proof that elimination of W' produces (the x derivative of) Eq. (2.1), and vice versa, makes use of properties of the $\mathbf{T}$ operator given in Appendix A, especially Eq. (A7).

Next, define the single dependent variable V through the equation,

$$V := i(W' - W). \tag{2.4}$$

Eliminating the $(W'+W)$ terms between Eqs. (2.2) and (2.3), and then using Eq. (2.4), we obtain the nonlinear evolution equation,

$$V_t + \left(\alpha + \frac{1}{\delta}\right)V_x + \beta V_x e^V + V_x\mathbf{T}(V_x) + \mathbf{T}(V_{xx}) = 0, \tag{2.5}$$

where $V=V(x,t)$. This is gauge equivalent to the MILW equation. The parameter α is not essential because it can be varied by a gauge transformation $x\to x+kt$. To get the standard form of the MILW equation, we invoke the boundary conditions $U(x,t)\to 0$ and $V(x,t)\to 0$ as $x\to\pm\infty$ and apply the limit expressed by Eq. (A4) to Eq. (2.2). These conditions force the constraint $\alpha=-\beta$. Thus the standard form of the MILW equation is

$$V_t + \frac{1}{\delta}V_x + \beta V_x(e^V - 1) + V_x\mathbf{T}(V_x) + \mathbf{T}(V_{xx}) = 0. \tag{2.6}$$

In the region $0<\delta\ll 1$, Eq. (2.6) contracts to Eq. (1.3), the latter being the self-focusing form of the MKdV equation. The transition from Eq. (2.6) to Eq. (1.3) requires

$$V = \delta\nu + O(\delta^2), \quad \beta = \delta^{-1} + O(\delta), \quad x = 2x', \quad t = 24\delta^{-1}t'. \tag{2.7}$$

Then, with the assistance of Eq. (A3), the left-hand side of Eq. (2.6) reduces to

$$\frac{\delta^2}{24}(\nu_{t'} + 6\nu^2\nu_{x'} + \nu_{x'x'x'}) + O(\delta^3).$$

Alternative forms of the MILW equation appear in the literature. Nakamura,[28] for example, used the auto–BT of the ILW equation to derive a version of the MILW equation in the form,

$$V_t + (u_0 - \mu + \delta^{-1})V_x + \beta V_x e^V + V_x \mathbf{T}(V_x) + \mathbf{T}(V_{xx}) = 0. \tag{2.8}$$

This is Eq. (2.5) with the parameter α renamed. Satsuma *et al.*[27] derived the equation,

$$\tfrac{1}{3}\delta V_t + \delta^{-1} V_x e^V + V_x \mathbf{T}(V_x) + \mathbf{T}(V_{xx}) = 0, \tag{2.9}$$

as their representative of the MILW equation. Gibbons and Kupershmidt[26] derived the equation,

$$V_t = \delta^{-2} V_x (e^{2i\delta V} - 1 - 2i\delta V) + 2iV_x \hat{\mathbf{T}}(V_x) + \delta^{-1}\hat{\mathbf{T}}(V_{xx}), \tag{2.10}$$

where $\hat{\mathbf{T}}$ is the operator defined by Eq. (A9), and we replaced their pure imaginary δ with $i\delta$ and adjusted a factor of 2 in the second to last term. All these equations are equivalent to the MILW equation Eq. (2.6) under gauge transformations of the form, $x' = \pm x + kt$, $t' = lt$, $V' = pV + q$. On the other hand, Degasperis and co-workers[32,33] derived a qualitatively different nonlinear singular integro-differential equation whose shallow-water limit is the MKdV equation, and so we can conclude that the MILW equation is not the only possible candidate for an intermediate version of the MKdV equation. We have selected Eq. (2.6) as our representative of the MILW equation because it is endowed with a transparent deep-water limit as well as a shallow-water limit that leads directly to the MKdV equation after a simple scaling.

Equation (2.2) contains an explicit relationship between solutions of the ILW and MILW equations. Setting $W' = W - iV$, $W_x = U$, and $\alpha = -\beta$, we get

$$U = \tfrac{1}{2}\{\mathbf{T}(V_x) + \beta(e^V - 1) + iV_x\}. \tag{2.11}$$

Equation (2.11) is the Miura-type transformation that maps *real-valued* solutions V of Eq. (2.6) into *complex-valued* solutions U of Eq. (1.5). If we substitute this U into the left-hand side of the ILW equation (1.5), we will obtain an expression that vanishes on account of Eq. (A7). Substituting Eqs. (1.7) and (2.7) into Eq. (2.11), and then using Eq. (A3) to obtain the shallow-water limit of the $\mathbf{T}$ operator, we will arrive at the classical Miura transformation Eq. (1.4).

In the context of this paper, Eq. (2.11) is essential to the scheme we develop to solve the initial value problem for the MILW equation; we now outline this scheme and provide necessary details in Secs. III–VII. Let $V(x,0)$ denote the known or given initial value of $V(x,t)$ in the MILW equation. We will assume that $V(x,0)$ is a sufficiently smooth real-valued function of x and that $V(x,0)$ and its first few derivatives tend to zero as $x \to \pm\infty$ and $\int_{-\infty}^{\infty} V(x,0)\mathrm{d}x$ converges absolutely. Equation (2.11) maps $V(x,0)$ into the complex-valued function $U(x,0)$, where

$$U(x,0) := \tfrac{1}{2}\{\mathbf{T}(V_x(x,0)) + \beta(e^{V(x,0)} - 1) + iV_x(x,0)\}. \tag{2.12}$$

This function $U(x,0)$, which will be the initial value of $U(x,t)$ in the complex-valued ILW equation, can be considered known because $V(x,0)$ has been specified. As a consequence of Eq. (A4) and the boundary conditions on $V(x,0)$, we have $U(x,0) \to 0$ as $|x| \to \infty$ and $\int_{-\infty}^{\infty} U(x,0)\mathrm{d}x$ is absolutely convergent. Equating imaginary parts on each side of Eq. (2.11), we obtain the important equation,

$$V_x(x,t) = 2\,\mathrm{Im}\{U(x,t)\}, \tag{2.13}$$

for $t \geqslant 0$.

We can solve the initial value problem for $U(x,t)$ by appropriately extending the IST for the real-valued ILW equation derived by Kodama, Ablowitz, and Satsuma (KAS)[19] to take account of the initial value given by Eq. (2.12). As soon as $U(x,t)$ is known, we then proceed to determine

$V_x(x,t)$ from Eq. (2.13), and thence $V(x,t)$ itself by a quadrature with respect to x. An arbitrary function of integration that remains in the formula for $V(x,t)$ will be determined by the boundary conditions on $V(x,t)$. The last stage of our solution scheme for Eq. (2.6) uses the equation,

$$\mathrm{Re}\{U(x,t)\} = \tfrac{1}{2}\{\mathbf{T}(V_x) + \beta(e^V - 1)\}, \tag{2.14}$$

to connect all parameters that originate from the IST (for the complex-valued ILW equation) to the fundamental parameter β in Eq. (2.6). Equation (2.14) is formed when we equate real parts on each side of Eq. (2.11).

The simplest conserved quantity for the ILW equation is

$$L := \frac{1}{2\delta}\int_{-\infty}^{\infty} U(x,t)\mathrm{d}x. \tag{2.15}$$

It is independent of time t on account of Eq. (1.5) and its boundary condition. But when $U(x,t)$ is the complex-valued function on the left-hand side of Eq. (2.11), the constant L is real on account of the boundary condition on $V(x,t)$.

Multisoliton solutions of Eq. (2.8) have been derived by Nakamura[28] by the use of Hirota's method.[34,35] These, of course, translate across to our version of the MILW equation (2.6). Suitable modifications of results contained in Refs. 28 and 36 lead to the one-soliton solution,

$$V(x,t) = \log\left(\frac{\cosh[\kappa(x-\varphi t - x_0)] + \cos(\kappa\delta - \gamma)}{\cosh[\kappa(x-\varphi t - x_0)] + \cos(\kappa\delta + \gamma)}\right), \tag{2.16}$$

where κ, x_0, and γ are arbitrary real parameters with $0 < \kappa < \pi/\delta$ and

$$\varphi = \delta^{-1} - \kappa\cot(\kappa\delta). \tag{2.17}$$

The parameter β in the MILW equation is

$$\beta = \frac{\kappa\sin(\kappa\delta + \gamma)}{\sin\kappa\delta\sin\gamma}. \tag{2.18}$$

In Sec. VII, we will derive this result from the IST and substitute it directly into the MILW equation with the aid of the **T** transform formulas in Appendix B. We will also construct the two-soliton and two-breather solutions from the IST.

The shallow-water limit of the one-soliton solution can be obtained from Eq. (2.7). With $\kappa = O(1)$ as $\delta \to 0^+$, we get $\varphi = \kappa^2\delta/3 + O(\delta^3)$. The limiting form of β given by Eq. (2.7) requires that $\gamma = \pm\pi/2 + O(\delta)$. Then with $\kappa = \kappa'/2$ and $x_0 = 2x_0'$, the shallow-water limit of Eq. (2.16) becomes

$$\nu(x',t') = \pm\frac{\kappa'}{\cosh\kappa'(x' - \kappa'^2 t' - x_0')}, \tag{2.19}$$

which is the one-soliton solution of the MKdV equation Eq. (1.3).

To get the deep-water limit $\delta \to \infty$ of Eq. (2.16), let $\kappa = \pi/\delta - \pi/(\lambda\delta^2)$ and $\gamma = \pi y_0/\delta$. The limiting solution is

$$Q(x,t) = \log\left(\frac{\lambda^2(x - \lambda t - x_0)^2 + (1 + \lambda y_0)^2}{\lambda^2(x - \lambda t - x_0)^2 + (1 - \lambda y_0)^2}\right), \tag{2.20}$$

which is the one-soliton solution of the MBO equation Eq. (1.11) with $\alpha = y_0^{-1} - \lambda$.

We would like to close this section by noting that the technique whereby one solves a nonlinear evolution equation by first solving an auxiliary complexified equation, and then using this solution to invert an appropriate Miura-type transformation is not new. The method was first employed by Wadati[37] to solve the Gardner equation.[8] A more traditional approach would be to solve the direct and inverse problems for a suitable set of linear scattering equations for the MILW

equation itself. The only such set that we are aware of are those given by Satsuma *et al.*[27] However, they can be seen by inspection to be gauge equivalent to the scattering equations that we study in the following sections, and so they are really scattering equations for the complexified ILW equation rather than the MILW equation.

III. JOST FUNCTIONS AND THE DIRECT PROBLEM

The initial value problem for the real-valued ILW equation has been solved by the IST developed by KAS.[18,19] A feature of this particular IST is that the solution of the associated inverse problem does not immediately produce a formula for $U(x,t)$, but the auxiliary function,

$$U^{+}(x,t) := \tfrac{1}{2}(\mathbf{I} - i\mathbf{T})U(x,t), \tag{3.1}$$

where $\mathbf{I}$ denotes the identity operator. In fact, both their left and right scattering problems lead to $U^{+}(x,t)$. But because KAS were working in the domain of real variables, they could recover $U(x,t)$ just by taking real parts. With a star (*) denoting complex conjugation, the result can be written,

$$U(x,t) = U^{+}(x,t) + \{U^{+}(x,t)\}^{*}.$$

As we mentioned in Sec. II, our $U(x,t)$ is an intrinsically complex-valued function because it evolves from Eq. (2.12). Therefore, we cannot retrieve the physical variable by such a simple device as taking real parts. Instead, we must construct separate formulas for $U^{+}(x,t)$ and $U^{-}(x,t)$, where

$$U^{\pm}(x,t) := \tfrac{1}{2}(\pm\mathbf{I} - i\mathbf{T})U(x,t), \tag{3.2}$$

before we can build $U(x,t)$ according to

$$U(x,t) = U^{+}(x,t) - U^{-}(x,t). \tag{3.3}$$

Separate equations that each express $U^{+}(x,t)$ and $U^{-}(x,t)$ in terms of appropriate scattering data can be derived through the suitable inclusion of an *indicator* in the linear scattering problem for the real-valued ILW equation. We will use the symbol ϵ, whose permissible values are

$$\epsilon = \pm 1,$$

to denote the necessary indicator. Except for this indicator we will attempt to keep the notation reasonably close to the original papers of KAS (Refs. 18 and 19) and Santini *et al.*[38]

The correct inclusion of ϵ into the linear scattering problem associated with the ILW equation results in the overdetermined system,

$$\psi_{x}^{+\epsilon} = \epsilon i(U-\mu)\psi^{+\epsilon} - \epsilon i\nu\,\psi^{-\epsilon}, \tag{3.4}$$

$$\psi_{t}^{\pm\epsilon} = \epsilon i\psi_{xx}^{\pm\epsilon} - 2\left(\mu + \frac{1}{2\delta}\right)\psi_{x}^{\pm\epsilon} + \{\pm U_{x} - \epsilon i\mathbf{T}(U_{x}) + \Omega\}\psi^{\pm\epsilon}, \tag{3.5}$$

where $\psi=\psi(x,t)$, U is the complex-valued function defined by Eq. (2.11), and μ, ν, and Ω are constants to be made more precise later. Equation (1.5) is produced from the compatibility condition, $\psi_{xt}^{+\epsilon}=\psi_{tx}^{+\epsilon}$.

The functions $\psi^{\pm\epsilon}$ denote continuous boundary values on the real axis of functions that are analytic in the horizontal strips between $\mathrm{Im}(z)=0$ and $\mathrm{Im}(z)=\pm 2\epsilon\delta$ in the complex z plane, where $z=x+iy$ defines the complex extension of x. The functions $\psi^{\pm\epsilon}(x)$ (with the argument t temporarily suppressed in this section and Secs. IV and VI) are connected by the periodicity condition,[18]

$$\psi^{-\epsilon}(x) = \psi^{+\epsilon}(x + 2\epsilon i\delta), \tag{3.6}$$

which prompts the definition,

$$\psi^{\epsilon}(x) := \psi^{\pm\epsilon}(x \pm \epsilon i\delta), \tag{3.7}$$

for an appropriate function $\psi^{\epsilon}(x)$. The reader is warned of a possible source of confusion in this notation. The symbol $\psi^{+\epsilon}$, for example, has two separate and independent indicators attached, the first indicator being inherited from the notation of KAS.[19] Alternative symbols that we could use are $\psi^{+,\epsilon}$ or $\psi^{+}(\ ;\epsilon)$. If we were to change the sign of ϵ, $\psi^{+\epsilon}$ would become $\psi^{+,-\epsilon}$, not $\psi^{-\epsilon}$.

We now begin our analysis of the direct problem for Eq. (3.4). Let λ denote the necessary spectral parameter, which will start off as a real nonzero parameter but will be extended into the complex domain at a later stage. It appears through the boundary conditions,

$$\psi^{\epsilon}(x;\lambda) \sim \exp\left(\pm\tfrac{1}{2}\epsilon i\lambda x\right) \quad \text{as } x \to \pm\infty, \tag{3.8}$$

where Eq. (3.7) contains the relation connecting $\psi^{\epsilon}(x)$ and the eigenfunctions $\psi^{\pm\epsilon}(x)$. The boundary conditions given by Eq. (3.8) induce the following parametrizations for the quantities μ and ν in Eq. (3.4):

$$\mu = \mu(\lambda) = -\tfrac{1}{2}\lambda \coth(\delta\lambda), \tag{3.9}$$

$$\nu = \nu(\lambda) = \tfrac{1}{2}\lambda \operatorname{cosech}(\delta\lambda). \tag{3.10}$$

Let $m^{+\epsilon}(x;\lambda)$ and $\bar{m}^{+\epsilon}(x;\lambda)$ denote the left-hand Jost functions for Eq. (3.4), and let $n^{+\epsilon}(x;\lambda)$ and $\bar{n}^{+\epsilon}(x;\lambda)$ denote the right-hand Jost functions. The Jost functions satisfy Eq. (3.4), are $(+\epsilon)$ functions in x, and possess the large x asymptotics,

$$m^{+\epsilon}(x;\lambda) \sim \exp\left\{-\tfrac{1}{2}\epsilon i\lambda(x-\epsilon i\delta)\right\}, \quad \bar{m}^{+\epsilon}(x;\lambda) \sim \exp\left\{\tfrac{1}{2}\epsilon i\lambda(x-\epsilon i\delta)\right\}, \tag{3.11}$$

as $x \to -\infty$, and

$$n^{+\epsilon}(x;\lambda) \sim \exp\left\{\tfrac{1}{2}\epsilon i\lambda(x-\epsilon i\delta)\right\}, \quad \bar{n}^{+\epsilon}(x;\lambda) \sim \exp\left\{-\tfrac{1}{2}\epsilon i\lambda(x-\epsilon i\delta)\right\}, \tag{3.12}$$

as $x \to +\infty$. The same asymptotics apply in the strips of analyticity adjacent to the real x axis. The following remarks will clarify several issues about these Jost functions:

(i) The bars on m and n do not denote complex conjugation. Thus m^{+} and $\bar{m}^{+}$, for example, denote distinct functions. Complex conjugation will be denoted by a star (*).

(ii) The Jost functions $m^{+\epsilon}$ and $m^{-\epsilon}$ have two separate indicators attached, as outlined in the text after Eq. (3.7). They are related to each other by the vertical periodicity property Eq. (3.6).

(iii) The phrase "$(+\epsilon)$ function in x" (respectively, $-\epsilon$) refers to a function of the real variable x that can be analytically continued into the horizontal strip between $\mathrm{Im}(z)=0$ and $\mathrm{Im}(z)=2\epsilon\delta$ (respectively, $-2\epsilon\delta$) in the complex z plane, where $z=x+iy$, with the function being continuous onto both edges of the strip.

Our analysis of the direct problem for Eq. (3.4) will proceed efficiently if we work with the modified eigenfunctions $\Psi^{\pm\epsilon}(x;\lambda)$, where

$$\Psi^{\pm\epsilon}(x;\lambda) := \psi^{\pm\epsilon}(x;\lambda)\exp\left\{\tfrac{1}{2}\epsilon i\lambda(x \mp \epsilon i\delta)\right\}. \tag{3.13}$$

An important property of the modified eigenfunctions is the vertical periodicity condition,

$$\Psi^{-\epsilon}(x;\lambda) = \Psi^{+\epsilon}(x+2\epsilon i\delta;\lambda), \tag{3.14}$$

which has the same shape as Eq. (3.6). Appropriate use of Eq. (3.13) to express Eqs. (3.4) and (3.5) in terms of $\Psi^{\pm\epsilon}(x;\lambda)$ leads to the system,

$$\epsilon i\Psi_x^{+\epsilon} + \left(\zeta_+(\lambda) + \frac{1}{2\delta}\right)(\Psi^{+\epsilon} - \Psi^{-\epsilon}) = -U\Psi^{+\epsilon}, \tag{3.15}$$

$$\Psi_t^{\pm\epsilon} = \epsilon i\Psi_{xx}^{\pm\epsilon} + 2\zeta_+(\lambda)\Psi_x^{\pm\epsilon} + \{\pm U_x - \epsilon i\mathbf{T}(U_x) + \Gamma\}\Psi^{\pm\epsilon}, \tag{3.16}$$

where $\Gamma := \Omega + \epsilon i\lambda\{\frac{1}{4}\lambda - \zeta_+(\lambda)\}$ and $\zeta_+(\lambda)$ is defined by

$$\zeta_+(\lambda) := \frac{1}{2}\lambda(1 + \coth\,\delta\lambda) - \frac{1}{2\delta} = \frac{\lambda e^{\delta\lambda}}{2\sinh\,\delta\lambda} - \frac{1}{2\delta}. \tag{3.17}$$

Later, we will also need the notation $\zeta_-(\lambda)$, both cases being contained in the definition,

$$\zeta_\epsilon(\lambda) := \frac{1}{2}\lambda(1 + \epsilon\coth\,\delta\lambda) - \frac{\epsilon}{2\delta} = \frac{\epsilon\lambda e^{\epsilon\delta\lambda}}{2\sinh\,\delta\lambda} - \frac{\epsilon}{2\delta}. \tag{3.18}$$

It will be convenient to have the following elementary identities on hand:

$$\zeta_\epsilon(\lambda) + \zeta_{-\epsilon}(\lambda) = \lambda,$$

$$\zeta_\epsilon(-\lambda) = -\zeta_{-\epsilon}(\lambda),$$

$$\left(\zeta_\epsilon(\lambda) + \frac{\epsilon}{2\delta}\right)e^{-2\epsilon\delta\lambda} = \frac{\epsilon}{2\delta} - \zeta_{-\epsilon}(\lambda),$$

$$\dot{\zeta}_\epsilon(\lambda) = \delta e^{\epsilon\delta\lambda}\,\mathrm{cosech}(\delta\lambda)\zeta_{-\epsilon}(\lambda).$$

As a consequence of the transition to modified eigenfunctions, our spectral parameter λ can be replaced by $\zeta_+ := \zeta_+(\lambda)$. In the real domain, this will be straightforward because $\zeta_+(\lambda)$ is a strictly increasing function of λ with range $(-1/(2\delta), +\infty)$. But because $\zeta_+(\lambda)$ has a somewhat complicated inverse in the complex domain, which is discussed below, we will need to keep using both λ and ζ_+ according to convenience.

The asymptotics of the modified Jost functions are

$$M^{+\epsilon}(x;\lambda) \sim 1, \quad \bar{M}^{+\epsilon}(x;\lambda) \sim \exp\{\epsilon i\lambda(x - \epsilon i\delta)\}, \tag{3.19}$$

as $x \to -\infty$ and

$$N^{+\epsilon}(x;\lambda) \sim \exp\{\epsilon i\lambda(x - \epsilon i\delta)\}, \quad \bar{N}^{+\epsilon}(x;\lambda) \sim 1, \tag{3.20}$$

as $x \to +\infty$, where

$$M^{+\epsilon}(x;\lambda) := m^{+\epsilon}(x;\lambda)\exp\left\{\tfrac{1}{2}\epsilon i\lambda(x - \epsilon i\delta)\right\},$$

and similarly for the other three Jost functions. Each of the modified (uppercase) Jost functions is a $(+\epsilon)$ function in x and satisfies the system of Eqs. (3.15) and (3.16). Thereafter, the $(-\epsilon)$ version of each modified Jost function can be constructed using Eq. (3.14).

The analytic properties of the (modified) Jost functions as functions of λ or ζ_+ are essential to our analysis of the direct problem for Eq. (3.15). Unless stated otherwise, in the remainder of this section, any reference to analyticity will be with respect to either λ or ζ_+ in domains to be specified later. The integral equation,

$$\Psi^{+\epsilon}(x;\lambda) = \Psi_0^{+\epsilon}(x;\lambda) + \int_{-\infty}^{\infty} G^\epsilon(x,\eta;\lambda)U(\eta)\Psi^{+\epsilon}(\eta;\lambda)\mathrm{d}\eta, \tag{3.21}$$

is the key to the analytic character of the Jost functions. The function $\Psi_0^{+\epsilon}(x;\lambda)$ denotes a homogeneous solution of Eq. (3.15), namely, a solution of Eq. (3.15) when $U \equiv 0$, and the Green's function $G^\epsilon(x,\eta;\lambda)$ is a $(+\epsilon)$ function in x that satisfies the periodicity condition (3.14) and the differential equation,

$$\epsilon i G_x^{\epsilon} + \left(\zeta_+(\lambda) + \frac{1}{2\delta}\right)(G^{\epsilon} - G^{-\varepsilon}) = -\delta(x-\eta), \tag{3.22}$$

where $G^{\epsilon}=G^{\epsilon}(x,\eta;\lambda)$, $G^{-\epsilon}=G^{\epsilon}(x+2\epsilon i\delta,\eta;\lambda)$, and $\delta(\ )$ denotes the Dirac delta function.

A Fourier integral representation of the Green's function $G^{\epsilon}(x,\eta;\lambda)$ is

$$G^{\epsilon}(x,\eta;\lambda) = \frac{1}{2\pi}\int_C \hat{g}(r;\lambda)e^{i(x-\eta)r}\,\mathrm{d}r, \tag{3.23}$$

where C denotes a suitable infinite horizontal line in the complex r plane and

$$\hat{g}(r;\lambda) := \frac{1+\epsilon\coth\delta r}{2(\epsilon\zeta_{\epsilon}(r)-\zeta_+(\lambda))}. \tag{3.24}$$

The function $\hat{g}(r;\lambda)$ has a straightforward pole structure in the complex r plane when the parameter λ is real. The symmetries,

$$\{\hat{g}(r;\lambda)\}^* = \hat{g}(r^*;\lambda), \quad \hat{g}(-r;\lambda,-\epsilon) = \hat{g}(r;\lambda,\epsilon),$$

allow us to focus on those poles of $\hat{g}(r;\lambda)$ for which $\mathrm{Im}(r)\geqslant 0$. Let $r=r_n(\lambda;\epsilon)$, where $\mathrm{Im}(r_n)>0$ and $n=1,2,3,\ldots$, be a solution of the equation,

$$\epsilon\zeta_{\epsilon}(r) - \zeta_+(\lambda) = 0. \tag{3.25}$$

Equation (3.25) has a countable infinity of solutions because of the multivalued inverse of $\zeta_{\epsilon}(r)$. A straightforward application of the argument principle to the denominator of Eq. (3.24) localizes the simple pole r_n to the horizontal strip,

$$\frac{\pi n}{\delta} < \mathrm{Im}(r_n) < \frac{\pi(2n+1)}{2\delta}, \tag{3.26}$$

for all $n\geqslant 1$. For large n, the asymptotic location of the nth pole is

$$r_n = \frac{(4n+1)i\pi}{4\delta} - \frac{\epsilon}{2\delta}\left\{\log\left(\frac{\pi n}{\delta}\right) - \log\left(\zeta_+(\lambda)+\frac{1}{2\delta}\right)\right\} + O\left(\frac{\log n}{n}\right).$$

In the strip $-\pi/\delta\leqslant \mathrm{Im}(r)\leqslant \pi/\delta$, there are exactly two poles of $\hat{g}(r;\lambda)$, counting multiplicity. These are both real and are located at

$$r_0 = \epsilon\lambda, \quad r_{-1} = 0,$$

in the notation of KAS.[19] If $\lambda=0$, these two poles coincide to form a double pole. There are also a countable infinity of complex values of λ, namely, the roots of $\zeta_-(\lambda)=0$, such that $\hat{g}(r;\lambda)$ has a double pole in r.

This is an appropriate time to discuss the conformal mapping $\lambda\to\zeta_+(\lambda)$ between the complex variables λ and ζ_+. This conformal mapping maps the complex λ plane to a multisheeted covering of the complex ζ_+ plane. The principal ζ_+ sheet is the one where the real interval $-1/(2\delta)<\zeta_+<+\infty$ is the image of the real λ axis. The point $\zeta_+=-1/(2\delta)$ is a logarithmic branch point of the inverse function $\lambda^{-1}(\zeta_+)$. Hence, the principal sheet has a branch cut along the real interval $-\infty<\zeta_+\leqslant -1/(2\delta)$. The inverse function also has quadratic branch points at the complex zeros of $\mathrm{d}\zeta_+/\mathrm{d}\lambda=\delta e^{\delta\lambda}\zeta_-(\lambda)/\sinh(\delta\lambda)$. On the principal sheet, these occur at $\zeta_+=\zeta_0^{\pm}$, where

$$\zeta_0^{\epsilon} := \delta^{-1}(1.044\,421\,5078 + \epsilon i 3.730\,744\,6428),$$

to 10 decimal places. The corresponding points in the complex λ plane are exactly the same because $\zeta_+(\zeta_0^{\epsilon})=\zeta_0^{\epsilon}-\zeta_-(\zeta_0^{\epsilon})=\zeta_0^{\epsilon}$. Let the branch cuts in the complex ζ_+ plane run horizontally to the right from $\zeta_0^{\pm}$ to $+\infty+\zeta_0^{\pm}$. The inverse image of the principal sheet is a region in the complex λ

plane that is symmetrically placed about the real axis. (This is the region denoted A in Fig. 1 of Ref. 19.) Its upper boundary consists of three curved pieces joined end to end. The first piece runs from $\lambda=-\infty+i\pi/(2\delta)$ to the pole at $i\pi/\delta$ and is the inverse image of the upper edge of the branch cut running from $\zeta_+=-1/(2\delta)$ to $-\infty$. The second piece runs from $\lambda=i\pi/\delta$ to ζ_0^+ and is the inverse image of the upper edge of the branch cut running from $\zeta_+=+\infty+\zeta_0^+$ to ζ_0^+. The third piece runs from $\lambda=\zeta_0^+$ to $+\infty+\zeta_0^+$ and is the inverse image of the lower edge of the same branch cut running in the opposite sense. Denote the region of the complex λ plane between the real axis and the upper boundary D^+ and the corresponding region in the lower half-plane D^-, and let the curved boundaries be included to the right-hand side of the points $\pm i\pi/\delta$.

A function of λ or ζ_+ whose domain covers the region D^ϵ will be denoted a $(+\epsilon)$ function in either λ or ζ_+ if it is analytic throughout the $(+\epsilon)$ half of the complex ζ_+ plane, which is the half-plane $\mathrm{Im}(\epsilon\zeta_+)>0$, and continuous onto the real interval $-1/(2\delta)<\zeta_+<+\infty$. The important point is that such a function cannot have a quadratic branch point at $\zeta_+=\zeta_0^\epsilon$. Generic entire or meromorphic functions of λ will fail this analyticity test, examples being λ itself, $e^{\pm i\lambda x}$, $\sinh(\delta\lambda)$, and $\zeta_-(\lambda)$. A necessary, but far from sufficient, condition for $f(\lambda)$ to be a $(+\epsilon)$ function in λ is $f'(\zeta_0^\epsilon)=0$.

If $\eta\neq x$, the integral in Eq. (3.23) can be evaluated by summing residues in an appropriate half of the complex r plane (according to Jordan's lemma applied to a semicircular contour of large radius passing between consecutive poles of the integrand). The correct half-plane is the upper half-plane when $\eta<x$ and the lower half-plane when $\eta>x$. The integral diverges logarithmically when $\eta=x$, but this will become an integrable singularity when the Green's function later appears inside an integral with respect to η. It is worth noting that the r_n (which depend on λ and ϵ) are above D^+ and the r_n^* are below D^- whenever λ resides anywhere in $D^\pm$ or the real axis.

