One must show, that $\Delta(A) = \varnothing$. Suppose the contrary, $\Delta(A) \neq \varnothing$. Denote $B_v := \{\Psi^v_\sigma\}_{\sigma \in S_{\hat{v}}}$ ($v \in V$), $\hat{B} := \{F_\pi\}_{\pi \in \Lambda}$. Take $\phi \in \Delta(A)$. The definition of $\Gamma(A) \supset \Delta(A)$ implies, that for every $v \in V$ one has an element $\phi(B_v) \in B_v$, i.e., $\phi(B_v) = \Psi^v_{\sigma_v^\phi}$, where σ_v^ϕ is some element of $S_{\hat{v}}$. Simillarly, $\phi(\hat{B}) = F_{\pi^\phi}$, where π^ϕ is some element of Λ. The definition of $\Delta(A)$ implies, that $\Psi^v_{\sigma_v^\phi}$ is not orthogonal to $\Psi^w_{\sigma_w^\phi}$ (for any $v \neq w$). Using the orthogonality relations one concludes, that $\sigma_v^\phi(vw) = \sigma_w^\phi(vw)$. It means, that a set of functions $\{\sigma_v^\phi\}_{v \in V}$ induces a function $\tau^\phi: E \to \mathbb{Z}_2$ by the formula $\tau^\phi(vw) := \sigma_v^\phi(vw) = \sigma_w^\phi(vw)$ (for any $vw \in E$). Now invoke the fact, that the definition of

$\Delta(A)$ also implies, that for every $v \in V$ the line $\phi(\hat{B})$ should not be orthogonal to $\phi(B_v)$, i.e., $\neg(F_{\pi^\phi} \perp \Psi_{\sigma_v^\phi})$. It follows, that $\forall v \in V: \nabla_{\sigma_v^\phi} = \pi^\phi(v)$. Taking the sum over all $v \in V$ and invoking the definition of Λ, one gets $\Sigma_{v \in V} \nabla_{\sigma_v^\phi} = \Sigma_{v \in V} \pi^\phi(v) = 1$. On the other hand,

$$\sum_{v \in V} \nabla_{\sigma_v^\phi} = \sum_{v \in V} \sum_{\epsilon \in E_v} \sigma_v^\phi(\epsilon) = \sum_{\epsilon \in E} (\tau^\phi(\epsilon) + \tau^\phi(\epsilon)) = 0.$$

Thus one arrives to a contradiction $0=1$. It means that $\nexists \phi \in \Delta(A)$, i.e., $\Delta(A) = \varnothing$.

The link with Mermin's example is established as follows. Let the standard basis in $\mathbb{C}^2$ play the role of the basis $\{\varphi_\alpha\}_{\alpha \in \mathbb{Z}_2}$ involved in the construction of A. Note, that in the proof of $\Delta(A) = \varnothing$ we have used only five complete subsets, B_v $(v = e, f, g, h)$ and $\hat{B}$. The proof of no-hidden-variables theorem by Mermin is given in terms of operators in $\mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2$. There are five complete sets of pairwise commuting orthogonal projectors present in that proof. If one looks at the one-dimensional eigenspaces (i.e., the projective lines) associated to each of these sets, one obtains $B_e \sqcup B_f \sqcup B_g \sqcup B_h \sqcup \hat{B}$.

VI. SATURATION PROPERTY, PART 1

The proof that the set A is saturated with respect to $\perp$ is more bulky. Recall that we have an injective map $\xi: \mathcal{P}(V)^\times \rightarrowtail C(\mathbb{P}(\mathcal{H}))$, where V is a set of 4 symbols $V = \{e, f, g, h\}$. This map has a property $\forall U, U' \in \mathcal{P}(V)^\times, U \neq U': \xi(U) \cap \xi(U') = \varnothing$. It follows, that one can define a map $\eta: A \rightarrow \mathcal{P}(V)$ as follows: one chooses $U \in \mathcal{P}(V)^\times$ to be the value $\eta(l)$ of the map η on a projective line $l \in A$ whenever $l \in \xi(U)$, i.e., η is defined from the requirement $\forall U \in \mathcal{P}(V)^\times: l \in \xi(U) \Leftrightarrow \eta(l) = U$. Note, that η induces a surjection onto $\mathcal{P}(V)^\times$.

The projective lines constituting A may be classified as follows. Call $\#\eta(l)$ the *type* of the projective line $l \in A$. There are four types of projective lines. The image $\eta(l)$ is termed the *kind* of the line l. There are 4 kinds in type 1, 6 kinds in type 2, 4 kinds in type 3, and 1 kind in type 4. We shall also refer to projective lines of the types 1, 2, 3, 4, as being projective lines of Ψ type, X type, Φ type, and F type, respectively. In a similar way, if $\eta(l) = \hat{e}$, the line l is said to be of Ψ^e kind, if $\eta(l) = ef$, the line l is said to be of X^{ef} kind, etc.

Naively, in order to prove the saturation property for A one may think of having to do the following: one must take every subset B of A and test if its elements are pairwise orthogonal; if it happens to be so, one must find a complete subset in A containing B. All this appears to be a very boring problem since $\#\mathcal{P}(A) = 2^{120}$. There is of course a group of permutations S_4 acting on $\mathcal{P}_\perp(A)$ and an observation about the existence of the duality map δ, but the $\#S_4$ is just $4! = 24$ and the order of δ as an element of $Bij_\perp(A)$ is just 2, i.e., $\delta^2 = id$. It means, that one must find a more sophisticated approach to prove the saturation.

We have a map $\eta: A \rightarrow \mathcal{P}(V)$. It induces a map $\mathcal{P}(\eta): \mathcal{P}(A) \rightarrow L := \mathcal{P}(\mathcal{P}(V))$. How to describe an image of the composition $\mathcal{P}_\perp(A) \rightarrowtail \mathcal{P}(A) \rightarrow L$, where the first arrow is the canonical injection?

There exists a natural monomorphism of groups m: $Bij(V) \rightarrowtail Bij(\mathcal{P}(V))$, $\beta \mapsto \mathcal{P}(\beta)$. There also exists a natural monomorphism μ: $Bij(V) \rightarrowtail Bij(A)$, such that for every $\beta \in Bij(V)$ there is a commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{\mu(\beta)} & A \\ \eta \downarrow & & \downarrow \eta \\ \mathcal{P}(V) & \xrightarrow[m(\beta)]{} & \mathcal{P}(V) \end{array} .$$

The monomorphism μ is defined as follows. Take any $\beta \in \mathcal{P}(V)$ and describe explicitly the values of $\mu(\beta)(\cdot)$ on the elements of the form Ψ_σ^v, $X_\varkappa^\epsilon$, Φ_ρ^v, and F_π, where $v \in V$, $\epsilon \in E$, $\sigma \in S_{\hat{v}}$, $\varkappa \in K_\epsilon$, $\rho \in R_{\bar{v}}$, and $\pi \in \Lambda$. Let $\mu(\beta)(\Psi_\sigma^v) := \Psi_{\sigma'}^{v'}$, where $v' = \beta(v)$ and $\forall \epsilon_1 \in E_{v'}: \sigma'(\epsilon_1) = \sigma(\mathcal{P}(\beta^{-1})(\epsilon_1))$;

$\mu(\beta)(X^{\epsilon}_{\varkappa}) := X^{\epsilon'}_{\varkappa'}$, where $\epsilon' = \mathcal{P}(\beta)(\epsilon)$ and $\varkappa'(\epsilon') = \varkappa(\epsilon)$, $\forall v_1 \in V \setminus \epsilon' : \varkappa'(v_1) = \varkappa(\beta^{-1}(v_1))$; $\mu(\beta)(\Phi^{v}_{\rho})$ $:= \Phi^{v'}_{\rho'}$, where $v' = \beta(v)$ and $\forall \epsilon_1 \in E_{v'} : \rho'^{*}(\epsilon_1) = \rho^{*}(\mathcal{P}(\beta^{-1})(\epsilon_1))$; finally $\mu(\beta)(F_{\pi}) := F_{\pi'}$, where $\forall v_1 \in V : \pi'(v_1) = \pi(\beta^{-1}(v_1))$. Note, that for every $\beta \in Bij(V)$ the map $\mu(\beta)$ respects the orthogonality relation $\perp$ on A, and the fact that this relation has a symmetry with respect to the group of permutations of e, f, g, and h can be expressed as

$$\forall \beta \in Bij(V)\ \forall\, l, l' \in A : l \perp l' \Rightarrow \mu(\beta)(l) \perp \mu(\beta)(l').$$

It follows, that whenever an element $Q \in L$ stems from some element $B \in \mathcal{P}_{\perp}(A)$, the element of the form $\mathcal{P}(m(\beta))(Q)$, $\beta \in Bij(V)$, also stems from an element of $\mathcal{P}_{\perp}(A)$, namely from $\mathcal{P}(\mu(\beta))(B)$. Factorize L with respect to the equivalence relation $\sim$ induced by permutations,

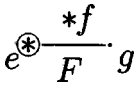
$$Q \sim Q' :\Leftrightarrow \exists\, \beta \in Bij(V) : \mathcal{P}(m(\beta))(Q) = Q'.$$

Denote $\Gamma := L/\sim$. The problem of the description of the image of $\mathcal{P}_{\perp}(A)$ in L is then reduced to describing the image of the composition

$$\mathcal{P}_{\perp}(A) \rightarrowtail \mathcal{P}(A) \xrightarrow{\mathcal{P}(\eta)} L \twoheadrightarrow \Gamma,$$

where the first arrow is the canonical injection and the last arrow is the canonical surjection.

It is convenient to introduce graphical notation for the elements of L and Γ. Consider an example. Let $Q = \{\hat{e}, \hat{f}, \overline{e}, eg, efgh\} \in L$. It is represented by a graph,



The general principle is the following. A graph may have up to four vertices labeled by the symbols e, f, g or h. If Q contains $\hat{v}$, introduce a vertex labeled by the symbol v and mark it with *; if Q contains $\overline{v}$, introduce a vertex v and draw a circle around it; if there is $vw \in Q$, introduce two vertices v and w and connect them by an edge; finally if Q contains $efgh$, set a letter F near the corresponding figure. Thus to each $Q \in L$ a graph is associated. Note, that if an element Q $\in L$ stems from some element $B \in \mathcal{P}(A)$, i.e., $\mathcal{P}(\eta)(B) = Q$, then by looking at a graph that represents Q one cannot tell everything about B, but the kinds of projective lines that are present in B can be understood.

The graphs representing the elements of Γ are similar to the graphs representing the elements of L. They are obtained by omitting the labels e, f, g, and h of the vertices. For instance, if Q $\in L$ is as in the example given above, and $[Q] \in \Gamma$ is its image under the natural surjection $L \twoheadrightarrow \Gamma$, then $[Q]$ is represented by the graph

Whenever one has an element of Γ of the form $[\mathcal{P}(\eta)(B)]$, where B is some subset of A, the graph that represents this element is called a *shadow* of B.

Let us introduce more terminology. A graph representing an element of Γ is called *admissible* iff by definition it represents an element of the image of $\mathcal{P}_{\perp}(A) \rightarrow \Gamma$; otherwise it is called *non-admissible*. One would like to describe all the admissible graphs. Whenever a graph represents an image of some $Q \in L$ under the canonical surjection $L \twoheadrightarrow \Gamma$, the cardinality $\#Q$ is called the *degree* of this graph. Whenever a graph represents an image of some $B \in \mathcal{P}_{\perp}(A)$ under $\mathcal{P}_{\perp}(A) \rightarrow \Gamma$, one says that B *hangs over* this graph. Any $B' \in P_{\perp}(A)$ containing B is called an *extension* of B. It is called a *pure* extension, iff by definition B' and B hang over the same graph. An extension satisfying $B' = B$ is called *trivial*. An extension B' of B is called *complete* iff by definition $\#B' = 8$ [recall that $8 = \dim_{\mathbb{C}}(\mathcal{H})$, $A \subset \mathbb{P}(\mathcal{H})$].

Proposition 1: (1) *The graph* $*$ *is admissible and any element of* $\mathcal{P}_\perp(A)$ *hanging over this graph admits a pure complete extension.*

(2) *The graph* $**$ *is admissible and any element of* $\mathcal{P}_\perp(A)$ *hanging over this graph admits a pure complete extension.*

(3) *The graph* $\triangle$ *is not admissible.*

(4) *The graph* $***$ *is admissible and any element of* $\mathcal{P}_\perp(A)$ *hanging over this graph admits a pure extension up to a set of cardinality 6. Any element of* $\mathcal{P}_\perp(A)$ *of cardinality 6, which hangs over this graph, has a complete extension hanging over* $***\odot$.

(5) *The graph* $***\odot$ *is admissible and any element of* $\mathcal{P}_\perp(A)$ *hanging over this graph admits a pure complete extension.*

(6) *The graph* $****$ *is admissible and any element of* $\mathcal{P}_\perp(A)$ *hanging over this graph does not have nontrivial pure extensions. Any element of* $\mathcal{P}_\perp(A)$ *hanging over this graph has a complete extension hanging over* $\circledast\circledast\circledast\circledast$.

(7) *The graph* $****F$ *is not admissible.*

Proof: (1) A set consisting of one projective line Ψ^e_σ, where σ is some element of $S_{\hat{e}}$, gives an example of a set hanging over $*$. Every set hanging over this graph is of the form $B=\{\Psi^v_\sigma\}_{\sigma\in S}$, where v is some element of V and S is some nonempty subset of $S_{\hat{v}}$. This subset B is always a subset of a complete set $\{\Psi^v_\sigma\}_{\sigma\in S_{\hat{v}}}$.

(2) Take any $a\in\mathbb{Z}_2$ and choose any $\sigma\in S_{\hat{e}}$ such that $\sigma(ef)=a$, and any $\sigma_1\in S_{\hat{f}}$ such that $\sigma_1(ef)=1+a$. Then the projective lines Ψ^e_σ and $\Psi^f_{\sigma_1}$ are orthogonal and one can take them two as a set which hangs over the graph $**$. An arbitrary set B hanging over this graph is always of the form $B=\{\Psi^v_\sigma\}_{\sigma\in S}\cup\{\Psi^w_{\sigma_1}\}_{\sigma_1\in S_1}$, where S and S_1 are some nonempty subsets of $S_{\hat{v}}$ and $S_{\hat{w}}$, respectively, v, $w\in V$, $v\neq w$. One associates to B a parameter $a:=\sigma(vw)=1+\sigma_1(vw)$, where σ is any element of S and σ_1 is any element of S_1. Denote $S':=\{\sigma\in S_{\hat{v}}|\,\sigma(vw)=a\}$ and $S'_1:=\{\sigma_1\in S_{\hat{w}}|\,\sigma_1(vw)=1+a\}$. Since $\#S'=\#S'_1=4$, the set $B':=\{\Psi^v_\sigma\}_{\sigma\in S'}\cup\{\Psi^w_{\sigma_1}\}_{\sigma_1\in S'_1}$ gives the required pure complete extension of B.

(3) If the graph $\triangle$ is admissible, then there should exist three pairwise orthogonal projective lines of the form $X^{ef}_\varkappa$, $X^{eg}_{\varkappa_1}$ and $X^{fg}_{\varkappa_3}$, where $\varkappa$, $\varkappa_1$, and $\varkappa_2$ are some elements of K_{ef}, K_{eg}, and K_{fg}, respectively. The orthogonality relations yield three equations,

$$X^{ef}_\varkappa \perp X^{eg}_{\varkappa_1} \Leftrightarrow \varkappa(ef)+\varkappa(h)=1+\varkappa_1(eg)+\varkappa_1(h),$$

$$X^{ef}_\varkappa \perp X^{fg}_{\varkappa_2} \Leftrightarrow \varkappa(ef)+\varkappa(h)=1+\varkappa_2(fg)+\varkappa_2(h),$$

$$X^{eg}_{\varkappa_1} \perp X^{fg}_{\varkappa_2} \Leftrightarrow \varkappa_1(eg)+\varkappa_1(h)=1+\varkappa_2(fg)+\varkappa_2(h).$$

Taking the sum of these three equations one arrives to a contradiction $0=1$. This means, that the mentioned triangle is not admissible.

(4) One can construct an example of three pairwise orthogonal lines of the form Ψ^e_σ, $\Psi^f_{\sigma_1}$, $\Psi^g_{\sigma_2}$ as follows: take any $a,b,c\in\mathbb{Z}_2$ and choose $\sigma\in S_{\hat{e}}$ such that $\sigma(ef)=a$, $\sigma(eg)=b$, any $\sigma_1\in S_{\hat{f}}$ such that $\sigma_1(ef)=1+a$, $\sigma_1(fg)=c$, and $\sigma_2\in S_{\hat{g}}$ such that $\sigma_2(eg)=1+b$, $\sigma_2(fg)=1+c$. Then the orthogonality relations between the mentioned three lines are fulfilled and the set consisting of these three hangs over the graph $***$. An arbitrary set hanging over this graph is of the form $B=\{\Psi^v_\sigma\}_{\sigma\in S}\cup\{\Psi^w_\sigma\}_{\sigma_1\in S_1}\cup\{\Psi^z_\sigma\}_{\sigma_2\in S_2}$, where S, S_1, and S_2 are some nonempty subsets of $S_{\hat{v}}$, $S_{\hat{w}}$, and $S_{\hat{z}}$, respectively, $v,w,z\in V$, $v\neq w$, $v\neq z$, $w\neq z$. Without loss of generality one may specialize v, w and z to e, f, and g, respectively. Associate to B three parameters $a,b,c\in\mathbb{Z}_2$: $a:=\sigma(ef)=1+\sigma_1(ef)$, $b:=\sigma(eg)=1+\sigma_2(eg)$, $c:=\sigma_1(fg)=1+\sigma_2(fg)$, where σ, σ_1 and σ_2 are elements of S, S_1, and S_2, respectively. Denote $S':=\{\sigma\in S_{\hat{e}}|\,\sigma(ef)=a\&\sigma(eg)=b\}$, $S'_1:=\{\sigma_1\in S_{\hat{f}}|\,\sigma_1(ef)=1+a\&\sigma_1(fg)=c\}$, and $S'_2:=\{\sigma_2\in S_{\hat{g}}|\,\sigma_2(eg)=1+b\&\sigma_2(fg)=1+c\}$. Since $\#S'=\#S'_1=\#S'_2=2$, the set

$B' := \{\Psi^v_\sigma\}_{\sigma\in S'} \cup \{\Psi^w_\sigma\}_{\sigma_1\in S'_1} \cup \{\Psi^z_\sigma\}_{\sigma_2\in S'_2}$ is a pure extension of B up to a set of cardinality 6. Now look for a projective line Φ^h_ρ, $\rho \in R_{\bar{h}}$, which is orthogonal to every element of B'. This yields the following equations:

$$\forall \sigma \in S' : \nabla_\sigma + \sigma(eh) = 1 + \nabla_{\rho^*} + \rho^*(eh),$$

$$\forall \sigma_1 \in S'_1 : \nabla_{\sigma_1} + \sigma_1(fh) = 1 + \nabla_{\rho^*} + \rho^*(fh),$$

$$\forall \sigma_2 \in S'_2 : \nabla_{\sigma_2} + \sigma_2(gh) = 1 + \nabla_{\rho^*} + \rho^*(gh).$$

Observe that the left-hand sides of these equations may be expressed in terms of parameters a, b, and c as $\nabla_\sigma + \sigma(eh) = \sigma(ef) + \sigma(eg) = a + b$, $\nabla_{\sigma_1} + \sigma_1(fh) = \sigma_1(ef) + \sigma_1(fg) = (1+a) + c$, and $\nabla_{\sigma_2} + \sigma_2(gh) = \sigma_1(eg) + \sigma_1(fg) = (1+b) + (1+c)$. Reduce the equations for ρ to $\rho^*(fh) + \rho^*(gh) = 1 + a + b$, $\rho^*(eh) + \rho^*(gh) = a + c$ and $\rho^*(eh) + \rho^*(fh) = 1 + b + c$. The latter equation is nothing but a sum of the first two and may be dropped. Denote $R' := \{\rho \in R_{\bar{h}} \mid \rho^*(fh) + \rho^*(gh) = 1 + a + b \,\&\, \rho^*(eh) + \rho^*(gh) = a + c\}$. Taking into account that $\#R = 2$, one obtains a set $B'' := B' \cup \{\Phi^h_\rho\}_{\rho\in R'}$, which is a complete extension of B' and hangs over $***\odot$.

(5) The admissibility of $***\odot$ follows from (4). Consider any $B \in \mathcal{P}_\perp(A)$ hanging over this graph. Without loss of generality, one may assume, that $B = \{\Psi^e_\sigma\}_{\sigma\in S} \cup \{\Psi^f_\sigma\}_{\sigma_1\in S_1} \cup \{\Psi^g_\sigma\}_{\sigma_2\in S_2} \cup \{\Phi^h_\rho\}_{\rho\in R}$, where S, S_1, S_2, and R are some nonempty subsets of $S_{\hat{e}}$, $S_{\hat{f}}$, $S_{\hat{g}}$, and $R_{\bar{h}}$, respectively. Consider a subset of B consisting of all projective lines of Ψ type and associate to it the parameters $a, b, c \in \mathbb{Z}_2$ in a way as described in the proof of (4). Let S', S'_1, S'_2, and R' be defined as in the proof of (4). Then the set $\tilde{B} := \{\Psi^e_\sigma\}_{\sigma\in S'} \cup \{\Psi^f_\sigma\}_{\sigma_1\in S'_1} \cup \{\Psi^g_\sigma\}_{\sigma_2\in S'_2} \cup \{\Phi^h_\rho\}_{\rho\in R'}$ is the required pure complete extension of B.

(6) A set of pairwise orthogonal projective lines Ψ^e_σ, $\Psi^f_{\sigma_1}$, $\Psi^g_{\sigma_2}$, and $\Psi^h_{\sigma_3}$, which is required to establish the admissibility of the graph $****$, can be constructed as follows. Take any $\mathbb{Z}_2$-valued function φ on $E := \{ef, eg, eh, fg, fh, gh\}$. Denote $a := \varphi(ef)$, $b := \varphi(eg)$, $c := \varphi(fg)$, $p := \varphi(eh)$, $q := \varphi(fh)$, $r := \varphi(gh)$. Take the following σ, σ_1, σ_2, and σ_3: $\sigma(ef) = a$, $\sigma(eg) = b$, $\sigma(eh) = p$; $\sigma_1(ef) = 1 + a$, $\sigma_1(fg) = c$, $\sigma_1(fh) = q$; $\sigma_2(eg) = 1 + b$, $\sigma_2(fg) = 1 + c$, $\sigma_2(gh) = r$; $\sigma_3(eh) = 1 + p$, $\sigma_3(fh) = 1 + q$, $\sigma_3(gh) = 1 + r$. Then the projective lines Ψ^e_σ, $\Psi^f_{\sigma_1}$, $\Psi^g_{\sigma_2}$, and $\Psi^h_{\sigma_3}$ constitute a set as required. An arbitrary set B hanging over the mentioned graph is of the form $B = \{\Psi^e_\sigma\}_{\sigma\in S} \cup \{\Psi^f_{\sigma_1}\}_{\sigma_1\in S_1} \cup \{\Psi^g_{\sigma_2}\}_{\sigma_2\in S_2} \cup \{\Psi^h_{\sigma_3}\}_{\sigma_3\in S_3}$, where S, S_1, S_2, and S_3 are some nonempty subsets of $S_{\hat{e}}$, $S_{\hat{f}}$, $S_{\hat{g}}$, and $S_{\hat{h}}$ respectively. To every such B associate φ: $E \to \mathbb{Z}_2$ by setting $\varphi(ef) = \sigma(ef)$, $\varphi(eg) = \sigma(eg)$, $\varphi(eh) = \sigma(eh)$, $\varphi(fg) = \sigma_1(fg)$, $\varphi(fh) = \sigma_1(fh)$, $\varphi(gh) = \sigma_2(gh)$, where σ, σ_1, and σ_2 can be taken to be any elements of S, S_1, and S_2, respectively. The set S is a nonempty subset of $S' := \{\sigma \in S_{\hat{e}} \mid \sigma(ef) = \varphi(ef) \,\&\, \sigma(eg) = \varphi(eg) \,\&\, \sigma(eh) = \varphi(eh)\}$. Since $\#S' = 1$, we see that $\#S = 1$. Similarly, $\#S_1 = \#S_2 = \#S_3 = 1$. In the latter case $S_3 \subset S'_3 := \{\sigma_3 \in S_{\hat{h}} \mid \sigma_3(eh) = 1 + \varphi(eh) \,\&\, \sigma_3(fh) = 1 + \varphi(fh) \,\&\, \sigma_3(gh) = 1 + \varphi(gh)\}$. This means that a set hanging over $****$ cannot have nontrivial pure extensions.

Let us now construct a complete extension of a set B, where B hangs over $****$. Let φ denote the function associated to $B = \{\Psi^e_\sigma, \Psi^f_{\sigma_1}, \Psi^g_{\sigma_2}, \Psi^h_{\sigma_3}\} \in \mathcal{P}_\perp(A)$ as described above, and let a, b, c, p, q, and r be its values on the edges ef, eg, fg, eh, fh, and gh, respectively. Looking for an extension which hangs over $\circledast\circledast\circledast\circledast$, we need to construct projective lines of the form Φ^e_ρ, $\Phi^f_{\rho_1}$, $\Phi^g_{\rho_2}$, and $\Phi^h_{\rho_3}$. Define ρ, ρ_1, ρ_2, and ρ_3 by the formulas $\rho^*(ef) = a + b + c + p + q$, $\rho^*(eg) = 1 + a + b + c + p + r$, $\rho^*(eh) = a + b + p + q + r$; $\rho^*_1(ef) = 1 + a + b + c + p + q$, $\rho^*_1(fg) = a + b + c + q + r$, $\rho^*_1(fh) = 1 + a + c + p + q + r$; $\rho^*_2(eg) = a + b + c + p + r$, $\rho^*_2(fg) = 1 + a + b + c + q + r$, $\rho^*_2(gh) = b + c + p + q + r$; $\rho^*_3(eh) = 1 + a + b + p + q + r$, $\rho^*_3(fh) = a + c + p + q + r$, $\rho^*_3(gh) = 1 + b + c + p + q + r$. Straightforward computation establishes that $B' := B \cup \{\Phi^e_\rho, \Phi^f_{\rho_1}, \Phi^g_{\rho_2}, \Phi^h_{\rho_3}\}$ is a complete extension of B.

(7) It is necessary to show that five projective lines of the form Ψ^e_σ, $\Psi^f_{\sigma_1}$, $\Psi^g_{\sigma_2}$, $\Psi^h_{\sigma_3}$, and F_π cannot be pairwise *orthogonal*. Recall that we already know that they cannot be pairwise *nonorthogonal*. The conditions of orthogonality between the projective lines of Ψ type yield a system of

equations, $\sigma(ef)+\sigma_1(ef)=1$, $\sigma(eg)+\sigma_2(eg)=1$, $\sigma(eh)+\sigma_3(eh)=1$, $\sigma_1(fg)+\sigma_2(fg)=1$, $\sigma_1(fh)+\sigma_3(fh)=1$, and $\sigma_2(gh)+\sigma_3(gh)=1$. By summation, one obtains $\nabla_\sigma+\nabla_{\sigma_1}+\nabla_{\sigma_2}+\nabla_{\sigma_3}=0$. On the other hand, the orthogonality conditions with F_π yield the equations, $\pi(e)=1+\nabla_\sigma$, $\pi(f)=1+\nabla_{\sigma_1}$, $\pi(g)=1+\nabla_{\sigma_2}$, and $\pi(h)=1+\nabla_{\sigma_3}$. Recalling that $\Sigma_{v\in V}\pi(v)=1$, and summing the foregoing equations yields $1=\nabla_\sigma+\nabla_{\sigma_1}+\nabla_{\sigma_2}+\nabla_{\sigma_3}$. Hence, the requirement that all five projective lines are pairwise orthogonal leads to a contradiction $1=0$. □

Proposition 2: Let $B\in\mathcal{P}_\perp(A)$ be a set hanging over ∗∗∗∗.

(1) *For every $v\in V$ there exists a unique projective line of Φ^v-kind which is orthogonal to every projective line belonging to B.*

(2) *There exist no extensions of B which contain a projective line of X type or of F type.*

(3) *The complete extension of B is unique and hangs over ⊛⊛⊛⊛.*

Proof: (1) It is sufficient to consider $v=e$. If Ψ^e_σ, $\Psi^f_{\sigma_1}$, $\Psi^g_{\sigma_2}$, and $\Psi^h_{\sigma_3}$ are four pairwise orthogonal projective lines, then the requirement that Φ^e_ρ is orthogonal to each of them yields four equations, $\nabla_{\rho^*}=1+\nabla_\sigma$, $\nabla_{\rho^*}+\rho^*(ef)=1+\nabla_{\sigma_1}+\sigma_1(ef)$, $\nabla_{\rho^*}+\rho^*(eg)=1+\nabla_{\sigma_2}+\sigma_2(eg)$, and $\nabla_{\rho^*}+\rho^*(eh)=1+\nabla_{\sigma_3}+\sigma_3(eh)$. Expressing ∇_{ρ^*} from the first equation and substituting it into the other three, one finds the expressions for the values of ρ^* via σ, σ_1, σ_2, and σ_3.

(2) The fact that B cannot have an extension containing a projective line of F type follows from the nonadmissibility of the graph $\ast\ast\ast\ast F$. Let us show that the graph $\ast$—$\ast$ is nonadmissible. This will imply that an extension of B cannot contain an element of X type. Consider three projective lines of the form Ψ^e_σ, $\Psi^f_{\sigma_1}$, and $X^{ef}_\varkappa$, and impose the condition that they are pairwise orthogonal. This yields the equations, $\sigma(ef)=1+\sigma_1(ef)$, $\sigma(ef)=1+\varkappa(ef)$, and $\sigma_1(ef)=1+\varkappa(ef)$. The sum of the second and the third equations yields $\sigma(ef)+\sigma_1(ef)=0$, contradicting the first equation. It means that the mentioned graph is not admissible.

(3) The existence of the extension of B hanging over ⊛⊛⊛⊛ has been proved in the previous proposition. Since an extension of B cannot contain elements of X or F type, it should hang over a graph which may contain only stars and circles. According to the previous proposition, a set hanging over a graph ∗∗∗∗ cannot have nontrivial pure extensions. It follows, that a complete extension of B contains projective lines of the form Φ^v_ρ. Every such projective line is uniquely defined according to (1). It follows that a complete extension of B hangs over ⊛⊛⊛⊛ and is unique. □

VII. GROUP OF SYMMETRY

We have given an *explicit* description of every element of the finite set A and by that we have an opportunity to *construct* the maps φ: $A\to A$ by simply saying for each $l\in A$ which $l'\in A$ corresponds to it under φ. One would like to have a similar opportunity for the set $\mathcal{P}_\perp(A)$, i.e., one needs to *characterize* the elements of $\mathcal{P}_\perp(A)$. In particular, for the set of all complete sets $C(A)\subset\mathcal{P}_\perp(A)$ it would be nice to have some group transitively acting on $C(A)$, so that having found just one complete set, one could automatically generate all the others.

Recall that there is a map η: $A\to\mathcal{P}(V)$, where V is a set of four symbols $V=\{e,f,g,h\}$. We shall describe a group G which acts on the set $L=\mathcal{P}(\mathcal{P}(V))$ and then describe a group $\mathcal{G}$ which acts on $\mathcal{P}_\perp(A)$.

We start with the definition of the group G. Consider the group $Bij(\mathcal{P}(V))$ of all bijections of the power set of V. One has $\#V=4$, $\#\mathcal{P}(V)=16$, $\#Bij(\mathcal{P}(V))=16!$. Associate to each $S\in\mathcal{P}(V)$ a map T_S: $\mathcal{P}(V)\to\mathcal{P}(V)$ defined by the formula

$$T_S(U) := \begin{cases} U, & \text{if } \#(S\cap U) \text{ is even},\\ \overline{U\Delta S}, & \text{if } \#(S\cap U) \text{ is odd}, \end{cases} \tag{3}$$

where U varies over $\mathcal{P}(V)$, the bar denotes the completion of a set in V and Δ denotes the symmetric difference of two subsets. For any S one has $T_S^2=id$. In particular, T_S is a bijection, $T_S\in Bij(\mathcal{P}(V))$. Define G to be a subgroup in $Bij(\mathcal{P}(V))$ generated by reflections T_S, $S\in\mathcal{P}(V)$:

$$G := \langle\{T_S | S\in\mathcal{P}(V)\}\rangle\subset Bij(\mathcal{P}(V)).$$

Note, that $T_{\varnothing}=T_{efgh}=id$. Note for any S, that $T_S(\varnothing)=\varnothing$.

For a given $S\in\mathcal{P}(V)$, write $U_1\leftrightarrow U_2$ to express that $T_S(U_1)=U_2\&T_S(U_2)=U_1$, and $U=inv$ to express $T_S(U)=U$. Then, for example, $T_{\hat{e}}$, T_{ef}, and $T_{\overline{e}}$ are explicitly described as follows. $T_{\hat{e}}$ corresponds to

$$\hat{e}\leftrightarrow efgh,\quad \overline{f}\leftrightarrow ef,\quad \overline{g}\leftrightarrow eg,\quad \overline{h}\leftrightarrow eh,$$

$$\varnothing,\overline{e},\hat{f},\hat{g},\hat{h},fg,fh,gh=inv;$$

T_{ef} corresponds to

$$e\leftrightarrow\overline{f},\quad f\leftrightarrow\overline{e},\quad eg\leftrightarrow eh,\quad fg\leftrightarrow fh,$$

$$\varnothing,g,h,\overline{g},\overline{h},ef,gh,efgh=inv;$$

and $T_{\overline{e}}$ corresponds to

$$\overline{e}\leftrightarrow efgh,\quad \hat{f}\leftrightarrow ef,\quad \hat{g}\leftrightarrow eg,\quad \hat{h}\leftrightarrow eh,$$

$$\varnothing,\hat{e},\overline{f},\overline{g},\overline{h},fg,fh,gh=inv.$$

Explicit descriptions of the other $T_{\hat{v}}$, T_{vw}, and $T_{\overline{v}}$ are obtatined via permutations of symbols e, f, g, and h. Note that for every $S\in\mathcal{P}(V)$,

$$T_{m(\beta)(S)}=m(\beta)T_S m(\beta^{-1}),\quad \beta\in Bij(V),$$

where m is the natural monomorphism of groups, m: $Bij(V)\rightarrowtail Bij(\mathcal{P}(V))$, $\beta\mapsto\mathcal{P}(\beta)$.

Recall that there also exists a natural monomorphism μ: $Bij(V)\rightarrowtail Bij(A)$ described in the previous section.

Every element $g\in G$ is a map $g:\mathcal{P}(V)\tilde{\to}\mathcal{P}(V)$. It induces a map $\mathcal{P}(g):L\tilde{\to}L$, $L=\mathcal{P}(\mathcal{P}(V))$. It means that there is a natural action of G on L. Recall that we have a map $\eta:A\to\mathcal{P}(V)$. It turns out that the maps T_S, $S\in\mathcal{P}(V)$, can be lifted up to maps $\theta_S:A\tilde{\to}A$ in such a way that the subgroup of $Bij(A)$ generated by $\{\theta_S\}_S$ has a natural action on the set $\mathcal{P}_{\perp}(A)$.

Proposition 3: For every $S\in\mathcal{P}(V)$ there exists a map $\theta_S:A\to A$ such that

(1) $\forall l,l'\in A: l\perp l'\Rightarrow\theta_S(l)\perp\theta_S(l')$;

(2) *The map θ_S renders the following diagram commutative:*

$$\begin{array}{ccc} A & \xrightarrow{\theta_S} & A \\ {\scriptstyle\eta}\downarrow & & \downarrow{\scriptstyle\eta} \\ \mathcal{P}(V) & \xrightarrow[T_S]{} & \mathcal{P}(V) \end{array} \tag{4}$$

(3) $\theta_S^2=id$.

Proof: If $S=\varnothing$ or $S=V$, then the corresponding $T_S=id$ and one may take $\theta_S=id$. It means that essentially one must to consider the cases of nonempty proper subsets $S\subset V$. We describe explicit formulas for $\theta_{\hat{e}}$, θ_{ef}, and $\theta_{\overline{e}}$. The other maps are defined by permutations of e, f, g, and h.

We start with $\theta_{\hat{e}}$. Invoking the explicit description for $T_{\hat{e}}$ given above, one has, for example, $\hat{e}\leftrightarrow efgh$. Thus, a projective line of the form Ψ^e_{σ}, $\sigma\in S_{\hat{e}}$, should map under the action of $\theta_{\hat{e}}$ to a projective line of the form $F_{\pi'}$, where π' is some element of Λ. Denote this by $\Psi^e_{\sigma}\overset{\theta_{\hat{e}}}{\rightsquigarrow}F_{\pi'}$. A complete description of $\theta_{\hat{e}}$ consists in the description of its actions on the elements of the form

$$\Psi^e_{\sigma},\quad \Psi^f_{\sigma_1},\quad \Psi^g_{\sigma_2},\quad \Psi^h_{\sigma_3},$$

$$\Phi^e_\rho, \quad \Phi^f_{\rho_1}, \quad \Phi^g_{\rho_2}, \quad \Phi^h_{\rho_3},$$

$$X^{ef}_\varkappa, \quad X^{eg}_{\varkappa_1}, \quad X^{eh}_{\varkappa_2}, \quad X^{fg}_{\varkappa_3}, \quad X^{fh}_{\varkappa_4}, \quad X^{gh}_{\varkappa_5}, \quad F_\pi.$$

Define $\theta_{\hat{e}}$ as follows:

$$\Psi^e_\sigma \overset{\theta_{\hat{e}}}{\rightsquigarrow} F_{\pi'}: \qquad F_\pi \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Psi^e_{\sigma'}:$$
$$\pi'(e) := 1 + \nabla_\sigma, \quad \sigma'(ef) := \pi(f),$$
$$\pi'(f) := \sigma(ef), \quad \sigma'(eg) := \pi(g),$$
$$\pi'(g) := \sigma(eg), \quad \sigma'(eh) := \pi(h).$$
$$\pi'(h) := \sigma(eh).$$

$$\Phi^f_{\rho_1} \overset{\theta_{\hat{e}}}{\rightsquigarrow} X^{ef}_{\varkappa'}: \qquad X^{ef}_\varkappa \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Phi^f_{\rho_1'}:$$
$$\varkappa'(ef) := \nabla_{\rho_1^*}, \qquad \rho_1'^*(ef) := \varkappa(ef) + \varkappa(g) + \varkappa(h),$$
$$\varkappa'(g) := \rho_1^*(ef) + \rho_1^*(fg), \qquad \rho_1'^*(fg) := \varkappa(ef) + \varkappa(h),$$
$$\varkappa'(h) := \rho_1^*(ef) + \rho_1^*(fh). \qquad \rho_1'^*(fh) := \varkappa(ef) + \varkappa(g).$$

$$\Phi^g_{\rho_2} \overset{\theta_{\hat{e}}}{\rightsquigarrow} X^{eg}_{\varkappa_1'}: \qquad X^{eg}_{\varkappa_1} \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Phi^g_{\rho_2'}:$$
$$\varkappa_1'(eg) := \nabla_{\rho_2^*}, \qquad \rho_2'^*(eg) := \varkappa_1(eg) + \varkappa_1(f) + \varkappa_1(h),$$
$$\varkappa_1'(f) := \rho_2^*(eg) + \rho_2^*(fg), \qquad \rho_2'^*(fg) := \varkappa_1(eg) + \varkappa_1(h),$$
$$\varkappa_1'(h) := \rho_2^*(eg) + \rho_2^*(gh). \qquad \rho_2'^*(gh) := \varkappa_1(eg) + \varkappa_1(f).$$

$$\Phi^h_{\rho_3} \overset{\theta_{\hat{e}}}{\rightsquigarrow} X^{eh}_{\varkappa_2'}: \qquad X^{eh}_{\varkappa_2} \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Phi^h_{\rho_3'}:$$
$$\varkappa_2'(eh) := \nabla_{\rho_3^*}, \qquad \rho_3'^*(eh) := \varkappa_2(eh) + \varkappa_2(f) + \varkappa_2(g),$$
$$\varkappa_2'(f) := \rho_3^*(eh) + \rho_3^*(fh), \qquad \rho_3'^*(fh) := \varkappa_2(eh) + \varkappa_2(g),$$
$$\varkappa_2'(g) := \rho_3^*(eh) + \rho_3^*(gh). \qquad \rho_3'^*(gh) := \varkappa_2(eh) + \varkappa_2(f).$$

$$\Psi^f_{\sigma_1} \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Psi^f_{\sigma_1'}: \qquad X^{gh}_{\varkappa_5} \overset{\theta_{\hat{e}}}{\rightsquigarrow} X^{gh}_{\varkappa_5'}:$$
$$\sigma_1'(ef) := \nabla_{\sigma_1}, \qquad \varkappa_5'(gh) := \varkappa_5(gh),$$
$$\sigma_1'(fg) := \sigma_1(fg), \qquad \varkappa_5'(e) := \varkappa_5(e),$$
$$\sigma_1'(fh) := \sigma_1(fh). \qquad \varkappa_5'(f) := 1 + \varkappa_5(e) + \varkappa_5(f).$$

$$\Psi^g_{\sigma_2} \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Psi^g_{\sigma_2'}: \qquad X^{fh}_{\varkappa_4} \overset{\theta_{\hat{e}}}{\rightsquigarrow} X^{fh}_{\varkappa_4'}:$$
$$\sigma_2'(eg) := \nabla_{\sigma_2}, \qquad \varkappa_4'(fh) := \varkappa_4(fh),$$
$$\sigma_2'(fg) := \sigma_2(fg), \qquad \varkappa_4'(e) := \varkappa_4(e),$$
$$\sigma_2'(gh) := \sigma_2(gh). \qquad \varkappa_4'(g) := 1 + \varkappa_4(e) + \varkappa_4(g).$$

$$\Psi^{h}_{\sigma_3} \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Psi^{h}_{\sigma'_3}: \qquad X^{fg}_{\varkappa_3} \overset{\theta_{\hat{e}}}{\rightsquigarrow} X^{fg}_{\varkappa'_3}:$$

$$\sigma'_3(eh) := \nabla_{\sigma_3}, \qquad \sigma'_3(fg) := \varkappa_3(fg),$$

$$\sigma'_3(fh) := \sigma_3(fh), \qquad \varkappa'_3(e) := \varkappa_3(e),$$

$$\sigma'_3(gh) := \sigma_3(gh). \qquad \varkappa'_3(h) := 1 + \varkappa_3(e) + \varkappa_3(h).$$

$$\Phi^{e}_{\rho} \overset{\theta_{\hat{e}}}{\rightsquigarrow} \Phi^{e}_{\rho'}:$$

$$\rho'^{*}(ef) := 1 + \rho^{*}(ef),$$

$$\rho'^{*}(eg) := 1 + \rho^{*}(eg),$$

$$\rho'^{*}(eh) := 1 + \rho^{*}(eh).$$

Note, that the formulas defining $\theta_{\hat{e}}$ have a symmetry with respect to the permutations of symbols f, g, h. It is a straightforward calculation to show that $\theta_{\hat{e}}$ respects the orthogonality relation $\perp$ on A. The commutativity of the mentioned diagram follows directly from the construction of $\theta_{\hat{e}}$. The verification that $\theta_{\hat{e}}$ is indeed a reflection is also straightforward.

Now define θ_{ef},

$$\Psi^{e}_{\sigma} \overset{\theta_{ef}}{\rightsquigarrow} \Phi^{f}_{\rho'_1}: \qquad \Phi^{f}_{\rho_1} \overset{\theta_{ef}}{\rightsquigarrow} \Psi^{e}_{\sigma'}:$$

$$\rho'^{*}_1(ef) := \sigma(ef), \qquad \sigma'(ef) := \rho^{*}_1(ef),$$

$$\rho'^{*}_1(fg) := \sigma(ef) + \sigma(eh), \qquad \sigma'(eg) := \rho^{*}_1(ef) + \rho^{*}_1(fh),$$

$$\rho'^{*}_1(fh) := \sigma(ef) + \sigma(eg). \qquad \sigma'(eh) := \rho^{*}_1(ef) + \rho^{*}_1(fg).$$

$$\Psi^{f}_{\sigma_1} \overset{\theta_{ef}}{\rightsquigarrow} \Phi^{e}_{\rho'}: \qquad \Phi^{e}_{\rho} \overset{\theta_{ef}}{\rightsquigarrow} \Psi^{f}_{\sigma'_1}:$$

$$\rho'^{*}(ef) := \sigma_1(ef), \qquad \sigma'_1(ef) := \rho^{*}(ef),$$

$$\rho'^{*}(eg) := \sigma_1(ef) + \sigma_1(fh), \qquad \sigma'_1(fg) := \rho^{*}(ef) + \rho^{*}(eh),$$

$$\rho'^{*}(eh) := \sigma_1(ef) + \sigma_1(fg). \qquad \sigma'_1(fh) := \rho^{*}(ef) + \rho^{*}(eg).$$

$$X^{eg}_{\varkappa_1} \overset{\theta_{ef}}{\rightsquigarrow} X^{eh}_{\varkappa'_2}: \qquad X^{eh}_{\varkappa_2} \overset{\theta_{ef}}{\rightsquigarrow} X^{eg}_{\varkappa'_1}:$$

$$\varkappa'_2(eh) := \varkappa_1(f), \qquad \varkappa'_1(eg) := \varkappa_2(f),$$

$$\varkappa'_2(f) := \varkappa_1(eg), \qquad \varkappa'_1(f) := \varkappa_2(eh),$$

$$\varkappa'_2(g) := 1 + \varkappa_1(eg) + \varkappa_1(f) + \varkappa_1(h). \qquad \varkappa'_1(h) := 1 + \varkappa_2(eh) + \varkappa_2(f) + \varkappa_2(g).$$

$$X^{fg}_{\varkappa_3} \overset{\theta_{ef}}{\rightsquigarrow} X^{fh}_{\varkappa'_4}: \qquad X^{fh}_{\varkappa_4} \overset{\theta_{ef}}{\rightsquigarrow} X^{fg}_{\varkappa'_3}:$$

$$\varkappa'_4(fh) := \varkappa_3(e), \qquad \varkappa'_3(fg) := \varkappa_4(e),$$

$$\varkappa'_4(e) := \varkappa_3(fg), \qquad \varkappa'_3(e) := \varkappa_4(fh),$$

$$\varkappa'_4(g) := 1 + \varkappa_3(fg) + \varkappa_3(e) + \varkappa_3(h). \qquad \varkappa'_3(h) := 1 + \varkappa_4(fh) + \varkappa_4(e) + \varkappa_4(g).$$

$$\Psi^{g}_{\sigma_2} \overset{\theta_{ef}}{\rightsquigarrow} \Psi^{g}_{\sigma_2'}: \qquad \Phi^{g}_{\rho_2} \overset{\theta_{ef}}{\rightsquigarrow} \Phi^{g}_{\rho_2'}:$$

$$\sigma_2'(eg) := \sigma_2(eg) + \sigma_2'(gh), \quad \rho_2'^{*}(eg) := \rho_2^{*}(eg) + \rho_2^{*}(gh),$$
$$\sigma_2'(fg) := \sigma_2'(fg) + \sigma_2'(gh), \quad \rho_2'^{*}(fg) := \rho_2^{*}(fg) + \rho_2^{*}(gh),$$
$$\sigma_2'(gh) := \sigma_2'(gh). \qquad \rho_2'^{*}(gh) := \rho_2^{*}(gh).$$

$$\Psi^{h}_{\sigma_3} \overset{\theta_{ef}}{\rightsquigarrow} \Psi^{h}_{\sigma_3'}: \qquad \Phi^{h}_{\rho_3} \overset{\theta_{ef}}{\rightsquigarrow} \Phi^{h}_{\rho_3'}:$$

$$\sigma_3'(eh) := \sigma_3(eh) + \sigma_3(gh), \quad \rho_3'^{*}(eh) := \rho_3^{*}(eh) + \rho_3^{*}(gh),$$
$$\sigma_3'(fh) := \sigma_3(fh) + \sigma_3(gh), \quad \rho_3'^{*}(fh) := \rho_3^{*}(fh) + \rho_3^{*}(gh),$$
$$\sigma_3'(gh) := \sigma_3(gh). \qquad \rho_3'^{*}(gh) := \rho_3^{*}(gh).$$

$$X^{ef}_{\varkappa} \overset{\theta_{ef}}{\rightsquigarrow} X^{ef}_{\varkappa'}: \qquad X^{gh}_{\varkappa_5} \overset{\theta_{ef}}{\rightsquigarrow} X^{gh}_{\varkappa_5'}:$$

$$\varkappa'(ef) := 1 + \varkappa(ef) + \varkappa(g) + \varkappa(h), \quad \varkappa_5'(gh) := \varkappa_5(gh),$$
$$\varkappa'(g) := \varkappa(g), \qquad \varkappa_5'(e) := \varkappa_5(e),$$
$$\varkappa'(h) := \varkappa(h). \qquad \varkappa_5'(f) := \varkappa_5(f).$$

$$F_{\pi} \overset{\theta_{ef}}{\rightsquigarrow} F_{\pi'}:$$

$$\pi'(e) := \pi(f), \quad \pi'(f) := \pi(e),$$
$$\pi'(g) := \pi(g), \quad \pi'(h) := \pi(h).$$

The verification that θ_{ef} satisfies all the conditions of the proposition is straightforward just as in the case with $\theta_{\hat{e}}$. Note, that the formulas for θ_{ef} are invariant under the transposition of symbols e and f and under the transposition of symbols g and h.

Now define $\theta_{\overline{e}}$,

$$\Phi^{e}_{\rho} \overset{\theta_{\overline{e}}}{\rightsquigarrow} F_{\pi'}: \qquad F_{\pi} \overset{\theta_{\overline{e}}}{\rightsquigarrow} \Phi^{e}_{\rho'}:$$

$$\pi'(e) := 1 + \nabla_{\rho^*}, \quad \rho'^{*}(ef) := \pi(f),$$
$$\pi'(f) := \rho^{*}(ef), \quad \rho'^{*}(eg) := \pi(g),$$
$$\pi'(g) := \rho^{*}(eg), \quad \rho'^{*}(eh) := \pi(h).$$
$$\pi'(h) := \rho^{*}(eh).$$

$$\Psi^{f}_{\sigma_1} \overset{\theta_{\overline{e}}}{\rightsquigarrow} X^{ef}_{\varkappa'}: \qquad X^{ef}_{\varkappa} \overset{\theta_{\overline{e}}}{\rightsquigarrow} \Psi^{f}_{\sigma_1'}:$$

$$\varkappa'(ef) := 1 + \sigma_1(ef), \qquad \sigma_1'(ef) := 1 + \varkappa(ef),$$
$$\varkappa'(g) := \sigma_1(ef) + \sigma_1(fh), \quad \sigma_1'(fg) := 1 + \varkappa(ef) + \varkappa(h),$$
$$\varkappa'(h) := \sigma_1(ef) + \sigma_1(fg). \quad \sigma_1'(fh) := 1 + \varkappa(ef) + \varkappa(g).$$

$$\Psi^{g}_{\sigma_2} \overset{\theta_{\overline{e}}}{\rightsquigarrow} X^{eg}_{\varkappa_1'}: \qquad X^{eg}_{\varkappa_1} \overset{\theta_{\overline{e}}}{\rightsquigarrow} \Psi^{g}_{\sigma_2'}:$$

$$\varkappa_1'(eg) := 1 + \sigma_2(eg), \qquad \sigma_2'(eg) := 1 + \varkappa_1(eg),$$
$$\varkappa_1'(f) := \sigma_2'(eg) + \sigma_2(gh), \quad \sigma_2'(fg) := 1 + \varkappa_1(eg) + \varkappa_1(h),$$
$$\varkappa_1'(h) := \sigma_2(eg) + \sigma_2(fg). \quad \sigma_2'(gh) := 1 + \varkappa_1(eg) + \varkappa_1(f).$$

$$\Psi^{h}_{\sigma_3} \overset{\theta_{\bar{e}}}{\rightsquigarrow} X^{eh}_{\varkappa'_2}: \qquad X^{eh}_{\varkappa_2} \overset{\theta_{\bar{e}}}{\rightsquigarrow} \Psi^{h}_{\sigma'_3}:$$

$$\varkappa'_2(eh) := 1 + \sigma_3(eh), \qquad \sigma'_3(eh) := 1 + \varkappa_2(eh),$$
$$\varkappa'_2(f) := \sigma_3(eh) + \sigma_3(gh), \qquad \sigma'_3(fh) := 1 + \varkappa_2(eh) + \varkappa_2(g),$$
$$\varkappa'_2(g) := \sigma_3(eh) + \sigma_3(fh). \qquad \sigma'_3(gh) := 1 + \varkappa_2(eh) + \varkappa_2(f).$$

$$\Phi^{f}_{\rho_1} \overset{\theta_{\bar{e}}}{\rightsquigarrow} \Phi^{f}_{\rho'_1}: \qquad X^{gh}_{\varkappa_5} \overset{\theta_{\bar{e}}}{\rightsquigarrow} X^{gh}_{\varkappa'_5}:$$

$$\rho'^{*}_1(ef) := \nabla_{\rho^{*}_1}, \qquad \varkappa'_5(gh) := 1 + \varkappa_5(gh) + \varkappa_5(f),$$
$$\rho'^{*}_1(fg) := \rho^{*}_1(fg), \qquad \varkappa'_5(e) := 1 + \varkappa_5(e) + \varkappa_5(f),$$
$$\rho'^{*}_1(fh) := \rho^{*}_1(fh). \qquad \varkappa'_5(f) := \varkappa_5(f).$$

$$\Phi^{g}_{\rho_2} \overset{\theta_{\bar{e}}}{\rightsquigarrow} \Phi^{g}_{\rho'_2}: \qquad X^{fh}_{\varkappa_4} \overset{\theta_{\bar{e}}}{\rightsquigarrow} X^{fh}_{\varkappa'_4}:$$

$$\rho'^{*}_2(eg) := \nabla_{\rho^{*}_2}, \qquad \varkappa'_4(fh) := 1 + \varkappa_4(fh) + \varkappa_4(g),$$
$$\rho'^{*}_2(fg) := \rho^{*}_2(fg), \qquad \varkappa'_4(e) := 1 + \varkappa_4(e) + \varkappa_4(g),$$
$$\rho'^{*}_2(gh) := \rho^{*}_2(gh). \qquad \varkappa'_4(g) := \varkappa_4(g).$$

$$\Phi^{h}_{\rho_3} \overset{\theta_{\bar{e}}}{\rightsquigarrow} \Phi^{h}_{\rho'_3}: \qquad X^{fg}_{\varkappa_3} \overset{\theta_{\bar{e}}}{\rightsquigarrow} X^{fg}_{\varkappa'_3}:$$

$$\rho'^{*}_3(eh) := \nabla_{\rho^{*}_3}, \qquad \varkappa'_3(fg) := 1 + \varkappa_3(fg) + \varkappa_3(h),$$
$$\rho'^{*}_3(fh) := \rho^{*}_3(fh), \qquad \varkappa'_3(e) := 1 + \varkappa_3(e) + \varkappa_3(h),$$
$$\rho'^{*}_3(gh) := \rho^{*}_3(gh). \qquad \varkappa'_3(h) := \varkappa_3(h).$$

$$\Psi^{e}_{\sigma} \overset{\theta_{\bar{e}}}{\rightsquigarrow} \Psi^{e}_{\sigma'}:$$

$$\sigma'(ef) := 1 + \sigma(ef),$$
$$\sigma'(eg) := 1 + \sigma(eg),$$
$$\sigma'(eh) := 1 + \sigma(eh).$$

In order to obtain formulas for $\theta_{\bar{e}}$ one may take the formulas defining $\theta_{\hat{e}}$ and perform the replacements of the symbols $\sigma \leftrightarrow \rho^{*}$, $\varkappa \to \tilde{\varkappa}$, $\pi \equiv \pi$, and similar for $(\cdot)'$ symbols. The verification that $\theta_{\bar{e}}$ satisfies the three conditions of the proposition is again straightforward.

The other $\theta_{\hat{v}}$, θ_{vw}, and $\theta_{\bar{v}}$ $(v, w \in V, v \neq w)$ are defined from $\theta_{\hat{e}}$, θ_{ef}, and $\theta_{\bar{e}}$ via the permutations of symbols e, f, g, and h, i.e., in such a way that for every $S \in \mathcal{P}(V)$,

$$\theta_{m(\beta)(S)} = \mu(\beta)\theta_S\mu(\beta^{-1}), \quad \beta \in Bij(V),$$

where μ is the natural monomorphism, μ: $Bij(V) \rightarrowtail Bij(A)$. □

Denote by $Bij_{\perp}(A)$ the subgroup of $Bij(A)$ consisting of all bijections of A which respect the orthogonality relation $\perp$ on A. We have constructed a family of reflections $\theta_S \in Bij_{\perp}(A)$, $S \in \mathcal{P}(V)$. Denote by $\mathcal{G}$ the subgroup of $Bij_{\perp}(A)$ generated by these reflections,

$$\mathcal{G} := \langle \{\theta_S | S \in \mathcal{P}(V)\} \rangle \subset Bij_{\perp}(A).$$

Note that the correspondence $T_S \mapsto \theta_S$ *does not* define a homomorphism from G to $\mathcal{G}$, since, for example, the order of an element $T_{\bar{f}}T_{\hat{e}} \in G$ is 2, and the order of $\theta_{\bar{f}}\theta_{\hat{e}} \in G$ is 4.

Let us mention some properties of the groups G and $\mathcal{G}$. First of all, recall that we have natural monomorphisms, m: $Bij(V)\rightarrowtail Bij(\mathcal{P}(V))$, μ: $Bij(V)\rightarrowtail Bij(A)$. It turns out, that the images of these monomorfisms are in fact contained in G and $\mathcal{G}$, respectively, i.e., each of the two groups contains a copy of S_4. Denote by t_{ef} the bijection $V\tilde{\rightarrow}V$ which interchanges the symbols e and f, i.e., $t_{ef}: e\mapsto f, f\mapsto e, g\mapsto g, h\mapsto h$. Let us write (ef) instead of $m(t_{ef})$ and $(\tilde{ef})$ instead of $\mu(t_{ef})$. One defines in a similar way the transformations (vw) and $(v\tilde{w})$ for all $v,w\in V, v\neq w$.

Proposition 4: For all $v,w,z\in V$, $v\neq w$, $v\neq z$, $w\neq z$,

$$T_{vw}T_{uz}T_{uw}=(wz),$$

$$\theta_{vw}\theta_{vz}\theta_{vw}=(\tilde{w}z). \tag{5}$$

Proof: It is sufficient to verify that $T_{ef}T_{eg}T_{ef}=(fg)$ and that $\theta_{ef}\theta_{eg}\theta_{ef}=(\tilde{fg})$. The latter is established by a straightforward computation. □

Consider a product $D:=(ef)(gh)T_{ef}T_{gh}$. For every $U\in\mathcal{P}(V)$, $D(U)=\overline{U}$ if $\#U$ is odd, and $D(U)=U$ if $\#U$ is even. Hence the map D is obtained by

$$\hat{e}\leftrightarrow\overline{e},\quad \hat{f}\leftrightarrow\overline{f},\quad \hat{g}\leftrightarrow\overline{g},\quad \hat{g}\leftrightarrow\overline{h},$$

$$\varnothing,ef,eg,eh,fg,fh,gh,efgh=inv.$$

Note, that for any $\epsilon\in E$, $D=(\epsilon)(\overline{\epsilon})T_{\epsilon}T_{\overline{\epsilon}}$. Consider an analog of D in $\mathcal{G}$, the product $\delta:=(\tilde{ef})(\tilde{gh})\theta_{ef}\theta_{gh}$. Observe that δ is just the duality transformation mentioned in the section describing the orthogonality relation on A, $\delta(\Psi^{v}_{\sigma})=\Phi^{v}_{\sigma^*}$, $\delta(X^{\epsilon}_{\varkappa})=X^{\epsilon}_{\tilde{\varkappa}}$, $\delta(\Phi^{v}_{\rho})=\Psi^{v}_{\rho^*}$, and $\delta(F_{\pi})=F_{\pi}$ (notation σ^*, ρ^*, and $\tilde{\varkappa}$ as in that section). More generally, for any $\epsilon\in E$ one has $\delta=(\tilde{\epsilon})(\tilde{\overline{\epsilon}})\theta_{\epsilon}\theta_{\overline{\epsilon}}$. The transformations $D\in G$ and $\delta\in\mathcal{G}$ allow to obtain $T_{\overline{v}}$ and $\theta_{\overline{v}}$ $(v\in V)$ from $T_{\hat{v}}$ and $\theta_{\hat{v}}$ according to $T_{\overline{v}}=DT_{\hat{v}}D$ and $\theta_{\overline{v}}=\delta\theta_{\hat{v}}\delta$. Any transformation T_{ϵ} $(\epsilon\in E)$ commutes with D, $DT_{\epsilon}=T_{\epsilon}D$, and any transformation θ_{ϵ} $(\epsilon\in E)$ commutes with δ, $\delta\theta_{\epsilon}=\theta_{\epsilon}\delta$.

Note that $(ev)T_{\hat{e}}(ev)=T_{\hat{v}}$, $v\in V$, $v\neq e$. Since every transformation of the form (vw) and the transformation D belong to a subgroup G_2 of G generated by $\{T_{\epsilon}\}_{\epsilon\in E}$, any set generating G_2 appended with an element $T_{\hat{e}}$, generates the whole group G. Similarly, if one denotes by $\mathcal{G}_2$ the subgroup of $\mathcal{G}$ generated by $\{\theta_{\epsilon}\}_{\epsilon\in E}$, then any set of generators of $\mathcal{G}_2$ appended with an element $\theta_{\hat{e}}$ generates the whole group $\mathcal{G}$.

The groups G_2 and $\mathcal{G}_2$ should be investigated in more detail. We start with the group G_2. It is convenient to consider $W_{vw}:=(vw)T_{vw}$ $(v,w\in V, v\neq w)$. Denote by G_2' the subgroup of G_2 generated by (vw)'s, and by G_2'' a subgroup of G_2 generated by W_{vw}'s. Together G_2' and G_2'' generate the whole G. The explicit description of W_{ef} is

$$\hat{e}\leftrightarrow\overline{e},\quad \hat{f}\leftrightarrow\overline{f},\quad eg\leftrightarrow fh,\quad eh\leftrightarrow fg,$$

$$\varnothing,\hat{g},\hat{h},\overline{g},\overline{h},ef,gh,efgh=inv.$$

and the explicit descriptions of the other W_{vw} are similar. One verifies that $W_{ef}W_{fg}=W_{eg}$. More generally, for any v, w, $z\in V$, $v\neq w$, $v\neq z$, $w\neq z$,

$$W_{vw}W_{wz}=W_{vz}.$$

It follows, that G_2'' consists of all elements of the form W_{ϵ}, $\epsilon\in E$, an element $D=W_{ef}W_{gh}$ and a unit element of G. Since every element $b\in G_2'$ preserves the cardinality [i.e., $\#b(U)=\#U$, $U\in\mathcal{P}(V)$], and no element $w\in G_2''$ except the unit preseves the cardinality, it follows that the intersection of G_2' and G_2'' is trivial. Moreover, the group G_2'' is normal in G_2 since $(ef)W_{ef}(ef)=W_{ef}$, $(eg)W_{ef}(eg)=W_{fg}$, and $(gh)W_{ef}(gh)=W_{ef}$, and there exists a natural action of G_2' on G_2'' defined as follows. From the explicit description of W_{vw} one observes that G_2'' is isomorphic to a group Λ_0 of

$\mathbb{Z}_2$-valued functions ϕ on V satisfying a condition $\Sigma_{v\in V}\phi(v)=0$, i.e., it is a sample of $(\mathbb{Z}_2)^3$. An element $\beta\in Bij(V)$ acts on Λ_0 by the formula $\phi\mapsto\phi\circ\beta^{-1}$. This induces an action of $G_2'\simeq Bij(V)$ on $G_2''\simeq\Lambda_0$. Since $Bij(V)\simeq S_4$ and $\Lambda_0\simeq(\mathbb{Z}_2)^3$, it follows that one may view the group G_2 as a semidirect product $(\mathbb{Z}_2)^3\rtimes S_4$.

The considerations about the group $\mathcal{G}_2$ are similar to the considerations about G_2. In particular, the elements $\omega_{vw}:=(v\tilde{w})\theta_{vw}$ have the properties similar to the properties of W_{vw}. As a result, one gets that $\mathcal{G}_2\simeq(\mathbb{Z}_2)^3\rtimes S_4$ as well.

G is a group generated by the following five elements: (ef), (fg), (gh), $T_{\hat{e}}$, and W_{ef}. The corresponding Coxeter matrix is defined by

$$\mathrm{ord}((ef)T_{\hat{e}})=3,\quad \mathrm{ord}((fg)T_{\hat{e}})=2,\quad \mathrm{ord}((gh)T_{\hat{e}})=2,$$

$$\mathrm{ord}((ef)W_{ef})=2,\quad \mathrm{ord}((fg)W_{ef})=4,\quad \mathrm{ord}((gh)W_{ef})=2,$$

$$\mathrm{ord}((ef)(fg))=3,\quad \mathrm{ord}((ef)(gh))=2,\quad \mathrm{ord}((fg)(gh))=3,$$

$$\mathrm{ord}(W_{ef}T_{\hat{e}})=3,$$

where $\mathrm{ord}(\cdot)$ denotes the order of a group element. One verifies that the Coxeter matrix associated to the original set of generators $\{T_S\}_S$, $S\in\mathcal{P}(V)$, is defined by the formula

$$\mathrm{ord}(T_{S_2}T_{S_1})=\begin{cases}2, & \text{if } \#(S_1\setminus S_2) \text{ is even and } \#(S_2\setminus S_1) \text{ is even},\\ 3, & \text{if } \#(S_1\setminus S_2) \text{ is odd and } \#(S_2\setminus S_1) \text{ is odd},\\ 4, & \text{otherwise}.\end{cases}$$

Note, that the group G contains other reflections besides the ones already mentioned. In particular, there exist reflections which interchange $ef\leftrightarrow efgh$, for example, $T_{\hat{f}}W_{ef}T_{\hat{e}}W_{ef}$. At least some of the reflections can be generated starting from $\{T_S\}_S$ by using the following facts: whenever R_1 and R_2 are two reflections, $R_2R_1R_2$ is again a reflection; if R_1 and R_2 commute, then their product R_2R_1 is again a reflection.

Note that there is another way of expressing (vw) and D in G. Verify that additioned to (5) there is also a formula $T_{\hat{e}}T_{\hat{f}}T_{\hat{e}}=(ef)$ and $T_{\hat{e}}T_{\bar{e}}T_{\hat{e}}=D$. After replacing the left-hand and right-hand sides of these equalities by their analoges in $\mathcal{G}$, one observes, that $\theta_{\hat{e}}\theta_{\bar{e}}\theta_{\hat{e}}=\delta$, but $\theta_{\hat{e}}\theta_{\hat{f}}\theta_{\hat{e}}\neq(\widetilde{ef})$. What is the deviation of the value of $(\widetilde{ef})\theta_{\hat{e}}\theta_{\hat{f}}\theta_{\hat{e}}$ from identity? We need more notation to express that. Consider an Abelian group $\mathcal{F}$ of all $\mathbb{Z}_2$-valued functions on the set of all edges $E=\{\epsilon\subset V|\,\#\epsilon=2\}$. We shall associate to every $\varphi\in\mathcal{F}$ a transformation $I_\varphi\in Bij(A)$ and then show that in fact I_φ falls into the group $\mathcal{G}$. The product $(v\tilde{w})\theta_{\hat{v}}\theta_{\hat{w}}\theta_{\hat{v}}$ will be equal to I_φ where φ is some element of $\mathcal{F}$.

Take any $\varphi\in\mathcal{F}$. Denote $a:=\varphi(ef)$, $b:=\varphi(eg)$, $c:=\varphi(fg)$, $p:=\varphi(eh)$, $q:=\varphi(fh)$, $r:=\varphi(gh)$. The transformation I_φ will not change the kind of a projective line and we will describe its action on Ψ^e_σ, $X^{ef}_\varkappa$, Φ^e_ρ, and F_π. The other cases are obtained by permutation of the symbols e, f, g, h. A projective line Ψ^e_σ is mapped by I_φ to $\Psi^e_{\sigma'}$ with $\sigma'(ef)=\sigma(ef)+a$, $\sigma'(eg)=\sigma(eg)+b$, $\sigma'(eh)=\sigma(eh)+p$. A projective line $X^\epsilon_\varkappa$ maps to $X^\epsilon_{\varkappa'}$ with $\varkappa'(ef)=\varkappa(ef)+a$, $\varkappa'(g)=\varkappa(g)+p+q$, $\varkappa'(h)=\varkappa(h)+b+c$. A projective line Φ^e_ρ maps to $\Phi^e_{\rho'}$ with $\rho'(\cdot)$ defined by $\rho'^*(ef)=\rho^*(ef)+b+c+p+q+r$, $\rho'^*(eg)=\rho^*(eg)+a+c+p+q+r$, $\rho'^*(eh)=\rho^*(eh)+a+b+c+q+r$. Finally, the projective line F_π is mapped by I_φ to $F_{\pi'}$, where $\pi'(\cdot)$ is defined as $\pi'(e)=\pi(e)+a+b+p$, $\pi'(f)=\pi(f)+a+c+q$, $\pi'(g)=\pi(g)+b+c+r$, $\pi'(h)=\pi(h)+p+q+r$. Note, that since $\Sigma_{v\in V}\pi(v)=1$, one gets $\Sigma_{v\in V}\pi'(v)=1$. The difference $\pi'-\pi$ satisfies $\Sigma_{v\in V}(\pi'-\pi)(v)=0$.

We have defined a collection $\{I_\varphi\}_{\varphi\in\mathcal{F}}$ of maps $A\to A$, such that $I_\varphi^2=id$. This implies, in particular, that I_φ is a bijection, and one may consider the subgroup in $Bij(A)$ generated by

$\{I_\varphi\}_{\varphi\in\mathcal{F}}$. Since for every $\varphi_1, \varphi_2 \in \mathcal{F}$ we have $I_{\varphi_1} I_{\varphi_2} = I_{\varphi_1+\varphi_2}$, this subgroup is Abelian. Denote by χ_ϵ ($\epsilon \in E$) the element of $\mathcal{F}$ which has a value 1 on the edge ϵ and a value 0 on all other edges. Straightforward computation establishes that

$$(v\tilde{w})\,\theta_{\hat{v}}\theta_{\hat{w}}\theta_{\hat{v}} = I_{\chi_{vw}} \tag{6}$$

(for every $v, w \in V$, $v \neq w$). Since every map I_φ, $\varphi \in \mathcal{F}$, may be represented as a composition of maps of the form I_{χ_ϵ}, $\epsilon \in E$, it follows from (6) that every map I_φ is in $\mathcal{G}$. It follows that the set $\{I_\varphi\}_{\varphi\in\mathcal{F}}$ generates some Abelian subgroup $\mathcal{N}$ in $\mathcal{G}$.

Proposition 5: The group $\mathcal{N}$ generated by $\{I_\varphi\}_{\varphi\in\mathcal{F}}$ is a normal subgroup of $\mathcal{G}$.

Proof: We define for $S \in \mathcal{P}(V)$ a morphism τ_S, $\mathcal{F}\to\mathcal{F}$, such that $\forall\varphi\in\mathcal{F}$: $\theta_S I_\varphi = I_{\tau_S(\varphi)}\theta_S$. Since $\theta_\varnothing = \theta_V = id$, set $\tau_\varnothing := id$ and $\tau_V := id$. The set of formulas for the other cases of S will have a symmetry with respect to the permutations of e, f, g, and h, and in fact the nontrivial part of the proof will consist in providing the definitions of $\tau_{\hat{e}}$, τ_{ef}, and $\tau_{\bar{e}}$.

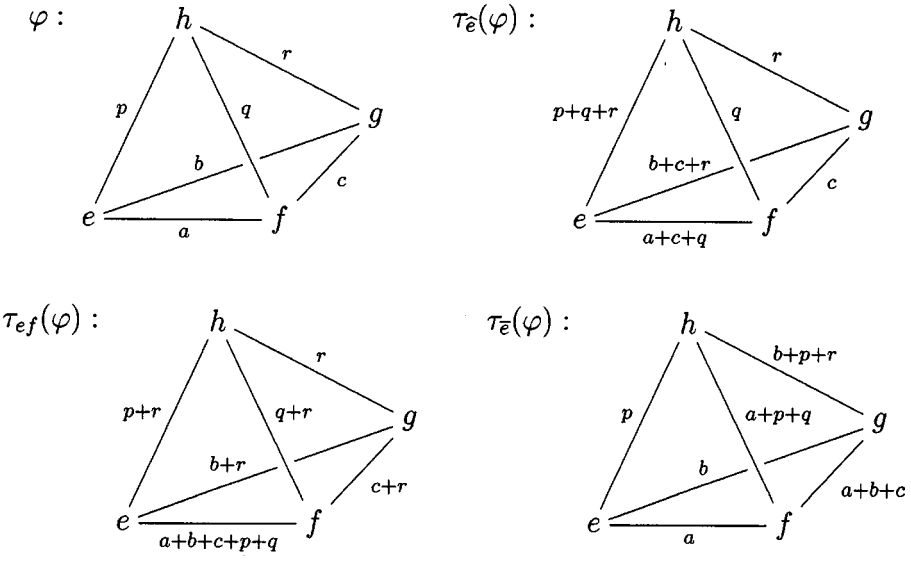
There exists a natural monomorphism ν: $Bij(V) \rightarrowtail End(\mathcal{F})$ defined as follows: for every $\beta \in Bij(V)$ the morphism $\nu(\beta)$: $\mathcal{F}\to\mathcal{F}$ is defined by $\varphi \mapsto \varphi'$, $\varphi'(\epsilon) := \varphi(m(\beta^{-1})(\epsilon))$ for all $\epsilon \in E$, where m is the natural monomorphism $Bij(V) \rightarrowtail Bij(\mathcal{P}(V))$. Recall that there also exists a natural monomorphism μ: $Bij(V) \rightarrowtail Bij(A)$.

The I_φ are defined in such a way, that $\forall\beta \in Bij(V): \mu(\beta) I_\varphi \mu(\beta^{-1}) = I_{\nu(\beta)(\varphi)}$. Recall that for every $\beta \in Bij(V)$ and every $S \in \mathcal{P}(V)$, $\mu(\beta)\theta_S\mu(\beta^{-1}) = \theta_{m(\beta)(S)}$. Hence,

$$\begin{aligned} I_{\tau_{m(\beta)(S)}(\varphi)} &= \theta_{m(\beta)(S)} I_\varphi \theta^{-1}_{m(\beta)(S)} = \mu(\beta)\theta_S\mu(\beta^{-1}) I_\varphi [\mu(\beta)\theta_S\mu(\beta^{-1})]^{-1} = \mu(\beta)\theta_S I_{\nu(\beta^{-1})(\varphi)}\theta_S^{-1}\mu(\beta^{-1}) \\ &= \mu(\beta) I_{(\tau_S\nu(\beta^{-1}))(\varphi)}\mu(\beta^{-1}) = I_{(\nu(\beta)\tau_S\nu(\beta^{-1}))(\varphi)}, \end{aligned}$$

where $\varphi \in \mathcal{F}$. It follows, that the collection $\{\tau_S\}_{S\in\mathcal{P}(V)}$ should satisfy $\nu(\beta)\tau_S\nu(\beta^{-1}) = \tau_{m(\beta)(S)}$, $\beta \in Bij(V)$. Hence it is necessary to describe just three morphisms $\tau_{\hat{e}}, \tau_{ef}, \tau_{\bar{e}}: \mathcal{F}\to\mathcal{F}$.

It is convenient to represent an element of $\mathcal{F}$ by a graph, which is a tetrahedron with vertices e, f, g, h, and equip its edges with the values of the considered element of $\mathcal{F}$ on the corresponding edge. Take any $\varphi \in \mathcal{F}$ and denote by a, b, c, p, q, and r the values of φ on the edges ef, eg, fg, eh, fh, and gh, respectively. Define $\tau_{\hat{e}}$, τ_{ef}, and $\tau_{\bar{e}}$ as follows:



(7)

The explicit descriptions of the other τ_S are induced by permutations of labels of vertices e, f, g,

and h. Recall that $\tau_{\varnothing}=\tau_V=id$. Straightforward computation establishes that $\theta_{\hat{e}}I_{\varphi}=I_{\tau_{\hat{e}}(\varphi)}\theta_{\hat{e}}$, $\theta_{ef}I_{\varphi}=I_{\tau_{ef}(\varphi)}\theta_{ef}$, and $\theta_{\bar{e}}I_{\varphi}=I_{\tau_{\bar{e}}(\varphi)}\theta_{\bar{e}}$. This completes the proof that the group $\mathcal{N}$ is a normal subgroup of the group $\mathcal{G}$. □

Note that now one has three types of transformations indexed by $S\in\mathcal{P}(V)$, a bijection $T_S\in Bij(\mathcal{P}(V))$ [refer to (3)], a bijection $\theta_S\in Bij_{\perp}(A)$ [refer to (4)], and an automorphism $\tau_S\in Aut(\mathcal{F})$ [refer to (7)].

The groups G and $\mathcal{G}$ will play a key role in the proof of the saturation property of A. In particular, it will be shown below that the image of the composition of maps $\mathcal{P}_{\perp}(A)\rightarrowtail\mathcal{P}(A)\xrightarrow{\mathcal{P}(\eta)}L$, where the first arrow is a canonical injection, is invariant under the G action. It will be shown, that an image of a complete set under this composition can have a cardinality only 1, 2, 4 or 8. This induces a partition of $C(A)$ into four subsets. The $\mathcal{G}$ action will fix each of these subsets and it will turn out that $\mathcal{G}$ acts transitively on each one of them.

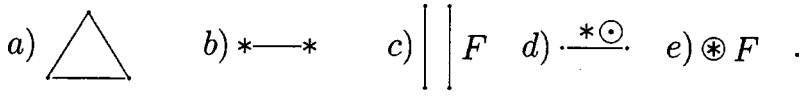
VIII. SATURATION PROPERTY, PART 2

We have constructed a group G and an action of G on L. Let H be a subgroup of G. Two graphs corresponding to some elements of Γ are called *H-equivalent* iff they can be represented in L by elements of the same H orbit.

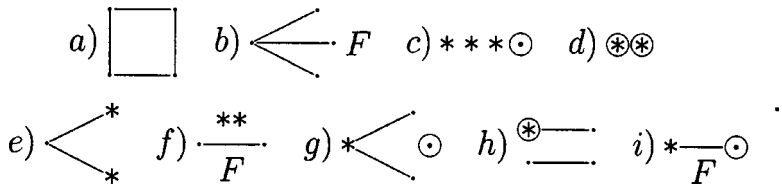
In the group G there is an element D. Its action on L induces a map $\partial:\Gamma\rightarrow\Gamma$, which in terms of graphs replaces a star $*$ by a circle $\odot$ around the same vertex and a circle $\odot$ by a star $*$ at the same vertex; the edges $\cdot$—$\cdot$ and the symbol F remain untouched. It means that if one is given a graph, then by applying if necessary the transformation ∂, it is possible to produce a graph with the number of stars $*$ greater or equal to the number of circles $\odot$. We shall call a graph satisfying this condition, *primary*, and a graph not satisfying this condition, *secondary*. For example, a graph $F*\circledast$—$\cdot$ is primary, and a graph $F\odot\circledast$—$\cdot$ is secondary. If the graphs represent the elements of Γ related to one another by the transformation ∂, one calls these graphs mutually *dual*. If a graph coincides with its dual, it is called *self-dual*. For example, the graph $*$—$\odot$ is self-dual.

Note, that any G-equivalence class is invariant under the transformation induced by ∂. The set of elements constituting a G-equivalence class, is completely determined by a list of all primary elements belonging to it; the other elements are obtained by duality.

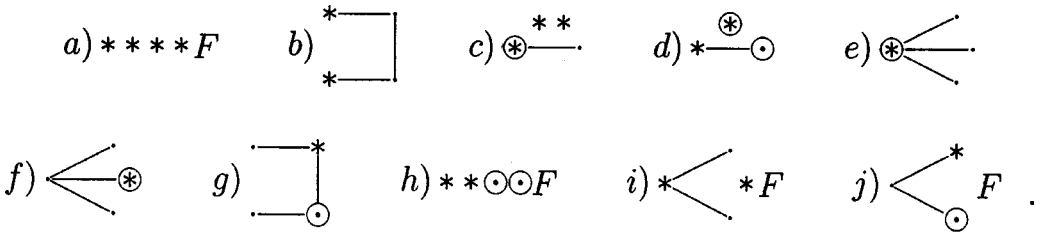
Proposition 6: (1) The complete list of primary graphs from the G-equivalence class of the graph $\triangle$ *is of the form*



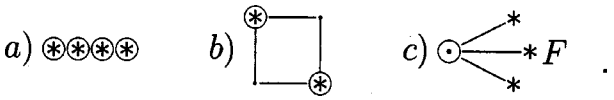
(2) The complete list of primary graphs from the G-equivalence class of the graph $***\odot$ *is of the form:*



(3) The complete list of primary graphs from the G-equivalence class of the graph $****F$ *is of the form:*

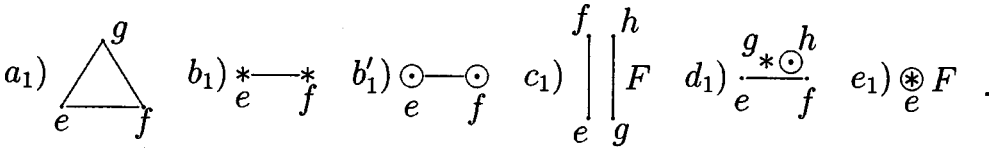


(4) The complete list of primary elements of the G-equivalence class of the graph ⊛⊛⊛⊛ is of the form



Proof: The proof is straightforward. Let us consider the proof of (1) in more detail. Note that all the graphs listed in (1) except the graph (b) are self-dual. Denote a graph obtained by duality from (b) as (b'); it is of the form $\odot$—$\odot$. Denote the set of graphs (1) appended with (b') as N_3 (N stands for nonadmissible and 3 stands for the degree).

That the G-equivalence class of the triangle indeed coincides with N_3, follows from two facts: (i) the list N_3 is complete, i.e., there is no other graph not present in the list, which is G-equivalent to some member of the list; (ii) any two members of the list N_3 are G-equivalent. In order to establish (i), let us choose and fix some representative in L for each element of N_3. This is equivalent to assigning some labels to the vertices of the graphs and can be done, for example, as follows:



Now for each of these labeled graphs calculate the result of the action on them of the transformations induced by $T_{\hat{v}}$ and T_{vw} $(v,w \in V, v \neq w)$, and after that delete the labels e, f, g, h. For example, if one takes the graph (a_1), then the transformation associated to $T_{\hat{e}}$ followed by the deletion of symbols e, f, g, and h, generates a graph $\odot$—$\odot$. If instead of $T_{\hat{e}}$ one takes $T_{\hat{h}}$, then the result will be the unlabeled triangle. Performing similar calculations, in each case one obtains an element of N_3, i.e., N_3 is complete.

Now let us establish (ii), i.e., the fact that N_3 is just one G-equivalence class. It is convenient to do this in several steps by taking bigger and bigger subgroups H of G and splitting N_3 into H-equivalence classes. Denote by G_1 the subgroup of G generated by $\{T_{\hat{v}}\}_{v \in V}$. Then N_3 splits into three G_1-equivalence classes: the first class consists of (a) and (b'); the second class consists of (b) and (e); and the third class consists of (c) and (d). Denote by $G_{1,3}$ the subgroup of G generated by $T_{\hat{v}}$ and $T_{\bar{v}}$, $v \in V$. Recall that $T_{\bar{v}} = DT_{\hat{v}}D$ where $D = T_{ef}T_{gh}$. Hence, $G_{1,3}$ is generated by the $\{T_{\hat{v}}\}_{v \in V}$ and D. The list N_3 splits into two $G_{1,3}$-equivalence classes, the first class contains the graphs (a), (b), (b'), and (e); and the other (c) and (d). Finally, the action associated to T_{eg} on the graph e^*—$^*f$ gives a graph, e—$h^*f \odot g$. Hence, one obtains a transition from (b) to (d), i.e., a

link between the two mentioned $G_{1,3}$-equivalence classes. It follows, that any two elements of N_3 are G-equivalent and this completes the proof of the first part of the proposition.

The proof of (2), (3), and (4) is similar. □

We have calculated some of the G-equivalence classes of some examples of graphs representing the elements of Γ. It will be interesting to describe for every given degree the sets of G-equivalence classes of admissible graphs.

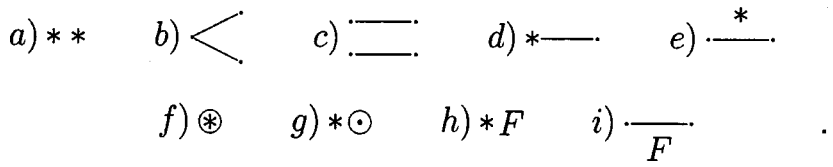
Proposition 7: If γ_1 is an admissible graph and γ_2 is a graph G-equivalent to γ_1, then it is also admissible. Moreover, if B_1 hangs over γ_1, then there exists a set B_2 which hangs over γ_2 and has the same cardinality as B_1.

Proof: Choose a representative Q_1 for γ_1 in L and a representative Q_2 for γ_2 in L. Hence γ_1 is associated to $[Q_1]\in\Gamma$ and γ_2 is associated to $[Q_2]\in\Gamma$. The assumption that γ_1 and γ_2 are G-equivalent implies that Q_1 and Q_2 are related as $Q_2=\hat{T}(Q_1)$, where $\hat{T}:=T_{S_1}T_{S_2}\cdots T_{S_m}\in G$, m is some natural number and $S_1,S_2,\ldots,S_m$ are some nonempty proper subsets of $V=\{e,f,g,h\}$. Since Q_1 is admissible, choose a set $B_1\in\mathcal{P}_\perp(A)\subset\mathcal{P}(A)$, such that $\mathcal{P}(\eta)(B_1)=Q_1$, where $\eta:A\to\mathcal{P}(V)$ is the natural map. For every $l\in B_1$ look at $l':=\hat{\theta}(l)$, where $\hat{\theta}:=\theta_{S_1}\theta_{S_2}\ldots\theta_{S_m}\in\mathcal{G}$. As l runs over the whole B_1, l' sweeps up some set $B_2\subset A$. Note, that since every θ_S is a bijection, $\hat{\theta}$ is a bijection as well, and the sets B_1 and B_2 have the same cardinality. Using the commutative diagram relating T_S and θ_S, $S\in\mathcal{P}(V)$, and the fact that every θ_S respects $\perp$, one concludes that $B_2\in\mathcal{P}_\perp(A)$ and that $\mathcal{P}(\eta)(B_2)=Q_2$. In particular, B_2 hangs over γ_2, and by that provides a realization of the admissiblity of γ_2. □

The graph * is an admissible graph of degree 1. The complete list of all primary elements from its G-equivalence class is of the form

It means, that the G-equivalence class of the graph $*$ coincides with the set of all graphs of degree 1.

Similarly, one has an admissible graph $**$ of degree 2. The complete list of all primary elements from its G-equivalence class is of the form



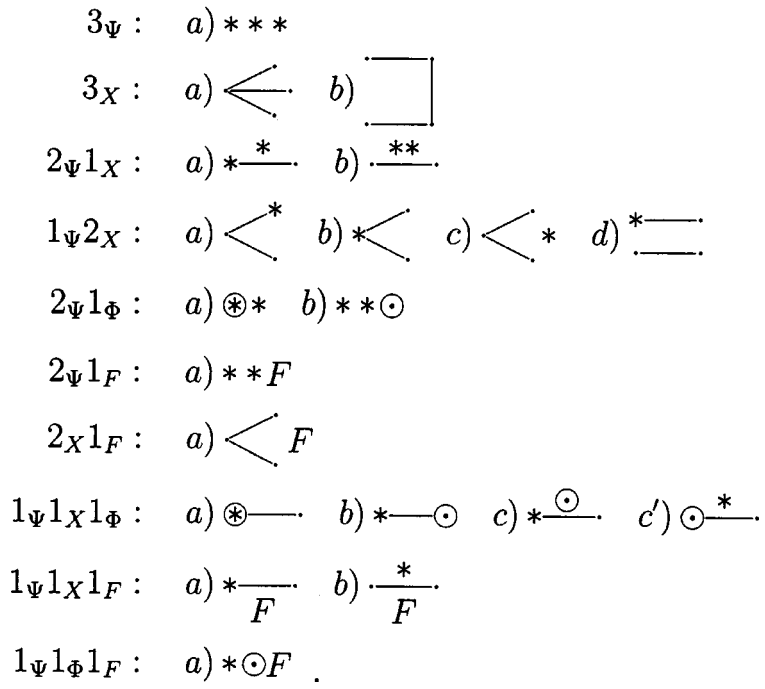
This G-equivalence class coincides with the set of all graphs of degree 2.

In degree 3 there exist admissible, as well as nonadmissible graphs.

Proposition 8: The set of all admissible graphs of degree 3 coincides with the G-equivalence class of the graph $***$.

Proof: Let us generate a list of all primary graphs of degree 3. It is convenient to present it in a systematic way. Denote by Γ_{k_1,k_2,k_3,k_4} a subset of Γ consisting of all the elements which are associated to the graphs which have k_1 stars, k_2 edges, k_3 circles, and k_4 instances of the symbol F. Look at all decompositions of 3 into a sum of four non-negative integers, $3=3+0+0+0=2+1+0+0=1+1+1+0$. Each of the mentioned three variants corresponds to some Γ_{k_1,k_2,k_3,k_4} with $k_1\geqslant k_2\geqslant k_3\geqslant k_4$, one gets $\Gamma_{3,0,0,0}$, $\Gamma_{2,1,0,0}$, and $\Gamma_{1,1,1,0}$. After that one generates the other Γ_{k_1,k_2,k_3,k_4} by permuting the arguments k_1, k_2, k_3, k_4 in the obtained three variants. Finally, one deletes from the list all the entries which do not satisfy $k_1\geqslant k_3$ and $k_4\leqslant 1$. Inside each of the sets Γ_{k_1,k_2,k_3,k_4} one

generates the corresponding graphs by exploring the different variants. After excluding the known nonadmissible graphs of degree 3, i.e., the graphs which are G-equivalent to a triangle, the list becomes



Here we use the labels of the form $1_\Psi 2_X$, $1_\Psi 1_X 1_F$, etc., to classify the graphs. The label $1_\Psi 2_X$ is associated to admissible graphs from $\Gamma_{1,2,0,0}$, $1_\Psi 1_X 1_F$ is associated to admissible graphs from $\Gamma_{1,1,0,1}$, etc. In a way, similar to the proof of the previous proposition, check that all the presented graphs are in fact a set of all primary graphs of a G-equivalence class of $***$. □

Now let us look at the graphs of degree 4. Note, that any admissible graph of degree 4 should satisfy a *necessary* condition, it does not contain a nonadmissible graph of degree 3. More precisely, one says that a graph γ_1 is *contained* in the graph γ_2 by definition iff these two graphs can be represented in L by Q_1 and Q_2, respectively, in such a way that $Q_1 \subset Q_2$.

Proposition 9: (1) A graph of degree 4 is admissible iff it does not contain a nonadmissible graph of degree 3.

(2) The set of all admissible graphs of degree 4 splits into two G-equivalence classes, one of the graph $***\odot$ *and the other of the graph* $****$.

Proof: Consider the set of *all* graphs of degree 4, which do not contain a nonadmissible graph of degree 3. The set of all *admissible* graphs of degree 4 is a subset of this set. One generates the required list in analogy with the case of degree 3. There are five ways to decompose 4 into a sum of four non-negative integers, $4=4+0+0+0=3+1+0+0=2+2+0+0=2+1+1+0=1+1+1+1$. It means, in particular, that one must have a series of graphs marked by labels 4_Ψ, $3_\Psi 1_X$, $2_\Psi 2_X$, $2_\Psi 1_X 1_\Phi$, and $1_\Psi 1_X 1_\Phi 1_F$. The label 4_Ψ generates 4_X, 4_Φ, and 4_F. Since a graph cannot contain more than one symbol F, delete 4_F. Since it suffices to consider only primary graphs, exclude the case 4_Φ. Treating the other labels in a similar fashion, one arrives at the following: $3_\Psi 1_X$ generates $3_\Psi 1_\Phi$, $3_\Psi 1_F$, $1_\Psi 3_X$, and $3_X 1_F$; $2_\Psi 2_X$ generates $2_\Psi 2_\Phi$; $2_\Psi 1_X 1_\Phi$ generates $2_\Psi 1_X 1_F$, $2_\Psi 1_\Phi 1_F$, $1_\Psi 2_X 1_\Phi$, and $1_\Psi 2_X 1_F$; finally, $1_\Psi 1_X 1_\Phi 1_F$ does not generate more labels. Having a set of all possible labels classifying the mentioned graphs, one generates a set of graphs present under each label by exploring different variants. The resulting complete list of primary graphs is given below,

4_Ψ : $a)\ ****$

4_X : $a)$ 

$3_\Psi 1_X$: $a)$ 

$3_\Psi 1_\Phi$: $a)\ \circledast **$ $b)\ ***\odot$

$3_\Psi 1_F$: $a)\ ***F$

$1_\Psi 3_X$: $a)$  $b)$  $c)$  $d)$ 

$3_X 1_F$: $a)$ 

$2_\Psi 2_X$: $a)$  $b)$  $c)$  $d)$ 

$2_\Psi 2_\Phi$: $a)\ \circledast\circledast$ $b)\ \circledast *\odot$ $c)\ **\odot\odot$

$2_\Psi 1_X 1_\Phi$: $a)$  $b)$  $c)$  $d)$ 

$2_\Psi 1_X 1_F$: $a)$  $b)$ 
$2_\Psi 1_\Phi 1_F$: $a)\ **\odot F$

$1_\Psi 2_X 1_\Phi$: $a)$  $b)$  $c)$  $d)$  $e)$

$f)$  $g)$  $h)$  $i)$  $j)$ 

$1_\Psi 2_X 1_F$: $a)$  $b)$  $c)$ 

$1_\Psi 1_X 1_\Phi 1_F$: $a)$  $b)$  $c)$ 

Note, that the existence of nonadmissible graphs of degree 3 excludes many variants of the graphs of degree 4. Now exclude all the graphs G-equivalent to $***\odot$. It is easily verified, that all the remaining graphs constitute in fact the set of all primary graphs from the G-equivalence class of $****$. □

We have shown, that the set of all admissible graphs of degree 4 splits into two G-equivalence classes, one containing the graph $****$ and the second, the graph $***\odot$. The elements from the first class will be referred to as *singlets* and the elements of the second class as *doublets*.

Now consider the case of the graphs of degree 5. Recall that one knows at least some of the nonadmissible graphs of this degree, these are the graphs from the G-equivalence class of the graph $****F$.

Proposition 10: (1) A graph of degree 5 is admissible iff it does not contain a nonadmissible graph of degree 3 and does not belong to the G-equivalence class of the graph $****F$;

(2) *Every admissible graph of degree 5 is G-equivalent to the graph* $\circledast***$.

Proof: Let us generate the list of all graphs of degree 5 which do not contain a non-admissible subgraph of degree 3. There exist six ways to decompose 5 into a sum of four non-negative integers, $5=5+0+0+0=4+1+0+0=3+2+0+0=3+1+1+0=2+2+1+0=2+1+1+1$. This gives six labels, 5_Ψ, $4_\Psi 1_X$, $3_\Psi 2_X$, $3_\Psi 1_X 1_\Phi$, $2_\Psi 2_X 1_\Phi$, $2_\Psi 1_X 1_\Phi 1_F$. By permuting the symbols Ψ, X, Φ, and F, one generates the other labels. Excluding from the resulting set of labels the ones, which do not satisfy the conditions $k_3 \leqslant k_1 \leqslant 4$ and $k_4 \leqslant 1$, where k_1, k_3, and k_4 are the numbers in a label associated to the symbols Ψ, Φ, and F, respectively, one arrives at the following: 5_Ψ generates 5_X, but itself is deleted from the list; $4_\Psi 1_X$ generates $4_\Psi 1_\Phi$, $4_\Psi 1_F$, $4_X 1_F$, and $1_\Psi 4_X$; $3_\Psi 2_X$ generates

$3_\Psi 2_\Phi$, $2_\Psi 3_X$; $3_\Psi 1_X 1_\Phi$ generates $3_\Psi 1_X 1_F$, $3_\Psi 1_\Phi 1_F$, $1_\Psi 3_X 1_\Phi$, and $1_\Psi 3_X 1_F$; $2_\Psi 2_X 1_\Phi$ generates $2_\Psi 2_X 1_F$, $2_\Psi 2_\Phi 1_F$, and $2_\Psi 1_X 2_\Phi$; finally, $2_\Psi 1_X 1_\Phi 1_F$ generates $1_\Psi 2_X 1_\Phi 1_F$. This yields 20 labels in total. Inside each label the corresponding graphs are generated by exploring all the possible variants. Note, that in some of the cases one inevitably obtains a graph containing a nonadmissible part of degree 3, a graph under the label 5_X should contain a triangle since there are maximum four vertices on a graph; a graph under the label $4_\Psi 1_X$ always contains $*$—$*$; and a graph under the label $4_X 1_F$ contains either a triangle or a graph $\|F$. It means that the labels 5_X, $4_\Psi 1_X$, and $4_X 1_F$ can be omitted. After deleting from the list the known nonadmissible graphs of degree 5, i.e., the graphs which are G-equivalent to the graph $****F$, the following list is obtained:

$4_\Psi 1_\Phi$: $a)\ \circledast***$

$4_\Psi 1_F$: $\emptyset$

$1_\Psi 4_X$: $a)$ 

$3_\Psi 2_X$: $a)$ 

$3_\Psi 2_\Phi$: $a)\ \circledast\circledast*$ $b)\ \circledast**\odot$

$2_\Psi 3_X$: $a)$  $b)$ 

$3_\Psi 1_X 1_\Phi$: $a)$ 

$3_\Psi 1_X 1_F$: $a)$ 

$3_\Psi 1_\Phi 1_F$: $a)\ ***\odot F$

$1_\Psi 3_X 1_\Phi$: $a)$  $b)$ $c)$  $d)$ 

$1_\Psi 3_X 1_F$: $a)$  F $b)$ F

$2_\Psi 2_X 1_\Phi$: $a)$  $b)$ $c)$ $d)$

$e)$  $f)$

$2_\Psi 2_X 1_F$: $a)$  F $b)$ $*F$

$2_\Psi 2_\Phi 1_F$: $\emptyset$

$2_\Psi 1_X 2_\Phi$: $a)$

$2_\Psi 1_X 1_\Phi 1_F$: $a)$  $b)$

$1_\Psi 2_X 1_\Phi 1_F$: $a)$  F $b)$ F .

One verifies, that this list coincides with the set of all primary graphs belonging to the G-equivalence class of the graph $***\circledast$. Since the latter graph is known to be admissible, all these graphs are admissible. □

One could proceed in a similar way and investigate the cases of the graphs of degree 6, 7, and

8, but it turns out that one does not have to do it. Recall that the aim is to prove that the set of projective lines A is saturated with respect to the orthogonality relation $\perp$.

Theorem 1: *The set A is saturated with respect to* $\perp$. *Moreover, for every* $B \in \mathcal{P}_{\perp}(A)$, *one has the following*:

(1) *If B has a shadow of degree* 1 *or* 2, *then it admits a pure complete extension.*
(2) *If B has a shadow of degree 3, then it admits a complete extension hanging over a doublet.*
(3) *If the shadow of B is a doublet, then B has a unique pure complete extension.*
(4) *If the shadow of B is a singlet, then B has a unique complete extension; this extension has a shadow of degree 8.*
(5) *If the degree of the shadow of B is* $\geqslant 5$, *then B has a unique complete extension; this extension has a shadow of degree 8.*

Proof: Take any $B \in \mathcal{P}_{\perp}(A)$ and denote $Q := \mathcal{P}(\eta)(B) \in L$. Let γ denote the shadow of B, i.e., the graph associated to $[Q] \in \Gamma$, and d denote the degree of γ.

(1) Suppose that $d=1$ or $d=2$. Then γ is G-equiavalent to $*$, or respectively, $**$. Represent the corresponding latter graph by some $Q' \in L$. There exists $\hat{T} := T_{S_1} T_{S_2} \ldots T_{S_m}$, where $S_1, S_2, \ldots, S_m$ are some nonempty proper subsets of V (m is some natural number), such that $Q' = \hat{T}(Q)$. Denote $B' := \hat{\theta}(B)$, where $\hat{\theta} := \theta_{S_1} \theta_{S_2} \cdots \theta_{S_m}$. Choose a complete set B'' containing B' such that $\mathcal{P}(\eta)(B'') = \mathcal{P}(\eta)(B')$. The set $\hat{B} := \hat{\theta}^{-1}(B)$ yields the required pure complete extension of B.

(2) The case of $d=3$ is similar and the difference is that γ is now G-equivalent to $***$. Let one choose Q' and construct $\hat{T}$, $\hat{\theta}$ and B' by analogy with the previous case. The complete set $B'' \supset B'$ cannot be chosen now to have the same shadow as B', but it can have a shadow $***\odot$. Denote $Q'' := \mathcal{P}(\eta)(B'')$. The set $\hat{B} := \hat{\theta}^{-1}(B'')$ gives the required extension of B. This extension hangs over a graph associated to $[\hat{Q}]$, where $\hat{Q} := \hat{T}^{-1}(Q'')$, which is G-equivalent to $***\odot$ and by that is a doublet.

(3) Suppose that $d=4$ and γ is a doublet. Then it is G-equivalent to $***\odot$. Choose Q' and define $\hat{T}$, $\hat{\theta}$, and B' in analogy with the two previous cases. There exists a unique pure extension B'' of B'. The required unique pure complete extension $\hat{B}$ of B will be of the form $\hat{B} := \hat{\theta}^{-1}(B'')$. Note that not all the complete extensions of a set B have to be pure.

(4) Suppose that $d=4$ and γ is a singlet. Then γ is G-equivalent to $****$. Choose Q' and construct $\hat{T}$, $\hat{\theta}$, and B' in analogy with the three previous cases, i.e., we have $Q' = \hat{T}(Q)$, $B' = \hat{\theta}(B)$, $\eta \circ \hat{\theta} = \hat{T} \circ \eta$. The set B' has a unique complete extension B'' and this extension hangs over $\circledast\circledast\circledast\circledast$. The set $\hat{B} := \hat{\theta}^{-1}(B'')$ is the unique complete extension of the original set B. The shadow of $\hat{B}$ is of degree 8 and is given by the graph associated to $[\hat{T}^{-1}(Q'')]$, where $Q'' := \mathcal{P}(\eta)(B'')$.

(5) Suppose that $d \geqslant 5$. Recall that the set of all admissible graphs of degree 5 is the G-equivalence class of the graph $***\circledast$. This graph contains a singlet $****$. It follows, that every admissible graph of degree 5 contains a singlet, since a singlet can be G-equivalent only to a singlet. Whenever a set B_0 hangs over a singlet $****$, the corresponding complete extension exists and is unique. At the same time, for every $v \in V$ there exists a unique projective line of the form Φ^v_ρ, $\rho \in R_{\overline{v}}$, which is orthogonal to every element of B_0; there exist no projective lines of X or F type, which are orthogonal to every element of B_0. Thus the construction of the complete extension of B_0 may be viewed as a step-by-step appending of the mentioned unique Φ^v_ρ to the set B_0 as v runs over V. One concludes, that whenever one has some sets B_1, B_2, B_3, and B_4 hanging over the graphs $***\circledast$, $**\circledast\circledast$, $*$, and $\circledast\circledast\circledast\circledast$, respectively, one may extract from each of them a part $B_i^0 \subset B_i$ ($i=1,2,3,4$) hanging over $****$; the unique complete extension $\hat{B}_i^0$ of B_i^0 at the same time plays a role of a unique complete extension of B_i and one has $B_i^0 \subset B_i \subset \hat{B}_i^0$, $i=1,2,3,4$.

Now let $B \in \mathcal{P}_{\perp}(A)$ have an arbitrary shadow γ of degree $d \geqslant 5$. Every such γ should contain an admissible graph $\overline{\gamma}$ of degree 5 and it is possible to choose in B a subset $\overline{B}$ hanging over $\overline{\gamma}$. Using the lists of graphs from the proofs of the two previous propositions, one verifies in a straightforward way that every admissible graph of degree 5 contains a singlet. It means, that one

can always find in $\overline{\gamma}$ some singlet γ_0 and choose $B_0 \subset \overline{B}$ which hangs over this singlet. The graph γ_0, as any other singlet, is G-equivalent to $****$. Denote $Q_0 := \eta(B_0)$ and choose any $Q_0' \in L$ representing the $****$. There exists a collection of nonempty proper subsets $S_i \subset V$, $i = 1, 2, \ldots, m$ (m is some integer), such that $Q_0' = \hat{T}(Q_0)$, where $\hat{T} := T_{S_1} T_{S_2} \cdots T_{S_m} \in G$. Denote $\hat{\theta} := \theta_{S_1} \theta_{S_2} \cdots \theta_{S_m}$. The set $\hat{\theta}(B_0)$ has a shadow $****$, the set $\hat{\theta}(\overline{B})$ has a shadow $\circledast***$ and the set $\hat{\theta}(B)$ has a shadow consisting of four stars $*$ and $d-4$ circles $\odot$. A unique complete extension $\tilde{B}$ of $\hat{\theta}(B_0)$ is at the same time a unique complete extension for $\hat{\theta}(\overline{B})$ and $\hat{\theta}(B)$. The shadow of $\tilde{B}$ has a degree 8 and is of the form $\circledast\circledast\circledast\circledast$. The set $\hat{B} := \hat{\theta}^{-1}(\tilde{B})$ has a shadow of degree 8 as well and provides the required unique complete extension of the set B. □

IX. TRANSITIVE ACTION

We have the set A of 120 projective lines in $\mathcal{H} \simeq \mathbb{C}^8$ which produces a Kochen–Specker-type contradiction and is saturated with respect to the orthogonality relation $\perp$. Note, that if one extracts a subset A_0 from A consisting of all projective lines of Ψ and Φ type, one can still prove that A_0 is saturated with respect to $\perp$, but A_0 will not produce a Kochen–Specker-type contradiction. Consider the set $C(A)$ of all complete subsets of A and denote by $C_d(A)$ the subset of $C(A)$ consisting of all the elements which have a shadow of degree $d \in \mathbb{N}$.

Theorem 2: (1) *The set* $C_d(A) \neq \emptyset$ *iff* d *is equal to* 1, 2, 4 *or* 8;
(2) *The group* $\mathcal{G}$ *acts transitively on each of the* $C_d(A)$, $d = 1, 2, 4, 8$.

Proof: (1) The statement that d cannot be other than 1, 2, 4 or 8 whenever $C_d(A) \neq \emptyset$ follows from the fact that a set hanging over a graph of degree 3 cannot have pure complete extensions and the fact that if a set hangs over a graph of degree $\geqslant 5$, then its complete extension always has a shadow of degree 8. The examples of realizations of all four mentioned possibilities have been given in the proof of Proposition 1.

(2) Recall that $\mathcal{G}$ is a subgroup of $Bij(A)$ and the action of $\theta \in \mathcal{G}$ on $B \in C(A)$ is given by $\mathcal{P}(\theta)(B)$. Let us start with the component $C_8(A)$. Every element $B \in C_8(A)$ can be viewed as $B = \mathcal{P}(\theta)(B_0)$, where B_0 is some element of $C_8(A)$ with a shadow $\circledast\circledast\circledast\circledast$ and θ is some element of $\mathcal{G}$. Denote by $C_8^0(A) \subset C_8(A)$ the set of all complete subsets with the specified shadow. It follows, that the problem is reduced to the following: for every two $B, B' \in C_8^0(A)$ show that there exists $\theta \in \mathcal{G}$ such that $\mathcal{P}(\theta)(B) = B'$. Every element of $C_8^0(A)$ is determined by its part which hangs over a singlet $****$. There are as many elements in $C_8^0(A)$ as the sets hanging over this singlet. Take any $B, B' \in C_8^0(A)$ and denote by $B_1 \subset B$ and by $B_1' \subset B'$ their parts hanging over $****$. One associates in the way described in part (6) of the proof of Proposition 1 to B_1 and B_1' some functions φ and φ', respectively, $\varphi, \varphi' : E \to \mathbb{Z}_2$, where E is the set of all edges of the tetrahedron representing $\mathcal{P}(V)^{\times}$. One verifies, that $B_1' = \mathcal{P}(I_{\varphi+\varphi'})(B_1)$. This implies that the action of $\mathcal{G}$ on $C_8(A)$ is transitive.

Now consider the case of $C_4(A)$. This set consists of all those complete subsets of A hanging over a doublet. Denote by $C_4^0(A) \subset C_4(A)$ the set of all complete subsets with shadow $***\odot$. In analogy to the case of $C_8(A)$, the original problem reduces to the problem to show that for every $B, B' \in C_4^0(A)$ such that $\mathcal{P}(\eta)(B) = \mathcal{P}(\eta)(B')$ [recall that $\eta : A \to \mathcal{P}(V)$ denotes the natural map], there exists $\theta \in \mathcal{G}$ such that $\mathcal{P}(\theta)(B) = B'$. Take any of the mentioned B and B' and assume without loss of generality that $\mathcal{P}(\eta)(B) \in L$ is visualized by a graph ${}_e*{}_f*{}_g\odot_h$. One associates in the way as pointed out in part (5) of the proof of Proposition 1 to B a triple of parameters a, b, and c. Let $\psi : \{ef, eg, fg\} \to \mathbb{Z}_2$ denote the function, which has values on the edges ef, eg, and fg given by a, b, and c, respectively. In a similar way a function $\psi' : \{ef, eg, fg\} \to \mathbb{Z}_2$ is associated to the set B'. Choose any $\varphi, \varphi' : E \to \mathbb{Z}_2$ such that their restrictions to $\{ef, eg, fg\}$ coincide with ψ and ψ', respectively. It is clear that $B' = \mathcal{P}(I_{\varphi+\varphi'})(B)$. This completes the proof for the case $C_4(A)$.

The investigation of the case $C_2(A)$ is similar and contains a graph $**$ and a pair of $\mathbb{Z}_2$-valued functions on just one edge. The case $C_1(A)$ involves a graph $*$ and does not require a similar construction of $\mathbb{Z}_2$-valued functions. □

We give a general expression for the normally ordered form of a function $F[\hat{w}(a,a^\dagger)]$ where $\hat{w}$ is a function of boson creation and annihilation operators satisfying $[a,a^\dagger]=1$. The expectation value of this expression in a coherent state becomes an exact generating function of Feynman-type graphs associated with the zero-dimensional quantum field theory defined by $F(\hat{w})$. This enables one to enumerate explicitly the graphs of given order in the realm of combinatorially defined sequences. We give several examples of the use of this technique, including the applications to Kerr-type and superfluidity-type Hamiltonians. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904161]

In the normally ordered form of a function $F(a,a^\dagger)$ of boson creation and annihilation operators all the annihilation operators are moved to the right using the commutation relation $[a,a^\dagger]=1$. The importance of the normal form, denoted by $\mathcal{N}[F(a,a^\dagger)]$ and satisfying $F(a,a^\dagger)=\mathcal{N}[F(a,a^\dagger)]$, is evident, as with it the expectation values of $F(a,a^\dagger)$ can be easily evaluated in such canonical states as the vacuum $|0\rangle$ and coherent states $|z\rangle=e^{-|z|^2/2}\Sigma_{n=0}^{\infty}z^n/\sqrt{n!}|n\rangle$, ($z$ complex and $a^\dagger a|n\rangle=n|n\rangle$). The role of the normal form in quantum field theory (QFT) is pre-eminent.[1,2]

In this work we consider functions $F(\hat{w})$ that involve operators $\hat{w}(a,a^\dagger)$ in the form of a product of positive powers of $a^\dagger$ and a, and powers of $(a+a^\dagger)$, although the formulas derived below are valid for more general $\hat{w}$'s. Our considerations are based on the following operational

property of formal power series. Let $f(x)=\Sigma_{n=0}^{\infty}f_n x^n/n!$ and $g(x)=\Sigma_{n=0}^{\infty}g_n x^n/n!$ be two formal power series, also called the exponential generating functions (egf) of sequences $\{f_n\}_{n=0}^{\infty}$ and $\{g_n\}_{n=0}^{\infty}$, respectively. Then it can be verified that

$$f\left(\lambda\frac{d}{dx}\right)g(x)\bigg|_{x=0}=g\left(\lambda\frac{d}{dx}\right)f(x)\bigg|_{x=0}=\sum_{n=0}^{\infty}f_n\cdot g_n\frac{\lambda^n}{n!},$$

which we shall call the product formula (PF). This implies the following property satisfied by $F(\lambda\hat{w})$ with indeterminate λ:

$$F(\lambda\hat{w})=F\left(\lambda\frac{d}{dx}\right)e^{x\hat{w}}\bigg|_{x=0}, \tag{1}$$

which by taking the normal form of both sides becomes

$$\mathcal{N}[F(\lambda\hat{w})]=F\left(\lambda\frac{d}{dx}\right)\mathcal{N}(e^{x\hat{w}})\bigg|_{x=0}. \tag{2}$$

Note that in Eq. (2) a separation has been achieved between the functional aspect (defined by F) and the operator aspect (defined by $\hat{w}$) of the normal ordering. Conventionally we implement $\mathcal{N}(e^{x\hat{w}})$ by using the auxiliary symbol $::$ with $\mathcal{N}(e^{x\hat{w}})\equiv :G_{\hat{w}}(x,a,a^{\dagger}):$, where under the symbol $::$ the function $G_{\hat{w}}(x,a,a^{\dagger})$ is normally ordered assuming that $a^{\dagger}$ and a *commute*.[3,4] Then Eq. (2) becomes

$$\mathcal{N}[F(\lambda\hat{w})]=F\left(\lambda\frac{d}{dx}\right):G_{\hat{w}}(x,a,a^{\dagger}):\bigg|_{x=0}. \tag{3}$$

Note that the expression of Eq. (3) arises in the evaluation of the partition function Z_{β} for the system defined by the Hamiltonian $\mathcal{H}(\hat{w})$,

$$Z_{\beta}=\mathrm{Tr}\,e^{-\beta\mathcal{H}(\hat{w})}=\frac{1}{\pi}\int d^2z[\,e^{-\beta\mathcal{H}(d/dx)}G_{\hat{w}}(x,z,z^{*})|_{x=0}],$$

taking the trace over the coherent state representation, $\beta=(k_BT)^{-1}$.[5] The problem of finding $\mathcal{N}[F(\lambda\hat{w})]$ reduces to that of finding $\mathcal{N}(e^{x\hat{w}})$, still however a nontrivial task, *vide* the classical references.[3,4,6] We have recently found expressions for $G_{\hat{w}}(x,a,a^{\dagger})$ for several types of operators $\hat{w}$ of the form $\hat{w}_{(r,s)}=(a^{\dagger})^r a^s$ (Ref. 7) as well as for $\hat{w}_{(\vec{r},\vec{s})}=\Pi_{k=1}^{M}\hat{w}_{(r_k,s_k)}$ with r, s, r_k, s_k positive integers.[8]

At this point it is already possible to relate Eq. (3) to enumerative formulas for Feynman-type graphs in QFT.[9] Assume that our formal power series $F(x)$ can be written in the form $F(x)=\exp[\Sigma_{m=1}^{\infty}L_m(x^m/m!)]$, and we similarly assume that we may define operators $V_n^{(\hat{w})}(a,a^{\dagger})$ by

$$:G_{\hat{w}}(x,a,a^{\dagger}):=:\exp\left(\sum_{n=1}^{\infty}V_n^{(\hat{w})}(a,a^{\dagger})\frac{x^n}{n!}\right):. \tag{4}$$

Explicit examples[7] from which the operators $V_n^{(\hat{w})}(a,a^{\dagger})$ may be read off include

$$\hat{w}=a^{\dagger}a,\quad \mathcal{N}[\exp(xa^{\dagger}a)]=:\exp[a^{\dagger}a(e^x-1)]:, \tag{5}$$

$$\hat{w} = (a^\dagger)^r a, \quad \mathcal{N}[\exp(x(a^\dagger)^r a)] = :\exp\left[a^\dagger a \sum_{n=1}^{\infty} (a^\dagger)^{(r-1)n} (r-1)^n \frac{\Gamma\left(n + \frac{1}{r-1}\right)}{\Gamma\left(\frac{1}{r-1}\right)} \frac{x^n}{n!} \right]: , \tag{6}$$

with $r=2,3,\ldots,$ as well as more involved expressions for other $\hat{w}(a,a^\dagger)$. Thus, Eq. (3) may be written as

$$\mathcal{N}[F(\lambda\hat{w})] = \exp\left(\sum_{m=1}^{\infty} \frac{L_m}{m!} \lambda^m \frac{d^m}{dx^m} \right) \cdot :\exp\left(\sum_{n=1}^{\infty} V_n^{(\hat{w})}(a,a^\dagger) \frac{x^n}{n!} \right): \Bigg|_{x=0} . \tag{7}$$

We eliminate the operators a and $a^\dagger$ by taking the matrix element of Eq. (7) in the coherent state $|z\rangle$ and using $a|z\rangle = z|z\rangle$. This yields

$$\langle z|\mathcal{N}[F(\lambda\hat{w})]|z\rangle = \exp\left(\sum_{m=1}^{\infty} \frac{L_m}{m!} \lambda^m \frac{d^m}{dx^m} \right) \cdot \exp\left(\sum_{n=1}^{\infty} V_n^{(\hat{w})}(z,z^*) \frac{x^n}{n!} \right) \Bigg|_{x=0} . \tag{8}$$

By specifying $z=1$ in Eq. (8), defining $V_n^{(\hat{w})}(1,1) = V_n^{(\hat{w})}$, $\mathbf{V} = \{V_n^{(\hat{w})}\}_{n=1}^{\infty}$, and $\mathbf{L} = \{L_m\}_{m=1}^{\infty}$ we obtain

$$Z(\mathbf{L},\mathbf{V},\lambda) \equiv \langle 1|\mathcal{N}[F(\lambda\hat{w})]|1\rangle = \exp\left(\sum_{m=1}^{\infty} \frac{L_m}{m!} \lambda^m \frac{d^m}{dx^m} \right) \cdot \exp\left(\sum_{n=1}^{\infty} V_n^{(\hat{w})} \frac{x^n}{n!} \right) \Bigg|_{x=0} \tag{9}$$

which is essentially the counting formula cited by Bender *et al.*[9] Due to the symmetry of the PF, we have $Z(\mathbf{L},\mathbf{V},\lambda) = Z(\mathbf{V},\mathbf{L},\lambda)$, which may facilitate the calculations. Furthermore it can be demonstrated that for all the forms of $\hat{w}$ used here the sequence $\mathbf{V}$ consists of positive integers. The formula Eq. (9) was employed in Ref. 9 as an enumerative tool for counting the Feynman-type graphs in zero-dimensional QFT models, where the values of all Feynman integrals are equal to 1. Our derivation sheds light on its quantum origin by tracing back its sources to the boson normal ordering problem. By specifying the sets $\mathbf{L}$ and $\mathbf{V}$ one can attempt to produce a (in general divergent) power series expansion in λ,

$$Z(\mathbf{L},\mathbf{V},\lambda) = \sum_{n=0}^{\infty} A_n(\mathbf{L},\mathbf{V}) \frac{\lambda^n}{n!} \tag{10}$$

in which $A_n(\mathbf{L},\mathbf{V})$ can be related to known objects. To see that, recall the definition of the multivariate Bell polynomials $\mathbb{B}(\mathbf{h},u)$ related to a function $h(x) = \Sigma_{n=1}^{\infty} h_n x^n/n!$ through ($\mathbf{h} = \{h_n\}_{n=1}^{\infty}$)

$$e^{uh(x)} = \sum_{n=0}^{\infty} \frac{x^n}{n!} \sum_{k=1}^{n} u^k \mathbb{B}_{nk}(\mathbf{h}) = \sum_{n=0}^{\infty} \frac{x^n}{n!} \mathbb{B}_n(\mathbf{h},u), \tag{11}$$

where the coefficients of the expansion $\mathbb{B}_n(\mathbf{h},u) = \Sigma_{k=1}^{n} u^k \mathbb{B}_{nk}(\mathbf{h})$ depend only on $h_1,\ldots,h_n$. We refer to Refs. 10 and 11 for further properties of $\mathbb{B}_n(\mathbf{h},u)$.

With $\mathbb{B}_n(\mathbf{f}) = \mathbb{B}_n(\mathbf{f},1)$ we see that the coefficients $A_n = A_n(\mathbf{L},\mathbf{V})$ factorize

$$A_n = \mathbb{B}_n(\mathbf{L}) \cdot \mathbb{B}_n(\mathbf{V}) \tag{12}$$

which for given $\mathbf{L}$ and $\mathbf{V}$ can be worked out (see below).

The utility of Eqs. (9) and (12) goes beyond the specific definition of initial $\hat{w}$, and this is the philosophy of Ref. 9 where it was suggested that $\mathbf{L}$ and $\mathbf{V}$ could be treated as initial *input* for QFT models. From this perspective Eqs. (9) and (12) provide the starting point for a Feynman-type graph representation of the coefficients A_n in Eq. (10), where A_n counts the number of graphs with n labeled lines. The graph construction rules are as follows: a line starts from a white dot, the *origin*, and ends at a black dot, the *vertex*. We further associate strengths V_k with each vertex

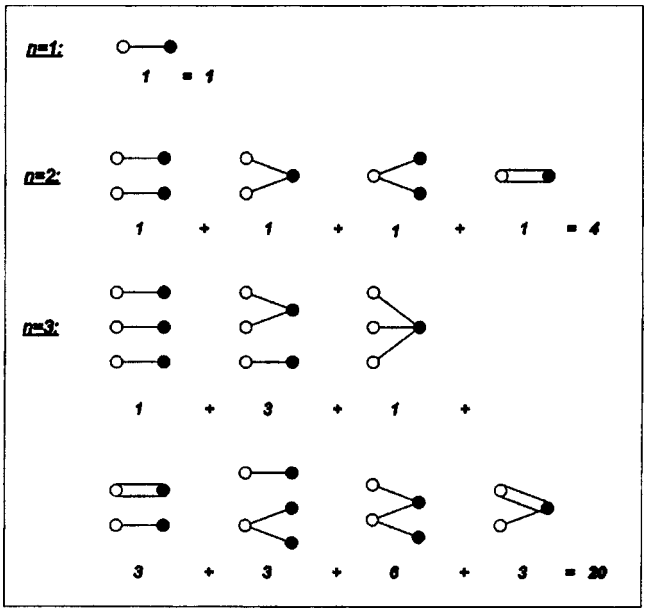

FIG. 1. Lowest order Feynman-type graphs for Example 1 with $n=1,2,3$ lines. The number below each graph is its multiplicity.

receiving k lines and multipliers L_m with a white dot which is the origin of m lines. Counting such graphs consists in calculating their multiplicity due to the labelling of lines and the factors L_m and V_k.

We now specify **L** and **V** and give some examples of the explicit evaluation of A_n along with the explicit graph representation.

Example 1: $L_1=1$, $L_M=1$ $(M>1)$, and $L_m=0$ otherwise, giving the function $F(x)=\exp(x+x^M/M!)$; $V_n^{(\hat{w})}=1$ for $n=1,2\ldots$, which arises from the string $\hat{w}=a^\dagger a$, see Eq. (5). This corresponds to the normal ordering problem $\mathcal{N}[\exp(\lambda a^\dagger a+(\lambda^M/M!)(a^\dagger a)^M)]$. Note that the case $M=2$ describes the normal ordering of the exponential of the Kerr-type Hamiltonian[12] $\mathcal{H}=\lambda a^\dagger a(1+(\lambda/2)a^\dagger a)$. Using the definition of the two variable Hermite–Kampé de Fériet polynomials $H_n^{(M)}(x,y)$ (see Ref. 13 and references therein)

$$\sum_{n=0}^{\infty} H_n^{(M)}(x,y)\frac{t^n}{n!}=e^{xt+yt^M}, \tag{13}$$

where $H_n^{(M)}(x,y)=n!\Sigma_{r=0}^{[n/M]}[(x^{n-Mr}y^r)/(n-Mr)!r!]$, $F(x)$ can be expanded as

$$F(x)=e^{x+(x^M/M!)}=\sum_{n=0}^{\infty} H_n^{(M)}\left(1,\frac{1}{M!}\right)\frac{x^n}{n!}. \tag{14}$$

Equation (10) yields $A_n=H_n^{(M)}(1,1/M!)\cdot B_n$, where the *Bell* numbers B_n are defined through their egf, $\exp(e^x-1)=\Sigma_{n=0}^{\infty}B_nx^n/n!$.[9–11] Observe that for $M=2$, $H_n^{(2)}(1,\frac{1}{2})=(i/\sqrt{2})^nH_n(-i/\sqrt{2})=1,2,4,10,26,76,232,\ldots$ are the *involution* numbers[10] expressible using Hermite polynomials $H_n(x)$. The initial terms of A_n for $M=2$ are 1,4,20,150,1352,15 428,…, see Fig. 1, and for $M=3$, are $1,2,10,75,527,6293,\ldots$, etc. Note that whereas B_n counts all the partitions of an n-set, $H_n^{(M)}(1,1/M!)$ counts partitions of an n-set into singletons and M-tons.

Example 2: $L_m=m$ for $m=1,2,\ldots$, giving rise to $F(x)=\exp[\Sigma_{m=1}^{\infty}m(x^m/m!)]=\exp(xe^x)=\Sigma_{n=0}^{\infty}I_nx^n/n!$, where $I_n=\Sigma_{k=0}^{\infty}\binom{n}{k}k^{n-k}$ are *idempotent* numbers.[10] Again choosing $V_n^{(\hat{w})}=1$, n

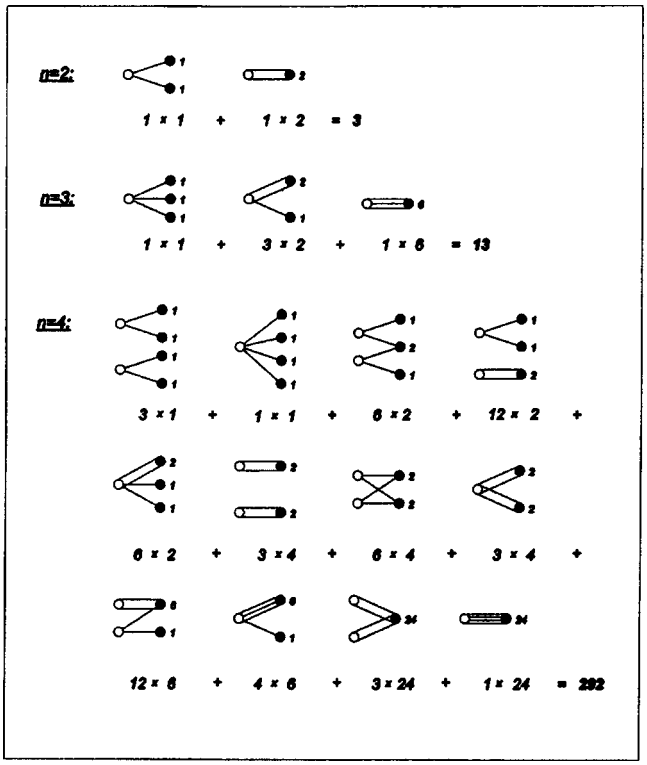

FIG. 2. Lowest order Feynman-type graphs for Example 3 with $n=2,3,4$ lines. The number below each graph is (*multiplicity*) $\times \Pi_k$(*vertex factor* $V_k=k!$). Numbers at black dots (vertices) are vertex factors.

$=1,2,\ldots$, with $\hat{w}=a^\dagger a$, gives $A_n=I_n$. $B_n=1,6,50,615,10\,192,214\,571,\ldots$. This corresponds to normally ordering $\mathcal{N}[\exp(\lambda(a^\dagger a)e^{\lambda(a^\dagger a)})]$.

Example 3: $L_1=0$, $L_m=1$ for $m=2,3,\ldots$, leading to $F(x)=\exp(e^x-1-x)=\Sigma_{n=0}^{\infty}B_n^{(1)}x^n/n!$, where $B_n^{(1)}$ are *restricted Bell* numbers which are defined as counting partitions without singletons. **(**Note that $B_n^{(1)}=(1/e)\Sigma_{k=0}^{\infty}[(k-1)^n/k!]$**)**. Here we choose $V_n^{(\hat{w})}=n!$, $n=1,2,\ldots$, derived from the string $\hat{w}=(a^\dagger)^2a$, and producing via $\exp[x/(1-x)]=\Sigma_{n=0}^{\infty}B_n^{(2,1)}x^n/n!$ [see Eq. (37) of Ref. 7], $A_n=B_n^{(1)}\cdot B_n^{(2,1)}=0,3,13,292,5511,166\,091,\ldots$, see Fig. 2. This corresponds to the normal ordering of $\exp(e^{\lambda(a^\dagger)^2a}-1-\lambda(a^\dagger)^2a)$.

Example 4: $L_{2m}=2m$, $L_{2m+1}=0$ for $m=0,1,2,\ldots$, giving $F(x)=\exp(x\sinh(x))$. If, as in Examples 1 and 2, $V_n^{(\hat{w})}=1$, $n=1,2,\ldots$, $\hat{w}=a^\dagger a$, then by defining the *indempotent* polynomials $I_n(t)=\Sigma_{k=0}^{n}\binom{n}{k}k^{n-k}t^k$ we obtain $A_n=I_n^{(2)}.B_n=0,4,0,240,0,49\,938,0,24\,608\,160,0,\ldots$, where $I_n^{(2)}=\Sigma_{k=0}^{n}\binom{n}{k}(-1)^kI_k(-\frac{1}{2})I_{n-k}(\frac{1}{2})$, yielding $\mathcal{N}[\exp(\lambda a^\dagger a\,\sinh(\lambda a^\dagger a))]$.

Example 5: In the last example we shall treat the function $\hat{w}=a+a^\dagger$, using $F(x)=e^{x^M/M!}$, $M=1,2,3,\ldots$. First observe that $\mathcal{N}(e^{x\hat{w}})=:G_{\hat{w}}(x,a,a^\dagger):=:e^{x^2/2}e^{x(a+a^\dagger)}:$ which is a consequence of the Heisenberg algebra. It follows that $V_1^{(\hat{w})}(a,a^\dagger)=a+a^\dagger$, $V_2^{(\hat{w})}(a,a^\dagger)=1$ and $V_n^{(\hat{w})}(a,a^\dagger)=0$ for $n>2$, see Eq. (4), giving $\mathbf{V}=\{2,1,0,0,\ldots\}$ and $\mathbf{L}=\{\delta_{m,M}\}_{m=1}^{\infty}$. Let us define the modified Hermite polynomials $h_n(x)=(-i/\sqrt{2})^nH_n(ix/\sqrt{2})$ and then $\exp(2x+x^2/2)=\Sigma_{n=0}^{\infty}[h_n(2)/n!]x^n$. Using Eqs. (10) and (12) we get

$$Z_M(\mathbf{L},\mathbf{V},\lambda)=\exp\left(\frac{\lambda^M}{M!}\frac{d^M}{dx^M}\right)\cdot\exp\left(2x+\frac{x^2}{2}\right)\Bigg|_{x=0}=\sum_{n=0}^{\infty}\frac{h_{Mn}(2)}{n!}\left(\frac{\lambda^M}{M!}\right)^n. \tag{15}$$

Starting with the simplest case $M=1$, the function $Z_1(\mathbf{L},\mathbf{V},\lambda)=\exp(2\lambda+\lambda^2/2)$ gives $A_n=h_n(2)=1,2,5,14,43,142,499,1850,\ldots$, $n=0,1,2,\ldots$, The series of Eq. (15) can also be written down

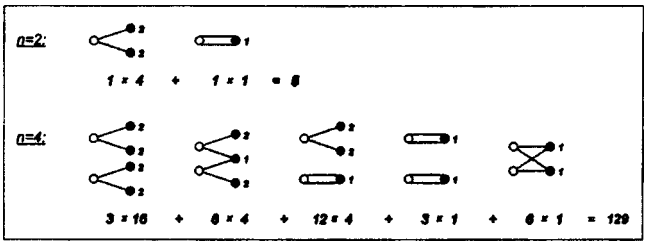

FIG. 3. Lowest order Feynman-type graphs for Example 5 with $n=2,4$ lines. The number below each graph is $(multiplicity)\times\Pi_k(vertex\ factor\ V_k=2\delta_{k,1}+\delta_{k,2})$.

in closed form for $M=2$, corresponding to a single mode superfluidity-type Hamiltonian $\mathcal{H}\sim(a+a^\dagger)^2$,[14] and for $M=3$,[15]

$$Z_2(\mathbf{L},\mathbf{V},\lambda)=\sum_{n=0}^{\infty}\frac{h_{2n}(2)}{n!}\left(\frac{\lambda^2}{2!}\right)^n=\frac{1}{(1-\lambda^2)^{1/2}}\exp\left(\frac{2\lambda^2}{1-\lambda^2}\right), \tag{16}$$

$$Z_3(\mathbf{L},\mathbf{V},\lambda)=\sum_{n=0}^{\infty}\frac{h_{3n}(2)}{n!}\left(\frac{\lambda^3}{3!}\right)^n=\frac{\exp\left(\phi^3\frac{\lambda^3}{6}-\phi^4\frac{\lambda^6}{8}\right)}{(1-\phi\lambda^3)^{1/2}}{}_2F_0\left(\frac{1}{6},\frac{5}{6};-;\frac{3\lambda^6}{2(1-\phi\lambda^3)^3}\right), \tag{17}$$

where $\phi(\lambda)=(1-\sqrt{1-4\lambda^3})/\lambda^3$ and ${}_2F_0$ is the hypergeometric function. In these examples Z_1 and Z_2 are convergent series in λ while Z_3 is formal power series. From Eq. (15) we can read off the values of A_n: $A_{Mn}=[(Mn)!/(M!)^n n!]h_{Mn}(2)$ and zero otherwise, giving for $M=2$, $A_{2n}=1,5,129,7485,755\,265,116\,338\,005,\ldots$, see Fig. 3. Note, that whenever Z is known in closed form the equation$Z(\lambda)=\exp[\lambda(d/dx)]Z(x)|_{x=0}$ leads immediately to a set of graphs for which $L_m=\delta_{m,1}$. Thus for $M=2$, with Eq. (16) we have the following alternative descriptions: (a) $L_m=\delta_{m,2}$; $V_1=2$, $V_2=1$, $V_{n>2}=0$ and (b) $L_m=\delta_{m,1}$; $V_{2n}=(4n+1)(2n-1)!$. However even if Z is not known explicitly method (a) leads to a simple, alternative, graphical description using Eq. (15).

In conclusion we see that the technique described herein and hinging on Eq. (9) leads to a combinatorial and graphical description of many physical systems.

Vortices set and the applied magnetic field for superconductivity in dimension three

Zuhan Liu[a)]
Department of Mathematics, Xuzhou Normal University, Xuzhou 221116, China

(Received 13 October 2004; accepted 4 March 2005; published online 4 May 2005)

In this paper, the structure of vortices set of the Ginzburg–Landau system of the superconductivity in dimension three was studied when applied magnetic field $|h_{\mathrm{ex}}|=O(|\ln \varepsilon|)$. This singularities set is one-dimensional rectifiable. Its generalized mean curvature was given. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1899987]

I. INTRODUCTION

Consider the following Ginzburg–Landau equations, referred to as GL:

$$\mathrm{GL}\begin{cases} -(\nabla - iA)^2 u = \dfrac{u}{\varepsilon^2}(1-|u|^2) & \text{in} \quad \Omega \\ -\operatorname{curl} h = (iu, \nabla_A u) & \text{in} \quad \Omega \\ h \times \nu = h_{\mathrm{ex}} \times \nu & \text{on} \quad \partial\Omega \\ (\nabla u - iAu)\cdot \nu = 0 & \text{on} \quad \partial\Omega. \end{cases}$$

The solutions of this system are the critical points of the following Ginzburg–Landau energy:

$$J(u,A) = \frac{1}{2}\int_{\Omega}\left[|\nabla_A u|^2 + \frac{1}{2\varepsilon^2}(1-|u|^2)^2 + |h-h_{\mathrm{ex}}|^2\right]. \tag{1.1}$$

This energy-functional was introduced by the physicists Ginzburg and Landau in the 1950s as a model for superconductivity. Ω is a bounded smooth domain in $\mathbb{R}^3$. $\kappa = 1/\varepsilon$ is a dimensionless constant (the Ginzburg–Landau parameter). h_{ex} is the applied magnetic field, $A:\Omega \mapsto \mathbb{R}^3$ is the vector potential, and the induced magnetic field in the material is $h = \operatorname{curl} A$. $\nabla_A = \nabla - iA$. The complex order parameter u indicates the local state of the material. $|u|$ represents the density of superconducting electron pairs, so that $|u| \simeq 1$ corresponds to the superconducting state, $|u| \simeq 0$ corresponds to the normal state.

We know that a superconductor placed in an applied magnetic field may change its phases when the field varies. When the lower critical value H_{c_1} of applied magnetic field is reached, there is a phase transition from the superconducting state to the "mixed state," where vortices appear (zero-set of u). The motion of vortices generates an electric field and leads to current dissipation. On the other hand, energy concentrates and blows up like the order $|\ln \varepsilon|$ on vortices set, hence singularities happen. So, to understand the vortices structure is of great importance not only in mathematical theory but also in application. The Ginzburg–Landau equations and functional are invariant under $U(1)$ gauge transformations of the type: $u \mapsto ue^{i\Phi}$, $A \mapsto A + \nabla\Phi$. We choose the Coulomb gauge

[a)]Electronic mail: zuhanl@yahoo.com

$$\operatorname{div} A = 0 \text{ in } \Omega, \quad A \cdot \nu = 0 \text{ on } \partial\Omega. \tag{1.2}$$

In the case $\Omega \subset \mathbb{R}^2$, Sandier and Serfaty[13–15] already studied global minimizers of energy-functional (1.1) and describe their vortices structure as $\varepsilon \to 0$. In Refs. 16–18, Serfaty studied vortices structure of local minimizer of (1.1), as $\varepsilon \to 0$, under assumption $\mathcal{E}_\varepsilon(u) = \frac{1}{2}\int_\Omega [|\nabla u|^2 + (1/2\varepsilon^2)(1-|u|^2)^2] \leqslant M_0 |\ln \varepsilon|$.

In the case $\Omega \subset \mathbb{R}^3$, experiments have indicated the possibility of quite complicated vortices configurations and it remains a challenge to capture these codimension two singularities in a rigorous mathematical way. In this paper, we are interested in the asymptotic behavior of vortices set (concentrating measures) associated with solutions to GL and concentrate our attention on singularities of codimension two, then it is natural to assume that the energy of u_ε blows up like $|\ln \varepsilon|$:

$$\mathcal{E}_\varepsilon(u_\varepsilon) = \frac{1}{2}\int_\Omega \left[|\nabla u_\varepsilon|^2 + \frac{1}{2\varepsilon^2}(1-|u_\varepsilon|^2)^2 \right] \mathrm{d}x \leqslant M_0 |\ln \varepsilon|, \tag{1.3}$$

where M_0 is a fixed constant. This condition implies that the length of the vortices set is finite. Such an assumption is automatically satisfied if $(u_\varepsilon, A_\varepsilon)$ is a minimizer of $J(u,A)$ with Dirichlet boundary condition (see Ref. 11).

In order to state our main result, it is convenient to introduce the following measures and Jacobian:[2,9,12]

$$\mu_\varepsilon := \frac{e_\varepsilon(u_\varepsilon)}{|\ln \varepsilon|}\mathrm{d}x, \quad Ju_\varepsilon = \Sigma_{i<j}(\partial_i u_\varepsilon \times \partial_j u_\varepsilon)\mathrm{d}x_i \wedge \mathrm{d}x_j,$$

where

$$e_\varepsilon(u_\varepsilon) = \frac{1}{2}\left[|\nabla u_\varepsilon|^2 + \frac{1}{2\varepsilon^2}(b_\varepsilon - |u_\varepsilon|^2)^2 \right], \; b_\varepsilon = 1 + \varepsilon^2 |A_\varepsilon|^2.$$

In view of assumption (1.3), μ_ε is bounded. Therefore, up to a subsequence we may assume

$$\mu_\varepsilon \rightharpoonup \mu_* \text{ as measures}. \tag{1.4}$$

By (1.3), Ju_ε is bounded in $[C^{0,\alpha}(K)]^*$ for any compact $K \subset \Omega$ any $0 < \alpha < 1$ (see Ref. 8). Going to a subsequence, we have

$$Ju_\varepsilon \to J_* \text{ in } [C^{0,\alpha}(K, \Lambda_2 \mathbb{R}^3)]^*, \tag{1.5}$$

for any compact $K \subset \Omega$. Recall that, for a radon measure $\nu \in \mathcal{M}(\Omega)$ and $m > 0$, the m dimensional density of ν at $x \in \Omega$ is defined by

$$\Theta_m(\nu, x) := \liminf_{r \to 0} \frac{\nu(B(x,r))}{r^m}.$$

Set

$$\Sigma_\mu = \{x \in \Omega : \Theta_1(\mu_*, x) > 0\}. \tag{1.6}$$

Then we have the following main theorem.

Theorem 1.1: *Let $(u_\varepsilon, A_\varepsilon)$ be the solutions to GL with (1.3). Assume h_{ex} is a given constant vector satisfying $|h_{\text{ex}}| \leqslant C|\ln \varepsilon|$. The following properties hold.*

i) The set Σ_μ is closed in Ω and 1-rectifiable. There exists a constant $\eta_0 > 0$ such that for each $x_0 \in \Sigma_\mu$,

$$\Theta_*(x_0) := \Theta_1(\mu_*, x_0) \geqslant \eta_0. \tag{1.7}$$

Moreover, for every compact set $K \subset \Omega \setminus \Sigma_\mu$,

$$|u_\varepsilon(x)| \to 1 \text{ uniformly on } K \text{ as } \varepsilon \to 0. \tag{1.8}$$

ii) The measure μ_* *can be decomposed as*

$$\mu_* = |\nabla h(x)|^2 \cdot \mathcal{H}^3 + \Theta_*(x) \cdot \mathcal{H}^1 \lfloor \Sigma_\mu , \tag{1.9}$$

where h is some harmonic function.

iii) The varifold $V := V(\Sigma_\mu, \Theta_*)$ *satisfies*

$$\vec{H}(x) = * \left(\vec{a} \wedge * \frac{dJ_*}{d\mu_*} \right) \text{ for } \mu_* - \text{a.e. } x \text{ in } \Sigma_\mu, \tag{1.10}$$

where $\vec{H}(x)$ *denotes the generalized mean curvature of V at x and is defined by*

$$\int_\Omega \operatorname{div}_{\Sigma_\mu} \vec{X} = - \int_\Omega \vec{H} \cdot \vec{X} \text{ for all } \vec{X} \in C_0^\infty(\Omega, \mathbb{R}^3),$$

$*$ *refers to the Hodge duality, and* $dJ_*/d\mu_*$ *is the Radon-Nikodym derivative of* J_* *with respect to* μ_*, $\vec{a} = \lim_{\varepsilon \to 0}(A_\varepsilon | / \ln \varepsilon |)$.

Remark 1.1: From the proof of Lemma 2.2, we have, for $h_{\text{ex}} = o(|\ln \varepsilon|)$, *that*

$$\vec{H}(x) = 0 \text{ for } \mu_* - \text{a.e. } x \text{ in } \Sigma_\mu.$$

This means that V is a stationary varifold. The limiting vortex set Σ_μ *consists of line segments. But, when* $h_{\text{ex}} = O(|\ln \varepsilon|)$, *for the solutions with the bound (1.3), vortices will be curved according to the equation* $\vec{\kappa} = \vec{a} \times \vec{\tau}$ *provided*

$$\frac{d\|J_*\|}{d\mu_*} = 1.$$

$\vec{\tau}$ *is the unit tangent vector to V and* $\vec{\kappa}$ *its curvature vector.*

Remark 1.2: The main motivation of assumption (1.3) come from Refs. 16, 17, and 3. Theorem 1.1 extend the results in Refs. 16 and 17 from two dimensions to three dimensions. We would like to mention that the method here is completely different than that in Refs. 16 and 17. Our proofs borrow many ingredients from Refs. 3–5 and 10, in particular, borrowing ideas from the proof of Theorem 3 of Ref. 5. The first important tool in our proof is monotonicity formula. In order to establish the monotonicity formula, we need to obtain the uniform estimate on A_ε *and refined estimates on Jacobian integrals, which is a conjecture by Bourgain, Brezis, and Mironescu (Ref. 7), were just proven by Bethuel, Orlandi, and Smets (Ref. 6). This step is different than that in Theorem 3 of Ref. 5. The second important ingredient is the* η*-compactness theorem.*

Remark 1.3: In Ref. 11, Rivière studied the global minimizer of the three-dimensional Higgs model. Theorem 1.1 can be extended to the critical points of that model which satisfy (1.3).

We organize the paper as follows: In Sec. II, we derive the monotonicity formula and η-compactness theorem. In Sec. III, we prove the main Theorem 1.1.

II. THE MONOTONICITY FORMULA AND η-COMPACTNESS THEOREM

In this section, we will derive the monotonicity formula of the energy. First of all, we establish some basic estimates on A_ε. By maximum principles, we have the following lemmas (see Ref. 11).

Lemma 2.1: Let $(u_\varepsilon, A_\varepsilon)$ *be the solutions to GL. We have*

$$\|u_\varepsilon\|_{L^\infty(\Omega)} \leqslant 1, \quad \|\nabla_A u\|_{L^\infty(\Omega)} \leqslant \frac{C}{\varepsilon}. \tag{2.1}$$

Now we establish an estimate of A_ε.

Lemma 2.2: Let $(u_\varepsilon, A_\varepsilon)$ *be the solutions to GL with assumption (1.3). We have*

$$\|A_\varepsilon\|_{w^{1,6}(\Omega)} \leqslant C_0|\ln \varepsilon|. \tag{2.2}$$

In particular,

$$\|A_\varepsilon\|_{C^\alpha(\bar{\Omega})} \leqslant C_0|\ln\ \varepsilon| \tag{2.3}$$

where $0<\alpha<1$ *and* C_0 *is independent of* ε.

Proof: It is well known that for the given h_{ex}, there exists a unique smooth vector field F on Ω such that

$$\operatorname{curl} F = h_{\text{ex}}, \quad \operatorname{div} F = 0 \text{ in } \Omega, \quad F\cdot\nu = 0 \text{ on } \partial\Omega. \tag{2.4}$$

From GL, we have

$$\operatorname{curl}^2(A-F) + |u|^2A = (iu, \nabla u) \text{ in } \Omega, \tag{2.5}$$

$$\operatorname{curl}(A-F)\times\nu = 0 \text{ on } \partial\Omega. \tag{2.6}$$

We see that $\|\operatorname{curl}A\|_{L^2(\Omega)}$ is an equivalent norm of space

$$H(\Omega,\operatorname{div}) = \{A\in H^1(\Omega,\mathbb{R}^2):\operatorname{div}A = 0 \text{ in } \Omega, A\cdot\nu = 0 \text{ on } \partial\Omega\}.$$

Multiplying (2.5) by $A-F$, integrating by parts, then using Lemma 2.1, (1.3), and Young's inequality, we obtain

$$\|A-F\|^2_{H^1(\Omega)} \leqslant C|\ln\varepsilon| + \|F\|^2_{L^2(\Omega)}. \tag{2.7}$$

So,

$$\|A\|^2_{H^1(\Omega)} \leqslant C|\ln\varepsilon| + \|F\|^2_{H^1(\Omega)} \leqslant C|\ln\varepsilon| + C\|\operatorname{curl}F\|^2_{L^2(\Omega)} \leqslant C|\ln\varepsilon|^2. \tag{2.8}$$

Since $\operatorname{div}A=0$ in Ω, we have, from GL, that

$$-\Delta A + |u|^2A = (iu, \nabla u) \text{ in } \Omega. \tag{2.9}$$

By elliptic estimate, we have the following interior estimate:

$$\|A\|^2_{H^2(K)} \leqslant C(K)(|\ln\varepsilon| + \|A\|^2_{H^1(\Omega)}) \leqslant C(K)|\ln\varepsilon|^2, \ \forall\, K\subset\subset\Omega. \tag{2.10}$$

To derive the boundary estimates, we shall straighten a portion of boundary and study the equation in the half ball B_R^+. Now, we fix a point x^0 on $\partial\Omega$. If there exists an R_0 such that $\Omega\cap B_{R_0}(x_0)\subset\{(x_1,x_2,x_3):x_3>0\}$, $\Gamma_{R_0}=\partial\Omega\cap B_{R_0}(x_0)\subset\{(x_1,x_2,0)\}$, then we have the boundary conditions

$$\partial_3A_1 = h^2_{\text{ex}}, \quad \partial_3A_2 = -h^1_{\text{ex}}, \quad A_3 = 0 \text{ on } \Gamma_{R_0}.$$

Combining this relation with (2.9), by the elliptic estimates, we have the following boundary estimate:

$$\|A\|_{H^2(B^+_{R_0/2})} \leqslant C[\|\nabla_A u\|_{L^2(\Omega)} + \|A\|_{H^1(\Omega)} + \|h_{\text{ex}}\|_{H^1(\Gamma_{R_0})}] \leqslant C|\ln\varepsilon|.$$

In general case, we will straighten a portion of $\partial\Omega$ around x_0. For simplicity, assume that $x^0=0$ and express a portion of $\partial\Omega$ around 0 by $r=r(y_1,y_2)$, $r(0,0)=0$. Let ∂_j denote ∂_{y_j}. Denote $r_i=\partial_i r$, $n=r_1\times r_2/|r_1\times r_2|$ and $g_{ij}=r_i\cdot r_j$. Choosing (y_1,y_2) as the normal coordinates of the portion of surface and ν to be the inward normal vector to $\partial\Omega$, we have $g_{ij}(0,0)=\delta_{ij}$. Denote $e_1=r_1$, $e_2=r_2$, and $e_3=n$. We will choose the isothermal coordinates (y_1,y_2). Denote k_1 and k_2 the principle curvature. Now, define a map

$$x = \mathcal{F}(y) = r(y_1, y_2) + y_3 n(y_1, y_2), \tag{2.11}$$

which is defined on some B_R^+ and straightens a portion of $\partial\Omega$ around x^0. We compute $\partial_j \mathcal{F}$ and $G_{ij} = \partial_i \mathcal{F} \cdot \partial_j \mathcal{F}$:

$$\partial_1 \mathcal{F} = [1 - k_1 y_3] r_1, \quad \partial_2 \mathcal{F} = [1 - k_2 y_3] r_2, \quad \partial_3 \mathcal{F} = n,$$

$$G_{11} = g_{11}[1 - k_1 y_3]^2,$$

$$G_{22} = g_{22}[1 - k_2 y_3]^2,$$

$$G_{33} = 1,$$

$$G_{12} = G_{13} = G_{23} = 0.$$

Let G^{ij} denote the element of the inverse of the matrix (G_{ij}). Then

$$G^{11} = 1/G_{11}, \quad G^{22} = 1/G_{22}, \quad G^{33} = 1, \quad G^{12} = G^{13} = G^{23} = 0.$$

Given a function u and a vector A, we write them in the new variables as follows:

$$\tilde{u}(y) = u(\mathcal{F}(y)), \tag{2.12}$$

$$\tilde{A}(y) = A(\mathcal{F}(y)) = \sum_{j=1}^{3} G^{jj} a_j \partial_j \mathcal{F}(y), \tag{2.13}$$

where

$$a_j = A(\mathcal{F}(y)) \cdot \partial_j \mathcal{F}(y).$$

Now, let $g_1 = 1 - y_3 k_1$, $g_2 = 1 - y_3 k_2$, then the differential operator in the new coordinates can be defined as

$$D_{\tilde{A}} W = (D_{\tilde{A}_1} W, D_{\tilde{A}_2} W, D_{\tilde{A}_3} W), \tag{2.14}$$

where $D_{\tilde{A}_1} W = (1/g_1)(\partial_1 - i\tilde{A}_1) W$, $D_{\tilde{A}_2} W = (1/g_2)(\partial_2 - i\tilde{A}_2) W$ and $D_{\tilde{A}_3} W = (\partial_3 - i\tilde{A}_3) w$. Then we have the following equations for $\tilde{A}$:

$$\frac{1}{G_{11}}(\partial_1^2 \tilde{A}) + \frac{1}{G_{22}}(\partial_2^2 \tilde{A}) + \partial_3^2 \tilde{A} = Y(\tilde{A}, \partial_1 \tilde{A}, \partial_2 \tilde{A}, \partial_3 \tilde{A}) + (i\tilde{u}, D_{\tilde{A}} \tilde{u}) \text{ in } B_R^+, \tag{2.15}$$

$$\partial_3 \tilde{A}_1 = h_{\text{ex}} g_{22}^{-1} e_2, \quad \partial_3 \tilde{A}_2 = -h_{\text{ex}} g_{11}^{-1} e_1, \quad \tilde{A}_3 = 0 \text{ on } \Gamma_R, \tag{2.16}$$

where $\Gamma_R = \{(y_1, y_2, 0) : |y_1|^2 + |y_2|^2 \leqslant R^2\}$, $Y(\tilde{A}, \partial_1 \tilde{A}, \partial_2 \tilde{A}, \partial_3 \tilde{A})$ denotes linear combination of these factors.

From the elliptic estimate to (2.15), (2.16), and (2.8), we have

$$\|\tilde{A}\|_{H^2(B_{R/2}^+)} \leqslant C(|\ln \varepsilon| + \|h_{\text{ex}} g_{11}^{-1} e_1\|_{H^1(\Gamma_R)} + \|h_{\text{ex}} g_{22}^{-1} e_2\|_{H^1(\Gamma_R)}) \leqslant C|\ln\ \varepsilon|. \tag{2.17}$$

From (2.10) and (2.17), we have

$$\|A\|_{H^2(\Omega)} \leqslant C|\ln \varepsilon|. \tag{2.18}$$

By Sobolev embedding, we have

$$\|A\|_{W^{1,6}(\Omega)} \leqslant C|\ln \varepsilon|, \quad \|A\|_{C^{\alpha}(\bar{\Omega})} \leqslant C|\ln \varepsilon|, \tag{2.19}$$

where $0<\alpha<1$. The proof of Lemma 2.2 is completed. □

For $x_0 \in \Omega$ and $r>0$ such that $B_r(x_0) \subset \Omega$, define

$$\widetilde{E}_{\varepsilon}(u_{\varepsilon},x_0,r) := \frac{1}{r}E_{\varepsilon}(u_{\varepsilon},x_0,r) \equiv \frac{1}{r}\int_{B_r(x_0)}\left[\frac{1}{2}|\nabla u_{\varepsilon}|^2 + \frac{(b_{\varepsilon}(x)-|u_{\varepsilon}|^2)^2}{4\varepsilon}\right]. \tag{2.20}$$

When this will not lead to a confusion, we will also denote it $\widetilde{E}_{\varepsilon}(x_0,r)$ or even $\widetilde{E}_{\varepsilon}(r)$. A computation directly gives the following (see Refs. 3 and 5).