An important issue in relation to Eq. (3.23) concerns the choice of the contour C. Poles on the real axis at $r_{-1}=0$ and $r_0=\epsilon\lambda$ (or a double pole when $\lambda=0$) dictate two distinct choices for C, and so we will obtain two distinct Green's functions. Use the notation $C_\pm$ for the horizontal line running from $-\infty\pm i0^+$ to $+\infty\pm i0^+$. The choice $C=C_+$ in Eq. (3.23) leads to the Green's function,

$$G_{-\epsilon}^\epsilon(x,\eta;\lambda)=\frac{\epsilon i}{2\delta}\theta(\eta-x)\left\{\frac{1}{\zeta_+(\lambda)}-\frac{e^{\epsilon i(x-\eta)\lambda}}{\zeta_-(\lambda)}-\epsilon\sum_{n=1}^{\infty}\frac{e^{i(x-\eta)r_n^*}}{r_n^*-\epsilon\zeta_+(\lambda)}\right\}+\frac{i}{2\delta}\theta(x-\eta)\sum_{n=1}^{\infty}\frac{e^{i(x-\eta)r_n}}{r_n-\epsilon\zeta_+(\lambda)},\tag{3.27}$$

$\eta\neq x$, where, for $x\neq 0$, $\theta(x)$ is the Heaviside step function,

$$\theta(x)=\begin{cases}1, & x>0,\\ 0, & x<0.\end{cases}$$

The alternative contour $C=C_-$ gives the Green's function,

$$G_\epsilon^\epsilon(x,\eta;\lambda)=G_{-\epsilon}^\epsilon(x,\eta;\lambda)+\frac{\epsilon i}{2\delta}\left(\frac{e^{\epsilon i(x-\eta)\lambda}}{\zeta_-(\lambda)}-\frac{1}{\zeta_+(\lambda)}\right).\tag{3.28}$$

In the remainder of this paper, superscripts attached to the Green's and Jost functions will continue to indicate analytic character with respect to x as above, whereas subscripts attached to these functions will designate analytic character with respect to λ or ζ_+, in cases when x and λ can be extended into the complex domain. The subscript ϵ denotes a $(+\epsilon)$ function in λ or ζ_+ as discussed above, and such functions must be free of the quadratic branch point at $\zeta_+=\zeta_0^\epsilon$ when written as functions of ζ_+. The analytic character of the Green's functions with respect to ζ_+ can be seen from the integral formulas,

$$G_\epsilon^\epsilon(x,\eta;\lambda)=\frac{1}{4\pi}\int_{C_{-\epsilon}}\frac{1+\coth\,\delta r}{\zeta_+(r)-\zeta_+(\lambda)}e^{\epsilon i(x-\eta)r}\,\mathrm{d}r,\tag{3.29}$$

$$G^{\epsilon}_{-\epsilon}(x,\eta;\lambda)=\frac{1}{4\pi}\int_{C_\epsilon}\frac{1+\coth\,\delta r}{\zeta_+(r)-\zeta_+(\lambda)}e^{\epsilon i(x-\eta)r}\,\mathrm{d}r, \tag{3.30}$$

which can be obtained from Eq. (3.23) by the substitution $r\to\epsilon r$. In the case of real λ, the replacement $\lambda\to-\lambda$ followed by the substitution $r\to r-\lambda$ in the integrals gives the useful reflection formulas,

$$G^{\epsilon}_{\epsilon}(x,\eta;-\lambda)=e^{-\epsilon i\lambda(x-\eta)}G^{\epsilon}_{\epsilon}(x,\eta;\lambda), \tag{3.31}$$

$$G^{\epsilon}_{-\epsilon}(x,\eta;-\lambda)=e^{-\epsilon i\lambda(x-\eta)}G^{\epsilon}_{-\epsilon}(x,\eta;\lambda). \tag{3.32}$$

The boundary conditions given by Eqs. (3.19) and (3.20) provide a means by which we can assign $G^{\epsilon}_{\pm\epsilon}(x,\eta;\lambda)$ to the kernel of Eq. (3.21). Preservation of Eqs. (3.19) and (3.20) leads to the following inhomogeneous Fredholm integral equations of the second kind,

$$\begin{pmatrix}M^{+\epsilon}(x;\lambda)\\ \bar{M}^{+\epsilon}(x;\lambda)\end{pmatrix}=\begin{pmatrix}1\\ \exp(\epsilon i\lambda(x-\epsilon i\delta))\end{pmatrix}+\int_{-\infty}^{\infty}G^{\epsilon}_{\epsilon}(x,\eta;\lambda)U(\eta)\begin{pmatrix}M^{+\epsilon}(\eta;\lambda)\\ \bar{M}^{+\epsilon}(\eta;\lambda)\end{pmatrix}\mathrm{d}\eta, \tag{3.33}$$

$$\begin{pmatrix}N^{+\epsilon}(x;\lambda)\\ \bar{N}^{+\epsilon}(x;\lambda)\end{pmatrix}=\begin{pmatrix}\exp(\epsilon i\lambda(x-\epsilon i\delta))\\ 1\end{pmatrix}+\int_{-\infty}^{\infty}G^{\epsilon}_{-\epsilon}(x,\eta;\lambda)U(\eta)\begin{pmatrix}N^{+\epsilon}(\eta;\lambda)\\ \bar{N}^{+\epsilon}(\eta;\lambda)\end{pmatrix}\mathrm{d}\eta. \tag{3.34}$$

Fredholm's second theorem,[39] when applied to Eqs. (3.33) and (3.34), allows us to conclude that $M^{+\epsilon}(x;\lambda)$, as a function of ζ_+, can be analytically continued to the half-plane $\mathrm{Im}(\epsilon\zeta_+)>0$ and $\bar{N}^{+\epsilon}(x;\lambda)$ can be continued to the half-plane $\mathrm{Im}(\epsilon\zeta_+)<0$. Hence, our conventions allow us to expand the notation as follows:

$$M^{+\epsilon}(x;\lambda)=M^{+\epsilon}_{\epsilon}(x;\lambda),\quad \bar{N}^{+\epsilon}(x;\lambda)=\bar{N}^{+\epsilon}_{-\epsilon}(x;\lambda).$$

The corresponding analytic character of the other two Jost functions is discussed in the next paragraph.

The reflection formulas Eqs. (3.31) and (3.32) for the Green's functions have immediate consequences for the Jost functions. The functions,

$$M^{+\epsilon}_{\epsilon}(x;-\lambda),\quad e^{-\epsilon i\lambda(x-\epsilon i\delta)}\bar{M}^{+\epsilon}(x;\lambda),$$

satisfy the same Fredholm equation. We take as a working hypothesis that the solutions of these Fredholm equations are unique, or, equivalently, that the corresponding homogeneous equations have no nontrivial solutions. Hence we obtain the connection formula,

$$M^{+\epsilon}_{\epsilon}(x;-\lambda)=\bar{M}^{+\epsilon}(x;\lambda)e^{-\epsilon i\lambda(x-\epsilon i\delta)}. \tag{3.35}$$

An identical argument produces the connection formula,

$$\bar{N}^{+\epsilon}_{-\epsilon}(x;-\lambda)=N^{+\epsilon}(x;\lambda)e^{-\epsilon i\lambda(x-\epsilon i\delta)}. \tag{3.36}$$

These play a vital role in Sec. VI. We derived them for real λ but they obviously analytically continue off the real axis. For example, $N^{+\epsilon}(x;\lambda)$ analytically continues into the $(+\epsilon)$ half of the complex ζ_+ plane but fails the analyticity test at $\zeta_+=\zeta_0^{\epsilon}$, having a quadratic branch point there. A similar comment applies to $\bar{M}^{+\epsilon}(x;\lambda)$ in the opposite half-plane.

Linear independence of $N^{+\epsilon}$ and $\bar{N}^{+\epsilon}_{-\epsilon}$ for real $\lambda\neq0$ leads to the identity,

$$M^{+\epsilon}_{\epsilon}(x;\lambda)=A(\lambda)\bar{N}^{+\epsilon}_{-\epsilon}(x;\lambda)+B(\lambda)N^{+\epsilon}(x;\lambda), \tag{3.37}$$

where $A(\lambda)$ and $B(\lambda)$ are defined through the functionals,

$$A(\lambda) = 1 - \frac{\epsilon i}{2\delta\zeta_+(\lambda)} \int_{-\infty}^{\infty} U(\eta) M_\epsilon^{+\epsilon}(\eta;\lambda) \mathrm{d}\eta, \tag{3.38}$$

$$B(\lambda) = \frac{\epsilon i}{2\delta\zeta_-(\lambda)} \int_{-\infty}^{\infty} U(\eta) M_\epsilon^{+\epsilon}(\eta;\lambda) e^{-\epsilon i\lambda(\eta-\epsilon i\delta)} \mathrm{d}\eta. \tag{3.39}$$

Equation (3.37) provides asymptotics for $M_\epsilon^{+\epsilon}(x;\lambda)$ as $x \to +\infty$, which supplements the limit $M_\epsilon^{+\epsilon}(x;\lambda) \to 1$ as $x \to -\infty$ given by Eq. (3.19).

To prove Eqs. (3.37)–(3.39), substitute Eq. (3.28) into Eq. (3.33), and then integrate term by term to obtain the equation

$$M_\epsilon^{+\epsilon}(x;\lambda) = 1 + \int_{-\infty}^{\infty} \tilde{M}(\eta;\lambda) \left\{ G_{-\epsilon}^{\epsilon}(x,\eta;\lambda) - \frac{\epsilon}{2\delta\zeta_+(\lambda)} + \frac{\epsilon i e^{\epsilon i\lambda(x-\eta)}}{2\delta\zeta_-(\lambda)} \right\} \mathrm{d}\eta, \tag{3.40}$$

where $\tilde{M}(\eta;\lambda) := U(\eta) M_\epsilon^{+\epsilon}(\eta;\lambda)$. Using Eq. (3.34) to replace $\bar{N}_{-\epsilon}^{+\epsilon}(x;\lambda)$ and $N^{+\epsilon}(x;\lambda)$ in Eq. (3.37), we obtain

$$M_\epsilon^{+\epsilon}(x;\lambda) = A(\lambda) + B(\lambda) e^{\epsilon i\lambda(x-\epsilon i\delta)} + \int_{-\infty}^{\infty} G_{-\epsilon}^{\epsilon}(x,\eta;\lambda) \tilde{M}(\eta;\lambda) \mathrm{d}\eta. \tag{3.41}$$

Equating (3.40) and (3.41) and then matching the coefficients of $\exp(\epsilon i\lambda x)$ on each side of the resultant identity, we arrive at Eqs. (3.38) and (3.39).

The functions $A(\lambda)$ and $B(\lambda)$, which depend on ϵ, are members of the continuous spectrum, and therefore we must ascertain their analytic character. From Eq. (3.38), we deduce that $A(\lambda)$ is a $(+\epsilon)$ function in λ, except for a possible simple pole at $\lambda=0$, but we will omit the subscript implied by this property except when we need to call attention to it. Analytic continuation of $B(\lambda)$ may be possible, but $B(\lambda)$ only plays a role in the inverse scattering when λ is real and for certain isolated nonreal values of λ for which the integral in Eq. (3.39) converges. The latter have relevance to the bound states below. In general, the integral in Eq. (3.39) diverges when λ is nonreal. If $A(\lambda)$ has a simple pole at $\lambda=0$, then the combinations $A(\lambda)+B(\lambda)$, $B(\lambda)/A(\lambda)$, and $A(\lambda)A(-\lambda)-B(\lambda)B(-\lambda)$ are nonsingular at $\lambda=0$ whenever $\int_{-\infty}^{\infty} xU(x)\mathrm{d}x$ converges absolutely.

In a similar fashion, linear independence of $M_\epsilon^{+\epsilon}$ and $\bar{M}^{+\epsilon}$ when λ is real and nonzero gives

$$\bar{N}_{-\epsilon}^{+\epsilon}(x;\lambda) = G(\lambda) M_\epsilon^{+\epsilon}(x;\lambda) + H(\lambda) \bar{M}^{+\epsilon}(x;\lambda), \tag{3.42}$$

where

$$G(\lambda) = 1 + \frac{\epsilon i}{2\delta\zeta_+(\lambda)} \int_{-\infty}^{\infty} U(\eta) \bar{N}_{-\epsilon}^{+\epsilon}(\eta;\lambda) \mathrm{d}\eta. \tag{3.43}$$

$$H(\lambda) = -\frac{\epsilon i}{2\delta\zeta_-(\lambda)} \int_{-\infty}^{\infty} U(\eta) \bar{N}_{-\epsilon}^{+\epsilon}(\eta;\lambda) e^{-\epsilon i\lambda(\eta-\epsilon i\delta)} \mathrm{d}\eta. \tag{3.44}$$

Equation (3.42) provides asymptotics for $\bar{N}_{-\epsilon}^{+\epsilon}(x;\lambda)$ as $x \to -\infty$. We now have enough information to construct the leading-term asymptotics as $\mathrm{Re}\, x \to \pm\infty$ of all four Jost functions in their strips of analyticity in x. The function $G(\lambda)$ is a $(-\epsilon)$ function in λ except for a possible simple pole at $\lambda=0$, whereas $H(\lambda)$ will only be needed for real λ and a finite number of isolated nonreal values. In the inverse scattering transform, the ratios,

$$R(\lambda) := \frac{B(\lambda)}{A(\lambda)}, \quad S(\lambda) := \frac{H(\lambda)}{G(\lambda)}, \tag{3.45}$$

play an important role and are known as reflection coefficients.

The four functions $A(\lambda)$, $B(\lambda)$, $G(\lambda)$, and $H(\lambda)$ of the real variable λ satisfy several identities. First, identities for argument $-\lambda$ can be deduced from the connection formulas (3.35) and (3.36). The results are

$$A(-\lambda) = -\frac{B(\lambda)G(\lambda)}{H(\lambda)}, \quad B(-\lambda) = \frac{1 - A(\lambda)G(\lambda)}{H(\lambda)}, \tag{3.46}$$

$$G(-\lambda) = -\frac{A(\lambda)H(\lambda)}{B(\lambda)}, \quad H(-\lambda) = \frac{1 - A(\lambda)G(\lambda)}{B(\lambda)}. \tag{3.47}$$

Additional identities involving the indicator $-\epsilon$ can be deduced from the differential equations (3.4) or (3.15). Let us work with lowercase Jost functions $m^{+\epsilon}$ and $\bar{n}^{+\epsilon}$, which satisfy Eq. (3.4). The relation to the corresponding uppercase functions is given by Eq. (3.14). Asymptotics for large positive and negative x can be deduced from Eqs. (3.11)–(3.13), (3.19), (3.20), (3.37), and (3.42).

Suppose $\psi_1^{+\epsilon}(x;\lambda_1)$ is one of these Jost functions and $\psi_2^{+,-\epsilon}(x;\lambda_2)$ is one with the sign of the indicator ϵ changed. Then Eqs. (3.4) and (3.6) imply

$$\psi_{1x}^{+\epsilon}(x;\lambda_1) = \epsilon i\{U(x) - \mu(\lambda_1)\}\psi_1^{+\epsilon}(x;\lambda_1) - \epsilon i\,\nu(\lambda_1)\psi_1^{+\epsilon}(x + 2\epsilon i\,\delta;\lambda_1), \tag{3.48}$$

$$\psi_{2x}^{+,-\epsilon}(x;\lambda_2) = -\epsilon i\{U(x) - \mu(\lambda_2)\}\psi_2^{+,-\epsilon}(x;\lambda_2) + \epsilon i\,\nu(\lambda_2)\psi_2^{+,-\epsilon}(x - 2\epsilon i\,\delta;\lambda_2). \tag{3.49}$$

Thence,

$$\begin{aligned}\epsilon i\frac{\partial}{\partial x}\{\psi_1^{+\epsilon}(x;\lambda_1)\psi_2^{+,-\epsilon}(x;\lambda_2)\} = {}& \{\mu(\lambda_1) - \mu(\lambda_2)\}\psi_1^{+\epsilon}(x;\lambda_1)\psi_2^{+,-\epsilon}(x;\lambda_2)\\ &+ \nu(\lambda_1)\psi_1^{+\epsilon}(x + 2\epsilon i\,\delta;\lambda_1)\psi_2^{+,-\epsilon}(x;\lambda_2)\\ &- \nu(\lambda_2)\psi_1^{+\epsilon}(x;\lambda_1)\psi_2^{+,-\epsilon}(x - 2\epsilon i\,\delta;\lambda_2).\end{aligned}$$

Integrate both sides with respect to x from $-R_1$ to R_2 where R_1 and R_2 are large positive numbers. The second to last and last terms on the right-hand side are, respectively, a $(-\epsilon)$ function in x and a $(+\epsilon)$ function in x, and so we can replace the definite integrals with contour integrals following three sides of a rectangle in their respective strips of analyticity as follows:

$$\int_{-R_1}^{R_2} = \int_{-R_1}^{-R_1-\epsilon i\,\delta} + \int_{-R_1-\epsilon i\,\delta}^{R_2-\epsilon i\,\delta} + \int_{R_2-\epsilon i\,\delta}^{R_2}, \quad \int_{-R_1}^{R_2} = \int_{-R_1}^{-R_1+\epsilon i\,\delta} + \int_{-R_1+\epsilon i\,\delta}^{R_2+\epsilon i\,\delta} + \int_{R_2+\epsilon i\,\delta}^{R_2}.$$

Thereafter, the results simplify with the help of Eq. (3.7). We obtain the result,

$$\begin{aligned}\epsilon i\left[\psi_1^{+\epsilon}(x;\lambda_1)\psi_2^{+,-\epsilon}(x;\lambda_2)\right]_{-R_1}^{R_2} = {}& \{\mu(\lambda_1) - \mu(\lambda_2)\}\int_{-R_1}^{R_2}\psi_1^{+\epsilon}(x;\lambda_1)\psi_2^{+,-\epsilon}(x;\lambda_2)\mathrm{d}x\\ &+ \{\nu(\lambda_1) - \nu(\lambda_2)\}\int_{-R_1}^{R_2}\psi_1^{\epsilon}(x;\lambda_1)\psi_2^{(-\epsilon)}(x;\lambda_2)\mathrm{d}x\\ &- \left\{\nu(\lambda_2)\int_{-R_1-\epsilon i\,\delta}^{-R_1} + \nu(\lambda_1)\int_{-R_1}^{-R_1+\epsilon i\,\delta} - \nu(\lambda_2)\int_{R_2-\epsilon i\,\delta}^{R_2} - \nu(\lambda_1)\int_{R_2}^{R_2+\epsilon i\,\delta}\right\}\\ &\psi_1^{\epsilon}(z;\lambda_1)\psi_2^{(-\epsilon)}(z;\lambda_2)\mathrm{d}z.\end{aligned} \tag{3.50}$$

Note that in all terms containing $\nu(\lambda_1)$ and $\nu(\lambda_2)$, the ψ functions appearing are of the type on the

left-hand side of Eq. (3.7). Because $\mu(\lambda)$ and $\nu(\lambda)$ are *even* functions of λ, a substantial simplification occurs in the two cases $\lambda_2 = \pm\lambda_1$. Then the last identity reduces to

$$\left[\psi_1^{+\epsilon}(x;\lambda)\psi_2^{+,-\epsilon}(x;\pm\lambda)\right]_{-R_1}^{R_2} = \epsilon i\nu(\lambda)\left\{\int_{-R_1-\epsilon i\delta}^{-R_1+\epsilon i\delta} - \int_{R_2-\epsilon i\delta}^{R_2+\epsilon i\delta}\right\}\psi_1^{\epsilon}(z;\lambda)\psi_2^{(-\epsilon)}(z;\pm\lambda)\mathrm{d}z, \tag{3.51}$$

which can be evaluated using asymptotic results alone.

With $+\lambda$ as the second argument of $\psi_2^{+,-\epsilon}$ and using the appropriate asymptotic formulas for $m^{+\epsilon}$ and $\bar{n}^{+\epsilon}$, we get the following four identities:

$$\zeta_+(\lambda)\{A(\lambda)A^{-\epsilon}(\lambda) - 1\} = e^{2\delta\lambda}\zeta_-(\lambda)B(\lambda)B^{-\epsilon}(\lambda), \tag{3.52}$$

$$\zeta_+(\lambda)\{G(\lambda)G^{-\epsilon}(\lambda) - 1\} = e^{2\delta\lambda}\zeta_-(\lambda)H(\lambda)H^{-\epsilon}(\lambda), \tag{3.53}$$

$$G^{-\epsilon}(\lambda) = A(\lambda), \tag{3.54}$$

$$A^{-\epsilon}(\lambda) = G(\lambda). \tag{3.55}$$

Here, $A^{-\epsilon}(\lambda)$ is the result of replacing ϵ with $-\epsilon$ throughout the right-hand side of Eq. (3.38), and similarly for the other functions with indicator $-\epsilon$ attached. Both sides of Eq. (3.54) are $(+\epsilon)$ functions in λ and both sides of Eq. (3.55) are $(-\epsilon)$ functions in λ. These analytic continuations are relevant to the bound states below.

With $-\lambda$ as the second argument of $\psi_2^{+,-\epsilon}$, we get

$$\zeta_+(\lambda)A(\lambda)B^{-\epsilon}(-\lambda) = e^{2\delta\lambda}\zeta_-(\lambda)B(\lambda)A^{-\epsilon}(-\lambda), \tag{3.56}$$

$$\zeta_+(\lambda)G(\lambda)H^{-\epsilon}(-\lambda) = e^{2\delta\lambda}\zeta_-(\lambda)H(\lambda)G^{-\epsilon}(-\lambda), \tag{3.57}$$

$$\zeta_+(\lambda)H^{-\epsilon}(-\lambda) = -e^{2\delta\lambda}\zeta_-(\lambda)B(\lambda), \tag{3.58}$$

$$\zeta_+(\lambda)B^{-\epsilon}(-\lambda) = -e^{2\delta\lambda}\zeta_-(\lambda)H(\lambda). \tag{3.59}$$

These identities allow 12 functions of the real variable λ to be written in terms of four others. They include the identities (3.46) and (3.47) above. In particular, we find

$$\{A(\lambda)A(-\lambda) - B(\lambda)B(-\lambda)\}\{A^{-\epsilon}(\lambda)A^{-\epsilon}(-\lambda) - B^{-\epsilon}(\lambda)B^{-\epsilon}(-\lambda)\} = 1,$$

which implies that $A(\lambda)A(-\lambda) - B(\lambda)B(-\lambda)$ cannot have any zeros on the real line (including $\lambda = 0$, which requires separate treatment). A further consequence is that $B(\lambda)$ and $H(\lambda)$ have the same real zeros, if any. Pure soliton solutions are characterized by $B(\lambda)$ vanishing identically on the real line. In that case, the above identities imply that $H(\lambda)$, $B^{-\epsilon}(\lambda)$, and $H^{-\epsilon}(\lambda)$ also vanish identically, which is of importance in the construction of MILW solitons.

Corresponding identities can be constructed in which the functions with indicator $-\epsilon$ are replaced by complex conjugates. These are less elegant because they contain the imaginary part of $U(x)$ inside definite integrals. The most interesting is the identity corresponding to Eq. (3.54) in which all functions appearing analytically extend to the $(+\epsilon)$ half of the complex ζ_+ plane. This identity is

$$2\delta\zeta_+(\lambda)\{(G(\lambda^*))^* - A(\lambda)\} = -\epsilon\int_{-\infty}^{\infty} V_x M_\epsilon^{+\epsilon}(x;\lambda)(\bar{N}_{-\epsilon}^{+\epsilon}(x;\lambda^*))^* \, dx, \tag{3.60}$$

where the factor V_x comes from Eq. (2.11). In the case of pure multisoliton solutions, we can calculate $A(\lambda)$ and $G(\lambda)$ explicitly (see Sec. VII), in which case we will see by inspection that the left-hand side of Eq. (3.60) vanishes.

IV. THE DISCRETE SPECTRUM

Our calculations have up to this point dealt exclusively with the continuous spectrum for Eq. (3.4). Discrete (complex) eigenvalues for Eq. (3.4) are also possible, leading to a finite number of bound states. While Eqs. (3.37) and (3.42) are not valid off the real λ axis, they survive as leading-term asymptotics in appropriate half-planes.

For the bound states, it is more natural to work with lowercase Jost functions. For $\mathrm{Im}(\epsilon\lambda) > 0$, $m^{+\epsilon}(x;\lambda)$ is locally analytic and has the asymptotic behavior,

$$m^{+\epsilon}(x;\lambda) \sim e^{-\epsilon i\lambda(x-\epsilon i\delta)/2} \quad \text{as } x \to -\infty, \tag{4.1}$$

$$m^{+\epsilon}(x;\lambda) \sim A(\lambda)e^{-\epsilon i\lambda(x-\epsilon i\delta)/2} \quad \text{as } x \to +\infty. \tag{4.2}$$

Thus, in general, $m^{+\epsilon}$ decays as $x \to -\infty$ and grows exponentially as $x \to +\infty$. The exceptional values of λ are the zeros of $A(\lambda)$, if any. Suppose there are q zeros of $A(\lambda)$ in the region D^ϵ of the complex λ plane, namely,

$$\lambda_1, \lambda_2, \ldots, \lambda_q,$$

and let $\zeta_{+j} := \zeta_+(\lambda_j)$. The λ_j are the discrete eigenvalues of Eq. (3.4) in the region D^ϵ and the ζ_{+j} are the corresponding discrete eigenvalues of Eq. (3.15) in the $(+\epsilon)$ half of the complex ζ_+ plane. The asymptotics of $m^{+\epsilon}(x;\lambda)$ as $x \to +\infty$ can be deduced from Eq. (3.28). By using the same argument that led to Eq. (3.37), we get the exact formula,

$$m^{+\epsilon}(x;\lambda_j) = B(\lambda_j)n^{+\epsilon}(x;\lambda_j), \tag{4.3}$$

where $B(\lambda_j)$ is defined by Eq. (3.39) with λ replaced by λ_j and $N^{+\epsilon}(x;\lambda_j)$ [the uppercase Jost function corresponding to $n^{+\epsilon}(x;\lambda_j)$] satisfies the Fredholm equation (3.22) for $N^{+\epsilon}(x;\lambda)$ with λ_j replacing λ. Note that $B(\lambda_j)$ is not, in general, the value that $B(\lambda)$ would take if it could be analytically continued off the real axis to λ_j. For example, $B(\lambda)$ can vanish identically for real λ, but the $B(\lambda_j)$ can never vanish. The asymptotics for $m^{+\epsilon}(x;\lambda_j)$ can now be written,

$$m^{+\epsilon}(x;\lambda_j) \sim \begin{cases} e^{-\epsilon i\lambda_j(x-\epsilon i\delta)/2} & \text{as } x \to -\infty, \\ B(\lambda_j)e^{\epsilon i\lambda_j(x-\epsilon i\delta)/2} & \text{as } x \to +\infty. \end{cases} \tag{4.4}$$

Bound states corresponding to discrete eigenvalues in the region $D^{-\epsilon}$ are constructed similarly. Let $\lambda_j^{-\epsilon}$ denote the result of changing the sign of the indicator ϵ in λ_j. According to Eq. (3.55), which is applicable to $D^{-\epsilon}$, the $\lambda_j^{-\epsilon}$ are the zeros of $G(\lambda)$ in $D^{-\epsilon}$. Then the functions $\bar{n}^{+\epsilon}(x;\lambda_j^{-\epsilon})$, $j=1,2,\ldots,q$, are bound states with

$$\bar{n}^{+\epsilon}(x;\lambda_j^{-\epsilon}) = H(\lambda_j^{-\epsilon})\bar{m}^{+\epsilon}(x;\lambda_j^{-\epsilon}), \tag{4.5}$$

where $H(\lambda_j^{-\epsilon})$ is defined by the integral Eq. (3.44) with $\lambda_j^{-\epsilon}$ replacing λ.

We need to know the precise relationship between the λ_j and the $\lambda_j^{-\epsilon}$. The integral formula Eq. (3.51) is valid for any real or complex value of λ for which the eigenfunctions $\psi_1^{+\epsilon}$ and $\psi_2^{+,-\epsilon}$ are defined. Let us apply it to the case $\psi_1^{+\epsilon} = m^{+\epsilon}(x;\lambda_j)$ and $\psi_2^{+,-\epsilon} = m^{+,-\epsilon}(x;-\lambda_j)$. Suppose that $-\lambda_j$ is not a discrete eigenvalue in $D^{-\epsilon}$ for the case of indicator $-\epsilon$. In that case, we must use the asymptotic formula Eq. (4.2) with the sign of ϵ changed. Equation (3.51) can be simplified to

$$\zeta_+(-\lambda_j)B(\lambda_j)A^{-\epsilon}(-\lambda_j)=0.$$

Now $B(\lambda_j)$ can never vanish and ζ_+ can only vanish at the origin of its own complex plane, which is on the real axis. It follows that the hypothesis that $-\lambda_j$ was not a discrete eigenvalue in $D^{-\epsilon}$ has led to a contradiction, namely, that it is indeed a discrete eigenvalue. For this case, the alternative asymptotics given by Eq. (4.4) with the sign of ϵ changed guarantee that Eq. (3.51) is identically satisfied. The same conclusion would result if we applied Eq. (3.51) to the case $\psi_1^{+\epsilon}=\bar{n}^{+\epsilon}(x;-\lambda_j)$ and $\psi_2^{+,-\epsilon}$ as before. Hence, we have proved that

$$A^{-\epsilon}(-\lambda_j)=0=G(-\lambda_j),\quad A(-\lambda_j^{-\epsilon})=0, \tag{4.6}$$

for $j=1,2,\ldots,q$. Equation (4.6) shows that the $\lambda_j^{-\epsilon}$ are the negatives of the λ_j in some order, and we are free to label these eigenvalues so that

$$\lambda_j^{-\epsilon}=-\lambda_j \tag{4.7}$$

and

$$\lambda_j =: \epsilon i\kappa_j,\quad \mathrm{Re}(\kappa_j)>0, \tag{4.8}$$

$j=1,2,\ldots,q$, with the κ_j being independent of ϵ. This result allows us to write Eq. (4.5) in terms of quantities with the same indicator, namely,

$$\bar{n}^{+\epsilon}(x;-\lambda_j)=H(-\lambda_j)\bar{m}^{+\epsilon}(x;-\lambda_j). \tag{4.9}$$

In view of Eq. (4.8), we can obtain more identities. First, by suitably combining Eqs. (3.28), (3.31), and (3.32), we can get a reflection formula for the Green's functions that extends off the real λ axis. Then it will be found that the connection formula Eq. (3.35) holds for $\lambda=-\lambda_j$ and Eq. (3.36) holds for $\lambda=\lambda_j$. This means that $N^{+\epsilon}(x;\lambda_j)$ is precisely the result that would be obtained by analytic continuation of $N^{+\epsilon}(x;\lambda)$ from the real λ axis to the point $\lambda=\lambda_j$ in D^{ϵ}, which is not obvious from the definition of $N^{+\epsilon}(x;\lambda_j)$, and similarly for $\bar{M}^{+\epsilon}(x;-\lambda_j)$. As already remarked, similar statements are false for $B(\lambda_j)$ and $H(-\lambda_j)$. The large x asymptotics of the connection formulas now give

$$H(-\lambda_j)=\frac{1}{B(\lambda_j)}. \tag{4.10}$$

This can also be proved by substituting $\lambda=-\lambda_j$ into Eq. (3.44) and rearranging.

The relationship between λ_j and λ_j^* is less easy to determine in the case of the complex-valued ILW equation. Calculations similar to the proof of Eq. (4.6) give

$$2\delta e^{\delta\lambda_j}\zeta_-(\lambda_j)B(\lambda_j)(A(-\lambda_j^*))^*=-\epsilon\int_{-\infty}^{\infty}V_x m^{+\epsilon}(x;\lambda_j)(m^{+\epsilon}(x;-\lambda_j^*))^*\,\mathrm{d}x, \tag{4.11}$$

which can also be deduced from Eq. (3.60) by setting $\lambda=-\lambda_j^*$. In the case of the real-valued ILW equation, the right-hand sides of Eqs. (3.60) and (4.11) are zero because V_x is proportional to the imaginary part of $U(x)$. Hence $A(-\lambda_j^*)=0$, which implies that the λ_j are either pure-imaginary or are distributed symmetrically about the imaginary axis of the complex λ plane. Equivalently, the κ_j are either real or are distributed in complex conjugate pairs. The real κ_j which do not have the same real part as any other κ_j give rise to solitons (solitary waves) that travel from left to right with a steady amplitude. When two or more of the κ_j have the same real part, the corresponding solitary waves travel together as a packet known as a *breather* because the combined wave pulsates. KAS (Ref. 19) concluded that all the λ_j were pure imaginary from a different integral identity. In view of the existence of breathers, their conclusion cannot be upheld.

The discrete eigenvalues are also either pure imaginary or are distributed in symmetric pairs across the imaginary axis of the complex λ plane in the case of the particular *complex-valued* ILW equation derived from the real-valued MILW equation via the Miura transformation Eq. (2.11).

Our argument is indirect because we have not found a direct way to prove that the integral on the right-hand side of Eq. (4.11) vanishes identically. In Sec. VII, we prove that the eigenvalues are so distributed for pure soliton solutions. But that implies that they are so distributed for all solutions because the solitary waves or breathers become widely separated from each other and from the background generated by the nonsoliton part at late times. If the eigenvalues were not distributed as stated, the function $V(x,t)$ constructed from Eq. (2.13) would fail the consistency condition Eq. (2.14). We could also employ the same indirect argument to prove that the discrete eigenvalues are *simple* zeros of $A(\lambda)$ and $G(\lambda)$ for the class of complex-valued ILW equations relevant to the MILW equation, but we shall omit that proof.

One final set of identities involves λ derivatives of $A(\lambda)$ at $\lambda=\lambda_j$ and of $G(\lambda)$ at $\lambda=-\lambda_j$. Define the *normalizing coefficients*,

$$C_j := -\epsilon i \frac{\dot{\zeta}_+(\lambda_j)B(\lambda_j)}{\dot{A}(\lambda_j)}, \tag{4.12}$$

$$F_j := \epsilon i \frac{\dot{\zeta}_+(-\lambda_j)H(-\lambda_j)}{\dot{G}(-\lambda_j)}, \tag{4.13}$$

where the dot denotes differentiation with respect to λ. Start again with Eqs. (3.48) and (3.49), but take a derivative of the first equation with respect to λ_1. The steps which led to Eq. (3.51) give the integral identity,

$$\begin{aligned}\left[\psi_{1\lambda}^{+\epsilon}(x;\lambda)\psi_2^{+,-\epsilon}(x;\pm\lambda)\right]_{-R_1}^{R_2} &= \epsilon i\nu(\lambda)\left\{\int_{-R_1-\epsilon i\delta}^{-R_1+\epsilon i\delta} - \int_{R_2-\epsilon i\delta}^{R_2+\epsilon i\delta}\right\}\psi_{1\lambda}^{\epsilon}(z;\lambda)\psi_2^{(-\epsilon)}(z;\pm\lambda)\mathrm{d}z \\ &\quad + \epsilon i\dot{\nu}(\lambda)\left\{\int_{-R_1}^{-R_1+\epsilon i\delta} - \int_{R_2}^{R_2+\epsilon i\delta}\right\}\psi_1^{\epsilon}(z;\lambda)\psi_2^{(-\epsilon)}(z;\pm\lambda)\mathrm{d}z \\ &\quad - \epsilon i\dot{\mu}(\lambda)\int_{-R_1}^{R_2}\psi_1^{+\epsilon}(x;\lambda)\psi_2^{+,-\epsilon}(x;\pm\lambda)\mathrm{d}x \\ &\quad - \epsilon i\dot{\nu}(\lambda)\int_{-R_1}^{R_2}\psi_1^{\epsilon}(x;\lambda)\psi_2^{(-\epsilon)}(x;\pm\lambda)\mathrm{d}x.\end{aligned} \tag{4.14}$$

This identity is applicable to the case $\lambda=\pm\lambda_j$ provided the eigenfunctions appearing are defined for such λ. With $\psi_1^{+\epsilon}=m^{+\epsilon}(x;\lambda_j)$ and $\psi_2^{+,-\epsilon}=m^{+,-\epsilon}(x;-\lambda_j)$, Eq. (4.14) yields

$$\begin{aligned}C_j = -\frac{1}{2\dot{A}(\lambda_j)\dot{A}^{-\epsilon}(-\lambda_j)}\Bigg\{&\frac{\dot{\mu}(\lambda_j)}{\sinh\,\delta\lambda_j}\int_{-\infty}^{\infty}m^{+\epsilon}(x;\lambda_j)m^{+,-\epsilon}(x;-\lambda_j)\mathrm{d}x \\ &+\frac{\dot{\nu}(\lambda_j)}{\sinh\,\delta\lambda_j}\int_{-\infty}^{\infty}m^{\epsilon}(x;\lambda_j)m^{(-\epsilon)}(x;-\lambda_j)\mathrm{d}x\Bigg\}.\end{aligned} \tag{4.15}$$

Similarly,

$$\begin{aligned}F_j = -\frac{1}{2\dot{G}(-\lambda_j)\dot{G}^{-\epsilon}(\lambda_j)}\Bigg\{&\frac{\dot{\mu}(\lambda_j)}{\sinh\,\delta\lambda_j}\int_{-\infty}^{\infty}\bar{n}^{+\epsilon}(x;-\lambda_j)\bar{n}^{+,-\epsilon}(x;\lambda_j)\mathrm{d}x \\ &+\frac{\dot{\nu}(\lambda_j)}{\sinh\,\delta\lambda_j}\int_{-\infty}^{\infty}\bar{n}^{\epsilon}(x;-\lambda_j)\bar{n}^{(-\epsilon)}(x;\lambda_j)\mathrm{d}x\Bigg\}.\end{aligned} \tag{4.16}$$

From these two formulas, we can read off the important identities,

$$C_j^{-\epsilon} = C_j, \quad F_j^{-\epsilon} = F_j. \tag{4.17}$$

In other words, C_j and F_j, like κ_j, are independent of the indicator ϵ. Now we can swap ϵ with $-\epsilon$ in either Eq. (4.12) or Eq. (4.13) and get the simple relationship,

$$\frac{F_j}{C_j} = H(-\lambda_j)H^{-\epsilon}(\lambda_j) = \frac{1}{B(\lambda_j)B^{-\epsilon}(-\lambda_j)}, \tag{4.18}$$

where we used Eq. (4.10). When a particular λ_j is purely imaginary, the coefficients $\dot{\mu}(\lambda_j)/\sinh \delta\lambda_j$ and $\dot{\nu}(\lambda_j)/\sinh \delta\lambda_j$ are real and negative. If, in addition, the function $U(x)$ is real, then C_j and F_j are themselves real and positive, as shown by KAS.[19] But for $U(x)$ derived from Eq. (2.11), the C_j and F_j are, in general, complex numbers. MILW solitons have a direct relationship to the imaginary parts of the C_j and F_j.

This completes our analysis of the direct problem for the complex-valued ILW equation. The *scattering data* consists of the functions,

$$A(\lambda), \quad B(\lambda), \quad G(\lambda), \quad H(\lambda), \tag{4.19}$$

of the real variable λ which comprise the continuous spectrum, with $A(\lambda)$ and $G(\lambda)$ having analytic extensions to half-planes of the complex variable ζ_+ as shown above, and the complex constants,

$$\lambda_j = \epsilon i\kappa_j, \quad B(\lambda_j), \quad H(-\lambda_j), \quad C_j, \quad F_j, \tag{4.20}$$

which form the discrete spectrum. We have derived several identities involving these quantities and the corresponding quantities obtained by changing the sign of the indicator ϵ.

V. TEMPORAL EVOLUTION OF THE SCATTERING DATA

The scattering data derived in the preceding section will evolve in a simple way with respect to time t. This is the standard way that the IST is used to solve an initial value problem. One calculates the scattering data for the initial value $V(x,0)$ at $t=0$ and then evolves the scattering data forward in time according to simple expressions. Finally, when the inverse problem is formulated and solved, one inputs the scattering data at time t and outputs the required potential $V(x,t)$. The solution of the inverse problem for the complex-valued ILW equation and real-valued MILW equation will be given in the next section.

Introduce the argument t into the notation for the scattering data,

$$A(\lambda;t), \quad B(\lambda;t), \quad G(\lambda;t), \quad H(\lambda;t),$$

$$\lambda_j(t), \quad B(\lambda_j;t), \quad H(-\lambda_j;t), \quad C_j(t), \quad F_j(t),$$

$j=1,2,\ldots,q$. Now the four Jost functions, $M_\epsilon^{+\epsilon}(x,t;\lambda)$, $\bar{M}^{+\epsilon}(x,t;\lambda)$, $N^{+\epsilon}(x,t;\lambda)$, and $\bar{N}_{-\epsilon}^{+\epsilon}(x,t;\lambda)$, satisfy Eq. (3.16) for $\Psi^{+\epsilon}(x,t)$. The boundary conditions given by Eqs. (3.19) and (3.20) force the parameter Γ in this equation to be

$$\Gamma = \begin{cases} 0 & \text{when } \Psi^{+\epsilon} = M_\epsilon^{+\epsilon} \text{ or } \bar{N}_{-\epsilon}^{+\epsilon}, \\ -\theta(\lambda) & \text{when } \Psi^{+\epsilon} = \bar{M}^{+\epsilon} \text{ or } N^{+\epsilon}, \end{cases}$$

where

$$\theta(\lambda) := \epsilon i\lambda(\lambda \coth(\delta\lambda) - \delta^{-1}). \tag{5.1}$$

With all terms appearing in Eqs. (3.37) and (3.42) depending on t, differentiation and application of Eq. (3.16) produces the simple differential identities,

$$A_t(\lambda;t)\bar{N}^{+\epsilon}_{-\epsilon}(x,t;\lambda)+\{B_t(\lambda;t)+\Gamma B(\lambda;t)\}N^{+\epsilon}(x,t;\lambda)=0,$$

$$G_t(\lambda;t)M^{+\epsilon}_{\epsilon}(x,t;\lambda)+\{H_t(\lambda;t)+\Gamma H(\lambda;t)\}\bar{M}^{+\epsilon}(x,t;\lambda)=0,$$

where the second value of Γ is applicable. Thus,

$$A(\lambda;t)=A(\lambda;0), \tag{5.2}$$

$$B(\lambda;t)=B(\lambda;0)e^{\theta(\lambda)t}, \tag{5.3}$$

$$G(\lambda;t)=G(\lambda;0), \tag{5.4}$$

$$H(\lambda;t)=H(\lambda,0)e^{\theta(\lambda)t}. \tag{5.5}$$

Because $A(\lambda;t)$ and $G(\lambda;t)$ are time independent, so also are their zeros. Hence, for $j=1,2,\ldots,q$,

$$\lambda_j(t)=\lambda_j(0), \tag{5.6}$$

$$B(\lambda_j;t)=B(\lambda_j;0)e^{\theta(\lambda_j)t}, \tag{5.7}$$

$$H(-\lambda_j;t)=H(-\lambda_j;0)e^{-\theta(\lambda_j)t}, \tag{5.8}$$

$$C_j(t)=C_j(0)e^{\theta(\lambda_j)t}, \tag{5.9}$$

$$F_j(t)=F_j(0)e^{-\theta(\lambda_j)t}. \tag{5.10}$$

Note that $\theta(\lambda_j)$ is independent of the indicator ϵ.

The scattering data at $t=0$ will be regarded as known because they have been constructed out of the initial value $U(x,0)$ of the complex-valued ILW equation, which in turn has been constructed out of the initial value $V(x,0)$ of the MILW equation according to Eq. (2.12). Thus the scattering data are now known for all t.

VI. THE INVERSE PROBLEM AND ITS SOLUTION

In this section, we will formulate and solve the inverse problem for the complex-valued ILW equation. The natural setting is the complex plane of the scattering variable ζ_+ obtained by the conformal mapping $\zeta_+=\zeta_+(\lambda)$, and we intend to use the notation $A(\zeta_+)$ interchangeably with $A(\lambda)$, and similarly with all the other functions of λ or of the λ_j. The scattering data are now understood to be the scattering data at time t,

$$A(\zeta_+),\quad B(\zeta_+;t),\quad G(\zeta_+),\quad H(\zeta_+;t),$$

$$\zeta_{+j}:=\zeta_+(\lambda_j),\quad \zeta_{-j}:=\zeta_-(\lambda_j)=-\zeta_+(-\lambda_j),$$

$$B(\zeta_{+j};t),\quad H(-\zeta_{-j};t),\quad C_j(t),\quad F_j(t),$$

derived in the preceding section. Our aim is to produce an expression for the auxiliary variable,

$$U^{\epsilon}(x,t) := \tfrac{1}{2}\{\epsilon U(x,t) - i(\mathbf{T}U)(x,t)\}, \tag{6.1}$$

in terms of the scattering data, and thence the solution $U(x,t)$ of the complex-valued ILW equation and the solution $V(x,t)$ of the real-valued MILW equation. For convenience, we again suppress the t dependence in the arguments of our functions.

The solution of our inverse problem relies on the interpretation of Eqs. (3.37) and (3.42) as Riemann-Hilbert problems[40] in the complex ζ_+ plane. With the indicator ϵ temporarily attached to A, B, G, and H and the subscript identifying the half-plane of analyticity attached to A and G, these Riemann-Hilbert problems read

$$M_{\epsilon}^{+\epsilon}(x;\zeta_+) = A_{\epsilon}^{\epsilon}(\zeta_+)\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+) + B^{\epsilon}(\zeta_+)N^{+\epsilon}(x;\zeta_+), \tag{6.2}$$

$$\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+) = G_{-\epsilon}^{\epsilon}(\zeta_+)M_{\epsilon}^{+\epsilon}(x;\zeta_+) + H^{\epsilon}(\zeta_+)\bar{M}^{+\epsilon}(x;\zeta_+), \tag{6.3}$$

for real $\zeta_+ > -1/(2\delta)$.

In Sec. III, we took care to identify those functions, denoted $(+\epsilon)$ functions and having the subscript ϵ, that are analytic in ζ_+ throughout the half-plane $\mathrm{Im}(\epsilon\zeta_+) > 0$, and similarly for $(-\epsilon)$ functions. In particular, we proved that

(i) $M_{\epsilon}^{+\epsilon}(x;\zeta_+)$ and $A(\zeta_+)$ are $(+\epsilon)$ functions in ζ_+,

(ii) $\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+)$ and $G(\zeta_+)$ are $(-\epsilon)$ functions in ζ_+,

(iii) $N^{+\epsilon}$ and $\bar{M}^{+\epsilon}$ also have analytic extensions into the half-planes $\mathrm{Im}(\epsilon\zeta_+) > 0$ and $\mathrm{Im}(\epsilon\zeta_+) < 0$, respectively, but they do not extend to the complete half-planes, having quadratic branch points at ζ_0^{ϵ} and $\zeta_0^{-\epsilon}$, respectively.

(iv) $A(\zeta_+)$ has simple zeros at ζ_{+j} and $G(\zeta_+)$ has corresponding simple zeros at $-\zeta_{-j}$, $j = 1,2,\ldots,q$.

(v) $B(\zeta_+)$ is defined for real $\zeta_+ > -1/(2\delta)$ and for the ζ_{+j}; $H(\zeta_+)$ is defined for real $\zeta_+ > -1/(2\delta)$ and for the $-\zeta_{-j}$.

Equation (6.2) can be written,

$$\frac{M_{\epsilon}^{+\epsilon}(x;\zeta_+)}{A(\zeta_+)} = \bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+) + R(\zeta_+)N^{+\epsilon}(x;\zeta_+), \tag{6.4}$$

for real $\zeta_+ > -1/(2\delta)$, where

$$R(\zeta_+) := \frac{B(\zeta_+)}{A(\zeta_+)}. \tag{6.5}$$

The ratio $M_{\epsilon}^{+\epsilon}(x;\zeta_+)/A(\zeta_+)$ is meromorphic in the $(+\epsilon)$ half of the complex ζ_+ plane. From Eqs. (3.27), (3.28), (3.33), and (3.38), this ratio tends to $1 + O(1/\zeta_+)$ as $\zeta_+ \to \infty$. Hence, we can write the partial fraction expansion,

$$\frac{M_{\epsilon}^{+\epsilon}(x;\zeta_+)}{A(\zeta_+)} = 1 + \sum_{j=1}^{q} \frac{D_j^{\epsilon}(x)}{\zeta_+ - \zeta_{+j}} + \phi_{\epsilon}^{\epsilon}(x;\zeta_+), \tag{6.6}$$

where $\phi_{\epsilon}^{\epsilon}(x;\zeta_+)$ is a $(+\epsilon)$ function in x and ζ_+ such that $\phi_{\epsilon}^{\epsilon}(x;\zeta_+) \to 0$ as $\zeta_+ \to \infty$, and

$$D_j^{\epsilon}(x) = \lim_{\zeta_+ \to \zeta_{+j}} (\zeta_+ - \zeta_{+j}) \frac{M_{\epsilon}^{+\epsilon}(x;\zeta_+)}{A(\zeta_+)}. \tag{6.7}$$

Examining the leading terms in Eq. (6.2) in the neighborhood of the ζ_{+j}, we arrive at the identification,

$$D_j^{\epsilon}(x) = \epsilon i C_j N^{+\epsilon}(x;\zeta_{+j}), \tag{6.8}$$

where C_j is defined by Eq. (4.12). With the dot denoting differentiation with respect to ζ_+, the expressions for C_j and F_j simplify to

$$C_j = -\epsilon i \frac{B(\zeta_{+j})}{\dot{A}(\zeta_{+j})}, \quad F_j = \epsilon i \frac{H(-\zeta_{-j})}{\dot{G}(-\zeta_{-j})}.$$

Substituting Eq. (6.6) into Eq. (6.2), we find

$$\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+) + R(\zeta_+)N^{+\epsilon}(x;\zeta_+) = 1 + \epsilon i \sum_{j=1}^{q} C_j \frac{N^{+\epsilon}(x;\zeta_{+j})}{\zeta_+ - \zeta_{+j}} + \phi_{\epsilon}^{\epsilon}(x;\zeta_+). \tag{6.9}$$

The function $R(\zeta_+)N^{+\epsilon}(x;\zeta_+)$ is only defined for real $\zeta_+ > -1/(2\delta)$, but we can employ the Plemelj formulas,[40]

$$\hat{R}_{\pm\epsilon}(x;\zeta_+) := \frac{1}{2\pi i}\int_{-1/(2\delta)}^{\infty} \frac{R(\tilde{\zeta})N^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta} - (\zeta_+ \pm \epsilon i 0^+)} \mathrm{d}\tilde{\zeta}, \tag{6.10}$$

to create the decomposition,

$$R(\zeta_+)N^{+\epsilon}(x;\zeta_+) = \epsilon\{\hat{R}_{\epsilon}(x;\zeta_+) - \hat{R}_{-\epsilon}(x;\zeta_+)\}. \tag{6.11}$$

Thus, up to sign, $\hat{R}_{\pm\epsilon}(x;\zeta_+)$ is the $(\pm\epsilon)$ part of $R(\zeta_+)N^{+\epsilon}(x;\zeta_+)$. Substituting Eqs. (6.10) and (6.11) into Eq. (6.9) and equating the $(-\epsilon)$ parts in a manner that respects the asymptotic condition $\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+) \to 1$ as $\zeta_+ \to \infty$ gives

$$\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+) = 1 + \epsilon i \sum_{j=1}^{q} C_j \frac{N^{+\epsilon}(x;\zeta_{+j})}{\zeta_+ - \zeta_{+j}} + \frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty} \frac{R(\tilde{\zeta})N^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta} - (\zeta_+ - \epsilon i 0^+)} \mathrm{d}\tilde{\zeta}. \tag{6.12}$$

Equation (6.12) solves the Riemann-Hilbert problem given by Eq. (6.2). It expresses $\bar{N}_{-\epsilon}^{+\epsilon}$ in terms of $N^{+\epsilon}$ and the scattering data. Both sides analytically extend to the half-plane $\mathrm{Im}(\epsilon\zeta_+) < 0$.

With the aid of the connection formula Eq. (3.36), we can eliminate $\bar{N}_{-\epsilon}^{+\epsilon}$ from Eq. (6.12) and get a system of coupled Fredholm equations for $N^{+\epsilon}(x;\zeta_+)$ and $N^{+\epsilon}(x;\zeta_{+j})$, $j = 1, 2, \ldots, q$. The connection formula gives

$$e^{\epsilon i\lambda(x-\epsilon i\delta)} N^{+\epsilon}(x;\zeta_+(-\lambda)) = \Lambda(x;-\zeta_+(\lambda)) + \frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty} \frac{R(\tilde{\zeta})N^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta} - \zeta_+(\lambda) + \epsilon i 0^+} \mathrm{d}\tilde{\zeta}, \tag{6.13}$$

where the auxiliary function Λ is defined by

$$\Lambda(x;\zeta) := 1 - \epsilon i \sum_{k=1}^{q} C_k \frac{N^{+\epsilon}(x;\zeta_{+k})}{\zeta + \zeta_{+k}}. \tag{6.14}$$

The involution $\lambda \to -\lambda$ together with the identity $\zeta_+(-\lambda) = -\zeta_-(\lambda)$ transforms Eq. (6.13) into the Fredholm equation,

$$N^{+\epsilon}(x;\zeta_+) = \left\{ \Lambda(x;\zeta_-) + \frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty} \frac{R(\tilde{\zeta})N^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta} + \zeta_- + \epsilon i 0^+} \mathrm{d}\tilde{\zeta} \right\} e^{\epsilon i\lambda(x-\epsilon i\delta)}. \tag{6.15}$$

In this equation ζ_- is understood to be the function of the real variable ζ_+ formed by composition of the increasing functions $\zeta_-=\zeta_-(\lambda)$ and $\lambda=\zeta_+^{-1}(\zeta_+)$. Passage to the limit $\lambda\to-\lambda_j$ throughout Eq. (6.13) yields the set of Fredholm equations,

$$N^{+\epsilon}(x;\zeta_{+j})=\left\{\Lambda(x;\zeta_{-j})+\frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty}\frac{R(\tilde{\zeta})N^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta}+\zeta_{-j}}\mathrm{d}\tilde{\zeta}\right\}e^{\epsilon i\lambda_j(x-\epsilon i\delta)},\tag{6.16}$$

$j=1,2,\ldots,q$, where $\zeta_{-j}:=\zeta_-(\lambda_j)$. Equations (6.15) and (6.16) form a closed system of $q+1$ Fredholm equations for the $q+1$ unknown functions $N^{+\epsilon}(x;\zeta_+)$ and $N^{+\epsilon}(x;\zeta_{+j})$. The kernels are built out of the scattering data $\zeta_{\pm j}$, C_j, and $R(\zeta_+)$. The other three Jost functions can be calculated in terms of $N^{+\epsilon}(x;\zeta_+)$ by Eqs. (6.12), (6.2), and (6.3).

Large ζ_+ asymptotics for $\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+)$ can be obtained from Eq. (6.12) by standard methods, the expansion to first order being

$$\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+)=1+\frac{1}{\zeta_+}\left\{\epsilon i\sum_{j=1}^{q}C_jN^{+\epsilon}(x;\zeta_{+j})-\frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty}R(\tilde{\zeta})N^{+\epsilon}(x;\tilde{\zeta})\mathrm{d}\tilde{\zeta}\right\}+O(1/\zeta_+^2),\tag{6.17}$$

as $\zeta_+\to\infty$. Equation (3.34) can furnish us with a different expression for the large ζ_+ asymptotics of $\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+)$. First, from the formula Eq. (3.30) for the Green's function, we get

$$G_{-\epsilon}^{\epsilon}(x,\eta;\zeta_+)=\frac{\epsilon i}{4\delta\zeta_+}\left\{1+\coth\left(\frac{\pi}{2\delta}(\eta-x-\epsilon i0^+)\right)\right\}+O(1/\zeta_+^2),\tag{6.18}$$

as $\zeta_+\to\infty$. Substituting Eq. (6.18) into Eq. (3.34) gives

$$\bar{N}_{-\epsilon}^{+\epsilon}(x;\zeta_+)=1-\frac{\epsilon}{\zeta_+}\left\{U^{\epsilon}(x)-\frac{1}{2}iL\right\}+O(1/\zeta_+^2),\tag{6.19}$$

where

$$U^{\epsilon}(x)=-\frac{i}{4\delta}\int_{-\infty}^{\infty}\coth\left(\frac{\pi}{2\delta}(\eta-x-\epsilon i0^+)\right)U(\eta)\mathrm{d}\eta=\frac{1}{2}\epsilon U(x)-\frac{1}{2}i\mathbf{T}(U(x))\tag{6.20}$$

and L is the real conserved quantity,

$$L:=\frac{1}{2\delta}\int_{-\infty}^{\infty}U(\xi)\mathrm{d}\xi.$$

Matching the $1/\zeta_+$ terms in the asymptotic expansions Eqs. (6.17) and (6.19), we obtain

$$U^{\epsilon}(x)=\frac{1}{2}iL-i\sum_{j=1}^{q}C_jN^{+\epsilon}(x;\zeta_{+j})+\frac{1}{2\pi i}\int_{-1/(2\delta)}^{\infty}R(\tilde{\zeta})N^{+\epsilon}(x;\tilde{\zeta})\mathrm{d}\tilde{\zeta}.\tag{6.21}$$

A corresponding set of Fredholm equations for the Jost function $\bar{M}^{+\epsilon}(x;\zeta_+)$ can be derived from the Riemann-Hilbert problem Eq. (6.3). These provide alternative expressions for the four Jost functions that are better adapted to asymptotics as $x\to-\infty$. The solution of this Riemann-Hilbert problem is

$$M_{\epsilon}^{+\epsilon}(x;\zeta_+)=1-\epsilon i\sum_{j=1}^{q}F_j\frac{\bar{M}^{+\epsilon}(x;-\zeta_{-j})}{\zeta_++\zeta_{-j}}-\frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty}\frac{S(\tilde{\zeta})\bar{M}^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta}-(\zeta_++\epsilon i0^+)}\mathrm{d}\tilde{\zeta}.\tag{6.22}$$

The Fredholm equations analogous to Eqs. (6.15) and (6.16) are

$$\bar{M}^{+\epsilon}(x;\zeta_+) = \left\{ \Lambda_2(x;\zeta_-) - \frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty} \frac{S(\tilde{\zeta})\bar{M}^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta}+\zeta_- - \epsilon i 0^+}\mathrm{d}\tilde{\zeta} \right\} e^{\epsilon i\lambda(x-\epsilon i\delta)}, \tag{6.23}$$

$$\bar{M}^{+\epsilon}(x;-\zeta_{-j}) = \left\{ \Lambda_2(x;-\zeta_{+j}) - \frac{\epsilon}{2\pi i}\int_{-1/(2\delta)}^{\infty} \frac{S(\tilde{\zeta})\bar{M}^{+\epsilon}(x;\tilde{\zeta})}{\tilde{\zeta}-\zeta_{+j}}\mathrm{d}\tilde{\zeta} \right\} e^{-\epsilon i\lambda_j(x-\epsilon i\delta)}, \tag{6.24}$$

where

$$S(\zeta_+) := \frac{H(\zeta_+)}{G(\zeta_+)},$$

$$\Lambda_2(x,\zeta) := 1 + \epsilon i\sum_{k=1}^{q} \frac{F_k\bar{M}^{+\epsilon}(x;-\zeta_{-k})}{\zeta-\zeta_{-k}}.$$

Finally, large ζ_+ asymptotics for $M_\epsilon^{+\epsilon}$ give

$$U^{\epsilon}(x) = -\frac{1}{2}iL + i\sum_{j=1}^{q} F_j\bar{M}^{+\epsilon}(x;-\zeta_{-j}) - \frac{1}{2\pi i}\int_{-1/(2\delta)}^{\infty} S(\tilde{\zeta})\bar{M}^{+\epsilon}(x;\tilde{\zeta})\mathrm{d}\tilde{\zeta}. \tag{6.25}$$

We have arrived at two equivalent expressions for $U^{\epsilon}(x,t)$. To get $U^{-\epsilon}(x,t)$, we need to solve the direct and inverse problems with the opposite indicator. This does not necessarily mean starting afresh from the beginning because formulas for the scattering data with the opposite indicator were given in Secs. III and IV. In particular, the κ_j, $C_j(t)$, and $F_j(t)$ are independent of ϵ. When $U^{\epsilon}(x,t)$ and $U^{-\epsilon}(x,t)$ have both been constructed, we can read off

$$U(x,t) = \epsilon\{U^{\epsilon}(x,t) - U^{-\epsilon}(x,t)\}, \tag{6.26}$$

$$(\mathbf{T}U)(x,t) = i\{U^{\epsilon}(x,t) + U^{-\epsilon}(x,t)\}. \tag{6.27}$$

To calculate $V(x,t)$, the solution of the MILW equation from the given initial value $V(x,0)$, first calculate

$$W(x,t) = \int_{-\infty}^{x} U(\xi,t)\mathrm{d}\xi. \tag{6.28}$$

Then

$$V(x,t) = 2\,\mathrm{Im}\{W(x,t)\}. \tag{6.29}$$

Because the operator $\mathbf{T}$ commutes with differentiation, Eq. (2.11) gives us a choice of two formulas for $\mathbf{T}(V_x)$,

$$\mathbf{T}(V_x) = 2\,\mathrm{Im}\{\mathbf{T}U\} = 2\,\mathrm{Re}\{U\} - \beta(e^V - 1), \tag{6.30}$$

which, of course, must be consistent with each other. [Consistency is guaranteed when one is solving an initial value problem, starting with a given $V(x,0)$, but becomes an issue when the starting point is somewhere else, as in the case of the multisoliton solutions in the next section.] One more quadrature will then give $\mathbf{T}V$.

The shallow-water limit of the full IST for the ILW and MILW equations is reasonably straightforward. The functions $U(x,t)$ and $V(x,t)$ require the simple scaling given by Eqs. (1.7) and (2.7), but the Jost functions and the scattering data do not require scaling, as shown by

Satsuma *et al.*[23] On the other hand, the deep-water limit of the IST is more subtle since the ISTs for the ILW and BO equations have features that do not correspond in an obvious way. We refer the reader to Santini *et al.*[38] for the handling of this limit.

VII. SOLITON SOLUTIONS FOR THE ILW AND MILW EQUATIONS

Pure soliton solutions for the real-valued and complex-valued ILW equations occur when the reflection coefficient $R(\lambda;t)$, also written $R(\zeta_+;t)$, vanishes. According to Eqs. (5.3) and (5.5) and identities in Sec. III, whenever the initial value $B(\lambda;0)$ vanishes for real λ, all of the functions,

$$B(\lambda;t), \quad H(\lambda;t), \quad B^{-\epsilon}(\lambda;t), \quad H^{-\epsilon}(\lambda;t),$$

$$R(\lambda;t), \quad S(\lambda;t), \quad R^{-\epsilon}(\lambda;t), \quad S^{-\epsilon}(\lambda;t),$$

vanish together for all real λ and $t \geqslant 0$.

So the integral terms in Eqs. (6.12), (6.15), (6.16), and (6.21)–(6.25) disappear, and the inverse problem reduces to a system of q linear algebraic equations for the case of the q-soliton solution. This will allow us to calculate the physical variables $U(x,t)$, $V(x,t)$, their **T** transforms, and all the Jost functions and other auxiliary functions explicitly in terms of determinants. General formulas for the ILW multisoliton solution have been given by KAS (Ref. 19) and general formulas for the MILW multisoliton solution have been given by Nakamura,[28] the latter demonstrating the power of Hirota's bilinear method.[34,35] However, for the questions that we want to examine regarding MILW solitons, it will be more instructive to look at large x asymptotics of the q-soliton solution and explicit expressions for just the one- and two-soliton solutions of the ILW and MILW equations.

With the help of the time-evolution results in Sec. V, we can write the system of equations for $N^{+\epsilon}(x,t;\lambda_j)$, $j=1,2,\ldots,q$, in the form,

$$N^{+\epsilon}(x,t;\lambda_j) = \left\{ 1 - \epsilon i \sum_{k=1}^{q} \frac{\kappa_k N^{+\epsilon}(x,t;\lambda_k)}{\zeta_{+k} + \zeta_{-j}} e^{\theta_k t - \nu_k} \right\} e^{-\kappa_j (x - \epsilon i \delta)}, \tag{7.1}$$

where

$$\lambda_j = \epsilon i \kappa_j = \zeta_{+j} + \zeta_{-j}, \tag{7.2}$$

$$\theta_j := \theta(\lambda_j) = \kappa_j (\delta^{-1} - \kappa_j \cot \delta \kappa_j), \tag{7.3}$$

$$\nu_j := \log\{\kappa_j / C_j(0)\}. \tag{7.4}$$

The θ_j are real and positive when the corresponding κ_j are real, and similarly for complex conjugate pairs. It will be convenient to define the following auxiliary functions:

$$E_j(x,t) := \exp\{\kappa_j x - \theta_j t + \nu_j\}, \tag{7.5}$$

$$E_j^{\epsilon}(x,t) := \exp\{\kappa_j (x - \epsilon i \delta) - \theta_j t + \nu_j\}. \tag{7.6}$$

Having obtained $N^{+\epsilon}(x,t;\lambda_j)$, the values of $U(x,t)$ and $V(x,t)$ can be deduced from

$$U^{\epsilon}(x,t) = \frac{1}{2} iL - i \sum_{k=1}^{q} \kappa_k N^{+\epsilon}(x,t;\lambda_k) e^{\theta_k t - \nu_k}, \tag{7.7}$$

where L is the real constant defined by Eq. (2.15), by following the steps at the end of the preceding section. An equivalent formula is given by Eq. (6.25) without the integral term. However, because we have disconnected the analysis from the initial value, we no longer know the parameter β in advance, but must calculate it in terms of the other parameters appearing in the

soliton solutions, and also determine any other constraints on the parameters needed to guarantee that $V(x,t)$ is actually a solution of the MILW equation. We also need to determine the relation between the discrete eigenvalues and their complex conjugates.

The asymptotics of $N^{+\epsilon}(x,t;\lambda_j)$ for large positive x are easy to calculate from Eq. (7.1). For large negative x, we get simple determinants that can be evaluated explicitly. The results are

$$N^{+\epsilon}(x,t;\lambda_j) \sim e^{-\kappa_j(x-\epsilon i\delta)}, \tag{7.8}$$

as $x \to +\infty$, and

$$N^{+\epsilon}(x,t;\lambda_j) \sim \frac{1}{B(\lambda_j;t)}\left\{1 - \epsilon i\sum_{k=1}^{q}\frac{\kappa_k e^{-2\nu_k}E_k^{\epsilon}(x,t)}{(\zeta_{+j}+\zeta_{-k})B(\lambda_k;0)B^{-\epsilon}(-\lambda_k;0)}\right\}, \tag{7.9}$$

as $x \to -\infty$, where

$$B(\lambda_j;t) = e^{\theta_j t-\nu_j}\prod_{k\neq j}\frac{\zeta_{+j}-\zeta_{+k}}{\zeta_{+j}+\zeta_{-k}}. \tag{7.10}$$

$$B^{-\epsilon}(-\lambda_j;t) = e^{\theta_j t-\nu_j}\prod_{k\neq j}\frac{\zeta_{-j}-\zeta_{-k}}{\zeta_{-j}+\zeta_{+k}}. \tag{7.11}$$

This $B(\lambda_j;t)$, also written $B(\zeta_{+j};t)$, is identifiable with the $B(\lambda_j)$ appearing on the right-hand side of Eq. (4.3). (In these truncated asymptotic expansions, the next terms involving squares and products of the decaying exponential functions appearing are not necessarily smaller than all of those exponential functions, but they are disjoint from the terms that we have kept.)