Lemma 2.3: Let $(u_{\varepsilon},A_{\varepsilon})$ satisfy GL and $B_R(x_0)\subset\Omega$, then for $0<r<R$,

$$\frac{\mathrm{d}}{\mathrm{d}r}(\widetilde{E}_{\varepsilon}(x_0,r)) = \frac{1}{r}\int_{\partial B_r(x_0)}\left|\frac{\partial u_{\varepsilon}}{\partial n}\right|^2 + \frac{1}{r^2}\int_{B_r(x_0)}\frac{(b_{\varepsilon}(x)-|u_{\varepsilon}|^2)}{2\varepsilon^2} - \frac{2}{r^2}\int_{B_r(x_0)}\langle Ju_{\varepsilon},A_{\varepsilon i}\xi_i(x-x_0)\rangle$$
$$-\frac{1}{2r^2}\int_{B_r(x_0)}((x-x_0)\cdot\nabla|A_{\varepsilon}|^2)(b_{\varepsilon}-|u_{\varepsilon}|^2), \tag{2.21}$$

where $\xi_j(x)=\Sigma_{i\neq j}x_i\mathrm{d}x_j\wedge\mathrm{d}x_i$, for $j=1,2,3$.

Lemma 2.4: There exists $C>0$ which is independent of ε such that for $B_R(x_0)\subset\Omega$,

$$\Lambda = C(C_0+1)|\ln\varepsilon| \tag{2.22}$$

and for any $(u_{\varepsilon},A_{\varepsilon})$ satisfying GL with (1.3), we have

$$\frac{\mathrm{d}}{\mathrm{d}r}(\exp(\Lambda r)(\widetilde{E}_{\varepsilon}(x_0,r)+CC_0\varepsilon^2|\ln\varepsilon|^3)) \geqslant \frac{1}{r}\int_{\partial B_r}\left|\frac{\partial u_{\varepsilon}}{\partial n}\right|^2 + \frac{1}{r^2}\int_{B_r}\frac{(b_{\varepsilon}(x)-|u_{\varepsilon}|^2)^2}{4\varepsilon^2} \geqslant 0 \tag{2.23}$$

for $0<r<R$. In particular, $\exp(\Lambda r)(\widetilde{E}_{\varepsilon}(x_0,r)+C\varepsilon^2|\ln\varepsilon|^3)$ is increasing.

Proof: From Lemma 2.3, we need to estimate the last two terms in (2.21). The conclusion follows by using Lemma 2.2 immediately. □

In order to establish the monotonicity formula on larger balls, refined estimates on Jacobian integrals are needed because we only have C^{α} estimate on A_{ε}.

Lemma 2.5: (Refs. 6 and 7) Let $w\in H^1_{\mathrm{loc}}(\Omega,\mathbb{C})$, $\varphi\in C_0^{\infty}(\Omega,\Lambda^1\mathbb{R}^3)$ and $K:=\mathrm{supp}\,\varphi$. Moreover, assume that there exists $q>6$ such that w verifies

$$\|w\|_{L^q(\Omega)} \leqslant C_q. \tag{2.24}$$

Then,

$$\left|\int_{\Omega}\langle Jw,\varphi\rangle\right| \leqslant C\left(\frac{\int_K e_{\varepsilon}(w)}{|\ln\varepsilon|} + \varepsilon^{\alpha_0}\left(\int_K e_{\varepsilon}(w)\right)^{\alpha_1}\right)\|\varphi\|_{\dot{W}^{1,3}(\Omega)}, \tag{2.25}$$

for some constants $C>0$ and $0<\alpha_0<1, 0<\alpha_1<1$, depending only on q, C_q.

Now we prove the following monotonicity formula.

Proposition 2.1: There exist $C>0$ and $\beta>0$ depending not on ε such that for $B_R(x_0)\subset\Omega$ and for any $(u_{\varepsilon},A_{\varepsilon})$ satisfying GL with (1.3), we have

$$\widetilde{E}_{\varepsilon}(x_0,\theta r) \leqslant C(\widetilde{E}_{\varepsilon}(x_0,r)+\varepsilon^{\beta}) \tag{2.26}$$

for $0<\theta<1/2$ and $0<r<\min(R,2/(C_0+1))$.

Proof: We follow closely the lines of Lemma A.6 in Ref. 5 and drop off the subscript ε for simplicity.

Step 1: We define a smooth cut-off function f by

$$f(r,a)=\begin{cases}1 & \text{if a} \leqslant \text{r}\\ 2-a/r & \text{if r} \leqslant \text{a} \leqslant \text{2r}\\ 0 & \text{if } a \geqslant 2r,\end{cases} \tag{2.27}$$

where $r>0$. For $x_0 \in \Omega$ and $r>0$ such that $B_{2r}(x_0) \subset \Omega$, set

$$\overline{E_\varepsilon}(x_0,r) := \frac{1}{r}\int_{B_{2r}(x_0)} e_\varepsilon(u) f(r,|x-x_0|)\mathrm{d}x, \tag{2.28}$$

then for $0<r<R/2$

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}r}(\overline{E_\varepsilon}(x_0,r)) = {}& \frac{1}{r}\int_1^2 t\int_{\partial B_{tr}(x_0)}\left|\frac{\partial u}{\partial n}\right|^2 + \frac{1}{r^2}\int_{B_{2r}(x_0)}\frac{(b_\varepsilon-|u|^2)^2}{2\varepsilon^2} f(r,|x-x_0|)\\ & -\frac{1}{r^2}\int_{B_{2r}(x_0)}\left\langle Ju, 2\sum_i A_i(x)\xi_i(x-x_0) f(r,|x-x_0|)\right\rangle - \frac{1}{2r^2}\int_{B_{2r}(x_0)}((x-x_0)\cdot\nabla|A|^2)\\ & \times(b_\varepsilon(x)-|u|^2) f(r,|x-x_0|).\end{aligned} \tag{2.29}$$

Step 2: There exists a constant $C>0$ such that for $B_{2r}(x_0)\subset\Omega$,

$$\overline{E_\varepsilon}(x_0,\theta r) \leqslant CC_0\exp(CC_0 r)\left(\overline{E_\varepsilon}(x_0,r)+\frac{\varepsilon^{\alpha_0}|\ln\varepsilon|^{\alpha_1+1}}{\theta r}+\varepsilon^2|\ln\varepsilon|^4\right) \tag{2.30}$$

for $0<\theta\leqslant 1$. In fact, we need to estimate the last two terms in (2.29). We may assume $x_0=0$. The second one is treated as before,

$$\left|\frac{1}{2r^2}\int_{B_{2r}(x_0)}((x-x_0)\cdot\nabla|A|^2)(b_\varepsilon(x)-|u|^2) f(r,|x-x_0|)\right| \leqslant \overline{E_\varepsilon}(2r)+CC_0\varepsilon^2|\ln\varepsilon|^4. \tag{2.31}$$

For the first term, note that the two-form

$$\varphi(x) := \sum_i 2A_i(x)\xi_i(x) f(r,|x|) \tag{2.32}$$

satisfies the estimates, using Lemma 2.2,

$$\|\varphi\|_{\dot{W}^{1,3}(B_{2r})} \leqslant CC_0|\ln\varepsilon| r. \tag{2.33}$$

Hence, using Lemma 2.5, we have

$$\frac{1}{r^2}\int_{B_{2r}(x_0)}\left\langle Ju, 2\sum_i A_i(x)\xi_i(x-x_0) f(r,|x-x_0|)\right\rangle \leqslant CC_0\overline{E_\varepsilon}(2r)+\frac{CC_0}{r}\varepsilon^{\alpha_0}|\ln\varepsilon|^{\alpha_1+1}. \tag{2.34}$$

Combining (2.31), (2.34), and (2.29), we have

$$\frac{\mathrm{d}}{\mathrm{d}r}(\overline{E_\varepsilon}(x_0,r)) \geqslant -CC_0\overline{E_\varepsilon}(2r)-CC_0\left(\varepsilon^2|\ln\varepsilon|^4+\frac{1}{r}\varepsilon^{\alpha_0}|\ln\varepsilon|^{\alpha_1+1}\right). \tag{2.35}$$

(2.30) then follows from a version of Gronwall's lemma given in Lemma A.7, Ref. 5.

Step 3: First, consider the case

$$\theta r < p := (|\ln\varepsilon|(C_0+1))^{-1} < r/2. \tag{2.36}$$

Using Lemma 2.4, we obtain that

$$\tilde{E}_\varepsilon(\theta r) \leqslant C(\tilde{E}_\varepsilon(\rho) + \varepsilon^2|\ln \varepsilon|^3). \tag{2.37}$$

Next, using (2.30) and the definition of ρ,

$$\tilde{E}_\varepsilon(\rho) \leqslant \overline{E}_\varepsilon(\rho) \leqslant C\left(\overline{E}_\varepsilon(r/2) + \frac{\varepsilon^{\alpha_0}|\ln \varepsilon|^{\alpha_1+1}}{\rho} + |\ln \varepsilon|^4\varepsilon^2\right) \leqslant C(\tilde{E}_\varepsilon(r) + \varepsilon^{\alpha_0}|\ln \varepsilon|^{\alpha_1+2} + \varepsilon^2|\ln \varepsilon|^4). \tag{2.38}$$

Letting $\beta = \alpha_0/2$ and combining (2.37) and (2.38), we get the desired (2.26). In the case $\theta r \geqslant \rho$ (respectively, $r \leqslant \rho$), it suffices to use (2.30) (respectively, Lemma 2.4) to obtain (2.26) directly. This completes the proof of Proposition 2.1. □

Using Lemma 2.2 and Proposition 2.1, the same argument of Theorem 2 in Ref. 5 gives the following η-compactness theorem, which bounds $|u_\varepsilon|$ away from zero as soon as the local energy is bounded by $\eta|\ln \varepsilon|$ with η small.

Theorem 2.6: *(η-compactness theorem) Let $(u_\varepsilon, A_\varepsilon)$ be a solution of GL with (1.3) and $\sigma > 0$ be given. Then, there exist $\eta > 0$ and $\varepsilon_0 > 0$, depending only on $\sigma > 0$, C_0 such that if $x_0 \in \Omega$, $\varepsilon \leqslant \varepsilon_0$, $\sqrt{\varepsilon} \leqslant r \leqslant 1/(1+C_0)$, $B_{2r}(x_0) \subset \Omega$, and*

$$\tilde{E}_\varepsilon(x_0, r) \leqslant \eta|\ln \varepsilon|, \tag{2.39}$$

then

$$|u_\varepsilon(x_0)| \geqslant 1 - \sigma. \tag{2.40}$$

Corollary 2.7: Under the assumption of Theorem 2.6. Let $0 < \sigma < 1$, $\eta > 0$, and $\varepsilon_0 > 0$ be given by Theorem 2.6. Let $x_0 \in \Omega$ and $r > 0$ such that $B(x_0, 2r) \subset \Omega$ and $4\sqrt{\varepsilon} < r < 4/(1+C_0)$. Then, for $\varepsilon < \varepsilon_0$, if

$$\tilde{E}_\varepsilon(x_0, r) \leqslant \tfrac{1}{4}\eta|\ln \varepsilon| \tag{2.41}$$

we have

$$|1 - |u(x)|| \leqslant \sigma \quad \forall\, x \in B(x_0, 3r/4). \tag{2.42}$$

III. PROOF OF THEOREM 1.1

In this section we will prove Theorem 1.1. Recall that, by Lemma 2.2 and assumption (1.3),

$$E_\varepsilon(u_\varepsilon) = \int_\Omega e_\varepsilon(u_\varepsilon) \leqslant (2M_0 + 1)|\ln \varepsilon|, \tag{3.1}$$

where $e_\varepsilon(u_\varepsilon) = (1/2)[|\nabla u_\varepsilon|^2 + (1/2\varepsilon^2)(b_\varepsilon - |u_\varepsilon|^2)^2]$. By (3.1), we have

$$\mu_\varepsilon := \frac{e_\varepsilon(u_\varepsilon)}{|\ln \varepsilon|}\mathrm{d}x$$

is bounded. Therefore, up to a subsequence we may assume that

$$\mu_\varepsilon \rightharpoonup \mu_* \text{ as measures.} \tag{3.2}$$

We set

$$\Sigma_\mu = \{x \in \Omega : \Theta_1(\mu_*, x) > 0\}, \tag{3.3}$$

where

$$\Theta_1(\mu_*,x) := \liminf_{r\to 0} \frac{\mu_*(B(x,r))}{r}.$$

Lemma 3.1: Let $\Theta_*(x_0) := \Theta_1(\mu_*,x_0)$. *Then, there exists a constant* $\eta_0>0$ *such that if* $x_0 \in \Sigma_\mu$, *we have*

$$\Theta_*(x_0) \geqslant \eta_0.$$

Proof: Let $\eta_0=\frac{1}{4}\eta$, where $\eta>0$ and $\varepsilon_0>0$ are given by Theorem 2.6. The conclusion follows by using contradiction argument as in the proof of Lemma B.11 in Ref. 5. □

By the upper-semicontinuity of Θ_*, we have the following lemma.

Lemma 3.2: Σ_μ *is closed in* Ω.

From Lemma 3.1 and Corollary 2.7 we have the following uniformly convergence result away from Σ_μ.

Lemma 3.3: Let $K\subset\Omega\backslash\Sigma_\mu$ *be any compact subset. For any* $\sigma>0$, *there exists a constant* $\varepsilon_2>0$ *depending on K,* σ *such that, for* $\varepsilon<\varepsilon_2$,

$$|1-|u|| \leqslant \sigma \text{ on } K. \tag{3.4}$$

Lemma 3.4: We have

$$\mu_* = g(x)\mathcal{H}^3 + h(x)\mathcal{H}^1\lfloor\Sigma_\mu\,,$$

where $g,h\in L^\infty_{\mathrm{loc}}(\Omega)$ *and*

$$\eta_0 \leqslant \Theta_*(x) \leqslant h(x) \leqslant \Theta^*(x) := \limsup_{r\to 0} \frac{\mu_*(B(x,r))}{r} \leqslant CM_0.$$

Proof: Since Σ_μ is closed in Ω, hence Σ_μ is measurable. We have

$$\mu_* = \mu_*\lfloor\Sigma_\mu + \mu_*\lfloor(\Omega\backslash\Sigma_\mu)\,.$$

By Corollary 2.7, the same argument of Theorem VIII.1 in Ref. 3 yields

$$\mathcal{H}^1(\Sigma_\mu) \leqslant CM_0.$$

By the monotonicity formula of Proposition 2.1, we have that for any $x\in\Omega$,

$$\Theta^*(x) := \limsup_{r\to 0} \frac{\mu_*(B(x,r))}{r} \leqslant CM_0.$$

According to the Radon–Nikodym theorem, we obtain

$$\mu_*\lfloor\Sigma_\mu = h(x)\ \mathcal{H}^1\lfloor\mu_* \tag{3.5}$$

for $\Theta_*\leqslant h(x)\leqslant\Theta^*$. Let $x_0\in\Omega\backslash\Sigma_\mu$, $r>0$ such that $\overline{B}(x_0,2r)\subset\Omega\backslash\Sigma_\mu$. By Lemma 3.3, we obtain

$$\sigma := \|1-|u|\|_{L^\infty(\overline{B}(x_0,2r))} = o(1) \text{ as } \varepsilon\to 0.$$

It is easy to show that

$$E_\varepsilon\left(x_0,\tfrac{3}{4}r\delta\right) \leqslant C(\delta^3+\sigma+C_0\varepsilon^2|\ln\varepsilon|+\varepsilon)E_\varepsilon(x_0,r) + CC_0\varepsilon|\ln\varepsilon|^2. \tag{3.6}$$

Note that $\sigma=\sigma(\varepsilon)=o(1)$. Dividing both sides of (3.6) by $|\ln\varepsilon|$ and sending $\varepsilon\to 0$ we obtain

$$\mu_*\left(B\left(x_0,\tfrac{3}{4}r\delta\right)\right) \leqslant C\delta^3\mu_*(B(x_0,r)),$$

which implies that $\mu_*\lfloor(\Omega\backslash\Sigma_\mu)$ is absolutely continuous with respect to the Lebesgue measure, and by the Radon–Nikodym theorem again we obtain

$$\mu_* = g(x)\mathcal{H}^3 + h(x)\mathcal{H}^1\lfloor\Sigma_\mu \tag{3.7}$$

for some locally bounded function g. The proof of Lemma 3.4 is completed. □

The same proof of Theorem A.(iv) in Ref. 4 gives

Lemma 3.5: We have

$$g(x) = |\nabla h_*(x)|^2 \text{a.e. in } \Omega,$$

where h_* is some harmonic function.

Lemma 3.6: Σ_μ is rectifiable,

$$\vec{H}(x) = *\left(\vec{a} \wedge *\frac{\mathrm{d}J_*}{\mathrm{d}\mu_*}\right)$$

for μ_*-a.e. x in Σ_μ.

Proof: Let $\vec{X} \in \mathcal{D}(\Omega, \mathbb{R}^3)$ be a smooth vector field. Then,

$$\frac{1}{|\ln\varepsilon|}\int_\Omega \left(e_\varepsilon(u)\delta_{ij} - \frac{\partial u}{\partial x_i}\frac{\partial u}{\partial x_j}\right)\frac{\partial X^i}{\partial x_j} = -\int_\Omega \left\langle *\left(\frac{2A_\varepsilon}{|\ln\varepsilon|} \wedge *Ju\right), \vec{X}\right\rangle + \frac{1}{2|\ln\varepsilon|}\int_\Omega (b_\varepsilon - |u|^2)\vec{X}\cdot\nabla|A_\varepsilon|^2, \tag{3.8}$$

where $*$ refers to the Hodge duality. Let

$$\alpha_\varepsilon^{ij} := \frac{1}{|\ln\varepsilon|}\left(e_\varepsilon(u)\delta_{ij} - \frac{\partial u}{\partial x_i}\frac{\partial u}{\partial x_j}\right).$$

$(\alpha_\varepsilon^{ij})$ is a symmetric matrix with trace larger than μ_ε. Hence, its eigenvalues are less or equal to μ_ε. Note that

$$|\alpha_\varepsilon^{ij}| \leqslant 3\mu_\varepsilon. \tag{3.9}$$

Passing to a subsequent, we may assume that

$$\alpha_\varepsilon^{ij} \to \alpha_*^{ij} \text{ in the sense of measures.}$$

By (3.9), we obtain $|\alpha_*^{ij}| \leqslant 3\mu_*$. Therefore,

$$\alpha_*^{ij}(x) = A^{ij}(x)\mu_* \text{ for } \mu_* - \text{a.e. } x \in \Omega,$$

where the matrix $A^{ij}(x)$ is symmetric and its trace equal to 1 and eigenvalues less or equal to 1. From (3.9), we also have

$$A^{ij} \geqslant -3\delta^{ij} \text{ for } \mu_* - a\,.\,e\,.\ x \in \Omega. \tag{3.10}$$

Now we deal with the last term of the right-hand side of (3.8). By Lemma 2.2, we have

$$\left|\frac{1}{2}\int_\Omega (b_\varepsilon - |u|^2)\frac{\vec{X}\cdot\nabla|A|^2}{|\ln\varepsilon|}\right| \leqslant C\varepsilon\|A\|_{L^\infty}\left(\int_\Omega |\nabla A|^2\right)^{1/2}\frac{1}{|\ln\varepsilon|}\left(\int_\Omega \frac{b_\varepsilon - |u|^2}{\varepsilon^2}\right)^{1/2}$$
$$\leqslant C\varepsilon|\ln\varepsilon| \to 0 \text{ as } \varepsilon \to 0. \tag{3.11}$$

On the other hand, from Lemma 2.2, passing to a subsequence, there exists an $\vec{a}$ such that

$$\frac{A_\varepsilon}{|\ln\varepsilon|} \to \vec{a} \text{ in } C^\alpha(\overline{\Omega}) \text{ as } \varepsilon \to 0. \tag{3.12}$$

Therefore, passing to the limit in (3.8), we have

$$\int_\Omega A^{ij}(x)\frac{\partial X^i}{\partial x_j}\mathrm{d}\mu_*(x) = -\int_\Omega \left\langle *\left(\vec{a}\wedge *\frac{dJ_*}{d\mu_*}\right),\vec{X}\right\rangle \mathrm{d}\mu_*. \tag{3.13}$$

We decompose the right-hand side of (3.13) as

$$\int_\Omega A^{ij}(x)\frac{\partial X^i}{\partial x_j}\mathrm{d}\mu_*(x) = \int_\Omega A^{ij}(x)\frac{\partial X^i}{\partial x_j}\mathrm{d}\mu_*(x)\lfloor\Sigma_\mu + \int_\Omega \left(\frac{|\nabla h_*|^2}{2}\delta_{ij} - \frac{\partial h_*}{\partial x_i}\frac{\partial h_*}{\partial x_j}\right)\frac{\partial X^i}{\partial x_j}\mathrm{d}x. \tag{3.14}$$

Since $\Delta h_* = 0$, we have

$$\int_\Omega \left(\frac{|\nabla h_*|^2}{2}\delta_{ij} - \frac{\partial h_*}{\partial x_i}\frac{\partial h_*}{\partial x_j}\right)\frac{\partial X^i}{\partial x_j}\mathrm{d}x = 0. \tag{3.15}$$

From (3.13) and (3.15), we obtain

$$\int_\Omega A^{ij}(x)\frac{\partial X^i}{\partial x_j}\mathrm{d}\mu_*(x)\lfloor\Sigma_\mu = -\int_\Omega \left\langle *\left(\vec{a}\wedge *\frac{dJ_*}{d\mu_*}\right),\vec{X}\right\rangle \mathrm{d}\mu_*\lfloor\Sigma_\mu . \tag{3.16}$$

Since $\vec{X}$ was arbitrary, (3.16) implies that the generalized 1-varifold (defined in Ref. 1) $\tilde{V} := \delta_{A^{ij}(x)}\mu_*\lfloor\Sigma_\mu$ has a first variation. By Theorem 3.8(c) in Ref. 1 we obtain that $\tilde{V}$ is a real rectifiable 1-varifold. In particular, Σ_μ is rectifiable which implies

$$\Theta_*(x) = \Theta^*(x)\ \ \mu_* - a.e.\ \ x\in\Sigma_\mu,$$

thus,

$$\mu_* = g(x)\mathcal{H}^3 + \Theta_*(x)\mathcal{H}^1\lfloor\Sigma_\mu, \quad \tilde{V} = V(\Sigma_\mu,\Theta_*). \tag{3.17}$$

By (3.16), we also have

$$\vec{H} = *\left(\vec{a}\wedge *\frac{\mathrm{d}J_*}{\mathrm{d}\mu_*}\right) \text{ for } \mu_* - a.e.\ \ x\in\Sigma_\mu.$$

The proof of Theorem 1.1 is now completed. □

Strong-electric-field eigenvalue asymptotics for the Iwatsuka model

Shin-ichi Shirai[a)]
Research Institute for Mathematical Sciences, Kyoto University, Sakyo, Kyoto 606-8502, Japan

(Received 6 May 2004; accepted 3 March 2005; published online 5 May 2005)

We consider the two-dimensional Schrödinger operator, $H_g(b)=-\partial^2/\partial x^2+[(1/\sqrt{-1})(\partial/\partial y)-b(x)]^2-gV(x,y)$, where V is a non-negative scalar potential decaying at infinity like $(1+|x|+|y|)^{-m}$, and $(0,b(x))$ is a magnetic vector potential. Here, b is of the form $b(x)=\int_0^x B(t)\mathrm{d}t$ and the magnetic field B is assumed to be positive, bounded, and monotonically increasing on $\mathbf{R}$ (the Iwatsuka model). Following the argument as in Refs. 15, 16, and 17 [Raikov, G. D., Lett. Math. Phys., **21**, 41–49 (1991); Raikov, G. D, Commun. Math. Phys., **155**, 415–428 (1993); Raikov, G. D. Asymptotic Anal., **16**, 87–89 (1998)], we obtain the asymptotics of the number of discrete spectra of $H_g(b)$ crossing a real number λ in the gap of the essential spectrum as the coupling constant g tends to $\pm\infty$, respectively. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897844]

I. INTRODUCTION

We consider the two-dimensional Schrödinger operator with electromagnetic field

$$H_g(b)=-\frac{\partial^2}{\partial x^2}+\left(\frac{1}{\sqrt{-1}}\frac{\partial}{\partial y}-b(x)\right)^2-gV(x,y).$$

Here, $V(x,y)$ is a scalar potential decaying at infinity and $(0,b(x))$ is a magnetic vector potential given by the form $b(x)=\int_0^x B(t)\mathrm{d}t$ for a positive magnetic field B, which depends only on the variable x of $(x,y)\in\mathbf{R}^2$.

The purpose of this paper is to investigate the number of discrete spectra of $H_g(b)$ crossing a real number λ in the gap of the essential spectrum as the coupling constant g tends to $\pm\infty$, respectively (the precise formulation is given below).

We fix some notations. We denote the set of all integers by $\mathbf{Z}$ and denote the set of *non-negative* integers by $\mathbf{N}$. We denote the cardinal number of set A by $\sharp A$. We denote both $\partial/\partial x$ and $\mathrm{d}/\mathrm{d}x$ by ∂_x, etc. We denote by $C^k(\Omega,\Omega')$ the set of all Ω'-valued, C^k-functions on Ω, and by $C_0^\infty(\Omega)$ the set of all compactly supported, smooth functions on Ω. We use $|\cdot|$ to denote the Euclidean norms and use the notations $\langle z\rangle=(1+|z|^2)^{1/2}$ for any $z\in\mathbf{R}^n$ and $\langle x;y\rangle=(1+|x|^2+|y|^2)^{1/2}$ for any $(x,y)\in\mathbf{R}^n\times\mathbf{R}^m$. We denote by $Q(z,r)$ the open cube of radius r, centered at z, with sides parallel to the coordinate axes. We denote by $\mathrm{Spec}(A)$ the spectrum of any self-adjoint operator A, and by $N(\alpha<A<\beta)$ the dimension of the range of the spectral projection for A on the interval (α,β). The notations $N(A>\alpha)$, $N(A<\beta)$, etc., are defined similarly.

To formulate our results we make the following assumptions for the magnetic field B and the electric potential V.

(B.1) The magnetic field B is a real-valued, smooth and monotonically increasing function on $\mathbf{R}$. Moreover, there exist positive numbers $B_\pm$ such that $B_-<B_+$, and $\lim_{x\to\pm\infty}B(x)=B_\pm$ hold, respectively.

[a)]Electronic mail: qzy05360@nifty.ne.jp

(B.2) In addition to (*B*.1), there exists a positive number M such that, for any multi-index α, the estimate $|\partial_x^\alpha(B(x)-B_\pm)| \leqslant C_\alpha \langle x\rangle^{-M}$ holds for $\pm x \geqslant 0$, respectively. Here, the constant C_α is independent of x, and $B_\pm$ are as in (B.1).

(V.1) The scalar potential V is a non-negative smooth function on $\mathbf{R}^2$. Moreover, there exists a positive number m such that, for any multi-index α, the estimate $|\partial_z^\alpha V(z)| \leqslant C_\alpha \langle z\rangle^{-m-|\alpha|}$ holds for all $z \in \mathbf{R}^2$. Here, the constant C_α is independent of z.

(V.2) There exists a positive number C such that the estimate $V(z) \geqslant C\langle z\rangle^{-m}$ holds for all $z \in \mathbf{R}^2$.

(V.3) Let $(r,\omega) \in [0,\infty)\times S^1$ be the polar coordinates of $z \in \mathbf{R}^2$, i.e., $r=|z|$ and $\omega = z/|z|$. There exists a measurable, bounded and positive function v on the unit circle S^1 such that $\lim_{r\to\infty} r^m V(z) = v(\omega)$ holds for any $\omega = z/|z| \in S^1$.

(V.4) In addition to (*V*.1), we have the limit

$$\lim_{\varepsilon\downarrow 0} \limsup_{\mu\downarrow 0} \mu^{2/m} \operatorname{Vol}\{z \in \mathbf{R}^2 | (1-\varepsilon)\mu < V(z) < (1+\varepsilon)\mu\} = 0.$$

Here, "Vol" stands for the Euclidean volume, and m is as in (*V*.1).

Under the assumptions (*B*.1) and (*V*.1), the operator $H_g(b)$ is essentially self-adjoint on $C_0^\infty(\mathbf{R}^2)$ for any $g \in \mathbf{R}$ [see Avron, Herbst, and Simon (1978)]. In what follows we identify any closable operator with its operator closure if there is no fear of confusion. Iwatsuka (1985) investigated the spectral properties of the unperturbed operator $H_0(b)$, which is called *the Iwatsuka model* by some authors [Mantoiu and Purice (1997), Exner and Kovařik (1999), and Shirai (2003)]. Iwatsuka's result says that, under (*B*.1), the spectrum of $H_0(b)$ is absolutely continuous and $\operatorname{Spec}(H_0(b)) = \cup_{n=0}^\infty [\Lambda_n^-, \Lambda_n^+]$ holds, where we set $\Lambda_n^\pm = (2n+1)B_\pm$ for any $n \in \mathbf{N}$, respectively, and for notational convenience, we set $\Lambda_{-1}^+ = \Lambda_{-1}^- = 0$.

Under (*B*.1) and (*V*.1), the multiplication operator V is relatively compact with respect to $H_0(b)$, so the essential spectrum of $H_g(b)$ coincides with that of $H_0(b)$ for any g [see, e.g., Reed and Simon (1978, Sec. XIII.4)]. In particular, the operator $H_g(b)$ may have discrete spectra (i.e., discrete eigenvalues of finite multiplicity) in the gaps of the essential spectrum.

We make some additional notations. Let v be as in (*V*.3). Set $S_\pm^1 = \{z=(x,y) \in \mathbf{R}^2 \,|\, |z|=1, \pm x \geqslant 0\}$ and set $\hat{v}_\pm = \int_{S_\pm^1} v(\omega)^{2/m}\, d\omega$, respectively. For any $\lambda \in \mathbf{R}\backslash \operatorname{Spec}(H_0(b))$ and for any $l \in \mathbf{N}$, set

$$\nu_l(\lambda) = \frac{1}{4\pi}(B_+\hat{v}_+|\Lambda_l^+ - \lambda|^{-2/m} + B_-\hat{v}_-|\Lambda_l^- - \lambda|^{-2/m}).$$

For any interval $[\lambda,\mu] \subset \mathbf{R}\backslash \operatorname{Spec}(H_0(b))$ and for any $l \in \mathbf{N}$, set

$$\nu_l([\lambda,\mu]) = \frac{1}{2\pi m}\left(B_+\hat{v}_+ \int_\lambda^\mu |\Lambda_l^+ - t|^{-2/m-1}\, dt + B_-\hat{v}_- \int_\lambda^\mu |\Lambda_l^- - t|^{-2/m-1}\, dt\right).$$

If we assume that $0 < \Lambda_n^+ < \lambda < \mu < \Lambda_{n+1}^-$ for some $n \in \mathbf{N}$, the sums $\Sigma_{l\in\mathbf{N}}\nu_l(\lambda)$ and $\Sigma_{l\in\mathbf{N}}\nu_l([\lambda,\mu])$ converge when $0<m<2$, and the relation $\nu_l([\lambda,\mu]) = \nu_l(\mu) - \nu_l(\lambda)$ holds when $l \geqslant n+1$.

We denote by $N_g^\pm(\lambda)$ the number of eigenvalues of $H_{\pm g'}(b)$ crossing λ as g' increases from zero to g, i.e., $N_g^\pm(\lambda) = \Sigma_{0<g'<g} \dim \operatorname{Ker}(H_{\pm g'}(b) - \lambda)$, respectively. Note that the sum above is meaningful under the assumptions (*B*.1) and (*V*.2), since the standard perturbation theory shows that for every fixed $g>0$ the set of values of $g' \in (0,g)$ for which $\dim \operatorname{Ker}(H_{\pm g'}(b) - \lambda)$ is not equal to zero is finite [see, e.g, Reed and Simon (1978)].

The main results in this paper are the following.

Theorem 1.1: *Let $\Lambda_{n-1}^+ < \lambda < \Lambda_n^-$ for some $n \in \mathbf{N}$. Assume that (B.1), (B.2), (V.1)–(V.4) hold. Moreover, assume that the constant m in (V.1) satisfies $0<m<2$. Then we have*

$$\lim_{g\to\infty} g^{-2/m} N_g^+(\lambda) = \sum_{l\geqslant n} \nu_l(\lambda). \tag{1.1}$$

Remark 1.2: In fact, the conclusion of Theorem 1.1 is still valid under weaker conditions on

B and V in the case of $\lambda<\Lambda_0^-$. *See Lemma 3.8 in Sec.* III *below*.

Corollary 1.3: Let $\Lambda_{n-1}^+<\lambda<\mu<\Lambda_n^-$ *for some* $n\in\mathbf{N}$. *Under the same assumption as in Theorem 1.1, we have* $\lim_{g\to\infty} g^{-2/m}N(\lambda\leqslant H_g(b)<\mu)=\Sigma_{l\geqslant n}\nu_l([\lambda,\nu])$.

Theorem 1.4: *Let* $\Lambda_n^+<\lambda<\Lambda_{n+1}^-$ *for some* $n\in\mathbf{N}$. *Assume that (B.1), (B.2), (V.1)–(V.4) hold. Then we have* $\lim_{g\to\infty} g^{-2/m}N_g^-(\lambda)=\Sigma_{0\leqslant l\leqslant n}\nu_l(\lambda)$.

Theorem 1.5: *Let* $\Lambda_{n-1}^+<\lambda<\mu<\Lambda_n^-$ *for some* $n\in\mathbf{N}$. *Assume that (B.1), (B.2), (V.1)–(V.4) hold. Moreover, assume that the constant m in (V.1) satisfies* $m>2$. *Then we have* $\liminf_{g\to\infty} g^{-2/m}N(\lambda\leqslant H_g(b)<\mu)\geqslant\Sigma_{l\geqslant n}\nu_l([\lambda,\mu])$.

At present, the author has not obtained the upper estimate for $N(\lambda\leqslant H_g(b)<\mu)$ in the case of $m>2$, nor the results for the case of $m=2$.

Remark 1.6:

(1) *The study of eigenvalues in the spectral gaps of the Schrödinger operators has a long history [see, e.g., Birman (1991), Alama, Deift, and Hempel (1989), Hempel and Levendorskiĭ (1998) and references therein]. In the case of constant magnetic fields (i.e., the case of* $B_+=B_-$ *in our notation), Raikov (1991, 1993) has obtained the strong-electric-field asymptotics as in Theorem 1.1 and Corollary 1.3 above when the scalar potential decays slowly at infinity (i.e., the case of* $0<m\leqslant 2$ *in our situation). Moreover, for a class of nonconstant magnetic fields which includes the Iwatsuka model, Raikov (1998, 1993) shows that the asymptotics of* $N_g^+(\lambda)$ *are Weylian, i.e., the asymptotic relation* $\lim_{g\to\infty} g^{-1}N_g^+(\lambda)=(1/4\pi)\int_{\mathbf{R}^2}V(x,y)\mathrm{d}x\,\mathrm{d}y$ *holds when the scalar potential decays rapidly (the case of* $m>2$ *in our situation).*

(2) *Hempel and Levendorskiĭ (1998) [see also Levendorskiĭ (1995, 1996)] study the asymptotics of* $N_g^\pm(\lambda)$ *for the magnetic Schrödinger operators* $H-gV=(-\sqrt{-1}\nabla-\mathbf{a})^2+W-gV$ *on* $L^2(\mathbf{R}^n)$ *under rather general conditions on* $\mathbf{a}$, W, *and* V. *Especially,* V *is not assumed to have a definite sign. They assume, however, the existence of the density of states* $\rho(\lambda,H)=\lim_{R\to\infty} N(H|_{Q_R}<\lambda)/\mathrm{Vol}(Q_R)$ *for the unperturbed operator* H, *for which the asymptotic coefficient as in Theorem 1.1 is expressed as*

$$\lim_{g\to\infty} g^{-n/m}N_g^+(\lambda)=\int_{\mathbf{R}^n}\mathrm{d}z\int_\lambda^{\lambda+v(\omega)r^{-m}}\mathrm{d}\rho(t,H)$$

when $V(z)=v(\omega)r^{-m}$ *at infinity and* $0<m<2$, *for example. Here,* Q_R *is a cube of side length R and we denote by* $H|_{Q_R}$ *the Dirichlét realization of H on* Q_R. *On the contrary, the Iwatsuka model has no canonical density of states because of lack of spacial symmetry of the magnetic field B. Thus, at least, we need modify their argument. Indeed, although the isotropic density of states* $\rho(\lambda,H_0(b))=(B_+/4\pi)\sharp\{l\in\mathbf{N}\,|\,\Lambda_l^+<\lambda\}+(B_-/4\pi)\sharp\{l\in\mathbf{N}\,|\,\Lambda_l^-<\lambda\}$ *for the Iwatsuka model do exist under the assumption in Theorem 1.1, the quantity*

$$\int_{\mathbf{R}^2}\mathrm{d}x\,\mathrm{d}y\int_\lambda^{\lambda+v(\omega)r^{-m}}\mathrm{d}\rho(t,H_0(b))=\frac{B_+}{4\pi}\frac{\hat{v}}{2}\sum_{l\geqslant n+1}|\Lambda_l^+-\lambda|^{-2/m}+\frac{B_-}{4\pi}\frac{\hat{v}}{2}\sum_{l\geqslant n+1}|\Lambda_l^--\lambda|^{-2/m},$$

where $\hat{v}=\int_{S^1}v(\omega)^{2/m}\,\mathrm{d}\omega$, *does not give the correct asymptotic coefficient* (1.1), *which can be expressed as*

$$\int_{\{x\geqslant 0\}}\mathrm{d}x\,\mathrm{d}y\int_\lambda^{\lambda+v(\omega)r^{-m}}\mathrm{d}\rho_+(t,H_0(b))+\int_{\{x\leqslant 0\}}\mathrm{d}x\,\mathrm{d}y\int_\lambda^{\lambda+v(\omega)r^{-m}}\mathrm{d}\rho_-(t,H_0(b)),$$

where $\rho_\pm(t,H_0(b))=(B_\pm/4\pi)\sharp\{l\in\mathbf{N}\,|\,\Lambda_l^\pm<t\}$, *respectively.*

The organization of this paper is as follows: Sec. II contains some preliminary results from functional analysis and the theory of pseudodifferential operators. In Sec. III, we give a proof of Theorem 1.1 in the case where the control point λ is fixed below the infimum of the essential spectrum of $H_g(b)$. In Sec. IV, we recall the spectral properties of the Iwatsuka model $H_0(b)$ and

derive some decay estimates for the band functions and the corresponding (generalized) eigenfunctions of $H_0(b)$. Proofs of Theorem 1.1 for λ in general gaps, Theorem 1.4 and Theorem 1.5 are given in Sec. V.

II. PRELIMINARIES

A. Variational principle

In this section we recall some results concerning the variational principle used mainly in Sec. III. All the results are well known, so we omit proofs.

For any sesquilinear form, which is referred to as *form* in the sequel, q on a Hilbert space, we denote its form domain by $D(q)$. For any semibounded, closable form q, there exists a unique self-adjoint operator A_q such that the operator domain $D(A_q)$ is a form core for the form closure $\overline{q}$ and the relation $q[u]=(A_q u,u)$ holds for any $u \in D(A_q)$. Throughout the paper, we identify such a form q with the corresponding self-adjoint operator A_q, and we denote the counting function $N(A_q<\lambda)$ simply by $N(q<\lambda)$ for any real number λ.

The following result is a consequence of the min–max principle [see, e.g., Reed and Simon (1978, Vol. IV), Colin de Verdiere (1986, Lemma 5.1)].

Lemma 2.1: Let $(\mathcal{H}_j,q_j,D(q_j))$ be a triplet of a Hilbert space $\mathcal{H}_j$, a semibounded, closable form q_j and the form domain $D(q_j)$ for $j=1,2$ and let J be an isometry from $D(q_1)$ to $D(q_2)$ with respect to norms of $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. Suppose that there exist positive constants C_1 and C_2 such that $q_1[u] \geqslant C_1 q_2[Ju]-C_2\|u\|^2_{\mathcal{H}_1}$ holds for all $u \in D(q_1)$. Then we have $N(q_1<\lambda) \leqslant N(q_2<(\lambda+C_2)/C_1)$ for any $\lambda \in \mathbf{R}$.

For any $\tilde{b} \in C^1(\mathbf{R}^2,\mathbf{R})$, we define

$$H_g(\tilde{b}) = -\frac{\partial^2}{\partial x^2} + \left(\frac{1}{\sqrt{-1}}\frac{\partial}{\partial y} - \tilde{b}(x,y)\right)^2 - gV(x,y). \tag{2.1}$$

In what follows, for any open subset Ω in $\mathbf{R}^2$, we denote by $H_g(\tilde{b})|_\Omega$ the minimal self-adjoint realization of $H_g(\tilde{b})$ starting from $C_0^\infty(\Omega)$, i.e., the Dirichlét realization of $H_g(\tilde{b})$ on Ω.

Proposition 2.2: [Colin de Verdiere (1986, Theorem 1.3)] Let r be a positive number and let Λ be a real number. Then we have the upper bound

$$N((-\infty,\Lambda)|H_0(B_0x)|_{Q(0,r)}) \leqslant \frac{B_0}{2\pi}r^2 \sharp\{l \in \mathbf{N}|(2l+1)B_0<\Lambda\},$$

where $H_0(B_0x)$ is the operator of the form (2.1) *with $\tilde{b}(x,y)=B_0x$ and $g=0$, and the lower bound*

$$N((-\infty,\Lambda)|H_0(B_0x)|_{Q(0,r)}) \geqslant \frac{B_0}{2\pi}(r-r_1)^2 \sharp\{l \in \mathbf{N}|(2l+1)B_0<\Lambda-Cr_1^{-2}\}.$$

Here, the constant C is independent of Λ, r and r_1 with $0<r_1<r$.

The following result is the so-called IMS (Ismagilov, Morgan, Sigal, Simon) localization formula for the magnetic Schrödinger operators [see Cycon *et al.*].

Lemma 2.3: Let $\tilde{\Omega}$ be an open subset of $\mathbf{R}^2$ and let $\{\Omega_j\}_{j\in J}$ be a locally finite open covering of $\tilde{\Omega}$. Let $\{\chi_j\}_{j\in J}$ be a partition of unity subject to the covering $\{\Omega_j\}$ satisfying the conditions $\mathrm{supp}(\chi_j) \subset \Omega_j, 0 \leqslant \chi_j \leqslant 1$ *and $\chi_j \in C^1(\Omega_j)$ for any $j \in J$. Moreover, $\Sigma_{j\in J}\chi_j^2=1$ on $\tilde{\Omega}$. Assume that $\tilde{b} \in C^\infty(\tilde{\Omega},\mathbf{R})$. Then we have $(H_g(\tilde{b})u,u)=\Sigma_{j\in J}(H_g(\tilde{b})\chi_j u,\chi_j u)-(\Sigma_{l\in J}|\nabla\chi l|^2 u,u)$ for any $u \in C_0^\infty(\tilde{\Omega})$.*

The next result follows from an elementary inequality $2XY \leqslant \varepsilon X^2+Y^2/\varepsilon$.

Lemma 2.4: Assume that $\tilde{b} \in C^1(\mathbf{R}^2,\mathbf{R})$ and $0<\varepsilon<1$. Then we have

$$(1-\varepsilon)(H_0(\tilde{b})u,u) - g(Vu,u) - (1+1/\varepsilon)\|(b-\tilde{b})u\|^2 \leqslant (H_g(b)u,u)$$
$$\leqslant (1+\varepsilon)(H_0(\tilde{b})u,u) - g(Vu,u) + (1+1/\varepsilon)\|(b-\tilde{b})u\|^2$$

for any $u \in C_0^\infty(\mathbf{R}^2)$.

B. Pseudodifferential operators

In this section we introduce a class of pseudodifferential operators (ΨDOs) and recall some basic results. All the results are well known in the theory of ΨDOs, so we omit proofs.

For any $m \in \mathbf{R}$ and $a \in C^\infty(\mathbf{R}^2)$, we say that *a belongs to the class of symbols* S^m if the quantity

$$\eta_{\alpha\beta}^{(m)}(a) = \sup_{(x,\xi)\in\mathbf{R}^2} \langle x;\xi\rangle^{-m+\alpha} |\partial_x^\beta \partial_\xi^\alpha a(x,\xi)| \tag{2.2}$$

is finite for each $\alpha,\beta \in \mathbf{N}$. The seminorms $\{\eta_{\alpha\beta}^{(m)}\}_{\alpha,\beta}$ gives a Fréchet space topology on the space S^m. We set $S^{-\infty} = \cap_{m\in\mathbf{R}} S^m$, which coincides with $S(\mathbf{R})$.

The symbol class S^m is an example of the class introduced by Beals (1975) [$\Phi(x,\xi) = \langle x;\xi\rangle, \varphi\langle x,\xi\rangle = 1, \lambda = \log(\langle x;\xi\rangle^m)$ and $S^\lambda_{\Phi,\varphi} = S^m$ in his convention], or by Robert (1978), Dauge and Robert (1987) [$m = \langle x;\xi\rangle^m, \phi = \langle x;\xi\rangle, \varphi = 1, S(m;\phi,\varphi) = S^m$ in their convention]. Hence, by the standard argument as in Beals (1975) or in Hörmander (1979) [$g_{x,\xi}(y,\eta) = |y|^2 + |\eta|^2/\langle x;\xi\rangle^2$ in his convention], one can find that, for any $a \in S^m$, the associated ΨDO,

$$Op(a)u(x) = \int\int_{\mathbf{R}^2} e^{\sqrt{-1}(x-y)\xi} a\left(\frac{x+y}{2},\xi\right) u(y)\mathrm{d}y\,\mathrm{d}\xi$$

is a well-defined oscillatory integral for any $u \in S(\mathbf{R})$. Here, we set $\mathrm{d}\xi = \mathrm{d}\xi/(2\pi)$. Moreover, $Op(a)$ maps $\mathcal{S}(\mathbf{R})$ to itself continuously [so, extends to a continuous map from $\mathcal{S}'(\mathbf{R})$ to itself by duality based on L^2-norm]. For an operator A from $\mathcal{S}'(\mathbf{R})$ to $\mathcal{S}'(\mathbf{R})$, we say $A \in OpS^m$ if A is expressed as $Op(a)$ for some $a \in S^m$.

Note that the original results in Beals (1975) are formulated in terms of the standard quantization $\int\int_{\mathbf{R}^2} e^{\sqrt{-1}(x-y)\xi} a(x,\xi)u(y)\mathrm{d}y\,\mathrm{d}\xi$. However, all the corresponding results below are still valid for the Weyl quantization; to see this, it suffices to chase the proofs in Beals (1975) carefully, or use the relation between the standard and the Weyl quantizations as in Theorem 4.5 in Hörmander (1979). For omitted proofs, we refer to Proposition 6.17, Theorems 6.1, 7.2, and 7.7 in Beals (1975), and for Lemma 2.7 below we refer to Proposition 26.2 in Shubin (1987). Although the class of symbols considered in Shubin's book is slightly defferent from the class S^m above, the proof of Proposition 26.2 in his book is valid also for symbols in S^m with obvious modifications.

Lemma 2.5: Let $m, m' \in \mathbf{R}$. *We have the following assertions.*

(1) *If* $A \in OpS^m$ *and* $B \in OpS^{m'}$, *then* $AB \in OpS^{m+m'}$ *and the symbol of* AB *has an asymptotic expansion as usual.*
(2) *If* $A \in OpS^m$, *then* $A^* \in OpS^m$ *and the symbol of* A^* *is expressed as usual.*
(3) *If* $A \in OpS^0$, *then* A *defines a bounded operator on* $L^2(\mathbf{R})$. *Moreover, if* $A \in OpS^m$ *for some negative* m, *then* A *defines a compact operator on* $L^2(\mathbf{R})$.
(4) *If* $m > 0$ *and* $a \in S^{-m}$, *then there exists* $l \in \mathbf{N}$ *such that* $\|Op(a)\|_{\mathbf{B}(L^2(\mathbf{R}))} \leqslant C\Sigma_{\alpha+\beta\leqslant l}\eta_{\alpha\beta}^{(-m)}(a)$ *holds for some constant* $C > 0$, *independent of* a.
(5) *If* $A \in OpS^{-\infty}$, *then* A *maps* $\mathcal{S}'(\mathbf{R})$ *to* $\mathcal{S}(\mathbf{R})$ *continuously.*

We introduce the weighted Sobolev space H^m as the (finite) linear hull of the set $\{Au \,|\, u \in L^2(\mathbf{R}), A \in OpS^{-m}\}$ equipped with the weakest topology which makes the map $(A: L^2(\mathbf{R}) \to H^m)$ continuous for all $A \in OpS^{-m}$. The basic properties of H^m are summarized as follows.

Lemma 2.6:

(1) *The space* H^0 *coincides with* $L^2(\mathbf{R})$ *topologically.*
(2) *The embeddings* $\mathcal{S}(\mathbf{R}) \subset H^m \subset \mathcal{S}'(\mathbf{R})$ *are densely and continuously for any* m.

(3) *$H^m \subset H^{m'}$ holds if $m' < m$, and $(H^m)' = H^{-m}$ topologically for any m.*
(4) *If $A \in OpS^m$, then A maps $H^{m+m'}$ to $H^{m'}$ continuously for all m, m'.*
(5) *For any m, m', there exists $A \in OpS^m$ which gives a topologically isomorphism from $H^{m+m'}$ onto $H^{m'}$. In particular, H^m has the topology of a Hilbert space for any m.*

Lemma 2.7: Let D_0 be a dense subspace of $\mathcal{S}(\mathbf{R})$. Let $m > 0$ and $a \in S^m$. Assume that $Op(a)$ is symmetric on D_0 and $|a(x,\xi)| \geqslant C\langle x;\xi\rangle^m$ holds for some $C > 0$. Then

(1) *The operator $Op(a)|_{D_0}$ [the restriction of $Op(a)$ on D_0] is essentially self-adjoint, and $D(\overline{Op(a)|_{D_0}})$ coincides with $\{u \in L^2(\mathbf{R}) \,|\, Op(a)u \in L^2(\mathbf{R})\}$.*
(2) *The space $D(\overline{Op(a)|_{D_0}})$ equipped with graph norm coincides with H^m topologically.*

The following result concerning the eigenvalue asymptotics of ΨDOs of negative order plays an important role in Sec. V.

Proposition 2.8: [Dauge and Robert (1987, Theorem 1.3)] Let $m > 0$ and let $a \in S^{-m}$ and a be real valued. Assume that the following two estimates,

$$\lim_{\varepsilon \downarrow 0} \limsup_{\mu \downarrow 0} \mu^{2/m} \mathrm{Vol}\{(x,\xi) \in \mathbf{R}^2 | (1-\varepsilon)\mu < \pm a(x,\xi) < (1+\varepsilon)\mu\} = 0, \tag{2.3}$$

are satisfied. Then we have $N(\pm Op(a) > \mu) = (1/2\pi)\mathrm{Vol}\{(z,\xi) \in \mathbf{R}^2 \,|\, \pm a(x,\xi) > \mu\} + o(\mu^{-2/m})$ as $\mu \downarrow 0$, respectively.

Note that the conditions (2.3) imply the condition (T) in Dauge and Robert (1987) for the volume functions $\mathrm{Vol}\{z \,|\, \pm a(z) > \mu\}$. As an immediate consequence of Proposition 2.8, for any $m > 0$ and any $a \in S^{-m}$, the following rough estimate,

$$N(\pm Op(a) > \mu) = O(\mu^{-2/m}), \tag{2.4}$$

holds as $\mu \downarrow 0$.

III. PROOF OF THEOREM 1.1 IN THE CASE OF $\lambda < B_-$

A. Upper bound for $N(H_g(b) < \lambda)$

1. Partition of $\mathbf{R}^2$ and sesquilinear forms

In this section, we give a proof of Theorem 1.1 in the case of $\lambda < \Lambda_0^-(=B_-)$. For general $\lambda > \Lambda_0^+$ the proof of Theorem 1.1 given in Sec. V needs this special case, as in Raikov (1993).

We introduce a partition of $\mathbf{R}^2$ and a corresponding partition of unity. Let $K = \{0, 1, +, -\}$. Take and fix positive numbers α, β, and σ so that

$$0 < \sigma < \min\left\{\frac{1}{4m}, \frac{1}{2-m}, \frac{M}{m(1+M)}, \frac{1}{2m(m+1)}\right\}, \quad \alpha = \frac{1}{m} - 2\sigma, \quad \beta = \frac{1}{m} + \sigma.$$

Note that $0 < \sigma < \alpha < 1/m < \beta$. For any $g > 0$, we set $\Omega_0 = \{(x,y) \in \mathbf{R}^2 \,|\, |x| \leqslant g^\alpha, |y| \leqslant g^\beta\}$, $\Omega_\pm = \{(x,y) \in \mathbf{R}^2 \,|\, g^\alpha \leqslant \pm x \leqslant g^\beta, |y| \leqslant g^\beta\}$, respectively, $\Omega_1 = \mathbf{R}^2 \setminus (\Omega_0 \cup \Omega_+ \cup \Omega_-)$ and $\tilde{\Omega}_k = \{z \in \mathbf{R}^2 \,|\, \mathrm{dist}(z, \Omega_k) < g^\sigma\}$ for any $k \in K$. Let $\{\varphi_k\}_{k \in K}$ be a partition of unity subject to the open covering $\{\tilde{\Omega}_k\}_{k \in K}$ of $\mathbf{R}^2$ satisfying the following:

$(P.1)$ $\varphi_k \in C^\infty(\tilde{\Omega}_k)$, $\mathrm{supp}(\varphi_k) \subset \tilde{\Omega}_k$ and $0 \leqslant \varphi_k \leqslant 1$ hold, and for each multi-index γ, there exists $C_\gamma > 0$ such that $\sup_{z \in \mathbf{R}^2} |\varphi_k(z)| \leqslant C_\gamma g^{-|\gamma|\sigma}$ holds for any $k \in K$. Moreover, $\Sigma_{k \in K} \varphi_k^2 = 1$ holds on $\mathbf{R}^2$.

For each $k \in K$, we define a form q_k by $q_k[u] = (H_g(b)u, u) - (\Sigma_{l \in K} |\nabla_{\varphi l}|^2 u, u)$ with form domain $C_0^\infty(\tilde{\Omega}_k)$. Then it follows from Lemma 2.3 that $(H_g(b)u, u) = \Sigma_{k \in K} q_k[\varphi_k u]$ holds for any $u \in C_0^\infty(\mathbf{R}^2)$. Considering the isometry J from $L^2(\mathbf{R}^2)$ to $\oplus_{k \in K} L^2(\tilde{\Omega}_k)$ defined by $J(u) = \oplus_{k \in K}(\varphi_k u)$, by Lemma 2.1, we find that $N(H_g(b) < \lambda) \leqslant \Sigma_{k \in K} N(q_k < \lambda)$ holds for any $g > 0$.

2. Estimates of $N(q_0<\lambda)$ and $N(q_1<\lambda)$

In what follows we use the symbols c and C (possibly with superscripts or subscripts) to denote various positive constants in estimates, which may vary from line to line.

Let $0<\eta<1$ and let $J=\{j\in\mathbf{Z}^2\,|\,\tilde{\Omega}_0\cap Q(j,1)\neq\emptyset\}$. Let $\{\chi_j\}_{j\in J}$ be a partition of unity subject to the open covering $\{Q(j,1+\eta)\}_{j\in J}$ of $\tilde{\Omega}_0$ satisfying the following:

(*P*.2) $\chi_j\in C_0^\infty(Q(j,1+\eta))$, and $0\leqslant\chi_j\leqslant 1$ hold, and for each multi-index γ, there exists $C_\gamma>0$, independent of j,η, such that $\sup_{z\in\mathbf{R}^2}|\chi_j(z)|\leqslant C_\gamma\eta^{-|\gamma|}$ holds for any $j\in J$. Moreover, $\Sigma_{j\in J}\chi_j^2=1$ holds on $\tilde{\Omega}_0$.

For each $j=(j_1,j_2)\in J$, we introduce the auxiliary magnetic potential $b_j(x)=\int_0^{j_1}B(t)\mathrm{d}t+B(j_1)\times(x-j_1)$, which gives the constant magnetic field $B(j_1)$.

Lemma 3.1: Let q_0 and λ be as above. We have $N(q_0<\lambda)=o(g^{2/m})$ as $g\to\infty$.

Proof: By Lemmata 2.3, 2.1, 2.4 and Proposition 2.2, we have the estimate

$$\begin{aligned}N(q_0<\lambda)&\leqslant\sum_{j\in J}N((1-\varepsilon)H_0(b_j)-Cg\langle j\rangle^{-m}-C_{\eta\varepsilon}<\lambda)\\&\leqslant\sum_{j=(j_1,j_2)\in J}\frac{B(j_1)}{2\pi}(1+\eta)^2\,\sharp\,\{l\in\mathbf{N}\,|\,(1-\varepsilon)(2l+1)B(j_1)<\lambda+Cg\langle j\rangle^{-m}+C_{\eta\varepsilon}\}\\&\leqslant C_{\eta\varepsilon\lambda}(\sharp J)+C_{\eta\varepsilon\lambda}g\sum_{j\in J}\langle j\rangle^{-m}\end{aligned}\tag{3.1}$$

for any small $\varepsilon>0$, where we used (*P*.2) and the fact that the estimates $|V(z)|\leqslant C\langle j\rangle^{-m}$ and $|b(x)-b_j(x)|\leqslant|\int_{j_1}^x(B(t)-B(j_1))\mathrm{d}t|\leqslant 2(1+\eta)B_+$ hold on $Q(j,1+\eta)$ in the first inequality. By the definition of J, there exists $C>0$, independent of g, such that $\sharp(J)\leqslant C\mathrm{Vol}(\tilde{\Omega}_0)\leqslant Cg^{\alpha+\beta}=o(g^{2/m})$ as $g\to\infty$, since $\alpha+\beta=2/m-\sigma$. The second term on the right-hand side (rhs) of (3.1) is less than or equal to

$$Cg\int_{\tilde{\Omega}_0}\langle z\rangle^{-m}\,\mathrm{d}z\leqslant 4Cg\int_0^{g^\alpha+g^\sigma}\mathrm{d}x\int_0^{g^\beta+g^\sigma}\mathrm{d}y\langle x;y\rangle^{-m}.\tag{3.2}$$

To estimate the above integral, we use the following elementary estimate: If $m>0$ and $1<A<B$, then there exists $C_m>0$, independent of A,B, such that

$$\int_0^A\mathrm{d}x\int_0^B\mathrm{d}y\langle x;y\rangle^{-m}\leqslant\begin{cases}C_mAB^{1-m} & \text{if } 0<m<1,\\ C_1A\log B & \text{if } m=1,\\ C_m(AB^{1-m}+1) & \text{if } m>1.\end{cases}$$

Then, if $0<m<1$, the rhs of (3.2) is estimated from above by $C_mg(g^\alpha+g^\sigma)(g^\beta+g^\sigma)^{1-m}=o(g^{1+\alpha+\beta(1-m)})=o(g^{2/m})$ as $g\to\infty$. Similarly, if $m=1$, the rhs of (3.2) is estimated from above by $C_1g(g^\alpha+g^\sigma)\log(g^\beta+g^\sigma)=o(g^{1+\alpha}\log g)=o(g^{2/m})$ as $g\to\infty$, and if $1<m<2$, the rhs of (3.2) is estimated from above by $C_mg((g^\alpha+g^\sigma)(g^\beta+g^\sigma)^{1-m}+1)=o(g^{1+\alpha-\beta(m-1)})=o(g^{2/m})$ as $g\to\infty$. This completes the proof. ■

Lemma 3.2: Let q_1 and λ be as above. We have $N(q_1<\lambda)=0$ for large $g>0$.

Proof: For any $u\in C_0^\infty(\tilde{\Omega}_1)$, we have $q_1[u]=(H_g(b)u,u)-g(Vu,u)-(\Sigma_{l\in K}|\nabla\varphi_l|^2u,u)\geqslant(H_g(b)u,u)-C(g^{1-m\beta}+g^{-2\sigma})\|u\|^2=(H_g(b)u,u)-o(1)\|u\|^2$ as $g\to\infty$, where we used (*V*.1), (*P*.1) and the fact that $1-m\beta=1-m(1/m+\sigma)=-m\sigma<0$. Then the min–max argument yields that $N(q_1<\lambda)\leqslant N(H_0(b)|_{\tilde{\Omega}_1}<\lambda+o(1))$ holds as $g\to\infty$. Hence we conclude that $N(H_0(b)|_{\tilde{\Omega}_1}<\lambda+o(1))=0$ for large g since $\inf\mathrm{Spec}(H_0(b)|_{\tilde{\Omega}_1})=\inf_{u\in C_0^\infty(\tilde{\Omega}_1),\|u\|=1}(H_0(b)u,u)\geqslant\inf\mathrm{Spec}(H_0(b))(=B_-)>\lambda)$ holds as $g\to\infty$ again by the min–max argument. ■

3. Estimate of $N(q_\pm<\lambda)$

Let $0<\eta<1$. For any $j=(j_1,j_1)\in\mathbf{Z}^2$, we set

$$Q_j=\{(x,y)\in\mathbf{R}^2|j_1<g^{-\sigma}x<j_1+1,j_2<g^{-\sigma}y<j_2+1\},\tag{3.3}$$

$$Q_{j\eta}=\{z\in\mathbf{R}^2|\mathrm{dist}(z,Q_j)<\eta g^{\sigma}\}\tag{3.4}$$

and $J_\pm=\{j\in\mathbf{Z}^2|Q_j\cap\tilde{\Omega}_\pm\neq\emptyset\}$. Let $\{\chi_j\}_{j\in J_\pm}$ be a partition of unity subject to the covering $\{Q_{j\eta}\}_{j\in J_\pm}$ of $\tilde{\Omega}_\pm$ satisfying the following conditions (respectively, for $\pm$):

$(P.3)$ ${}_\pm\chi_j\in C_0^\infty(Q_{j\eta}),0\leqslant\chi_j\leqslant1$, and for each multi-index γ, there exists $C_\gamma>0$, independent of g,η,j, such that $\sup_{z\in\mathbf{R}^2}|\partial^\gamma\chi_j(z)|\leqslant C_\gamma(\eta g^\sigma)^{-|\gamma|}$ holds for any $j\in J_\pm$. Moreover, $\Sigma_{j\in J_\pm}\chi_j^2=1$ holds on $\tilde{\Omega}_\pm$.

In what follows, for simplicity, we omit the phrase "respectively (for $\pm$)" if there is no fear of confusion.

Let $z_j=(x_j,y_j)$ be the center of Q_j and we introduce the auxiliary magnetic potentials,

$$b_{j,\pm}(x)=\int_0^{x_j}B(t)\mathrm{d}t+B_\pm(x-x_j),\tag{3.5}$$

which gives the constant magnetic field $B_\pm$.

Lemma 3.3: Let $j\in J_\pm$. There exists $C>0$, independent of j,g, and η, such that $\|(b-b_{j,\pm})u\|\leqslant Cg^{\sigma-M\alpha}\|u\|$ holds for any $u\in C_0^\infty(Q_{j\eta})$, and for any $g\geqslant1$.

Proof: On $Q_{j\eta}$, we have $|b(x)-b_{j,\pm}(x)|\leqslant|\int_{x_j}^x(B(t)-B_\pm)\mathrm{d}t|\leqslant C\langle g^\alpha-g^\sigma-\eta g^\sigma\rangle^{-M}|x-x_j|\leqslant Cg^{-M\alpha+\sigma}$ as $g\to\infty$, where we used (B.2) in the second inequality. ■

Lemma 3.4: Let $j\in J_\pm$. There exists $C>0$, independent of j,g, and η such that $(1-Cg^{-(\alpha-2\sigma)})V(z)\leqslant V(z')\leqslant(1+Cg^{-(\alpha-2\sigma)})V(z)$ holds for any $z,z'\in Q_{j\eta}$. Here, $\overline{Q}$ stands for the closure of Q.

Proof: Let $z,z'\in\overline{Q_{j\eta}}$. If we write $z=(x,y)$, then

$$|z|\geqslant|x|\geqslant g^\alpha-g^\sigma-(1+\eta)g^\sigma\geqslant g^\alpha/2\tag{3.6}$$

and $|z|\leqslant|z'|+|z-z'|\leqslant|z'|+\sqrt{2}(1+\eta)g^\sigma\leqslant|z'|+Cg^{-(\alpha-\sigma)}|z|$ hold for large $g>0$, so there exists $C>0$, independent of j,g,z,z', such that

$$C^{-1}\langle z\rangle\leqslant\langle z'\rangle\leqslant C\langle z\rangle\tag{3.7}$$

holds. The first order Taylor expansion yields $|V(z)-V(z')|\leqslant|z-z'|\sup_{w\in Q_{j\eta}}|\nabla V(w)|\leqslant C(1+\eta)^2g^{2\sigma}\sup_{w\in Q_{j\eta}}\langle w\rangle^{-m-1}\leqslant C(1+\eta)^2g^{-(\alpha-2\sigma)}\sup_{w\in Q_{j\eta}}\langle w\rangle^{-m}\leqslant Cg^{-(\alpha-2\sigma)}V(z)$ for large g, where we used (3.6) in the third inequality, $(V.1)$, $(V.2)$ in the second and the fourth inequalities, (3.7) in the last inequality. Here, the constant C is independent of j,η,g,z, and z'. This proves the lemma. ■

Lemma 3.5: For any ε satisfying $0<\varepsilon<1$, we have

$$N(q_\pm<\lambda)\leqslant(1+\varepsilon)^2\frac{B_\pm}{2\pi}\sum_{l\in N}\mathrm{Vol}(\Omega_\pm^{(+)}(\varepsilon,l)),\tag{3.8}$$

where we set $\Omega_\pm^{(+)}(\varepsilon,l)=\{z\in\mathbf{R}^2|\pm x\geqslant0,(1-2\varepsilon)\Lambda_l^\pm<\lambda+g(1+\varepsilon)V(z)\}$. In fact, the sum on the rhs of (3.8) *terminates for each ε and g.*

Proof: By Lemma 2.1 and $(P.3)$, there exists $C>0$, independent of j,g,η, such that

$$q_{\pm}[u] \geqslant \sum_{j\in J_{\pm}} ((1-\varepsilon)(H_0(b_{j,\pm})\chi_j u,\chi_j u) - g(V\chi_j u,\chi_j u) - (1+1/\varepsilon)\|(b-b_{j,\pm})\chi_j u\|^2 - C(\eta g^{\sigma})^{-2}\|\chi_j u\|^2$$
$$- Cg^{-2\sigma}\|\chi_j u\|^2) \geqslant \sum_{j\in J_{\pm}} \left((1-\varepsilon)(H_0(b_{j,\pm})\chi_j u,\chi_j u) - g\sup_{Q_{j\eta}}|V|(\chi_j u,\chi_j u) - o(1)\|\chi_j u\|^2\right)$$

holds for any $u \in C_0^{\infty}(\tilde{\Omega}_{\pm})$, where we write $\sup_Q|V|$ for $\sup_{z\in Q}|V(z)|$ for short. Then the min–max theorem yields that

$$N(q_{\pm}<\lambda) \leqslant \sum_{j\in J_{\pm}} N((1-2\varepsilon)H_0(b_{j,\pm}) < \lambda + g\sup_{Q_{j\eta}}|V|)$$
$$\leqslant (1+\eta)^2 g^{2\sigma}\frac{B_{\pm}}{2\pi}\sum_{j\in J_{\pm}} \sharp\{l\in\mathbf{N}|(1-2\varepsilon)\Lambda_l^{\pm} < \lambda + g\sup_{Q_{j\eta}}|V|\}$$
$$= (1+\eta)^2 g^{2\sigma}\frac{B_{\pm}}{2\pi}\sum_{l\in N}\sum_{j\in J_{\pm}} F((1-2\varepsilon)\Lambda_l^{\pm} < \lambda + g\sup_{Q_{j\eta}}|V|) \tag{3.9}$$

holds for large g, where we used Proposition 2.2 in the second inequality. Here, $F(P)=0$ if P is true and $F(P)=1$ if P is false.

Set $\tilde{J}_{\pm}=\{j\in J_{\pm}|\,Q_j\subset\Omega_{\pm}^{(+)}(\varepsilon,l)\}$. We claim that, if $j\in J_{\pm}\backslash\tilde{J}_{\pm}$, then $F((1-2\varepsilon)\Lambda_l^{\pm}<\lambda+g\sup_{Q_{j\eta}}|V|)=0$ holds for large $g>0$ uniformly in j,l. Indeed, for such j, there exists $\overline{z}\in Q_j$ such that $\overline{z}\notin\Omega_{\pm}^{(+)}(\varepsilon,l)$, i.e.,

$$(1-2\varepsilon)\Lambda_l^{\pm} \geqslant \lambda + g(1+\varepsilon)V(\overline{z}). \tag{3.10}$$

Note that if we write $\overline{z}=(\overline{x},\overline{y})\in Q_j$, then $\pm\overline{x}\geqslant 0$ since $0<\sigma<\alpha$. Then we find that, for any $\varepsilon>0$ fixed, $(1-2\varepsilon)\Lambda_l^{\pm}-\lambda-g\sup_{Q_{j\eta}}|V|=(1-2\varepsilon)\Lambda_l^{\pm}-\lambda-g(1+\varepsilon)V(\overline{z})+g((1+\varepsilon)V(\overline{z})-\sup_{Q_{j\eta}}|V|)\geqslant g((1+\varepsilon)V(\overline{z})-\sup_{Q_{j\eta}}|V|)\geqslant g((1+\varepsilon)V(\overline{z})-(1+Cg^{-(\alpha-2\sigma)})V(\overline{z}))=g(\varepsilon-Cg^{-(\alpha-2\alpha)})V(\overline{z})\geqslant 0$ holds for large g (uniformly in j,l), where we used (3.10) in the first inequality, Lemma 3.4 in the second inequality and (V.2) in the last. This shows the claim.

Hence, it follows that, for large g, the rhs of (3.9) is less than or equal to $(1+\eta)^2(B_{\pm}/2\pi)\Sigma_{l\in N}\Sigma_{j\in J_{\pm}}\mathrm{Vol}(Q_j)\leqslant(1+\eta)^2(B\pm/2\pi)\Sigma_{l\in N}\mathrm{Vol}(\Omega_{\pm}^{(+)}(\varepsilon,l))$. Then the lemma follows since the set $\Omega_{\pm}^{(+)}$ is empty if l is so large that $(1-2\varepsilon)\Lambda_l^{\pm}\geqslant\lambda+Cg\sup_{\mathbf{R}^2}|V|$. ■

Lemma 3.6: Assume that $\lambda<B_-$. *Then we have* $\limsup_{g\to\infty} g^{-2/m}N_g^+(\lambda)\leqslant\Sigma_{l\in\mathbf{N}}\nu_l(\lambda)$.

Proof: Let $\Omega_{\pm}^{(+)}(\varepsilon,l)$ be as in the previous lemma. Set $I_0=\mathrm{Vol}\{z\in\Omega_{\pm}^{(+)}(\varepsilon,l)\,|\,|z|\leqslant R\}$ and $I_{\infty}^{\pm}=\{z=(x,y)\in\Omega_{\pm}^{(+)}(\varepsilon,l)\,|\,\pm x\geqslant 0,|z|\geqslant R\}$. Then $\mathrm{Vol}(\Omega_{\pm}^{(+)}(\varepsilon,l))=I_0+I_{\infty}^{+}+I_{\infty}^{-}$. We observe that $I_0\leqslant\pi R^2$, and $I_{\infty}^{\pm}\leqslant\frac{1}{2}g^{2/m}(\Lambda_l^{\pm}-\lambda)^{-2/m}\int_{S^1}v(\omega)^{2/m}\,\mathrm{d}\omega+O(1)$ as $\varepsilon\downarrow 0$ (the remainder term is uniformly bounded in g), since by (V.3), for any small $\varepsilon>0$, there exists $R>0$ such that $|r^mV(z)-v(\omega)|<\varepsilon$ if $r=|z|\geqslant R$. Then, taking a limit $\varepsilon\downarrow 0$ in (3.8), we derive from Lemmas 3.2, 3.1, and 3.5 that $\limsup_{g\to\infty}g^{-2/m}N(H_g(b)<\lambda)\leqslant\Sigma_{l\in N}\nu_l(\lambda)$, by Lebesgue's dominated convergence theorem. The lemma follows since $N(H_g(b)<\lambda)=N_g^+(\lambda)$ holds if $\lambda<B_-$ because of the non-negativity of V. ■

B. Lower bound for $N(H_g(b)<\lambda)$

Let K and $\{\Omega_k\}_{k\in K}$ be as in the beginning of this section. Applying Lemma 2.1 to the pair of triplets $(\Sigma_{k\in K}\oplus L^2(\Omega_k),t_1,\oplus_{k\in K}C_0^{\infty}(\Omega_k))$ and $(L^2(\mathbf{R}^2),t_2,C_0^{\infty}(\mathbf{R}^2))$, where we set $t_1[\oplus_{k\in K}v_k]=\Sigma_{k\in K}(H_g(b)|_{\Omega_k}v_k,v_k)$ for $\oplus_{k\in K}(v_k)\in\oplus_{k\in K}C_0^{\infty}(\Omega_k)$, $t_2[u]=(H_g(b)u,u)$ for $u\in C_0^{\infty}(\mathbf{R}^2)$ and $J:\oplus_{k\in K}C_0^{\infty}(\Omega_k)\ni\oplus_{k\in K}(v_k)\mapsto\Sigma_{k\in K}v_k\in C_0^{\infty}(\mathbf{R}^2)$, we have

$$N(H_g(b)<\lambda) \geqslant \sum_{k\in K} N(H_g(b)|_{\Omega_k}<\lambda). \tag{3.11}$$

As in the proof of Lemma 3.1, we can show that

$$N\big(H_g(b)\big|_{\Omega_0} < \lambda\big) = o(g^{2/m}) \tag{3.12}$$

as $g \to \infty$, using the upper estimate in Lemma 2.4. Also, as in the proof of Lemma 3.2, we can show that

$$N\big(H_g(b)\big|_{\Omega_1} < \lambda\big) \leqslant N\big(H_0(b)\big|_{\Omega_1} < \lambda + o(1)\big) = 0 \tag{3.13}$$

holds for large $g > 0$.

Lemma 3.7: For any $l \in \mathbf{N}$ and any ε satisfying $0 < \varepsilon < 1$, set

$$\Omega_{\pm}^{(-)}(\varepsilon, l) = \{z \in \mathbf{R}^2 \,|\, \pm x \geqslant 0, (1+2\varepsilon)\Lambda_l^{\pm} < \lambda + (1-\varepsilon)gV(z)\},$$

respectively. Then for any ε satisfying $0 < \varepsilon < 1$, we have

$$N(H_g(b)|_{\Omega_{\pm}} < \lambda) \geqslant (1-\varepsilon)^2 \frac{B_{\pm}}{2\pi} \sum_{l \in \mathrm{N}} \mathrm{Vol}(\Omega_{\pm}^{(-)}(\varepsilon, l)) + o(g^{2/m})$$

as $g \to \infty$, respectively.

Proof: Let $0 < \eta < 1$ and $j \in \mathbf{Z}^2$. Let Q_j and $Q_{j\eta}$ be the cubes defined by (3.3) and (3.4), respectively. Set $J'_{\pm} = \{j \in \mathbf{Z}^2 \,|\, Q_j \subset \tilde{\Omega}_{\pm}, Q_j \cap \Omega_{\pm}^{(-)}(\varepsilon, l) \neq \emptyset\}$, respectively. Let $b_{j,\pm}$ be as in (3.5). Then, as in the proof of Lemma 3.5, it follows from Lemma 2.4, Lemma 2.1, and Lemma 2.3 that, for any ε satisfying $0 < \varepsilon < 1$,

$$\begin{aligned} N(H_g(b)|_{\Omega_{\pm}} < \lambda) &\geqslant \sum_{j \in J'_{\pm}} N((1+2\varepsilon)H_0(b)|Q_j < \lambda + g \sup_{Q_{j\eta}} |V|) \\ &\geqslant (1-\varepsilon)^2 \frac{B_{\pm}}{2\pi} \sum_{j \in J'_{\pm}} \mathrm{Vol}(Q_j) \sharp \{l \in \mathbf{N} | (1+2\varepsilon)\Lambda_l^{\pm} < \lambda + g \sup_{Q_{j\eta}} |V|\} \\ &\geqslant (1-\varepsilon)^2 \frac{B_{\pm}}{2\pi} \sum_{l \in \mathrm{N}} \sum_{j \in J'_{\pm}} \mathrm{Vol}(Q_j) F((1+2\varepsilon)\Lambda_l^{\pm} < \lambda + g \sup_{Q_{j\eta}} |V|), \end{aligned} \tag{3.14}$$

where we used Proposition 2.2 with $r_1 = \varepsilon$ in the third inequality.

We claim that, if $j \in J'_{\pm}$, then $F((1+2\varepsilon)\Lambda_l^{\pm} < \lambda + g \sup_{Q_{j\eta}} |V|) = 1$ holds for large $g > 0$ uniformly in j, l. Indeed, if $j \in J'_{\pm}$, there exists $\overline{z} \in Q_j \cap \Omega_{\pm}^{(-)}(\varepsilon, l)$, i.e., $\overline{z} \in Q_j$ and $(1+2\varepsilon)\Lambda_l^{\pm} < \lambda + g(1-\varepsilon)V(\overline{z})$ hold. Then, by Lemma 3.4 and $(V.2)$, we have $\lambda + g \sup_{Q_{j\eta}} |V| - (1+2\varepsilon)\Lambda_l^{\pm} \geqslant g(\sup_{Q_{j\eta}} |V| - (1-\varepsilon)V(\overline{z})) \geqslant g(\varepsilon - Cg^{-(\alpha-2\sigma)})V(\overline{z}) > 0$ for large $g > 0$. This shows the claim. So, for large $g > 0$, the rhs of (3.14) is bounded from below by

$$\begin{aligned} &(1-\varepsilon)^2 \frac{B_{\pm}}{2\pi} \sum_{l \in \mathbf{N}} \sum_{j \in J'_{\pm}} \mathrm{Vol}(Q_j) \\ &\geqslant (1-\varepsilon)^2 \frac{B_{\pm}}{2\pi} \sum_{l \in N} \mathrm{Vol}((\Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon, l)) \setminus \{z \in \Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon, l) | \mathrm{dist}(z, \partial\Omega_{\pm}) \leqslant g^{\sigma}\}) \\ &\geqslant (1-\varepsilon)^2 \frac{B_{\pm}}{2\pi} \sum_{l \in \mathbf{N}} \mathrm{Vol}(\Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon, l)) - (1-\varepsilon)^2 \frac{B_{\pm}}{2\pi} \sum_{l=0}^{C_g 1-m\alpha} \mathrm{Vol}\{z \in \Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon, l) | \mathrm{dist}(z, \partial\Omega_{\pm}) \\ &\leqslant g^{\sigma}\}, \end{aligned} \tag{3.15}$$

where we used the fact that $(\Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon, l)) \setminus \{z \in \Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon, l) \,|\, \mathrm{dist}(z, \partial\Omega_{\pm}) \leqslant g^{\sigma}\} \subset \cup_{j \in J'_{\pm}} Q_j$, where the rhs is a disjoint union, in the first inequality and used, in the last inequality, the fact that the set $\Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon, l) = \{z \in \Omega_{\pm} | (1+2\varepsilon)\Lambda_l^{\pm} < \lambda + (1-\varepsilon)gV(z)\}$ is empty for all l satisfying $(1+2\varepsilon)\Lambda_l^{\pm} \geqslant \lambda + Cg^{1-m\alpha}$ since $\sup_{\Omega_{\pm}} |V| \leqslant C\langle g^{\alpha} - g^{\sigma}\rangle^{-m} \leqslant Cg^{-m\alpha}$ holds for large g.

From geometry, we have $\mathrm{Vol}(\Omega_0 \cap \Omega_{\pm}^{(-)}(\varepsilon,l)) \leqslant \mathrm{Vol}\,\Omega_0 \leqslant Cg^{\alpha+\beta} = o(g^{2/m})$ and $\mathrm{Vol}(\Omega_{\mp} \cap \Omega_{\pm}^{(-)}(\varepsilon,l)) = \mathrm{Vol}(\Omega_1 \cap \Omega_{\pm}^{(-)}(\varepsilon,l)) = 0$ as $g \to \infty$, where we used the fact that $\Omega_1 \subset \{z \in \mathbf{R}^2 \,|\, |z| \geqslant g^{\beta}\} \subset \{z \in \mathbf{R}^2 \,|\, |z| \geqslant 2Cg^{1/m}\}$ and $\Omega_{\pm}^{(-)} \subset \{z \in \mathbf{R}^2 \,|\, B_- < \lambda + Cg\langle z\rangle^{-m}\} \subset \{z \in \mathbf{R}^2 \,|\, |z| \leqslant Cg^{1/m}\}$ for some $C > 0$. Hence, we have

$$\mathrm{Vol}\big(\Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon,l)\big) = \mathrm{Vol}\big(\Omega_{\pm}^{(-)}(\varepsilon,l)\big) + o(g^{2/m}) \tag{3.16}$$

as $g \to \infty$, and we observe that

$$\sum_{l=0}^{Cg^{1-m\alpha}} \mathrm{Vol}\{z \in \Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon,l) \,|\, \mathrm{dist}(z, \partial\Omega_{\pm}) \leqslant g^{\sigma}\} \leqslant Cg^{1-m\alpha} g^{\beta+\sigma} = o(g^{2/m}) \tag{3.17}$$

as $g \to \infty$, since $\Omega_{\pm} \cap \Omega_{\pm}^{(-)}(\varepsilon,l) \subset \Omega_{\pm}$ and $1 - m\alpha + \beta + \sigma = 2/m - (1/m - 2(m+1)\sigma) < 2/m$. Then the lemma follows from (3.14)–(3.17). ■

Lemma 3.8: Let $\lambda < B_-$. Under the same assumption on B and V as in Theorem 1.1, we have $\lim_{g\to\infty} g^{-2/m} N_g^+(\lambda) = \Sigma_{l\in\mathbf{N}} \nu_l(\lambda)$.

Proof: We can deduce from (3.11) and (3.12) and Lemma 3.7 that $\liminf_{g\to\infty} g^{-2/m} N_g^+(\lambda) \geqslant \Sigma_{l\in\mathbf{N}} \nu_l(\lambda)$ in the same way as in the proof of Lemma 3.6. Then, combining this and Lemma 3.6, we have the result. ■

Remark 3.9: Our proof shows that we can replace the assumptions on B and V in Lemma 3.8 by the following weaker assumptions.

$(B)'$ In addition to (B.1), there exist $M > 0$ and $C > 0$ such that $|B(x) - B_{\pm}| \leqslant C\langle x\rangle^{-M}$ hold as $x \to \pm\infty$, respectively.

$(V)'$ The non-negative scalar potential V belongs to $C^1(\mathbf{R})$, and there exist $m > 0$ and $C > 0$ such that $0 < m < 2$ and $|\partial^{\alpha} V(z)| \leqslant C\langle z\rangle^{-m-|\alpha|}$ holds for all $z \in \mathbf{R}^2$ and for any multi-index α satisfying $|\alpha| \leqslant 1$. Moreover, the conditions (V.2) and (V.3) hold.

IV. SPECTRAL PROPERTIES OF THE IWATSUKA MODEL

A. Direct decomposition

In this section we recall from Iwatsuka (1985) the spectral representation of the Iwatsuka $H_0(b)$. We introduce the partial Fourier transform $(\mathcal{F}u)(x,\eta) = (2\pi)^{-1/2} \int_{\mathbf{R}} e^{-\sqrt{-1}y\eta} u(x,y)\mathrm{d}y$, which defines a unitary operator on $L^2(\mathbf{R}^2)$. We write L_0 for $\mathcal{F}H_0(b)\mathcal{F}^{-1}$. Then L_0 has the direct integral decomposition $L_0 = \int_{\mathbf{R}}^{\oplus} L(\eta)\mathrm{d}\eta$ acting on the Hilbert space $\int_{\mathbf{R}}^{\oplus} L^2(\mathbf{R})\mathrm{d}\eta$. Here, for each $\eta \in \mathbf{R}$, the fiber $L(\eta)$ of L_0 is given by

$$L(\eta) = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + (\eta - b(x))^2, \tag{4.1}$$

acting on the fiber $L^2(\mathbf{R})$ of $\int_{\mathbf{R}}^{\oplus} L^2(\mathbf{R})\mathrm{d}\eta$.

The spectral properties of $L(\eta)$ are summarized as follows.

Lemma 4.1: [Iwatsuka[11], Lemmas 2.3 and 3.5)] Assume that (B.1) holds. For each $\eta \in \mathbf{R}$, the operator $L(\eta)$ is essentially self-adjoint on $C_0^{\infty}(\mathbf{R})$ and has a complete orthonormal system of eigenfunctions $\{\varphi_n(\cdot,\eta)\}_{n\in\mathbf{N}}$ and the corresponding eigenvalues $\{\lambda_n(\eta)\}_{n\in\mathbf{N}}$ so that $L(\eta)\varphi_n(\cdot,\eta) = \lambda_n(\eta)\varphi_n(\cdot,\eta)$ and $0 < \lambda_0(\eta) < \lambda_1(\eta) < \lambda_2(\eta) < \cdots \to \infty$ hold for each $n \in \mathbf{N}$.

Moreover, the following properties (1)–(5) hold for each $n \in \mathbf{N}$.

(1) *$\lambda_n(\eta)$ is nondegenerate and depends analytically on η.*
(2) *$\lambda_n(\eta)$ is monotonically increasing in η, and $\lim_{\eta\to\pm\infty} \lambda_n(\eta) = \Lambda_n^{\pm}$ hold, respectively.*
(3) *$\varphi_n(\cdot,\eta)$ belongs to $D(L(0))$ and depends analytically on η with respect to the graph norm $(\|u\|^2 + \|L(0)u\|^2)^{1/2}$.*
(4) *$\varphi_n(x,\eta)$ is a real-valued continuous function of x and η, and moreover, $\varphi_n(x,\eta)$ is infinitely differentiable in x for each η and is analytic in η for each x.*
(5) *The estimate $|\varphi_n(x,\eta)| \leqslant \Phi_n(x - b^{-1}(\eta))$ holds for a function Φ_n satisfying $0 < \Phi_0(x) < \cdots$*

$<\Phi_n(x)<\cdots$ *and*

$$\Phi_n(x) \leqslant \begin{cases} \sqrt{2}(\Lambda_n^+)^{1/4} & \text{if } |x| \leqslant \sqrt{\Lambda_n^+}/B_-, \\ \sqrt{2}(\Lambda_n^+)^{1/4} \exp\{-B_-(|x|-L_n)^2/2\} & \text{if } |x| \geqslant \sqrt{\Lambda_n^+}/B_-. \end{cases}$$

The next result follows easily from (*B*.1) and the definition of b.

Lemma 4.2: Under the assumption (B.1), the function b has the inverse b^{-1} *and moreover, for any* x,y,η, *we have* $B_-|x-b^{-1}(\eta)| \leqslant |b(x)-\eta| \leqslant B_+|x-b^{-1}(\eta)|$ *and* $B_-|x-y| \leqslant |b(x)-b(y)| \leqslant B_+|x-y|$.

For any $k \in \mathbf{N}$, we introduce the Banach space $B^k=\{u \in \mathcal{S}'(\mathbf{R}) \,|\, x^\alpha \partial_x^\beta u \in L^2(\mathbf{R})$ if $\alpha+\beta \leqslant k\}$ with norm $\|u\|_{B^k}=(\Sigma_{\alpha+\beta\leqslant k}\|x^\alpha\partial_x^\beta u\|^2)^{1/2}$.

Lemma 4.3: Let D_0 *denote either* $C_0^\infty(\mathbf{R})$ *or* $\mathcal{S}(\mathbf{R})$. *We have the following assertions.*

(1) *For any* $k \in \mathbf{N}$, *the operator* $L(\eta)^k|_{D_0}$ *is essentially self-adjoint and* $\overline{L(\eta)^k|_{D_0}}=(\overline{L(\eta)|_{D_0}})^k$. *Moreover,* $D(\overline{L(\eta)^k|_{D_0}})=\{u \in L^2(\mathbf{R}) \,|\, L(\eta)^k_{\mathrm{dist}} u \in L^2(\mathbf{R})\}$. *Here,* L_{dist} *stands for the differential operator L with domain* $\mathcal{S}'(\mathbf{R})$.

(2) *The Banach space* $D(\overline{L(\eta)^k|_{D_0}})$ *equipped with the graph norm* $\overline{L(\eta)^k|_{D_0}}$ *coincides with the Banach space* $D(\overline{L(0)^k|_{D_0}})$ *equipped with (equivalent) norm by* $\overline{L(0)^k|_{D_0}}$.

(3) *If we denote by* $\widetilde{B}^k$ *the space as in the assertion (2) above, then* $\widetilde{B}^k$ *coincides with* B^k *as a Banach space. In particular, the space* $\cap_{k\in\mathbf{N}}\widetilde{B}^k$ *coincides with* $\mathcal{S}(\mathbf{R})$ *as a Fréchet space.*

Proof: We note that $L(\eta) \in OpS^2$, so $L(\eta)^k \in OpS^{2k}$ for any η. It is easy to see that the symbol of $L(\eta)^k$ satisfies the ellipticity condition as in Lemma 2.7 and $L(\eta)$ is symmetric on D_0. Then, by Lemma 2.7, the operator $L(\eta)^k|_{D_0}$ is essentially self-adjoint and $D(\overline{L(\eta)^k|_{D_0}})=\{u \in L^2(\mathbf{R}) \,|\, L(\eta)^k_{\mathrm{dist}} u \in L^2(\mathbf{R})\}$. Also, we find that $L(\eta)^k|_{D_0}=(\overline{L(\eta)|_{D_0}})^k|_{D_0}$ since $L(\eta)$ leaves D_0 invariant. This implies that $\overline{L(\eta)^k|_{D_0}} \subset (\overline{L(\eta)|_{D_0}})^k$, which are both self-adjoint, so coincide. This shows the assertion (1).

The assertion (2) follows from Lemma 2.7 with $Op(a)=L(\eta)^k$ and with $Op(a)=L(0)^k$ since the topology of the weighted Sobolev spaces H^m is independent of specific $Op(a)$ by the (original) definition. As a byproduct, we find that $D(\overline{L(\eta)^k|_{D_0}})$ coincides with H^{2k}.

Finally we show the assertion (3). It is enough to show in the case of $\eta=0$. Note that $B_-|x| \leqslant |b(x)| \leqslant B_+|x|$ holds for all $x \in \mathbf{R}$ by Lemma 4.2, and each derivative of b is bounded. Then there exists $C_k>0$ such that

$$\|L(0)^k u\|^2 + \|u\|^2 \leqslant C_k \|u\|^2_{B^{2k}} \tag{4.2}$$

holds for any $u \in D_0$. Conversely, by the assertion (4) in Lemma 2.6, the operator $x^\beta\partial_x^\alpha$ maps H^{2k}, which coincides with $D(\overline{L(\eta)^k|_{D_0}})$ as stated above, to $L^2(\mathbf{R})$ continuously provided $\alpha+\beta \leqslant 2k$. This means the inequality $\|x^\beta\partial_x^\alpha u\| \leqslant C(\|L(0)^k u\|+\|u\|)$ for any $u \in D_0$. The density of D_0 completes the proof. ■

B. Exponential decay of φ_n

In this section, using the so-called Agmon estimate, we derive an exponential decay estimates of the eigenfunction φ_n and obtain the estimates for the band function λ_n. To the end of this section, we set $g(x,\eta)=(x-b^{-1}(\eta))^2$ for any $x,\eta \in \mathbf{R}$.

Lemma 4.4: Let $\eta \in \mathbf{R}$ *and let* $L(\eta)$ *be as in* (4.1). *Assume that* $f \in L^2(\mathbf{R})$ *and there exists* $\kappa>0$ *such that* $\|e^{\kappa g(\cdot,\eta)} f\|$ *is finite. Assume that* ψ *in* $D(L(\eta))$ *satisfies the equation* $(L(\eta)-\lambda_n(\eta))\psi=f$. *Then there exists* $C_n=C_n(\kappa,B_-)>0$, *independent of* η, *such that*

$$\|e^{\alpha g(\cdot,\eta)}\psi\| \leqslant C_n(\|e^{\kappa g(\cdot,\eta)} f\| + \|\psi\|)$$

holds if $0<\alpha<\min\{\kappa, B_-^2/\sqrt{8}\}$.

Proof: This is an easy consequence of the method of Agmon estimates. However, we give a

proof for the sake of completeness. Let $\chi \in C^\infty([0,\infty))$ such that $\chi(t)=t$ if $0\leqslant t\leqslant 1/2$, $\chi(t)=1$ if $t\geqslant 2$, $\sup_{t\geqslant 0}|\chi'(t)|\leqslant 1$ and χ is monotonically increasing. For any large $R>0$, we set $g_R(x,\eta)=R^2\chi(g(x,\eta)/R^2)$. We can find that

$$|g_R(x,\eta)|\leqslant \min\{R^2, g(x,\eta)\}, \quad |\partial_x g_R(x,\eta)|\leqslant 2|x-b^{-1}(\eta)| \tag{4.3}$$

and $\lim_{R\to\infty} g_R(x,\eta)=g(x,\eta)$ for any (x,η).

We may assume that ψ is not identically zero. The standard Agmon-type argument shows that $\mathrm{Re}(e^{\alpha g_R}(L(\eta)-\lambda_n(\eta))e^{\alpha g_R})\geqslant (b-\eta)^2-\alpha^2|\partial_x g_R|^2-\lambda_n\geqslant (B_-^2-4\alpha^2)|x-b^{-1}(\eta)|^2-\Lambda_n^+$ holds for any $\alpha \in \mathbf{R}$, where we used Lemma 4.2 in the first inequality and "Re" stands for the real part. Then it follows that

$$\|e^{\alpha g_R}\psi\|\|e^{\alpha g_R}f\|\geqslant |\mathrm{Re}(e^{2\alpha g_R}\psi, f)|\geqslant (e^{\alpha g_R}\psi, ((B_-^2-4\alpha^2)|x-b^{-1}|^2-\Lambda_n^+)e^{\alpha g_R}f). \tag{4.4}$$

Take $\phi\in C_0^\infty([0,\infty))$ so that $\phi(t)=1$ if $0\leqslant t\leqslant 1$, $\phi(t)=0$ if $t\geqslant 2$ and ϕ is monotonically decreasing. Set $\phi_\eta(x)=\phi(B_-^2 g(x,\eta)/(2\Lambda_n^+))$. Then we find that

$$(B_-^2-4\alpha^2)|x-b^{-1}|^2-\Lambda_n^+\geqslant (1-8\alpha^2/B_-^2)\Lambda_n^+-6\Lambda_n^+\phi_\eta \tag{4.5}$$

using the fact that $g(x,\eta)\leqslant 4\Lambda_n^+/B_-^2$ holds on supp ϕ_η and $g(x,\eta)\geqslant 2\Lambda_n^+/B_-^2$ holds on supp $(1-\phi_\eta)$, and we find from (4.4) and (4.5) that $(1-8\alpha^2/B_-^2)\Lambda_n^+\|e^{\alpha g_R}\psi\|\leqslant \|e^{\alpha g_R}f\|+6\Lambda_n^+ e^{4\alpha\Lambda_n^+/B_-^2}\|\psi\|$, since $g_R(x,\eta)\leqslant g(x,\eta)\leqslant 4\Lambda_n^+/B_-^2$ holds on supp ϕ_η. Taking a limit $R\to\infty$, we have the conclusion. ■

Lemma 4.5: Let $\alpha\in\mathbf{N}$. There exists $\kappa=\kappa_{\alpha,n}>0$ such that

$$\sup_{\eta\in\mathbf{R}}\|e^{\kappa g}\partial_\eta^{\alpha'}\varphi_n(\eta)\|<\infty \quad \text{and} \quad \sup_{\eta\in\mathbf{R}}|\partial_\eta^{\alpha'+1}\lambda_n(\eta)|<\infty \tag{4.6}$$

hold if $0\leqslant\alpha'\leqslant\alpha$.

Proof: We show this by induction on α. We abbreviate the assertion to $P(\alpha)$. When $\alpha=0$, the first estimate in (4.6) follows from Lemma 4.1 (v). The Feynman–Hellman formula yields that

$$\partial_\eta\lambda_n(\eta)=(\varphi_n,(\partial_\eta L(\eta))\varphi_n)=2(\varphi_n,(\eta-b)\varphi_n). \tag{4.7}$$

Then the second estimate in (4.6) follows from the exponential decay of φ_n with respect to $\eta-b$. This shows that $P(0)$ is true.

We assume that $P(\alpha)$ is true. First, under this assumption, we show the estimate

$$\sup_{\eta\in\mathbf{R}}\|\partial_\eta^{\alpha+1}\varphi_n(\eta)\|<\infty. \tag{4.8}$$

Differentiating the equation $(L(\eta)-\lambda_n(\eta))\varphi_n(\eta)=0$ with respect to η in $(\alpha+1)$ times, we obtain

$$(L(\eta)-\lambda_n(\eta))\partial_\eta^{\alpha+1}\varphi_n(\eta)=-\sum_{0\leqslant\alpha'\leqslant\alpha} C_{\alpha+1,\alpha'}\partial_\eta^{\alpha+1-\alpha'}((b-\eta)^2-\lambda_n(\eta))\partial_\eta^{\alpha'}\varphi_n(\eta). \tag{4.9}$$

In the case of $j\neq n$, taking an inner product with φ_j, we obtain

$$(\lambda_j(\eta)-\lambda_n(\eta))(\partial_\eta^{\alpha+1}\varphi_n,\varphi_j)=-\sum_{0\leqslant\alpha'\leqslant\alpha} C_{\alpha+1,\alpha'}(\partial_\eta^{\alpha+1-\alpha'}((b-\eta)^2-\lambda_n(\eta))\partial_\eta^{\alpha'}\varphi_n,\varphi_j).$$

Then the Schwarz inequality yields that

$$|(\partial_\eta^{\alpha+1}\varphi_n,\varphi_j)|^2 \leqslant \left(C_\alpha\delta_n^{-1}\sum_{0\leqslant\alpha'\leqslant\alpha}|(\partial_\eta^{\alpha+1-\alpha'}((b-\eta)^2-\lambda_n(\eta))\partial_\eta^{\alpha'}\varphi_n,\varphi_j)|\right)^2$$
$$\leqslant C'_\alpha\delta_n^{-2}\sum_{0\leqslant\alpha'\leqslant\alpha}|(\partial_\eta^{\alpha+1-\alpha'}((b-\eta)^2-\lambda_n(\eta))\partial_\eta^{\alpha'}\varphi_n,\varphi_j)|^2 \tag{4.10}$$

for some $C_\alpha, C'_\alpha>0$ independent of η. Here, we introduced a positive number δ_n as

$$\delta_n=\begin{cases}\min\{\inf_{\eta\in\mathbf{R}}(\lambda_{n+1}(\eta)-\lambda_n(\eta)),\inf_{\eta\in\mathbf{R}}(\lambda_n(\eta)-\lambda_{n-1}(\eta))\} & \text{if } n\geqslant 2,\\ \inf_{\eta\in\mathbf{R}}(\lambda_2(\eta)-\lambda_1(\eta)) & \text{if } n=1.\end{cases}$$

In the case of $j=n$, differentiating the relation $(\varphi_n,\varphi_n)=1$ with respect to η in $(\alpha+1)$ times, we find that $2(\partial_\eta^{\alpha+1}\varphi_n,\varphi_n)=-\Sigma_{1\leqslant\alpha'\leqslant\alpha}C_{\alpha+1,\alpha'}(\partial_\eta^{\alpha+1-\alpha'}\varphi_n,\partial_\eta^{\alpha'}\varphi_n)$, where we used the reality of φ_n. Then we have

$$|(\partial_\eta^{\alpha+1}\varphi_n,\varphi_n)|\leqslant C_\alpha\sum_{1\leqslant\alpha'\leqslant\alpha}\|\partial_\eta^{\alpha+1-\alpha'}\varphi_n\|\|\partial_\eta^{\alpha'}\varphi_n\| \tag{4.11}$$

for some $C_\alpha>0$ independent of η. Hence it follows from (4.10) and (4.11) that

$$\|\partial_\eta^{\alpha+1}\varphi_n\|^2=\sum_{j\in N}|(\partial_\eta^{\alpha+1}\varphi_n,\varphi_j)|^2\leqslant C'_\alpha\delta_n^{-2}\sum_{0\leqslant\alpha'\leqslant\alpha}\|(\partial_\eta^{\alpha+1-\alpha'}((b-\eta)^2-\lambda_n(\eta)))\partial_\eta^{\alpha'}\varphi_n\|^2$$
$$+\left(C_\alpha\sum_{1\leqslant\alpha'\leqslant\alpha}\|\partial_\eta^{\alpha+1-\alpha'}\varphi_n\|\|\partial_\eta^{\alpha'}\varphi_n\|\right)^2, \tag{4.12}$$

where we used the fact that $\{\varphi_j(\cdot,\eta)\}_{j\in\mathbf{N}}$ is an ONB in $L^2(\mathbf{R})$. By the assumption $P(\alpha)$, all terms on the rhs of (4.12) are bounded uniformly in η. Thus we have proved (4.8) under $P(\alpha)$.

Next, we apply Lemma 4.4 to (4.9) with $\psi=\partial_\eta^{\alpha+1}\varphi_n, f=f_\alpha$=the rhs of (4.9). We may assume that the constant α in the exponent in Lemma 4.4 is equal to κ since we can take κ small enough. Then it follows that there exists $C_n>0$ such that the estimate $\|e^{\kappa g}\partial_\eta^{\alpha+1}\varphi_n\|\leqslant C_n(\|e^{\kappa g}f_\alpha\|+\|\partial_\eta^{\alpha+1}\varphi_n\|)$. The first term on the rhs is bounded uniformly in η under $P(\alpha)$, since the maximal order of derivatives of φ_n is less than or equal to α and the maximal order of derivatives of λ_n is less than or equal to $\alpha+1$ in the expression of f_α. The second term on the rhs is also uniformly bounded because of (4.8) we have already proved. Hence, we have proved the first estimate in (4.6) for $P(\alpha+1)$, assuming $P(\alpha)$.

Finally, we show the second estimate in (4.6) for $P(\alpha+1)$, assuming $P(\alpha)$. Differentiating (4.7) with respect to η in $(\alpha+1)$ times, we obtain

$$\partial_\eta^{\alpha+2}\lambda_n(\eta)=2\partial_\eta^{\alpha+1}(\varphi_n,(\eta-b)\varphi_n)=2\sum_{0\leqslant\alpha'\leqslant\alpha+1}C_{\alpha+1,\alpha'}(\partial_\eta^{\alpha+1-\alpha'}\varphi_n,\partial_\eta^{\alpha'}((\eta-b)\varphi_n)). \tag{4.13}$$

Since the maximal order of derivatives of φ_n on the rhs of (4.13) is less than or equal to $\alpha+1$, the uniform boundedness of the rhs of (4.13) with respect to η follows from the first estimate in (4.6) for $P(\alpha)$ and the exponential decay property of $\partial_\eta^{\alpha+1}\varphi_n$ we have proved above. Thus we have proved all the assertion of $P(\alpha+1)$, assuming $P(\alpha)$. This completes the induction. ■

Lemma 4.6: Let $\beta\in\mathbf{N}$. *For any* $\alpha\in\mathbf{N}$, *there exists* $\kappa=\kappa(\alpha,\beta,n)>0$ *such that* $\sup_{\eta\in\mathbf{R}}\|e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n(\eta)\|<\infty$.

Proof: We show this by induction on β. We abbreviate the assertion to $P(\beta)$. The assertion $P(0)$ is true by Lemma 4.5.

We assume that $P(\beta)$ is true. Then, for any α, we have

$$\|e^{\kappa g}\partial_x^{\beta+1}\partial_\eta^\alpha\varphi_n(\eta)\|^2=-(e^{2\kappa g}\partial_x^\beta\partial_\eta^\alpha\partial_x^2\varphi_n,\partial_x^\beta\partial_\eta^\alpha\varphi_n)-4\kappa((x-b^{-1}(\eta))e^{2\kappa g}\partial_x^{\beta+1}\partial_\eta^\alpha\varphi_n,\partial_x^\beta\partial_\eta^\alpha\varphi_n)$$
$$=(e^{2\kappa g}\partial_x^\beta\partial_\eta^\alpha(\lambda_n(\eta)-(b-\eta)^2)\varphi_n,\partial_x^\beta\partial_\eta^\alpha\varphi_n)$$
$$-4\kappa(\partial_x^{\beta+1}\partial_\eta^\alpha\varphi_n,(x-b^{-1}(\eta))e^{2\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n), \tag{4.14}$$

where we used the equation $(L-\lambda_n)\varphi_n=0$ in the third equality. The first term on the rhs of (4.14) is bounded uniformly in η by the assumption $P(\beta)$ and the second estimate in (4.6) if we choose $\kappa>0$ sufficiently small (the choice is independent of η). The second term on the rhs of (4.14) is bounded from above by $4\kappa\|e^{\kappa g}\partial_x^{\beta+1}\partial_\eta^\alpha\varphi_n\|\|(x-b^{-1}(\eta))e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n\|\leq 2\kappa\|e^{\kappa g}\partial_x^{\beta+1}\partial_\eta^\alpha\varphi_n\|^2+2\kappa\|(x-b^{-1})e^{\kappa g}\partial_\beta\partial_\eta^\alpha\varphi_n\|^2$, which is uniformly bounded since $P(\beta)$ is assumed to be true. ■

Lemma 4.7: For any $n,\alpha,\beta\in\mathbf{N}$, there exists a positive constant $\kappa=\kappa(\alpha,\beta,n)$ such that $\sup_{(x,\eta)\in\mathbf{R}^2}|e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n(x,\eta)|<\infty$ holds.

Proof: For any $\gamma\in\mathbf{N}$, we have $\partial_x^\gamma(e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n)=\Sigma_{0\leq\gamma'\leq\gamma}C_{\gamma,\gamma'}(\partial_x^{\gamma-\gamma'}e^{\kappa g})(\partial_x^{\beta+\gamma'}\partial_\eta^\alpha\varphi_n)$. Since each of the functions $\partial_x^{\gamma-\gamma'}e^{\kappa g}$ is of the form "a polynomial of $(x-b^{-1}(\eta))$ times $e^{\kappa g}$," we obtain the estimate

$$\|\partial_x^\gamma(e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n)\|\leq\sum_{0\leq\gamma'\leq\gamma}C_{\gamma,\gamma'}\|e^{\kappa' g}\partial_x^{\beta+\gamma'}\partial_\eta^\alpha\varphi_n\| \tag{4.15}$$

for some $\kappa'>0$ satisfying $0<\kappa'<\kappa$ uniformly in η. The rhs of (4.15) is bounded uniformly in η by Lemma 4.6 for an appropriate choice of κ,κ'. This means that the γth Sobolev norm of $e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n$ is bounded uniformly in η for each γ. Hence, Sobolev's embedding theorem yields that

$$\sup_{x\in\mathbf{R}}|e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n|\leq C(\|e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n\|+\|\partial_x(e^{\kappa g}\partial_x^\beta\partial_\eta^\alpha\varphi_n)\|) \tag{4.16}$$

for some $C>0$. The above observation shows that the rhs of (4.16) is uniformly bounded in η if we choose κ small enough. This shows the lemma. ■

C. Decay estimate of λ_n

In this section, we derive the following decay estimate of the band function λ_n at infinity.

Lemma 4.8: Assume that $(B.2)_+$ holds. Then, for any $n\in\mathbf{N}$, there exists $C_n>0$ such that $|\Lambda_n^+-\lambda_n(b(x))|\leq C_n\langle x\rangle^{-M}$ holds if $x\geq 0$. Similarly, if we assume $(B.2)_-$ then the same estimate replaced Λ_n^+ by Λ_n^- holds if $x\leq 0$.

Proof: We mimic the proof of Lemma 4.1 in Iwatsuka (1985). We first consider the case of $x\geq 0$. Let n be fixed and $j,k\leq n$. Set $L_c(s)=-\partial_x^2+B_+^2(x-s)^2$ in $L^2(\mathbf{R})$ and $\alpha_{jk}(s)=(L_c(s)\varphi_j(\cdot,b(s)),\varphi_k(\cdot,b(s)))$. Then, using the equation $(L(b(s))\varphi_j(\cdot,b(s)),\varphi_k(\cdot,b(s)))=\lambda_j(b(s))\delta_{jk}$, we find that

$$\begin{aligned}
|\alpha_{jk}(s)-\lambda_j(b(s))\delta_{jk}| &\leq \int_{\mathbf{R}}|B_+^2(x-s)^2-(b(x)-b(s))^2|\varphi_j(x,b(s))\|\varphi_k(x,b(s))|\mathrm{d}x\\
&\leq 2B_+\int_{\mathbf{R}}\left\{|x-s|\left|\int_s^x(B_+-B(t))\mathrm{d}t\right|\Phi_n(x-s)^2\right\}\mathrm{d}x\\
&=2B_+\int_{-\infty}^{-s/2}\left\{|y|\left|\int_s^{y+s}(B_+-B(t))\mathrm{d}t\right|\Phi_n(y)^2\right\}\mathrm{d}y\\
&\quad+2B_+\int_{-s/2}^{\infty}\left\{|y|\left|\int_s^{y+s}(B_+-B(t))\mathrm{d}t\right|\Phi_n(y)^2\right\}\mathrm{d}y,
\end{aligned} \tag{4.17}$$

where we used the facts that $|B_+^2(x-s)^2-(b(x)-b(s))^2|=|\int_s^x(B_++B(t))\mathrm{d}t\|\int_s^x(B_+-B(t))\mathrm{d}t|\leq 2B_+|x-s\|\int_s^x(B_+-B(t))\mathrm{d}t|$ holds and that $|\varphi_j(x,b(s))|\leq\Phi_n(x-s)$ hold if $j\leq n$ by Lemma 4.1. For any large $N\in\mathbf{N}$ and any large $s>0$, the first term on the rhs of (4.17) is bounded from above by

$$(2B_+)^2\int_{-\infty}^{-s/2}|y|^2\Phi_n(y)^2\,dy \leqslant 4B_+^2\int_{-\infty}^{-s/2}C_{N,n}\langle y\rangle^{-2N}\,dy \leqslant C'_{N,n}\langle s\rangle^N \tag{4.18}$$

for some constant $C'_{N,n}$, where we used Lemma 4.1. Since $(B.2)_+$ implies that there exists $s_0>0$ and $C_n>0$ such that $\sup_{t\geqslant s/2}|B_+-B(t)|\leqslant C_n\langle s\rangle^{-N}$ holds if $s>s_0$, it follows that the second term on the rhs of (4.17) is bounded from above by

$$2B_+C_n\langle s\rangle^{-M}\int_{-s/2}^{\infty}|y|^2\Phi_n(y)^2\,dy \leqslant C'_nB_+\langle s\rangle^{-M} \tag{4.19}$$

if $s>s_0$. Hence it follows from (4.17)–(4.19) that

$$\sup_{s>s_0}s^M|\alpha_{jk}(s)-\lambda_j(b(s))\delta_{jk}|\leqslant C_n \tag{4.20}$$

holds for some $C_n>0$, if we choose s_0 sufficiently large.

If we denote by $V_n(s)$ the linear subspace of $L^2(\mathbf{R})$ spanned by $\{\varphi_j(\cdot,b(s))\}_{j\leqslant n}$, then $(\alpha_{jk}(s))_{j,k\leqslant n}$ is the Hermitian symmetric matrix of $L_c(s)|_{V_n(s)}$ with respect to the basis $\{\varphi_j(\cdot,b(s))\}_{j\leqslant n}$. Let $\mu_0(s)\leqslant\cdots\leqslant\mu_n(s)$ be the eigenvalues of $(\alpha_{jk}(s))_{j,k\leqslant n}$. Let (a_{ij}) and (b_{ij}) be $n\times n$ Hermitian matrices and let $\alpha_1\leqslant\cdots\leqslant\alpha_n$ and $\beta_1\leqslant\cdots\leqslant\beta_n$ be their eigenvalues, respectively. Then it is easy to see that $|\alpha_k-\beta_k|^2\leqslant\Sigma_{i,j}|a_{ij}-b_{ij}|^2$ holds for any k. Hence it follows from (4.20) that

$$\sup_{s>s_0}s^M|\mu_j(s)-\lambda_j(b(s))|\leqslant C'_n. \tag{4.21}$$

Then, by the variational principle [Reed and Simon (1978, Vol. IV, Theorem XIII.3)], we have $\Lambda_j^+\leqslant\mu_j(s)$ for any $j\leqslant n$. Since Λ_j^+ is the jth eigenvalue of $L_c(s)$ and $\lambda_j(b(s))\leqslant\Lambda_j^+$, we can deduce from (4.21) that

$$\sup_{s>s_0}s^M|\Lambda_j^+-\lambda_j(b(s))|\leqslant C''_n \tag{4.22}$$

holds if $j\leqslant n$. This shows the first assertion of the lemma.

In the case of $s\to-\infty$, we have the conclusion in a similar way, replacing the objects $\alpha_{jk},L_c(s),L(b(s))$ and $\mu_j(s)$'s by $(L(b(s))\psi_j(\cdot,s),\psi_k(\cdot,s)),L(b(s)),-\partial_x^2+B_-^2(x-s)^2$ and the eigenvalues of the matrix $((L(b(s))\psi_j(\cdot,s),\psi_k(\cdot,s)))_{j,k\leqslant n}$, respectively. Here, $\psi_k(\cdot,s)$ is the eigenfunction of $-\partial_x^2+B_-^2(x-s)^2$ corresponding to the kth eigenvalue Λ_k^-. ■

V. PROOF OF THEOREMS

A. Operators on the direct sum

To the end of this paper, we always assume $(B.1)$, $(B.2)$, $(V.1)$–$(V.4)$.

Let $\{\varphi_n\}_{n\in\mathbf{N}}$ be the eigenfunctions given in Lemma 4.1. Because of Lemma 4.1, for any $l\in\mathbf{N}$, we can define a partial isometry T_l from $L^2(\mathbf{R})$ into $L^2(\mathbf{R}^2)$ by $(T_lf)(x,\eta)=\varphi_l(x,\eta)f(\eta)$ for any $f\in L^2(\mathbf{R})$. The adjoint operator T_l^* from $L^2(\mathbf{R}^2)$ onto $L^2(\mathbf{R})$ is given by $(T_l^*F)(\eta)=\int_{\mathbf{R}}\varphi_l(x,\eta)F(x,\eta)dx$ for any $F\in L^2(\mathbf{R}^2)$. We now extend T_ls to an operator on the direct sum of Hilbert spaces $\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$, more precisely, we define a partial isometry T from $\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$ into $L^2(\mathbf{R}^2)$ by $T(\oplus_{l\in\mathbf{N}}(f_l))=\Sigma_{l\in\mathbf{N}}T_lf_l$ for any $\oplus_{l\in\mathbf{N}}(f_l)\in\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$. The unitarity of T follows from the L^2-orthogonality of φ_l's with respect to the first variable. The adjoint operator T^* from $L^2(\mathbf{R}^2)$ onto $\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$ is given by $T^*F=\oplus_{l\in\mathbf{N}}T_l^*F$ for any $F\in L^2(\mathbf{R}^2)$. We set

$$\mathcal{W}=T^*\mathcal{F}W\mathcal{F}^*T \tag{5.1}$$

for any multiplication operator W on $L^2(\mathbf{R}^2)$ and set $\mathcal{H}_g=T^*\mathcal{F}H_g(b)\mathcal{F}^*T(=\mathcal{H}_0-g\mathcal{V})$, both acting on the Hilbert space $\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$, where $\mathcal{F}$ is the partial Fourier transform as in the preceding section and $\mathcal{V}$ is the operator (5.1) with $W=V$.

For an operator A acting on the space $\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$, we say *$A$ belongs to OpS^m* if all the matrix elements $A_{jk}(j,k\in\mathbf{N})$ of A (with respect to the direct sum decomposition) belong to the class OpS^m. When all the matrix-valued ΨDOs under consideration have finitely many nonzero components, the standard ΨDO calculus as in Sec. II B is applicable also for the matrix-valued ΨDOs. In particular, Proposition 2.8 remains valid for the matrix-valued ΨDO with obvious modifications (e.g., we regard the product of symbols as the usual matrix product, etc.).

In the rest of this section we are concerned with the matrix-valued ΨDO $\mathcal{V}=T^*\mathcal{F}V\mathcal{F}^*T$.

Lemma 5.1: Let $m>0$ be as in (V.1). We have the following assertions.

(1) *The operator $T_n^*\mathcal{F}V\mathcal{F}^*T_n$ on $L^2(\mathbf{R})$ belongs to OpS^{-m} for any $n\in\mathbf{N}$, and moreover, for any $\alpha,\beta\in\mathbf{N}$, there exists $C_{\alpha\beta}>0$ such that the Weyl symbol p_V of $T_n^*\mathcal{F}V\mathcal{F}^*T_n$ on $L^2(\mathbf{R})$ satisfies the estimate*

$$\eta_{\alpha\beta}^{(-m)}(p_V)\leqslant C_{\alpha\beta}\eta_{\alpha\beta}^{(-m)}(V). \tag{5.2}$$

Here, $\eta_{\alpha\beta}^{(m)}$ is the seminorm as in (2.2).

(2) *A principal symbol q_V of $T_n^*\mathcal{F}V\mathcal{F}^*T_n$ is given by $q_V(\eta,\eta^*)=V(b^{-1}(\eta),-\eta^*)$, and moreover, for any $\alpha,\beta\in\mathbf{N}$, there exists $C_{\alpha\beta}>0$ such that the remainder estimates*

$$\eta_{\alpha\beta}^{(-m-1)}(p_V-q_V)\leqslant C_{\alpha\beta}\eta_{\alpha\beta}^{(-m-1)}(\nabla V) \tag{5.3}$$

holds. Here, we denote by ∇V the first order derivatives of V.

(3) *The operator $T_i^*\mathcal{F}V\mathcal{F}^*T_j$ on $L^2(\mathbf{R})$ belongs to OpS^{-m-1} for any $i,j\in\mathbf{N}$ satisfying $i\neq j$, and moreover, for any $\alpha,\beta\in\mathbf{N}$, there exists $C_{\alpha\beta}>0$ such that the Weyl symbol r_V of $T_i^*\mathcal{F}V\mathcal{F}^*T_j$ on $L^2(\mathbf{R})$ satisfies the estimate*

$$\eta_{\alpha\beta}^{(-m-1)}(r_V)\leqslant C_{\alpha\beta}\eta_{\alpha\beta}^{(-m-1)}(\nabla V). \tag{5.4}$$

Proof: First, assuming further that $V\in\mathcal{S}(\mathbf{R}^2)$, we show the assertions (1)–(3). For any $i,j\in\mathbf{N}$, we find that the operator $T_i^*\mathcal{F}V\mathcal{F}^*T_j$ has the integral kernel $K(\eta,\eta')=\int\int_{\mathbf{R}^2}\varphi_i(x,\eta)\varphi_j(x,\eta')V(x,y)e^{-\sqrt{-1}y(\eta-\eta')}\,dx\bar{d}y$, which converges absolutely for each η,η', and so the Weyl symbol p_V is given by

$$\begin{aligned}p_V(\eta,\eta^*)&=\int_{\mathbf{R}}e^{-\sqrt{-1}w\eta^*}K(\eta+w/2,\eta-w/2)dw\\&=\int\int\int_{\mathrm{R}^3}dx\,\bar{d}w\,dz\,e^{-\sqrt{-1}wz}\varphi_i(x,\eta+w/2)\varphi_j(x,\eta-w/2)V(x,z-\eta^*),\end{aligned} \tag{5.5}$$

where we changed the variable $z=y+\eta^*$ in the last line. An integration by parts yields that the rhs of (5.5) is equal to

$$\int\int\int_{\mathbf{R}^3}\dot{d}x\,\bar{d}w\,dz\langle z\rangle^{-2N}e^{-\sqrt{-1}wz}\langle D_w\rangle^{2N}(\varphi_n(x,\eta+w/2)\varphi_n(x,\eta-w/2))V(x,z-\eta^*) \tag{5.6}$$

for any $N\in\mathbf{N}$. Using the estimate $\langle\eta;\eta^*\rangle\leqslant C\langle x;z-\eta^*\rangle\langle\eta-b(x)\rangle\langle z\rangle$, we find that, for any α,β,

$$\begin{aligned}&\langle\eta;\eta^*\rangle^{m+\alpha}|\partial_\eta^\beta\partial_{\eta^*}^\alpha p_V(\eta,\eta^*)|\\&\leqslant C\int\int\int_{\mathbf{R}^3}dx\,\bar{d}w\,dz\langle z\rangle^{-2N+m+\alpha}\langle\eta-b(x)\rangle^{m+\alpha}\\&\times|\partial_\eta^\beta\langle D_w\rangle^{2N}(\varphi_i(x,\eta+w/2)\varphi_j(x,\eta-w/2))|\langle x;z-\eta^*\rangle^{m+\alpha}\\&|\partial_{\eta^*}^\alpha V(x,z-\eta^*)|\end{aligned}$$

$$\leqslant C'\,\eta_{\alpha 0}^{(-m)}(V)\int\int_{\mathbf{R}^2}\mathrm{d}x\,\bar{d}w\langle\eta-b(x)\rangle^{m+\alpha}|\partial_\eta^\beta\langle D_w\rangle^{2N}(\varphi_i(x,\eta+w/2)\varphi_j(x,\eta-w/2))| \tag{5.7}$$

if we take N so that $2N-m-\alpha>1$. By Lemma 4.7, we have

$$\begin{aligned}
&|\partial_\eta^\beta\langle D_w\rangle^{2l}(\varphi_i(x,\eta+w/2)\varphi_j(x,\eta-w/2))|\\
&\quad\leqslant C_{\beta N}\sum_{0\leqslant\beta'\leqslant\beta}\sum_{0\leqslant N'\leqslant 2N}\left|\partial_\eta^{\beta-\beta'+2N-N'}\varphi_i(x,\eta+w/2)\partial_\eta^{\beta'+N'}\varphi_j(x,\eta-w/2)\right|\\
&\quad\leqslant C'_{\beta N}\exp(-c((b(x)-\eta-w/2)^2-(b(x)-\eta+w/2)^2))=C'_{\beta N}\exp(-2c(b(x)-\eta)^2-cw^2/2)
\end{aligned}$$

Hence, the integral on the rhs of (5.7) converges absolutely, because of Lemma 4.2. Especially, when $i=j=n$, this proves the assertion (1) under the temporal assumption on V.

We show the assertions (2) and (3). The first order Taylor expansion yields that

$$\begin{aligned}
V(x,z-\eta^*)&=V(b^{-1}(\eta),-\eta^*)+(x-b^{-1}(\eta))\int_0^1(\partial_1V)(\theta x+(1-\theta)b^{-1}(\eta),\theta(z-\eta^*)-(1-\theta)\eta^*)\mathrm{d}\theta\\
&\quad+z\int_0^1(\partial_2V)(\theta x+(1-\theta)b^{-1}(\eta),\theta(z-\eta^*)-(1-\theta)\eta^*)\mathrm{d}\theta,
\end{aligned}\tag{5.8}$$

where ∂_jV denotes the derivative of V with respect to the jth variable. In (5.5), the symbol corresponding to the first term on the rhs of (5.8) is given by

$$\begin{aligned}
&\int\int\int_{\mathbf{R}^3}\mathrm{d}x\,\bar{d}w\,\mathrm{d}z\,e^{-\sqrt{-1}wz}\varphi_i(x,\eta+w/2)\varphi_j(x,\eta-w/2)V(b^{-1}(\eta),-\eta^*)\\
&\quad=\int_{\mathbf{R}}\varphi_i(x,\eta)\varphi_j(x,\eta)\mathrm{d}x\,V(b^{-1}(\eta),-\eta^*)=V(b^{-1}(\eta),-\eta^*)\delta_{ij},
\end{aligned}$$

where we used the Fourier inversion formula. We can derive the estimate (5.3) for the symbols corresponding to the second and the third terms on the rhs of (5.8) in the same way as in the proof of (5.2), using the facts that $|\partial_\eta^\alpha(x-b^{-1}(\eta))|\leqslant C_\alpha\langle x-b^{-1}(\eta)\rangle$, which follows from (*B*.2), and that $\langle\eta;\eta^*\rangle\leqslant C\langle b^{-1}(\eta);-\eta^*\rangle\leqslant C'\langle\theta x+(1-\theta)b^{-1}(\eta);\theta(z-\eta^*)-(1-\theta)\eta^*\rangle\langle x-b^{-1}(\eta)\rangle\langle z\rangle$. Then we have the assertions (2) and (3) when $V\in\mathcal{S}(\mathbf{R}^2)$.

Finally, we give a proof for general Vs. We consider only the case of $i=j=n$, since the case of $i\neq j$ is similar. Since the space $\mathcal{S}(\mathbf{R})$ is dense in S^{-k} for any $k>0$, we can approximate V by an appropriate sequence$\{V_l\}_{l=1}^\infty(\subset\mathcal{S}(\mathbf{R}^2))$ in S^{-k} for any $k>0$. We consider the equality

$$T_n^*\mathcal{F}V_l\mathcal{F}^*T_n=Op(q_{V_1})+R(\nabla V_l), \tag{5.9}$$

where $R(\nabla V_l)$ stands for the remainder term. Then it follows from Lemma 2.5, (5.2) and (5.3) that the rhs of (5.9) converges to $Op(q_V)+R(\nabla V)$ as $l\to\infty$ in the norm operator topology. On the other hand, the left-hand side (lhs) of (5.9) converges to $T_n^*\mathcal{F}V\mathcal{F}^*T_n$ as $l\to\infty$ in the weak operator topology by definition. Thus, the lemma is true for general V's. ■

The next lemma follows immediately from Lemma 5.1 if we replace V by V^α.

Lemma 5.2: Let $\mathcal{V}$ *be the operator* (5.1) *with* $W=V$. *Let* $\alpha>0$. *Set* $\mathcal{V}_{ij}^\alpha=T_i\mathcal{F}V^\alpha\mathcal{F}^*T_j$ *for any* $i,j\in\mathbf{N}$. *If we regard* $\mathcal{V}_{ij}^\alpha$ *as an operator from the* jth *component to the* ith *component of* $\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$, *then* $\mathcal{V}_{ij}^\alpha$ *is a*Ψ DO *whose symbol is given by the form* $V(b^{-1}(\eta),-\eta^*)\delta_{ij}+OpS^{-m\alpha-1}$.

We need the following result in the place where we use Proposition 2.8.

Lemma 5.3: Let $\lambda\in\mathbf{R}\backslash\mathrm{Spec}(H_0(b))$ *and let*ν_l *be as in* Sec. I. *For any* $l\in\mathbf{N}$, *we have* $\lim_{g\to\infty}g^{-2/m}\,\mathrm{Vol}\{(x,\xi)\in\mathbf{R}^2\,|\,V(b^{-1}(x),-\xi)>g^{-1}|\lambda_l(x)-\lambda|\}=\nu_l(\lambda)$.

Proof: Note that $|\lambda_l(b(x))-\lambda|\geqslant C_\lambda>0$ holds for some C_λ, independent of l,x. For simplicity,

we set $F_l=\{(x,\xi)\in\mathbf{R}^2\,|\,V(b^{-1}(x),-\xi)>g^{-1}|\lambda_l(x)-\lambda|\}$, $F_l'=\{(x,\xi)\in\mathbf{R}^2\,|\,V(x,\xi)>g^{-1}|\lambda_l(b(x))-\lambda|\}$ for any $l\in\mathbf{N}$. By changing the variables $(x,\xi)\to(b(x),-\xi)$, we find that $(1/2\pi)\mathrm{Vol}(F_l)=\int\int_{F_l'}B(x)\mathrm{d}x\,\mathrm{d}\xi=J_0+J_++J_-$, where we set

$$J_0=\int\int_{F_l'\cap\{|x|\leqslant g^{1/2m}\}}B(x)\mathrm{d}x\,\mathrm{d}\xi,\quad J_\pm=\int\int_{F_l'\cap\{\pm x\geqslant g^{1/2m}\}}B(x)\mathrm{d}x\,\mathrm{d}\xi,$$

respectively. We first consider the integral J_0. By $(B.1)$, $(V.1)$, there exists $C>0$ such that $J_0\leqslant B_+\,\mathrm{Vol}\{(x,\xi)\in\mathbf{R}^2\,|\,C\langle x,\xi\rangle^{-m}>C_\lambda g^{-1},|x|\leqslant g^{1/2m}\}=o(g^{2/m})$ holds as $g\to\infty$. Next, we consider the integral J_+. We divide $J_+=J_{+,1}+J_{+,2}$ with

$$J_{+,1}=\int\int_{F_l'\cap\{x\geqslant g^{1/2m}\}}(B(x)-B_+)\mathrm{d}x\,\mathrm{d}\xi,$$

$$J_{+,2}=\frac{B_+}{2\pi}\mathrm{Vol}\{(x,\xi)\in\mathbf{R}^2|V(x,\xi)>g^{-1}|\lambda_l(b(x))-\lambda|,x\geqslant g^{1/2m}\}.$$

Using $(B.2)$ we find that $|J_{+,1}|$ is bounded from above by

$$C\int\int_{F_l'\cap\{x\geqslant g^{1/2m}\}}\langle x\rangle^{-M}\,\mathrm{d}x\mathrm{d}\xi\leqslant Cg^{-M/2m}\,\mathrm{Vol}\{(x,\xi)\in\mathbf{R}^2|\langle x;\xi\rangle^{-m}>C_\lambda g^{-1},x\geqslant g^{1/2m}\},$$

which is of order $o(g^2/m)$ as $g\to\infty$. If $x\leqslant g^{1/2m}$, then $|\lambda_l(b(x))-\lambda|\geqslant|\Lambda_l^+-\lambda|-|\lambda_l(b(x))-\Lambda_l^+|\geqslant|\Lambda_l^+-\lambda|-C\langle x\rangle^{-M}\geqslant|\Lambda_l^+-\lambda|-Cg^{-M/2m}$ holds because of Lemma 4.8. Then we find that $J_{+,2}=(B_+/4\pi)|\Lambda_l^+-\lambda|^{-2/m}\hat{v}+g^{2/m}+o(g^{2/m})$ as $g\to\infty$ in the same way as in the proof of Lemma 3.6. We can estimate the integral J_- similarly. ■

B. Preliminary estimates

The proofs of Theorems 1.1, 1.4, and 1.5 given below are essentially the same as those of Theorems 1.2, 1.1 in Raikov (1993) and that of Theorem 2.2 in Raikov (1998), respectively. However, we reproduce the proofs of Theorems 1.1–1.5 for the sake of completeness.

Let $\Lambda_{n-1}^+<\lambda<\Lambda_n^-$. Take an integer N_0 greater than n and set $I_-=\{-1,0,\ldots,n-1\}$, $I_+=\{n,n+1,\ldots,N_0\}$. Define the orthogonal projections P_+,P_-,P_∞, and P_-^c on the space $\Sigma_{l\in\mathbf{N}}\oplus L^2(\mathbf{R})$ by $P_\pm=\Sigma_{l\in I_\pm}\oplus\mathrm{id}L^2(\mathbf{R})$, respectively, $P_\infty=\mathrm{id}-P_--P_+$ and $P_-^c=P_++P_\infty=\mathrm{id}-P_-$. Here, "id" stands for the identity operator. These projections $P_\pm,P_\infty$ commute with each other and with the operator $\mathcal{H}_0$.

Lemma 5.4: We have the asymptotic relations

$$\lim_{g\to\infty}g^{-2/m}N(g^{-1}<\mathcal{V}^{1/2}P_\pm|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2})=\sum_{l\in I_\pm}\nu_l(\lambda),\tag{5.10}$$

$$\lim_{g\to\infty}g^{-2/m}N(g^{-1}<P_\pm\mathcal{V}^{1/2}P_\pm|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_\pm)=\sum_{l\in I_\pm}\nu_l(\lambda),\tag{5.11}$$

respectively. Here, the operators $\mathcal{H}_0$ and $\mathcal{V}$ are as in Sec. V A.

Proof: It follows from $\mathrm{Spec}(A^*A)\backslash\{0\}=\mathrm{Spec}(AA^*)\backslash\{0\}$ that

$$N(g^{-1}<\mathcal{V}^{1/2}P_\pm|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2})=N(g^{-1}<|\mathcal{H}_0-\lambda|^{-1/2}P_\pm\mathcal{V}P_\pm|\mathcal{H}_0-\lambda|^{-1/2}).$$

The operators $|\mathcal{H}_0-\lambda|^{-1}P_\pm$ are matrix-valued ΨDOs on $\Sigma_{l\in I_\pm}\oplus L^2(\mathbf{R})$ and have the symbol $(|\lambda_l(\eta)-\lambda|^{-1}\delta_{ij})_{i,j\in I_\pm}$, which belong to the class OpS^0 by Lemma 4.5, and the operators $|\mathcal{H}_0-\lambda|^{-1/2}P_\pm\mathcal{V}P_\pm|\mathcal{H}_0-\lambda|^{-1/2}$ are matrix-valued ΨDOs whose principal symbols are given by $(|\lambda_l(\eta)$

$-\lambda|^{-1}V(b^{-1}(\eta),\eta^*)\delta_{ij})_{i,j\in I_\pm}$, respectively, because of Lemma 5.2. Then (5.10) follows from a matrix-valued ΨDO version of Proposition 2.8. The proof of (5.11) is similar. ■

Lemma 5.5: We have the asymptotic relations

$$\lim_{\mu\downarrow 0}\mu^{2/m}N(\mu<P_-^c\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-^c)=0, \tag{5.12}$$

$$\lim_{\mu\downarrow 0}\mu^{2/m}N(\mu<P_-\mathcal{V}^{1/2}P_+|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)=0, \tag{5.13}$$

$$\lim_{N_0\to\infty}\limsup_{\mu\downarrow 0}\mu^{2/m}N(\mu<P_-\mathcal{V}^{1/2}P_\infty|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)=0. \tag{5.14}$$

Proof: Since $P_-\mathcal{V}^{1/2}P_-^c\mathcal{V}^{1/2}P_-=P_-\mathcal{V}^{1/2}(\mathrm{id}-P_-)\mathcal{V}^{1/2}P_-=P_-\mathcal{V}P_--(P_-\mathcal{V}^{1/2}P_-)^2$, we can deduce from Lemma 5.2 that $P_-\mathcal{V}^{1/2}P_-^c\mathcal{V}^{1/2}P_-$ belongs to OpS^{-m-1}. Then it follows from (2.4) that $N(\mu<|\mathcal{H}_0-\lambda|^{-1/2}P_-\mathcal{V}^{1/2}P_-^c\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1/2})=O(\mu^{-2/(m+1)})=o(\mu^{-2/(m+1)})$ as $\mu\downarrow 0$. This proves (5.12) since $\mathrm{Spec}(A^*A)\backslash\{0\}=\mathrm{Spec}(AA^*)\backslash\{0\}$.

The operator $P_-\mathcal{V}^{1/2}P_+$ belongs to $OpS^{-m/2-1}$ by Lemma 5.2 since $\Sigma_{l\in I_-}\oplus L^2(\mathbf{R})$ and $\Sigma_{l\in I_+}\oplus L^2(\mathbf{R})$ are orthogonal, and $P_+\mathcal{V}^{1/2}P_-\mathcal{V}^{1/2}P_+=(P_-\mathcal{V}^{1/2}P_+)^*(P_-\mathcal{V}^{1/2}P_+)$ belongs to OpS^{-m-2}. Then (2.4) proves (5.13).

By the definition of P_∞ and the min–max argument, we have

$$N(\mu<P_-\mathcal{V}^{1/2}P_\infty|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)\leqslant N((\Lambda^-_{N_0+1}-\lambda)_\mu<P_-\mathcal{V}P_-)\leqslant C(\Lambda^-_{N_0+1}-\lambda)^{-2/m}\mu^{-2/m},$$

where we used the fact that $P_-\mathcal{V}P_-\in OpS^{-m}$ and (2.4) in the last inequality. Since $\Lambda^-_{N_{0+1}}$ tends to infinity as $N_0\to\infty$, we have the conclusion. ■

Lemma 5.6: We have $\lim_{N_0\to\infty}\limsup_{\mu\downarrow 0}\mu^{2/m}N(\mu<\mathcal{V}^{1/2}P_\infty|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2})=0$.

Proof: If we choose $N_0>0$ so large that $\lambda\leqslant\Lambda^-_{N_0+1}/2$ holds, then $\Lambda_j(\eta)-\lambda\geqslant\lambda_j(\eta)-\Lambda^-_{N_0+1}/2\geqslant(\lambda_j(\eta)+\Lambda^-_{N_0+1})/4$ holds for any $j\geqslant N_0+1$ and for any $\eta\in\mathbf{R}$, from which we have $P_\infty|\mathcal{H}_0-\lambda|^{-1}\leqslant 4(\mathcal{H}_0+\Lambda^-_{N_0+1})^{-1}$. Then the variational principle yields the estimate $N(\mu<\mathcal{V}^{1/2}P_\infty|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2})\leqslant N(\mu<4\mathcal{V}^{1/2}(\mathcal{H}_0+\Lambda^-_{N_0+1})^{-1}\mathcal{V}^{1/2})=N(H_{4/\mu}(b)<-\Lambda_{N_0+1})=\Sigma_{l\in\mathbf{N}}\nu_l(-\Lambda^-_{N_0+1})(4/\mu)^{2/m}(1+o(1))$ as $\mu\downarrow 0$, where we used Theorem 1.1 proved in Sec. III in the last inequality. Finally, the lemma follows from the asymptotic relation $\lim_{N_0\to\infty}\Sigma_{l\in\mathbf{N}}\nu_l(-\Lambda^-_{N_0+1})=0$. ■

C. Proof of Theorem 1.1

Using the inequality $\mathcal{V}^{1/2}(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}\leqslant\mathcal{V}^{1/2}P_-^c|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}$, we have, for any small $\varepsilon>0$,

$$\begin{aligned}N_g^+(\lambda)&\leqslant N(g^{-1}<\mathcal{V}^{1/2}P_-^c|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2})\leqslant N((1-\varepsilon)g^{-1}<\mathcal{V}^{1/2}P_+|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2})\\&\quad+N(\varepsilon g^{-1}<\mathcal{V}^{1/2}P_\infty|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}),\end{aligned}$$

where we used the (generalized) Birman–Schwinger principle [see, e.g., Alama, Deift, and Hempel (1989), Birman (1991)] and the Weyl–KyFan inequality. Then by Lemma 5.4 and Lemma 5.6, we obtain the upper bound $\limsup_{g\to\infty}g^{-2/m}N_g^+(\lambda)\leqslant\Sigma_{l\in I_+}\nu_l(\lambda)$, taking a limit $\varepsilon\downarrow 0$ and $N_0\to\infty$. Next, we obtain the lower bound. For any small $\varepsilon>0$, we have

$$\begin{aligned}P_-^c\mathcal{V}^{1/2}(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}P_-^c&=P_-^c\mathcal{V}^{1/2}P_-(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}P_-^c+P_-^c\mathcal{V}^{1/2}P_-^c(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}P_-^c\\&\geqslant P_-^c\mathcal{V}^{1/2}P_-(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}P_-^c+\mathcal{V}^{1/2}P_-^c(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}\\&\quad-2\,\mathrm{Re}(P_-\mathcal{V}^{1/2}P_-^c(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2})\geqslant(1-\varepsilon)\mathcal{V}^{1/2}P_-^c|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}\\&\quad-P_-^c\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-^c-\varepsilon^{-1}P_-\mathcal{V}^{1/2}P_-^c|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-,\end{aligned}$$

where we used the inequality $P_-\mathcal{V}^{1/2}P_-^c(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}P_-\geqslant 0$ in the first inequality and used the estimate $2|(u,\mathcal{V}^{1/2}P_-^c(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}P_-u)|\leqslant\varepsilon\||\mathcal{H}_0-\lambda|^{-1/2}P_-^c\mathcal{V}^{1/2}u\|^2+\varepsilon^{-1}\|P_-^c|\mathcal{H}_0-\lambda|^{-1/2}\mathcal{V}^{1/2}P_-u\|^2$ in

the second inequality. Then, by a variational argument similar to that used in the case of the upper bound, we can derive the lower bound $\liminf_{g\to\infty} g^{-2/m}N_g^+(\lambda)\geqslant\Sigma_{l\in I_+}\nu_l(\lambda)$, using Lemma 5.4 and Lemma 5.5. This completes the proof of Theorem 1.1.

D. Proof of Theorem 1.4

By the Birman–Schwinger principle, we have the upper bound

$$N_g^-(\lambda)=N(g^{-1}<-\mathcal{V}^{1/2}(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2})\leqslant N(g^{-1}<\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2})$$
$$\leqslant\sum_{l\in I_-}\nu_l(\lambda)g^{-2/m}(1+o(1))$$

as $g\to\infty$, where we used the inequality $-\mathcal{V}^{1/2}(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}=\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}-\mathcal{V}^{1/2}P_-^c|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}\leqslant\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}$ in the first inequality and used (5.10) in the last inequality. Next, for any small $\varepsilon>0$, there exists $C_\varepsilon>0$, independent of g,N_0, such that

$$\begin{aligned}N_g^-(\lambda)&\geqslant N(g^{-1}<-P_-\mathcal{V}^{1/2}(\mathcal{H}_0-\lambda)^{-1}\mathcal{V}^{1/2}P_-)\geqslant N((1+\varepsilon)g^{-1}<P_-\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)\\&\quad-N(C_\varepsilon g^{-1}<P_-\mathcal{V}^{1/2}P_-^c|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)\geqslant N((1+\varepsilon)g^{-1}<P_-\mathcal{V}^{1/2}P_-|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)\\&\quad-N(C'_\varepsilon g^{-1}<P_-\mathcal{V}^{1/2}P_+|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)-N(C'_\varepsilon g^{-1}<P_-\mathcal{V}^{1/2}P_\infty|\mathcal{H}_0-\lambda|^{-1}\mathcal{V}^{1/2}P_-)\\&\geqslant\sum_{l\in I_-}\nu_l(\lambda)(g/(1+\varepsilon))^{2/m}(1+o(1))\end{aligned}$$

as $g,N_0\to\infty$, where we used the Weyl–KyFan inequality in the second and the third inequalities and Lemma 5.4 in the last line. This gives the lower bound and we complete the proof.

E. Proof of Theorem 1.5

Let $\Lambda_{n-1}^+<\lambda<\mu<\Lambda_n^-$. Set $\gamma=(\mu+\lambda)/2,\tau=(\mu-\lambda)/2$ and set $P_+^c=P_-+P_\infty$. Since $P_+(\mathcal{H}_g-\gamma)^2P_+=(P_+(\mathcal{H}_g-\gamma)P_+)^2-g^2P_+\mathcal{V}P_+^c\mathcal{V}P_+$, we have, for small $\varepsilon>0$, $N(\lambda\leqslant H_g(b)<\mu)\geqslant N((\mathcal{H}_g-\gamma)^2<\tau^2)\geqslant N(P_+(\mathcal{H}_g-\gamma)^2P_+<\tau^2)\geqslant N((P_+(\mathcal{H}_g-\gamma)P_+)^2<\tau^2-\varepsilon)-N(C_\varepsilon<g^2P_+\mathcal{V}P_+^c\mathcal{V}P_+)=N((P_+(\mathcal{H}_g-\gamma)P_+)^2<\tau^2-\varepsilon)+o(g^{2/m})$ as $g\to\infty$. Here, we used the fact that the operator $P_+\mathcal{V}P_+^c\mathcal{V}P_+=P_+\mathcal{V}^2P_+-(\underline{P_+\mathcal{V}P_+})^2$ is a matrix-valued ΨDO of the class OpS^{-2m-1}. Setting $\lambda_1=\gamma-\sqrt{\tau^2-\varepsilon}$ and $\mu_1=\gamma+\sqrt{\tau^2-\varepsilon}$, we have $N(\lambda_1<P_+\mathcal{H}_gP_+<\mu_1)\geqslant N(g^{-1}<\mathcal{V}^{1/2}P_+(\mathcal{H}_0-\mu_1)^{-1}P_+\mathcal{V}^{1/2})-N(g^{-1}<\mathcal{V}^{1/2}P_+(\mathcal{H}_0-\lambda_1)^{-1}P_+\mathcal{V}^{1/2})=\Sigma_{l\in I_+}\nu_l([\lambda_1,\mu_1])g^{2/m}(1+o(1))$ as $g\to\infty$, where we used the Birman–Schwinger principle and Theorem 1.1. Finally, we have Theorem 1.5 from these, letting $\varepsilon\downarrow 0$ and $N_0\to\infty$.

Phase space properties and the short distance structure in quantum field theory

Henning Bostelmann[a)]
Universität Göttingen, Institut für Theoretische Physik, 37077 Göttingen, Germany

(Received 18 September 2004; accepted 2 February 2005; published online 7 April 2005)

The paper investigates relations between the phase space structure of a quantum field theory ("nuclearity") and the concept of pointlike localized fields. Given a net of local observable algebras, a phase space condition is introduced that allows a very detailed description of the theory's field content. An appendix discusses non-interacting models as examples. © *2005 American Institute of Physics.*

I. INTRODUCTION

Quantum fields are a basic ingredient of relativistic quantum physics. It is common to express almost all aspects of a theory, including the dynamics, in terms of these pointlike localized fields and related concepts (Lagrangians, field equations, path integrals). While this *ansatz* has proved to be very fruitful for the construction of models and in perturbation theory, it contains technical pitfalls which make its consistent handling rather difficult.

The main problem arises from Heisenberg's uncertainty relation, which says that measurements with sharp localization in configuration space are completely delocalized in momentum space, i.e., they show a singular high energy behavior. This is reflected in peculiar mathematical properties of quantum fields: They cannot be defined as operators, their products do not exist, and nonlinear field equations require subtle limiting processes which are difficult to control.

Thus, the concept of pointlike localized fields may be regarded as an over-idealization. Since it is well known that physical operations in finite space–time regions (rather than at points) do not show the singular behavior mentioned above, it seems worth while to study how pointlike fields emerge from such a physically more meaningful setting, and in that way to gain more information about the fields' properties.

A framework for such an investigation is provided by algebraic field theory,[1] where operations localized in an open space–time region $\mathcal{O}$ form an algebra $\mathfrak{A}(\mathcal{O})$ of bounded operators. It is possible to encode all physically relevant properties (locality, covariance, positivity of energy) in terms of these algebras and their transformation behavior under the Poincaré group, without reference to pointlike structures.

While it has extensively been discussed in the literature how to pass to the local algebras from a given field-theoretic model,[2] the reverse step is less well understood. Heuristically, pointlike fields $\phi(x)$ should be derived as limits of operations localized in regions shrinking to the point x.[3,4] However, the details of this limit depend on the high energy behavior of the fields. Following Fredenhagen and Hertel,[3] we will focus on fields satisfying *polynomial H-bounds*, i.e., fulfilling for some $\ell > 0$,

$$\|R^\ell \phi(x) R^\ell\| < \infty, \quad \text{where } R = (1+H)^{-1}; \tag{1.1}$$

H denotes the (positive) Hamiltonian. These H-bounds are satisfied in all models constructed so far, more generally in theories which satisfy a sharpened version of the Osterwalder–Schrader

a)Electronic mail: bostelm@theorie.physik.uni-goettingen.de

axioms.[5] It has been shown in Ref. 3 that fields of this kind can be recovered from the local algebras by means of the formula

$$R^\ell \phi(x) R^\ell \in \bigcap_{\mathcal{O} \ni x} \overline{R^\ell \mathfrak{A}(\mathcal{O}) R^\ell}^w, \tag{1.2}$$

where $\overline{}^w$ denotes the weak closure.[6] So one can calculate the field content of an algebraic theory; however, many details about the fields' properties remained unclear, e.g., the question whether the fields possess finite spin, or the existence of product expansions.

To gain more insight in this respect, we will make use of an additional property of quantum field theories, known as *phase space conditions*. These reflect the heuristic expectation that the number of local degrees of freedom of a physical system is limited: A system restricted both in momentum and configuration space, thus being localized in a finite phase space volume, will possess only a finite number of independent physical states. (This is easily understood by appealing to a semiclassical picture, such as Bohr–Sommerfeld quantization.) Clearly, the notion of a "finite phase space volume" must be handled with care; however, such properties can be formulated in a mathematically precise way in terms of *compactness* or *nuclearity* conditions,[7–9] which lead to interesting structural results on the system's physical behavior.[10] For the sake of concreteness, consider the following compactness condition:[11] Let $\mathcal{H}$ be the theory's underlying Hilbert space, Σ the set of weak-$*$-continuous functionals on $\mathfrak{B}(\mathcal{H})$ ("state space"), $P_H(E)$ the spectral projectors of H, and $\mathcal{O}_r$ the standard double cone of radius r centered at the origin. We require that for any E, $r>0$, the map

$$\Xi_{E,r}\colon P_H(E)\Sigma P_H(E) \to \mathfrak{A}(\mathcal{O}_r)_*, \tag{1.3}$$

$$\sigma \mapsto \sigma\restriction \mathfrak{A}(\mathcal{O}_r)$$

is compact, i.e., can be expanded into a series of rank-1 operators in the norm topology. This condition was verified explicitly in noninteracting models.[9]

The connection of these properties with the point field structure was first realized by Haag and Ojima:[12,13] Following the compactness condition mentioned above, the image of the map $\Xi_{E,r}$ is "almost finite-dimensional" (up to some degree of precision). If we assume that this finite-dimensional space does not change in the limit $r \to 0$ (which may be expected in theories that are dilation invariant in their short distance limit), then we have found finitely many independent states that represent the short distance structure of the theory, and one may hope to interpret a corresponding dual basis as pointlike localized quantum fields located at $x=0$.

The present paper aims at putting these heuristic ideas into a precise mathematical form. We introduce a phase space condition, specifically sensitive in the short distance limit, that selects a relevant class of models with "regular" short distance behavior. Its implications can be summarized as follows.

(1) The field content of these theories can be determined, with detailed results on the singular properties of the fields and their connection to the theory in finite regions. All fields can be shown to comply with the Wightman axioms; moreover, they transform covariantly both under unbroken and spontaneously broken symmetries.
(2) Operator product expansions[14] can be established rigorously with specific convergence properties, and allow for a model-independent, nonperturbative definition of normal products in the sense of Zimmermann.[15,16] The field content includes all composite fields.

In this paper, we shall restrict ourselves to the first named aspect; the latter point will be treated in another publication.[17] Section II introduces the phase space condition which lies at the root of our analysis. Using this condition, we construct the field content of the algebraic theory in Sec. III, while symmetry aspects and the proof of Wightman's axioms are discussed in Sec. IV. We end with a brief outlook on generalizations in Sec. V. In the Appendix, we show that the phase space condition is fulfilled in models from free field theory.

The present paper is based on the author's thesis.[18] It presents an abbreviated and somewhat simplified version of material developed there; for further details and additional technical and mathematical aspects, the reader is referred to the original work.

II. A PHASE SPACE CONDITION

This section will introduce the specific phase space condition which characterizes the short distance structure of a quantum field theory. First of all, we shall briefly define our mathematical setting.

We use the framework of local quantum physics.[1] Our field-theoretic model is given by means of a net $\mathcal{O}\mapsto\mathfrak{A}(\mathcal{O})$, which associates with any open space–time region $\mathcal{O}\subset\mathbb{R}^{s+1}$ a von Neumann algebra $\mathfrak{A}(\mathcal{O})\subset\mathfrak{B}(\mathcal{H})$, where $\mathcal{H}$ is some fixed Hilbert space. We assume isotony and locality. In most cases, it will suffice to consider the algebras $\mathfrak{A}(r):=\mathfrak{A}(\mathcal{O}_r)$ associated with standard double cones $\mathcal{O}_r$ of radius r centered at the origin. We will restrict our attention to the vacuum sector; i.e., we assume a strongly continuous unitary representation $U(x,\Lambda)$ of the connected Poincaré group on $\mathcal{H}$ that has a geometric action on the net $\mathfrak{A}$ (*covariance*), and a vector $\Omega\in\mathcal{H}$ (the *vacuum*), unique up to a phase, which is invariant under all $U(x,\Lambda)$. For the translation part of this representation, $U(x)=\exp(iP_\mu x^\mu)$, we will assume the *spectrum condition*, i.e., the joint spectrum of its generators P_μ falls into the closed forward light cone $\overline{\mathcal{V}_+}$; here $H=P_0\geqslant 0$ is the Hamiltonian. We also require the net $\mathfrak{A}$ to act *irreducibly* on $\mathcal{H}$, in the sense that $\cup_{\mathcal{O}}\mathfrak{A}(\mathcal{O})\Omega$ is dense in $\mathcal{H}$, where the union runs over bounded regions $\mathcal{O}$ only. $\Sigma:=\mathfrak{B}(\mathcal{H})_*$ is the set of weak-$*$-continuous functionals on $\mathfrak{B}(\mathcal{H})$, the positive normed elements of which represent the physical states. Both $\mathfrak{B}(\mathcal{H})$ and Σ will be considered with their norm topology unless otherwise noted.

In analogy to Ref. 3, we will often use the space of polynomially energy-damped functionals,

$$\mathcal{C}^\infty(\Sigma):=\bigcap_{\ell>0}R^\ell\Sigma R^\ell\subset\Sigma, \tag{2.1}$$

where $R=(1+H)^{-1}$ as before. On this space, we define the norms $\|\sigma\|^{(\ell)}:=\|R^{-\ell}\sigma R^{-\ell}\|$ $(\ell>0)$, and equip $\mathcal{C}^\infty(\Sigma)$ with the locally convex (metrizable) topology of simultaneous convergence with respect to all these norms. As is easily seen, a linear map φ from $\mathcal{C}^\infty(\Sigma)$ to some Banach space $(\mathcal{E},\|\cdot\|_{\mathcal{E}})$ is continuous with respect to this topology if and only if

$$\|\varphi\|^{(\ell)}:=\sup_\sigma\frac{\|\varphi(\sigma)\|_\mathcal{E}}{\|\sigma\|^{(\ell)}}<\infty\quad\text{for some }\ell>0. \tag{2.2}$$

We set $\Psi:=\mathcal{L}(\mathcal{C}^\infty(\Sigma),\Sigma)$, the space of continuous linear maps between these spaces. A prominent element of Ψ is the inclusion

$$\Xi:\mathcal{C}^\infty(\Sigma)\to\Sigma,$$

$$\sigma\mapsto\sigma, \tag{2.3}$$

which bears some analogy with (1.3). A map $\psi\in\Psi$ of finite rank has the form

$$\psi=\sum_{j=1}^{J}\sigma_j\phi_j\quad\text{with }\sigma_j\in\Sigma\quad\text{and }\phi_j\in\mathcal{C}^\infty(\Sigma)^*. \tag{2.4}$$

(This means that the ϕ_j are linear forms with $\|\phi_j\|^{(\ell)}=\|R^\ell\phi_jR^\ell\|<\infty$ for large ℓ.)