From Eq. (6.12), we get the asymptotic expansion,

$$\bar{N}_{-\epsilon}^{+\epsilon}(x,t;\lambda) \sim \frac{1}{A(\lambda)}\left\{1 - \epsilon i\sum_{k=1}^{q}\frac{\kappa_k e^{-2\nu_k}E_k^{\epsilon}(x,t)}{(\zeta_{+}(\lambda)+\zeta_{-k})B(\lambda_k;0)B^{-\epsilon}(-\lambda_k;0)}\right\}, \tag{7.12}$$

as $x \to -\infty$, where

$$A(\lambda) = \prod_{k=1}^{q}\frac{\zeta_{+}(\lambda)-\zeta_{+k}}{\zeta_{+}(\lambda)+\zeta_{-k}}. \tag{7.13}$$

This $A(\lambda)$ is identifiable with the $A(\lambda)$ appearing in Eq. (3.37).

Further calculations along these lines will confirm all the identities among the scattering data given in Secs. III and IV restricted to the case of pure solitons. In particular,

$$G(\lambda) = \frac{1}{A(\lambda)}, \quad H(-\lambda_j;t) = \frac{1}{B(\lambda_j;t)}. \tag{7.14}$$

If we start again with the alternative system Eqs. (6.22)–(6.24), we would arrive at the same asymptotics for the Jost functions with the coefficients $F_j(t)$ given by

$$F_j(t) = \frac{\kappa_j e^{-\theta_j t-\nu_j}}{B(\lambda_j;0)B^{-\epsilon}(-\lambda_j;0)}, \tag{7.15}$$

in agreement with Eq. (4.18). This result permits a simplification of Eqs. (7.9) and (7.12).

The corresponding asymptotics for $U^{\epsilon}(x,t)$ can be calculated from Eq. (7.7) or the corresponding formula deduced from Eq. (6.25). Equation (7.7) yields

$$U^{\epsilon}(x,t) \sim \frac{1}{2}iL - i\sum_{j=1}^{q} \kappa_j E_j^{\epsilon}(x,t)^{-1}, \tag{7.16}$$

as $x \to +\infty$. Similarly, Eq. (6.25) gives

$$U^{\epsilon}(x,t) \sim -\frac{1}{2}iL + i\sum_{j=1}^{q} F_j(t) e^{\kappa_j(x-\epsilon i\delta)}, \tag{7.17}$$

as $x \to -\infty$. Equation (7.7) also gives the same asymptotics as $x \to -\infty$ except that the constant term appears to differ. Equating the constant terms gives the useful identity,

$$\kappa_1 + \kappa_2 + \cdots + \kappa_q = L. \tag{7.18}$$

Thus U^{ϵ} tends to opposite limits at opposite ends of the real axis, in agreement with Eq. (A4) and the boundary condition on U.

The asymptotics for U, $\mathbf{T}U$, W, V, and $\mathbf{T}V$ as $x \to \pm\infty$ can now be calculated from Eqs. (7.16)–(7.18) and (6.26)–(6.30). Our purpose here is to find the constraints, if any, on the real and imaginary parts of the κ_j and ν_j so that we get a consistent q-soliton solution of the MILW equation. For the case $x \to +\infty$, we get

$$U(x,t) \sim \sum_{j=1}^{q} 2\kappa_j \sin \delta\kappa_j E_j(x,t)^{-1}, \tag{7.19}$$

$$\mathbf{T}U(x,t) \sim -L + \sum_{j=1}^{q} 2\kappa_j \cos \delta\kappa_j E_j(x,t)^{-1}, \tag{7.20}$$

$$W(x,t) \sim 2\delta L - \sum_{j=1}^{q} 2 \sin \delta\kappa_j E_j(x,t)^{-1}. \tag{7.21}$$

Before taking the imaginary part of W, let

$$\kappa_j = \mu_j + i\rho_j, \quad \nu_j = \sigma_j + i\tau_j, \tag{7.22}$$

$\mu_j > 0$. Then

$$\theta_j = \frac{\mu_j}{\delta} - \frac{(\mu_j^2 - \rho_j^2)\sin 2\delta\mu_j + 2\mu_j\rho_j \sinh 2\delta\rho_j}{\cosh 2\delta\rho_j - \cos 2\delta\mu_j} + i\left\{\frac{\rho_j}{\delta} + \frac{(\mu_j^2 - \rho_j^2)\sinh 2\delta\rho_j - 2\mu_j\rho_j \sin 2\delta\mu_j}{\cosh 2\delta\rho_j - \cos 2\delta\mu_j}\right\} =: \theta_{jR} + i\theta_{jI}.$$

Then Eq. (6.29) and the first part of Eq. (6.30) give

$$V(x,t) \sim 4\sum_{j=1}^{q} e^{-\mu_j x + \theta_{jR} t - \sigma_j}\{\cosh \delta\rho_j \sin \delta\mu_j \sin(\rho_j x - \theta_{jI} t + \tau_j) - \sinh \delta\rho_j \cos \delta\mu_j \cos(\rho_j x - \theta_{jI} t + \tau_j)\}, \tag{7.23}$$

$$\mathbf{T}V(x,t) \sim 4\sum_{j=1}^{q} e^{-\mu_j x+\theta_{jR}t-\sigma_j}\{\cosh\,\delta\rho_j \cos\,\delta\mu_j \sin(\rho_j x-\theta_{jI}t+\tau_j) - \sinh\,\delta\rho_j \sin\,\delta\mu_j \cos(\rho_j x-\theta_{jI}t+\tau_j)\} + \text{const}, \tag{7.24}$$

as $x \to +\infty$.

An important issue that we did not settle in Sec. IV concerns how the discrete eigenvalues are distributed in the complex plane when the initial value $U(x,0)$ is complex according to Eq. (2.12). We shall now prove that the κ_j are either real or are distributed in complex conjugate pairs, just like the case of the real-valued ILW equation. We will deduce this from the asymptotics of the pure q-soliton solution of the MILW equation. However, the result must hold for all solutions of the complex-valued ILW equation deduced from the real-valued MILW equation because at late times the solitary waves or packets of solitary waves traveling together at the same velocity separate from each other and from the nonsoliton background. If the κ_j were not distributed as stated, the function $V(x,t)$ constructed from Eq. (6.29) would fail the consistency condition given by the second part of Eq. (6.30).

Let us now examine this consistency condition for large $|x|$. At the order at which we are working, e^V-1 has the same asymptotics as V itself. Thus Eqs. (6.30), (7.19), (7.23), and (7.24) give the constraint,

$$\begin{aligned}
&\beta\sum_{j=1}^{q} e^{-\mu_j x+\theta_{jR}t-\sigma_j}\{\cosh\,\delta\rho_j \sin\,\delta\mu_j \sin(\rho_j x-\theta_{jI}t+\tau_j) - \sinh\,\delta\rho_j \cos\,\delta\mu_j \cos(\rho_j x-\theta_{jI}t+\tau_j)\} \\
&= \sum_{j=1}^{q} e^{-\mu_j x+\theta_{jR}t-\sigma_j+\delta\rho_j}\{(\mu_j \cos\,\delta\mu_j + \rho_j \sin\,\delta\mu_j)\sin(\rho_j x-\theta_{jI}t+\tau_j) \\
&\quad + (\mu_j \sin\,\delta\mu_j - \rho_j \cos\,\delta\mu_j)\cos(\rho_j x-\theta_{jI}t+\tau_j)\}.
\end{aligned}$$

Because β is a constant, this equation gives as many distinct equations for β as there are linearly independent functions of x and t appearing.

Suppose that a particular κ_j is not real and that its complex conjugate is not found among the other κ_j. Then the functions of x and t appearing in the jth term are linearly independent of the functions of x and t in the other terms and we can immediately separate out two distinct equations for β,

$$\beta \cosh\,\delta\rho_j \sin\,\delta\mu_j = e^{\delta\rho_j}(\mu_j \cos\,\delta\mu_j + \rho_j \sin\,\delta\mu_j),$$

$$\beta \sinh\,\delta\rho_j \cos\,\delta\mu_j = e^{\delta\rho_j}(\rho_j \cos\,\delta\mu_j - \mu_j \sin\,\delta\mu_j).$$

The same method works for the asymptotics as $x \to -\infty$. The equations analogous to the last two are found to be

$$\beta \cosh\,\delta\rho_j \sin\,\delta\mu_j = e^{-\delta\rho_j}(\mu_j \cos\,\delta\mu_j - \rho_j \sin\,\delta\mu_j),$$

$$\beta \sinh\,\delta\rho_j \cos\,\delta\mu_j = e^{-\delta\rho_j}(\rho_j \cos\,\delta\mu_j + \mu_j \sin\,\delta\mu_j).$$

These four equations admit only the trivial solution $\mu_j=0=\rho_j$, which is out of range. Consequently, we must drop the hypothesis that one of the κ_j is not real while its complex conjugate is not found among the other κ_j. This completes the proof that the κ_j are either real or are distributed in complex conjugate pairs. Since $\lambda_j=\epsilon i\kappa_j$, the eigenvalues λ_j, which live in the region D^ϵ, are therefore either pure imaginary or are distributed symmetrically about the imaginary axis of the complex λ plane. Because the curved boundaries of the regions $D^\pm$ are not symmetric about the imaginary axis, we get the slightly improved inequalities,

$$0 < \mathrm{Re}(\kappa_j) < \pi/\delta, \quad 0 < \mathrm{Im}(\epsilon\lambda_j) < \pi/\delta. \tag{7.25}$$

We now know that $A(-\lambda_j^*)=0=G(\lambda_j^*)$. Hence, we have proved indirectly that the integral on the right-hand side of Eq. (4.11) vanishes identically. Similarly, for the pure soliton solutions at least, Eqs. (7.13) and (7.14) show that $A(\lambda)$ and $G(\lambda^*)$ are complex conjugates of each other when $\mathrm{Re}(\epsilon\lambda)\geqslant 0$ and so the integral on the right-hand side of Eq. (3.60) must vanish in these circumstances.

In the case where all or some of the κ_j are real, the asymptotics of the MILW q-soliton solution give the set of constraints,

$$\beta = \kappa_j(\cot\,\delta\kappa_j + \cot\,\tau_j), \tag{7.26}$$

for each j for which κ_j is real. These express the corresponding τ_j in terms of β and κ_j, there being no loss of generality in restricting τ_j to the interval $(-\pi,\pi)$, with $\tau_j\neq 0$, which allows two values of τ_j for given β and κ_j.

Consider the case where $\kappa_1=\mu_1+i\rho_1$ and $\kappa_2=\mu_1-i\rho_1$, with corresponding ν-parameters, ν_1 and ν_2, which are independent complex numbers (not necessarily complex conjugates). The two corresponding equations for β can be arranged into the form

$$\beta = \kappa_1\{\cot\,\delta\kappa_1 + \cot(i(\nu_2)^* - i\nu_1)\},$$

$$\beta = \kappa_2\{\cot\,\delta\kappa_2 + \cot(i(\nu_1)^* - i\nu_2)\},$$

which have the same shape as Eq. (7.26). Soliton pairs formed in this fashion are known as *breathers*. Physically, they are pulsating solitary waves. Mathematically, the exponential functions appearing will be multiplied by trigonometric functions. More complicated breathers occur when three of more of the κ_j have the same real part.

We have a choice of two ways to construct breathers, both giving the same class of solutions but with different parametrizations. One is to continue with two or more of the κ_j being complex conjugate pairs and use Eq. (2.13) to calculate the real-valued function $V(x,t)$. But a more efficient way is to deduce the breather solutions from the q-soliton solution of the MILW equation having *all real* κ_j by complexifying all the parameters (κ_j, σ_j, and τ_j) *after* applying Eq. (2.13) and taking real slices. Thus, for example, when κ_1 and κ_2 are complex conjugates, take the corresponding parameters σ_1 and σ_2 to be complex conjugates, and similarly for τ_1 and τ_2. Then the complex τ_j obtained in this way will also be constrained by Eq. (7.26).

Let us conclude this section with complete calculations of the one- and two-soliton solutions of the MILW equation and the corresponding Jost functions. For the case $q=1$, Eq. (7.1) gives

$$N^{+\epsilon}(x;\lambda_1) = \frac{e^{-\theta_1 t+\nu_1}}{1+E_1^\epsilon(x,t)}, \tag{7.27}$$

where θ_1 and $E_1^\epsilon(x,t)$ are defined by Eqs. (7.3) and (7.6), respectively. Then Eq. (7.7) gives

$$U^\epsilon(x,t) = \frac{1}{2}i\kappa_1\frac{E_1^\epsilon(x,t)-1}{E_1^\epsilon(x,t)+1}. \tag{7.28}$$

From this we can read off

$$U(x,t) = \frac{\kappa_1\,\sin\,\delta\kappa_1}{\cosh(\kappa_1 x-\theta_1 t+\nu_1)+\cos\,\delta\kappa_1}, \tag{7.29}$$

$$(\mathbf{T}U)(x,t) = -\frac{\kappa_1 \sinh(\kappa_1 x - \theta_1 t + \nu_1)}{\cosh(\kappa_1 x - \theta_1 t + \nu_1) + \cos\,\delta\kappa_1}. \tag{7.30}$$

This is the one-soliton solution of the complex-valued ILW equation. In Appendix B, we give a direct proof that $\mathbf{T}U$ is the $\mathbf{T}$ transform of U according to the definition Eq. (1.6). An easy calculation shows that $U(x,t)$ satisfies the ILW equation.

The four Jost functions for the one-soliton solution are

$$M_\epsilon^{+\epsilon}(x,t;\lambda) = 1 - \frac{\epsilon i\kappa_1 E_1^\epsilon(x,t)}{[\zeta_+(\lambda) + \zeta_{-1}][E_1^\epsilon(x,t)+1]}, \tag{7.31}$$

$$\bar{M}^{+\epsilon}(x,t;\lambda) = e^{\epsilon i\lambda(x-\epsilon i\delta)}\left\{1 + \frac{\epsilon i\kappa_1 E_1^\epsilon(x,t)}{[\zeta_-(\lambda) - \zeta_{-1}][E_1^\epsilon(x,t)+1]}\right\}, \tag{7.32}$$

$$N^{+\epsilon}(x,t;\lambda) = e^{\epsilon i\lambda(x-\epsilon i\delta)}\left\{1 - \frac{\epsilon i\kappa_1}{[\zeta_-(\lambda) + \zeta_{+1}][E_1^\epsilon(x,t)+1]}\right\}, \tag{7.33}$$

$$\bar{N}_{-\epsilon}^{+\epsilon}(x,t;\lambda) = 1 + \frac{\epsilon i\kappa_1}{[\zeta_+(\lambda) - \zeta_{+1}][E_1^\epsilon(x,t)+1]}. \tag{7.34}$$

These can be shown directly to satisfy Eqs. (3.15) and (3.16). The formulas also give the values of $M_\epsilon^{+\epsilon}$ and $N^{+\epsilon}$ at $\lambda=\lambda_1$ and of $\bar{M}^{+\epsilon}$ and $\bar{N}_{-\epsilon}^{+\epsilon}$ at $\lambda=-\lambda_1$. We already know from the general q-soliton results above that

$$A(\lambda) = \frac{\zeta_+(\lambda) - \zeta_{+1}}{\zeta_+(\lambda) + \zeta_{-1}}, \quad G(\lambda) = \frac{1}{A(\lambda)},$$

$$B(\lambda;t) = H(\lambda;t) = 0, \quad B(\lambda_1;t) = e^{\theta_1 t - \nu_1}, \quad H(-\lambda_1;t) = e^{-\theta_1 t + \nu_1},$$

but we can also confirm these results by evaluating the original integrals (3.38), (3.39), (3.43), and (3.44), the integrals for $B(\lambda;t)$ and $H(\lambda;t)$ requiring the rectangular contour with corners at $\eta = \pm R$ and $\pm R + 2\pi i/\kappa_1$.

To get the corresponding one-soliton solution of the MILW equation, follow the steps at the end of Sec. VI. Integrating U gives

$$W(x,t) = 2\tan^{-1}\left(\frac{E_1(x,t)\sin\,\delta\kappa_1}{1 + E_1(x,t)\cos\,\delta\kappa_1}\right), \tag{7.35}$$

where $E_1(x,t)$ is defined by Eq. (7.5). The only parameter that is allowed to be complex is ν_1. Let $\nu_1 = \sigma_1 + i\tau_1$. Then

$$V(x,t) = \log\left(\frac{\cosh(\kappa_1 x - \theta_1 t + \sigma_1) + \cos(\delta\kappa_1 - \tau_1)}{\cosh(\kappa_1 x - \theta_1 t + \sigma_1) + \cos(\delta\kappa_1 + \tau_1)}\right), \tag{7.36}$$

$$(\mathbf{T}V)(x,t) = -2\tan^{-1}\left(\frac{\sin\,\tau_1 \sinh(\kappa_1 x - \theta_1 t + \sigma_1)}{\cos\,\tau_1 \cosh(\kappa_1 x - \theta_1 t + \sigma_1) + \cos\,\delta\kappa_1}\right). \tag{7.37}$$

Appendix B also contains a direct proof that $\mathbf{T}V$ is the $\mathbf{T}$ transform of V. This $V(x,t)$ satisfies the MILW equation with

$$\beta = \kappa_1(\cot\,\delta\kappa_1 + \cot\,\tau_1). \tag{7.38}$$

It is now an easy matter to evaluate the integrals on the right-hand sides of Eqs. (3.60) and (4.11) for the case of the one-soliton solution of the MILW equation. The result in both cases is zero because the integrands are odd functions of $\kappa_1 x - \theta_1 t + \sigma_1$.

For the two-soliton solution, we begin the calculation with

$$N^{+\epsilon}(x,t;\lambda_1) = \frac{N_1}{D_1}, \quad N^{+\epsilon}(x,t;\lambda_2) = \frac{N_2}{D_1}, \tag{7.39}$$

where

$$N_1 = f_3 e^{-\theta_1 t + \nu_1}\{f_4 E_2^{\epsilon}(x,t) + f_2\}, \tag{7.40}$$

$$N_2 = f_4 e^{-\theta_2 t + \nu_2}\{f_3 E_1^{\epsilon}(x,t) - f_2\}, \tag{7.41}$$

$$D_1 = f_3 f_4\{E_1^{\epsilon}(x,t)E_2^{\epsilon}(x,t) + E_1^{\epsilon}(x,t) + E_2^{\epsilon}(x,t)\} + f_1 f_2, \tag{7.42}$$

and the auxiliary constants f_1, f_2, f_3, and f_4 are defined by

$$f_1 := \zeta_{+1} - \zeta_{+2}, \quad f_2 := \zeta_{-1} - \zeta_{-2},$$

$$f_3 := \zeta_{+1} + \zeta_{-2}, \quad f_4 := \zeta_{-1} + \zeta_{+2}.$$

The four Jost functions can be calculated from Eqs. (6.12), (6.15), (6.22), and (6.23). Equation (6.22) gives

$$M_{\epsilon}^{+\epsilon}(x,t;\lambda) = \frac{N_3}{[\zeta_+(\lambda) + \zeta_{-1}][\zeta_+(\lambda) + \zeta_{-2}]D_1}, \tag{7.43}$$

where

$$\begin{aligned} N_3 = f_3 f_4\{&[\zeta_+(\lambda) - \zeta_{+1}][\zeta_+(\lambda) - \zeta_{+2}]E_1^{\epsilon}(x,t)E_2^{\epsilon}(x,t) \\ &+ [\zeta_+(\lambda) - \zeta_{+1}][\zeta_+(\lambda) + \zeta_{-2}]E_1^{\epsilon}(x,t) \\ &+ [\zeta_+(\lambda) + \zeta_{-1}][\zeta_+(\lambda) - \zeta_{+2}]E_2^{\epsilon}(x,t)\} + f_1 f_2[\zeta_+(\lambda) + \zeta_{-1}][\zeta_+(\lambda) + \zeta_{-2}]. \end{aligned} \tag{7.44}$$

Then $\bar{N}_{-\epsilon}^{+\epsilon} = M_{\epsilon}^{+\epsilon}/A(\lambda)$, and the other two Jost functions can be deduced from the connection formulas.

According to Eqs. (6.21) and (6.25),

$$U^{\epsilon}(x,t) = \frac{iN_4}{2D_1}, \tag{7.45}$$

where

$$N_4 = f_3 f_4\{(\kappa_1 + \kappa_2)E_1^{\epsilon}(x,t)E_2^{\epsilon}(x,t) + (\kappa_1 - \kappa_2)[E_1^{\epsilon}(x,t) - E_2^{\epsilon}(x,t)]\} - f_1 f_2(\kappa_1 + \kappa_2). \tag{7.46}$$

Then the two-soliton solution of the complex-valued ILW equation is given by

$$U(x,t) = \frac{N_5}{D_5}, \quad (\mathbf{T}U)(x,t) = \frac{N_6}{D_5}, \tag{7.47}$$

where

$$N_5 = 2f_3f_4\{f_3f_4[\kappa_2 \sin \delta\kappa_2 E_1(x,t) + \kappa_1 \sin \delta\kappa_1 E_2(x,t) + (\kappa_1 - \kappa_2)\sin \delta(\kappa_1 - \kappa_2)]E_1(x,t)E_2(x,t) + f_1f_2[(\kappa_1 + \kappa_2)\sin \delta(\kappa_1 + \kappa_2)E_1(x,t)E_2(x,t) + \kappa_1 \sin \delta\kappa_1 E_1(x,t) + \kappa_2 \sin \delta\kappa_2 E_2(x,t)]\}, \tag{7.48}$$

$$N_6 = -f_3^2f_4^2\{(\kappa_1 + \kappa_2)E_1^2(x,t)E_2^2(x,t) + 2[\kappa_1 \cos \delta\kappa_2 E_1(x,t) + \kappa_2 \cos \delta\kappa_1 E_2(x,t)]E_1(x,t)E_2(x,t) + (\kappa_1 - \kappa_2)[E_1^2(x,t) - E_2^2(x,t)]\} + 2f_1f_2f_3f_4\{\kappa_2 \cos \delta\kappa_1 E_1(x,t) + \kappa_1 \cos \delta\kappa_2 E_2(x,t)\} + f_1^2f_2^2(\kappa_1 + \kappa_2), \tag{7.49}$$

$$D_5 = f_3^2f_4^2\{E_1^2(x,t)E_2^2(x,t) + 2[\cos \delta\kappa_2 E_1(x,t) + \cos \delta\kappa_1 E_2(x,t)]E_1(x,t)E_2(x,t) + E_1^2(x,t) + 2 \cos \delta(\kappa_1 - \kappa_2)E_1(x,t)E_2(x,t) + E_2^2(x,t)\} + 2f_1f_2f_3f_4 \times\{\cos \delta(\kappa_1 + \kappa_2)E_1(x,t)E_2(x,t) + \cos \delta\kappa_1 E_1(x,t) + \cos \delta\kappa_2 E_2(x,t)\} + f_1^2f_2^2. \tag{7.50}$$

To construct the two-soliton solution of the MILW equation, first integrate U to get the potential,

$$W(x,t) = 2 \tan^{-1}\left(\frac{N_7}{D_7}\right), \tag{7.51}$$

where

$$N_7 = f_3f_4\{\sin \delta(\kappa_1 + \kappa_2)E_1(x,t)E_2(x,t) + \sin \delta\kappa_1 E_1(x,t) + \sin \delta\kappa_2 E_2(x,t)\}, \tag{7.52}$$

$$D_7 = f_3f_4\{\cos \delta(\kappa_1 + \kappa_2)E_1(x,t)E_2(x,t) + \cos \delta\kappa_1 E_1(x,t) + \cos \delta\kappa_2 E_2(x,t)\} + f_1f_2. \tag{7.53}$$

There are two ways to arrange the complex parameters to arrive at a real MILW solution using Eq. (6.29), namely, the usual two-soliton consisting of two solitary waves and the two-breather. For the case of two solitary waves, let κ_1 and κ_2 be real with $0 < \kappa_1 < \kappa_2 < \pi/\delta$ and, for $j = 1, 2$, let $\nu_j = \sigma_j + i\tau_j$ and define the auxiliary functions,

$$\widetilde{E}_j(x,t) := \exp(\kappa_j x - \theta_j t + \sigma_j). \tag{7.54}$$

Equations (6.29) and (6.30) give

$$V(x,t) = \log\left(\frac{N_8}{D_8}\right), \quad (\mathbf{T}V)(x,t) = -2 \tan^{-1}\left(\frac{N_9}{D_9}\right), \tag{7.55}$$

where

$$N_8 = f_3^2f_4^2\{\widetilde{E}_1^2(x,t)\widetilde{E}_2^2(x,t) + 2[\cos(\delta\kappa_2 - \tau_2)\widetilde{E}_1(x,t) + \cos(\delta\kappa_1 - \tau_1)\widetilde{E}_2(x,t)]\widetilde{E}_1(x,t)\widetilde{E}_2(x,t) + \widetilde{E}_1^2(x,t) + \widetilde{E}_2^2(x,t) + 2 \cos(\delta\kappa_1 - \delta\kappa_2 - \tau_1 + \tau_2)\widetilde{E}_1(x,t)\widetilde{E}_2(x,t)\} + 2f_1f_2f_3f_4\{\cos(\delta\kappa_1 + \delta\kappa_2 - \tau_1 - \tau_2)\widetilde{E}_1(x,t)\widetilde{E}_2(x,t) + \cos(\delta\kappa_1 - \tau_1)\widetilde{E}_1(x,t) + \cos(\delta\kappa_2 - \tau_2)\widetilde{E}_2(x,t)\} + f_1^2f_2^2, \tag{7.56}$$

$$D_8 = f_3^2f_4^2\{\widetilde{E}_1^2(x,t)\widetilde{E}_2^2(x,t) + 2[\cos(\delta\kappa_2 + \tau_2)\widetilde{E}_1(x,t) + \cos(\delta\kappa_1 + \tau_1)\widetilde{E}_2(x,t)]\widetilde{E}_1(x,t)\widetilde{E}_2(x,t) + \widetilde{E}_1^2(x,t) + \widetilde{E}_2^2(x,t) + 2 \cos(\delta\kappa_1 - \delta\kappa_2 + \tau_1 - \tau_2)\widetilde{E}_1(x,t)\widetilde{E}_2(x,t)\} + 2f_1f_2f_3f_4\{\cos(\delta\kappa_1 + \delta\kappa_2 + \tau_1 + \tau_2)\widetilde{E}_1(x,t)\widetilde{E}_2(x,t) + \cos(\delta\kappa_1 + \tau_1)\widetilde{E}_1(x,t)$$

$$+\cos(\delta\kappa_2+\tau_2)\tilde{E}_2(x,t)\}+f_1^2f_2^2, \tag{7.57}$$

$$N_9=f_3^2f_4^2\{\sin(\tau_1+\tau_2)\tilde{E}_1^2(x,t)\tilde{E}_2^2(x,t)+2[\cos\,\delta\kappa_2\sin\,\tau_1\tilde{E}_1(x,t)+\cos\,\delta\kappa_1\sin\,\tau_2\tilde{E}_2(x,t)]\tilde{E}_1(x,t)\tilde{E}_2(x,t)$$
$$+\sin(\tau_1-\tau_2)[\tilde{E}_1^2(x,t)-\tilde{E}_2^2(x,t)]\}-2f_1f_2f_3f_4\{\cos\,\delta\kappa_1\sin\,\tau_2\tilde{E}_1(x,t)+\cos\,\delta\kappa_2\sin\,\tau_1\tilde{E}_2(x,t)\}$$
$$-f_1^2f_2^2\sin(\tau_1+\tau_2), \tag{7.58}$$

$$D_9=f_3^2f_4^2\{\cos(\tau_1+\tau_2)\tilde{E}_1^2(x,t)\tilde{E}_2^2(x,t)+2[\cos\,\delta\kappa_2\cos\,\tau_1\tilde{E}_1(x,t)$$
$$+\cos\,\delta\kappa_1\cos\,\tau_2\tilde{E}_2(x,t)]\tilde{E}_1(x,t)\tilde{E}_2(x,t)+\cos(\tau_1-\tau_2)[\tilde{E}_1^2(x,t)+\tilde{E}_2^2(x,t)]$$
$$+2\cos\,\delta(\kappa_1-\kappa_2)\tilde{E}_1(x,t)\tilde{E}_2(x,t)\}+2f_1f_2f_3f_4$$
$$\times\{\cos\,\delta(\kappa_1+\kappa_2)\tilde{E}_1(x,t)\tilde{E}_2(x,t)+\cos\,\delta\kappa_1\cos\,\tau_2\tilde{E}_1(x,t)+\cos\,\delta\kappa_2\cos\,\tau_1\tilde{E}_2(x,t)\}$$
$$+f_1^2f_2^2\cos(\tau_1+\tau_2). \tag{7.59}$$

This $V(x,t)$ satisfies the MILW equation with

$$\beta=\kappa_1(\cot\,\delta\kappa_1+\cot\,\tau_1)=\kappa_2(\cot\,\delta\kappa_2+\cot\,\tau_2). \tag{7.60}$$

This two-soliton solution describes two solitary waves traveling from left to right at different speeds, with the taller and thinner wave catching up to the shorter and thicker wave and overtaking it. After the interaction, both waves end up identical in shape to the original waves except for a phase shift, in accordance with the classic profile.

As already mentioned, the best way to construct the two-breather is to complexify the six real parameters in the two-soliton solution just constructed and take the real slice with $\kappa_2=(\kappa_1)^*$, $\sigma_2=(\sigma_1)^*$, and $\tau_2=(\tau_1)^*$. The functions N_8 and D_8 in Eq. (7.55) are real and positive definite for both the two-soliton and two-breather solutions.

To obtain the shallow-water limit of the multisoliton solutions, apply the scalings given by Eq. (2.7) and let all parameters be $O(1)$ as $\delta\to 0^+$ except

$$\tau_j=\pm\tfrac{1}{2}\pi+\delta\tilde{\tau}_j+O(\delta^2).$$

To take the deep-water limit $\delta\to\infty$, let

$$\kappa_j=\frac{\pi}{\delta}-\frac{\pi}{\delta^2\tilde{\lambda}_j},\quad \sigma_j=\frac{\pi\tilde{\sigma}_j}{\delta},\quad \tau_j=\frac{\pi\tilde{\tau}_j}{\delta}.$$

Then the constraints given by Eq. (7.26) reduce to $\tilde{\tau}_j=1/(\beta+\tilde{\lambda}_j)$.

APPENDIX A: PROPERTIES OF THE OPERATOR T

The singular integral operator **T**, defined by

$$(\mathbf{T}f)(x):=\frac{1}{2\delta}(P)\int_{-\infty}^{\infty}\coth\left(\frac{\pi}{2\delta}(\xi-x)\right)f(\xi)\mathrm{d}\xi=\mathbf{T}(f(x)), \tag{A1}$$

where (P) indicates that the integral is in the Cauchy principal-value sense, appears in the ILW and MILW equations. In this appendix we collate several useful mathematical properties of this

operator. Most of these results are easily proved directly from the definition (some require contour integration), and so we omit these proofs. However, we supply a proof of Eq. (A3) below because of its importance for the shallow-water limit.

The deep-water limit to the BO and MBO equations involves the Hilbert transform operator **H** defined by

$$(\mathbf{H}f)(x) := \frac{1}{\pi}(P)\int_{-\infty}^{\infty}\frac{f(\xi)}{\xi - x}\mathrm{d}\xi = \mathbf{H}(f(x)).$$

Without any additional hypotheses on $f(x)$ apart from the absolute convergence of $\int_{-\infty}^{\infty} f(x)\mathrm{d}x$, we get

$$(\mathbf{T}f)(x) = (\mathbf{H}f)(x) + O(1/\delta), \tag{A2}$$

as $\delta \to \infty$, uniformly for all real x. The O bound can be improved to $O(1/\delta^2)$ uniformly for x on finite intervals if $\int_{-\infty}^{\infty} xf(x)\mathrm{d}x$ converges absolutely.

The corresponding shallow-water limit is given by

$$(\mathbf{T}f)(x) = -\frac{1}{\delta}\int_{-\infty}^{x} f(\xi)\mathrm{d}\xi + L_f + \frac{\delta}{3}f'(x) + \frac{\delta^3}{45}f'''(x) + O(\delta^5), \tag{A3}$$

as $\delta \to 0^+$, where

$$L_f := \frac{1}{2\delta}\int_{-\infty}^{\infty} f(\xi)\mathrm{d}\xi.$$

This is a truncated version of a more general result derived below.