For our purposes, it will be critical to control the behavior of the objects mentioned above in the short distance limit. To achieve this, we introduce some additional structure. For $\sigma\in\Sigma$, we define

$$\|\sigma\|_r:=\|\sigma\lceil\mathfrak{A}(r)\|\quad(r>0). \tag{2.5}$$

Likewise, for $\psi\in\Psi$ we consider

$$\|\psi\|_r^{(\ell)} := \|\psi(\cdot)\lceil\mathfrak{A}(r)\|^{(\ell)} = \sup_{\sigma\in\Sigma}\sup_{A\in\mathfrak{A}(r)}\frac{|\psi(R^\ell\sigma R^\ell)(A)|}{\|\sigma\|\,\|A\|}, \tag{2.6}$$

which is finite for sufficiently large ℓ. We devote special attention to the question how fast such a seminorm $\|\cdot\|_r^{(\ell)}$ vanishes in the limit $r\to 0$, and therefore define for $\gamma\geqslant 0$,

$$\delta_\gamma(\psi) := \begin{cases} 0 & \text{if } r^{-\gamma}\|\psi\|_r^{(\ell)} \xrightarrow[r\to 0]{} 0 \quad \text{for some } \ell > 0, \\ 1 & \text{otherwise.} \end{cases} \tag{2.7}$$

Each δ_γ induces a pseudometric on Ψ. Equipping Ψ with the pseudometric

$$\hat{\delta}(\psi,\psi') := \int_0^\infty e^{-\gamma}\delta_\gamma(\psi-\psi')\mathrm{d}\gamma, \tag{2.8}$$

we have found a topology on Ψ which describes short-distance convergence "to all polynomial orders."

[Note that Ψ is a presheaf over $\mathbb{R}^{s+1}$ with respect to $\Psi(\mathcal{O}) := \Psi\lceil\mathfrak{A}(\mathcal{O})$, and that the δ_γ are not so much functions on Ψ, but rather on the stalk of Ψ at $x=0$; so we have defined a topology on the stalk. However, we shall not consider these sheaf-theoretic aspects any further.]

We can now turn to formulating the approximation of Ξ with operators of finite rank. We start with a net $\mathcal{O}\mapsto\mathfrak{A}(\mathcal{O})$ that meets the standard requirements listed at the beginning of this section. We can analyze the short distance behavior of the theory with the help of the concepts introduced above by considering the numbers

$$N_\gamma := \min\{n \mid \exists\, \psi\in\Psi\text{: rank } \psi = n,\ \delta_\gamma(\Xi-\psi)=0\}, \tag{2.9}$$

setting $N_\gamma=\infty$ if the set on the right-hand side is empty. It is obvious that $N_\gamma\geqslant N_{\gamma'}$ for $\gamma\geqslant\gamma'$. Thus, our theory falls into one out of the following three classes:

(1) $N_\gamma\to\infty$ for $\gamma\to\infty$, but $N_\gamma<\infty$ for all $\gamma\geqslant 0$. We shall show in the subsequent sections that the theory then has a nontrivial field content of Wightman fields. As will be discussed in the Appendix, a large variety of free field theories falls into this class; one may expect that physically relevant interacting models exhibit the same behavior.

(2) $N_\gamma\leqslant N$ for some fixed $N<\infty$ and all $\gamma\geqslant 0$. In this case, only very few observables "survive" in the short distance limit. In fact, we shall see that in this case necessarily $N_\gamma=1$ for all γ, and that the theory's field content is trivial. An example for this behavior was discussed by Lutz;[19] cf. also the Appendix. More generally, one expects that models of this kind are *not* generated by pointlike fields, but possibly by other, nonpointlike objects, such as Mandelstam strings or Wilson loops.

(3) $N_\gamma=\infty$ for some finite $\gamma\geqslant 0$. Such theories have a peculiar complex short distance behavior which does not allow Ξ to be approximated by maps of finite rank in the specified sense. Examples are free theories with infinitely many species of particles. One also expects that theories in $1+1$ dimensions, where the fields as well as their Wick products have a "scaling dimension" of 0, are members of this class.

In what follows, we will disregard the latter case and assume that N_γ is finite for all γ. We may encode this into a phase space criterion which selects theories of a sufficiently regular short distance behavior.

Definition 2.1: A net $\mathcal{O}\mapsto\mathfrak{A}(\mathcal{O})$ is said to satisfy the microscopic phase space condition *if for every $\gamma\geqslant 0$, there exists a map $\psi\in\Psi$ of finite rank such that*

$$\delta_\gamma(\Xi-\psi)=0,$$

or, equivalently,

$$r^{-\gamma}\|\Xi - \psi\|_r^{(\ell)} \to 0 \quad \textit{for sufficiently large } \ell > 0.$$

This condition shows a formal analogy with the well-known compactness and nuclearity conditions in finite regions:[8,9] It demands that the map Ξ can be expanded into a series of rank-1 operators, where the series is meant to converge in the pseudometric $\hat{\delta}$ introduced in Eq. (2.8).

Our task will be to analyze the consequences of the microscopic phase space condition, especially regarding the theory's point field structure. We will show that the size of the field content is determined by the "approximation numbers" N_γ, and prove that these fields fulfill certain regularity properties.

III. DETERMINING THE FIELD CONTENT

We will now set out from a net $\mathcal{O} \mapsto \mathfrak{A}(\mathcal{O})$ that satisfies the microscopic phase space condition. Our task is to analyze the point field content of this net. Our line of analysis can be sketched as follows.

Given $\gamma \geqslant 0$, let $\psi \in \Psi$ be a map of finite rank that approximates Ξ in the short distance limit: $\delta_\gamma(\Xi - \psi) = 0$. Provided that rank ψ is minimal with this property (i.e., ψ does not contain redundant terms that do not contribute to the approximation), one will expect that the image of the dual map $\psi^* : \mathfrak{B}(\mathcal{H}) \to \mathcal{C}^\infty(\Sigma)^*$ consists of pointlike fields. [Note that img ψ^* is spanned by the linear forms ϕ_j in Eq. (2.4).] In fact, we will show that $\Phi_\gamma := \text{img } \psi^*$ depends on γ only, and that its elements are indeed localized fields. Furthermore, we will prove that the union of the spaces Φ_γ exhausts the field content as defined by Fredenhagen and Hertel.[3]

Let $\gamma \geqslant 0$ be fixed in the following. We begin our analysis of the map ψ with the following lemma.

Lemma 3.1: Let $\psi \in \Psi$ *such that* rank $\psi = N_\gamma$ *and* $\delta_\gamma(\Xi - \psi) = 0$. *Then it holds for all* $\sigma \in \text{img } \psi \backslash \{0\}$ *that*

$$r^{-\gamma}\|\sigma\|_r \not\to 0 \quad (r \to 0).$$

Proof: Assume that the proposition is violated for some $\sigma \in \text{img } \psi \backslash \{0\}$. We choose a decomposition $\psi = \psi' \oplus \sigma\phi$, where $\phi \in \mathcal{C}^\infty(\Sigma)^*$, $\psi' \in \Psi$, and rank $\psi' = N_\gamma - 1$. Since $r^{-\gamma}\|\sigma\|_r \to 0$ and $\|\phi\|^{(\ell)} < \infty$ for large ℓ, we obviously have $\delta_\gamma(\sigma\phi) = 0$ and thus $\delta_\gamma(\Xi - \psi') = 0$, in contradiction to the minimality property of N_γ [cf. Eq. (2.9)]. □

Certainly, ψ is not fixed uniquely by the conditions of Lemma 3.1. However, we shall show that these conditions fix img ψ^*. To this end, we prove the following.

Lemma 3.2: Let ψ *be as in Lemma 3.1. For arbitrary* $\sigma \in \mathcal{C}^\infty(\Sigma)$, *the following equivalences hold*:

$$\sigma[\text{img } \psi^* = 0 \;\Leftrightarrow\; \psi(\sigma) = 0 \;\Leftrightarrow\; r^{-\gamma}\|\sigma\|_r \to 0.$$

Proof: The first equivalence is obvious. Moreover, for $\sigma \neq 0$, the approximation property $\delta_\gamma(\Xi - \psi) = 0$ gives $r^{-\gamma}\|(\Xi - \psi)(\sigma)\|_r = r^{-\gamma}\|\sigma - \psi(\sigma)\|_r \to 0$. So $\psi(\sigma) = 0$ implies $r^{-\gamma}\|\sigma\|_r \to 0$. Conversely, if $r^{-\gamma}\|\sigma\|_r \to 0$, we conclude $r^{-\gamma}\|\psi(\sigma)\|_r \to 0$, and thus $\psi(\sigma) = 0$ according to Lemma 3.1.□

Since the right-hand side of the equivalence in Lemma 3.2 does not refer to ψ, the space img ψ^* is independent of ψ as well. Thus, we have established the following.

Theorem 3.3: *Let the net* $\mathfrak{A}$ *fulfill the microscopic phase space condition. For each* $\gamma \geqslant 0$, *there is a unique subspace* $\Phi_\gamma \subset \mathcal{C}^\infty(\Sigma)^*$ *of dimension* N_γ *with the following property: If* $\psi \in \Psi$, rank $\psi = N_\gamma$, *and* $\delta_\gamma(\Xi - \psi) = 0$, *then* img $\psi^* = \Phi_\gamma$.

Note that the microscopic phase space condition guarantees such a ψ to exist for every γ. The theorem requires the rank of ψ to be "minimized" (rank $\psi = N_\gamma$). If rank $\psi > N_\gamma$, we can still find a representation

$$\psi = \psi_{\text{I}} \oplus \psi_{\text{II}},$$

$$\text{where} \quad \operatorname{img} \psi_{\mathrm{I}}^{*} = \Phi_{\gamma}, \quad r^{-\gamma}\|\sigma\|_r \to 0 \;\forall\; \sigma \in \operatorname{img} \psi_{\mathrm{II}}. \tag{3.1}$$

[To see this, choose a map ψ_{I} of rank N_γ such that $\delta_\gamma(\Xi - \psi_{\mathrm{I}}) = 0$, and set $\psi_{\mathrm{II}} := \psi - \psi_{\mathrm{I}}$. It follows that $\delta_\gamma(\psi_{\mathrm{II}}) = 0$, so $r^{-\gamma}\|\sigma\|_r \to 0$ for all $\sigma \in \operatorname{img} \psi_{\mathrm{II}}$. Since Lemma 3.1 applies to ψ_{I}, the intersection of img ψ_{I} with img ψ_{II} is trivial; thus $\psi = \psi_{\mathrm{I}} + \psi_{\mathrm{II}}$ is a direct sum.] As a consequence hereof, and since $\delta_\gamma(\cdot) \leqslant \delta_{\gamma'}(\cdot)$ for $\gamma \leqslant \gamma'$, we obviously have $\Phi_\gamma \subset \Phi_{\gamma'}$—the Φ_γ form an increasing sequence of vector spaces.

We will show now that the elements of Φ_γ are Wightman fields. To this end, we will approximate $\phi \in \Phi_\gamma$ with a sequence of bounded operators localized in smaller and smaller regions. Our aim is the following proposition.

Proposition 3.4: Let $\phi \in \Phi_\gamma$. One can find a sequence of operators $A_r \in \mathfrak{A}(r)$ $(r > 0)$ such that

$$\|\phi - A_r\|^{(\ell)} \to 0 \quad \textit{for some } \ell > 0$$

(*more precisely* $\|\phi - \Xi^* A_r\|^{(\ell)} \to 0$).

We will carry out—or rather sketch—the proof in four steps. We choose $\psi \in \Psi$ of rank N_γ such that $\delta_\gamma(\Xi - \Psi) = 0$ and set $S := \operatorname{img} \psi$.

(a) First, consider the case of a rank-1 operator $\psi = \sigma\phi$. According to Lemma 3.1, we may choose a null sequence ρ such that $\|\sigma\|_r \geqslant c \cdot r^\gamma$ for some $c > 0$, where $r \in \rho$. For $r \in \rho$, we define A_r as a linear form on the one-dimensional subspace of $\mathfrak{A}(r)_*$ spanned by $\sigma\lceil\mathfrak{A}(r)$, namely by setting $\sigma(A_r) = 1$. We can then apply the Hahn–Banach theorem to continue this form to an operator $A_r \in \mathfrak{A}(r) = (\mathfrak{A}(r)_*)^*$; its norm is bounded by $\|A_r\| \leqslant (\|\sigma\|_r)^{-1} \leqslant c^{-1} r^{-\gamma}$. We must show that $\|\phi - \Xi^* A_r\|^{(\ell)} \to 0$: This follows from

$$\|\phi - \Xi^* A_r\|^{(\ell)} = \|\psi^* A_r - \Xi^* A_r\|^{(\ell)} \leqslant \|\psi - \Xi\|_r^{(\ell)} \|A_r\| \leqslant c^{-1} r^{-\gamma} \|\psi - \Xi\|_r^{(\ell)} \to 0 \tag{3.2}$$

for large ℓ and for $r \in \rho$. Thus $A_r \to \phi$ on ρ, and we may easily find suitable A_r for any $r > 0$ by choosing A_r to be "piecewise constant."

(b) Now let $\dim S > 1$, but let all $\sigma \in S$ have "the same short distance behavior," i.e., we assume that a function $\eta : \mathbb{R}^+ \to \mathbb{R}^+$ exists such that

$$c_1(\sigma)\,\eta(r) \geqslant \|\sigma\|_r \geqslant c_2(\sigma)\,\eta(r) \quad \text{for all } r \in \rho, \sigma \in S, \tag{3.3}$$

where ρ is some fixed null sequence, and c_1, c_2 are positive constants depending on σ. We also assume $\eta(r) \geqslant r^\gamma$ for $r \in \rho$. It is easily seen that c_1, c_2 can be chosen to be locally uniform in S, and thus we can choose them uniformly on the unit sphere of S (with respect to some fixed norm $\|\cdot\|_S$, independent of r). We can find constants $c_1', c_2' > 0$ such that

$$c_1'\,\eta(r)\|\sigma\|_S \geqslant \|\sigma\|_r \geqslant c_2'\,\eta(r)\|\sigma\|_S \quad \text{for all } r \in \rho, \sigma \in S. \tag{3.4}$$

Now let $\phi \in \Phi_\gamma$, and write $\psi = \sigma_0\phi \oplus \psi'$ with some fixed $\sigma_0 \in S$ and rank $\psi' = N_\gamma - 1$. Again, we define A_r $(r \in \rho)$ as a linear form on $S\lceil\mathfrak{A}(r)$ by

$$\sigma_0(A_r) = 1, \quad A_r\lceil\operatorname{img} \psi' = 0, \tag{3.5}$$

thus achieving $\psi^* A_r = \phi$. The norm of A_r can be estimated as

$$\|A_r\lceil S\| = \sup_{\sigma \in S} \frac{|\sigma(A_r)|}{\|\sigma\|_r} \leqslant \frac{\|A_r\|_S}{c_2'\,\eta(r)} \leqslant \frac{c_3}{\eta(r)} \quad (r \in \rho) \tag{3.6}$$

with some constant $c_3 > 0$. We may now extend A_r to an element of $\mathfrak{A}(r)$ and establish convergence using the methods outlined in (a).

(c) More generally, let us assume that S has the structure

$$S = S_1 \oplus \cdots \oplus S_k \tag{3.7}$$

with finite-dimensional spaces S_j which fulfill conditions of the type (3.3) with respect to functions $\eta_j(r)$ and a common null sequence ρ; moreover, we require $\eta_{j+1}(r)/\eta_j(r) \to 0$ and $\eta_k(r) \geqslant r^\gamma$ on ρ.

[For example, this is the situation met in free field theory, where the functions $\eta_j(r)$ are powers of r, and ρ is arbitrary.] We write $\psi=\psi_1\oplus\cdots\oplus\psi_k$ with respect to the direct sum (3.7), and prove the proposition for $\phi\in\mathrm{img}\,\psi_j^*$ by induction on j. Let the statement be true for all $j'<j$ in place of j (we include the case $j=1$ here). For $\phi\in\mathrm{img}\,\psi_j^*$, define A_r $(r\in\rho)$ as a linear form on S_j by $\psi_j^*A_r=\phi$; as in (b), we have $\|A_r\lceil S_j\|\leqslant c/\eta_j(r)$ with some constant $c>0$, and thus we can extend A_r to an element of $\mathfrak{A}(r)$ with the same bounds on its norm. Now observe that for ℓ sufficiently large,

$$\|\phi-\Xi^*A_r+\sum_{m=1}^{j-1}\psi_m^*A_r\|^{(\ell)}\leqslant\|\psi^*A_r-\Xi^*A_r\|^{(\ell)}+\sum_{m=j+1}^{k}\|\psi_m^*A_r\|^{(\ell)}\leqslant\|\psi-\Xi\|_r^{(\ell)}\|A_r\|+\sum_{m=j+1}^{k}\|\psi_m\|_r^{(\ell)}\|A_r\|$$

$$\leqslant\|\psi-\Xi\|_r^{(\ell)}\frac{c}{\eta_j(r)}+\sum_{m=j+1}^{k}\frac{\eta_m(r)}{\eta_j(r)}\cdot\mathrm{const}\to 0\quad(r\in\rho).\tag{3.8}$$

Thus we conclude by induction,

$$\phi\in\overline{\mathfrak{A}(r)+\bigoplus_{m=1}^{j-1}\mathrm{img}\,\psi_m^*}\subset\overline{\mathfrak{A}(r)+\mathfrak{A}(r)}=\overline{\mathfrak{A}(r)}\quad\text{for any } r>0,\tag{3.9}$$

where the bar denotes closure with respect to $\|\cdot\|^{(\ell)}$.

(d) In the general case, the short distance behavior within S may be more complicated than assumed above, and possibly depend crucially on the choice of ρ. Let ρ be any fixed null sequence. Instead of considering $\delta_\gamma(\cdot)$, we introduce a weaker pseudometric $\delta_\gamma^\rho(\cdot)$ defined as in Eq. (2.7), but restricting convergence to $r\in\rho$. The results established so far for $\delta_\gamma(\cdot)$ and Φ_γ hold in an analogous way for $\delta_\gamma^\rho(\cdot)$ and corresponding spaces $\Phi_\gamma^\rho\subset\Phi_\gamma$. If $\rho'\subset\rho$ is a subsequence, then $\Phi_\gamma^{\rho'}\subset\Phi_\gamma^\rho$; in case equality holds here for all subsequences ρ', we will call ρ a *stable* sequence. Let ρ fulfill this condition, and choose rank ψ' minimal such that $\delta_\gamma^\rho(\Xi-\psi')=0$. By passing to subsequences of ρ, we can step by step enforce an "ordering" in the short distance behavior of the elements of $\mathrm{img}\,\psi'$, and arrive at a situation as outlined in (c). Since ρ is stable, passing to subsequences does not affect the approximation property of ψ'; so we can use the methods developed in (c) to establish the proposition for $\phi\in\mathrm{img}\,\psi'^*=\Phi_\gamma^\rho$.

It remains to verify that $\cup_\rho\Phi_\gamma^\rho$ spans all of Φ_γ, where the union runs over all stable sequences ρ. To accomplish this, assume that $\Phi_{\mathrm{st}}:=\mathrm{span}(\cup_\rho\Phi_\gamma^\rho)$ is a proper subspace of Φ_γ. Choose $\phi\in\Phi_\gamma\backslash\Phi_{\mathrm{st}}$ and appropriate $\sigma_0\in\Sigma$, $\psi_{\mathrm{st}}\in\Psi$ such that

$$\psi=\psi_{\mathrm{st}}\oplus\sigma_0\phi,\quad\mathrm{img}\,\psi_{\mathrm{st}}^*\supset\Phi_{\mathrm{st}}.\tag{3.10}$$

According to Lemma 3.1, we may choose ρ such that $\|\sigma_0\|_r\geqslant r^\gamma\cdot\mathrm{const}$ for $r\in\rho$, where we may take ρ to be stable, possibly replacing it by a subsequence. In analogy with (3.1), we split up ψ as

$$\psi=\psi_{\mathrm{I}}\oplus\psi_{\mathrm{II}},$$

$$\text{where } \mathrm{img}\,\psi_{\mathrm{I}}^*=\Phi_\gamma^\rho,\quad r^{-\gamma}\|\sigma\|_r\underset{\rho}{\to}0\ \forall\,\sigma\in\mathrm{img}\,\psi_{\mathrm{II}}.\tag{3.11}$$

But since $\Phi_\gamma^\rho\subset\Phi_{\mathrm{st}}$, it follows from Eqs. (3.10) and (3.11) that $\sigma_0\in\mathrm{img}\,\psi_{\mathrm{II}}$; thus $r^{-\gamma}\|\sigma_0\|_r\to 0$ on ρ, which gives us a contradiction. This completes the proof. □

Having verified Proposition 3.4, we may now apply the results of Fredenhagen and Hertel,[3] who considered (when expressed in our notation) the following set of linear forms:

$$\Phi_{\mathrm{FH}}:=\{\phi\in\mathcal{C}^\infty(\Sigma)^*\,|\,R^\ell\phi R^\ell\in\bigcap_{r>0}\overline{R^\ell\mathfrak{A}(r)R^\ell}^w\ \text{for some } \ell>0\},\tag{3.12}$$

where $-^w$ denotes the weak closure. Φ_{FH} can be interpreted as the theory's field content. The authors showed that any $\phi\in\Phi_{\mathrm{FH}}$ is a local field associated with the net $\mathfrak{A}$; more precisely,

$$f \mapsto \phi(f) = \int f(x) U(x) \phi U(x)^* d^{s+1}x \tag{3.13}$$

can be extended to an operator valued tempered distribution on the domain $\mathcal{C}^\infty(\mathcal{H}) = \cap_{\ell>0} R^\ell \mathcal{H}$, which is local and relatively local; $\phi(f)$ is closable, and its closure $\phi(f)^-$ is affiliated with the local algebras,

$$\phi(f)^- \eta \mathfrak{A}(\mathcal{O}) \quad \text{if supp } f \subset \mathcal{O}. \tag{3.14}$$

In particular, these statements apply to the fields constructed here, since Proposition 3.4 shows that $\Phi_\gamma \subset \Phi_{\mathrm{FH}}$ for any $\gamma \geqslant 0$. In fact, we will show that our spaces Φ_γ exhaust Φ_{FH}. To this end, we first derive improved approximation properties for the fields $\phi \in \Phi_{\mathrm{FH}}$.

Lemma 3.5: Let $\phi \in \Phi_{\mathrm{FH}}$. One can find constants $\ell > 0$, $k > 0$ and operators $A_r \in \mathfrak{A}(r)$ for each $r > 0$ such that

$$\|A_r - \phi\|^{(\ell)} = O(r), \quad \|A_r\| = O(r^{-k}).$$

Proof: We choose a test function $f \in \mathcal{S}(\mathbb{R}^{s+1})$ with $f \geqslant 0$, $\int f(x) d^{s+1}x = 1$, supp $f \subset \mathcal{O}_{r=1}$, and set $f_r := r^{-(s+1)} f(r^{-1}x)$. Now let r be fixed, and let $\phi(f_r)^- = V_r D_r$ be the polar decomposition of this operator, where V_r is a partial isometry, and D_r is self-adjoint. Since $\phi(f_r)^- \eta \mathfrak{A}(r)$, both V_r and all bounded functions of D_r belong to $\mathfrak{A}(r)$.[20] Let ℓ be sufficiently large such that $\|\phi\|^{(\ell)} < \infty$; for $\epsilon > 0$, set

$$A_{r,\epsilon} := \epsilon^{-1} V_r \sin(\epsilon D_r) \in \mathfrak{A}(r). \tag{3.15}$$

Using the inequality

$$(x - \epsilon^{-1} \sin \epsilon x)^2 \leqslant \epsilon^2 x^4 \quad \forall\, x \geqslant 0,\ \epsilon > 0, \tag{3.16}$$

we can establish the estimate

$$\|(A_{r,\epsilon} - \phi(f_r)) R^{4\ell}\|^2 \leqslant \|(\epsilon^{-1} \sin(\epsilon D_r) - D_r) R^{4\ell}\|^2 \leqslant \epsilon^2 \|D_r^2 R^{4\ell}\|^2 = \epsilon^2 \|\phi(f_r)^* \phi(f_r) R^{4\ell}\|^2. \tag{3.17}$$

By repeated use of the relation

$$[R, \phi(f_r)] = -iR\phi(\partial_0 f_r)R \tag{3.18}$$

[compare Eq. (2.4) in Ref. 3] and of the bound $\|\phi(g)\|^{(\ell)} \leqslant \int |g(x)| d^{s+1}x \cdot \text{const}$, we can establish

$$\|\phi(f_r)^* \phi(f_r) R^{4\ell}\| \leqslant r^{-4\ell} c \tag{3.19}$$

with some constant $c > 0$ independent of r. Applying Eq. (3.17), that yields

$$\|A_{r,\epsilon} - \phi(f_r)\|^{(4\ell)} \leqslant \epsilon r^{-4\ell} c. \tag{3.20}$$

Using the integral representation of $\phi(f_r)$ and the spectral properties of the translation operators, one also verifies that

$$\|\phi(f_r) - \phi\|^{(\ell+1)} = O(r). \tag{3.21}$$

Choosing now $A_r := A_{r,\epsilon}$ with $\epsilon = r^{4\ell+1}$, we can combine (3.20) and (3.21) to show

$$\|\phi - A_r\|^{(4\ell+1)} = O(r), \tag{3.22}$$

which proves the lemma, since the required bounds on $\|A_r\|$ are obvious. □

Remarks: Certainly, ℓ and k can be chosen uniformly on any finite-dimensional subspace of Φ_{FH}. Furthermore, by again smearing $A_{r,\epsilon}$ with f_r and rescaling, we may assume that A_r is of the form $\hat{A}_r(f_r)$.

We are now in the position to prove that the Φ_γ exhaust Φ_{FH}. To this end, let $\phi \in \Phi_{\mathrm{FH}}$. Choose a sequence A_r as in Lemma 3.5, and fix γ such that $\|A_r\| = O(r^{-\gamma})$. We will show that $\phi \in \Phi_\gamma$: Choosing $\psi \in \Psi$, $\ell > 0$ such that img $\psi^* = \Phi_\gamma$ and $r^{-\gamma}\|\Xi - \psi\|_r^{(\ell)} \to 0$, we can achieve

$$\|\Xi^* A_r - \psi^* A_r\|^{(\ell)} \to 0. \tag{3.23}$$

Since $\|\Xi^* A_r - \phi\|^{(\ell)} \to 0$ by construction (if ℓ is sufficiently large), this means

$$\psi^* A_r \underset{r\to 0}{\to} \phi \quad \text{with respect to } \|\cdot\|^{(\ell)}. \tag{3.24}$$

Note that the left-hand side of Eq. (3.24) does not leave the finite-dimensional space Φ_γ, which is closed; thus $\phi \in \Phi_\gamma$. We have shown the following.

Theorem 3.6: *If the net* $\mathfrak{A}$ *satisfies the microscopic phase space condition, then*

$$\Phi_{\mathrm{FH}} = \bigcup_{\gamma \geqslant 0} \Phi_\gamma.$$

According to the results in Ref. 3, this means that our construction describes all local fields affiliated with the net and satisfying polynomial *H*-bounds.

IV. SYMMETRY ASPECTS

In this section, we will investigate the action of symmetry transformations on the pointlike fields we have constructed, and eventually show that these fields satisfy the Wightman axioms.

First, we will revisit the structure connected with the spaces Φ_γ of local fields. Given $\gamma \geqslant 0$, we choose a map $\psi \in \Psi$ of rank N_γ such that $\delta_\gamma(\Xi - \psi) = 0$; then img $\psi^* = \Phi_\gamma$. We can define the finite-dimensional space

$$\Sigma_\gamma := \mathcal{C}^\infty(\Sigma)/\ker \psi; \tag{4.1}$$

by virtue of Lemma 3.2, this definition is independent of ψ. In a natural way, we have $\Sigma_\gamma^* = \Phi_\gamma$, and denoting the canonical projection onto Σ_γ by p_γ, its dual map p_γ^* is just the inclusion $\Phi_\gamma \hookrightarrow \mathcal{C}^\infty(\Sigma)^*$. In summary, we get the following diagram, where dashed lines connect pairs of dual spaces:

$$\begin{array}{ccc} \mathcal{C}^\infty(\Sigma) & \xrightarrow{\;p_\gamma\;} & \Sigma_\gamma \\ \vdots & & \vdots \\ \mathcal{C}^\infty(\Sigma)^* & \xleftarrow[\;p_\gamma^*\;]{} & \Phi_\gamma \end{array} \tag{4.2}$$

The elements of Σ_γ correspond to "germs of states" as described by Haag and Ojima.[13]

The phase space approximation "$\Xi \approx \psi$" can be introduced into this scheme in a simple way: Let $p: \mathcal{C}^\infty(\Sigma)^* \to \mathcal{C}^\infty(\Sigma)^*$ be an arbitrary projection onto Φ_γ, continuous with respect to the weak topology on $\mathcal{C}^\infty(\Sigma)^*$. Then the predual map p_* exists, and since Φ_γ is finite dimensional, we have

$$\|p_*\|^{(\ell)} = \sup_{\sigma \in \mathcal{C}^\infty(\Sigma)} \frac{\|p_*\sigma\|^{(\ell)}}{\|\sigma\|^{(\ell)}} < \infty \tag{4.3}$$

for large ℓ. This implies

$$\|\Xi p_* - \Xi\|_r^{(\ell)} \leqslant \|(\Xi - \psi)p_*\|_r^{(\ell)} + \|\Xi - \psi p_*\|_r^{(\ell)} \leqslant \|\Xi - \psi\|_r^{(\ell)} \|p_*\|^{(\ell)} + \|\Xi - \psi\|_r^{(\ell)} = o(r^\gamma), \tag{4.4}$$

so we can express the approximation by $\delta_\gamma(\Xi p_* - \Xi) = 0$, without referring to a specific map ψ.

Now we will turn to the investigation of symmetry operations. The action of such symmetries (e.g., Lorentz transformations) is usually given on $\mathfrak{B}(\mathcal{H})$, and by virtue of diagram (4.2) we will transfer this action to the spaces Φ_γ. First of all, let us define the class of "admissible transformations" that we will consider.

Definition 4.1: Let $U \in \mathfrak{B}(\mathcal{H})$ be a unitary. The transformation $\alpha = \mathrm{ad}\, U : \mathfrak{B}(\mathcal{H}) \to \mathfrak{B}(\mathcal{H})$ is called a microscopic symmetry *if the following two conditions hold:*

(1) *For every $\ell > 0$, there is an $\ell' > 0$ such that $\|R^{-\ell} U R^{\ell'}\| < \infty$.*
(2) *There are constants $c, R > 0$ such that $\alpha\mathfrak{A}(r) \subset \mathfrak{A}(c \cdot r)\ \forall\, r \in (0, R)$.*

Condition (1) allows us to extend α to a map $\alpha : \mathcal{C}^\infty(\Sigma)^* \to \mathcal{C}^\infty(\Sigma)^*$. Regarding this extension, we prove the following.

Proposition 4.2: Let α be a microscopic symmetry. Then

$$\alpha\Phi_\gamma \subset \Phi_\gamma \quad \forall\ \gamma \geqslant 0.$$

Proof: Using condition (1) in Definition 4.1, we can define the predual map $\alpha_* : \mathcal{C}^\infty(\Sigma) \to \mathcal{C}^\infty(\Sigma)$. Let $\gamma \geqslant 0$ be fixed. Lemma 3.2 shows us that in diagram (4.2),

$$\ker p_\gamma = \{\sigma \in \mathcal{C}^\infty(\Sigma) \mid r^{-\gamma} \|\sigma\|_r \to 0\}. \tag{4.5}$$

Together with condition (2) in Definition 4.1, this yields $\alpha_* \ker p_\gamma \subset \ker p_\gamma$; thus α has a well-defined action on the quotient space Σ_γ and on its dual Φ_γ. By construction, this action is compatible with the inclusion $p_\gamma^* : \Phi_\gamma \hookrightarrow \mathcal{C}^\infty(\Sigma)^*$, which proves the proposition. □

Microscopic symmetries α thus leave the spaces Φ_γ of pointlike fields stable. In the case of a group representation $g \mapsto \alpha(g)$, we get corresponding finite-dimensional representations on every field space Φ_γ. An example for this case are Lorentz transformations: Each Φ_γ carries a finite-dimensional representation of the Lorentz group. Another example for microscopic symmetries are dilations, provided they exist as a symmetry of the net. Furthermore, our analysis allows us to handle inner symmetries, both broken and unbroken. In the case of a spontaneously broken symmetry, one expects that $\alpha = \mathrm{ad}\, U$ preserves localization only in regions of some limited size—this corresponds to the case $R < \infty$ in Definition 4.1. [Compare Ref. 21. To include the situation considered there in our context, it is necessary to extend our framework from the observable algebras $\mathfrak{A}(\mathcal{O})$ to the field algebras $\mathfrak{F}(\mathcal{O})$, including also nonobservable fields, which should however be straightforward.]

In extension of our methods introduced above, one observes that the antilinear involution $A \mapsto A^*$ can be treated in a similar manner, showing that the field spaces Φ_γ are invariant under Hermitean conjugation $\phi \mapsto \phi^*$. Defining the translated fields as $\phi(x) := U(x)\phi U(x)^*$, or passing over to the "smeared" fields $\phi(f)$, we may also derive symmetry properties under the (connected part of the) full Poincaré group.

The only remaining part in establishing the Wightman axioms then is irreducibility, i.e., the question whether the vacuum vector Ω is cyclic for the fields. As will be discussed below, we cannot expect this in the general case. However, for each γ we may consider a "reduced" Hilbert space,

$$\mathcal{H}_\gamma := \overline{\mathcal{P}_\gamma(\mathcal{O})\Omega} \subset \mathcal{H}, \tag{4.6}$$

where $\mathcal{O}$ is some open subset of $\mathbb{R}^{s+1}$, and $\mathcal{P}_\gamma(\mathcal{O})$ is the polynomial algebra generated by the fields $\phi(f)$ with $\phi \in \Phi_\gamma$ and $\mathrm{supp}\, f \subset \mathcal{O}$. (Due to the Reeh–Schlieder theorem, the space $\mathcal{H}_\gamma$ does not depend on $\mathcal{O}$.) Considered on $\mathcal{H}_\gamma$, the set Φ_γ is certainly irreducible. Thus, we have established the following.

Theorem 4.3: *Let $\mathcal{O} \mapsto \mathfrak{A}(\mathcal{O})$ satisfy the microscopic phase space condition. For every $\gamma \geqslant 0$, there exists a basis $\{\phi_1, \ldots, \phi_{N_\gamma}\}$ of Φ_γ and a Hilbert space $\mathcal{H}_\gamma \subset \mathcal{H}$ such that $\{f \mapsto \phi_j(f)\}$ is a set of quantum fields on $\mathcal{H}_\gamma$ in the sense of the Wightman axioms.*

Here we refer to the Wightman axioms as put forward in Ref. 22. Note that in our case, the fields always have finite spin. In the more general framework of Ref. 3, this is not guaranteed. Also note that we need to allow $\mathcal{H}_\gamma$ to grow with γ: While at any fixed γ, we are sure to find only a finite number of fields, more and more independent fields may occur in the phase space approximation as we increase the energy dimension.

Let us briefly return to the question whether, or on which Hilbert space, the entire field content Φ_{FH} is irreducible. In general, we cannot expect Φ_{FH} to be an irreducible set on $\mathcal{H}$, since there exist nontrivial theories which fulfill the microscopic phase space condition, but have a trivial field content, i.e., $\Phi_{\mathrm{FH}}=\mathbb{C}\mathrm{l}$ (cf. the Appendix). These theories might always occur as a tensor factor of $\mathfrak{A}$. To exclude such nonpointlike components from the theory, we can define the following subnet $\mathfrak{A}_F$ of $\mathfrak{A}$ using the methods exposed in Ref. 23:

$$\mathfrak{A}_F(\mathcal{O}) := \mathcal{P}(\mathcal{O})'', \tag{4.7}$$

where $\mathcal{P}(\mathcal{O})$ is the polynomial algebra generated by Φ_{FH}, and $(\cdots)'$ denotes the weak commutant. If $\mathfrak{A}$ fulfills the microscopic phase space condition, then so does $\mathfrak{A}_F$, leading to the same field content as $\mathfrak{A}$; thus we may call $\mathfrak{A}_F$ the point field part of the theory. It is $\mathcal{H}_F := \overline{\mathcal{P}(\mathcal{O})\Omega}$ which we should consider as the natural Hilbert space for the Wightman fields. In fact, using the techniques of Bisognano and Wichmann,[24] it should be possible to show that

$$\mathcal{H}_F = \mathcal{H} \;\Leftrightarrow\; \mathfrak{A}_F = \mathfrak{A}, \tag{4.8}$$

meaning that Φ_{FH} is irreducible on $\mathcal{H}$ if, and only if, the theory is completely determined by pointlike observables.

We can incorporate derivatives of fields into our context as well. It is easy to see that together with ϕ, its derivatives

$$\partial_\mu \phi := \frac{\partial}{\partial x^\mu}\, U(x)\phi U(x)^*\big|_{x=0} = i[P_\mu, \phi] \tag{4.9}$$

are contained in Φ_{FH}; so we can take ∂_μ to be a linear operator from Φ_γ into some $\Phi_{\gamma'}$. Usually, we must choose $\gamma' > \gamma$ here, since the "energy dimension" of fields increases when applying time derivatives: If $\|\partial_0^n \phi\|^{(\ell)} < \infty$ for some fixed ℓ and *any* $n \in \mathbb{N}$, then it follows that $\|\phi\Omega\| < \infty$; however, this is only possible if ϕ is a multiple of the identity.[25] In particular, the case of a finite-dimensional Φ_{FH} automatically leads to $\Phi_{\mathrm{FH}}=\mathbb{C}\mathrm{l}$.

V. CONCLUSIONS AND OUTLOOK

Starting from a relativistic quantum theory in the algebraic framework, i.e., expressed in terms of observables localized at finite distances, we have shown that its field content can be characterized by its phase space structure in the short distance limit. We have introduced a physically motivated phase space criterion that distinguishes a class of models with "regular" short distance behavior. Assuming that this criterion is fulfilled, we have established very detailed results on the approximation of pointlike fields by bounded local observables. The field content is exhausted by an increasing sequence of finite-dimensional spaces Φ_γ, each of which is invariant under Lorentz transformations, Hermitian conjugation and other symmetries. Their dimension $N_\gamma = \dim \Phi_\gamma$ can be read off directly from the phase space behavior. The label γ may be interpreted as a "short distance dimension" of the fields.

In mathematical terms, we have developed a method of classifying the short distance behavior of a net of algebras $\mathcal{O} \mapsto \mathfrak{A}(\mathcal{O})$; the field space dimensions N_γ are "invariants" of the net. Such a classification should depend on local properties at small distances only. Strictly speaking, this goal is not completely reached in our analysis: We incorporate the energy operator H as a global property. However, H enters the construction not as the generator of a global symmetry, but only through the more qualitative feature of energy damping, and via its role as a generator of the unitary group used for "smearing" the fields. One should therefore be able to replace the Hamil-

tonian with the local symmetry generators established by Buchholz, D'Antoni, and Longo[26] through the use of a "universal localizing map." It is also worth noting that with respect to certain phase space properties, H may be replaced[27] with a suitable modular operator Δ. This might point to an extension of our results even to situations without any space–time symmetries. Since $-\log \Delta$ corresponds to energy-momentum *transfer* rather than to total energy, though, it is unclear how the concept of polynomial bounds can be substituted.

Besides a characterization of the short distance limit, our results provide a sufficient technical basis for a rigorous proof of the existence of operator product expansions; this will be discussed in a forthcoming paper.[17]

ACKNOWLEDGMENTS

The author wishes to thank D. Buchholz for posing the problem, and is grateful to him for many helpful discussions and remarks. The author would also like to thank R. Haag and I. Ojima for a discussion on the subject, as well as H. Reeh for his support in the beginning of the work that lead to the present paper. The work has profited from financial support by Evangelisches Studienwerk, Villigst, which the author gratefully acknowledges.

APPENDIX: SOME SIMPLE MODELS

The claim that our phase space condition should hold in physically relevant theories may be supported by the fact that it is fulfilled at least in some simple situations. In this appendix, we will therefore investigate the structures introduced in the main text in specific noninteracting models.

We will first consider a real scalar free field and argue that this theory fulfills the microscopic phase space condition in $s \geqslant 3$ spatial dimensions. Then we discuss extensions of this result to more general (still noninteracting) situations.

The real scalar free field

Most of the relevant techniques that allow us to discuss the short distance structure of free fields are already visible in the case of a single real scalar field. For this theory, the following theorem holds.

Theorem A.1: *The theory of a real scalar free field of mass $m \geqslant 0$ in $s+1$ space–time dimensionsl, $s \geqslant 3$, satisfies the microscopic phase space condition.*

This result was proved in Chap. 7 of Ref. 18 for a slightly modified version of the phase space condition. The proof carries over to our situation; however, the construction is quite involved, and it would go beyond the scope of the current paper to reproduce the complete discussion. Instead, we shall confine ourselves to a rough and somewhat heuristic sketch of the arguments; the reader is referred to Ref. 18 for details.

In order to fix our notation, we shall briefly recall the definition of a real scalar free field. Our Hilbert space $\mathcal{H}$ is the symmetric Fock space over the single particle space $\mathcal{K} = \mathcal{L}^2(\mathbb{R}^s, d^s p)$ ("wave functions in momentum space"). The scalar product on $\mathcal{K}$ will be denoted as $\langle \cdot | \cdot \rangle$, as opposed to the scalar product $(\cdot|\cdot)$ on $\mathcal{H}$. On $\mathcal{K}$, we have the generator of time translations $\omega = \sqrt{\mathbf{p}^2 + m^2}$, which fixes the Hamiltonian H on Fock space by means of "second quantization." The spectral projectors of ω will be denoted as $P_\omega(E)$, those of H as $P_H(E)$.

The local algebras $\mathfrak{A}(r)$ are then generated by Weyl operators $W(f) = \exp i(a(f) + a^*(f))$ with $f = f^+ + if^-$, where $f^\pm \in \mathcal{K}$ are localized functions in configuration space, in the sense that the Fourier transforms of $\omega^{\pm 1/2} f^\pm$ are real-valued and smooth and have their support within the ball $|\mathbf{x}| < r$.

In order to prove Theorem A.1, we must find a series expansion of the kind

$$\Xi = \sum_j \sigma_j \phi_j. \tag{A1}$$

with linear forms $\phi_j \in \mathcal{C}^\infty(\Sigma)^*$ and functionals $\sigma_j \in \Sigma$, valid for localized arguments of σ_j and energy-damped expectation values of ϕ_j. We will establish this expansion in four steps.

Step 1: Single particle space. For a start, we will derive a series expansion of the single–particle scalar product

$$\langle f^\pm | k \rangle = \langle \omega^{\pm 1/2} f^\pm | \omega^{\mp 1/2} k \rangle, \tag{A2}$$

where $f^\pm$ is localized with radius r (as above), and k is an energy-bounded function, i.e., $k \in P_\omega(E)\mathcal{K}$ for some E. Since $\omega^{\mp 1/2}k$ is also energy bounded, its Fourier transform $\mathcal{F}[\omega^{\mp 1/2}k]$ is analytic, and thus we can replace it with its Taylor series,

$$\mathcal{F}[\omega^{\mp 1/2}k](\mathbf{x}) = \sum_\kappa \frac{1}{\kappa!} \frac{\partial^\kappa}{\partial x^\kappa} \mathcal{F}[\omega^{\mp 1/2}k]|_{\mathbf{x}=0} x^\kappa \tag{A3}$$

—the sum runs over multi-indices κ here. Inserting this expansion into Eq. (A2), and rewriting the spatial derivatives as integrals in momentum space, we arrive at

$$\langle f^\pm | k \rangle = \sum_\kappa \langle f^\pm | \underbrace{\frac{\sqrt{2}}{\kappa!} \omega^{\pm 1/2} \mathcal{F}^{-1}[x^\kappa]}_{=: h_\kappa^\pm} \rangle \langle \underbrace{\frac{i^{-|\kappa|}}{\sqrt{2}(2\pi)^{s/2}} \omega^{\mp 1/2} p^\kappa}_{=: g_\kappa^\pm} | k \rangle = \sum_\kappa \langle f^\pm | h_\kappa^\pm \rangle \langle g_\kappa^\pm | k \rangle. \tag{A4}$$

The scalar products with the "improper vectors" $g_\kappa^\pm$ and $h_\kappa^\pm$ can be justified due to the given localization properties of $f^\pm$ and k. Note that $g_\kappa^\pm$ and $h_\kappa^\pm$ are independent not only of $f^\pm$ and k, but also of E and r. Using that the coefficients $\langle f^\pm | h_\kappa^\pm \rangle$ are real, we can thus write

$$f^\pm = \sum_\kappa \langle f^\pm | h_\kappa^\pm \rangle g_\kappa, \tag{A5}$$

where the sum is to be read "under energy restriction."

We note that regarding the short-distance or high-energy behavior of the functions introduced above, one has

$$\| P_\omega(E) g_\kappa^\pm \| \sim E^{|\kappa| + (s \mp 1)/2}, \quad |\langle f^\pm | h_\kappa^\pm \rangle| \sim r^{|\kappa| + (s \mp 1)/2}; \tag{A6}$$

in particular, there are only finitely many terms in the sum (A4) which correspond to a given "scaling dimension."

Step 2: Expansion of Weyl operators. In order to transfer our results in single-particle space to the theory in Fock space, we will next aim at a series expansion of local Weyl operators $W(f)$, where $f = f^+ + if^-$ as before. We can certainly expand them as

$$W(f) = e^{-\|f\|^2/2} e^{ia^*(f)} e^{ia(f)} = e^{-\|f\|^2/2} \sum_{m^\pm, n^\pm \in \mathbb{N} \cup \{0\}} \frac{i^{m^+ + n^+ + 2m^-}}{m^+! m^-! n^+! n^-!} a^*(f^+)^{m^+} a^*(f^-)^{m^-} a(f^+)^{n^+} a(f^-)^{n^-}. \tag{A7}$$

If this sum is evaluated in energy-restricted states, we can insert our result (A5) here, writing, for example,

$$a^*(f^+) = \sum_\kappa \langle f^+ | h_\kappa^+ \rangle a^*(g_\kappa^+). \tag{A8}$$

However, this leaves us with additional $m^+ + m^- + n^+ + n^-$ summation (multi-)indices in each summand of (A7). In order to simplify the notation, we will reorganize this multiple sum by the following:

(i) relabeling the functions $g_\kappa^\pm$ and $h_\kappa^\pm$ with natural numbers j instead of multi-indices κ,

(ii) grouping terms with equal powers of $\langle f^+|h_j^+\rangle$ and $\langle f^-|h_j^-\rangle$ into one, and
(iii) labeling these terms with two multi-indices $\mu^\pm=(\mu_1^\pm,\ldots)$, where μ_1^+ counts the power of $\langle f^+|h_1^+\rangle$, etc. Additionally, we will combine μ^+ and μ^- into a single multi-index $\mu=(\mu^+,\mu^-)$.

This leads us to an expression

$$W(f)=\sum_\kappa e^{-\|f\|^2/2}\prod_j \langle f^+|h_j^+\rangle^{\mu_j^+}\langle f^-|h_j^-\rangle^{\mu_j^-}\cdot\phi_\mu, \tag{A9}$$

where ϕ_μ are quadratic forms of the sort

$$\phi_\mu=\sum \frac{i^{m^++n^++2m^-}}{m^+!m^-!n^+!n^-!}a^*(g_?)\cdots a(g_?)\cdots\ . \tag{A10}$$

Here $a^*(g_?)\cdots a(g_?)\cdots$ are certain products of annihilation and creation operators of $g_j^\pm$, with their multiplicity given by $\mu^\pm$. The ϕ_μ can be shown to be elements of $\mathcal{C}^\infty(\Sigma)^*$. Their detailed structure is not relevant for our purposes—see, however, the end of this section for some examples. Regarding the scaling properties of the expansion terms, we find

$$\|P_H(E)\phi_\mu P_H(E)\|\sim E^{\vartheta(\mu)},\quad \prod_j \langle f^+|h_j^+\rangle^{\mu_j^+}\langle f^-|h_j^-\rangle^{\mu_j^-}\sim r^{\vartheta(\mu)}. \tag{A11}$$

The exponent $\vartheta(\mu)$ results from Eq. (A6), and its detailed form is not of much importance; the crucial point is that for every $\gamma\geqslant 0$, the set $\{\mu|\,\vartheta(\mu)\leqslant\gamma\}$ is finite, given that $s\geqslant 2$.

Step 3: Linear extension. Our next step is to generalize the expansion (A9) to arbitrary $A\in\mathfrak{A}(r)$ in place of the generating $W(f)$. To that end, we need to replace the numerical factors involving $f^\pm$ with an expression that is linear in $W(f)$; i.e., we need to find linear functionals σ_μ such that

$$\sigma_\mu(W(f))=e^{-\|f\|^2/2}\prod_j \langle f^+|h_j^+\rangle^{\mu_j^+}\langle f^-|h_j^-\rangle^{\mu_j^-}. \tag{A12}$$

In fact, we note that functionals of the type

$$\sigma(\cdot)=(\Omega|[a(b),[a^*(b'),\cdot\,]]\Omega)\quad \text{with } b,b'\in\mathcal{K} \tag{A13}$$

evaluate on Weyl operators to

$$\sigma(W(f))=e^{-\|f\|^2/2}\langle b|if\rangle\langle if|b'\rangle. \tag{A14}$$

For a given multi-index $\mu=(\mu^+,\mu^-)$, we can construct a functional τ_μ in a similar way such that for given b_j, $b_j'\in\mathcal{K}$,

$$\tau_\mu(W(f))=e^{-\|f\|^2/2}\prod_j \langle b_j|if\rangle^{\mu_j^+}\langle if|b_j'\rangle^{\mu_j^-}. \tag{A15}$$

This is not exactly the form (A12) we need. However, inserting $f=f^++if^-$, we may build certain linear combinations of the τ_μ in order to form the σ_μ we require; this combinatorial problem can be solved by means of a generating function technique, which we shall not present in detail here.

After establishing the functionals σ_μ, we can rewrite (A9) as

$$\Xi=\sum_\mu \sigma_\mu\phi_\mu, \tag{A16}$$

where, at this time, the series is meaningful on a sufficiently restricted domain.

Step 4: Convergence. In order to establish the phase space condition, our objective is to show that the series expansion of Ξ in Eq. (A16) holds with respect to the pseudometric $\hat{\delta}$ defined in Eq.

(2.8). Loosely speaking, we have dealt with the algebraic aspects of this expansion up to now, while we still must handle the topological problems, i.e., establish convergence. Roughly, this includes the following tasks.

First, we need to establish precise estimates for the norms of ϕ_μ and σ_μ, depending on the energy and configuration space localization E and r. This involves all parts of the calculation in steps 1–3 above. The goal is to establish an estimate of the form

$$\|\sigma_\mu[\mathfrak{A}(r)\| \cdot \|P_H(E)\phi_\mu P_H(E)\| \leqslant c_\mu (Er)^{\vartheta(\mu)}, \tag{A17}$$

where the constants c_μ do not increase too fast when varying μ.

Second, we need to sum the terms in Eq. (A17) in order to establish norm convergence of the series (A16) at fixed E and r. Unfortunately, it turns out that the estimates which we can establish in Eq. (A17) are not strict enough: We encounter convergence problems at "high particle numbers," i.e., at high values of $|\mu|$. This problem is solved by handling the terms for high $|\mu|$ according to a different expansion with better convergence properties, using the techniques developed by Buchholz and Porrmann.[9] Their methods, however, result in expansion terms that are explicitly dependent of E and r, so that they are useful for discussing the convergence issues in question, but cannot be used in our main expansion. In this part of the construction, the condition $s \geqslant 3$ is needed.

Third, once that the series is established at fixed E and r, we need to apply the results to the pseudometrics δ_γ, which means in particular to pass from the sharp energy bounds to the polynomial bounds used in the main text, and to consider the limit $r \to 0$. As a result of this calculation, we can show that for each $\gamma \geqslant 0$,

$$\delta_\gamma\left(\Xi - \sum_{\vartheta(\mu)\leqslant\gamma} \sigma_\mu \phi_\mu\right) = 0. \tag{A18}$$

This relation finally proves Theorem A.1.

It is instructive to see how the approximation terms $\sigma_\mu\phi_\mu$ are formed explicitly. When working out the details of the construction, one easily sees that the first term of the expansion, corresponding to $\mu=(0,0,0,\ldots)$, leads to $\phi_\mu=\mathbb{1}$ and $\sigma_\mu=(\Omega|\cdot|\Omega)$. In the next term [with the next lowest value of $\vartheta(\mu)$] the form ϕ_μ is the usual scalar field $\phi(0)$. Higher-order terms involve derivatives of the field and Wick products. For $s=3$, the beginning of the expansion reads

$$\begin{aligned}
\Xi = {} & (\Omega|\cdot|\Omega) && \cdot \mathbb{1} && \Big\} \vartheta(\mu)=0 \\
& + \frac{1}{2}((h|\cdot|\Omega) + (\Omega|\cdot|h)) && \cdot \phi(0) && \Big\} \vartheta(\mu)=1 \\
& + \frac{1}{2}\sum_{j=1}^{3} ((\hat{x}_j h|\cdot|\Omega) + (\Omega|\cdot|\hat{x}_j h)) && \cdot \partial_j\phi(0) && \Big\} \vartheta(\mu)=2 \\
& + \frac{1}{2i}((\omega^{-1}h|\cdot|\Omega) - (\Omega|\cdot|\omega^{-1}h)) && \cdot \partial_0\phi(0) && \\
& + \sigma_Q(\cdot) && \cdot :\phi^2:(0) && \\
& + \cdots . && &&
\end{aligned} \tag{A19}$$

Here $h=h_{\kappa=0}$ is the function introduced in (A4), the operator $\hat{x}_j$ stands for $\omega^{1/2}\mathcal{F}^{-1}x_j\mathcal{F}\omega^{-1/2}$, with $\mathcal{F}$ being the operator of Fourier transformation, and σ_Q denotes the following functional:

$$\sigma_Q(\cdot) = \frac{1}{4\sqrt{2}}((h \otimes h| \cdot |\Omega) + (\Omega| \cdot |h \otimes h)) + \frac{1}{4}(h| \cdot |h) - \frac{\|h\|^2}{4}(\Omega| \cdot |\Omega). \tag{A20}$$

We have $N_0=1$, $N_1=2$, $N_2=7$, and $N_3=21$ [the latter not being shown in Eq. (A19)]. The corresponding spaces Φ_γ have the following form:

$$\Phi_0 = \mathrm{span}\{\mathbb{1}\},$$

$$\Phi_1 = \mathrm{span}\{\mathbb{1}, \phi\},$$

$$\Phi_2 = \mathrm{span}\{\mathbb{1}, \phi, \partial_j\phi, \partial_0\phi, :\phi^2:\},$$

$$\Phi_3 = \mathrm{span}\{\mathbb{1},\ \phi,\ \partial_j\phi,\ \partial_0\phi,\ :\phi^2:,\ \partial_j^2\phi,\ \partial_j\partial_k\phi,\ \partial_0\partial_j\phi,\ :\phi\partial_j\phi:,\ :\phi\partial_0\phi:,\ :\phi^3:\}, \tag{A21}$$

where $j,k=1\ldots3, j>k$, and the argument of the field has been omitted. Note that the second-order time derivative $\partial_0^2\phi$ lies in Φ_3, but is a linear combination of the basis elements listed above—this reflects the field equation of the model.

More applications

The methods we have sketched above are not restricted to the simple case of a real scalar field. Similar results can be derived in a large class of free theories, including

(i) charged fields and fields of higher spin,
(ii) theories with more than one field (but finitely many), massive or massless, in $s \geqslant 3$ dimensions,
(iii) massive theories in $s=2$,

where on the technical side, only the single particle space expansions must be adapted appropriately.

It has not yet been possible to establish the criterion in the $(2+1)$-dimensional massless case. This results from the model's peculiar infrared structure that causes certain nuclearity conditions to be violated (cf. Ref. 9), leading to convergence problems at high particle numbers. Also, there is no result for the $(1+1)$-dimensional case (irrespective of m); here the Wick powers $:\phi^n:$ have the same energy dimension as the field itself, thus one would not expect finite-dimensional field spaces Φ_γ to exist.

The criterion is explicitly violated in theories with infinitely many free fields (see Sec. 8.1 of Ref. 18). In this case, we find $N_\gamma=\infty$ for all $\gamma \geqslant 1$.

In conclusion, we briefly sketch a model discussed by Lutz,[19] which is interesting in this context since its field content is trivial. We proceed from a free massless theory in $(s+1)+1$ space–time dimensions, with the local algebras generated by Weyl operators $W(f)$ as before, but with test functions f of the type

$$f(\mathbf{p}) = (p_{s+1})^{2n(r)} f_0(\mathbf{p}), \tag{A22}$$

where $n(r)$ is an integer function tending to infinity as $r \to 0$, and x_{s+1} is the "additional" spatial coordinate. When restricting the net to $s+1$ space–time dimensions, we can apply the above arguments to show that the theory fulfills the microscopic phase space condition. Indeed, we see from (A4) that every fixed expansion term h_κ in the single particle space simply drops out if $n(r)$ is sufficiently large, i.e., if r is sufficiently small. This leads to the result

$$\delta_\gamma(\Xi - (\Omega| \cdot |\Omega)\mathbb{1}) = 0 \quad \forall\ \gamma \geqslant 0, \tag{A23}$$

which implies $\Phi_\gamma = \mathbb{C}\mathbb{1}$ for all γ.

Wilson polynomials and the Lorentz transformation properties of the parity operator

Carl M. Bender, Peter N. Meisinger, and Qinghai Wang

(Received 2 December 2004; accepted 21 January 2005; published online 7 April 2005)

The parity operator for a parity-symmetric quantum field theory transforms as an infinite sum of irreducible representations of the homogeneous Lorentz group. These representations are connected with Wilson polynomials. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1870733]

I. INTRODUCTION

The objective of this paper is to determine the Lorentz transformation properties of the parity operator $\mathcal{P}$. The operator $\mathcal{P}$ for a quantum field theory has the effect

$$\mathcal{P}\varphi(\mathbf{x},t)\mathcal{P} = \varphi(-\mathbf{x},t) \quad \text{(scalar field)},$$

$$\mathcal{P}\varphi(\mathbf{x},t)\mathcal{P} = -\varphi(-\mathbf{x},t) \quad \text{(pseudoscalar field)}.$$

For purposes of comparison, we can also define an *intrinsic* parity operator $\mathcal{P}_I$. This operator has the same effect as $\mathcal{P}$ except that it does not reverse the sign of the spatial argument of the quantum field,[1]

$$\mathcal{P}_I\varphi(\mathbf{x},t)\mathcal{P}_I = \varphi(\mathbf{x},t) \quad \text{(scalar field)},$$

$$\mathcal{P}_I\varphi(\mathbf{x},t)\mathcal{P}_I = -\varphi(\mathbf{x},t) \quad \text{(pseudoscalar field)}.$$

To determine the Lorentz transformation properties of any operator in a quantum field theory one must calculate the commutator of this operator with the generators of the Lorentz group $J^{\mu\nu}$. If this operator, like the parity operator $\mathcal{P}$, does not depend on the space–time coordinates $(\mathbf{x},t)$ and it commutes with $J^{\mu\nu}$, then it is a scalar under Lorentz transformations.

In this paper we will assume that the Hamiltonian H of our quantum field theory has parity symmetry; that is, $[\mathcal{P},H]=0$. An example of such a theory is the free scalar quantum field theory whose Hamiltonian is

$$H = \int d\mathbf{x}\left\{\tfrac{1}{2}\pi^2(\mathbf{x},t) + \tfrac{1}{2}[\nabla\varphi(\mathbf{x},t)]^2 + \tfrac{1}{2}\mu^2\varphi^2(\mathbf{x},t)\right\}.$$

For such a theory it is easy to see that the intrinsic parity operator is not only a rotational scalar but also a Lorentz scalar because it commutes with all six generators of the homogeneous Lorentz group,

$$[\mathcal{P}_I, J^{\mu\nu}] = 0.$$

Like the intrinsic parity operator $\mathcal{P}_I$, the conventional parity operator $\mathcal{P}$ is a rotational scalar because it commutes with the three generators of spatial rotations,

$$[\mathcal{P}, J^{ij}] = 0.$$

However, in contrast with $\mathcal{P}_I$, $\mathcal{P}$ does *not* commute with the Lorentz-boost generators. Either by

direct calculation or by using the fact that J^{0i} is a vector (like the electric field vector) under spatial reflection, we can show that

$$[\mathcal{P}, J^{0i}] = -2J^{0i}\mathcal{P}. \tag{1}$$

Therefore, the parity operator $\mathcal{P}$ is not a Lorentz scalar. Furthermore, as we will see, $\mathcal{P}$ is not the spin-0 component of a vector, a tensor, or indeed any finite-dimensional representation of the Lorentz group.

This observation raises a fundamental question: How does $\mathcal{P}$ transform under the Lorentz group? In this paper we provide a partial answer to this question. We argue that $\mathcal{P}$ transforms as an infinite direct sum of finite-dimensional tensorial representations of the Lorentz group.

This paper is organized as follows: In Sec. II we review the general theory of the irreducible representations of the Lorentz group. Then in Sec. III we show that $\mathcal{P}$ transforms as a direct sum of irreducible representations of the Lorentz group, and that to identify each of these irreducible representations one must solve a difference-equation eigenvalue problem. In Secs. IV and V we perform an analysis of special cases of this difference equation and show that the eigenfunctions are closely associated with the Wilson polynomials. Finally, in Sec. VI we make some concluding remarks about the structure of the solutions to the general difference-equation eigenvalue problem that is derived in Sec. III. The properties of the Wilson polynomials are summarized in the Appendixes.

II. IRREDUCIBLE REPRESENTATIONS OF THE LORENTZ GROUP

In this section we review briefly the classification of irreducible representations of the Lorentz group. Following the exposition of the irreducible representations of the Lorentz group by Gel'fand, Minlos, and Shapiro,[2] Bender and Griffiths,[3] and Griffiths,[4] we note that all irreducible representations of the Lorentz group are characterized and labeled by a pair of numbers (ℓ_0, ℓ_1). The first number, ℓ_0, is a non-negative integer and the second number, ℓ_1, is in general complex. Any irreducible representation of the Lorentz group is a direct sum of irreducible representations of the rotation subgroup SO(3) and ℓ_0 is the lowest-spin of the representations contained in this sum.

If $\ell_1 - \ell_0 = 0$ or noninteger, then the representation belongs to the *nonsingular class* of infinite-dimensional representations. Such a representation contains an infinite tower of spins beginning with ℓ_0; the spins ℓ in this representation are $\ell = \ell_0, \ell_0+1, \ell_0+2, \ldots$. Each spin in this sequence occurs once and only once.

If $\ell_1 - \ell_0$ is a nonzero integer, then the representation belongs to the *singular class*. For this case if $|\ell_1| > \ell_0$, the representation is finite dimensional; it contains all spins ℓ with $\ell_0 \leqslant \ell \leqslant |\ell_1| - 1$ and each spin occurs exactly once. If $|\ell_1| < \ell_0$, the representation is infinite dimensional; it contains all spins, ℓ, $\ell_0 \leqslant \ell < \infty$ and again each spin occurs exactly once.

Since the Lorentz group is noncompact, it also has indecomposable representations. However, this situation does not arise in this paper.

To describe the Lorentz transformation properties of a space–time-dependent quantity, such as a quantum field, we must specify all of the spin components of the field $(Q_{\ell_0}, Q_{\ell_0+1}, Q_{\ell_0+2}, \ldots)$. Let us suppose first that this field transforms irreducibly under the Lorentz group and let us also suppose that the lowest-spin component has spin 0. Then, an infinitesimal Lorentz transformation of the spin-0 component $Q_0(\mathbf{x}, t)$ has an orbital and a spin part. Specifically,

$$-i[Q_0, J^{0i}] = t\partial^i Q_0 - x^i \partial^0 Q_0 + Q_1^i, \tag{2}$$

where Q_1^i is the spin-1 component of the irreducible representation. Under an infinitesimal Lorentz transformation, this spin-1 component then transforms like

$$-i[Q_1^j, J^{0i}] = t\partial^i Q_1^j - x^i \partial^0 Q_1^j + Q_2^{ij} + \alpha \delta^{ij} Q_0, \tag{3}$$

where Q_2^{ij} is the spin-2 component of the representation. Note that Q_2^{ij} is a *pure* spin-2 object and

is therefore symmetric and traceless, $Q_2^{ii}=0$. (Repeated indices indicate summation.) The number α in (3) is directly related to the parameter ℓ_1 for the irreducible representation by the formula[3]

$$\alpha = \tfrac{1}{3}(\ell_1^2 - 1). \tag{4}$$

This process of evaluating commutators can be used iteratively to calculate all of the spin components of the irreducible representation.

Now suppose that Q_0 is the spin-0 component of a representation of the Lorentz group, but that this representation is not irreducible. This means that there may be more than one component of each spin. Thus, under an infinitesimal transformation we have

$$-i[Q_0, J^{0i}] = t\partial^i Q_0 - x^i \partial^0 Q_0 + N_1^i(Q_0), \tag{5}$$

where N_1^i is one of the spin-1 components of the representation. An infinitesimal Lorentz transformation of this spin-1 component produces a spin-2 component $N_2^{ij}(Q_0)$, for which $N_2^{ii}(Q_0)=0$, and a new spin-0 component $N_0(Q_0)$,

$$-i[N_1^j(Q_0), J^{0i}] = t\partial^i N_1^j(Q_0) - x^i \partial^0 N_1^j(Q_0) + N_2^{ij}(Q_0) + \delta^{ij} N_0(Q_0). \tag{6}$$

Since this representation is not irreducible, $N_0(Q_0)$ is not a multiple of Q_0.

This process of calculating commutators can again be used to generate all of the spin components of the representation. For example, commuting $N_2^{ij}(Q_0)$ with the Lorentz boost will define a spin-3 component $N_3^{ijk}(Q_0)$. However, the procedure is significantly more complicated than that for an irreducible representation because there may be many components for each spin. Indeed, it may be that there are an infinite number of spin-0 components, Q_0, $N_0(Q_0)$, $N_0'(Q_0)$, and so on, and we will see that this is the case with the parity operator $\mathcal{P}$.

III. INFINITESIMAL LORENTZ TRANSFORMATION OF THE $\mathcal{P}$ OPERATOR

Like the generators of space–time translations P^μ, the parity operator $\mathcal{P}$ is a global symmetry operator and is not an explicit function of the space–time coordinates x^μ; that is, $\partial^\mu \mathcal{P}=0$. As a consequence, the orbital terms in (5) vanish and we get [see (1)]

$$N_1^i(\mathcal{P}) \equiv -i[\mathcal{P}, J^{0i}] = 2iJ^{0i}\mathcal{P}. \tag{7}$$

This identifies the spin-1 term that arises after commuting with the generator of a Lorentz boost.

A second commutation with the Lorentz boost gives a spin-2 component and a new spin-0 component,

$$-i[N_1^j(\mathcal{P}), J^{0i}] = N_2^{ij}(\mathcal{P}) + \delta^{ij} N_0(\mathcal{P}), \tag{8}$$

where the new spin-0 component is

$$N_0(\mathcal{P}) = -\tfrac{4}{3} J^{0i} J^{0i} \mathcal{P}. \tag{9}$$

Since $N_0(\mathcal{P})$ is not a constant multiple of $\mathcal{P}$, we conclude immediately that $\mathcal{P}$ does not belong to an irreducible representation of the Lorentz group.

To analyze the Lorentz transformation properties of the parity operator it is convenient to introduce the following notation. First, we define two 3-vectors:

$$K^i \equiv J^{0i}, \qquad L^i \equiv \tfrac{1}{2}\epsilon^{ijk} J^{jk}. \tag{10}$$

These operator quantities satisfy the following commutation relations:

$$[L^i, L^j] = i\epsilon^{ijk} L^k,$$

$$[K^i,L^j] = i\epsilon^{ijk}K^k,$$

$$[K^i,K^j] = -i\epsilon^{ijk}L^k. \tag{11}$$

Next, we define three operator products,

$$W \equiv K^iK^i,$$

$$A \equiv L^iL^i, \tag{12}$$

$$m \equiv K^iL^i = L^iK^i.$$

These three operators are mutually commuting,

$$[W,A] = [A,m] = [m,W] = 0. \tag{13}$$

The W, A, and m operators have the following commutation relations with the generators of the Lorentz group:

$$\begin{aligned} [W,K^i] = [A,K^i] &= -2i\epsilon^{ijk}L^jK^k - 2K^i, \\ [W,L^i] = [A,L^i] = [m,K^i] &= [m,L^i] = 0. \end{aligned} \tag{14}$$

Next, we define the operator B,

$$B \equiv A - W. \tag{15}$$

Observe that from (14) the operator B commutes with the generators of the Lorentz group,

$$[B,K^i] = [B,L^i] = 0. \tag{16}$$

Since B commutes with L^i, it is a rotational scalar, and since it also commutes with K^i, it is either a Lorentz scalar or a Lorentz pseudoscalar. However, B also commutes with the parity operator $\mathcal{P}$,

$$[B,\mathcal{P}] = 0. \tag{17}$$

Thus, B transforms as a Lorentz scalar. The operator m also commutes with the generators of the Lorentz group but m is a pseudoscalar because

$$\mathcal{P}m\mathcal{P} = -m. \tag{18}$$

Finally, we define the scalar operator M by

$$M \equiv m^2. \tag{19}$$

The four operators B, M, W, and parity $\mathcal{P}$ are a mutually commuting set

$$[B,M] = [B,W] = [M,W] = [B,\mathcal{P}] = [M,\mathcal{P}] = [W,\mathcal{P}] = 0. \tag{20}$$

We know that the parity operator does not transform irreducibly under the Lorentz group. We will assume that it transforms as a direct sum of operators that *do* transform irreducibly. From the commutation properties of the operators defined above we know that the most general form of the spin-0 component of any operator that could be produced by repeated commutation of $\mathcal{P}$ with the generators of the Lorentz group has the form $f(B,M,W)\mathcal{P}$, where $f(B,M,W)$ is an as yet unknown function of the operators B, M, and W. Let us assume that the function $f(B,M,W)$ has a general power series representation of the form

$$f(B,M,W)=\sum_{l,m,n} a_{lmn}B^l M^m W^n. \tag{21}$$

Using these series as a starting *ansatz*, we use mathematical induction to calculate the double commutator of $f(B,M,W)\mathcal{P}$ with the generators of the Lorentz group, and obtain the new spin-0 component,

$$\begin{aligned}N_0[f(B,M,W)\mathcal{P}] = &-\frac{2}{3}\left(W+\frac{M}{B+W}\right)f(B,M,W)\mathcal{P}-\frac{1}{3\sqrt{1+4B+4W}}\\ &\times\left\{\left[2B+4W+\left(W-\frac{M}{B+W}\right)(\sqrt{1+4B+4W}-1)\right]\right.\\ &\times f(B,M,W+1+\sqrt{1+4B+4W})\\ &+\left[-2B-4W+\left(W-\frac{M}{B+W}\right)(\sqrt{1+4B+4W}+1)\right]\\ &\left.\times f(B,M,W+1-\sqrt{1+4B+4W})\right\}\mathcal{P}.\end{aligned} \tag{22}$$

Let us now suppose that $f(B,M,W)\mathcal{P}$ transforms as the irreducible $(0,\ell_1)$ representation of Lorentz group. Then, from (4) we have[5]

$$N_0[f(B,M,W)\mathcal{P}]=\tfrac{1}{3}(\ell_1^2-1)f(B,M,W)\mathcal{P}. \tag{23}$$

Combining (22) and (23), we conclude that $f(B,M,W)$ satisfies the functional relation

$$\begin{aligned}&2\left(W+\frac{M}{B+W}\right)f(B,M,W)+\frac{1}{\sqrt{1+4B+4W}}\\ &\quad\times\left\{\left[2B+4W+\left(W-\frac{M}{B+W}\right)(\sqrt{1+4B+4W}-1)\right]f(B,M,W+1+\sqrt{1+4B+4W})\right.\\ &\quad\left.+\left[-2B-4W+\left(W-\frac{M}{B+W}\right)(\sqrt{1+4B+4W}+1)\right]f(B,M,W+1-\sqrt{1+4B+4W})\right\}\\ &=(1-\ell_1^2)f(B,M,W).\end{aligned} \tag{24}$$

This functional equation is a *difference-equation eigenvalue problem* in which the eigenvalue $(1-\ell_1^2)$ determines the representation of the Lorentz group under which the operator $f(B,M,W)\mathcal{P}$ transforms. We do not yet know how to find the general analytical solution to this equation. However, in the next two sections we show how to solve analytically this master equation for two important special cases.

IV. SPECIAL CASE I: $B=0$ AND $M=0$

In this section we solve a special case of the difference-equation eigenvalue problem (24). This special case serves as a useful toy model that will teach us how to approach the difficult equation (24). Let us set $B=0$ and $M=0$. Then, (24) simplifies to

$$\begin{aligned}&2Wf(W)+\frac{(3+\sqrt{1+4W})W}{\sqrt{1+4W}}f(W+1+\sqrt{1+4W})-\frac{(3-\sqrt{1+4W})W}{\sqrt{1+4W}}f(W+1-\sqrt{1+4W})\\ &=(1-\ell_1^2)f(W).\end{aligned} \tag{25}$$

To solve this equation we make the change of independent variable

$$z = \sqrt{W + \tfrac{1}{4}}. \tag{26}$$

In terms of this new variable $f(W) = f\left(z^2 - \frac{1}{4}\right)$. Next, we introduce the dependent variable $g(z)$ by

$$g(z) = e^{-i\pi z} \frac{f\left(z^2 - \frac{1}{4}\right)}{z^2 - \frac{1}{4}}. \tag{27}$$

The functional equation satisfied by $g(z)$ is

$$(2z+1)(2z+3)^2 g(z+1) - 4z(2z-1)(2z+1)g(z) + (2z-1)(2z-3)^2 g(z-1) = 8z(\ell_1^2 - 1)g(z). \tag{28}$$

In order to determine the eigenvalues $(\ell_1^2 - 1)$ we must impose an eigenvalue condition, to wit, we will assume that $f(W)$ is an *entire* function of W. This condition is difficult to justify at a physical level but it is a natural mathematical choice because it eliminates the possibility that the irreducible representation of the Lorentz group in (23) could be a nonsmooth function of the physical parameters B, M, and W. The condition that we use here leads us to make a polynomial truncation in the same way that the eigenfunctions of the quantum harmonic oscillator truncate into Hermite polynomials. (A similar eigenvalue condition based on the entirety of a solution to a difference equation may be found in Ref. 6.)

Imposing this constraint gives an infinite sequence of allowed values for ℓ_1,

$$\ell_1(n) = 2n + 1 \quad (n = 0, 1, 2, 3, \ldots). \tag{29}$$

Note that the eigenvalues involve the square of ℓ_1 but we may assume that ℓ_1 is positive.[7] The irreducible representations of the Lorentz group corresponding to these values of $\ell_1(n)$ are traceless, totally symmetric tensors of rank $2n$: T, $T^{\mu\nu}$, $T^{\mu\nu\lambda\sigma}$, and so on. Thus, we see that the parity operator transforms as a direct sum of the spin-0 components of these tensors [see (47)].

The eigenfunctions corresponding to the above eigenvalues are all polynomials in z^2 except for the eigenfunction corresponding to the lowest eigenvalue for which the eigenfunction is a rational function,

$$\begin{aligned}
g_0(z) &= \frac{1}{z^2 - \frac{1}{4}}, \\
g_1(z) &= 1, \\
g_2(z) &= z^2 + \tfrac{3}{4}, \\
g_3(z) &= z^4 + \tfrac{7}{2}z^2 + \tfrac{117}{80}, \\
g_4(z) &= z^6 + \tfrac{37}{4}z^4 + \tfrac{1957}{112}z^2 + \tfrac{2385}{448}, \\
g_5(z) &= z^8 + 19z^6 + \tfrac{747}{8}z^4 + \tfrac{2011}{16}z^2 + \tfrac{55575}{1792},
\end{aligned} \tag{30}$$

and so on. We have normalized the eigenfunctions so that each of the polynomials is *monic*; that is, the coefficient of the highest power of z^2 is unity.

The polynomial eigenfunctions in (30) are *Wilson* polynomials $W_n(x^2; a, b, c, d)$, where the parameters are given by $a = b = 1/2$ and $c = d = 3/2$ (see Appendix A),

$$g_n(z) = \frac{(n+1)!}{(2n)!} W_{n-1}\left(-z^2; \frac{1}{2}, \frac{1}{2}, \frac{3}{2}, \frac{3}{2}\right). \tag{31}$$

These polynomials can be expressed as generalized hypergeometric functions,

$$g_n(z) = \frac{(n-1)!(n!)^2(n+1)!}{(2n)!} {}_4F_3\left(1-n, n+2, \frac{1}{2}-z, \frac{1}{2}+z; 1, 2, 2; 1\right). \tag{32}$$

From the solutions $g_0(z)$ in (30) and $g_n(z)$ in (32) we can construct the eigenfunction solutions to (25),

$$f_n(W) = \begin{cases} e^{i\pi\sqrt{W+1/4}} \quad (n=0), \\ e^{i\pi\sqrt{W+1/4}} \dfrac{(n-1)!(n!)^2(n+1)!}{(2n)!} W \\ \times {}_4F_3\left(1-n, n+2, \dfrac{1}{2}-\sqrt{W+\dfrac{1}{4}}, \dfrac{1}{2}+\sqrt{W+\dfrac{1}{4}}; 1, 2, 2; 1\right) \quad (n>0). \end{cases} \tag{33}$$

Here are the first six solutions,

$$\begin{aligned} f_0(W) &= e^{i\pi\sqrt{W+1/4}}, \\ f_1(W) &= e^{i\pi\sqrt{W+1/4}} W, \\ f_2(W) &= e^{i\pi\sqrt{W+1/4}} W(W+1), \\ f_3(W) &= e^{i\pi\sqrt{W+1/4}} W\left(W^2 + 4W + \tfrac{12}{5}\right), \\ f_4(W) &= e^{i\pi\sqrt{W+1/4}} W\left(W^3 + 10W^2 + \tfrac{156}{7} W + \tfrac{72}{7}\right), \\ f_5(W) &= e^{i\pi\sqrt{W+1/4}} W\left(W^4 + 20W^3 + 108W^2 + 176W + \tfrac{480}{7}\right). \end{aligned} \tag{34}$$

The difference equation (28) is second order and linear, and this means that for each eigenvalue there are two linearly independent solutions. It is straightforward to use the method of reduction of order (which is ordinarily used for linear differential equations) to calculate the second solution. We seek a second solution of the general form

$$h_n(z) = g_n(z) u_n(z), \tag{35}$$

where $u_n(z)$ is an unknown function to be determined. The function $u_n(z)$ is easy to find because it satisfies a first-order difference equation,

$$\frac{u_n(z+1) - u_n(z)}{u_n(z) - u_n(z-1)} = \frac{(2z-1)(2z-3)^2 g_n(z-1)}{(2z+1)(2z+3)^2 g_n(z+1)}. \tag{36}$$

From this equation we find that apart from a multiplicative constant, we have

$$u_n(z) - u_n(z-1) = \frac{1}{(2z-3)^2(2z-1)^3(2z+1)^2 g_n(z-1) g_n(z)}. \tag{37}$$

Summing both sides of this equation, we get $u_n(z)$ (apart from an additive constant),

$$u_n(z) = \sum_{x=z_0}^{z} \frac{1}{(2x-3)^2(2x-1)^3(2x+1)^2 g_n(x-1)g_n(x)}, \tag{38}$$

where z_0 is arbitrary.

This sum can be evaluated analytically for the case $n=0$ and we obtain

$$h_0(z) = \frac{1}{\left(z^2-\frac{1}{4}\right)^2}. \tag{39}$$

When $n>0$ we must leave the second solution in the form of a sum,

$$h_n(z) = g_n(z)\sum_{x=z_0}^{z} \frac{1}{(2x-3)^2(2x-1)^3(2x+1)^2 g_n(x-1)g_n(x)}. \tag{40}$$

The general solution to (28) is a linear combination of $g_n(z)$ and $h_n(z)$. However, as a quantization condition, if we demand that the solution to (25) be entire, then the coefficient of $h_n(z)$ must vanish.

Our objective now is to reconstruct the parity operator as a direct sum over the irreducible representations constructed by multiplying $f_n(W)$ in (33) by the parity operator $\mathcal{P}$,

$$\mathcal{P} = \sum_{n=0}^{\infty} c_n f_n(W)\mathcal{P}, \tag{41}$$

where $\{c_n\}$ are coefficients that must be determined from the equation

$$1 = \sum_{n=0}^{\infty} c_n f_n(W) = e^{i\pi z}\left[c_0 + \left(z^2-\frac{1}{4}\right)\sum_{n=1}^{\infty} c_n g_n(z)\right], \tag{42}$$

which is obtained from (41) by multiplying by $\mathcal{P}$.

Equation (42) must hold for every value of z. Thus, if we let $z=\frac{1}{2}$, we obtain

$$c_0 = -i. \tag{43}$$

For $n\geqslant 1$, the coefficients c_n satisfy

$$\frac{e^{-i\pi z}+i}{z^2-\frac{1}{4}} = \sum_{n=1}^{\infty} c_n g_n(z) = \sum_{n=0}^{\infty} (-1)^n c_{n+1} P_n(-z^2), \tag{44}$$

where $P_n(x^2)$ is defined in (A1). We solve this formal functional equation by continuing it analytically into the complex z-plane and then making the change of variable $x=iz$. Equation (44) then becomes

$$-\frac{4(e^{-x\pi}+i)}{1+4x^2} = \sum_{n=0}^{\infty} (-1)^n c_{n+1} P_n(x^2). \tag{45}$$

We then multiply both sides of this equation by $\frac{1}{4}\pi^2 x(1+4x^2)^2 \sinh(x\pi)P_m(x^2)/\cosh^3(x\pi)$ and integrate over x from 0 to ∞. Using the orthogonality property of the Wilson polynomials in (A2), we obtain the following quadrature formula for c_n for $n\geqslant 1$:

$$c_n = \pi^2 \frac{(-1)^n[(2n)!]^2(2n+1)!}{[(n-1)!]^2(n!)^4[(n+1)!]^4}\int_0^{\infty} dx\, x(1+4x^2)\frac{(e^{-x\pi}+i)\sinh(x\pi)}{\cosh^3(x\pi)}P_{n-1}(x^2). \tag{46}$$

Note that this analytic continuation is an extremely delicate process because the series in (41) has only a formal existence. Indeed, while the Wilson polynomials (A1) are complete and orthogo-

nal, the polynomials obtained by replacing x^2 by $-z^2$ [see (44)] are not orthogonal with a positive weight function and not complete in the usual sense. Thus, the analytic continuation above is a procedure that converts a purely formal series identity into a series that actually converges with coefficients that can be determined.

If we substitute the expression for c_n ($n \geqslant 1$) in (46) and also the value of c_0 in (43) into (41), then (41) becomes an identity. This implies that we have decomposed the representation under which $\mathcal{P}$ transforms into a direct sum of finite-dimensional irreducible representations

$$(0,1) \oplus (0,3) \oplus (0,5) \oplus (0,7) \oplus \cdots . \tag{47}$$

That is, we have shown that $\mathcal{P}$ transforms as a scalar plus the spin-0 component of a two-index symmetric traceless tensor plus the spin-0 component of a four-index symmetric traceless tensor plus the spin-0 component of a six-index symmetric traceless tensor, and so on. This is the central result of our analysis.

We conclude this section with the remark that the first term in the direct sum above is a scalar; that is, the term $f_0(W)\mathcal{P}$ transforms like a Lorentz scalar. Thus, $\mathcal{P}$ transforms like the elementary structure $e^{-i\pi\sqrt{W+1/4}}$.

V. SPECIAL CASE II: $M=0$

In this section we solve an eigenvalue equation that is much more general than that solved in Sec. IV. We consider here the case $M=0$ but we allow B and W to be arbitrary. Now, (24) simplifies to

$$2Wf(B,W) + \frac{1}{\sqrt{1+4B+4W}}\left[(2B+3W+W\sqrt{1+4B+4W})f(B,W+1+\sqrt{1+4B+4W})\right.$$
$$\left. -(2B+3W-W\sqrt{1+4B+4W})f(B,W+1-\sqrt{1+4B+4W})\right] = (1-\ell_1^2)f(B,W). \tag{48}$$

To analyze this equation we generalize the substitution that we made in (26) and make the change of independent variable

$$z = \sqrt{W+B+\tfrac{1}{4}}. \tag{49}$$

In terms of this new variable we have $f(B,W) = f\left(B, z^2 - B - \frac{1}{4}\right)$. Next, we introduce the new dependent variable by the substitution

$$g(B,z) = e^{-i\pi z} f\left(B, z^2 - B - \tfrac{1}{4}\right), \tag{50}$$

which is a generalization of (27). We obtain the following functional equation satisfied by $g(B,z)$:

$$2\left(z^2 - B - \frac{1}{4}\right)g(B,z) - \frac{1}{2z}\left[3z^2 - B - \frac{3}{4} + 2z\left(z^2 - B - \frac{1}{4}\right)\right]g(B,z+1)$$
$$+ \frac{1}{2z}\left[3z^2 - B - \frac{3}{4} - 2z\left(z^2 - B - \frac{1}{4}\right)\right]g(B,z-1) = (1-\ell_1^2)g(B,z). \tag{51}$$

The solutions to this difference equation are Wilson polynomials $W_n(x^2;a,b,c,d)$ with parameters $a=b=\frac{1}{2}$, $c=\frac{1}{2}-\sqrt{B+1}$, $d=\frac{1}{2}+\sqrt{B+1}$ (see Appendix B). Thus,

$$g_n(B,z) = \frac{n!}{(2n)!} W_n\left(-z^2; \frac{1}{2}, \frac{1}{2}, \frac{1}{2} - \sqrt{B+1}, \frac{1}{2} + \sqrt{B+1}\right)$$
$$= \frac{(n!)^2 \Gamma(n+1-\sqrt{B+1})\Gamma(n+1+\sqrt{B+1})}{(2n)!\Gamma(1-\sqrt{B+1})\Gamma(1+\sqrt{B+1})}$$
$$\times {}_4F_3\left(-n, n+1, \frac{1}{2} - z, \frac{1}{2} + z; 1, 1-\sqrt{B+1}, 1+\sqrt{B+1}; 1\right). \tag{52}$$

The first four of these polynomials are

$$\begin{aligned} g_0(B,z) &= 1, \\ g_1(B,z) &= z^2 - \tfrac{1}{2}B - \tfrac{1}{4}, \\ g_2(B,z) &= z^4 - \left(B - \tfrac{1}{2}\right)z^2 + \tfrac{1}{6}B^2 - \tfrac{1}{4}B - \tfrac{3}{16}, \\ g_3(B,z) &= z^6 - \left(\tfrac{3}{2}B - \tfrac{13}{4}\right)z^4 + \left(\tfrac{3}{5}B^2 - \tfrac{57}{20}B + \tfrac{47}{80}\right)z^2 - \tfrac{1}{20}B^3 + \tfrac{2}{5}B^2 - \tfrac{63}{160}B - \tfrac{117}{320}. \end{aligned} \tag{53}$$

Correspondingly, the solutions of (48) are

$$f_n(B,W) = e^{i\pi\sqrt{W+B+1/4}} \frac{(n!)^2 \Gamma(n+1-\sqrt{B+1})\Gamma(n+1+\sqrt{B+1})}{(2n)!\Gamma(1-\sqrt{B+1})\Gamma(1+\sqrt{B+1})} {}_4F_3\left(-n, n+1, \frac{1}{2} - \sqrt{W+B+\frac{1}{4}}, \frac{1}{2}\right.$$
$$\left. + \sqrt{W+B+\frac{1}{4}}; 1, 1-\sqrt{B+1}, 1+\sqrt{B+1}; 1\right) \tag{54}$$

and the first four of these solutions are

$$\begin{aligned} f_0(B,W) &= e^{i\pi\sqrt{B+W+1/4}}, \\ f_1(B,W) &= e^{i\pi\sqrt{B+W+1/4}}\left(\tfrac{1}{2}B + W\right), \\ f_2(B,W) &= e^{i\pi\sqrt{B+W+1/4}}\left[\tfrac{1}{6}B^2 + B\left(W + \tfrac{1}{2}\right) + W(W+1)\right], \\ f_3(B,W) &= e^{i\pi\sqrt{B+W+1/4}}\left[\tfrac{1}{20}B^3 + B^2\left(\tfrac{3}{5}W + \tfrac{19}{20}\right) + B\left(\tfrac{3}{2}W^2 + \tfrac{22}{5}W + \tfrac{6}{5}\right) + W\left(W^2 + 4W + \tfrac{12}{5}\right)\right]. \end{aligned} \tag{55}$$

It is interesting that while we are now treating B as an arbitrary parameter, the eigenvalues are independent of B and thus are the same as in the case considered in Sec. IV [see (29)]. Note that in the limit $B \to 0$ the eigenfunctions in (55) smoothly reduce to the simpler simpler eigenfunctions in (34).

To find the Lorentz transformation properties of the parity operator we need to reconstruct the parity operator in terms of these solutions $f_n(B,W)$,

$$\mathcal{P} = \sum_{n=0}^{\infty} c_n f_n(B,W)\mathcal{P}. \tag{56}$$

This requires that we find the coefficients c_n in the identity

$$1 = \sum_{n=0}^{\infty} c_n f_n(B,W) = e^{i\pi z} \sum_{n=0}^{\infty} c_n g_n(B,z). \tag{57}$$

To analyze this identity we multiply it by $e^{-i\pi z}$ and obtain

$$e^{-i\pi z} = \sum_{n=0}^{\infty} c_n g_n(B,z). \tag{58}$$

Next, we continue analytically this formal functional equation to the complex z-plane and let $x = iz$. Equation (58) now becomes

$$e^{-x\pi} = \sum_{n=0}^{\infty} (-1)^n c_n P_n(x^2), \tag{59}$$

where $P_n(x^2)$ is defined in (B1). Next, we multiply both sides of (59) by

$$\frac{4\pi^2(2n)!(2n+1)!x\tanh(x\pi)}{(n!)^4\Gamma^2(n+1-\sqrt{B+1})\Gamma^2(n+1+\sqrt{B+1})[\cos(2\pi\sqrt{B+1})+\cosh(2x\pi)]}P_m(x^2)$$

and then integrate over x from 0 to ∞. Using the orthogonality property of Wilson polynomials in (B2), we get the formula for c_n,

$$c_n = \frac{4(-1)^n\pi^2(2n)!(2n+1)!}{(n!)^4\Gamma^2(n+1-\sqrt{B+1})\Gamma^2(n+1+\sqrt{B+1})}\int_0^{\infty} dx \frac{xe^{-x\pi}\tanh(x\pi)}{\cos(2\pi\sqrt{B+1})+\cosh(2x\pi)}P_n(x^2). \tag{60}$$

We conclude that we have decomposed the representation under which $\mathcal{P}$ transforms into a direct sum of finite-dimensional irreducible representations. Even though the operator B is taken to be nonzero, the eigenvalues in the difference-equation eigenvalue problem (48) remain unchanged. Thus, the conclusion of Sec. IV that the parity operator $\mathcal{P}$ transforms as the direct sum of the spin-0 components of the finite-dimensional tensor representations $(0,1)\oplus(0,3)\oplus(0,5)\oplus(0,7)\oplus\cdots$ remains unchanged.

Finally, as we observed at the end of Sec. IV, we point out that the first irreducible representation $f_0(B,W)\mathcal{P}$ in the direct sum (56) is a scalar. Thus, we may conclude that under a Lorentz transformation the parity operator $\mathcal{P}$ transforms as the operator $e^{-i\pi\sqrt{B+W+1/4}}$.

VI. FINAL REMARKS

The general case for (24) is obtained when all three parameters, B, M, and W, are nonzero. For this case we cannot solve (24) in terms of polynomials but we conjecture that the eigenvalues in (29) remain unchanged.[8] Assuming that this is indeed the case, we may conclude that the Lorentz transformation properties of the parity operator are unchanged from what we found in Secs. IV and V; namely, the parity operator transforms like the direct sum of irreducible representations in (47).

ACKNOWLEDGMENTS

The authors are greatly indebted to R. Askey for identifying the polynomials in (30) as Wilson polynomials. This work was supported in part by the U.S. Department of Energy.

APPENDIX A: PROPERTIES OF WILSON POLYNOMIALS

In this appendix, we list the properties of the Wilson polynomials $W_n(x^2;a,b,c,d)$ with parameters $a=b=\frac{1}{2}$, $c=d=\frac{3}{2}$.[9–11] For simplicity, we define the associated *monic* Wilson polynomials

$$P_n(x^2) \equiv \frac{(-1)^n(n+2)!}{(2n+2)!}W_n\left(x^2;\frac{1}{2},\frac{1}{2},\frac{3}{2},\frac{3}{2}\right). \tag{A1}$$

(The coefficient of the highest power in a *Monic* polynomial is unity.) These polynomials are used in Sec. IV.

The orthogonality condition is[11]

$$\frac{\pi^2}{4}\int_0^\infty dx\, x(1+4x^2)^2\frac{\sinh(x\pi)}{\cosh^3(x\pi)}P_n(x^2)P_m(x^2)=\frac{(n!)^2[(n+1)!]^4[(n+2)!]^4}{[(2n+2)!]^2(2n+3)!}\delta_{nm}. \tag{A2}$$

The polynomials $P_n(x^2)$ satisfy a three-term recurrence relation,

$$P_n(x^2)=\left[x^2-\frac{1}{2}n(n+1)\right]P_{n-1}(x^2)+\frac{(n-1)^2n^2(n+1)^2}{4(2n-1)(2n+1)}P_{n-2}(x^2), \tag{A3}$$

where the first two polynomials are $P_0(x^2)=1$ and $P_1(x^2)=x^2-\frac{3}{4}$.

Some generating functions for these polynomials are

$$\sum_{n=0}^\infty\frac{2(2n+2)!P_n(x^2)t^n}{(n!)^2[(n+2)!]^2}={}_2F_1\left(\frac{1}{2}+ix,\frac{1}{2}+ix;1;-t\right){}_2F_1\left(\frac{3}{2}-ix,\frac{3}{2}-ix;1;-t\right),$$

$$\sum_{n=0}^\infty\frac{(2n+2)!P_n(x^2)t^n}{n![(n+1)!]^2(n+2)!}={}_2F_1\left(\frac{1}{2}+ix,\frac{3}{2}+ix;2;-t\right){}_2F_1\left(\frac{1}{2}-ix,\frac{3}{2}-ix;2;-t\right), \tag{A4}$$

$$\sum_{n=0}^\infty\frac{(2n+2)!P_n(x^2)t^n}{(n!)^2[(n+1)!]^2}=\frac{1}{(1+t)^3}{}_4F_3\left[\frac{3}{2},2,\frac{1}{2}+ix,\frac{1}{2}-ix;1,2,2;\frac{4t}{(1+t)^2}\right].$$

APPENDIX B: FURTHER PROPERTIES OF WILSON POLYNOMIALS

In this appendix, we list the properties of the Wilson polynomials $W_n(x^2;a,b,c,d)$ with parameters $a=b=\frac{1}{2}$, $c=\frac{1}{2}-\sqrt{B+1}$, $d=\frac{1}{2}+\sqrt{B+1}$.[9–11] We define the associated monic polynomials,

$$P_n(x^2)\equiv\frac{(-1)^n n!}{(2n)!}W_n\left(x^2;\frac{1}{2},\frac{1}{2},\frac{1}{2}-\sqrt{B+1},\frac{1}{2}+\sqrt{B+1}\right). \tag{B1}$$

These polynomials are used in Sec. V.

Orthogonality,[11]

$$4\pi^2\int_0^\infty dx\, x\frac{\tanh(x\pi)}{\cos(2\pi\sqrt{B+1})+\cosh(2x\pi)}P_n(x^2)P_m(x^2)$$
$$=\frac{(n!)^4\Gamma^2(n+1-\sqrt{B+1})\Gamma^2(n+1+\sqrt{B+1})}{(2n)!(2n+1)!}\delta_{nm}. \tag{B2}$$

Recurrence relation,

$$P_n(x^2)=\left[x^2-\frac{B}{2}-\frac{1}{4}+\frac{n(n+1)}{2}\right]P_{n-1}(x^2)+\frac{n^2[B-(n-1)(n+1)]^2}{4(2n-1)(2n+1)}P_{n-2}(x^2), \tag{B3}$$

with $P_0(x^2)=1$ and $P_1(x^2)=x^2+\frac{1}{2}B+\frac{1}{4}$.

Generating functions,

$$\sum_{n=0}^{\infty} \frac{(2n)!P_n(x^2)t^n}{(n!)^4} = {}_2F_1\left(\frac{1}{2}+ix,\frac{1}{2}+ix;1;-t\right)\,{}_2F_1\left(\frac{1}{2}-\sqrt{B+1}-ix,\frac{1}{2}+\sqrt{B+1}-ix;1;-t\right) \tag{B4}$$

and

$$\begin{aligned}\sum_{n=0}^{\infty} &\frac{(2n)!P_n(x^2)t^n}{(n!)^2\Gamma(n+1-\sqrt{B+1})\Gamma(n+1+\sqrt{B+1})}\\ &= \frac{\sin(\pi\sqrt{B+1})}{\pi\sqrt{B+1}}\,{}_2F_1\left(\frac{1}{2}+ix,\frac{1}{2}-\sqrt{B+1}+ix;1-\sqrt{B+1};-t\right)\\ &\quad\times {}_2F_1\left(\frac{1}{2}-ix,\frac{1}{2}+\sqrt{B+1}-ix;1+\sqrt{B+1};-t\right)\\ &= \frac{\sin(\pi\sqrt{B+1})}{\pi(1+t)\sqrt{B+1}}\,{}_4F_3\left(\frac{1}{2},1,\frac{1}{2}+ix,\frac{1}{2}-ix;1,1-\sqrt{B+1},1+\sqrt{B+1};\frac{4t}{(1+t)^2}\right).\end{aligned} \tag{B5}$$

[1] Note that both $\mathcal{P}$ and $\mathcal{P}_I$ are reflection operators in the sense that their squares are the unity operator, $\mathcal{P}^2=\mathcal{P}_I^2=\mathbb{1}$.

[5] Note that this equation makes use of a specified function $f(B,M,W)$ in (21), where the series coefficients are determined by (22) and (23). These equations are equivalent to (24), which is the statement that $f(B,M,W)\mathcal{P}$ is the spin-0 component of the irreducible $(0,\ell_1)$ representation.

[6] C. M. Bender and S. A. Orszag, *Advanced Mathematical Methods for Scientists and Engineers* (Springer, New York, 1999), pp. 231–233.

[7] For the irreducible representations of the Lorentz group if the parameter $\ell_0=0$, then $(0,\ell_1)$ and $(0,-\ell_1)$ label exactly the same representation. Thus, we may assume without loss of generality that ℓ_1 is a positive number. See Ref. 2.

[8] Verifying this claim is difficult and requires heavy numerical analysis. We believe that the situation is similar to that for the eigenfunctions for the quantum harmonic and anharmonic oscillators. In the former case, after the Gaussian is divided off, the eigenfunctions satisfy the boundary conditions in a simple way; namely, by truncating in the form of Hermite polynomials. In the latter case, after the Gaussian is removed, the eigenfunctions do not truncate, but they still satisfy the boundary conditions as one can verify numerically.

(Received 15 March 2004; accepted 12 January 2005; published online 8 April 2005)

We study the gauged sigma model. In $\mathbb{R}^{1+1}$ the existence of the global smooth solution will be proved. Furthermore we show that the global weak solutions exist in $\mathbb{R}^{n+1}$ $(n=2,3)$. © *2005 American Institute of Physics.*

I. INTRODUCTION

The O (3) sigma model is a popular one in theoretical physics. From the point of view of a particle physicist, however, the model has one important drawback, it is scale invariant and as a result its soliton solutions have arbitrary size, making them unsuitable as models for particles. In Ref. 13, the new possibility of breaking the scale invariance of the sigma model was proposed by introducing a U (1) gauge field whose dynamics is governed by Maxwell terms. Adding also a suitable potential one obtains a field theory of Bogomol'nyi type with topological solitons. Some analysis of the self-dual equations can be found in Refs. 3 and 21.

We will study time-dependent problems. In the usual sigma model (called wave map), evolution problems have been studied extensively (see Refs. 16 and 18). Let us review briefly the results for global existence in time. Wave map in $(1+1)$ dimension extends smoothly all the time.[6,15] In $(3+1)$ dimension, development of singularities from smooth initial data was showed in Ref. 15 by using the self-similar structure of the sigma model. Also Shatah proved that there exists global weak solution to wave map which has a S^n target manifold. Space two-dimensional case is critical. Recently Tatatu[19] and Tao[20] proved global regularity of wave maps in $(2+1)$-dimension under the assumption of small Besov norm, respectively, small energy. Also we refer to the subsequent works by Klainerman-Rodnianski,[9] Nahmod–Stefanov–Uhlenbeck,[12] Shatah-Struwe,[17] as well as Krieger.[10]

We shall pursue the similar results for the gauged sigma model. In Sec. II the equations and basic facts will be presented. In Sec. III the global existence of a smooth solution in $(1+1)$ will be proved, while the global weak solution in $n+1$ $(n=2,3)$ will be treated in Sec. IV.

II. EQUATIONS AND BASIC FACTS

A point in the $(n+1)$-dimensional Minkowski space will be denoted by $(t,x)=(x_\alpha)_{0\le\alpha\le n}$. The space–time derivatives of a function $f:=\mathbb{R}\times\mathbb{R}^n\to\mathbb{R}$ are denoted by $\partial f=(\partial_t f,\nabla f)=(\partial_t f,\partial_1 f,\ldots,\partial_n f)$. We raise and lower indices with the Minkowski metric $\eta=(\eta_{\alpha\beta})=\eta^{-1}=(\eta^{\alpha\beta})=\mathrm{diag}(-1,1,\ldots,1)$. We also use the summation convention where we sum over repeated indices. Therefore, the wave operator is denoted by $\Box=\partial_\alpha\partial^\alpha$. Greek indices are used for denoting $0,\ldots,n$ while italic for $1,\ldots,n$.

The target manifold of ϕ is S^2, i.e., $\phi=(\phi_1,\phi_2,\phi_3)$ such that $\phi_1^2+\phi_2^2+\phi_3^2=1$. Introduce the Maxwell field $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$. The Lagrangian of the gauged O (3) model is

$$\mathcal{L}(\phi,A)=\frac{1}{2}\int\langle D^\mu\phi,D_\mu\phi\rangle+(1-n\cdot\phi)^2+\frac{1}{2}F^{\mu\nu}F_{\mu\nu},\tag{1}$$

where $\langle .,.\rangle$ is usual inner product in $\mathbb{R}^3$ and the gauge-covariant derivatives on ϕ are defined by

[a)]Electronic mail: hjhuh3@math.snu.ac.kr

$$D_\mu\phi = \partial_\mu\phi + A_\mu(n\times\phi) \quad [n=(0,0,1)].$$

The Euler–Lagrange equations are

$$D_\mu D^\mu\phi + (0,0,1-\phi_3) + \phi(\langle D^\mu\phi, D_\mu\phi\rangle + \phi_3(\phi_3-1)) = 0, \tag{2}$$

$$\partial_\mu F^{\mu\nu} = \langle D^\nu\phi, n\times\phi\rangle. \tag{3}$$

The Lagrangian action is invariant under the following gauge transformations:

$$\phi=(z,\phi_3)\to(ze^{i\chi},\phi_3), \quad A_\mu\to A_\mu-\partial_\mu\chi,$$

where $\chi:\mathbb{R}^{n+1}\to\mathbb{R}$ is a smooth function and we use the notation $(\phi_1,\phi_2)=z_1+iz_2=z$. A suitable gauge condition will be chosen according to the problem.

The constraint $|\phi|=1$ will be preserved as follows. If the equations (2) are satisfied in the $[0,T]\times\mathbb{R}^n$ then $\rho=|\phi|^2-1$ is the solution of the following equation:

$$[\partial_\mu\partial^\mu + 2\langle D_\mu\phi, D^\mu\phi\rangle + 2\phi_3(\phi_3-1)](|\phi|^2-1)=0.$$

This is a linear Klein–Gordon equation for the function ρ with external potential $2\langle D_\mu, D^\mu\rangle + 2\phi_3(\phi_3-1)$. Together with the initial conditions $\rho(0)=|\phi(0,\cdot)|^2-1$ and $\partial_t\rho(0)=\langle\phi(0,\cdot),\partial_t\phi(0,\cdot)\rangle=0$, it implies that $\rho=0$ in $[0,T]\times\mathbb{R}^n$.

The conserved energy $\mathcal{E}(t)$ for gauged O (3) model is

$$\mathcal{E}(t)=\int_{\Sigma_t}\langle D_\mu\phi, D_\mu\phi\rangle + (1-n\cdot\phi)^2 + \frac{1}{2}F_{\mu\nu}F_{\mu\nu} = \mathcal{E}(0), \tag{4}$$

where $\Sigma_\tau=\{(t,x)\in\mathbb{R}^{n+1}\,|\,t=\tau\}$. $H^s(\mathbb{R}^n)$ denotes the usual Sobolev space $W^{s,2}(\mathbb{R}^n)$ and $\dot{H}^s(\mathbb{R}^n)$ homogeneous Sobolev space $\dot{W}^{s,2}(\mathbb{R}^n)$.

III. EXISTENCE OF A SMOOTH SOLUTION IN $\mathbb{R}^{1+1}$

Here Lorentz gauge will be considered. Equations (2) and (3) with the condition $\partial_\mu A^\mu=0$ can be rewritten as

$$D_\mu D^\mu\phi + (0,0,1-\phi_3) + \phi(\langle D^\mu\phi, D_\mu\phi\rangle + \phi_3(\phi_3-1)) = 0, \tag{5}$$

$$\partial_\mu\partial^\mu A^\nu = \langle D^\nu\phi, n\times\phi\rangle, \tag{6}$$

$$\partial_\mu A^\mu = 0. \tag{7}$$

With the finite energy smooth initial data $(\phi(0,\cdot),\partial_t\phi(0,\cdot),A_\mu(0,\cdot),\partial_t A_\mu(0,\cdot))$ such that $|\phi(0,\cdot)|=1, \langle\phi(0,\cdot),\partial_t\phi(0,\cdot)\rangle=0$ and $\partial_\mu A^\mu=0$ the Cauchy problem will be considered. Note that the equation (7) is automatically satisfied as long as the solutions of the equations (5) and (6) exist if the initial data satisfy $\partial_\mu A^\mu(0,\cdot)=0$.

The short time existence of smooth solution is classical. We introduce the pseudoenergy of the equations

$$E^{(1)}(t)=\sum_{|I|\le 1}\|\partial^I A_\alpha(t,\cdot)\|_{L^2(\mathrm{R})} + \|(1-n\cdot\phi)(t,\cdot)\|_{L^2(\mathrm{R})} + \sum_{\alpha=0,1}\|\partial_\alpha\phi(t,\cdot)\|_{L^2(\mathrm{R})}.$$

It is seen that

$$E^{(1)}(t)\le C(1+t^2)\mathcal{E}^{1/2}(0).$$

Especially $\|A_\alpha\|_{L^2(R)}$ may be estimated in the following way:

$$\partial_t \|A_\alpha(t)\|_{L^2(\mathrm{R})} \leqslant \|\partial_t A_\alpha(t)\|_{L^2(\mathrm{R})} \leqslant \int_0^t \|\langle D_\alpha \phi, n \times \phi\rangle\|_{L^2(\mathrm{R})}\, \mathrm{d}s \leqslant t\mathcal{E}^{1/2}(0).$$

Our main purpose is to *a priori* estimate the L^2 norm of the second derivative of (A, ϕ),

$$E^{(2)}(t) = \sum_{|I|\leqslant 2} \|\partial^I A_\alpha(t,\cdot)\|_{L^2(\mathrm{R})} + \|(1 - n\cdot\phi)(t,\cdot)\|_{L^2(\mathrm{R})} + \sum_{1\leqslant|I|\leqslant 2} \|\partial^I \phi(t,\cdot)\|_{L^2(\mathrm{R})}.$$

If we can control $\|D_\mu D_\nu \phi(t,\cdot)\|_{L^2(\mathrm{R})}$, then $\|\partial^2 A(t,\cdot)\|_{L^2(R)}$ is bounded by an energy estimate applied to (6). *A priori* bound for $E^{(2)}(t)$ will be obtained by Gronwall's inequality. Considering the fact $|\phi|=1$ in $[0,T]\times\mathbb{R}^n$ and the definition of D_μ, we know

$$\partial_\mu\langle\phi,\psi\rangle = \langle D_\mu\phi,\psi\rangle + \langle\phi, D_\mu\psi\rangle, \tag{8}$$

$$0 = \langle D_\mu\phi, D_\nu\phi\rangle + \langle\phi, D_\mu D_\nu\phi\rangle, \tag{9}$$

$$D_\mu D_\nu\phi - D_\nu D_\mu\phi = F_{\mu\nu}(n\times\phi), \tag{10}$$

which are used in next inequality.

$$\frac{1}{2}\frac{d}{dt}\int_{\mathrm{R}} \langle D_\mu D_\nu\phi, D_\mu D_\nu\phi\rangle \leqslant \int_{\mathrm{R}} \langle (D_0D_0 - D_1D_1)(D_\nu\phi), D_0D_\nu\phi\rangle + F_{01}\langle n\times D_\nu\phi, D_1D_\nu\phi\rangle. \tag{11}$$

Operating D_ν on the equation (5) and using the fact that

$$\langle\phi\langle DD\phi, D\phi\rangle, D_\mu D_\nu\phi\rangle = -\langle DD\phi, D\phi\rangle\langle D_\mu\phi, D_\nu\phi\rangle,$$

we obtain the following inequality:

$$\frac{1}{2}\frac{d}{dt}\int_{\mathrm{R}} \langle D_\mu D_\nu\phi, D_\mu D_\nu\phi\rangle \leqslant C\int_{\mathrm{R}} |DD\phi||\partial F| + |F||D\phi| + |DD\phi||D\phi| + C\int_{\mathrm{R}} |DD\phi||D\phi|^3 + |F||DD\phi||D\phi|, \tag{12}$$

where $D\phi$ and F are used schematically. At first ∂F consist of $\partial_0 F_{01}$ and $\partial_1 F_{01}$. Lorentz gauge shows that

$$|\partial_0 F_{01}| = |\partial_0\partial_0 A_1 - \partial_1\partial_1 A_1| = |\langle D_1\phi, n\times\phi\rangle| \leqslant |D_1\phi|,$$

$$|\partial_1 F_{01}| = |\partial_0\partial_0 A_0 - \partial_1\partial_1 A_0| = |\langle D_0\phi, n\times\phi\rangle| \leqslant |D_0\phi|.$$

Therefore the term $|\partial F|$ may be bounded by $|D\phi|$. The most difficult terms which we must treat are the integrand of the second line of (12). The formulation of the following covariant Sobolev inequalities is essentially the same as Proposition A.1. of Ref. 5.

Proposition 3.1: Let $n\geqslant 1, 1\leqslant q\leqslant\infty, 1\leqslant r\leqslant\infty$, *and let* σ *and* p *satisfy* $0\leqslant\sigma\leqslant 1, 1\leqslant p\leqslant\infty$, *and* $1/p=[(1-\sigma)/r]+\sigma[(1/q)-(1/n)]$. *Assume in addition that if* $p=\infty$, *then* $r<\infty$ *and* $\sigma<1$. *Then there exists a constant C, depending only on* n,p,q,r *such that the following inequality holds:*

$$\|\|\phi\|\|_{L^p} \leqslant C\|\|\phi\|\|_{L^r}^{1-\sigma}\left\{\sum_{1\leqslant j\leqslant n} \|\|D_j\phi\|\|_{L^q}\right\}^{\sigma},$$

provided in the case $r=\infty$ *and* $q<n$, *we assume in addition that either* ϕ *tends to zero at infinity or* $\phi\in L^{r_0}$ *for some finite* $r_0>0$.

Using the covariant Sobolev inequality, we know

$$\int_{\mathrm{R}} |DD\phi||D\phi|^3 \leqslant \|D\phi\|^3_{L^6(\mathrm{R})}\|DD\phi\|_{L^2(\mathrm{R})} \leqslant C\|D\phi\|^2_{L^2(\mathrm{R})}\|DD\phi\|^2_{L^2(\mathrm{R})}$$

and

$$\begin{aligned}\int_{\mathrm{R}} |DD\phi||D\phi||F| &\leqslant C\|DD\phi\|_{L^2(\mathrm{R})}\|D\phi\|_{L^4(\mathrm{R})}\|F\|_{L^4(\mathrm{R})} \leqslant C\|DD\phi\|^{5/4}_{L^2}\|D\phi\|^{3/4}_{L^2}\|F\|^{3/4}_{L^2}\|\partial F\|^{1/4}_{L^2}\\ &\leqslant C\|DD\phi\|^{5/4}_{L^2}\|D\phi\|_{L^2}\|\partial A\|^{3/4}_{L^2} \leqslant C\|DD\phi\|^{5/4}_{L^2}\mathcal{E}^{1/2}(0)\left(1+\int_0^t \|\langle D\phi, n\times\phi\rangle\|_{L^2}\right)^{3/4}\\ &\leqslant C\mathcal{E}^{1/2}(0)(1+t\mathcal{E}^{1/2}(0))^{3/4}\|DD\phi\|^{5/4}_{L^2(\mathrm{R})},\end{aligned}$$

where the usual Gagliardo–Nirenberg inequality $\|F\|_{L^4(\mathrm{R})} \leqslant C\|F\|^{3/4}_{L^2(\mathrm{R})}\|\nabla F\|^{1/4}_{L^2(\mathrm{R})}$ is used. Therefore, we conclude that

$$\frac{d}{dt}\|D_\mu D_\nu\phi\|^2_{L^2(\mathrm{R})} \leqslant C(\mathcal{E}(0)+1)\|D_\mu D_\nu\phi\|^2_{L^2(\mathrm{R})} + C(1+t\mathcal{E}^{7/6}(0))^{3/4}\|D_\mu D_\nu\phi\|^{5/4}_{L^2(\mathrm{R})}.$$

It is sufficient to conclude that $E^{(2)}$ is bounded. We can proceed to get the higher regularities by a boostrap argument, hence (ϕ, A) extends as smooth solution.

IV. EXISTENCE OF THE WEAK SOLUTION

First we shall prove the existence of weak solutions to the gauged O(3) sigma model in the three-dimensional spatial case. Here the Coulomb gauge $\nabla_i A^i = 0$ will be considered. Equations (2) and (3) under the Coulomb gauge condition can be rewritten as

$$D_\mu D^\mu\phi + (0,0,1-\phi_3) + \phi(\langle D^\mu\phi, D_\mu\phi\rangle + \phi_3(\phi_3-1)) = 0, \tag{13}$$

$$\partial_\mu\partial^\mu A_i = \langle D_i\phi, n\times\phi\rangle + \partial_i\partial^0 A_0, \tag{14}$$

$$\Delta A_0 = \langle D_0\phi, n\times\phi\rangle, \tag{15}$$

$$\nabla_i A^i = 0. \tag{16}$$

Following the idea of Ref. 8, we take the divergence-free projection operator $\mathcal{P}$ on (14), i.e., for any vector field A,

$$\mathcal{P}A = \Delta^{-1}(\nabla\times(\nabla\times A)).$$

If $\nabla_i A^i = 0$ then $\mathcal{P}A = A$. In view of this, the equation (14) implies

$$\partial_\mu\partial^\mu A_i = \mathcal{P}\langle D_i\phi, n\times\phi\rangle.$$

Note that the equation (16) is automatically satisfied as long as (14) are satisfied if the initial data are taken as $\nabla_i A^i(0) = 0$. Therefore our initial value problem reduces to the following one:

$$D_\mu D^\mu\phi + (0,0,1-\phi_3) + \phi(\langle D^\mu\phi, D_\mu\phi\rangle + \phi_3(\phi_3-1)) = 0, \tag{17}$$

$$\partial_\mu\partial^\mu A_i = \mathcal{P}\langle D_i\phi, n\times\phi\rangle, \tag{18}$$

$$\Delta A_0 = \langle D_0\phi, n \times \phi\rangle, \tag{19}$$

with the initial data $(\phi_0(0,\cdot)-n, \phi_1(0,\cdot), A_i(0,\cdot), \partial A_i(0,\cdot))$ in $(H^1(\mathbb{R}^3)\times L^2(\mathbb{R}^3)\times \dot{H}^1(\mathbb{R}^3) \times L^2(\mathbb{R}^3))$ satisfying

$$|\phi(0,\cdot)| = 1, \quad \langle \phi(0,\cdot), \phi_1(0,\cdot)\rangle = 0,$$

$$\nabla^i A_i(0,\cdot) = 0, \quad \Delta A_0(0,\cdot) = \langle D_0\phi(0,\cdot), n \times \phi(0,\cdot)\rangle.$$

We consider the following approximation equations:

$$D_\mu D^\mu \phi^l + (0,0,1-\phi_3^l) + l(|\phi^l|^2 - 1)\phi^l = 0, \tag{20}$$

$$\Box A_i^l = \mathcal{P}\langle D_i\phi^l, n \times \phi^l\rangle, \tag{21}$$

$$\Delta A_0^l = \langle D_0\phi^l, n \times \phi^l\rangle \tag{22}$$

with the same data $(\phi_0(0,\cdot)-n, \phi_1(0,\cdot), A_i(0,\cdot), \partial A_i(0,\cdot))$. The main part of equations (20)–(22) look like Maxwell–Klein–Gordon with potential under Coulomb gauge. The global existence of finite energy solutions is shown in the Appendix. We will use the fact that (20)–(22) admit global finite energy solution for all l. Then the solution (A^l, ϕ^l) satisfy the energy inequality

$$\begin{aligned} E_l(t) &= \int_{\Sigma_t} \langle D_\mu\phi^l, D_\mu\phi^l\rangle + (1 - n\cdot\phi^l)^2 + \frac{1}{2}|F_{\mu\nu}^l|^2 + \frac{l}{4}\int_{\Sigma_t}(|\phi^l|^2-1)^2 \leqslant E_l(0) = E(0) \\ &= \int_{\Sigma_0} \langle D_\mu\phi, D_\mu\phi\rangle + (1-n\cdot\phi)^2 + \frac{1}{2}|F_{\mu\nu}|^2 \end{aligned} \tag{23}$$

uniformly in t for all l. Note that the initial condition $|\phi(0,\cdot)|=1$ is used at the last equality in (23).

The Coulomb gauge condition implies $\Delta A_j^l = \partial^i F_{ij}^l, \Delta A_0^l = \partial^i F_{i0}^l$. Thus given $F_{\alpha\beta}^l \in L^2(\mathbb{R}^3)$ there exists a unique A_μ^l which belongs to the homogeneous Sobolev space $\dot{H}^1(\mathbb{R}^3)$. Furthermore, we have

$$\|\nabla A_\mu^l\|_{L^2(\mathbb{R}^3)} \leqslant C\|F^l\|_{L^2(\mathbb{R}^3)} \leqslant CE(0)^{1/2}, \tag{24}$$

and

$$\|\partial_\mu\phi^l\|_{L^2(\mathbb{R}^3)} \leqslant \|D_\mu\phi^l\|_{L^2(\mathbb{R}^3)} + \|A_\mu^l\|_{L^6(\mathbb{R}^3)}\|n\times\phi^l\|_{L^3(\mathbb{R}^3)} \leqslant \|D_\mu\phi^l\|_{L^2(\mathbb{R}^3)} + C\|\nabla A_\mu^l\|_{L^2(\mathbb{R}^3)}\|n\times\phi^l\|_{L^3(\mathbb{R}^3)}, \tag{25}$$

where we used $\|A^l\|_{L^6(\mathbb{R}^3)} \leqslant C\|\nabla A^l\|_{L^2(\mathbb{R}^3)}$ for $A^l \in \dot{H}^1(\mathbb{R}^3)$. To estimate $\|n\times\phi^l\|_{L^3(\mathbb{R}^3)}^2$ the two facts will be used.

(i) $$\begin{aligned} \frac{\partial}{\partial t}\int_{\mathbb{R}^3}|n\times\phi^l|^2\,dx &= \frac{\partial}{\partial t}\int_{\mathbb{R}^3}|(\phi_1^l,\phi_2^l,0)|^2\,dx = \int_{\mathbb{R}^3} 2\langle(\phi_1^l,\phi_2^l,0), D_t(\phi_1^l,\phi_2^l,0)\rangle \\ &\leqslant 2\|(\phi_1^l,\phi_2^l,0)\|_{L^2(\mathbb{R}^3)}\|D_t\phi^l\|_{L^2(\mathbb{R}^3)}. \end{aligned}$$

Therefore we have

$$\|(n\times\phi^l)(t,\cdot)\|_{L^2(\mathbb{R}^3)} \leqslant C(1+t),$$

where C depends only on the initial data.

(ii) The algebraic inequality $x^4 \leqslant 10(y-1)^2+10(x^2+y^2-1)^2$ implies that $\|(n\times\phi^l)\|^4_{L^4(\mathbb{R}^3)} \leqslant 10\|1-n\cdot\phi^l\|^2_{L^2(\mathbb{R}^3)}+10\||\phi^l|^2-1\|^2_{L^2(\mathbb{R}^3)} \leqslant CE(t) \leqslant CE(0)$. Note that (i), (ii) do not depend on the dimension of space. With (i), (ii) the interpolation inequality shows that

$$\|(n\times\phi^l)(t,\cdot)\|_{L^3(\mathbb{R}^3)} \leqslant C(1+t),$$

which implies $\|\partial_\mu\phi^l\|_{L^2(\mathbb{R}^3)} \leqslant C(1+t)$.

To estimate $\partial_t A^l_0$ the following lemma will be used.

Lemma 4.1: Let f be a compactly supported integrable function and u the unique solution of the Poisson equation $\Delta u = f$ in $\mathbb{R}^n$, sufficiently small at $|x|\to\infty$. Then for $f\in L^p(\mathbb{R}^n)(1<p<n), 1/q=(1/p)-(1/n)$,

$$\nabla u \in L^q(\mathbb{R}^n) \quad \textit{and} \quad \|\nabla u\|_{L^q(\mathbb{R}^n)} \leqslant C\|f\|_{L^p(\mathbb{R}^n)}.$$

We should mention that the equation (20) implies

$$\partial^\alpha\langle D_\alpha\phi^l, n\times\phi^l\rangle = 0. \tag{26}$$

In fact,

$$\begin{aligned}\partial^\alpha\langle D_\alpha\phi^l, n\times\phi^l\rangle = \langle D_\alpha D^\alpha\phi^l, n\times\phi^l\rangle + \langle D_\alpha\phi^l, D^\alpha(n\times\phi^l)\rangle = -l(|\phi^l|^2-1)\langle\phi^l, n\times\phi^l\rangle + \langle\partial_\alpha\phi^l, \partial^\alpha(n\\ \times\phi^l)\rangle + A^{l\alpha}A^l_\alpha\langle n\times\phi^l, n\times n\times\phi^l\rangle + A^l_\alpha\langle\partial^\alpha\phi^l, n\times n\times\phi^l\rangle + A^l_\alpha\langle n\times\phi^l, \partial^\alpha(n\\ \times\phi^l)\rangle = 0.\end{aligned}$$

We differentiate equation (22) with respect to t and derive, with the help of (26), $\Delta\partial_t A^l_0 = \partial_i\langle D_i\phi^l, n\times\phi^l\rangle$. By Lemma 4.1 we show

$$\|\partial_t A^l_0\|_{L^2(\mathbb{R}^3)} \leqslant \|\Delta^{-1/2}\partial_i\langle D_i\phi^l, n\times\phi^l\rangle\|_{L^{6/5}(\mathbb{R}^3)} \leqslant \|D_i\phi^l\|_{L^2(\mathbb{R}^3)}\|n\times\phi^l\|_{L^3(\mathbb{R}^3)} \leqslant C(1+t).$$

Therefore for a given T, we can select a subsequence of $\{\phi^l, A^l\}$ which converges to a limit ϕ, A in the sense that as $l\to\infty$,

$$\partial_\mu\phi^l \to \partial_\mu\phi \text{ weakly}\star \text{ in } L^\infty([0,T];L^2(\mathbb{R}^3)), \tag{27}$$

$$\phi^l \to \phi \text{ locally in } L^2_{\text{loc}}([0,T]\times\mathbb{R}^3), \tag{28}$$

$$\partial A^l \to \partial A \text{ weakly}\star \text{ in } L^\infty([0,T];L^2(\mathbb{R}^3)). \tag{29}$$

Moreover, $\phi^l(t)\to\phi(t)$ in $L^2_{\text{loc}}(\mathbb{R}^3)$ locally uniformly in $t\in[0,T]$. Hence for any $t\in[0,T]$, by Fatou's lemma

$$\int_{\mathbb{R}^3}(|\phi|^2-1)^2 \leqslant \liminf\int_{\mathbb{R}^3}(|\phi^l|^2-1)^2 = 0.$$

So we conclude that $\phi:\mathbb{R}^{3+1}\to S^2$. Passing to the limit in (20), we just follow the idea of Ref. 15. We consider equivalent equations to (17)–(19), i.e.,

$$D_\mu(D^\mu\phi\wedge\phi) + (0,0,1-\phi_3)\wedge\phi = 0, \tag{30}$$

$$\partial_\mu\partial^\mu A_i = \mathcal{P}\langle D_i\phi, n\times\phi\rangle, \tag{31}$$

$$\Delta A_0 = \langle D_0\phi, n\times\phi\rangle. \tag{32}$$

Proposition 4.2: Assume (ϕ, A) satisfy the properties (27)–(29) *then (ϕ, A) is a weak solution*

of (17)–(19) *if and only if* (ϕ,A) *is a weak solution of* (30)–(32).

Proof: There is just one nontrivial relation between (17) and (30) which we must verify. We take the wedge product of (17) with ϕ to obtain

$$D^\mu D_\mu \phi \wedge \phi + (0,0,1-\phi_3)\wedge\phi = D^\mu(D_\mu\phi\wedge\phi) - D^\mu\phi\wedge D_\mu\phi + (0,0,1-\phi_3)\wedge\phi = 0,$$

i.e., $D^\mu(D_\mu\phi\wedge\phi)+(0,0,1-\phi_3)\wedge\phi=0$ in the sense of distribution.

Conversely, if $D^\mu(D_\mu\phi\wedge\phi)+(0,0,1-\phi_3)\wedge\phi=0$ then $D^\mu D_\mu\phi\wedge\phi+(0,0,1-\phi_3)\wedge\phi=0$ which implies

$$D^\mu D_\mu \phi + (0,0,1-\phi_3) + \lambda\phi = 0. \tag{33}$$

Multiplying equation (33) by ϕ and considering $|\phi|=1$, almost everywhere, we obtain

$$\lambda = \langle D_\mu\phi, D^\mu\phi\rangle + \phi_3(\phi_3-1).$$

Taking the exterior product of (20) with ϕ^l and using the fact that the nonlinear term always points in the direction of ϕ^l, we obtain

$$D_\mu(D^\mu\phi^l\wedge\phi^l) + (0,0,1-\phi_3^l)\wedge\phi^l = 0 \tag{34}$$

for all l. In the limit $l\to\infty$, the equation (34) is valid in the sense of distributions implying that (A,ϕ) weakly solve (17). Since $\phi^l-n\in L^2([0,T]\times\mathbb{R}^3)$ with $\partial\phi^l\in L^\infty([0,T];L^2(\mathbb{R}^3))$ we have $\phi^l\to\phi$ in $C([0,T];L^2(\mathbb{R}^3))$. Moreover testing (30) and (34) by a vector $\psi\in C_0^\infty(\mathbb{R}\times\mathbb{R}^3)$ over $\mathbb{R}^{3+1}$ and integrating by parts we get

$$\int_{\{0\}\times\mathrm{R}^3}\langle D_0\phi\wedge\phi - D_0\phi^l\wedge\phi^l,\psi\rangle \mathrm{d}x = \int_0^\infty\int_{\mathrm{R}^3}\langle (D_\alpha\phi^l\wedge\phi^l) - D_\alpha\phi\wedge\phi), D^\alpha\psi\rangle \mathrm{d}x\,\mathrm{d}t$$
$$+\int_0^\infty\int_{\mathrm{R}^3}\langle (0,0,1-\phi_3)\wedge\phi - (0,0,1-\phi_3^l)\wedge\phi^l,\psi\rangle \mathrm{d}x\,\mathrm{d}t.$$

In the limit $l\to\infty$, we can conclude that

$$D_0\phi(0,\cdot)\wedge\phi(0,\cdot) - D_0\phi^l(0,\cdot)\wedge\phi^l(0,\cdot) = (\partial_t\phi(0,\cdot)-\phi_1)\wedge\phi_0 = 0,$$

i.e., $\partial_t\phi(0,\cdot)=\phi_1$ in the sense of traces. Here we used the fact that both $\partial_t\phi(0,\cdot)$ and ϕ_1 are tangent to S^2 along ϕ_0.

From now on, we are concerned about the two-dimensional spatial case. The approximate equations can be obtained through the similar reduction procedure but we do not know if there is a result which states that Maxwell–Higgs equations in $\mathbb{R}^{2+1}$ under the condition of Coulomb gauge exist global in time with the initial data $(\phi-n,\partial\phi,A,\partial A)\in H^1(\mathbb{R}^2)\times L^2(\mathbb{R}^2)\times\dot{H}^1(\mathbb{R}^2)\times L^2(\mathbb{R}^2)$. Here we assume that the initial data $(\phi-n,\partial\phi,A,\partial A)$ can be approximated by the smooth function sequences $(\phi^k-n,\partial\phi^k,A^k,\partial A^k)$ with the constraint $|\phi^k(0,\cdot)|=1$. In fact we should note the following.

Remark: Let Σ be a smooth compact Riemannian surface and N be compact k-manifold. Then by a result of Ref. 13 the space $C^\infty(\Sigma;N)$ of smooth maps $u:\Sigma\to N\subset\mathbb{R}^m$ is dense in $H^1(\Sigma;N)$. But we do not know what happens if Σ is unbounded surface. Moreover is it possible that (ϕ_0-n,ϕ_1) satisfying $|\phi_0|=1$, $\langle\phi_0,\phi_1\rangle$ can be approximated in the $H^1(\mathbb{R}^2)\times L^2(\mathbb{R}^2)$ norm by the smooth function sequences $(\phi^k(0,\cdot)-n,\partial_t\phi^k(0,\cdot))$ with the constraint $|\phi^k(0,\cdot)|=1$, $\langle\phi^k(0,\cdot),\partial_t\phi^k(0,\cdot)\rangle=0$? Therefore our results below are conditional.

Remark: For a domain manifold M of dimension $m>2$ a result of Ref. 1 shows that the space $C^\infty(M;N)$ is dense in $H^1(M;N)$ if and only if $\pi_2(N)=0$ [where $\pi_2(N)$ is a second fundamental group of N]. Therefore in the three-dimensional spatial case we cannot assume approximation sequence ϕ^k generally.

We will use the fact that equations (20)–(22) with initial data $[\phi^k(0)-n, \partial\phi^k(0), A^k(0), \partial A^k(0)]$ admit global smooth solution for all k. In fact Maxwell–Higgs equations have the global smooth solution under the Lorentz gauge $\partial_\mu \tilde{A}^\mu = 0$ (see Ref. 2). Then by the suitable gauge transform the equations are changed into one with Coulomb gauge $\partial_i \tilde{A}^i = 0 (A_\mu = \tilde{A}_\mu + \partial_\mu \chi)$. The solutions (A^k, ϕ^k) satisfy the energy inequality

$$E_k(\phi^k, A^k)(t) = \int_{\Sigma_t} \langle D_\mu \phi^k, D_\mu \phi^k \rangle + (1 - n \cdot \phi^k)^2 + \frac{1}{2}|F^k_{\mu\nu}|^2 + \frac{l}{4}\int_{\Sigma_t} (|\phi^k|^2 - 1)^2 \leqslant E(\phi^k, A^k)(0)$$

$$= E(\phi, A)(0) + \frac{1}{2^k}. \tag{35}$$

The inequality (24) can be also obtained,

$$\| \nabla A^k_\mu \|_{L^2(R^2)} \leqslant C \| F^k_\mu \|_{L^2(R^2)} \leqslant C E(0)^{1/2},$$

and

$$\| \partial_\mu \phi^k \|_{L^2(R^2)} \leqslant \| D_\mu \phi^k \|_{L^2(R^2)} + \| A^k_\mu \|_{L^4(R^2)} \| n \times \phi^k \|_{L^4(R^2)}.$$

To estimate $\|A^k_\mu\|_{L^4(\mathrm{R}^2)}$ the two facts will be used. Note that $\dot{H}^1(\mathbb{R}^2)$ does not embed into $L^4(\mathbb{R}^2)$.

(a) To estimate L^2 norm of the solution itself A_i, use will be made of the following lemma. The proof is in Ref. 11.

Lemma 4.3: If u solves the Cauchy problem,

$$\Box u = \sum_{\alpha=0}^{2} \partial_\alpha G_\alpha, \quad u(0, \cdot) = f, \quad \partial_t u(0, \cdot) = g,$$

then

$$\| u(t, \cdot) \|_{L^2(R^2)} \leqslant \sum_{\alpha=0}^{2} \int \| G_\alpha(s, \cdot) \|_{L^2(R^2)} \, ds + C(f, g, G_0(0, \cdot)) \log(2 + t),$$

where $C(f, g, G_0(0, \cdot))$ is some constant depending on some weighted Sobolev norm of initial data f and g.

Applying Lemma 4.3 to $\Box A^k_j = \partial^\mu F^k_{\mu j} + \partial^0 \partial_j A^k_0$ we have

$$\| A^k_j(t) \|_{L^2(R^2)} \leqslant C \log(2 + t) + \int_0^t \| F^k(s) \|_{L^2(R^2)} \, ds \leqslant C(1 + tE(0)^{1/2}).$$

Therefore given $t \in [0, T]$, $A^k_j(t) \in H^1(\mathbb{R}^2)$ which implies

$$\| A^k_j(t) \|^2_{L^4(R^2)} \leqslant \| A^k_j(t) \|_{L^2(R^2)} \| \nabla A^k_j(t) \|_{L^2(R^2)} \leqslant C(1 + tE(0)^{1/2}).$$

(b) To estimate $\|A^k_0(t)\|_{L^4(\mathrm{R}^2)}$ we are going to estimate $\partial_t A^k_0$. We differentiate Eq. (22) with respect to t and derive, with the help of (26), $\Delta \partial_t A^k_0 = \partial_i \langle D_i \phi^k, n \times \phi^k \rangle$. By Lemma 4.1 we show

$$\| \partial_t A^k_0(t) \|_{L^4(R^2)} \leqslant \| \Delta^{-1/2} \partial_i \langle D_i \phi^k, n \times \phi^k \rangle \|_{L^{4/3}(R^2)} \leqslant \| D_i \phi^k \|_{L^2(R^2)} \| n \times \phi^k \|_{L^4(R^2)} \leqslant C E(0)^{1/4}. \tag{36}$$

Now using the inequality

$$4\|A_0^k\|_{L^4(R^2)}^3 \partial_t \|A_0^k\|_{L^4(R^2)} = \partial_t \int_{R^2} (A_0^k)^4 \, dx \leqslant 4\|A_0^k\|_{L^4(R^2)}^3 \|\partial_t A_0^k\|_{L^4(R^2)},$$

we derive

$$\|A_0^k(t)\|_{L^4(R^2)} \leqslant \|A_0^k(0)\|_{L^4(R^2)} + \int_0^t \|\partial_t A_0^k(s)\|_{L^4(R^2)} \, ds \leqslant C(1 + tE(0)^{1/4}).$$

By the observation (a), (b) we have

$$\|\partial_\mu \phi^k\|_{L^2(R^2)} \leqslant C(1 + t).$$

The remaining argument is the same as the previous one given in the case of three dimensions.

The author would like to thank Professor Dongho Chae for his valuable comments and continuous encouragement. This work was supported by the Brain Korea 21 Project in 2005.

APPENDIX

Here we show that the system (20)–(22) admits a global finite energy solution. The fine structure was used to prove the global finite energy solution of Maxwell–Klein–Gordon (MKG) equation in Ref. 8. Following the line of Ref. 8 we check the nontrivial points. To compare with Maxwell–Klein–Gordon equation in Ref. 8 we rewrite (20)–(22) with the notation $u = \phi_1 + \sqrt{-1}\phi_2$, $v = \phi_3 - 1$, and $D_\mu u = \partial_\mu u + \sqrt{-1}A_\mu u$,

$$D_\mu D^\mu u + \underbrace{l(|u|^2 + v^2 + 2v)u} = 0, \tag{A1}$$

$$\partial_\mu \partial^\mu v - v + l(|u|^2 + v^2 + 2v)(v + 1) = 0, \tag{A2}$$

$$\partial_\mu \partial^\mu A_i = -\mathcal{P}\,\mathrm{Im}(u\overline{D_i u}), \tag{A3}$$

$$\Delta A_0 = -\mathrm{Im}(u\overline{D_0 u}). \tag{A4}$$

Note that (A1)–(A4) are the same as equations in Ref. 8 except the braced part of (A1) and (A2). Let $A = (A_1, A_2, A_3)$ and define pseudoenergy,

$$\mathcal{Q}(A,u,v)(t) = \|\partial A(t,\cdot)\|_{L^2} + \|u(t,\cdot)\|_{L^2} + \|\partial u(t,\cdot)\|_{L^2} + \|v(t,\cdot)\|_{L^2} + \|\partial v(t,\cdot)\|_{L^2}.$$

The main theorem is as follows.

Theorem 5.1: *Consider initial data satisfying* $\nabla_i A^i(0,\cdot) = 0$ *such that* $\mathcal{Q}(0)$ *is finite. Under this hypothesis there exists a unique global generalized solution to the equation (A1)–(A4) verifying the energy inequality*

$$E_l(t) \leqslant C\mathcal{Q}^2(0)$$

as well as

$$(i) \quad \mathcal{Q}(t) \leqslant C(1 + t)\mathcal{Q}(0).$$

And on any finite interval $[0, T]$,

$$(ii) \quad \int_0^T (\|\Box A(t,\cdot)\|_{L^2} + \|\Box u(t,\cdot)\|_{L^2} + \|\Box v(t,\cdot)\|_{L^2}) dt \leqslant \infty.$$

The first nontrivial check point is the pp. 31–35 of Ref. 8. To estimate $\partial_t A_0$, the precise form of MKG equation was used. It is possible to construct the corresponding parts despite of the different form of potential. With the help of the relation (26) we have

$$\Delta \partial_t A_0 = \partial_t \langle D_0 \phi, n \times \phi \rangle = \partial_i \langle D_i \phi, n \times \phi \rangle.$$

So we may obtain the corresponding one of Proposition 3.2 in Ref. 8.

The second part is the pp. 35–39 in Ref. 8. Following the idea of Ref. 8 we will show the estimate

$$X(T) \leqslant CT^{1/2}(1 + \mathcal{Q}(0) + X(T))^4, \tag{A5}$$

where $X(T) = \int_0^T (\|\Box A(t,\cdot)\|_{L^2} + \|\Box u(t,\cdot)\|_{L^2} + \|\Box v(t,\cdot)\|_{L^2}) \mathrm{d}t$ and $0 < T < T^*$ is small, C is independent on both T^* and $\mathcal{Q}(0)$. With the standard form of the energy estimate applied to u, v, and A we have

$$\mathcal{Q}(t) \leqslant (\mathcal{Q}(0) + X(t)).$$

In view of the equation (A1)–(A3) we have

$$\begin{aligned} X(T) \leqslant & \int_0^T \|\mathcal{P}\,\mathrm{Im}(u\overline{Du})\|_{L^2} + 2\|u\partial_t A_0\|_{L^2} + 2\|A_0 \partial_t u\|_{L^2} + \int_0^T \|A \cdot \nabla u\|_{L^2} + \||A_0|^2 u\|_{L^2} + \||A|^2 u\|_{L^2} \\ & + \int_0^T l\|(|u|^2 + v^2 + 2v)u\|_{L^2} + l\|(|u|^2 + v^2 + 2v)(v+1)\|_{L^2}. \end{aligned} \tag{A6}$$

The first and second line of (A6) can be estimated in the same way as Ref. 8 using Sobolev inequalities, Strichartz and null form estimates. The third line can be estimated in a easier way,

$$\int_0^T \|uv^2\|_{L^2} \leqslant \int_0^T \|u\|_{L^6} \|v\|_{L^6}^2 \leqslant C \int_0^T \|\nabla u\|_{L^2} \|\nabla v\|_{L^2}^2 \leqslant C(\mathcal{Q}(0) + X(T))^3.$$

We show the inequality (A5) then the rest is straightforward as in Ref. 8.

(Received 13 December 2004; accepted 7 February 2005; published online 11 April 2005)

We calculate all symmetries of the Dirac–Pauli equation in two-dimensional and three-dimensional Euclidean space. Further, we use our results for an investigation of the issue of zero mode degeneracy. We construct explicitly a class of multiple zero modes with their gauge potentials. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1884885]

I. INTRODUCTION

The abelian Dirac equation in Euclidean space in two and three dimensions is

$$\mathcal{D}\Psi \equiv \sigma^k(-i\partial_k - G^k(\mathbf{r}))\Psi(\mathbf{r}) = 0, \tag{1}$$

where, in three dimensions, $\mathbf{r}=(x,y,z)^t$, $k=x,y,z$, σ^k are the Pauli matrices, and $G^k \equiv (G^x,G^y,G^z)$ is the gauge potential (we use superscripts for the components because subscripts will be exclusively reserved to describe partial derivatives). In two dimensions all z components are absent. Further, $\Psi=(\Phi,\chi)^t$ is a two-component spinor.

The Pauli equation is obtained from the Dirac equation by simply squaring the Dirac operator $\mathcal{D}$ acting on Ψ,

$$((-i\partial_k - G^k)^2 - \sigma^l H^l)\Psi = 0, \tag{2}$$

where $\vec{H}$ is the magnetic field, $\vec{H}=\nabla\times\vec{G}$. Solutions of the Dirac equation (1) are, at the same time, solutions of the Pauli equation, therefore we shall treat them on an equal footing.

Solutions to the Pauli or Dirac equation are relevant in several instances. They describe the behavior of nonrelativistic electrons in the presence of magnetic fields, and their existence, among other issues, influences the stability of nonrelativistic matter.[1,2] On the other hand, they influence the behavior of the fermion determinant $\det \mathcal{D}$ for relativistic electrons and are, therefore, relevant for the strong field behavior of relativistic electrons,[3–5] and for a proper path-integral quantization of quantum electrodynamics (QED) in two[6–8] and three dimensions.

For the Dirac equation in two dimensions the most important information on solutions is provided by the Aharanov–Casher theorem,[9] which states that there are n square-integrable solutions when the magnetic flux divided by 2π is between n and $n+1$, i.e., $n<(\text{flux}/2\pi)\leqslant n+1$. For the Dirac equation in three dimensions the available information is much scarcer. The first examples of solutions have been given in 1986, see Ref. 2. Further examples have been provided in Refs. 10–12, and the existence of multiple solutions (zero mode degeneracy) has been first demonstrated in Refs. 13–15. Further results on zero-mode supporting gauge potentials may be found in Refs. 16–18. A general classification of zero-mode supporting gauge fields is still missing.

In this paper we study the symmetries of the Dirac equation (1) both in two and three dimensions, in order to gain some further insight into the solution space of these equations. In Sec. II we calculate the symmetries of the Dirac equation in two dimensions and briefly apply our results to the issue of multiple zero modes. In Sec. III we calculate the symmetries of the Dirac equation in three dimensions. We use the method of prolongations for all our symmetry calculations, which is described in detail in Ref. 19. In Sec. IV, we use our results on symmetries of the three-dimensional Dirac equation for a discussion of the issue of zero mode degeneracy (i.e., multiple solutions) in three dimensions. In Sec. IV A, we discuss how our results on symmetries can be used to construct multiple zero modes in principle. In Sec. IV B, we apply the results of Sec. IV A for the explicit construction of a class of multiple zero modes together with their corresponding gauge potentials.

II. SYMMETRIES OF THE DIRAC EQUATION IN TWO DIMENSIONS

For the Dirac equation in two dimensions it is known from the Aharanov–Casher theorem that all zero modes (i.e., square-integrable solutions) are either left handed (i.e., the lower component of Ψ is zero) or right handed (the upper component of Ψ is zero). Further, a solution of the first type (left handed) may be mapped into a solution of the second type by the simple replacement $G^k \rightarrow -G^k$, therefore we may restrict, e.g., to the left-handed case

$$(-i\partial_x - G^x + \partial_y - iG^y)\Phi = 0. \tag{3}$$

By introducing the modulus and phase of Φ via $\ln \Phi = \rho + i\lambda$ we may rewrite Eq. (3) in terms of two real first order equations as

$$\Delta_1 \equiv \rho_y + \lambda_x - G^x = 0, \tag{4}$$

$$\Delta_2 \equiv \rho_x - \lambda_y + G^y = 0, \tag{5}$$

where from now on subscripts denote partial derivatives, i.e., $\rho_x \equiv \partial_x \rho$, etc.

The vector field generating generic transformations on the independent and dependent variables is

$$v = X\partial_x + Y\partial_y + R\partial_\rho + L\partial_\lambda + F^x\partial_{G^x} + F^y\partial_{G^y}, \tag{6}$$

where X, Y, R, L, F^x, F^y may depend on all independent and dependent variables. The equations (4) and (5) contain first derivatives of the variables λ and ρ, therefore we need the first prolongation of v with respect to these variables,

$$\mathrm{pr}\, v = v + R^x\partial_{\rho_x} + R^y\partial_{\rho_y} + L^x\partial_{\lambda_x} + L^y\partial_{\lambda_y}, \tag{7}$$

where, e.g.,

$$R^x = D_x R - \rho_x D_x X - \rho_y D_x Y. \tag{8}$$

Here D_x is a total derivative, and we give the explicit (rather lengthy) expressions in Appendix A.

Now, a symmetry of a partial differential equation (PDE) $F(\rho, \rho_j, \ldots) = 0$ (of nth order, say) is a solution of the equation $\mathrm{pr}^{(n)} v(F) = 0$ which holds on-shell, i.e., when the original PDE is used together with its prolongations (PDEs that follow from $F = 0$ by applying total derivatives). As said, for the details of the used formalism we refer to Ref. 19.

Concretely, the determination of the symmetry transformation proceeds as follows. We require that $\mathrm{pr}\, v(\Delta_1) = 0 = \mathrm{pr}\, v(\Delta_2)$ whenever the equations (4) and (5) hold. Explicitly this means that

$$R^y + L^x - F^x = 0, \tag{9}$$

$$R^x - L^y + F^y = 0, \tag{10}$$

whenever the equations (4) and (5) hold. Equations (9) and (10) contain a number of algebraically independent functions (like ρ_x, $\rho_x G^y_x$, etc.) multiplying the coefficients (like R_x, R_ρ, etc.) which we want to determine. We may use the equations (4) and (5) to eliminate, e.g., λ_x and λ_y from the equations (9) and (10). Then we demand that the coefficient of each algebraically independent function (like ρ_x, $\rho_x G^y_x$, etc.) vanishes separately. This leads to more than 30 conditions for each of the two equations (9) and (10). Fortunately, most of these conditions are quite trivial, like, e.g., $X_\lambda = 0 = X_{A^x}$, etc. The final result is that Eq. (9) leads to the conditions

$$X = X(x,y), \quad Y = Y(x,y), \tag{11}$$

$$R = R(\rho,\lambda,x,y), \quad L = L(\rho,\lambda,x,y), \tag{12}$$

$$R_\rho - L_\lambda = Y_y - X_x, \tag{13}$$

$$L_\rho + R_\lambda = X_y + Y_x, \tag{14}$$

and

$$F^x = L_x + R_y + (L_\lambda - X_x)G^x + (R_\lambda - Y_x)G^y, \tag{15}$$

whereas Eq. (10) leads to the conditions

$$X = X(x,y), \quad Y = Y(x,y), \tag{16}$$

$$R = R(\rho,\lambda,x,y), \quad L = L(\rho,\lambda,x,y), \tag{17}$$

$$R_\rho - L_\lambda = -Y_y + X_x, \tag{18}$$

$$L_\rho + R_\lambda = -X_y - Y_x, \tag{19}$$

and

$$F^y = L_y - R_x - (R_\lambda + X_y)G^x + (L_\lambda - Y_y)G^y. \tag{20}$$

For later convenience we introduce the complex notation

$$z \equiv x + iy, \quad Z \equiv X + iY, \quad \sigma \equiv \rho + i\lambda, \quad \Sigma \equiv R + iL \tag{21}$$

and

$$G \equiv \tfrac{1}{2}(G^x + iG^y), \quad F \equiv \tfrac{1}{2}(F^x + iF^y) \tag{22}$$

which implies

$$\partial_\sigma \equiv \tfrac{1}{2}(\partial_\rho - i\partial_\lambda), \tag{23}$$

etc. Compatibility between the two sets of equations requires

$$X_x = Y_y, \quad X_y = -Y_x \tag{24}$$

which are just the Cauchy–Riemann equations, and

$$L_\rho = L_\lambda, \quad R_\lambda = -L_\rho, \tag{25}$$

which are the Cauchy–Riemann equations with respect to the target space variable $\sigma=\rho+i\lambda$. Therefore, X and Y are the real and imaginary part of a holomorphic function,

$$X + iY = Z(z), \quad z = x + iy, \tag{26}$$

whereas L and R are the real and imaginary part of a holomorphic function in the variable σ,

$$R + iL = \Sigma(\sigma, z, \bar{z}), \tag{27}$$

where Σ may still depend on $z, \bar{z}$. Finally, for F we find

$$F \equiv \tfrac{1}{2}(F^x + iF^y) = -i\Sigma_{\bar{z}} - G\bar{Z}_{\bar{z}} + G\Sigma_\sigma. \tag{28}$$

The most general symmetry generator

$$v = Z\partial_z + \bar{Z}\partial_{\bar{z}} + \Sigma\partial_\sigma + \bar{\Sigma}\partial_{\bar{\sigma}} + F\partial_G + \bar{F}\partial_{\bar{G}} \tag{29}$$

may be expressed as the semidirect sum of a symmetry generator v_Z with respect to the holomorphic function $Z(z)$ and a generator v_Σ with respect to the function $\Sigma(\sigma, z, \bar{z})$, where

$$v_Z = Z\partial_z + \bar{Z}\partial_{\bar{z}} - G\bar{Z}_{\bar{z}}\partial_G - \bar{G}Z_z\partial_{\bar{G}} \tag{30}$$

and

$$v_\Sigma = \Sigma\partial_\sigma + \bar{\Sigma}\partial_{\bar{\sigma}} + (-i\Sigma_{\bar{z}} + G\Sigma_\sigma)\partial_G + (i\bar{\Sigma}_z + \overline{G\Sigma_\sigma})\partial_{\bar{G}}. \tag{31}$$

Further, they obey the infinite-dimensional Lie algebra,

$$[v_{Z_1}, v_{Z_2}] = v_{Z_3}, \quad Z_3 = Z_1 Z_2' - Z_2 Z_1', \tag{32}$$

$$[v_{\Sigma_1}, v_{\Sigma_2}] = v_{\Sigma_3}, \quad \Sigma_3 = \Sigma_1 \Sigma_{2,\sigma} - \Sigma_2 \Sigma_{1,\sigma}, \tag{33}$$

which are just two copies of the Virasoro algebra in coordinate and target space, and

$$[v_Z, v_\Sigma] = v_{\tilde{\Sigma}}, \quad \tilde{\Sigma} = \Sigma_z Z + \Sigma_{\bar{z}}\bar{Z}. \tag{34}$$

It is quite interesting that the symmetry turns out to be so large, the semidirect product of two conformal groups in two dimensions.

[*Remark:* the symmetry transformations we found cover the whole solution space in the sense that any solution Φ of the Dirac equation (3) for any gauge potential G can be found by applying a symmetry transformation to the trivial solution $\Phi=1$, $G=0$. In fact, a target space transformation Σ of the type $\Sigma=f(z,\bar{z})$ is sufficient. For this subclass of transformations the above Lie algebra is abelian, therefore the exponentiation for finite Σ is trivial.]

As an application let us briefly discuss the issue of degeneracy of zero modes (i.e., multiple solutions of the Dirac equation for one gauge field G). The condition that the gauge field does not change is, of course, that the F in Eq. (28) is zero, which leads to the conditions $\Sigma_\sigma=\Sigma_{\bar{z}}=0$, that is $\Sigma=g(z)$ is a function in the variable z only. As said, the exponentiation of such Σ is trivial, therefore a

$$\Phi' = e^{g(z)}\Phi \tag{35}$$

is a local zero mode for the same gauge potential as Φ. Single valuedness of Φ' on the whole Euclidean plane restricts the allowed g [$\exp g(z)$ should be single valued] and the condition of square integrability further restricts the allowed $g(z)$. The fact that further zero modes of the same

Dirac operator may be produced by multiplying the given one with analytic functions of z is, of course, well known.

III. SYMMETRIES OF THE DIRAC EQUATION IN THREE DIMENSIONS

Introducing the real and imaginary part of the spinor components via $\Phi=\alpha+i\beta$, $\chi=\gamma+i\delta$, the Dirac equation (1) in three dimensions is equivalent to the four real equations,

$$\begin{aligned} \mathrm{I} &\equiv \beta_z + \delta_x - \gamma_y - G^z\alpha - G^x\gamma - G^y\delta = 0, \\ \mathrm{II} &\equiv \alpha_z + \gamma_x + \delta_y + G^z\beta + G^x\delta - G^y\gamma = 0, \\ \mathrm{III} &\equiv \beta_x + \alpha_y - \delta_z - G^x\alpha + G^y\beta + G^z\gamma = 0, \\ \mathrm{IV} &\equiv \alpha_x - \beta_y - \gamma_z + G^x\beta + G^y\alpha - G^z\delta = 0. \end{aligned} \tag{36}$$

If viewed as a system of algebraic equations for the three real unknowns (G^x, G^y, G^z), these four equations must be algebraically dependent. The dependence is given by the condition

$$V \equiv \nabla \cdot \vec{\Sigma} = 2(\alpha\gamma+\beta\delta)_x + 2(\alpha\delta-\beta\gamma)_y + (\alpha^2+\beta^2-\gamma^2-\delta^2)_z = 0, \tag{37}$$

where

$$\vec{\Sigma} \equiv \Psi^\dagger \vec{\sigma} \Psi = \begin{pmatrix} 2(\alpha\gamma+\beta\delta) \\ 2(\alpha\delta-\beta\gamma) \\ \alpha^2+\beta^2-\gamma^2-\delta^2 \end{pmatrix} \tag{38}$$

is the spin density of the spinor Ψ.