The operator **T** also possesses the following additional properties:[26,27,35,41]

$$\lim_{x\to\pm\infty}(\mathbf{T}f)(x) = \mp L_f, \tag{A4}$$

$$\frac{d}{\mathrm{d}x}\{(\mathbf{T}f)(x)\} = (\mathbf{T}f')(x) = \mathbf{T}(f'(x)), \tag{A5}$$

$$\int_{-\infty}^{\infty} f(x)(\mathbf{T}g)(x)\mathrm{d}x = -\int_{-\infty}^{\infty} g(x)(\mathbf{T}f)(x)\mathrm{d}x, \tag{A6}$$

$$\mathbf{T}(f\mathbf{T}g + g\mathbf{T}f)(x) = (\mathbf{T}f)(x)(\mathbf{T}g)(x) - f(x)g(x) - L_fL_g, \tag{A7}$$

$$\mathbf{T}\left(\log\frac{h(x+i\delta)}{h(x-i\delta)}\right) = -i\log\{h(x+i\delta)h(x-i\delta)\}. \tag{A8}$$

In all cases, it is understood that $f(x)$ and $g(x)$ are sufficiently smooth and decay at a sufficient rate to guarantee existence of the relevant derivatives and integrals and allow interchange of limit operations. In Eq. (A8), $h(z)$ denotes a function of a complex variable z that is analytic in the open strip $-\delta < \mathrm{Im}\, z < \delta$, is continuous and nonzero on the closure of that strip, and tends to 1 uniformly as $\mathrm{Re}\, z \to \pm\infty$ in the closed strip.

A proof of Eq. (A3) is given by Satsuma *et al.*[23] It calls upon a result of Gibbons and Kupershmidt.[26] We believe that the reader would be interested in seeing a proof that proceeds directly from the definition of the **T** operator.

To assist in the derivation, we prefer to use the auxiliary operator,[21]

$$(\hat{\mathbf{T}}f)(x) := \frac{1}{2\delta}(P)\int_{-\infty}^{\infty}\left\{\coth\left(\frac{\pi}{2\delta}(\xi-x)\right)-\operatorname{sgn}(\xi-x)\right\}f(\xi)\mathrm{d}\xi, \tag{A9}$$

which converges more rapidly than the integral for $(\mathbf{T}f)(x)$ (although, of course, it is not suited to contour integration). The two operators $\mathbf{T}$ and $\hat{\mathbf{T}}$ are related by the identity,

$$(\mathbf{T}f)(x) = (\hat{\mathbf{T}}f)(x) + \frac{1}{2\delta}\int_{x}^{\infty} f(\xi)\mathrm{d}\xi - \frac{1}{2\delta}\int_{-\infty}^{x} f(\xi)\mathrm{d}\xi. \tag{A10}$$

First, observe that the change of variable $y=(\xi-x)/\delta$ maps Eq. (A9) into

$$(\hat{\mathbf{T}}f)(x) = \frac{1}{2}(P)\int_{-\infty}^{\infty}\left\{\coth\left(\frac{\pi y}{2}\right)-\operatorname{sgn}(y)\right\}f(x+\delta y)\mathrm{d}y. \tag{A11}$$

Focus now on the shallow-water region, $0<\delta\ll 1$. Assume that $f(x)$ possesses at least three derivatives. The Taylor series (with remainder) for the function $f(x+\delta y)$ in ascending powers of δ or y is

$$f(x+\delta y) = \sum_{m=0}^{2N}\frac{\delta^m y^m}{m!}f^{(m)}(x) + \frac{\delta^{2N+1}y^{2N+1}}{(2N+1)!}f^{(2N+1)}(x+\delta\theta y), \tag{A12}$$

where $0<\theta=\theta(x,y,\delta,N)<1$. Substituting Eq. (A12) into Eq. (A11) and interchanging the order of summation and integration, we obtain

$$(\hat{\mathbf{T}}f)(x) = \frac{1}{2}\sum_{m=0}^{2N}\frac{\delta^m}{m!}f^{(m)}(x)(P)\int_{-\infty}^{\infty}\left\{\coth\left(\frac{\pi y}{2}\right)-\operatorname{sgn}(y)\right\}y^m\,\mathrm{d}y + R_N, \tag{A13}$$

where the remainder term R_N will be given a suitable bound below.

The integral in Eq. (A13) is a principal-value integral only for $m=0$ and, in this case, it vanishes because the integrand is odd. For all other m, the integrals are just convergent improper Riemann integrals. Again, when m is even, they all vanish because the integrands are odd. Hence, the series Eq. (A13) simplifies to

$$(\hat{\mathbf{T}}f)(x) = \sum_{k=1}^{N}\frac{\delta^{2k-1}}{(2k-1)!}f^{(2k-1)}(x)I_k + R_N, \tag{A14}$$

where

$$I_k := \int_0^{\infty}\left\{\coth\left(\frac{\pi y}{2}\right)-1\right\}y^{2k-1}\,\mathrm{d}y. \tag{A15}$$

The integrals I_k can be evaluated in terms of zeta-function values or Bernoulli numbers as follows:

$$I_k = \frac{2}{\pi^{2k}}\int_0^{\infty}\frac{z^{2k-1}}{e^z-1}\mathrm{d}z = \frac{2}{\pi^{2k}}(2k-1)!\zeta(2k) = \frac{2^{2k-1}}{k}|B_{2k}|. \tag{A16}$$

(To distinguish between various conventions for the Bernoulli numbers, we state here that $B_0=1$, $B_1=-1/2$, $B_2=1/6$, $B_3=0$, and $B_4=-1/30$.)

The remainder term can be written,

$$R_N = \frac{\delta^{2N+1}}{2(2N+1)!}\int_0^\infty \left\{\coth\left(\frac{\pi y}{2}\right) - 1\right\} y^{2N+1}\{f^{(2N+1)}(x+\delta\theta y) + f^{(2N+1)}(x-\delta\theta_1 y)\}\mathrm{d}y, \tag{A17}$$

where $\theta_1 := \theta(x,-y,\delta,N)$. A straightforward bound can be obtained if we just assume that the derivatives of $f(x)$ are bounded, that is,

$$|f^{(k)}(x)| \leqslant M_k, \quad -\infty < x < \infty, \tag{A18}$$

at least in the case $k=2N+1$. (Of course, this might not be sharp enough for some applications.) Then the triangle inequality for integrals gives

$$|R_N| \leqslant \frac{M_{2N+1} I_{N+1} \delta^{2N+1}}{(2N+1)!} = \frac{2^{2N+2}\delta^{2N+1}}{(2N+2)!}|B_{2N+2}|M_{2N+1}. \tag{A19}$$

Substituting Eq. (A16) into Eq. (A14), we obtain

$$(\hat{\mathbf{T}}f)(x) = \sum_{k=1}^{N} \frac{2^{2k}\delta^{2k-1}}{(2k)!}|B_{2k}|f^{(2k-1)}(x) + R_N, \tag{A20}$$

which is the (truncated) shallow-water expansion of the operator $\hat{\mathbf{T}}$ in terms of known quantities. According to Eq. (A10), the corresponding expansion for $\mathbf{T}$ is

$$(\mathbf{T}f)(x) = \frac{1}{2\delta}\int_x^\infty f(\xi)\mathrm{d}\xi - \frac{1}{2\delta}\int_{-\infty}^x f(\xi)\mathrm{d}\xi + \sum_{k=1}^{N} \frac{2^{2k}\delta^{2k-1}}{(2k)!}|B_{2k}|f^{(2k-1)}(x) + R_N. \tag{A21}$$

If $f(x)$ were real-analytic or differentiable to all orders, we would obtain an infinite series in ascending powers of δ. Depending on the remainder, it could be either convergent or valid as an asymptotic series for small positive δ. If $f(x)$ is differentiable five times, with a bounded fifth derivative, we get the truncated formula Eq. (A3).

APPENDIX B: SELECTED T TRANSFORMS

In this appendix, we give direct evaluations of $(\mathbf{T}f)(x)$ for a useful class of functions that includes the one-soliton solutions of the ILW and MILW equations (with the time dependence and phase shift suppressed as these can be trivially reinstated later). These results are used in Sec. VII to confirm that the one-soliton solutions do indeed satisfy their respective equations and also to evaluate the parameter β in the one-soliton solution of the MILW equation.

Begin with the two-parameter family of functions,

$$f(x) = \frac{1}{\cosh \kappa x + \cos\theta_0}, \tag{B1}$$

where κ and θ_0 are real with $\kappa > 0$ and $-\pi < \theta_0 < \pi$. In general, the $\mathbf{T}$ transform of $f(x)$ does not have a simple explicit formula, but there are simple formulas in cases where one parameter is arbitrary and the other is suitably restricted. For example, in the case where θ_0 is arbitrary and κ is a rational multiple of π/δ, the integral defining $(\mathbf{T}f)(x)$ can be evaluated by summing residues inside a suitable indented rectangular contour. However, the rectangular contour cannot work in the case relevant to the one-soliton solution of the ILW equation, where κ is arbitrary and $\theta_0 = \kappa\delta$. Several of the more elementary integrals appearing below without proof can be reduced to linear combinations of the following integrals:

$$\int_{-\infty}^{\infty} \frac{\sinh \alpha\mu}{\sinh \beta\mu} \mathrm{d}\mu = \frac{\pi}{\beta} \tan\left(\frac{\pi\alpha}{2\beta}\right), \tag{B2}$$

β real, α complex, $-\beta < \mathrm{Re}\ \alpha < \beta$,

$$\int_{-R}^{R} \frac{\sinh \alpha\mu}{\sinh \beta\mu} \mathrm{d}\mu = \frac{\pi}{\beta} \tan\left(\frac{\pi\alpha}{2\beta}\right) + \frac{2}{\alpha - \beta} e^{(\alpha-\beta)R} + O(e^{-(3\beta - \mathrm{Re}\ \alpha)R}), \tag{B3}$$

as $R \to \infty$, $\beta \leqslant \mathrm{Re}\ \alpha < 3\beta$, $\alpha \neq \beta$, and

$$\int_{-\infty}^{\infty} \frac{\cosh \kappa\alpha x}{\cosh \kappa x + \cos\ \theta_0} \mathrm{d}x = \frac{2\pi \sin\ \alpha\theta_0}{\kappa \sin\ \theta_0 \sin\ \pi\alpha}, \tag{B4}$$

$-1 < \mathrm{Re}\ \alpha < 1$.

Take a Fourier transform of $f(x)$ and rearrange to give the formula,

$$\frac{1}{\cosh \kappa x + \cos\ \theta_0} = \frac{1}{\sin\ \theta_0} \int_{-\infty}^{\infty} \frac{\sinh\ \theta_0\mu}{\sinh\ \pi\mu} e^{i\kappa\mu x}\, \mathrm{d}\mu. \tag{B5}$$

Apply the $\hat{\mathbf{T}}$ operator and interchange the order of integration. A straightforward application of a rectangular contour with corners at $\xi = \pm R$ and $\pm R + 2i\delta$ and indents at $\xi = x$ and $x + 2i\delta$ gives

$$\hat{\mathbf{T}}(e^{i\kappa\mu x}) = i\left(\coth\ \kappa\delta\mu - \frac{1}{\kappa\delta\mu}\right) e^{i\kappa\mu x}.$$

Thence

$$\hat{\mathbf{T}}\left(\frac{1}{\cosh \kappa x + \cos\ \theta_0}\right) = -\frac{1}{\sin\ \theta_0} \int_{-\infty}^{\infty} \frac{\sinh\ \theta_0\mu \sin\ \kappa\mu x}{\sinh\ \pi\mu} \left(\coth\ \kappa\delta\mu - \frac{1}{\kappa\delta\mu}\right) \mathrm{d}\mu. \tag{B6}$$

Parameter differentiation and a rectangular contour give the result,

$$\int_{-\infty}^{\infty} \frac{\sinh\ \theta_0\mu \sin\ \kappa\mu x}{\mu \sinh\ \pi\mu} \mathrm{d}\mu = 2 \tan^{-1}\left(\tan \frac{1}{2}\theta_0 \tanh \frac{1}{2}\kappa x\right). \tag{B7}$$

Thence Eq. (A10) gives our main formula,

$$\mathbf{T}\left(\frac{1}{\cosh \kappa x + \cos\ \theta_0}\right) = -\frac{1}{\sin\ \theta_0} \int_{-\infty}^{\infty} \frac{\sinh\ \theta_0\mu \sin\ \kappa\mu x}{\sinh\ \pi\mu} \coth\ \kappa\delta\mu\, \mathrm{d}\mu, \tag{B8}$$

valid for $\kappa \neq 0$ and $-\pi < \theta_0 < \pi$. Validity extends to $\kappa = 0$ if the $\mathbf{T}$ operator is understood to be a principal value integral in two senses, the second being $(P)\int_{-\infty}^{\infty} = \lim_{R\to\infty} (P)\int_{-R}^{R}$.

It is immediately clear from Eq. (B8) that the case $\theta_0 = \kappa\delta$ can be reduced to two applications of Eq. (B2). The result is

$$\mathbf{T}\left(\frac{1}{\cosh \kappa x + \cos\ \kappa\delta}\right) = -\frac{1}{\sin\ \kappa\delta} \frac{\sinh\ \kappa x}{\cosh\ \kappa x + \cos\ \kappa\delta}, \tag{B9}$$

valid for $-\pi/\delta < \kappa < \pi/\delta$. This integral (with an appropriate shift in x) confirms Eq. (7.30) for the one-soliton solution of the ILW equation.

The integral on the right-hand side of Eq. (B8) also simplifies when θ_0 is a nonzero integer multiple of $\kappa\delta$ or differs from such a value by π. Examples are

$$\mathbf{T}\left(\frac{1}{\cosh \kappa x - \cos \kappa\delta}\right) = \frac{1}{\sin \kappa\delta}\left(\frac{\sinh \kappa x}{\cosh \kappa x - \cos \kappa\delta} - \frac{\pi}{\kappa\delta}\tanh \frac{\pi x}{2\delta}\right), \tag{B10}$$

valid for $0<\kappa<2\pi/\delta$,

$$\mathbf{T}\left(\frac{1}{\cosh \kappa x + \cos 2\kappa\delta}\right) = -\frac{1}{\sin 2\kappa\delta}\left(\frac{\sinh \kappa x}{\cosh \kappa x + \cos 2\kappa\delta} + \tanh \frac{\kappa x}{2}\right), \tag{B11}$$

valid for $-\pi/(2\delta)<\kappa<\pi/(2\delta)$, and

$$\mathbf{T}\left(\frac{1}{\cosh \kappa x - \cos 2\kappa\delta}\right) = \frac{1}{\sin 2\kappa\delta}\left(\frac{\sinh \kappa x}{\cosh \kappa x - \cos 2\kappa\delta} + \coth \frac{\kappa x}{2} - \frac{\pi}{\kappa\delta}\coth \frac{\pi x}{2\delta}\right), \tag{B12}$$

valid for $0<\kappa<\pi/\delta$.

The small κ limits of Eqs. (B10) and (B12) give

$$\mathbf{T}\left(\frac{1}{x^2+\delta^2}\right) = \frac{x}{\delta(x^2+\delta^2)} - \frac{\pi}{2\delta^2}\tanh \frac{\pi x}{2\delta}, \tag{B13}$$

$$\mathbf{T}\left(\frac{1}{x^2+4\delta^2}\right) = \frac{1}{2\delta x} + \frac{x}{2\delta(x^2+4\delta^2)} - \frac{\pi}{4\delta^2}\coth \frac{\pi x}{2\delta}, \tag{B14}$$

which can be proved directly by summing residues in the upper-half ξ plane. More generally,

$$\mathbf{T}\left(\frac{1}{x^2+n^2\delta^2}\right) = \frac{x}{n\delta}\sum_{k=1}^{n}\left(\frac{1}{x^2+(2k-n)^2\delta^2}\right) - \frac{\pi}{2n\delta^2}\coth\left(\frac{\pi x}{2\delta} + \frac{n\pi i}{2}\right). \tag{B15}$$

The aforementioned elementary case where κ is a rational multiple of π/δ is best handled by applying the rectangular contour to the right-hand side of Eq. (B8). The simplest examples are

$$\mathbf{T}\left(\frac{1}{\cosh(\pi x/\delta) + \cos \theta_0}\right) = -\frac{\delta\theta_0 \sinh(\pi x/\delta) + \pi x \sin \theta_0}{\delta\pi \sin \theta_0\{\cosh(\pi x/\delta) + \cos \theta_0\}}, \tag{B16}$$

$$\mathbf{T}\left(\frac{1}{\cosh(\pi x/(2\delta)) + \cos \theta_0}\right) = -\frac{2\delta\theta_0 \sinh(\pi x/\delta) - \pi x \sin 2\theta_0}{\delta\pi \sin \theta_0\{\cosh(\pi x/\delta) - \cos 2\theta_0\}}. \tag{B17}$$

More generally,

$$\begin{aligned}\mathbf{T}\left(\frac{1}{\cosh(m\pi x/(n\delta)) + \cos \theta_0}\right) = &-\frac{1}{m\pi \sin \theta_0\{\cosh(m\pi x/\delta) - (-1)^n \cos n\theta_0\}} \\ &\times \left\{ n\theta_0 \sinh \frac{m\pi x}{\delta} - (-1)^n \frac{m\pi x}{\delta} \sin n\theta_0 \right. \\ &+ 2m\pi \sum_{k=1}^{n-1} (-1)^k \cot \frac{km\pi}{n} \sin k\theta_0 \sinh \frac{(n-k)m\pi x}{n\delta} \\ &\left. + 2n\pi \sum_{h=1}^{m-1} \operatorname{cosec} \frac{hn\pi}{m} \sin \frac{hn\theta_0}{m} \sinh \frac{(m-h)\pi x}{\delta} \right\}.\end{aligned} \tag{B18}$$

Additional consequences of Eq. (B8) can be deduced by parameter differentiation or integration. Multiply both sides by $\sin \theta_0$ and integrate with respect to θ_0. We get

$$\mathbf{T}\left(\log\frac{\cosh\kappa x+\cos\theta_2}{\cosh\kappa x+\cos\theta_1}\right)=\int_{-\infty}^{\infty}\frac{(\cosh\theta_2\mu-\cosh\theta_1\mu)\sin\kappa\mu x}{\mu\sinh\pi\mu}\coth\kappa\delta\mu\,\mathrm{d}\mu, \tag{B19}$$

valid for $-\pi<\theta_j<\pi$, $j=1,2$. A cancellation occurs when $\theta_2+\theta_1=2\kappa\delta$. The result is

$$\begin{aligned}\mathbf{T}\left(\log\frac{\cosh\kappa x+\cos(\kappa\delta+\gamma)}{\cosh\kappa x+\cos(\kappa\delta-\gamma)}\right)&=2\int_{-\infty}^{\infty}\frac{\sinh\gamma\mu\cosh\kappa\delta\mu\sin\kappa\mu x}{\mu\sinh\pi\mu}\mathrm{d}\mu\\&=2\tan^{-1}\left(\frac{\sin\gamma\sinh\kappa x}{\cos\gamma\cosh\kappa x+\cos\kappa\delta}\right).\end{aligned} \tag{B20}$$

Apart from a shift in x, this is the **T** transform of the one-soliton solution of the MILW equation, confirming Eq. (7.37).

(Received 30 March 2004; accepted 9 June 2005; published online 7 October 2005)

We present the formulas for twist quantization of g_2, corresponding to the solution of a classical YB equation with support in the eight-dimensional Borel subalgebra of g_2. The considered chain of twists consists of the four factors describing the four steps of quantization: Jordanian twist, the two twist factors extending Jordanian twist and the deformed Jordanian or in a second variant additional Abelian twist. The first two steps describe as well the $sl(3)$ quantization. The coproducts are calculated for each step in explicit form, and for that purpose we present new formulas for the calculation of similarity transformations on the tensor product. We introduce new basic generators in universal enveloping algebra $U(g_2)$ that provide nonlinearities in the algebraic sector maximally simplifying the deformed coproducts. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2041849]

I. INTRODUCTION

In this paper we shall consider the basic nonstandard quantum deformations of complex exceptional Lie algebra g_2. There are four complex semisimple Lie algebras of rank 2, given by $A_2 \simeq sl(3)$, $D_2 \simeq o(4) = o(3) \oplus o(3)$, $B_2 \simeq C_2 \simeq o(5) \simeq sp(4)$ and g_2, with 8, 6, 10, and 14 generators, respectively. The eight-dimensional carrier of classical r matrices that describe our deformations is equal to the Borel subalgebra $\mathfrak{b}_+(g_2)$ of g_2.

There are two natural embeddings related with the group G_2.

(i) $G_2 \subset O(7)$. The fundamental matrix representation of G_2 is seven dimensional. The 7×7 orthogonal matrices $(L_{ab}) \in O(7)$ $(a,b=1,2,\ldots,7)$ belong to the group G_2 if the following cubic constraint is satisfied:[1,2]

$$f_{a_1a_2a_3} = f_{b_1b_2b_3} L_{a_1b_1} L_{a_2b_2} L_{a_3b_3}, \tag{1.1}$$

where the totally antisymmetric cubic tensor f_{abc} describes the multiplication table for imaginary octonions t_a,

$$t_a t_b = f_{abc} t_c, \tag{1.2}$$

and the values of f_{abc} are determined by the following choice (we list only nonvanishing values):

$$f_{127} = f_{157} = f_{163} = f_{264} = f_{245} = f_{374} = f_{576} = 1. \tag{1.3}$$

Therefore there are only seven independent equations (1.1) reducing 21 parameters of $O(7)$ to 14 parameters of the group G_2.

We see that the fundamental seven-dimensional representation $\{7\}$ of Lie algebra g_2 inherits basic properties of the fundamental $o(7)$ representation: reality and its dimensionality. The generators (E^l_k, A_k, B^l) $(k,l=1,2,3)$ of g_2 satisfy the following relations (Refs. 1–5):

[a)]On leave of absence from Sankt-Petersburg University, Ulianovskaya 1, Petrodvoretz, 198904 Sankt Petersburg, Russia
[b)]On leave of absence from Institute of Nuclear Physics, Moscow State University, 119 992 Moscow, Russia

$$[E_k{}^l, E_m{}^n] = \delta_m{}^l E_k{}^n - \delta_k{}^n E_m{}^l, \tag{1.4a}$$

$$[E_k{}^l, A_m] = \delta_m{}^l A_k - \frac{1}{3}\delta_k{}^l A_m, \tag{1.4b}$$

$$[E_k{}^l, B^n] = -\delta_k{}^n B^l + \frac{1}{3}\delta_k{}^l B^n, \tag{1.4c}$$

$$[A_m, B^n] = E_m{}^n, \tag{1.4d}$$

$$[A_m, A_n] = -\frac{4}{3}\epsilon_{mnl} B^l, \tag{1.4e}$$

$$[B^m, B^n] = \epsilon^{mnl} A_l, \tag{1.4f}$$

where

$$E_k{}^k = 0, \tag{1.4g}$$

and we employ the $su(3)$ tensorial basis.

(ii) $sl(3) \subset g_2$ or $su(3) \subset g_2$ (real form). The generators $E_k{}^l$ forming the subalgebra (1.4a) describe $sl(3)$ (if g_2 is a complex Lie algebra) or $su(3)$ (if we introduce in g_2 the suitable real structure). The Lie algebra generators of g_2 belong to a 14-dimensional adjoint representation $\{\underline{14}\}$ that decomposes under $sl(3)$ [or $su(3)$] as follows:

$$\{\underline{14}\} = \{\underline{8}\} + \{\underline{3}\} + \{\overline{\underline{3}}\}. \tag{1.5}$$

In the realization [(1.4a), (1.4b), (1.4c), (1.4d), (1.4e), and (1.4f)] of the Lie algebra g_2, the generators A_m (B^m) transform as fundamental triplet (antitriplet) representations of $sl(3)$ or $su(3)$. These properties can also be seen from the root diagram of g_2 (see Sec. II).

The relations (1.4a), (1.4b), (1.4c), (1.4d), (1.4e), (1.4f), and (1.4g) show that the coset space $S^6 = G_2/SU(3)$ is a nonsymmetric Riemannian space, with torsion described by the nonvanishing rhs of relations (1.4e) and (1.4f). One of our aims in this paper is to provide an algebraic ground for new quantum deformation of the sphere S^6 with torsion.

The embedding of a three-dimensional fundamental representation of $su(3)$ described by Gell-Mann fundamental matrices λ_k ($k=1,\ldots,8$) into a seven-dimensional fundamental representation of g_2 looks as follows:

$$\Lambda_k = \frac{1}{\sqrt{2}}\begin{pmatrix} \lambda_k & 0 & 0 \\ 0 & -\lambda_k^* & 0 \\ 0 & 0 & 0 \end{pmatrix}, \tag{1.6}$$

where we use the standard normalization

$$\mathrm{Tr}\,\lambda_k\lambda_l = \mathrm{Tr}\,\Lambda_k\Lambda_l = 2\delta_{kl}. \tag{1.7}$$

We identify two Cartan generators of g_2 with the $su(3)$ generators Λ_3 and Λ_8.

Our plan for this paper is the following:

In Sec. II we shall consider the Lie algebra g_2 in the Cartan-Weyl basis (see, e.g., Ref. 6), which is directly linked with the generators (E_k^l, A_k, B^l) satisfying the algebra (1.4a), (1.4b), (1.4c), (1.4d), (1.4e), (1.4f), and (1.4g). We present the important class of triangular r matrices for g_2, satisfying the classical Yang–Baxter equation (CYBE). It appears that the two-parameter families of such r matrices have as its carrier algebra the whole eight-dimensional Borel subalgebra

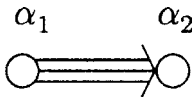

FIG. 1. Dynkin diagram of the Lie algebra g_2.

$\mathfrak{b}_+(g_2) \subset g_2$. We show that the parameters of the considered classical r matrices can achieve fixed nonzero values by means of inner automorphism maps inside g_2 algebra. In Sec. III we shall recall the general formulas that describe the twist quantization method,[7–12] and we shall introduce the general twisting function, describing the twist quantization procedure for g_2 with the eight-dimensional carrier space for its r matrix. In Sec. IV we obtain first the explicit formulas describing the twist quantization of g_2 generated by the $sl(3)$ classical r matrix. It appears that these quantization formulas for g_2 describe the extension of known relations describing the twist quantization of $sl(3)$.[12] In particular, following general techniques presented in Ref. 13, we shall introduce a suitable nonlinear basis in the deformed Hopf algebras. In Sec. V we consider the most general g_2 quantizations containing two additional twists, depending on the g_2 generators from the coset $G_2/sl(3)$. In Sec. VI we present a general discussion and some conclusions. We remark that in Secs. IV and V we shall use new algebraic formulas for calculating twisted coproducts presented in Sec. III D and shall introduce a new basis of $U(g_2)$, which will simplify the twisted coproduct formulas.

The motivation for our work is mainly to present a new mathematical result—an interesting class of quantum deformations for an important Lie algebra. On the other side, it should be stressed that g_2 algebra recently has attracted attention of physicists in the domain of elementary particle physics and fundamental interactions theory. In particular, we recall the following.

(i) In 11-dimensional M theory, there were proposed the internal manifolds with g_2 holonomy as a base for the grand unification describing an extension of the standard model in particle physics (see, e.g., Refs. 14–17). The algebra g_2 implies seven-dimensional internal symmetry space as the privileged one, in obvious connection with the relation $11=4+7$.

(ii) In the reduction of supersymmetric theories from $D=11$ to $D=4$, the g_2 internal symmetry implies a phenomenologically interesting case of $D=4$ models with $N=1$ supersymmetry.[5] In particular, there were also considered standard and supersymmetric extensions of $D=4$ chromodynamics to G_2 gauge theories[5] with an interesting exceptional quark confinement mechanism.

(iii) There are four Hurwitz algebras (real numbers R, complex numbers C, quaternions H, and octonions O); G_2 acts on seven imaginary octonionic units and describes the automorphism group of the octonion algebra. All applications of exceptional and octonions groups to the description of symmetries in elementary particle physics (see, e.g., Ref. 18) is therefore strongly linked with the appearance of G_2 symmetry.

In this paper we consider only the quantum deformations of universal enveloping algebra $U(g_2)$; it is an interesting problem to supplement the considerations with deformations of dual Hopf algebra describing matrix quantum G_2 group and, further, describe, e.g., the quantum deformations of $S^6=G_2/SL(3)$. In such a way one can obtain an example of the six-dimensional counterpart of a two-dimensional Podleś sphere,[19] provided by the deformed coset $SU(2)/U(1)$.

II. CARTAN–WEYL BASIS OF g_2 AND JORDANIAN TYPE CLASSICAL r MATRICES

A. Cartan–Weyl basis of g_2

In order to describe a Cartan–Weyl basis of g_2, let us introduce the Dynkin diagram for its simple roots $\Pi=\{\alpha_1,\alpha_2\}$ (see Fig. 1):

The corresponding standard $A=(a_{ij})$ $(i,j=1,2)$ and symmetric $A^{\mathrm{sym}}=(a_{ij}^{\mathrm{sym}})_{i,j}$ Cartan matrices are given by

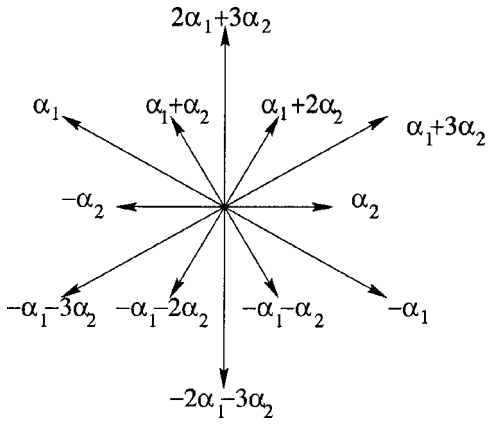

FIG. 2. The root diagram for g_2.

$$A=\begin{pmatrix}2 & -1\\ -3 & 2\end{pmatrix},\quad A^{\mathrm{sym}}=\begin{pmatrix}6 & -3\\ -3 & 2\end{pmatrix}. \tag{2.1}$$

The Lie algebra g_2 is generated by the six Chevalley elements e_{α_i}, $e_{-\alpha_i}$, h_{α_i} $(i=1,2)$ with the defining relations (see, e.g., Ref. 6)

$$[h_{\alpha_i},h_{\alpha_j}]=0,$$

$$[h_{\alpha_i},e_{\pm\alpha_j}]=\pm a_{ij}^{\mathrm{sym}}e_{\pm\alpha_j},$$

$$[e_{\alpha_i},e_{-\alpha_j}]=\delta_{ij}h_{\alpha_i},$$

$$[e_{\pm\alpha_1},[e_{\pm\alpha_1},e_{\pm\alpha_2}]]=0,$$

$$[[[[e_{\pm\alpha_1},e_{\pm\alpha_2}],e_{\pm\alpha_2}],e_{\pm\alpha_2}],e_{\pm\alpha_2}]=0. \tag{2.2}$$

The positive $\Sigma_+(g_2)$ and total $\Sigma(g_2)=\Sigma_+(g_2)\cup(-\Sigma_+(g_2))$ root systems of g_2 are presented in terms of an orthonormalized basis $\{\epsilon_1,\epsilon_2\}$ of a two-dimensional Euclidian space as follows:

$$\Sigma_+(g_2)=\left\{\sqrt{3}\epsilon_1,\epsilon_2,\frac{\sqrt{3}}{2}\epsilon_1\pm\frac{1}{2}\epsilon_2,\frac{\sqrt{3}}{2}\epsilon_1\pm\frac{3}{2}\epsilon_2\right\}, \tag{2.3}$$

$$\Sigma(g_2)=\left\{\pm\sqrt{3}\epsilon_1,\pm\epsilon_2,\pm\frac{\sqrt{3}}{2}\epsilon_1\pm\frac{1}{2}\epsilon_2,\pm\frac{\sqrt{3}}{2}\epsilon_1\pm\frac{3}{2}\epsilon_2\right\}, \tag{2.4}$$

where the simple roots are given by $\alpha_1=(\sqrt{3}/2)\epsilon_1-\frac{3}{2}\epsilon_2$ and $\alpha_2=\epsilon_2$. It is convenient to present the total root system by the root diagram presented in Fig. 2.