Again, we want to study the symmetries of the above equations (36) using the method of prolongations. The symmetry generating vector field is

$$v = X\partial_x + Y\partial_y + Z\partial_z + A\partial_\alpha + B\partial_\beta + C\partial_\gamma + D\partial_\delta + F^x\partial_{G^x} + F^y\partial_{G^y} + F^z\partial_{G^z} \tag{39}$$

and its prolongation to the needed order is

$$\begin{aligned} \mathrm{pr}\, v = v &+ A^x\partial_{\alpha_x} + A^y\partial_{\alpha_y} + A^z\partial_{\alpha_z} + B^x\partial_{\beta_x} + B^y\partial_{\beta_y} + B^z\partial_{\beta_z} + C^x\partial_{\gamma_x} + C^y\partial_{\gamma_y} + C^z\partial_{\gamma_z} + D^x\partial_{\delta_x} + D^y\partial_{\delta_y} \\ &+ D^z\partial_{\delta_z}, \end{aligned} \tag{40}$$

where, e.g., A^x is given by

$$A^x = A_x + A_\alpha\alpha_x + A_\beta\beta_x + A_\gamma\gamma_x + A_\delta\delta_x - \alpha_x X_x - \alpha_y Y_x - \alpha_z Z_x. \tag{41}$$

Here, we have already used some first results of the calculation below, namely that (analogously to the case in two dimensions) no coefficient depends on the gauge potential, and that the coefficients X, Y, Z of the translations in base space only depend on the base space coordinates x, y, z [otherwise the resulting expression (41) would be more complicated, analogously to the R^x of the two-dimensional case, which is given in Appendix A].

Acting with the prolonged vector field on the four equations (36) [$\mathrm{pr}\, v(I)=0$, etc.] leads to the following set of four equations:

$$G^x C + G^y D + G^z A + F^x \gamma + F^y \delta + F^z \alpha - D^x + C^y - B^z = 0,$$

$$G^x D - G^y C + G^z B + F^x \delta - F^y \gamma + F^z \beta + C^x + D^y + A^z = 0,$$

$$- G^x A + G^y B + G^z C - F^x \alpha + F^y \beta + F^z \gamma + B^x + A^y - D^z = 0, \tag{42}$$

$$G^x B + G^y A - G^z D + F^x \beta + F^y \alpha - F^z \delta + A^x - B^y - C^z = 0.$$

Next we must insert the explicit expressions for A^x, etc. We obtain algebraic expressions in terms of the target space variables and their partial derivatives, where we may eliminate four derivative terms with the help of the Dirac equations (36). (Explicitly, we eliminated δ_x, δ_y, δ_z, and γ_z.) For the resulting expressions one must require that the coefficient multiplying each partial derivative of the target space variables (like α_x or G^x_x) or product of partial derivatives vanishes separately. Doing this one realizes quickly that nothing may depend on the gauge potential and that the coefficients X, Y, Z may only depend on x, y, z.

The remaining coefficients which are multiplied by at least one partial derivative of a target space variable serve to determine the coefficients X, Y, Z and A, B, C, D. They are of two types. The first type consists of pairs of equations like

$$A_\delta + D_\alpha = Y_z + Z_y, \quad A_\delta + D_\alpha = - Y_z - Z_y \Rightarrow A_\delta + D_\alpha = 0, \quad Y_z + Z_y = 0$$

which lead to equations for the X, Y, Z and A, B, C, D independently. The equations for X, Y, Z are

$$X_x = Y_y = Z_z,$$

$$X_y + Y_x = 0, \quad X_z + Z_x = 0, \quad Y_z + Z_y = 0 \tag{43}$$

and have the conformal transformations in three-dimensional space as general solutions,

$$X = \frac{\theta^1}{2}(x^2 - y^2 - z^2) + \theta^2 xy + \theta^3 xz - l^3 y + l^2 z + \sigma x + x^0,$$

$$Y = \frac{\theta^2}{2}(y^2 - x^2 - z^2) + \theta^1 xy + \theta^3 yz + l^3 x - l^1 z + \sigma y + y^0, \tag{44}$$

$$Z = \frac{\theta^3}{2}(z^2 - x^2 - y^2) + \theta^1 xz + \theta^2 yz - l^2 x + l^1 y + \sigma z + z^0.$$

Here θ^i, l^i, σ, and $\vec{r}^0$ are constant parameters which parametrize the infinitesimal conformal transformations.

The equations for A, B, C, D are

$$A_\alpha = B_\beta = C_\gamma = D_\delta,$$

$$A_\beta + B_\alpha = 0, \quad A_\gamma + C_\alpha = 0, \quad A_\delta + D_\alpha = 0, \tag{45}$$

$$B_\gamma + C_\beta = 0, \quad B_\delta + D_\beta = 0, \quad C_\delta + D_\gamma = 0,$$

and have the conformal transformations in the four-dimensional target space as solutions,

$$A = \frac{\zeta^1}{2}(\alpha^2 - \beta^2 - \gamma^2 - \delta^2) + \zeta^2\alpha\beta + \zeta^3\alpha\gamma + \zeta^4\alpha\delta + \lambda\alpha - v^3\beta + v^2\gamma - v^1\delta + \alpha^0,$$

$$B = \frac{\zeta^2}{2}(\beta^2 - \alpha^2 - \gamma^2 - \delta^2) + \zeta^1\alpha\beta + \zeta^3\beta\gamma + \zeta^4\beta\delta + \lambda\beta + v^3\alpha - u^1\gamma - u^2\delta + \beta^0,$$

$$C = \frac{\zeta^3}{2}(\gamma^2 - \alpha^2 - \beta^2 - \delta^2) + \zeta^1\alpha\gamma + \zeta^2\beta\gamma + \zeta^4\gamma\delta + \lambda\gamma - v^2\alpha + u^1\beta - u^3\delta + \gamma^0, \tag{46}$$

$$D = \frac{\zeta^4}{2}(\delta^2 - \alpha^2 = \beta^2 - \gamma^2) + \zeta^1\alpha\delta + \zeta^2\beta\delta + \zeta^3\gamma\delta + \lambda\delta + v^1\alpha + u^2\beta + u^3\gamma + \delta^0.$$

Here the parameters ζ^j, u^i, v^i, λ and α^0, β^0, γ^0, δ^0 may still depend on the base space coordinates (x,y,z).

The second type of equations consists of equations like $C_\delta - A_\beta = X_y$ and establishes relations between the A, B, C, D and the X, Y, Z, thereby further restricting the possible A, B, C, D. The result is that the proper conformal transformation on target space must be absent, $\zeta^j \equiv 0$, and that the six target space rotation parameters are no longer independent,

$$u^1 - v^1 = l^1 + \theta^2 z - \theta^3 y \equiv L^1,$$

$$u^2 - v^2 = l^2 + \theta^3 x - \theta^1 z \equiv L^2, \tag{47}$$

$$u^3 - v^3 = l^3 + \theta^1 y - \theta^2 x \equiv L^3$$

leading to

$$A = \lambda\alpha - v^3\beta + v^2\gamma - v^1\delta + \alpha^0,$$

$$B = \lambda\beta + v^3\alpha - (v^1 + L^1)\gamma - (v^2 + L^2)\delta + \beta^0,$$

$$C = \lambda\gamma - v^2\alpha + (v^1 + L^1)\beta - (v^3 + L^3)\delta + \gamma^0, \tag{48}$$

$$D = \lambda\delta + v^1\alpha + (v^2 + L^2)\beta + (v^3 + L^3)\gamma + \delta^0,$$

where λ, v^i, and $\alpha^0, \cdots$ may still depend on (x,y,z). By shifting $v^i \to v^i - (L^i/2)$ the L^i are distributed more symmetrically,

$$
\begin{aligned}
A &= \lambda\alpha - \left(v^3 - \frac{L^3}{2}\right)\beta + \left(v^2 - \frac{L^2}{2}\right)\gamma - \left(v^1 - \frac{L^1}{2}\right)\delta + \alpha^0, \\
B &= \lambda\beta + \left(v^3 - \frac{L^3}{2}\right)\alpha - \left(v^1 + \frac{L^1}{2}\right)\gamma - \left(v^2 + \frac{L^2}{2}\right)\delta + \beta^0, \\
C &= \lambda\gamma - \left(v^2 - \frac{L^2}{2}\right)\alpha + \left(v^1 + \frac{L^1}{2}\right)\beta - \left(v^3 + \frac{L^3}{2}\right)\delta + \gamma^0, \\
D &= \lambda\delta + \left(v^1 - \frac{L^1}{2}\right)\alpha + \left(v^2 + \frac{L^2}{2}\right)\beta + \left(v^3 + \frac{L^3}{2}\right)\gamma + \delta^0,
\end{aligned}
\tag{49}
$$

and we find the half-integer valued representation of the base space rotations (with parameters l^i) acting on the (spinor) target space variables. It is interesting to note that the half-integer values appear also for the parameters of the proper conformal transformations on base space (remember $L^i \equiv l^i + \epsilon^{ijk}\theta^j r^k$).

[*Remark:* for a Dirac equation without the additional condition $\nabla\cdot\vec{\Sigma}=0$, see Eq. (37), the above expressions would be the final result. This is the case, for instance, for the Dirac equation for a Weyl (i.e., two component) spinor in Euclidean space in four dimensions, for which expressions analogous to (49) would constitute the final result (with the conformal base space transformations in four instead of three dimensions, of course).]

We have used all information from the coefficients of Eqs. (42) which contain at least one partial derivative of a target space variable. It remains to evaluate the parts without a partial derivative (i.e., the coefficients of the identity). These contain the coefficients F^x, F^y, F^z linearly and are therefore just the determining linear equations for these coefficients. However, they give four equations for three unknowns, therefore they must be linearly dependent, which leads to one further constraint equation. An easier way to calculate this constraint is to calculate the action of the prolonged vector field (40) on the original constraint (37),

$$\mathrm{pr}\, v(V) = 0 \tag{50}$$

or explicitly

$$
\begin{aligned}
&A^x\gamma + \alpha_x C + A\gamma_x + \alpha C^x + B^x\delta + \beta_x D + B\delta_x + \beta D^x + A^y\delta + \alpha_y D + A\delta_y + \alpha D^y - B^y\gamma - \beta_y C - B\gamma_y \\
&\quad - \beta C^y + A^z\alpha + \alpha_z A + B^z\beta + \beta_z B - C^z\gamma - \gamma_z C - D^z\delta - \delta_z D = 0.
\end{aligned}
\tag{51}
$$

Inserting the explicit expressions for A^x, etc., leads to an expression containing both coefficients multiplying partial derivatives of the target space variables (like α_x) and a coefficient of the identity 1. After eliminating four partial derivatives (e.g., δ_x, δ_y, δ_z, and γ_z) with the help of the equations of motion, one realizes that the coefficients of the remaining partial derivatives vanish identically. It remains to evaluate the coefficient of the identity. This leads in fact to four conditions, because the use of the equations of motion has reintroduced the gauge potential functions G^x, G^y, G^z into the above expression. As none of the coefficients (A, etc.) may depend on the gauge potential, the total coefficient multiplying each gauge potential function must vanish separately, as well as the remainder. The conditions that the coefficients multiplying G^x, G^y, G^z vanish leads to

$$\alpha^0 = \beta^0 = \gamma^0 = \delta^0 = 0, \quad v^1 = v^2 = 0, \tag{52}$$

and the condition that the remainder vanishes leads to

$$(\nabla\lambda + \vec{\theta})\cdot\vec{\Sigma} = 0. \tag{53}$$

With the shift

$$\lambda \to \lambda - \Theta, \quad \Theta \equiv \vec{\theta} \cdot \vec{r} \equiv \theta^1 x + \theta^2 y + \theta^3 z \tag{54}$$

and the definition

$$\phi \equiv - v^3 \tag{55}$$

we therefore arrive at

$$\begin{aligned} A &= \lambda\alpha + \phi\beta - \Theta\alpha + \frac{L^3}{2}\beta - \frac{L^2}{2}\gamma + \frac{L^1}{2}\delta, \\ B &= \lambda\beta - \phi\alpha - \Theta\beta - \frac{L^3}{2}\alpha - \frac{L^1}{2}\gamma - \frac{L^2}{2}\delta, \\ C &= \lambda\gamma + \phi\delta - \Theta\gamma + \frac{L^2}{2}\alpha + \frac{L^1}{2}\beta - \frac{L^3}{2}\delta, \\ D &= \lambda\delta - \phi\gamma - \Theta\delta - \frac{L^1}{2}\alpha + \frac{L^2}{2}\beta + \frac{L^3}{2}\gamma, \end{aligned} \tag{56}$$

with

$$(\nabla\lambda) \cdot \vec{\Sigma} = 0. \tag{57}$$

Here λ and ϕ are scale and gauge transformations on (spinor) target space, whereas the remainder is the representation on spinor space of the infinitesimal base space symmetries.

However, there is a problem with the constraint (57). The constrained function λ is still algebraically independent of $\vec{\Sigma}$ (i.e., of the α, β, etc.), therefore the constraint does not contradict our basic assumptions. The problem is that the Lie algebra of all infinitesimal transformations does not close on the constraint (57). For example, the commutator of a target space scale transformation and a base space rotation about the z axis leads to another target space scale transformation which no longer obeys the constraint (57),

$$[v_\lambda, v_{l^3}] = v_{\tilde{\lambda}}, \quad (\nabla\tilde{\lambda}) \cdot \vec{\Sigma} \neq 0. \tag{58}$$

This is, in fact, not a surprise, because the gradient of the rotated scale function $\tilde{\lambda}$ must be perpendicular to the rotated vector $\vec{\tilde{\Sigma}}$, $(\nabla\tilde{\lambda}) \cdot \vec{\tilde{\Sigma}} = 0$, and analogously for other base space transformations.

Therefore, in order to have a closing Lie algebra of base space and target space transformations, we must restrict to constant target space scale transformations, $\lambda = \text{const}$.

However, as transformations with nonconstant λ obeying the constraint (57) map solutions of the Dirac equation to new solutions and are of some interest as such, one may instead choose another restriction by restricting to the target space transformations parametrized by λ and ϕ (i.e., by setting all base space transformation parameters equal to zero). The resulting Lie algebra is abelian and closes therefore trivially.

We still must calculate the coefficients F^x, F^y, F^z from the coefficients of the identity of Eqs. (42). After a lengthy calculation one obtains the simple result

$$\vec{F} = - (\Theta + \sigma)\vec{G} + \vec{L} \times \vec{G} - \nabla\phi - \frac{1}{|\vec{\Sigma}|}\vec{\Sigma} \times \nabla\lambda. \tag{59}$$

IV. MULTIPLE ZERO MODES

In this section, we would like to apply the results on symmetries of Sec. III to the issue of zero mode degeneracy (i.e., multiple solutions for a Dirac equation with the same gauge potential). We shall give a more general discussion in Sec. IV A, whereas we will provide some explicit, new examples of multiple zero modes in Sec. IV B.

A. General discussion

The condition that a target space symmetry transformation of a spinor does not change the gauge field is $\vec{F}=0$, see Eq. (59), or

$$\nabla\phi = -\frac{1}{|\vec{\Sigma}|}\vec{\Sigma}\times\nabla\lambda \tag{60}$$

which, together with condition (57), implies that $\vec{\Sigma}$, $\nabla\phi$, and $\nabla\lambda$ are mutually perpendicular. Further, Darboux's theorem tells us that (at least locally) we may express $\vec{\Sigma}$ like

$$\vec{\Sigma} = \nabla\xi^1\times\nabla\xi^2, \tag{61}$$

where $\xi^a=\xi^a(\mathbf{r})$, $a=1,2$. If we now assume that ϕ and λ are functions of ξ^a only, then their gradients are automatically perpendicular to $\vec{\Sigma}$, and it remains to solve

$$|\nabla\phi| = |\nabla\lambda|, \quad \nabla\phi\cdot\nabla\lambda = 0. \tag{62}$$

This problem can be solved relatively easily for a subclass of functions ξ^a which fulfill one additional requirement, namely that the scalar products of the gradients of the ξ^a can be expressed in terms of the ξ^a again, up to a *common* factor, that is

$$\nabla\xi^a\cdot\nabla\xi^b = h(\mathbf{r})g^{ab}(\xi^c). \tag{63}$$

Here g^{ab} plays the role of a metric in some two-dimensional space parametrized by the coordinates ξ^a. If Eq. (63) holds, then Eq. (60) simplifies to

$$\phi_a\tilde{\epsilon}^{ac} = g^{cb}\lambda_b, \tag{64}$$

where $\phi_a\equiv\partial_{\xi^a}\phi$, etc., and

$$\tilde{\epsilon}^{ab} = g^{1/2}\epsilon^{ab}, \quad g\equiv\det(g_{ab}) = g_{11}g_{22}-g_{12}g_{21}, \tag{65}$$

and ϵ^{ab} is the usual antisymmetric symbol in two dimensions. Equations (64) can be solved by observing that they just provide a generalization of the Cauchy–Riemann equations to the case of a general surface. We must only find the coordinate transformation from ξ'^a to some new coordinates ξ'^a such that the metric g'^{ab} with respect to the new coordinates is conformally equivalent to the flat metric δ^{ab}, that is

$$g'^{ab} \equiv \frac{\partial\xi'^a}{\partial\xi^c}\frac{\partial\xi'^b}{\partial\xi^d}g^{cd} = h(\xi')\delta^{cd}. \tag{66}$$

This problem always has a solution in two dimensions.[20] In terms of the coordinates ξ'^a, Eq. (64) reads

$$\phi_a\epsilon^{ac} = \delta^{cb}\lambda_b \tag{67}$$

which is just the Cauchy–Riemann equation. Therefore, our problem is solved by an arbitrary complex function u of the complex variable ζ', where

$$u(\zeta') = \exp(\lambda + i\phi), \quad \zeta' = \xi'^1 + i\xi'^2. \tag{68}$$

Here "solution" means that if a spinor Ψ with $\Psi^\dagger \vec{\sigma} \Psi \equiv \vec{\Sigma}$ solves a certain Dirac equation, then $u\Psi$ locally solves the same Dirac equation,

$$\mathcal{D}\Psi = 0 \Rightarrow \mathcal{D}u\Psi = 0. \tag{69}$$

Regularity requirements further restrict the allowed u. For instance, the functions ξ^a need not be well defined in all $\mathbb{R}^3$ (they usually are not), but u certainly must be well-defined (which may not be possible, in which case the problem has no acceptable solution). The condition that $u\Psi$ is square-integrable restricts to a finite number (which, again, may be zero) of linearly independent functions u. It should be emphasized that *all* known examples of multiple zero modes are of the above type (69), see Refs. 13–15. It is an interesting open question whether there exist other types, as well.

Finally, let us point out that the procedure described above can certainly be reversed. That is to say, choose a pair of functions ξ^a which obey Eq. (63) and calculate the corresponding ξ'^a via Eq. (66). Then $u\Psi$ with u given by Eq. (68) will provide additional local zero modes for a whole class of spinors Ψ with spin densities given by $\vec{\Sigma} = F(\xi^a)\nabla\xi^1 \times \nabla\xi^2$ for (almost) arbitrary real functions $F(\xi^a)$ (of course, F should be well defined in all $\mathbb{R}^3$). It is not difficult to reconstruct the spinor Ψ from the spin density $\vec{\Sigma}$ and the gauge potential $\vec{G}$ from the spinor Ψ (see, e.g., Ref. 2). We shall explicitly demonstrate how this works by constructing a class of multiple zero modes in the next section.

[*Remark:* Equations (62) can be expressed in terms of the complex variable $u = \exp(\lambda + i\phi)$ like

$$(\nabla u)^2 = 0 \tag{70}$$

which is the complex static eikonal equation. Further, condition (63) is equivalent to the condition that u—when interpreted as a map from one-point compactified $\mathbb{R}^3_0$ to one-point compactified $\mathbb{C}_0$—is a Riemannian submersion up to Weyl transformations (local conformal rescalings of the metric). That is to say, u is a composition of maps

$$u: \mathbb{R}^3_0 \overset{\text{W}}{\rightarrow} \mathcal{M}^3 \overset{\text{RS}}{\longrightarrow} \mathcal{N}^2 \overset{\text{W}}{\rightarrow} \mathbb{C}_0, \tag{71}$$

where W is a Weyl transformation, RS is a Riemannian submersion, and $\mathcal{M}^3$ and $\mathcal{N}^2$ are compact manifolds in three and two dimensions, respectively. A detailed discussion of these issues can be found in Ref. 21. In Ref. 15, Riemannian submersions were used to construct multiple zero modes within a more geometrical context.]

B. A class of multiple zero modes

Here we want to construct explicitly a class of multiple zero modes by starting with a pair of functions ξ^a which obey Eq. (63), as explained in the preceding section. In particular, we want to make use of the results of Ref. 21, where a class of Hopf maps obeying the eikonal equation (70) were found, and where the geometric explanation for their existence was provided. In concordance with these results, we therefore choose the functions

$$\xi^1 = \ln \sinh \eta \equiv \tfrac{1}{2} \ln T, \quad \xi^2 = m\vartheta + n\varphi, \tag{72}$$

where we introduced toroidal coordinates $(\eta, \vartheta, \varphi)$ (and, for later convenience, the variable $T \equiv \sinh^2 \eta$) related to the Cartesian coordinates (x, y, z) via

$$T \equiv \sinh^2 \eta = \frac{4(x^2+y^2)}{4z^2+(r^2-1)^2}, \quad \vartheta = \arctan \frac{2z}{r^2-1}, \quad \varphi = \arctan \frac{y}{x}. \tag{73}$$

Further, m and n are nonzero integers such that $\exp(2\pi i l \xi^2)$ is a single-valued function for integer l [the geometric significance of the integers m and n is that they provide the complex function (Hopf map) $f=\exp(\xi^1+i\xi^2)$ with the Hopf index $H=mn$].

Following the results of Ref. 21, it can be shown that the pair ξ^1, ξ^2 obeys Eq. (63), and that a new pair ξ'^1, ξ'^2 obeying Eq. (66) can be found without difficulty. Indeed, one finds easily that ξ^a obey Eq. (63) with

$$h(\mathbf{r}) = \frac{(\cosh \eta - \cos \vartheta)^2 \cosh^2 \eta}{\sinh^2 \eta}, \tag{74}$$

$$g^{11}=1, \quad g^{12}=g^{21}=0, \quad g^{22}=\frac{m^2 \sinh^2 \eta + n^2}{\cosh^2 \eta}. \tag{75}$$

Hence, the induced metric g^{ab} is already diagonal but not yet conformally flat. However, as g^{22} only depends on ξ^1 (i.e., on η), a coordinate transformation involving only ξ^1 is sufficient, $\xi^1 \rightarrow \xi'^1(\xi^1)$, $\xi'^2 \equiv \xi^2$, such that $g^{11} \rightarrow g'^{11}=g^{22} \equiv g'^{22}$. Explicitly, the transformation reads

$$\xi'^1 = \ln\left(\sinh^{|n|} \eta \, \frac{(|m|\cosh \eta + \sqrt{n^2+m^2 \sinh^2 \eta})^{|m|}}{(|n|\cosh \eta + \sqrt{n^2+m^2 \sinh^2 \eta})^{|n|}} \right), \tag{76}$$

see Ref. 21. The function $\zeta' = \xi'^1 + i\xi'^2$ itself is not single valued, but the function

$$\zeta \equiv \exp \zeta' = \exp(\xi'^1 + i\xi'^2) \tag{77}$$

is. It follows that for each spinor Ψ with spin density $\vec{\Sigma} \equiv \Psi^\dagger \vec{\sigma} \Psi = F(\xi^a) \nabla \xi^1 \times \nabla \xi^2$ (which is a formal zero mode for some gauge potential, because $\vec{\Sigma}$ obeys $\nabla \cdot \vec{\Sigma}=0$), $u(\zeta)\Psi$ are further formal zero modes for the same gauge potential, where u is a rational function of its argument. A customary basis for the functions u is $u=\zeta^l$ for integer l.

The formal zero modes described so far (implicitly via their spin density) are single-valued functions on all $\mathbb{R}^3$, but we have not yet taken into account the condition of square integrability. Before doing so, we want to make some simplifying assumptions on the type of spin density we want to discuss. First, we assume that the function F depends on ξ^1 (i.e., on η or T) only. Second, we reexpress F like $F=e^M[4T/(1+T)^2]$, where the function of $M(T)$ will be specified below, that is, we write for a general spin density

$$\vec{\Sigma}^{(M)} = e^{M(T)} \vec{\Sigma}^{(0)}, \quad \vec{\Sigma}^{(0)} = \frac{4T}{(1+T)^2} \nabla \xi^1 \times \nabla \xi^2. \tag{78}$$

The reason for this is that $\vec{\Sigma}^{(0)}$ is a well behaved and integrable spin density, whereas $\nabla \xi^1 \times \nabla \xi^2$ is not (clearly, integrability of the spin density $\int d^3\mathbf{r} |\vec{\Sigma}| < \infty$ is the same as square integrability of the corresponding spinor). Another reason for the choice of $\vec{\Sigma}^{(0)}$, which does not concern us much here, is the fact that $\vec{\Sigma}^{(0)}$ is the Hopf curvature for the Hopf map $\exp(\xi^1+i\xi^2)$. In Cartesian coordinates, $\vec{\Sigma}^{(0)}$ reads

$$\vec{\Sigma}^{(0)} = \frac{16}{(1+r^2)^3} \begin{pmatrix} 2nxz - 2my \\ 2nyz + 2mx \\ n(1-r^2+2z^2) \end{pmatrix} \tag{79}$$

and its spinor $\Psi^{(0)}$ with $\vec{\Sigma}^{(0)} = \Psi^{(0)\dagger} \vec{\sigma} \Psi^{(0)}$ is

$$\Psi^{(0)} = \frac{2\sqrt{2}}{(1+r^2)^{3/2}\sqrt{(1+r^2)\Gamma + n(2z^2+1-r^2)}} \tag{80}$$

$$\times \begin{pmatrix} n(2z^2+1-r^2) + (1+r^2)\Gamma \\ 2(x+iy)(nz+im) \end{pmatrix}, \tag{81}$$

where

$$\Gamma := \left(\frac{n^2 + m^2 T}{1+T}\right)^{1/2} = \left(\frac{n^2 + m^2 \sinh^2 \eta}{\cosh^2 \eta}\right)^{1/2} \tag{82}$$

and we choose the gauge such that the upper component is real. The calculation of the spinor $\Psi^{(0)}$ from the spin density $\vec{\Sigma}^{(0)}$ is explained in Appendix B. The spinor (81) is regular everywhere. Further, it is a zero mode for some gauge potential $\vec{G}^{(0)}$, by construction (this gauge potential is well behaving and leads to a square-integrable magnetic field $\vec{H}^{(0)} = \nabla \times G^{(0)}$; its explicit expression, which is quite lengthy, is displayed in Appendix B, together with an explanation of its calculation). Additional formal zero modes $\zeta^l \Psi^{(0)}$ for the same gauge potential are not square integrable, i.e., the corresponding spin density $|\zeta^* \zeta|^l \vec{\Sigma}^{(0)}$ is not integrable (for either positive or negative integer l), as may be inferred easily from the explicit expression for $\vec{\Sigma}^{(0)}$ and from the limiting behavior,

$$\lim_{T\to 0} |\zeta^* \zeta| \sim T^{|n|}, \quad \lim_{T\to\infty} |\zeta^* \zeta| \sim T^{|m|}. \tag{83}$$

But with an appropriate choice of M, it is easy to find spin densities $\vec{\Sigma}^{(M)}$ such that $|\zeta^* \zeta|^l \vec{\Sigma}^{(M)}$ remains integrable for some nonzero values of l.

Concretely, we assume that $M(T)$ and $M'(T)$ are finite for all finite values of T, i.e.,

$$|M(T)| < \infty \ \wedge \ |M'(T)| < \infty \quad \text{for } T < \infty, \tag{84}$$

and that M behaves for large T like

$$\lim_{T\to\infty} M(T) \sim -mk \ln T + \overline{M}(T), \tag{85}$$

where k is a postive integer and the remainder $\overline{M}$ must obey

$$\lim_{T\to\infty} |T\overline{M}(T)| < \infty. \tag{86}$$

Here the conditions (84) and (86) are chosen in order to avoid both spurious (i.e., pure gauge) and physical singularities for the corresponding gauge potential, and condition (85) is chosen in order to have a nontrivial result (i.e., multiple square-integrable zero modes). Condition (85) induces a spurious (gauge) singularity in the corresponding gauge potential at $T=\infty$ which must be cured by an appropriate gauge fixing. Consequently, the spinor $\Psi^{(M)}$ for the spin density $\vec{\Sigma}^{(M)}$ with the appropriate gauge fixing is

$$\Psi^{(M)} := e^{M/2} e^{ikm\vartheta} \Psi^{(0)}, \tag{87}$$

where the additional factor $\exp(ikm\vartheta)$ provides the gauge fixing, see below. Under the above assumptions the spinors

$$\Psi_l^{(M)} = \zeta^l \Psi^{(M)}, \quad l = 0, \ldots, k \tag{88}$$

are all square-integrable zero modes for the same gauge potential $\vec{G}^{(M)}$.

It remains to determine $\vec{G}^{(M)}$ explicitly, which will be obtained with Eq. (59) of Sec. III. In fact, using Eq. (59) [where $M/2 \sim \lambda$ and $km\vartheta \sim \phi$; remember that Eq. (59) also holds for finite λ and ϕ because of the abelian nature of the target space symmetry transformations] one easily calculates

$$\vec{G}^{(M)} = \vec{G}^{(0)} - \frac{M'T}{\Gamma}(m\nabla\vartheta + n\nabla\varphi) - mk\nabla\vartheta \tag{89}$$

(as said, the expression for $\vec{G}^{(0)}$ is provided in Appendix B). Here the additional pure gauge term precisely cancels a pure gauge singularity at $T=\infty$, as may be checked easily. Further, we may see how it works that multiplication of the spinor $\Psi^{(M)}$ by ζ does not change the gauge potential. The crucial point is that multiplication by ζ corresponds to choosing $M=|\zeta^*\zeta|$, and for this M it holds that $M'T/\Gamma=-1$, so that the M dependent term in (89) is, in fact, pure gauge and is cancelled by the contribution $\nabla \arg\zeta = \nabla\xi^2$, see (72). This just shows explicitly that $M/2 \equiv \xi'^1 \sim \lambda$ and $\xi^2 \sim \phi$ fulfill Eq. (60) which, of course, must be true by construction.

Therefore, we have succeeded in constructing explicitly a class of multiple zero modes together with their gauge potentials starting from the functions (72) (or, equivalently, starting from the higher toroidal Hopf maps of Ref. 21). For the simplest Hopf map (i.e., for $m=n=1$) these zero modes have already been obtained in Refs. 13–15, whereas for the higher toroidal Hopf maps they are new.

APPENDIX A

The coefficients for the prolongation $\mathrm{pr}\, v$ of the vector field v in Sec. II are

$$R^x = D_x R - \rho_x D_x X - \rho_y D_x Y, \tag{A1}$$

$$R^y = D_y R - \rho_x D_y X - \rho_y D_y Y, \tag{A2}$$

$$L^x = D_x L - \lambda_x D_x X - \lambda_y D_x Y, \tag{A3}$$

$$L^y = D_y L - \lambda_x D_y X - \lambda_y D_y Y, \tag{A4}$$

where D_x and D_y are total derivatives with respect to x and y, respectively. Explicitly, R^x reads

$$\begin{aligned} R^x = {} & R_x + R_\rho\rho_x + R_\lambda\lambda_x + R_{G^x}G^x_x + R_{G^y}G^y_x - \rho_x(X_x + X_\rho\rho_x + X_\lambda\lambda_x + X_{G^x}G^x_x + X_{G^y}G^y_x) \\ & - \rho_y(Y_x + Y_\rho\rho_x + Y_\lambda\lambda_x + Y_{G^x}G^x_x + Y_{G^y}G^y_x) \end{aligned} \tag{A5}$$

and analogously for the other coefficients.

APPENDIX B

The calculation of the spinor $\Psi^{(0)}$ from the spin density $\vec{\Sigma}^{(0)}$ proceeds as follows. For a gauge such that the upper component of the spinor is real, a spinor Ψ may be obtained from its spin density $\vec{\Sigma}$ formally by the algebraic relation, see Ref. 2,

$$\Psi = \frac{1}{\sqrt{2(|\vec{\Sigma}| + \Sigma^3)}} \begin{pmatrix} |\vec{\Sigma}| + \Sigma^3 \\ \Sigma^1 + i\Sigma^2 \end{pmatrix}. \tag{B1}$$

This gauge is globally admissible provided that the third component of $\vec{\Sigma}$ is positive whenever its first and second component are zero, i.e.,

$$\Sigma^1 = 0 \ \wedge \ \Sigma^2 = 0 \ \Rightarrow \ \Sigma^3 > 0 \tag{B2}$$

which holds for the spin density $\vec{\Sigma}^{(0)}$ of Eq. (79). Therefore, the spinor $\Psi^{(0)}$ of Eq. (80) may be computed with the help of the above expression.

The calculation of the gauge potential $\vec{G}^{(0)}$ for the spinor (zero mode) $\Psi^{(0)}$ proceeds as follows. Remember that once a zero mode Ψ is given, the Dirac equation may be viewed as an overconstrained system of linear, algebraic equations for the three components of the gauge potential. If the constraint is fulfilled, this system can be solved explicitly and results in the following expression for the corresponding gauge potential $\vec{G}$, see Ref. 2:

$$\vec{G} = \frac{1}{2|\vec{\Sigma}|}(\nabla \times \vec{\Sigma} + 2\,\mathrm{Im}(\Psi^\dagger \nabla \Psi)). \tag{B3}$$

Inserting the explicit expression for $\Psi^{(0)}$ into the above formula leads to the following rather lengthy expression for $\vec{G}^{(0)}$:

$$\vec{G}^{(0)} = \frac{1}{\Gamma(1+r^2)^2} \begin{pmatrix} -n(5-r^2)y + 6mxz \\ n(5-r^2)x + 6myz \\ m(6z^2 + 2 - 4r^2) \end{pmatrix} + \frac{2}{\Gamma(1+r^2)[\Gamma(1+r^2) + n(2z^2 + 1 - r^2)]} \begin{pmatrix} -(n^2z^2 + m^2)y \\ (n^2z^2 + m^2)x \\ mn(r^2 - z^2) \end{pmatrix} \tag{B4}$$

[for a direct comparison with the results of Refs. 13 and 14 for the case $m=n=1$, one must take into account the fact that the gauge chosen in Refs. 13 and 14 differs from the one chosen here by the gauge function $\phi = \arctan(z)$]. Further, Eq. (B3) shows that $\vec{G}$ is singular whenever $|\vec{\Sigma}|$ is zero. This singularity may be a spurious (gauge) singularity, in which case it can be cured by an appropriate gauge fixing as in Eq. (89), or it may be physical, in which case the corresponding zero mode is not admissible (of course, all the zero modes given in Sec. IV B are admissible).

The Kähler potential of Abelian Higgs vortices

Heng-Yu Chen[a] and N. S. Manton[b]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge,, Wilberforce Road, Cambridge CB3 0WA, United Kingdom

(Received 16 August 2004; accepted 23 November 2004; published online 12 April 2005)

We calculate the Kähler potential for the Samols metric on the moduli space of Abelian Higgs vortices on $\mathbb{R}_2$, in two different ways. The first uses a scaling argument. The second depends on a variant of the relationship between accessory parameters and the regularized action in Liouville field theory. The Kähler potential on the moduli space of vortices on $\mathbb{H}_2$ is also derived, and we are led to a geometrical reinterpretation of these vortices. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1874334]

I. INTRODUCTION

The $(2+1)$-dimensional Abelian Higgs model, with Lagrangian density

$$\mathcal{L} = -\frac{1}{4}F^{\mu\nu}F_{\mu\nu} + \frac{1}{2}\overline{D_\mu\Phi}D^\mu\Phi - \frac{\lambda}{8}(|\Phi|^2-1)^2, \tag{1.1}$$

is known to have static and moving vortex solutions.[1,2] The static solutions are the field configurations minimizing the potential energy functional. When the coupling constant λ takes the critical value of 1, there are no net forces between the vortices, and they satisfy first-order Bogomolny equations [see (2.3) and (2.4)). Static N-vortex solutions in $\mathbb{R}^2$ or equivalently the complex plane $\mathcal{C}$ are uniquely characterized by the N unordered, and not necessarily distinct points $\{Z_1,\ldots,Z_N\}$ in $\mathcal{C}$ where the Higgs field Φ vanishes. As a manifold, the moduli space $\mathcal{M}_N$ of solutions is therefore $\mathcal{C}^N$, with the fundamental symmetrized polynomials in $\{Z_1,\ldots,Z_N\}$ as coordinates. In practice, these are awkward to deal with, and it is more convenient to treat the vortex positions $\{Z_1,\ldots,Z_N\}$ as local coordinates on moduli space, which is justified when they are distinct. This is what we shall do in this paper. Vortex coalescence may be investigated by a limiting procedure.

The so-called "moduli space approximation" is a powerful approach for studying the low-energy dynamics of N solitonic objects in field theories with Bogomolny equations.[3] The idea is that, in the low-energy limit, most of the field degrees of freedom are effectively frozen, and the field approximately follows a trajectory in moduli space. The field is at each instant a static solution of the Bogomolny equations, but with moduli that are time dependent. The kinetic terms in the field theory Lagrangian restrict to a kinetic energy expression for trajectories in moduli space. For N vortices, the resulting quadratic form on tangent vectors to $\mathcal{M}_N$ defines the Samols metric on $\mathcal{M}_N$.[4] The field potential energy in the N-vortex sector takes its minimal, constant value on $\mathcal{M}_N$, and can be neglected, so the dynamical trajectories are the geodesics on $\mathcal{M}_N$. These accurately model the scattering of vortices.[5]

Samols found a general, but not explicit, formula for the metric on $\mathcal{M}_N$, and using this, showed that the metric is Kähler.[4] The metric is smooth and complete, but not flat. The most interesting geodesic describes a head-on collision, where two vortices scatter through a right angle. Recently, an explicit formula in terms of modified Bessel functions was given for N

[a]Electronic mail: H.Y.Chen@damtp.cam.ac.uk
[b]Electronic mail: N.S.Manton@damtp.cam.ac.uk

well-separated vortices, and a formula for the Kähler potential was also found.[6] Our main purpose in this paper is to construct a Kähler potential $\mathcal{K}$ for the Samols metric with vortices at arbitrary separation.

We present two different approaches to calculating $\mathcal{K}$. The first is to explicitly construct it from the quantities in Samols' metric. This reduces to a $\overline{\partial}$ problem, which can be solved here by a scaling argument. The second approach is inspired by the relationship between the so-called "accessory parameters" in the context of uniformization of Riemann surfaces, and a regularized Liouville action. This relationship was first conjectured by Polyakov and later proved by Takhtajan and Zograf,[7] and an accessible recent account with a simplified proof can be found in Ref. 8. Similar results on Riemann surfaces with a range of singularities have also been investigated in Refs. 9 and 10. It turns out that in the vortex situation, there are analogous quantities to the accessory parameters, and we can construct a modification of the regularized Liouville action as their generating function. This regularized action is the interacting part of the Kähler potential on $\mathcal{M}_N$.

Also interesting is the Abelian Higgs model for vortices defined on the hyperbolic plane $\mathbb{H}^2$ with Ricci scalar -1. Such vortices were shown to be integrable by Witten,[11] as the Bogomolny equations in this case reduce to the Liouville equation. The metric on the moduli space of N hyperbolic vortices was first derived and shown to be Kähler by Strachan.[12] We construct the Kähler potential and also uncover a new geometrical interpretation of the Higgs field.

This paper is organized as follows: In Sec. II, we briefly review Abelian Higgs vortices in $\mathbb{R}^2$, and the Samols metric on $\mathcal{M}_N$. In Sec. III, a general formula for the Kähler potential on $\mathcal{M}_N$ is derived using the scaling argument. In Sec. IV, we review the regularized action of Liouville field theory and the results of Takhtajan and Zograf, and show how the interacting part of the Kähler potential on $\mathcal{M}_N$ can be constructed from an analogous action. In Sec. V, we discuss vortices in the hyperbolic plane, present the geometrical interpretation of the Higgs field, and show that in this case the regularized Liouville action is the entire Kähler potential. In Sec. VI we summarize our results.

II. ABELIAN HIGGS VORTICES

At critical coupling, $\lambda=1$, the field potential energy in the Abelian Higgs model is

$$E=\frac{1}{2}\int d^2x\left\{F_{12}^2+\overline{D_i\Phi}D_i\Phi+\frac{1}{4}(|\Phi|^2-1)^2\right\}, \tag{2.1}$$

where $F_{12}=\partial_1A_2-\partial_2A_1=B$ is the magnetic field in the plane and $D_j\Phi=\partial_j\Phi-iA_j\Phi$, $j=1,2$, is the covariant derivative of the complex Higgs field Φ. The boundary conditions are that $|\Phi|\to 1$ as $|\mathbf{x}|\to\infty$, so Φ becomes pure phase, and the gauge field becomes pure gauge at spatial infinity, such that F_{12} and $D_j\Phi$ vanish. The winding number of Φ at infinity is denoted by N, and is assumed to be a positive integer.

We can rearrange E into the Bogomolny form by completing the square

$$E=\frac{1}{2}\int d^2x\left\{\left(F_{12}+\frac{1}{2}(|\Phi|^2-1)\right)^2+(\overline{D_1\Phi}-i\overline{D_2\Phi})(D_1\Phi+iD_2\Phi)+F_{12}\right\}, \tag{2.2}$$

and discarding boundary terms that vanish at spatial infinity. As the first two terms in (2.2) are both non-negative, the minimal value of E is obtained when A_i and Φ satisfy the Bogomolny equations

$$F_{12}+\frac{1}{2}(|\Phi|^2-1)=0, \tag{2.3}$$

$$D_1\Phi+iD_2\Phi=0. \tag{2.4}$$

E is then related to the winding number through Stokes' theorem,

$$E = \frac{1}{2}\int d^2x\, F_{12} = N\pi, \tag{2.5}$$

and it can be interpreted as the energy of N vortices with no static interactions.

Let us rewrite (2.3) and (2.4) in terms of the complex coordinate $z = x^1 + ix^2$,

$$iF_{z\bar{z}} = \frac{1}{4}(|\Phi|^2 - 1), \tag{2.6}$$

$$D_{\bar{z}}\Phi = \partial_{\bar{z}}\Phi - iA_{\bar{z}}\Phi = 0. \tag{2.7}$$

Equation (2.7) is solved by $A_{\bar{z}} = -i\partial_{\bar{z}}\log\Phi$. Next express Φ in terms of a gauge-invariant quantity h and a phase factor χ as $\Phi = e^{(1/2)h+i\chi}$, where $h \to 0$ as $|\mathbf{x}| \to \infty$. Substituting these into (2.6), we obtain the gauge-invariant, Taubes equation for the vortices[1]

$$4\partial_z\partial_{\bar{z}}h - e^h + 1 = 4\pi\sum_{r=1}^{N}\delta(z - Z_r), \tag{2.8}$$

where $\{Z_1, \ldots, Z_N\}$ are the vortex positions in $\mathcal{C}$. Here, these positions are taken as distinct, simple zeros of Φ, which fixes the strength of the δ functions, although the zeros can coalesce. There is a unique solution for any choice of positions, as proved by Jaffe and Taubes.[1] Therefore, on a large stratum of the moduli space $\mathcal{M}_N$ of N-vortex solutions, $\{Z_1, \ldots, Z_N\}$ are good local coordinates. Notice that (2.8) has a form very similar to the Liouville equation on a punctured Riemann surface. However, the constant 1 in (2.8), the Higgs vacuum expectation value, sets the scale for the system, and breaks conformal invariance.

Close to the rth vortex position Z_r, h has the following expansion:

$$h = \log|z - Z_r|^2 + a_r + \frac{1}{2}\bar{b}_r(z - Z_r) + \frac{1}{2}b_r(\bar{z} - \bar{Z}_r) + \bar{c}_r(z - Z_r)^2 - \frac{1}{4}|z - Z_r|^2 + c_r(\bar{z} - \bar{Z}_r)^2 + \cdots. \tag{2.9}$$

The expansion coefficients a_r, b_r, $\bar{b}_r$, c_r, and $\bar{c}_r$ are functions of the separations between Z_r and all other vortex positions Z_s, $s \neq r$. The coefficient a_r plays the role of a local scaling factor. b_r and $\bar{b}_r$ measure the deviation from circular symmetry of h around Z_r due to the overlap with the other vortices.

Starting from the field kinetic energy in the Abelian Higgs model, Samols showed that b_r and $\bar{b}_r$ determine the metric G on the moduli space, the formula being[4]

$$G = \sum_{r,s=1}^{N}\left(\delta_{rs} + 2\frac{\partial b_s}{\partial Z_r}\right)dZ_r\, d\bar{Z}_s. \tag{2.10}$$

The δ_{rs} term gives a flat, noninteracting metric, and the remaining term, which decays exponentially as the vortices separate, leads to dynamical vortex interactions in the moduli space approximation. Although the coefficients of G become singular as the vortices coalesce, these singularities can be removed by a change of coordinates, and the metric is smooth and complete. The reality of the field kinetic energy implies that the metric is Hermitian, so

$$\frac{\partial b_s}{\partial Z_r} = \frac{\partial \bar{b}_r}{\partial \bar{Z}_s}. \tag{2.11}$$

From this it follows that the metric is Kähler, and there is therefore a Kähler potential $\mathcal{K}$ related to the metric coefficients by

$$\frac{\partial^2 \mathcal{K}}{\partial Z_r \, \partial \overline{Z}_s} = \delta_{rs} + 2\frac{\partial b_s}{\partial Z_r}. \tag{2.12}$$

In addition, b_r has been shown to obey a symmetric identitity,[13]

$$\frac{\partial b_r}{\partial \overline{Z}_s} = \frac{\partial b_s}{\partial \overline{Z}_r}. \tag{2.13}$$

Both (2.11) and (2.13) have recently been proved directly, as symmetry properties of the Green's function of the linearized Taubes equation (see Ref. 2 p. 209). The Kähler property and translational invariance imply that $\Sigma_{r=1}^N b_r = \Sigma_{r=1}^N \overline{b}_r = 0$, and rotational invariance implies that $\Sigma_{r=1}^N Z_r \overline{b}_r$ is real.[14]

III. THE VORTEX KÄHLER POTENTIAL AND THE SCALING INTEGRAL

We seek a real function $\widetilde{\mathcal{K}}$ of the coordinates $\{Z_1, \ldots, Z_N; \overline{Z}_1, \ldots, \overline{Z}_N\}$ such that

$$\frac{\partial \widetilde{\mathcal{K}}}{\partial \overline{Z}_r} = 2b_r, \quad \frac{\partial \widetilde{\mathcal{K}}}{\partial Z_r} = 2\overline{b}_r. \tag{3.1}$$

Given $\widetilde{\mathcal{K}}$, the identities (2.11) and (2.13) trivially follow. $\widetilde{\mathcal{K}}$ is a Kähler potential for the interacting part of the metric. The first of Eqs. (3.1) is a $\overline{\partial}$ problem, and the second its conjugate. We do not solve these equations separately, but consider the following linear combination:

$$\sum_{r=1}^N \left\{ Z_r \frac{\partial}{\partial Z_r} + \overline{Z}_r \frac{\partial}{\partial \overline{Z}_r} \right\} \widetilde{\mathcal{K}} = 2 \sum_{r=1}^N \{ Z_r \overline{b}_r + \overline{Z}_r b_r \}. \tag{3.2}$$

On the left-hand side we have the overall scaling operator on the vortex moduli space acting on $\widetilde{\mathcal{K}}$.

We make the ansatz that all Z_r are parametrized by a single scale variable τ, i.e., $Z_r(\tau) = Z_r \tau$. We can then express the overall scaling operator in terms of τ,

$$\tau \frac{d}{d\tau} \widetilde{\mathcal{K}} = \sum_{r=1}^N \left\{ Z_r(\tau) \frac{\partial}{\partial Z_r(\tau)} + \overline{Z}_r(\tau) \frac{\partial}{\partial \overline{Z}_r(\tau)} \right\} \widetilde{\mathcal{K}}. \tag{3.3}$$

Combining this with (3.2), and integrating, we find

$$\widetilde{K} = 2 \int_\infty^1 \frac{d\tau}{\tau} \sum_{r=1}^N \left(Z_r(\tau) \overline{b}_r(\tau) + \overline{Z}_r(\tau) b_r(\tau) \right). \tag{3.4}$$

$b_r(\tau)$ are the expansion parameters b_r in (2.9) when the vortices are at $Z_r(\tau)$.

In an analysis of a model of first-order vortex dynamics,[15] it was shown that some conserved quantities can be expressed in terms of integrals involving h and its derivatives. The integral of h itself, which remains finite despite the logarithmic divergences of h, was also computed by using a Pohozaev hozaev identity. For N noncoincident vortices

$$\int_{\mathcal{C}} d^2x \, h = -\pi \sum_{r=1}^N (Z_r \overline{b}_r + \overline{Z}_r b_r + 6). \tag{3.5}$$

This result combined with (3.4) gives the rather interesting expression

$$\tilde{\mathcal{K}} = -2\int_{\infty}^{1}\frac{d\tau}{\tau}\left\{\frac{1}{\pi}\int d^2x\, h(\mathbf{x};\tau) + 6N\right\}. \tag{3.6}$$

Here, $h(\mathbf{x};\tau)$ denotes $h(\mathbf{x})$ with the vortices at $Z_r(\tau)$. The entire Kähler potential by this scaling argument is therefore

$$\mathcal{K} = \sum_{r=1}^{N} Z_r\overline{Z_r} - 2\int_{\infty}^{1}\frac{d\tau}{\tau}\left\{\frac{1}{\pi}\int d^2x\, h(\mathbf{x};\tau) + 6N\right\}, \tag{3.7}$$

where the first term gives the δ_{rs} in Samols' metric (2.10). With a suitable change of coordinates, this reduces to the expression given in Ref. 16 for the case of $N=2$.

As a simple test, we consider two well-separated vortices. We work in the center of mass frame, and use the asymptotic b_r values as calculated in Ref. 6. Using the notation $Z_1=\sigma e^{i\theta}=-Z_2$ and $b_1=b(\sigma)e^{i\theta}=-b_2$, where σ is the separation from the origin, we have $\Sigma_{r=1}^{2}\{Z_r\overline{b_r}+\overline{Z_r}b_r\}=4\sigma b(\sigma)$. $b(\sigma)$ equals $\sqrt{32}K_1(2\sigma)$ for large σ, where the prefactor derives from a string duality argument of Tong.[17] Calculating the integral (3.4), and adding the flat term, gives the asymptotic Kähler potential,

$$\mathcal{K} = 2\sigma^2 - 8\sqrt{8}K_0(2\sigma), \tag{3.8}$$

which coincides with the formula in Ref. 6 (after a change in normalization convention). K_0, K_1 are the modified Bessel functions of the second kind, and we have used Bessel function identities in deriving (3.8).

IV. REGULARIZED LIOUVILLE ACTION AND VORTEX KÄHLER POTENTIAL

In this section we present a different approach to solving the equations (3.1). We show that $\tilde{\mathcal{K}}$ is a suitably regularized modified Liouville action, whose variational equation is the Taubes equation (2.8). Our motivation came from the striking similarity of $\overline{b_r}$ to the accessory parameters in the Liouville field theory. We first review the relevant aspects of Liouville theory, following Ref. 8.

Consider a Liouville field ϕ, satisfying

$$\partial_z\partial_{\bar{z}}\phi = \frac{1}{2}e^{\phi}, \tag{4.1}$$

and defined over an n-punctured Riemann sphere, $\Sigma\cong\hat{\mathcal{C}}/\{z_1,z_2,\ldots,z_n\}$, $\hat{\mathcal{C}}=\mathcal{C}\cup\{\infty\}$, where $z_{n-2}=0$, $z_{n-1}=1$, $z_n=\infty$ and $n\geqslant 3$. Assume the punctures are parabolic singularities, where ϕ has asymptotic behavior,

$$\phi = \begin{cases} -2\log|z-z_r| - 2\log|\log|z-z_r|| + O(1), & \text{as } z\to z_r, \quad r\neq n, \\ -2\log|z| - 2\log\log|z| + O(1), & \text{as } z\to z_n=\infty. \end{cases} \tag{4.2}$$

The Liouville equation (4.1) implies that the Poincaré metric $ds^2=e^{\phi}\,dz\,d\bar{z}$ on Σ has constant Ricci scalar $R_\Sigma=-2$. (The Gaussian curvature is half this.)

The zz component of the energy–momentum tensor for ϕ is defined by

$$T_\phi(z) = \partial_z\partial_z\phi - \frac{1}{2}(\partial_z\phi)^2, \tag{4.3}$$

and the Liouville equation implies that $T_\phi(z)$ is a meromorphic function, $\partial_{\bar{z}}T_\phi(z)=0$. For the punctured sphere with parabolic singularities, $T_\phi(z)$ is given by the finite sum

$$T_\phi(z) = \sum_{r=1}^{n-1} \left\{ \frac{1}{2(z-z_r)^2} + \frac{c_r}{(z-z_r)} \right\}, \tag{4.4}$$

and has the expansion around $z=\infty$,

$$T_\phi(z) \sim \frac{1}{2z^2} + \frac{c_n}{z^3} + O\left(\frac{1}{z^4}\right). \tag{4.5}$$

The coefficient of each term $1/(z-z_r)^2$, $r=1,\ldots,n-1$ and also of $1/z^2$ for $z_n=\infty$, is half the conformal weight, so each parabolic singularity z_r has conformal weight 1. The complex constants c_r, $r=1,\ldots,n$, are the accessory parameters. They are uniquely determined by the positions of the punctures $z_1,\ldots,z_n$. Matching the first expression with the second expression for $T_\phi(z)$ as $z\to\infty$, gives the constraints

$$\sum_{r=1}^{n-1} c_r = 0, \quad \sum_{r=1}^{n-1} c_r z_r = 1 - \frac{n}{2}, \quad \sum_{r=1}^{n-1} (z_r + c_r z_r^2) = c_n. \tag{4.6}$$

Polyakov conjectured, and Takhtajan and Zograf then proved,[7,8] that for a Riemann sphere with n punctures, a suitably regularized Liouville action evaluated at the classical solution is the generating function for c_r, i.e.,

$$c_r = -\frac{1}{2\pi}\frac{\partial S_{\rm cl}}{\partial z_r}, \quad r=1,\ldots,n-3. \tag{4.7}$$

The regularized Liouville action is

$$S_{\rm cl} = \lim_{\epsilon\to 0}\left\{ \frac{i}{2}\int_{\Sigma_\epsilon} dz\wedge d\bar{z}(\partial_z\phi\,\partial_{\bar z}\phi + e^\phi) + 2\pi(n\log\epsilon + 2(n-2)\log|\log\epsilon|) \right\}, \tag{4.8}$$

where $(i/2)dz\wedge d\bar{z} = dx^1\wedge dx^2$, and the integration region is $\Sigma_\epsilon = \mathcal{C}/(\{\cup_{r=1}^{n-1}|z-z_r|<\epsilon\}\cup\{|z|>1/\epsilon\})$, whose boundaries are a circle near ∞ and infinitesimal circles around the punctures.

We now turn to the Taubes equation (2.8) for N vortices in $\mathcal{C}$. Define, by analogy with the Liouville field, $T_h = \partial_z\partial_z h - \frac{1}{2}(\partial_z h)^2$. Using the expansion of h around each vortex center (2.9), we have

$$T_h = T_h(z,\bar z) = \sum_{r=1}^{N}\left\{ -\frac{3}{2(z-Z_r)^2} - \frac{\bar{b_r}}{2(z-Z_r)} \right\} + O(1), \tag{4.9}$$

where the $O(1)$ terms are not all holomorphic. The conformal weight is -3 at each point Z_r, and we may identify $-\bar{b_r}/2$ as the accessory parameter at Z_r. Notice that the constraints $\Sigma_{r=1}^N \bar{b_r}=0$ and $\Sigma_{r=1}^N Z_r\bar{b_r}$ are real, and look remarkably similar to the first two constraints (4.6). If we consider the Poincaré-type metric $ds^2 = e^h\,dz\,d\bar z$, then each vortex corresponds to a conical singularity of deficit angle -2π. For the Liouville equation on Σ, it would not be possible for the conformal weight at each singularity to be negative, but for the Taubes equation with our boundary conditions, it is.

We now show that the regularized action for h is the generating function for $\bar{b_r}$. The unregularized action for h, whose formal variation gives Taubes' equation, is

$$S_h = \frac{i}{2\pi}\int_{\tilde{\mathcal{C}}} dz\wedge d\bar z(2\,\partial_z h\,\partial_{\bar z}h + e^h - h - 1), \tag{4.10}$$

where the integration region $\tilde{\mathcal{C}}$ is $\mathcal{C}$ with N small disks of radius ϵ centered at the vortex locations $\{Z_1,\ldots,Z_N\}$ being punctured out, and the limit $\epsilon\to 0$ taken. As the integrals of h and e^h-1 are known to be finite as $\epsilon\to 0$, the only singular term in the integral comes from $\partial_z h\,\partial_{\bar z}h$, which gives a contribution of $-4N\log\epsilon + O(1)$. This $\log\epsilon$ term needs to be removed. We also require of a

regularized action that at a classical solution, i.e., h satisfying the Taubes equation (2.8), the action should be stationary against variations δh. Now, the variation of S_h only comes from boundary contributions, as other terms can be eliminated by using (2.8), so we have

$$\delta S_h = \frac{i}{2\pi}\int_{\tilde{C}} dz \wedge d\bar{z}\big(2\partial_z(\delta h\, \partial_{\bar{z}} h) + 2\partial_{\bar{z}}(\delta h\, \partial_z h)\big) = -\frac{i}{2\pi}\sum_{r=1}^{N}\left\{2\int_{\gamma_r} d\bar{z}\, \delta h\, \partial_{\bar{z}} h - 2\int_{\gamma_r} dz\, \delta h\, \partial_z h\right\}, \tag{4.11}$$

where γ_r is the small circle of radius ϵ centered at Z_r. We allow δh to be as general as possible, but keep the vortex centers $\{Z_1, \ldots, Z_N\}$ fixed, and restrict the leading-order behavior of h around Z_r to remain $h = \log|z - Z_r|^2$, because the Higgs field Φ would acquire a branch point at Z_r if the power dependence varied. So near Z_r,

$$\delta h = \delta a_r + \frac{1}{2}\delta\bar{b}_r(z - Z_r) + \frac{1}{2}\delta b_r(\bar{z} - \bar{Z}_r) + O(\epsilon^2). \tag{4.12}$$

Substituting (4.12) into (4.11), we find that $\delta S_h = -4\Sigma_{r=1}^{N}\, \delta a_r$ by a similar calculation to those in Ref. 15. This variation can be cancelled by adding a term $4\Sigma_{r=1}^{N} a_r$ to S_h. So combined with the additional $\log \epsilon$ term, we obtain the regularized action

$$S_h^{\text{reg.}} = \lim_{\epsilon\to 0}\left\{\frac{i}{2\pi}\int_{\tilde{C}} dz \wedge d\bar{z}(2\,\partial_z h\, \partial_{\bar{z}} h + e^h - h - 1) + 4\sum_{r=1}^{N} a_r + 4N\log\epsilon\right\}, \tag{4.13}$$

which is finite, and stationary for solutions of the Taubes equation.

From now on, only consider $S_h^{\text{reg.}}$ evaluated at the classical solutions, and hence a function of $\{Z_1, \ldots, Z_N; \bar{Z}_1, \ldots, \bar{Z}_N\}$. Then

$$\frac{\partial S_h^{\text{reg.}}}{\partial Z_s} = \frac{i}{2\pi}\int_{\tilde{C}} dz \wedge d\bar{z}\frac{\partial}{\partial Z_s}(2\,\partial_z h\, \partial_{\bar{z}} h + e^h - h - 1) + 4\sum_{r=1}^{N}\frac{\partial a_r}{\partial Z_s} - \frac{i}{2\pi}\int_{\gamma_s} d\bar{z}(2\,\partial_z h\, \partial_{\bar{z}} h + e^h - h - 1). \tag{4.14}$$

The contribution on the second line of (4.14) comes because a displacement of Z_s, the sth vortex position, induces a displacement of the small circle γ_s. One can use the field equation to derive the useful identity

$$dz \wedge d\bar{z}\frac{\partial}{\partial Z_s}(2\,\partial_z h\, \partial_{\bar{z}} h + e^h - h - 1) = d\{2\, d\bar{z}(\partial_{Z_s} h\, \partial_{\bar{z}} h) - 2\, dz(\partial_{Z_s} h\, \partial_z h)\}. \tag{4.15}$$

Using this, the terms on the first line of (4.14) become boundary integrals, hence

$$\frac{\partial S_h^{\text{reg.}}}{\partial Z_s} = -\frac{i}{2\pi}\sum_{r=1}^{N}\left\{2\int_{\gamma_r} d\bar{z}(\partial_{Z_s} h\, \partial_{\bar{z}} h) - 2\int_{\gamma_r} dz(\partial_{Z_s} h\, \partial_z h)\right\} + 4\sum_{r=1}^{N}\frac{\partial a_r}{\partial Z_s} - \frac{i}{2\pi}\int_{\gamma_s} d\bar{z}(2\,\partial_z h\, \partial_{\bar{z}} h + e^h - h - 1). \tag{4.16}$$

Evaluating these boundary integrals using the expansion (2.9), we find

$$\frac{\partial S_h^{\text{reg.}}}{\partial Z_s} = \left(\bar{b}_s - 2\sum_{r=1}^{N}\frac{\partial a_r}{\partial Z_s}\right) + \left(2\bar{b}_s - 2\sum_{r=1}^{N}\frac{\partial a_r}{\partial Z_s}\right) + 4\sum_{r=1}^{N}\frac{\partial a_r}{\partial Z_s} - \bar{b}_s = 2\bar{b}_s, \tag{4.17}$$

which is our main result. As $S_h^{\text{reg.}}$ is manifestly real, we also have $\partial S_h^{\text{reg.}}/\partial \bar{Z}_s = 2b_s$. $S_h^{\text{reg.}}$ is therefore the generating function of b_s and $\bar{b}_s$, and hence by the remark following (3.1), $S_h^{\text{reg.}}$ is the inter-

acting part $\tilde{\mathcal{K}}$ of the Kähler potential for the Samols metric on $\mathcal{M}_N$. The entire Kähler potential on $\mathcal{M}_N$ is

$$\mathcal{K} = \sum_{r=1}^{N} Z_r \overline{Z_r} + S_h^{\text{reg.}}. \tag{4.18}$$

$S_h^{\text{reg.}}$ has the symmetries of the N-vortex system, namely the translational invariance,

$$\sum_{r=1}^{N} \frac{\partial S_h^{\text{reg.}}}{\partial Z_r} = 0, \tag{4.19}$$

and rotational invariance

$$\sum_{r=1}^{N} \left\{ Z_r \frac{\partial}{\partial Z_r} - \overline{Z}_r \frac{\partial}{\partial \overline{Z}_r} \right\} S_h^{\text{reg.}} = 0, \tag{4.20}$$

which translate into $\Sigma_{r=1}^{N} \overline{b_r} = 0$ and $\Sigma_{r=1}^{N} Z_r \overline{b_r} = \Sigma_{r=1}^{N} \overline{Z_r} b_r$, respectively. Notice that these symmetries restrict the forms of additional holomorphic or antiholomorphic functions we could add to our Kähler potential.

One final remark about $S_h^{\text{reg.}}$ is that it can be simplified, because $1 - e^h$ is twice the magnetic field, whose integral over the plane is a constant in the N-vortex sector. The term proportional to $1 - e^h$ in the integrand of (4.13) can therefore be dropped. However, this simplification only applies to $S_h^{\text{reg.}}$ evaluated on the classical solutions.

V. THE KÄHLER POTENTIAL FOR HYPERBOLIC VORTICES

Abelian Higgs vortices on the hyperbolic plane $\mathbb{H}^2$ with Ricci scalar -1 were first considered by Witten,[11] and an expression for the Kähler metric on the moduli space was derived by Strachan.[12] A feature of the hyperbolic case is that the N-vortex system can be described by a Liouville field ψ with sources, as an alternative to h.

On a general curved surface, we can always choose coordinates such that the metric is $g = e^{\sigma(z,\overline{z})}\, dz\, d\overline{z}$. The gauge-invariant field equation for N vortices becomes

$$4\partial_z \partial_{\overline{z}} h - e^{\sigma(z,\overline{z})}(e^h - 1) = 4\pi \sum_{r=1}^{N} \delta(z - Z_r), \tag{5.1}$$

with the boundary condition $h \to 0$. Solutions exist as before, with arbitrary locations Z_r,[18] and the generalized Samols metric on the N-vortex moduli space, again derived from the kinetic terms of the Lagrangian, is[19]

$$G = \sum_{r,s=1}^{N} \left\{ e^{\sigma(Z_r,\overline{Z}_r)} \delta_{rs} + 2\frac{\partial b_s}{\partial Z_r} \right\} dZ_r\, d\overline{Z}_s. \tag{5.2}$$

The quantities b_r are defined as earlier, through the expansion (2.9) of h near the vortex centers; the only difference being that in the middle quadratic term of (2.9), the coefficient $\frac{1}{4}$ is replaced by $\frac{1}{4} e^{\sigma(Z_r,Z_r)}$.

For vortices on the hyperbolic plane $\mathbb{H}^2$ in the standard disk model, with Ricci scalar $R = -1$, the conformal factor is

$$e^{\sigma} = \frac{8}{(1 - z\overline{z})^2}, \quad |z| < 1, \tag{5.3}$$

and σ satisfies the Liouville equation $\partial_z \partial_{\overline{z}} \sigma = \frac{1}{4} e^{\sigma}$. Now consider the conformal transformation on the hyperbolic plane, $g \to \hat{g} = e^h g = e^{h+\sigma}\, dz\, d\overline{z}$. The Ricci scalar transforms to

$$\hat{R} = e^{-h}(R - 4e^{-\sigma}\partial_z \partial_{\bar{z}} h) = e^{-h}(-1 - 4e^{-\sigma}\partial_z \partial_{\bar{z}} h). \tag{5.4}$$

We see that if h satisfies (5.1), then, away from the singularities, $\hat{R}=-1$. Moreover, the field $\psi = \sigma + h$ also satisfies the Liouville equation $\partial_z \partial_{\bar{z}} \psi = \frac{1}{4} e^{\psi}$.

The squared magnitude of the Higgs field $|\Phi|^2 = e^h$ of hyperbolic vortices therefore has a geometrical interpretation; it plays the role of a conformal factor changing the hyperbolic plane into a hyperbolic plane $\hat{\mathbb{H}}^2$ of the same curvature, however, with conical singularities at $\{Z_1, \ldots, Z_N\}$.

Since ψ is a Liouville field, e^{ψ} can be expressed in terms of some rational function $f(z)$. f needs to satisfy the condition $|f|<1$ for $|z|<1$, to map disk into disk, and also the boundary condition $|f| \to 1$ as $|z| \to 1$. The metric $\hat{g}$ is

$$\hat{g} = e^{\psi}\, dz\, d\bar{z} = \frac{8\left|\frac{df}{dz}\right|^2 dz\, d\bar{z}}{(1 - f\bar{f})^2} = \frac{8\, df\, d\bar{f}}{(1 - f\bar{f})^2}. \tag{5.5}$$

$f(z)$ is a map from $\hat{\mathbb{H}}^2$ to $\mathbb{H}^2$, and the metric $\hat{g}$ is the pull-back of the standard hyperbolic metric on $\mathbb{H}^2$. Conical singularities occur on $\hat{\mathbb{H}}^2$, because the inverse of f is multivalued in general. Using (5.3), we see that

$$|\Phi|^2 = e^h = \left|\frac{df}{dz}\right|^2 \frac{(1 - z\bar{z})^2}{(1 - f\bar{f})^2}, \tag{5.6}$$

and the phase of Φ can be chosen so that

$$\Phi = \left(\frac{df}{dz}\right)\frac{(1 - z\bar{z})}{(1 - f\bar{f})}. \tag{5.7}$$

For N distinct vortices, df/dz should vanish at N distinct points within the unit disk. The general form of f satisfying these requirements is given in Ref. 12.

Consider now the expansion of ψ around the rth vortex position Z_r,

$$\psi = \log|z - Z_r|^2 + A_r + \frac{1}{2}\bar{B}_r(z - Z_r) + \frac{1}{2}B_r(\bar{z} - \bar{Z}_r) + \bar{C}_r(z - Z_r)^2 + C_r(\bar{z} - \bar{Z}_r)^2 + \cdots. \tag{5.8}$$

Since $\psi = h + \sigma = h + \log(8/(1 - z\bar{z})^2)$, the expansion coefficients of ψ are related to those of h by

$$A_r = a_r + \log\left\{\frac{8}{(1 - Z_r\bar{Z}_r)^2}\right\},$$

$$\bar{B}_r = \bar{b}_r + \frac{4\bar{Z}_r}{(1 - Z_r\bar{Z}_r)}, \quad B_r = b_r + \frac{4Z_r}{(1 - Z_r\bar{Z}_r)},$$

$$\bar{C}_r = \bar{c}_r + \frac{\bar{Z}_r^2}{(1 - Z_r\bar{Z}_r)^2}, \quad C_r = c_r + \frac{Z_r^2}{(1 - Z_r\bar{Z}_r)^2}. \tag{5.9}$$

One can show by computing the zz component of the energy–momentum tensor for ψ, that at Z_r the conformal weight is -3 and the accessory parameter is $-\bar{B}_r/2$.

The regularized Liouville action for ψ is

$$S_\psi^{\text{reg.}} = \lim_{\epsilon\to 0}\left\{ \frac{i}{2\pi}\int_{\tilde{\mathbb{D}}} dz\wedge d\bar{z}(2\,\partial_z\psi\,\partial_{\bar{z}}\psi + e^{\psi}) + 4\sum_{r=1}^{N} A_r - \frac{8}{\epsilon} + (4N-8)\log\epsilon \right\}, \tag{5.10}$$

where $\tilde{\mathbb{D}}=\mathbb{D}/(\{\cup_{r=1}^{N}|z-Z_r|<\epsilon\}\cup\{|z|>1-\epsilon\})$ and $\mathbb{D}$ is the unit disk. As before, $S_\psi^{\text{reg.}}$ evaluated on an N-vortex solution becomes a function just of the vortex positions. By differentiating $S_\psi^{\text{reg.}}$, we obtain, by a calculation similar to that in Sec. IV.,

$$\frac{\partial S_\psi^{\text{reg.}}}{\partial Z_r} = 2\overline{B_r}, \quad \frac{\partial S_\psi^{\text{reg.}}}{\partial \overline{Z_r}} = 2B_r, \tag{5.11}$$

and therefore

$$\frac{\partial^2 S_\psi^{\text{reg.}}}{\partial Z_s\,\partial\overline{Z_r}} = 2\frac{\partial B_r}{\partial Z_s} = \left\{ \frac{8\delta_{rs}}{(1-Z_r\overline{Z_r})^2} + 2\frac{\partial b_r}{\partial Z_s} \right\}. \tag{5.12}$$

By comparing with (5.2), we see that (5.12) is the coefficient of $dZ_r d\overline{Z_s}$ in the Samols/Strachan metric on the N-vortex moduli space. This shows that $S_\psi^{\text{reg.}}$ is the entire Kähler potential for the hyperbolic vortices. Unlike vortices in $\mathbb{R}^2$, we do not have to add a further term.

VI. CONCLUSION

In this paper, we presented two expressions for the Kähler potential for N distinct Abelian Higgs vortices on $\mathbb{R}^2$, both involving integrals of the gauge invariant quantity $h=\log|\Phi|^2$.

Our first approach used a scaling argument and appears to be the easiest. The result agrees with the Kähler potential for two well-separated vortices given in Ref. 6. The second approach exploits the striking analogy between the expansion coefficients $\overline{b_r}$ of the field h, and the accessory parameters c_r in Liouville field theory. The regularized action for h evaluated on classical solutions was shown to be the interacting part of the Kähler potential. By adding the flat part $\Sigma_{r=1}^{N} Z_r\overline{Z_r}$, we obtained the full Kähler potential on the N-vortex moduli space.

We also investigated vortices on the hyperbolic plane $\mathbb{H}_2$ with Ricci scalar -1. It was convenient to describe hyperbolic vortices using the Liouville field ψ, instead of the related h. The expansion coefficients $\overline{b_r}$ in this case are directly related to the accessory parameters of the Liouville field. The regularized action for ψ was shown to be the entire Kähler potential on the N-vortex moduli space. It would be interesting to compare the N-vortex metric and the Weil–Petersson metric for the hyperbolic plane with N punctures.

Spectral properties of a Dirac operator in the chiral quark soliton model

Asao Arai,[a] Kunimitsu Hayashi, and Itaru Sasaki
Department of Mathematics, Hokkaido University, Sapporo 060-0810, Japan

(Received 16 December 2004; accepted 1 March 2005; published online 20 April 2005)

We consider a Dirac operator H acting in the Hilbert space $L^2(\mathbb{R}^3;\mathbb{C}^4)\otimes\mathbb{C}^2$, which describes a Hamiltonian of the chiral quark soliton model in nuclear physics. The mass term of H is a matrix-valued function formed out of a function $F:\mathbb{R}^3\to\mathbb{R}$, called a profile function, and a vector field $\mathbf{n}$ on $\mathbb{R}^3$, which fixes pointwise a direction in the isospin space of the pion. We first show that, under suitable conditions, H may be regarded as a generator of a supersymmetry. In this case, the spectra of H are symmetric with respect to the origin of $\mathbb{R}$. We then identify the essential spectrum of H under some condition for F. For a class of profile functions F, we derive an upper bound for the number of discrete eigenvalues of H. Under suitable conditions, we show the existence of a positive energy ground state or a negative energy ground state for a family of scaled deformations of H. A symmetry reduction of H is also discussed. Finally a unitary transformation of H is given, which may have a physical interpretation. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1896388]

I. INTRODUCTION

Let $\sigma_j (j=1,2,3)$ be the Pauli matrices,

$$\sigma_1 := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 := \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{1.1}$$

and

$$\alpha_j := \begin{pmatrix} \sigma_j & 0_2 \\ 0_2 & -\sigma_j \end{pmatrix} \quad (j=1,2,3), \quad \beta := \begin{pmatrix} 0_2 & 1_2 \\ 1_2 & 0_2 \end{pmatrix}, \tag{1.2}$$

where 0_2 and 1_2 are the 2×2 zero matrix and the 2×2 identity matrix, respectively. The matrix

$$\gamma_5 := -i\alpha_1\alpha_2\alpha_3 \tag{1.3}$$

is Hermitian with $\gamma_5^2 = 1_4$ (the 4×4 identity matrix) satisfying the following relations:

$$[\alpha_j, \gamma_5] = 0 \ (j=1,2,3), \quad \{\beta, \gamma_5\} = 0, \tag{1.4}$$

where $[A,B] := AB - BA$ and $\{A,B\} := AB + BA$. We set

$$\boldsymbol{\sigma} := (\sigma_1, \sigma_2, \sigma_3), \quad \boldsymbol{\alpha} := (\alpha_1, \alpha_2, \alpha_3). \tag{1.5}$$

For objects $\mathbf{A} = (A_1, A_2, A_3)$ and $\mathbf{B} = (B_1, B_2, B_3)$ such that the products $A_j B_j$ $(j=1,2,3)$ and their sum are defined, we write $\mathbf{A}\cdot\mathbf{B} := \sum_{j=1}^3 A_j B_j$.

We consider a Dirac operator acting in the Hilbert space

[a]Author to whom correspondence should be addressed. Electronic mail: arai@math.sci.hokudai.ac.jp

$$\mathcal{H} := L^2(\mathbb{R}^3;\mathbb{C}^4) \otimes \mathbb{C}^2, \tag{1.6}$$

where $L^2(\mathbb{R}^3;\mathbb{C}^4)$ is the Hilbert space of $\mathbb{C}^4$-valued square integrable functions on $\mathbb{R}^3$. Let $\nabla := (D_1, D_2, D_3)$ with D_j the generalized partial differential operator in the variable x_j, the jth component of $\mathbf{x} = (x_1, x_2, x_3) \in \mathbb{R}^3$. Then the free Dirac operator with mass zero is defined by

$$H_0 := -i\boldsymbol{\alpha} \cdot \nabla \otimes 1_2 \tag{1.7}$$

acting in $\mathcal{H}$. To introduce a perturbation to H_0, let $F : \mathbb{R}^3 \to \mathbb{R}$ be Borel measurable and finite almost everywhere (a.e.) in $\mathbb{R}^3$ and set

$$U_F := \cos F + i\gamma_5 \otimes \boldsymbol{\tau} \cdot \mathbf{n} \sin F, \tag{1.8}$$

where $\boldsymbol{\tau} := (\tau_1, \tau_2, \tau_3)$ with $\tau_j := \sigma_j (j = 1, 2, 3)$, $\mathbf{n} := (n_1, n_2, n_3)$ with n_j a real-valued measurable function on $\mathbb{R}^3$ such that

$$|\mathbf{n}(\mathbf{x})|^2 = 1, \quad \text{a.e. } \mathbf{x} \in \mathbb{R}^3. \tag{1.9}$$

Let $M > 0$ be a constant. Then, by the second relation in (1.4), $M(\beta \otimes 1_2)U_F$ is a bounded self-adjoint operator on $\mathcal{H}$. Hence, by the Kato–Rellich theorem, the operator

$$H := H_0 + M(\beta \otimes 1_2)U_F \tag{1.10}$$

is self-adjoint with domain $D(H) = D(H_0)$. This is the Dirac operator we consider in this paper. The operator H appears as the Hamiltonian of the so-called the chiral quark soliton model in nuclear physics (e.g., Ref. 1 and references therein). In this context, M and

$$\Phi_F := \cos F + i \sin F \otimes \boldsymbol{\tau} \cdot \mathbf{n} \tag{1.11}$$

(U_F with γ_5 replaced by 1_4) denote the mass of a quark and the pion field, respectively, and F is called a profile function. The Dirac operator H is not only physically important, but also may have interests from purely mathematical points of view. As far as we know, no mathematically rigorous analysis has been made on the Dirac operator H (a study of a Dirac operator with a variable mass is given in Ref. 2, but, in that paper, the mass is a scalar function and the point there is to establish self-adjointness of such a Dirac opeartor in cases where the Kato–Rellich theorem is no longer applicable to it; in this sense Ref. 2 does not bear upon the topics of the present paper).

The present paper is organized as follows. In Sec. II, we show that the Dirac operator H can be regarded as a generator of a supersymmetry, and describe its implications on the spectra of H. In Sec. III we identify the essential spectrum of H. We also derive an upper bound for the number of discrete eigenvalues of H. In particular, for a class of F and $\mathbf{n}$, the absence of discrete eigenvalues of H is proven. Sections IV and V are concerned with existence of discrete eigenvalues of H. In Sec. IV we introduce a concept of a positive energy ground state and that of a negative energy ground state of H and show, under some condition for F, that a scaled deformation of H has a positive energy ground state or a negative ground state. In Sec. V we discuss a symmetry reduction of H to smaller mutually orthogonal closed subspaces which are indexed by triples $(\ell, s, t) \in \mathbb{Z} \times \{\pm 1\} \times \{\pm 1\}$, where ℓ denote an eigenvalue of the third component of the angular momentum operator, $s/2$ the spin of the quark and $t/2$ the isospin of the pion. We prove that, under suitable conditions, each reduced part of H or its scaled version has a discrete positive ground state or a discrete negative ground state. In the last section we present a unitary transformation which brings H to a Dirac operator with a magnetic moment.

II. SUPERSYMMETRIC ASPECTS

In this section we assume the following.

Hypothesis (I): Each $n_j (j = 1, 2, 3)$ is continuously differentiable on $\mathbb{R}^3$ and

$$(n_1(\mathbf{x}), n_2(\mathbf{x})) \neq (0, 0), \quad \mathbf{x} \in \mathbb{R}^3. \tag{2.1}$$

Let

$$\xi(\mathbf{x}) := \frac{(\tau_1 n_2(\mathbf{x}) - \tau_2 n_1(\mathbf{x}))}{\sqrt{n_1(\mathbf{x})^2 + n_2(\mathbf{x})^2}}, \quad \mathbf{x} \in \mathbb{R}^3. \tag{2.2}$$

Then $\xi(\mathbf{x})^2 = 1$, $\mathbf{x} \in \mathbb{R}^3$. For all $\mathbf{x} \in \mathbb{R}^3$, we can define a matrix tensor

$$\Gamma(\mathbf{x}) := \alpha_1\alpha_2\alpha_3\beta \otimes \xi(\mathbf{x}) \tag{2.3}$$

acting on $\mathbb{C}^4 \otimes \mathbb{C}^2$. It is easy to see that $\Gamma(\mathbf{x})$ is self-adjoint with $\Gamma(\mathbf{x})^2 = I$ (I denotes identity). By the natural identification $\mathcal{H} = L^2(\mathbb{R}^3; \mathbb{C}^4 \otimes \mathbb{C}^2)$, we denote the multiplication operator by the matrix-tensor valued function $\Gamma(\cdot)$ by the same symbol Γ. Then Γ is self-adjoint and unitary on $\mathcal{H}$.

Proposition 2.1: *Suppose that Hypothesis (I) holds and $\xi(\mathbf{x})$ is a constant matrix. Then, for all $\psi \in D(H)$, $\Gamma\psi \in D(H)$ and*

$$\{\Gamma, H\}\psi = 0, \quad \psi \in D(H). \tag{2.4}$$

Proof: By direct computations, we have

$$\{\alpha_1\alpha_2\alpha_3\beta, \alpha_j\} = 0 \quad (j = 1,2,3), \quad \{\xi(\mathbf{x}), \boldsymbol{\tau} \cdot \mathbf{n}(\mathbf{x})\} = 0. \tag{2.5}$$

Using these relations and the constancy of $\xi(\cdot)$, we see that, for all $\psi \in D(H) = D(H_0)$, $\Gamma\psi \in D(H_0)$ and $H_0\Gamma\psi = -\Gamma H_0\psi$. Similarly, using (2.5) and $[\alpha_1\alpha_2\alpha_3\beta, \beta\gamma_5] = 0$, we see that $\{M(\beta \otimes 1_2)U_F, \Gamma\}\psi = 0$. Thus (2.4) follows. ■

Proposition 2.1 shows that the Dirac operator H may be regarded as a generator of a supersymmetry, i.e., a supercharge with respect to Γ (e.g., p. 140 in Ref. 3).

For a self-adjoint operator T, we denote by $\sigma(T)$ [respectively, $\sigma_{\mathrm{p}}(T)$] the spectrum of T (respectively, the point spectrum of T). The discrete spectrum of T (the set of isolated eigenvalues of T with finite multiplicity) is denoted $\sigma_{\mathrm{d}}(T)$.

Theorem 2.2: *Suppose that Hypothesis (I) holds and $\xi(\mathbf{x})$ is a constant matrix. Then*

(i) *$\sigma(H)$ is symmetric with respect to the origin of $\mathbb{R}$, i.e., if $\lambda \in \sigma(H)$, then $-\lambda \in \sigma(H)$.*
(ii) *$\sigma_{\#}(H)(\#=\mathrm{p},\mathrm{d})$ is symmetric with respect to the origin of $\mathbb{R}$. The multiplicity $\lambda \in \sigma_{\#}(H)$ coincides with that of $-\lambda \in \sigma_{\#}(H)$.*

Proof: By Proposition 2.1 we have $\Gamma H \Gamma^{-1} = -H$ (the unitary equivalence of H and $-H$). This implies the desired results. ■

Remark 2.1: The properties stated in Theorem 2.2 may differ from spectral properties of the usual Dirac operator $H_0 + M\beta + V$, where V is a scalar potential.

III. THE ESSENTIAL SPECTRUM AND FINITENESS OF THE DISCRETE SPECTRUM OF *H*

A. Structure of the spectrum of *H*

For a self-adjoint operator T, we denote by $\sigma_{\mathrm{ess}}(T)$ the essential spectrum of T.

Theorem 3.1: *Suppose that*

$$\lim_{|\mathbf{x}| \to \infty} F(\mathbf{x}) = 0. \tag{3.1}$$

Then

$$\sigma_{\mathrm{ess}}(H) = (-\infty, -M] \cup [M, \infty), \tag{3.2}$$

$$\sigma_{\mathrm{d}}(H) \subset (-M, M). \tag{3.3}$$

Proof: We write $H = H_0 + M(\beta \otimes I_2) + V$ with $V := M(\beta \otimes I_2)(U_F - I)$. We have $\|V(x)\| \leqslant M(|1 - \cos F(x)| + |\sin F(x)|) \to 0 (|x| \to \infty)$. Hence we can apply Theorem 4.7, Remark 2 on p. 117 in Ref.

3 to H to obtain (3.2). This implies (3.3). ■

B. Bound for the number of discrete eigenvalues of *H*

Assume (3.1). Then, by Theorem 3.1, we can define the number of discrete eigenvalues of H counting multiplicities,

$$N_H := \dim \mathrm{Ran}\, E_H((-M,M)), \tag{3.4}$$

where E_H is the spectral measure of H and $\mathrm{Ran}\, E_H((-M,M))$ means the range of $E_H((-M,M))$. To estimate an upper bound for N_H, we introduce a hypothesis for F and $\mathbf{n}$.

Hypothesis (II):

(i) The functions F and n_j $(j=1,2,3)$ are continuously differentiable on $\mathbb{R}^3$.
(ii) The functions D_jF and D_jn_k $(j,k=1,2,3)$ are bounded on $\mathbb{R}^3$.

Under this assumption, we can define

$$V_F(\mathbf{x}) := \sqrt{|\nabla F(\mathbf{x})|^2 + \sum_{k=1}^{3} |\nabla n_k(\mathbf{x})|^2 \sin^2 F(\mathbf{x})}, \quad \mathbf{x} \in \mathbb{R}^3. \tag{3.5}$$

Theorem 3.2: *Assume (3.1) and Hypothesis (II). Suppose that*

$$C_F := \int_{\mathbb{R}^6} \frac{V_F(\mathbf{x})V_F(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^2} d\mathbf{x}\, d\mathbf{y} < \infty. \tag{3.6}$$

Then N_H is finite with

$$N_H \leqslant \frac{M^2 C_F}{2\pi^2}. \tag{3.7}$$

To prove this theorem we present a general lemma. Let $\mathcal{K}$ be a complex Hilbert space and $\mathsf{B}(\mathcal{K})$ be the Banach space of bounded linear operators on $\mathcal{K}$. Let $V:\mathbb{R}^d \to \mathsf{B}(\mathcal{K})$ $(d \in \mathbb{N})$ be a measurable function. The function V defines a unique multiplication operator acting in the Hilbert space $L^2(\mathbb{R}^d;\mathcal{K})$ of $\mathcal{K}$-valued square integrable functions on $\mathbb{R}^d$. We denote it by the same symbol V. We assume the following (Δ is the d-dimensional generalized Laplacian):

(V.1) $D((-\Delta)^{1/2}) \subset D(|V|^{1/2}) \cap D(|V^*|^{1/2})$ and the form sum

$$L_0 := -\Delta \dotplus \begin{pmatrix} -|V| & 0 \\ 0 & -|V^*| \end{pmatrix}$$

acting in $\oplus^2 L^2(\mathbb{R}^d;\mathcal{K})$ with form domain $D((-\Delta)^{1/2})$ defines a unique self-adjoint operator bounded from below. Moreover, $\sigma_{\mathrm{ess}}(L_0) \subset [0,\infty)$.

(V.2) The operator

$$L := -\Delta + \begin{pmatrix} 0 & V^* \\ V & 0 \end{pmatrix}$$

acting in $\oplus^2 L^2(\mathbb{R}^d;\mathcal{K})$ is self-adjoint on $D(\Delta)$, bounded from below, and $\sigma_{\mathrm{ess}}(L) \subset [0,\infty)$.

For a self-adjoint operator A, we denote by $N_-(A)$ the number of negative eigenvalues of A counting multiplicities.

Lemma 3.3: *Assume (V.1) and (V.2). Then $N_-(L) \leqslant N_-(L_0)$.*

Proof: Let

$$Q := \begin{pmatrix} 0 & V^* \\ V & 0 \end{pmatrix}.$$

Then Q is self-adjoint and

$$Q^2 = \begin{pmatrix} |V|^2 & 0 \\ 0 & |V^*|^2 \end{pmatrix},$$

which implies that

$$|Q| = \begin{pmatrix} |V| & 0 \\ 0 & |V^*| \end{pmatrix}.$$

It is obvious that $Q \geqslant -|Q|$. Hence $L \geqslant L_0$. This inequality and the min–max principle (e.g., Theorem XIII.1, Problem 1 in Ref. 4) imply the inequality $N_-(L) \leqslant N_-(L_0)$. ■

Proof of Theorem 3.2: We note that H has the operator matrix representation

$$H = H_0 + M \begin{pmatrix} 0 & \Phi_F^* \\ \Phi_F & 0 \end{pmatrix}, \tag{3.8}$$

where Φ_F is defined by (1.11). Hence

$$H^2 = L(F) + M^2 \tag{3.9}$$

with

$$L(F) := -\Delta + M \begin{pmatrix} 0 & W_F^* \\ W_F & 0 \end{pmatrix}, \tag{3.10}$$

where $W_F := i\boldsymbol{\sigma} \cdot (\nabla \Phi_F)$. Note that, by Hypothesis (II) (ii), the second term on the right-hand side of (3.10) is a bounded self-adjoint operator and hence $L(F)$ is self-adjoint with $D(L(F)) = D(\Delta)$. By direct computations, we have

$$W_F(\mathbf{x})^* W_F(\mathbf{x}) = W_F(\mathbf{x}) W_F(\mathbf{x})^* = |\nabla F(\mathbf{x})|^2 + \sum_{j=1}^{3} |\nabla n_j(\mathbf{x})|^2 \sin^2 F(\mathbf{x}),$$

where we have used (1.9). Hence $|W_F| = |W_F^*| = V_F$. Let $L_0(F) := -\Delta - MV_F$. By Theorem 3.1, $\sigma_{\mathrm{ess}}(L(F)) = [0, \infty)$. Condition (3.6) implies that V_F is a potential in the Rollnik class (p. 170 in Ref. 5). Hence it follows from Example 7, p. 118 in Ref. 4 and Weyl's essential spectrum theorem (Theorem XIII.14, p. 112 in Ref. 4) that $\sigma_{\mathrm{ess}}(L_0(F)) = \sigma_{\mathrm{ess}}(-\Delta) = [0, \infty)$. Therefore the assumption of Lemma 3.3 with $L = L(F)$ and $L_0 = L_0(F)$ is satisfied. Hence $N_-(L(F)) \leqslant N_-(L_0(F))$. It is well known that $N_-(L_0(F)) \leqslant 8M^2 C_F / (4\pi)^2$ (Theorem XIII.10 in Ref. 4), where the factor $8 = \dim \mathbb{C}^4 \otimes \mathbb{C}^2$. On the other hand, by the spectral theorem, $N_H \leqslant N_-(L_F)$. Thus (3.7) follows. ■

Theorem 3.2 implies the absence of discrete eigenvalues of H for F's such that the Rollnik norm of MV_F is sufficiently small.

Corollary 3.4: *Assume (3.1) and Hypothesis (II). Let* $M^2 C_F < 2\pi^2$. *Then* $\sigma_{\mathrm{d}}(H) = \emptyset$.

IV. EXISTENCE OF DISCRETE GROUND STATES

For a self-adjoint operator A bounded from below, we set

$$E_0(A) := \inf \sigma(A).$$

If $E_0(A) \in \sigma_{\mathrm{p}}(A)$, then we say that A has a ground state and we call a nonzero vector in $\ker(A - E_0(A))$ a ground state of A. If $E_0(A) \in \sigma_{\mathrm{d}}(A)$, then we say that A has a discrete ground state.

Definition 4.1: Let

$$E_0^+(H) := \inf(\sigma(H) \cap [0,\infty)), \quad E_0^-(H) := \sup(\sigma(H) \cap (-\infty,0]). \tag{4.1}$$

If $E_0^+(H)$ [respectively, $E_0^-(H)$] is an eigenvalue of H, then we say that H has a positive (respectively, negative) energy ground state and we call a nonzero vector in $\ker(H-E_0^+(H))$ [respectively, $\ker(H-E_0^-(H))$] a positive (respectively, negative) energy ground state of H. If $E_0^+(H)$ [respectively, $E_0^-(H)$] is a discrete eigenvalue of H, then we say that H has a discrete positive (respectively, negative) energy ground state.

Remark 4.1: If the spectrum of H is symmetric with respect to the origin of $\mathbb{R}$ as in Theorem 2.2, then $E_0^+(H) = -E_0^-(H)$, and H has a positive energy ground state if and only if it has a negative energy ground state.

We assume Hypothesis (II). Then the operators

$$S_\pm(F) := -\Delta \pm M(D_3 \cos F) = -\Delta \mp M(D_3 F)\sin F \tag{4.2}$$

are self-adjoint with $D(S_\pm(F)) = D(\Delta)$ and bounded from below.

Theorem 4.2: *Assume Hypothesis (II) and (3.1). Suppose that $E_0(S_+(F)) < 0$ or $E_0(S_-(F)) < 0$. Then H has a discrete positive energy ground state or a discrete negative ground state.*

Proof: For each $f \in D(\Delta)$ and $u \in \mathbb{C}^2$ with $\|u\| = 1$, we define

$$\psi_f^+ := (f \otimes u, 0, if \otimes u, 0) \in \mathcal{H}, \quad \psi_f^- := (0, f \otimes u, 0, if \otimes u) \in \mathcal{H}.$$

Then we have

$$\langle \psi_f^\pm, L(F)\psi_f^\pm \rangle = 2\langle f, S_\pm(F) f \rangle.$$

In the case where $E_0(S_+(F)) < 0$, there exists a unit vector $f \in D(\Delta)$ such that $\langle f, S_+(F) f \rangle < 0$. Hence $\langle \psi_f^+, L(F)\psi_f^+ \rangle < 0$. By Theorem 3.1 and the spectral theorem, we have

$$\sigma_{\mathrm{ess}}(L(F)) = [0,\infty). \tag{4.3}$$

Thus, by the min–max principle, $L(F)$ has a discrete ground state. Similarly, in the case where $E_0(S_-(F)) < 0$ too, $L(F)$ has a discrete ground state. This implies that H has a discrete positive energy ground state or a discrete negative ground state. ■

To construct examples of F satisfying the conditions as stated in Theorem 4.2, we consider a scaling. For a constant $\varepsilon > 0$ and a function f on $\mathbb{R}^d$, we define a function f_ε on $\mathbb{R}^d$ by

$$f_\varepsilon(x) := f(\varepsilon x), \quad x \in \mathbb{R}^d.$$

Lemma 4.3: *Let $V: \mathbb{R}^d \to \mathbb{R}$ be in $L^2_{\mathrm{loc}}(\mathbb{R}^d)$ and, for a constant $\varepsilon > 0$,*

$$S_\varepsilon := -\Delta + V_\varepsilon.$$

Suppose that the following conditions are satisfied:

(i) *For all $\varepsilon > 0$, S_ε is self-adjoint and bounded from below and $\sigma_{\mathrm{ess}}(S_\varepsilon) \subset [0,\infty)$.*
(ii) *There exists a nonempty open set $\Omega \subset \{x \in \mathbb{R}^d \mid V(x) < 0\}$.*

Then there exists a constant $\varepsilon_0 > 0$ such that, for all $\varepsilon \in (0,\varepsilon_0)$, S_ε has a discrete ground state.

Proof: By condition (ii), we can take a nonzero vector $f \in C_0^\infty(\Omega)$ (the set of infinitely differentiable functions on $\mathbb{R}^d$ with compact support in Ω). Then it is easy to see that $\langle f_\varepsilon, S_\varepsilon f_\varepsilon \rangle = \varepsilon^{-d}(a_f \varepsilon^2 - |b_f|)$, where $a_f := \|\nabla f\|^2$, $b_f = \langle f, Vf \rangle < 0$. Hence, taking $\varepsilon_0 := \sqrt{|b_f|/a_f}$ (note that $a_f \neq 0$), we have $\langle f_\varepsilon, S_\varepsilon f_\varepsilon \rangle < 0$ for all $\varepsilon \in (0,\varepsilon_0)$. Hence, by the min–max principle and condition (i), $E_0(S_\varepsilon) \in \sigma_{\mathrm{d}}(S_\varepsilon)$. ■

Lemma 4.4: *Let $V: \mathbb{R}^d \to \mathbb{R}$ be continuous on $\mathbb{R}^d$ with $\lim_{|\mathbf{x}|\to\infty} V(\mathbf{x}) = 0$. Suppose that $\Omega_- := \{x \in \mathbb{R}^d \mid V(x) < 0\} \neq \emptyset$. Then the following hold:*

(i) *$-\Delta + V$ acting in $L^2(\mathbb{R}^d)$ is self-adjoint and bounded from below.*
(ii) *$\sigma_{\mathrm{ess}}(-\Delta + V) = [0,\infty)$.*

(iii) *S_ε has a discrete ground state for all $\varepsilon\in(0,\varepsilon_0)$ with some $\varepsilon_0>0$.*

Proof: Part (i) follows from the Kato–Rellich theorem. Part (ii) is proven by a simple application of Theorem XIII.15-(b) in Ref. 4.

Since V is continuous, the set Ω_- is open. Hence Lemma 4.3 implies the existence of a ground state of S_ε for all $\varepsilon\in(0,\varepsilon_0)$ with some $\varepsilon_0>0$. ■

We consider a one-parameter family of Dirac operators,

$$H_\varepsilon := H_0 + \frac{1}{\varepsilon} M(\beta\otimes 1_2)U_{F_\varepsilon}, \tag{4.4}$$

which is a scaled deformation of H.

Theorem 4.5: *Assume Hypothesis (II) and (3.1). Suppose that $D_3\cos F$ is not identically zero. Then there exists a constant $\varepsilon_0>0$ such that, for all $\varepsilon\in(0,\varepsilon_0)$, H_ε has a discrete positive energy ground state or a discrete negative ground state.*

Proof: We write $S_\pm(F,M):=S_\pm(F)$ to make explicit the dependence of $S_\pm(F)$ on M. At least one of the sets $\{\mathbf{x}\in\mathbb{R}^3|(D_3\cos F)(\mathbf{x})>0\}$ and $\{\mathbf{x}\in\mathbb{R}^3(D_3\cos F)(\mathbf{x})<0\}$ is not empty. The function $D_3\cos F=-(D_3F)\sin F$ is bounded and continuous satisfying $\lim_{|\mathbf{x}|\to\infty}(D_3F)(\mathbf{x})=0$. Hence we can apply Lemma 4.4 to conclude that $S_+(F_\varepsilon,\varepsilon^{-1}M)$ or $S_-(F_\varepsilon,\varepsilon^{-1}M)$ has a discrete ground state for all $\varepsilon\in(0,\varepsilon_0)$ with some $\varepsilon_0>0$. This fact and Theorem 4.2 yield the desired result. ■

V. SYMMETRY REDUCTION OF *H*

In this section, we show that, if F is invariant under the rotations around the x_3 axis, then there exist infinitely many mutually orthogonal closed subspaces of $\mathcal{H}$ that reduce H_ε for all $\varepsilon>0$ and each reduced part of H_ε may have a positive energy ground state or a negative energy ground state. We use the cylindrical coordinates for points $\mathbf{x}=(x_1,x_2,x_3)\in\mathbb{R}^3$,

$$x_1 = r\cos\theta, \quad x_2 = r\sin\theta, \quad x_3 = z,$$

where $\theta\in[0,2\pi)$, $r>0$. We assume the following.

Hypothesis (III): There exists a continuously differentiable function $G:(0,\infty)\times\mathbb{R}\to\mathbb{R}$ such that (i) $F(\mathbf{x})=G(r,z)$, $\mathbf{x}\in\mathbb{R}^3\backslash\{0\}$; (ii) $\lim_{r+|z|\to\infty}G(r,z)=0$; (iii) $\sup_{r>0,z\in\mathbb{R}}(|\partial G(r,z)/\partial r|+|\partial G(r,z)/\partial z|)<\infty$.

We take the vector field $\mathbf{n}$ to be of the form

$$\mathbf{n}(\mathbf{x}) := (\sin\Theta(r,z)\cos(m\theta), \sin\Theta(r,z)\sin(m\theta), \cos\Theta(r,z)), \tag{5.1}$$

where $\Theta:(0,\infty)\times\mathbb{R}\to\mathbb{R}$ is continuous and m is a real constant.

Let $L_3 := -ix_1D_2+ix_2D_1$, the third component of the angular momentum. It is well known that L_3 is essentially self-adjoint on $C_0^\infty(\mathbb{R}^3)$. We denote its closure by the same symbol L_3. We set

$$\Sigma_3 := \sigma_3\oplus\sigma_3$$

acting on $\mathbb{C}^4$ and define

$$K_3 := L_3\otimes 1_2 + \frac{1}{2}\Sigma_3\otimes 1_2 + \frac{m}{2}I\otimes\tau_3, \tag{5.2}$$

which is a self-adjoint operator acting in $\mathcal{H}$.

We denote by T_ε ($\varepsilon>0$) the unitary dilation on $L^2(\mathbb{R}^3)$ with power ε,

$$(T_\varepsilon f)(\mathbf{x}) := \varepsilon^{3/2} f(\varepsilon\mathbf{x}), \quad f\in L^2(\mathbb{R}^3), \text{ a.e. } \mathbf{x}. \tag{5.3}$$

Lemma 5.1: *For all $\varepsilon>0$, $T_\varepsilon L_3 T_\varepsilon^{-1}=L_3$. Hence $(T_\varepsilon\otimes 1_2)K_3(T_\varepsilon\otimes 1_2)^{-1}=K_3$ for all $\varepsilon>0$.*

Proof: It is straightforward to see that, for all $f\in C_0^\infty(\mathbb{R}^3)$, $T_\varepsilon L_3 f=L_3T_\varepsilon f$. Since $C_0^\infty(\mathbb{R}^3)$ is a core of L_3, this equality extends to all $f\in D(L_3)$ showing that $L_3\subset T_\varepsilon^{-1}L_3T_\varepsilon$. The both sides are

self-adjoint. Hence they coincide. ■

Lemma 5.2: *Assume that*

$$\Theta(\varepsilon r, \varepsilon z) = \Theta(r,z), \quad (r,z) \in (0,\infty) \times \mathbb{R}, \quad \varepsilon > 0. \tag{5.4}$$

Then, for all $t \in \mathbb{R}$ *and* $\varepsilon > 0$, *the operator equality*

$$e^{itK_3} H_\varepsilon e^{-itK_3} = H_\varepsilon \tag{5.5}$$

holds.

Proof: We first prove (5.5) with $\varepsilon = 1$. We have for all $t \in \mathbb{R}$,

$$e^{itK_3} = e^{itL_3} e^{it\Sigma_3/2} \otimes e^{itm\tau_3/2}.$$

For all $f \in C_0^\infty(\mathbb{R}^3)$, we have

$$(e^{itL_3} f)(\mathbf{x}) = f(x_1 \cos t - x_2 \sin t, x_1 \sin t + x_2 \cos t, z), \quad \mathbf{x} \in \mathbb{R}^3.$$

Hence e^{itL_3} leaves $C_0^\infty(\mathbb{R}^3)$ invariant. It follows that, for all $f \in C_0^\infty(\mathbb{R}^3; \mathbb{C}^4) \otimes \mathbb{C}^2$, $e^{itK_3} f \in D(H_0) = D(H)$ and

$$H_0 e^{itL_3} f = e^{itL_3}\{(-i\alpha_1 \cos t + i\alpha_2 \sin t) D_1 f + (-i\alpha_1 \sin t - i\alpha_2 \cos t) D_2 f - i\alpha_3 D_3 f\}. \tag{5.6}$$

Using the matrix representation of α_j, one can check that

$$\alpha_j e^{it\Sigma_3/2} = e^{-it\Sigma_3/2} \alpha_j \quad (j = 1,2), \quad [\alpha_3, e^{it\Sigma_3}] = 0.$$

It follows from these relations and (5.6),

$$H_0 e^{itK_3} f = e^{itK_3} H_0 f. \tag{5.7}$$

We have

$$\tau_j e^{itm\tau_3/2} = e^{itm\tau_3/2} \tau_j e^{itm\tau_3} \quad (j = 1,2), \quad \tau_3 e^{itm\tau_3/2} = e^{itm\tau_3/2} \tau_3$$

and

$$e^{-itL_3} \mathbf{n}(\mathbf{x}) e^{itL_3} = (\sin\Theta(r,z)\cos m(\theta - t), \sin\Theta(r,z)\sin m(\theta - t), \cos\Theta(r,z)).$$

It follows from these relations that

$$\beta \otimes 1_2 U_F e^{itK_3} f = e^{itK_3} (\beta \otimes 1_2) U_F f. \tag{5.8}$$

Combining (5.7) together with (5.8), we obtain $He^{itK_3} f = e^{itK_3} Hf$. Since $C_0^\infty(\mathbb{R}^3; \mathbb{C}^4) \otimes \mathbb{C}^2$ is a core of H, this equality extends to all $f \in D(H) = D(H_0)$ showing $H \subset e^{-itK_3} H e^{itK_3}$. The both sides are self-adjoint. Thus (5.5) follows.

We next consider the case where $\varepsilon \neq 1$. We write $U_F = U(F, \mathbf{n})$. By Lemma 5.1, (5.8) and the fact that T_ε is a bijection from $C_0^\infty(\mathbb{R}^3)$ onto itself, we have $\beta \otimes 1_2 U(F_\varepsilon, \mathbf{n}_\varepsilon) e^{itK_3} f = e^{itK_3} (\beta \otimes 1_2) U(F_\varepsilon, \mathbf{n}_\varepsilon) f$. By condition (5.4), $\mathbf{n}_\varepsilon = \mathbf{n}$. Hence $\beta \otimes 1_2 U(F_\varepsilon, \mathbf{n}_\varepsilon) e^{itK_3} f = e^{itK_3} (\beta \otimes 1_2) U(F_\varepsilon, \mathbf{n}) f$. Therefore (5.8) holds with F replaced by F_ε. Thus, in the same way as in the preceding paragraph, one can prove (5.5). ■

We say that two self-adjoint operators on a Hilbert space strongly commute if their spectral measures commute.

Lemma 5.3: *Assume (5.4). Then, for all* $\varepsilon > 0$, H_ε *and* K_3 *strongly commute.*

Proof: It follows from Lemma 5.2 and the functional calculus for self-adjoint operators that $e^{itK_3} e^{isH_\varepsilon} = e^{isH_\varepsilon} e^{itK_3}$ for all s, $t \in \mathbb{R}$ and all $\varepsilon > 0$. This implies the strong commutativity of H_ε and K_3 (see Theorem VIII.13 in Ref. 6 for general criteria of the strong commutativity of self-adjoint operators). ■

Let

$$E := (0,\infty) \times [0,2\pi) \times \mathbb{R} = \{(r,\theta,z) | r > 0, \theta \in [0,2\pi), z \in \mathbb{R}\}$$

and $\mathrm{d}\mu := r\,\mathrm{d}r \otimes \mathrm{d}\theta \otimes \mathrm{d}z$, a measure on E. Then one can define a unitary operator $Y: L^2(\mathbb{R}^3) \to L^2(E, \mathrm{d}\mu)$ by

$$(Yf)(r,\theta,z) := f(r\cos\theta, r\sin\theta, z), \quad f \in L^2(\mathbb{R}^3).$$

For each $\ell \in \mathbb{Z}$, we define $\phi_\ell : [0,2\pi) \to \mathbb{C}$ by

$$\phi_\ell(\theta) := \frac{1}{\sqrt{2\pi}} e^{i\ell\theta}, \quad \theta \in [0,2\pi). \tag{5.9}$$

It is well known that $\{\phi_\ell\}_{\ell\in\mathbb{Z}}$ is a complete orthonormal system of $L^2([0,2\pi))$. For each $f \in L^2(E, \mathrm{d}\mu)$, we define $\hat{f} : (0,\infty) \times \mathbb{Z} \times \mathbb{R}$ by

$$\hat{f}(r, \ell, z) := \int_0^{2\pi} \phi_\ell(\theta)^* f(r,\theta,z)\mathrm{d}\theta.$$

We define an operator D_θ on $L^2(E, \mathrm{d}\mu)$ as follows:

$$D(D_\theta) := \left\{ f \in L^2(E,\mathrm{d}\mu) \middle| \sum_{\ell=-\infty}^{\infty} \ell^2 \int_0^\infty \mathrm{d}r\, r \int_{\mathbb{R}} \mathrm{d}z |\hat{f}(r, \ell, z)|^2 < \infty \right\},$$

$$(\widehat{D_\theta f})(r, \ell, \theta) = i\,\ell\,\hat{f}(r, \ell, \theta), \quad f \in D(D_\theta).$$

Then $-iD_\theta$ is self-adjoint with

$$\sigma(-iD_\theta) = \sigma_{\mathrm{p}}(-iD_\theta) = \{\ell\}_{\ell\in\mathbb{Z}} = \mathbb{Z}, \tag{5.10}$$

$$\ker(-iD_\theta - \ell) = \left\{ g\phi_\ell \middle| g: (0,\infty) \times \mathbb{R} \to \mathbb{C}, \int_0^\infty \mathrm{d}r\, r \int_{\mathbb{R}} \mathrm{d}z |g(r,z)|^2 < \infty \right\}. \tag{5.11}$$

It is not so hard to see that

$$YL_3Y^{-1} = -iD_\theta. \tag{5.12}$$

Hence

$$\sigma(L_3) = \sigma_{\mathrm{p}}(L_3) = \mathbb{Z}. \tag{5.13}$$

Let

$$\mathcal{M}_\ell := \ker(L_3 - \ell) = Y^{-1} \ker(-iD_\theta - \ell). \tag{5.14}$$

Then we have the orthogonal decomposition

$$L^2(\mathbb{R}^3) = \oplus_{\ell=-\infty}^{\infty} \mathcal{M}_\ell, \quad L^2(E,\mathrm{d}\mu) = \oplus_{\ell=-\infty}^{\infty} Y\mathcal{M}_\ell. \tag{5.15}$$

By (5.13), we have

$$\sigma(K_3) = \sigma_{\mathrm{p}}(K_3) = \left\{ \ell + \frac{s}{2} + \frac{mt}{2} \middle| \ell \in \mathbb{Z}, s = \pm 1, t = \pm 1 \right\}. \tag{5.16}$$

The eigenspace of K_3 with eigenvalue $\ell + (s/2) + (mt/2)$ is given by

$$\mathcal{M}_{\ell,s,t} := \mathcal{M}_\ell \otimes \mathcal{C}_s \otimes \mathcal{T}_t \tag{5.17}$$

under the natural identificaion $\mathcal{H}=L^2(\mathbb{R}^3)\otimes\mathbb{C}^4\otimes\mathbb{C}^2$, where $\mathcal{C}_s := \ker(\Sigma_3 - s)$ and $\mathcal{T}_t := \ker(\tau_3 - t)$. Then $\mathcal{H}$ has the orthogonal decomposition

$$\mathcal{H} = \oplus_{\ell\in\mathbb{Z},s,t\in\{\pm1\}}\mathcal{M}_{\ell,s,t}. \tag{5.18}$$

Lemma 5.3 implies the following fact.

Lemma 5.4: *Assume (5.4). Then, for all $\varepsilon>0$, H_ε is reduced by each $\mathcal{M}_{\ell,s,t}$.*

We denote by $H_\varepsilon(\ell,s,t)$ by the reduced part of H_ε to $\mathcal{M}_{\ell,s,t}$ and set

$$H(\ell,s,t) := H_1(\ell,s,t), \tag{5.19}$$

the reduced part of H to $\mathcal{M}_{\ell,s,t}$.

For $s=\pm1$ and $\ell\in\mathbb{Z}$, we define

$$S_s(G,\ell) := -\frac{\partial^2}{\partial r^2} - \frac{1}{r}\frac{\partial}{\partial r} + \frac{\ell^2}{r^2} + \frac{\partial^2}{\partial z^2} + sM\frac{\partial \cos G}{\partial z} \tag{5.20}$$

acting in $L^2((0,\infty)\times\mathbb{R}, r\,\mathrm{d}r\,\mathrm{d}z)$ with domain $D(S_s(G,\ell)) := C_0^\infty((0,\infty)\times\mathbb{R})$ and set

$$\mathcal{E}_0(S_s(G,\ell)) := \inf_{f\in C_0^\infty((0,\infty)\times\mathbb{R}),\|f\|_{L^2((0,\infty)\times\mathbb{R},r\,\mathrm{d}r\,\mathrm{d}z)}=1} \langle f, S_s(G,\ell) f\rangle.$$

Theorem 5.5: *Assume Hypothesis (III). Fix an $\ell\in\mathbb{Z}$ arbitrarily and $s=\pm1$. Suppose that $\mathcal{E}_0(S_s(G,\ell))<0$. Then, for each $t=\pm1$, $H(\ell,s,t)$ has a discrete positive energy ground state or a discrete negative ground state.*

Proof: Let

$$c_\ell := \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} \mathrm{d}\theta e^{-i\ell\theta}\cos(m\theta), \quad \mathrm{d}_\ell := \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} \mathrm{d}\theta e^{-i\ell\theta}\sin(m\theta),$$

$$n_{j,\ell}(r,z) := (\sin\Theta(r,z)c_\ell, \sin\Theta(r,z)d_\ell, \cos\Theta(r,z)),$$

$$\Phi_{G,\ell,t} := \cos G + i\sum_{j=1} n_{j,\ell}\sin G\otimes\tau_j + itn_{3,\ell}\sin G,$$

$$D_{1,\ell} := c_\ell\frac{\partial}{\partial r} - \frac{d_\ell}{r}\frac{\partial}{\partial\theta}, \quad D_{2,\ell} := d_\ell\frac{\partial}{\partial r} + \frac{c_\ell}{r}\frac{\partial}{\partial\theta}$$

and

$$W_{G_\varepsilon,\ell,s,t} := i\sum_{j=1}^{2}\sigma_j D_{j,\ell}\Phi_{G_\varepsilon,\ell,t} + isD_z\Phi_{G_\varepsilon,\ell,t}, \quad \varepsilon>0.$$

Then we have

$$(Y\otimes 1_2)H_\varepsilon(\ell,s,t)^2(Y\otimes 1_2)^{-1} = -\frac{\partial^2}{\partial r^2} - \frac{1}{r}\frac{\partial}{\partial r} + \frac{\ell^2}{r^2} + \frac{\partial^2}{\partial z^2} + \varepsilon^{-1}M\begin{pmatrix} 0 & W^*_{G_\varepsilon,\ell,s,t} \\ W_{G_\varepsilon,\ell,s,t} & \end{pmatrix} + M^2$$
$$=: L_\varepsilon(\ell,s,t) + M^2$$

on $C_0^\infty((0,\infty)\times\mathbb{R})$.

For each $f\in C_0^\infty((0,\infty)\times\mathbb{R})$ and $u_t\in\mathbb{C}^2$ satisfying $\|f\|=1$, $\|u_t\|=1$, and $\tau_3 u_t = tu_t (t=\pm1)$, we define

$$\psi_f^{(1)} := (f \otimes u_t, 0, if \otimes u_t, 0) \in \mathcal{M}(\ell, 1, t),$$

$$\psi_f^{(-1)} := (0, f \otimes u_t, 0, if \otimes u_t) \in \mathcal{M}(\ell, -1, t).$$

Then we have

$$\langle \psi_f^{(s)}, YL_1(\ell, s, t) Y^{-1} \psi_f^{(s)} \rangle = 2\langle f, S_s(F, \ell) f \rangle.$$

By the present assumption, there exists a unit vector $f \in C_0^\infty((0,\infty) \times \mathbb{R})$ such that $\langle f, S_s(F, \ell) f \rangle < 0$. Note that $\sigma_{\mathrm{ess}}(L_1(\ell, s, t)) \subset [0, \infty)$. Hence, by the min–max principle, $L_1(\ell, s, t)$ has a discrete ground state. This implies that $H(\ell, s, t)$ has a discrete positive energy ground state or a discrete negative ground state. ■

Theorem 5.6: *Assume Hypothesis (III) and (5.4). Suppose that* $\partial \cos G / \partial z$ *is not identically zero. Then, for each* $\ell \in \mathbb{Z}$, *there exists a constant* $\varepsilon_\ell > 0$ *such that, for all* $\varepsilon \in (0, \varepsilon_\ell)$, *each* $H_\varepsilon(\ell, s, t)$ *has a discrete positive energy ground state or a discrete negative ground state.*

Proof: We write $S_{s,M}(F, \ell) := S_s(F, \ell)$ to make explicit the dependence of $S_s(F, \ell)$ on M. In the same way as in the proof of Theorem 4.5, one can take a vector $f_\varepsilon \in C_0^\infty((0,\infty) \times \mathbb{R})$ such that $\langle f_\varepsilon, S_{s,\varepsilon^{-1}M}(F_\varepsilon(\ell)) f_\varepsilon \rangle < 0$ for all sufficiently small $\varepsilon > 0$, where the smallness depends on ℓ. It follows from the proof of the preceding theorem that $L_\varepsilon(\ell, s, t)$ has a discrete ground state. ■

Corollary 5.7: *Assume Hypothesis (III) and (5.4). Suppose that* $\partial \cos G / \partial z$ *is not identically zero. Let* ε_ℓ *be as in Theorem 5.6 and, for each* $N \in \mathbb{N}$ *and* $k > n$ $(k, n \in \mathbb{Z})$, $\nu_{k,n} := \min_{n+1 \leqslant \ell \leqslant k} \varepsilon_\ell$. *Then, for each* $\varepsilon \in (0, \nu_{k,n})$, H_ε *has at least* $(k-n)$ *discrete eigenvalues counting multiplicities.*

Proof: We have $\sigma_{\mathrm{p}}(H_\varepsilon) = \cup_{\ell \in \mathbb{Z}, s, t = \pm 1} \sigma_{\mathrm{p}}(H_\varepsilon(\ell, s, t))$. By the preceding theorem, for each $\ell = n+1, \ldots, k$, $H_\varepsilon(\ell, s, t)$ has a discrete eigenvalue. Thus the desired result follows. ■

Remark 5.1: This result is consistent with Theorem 3.2, because it reads in the present case

$$N_{H_\varepsilon} \leqslant \frac{1}{\varepsilon^4} \frac{M^2 C_F}{2\pi^2}$$

and the right-hand side diverges as $\varepsilon \to 0$.

VI. A UNITARY TRANSFORMATION

In this section we show that, under Hypothesis (II), the Hamiltonian H with $\mathbf{n}$ constant is unitarily equivalent to an operator which resembles a Dirac operator with a magnetic moment.

It is easy to see that the operator

$$X_F := \begin{pmatrix} e^{iF \otimes \boldsymbol{\tau} \cdot \mathbf{n}/2} & 0 \\ 0 & e^{-iF \otimes \boldsymbol{\tau} \cdot \mathbf{n}/2} \end{pmatrix} \tag{6.1}$$

is unitary. Under Hypothesis (II), we can define the following functions:

$$B_j(\mathbf{x}) := \tfrac{1}{2} D_j(F(\mathbf{x}) \otimes \boldsymbol{\tau} \cdot \mathbf{n}(\mathbf{x})), \quad \mathbf{x} \in \mathbb{R}^3, \ j = 1,2,3. \tag{6.2}$$

We set

$$\mathbf{B} := (B_1, B_2, B_3) \tag{6.3}$$

and introduce

$$H(\mathbf{B}) := H_0 + M\beta - \boldsymbol{\sigma} \cdot \mathbf{B} \tag{6.4}$$

acting in $\mathcal{H}$. Note that, under Hypothesis (II), the operator $-\boldsymbol{\sigma} \cdot \mathbf{B}$ is a bounded self-adjoint operator. Hence, by a simple application of the Kato–Rellich theorem, $H(\mathbf{B})$ is self-adjoint with $D(H(\mathbf{B})) = D(H_0)$.

Proposition 6.1: *Assume Hypothesis (II) and that* $\mathbf{n}$ *is constant. Then*

$$X_F H X_F^{-1} = H(\mathbf{B}). \tag{6.5}$$

Proof: Noting the fact that $(\boldsymbol{\tau}\cdot\mathbf{n})^2 = 1_2$, we have

$$\Phi_F = e^{iF\otimes\boldsymbol{\tau}\cdot\mathbf{n}}.$$

It follows from this fact and (3.8) that $X_F H X_F^{-1}\psi = H(\mathbf{B})\psi$ for all $\psi \in [\oplus^4 C_0^\infty(\mathbb{R}^3)]\otimes\mathbb{C}^2$. Since $[\oplus^4 C_0^\infty(\mathbb{R}^3)]\otimes\mathbb{C}^2$ is a core of $H(\mathbf{B})$, the operator equality (6.5) follows. ■

The large-Z Behavior of pseudorelativistic atoms

Thomas Østergaard Sørensen[a)]

(Received 24 January 2005; accepted 2 March 2005; published online 3 May 2005)

In this paper we study the large-Z behavior of the ground state energy of atoms with electrons having relativistic kinetic energy $\sqrt{p^2c^2+m^2c^4}-mc^2$. We prove that to leading order in Z the energy is the same as in the nonrelativistic case, given by (nonrelativistic) Thomas–Fermi theory. For the problem to make sense, we keep the product $Z\alpha$ fixed (here α is Sommerfeld's fine structure constant), and smaller than, or equal to, $2/\pi$, which means that as Z tends to infinity, α tends to zero. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897645]

I. INTRODUCTION AND RESULTS

As a model for a relativistic atom with nuclear charge Z and N electrons, we consider the operator

$$H_{\mathrm{rel}}=\sum_{i=1}^{N}\left\{\sqrt{-\alpha^{-2}\Delta_i+\alpha^{-4}}-\alpha^{-2}-\frac{Z}{|x_i|}\right\}+\sum_{1\leqslant i<j\leqslant N}\frac{1}{|x_i-x_j|}.$$

Here, $x_i\in\mathbb{R}^3$ is the coordinate of the ith electron, Δ_i is the Laplacian with respect to x_i, and α is Sommerfeld's fine structure constant (the physical value of α is approximately $1/137.037$). This is the expression one obtains using $\sqrt{p^2c^2+m^2c^4}-mc^2$ for the kinetic energy of the electrons (and making the substitution $p\to-i\hbar\nabla$), measuring energies (H_{rel}) in units of Rydberg, and lengths (the x_i's) in units of the Bohr radius.

This model has been much studied over the past 30 years. Stability in the case $N=1$ was proved independently by Herbst[9] and Weder.[22] The stability of matter for the model was first proved by Conlon,[2] later by Fefferman and de la Llave,[7] and also by Lieb and Yau;[17] see the latter for an overview. A nonexhaustive list of other works on this model is Refs. 10, 21, 20, 19, and 1.

It is well known that the operator H_{rel} is bounded from below on $C_0^\infty(\mathbb{R}^{3N})$ if, and only if, $Z\alpha\leqslant 2/\pi$. Only in this case is the atom stable; and we define the operator H_{rel} as a self-adjoint, unbounded operator by Friedrichs extending this semibounded operator. To study the energy of large atoms, one would normally then consider the limit as $Z\to\infty$ of the infimum of the spectrum of this operator. However, due to the upper bound on Z resulting from the restriction $Z\alpha\leqslant 2/\pi$, this is not possible here. To overcome this problem, we consider

$$H_{\mathrm{rel}}=\alpha^{-1}\left\{\sum_{i=1}^{N}\left\{\sqrt{-\Delta_i+\alpha^{-2}}-\alpha^{-1}-\frac{\delta}{|x_i|}\right\}+\sum_{1\leqslant i<j\leqslant N}\frac{\alpha}{|x_i-x_j|}\right\},$$

where $\delta=Z\alpha$ is held *fixed*. This ensures that as $Z\to\infty$, and therefore $\alpha\to 0$, the operator H_{rel} remains well defined—as long as $0\leqslant\delta\leqslant 2/\pi$. Also, we shall keep $\lambda\equiv N/Z$ fixed. The energy of the atom is then defined as

[a)]On leave from Department of Mathematical Sciences, Aalborg University, Fredrik Bajers Vej 7G, DK-9220 Aalborg East, Denmark. Electronic mail: sorensen@mathematik.uni-muenchen.de

$$E_N(Z,\delta) := \inf \sigma_{\mathcal{H}_F}(H_{\mathrm{rel}}),$$

where the spectrum of H_{rel} is calculated on $\mathcal{H}_F = \wedge^N L^2(\mathbb{R}^3, \mathbb{C}^q)$, the Fermionic Hilbert space, describing N Fermions, each with q possible spin states. We will take $q=2$ from now on (but this is no restriction). We note that since (the extension of) H_{rel} is self-adjoint and bounded from below, we have the Rayleigh–Ritz principle. If $\mathcal{C}$ is a form core for the corresponding quadratic form, then

$$\inf \sigma_{\mathcal{H}_F}(H_{\mathrm{rel}}) = \inf_{\{\psi \in \mathcal{C} \| \|\psi\|=1\}} \langle \psi, H_{\mathrm{rel}} \psi \rangle.$$

Our main result is the following.

Theorem 1.1: *Let $\delta \in (0, 2/\pi]$ and $\lambda > 0$ be fixed and let H_{rel} and $E_{N=\lambda Z}(Z,\delta)$ be as above. Then*

$$E_{\lambda Z}(Z,\delta) = -C_{\mathrm{TF}}(\lambda) Z^{7/3} + o(Z^{7/3}), \quad Z \to \infty, \tag{1.1}$$

where $-C_{\mathrm{TF}}(\lambda) Z^{7/3}$ is the (nonrelativistic) Thomas–Fermi energy of the atom.

This shows that, to leading order, the ground-state energy of a relativistic atom is given by the (nonrelativistic) semiclassical Thomas–Fermi energy approximation, as it is for the nonrelativistic atom (note that the case $\delta = 2/\pi$ is included). (In the nonrelativistic case this was first proved by Lieb and Simon;[14] see also Lieb.[11]) This expresses the fact that for large atoms the majority of the electrons are nonrelativistic.

The second term in the expansion (1.1) will be studied in a forthcoming paper.[18]

The proof of Theorem 1.1 will be by finding upper and lower bounds on $E_{\lambda Z}(Z,\delta)$. Note that the relativistic kinetic energy is always lower than the nonrelativistic one,

$$\sqrt{\alpha^{-2} q^2 + \alpha^{-4}} - \alpha^{-2} = \alpha^{-2}\left(\sqrt{1 + (\alpha q)^2} - 1\right) \leqslant \frac{q^2}{2}. \tag{1.2}$$

(Note, since we will later make Taylor expansions of the square root in the relativistic kinetic energy, we will have to insist on the nonrelativistic kinetic energy being $-\Delta/2$.) This means that all upper bounds derived earlier[14,11] for the nonrelativistic operator

$$H_{\mathrm{cl}} = \sum_{i=1}^{N} \left\{ \frac{p_i^2}{2} - \frac{Z}{|x_i|} \right\} + \sum_{1 \leqslant i < j \leqslant N} \frac{1}{|x_i - y_i|}$$

will also be upper bounds for H_{rel}; in particular, to prove Theorem 1.1, we need only derive a lower bound.

II. ORGANIZATION OF THE PAPER

We start in Sec. III by reducing the N-body operator H_{rel} to a one-particle one; having done that, we only need to consider wave functions given as Slater determinants when trying to minimize the energy. To proceed, we need to localize the kinetic energy. To do so, we use (in Sec. IV) an analogue of the IMS localization formula for the Schrödinger operator, see Ref. 3, p.27. This formula has already been developed by Lieb and Yau in Ref. 17 for both the operator $\sqrt{-\Delta + \alpha^{-2}} - \alpha^{-1}$ and the hyperrelativistic kinetic energy $|p|$. This is essentially done by finding the integral kernels of these operators. For $\sqrt{-\Delta + \alpha^{-2}} - \alpha^{-1}$, this involves the modified Bessel function K_2, and the derivation of the formula and of needed properties of K_2 are carried out in Appendix A. The localization error, given by a bounded operator $L^{(\alpha)}$ expressed as an integral operator involving K_2, is then estimated (in Sec. V). Estimating the error is rather technical (calculative) and involves localization of the operator and the above-mentioned properties of K_2. Some of the localized terms are estimated with the localized energy itself (Secs. VI and VII).

Coming to the localized energy, we must estimate the kinetic energy close to the nucleus. Since this is the high-energy region, this is where the electrons are relativistic, and so this term should be of lower order, since, to leading order, there should be no relativistic contribution to the

energy. As the relativistic kinetic energy is asymptotically linear in p in the high-energy region—as opposed to the classical one which is quadratic—the singularity in the potential causes substantially more trouble. This problem is solved (in Sec. VI) by a clever choice of parameters in an estimate by Lieb and Yau in Ref. 17 on the sum of the eigenvalues of the energy in a ball around the nucleus. This also determines the scale on which one can localize close to the nucleus. A part of two of the localized terms of the operator $L^{(\alpha)}$ is estimated along with this term.

In the outer region, one uses (in Sec. VIII) essentially the same idea as Lieb did in the classical case, see Ref. 12, to refind the desired phase space integral, which is to give the semiclassical Thomas–Fermi energy. This involves introducing coherent states and estimating the error by doing so. The formulas for the relativistic case were developed in Ref. 16, but the error obtained there is too rough for our purposes. We therefore develop (in Appendix B) a better estimate by a more careful analysis. In order to make all this work, one needs the coherent state to be supported further out than the initial cutoff around the nucleus. To get this, an intermediary zone is introduced (also in Sec. IV) by an additional cutoff. The energy in this shell is estimated (in Sec. VII) by a generalized version of the Lieb–Thirring inequality, proved by Daubechies in Ref. 4. Also the other part of the previously mentioned two terms of the localized operator $L^{(\alpha)}$ is estimated in this way. (For another work which uses coherent states in a relativistic setup, see Ref. 6.)

Finally we relate (in Sec. VIII) the energy in the outer region to the Thomas–Fermi energy from the classical (that is, the Schrödinger) case. In this region, the kinetic energy is small, and using the specific scaling property of Thomas–Fermi theory allows one to make the change from the relativistic energy $\sqrt{-\alpha^{-2}\Delta+\alpha^{-4}}-\alpha^{-2}$ to the nonrelativistic one, $-\Delta/2$, getting errors of the desired order.

III. REDUCTION TO A ONE-PARTICLE PROBLEM

We will use the notation

$$H=\alpha H_{\mathrm{rel}}=\sum_{i=1}^{N}\left\{\sqrt{-\Delta_i+\alpha^{-2}}-\alpha^{-1}-\frac{\delta}{|x_i|}\right\}+\sum_{1\leqslant i<j\leqslant N}\frac{\alpha}{|x_i-x_j|}. \tag{3.1}$$

Recall that $\delta=Z\alpha$ is *fixed* and that the ground state energy of H_{rel} is to be proven to be of leading order $Z^{7/3}$. Since we wish to consider α as the free parameter, the relevant order of all error terms will be $o(\alpha^{-4/3})$. Also, we will denote the operator $\sqrt{-\Delta+\alpha^{-2}}$ by $\sqrt{p^2+\alpha^{-2}}$, and so $T(p)=\sqrt{p^2+\alpha^{-2}}-\alpha^{-1}$ will be the kinetic energy.

We start by reducing the problem from an N-particle problem to a one-particle one. This is done by using an inequality on the electron–electron interaction $\Sigma_{i<j}|x_i-x_j|^{-1}$, which will reduce this to a one-particle potential.

Choose a spherically symmetric function $g\in C_0^\infty(\mathbb{R}^3)$, non-negative, supported in the unit ball $B(0,1)$ of $\mathbb{R}^3$, and such that $\int g(x)^2d^3x=1$. Let $\phi(x)=g(x)^2$ and let for $a>0$ (a to be chosen later), $\phi_a(x)=a^{-3}\phi(x/a)$, so that $\int\phi_a(x)d^3x=1$. Then for all $\rho:\mathbb{R}^3\to\mathbb{R}$ we have

$$\begin{aligned}\sum_{1\leqslant i<j\leqslant N}\frac{1}{|x_i-x_j|}&\geqslant\sum_{1\leqslant i<j\leqslant N}\int\int\frac{\phi_a(x-x_i)\phi_a(y-x_j)}{|x-y|}d^3x\,d^3y\\&=\frac{1}{2}\sum_{i,j=1}^{N}\int\int\frac{\phi_a(x-x_i)\phi_a(y-x_j)}{|x-y|}d^3x\,d^3y-\frac{1}{2}N\int\int\frac{\phi_a(x)\phi_a(y)}{|x-y|}d^3x\,d^3y\\&=\sum_{i=1}^{N}\int\int\frac{\rho(y)\phi_a(x-x_i)}{|x-y|}d^3x\,d^3y-\frac{1}{2}\int\int\frac{\rho(x)\rho(y)}{|x-y|}d^3x\,d^3y-c(\phi)Na^{-1}\\&\quad+\frac{1}{2}\int\int\frac{\left(\sum_i\phi_a(x-x_i)-\rho(x)\right)\left(\sum_j\phi_a(y-x_j)-\rho(y)\right)}{|x-y|}d^3x\,d^3y\end{aligned}$$

$$\geqslant \sum_{i=1}^{N} \int\int \frac{\rho(y)\phi_a(x-x_i)}{|x-y|} d^3x\, d^3y - \frac{1}{2}\int\int \frac{\rho(x)\rho(y)}{|x-y|} d^3x\, d^3y - c(\phi)Na^{-1}.$$

In the last inequality we used that $|x-y|^{-1}$ is of positive type (a positive kernel) since

$$\int\int \frac{\overline{f(x)}f(y)}{|x-y|} d^3x\, d^3y = 4\pi \int \frac{|\hat{f}(p)|^2}{|p|^2} d^3p.$$

The constant $c(\phi)$ is independent of a,

$$c(\phi) = \frac{1}{2}\int\int \frac{\phi(x)\phi(y)}{|x-y|} d^3x\, d^3y = 2\pi \int \frac{|\hat{\phi}(p)|^2}{|p|^2} d^3p.$$

Noting that (using the spherical symmetry of ϕ_a)

$$\int\int \frac{\rho(y)\phi_a(x-x_i)}{|x-y|} d^3x\, d^3y = \int\int \frac{\rho(y)\phi_a(z)}{|z-(x_i-y)|} d^3z\, d^3y$$

$$= \int \rho(y)(\phi_a * |\cdot|^{-1})(x_i-y) d^3y = (\rho * \phi_a * |\cdot|^{-1})(x_i) \equiv \rho * \phi_a * |x_i|^{-1},$$

we get the operator inequality [see (3.1) for H],

$$H \geqslant \sum_{i=1}^{N} \left\{ \sqrt{p_i^2 + \alpha^{-2}} - \alpha^{-1} - \frac{\delta}{|x_i|} + \alpha\rho * \phi_a * |x_i|^{-1} \right\} - \frac{\alpha}{2}\int\int \frac{\rho(x)\rho(y)}{|x-y|} d^3x\, d^3y - \alpha c(\phi)Na^{-1}. \tag{3.2}$$

Having reduced the N-body operator H to a one-body operator, we only need to consider Slater determinants when trying to minimize the energy. That is, when considering $\langle \psi, H\psi \rangle$ we need only consider those $\psi \in \mathcal{H}_F$ which are given by

$$\psi(x_1, \ldots, x_N) = \frac{1}{\sqrt{N!}} \det(m_i(x_j)),$$

where $m_i \in L^2(\mathbb{R}^3)$, $i = 1, \ldots, N$, are orthonormal. Note also that since $C_0^\infty(\mathbb{R}^3)$ is a core for the operator $\sqrt{p^2+\alpha^{-2}} - \alpha^{-1} - \delta/|x|$, $\delta \in [0, 2/\pi]$ (see Herbst[9]), we need only consider m_i's in this space. Then, as soon as h is a one-particle operator acting on $L^2(\mathbb{R}^3)$, we have that

$$\left\langle \psi, \sum_{i=1}^{N} h_i \psi \right\rangle = \sum_{i=1}^{N} (m_i, h m_i).$$

Here, $\langle , \rangle$ and $(,)$ denote inner products in $L^2(\mathbb{R}^{3N})$, respectively, $L^2(\mathbb{R}^3)$, both linear in the second variable, and h_i is h acting on the variable x_i of ψ. Also, we will use $\|\cdot\|_p$ for the norm in $L^p(\mathbb{R}^3)$.

IV. LOCALIZATION OF THE KINETIC ENERGY

In order to treat the one-body operator in (3.2) and in particular the singularity in the Coulomb potential—which causes considerably more trouble than in the nonrelativistic case—we introduce, following Lieb and Yau,[17] a partition of unity (see also Cycon *et al.*, Ref. 3, Definition 3.1), For some $\beta \in (0, \frac{1}{2})$, let θ_1 and θ_2 be monotone positive smooth functions on $\mathbb{R}_+$, $0 \leqslant \theta_i \leqslant 1$, such that

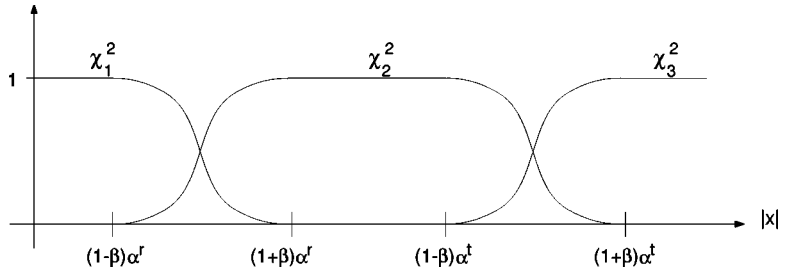

FIG. 1. The partition of unity.

$$\theta_1(\xi) = \begin{cases} 1 & \text{if } \xi < 1-\beta, \\ 0 & \text{if } \xi > 1+\beta, \end{cases} \qquad \theta_2(\xi) = \begin{cases} 0 & \text{if } \xi < 1-\beta, \\ 1 & \text{if } \xi > 1+\beta, \end{cases}$$

and such that $\theta_1(\xi)^2+\theta_2(\xi)^2=1$ for all $\xi \in \mathbb{R}_+$. Now define, with $8/9<r<1$ and $1/3<t<2/3$ (these choices of parameters are governed by the later analysis), the following three functions, which (for α sufficiently small) is a partition of unity in $\mathbb{R}^3$:

$$\chi_1(x) = \theta_1\left(\frac{|x|}{\alpha^r}\right), \quad \chi_2(x) = \theta_1\left(\frac{|x|}{\alpha^t}\right)\theta_2\left(\frac{|x|}{\alpha^r}\right), \quad \chi_3(x) = \theta_2\left(\frac{|x|}{\alpha^t}\right). \tag{4.1}$$

Then, at least for α sufficiently small, we have the picture in Fig. 1.

According to Lieb and Yau (Ref. 17, Theorem 9; α^{-1} corresponds to m) we have for $f \in C_0^\infty(\mathbb{R}^3)$ that

$$(f, \sqrt{p^2+\alpha^{-2}}f) = \sum_{j=1}^{3} (f, \chi_j\sqrt{p^2+\alpha^{-2}}\chi_j f) - (f, L^{(\alpha)}f), \tag{4.2}$$

where $L^{(\alpha)}$ is a bounded operator on $L^2(\mathbb{R}^3)$, given by the kernel

$$L^{(\alpha)}(x,y) = \frac{\alpha^{-2}}{4\pi^2}\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}\sum_{j=1}^{3}(\chi_j(x)-\chi_j(y))^2.$$

Here K_2 is a modified Bessel function, defined on $(0,\infty)$ by

$$K_2(t) = \frac{1}{2}\int_0^\infty x e^{-(1/2)t(x+x^{-1})}\,dx.$$

For completeness, we derive this in Appendix A.

Using this we find, with $T(p)=\sqrt{p^2+\alpha^{-2}}-\alpha^{-1}$, $V(x)=\delta/|x|$ and ψ a Slater determinant as mentioned in the preceding section, that

$$\begin{aligned}\left\langle \psi, \sum_{i=1}^{N}\{T(p_i)-V(x_i)+\alpha\rho * \phi_a * |x_i|^{-1}\}\psi \right\rangle &= \sum_{i=1}^{N}(m_i, \{T(p)-V(x)+\alpha\rho * \phi_a * |x|^{-1}\}m_i) \\ &= \sum_{j=1}^{3}\sum_{i=1}^{N}(m_i, \chi_j\{T(p)-V(x)+\alpha\rho * \phi_a * |x|^{-1}\}\chi_j m_i) \\ &\quad - \sum_{i=1}^{N}(m_i, L^{(\alpha)}m_i),\end{aligned} \tag{4.3}$$

since $\Sigma_{j=1}^3 \chi_j(x)^2=1$ for all $x \in \mathbb{R}^3$ (and α sufficiently small).

V. THE LOCALIZATION ERROR

We now estimate the error introduced by the localization of the kinetic energy carried out in the last section. This error is given by a bounded operator $L^{(\alpha)}$,

$$L^{(\alpha)}(x,y) = \sum_{j=1}^{3} L_j^{(\alpha)}(x,y), \quad L_j^{(\alpha)}(x,y) = \frac{\alpha^{-2}}{4\pi^2} \frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2} (\chi_j(x) - \chi_j(y))^2.$$

As noted above, this expression is derived in Appendix A. We shall start by localizing this operator, thereby splitting it into 12 terms which we will then treat individually. These terms are going to fall into groups though, and the terms in each of these will be estimated together by different means. Two of the terms will be estimated in later sections, together with the energies near the nucleus and in the intermediary zone, related to, respectively, χ_1 and χ_2.

In this section, the scale of the inner cutoff will be called l, that is, $l=\alpha^r$, $8/9<\mathrm{r}<1$. Let χ_- be the characteristic function of the ball $B(0,2l)$ in $\mathbb{R}^3$ and χ_+ that for the complement of this ball. Then each $L_j^{(\alpha)}$, $j=1$, 2, 3, splits into four terms,

$$L_j^{(\alpha)}(x,y) = \chi_+(x)L_j^{(\alpha)}(x,y)\chi_+(y) + \chi_+(x)L_j^{(\alpha)}(x,y)\chi_-(y) + \chi_-(x)L_j^{(\alpha)}(x,y)\chi_+(y) + \chi_-(x)L_j^{(\alpha)}(x,y)\chi_-(y).$$

The following lemma will eventually take care of six of these 12 terms.

Lemma 5.1: *Let* $l=\alpha^r$, $8/9<r<1$ *and assume that, with* $\gamma \equiv 1-(b/a)>0$,

$$|x| > al \quad \text{and } |y| < bl \text{ on supp } \chi_+(x)L_j^{(\alpha)}(x,y)\chi_-(y).$$

Then, for $f \in L^2(\mathbb{R}^3)$,

$$|(f,\chi_+L_j^{(\alpha)}\chi_-f)| \leq \rho(\alpha)\|f\|_2^2,$$

where $\rho(\alpha)=o(e^{-2\epsilon\alpha^{r-1}})$ *as* $\alpha\to 0$ *for all* ϵ *such that* $0<\epsilon<\gamma$. *In particular,* $\rho(\alpha)=o(\alpha^n)$ *as* $\alpha \to 0$ *for all* $n \in \mathbb{N}$.

Remark 5.2: Note that the result with x and y interchanged also holds.

Proof: By assumption we have that

$$|x-y| > \gamma|x| \quad \text{on supp } \chi_+L_j^{(\alpha)}\chi_-.$$

Since both $|x|^{-2}$ and $K_2(\alpha^{-1}|x|)$ are decreasing in $|x|$ (the last is obvious from the definition of K_2), and since $(\chi_j(x)-\chi_j(y))^2 \leq 1$, we get that pointwise,

$$\chi_+(x)L_j^{(\alpha)}(x,y)\chi_-(y) \leq \chi_+(x)\frac{\alpha^{-2}}{4\pi^2}\frac{K_2(\alpha^{-1}\gamma|x|)}{(\gamma|x|)^2}\chi_-(y)$$

on supp $\chi_+L_j^{(\alpha)}\chi_-$. Therefore

$$|(f,\chi_+L_j^{(\alpha)}\chi_-f)| \leq \left(\int |f(y)|\chi_-(y)d^3y\right)\left(\frac{(\alpha\gamma)^{-2}}{4\pi^2}\int |f(x)|\chi_+(x)\frac{K_2(\alpha^{-1}\gamma|x|)}{|x|^2}d^3x\right). \tag{5.1}$$

We estimate both of these terms using the Cauchy–Schwartz inequality. For the first we get

$$\int |f(y)|\chi_-(y)d^3y \leq \|f\|_2\|\chi_-\|_2 = Cl^{3/2}\|f\|_2, \tag{5.2}$$

and for the second

$$\int |f(x)|\chi_+(x)\frac{K_2(\alpha^{-1}\gamma|x|)}{|x|^2}d^3x \leq \|f\|_2\left(\int \left(\chi_+(x)\frac{K_2(\alpha^{-1}\gamma|x|)}{|x|^2}\right)^2 d^3x\right)^{1/2}. \tag{5.3}$$

Using the estimate (A7) in Appendix A on K_2, we get the estimate

$$\int \left(\chi_+(x)\frac{K_2(\alpha^{-1}\gamma|x|)}{|x|^2}\right)^2 d^3x \leqslant 4\pi\int_{2l}^{\infty}\frac{16}{|x|^4}\frac{\pi e^{-2\alpha^{-1}\gamma|x|}}{2\alpha^{-1}\gamma|x|}(1+(2\alpha^{-1}\gamma|x|)^{-1}+(2\alpha^{-1}\gamma|x|)^{-2})^2|x|^2\mathrm{d}|x|$$

$$= 128\pi^2\alpha^{-1}\gamma\int_{4\gamma l\alpha^{-1}}^{\infty} t^{-3}e^{-t}\left(1+\frac{1}{t}+\frac{1}{t^2}\right)^2 \mathrm{d}t,$$

where the last equality follows by the change of variables $t=2\gamma\alpha^{-1}|x|$. Dominating e^{-t} in the integrand by $e^{-4\gamma l\alpha^{-1}}$ and working out the resulting integral, we arrive at [using (5.1)–(5.3); recall that $l=\alpha^r$]

$$|(f,\chi_+L_j^{(\alpha)}\chi_-f)| \leqslant C\|f\|_2^2\alpha^{(3r-5)/2}e^{-2\gamma\alpha^{r-1}}\{\cdots\}^{1/2},$$

where

$$\{\cdots\}^{1/2}=\left\{\tfrac{1}{4}(4\gamma)^{-4}\alpha^{4(1-r)}+\tfrac{2}{5}(4\gamma)^{-5}\alpha^{5(1-r)}+\tfrac{1}{2}(4\gamma)^{-6}\alpha^{6(1-r)}+\tfrac{2}{7}(4\gamma)^{-7}\alpha^{7(1-r)}+\tfrac{1}{8}(4\gamma)^{-8}\alpha^{8(1-r)}\right\}^{1/2}.$$

Now, since $8/9<r<1$, this term tends to zero as α tends to zero. Also

$$\alpha^{(3r-5)/2}e^{-2\gamma\alpha^{r-1}}=o(e^{-2\epsilon\alpha^{r-1}}),\quad \alpha\to 0,$$

for all ϵ satisfying $0<\epsilon<\gamma$. This proves the lemma. □

We now return to investigating the above-mentioned 12 terms. First, note that two of these terms are actually zero,

$$\chi_+(x)L_1^{(\alpha)}(x,y)\chi_+(y)\equiv 0,$$

$$\chi_-(x)L_3^{(\alpha)}(x,y)\chi_-(y)\equiv 0,$$

as is easily seen by looking at the supports of χ_+, χ_-, χ_1, and χ_3. Next, we note that the following three terms fulfill the conditions in Lemma 5.1 and therefore are $o(\alpha^n)$, $\alpha\to 0$, for all $n\in\mathbb{N}$:

$$\chi_+(x)L_1^{(\alpha)}(x,y)\chi_-(y)\neq 0 \quad \text{for} \quad |x|>2l \quad \text{and} \quad |y|<(1+\beta)l,$$

$$\chi_+(x)L_3^{(\alpha)}(x,y)\chi_-(y)\neq 0 \quad \text{for} \quad |x|>(1-\beta)\alpha^t \quad \text{and} \quad |y|<2l,$$

$$\chi_+(x)L_2^{(\alpha)}(x,y)\chi_-(y)\neq 0 \quad \text{for} \quad |x|>(1-\beta)\alpha^t \quad \text{and} \quad |y|<2l,$$

$$\text{and for } |x|\in[2l,(1-\beta)\alpha^t] \quad \text{and} \quad |y|<(1+\beta)l.$$

This is due to the fact that for α small enough, $\alpha^t>\alpha^r$, since $t<2/3<8/9<r$. The above is symmetric in x and y, which gives another three terms.

We are then left with four terms. For these we will use that, by the mean value theorem, $(\chi_j(x)-\chi_j(y))^2\leqslant\|\nabla\chi_j\|_\infty^2|x-y|^2$. Note that for the four remaining terms,

$$\chi_+L_2^{(\alpha)}\chi_+,\quad \chi_-L_1^{(\alpha)}\chi_-,\quad \chi_+L_3^{(\alpha)}\chi_+,\quad \chi_-L_2^{(\alpha)}\chi_-, \tag{5.4}$$

we only need to take the supremum of $|\nabla\chi_j(\xi)|$ over the ξ's between x and y in the support of the relevant term. In this way we get

$$|(f,\chi_\pm L_j^{(\alpha)}\chi_\pm f)| \leqslant \int\int |f(x)|\chi_\pm(x)|f(y)|\chi_\pm(y)L_j^{(\alpha)}(x,y)d^3x\,d^3y$$
$$\leqslant \frac{c_j^\pm(\alpha)\alpha^{-2}}{4\pi^2}\int |f(x)|\chi_\pm(x)((|f|\chi_\pm)*G_\alpha)(x)d^3x,$$

where $G_\alpha(x)=K_2(\alpha^{-1}|x|)$ and $c_j^\pm(\alpha)=\sup_{|x|\gtrless 2l}|\nabla\chi_j(x)|^2$. By first using the Cauchy–Schwartz inequality, then Young's inequality, we get

$$|(f,\chi_\pm L_j^{(\alpha)}\chi_\pm f)| \leqslant \frac{c_j^\pm(\alpha)\alpha^{-2}}{4\pi^2}\|f\chi_\pm\|_2\|(|f|\chi_\pm)*G_\alpha\|_2 \leqslant \frac{c_j^\pm(\alpha)}{4\pi^2\alpha^2}\|f\chi_\pm\|_2^2\|G_\alpha\|_1.$$

Since

$$\|G_\alpha\|_1 = \int K_2(\alpha^{-1}|x|)d^3x = 4\pi\int_0^\infty \alpha^2t^2K_2(t)\alpha\,\mathrm{d}t = 6\pi^2\alpha^3$$

[see (A6) in Appendix A for $\int_0^\infty t^2K_2(t)\mathrm{d}t$] we get the following inequality:

$$|(f,\chi_\pm L_j^{(\alpha)}\chi_\pm f)| \leqslant \frac{3c_j^\pm(\alpha)\alpha}{2}\|f\chi_\pm\|_2^2. \tag{5.5}$$

For two of the terms in (5.4), $\chi_+L_2^{(\alpha)}\chi_+$ and $\chi_+L_3^{(\alpha)}\chi_+$, this is sufficient, since [see (4.1); recall that $l=\alpha^r$]

$$c_j^+(\alpha) = \sup_{|x|>2l}|\nabla\chi_j|^2 = c_j^+\alpha^{-2t}, \quad j=2,3,$$

and since $t<2/3$ we get, using (5.5), that

$$\sum_{i=1}^N (m_i,\chi_+L_3^{(\alpha)}\chi_+m_i) \leqslant N\frac{3}{2}c_j^+\alpha^{1-2t} = o(\alpha^{-4/3}), \quad \alpha\to 0,$$

as $N=\lambda Z=\lambda\delta\alpha^{-1}$ (λ and δ fixed) and $\|m_i\|_2=1$. Similarly for $\chi_+L_2^{(\alpha)}\chi_+$.

For the other two terms in (5.4), note that

$$\|f\chi_-\|_2^2 = \int |f(x)|^2|\chi_-(x)|^2\,d^3x$$
$$= \int |f(x)|^2\chi_-(x)d^3x = (f,\chi_-f) = (f,\chi_-(\chi_1^2+\chi_2^2)f) = (\chi_1f,\chi_-\chi_1f) + (\chi_2f,\chi_-\chi_2f),$$

since $\chi_-^2=\chi_-$ and $\chi_1^2+\chi_2^2=1$ on supp χ_-. Using this and (5.5), we obtain (since $\chi_-\chi_1=\chi_1$):

$$\sum_{i=1}^N (m_i,\chi_-(L_1^{(\alpha)}+L_2^{(\alpha)})\chi_-m_i) \leqslant C\alpha^{1-2r}\left(\sum_{i=1}^N(\chi_1m_i,\chi_1m_i) + \sum_{i=1}^N(\chi_2m_i,\chi_-\chi_2m_i)\right), \tag{5.6}$$

where

$$C=\tfrac{3}{2}(c_1+c_2), \quad c_j\alpha^{-2r} = \sup_{|x|<2l}|\nabla\chi_j(x)|^2, \quad j=1,2.$$

The two terms in (5.6) will be estimated in the following two sections, the first one along with the energy at the nucleus, the second one with the energy in the intermediary zone.

VI. THE ENERGY NEAR THE NUCLEUS

In this section we estimate the energy at the nucleus, that is [see (4.3)], the term

$$\sum_{i=1}^{N} (m_i, \chi_1\{T(p) - V(x) + \alpha\rho * \phi_a * |x|^{-1}\}\chi_1 m_i). \tag{6.1}$$

Also, half of the remaining term (5.6) of the localization error, treated in the preceding section, will be estimated here. We start by noting that $\rho * \phi_a * |x|^{-1}$ is positive, so that we get a lower bound to (6.1) by dropping this term. The remaining expression will be treated by using the following result by Lieb and Yau (Ref. 17, Theorem 11) on the hyperrelativistic operator $|p|$.

Theorem 6.1: *Let* $C_0 > 0$ *and* $R > 0$ *and let*

$$H_{C_0R} = |p| - \frac{2}{\pi}|x|^{-1} - C_0/R$$

be defined on $L^2(\mathbb{R}^3)$ *as a quadratic form. Let* $0 \leqslant \gamma \leqslant q$ *be a density matrix [that is, any bounded operator on* $L^2(\mathbb{R}^3)$ *which satisfies the operator inequality* $0 \leqslant \gamma \leqslant q$ *and for which* $\mathrm{Tr}(\gamma) < \infty$*] and let* χ *be any function with support in* $B_R = \{x \,|\, |x| \leqslant R\}$. *Then*

$$\mathrm{Tr}(\overline{\chi}\gamma\chi H_{C_0R}) \geqslant -4.4827\ C_0^4 R^{-1} q\{(3/4\pi R^3) \int |\chi(x)|^2\, d^3x\}. \tag{6.2}$$

Note, that when $\chi \equiv 1$ *in* B_R, *then the factor in braces* { } *in* (6.2) *is 1*.

Here, $\mathrm{Tr}(\gamma h)$ is shorthand for $\Sigma_k (f_k, hf_k)\gamma_k$, where (f_k, γ_k) are the eigenfunctions and eigenvalues of γ. For more details, see Lieb.[13] In our situation, $q = 2$. For our purpose, let Π be the projection on $\mathrm{span}\{m_i \,|\, i = 1, \ldots, N\}$, then Π is a density matrix as above, and

$$\mathrm{Tr}(\chi_1 \Pi \chi_1 H_{C_0R}) = \sum_{i=1}^{N} (m_i, \chi_1 H_{C_0R} \chi_1 m_i).$$

Since $\mathrm{supp}\, \chi_1 \subseteq B(0, (1+\beta)\alpha^r)$ with $8/9 < r < 1$, set $R = (1+\beta)\alpha^r$ and $C_0 = 2(1+\beta)\alpha^{r-1}$. Then

$$T(p) - V(x) = \sqrt{p^2 + \alpha^{-2}} - \alpha^{-1} - \frac{\delta}{|x|} \geqslant |p| - \alpha^{-1} - \frac{2}{\pi}|x|^{-1} = H_{C_0R} + \alpha^{-1},$$

since $\sqrt{p^2 + \alpha^{-2}} - \alpha^{-1} \geqslant |p| - \alpha^{-1}$ and $\delta \leqslant 2/\pi$. Including the first term in (5.6) we now have, applying (6.2),

$$\begin{aligned} &\sum_{i=1}^{N} (m_i, \chi_1\{T(p) - V(x)\}\chi_1 m_i) - C\alpha^{1-2r} \sum_{i=1}^{N} (m_i, \chi_1\chi_1 m_i) \\ &\quad \geqslant \sum_{i=1}^{N} (m_i, \chi_1\{H_{C_0R} + \alpha^{-1} - C\alpha^{1-2r}\}\chi_1 m_i) \\ &\quad \geqslant \sum_{i=1}^{N} (m_i, \chi_1 H_{C_0R}\chi_1 m_i) = \mathrm{Tr}(\overline{\chi_1}\Pi\chi_1 H_{C_0R}) \geqslant -C\alpha^{3r-4}. \end{aligned} \tag{6.3}$$

The second inequality is valid for α small enough, since $r < 1$, so that $\alpha^{2(1-r)} \to 0$ for $\alpha \to 0$. Since $3r - 4 > -4/3$ (as $8/9 < r$), the right-hand side (RHS) of (6.3) is $o(\alpha^{-4/3})$, $\alpha \to 0$, which is the desired order. Note that the above procedure is what decides the scale α^r, $8/9 < r < 1$, on which one can localize near the nucleus.

VII. THE INTERMEDIARY ZONE

The energy in this area is given by the term [see (4.3)]

$$\sum_{i=1}^{N} (m_i, \chi_2\{T(p) - V(x) + \alpha\rho * \phi_a * |x_i|^{-1}\}\chi_2 m_i). \tag{7.1}$$

The zone defined by the χ_2 was introduced to separate the outer zone defined by χ_3 and the support of the coherent states to be introduced later. As in the preceding section we note that by dropping the term involving $\rho * \phi_a * |x|^{-1}$, we get a lower bound of the energy in (7.1). The remaining expression will be estimated by a generalization of the Lieb–Thirring inequality (see Lieb and Thirring[15]), proved by Daubechies in Ref. 4, p. 518. See also p. 516, Ref. 4, for the conditions on the function $T(p)$.

Proposition 7.1: *Let* $F(s) = \int_0^s \mathrm{d}t[T^{-1}(t)]^3$, *where* $T(p) = T(|p|) = \sqrt{|p|^2 + \alpha^{-2}} - \alpha^{-1}$ *as a function. Then*

$$\left\langle \psi, \sum_{i=1}^{N} \{T(p_i) - V(x_i)\}\psi \right\rangle \geqslant -q\tilde{C} \int F(|V(x)|) d^3x,$$

where $\tilde{C} \leqslant 0.163$.

Note that this in particular means that the negative part of the spectrum of the operator $T(p) - V(x)$ is discrete and that the sum of the negative eigenvalues of this operator is bounded from below by the quantity $-q\tilde{C}\int F(|V(x)|)d^3x$. To see this, let $\{e_j\}_{j=0}^{\infty}$ be these negative eigenvalues, $e_0 \leqslant e_1 \leqslant \cdots$, and $\{g_j\}_{j=0}^{\infty}$ corresponding orthonormal eigenfunctions, and let ψ be the Slater determinant of the first N of the g_j's. Then, by the above proposition,

$$-q\tilde{C} \int F(|V(x)|) d^3x \leqslant \left\langle \psi, \sum_{i=1}^{N} \{T(p_i) - V(x_i)\}\psi \right\rangle = \sum_{j=1}^{N} (g_j, \{T(p) - V(x)\}g_j) = \sum_{j=1}^{N} e_j. \tag{7.2}$$

Since the left-hand-side is independent of N, we get the statement by taking the limit $N \to \infty$. This will, as mentioned above, be used on the energy related to the cutoff χ_2, but also on the remaining half of the term $\chi_-(L_1^{(\alpha)} + L_2^{(\alpha)})\chi_-$ discussed in Sec. V, see (5.6). First, let us calculate F,

$$T(p) = T(|p|) = \sqrt{|p|^2 + \alpha^{-2}} - \alpha^{-1} \Rightarrow T^{-1}(t) = \sqrt{t^2 + 2\alpha^{-1}t}.$$

Then

$$F(s) = \int_0^s (t^2 + 2\alpha^{-1}t)^{3/2}\, \mathrm{d}t = \int_0^s \left(\frac{2t}{\alpha}\right)^{3/2} \left(1 + \frac{\alpha t}{2}\right)^{3/2} \mathrm{d}t.$$

Now, by a Taylor expansion of the second term in the integral, we get

$$(1 + (\alpha t)/2)^{3/2} \leqslant 1 + \frac{3\alpha}{4}t + \frac{3\alpha^2}{32}t^2. \tag{7.3}$$

That is, for $s \geqslant 0$,

$$F(s) \leqslant \left(\frac{2}{\alpha}\right)^{3/2} \left\{ \frac{2}{5}s^{5/2} + \frac{3\alpha}{14}s^{7/2} + \frac{\alpha^2}{48}s^{9/2} \right\}. \tag{7.4}$$

The two terms we wish to estimate in this section are, as mentioned above,

$$\sum_{i=1}^{N} (m_i, \chi_2\{T(p) - V(x)\}\chi_2 m_i) \quad \text{and } C\alpha^{1-2r} \sum_{i=1}^{N} (\chi_2 m_i, \chi_- \chi_2 m_i).$$

In order to do so, note that on $\operatorname{supp} \chi_-\chi_2$ we have [χ_- being the characteristic function of $B(0, 2\alpha^r)$]

$$V(x) = \frac{\delta}{|x|} \geqslant \frac{\delta}{2\alpha^r} \geqslant C\alpha^{1-2r}$$

for α small enough, since $r<1$, so that $\alpha^{1-r}\to 0$ as $\alpha\to 0$. Therefore, by the estimate (7.4) on $F(s)$, and still for α small enough, we have

$$\sum_{i=1}^{N}(m_i,\chi_2\{T(p)-V(x)\}\chi_2 m_i) - C\alpha^{1-2r}\sum_{i=1}^{N}(m_i,\chi_2\chi_-\chi_2 m_i) \geqslant \sum_{i=1}^{N}(m_i,\chi_2\{T(p)-2\hat{V}(x)\}\chi_2 m_i) \tag{7.5}$$

with $\hat{V}(x)=\chi_2(x)V(x)$. Letting (e_j,g_j) be the negative eigenvalues and corresponding orthonormal eigenvectors for the operator $T(p)-2\hat{V}(x)$ as before, we then have

$$\begin{aligned}\sum_{i=1}^{N}(m_i,\chi_2\{T(p)-2\hat{V}(x)\}\chi_2 m_i) &\geqslant \sum_{i=1}^{N}\left(\chi_2 m_i,\left\{\sum_j e_j(g_j,\cdot)g_j\right\}\chi_2 m_i\right) = \sum_j\sum_{i=1}^{N} e_j|(\chi_2 m_i,g_j)|^2\\ &= \sum_j\sum_{i=1}^{N} e_j|(m_i,\chi_2 g_j)|^2 \geqslant \sum_j e_j\|\chi_2 g_j\|^2 \geqslant \sum_j e_j.\end{aligned} \tag{7.6}$$

Here we used Bessel's inequality (remember that the m_i's are orthonormal), that $e_j<0$ and that $0\leqslant\chi_2\leqslant 1$. Using (7.2) on $T(p)-2\hat{V}(x)$, in the limit $N\to\infty$, we now reach [using (7.4)–(7.6)]

$$\begin{aligned}&\sum_{i=1}^{N}(m_i,\chi_2\{T(p)-V(x)\}\chi_2 m_i) - C\alpha^{1-2r}\sum_{i=1}^{N}(m_i,\chi_2\chi_-\chi_2 m_i) \geqslant -2\tilde{C}\int_{\operatorname{supp}\chi_2} F(2|V(x)|)d^3x\\ &\geqslant -C\int_{\operatorname{supp}\chi_2}\left(\frac{2}{\alpha}\right)^{3/2}\left\{\frac{2}{5}(2|V(x)|)^{5/2}+\frac{3\alpha}{14}(2|V(x)|)^{7/2}+\frac{\alpha^2}{48}(2|V(x)|)^{9/2}\right\}d^3x\\ &= -C4\pi\int_{\alpha^r}^{\alpha^t}\left(\frac{2}{\alpha}\right)^{3/2}\left\{\frac{2}{5}\left(\frac{2\delta}{|x|}\right)^{5/2}+\frac{3\alpha}{14}\left(\frac{2\delta}{|x|}\right)^{7/2}+\frac{\alpha^2}{48}\left(\frac{2\delta}{|x|}\right)^{9/2}\right\}|x|^2\mathrm{d}|x|\\ &= -C\left[\frac{4}{5}(\alpha^{(t-3)/2}-\alpha^{(r-3)/2})+\frac{6\delta}{7}(\alpha^{[-(r+1)]/2}-\alpha^{[-(t+1)]/2})+\frac{4\delta^2}{72}(\alpha^{(1-3r)/2}-\alpha^{(1-3t)/2})\right].\end{aligned}$$

Since $8/9<r<1$ and $1/3<t<2/3$, all of these terms are $o(\alpha^{-4/3})$, which is the desired order. We note that it is this analysis that decides the scale α^t of the outer cutoff χ_3.

VIII. THE OUTER ZONE AND THOMAS–FERMI TEORY

Up to order $o(\alpha^{-4/3})$ we are now left with

$$\sum_{i=1}^{N}(m_i,\chi_3\{T(p)-V(x)+\alpha\rho*\phi_a*|x|^{-1}\}\chi_3 m_i) - \frac{\alpha}{2}\int\int\frac{\rho(x)\rho(y)}{|x-y|}d^3x\,d^3y - \alpha\, c(\phi)Na^{-1}.$$

This expression will now be related to the semiclassical Thomas–Fermi energy. This is done by introducing coherent states, following Lieb and Yau in Ref. 16, proof of Lemma B.3. Let g be the function chosen in Sec. III, that is, $g\in C_0^\infty(\mathbb{R}^3)$, spherically symmetric, non-negative, supported in the unit ball $B(0,1)$ of $\mathbb{R}^3$ and such that $\int g(x)^2d^3x=1$. Let $g_\alpha(x)=\alpha^{-3s/2}g(x/\alpha^s)$, $1/3<t<s<2/3$, that is, $\phi_a(x)=g_\alpha(x)^2$ with $a=\alpha^s$. In this way, since $N=\lambda Z=\lambda\delta\alpha^{-1}$,

$$\alpha\, c(\phi)Na^{-1} = \lambda\delta\, c(\phi)\alpha^{-s} = o(\alpha^{-2/3}),$$

which is also $o(\alpha^{-4/3})$, $\alpha\to 0$. Define now the coherent states $g_\alpha^{p,q}, p, q\in\mathbb{R}^3$ by

$$g_\alpha^{p,q}(x) = g_\alpha(x-q)e^{ipx}.$$

With $\tilde{T}(p)$ the function $\sqrt{p^2+\alpha^{-2}}-\alpha^{-1}$, we then have the formulas

$$(f,f) = \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q (f,g_\alpha^{p,q})(g_\alpha^{p,q},f),$$

$$(f,(V*g_\alpha^2)f) = \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q V(q)(f,g_\alpha^{p,q})(g_\alpha^{p,q},f),$$

$$(f,T(p)f) \geqslant \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q \tilde{T}(p)(f,g_\alpha^{p,q})(g_\alpha^{p,q},f) - o(\alpha^{-1/3}). \tag{8.1}$$

The proof of these formulas is carried out in Appendix B. In this way, letting $\tilde{V}(x)=\delta/|x| - \alpha\rho * |x|^{-1}$ (remember that $\phi_{\alpha^s}=g_\alpha^2$),

$$\begin{aligned}
&\sum_{i=1}^N (m_i,\chi_3\{T(p)-V(x)+\alpha\rho*\phi_a*|x|^{-1}\}\chi_3 m_i)\\
&\quad=\sum_{i=1}^N\left(m_i,\chi_3\left\{T(p)-\tilde{V}(x)*\phi_{\alpha^s}+\frac{\delta}{|x|}*\phi_{\alpha^s}-\frac{\delta}{|x|}\right\}\chi_3 m_i\right)\\
&\quad=\sum_{i=1}^N (m_i,\chi_3\{T(p)-\tilde{V}(x)*\phi_{\alpha^s}\}\chi_3 m_i)\\
&\quad=\frac{1}{(2\pi)^3}\int\int d^3p\, d^3q(\tilde{T}(p)-\tilde{V}(q))\left(\sum_{i=1}^N |(m_i\chi_3,g_\alpha^{p,q})|^2\right) - No(\alpha^{-1/3}).
\end{aligned}$$

The second equality follows from Newton's theorem (since ϕ_{α^s} is spherically symmetric), $|x|^{-1} - |x|^{-1}*\phi_{\alpha^s}\equiv 0$ outside supp ϕ_{α^s}, and since supp $\chi_3\cap$ supp $\phi_{\alpha^s}=\varnothing$ for α sufficiently small (as $s>t$),

$$\sum_{i=1}^N\left(m_i,\chi_3\left\{\frac{\delta}{|x_i|}*\phi_{\alpha^s}-\frac{\delta}{|x_i|}\right\}\chi_3 m_i\right)=0.$$

This is one of the reasons for introducing the intermediary zone by the function χ_2. Note also that $No(\alpha^{-1/3})=o(\alpha^{-4/3})$. Now, for α small enough, $\alpha^{s-t}<1/4$, since $s>t$, so that if $|q|<\frac{1}{4}\alpha^t$, then

$$|x-q|<\alpha^s \Rightarrow |x|<\tfrac{1}{2}\alpha^t,$$

and so $(m_i\chi_3,g_\alpha^{p,q})=0$, since supp $g_\alpha\subset B(0,\alpha^s)$ and supp $\chi_3\subset\mathbb{R}^3\setminus B(0,\frac{1}{2}\alpha^t)$. That is, for α small enough

$$\text{supp}_q|(m_i\chi_3,g_\alpha^{p,q})|^2\subseteq\mathbb{R}^3\setminus B\left(0,\tfrac{1}{4}\alpha^t\right),$$

so that for any $\mu\geqslant 0$ we have, with $M(p,q)=\Sigma_{i=1}^N|(m_i\chi_3,g_\alpha^{p,q})|^2$ and $[f]_\pm=\max\{\pm f,0\}$,

$$\frac{1}{(2\pi)^3}\int\int d^3p\, d^3q(\tilde{T}(p)-\tilde{V}(q))\left(\sum_{i=1}^{N}|(m_i\chi_3,g_\alpha^{p,q})|^2\right)$$

$$=\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t} d^3p\, d^3q(\tilde{T}(p)-(\tilde{V}(q)-\alpha\mu))M(p,q)-\alpha\mu\sum_{i=1}^{N}(\chi_3 m_i,\chi_3 m_i)$$

$$\geqslant -\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t} d^3p\, d^3q[\tilde{T}(p)-(\tilde{V}(q)-\alpha\mu)]_- -\alpha\mu N,$$

since $0\leqslant M(p,q)\leqslant 1$ and $(\chi_3 m_i,\chi_3 m_i)\leqslant\|m_i\|_2^2=1$. The first is seen by Bessel's inequality, since the m_i's are orthonormal and $\|\chi_3 g_\alpha^{p,q}\|_2\leqslant\|g_\alpha^{p,q}\|_2=1$. In this way we have shown that for $\mu\leqslant 0$, $\rho:\mathbb{R}^3\to\mathbb{R}$ and $\psi\in\mathcal{H}_F=\wedge^N L^2(\mathbb{R}^3,\mathbb{C}^2)$,

$$\langle\psi,H\psi\rangle\geqslant -\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t} d^3p\, d^3q[\tilde{T}(p)-(\tilde{V}(q)-\alpha\mu)]_- -\frac{\alpha}{2}\int\int\frac{\rho(x)\rho(y)}{|x-y|}d^3x\, d^3y-\alpha\mu N$$
$$-o(\alpha^{-4/3}). \tag{8.2}$$

Choose now ρ to be the Thomas–Fermi density $\rho_{\mathrm{TF}}^{N,Z}$, that is, the function that minimizes the Thomas–Fermi functional [here, $\gamma=(3\pi^2)^{2/3}$],

$$\mathcal{E}_{\mathrm{TF}}(\rho)=\frac{3}{5}\gamma\int\rho(x)^{5/3}\,d^3x-\int\rho(x)\frac{Z}{|x|}d^3x+\frac{1}{2}\int\int\frac{\rho(x)\rho(y)}{|x-y|}d^3x\, d^3y \tag{8.3}$$

over the set

$$\left\{\rho\in L^{5/3}(\mathbb{R}^3)\cap L^1(\mathbb{R}^3)\,|\,\rho\geqslant 0,\int\rho(x)d^3x\leqslant N\right\}.$$

(For the Thomas–Fermi theory, see Lieb and Simon[14] and Lieb.[11]) Then $\rho_{\mathrm{TF}}^{N,Z}$ satisfies the Thomas–Fermi equation,

$$\gamma\rho(x)^{2/3}=\left[\frac{Z}{|x|}-\rho*|x|^{-1}-\mu\right]_+ \tag{8.4}$$

for some unique $\mu=\mu(N)$. Furthermore,

$$\text{for } N\leqslant Z,\quad \int\rho_{\mathrm{TF}}^{N,Z}(x)d^3x=N\quad\text{and}\quad\mu(N)>0,$$

$$\text{for } N>Z,\quad \int\rho_{\mathrm{TF}}^{N,Z}(x)d^3x=Z\quad\text{and}\quad\mu(N)=0$$

[see Lieb and Simon (Ref. 14, Theorems II.17, 18, and 20)]. In this way, $\int\rho_{\mathrm{TF}}^{N,Z}(x)d^3x<N$ implies $N>Z$, and therefore $\mu(N)=0$, so that we always have

$$\mu(N)\int\rho_{\mathrm{TF}}^{N,Z}(x)d^3x=\mu(N)N. \tag{8.5}$$

Let $\mathcal{E}_{\mathrm{TF}}(N,Z)\equiv\mathcal{E}_{\mathrm{TF}}(\rho_{\mathrm{TF}}^{N,Z})$ and define the Thomas–Fermi potential by

$$V_{\mathrm{TF}}^{N,Z}(x)\equiv Z/|x|-\rho_{\mathrm{TF}}^{N,Z}*|x|^{-1}-\mu(N),$$

then we have the following scaling [Ref. 14, (2.24) p. 608] (remember, that $\lambda=N/Z$ is fixed):

$$\mathcal{E}_{\mathrm{TF}}(N,Z) = Z^{7/3}\mathcal{E}_{\mathrm{TF}}(\lambda,1) \equiv -C_{\mathrm{TF}}(\lambda)Z^{7/3}, \tag{8.6}$$

$$V_{\mathrm{TF}}^{N,Z}(x) = Z^{4/3}V_{\mathrm{TF}}^{\lambda,1}(Z^{1/3}x) \equiv Z^{4/3}V_{\mathrm{TF}}(Z^{1/3}x). \tag{8.7}$$

The idea is now to estimate the difference between the integral in (8.2) [with $\rho=\rho_{\mathrm{TF}}^{N,Z}$ and $\mu = \mu(N)$] and

$$-\frac{\alpha}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t} d^3p\, d^3q\left[\frac{p^2}{2} - \left(\frac{Z}{|q|} - \rho_{\mathrm{TF}}^{N,Z} * |q|^{-1} - \mu(N)\right)\right]_-.$$

This is done in two step, first, we change the domain of the integration, then we change the integrand, each time estimating the error.

First,

$$\begin{aligned}
&-\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t} d^3p\, d^3q[\tilde{T}(p) - \alpha V_{\mathrm{TF}}^{N,Z}(q)]_- \\
&\quad= \frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\tilde{T}(p)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\, d^3q(\tilde{T}(p) - \alpha V_{\mathrm{TF}}^{N,Z}(q)) \\
&\quad= \frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\, d^3q(\tilde{T}(p) - \alpha V_{\mathrm{TF}}^{N,Z}(q)) \\
&\quad+ \frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\tilde{T}(p)<\alpha V_{\mathrm{TF}}^{N,Z}(q)<\alpha(p^2/2)} d^3p\, d^3q(\tilde{T}(p) - \alpha V_{\mathrm{TF}}^{N,Z}(q)).
\end{aligned}$$

Since $\tilde{T}(p) \geqslant 0$, we get

$$\begin{aligned}
&\int\int_{|q|>\frac{1}{4}\alpha^t;\tilde{T}(p)<\alpha V_{\mathrm{TF}}^{N,Z}(q)<\alpha(p^2/2)} d^3p\, d^3q(\alpha V_{\mathrm{TF}}^{N,Z}(q) - \tilde{T}(p)) \\
&\quad\leqslant \alpha\int\int_{|q|>\frac{1}{4}\alpha^t;\tilde{T}(p)<\alpha V_{\mathrm{TF}}^{N,Z}(q)<\alpha(p^2/2)} d^3p\, d^3q V_{\mathrm{TF}}^{N,Z}(q).
\end{aligned}$$

Using the scaling (8.7) and the change of variables $\omega = \delta^{1/3}\alpha^{-1/3}q$, the above is equal to

$$\delta^{1/3}\alpha^{2/3}\int\int_{|\omega|>\frac{1}{4}\delta^{1/3}\alpha^{t-1/3}\tilde{T}(p)<\delta^{4/3}\alpha^{-1/3}V_{\mathrm{TF}}(\omega)<\alpha(p^2/2)} d^3p\, d^3\omega\, V_{\mathrm{TF}}(\omega). \tag{8.8}$$

The limits in the integral means that

$$2\delta^{4/3}\alpha^{-4/3}V_{\mathrm{TF}}(\omega) \leqslant p^2 \leqslant 2\delta^{4/3}\alpha^{-4/3}V_{\mathrm{TF}}(\omega)\left(1 + \tfrac{1}{2}\delta^{4/3}\alpha^{2/3}V_{\mathrm{TF}}(\omega)\right)$$

so that with

$$X = 2\delta^{4/3}\alpha^{-4/3}V_{\mathrm{TF}}(\omega), \quad Y = \tfrac{1}{2}\delta^{4/3}\alpha^{2/3}V_{\mathrm{TF}}(\omega), \quad Z = |p|^2, \quad W = \tfrac{1}{4}\delta^{1/3}\alpha^{t-1/3},$$

we have

$$(8.8) = (4\pi)^2\delta^{1/3}\alpha^{2/3}\int_W^\infty \mathrm{d}|\omega||\omega|^2 V_{\mathrm{TF}}(\omega)\left(\int_X^{X(1+Y)}\frac{\sqrt{Z}}{2}\mathrm{d}Z\right)$$
$$= (4\pi)^2\delta^{1/3}\alpha^{2/3}\int_W^\infty \mathrm{d}|\omega||\omega|^2 V_{\mathrm{TF}}(\omega)\frac{X^{3/2}}{3}((1+Y)^{3/2}-1).$$

By the Taylor expansion (7.3), we have $(1+Y)^{3/2}\leqslant 1+\frac{3}{2}Y+\frac{3}{8}Y^2$, and so

$$(8.8) \leqslant C\delta^{7/3}\alpha^{-4/3}\int_W^\infty |\omega|^2 V_{\mathrm{TF}}(\omega)^{5/2}\left(\frac{3}{4}\delta^{4/3}\alpha^{2/3}V_{\mathrm{TF}}(\omega)+\frac{3}{32}\delta^{8/3}\alpha^{4/3}V_{\mathrm{TF}}(\omega)^2\right)\mathrm{d}|\omega|.$$

Using that $V_{\mathrm{TF}}^{N,Z}(x)\leqslant Z/|x|$, since $\mu(N)\geqslant 0$ and $\rho_{\mathrm{TF}}^{N,Z}\geqslant 0$ (remember that $V_{\mathrm{TF}}\equiv V_{\mathrm{TF}}^{\lambda,1}$), we arrive at

$$(8.8) \leqslant C\delta^{11/3}\alpha^{-2/3}\int_W^\infty \mathrm{d}|\omega||\omega|^{-3/2}+\sqrt{2}\pi^2\delta^5\int_W^\infty \mathrm{d}|\omega||\omega|^{-5/2}$$
$$\sim \alpha^{-2/3}W^{-1/2}+W^{-3/2}\sim \alpha^{-2/3}\alpha^{1/6-t/2}+\alpha^{(1-3t)/2}=o(\alpha^{-5/6})+o(\alpha^{-1/2}),$$

since $t<2/3$. This means, that

$$-\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t} d^3p\,d^3q[\tilde{T}(p)-\alpha V_{\mathrm{TF}}^{N,Z}(q)]_-$$
$$\geqslant \frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\,d^3q(\tilde{T}(p)-\alpha V_{\mathrm{TF}}^{N,Z}(q))-o(\alpha^{-4/3}).$$

Next note that since $|q|>\frac{1}{4}\alpha^t$ and $\alpha V_{\mathrm{TF}}^{N,Z}(q)\leqslant \delta/|q|$ in the area of integration, we have that

$$\tilde{T}(p)=\sqrt{p^2+\alpha^{-2}}-\alpha^{-1}\geqslant \alpha\frac{p^2}{2}-\alpha^3\frac{p^4}{8}.$$

In this way, we get

$$\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\,d^3q(\tilde{T}(p)-\alpha V_{\mathrm{TF}}^{N,Z}(q))$$
$$\geqslant \frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\,d^3q\left(\alpha\frac{p^2}{2}-\alpha^3\frac{p^4}{8}-\alpha V_{\mathrm{TF}}^{N,Z}(q)\right)$$
$$=\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\,d^3q\left(a\frac{p^2}{2}-\alpha V_{\mathrm{TF}}^{N,Z}(q)\right)$$
$$-\alpha^3\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)}\frac{p^4}{8}d^3p\,d^3q. \tag{8.9}$$

Note that

$$\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\,d^3q\left(\alpha\frac{p^2}{2}-\alpha V_{\mathrm{TF}}^{N,Z}(q)\right)$$
$$=-\frac{\alpha}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t} d^3p\,d^3q\left[\frac{p^2}{2}-\left(\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right)\right]_-$$
$$\geqslant-\frac{\alpha}{(2\pi)^3}\int\int d^3p\,d^3q\left[\frac{p^2}{2}-\left(\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right)\right]_-.$$

Let us now look at the last term in (8.9). Again using that $V_{\mathrm{TF}}^{N,Z}(x)\leqslant Z/|x|$, we have that

$$\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)}\frac{p^4}{8}d^3p\,d^3q$$
$$\leqslant\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\delta/|q|}\frac{p^4}{8}d^3p\,d^3q$$
$$=(4\pi)^2\int_{\frac{1}{4}\alpha^t}^{\infty}\mathrm{d}|q|\left(|q|^2\int_0^{\sqrt{2Z/|q|}}\frac{|p|^4}{8}|p|^2\mathrm{d}|p|\right)$$
$$=2\pi^2\int_{\frac{1}{4}\alpha^t}^{\infty}\mathrm{d}|q|\left(|q|^2[t^7/7]_0^{\sqrt{2Z/|q|}}\right)=\frac{2\pi^2(2Z)^{7/2}}{7}\int_{\frac{1}{4}\alpha^t}^{\infty}|q|^{-3/2}\mathrm{d}|q|=\frac{8\pi^2(2Z)^{7/2}}{7}\alpha^{-t/2}.$$

Using this, we then get the following:

$$\frac{1}{(2\pi)^3}\int\int_{|q|>\frac{1}{4}\alpha^t;\alpha(p^2/2)<\alpha V_{\mathrm{TF}}^{N,Z}(q)} d^3p\,d^3q(\tilde{T}(p)-\alpha V_{\mathrm{TF}}^{N,Z}(q))$$
$$\geqslant-\frac{\alpha}{(2\pi)^3}\int\int d^3p\,d^3q\left[\frac{p^2}{2}-\left(\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right)\right]_--\alpha^{(6-t)/2}\frac{(2Z)^{7/2}}{7\pi}.$$

Hence, since $\delta=Z\alpha$ is fixed and $t<2/3$, we have

$$\alpha^{(6-t)/2}\frac{(2Z)^{7/2}}{7\pi}=\frac{8\sqrt{2}}{7\pi}\alpha^{-(1+t)/2}\delta^{7/2}=o(\alpha^{-4/3}),\quad \alpha\to 0.$$

Summing up, we have now proved that for $\psi\in\mathcal{H}_F=\wedge^N L^2(\mathbb{R}^3,\mathbb{C}^2)$,

$$\langle\psi,H\psi\rangle\geqslant-\frac{\alpha}{(2\pi)^3}\int\int d^3p\,d^3q\left[\frac{p^3}{2}-\left(\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right)\right]_-$$
$$-\frac{\alpha}{2}\int\int\frac{\rho_{\mathrm{TF}}^{N,Z}(x)\rho_{\mathrm{TF}}^{N,Z}(y)}{|x-y|}d^3x\,d^3y-\alpha\mu(N)N-o(\alpha^{-4/3}).\tag{8.10}$$

Integrating first in p in the first integral in (8.10), we get, for each q fixed,

$$\int d^3p\left[\frac{p^2}{2}-\left(\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right)\right]_-$$
$$=\int_{(p^2/2)<V_{\mathrm{TF}}^{N,Z}}\left(\frac{p^2}{2}-\left(\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right)\right)d^3p$$
$$=-\frac{16\sqrt{2}\pi}{15}\left[V_{\mathrm{TF}}^{N,Z}(q)\right]_+^{5/2}.\tag{8.11}$$

The $[\cdots]_+$, since, if the term in brackets is negative, the integrand in (8.11) will be zero.

Now, because $\rho_{\mathrm{TF}}^{N,Z}$ satifies the equation (8.4), we get, that

$$\left[\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right]_+^{5/2}=\gamma^{5/2}\rho_{\mathrm{TF}}^{N,Z}(q)^{5/3}=\gamma^{3/2}\rho_{\mathrm{TF}}^{N,Z}(q)\left[\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right].$$

In the last equation, no $[\cdots]_+$ is needed, since, if the last term is negative, $\rho_{\mathrm{TF}}^{N,Z}$ is zero, because of (8.4). In this way, by the above and by (8.5),

$$\begin{aligned}
&-\frac{\alpha}{(2\pi)^3}\int\int d^3p\,d^3q\left[\frac{p^2}{2}-\left(\frac{Z}{|q|}-\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}-\mu(N)\right)\right]_- -\frac{\alpha}{2}\int\int\frac{\rho_{\mathrm{TF}}^{N,Z}(x)\rho_{\mathrm{TF}}^{N,Z}(y)}{|x-y|}d^3x\,d^3y\\
&\quad-\alpha\mu(N)N=\alpha\frac{3}{5}\gamma\int\rho_{\mathrm{TF}}^{N,Z}(q)^{5/3}\,d^3q-\alpha\int\rho_{\mathrm{TF}}^{N,Z}(q)\frac{Z}{|q|}d^3q+\alpha\int\rho_{\mathrm{TF}}^{N}(q)\rho_{\mathrm{TF}}^{N,Z}*|q|^{-1}\,d^3q\\
&\quad+\alpha\mu(N)\int\rho_{\mathrm{TF}}^{N,Z}(q)d^3q-\frac{\alpha}{2}\int\int\frac{\rho_{\mathrm{TF}}^{N,Z}(x)\rho_{\mathrm{TF}}^{N,Z}(y)}{|x-y|}d^3x\,d^3y-\alpha\mu(N)N\\
&=\alpha\left(\frac{3}{5}\gamma\int\rho_{\mathrm{TF}}^{N,Z}(x)^{5/3}\,d^3x-\int\rho_{\mathrm{TF}}^{N,Z}(x)\frac{Z}{|x|}d^3x+\frac{1}{2}\int\int\frac{\rho_{\mathrm{TF}}^{N,Z}(x)\rho_{\mathrm{TF}}^{N,Z}(y)}{|x-y|}d^3x\,d^3y\right)=\alpha\mathcal{E}_{\mathrm{TF}}(N,Z).
\end{aligned}$$

Since $H_{\mathrm{rel}}=\alpha^{-1}H$, and $Z=\delta\alpha^{-1}$, with δ fixed, $0\leqslant\delta\leqslant 2/\pi$, this shows, that for all $\psi\in\mathcal{H}_F=\wedge^N L^2(\mathbb{R}^3,\mathbb{C}^2)$,

$$\langle\psi,H_{\mathrm{rel}}\psi\rangle\geqslant -C_{\mathrm{TF}}Z^{7/3}-o(Z^{7/3}),\quad Z\to\infty,$$

because of the scaling (8.6). This ends the proof of Theorem 1.1. □

APPENDIX A: A FORMULA FOR THE KINETIC ENERGY

In this appendix we shall prove the localization-formula (4.2) for the operator $\sqrt{p^2+\alpha^{-2}}$ [which is the equivalent of the IMS Localization Formula for the Laplace operator $-\Delta$, see Cycon *et al.* (Ref. 3, Theorem 3.2)]. Let first K_2 be a modified Bessel function of second order, defined on $(0,\infty)$ by

$$K_2(t)=\frac{1}{2}\int_0^\infty xe^{-\frac{1}{2}t(x+x^{-1})}\,\mathrm{d}x.$$

It is easily seen that K_2 is well-defined, decreasing and differentiable. Other properties of K_2 will be derived later. Let then χ_j, $j=1,\ldots,k$ be smooth positive functions on $\mathbb{R}^3$, such that $\Sigma_j\chi_j^2(x)=1$ for all x in $\mathbb{R}^3$ and define on $L^2(\mathbb{R}^3)$ the bounded operator $L^{(\alpha)}$ by the kernel

$$L^{(\alpha)}(x,y)=\frac{\alpha^{-2}}{(2\pi)^2}\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}\sum_{j=1}^k(\chi_j(x)-\chi_j(y))^2.$$

Then for $f\in\mathcal{S}(\mathbb{R}^3)$ one has the formula

$$(f,\sqrt{p^2+\alpha^{-2}}f)=\sum_{j=1}^k(f,\chi_j\sqrt{p^2+\alpha^{-2}}\chi_j f)-(f,L^{(\alpha)}f).\tag{A1}$$

The proof of the localization formula (A1) will be a consequence of the following formula.

Lemma A.1: For $f\in\mathcal{S}(\mathbb{R}^3)$,

$$(f,(\sqrt{p^2+\alpha^{-2}}-\alpha^{-1})f)=\frac{\alpha^{-2}}{(2\pi)^2}\int\int|f(x)-f(y)|^2\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y.\tag{A2}$$

Proof: Let $\hat{f}$ be the Fourier transform of f. Note that by dominated convergence in momentum space, we have

$$(f,\sqrt{p^2+\alpha^{-2}}f)=\lim_{t\searrow 0}\frac{1}{t}\{(f,f)-(f,e^{-t\sqrt{p^2+\alpha^{-2}}}f)\}.$$

To calculate the integral kernel $\exp[-t\sqrt{p^2+\alpha^{-2}}](x,y)$, expand the Fourier transforms:

$$(f,e^{-t\sqrt{p^2+\alpha^{-2}}}f)=\int|\hat{f}(p)|^2e^{-t\sqrt{p^2+\alpha^{-2}}}d^3p=\frac{1}{(2\pi)^3}\int\int\overline{f(x)}f(y)\left(\int e^{-t\sqrt{p^2+\alpha^{-2}}}e^{i(x-y)\cdot p}\,d^3p\right)d^3x\,d^3y.$$

This is justified by the fact that $f\in\mathcal{S}(\mathbb{R}^3)$. Now, for x,y fixed, choose polar coordinates $(|p|,\theta,\phi)$, for p such that $(x-y)\cdot p=-|p||x-y|\cos\theta$. Then

$$\int e^{-t\sqrt{p^2+\alpha^{-2}}}e^{i(x-y)\cdot p}\,d^3p=\int_0^\infty\int_0^{2\pi}\int_0^{\pi}e^{-t\sqrt{p^2+\alpha^{-2}}}e^{-i|p||x-y|\cos\theta}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi|p|^2\mathrm{d}|p|$$

$$=2\pi\int_0^\infty|p|^2e^{-t\sqrt{p^2+\alpha^{-2}}}\left(\int_{-1}^{1}e^{i|p||x-y|u}\,\mathrm{d}u\right)\mathrm{d}|p|,\ u=-\cos\theta$$

$$=\frac{4\pi}{|x-y|}\int_0^\infty|p|e^{-t\sqrt{p^2+\alpha^{-2}}}\sin(|p||x-y|)\mathrm{d}|p|$$

$$=\frac{4\pi}{|x-y|}t\alpha^{-2}|x-y|(|x-y|^2+t^2)^{-1}K_2[\alpha^{-1}(|x-y|^2+t^2)^{1/2}],$$

where the last equality is given in Erdelyi *et al.* [Ref. 5, p. 75, 2.4 (35)]. In this way,

$$(f,e^{-t\sqrt{p^2+\alpha^{-2}}}f)=\frac{t\alpha^{-2}}{2\pi 2}\int\int\overline{f(x)}f(y)\frac{K_2[\alpha^{-1}(|x-y|^2+t^2)^{1/2}]}{|x-y|^2+t^2}d^3x\,d^3y. \tag{A3}$$

Now, letting $F_t(p)=e^{-t\sqrt{p^2+\alpha^{-2}}}$, the above shows that

$$\check{F}_t(x)=\frac{1}{(2\pi)^{3/2}}\int F_t(p)e^{ix\cdot p}\,d^3p=\sqrt{\frac{2}{\pi}}t\alpha^{-2}\frac{K_2[\alpha^{-1}(|x|^2+t^2)^{1/2}]}{|x|^2+t^2},$$

and therefore, for all $y\in\mathbb{R}^3$:

$$\frac{t\alpha^{-2}}{2\pi 2}\int\frac{K_2[\alpha^{-1}(|x-y|^2+t^2)^{1/2}]}{|x-y|^2+t^2}d^3x=F_t(0)=e^{-t\alpha^{-1}}. \tag{A4}$$

Hence we get, using (A3) and (A4), which are both symmetric in x and y, that

$$\begin{aligned}\frac{1}{t}\{(f,f)-(f,e^{-t\sqrt{p^2+\alpha^{-2}}}f)\}&=\frac{1}{t}\{(f,f)-(f,e^{-t\alpha^{-1}}f)\}+\frac{1}{t}\{(f,e^{-t\alpha^{-1}}f)-(f,e^{-t\sqrt{p^2+\alpha^{-2}}}f)\}\\&=-\frac{e^{-t\alpha^{-1}}-e^{-0\cdot\alpha^{-1}}}{t-0}(f,f)+\frac{1}{t}\left\{\int\frac{1}{2}((|f(x)|^2+|f(y)|^2)-\overline{f(x)}f(y)-\overline{f(y)}f(x))\right.\\&\quad\left.\times\frac{t\alpha^{-2}}{2\pi^2}\frac{K_2[\alpha^{-1}(|x-y|^2+t^2)^{1/2}]}{|x-y|^2+t^2}d^3x\,d^3y\right\}.\end{aligned}$$

Cancelling t and noting that

$$\lim_{t\searrow 0}\frac{e^{-t\alpha^{-1}}-e^{-0\cdot\alpha^{-1}}}{t-0}=\left.\frac{d}{dt}(e^{-t\alpha^{-1}})\right|_{t=0}=-\alpha^{-1},$$

we get that

$$\lim_{t\searrow 0}\frac{1}{t}\{(f,f)-(f,e^{-t\sqrt{p^2+\alpha^{-2}}}f)\}=\alpha^{-1}+\frac{\alpha^{-2}}{(2\pi)^2}\int\int|f(x)-f(y)|^2\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y.$$

This proves the lemma. □

Now, to prove the formula (A1), we simply use the fact that $\Sigma_j\chi_j^2(x)=1$ for all x in $\mathbb{R}^3$:

$$\sum_{j=1}^{k}|\chi_j(x)f(x)-\chi_j(y)f(y)|^2=|f(x)|^2+|f(y)|^2-\sum_{j=1}^{k}\chi_j(x)\chi_j(y)(\overline{f(y)}f(x)+\overline{f(x)}f(y))$$

$$=|f(x)-f(y)|^2+\sum_{j=1}^{k}\chi_j(x)(\overline{f(y)}f(x)+\overline{f(x)}f(y))(\chi_j(x)-\chi_j(y)).$$

Note that $\chi_j f\in\mathcal{S}(\mathbb{R}^3)$, since χ_j is smooth and bounded, so that using the formula (A2),

$$\sum_{j=1}^{k}(f,\chi_j(\sqrt{p^2+\alpha^{-2}}-\alpha^{-1})\chi_j f)=\sum_{j=1}^{k}(\chi_j f,(\sqrt{p^2+\alpha^{-2}}-\alpha^{-1})\chi_j f)$$

$$=\frac{\alpha^{-2}}{(2\pi)^2}\int\int\sum_{j=1}^{k}|\chi_j(x)f(x)-\chi_j(y)f(y)|^2\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y$$

$$=\frac{\alpha^{-2}}{(2\pi)^2}\int\int\left\{|f(x)-f(y)|^2+\sum_{j=1}^{k}\chi_j(x)(\overline{f(y)}f(x)\right.$$

$$\left.+\overline{f(x)}f(y))(\chi_j(x)-\chi_j(y))\right\}\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y. \tag{A5}$$

Using now that

$$\int\int\chi_j(x)\overline{f(y)}f(x)(\chi_j(x)-\chi_j(y))\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y$$

$$=-\int\int\chi_j(y)\overline{f(x)}f(y)(\chi_j(x)-\chi_j(y))\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y$$

simply by interchanging x and y, we finally get from (A5) that

$$\sum_{j=1}^{k}(f,\chi_j\sqrt{p^2+\alpha^{-2}}\chi_j f)=\frac{\alpha^{-2}}{(2\pi)^2}\int\int|f(x)-f(y)|^2\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y$$

$$+\frac{\alpha^{-2}}{(2\pi)^2}\int\int\overline{f(x)}f(y)\sum_{j=1}^{k}(\chi_j(x)-\chi_j(y))^2\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}d^3x\,d^3y$$

which, using (A2), proves the formula (A1). □

We now derive two facts about the function K_2,

$$\int_0^\infty t^2K_2(t)\mathrm{d}t=\frac{3\pi}{2}, \tag{A6}$$

$$K_2(t) \leqslant 4\sqrt{\frac{\pi}{2t}}e^{-t}\left(1+\frac{1}{2t}+\frac{1}{(2t)^2}\right) \quad \text{for all } t \in \mathbb{R}_+. \tag{A7}$$

The proof of (A6) is straightforward by using the definition of K_2,

$$\int_0^\infty t^2 K_2(t)\mathrm{d}t = \int_0^\infty t^2\left(\frac{1}{2}\int_0^\infty x e^{-\frac{1}{2}(x+x^{-1})}\,\mathrm{d}x\right)\mathrm{d}t = \frac{1}{2}\int_0^\infty x\left(\int_0^\infty t^2 e^{-\frac{1}{2}(x+x^{-1})}\,\mathrm{d}t\right)\mathrm{d}x$$

where the interchanging of the order of integration is allowed by Tonelli's theorem. By applying partial integration three times,

$$\int_0^\infty t^2 e^{-\frac{1}{2}(x+x^{-1})}\,\mathrm{d}t = \frac{16}{(x+x^{-1})},$$

and so

$$\int_0^\infty t^2 K_2(t)\mathrm{d}t = \frac{1}{2}\int_0^\infty \frac{16x}{(x+x^{-1})}\mathrm{d}x = 4\int_{-\infty}^\infty \frac{x^4}{(x^2+1)^3}\mathrm{d}x = 4\cdot 2\pi i\,\mathrm{Res}\left(\frac{z^4}{(z^2+1)^3}, i\right) = 8\pi i\frac{6}{32i} = \frac{3\pi}{2}.$$

For the estimate (A7), we need to rewrite K_2. This is done following Gray and Mathews (Ref. 18, pp. 50).

Observation A.2:

$$K_2(t) = \sqrt{\frac{\pi}{2t}}\frac{1}{\Gamma\left(\frac{5}{2}\right)}e^{-t}\int_0^\infty e^{-\xi}\xi^{3/2}\left(1+\frac{\xi}{2t}\right)^{3/2}\mathrm{d}\xi. \tag{A8}$$

To prove the observation, we start on the right-hand side of (A8). Setting $t+\xi=\sqrt{t^2+\eta}$, one gets, since then $\eta=\xi^2+2t\xi$, that

$$\mathrm{RHS(A8)} = \sqrt{\frac{\pi}{2t}}\frac{1}{\Gamma\left(\frac{5}{2}\right)}\int_0^\infty e^{-\sqrt{t^2+\eta}}\left(\frac{\eta}{2t}\right)^{3/2}\frac{\mathrm{d}\eta}{2\sqrt{t^2+\eta}}.$$

Using the formula

$$\int_0^\infty e^{-(a^2\xi^2+b^2/\xi^2)}\,\mathrm{d}\xi = \frac{\sqrt{\pi}}{2a}e^{-2ab}$$

[which holds since both sides satisfy the differential equation $\mathrm{d}f/\mathrm{d}b=-2af$, $f(b=0)=\sqrt{\pi}/2a$] with $a=\sqrt{t^2+\eta}$, $b=1/2$, we arrive at

$$\begin{aligned}\mathrm{RHS(A8)} &= \frac{1}{\Gamma\left(\frac{5}{2}\right)(2t)^2}\int_0^\infty \eta^{3/2}\left(\int_0^\infty e^{-((t^2+\eta)\xi^2+1/(2\xi)^2)}\,\mathrm{d}\xi\right)\mathrm{d}\eta \\ &= \frac{1}{\Gamma\left(\frac{5}{2}\right)(2t)^2}\int_0^\infty e^{-(t^2\xi^2+1/(2\xi)^2)}\left(\int_0^\infty e^{-\eta\xi^2}\eta^{3/2}\,\mathrm{d}\eta\right)\mathrm{d}\xi \\ &= \frac{1}{(2t)^2}\int_0^\infty e^{-(t^2\xi^2+1/(2\xi)^2)}\xi^{-5}\,\mathrm{d}\xi\end{aligned}$$

since one has the formula

$$\int_0^\infty e^{-\eta\xi^2}\eta^{3/2}\,\mathrm{d}\eta = \xi^{-5}\Gamma\left(\frac{5}{2}\right).$$

Making the change of variables $x=1/2t\xi^2$, we finally get

$$\mathrm{RHS(A8)} = \frac{1}{2}\int_0^\infty x e^{-(1/2)t(x+x^{-1})}\,\mathrm{d}x = K_2(t).$$

Now, to prove the estimate (A7), use the Tayloer expansion (7.3) on the integrand in (A8), to get

$$\begin{aligned}
K_2(t) &\leqslant \sqrt{\frac{\pi}{2t}}\frac{1}{\Gamma\left(\frac{5}{2}\right)}e^{-t}\int_0^\infty e^{-\xi}\xi^{3/2}\left(1+\frac{3}{4t}\xi+\frac{3}{32t^2}\xi^2\right)\mathrm{d}\xi \\
&= \sqrt{\frac{\pi}{2t}}\frac{1}{\Gamma\left(\frac{5}{2}\right)}e^{-t}\left(\int_0^\infty e^{-\xi}\xi^{3/2}\,\mathrm{d}\xi+\frac{3}{4t}\int_0^\infty e^{-\xi}\xi^{5/2}\,\mathrm{d}\xi+\frac{3}{32t^2}\int_0^\infty e^{-\xi}\xi^{7/2}\,\mathrm{d}\xi\right) \\
&= \sqrt{\frac{\pi}{2t}}\frac{1}{\Gamma\left(\frac{5}{2}\right)}e^{-t}\left(\Gamma\left(\tfrac{5}{2}\right)+\frac{3}{4t}\Gamma\left(\tfrac{7}{2}\right)+\frac{3}{32t^2}\Gamma\left(\tfrac{9}{2}\right)\right) \\
&= \sqrt{\frac{\pi}{2t}}e^{-t}\left(1+\frac{15}{8t}+\frac{105}{128t^2}\right) \leqslant 4\sqrt{\frac{\pi}{2t}}e^{-t}\left(1+\frac{1}{2t}+\frac{1}{(2t)^2}\right).
\end{aligned}$$

APPENDIX B: INTRODUCING COHERENT STATES

In this section we will introduce coherent states and prove the formulas in Sec. VIII. The error introduced by using coherent states will also be estimated here.

Lemma B.1: Let $g \in C_0^\infty(\mathbb{R}^3)$ be spherically symmetric, non-negative, supported in the unit ball and such that $\|g\|_2=1$, and let $g^{p,q}(x)=g(x-q)e^{ipx}$. Then

$$(f,f) = \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q (f,g^{p,q})(g^{p,q},f),$$

$$(f,(V*|g|^2)f) = \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q\, V(q)(f,g^{p,q})(g^{p,q},f),$$

$$(f,\sqrt{p^2+\alpha^{-2}}f) \geqslant \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q \sqrt{p^2+\alpha^{-2}}(f,g^{p,q})(g^{p,q},f) - 3\alpha\|\nabla g\|_\infty^2 \mathrm{Vol}(\mathrm{supp}\, g)\|f\|_2^2. \tag{B1}$$

Proof: The idea of the above formulas is to write the identity and other operators on $L^2(\mathbb{R}^3)$ as superpositions of the one-rank operators $\pi_{pq}=(\ ,g^{p,q})g^{p,q}$. To prove the above formulas, start with the right-hand side of the second formula (the proof of the first formula is similar, just more simple):

$$\begin{aligned}
\frac{1}{(2\pi)^3}\int\int d^3p\, d^3q V(q)(f,g^{p,q})(g^{p,q},f) &= \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q\, V(q)\left[\overline{\int f(y)\overline{g(y-q)}e^{-ipy}\,d^3y}\right] \\
&\quad\times\left[\int f(x)\overline{g(x-q)}e^{-ipx}\,d^3x\right].
\end{aligned} \tag{B2}$$

Notice, that the function in the last brackets is $(2\pi)^{3/2}$ times the Fourier transform of the function $F_q(x)=f(x)\overline{g(x-q)}$. In this way we get, by Parseval's formula,

$$\begin{aligned}(\mathrm{B2}) &= \int\int d^3p\, d^3q\, V(q)|\hat{F}_q(p)|^2 = \int d^3q\, V(q)\|\hat{F}_q\|_2^2 = \int d^3q\, V(q)\|F_q\|_2^2 \\ &= \int d^3q\, V(q)\left(\int |f(x)|^2|g(x-q)|^2\, d^3x\right) = \int d^3x|f(x)|^2\left(\int V(q)|g(x-q)|^2\, d^3q\right) \\ &= (f,(V*|g|^2)f).\end{aligned}$$

This proves the second (and the first) formula.

To prove the formula for the operator $\sqrt{p^2+\alpha^{-2}}$, note that

$$\int g(x-q)^2\, d^3q = 1 \text{ for all } x \text{ in } \mathbb{R}^3,$$

so that, by the symmetry of the operator $\sqrt{p^2+\alpha^{-2}}$,

$$\begin{aligned}(f,\sqrt{p^2+\alpha^{-2}}f) &= \frac{1}{2}\int\int \overline{f(x)}g(x-q)^2(\sqrt{p^2+\alpha^{-2}}f)(x)d^3q\, d^3x \\ &\quad + \frac{1}{2}\int\int \overline{(\sqrt{p^2+\alpha^{-2}}f)(x)}g(x-q)^2 f(x)d^3q\, d^3x \\ &= \frac{1}{2}\int\int \overline{f(x)}g_q(x)^2(\sqrt{p^2+\alpha^{-2}}f)(x)d^3q\, d^3x \\ &\quad + \frac{1}{2}\int\int \overline{f(x)}(\sqrt{p^2+\alpha^{-2}}(g_q^2 f))(x)d^3q\, d^3x. \qquad (\mathrm{B3})\end{aligned}$$

Here, $g_q(x)=g(x-q)$. Remembering that $g_q(x)^2$ is real and letting g_q^2 denote the multiplication operator defined by this function, we have

$$\begin{aligned}(\mathrm{B3}) &= \int\int \overline{(g_q f)(x)}[\sqrt{p^2+\alpha^{-2}}(g_q f)](x)d^3q\, d^3x + \frac{1}{2}\int\int \overline{f(x)}[({g_q}^2\sqrt{p^2+\alpha^{-2}} + \sqrt{p^2+\alpha^{-2}}{g_q}^2 \\ &\quad - 2g_q\sqrt{p^2+\alpha^{-2}}g_q)f](x)d^3q\, d^3x = \frac{1}{2}\int\int \overline{f(x)}(L_q f)(x)d^3q\, d^3x \\ &\quad + \int\int\left(\int \sqrt{p^2+\alpha^{-2}}\left(\int e^{-ipy}g_q(y)f(y)d^3y\right)e^{ipx}\, d^3p\right)g_q(x)\overline{f(x)}d^3q\, d^3x, \qquad (\mathrm{B4})\end{aligned}$$

where

$$(L_q f)(x) = \int\left\{\int [g_q(y)^2 + g_q(x)^2 - 2g_q(x)g_q(y)]\sqrt{p^2+\alpha^{-2}}e^{ip(x-y)}\, d^3p\right\}f(y)d^3y. \qquad (\mathrm{B5})$$

The second term in (B4) is equal to

$$\begin{aligned}&\int\int d^3p\, d^3q\sqrt{p^2+\alpha^{-2}}\left(\int \overline{f(x)}g_q(x)e^{ipx}d^3x\right)\left(\int f(y)g_q(y)e^{-ipy}\, d^3y\right) \\ &\quad = \int\int d^3p\, d^3q\sqrt{p^2+\alpha^{-2}}(f,g^{p,q})(g^{p,q},f).\end{aligned}$$

The first term in (B4) is the error, which will now be estimated. Keeping x and y fixed, we have, as showed in the proof of (A2),

$$L_q(x,y) = \int [g_q(y)^2 + g_q(x)^2 - 2g_q(x)g_q(y)]\sqrt{p^2+\alpha^{-2}}e^{ip(x-y)}\,d^3p$$
$$= [g_q(x) - g_q(y)]^2 \frac{\alpha^{-2}}{4\pi^2}\frac{K_2(\alpha^{-1}|x-y|)}{|x-y|^2}.$$

In this way, using the same ideas as in Sec. V, we reach the estimate

$$L_q(x,y) \leqslant \|\nabla g_q\|_\infty^2 \frac{\alpha^{-2}}{4\pi^2} K_2(\alpha^{-1}|x-y|)(\chi_{\text{supp } g_q}(x) + \chi_{\text{supp } g_q}(y)),$$

where $\chi_{\text{supp } g_q}$ is the characteristic function of supp g_q. This gives us that

$$\int L_q(x,y)d^3q \leqslant \int \|\nabla g_q\|_\infty^2 \frac{\alpha^{-2}}{4\pi^2} K_2(\alpha^{-1}|x-y|)(\chi_{\text{supp } g_q}(x) + \chi \text{ supp } g_q(y))d^3q$$
$$= 2\|\nabla g\|_\infty^2 \frac{\alpha^{-2}}{4\pi^2} K_2(\alpha^{-1}|x-y|)\text{Vol}(\text{supp } g).$$

By this we finally get, by using first the Cauchy–Schwartz, then Young's inequality, that

$$\left|\int\int \overline{f(x)} \int L_q(x,y)d^3q\, f(y)d^3x\, d^3y\right| \leqslant \int\int |f(x)|\left(2\|\nabla g\|_\infty^2 \frac{\alpha^{-2}}{4\pi^2} K_2(\alpha^{-1}|x-y|)\text{Vol}(\text{supp } g)\right)$$
$$\times |f(y)|d^3x\, d^3y$$
$$\leqslant 2\|\nabla g\|_\infty^2 \frac{\alpha^{-2}}{4\pi^2}\|f\|_2 \||f| * G_\alpha\|_2 \text{Vol}(\text{supp } g),$$
$$G_\alpha(x) = K_2(\alpha^{-1}|x|) \leqslant \|\nabla_g\|_\infty^2 \frac{\alpha^{-2}}{2\pi^2}\|f\|_2^2 \|G_\alpha\|_1 \text{Vol}(\text{supp } g)$$
$$= \|\nabla g\|_\infty^2 \frac{\alpha^{-2}}{2\pi^2} 6\pi^2\alpha^3 \|f\|_2^2 \text{Vol}(\text{supp } g) \quad [\text{see (A6) for } \|G_\alpha\|_1]$$
$$= 3\alpha\|\nabla g\|_\infty^2 \text{Vol}(\text{supp } g)\|f\|_2^2.$$

□

For the case (8.1) in Sec. VIII, let the coherent state $g^{p,q}$ be defined from the scaled version of the function g chosen there—that is, $g \in C_0^\infty(\mathbb{R}^3)$, spherically symmetric, non-negative and with support in the unit ball $B(0,1)$ of $\mathbb{R}^3$. Then the coherent states are

$$g_\alpha^{p,q}(x) = g_\alpha(x-q)e^{ipx} = \alpha^{-3s/2} g\left(\frac{x-q}{\alpha^s}\right)e^{ipx}.$$

In this way, $\|\nabla g_\alpha\|_\infty^2 = \alpha^{-5s}\|\nabla g\|_\infty^2$ and $\text{Vol}(\text{supp } g_\alpha) = (4\pi/3)\alpha^{3s}$, and therefore

$$(f, \sqrt{p^2+\alpha^{-2}}f) \geqslant \frac{1}{(2\pi)^3}\int\int d^3p\, d^3q \sqrt{p^2+\alpha^{-2}}(f, g_\alpha^{p,q})(g_\alpha^{p,q}, f) - o(\alpha^{-1/3}),$$

since, as $s < 2/3$,

$$3\alpha\alpha^{-5s}\|\nabla g\|_\infty^2 \frac{4\pi}{3}\alpha^{3s}\|f\|_2^2 = C\alpha^{1-2s} = o(\alpha^{-1/3}), \quad \alpha \to 0.$$

This proves the formula (8.1), since

$$(f,f) = \frac{1}{(2\pi)^3} \int \int d^3p\, d^3q (f, g_\alpha^{p,q})(g_\alpha^{p,q}, f)$$

and $T(p) = \sqrt{p^2 + \alpha^{-2}} - \alpha^{-1}$.

Local existence of quasispherical space–time initial data

Jason Sharples[a)]

(Received 8 June 2004; accepted 6 December 2004; published online 6 April 2005)

We consider the system of Einstein constraint equations in the special case when the spacelike 3-manifold is assumed to satisfy the quasispherical ansatz of Bartnik. We introduce two different time slicing conditions, under each of which we may view the resulting constraint equations as a parabolic/elliptic/ODE system of partial differential equations. We combine recent existence results for parabolic equations in Sobolev space with an iterative method to prove local existence results for the quasispherical Einstein constraint equations under the two different time slicing conditions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1864250]

I. INTRODUCTION

In general relativity, the Einstein field equations allow us to study the evolution of a spacelike 3-manifold, provided that its metric and extrinsic curvature satisfy a system of geometric constraint equations. The Einstein constraint equations, arise as a consequence of the fact that the 3-manifold in question is necessarily a submanifold of the spacetime its evolution defines. The constraint equations on a 3-manifold Σ with metric h and second fundamental form K are

$$\mathcal{R}_h + (\mathrm{tr}_h K)^2 - \|K\|^2 = 16\pi T_{00}, \tag{1.1}$$

$$D^j K_{ij} - D_i(\mathrm{tr}_h K) = 8\pi T_{0i}, \quad i = 1,2,3. \tag{1.2}$$

Here T is the stress-energy tensor and $\mathcal{R}_h$ and D denote the scalar curvature and Levi–Civita connection of the metric h.

Traditionally, solutions of the constraint equations are constructed using the method of Lichnerowicz,[12] which is based on the conformal class of h. This method has been studied extensively, for example in Refs. 7–10. Accordingly, the data set

$$h = \phi^4 \hat{h},$$

$$K = \phi^{-2}\hat{A} + \phi^{-2} l_{\hat{h}}(W) + \tfrac{1}{3}\tau\phi^4\hat{h},$$

satisfies the initial data constraints (1.1) and (1.2) if ϕ and W satisfy the semilinear elliptic system

$$8\Delta_{\hat{h}}\phi = \phi\mathcal{R}_{\hat{h}} - \|\hat{A} + l_{\hat{h}}(W)\|^2\phi^{-7} + \tfrac{2}{3}\tau^2\phi^5 - 16\pi\hat{T}_{00}, \tag{1.3}$$

$$\hat{D}_j[l_{\hat{h}}(W)]^{ij} = \tfrac{2}{3}\phi^6\hat{D}^i\tau + 8\pi\hat{T}^{0i}, \tag{1.4}$$

where l_h is the conformal Killing operator; $l_h(W) = \mathcal{L}_W h - \frac{1}{3}h\,\mathrm{tr}_h(\mathcal{L}_W h)$.

This conformal method has both advantages and disadvantages; on the one hand, every solution of (1.1) and (1.2) may be obtained in this manner from suitable $\hat{h}$, τ, $\hat{A}$, while on the other

[a)]Present address: Centre for Resource and Environmental Studies, Australian National University, Canberra, Australia, 0200. Electronic mail: jasons@cres.anu.edu.au

hand, the elliptic system (1.3) and (1.4) does not always admit solutions, it is difficult to solve numerically in general, and distinct data can give rise to diffeomorphically equivalent solutions of the constraint equations.[5]

More particularly, the conformal method has been shown to be inadequate for the solution of a problem encountered when considering the notion of quasilocal mass in general relativity.[3] In Ref. 2 one is confronted with the following extension problem:

Given a bounded data set (Σ_0, h_0, K_0), find an asymptotically flat data set (Σ, h, K) with boundary $\Gamma = \partial\Sigma \simeq \partial\Sigma_0$ such that the complete manifold $\Sigma \cup_\Gamma \Sigma_0$, obtained by gluing Σ and Σ_0 along Γ, forms an initial data set.

Requiring that (Σ, h) have bounded curvature across Γ implies the boundary conditions for the metric h and mean curvature $H_\Gamma = \mathrm{tr}_\Gamma K$,

$$h|_{T\Gamma} = h_0|_{T\partial\Sigma_0}, \quad H_\Gamma = H_{\partial\Sigma_0}. \tag{1.5}$$

Given a metric $\hat{h}$ on $\Sigma \setminus \Sigma_0$, for the conformal method, we must solve the semilinear elliptic equation,[3]

$$\left(\Delta_{\hat{h}} - \tfrac{1}{8}\mathcal{R}_{\hat{h}}\right)\phi = -\tfrac{1}{8}\phi^5 \mathcal{R}_h,$$

where $h = \phi^4 \hat{h}$ is the required 3-metric. The boundary conditions (1.5) imply that $\hat{h}|_{T\Gamma} = h_0|_{T\partial\Sigma}$ without loss of generality.

Under conformal change of the metric the mean curvature of Γ transforms as

$$H_{\Gamma,h} = 8\phi^{-3}\partial_{\hat{n}}\phi + \phi^{-2} H_{\Gamma,\hat{h}}, \tag{1.6}$$

where $\partial_{\hat{n}}$ is the outward $\hat{h}$-unit normal derivative.

Equation (1.6) implies that the boundary conditions (1.5) are equivalent to the boundary conditions for ϕ on Γ

$$\phi = 1, \quad \partial_n \phi = H_{\Gamma,\hat{h}} - H_{\partial\Sigma_0,h_0},$$

where $H_{\Gamma,\hat{h}}$ and $H_{\partial\Sigma_0,h_0}$ are the given mean curvatures. Clearly these boundary conditions are ill-posed.

In this paper we outline an alternative method for constructing solutions to the constraint equations based on the quasispherical (QS) ansatz of Bartnik.[4] Moreover, we establish local existence results for the constraint equations for a spacelike hypersurface in the QS gauge (Theorems 5.25 and 5.20). We make no mention of the generality of this gauge; the extent to which the QS ansatz applies remains an open problem.

After briefly describing and imposing the quasispherical gauge in Sec. II, we provide an argument to show that the resulting system of constraint equations may be viewed as a coupled system of partial differential equations consisting of a parabolic equation, a first-order elliptic system and (essentially) a system of ordinary differential equations. This system admits several Cauchy problem formulations, depending on which fields are considered as prescribed. In Sec. III we describe two such formulations that arise naturally through geometric considerations. In Sec. IV we reformulate the systems via a complexification of the sphere and introduce an additional constraint equation that allows us to write the systems in a more tractable form. In Sec. V we use a contraction mapping argument, based on an iterative system of partial differential equations, to prove local existence results for the two Einstein constraint systems that were formulated in the preceding sections of the paper.

II. THE QUASISPHERICAL METHOD

We assume that the 3-manifold, Σ, can be foliated by surfaces of constant positive Gauss curvature (i.e., rescaled 2-spheres), such that the area function $4\pi r^2 \in C^\infty(\Sigma)$ can be used as a

global coordinate. Using standard polar coordinates (ϑ,φ) on the 2-spheres, the most general metric compatible with these assumptions may be written as (Ref. 4, Lemma 2.1)

$$ds^2 = u^2\,dr^2 + (\beta^1\,dr + r\,d\vartheta)^2 + (\beta^2\,dr + r\sin\vartheta\,d\varphi)^2, \tag{2.1}$$

for functions $u(r,\vartheta,\varphi)>0$, $\beta^A(r,\vartheta,\varphi)$, $A=1,2$. We call the metric in these coordinates *quasispherical*, since this naturally generalizes the class of spherically symmetric metrics.

Computing the scalar curvature $\mathcal{R}$ of (2.1) we find that[4]

$$2r\partial_r u - 2\beta_A\nabla_A u = \gamma u^2\Delta u + (1+\gamma B)u - \gamma\left(1-\tfrac{1}{2}\mathcal{R}r^2\right)u^3, \tag{2.2}$$

where

$$B = \tfrac{1}{2}|\mathrm{div}\,\beta|^2 + \tfrac{1}{2}\left|\nabla_{(A}\beta_{B)}\right|^2 - r\partial_r(\mathrm{div}\,\beta) + \beta_A\nabla_A(\mathrm{div}\,\beta) - \tfrac{3}{2}\mathrm{div}\,\beta,$$

and

$$\gamma = \left(1-\tfrac{1}{2}\mathrm{div}\,\beta\right)^{-1}, \quad \mathrm{div}\,\beta = \nabla^A\beta_A.$$

Equation (2.2) is a semilinear parabolic equation on S^2 for u, with β^A and $\mathcal{R}$ regarded as prescribed fields. General global existence theorems for solutions of (2.2) have been proven in Ref. 4, under suitable regularity and boundedness assumptions about the prescribed fields. In particular, to ensure that (2.2) is parabolic evolution in the direction of increasing r, β is required to satisfy

$$2 - \mathrm{div}\,\beta > 0. \tag{2.3}$$

The parabolic equation (2.2) provides a method of solving the Hamiltonian constraint. Using the Hamiltonian constraint (1.1) to *define* the scalar curvature $\mathcal{R}$ in terms of $T_{00}, \|K\|^2$ and $\mathrm{tr}_h K$, specifying β appropriately and solving (2.2) for u yields a quasispherical metric satisfying the Hamiltonian constraint. It is of interest to point out in passing that the quasispherical form of the metric fares much better with the extension problem than the conformal method. If S_r^2 denotes a leaf of the quasispherical foliation, defined by

$$S_r^2 = \{p\in\Sigma : r(p) = r\}$$

then the mean curvature of S_r^2 is

$$H_r = H_{S_r^2} = \frac{1}{ru}(2 - \mathrm{div}\,\beta).$$

Therefore if β is given and satisfies (2.3), then prescribing $H_{r_0}>0$ amounts to specifying $u(r_0)$ which may then be taken as initial data for (2.2). Solution of (2.2), with initial data so defined, then yields an extension metric, at least in the case when the mean curvature is prescribed on a standard S^2. This idea has also been exploited in recent works concerning the connectedness of the space of initial data sets for the Einstein equations[17] and in connection with the positive mass theorem and boundary behaviour of compact manifolds.[16]

To solve the momentum constraints (1.2) it is convenient to reparametrize K. We define the quasispherical orthonormal coframe

$$\theta^1 = \beta^1\,dr + r\,d\vartheta,$$

$$\theta^2 = \beta^2\,dr + r\sin\vartheta\,d\varphi,$$

$$\theta^3 = u\,dr$$

and write

$$K_{ij}\theta^i\theta^j = \left(\eta_{AB} + \tfrac{1}{2}\mu\delta_{AB}\right)\theta^A\theta^B + \kappa_A(\theta^A\theta^3 + \theta^3\theta^A) + (H-\mu)\theta^3\theta^3, \tag{2.4}$$

where η_{AB} is a symmetric, traceless, 2-tensor on S^2. The momentum constraints (1.2) may then be written in terms of this quasispherical parametrization as

$$8\pi T_{03} ru = -(r\partial_r\mu - \beta^A\nabla_A\mu + (3 - \operatorname{div}\beta)\mu) + u \operatorname{div}\kappa + \kappa^A\nabla_A u + \eta^{AB}\nabla_{(B}\beta_{A)} + (2 - \operatorname{div}\beta)H, \tag{2.5}$$

$$8\pi T_{0\hat{A}} ru = \nabla^B(u\eta_{AB}) + \mu\nabla_A u + \nabla_A\left(u\left(\tfrac{1}{2}\mu - H\right)\right) + r\partial_r\kappa_A - \beta^B\nabla_B\kappa_A + ((3 - \operatorname{div}\beta)\delta_{AB} - \nabla_{(A}\beta_{B)})\kappa^B. \tag{2.6}$$

Hence if we consider the scalar curvature $\mathcal{R}$ as given in terms of μ, η, κ, and H via (1.1) and (2.4); that is,

$$\mathcal{R} = 16\pi T_{00} + \|\eta\|^2 + 2\|\kappa\|^2 + \tfrac{3}{2}\mu^2 - 2\mu H,$$

then the system of equations (2.2), (2.5), and (2.6) comprise the spacetime intial data constraints in the quasispherical gauge, and so will be referred to as the *quasispherical Einstein constraint system* (QSECS).

As mentioned already, for Eq. (2.2) to be considered parabolic it is required that β satisfy the condition (2.3). To ensure that this condition is met we *prescribe* β as any element of the set $\{f \in \Gamma^\infty(TS^2 \times [0,\infty)) : 2 - \operatorname{div} f > 0.\}$. This leaves u as the only remaining metric parameter. We therefore cannot prescribe u; it must be found by solving the QSECS subject to appropriate boundary conditions.

Now that we have established that u cannot be prescribed, we must consider the remaining fields μ, η_{11}, η_{12}, κ_1, κ_2, and H. Since we have only four equations in the QSECS, it is obvious that we need to prescribe at least three of these fields and consider the other three as to be determined by the QSECS, subject to suitable boundary conditions. The following question remains: Which of the fields μ, η_{11}, η_{12}, κ_1, κ_2, and H should we consider as prescribed? As we will see in a moment, prescribing either H or μ allows us to gain a certain control over the geometrical nature of the initial data. We will thus consider μ *or* H as prescribed, never both. This leaves us with two remaining fields to prescribe. The only choices are the components of η or the components of κ (it seems implausible to prescribe one component of each). Seeing that κ appears more frequently in the QSECS than does η, we choose to prescribe κ. As we might have hoped, we will see that this choice simplifies the structure of the QSECS, for only a minor cost. We make the comment, in passing, that the case for prescribing η is potentially interesting as well. This case will not be treated here, however.

III. TIME SLICING CONDITIONS

In the conformal method approach to constructing spacetime initial data, prescribing the mean curvature has been made standard practice. This has many advantages both geometrically and physically. Indeed the so-called maximal gauge or maximal time slicing, which amounts to the assumption that the mean curvature is zero, is quite often employed since it greatly simplifies the analysis and may be assumed, without loss of generality, for any asymptotically flat spacetime satisfying an interior condition.[1] These considerations suggest the following boundary value problem.

Problem 1a: QSECS with prescribed mean curvature. Given the prescribed fields $T_{0\alpha}$, β, κ, and H, do there exist solutions u, μ, and η of (2.2), (2.5), and (2.6) satisfying the boundary conditions $(u,\mu)|_{S^2_1} = (u_0,\mu_0)$? Note that $S^2_1 = \{p \in \Sigma : r(p) = 1\}$ is the unit sphere. It may be possible to assign boundary values on a more general 2-surface but in this work we will only treat the case where boundary values are assigned on the unit sphere.

Another less familiar but potentially interesting time slicing condition is given by prescribing μ. In general μ is defined as

$$\mu = g^{AB}K_{AB},$$

where g^{AB}, $A, B=1, 2$ refers to the components of the inverse of the induced (spherical) metric.

To illustrate the geometric meaning of prescribing μ we consider the case of spherically symmetric spacetimes with metric given by

$$ds^2 = -X^2\,dt^2 + 2Y\,dr\,dt + Z^2\,dr^2 + r^2\,d\sigma^2. \tag{3.1}$$

Calculating μ for the surfaces defined by constant t in this metric, we easily obtain

$$r\mu = 2X^{-1}Y.$$

If it were the case that the metric were written in polar coordinates (for which $Y=0$), we would find that $\mu=0$. For this reason we will refer to the slicing defined by $\mu=0$ as the *polar gauge* and we will call the quantity μ the *polar curvature*.

Next consider a surface defined by $t=f(r)$ in the metric (3.1). The tangent to this surface is given by $\dot{x}=\partial_r+f'\partial_t$. The normal to the surface is given by $n=a\partial_r+b\partial_t$, where a and b are determined by the conditions $g(\dot{x},n)=0$ and $g(n,n)=-1$, which lead to

$$a = \frac{X^2f' - Y}{Z^2 + Yf'}b,$$

$$b^{-2} = X^2 - \frac{2Y(X^2f' - Y)}{Z^2 + Yf'} - \frac{(X^2f' - Y)^2}{(Z^2 + Yf')^2}.$$

The polar curvature is given by

$$r\mu = 2a.$$

The polar gauge ($\mu=0$) then implies that $f'=YX^{-2}$ and so the tangent to the surface is given by

$$\dot{x} = \partial_r + YX^{-2}\partial_t,$$

while its normal is

$$n = X^{-1}\partial_t.$$

Calculating the gradient of r, we have

$$\nabla r = g^{\alpha\beta}\partial_\alpha r\partial_\beta = \frac{X^2}{X^2Z^2 + Y^2}(\partial_r + YX^{-2}\partial_t).$$

Hence, at least in the case of spherically symmetric spacetimes, the $\mu=0$ surfaces are those which have ∇r, the gradient of r, as their tangent vector.

Furthermore, the polar curvature arises naturally upon consideration of the trapped surface condition. If we condsider a spacelike 2-surface S, with normal N and second fundamental form $\mathbb{II}$, embedded in a spacelike 3-manifold with normal T and second fundamental form K, the expansion of the null congruences associated with $T\pm N$ are given by

$$\theta_\pm = \mathrm{tr}_S\langle\nabla_{e_A}e_B, T \pm N\rangle, = \mathrm{tr}_S(K_{AB} \pm \mathbb{II}_{AB}) = \mu \pm \mathrm{tr}_S\,\mathbb{II}.$$

Thus the trapped surface condition is $\mu = \pm\mathrm{tr}_S\mathbb{II}$.

The role the polar curvature plays in more general spacetimes is potentially very interesting but has not as yet been investigated in any detail. However, in anticipation of this investigation we will consider the QSECS with μ a prescribed field. This gives us a second formulation of the QSECS as a boundary value problem.

Problem 2a: QSECS with prescribed polar curvature. Given the prescribed fields $T_{0\alpha}$, β, κ and μ, do there exist solutions u, H, and η of (2.2), (2.5), and (2.6) satisfying the boundary conditions $u|_{S_1^2}=u_0$?

IV. REWRITING THE EQUATIONS

In this section we introduce a complex notation and a coordinate transformation that enables us to write the QSECS in a more tractable form. We define the following complex fields:

$$\beta = \frac{1}{\sqrt{2}}(\beta^1 - i\beta^2),$$

$$\kappa = \frac{1}{\sqrt{2}}(\kappa^1 - i\kappa^2),$$

$$\eta = \eta_{11} - i\eta_{12},$$

$$T_0 = \frac{1}{\sqrt{2}}(T_{01} - iT_{02}),$$

and the subsidiary field

$$\rho = 2 - \operatorname{div}\beta = \gamma^{-1}.$$

We may consider β and κ as S^2 vector fields or as spin-1 sections of the complex line bundle over S^2.[6,13] Similarly we may consider η as a symmetric, traceless 2-tensor over S^2 or as a spin-2 section of the complex line bundle over S^2. The context in which these fields are used should make it clear which representation is being employed.

The complex notation suggests encoding the angular derivatives in terms of the differential operator ð (a phonetic symbol pronounced "eth"[13]) defined on a spin-s field ψ by

$$ð\psi = \frac{1}{\sqrt{2}}\sin^s\vartheta(\partial_\vartheta - i\csc\vartheta\,\partial_\varphi)(\psi\sin^{-s}\vartheta).$$

All the standard differential operators on S^2 may be expressed in terms of ð, for example,

$$\operatorname{div}\beta = ð\bar{\beta} + \bar{ð}\beta,$$

$$\operatorname{curl}\beta = i(\bar{ð}\beta - ð\bar{\beta},$$

$$\Delta\psi = (ðð + \bar{ð}ð)\psi.$$

The spin-weighted spherical harmonics Y^s_{lm} are then the eigenfields of the Laplacian, satisfying

$$\Delta Y^s_{lm} = (s^2 - l(l+1))Y^s_{lm},$$

with $|s|\leqslant l$. The eigenfields Y^s_{lm} may be taken proportional to $ð^sY_{lm}$ for $s\geqslant 0$ and $\bar{ð}^{-s}Y_{lm}$ for $s<0$, where Y_{lm} are the usual spherical harmonics.[14]

An important result concerning $\bar{ð}$ which will have bearing on our consideration of the QSECS is as follows.[13,14]

Lemma 4.1: Suppose $s \geqslant 0$ *and let* $\mathcal{L}^s$ *denote the space of spin-s sections. The mapping* $\bar{\eth}: \mathcal{L}^{s+1} \to \mathcal{L}^s$ *has cokernel* $\mathcal{C} = \mathrm{span}\{Y^s_{sm}\}$.

We have the obvious corollary.

Corollary 4.2: Suppose $s \geqslant 0$. *The mapping* $\bar{\eth}: \mathcal{L}^{s+1} \to \mathrm{span}\{Y^s_{lm}: l \geqslant s+1\}$ *is a surjection.*

Due to the repeated appearance of the operator $r\partial_r - \nabla_\beta$ we will find it convenient to make a change of coordinates that will simplify the structure. We introduce the diffeomorphism of $S^2 \times \mathbb{R}$

$$\Phi: (t, \xi^A) \mapsto (e^t, \Theta^A(t,\xi)) = (r, \zeta^A), \tag{4.1}$$

where $\zeta = (\vartheta, \varphi)$ and $\Theta(t,\xi)$ is defined to be the solution of

$$\frac{\partial}{\partial t}\Theta(t,\xi) = -\beta(e^t, \Theta(t,\xi)), \tag{4.2}$$

subject to suitable boundary conditions, $\beta|_{t=0} = \beta_0$.

Hence, defining $\tilde{f}(t,\xi) = f(e^t, \Theta(t,\xi))$, we then have

$$\partial_t \tilde{f}(t,\xi) = \left. e^t \frac{\partial f}{\partial r} + \frac{\partial f}{\partial \zeta^A}\frac{\partial \Theta^A}{\partial t}\right|_{(r,\zeta)=(e^t,\Theta(t,\xi))} = \left(r\frac{\partial}{\partial r} - \beta^A \frac{\partial}{\partial \zeta^A}\right) f(e^t, \Theta(t,\xi)) = (r\partial_r - \nabla_\beta) f(e^t, \Theta(t,\xi)).$$

We may then write (2.2), (2.5), and (2.6) in terms of (t,ξ) as

$$2\tilde{\rho}\partial_t \tilde{u} = \tilde{u}^2 \tilde{\Delta}\tilde{u} + \tilde{\rho}(1 + \tilde{\gamma}\tilde{B})\tilde{u} - \left(1 - \tfrac{1}{2}\tilde{\mathcal{R}}e^{2t}\right)\tilde{u}^3,$$

$$8\pi \tilde{T}_{03}\tilde{u}e^t = -(\partial_t \tilde{\mu} + (1+\tilde{\rho})\tilde{\mu}) + \tilde{u}(\widetilde{\mathrm{div}\,\kappa}) + (\widetilde{\kappa^A \nabla_A u}) + (\widetilde{\eta^{AB}\nabla_{(B}\beta_{A)}}) + \tilde{\rho}\tilde{H},$$

$$8\pi \tilde{T}_0 \tilde{u}e^t = \partial_t \tilde{\kappa} + \left(\bar{\eth}(u\eta) + \mu \eth u + \tfrac{1}{2}\eth(u\mu) - \eth(uH) + (1+\rho)\kappa + \bar{\kappa}\eth\beta + \kappa\eth\bar{\beta}\right).$$

We note that since we have employed the coordinate transformation given by Φ, the Laplacian $\tilde{\Delta}$ appearing in the first of the above equations is with respect to the pulled back metric $\tilde{h} = \Phi^* h$.

As we can see, implementing the coordinate transformation Φ, simplifies the structure of the system in question. It does, however, leave us with a technical hitch. Since the natural angular derivatives will now be in terms of the ξ^A-coordinates, when we come to differentiate the equations, terms involving derivatives of β will arise via (4.2). This is not a problem, as we will assume throughout that β is a smooth, prescribed field and so the terms that arise will be bounded by uniform constants. Moreover, since we assume that β is smooth, the standard regularity theory for ordinary differential equations dependent upon a parameter implies that Φ is a smooth diffeomorphism.

With this observation in mind we may supress the tilde's. Introducing the notation $\dot{f} = \partial_t f$ and defining the auxiliary field $\hat{\eta} = u\eta$ we then write the QSECS as

$$2\rho\dot{u} = u^2 \Delta u + \rho(1+\gamma B)u - \left(1 - \tfrac{1}{2}\mathcal{R}\mathrm{e}^{2t}\right)u^3, \tag{4.3}$$

$$8\pi T_{03} u e^t = -(\dot{\mu} + (1+\rho)\mu) + u\,\mathrm{div}\,\kappa + \kappa^A \nabla_A u + \eta^{AB}\nabla_{(B}\beta_{A)} + \rho H, \tag{4.4}$$

$$8\pi T_0 u e^t = \bar{\eth}(\hat{\eta}) + \mu\eth u + \tfrac{1}{2}\eth(u\mu) - \eth(uH) + \dot{\kappa} + (1+\rho)\kappa + \bar{\kappa}\eth\beta + \kappa\eth\bar{\beta}. \tag{4.5}$$

To simplify the discussion and to be in keeping with the usual notions accompanying parabolic equations, we will call $t = \ln r$ "time" and refer to the values of the various fields on the unit sphere as initial values.

Unfortunately a problem arises if we consider (4.5) as giving an equation for $\hat{\eta}$. In making such a consideration we find that (4.5) is of the form $\bar{\eth} f = g$ with $f \in \mathcal{L}^2$. Observing Lemma 4.1, an equation of this form is only solvable if $g \in \text{span}\{Y^1_{lm} : l \geqslant 2\}$, that is to say if g is devoid of $l=1$ spherical harmonic components. Hence if we consider (4.5) as giving an equation for $\hat{\eta}$, then we do not have the freedom to prescribe all the fields we have thus far considered prescribed.

Typically the stress-energy tensor will be determined by the matter occupying the spacetime, and we would like to freely specify H or μ for geometric reasons. It is also best to completely specify the metric parameter β so that there is no chance of (2.3) being violated. That leaves us with κ, and we conclude that it is not possible to consider (4.5) as giving an equation for $\hat{\eta}$ and at the same time treat κ as freely specifiable.

We thus look to constrain κ in such a way that (4.5) is solvable. This will produce another equation (the κ constraint) which must then be included as part of the QSECS.

To obtain the required equation we spectrally decompose κ as follows:

$$\kappa = \sum_{m=-1}^{1} k^m Y^1_{1m} + \sum_{l=2}^{\infty} \sum_{m=-l}^{l} \kappa^{lm} Y^1_{lm} = k + \sigma,$$

where $\sigma = \Sigma_{l \geqslant 2} \Sigma_{|m| \leqslant l} \kappa^{lm} Y^1_{lm}$ is devoid of $l=1$ components.

Let $\mathcal{P}_1$ denote the projection onto the subspace spanned by $\{Y^1_{1m} : m = -1, 0, 1\}$. It is easy to check that if k satisfies

$$-\dot{k} = \mathcal{P}_1 \left\{ \mu \eth u + \tfrac{1}{2} \eth (u\mu) - \eth (uH) + (1+\rho)\kappa + \bar{\kappa} \eth \beta + \kappa \eth \bar{\beta} + 8\pi T_0 u e^t \right\} \tag{4.6}$$

then (4.5) reduces to

$$-\bar{\eth} \hat{\eta} = \dot{\sigma} + (1 - \mathcal{P}_1) \left\{ \mu \eth u + \tfrac{1}{2} \eth (u\mu) - \eth (uH) + (1+\rho)\kappa + \bar{\kappa} \eth \beta + \kappa \eth \bar{\beta} + 8\pi T_0 u e^t \right\}. \tag{4.7}$$

This equation is of the form $\bar{\eth} f = g$ with $g \in \text{span}\{Y^1_{lm} : l \geqslant 2\}$, and so is uniquely solvable by Corollary 4.2.

Replacing (4.5) with (4.6) and (4.7), the constraint system may now be written as

$$2\rho \dot{u} = u^2 \Delta u - u^3 \left(1 - \tfrac{1}{2} e^{2t} \left(16\pi T_{00} + 2\|\kappa\|^2 + \tfrac{3}{2}\mu^2 - 2\mu H \right) \right) + \rho \left(1 + \tfrac{1}{2} \gamma e^{2t} \|\hat{\eta}\|^2 + \gamma B \right) u, \tag{4.8}$$

$$\dot{\mu} = \text{div}(u\kappa) - (1+\rho)\mu + u^{-1} \hat{\eta}^{AB} \nabla_{(B} \beta_{A)} + \rho H - 8\pi T_{03} u e^t, \tag{4.9}$$

$$-\dot{k} = \mathcal{P}_1 \left\{ \mu \eth u + \tfrac{1}{2} \eth (u\mu) - \eth (uH) + (1+\rho)\kappa + \bar{\kappa} \eth \beta + \kappa \eth \bar{\beta} + 8\pi T_0 u e^t \right\}, \tag{4.10}$$

$$-\bar{\eth} \hat{\eta} = \dot{\sigma} + (1 - \mathcal{P}_1) \left\{ \mu \eth u + \tfrac{1}{2} \eth (u\mu) - \eth (uH) + (1+\rho)\kappa + \bar{\kappa} \eth \beta + \kappa \eth \bar{\beta} + 8\pi T_0 u e^t \right\}. \tag{4.11}$$

The problems 1a and 1b may now be stated more correctly as follows.

Problem 1b: QSECS with prescribed mean curvature. Given the prescribed fields $T_{0\alpha}$, β, σ, and H, do there exist solutions u, μ, $\hat{\eta}$, and k of (4.8)–(4.11) satisfying the initial conditions $(u, \mu, k)|_{S^2 \times \{0\}} = (u_0, \mu_0, k_0)$?

Problem 2b: QSECS with prescribed polar curvature. Given the prescribed fields $T_{0\alpha}$, β, σ, and μ, do there exist solutions u, H, $\hat{\eta}$, and k of (4.8)–(4.11) satisfying the initial conditions $(u, k)|_{S^2 \times \{0\}} = (u_0, k_0)$?

We have not yet made mention about which function spaces we will be posing Problems 1b and 2b in. Which spaces are to be used will be made clear in the next section after we discuss an iterative, linear system of partial differential equations based on the QSECS. In fact, the existence of solutions to the QSECS will follow from the convergence of the iterative system to a fixed point.

We will begin by considering Problem 1b.

V. LOCAL EXISTENCE

In Ref. 4 the author gives a detailed proof of the global existence and uniqueness of solutions of (2.2) with β and $\mathcal{R}$ prescribed, and satisfying certain conditions. When considering the QSECS with prescribed mean curvature, however, we may not consider $\mathcal{R}$ as completely prescribed, but as determined by the additional fields μ, $\hat{\eta}$, and k, each of which is constrained so as to satisfy (2.5) and (2.6).

To prove the local existence and uniqueness of solutions to the QSECS with prescribed mean curvature, we will not borrow from Bartnik's treatment. Instead we will define a linear system of partial differential equations and produce a sequence of iterates that converge to a solution of the QSECS. In defining the iterative scheme we will see that it is imperative that we have a theory dealing with linear parabolic equations in which the regularity of the coefficients is comparable to that of the solution. Such results were obtained in Ref. 15 where the following general second order parabolic equation was considered:

$$\partial_t u + A_t u = g \quad \text{on } S^2 \times [0,T],$$

$$u = u_0 \quad \text{on } S^2 \times \{0\}. \tag{5.1}$$

Here A_t is a linear differentiable operator of second order on S^2, which is expressible in divergence form. That is, for a twice differentiable function $u: S^2 \times [0,T] \to \mathbb{R}$, we may write $A_t u$ in local coordinates as

$$A_t u(x,t) = -\nabla_j (a^{ij}(x,t)\nabla_i u(x,t)) + b^i(x,t)\nabla_i u(x,t) + c(x,t)u(x,t), \tag{5.2}$$

where ∇ denotes the S^2 covariant derivative.

To ensure that (5.1) is a parabolic equation we assume that the operator A_t is an elliptic operator for each value of t, in the sense that for each $\xi \in TS^2$, and each fixed $t \in [0,T]$ we have

$$a^{ij}(x,t)\xi_i\xi_j \geqslant \theta \bar{g}^{ij}\xi_i\xi_j,$$

for a.e. $x \in S^2$, where $\theta > 0$ is a constant and where $\bar{g}$ is the standard S^2-metric.

Before stating the existence result for (5.1) we define the parabolic Sobolev spaces in which the solutions reside. Let $f, g: S^2 \times [0,T] \to \mathbb{R}$ be smooth functions and let

$$\langle f, g \rangle_{LH^s_{\nu,T}} = \int_0^T e^{-2\nu t} \langle f(\cdot,t), g(\cdot,t) \rangle_{H^s(S^2)} \, \mathrm{d}t.$$

We define LH^s_ν to be the Hilbert space formed by completion of $C^\infty(S^2 \times [0,T])$ in the corresponding norm. The parabolic Sobolev spaces we require may then be defined as

$$P^m_{\nu,T} = \left\{ f: S^2 \times [0,T] \to \mathbb{R} : \|\partial_t^i f\|_{LH^{2(m-i)}_{\nu,T}} < \infty, \ \forall\, i \leqslant m \right\}$$

and its associated inner product

$$\langle f, g \rangle_{P^m_{\nu,T}} = \sum_{i \leqslant m} \langle \partial_t^i f, \partial_t^i g \rangle_{LH^{2(m-i)}_{\nu,T}}.$$

Roughly speaking, a parabolic equation tells us that one time derivative is equivalent to two space derivatives. Hence, in a sense, the Hilbert space $P^m_{\nu,T}$ describes the set of functions that are in total $2m$ times differentiable. We also make the following definition in order to classify functions that have odd total derivative:

$$P^{m+1/2}_{\nu,T} = \left\{ f{:}S^2 \times [0,T] \to \mathbb{R}{:} \|\partial_t^i f\|_{LH^{2(m-i)+1}_{\nu,T}} < \infty,\ \forall\ i \leqslant m \right\}$$

and its associated inner product,

$$\langle f,g\rangle_{P^{m+1/2}_{\nu,T}} = \sum_{i\leqslant m} \langle \partial_t^i f, \partial_t^i g\rangle_{LH^{2(m-i)+1}_{\nu,T}}.$$

We note that $P^0_{\nu,T}=LH^0_{\nu,T}$ and $P^{1/2}_{\nu,T}=LH^1_{\nu,T}$. The required existence theorem may now be stated as Ref. 15.

Theorem 5.1: *Suppose* $m \geqslant m_0 = 4\frac{1}{2}$, $u_0 \in H^{2m}(S^2)$ *and* $g \in P^{m-1/2}_{\nu,T}$. *There is a unique solution* u of *(5.1) belonging to the class* $P^{m+1/2}_{\nu,T}$ *and satisfying the estimate*

$$\|u\|^2_{P^{m+1/2}_{\nu,T}} \leqslant \mathcal{Q}\left(\|u_0\|^2_{H^{2m}(S^2)} + \|g\|^2_{P^{m-1/2}_{\nu,T}} \right). \tag{5.3}$$

The constant $\mathcal{Q}$ *depends only on* m *and the norms* $\|a\|_{P^m_{\nu,T}}$, $\|b\|_{P^{m-1/2}_{\nu,T}}$ *and* $\|c\|_{P^{m-1/2}_{\nu,T}}$.

In addition to the already mentioned linear parabolic theory, we will need to employ results from linear elliptic equations and linear ordinary differential equations. These will be derived as they are needed.

We begin by proposing an iterative system of partial differential equations before going on to prove that it is well defined.

A. The iteration scheme

Keeping in mind that we are dealing with the QSECS with prescribed mean curvature, we may consider H as some given field. We therefore define the following iterative system for generating the sequence $\{(u_n,\mu_n,\hat{\eta}_n,k_n)\}_{n=0}^{\infty}$:

$$\dot{u}_{n+1} = \hat{\gamma} u_n^2 \Delta u_{n+1} - \hat{\gamma} u_n^3 \left(1 - \tfrac{1}{2} e^{2t}\left(16\pi T_{00} + 2\|\kappa_n\|^2 + \tfrac{3}{2}\mu_n^2 - 2\mu_n H\right)\right) + \tfrac{1}{2}\left(1 + \tfrac{1}{2}\gamma e^{2t}\|\hat{\eta}_n\|^2 + \gamma B\right) u_n, \tag{5.4}$$

$$\dot{\mu}_{n+1} = \mathrm{div}(u_{n+1}\kappa_{n+1}) - (1+\rho)\mu_{n+1} + u_n^{-1}\hat{\eta}_n^{AB}\nabla_{(B}\beta_{A)} + \rho H - 8\pi T_{03} u_{n+1} e^t, \tag{5.5}$$

$$\dot{k}_{n+1} = -\mathcal{P}_1\left\{ \mu_{n+1}\eth u_{n+1} + \tfrac{1}{2}\eth(u_{n+1}\mu_n) - \eth(u_{n+1}H) + (1+\rho)\kappa_n + \overline{\kappa}_n\eth\beta + \kappa_n\eth\overline{\beta} + 8\pi e^t u_{n+1} T_0 \right\}, \tag{5.6}$$

$$\begin{aligned} -\overline{\eth}\,\hat{\eta}_{n+1} = \dot{\sigma} + (1-\mathcal{P}_1)\Big\{ & \mu_{n+1}\eth u_{n+1} + \tfrac{1}{2}\eth(u_{n+1}\mu_{n+1}) - \eth(u_{n+1}H) + (1+\rho)\kappa_{n+1} + \overline{\kappa}_{n+1}\eth\beta + \kappa_{n+1}\eth\overline{\beta} \\ & + 8\pi e^t u_{n+1} T_0 \Big\}. \end{aligned} \tag{5.7}$$

We have set $\hat{\gamma}=\frac{1}{2}\gamma$ and $\hat{\rho}=\frac{1}{2}\rho$ for convenience. $\hat{\gamma}$ and $\hat{\rho}$ are still just smooth fields depending on β. From here on, unless otherwise stated, we assume that all of the prescribable fields are elements of $C^\infty(S^2\times[0,\infty))$. Note also that $\kappa_n = k_n + \sigma$.

The proposed iteration scheme is comprised of a hierarchical system of partial differential equations. The basic idea behind using (5.4)–(5.7) to generate a sequence of iterates may be stated informally as follows. Define the zeroth iterate $(u,\mu,k,\hat{\eta})_{\tilde{0}}$, by making an identification between the initial values u_0, μ_0, and k_0, and the zeroth iterates $u_{\tilde{0}}$, $\mu_{\tilde{0}}$, and $k_{\tilde{0}}$. The zeroth $\hat{\eta}$ iterate, $\hat{\eta}_{\tilde{0}}$, is then defined as the solution of (5.7), with $n=-1$.

Equation (5.4) is a linear parabolic equation, and so given appropriate initial data u_0, we may define its solution u_{n+1}, a function of prescribed regularity, provided that u_n, μ_n, k_n, and $\hat{\eta}_n$ are known functions of suitable regularity. Equations (5.5) and (5.6) form a coupled system of ordinary differential equations for (μ_{n+1}, k_{n+1}). Hence if we are given appropriate initial data (μ_0, k_0), we may define (μ_{n+1}, k_{n+1}) as the (prescribed regularity) solution of (5.5) and (5.6) provided that u_{n+1}, as given by (5.4), and u_n, μ_n, k_n, and $\hat{\eta}_n$ are functions of suitable regularity.

The last equation (5.7), is a first order elliptic system which, by construction, may be uniquely solved for $\hat{\eta}_{n+1}$ provided that u_{n+1}, μ_{n+1}, and k_{n+1}, as given by (5.4)–(5.6), are suitably regular.

The claim is that by iterating the procedure described above, we can construct a sequence of iterates $(u,\mu,k,\hat{\eta})_n$. We will now make these ideas more precise by showing that the above iteration scheme is consistently defined.

B. Consistency of the iteration scheme

As suggested by the preceding remarks about the iteration scheme, we begin by considering Eq. (5.4). Let us suppose that u_n, μ_n, k_n, $\hat{\eta}_n \in P^m_{0,T}$, $u_n(\xi,t) \geqslant \delta_1 > 0$, for all $(\xi,t) \in S^2 \times [0,T]$ and that $u_0 \in H^{2m}(S^2)$ with $u_0(\xi) \geqslant \delta_2 > 0$, for all $\xi \in S^2$. Note here that the u_0 we have referred to is the initial value, not the zeroth iterate $\tilde{u_0}$ which is defined as the time constant extension of $u_0 \in H^{2m}(S^2)$ to $S^2 \times [0,\infty)$, that is

$$\tilde{u_0}(\xi,t) = u_0(\xi).$$

Equation (5.4) is a linear parabolic equation for u_{n+1} subject to the initial condition $u_{n+1}|_{S^2\times\{0\}} = u_0$, which is seen to be of the form

$$\dot{u}_{n+1} = \mathcal{A}^n_t u_{n+1} + F_n, \qquad u_{n+1}|_{t=0} = u_0,$$

where the operator $\mathcal{A}^n_t$ is given as

$$\mathcal{A}^n_t = \hat{\gamma} u_n^2 \Delta.$$

The operator $\mathcal{A}^n_t$ may be written in divergence form (5.2), with

$$a^{ij} = \hat{\gamma} u_n^2 \bar{g}^{ij},$$

$$b^i = -(u_n^2 \nabla_k \hat{\gamma} \bar{g}^{ik} + 2\hat{\gamma} u_n \nabla_k u_n \bar{g}^{ik}),$$

$$c = 0. \tag{5.8}$$

The source field F_n is defined as

$$F_n = \tfrac{1}{2}\left(1 + \tfrac{1}{2}\gamma e^{2t}\|\hat{\eta}_n\|^2 + \gamma B\right)u_n - \hat{\gamma}\left(1 - \tfrac{1}{2}e^{2t}\left(16\pi T_{00} + 2\|\kappa_n\|^2 + \tfrac{3}{2}\mu_n^2 - 2\mu_n H\right)\right)u_n^3.$$

Recalling Theorem 5.1 we find that if $m \geqslant m_0$, u_n, $\hat{\eta}_n$, $k_n \in P^m_{0,T}$ and the prescribable fields are smooth then u_{n+1} is uniquely defined as an element of $P^{m+1/2}_{0,T}$.

It is important to note that for Theorem 5.1 to apply it is imperative that $\hat{\gamma} u_n^2 \Delta$ be an elliptic operator. The ellipticity of this operator is solely dependent upon u_n's capacity to stay above zero. Although we have assumed that $u_n(\xi,t) \geqslant \delta_1 > 0$ for all $(\xi,t) \in S^2 \times [0,T]$, it could happen that u_{n+1} falls below δ_1 after some time $T_* < T$. This possibility means that successive iterates might only be defined as elements of $P^{m+1/2}_{0,T_n}$, with $\{T_n\}$ a decreasing sequence of times. We will say more about this point later on.

Given that u_{n+1} exists and belongs to the class $P^{m+1/2}_{0,T}$ we move on to consider the coupled ordinary differential equation system (5.5) and (5.6).

We note first that, given $t \in [0,\infty)$, $k(\cdot,t)$ is an element of $\mathrm{Span}\{Y^1_{1m} : m = -1,0,1\}$ and as such we may equivalently consider $k(\cdot,t)$ simply as an element of $\mathbb{C}^3$. Indeed, we may write

$$k(\xi,t) = k^m(t) Y^1_{1m}(\xi), \quad m = -1,0,1,$$

and since the Y^1_{1m}'s are given, we may think of k as mapping $[0,\infty)$ into $\mathbb{C}^3$ as follows:

$$k:[0,\infty) \to \mathbb{C}^3 t \mapsto (k^{-1}(t), k^0(t), k^1(t)).$$

For simplicity, we will refer to $k(\cdot,t)$ simply as $k(t)$. Note that there will now be an ambiguity surrounding our use of the symbol $k(t)$ since we will use it to denote both a field over S^2, and the components of that field over $\mathbb{C}^3$. When we say "$k \in P^m_{0,T}$" we mean $k(t) \in \mathrm{Span}\{Y^1_{1m} : m = -1, 0, 1\}$. Drawing the distinction between this representation and k's representation over $\mathbb{C}^3$, we have that

$$k = (k^{-1}, k^0, k^1) \in H^m([0,T];\mathbb{C}^3) \quad \text{if and only if } k = k^m Y^1_{1m} \in P^m_{0,T},$$

where $H^m([0,T];\mathbb{C}^3)$ is the Sobolev space with norm given by

$$\|f\|^2_{H^m([0,T];\mathbb{C}^3)} = \sum_{i=1}^{m} \int_0^T \|\partial_t^i f(s)\|^2_{\mathbb{C}^3} \, \mathrm{d}s.$$

The context in which the symbol k (or k_n) is used should make it clear which representation we are employing.

Furthermore, for any fixed value of t we have $(\mu(t), k(t)) \in \mathcal{F}(S^2) \times \mathbb{C}^3$, where $\mathcal{F}(S^2)$ is some appropriate function space; we will see that the Sobolev spaces $H^{2j}(S^2)$, with $j \geqslant m_0$, will suit our needs. Hence we can view the equations (5.5) and (5.6) as a coupled system of ordinary differential equations on $E^j := H^{2j}(S^2) \times \mathbb{C}^3$, and so writing

$$\mathcal{M}(t) := (\mu(t), k(t)),$$

we have

$$\dot{\mathcal{M}}_{n+1} = A_n \mathcal{M}_{n+1} + B_n, \tag{5.9}$$

where

$$A_n \mathcal{M} = (k^m[\eth(u_{n+1}\bar{\eth}Y_{1m}) + \bar{\eth}(u_{n+1}\eth Y_{1m})] - (1+\rho)\mu - \mathcal{P}_1[\mu \eth u_{n+1}]), \tag{5.10}$$

and

$$B_n = \Big(\mathrm{div}(u_{n+1}\sigma) + u_n^{-1}\hat{\eta}_n^{AB}\nabla_{(B}\beta_{A)} + \rho H - 8\pi T_{03}u_{n+1}e^t - \mathcal{P}_1\Big[\tfrac{1}{2}\eth(u_{n+1}\mu_n) - \eth(u_{n+1}H) + (1+\rho)\kappa_n + \bar{\kappa}_n\eth\beta + \kappa_n\eth\bar{\beta} - 8\pi T_0 u_{n+1}e^t\Big]\Big). \tag{5.11}$$

We then have the following result, which asserts that the operator A_n is bounded, provided u_{n+1} satisfies certain conditions. We note also, in passing, that the operator A_n is linear.

Lemma 5.2: Let $u_{n+1}(t) \in H^{2j+1}(S^2)$ *for all* $t \in [0,T]$, and $\beta \in \Gamma^\infty(TS^2 \times [0,\infty))$. *The operator defined above by (5.10) satisfies*

$$A_n(t): H^{2j}(S^2) \times \mathbb{C}^3 \to H^{2j}(S^2) \times \mathbb{C}^3$$

and

$$\|A_n \mathcal{M}(t)\|_{H^{2j}(S^2)\times\mathbb{C}^3} \leqslant C(1 + \|u_{n+1}(t)\|_{H^{2j+1}(S^2)})\|\mathcal{M}(t)\|_{H^{2j}(S^2)\times\mathbb{C}^3},$$

for each $t \in [0,T]$ *and some constant* C *depending only on the smooth field* β. *That is to say that* $A_n(t)$ *is a uniformly bounded operator for each* n, *with norm given by*

$$\|A_n(t)\|_j = C(1 + \|u_{n+1}(t)\|_{H^{2j+1}(S^2)}).$$

Proof: Let $E^j := H^{2j}(S^2) \times \mathbb{C}^3$ and note that

$$\|A_n\mathcal{M}\|_{E^j}^2 = \|k^m[\eth(u_{n+1}\bar{\eth}Y_{1m}) + \bar{\eth}(u_{n+1}\eth Y_{1m})] - (1+\rho)\mu\|_{H^{2j}(S^2)}^2 + \|\mathcal{P}_1(\mu\eth u_{n+1})\|_{\mathbb{C}^3}^2$$
$$\leqslant 2\|k^m[\eth(u_{n+1}\bar{\eth}Y_{1m}) + \bar{\eth}(u_{n+1}\eth Y_{1m})]\|_{H^{2j}(S^2)}^2 + 2\|(1+\rho)\mu\|_{H^{2j}(S^2)}^2 + \|\mathcal{P}_1(\mu\eth u_{n+1})\|_{\mathbb{C}^3}^2.$$

Estimating the first term on the right-hand side we have

$$\|k^m[\eth(u_{n+1}\bar{\eth}Y_{1m}) + \bar{\eth}(u_{n+1}\eth Y_{1m})]\|_{H^{2j}(S^2)} \leqslant \|k^m\eth u_{n+1}\bar{\eth}Y_{1m}\|_{H^{2j}(S^2)} + \|k^m\bar{\eth}u_{n+1}\eth Y_{1m}\|_{H^{2j}(S^2)}$$
$$+ \|k^m u_{n+1}\Delta Y_{1m}\|_{H^{2j}(S^2)} \leqslant C\|u_{n+1}\|_{H^{2j+1}(S^2)}\|k\|_{\mathbb{C}^3}, \tag{5.12}$$

while for the second term we have

$$\|(1+\rho)\mu\|_{H^{2j}(S^2)} \leqslant C\|\mu\|_{H^{2j}(S^2)}. \tag{5.13}$$

The remaining term is estimated as follows:

$$\|\mathcal{P}_1(\mu\eth u_n)\|_{\mathbb{C}^3}^2 = \sum_{m=-1}^{1}\left|\oint \mu\eth u_{n+1}Y_{1m}^1\,\mathrm{d}\Omega^2\right|^2 \leqslant C\sum_{m=-1}^{1}\left(\oint|\mu\eth u_{n+1}|\,\mathrm{d}\Omega^2\right)^2 \leqslant C\|\mu\|_{L^2(S^2)}^2\|\eth u_{n+1}\|_{L^2(S^2)}^2 \tag{5.14}$$

for any $j \geqslant 0$.

Adding (5.12), (5.13), and (5.14) we obtain

$$\|A_n\mathcal{M}\|_{E^j} \leqslant C(1+\|u_{n+1}\|_{H^{2j+1}(S^2)})(\|\mu\|_{H^{2j}(S^2)} + \|k\|_{\mathbb{C}^3}),$$

as required. ■

The boundedness of a linear operator A_n, such as that just established in Lemma 5.2, is the standard property required to infer the existence of solutions of (5.9). The following result is a special case of the standard local existence result for ordinary differential equations in Banach space. See Ref. 11, for example.

Lemma 5.3: Let $E^j = H^{2j}(S^2)\times\mathbb{C}^3$, and suppose $A(t): E^j \to E^j$ is a uniformly bounded linear operator for each $t\in[0,T]$, with norm $\|A(t)\|_j$. Further suppose that $\mathcal{M}_0 \in E^j$ and $B\in L^1([0,T];E^j)$. Then there exists a unique $\mathcal{M}\in C^1([0,T];E^j)$ satisfying

$$\dot{\mathcal{M}} = A\mathcal{M} + B,$$

$$\mathcal{M}(0) = \mathcal{M}_0.$$

The boundedness of the operator A_n is also the foundation for *a priori* estimates for solutions of (5.9). The basic result is as follows.

Lemma 5.4: Let A and B satisfy the hypotheses of Lemma 5.3 and let $\mathcal{M}$ be a solution of

$$\dot{\mathcal{M}} = A\mathcal{M} + B,$$

with initial value $\mathcal{M}_0$. For all $t\in[0,T]$, we have the estimate

$$\|\mathcal{M}(t)\|_{E^j}e^{-t\|A\|_j} \leqslant \|\mathcal{M}_0\|_{E^j} + \int_0^t \|B(s)\|_{E^j}\,\mathrm{d}s.$$

Proof: We note first that $E^j = H^{2m}(S^2)\times\mathbb{C}^3$ is in fact a Hilbert space and so, fixing $t\in[0,T]$,

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\mathcal{M}(t)\|_{E^j}^2 = 2\langle\mathcal{M}(t),\dot{\mathcal{M}}(t)\rangle_{E^j} \leqslant 2\|\mathcal{M}(t)\|_{E^j}\|\dot{\mathcal{M}}(t)\|_{E^j}.$$

Hence we must have

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\mathcal{M}(t)\|_{Ej} \leqslant \|\dot{\mathcal{M}}(t)\|_{Ej} \leqslant \|A\mathcal{M}(t)\|_{Ej} + \|B(t)\|_{Ej} \leqslant C\|\mathcal{M}(t)\|_{Ej} + \|B(t)\|_{Ej},$$

where it is clear that the smallest such C for which this inequality holds is the norm $\|A\|_j$ of the operator A.

Gronwall's inequality then gives

$$\|\mathcal{M}(t)\|_{Ej} \leqslant e^{Ct}\left(\|\mathcal{M}_0\|_{Ej} + \int_0^t \|B(s)\|_{Ej}\,\mathrm{d}s\right)$$

as required. ■

Applying Lemmas 5.3 and 5.4 to (5.9), noting Lemma 5.2, we have the following result.

Corollary 5.5: *Suppose that* u_n, μ_n, k_n, $\hat{\eta}_n \in P^m_{0,T}$ *and* $u_{n+1} \in P^{m+1//2}_{0,T}$ *is the solution of (5.4), subject to the initial condition* $u_0 \in H^{2m}(S^2)$. *Equation (5.9), subject to the initial condition* $\mathcal{M}_{n+1}|_{t=0} = \mathcal{M}_0 \in E^m$, *defines* $\mathcal{M}_{n+1} \in C^1([0,T];E^m)$, *which satisfies*

$$\|\mathcal{M}_{n+1}(t)\|_{E^m} e^{-t\|A_n\|_m} \leqslant \|\mathcal{M}_0\|_{E^m} + \int_0^t \|B_n(s)\|_{E^m}\,\mathrm{d}s, \tag{5.15}$$

for all $t \in [0,T]$.

Proof: Since we have already assumed that $m \geqslant m_0$ we have no problem meeting the conditions $u_{n+1}(t) \in H^{2j+1}(S^2)$ and $B_n \in L^1([0,T];E^m)$. Lemma 5.3 applies and so $\mathcal{M}_{n+1}$ is uniquely defined as the solution of (5.9) with $\mathcal{M}|_{t=0} = \mathcal{M}_0$. Lemma 5.4 also applies and gives (5.15). ■

To establish the higher temporal regularity of solutions of (5.9) we will consider the following Banach spaces:

$$\mathcal{O}^m_{0,T} := P^m_{0,T} \times H^m([0,T];\mathbb{C}^3),$$

and their respective norms,

$$\|\mathcal{M}\|^2_{\mathcal{O}^m_{0,T}} = \sum_{l=0}^{m} \int_0^T \|\partial_t^l \mathcal{M}(s)\|^2_{E^{m-l}}\,\mathrm{d}s.$$

We note that upon inspection of (5.5) and (5.6), $\mathcal{O}^m_{0,T}$ is the natural space in which to look for solutions of (5.9) given $u_{n+1} \in P^{m+1/2}_{0,T}$.

To obtain the desired estimate, from which the higher regularity of solutions of (5.9) will follow, we will first need to establish some (essentially trace-type) results concerning the properties of the $P^m_{0,T}$ spaces.

Lemma 5.6: *Suppose that* $T \geqslant \epsilon > 0$. *Let* u *be a function belonging to the class* $P^{k+1/2}_{0,T}$ *with* $k \geqslant 1$. *Then*

$$\|u(\cdot,t)\|_{H^{2k}(S^2)} \leqslant C\|u\|_{P^{k+1/2}_{0,T}},$$

for any $t \in [0,T]$. *The constant depends only on* ϵ.

Proof: We first suppose that $u \in C^\infty(S^2 \times [0,T])$. We have that $u(\cdot,t) \in L^2(S^2)$, for each $t \in \mathbb{R}^+$, we may write u spectrally as follows:

$$u(x,t) = \sum_j c_j(t)\phi_j(x),$$

where the ϕ_j's form an orthonormal basis for $L^2(S^2)$ satisfying $\Delta\phi_j = -\lambda_j^2\phi_j$.

We define the function $\tilde{u}(\cdot,t) = u(\cdot,t_0+t)\chi(t)$, where χ is a smooth function satisfying

$$\chi(s) = \begin{cases} 1, & s < \dfrac{T}{4}, \\ 0, & s > \dfrac{3T}{4}, \end{cases}$$

so that $\tilde{u}(\cdot,T)=0$ and $\tilde{u}(\cdot,0)=u(\cdot,t_0)$. Then given that $k\geqslant 1$, we have

$$\begin{aligned} \|u(\cdot,t_0)\|^2_{H^{2k}(S^2)} &= \sum_j |c_j(t_0)|^2 |\lambda_j|^{2k} \\ &= \sum_j |\tilde{c}_j(0)|^2 |\lambda_j|^{2k} \\ &= \sum_j |\lambda_j|^{2k} \int_0^T \frac{\mathrm{d}}{\mathrm{d}s} |\tilde{c}_j(s)|^2 \,\mathrm{d}s \\ &\leqslant \sum_j \int_0^T |\tilde{c}_j(s)|^2 |\lambda_j|^{2k+1} + |\dot{\tilde{c}}_j(s)|^2 |\lambda_j|^{2k-1} \,\mathrm{d}s \leqslant \|\tilde{u}\|^2_{P^{k+1/2}_{0,T}} \leqslant C\|u\|^2_{P^{k+1/2}_{0,T}}. \end{aligned}$$

Note that the constant depends only on the cutoff function χ. With the result now established for smooth functions it is an easy matter to get the result for $u\in P^{k+1/2}_{0,T}$; it follows, after mollifying u, by a standard approximation argument. ■

Corollary 5.7: *Suppose that* $T\geqslant\epsilon>0$. *Let u belong to the class* $P^{m+1/2}_{0,T}$, *then*

$$\|\partial_t^j u(\cdot,t)\|_{H^{2(m-j)}(S^2)} \leqslant C\|u\|_{P^{m+1/2}_{0,T}},$$

for all $j\leqslant m$ *and* $t\in[0,T]$. *The constant depends only on* ϵ.

Proof: We note that $u\in P^{m+1/2}_{0,T}$ means that $\partial_t^j u\in P^{m-j+1/2}_{0,T}$ and so applying Lemma 5.6 with $k=m-j$ we have the result. ■

In the above trace-type results we saw that we may control the spatial norms of time derivatives of functions, by a constant multiple of the $P^{m+1/2}_{0,T}$-norm. Unfortunately the constant's dependence upon ϵ means that we lose that control as ϵ approaches zero. The following result shows how, with the loss of one time derivative of regularity, we may control the spatial norms of time derivatives by a constant which approaches zero as we consider smaller and smaller time intervals.

Lemma 5.8: *Let* $u\in P^{k+1}_{0,T}$, *with* $k\geqslant 0$, *then*

$$\|u(t)\|^2_{H^{2k}(S^2)} \leqslant \|u_0\|^2_{H^{2k}(S^2)} + CT\|u\|^2_{P^{k+1}_{0,T}},$$

for any $t\in[0,T]$. *The constant C depends only on k*.

Proof: Fixing $\xi\in S^2$, we have

$$u(\xi,t) = u(\xi,0) + \int_0^t \partial_t u(\xi,s)\mathrm{d}s.$$

It follows, using the Hölder inequality, that

$$|\nabla^{2j}(u(\xi,t)-u_0(\xi))| \leqslant \sqrt{T}\left(\int_0^T |\partial_t \nabla^{2j} u(\xi,s)|^2 \,\mathrm{d}s\right)^{1/2}$$

for any $0\leqslant j\leqslant m$ and $t\in[0,T]$. Integrating this result gives

$$\|u(\cdot,t)-u_0\|^2_{H^{2k}(S^2)} \leqslant C\oint |\nabla^{2k}(u-u_0)|^2+|u-u_0|^2\,\mathrm{d}\mu_g$$
$$\leqslant \oint T\int_0^T |\partial_t u|^2+|\partial_t\nabla^{2k}u|^2\,\mathrm{d}t\,\mathrm{d}\mu_g \leqslant T\|u\|^2_{P^{k+1}_{0,T}}.$$

The result follows after observing the elementary inequality $\|x\|-\|y\|\leqslant\|x-y\|$. ■

Remark: Applying Lemma 5.8 to $\partial_t^l u$ gives

$$\|\partial_t^l u(t)\|^2_{H^{2(k-l)}(S^2)} \leqslant \|\partial_t^l u(0)\|^2_{H^{2(k-l)}(S^2)} + CT\|u\|^2_{P^{k+1}_{0,T}}.$$

If it happened that u was also the solution of say a parabolic equation, then we could reduce the above estimate to

$$\|\partial_t^l u(t)\|^2_{H^{2(k-l)}(S^2)} \leqslant C\Big(\|u_0\|^2_{H^{2k}(S^2)} + T\|u\|^2_{P^{k+1}_{0,T}}\Big),$$

where the constant C now depends on the coefficients and source functions appearing in the parabolic equation.

We now proceed to derive the basic $\mathcal{O}^m_{0,T}$ *a priori* estimates for $\mathcal{M}_{n+1}$, the solutions of (5.9).

Proposition 5.9: Suppose $u_{n+1}\in P^{m+1/2}_{0,T}$ *and let* $\mathcal{M}_{n+1}$ *be the solution of* (5.9). *Then* $\mathcal{M}_{n+1}$ *satisfies the inequality*,

$$\|\mathcal{M}_{n+1}\|^2_{\mathcal{O}^m_{0,T}} \leqslant TC\Big\{1+\|B_n\|^2_{\mathcal{O}^m_{0,T}}\Big\}. \tag{5.16}$$

The constant C depends on $\|u_{n+1}\|_{P^{m+1/2}_{0,T}}$, $\|u_0\|_{H^{2m}(S^2)}$ *and* $\|\mathcal{M}_0\|_{E^m}$.

Proof: We begin by noting that if we square, then integrate (5.15), we obtain

$$\int_0^T \|\mathcal{M}_{n+1}(t)\|^2_{E^m}\,\mathrm{d}t \leqslant 2Te^{TC}\Big(\|\mathcal{M}_0\|^2_{E^m}+\|B_n\|^2_{\mathcal{O}^m_{0,T}}\Big), \tag{5.17}$$

where the constant C depends on $\|u_{n+1}\|_{P^{m+1/2}_{0,T}}$. This gives us a bound for the first term in the sum

$$\|\mathcal{M}_{n+1}\|^2_{\mathcal{O}^m_{0,T}} = \sum_{l=0}^m \int_0^T \|\partial_t^l\mathcal{M}_{n+1}\|^2_{E^{m-l}}\,\mathrm{d}t. \tag{5.18}$$

Considering the $(j+1)^{\text{th}}$ term in (5.18) we have, upon differentiating (5.24),

$$\int_0^T \|\partial_t^j\mathcal{M}_{n+1}\|^2_{E^{m-j}}\,\mathrm{d}t \leqslant \int_0^T C_j\sum_{l=0}^{j-1}\|\partial_t^l A_n\partial_t^{j-l-1}\mathcal{M}_{n+1}\|^2_{E^{m-j}}+\|\partial_t^{j-1}B_n\|^2_{E^{m-j}}\,\mathrm{d}t, \tag{5.19}$$

where C_j is a constant dependent upon j. The expression $\partial_t^l A_n\partial_t^{j-l-1}\mathcal{M}_{n+1}$ represents the outcome of the operator $\partial_t^l A_n$, given by (5.10) with u_{n+1} replaced by $\partial_t^l u_{n+1}$, acting on $\partial_t^{j-l-1}\mathcal{M}_{n+1}$. It is obvious that results analagous to Lemma 5.2 exist for $\partial_t^l A_n$ as well. Hence

$$\|\partial_t^l A_n\partial_t^{j-l-1}\mathcal{M}_{n+1}\|^2_{E^{m-j}} \leqslant C_l\|\partial_t^{j-l-1}\mathcal{M}_{n+1}\|^2_{E^{m-j}},$$

where, by virtue of Lemma 5.8, we see that

$$C_l \leqslant C\Big(\|u_0\|^2_{H^{2m}(S^2)}+T\|u_{n+1}\|^2_{P^{m+1/2}_{0,T}}\Big),$$

where we have used the fact that u_{n+1} is the solution of (4.8) to control the initial values of the time derivatives of u_{n+1}.

Observing that Lemma 5.8 may easily be extended to apply to the E^{m-j} and $\mathcal{O}^m_{0,T}$ spaces, the second term on the right-hand side of (5.19) satisfies

$$\|\partial_t^{j-1}B_n(\cdot,s)\|^2_{E^{m-j}} \leqslant \mathcal{C}\Big(1+T\|B_n\|^2_{\mathcal{O}^m_{0,T}}\Big),$$

for all $s\leqslant T$. The constant $\mathcal{C}$ depends on $\|\partial_t^{j-1}B_n(\cdot,0)\|_{E^{m-j}}$. This quantity can be expressed in terms of E^{m-j}-norms of the $(j-1)$th time derivatives of u_{n+1}, μ_n, k_n, and $\hat{\eta}_n$ evaluated at $t=0$. Since these functions are themselves solutions of their respective equations, we may in turn express time derivatives of u_{n+1}, μ_n, k_n, and $\hat{\eta}_n$, evaluated at $t=0$, in terms of the initial values u_0, μ_0, and k_0. We therefore have

$$\begin{aligned}\int_0^T \|\partial_t^j\mathcal{M}_{n+1}\|^2_{E^{m-j}}\,\mathrm{d}t &\leqslant C\sum_{l=0}^{j-1}\int_0^T \|\partial_t^{j-l-1}\mathcal{M}_{n+1}\|^2_{E^{m-j}} + T\|B_n\|^2_{\mathcal{O}^m_{0,T}} + 1\,\mathrm{d}t\\ &\leqslant CT\Big(1+T\|B_n\|^2_{\mathcal{O}^m_{0,T}}\Big) + C\sum_{l=0}^{j-1}\int_0^T \|\partial_t^{j-l-1}\mathcal{M}_{n+1}\|^2_{E^{m-j}}\,\mathrm{d}t, \qquad (5.20)\end{aligned}$$

where C depends on $\|u_{n+1}\|_{P^{m+1/2}_{0,T}}$, $\|u_0\|_{H^{2m-1}(S^2)}$, $\|\mu_0\|_{H^{2(m-1)}(S^2)}$, and $\|k_0\|_{\mathbb{C}^3}$.

The estimate (5.16) is then obtained by using (5.20) to iterate from $j=1$ to m starting from (5.17). ■

Thus in light of Lemma 5.3 and Proposition 5.9, we find that if $u_0\in H^{2m}(S^2)$, $\mathcal{M}_0\in E^m$, $u_n\in P^{m+1/2}_{0,T}$, $u_{n+1}\in P^{m+1/2}_{0,T}$, and $\mathcal{M}_n\in\mathcal{O}^m_{0,T}$ then $\mathcal{M}_{n+1}$ exists and belongs to $\mathcal{O}^m_{0,T}$.

Moving now to the final equation in the iteration scheme, the elliptic system for $\hat{\eta}_{n+1}$. We note again that by construction (5.7) is guaranteed to have a solution. Hence $\hat{\eta}_{n+1}$ exists and the following results establish that $\hat{\eta}_{n+1}\in P^m_{0,T}$ provided $(u_{n+1},\mathcal{M}_{n+1})\in P^{m+1/2}_{0,T}\times\mathcal{O}^m_{0,T}$.

Lemma 5.10: Suppose $g\in L^2(\mathrm{span}\{Y^1_{lm}: l\geqslant 2\})$ *and let* $\hat{\eta}$ *be the solution of*

$$\bar{\eth}\,\hat{\eta} = g. \qquad (5.21)$$

We have the estimate

$$\|\hat{\eta}\|^2_{H^1(S^2)} \leqslant C\|g\|^2_{L^2(S^2)},$$

where C is a constant.

Proof: The result follows easily from the observation that since $\bar{\eth}\,\hat{\eta}$ is devoid of $l=1$ spherical harmonics, we may solve (5.21). Moreover, we are able to write $\hat{\eta}$ explicitly, using spectral decomposition as

$$\hat{\eta} = \sum_{l=2}^{\infty}\sum_{m=-l}^{l}\hat{\eta}_{lm}Y^2_{lm}.$$

It follows that we may write

$$\bar{\eth}\,\hat{\eta} = \sum_{l=2}^{\infty}\sum_{m=-l}^{l}C_l\hat{\eta}_{lm}Y^1_{lm},$$

where C_l, $l=0,2,3,\ldots$ are constants. Checking the norms in question we then find

$$\|\bar{\eth}\,\hat{\eta}\|^2_{L^2(S^2)} = \oint\left|\sum_{l,m}C_l\hat{\eta}_{lm}Y^1_{lm}\right|^2\mathrm{d}\Omega^2 \geqslant \sum_{l,m}C_l^2\hat{\eta}^2_{lm},$$

and

$$\|\hat{\eta}\|^2_{H^1(S^2)} = \oint|\nabla\hat{\eta}|^2 + |\hat{\eta}|^2\,\mathrm{d}\Omega^2 \leqslant \oint 2|\bar{\eth}\,\hat{\eta}|^2 + |\hat{\eta}|^2\,\mathrm{d}\Omega^2 \leqslant C\sum_{l,m}C_l^2\hat{\eta}^2_{lm}.$$

Thus we have

$$\|\hat{\eta}\|^2_{H^1(S^2)} \leqslant C\sum_{l,m} C_l^2 \hat{\eta}^2_{lm} \leqslant C\|\bar{\eth}\hat{\eta}\|^2_{L^2(S^2)},$$

and the result follows from Eq. (5.21). ■

Lemma 5.11: Suppose $\hat{\eta}$ is a solution of (5.21), where now $g \in H^k(\mathrm{span}\{Y^1_{lm} : l \geqslant 2\})$. We have the estimate

$$\|\hat{\eta}\|^2_{H^{k+1}(S^2)} \leqslant C_k \|g\|^2_{H^k(S^2)}, \tag{5.22}$$

where C_k is a constant depending only on k.

Proof: Estimating the right-hand side of (5.22) we have

$$\begin{aligned}
\|\hat{\eta}\|^2_{H^{k+1}(S^2)} &= \|\nabla^{k+1}\eta\|^2_{L^2(S^2)} + \|\hat{\eta}\|^2_{H^k(S^2)} \\
&\leqslant \|\nabla^k \hat{\eta}\|^2_{H^1(S^2)} + C_k\|\bar{\eth}\hat{\eta}\|^2_{H^{k-1}(S^2)} \\
&\leqslant C\|\bar{\eth}\nabla^k\eta\|^2_{L^2(S^2)} + C_k\|\bar{\eth}\hat{\eta}\|^2_{H^k(S^2)} \\
&= C\|\nabla^k\bar{\eth}\hat{\eta}\|^2_{L^2(S^2)} + C'_k\|\bar{\eth}\hat{\eta}\|^2_{H^k(S^2)} \leqslant C\|\bar{\eth}\hat{\eta}\|^2_{H^k(S^2)} + C'_k\|\bar{\eth}\hat{\eta}\|^2_{H^k(S^2)} \leqslant C''_k\|\bar{\eth}\hat{\eta}\|^2_{H^k(S^2)}.
\end{aligned}$$

The result follows from Eq. (5.21). ■

The following result is now immediate from the definition of $P^k_{0,T}$.

Corollary 5.12: Let g, belonging to the class $P^k_{0,T}$, be devoid of $l=1$ spherical harmonic components so that $\hat{\eta}$ exists as a solution of (5.21). Then

$$\|\hat{\eta}\|_{P^{k+1/2}_{0,T}} \leqslant C_k\|g\|_{P^k_{0,T}}.$$

C_k is a constant depending only on k.

The foregoing results have shown that if,

$$(u_n, \mu_n, k_n, \hat{\eta}_n) \in P^{m+1/2}_{0,T} \times \mathcal{O}^m_{0,T} \times P^m_{0,T}$$

and

$$(u_0, \mu_0, k_0) \in H^{2m+1}(S^2) \times E^{m+1/2}$$

then

$$(u_{n+1}, \mu_{n+1}, k_{n+1}, \hat{\eta}_{n+1}) \in P^{m+1/2}_{0,T} \times \mathcal{O}^m_{0,T} \times P^m_{0,T}$$

also.

For the sake of brevity we consider the four iterates as a single entity residing in the appropriate Banach space. In particular we define the four-tuple,

$$\mathbf{U}_n := (u_n, \mu_n, k_n, \hat{\eta}_n),$$

residing in the Banach space,

$$\Psi^m_{0,T} := P^{m+1/2}_{0,T} \times P^m_{0,T} \times H^m([0,T];\mathbb{C}^3) \times P^m_{0,T}.$$

To summarize, we have proven the following result.

Theorem 5.13: *Let $m \geqslant m_0$ and let $u_0 \in H^{2m+1}(S^2)$, $\mu_0 \in H^{2m}(S^2)$, and $k_0 \in \mathbb{C}^3$. There exists a nonincreasing, but possibly decreasing sequence $\{T_n\}_{n=1}^{\infty}$ with $T_n > 0$, and a sequence of iterates $\mathbf{U}_n \in \Psi^m_{0,T_n}$ which satisfy (5.4)–(5.7).*

Theorem 5.13 is not ideal. It tells us that the iterates exist as elements of Ψ^m_{0,T_n}, with the possibilty of $T_n \to 0$. To be able to prove local existence for the QSECS however, we will need the

iterates to be defined over some nonzero time interval. This means that we will need to show that there exists an $\epsilon > 0$ such that $T_n \geqslant \epsilon$, for all n. This fact will follow from the uniform estimates we derive for the iterates in the next section.

C. Uniform estimates for the iterates

In this section we will show that all of the iterates satisfy uniform bounds, at least locally in time. We consider the iteration scheme proposed by (5.4)–(5.7), which we may write more simply as

$$\dot{u}_{n+1} = \hat{\gamma} u_n^2 \Delta u_{n+1} + F_n, \tag{5.23}$$

$$\dot{\mathcal{M}}_{n+1} = A_n \mathcal{M}_{n+1} + B_n, \tag{5.24}$$

$$\bar{\eth}\,\hat{\eta}_{n+1} = \mathcal{L}(u_{n+1}, \mathcal{M}_{n+1}) - \dot{\sigma}, \tag{5.25}$$

where A_n and B_n are defined by (5.10) and (5.11), respectively, and where

$$F_n = \tfrac{1}{2}\Big(1 + \tfrac{1}{2}\gamma e^{2t}\|\hat{\eta}_n\|^2 + \gamma B\Big)u_n - \hat{\gamma}\Big(1 - \tfrac{1}{2}e^{2t}\Big(16\pi T_{00} + 2\|\kappa_n\|^2 + \tfrac{3}{2}\mu_n^2 - 2\mu_n H\Big)\Big)u_n^3 \tag{5.26}$$

and

$$\mathcal{L}(u, \mathcal{M}) = (1 - \mathcal{P}_1)\Big\{\mu \eth u + \tfrac{1}{2}\eth(u\mu) - \eth(uH) + (1 + \rho)\kappa + \bar{\kappa}\eth\beta + \kappa\eth\bar{\beta} + 8\pi T_0 u e^t\Big\}. \tag{5.27}$$

The key result needed to prove that the iterates satisfy uniform bounds is the following simple inequality.

Lemma 5.14: Suppose u belongs to the localized parabolic space $P^1_{0,T}$. Then

$$\|u\|^2_{P^0_{0,T}} \leqslant 2T\Big(\|u_0\|^2_{L^2(S^2)} + \|u\|^2_{P^1_{0,T}}\Big).$$

Proof: From the definition of $P^0_{0,T}$ we have

$$\|u - u_0\|^2_{P^0_{0,T}} \leqslant \int_0^T \oint \int_0^t |\partial_t u(\xi, s)|^2 \, \mathrm{d}s \, \mathrm{d}\mu_{\bar{g}} \mathrm{d}t \leqslant \int_0^T (T - s) \oint |\partial_t u(\xi, s)|^2 \, \mathrm{d}\mu_{\bar{g}} \mathrm{d}s \leqslant T\|\partial_t u\|^2_{P^0_{0,T}}.$$

The result then follows since $\|u_0\|^2_{P^0_{0,T}} = T\|u_0\|^2_{L^2(S^2)}$.

Corollary 5.15: Any $u \in P^{m+1}_{0,T}$ satisfies the estimate

$$\|u\|^2_{P^m_{0,T}} \leqslant CT\Big(1 + \|u\|^2_{P^{m+1}_{0,T}}\Big). \tag{5.28}$$

The constant C depends on m and $\|\partial_t^j u(\cdot, 0)\|_{H^{2(m-j)}(S^2)}$, $j = 0, \ldots, m$.

Proof: We need only check terms of the form $\int_0^T \|\partial_t^j u\|^2_{H^{2(m-j)}(S^2)} \, \mathrm{d}t$. We have

$$\int_0^T \|\partial_t^j u\|^2_{H^{2(m-j)}(S^2)} \, \mathrm{d}t \leqslant C \int_0^T \|\partial_t^j \nabla^{2(m-j)} u\|^2_{L^2(S^2)} + \|\partial_t^j u\|^2_{L^2(S^2)} \, \mathrm{d}t$$

$$= C\Big(\|\partial_t^j \nabla^{2(m-j)} u\|^2_{P^0_{0,T}} + \|\partial_t^j u\|^2_{P^0_{0,T}}\Big) \leqslant 4CT\Big(\|\partial_t^j u(\cdot, 0)\|_{H^{2(m-j)}(S^2)} + \|u\|^2_{P^{m+1}_{0,T}}\Big).$$

The estimate (5.28) is then obtained by summing the terms above from $j = 0$ to m. ■

Remark: If we also know that u is a solution of a parabolic equation we may express the constant C in terms of the initial values of u, the coefficients and source function. In particular, if u_n is the solution of (5.4) we have

$$\|u_n\|^2_{P^m_{0,T}} \leqslant T\mathcal{C}\left(1+\|u_n\|^2_{P^{m+1}_{0,T}}\right), \tag{5.29}$$

where the constant $\mathcal{C}$ depends on m, $\|u_0\|_{H^{2m}(S^2)}$, $\|\mu_0\|_{H^{2m}(S^2)}$, and $\|k_0\|_{\mathbb{C}^3}$.

We now prove that given suitable bounds on the initial data (which constitute $\mathbf{U}_0$), all the iterates $\{\mathbf{U}_n\}_{n=0}^{\infty}$ may be confined within a ball in $\Psi^m_{0,T}$, for some $T>0$.

Proposition 5.16: Let $m\geqslant m_0$ and suppose $u_0\in H^{2m+1}(S^2)$, $\mu_0\in H^{2m}(S^2)$, and $k_0\in\mathbb{C}^3$. There exists $T^*>0$ and $N>0$, depending only on m, the initial data and the prescribable fields, such that

$$\|\mathbf{U}_n\|_{\Psi^m_{0,T^*}} \leqslant N$$

for all $n\in\mathbb{N}$.

Proof: Since $u_0\in H^{2m+1}(S^2)$, $\mu_0\in H^{2m}(S^2)$, and $k_0\in\mathbb{C}^3$, there exist numbers N_1, N_2, N_3, and N_4 such that

$$\|u_0\|_{H^{2m+1}(S^2)} \leqslant N_1, \quad \|\mu_0\|_{H^{2m}(S^2)} \leqslant N_2, \quad \|k_0\|_{\mathbb{C}^3} \leqslant N_3, \quad \|\hat{\eta}_0\|_{H^{2m}(S^2)} \leqslant N_4. \tag{5.30}$$

Defining the zeroth iterates as the time constant extensions of these initial values and assuming, without loss of generality, that $T\leqslant 1$ we find that (5.30) implies

$$\|u_{\tilde{0}}\|_{P^{m+1/2}_{0,T}} \leqslant N_1, \quad \|\mu_{\tilde{0}}\|_{P^m_{0,T}} \leqslant N_2, \quad \|k_{\tilde{0}}\|_{H^m([0,T];\mathbb{C}^3)} \leqslant N_3, \quad \|\hat{\eta}_{\tilde{0}}\|_{P^m_{0,T}} \leqslant N_4,$$

where we have used the subscript $\tilde{0}$ to distinguish the zeroth iterates $u_{\tilde{0}}$, $\mu_{\tilde{0}}$, $k_{\tilde{0}}$, and $\hat{\eta}_{\tilde{0}}$ from the intial values u_0, μ_0, k_0, and $\hat{\eta}_0$. Hence Proposition 5.16 holds for $n=\tilde{0}$, with $N=\Sigma_{i=1}^4 N_i$.

Hypothesizing then, that

$$\|u_j\|_{P^{m+1/2}_{0,T}} \leqslant N_1, \quad \|\mu_j\|_{P^m_{0,T}} \leqslant N_2, \quad \|k_j\|_{H^m([0,T];\mathbb{C}^3)} \leqslant N_3, \quad \|\hat{\eta}_j\|_{P^m_{0,T}} \leqslant N_4,$$

for all $j\in[0,n]_{\mathbb{N}}$ and some $T>0$, we aim to show the same is true for the $(n+1)$th iterates.

We consider (5.23), which is a linear parabolic equation for u_{n+1}. Since $m\geqslant m_0$, (5.3) gives

$$\|u_{n+1}\|^2_{P^{m+1/2}_{0,T_1}} \leqslant \mathcal{Q}\left(\|u_0\|^2_{H^{2m}(S^2)}+\|F_n\|^2_{P^{m-1/2}_{0,T_1}}\right).$$

We note that the constant $\mathcal{Q}$ depends on the P^m_{0,T_1} norm of the coefficients, which in this case, observing (5.8), amount to u_n. Hence

$$\mathcal{Q}=\mathcal{Q}(\|u_n\|_{P^m_{0,T_1}}).$$

However, since u_n is itself the solution of a linear parabolic equation, (5.29) applies and we have

$$\|u_n\|^2_{P^m_{0,T_1}} \leqslant T_1\mathcal{C}\left(1+\|u_n\|^2_{P^{m+1}_{0,T_1}}\right). \tag{5.31}$$

Moreover, by inspection of the proof of (Ref. 15, Theorem 4.6, p. 132), it can be seen that the constant $\mathcal{Q}$ depends on $\|u_n\|_{P^m_{0,T_1}}$ in such a way that, if $\|u_n\|_{P^m_{0,T_1}}$ is bounded as in (5.31), then $\mathcal{Q}(\|u_n\|_{P^m_{0,T_1}})$ is also bounded and satisfies the inequality

$$\mathcal{Q}(\|u_n\|_{P^m_{0,T_1}}) \leqslant T_1\tilde{\mathcal{Q}}, \tag{5.32}$$

where the constant $\tilde{\mathcal{Q}}$ depends on $\|u_n\|_{P^{m+1}_{0,T_1}}$.

The P^{m+1}_{0,T_1} norm of u_n can also be estimated using (5.3),

$$\|u_n\|^2_{P^{m+1}_{0,T_1}} \leqslant \mathcal{Q}^*\left(\|u_0\|^2_{H^{2m+1}(S^2)} + \|F_n\|^2_{P^m_{0,T_1}}\right). \tag{5.33}$$

The constant $\mathcal{Q}^*$ depends only on $\|u_{n-1}\|_{P^{m+1/2}_{0,T_1}}$ which by hypothesis is less than N_1. Similarly, $\|F_n\|^2_{P^m_{0,T_1}}$ can be controlled by a constant depending on N_1, N_2, N_3, N_4 and the prescribable fields. Hence $\|u_n\|_{P^{m+1}_{0,T_1}}$ is bounded by a constant that depends only on N_1, N_2, N_3, N_4 and the prescribable fields also. This in turn implies that the constant $\tilde{\mathcal{Q}}$ is also bounded by a term involving only N_1, N_2, N_3, N_4 and the norms of the prescribable fields.

The above argument implies that, given the induction hypotheses, if we take $T_1 \leqslant T$ then

$$\|u_{n+1}\|^2_{P^{m+1/2}_{0,T_1}} \leqslant T_1 C_1, \tag{5.34}$$

where C_1 is a constant depending on the prescribable fields, N_1, N_2, N_3, and N_4. Thus provided that

$$T_1 \leqslant \min\left\{T, \frac{N_1^2}{C_1}\right\}$$

we have

$$\|u_{n+1}\|_{P^{m+1/2}_{0,T_1}} \leqslant N_1. \tag{5.35}$$

Turning our attention now to (5.24), Proposition 5.9 gives

$$\|\mathcal{M}_{n+1}\|^2_{\mathcal{O}^m_{0,T_2}} \leqslant C T_2\left(1 + \|B_n\|^2_{\mathcal{O}^m_{0,t_2}}\right)$$

provided that $T_2 \leqslant T_1$. By hypothesis again, we can control the $\mathcal{O}^m_{0,T_2}$ norm of B_n by a constant depending on N_1, N_2, N_3, and N_4. That is,

$$\|\mathcal{M}_{n+1}\|^2_{\mathcal{O}^m_{0,T_2}} \leqslant T_2 C_2. \tag{5.36}$$

Therefore, so long as

$$T_2 \leqslant \min\left\{T_1, \frac{N_2^2}{C_2}, \frac{N_3^2}{C_2}\right\},$$

we have

$$\|\mu_{n+1}\|_{P^m_{0,T_2}} \leqslant N_2, \quad \text{and } \|k_{n+1}\|_{H^m([0,T_2];\mathbb{C}^3)} \leqslant N_3. \tag{5.37}$$

Finally, from Corollary 5.12, we have

$$\|\hat{\eta}_{n+1}\|_{P^m_{0,T_3}} \leqslant C_m \|\bar{\eth}\hat{\eta}_{n+1}\|_{P^{m-1/2}_{0,T_3}} \leqslant C_m \|\mathcal{L}(u_{n+1}, \mathcal{M}_{n+1}) - \dot{\sigma}\|_{P^{m-1/2}_{0,T_3}}.$$

Observing (5.27), we thus find that

$$\|\hat{\eta}_{n+1}\|^2_{P^m_{0,t_3}} \leqslant C\left(\|u_{n+1}\|^2_{P^m_{0,T_3}} + \|\mu_{n+1}\|^2_{P^m_{0,T_3}} + \|k_{n+1}\|^2_{H^m([0,T_3];\mathbb{C}^3)} + \|\sigma\|^2_{P^{m+1/2}_{0,T_3}}\right) \leqslant T_3 C_3 + C_4 \|\sigma\|^2_{P^{m+1/2}_{0,T}},$$

provided that $T_3 \leqslant T_2$, so that our use of (5.34) and (5.36) is justified. The constant C_3 depends only on the prescribable fields, N_1, N_2, and N_3 and the constant C_4 depends only on the prescribable fields.

Hence, given that

$$T_3 \leqslant \min\left\{ T_2, \frac{N_4^2 - C_4\|\sigma\|^2_{P^{m+1/2}_{0,T}}}{C_3} \right\},$$

we find that

$$\|\hat{\eta}_{n+1}\|_{P^m_{0,T_3}} \leqslant N_4. \tag{5.38}$$

Note that we require $N_4^2 > C_4\|\sigma\|^2_{P^{m+1/2}_{0,T}}$, but this is easily arranged.

Hence, setting $T^* = T_3$, (5.35), (5.37), and (5.38) imply $\|u_{n+1}\|_{P^{m+1/2}_{0,T^*}} \leqslant N_1$, $\|\mu_{n+1}\|_{P^m_{0,T^*}} \leqslant N_2$, $\|k_{n+1}\|_{H^m([0,T^*];\mathbb{C}^3)} \leqslant N_3$, and $\|\hat{\eta}_{n+1}\|_{P^m_{0,T^*}} \leqslant N_4$. The result follows by induction with $N = \Sigma_{i=1}^4 N_i$. ■

This last result has bearing on the problem encountered in Theorem 5.13. There we found that, due to the possibility that u_n might become negative after some ever decreasing interval of time, the iterates were possibly only defined on the interval $[0, T_n]$ with $T_n \to 0$. Now that we have uniform bounds for all of the iterates in a Sobolev space of high enough order, however, we may conclude that the supremum of $|\partial_t u_n|$ over $S^2 \times [0, T^*]$ is no greater than N_1. This leads to the following result.

Theorem 5.17: *Let $m \geqslant m_0$ and let $u_0 \in H^{2m+1}(S^2)$ satisfy $\inf_{S^2} u_0 \geqslant 2\delta > 0$. Also suppose $\mu_0 \in H^{2m}(S^2)$ and $k_0 \in \mathbb{C}^3$. There exists a $T > 0$, depending on the initial values and prescribable fields, such that u_n, as defined by (5.4), satisfies*

$$\inf_{S^2 \times [0,T]} u_n \geqslant \delta.$$

Hence there exists a sequence of iterates $\{\mathbf{U}_n\}_{n=0}^{\infty} \subset \Psi^m_{0,T}$ which satisfy (5.4)–(5.7) and $\|\mathbf{U}_n\|_{\Psi^m_{0,T}} \leqslant N$.

Proof: We already mentioned above that $\sup_{S^2 \times [0,T]} |\partial_t u_n| \leqslant N_1$. This fact implies that $\inf_{S^2 \times [0, \delta/N_1]} u_n \geqslant \delta$, since

$$u_n(\xi, t) = u_n(\xi, 0) + \int_0^t \partial_t u_n(\xi, s)\mathrm{d}s \geqslant 2\delta - T \sup_{S^2 \times [0,T]} |\partial_t u_n| \geqslant 2\delta - TN_1 \geqslant \delta$$

if $T \leqslant \delta / N_1$. ■

D. Convergence of the iteration scheme

The uniform bounds obtained in Proposition 5.16 will now be used to prove that $\{\mathbf{U}_n\}_{n=0}^{\infty}$ is a Cauchy sequence in an appropriate Banach space. The Banach space we will aim to show convergence in $\Psi^1_{0,T}$, for some appropriate $T > 0$. This will be enough to infer the existence of strong local solutions to the quasispherical constraint system; the higher regularity of these solutions will follow from Proposition 5.16. In what follows we will use the shorthand notation $f(t) = f(\cdot, t)$.

If we define

$$w_{n+1} = u_{n+1} - u_n,$$

then w_{n+1} satisfies the following equation:

$$\dot{w}_{n+1} = \gamma u_n^2 \Delta w_{n+1} + \gamma w_n \overline{w}_n \Delta u_n + F_n - F_{n-1}, \tag{5.39}$$

where $\overline{w}_n = u_n + u_{n-1}$ and where F_n is given by (5.26).

Estimating the $H^3(S^2)$-norm of w_{n+1} we have

$$\tfrac{1}{2}\partial_t\|\nabla^3 w_{n+1}\|^2_{L^2(S^2)} = \oint \nabla^3 w_{n+1}\nabla^3\dot{w}_{n+1}\,\mathrm{d}\Omega^2 = \oint \nabla^3 w_{n+1}\nabla^3(\gamma u_n^2\Delta w_{n+1} + \gamma w_n\overline{w}_n\Delta u_n + F_n - F_{n-1})\mathrm{d}\Omega^2.$$

It is apparent upon inspection of this expression, that the highest order derivatives are fourth order (integrating by parts wherever necessary). Using the parabolic Sobolev imbedding (Ref. 14, Lemma 3.3.5), Proposition 5.16 gives us pointwise bounds for all such derivatives, and it is an easy matter to obtain an expression of the form

$$\partial_t\|\nabla^3 w_{n+1}(t)\|^2_{L^2(S^2)} \leqslant C_1\|w_{n+1}(t)\|^2_{H^3(S^2)} + C_2\|w_n(t)\|^2_{H^3(S^2)}.$$

This expression should only be considered true if $t\in[0,T^*]$. The constants C_1 and C_2 depend on the prescribable fields and N.

Estimating $\partial_t\|\nabla^2 w_{n+1}(t)\|^2_{L^2(S^2)}$, $\partial_t\|\nabla w_{n+1}(t)\|^2_{L^2(S^2)}$, and $\partial_t\|w_{n+1}(t)\|^2_{L^2(S^2)}$ in the same way, we find

$$\partial_t\|w_{n+1}(t)\|^2_{H^3(S^2)} \leqslant C_1'\Big(\|w_{n+1}(t)\|^2_{H^3(S^2)} + \|w_n(t)\|^2_{H^3(S^2)}\Big), \tag{5.40}$$

for all $t\in[0,T^*]$.

To obtain a similar sort of control over the other fields let us also define the following differences:

$$\upsilon_{n+1} = \mu_{n+1} - \mu_n,$$

$$q_{n+1} = k_{n+1} - k_n,$$

$$\chi_{n+1} = \hat{\eta}_{n+1} - \hat{\eta}_n.$$

Then since the iterative system defining these quantities is linear it is a simple matter to show that υ_{n+1}, q_{n+1}, and χ_{n+1} satisfy the following equations:

$$\dot{\upsilon}_{n+1} = \mathrm{div}(u_{n+1}q_{n+1}) + \mathrm{div}(w_{n+1}k_n) + \mathrm{div}(w_{n+1}\sigma) - (1+\rho)\upsilon_{n+1} - w_n u_n^{-1}u_{n-1}^{-1}\hat{\eta}_n^{AB}\nabla_{(B}\beta_{A)} + u_n^{-1}\chi_n\nabla_{(B}\beta_{A)} - 8\pi T_{03}\mathrm{e}^t w_{n+1}, \tag{5.41}$$

$$\dot{q}_{n+1} = -\mathcal{P}_1\big\{\mu_{n+1}\eth w_{n+1} + \upsilon_{n+1}\eth u_n + \tfrac{1}{2}\eth(u_{n+1}\upsilon_n) + \tfrac{1}{2}\eth(w_{n+1}\mu_{n-1}) - \eth(w_{n+1}H) + (1+\rho)q_n + \overline{q}_n\eth\beta + q_n\eth\overline{\beta} + 8\pi T_0 e^t w_{n+1}\big\}, \tag{5.42}$$

$$\overline{\eth}\chi_{n+1} = (1-\mathcal{P}_1)\big\{\upsilon_{n+1}\eth u_{n+1} + \mu_n\eth w_{n+1} + \tfrac{1}{2}\eth(u_{n+1}\upsilon_{n+1}) + \tfrac{1}{2}\eth(u_n\upsilon_{n+1}) - \eth(w_{n+1}H) + (1+\rho)q_{n+1} + \overline{q}_{n+1}\eth\beta + q_{n+1}\eth\overline{\beta} + 8\pi T_0\mathrm{e}^t w_{n+1}\big\}. \tag{5.43}$$

Focusing on (5.41), we may again use Proposition 5.16 to infer pointwise control over spatial derivatives of up to third order. Estimating the $H^2(S^2)$-norm of $\upsilon_{n+1}(t)$, we then have

$$\begin{aligned}\partial_t\|\nabla^2\upsilon_{n+1}(t)\|^2_{L^2(S^2)} &= 2\oint \nabla^2\upsilon_{n+1}(t)\nabla^2\dot{\upsilon}_{n+1}(t)\mathrm{d}\Omega^2\\ &\leqslant C_1\|\upsilon_{n+1}(t)\|^2_{H^2(S^2)} + C_2\|w_{n+1}(t)\|^2_{H^3(S^2)}\\ &\quad + C_3\|q_{n+1}(t)\|^2_{\mathbb{C}^3} + C_4\|\chi_n(t)\|^2_{H^2(S^2)} + C_5\|w_n(t)\|^2_{H^3(S^2)},\end{aligned}$$

for all $t\in[0,T^*]$. The constants $C_1,\ldots,C_5$ depend only on the prescribable fields and N. Similar estimates for $\partial_t\|\nabla\upsilon_{n+1}(t)\|^2_{L^2(S^2)}$ and $\partial_t\|\upsilon_{n+1}(t)\|^2_{L^2(S^2)}$ combine to give

$$\partial_t \|v_{n+1}(t)\|^2_{H^2(S^2)} \leqslant C_2'\Big(\|v_{n+1}(t)\|^2_{H^2(S^2)} + \|w_{n+1}(t)\|^2_{H^3(S^2)} + \|q_{n+1}(t)\|^2_{\mathbb{C}^3} + \|\chi_n(t)\|^2_{H^2(S^2)} + \|w_n(t)\|^2_{H^3(S^2)}\Big), \tag{5.44}$$

for all $t\in[0,T^*]$. In a similar fashion we may obtain

$$\partial_t \|q_{n+1}(t)\|^2_{\mathbb{C}^3} \leqslant C_3'(\|q_{n+1}(t)\|^2_{\mathbb{C}^3} + \|v_{n+1}(t)\|^2_{H^2(S^2)} + \|w_{n+1}(t)\|^2_{H^3(S^2)} + \|q_n(t)\|^2_{\mathbb{C}^3} + \|v_n(t)\|^2_{H^2(S^2)}), \tag{5.45}$$

for all $t\in[0,T^*]$, from (5.42).

Adding (5.40), (5.44), and (5.45) and integrating via Gronwall's inequality, we find

$$\|w_{n+1}(t)\|^2_{H^3(S^2)} + \|v_{n+1}(t)\|^2_{H^2(S^2)} + \|q_{n+1}(t)\|^2_{\mathbb{C}^3} \leqslant C\int_0^t \|w_n(s)\|^2_{H^3(S^2)} + \|v_n(s)\|^2_{H^2(S^2)} + \|q_n(s)\|^2_{\mathbb{C}^3} + \|\chi_n(s)\|^2_{H^2(S^2)}\,\mathrm{d}s, \tag{5.46}$$

for all $t<T^*$.