For a construction of the composite root vectors e_γ $(\gamma\neq\pm\alpha_1,\pm\alpha_2)$, we fix the following normal ordering of the positive root system $\Sigma_+(g_2)$ (see Ref. 6):

$$\alpha_1,\alpha_1+\alpha_2,2\alpha_1+3\alpha_2,\alpha_1+2\alpha_2,\alpha_1+3\alpha_2,\alpha_2, \tag{2.5}$$

which corresponds to "clockwise" ordering for positive roots in Fig. 2 if we start from the root α_1 to the root α_2. For convenience we introduce the short notations,

$$e_{k,l} := e_{k\alpha_1+l\alpha_2}, \quad h_{k,l} := kh_{\alpha_1} + lh_{\alpha_2}, \tag{2.6}$$

for $k,l=0,\pm 1,\ldots$. According to the ordering (2.5), we set the composite roots generators with suitably chosen numerical coefficients as follows:

$$e_{1,1} = [e_{1,0}, e_{0,1}], \quad e_{-1,-1} = -[e_{-1,0}, e_{0,-1}],$$

$$e_{1,2} = [e_{1,1}, e_{0,1}], \quad e_{-1,-2} = -\frac{3}{4}[e_{0,-1}, e_{-1,-1}],$$

$$e_{1,3} = [e_{1,2}, e_{0,1}], \quad e_{-1,-3} = -\frac{3}{4}[e_{0,-1}, e_{-1,-2}],$$

$$e_{2,3} = [e_{1,3}, e_{1,0}], \quad e_{-2,-3} = -\frac{3}{4}[e_{-1,0}, e_{-1,-3}]. \tag{2.7}$$

The complete set of relations for the Cartan–Weyl basis of g_2 can be read off from the formulas (1.4a), (1.4b), (1.4c), (1.4d), (1.4e), and (1.4f) after the identification

$$h_{1,0} \equiv h_1 = E_2{}^2 - E_3{}^3, \quad h_{0,1} \equiv h_2 = \frac{1}{6}(E_1{}^1 - 2E_2{}^2 + E_3{}^3), \tag{2.8a}$$

and

$$e_{1,0} = E_2{}^3, \quad e_{-1,0} = E_3{}^2,$$

$$e_{0,1} = B^2, \quad e_{0,-1} = A_2,$$

$$e_{1,1} = -B^3, \quad e_{-1,-1} = -A_3,$$

$$e_{1,2} = A_1, \quad e_{-1,-2} = B^1,$$

$$e_{1,3} = E_1{}^2, \quad e_{-1,-3} = E_2{}^1,$$

$$e_{2,3} = E_1{}^3, \quad e_{-2,-3} = E_3{}^1. \tag{2.8b}$$

B. Jordanian-type classical *r* matrices for g_2

First, we introduce some definitions concerning classical r matrices. Let $\mathfrak{g}$ be any simple Lie algebra; then $\mathfrak{g}=\mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}_+$, where $\mathfrak{n}_\pm$ are maximal nilpotent subalgebras and $\mathfrak{h}$ is a Cartan subalgebra. The subalgebra $\mathfrak{n}_+$ ($\mathfrak{n}_-$) is generated by the positive (negative) root vectors e_β ($e_{-\beta}$) for all $\beta \in \Sigma_+(\mathfrak{g})$. The symbol $\mathfrak{b}_+$ will denote the Borel subalgebra of $\mathfrak{g}$, $\mathfrak{b}_+ := \mathfrak{h} \oplus \mathfrak{n}_+$. Let the elements $h_\theta \in \mathfrak{h}$ and $e_\theta \in \mathfrak{n}_+$ satisfy the relation

$$[h_\theta, e_\theta] = e_\theta. \tag{2.9}$$

A two-tensor $r_J(\xi_\theta) \in \mathfrak{b}_+ \otimes \mathfrak{b}_+$ of the form

$$r_\theta(\xi_\theta) = \xi_\theta h_\theta \wedge e_\theta := \xi_\theta(h_\theta \otimes e_\theta - e_\theta \otimes h_\theta) \tag{2.10}$$

satisfies CYBE and it is called the Jordanian classical r matrix. The symbol $\xi_\theta \in \mathbb{C}$ is a deformation parameter. Moreover, let elements $e_{\gamma \pm i}$, indexed by the symbols i and $-i$, $i \in I=\{1,2,\ldots,N\}$, satisfy the relations

$$[h_\theta, e_{\gamma_i}] = (1 - t_{\gamma_i}) e_{\gamma_i}, \quad [h_\theta, e_{\gamma_{-i}}] = t_{\gamma_i} e_{\gamma_{-i}}, \tag{2.11a}$$

$$[e_{\gamma_i}, e_{-\gamma_j}] = \delta_{ij} e_{\gamma_0}, \quad [e_{\gamma \pm i}, e_{\gamma \pm j}] = 0, \tag{2.11b}$$

$$[e_{\gamma \pm i}, e_{\gamma_0}] = 0. \tag{2.11c}$$

It is not difficult to check (see also Ref. 8) that the element

$$r_{\theta;N}(\xi_\theta) = \xi_\theta \left(h_\theta \wedge e_\theta + \sum_{i=1}^{N} e_{\gamma_i} \wedge e_{\gamma - i} \right) \tag{2.12}$$

satisfies CYBE, and it will be called the extended Jordanian r matrix of N order. Let N be of maximal order, i.e., there do not exist other elements $e_{\gamma \pm j} \in \mathfrak{n}_+$, $j > N$ that satisfy the relations (2.11c); then the element (2.12) will be called the extended Jordanian r matrix of maximal order.[20] It is evident that the extended Jordanian r matrix of maximal order is defined by the elements $h_\theta \in \mathfrak{h}$, $e_\theta \in \mathfrak{n}_+$ and the Borel subalgebra $\mathfrak{b}_+$. Here we shall consider a special ("canonical") case when e_θ and $e_{\gamma \pm i}$ $(i = 1, 2, \ldots, N)$ are weight elements with respect to the Cartan subalgebra $\mathfrak{h}$,

$$[h, e_\theta] = (h, \theta) e_\theta, \quad [h, e_{\gamma \pm i}] = (h, \gamma_{\pm i}) e_{\gamma \pm i} \tag{2.13}$$

for any $h \in \mathfrak{h}$ and for all $i = 1, 2, \ldots, N$. Analyzing the structure of the positive root systems of the complex simple Lie algebras, we see that if $e_{\gamma \pm j} \in \mathfrak{n}_+$, the maximal order N of the extended Jordanian r matrix is associated with the maximal root, i.e., the root θ is maximal.

Let us pass now to the Lie algebra $\mathfrak{g} = g_2$. The maximal root generator e_θ is $e_{2,3} = e_{2\alpha_1 + 3\alpha_2}$ and the extended Jordanian matrix of maximal order is provided by formula (2.12) with $N = 2$. It takes the form

$$r_{2,3;2}(\xi) = \xi (h_{2,3} \wedge e_{2,3} + e_{1,1} \wedge e_{1,2} + e_{1,3} \wedge e_{1,0}). \tag{2.14}$$

In order to obtain the generalizations of the r matrix (2.14), one can use the theorem by Belavin and Drinfeld, which states that the sum of two r matrices r_1, r_2 is again a classical r matrix[21] if r_2 has a carrier $L \in g_2$ ($r_2 \in L \otimes L$) that cocommutes with r_1 (i.e., it is a kernel of the bialgebra cobracket).

The maximal subalgebra in g_2, which is a kernel of the Lie bialgebra cobracket determined by the r matrix (2.14) has the following linear basis:

$$L = (h_{0,1}, e_{0,1}, e_{0,-1}, e_{2,3}), \tag{2.15}$$

i.e., $[r_{2,3;2}(\xi), l \otimes 1 + 1 \otimes l] = 0 (l \in L)$. From the generators of the subalgebra L, one can construct the following five classical r matrices: (a) $h_{0,1} \wedge e_{0,1}$, (b) $h_{0,1} \wedge e_{2,3}$, (c) $e_{0,1} \wedge e_{2,3}$, (d) $h_{0,1} \wedge e_{0,-1}$, (e) $e_{0,-1} \wedge e_{2,3}$.

The r matrices that we shall consider below are obtained as the linear combination of (2.14) and the r matrices (a) and (b). One can show that the results of the addition of the r matrix (2.14) and the r matrices (c)–(e) can be obtained from the previous two cases by suitable automorphisms of the algebra g_2.

It follows that we can consider two r matrices as basic ones, or, more explicitly,

$$r_1 = \alpha h_{0,1} \wedge e_{0,1} + \xi (h_{2,3} \wedge e_{2,3} + e_{1,1} \wedge e_{1,2} + e_{1,3} \wedge e_{1,0}), \tag{2.16a}$$

$$r_2 = \beta h_{0,1} \wedge e_{2,3} + \xi (h_{2,3} \wedge e_{2,3} + e_{1,1} \wedge e_{1,2} + e_{1,3} \wedge e_{1,0}), \tag{2.16b}$$

where ξ, α, β are arbitrary.

One can raise the question of whether the classical r matrices (2.16a) and (2.16b) can be extended to carrier space containing also the generators belonging to $\mathfrak{b}_-$. Unfortunately, such an extension, which cannot be eliminated by the inner automorphism of g_2, is not possible for a

purely algebraic reason. One can show that there does not exist an even dimensional subalgebra of g_2, with dimension ten (two extra generators from $\mathfrak{b}_-$), which extends the full Borel subalgebra $\mathfrak{b}_+$. In fact, the consideration of classical r matrices with the carrier in both Borel subalgebras of g_2 that, however, are not simultaneously the classical r matrices for a $sl(3)$ subalgebra is an interesting problem to study, going beyond the scope of the present paper.

Below we shall consider the quantization of g_2 in the four steps, corresponding to the quantization of the following sequence of r matrices.

(i) Jordanian twist quantization,

$$r_J = \xi h_{2,3} \wedge e_{2,3}. \tag{2.17}$$

(ii) Two extended Jordanian twist quantizations,

$$r_{EJ} = \xi(h_{2,3} \wedge e_{2,3} + e_{1,1} \wedge e_{1,2}), \tag{2.18a}$$

$$r_{E'EJ} = \xi(h_{2,3} \wedge e_{2,3} + e_{1,1} \wedge e_{1,2} + e_{1,3} \wedge e_{1,0}). \tag{2.18b}$$

The r matrix r_{EJ} describes the extended Jordanian twist quantization of the $sl(3)$ subalgebra.

(iii) Full twist quantization with additional twist factors describing the deformed Jordanian twist [classical r matrix (2.16a)] and the Abelian twist [classical r matrix (2.16b)].

It should be observed that the parameters α, β, and ξ occurring in the classical r matrices (2.16a) and (2.16b) can be rescaled by inner automorphisms of g_2 algebra as well as by the overall scaling of the r matrices. In particular, performing the two-parameter rescaling by Cartan generators (we use the notation $(ad^{\otimes}a)A \otimes B \equiv [a,A] \otimes B + A \otimes [a,B]$):

$$\exp[ad^{\otimes}(c_1 h_{1,0} + c_2 h_{0,1})] r_1 = e^{(1/2)c_1} r_1,$$

$$\exp[ad^{\otimes}(c_1 h_{1,0} + c_2 h_{0,1})] r_2 = e^{(-(1/2)c_1 + (1/3)c_2)} \beta h_{0,1} \wedge e_{0,1} + e^{(1/2)c_1} r_{E'EJ}, \tag{2.19}$$

we see that while the parameter α remains unchanged, the parameters β and ξ can be rescaled, e.g., to unity. In order to modify the parameter α we can employ the overall scaling of the r matrix. We see therefore, that similarly like in the case of Jordanian deformation of $sl(2)$ or κ deformation of Poincaré algebra, the deformations with different values of the parameters α, β, and ξ are mathematically equivalent (provided $\alpha \neq 0$, $\beta \neq 0$, $\xi \neq 0$) but distinguishable if applied to physical models.

III. TWIST QUANTIZATION METHOD AND THE GENERAL TWIST FUNCTIONS FOR g_2

A. Quantum deformations by twisting coproducts of universal enveloping algebras

Consider the universal enveloping algebra $U(\mathfrak{g})$ of a Lie algebra $\mathfrak{g}$ as a Hopf algebra with the comultiplication $\Delta^{(0)}$ generated by the primitive coproduct in $\mathfrak{g}$. The parametric invertible solution $\mathcal{F}(\xi) = \Sigma f_i^{(1)} \otimes f_i^{(2)} \in U(\mathfrak{g}) \otimes U(\mathfrak{g})$ of the twist equations,[8]

$$\mathcal{F}_{12}(\Delta^{(0)} \otimes 1)(\mathcal{F}) = \mathcal{F}_{23}(1 \otimes \Delta^{(0)})(\mathcal{F}), \tag{3.1}$$

$$(\varepsilon \otimes \mathrm{id})(\mathcal{F}) = (\mathrm{id} \otimes \varepsilon)(\mathcal{F}) = 1 \otimes 1, \tag{3.2}$$

defines the deformed (twisted) Hopf algebra $U_{\mathcal{F}}(\mathfrak{g})$ with the unchanged multiplication, unit and counit [as in $U(\mathfrak{g})$], the twisted comultiplication and antipode defined by the relations

$$\Delta_{\mathcal{F}}(u) = \mathcal{F}\Delta^{(0)}(u)\mathcal{F}^{-1}, \quad u \in U(\mathfrak{g}), \tag{3.3a}$$

$$S_{\mathcal{F}}(u) = vS^{(0)}(u)v^{-1}, \quad v = \sum f_i^{(1)} S^{(0)}(f_i^{(2)}). \tag{3.3b}$$

The twisted algebra $U_{\mathcal{F}}(\mathfrak{g})$ is triangular, with the universal $\mathcal{R}$ matrix,

$$\mathcal{R}_{\mathcal{F}} = \mathcal{F}_{21}\mathcal{F}^{-1}, \tag{3.4}$$

which belongs to some extension of $U(\mathfrak{g}) \otimes U(\mathfrak{g})$. When $\mathcal{F}$ is a smooth function of ξ and $\lim_{\xi\to 0} \mathcal{F} = 1 \otimes 1$ then in the neighborhood of the origin the $\mathcal{R}$-matrix can be presented as

$$\mathcal{R}_{\mathcal{F}} = 1 \otimes 1 + \xi r_{\mathcal{F}} + o(\xi), \tag{3.5}$$

where $r_{\mathcal{F}}$ is the skew-symmetric classical r matrix corresponding to the twist $\mathcal{F}$. Let us write explicitly the r matrix as follows:

$$r_{\mathcal{F}} = a^{ij} I_i \wedge I_j. \tag{3.6}$$

Then we obtain

$$\mathcal{F} = 1 \otimes 1 + \xi \tilde{a}^{ij} I_i \otimes I_j + \mathcal{O}(\xi), \tag{3.7}$$

where $a^{ij} = \frac{1}{2}(\tilde{a}^{ij} - \tilde{a}^{ji})$.

By a nonlinear change of basis in $U(\mathfrak{g})$, one can modify the twisted coproducts and locate part of the deformation in the algebraic sector.

B. Twist deformations for $U(g_2)$ Hopf algebra

Our aim is to construct explicitly such a sequence of the twist deformations $U_{\mathcal{F}}(g_2)$ of the algebra $U(g_2)$ that will lead to the largest possible carrier subalgebra for the corresponding classical r matrices. The final element of the corresponding twists will be the full chain of extended twists whose carrier coincides with the Borel subalgebra of g_2. The peculiarity of the chain twist deformation is that the deformed algebra can be twisted step by step by the consecutive twisting factors with their specific properties. One of the important aims will also be the construction of proper nonlinear basis in $U(g_2)$. Indeed, on each step we shall construct the nonlinear basis in which the costructure of the Hopf algebra $U_{\mathcal{F}}(g_2)$ becomes more transparent.

In Sec. II we have presented the sequence of classical r matrices for $U(g_2)$ [see (2.17), (2.18a), (2.18b), (2.16a), and (2.16b)]. The quantization of these classical r-matrices is performed as follows.

(a) First, we introduce the standard Jordanian twist quantizing the classical r matrix (2.17), corresponding to the long root $2\alpha_1 + 3\alpha_2$ in g_2. We have the following twisting element:[22]

$$\mathcal{F}_J = e^{h_{2,3} \otimes \sigma_{2,3}} = e^{H \otimes \sigma}, \tag{3.8}$$

where

$$H = h_{2,3} = 2h_{1,0} + 3h_{0,1}, \quad \sigma = \ln(1 + e_{2,3}). \tag{3.9}$$

(b) There are four types of the extension twisting factors that can be applied to $U_J(g_2)$:[12]

$$\mathcal{F}_{E_+} = e^{e_{1,1} \otimes e_{1,2} e^{-(1/2)\sigma}}$$

$$\mathcal{F}_{E_-} = e^{-e_{1,2} \otimes e_{1,1} e^{-(1/2)\sigma}}$$

$$\tilde{\mathcal{F}}_{E_+} = e^{e_{1,3} \otimes e_{1,0} e^{-(1/2)\sigma}}$$

$$\widetilde{\mathcal{F}}_{E_-} = e^{-e_{1,0}\otimes e_{1,3}e^{-(1/2)\sigma}}. \tag{3.10}$$

They can be composed to provide the following four types of the two-element extensions of (3.8):

$$\mathcal{F}_{E_{++}} = e^{e_{1,3}\otimes e_{1,0}e^{-(1/2)\sigma}}e^{e_{1,1}\otimes e_{1,2}e^{-(1/2)\sigma}},$$

$$\mathcal{F}_{E_{+-}} = e^{e_{1,3}\otimes e_{1,0}e^{-(1/2)\sigma}}e^{-e_{1,2}\otimes e_{1,1}e^{-(1/2)\sigma}},$$

$$\mathcal{F}_{E_{-+}} = e^{-e_{1,0}\otimes e_{1,3}e^{-(1/2)\sigma}}e^{e_{1,1}\otimes e_{1,2}e^{-(1/2)\sigma}},$$

$$\mathcal{F}_{E_{--}} = e^{-e_{1,0}\otimes e_{1,3}e^{-(1/2)\sigma}}e^{-e_{1,2}\otimes e_{1,1}e^{-(1/2)\sigma}}. \tag{3.11}$$

One can note that exponential factors in the twists (3.11) commute with each other, and do not describe themselves as the solutions of twist equations (3.1) and (3.2) with primitive coproduct $\Delta^{(0)}$. The four twists (3.11) lead to the equivalent Hopf algebras, however, their coalgebra relations differ considerably. The most elegant result is obtained when the extension is chosen as follows:

$$\mathcal{F}_E := \mathcal{F}_{E_{-+}} = \mathcal{F}_{E_-}\mathcal{F}_{E_+} = e^{-e_{1,2}\otimes e_{1,1}e^{-(1/2)\sigma}}e^{e_{1,3}\otimes e_{1,0}e^{-(1/2)\sigma}}, \tag{3.12}$$

with the extended twist

$$\mathcal{F}_{EJ} := e^{-e_{1,2}\otimes e_{1,1}e^{(-1/2)\sigma}}e^{e_{1,3}\otimes e_{1,0}e^{(-1/2)\sigma}}e^{H\otimes\sigma}. \tag{3.13}$$

It should be added that the products of twists $\mathcal{F}_{E_\pm}\mathcal{F}_J$ describe the twist quantization of $sl(3)$ subalgebra.

(c) The additional Abelian twist factor ($h \equiv 3h_{0,1}$),

$$\mathcal{F}_A = e^{h\otimes\sigma}, \tag{3.14}$$

that produces a kind of a "rotation" in the root space of g_2, can enlarge the extended twist (3.13):

$$\mathcal{F}_{AEJ} := e^{h\otimes\sigma}e^{-e_{1,2}\otimes e_{1,1}e^{(-1/2)\sigma}}e^{e_{1,3}\otimes e_{1,0}e^{(-1/2)\sigma}}e^{H\otimes\sigma}. \tag{3.15}$$

In such a way we obtain the quantization of the classical r matrix (2.16b).

(d) We can construct the chain of twists (see, e.g., Refs. 9 and 10) for g_2 by additionally deforming the twisted $U_{EJ}(g_2)$ by the second link of the chain, which is the Jordanian factor:

$$\mathcal{F}_{J'} = e^{h\otimes\sigma}, \tag{3.16}$$

with

$$\omega = \ln\left(1 + e_{0,1} + \frac{1}{2}(e_{1,2})^2\right). \tag{3.17}$$

This gives the quantization with the largest carrier

$$\mathcal{F}_{J'EJ} := e^{h\otimes\omega}e^{-e_{1,2}\otimes e_{1,1}e^{(-1/2)\sigma}}e^{e_{1,3}\otimes e_{1,0}e^{(-1/2)\sigma}}e^{H\otimes\sigma}. \tag{3.18}$$

The twist function (3.18) describes the quantization of the classical r matrix (2.16a). The twist (3.15) can also form the chain with $\mathcal{F}_{J''}=e^{h\otimes\omega''}$ (see Sec. V C). But the Abelian twist factors $\mathcal{F}_A$ and this new Jordanian factor are related by the formula $\mathcal{F}_{J''}\mathcal{F}_A=\mathcal{F}_{J'}$. This means that for any "rotated" extended twist $\mathcal{F}_{AEJ}$ we get the unique chain (3.18).

In Secs. IV and V we shall present the deformed Hopf algebras $U_{\mathcal{F}}(g_2)$ with more details, discuss their properties, and introduce the suitable bases of $U(g_2)$. In such a way we obtain the twist quantizations for g_2 with the largest carrier, which can be described by the chain of twists.

The following paragraph Sec. III C will be devoted to the description of the mathematical framework, which permits us to choose the basis in $U(g_2)$ with simplified coproduct formulas. Subsequently, in Sec. III D we shall derive some new mathematical formulas simplifying the calculation of coproducts in Secs. IV and V.

C. Dual bases and simplification of coalgebra structure

Let $(\mathfrak{g},\mathfrak{g}^{\#})$ be a coboundary Lie bialgebra. The dual Lie algebra $\mathfrak{g}^{\#}$ is determined by the r matrix and can be written explicitly in the form of Lie coalgebra with the cocommutators $\delta(a)=[a\otimes 1+1\otimes a,r]$, $(a\in\mathfrak{g})$. Let $\mathfrak{G}^{\#}$ denote the dual group for $(\mathfrak{g},\mathfrak{g}^{\#})$—the universal covering Lie group with the Lie algebra $\mathfrak{g}^{\#}$. According to the quantum duality principle,[13] the Hopf algebra $U_{\mathcal{F}}(\mathfrak{g})$ naturally treated as quantum algebra with respect to $U(\mathfrak{g})$ can be also considered as a quantum group with respect to Fun $(\mathfrak{G}^{\#})$: $U_{\mathcal{F}}(\mathfrak{g})\approx \mathrm{Fun}_{\xi}(\mathfrak{G}^{\#})$. The coproducts in $U_{\mathcal{F}}(\mathfrak{g})$ describe the deformed group multiplication law of the dual group $\mathfrak{G}^{\#}$. These multiplications are deformed due to the fact that generators in $\mathrm{Fun}_{\xi}(\mathfrak{G}^{\#})$ are subject to the relations of $U(\mathfrak{g})$. The undeformed coproducts for Fun $(\mathfrak{G}^{\#})$ can be obtained by constructing the second classical limit $\mathrm{Fun}_{\xi}(\mathfrak{G}^{\#})\to \mathrm{Fun}(\mathfrak{G}^{\#})$ for the Hopf algebra $U_{\mathcal{F}}(\mathfrak{g})$.[26] Among other important consequences, the quantum duality prescribes the existence of two preferred bases for the Hopf algebra $U_{\mathcal{F}}(\mathfrak{g})$:[25] the natural set of generators for $\mathfrak{g}$ (usually they form the Cartan–Weil basis in $\mathfrak{g}$) and the basis natural for $\mathfrak{G}^{\#}$. The latter may be the exponential basis, generated by the Cartan–Weil basis in $\mathfrak{g}^{\#}$. Evidently, the costructure of $U_{\mathcal{F}}(\mathfrak{g})$ becomes transparent only in terms of the group $\mathfrak{G}^{\#}$ that is in the dual group basis or (keeping in mind the exponential map) in a $\mathfrak{g}^{\#}$ basis. For algebras of $\mathrm{rank}(\mathfrak{g})=1$ one can use the $\mathfrak{g}$ coordinates for the multiplications as well as for the comultiplications. Starting with $\mathrm{rank}(\mathfrak{g})=2$ [see, for example, $U_{\mathcal{F}}(sl(3))$] in Ref. 12 some of the coproducts written in a classical $\mathfrak{g}$ basis (natural $\mathfrak{g}$ coordinates) are complicated, and it is difficult to study their properties. To pass from $\mathfrak{g}$ to $\mathfrak{g}^{\#}$ basis, it is necessary to compare the generators in $U_{\mathcal{F}}(\mathfrak{g})$ induced by the undeformed $U(\mathfrak{g})$ with those corresponding to Fun $(\mathfrak{G}^{\#})$ or to its canonical dual $[\mathrm{Fun}(\mathfrak{G}^{\#})]^{*}\approx U(\mathfrak{g}^{\#})$. The general description of the corresponding algorithm and, in particular, the transformation of the Lie-algebra bases (i.e., the change of coordinates $\mathfrak{g}\leftrightarrow\mathfrak{g}^{\#}$), was presented in Ref. 13. In Sec. IV for the obtained quantum algebras $U_{\mathcal{F}}(\mathfrak{g})$, we shall use both $\mathfrak{g}$ and $\mathfrak{g}^{\#}$ bases and demonstrate their role in the description of algebraic and coalgebraic properties of twist deformations.

D. New algebraic formulas for the similarity transformation of tensor products

Calculations of deformed coproducts rely on the successive application of the following version of the Baker-Campbell-Hausdorff (BCH) formula (the adjoint action in terms of the exponential map):

$$e^{X}Ae^{-X}=\exp(\mathrm{ad}_X)A\equiv\sum_{k=0}^{\infty}\frac{1}{k!}\mathrm{ad}_X^k A=\sum_{k=0}^{\infty}\frac{1}{k!}[X,[\ldots[X,A]\ldots]]. \tag{3.19}$$

More exactly, since one works in the tensor product of two algebras $U\otimes U$, the BCH formula we need is as follows:

$$\begin{aligned} e^{X\otimes Y}(A\otimes B)e^{-X\otimes Y}&=\exp(\mathrm{ad}_{X\otimes Y})(A\otimes B)\\ &=\exp(\mathrm{ad}_X\otimes Y)(A\otimes 1)\exp(X\otimes \mathrm{ad}_Y)(1\otimes B)\\ &=\sum_{k=0}^{\infty}\frac{1}{k!}\mathrm{ad}_X^k A\otimes Y^k\sum_{m=0}^{\infty}\frac{1}{m!}X^m\otimes \mathrm{ad}_Y^m B. \end{aligned} \tag{3.20}$$

The above expression is a product of two infinite series. Fortunately, in most applications impor-

tant for our study here, both series truncate and become finite due to the fact that one acts in the enveloping algebra $U=U_g$ of some finite-dimensional simple Lie algebra g and adjoint actions of non-Cartan elements are nilpotent. The other case that can be handled well occurs when one of the elements, say X, belongs to Cartan subalgebra. Then $\mathrm{ad}_X A \equiv [X,A]=aA$ and $\mathrm{ad}_X^k A=a^k A$, with $a \in \mathbb{C}$. In this case the first factor shrinks into the following simple expression:

$$\sum_{k=0}^{\infty} \frac{1}{k!} \mathrm{ad}_X^k A \otimes Y^k = A \otimes e^{aY}. \tag{3.21}$$

We see that the complexity of calculations heavily depends on the degree of nilpotency. We should also notice that in applications, one of the factors, say $Y=f(E)$, might have a functional form in terms of some generator E, e.g., corresponding to the maximal root vector. We are particularly interested when $f(E)=\ln(1+E)$ or $f(E)=e^E$.

When the degree of nilpotency is lower than two, i.e. $\mathrm{ad}_E^2 B \equiv [E,[E,B]]=0$, one can use the following obvious expression $[f(E),B]=[E,B]f'(E)$ (where f' denotes the derivative of f). This leads to

$$\sum_{m=0}^{\infty} \frac{1}{m!} X^m \otimes \mathrm{ad}_{f(E)}^m B = 1 \otimes B + X \otimes [E,B] f'(E). \tag{3.22}$$

Dealing with these simple techniques permits us to calculate almost all deformed coproducts except the one described by the last twist factor $\mathcal{F}_C$ [see Eq. (5.22)]. In order to complete calculations one needs more general and more sophisticated methods. For this purpose we have found two combinatorial expressions, which turned out to be very useful.

If X and Y are two commuting elements and, in addition, $[X,B]=0$, then

$$Y^X B Y^{-X} \equiv e^{X \ln Y} B e^{-X \ln Y} = \sum_{k=0}^{\infty} X^{\underline{k}} \frac{\mathrm{ad}_Y^k B}{k!} Y^{-k}, \tag{3.23}$$

where the sequence

$$x^{\underline{k}} \equiv \frac{\Gamma(x+1)}{\Gamma(x-k+1)} = x(x-1)\ldots(x-k+1) = \sum_{m=1}^{k} s(k,m) x^m \tag{3.24}$$

stands for the so-called lower (or falling) factorial polynomials and $s(n,k)$ are the Stirling numbers of the first kind.

Notice that if $[Y,B]=0$ and $[Y,X]=0$, one gets

$$Y^X B Y^{-X} \equiv e^{X \ln Y} B e^{-X \ln Y} = \sum_{k=0}^{\infty} \frac{1}{k!} (\ln Y)^k \mathrm{ad}_X^k B. \tag{3.25}$$

Another useful combinatorial formula is

$$e^{Ye^E} B e^{-Ye^E} = \sum_{k=0} \frac{\mathrm{ad}_E^k B}{k!} q_k(Ye^E) = \sum_{m=0} \left(\sum_{k=m} \frac{\mathrm{ad}_E^k B}{k!} S(k,m) \right) Y^m e^{mE}, \tag{3.26}$$

whenever E and B commute with Y. Here the sequence

$$q_k(x) = \sum_{m=0}^{k} S(k,m) x^m \tag{3.27}$$

is given by the so-called Bell polynomials and $S(n,k)$ are Stirling numbers of the second kind. It should be also remarked that both families of polynomials, $x^{\underline{k}}$ and $q_k(x)$, belong to the wide class

of so-called convolution polynomials known also as polynomial sequences of binomial type since, e.g.,

$$q_k(x+y)=\sum_{m=0}^{k}\binom{k}{m}q_m(x)x_{k-m}(y). \tag{3.28}$$

Such polynomials are extensively discussed in combinatorial analysis and umbral calculus (see Refs. 23 and 24). Here we have found operator analogs of some fundamental formulas involving polynomial sequences of binomial type. All of the above formulas can be checked by direct calculation in any order of the power expansion, the nonperturbative proof will be presented elsewhere.

Both formulas (3.23) and (3.26) can be adjusted to the particular situation for nonstandard (Jordanian) and extended twists. For example, adapting to the case of Jordanian twist $\mathcal{F}_J=e^{H\otimes\omega}$ with H being a Cartan element: $[H,A]=aA,\omega=\ln(1+E)$, one gets

$$\mathcal{F}_J A\otimes B\mathcal{F}_J^{-1}=\sum_{k=0}^{\infty}H^k\otimes\frac{\mathrm{ad}_E^k B}{k!}e^{-k\omega}(A\otimes e^{a\omega})=\sum_{k=0}^{\infty}H^kA\otimes\frac{\mathrm{ad}_E^k B}{k!}e^{(a-k)\omega}. \tag{3.29}$$

Similarly, the counterpart of (3.29) for extended twist (double exponential) $\mathcal{F}_E=e^{X\otimes Ye^{f(E)}}$ takes the form

$$\begin{aligned}\mathcal{F}_E(A\otimes B)\mathcal{F}_E^{-1}&=\sum_{m=0}^{\infty}\frac{1}{m!}X^m\otimes\mathrm{ad}_{f(E)}^m Bq_m(Ye^{f(E)})\sum_{k=0}^{\infty}\frac{1}{k!}\mathrm{ad}_X^k A\otimes Y^ke^{kf(E)}\\&=\sum_{k,m\geqslant 0}\frac{1}{m!k!}X^m\,\mathrm{ad}_X^k A\otimes\mathrm{ad}_{f(E)}^m B\sum_{i=0}^{m}S(m,i)Y^{k+i}e^{(k+i)f(E)},\end{aligned} \tag{3.30}$$

provided that $[Y,B]=[Y,E]=0$.

In Secs. IV and V, these last formulas shall be particularly useful.

IV. TWIST QUANTIZATIONS OF g_2 GENERATED BY THE $sl(3)$ TWISTS

We start by considering the two twist factors $\mathcal{F}$ corresponding to the classical r matrix (2.18a) with the carrier subalgebras inside the Borel subalgebra of $sl(3)\subset g_2$. This choice will permit us to construct the first two steps of the twist deformation corresponding to the r matrices (2.16a) and (2.16b). Performing such twisting, one can compare deformed Hopf algebras $U_{\mathcal{F}}(g_2)$ with the known deformation $U_{\mathcal{F}}(sl(3))$.[8,12]

A. The first Jordanian twist

The Jordanian twist $\mathcal{F}_J$ can be based on any two-dimensional Borel subalgebra $\mathfrak{b}_+(sl(2))\subset g_2$. In our case this subalgebra is generated by $\{H\equiv h_{2,3},e_{2,3}\}$. The Jordanian r matrix is given by (2.17), and the corresponding twisting element is $\mathcal{F}_J=e^{H\otimes\sigma}$ [see Eq. (3.8)].