Finally from the elliptic estimate (5.22) and (5.43) we have

$$\|\chi_{n+1}\|^2_{H^2(S^2)} \leqslant C_4\Big(\|w_{n+1}\|^2_{H^3(S^2)} + \|v_{n+1}\|^2_{H^2(S^2)} + \|q_{n+1}\|^2_{\mathbb{C}^3}\Big). \tag{5.47}$$

For convenience we define

$$\mathcal{H}^j := H^{j+1}(S^2)\times H^j(S^2)\times\mathbb{C}^3\times H^j(S^2),$$

so that upon combining (5.46) and (5.47) and integrating from 0 to $T<T^*$, we have

$$\int_0^T \|(w_{n+1},v_{n+1},q_{n+1},\chi_{n+1})\|^2_{\mathcal{H}^2}\,\mathrm{d}t \leqslant CT\int_0^T \|(w_n,v_n,q_n,\chi_n)\|^2_{\mathcal{H}^2}\,\mathrm{d}t. \tag{5.48}$$

The constant C depends on the prescribable fields and the number N encountered in Proposition 5.16.

Returning to Eqs. (5.39) and (5.41)–(5.43) we may use (5.48) to obtain

$$\int_0^T \|(\dot{w}_{n+1},\dot{v}_{n+1},\dot{q}_{n+1},\dot{\chi}_{n+1})\|^2_{\mathcal{H}^0}\,\mathrm{d}t \leqslant CT\int_0^T \|(w_n,v_n,q_n,\chi_n)\|^2_{\mathcal{H}^2}\,\mathrm{d}t,$$

with the constant C depending on the same quantities as the constant in (5.48).

Let $\delta\mathbf{U}_{n+1}=\mathbf{U}_{n+1}-\mathbf{U}_n$ denote the difference between two successive iterates, then choosing $T<1/C$ we have proven the following result.

Proposition 5.18: Let the initial data satisfy the hypotheses of Proposition 5.16. There exists a $T_*>0$, depending on the prescribable fields and the initial data, such that

$$\|\delta\mathbf{U}_{n+1}\|_{\Psi^1_{0,T_*}} \leqslant \alpha\|\delta\mathbf{U}_n\|_{\Psi^1_{0,T_*}},$$

with $\alpha<1$.

Proposition 5.18 asserts that the iteration scheme defined by (5.4)–(5.7), when considered over $S^2\times[0,T_*]$, defines a mapping $\Gamma:\mathbf{U}_n\mapsto\mathbf{U}_{n+1}$ which is a contraction with respect to the Ψ^1_{0,T_*} norm. This fact gives us the following corollary.

Corollary 5.19: Let the initial data satisfy the hypotheses of Proposition 5.16. There exists a $T_*>0$, depending on the prescribable fields and the initial data, such that the sequence $\{\mathbf{U}_n\}_{n=0}^{\infty}$ is a Cauchy sequence with respect to the Ψ^1_{0,T_*} norm.

Proof: From Proposition 5.18 it is clear, upon iterating the result, that

$$\|\delta\mathbf{U}_{n+1}\|_{\Psi^1_{0,T_*}} \leqslant \alpha^n \|\delta\mathbf{U}_1\|_{\Psi^1_{0,T_*}}.$$

Since $\alpha<1$ it is obvious that $\|\delta\mathbf{U}_{n+1}\|_{\Psi^1_{0,T_*}} \to 0$ as $n\to\infty$. Clearly this means that $\{\mathbf{U}_n\}_{n=0}^{\infty}$ is a Cauchy sequence in Ψ^1_{0,T_*}. ■

Theorem 5.20: *Let the prescribable fields β, H, $T_{0\alpha}$, $\sigma\in C^\infty(S^2\times\mathbb{R}^+)$ and let the initial data satisfy $u_0\in H^{2m+1}(S^2)$, $\mu_0\in H^{2m}(S^2)$, and $k_0\in\mathbb{C}^3$, with $m>m_0$. There exists a $T>0$ depending on the prescribable fields and the initial data such that the system of equations (4.8)–(4.11) with the above data, has a unique solution*

$$\mathbf{U} = (u, \mu, k, \hat{\eth}) \in \Psi^m_{0,T}.$$

Proof: Given the hypotheses of the theorem, Corollary 5.19 applies and so there exists a $T>0$ such that the sequence $\{\mathbf{U}_n\}_{n=0}^{\infty}$ is Cauchy in $\Psi^1_{0,T}$. Now $\Psi^1_{0,T}$ is a complete space, and so $\mathbf{U}_n$ converges to $\mathbf{U}\in\Psi^1_{0,T}$. The limit $\mathbf{U}$ is the unique fixed point of the iteration and so clearly uniquely satisfies the system (4.8)–(4.11), with the given data. We note that since $\mathbf{U}\in\Psi^1_{0,T}$, $\mathbf{U}$ is regular enough to satisfy the system in the strong sense. Moreover, Proposition 5.16 states that $\|\mathbf{U}_n\|_{\Psi^m_{0,T}}\leqslant N$ and so there is a subsequence $\{\mathbf{U}_{n_j}\}_{j=0}^{\infty}\subset\{\mathbf{U}_n\}_{n=0}^{\infty}$ and $\mathbf{V}\in\Psi^m_{0,T}$ such that $\mathbf{U}_{n_j}\rightharpoonup\mathbf{V}$ in $\Psi^m_{0,T}$. However, since the fixed point $\mathbf{U}$ is unique, we conclude that $\mathbf{U}=\mathbf{V}\in\Psi^m_{0,T}$. ■

This last result gives us a partial solution to Problem 1b. It says that the QSECS with prescribed mean curvature is uniquely solvable at least on some finite interval of time. We will now derive a similar result concerning Problem 2b, the QSECS with prescribed polar curvature.

E. Prescribing the polar curvature

In Sec. III we saw that we could ascribe a potentially interesting geometric nature to our space–time initial data if we were to allow for the possibility of prescribing the polar curvature. Our aim in this section then, is to prove a theorem analagous to Theorem 5.20, where now μ is taken as prescribed instead of H. Our method will again be to look at an associated linear iterative system of partial differential equations, and infer the convergence of this system to a unique fixed point. To this end we will consider the following iterative system of equations:

$$\dot{u}_{n+1} = \hat{\gamma}u_n^2\Delta u_{n+1} - \hat{\gamma}u_n^3\left(1-\tfrac{1}{2}e^{2t}\left(16\pi T_{00}+2\|\kappa_n\|^2+\tfrac{3}{2}\mu^2-2\mu H_n\right)\right)+\tfrac{1}{2}(1+\hat{\gamma}e^{2t}\|\hat{\eta}_n\|^2+\gamma B)u_n, \tag{5.49}$$

$$\dot{k}_{n+1} = -\mathcal{P}_1\left\{\mu\eth u_{n+1}+\tfrac{1}{2}\eth(\mu u_{n+1})-\eth(u_{n+1}H_n)+(1+\rho)\kappa_{n+1}+\overline{\kappa}_n\eth\beta+\kappa_n\eth\overline{\beta}+8\pi e^t u_{n+1}T_0\right\}, \tag{5.50}$$

$$\begin{aligned}-\overline{\eth}\hat{\eta}_{n+1} = \dot{\sigma}+(1-\mathcal{P}_1)\Big\{&\mu\eth u_{n+1}+\tfrac{1}{2}\eth(\mu u_{n+1})-\eth(u_{n+1}H_n)+(1+\rho)\kappa_{n+1}+\overline{\kappa}_{n+1}\eth\beta+\kappa_{n+1}\eth\overline{\beta}\\&+8\pi e^t u_{n+1}T_0\Big\},\end{aligned} \tag{5.51}$$

$$\rho H_{n+1} = \dot{\mu}-\operatorname{div}(u_{n+1}\kappa_{n+1})+(1+\rho)\mu+u_{n+1}^{-1}\hat{\eta}^{AB}_{n+1}\nabla_{(B}\beta_{A)}+8\pi T_{03}u_{n+1}e^t. \tag{5.52}$$

Informally, we implement the scheme as follows.

Define the zeroth iterate $(u,\hat{\eta},k,H)_0^{\sim}$ by first defining $u_0^{\sim}$ and $k_0^{\sim}$ as the time constant extensions of the initial data u_0 and k_0, respectively. We may then use Eq. (5.50) with $n=-1$, to define H_{-1}. Note that this is possible since (5.50) may be considered as an algebraic equation for H_n since $\mathcal{P}_1\eth$ is just a multiplier. This is the only time we will consider (5.50) as an equation for H_n; from now on we will consider it as an equation for k_n. Moreover, we may dispense with H_{-1} after we substitute it into (5.51) with $n=-1$, and we define $\hat{\eta}_0^{\sim}$ as the solution of the resulting equation. With $u_0^{\sim}, k_0^{\sim}$, and $\hat{\eta}_0^{\sim}$ all defined, we may take $n=-1$ and define $H_0^{\sim}$ as the solution of the algebraic equation (5.52).

If we take $u_0 \in H^{2m+1}(S^2)$ and $k_0 \in \mathbb{C}^3$ then it is clear that $(u, \hat{\eta}, k, H)_0^{\sim} \in \Psi_{0,T}^m$.

Using Theorem 5.1, it is an easy matter to see that if $(u, \hat{\eta}, k, H)_n \in \Psi_{0,T}^m$ then $u_{n+1} \in P_{0,T}^{m+1/2}$ exists as the solution to (5.49) with data u_0, for any $T \in [0, \infty)$.

Moving on to (5.50), we may pose this equation equivalently as the following ordinary differential equation over $\mathbb{C}^3$:

$$\dot{k}_{n+1} = Ak_{n+1} + B_n, \tag{5.53}$$

where now

$$Ak = -\mathcal{P}_1\{(1+\rho)k\} \tag{5.54}$$

and

$$B_n = -\mathcal{P}_1\Big\{\mu \eth u_{n+1} + \tfrac{1}{2}\eth(\mu u_{n+1}) - \eth(u_{n+1}H_n) + (1+\rho)\sigma + \overline{\kappa}_n \eth\beta + \kappa_n \eth\overline{\beta} + 8\pi e^t u_{n+1} T_0\Big\}.$$

The following result, which is analogous to Lemma 5.2, is a simple consequence of the definition (5.54)

Lemma 5.21: Let $\beta \in \Gamma^\infty(TS^2 \times [0,\infty))$. The operator $A: \mathbb{C}^3 \to \mathbb{C}^3$ defined by (5.54) is a bounded linear operator.

Proof: Linearity is obvious from the definition as is the fact that

$$\|Ak\|_{\mathbb{C}^3}^2 \leqslant C_\rho \|k\|_{\mathbb{C}^3}^2.$$

■

We may use Lemma 5.3, substituting $\mathbb{C}^3$ for E^j, to infer the unique existence of $k_{n+1} \in C^1([0,T]; \mathbb{C}^3)$, the solution of (5.53) subject to the initial value $k_0 \in \mathbb{C}^3$, provided that $u_{n+1} \in P_{0,T}^{m+1/2}$, $k_n \in H^m([0,T]; \mathbb{C}^3)$, and $H_n \in P_{0,T}^m$. Similarly we may use Lemma 5.4 to obtain the estimate

$$\|k_{n+1}(t)\|_{\mathbb{C}^3} e^{-C_\rho t} \leqslant \|k_0\|_{\mathbb{C}^3} + \int_0^t \|B_n(s)\|_{\mathbb{C}^3}\, \mathrm{d}s,$$

for all $t \in [0,T]$.

It is an easy matter to amend the proof of Proposition 5.9 to give the following result which establishes the higher regularity of solutions to (5.53).

Lemma 5.22: Let $k_0 \in \mathbb{C}^3$ and suppose $u_{n+1} \in P_{0,T}^{m+1/2}$ and $(H_n, k_n) \in \mathcal{O}_{0,T}^m$. Then k_{n+1}, the solution of (5.53) satisfies

$$\|k_{n+1}\|_{H^m([0,T];\mathbb{C}^3)}^2 \leqslant TC\Big(1 + \|B_n\|_{H^m([0,T];\mathbb{C}^3)}^2\Big).$$

The constant C depends on β, $\|u_0\|_{H^{2m}(S^2)}$ and $\|k_0\|_{\mathbb{C}^3}$.

Proof: The result is just Proposition 5.9 with k_{n+1} replacing $\mathcal{M}_{n+1}$ and the much simpler equation (5.53) replacing (5.9). Note in particular that there is no dependence of the constant on u_n, only β. Other than these minor details, the proof is identical. ■

In light of this last result we see that if $u_0 \in H^{2m}(S^2)$, $k_0 \in \mathbb{C}^3$, $u_{n+1} \in P_{0,T}^{m+1/2}$, and $(H_n, k_n) \in \mathcal{O}_{0,T}^m$ then k_{n+1} exists and belongs to $H^m([0,T]; \mathbb{C}^3)$.

As was the case with (5.7), (5.51) is solvable by construction, with the higher regularity of solutions being governed by Corollary 5.12. The equation for H_{n+1}, (5.52), is algebraic and so it is easy to see that $\hat{\eta}_{n+1}$, $H_{n+1} \in P_{0,T}^m$ provided that $u_{n+1} \in P_{0,T}^{m+1/2}$ and $k_{n+1} \in H^m([0,T]; \mathbb{C}^3)$.

For brevity we introduce the following notation:

$$\tilde{\mathbf{U}}_n = (u, \hat{\eta}, k, H)_n.$$

Despite being rather heuristic in nature, the foregoing discussion shows how the results proven in the preceding section can be amended to give analogous results concerning the iteration scheme

presently under consideration. In particular, we have the following analog of Theorem 5.13.

Theorem 5.23: *Let* $m \geqslant m_0$ *and let* $u_0 \in H^{2m+1}(S^2)$ *and* $k_0 \in \mathbb{C}^3$. *There exists a nonincreasing, but possibly decreasing sequence* $\{T_n\}_{n=1}^{\infty}$ *with* $T_n \geqslant 0$, *and a sequence of iterates* $\tilde{\mathbf{U}}_n \in \Psi^m_{0,T_n}$ *which satisfy (5.4)–(5.7).*

Proposition 5.16 also has an analogous result concerning the iteration scheme presently under consideration. In fact, using the same ideas as those found in the proof of Proposition 5.16 it is a fairly simple matter to obtain.

Proposition 5.24: Let $m \geqslant m_0$ *and suppose* $u_0 \in H^{2m+1}(S^2)$ *and* $k_0 \in \mathbb{C}^3$. *There exists* $T^* > 0$ *and* $\tilde{N} > 0$, *depending only on m, the initial data and the prescribable fields, such that*

$$\|\tilde{\mathbf{U}}_n\|_{\tilde{\Psi}^m_{0,T^*}} \leqslant \tilde{N}$$

for all $n \in \mathbb{N}$.

As in Theorem 5.17, we can use Proposition 5.24 to deduce that the proposed iteration scheme (5.49)–(5.52) is consistently defined and produces a sequence of iterates $\{\tilde{\mathbf{U}}_n\}_{n=0}^{\infty} \subset \Psi^m_{0,T^*}$. Moreover, results analogous to Proposition 5.18 and Corollary 5.19 are obtained with practically identical proofs and the counterpart to Theorem 5.20 follows easily.

Theorem 5.25: *Let the prescribable fields* β, μ, $T_{0\alpha}$, $\sigma \in C^{\infty}(S^2 \times \mathbb{R}^+)$ *and let the initial data satisfy* $u_0 \in H^{2m+1}(S^2)$ *and* $k_0 \in \mathbb{C}^3$, *with* $m \geqslant m_0$. *There exists a* $T > 0$ *depending on the prescribable fields and the initial data such that the system of equations (4.8)–(4.11), with the above data, has a unique solution*

$$\tilde{\mathbf{U}} = (u, \hat{\eta}, k, H) \in \Psi^m_{0,T}.$$

This gives us the sought after result concerning Problem 2b.

It is clear that by construction we may transform the solutions given by Theorems 5.20 and 5.25 under the inverse of (4.1) and thereby construct quasispherical initial data which locally satisfies the Einstein constraint equations.[7–10]

(Received 22 October 2004; accepted 22 February 2005; published online 13 April 2005)

By applying Ehlers transformation to Schwarzschild and Kerr solutions of Ernst equation and choosing the suitable coordinate transformations, the two NUT-like solutions, i.e., the so called NUT–Taub-like and the Kerr–NUT-like solutions are obtained which not only can, respectively, reduce to Schwarzschild and Kerr solutions when the parameter $\ell' = 0$, but also can also reduce to the NUT–Taub metric and Kerr–NUT metric, respectively, when ℓ' satisfies the some approximation. Meanwhile it is shown that in the NUT–Taub and Kerr–NUT solutions the range of value for the parameter ℓ interpreted as the gravomagnetic monopole cannot be arbitrary and should be confined by mass of the source to $|\ell| \ll m$. Furthermore, the differences in the geometrical structure between the NUT–Taub-like and NUT–Taub solutions are discussed and the physical properties of the horizons on the Kerr–NUT-like space–time are analyzed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1895825]

I. INTRODUCTION

The Ernst equation[1] is the basic equation for finding stationary axisymmetric vacuum solutions of Einstein's equations. The symmetric groups and generation of new solutions of Ernst equation have been extensively studied.[2–9] Especially, Reina and Treves[10] obtained NUT–Taub(NT) and Kerr–NUT(KN) solutions[11,12] by using an unitary transformation on Schwarzschild solution ξ_S and Kerr solution ξ_K, respectively. In this paper, by applying Ehlers transformation[13] to ξ_S and ξ_K we find two solutions, one with three parameters and the other with four parameters. Furthermore, by means of the mappings and coordinates transformations given by us, we obtain two NUT-like solutions, i.e., the so-called NUT–Taub-like (NT-like) and Kerr–NUT-like (KN-like) solutions, which can be reduced to NT metric and KN metric, respectively, when we consider some special case. In Sec. II, some brief recalls of the Ernst equation and its solutions, especially the general process of the resolution are given. In Sec. III the NUT–Taub-like metric is obtained and the differences in the geometrical structure between the NUT–Taub-like and NUT–Taub solutions are discussed according to the curvature tensors of the NUT–Taub-like metric given by us. The Kerr–NUT-like metric is obtained successively and the properties of the horizons on the Kerr–NUT-like space–time are analyzed in Sec. IV. Finally, Sec. V is devoted to the conclusions. Appendixes A and B follow.

II. BRIEF RECALL ON THE RESOLUTION OF THE ERNST EQUATION

The line element of a stationary axisymmetric Einstein vacuum field called the Papapetrou form in the cylindrical coordinates (ρ, z, ϕ) reads

$$ds^2 = f(dt - \omega\, d\phi)^2 - f^{-1}[e^{2\gamma}(d\rho^2 + dz^2) + \rho^2\, d\phi^2], \tag{1}$$

where the gravitational potentials f, ω, and γ are real functions of ρ and z only. It is known that γ is determined by f and ω. The Ernst equation[1] is

[a]Electronic mail: zwyb@mail.dlptt.ln.cn

$$(\xi\bar{\xi}-1)\nabla^2\xi = 2\bar{\xi}\nabla\,\xi\cdot\nabla\,\xi, \tag{2}$$

where $\nabla\equiv(\partial_\rho,\partial_z)$ and $\nabla^2\equiv\partial_\rho^2+\rho^{-1}\partial_\rho+\partial_z^2$ denote the three-dimensional divergence and Laplacian operators, respectively, $\bar{\xi}$ is the conjugated complex potential of ξ.

The canonical coordinates of Weyl, ρ and z, can be given in terms of prolate spheroidal coordinates, x and y, by the relations

$$\rho = k(x^2-1)^{1/2}(1-y^2)^{1/2} \quad \text{and } z = kxy, \tag{3}$$

with

$$x \geqslant 1, \quad -1 \leqslant y \leqslant 1, \quad k = \text{constant}. \tag{4}$$

In these coordinates, the line element (1) assumes the form

$$\mathrm{d}s^2 = f(\mathrm{d}t-\omega\,\mathrm{d}\phi)^2 - k^2f^{-1}\left[e^{2\gamma}(x^2-y^2)\left(\frac{\mathrm{d}x^2}{x^2-1}+\frac{\mathrm{d}y^2}{1-y^2}\right)+(x^2-1)(1-y^2)\mathrm{d}\phi^2\right]. \tag{5}$$

To determine the potentials f,ω, and γ of the metric (5), the method often to be used is the following relation between f, the twist potential Φ and ξ:

$$f+i\Phi = \frac{\xi-1}{\xi+1}, \tag{6}$$

where Φ is the twist potential defined up to a constant and related to the dragging ω by the following differential equations:[14]

$$\frac{\partial\omega}{\partial x} = \frac{k(1-y^2)}{f^2}\frac{\partial\Phi}{\partial y} \quad \text{and} \quad \frac{\partial\omega}{\partial y} = -\frac{k(x^2-1)}{f^2}\frac{\partial\Phi}{\partial x}, \tag{7}$$

and γ is determined by the following equation:

$$e^{2\gamma} = C\frac{A}{(x^2-y^2)^\delta}, \tag{8}$$

where C is integral constant, and C and δ is determined by the boundary condition,

$$e^{2\gamma}\to 1 \quad \text{when } x\to\infty. \tag{9}$$

It is well known that there are two classical solutions of the Ernst equation, one is Schwarzschild solution,

$$\xi_S = x, \tag{10}$$

the other is Kerr solution,

$$\xi_K = px+iqy, \tag{11}$$

where p and q are real constants satisfying

$$p^2+q^2 = 1. \tag{12}$$

Reina and Treves performed a unitary transformation on ξ_S and ξ_K and obtained NUT–Taub (NT) and Kerr–NUT (KN) solutions[10] as follows:

$$ds^2=\left(1-2\frac{mr+\ell^2}{r^2+\ell^2}\right)(dt-2\ell\cos\theta\,d\phi)^2-\left(1-2\frac{mr+\ell^2}{r^2+\ell^2}\right)^{-1}dr^2-(r^2+\ell^2)(d\theta^2+\sin^2\theta\,d\phi^2) \tag{13}$$

and

$$\begin{aligned}ds^2=&\left(1-2\frac{mr-a\ell\cos\theta+\ell^2}{r^2+a^2\cos^2\theta+\ell^2-2a\ell\cos\theta}\right)\left[dt-\left(2a\sin^2\theta\frac{mr-a\ell\cos\theta+\ell^2}{r^2-2mr+a^2\cos^2\theta-\ell^2}\right.\right.\\&\left.\left.-2\ell\cos\theta\right)d\phi\right]^2-(r^2+a^2\cos^2\theta+\ell^2-2a\ell\cos\theta)\left(\frac{dr^2}{r^2-2mr+a^2-\ell^2}+d\theta^2\right)\\&-\frac{(r^2+a^2\cos^2\theta+\ell^2-2a\ell\cos\theta)(r^2-2mr+a^2-\ell^2)}{r^2-2mr+a^2\cos^2\theta-\ell^2}\sin^2\theta\,d\phi^2.\end{aligned} \tag{14}$$

III. THE NUT–TAUB-LIKE METRIC

Let ξ_0 and ξ be any two solutions of Ernst equation (2), which can be related by Ehlers transformation,

$$T:\xi_0\to\xi,\quad \text{i.e., } \xi=\frac{a\xi_0+\overline{b}}{b\xi_0+\overline{a}}, \tag{15}$$

where a and b are complex numbers and $\overline{a},\overline{b}$ are their complex conjugate, respectively, which satisfy

$$\begin{pmatrix}a & \overline{b}\\ b & \overline{a}\end{pmatrix}\in \mathrm{SU}(1,1),\quad a\overline{a}-b\overline{b}=1. \tag{16}$$

Now taking $\xi_0=\xi_S$, then we can find the potentials corresponding to the solution ξ of the Ernst equation,

$$f=\frac{x^2-1}{(\beta_1^2+\beta_2^2)x^2+2(\beta_1^2-\beta_2^2)x+\beta_1^2+\beta_2^2}, \tag{17}$$

$$\Phi=\frac{(\alpha_2\beta_1-\alpha_1\beta_2)(x^2-1)+2(\alpha_2\beta_1-\alpha_1\beta_2)}{(\beta_1^2+\beta_2^2)x^2+2(\beta_1^2-\beta_2^2)x+\beta_1^2+\beta_2^2}, \tag{18}$$

$$\omega=-4k\beta_1\beta_2 y, \tag{19}$$

$$e^{2\gamma}=\frac{x^2-1}{x^2-y^2}, \tag{20}$$

where α and β are introduced by $\alpha=a-b$, $\beta=a+b$, and can be decomposed as $\alpha=\alpha_1+i\alpha_2$, $\beta=\beta_1+i\beta_2$, where $\alpha_1,\alpha_2,\beta_1$, and β_2 satisfy

$$\alpha_1\beta_1+\alpha_2\beta_2=1. \tag{21}$$

We see from Eqs. (17)–(21) that the solution has three free parameters.

If we let

$$\alpha_1 = \beta_1 \quad \text{and } \alpha_2 = \beta_2, \tag{22}$$

then we can get the known NUT–Taub (KN) solution.

If taking

$$\alpha_1 = \beta_1 \quad \text{and } \alpha_2 = -\beta_2, \tag{23}$$

Eq. (21) turns into

$$\beta_1^2 - \beta_2^2 = 1. \tag{24}$$

Now we introduce the hyperbolic function

$$\beta_1 = \coth \varphi \quad \text{and } \beta_2 = \sinh \varphi, \tag{25}$$

which satisfy the relation (24) obviously. In order to write this metric in Boyer–Lindquist-type coordinates[4] the following mappings are introduced:

$$\begin{gathered} x \to \frac{r-m}{k}, \quad y \to \cos\theta, \\ \coth 2\varphi \to \frac{m}{\sqrt{m^2 - \ell'^2}}, \quad \sinh 2\varphi \to \frac{-\ell'}{\sqrt{m^2 - \ell'^2}}, \end{gathered} \tag{26}$$

with

$$k \to \frac{m^2}{\sqrt{m^2 - \ell'^2}}. \tag{27}$$

We see from above that the value of parameter ℓ' has a range of

$$-m < \ell' < m, \ \ell' \neq \pm m. \tag{28}$$

By the complicated calculation, we can finally find the following metric:

$$\begin{aligned} ds^2 = {} & \sqrt{\frac{m^2 - \ell'^2}{m^2}}\left(1 - 2\frac{mr + \frac{m^2}{m^2-\ell'^2}\ell'^2}{r^2 + \frac{m^2}{m^2-\ell'^2}\ell'^2}\right)\left(dt - 2\frac{m^2}{m^2 - \ell'^2}\ell' \cos\theta\, d\phi\right)^2 - \sqrt{\frac{m^2}{m^2 - \ell'^2}}\Bigg(1 \\ & - 2\frac{mr + \frac{m^2}{m^2-\ell'^2}\ell'^2}{r^2 + \frac{m^2}{m^2-\ell'^2}\ell'^2}\Bigg)^{-1} dr^2 - \sqrt{\frac{m^2}{m^2 - \ell'^2}}\left(r^2 + \frac{m^2}{m^2 - \ell'^2}\ell'^2\right)(d\theta^2 + \sin^2\theta\, d\phi^2), \end{aligned} \tag{29}$$

where r and θ are spherical coordinates. When $\ell' = 0$, this metric becomes the Schwarzschild solution, which indicates that the parameter m is mass of the source and ℓ' is a parameter with mass dimension obviously. It is more worthy of note that if we assume the following approximation,

$$1 - \left(\frac{\ell'}{m}\right)^2 \approx 1 \quad \text{when } |\ell'| \ll m, \tag{30}$$

then this metric becomes

$$ds^2 = \left(1 - 2\frac{mr + \ell'^2}{r^2 + \ell'^2}\right)(dt + 2\ell' \cos\theta\, d\phi)^2 - \left(1 - 2\frac{mr + \ell'^2}{r^2 + \ell'^2}\right)^{-1} dr^2 - (r^2 + \ell'^2)(d\theta^2 + \sin^2\theta\, d\phi^2). \tag{31}$$

It is just the NT solution (13) when $\ell' = \ell$. Thus here we call this solution (29) the NT-like metric and give the following comments.

(1) The value of the parameter ℓ interpreted as the gravomagnetic monopole[5,12] in the NT solution (13) is limited by the mass of source, i.e., $|\ell| \ll m$. But in the NT-like solution (29), the parameter satisfies $-m < \ell' < m$.

(2) According to the curvature tensors $R_{\mu\nu\lambda\rho}$ (see the Appendixes) corresponding to the NT and NT-like metrics we can see the space–time structure of the NT-like solution is different from the one for the NT solution. And the case of $\ell' = \pm m$ leads the curvature of NUT-like space–time to diverge, this implies that the solution is "everywhere" singular and therefore meaningless when $\ell' = \pm m$. But in the case of $|\ell'| \ll m$, the geometrical properties of both are the same owing to having the same curvature tensors.

IV. THE KERR–NUT-LIKE METRIC

If we take $\xi_0 = \xi_K$ (Kerr solution) in Ehlers transformation (15), we get

$$\xi' = \frac{a\xi_K + \overline{b}}{b\xi_K + \overline{a}}, \tag{32}$$

By applying the same method as Sec. III and making the complicated calculation, we can find the potentials corresponding to the solution ξ' of the Ernst equation,

$$f = \frac{p^2x^2 + q^2y^2 - 1}{(\beta_1^2 + \beta_2^2)(p^2x^2 + q^2y^2) + 2(\beta_1^2 - \beta_2^2)px - 4\beta_1\beta_2 qy + \beta_1^2 + \beta_2^2}, \tag{33}$$

$$\Phi = \frac{(\alpha_2\beta_1 - \alpha_1\beta_2)(p^2x^2 + q^2y^2 + 2qy + 1) - 2(\alpha_2\beta_1 + \alpha_1\beta_2)px}{(\beta_1^2 + \beta_2^2)(p^2x^2 + q^2y^2) + 2(\beta_1^2 - \beta_2^2)px - 4\beta_1\beta_2 qy + \beta_1^2 + \beta_2^2}, \tag{34}$$

$$\omega = -\frac{2kq}{p}\frac{1 - y^2}{p^2x^2 + q^2y^2 - 1}(2\beta_1\beta_2 qy - px - \beta_1^2 - \beta_2^2) - \frac{4\beta_1\beta_2 ky}{p}, \tag{35}$$

$$e^{2\gamma} = \frac{p^2x^2 + q^2y^2 - 1}{p^2(x^2 - y^2)}, \tag{36}$$

where $\alpha_1, \alpha_2, \beta_1$, and β_2 still satisfy Eq. (21). We easily see from Eqs. (33)–(36) the above solution contains four free parameters, and Kerr–NUT (KN) solution is contained as a special case which satisfies the relation (22). On the other hand, if we consider Eqs. (23)–(25), and introduce the following crucial mappings in Boyer–Lindquist-type coordinates:

$$x \to \frac{r - m}{k}, \quad y \to \cos\theta,$$

$$\coth 2\varphi \to \frac{m}{\sqrt{m^2 - \ell'^2}}, \quad \sinh 2\varphi \to \frac{\ell'}{\sqrt{m^2 - \ell'^2}},$$

$$p \to \frac{\sqrt{m^2 - a^2}}{m}, \quad q \to \frac{a}{m}, \tag{37}$$

with

$$k \to m\sqrt{\frac{m^2 - a^2}{m^2 - \ell'^2}},$$

then we see from Eq. (37) that the value of parameter ℓ' has the same range as (28). And under the above mappings we can finally get the metric

$$\begin{aligned} ds^2 = & \sqrt{\frac{m^2 - \ell'^2}{m^2}}\left(1 - 2\frac{\frac{m^2-\ell'^2}{m^2}mr - a\ell' \cos\theta + \ell'^2}{\frac{m^2-\ell'^2}{m^2}r^2 + a^2\cos^2\theta - 2a\ell' \cos\theta + \ell'^2}\right)\Bigg[dt \\ & - \left(2a\sin^2\theta \frac{mr - \frac{m^2}{m^2-\ell'^2}(a\ell' \cos\theta - \ell'^2)}{\frac{m^2-\ell'^2}{m^2}(r^2 - 2mr) + a^2\cos^2\theta - \ell'^2} - 2\frac{m^2}{m^2 - \ell'^2}\ell' \cos\theta\right)d\phi\Bigg]^2 \\ & - \sqrt{\frac{m^2}{m^2 - \ell'^2}}\left(\frac{m^2 - \ell'^2}{m^2}r^2 + a^2\cos^2\theta - 2a\ell' \cos\theta + \ell'^2\right)\left(\frac{dr^2}{\frac{m^2-\ell'^2}{m^2}(r^2 - 2mr) + a^2 - \ell'^2}\right. \\ & \left. + \frac{m^2}{m^2 - \ell'^2}d\theta^2\right) - \sqrt{\frac{m^2}{m^2 - \ell'^2}}\left(1 - 2\frac{\frac{m^2-\ell'^2}{m^2}mr - a\ell' \cos\theta + \ell'^2}{\frac{m^2-\ell'^2}{m^2}r^2 + a^2\cos^2\theta - 2a\ell' \cos\theta + \ell'^2}\right)^{-1}\Bigg[r^2 - 2mr \\ & + \frac{m^2}{m^2 - \ell'^2}(a^2 - \ell'^2)\Bigg]\sin^2\theta\, d\phi^2, \end{aligned} \tag{38}$$

where r and θ are spherical coordinates. When $\ell' = 0$, this metric becomes the Kerr metric which indicates that the parameters m and a are the mass and the angular momentum per unit mass of the source, respectively, and ℓ' is a parameter with mass dimension obviously. It is noted that for the parameter ℓ' its range of the value and the physical explanation are the same as those in NT-like metric. On the other hand, this metric can be reduced to NT-like metric, when $a = 0$. It is worthy of emphasizing that if we take the approximation (28), i.e., $1 - (\ell'/m)^2 \approx 1$ when $|\ell'| \ll m$, then we find that the metric (38) can be reduced to KN metric (14). It follows that this metric contains KN metric as a special case. Hence here we call it the KN-like metric. Furthermore, we find the KN-like solution has the different physical properties from the KN solution. As an example, below we will discuss the horizons on the KN-like space–time in order to show the differences between both.

Generally, the horizon function $f(x^\mu)$ (exactly null-hypersurface) satisfies[13]

$$n_\mu n^\mu = g^{\mu\nu}\frac{\partial f}{\partial x^\mu}\frac{\partial f}{\partial x^\nu} = 0, \tag{39}$$

where $n_\mu \equiv \partial f/\partial x^\mu$ is the normal vector of the null hypersurface. For a stationary axisymmetric space–time, Eq. (39) can be written as

$$\hat{g}_{00}\left[g^{11}\left(\frac{\partial f}{\partial r}\right)^2 + g^{22}\left(\frac{\partial f}{\partial \theta}\right)^2\right] = 0, \tag{40}$$

where

$$\hat{g}_{00} \equiv g_{00} - \frac{g_{03}^2}{g_{33}}. \tag{41}$$

Thus we get the following two equations:

$$g^{11}\left(\frac{\partial f}{\partial r}\right)^2 + g^{22}\left(\frac{\partial f}{\partial \theta}\right)^2 = 0 \quad \text{or } \hat{g}_{00} = 0, \tag{42}$$

it is easy to identify that the two equations in (42) give the same equation as follows according to the KN-like metric (38):

$$\frac{m^2 - \ell'^2}{m^2}(r^2 - 2mr) + a^2 - \ell'^2 = 0. \tag{43}$$

The solutions of the above equation are

$$r_{\pm}^h = m\left(1 \pm \sqrt{\frac{m^2 - a^2}{m^2 - \ell'^2}}\right). \tag{44}$$

These horizons split into the Cauchy horizon, with radius $r_{ch}=m(1-\sqrt{(m^2-a^2)/(m^2-\ell'^2)})$, and the event horizon, with radius $r_{eh}=m(1+\sqrt{(m^2-a^2)/(m^2-\ell'^2)})$. Obviously by comparing with the horizons of the KN metric, $r_{\pm}^h(\mathrm{KN})=m(1\pm\sqrt{(m^2-a^2+\ell^2)/m^2})$, we can see there is the difference between the radial location of the horizons of the KN-like and KN solutions due to the property of the latter to hold if $|\ell| \ll m$, i.e., $r_{\pm}^h(\mathrm{KN})$ can be deduced from $r_{\pm}^h$ in (44) as follows:

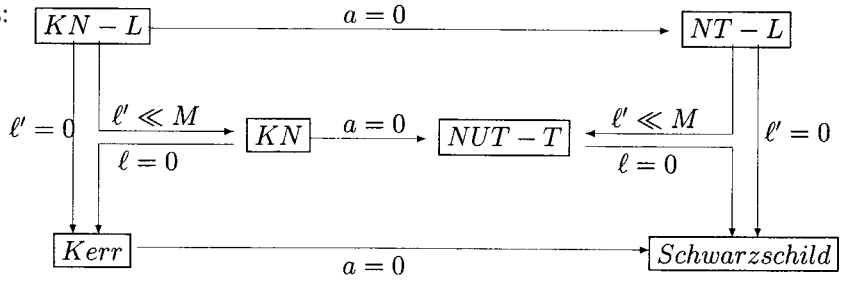
$$\begin{aligned} r_{\pm}^h &= m\left(1 \pm \sqrt{\frac{1-\frac{a^2}{m^2}}{1-\frac{\ell'^2}{m^2}}}\right) \doteq m\left(1 \pm \sqrt{1 - \frac{a^2}{m^2} + \frac{\ell'^2}{m^2} - \frac{a^2\ell'^2}{m^4}}\right) = m\left(1 \pm \sqrt{\frac{m^2 - a^2 + \ell'^2 - \frac{a^2\ell'^2}{m^2}}{m^2}}\right) \\ &\doteq m\left(1 \pm \sqrt{\frac{m^2 - a^2 + \ell^2}{m^2}}\right) = r_{\pm}^h(\mathrm{KN}), \end{aligned} \tag{45}$$

where $\ell' = \ell$ when $|\ell'| \ll m$. And this justifies neglecting the term $a^2\ell'^2/m^2$ with respect to a^2 in (45). Especially, it should be noted that the extreme black hole of the KN-like solution satisfies the condition $a=m$ which is the same as the Kerr metric's case, but differs from the condition corresponding to the extreme black hole of the Kerr–NUT metric, which is $a=\sqrt{m^2+\ell^2}$.

V. CONCLUSIONS

So far we have obtained the NUT–Taub-like metric and the Kerr–NUT-like metric by applying Ehlers transformation to Schwarzschild and Kerr solutions of Ernst equation and choosing the suitable mappings in Boyer–Lindquist-like coordinates. When $\ell'=0$ the two solutions can, respectively, reduce to Schwarzschild and Kerr solutions; and when ℓ' satisfies the approximation (30) they can also reduce to the NUT–Taub metric and Kerr–NUT metric, respectively. In this sense, we believe that in the NUT–Taub and Kerr–NUT metrics the value of the NUT parameter ℓ interpreted as the gravomagnetic monopole[10,14] cannot be arbitrary and should be confined to $|\ell| \ll m$. Whether the limit of the parameter ℓ may influence on the prediction of observable effects[10,14] for the parameter ℓ is worthy of taking a further investigation. In addition, as concrete examples we not only calculated the curvature tensors of the NT-like solution and pointed out there are the differences in the geometrical structure between the NUT–Taub-like and NUT–Taub solutions, but also gave the horizons on the Kerr–NUT-like space–time and discussed the difference of the extreme black hole between the Kerr–NUT-like metric and the Kerr–NUT metric. For other physical properties of the two solutions such as ergospheres, singularities, geodesics, and so on we will investigate in our forthcoming paper. The relation among the above solutions can be

figured as follows:



where KN and NUT–T denote Kerr–NUT and NUT–Taub solutions, while KN-L and NT-L denote, respectively, Kerr–NUT-like and NUT–Taub-like solutions.

APPENDIX A: THE NONZERO CURVATURE TENSORS OF THE NUT–TAUB (NT) METRIC

The NUT–Taub metric in spheroidal coordinates are

$$g_{\mu\nu}=\begin{pmatrix} \frac{\mathcal{H}}{\mathcal{U}} & 0 & 0 & -2\ell\cos\theta\left(\frac{\mathcal{H}}{\mathcal{U}}\right) \\ 0 & -\left(\frac{\mathcal{U}}{\mathcal{H}}\right) & 0 & 0 \\ 0 & 0 & -\mathcal{U} & 0 \\ -2\ell\cos\theta\left(\frac{\mathcal{H}}{\mathcal{U}}\right) & 0 & 0 & 4\ell^2\cos^2\theta\left(\frac{\mathcal{H}}{\mathcal{U}}\right)-\mathcal{U}\sin^2\theta \end{pmatrix} \tag{A1}$$

and its inverse

$$g^{\mu\nu}=\begin{pmatrix} \frac{(r^2+\ell^2)}{(r^2-2mr-\ell^2)}-\frac{4\ell^2\cos^2\theta}{(r^2+\ell^2)\sin^2\theta} & 0 & 0 & \frac{-2\ell\cos\theta}{(r^2+\ell^2)\sin^2\theta} \\ 0 & -\left(\frac{r^2-2mr-\ell^2}{r^2+\ell^2}\right) & 0 & 0 \\ 0 & 0 & -\frac{1}{r^2+\ell^2} & 0 \\ \frac{-2\ell\cos\theta}{(r^2+\ell^2)\sin^2\theta} & 0 & 0 & -\frac{1}{(r^2+\ell^2)\sin^2\theta} \end{pmatrix}, \tag{A2}$$

where

$$\mathcal{U}=r^2+\ell^2, \quad \mathcal{H}=r^2-2Mr-\ell^2.$$

The nonzero curvature tensors of the NUT–Taub metric are

$$R_{1212}=\frac{\mathcal{N}}{\mathcal{H}\mathcal{U}}, \quad R_{0101}=2\frac{\mathcal{N}}{\mathcal{U}^3}, \quad R_{1301}=4\frac{\mathcal{N}}{\mathcal{U}^3}\ell\cos\theta, \quad R_{2301}=-2\frac{\mathcal{K}}{\mathcal{U}^2}\ell\sin\theta,$$

$$R_{1302}=-\frac{\mathcal{K}}{\mathcal{U}^2}\ell\sin\theta, \quad R_{2302}=-2\frac{\mathcal{N}\mathcal{H}}{\mathcal{U}^3}\ell\cos\theta, \quad R_{1203}=\frac{\mathcal{K}}{\mathcal{U}^2}\ell\sin\theta,$$

$$R_{0303}=-\frac{\mathcal{N}\mathcal{H}}{\mathcal{U}^3}\sin^2\theta, \quad R_{2313}=-6\frac{\mathcal{K}}{\mathcal{R}^2}\ell^2\cos\theta\sin\theta, \quad R_{2002}=\frac{\mathcal{N}\mathcal{H}}{\mathcal{U}^3},$$

$$R_{1313}=\frac{\mathcal{N}}{\mathcal{HR}}\left(8\frac{\mathcal{H}}{\mathcal{U}^2}\ell^2\cos^2\theta+\sin^2\theta\right),\quad R_{2323}=-2\frac{\mathcal{N}}{\mathcal{U}}\left(2\frac{\mathcal{H}}{\mathcal{U}^2}\ell^2\cos^2\theta+\sin^2\theta\right),\tag{A3}$$

where

$$\mathcal{N}=mr^3+3\ell^2r^2-3m\ell^2r-\ell^4,\quad \mathcal{K}=r^3-3mr^2-3\ell^2r+m\ell^2.$$

APPENDIX B: THE NONZERO CURVATURE TENSORS OF THE NUT–TAUB-LIKE (NT-LIKE) METRIC

The NUT–Taub-like metric is

$$g_{\mu\nu}=\begin{pmatrix}\Delta\frac{G}{H} & 0 & 0 & -2\frac{G}{H}S\cos\theta\\ 0 & -\Delta^{-1}\frac{H}{G} & 0 & 0\\ 0 & 0 & -\Delta^{-1}H & 0\\ -2\frac{G}{H}S\cos\theta & 0 & 0 & \Delta^{-1}\left(4\frac{G}{H}S^2\cos^2\theta-H\sin^2\theta\right)\end{pmatrix}\tag{B1}$$

and its inverse is

$$g^{\mu\nu}=\begin{pmatrix}\Delta^{-1}\left[\frac{H}{G}-\frac{4S\cos^2\theta}{H\sin^2\theta}\right] & 0 & 0 & -\frac{2S\cos\theta}{H\sin^2\theta}\\ 0 & -\Delta\left(\frac{G}{H}\right) & 0 & 0\\ 0 & 0 & -\frac{\Delta}{H} & 0\\ -\frac{2S\cos\theta}{H\sin^2\theta} & 0 & 0 & -\frac{\Delta}{H\sin^2\theta}\end{pmatrix},\tag{B2}$$

where

$$\Delta=\sqrt{\frac{m^2-\ell'^2}{m^2}},\quad G=r^2-2mr-S^2,\quad H=r^2+S^2,\quad \mathrm{S}=\ell'\sqrt{\frac{m^2}{m^2-\ell'^2}}.$$

The nonzero curvature tensors of the NUT–Taub-like metric are

$$R_{1212}=\Delta^{-1}\frac{N}{HG},\quad R_{0101}=2\Delta\frac{N}{H^3},\quad R_{1301}=4\frac{N}{H^3}S\cos\theta,$$

$$R_{2301}=-2\frac{K}{H^2}S\sin\theta,\quad R_{1302}=-\frac{K}{H^2}S\sin\theta,\quad R_{2302}=-2\frac{NG}{H^3}S\cos\theta,$$

$$R_{1203}=H^2S\sin\theta,\quad R_{0303}=-\Delta\frac{NG}{H^3}\sin^2\theta,\quad R_{2313}=-6\Delta^{-1}\frac{K}{H^2}S^2\cos\theta\sin\theta,$$

$$R_{2002}=\Delta\frac{NG}{H^3},\quad R_{1313}=\Delta^{-1}\frac{N}{HG}\left(8\frac{G}{H^2}S^2\cos^2\theta+\sin^2\theta\right),$$

$$R_{2323}=-2\Delta^{-1}\frac{N}{H}\left(2\frac{G}{H^2}S^2\cos^2\theta+\sin^2\theta\right),\tag{B3}$$

where

$$N=mr^3+3S^2r^2-3mS^2r-S^4,\quad K=r^3-3mr^2-3S^2r+mS^2.$$

(Received 10 April 2004; accepted 25 February 2005; published online 25 April 2005)

We consider the low-energy effective action of the five-dimensional (5D) Einstein–Maxwell–Kalb–Ramond theory. After compactifying this truncated model on a two-torus and switching off the U(1) vector fields of this theory, we recall a formulation of the resulting three-dimensional action as a double Ernst system coupled to gravity. Further, by applying the so-called normalized Harrison transformation on a generic solution of this double Ernst system we recover the U(1) vector field sector of the theory. Afterward, we compute the field content of the generated charged configuration for the special case when the starting Ernst potentials correspond to a pair of interacting Kerr black holes, obtaining in this way an exact field configuration of the 5D Einstein–Maxwell–Kalb–Ramond theory endowed with effective Coulomb and dipole terms with momenta. Some physical properties of this object are analyzed as well as the effect of the normalized Harrison transformation on the double Kerr seed solution. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897843]

I. INTRODUCTION

Recently some natural interest has been shown to the study of field configurations that describe interacting black holes coupled to some matter fields, both in the framework of general relativity[1,2] and string theory.[3–5] One of the reasons for such an interest is the development reached in the statistical approach to physics of single black holes (for a review, see for instance, Refs. 6 and 7) and its possible generalization to more complicated systems of interacting black holes coupled to matter.

In this paper we construct a charged field configuration that consists of a pair of interacting sources of black hole type coupled to an antisymmetric Kalb–Ramond tensor field and a set of Abelian gauge fields in the framework of the truncated five-dimensional Einstein–Maxwell–Kalb–Ramond (EMKR) theory. The construction is carried out by applying the normalized Harrison charging symmetry, which acts on the target space of the effective three-dimensional heterotic string theory and preserves the asymptotic properties of the starting field configurations, on a seed solution that corresponds to a double Ernst system in the framework of the toroidally reduced five-dimensional Einstein–Kalb–Ramond (EKR) theory. Several interesting results have been achieved regarding the physical properties of five-dimensional black objects;[8] it turns out that the Bogomolnyi-Prasad-Sommerfield (BPS) bound of rotating black holes is saturated precisely in five or more dimensions.

[a)]Electronic mail: becerril@ifm.umich.mx
[b)]Electronic mail: aherrera@auth.gr

The paper is organized as follows: in Sec. II we briefly review the matrix Ernst potential (MEP) formalism for the effective field theory of the heterotic string (for an arbitrary number of dimensions) and its formal analogy to the stationary Einstein–Maxwell (EM) system. It turns out that after setting to zero the dilaton and all U(1) vector fields, and considering the compactification of this theory on a two-torus, the resulting three-dimensional subsystem admits a Kähler representation which is defined by two vacuum Ernst potentials.

In Sec. III the parametrization which gives rise to this double Ernst system is pointed out and a discrete transformation between the metric and Kalb–Ramond degrees of freedom is established. In Sec. IV we recall the normalized Harrison transformation (NHT) and apply it on a generic seed solution of the EKR theory which corresponds to two complex Ernst potentials in order to get a charged field configuration and recover, in this way, the U(1) vector field sector of the EMKR theory.

Further, in Sec. V we reduce the system to two effective dimensions (dependence of just two dynamical coordinates) in order to be able to consider as seed solution a pair of Ernst potentials which correspond to interacting Kerr black holes. In this case, the five-dimensional line element explicitly depends on the Ernst potentials and the resulting field configuration contains a Kalb–Ramond dipole hidden inside a horizon. In Sec. VI we explicitly compute the generated charged solution, study its asymptotical behavior and give an interpretation of the field configuration. Finally, we sketch our conclusions and discuss on the further development of the present work.

II. MATRIX ERNST POTENTIAL FORMALISM

In this section we review the MEP formalism for the D-dimensional effective field theory of the heterotic string and indicate an algorithm for generating a charged solution of the double Ernst system starting from a neutral one by making use of a matrix Lie–Bäcklund transformation of Harrison type.

We consider the effective action of the heterotic string theory at tree level,

$$S^{(D)}=\int d^{(D)}x|G^{(D)}|^{1/2}e^{-\phi^{(D)}}\left(R^{(D)}+\phi^{(D)}_{;M}\phi^{(D);M}-\tfrac{1}{12}H^{(D)}_{MNP}H^{(D)MNP}-\tfrac{1}{4}F^{(D)I}_{MN}F^{(D)IMN}\right), \tag{1}$$

where

$$F^{(D)I}_{MN}=\partial_M A^{(D)I}_N-\partial_N A^{(D)I}_M, \quad H^{(D)}_{MNP}=\partial_M B^{(D)}_{NP}-\tfrac{1}{2}A^{(D)I}_M F^{(D)I}_{NP}+\text{cycl perms of } M,N,P.$$

Here $G^{(D)}_{MN}$ is the metric, $B^{(D)}_{MN}$ is the antisymmetric Kalb–Ramond field, $\phi^{(D)}$ is the dilaton, $A^{(D)I}_M$ is a set of U(1) vector fields ($I=1,2,\ldots,n$), D is the original number of space–time dimensions; capital letters $M,N,\ldots,P$ are related to the whole set of space–time coordinates, lower case letters m,n label the extra dimensions, whereas Greek letters μ,ν stand for the noncompactified coordinates. In the consistent critical case $D=10$ and $n=16$, but we shall leave these parameters arbitrary for the time being and will fix them later in Sec. III. In Refs. 9 and 10 it was shown that after the compactification of this model on a $D-3=d$-torus, the resulting three-dimensional theory possesses the SO $(d+1,d+n+1)$ symmetry group that later was identified as U-duality[11] and describes gravity through the metric tensor

$$g_{\mu\nu}=e^{-2\phi}(G^{(D)}_{\mu\nu}-G^{(D)}_{m+3,\mu}G^{(D)}_{n+3,\nu}G^{mn}),$$

coupled to the following set of three-dimensional fields:

(a) scalar fields,

$$G\equiv G_{mn}=G^{(D)}_{m+3,n+3}, \quad B\equiv B_{mn}=B^{(D)}_{m+3,n+3}, \quad A\equiv A^I_m=A^{(D)I}_{m+3}, \quad \phi=\phi^{(D)}-\tfrac{1}{2}\ln|\det G|, \tag{2}$$

(b) tensor field,

$$B_{\mu\nu} = B^{(D)}_{\mu\nu} - 4B_{mn}A^m_\mu A^n_\nu - 2(A^m_\mu A^{m+d}_\nu - A^m_\nu A^{m+d}_\mu), \tag{3}$$

(c) vector fields $A^{(a)}_\mu = ((A_1)^m_\mu, (A_2)^{m+d}_\mu, (A_3)^{2d+I}_\mu)$,

$$(A_1)^m_\mu = \tfrac{1}{2}G^{mn}G^{(D)}_{n+3,\mu}, \quad (A_3)^{I+2d}_\mu = -\tfrac{1}{2}A^{(D)I}_\mu + A^I_n A^n_\mu, \quad (A_2)^{m+d}_\mu = \tfrac{1}{2}B^{(D)}_{m+3,\mu} - B_{mn}A^n_\mu + \tfrac{1}{2}A^I_m A^{I+2d}_\mu, \tag{4}$$

where the subscripts $m,n=1,2,\ldots,d$; and $a=1,\ldots,2d+n$. In this paper we set $B_{\mu\nu}=0$ since an antisymmetric tensor has no dynamical degrees of freedom in three dimensions; this is equivalent to removing the effective cosmological constant which, in general, is included in the spectrum of the three-dimensional effective theory.

We dualize all vector fields on-shell with the aid of the pseudoscalar fields u, v, and s as follows:

$$\nabla \times \vec{A}_1 = \tfrac{1}{2}e^{2\phi}G^{-1}\left(\nabla u + \left(B + \tfrac{1}{2}AA^T\right)\nabla v + A\nabla s\right),$$

$$\nabla \times \vec{A}_3 = \tfrac{1}{2}e^{2\phi}(\nabla s + A^T\nabla v) + A^T\nabla \times \vec{A}_1, \tag{5}$$

$$\nabla \times \vec{A}_2 = \tfrac{1}{2}e^{2\phi}G\nabla v - \left(B + \tfrac{1}{2}AA^T\right)\nabla \times \vec{A}_1 + A\nabla \times \vec{A}_3.$$

Thus, the effective three-dimensional theory describes gravity $g_{\mu\nu}$ coupled to the scalars G, B, A, ϕ and pseudoscalars u, v, s. In Ref. 12 it was shown that all these matter fields can be arranged in the following pair of MEP:

$$\mathcal{X} = \begin{pmatrix} -e^{-2\phi} + v^TXv + v^TAs + \frac{1}{2}s^Ts & v^TX - u^T \\ Xv + u + As & X \end{pmatrix}, \quad \mathcal{A} = \begin{pmatrix} s^T + v^TA \\ A \end{pmatrix}, \tag{6}$$

where $X=G+B+\frac{1}{2}AA^T$, in such a way that they reproduce the field equations of the three-dimensional theory. These matrices have dimensions $(d+1)\times(d+1)$ and $(d+1)\times n$, respectively.

In terms of the MEP the effective three-dimensional theory adopts the form

$${}^3S = \int d^3x|g|^{1/2}\left\{-R + \mathrm{Tr}\left[\tfrac{1}{4}(\nabla\mathcal{X} - \nabla\mathcal{A}\mathcal{A}^T)\mathcal{G}^{-1}(\nabla\mathcal{X}^T - \mathcal{A}\nabla\mathcal{A}^T)\mathcal{G}^{-1} + \tfrac{1}{2}\nabla\mathcal{A}^T\mathcal{G}^{-1}\nabla\mathcal{A}\right]\right\}, \tag{7}$$

where $\mathcal{X}=\mathcal{G}+\mathcal{B}+\frac{1}{2}\mathcal{A}\mathcal{A}^T$, then $\mathcal{G}=\frac{1}{2}(\mathcal{X}+\mathcal{X}^T-\mathcal{A}\mathcal{A}^T)$ and

$$\mathcal{G} = \begin{pmatrix} -e^{-2\phi} + v^TGv & v^TG \\ Gv & G \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} 0 & v^TB - u^T \\ Bv + u & B \end{pmatrix}. \tag{8}$$

In Ref. 12 it also was shown that there exists a map between the stationary actions of the heterotic string and EM theories. The map reads

$$\mathcal{X} \leftrightarrow -E, \quad \mathcal{A} \leftrightarrow F,$$
$$\text{matrix transposition} \leftrightarrow \text{complex conjugation}, \tag{9}$$

where E and F are the conventional complex Ernst potentials of the stationary EM theory.[13] This map allows us to extrapolate the results obtained in the EM theory to the heterotic string realm using the MEP formulation.

The normalized Harrison transformation

In the language of the MEP the three-dimensional action (7) possesses a set of symmetries which has been classified according to their charging properties in Ref. 14. Among them one finds

the matrix Ehlers and Harrison transformations,[15] which are symmetries that change the properties of the space–time in a nontrivial way; they represent the matrix counterpart of the Bäcklund transformation of the sine-Gordon equation in the realm of the stationary heterotic string theory. For instance, the so-called normalized Harrison transformation allows us to construct charged string vacua from neutral ones preserving the asymptotical values of the three-dimensional seed fields. Namely, the matrix transformation

$$\begin{aligned}\mathcal{A} &\to \left(1+\tfrac{1}{2}\Sigma\lambda\lambda^T\right)\left(1-\mathcal{A}_0\lambda^T+\tfrac{1}{2}\mathcal{X}_0\lambda\lambda^T\right)^{-1}(A_0-\mathcal{X}_0\lambda)+\Sigma\lambda,\\ \mathcal{X} &\to \left(1+\tfrac{1}{2}\Sigma\lambda\lambda^T\right)\left(1-\mathcal{A}_0\lambda^T+\tfrac{1}{2}\mathcal{X}_0\lambda\lambda^T\right)^{-1}\left[\mathcal{X}_0+\left(\mathcal{A}_0-\tfrac{1}{2}\mathcal{X}_0\lambda\right)\lambda^T\Sigma\right]+\tfrac{1}{2}\Sigma\lambda\lambda^T\Sigma,\end{aligned} \tag{10}$$

where $\Sigma=\mathrm{diag}(-1,-1,1,\ldots,1)$ stands for the signature that the MEP $\mathcal{X}$ adopts at spatial infinity and λ is an arbitrary constant $(d+1)\times n$-matrix, generates charged string solutions (with nonzero potential $\mathcal{A}$) from neutral ones if we start from the seed potentials

$$\mathcal{X}_0 \neq 0, \quad \mathcal{A}_0 = 0.$$

The parameters that enter the matrix λ can be interpreted as electromagnetic charges that couple to the original seed object. It is precisely with the aid of this Bäcklund transformation that we shall charge the double 5D Ernst system in the next section.

III. 5D EINSTEIN–KALB–RAMOND VS DOUBLE ERNST SYSTEM

In this section we present a formulation of the resulting three-dimensional model, upon toroidal compactification of the 5D EKR theory, as a double Ernst system by means of a complete parametrization of the matrices $\mathcal{G}$ and $\mathcal{B}$ in terms of the real and imaginary parts of a pair of complex Ernst potentials.

Let us begin by setting to zero all the U(1) gauge fields which correspond to the winding modes of the three-dimensional theory [this is equivalent to dropping the matrix $\mathcal{A}$ in (7)]. Thus, we obtain the following action in terms of the MEP $\mathcal{X}$:

$${}^3S=\int d^3x|g|^{1/2}\left\{-R+\frac{1}{4}\mathrm{Tr}[\nabla\mathcal{X}\mathcal{G}^{-1}\nabla\mathcal{X}^T\mathcal{G}^{-1}]\right\}=\int d^3x|g|^{1/2}\left\{-R+\frac{1}{4}\mathrm{Tr}(J^{\mathcal{X}}J^{\mathcal{X}^T})\right\}, \tag{11}$$

where now $\mathcal{X}=\mathcal{G}+\mathcal{B}$, $\mathcal{G}=\frac{1}{2}(\mathcal{X}+\mathcal{X}^T)$, and $J^{\mathcal{X}}=\nabla\mathcal{X}\mathcal{G}^{-1}$.

There are two physically different effective theories that can be expressed by the action (11), and hence admit a double Ernst formulation. On the one hand, we have the $D=5$ EKR model, where the dilaton field is set to zero as well.[3] On the other hand, we have the $D=4$ bosonic string theory, for which a charged pair of rotating interacting black holes coupled to dilaton and Kalb–Ramond fields was constructed in Ref. 5 and its charged dual string vacua were studied in Ref. 16. Here we will consider again the 5D EKR theory in order to apply the NHT on a neutral family of field configurations that correspond to the double Ernst system.

Thus, we start with the five-dimensional truncated action

$${}^5S=\int d^5x|{}^5G|^{1/2}\left({}^5R-\frac{1}{12}{}^5H^2\right), \tag{12}$$

where ${}^5R$ is the Ricci scalar constructed on the five-dimensional metric ${}^5G_{MN}$ and

$${}^5H_{MNP}=\partial_M{}^5B_{NP}+\text{cycl perms of } M,N,P. \tag{13}$$

It is worth noticing that we are considering a truncation which imposes the following condition on the Kaluza–Klein and Kalb–Ramond vector fields:

$$^5G_{\mu,n+2} = {}^5B_{\mu,n+2} = 0; \tag{14}$$

this implies that the vector fields A_1 and A_2 must vanish identically, and hence, the pseudoscalar fields u and v also vanish [see (5)]. Such a restriction does not provide any constraint on the remaining dynamical variables and can be considered as a consistent nontrivial ansatz for the EKR theory.

After the Kaluza–Klein reduction on T^2 we get the stationary effective action (11) (see, for instance, Refs. 3 and 10) with the matter field spectrum of the theory encoded in the (2×2)-matrices $\mathcal{G}\equiv G$ and $\mathcal{B}\equiv B$ which can be parametrized in the following form:

$$\mathcal{G} = \frac{p_1}{p_2}\begin{pmatrix} 1 & q_2 \\ q_2 & p_2^2+q_2^2 \end{pmatrix}, \quad \mathcal{B} = q_1\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = q_1\sigma_2, \tag{15}$$

where σ_2 is the Pauli matrix. Under such assumptions, the five-dimensional interval reads

$$\mathrm{d}s_5^2 = g_{\mu\nu}\,\mathrm{d}x^\mu\,\mathrm{d}x^\nu + \mathcal{G}_{mn}\,\mathrm{d}x^m\,\mathrm{d}x^n. \tag{16}$$

By substituting (15) into (11) the action of the "matter fields" adopts the form

$$^3S_m = \frac{1}{2}\int d^3x|g|^{1/2}\{p_1^{-2}[(\nabla p_1)^2+(\nabla q_1)^2]+p_2^{-2}[(\nabla p_2)^2+(\nabla q_2)^2]\}, \tag{17}$$

which allows us to introduce two independent Ernst potentials,

$$\epsilon_1 = p_1 + iq_1, \quad \epsilon_2 = p_2 + iq_2. \tag{18}$$

In terms of these field variables, the action of the system can be rewritten as a double Ernst system in the Kähler form,[17]

$$^3S = \int d^3x|g|^{1/2}\{-\,{}^3R + 2(J^{\epsilon_1}J^{\bar{\epsilon_1}} + J^{\epsilon_2}J^{\bar{\epsilon_2}})\}, \tag{19}$$

where $J^{\epsilon_1} = \nabla\epsilon_1(\epsilon_1+\bar{\epsilon_1})^{-1}$ and $J^{\epsilon_2} = \nabla\epsilon_2(\epsilon_2+\bar{\epsilon_2})^{-1}$.

A mathematically equivalent, but physically different 2×2-matrix representation arises from (12) by making use of the discrete symmetry $p_1\leftrightarrow p_2$, $q_1\leftrightarrow q_2$. This fact allows us to define new matrices

$$\mathcal{G}' = \frac{p_2}{p_1}\begin{pmatrix} 1 & q_1 \\ q_1 & p_1^2+q_1^2 \end{pmatrix}, \quad \mathcal{B}' = q_2\sigma_2 \tag{20}$$

and, hence, $\mathcal{X}' = \mathcal{G}' + \mathcal{B}'$ and to write down the action that corresponds to these magnitudes,

$$^3S = \int d^3x|g|^{1/2}\left\{-R + \frac{1}{4}\mathrm{Tr}(J^{\mathcal{X}'}J^{\mathcal{X}'^T})\right\} = \int d^3x|g|^{1/2}\{-R + 2(J^{\epsilon_1'}J^{\bar{\epsilon_1'}} + J^{\epsilon_2'}J^{\bar{\epsilon_2'}})\}, \tag{21}$$

where similarly $J^{\mathcal{X}'} = \nabla\mathcal{X}'\mathcal{G}'^{-1}$, $J^{\epsilon_1'} = \nabla\epsilon_1'(\epsilon_1'+\bar{\epsilon_1'})^{-1}$, $J^{\epsilon_2'} = \nabla\epsilon_2'(\epsilon_2'+\bar{\epsilon_2'})^{-1}$, $\epsilon_1' = p_2 + iq_2$, and $\epsilon_2' = p_1 + iq_1$.

In terms of the MEP the above-mentioned discrete transformation reads

$$\mathcal{X}\leftrightarrow\mathcal{X}'; \tag{22}$$

thus, the matrices $\mathcal{G}'$ and $\mathcal{B}'$ must be interpreted as new Kaluza–Klein and Kalb–Ramond fields, respectively. This symmetry mixes the gravitational and matter degrees of freedom of the theory. It recalls the Bonnor transformation of the EM theory,[18] but in the bosonic string realm. It can be used to generate new solutions starting, for instance, from pure Kaluza–Klein string vacua (see Ref. 16 as well).

IV. APPLYING THE NHT ON THE DOUBLE ERNST SYSTEM

Let us now proceed to apply the NHT on the neutral double Ernst system. This will generate a nonzero electromagnetic potential $\mathcal{A}$ which accounts for nontrivial Abelian U(1) gauge fields. In order to achieve this aim, we must consider the following seed MEP:

$$\mathcal{X}_0 = \begin{pmatrix} \frac{p_1}{p_2} & \frac{p_1q_2 - q_1p_2}{p_2} \\ \frac{p_1q_2 + q_1p_2}{p_2} & \frac{p_1}{p_2}(p_2^2 + q_2^2) \end{pmatrix}, \quad \mathcal{A}_0 = 0. \tag{23}$$

In this case, the charge matrix λ that parametrizes the NHT has the form

$$\lambda = \begin{pmatrix} \lambda_{11} & \lambda_{12} & \cdots & \lambda_{1n} \\ \lambda_{21} & \lambda_{22} & \cdots & \lambda_{2n} \end{pmatrix}, \tag{24}$$

where $n \geqslant 2$ for consistency. Thus after applying the NHT on this double Ernst seed solution, the transformed MEP read

$$\mathcal{X}_{11} = \frac{1}{\Xi}[(4 + \Lambda^2|\epsilon_2|^2)\mathrm{Re}\,\epsilon_1 + 2(\lambda_{1j}^2 + \lambda_{2j}^2|\epsilon_1|^2)\mathrm{Re}\,\epsilon_2 + 4\lambda_{1j}\lambda_{2j}\,\mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1], \tag{25}$$

$$\mathcal{X}_{12} = \frac{1}{\Xi}\{\Gamma_+(\mathrm{Re}\,\epsilon_1\,\mathrm{Im}\,\epsilon_2 - \mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1) + 2\lambda_{1j}\lambda_{2j}[(1 - |\epsilon_1|^2)\mathrm{Re}\,\epsilon_2 - (1 - |\epsilon_2|^2)\mathrm{Re}\,\epsilon_1]\}, \tag{26}$$

$$\mathcal{X}_{21} = \frac{1}{\Xi}\{\Gamma_-(\mathrm{Re}\,\epsilon_1\,\mathrm{Im}\,\epsilon_2 + \mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1) + 2\lambda_{1j}\lambda_{2j}[(1 - |\epsilon_2|^2)\mathrm{Re}\,\epsilon_1 + (1 - |\epsilon_1|^2)\mathrm{Re}\,\epsilon_2]\}, \tag{27}$$

$$\mathcal{X}_{22} = \frac{1}{\Xi}[(\Lambda^2 + 4|\epsilon_2|^2)\mathrm{Re}\,\epsilon_1 + 2(\lambda_{2j}^2 + \lambda_{1j}^2|\epsilon_1|^2)\mathrm{Re}\,\epsilon_2 - 4\lambda_{1j}\lambda_{2j}\,\mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1], \tag{28}$$

$$\mathcal{A}_{1j} = \frac{2}{\Xi}\{[(2 - \lambda_{2j}^2|\epsilon_1|^2)\mathrm{Re}\,\epsilon_2 - (2 - \lambda_{2j}^2|\epsilon_2|^2)\mathrm{Re}\,\epsilon_1 + \lambda_{1j}\lambda_{2j}(\mathrm{Re}\,\epsilon_1\,\mathrm{Im}\,\epsilon_2 - \mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1)]\lambda_{1j} - [(2 + \lambda_{1j}^2)(\mathrm{Re}\,\epsilon_1\,\mathrm{Im}\,\epsilon_2 - \mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1) + \lambda_{1j}\lambda_{2j}(|\epsilon_2|^2\,\mathrm{Re}\,\epsilon_1 - |\epsilon_1|^2\,\mathrm{Re}\,\epsilon_2)]\lambda_{2j}\}, \tag{29}$$

$$\mathcal{A}_{2j} = \frac{-2}{\Xi}\{[(2 + \lambda_{2j}^2)(\mathrm{Re}\,\epsilon_1\,\mathrm{Im}\,\epsilon_2 + \mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1) + \lambda_{1j}\lambda_{2j}(\mathrm{Re}\,\epsilon_1 - |\epsilon_1|^2\,\mathrm{Re}\,\epsilon_2)]\lambda_{1j} - [(\lambda_{1j}^2 - 2|\epsilon_2|^2)\mathrm{Re}\,\epsilon_1 + (2 - \lambda_{1j}^2|\epsilon_1|^2)\mathrm{Re}\,\epsilon_2 + \lambda_{1j}\lambda_{2j}(\mathrm{Re}\,\epsilon_1\,\mathrm{Im}\,\epsilon_2 + \mathrm{Re}\,\epsilon_2\,\mathrm{Im}\,\epsilon_1)]\lambda_{2j}\}, \tag{30}$$

$$\Xi = 2(\lambda_{1j}^2 + \lambda_{2j}^2|\epsilon_2|^2)\mathrm{Re}\,\epsilon_1 + (4 + \Lambda^2|\epsilon_1|^2)\mathrm{Re}\,\epsilon_2 + 4\lambda_{1j}\lambda_{2j}\,\mathrm{Re}\,\epsilon_1\,\mathrm{Im}\,\epsilon_2, \tag{31}$$

where $\Lambda^2 = \lambda_{1j}^2\lambda_{2j}^2 - (\lambda_{1j}\lambda_{2j})^2$, $\Gamma_+ = 4 + 2\lambda_{1j}^2 - 2\lambda_{2j}^2 - \Lambda^2$, $\Gamma_- = 4 - 2\lambda_{1j}^2 + 2\lambda_{2j}^2 - \Lambda^2$, and the nontrivial character of the matrix $\mathcal{A}$ is evident. The fields configurations corresponding to these potentials live now in the 5D EMKR theory since we have recovered the U(1) vector fields of the system.

V. DOUBLE KERR SEED SOLUTION

In this section, following Ref. 3 we impose one more symmetry on the fields of the three-dimensional effective theory under consideration in order to use as seed solution a pair of Kerr black holes. Thus, we can write the line element in the Lewis–Papapetrou form making use of the Weyl coordinates as follows:

$$^{5}ds^2 = \mathcal{G}_{mn}\, dx^m\, dx^n + e^{2\gamma}(d\rho^2 + dz^2) - \rho^2\, d\tau^2, \tag{32}$$

where $\mathcal{G}_{mn}$ and γ are τ-independent. Thus, a solution of our system can be constructed using the solutions of the double vacuum Einstein equations written in the Ernst form in terms of ϵ_k and γ^{ϵ_k} $(k=1,2)$,

$$\nabla(\rho J^{\epsilon_k}) = \rho J^{\epsilon_k}(J^{\epsilon_k} - J^{\overline{\epsilon_k}}),$$

$$\partial_z \gamma^{\epsilon_k} = \rho[(J^{\epsilon_k})_z (J^{\overline{\epsilon_k}})_\rho + (J^{\overline{\epsilon_k}})_z (J^{\epsilon_k})_\rho], \tag{33}$$

$$\partial_\rho \gamma^{\epsilon_k} = \rho[|(J^{\epsilon_k})_\rho|^2 - |(J^{\epsilon_k})_z|^2],$$

if one identifies the function γ that accounts for the general relativistic interaction between the black holes, in the following way: $\gamma \equiv \gamma^{\epsilon_1} + \gamma^{\epsilon_2}$.

For instance, we can take as seed solution a double Kerr system consisting of a pair of rotating interacting black holes. In the framework of general relativity, the Ernst potentials corresponding to two Kerr solutions with sources in different points of the symmetry axis read

$$\epsilon_k = 1 - \frac{2m_k}{r_k + i\alpha_k \cos\theta_k}, \tag{34}$$

where m_k and α_k are constant parameters which define the masses and rotations of the sources of the Kerr field configurations. Weyl and Boyer–Lindquist coordinates are related through

$$\rho = [(r_k - m_k)^2 - \zeta_k^2]^{1/2} \sin\theta_k, \quad z = z_k + (r_k - m_k)\cos\theta_k, \tag{35}$$

where the sources are located at z_k and $\zeta_k^2 = m_k^2 - a_k^2$. Thus, for the function γ_k we have

$$e^{2\gamma_k} = \frac{P_k}{Q_k}, \tag{36}$$

where $P_k = \Delta_k - \alpha_k^2 \sin^2\theta_k$, $Q_k = \Delta_k + \zeta_k^2 \sin^2\theta_k$, and $\Delta_k = r_k^2 - 2m_k r_k + \alpha_k^2$.

We would like to make a remark at this point. When parametrizing the 5D interval (32) in the Lewis–Papapetrou form, one could choose a completely spatial (Euclidean) three-dimensional interval and require that the signature of the matrix $\mathcal{G}$ to be negative definite, i.e., $\mathcal{G}|_\infty = -I_2$ (the same signature holds for the matrix $\mathcal{X}|_\infty$). Thus, the five-dimensional metric would possess a signature with two timelike coordinates. Such kind of models have been studied in Ref. 19 and represent another line of investigation within this approach. It is clear that in order to fulfill this condition either ϵ_1 or ϵ_2 must adopt the asymptotic value -1, since when both potentials have the same asymptotic behavior (with the same sign) the signature of the matrix $\mathcal{G}$ is positive definite.

Thus, in the language of the complex Ernst potentials the field configuration adopt the form

$$ds_5^2 = e^{2\gamma}(d\rho^2 + dz^2) - \rho^2\, d\tau^2 + \frac{\epsilon_1 + \overline{\epsilon_1}}{\epsilon_2 + \overline{\epsilon_2}} |du + i\overline{\epsilon_2}\, dv|^2, \tag{37}$$

$$\mathcal{B} = \frac{\epsilon_1 - \overline{\epsilon_1}}{2i}\sigma_2, \tag{38}$$

where $u = x^4$, $v = x^5$, and $\gamma = \gamma^{\epsilon_1} + \gamma^{\epsilon_2}$ as it was pointed out above.

In the case when the Ernst potentials correspond to two interacting Kerr black holes, the symmetric matrix $\mathcal{G}$ is determined by the follow

$$\mathcal{G}_{uu}=\frac{(r_1^2-2m_1r_1+\alpha_1^2\cos^2\theta_1)(r_2^2+\alpha_2^2\cos^2\theta_2)}{(r_2^2-2m_2r_2+\alpha_2^2\cos^2\theta_2)(r_1^2+\alpha_1^2\cos^2\theta_1)},$$

$$\mathcal{G}_{uv}=\frac{2m_2\alpha_2\cos\theta_2(r_1^2-2m_1r_1+\alpha_1^2\cos^2\theta_1)}{(r_2^2-2m_2r_2+\alpha_2^2\cos^2\theta_2)(r_1^2+\alpha_1^2\cos^2\theta_1)}, \tag{39}$$

$$\mathcal{G}_{vv}=\frac{(r_1^2-2m_1r_1+\alpha_1^2\cos^2\theta_1)(r_2^2-4m_2r_2+4m_2^2+\alpha_2^2\cos^2\theta_2)}{(r_2^2-2m_2r_2+\alpha_2^2\cos^2\theta_2)(r_1^2+\alpha_1^2\cos^2\theta_1)},$$

ing relations:the factor $e^{2\gamma}$ reads

$$e^{2\gamma}=\frac{(r_1^2-2m_1r_1+\alpha_1^2\cos^2\theta_1)(r_2^2-2m_2r_2+\alpha_2^2\cos^2\theta_2)}{(r_1^2-2m_1r_1+\alpha_1^2\cos^2\theta_1+m_1^2\sin^2\theta_2)(r_2^2-2m_2r_2+\alpha_2^2\cos^2\theta_2+m_2^2\sin^2\theta_2)}, \tag{40}$$

and the Kalb–Ramond matrix $\mathcal{B}$ is defined as

$$\mathcal{B}=\frac{2m_1\alpha_1\cos\theta_1}{r_1^2+\alpha_1^2\cos^2\theta_1}\sigma_2 \tag{41}$$

and can be interpreted as a matrix Kalb–Ramond dipole configuration with momentum $m_1\alpha_1$ located at z_1 and hidden inside the horizon $r_1=m_1+\sqrt{m_1^2-\alpha_1^2}$ of the metric (37). Simultaneously, the $\mathcal{G}_{uv}$ metric component also constitutes a dipole configuration but possesses momentum $m_2\alpha_2$ and is located at z_2, hidden inside the horizon $r_2=m_2+\sqrt{m_2^2-\alpha_2^2}$.

VI. CHARGED FIELD CONFIGURATIONS IN 5D EMKR THEORY

After applying the NHT on the double Ernst seed solution we get the following field configurations:

$$\mathcal{G}_{uu}=\mathcal{X}_{11}-\tfrac{1}{2}\mathcal{A}_{1j}^2,\quad \mathcal{G}_{uv}=\tfrac{1}{2}(\mathcal{X}_{12}+\mathcal{X}_{21}-\mathcal{A}_{1j}\mathcal{A}_{2j}),\quad \mathcal{G}_{vv}=\mathcal{X}_{22}-\tfrac{1}{2}\mathcal{A}_{2j}^2, \tag{42}$$

$$\mathcal{B}=\tfrac{1}{2}(\mathcal{X}_{21}-\mathcal{X}_{12})\sigma_2,\quad \mathcal{A}\equiv A=\begin{pmatrix}\mathcal{A}_{1j}\\ \mathcal{A}_{2j}\end{pmatrix}, \tag{43}$$

where the appearance of the electromagnetic potential is obvious. By substituting the Ernst potentials ϵ_k by the corresponding double Kerr black hole system we obtain the following charged field configuration:

$$\mathcal{G}_{uu}=\frac{DQ\Delta_1\Delta_2+4m_1(L^2r_1+2m_1\lambda_{2j}^2+2\lambda_{1j}\lambda_{2j}\alpha_1\cos\theta_1)\Delta_2+2m_2[(4-\Lambda^2)r_2+2\Lambda^2m_2]\Delta_1}{DQ\Delta_1\Delta_2+4m_2(L^2r_2+2m_2\lambda_{2j}^2+2\lambda_{1j}\lambda_{2j}\alpha_2\cos\theta_2)\Delta_1+2m_1[(4-\Lambda^2)r_1+2\Lambda^2m_1]\Delta_2}$$
$$-\frac{8(h_1\lambda_{1j}-h_2\lambda_{2j})^2+2\Lambda^2(h_2\lambda_{1j}-h_3\lambda_{2j})^2-8\Lambda^2(h_1h_3-h_2^2)}{[DQ\Delta_1\Delta_2+4m_2(L^2r_2+2m_2\lambda_{2j}^2+2\lambda_{1j}\lambda_{2j}\alpha_2\cos\theta_2)\Delta_1+2m_1[(4-\Lambda^2)r_1+2\Lambda^2m_1]\Delta_2]^2}, \tag{44}$$

$$\mathcal{G}_{uv}=\frac{4m_1[2\lambda_{1j}\lambda_{2j}(r_1-m_1)-L^2\alpha_1\cos\theta_1]\Delta_2+2(4-\Lambda^2)m_2\alpha_2\cos\theta_2\Delta_1}{DQ\Delta_1\Delta_2+4m_2(L^2r_2+2m_2\lambda_{2j}^2+2\lambda_{1j}\lambda_{2j}\alpha_2\cos\theta_2)\Delta_1+2m_1[(4-\Lambda^2)r_1+2\Lambda^2m_1]\Delta_2}$$

$$\mathcal{A}_{2j} = \frac{-2[(2+\lambda_{2i}^2)h_4 + \lambda_{1i}\lambda_{2i}h_5]\lambda_{1j} + 2[\lambda_{1i}^2 h_5 + \lambda_{1i}\lambda_{2i}h_4 + 2h_6]\lambda_{2j}}{DQ\Delta_1\Delta_2 + 4m_2(L^2 r_2 + 2m_2\lambda_{2j}^2 + 2\lambda_{1j}\lambda_{2j}\alpha_2\cos\theta_2)\Delta_1 + 2m_1[(4-\Lambda^2)r_1 + 2\Lambda^2 m_1]\Delta_2}, \tag{49}$$

where

$$h_1 = 2(m_1 r_1\Delta_2 - m_2 r_2\Delta_1), \quad h_2 = 2(m_2\alpha_2\cos\theta_2\Delta_1 - m_1\alpha_1\cos\theta_1\Delta_2),$$

$$h_3 = 4(m_1^2\Delta_2 - m_2^2\Delta_1) - h_1, \quad h_4 = 2(m_1\alpha_1\cos\theta_1\Delta_2 + m_2\alpha_2\cos\theta_2\Delta_1),$$

$$h_5 = 2[m_1(r_1 - 2m_1)\Delta_2 + m_2 r_2\Delta_1], \quad h_6 = 2[m_1 r_1\Delta_2 + m_2(r_2 - 2m_2)\Delta_1], \tag{50}$$

$L^2 = \lambda_{1j}^2 - \lambda_{2j}^2$, $l_k^2 = 2\lambda_{kj}^2 + \Lambda^2$, $\Delta_k = r_k^2 - 2m_k r_k + \alpha_k^2\cos^2\theta_k$ $(k=1,2)$ and, finally, $DQ = 4 + 2\lambda_{1j}^2 + 2\lambda_{2j}^2 + \Lambda^2$.

A consistency checking of the generated solution consists of setting the parameters λ_{1j} and λ_{2j} to zero in order to recover the starting field configuration (39)–(41). It is straightforward to verify that this is indeed the case.

The asymptotical behavior of the generated three-dimensional field configurations read

$$\mathcal{G}_{uu}|_\infty \sim 1 - \frac{2\Gamma_-(m_1 - m_2)}{DQr} + \frac{8\lambda_{1j}\lambda_{2j}(m_1\alpha_1\cos\theta_1 - m_2\alpha_2\cos\theta_2)}{DQr^2} + \mathcal{O}(r^{-2}), \tag{51}$$

$$\mathcal{G}_{uv}|_\infty \sim \frac{8\lambda_{1j}\lambda_{2j}m_1}{DQr} - \frac{4L^2 m_1\alpha_1\cos\theta_1 - 2(4-\Lambda^2)m_2\alpha_2\cos\theta_2}{DQr^2} + \mathcal{O}(r^{-2}), \tag{52}$$

$$\mathcal{G}_{vv}|_\infty \sim 1 - \frac{2\Lambda_+(m_1 + m_2)}{DQr} - \frac{8\lambda_{1j}\lambda_{2j}(m_1\alpha_1\cos\theta_1 + m_2\alpha_2\cos\theta_2)}{DQr^2} + \mathcal{O}(r^{-2}), \tag{53}$$

$$\mathcal{B}_{uv}|_\infty \sim \frac{8\lambda_{1j}\lambda_{2j}m_2}{DQr} + \frac{2(4-\Lambda^2)m_1\alpha_1\cos\theta_1 - 4L^2 m_2\alpha_2\cos\theta_2}{DQr^2} + \mathcal{O}(r^{-2}), \tag{54}$$

$$\mathcal{A}_{1j}|_{\infty} \sim \frac{4[(2+\lambda_{2i}^2)\lambda_{1j}-\lambda_{1i}\lambda_{2i}\lambda_{2j}](m_1-m_2)}{DQr} - \frac{4[\lambda_{1i}\lambda_{2i}\lambda_{1j}-(2+\lambda_{1i}^2)\lambda_{2j}](m_1\alpha_1\cos\theta_1-m_2\alpha_2\cos\theta_2)}{DQr^2}+\mathcal{O}(r^{-2}), \tag{55}$$

$$\mathcal{A}_{2j}|_{\infty} \sim \frac{-4[\lambda_{1i}\lambda_{2i}\lambda_{1j}-(2+\lambda_{1i}^2)\lambda_{2j}](m_1+m_2)}{DQr} + \frac{4[(2+\lambda_{2i}^2)\lambda_{1j}-\lambda_{1i}\lambda_{2i}\lambda_{2j}](m_1\alpha_1\cos\theta_1+m_2\alpha_2\cos\theta_2)}{DQr^2}+\mathcal{O}(r^{-2}). \tag{56}$$

From this analysis it is clear that under the NHT, all the generated fields (gravitational, Kalb–Ramond, and electromagnetic) effectively develop both Coulomb and dipole terms. Thus, from one side, the $\mathcal{G}_{uu}$ component of the constructed metric possesses mass terms defined by $M_{uu_1}=\Gamma_- m_1/DQ$ at z_1 and $M_{uu_2}=\Gamma_- m_2/DQ$ at z_2, and from the other side, it acquires dipole sources with masses $\tilde{M}_{uu_1}=8\lambda_{1j}\lambda_{2j}m_1/DQ$, $\tilde{M}_{uu_2}=-8\lambda_{1j}\lambda_{2j}m_2/DQ$, and their corresponding momenta $\tilde{M}_{uu_1}\alpha_1$, $\tilde{M}_{uu_2}\alpha_2$, located at z_1 and z_2, respectively. In a similar way the $\mathcal{G}_{vv}$ component of the metric has masses $M_{vv_1}=\Gamma_+ m_1/DQ$ at z_1 and $M_{vv_2}=\Gamma_+ m_2/DQ$ at z_2; indeed, it possesses as well the massive dipole terms defined by $\tilde{M}_{vv_1}=-8\lambda_{1j}\lambda_{2j}m_1/DQ$ at z_1 and $\tilde{M}_{uu_2}=-8\lambda_{1j}\lambda_{2j}m_2/DQ$ at z_2 with the momenta $\tilde{M}_{vv_1}\alpha_1$ and $\tilde{M}_{vv_2}\alpha_2$, respectively.

The transformed Kalb–Ramond tensor field also acquires a Coulomb term determined by the charge $M_B=8\lambda_{1j}\lambda_{2j}m_2/DQ$ located at z_2 and now possesses two dipole sources with masses $M_{B_1}=(4-\Lambda^2)m_1/DQ$, $M_{B_2}=-4L^2m_2/DQ$ and momenta $M_{B_1}\alpha_1$, $M_{B_2}\alpha_2$, located at z_1 and z_2, respectively. The same situation exactly takes place for the $\mathcal{G}_{uv}$ component of the metric, which usually corresponds to the rotation of the gravitational field. Thus, the generated gravitational potential $\mathcal{G}_{uv}$ has a Coulomb source with mass $M_{uv}=8\lambda_{1j}\lambda_{2j}m_1/DQ$ located at z_1 and dipole sources with masses $\tilde{M}_{uv_1}=-2L^2m_1/DQ$, $\tilde{M}_{uv_2}=(4-\Lambda^2)m_2/DQ$ and momenta $\tilde{M}_{uv_1}\alpha_1$, $\tilde{M}_{uv_2}\alpha_2$, located at z_1 and z_2, respectively.

At this point we would like to point out that the discrete symmetry (22) which relates gravitational and Kalb–Ramond degrees of freedom is still present asymptotically and is quite evident in the language of the masses and charges of the components $\mathcal{G}_{uv}$ and $\mathcal{B}_{uv}$, since one can clearly see that these components transform into each other under the interchange of the respective masses and charges, even after the implementation of the nonlinear NHT.

Finally, the generated field configuration possesses an evidently nontrivial electromagnetic sector and its asymptotic structure reveals its usual Coulomb form, defining in this way the effective electromagnetic charges of the system. These fields also have effective dipole sources. Thus, the electromagnetic fields $\mathcal{A}_{1j}$ possess momenta defined by the expressions $4[\lambda_{1i}\lambda_{2i}\lambda_{1j}-(2+\lambda_{1i}^2)\lambda_{2j}]m_1\alpha_1/DQ$ and $-4[\lambda_{1i}\lambda_{2i}\lambda_{1j}-(2+\lambda_{1i}^2)\lambda_{2j}]m_2\alpha_2/DQ$, whereas the respective momenta for the electromagnetic fields $\mathcal{A}_{2j}$ read $4[(2+\lambda_{2i}^2)\lambda_{1j}-\lambda_{1i}\lambda_{2i}\lambda_{2j}]m_1\alpha_1/DQ$ and $4[(2+\lambda_{2i}^2)\lambda_{1j}-\lambda_{1i}\lambda_{2i}\lambda_{2j}]m_2\alpha_2/DQ$.

Thus, under the NHT, the double Kerr seed solution does not acquire just the electromagnetic charges, but it develops as well effective Coulomb and dipole terms for all the fields of the field configuration, gravitational, Kalb–Ramond, and electromagnetic fields.

VII. CONCLUSION AND DISCUSSION

In this paper we have obtained a charged field configuration of the five-dimensional EMKR theory starting from a neutral one that corresponds to a double Ernst (double Kerr, in particular) system. The generation of the new charged solution was carried out via a matrix Lie–Bäcklund transformation of Harrison type that preserves the asymptotical values of the seed fields.

An interesting feature of the generated exact solution is that all the fields of the field configuration develop effective Coulomb and dipole terms asymptotically. Thus, after applying the NHT, the 5D double Kerr seed solution acquires effective Coulomb terms and dipole sources with momenta. This is in contrast with the effect that the NHT produces on a neutral seed solution in the framework of the general theory of relativity where it just endows the initial field configuration with a set of electromagnetic charges.

The statistical analysis of such a configuration is an appealing direction to conduct the present research. The equilibrium properties of the generated solution is of interest as well and would generalize to the 5D case some previous results obtained in the framework of the four-dimensional general relativity.[2,20,21] These issues are under current investigation.

ACKNOWLEDGMENTS

One of the authors (A.H.A.) is really grateful to the Theoretical Physics Department of the Aristotle University of Thessaloniki and, especially, to Professor J.E. Paschalis for useful discussions and for providing a stimulating atmosphere while part of this work was being done. A.H.A. is also grateful to S. Kousidou for her support while this research was in progress and acknowledges a grant for postdoctoral studies provided by the Greek Government. Both authors thank IMATE–UNAM campus Morelia and CINVESTAV–IPN for library facilities provided during this investigation. The work of one of the authors (R.B.) was supported by Grant No. CIC-UMSNH-4.11, while the research by A.H.A. was supported by Grants Nos. CONACYT-J34245-E, CONACYT-42064-F, and CIC-UMSNH-4.16.

(Received 22 April 2004; accepted 20 December 2004; published online 6 April 2005)

We discuss commuting flows and conservation laws for Lax hierarchies on noncommutative spaces in the framework of the Sato theory. On commutative spaces, the Sato theory has revealed essential aspects of the integrability for wide class of soliton equations which are derived from the Lax hierarchies in terms of pseudo-differential operators. Noncommutative extension of the Sato theory has been already studied by the author and Toda, and the existence of various noncommutative Lax hierarchies are guaranteed. In this paper, we present conservation laws for the noncommutative Lax hierarchies with both space–space and space–time noncommutativities and prove the existence of infinite number of conserved densities. We also give the explicit representations of them in terms of Lax operators. Our results include noncommutative versions of KP, KdV, Boussinesq, coupled KdV, Sawada-Kotera, modified KdV equation and so on. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1865321]

I. INTRODUCTION

Noncommutative (NC) extension of field theories has been studied intensively for the last several years.[1] NC gauge theories are equivalent to ordinary gauge theories in the presence of background magnetic fields and succeeded in revealing various aspects of them.[2] NC solitons especially play important roles in the study of D-brane dynamics, such as the confirmation of Sen's conjecture on tachyon condensation.[3] One of the distinguished features of NC theories is resolution of singularities. This gives rise to various new physical objects such as U(1) instantons and makes it possible to analyze singular configurations as usual.

NC extension of integrable equations such as the Korteweg–de Vries (KdV) equation[4] is also one of the hot topics.[5–37] These equations imply no gauge field and NC extension of them perhaps might have no physical picture or no good property on integrabilities. To make matters worse, the NC extension of $(1+1)$-dimensional equations introduces infinite number of time derivatives, which makes it hard to discuss or define the integrability. However, some of them actually possess integrable properties, such as the existence of infinite number of conserved quantities[7–9,20] and the linearizability[30,31] which are widely accepted as definition of complete integrability of equations. Furthermore, a few of them can be derived from NC (anti-)self-dual Yang–Mills (YM) equations by suitable reductions.[14,30,33] This fact may give some physical meanings and good properties to the lower-dimensional NC field equations and makes us expect that the Ward conjecture[38] still holds on NC spaces.[27] So far, however, those equations have been examined one by one. Now it is very natural to discuss their integrabilities in more general framework.

The author and Toda have studied systematic NC extension of integrable systems.[27,30,36] In the previous paper,[36] we have obtained wide class of NC Lax hierarchies which include various NC versions of soliton equations in the framework of the Sato theory.[39] On commutative spaces, the Sato theory is known to be one of the most beautiful theories of solitons and reveals essential

a)Electronic mail: hamanaka@math.nagoya-u.ac.jp

aspects of the integrability, such as, the construction of exact multisoliton solutions, the structure of the solution space, the existence of infinite conserved quantities, and the hidden symmetry of them. In the Sato theory, the soliton equations are described by Lax hierarchies in terms of pseudodifferential operators.

In the present paper, we prove the existence of infinite conserved quantities for Lax hierarchies on NC spaces in the framework of the Sato theory. We show the conservation laws for them and give the explicit representations with both space–space and space–time noncommutativities. This suggests that the NC soliton equations are also completely integrable and infinite-dimensional symmetries would be hidden. Our results include wide class of NC soliton equations, such as, NC versions of Kadomtsev–Petviashvili (KP),[40] KdV, Boussinesq,[41] coupled KdV,[42] Sawada–Kotera,[43] modified KdV (mKdV) equations and so on.

II. COMMENTS ON NONCOMMUTATIVE FIELD THEORIES

NC spaces are defined by noncommutativity of the coordinates,

$$[x^i,x^j]=i\theta^{ij}, \tag{2.1}$$

where θ^{ij} are real constants and called the *NC parameters*.

NC field theories are obtained from given commutative field theories by exchange of ordinary products in the commutative field theories for *star-products*. The star-product is defined for ordinary fields on commutative spaces. On Euclidean spaces, it is explicitly given by

$$f(x)\star g(x):=f(x)\exp\left(\frac{i}{2}\overleftarrow{\partial}_i\theta^{ij}\overrightarrow{\partial}_j\right)g(x)=f(x)g(x)+\frac{i}{2}\theta^{ij}\partial_i f(x)\partial_j g(x)+\mathcal{O}(\theta^2), \tag{2.2}$$

where $\partial_i:=\partial/\partial x^i$. This explicit representation is known as the *Moyal product*.[44]

The star-product possesses associativity, $f\star(g\star h)=(f\star g)\star h$, and returns back to the ordinary product in the commutative limit, $\theta^{ij}\to 0$. The modification of the product makes the ordinary spatial coordinates "noncommutative," that is, $[x^i,x^j]_\star:=x^i\star x^j-x^j\star x^i=i\theta^{ij}$.

We note that the fields themselves take c-numbers values and the differentiation and the integration for them are well-defined as usual. NC field theories should be interpreted as deformed theories from commutative ones. One of the nontrivial points in the NC extension is the order of nonlinear terms. The difference between commutative equations and the NC equations arises as commutators of fields which sometimes become serious obstructions.

Here we point out a special property of the NC commutators of fields. It is convenient to introduce the following symbol:

$$P:=\tfrac{1}{2}\overleftarrow{\partial}_i\theta^{ij}\overrightarrow{\partial}_j, \tag{2.3}$$

and the *Strachan product*[45]

$$f(x)\ \diamondsuit\ g(x):=f(x)\left(\sum_{s=0}^{\infty}\frac{(-1)^s}{(2s+1)!}P^{2s}\right)g(x). \tag{2.4}$$

A commutator of fields is straightforwardly calculated as follows:

$$\begin{aligned}[f(x),g(x)]_\star &= f(x)(e^{iP}-e^{-iP})g(x)=:2if(x)(\sin P)g(x)\\ &=-\theta^{ij}\partial_i f(x)\ \diamondsuit\ \partial_j g(x)=-\theta^{ij}\partial_i(f(x)\ \diamondsuit\ \partial_j g(x)).\end{aligned} \tag{2.5}$$

In the second line, we use the fact that $\sin P$ is the composite of P and "$P^{-1}\sin P$" and the Strachan product "$\diamondsuit$" corresponds to the latter. This derivation was first presented by Dimakis and Müller-Hoissen in order to generate infinite number of conserved densities of the NC nonlinear Schrödinger (NLS) equation,[7] the NC KdV equation,[8] and the NC extended matrix-NLS equation.[9] Here more widely, we would like to stress that *commutators of fields on NC spaces*

always appear as total derivatives in the NC directions. This will be crucial in the derivation of conservation laws in Sec. V.

As a consequence, we can prove

$$\int \mathrm{d}^D x\, f(x) \star g(x) = \int d^D x\, f(x) g(x), \tag{2.6}$$

where the integration is taken in all NC directions.

III. NONCOMMUTATIVE LAX HIERARCHIES IN SATO'S FRAMEWORK

In this section, we derive various NC Lax equations in terms of pseudodifferential operators which include negative powers of differential operators. We note that the present discussion in this section can be applied to more general cases where the products are not necessarily the star-products but noncommutative associative products with differentiations, which has already been discussed in, e.g., Ref. 46. However, we believe that some explicit examples here are new equations and would be useful for further studies.

An Nth order (monic) pseudodifferential operator A is represented as follows:

$$A = \partial_x^N + a_{N-1}\partial_x^{N-1} + \cdots + a_0 + a_{-1}\partial_x^{-1} + a_{-2}\partial_x^{-2} + \cdots . \tag{3.1}$$

Here we introduce useful symbols,

$$A_{\geqslant r} := \partial_x^N + a_{N-1}\partial_x^{N-1} + \cdots + a_r \partial_x^r, \tag{3.2}$$

$$A_{\leqslant r} := A - A_{\geqslant r+1} = a_r \partial_x^r + a_{r-1}\partial_x^{r-1} + \cdots , \tag{3.3}$$

$$\mathrm{res}_r A := a_r. \tag{3.4}$$

The symbol $\mathrm{res}_{-1} A$ is especially called the *residue* of A.

The action of a differential operator ∂_x^n on a multiplicity operator f is formally defined as the following generalized Leibniz rule:

$$\partial_x^n \cdot f := \sum_{i \geqslant 0} \binom{n}{i} (\partial_x^i f) \partial^{n-i}, \tag{3.5}$$

where the binomial coefficient is given by

$$\binom{n}{i} := \frac{n(n-1)\cdots(n-i+1)}{i(i-1)\cdots 1}. \tag{3.6}$$

We note that the definition of the binomial coefficient (3.6) is applicable to the case for negative n, which just defines the action of negative power of differential operators. The examples are

$$\begin{aligned} \partial_x^{-1} \cdot f &= f\partial_x^{-1} - f'\partial_x^{-2} + f''\partial_x^{-3} - \cdots , \\ \partial_x^{-2} \cdot f &= f\partial_x^{-2} - 2f'\partial_x^{-3} + 3f''\partial_x^{-4} - \cdots , \\ \partial_x^{-3} \cdot f &= f\partial_x^{-3} - 3f'\partial_x^{-4} + 6f''\partial_x^{-5} - \cdots , \end{aligned} \tag{3.7}$$

where $f' := \partial f/\partial x$, $f'' := \partial^2 f/\partial x^2$ and so on, and ∂_x^{-1} in the RHS acts as an integration operator $\int^x \mathrm{d}x$.

The composition of pseudodifferential operators is also well-defined and the total set of pseudodifferential operators forms an operator algebra. For more on pseudodifferential operators and the Sato theory, see, e.g., Refs. 47–49.

Let us introduce a Lax operator as the following first-order pseudodifferential operator:

$$L = \partial_x + u_1 + u_2\partial_x^{-1} + u_3\partial_x^{-2} + u_4\partial_x^{-3} + \cdots, \tag{3.8}$$

where the coefficients $u_k(k=1,2,\ldots)$ are functions of infinite variables $(x^1,x^2,\ldots)$ with $x^1 \equiv x$,

$$u_k = u_k(x^1,x^2,\ldots). \tag{3.9}$$

The noncommutativity is arbitrarily introduced for the variables $(x^1,x^2,\ldots)$ as Eq. (2.1) here.

The Lax hierarchy is defined in Sato's framework as

$$\partial_m L = [B_m, L]_\star, \quad m = 1,2,\ldots, \tag{3.10}$$

where the action of ∂_m on the pseudodifferential operator L should be interpreted to be coefficient-wise, that is, $\partial_m L := [\partial_m, L]$ or $\partial_m \partial_x^k = 0$. The operator B_m is given by

$$B_m := \underbrace{(L\star\cdots\star L)}_{m \text{ times}}{}_{\geqslant r} =: (L^m)_{\geqslant r}, \tag{3.11}$$

where r is 0 for $u_1=0$ and 1 for $u_1 \neq 0$ as commutative cases.[50,51] The Lax hierarchy gives rise to a set of infinite differential equations with respect to infinite kinds of fields from the coefficients in Eq. (3.10) for a fixed m. Hence it contains huge amount of differential (evolution) equations for all m. The left-hand side (LHS) of Eq. (3.10) becomes $\partial_m u_k$ which shows a flow in the x^m direction.

If we set the constraint $L^l = B_l$ on the Lax hierarchy (3.10), we get an infinite set of NC (reduced) Lax hierarchies. We can easily show

$$\frac{\partial u_k}{\partial x^{Nl}} = 0, \tag{3.12}$$

for all N, k because

$$\frac{\mathrm{d}L^l}{\mathrm{d}x^{Nl}} = [B_{Nl}, L^l]_\star = [(L^l)^N, L^l]_\star = 0, \tag{3.13}$$

which implies Eq. (3.12). The reduced NC hierarchy is called the *l-reduction* of the NC KP hierarchy. This time, the constraint $L^l = B_l$ gives simple relationships which make it possible to represent infinite kind of fields $u_{l-r+1}, u_{l-r+2}, u_{l-r+3}, \ldots$ in terms of $(l-1)$ kind of fields $u_{2-r}, u_{3-r}, \ldots, u_{l-r}$ (cf. Appendix).

From now on, let us see that those equations in the Lax hierarchy contain various soliton equations with some constraints. We discuss it separately in the following two cases: $u_1=0 (r=0)$ case and $u_1 \neq 0 (r=1)$ case. Some of them are already discussed in Ref. 36. For commutative discussions, see also Ref. 52.

For $u_1 = 0$ $(r=0)$: In this case, the Lax hierarchy (3.10) is just the NC KP hierarchy which includes the NC KP equation.[16,46] Let us see it explicitly.

(i) NC KP hierarchy. The coefficients of each powers of (pseudo) differential operators in the Lax hierarchy (3.10) yield a series of infinite NC "evolution equations," that is, for $m=1$,

$$\partial_x^{1-k} \quad \partial_1 u_k = u_k', \quad k = 2,3,\ldots \Rightarrow x^1 \equiv x, \tag{3.14}$$

for $m=2$,

$$\begin{aligned} &\partial_x^{-1} \quad \partial_2 u_2 = u_2'' + 2u_3', \\ &\partial_x^{-2} \quad \partial_2 u_3 = u_3'' + 2u_4' + 2u_2 \star u_2' + 2[u_2, u_3]_\star, \\ &\partial_x^{-3} \quad \partial_2 u_4 = u_4'' + 2u_5' + 4u_3 \star u_2' - 2u_2 \star u_2'' + 2[u_2, u_4]_\star, \end{aligned} \tag{3.15}$$

$$\partial_x^{-4} \quad \partial_2 u_5 = \cdots,$$

and for $m=3$,

$$\partial_x^{-1} \quad \partial_3 u_2 = u_2''' + 3u_3'' + 3u_4' + 3u_2' \star u_2 + 3u_2 \star u_2',$$

$$\partial_x^{-2} \quad \partial_3 u_3 = u_3''' + 3u_4'' + 3u_5' + 6u_2 \star u_3' + 3u_2' \star u_3 + 3u_3 \star u_2' + 3[u_2, u_4]_\star,$$

$$\partial_x^{-3} \quad \partial_3 u_4 = u_4''' + 3u_5'' + 3u_6' + 3u_2' \star u_4 + 3u_2 \star u_4' + 6u_4 \star u_2' - 3u_2 \star u_3'' - 3u_3 \star u_2'' + 6u_3 \star u_3' + 3[u_2, u_5]_\star + 3[u_3, u_4]_\star,$$

$$\partial_x^{-4} \quad \partial_3 u_5 = \cdots. \tag{3.16}$$

These just imply the $(2+1)$-dimensional NC KP equation[16,46] with $2u_2 \equiv u, x^2 \equiv y, x^3 \equiv t$,

$$\frac{\partial u}{\partial t} = \frac{1}{4}\frac{\partial^3 u}{\partial x^3} + \frac{3}{4}\frac{\partial (u \star u)}{\partial x} + \frac{3}{4}\int^x dx' \frac{\partial^2 u(x')}{\partial y^2} - \frac{3}{4}\left[u, \int^x dx' \frac{\partial u(x')}{\partial y} \right]_\star. \tag{3.17}$$

The important point is that infinite kinds of fields $u_3, u_4, u_5, \ldots$ are represented in terms of one kind of field $2u_2 \equiv u$ as is seen in Eq. (3.15). This guarantees the existence of the NC KP hierarchy which implies the existence of reductions of the NC KP hierarchy. The order of nonlinear terms are determined in this way.

(ii) NC KdV hierarchy (2-reduction of the NC KP hierarchy). Taking the constraint $L^2 = B_2 =: \partial_x^2 + u$ for the NC KP hierarchy, we get the NC KdV hierarchy. This time, the following NC Lax hierarchy,

$$\frac{\partial u}{\partial x^m} = [B_m, L^2]_\star, \tag{3.18}$$

include neither positive nor negative power of (pseudo) differential operators for the same reason as the commutative case (see, e.g., Ref. 53) and gives rise to the mth KdV equation for each m. For example, the NC KdV hierarchy (3.18) becomes the $(1+1)$-dimensional NC KdV equation[8] for $m=3$ with $x^3 \equiv t$,

$$\dot{u} = \tfrac{1}{4} u''' + \tfrac{3}{4}(u \star u)', \tag{3.19}$$

and the $(1+1)$-dimensional fifth NC KdV equation[23] for $m=5$ with $x^5 \equiv t$,

$$\dot{u} = \tfrac{1}{16} u'''''' + \tfrac{5}{16}(u \star u'''' + u'''' \star u) + \tfrac{5}{8}(u' \star u' + u \star u \star u)', \tag{3.20}$$

where $\dot{u} =: \partial u / \partial t$.

(iii) NC Boussinesq hierarchy (3-reduction of the NC KP hierarchy). The 3-reduction $L^3 = B_3$ yields the NC Boussinesq hierarchy which includes the $(1+1)$-dimensional NC Boussinesq equation[23] with $t \equiv x^2$,

$$\ddot{u} = \tfrac{1}{3} u'''' + (u \star u)'' + ([u, \partial_x^{-1} \dot{u}]_\star)', \tag{3.21}$$

where $\ddot{u} =: \partial^2 u / \partial t^2$ and $\partial_x^{-1} = \int^x dx$.

(iv) NC coupled KdV hierarchy (4-reduction of the NC KP hierarchy). The hierarchy includes the $(1+1)$-dimensional NC coupled KdV equation $t \equiv x^3$,

$$\dot{u} = \tfrac{1}{4} u''' + \tfrac{3}{4}(u \star u)' + \tfrac{3}{4}(\omega - \phi^2)' - \tfrac{3}{4}[u, \phi']_\star, \tag{3.22}$$

and the other two equations with respect to three kinds of fields u, ω, and ϕ, which are determined by Eqs. (3.15) and (3.16). The x^2-dependence of the fields is absorbed by the fields ω, ϕ. In this way, we can generate infinite set of the l-reduced NC hierarchies. If we take other set-up, we can get many other hierarchies.

(v) NC Sawada–Kotera hierarchy (3-reduction of the NC BKP hierarchy). The NC version of BKP hierarchy[54] is obtained from the NC KP hierarchy by the constraint that the constant terms of B_m for $m=1,3,5,\ldots$ should vanish. The 3-reduction of the NC BKP hierarchy includes the $(1+1)$-dimensional NC Sawada–Kotera equation with $t\equiv x^5$, $u\equiv 3u_2$,

$$\dot{u}+\tfrac{1}{9}u''''+\tfrac{5}{9}u'''\star u+\tfrac{5}{9}u''\star u'+\tfrac{5}{9}u\star u'\star u=0, \tag{3.23}$$

which is new.

For $u_1\neq 0(r=1)$: On commutative spaces, this situation generates modified KP (mKP) hierarchy and its reductions. On NC spaces, however, the existence of them is not always guaranteed. For the NC KP hierarchy, infinite kinds of fields are described by one kind of x^2-flow equations (3.15). However, this time the flow equation becomes

$$\begin{aligned}
&\partial_x^0 \quad \partial_2 u_1 = u_1''+2u_2'+2u_1\star u_1'+2[u_1,u_2]_\star,\\
&\partial_x^{-1} \quad \partial_2 u_2 = u_2''+2u_3'+2u_1\star u_2'+2[u_1,u_3]_\star,\\
&\partial_x^{-2} \quad \partial_2 u_3 = \cdots .
\end{aligned} \tag{3.24}$$

Hence due to the commutator $[u_1,u_k]$, it is very hard to represent the field u_k in terms of $u_1,u_2,\ldots,u_{k-1}$. The same is true of other flows. That is why the existence of NC modified KP hierarchy is nontrivial.

Some reduced hierarchies are obtained from constraint conditions.

(i) NC mKdV hierarchy (2-reduction of the "NC mKP hierarchy"). This time, the 2-reduction constraint $L^2=B_2$ makes it possible to represent infinite kinds of fields $u_2,u_3,\ldots$ in terms of one kind of field $2u_1\equiv v$. The NC mKdV hierarchy includes the $(1+1)$-dimensional NC mKdV equation for $m=3$ with $t_3\equiv t$,

$$\dot{v}=\tfrac{1}{4}v'''-\tfrac{3}{8}v\star v'\star v+\tfrac{3}{8}[v,v'']_\star. \tag{3.25}$$

(ii) NC Burgers hierarchy.[30] This is obtained by an irregular reduction. Setting the constraint $L_{\leqslant -1}=0$ or $L=:\partial_x+v$, the Lax hierarchy (3.10) yields the NC Burgers hierarchy which includes neither positive nor negative power of differential operator. For $m=2$, the hierarchy becomes the $(1+1)$-dimensional NC Burgers equation with $t\equiv x^2$,

$$\dot{v}=[B_2,L]_\star=[\partial_x^2+2v\partial_x,\partial_x+v]_\star=v''+2v\star v'. \tag{3.26}$$

The NC Burgers equation is linearizable and easily solved via NC Cole–Hopf transformation.[30,31] In the linearization, the order of the nonlinear term plays crucial roles. This order is automatically realized from Sato's framework.

The present discussion is applicable to the matrix Sato theory where the fields $u_k(k=1,2,\ldots)$ are $N\times N$ matrices. For $N=2$, the Lax hierarchy includes the Ablowitz–Kaup–Newell–Segur (AKNS) system,[55] the Davey–Stewarson equation, the NLS equation and so on. (For commutative discussion, see, e.g., Ref. 48.)

NC version[23] of the Bogoyavlenskii–Calogero–Schiff (BCS) equation[56] is also derived from this framework because the Sato theory works well on the commutative BCS equation.

IV. COMMUTING FLOWS FOR NC LAX HIERARCHIES

First let us show all flows are commuting,

$$\partial_m \partial_n u_k = \partial_n \partial_m u_k \tag{4.1}$$

for any m, n, k. The derivation in this section is straightforward as the commutative case[57,53] and already discussed in a more general situation where the products are noncommutative associative products with differentiations. (See, e.g., Refs. 46, 58, and 59.)

From NC Lax equation (3.10), we get

$$\partial_m \partial_n L = [\partial_m B_n, L]_\star + [B_n, \partial_m L]_\star = [\partial_m B_n, L]_\star + [B_n, [B_m, L]_\star]_\star. \tag{4.2}$$

Hence

$$[\partial_m, \partial_n] L = [F_{mn}, L]_\star, \tag{4.3}$$

where

$$F_{mn} := \partial_m B_n - \partial_n B_m - [B_m, B_n]_\star. \tag{4.4}$$

Now we show the "zero-curvature equation" $F_{mn}=0$. We note that

$$\partial_m B_n = \partial_m (L^n)_{\geqslant r} = (\partial_m L^n)_{\geqslant r} = [B_m, L^n]_{\star \geqslant r} = -[B_m^c, L^n]_{\star \geqslant r} = -[B_m^c, B_n]_{\star \geqslant r}, \tag{4.5}$$

where the operator B_m^c is the compliment of B_m and defined by

$$B_m^c := L^m - B_m, \tag{4.6}$$

and the suffix r is equal to 0 for $u_1=0$ and 1 for $u_1 \neq 0$. Therefore we get

$$\begin{aligned} F_{mn} &= -[B_m^c, B_n]_{\star \geqslant r} + [B_n^c, B_m]_{\star \geqslant r} - [B_m, B_n]_\star = -[B_m^c, L^n - B_n^c]_{\star \geqslant r} + [L^n - B_n, B_m]_{\star \geqslant r} - [B_m, B_n]_{\star \geqslant r} \\ &= [B_m^c, B_n^c]_{\star \geqslant r} = 0, \end{aligned} \tag{4.7}$$

which implies

$$\partial_m \partial_n L = \partial_n \partial_m L. \tag{4.8}$$

Hence Eq. (4.1) is proved.

We note that the present discussion works well for arbitrary noncommutativity. Here we call the Eq. (4.7) the *NC Zakharov–Shabat equation* because reduces to the usual Zakharov–Shabat equation in the commutative limit,

$$\partial_m B_n - \partial_n B_m - [B_m, B_n]_\star = 0. \tag{4.9}$$

Of course, we can get the conjugate of the NC Zakharov–Shabat equation in terms of B_n^c,

$$\partial_m B_n^c - \partial_n B_m^c + [B_m^c, B_n^c]_\star = 0. \tag{4.10}$$

V. CONSERVATION LAWS FOR NC LAX HIERARCHIES

Here let us prove the conservation laws for NC Lax equations, which are the main results in the present paper.

First we would like to comment on conservation laws of NC field equations.[30] The discussion is basically the same as the commutative case because both the differentiation and the integration are the same as the commutative ones in the Moyal representation.

Let us suppose the conservation law,

$$\frac{\partial \sigma(t, x^i)}{\partial t} = \partial_i J^i(t, x^i), \tag{5.1}$$

where $\sigma(t, x^i)$ and $J^i(t, x^i)$ are called the *conserved density* and the *associated flux*, respectively. The conserved quantity is given by spatial integral of the conserved density,

$$Q(t) = \int_{\text{space}} \mathrm{d}^D x\, \sigma(t,x^i), \tag{5.2}$$

where the integral $\int_{\text{space}} \mathrm{d}x^D$ is taken for spatial coordinates. The proof is straightforward,

$$\frac{\mathrm{d}Q}{\mathrm{d}t} = \frac{\partial}{\partial t}\int_{\text{space}} \mathrm{d}^D x\, \sigma(t,x^i) = \int_{\text{space}} \mathrm{d}^D x\, \partial_i J_i(t,x^i) = \int_{\substack{\text{spatial}\\ \text{infinity}}} \mathrm{d}S^i\, J_i(t,x^i) = 0, \tag{5.3}$$

unless the surface term of the integrand $J_i(t,x^i)$ vanishes. The convergence of the integral is also expected because the star-product naively reduces to the ordinary product at spatial infinity due to $\partial_i \sim \mathcal{O}(r^{-1})$ where $r := |x|$.

For commutative field equations, the existence of infinite number of conserved quantities is expected to lead to infinite-dimensional hidden symmetry from Noether's theorem. For NC field equations, this would also be true and the existence of infinite number of conserved quantities would be special and meaningful, and suggest an infinite-dimensional hidden symmetry deformed from the commutative one.

In order to discuss conservation laws for the NC Lax hierarchies, let us first calculate the differential of the residue of L^n following Wilson's approach:[57]

$$\partial_m \operatorname{res}_{-1} L^n = \operatorname{res}_{-1}(\partial_m L^n) = \operatorname{res}_{-1}[B_m, L^n]_\star. \tag{5.4}$$

Here we note that

$$\begin{aligned}\operatorname{res}_{-1}[f\partial_x^p, g\partial_x^q]_\star &= \binom{p}{p+q+1}(f\star g^{(p+q+1)} - (-1)^{p+q+1} g\star f^{(p+q+1)}) \\ &= \binom{p}{p+q+1}\left\{\left(\sum_{k=0}^{p+q}(-1)^k f^{(k)}\star g^{(p+q-k)}\right)' + (-1)^{p+q}[g, f^{(p+q+1)}]_\star\right\},\end{aligned} \tag{5.5}$$

where $f^{(N)} := \partial^N f/\partial x^N$. Hence we can see that on NC spaces, there is an additional term as a commutator in Eq. (5.5) which vanishes in the commutative limit. However as we saw in Sec. II, commutators of fields can be represented as total derivatives, which is very important here.

Let us describe the explicit representations of the conservation laws. From the explicit forms of the Lax pair,

$$\begin{aligned} L^n &= \partial_x^n + \sum_{l=1}^{\infty} a_{n-l}\partial_x^{n-l}, \\ B_m &= \partial_x^m + \sum_{k=1}^{m} b_{m-k}\partial_x^{m-k}, \end{aligned} \tag{5.6}$$

we can evaluate Eq. (5.4) as

$$\begin{aligned}\partial_m \operatorname{res}_{-1} L^n &= \operatorname{res}_{-1}\left[\partial_x^m + \sum_{k=1}^{m} b_{m-k}\partial_x^{m-k}, \partial_x^n + \sum_{l=1}^{\infty} a_{n-l}\partial_x^{n-l}\right]_\star \\ &= \sum_{l=n+1}^{m+n}\binom{m}{l-n-1} a_{n-l}^{(m+n-l+1)} + \sum_{k=1}^{m}\sum_{l=n+1}^{n+1+m-k}\binom{m-k}{l-n-1} \\ &\quad\times\left\{\left(\sum_{N=0}^{m+n-k-l}(-1)^N b_{m-k}^{(N)}\star a_{n-l}^{(m+n-k-l-N)}\right)' + (-1)^{m+n-k-l}[a_{n-l}, b_{m-k}^{(m+n-k-l+1)}]_\star\right\}\end{aligned}$$

$$= \left\{ \sum_{l=n+1}^{m+n} \binom{m}{l-n-1} a_{n-l}^{(m+n-l)} + \sum_{k=1}^{m} \sum_{l=n+1}^{n+1+m-k} \binom{m-k}{l-n-1} \right.$$
$$\left. \times \sum_{N=0}^{m+n-k-l} (-1)^N b_{m-k}^{(N)} \star a_{n-l}^{(m+n-k-l-N)} \right\}' - \sum_{k=1}^{m} \sum_{l=n+1}^{n+1+m-k} \binom{m-k}{l-n-1}$$
$$\times (-1)^{m+n-k-l} \theta^{ij} \partial_i \left(a_{n-l} \diamondsuit \partial_j b_{m-k}^{(m+n-k-l+1)} \right).$$

This is the generalized conservation laws for the NC Lax hierarchies. The right-hand side (RHS) contains derivatives in all NC directions. When we interpret this as conservation laws, we must specify what coordinates correspond to time and space and introduce the noncommutativities in the space–time directions only.

If we identify the coordinate x^m with time t, we get the conserved density as follows:

$$\sigma = \mathrm{res}_{-1} L^n + \theta^{im} \sum_{k=0}^{m-1} \sum_{l=0}^{k} (-1)^{k-l} \binom{k}{l} \mathrm{res}_{-(l+1)} L^n \diamondsuit \partial_i \partial_x^{k-l} \mathrm{res}_k L^m, \tag{5.7}$$

for $n=1,2,\ldots$, where the suffices i must run in the space–time directions only. We can easily see that deformation terms appear in the second term of Eq. (5.7) in the case of space-time noncommutativity. On the other hand, in the case of space–space noncommutativity, the conserved density is given by the residue of L^n as the commutative case.

Let us show more explicit representations as follows.

(i) In the case that the space–time coordinates are $(x,y,t) \equiv (x^1,x^2,x^3)$. The conserved density is given by

$$\sigma = \mathrm{res}_{-1} L^n + \theta^{i3} \sum_{k=0}^{2} \sum_{l=0}^{k} (-1)^{k-l} \binom{k}{l} \mathrm{res}_{-(l+1)} L^n \diamondsuit \partial_i \partial_x^{k-l} \mathrm{res}_k L^3, \tag{5.8}$$

more explicitly, for $u_1=0$ and $[t,x]=i\theta$, which includes the NC KP equation with space–time noncommutativity, the NC KdV equation and so on,

$$\sigma = \mathrm{res}_{-1} L^n - 3\theta((\mathrm{res}_{-1} L^n) \diamondsuit u_3' + (\mathrm{res}_{-2} L^n) \diamondsuit u_2'), \tag{5.9}$$

and for $u_1 \neq 0$ and $[t,x]=i\theta$, which includes the NC modified KdV equation and so on,

$$\sigma = \mathrm{res}_{-1} L^n + 3\theta((\mathrm{res}_{-1} L^n) \diamondsuit (u_2 + u_1^2)'' - (\mathrm{res}_{-2} L^n) \diamondsuit (u_2 - u_1' - u_1^2)' - (\mathrm{res}_{-3} L^n) \diamondsuit u_1'). \tag{5.10}$$

(ii) In the case that the space–time coordinates are $(x,t) \equiv (x^1,x^2)$ with $[t,x]=i\theta$. The conserved density is given by

$$\sigma = \mathrm{res}_{-1} L^n - \theta \sum_{k=0}^{1} \sum_{l=0}^{k} (-1)^{k-l} \binom{k}{l} \mathrm{res}_{-(l+1)} L^n \diamondsuit \partial_i \partial_x^{k-l} \mathrm{res}_k L^2, \tag{5.11}$$

more explicitly, for $u_1=0$, which includes the NC Boussinesq equation and so on,

$$\sigma = \mathrm{res}_{-1} L^n + 2\theta(\mathrm{res}_{-1} L^n) \diamondsuit u_2', \tag{5.12}$$

and for $u_1 \neq 0$:

$$\sigma = \mathrm{res}_{-1} L^n + 2\theta((\mathrm{res}_{-1} L^n) \diamondsuit u_1'' - (\mathrm{res}_{-2} L^n) \diamondsuit u_1'). \tag{5.13}$$

We note that for space–space noncommutativity, conserved quantities (not densities) are all the same as commutative ones because of Eq. (2.6). This is consistent with the present results, of course. Furthermore, for l-reduced hierarchies, the conserved densities (5.7) become trivial for

$n=Nl$ $(N=1,2,\ldots)$. The NC Burgers hierarchy is obtained by a "1-reduction" and contains no negative power of differential operators. Hence we cannot generate any conserved density for the NC Burgers equation in the present approach. This is considered to suggest that the NC Burgers equation is not a conservative system but a dispersive system as a commutative case.

We have one comment on conserved densities for the one-soliton configuration. One soliton solutions can always reduce to the commutative ones because $f(t-x)\star g(t-x)=f(t-x)g(t-x)$.[8,30] Hence the conserved densities are not deformed in the NC extension.

The present discussion is applicable to the NC matrix Sato theory, including the NC AKNS system, the NC Davey–Stewarson equation, the NC NLS equation, and the NC BCS equation.

VI. CONCLUSION AND DISCUSSION

In the present paper, we showed that the existence of an infinite number of conserved densities for a wide class of NC Lax hierarchies and obtained the explicit representations of them for both space–space and space–time noncommutativities. This suggests that NC soliton equations are completely integrable and infinite-dimensional symmetries would be hidden, which would be considered as some deformed affine Lie algebras.

In order to reveal what the hidden symmetry is, we must first study NC extension of Hirota's bilinearization.[60] This could be realized as a simple generalization of the Cole–Hope transformation whose extension to NC spaces are already successful in Refs. 30 and 31. Hirota's bilinearization leads to the theory of tau-functions which is essential in the discussion of the Lie algebraic structure of symmetry of the solution space.[47,54,61,62] After submission of the present paper, progress has been reported in, e.g., Refs. 63–65.

Our results guarantee that NC extension of soliton theories would be actually fruitful and worth studying. There are many further directions, such as, the study of relation to q-deformations of integrable systems, NC extension of the r-matrix formalism,[48,66] the inverse scattering method and the Bäcklund transformation, and so on. NC extension of the Ward conjecture[38] (see also Ref. 67) would be also very interesting.[27] Some NC equations are actually derived from NC (anti-)self-dual YM equations by reduction[14,30,33] and embedded[15,17,68] in $N=2$ string theories.[69] This guarantees that NC soliton equations would have physical meanings and might be helpful to understand new aspects of the corresponding string theory.

APPENDIX: MISCELLANEOUS FORMULAS

We present explicit calculations of L^n for $n=1$, 2, 3, 4, 5 up to some order of the pseudodifferential operator ∂_x. We can read reduction conditions, e.g., $L^l=B_l$, and the explicit representations of $\mathrm{res}_r L^n$ and B_m.

For $u_1=0(r=0)$:

$$L=\partial_x+u_2\partial_x^{-1}+u_3\partial_x^{-2}+u_4\partial_x^{-3}+u_5\partial_x^{-4}+u_6\partial_x^{-5}+\cdots,$$

$$\begin{aligned}L^2=\partial_x^2+2u_2+(2u_3+u_2')\partial_x^{-1}+(2u_4+u_3'+u_2\star u_2)\partial_x^{-2}+(2u_5+u_4'+u_2\star u_3+u_3\star u_2-u_2\star u_2')\partial_x^{-3}\\+(2u_6+u_5'+u_2\star u_4+u_4\star u_2+u_3\star u_3-u_2\star u_3'-2u_3\star u_2'+u_2\star u_2'')\partial_x^{-4}+\cdots,\end{aligned}$$

$$L^3=\partial_x^3+3u_2\partial_x+3(u_3+u_2')+(3u_4+3u_3'+u_2''+3u_2\star u_2)\partial_x^{-1}+(3u_5+3u_4'+u_3''+3u_2\star u_3+3u_3\star u_2+u_2'\star u_2-u_2\star u_2')\partial_x^{-2}+(3u_6+3u_5'+u_4''+3u_2\star u_4+3u_4\star u_2+3u_3\star u_3+u_2\star u_2\star u_2+u_2'\star u_3-u_2\star u_3'+u_3'\star u_2-4u_3\star u_2'-u_2'\star u_2'+u_2\star u_2'')\partial_x^{-3}+\cdots,$$

$$L^4=\partial_x^4+4u_2\partial_x^2+(4u_3+6u_2')\partial_x+(4u_4+6u_3'+4u_2''+6u_2\star u_2)+(4u_5+6u_4'+4u_3''+u_2'''+6u_2\star u_3+6u_3\star u_2+4u_2'\star u_2+2u_2\star u_2')\partial_x^{-1}+(4u_6+6u_5'+4u_4''+u_3'''+6u_2\star u_4+6u_4\star u_2+6u_3\star u_3+4u_2\star u_2\star u_2+4u_2'\star u_3+2u_2\star u_3'+4u_3'\star u_2-4u_3\star u_2'-u_2'\star u_2'+u_2''\star u_2+u_2\star u_2'')\partial_x^{-2}+\cdots,$$

$$L^5=\partial_x^5+5u_2\partial_x^3+5(u_3+2u_2')\partial_x^2+5(u_4+2u_3'+2u_2''+2u_2\star u_2)\partial_x+5(u_5+2u_4'+2u_3''+u_2'''+2u_2\star u_3+2u_3\star u_2+2u_2'\star u_2+2u_2\star u_2')+(5u_6+10u_5'+10u_4''+5u_3'''+u_2''''+10u_2\star u_4+10u_4\star u_2+10u_3\star u_3+10u_2\star u_2\star u_2+10u_2'\star u_3+10u_2\star u_3'+10u_3'\star u_2+5u_2'\star u_2'+5u_2''\star u_2+5u_2\star u_2'')\partial_x^{-1}+\cdots.$$

For $u_1\neq 0 (r=1)$:

$$L=\partial_x+u_1+u_2\partial_x^{-1}+u_3\partial_x^{-2}+u_4\partial_x^{-3}+u_5\partial_x^{-4}+u_6\partial_x^{-5}+\cdots,$$

$$L^2=\partial_x^2+2u_1\partial_x+(2u_2+u_1'+u_1^2)+(2u_3+u_2'+u_1\star u_2+u_2\star u_1)\partial_x^{-1}+(2u_4+u_3'+u_1\star u_3+u_3\star u_1+u_2\star u_2-u_2\star u_1')\partial_x^{-2}+(2u_5+u_4'+u_1\star u_4+u_4\star u_1+u_2\star u_3+u_3\star u_2-2u_3\star u_1'-u_2\star u_2'+u_2\star u_1'')\partial_x^{-3}+\cdots,$$

$$L^3=\partial_x^3+3u_1\partial_x^2+3(u_2+u_1'+u_1\star u_1)\partial_x+(3u_3+3u_2'+3u_1''+3u_1\star u_2+3u_2\star u_1+u_1'\star u_1+2u_1\star u_1'+u_1\star u_1\star u_1)+(3u_4+3u_3'+u_2''+3u_1\star u_3+3u_3\star u_1+3u_2\star u_2+u_1'\star u_2+2u_1\star u_2'+u_2'\star u_1-2u_2\star u_1'+u_1\star u_1\star u_2+u_1\star u_2\star u_1+u_2\star u_1\star u_1)\partial_x^{-1}+\cdots,$$

$$L^4=\partial_x^4+4u_1\partial_x^3+(4u_2+6u_1'+6u_1\star u_1)\partial_x^2+(4u_3+6u_2'+4u_1''+6u_1\star u_2+6u_2\star u_1+4u_1'\star u_1+8u_1\star u_1'+4u_1\star u_1\star u_1)\partial_x+(4u_4+6u_3'+4u_2''+u_1'''+6u_1\star u_3+6u_3\star u_1+6u_2\star u_2+4u_1'\star u_2+6u_1\star u_2'+4u_2'\star u_1-2u_2\star u_1'+2u_1''\star u_1+2u_1\star u_1''+3u_1'\star u_1'+4u_1\star u_1\star u_2+4u_1\star u_2\star u_1+4u_2\star u_1\star u_1+u_1'\star u_1\star u_1+2u_1\star u_1'\star u_1+3u_1\star u_1\star u_1'+u_1\star u_1\star u_1\star u_1)+\cdots,$$

$$L^5=\partial_x^5+5u_1\partial_x^4+5(u_2+2u_1'+2u_1\star u_1)\partial_x^3+5(u_3+2u_2'+2u_1''+2u_1\star u_2+2u_2\star u_1+2u_1'\star u_1+4u_1\star u_1'+2u_1\star u_1\star u_1)\partial_x^2+(5u_4+10u_3'+10u_2''+5u_1'''+10u_1\star u_3+10u_3\star u_1+10u_2\star u_2+10u_1'\star u_2+20u_1\star u_2'+10u_2'\star u_1+4u_2\star u_1'+6u_1''\star u_1+15u_1'\star u_1'+11u_1\star u_1''+10u_1\star u_1\star u_2+10u_1\star u_2\star u_1+10u_2\star u_1\star u_1+5u_1'\star u_1\star u_1+10u_1\star u_1'\star u_1+15u_1\star u_1\star u_1'+5u_1\star u_1\star u_1\star u_1)\partial_x+\cdots.$$

(Received 1 July 2004; accepted 22 February 2005; published online 11 April 2005)

The Kepler problem is a dynamical system that is well defined not only on the Euclidean plane but also on the sphere and on the hyperbolic plane. First, the theory of central potentials on spaces of constant curvature is studied. All the mathematical expressions are presented using the curvature κ as a parameter, in such a way that they reduce to the appropriate property for the system on the sphere S^2, or on the hyperbolic plane H^2, when particularized for $\kappa>0$, or $\kappa<0$, respectively; in addition, the Euclidean case arises as the particular case $\kappa=0$. In the second part we study the main properties of the Kepler problem on spaces with curvature, we solve the equations and we obtain the explicit expressions of the orbits by using two different methods, first by direct integration and second by obtaining the κ-dependent version of the Binet's equation. The final part of the paper, that has a more geometric character, is devoted to the study of the theory of conics on spaces of constant curvature. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1893214]

I. INTRODUCTION

The hydrogen atom in a spherical geometry S^3 was first studied by Schrödinger[1] in 1940 and analyzed by Infeld[2] and Stevenson[3] at the next year; some five years later Infeld and Schild[4] obtained the spectrum of this system in an "open universe of constant negative curvature" (hyperbolic space H^3). Later on, Higgs[5] and Leemon[6] analyzed the characteristics of the two fundamental central potentials, Kepler problem and harmonic oscillator, on the N-dimensional sphere and Kalnins *et al.*, in a study of the dynamical $O(4)$ symmetry of the hydrogen atom,[7] considered the separation of variables of the Schrödinger equation with a Coulomb potential on the sphere S^3 using a classification of coordinate systems separating the Laplace equation in the Riemannian spaces of constant curvature previously obtained by Olevskii.[8] Since then, a certain number of authors have studied this question from both the classical (Kepler problem) and the quantum (hydrogen atom) points of view.[9–24] The Kepler problem and the harmonic oscillator are the two most important superseparable systems and, because of this, their spherical and hyperbolic versions have been occasionally obtained, in some of the quoted references, as particular cases in the study of superintegrable systems on non-Euclidean configuration spaces.

The Euclidean superintegrable systems in the plane were studied by Fris *et al.*[25] and in the three-dimensional space by Evans;[26] later on different authors have considered this question[27–39]

from different points of view. In Ref. 16 we studied the existence of the spherical and hyperbolic versions of these superintegrable systems taking the space curvature as a parameter; next the properties of the isotropic and nonisotropic harmonic oscillator and of those superintegrable systems related with the harmonic oscillator were analyzed.[19,20,23,24] Now, our objective is the study of the Kepler problem on the sphere S^2 and the hyperbolic plane H^2, both coming naturally from reduction from the true Kepler problem in a three-dimensional curved space S^3 or H^3.

In differential geometric terms, the Euclidean plane $\mathbb{E}^2$ is in fact a very particular limiting case of the constant curvature spaces; accordingly, in dynamical terms, certain classical and well-known potentials (Kepler problem, harmonic oscillator, and systems related with them) can also be considered as very particular limiting cases of more general curved systems. If the curvature κ is introduced as a parameter then the question is the analysis of certain potentials in the space with constant curvature κ (we may term these as κ-dependent potentials) with appropriate flat limit. As many different κ-dependent functions may have the same limit when $\kappa \to 0$ we must require that certain fundamental properties of the Euclidean system continue to hold for the curved system. By fundamental properties we mean those related with separability (superseparability) and integrability (superintegrability). The important point is that the spherical and hyperbolic Kepler potential, to be studied in this paper, can be characterized as a very specific κ deformation of the well-known Euclidean system, and conversely, the Euclidean Kepler potential arises as the particular $\kappa=0$ case of the κ-dependent curved system.

The main purpose of this paper is to study and solve the Kepler problem in the space of constant curvature κ. As we will see, one of the advantages of this κ-dependent formalism is that the study runs parallel to that of the Euclidean case. So the structure of this paper is very similar to that of the corresponding chapter (or sections) devoted to central potentials and Kepler problem in some classical books of theoretical mechanics.[40,41] In fact this is the idea of using the deformation as an approach, the curvature κ will modify many things but will preserve the fundamental structure; this is so because the deep properties ensuring the possibility of exact solution for the Euclidean Kepler problem are preserved when a constant curvature is ascribed to the space. Of course, there are significant differences; one of them will be the geometric interpretation of the solutions that, although rather simple in the Euclidean plane, will pose some interesting geometric questions in spaces of constant curvature.

In more detail, the plan of this paper is as follows: In Sec. II we analyze the free geodesic motion on the spaces S^2, $\mathbb{E}^2$, and H^2, as well as the existence of κ-dependent Noether symmetries. In Sec. III we study some general questions concerning the central potentials on spaces of constant curvature. Section IV, that can be considered as the central part of the paper, is devoted to the study of the κ-dependent Kepler problem on the spaces $(S^2, \mathbb{E}^2, H^2)$. We have divided this section into three sections. In the first part we consider the equivalent one-dimensional problem and we draw a rough classification of the orbits without requiring explicit solutions; in the second part we solve explicitly the problem and we obtain the expressions of the orbits; we arrive at the results by using two different methods. First by direct integration and second by obtaining the κ-dependent version of the Binet's equation. The third section is devoted to the analysis and classification of the κ-dependent orbits; first on the sphere S^2 $(\kappa>0)$, and then in the hyperbolic plane H^2 $(\kappa<0)$. This third section poses the difficult problem of interpreting the κ-dependent equations as conics in curved spaces; of course all the obtained results reduce to well-known Euclidean trajectories when we consider the particular value $\kappa=0$. Section V, that has a geometric character, is devoted to the study of (non-Euclidean) conics on the sphere S^2 and on the hyperbolic plane H^2, which leads to the identification of the orbits of the Kepler problem with conics for any value of the curvature. Finally, in Sec. VI we discuss the results and make some final comments.

II. GEODESIC MOTION, NOETHER SYMMETRIES AND CONSTANTS OF MOTION ON $(S^2, \mathbb{E}^2, H^2)$

In the following we will make use of the same notation and techniques introduced for the oscillator in the above-mentioned previous articles. That is, from now on all the mathematical expressions will depend on the curvature κ as a parameter, in such a way that when assuming

$\kappa>0$, $\kappa=0$, or $\kappa<0$, we will obtain the corresponding property particularized on the sphere, on the Euclidean plane, or on the hyperbolic plane. In order to present these expressions in a form which holds simultaneously for any value of κ, we will use the following "tagged" trigonometric functions:

$$C_\kappa(x)=\begin{cases}\cos\sqrt{\kappa}x & \text{if } \kappa>0,\\ 1 & \text{if } \kappa=0,\\ \cosh\sqrt{-\kappa}x & \text{if } \kappa<0,\end{cases}\qquad S_\kappa(x)=\begin{cases}\dfrac{1}{\sqrt{\kappa}}\sin\sqrt{\kappa}x & \text{if } \kappa>0,\\ x & \text{if } \kappa=0,\\ \dfrac{1}{\sqrt{-\kappa}}\sinh\sqrt{-\kappa}x & \text{if } \kappa<0,\end{cases}\tag{1}$$

and the κ-dependent tangent function $T_\kappa(x)$ defined in the natural way, $T_\kappa(x)=S_\kappa(x)/C_\kappa(x)$. The fundamental properties of these curvature-dependent trigonometric functions are

$$C_\kappa^2(x)+\kappa S_\kappa^2(x)=1,$$

and

$$C_\kappa(2x)=C_\kappa^2(x)-\kappa S_\kappa^2(x),\quad \frac{\mathrm{d}}{\mathrm{d}x}S_\kappa(x)=C_\kappa(x),$$

$$S_\kappa(2x)=2S_\kappa(x)C_\kappa(x),\quad \frac{\mathrm{d}}{\mathrm{d}x}C_\kappa(x)=-\kappa S_\kappa(x).\tag{2}$$

It is well known that the appropriate coordinates for the study of central potentials are polar (r,ϕ) coordinates (see the Appendix); according to the intrinsic viewpoint, the coordinate r in any space of constant curvature κ is the actual distance measured along the geodesics emanating from an arbitrarily chosen origin point O, while ϕ has the same meaning as in E^2, the angle between this geodesic and a reference geodesic through O.[42] The range of r depends on κ; specifically $r\in[0,\pi/2\sqrt{\kappa}]$ for $\kappa>0$ and $r\in[0,\infty]$ for $\kappa\leqslant 0$. The range of ϕ is the interval $[0,2\pi]$. So we start with the following κ-dependent expression:

$$\mathrm{d}s^2=\mathrm{d}r^2+S_\kappa^2(r)\mathrm{d}\phi^2,$$

that represents the differential line element on the spaces $(S^2,\mathbb{E}^2,H^2)$ with constant curvature κ. This metric reduces to

$$\mathrm{d}s_1^2=\mathrm{d}r^2+(\sin^2 r)\mathrm{d}\phi^2,\quad \mathrm{d}s_0^2=\mathrm{d}r^2+r^2\,\mathrm{d}\phi^2,\quad \mathrm{d}s_{-1}^2=\mathrm{d}r^2+(\sinh^2 r)\mathrm{d}\phi^2,$$

in the three particular cases of the unit sphere $\kappa=1$, Euclidean plane $\kappa=0$, and unit Lobachewski plane $\kappa=-1$.

The three κ-dependent vector fields Y_1, Y_2, Y_J, with coordinate expressions given by

$$Y_1(\kappa)=(\cos\phi)\frac{\partial}{\partial r}-\left(\frac{C_\kappa(r)}{S_\kappa(r)}\sin\phi\right)\frac{\partial}{\partial\phi},$$

$$Y_2(\kappa)=(\sin\phi)\frac{\partial}{\partial r}+\left(\frac{C_\kappa(r)}{S_\kappa(r)}\cos\phi\right)\frac{\partial}{\partial\phi},$$

$$Y_J = \frac{\partial}{\partial \phi},$$

are generators of three different one-parameter groups of diffeomorphisms preserving the metric ds^2 (isometries of the Riemannian manifold).[24] In fact, the commutators of these vector fields are given by

$$[Y_1(\kappa), Y_2(\kappa)] = -\kappa Y_J, \quad [Y_1(\kappa), Y_J] = -Y_2(\kappa), \quad [Y_2(\kappa), Y_J] = Y_1(\kappa),$$

so that they close the Lie algebra of the group of isometries of the spherical (Euclidean, hyperbolic) space. Notice that only when $\kappa=0$ (Euclidean plane) Y_1 and Y_2 will commute. Moreover, the Lagrangian for the geodesic (free) motion is given by the kinetic term arising from the Riemannian metric; that is

$$L_0(r, \phi, v_r, v_\phi; \kappa) = T(\kappa) = \left(\tfrac{1}{2}\right)(v_r^2 + S_\kappa^2(r) v_\phi^2),$$

and is invariant under the actions of $Y_1(\kappa)$, $Y_2(\kappa)$, and $Y_J(\kappa)$.

A general standard Lagrangian (κ-dependent kinetic term minus a potential) has the following form:

$$L(r, \phi, v_r, v_\phi; \kappa) = \left(\tfrac{1}{2}\right)(v_r^2 + S_\kappa^2(r) v_\phi^2) - U(r, \phi; \kappa),$$

in such a way that for $\kappa=0$ we recover a standard Euclidean system

$$\lim_{\kappa \to 0} L = \left(\tfrac{1}{2}\right)(v_r^2 + r^2 v_\phi^2) - V(r, \phi), \quad V(r, \phi) = U(r, \phi; 0).$$

In some particular cases this Lagrangian system possesses the vector fields Y_1, Y_2, or Y_J, as exact Noether symmetries. If we denote by Y_s^t, $s=1,2,J$, the natural lift to the tangent bundle (phase space) of the vector field Y_s and by θ_L the Cartan semibasic one-form[43]

$$\theta_L = \frac{\partial L}{\partial v_r} \mathrm{d}r + \frac{\partial L}{\partial v_\phi} \mathrm{d}\phi = v_r \, \mathrm{d}r + S_\kappa^2(r) v_\phi \, \mathrm{d}\phi,$$

then the cases with exact Noether symmetries are the following:

(1) If the potential U is of the form $U=U(z_2)$, with $z_2=S_\kappa(r)\sin\phi$, then

$$P_1(\kappa) = i(Y_1^t(\kappa))\theta_L = (\cos\phi) v_r - (C_\kappa(r) S_\kappa(r) \sin\phi) v_\phi$$

is a constant of motion.

(2) If the potential U is of the form $U=U(z_1)$, $z_1=S_\kappa(r)\cos\phi$, then

$$P_2(\kappa) = i(Y_2^t(\kappa))\theta_L = (\sin\phi) v_r + (C_\kappa(r) S_\kappa(r) \cos\phi) v_\phi$$

is a constant of motion.

(3) If the potential U depends only on the coordinate r (central potential), then

$$J(\kappa) = i(Y_J^t)\theta_L = S_\kappa^2(r) v_\phi$$

is a constant of motion.

We remark that the dependence on the curvature κ is only explicit in the radial dependence of these functions; the angular dependence, contained in $\cos\phi$ or $\sin\phi$, is κ independent. As an example, the vector field Y_J is κ independent but the integral of motion $J(\kappa)$ is κ dependent. These quantities P_1, P_2, J, are the κ-dependent versions of the two components of the linear momentum and the angular momentum.

III. CENTRAL POTENTIALS ON ($S^2, \mathbb{E}^2, H^2$)

Making use of the three κ-dependent functions, P_1, P_2, and J, the kinetic energy $T(\kappa)$ can be rewritten as follows:

$$T(\kappa) = \left(\tfrac{1}{2}\right)(P_1^2(\kappa) + P_2^2(\kappa) + \kappa J^2(\kappa)),$$

so that the total energy becomes

$$E(\kappa) = \left(\tfrac{1}{2}\right)(P_1^2(\kappa) + P_2^2(\kappa) + \kappa J^2(\kappa)) + U(r, \phi; \kappa),$$

showing that, on spaces of (constant) nonzero curvature, the angular momentum has a contribution to the total energy of the system, proportional to the curvature κ.

A κ-dependent potential U whose expression in polar coordinates (r, ϕ) has the structure

$$U = F(r) + \frac{G(\phi)}{S_\kappa^2(r)},$$

is Hamilton–Jacobi separable.[24] It is, therefore, integrable and has the following two quadratic integrals of motion:

$$I_1(\kappa) = P_1^2(\kappa) + P_2^2(\kappa) + 2F(r) + \frac{2G(\phi)}{T_\kappa^2(r)},$$

$$I_2(\kappa) = J^2(\kappa) + 2G(\phi).$$

Then, in this separable case, the total energy splits as a sum of two independent constants of motion

$$E(\kappa) = \left(\tfrac{1}{2}\right)I_1(\kappa) + \left(\tfrac{1}{2}\right)\kappa I_2(\kappa).$$

Of course, if $G=0$ then $U=F(r)$ is a central potential and the function $I_2(\kappa)$ just reduces to $I_2 = J^2(\kappa)$.

The Lagrangian of a κ-dependent central potential is given by

$$L(\kappa) = \left(\tfrac{1}{2}\right)(v_r^2 + S_\kappa^2(r)v_\phi^2) - U(r; \kappa),$$

so that the dynamics is represented by the vector field

$$X_L = v_r\frac{\partial}{\partial r} + v_\phi\frac{\partial}{\partial \phi} + f_r\frac{\partial}{\partial v_r} + f_\phi\frac{\partial}{\partial v_\phi}$$

with the functions f_r and f_ϕ given by

$$f_r = S_\kappa(r)C_\kappa(r)v_\phi^2 - U_r',$$

$$f_\phi = -2\left(\frac{C_\kappa(r)}{S_\kappa(r)}\right)v_r v_\phi.$$

The associated two equations are

$$\frac{\mathrm{d}}{\mathrm{d}t}v_r = S_\kappa(r)C_\kappa(r)v_\phi^2 - U_r', \quad U_r' = \frac{\mathrm{d}U}{\mathrm{d}r},$$

$$\frac{\mathrm{d}}{\mathrm{d}t}J(\kappa)=0, \quad J(\kappa)=S_\kappa^2(r)v_\phi,$$

where the time derivative $\mathrm{d}/\mathrm{d}t$ can be interpreted, in geometric terms, as the Lie derivative along X_L. The ϕ equation just gives the conservation law of the κ-dependent angular momentum (or the law of areas); concerning the radial equation it can be rewritten as follows:

$$\dot{v}_r=\ddot{r}=-\frac{\mathrm{d}}{\mathrm{d}t}\left[\left(\frac{1}{2}\right)\frac{J^2}{S_\kappa^2(r)}+U(r;\kappa)\right],$$

so that, after multiplying by $v_r=\dot{r}$, it leads to

$$\frac{\mathrm{d}}{\mathrm{d}t}\left[\left(\frac{1}{2}\right)v_r^2+\left(\frac{1}{2}\right)\frac{J^2}{S_\kappa^2(r)}+U(r;\kappa)\right]=0,$$

that represents the conservation law of the energy

$$\left(\frac{1}{2}\right)v_r^2+\left(\frac{1}{2}\right)\frac{J^2}{S_\kappa^2(r)}+U(r;\kappa)=E, \quad \frac{\mathrm{d}}{\mathrm{d}t}E=0.$$

Solving for $\dot{r}$, we obtain

$$\frac{\mathrm{d}r}{\mathrm{d}t}=\sqrt{2\left(E-U(r;\kappa)-\left(\frac{1}{2}\right)\frac{J^2}{S_\kappa^2(r)}\right)},$$

that can be solved for $\mathrm{d}t$ and integrated

$$t=\int\frac{\mathrm{d}r}{\sqrt{2\left[E-U(r;\kappa)-\left(\frac{1}{2}\right)(J^2/S_\kappa^2(r))\right]}},$$

so that in the particular $\kappa=0$ case we recover the integral of the Euclidean case appearing in the books of theoretical mechanics

$$t=\int\frac{\mathrm{d}r}{\sqrt{2\left[E-V(r)-\left(\frac{1}{2}\right)(J^2/r^2)\right]}}.$$

Coming back to the general $\kappa\neq 0$ case, if we consider a change of variable from r to a new variable $u_\kappa=C_\kappa(r)/S_\kappa(r)$, by using (2) we get

$$\mathrm{d}r=-\frac{\mathrm{d}u_\kappa}{u_\kappa^2+\kappa},$$

and by considering the potential $U=U(r;\kappa)$ as a function of the new radial variable, $U=U(u_\kappa;\kappa)$, the above integral for t becomes

$$t=\int\frac{\mathrm{d}u_\kappa}{(u_\kappa^2+\kappa)\sqrt{2\left[E_P-U(u_\kappa;\kappa)-\left(\frac{1}{2}\right)J^2u_\kappa^2\right]}},$$

where E_P denotes a constant of motion which plays an important role,

$$E_P=E-\left(\frac{1}{2}\right)\kappa J^2.$$

(Notice the true energy for curvature κ is E and not E_P; however E_P can be seen as a kind of κ deformation of the Euclidean energy because $E_P=E$ for $\kappa=0$.) This integral gives the value of t as a function of u_κ and consequently also of r; it can be inverted, at least formally, and we can obtain

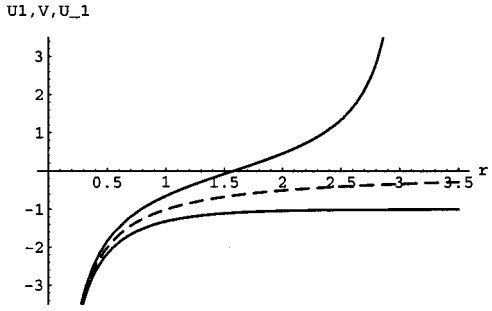

FIG. 1. Plot of the Kepler potential as a function of r, for the unit sphere $\kappa=1$ (upper curve), Euclidean plane $\kappa=0$ (dashed line), and unit Lobachewski plane $\kappa=-1$ (lower curve). The three functions are singular at $r=0$ but the Euclidean function $U_0=V$ appears in this formalism as making a separation between two different behaviors. In fact $U_0=V$ is the only potential that vanishes at long distances.

u_κ (or r) as a function of t and the two constants E_P and J. The expression of ϕ as a function of t is just given by

$$\phi = J \int (u_\kappa^2 + \kappa)\mathrm{d}t + \phi_0.$$

We close this section by calling attention to the factor $(u_\kappa^2+\kappa)$ in the above integral for t that clearly resembles the factor appearing in the elliptic integrals of the third kind.

IV. THE KEPLER PROBLEM ON $(S^2, \mathbb{E}^2, H^2)$

The following spherical (hyperbolic) Lagrangian with curvature κ,

$$L_K(\kappa)\left(\tfrac{1}{2}\right) = (v_r^2 + S_\kappa^2(r)v_\phi^2) - U_K(r;\kappa), \quad U_K = -\frac{k}{T_\kappa(r)},$$

represents the κ-dependent version of the Euclidean Kepler problem; the potential U_K reduces to

$$U_1(r) = -\frac{k}{\tan r}, \quad U_0(r) = V(r) = -\frac{k}{r}, \quad U_{-1}(r) = -\frac{k}{\tanh r},$$

in the three particular cases of the unit sphere $(\kappa=1)$, Euclidean plane $(\kappa=0)$, and unit Lobachewski plane $(\kappa=-1)$; the Euclidean function $V(r)$ appears in this formalism as making separation between two different behaviors (see Fig. 1). The global sign has been chosen so that $k>0$ corresponds to an attractive potential.

This potential is actually worthy of the name Kepler in curvature κ due to two reasons. First, this potential is the spherically symmetric potential satisfying Gauss law in a *three-dimensional space of constant curvature* κ, where the area of a sphere of radius r is $4\pi S_\kappa^2(r)$, where the flux of the corresponding radial force field across a sphere of radius r, which clearly equals $4\pi S_\kappa^2(r) \times(\mathrm{d}U_K/\mathrm{d}r)$ should be a constant independent of r; this condition leads directly to the potential U_K. [As in the Euclidean case, the potential $-(k/T_\kappa(r))$ does not satisfy the Gauss law in two dimensions.] The second reason is based on superintegrability; what singularizes U_K among other central potentials with the correct $-k/r$ Euclidean limit is the property of being a superintegrable system for all the values of the curvature κ.[16] In fact, U_K is endowed with the following two additional integrals of motion:

$$I_3(\kappa) = P_2(\kappa)J(\kappa) - k\cos\phi,$$

$$I_4(\kappa) = P_1(\kappa)J(\kappa) + k \sin \phi,$$

that represent the two-dimensional curvature versions of the Runge–Lenz constant of motion, whose existence is a consequence of the additional separability of $U_K(r;\kappa)$ in two different systems of κ-dependent parabolic coordinates (this superseparability is not studied in this paper). Of course only three of the four integrals are functionally independent; so we have several possibilities for the choice of a fundamental set of κ-dependent integrals of motion as, for example, $\{E(\kappa), J(\kappa), I_3(\kappa)\}$, $\{E(\kappa), J(\kappa), I_4(\kappa)\}$, or $\{E(\kappa), I_3(\kappa), I_4(\kappa)\}$.