The costructure of the deformed algebra $U_J(g_2)$ is obtained by applying the similarity map (3.3a) to the primitive coproducts in $U(g_2)$. In the carrier subalgebra $\mathfrak{b}_+(sl(2))$, we obtain

$$\Delta_J(e_{2,3})=e_{2,3}\otimes e^{\sigma}+1\otimes e_{2,3},\quad\text{or}\quad\Delta_J(\sigma)=\sigma\otimes 1+1\otimes\sigma, \tag{4.1}$$

$$\Delta_J(H)=H\otimes e^{-\sigma}+1\otimes H. \tag{4.2}$$

The generators of the long root sequences $\pm(\alpha_1+k\alpha_2)$ $(k=0,1,2,3)$ have the coproducts

$$\Delta_J(e_{1,k})=e_{1,k}\otimes e^{1/2\sigma}+1\otimes e_{1,k}, \tag{4.3}$$

$$\Delta_J(e_{-1,-k}) = e_{-1,-k} \otimes e^{-1/2\sigma} + 1 \otimes e_{-1,-k} + (-1)^k H \otimes e_{1,(3-k)} e^{-\sigma}, \tag{4.4}$$

describing one- and two-dimensional subrepresentations of the Borel subalgebra $\mathfrak{b}_+(sl(2))$. The generators with the roots "orthogonal" to $2\alpha_1+3\alpha_2$ remain primitive:

$$\Delta_J(h) = h \otimes 1 + 1 \otimes h, \tag{4.5}$$

$$\Delta_J(e_{0,\pm 1}) = e_{0,\pm 1} \otimes 1 + 1 \otimes e_{0,\pm 1}. \tag{4.6}$$

and describe two-dimensional subrepresentations of $\mathfrak{b}_+(sl(2))$. One can check that in $\mathfrak{g}^{\#} \backslash \mathfrak{b}_+(sl(2))$, the generator H induces a shift $\mathrm{ad}_H : e_{1,(3-k)} \to e_{-1,-k}$, and this is exactly what indicates the last terms of the above coproducts $\Delta_J(e_{-1,-k})$.

The coproduct for the lowest root generator $e_{-2,-3}$,

$$\Delta_J(e_{-2,-3}) = e_{-2,-3} \otimes e^{-\sigma} + 1 \otimes e_{-2,-3} + (H - H^2) \otimes (e^{-\sigma} - e^{-2\sigma}) + 2H \otimes H e^{-\sigma}, \tag{4.7}$$

also refers to a one-dimensional subrepresentation. This can be seen when we pass to the $\mathfrak{g}^{\#}$ basis. The following generator should be redefined here:

$$\widetilde{e_{-2,-3}} := e_{-2,-3} - H^2. \tag{4.8}$$

The coproduct $\Delta_J(\widetilde{e_{-2,-3}})$ is quasiprimitive and similar to $\Delta_J(H)$:

$$\Delta_J(\widetilde{e_{-2,-3}}) = \widetilde{e_{-2,-3}} \otimes e^{-\sigma} + 1 \otimes \widetilde{e_{-2,-3}}. \tag{4.9}$$

For the case of twisted $U_J(sl(2))$ the nonlinear transformation (4.8) was first indicated in Ref. 22.

B. The first extended Jordanian twist

The peculiarity of the chain twist deformation is that the deformed algebra can be twisted further by other twisting factors. The quantization goes step by step and on each level you get the deformed symmetry with its specific properties.

For the carrier $\mathfrak{g}^c \subset sl(3) \subset g_2$, the extension factor should be

$$\mathcal{F}_{E_+} = e^{e_{1,3} \otimes e_{1,0} e^{-(1/2)\sigma}}. \tag{4.10}$$

We remind the reader that $sl(3)$ subalgebra is generated by the following eight elements: $\{H, h, e_{\pm 2,\pm 3}, e_{\pm 1,0}, e_{\pm 1,\pm 3}\}$.

The twist (4.10) is a solution of the twist equations (3.1) and (3.2) for $U_J(g_2)$ and the adjoint operator $\exp(\mathrm{ad}(e_{1,3} \otimes e_{1,0} e^{-(1/2)\sigma}))$ applied to the coproducts in $U_J(g_2)$ will perform the deformation $\mathcal{F}_{E_+} : U_J(g_2) \to U_{E_+J}(g_2)$. The same result can be obtained directly by applying the twist $\mathcal{F}_{E_+J} = (\mathcal{F}_{E_+} \mathcal{F}_J) : U(g_2) \to U_{E_+J}(g_2)$.

In the costructure of $U_{E_+J}(g_2)$, we see the group multiplication of the solvable four-dimensional Lie group (see Ref. 12) with the Lie algebra equivalent to the carrier subalgebra $\mathfrak{g}^c_{E_+J}$ of the twist $\mathcal{F}_{E_+J}$:

$$\Delta_{E_+J}(e_{2,3}) = e_{2,3} \otimes e^{\sigma} + 1 \otimes e_{2,3},$$

$$\Delta_{E_+J}(H) = H \otimes e^{-\sigma} + 1 \otimes H - e_{1,3} \otimes e_{1,0} e^{-(3/2)\sigma},$$

$$\Delta_{E_+J}(e_{1,0}) = e_{1,0} \otimes e^{(1/2)\sigma} + e^{\sigma} \otimes e_{1,0},$$

$$\Delta_{E_+J}(e_{1,3}) = e_{1,3} \otimes e^{-(1/2)\sigma} + 1 \otimes e_{1,3}. \tag{4.11}$$

The other generators of the subalgebra $sl(3)$ form the four-dimensional representation of $\mathcal{L}$:

$$\Delta_{E_+J}(h) = h \otimes 1 + 1 \otimes h,$$

$$\Delta_{E_+J}(e_{-1,-3}) = e_{-1,-3} \otimes e^{-(1/2)\sigma} + 1 \otimes e_{-1,-3} + h \otimes e_{1,0}e^{-\sigma},$$

$$\begin{aligned}\Delta_{E_+J}(e_{-1,0}) = {} & + e_{-1,0} \otimes e^{-(1/2)\sigma} + 1 \otimes e_{-1,0} + H \otimes e_{1,3}e^{-\sigma} - e_{1,3} \otimes e_{1,0}e_{1,3}e^{-(3/2)\sigma} \\ & + e_{1,3} \otimes (H-h)e^{-(1/2)\sigma} - (e_{1,3})^2 \otimes e_{1,0}e^{-2\sigma} - He_{1,3} \otimes (e^{\sigma}-1)e^{-(3/2)\sigma},\end{aligned}$$

$$\begin{aligned}\Delta_{E_+J}(\widetilde{e_{-2,-3}}) = {} & + \widetilde{e_{-2,-3}} \otimes e^{-\sigma} + 1 \otimes \widetilde{e_{-2,-3}} - e_{-1,0} \otimes e_{1,0}e^{-(3/2)\sigma} \\ & + He_{1,3} \otimes e_{1,0}e^{-(3/2)\sigma} + e_{1,3} \otimes e_{-1,-3}e^{-(1/2)\sigma}.\end{aligned} \tag{4.12}$$

Finally on the remaining six-dimensional space we also observed the adjoint action of the carrier subalgebra $\mathfrak{g}^c_{E_+J}$ $(k=1,2)$,

$$\Delta_{E_+J}(e_{1,k}) = e_{1,k} \otimes e^{(1/2)\sigma} + 1 \otimes e_{1,k},$$

$$\Delta_{E_+J}(e_{0,\pm 1}) = e_{0,\pm 1} \otimes 1 + 1 \otimes e_{0,\pm 1} + e_{1,(5+1)/2} \otimes e_{1,(1\pm 1)/2}e^{-(1/2)\sigma},$$

$$\begin{aligned}\Delta_{E_+J}(e_{-1,-k}) = {} & e_{-1,-k} \otimes e^{-(1/2)\sigma} + 1 \otimes e_{-1,-k} + (-1)^k H \otimes e_{1,(3-k)}e^{-\sigma} - e_{(2-k),(5-2k)} \otimes e_{(k-1),(k-2)}e^{-\sigma} \\ & - e_{1,3} \otimes e_{1,0}e_{1,(3-k)}e^{-(3/2)\sigma}.\end{aligned} \tag{4.13}$$

First of all, notice that $sl(3)$ generates the well-known twisted algebra $U_{EJ}(sl(3))$ (8) which here is a Hopf subalgebra $U_{EJ}(sl(3)) \subset U_{E_+J}(g_2)$. Thus, we obtain the intermediate $U_{\mathcal{F}}(sl(3))$ twist quantization inside $U_{\mathcal{F}}(f_2)$.

The nonprimitive terms in $\Delta_{E_+J}(e_{0,\pm 1})$ are in agreement with the structure of $\mathfrak{g}^{\#}$. They describe the action of the dual carrier group $G^{\#}_c$ in the two-dimensional indecomposable representations. The third term in $\Delta_{E_+J}(H)$ [see Eq. (4.11)] is just due to the Heisenberg subgroup in G^*_c.

The essential nonlinearities in the costructure are present in the last terms in $\Delta_{E_+J}(e_{-1,-k})$ as well as in $\Delta_{E_+J}(\widetilde{e_{-2,-3}})$ and $\Delta_{E_+J}(e_{-1,0})$. It should be noticed that the generator $\widetilde{e_{-2,-3}} = e_{-2,-3} - H^2$ is not modified. This is a common property of all the generators with roots opposite the Jordanian carrier.

Let us return to the nontrivial terms in the costructure Δ_{E_+J}. Comparing $\Delta_{E_+J}(e_{-1,0})$, $\Delta_{E_+J}(e_{-1,-k})$ and $\Delta_{E_+J}(e_{0,\pm 1})$ with the canonical multiplication in $U(\mathfrak{g}^{\#})$, we find the following $\mathfrak{g}^{\#}$ basis:

$$\widetilde{e_{-1,0}} = e_{-1,0} - He_{1,3},$$

$$\widetilde{e_{0,-1}} = e_{0,-1} - e_{1,0}e_{1,2}e^{-\sigma},$$

$$\widetilde{e_{0,1}} = e_{0,1} - e_{1,3}e_{1,1},$$

$$\widetilde{e_{-1,-2}} = e_{-1,-2} - He_{1,1}. \tag{4.14}$$

In these terms the action of G^c on the six-dimensional space becomes transparent:

$$\Delta_{E_+J}(\widetilde{e_{0,1}}) = \widetilde{e_{0,1}} \otimes 1 + 1 \otimes \widetilde{e_{0,1}} - e_{1,1} \otimes e_{1,3}e^{(1/2)\sigma},$$

$$\Delta_{E_+J}(\widetilde{e_{0,-1}}) = \widetilde{e_{0,-1}} \otimes 1 + 1 \otimes \widetilde{e_{0,-1}} - e_{1,0}e^{-\sigma} \otimes e_{1,2}e^{-(1/2)\sigma},$$

$$\Delta_{E_+J}(e_{-1,-1}) = e_{-1,-1} \otimes e^{-(1/2)\sigma} + 1 \otimes e_{-1,-1} - H \otimes e_{1,2}e^{-\sigma} - e_{1,3} \otimes \widetilde{e_{0,-1}}e^{-(1/2)\sigma},$$

$$\Delta_{E_+J}(\widetilde{e_{-1,-2}}) = \widetilde{e_{-1,-2}} \otimes e^{-(1/2)\sigma} + 1 \otimes \widetilde{e_{-1,-2}} - e_{1,1} \otimes He^{(1/2)\sigma} - \widetilde{e_{0,1}} \otimes e_{1,0}e^{-\sigma},$$

$$\Delta_{E_+J}(\widetilde{e_{-1,0}}) = \widetilde{e_{-1,0}} \otimes e^{-(1/2)\sigma} + 1 \otimes \widetilde{e_{-1,0}} - e_{1,3} \otimes he^{-(1/2)\sigma},$$

$$\Delta_{E_+J}(\widetilde{e_{-2,-3}}) = \widetilde{e_{-2,-3}} \otimes e^{-\sigma} + 1 \otimes \widetilde{e_{-2,-3}} - \widetilde{e_{-1,0}} \otimes e_{1,0}e^{-(3/2)\sigma} + e_{1,3} \otimes e_{-1,-3}e^{-(1/2)\sigma}. \quad (4.15)$$

V. TWIST DEFORMATIONS SPECIFIC TO g_2

A. The full extended twist

The Jordanian twist $\mathcal{F}_J$ (4.1) can be enlarged by the second extension factor $\mathcal{F}_{E_-}$. Such an extension is the special property of the g_2 root system. It does not exist for any other rank 2 simple Lie algebra. The following element is the solution of the twist equations for the Hopf algebra $U_{E_+J}(g_2)$:

$$\mathcal{F}_{E_-} = e^{-e_{1,2}\otimes e_{1,1}e^{-(1/2)\sigma}}. \quad (5.1)$$

Together with the previously studied twist $\mathcal{F}_{E_+J}$ we obtain the full extended twist,

$$\mathcal{F}_{EJ} = e^{-e_{1,2}\otimes e_{1,1}e^{-(1/2)\sigma}}e^{e_{1,3}\otimes e_{1,0}e^{-(1/2)\sigma}}e^{H\otimes\sigma}. \quad (5.2)$$

The carrier subalgebra $\mathfrak{g}^c_{EJ} \approx \mathfrak{g}^{c\#}_{EJ}$ is six-dimensional, it contains two Heisenberg subalgebras with common central element $e_{2,3}$ and the Cartan generator H. Applying the twist (5.2) to $U(g_2)$ or the second extension (5.1) to the Hopf algebra $U_{E_+J}(g_2)$ (constructed in the previous section) we obtain the new deformed costructure $\Delta_{E_{-+}J}$. The coproducts $\Delta_{EJ} := \Delta_{E_{-+}J}$ for the generators of $\mathfrak{g}^c_{EJ}$ describe the group multiplication in $G^{c\#}_{EJ}$, which is defined by the following relations:

$$\Delta_{EJ}(e_{2,3}) = e_{2,3} \otimes e^{\sigma} + 1 \otimes e_{2,3},$$

$$\Delta_{EJ}(H) = H \otimes e^{-\sigma} + 1 \otimes H - e_{1,3} \otimes e_{1,0}e^{-(3/2)\sigma} + e_{1,2} \otimes e_{1,1}e^{-(3/2)\sigma}. \quad (5.3)$$

$$\Delta_{EJ}(e_{1,l}) = e_{1,l} \otimes e^{(1/2)\sigma} + e^{\sigma} \otimes e_{1,l}, \quad l = 0,1.$$

$$\Delta_{EJ}(e_{1,2+l}) = e_{1,2+l} \otimes e^{-(1/2)\sigma} + 1 \otimes e_{1,2+l}, \quad (5.4)$$

These six coproducts are typical for the extended Jordanian twists:[8] each extension adds a summand in $\Delta_{E_{-+}J}(H)$, the constituent roots generators remain quasiprimitive, and the generator σ deformed by the extension factors.

On the plane "orthogonal" to the initial root $\lambda_0 = 2\alpha + 3\beta$, we find only one primitive generator,

$$\Delta_{EJ}(h) = h \otimes 1 + 1 \otimes h. \quad (5.5)$$

Other two coproducts are deformed:

$$\Delta_{E_{-+}J}(e_{0,1}) = e_{0,1} \otimes 1 + 1 \otimes e_{0,1} - e_{1,2} \otimes e_{1,2}e^{-(1/2)\sigma} + \frac{1}{2}(e_{1,2})^2 \otimes (1 - e^{-\sigma}),$$

$$\Delta_{E_{-+}J}(e_{0,-1}) = e_{0,-1}\otimes 1 + 1\otimes e_{0,-1} - \frac{4}{3}e_{1,1}\otimes e_{1,1}e^{-(1/2)\sigma} - \frac{2}{3}(e^{\sigma}-1)\otimes (e_{1,1})^2 e^{-\sigma}. \tag{5.6}$$

The generators in the negative sector have quite complicated coproducts in $U_{EJ}(g_2)$. For example,

$$\begin{aligned}\Delta_{EJ}(\widetilde{e_{-2,-3}}) = {} & \widetilde{e_{-2,-3}}\otimes e^{-\sigma} + 1\otimes \widetilde{e_{-2,-3}} - (e_{-1,0} - He_{1,3})\otimes e_{1,0}e^{-(3/2)\sigma} + e_{1,3}\otimes e_{-1,-3}e^{-(1/2)\sigma} \\ & - \left(e_{-1,-1} - \frac{1}{4}e_{1,2} + He_{1,2}\right)\otimes e_{1,1}e^{-(3/2)\sigma} - \left(\frac{2}{3}e_{0,1} + \frac{1}{4}(e_{1,2})^2\right)\otimes (e_{1,1})^2 e^{-2\sigma} \\ & + e_{1,2}\otimes \left(e_{-1,-2} - \frac{1}{4}e_{1,1}e^{-\sigma}\right)e^{-(1/2)\sigma} + \frac{1}{2}(e_{1,2})^2\otimes \left(\frac{1}{2}(e_{1,1})^2 e^{-\sigma} + e_{0,-1}\right)e^{-\sigma} \\ & + \frac{2}{9}e_{1,3}\otimes (e_{1,1})^3 e^{-(5/2)\sigma} - \frac{1}{6}(e_{1,2})^3\otimes e_{1,0}e^{-(3/2)\sigma}. \end{aligned}\tag{5.7}$$

Notice that in this expression we use the generators $\widetilde{e_{-2,-3}}$, i.e., we suppose that $\widetilde{e_{-2,-3}}$ will be appropriate for the deformed costructure, not only in $U_{E_{+}J}(g_2)$ but also in $U_{EJ}(g_2)$.

The coproducts for the elements $\{h, e_{0,\pm 1}, e_{-1,-k}, e_{-2,-3}; k=0,\ldots,3\}$ describe the action of the carrier group $G^{c\#}_{EJ}$ in the eight-dimensional subrepresentation.

To make this adjoint action transparent, we perform the coordinate transformation $\mathfrak{g}\Rightarrow\mathfrak{g}^{\#}$ (see Sec. III C). According to the algorithm presented in Ref. 12, the new basic elements are introduced:

$$\widetilde{\widetilde{e_{0,1}}} = e_{0,1} + \frac{1}{2}(e_{1,2})^2,$$

$$\widetilde{\widetilde{e_{0,-1}}} = e_{0,-1} + \frac{2}{3}(e_{1,1})^2 e^{-\sigma},$$

$$\widetilde{\widetilde{e_{-1,-3}}} = e_{-1,-3} + \frac{2}{9}(e_{1,1})^3 e^{-2\sigma},$$

$$\widetilde{\widetilde{e_{-1,-2}}} = e_{-1,-2},$$

$$\widetilde{\widetilde{e_{-1,-1}}} = e_{-1,-1} + He_{1,2},$$

$$\widetilde{\widetilde{e_{-1,0}}} = e_{-1,0} - He_{1,3} + \frac{1}{6}(e_{1,2})^3,$$

$$\widetilde{\widetilde{e_{-2,-3}}} = \widetilde{e_{-2,-3}}. \tag{5.8}$$

We see that the element $e_{-1,-2}$ belongs to the $\mathfrak{g}^{\#}$ basis for the group $G^{\#}_{EJ}$ while the generator $\widetilde{e_{-2,-3}}$ remains unchanged, however, we recall that on the previous step of quantization [in $U_{E_{+}J}(g_2)$] it was nontrivially deformed. The coproducts of generators (5.8) are the following:

$$\Delta_{EJ}(\widetilde{\widetilde{e_{0,1}}}) = \widetilde{\widetilde{e_{0,1}}}\otimes 1 + 1\otimes \widetilde{\widetilde{e_{0,1}}},$$

$$\Delta_{EJ}(\widetilde{\widetilde{e_{0,-1}}}) = \widetilde{\widetilde{e_{0,-1}}}\otimes 1 + 1\otimes \widetilde{\widetilde{e_{0,-1}}},$$

$$\Delta_{EJ}(h) = h \otimes 1 + 1 \otimes h$$

$$\Delta_{EJ}(\widetilde{\widetilde{e_{-1,-3}}}) = (\widetilde{\widetilde{e_{-1,-3}}}) \otimes e^{-(1/2)\sigma} + 1 \otimes (\widetilde{\widetilde{e_{-1,-3}}}) + 3h_{0,1} \otimes e_{1,0}e^{-\sigma} + \widetilde{\widetilde{e_{0,-1}}} \otimes e_{1,1}e^{-\sigma},$$

$$\Delta_{EJ}(e_{-1,-2}) = e_{-1,-2} \otimes e^{-(1/2)\sigma} + 1 \otimes e_{-1,-2} - h_{0,1} \otimes e_{1,1}e^{-\sigma} - \widetilde{\widetilde{e_{0,1}}} \otimes e_{1,0}e^{-\sigma} + e_{1,2} \otimes \widetilde{\widetilde{e_{0,-1}}}e^{-(1/2)\sigma},$$

$$\Delta_{EJ}(\widetilde{\widetilde{e_{-1,-1}}}) = \widetilde{\widetilde{e_{-1,-1}}} \otimes e^{-(1/2)\sigma} + 1 \otimes \widetilde{\widetilde{e_{-1,-1}}} + e_{1,2} \otimes h_{0,1}e^{-(1/2)\sigma} - e_{1,3} \otimes (\widetilde{\widetilde{e_{0,-1}}})e^{-(1/2)\sigma} + \frac{4}{3}(\widetilde{\widetilde{e_{0,1}}}) \otimes e_{1,1}e^{-\sigma},$$

$$\Delta_{EJ}(\widetilde{\widetilde{e_{-1,0}}}) = \widetilde{\widetilde{e_{-1,0}}} \otimes e^{-(1/2)\sigma} + 1 \otimes \widetilde{\widetilde{e_{-1,0}}} - e_{1,3} \otimes 3h_{0,1}e^{-(1/2)\sigma} + e_{1,2} \otimes \widetilde{\widetilde{e_{0,1}}}e^{-(1/2)\sigma},$$

$$\Delta_{EJ}(\widetilde{\widetilde{e_{-2,-3}}}) = \widetilde{\widetilde{e_{-2,-3}}} \otimes e^{-\sigma} + 1 \otimes \widetilde{\widetilde{e_{-2,-3}}} - \widetilde{\widetilde{e_{-1,0}}} \otimes e_{1,0}e^{-(3/2)\sigma} + e_{1,3} \otimes \widetilde{\widetilde{e_{-1,-3}}}e^{-(1/2)\sigma} - \widetilde{\widetilde{e_{-1,-1}}} \otimes e_{1,1}e^{-(3/2)\sigma} - \frac{2}{3}\widetilde{\widetilde{e_{0,1}}} \otimes (e_{1,1})^2e^{-2\sigma} + e_{1,2} \otimes e_{-1,-2}e^{-(1/2)\sigma} + \frac{1}{2}(e_{1,2})^2 \otimes \widetilde{\widetilde{e_{0,-1}}}e^{-\sigma}. \tag{5.9}$$

These coproducts correspond to the adjoint action of the algebra $G_{EJ}^{c\#}$ on the eight-dimensional space $G_2 \backslash \mathfrak{g}_{EJ}^c$. One can notice two subrepresentations on the subspaces spanned by $\{\widetilde{\widetilde{e_{0,\pm 1}}}, h\}$ and $\{\widetilde{\widetilde{e_{-1,-k}}}, \widetilde{\widetilde{e_{-2,-3}}}\}$. On the subspace with the generators $\{\widetilde{\widetilde{e_{0,\pm 1}}}, h\}$, we have the trivial factor representation. This property means that on the plane orthogonal to the initial root we have the $sl(2)$ subalgebra with primitive generators $\{\widetilde{\widetilde{e_{0,\pm 1}}}, h\}$. Such an effect was first described in Ref. 9.

In the deformation $U(g_2) \to U_{EJ}(g_2)$ the costructure (5.3) and (5.4) on the carrier subalgebra is the extended Jordanian twist with two extension factors [as can be seen, for example, in $U_{EJ}(sl(4))$]. The specific properties of g_2 become important in the negative sector [relations (5.9)], where the pecularities of the root system induce additional terms. For example, the coproducts $\Delta_{EJ}(\widetilde{\widetilde{e_{-1,-1}}})$ and $\Delta_{EJ}(\widetilde{\widetilde{e_{-1,-2}}})$ contain the last two terms depending on the generators $\widetilde{\widetilde{e_{0,1}}}$ and $\widetilde{\widetilde{e_{0,-1}}}$.

Comparing the generators $\tilde{\tilde{e}}_{k,l}$ in (5.8) with $\tilde{e}_{k,l}$ [see (4.9) and (4.15)] one can see that most of them have different expressions in terms of the initial $\mathfrak{g}$ basis. The reason is that the twisting (5.2) not only deforms the group $G_{E_+J}^{\#}$ but also changes its realization in terms of the initial g_2 generators.

B. The full chain of twists for G_2: Adding the second Jordanian twist

The existence of the subalgebra $U(sl(2)) \subset U_{EJ}(g_2)$ with primitive generators $\{\widetilde{\widetilde{e_{0,\pm 1}}}, h\}$ shows that the Hopf algebra $U_{EJ}(g_2)$ can be additionally deformed by the second Jordanian twist. In other words, the twist equations (3.1) and (3.2) with $\Delta^{(0)}$ replaced by Δ_{EJ} have the solution $\mathcal{F}_{J'} = e^{h \otimes \omega}$, where ω is given by (3.17), i.e., one can perform the transformation $\mathcal{F}_{J'}: U_{EJ}(g_2) \to U_{J'EJ}(g_2) := U_C(g_2)$. The same result can be achieved by the chain of twists (3.18):

$$\mathcal{F}_C = \mathcal{F}_{J'EJ} = e^{h \otimes \omega}e^{-e_{1,2} \otimes e_{1,1}e^{-(1/2)\sigma}}e^{e_{1,3} \otimes e_{1,0}e^{-(1/2)\sigma}}e^{H \otimes \sigma}, \tag{5.10}$$

applied to the initial $U(g_2)$.

The carrier subalgebra $\mathfrak{g}_C^c$ is the Borel subalgebra $\mathfrak{b}^+(g_2)$. Applying the twist (5.10) to $U(g_2)$, we obtain the deformed costructure $\Delta_{J'EJ} := \Delta_C$ corresponding to the maximal carrier subalgebra in g_2. In the Hopf algebra $U_C(g_2)$ we have two σ-like generators,

$$\Delta_C(\sigma) = \sigma \otimes 1 + 1 \otimes \sigma,$$

$$\Delta_C(\omega) = \omega \otimes 1 + 1 \otimes \omega, \tag{5.11}$$

and the ordinary form of the coproduct for the Cartan generator of $\mathfrak{b}\ sl(2)$ twisted by $\mathcal{F}_{J'} = e^{h\otimes\omega}$:

$$\Delta_C(h) = h \otimes e^{-\omega} + 1 \otimes h.$$

In the coproducts for the elements corresponding to the positive long sequence $\alpha_1 + k\alpha_2$ ($k = 0,1,2,3$), one can trace the adjoint action of the algebra $\mathfrak{g}_C^{\#}$:

$$\Delta_C(e_{1,3}) = e_{1,3} \otimes e^{-(1/2)\sigma+(3/2)\omega} + 1 \otimes e_{1,3},$$

$$\Delta_C(e_{1,2}) = e_{1,2} \otimes e^{-(1/2)\sigma+(1/2)\omega} + 1 \otimes e_{1,2} - h \otimes e_{1,3}e^{-\omega},$$

$$\Delta_C(e_{1,1}) = e_{1,1} \otimes e^{(1/2)\sigma-(1/2)\omega} + e^{\sigma} \otimes e_{1,1} - he^{\sigma} \otimes \left(e_{1,2}e^{-\omega} + \frac{1}{2}e_{1,3}e^{-2\omega}\right) + \frac{1}{2}h^2e^{\sigma} \otimes e_{1,3}e^{-2\omega}, \tag{5.12}$$

$$\Delta_C(e_{1,0}) = e_{1,0} \otimes e^{(1/2)\sigma(3/2)\omega} + e^{\sigma} \otimes e_{1,0} - he^{\sigma} \otimes \left(e_{1,1}e^{-\omega} + \frac{1}{12}e_{1,3}e^{-3\omega} + \frac{1}{2}e_{1,2}e^{-2\omega}\right)$$
$$+ \frac{1}{2}h^2e^{\sigma} \otimes (e_{1,2}e^{-2\omega} + e_{1,3}e^{-3\omega}) - \frac{1}{6}h^3e^{\sigma} \otimes e_{1,3}e^{-3\omega}. \tag{5.13}$$

The terms corresponding to the powers of ad (X_h) of the short root operator dual to h (such as $-\frac{1}{6}h^3e^{\sigma}\otimes e_{1,3}e^{-3w}$ in the last row) are accompanied by the additional summands that will disappear when we pass (via the second classical limit) to the group costructure for $G_C^{\#}$. This is especially evident when $\Delta_C(H)$ is considered:

$$\Delta_C(H) = e^{\mathrm{ad}\ h\otimes\omega}\begin{pmatrix} H \otimes e^{-\sigma} + 1 \otimes H \\ -e_{1,3} \otimes e_{1,0}e^{-(3/2)\sigma} + e_{1,2} \otimes e_{1,1}e^{-(3/2)\sigma} \end{pmatrix}$$
$$= H \otimes e^{-\sigma} + 1 \otimes H + h \otimes \left(-\frac{1}{2}(e_{1,2})^2e^{-\omega} - \frac{1}{2}e_{1,2}e_{1,3}e^{-2\omega} - \frac{1}{3}(e_{1,3})^2e^{-3\omega}\right)$$
$$+ \frac{1}{2}h^2 \otimes (e_{1,3}e_{1,2}e^{-2\omega} + (e_{1,3})^2e^{-3\omega}) + \frac{1}{6}h^3 \otimes (-(e_{1,3})^2e^{-3\omega}) - e_{1,3} \otimes e_{1,0}e^{-(3/2)(\sigma-\omega)}$$
$$- he_{1,3} \otimes \left(-e_{1,1}e^{-(5/2)\sigma+(3/2)\omega} - \frac{1}{12}e_{1,3}e^{-(9/2)\sigma+(3/2)\omega} - \frac{1}{2}e_{1,2}e^{-(7/2)\sigma+(3/2)\omega}\right)$$
$$- \frac{1}{2}h^2e_{1,3} \otimes (e_{1,2}e^{-(7/2)\sigma+(3/2)\omega} + e_{1,3}e^{-(9/2)\sigma+(3/2)\omega})$$
$$+ \frac{1}{6}h^3e_{1,3} \otimes e_{1,3}e^{-(9/2)+\sigma(3/2)\omega} + e_{1,2} \otimes e_{1,1}e^{-(3/2)\sigma+(1/2)\omega} - he_{1,2} \otimes e_{1,2}e^{-(3/2)\sigma-(1/2)\omega}$$
$$- \frac{1}{2}he_{1,2} \otimes e_{1,3}e^{-(3/2)\sigma-(3/2)\omega} + \frac{1}{2}h^2e_{1,2} \otimes e_{1,3}e^{-(3/2)\sigma-(3/2)\omega}. \tag{5.14}$$

One can show that in the second classical limit the large number of terms in (5.14) will disappear.

Let us turn now to the determination of the $\mathfrak{g}_C^{\#}$ basis in $U_C(g_2)$.