A. The classification of orbits and the equivalent one-dimensional problem

Let us start for an arbitrary central potential $U(r)$. We have previously obtained

$$\left(\frac{1}{2}\right)v_r^2 + U(r;\kappa) + \left(\frac{1}{2}\right)\frac{J^2}{S_\kappa^2(r)} = E,$$

so, if we introduce the effective one-dimensional equivalent κ-dependent potential W defined as

$$W_\kappa(r) = U(r;\kappa) + \frac{J^2}{2S_\kappa^2(r)},$$

where the term $J^2/(2S_\kappa^2(r))$ plays clearly the role of the centrifugal barrier potential, then the above property reduces to conservation of the energy for the fictitious κ-dependent one-dimensional problem arising from the potential W_κ,

$$\left(\tfrac{1}{2}\right)v_r^2 + W_\kappa(r) = E,$$

so that we can use, also in this κ-dependent case, the method of the classification of the orbits by analyzing the behavior of W_κ.

Next we will study the main characteristics of the orbits for the Kepler potential in curvature κ where W_κ is given by

$$W_\kappa(r) = -\frac{k}{T_\kappa(r)} + \frac{J^2}{2S_\kappa^2(r)},$$

so it reduces to

$$W_1 = -\frac{k}{\tan r} + \frac{J^2}{2\sin^2 r},$$

$$W_0 = -\frac{k}{r} + \frac{J^2}{2r^2},$$

$$W_{-1} = -\frac{k}{\tanh r} + \frac{J^2}{2\sinh^2 r},$$

in the three particular one-dimensional problems associated to the unit sphere ($\kappa=1$), Euclidean plane ($\kappa=0$), and unit Lobachewski plane ($\kappa=-1$).

(1) Analysis of the potentials W_1 and W_c ($c=\sqrt{\kappa}>0$).

The function W_1 satisfies the following limits in the boundaries:

$$\lim_{r\to 0} W_1(r) = +\infty, \quad \lim_{r\to \pi} W_1(r) = +\infty,$$

it cuts the r axis at the points $r_{1,2}$ solutions of the equation $\sin(2r_{1,2}) = J^2/k$, and it has a minimum at the point r_m^s given by $r_m^s = \mathrm{tg}^{-1}(J^2/k)$. It represents, therefore, a potential well with barriers of

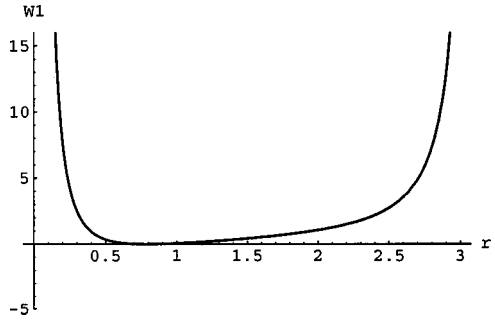

FIG. 2. Plot of W_c as a function of r, for $\kappa=1$ with k and J given by $(k=1, J=1)$.

infinite height at both extremes, $r=0$ and $r=\pi$, and one single minimum placed inside the left half-interval ($r_m^s<\pi/2$) with a value $W_m^s=(1/2)(J^2-k^2/J^2)$ (Fig. 2). Thus, all the trajectories are bounded and all of them describe nonlinear one-dimensional oscillations between the two turning points.

In the general case of the function W_c, the points $r_{1,2}$ are given by the two roots of $\sin(2cr_{1,2})=c(J^2/k)$ and the minimum is placed in the point $r_m^s=(1/c)\mathrm{tg}^{-1}(cJ^2/k)$ with a value given by $W_m^s=(1/2)(c^2J^2-k^2/J^2)$. All these expressions are c dependent and have the correct limits for W_0,

$$\lim_{c\to 0} r_1=\frac{J^2}{2k},\quad \lim_{c\to 0} r_2=+\infty,\quad \lim_{c\to 0} r_m^s=\frac{J^2}{k},\quad \lim_{c\to 0} W_m^s=-\frac{k^2}{2J^2}$$

(see Fig. 3).

(2) Analysis of the potentials W_{-1} and W_{-c} ($c=\sqrt{-\kappa}>0$).

The function W_{-1} satisfies the two following limits:

$$\lim_{r\to 0} W_{-1}(r)=+\infty,\quad \lim_{r\to\infty} W_{-1}(r)=-k,$$

it cuts the r axis in the point r_1 unique solution of the equation $\sinh(2r_1)=J^2/k$ and, in the case that k and J satisfy the condition $J^2/k<1$, then it has a unique minimum in the point r_m^h given by $r_m^h=\tanh^{-1}(J^2/k)$ with the value $W_m^h=-(1/2)(J^2+k^2/J^2)$. There exist therefore two possible situations, as follows:

(1) If $J^2/k<1$ the motion is bounded (periodic) for small energies $W_m^h\leqslant E<-k$, and unbounded for higher energies $E\geqslant -k$.

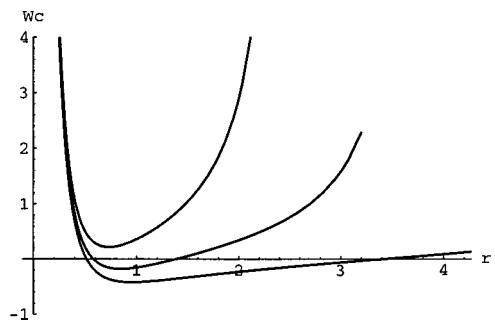

FIG. 3. Plot of W_c as a function of r, for $(k=1, J=1)$ and three different values of the curvature $c=\sqrt{\kappa}$, $c=1.2$ (upper curve), $c=0.8$ (middle curve), and $c=0.4$ (lower curve).

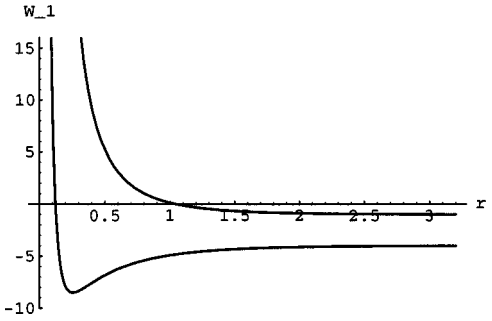

FIG. 4. Plot of W_{-c} as a function of r, for $c=1$ ($\kappa=-1$). The upper curve corresponds to ($k=1, J=2$) and lower curve corresponds to ($k=4, J=1$).

(2) If $J^2/k \geqslant 1$ the function W_{-1} will take the form of a potential barrier with infinite height at the the origin $r=0$; only energies satisfying $E \geqslant -k$ will be allowed and all the trajectories will be unbounded (scattering) open curves.

These two possible behaviors are represented in Fig. 4.
The general hyperbolic function W_{-c} satisfies

$$\lim_{r\to 0} W_{-c}(r) = +\infty, \quad \lim_{r\to\infty} W_{-c}(r) = -ck,$$

it cuts the r axis in the point r_1 solution of $\sinh(2cr_1)=c(J^2/k)$ and, if the condition $c(J^2/k)<1$ is satisfied, then it has a unique minimum in the point $r_m^h=(1/c)\tanh^{-1} c(J^2/k)$ with a value W_m^h given by $W_m^h=-(1/2)(c^2J^2+k^2/J^2)$. It is clear that the smaller the value of c is, the easier of satisfying is the condition for the existence of a well, so that the behavior (1) is becoming more and more dominant. Finally, the Euclidean limit is given by

$$\lim_{c\to 0} r_1 = \frac{J^2}{2k}, \quad \lim_{c\to 0} r_m^h = \frac{J^2}{k}, \quad \lim_{c\to 0} W_m^h = -\frac{k^2}{2J^2}.$$

The convergence of W_{-c} into W_0 is represented in Fig. 5.

B. Determination of the orbits of the κ-dependent Kepler problem

1. Method I: Direct integration

We have previously obtained, making use of the conservation of the total energy E and the angular momentum J, two expressions for $\dot{r}$ and $\dot{\phi}$, which can be written as

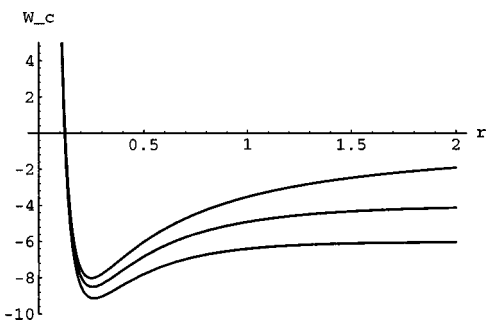

FIG. 5. Plot of W_{-c} as a function of r, for ($k=4, J=1$) and three different values of the curvature $c=\sqrt{-\kappa}$, $c=1.5$ (lower curve), $c=1$ (middle curve), and $c=0.5$ (upper curve).

$$\mathrm{d}t = \frac{\mathrm{d}r}{\sqrt{2[E - U - (1/2)(J^2/S_\kappa^2(r))]}}, \quad \mathrm{d}t = \left(\frac{S_\kappa^2(r)}{J}\right)\mathrm{d}\phi.$$

Eliminating t between both equations we have

$$\mathrm{d}\phi = \frac{J\,\mathrm{d}r}{S_\kappa^2(r)\sqrt{2[E - U - (1/2)(J^2/S_\kappa^2(r))]}},$$

that after the change of variable $r \to u_\kappa$ with $u_\kappa = 1/T_\kappa(r)$, $\mathrm{d}r = -S_\kappa^2(r)\mathrm{d}u_\kappa$, becomes

$$\mathrm{d}\phi = -\frac{\mathrm{d}u_\kappa}{\sqrt{R(u_\kappa)}},$$

where $R(u_k)$ denotes the following function:

$$R(u_k) = \frac{2E}{J^2} - \frac{2U}{J^2} - (u_\kappa^2 + r_\kappa^2) = \frac{2E_P}{J^2} - \frac{2U}{J^2} - u_\kappa^2.$$

All this is valid for a general potential. Next we particularize for the κ-Kepler problem, $U_K(r;\kappa) = -k/T_\kappa(r)$, and then we obtain

$$\phi = \phi_0 - \frac{\mathrm{d}u_\kappa}{\sqrt{R(u_\kappa)}}, \quad R(u_k) = \alpha + \beta u_\kappa + \gamma u_\kappa^2,$$

with coefficients α, β, and γ given by

$$\alpha = \frac{2E_P}{J^2}, \quad \beta = \frac{2k}{J^2}, \quad \gamma = -1.$$

In this particular case the integration is elementary and we arrive at

$$\phi = \phi_0 - \cos^{-1}\left(\frac{u_\kappa - (k/J^2)}{(k/J^2)\sqrt{1 + z_\kappa}}\right), \quad z_\kappa = \left(\frac{2J^2}{k^2}\right)E_P,$$

leading to

$$u_\kappa(\phi) = \left(\frac{k}{J^2}\right)[1 + e_\kappa \cos(\phi - \phi_0)], \quad e_\kappa = \sqrt{1 + z_\kappa}. \tag{3}$$

This is the polar equation of the orbit in either space $(S_\kappa^2, \mathbb{E}^2, H_\kappa^2)$, for any value of the curvature κ. It reduces to

$$\frac{1}{\tan r} = \left(\frac{k}{J^2}\right)[1 + e_1 \cos(\phi - \phi_0)],$$

$$\frac{1}{r} = \left(\frac{k}{J^2}\right)[1 + e_0 \cos(\phi - \phi_0)],$$

$$\frac{1}{\tanh r} = \left(\frac{k}{J^2}\right)[1 + e_{-1} \cos(\phi - \phi_0)],$$

in the three particular cases of the unit sphere ($\kappa = 1$), Euclidean plane ($\kappa = 0$), and unit Lobachewski plane ($\kappa = -1$), respectively.

We recall that, as only three of the several integrals of motion can be functionally independent, there must exist some relations between them. Concerning the couple $I_3(\kappa)$, $I_4(\kappa)$, that, as stated above, represent the κ-dependent version of the Euclidean Runge–Lenz constants of motion, they are related with E_P and J by

$$I_3^2 + I_4^2 = 2E_P J^2 + k^2$$

so that we arrive to

$$e_\kappa = \frac{1}{k}\sqrt{I_3^2 + I_4^2}$$

that represents the natural extension to the curvature-dependent case of a well-known property of the Euclidean case.

Let us close this direct integration approach with three observations. First, it turns out that in any of the three manifolds $(S_\kappa^2, \mathbb{E}^2, H_\kappa^2)$, and for any value of κ, this curve is a *conic with a focus at the origin*, where conic must be taken in a metric sense, relative to the intrinsic metric in each space. This follows from the geometrical study to be presented in Sec. V. Second, notice that the quantity e_κ is related to the partial energy E_P exactly as the Euclidean eccentricity of the conic is related to the total energy, yet only in the Euclidean case $(\kappa=0)$ this function E_P coincides with E. In the general case $(\kappa\neq 0)$ the characteristics of the orbit will be more easily associated to the values of the e_κ and/or E_P than to the total energy E. Third, both the method and the results obtained show a close similarity with the Euclidean ones. In fact, the important point is that the classical and well known change of variable $r\to u=1/r$ admits as a generalization the κ-dependent change $r\to u_\kappa=1/T_\kappa(r)$ which affords a significant simplification for all values of κ; conversely, this κ-dependent change reduces to the Euclidean change $r\to u_0=1/r$ for $\kappa=0$.

2. Method II: Equation of Binet

The definition of the angular momentum J determines a κ-dependent relation between the differentials of the time t and the angle ϕ.

$$J\,\mathrm{d}t = S_\kappa^2(r)\mathrm{d}\phi.$$

The corresponding relation between the derivatives with respect to t and ϕ is

$$\frac{\mathrm{d}}{\mathrm{d}t} = \left(\frac{J}{S_\kappa^2(r)}\right)\frac{\mathrm{d}}{\mathrm{d}\phi},$$

so that the second derivative with respect to t is given by

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2} = \left(\frac{J}{S_\kappa^2(r)}\right)\frac{\mathrm{d}}{\mathrm{d}\phi}\left[\left(\frac{J}{S_\kappa^2(r)}\right)\frac{\mathrm{d}}{\mathrm{d}\phi}\right].$$

Introducing this notation in the radial equation, it becomes

$$\left(\frac{J}{S_\kappa^2(r)}\right)\frac{\mathrm{d}}{\mathrm{d}\phi}\left[\left(\frac{J}{S_\kappa^2(r)}\right)\frac{\mathrm{d}r}{\mathrm{d}\phi}\right] - \left(\frac{C_\kappa(r)}{S_\kappa^3(r)}\right)J^2 = -U_r'.$$

This equation can be simplified in two steps, first, the left-hand side can be rewritten by making use of

$$\frac{\mathrm{d}}{\mathrm{d}\phi}\left(\frac{C_\kappa(r)}{S_\kappa(r)}\right) = -\left(\frac{1}{S_\kappa^2(r)}\right)\frac{\mathrm{d}r}{\mathrm{d}\phi};$$

second, we introduce the change $r\to u_\kappa$ in such a way that the potential $U=U(r;\kappa)$ be considered as a function of u_κ; then we have

$$U_r' = -\left(\frac{1}{S_\kappa^2(r)}\right)U_u', \quad U_u' = \frac{\mathrm{d}U}{\mathrm{d}u_\kappa}.$$

In this way we arrive at the differential equation of the orbit

$$\frac{\mathrm{d}^2 u_\kappa}{\mathrm{d}\phi^2} + u_\kappa = -\left(\frac{1}{J^2}\right)U_u',$$

that permits us to obtain ϕ as a function of u_κ for the given potential $U(r;\kappa)$ when considered as a function of u_κ,

$$\phi = \int \left\{c - \left(\frac{2}{J^2}\right)U - u_\kappa^2\right\}^{-(1/2)} \mathrm{d}u_\kappa.$$

Let us now particularize for the Kepler problem. In this case the potential U_K is given by $U_K = -ku_\kappa$, and the equation reduces to a linear equation with constant coefficients,

$$\frac{\mathrm{d}^2 u_\kappa}{\mathrm{d}\phi^2} + u_\kappa = \frac{k}{J^2},$$

which has the general solution

$$u_\kappa = A\cos(\phi - \phi_0) + \frac{k}{J^2} = \left(\frac{k}{J^2}\right)[1 + e\cos(\phi - \phi_0)], \tag{4}$$

where A [or $e = A(J^2/k)$] and ϕ_0 are the two constants of integration.

Remark that the differential equation of the orbit, usually known as the Binet's equation, is preserved by the κ deformation. That is, u_0 deforms to u_κ but the the equation by itself remains invariant.

C. Analysis of the orbits

From the geometrical viewpoint, one of the integration constants in (3) or (4) can be made to disappear by simply choosing ϕ to be measured from the orbit position closest to the focus. Thus the orbit is

$$T_\kappa(r) = \frac{D}{1 + e\cos\phi} \tag{5}$$

which depends on two geometric parameters, the constants D and e. Comparing with (3) or (4), these two geometric parameters are related to the angular momentum J and the total energy E by means of the expressions

$$D = \frac{J^2}{k}, \quad e_\kappa = \sqrt{1 + \frac{2J^2}{k^2}\left(E - \kappa\frac{J^2}{2}\right)}, \tag{6}$$

remaining valid for any value of the curvature κ and reducing to the known expressions for the Euclidean case, $\kappa = 0$. Thus, as advanced before, the relation between the geometric constants D, e, and the physical constants J, $E - (1/2)\kappa J^2 = E_P$, is the same for all values of curvature; here we see again the quantity E_P plays a role; it can be considered as a kind of translational part of the energy, not taking into account the contribution to the energy of the angular momentum.

The nature of the orbit depends on the values of these constants. We discuss separately the cases with positive and negative κ.

(i) Spherical space, $\kappa > 0$. The polar equation of the orbits is

$$\frac{1}{T_\kappa(r)} = \frac{\sqrt{\kappa}}{\tan\sqrt{\kappa}r} = \left(\frac{k}{J^2}\right)[1 + e_\kappa \cos(\phi - \phi_0)].$$

The orbit is always a closed curve and for any value of e_κ this curve is a spherical ellipse with a focus at the origin. For a fixed J the minimal value of the total energy corresponds to orbits with $e_\kappa = 0$, which are circles with radius $r = J^2/k$ and total energy $E_{\text{cir}} = (1/2)(-k^2/J^2 + \kappa J^2)$ (which may be either negative or positive). The possible energies for given J fill the interval $[E_{\text{cir}}, \infty]$ and correspond to the parameter e_κ in the interval $[0, \infty]$ and to E_P in the interval $[-(1/2)(k^2/J^2), \infty]$. In the following description the focus will be conventionally placed at the North pole, and upper and lower half-spheres refer to the North and South hemispheres. This orbit has always a vertex closest to the focus given by the unique solution of the equation $1/T_\kappa(r) = (k/J^2)(1 + e_\kappa)$, and depending on the value of e_κ we may however distinguish three possible behaviors for the second vertex.

(a) When $e_\kappa < 1$ the orbit is completely contained in the upper half-sphere centered at the focus, and the values of r always remain less than the length $\pi/(2\sqrt{\kappa})$ of a quadrant on the sphere of curvature κ. In some respects this reminds the case of Euclidean ellipses.

(b) If $e_\kappa = 1$, the ellipse has the second vertex at $r = \pi/(2\sqrt{\kappa})$ (reducing to $r = \pi/2$ when $\kappa = 1$), and is a curve touching tangentially the equator associated to the focus at the origin. When $\kappa \to 0$, the limit of the distance $r = \pi/(2\sqrt{\kappa})$ between the origin and the equator on a sphere S^2_κ is $r = \infty$ and thus this curve is analogous to a Euclidean parabola, touching the spatial infinity at a point.

(c) When $e_\kappa > 1$, the orbit has the second vertex at $r > \pi/(2\sqrt{\kappa})$; it is a big spherical ellipse crossing the equator of the focus and entering into the lower half-sphere. This is somehow analogous to an Euclidean hyperbola.

(ii) Hyperbolic space $\kappa < 0$. Let us consider the general case of arbitrary negative curvature. The orbit equation is now

$$\frac{1}{T_\kappa(r)} = \frac{\sqrt{-\kappa}}{\tanh\sqrt{-\kappa}r} = \left(\frac{k}{J^2}\right)[1 + e_\kappa \cos(\phi - \phi_0)], \quad \kappa < 0,$$

and the relations (6) also apply but now with $\kappa < 0$. For a fixed value of J, the diagram of the effective equivalent potential reveals two essentially different situations for the behavior of $W(r)$, corresponding to values of J smaller or larger than the particular value J_∞ of J,

$$J^2_\infty = \frac{k}{\sqrt{-\kappa}}.$$

When $J < J_\infty$ ($J^2/k < 1/\sqrt{-\kappa}$), the equivalent potential is qualitatively as its Euclidean counterpart; it has a minimum at $r = r_{\text{cir}}$ determined by $T_\kappa(r_{\text{cir}}) = J^2/k$, with a *negative* value for $W(r_{\text{cir}}) = E_{\text{cir}} = -k^2/2J^2 + \kappa J^2/2$ and when r increases from r_{cir} to $r \to \infty$, the effective potential tends from below to a *negative* constant value $-k\sqrt{-\kappa}$. When $J = J_\infty$ then the minimum occurs at $r = \infty$. When $J > J_\infty$ there is no longer a minimum in the equivalent potential, which is a monotone function of r, tending when $r \to \infty$ to the value $-k\sqrt{-\kappa}$ from above. This discussion alone suffices to establish two landmark values for the energies (at a fixed value of J) as follows:

(a) $E = E_{\text{cir}} = (1/2)(-k^2/J^2 + \kappa J^2)$, with $J^2/k < 1/\sqrt{-\kappa}$, corresponding to the circular orbits with $E_{P_{\text{cir}}} = -(1/2)(k^2/J^2)$;

(b) $E = E_\infty = -k\sqrt{-\kappa}$, with $E_{P\infty} = -k\sqrt{-\kappa} - (1/2)\kappa J^2_\infty = -(1/2)k\sqrt{-\kappa}$ for orbits where the particle barely reaches spatial infinity with velocity 0.

To go further in any analysis about the exact nature of the orbits is easier starting from some

geometric knowledge of the properties of conics, to be sketched in the next section. However, at this point we can provide a first classification into closed and open orbits, and we may discuss its main characteristics.

When the energy is in the interval $[E_{\mathrm{cir}}, E_\infty)$, the motion is bounded and periodic, while for E in the interval $(E_\infty, \infty]$, the motion is not periodic and the orbit goes to the infinity; notice that $E=0$ is contained *within* this second interval, and thus is *not* the separating value between bounded and unbounded orbits. The angular momentum provides a second constant of motion, which may have values in the two subintervals $J^2/k \in [T_\kappa(r_{\mathrm{cir}}), 1/\sqrt{-\kappa}]$ or $J^2/k \in [1/\sqrt{-\kappa}, \infty]$; it is pertinent to discuss these two possibilities successively.

Let us first discuss the subcase $J < J_\infty$, where the equivalent potential has a minimum.

(1) If the parameter $e_\kappa = 0$ then the solution is clearly a circular orbit (circle in the hyperbolic plane) of radius r_{cir} such that $T_\kappa(r_{\mathrm{cir}}) = J^2/k$ which happens precisely at the minimum for the equivalent potential. The total energy for a circular orbit is given by $E_{\mathrm{cir}} = -(1/2)(k^2/J^2 - \kappa J^2)$ that corresponds to $E_{P_{\mathrm{cir}}} = -(1/2)(k^2/J^2)$. This is, the angular momentum of any circular orbit should remain lower than the limit value J_∞ which is approached for the circular orbit with $r \to \infty$. In the Euclidean case the value of J is not bounded for circular orbits (J_∞ tends to infinity for $\kappa \to 0$).

(2) If e_κ is greater than 0 but in the interval $0 < e_\kappa < 1 - \sqrt{-\kappa}(J^2/k)$ then the orbit will be a closed curve not reaching the spatial infinity. As we will check in Sec. V, this curve is indeed a hyperbolic *ellipse*, with a focus at the potential origin. The interval of allowed values for the total energy E turns out to be

$$-\frac{k^2}{2J^2} + \frac{1}{2}\kappa J^2 < E < -k\sqrt{-\kappa},$$

or equivalently, if we consider the "translational" part of the energy,

$$-\frac{k^2}{2J^2} < E_P < \frac{1}{2}\kappa J^2 - k\sqrt{-\kappa}.$$

(3) If e_κ is in the remaining interval, $1 - \sqrt{-\kappa}(J^2/k) < e_\kappa$, corresponding to the values $-\sqrt{-\kappa}k < E < \infty$ of the energy E, then the motion is nonperiodic and the orbits are unbounded open curves. The border value for e between these closed periodic and open not periodic types of orbits is the value $e_\kappa = 1 - \sqrt{-\kappa}(J^2/k)$, which should be thought of as corresponding to the last ellipse, or *horoellipse*. It is not immediately clear whether the orbits with e above this value are *parabolas* or *hyperbolas* in the hyperbolic plane. However, it is natural to expect some special status for the orbits with $E=0$, $e_\kappa = \sqrt{1 - \kappa(J^4/k^2)} > 1$, which we might expect to be *parabolas* in the hyperbolic plane. This would imply that at least all orbits in a finite interval of values of the e_κ parameter, whose lower bound is $1 - \sqrt{-\kappa}(J^2/k)$ and which contains $e_\kappa = \sqrt{1 - \kappa(J^4/k^2)}$ are parabolas; notice that this interval should reduce to the single value $e_\kappa = 1$ in the Euclidean limit $\kappa \to 0$, so the existence of many different parabolic orbits does not spoil the known fact that there is only a parabolic orbit in E^2. All these conjectural properties are indeed true, as we will confirm in Sec. V.

We can summarize these three points as follows: the different types of trajectories in H^2_κ, $\kappa < 0$ as a function of the parameter e_κ are the following:

$$\text{hyperbolic circle,} \quad 0 = e_\kappa,$$

$$\text{hyperbolic ellipses,} \quad 0 < e_\kappa < 1 - \sqrt{-\kappa}(J^2/k),$$

$$\text{hyperbolic horoellipse,} \quad 1 - \sqrt{-\kappa}(J^2/k) = e_\kappa,$$

$$\text{hyperbolic open conics,} \quad 1-\sqrt{-\kappa}(J^2/k) < e_\kappa < \infty.$$

Alternatively, the landmark values can also be given for the classification as a function of the total energy E,

$$\text{hyperbolic circle,} \quad E = -(1/2)(k^2/J^2 - \kappa J^2),$$

$$\text{hyperbolic ellipses,} \quad -(1/2)(k^2/J^2 - \kappa J^2) < E < -k\sqrt{-\kappa},$$

$$\text{hyperbolic horoellipse,} \quad E = -k\sqrt{-\kappa},$$

$$\text{hyperbolic open conics,} \quad -k\sqrt{-\kappa} < E < \infty.$$

Thus the behavior of the hyperbolic dynamics shows some important differences with respect to the Euclidean case. We postpone until the next section the establishment of the particular value of e_κ, or E, separating the open conics into parabolic and hyperbolic regimes, and we simply state that $e_\kappa = \sqrt{1-\kappa(L^4/k^2)}$, corresponding to $E=0$, gives an orbit which is a parabola in H^2. The value of e_κ, or the corresponding energy E, separating from parabolic to hyperbolic trajectories is a κ-dependent positive value to be determined; this will be done in the next section. When the parameter e_κ is greater than the upper value for parabolic orbits, then we will have hyperbolas in H^2 as orbits.

The remaining cases happen when $J > J_\infty$. For these values of J the equivalent potential is a decreasing function of r with no minimum at all, and hence the possible motions should have energies above E_∞; these would be always nonperiodic motions and open orbits. We will classify them into parabolas and hyperbolas in the next section.

V. CONICS ON SPACES OF CONSTANT CURVATURE

In this section we give a geometric description of conics in the three $\kappa > 0$, $\kappa = 0$, $\kappa < 0$, constant curvature spaces S^2_κ, E^2, H^2_κ, emphasizing those aspects relevant in relation with Kepler motion in these spaces. To stay within a reasonable extension limits we restrict to a mainly statement of facts presentation, which should either confirm the conjectures advanced in the dynamical part, or serve as a geometric foundation for them. The important thing is the perfect matching between the dynamical approach in Sec. IV and the results here.

As customary in this context, *lines* will mean the *geodesics* of the constant curvature space. The metric intrinsic *geometric* definition of conics, that can be applied to any two-dimensional (2D) space of constant curvature κ involves *focal elements*, i.e., either oriented points or cooriented lines. In any such space, and by definition.

An *ellipse/hyperbola* will be the set of points with a constant sum/difference $2a$ of distances r_1, r_2, to two fixed points F_1, F_2, called *foci* and separated a distance $2f$.

A *parabola* will be the set of points with a constant sum/difference 2α of distances r_1, $\tilde{r}_2$, to a fixed point F_1, called *focus*, and to a fixed cooriented line f_2, called *focal line*; the *oriented* distance 2φ between F_1 and f_2 plays here the role of focal separation.

An *ultraellipse/ultrahyperbola* will be the set of points with a constant sum/difference $2a$ of oriented distances $\tilde{r}_1$, $\tilde{r}_2$, to two fixed intersecting lines f_1, f_2, separated by an angle $2F$ and called *focal lines*.

In the generic case of constant curvature $\kappa \neq 0$ these three pairs of curves, each pair sharing the same focal elements, are the *generic* conics; Euclidean plane is *not generic* among the family of constant curvature spaces, thus some Euclidean properties of conics are very special and do not provide a good starting viewpoint to discuss the $\kappa \neq 0$ properties.

Further to generic conics, *particular distinguished conics* appear for instance when the focal separation vanishes ($f=0, \varphi=0, F=0$) and *limiting conics* when some focal elements go to infinity

(if possible at all); both particular and limiting conics can be obtained as suitable limits from the generic ones.

We first list some particular conics. When the focal separation vanishes $f=0$, the ellipse is a *circle* and the hyperbola is a pair of intersecting *lines*. No useful intuition about parabolas can be drawn from the nongeneric Euclidean case; a parabola with vanishing focal separation $\varphi=0$ is only a particular instance of parabola, to be named here *equiparabola*, but when $\kappa\neq 0$ there are other parabolas, with any positive or negative $\varphi\neq 0$, which are not equiparabolas. The main point is that general parabolas are *not* to be considered here as limiting conics, as usually done in E^2. An ultraellipse with focal angle $F=0$ is a *ultracircle* (an equidistant curve, the set of points equidistant from a fixed line), while an ultrahyperbola with $F=0$ is a pair of *lines*.

The three *generic types* of conics, as well as these *particular* conics with zero focal separation do exist in any space of constant curvature κ. Further to that, when the curvature is *negative*, there are new types of *limiting conics*, where either the foci or the focal lines may go to infinity.

A. Conics in geodesic polar coordinates in a space of curvature κ

Now let us describe conics in the three essentially different spaces S^2_κ, E^2, H^2_κ.

In the sphere S^2_κ, with $\kappa>0$ the situation is rather simple. First, as there are neither points nor lines at the infinity, there are no limiting cases in the sense they will appear in H^2_κ. Second, as there is a one-to-one correspondence (the usual polarity) between oriented points and co-oriented lines (North Pole versus Equator), with a constant distance $\pi/2\sqrt{\kappa}$ separating them, it follows that any focal element (either point or line) implies the existence of a polar focal element (line or point); thus any conic of one of the three given type pairs may be considered as a conic of any other prescribed type pair. And further, as the distance between two antipodal points is constant $\pi/\sqrt{\kappa}$, by changing a focus F_2 to its antipodal point $\overline{F_2}$ (which according to the definition is again a focus of the conic), an hyperbola with focus F_1, F_2, will be as well an ellipse with focus F_1, $\overline{F_2}$. A similar possibility exists for focal lines which may be changed to their antipodal lines, with coorientation changed. Thus all spherical conics can be seen as *spherical ellipses*, including the two particular zero focal separation cases, i.e., circles (spherical parallel circles) and pairs of lines (a pair of intersecting large circles in the sphere). For the purposes of getting a common view we may still think in three generic types, keeping in mind that all three coincide and there is complete freedom in understanding a given spherical conic as either an ellipse, or a parabola or a hyperbola (just as a geodesic circle can be seen at the same time as a geodesic circle, with center at O or as an equidistant curve to the polar of O); more on this will be said later.

In the Euclidean plane E^2 ultraellipses and ultrahyperbolas (with any focal angle F) are just pairs of parallel lines, in directions parallel to the two bisectors of the focal angle; in the standard algebraic classification of Euclidean conics these appear as degenerate conics. But when compared to S^2_κ or H^2_κ, another more important degeneracy happens in E^2: two families of parabolas with the same focus and any two parallel focal lines will coincide (because a pair of parallel lines are equidistant in E^2). This means that the *parabolic focal separation* between the focus and the focal line can be chosen arbitrarily for a fixed Euclidean parabola, which only determines its focus and the direction of the focal line. As a consequence parabolas are no longer generic conics in E^2. While parabolas have always some intermediate status between ellipses and hyperbolas, in the Euclidean case parabolas appear exclusively as limiting cases between ellipses and hyperbolas, and not as the full fledged species of conics they are in the generic $\kappa\neq 0$ case.

The hyperbolic case H^2_κ with *negative* constant curvature is richer. The limiting conics obtained from an ellipse/hyperbola through a point P when a focus stays fixed and the other goes to infinity are called *horoellipse/horohyperbola*. The limiting conics obtained from an ultraellipse/ultrahyperbola through a point P when a focal line stays fixed and the other goes to infinity are called *horoultraellipse/horoultrahyperbola*. These four types of conics are also limiting forms of parabolas, with either focus fixed and focal line going to infinity, or focal line fixed and focus going to infinity. In E^2 all these limiting conics collapse precisely to either Euclidean parabolas or pairs of lines.

There are more limiting conics in H^2_κ: the *horocycle*, obtained either from a circle through P

when its center goes to infinity, or from an ultracircle through P when the baseline goes to infinity, and the *osculating parabola*, the limit of a parabola when the focus goes to infinity along the fixed focal line.

In order to make contact with the results in the dynamical part, let us draw our attention precisely on the conics with a proper focus. From now on we completely disregard ultraellipses and ultrahyperbolas, which have two focal lines, and osculating parabolas, which have not a proper focus. We consider exclusively ellipses/hyperbolas and parabolas, as well as their limiting cases—horoellipses and horohyperbolas—and particular cases—circles, lines and equiparabolas corresponding to vanishing focal separations. All these conics have a proper focus, which we may place at the origin point, as well as another focal element, which may be another focus or a focal line. In either case the conics have as a symmetry axis the line joining the two foci or going through the focus and orthogonal to the focal line. To match with the familiar Euclidean expressions, we introduce polar coordinates in S^2_κ, E^2, H^2_κ, taking the origin at the fixed focus and the symmetry axis of the conic as the half-line $\phi=0$. With this choice, the common equation of the whole family of conics described above may be written in the form

$$T_\kappa(r) = \frac{D}{1 + e\cos\phi} \tag{7}$$

with D and e non-negative. This can be derived by trigonometric considerations from the definition of the conic in the space of constant curvature κ using the relations given in Ref. 44 and will be discussed elsewhere. This relation justifies the claim made in Sec. V: the orbits of the Kepler problem in either S^2_κ, E^2, H^2_κ, are conics with a focus at the origin of the potential. The dependence on the polar angle ϕ is exactly the same as in the Euclidean case and this may suggest to consider e as the non-Euclidean analog of the *eccentricity of the conic*, though when $\kappa\neq 0$ the link between the values of e and the *type* of the conic is not so direct as in E^2. We should mention that there are at least two other quantities keeping different properties of the Euclidean eccentricity, and no single quantity keeps all properties; in this paper we will only be concerned with e, and for brevity we shall refer to it as eccentricity.

For an ellipse/hyperbola with focal distance $2f$ and $2a$ as the sum/difference of distances to the focus, and for a parabola with focal separation 2φ and 2α as sum/difference of distances to focus and focal line, the eccentricities turn out to be

$$e_{\text{ell/hyp}} = \frac{S_\kappa(2f)}{S_\kappa(2a)}, \quad e_{\text{par}} = \frac{C_\kappa(2\varphi)}{C_\kappa(2\alpha)}$$

reducing in the Euclidean $\kappa=0$ case to the well known f/a for ellipses/hyperbolas and 1 for parabolas.

In the polar coordinate system (r,ϕ), when $\kappa>0$ or $\kappa=0$, the range of values of $T_\kappa(r)$ is the whole real line (completed with ∞), but when $\kappa<0$, the values of $T_\kappa(r)$ are confined to the interval $[0, 1/\sqrt{-\kappa}]$, or to $[-1/\sqrt{-\kappa}, 1/\sqrt{-\kappa}]$ if negative values for r are allowed along the opposite semiaxis according to the usual practice.

Now, for the conic (7) the minimum value for r happens when $\phi=0$. This means that D and e are independent constants when $\kappa\geqslant 0$ but must fulfill the inequality $0\leqslant D/(1+e)<1/\sqrt{-\kappa}$ when $\kappa<0$.

Notice that in (7) the periastron of the orbit is placed on the semiaxis $\phi=0$ at $r=r_{\text{per}}$, and thus r_{per} is related to D and e by

$$T_\kappa(r_{\text{per}}) = \frac{D}{1+e}$$

which for any value of κ has always a unique root for r_{per}. Next, let us look for the intersection of the conic with the line orthogonal to the conic symmetry axis through the focus, which corresponds to $\phi=\pi/2$. The distance between this intersection point and the focus is traditionally called

semilatus rectum of the conic (in the Euclidean case) and will be denoted by p. For $\kappa=0$ all Euclidean conics (except the limiting double straight line with $p=\infty$) intersect this semilatus line. For any $\kappa\neq 0$, p would satisfy

$$T_\kappa(p) = D,$$

but there is a difference between the cases with $\kappa\geqslant 0$ or $\kappa\leqslant 0$. While for $\kappa>0$, any D will determine a unique p, when $\kappa<0$ this equation will define a real semilatus rectum only when $D<1/\sqrt{-\kappa}$, the semilatus rectum will be formally infinite when $D=1/\sqrt{-\kappa}$ and will not exist at all when $D>1/\sqrt{-\kappa}$. This means that in the case of the hyperbolic plane H^2_κ the family of conics we are considering includes conics intersecting the semilatus line at a proper point, only at infinity or not intersecting at all. We have arrived at the following situation: all conics with given fixed focus and symmetry axis intersect this line in S^2_κ, exactly one does not intersect in E^2, and an infinite number of them do not intersect in H^2_κ.

Thus, when $\kappa\geqslant 0$ the equation of the complete family of conics we are considering is

$$T_\kappa(r) = \frac{T_\kappa(p)}{1 + e\cos\phi} \tag{8}$$

but in the negative curvature case $\kappa<0$, there will be some conics—precisely those with $D>1/\sqrt{-\kappa}$—not described under (8). To cater for these cases it will prove useful to introduce another real distance $\tilde{p}$, complementary to the ideal semilatus rectum, related to D by

$$\frac{1}{(-\kappa)T_\kappa(\tilde{p})} = D$$

and in terms of this choice, when $\kappa<0$ the equation of the complete family of conics we are considering is given by one of the two mutually exclusive possibilities,

$$T_\kappa(r) = \frac{T_\kappa(p)}{1 + e\cos\phi}, \quad T_\kappa(r) = \frac{1}{(-\kappa)T_\kappa(\tilde{p})(1 + e\cos\phi)}, \tag{9}$$

where the ranges are $0\leqslant p<\infty$ and $\infty>\tilde{p}\geqslant 0$, respectively. The conic

$$T_\kappa(r) = \frac{1}{\sqrt{-\kappa}(1 + e\cos\phi)} \tag{10}$$

is the common limit $p\to\infty$ and $\tilde{p}\to\infty$ of (9). Notice the two expressions (9) can be used as well when $\kappa>0$ but then each of the two alternatives covers actually all cases, and are then redundant. Only the first possibility in (9) has a sensible Euclidean limit because the $\kappa\to 0$ limit of the $\tilde{p}$ family gives a straight line at the infinity of the Euclidean plane; thus the family $\tilde{p}$ as a set of conics different from the p family is specific to the hyperbolic plane.

Now the only remaining problem is to link the values of the two parameters D and e to the type the conic belongs. When is such a conic an ellipse, a parabola or a hyperbola according to their definitions in the space of curvature κ? When is it a particular conic, either a circle, a equiparabola or a line? And finally, only for the hyperbolic plane H^2_κ, when is it a limiting horoellipse or horohyperbola?

In the Euclidean plane the answer is well known and easy, the conic type depends *only* on e, and not on p. This is *not so* when $\kappa\neq 0$.

B. Conics on the sphere S^2_κ

A given conic in S^2_κ will have a unique and well defined parameter e in (8). But labelling it as an ellipse, or parabola or hyperbola, requires to choose a particular set of two focal elements, and a $\pm$ sign to decide between the sum or difference in the definitions. Unlike on H^2_κ where these choices are unique, for the sphere they may be made in several ways. By means of suitable

choices, *any spherical conic with any* $0 \leqslant e \leqslant \infty$ may be considered as an ellipse, as a parabola or as a hyperbola. This is an unavoidable consequence of the definitions, which are clearly natural ones for nonzero curvature.

If we want to classify conics in S^2 into three *disjoint* species, this would require adopting an additional convention (somehow bypassing the definition), which may be chosen in several reasonable ways, but which nevertheless remains as a convention.

A possibility would be to class spherical ellipses with $0<e<1$ as ellipses, those with $e=1$ as parabolas, and those with $e>1$ as hyperbolas. This is the convention adopted by Higgs[5] who formulated it according to the property of not crossing, touching or crossing the equator, which can be easily shown to be equivalent to the requirement $e<1$, $e=1$, or $e>1$, respectively. Another different convention follows from the fact that any ellipse/hyperbola with focus F_1, F_2 (and focal separation $2f$) can also be considered as a hyperbola/ellipse with focus $F_1, \overline{F_2}$ [and focal separation $2\tilde{f}=2(\pi/2\sqrt{\kappa}-f)$]. The sum of the two focal half-separations f and $\tilde{f}$ is $\pi/2\sqrt{\kappa}$, this is, the length of a quadrant on the sphere. Thus, we may consider as ellipses exclusively those spherical ellipses with a value of the focal separation $2f$ less than a quadrant, that is, $2f<\pi/2\sqrt{\kappa}$, and as hyperbolas exclusively those spherical ellipses with a value of $2f$ greater than a quadrant, that is, $2f>\pi/2\sqrt{\kappa}$. Within this convention, and if we want artificially to enforce nonredundancy, the name parabolas will only be left for the spherical ellipses with precisely $2f=\pi/2\sqrt{\kappa}$, which in our previous nomenclature were called equiparabola (as $2f=\pi/2\sqrt{\kappa}$ between two focus means that one focus will be incident with the polar of the other focus, which is the focal line). In this view ellipses are completely contained in the half-sphere with center at the ellipse center, while hyperbolas will go through the boundary of the half-sphere centered at the hyperbola center.

C. Conics on the hyperbolic plane H^2_κ

The case of the hyperbolic plane H^2_κ is different and there is no conventionality in it. In the following paragraphs we are implicitly assuming $\kappa<0$.

When is the conic (9) an *ellipse*? In addition to the actual vertex at the point of closest approach to the focus, placed on the $\phi=0$ axis, ellipses will have another vertex, placed on the $\phi=\pi$ semiaxis with a *positive* value for $T_\kappa(r_{\text{apo}})$ which anyhow should belong to the interval $[T_\kappa(r_{\text{per}}), 1/\sqrt{-\kappa}]$. The lower bound in this interval corresponds to circular orbits while the upper places the apoastron at the infinity, and the ellipse will go to a *horoellipse*. It is easy to conclude that the positivity condition requires e to be in the interval $[0, 1]$ and then $T_\kappa(r_{\text{apo}}) \in [T_\kappa(r_{\text{peri}}), 1/\sqrt{-\kappa}]$ only happens within the first alternative in (9), provided that the eccentricities lie in the interval

$$0 < e_{\text{ell}} < 1 - \sqrt{-\kappa}\,T_\kappa(p).$$

Notice this interval *depends on p* and for any $p \neq 0$ is strictly smaller than the Euclidean one, which is recovered of course, when $\kappa \to 0$. The lower bound for e corresponds to circular orbits, while the upper bound is the limiting value corresponding to *horoellipses*,

$$e_{\text{cir}} = 0, \quad e_{\text{horoell}} = 1 - \sqrt{-\kappa}\,T_\kappa(p).$$

When will the conic (9) be a *hyperbola*? In this case, in addition to the vertex at the periastron, the conic will have another vertex point (on the other hyperbola branch, thus not actually on the physical orbit) on the $\phi=0$ semiaxis, which will appear on the equation as a *negative* value for $T_\kappa(r_{\text{apo}})$ on the $\phi=\pi$ semiaxis. Hence, the values of $T_\kappa(r)$ for $\phi=\pi$ must belong to the interval $[-1/\sqrt{-\kappa}, -T_\kappa(r_{\text{per}})]$, with the lower value corresponding to *horohyperbolas*, and the upper value to lines. By using the same strategy, it is easy to conclude that the negativity condition requires $e \in [1, \infty]$, and then $T_\kappa(r_{\text{apo}})$ may lie in the required interval in either of the two alternatives (9), with e parameters, respectively, in the intervals

$$1+\sqrt{-\kappa}T_\kappa(p)<e_{\text{hyp}},\quad 1+\frac{1}{\sqrt{-\kappa}T_k(\tilde{p})}<e_{\text{hyp}}.$$

Notice both conditions lead to a common limit when $p,\tilde{p}\to\infty$, namely, $2<e_{\text{hyperbolas}}$ for the conics (10). Here particular and limiting conics correspond to

$$e_{\text{horohyp}}=1+\sqrt{-\kappa}T_\kappa(p),\quad e_{\text{horohyp}}=1+\frac{1}{\sqrt{-\kappa}T_\kappa(\tilde{p})},\quad e_{\text{lines}}=\infty.$$

Once we have characterized the intervals of eccentricity for ellipses and hyperbolas, the remaining gap correspond to parabolas. Thus, within the first family,

$$1-\sqrt{-\kappa}T_\kappa(p)<e_{\text{par}}<1+\sqrt{-\kappa}T_\kappa(p),$$

and within the second,

$$1-\frac{1}{\sqrt{-\kappa}T_\kappa(\tilde{p})}<e_{\text{par}}.$$

The particular parabolas with zero focal separation, this is, the equiparabolas, corresponds to the values,

$$e_{\text{equipar}}=1/C_k(p)=\sqrt{1+\kappa T_\kappa^2(p)},\quad e_{\text{equipar}}=C_k(\tilde{p})=1/\sqrt{1+\kappa T_\kappa^2(\tilde{p})},$$

and are different from the parabolas with $e=1$.

This way we get the following result. Conics (9) in the hyperbolic plane H^2, with a fixed value of p may be either ellipses, parabolas or hyperbolas, according to the value of their eccentricity as follows:

$$\text{circle},\quad e_{\text{cir}}=0,$$

$$\text{ellipses},\quad 0<e_{\text{ell}}<1-\sqrt{-\kappa}T_\kappa(p),$$

$$\text{horoellipse},\quad e_{\text{horoell}}=1-\sqrt{-\kappa}T_\kappa(p),$$

$$\text{parabolas},\quad 1-\sqrt{-\kappa}T_\kappa(p)<e_{\text{par}}<1+\sqrt{-\kappa}T_\kappa(p),$$

$$\text{horohyperbolas},\quad e_{\text{horohyp}}=1+\sqrt{-\kappa}T_\kappa(p),$$

$$\text{hyperbolas},\quad 1+\sqrt{-\kappa}T_\kappa(p)<e_{\text{hyp}}<\infty,$$

and conics (9) with a fixed $\tilde{p}$ may be only parabolas or hyperbolas,

$$1-\frac{1}{\sqrt{-\kappa}T_\kappa(\tilde{p})}<e_{\text{par}}<1+\frac{1}{\sqrt{-\kappa}T_\kappa(\tilde{p})}<e_{\text{hyp}}<\infty.$$

The most remarkable property is the existence, for a fixed value of the semilatus rectum p, of a full interval of values for eccentricity corresponding to parabolas, including always two special values, $e=1/C_k(p)$ and $e=1$; in the Euclidean limit $\kappa\to 0$ this interval collapses to the single value $e_{\text{par}}=1$, and there is a single Euclidean parabola for a given p.

Now let us consider the complete family of conics corresponding to trajectories with a given *periastron* distance, say r_{per}; these would correspond to the trajectories of a particle launched orthogonally to the radial direction from a point at distance r_{per} from the potential origin and with a given velocity. The corresponding pattern for the Kepler problem in the Euclidean case is well

known, a circle, a family of ellipses of increasing eccentricity $0<e<1$, a separating parabola, a family of hyperbolas of increasing eccentricity $1<e<\infty$ and finally a limiting straight line corresponding to infinite velocity. How about the analog of this pattern in the nonzero curvature case?

First we require all conics will have a periastron at r_{per}. Within the two families the relation between p or $\tilde{p}$ with r_{per} is given by

$$T_\kappa(r_{\mathrm{per}})=\frac{T_\kappa(p)}{1+e},\quad T_\kappa(r_{\mathrm{per}})=\frac{1}{(-\kappa)T_\kappa(\tilde{p})(1+e)},$$

and, using these expressions in the classification stated above, we get the landmark values of p or $\tilde{p}$ corresponding to the different types of conic,

$$T_\kappa(r_{\mathrm{per}})<T_\kappa(p_{\mathrm{ell}})<\frac{2T_\kappa(r_{\mathrm{per}})}{1+\sqrt{-\kappa}T_\kappa(r_{\mathrm{per}})}<T_\kappa(p_{\mathrm{par}})<\frac{2T_\kappa(r_{\mathrm{per}})}{1-\sqrt{-\kappa}T_\kappa(r_{\mathrm{per}})}<T_\kappa(p_{\mathrm{hyp}}),$$

which in the Euclidean limit, with $\kappa=0$ and $T_0(x)=x$, reduces to the well known

$$r_{\mathrm{per}}<p_{\mathrm{ell}}<2r_{\mathrm{per}}=p_{\mathrm{par}}=2r_{\mathrm{per}}<p_{\mathrm{hyp}},\quad \text{when } \kappa=0.$$

For the hyperbolic $\tilde{p}$ family, which has no Euclidean limit, we have

$$T_\kappa(\tilde{p}_{\mathrm{hyp}})<\frac{1-\sqrt{-\kappa}T_\kappa(r_{\mathrm{per}})}{(-2\kappa)T_\kappa(r_{\mathrm{per}})}<T_\kappa(\tilde{p}_{\mathrm{par}}).$$

Figures 6(a) and 6(b) represent a set of Kepler orbits in the hyperbolic plane H^2.

VI. FINAL COMMENTS AND OUTLOOK

We have solved the Kepler problem on the three spaces of constant curvature. As we have stated in the introduction, one of the fundamental characteristic of this approach is the use of the curvature κ as a parameter. In this way, all the κ-dependent properties that we have obtained reduce to the appropriate property for the system on the sphere S^2, or on the hyperbolic plane H^2, when particularized for $\kappa>0$, or $\kappa<0$, respectively; in addition, the Euclidean case arises as the very particular (but important) case $\kappa=0$. So, we can summarize this situation pointing out two important facts.

(1) The Kepler problem is not a specific or special characteristic of the Euclidean space but it is well defined in all the three spaces of constant curvature.
(2) There are not three different Kepler problems but only one that is defined, at the same time, in three different manifolds.

Of course, since the three manifolds are geometrically different, many dynamical properties show differences according to the characteristics of the manifolds; nevertheless, the important point is that there is only one theory that is simultaneously valid for the three manifolds and for any value of the curvature. We illustrate this situation recalling the following two important results:

(1) the equation of Binet remains true in the three cases;
(2) the orbits are conics in the three cases.

It is well known that the classical Euclidean Kepler problem is one of the systems endowed with more interesting properties. Therefore, it would be interesting to study all of them, in the general non-Euclidean $\kappa\neq 0$ case; as an example, we have made use, in Sec. IV, of two constants of motion, $I_3(\kappa)$ and $I_4(\kappa)$, that represent the κ-dependent version of the Runge–Lenz vector. The Runge–Lenz vector plays a very important role in the Euclidean case, so it is natural to suppose that the same situation will be true for the case of the general curved system. In fact, we think that, as the Euclidean system is just a very particular case of a much more general system, all the

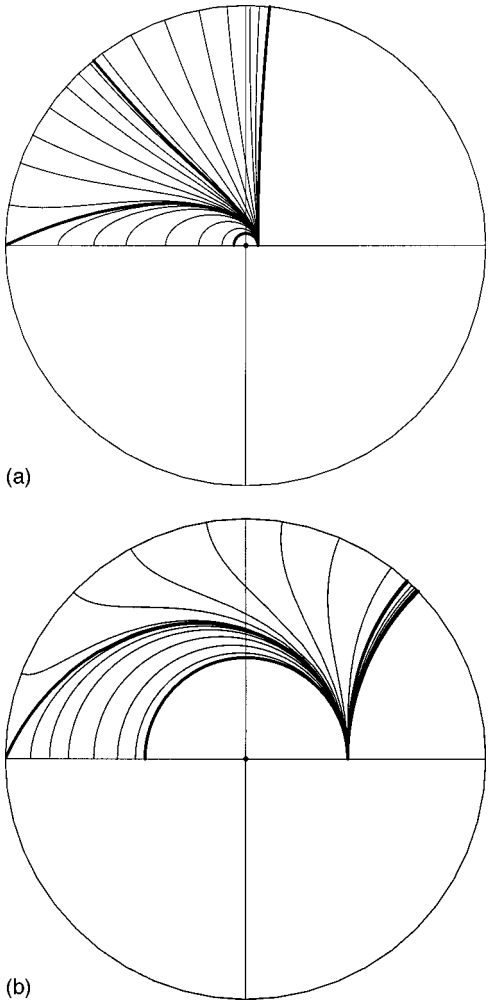

FIG. 6. (A) and (B) A set of Kepler orbits with a fixed periastron distance, depicted in the conformal Poincare disk model of hyperbolic plane, for small r_{per} (A) and large r_{per} (B). The potential center is at the origin, which is a focus of the conics. Thick lines represent particular and limiting conics, circle, horoellipse, horohyperbola, and straight line. A suitable selection (with the other focal elements chosen as to make the diagram clear) of ellipses, parabolas, and hyperbolas are represented as thin lines in each of the three ranges determined by the previous conics. For ellipses and hyperbolas the other focus (not marked) is on the horizontal line; for parabolas the focal line is perpendicular to this horizontal line. The semilatus rectum of the conic lies on the vertical straight line through the origin; notice in (A) only some hyperbolas do not intersect this line, while in (B) conics which do not intersect the semilatus line include all hyperbolas as well as many parabolas; these are the two generic behaviors, as explained in the text.

Euclidean characteristics that are obtained and discussed in the books of theoretical mechanics, must admit a κ-dependent deformed version appropriate for the general "curved" system. We think that these questions are open problems that must be investigated. We also note that in all of this paper we have only dealt with the two-dimensional case since we assumed that it arises from a reduction of the three-dimensional Kepler problem on S^3 and H^3; this dimensional reduction is worthy of a further study.

Finally, the analysis of the orbits has led us, in a natural way, to the theory of conics on spaces of constant curvature. Notice that, although Secs. III and IV were mainly concerned with dynamical questions, Sec. V was written emphasizing its geometrical character; in fact, it can be considered by itself and independently of the other preceding sections. It is clear that the theory of conics on spaces of constant curvature is a geometrical matter of great importance deserving a deeper study that we hope to present elsewhere. On the one hand, there exist some general points and

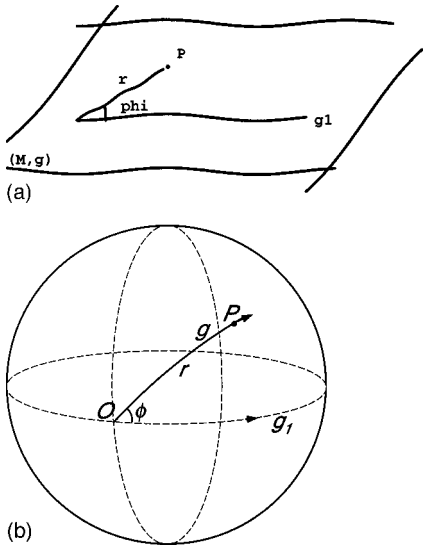

FIG. 7. Polar geodesic coordinates in a two-dimensional Riemannian space (M,g) (A) and in the sphere S^2 (B).

basic properties that, although perfectly known and clearly stated in the Euclidean plane, remain to be studied in the case of spaces of constant curvature; on the other hand, we have already obtained some particular points as, for example, the existence of several different parabolas in the hyperbolic plane, or the possibility of some different alternative ways of defining the eccentricity for a conic in a $\kappa \neq 0$ space, which are really noteworthy. These geometrical questions are also open problems to be investigated.

APPENDIX: POLAR GEODESIC COORDINATES

A two-dimensional manifold M can be described by using different coordinate systems. If we consider it as an imbedded submanifold of $\mathbb{R}^3$, then the points of M can be characterized by the three external coordinates, as (x,y,z) or (r,ϕ,θ), plus an additional constraint relation. Nevertheless, in differential geometric terms, a more appropriate approach is to develop the study by using two-dimensional systems of coordinates adapted to M.

On any general two-dimensional Riemannian space, not necessarily of constant curvature, there are two distinguished types of local coordinate systems, "geodesic parallel" and "geodesic polar" coordinates. They reduce to the familiar Cartesian and polar coordinates on the Euclidean plane (see Refs. 16 and 42) and both are based on an origin point O and an oriented geodesic g_1 through O.

For any point P in some suitable neighborhood of O, there is a unique geodesic g joining P with O. The (geodesic) polar coordinates (r,ϕ) of P, relative to the origin O and the positive geodesic ray of g_1, are the (positive) distance r between P and O measured along g, and the angle ϕ between g and the positive ray g_1, measured around O (Fig. 7). These coordinates are defined in a neighborhood of O not extending beyond the cut locus of O; polar coordinates are singular at O, and ϕ is discontinuous on the positive ray of g_1.

In the case of M being a space of constant curvature κ, the expression for the differential element of distance ds^2 is given by

$$ds_\kappa^2 = dr^2 + S_\kappa^2(r)d\phi^2,$$

so that we get $ds^2 = dr^2 + r^2\, d\phi^2$ for the particular $\kappa = 0$ Euclidean case.

(Received 2 December 2004; accepted 26 January 2005; published online 13 April 2005)

The first aim of this paper is to extend the Skinner–Rusk formalism on classical mechanics for first-order field theories. The second is to generalize the definition and properties of the evolution *K*-operator on classical mechanics for first-order field theories using in both cases Günther's formalism (*k*-symplectic formalism).
 [DOI: 10.1063/1.1876872]

I. INTRODUCTION

The Skinner–Rusk formalism [1] was developed in order to give a geometrical unified formalism for describing mechanical systems. It incorporates all the characteristics of Lagrangian and Hamiltonian descriptions of these systems (including dynamical equations and solutions, constraints, Legendre map, evolution operators, equivalence, etc.).

This formalism has been generalized to time-dependent mechanical systems,[2] and also to the multisymplectic description of first-order field theories.[3,4]

The first aim of this paper is to extend this unified framework to Günther's description of first-order classical field theories,[5] and show how this description comprises the main features of the Lagrangian and Hamiltonian formalisms, both for the regular and singular cases.

Let us point out that Günther's formalism should be also called *k*-symplectic formalism because the base of this formalism are the standard polysymplectic manifolds, introduced by Günther in Ref. 5, which coincide with the *k*-symplectic manifolds introduced by Awane in Refs. 6–8. Günther's paper gives a geometric Hamiltonian formalism for field theories. The crucial device is the introduction of a vector-valued generalization of a symplectic form, called a polysymplectic form. One of the advantages of this formalism is that only the tangent and cotangent bundle of a manifold are required to develop it. In Ref. 9 Günther's formalism was revised and clarified. It was shown that the polysymplectic structures used by Günther to develop his formalism could be replaced by the *k*-symplectic structures defined by Awane.[6–8] So this formalism could be called *k*-symplectic formalism.

The *k*-symplectic formalism is the generalization to field theories of the standard symplectic formalism in mechanics, which is the geometric framework for describing autonomous dynamical systems. In this sense, the *k*-symplectic formalism is used to give a geometric description of

[a)]Electronic mail: angelmrey@edu.xunta.es

[c)]Electronic mail: modesto@zmat.usc.es

certain kind of field theories: in a local description, those whose Lagrangian does not depend on the coordinates in the basis (in many of them, the space–time coordinates); that is, it is only valid for Lagrangian $L(q^i, v_A^i)$ and Hamiltonian $H(q^i, p_i^A)$ that depends on the field coordinates q^i and on the partial derivatives of the field v_A^i. A natural extension of this formalism is the so-called *k*-cosymplectic formalism, which is the generalization to field theories of the cosymplectic formalism which describes geometrically nonautonomous mechanical systems (this description can be found in Refs. 10 and 11). It is devoted to describing field theories involving the independent parameters $(t^1, \ldots, t^k)$ on the Lagrangian $L(t^A, q^i, v_A^i)$ and on the Hamiltonian $H(t^A, q^i, p_i^A)$.

It is interesting to remark here that the polysymplectic formalism developed by Sardanashvily *et al.*,[12–14] based on a vector valued form on some associated fiber bundle, is a different description of classical field theories of first order than the polysymplectic formalism proposed by Günther. (See also Ref. 15 for more details on the polysymplectic formalism.) In addition, we must remark that the soldering form on the linear frames bundles is a polysymplectic form, and its study and applications to field theory constitute the *n*-symplectic geometry developed by Norris in Refs. 16–20.

The so-called *time-evolution K-operator* in mechanics (also known by some authors as the *relative Hamiltonian vector field* [21]) is a tool which has mainly been developed in order to study the Lagrangian and Hamiltonian formalisms for singular mechanical systems and their equivalence. This operator was introduced in Refs. 22 and 23, and later it was defined geometrically in two different but equivalent ways [24,25] for autonomous dynamical systems. In Ref. 25, a further different geometric construction is given, using a canonical map introduced by Tulczyjew.[26] The *K*-operator relates the sets of solutions of the Euler–Lagrange equations and the Hamilton equations; it also relates constraints on the Lagrangian and Hamiltonian sides, and allows us to obtain a complete classification of constraints;[22] as well as Lagrangian Noether infinitesimal symmetries from a Hamiltonian generator of symmetries.[21,27–29] It is also used for studying Lagrangian systems whose Legendre map has generic singularities.[21,30]

The second aim of this paper is to generalize the definition and properties of this operator for first-order field theories in order to describe the relationship between the Lagrangian and Hamiltonian *k*-symplectic formalisms. In particular we extend the results in Ref. 25, showing how to obtain the solutions of Lagrangian and Hamiltonian field equations by means of this operator. The same idea has been developed in Ref. 31 but using the multisymplectic description of classical field theories.

The organization of the paper is as follows: Section II–IV are devoted to reviewing the main features of Günther's formalism or *k*-symplectic formalism [5,9] of Lagrangian and Hamiltonian field theories.

In particular, in Sec. II the field theoretic phase space is introduced as the Whitney sum $(T_k^1)^*Q = T^*Q \overset{k}{\oplus} \ldots \oplus T^*Q$ of *k*-copies of the cotangent bundle T^*Q of a manifold Q. This space is the canonical example of a polysymplectic manifold. A particular case of polysymplectic manifolds are the *k*-symplectic manifolds (see Refs. 3–5, 8, and 9) which coincide with the standard polysymplectic manifolds.

The field theoretic state space is introduced as the Whitney sum $T_k^1Q = TQ \overset{k}{\oplus} \ldots \oplus TQ$ of *k*-copies of the tangent bundle TQ of a manifold Q. This manifold has a canonical *k*-tangent structure defined by *k* tensor fields of type (1, 1) satisfying certain algebraic properties. The *k*-tangent manifolds were introduced in de León *et al.*,[32,33] and they generalize the tangent manifolds (see Refs. 34–38).

Section III is devoted to giving a geometric interpretation of the second-order partial differential equations. Here we show that these equations can be characterized by using the canonical *k*-tangent structure of T_k^1Q, which generalizes the case of classical mechanics.

The Hamiltonian and Lagrangian formalisms are developed in Sec. IV. Lagrangian formalism is developed using the canonical *k*-tangent structure of T_k^1Q, or the Legendre transformation as in Günther.[5]

In Sec. V we develop the unified formalism for field theories, which is based on the use of the Whitney sum $T^1_kQ\oplus_Q(T^1_k)^*Q$ of T^1_kQ and $(T^1_k)^*Q$. There are canonical presymplectic forms on it (the pull-back of the canonical symplectic form on each T^*Q) and a natural coupling function which is defined by the contraction between vectors and covectors. Then, given a Lagrangian $L\in C^\infty(T^1_kQ)$ we can state a field equation on $T^1_kQ\oplus_Q(T^1_k)^*Q$. This equation has solution only on a submanifold M_L, which is the graph of the Legendre map. Then we prove that if $\mathbf{Z}=(Z_1,\ldots,Z_k)$ is an integrable k-vector field, solution to this equation and tangent to M_L, then the projection onto the first factor T^1_kQ of the integral sections of $\mathbf{Z}$ are solutions of the Euler–Lagrange field equations. If L is regular the converse also holds. Furthermore, we establish the relationship between $\mathbf{Z}$ and the Hamiltonian and the Lagrangian k-vector fields of the k-symplectic formalism, $\mathbf{X_H}$ and $\mathbf{X_L}$.

In Sec. VI we review the definition and the main properties of the evolution operator K for autonomous mechanics. Next we define the field operators which, as a consequence of the field equations on the k-symplectic formalism, are given as a k-vector field along the Legendre transformation FL, associated to the Lagrangian $L:T^1_kQ\to\mathbb{R}$, satisfying certain properties. Finally we finish with similar results for field theories to those obtained in Refs. 25 and 31.

In a forthcoming paper we shall extend the results of this paper to the k-cosymplectic formalism.[10,11]

Manifolds are real, paracompact, connected and C^∞. Maps are C^∞. Sum over crossed repeated indices is understood.

II. GEOMETRIC FRAMEWORK

A. The cotangent bundle of k^1-covelocities of a manifold

Let Q be a differentiable manifold of dimension n and $\tau^*:T^*Q\to Q$ its cotangent bundle. Let us denote by $(T^1_k)^*Q=T^*Q\overset{k}{\oplus}\ldots\oplus T^*Q$ the Whitney sum of k copies of T^*Q, with projection map $\tau^*_Q:(T^1_k)^*Q\to Q$, $\tau^*_Q(\alpha^1_q,\ldots,\alpha^k_q)=q$, for every $(\alpha^1_q,\ldots,\alpha^k_q)\in(T^1_k)^*Q$.

$(T^1_k)^*Q$ can be canonically identified with the vector bundle $J^1(Q,\mathbb{R}^k)_0$ of k^1-covelocities of the manifold Q, that is the vector bundle of 1-jets of maps $\sigma:Q\to\mathbb{R}^k$ with target at $0\in\mathbb{R}^k$ and projection map $\tau^*_Q:J^1(Q,\mathbb{R}^k)_0\to Q$, $\tau^*_Q(j^1_{q,0}\sigma)=q$, say,

$$J^1(Q,\mathbb{R}^k)_0\equiv T^*Q\overset{k}{\oplus}\ldots\oplus T^*Q,$$

$$j^1_{q,0}\sigma\equiv(\mathrm{d}\sigma^1(q),\ldots,\mathrm{d}\sigma^k(q)),$$

where $\sigma^A=\pi^A\circ\sigma:Q\to\mathbb{R}$ is the Ath component of σ, and $\pi^A:\mathbb{R}^k\to\mathbb{R}$ is the canonical projection $1\leqslant A\leqslant k$. For this reason to $(T^1_k)^*Q$ is also called *the bundle of k^1-covelocities of the manifold Q*.

If (q^i) are local coordinates on $U\subseteq Q$, then the induced local coordinates (q^i,p_i), $1\leqslant i\leqslant n$, on $T^*U=(\tau^*)^{-1}(U)$, are given by

$$q^i(\alpha_q)=q^i(q),\quad p_i(\alpha_q)=\alpha_q\left(\left.\frac{\partial}{\partial q^i}\right|_q\right),\quad \alpha_q\in T^*Q,$$

and the induced local coordinates (q^i,p^A_i), $1\leqslant i\leqslant n$, $1\leqslant A\leqslant k$, on $(T^1_k)^*U=(\tau^*_Q)^{-1}(U)$ are given by

$$q^i(\alpha^1_q,\ldots,\alpha^k_q)=q^i(q),\quad p^A_i(\alpha^1_q,\ldots,\alpha^k_q)=\alpha^A_q\left(\left.\frac{\partial}{\partial q^i}\right|_q\right).$$

Let us denote by $\{r_1,\ldots,r_k\}$ the canonical basis of $\mathbb{R}^k$.

Definition 2.1 (Günther [5]): A closed nondegenerate $\mathbb{R}^k$-valued 2-form,

$$\overline{\omega}=\sum_{A=1}^{k}\omega_A\otimes r_A$$

on a manifold M of dimension N is called a polysymplectic form. *The pair* $(M,\overline{\omega})$ *is a* polysymplectic manifold.

The manifold $(T^1_k)^*Q$ is endowed with a *canonical polysymplectic structure*. This canonical structure $\overline{\omega}=\Sigma_{A=1}^{k}(\omega_0)_A\otimes r_A$, on $(T^1_k)^*Q$ is defined by

$$(\omega_0)_A=(\tau_A^*)^*(\omega_0),\quad 1\leqslant A\leqslant k,$$

where $\tau_A^*:(T^1_k)^*Q\to T^*Q$ is the projection on the A^{th}-copy T^*Q of $(T^1_k)^*Q$, and $\omega_0=-\mathrm{d}\theta_0$ is the canonical symplectic structure of T^*Q, θ_0 being the Liouville 1-form defined by

$$\theta_0(\alpha_q)(\tilde{X}_{\alpha_q})=\alpha_q((\tau^*)_*(\alpha_q)(\tilde{X}_{\alpha_q})),\quad \alpha_q\in T^*Q,\quad \tilde{X}_{\alpha_q}\in T_{\alpha_q}(T^*Q).$$

One can also define the 2-forms $(\omega_0)_A$ by $(\omega_0)_A=-d(\theta_0)_A$ where $(\theta_0)_A=(\tau_A^*)^*\theta_0$.

Thus the Liouville 1-form and the canonical symplectic structure on T^*Q are locally given by

$$\theta_0=p_i\,\mathrm{d}q^i,\quad \omega_0=-\,\mathrm{d}\theta_0=\mathrm{d}q^i\wedge\mathrm{d}p_i,$$

and the canonical polysymplectic structure $((\omega_0)_1,\ldots,(\omega_0)_k)$ on $(T^1_k)^*Q$ is locally given by

$$(\omega_0)_A=-\,d(\theta_0)_A=-\,d(p_i^A\,\mathrm{d}q^i)=\mathrm{d}q^i\wedge\mathrm{d}p_i^A. \tag{1}$$

Definition 2.2 (Günther [5]): A polysymplectic form $\overline{\omega}$ *on a manifold M is called standard iff for every point of M there exists a local coordinate system such that* ω_A *is written locally as in (1).*

So the canonical polysymplectic form $\overline{\omega}$ on $(T^1_k)^*Q$ is standard.

Remark 2.1: The *k*-symplectic manifolds were introduced in Refs. 6–8 and they coincide with the *standard polysymplectic manifolds*, as we now shall show.

Definition 2.3 (Awane [6]): A k-symplectic structure on a manifold M of dimension $N=n+kn$ *is a family* $(\omega_A,V;\ 1\leqslant A\leqslant k)$, *where each* ω_A *is a closed* 2*-form and V is an integrable nk-dimensional distribution on M such that*

$$\text{(i) } \omega_{A_{|V\times V}}=0,\quad \text{(ii) } \cap_{A=1}^{k}\ker\omega_A=\{0\}.$$

In this case (M,ω_A,V) *is called a k-symplectic manifold.*

Theorem 2.1 (Awane [6]): *Let* $(\omega_A,V;\ 1\leqslant A\leqslant k)$ *be a k-symplectic structure on M. About every point of M we can find a local coordinate system* (q^i,p_i^A), $1\leqslant i\leqslant n$, $1\leqslant A\leqslant k$, *such that*

$$\omega_A=\mathrm{d}q^i\wedge\mathrm{d}p_i^A,\quad 1\leqslant A\leqslant k. \tag{2}$$

The canonical model of *k*-symplectic manifolds is also $(T^1_k)^*Q$ and the canonical *k*-symplectic structure $(\omega_A,V;\ 1\leqslant A\leqslant k)$, on $(T^1_k)^*Q$ is given by

$$\omega_A=(\omega_0)_A=(\tau_A^*)^*(\omega_0),\quad V(j^1_{q,0}\sigma)=\ker(\tau_Q^*)_*(j^1_{q,0}\sigma).$$

Therefore, the 2-forms of the canonical polysymplectic structure and the canonical *k*-symplectic structure on $(T^1_k)^*Q$ coincide.

From (2) we know that the standard polysymplectic structures and the *k*-symplectic structures coincide. Indeed, if $\overline{\omega}=\Sigma_{A=1}^{k}\omega_A\otimes r_A$ is a standard polysymplectic structure on *M*, given a local adapted coordinate system (q^i,p_i^A) we can define, locally, the distribution *V*, of dimension *nk*, by $\mathrm{d}q^1=\cdots=\mathrm{d}q^n=0$. Then, $(\omega_1,\ldots,\omega_k,V)$ is a *k*-symplectic structure on *M*.

Conversely if $(\omega_1,\ldots,\omega_k,V)$ is a *k*-symplectic structure on *M* then $\overline{\omega}=\Sigma_{A=1}^{k}\omega_A\otimes r_A$ is a standard polysymplectic structure on *M*, because it is trivially standard and is nondegenerate as a consequence of (ii) in Definition 2.3.

As we shall see later, in his Hamiltonian formalism, Günther uses a standard polysymplectic manifold because he needs to have local coordinates (q^i,p_i^A) in the manifold *M* where the Hamiltonian is defined, which is equivalent to considering a *k*-symplectic manifold. For this reason we will call the Günther's formalism, called polysymplectic formalism, *k*-symplectic formalism.

B. The tangent bundle of k^1-velocities of a manifold

Let $\tau: TQ \to Q$ be the tangent bundle of Q. Let us denote by T^1_kQ the Whitney sum $TQ \oplus \overset{k}{\cdots} \oplus TQ$ of k copies of TQ, with projection $\tau_Q: T^1_kQ \to Q$, $\tau_Q(v_{1q}, \ldots, v_{kq}) = q$.

T^1_kQ can be identified with the vector bundle $J^1_0(\mathbb{R}^k, Q)$ of the k^1-velocities of the manifold Q, that is, the vector bundle of 1-jets of maps $\sigma: \mathbb{R}^k \to Q$ with source at $0 \in \mathbb{R}^k$, and projection map $\tau_Q: T^1_kQ \to Q$, $\tau_Q(j^1_{0,q}\sigma) = \sigma(0) = q$, say

$$J^1_0(\mathbb{R}^k, Q) \equiv TQ \oplus \overset{k}{\cdots} \oplus TQ,$$

$$j^1_{0,q}\sigma \equiv (v_{1q}, \ldots, v_{kq}),$$

where $q = \sigma(0)$, and $v_{Aq} = \sigma_*(0)[(\partial/\partial t^A)(0)]$, $1 \leqslant A \leqslant k$. For this reason T^1_kQ is called the *tangent bundle of k^1-velocities of Q*.

If (q^i) are local coordinates on $U \subseteq Q$ then the induced local coordinates (q^i, v^i), $1 \leqslant i \leqslant n$, on $TU = \tau^{-1}(U)$ are given by

$$q^i(v_q) = q^i(q), \quad v^i(v_q) = v_q(q^i), \quad v_q \in TQ,$$

and the induced local coordinates (q^i, v^i_A), $1 \leqslant i \leqslant n$, $1 \leqslant A \leqslant k$, on $T^1_kU = \tau_Q^{-1}(U)$ are given by

$$q^i(v_{1q}, \ldots, v_{kq}) = q^i(q), \quad v^i_A(v_{1q}, \ldots, v_{kq}) = v_{Aq}(q^i).$$

We now introduce the *canonical k-tangent structure* on T^1_kQ.

Definition 2.4: For a vector X_q at Q, and for $1 \leqslant A \leqslant k$, we define its vertical A-lift $(X_q)^A$ as the vector on T^1_kQ given by

$$(X_q)^A(v_{1q}, \ldots, v_{kq}) = \frac{d}{ds}(v_{1q}, \ldots, v_{A-1q}, v_{Aq} + sX_q, v_{A+1q}, \ldots, v_{kq})_{|s=0}$$

for all points $(v_{1q}, \ldots, v_{kq}) \in T^1_kQ$.

In local coordinates we have

$$(X_q)^A = a^i \frac{\partial}{\partial v^i_A}\bigg|_q \tag{3}$$

for a vector $X_q = a^i(\partial/\partial q^i)(q)$.

The *canonical k-tangent structure* on T^1_kQ is the set $(S^1, \ldots, S^k)$ of tensor fields of type (1, 1) defined by

$$S^A(v)(Z_v) = ((\tau_Q)_*(v)(Z_v))^A \quad \text{for all } Z_v \in T_v(T^1_kQ), \quad v = (v_{1q}, \ldots, v_{kq}),$$

for each $1 \leqslant A \leqslant k$.

From (3) we have in local coordinates,

$$S^A = \frac{\partial}{\partial v^i_A} \otimes dq^i. \tag{4}$$

The tensors S^A can be regarded as the $(0, \ldots, 0, \overset{A}{1}, 0, \ldots, 0)$-lift of the identity tensor on Q to T^1_kQ defined by Morimoto.[39]

Remark 2.2: The *k*-tangent manifolds were introduced as a generalization of the tangent manifolds by de León *et al.* [32,33] The canonical model of these manifolds is T^1_kQ with the structure given by $(S^1, \ldots, S^k)$.

To develop later the Lagrangian formalism, we now construct a polysymplectic structure on T^1_kQ, for each regular Lagrangian $L: T^1_kQ \to \mathbb{R}$, , using its canonical *k*-tangent structure.

Definition 2.5: A Lagrangian $L:T^1_kQ\to\mathbb{R}$ *is called regular if and only if*

$$\det\left(\frac{\partial^2 L}{\partial v^i_A\,\partial v^j_B}\right)\neq 0,\quad 1\leqslant i,j\leqslant n,\quad 1\leqslant A,B\leqslant k.$$

Let us consider the 1-forms $(\theta_L)_A=\mathrm{d}L\circ S^A$, $1\leqslant A\leqslant k$. In a local coordinate system (q^i,v^i_A) we have

$$(\theta_L)_A=\frac{\partial L}{\partial v^i_A}\mathrm{d}q^i,\quad 1\leqslant A\leqslant k. \tag{5}$$

Introducing the following 2-forms $(\omega_L)_A=-d(\theta_L)_A$, $1\leqslant A\leqslant k$, one can easily prove the following proposition.

Proposition 2.1: $L:T^1_kQ\to\mathbb{R}$ *is a regular Lagrangian if and only if* $((\omega_L)_1,\ldots,(\omega_L)_k)$ *is a polysymplectic structure on* T^1_kQ.

This polysymplectic structure, associated to L, was also introduced by Günther [5] using the Legendre transformation.

The Legendre map $FL:T^1_kQ\to(T^1_k)^*Q$, was introduced by Günther,[5] and we rewrite it as follows: if $(v_{1q},\ldots,v_{kq})\in(T^1_k)_qQ$,

$$[FL(v_{1q},\ldots,v_{kq})]^A(w_q)=\frac{d}{\mathrm{d}s}L(v_{1q},\ldots,v_{Aq}+sw_q,\ldots,v_{kq})_{|s=0},$$

for each $1\leqslant A\leqslant k$. We deduce that FL is locally given by

$$(q^i,v^i_A)\to\left(q^i,\frac{\partial L}{\partial v^i_A}\right). \tag{6}$$

In fact, from (5) and (6), we easily obtain the following Lemma.

Lemma 2.1: For every $1\leqslant A\leqslant k$, $(\omega_L)_A=(FL)^*(\omega_0)_A$, *where* $(\omega_0)_1,\ldots,(\omega_0)_k$ *are the 2-forms of the canonical polysymplectic structure or canonical k-symplectic structure of* $(T^1_k)^*Q$.

Then, from (6) we get the following.

Proposition 2.2: Let L be a Lagrangian. The following conditions are equivalent.

(1) L is regular. (2) FL is a local diffeomorphism. (3) $((\omega_L)_1,\ldots,(\omega_L)_k)$ *is a polysymplectic structure on* T^1_kQ.

Remark 2.3: If FL is a global diffeomorphism, then L is called a *hyper-regular Lagrangian*.

III. *k*-VECTOR FIELDS. SECOND-ORDER PARTIAL DIFFERENTIAL EQUATIONS ON T^1_kQ

A. *k*-vector fields

Let M be an arbitrary manifold and $\tau_M:T^1_kM\to M$ its tangent bundle of k^1 velocities.

Definition 3.1: A section $\mathbf{X}:M\to T^1_kM$ *of the projection* τ_M *will be called a* k-vector field *on* M.

Since T^1_kM is the Whitney sum $TM\overset{k}{\oplus}\ldots\oplus TM$ of k copies of TM, we deduce that a k-vector field $\mathbf{X}$ defines a family of k vector fields $\{X_1,\ldots,X_k\}$ on M by projecting $\mathbf{X}$ onto every factor. For this reason we will denote a k-vector field $\mathbf{X}$ by $(X_1,\ldots,X_k)$.

Definition 3.2: An integral section *of the k-vector field* $\mathbf{X}=(X_1,\ldots,X_k)$ *passing through a point* $x\in M$ *is a map* $\phi:U_0\subset\mathbb{R}^k\to M$, *defined on some neighborhood* U_0 *of* $0\in\mathbb{R}^k$, *such that*

$$\phi(0)=x,\quad \phi_*(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right)=X_A(\phi(t))\quad \textit{for every } t\in U_0,\quad 1\leqslant A\leqslant k,$$

or equivalently, ϕ *satisfies* $\mathbf{X}\circ\phi=\phi^{(1)}$, *where* $\phi^{(1)}$ *is the first prolongation of* ϕ *defined by*

$$\phi^{(1)}: U_0 \subset \mathbb{R}^k \to T_k^1 M,$$

$$t \to \phi^{(1)}(t) = j_0^1 \phi_t, \quad \phi_t(\overline{t}) = \phi(\overline{t} + t),$$

for every $\overline{t}$, $t \in \mathbb{R}^k$ *such that* $\overline{t}+t \in U_0$.

In local coordinates,

$$\phi^{(1)}(t^1,\ldots,t^k) = \left(\phi^i(t^1,\ldots,t^k), \frac{\partial \phi^i}{\partial t^A}(t^1,\ldots,t^k)\right), \quad 1 \leqslant A \leqslant k, \quad 1 \leqslant i \leqslant n. \tag{7}$$

We say that a k-vector field $\mathbf{X}=(X_1,\ldots,X_k)$ on M is integrable if there is an integral section passing through each point of M.

We remark that a k-vector field $\mathbf{X}$ is integrable if, and only if, $\{X_1,\ldots,X_k\}$ define an involutive distribution on M.

B. Second-order partial differential equations in $T_k^1 Q$

The aim of this section is to characterize the integrable k-vector fields on $T_k^1 Q$ such that their integral sections are canonical prolongations of maps from $\mathbb{R}^k$ to Q.

In general, if $F: M \to N$ is a differentiable map, then the induced map $T_k^1(F): T_k^1 M \to T_k^1 N$ defined by $T_k^1(F)(j_0^1 g) = j_0^1(F \circ g)$ is given by

$$T_k^1(F)(v_{1q},\ldots,v_{kq}) = (F_*(q)v_{1q},\ldots,F_*(q)v_{kq}),$$

where $v_{1q},\ldots,v_{kq} \in T_q Q$, $q \in Q$, and $F_*(q): T_q M \to T_{F(q)} N$.

Definition 3.3: A k-vector field on $T_k^1 Q$, *that is, a section* $\mathbf{X}: T_k^1 Q \to T_k^1(T_k^1 Q)$ *of the projection* $\tau_{T_k^1 Q}: T_k^1(T_k^1 Q) \to T_k^1 Q$, *is a* second-order partial differential equation (SOPDE) *if it is also a section of the vector bundle* $T_k^1(\tau_Q): T_k^1(T_k^1 Q) \to T_k^1 Q$; *that is,*

$$T_k^1(\tau_Q) \circ \mathbf{X} = Id_{T_k^1 Q}, \tag{8}$$

where $T_k^1(\tau)$ *is defined by* $T_k^1(\tau_Q)(j_0^1 \gamma) = j_0^1(\tau_Q \circ \gamma)$.

Let (q^i) be a coordinate system on Q and (q^i, v_A^i) the induced coordinate system on $T_k^1 Q$. From a direct computation in local coordinates we obtain that the local expression of a SOPDE $(X_1,\ldots,X_k)$ is

$$X_A(q^i, v_A^i) = v_A^i \frac{\partial}{\partial q^i} + (X_A)_B^i \frac{\partial}{\partial v_B^i}, \quad 1 \leqslant A \leqslant k. \tag{9}$$

If $\varphi: \mathbb{R}^k \to T_k^1 Q$, is an integral section of $(X_1,\ldots,X_k)$ locally given by $\varphi(t) = (\varphi^i(t), \varphi_B^i(t))$ then $X_A(\varphi(t)) = \varphi_*(t)[\partial/\partial t^A(t)]$ and thus

$$\frac{\partial \varphi^i}{\partial t^A}(t) = v_A^i(\varphi(t)) = \varphi_A^i(t), \quad \frac{\partial \varphi_B^i}{\partial t^A}(t) = (X_A)_B^i(\varphi(t)).$$

From (7) we obtain the following.

Proposition 3.1: Let $\mathbf{X}=(X_1,\ldots,X_k)$ *be an integrable* SOPDE. *If* φ *is an integral section then* $\varphi = \phi^{(1)}$ *where* $\phi^{(1)}$ *is the first prolongation of the map* $\phi = \tau_Q \circ \varphi: \mathbb{R}^k \xrightarrow{\varphi} T_k^1 Q \xrightarrow{\tau_Q} Q$, *and satisfies*

$$\frac{\partial \phi^i}{\partial t^A \partial t^B}(t) = (X_A)_B^i(\phi^{(1)}(t)). \tag{10}$$

Conversely, if $\phi: \mathbb{R}^k \to Q$ *is any map satisfying (10) then* $\phi^{(1)}$ *is an integral section of* $(X_1,\ldots,X_k)$.

Definition 3.4: Let $(X_1,\ldots,X_k)$ *be an integrable* SOPDE. *A map* $\phi: \mathbb{R}^k \to Q$ *is said to be a* solution to the SOPDE *if the first prolongation* $\phi^{(1)}$ *is an integral section of* $(X_1,\ldots,X_k)$.

A k-vector field which is an integrable SOPDE *is called a* holonomic *k*-vector field, *and its integral sections* $\varphi=\phi^{(1)}$ *are called* holonomic sections.

Now we show how to characterize the SOPDE using the canonical *k*-tangent structure of T^1_kQ.

Definition 3.5: The Liouville vector field C *on* T^1_kQ *is the infinitesimal generator of the following flow:*

$$\mathbb{R}\times T^1_kQ\to T^1_kQ,$$

$$(s,(v_{1_q},\ldots,v_{k_q}))\to(e^sv_{1_q},\ldots,e^sv_{k_q}),$$

and in local coordinates has the form

$$C=\sum_{i,B}v^i_B\frac{\partial}{\partial v^i_B}. \tag{11}$$

We can write $C=C_1+\cdots+C_k$ where C_A, $1\leqslant A\leqslant k$, are the canonical vector fields on T^1_kQ given by the following flows:

$$\mathbb{R}\times T^1_kQ\to T^1_kQ,$$

$$(s,(v_{1_q},\ldots,v_{k_q}))\to(v_{1_q},\ldots,v_{A-1_q},e^sv_{A_q},v_{A+1_q},\ldots,v_{k_q}).$$

In local coordinates,

$$C_A=\sum_i v^i_A\frac{\partial}{\partial v^i_A}. \tag{12}$$

From (4), (9), (11), and (12) we deduce the following.

Proposition 3.2: A k-vector field $\mathbf{X}=(X_1,\ldots,X_k)$ *on* T^1_kQ *is a* SOPDE *if, and only if,* $S^A(X_A)=C_A$, *for all* $1\leqslant A\leqslant k$, *where* $(S^1,\ldots,S^k)$ *is the canonical k-tangent structure on* T^1_kQ.

IV. HAMILTONIAN AND LAGRANGIAN FORMALISM (Refs. 5 and 9)

A. Hamiltonian formalism

Let (M,ω_A,V) be a *k*-symplectic manifold, and $H:M\to\mathbb{R}$ a Hamiltonian function. Let $\mathbf{X}=(X_1,\ldots,X_k)$ be a *k*-vector field on M that satisfies the equations

$$\sum_{i=1}^{k}\imath_{X_A}\omega_A=\mathrm{d}H. \tag{13}$$

If X_A is locally given by

$$X_A=(X_A)^i\frac{\partial}{\partial q^i}+(X_A)^B_i\frac{\partial}{\partial P^B_i}$$

in a local system of canonical coordinates (q^i,p^A_i) (whose existence is ensured by the Theorem 2.1), then (13) is equivalent to the equations

$$\frac{\partial H}{\partial q^i}=-\sum_{A=1}^{k}(X_A)^A_i,\quad \frac{\partial H}{\partial p^A_i}=(X_A)^i.$$

So if $(X_1,\ldots,X_k)$ is also integrable then its integral sections $\varphi:\mathbb{R}^k\to M$, with $\varphi(t)=(\varphi^i(t),\varphi^A_i(t))$ are solutions to the *Hamilton–De Donder–Weyl field equations*,

$$\frac{\partial H}{\partial q^i} = -\sum_{A=1}^{k} \frac{\partial \varphi_i^A}{\partial t^A}, \quad \frac{\partial H}{\partial p_i^A} = \frac{\partial \varphi^i}{\partial t^A}, \quad 1 \leqslant A \leqslant k, \quad 1 \leqslant i \leqslant n. \tag{14}$$

So, Eq. (13) is a geometric version of the Hamilton–De Donder–Weyl field equations.

B. Lagrangian formalism

In this section, we recall the Lagrangian formalism developed by Günther.[5]

In general, given a Lagrangian function of the form $L=L(q^i, v_A^i)$, and using a variational principle, one obtains the *Euler–Lagrange field equations* for L,

$$\sum_{A=1}^{k} \frac{d}{dt^A}\left(\frac{\partial L}{\partial v_A^i}\right) - \frac{\partial L}{\partial q^i} = 0, \quad v_A^i = \frac{\partial q^i}{\partial t^A}. \tag{15}$$

Then, let $L: T_k^1 Q \to \mathbb{R}$ be a Lagrangian, and let us consider the 2-forms $((\omega_L)_1, \ldots, (\omega_L)_k)$ on $T_k^1 Q$ defined by L, and $E_L = C(L) - L$, C being the Liouville vector field in $T_k^1 Q$. Now, let $\mathbf{X} = (X_1, \ldots, X_k)$ be a k-vector field in $T_k^1 Q$ (that is, a section $\mathbf{X}: T_k^1 Q \to T_k^1(T_k^1 Q)$) of the projection $\tau_{T_k^1 Q}: T_k^1(T_k^1 Q) \to T_k^1 Q$. Then we have the following.

Proposition 4.1: If $\mathbf{X}=(X_1, \ldots, X_k)$ *is an integrable* SOPDE, *and* $\psi \equiv \phi^{(1)}: \mathbb{R}^k \to T_k^1 Q$ *is an integral section of* $\mathbf{X}$, *then* $\mathbf{X}$ *is a solution to the equation*

$$\sum_{A=1}^{k} \imath_{X_A}(\omega_L)_A = dE_L, \tag{16}$$

if, and only if, $\phi: \mathbb{R}^k \to Q$ *is a solution to the Euler–Lagrange equations (15).*

Proof: If each X_A is locally given by

$$X_A = (X_A)^i \frac{\partial}{\partial q^i} + (X_A)_B^i \frac{\partial}{\partial v_B^i}$$

then, from (5), (11), and (16) we deduce that $(X_1, \ldots, X_k)$ is a solution to (16) if, and only if, $(X_A)^i$ and $(X_A)_B^i$ satisfy the system of equations

$$\left(\frac{\partial^2 L}{\partial q^i \partial v_A^j} - \frac{\partial^2 L}{\partial q^j \partial v_A^i}\right)(X_A)^j - \frac{\partial^2 L}{\partial v_A^i \partial v_B^j}(X_A)_B^j = v_A^j \frac{\partial^2 L}{\partial q^i \partial v_A^j} - \frac{\partial L}{\partial q^i}, \tag{17}$$

$$\frac{\partial^2 L}{\partial v_B^j \partial v_A^i}(X_A)^i = \frac{\partial^2 L}{\partial v_B^j \partial v_A^i} v_A^i. \tag{18}$$

But, as $\mathbf{X}$ is a SOPDE, we have

$$(X_A)^i = v_A^i, \tag{19}$$

then (18) holds identically, and (17) is equivalent to

$$\frac{\partial^2 L}{\partial q^j \partial v_A^i} v_A^j + \frac{\partial^2 L}{\partial v_A^i \partial v_B^j}(X_A)_B^j = \frac{\partial L}{\partial q^i}. \tag{20}$$

Now, if $\psi(t) = \phi^{(1)} = (\phi^i(t), \phi_A^i(t))$ is an integral section of $\mathbf{X}$, then

$$(X_A)^i(\psi(t)) = \phi_A^i(t) = \frac{\partial \phi^i}{\partial t^A}, \tag{21}$$

$$(X_A)^i_B(\psi(t)) = \frac{\partial \phi^i_B}{\partial t^A} = \frac{\partial^2 \phi^i}{\partial t^A \partial t^B}, \tag{22}$$

and going to (20) we obtain that

$$\frac{\partial^2 L}{\partial q^i \partial v^j_A}(\phi(t))\frac{\partial \phi^i}{\partial t^A} + \frac{\partial^2 L}{\partial v^i_B \partial v^j_A}(\phi(t))\frac{\partial \phi^i_B}{\partial t^A} = \frac{\partial^2 L}{\partial q^i \partial v^j_A}(\phi(t))\frac{\partial \phi^i}{\partial t^A} + \frac{\partial^2 L}{\partial v^i_B \partial v^j_A}(\phi(t))\frac{\partial^2 \phi^i}{\partial t^A \partial t^B} = \frac{\partial L}{\partial q^i}(\phi(t)) \tag{23}$$

which are the Euler–Lagrange equations for the map ϕ.

Conversely, let $\mathbf{X}$ be an integrable SOPDE having $\psi(t)=\phi^{(1)}=(\phi^i(t),\phi^i_A(t))$ as integral sections, for every $(\phi^i(t))$ solution to the Euler–Lagrange equations. Therefore (21) and (22) hold since $\mathbf{X}$ is a SOPDE, and then (23), which holds because $(\phi^i(t))$ is a solution to the Euler–Lagrange equations, is equivalent to (20). Hence $\mathbf{X}$ is a solution to (16). ■

In this way, Eq. (16) can be considered as a geometric version of the Euler–Lagrange field equations.

Observe that, if the Lagrangian is regular, Eq. (18) leads to conclude that every solution to (16) is a SOPDE. In addition, Eq. (20) leads to defining local solutions to (16) in a neighborhood of each point of T^1_kQ and, using a partition of unity, global solutions to (16).

Now let us suppose that the Lagrangian $L:T^1_kQ\to\mathbb{R}$ is hyper-regular, that is, FL is a diffeomorphism. We consider the Hamiltonian $H:(T^1_k)^*Q\to\mathbb{R}$ defined by $H=E_L\circ FL^{-1}$ where FL^{-1} is the inverse map of FL. Then we have the following.

Theorem 4.1: *(a) If $\mathbf{X}_L=((X_L)_1,\ldots,(X_L)_k)$ is a solution to (16) then $\mathbf{X}_H=((X_H)_1,\ldots,(X_H)_k)$, where $(X_H)_A=FL_*((X_L)_A)$, $1\leqslant A\leqslant k$, is a solution to (13) with $\omega_A=(\omega_0)_A$ and $H=E_L\circ FL^{-1}$.*

(b) If $\mathbf{X}_L=((X_L)_1,\ldots,(X_L)_k)$ is integrable, $\phi^{(1)}$ is an integral section and $\phi=\tau_Q\circ\phi^{(1)}$, then $\varphi=FL\circ\phi^{(1)}$ is an integral section of $\mathbf{X}_H=((X_H)_1,\ldots,(X_H)_k)$ and thus it is a solution to the Hamilton–De Donder–Weyl equations (14) for $H=E_L\circ FL^{-1}$.

Proof: (a) It is an immediate consequence of (13) and (16) using that $FL^*(\omega_0)_A=(\omega_L)_A$ and $E_L=H\circ FL^{-1}$.

(b) It is an immediate consequence of Definition 3.2 of integral section of a k-vector field. ■

Definition 4.1: A singular Lagrangian system $(T^1_kQ,(\omega_L)_1,\ldots,(\omega_L)_k)$ is called almost regular if $\mathcal{P}:=FL(T^1_kQ)$ is a closed submanifold of $(T^1_k)^*Q$ (we will denote the natural imbedding by $j_0:\mathcal{P}\hookrightarrow(T^1_k)^*Q$), FL is a submersion onto its image, and the fibers $FL^{-1}(FL(v))$, for every $v\in T^1_kQ$, are connected submanifolds of T^1_kQ.

In this case there exists $H_0\in\mathrm{C}^\infty(\mathcal{P})$ such that $(FL_0)^*H_0=E_L$, where $FL_0:T^1_kQ\to\mathcal{P}$ is defined by $j_0\circ FL_0=FL$, and the Hamiltonian field equation analogous to (13) is

$$\sum_{i=1}^{k} \imath_{(X_0)_A}\omega^0_A = \mathrm{d}H_0, \tag{24}$$

where $\omega^0_A=j_0^*(\omega_0)_A$, for every $1\leqslant A\leqslant k$, and $\mathbf{X}_0=((X_0)_1,\ldots,(X_0)_k)$ (if it exists) is a k-vector field on $\mathcal{P}$.

V. SKINNER–RUSK FORMULATION

A. The Skinner–Rusk formalism for *k*-symplectic field theories

Let us consider the *Whitney sum* $T^1_kQ\oplus_Q(T^1_k)^*Q$, with coordinates (q^i,v^i_A,p^A_i). It has natural bundle structures over T^1_kQ and $(T^1_k)^*Q$. Let us denote by $pr_1:T^1_kQ\oplus_Q(T^1_k)^*Q\to T^1_kQ$ the projection into the first factor, $pr_1(q^i,v^i_A,p^A_i)=(q^i,v^i_A)$, and $pr_2:T^1_kQ\oplus_Q(T^1_k)^*Q\to(T^1_k)^*Q$ the projection into the second factor, $pr_2(q^i,v^i_A,p^A_i)=(q^i,p^A_i)$.

In this bundle, we have some canonical structures. First, let $((\omega_0)_1,\ldots,(\omega_0)_k)$ be the canonical polysymplectic structure on $(T^1_k)^*Q$. We shall denote by $(\Omega_1,\ldots,\Omega_k)$ the pull-back by pr_2 of these 2-forms to $T^1_kQ\oplus_Q(T^1_k)^*Q$, that is, $\Omega_A=(pr_2)^*(\omega_0)_A$, $1\leqslant A\leqslant k$.

Furthermore, the *coupling function* in $T^1_kQ\oplus_Q(T^1_k)^*Q$, denoted by $\mathcal{C}$, is defined as follows:

$$\mathcal{C}\colon T^1_kQ\oplus_Q(T^1_k)^*Q\to\mathbb{R},$$

$$(v_{1_q},\ldots,v_{kq},\alpha^1_q,\ldots,\alpha^k_q)\mapsto\sum_{A=1}^{k}\alpha^A_q(v_{A_q}).$$

Given a Lagrangian $L\in C^\infty(T^1_kQ)$, we can define the *Hamiltonian function* in $T^1_kQ\oplus_Q(T^1_k)^*Q$, denoted by $\mathcal{H}\in C^\infty(T^1_kQ\oplus_Q(T^1_k)^*Q)$, as

$$\mathcal{H}(v_{1_q},\ldots,v_{k_q},\alpha^1_q,\ldots,\alpha^k_q)=\mathcal{C}(v_{1_q},\ldots,v_{k_q},\alpha^1_q,\ldots,\alpha^k_q)-(pr_1^*L)(v_{1_q},\ldots,v_{k_q},\alpha^1_q,\ldots,\alpha^k_q)$$

which, in local coordinates, is given by

$$\mathcal{H}=\sum_{A=1}^{k}\sum_{i=1}^{n}p^A_iv^i_A-L(q^i,v^i_A). \tag{25}$$

Now, the problem consists in finding the integral sections $\psi\colon\mathbb{R}^k\to T^1_kQ\oplus(T^1_k)^*Q$ of an integrable k-vector field $\mathbf{Z}=(Z_1,\ldots,Z_k)$ on $T^1_kQ\oplus_Q(T^1_k)^*Q$, such that

$$\sum_{A=1}^{k}\imath_{Z_A}\Omega_A=\mathrm{d}\mathcal{H}. \tag{26}$$

Equation (26) gives a different kind of information. In fact, writing locally each Z_A as

$$Z_A=(Z_A)^i\frac{\partial}{\partial q^i}+(Z_A)^i_B\frac{\partial}{\partial v^i_B}+(Z_A)^B_i\frac{\partial}{\partial p^B_i},$$

then, from (1), (25), and (26) we obtain

$$p^A_i=\frac{\partial L}{\partial v^i_A}\circ pr_1, \tag{27}$$

$$(Z_A)^i=v^i_A, \tag{28}$$

$$\sum_{A=1}^{k}(Z_A)^A_i=\frac{\partial L}{\partial q^i}\circ pr_1, \tag{29}$$

where $1\leqslant A\leqslant k, 1\leqslant i\leqslant n$. Then from (28) we have that Z_A is locally given by

$$Z_A=v^i_A\frac{\partial}{\partial q^i}+(Z_A)^i_B\frac{\partial}{\partial v^i_B}+(Z_A)^B_i\frac{\partial}{\partial p^B_i}. \tag{30}$$

So, in particular, we have obtained information of three different classes.

(1) The constraint equations (27), which are algebraic (not differential) equations defining a submanifold M_L of $T^1_kQ\oplus_Q(T^1_k)^*Q$ where the equation (26) has solution. Let us observe that this submanifold is just the graph of the Legendre map FL defined by the Lagrangian L. We denote by $j\colon M_L\to T^1_kQ\oplus_Q(T^1_k)^*Q$ the natural imbedding, and by $pr^0_1\colon M_L\to T^1_kQ$ and $pr^0_2\colon M_L\to(T^1_k)^*Q$ the restricted projections of pr_1 and pr_2.

(2) Equations (28) which are a holonomy condition similar to (19) and, as we will see in the next section (see Theorem 5.1), they force the integral sections of the k-vector field $\mathbf{Z}$ to be lifting

of sections $\phi:\mathbb{R}^k\to Q$. This property is similar to the one in the unified formalism of classical mechanics, and it reflects the fact that the geometric condition in the unified formalism is stronger than the usual one in the Lagrangian formalism.

(3) Equations (29) which, taking into account (27) and (28), are just the classical Euler–Lagrange equations (see Theorem 5.1).

If $\mathbf{Z}=(Z_1,\ldots,Z_k)$ is a solution to (26), then each Z_A is tangent to the submanifold M_L if, and only if, the functions $Z_A(p_j^B-(\partial L/\partial v_B^j)\circ pr_1)$ vanish at the points of M_L, for every $1\leqslant A,\ B\leqslant k$, $1\leqslant j\leqslant n$. Then from (30) we deduce that this is equivalent to the following equations:

$$(Z_A)_j^B=v_A^i\frac{\partial^2 L}{\partial q^i\,\partial v_B^j}+(Z_A)_C^i\frac{\partial^2 L}{\partial v_C^i\,\partial v_B^j}. \tag{31}$$

Thus the problem to be solved is the following.

Statement 5.1: To find an integral section $\psi:\mathbb{R}^k\to M_L\subset T_k^1Q\oplus(T_k^1)^*Q$ of an integrable k-vector field $\mathbf{Z}=(Z_1,\ldots,Z_k)$ on $T_k^1Q\oplus_Q(T_k^1)^*Q$ solution to (26) taking values on M_L. (This means that $\mathbf{Z}$ is tangent to M_L.)

Remark 5.1: (1) Equations (26) do not, in general, have a unique solution. The solutions to (26) are given by $(Z_1,\ldots,Z_k)+\ker\Omega^\sharp$, where $(Z_1,\ldots,Z_k)$ is a particular solution, and $\Omega^\sharp:T_k^1(T_k^1Q\oplus_Q(T_k^1)^*Q)\to T^*(T_k^1Q\oplus_Q(T_k^1)^*Q)$ is defined as $\Omega^\sharp(Y_1,\ldots,Y_k)=\Sigma_{A=1}^k\imath_{Y_A}\Omega_A$.

(2) If L is regular, then taking into account (28) and (29) we can define a local k-vector field $(Z_1,\ldots,Z_k)$ on a neighborhood of each point in M_L which is a solution to (26). Each Z_A is locally given by

$$(Z_A)^i=v_A^i,\quad (Z_A)_i^B=\frac{1}{k}\frac{\partial L}{\partial q^i}\delta_A^B,$$

with $(Z_A)_B^i$ satisfying (31). Now, by using a partition of the unity, one can construct a global k-vector field which is a solution to (26).

When the Lagrangian function L is singular we cannot assure the existence of consistent solutions for Eq. (26). Then we must develop a constraint algorithm for obtaining a constraint submanifold (if it exists) where these solutions exist. Next, we outline this procedure (see also Ref. 4, where a similar algorithm is sketched in the multisymplectic formulation).

First, in order to assure the existence of a Hamiltonian counterpart for the singular Lagrangian system we assume, from now on, that the singular Lagrangians are almost regular.

We begin with $P_0=M_L$. Then, let P_1 be the subset of P_0 made of those points where there exists a solution to (26), that is,

$$P_1=\{z\in P_0\,|\,\exists\,(Z_1\ldots,Z_k)\in(T_k^1)_zP_0 \text{ solution to (26)}\}.$$

If P_1 is a submanifold of P_0, then there exists a section of the canonical projection $\tau_{P_0}:T_k^1P_0\to P_0$ defined on P_1 which is a solution to (26), but that does not define, in general, a k-vector field on P_1. To find solutions taking values into $T_k^1P_1$, we define a new subset P_2 of P_1 as follows:

$$P_2=\{z\in P_1\,|\,\exists\,(Z_1,\ldots,Z_k)\in(T_k^1)_zP_1 \text{ solution to (26)}\}.$$

If P_2 is a submanifold of P_1, then there exists a section of the canonical projection $\tau_{P_1}:T_k^1P_1\to P_1$ defined on P_2 which is a solution to (26), but that does not define, in general, a k-vector field on P_2.

Proceeding further, we get a family of constraint manifolds

$$\cdots\hookrightarrow P_2\hookrightarrow P_1\hookrightarrow P_0=M_L\hookrightarrow T_k^1Q\oplus_Q(T_k^1)^*Q.$$

If there exists a natural number f such that $P_{f+1}=P_f$ and $\dim P_f>k$ then we call P_f the *final constraint submanifold* over which we can find solutions to Eq. (26). Let us observe that the solutions will not be unique (even in the regular case) and, in general, will not be integrable. In

order to find integrable solutions to Eq. (26), a constraint algorithm based on the same idea must be developed.

B. The field equations for sections

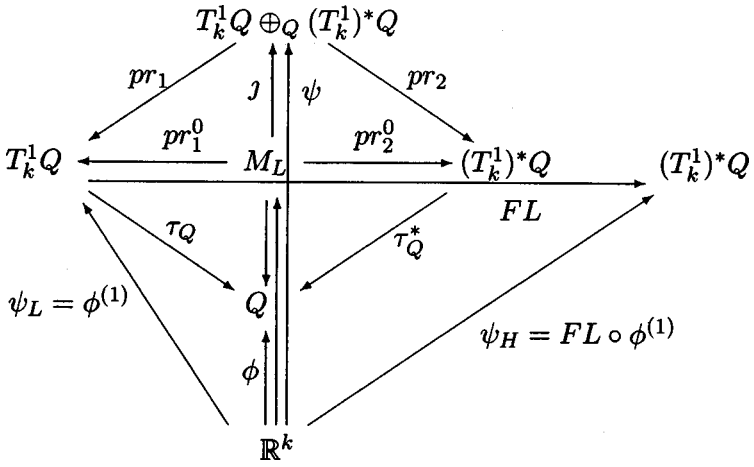
M_L being the graph of FL, it is diffeomorphic to T^1_kQ (so pr^0_1 is a diffeomophism). Let $\mathbf{Z}=(Z_1,\ldots,Z_k)$ be an integrable k-vector field solution to (26). Every integral section $\psi: t\in\mathbb{R}^k \to (\psi^j(t),\psi^j_A(t),\ \psi^A_i(t))\in T^1_kQ\oplus_Q(T^1_k)^*Q$ of $\mathbf{Z}$ solution to (26) is of the form $\psi=(\psi_L,\psi_H)$, with $\psi_L=pr_1\circ\psi:\mathbb{R}^k\to T^1_kQ$, and if ψ takes values in M_L then $\psi_H=FL\circ\psi_L$; in fact, from (27) we obtain

$$\psi_H(t)=(pr_2\circ\psi)(t)=(\psi^j(t),\psi^A_i(t))=\left(\psi^j(t),\left.\frac{\partial L}{\partial v^i_A}\right|_{\psi_L(t)}\right)=(FL\circ\psi_L)(t).$$

In this way, every constraint, differential equation, etc., in the unified formalism can be translated to the Lagrangian or the Hamiltonian formalisms by restriction to the first or the second factors of the product bundle. In particular, conditions (27) generate, by pr_2-projection, the primary constraints of the Hamiltonian formalism for singular Lagrangians [i.e., the image of the Legendre transformation, $FL(T^1_kQ)\subset(T^1_k)^*Q$], and they can be called *primary Hamiltonian constraints*.

In this way the main result in this section is the following.

Theorem 5.1: *Let* $\mathbf{Z}=(Z_1,\ldots,Z_k)$ *be an integrable k-vector field in* $T^1_kQ\oplus_Q(T^1_k)^*Q$ *solution to (26) and let* $\psi:\mathbb{R}^k\to M_L\subset T^1_kQ\oplus_Q(T^1_k)^*Q$ *be an integral section of* $\mathbf{Z}=(Z_1,\ldots,Z_k)$, *with* $\psi=(\psi_L,\psi_H)=(\psi_L,FL\circ\psi_L)$. *Then* ψ_L *is the canonical lift* $\phi^{(1)}$ *of the projected section* $\phi=\tau_Q\circ pr_1\circ\psi:\mathbb{R}^k\to Q$, *and* ϕ *is a solution to the Euler–Lagrange field equations (15).*



Proof: If $\psi(t)=(\psi^j(t),\psi^j_A(t),\psi^A_i(t))$ is an integral section of $\mathbf{Z}=(Z_1,\ldots,Z_k)$, then

$$Z_A(\psi(t))=\left.\frac{\partial\psi^j}{\partial t^A}(t)\frac{\partial}{\partial q^i}\right|_{\psi(t)}+\left.\frac{\partial\psi^B_i}{\partial t^A}(t)\frac{\partial}{\partial p^B_i}\right|_{\psi(t)}+\left.\frac{\partial\psi^j_B}{\partial t^A}(t)\frac{\partial}{\partial v^i_B}\right|_{\psi(t)}. \tag{32}$$

From (27), (28), and (32) we obtain

$$\psi^j_A(t)=v^i_A(\psi(t))=(Z_A)^i(\psi(t))=\frac{\partial\psi^j}{\partial t^A}(t), \tag{33}$$

$$\psi^A_i(t)=p^A_i(\psi(t))=\left(\frac{\partial L}{\partial v^i_A}\circ pr_1\right)(\psi(t))=\left.\frac{\partial L}{\partial v^i_A}\right|_{\psi_L(t)}, \tag{34}$$

$$\frac{\partial \psi_i^B}{\partial t^A}(t) = (Z_A)_i^B(\psi(t)). \tag{35}$$

Therefore from (29), (34), and (35) we obtain

$$\frac{\partial L}{\partial q^i}(\psi_L(t)) = \sum_{A=1}^{k} (Z_A)_i^A(\psi(t)) = \sum_{A=1}^{k} \frac{\partial \psi_i^A}{\partial t^A}(t) = \sum_{A=1}^{k} \frac{\partial}{\partial t^A}\left(\frac{\partial L}{\partial v_A^i}\bigg|_{\psi_L(t)} \right)$$

and from (33),

$$\psi_A^i(t) = \frac{\partial \psi^i}{\partial t^A}(t).$$

The last two equations are the Euler–Lagrange field equations for the section $\phi(t)=(\psi^i(t))$ $=(\tau\circ pr_1\circ\psi)(t)$, and $\psi_L=\phi^{(1)}$. ■

In addition, for the regular case we can prove the following.

Proposition 5.1: Under the hypothesis of Theorem 5.1, if L is regular then $\psi_H=FL\circ\psi_L$ is a solution to the Hamilton–De Donder–Weyl field equations (14), where the Hamiltonian H is locally given by $H\circ FL=E_L$.

Proof: Since L is regular, FL is a local diffeomorphism and thus we can choose for each point in T_k^1Q an open neighborhood $U\subset T_k^1Q$ such that $FL_{|U}: U\to FL(U)$ is a diffeomorphism. So we can define $H_U: FL(U)\to\mathbb{R}$ as $H_U=(E_L)_{|U}\circ(FL_{|U})^{-1}$.

Denoting by $H\equiv H_U$, $E_L\equiv(E_L)_{|U}$ and $FL\equiv FL_{|U}$, we have $E_L=H\circ FL$ where we provide the identities

$$\frac{\partial H}{\partial p_i^A}\circ FL = v_A^i, \quad \frac{\partial H}{\partial q^i}\circ FL = -\frac{\partial L}{\partial q^i}. \tag{36}$$

Now considering the open subset $V=\psi_L^{-1}(U)\subset\mathbb{R}^k$ we have $\psi_{|V}: V\subset\mathbb{R}^k\to U\oplus FL(U)\subset M_L$, where $(\psi_L)_{|V}: V\subset\mathbb{R}^k\to U\subset T_k^1Q$ and $(\psi_H)_{|V}=FL\circ(\psi_L)_{|V}: V\subset\mathbb{R}^k\to FL(U)\subset(T_k^1)^*Q$.

Therefore from (29), (33), (35), and (36), for every $t\in V\subset\mathbb{R}^k$ we obtain

$$\frac{\partial H}{\partial p_i^A}\bigg|_{\psi_H(t)} = \left(\frac{\partial H}{\partial p_i^A}\circ FL\right)(\psi_L(t)) = v_A^i(\psi_L(t)) = \frac{\partial \psi^i}{\partial t^A}(t)$$

and

$$\frac{\partial H}{\partial q^i}\bigg|_{\psi_H(t)} = \left(\frac{\partial L}{\partial q^i}\circ FL\right)(\psi_L(t)) = -\frac{\partial L}{\partial q^i}\bigg|_{\psi_L(t)} = -\sum_{A=1}^{k}(Z_A)_i^A(\psi(t)) = -\sum_{A=1}^{k}\frac{\partial \psi_i^A}{\partial t^A}(t)$$

from which we deduce that $(\psi_H)_{|V}$ is a solution to the Hamilton–De Donder–Weyl field equations (14). ■

Conversely, we can state the following.

Proposition 5.2: If L is regular and $\mathbf{X}=(X_1,\ldots,X_k)$ is a solution to (16) then

(1) *The k-vector field $\mathbf{Z}=(Z_1,\ldots,Z_k)$ given by $Z_A=(Id_{T_k^1Q}\oplus FL)_*(X_A)$, $1\leqslant A\leqslant k$ is a solution to (26).*
(2) *If $\psi_L:\mathbb{R}^k\to T_k^1Q$ is an integral section of $\mathbf{X}=(X_1,\ldots,X_k)$ (and thus, from Proposition 4.1, a solution to the Euler–Lagrange field equations) then $\psi=(\psi_L, FL\circ\psi_L):\mathbb{R}^k\to M_L\subset T_k^1Q \oplus_Q (T_k^1)^*Q$ is an integral section of $\mathbf{Z}=(Z_1,\ldots,Z_k)$.*

Proof:

(1) If L is regular and $\mathbf{X}=(X_1,\ldots,X_k)$ is a solution to (16), then from Proposition 4.1 we know that X_A is a SOPDE and thus X_A is locally given by

$$X_A = v_A^i \frac{\partial}{\partial q^i} + (X_A)_B^i \frac{\partial}{\partial v_B^i}, \tag{37}$$

where $(X_A)_B^i$ satisfy (20). Since the map $Id_{T_k^1Q} \oplus FL : T_k^1Q \to M_L \subset T_k^1Q \oplus (T_k^1)^*Q$, is locally given by

$$(q^i, v_A^i) \to \left(q^i, v_A^i, \frac{\partial L}{\partial v_A^i} \right), \tag{38}$$

from (37) and (38) we obtain

$$Z_A = (Id_{T_k^1Q} \oplus FL)_*(X_A) = v_A^i \frac{\partial}{\partial q^i} + \left(v_A^i \frac{\partial^2 L}{\partial q^i \, \partial v_C^j} + (X_A)_B^i \frac{\partial^2 L}{\partial v_B^i \, \partial v_C^j} \right) \frac{\partial}{\partial p_j^C} + (X_A)_B^i \frac{\partial}{\partial v_B^i}. \tag{39}$$

Then from (20) and (39) we have that

$$\sum_{A=1}^{k} (Z_A)_j^A = v_A^i \frac{\partial^2 L}{\partial q^i \, \partial v_A^j} + (X_A)_B^i \frac{\partial^2 L}{\partial v_B^i \, \partial v_A^j} = \frac{\partial L}{\partial q^j}, \quad (Z_A)^i = v_A^i, \quad Z_A \left(p_k^B - \frac{\partial L}{\partial v_B^k} \right) = 0,$$

that is, the k-vector field $\mathbf{Z} = (Z_1, \ldots, Z_k)$ is a solution to (26) and each Z_A is tangent to M_L for $A : 1, \ldots, k$.

(2) It follows from Definition 3.2 taking into account that $pr_2 \circ \psi = FL \circ \psi_L$. ■

Remark 5.2: The last result really holds for regular and almost-regular Lagrangians. In the almost-regular case, the proof is the same, but the sections ψ, ψ_L, and ψ_H take values not on M_L, T_k^1Q, and $(T_k^1)^*Q$, but in the final constraint submanifold P_f and on the projection submanifolds $pr_1(P_f) \hookrightarrow T_k^1Q$ and $pr_2(P_f) \hookrightarrow (T_k^1)^*Q$, respectively.

C. The field equations for *k*-vector fields

The aim of this section is to establish the relationship between k-vector fields that are solutions to (16) and k-vector fields that are solutions to (26). The main result is the following.

Theorem 5.2: *Let $\mathbf{Z} = (Z_1, \ldots, Z_k)$ be a k-vector field on M_L solution to (26). Then the k-vector field $\mathbf{X}_L = ((X_L)_1, \ldots, (X_L)_k)$ on T_k^1Q defined by*

$$\mathbf{X}_L \circ pr_1^0 = T_k^1(pr_1^0) \circ \mathbf{Z} \tag{40}$$

is a k-vector field solution to (16) [where $T_k^1(pr_1^0) : T_k^1(M_L) \to T_k^1(T_k^1Q)$ is the natural extension of $(pr_1^0)_*$].

Conversely, every k-vector field $\mathbf{X}_L$ solution to (16) can be recovered in this way from a k-vector field $\mathbf{Z}$ in M_L solution to (26).

Moreover, the k-vector field $\mathbf{Z}$ is integrable iff the k-vector field $\mathbf{X}_L$ is holonomic.

Proof: Since $pr_1^0 : M_L \to T_k^1Q$ is a diffeomorphism, then the k-vector field $\mathbf{X}_L$ on T_k^1Q defined by (40) is given by

$$(X_L)_A = ((pr_1^0)^{-1})^* Z_A, \quad 1 \leqslant A \leqslant k. \tag{41}$$

Now, for every $1 \leqslant A \leqslant k$ we have that

$$j^* \Omega_A = (pr_1^0)^* (\omega_L)_A, \tag{42}$$

which follows from Lemma 2.1,

$$j^* \Omega_A = j^* (pr_2)^* (\omega_0)_A = (pr_2^0)^* (\omega_0)_A = (FL \circ pr_1^0)^* (\omega_0)_A = (pr_1^0)^* FL^* (\omega_0)_A = (pr_1^0)^* (\omega_L)_A.$$

On the other hand we obtain that

$$j^*\mathcal{H} = (pr_1^0)^* E_L, \tag{43}$$

from the following computation:

$$j^*\mathcal{H} = j^*(\mathcal{C} - (pr_1)^* L) = j^*\mathcal{C} - j^*(pr_1)^* L = (pr_1^0)^* CL - (pr_1^0)^* L = (pr_1^0)^* E_L.$$

From (41) and (42) we deduce that

$$\sum_{A=1}^{k} \imath_{Z_A} j^*\Omega_A = \sum_{A=1}^{k} \imath_{(pr_1^0)^*(X_L)_A} (pr_1^0)^*(\omega_L)_A = (pr_1^0)^* \left(\sum_{A=1}^{k} \imath_{(X_L)_A} (\omega_L)_A \right), \tag{44}$$

and from (43) we deduce that

$$\mathrm{d}(j^*\mathcal{H}) = \mathrm{d}((pr_1^0)^* E_L) = (pr_1^0)^* \, \mathrm{d}E_L. \tag{45}$$

Since pr_1^0 is a diffeomorphism, from (44) and (45) we deduce that the k-vector field $\mathbf{Z}$ is a solution to (26) iff the k-vector field $\mathbf{X}_L$ is a solution to (16).

Let us suppose now that the k-vector field $\mathbf{Z}$ is integrable. As a consequence of Theorem 5.1, for every integral section $\psi = (\psi_L, FL \circ \psi_L)$ of $\mathbf{Z}$, $\psi_L = \phi^{(1)}$, for $\phi = \tau \circ pr_1 \circ \psi$. Then

$$(X_L)_A(pr_1^0(\psi(t))) = (pr_1^0)_*(\psi(t))(Z_A(\psi(t))) = (pr_1^0 \circ \psi)_*(t)\left(\frac{\partial}{\partial t^A}\bigg|_q \right) = (\psi_L)_*(t)\left(\frac{\partial}{\partial t^A}\bigg|_q \right).$$

So, $\psi_L = \phi^{(1)}$ is an integral section of $\mathbf{X}_L$, and hence $\mathbf{X}_L$ is holonomic.

Conversely, if $\mathbf{X}_L$ is holonomic then for every integral section $\psi_L = \phi^{(1)}$ with $\phi : \mathbb{R}^k \to Q$, the map $\psi = (\psi_L, FL \circ \psi_L)$ is an integral section of $\mathbf{Z}$. In fact, from (41), for every $1 \leqslant A \leqslant k$,

$$\begin{aligned} Z_A(\psi(t)) = ((pr_1^0)^*(X_L)_A)(\psi(t)) &= ((pr_1^0)^{-1})_*(\psi_L(t))((X_L)_A(\psi_L(t))) \\ &= ((pr_1^0)^{-1})_*(\psi_L(t))\left((\psi_L)_*(t)\left(\frac{\partial}{\partial t^A}(t) \right) \right) \\ &= ((pr_1^0)^{-1} \circ \psi_L)_*(t)\left(\frac{\partial}{\partial t^A}\bigg|_q \right) = \psi_*(t)\left(\frac{\partial}{\partial t^A}\bigg|_q \right). \end{aligned}$$

■

If L is regular, in a neighborhood of each point of $T_k^1 Q$ there exists a local solution $\mathbf{X}_L = ((X_L)_1, \ldots, (X_L)_k)$ to (16). As L is regular, FL is a local diffeomorphism, so this open neighborhood can be chosen in such a way that FL is a diffeomorphism onto its image. Thus in a neighborhood of each point of $FL(T_k^1 Q)$ we can define

$$(X_H)_A = [(FL)^{-1}]^*(X_L)_A, \quad 1 \leqslant A \leqslant k,$$

or equivalently, in terms of k-vector fields

$$T_k^1(FL) \circ X_L = X_H.$$

Proposition 5.3: (1) The local k-vector field $\mathbf{X}_H = ((X_H)_1, \ldots, (X_H)_k)$ is a solution to (13), where the Hamiltonian H is locally given by $H \circ FL = E_L$. (In other words, the local k-vector fields $\mathbf{X}_L$ and $\mathbf{X}_H$ solution to (13) and (16), respectively, are FL related).

(2) Every local integrable k-vector field solution to (13) can be recovered in this way from a local integrable k-vector field $\mathbf{Z}$ in $T_k^1 Q \oplus_Q (T_k^1)^* Q$ solution to (26).

Proof:

(1) This is the local version of Theorem 4.1 (a).

(2) On the other hand, if $\mathbf{X}_H$ is a local integrable k-vector field solution to (13), then we can obtain the FL-related local integrable k-vector field $\mathbf{X}_L$ solution to (16). By Theorem 5.2, we recover $\mathbf{X}_L$ by a local integrable k-vector field $\mathbf{Z}$ solution to (26). ■

VI. FIELD OPERATORS

A. The evolution operator $\mathcal{K}$ in mechanics

The so-called *time-evolution $\mathcal{K}$-operator* in mechanics (also known by some authors as the *relative Hamiltonian vector field* [21]) is a tool which has mainly been developed in order to study the Lagrangian and Hamiltonian formalisms for singular mechanical systems and their equivalence. It was first introduced in a nonintrinsic way in Ref. 22 as an "evolution operator" to connect both formalisms.

In classical mechanics, the evolution operator $\mathcal{K}$ associated with a Lagrangian $L: TQ \to \mathbb{R}$ is a map $\mathcal{K}: TQ \to T(T^*Q)$ satisfying the following conditions (see Ref. 25).

(1) (Structural condition) $\mathcal{K}$ is a vector field along FL, that is, $\tau_{T^*Q} \circ \mathcal{K} = FL$, where FL is the Legendre map defined by L and $\tau_{T^*Q}: T(T^*Q) \to T^*Q$ is the natural projection.
(2) (Dynamical condition) $(FL)^*(\imath_{\mathcal{K}}(\omega \circ FL)) = \mathrm{d}E_L$, where ω is the canonical symplectic form on T^*Q and $E_L = CL - L$, being C the Liouville vector field on TQ.
(3) (Second-order condition) $T(\tau^*) \circ \mathcal{K} = Id_{TQ}$, where $\tau^*: T^*Q \to Q$ is the canonical projection.

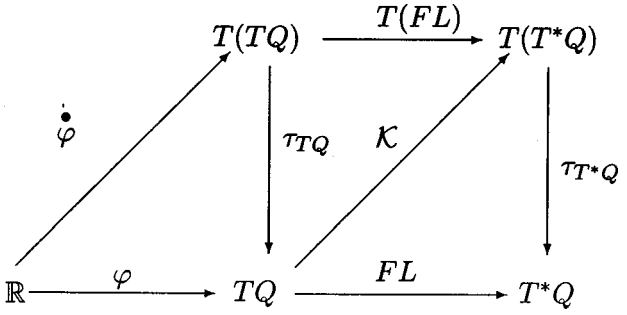
The existence and uniqueness of this operator is studied in Ref. 25. Its local expression is

$$\mathcal{K} = v^i \left(\frac{\partial}{\partial q^i} \circ FL \right) + \frac{\partial L}{\partial q^i} \left(\frac{\partial}{\partial p_i} \circ FL \right).$$

By definition $\varphi: \mathbb{R} \to TQ$ is an integral curve of $\mathcal{K}$ if

$$T(FL) \circ \dot{\varphi} = \mathcal{K} \circ \varphi, \tag{46}$$

where $\dot{\varphi}: \mathbb{R} \to T(TQ)$ is the prolongation of φ to the tangent bundle $T(TQ)$ of TQ. So we have the diagram



Moreover, (2) $\varphi = \dot{\phi}$, for $\phi: \mathbb{R} \to Q$, that is, φ is holonomic.

The most relevant properties of this operator are the following.

(i) If there exists a Euler–Lagrange vector field X_L on TQ, that is, a solution to the equation $\imath_{X_L}\omega_L = \mathrm{d}E_L$, then $\varphi: \mathbb{R} \to TQ$ is an integral curve of X_L if, and only if, it is an integral curve of $\mathcal{K}$; that is, relation (46) holds.
As a direct consequence of this fact, the relation between $\mathcal{K}$ and X_L is

$$T(FL) \circ X_L = \mathcal{K}. \tag{47}$$

In general, if the dynamical system is singular, the Euler–Lagrange vector fields exist only on a submanifold $S \hookrightarrow TQ$.

(ii) If there exists a Hamilton–Dirac vector field X_H on T^*Q associated with the the Lagrangian system (TQ, ω_L, E_L) (that is, a vector field solution to the Hamilton–Dirac equations in the Hamiltonian formalism), then $\psi: \mathbb{R} \to T^*Q$ is an integral curve of X_H if, and only if,

$$\dot{\psi} = K \circ T(\tau_Q^*) \circ \dot{\psi}. \tag{48}$$

As a consequence, the relation between $\mathcal{K}$ y X_H is

$$X_H \circ FL = \mathcal{K}. \tag{49}$$

(iii) If $\xi \in C^\infty(T^*Q)$ is a Hamiltonian constraint, then $\imath_{\mathcal{K}}(\mathrm{d}\xi \circ FL)$ is a Lagrangian constraint.

Relations (46)–(49) show how the Lagrangian and Hamiltonian descriptions can be unified by means of the operator $\mathcal{K}$.

Some relevant results obtained using this operator are the following.

(i) The equivalence between the Lagrangian and Hamiltonian formalisms is proved by means of this operator in the following way: there is a bijection between the sets of solutions of Euler–Lagrange equations and Hamilton equations, even though the dimensions of the final constraint submanifold in both formalisms are not the same, in general.[22,40]
(ii) The complete classification of constraints is achieved. All the Lagrangian constraints can be obtained from the Hamiltonian ones using the $\mathcal{K}$ operator.[22]
(iii) Noether's theorem is proved and the relation between the generators of gauge and "rigid" symmetries in the Lagrangian and Hamiltonian formalisms is studied.[27–29,41]
(iv) This operator has been applied to studying Lagrangian systems whose Legendre map has *generic singularities*; that is, it degenerates on a hypersurface.[21,30]

B. Field operators $\mathcal{K}$ in field theories

Next we generalize the definition, properties and some of the applications of the evolution operator for the *k*-symplectic formulation of field theories, in order to describe the relationship between the Lagrangian and Hamiltonian formalisms (the generalization for the multisymplectic formulation is given[31]). In particular, we will study how to obtain the solutions of Lagrangian and Hamiltonian field equations by means of this operator, and the relation between them.

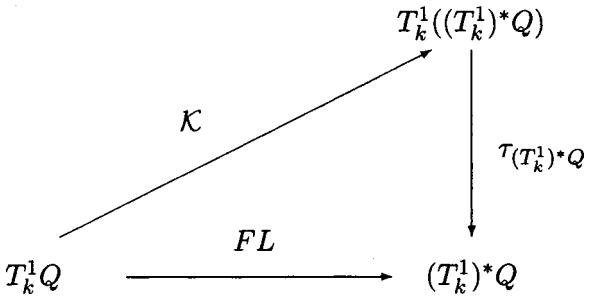
Definition 6.1: *A* field operator $\mathcal{K}$ *associated with a Lagrangian* $L: T_k^1Q \to \mathbb{R}$ *is a map*

$$\mathcal{K}: T_k^1Q \to T_k^1((T_k^1)^*Q)$$

satisfying the following conditions.

(1) *Structural condition:* $\mathcal{K}$ *is a k-vector field along FL, that is*

$$\tau_{(T_k^1)^*Q} \circ \mathcal{K} = FL. \tag{50}$$



Hence $\mathcal{K} = (\mathcal{K}_1, \ldots, \mathcal{K}_k)$, *where each* $\mathcal{K}_A$, $1 \leqslant A \leqslant k$, *is a vector field along FL.*

(2) *Field equation condition,*

$$\sum_{A=1}^{k} (FL)^*[\imath_{\mathcal{K}_A}(\omega_0)_A \circ FL) = \mathrm{d}E_L. \tag{51}$$

(3) *Second-order condition,*

$$T_k^1(\tau_Q^*)\circ\mathcal{K}=Id_{T_k^1Q}. \tag{52}$$

Now we are going to calculate the local expression of a field operator $\mathcal{K}$. If $v=(v_{1q},\ldots,v_{kq})\in T_k^1Q$ then from (50) we have that

$$\mathcal{K}_A(v)=(\mathcal{K}_A)^i(v)\left.\frac{\partial}{\partial q^i}\right|_{FL(v)}+(\mathcal{K}_A)_i^B(v)\left.\frac{\partial}{\partial p_i^B}\right|_{FL(v)},\quad 1\leqslant A\leqslant k.$$

Taking into account (52) and that the map $T_k^1(\tau_Q^*):T_k^1((T_k^1)^*Q)\to T_k^1Q$ is locally given by $T_k^1(\tau_Q^*)(q^i,p_i^A,(u_A)^i,(u_A)_i^B)=(q^i,(u_A)^i)$, we obtain that

$$(\mathcal{K}_A)^i=v_A^i. \tag{53}$$

Then, writing in local coordinates the expression (51)

$$\sum_{A=1}^k(\omega_0)_A(FL(v))\left(\mathcal{K}_A(v),(FL)_*(v)\left(\left.\frac{\partial}{\partial q^i}\right|_v\right)\right)=\mathrm{d}E_L\left(\left.\frac{\partial}{\partial q^i}\right|_v\right),$$

we obtain that

$$\sum_{A=1}^k\left(v_A^k\frac{\partial^2L}{\partial q^i\,\partial v_A^k}(v)-(\mathcal{K}_A)_j^A(v)\right)=\sum_{A=1}^k v_A^k\frac{\partial^2L}{\partial q^i\,\partial v_A^k}(v)-\frac{\partial L}{\partial q^i}(v).$$

Therefore

$$\sum_{A=1}^k(\mathcal{K}_A)_j^A=(\mathcal{K}_1)_i^1+(\mathcal{K}_2)_i^2+\cdots+(\mathcal{K}_k)_i^k=\frac{\partial L}{\partial q^i}, \tag{54}$$

which means that every field operator $\mathcal{K}_A$ is locally given by

$$\mathcal{K}_A=v_A^i\left(\frac{\partial}{\partial q^i}\circ FL\right)+(\mathcal{K}_A)_i^B\left(\frac{\partial}{\partial p_i^B}\circ FL\right),\quad 1\leqslant A\leqslant k,$$

where the components $(\mathcal{K}_A)_i^B$ satisfy the identity (54).

Equations (53) and (54) lead us to define local solutions in a neighborhood of each point of T_k^1Q satisfying conditions (1), (2), and (3) in Definition 6.1,

$$\mathcal{K}_A=v_A^i\left(\frac{\partial}{\partial q^i}\circ FL\right)+\frac{1}{k}\frac{\partial L}{\partial q^i}\left(\frac{\partial}{\partial p_i^A}\circ FL\right),\quad 1\leqslant A\leqslant k,$$

and, by using a partition of the unity, we obtain global solutions.

Definition 6.2: $\psi:\mathbb{R}^k\to T_k^1Q$ is an integral section of the field operator $\mathcal{K}$ if

$$T_k^1(FL)\circ\psi^{(1)}=\mathcal{K}\circ\psi.$$

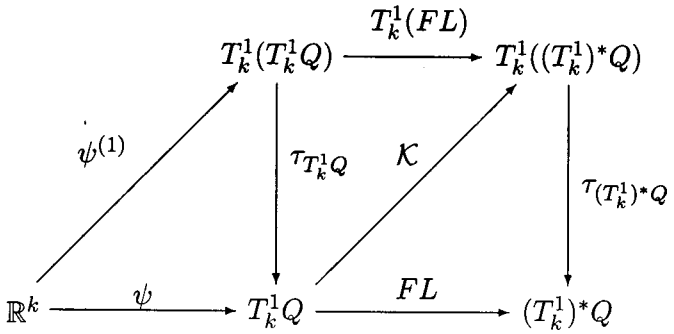
Definition 6.2 means that, for every $t\in\mathbb{R}^k$,

$$\mathcal{K}_A(\psi(t))=(FL)_*(\psi(t))\left(\psi_*(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right)\right),\quad 1\leqslant A\leqslant k,$$

because

$$(T_k^1(FL)\circ\psi^{(1)})(t)=T_k^1(FL)(j_0^1\psi_t)=j_0^1(FL\circ\psi_t),$$

where $\psi_t(\overline{t})=\psi(t+\overline{t})$. Thus we have the following diagram:



C. Properties of the field operators related to the Lagrangian formalism

In this section we study the properties of the field operator in relation to the Lagrangian field equations. In particular, we generalize the properties of the evolution operator in mechanics given in Eq. (47).

Proposition 6.1: Let $L:T_k^1Q\to\mathbb{R}$ be a Lagrangian. $\psi:\mathbb{R}^k\to T_k^1Q$ is an integral section of $\mathcal{K}$ if, and only if, $\tau_Q\circ\psi:\mathbb{R}^k\overset{\psi}{\to}T_k^1Q\overset{\tau_Q}{\to}Q$ is a solution to the Euler–Lagrange equations (15).

Proof: If $\psi:\mathbb{R}^k\to T_k^1Q$ is locally given by $\psi(t)=(\psi^i(t),\psi_A^i(t))$, then from (6) we obtain that

$$(FL\circ\psi)_*(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right)=\frac{\partial\psi^j}{\partial t^A}(t)\left.\frac{\partial}{\partial q^j}\right|_{FL(\psi(t))}+\left(\frac{\partial^2L}{\partial q^i\,\partial v_C^j}(\psi(t))\frac{\partial\psi^i}{\partial t^A}(t)+\frac{\partial\psi_B^j}{\partial t^A}(t)\frac{\partial^2L}{\partial v_B^i\,\partial v_C^j}(\psi(t))\right)\times\left.\frac{\partial}{\partial p_j^C}\right|_{FL(\psi(t))}. \tag{55}$$

On the other hand,

$$\mathcal{K}_A(\psi(t))=v_A^j(\psi(t))\left.\frac{\partial}{\partial q^j}\right|_{FL(\psi(t))}+(\mathcal{K}_A)_j^C(\psi(t))\left.\frac{\partial}{\partial p_j^C}\right|_{FL(\psi(t))}. \tag{56}$$

So if ψ is a solution to $\mathcal{K}$, then from (55) and (56) we obtain the equations

$$\frac{\partial\psi^j}{\partial t^A}(t)=v_A^j(\psi(t))=\psi_A^j(t), \tag{57}$$

and

$$\left.\frac{\partial}{\partial t^A}\right|_t\left(\frac{\partial L}{\partial v_C^j}(\psi(t))\right)=\frac{\partial^2L}{\partial q^i\,\partial v_C^j}(\psi(t))\frac{\partial\psi^i}{\partial t^A}(t)+\frac{\partial^2\psi^i}{\partial t^A\,\partial t^B}(t)\frac{\partial^2L}{\partial v_B^i\,\partial v_C^j}(\psi(t))=(\mathcal{K}_A)_j^C(\psi(t)), \tag{58}$$

for every $A=1,\ldots,k$. Therefore, from (54), (57), and (58) we obtain

$$\sum_{A=1}^k\left.\frac{\partial}{\partial t^A}\right|_t\left(\frac{\partial L}{\partial v_A^i}(\psi(t))\right)=\sum_{A=1}^k(\mathcal{K}_A)_i^A(\psi(t))=\frac{\partial L}{\partial q^i}(\psi(t)),\quad \psi_A^i(t)=\frac{\partial\psi^i}{\partial t^A}(t),$$

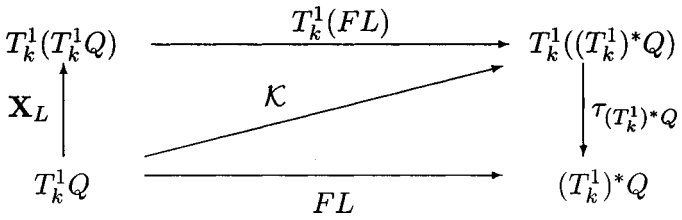
that is $(\tau_Q\circ\psi)(t)=(\psi^i(t))$ is a solution to the Euler–Lagrange equations (15).

The proof of the converse follows the same pattern than in the proof of the converse statement of Proposition 4.1. ■

Theorem 6.1: *Let $L:T_k^1Q\to\mathbb{R}$ be a Lagrangian and let $\mathcal{K}$ be a k vector field along the Legendre map $FL:T_k^1Q\to(T_k^1)^*Q$. If $\mathbf{X}_L:T_k^1Q\to T_k^1(T_k^1Q)$ is a k-vector field on T_k^1Q and $j_S:S\hookrightarrow T_k^1Q$ is a submanifold of T_k^1Q such that*

$$T_k^1(FL)\circ \mathbf{X}_L \underset{S}{=} \mathcal{K}, \tag{59}$$

then $\mathcal{K}$ *is a field operator associated with the Lagrangian* L *if, and only if,* $\mathbf{X}_L$ *is a* SOPDE *solution to the equation (16).*



Proof: We must prove that both the second-order condition, and the field equation condition hold for $\mathcal{K}$ if, and only if, they hold for $\mathbf{X}_L$. In this proof all the equalities hold on S.

First, if $\mathcal{K}=(\mathcal{K}_1,\ldots,\mathcal{K}_k)$ and $\mathbf{X}_L=((X_L)_1,\ldots,(X_L)_k)$, then Eq. (59) is equivalent to

$$T(FL)\circ (X_L)_A \underset{S}{=} \mathcal{K}_A, \quad 1\leqslant A\leqslant k.$$

On the other hand $(\omega_L)_A=(FL)^*(\omega_0)_A$ so one easily proves that

$$\imath_{(X_L)_A}(\omega_L)_A \underset{S}{=} (FL)^*(\imath_{\mathcal{K}_A}(\omega_0)_A\circ FL),$$

and for the field equation we obtain

$$\sum_{A=1}^{k}[(FL)^*(\imath_{\mathcal{K}_A}(\omega_A\circ FL)] - \mathrm{d}E_L \underset{S}{=} \sum_{A=1}^{k}[\imath_{X_A}(\omega_L)_A] - \mathrm{d}E_L,$$

hence the field equation condition holds for $\mathcal{K}$ if, and only if, the Lagrangian field equation holds for $\mathbf{X}_L$.

Furthermore, in relation to the second-order condition (see Definition 3.3) we have that

$$T_k^1(\tau_Q^*)\circ\mathcal{K}=Id_{T_k^1Q} \Leftrightarrow T_k^1(\tau_Q^*)\circ T_k^1(FL)\circ\mathbf{X}_L=Id_{T_k^1Q} \Leftrightarrow T_k^1(\tau_Q)\circ\mathbf{X}_L=Id_{T_k^1Q}$$

because FL is a fiber preserving map, that is $\tau_Q^*\circ FL=\tau_Q$, and hence $T_k^1(\tau_Q^*)\circ T_k^1(FL)=T_k^1(\tau_Q)$. Thus the last equality is equivalent to (8), and so the second-order conditions for $\mathcal{K}$ and $\mathbf{X}_L$ are related. ■

Finally, as an immediate consequence of Propositions 4.1 and 6.1, and Theorem 6.1, we have the following.

Corollary 6.1: Under the hypotheses of Theorem 6.1, $\psi:\mathbb{R}^k\to S\subset T_k^1Q$ *is an integral section of the field operator* $\mathcal{K}$ *if, and only if, it is an integral section of the* SOPDE $\mathbf{X}_L$. *(This means that* $\mathcal{K}$ *is integrable if, and only if,* $\mathbf{X}_L$ *is integrable).*

Moreover, every integral section $\psi:\mathbb{R}^k\to S\subset T_k^1Q$ *is a holonomic section.*

D. Properties of the field operators related to the Hamiltonian formalism

Next we analyze the properties of the field operator in relation to the Hamilton–de Donder–Weyl field equations, generalizing the properties of the evolution operator in mechanics given in Eqs. (48) and (49).

Theorem 6.2: *Let* L *be an almost-regular Lagrangian function, and* $\mathcal{K}$ *a field operator associated with* L. *If there exists a k-vector field* $\mathbf{X}_0:\mathcal{P}\to T_k^1\mathcal{P}$, *and a submanifold* $j_S:S\hookrightarrow T_k^1Q$, *such that*

$$T_k^1 j_0\circ\mathbf{X}_0\circ FL_0 \underset{S}{=} \mathcal{K}, \tag{60}$$

then $\mathbf{X}_0$ *is a solution to the equation (24) on* $P=FL_0(S)$.

Conversely, if $\mathbf{X}_0$ *is a k-vector field solution to the equation (24), then the above relation defines a k-vector field* $\mathcal{K}$ *along FL, which satisfy conditions (1) and (2) of Definition 6.1, on S, but not condition (3) (second-order condition) necessarily.*

If L is a hyper-regular Lagrangian function, then the same results hold (with $S=T^1_kQ$*). But in addition, in the converse statements the k-vector field* $\mathcal{K}$ *along FL also satisfies the second-order condition (3) of Definition 6.1, and hence it is a field operator for L.*

Proof: Equation (60) means that

$$(j_0)_*(FL_0(s))((X_0)_A(FL_0(s))) = \mathcal{K}_A(s), \quad s \in S, \quad 1 \leqslant A \leqslant k. \tag{61}$$

Then, since $j_0 \circ FL_0 = FL$ and $(j_0)^*(\omega_0)_A = \omega^0_A$ we deduce from (61) that

$$(FL)^*(\imath_{\mathcal{K}_A}((\omega_0)_A \circ FL)) \underset{S}{=} (FL_0)^*(\imath_{(X_0)_A}\omega^0_A)$$

and since $(FL_0)^*H_0 = E_L$ we obtain

$$\sum_{A=1}^{k} (FL)^*(\imath_{\mathcal{K}_A}((\omega_0)_A \circ FL)) - \mathrm{d}E_L \underset{S}{=} (FL_0)^*\left(\sum_{A=1}^{k} (\imath_{(X_0)_A}\omega^0_A) - \mathrm{d}H_0\right),$$

where all the equalities hold on S. But, as FL_0 is a submersion, we obtain that

$$\sum_{A=1}^{k} (FL)^*(\imath_{\mathcal{K}_A}((\omega_0)_A \circ FL)) - \mathrm{d}E_L \underset{S}{=} 0 \Leftrightarrow \sum_{A=1}^{k} (\imath_{(X_0)_A}\omega^0_A) - \mathrm{d}H_0 \underset{P}{=} 0,$$

hence the field equation condition holds for $\mathcal{K}$ on S if, and only if, the Hamiltonian field equation holds for X_0 on $P=FL_0(S)$.

For hyper-regular systems, the proof of these properties is the same, but taking into acount that now $\mathcal{P}=(T^1_k)^*Q$, and $FL_0=FL$. In addition, the k-vector field $\mathbf{X}_0 \equiv \mathbf{X}$ is defined everywhere in $(T^1_k)^*Q$. Thus, the only addendum is to prove that, if $\mathbf{X}$ is a solution to the equation (24), then its associated k-vector field along $FL, \mathcal{K}$, satisfies the second-order condition. As $\mathbf{X}$ is a k-vector field in $(T^1_k)^*Q$, by definition it is a section of $\tau_{(T^1_k)^*Q}$, thus $\tau_{(T^1_k)^*Q} \circ \mathbf{X} = Id_{(T^1_k)^*Q}$. Then, taking into account that FL is a diffeomorphism, and that (60) reduces to $\mathbf{X} \circ FL = \mathcal{K}$, we have that

$$T^1_k(\tau^*_Q) \circ \mathcal{K} = T^1_k(\tau^*_Q) \circ \mathbf{X} \circ FL = FL^{-1} \circ \tau_{(T^1_k)^*Q} \circ \mathbf{X} \circ FL = Id_{T^1_kQ}$$

which is the second-order condition for $\mathcal{K}$. ■

Then assuming all these relations, we have the following

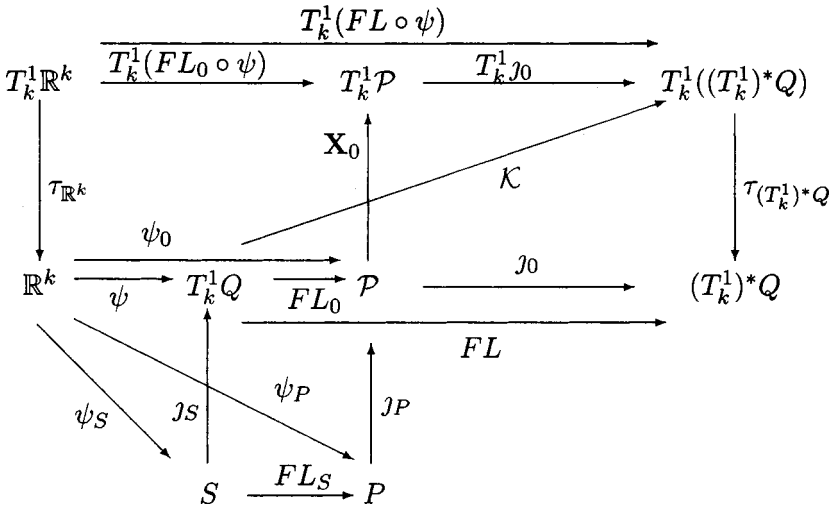
Theorem 6.3: $\mathcal{K}$ *is integrable if, and only if,* $\mathbf{X}_0$ *is integrable. In particular* we have the following.

(1) *Let* $FL_S: S \to P$ *be the restriction of* FL_0 *to S (that is,* $j_P \circ FL_S = FL_0 \circ j_S$*). If* $\psi: \mathbb{R}^k \overset{\psi_S}{\to} S \overset{j_S}{\hookrightarrow} T^1_kQ$ *is an integral section of* $\mathcal{K}$ *on S, then* $\psi_0: \mathbb{R}^k \overset{\psi_P}{\to} P \overset{j_P}{\hookrightarrow} \mathcal{P}$ *is an integral section of* $\mathbf{X}_0$ *on P, where* $\psi_P := FL_S \circ \psi_S$.

(2) *Conversely, if* $\psi_0: \mathbb{R}^k \overset{\psi_P}{\to} P \overset{j_P}{\hookrightarrow} \mathcal{P}$ *is an integral section of* $\mathbf{X}_0$ *on P, then the section* $\psi: \mathbb{R}^k \overset{\psi_S}{\to} S \overset{j_S}{\hookrightarrow} T^1_kQ$ *is an integral section of* $\mathcal{K}$ *on S, for every* $\psi_S: \mathbb{R}^k \to S \subseteq T^1_kQ$ *such that* $\psi_P = FL_S \circ \psi_S$.

The section ψ_S*, and hence* $\psi := j_S \circ \varphi_S$*, are holonomic if, and only if,* $\mathcal{K}$ *satisfies the second-order condition (and hence it is a field operator).*

Proof: If the system is almost regular, consider the diagram



(62)

(where $\mathbf{X}_0$ denotes any extension of the k-vector field solution on P to $\mathcal{P}$).

(1) If ψ is an integral section of $\mathcal{K}$ then

$$\mathcal{K}_A(\psi(t)) = (FL\circ\psi)_*(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right), \quad 1\leqslant A\leqslant k, \tag{63}$$

but $FL\circ\psi=j_0\circ\psi_0$ because

$$FL\circ\psi = FL\circ j_S\circ\psi_S = j_0\circ j_P\circ FL_S\circ\psi_S = j_0\circ j_P\circ\psi = j_0\circ\psi_0,$$

therefore (63) is equivalent to

$$\mathcal{K}_A(\psi(t)) = (j_0)_*(\psi_0(t))\left((\psi_0)_*(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right)\right), \quad 1\leqslant A\leqslant k. \tag{64}$$

Furthermore, from (61) and taking into account that $FL_0\circ\psi=\psi_0$, we have that

$$\mathcal{K}_A(\psi(t)) = (j_0)_*(FL_0(\psi(t)))(X_0)_A(FL_0(\psi(t))) = (j_0)_*(\psi_0(t))((X_0)_A(\psi_0(t))), \tag{65}$$

then, from (64) and (65), taking into account that j_0 is an imbedding, we deduce

$$(\psi_0)_*(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right) = (X_0)_A(\psi_0(t)), \quad 1\leqslant A\leqslant k.$$

Hence, ψ_0 is integral section of $\mathbf{X}_0$.

(2) The converse is proved by reversing the above reasoning. In addition, the sections ψ_S and $\psi:=j_S\circ\psi_S$ are holonomic if, and only if, they are integral sections of a second-order k-vector field along the Legendre map.

If the system is hyper-regular the proof is analogous, but taking $\mathcal{P}=(T_k^1)^*Q$ and $FL_0=FL$. ■

It is important to point out that, if the integrability condition holds only in a submanifold $\mathcal{I}\hookrightarrow S$, then Theorem 6.3 only holds on $\mathcal{I}$ and $FL(\mathcal{I})$ (which is assumed to be a submanifold of P).

Observe also that Theorem 6.3, together with Theorem 6.1, establish the equivalence between the Lagrangian and Hamiltonian formalisms.

In this paper we explore the general conditions in order that a two-dimensional natural Hamiltonian system possess a second invariant which is a polynomial in the momenta and is therefore Liouville integrable. We examine the possibility that the invariant is preserved by the Hamiltonian flow on a given energy hypersurface only (weak integrability) and derive the additional requirement necessary to have conservation at arbitrary energy (strong integrability). Using null complex coordinates, we show that the leading order coefficient of the polynomial is an arbitrary holomorphic function in the case of weak integrability and a polynomial in the coordinates in the strongly integrable one. We review the results obtained so far with strong invariants up to degree four and provide some new examples of weakly integrable systems with linear and quadratic invariants. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1888565]

I. INTRODUCTION

In 1983 Hall[1] published a remarkable paper devoted to a theory of *configurational invariants* of classical Hamiltonian systems. The main virtue of the work consisted in an elegant and powerful technique to solve the equations for the existence of a second polynomial invariant of arbitrary degree in the momenta for two-dimensional Hamiltonian systems. As a result of this approach, Hall was able to get some new examples of integrable systems admitting a second invariant of degree four in the momenta.

Unfortunately, the paper was flawed by a definitely wrong statement and also by many inaccurate arguments and deductions. In fact, Hall purported to remedy supposed oversights in previous works on the search for the second invariant, in particular criticizing the classical account by Whittaker.[2] In Hall's view, Whittaker's (and all others' since then) treatment provides only sufficient conditions for the existence of a second invariant (linear and quadratic in the specific instance), whereas, due to overlooking the link established on phase-space variables by energy conservation, it was not able to find all possible solutions. Actually, as it is, this statement is wrong, in looking for a *strong* second invariant, namely a phase-space function which commutes with the Hamiltonian function, Whittaker's approach is indeed correct and leads to *necessary and sufficient* conditions for its existence. This point was already stressed by Sarlet *et al.*[3] in their criticism to Hall's paper.