In the negative root sector $\mathfrak{n}_-$, the element $e_{0,-1}$ must be evidently changed:

$$\widehat{e_{0,-1}} = \widetilde{\widetilde{e_{0,-1}}} - \frac{1}{3}h^2. \tag{5.15}$$

This is due to the fact that on the subspace generated by $\widetilde{\widetilde{e_{0,1}}}$, $\widetilde{\widetilde{e_{0,-1}}}$, and h the twist deformation performed by $\mathcal{F}_{J'}$ is an ordinary Jordanian deformation for the algebra $sl(2)$. The coproduct for $\widehat{e_{0,-1}}$ is quasiprimitive:

$$\Delta_C(\widehat{e_{0,-1}}) = \widehat{e_{0,-1}} \otimes e^{-\omega} + 1 \otimes \widehat{e_{0,-1}}. \tag{5.16}$$

The other coproducts for negative sector generators are quite complicated, despite the fact that they are obtained in the improved (dual group $G^{\#}_{EJ}$) basis $\{\tilde{\tilde{x}}\}$. The factor $\mathcal{F}_{J'}$ changes the dual group,

$$\mathcal{F}_{J'}: G^{\#}_{EJ} \to G^{\#}_{C}, \tag{5.17}$$

and the corresponding Lie algebra generators must be redefined. Using the technique demonstrated in Sec. III D we get the set of new generators:

$$\widehat{e_{0,1}} = \widetilde{\widetilde{e_{0,1}}} = e_{0,1} + \frac{1}{2}(e_{1,2})^2 = e^{\omega} - 1; \tag{5.18a}$$

$$\widehat{e_{0,-1}} = \widetilde{\widetilde{e_{0,-1}}} - \frac{1}{3}h^2 = e_{0,-1} + \frac{2}{3}(e_{1,1})^2 e^{-\sigma} - \frac{1}{3}h^2; \tag{5.18b}$$

$$\widehat{e_{-1,0}} = \widetilde{\widetilde{e_{-1,0}}} + e_{1,2} + he_{1,3} = e_{-1,0} + (h - H)e_{1,3} + \frac{1}{6}(e_{1,2})^3 + e_{1,2}; \tag{5.18c}$$

$$\widehat{e_{-1,-1}} = \widetilde{\widetilde{e_{-1,-1}}} - \frac{4}{3}e_{1,1}e^{-\sigma+\omega} - \frac{1}{3}he_{1,2} + \frac{1}{3}h^2e_{1,3} = e_{-1,-1} + \left(H - \frac{1}{3}h\right)e_{1,2} - \frac{4}{3}e_{1,1}e^{-\sigma+\omega} + \frac{1}{3}h^2e_{1,3}; \tag{5.18d}$$

$$\widehat{e_{-1,-2}} = \widetilde{\widetilde{e_{-1,-2}}} + e_{1,0}e^{-\sigma+\omega} - \frac{1}{3}h^2e_{1,2} = e_{-1,-2} + e_{1,0}e^{-\sigma+\omega} - \frac{1}{3}h^2e_{1,2}; \tag{5.18e}$$

$$\widehat{e_{-1,-3}} = \widetilde{\widetilde{e_{-1,-3}}} = e_{-1,-3} + \frac{2}{9}(e_{1,1})^3 e^{-2\sigma}; \tag{5.18f}$$

$$\widehat{e_{-2,-3}} = \widetilde{\widetilde{e_{-2,-3}}} + \frac{2}{3}(e_{1,1})^2 e^{-2\sigma+\omega} - \frac{1}{6}h^2(e_{1,2})^2 - \frac{2}{3}h = e_{-2,-3} - H^2 + \frac{2}{3}(e_{1,1})^2 e^{-2\sigma+\omega} - \frac{1}{6}h^2(e_{1,2})^2 - \frac{2}{3}h. \tag{5.18g}$$

In the new basis we find fewer nonzero costructure constants. One of the new generators corresponds to the boundary of $\mathfrak{n}_-$ and thus is quasiprimitive,

$$\Delta_C(\widehat{e_{-1,0}}) = \widehat{e_{-1,0}} \otimes e^{-(1/2)\sigma+(3/2)\omega} + 1 \otimes \widehat{e_{-1,0}} \tag{5.19}$$

[notice that the other boundary element is $\widehat{e_{0,-1}}$ with the coproduct (5.16)].

The number of independent terms in the coproducts corresponds to the number of different decompositions of the vector $\beta \in \Sigma_{\mathfrak{n}_-}$ in terms of the $\mathfrak{g}^{c\#}_C$ roots. This explains why in the sequence $e_{-\alpha_1-k\alpha_2}$ $(k=0,1,2,3)$ the number of terms rapidly increases with k:

$$\Delta_C(\widehat{e_{-1,-1}}) = \widehat{e_{-1,-1}} \otimes e^{-(1/2)\sigma+(1/2)\omega} + 1 \otimes \widehat{e_{-1,-1}} + h \otimes (\widehat{e_{-1,0}} + e_{1,3})e^{-\omega} - e_{1,3} \otimes \widehat{e_{0,-1}}e^{-(1/2)\sigma+(3/2)\omega}; \tag{5.20a}$$

$$\begin{aligned}\Delta_C(\widehat{e_{-1,-2}}) = {} & \widehat{e_{-1,-2}} \otimes e^{-(1/2)\sigma-(1/2)\omega} + 1 \otimes \widehat{e_{-1,-2}} + h \otimes \widehat{e_{-1,-1}}e^{-\omega} + \frac{1}{2}h^2 \otimes \widehat{e_{-1,0}}e^{-2\omega} + e_{1,2} \\ & \otimes \widehat{e_{0,-1}}e^{-(1/2)\sigma+(1/2)\omega} - \frac{1}{2}h \otimes \widehat{e_{-1,0}}e^{-2\omega} - \frac{1}{3}h \otimes e_{1,2}e^{-\omega} - \frac{2}{3}(h-h^2) \otimes e_{1,3}e^{-2\omega};\end{aligned} \tag{5.20b}$$

$$\begin{aligned}\Delta_C(\widehat{e_{-1,-3}}) = {} & \widehat{e_{-1,-3}} \otimes e^{-(1/2)\sigma-(3/2)\omega} + 1 \otimes \widehat{e_{-1,-3}} \\ & + h \otimes \begin{pmatrix} \widehat{e_{-1,-2}}e^{-\omega} + \frac{1}{3}\widehat{e_{-1,0}}e^{-3\omega} - \widehat{e_{0,-1}}e_{1,2}e^{-\omega} - \frac{4}{3}e_{1,1}e^{-\sigma-\omega} \\ - \frac{1}{2}\widehat{e_{-1,-1}}e^{-2\omega} - \frac{1}{2}e_{1,2}e^{-2\omega} - \frac{1}{2}\widehat{e_{0,-1}}e_{1,3}e^{-2\omega} + \end{pmatrix} \\ & + h^2 \otimes \begin{pmatrix} \frac{1}{2}\widehat{e_{-1,-1}}e^{-2\omega} + \frac{1}{2}\widehat{e_{0,-1}}e_{1,3}e^{-2\omega} + \\ + \frac{1}{6}e_{1,2}e^{-2\omega} - \frac{1}{3}e_{1,3}e^{-3\omega} - \frac{1}{2}\widehat{e_{-1,0}}e^{-3\omega} \end{pmatrix} + h^3 \otimes \left(\frac{1}{6}\widehat{e_{-1,0}}e^{-3\omega} + \frac{1}{3}e_{1,3}e^{-3\omega}\right) \\ & + h\widehat{e_{0,-1}} \otimes \left(-e_{1,2}e^{-2\omega} - \frac{1}{2}e_{1,3}e^{-3\omega}\right) + \widehat{e_{0,-1}} \otimes e_{1,1}e^{-\sigma-\omega} + \frac{1}{2}h^2\widehat{e_{0,-1}} \otimes e_{1,3}e^{-3\omega}.\end{aligned} \tag{5.20c}$$

In the twisted algebra $U_C(g_2)$ the group multiplication of $G_C^{\#}$ is nontrivially deformed. In particular, the remaining coproduct $\Delta_C(\widehat{e_{-2,-3}})$ is the largest one: it has 23 terms that correspond to the adjoint action of the dual carrier group $G_C^{c\#}$ on the space of its six-dimensional subrepresentation, and the other 28 terms do appear only due to the noncommutativity of the coordinates:

$$\begin{aligned}\Delta_C(\widehat{e_{-2,-3}}) = {} & \widehat{e_{-2,-3}} \otimes e^{-\sigma} + 1 \otimes \widehat{e_{-2,-3}} - \widehat{e_{-1,0}} \otimes e_{1,0}e^{-(3/2)\sigma+(3/2)\omega} - \widehat{e_{-1,-1}} \otimes e_{1,1}e^{-(3/2)\sigma+(1/2)\omega} \\ & + e_{1,2} \otimes \widehat{e_{-1,-2}}e^{-(1/2)\sigma+(1/2)\omega} + e_{1,3} \otimes \widehat{\widehat{e_{-1,-3}}}e^{-(1/2)\sigma+(3/2)\omega} + \frac{1}{2}(e_{1,2})^2 \otimes \widehat{e_{0,-1}}e^{-\sigma+\omega} \\ & + h \otimes \widehat{e_{-1,-1}}e_{1,2}e^{-\omega} - \frac{1}{2}h^2 \otimes \widehat{e_{-1,-1}}e_{1,3}e^{-2\omega} + he_{1,2} \otimes \widehat{e_{-1,-1}}e^{-(1/2)\sigma-(1/2)\omega} + h\widehat{e_{-1,-1}} \\ & \otimes e_{1,2}e^{-(1/2)\sigma-(1/2)\omega} + \frac{1}{2}h^2e_{1,3} \otimes \widehat{e_{-1,-1}}e^{-(1/2)\sigma-(1/2)\omega} - \frac{1}{2}h^2\widehat{e_{-1,-1}} \otimes e_{1,3}e^{-(1/2)\sigma-(3/2)\omega} \\ & + \frac{1}{2}h^2 \otimes \widehat{e_{-1,0}}e_{1,2}e^{-2\omega} + \frac{1}{2}h^2e_{1,3} \otimes \widehat{e_{0,-1}}e_{1,3}e^{-(1/2)\sigma-(1/2)\omega} - \frac{1}{3}h^3 \otimes \widehat{e_{-1,0}}e_{1,3}e^{-3\omega} \\ & + h\widehat{e_{-1,0}} \otimes e_{1,1}e^{-(3/2)\sigma+(1/2)\omega} - \frac{1}{2}h^2\widehat{e_{-1,0}} \otimes e_{1,2}e^{-(1/2)\sigma+(1/2)\omega} + \frac{1}{2}h^2e_{1,2} \\ & \otimes \widehat{e_{-1,0}}e^{-(1/2)\sigma-(3/2)\omega} + \frac{1}{6}h^3e_{1,3} \otimes \widehat{e_{-1,0}}e^{-(1/2)\sigma-(3/2)\omega} + \frac{1}{6}h^3\widehat{e_{-1,0}} \otimes e_{1,3}e^{-(1/2)\sigma-(3/2)\omega} \\ & + he_{1,3} \otimes \widehat{e_{-1,-2}}e^{-(1/2)\sigma+(1/2)\omega} - he_{1,3} \otimes \widehat{e_{0,-1}}e_{1,2}e^{-(1/2)\sigma+(1/2)\omega}\end{aligned}$$

$$
\begin{aligned}

&+ h \widehat{e_{-1,0}} \otimes \left(\frac{1}{3} e_{1,3} e^{-(1/2)\sigma-(3/2)\omega} + \frac{1}{2} e_{1,2} e^{-(1/2)\sigma-(1/2)\omega} \right) \\
&+ \frac{1}{2} h \widehat{e_{-1,-1}} \otimes e_{1,3} e^{-(1/2)\sigma-(3/2)\omega} - \frac{1}{2} h^2 \widehat{e_{-1,0}} \otimes e_{1,3} e^{-(1/2)\sigma-(3/2)\omega}. \qquad (5.21)
\end{aligned}
$$

Comparing these results with those for other simple Lie algebras (deformed by the full chains of twists) we see that contrary, e.g., to the $sl(n)$ case in the twisted algebra $U_C(G_2)$, the dual generator $\widehat{e_{-2,-3}}$ differs considerably from the "Jordanian" $\widehat{\widehat{e_{-2,-3}}} = e_{-2,-3} - H^2$ and as well most of the coproducts in the negative sector are strongly deformed. In this situation the appropriate basis for the presentation of the costructure plays a very essential role. In the initial $\mathfrak{g}$ basis, the decomposition of the coproduct $\Delta_C(e_{-2,-3})$ contains more than 400 terms. Using the $\mathfrak{g}^{\#}_{EJ}$ basis $\{\tilde{\tilde{x}}\}$, we can reduce this number to 109 and, finally, in the $\mathfrak{g}^{\#}_{C}$ basis, we get the expression (5.21) with 51 terms. The effective technique is needed to perform the corresponding calculations and this is where the modified BCH formulas (3.29) and (3.30) presented in Sec. III D are very useful. The expressions (5.20a), (5.20b), (5.20c), and (5.21) were obtained with their help.

The full chain of twists (5.10) can be parametrized as follows:

$$
\mathcal{F}_C = \mathcal{F}_{J'} \mathcal{F}_E \mathcal{F}_J = e^{h \otimes \omega(\xi,\psi)} e^{-\xi e_{1,2} \otimes e_{1,1} e^{-(1/2)\sigma(\xi)}} e^{\xi e_{1,3} \otimes e_{1,0} e^{-(1/2)\sigma(\xi)}} e^{H \otimes \sigma(\xi)}, \qquad (5.22)
$$

with

$$
\sigma(\xi) = \ln(1 + \xi e_{2,3}),
$$

$$\omega(\xi,\psi)=\ln\left(1+\psi e_{0,1}+\frac{1}{2}\xi\psi(e_{1,2})^2\right). \tag{5.23}$$

Thus, the full chain leads to the two-parameter set of Hopf algebras $U_C(G_2;\xi,\psi)$. In particular, this parametrization provides the possibility to study the second classical limit for $U_C(G_2)$. The latter is obtained by scaling the generators $x\to(1/\varepsilon)x$ and by going to the limit $\varepsilon,\xi,\psi\to 0$, with finite values of $\xi/\varepsilon=\zeta$, $\psi/\varepsilon=\eta$. In such a limit we get the composition law of the dual group $G_C^{\#}$:

$$\begin{aligned}\Delta_C^{\#}(H)&=H\otimes e^{-\sigma(\zeta)}+1\otimes H-\zeta e_{1,3}\otimes e_{1,0}e^{-(3/2)(\sigma(\zeta)-\omega(\zeta,\eta))}+\zeta e_{1,2}\otimes e_{1,1}e^{-(3/2)\sigma(\zeta)+(1/2)\omega(\zeta,\eta)}\\&\quad-\frac{1}{2}\zeta\eta h\otimes(e_{1,2})^2e^{-\omega(\zeta,\eta)}-\zeta\eta he_{1,2}\otimes e_{1,2}e^{-(3/2)\sigma(\zeta)-(1/2)\omega(\zeta,\eta)}\\&\quad+\zeta\eta he_{1,3}\otimes e_{1,1}e^{-(5/2)\sigma(\zeta)+(3/2)\omega(\zeta,\eta)}+\frac{1}{2}\zeta\eta^2h^2e_{1,2}\otimes e_{1,3}e^{-(3/2)\sigma(\zeta)-(3/2)\omega(\zeta,\eta)}\\&\quad+\frac{1}{2}\zeta\eta^2h^2\otimes e_{1,3}e_{1,2}e^{-2\omega(\zeta,\eta)}-\frac{1}{2}\zeta\eta^2h^2e_{1,3}\otimes e_{1,2}e^{-(7/2)\sigma(\zeta)+(3/2)\omega(\zeta,\eta)}\\&\quad-\frac{1}{6}\zeta\eta^3h^3\otimes(e_{1,3})^2e^{-3\omega(\zeta,\eta)}+\frac{1}{6}\zeta\eta^3h^3e_{1,3}\otimes e_{1,3}e^{-(9/2)\sigma(\zeta)(3/2)\omega(\zeta,\eta)},\end{aligned} \tag{5.24a}$$

We have finished the construction of the universal enveloping algebra $U_C(g_2)$ twisted by the full chain of extended twists. The sequence of factors (5.10) cannot be essentially enlarged due to the absence of the Lie-Frobenius subalgebras in g_2 that nontrivially contain $\mathfrak{b}_+(g_2)$ (see the discussion in Sec. II). It is certainly possible to perform the additional Abelian twist $\mathcal{F}_{A'} = e^{\sigma\otimes\omega}$, but in such a case the carrier $\mathfrak{g}_C^{\#}$ is not changed. It appears that adding the twist $\mathcal{F}_{A'}$ leads to the different realization of the same $\mathfrak{g}_C^{\#}$ in terms of the generators of $U_C(g_2)$.

When such a change of the realization of the carrier happens in the intermediate steps of the quantization this can lead to interesting results. We shall study this possibility in the next section.

C. General form of extended twist for g_2: Additional Abelian twist

Let us construct the quantization for the r matrix (2.16b). As it was indicated in Sec. III, this can be performed by the twisting element

$$\mathcal{F}_{AE}(\rho) = e^{\rho h\otimes\sigma} e^{-e_{1,2}\otimes e_{1,1} e^{-(1/2)\sigma}} e^{e_{1,3}\otimes e_{1,0} e^{-(1/2)\sigma}} e^{H\otimes\sigma}. \tag{5.25}$$

Here the parameter ρ is written explicitly because of its specific role. Notice that for any fixed ρ the element $\mathcal{F}_{AE}$ depends on the deformation parameter ξ [due to the ξ-dependence of σ (see Eq. (5.22)]. Studying the parametrized set $\{\mathcal{F}_{AE}(\xi,\rho)\}$ we are dealing with the family of twists indexed by the parameter ρ. We shall demonstrate that, contrary to the case of the deformation parameter ξ where we get equivalent deformed algebras $U_{\mathcal{F}_{AE(\xi,\rho)}} \sim U_{\mathcal{F}_{AE(\xi',\rho)}}$, there are nonzero values of ρ for which the twisted algebras are inequivalent, $U_{\mathcal{F}_{AE(\xi,\rho)}} \not\sim U_{\mathcal{F}_{AE(\xi,\rho')}}$.

In order to construct the twisted Hopf algebra $U_{\mathcal{F}_{AE(\rho)}}(g_2)$, we use the coproducts Δ_{EJ} (5.18)–(5.21) of the full extended twisting (5.3) obtained in Sec. V A and apply the transformation $e^{\rho \mathrm{ad} h\otimes\sigma}$ corresponding to the Abelian twist factor $\mathcal{F}_A = e^{\rho h\otimes\sigma}$. Each nontrivial twisting factor induces the transformation of the dual group and the new dual coordinates are to be constructed. Omitting the intermediate steps we present the results in terms of the new dual $\mathfrak{g}^{\#}_{AE}$ basis:

$$\overline{H} = H + \rho h,$$

$$\overline{e_{-2,-3}} = \widetilde{\widetilde{e_{-2,-3}}} + \rho^2 h^2,$$

$$\overline{e_{-1,0}} = \widetilde{\widetilde{e_{-1,0}}} - \rho h e_{1,3},$$

$$\overline{e_{-1,-1}} = \widetilde{\widetilde{e_{-1,-1}}} + \rho h e_{1,2} \tag{5.26}$$

(the other $\mathfrak{g}^{\#}_{E}$ coordinates $\tilde{\tilde{x}}$ remain unchanged).

According to the properties of the twist $\mathcal{F}_A$ the costructure on its carrier is conserved:

$$\Delta_{AE}(h) = h\otimes 1 + 1\otimes h,$$

$$\Delta_{AE}(e_{2,3}) = e_{2,3}\otimes e^{\sigma} + 1\otimes e_{2,3}. \tag{5.27}$$

The changes in $\Delta_{AE}(\overline{H})$ and in the long sequence $\Delta_{AE}(e_{1,l})$ $(l=0,1,2,3)$ are correlated with the root structure of the extensions:

$$\begin{aligned}\Delta_{AE}(\overline{H}) &= (\overline{H})\otimes e^{-\sigma} + 1\otimes(\overline{H}) - e_{1,3}\otimes e_{1,0} e^{(\rho(\alpha+3\beta)(h)-3/2)\sigma} + e_{1,2}\otimes e_{1,1} e^{(\rho(\alpha+2\beta)(h)-3/2)\sigma} \\ &= (\overline{H})\otimes e^{-\sigma} + 1\otimes(\overline{H}) - e_{1,3}\otimes e_{1,0} e^{(3/2)(\rho-1)\sigma} + e_{1,2}\otimes e_{1,1} e^{(1/2)(\rho-3)\sigma}.\end{aligned}$$

$$\Delta_{AE}(e_{1,k}) = e_{1,0}\otimes e^{(1/2+\rho(\alpha+k\beta)(h))\sigma} + e^{\sigma}\otimes e_{1,0}, \quad k=0,1,$$

$$\Delta_{AE}(e_{1,m}) = e_{1,0}\otimes e^{(-1/2+\rho(\alpha+m\beta)(h))\sigma} + 1\otimes e_{1,0}, \quad m=2,3. \tag{5.28}$$

On the plane orthogonal to the highest root, we find the quasiprimitive costructure:

$$\Delta_{AE}(\widetilde{\widetilde{e_{0,1}}}) = \widetilde{\widetilde{e_{0,1}}}\otimes e^{\rho\sigma} + 1\otimes\widetilde{\widetilde{e_{0,1}}},$$

$$\Delta_{AE}(\widetilde{\widetilde{e_{0,-1}}}) = \widetilde{\widetilde{e_{0,-1}}}\otimes e^{-\rho\sigma} + 1\otimes\widetilde{\widetilde{e_{0,-1}}}. \tag{5.29}$$

In the coproducts for the other basic elements (belonging to $\mathfrak{n}_-$) the additional terms proportional to ρ do appear,

$$\Delta_{AE}(\widetilde{\widetilde{e_{-1,-3}}}) = \widetilde{\widetilde{e_{-1,-3}}} \otimes e^{-(1/2)(1+3\rho)\sigma} + 1 \otimes \widetilde{\widetilde{e_{-1,-3}}} + (1-\rho)h \otimes e_{1,0}e^{-\sigma} + \widetilde{\widetilde{e_{0,-1}}} \otimes e_{1,1}e^{-(1+\rho)\sigma}, \tag{5.30a}$$

$$\Delta_{AE}(e_{-1,-2}) = e_{-1,-2} \otimes e^{-(1/2)(1+\rho)\sigma} + 1 \otimes e_{-1,-2} + \left(\rho - \frac{1}{3}\right)h \otimes e_{1,1}e^{-\sigma} - \widetilde{\widetilde{e_{0,1}}} \otimes e_{1,0}e^{(\rho-1)\sigma} + e_{1,2} \otimes \widetilde{\widetilde{e_{0,-1}}}e^{-(1/2)\sigma(1-\rho)}, \tag{5.30b}$$

$$\Delta_{AE}(\overline{e_{-1,-1}}) = \overline{e_{-1,-1}} \otimes e^{(1/2)(\rho-1)\sigma} + 1 \otimes \overline{e_{-1,-1}} + \left(\frac{1}{3} + \rho\right)e_{1,2} \otimes he^{(1/2)(\rho-1)\sigma} - e_{1,3} \otimes \widetilde{\widetilde{e_{0,-1}}}e^{(1/2)(3\rho-1)\sigma} + \frac{4}{3}\widetilde{\widetilde{e_{0,1}}} \otimes e_{1,1}e^{(\rho-1)\sigma}, \tag{5.30c}$$

$$\Delta_{AE}(\overline{e_{-1,0}}) = \overline{e_{-1,0}} \otimes e^{(1/2)(3\rho-1)\sigma} + 1 \otimes \overline{e_{-1,0}} + e_{1,2} \otimes \widetilde{\widetilde{e_{0,1}}}e^{-(1/2)\sigma(1-\rho)} - (\rho+1)e_{1,3} \otimes he^{(1/2)(3\rho-1)\sigma}, \tag{5.30d}$$

$$\Delta_{AE}(\overline{e_{-2,-3}}) = \overline{e_{-2,-3}} \otimes e^{-\sigma} + 1 \otimes \overline{e_{-2,-3}} + 2\rho h \otimes \overline{H} - \overline{e_{-1,0}} \otimes e_{1,0}e^{(3/2)(\rho-1)\sigma} - \overline{e_{-1,-1}} \otimes e_{1,1}e^{(1/2)(\rho-3)\sigma} + e_{1,2} \otimes e_{-1,-2}e^{(1/2)(\rho-1)\sigma} + e_{1,3} \otimes \widetilde{\widetilde{e_{-1,-3}}}e^{(1/2)(3\rho-1)\sigma} - \frac{2}{3}\widetilde{\widetilde{e_{0,1}}} \otimes (e_{1,1})^2e^{(\rho-2)\sigma} + \frac{1}{2}(e_{1,2})^2 \otimes \widetilde{\widetilde{e_{0,-1}}}e^{(\rho-1)\sigma} + 2\rho he_{1,2} \otimes e_{1,1}e^{(1/2)(\rho-3)\sigma}. \tag{5.30e}$$

In the last expression the additional terms signify that the root vector $\overline{H^*}$ is no longer orthogonal to h^* and the adjoint operator $\mathrm{ad}(\overline{H^*})$ transforms h^* into $\overline{e_{-2,-3}}$.

In comparison with $\Delta_E(\tilde{x})$, the changes of the form of the coproducts Δ_{AE} are small but essential. We immediately see five singular points $\rho = 0, \pm 1, \pm\frac{1}{3}$. In each of them one of the coproducts loses some terms and becomes closer to a quasiprimitive. For example, in the cases $\Delta_{AE_+}(\widetilde{\widetilde{e_{-1,-3}}})$ and $\Delta_{AE_+}(\overline{e_{-1,0}})$ if we use only the $sl(3)$ extension $\mathcal{F}_+ = e^{e_{1,3}\otimes e_{1,0}e^{(-1/2)\sigma}}$ then for $\rho = \pm 1$ these coproducts become quasiprimitive, and we obtain the possibility to perform additional twistings with the carrier algebra nontrivially intersecting with $\mathfrak{n}_-$. In the costructure Δ_{AE} the corresponding enlargement of the carrier cannot be achieved, nevertheless, the singular points are also important. In particular, we see that the standard case Δ_{EJ} corresponds to the singular point $\rho = 0$ while in the general situation the coproduct $\Delta_{AE(\rho)}(\overline{e_{-2,-3}})$ has additional components, and we arrive at different dual algebra $\mathfrak{g}^{\#}_{AE} \neq \mathfrak{g}^{\#}_{E}$. Notice that in all the singular points the corresponding r matrices differ only by the value of the numerical parameter ρ but the results of the quantizations are different and refer to Lie–Poisson structures.

We have already seen that the coproducts $\Delta_{AE}(\widetilde{\widetilde{e_{0,\pm 1}}})$ are now quasiprimitive. Consequently, there still exists the possibility to perform further twisting with the Jordanian factor similar to $\mathcal{F}_{J'}$,

$$\mathcal{F}_{J''} = e^{h\otimes\omega'}, \tag{5.31}$$

with $\omega' = \ln(\widetilde{\widetilde{e_{0,1}}}e^{-\rho\sigma} + e^{-\rho\sigma})$. The twisting element,

$$\mathcal{F}_{J''AE} = e^{h\otimes\omega'} e^{\rho h\otimes\sigma} e^{-e_{1,2}\otimes e_{1,1}e^{-(1/2)\sigma}} e^{e_{1,3}\otimes e_{1,0}e^{-(1/2)\sigma}} e^{H\otimes\sigma}, \tag{5.32}$$

is the solution of the twist equation. Here, contrary to the situation with the full chain of extended twists, we do not obtain a parametrized family of chain deformations. It can be easily checked that [see also Eq. (5.10)]

$$\mathcal{F}_{J''AE} = \mathcal{F}_C = e^{h\otimes\omega} e^{-e_{1,2}\otimes e_{1,1}e^{-(1/2)\sigma}} e^{e_{1,3}\otimes e_{1,0}e^{-(1/2)\sigma}} e^{H\otimes\sigma}. \tag{5.33}$$

The dependence on ρ cancels and we are again with the full chain studied above in Sec. V B. Thus, we have obtained the following result: there is the ρ family of quantum algebras $U_{AE(\rho)}(g_2)$, but the full chain quantization $U_C(g_2)$ is unique.

To complete the analysis of the set of twist deformations for $U(g_2)$, let us consider the generators that can become quasiprimitive (in general, nonsimultaneously) after the action of the full chain of twists $\mathcal{F}_C$. The number q_C^- of such generators is equal to the rank of $\mathfrak{g}$. In our case we have $q_C^-(g_2)=2$, and the corresponding generators are $\widehat{e_{0,-1}}$ and $\widehat{e_{-1,0}}$. Both are quasiprimitive simultaneously but cannot enlarge the space of $\mathfrak{g}_c^C$ up to a (quasi-) Frobenius subalgebra in $U(g_2)$. In the Borel subalgebra $U_C(\mathfrak{b}_+(g_2))$ the number q_C^+ of quasiprimitive generators is equal to the number of simultaneously primitive. For the full chains we have $q_C^+=r$ and in our case (as we have seen above) these primitive generators are σ and ω. This certainly provides the possibility to perform the additional Abelian twist but the corresponding deformation will be equivalent to the redefinition of the Cartan elements in the Jordanian twisting factors.

VI. DISCUSSION AND OUTLOOK

We have described the set $\{U_J, U_{E_+J}, U_{EJ}, U_{J'EJ}, U_{A(\rho)EJ}\}$ of quantized Lie–Poisson structures that were constructed on the space $U(g_2)$ by chains of twist deformations. The dual group coordinates ($\mathfrak{g}^{\#}$ basis) obtained through the second classical limit procedure provide us with the possibility of writing down the explicit form of these Lie–Poisson structures. We have presented in this paper the algebraic and coalgebraic formulas determined by the exceptional Lie algebra g_2, in particular, we get the additional [in comparison with the situation in $U(sl(3))$ and $U(so(5))$] Hopf algebra U_{EJ}; the carrier space for the second Jordanian twist $\mathcal{F}_{J'}$ is deformed [the analogous result was found for $U_{E_+J}(so(5))$ (Refs. 11 and 12)]; the Hopf algebras $\{U_{E_+J}, U_{J'EJ}, U_{AEJ}\}$ in comparison with the analogous quantizations of $U(sl(3))$ and $U(so(5))$ have a more complicated constructure determined by the root system of g_2.

We have also found the peripheric twisted algebras in the set of Hopf algebras $\{U_{A(\rho)EJ}\}$. The number s_C of inequivalent algebras in this set depends on the number l_C^n of extended Jordanian factors in the chain $\mathcal{F}_C$. We conjecture the following relation;

$$s_C = \sum_{i=1}^{l_C^n} (\dim(\mathfrak{g}_c^{(i)}) - 1), \tag{6.1}$$

where $\mathfrak{g}_c^{(i)}$ is the carrier subalgebra of the link $\mathcal{F}^{(i)} \subset \mathcal{F}_C$. This gives three inequivalent subsets for $U_{A(\rho)EJ}(sl(3))$ as well as $U_{A(\rho)EJ}(so(5))$ and five for $U_{A(\rho)EJ}(g_2)$. One of the algebras, $U_{A(0)EJ}(g_2)$, corresponds to the canonical extended twist and four others are the analogs of the peripheric extended deformations[12] in $U_{EJ}(sl(N))$. At the same time we do not have peripheric chains in $U_{\mathcal{F}}(g_2)$. As we have already stressed above, the full chain deformation $U_{\mathcal{F}}(g_2)$ is invariant under the rotation generated by an additional Abelian twist.

On the continuous spectral component of the Floquet operator for a periodically kicked quantum system

James McCaw[a] and B. H. J. McKellar[b]
School of Physics, Research Centre for High Energy Physics,
The University of Melbourne, Victoria, 3010, Australia

(Received 1 June 2005; accepted 11 July 2005; published online 7 October 2005)

By a straightforward generalization, we extend the work of Combescure [J. Stat. Phys. **59**, 679 (1990)] from rank-1 to rank-*N* perturbations. The requirement for the Floquet operator to be pure point is established and compared to that in Combescure. The result matches that in McCaw and McKeller [J. Math. Phys. **46**, 032108 (2005)]. The method here is an alternative to that work. We show that if the condition for the Floquet operator to be pure point is relaxed, then in the case of the δ-kicked Harmonic oscillator, a singularly continuous component of the Floquet operator spectrum exists. We also provide an in-depth discussion of the conjecture presented in the work of Combescure of the case where the unperturbed Hamiltonian is more general. We link the physics conjecture directly to a number-theoretic conjecture of Vinogradov [*The Method of Trigonometrical Sums in the Theory of Numbers* (Interscience, London, 1954)] and show that a solution of Vinogradov's conjecture solves the physics conjecture. The result is extended to the rank-*N* case. The relationship between our work and the work of Bourget [J. Math. Anal. Appl. **276**, 28 (2002); **301**, 65 (2005)], on the physics conjecture is discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2035027]

I. INTRODUCTION

The spectral analysis of the Floquet operator (the unitary time-evolution operator over a single kick period) is of great interest for periodically perturbed Hamiltonian systems. There are general arguments[1–5] which indicate that an understanding or classification of the spectrum of the time-evolution operator can provide information on the dynamics of the system. In particular, the existence of a singularly continuous spectrum of the Floquet operator allows for a slow diffusive energy growth over time, typical of a chaotic system. Thus, this work has significance in the broad field of quantum chaos. For a more detailed discussion of the links among spectral analysis, dynamics, and chaos, see the introductory sections of Ref. 1 and references therein.

The work in Ref. 1 established a nonperturbative stability result on the spectral nature of the Floquet operator for simple systems with a rank-*N* perturbation periodic in time. The conditions under which the Floquet spectrum remains pure point were established. Here, we will first show the same result, but in a very different manner, before proceeding to determine when a continuous spectrum may arise. This result sheds further light on the array of possible dynamics that periodically perturbed systems may experience.

We consider Hamiltonians of the form