Moreover, Hall's discussion contained a confusion between the concept of configurational (or *weak*) invariant, as a function which exactly commutes with the Hamiltonian only on a subset (possibly one) of the energy hypersurfaces (see again Ref. 3 and, e.g., Ref. 4), and the notion of what we may call *formal integral* as it emerges in the analysis of regular portions of the phase space of generic nonintegrable systems (see, e.g., Ref. 5). In particular, the approximate invariants

[a)]Electronic mail: pucacco@roma2.infn.it
[b)]Electronic mail: kr@physto.se

obtained by Hall as a result of his perturbative approach have little to do with those that can be obtained by truncating a normal form expansion.

Nonetheless, in spite of all the above shortcomings, the form in which the problem has been set by Hall and the approach followed for its partial solution deserve attention, since they can still be very useful. Already Hietarinta,[6] in his account of the direct methods for the search of the second invariant, provides a review of all the known systems admitting one or more configurational invariants and works out again the integrability conditions found by Hall for the existence of weak invariants up to degree four. However, in Hietarinta's review, the two settings of weak and strong integrability are still kept well separated. More recently, in a series of works about a unified approach to treat both kinds of invariants,[7–10] the same integrability conditions have been obtained, *supplemented by the additional constraint imposed by strong integrability*. This last step is essential for a neat distinction between the two notions of weak and strong integrability. In these works, this step is a straightforward consequence of the geometric approach in which the existence of the second invariant is addressed by studying the corresponding Killing tensor equations for the Jacobi metric. This metric depends on the mechanical energy as a parameter. Therefore, any tensor object on the corresponding manifold in general depends on the energy. With due care about formal relations between the two approaches, the geometric approach and Hall's approach are equivalent. The essential remark is that, to identify the cases of strong integrability, it is sufficient that in the final results concerning the existence of the invariant, a subset can be isolated which is independent of the energy parameter. In this framework, in Ref. 7, quadratic invariants at arbitrary and fixed energy for two-dimensional Hamiltonian systems were treated in a unified way, whereas in Refs. 8 and 9 the existence of, respectively, *cubic* and *quartic* invariants was discussed accompanied with the discovery of some new examples not given in earlier works (see, e.g., Refs. 10–13). In Ref. 14 the case of Hamiltonian systems with vector potentials is treated, extending previous investigations.[15–20]

The aim of the present paper is to discuss the techniques for solving the equations for a second invariant having a momentum dependence of arbitrary polynomial degree. The analysis is based on a combination of both the above-mentioned approaches, with particular attention dedicated to the conformal transformations used to simplify the equations. The treatment is in general effective for both classes of invariants, configurational (or weak) and strong. After that, we impose the additional condition needed to isolate the class of strongly integrable systems, obtaining the general form of the simplifying family of transformations for each degree of the strong invariant looked for. This in turn implies determining the leading order terms in the invariant itself. An alternative route to this result in the geometric approach is based on the invariance, under conformal transformations, of the conformal part of the Killing tensor. Moreover, a general review of the results obtained so far is provided.

The plan of the paper is as follows: in Sec. II we compare the notion of weak and strong invariants and, working out in detail the quadratic case, we correct Hall's misunderstanding, providing the constraint to be satisfied in order to get strong integrability as a restriction of weak integrability; in Sec. III we recall time reparametrization of the null Hamiltonian and complex ("null") coordinates used to simplify the direct approach; in Sec. IV these tools are exploited to set the general approach to find polynomial invariants of arbitrary degree; in Sec. V we recall the main results concerning invariants of degree up to four; in Sec. VI we present our conclusions and the prospects for future works.

II. CONFIGURATIONAL INVARIANTS VERSUS STRONG INVARIANTS

As it is well known (see, e.g., Ref. 21), to grant the complete integrability of an N-dimensional Hamiltonian system, it is necessary and sufficient to find N independent integrals of motion or *invariants*, for short. In the following, we will limit ourselves to the simplest case of a conservative Hamiltonian system in two dimensions ($N=2$). Since the Hamiltonian itself

$$H = \tfrac{1}{2}(p_x^2 + p_y^2) + V(x,y), \tag{1}$$

is a conserved function, it is enough to find just a second independent invariant.

In his search for polynomial invariants, Hall[1] exploits what is usually called the "direct approach" of Darboux[22] and Whittaker.[2] As an "educated guess" we may start with the working hypothesis of an invariant with a structure analogous to that of the Hamiltonian, namely a second degree polynomial in the momenta. (Since all the work is made in a Hamiltonian context, contrary to the original treatment by Hall, we use canonical phase-space coordinates. However, we have tried to stay as close as possible to his treatment as refers to the procedure and notations.) Clearly, one could start with a polynomial of arbitrary degree or even with a more general expression. In the core part of the paper we will examine the general case. Now, as an introduction aimed at giving the proper settings, we work out in detail the quadratic case. We may then look for a phase-space function of the form

$$I_2(p_x,p_y,x,y) = Ap_x^2 + Bp_xp_y + Cp_y^2 + K, \tag{2}$$

which is preserved along the flow given by Eq. (1), namely

$$\{I_2,H\} = 0. \tag{3}$$

In Eq. (2), A, B, C, and K are each functions of x and y. Actually Hall, probably motivated by his interest in accelerator physics, manages to work out the integrability of Hamiltonians including also a vector potential and henceforth terms which are linear in the momenta. This, in turn, suggests the inclusion of analogous terms in the invariant. However, in the standard case of a Hamiltonian invariant under momentum inversion, $p \to -p$, the equations for the coefficients of even and odd degree terms decouple, greatly reducing the complexity of the system to solve. Therefore, since the main purpose of this paper is to fully clarify the issues of weak and strong integrability, which are unaffected by such generalizations, we prefer to limit ourselves to the standard case of Eq. (1). The treatment of the vector potential is presented elsewhere[14] where new strongly integrable systems with quadratic invariants are presented.

In the direct approach, one inserts the functions (1) and (2) into the Poisson bracket (3). The resulting polynomial in the momenta, of third degree in the present instance, must be identically vanishing. In view of the independence and arbitrariness of the momentum coordinates, each coefficient of the polynomial must vanish, determining in turn the following system of PDEs in the coordinates

$$A_x = 0, \tag{4}$$

$$A_y + B_x = 0, \tag{5}$$

$$B_y + C_x = 0, \tag{6}$$

$$C_y = 0, \tag{7}$$

$$K_x = 2AV_x + BV_y, \tag{8}$$

$$K_y = BV_x + 2CV_y, \tag{9}$$

where, in order to compactify expressions, suffixes denote partial differentiation. As mentioned above, Darboux[22] addressed the problem and the equation ensuing from the integrability condition for K, that is

$$B(V_{yy} - V_{xx}) + 2(A - C)V_{xy} + 3(B_yV_y - B_xV_x) = 0, \tag{10}$$

is known as *Darboux's equation*. Whittaker[2] also analyzed the problem and, for a complete account of the solution of this system, the standard reference is again the review by Hietarinta.[6]

Equations involving only the leading order terms (A, B, and C) in the invariant are readily solved,

$$A = ay^2 + by + c, \tag{11}$$

$$B = -2axy - bx - \mathrm{d}y - e, \tag{12}$$

$$C = ax^2 + \mathrm{d}x + f. \tag{13}$$

Exploiting linear transformations of the coordinates, it can be shown[6,7] that these functions can be reduced to four canonical forms that, inserted into Darboux equation (10), lead to the complete solution of the problem, there exist four fundamental separating coordinate systems (elliptical, polar, parabolic, and Cartesian) in which the potential and the remaining unknown of the invariant, K, can be expressed in terms of combinations of arbitrary functions of each of the separating coordinates. Actually, in his reference to Whittaker's result, Hall mentions only the elliptical solution, but, as shown in Ref. 7 (see also Ref. 23), using conformal transformations, all the separable cases possess the same structure. Moreover, we remark on the additional possibility of complex potentials, which provides four more cases with complex separating coordinates, which are listed in Ref. 6 and can also be obtained with the techniques in Ref. 7.

At this point Hall states that (Ref. 1, p.93) "Whittaker's work $|\cdots|$ was flawed by his failure to recognize that terms in $\dot{x}^2$ and $\dot{y}^2$ are not independent for the purpose of setting the coefficients of their various powers to zero $|\cdots|$. They are related by conservation of energy. Therefore, Whittaker's constraints were over-restrictive; the solutions he found are valid, but others may also exist." On these bases, Hall elaborates a generalized approach that, in his view, provides necessary and sufficient conditions for the existence of the given invariant. Actually, as we will shortly see, Hall fails in recognizing that the possible extension of the family of solutions implies a different status for the additional invariants, they are "fixed energy" or *configurational* invariants.

Configurational (or "conditional" or even "weak") integrals hold for *a specified particular value of the energy constant* and were first investigated by Birkhoff[24] and considered by Fomenko,[25] Kozlov,[26] and others. Weak invariants enjoy weaker properties than their "nobler" cousins, the *strong* invariants, which are constant on *every* energy hypersurface admitted by the dynamics of the system. To clarify this essential point, let us again work with the quadratic case, concretely introducing Hall's argument. This goes as follows: for every value E of the energy, the function (1) defines the hypersurface

$$\tfrac{1}{2}(p_x^2 + p_y^2) + V(x,y) = E. \tag{14}$$

Let us construct the following linear combinations of the squares of the momenta:

$$\Sigma = p_x^2 + p_y^2, \tag{15}$$

$$\Delta = p_x^2 - p_y^2 \tag{16}$$

and observe that, in view of (14), we can impose the constraint

$$\Sigma = 2G(x,y), \tag{17}$$

where we have introduced the *"Jacobi" potential* [the origin of this denomination comes from the close relationship between the picture of a system constrained on the fixed energy surface and the geometric picture of a geodesic flow over a Riemannian manifold endowed with a "Jacobi" metric (see, e.g., Ref. 27)]

$$G = E - V. \tag{18}$$

The quadratic terms in the standard form of the invariant of Eq. (2) can now be written as

$$Ap_x^2 + Bp_xp_y + Cp_y^2 = \tfrac{1}{2}[(A + C)\Sigma + (A - C)\Delta + B\sqrt{\Sigma^2 - \Delta^2}]. \tag{19}$$

Exploiting the energy constraint (17) and redefining coefficients, the quadratic invariant can then be written as

$$I_2(p_x,p_y,x,y) = \tfrac{1}{2}D(p_x^2 - p_y^2) + Bp_xp_y + \tilde{K}, \tag{20}$$

where

$$D = A - C, \tag{21}$$

$$\tilde{K} = K + (A + C)G. \tag{22}$$

Now, we may proceed along the same lines followed above. The commutation relations (3) of the weak invariant (20) with the Hamiltonian reduce to the system

$$D_y + B_x = 0, \tag{23}$$

$$D_x - B_y = 0, \tag{24}$$

$$\tilde{K}_x = BV_y + DV_x - GB_y, \tag{25}$$

$$\tilde{K}_y = BV_x - DV_y - GB_x. \tag{26}$$

The integrability condition for $\tilde{K}$ is now the *generalized Darboux equation*,

$$B(V_{yy} - V_{xx}) + 2DV_{xy} + 3(B_yV_y - B_xV_x) - 2(E - V)D_{xy} = 0, \tag{27}$$

where we have explicitly pointed out the presence of the energy parameter. In practice, since the energy of the system is in general an arbitrary real number, we can write Eq. (27) in the form

$$f_1E + f_0 = 0, \tag{28}$$

where f_1, f_0 are functions of the coordinates, both explicitly and through V and its derivatives.

If we want that the looked for invariant has an identically vanishing Poisson bracket with the Hamilton *regardless of the value of the energy* (in other words that I_2 should be a *strong* invariant), Eq. (28) must be satisfied for every value of the parameter E so that the two equations

$$f_1 = 0, \tag{29}$$

$$f_0 = 0, \tag{30}$$

must separately be satisfied. The first of these equations is simply

$$D_{xy} = 0. \tag{31}$$

As a consequence of this, the second, by a direct comparison, turns out to coincide with the standard Darboux equation (10). This time, the solution of Eq. (31), together with (23) and (24) for the leading order terms (now D and B), gives

$$D = a(y^2 - x^2) + by - \mathrm{d}x + g, \tag{32}$$

$$B = -2axy - bx - dy - e. \tag{33}$$

Recalling (21) and comparing with (11)–(13), we see that we have arrived at a result completely equivalent to that of the standard Darboux–Whittaker approach. In fact, Eq. (30) now coincides with Eq. (10) and, therefore, the same possible separable potentials in two dimensions can be found also following this alternative route.

In our general presentation in Sec. IV, we will see how this strategy reveals to be useful also in the case of higher degree invariants. While used mostly for its pedagogical role in the present instance, what is important to stress is the key role of the integrability condition in the form (28): in the general case of a polynomial invariant of degree M, it turns out that Eq. (28) is a polynomial in E of degree $M/2$ for M even and $(M+1)/2$ for M odd.

In the case of invariance at fixed energy, the problem admits additional solutions. Now we have that Eq. (31) is no more necessary and therefore (23) and (24) are unconstrained Cauchy–Riemann equations. Instead of (32) and (33), the solution is now given by an arbitrary analytic function: its real and imaginary parts, respectively, provide the functions D and B. Because of this feature, we will see in the following how it is more convenient to work with complex variables.

Summarizing, the above procedure shows that the strategy for finding weak invariants is well defined and points out where it must be constrained to get strong invariants. This objective being the most important for applications, it may appear that, going this way, nothing is gained with respect to the usual direct approach. However, the procedure instead proves to be very effective in simplifying the system of equations resulting from implementing the direct approach. This simplification is actually one of the reasons why Hall's work is still useful. At the same time, since the approach based on the constrained invariant ansatz (20), complemented by a correct use of the general Darboux equation (28), provides the same results as the standard approach, we get a simple proof of the invalidity of Hall's criticism towards Whittaker. However, Hall is right in envisaging additional solutions to the problem, in the example we have just seen, it is conceivable to obtain, for *particular* values of E, solutions of Eq. (28) not included in those of (29) and (30). In Ref. 7, we have produced several classes of solutions corresponding to $E=0$.

The investigation of such *weakly integrable systems* (WIS) offers several additional issues to study. We mention some of them.

(i) Possible solutions defined for a continuous but finite range of energy values $E_1 < E < E_2$.
(ii) WIS which are actually SIS (*strongly integrable systems*) with a more general form for the second invariant (examples, the Kepler problem, the Sarlet *et al.* case[3]).
(iii) The main property of the integrable dynamics on the E surface may help in understanding some of the main features in the nonintegrable regime (see, e.g., Ref. 28).

III. THE NULL HAMILTONIAN AND TIME REPARAMETRIZATION

As already put forward by Hietarinta (see Ref. 6, Sec. 7.2), canonical point transformations generated by analytical functions preserve the form of a *null* Hamiltonian. This invariance allows a straightforward way to reduce the set of equations to be solved in the search for a polynomial invariant. In the present section we show how, in the case of two-dimensional systems, the above transformations are actually conformal transformations and are related with the time reparametrization of the dynamics. These tools, exploited in the remaining part of the paper, were implicit in Hall's work.

In general the Hamiltonian itself has the form

$$H = T + V(q) = E, \tag{34}$$

where T is a quadratic form in the momenta. The independent variable, let us say t, is often but not always the time. For any given energy E of the system, to represent the dynamics, we can use the *null* Hamiltonian,

$$H_0 = H - E, \tag{35}$$

provided that we impose the constraint

$$H_0 = 0. \tag{36}$$

For any such zero energy Hamiltonian we can reparametrize the system by introducing a new time variable $\overline{t}$ defined by the relation

$$\mathrm{d}t = N(p,q)\mathrm{d}\overline{t}, \tag{37}$$

together with a redefined Hamiltonian

$$\overline{H_0} = N(p,q)H_0 = NT + N(V - E) = 0. \tag{38}$$

The new Hamiltonian will then give the same equations of motion on the constraint surface $\overline{H_0} = 0$. We shall use the term *lapse function* for $N(p,q)$ which defines the independent variable gauge. This usage is borrowed from cosmological applications where the lapse gives the rate of physical time change relative to coordinate time. The lapse function can be taken as any nonzero function on the phase space.

It is simpler to work with complex, or "null," coordinates,

$$z = x + iy, \quad p_z = p = \tfrac{1}{2}(p_x - ip_y), \tag{39}$$

$$\overline{z} = x - iy, \quad p_{\overline{z}} = \overline{p} = \tfrac{1}{2}(p_x + ip_y). \tag{40}$$

The null Hamiltonian can then be written in the form

$$H_0 = 2p\overline{p} - G(z,\overline{z}) = 0, \tag{41}$$

where G is the function introduced in (18). The equations of motion given by (41) are

$$\frac{\mathrm{d}z}{\mathrm{d}t} = 2\overline{p}, \tag{42}$$

$$\frac{\mathrm{d}p}{\mathrm{d}t} = G_z = -V_z, \tag{43}$$

and corresponding complex conjugates. G and V are always assumed to be real functions. In the following we will spare to mention explicitly to the complex conjugates.

We use a conformal transformation to standardize the frame and coordinate representation of the invariant. To that end we introduce a new complex coordinate w by means of the transformation

$$z = F(w). \tag{44}$$

The conformal transformation

$$z \to w = X + iY, \tag{45}$$

given by the holomorphic function (44) determines the canonical point transformation

$$w = F^{-1}(z), \quad P = F'p, \tag{46}$$

so that (1) transforms into the new null Hamiltonian

$$\widetilde{H}_0 = \frac{2P\overline{P} - \widetilde{G}(w,\overline{w})}{|F'|^2} = 0. \tag{47}$$

Let us introduce the "standard" null Hamiltonian

$$H_S = 2P\overline{P} - \widetilde{G}(w,\overline{w}) = 0, \tag{48}$$

that implies the use of the new "time" s, such that

$$\frac{d}{\mathrm{d}s} = |F'|^2 \frac{d}{\mathrm{d}t}. \tag{49}$$

Equations of motion (42) and (43) becomes

$$\frac{\mathrm{d}w}{\mathrm{d}s} = 2\overline{P}, \tag{50}$$

$$\frac{\mathrm{d}P}{\mathrm{d}s} = \widetilde{G}_w. \tag{51}$$

At the same time, a conserved quantity stays conserved if transformed between the two gauges (47) and (48). In terms of real variables, (48) is given by

$$H_S = \tfrac{1}{2}(P_X^2 + P_Y^2) - \widetilde{G}(X,Y) = 0. \tag{52}$$

IV. INVARIANTS OF ARBITRARY DEGREE

With the choice of polynomial invariants, the time reflection symmetry of Hamiltonian (1) allows a further simplification in the procedure. In fact, it can been proved (see Hietarinta,[6] Sec. 2.3 and Ref. 29) that the algebra of commuting functions with the Hamiltonian, which is an even function with respect to time reflection, has "good" time reflection parity. Therefore, a polynomial second invariant can be either even or odd polynomial in the momenta. We can therefore assume a phase-space function of the following form:

$$I_M = \sum_{k=0}^{[M/2]} \sum_{j=0}^{M-2k} p_x^j p_y^{M-2k-j} A_{(j,M-2k)}(x,y), \tag{53}$$

where the functions $A_{(j,M-2k)}(x,y)$, not necessarily polynomials, must be determined. In the first summation, with $[M/2]$ we denote the greatest integer less than $M/2$, so that if, e.g., $M=1$, k takes only the value zero.

A. The direct approach in the Cartesian frame

The simplest procedure (also called the *direct approach*) is now to compute the Poisson brackets of I_M with H, collect terms with various power of momenta and let vanish their respective coefficients. Using at first the form (53) in the usual Cartesian frame, we then get a system of partial differential equations of the form

$$(j+1)A_{(j+1,k+1)}\partial_x V + (k+1-j)A_{(j,k+1)}\partial_y V = \partial_x A_{(j-1,k-1)} + \partial_y A_{(j,k-1)}, \tag{54}$$

with $j=0,\ldots,k$ and $k=M+1$, $M-1$, $M-3,\ldots,0$ or 1 and it is implicit that $A_{(s,t)}=0$ if $s<0$ or $s>t$ and $t<0$ or $t>M$. In order to simplify formulas, in the present section we reintroduce the standard notation ∂ to denote partial differentiation with respect to the variable in the subscript. The set (54) is a complicated set of PDEs, in general overdetermined: if M is even we have $(M+2)(M+4)/4$ equations for $(M+2)^2/4$ unknowns; if M is odd we have $(M+3)^2/4$ equations for

$(M+1)(M+3)/4$ unknowns. Actually, in the general case, to these figures the potential V enters as an additional unknown.

B. The direct approach in the null frame

Introducing the complex null frame (39) and (40), we have the following generic expression of the invariant:

$$I_M = 2\,\mathrm{Re}\left\{\sum_{k=0}^{M/2} C_{2k}p^{2k}\right\}, \quad M \text{ even}, \tag{55}$$

$$I_M = 2\,\mathrm{Re}\left\{\sum_{k=0}^{(M-1)/2} C_{2k+1}p^{2k+1}\right\}, \quad M \text{ odd}, \tag{56}$$

where the complex functions $C_{2k}, k=0,\ldots,M/2$ or $C_{2k+1}, k=0,\ldots,(M-1)/2$ depend on z, $\overline{z}$ and, with the exclusion of the leading order coefficients C_M, implicitly on E. Their explicit expression in terms of the coefficients of the invariant in Cartesian form are

$$C_{2k}^{(M)} = \sum_{a=0}^{(M/2)-k} \left(\frac{G}{2}\right)^a \times \left\{\sum_{\ell=0}^{2(a+k)} i^{2(a+k)-\ell}\left[\sum_{r=0}^{a}(-1)^r\binom{\ell}{\ell-a+r}\binom{2(a+k)-\ell}{2(a+k)-\ell-r}\right]A_{(\ell,2(a+k))}\right\}, \tag{57}$$

when M is even and

$$C_{2k+1}^{(M)} = \sum_{a=0}^{(M-1)/2-k} \left(\frac{G}{2}\right)^a \times \left\{\sum_{\ell=0}^{2(a+k)+1} i^{2(a+k)+1-\ell}\left[\sum_{r=0}^{a}(-1)^r\binom{\ell}{\ell-a+r}\times\binom{2(a+k)+1-\ell}{2(a+k)+1-\ell-r}\right]A_{(\ell,2(a+k)+1)}\right\}, \tag{58}$$

when M is odd. In these expressions a superscript (M) has been introduced in order to let them apply in general, namely, $C_a^{(M)}$ denotes the ath coefficient of the invariant of degree M. In the following this superscript will not be used unless it is strictly needed to prevent confusion. As usual, in (57) and (58),

$$\binom{n}{k} = \frac{n!}{(n-k)!k!} \tag{59}$$

denotes the binomial coefficient.

The forms (55) and (56) of the invariant do not contain cross terms, namely terms with powers of $p\overline{p}$, since they have been eliminated exploiting the constraint

$$2p\overline{p} = G(z,\overline{z}) \tag{60}$$

dictated by (41). A simple check of this statement can be performed with the quadratic invariant with which we are familiar from Sec. II. Equation (57) with $M=2$ gives

$$C_2^{(2)} = A_{22} - A_{02} + iA_{12}, \tag{61}$$

$$C_0^{(2)} = A_{00} + (A_{02} + A_{22})G. \tag{62}$$

Posing $A_{22}=A$, $A_{12}=B$, $A_{02}=C$, $A_{00}=K$ and $C_2^{(2)}=D+iB$, $C_0^{(2)}=\tilde{K}$ we again find relations (21) and (22) and see that the expression (20) of the invariant is equivalent to

$$I_2(p,\overline{p},z,\overline{z}) = C_2^{(2)}p^2 + \overline{C_2^{(2)}}\overline{p}^2 + \widetilde{K}. \tag{63}$$

The use of the energy constraint leads to the maximal reduction in the number of equations ensuing from the direct approach. However, in the case of integrability at arbitrary energy, to this reduced number one must add the integrability conditions which results in a set of equations generalizing (29). The constraint (60) can also be used to "homogeneize" the polynomial invariant. In this form, used in the geometric framework in connection with the geodesic flow over a Riemannian manifold, the coefficients of the invariant give rise to a symmetric M-rank tensor, known as a *Killing tensor*.

The commutation relation of the functions (55) or (56) with the null Hamiltonian (41) gives the system of equations

$$\partial_{\overline{z}} C_{k-1} + \tfrac{1}{2}(\partial_z C_{k+1})G + \tfrac{1}{2}(k+1)C_{k+1}\partial_z G = 0, \quad k = 0,1,\ldots,M, \tag{64}$$

where it is implicitly assumed that $C_j = 0$ for $j < 0$ and for $j > M$. The set of equation (64) must be supplemented by the closure equations

$$\partial_{\overline{z}} C_M = 0 \tag{65}$$

and

$$\Re\{\partial_z(C_1 G)\} = 0. \tag{66}$$

Clearly, this last condition must be stated only in the case of odd degree, since for M even, a closure condition of the form

$$\Im\{C_0\} = 0 \tag{67}$$

is implicit since C_0 is real by definition.

In both cases, using the null complex coordinates, we have $M+2$ real equations for $M+1$ real unknowns: the substantial reduction of the number of independent equations with respect to that in the Cartesian frame was already remarked by Hietarinta (see Ref. 6, Sec. 7.5). However, he thought that reintroducing the explicit dependence on energy would reestablish the original number, whereas, as we will see, the gain in saving equation still remains when going to the Cartesian frame.

C. Solving the equations for the *M*th-degree invariant

At present a general solution of system (64) is still lacking. In Refs. 7–9 we found the general solutions for $1 \leqslant M \leqslant 4$. In the present section we illustrate the aspect of the procedure which are common to all Mth-degree invariant. The first steps are essentially the same as in the original paper by Hall.

Looking at the system above, we see that Eq. (65) is readily solved,

$$C_M = C_M(z), \tag{68}$$

that is C_M is an arbitrary holomorphic function. The first important result we get is therefore that the leading order coefficient of a polynomial invariant is given by an arbitrary holomorphic function. This fact is already known in the case of homogeneous polynomial invariants (Kolokoltsov,[30] Kozlov[26]) and was obtained by Birkhoff (Ref. 24, Chap. 2) for $M \leqslant 2$. We remark that, in agreement with notations in (57) and (58), here we are referring to $C_M^{(M)}$, that is the leading order coefficient of the polynomial invariant of degree M with various values of M. Therefore, in order to avoid confusion with lower order coefficients in a polynomial with a given M and also to conform with the notation in previous works, in the following we will denote the leading order coefficient with S_M.

In order to attack the remaining equations in (64), we may further simplify them by performing a coordinate transformation. This is a conformal transformation of the form (44), where the generating function $F(w)$ is chosen such that

$$F'(w(z)) = S_M{}^{1/M}. \tag{69}$$

In this case, we see that the first equation of the chain (64) can be rewritten as

$$S_M{}^{(2/M)-1}\partial_{\bar{w}}C_{M-2} + \frac{M}{2}\partial_w \tilde{G} = 0, \tag{70}$$

where, in agreement with (47), the new "conformal" potential

$$\tilde{G}(w,\bar{w}) = |F'(w)|^2 G = (S_M \bar{S_M})^{1/M} G, \tag{71}$$

has been introduced. Defining the function

$$\tilde{C}_{M-2}(w,\bar{w}) = S_M^{(2-M)/M} C_{M-2}, \tag{72}$$

Eq. (70) becomes

$$\partial_{\bar{w}}\tilde{C}_{M-2} + \frac{M}{2}\partial_w \tilde{G} = 0 \tag{73}$$

and, defining in an analogous way,

$$\tilde{C}_{2k}(w,\bar{w}) = S_M^{-2k/M} C_{2k}, \quad k = 0,1,\ldots,[N/2], \tag{74}$$

the rest of the system becomes

$$\partial_{\bar{w}}\tilde{C}_{j-2} + \frac{1}{2\tilde{G}^{j-1}}\partial_w(\tilde{C}_j \tilde{G}^j) = 0, \tag{75}$$

with the ranges $j=4,5,\ldots,N-2$ if N is even and $j=3,4,\ldots,N-2$ if N is odd.

D. The Kähler potential

Equation (70), or better its transformed form (73), plays a special role. In view of the fact that the new potential $\tilde{G}$ is still a real function, (73) can be solved introducing a real function $\mathcal{K}(w,\bar{w})$ such that

$$\tilde{G} = \partial^2_{w\bar{w}}\mathcal{K}, \tag{76}$$

$$\tilde{C}_{M-2} = -\frac{M}{2}\partial^2_{ww}\mathcal{K}. \tag{77}$$

The first equation says that the Jacobi potential is the Laplacian of the function $\mathcal{K}(w,\bar{w})$. Since, in the geometric picture, G is the conformal factor of the metric element, using $\mathcal{K}$ it gives rise to a Hermitian form and therefore it is referred to as the *Kähler potential*. Without loss of generality, in Ref. 9, Sec. IV, it has been shown that the Kähler potential can be assumed to be of the form

$$\mathcal{K} = E[F(w)\bar{F}(\bar{w}) + 2\Re\{\Lambda(z(w))\}] - \Psi, \tag{78}$$

where Λ is an arbitrary holomorphic function independent of E and the real *prepotential* Ψ is such that

$$\partial^2_{w\bar{w}}\Psi = F'\overline{F'}\,\partial^2_{z\bar{z}}\Psi = |F'|^2 V. \tag{79}$$

In the case of invariants up to the fourth degree, $M \leqslant 4$, we see that the closure equations (66) and (67) are themselves expressed only in terms of the Kähler potential. In these cases, to get a complete solution of the problem, it remains *only* to solve an integrability condition for $\mathcal{K}(w,\bar{w})$.

In the cases of linear and quadratic invariants, the integrability condition is linear and we have the general solution depending, respectively, on one and two arbitrary real functions (see Ref. 7). In the higher degree cases, the integrability conditions are nonlinear and a general solution is lacking: moreover, in general, they give rise to an overdetermined system for the unknowns Λ and Ψ. This is consistent with the fact that only isolated cases of integrable Hamiltonian systems with invariant of degree higher than two are known. Failing to work in full generality, a useful approach is to make an ansatz for one of the unknowns (e.g., Λ) and solve for Ψ. In this way several new integrable and superintegrable systems have been found with a cubic[8] and a quartic[9] second invariant.

E. The leading order term of strong invariants

Looking for a strong invariant, so that the integrability condition must be solved for arbitrary values of E, it turns out that the function C_M can no longer be arbitrary. In our previous works we have shown its polynomial structure with degree equal to M for $M \leqslant 4$ and guessed that this is the generic behavior for any value of M. In this section we prove that this conjecture is true by explicitly computing the function with the aid of the already known solution in the Cartesian case.

In Ref. 7 for the linear and quadratic cases we have found, respectively, the conditions

$$\Re\{S_1'(z)\} = 0, \tag{80}$$

$$\Im\{S_2''(z)\} = 0. \tag{81}$$

In Ref. 8, for the cubic case, the condition

$$\Re\left\{\frac{d^3}{dz^3}S_3\right\} = 0 \tag{82}$$

was found, whereas in Ref. 9, for the quartic case, the condition

$$\Im\left\{\frac{d^4}{dz^4}S_4\right\} = 0 \tag{83}$$

was found. Therefore we can guess the general conditions

$$\Re\left\{\frac{d^M}{dz^M}S_M\right\} = 0, \quad M \text{ odd}, \tag{84}$$

$$\Im\left\{\frac{d^M}{dz^M}S_M\right\} = 0, \quad M \text{ even}. \tag{85}$$

Conditions from (80)–(83) have been obtained working on the integrability condition for the Kähler potential $\mathcal{K}$. Since it is not possible to write an explicit expression for the integrability condition at arbitrary M, we prove (84) and (85) by explicitly calculating them. The easiest way to proceed is to exploit the solution in Cartesian coordinates and after that performing the transformation to complex coordinates: the reason for not working directly in the complex frame is that, in (55) and (56), part of the information on the structure of S_M is hidden in the lower order coefficients through the energy constraint, this information could be recovered only having the solution of the complete system of equations for C_k up to the integrability for C_0.

Comparing (55) and (56) with (53) we get the relation

$$S_M(x+iy) \equiv C_M = \sum_{m=0}^{M} i^{M-m} A_{(m,M)}(x,y). \tag{86}$$

As it is natural, the leading order complex coefficient depends only on leading order Cartesian coefficients. Considering (54) with $k=M+1$, we get the equation for the leading order Cartesian coefficients, namely

$$\partial_x A_{(j-1,M)} + \partial_y A_{(j,M)} = 0, \quad j = 0,1,\ldots,M+1, \tag{87}$$

whose solution can be immediately found (see Hietarinta,[6] Sec. 3.0):

$$A_{(m,M)} = \sum_{k=0}^{m} \sum_{j=0}^{M-m} (-1)^k \frac{(j+k)!}{j!k!} a_{(j+k,m-k,M)} x^j y^k, \tag{88}$$

where $a_{(j+k,m-k,M)}$ are *real* integration constants.

From the relation

$$\partial_z = \tfrac{1}{2}(\partial_x - i\partial_y) \tag{89}$$

we have the expression for the rth derivative

$$\partial_z^r = \frac{1}{2^r} \sum_{s=0}^{r} \frac{r!}{(r-s)!s!} (-i)^s \partial_x^{r-s} \partial_y^s. \tag{90}$$

In order to compute the operator (90) we need the following intermediate result:

$$\partial_x^{r-s} \partial_y^s x^j y^k = \frac{j!}{(j-r+s)!} \frac{k!}{(k-s)!} x^{j-r+s} y^{k-s}, \quad \text{for } k \geqslant s \text{ and } j \geqslant r-s, \tag{91}$$

whereas the result is zero if $k<s$ or $j<r-s$. Using it, the action of the operator (90) on the monomial $x^j y^k$ is

$$\partial_z^r x^j y^k = \frac{1}{2^r} \sum_{s=0}^{r} (-i)^s \frac{r!}{(r-s)!s!} \frac{j!k!}{(j-r+s)!(k-s)!} x^{j-r+s} y^{k-s}. \tag{92}$$

Actually, we are interested only in the action of ∂_z^M: in this case, since each derivative corresponds to decreasing the degree of the monomial by one, only the highest degree terms, with $j+k=M$, survive the action of ∂_z^M. Applying (92) we get

$$\partial_z^M x^{M-k} y^k = \frac{1}{2^M} \sum_{s=0}^{M} (-i)^s \frac{M!}{(M-s)!s!} \frac{k!(M-k)!}{(s-k)!(k-s)!} x^{s-k} y^{k-s}. \tag{93}$$

Analogously to those in (91), we have that both conditions $s-k \geqslant 0$ and $k-s \geqslant 0$ must be satisfied. This implies just $s=k$ so that (93) turns out to be simply

$$\partial_z^M x^{M-k} y^k = \frac{1}{2^M} (-i)^k \frac{M!}{(M-k)!k!} k!(M-k)! = (-i)^k \frac{1}{2^M} M!. \tag{94}$$

The same result holds exchanging k with $M-k$,

$$\partial_z^M x^k y^{M-k} = (-i)^k \frac{1}{2^M} M!. \tag{95}$$

Let us now denote with $\hat{A}_{(m,M)}$ the highest degree part of $A_{(m,M)}$,

$$\hat{A}_{(m,M)} = (-1)^m \frac{M!}{(M-m)!m!} a_{(M,0,M)} x^{M-m} y^m. \tag{96}$$

Using (94) we then have

$$\partial_z^M A_{(m,M)} = \partial_z^M \hat{A}_{(m,M)} = \frac{i^m}{2^M} \frac{M!^2}{(M-m)!m!} a_{(M,0,M)}. \tag{97}$$

Remembering (86) we finally get

$$\partial_z^M S_M = \sum_{m=0}^{M} i^{M-m} \partial_z^M A_{(m,M)} \tag{98}$$

$$= \sum_{m=0}^{M} i^{M-m} \frac{i^m}{2^M} \frac{M!^2}{(M-m)!m!} a_{(M,0,M)} \tag{99}$$

$$= \frac{i^m}{2^M} M! a_{(M,0,M)} \sum_{m=0}^{M} \frac{M!}{(M-m)!m!} \tag{100}$$

$$= i^m M! a_{(M,0,M)} \tag{101}$$

which is just what we wanted to prove since it is equivalent to (84) and (85).

V. EXAMPLES

We illustrate the applications of the general approach described so far with a selection of results, many of which are new. In particular, we provide some weakly integrable systems with linear and quadratic invariants and a recipe for higher order examples. In order to compactify formulas, from hereinafter with the subscript we denote the partial derivative with respect to the corresponding variable (except when used to denote a component of momentum).

A. Weakly integrable systems with linear invariants

The ansatz is

$$I_1 = Sp + \overline{S}\overline{p}, \tag{102}$$

where for simplicity we have suppressed the subscript in the S function. The system of equations ensuing from the conservation condition is the following:

$$S_{\bar{z}} = 0, \tag{103}$$

$$\Re\{(GS)_z\} = 0. \tag{104}$$

Equation (103) agrees with (68), confirming that S can be an arbitrary analytic function,

$$S = S(z). \tag{105}$$

According to (69), the conformal transformation is given by

$$\frac{\mathrm{d}z}{\mathrm{d}w} = F'(w) \equiv S(z(w)) \tag{106}$$

or equivalently

$$w = X + iY = \int \frac{dz}{S(z)}. \tag{107}$$

Introducing the "conformal" potential

$$\tilde{G} = |F'|^2 G = |S|^2 G = S\bar{S}G, \tag{108}$$

Eq. (104) reduces to

$$\Re\{\tilde{G}_w\} = 0, \tag{109}$$

which is readily solved in

$$\tilde{G} = g(Y), \tag{110}$$

where g is an arbitrary real function and, according to the definition of the coordinate transformation, Y is the imaginary part of w. In this coordinates, the invariant assumes the normal form

$$I_1 = P + \bar{P} \tag{111}$$

or simply

$$I_1 = P_X. \tag{112}$$

Equation (104), in view of (105) and recalling the definition of G, can be rewritten as

$$\Re\{S'(E - V) - SV_z\} = 0. \tag{113}$$

We recognize the structure of Eq. (28), where now

$$f_1 = \Re\{S'(z)\} = 0 \tag{114}$$

and

$$f_0 = \Re\{(SV)_z\} = 0 \tag{115}$$

and we see that (114) coincides with (80) and solution (110) now applies to V, so that we have

$$V = \frac{g(Y(x,y))}{|S|^2}, \tag{116}$$

with g arbitrary. The general form of the second invariant in the original real coordinates is

$$I_1 = \Re\{S\}p_x + \Im\{S\}p_y. \tag{117}$$

We may provide two interesting classes of weakly integrable systems admitting linear invariants. The first is obtained by the simple observation that, if we choose the level surface $E=0$, it is no longer necessary that condition (114) be satisfied. *Any* analytic function $S=S(z)$ provides a solution through the corresponding conformal transformation. If Y, as above, denotes the new coordinate

$$Y = \mathrm{Im}\left\{\int \frac{dz}{S(z)}\right\}, \tag{118}$$

then the solution is given by the pair (116) and (117), provided we consider only motions at the energy level $E=0$.

The second class of weakly integrable systems is obtained with the following trick. Let us consider the analytic function $f(z)$ and consider then the conformal transformation (106) with $S(z)$ given by

$$S = \frac{1}{a + f'(z)}, \tag{119}$$

with a constant. Recalling definition (108), let us consider the "flat" conformal potential $\widetilde{G}=1$. In this case, relation (108), using (119) gives

$$G = E - V = \frac{1}{|S|^2} = a^2 + a(f' + \overline{f'}) + |f'|^2. \tag{120}$$

We can therefore interpret a^2 as the fixed value of the energy constant and get as a consequence the family of potentials

$$V(z,\overline{z};E) = -\sqrt{E}(f' + \overline{f'}) - |f'|^2. \tag{121}$$

To complete the solution, we must write explicitly the coordinate transformation generated by (119), that is

$$w = \int \frac{\mathrm{d}z}{S(z)} = az + f(z). \tag{122}$$

The invariant is still of the form (117).

B. Weakly integrable systems with quadratic invariants

The ansatz is

$$I_2 = Sp^2 + \overline{S}\overline{p}^2 + \widetilde{K}. \tag{123}$$

The system of equations ensuing from the conservation condition is the following:

$$S_{\overline{z}} = 0, \tag{124}$$

$$\widetilde{K}_{\overline{z}} + SG_z + \tfrac{1}{2}S'G = 0. \tag{125}$$

Equation (124) is already familiar. Since $\widetilde{K}$ is real, Eq. (125) has the following integrability condition:

$$\Im\{S''G + 3S'G_z + 2SG_{zz}\} = 0. \tag{126}$$

However, as above, we can directly simplify Eq. (125). According to (69), the conformal transformation is now given by

$$\frac{\mathrm{d}z}{\mathrm{d}w} = F'(w) \equiv \sqrt{S(z(w))} \tag{127}$$

or equivalently

$$w = \int \frac{\mathrm{d}z}{\sqrt{S(z)}}. \tag{128}$$

With the conformal potential

$$\widetilde{G} = |F'|^2 G = |S|G = \sqrt{S\overline{S}}G, \tag{129}$$

Eq. (125) reduces to

$$\widetilde{K}_{\overline{w}} + \widetilde{G}_w = 0, \tag{130}$$

that is the first example of the set (73). Its integrability condition is

$$\Im\{\widetilde{G}_{ww}\} = 0 \tag{131}$$

which is readily solved by

$$\widetilde{G} = \widetilde{A}(w + \overline{w}) + \widetilde{B}(w - \overline{w}), \tag{132}$$

where $\widetilde{A}$ and $\widetilde{B}$ are arbitrary real functions. Setting this solution in (125) gives

$$\widetilde{K} = \widetilde{B} - \widetilde{A}. \tag{133}$$

Comparing with (129) and using real "separating" coordinates,

$$X = \Re\{w\}, \quad Y = \Im\{w\}, \tag{134}$$

the solution for the original function G is then

$$G = \frac{\widetilde{A}(X;E) + \widetilde{B}(Y;E)}{|S|}. \tag{135}$$

The invariant takes the normal form

$$I_2 = P^2 + \overline{P^2} + \widetilde{B} - \widetilde{A} = \tfrac{1}{2}(P_X^2 - P_Y^2) + \widetilde{B} - \widetilde{A} \tag{136}$$

or, in the original real coordinates,

$$I_2 = \tfrac{1}{2}\,\mathrm{Re}(S)(p_x{}^2 - p_y{}^2) + \mathrm{Im}(S)p_x p_y + \widetilde{B}(Y(x,y)) - \widetilde{A}(X(x,y)). \tag{137}$$

Equation (131) can be rewritten as

$$\Im\{S''(E - V) - 3S'V_z - 2SV_{zz}\} = 0. \tag{138}$$

We again recognize the structure of Eq. (28), where now

$$f_1 = \Im\{S''(z)\} = 0 \tag{139}$$

and

$$f_0 = \Im\{S''V + 3S'V_z + 2SV_{zz}\} = 0 \tag{140}$$

and we see that (139) coincides with (81). It can be proven (see Ref. 28, Sec. II) that this condition, in addition to warrant strong integrability, is also necessary and sufficient in order that the conformal factor $|S|$ can be written as a *sum* of two functions of X and Y, say

$$|S| = S_X(X) + S_Y(Y). \tag{141}$$

Since from (140) we have that solution (135) now applies to V, we get

$$V = \frac{A(X) + B(Y)}{|S|} \tag{142}$$

with suitable A and B. In this case, X and Y are properly referred to as *separable* coordinates. From (135) and (141), we deduce the relations

$$\widetilde{A}(X;E) = ES_X - A(X), \tag{143}$$

$$\widetilde{B}(Y;E) = ES_Y - B(Y), \tag{144}$$

so that, eliminating the energy parameter through the Hamiltonian

$$E = H = \frac{\frac{1}{2}(P_X^2 + P_Y^2) + A + B}{S_X + S_Y}, \tag{145}$$

the general form of the strong quadratic invariant is

$$I_2 = \frac{S_Y(P_X^2 + 2A) - S_X(P_Y^2 + 2B)}{S_X + S_Y}. \tag{146}$$

We mention here some interesting examples of weak integrability with quadratic invariants. Consider first the polynomial function $S(z) = iz^2$. This is the simplest polynomial which gives a potential which is not automatically integrable at arbitrary energy. The corresponding conformal transformation is given by

$$w = 2^{-1/2}(1 - i)\ln z \tag{147}$$

or in terms of the real variables using polar coordinates

$$X = \frac{1}{\sqrt{2}}(\theta + \ln r), \tag{148}$$

$$Y = \frac{1}{\sqrt{2}}(\theta - \ln r). \tag{149}$$

From the relation (135) it then follows that the potential given by

$$V = r^{-2}[A(re^{\theta}) + B(re^{-\theta})], \tag{150}$$

is integrable at zero energy for arbitrary functions A and B. In Ref. 28, the class of systems with

$$A(X) = \tfrac{1}{2}(C - \sin\sqrt{2}X), \tag{151}$$

$$B(Y) = \tfrac{1}{2}(C - \sin\sqrt{2}Y), \tag{152}$$

where C is a real constant, has been investigated. Using polar coordinates, the explicit form of the potential is

$$V(r,\theta) = \frac{C - \sin\theta\cos(\ln r)}{r^2} \tag{153}$$

and that of the second invariant is

$$I_2(p_r, p_\theta, r, \theta) = rp_r p_\theta - \cos\theta\sin(\ln r), \tag{154}$$

where

$$rp_r = xp_x + yp_y, \tag{155}$$

$$p_\theta = xp_y - yp_x. \tag{156}$$

A natural question one can ask is if the system is still integrable at arbitrary energy values. As it is well known, it is possible to answer this question by performing careful numerical investigations, but, on purely analytical grounds, the problem is in general quite difficult. In Ref. 28, this potential has been proven to be nonintegrable at values of the energy $-\epsilon_1 < E < \epsilon_2$, with small

enough $\epsilon_{1,2}$, for every value of C in the interval $(0,1]$. The proof has been obtained by applying the Poincaré nonexistence theorem of additional invariants (see, e.g., Refs. 31 and 32), working in the transformed coordinates X, Y, taking asunperturbed part of the Hamiltonian the integrable system at $E=0$ and as a small perturbation the term associated to the conformal factor.

A second example is that given by a generating function of the form

$$S(z) = z^{-2}. \tag{157}$$

The conformal transformation can then be written in terms of the real variables as

$$X = \tfrac{1}{2}r^2 \cos 2\theta = \tfrac{1}{2}(x^2 - y^2), \tag{158}$$

$$Y = \tfrac{1}{2}r^2 \sin 2\theta = xy. \tag{159}$$

The corresponding potential is

$$V(X,Y) = r^2[A(X) + B(Y)], \tag{160}$$

since the conformal factor is

$$|S(X,Y)| = \frac{1}{2\sqrt{X^2 + Y^2}} = \frac{1}{r^2}. \tag{161}$$

Choosing, for example,

$$A(X) = 4X^2, \tag{162}$$

$$B(Y) = (2 + a)Y^2 + b, \tag{163}$$

where a is a constant such that $0 \leqslant a \leqslant 2$ and $b > 0$, we get the family of potentials

$$V(x,y) = r^2(x^4 + y^4 + ax^2y^2 + b). \tag{164}$$

This potential has a relative maximum at the origin where $V(0,0)=0$, absolute minima placed symmetrically in the four quadrants around the origin and grows as r^6 for $r \to \infty$. It allows bound motion for all the admissible values of the energy. For $a=2$ it is rotationally symmetric and therefore it is "superintegrable" at zero energy. The second invariant is

$$I_2(p_x,p_y,x,y) = \frac{x^2 - y^2}{2r^4}(p_x^2 - p_y^2) - \frac{2xy}{r^4}p_xp_y + x^4 + y^4 - (4 + a)x^2y^2. \tag{165}$$

What is remarkable in this case is that already at energies slightly below or above the integrable level $E=0$, the dynamics is strongly *chaotic*. This shows that identifying weakly integrable systems does not necessarily provide a *nearly* integrable system.

C. Weakly integrable systems with higher-order invariants

Exploiting the results obtained in Refs. 8 and 9, several families of weakly integrable systems admitting cubic and quartic invariants can be obtained. Both cases can be described with a similar approach. The invariants have the form

$$I_3 = 2\,\mathrm{Re}\{S_3p^3 + R_3p\}, \tag{166}$$

$$I_4 = 2\,\mathrm{Re}\{S_4p^4 + R_4p^2\} + C_0. \tag{167}$$

The conformal transformations (69), respectively, give the normal forms

$$I_3 = 2\,\mathrm{Re}\{P^3 + \widetilde{R}_3 P\}, \tag{168}$$

$$I_4 = 2\,\mathrm{Re}\{P^4 + \widetilde{R}_4 P^2\} + C_0, \tag{169}$$

with

$$\widetilde{R}_M = S_M^{(2-M)/M} R_M, \quad M = 3,4, \tag{170}$$

in agreement with definition (72). Introducing the Kähler potential, Eq. (77) provides the solutions for $\widetilde{R}_M$,

$$\widetilde{R}_M = -\frac{M}{2}\mathcal{K}_{ww}. \tag{171}$$

In the cubic case, the closure equation (66) expressed in terms of the Kähler potential gives

$$\Re\{(\mathcal{K}_{ww}\mathcal{K}_{w\bar{w}})_w\} = 0. \tag{172}$$

In the quartic case, the closure equation is that determined by Eq. (75) that, with $j=2$ and the notations adopted here, gives

$$(C_0)_{\bar{w}} = -\frac{1}{2\widetilde{G}}(\widetilde{R}_4\widetilde{G}^2)_w. \tag{173}$$

The reality of C_0 requires the integrability condition

$$\Im\{(\mathcal{K}_{www}\mathcal{K}_{w\bar{w}} + 2\mathcal{K}_{ww\bar{w}}\mathcal{K}_{ww})_w\} = 0. \tag{174}$$

Equations (172) and (174) illustrate the important difference between the previous linear and quadratic cases ($M=1,2$) and the higher order ($M>2$) cases. In the linear [see Eq. (109)] and the quadratic case [see Eq. (131)], the integrability conditions are *linear* differential equations: their solution is in terms of one or two arbitrary functions, respectively. Now, Eqs. (172) and (174) are both *nonlinear* partial differential equations, they appear very complicated and in practice impossible to solve in full generality. Only isolated systems can be identified. Using the general expression (78), we get in both $M=3$ and $M=4$ cases a *quadratic* equation of the form

$$f_2 E^2 + f_1 E + f_0 = 0, \tag{175}$$

where the f_k, $k=0,1,2$ depend on S, Λ, Ψ and their derivatives. Looking for strong invariants, S is determined as above [cf. Eq. (82) and Eq. (83)] and several solutions can be obtained by suitable assumptions on Λ and Ψ.[8,9]

Looking for weak invariants, a large class of solutions can be obtained in the simplest eventuality $E=0$. In fact, in this case the only condition we must satisfy is $f_0=0$ and it can be proven that this equation is a nonlinear PDE in the variable Ψ only. In fact, we get, respectively,

$$\Re\{(\Psi_{ww}\Psi_{w\bar{w}})_w\} = 0, \quad M = 3 \tag{176}$$

and

$$\Im\{(\Psi_{www}\Psi_{w\bar{w}} + 2\Psi_{ww\bar{w}}\Psi_{ww})_w\} = 0, \quad M = 4. \tag{177}$$

Now, *any* solution of these equations in whatever coordinate system can be used to generate a new weakly integrable system (at $E=0$) using an arbitrary conformal transformation not included in the families (82) and (83).

VI. CONCLUSIONS

Much of the structure and ideas presented in this work has come from the geometric formulation using the Jacobi metric as described in Ref. 7 and further developed in Refs. 8 and 9. One of the important results of those earlier works was the unification of the notions of weak and strong integrability in a common framework. Another was the identification of the crucial role of the conformal transformations for analyzing integrability in two dimensions. However, while the geometric picture has been very useful in these and other respects, it is clear from the present work that an approach which is more closely related to the more traditional Hamiltonian picture can also be very effective.

The conformal transformations have provided the clue for finding explicit conditions for the leading order term of strong invariants of arbitrary degree. The conditions, as given in Eqs. (84) and (85), are natural generalizations of the conditions for low order invariants. The examples given in Sec. V provide an illustration of the apparent ease by which it is possible to construct interesting weak invariants. We hope that this work can serve as a starting point for improving the understanding of higher order invariants of both the strong and the weak type.

(Received 26 January 2005; accepted 16 February 2005; published online 5 May 2005)

We present the theory of higher order local variational principles in fibered manifolds, in which the fundamental global concept is a locally variational dynamical form. Any two Lepage forms, defining a local variational principle for this form, differ on intersection of their domains, by a variationally trivial form. In this sense, but in a different geometric setting, the local variational principles satisfy analogous properties as the variational functionals of the Chern–Simons type. The resulting theory of extremals and symmetries extends the first order theories of the Lagrange–Souriau form, presented by Grigore and Popp, and closed equivalents of the first order Euler–Lagrange forms of Haková and Krupková. Conceptually, our approach differs from Prieto, who uses the Poincaré–Cartan forms, which do not have higher order global analogues. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1901323]

I. INTRODUCTION

It is well known that differential equations for critical points of a variational functional in a fibered manifold can be represented by a global differential form, the *Euler–Lagrange form*, whose components are the Euler–Lagrange expressions. It is also well known that there exist differential equations, represented by similar global differential forms, the *dynamical forms*, which are *locally variational*, but do not admit a *global* Lagrangian. A deeper understanding of this phenomenon is provided by the variational bicomplex theory (Vinogradov,[31] Takens,[28] Anderson and Duchamp,[2] Dedecker and Tulczyjew,[6] and Tulczyjew[30]), and the (finite order) variational sequence theory (Krupka,[20] Grigore,[10,11] Vitolo,[32] and Krbek and Musilová[14]).

The corresponding variational principles in the first order field theory have been recently studied by several authors. Grigore and Popp[12] extended the ideas of Souriau[27] on the role of closed 2-forms in mechanics to $(n+1)$-forms in the variational theory for n-dimensional submanifolds of a given manifold. They introduced the *Lagrange–Souriau form*, representing the Euler–Lagrange equations, and proved that this form is equal to the exterior derivative of the *fundamental Lepage form* in the sense of Krupka,[15,18] (see also Betounes[3,4] and Rund[25]). The theory presented by Prieto[23,24]), is based on the existence of the global Poincaré–Cartan form (Sniatycki,[26] Goldschmidt and Sternberg,[9] Krupka,[17,15] and García[8]), and is aimed to extend basic properties of variational principles of the Chern–Simons type (see, e.g., Freed[7]) to fibered manifolds. Haková and Krupková[13] showed that the closed $(n+1)$-forms related to variational systems of first order partial differential equations are exactly the exterior derivative of the fundamental Lepage form.

Closed 2-forms in higher order mechanics, equivalent with the Euler–Lagrange forms, were studied by Krupková.[21,22]

This paper is devoted to local variationality in the framework of the *higher order* variational theory on fibered spaces (Krupka[19,15]), and the variational sequence theory. In general, for higher order Lagrangians in field theory a global analogue of the Poincaré–Cartan form does not exist. We show that instead of this form one can use *any* Lepage form; the Poincaré–Cartan form is an example of a first order Lepage form. Any (higher order) Lepage form gives rise, by means of the global variation formula, to the (higher order) *Euler–Lagrange form*. Conceptually, the theory is quite simple and clear. In particular, it is easy to understand, in full generality, that there exist (global) dynamical forms, admitting local higher order Lagrangians, but not a global one.

In Sec. II we give a survey of the higher order variational theory on fibered spaces. Section III is devoted to some new results on infinitesimal symmetries, based on the fundamental Lepage form. In Sec. IV we introduce a *local variational principle* for a *locally variational* dynamical form. We give the *first variation formula* and discuss properties of transformations, leaving invariant the local variational principle, and the locally variational form.

In this paper we suppose that we have a fibered manifold $\pi: Y \to X$, and write $n = \dim X$, and $n+m = \dim Y$. $J^r Y$ is the *r-jet prolongation* of Y, and $\pi^{r,s}: J^r Y \to J^s Y$, $\pi^r: J^r Y \to X$ are the *canonical jet projections*. The *r-jet prolongation* of a section γ is defined to be the mapping $x \to J^r\gamma(x) = J^r_x\gamma$. For any set $W \subset Y$ we denote $W^r = (\pi^{r,0})^{-1}(W)$. Any *fibered chart* (V, ψ), $\psi = (x^i, y^\sigma)$, on Y, induces the *associated charts* on X and on $J^r Y$, denoted by (U, φ), $\varphi = (x^i)$, and (V^r, ψ^r), $\psi^r = (x^i, y^\sigma, y^\sigma_{j_1}, y^\sigma_{j_1 j_2}, \ldots, y^\sigma_{j_1 j_2 \ldots j_r})$, respectively; here $1 \leqslant i \leqslant n$, $1 \leqslant \sigma \leqslant m$, and $V^r = (\pi^{r,0})^{-1}(V)$, $U = \pi^r(V)$. We denote $\omega_0 = \mathrm{d}x^1 \wedge \mathrm{d}x^2 \wedge \cdots \wedge \mathrm{d}x^n$, and

$$\omega_k = i_{\partial/\partial x^k}\omega_0 = (-1)^{k-1}\,\mathrm{d}x^1 \wedge \mathrm{d}x^2 \wedge \cdots \wedge \mathrm{d}x^{k-1} \wedge \mathrm{d}x^{k+1} \wedge \cdots \wedge \mathrm{d}x^n.$$

We define the *formal derivative operator* by

$$d_i = \frac{\partial}{\partial x^i} + y^\sigma_i \frac{\partial}{\partial y^\sigma} + y^\sigma_{i_1 i} \frac{\partial}{\partial y^\sigma_{i_1}} + \cdots + y^\sigma_{i_1 i_2 \cdots i_r i} \frac{\partial}{\partial y^\sigma_{i_1 i_2 \cdots i_r}}.$$

II. LAGRANGE STRUCTURES

A. Differential forms on jet spaces

For any open set $W \subset Y$, let $\Omega^r_0 W$ be the ring of functions on W^r. The $\Omega^r_0 W$-module of differential q-forms on W^r is denoted by $\Omega^r_q W$, and the exterior algebra of forms on W^r is denoted by $\Omega^r W$. The module of $\pi^{r,0}$-horizontal (π^r-horizontal) q-forms is denoted by $\Omega^r_{q,Y} W$ ($\Omega^r_{q,X} W$, respectively); forms belonging to these spaces are sometimes called $\pi^{r,0}$-semibasic, or π^r-semibasic, respectively.

Let $W \subset Y$ be an open set. The fibered structure of Y induces a morphism of exterior algebras $h: \Omega^r W \to \Omega^{r+1} W$, called the *horizontalization*. In a fibered chart (V, ψ), $\psi = (x^i, y^\sigma)$, h is defined by

$$hf = f \circ \pi^{r+1,r}, \quad h\,\mathrm{d}x^i = \mathrm{d}x^i, \quad h\,\mathrm{d}y^\sigma_{j_1 j_2 \cdots j_p} = y^\sigma_{j_1 j_2 \cdots j_p k}\,\mathrm{d}x^k,$$

where $f: W^r \to \mathbb{R}$ is a function, and $0 \leqslant p \leqslant r$. Note that h can be defined intrinsically: for a k-form $\eta \in \Omega^r_k W$, where $0 \leqslant k \leqslant n$, we define $h\eta$ to be a unique π^{r+1}-horizontal form such that $J^r\gamma^* \eta = J^{r+1}\gamma^* h\eta$ for every section γ of Y (here * denotes the pull-back operation).

We say that a form $\eta \in \Omega^r_k W$ is *contact*, if $h\eta = 0$. For any fibered chart (V, ψ), $\psi = (x^i, y^\sigma)$, the 1-forms

$$\omega^\sigma_{j_1 j_2 \cdots j_p} = \mathrm{d}y^\sigma_{j_1 j_2 \cdots j_p} - y^\sigma_{j_1 j_2 \cdots j_p k}\,\mathrm{d}x^k,$$

where $1 \leqslant p \leqslant r-1$, are examples of contact 1-forms. Note that these forms define a basis of 1-forms on V^r, $(\mathrm{d}x^i, \omega^\sigma_{j_1 j_2 \cdots j_p}, \mathrm{d}y^\sigma_{j_1 j_2 \cdots j_r})$.

It is known that a form $\eta \in \Omega^r_k W$ has a unique decomposition

$$(\pi^{r+1,r})^* \eta = h\eta + p_1\eta + p_2\eta + \cdots + p_k\eta, \tag{1}$$

such that $p_i\eta$ contains, in any fibered chart, exactly i exterior factors $\omega^\sigma_{j_1 j_2 \cdots j_l}$, $1 \leqslant l \leqslant r$. In particular, this gives us a simple formulation of the fact that the forms $\omega^\sigma_{j_1 j_2 \cdots j_l}$ generate an *ideal* in the exterior algebra $\Omega^r V$ (the *contact ideal*).

$h\eta$ ($p_i\eta$) is the *horizontal* (*i*th *contact*) *component* of η. The decomposition (1) is *invariant*, and is called the *canonical decomposition* of η.

η is π^r*-horizontal* if and only if $(\pi^{r+1,r})^*\eta = h\eta$. We say that η is *k-contact*, if $(\pi^{r+1,r})^*\eta = p_k\eta$; in this case k is the *order of contactness* of η.

Let $k \geqslant n+1$. Then for any k-form $\eta \in \Omega^r_k W$, $h\eta = 0$, $p_1\eta = 0$, $p_2\eta = 0, \ldots, p_{k-n-1}\eta = 0$, because each of these forms contains more than n exterior factors $\mathrm{d}x^i$. η is said to be *strongly contact*, if $p_{k-n}\eta = 0$.

B. Lagrangians

A *Lagrangian* (of *order r*) for Y is any π^r-horizontal n-form on some $W^r \subset J^r Y$, i.e., any element of the set $\Omega^r_{n,X} W$. In a fibered chart (V, ψ), $\psi = (x^i, y^\sigma)$, a Lagrangian of order r defined on $V^r = (\pi^{r,0})^{-1}(V)$ has an expression

$$\lambda = \mathcal{L}\omega_0, \tag{2}$$

where $\mathcal{L}: V^r \to \mathbb{R}$ is a function (the *Lagrange function* associated with λ and (V, ψ)). Clearly, in general a Lagrangian cannot be determined by a *globally* defined function unless a volume element on X is specified.

A pair (Y, λ), consisting of a fibered manifold Y and a Lagrangian λ of order r for Y is called a *Lagrange structure* (of order r).

Sometimes it is convenient to use Lagrangians of the form $\lambda = h\eta$, where $\eta \in \Omega^{r-1}_n W$. These Lagrangians have a certain polynomial structure in the highest order variables $y^\sigma_{j_1 j_2 \cdots j_r}$. The assumption $\lambda = h\eta$ appears naturally in the variational sequence theory, but does not restrict the generality.

Note that our definition includes Lagrangians defined over any open subsets $W \subset Y$; we need such a definition to describe phenomena arising in connection with the so-called *local variational principles* for *globally defined* Euler–Lagrange equations. The discussion of this situation is a main objective of this paper.

C. Lepage forms

We now give a formal definition of a Lepage form (Krupka[15]). A principal geometric meaning of this concept consists in the fact, that Lepage forms describe the relationship between the equations for extremals of variational principles on one side, and the exterior derivative operator, acting on differential forms, on the other side.

A differential form $\rho \in \Omega^s_n W$, where $n = \dim X$, is called a *Lepage form*, if $p_1\,\mathrm{d}\rho$ is $\pi^{s+1,0}$-horizontal, i.e., $p_1\,\mathrm{d}\rho \in \Omega^{s+1}_{n+1,Y} W$. A Lepage form ρ is a *Lepage equivalent* of a Lagrangian $\lambda \in \Omega^r_{n,X} W$, if the horizontal component of ρ coincides with λ, i.e., $h\rho = \lambda$ (possibly up to a jet projection).

If ρ is a Lepage equivalent of a Lagrangian $\lambda \in \Omega^r_{n,X} W$, expressed by (2), then one can get by a direct calculation

$$p_1\,\mathrm{d}\rho = E_\sigma(\mathcal{L})\omega^\sigma \wedge \omega_0, \tag{3}$$

where

$$E_\sigma(\mathcal{L}) = \sum_{k=0}^{r} (-1)^k d_{i_1} d_{i_2} \cdots d_{i_k} \frac{\partial \mathcal{L}}{\partial y^\sigma_{i_1 i_2 \cdots i_k}} \tag{4}$$

are the *Euler–Lagrange expressions* associated with the Lagrange function $\mathcal{L}$. In particular, $p_1\,\mathrm{d}\rho$ depends on the Lagrangian λ only. The $(n+1)$-form

$$E_\lambda = p_1\,\mathrm{d}\rho$$

is called the *Euler–Lagrange form* associated with λ.

We give three examples of Lepage equivalents.

(1) Every first order Lagrangian $\lambda \in \Omega^1_{n,X}W$ has a unique Lepage equivalent $\Theta_\lambda \in \Omega^1_{n,Y}W$ whose order of contactness is $\leqslant 1$. If λ is expressed in a fibered chart by $\lambda = \mathcal{L}\omega_0$, then

$$\Theta_\lambda = \mathcal{L}\omega_0 + \frac{\partial \mathcal{L}}{\partial y^\sigma_i}\omega^\sigma \wedge \omega_i.$$

Θ_λ is the *Poincaré–Cartan equivalent* of λ, or the *Poincaré–Cartan form*.

(2) Let $\lambda \in \Omega^1_{n,X}W$ be as above. The *fundamental Lepage equivalent* $\Phi_\lambda \in \Omega^1_{n,Y}W$ of λ is given by

$$\Phi_\lambda = \sum_{k=0}^{n}\left(\frac{1}{k!}\right)^2 \frac{\partial^k \mathcal{L}}{\partial y^{\sigma_1}_{j_1}\partial y^{\sigma_2}_{j_2}\cdots\partial y^{\sigma_k}_{j_k}}\omega^{\sigma_1}\wedge\omega^{\sigma_2}\wedge\cdots\wedge\omega^{\sigma_k}\wedge\omega_{j_1 j_2\cdots j_k}, \tag{5}$$

where

$$i_{\partial/\partial x^{i_k}}\cdots i_{\partial/\partial x^{i_2}} i_{\partial/\partial x^{i_1}}\omega_0 = \omega_{i_1 i_2\cdots i_k}.$$

Φ_λ has the following remarkable properties: (a) $\mathrm{d}\Phi_\lambda = 0$ if and only if $E_\lambda = 0$, and (b) $\lambda = h\eta$ for some $\eta \in \Omega^0_n W$ if and only if E_λ is $\pi^{2,1}$-projectable. The form Φ_λ was introduced for the first time by Krupka,[15,18] and it was rediscovered by Betounes,[3,4] and Rund[25] who wrote Φ_λ in a more simple way as it stands in (5).

(3) Expression

$$\Theta_\lambda = \mathcal{L}\omega_0 + \left(\frac{\partial \mathcal{L}}{\partial y^\sigma_i} - d_p\frac{\partial \mathcal{L}}{\partial y^\sigma_{pi}}\right)\omega^\sigma \wedge \omega_i + \frac{\partial \mathcal{L}}{\partial y^\sigma_{ji}}\omega^\sigma_j \wedge \omega_i \tag{6}$$

generalizes the Poincaré–Cartan form to *second order* Lagrangians $\lambda \in \Omega^2_{n,X}W$ (Krupka[15]), higher order generalizations can be found in Krupka.[19] It can be shown that every Lepage equivalent of a Lagrangian $\lambda = \mathcal{L}\omega_0$ of order r has the chart expression $\rho = \Theta_\lambda + \mathrm{d}\mu + \nu$, where

$$\Theta_\lambda = \mathcal{L}\omega_0 + \sum_{k=0}^{s}\left(\sum_{l=0}^{r-k}(-1)^l d_{i_1} d_{i_2}\cdots d_{i_l}\frac{\partial \mathcal{L}}{\partial y^\sigma_{i_1 i_2\cdots i_l j_1 j_2\cdots j_k}}\right)\omega^\sigma_{j_1 j_2\cdots j_k}\wedge\omega_i, \tag{7}$$

μ is a contact form, and ν is of order of contactness $\geqslant 2$. Expression (6) defines a differential form on J^3Y, but for $r \geqslant 3$, the (local) Lepage equivalents (7) of λ are no longer invariant.

D. Automorphisms, variations

By an *automorphism* of Y we mean a diffeomorphism $\alpha: W \to Y$, where $W \subset Y$ is an open set, such that there exists a diffeomorphism $\alpha_0: \pi(W) \to X$ such that $\pi\alpha = \alpha_0\pi$. If α_0 exists, it is unique, and is called the *π-projection* of α. The *r-jet prolongation* of α is an automorphism $J^r\alpha: W^r \to J^rY$ of J^rY, defined by

$$J^r\alpha(J^r_x\gamma) = J^r_{\alpha_0(x)}(\alpha\gamma\alpha_0^{-1}).$$

Let $U \subset X$ be an open set, and let $\gamma: U \to Y$ be a section. Let ξ be a π-projectable vector field on an open set $W \subset Y$ such that $\gamma(U) \subset W$. If α_t is the local one-parameter group of ξ, and $\alpha_{(0)t}$ is its projection, then since $\pi\alpha_t = \alpha_{(0)t}\pi$,

$$\gamma_t = \alpha_t \gamma \alpha_{(0)t}^{-1}$$

is one-parameter family of sections of Y, depending smoothly on t. γ_t is called the *variation*, or the *deformation* of γ, *induced* by ξ.

We define the *r-jet prolongation* of ξ to be the vector field $J^r\xi$ on J^rY whose local one-parameter group is $J^r_{\alpha_t}$. Thus,

$$J^r\xi(J^r_x\gamma) = \left\{ \frac{\mathrm{d}}{\mathrm{d}t} J^r_{\alpha_{(0)t}(x)}(\alpha_t \gamma \alpha_{(0)t}^{-1}) \right\}_0 .$$

E. Global variational functionals

Let Ω be a piece of X (a compact, n-dimensional submanifold of X with boundary $\partial\Omega$), let $\Gamma_{\Omega,W}(\pi)$ be the set of smooth sections γ over Ω such that $\gamma(\Omega) \subset W$. Suppose that we have a Lagrangian $\lambda \in \Omega^r_{n,X}(W)$. This gives rise to the *variational functional*, or the *action function* associated with λ, $\Gamma_{\Omega,W}(\pi) \ni \gamma \to \lambda_\Omega(\gamma) \in \mathbb{R}$, defined by

$$\lambda_\Omega(\gamma) = \int_\Omega J^r\gamma^*\lambda .$$

Choose a section $\gamma \in \Gamma_{\Omega,W}(\pi)$ and a π-projectable vector field ξ on Y, and consider the induced variation γ_t of γ. Since the domain of γ_t contains Ω for all sufficiently small t, we get a real-valued function on a neighborhood $(-\epsilon, \epsilon)$ of the origin $0 \in \mathbb{R}$,

$$(-\epsilon, \epsilon) \ni t \to \lambda_{\alpha_{(0)t}(\Omega)}(\alpha_t \gamma \alpha_{(0)t}^{-1}) = \int_{\alpha_{(0)t}(\Omega)} J^r(\alpha_t \gamma \alpha_{(0)t}^{-1})^* \lambda \in \mathbb{R}.$$

Differentiating this function at $t=0$ we obtain

$$(\partial_{J^r\xi}\lambda)_\Omega(\gamma) = \int_\Omega J^r\gamma^* \partial_{J^r\xi}\lambda, \tag{8}$$

where $\partial_{J^r\xi}\lambda$ is the Lie derivative of λ by $J^r\xi$. The number (8) is the *variation* of the variational function λ_Ω at γ, *induced* by the vector field ξ. This formula shows, in particular, that the function $\Gamma_{\Omega,W}(\pi) \ni \gamma \to (\partial_{J^r\xi}\lambda)_\Omega(\gamma) \in \mathbb{R}$ is the variational functional (over Ω) associated with the Lagrangian $\partial_{J^r\xi}\lambda$. We call this function the *variational derivative*, or the *first variation* of λ_Ω by ξ.

We now compute the Lie derivative $\partial_{J^r\xi}\lambda$. Choose for this purpose a Lepage equivalent ρ of λ, and denote by s the *order* of ρ. Since $\lambda = h\rho$, or, which is the same, $J^r\gamma^*\lambda = J^s\gamma^*\rho$ for all sections γ, we obtain

$$J^r\gamma^*\partial_{J^r\xi}\lambda = J^s\gamma^*\partial_{J^s\xi}\rho = J^s\gamma^*(i_{J^s\xi}\,\mathrm{d}\rho + \mathrm{d}i_{J^s\xi}\rho).$$

Omitting γ and using the Euler–Lagrange form (3) and (4), we get

$$\partial_{J^r\xi}\lambda = h i_{J^{s+1}\xi} E_\lambda + h\,\mathrm{d}i_{J^s\xi}\rho. \tag{9}$$

This is the *differential first variation formula*; the first term on the right-hand side is the *Euler–Lagrange term*, and the second one is the *boundary term*.

Writing (9) in coordinates, we obtain the well-known classical expressions, standing behind the variation integral.

F. Extremals

Let $\lambda \in \Omega^r_{n,X}W$ be a Lagrangian, and let $\rho \in \Omega^s_n W$ be a Lepage equivalent of λ. We say that a section $\gamma \in \Gamma_{\Omega,W}(\pi)$ is *stable* with respect to a variation ξ of γ, if $(\partial_{J^r\xi}\lambda)_\Omega(\gamma) = 0$. Stable sections with respect to *families* of variations are defined in an obvious way. If γ is stable with respect to

all ξ with support contained in $\pi^{-1}(\Omega)$, we say that γ is an *extremal* of λ_Ω. A section γ which is an extremal of every λ_Ω is called an *extremal* of λ.

The following conditions are equivalent: (1) γ is an extremal of λ, (2) γ satisfies

$$J^s\gamma^* i_{J^s\xi}\,\mathrm{d}\rho = 0$$

for all π-vertical vector fields ξ, and (3) for every fibered chart on Y, γ satisfies the system of partial differential equations

$$E_\sigma(\mathcal{L})\circ J^{2r}\gamma = 0.$$

G. Trivial Lagrangians

A Lagrangian $\lambda \in \Omega^r_{n,X}W$ is called *trivial* (or *variationally trivial*, or *null*) if there exists an $(n-1)$-form $\eta \in \Omega^s_{n-1}W$ such that $\lambda = h\,\mathrm{d}\eta$. λ is called *locally trivial* if there exists an open covering $\{W_\iota\}_{\iota\in I}$ of Y, and to each $\iota \in I$ an $(n-1)$-form $\eta_\iota \in \Omega^s_{n-1}W_\iota$, such that $\lambda = h\,\mathrm{d}\eta_\iota$ over W_ι.

The following is a standard consequence of variational sequence theory.

Theorem 1: *A Lagrangian* λ *is locally trivial if and only if* $E_\lambda = 0$.

H. Locally variational forms

A 1-contact, $\pi^{s,0}$-horizontal form $\varepsilon \in \Omega^s_{n+1,Y}W$ is called a *dynamical form* (Krupková[22]); Takens[28] calls such forms *source forms*. From the definition it follows that in a fibered chart (V,ψ), $\psi=(x^i,y^\sigma)$,

$$\varepsilon = \varepsilon_\sigma \omega^\sigma \wedge \omega_0,$$

where $\varepsilon_\sigma = \varepsilon_\sigma(x^i, y^\sigma, y^\sigma_{j_1}, y^\sigma_{j_1 j_2}, \ldots, y^\sigma_{j_1 j_2 \cdots j_s})$. We say that a dynamical form ε is *variational*, if $\varepsilon = E_\lambda$ for some Lagrangian $\lambda \in \Omega^r_{n,X}W$. ε is said to be *locally variational*, if there are an open covering $\{V_\iota\}_{\iota\in I}$ of Y and a family $\{\lambda_\iota\}_{\iota\in I}$ of Lagrangians $\lambda_\iota \in \Omega^r_{n,X}V_\iota$ such that for every $\iota \in I$,

$$\varepsilon | V_\iota = E_{\lambda_\iota}.$$

Denote

$$H^{j_1 j_2 \cdots j_i}_{\sigma\ \ \ \ \ \ \ \nu}(\varepsilon) = \frac{\partial \varepsilon_\nu}{\partial y^\sigma_{j_1 j_2 \cdots j_i}} - (-1)^i \frac{\partial \varepsilon_\sigma}{\partial y^\nu_{j_1 j_2 \cdots j_i}} - \sum_{k=i+1}^{s} (-1)^k \binom{k}{i} d_{j_{i+1}} d_{j_{i+2}} \cdots d_{j_k} \frac{\partial \varepsilon_\sigma}{\partial y^\nu_{j_1 j_2 \cdots j_1 j_{i+1} \cdots j_k}}$$

and

$$H_\varepsilon = \frac{1}{2}\sum_{i=1}^{s} H^{j_1 j_2 \cdots j_i}_{\sigma\ \ \ \ \ \ \ \nu}(\varepsilon)\,\omega^\sigma_{j_1 j_2 \cdots j_i} \wedge \omega^\nu \wedge \omega_0.$$

The functions $H^{j_1 j_2 \cdots j_i}_{\sigma\ \ \ \ \ \ \ \nu}(\varepsilon)$, called the *Helmholtz expressions*, appeared for the first time in Aldersley;[1] H_ε is the (global) *Helmholtz form* (Anderson,[2] Krupka,[16,20] Krbek and Musilová[14]).

The following is a consequence of the variational sequence theory.

Theorem 2: *A source form* ε *is locally variational if and only if* $H_\varepsilon = 0$.

I. Invariant transformations

An automorphism $\alpha: W \to Y$ of the fibered manifold Y is said to be an *invariant transformation* of a form $\eta \in \Omega^s_p W$, if

$$J^s\alpha^*\eta = \eta.$$

We also say that η is *invariant* with respect to α. Let ξ be a π-projectable vector field on Y. We say that ξ is the *generator* of invariant transformations of η, if

$$\partial_{J^s\xi}\eta = 0.$$

In this case we also say that η is *invariant* with respect to ξ. These definitions include the notions of invariance of *Lagrangians, dynamical forms*, and, in particular, the *Euler–Lagrange forms*.

Note that for *any* π-projectable vector field ξ, and any $\lambda \in \Omega^r_{n,X}W$,

$$\partial_{J^s\xi}E_\lambda = E_{\partial_{J^r\xi}\lambda}, \tag{10}$$

where s is the order of the Euler–Lagrange form E_λ. Thus, E_λ is invariant with respect to ξ if and only if $\partial_{J^r\xi}\lambda$ is a trivial Lagrangian.

The following result is standard.

Theorem 3: *Let ξ be a π-projectable vector field on Y, and let $\lambda \in \Omega^{r+1}_{n,X}W$ be a Lagrangian. The following conditions are equivalent:*

(a) *ξ generates invariant transformations of the Euler–Lagrange form E_λ.*
(b) *There exist an open covering $\{V_\iota\}_{\iota\in I}$ of Y and a system of $(n-1)$-forms $\{\eta_\iota\}_{\iota\in I}$, where $\eta_\iota \in \Omega^r_{n-1}V_\iota$, such that*

$$\partial_{J^{r+1}\xi}\lambda = h\,\mathrm{d}\eta_\iota.$$

The following simple consequence of the first variation formula is known as the *Noether's theorem*.

Theorem 4: *Let $\lambda \in \Omega^{r+1}_{n,X}W$ be a Lagrangian. Let $\rho \in \Omega^s_n W$ be a Lepage equivalent of λ, and let γ be an extremal.*

(a) *For any generator ξ of invariant transformations of λ,*

$$\mathrm{d}J^s\gamma^* i_{J^s\xi}\rho = 0.$$

(b) *For any generator ξ of invariant transformations of E_λ, there exist an open covering $\{V_\iota\}_{\iota\in I}$ of W and a family $\{\eta_\iota\}_{\iota\in I}$ of $(n-1)$-forms $\eta_\iota \in \Omega^r_{n-1}V_\iota$ such that for every $\iota \in I$,*

$$\mathrm{d}J^s\,\gamma^*(i_{J^s\xi}\rho - \eta_\iota) = 0.$$

III. INVARIANCE: FIRST ORDER VARIATIONAL PRINCIPLES

One of specific features of the *first order* Lagrange structures consists in existence of two "simple" Lepage forms (Sec. II C). The first one is the *Poincaré–Cartan form*, whose order of contactness is $\leqslant 1$ (see, e.g., García,[8] Goldschmidt and Sternberg,[9] Krupka,[17] Prieto[24]). The second one is the *fundamental Lepage form*, whose order of contactness is, in general, maximal, i.e., $\leqslant n$. We now compare invariance properties of these forms. Our results extend the usual concepts, based on the use of the Poincaré–Cartan form. For general approach to invariance we refer to Trautman[29] and Krupka.[17,15]

As before, we denote by Φ_λ the fundamental Lepage equivalent, associated with a first order Lagrangian λ, and by Θ_λ the Poincaré–Cartan equivalent.

Theorem 5: *For any automorphism $\alpha: W \to Y$ of Y,*

$$J^1\alpha^*\Phi_\lambda = \Phi_{J^1\alpha^*\lambda}. \tag{11}$$

Proof: (1) Let α_0 be the projection of α, and let (V,ψ), $\psi=(x^i,y^\sigma)$, and $(\overline{V},\overline{\psi})$, $\overline{\psi}=(\overline{x^i},\overline{y^\sigma})$, be two fibered charts such that $\alpha(V)\subset\overline{V}$. Let (U,φ), $\varphi=(x^i)$, and $(\overline{U},\overline{\varphi})$, $\overline{\varphi}=(\overline{x^i})$ be the associated charts on X. Denote

$$\overline{x^i}\alpha_0\varphi^{-1} = f^i, \quad \overline{y^\sigma}\alpha\psi^{-1} = F^\sigma,$$

and

$$x^p \alpha_0^{-1} \overline{\varphi}^{-1} = g^p.$$

Clearly, on the corresponding domains,

$$f^i(g^1(\overline{x^1}, \overline{x^2}, \ldots, \overline{x^n}), g^2(\overline{x^1}, \overline{x^2}, \ldots, \overline{x^n}), \ldots, g^n(\overline{x^1}, \overline{x^2}, \ldots \overline{x^n})) = \overline{x^i},$$

$$g^p(f^1(x^1, x^2, \ldots, x^n), f^2(x^1, x^2, \ldots x^n), \ldots, f^n(x^1, x^2, \ldots, x^n)) = x^p.$$

From these formulas, we can easily derive equations of the mapping $J^1\alpha: W^1 \to J^1Y$ in terms of the associated coordinates. By definition, we have for every $J^1_x\gamma \in W^1$, $J^1\alpha(J^1_x\gamma) = J^1_{\alpha_0(x)}(\alpha\gamma\alpha_0^{-1})$. On $V^1 \subset W^1$,

$$\overline{x^i} J^1\alpha(J^1_x\gamma) = \overline{x^i} J^1_{\alpha_0(x)}(\alpha\gamma\alpha_0^{-1}) = \overline{x^i}\alpha_0(x) = \overline{x^i}\alpha_0\varphi^{-1}(\varphi(x)),$$

$$\overline{y^\sigma} J^1\alpha(J^1_x\gamma) = \overline{y^\sigma} J^1_{\alpha_0(x)}(\alpha\gamma\alpha_0^{-1}) = \overline{y^\sigma}\alpha\psi^{-1}(\psi(\gamma(x))),$$

and

$$\overline{y^\sigma_j} J^1\alpha(J^1_x\gamma) = \overline{y^\sigma_j} J^1_{\alpha_0(x)}(\alpha\gamma\alpha_0^{-1}) = D_j(\overline{y^\sigma}\alpha\gamma\alpha_0^{-1}\overline{\varphi}^{-1})(\overline{\varphi}(\alpha_0(x))).$$

Computing the derivative by the chain rule, we get

$$\begin{aligned} D_j(\overline{y^\sigma}\alpha\gamma\alpha_0^{-1}\overline{\varphi}^{-1})(\overline{\varphi}(\alpha_0(x))) &= D_{1,k}(\overline{y^\sigma}\alpha\psi^{-1})(\psi(\gamma(x)))D_j(x^k\alpha_0^{-1}\overline{\varphi}^{-1})(\overline{\varphi}(\alpha_0(x))) \\ &\quad + D_{2,\nu}(\overline{y^\sigma}\alpha\psi^{-1})(\psi(\gamma(x)))D_k(y^\nu\gamma\varphi^{-1})(\varphi(x)) \\ &\quad \times D_j(x^k\alpha_0^{-1}\overline{\psi}^{-1})(\overline{\psi}(\alpha_0(x))). \end{aligned}$$

We define functions $F^\sigma_j: V^1 \to \mathbb{R}$ by

$$\begin{aligned} F^\sigma_j(x^i(J^1_x\gamma), y^\tau(J^1_x\gamma), y^\tau_p(J^1_x\gamma)) &= D_{1,k}(\overline{y^\sigma}\alpha\psi^{-1})(\psi(\gamma(x)))D_j(x^k\alpha_0^{-1}\overline{\varphi}^{-1})(\overline{\varphi}(\alpha_0(x))) + D_{2,\nu}(\overline{y^\sigma}\alpha\psi^{-1}) \\ &\quad \times(\psi(\gamma(x)))D_k(y^\nu\gamma\varphi^{-1})(\varphi(x))D_j(x^k\alpha_0^{-1}\overline{\varphi}^{-1})(\overline{\varphi}(\alpha_0(x))), \end{aligned}$$

or, which is the same, by

$$\begin{aligned} F^\sigma_j(x^i, y^\tau, y^\tau_p) &= \left(\left(\frac{\partial F^\sigma}{\partial x^k}\right)_{(x^i, y^\tau)} + \left(\frac{\partial F^\sigma}{\partial y^\nu}\right)_{(x^i, y^\tau)} y^\nu_k\right)\left(\frac{\partial g^k}{\partial \overline{x^j}}\right)_{(f^1(x^i), f^2(x^i), \ldots, f^n(x^i))} \\ &= (d_k F^\sigma)(x^i, y^\tau, y^\tau_j)\left(\frac{\partial g^k}{\partial \overline{x^j}}\right)_{(f^1(x^i), f^2(x^i), \ldots f^n(x^i))}. \end{aligned}$$

Then

$$\overline{y^\sigma_j} J^1\alpha(\psi^1)^{-1} = F^\sigma_j.$$

Summarizing, we see that the mapping $J^1\alpha$ is expressed by equations

$$\overline{x^i}\alpha_0\varphi^{-1} = f^i, \quad \overline{y^\sigma}\alpha\psi^{-1} = F^\sigma,$$

$$\overline{y^\sigma_j} J^1\alpha(\psi^1)^{-1} = d_k F^\sigma \cdot \left(\frac{\partial g^k}{\partial \overline{x^j}} \circ \overline{\varphi}\alpha_0\varphi^{-1}\right).$$

(2) We now derive chart expressions for the forms $\alpha_0^* \overline{\omega_0}$ and $\alpha_0^* \overline{\omega}_{i_1 i_2 \cdots i_k}$, where $1 \leqslant k \leqslant n$. We have, with obvious conventions,

$$\alpha_0^*\overline{\omega_0}(x) = \mathrm{d}(\overline{x^1}\alpha_0)(x) \wedge \mathrm{d}(\overline{x^2}\alpha_0)(x) \wedge \cdots \wedge \mathrm{d}(\overline{x^n}\alpha_0)(x) = \det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)} \omega_0(x).$$

Analogously, since

$$T_{\alpha_0(x)}\alpha_0^{-1} \cdot \left(\frac{\partial}{\partial \overline{x^i}}\right)_{\overline{\varphi}\alpha_0(x)} = \left(\frac{\partial g^j}{\partial \overline{x^i}}\right)_{\alpha_0(x)} \left(\frac{\partial}{\partial x^j}\right)_x$$

and

$$\alpha_0^*\overline{\omega_i}(x)(\xi_2, \xi_3, \ldots, \xi_n) = \left(\frac{\partial(x^j\alpha_0^{-1}\overline{\varphi}^{-1})}{\partial \overline{x^i}}\right)_{\overline{\varphi}\alpha_0(x)} \det\left(\frac{\partial(\overline{x^p}\alpha_0\varphi^{-1})}{\partial x^q}\right)_{\varphi(x)} \omega_j(x)(\xi_2, \xi_3, \ldots, \xi_n)$$

we have

$$\alpha_0^*\overline{\omega_i}(x) = \left(\frac{\partial g^j}{\partial \overline{x^i}}\right)_{\overline{\varphi}\alpha_0(x)} \det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)} \omega_j(x).$$

Continuing in the same way we obtain

$$\alpha_0^*\overline{\omega}_{i_1 i_2 \cdots i_k}(x)(\xi_{k+1}, \xi_{k+2}, \ldots, \xi_n) = \left(\frac{\partial g^{j_1}}{\partial \overline{x^i}_1}\right)_{\overline{\varphi}\alpha_0(x)} \left(\frac{\partial g^{j_2}}{\partial \overline{x^i}_2}\right)_{\overline{\varphi}\alpha_0(x)} \cdots \left(\frac{\partial g^{j_k}}{\partial \overline{x^i}_k}\right)_{\overline{\varphi}\alpha_0(x)} \det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)} \times \omega_{j_1 j_2 \cdots j_k}(x)(\xi_{k+1}, \xi_{k+2}, \ldots, \xi_n),$$

i.e.,

$$\alpha_0^*\overline{\omega}_{i_1 i_2 \cdots i_k}(x) = \left(\frac{\partial g^{j_1}}{\partial \overline{x^i}_1}\right)_{\overline{\varphi}\alpha_0(x)} \left(\frac{\partial g^{j_2}}{\partial \overline{x^i}_2}\right)_{\overline{\varphi}\alpha_0(x)} \cdots \left(\frac{\partial g^{j_k}}{\partial \overline{x^i}_k}\right)_{\overline{\varphi}\alpha_0(x)} \det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)} \omega_{j_1 j_2 \cdots j_k}(x).$$

(3) Similarly,

$$(J^1\alpha)^*\overline{\omega}^\sigma(J^1_x\gamma) = \left(\frac{\partial F^\sigma}{\partial y^\nu}\right)_{\psi\gamma(x)} \omega^\nu(J^1_x\gamma).$$

(4) We now prove Theorem 5. To simplify our formulas, we sometimes write x, or $\gamma(x)$, instead of $J^1_x\gamma$. Let the Lagrangian λ be expressed over $\overline{V}$ by

$$\lambda = \overline{\mathcal{L}}\,\overline{\omega_0}.$$

Then over V,

$$(J_1\alpha)^*\lambda(J^1_x\gamma) = (\overline{\mathcal{L}} \circ J^1\alpha(J^1_x\gamma))\det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)} \omega_0(x).$$

We can express the form $\Phi_{J^1\alpha^*\lambda}$ over V. Taking into account the summand containing k exterior factors ω^σ, we have the form from formula (5),

$$\left(\frac{\partial^k(\overline{\mathcal{L}} \circ J^1\alpha \circ (\psi^1)^{-1})}{\partial y^{\sigma_1}_{j_1} \partial y^{\sigma_2}_{j_2} \cdots \partial y^{\sigma_k}_{j_k}}\right)_{\psi^1(J^1_x\gamma)} \det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)} \times \omega^{\sigma_1}(J^1_x\gamma) \wedge \omega^{\sigma_2}(J^1_x\gamma) \wedge \cdots \wedge \omega^{\sigma_k}(J^1_x\gamma) \wedge \omega_{j_1 j_2 \cdots j_k}(J^1_x\gamma). \quad (12)$$

But

$$\left(\frac{\partial(\overline{\mathcal{L}}\circ J^1\alpha\circ(\psi^1)^{-1})}{\partial y^{\sigma_1}_{j_1}}\right)_{\psi^1(J^1_x\gamma)} = \left(\frac{\partial\overline{\mathcal{L}}}{\partial\overline{y}^{\nu_1}_{p_1}}\right)_{\overline{\psi}^1J^1\alpha(J^1_x\gamma)}\left(\frac{\partial F^{\nu_1}}{\partial y^{\sigma_1}}\right)_{\psi\gamma(x)}\left(\frac{\partial g^{j_1}}{\partial\overline{x}^{p_1}}\right)_{\overline{\varphi}\alpha_0(x)},$$

and in the same way

$$\left(\frac{\partial^k(\overline{\mathcal{L}}\circ J^1\alpha\circ(\psi^1)^{-1})}{\partial y^{\sigma_1}_{j_1}\partial y^{\sigma_2}_{j_2}\cdots\partial y^{\sigma_k}_{j_k}}\right)_{\psi^1(J^1_x\gamma)} = \left(\frac{\partial^k\overline{\mathcal{L}}}{\partial\overline{y}^{\nu_1}_{p_1}\partial\overline{y}^{\nu_2}_{p_2}\cdots\partial\overline{y}^{\nu_k}_{p_k}}\right)_{\overline{\psi}^1J^1\alpha(J^1_x\gamma)}\left(\frac{\partial F^{\nu_1}}{\partial y^{\sigma_1}}\right)_{\psi\gamma(x)}\left(\frac{\partial g^{j_1}}{\partial\overline{x}^{p_1}}\right)_{\overline{\varphi}\alpha_0(x)}\left(\frac{\partial F^{\nu_2}}{\partial y^{\sigma_2}}\right)_{\psi\gamma(x)}$$
$$\times\left(\frac{\partial g^{j_2}}{\partial\overline{x}^{p_2}}\right)_{\overline{\varphi}\alpha_0(x)}\cdots\left(\frac{\partial F^{\nu_k}}{\partial y^{\sigma_k}}\right)_{\psi\gamma(x)}\left(\frac{\partial g^{j_k}}{\partial\overline{x}^{p_k}}\right)_{\overline{\varphi}\alpha_0(x)}.$$

Consequently, (12) gives the expression

$$\left(\frac{\partial^k\overline{\mathcal{L}}}{\partial\overline{y}^{\nu_1}_{p_1}\partial\overline{y}^{\nu_2}_{p_2}\cdots\partial\overline{y}^{\nu_k}_{p_k}}\right)_{\overline{\psi}^1J^1\alpha(J^1_x\gamma)}\left(\frac{\partial F^{\nu_1}}{\partial y^{\sigma_1}}\right)_{\psi\gamma(x)}\left(\frac{\partial g^{j_1}}{\partial\overline{x}^{p_1}}\right)_{\overline{\varphi}\alpha_0(x)}\left(\frac{\partial F^{\nu_2}}{\partial y^{\sigma_2}}\right)_{\psi\gamma(x)}\left(\frac{\partial g^{j_2}}{\partial\overline{x}^{p_2}}\right)_{\overline{\varphi}\alpha_0(x)}\cdots\left(\frac{\partial F^{\nu_k}}{\partial y^{\sigma_k}}\right)_{\psi\gamma(x)}$$
$$\times\left(\frac{\partial g^{j_k}}{\partial\overline{x}^{p_k}}\right)_{\overline{\varphi}\alpha_0(x)}\det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)}\omega^{\sigma_1}(J^1_x\gamma)\wedge\omega^{\sigma_2}(J^1_x\gamma)\wedge\cdots\wedge\omega^{\sigma_k}(J^1_x\gamma)\wedge\omega_{j_1j_2\cdots j_k}(J^1_x\gamma). \tag{13}$$

On the other hand, consider in Φ_λ the summand

$$\frac{\partial^k\overline{\mathcal{L}}}{\partial\overline{y}^{\sigma_1}_{j_1}\partial\overline{y}^{\sigma_2}_{j_2}\cdots\partial\overline{y}^{\sigma_k}_{j_k}}\overline{\omega}^{\sigma_1}\wedge\overline{\omega}^{\sigma_2}\wedge\cdots\wedge\overline{\omega}^{\sigma_k}\wedge\overline{\omega}_{j_1j_2\cdots j_k} \tag{14}$$

over $\overline{V}$. Computing the pull-back $J^1\alpha^*\Phi_\lambda$, and in particular, the pull-back of the differential form (14), we obtain

$$\left(\frac{\partial^k\overline{\mathcal{L}}}{\partial\overline{y}^{\sigma_1}_{j_1}\partial\overline{y}^{\sigma_2}_{j_2}\cdots\partial\overline{y}^{\sigma_k}_{j_k}}\right)_{\overline{\psi}^1J^1\alpha(J^1_x\gamma)}\left(\frac{\partial F^{\sigma_1}}{\partial y^{\nu_1}}\right)_{\psi\gamma(x)}\left(\frac{\partial F^{\sigma_2}}{\partial y^{\nu_2}}\right)_{\psi\gamma(x)}\cdots\left(\frac{\partial F^{\sigma_k}}{\partial y^{\nu_k}}\right)_{\psi\gamma(x)}\left(\frac{\partial g^{l_1}}{\partial\overline{x}^{l_1}}\right)_{\overline{\varphi}\alpha_0(x)}$$
$$\times\left(\frac{\partial g^{l_2}}{\partial\overline{x}^{l_2}}\right)_{\overline{\varphi}\alpha_0(x)}\cdots\left(\frac{\partial g^{l_k}}{\partial\overline{x}^{l_k}}\right)_{\overline{\varphi}\alpha_0(x)}\det\left(\frac{\partial f^p}{\partial x^q}\right)_{\varphi(x)}\omega^{\nu_1}(J^1_x\gamma)\wedge\omega^{\nu_2}(J^1_x\gamma)$$
$$\wedge\cdots\wedge\omega^{\nu_k}(J^1_x\gamma)\wedge\omega_{l_1l_2\cdots l_k}(J^1_x\gamma). \tag{15}$$

Since (13) and (15) agree, we are done.

Corollary 1: For every π-projectable vector field ξ, the fundamental Lepage form Φ_λ satisfies

$$\partial_{J^1\xi}\Phi_\lambda = \Phi_{\partial_{J^1\xi}\lambda}.$$

Corollary 2: The Poincaré–Cartan form Θ_λ satisfies

$$J^1\alpha^*\Theta_\lambda = \Theta_{J^1\alpha^*\lambda} \tag{16}$$

and

$$\partial_{J^1\xi}\Theta_\lambda = \Theta_{\partial_{J^1\xi}\lambda}. \tag{17}$$

Proof: From the properties of contact forms it follows that the forms of the same order of contactness on the left- and right-hand side of formula (11) agree. Formula (16) means just the equality of forms of order of contactness $\leqslant 1$.

From Theorem 5 we can easily derive, for Lagrangians of order 1, formula (10) of Sec. II I

Corollary 3: The Euler–Lagrange form E_λ satisfies

$$\partial_{J^2\xi} E_\lambda = E_{\partial_{J^1\xi}\lambda}. \tag{18}$$

Proof: From Theorem 5 it follows that

$$\partial_{J^2\xi} p_1\, \mathrm{d}\Phi_\lambda = p_1 \partial_{J^1\xi}\, \mathrm{d}\Phi_\lambda = p_1\, \mathrm{d}\Phi_{\partial_{J^1\xi}\lambda},$$

which is exactly formula (18).

We are now in the position to study symmetries of the first order Lagrange structures. According to the definition used by Prieto,[24] an *infinitesimal symmetry* of a first order Lagrangian λ is a vector field Ξ on J^1Y such that $\partial_\Xi \Theta_\lambda = -\mathrm{d}\eta$ for some $(n-1)$-form η. Clearly, if Ξ is an infinitesimal symmetry, then $\mathrm{d}\partial_\Xi \Theta_\lambda = 0$, and the converse holds locally. In the following theorem we consider infinitesimal symmetries of the form $\Xi = J^1\xi$, where ξ is a π-projectable vector field, and compare them with generators of invariant transformations of the Euler–Lagrange form.

Theorem 6: Let λ *be a first order Lagrangian, and let* ξ *be a* π*-projectable vector field.*

(a) ξ *is the generator of invariant transformations of the Euler–Lagrange form* E_λ *if and only if* $\partial_{J^1\xi}\, \mathrm{d}\Phi_\lambda = 0$.

(b) *If* $\Xi = J^1\xi$ *is an infinitesimal symmetry, then* ξ *generates invariant transformations of* E_λ.

Proof: (a) Suppose that $\partial_{J^2\xi} E_\lambda = 0$. Then from Corollary 3, $E_{\partial_{J^1\xi}\lambda} = 0$, hence $\mathrm{d}\Phi_{\partial_{J^1\xi}\lambda} = 0$ and according to Theorem 5, $\partial_{J^1\xi}\, \mathrm{d}\Phi_\lambda = 0$. The converse is proved by reversing the arguments.

(b) Supposing that $\mathrm{d}\partial_{J^1\xi}\, \mathrm{d}\Theta_\lambda = 0$ we obtain $\mathrm{d}\Theta_{\partial_{J^1\xi}\lambda} = 0$ (Corollary 2) and by definition,

$$p_1\, \mathrm{d}\Theta_{\partial_{J^1\xi}\lambda} = E_{\partial_{J^1\xi}\lambda} = \partial_{J^2\xi} E_\lambda = 0.$$

Remark 1: In Theorem 6, we give some properties of generators of invariant transformations of the Euler–Lagrange form on one side, and infinitesimal symmetries on the other side. Note that for several reasons, the definition of infinitesimal symmetry in its full generality does not seem well motivated. First, variations, induced by general vector fields on J^1Y do not transform sections of the fibered manifold Y into sections of Y; in particular, such variations do not transform solutions of the Euler–Lagrange equations into solutions. Second, according to Theorem 6, infinitesimal symmetries do not include all generators of invariant transformations of the Euler–Lagrange form. The third reason consists in impossibility to generalize the definition of an infinitesimal symmetry to rth order Lagrange structures, because for Lagrangians of order $r \geqslant 3$ we do not have a global analogue of the Poincaré–Cartan form. For these reasons, we prefer, in the theory of local variational principles presented below, the concept of a generator of invariant transformations of the Euler–Lagrange form.

Remark 2: It is not known whether there exists a generalization of the fundamental Lepage form Φ_λ to higher order Lagrange structures.

IV. LOCAL VARIATIONAL PRINCIPLES

A. Local variational principles

Let $\varepsilon \in \Omega^s_{n+1,Y} Y$ be a locally variational form (ε is supposed to be defined globally). According to Sec. II H, the fibered manifold Y can be covered by open sets V_ι, $\iota \in I$, such that to every ι, there exists a Lagrangian λ_ι over V_ι for the form $\varepsilon|_{V_\iota}$; over the intersections $V_\iota \cap V_\kappa$, the Lagrangians λ_ι and λ_κ differ by a trivial Lagrangian. In general, a globally defined Lagrangian for ε need not exist.

In our definition of a local variational principle, we rephrase these properties of locally variational forms in terms of the Lepage forms. We say that a family $\{(V_\iota, \rho_\iota)\}_{\iota \in I}$, in which $\{V_\iota\}_{\iota \in I}$ is an open covering of Y and for every $\iota \in I$, $\rho_\iota \in \Omega^s_n V_\iota$ is a Lepage form, is said to be a *local variational principle*, if for every $\iota, \kappa \in I$,

$$p_1\, \mathrm{d}\rho_\iota = p_1\, \mathrm{d}\rho_\kappa$$

over $V_\iota \cap V_\kappa$. The integer s is called the *order* of the local variational principle $\{(V_\iota, \rho_\iota)\}_{\iota \in I}$.

Suppose that we have a local variational principle $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$ of order s. For every $\iota \in I$, we denote

$$E_\iota = p_1\, \mathrm{d}\rho_\iota.$$

E_ι is the Euler–Lagrange form of the *associated Lagrangian* $\lambda_\iota = h\rho_\iota$, defined over V_ι. Since by definition, $E_\iota = E_\kappa$ for all $\iota, \kappa \in I$, setting

$$E = E_\iota$$

over V_ι, we obtain a global differential form E on $J^{s+1}Y$. This form is called the *Euler–Lagrange form*, associated with the local variational principle $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$. Obviously, the Euler–Lagrange form is dynamical, locally variational form; it is not necessarily (globally) variational.

A local variational principle in another geometric context (i.e., on manifolds without fibration) was formulated by Dedecker.[5] Our definition is close to the Dedecker's approach.

Two local variational principles $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$, $\{(V'_\kappa, \rho'_\kappa)\}_{\kappa\in K}$ are *equivalent*, if the associated Euler–Lagrange forms E, E' coincide, i.e., $E = E'$.

Theorem 7: *A family* $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$, *in which* $\{V_\iota\}_{\iota\in I}$ *is an open covering of* Y *and for every* $\iota \in I$, $\rho_\iota \in \Omega^s_n V_\iota$ *is a Lepage form, is a local variational principle if and only if to every* $\iota, \kappa \in I$, *there exists a form* $\eta_{\iota\kappa} \in \Omega^r_{n-1}(V_\iota \cap V_\kappa)$ *and a contact form* $\chi_{\iota\kappa} \in \Omega^r_n(V_\iota \cap V_\kappa)$ *such that over* $V_\iota \cap V_\kappa$,

$$\rho_\iota - \rho_\kappa = \mathrm{d}\eta_{\iota\kappa} + \chi_{\iota\kappa}. \tag{19}$$

Proof: If $\rho_\iota - \rho_\kappa = \mathrm{d}\eta_{\iota\kappa} + \chi_{\iota\kappa}$, for some $\eta_{\iota\kappa}$ and $\chi_{\iota\kappa}$, then $\mathrm{d}(\rho_\iota - \rho_\kappa) = \mathrm{d}\chi_{\iota\kappa}$. This means that the class of $\chi_{\iota\kappa}$ is a contact Lepage form. Since $p_1\, \mathrm{d}\chi_{\iota\kappa}$ depends on the corresponding Lagrangian only, that is, on $h\chi_{\iota\kappa}$ (see Sec. II C), and this Lagrangian is zero, we have $p_1\, \mathrm{d}\chi_{\iota\kappa} = 0$. Consequently, $p_1\, \mathrm{d}\rho_\iota = p_1\, \mathrm{d}\rho_\kappa$. Conversely, if $p_1\, \mathrm{d}\rho_\iota = p_1\, \mathrm{d}\rho_\kappa$, then the Euler–Lagrange form $E_{h(\rho_\iota - \rho_\kappa)}$ vanishes. This means that the Lagrangian $h(\rho_\iota - \rho_\kappa)$ is trivial, which implies (19).

B. First variation formula, extremals

A basic tool for an analysis of extremals and invariant transformations of a variational functional is the first variation formula. We now give a formulation of the first variation formula for local variational principles.

Let $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$ be a local variational principle of order s. Fix an index $\iota \in I$, and choose a piece $\Omega \subset \pi(V_\iota)$. Then we have the variational functional

$$\Gamma_{\Omega, V_\iota}(\pi) \ni \gamma \to \rho_{\iota,\Omega}(\gamma) = \int_\Omega J^s\gamma^* \rho_\iota \in \mathbb{R}.$$

For any π-projectable vector field ξ on Y, we have the *first variation formula*

$$\partial_{J^s\xi}\rho_\iota = i_{J^s\xi}\, \mathrm{d}\rho_\iota + \mathrm{d}i_{J^s\xi}\rho_\iota.$$

This formula can easily be written by means of the associated Lagrangian $\lambda_\iota = h\rho_\iota$. Since $\partial_{J^{s+1}\xi} h\rho_\iota = h\partial_{J^s\xi}\rho_\iota = hi_{J^s\xi}\, \mathrm{d}\rho_\iota + h\, \mathrm{d}i_{J^s\xi}\rho_\iota$, we have

$$\partial_{J^{s+1}\xi} h\rho_\iota = hi_{J^{s+1}\xi} p\, \mathrm{d}\rho_\iota + h\, \mathrm{d}i_{J^s\xi}\rho_\iota = hi_{J^{s+1}\xi} E + h\, \mathrm{d}i_{J^s\xi}\rho_\iota$$

and

$$\partial_{J^{s+1}\xi}\lambda_\iota = hi_{J^{s+1}\xi} E + h\mathrm{d}i_{J^s\xi}\rho_\iota,$$

where E is the Euler–Lagrange form of $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$. This is another formulation of the first variation formula for the local variational principle $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$.

We have the following simple observation.

Theorem 8: *Let* $\{(V_\iota, \rho_\iota)\}_{\iota\in I}$ *be a local variational principle of order* s. *Let* γ *be a section of*

Y. The following conditions are equivalent:

(a) *For every* $\iota \in I$, $\gamma_\iota = \gamma|_{\pi(V_\iota)}$ *is an extremal of the variational functional* $\rho_{\iota,\Omega}$.
(b) *For every* π*-projectable vector field* ξ, γ *satisfies*

$$J^{s+1}\gamma^* i_{J^{s+1}\xi} E = 0.$$

A section γ, satisfying any of these two equivalent conditions, is called an *extremal* of the local variational principle $\{(V_\iota, \rho_\iota)\}_{\iota \in I}$.

C. Invariant transformations

It is straightforward to extend the theory of invariant transformations as introduced in Sec. II I, to *local variational principles*. The concept of a Lagrangian in this case is defined only locally, but we still have the notions of invariance of the Euler–Lagrange form.

Suppose that we have a local variational principle $\{(V_\iota, \rho_\iota)\}_{\iota \in I}$ of order s, and denote by E its Euler–Lagrange form. Let $\alpha: W \to Y$ be an automorphism of Y. We say that α is an *invariant transformation* of E, if

$$J^{s+1}\alpha^* E = E.$$

A π-projectable vector field ξ on Y is said to be the *generator of invariant transformations* of E, if

$$\partial_{J^{s+1}\xi} E = 0.$$

The following is straightforward.

Theorem 9: *Let* $\{(V_\iota, \rho_\iota)\}_{\iota \in I}$ *be a local variational principle, and let* ξ *be a* π*-projectable vector field. Let E be the Euler–Lagrange form of* $\{(V_\iota, \rho_\iota)\}_{\iota \in I}$. *The following conditions are equivalent:*

(a) ξ *is a generator of invariant transformations of E.*
(b) *There exists a family* $\{\eta_\iota\}_{\iota \in I}$ *of* $(n-1)$*-forms* $\eta_\iota \in \Omega^s_{n-1} V_\iota$ *such that for every* $\iota \in I$,

$$h i_{J^{s+1}\xi} E + h\mathrm{d}(i_{J^s\xi}\rho_\iota - \eta_\iota) = 0. \tag{20}$$

Proof: Let ξ be a generator of invariant transformations of E, let $\iota \in I$. Over V_ι, $E = E_{\lambda_\iota}$, where $\lambda_\iota = h\rho_\iota$, and $\partial_{J^{s+1}\xi} E = E_{\partial_{J^{s+1}\xi}\lambda_\iota} = 0$, hence by Theorem 3, $\partial_{J^{s+1}\xi}\lambda_\iota = h\,\mathrm{d}\,\eta_\iota$ for some $(n-1)$-form η_ι over V_ι. Then

$$\partial_{J^{s+1}\xi}\lambda_\iota = h i_{J^{s+1}\xi} E + h\,\mathrm{d} i_{J^s\xi}\rho_\iota = h\,\mathrm{d}\,\eta_\iota,$$

proving (20).

Consider the Euler–Lagrange form E of the local variational principle $\{(V_\iota, \rho_\iota)\}_{\iota \in I}$, and a vector field ξ on Y. Let (V, ψ), $\psi = (x^i, y^\sigma)$, be a fibered chart on Y such that $V \subset V_\iota$. Suppose that over V,

$$h\rho_\iota = \mathcal{L}_\iota \omega_0$$

and

$$\xi = \xi_0^k \frac{\partial}{\partial x^k} + \xi^\sigma \frac{\partial}{\partial y^\sigma}.$$

Then over V,

$$E = E_\sigma(\mathcal{L}_\iota)\omega^\sigma \wedge \omega_0,$$

where

$$E_\sigma(\mathcal{L}_\iota) = \sum_{k=0}^{r} (-1)^k d_{i_1} d_{i_2} \cdots d_{i_k} \frac{\partial \mathcal{L}_\iota}{\partial y^\sigma_{i_1 i_2 \cdots i_k}}$$

and

$$hi_{J^{s+1}\xi} E = E_\sigma(\mathcal{L}_\iota)(\xi^\sigma - y^\sigma_k \xi^k_0)\omega_0. \tag{21}$$

Formula (21) shows that the Euler–Lagrange equations for extremals are, over V,

$$E_\sigma(\mathcal{L}_\iota) = 0. \tag{22}$$

Thus, if ξ generates invariant transformations of E, we have a *conservation law*

$$\mathrm{d}(i_{J^s\xi}\rho_\iota - \eta_\iota) = 0 \tag{23}$$

(along any extremal). The arising equation (23) should be considered together with Eq. (22).

The set of generators of invariant transformations of the Euler–Lagrange form is a Lie algebra. Indeed, if two π-projectable fields ξ and ζ, satisfy

$$\partial_{J^s\xi} E = 0, \quad \partial_{J^s\zeta} E = 0,$$

then since $J^s[\xi,\zeta]=[J^s\xi, J^s\zeta]$, we have

$$\partial_{J^s[\xi,\zeta]} E = \partial_{J^s\xi}\partial_{J^s\zeta} E - \partial_{J^s\zeta}\partial_{J^s\xi} E = 0.$$

Institute of Mathematics of NAS of Ukraine, 01601 Kyiv, Ukraine

(Received 9 November 2004; accepted 8 February 2005; published online 11 April 2005)

We perform complete group classification of the general class of quasilinear wave equations in two variables. This class may be seen as a generalization of the nonlinear d'Alembert, Liouville, sin/sinh-Gordon and Tzitzeica equations. We derive a number of new genuinely nonlinear invariant models with high symmetry properties. In particular, we obtain four classes of nonlinear wave equations that admit five-dimensional invariance groups. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1884886]

INTRODUCTION

More than a century ago Lie introduced the concept of continuous transformation group into mathematical physics and mechanics. His initial motivation was to develop a theory of integration of ordinary differential equations enabling to answer the basic questions, like, why some equations are integrable and others are not. His fundamental results obtained on this way, can be seen as a far reaching generalization of the Galois's and Abel's theory of solubility of algebraic equations by radicals. Since that time the Lie's theory of continuous transformation groups has become applicable to an astonishingly wide range of mathematical and physical problems.

It was Lie who was the first to utilize group properties of differential equations for constructing of their exact solutions. In particular, he computed the maximal invariance group of the one-dimensional heat conductivity equation and applied this symmetry to construct its explicit solutions. Saying it the modern way, he performed symmetry reduction of the heat equation. Since late 1970s symmetry reduction becomes one of the most popular tools for solving nonlinear partial differential equations (PDEs).

By now symmetry properties of the majority of fundamental equations of mathematical and theoretical physics are well known. It turns out that for the most part these equations admit wide symmetry groups. Especially this is the case for linear PDEs and it is this rich symmetry that enables developing a variety of efficient methods for mathematical analysis of linear differential equations. However, linear equations give mathematical description of physical, chemical or biological processes in a first approximation only. To provide a more detailed and precise description a mathematical model must incorporate nonlinear terms. Note that some important differential equations are intrinsically nonlinear and have no linear counterpart.

Hyperbolic type second-order nonlinear PDEs in two independent variables play a fundamental role in modern mathematical physics. Equations of this type are utilized to describe various types of wave propagation. They are used in differential geometry, in various fields of hydrodynamics and gas dynamics, chemical technology, superconductivity, crystal dislocation to mention only a few applications areas. Surprisingly the list of equations utilized is rather narrow. In fact, it is comprised by the Liouville, sine/sinh-Gordon, Goursat, d'Alembert, and Tzitzeica equations and a couple of others. Popularity of these very models has a natural group-theoretical interpretation, namely, all of them have nontrivial Lie or Lie–Bäcklund symmetry. By this very reason some of them are integrable by the inverse problem methods (see, e.g., Refs. 1–3) or linearizable[4–6] and completely integrable.[7,8]

Knowing symmetry group of the equation under study provides us with the powerful equation exploration tool. So it is natural to attempt classifying a reasonably extensive class of nonlinear hyperbolic type PDEs into subclasses of equations enjoying the best symmetry properties. Saying reasonably extensive we mean that (i) this class should contain the above enumerated equations as particular cases, and (ii) it should contain a variety of new invariant models of potential interest for applications. The list of the so obtained invariant equations will contain candidates for realistic nonlinear mathematical models of the physical and chemical processes mentioned above.

The history of group classification methods goes back to Lie itself. Probably, the very first paper on this subject is Ref. 9, where Lie proves that a linear two-dimensional second-order PDE may admit at most a three-parameter invariance group (apart from the trivial infinite-parameter symmetry group, which is due to linearity).

The modern formulation of the problem of group classification of PDEs was suggested by Ovsyannikov in Ref. 10. He developed a regular method (we will refer to it as the Lie–Ovsyannikov method) for classifying differential equations with nontrivial symmetry and performed complete group classification of the nonlinear heat conductivity equation. In a number of subsequent publications more general types of nonlinear heat equations were classified (review of these results can be found in Ref. 11).

However, even a very quick analysis of the papers on group classification of PDEs reveals that an overwhelming majority of them deals with equations whose arbitrary elements (functions) depend on one variable only. The reason for this is that Lie–Ovsyannikov method becomes inefficient for PDEs containing arbitrary functions of several variables. To achieve a complete classification one either needs to specify the transformation group realization or restrict somehow an arbitrariness of the functions contained in the equation under study. We have recently, developed an efficient approach enabling to overcome this difficulty for low dimensional PDEs.[12,13] Utilizing it we have derived the complete group classification of the general quasilinear heat conductivity equation in two independent variables. In this paper we apply the approach in question to perform group classification of the most general quasilinear hyperbolic PDE in two independent variables.

I. GROUP CLASSIFICATION ALGORITHM

While classifying a given class of differential equations into subclasses, one can use different classifying features, like linearity, order, the number of independent or dependent variables, etc. In group analysis of differential equations the principal classifying features are symmetry properties of equations under study. This means that classification objects are equations considered together with their symmetry groups. This point of view is based on the well-known fact that any PDE admits a (possibly trivial) Lie transformation group. And what is more, any transformation group corresponds to a class of PDEs, which are invariant under this group. So the problem of group classification of a class of PDEs reduces to describing all possible (inequivalent) pairs (PDE, maximal invariance group), where PDE should belong to the class of equations under consideration.

We perform group classification of the following class of quasilinear wave equations:

$$u_{tt} = u_{xx} + F(t,x,u,u_x). \tag{1.1}$$

Here F is an arbitrary smooth function, $u=u(t,x)$. Hereafter we adopt notations $u_t=\partial u/\partial t$, $u_x=\partial_u/\partial_x$, $u_{tt}=\partial^2 u/\partial t^2$, etc.

Our aim is describing *all* equations of the form (1.1) that admit nontrivial symmetry groups. The challenge of this task is in the word *all*. If, for example, we somehow constrain the form of invariance group to be found, then the classification problem simplifies enormously. A slightly more cumbersome (but still tractable with the standard Lie–Ovsyannikov approach) is the problem of group classification of equation with arbitrary functions of, at most, one variable.

As equations invariant under similar Lie groups are identical within the group-theoretic framework, it makes sense to consider nonsimilar transformation groups[14,15] only. The important example of similar Lie groups is provided by Lie transformation groups obtained one from another

by a suitable change of variables. Consequently, equations obtained one from another by a change of variables have similar symmetry groups and cannot be distinguished within the group-theoretical viewpoint. That is why, we perform group classification of (1.1) within a change of variables preserving the class of PDEs (1.1).

The problem of group classification of linear hyperbolic type equation

$$u_{tx} + A(t,x)u_t + B(t,x)u_x + C(t,x)u = 0 \tag{1.2}$$

with $u = u(t,x)$, was solved by Lie[9] (see, also, Ref. 16). In view of this fact, we consider only those equations of the form (1.1) which are not (locally) equivalent to the linear equation (1.2).

As we have already mentioned in the Introduction, the Lie–Ovsyannikov method of group classification of differential equations has been suggested in Ref. 10. Utilizing this method enabled solving the group classification problem for a number of important one-dimensional nonlinear wave equations:

$$u_{tt} = u_{xx} + F(u) \quad \text{(Refs. 17–19)},$$

$$u_{tt} = [f(u)u_x]_x \quad \text{(Refs. 20–22)},$$

$$u_{tt} = f(u_x)u_{xx} \quad \text{(Refs. 22,23)},$$

$$u_{tt} = F(u_x)u_{xx} + H(u_x) \quad \text{(Ref. 24)},$$

$$u_{tt} = F(u_{xx}) \quad \text{(Ref. 22)},$$

$$u_{tt} = u_x^m u_{xx} + f(u) \quad \text{(Ref. 25)},$$

$$u_{tt} + f(u)u_t = (g(u)u_x)_x + h(u)u_x \quad \text{(Ref. 26)},$$

$$u_{tt} = (f(x,u)u_x)_x \quad \text{(Ref. 27)}.$$

Analysis of the above list shows that most of all arbitrary elements (=arbitrary functions) depend on one variable. This is not coincidental. As we already mentioned, the Lie–Ovsyannikov approach works smoothly for the case when the arbitrary elements are functions of one variable. The reason for this is that the obtained system of determining equations is still over-determined. So it can be effectively solved within the same techniques used to compute maximal symmetry group of PDEs containing no arbitrary elements.

The situation becomes much more complicated for the case when arbitrary elements are functions of two (or more) arguments. By this very reason the group classification of nonlinear wave equations,

$$u_{tt} + \lambda u_{xx} = g(u,u_x) \quad \text{(Refs. 28,29)},$$

$$u_{tt} = [f(u)u_x + g(x,u)]_x \quad \text{(Ref. 30)},$$

$$u_{tt} = f(x,u_x)u_{xx} + g(x,u_x) \quad \text{(Ref. 31)},$$

is not complete.

We suggest an efficient approach to the problem of group classification of low dimensional PDEs in Refs. 12 and 13. This approach is based on the Lie–Ovsyannikov infinitesimal method

and classification results for abstract finite-dimensional Lie algebras. It enables us to obtain the complete solution of the group classification problem for the general heat equation with a nonlinear source

$$u_t = u_{xx} + F(t,x,u,u_x).$$

Later on, we perform complete group classification of the most general quasilinear evolution equation,[32–34]

$$u_t = f(t,x,u,u_x)u_{xx} + g(t,x,u,u_x).$$

We utilize the above approach to obtain complete solution of the group classification problem for the class of Eqs. (1.1).

Our algorithm of group classification of the class of PDEs (1.1) is implemented in the following three steps (further details can be found in Ref. 34):

(I) Using the infinitesimal Lie method we derive the system of determining equations for coefficients of the first-order operator that generates symmetry group of equation (1.1). (Note that the determining equations which explicitly depend on the function F and its derivatives are called classifying equations.) Integrating equations that do not depend on F we obtain the form of the most general infinitesimal operator admitted by Eq. (1.1) under arbitrary F. Another task of this step is calculating the equivalence group $\mathcal{E}$ of the class of PDEs (1.1).

(II) We construct all realizations of Lie algebras A_n of the dimension $n \leqslant 3$ in the class of operators obtained at the first step within the equivalence relation defined by transformations from the equivalence group $\mathcal{E}$. Inserting the so obtained operators into classifying equations we select those realizations that can be symmetry algebras of a differential equation of the form (1.1).

(III) We compute all possible extensions of realizations constructed at the previous step to realizations of higher dimensional ($n > 3$) Lie algebras. Since extending symmetry algebras results in reducing arbitrariness of the function F, at some point this function will contain either arbitrary functions of at most one variable or arbitrary constants. At this point, we apply the standard classification method (which is due to Lie and Ovsyannikov) to derive the maximal symmetry group of the equation under study. This completes group classification of (1.1).

Performing the above enumerated steps yields the complete list of inequivalent equations of the form (1.1) together with their maximal (in Lie's sense) symmetry algebras.

We say that the group classification problem is completely solved when it is proved that

(1) the constructed symmetry algebras are maximal invariance algebras of the equations under consideration;

(2) the list of invariant equations contains only inequivalent ones, namely, no equation can be transformed into another one from the list by a transformation from the equivalence group $\mathcal{E}$.

II. PRELIMINARY GROUP CLASSIFICATION OF Eq. (1.1)

We look for the infinitesimal operator of symmetry group of equation (1.1) in the form

$$Q = \tau(t,x,u)\partial_t + \xi(t,x,u)\partial_x + \eta(t,x,u)\partial_u, \tag{2.1}$$

where τ, ξ, η are smooth functions defined on an open domain Ω of the space $V = \mathbb{R}^2 \times \mathbb{R}^1$ of independent $\mathbb{R}^2 = \langle t,x \rangle$ and dependent $\mathbb{R}^1 = \langle u \rangle = u(t,x)$ variables.

Operator (2.1) generates one-parameter invariance group of (1.1) iff its coefficients τ, ξ, η, ϵ satisfy the equation (Lie's invariance criterion)

$$\varphi^{tt} - \varphi^{xx} - \tau F_t - \xi F_x - \eta F_u - \varphi^x F_{u_x}\big|_{(1.1)} = 0, \tag{2.2}$$

where

$$\varphi^t = D_t(\eta) - u_t D_t(\tau) - u_x D_t(\xi),$$

$$\varphi^x = D_x(\eta) - u_t D_x(\tau) - u_x D_x(\xi),$$

$$\varphi^{tt} = D_t(\varphi^t) - u_{tt} D_t(\tau) - u_{tx} D_t(\xi),$$

$$\varphi^{xx} = D_x(\varphi^x) - u_{tx} D_x(\tau) - u_{xx} D_x(\xi),$$

and D_t, D_x are operators of total differentiation with respect to the variables t, x. As customary, by writing (1.1) we mean that one needs to replace u_{tt} and its differential consequences with the expression $u_{xx}+F$ and its differential consequences in (2.2).

After a simple transformations algebra we reduce (2.2) to the form

$$\begin{aligned}
&(1) \quad \xi_u = \tau_u = \eta_{uu} = 0,\\
&(2) \quad \tau_t - \xi_x = 0, \quad \xi_t - \tau_x = 0,\\
&(3) \quad 2\eta_{tu} + \tau_x F_{u_x} = 0,\\
&(4) \quad \eta_{tt} - \eta_{xx} - 2u_x \eta_{xu} + [\eta_u - 2\tau_t]\\
&\qquad \times F - \tau F_t - \xi F_x - \eta F_u - [\eta_x + u_x(\eta_u - \xi_x)]F_{u_x} = 0.
\end{aligned} \tag{2.3}$$

The first two groups of PDEs from (2.3) are to be used to derive the form of the most general infinitesimal operator admitted by (1.1). The remaining PDEs are classifying equations.

We prove in Ref. 35 that the following assertion holds.

Theorem 1: *Provided* $F_{u_x u_x} \neq 0$, *the maximal invariance group of equation (1.1) is generated by the following infinitesimal operator:*

$$Q = (\lambda t + \lambda_1)\partial_t + (\lambda x + \lambda_2)\partial_x + [h(x)u + r(t,x)]\partial_u, \tag{2.4}$$

where λ, λ_1, λ_2 *are real constants and* $h=h(x)$, $r=r(t,x)$, $F=F(t,x,u,u_x)$ *are functions obeying the constraint*

$$\begin{aligned}
&r_{tt} - r_{xx} - \frac{\mathrm{d}^2 h}{\mathrm{d}x^2}u - 2\frac{\mathrm{d}h}{\mathrm{d}x}u_x + (h - 2\lambda)F - (\lambda t + \lambda_1)F_t - (\lambda x + \lambda_2)F_x - (hu + r)F_u\\
&\quad - \left(r_x + \frac{\mathrm{d}h}{\mathrm{d}x}u + (h - \lambda)u_x\right)F_{u_x} = 0.
\end{aligned} \tag{2.5}$$

If $F=g(t,x,u)u_x+f(t,x,u)$, $g_u \neq 0$, *then the maximal invariance group of equation (1.1) is generated by infinitesimal operator (2.4), where* λ, λ_1, λ_2 *are real constants* h, r, g, f *are functions satisfying system of two equations*

$$\begin{aligned}
&-2h' - \lambda g = (\lambda t + \lambda_1)g_t + (\lambda x + \lambda_2)g_x + (hu + r)g_u,\\
&-h''u + r_{tt} - r_{xx} + (h - 2\lambda)f = (\lambda t + \lambda_1)f_t + (\lambda x + \lambda_2)f_x + (hu + r)f_u + g(h'u + r_x).
\end{aligned} \tag{2.6}$$

Next, if $F=g(t,x)u_x+f(t,x,u)$, $q \not\equiv 0$, $f_{uu} \neq 0$, *then the infinitesimal operator of the invariance group of equation (1.1) reads as*

$$Q = \tau(t,x)\partial_t + \xi(t,x)\partial_x + (h(t,x)u + r(t,x))\partial_u,$$

where τ, ξ, h, r, g, f are functions satisfying system of PDEs

$$\tau_t - \xi_x = 0, \quad \xi_t - \tau_x = 0,$$

$$2h_t = -\tau_x g, \quad 2h_x = -\tau_t g - \tau g_t - \xi g_x,$$

$$(h_{tt} - h_{xx})u + r_{tt} - r_{xx} + f(h - 2\tau_t) - \tau f_t - \xi f_x - (hu + r)f_u - (h_x u + r_x)g = 0.$$

Finally, if $F = f(t,x,u)$, $f_{uu} \neq 0$, then the maximal invariance group of equation (1.1) is generated by infinitesimal operator

$$Q = [\varphi(\theta) + \psi(\sigma)]\partial_t - [\varphi(\theta) - \psi(\sigma)]\partial_x + [ku + r(t,x)]\partial_u,$$

where $k \in \mathbb{R}$, $\theta = t - x$, $\sigma = t + x$ and functions φ, ψ, r, f and constant k satisfy the following equation:

$$r_{tt} - r_{xx} + [k - 2\varphi' - 2\psi']f - (\varphi + \psi)f_t + (\varphi - \psi)f_x - (ku + r)f_u = 0, \quad \varphi' = \frac{d\varphi}{d\theta}, \quad \psi' = \frac{d\psi}{d\theta}.$$

By virtue of the above theorem the problem of group classification of equation (1.1) reduces to the one of classifying equations of more specific forms,

$$u_{tt} = u_{xx} + F(t,x,u,u_x), \quad F_{u_x u_x} \neq 0, \tag{2.7}$$

$$u_{tt} = u_{xx} + g(t,x,u)u_x + f(t,x,u), \quad g_u \neq 0, \tag{2.8}$$

$$u_{tx} = g(t,x)u_x + f(t,x,u), \quad g_x \neq 0, \quad f_{uu} \neq 0, \tag{2.9}$$

$$u_{tx} = f(t,x,u), \quad f_{uu} \neq 0. \tag{2.10}$$

Note that condition $g_x \neq 0$ is essential, since otherwise (2.9) is locally equivalent (2.10).

Summing up, we conclude that the problem of group classification of (1.1) reduces to classifying more specific classes of PDEs (2.7)–(2.10).

First, we consider equations (2.8)–(2.10).

III. GROUP CLASSIFICATION OF EQ. (2.8)

According to Theorem 1 invariance group of equation (2.8) is generated by infinitesimal operator (2.4). And what is more, the real constants λ, λ_1, λ_2 and functions h, r, g, f satisfy equations (2.6). System (2.6) is to be used to specify both the form of functions f, g from (2.8) and functions h, r and constants λ, λ_1, λ_2 in (2.4). It is called the determining (sometimes classifying) equations.

Efficiency of the Lie method for calculation of maximal invariance group of PDE is essentially based on the fact that routinely system of determining equations is over-determined. This is clearly not the case, since we have only one equation for four (!) arbitrary functions and three of the latter depend on two variables. By this very reason direct application of Lie approach in the Ovsyannikov's spirit is no longer efficient when we attempt classifying PDEs with arbitrary functions of several variables.

Compute the equivalence group E of equation (2.8). This group is generated by invertible transformations of the space V preserving the differential structure of equation (2.8) (see, e.g., Ref. 14). Saying it another way, group transformation from $\mathcal{E}$

$$\overline{t} = \alpha(t,x,u), \quad \overline{x} = \beta(t,x,u), \quad v = U(t,x,u), \quad \frac{D(\overline{t},\overline{x},v)}{D(t,x,u)} \neq 0,$$

should reduce (2.8) to equation of the same form

$$v_{\overline{t}\overline{t}} = v_{\overline{x}\overline{x}} + \tilde{g}(\overline{t},\overline{x},v)v_{\overline{x}} + \tilde{f}(\overline{t},\overline{x},v), \quad \tilde{g}_v \neq 0$$

with possibly different $\tilde{f}$, $\tilde{g}$.

As proved by Ovsyannikov,[14] it is possible to modify the Lie's infinitesimal approach to calculate equivalence group in essentially same way as invariance group. We omit the simple intermediate calculations and present the final result.

Assertion 1: The maximal equivalence group $\mathcal{E}$ of Eq. (2.8) reads as

$$\overline{t} = kt + k_1, \quad \overline{x} = \epsilon kx + k_2, \quad v = X(x)u + Y(t,x), \tag{3.1}$$

where $k \neq 0$, $X \neq 0$, $\epsilon = \pm 1, k, k_1, k_2 \in \mathbb{R}$, and X, Y are arbitrary smooth functions.

This completes the first step of the algorithm.

A. Preliminary group classification of Eq. (2.8)

First, we derive inequivalent classes of equations of the form (2.8) admitting one-parameter invariance groups.

Lemma 1: There exist transformations (3.1) that reduce operator (2.4) to one of the six possible forms,

$$Q = m(t\partial_t + x\partial_x), \quad m \neq 0, \quad Q = \partial_t + \beta\partial_x, \quad \beta \geqslant 0,$$

$$Q = \partial_t + \sigma(x)u\partial_u, \quad \sigma \neq 0, \quad Q = \partial_x, \tag{3.2}$$

$$Q = \sigma(x)u\partial_u, \quad \sigma \neq 0, Q = \theta(t,x)\partial_u, \quad \theta \neq 0.$$

Proof: Change of variables (3.1) reduces operator (2.4) to become

$$\tilde{Q} = k(\lambda t + \lambda_1)\partial_{\overline{t}} + \epsilon k(\lambda x + \lambda_2)\partial_{\overline{x}} + [Y_t(\lambda t + \lambda_1) + (\lambda x + \lambda_2)(X'u + Y_x) + X(hu + r)]\partial_v. \tag{3.3}$$

If $\lambda \neq 0$ in (2.4), then setting $k_1 = \lambda^{-1}\lambda_1 k$, $k_2 = \epsilon\lambda^{-1}\lambda_2 k$, and taking as X, Y ($X \neq 0$) integrals of system of PDEs,

$$X'(\lambda x + \lambda_2) + Xh = 0,$$

$$Y_t(\lambda t + \lambda_1) + Y_x(\lambda x + \lambda_2) + Xr = 0,$$

we reduce (3.3) to the form

$$\tilde{Q} = \lambda(\overline{t}\partial_{\overline{t}} + \overline{x}\partial_{\overline{x}}).$$

Provided $\lambda = 0$ and $\lambda_1 \neq 0$, we similarly obtain

$$\tilde{Q} = \partial_{\overline{t}} + \beta\partial_{\overline{x}}, \quad \beta \geqslant 0, \quad Q = \partial_{\overline{t}} + \sigma(\overline{x})v\partial_v, \quad \sigma \neq 0.$$

Next, if $\lambda = \lambda_1 = 0$, $\lambda_2 \neq 0$ in (2.4), then setting $k = \epsilon\lambda_2^{-1}$, and taking as X, Y ($X \neq 0$) integrals of equations

$$\lambda_2 X' + hX = 0, \quad Y_x + rX = 0,$$

we reduce operator (3.3) to become $\tilde{Q} = \partial_{\overline{x}}$.

Finally, the case $\lambda=\lambda_1=\lambda_2=0$, gives rise to operators $\tilde{Q}=\sigma(\overline{x})v\partial_v$, $\tilde{Q}=\theta(\overline{t,x})\partial_v$.

Rewriting the above operators in the initial variables t, x completes the proof.

Theorem 2: *There are exactly five inequivalent equations of the form (2.8) that admit one-parameter transformation groups. Below we list these equations together with one-dimensional Lie algebras generating their invariance groups (note that we do not present the full form of invariant PDEs we just give the functions f and g),*

$$A_1^1=\langle t\partial_t+x\partial_x\rangle,\quad g=x^{-1}\tilde{g}(\psi,u),$$

$$f=x^{-2}\tilde{f}(\psi,u),\quad \psi=tx^{-1},\quad \tilde{g}_u\neq 0,$$

$$A_1^2=\langle \partial_t+\beta\partial_x\rangle,\quad g=\tilde{g}(\eta,u),\quad f=\tilde{f}(\eta,u),$$

$$\eta=x-\beta t,\quad \beta\geqslant 0,\quad \tilde{g}_u\neq 0,$$

$$A_1^3=\langle \partial_t+\sigma(x)u\partial_u\rangle,\quad g=-2\sigma'\sigma^{-1}\ln|u|+\tilde{g}(\rho,x),$$

$$f=(\sigma'\sigma^{-1})^2u\ln^2|u|-\sigma'\sigma^{-1}\tilde{g}(\rho,x)u\ln|u|-\sigma^{-1}\sigma''u\ln|u|+u\tilde{f}(\rho,x),$$

$$\rho=u\exp(-t\sigma),\quad \sigma\neq 0,$$

$$A_1^4=\langle \partial_x\rangle,\quad g=\tilde{g}(t,u),\quad f=\tilde{f}(t,u),\quad \tilde{g}_u\neq 0,$$

$$A_1^5=\langle \sigma(x)u\partial_u\rangle,\quad g=-2\sigma'\sigma^{-1}\ln|u|+\tilde{g}(t,x),\quad f=(\sigma'\sigma^{-1})^2u\ln^2|u|$$
$$-(\sigma^{-1}\sigma''+\sigma^{-1}\sigma'\tilde{g}(t,x))u\ln|u|+u\tilde{f}(t,x),\quad \sigma'\neq 0.$$

Proof: If Eq. (2.8) admits a one-parameter invariance group, then it is generated by operator of the form (2.4). According to Lemma 1, the latter is equivalent to one of the six operators (3.2). That is why, all we need to do is integrate six systems of determining equations corresponding to operators (2.6). For the first five operators solutions of determining equations are easily shown to have the form given in the statement of the theorem.

We consider in more detail the operator $Q=\theta(t,u)\partial_u$. Determining Eqs. (2.6) for this operator reduce to the form

$$\theta_{tt}-\theta_{xx}=\theta f_u+\theta_x g,\quad \theta g_u=0,$$

whence we get $g_u=0$. Consequently, the system of determining equations is incompatible and the corresponding invariant equation fails to exist.

Nonequivalence of the invariant equations follows from nonequivalence of the corresponding symmetry operators.

The theorem is proved.

Note that in the sequel we give the formulations of theorems omitting routine proofs. The detailed proofs of the most of the statements presented in this paper can be found in Ref. 35.

It is a common knowledge that there exist two inequivalent two-dimensional solvable Lie algebras[36–40]

$$A_{2.1}=\langle e_1,e_2\rangle,\quad [e_1,e_2]=0,$$

$$A_{2.2} = \langle e_1, e_2 \rangle, \quad [e_1, e_2] = e_2.$$

To construct all possible realizations of the above algebras we take as the first basis element one of the realizations of one-dimensional invariance algebras listed in Lemma 1. The second operator is looked for in the generic form (2.4).

Algebra $A_{2.1}$: Let operator e_1 be of the form $\partial_t + x\partial_x$ and operator e_2 read as (2.4). Then it follows from the relation $[e_1, e_2] = 0$ that $\lambda_1 = \lambda_2 = xh' = 0$, $tr_t + xr_x = 0$. Consequently, we can choose basis elements of the algebra in question in the form $\langle t\partial_t + x\partial_x, (mu + r(\psi))\partial_u \rangle$, where $m \in \mathbb{R}$, $\psi = tx^{-1}$. Provided $m = 0$, the operator e_2 becomes $r(\psi)\partial_u$. It is straightforward to verify that this realization does not satisfy the determining equations. Hence, $m \neq 0$. Making the change of variables

$$\overline{t} = t, \quad \overline{x} = x, \quad v = u + m^{-1} r(\psi)$$

reduces the basis operators in question to the form $\overline{t}\partial_{\overline{t}} + \overline{x}\partial_{\overline{x}}$, $mv\partial_v$. That is why we can restrict our considerations to the realization $\langle t\partial_t + x\partial_x, u\partial_u \rangle$.

The second determining equation from (2.6) takes the form $ug_u = 0$. Hence it follows that the realization under consideration does not satisfy the determining equations. Consequently, the realization A_1^1 cannot be extended to a realization of the two-dimensional algebra $A_{2.1}$.

Algebra $A_{2.2}$: If operator e_1 is of the form $t\partial_t + x\partial_x$, then it follows from $[e_1, e_2] = e_2$ that $\lambda = \lambda_1 = \lambda_2 = 0$, $xh' = h$, $tr_t + xr_x = r$.

Next, if e_2 reads as $t\partial_t + x\partial_x$, then we get from $[e_1, e_2] = e_2$ the erroneous equality $1 = 0$.

That is why, the only possible case is when $e_2 = (mxu + xr(\psi))\partial_u$, $m \neq 0$, $\psi = tx^{-1}$, which gives rise to the following realization of the algebra $A_{2.2}$: $\langle t\partial_t + x\partial_x, xu\partial_u \rangle$. This is indeed invariance algebra of an equation from the class (2.8) and the functions f and g read as $g = -2x^{-1} \ln|u| + x^{-1}\tilde{g}(\psi)$, $f = x^{-2}u \ln^2|u| - x^{-2}\tilde{g}(\psi)u \ln|u| + x^{-2}u\tilde{f}(\psi)$, $\psi = tx^{-1}$.

Analysis of the remaining realizations of one-dimensional Lie algebras yields 10 inequivalent $A_{2.1}$- and $A_{2.2}$-invariant equations (see the assertions below). What is more, the obtained (two-dimensional) algebras are maximal symmetry algebras of the corresponding equations.

Theorem 3: *There are, at most, four inequivalent* $A_{2.1}$ *-invariant nonlinear equations (2.8). Below we list the realizations of* $A_{2.1}$ *and the corresponding expressions for* f *and* g.

$$(1) \quad \langle \partial_t, \sigma(x)u\partial_u, \rangle, \quad g = -2\sigma'\sigma^{-1} \ln|u|,$$

$$f = (\sigma'\sigma^{-1})^2 u \ln^2|u| - \sigma^{-1}\sigma' u \ln|u| + u\tilde{f}(x), \quad \sigma' \neq 0,$$

$$(2) \quad \langle \partial_t, \partial_x \rangle, \quad g = \tilde{g}(u), \quad f = \tilde{f}(u), \quad \tilde{g}_u \neq 0,$$

$$(3) \quad \langle \partial_x, \partial_t + u\partial_u \rangle, \quad g = \tilde{g}(\omega), \quad f = \exp(t)\tilde{f}(\omega), \quad \omega = \exp(-t), \quad \tilde{g}_\omega \neq 0,$$

$$(4) \quad \left\langle \sigma(x)u\partial_u, \partial_t - \tfrac{1}{2}k\sigma(x)\psi(x)u\partial_u \right\rangle, \quad g = -2\sigma'\sigma^{-1} \ln|u| + kt + \tilde{g}(x),$$

$$f = (\sigma'\sigma^{-1})^2 u \ln^2|u| - \sigma^{-1}\sigma'' u \ln|u| - \sigma^{-1}\sigma'(kt + \tilde{g}(x))u \ln|u| + u\left[\tfrac{1}{2}k\sigma'\sigma^{-1}t + \tfrac{1}{4}k^2t^2 + \tfrac{1}{2}k\tilde{g}(x) + \tilde{f}(x)\right],$$

$$k \neq 0, \quad \sigma' \neq 0, \quad \psi = \int \sigma^{-1}\, dx.$$

Theorem 4: *There exist, at most, six inequivalent* $A_{2.2}$*-invariant nonlinear equations (2.8). Below we list the realizations of* $A_{2.1}$ *and the corresponding expressions for* f *and* g.

$$(1)\quad \langle t\partial_t + x\partial_x, k^{-1}|x|^k u\partial_u\rangle,\quad g = x^{-1}(-2k\ln|u| + \tilde{g}(\psi)),$$

$$f = x^{-2}u(-k^2\ln^2|u| + k\tilde{g}(\psi)\ln|u| + k(k-1)\ln|u| + \tilde{f}(\psi)),$$

$$k \neq 0,\quad \psi = tx^{-1},$$

$$(2)\quad \langle \partial_t + \beta\partial_x, \exp(\beta^{-1}x)u\partial_u\rangle,\quad g = -2\beta^{-1}\ln|u| + \tilde{g}(\eta),$$

$$f = \beta^{-2}u\ln^2|u| - (\beta^{-2} + \beta^{-1}\tilde{g}(\eta))u\ln|u| + u\tilde{f}(\eta),$$

$$\beta > 0,\quad \eta = x - \beta t,$$

$$(3)\quad \langle -t\partial_t - x\partial_x, \partial_t + \beta\partial_x\rangle,\quad g = \eta^{-1}\tilde{g}(u),\quad f = \eta^{-2}\tilde{f}(u),\quad \beta \geqslant 0,$$

$$\eta = x - \beta t,\quad \tilde{g}_u \neq 0,$$

$$(4)\quad \langle -t\partial_t - x\partial_x, \partial_t + mx^{-1}u\partial_u\rangle,\quad g = x^{-1}(2m\psi + \tilde{g}(\omega)),$$

$$f = x^{-1}[-2m\psi u - 2m\psi - 2 - \tilde{g}(\omega) + \exp(m\psi)\tilde{g}(\omega)],$$

$$m > 0,\quad \omega = u\exp(-m\psi),\quad \psi = tx^{-1},\quad \tilde{g}_\omega \neq 0,$$

$$(5)\quad \langle \partial_x, e^x u\partial_u\rangle,\quad g = -2\ln|u| + \tilde{g}(t),\quad f = u\ln^2|u| - u\ln|u|(1 + \tilde{g}(t)) + u\tilde{f}(t),$$

$$(6)\quad \langle -t\partial_t - x\partial_x, \partial_x\rangle,\quad g = t^{-1}\tilde{g}(u),\quad f = t^{-2}\tilde{f}(u),\quad \tilde{g}_u \neq 0.$$

B. Completing group classification of (2.8)

As the invariant equations obtained in the previous subsection contain arbitrary functions of, at most, one variable, we can now apply the standard Lie–Ovsyannikov routine to complete the group classification of (2.8). We give the computation details for the case of the first $A_{2.1}$-invariant equation, the remaining cases are handled in a similar way.

Setting $g = -2\sigma'\sigma^{-1}\ln|u|$, $f = (\sigma'\sigma^{-1})u\ln^2|u| - \sigma^{-1}\sigma'' u\ln|u| + u\tilde{f}(x)$, $\sigma = \sigma(x)$, $\sigma' \neq 0$ we rewrite the first determining equation to become

$$-2h' + 2\lambda\sigma'\sigma^{-1}\ln|u| = -2(\lambda x + \lambda_2)(\sigma'\sigma^{-1})'_x\ln|u| - 2h\sigma'\sigma^{-1} - 2r\sigma'\sigma^{-1}u^{-1}.$$

As $h = f(x)$, $\sigma = \sigma(x)$, $r = r(t,x)$, λ, $\lambda_2 \in \mathbb{R}$, the above relation is equivalent to the following ones:

$$h' = \sigma'\sigma^{-1}h,\quad r = 0,\quad \lambda\sigma'\sigma^{-1} = -(\lambda x + \lambda_2)(\sigma'\sigma^{-1})'.$$

If σ is an arbitrary function, then $\lambda = \lambda_2 = r = 0$, $h = C\sigma$, $C \in \mathbb{R}$ and we get $\langle \partial_t, \sigma(x)u\partial_u\rangle$ as the maximal symmetry algebra. Hence, extension of the symmetry algebra is only possible when the function $\psi = \sigma'\sigma^{-1}$ is a (nonvanishing identically) solution of the equation

$$(\alpha x + \beta)\psi' + \alpha\psi = 0,\quad \alpha, \beta \in R,\quad |\alpha| + |\beta| \neq 0.$$

If $\alpha \neq 0$, then at the expense of displacements by x we can get $\beta = 0$, so that $\psi = mx^{-1}$, $m \neq 0$. Integrating the remaining determining equations yields

$$g=-2mx^{-1}\ln|u|,\quad f=mx^{-2}[mu\ln^2|u|-(m-1)u\ln|u|+nu],\quad m\neq 0,\quad m,n\in\mathbb{R}.$$

The maximal invariance algebra of the obtained equation is the three-dimensional Lie algebra $\langle\partial_t,|x|^m u\partial_u,t\partial_t+x\partial_x\rangle$ isomorphic to $A_{3.7}$.

Next, if $\alpha=0$, then $\beta\neq 0$ and $\psi=m$, $m\neq 0$. If this is the case, we have

$$g=\ln|u|,\quad f=\tfrac{1}{4}u\ln^2|u|-\tfrac{1}{4}u\ln|u|+nu,\quad n\in\mathbb{R}.$$

The maximal invariance algebra of the above equation reads as

$$\left\langle\partial_t,\partial_x,\exp\left(-\tfrac{1}{2}x\right)u\partial_u\right\rangle.$$

It is isomorphic to $A_{3.2}$.

Similarly, we prove that the list of inequivalent equations of the form (2.8) admitting three-dimensional symmetry algebras is exhausted by the equations given below. Note that the presented algebras are maximal. This means, in particular, that maximal symmetry algebra of Eq. (2.8) is, at most, three dimensional.

$A_{3.2}$-invariant equations,

$$(1)\quad u_{tt}=u_{xx}+u_x\ln|u|+\tfrac{1}{4}u\ln^2|u|-\tfrac{1}{4}u\ln|u|+nu(n\in\mathbb{R}),\left\langle\partial_t,\partial_x,\exp\left(-\tfrac{1}{2}x\right)u\partial_u\right\rangle,$$

$$(2)\quad u_{tt}=u_{xx}+m[\ln|u|-t]u_x+(m^2/4)u[(\ln|u|-t)(\ln|u|-t-1)]+nu(m>0,n\in\mathbb{R}),$$
$$\left\langle\partial_x,\partial_t+u\partial_u,\exp\left(-\tfrac{1}{2}mx\right)u\partial_u\right\rangle.$$

$A_{3.4}$-invariant equations,

$$(1)\quad u_{tt}=u_{xx}+x^{-1}[2\ln|u|+mx^{-1}t+n]u_x+x^{-2}u\ln|u|+(mx^{-1}t+n-2)x^{-2}u\ln|u|+\tfrac{1}{4}m^2x^{-4}t^2u$$
$$+\tfrac{1}{2}m(n-3)x^{-3}tu+px^{-2}u(m\neq 0,n,p\in\mathbb{R}),\quad\langle t\partial_t+x\partial_x,x^{-1}u\partial_u,\partial_t-(m/2)x^{-1}\ln|x|u\partial_u\rangle.$$

$A_{3.5}$-invariant equations,

$$(1)\quad u_{tt}=u_{xx}+|u|^m u_x+n|u|^{1+2m}\quad(m\neq 0,n\in\mathbb{R}),\quad\langle\partial_t,\partial_x,t\partial_t+x\partial_x-m^{-1}u\partial_u\rangle,$$

$$(2)\quad u_{tt}=u_{xx}+e^u u_x+ne^{2u}\quad(n\in\mathbb{R}),\quad\langle\partial_t,\partial_x,t\partial_t+x\partial_x-\partial_u\rangle,$$

$$(3)\quad u_{tt}=u_{xx}-x^{-1}[2\ln|u|-mx^{-1}t-n]u_x+x^{-2}u\ln^2|u|-x^{-2}(mx^{-1}t+n)u\ln|u|+ux^{-2}[(m/4)x^{-2}t^2$$
$$+(m/2)(n-1)x^{-1}t+p](m,n,p\in\mathbb{R}),\quad\langle t\partial_t+x\partial_x,xu\partial_u,\partial_t+(m/4)x^{-1}u\partial_u\rangle.$$

$A_{3.7}$-invariant equations,

$$(1)\quad u_{tt}=u_{xx}-2mx^{-1}u_x\ln|u|+mx^{-2}[mu\ln^2|u|-(m-1)u\ln|u|+nu]$$
$$\times(m\neq 0,1;n\in\mathbb{R}),\quad\langle\partial_t,|x|^m u\partial_u,t\partial_t+x\partial_x\rangle,$$

$$(2)\quad u_{tt}=u_{xx}-x^{-1}[2k+\ln|u|-mx^{-1}t-n]u_x+k^2x^{-2}u\ln^2|u|-kx^{-2}[mtx^{-1}+k+n-1]u\ln|u|+\tfrac{1}{2}m(k$$
$$-2+n)tx^{-3}u+\tfrac{1}{4}m^2t^2x^{-4}u+px^{-2}u\quad(|k|\neq 0,1;m\neq 0,n,p\in\mathbb{R}),$$
$$\langle t\partial_t+x\partial_x,|x|^k u\partial_u,\partial_t+[m/2(1+k)]x^{-1}u\partial_u\rangle.$$

This completes the group classification of nonlinear equations (2.8).

IV. GROUP CLASSIFICATION OF Eq. (2.9)

Omitting calculation details we present below the determining equations for symmetry operators admitted by Eq. (2.9).

Assertion 2: The maximal invariance group of PDE (2.9) is generated by the infinitesimal operator,

$$Q = \tau(t)\partial_t + \xi(x)\partial_x + [h(t)u + r(t,x)]\partial_u, \tag{4.1}$$

where τ, ξ, h, r, f, g are smooth functions satisfying the conditions

$$\begin{gathered} r_{tx} + f[h - \tau_t - \xi_x] = gr_x + \tau f_t + \xi f_x + [hu + r]f_u, \\ h_t = \tau_t g + \tau g_t + \xi g_x. \end{gathered} \tag{4.2}$$

Assertion 3: The equivalence group $\mathcal{E}$ of (2.9) is formed by the following transformations of the space V :

$$(1) \quad \overline{t} = T(t), \quad \overline{x} = X(x), \quad v = U(t)u + Y(t,x), \quad t'X'U \neq 0,$$

$$(2) \quad \overline{t} = T(x), \quad \overline{x} = X(t), \quad v = \Psi(x)\Phi(t,x)u + Y(t,x), \quad t'X'\Psi \neq 0, \tag{4.3}$$

$$\Phi(t,x) = \exp\left(-\int g(t,x)\mathrm{d}t\right), g_x \neq 0.$$

As the direct verification shows, given arbitrary functions g and f, it follows from (4.2) that $\tau = h = \xi = r = 0$. So that in the generic case the maximal invariance group of (2.9) is the trivial group of identical transformations.

We begin classification of (2.9) by constructing equations that admit one-dimensional symmetry algebras. The following assertions hold.

Lemma 2: There exist transformations (4.3) reducing operator (4.1) to one of the seven canonical forms given below

$$\begin{gathered} Q = t\partial_t + x\partial_x, \quad Q = \partial_t, \quad Q = \partial_x + tu\partial_u, \\ Q = \partial_x + \epsilon u\partial_u, \quad \epsilon = 0,1, \quad Q = tu\partial_u, \\ Q = u\partial_u, \quad Q = r(t,x)\partial_u, \quad r \neq 0. \end{gathered} \tag{4.4}$$

Theorem 5: *There exist, at most, three inequivalent nonlinear equations (2.9) that admit one-dimensional invariance algebras. The form of functions f, g and the corresponding symmetry algebras are given below,*

$$A_1^1 = \langle t\partial_t + x\partial_x \rangle, \quad g = t^{-1}\tilde{g}(\omega), \quad f = t^{-2}f(u,\omega), \quad \omega = tx^{-1}, \quad \tilde{g}_\omega \neq 0, \quad f_{uu} \neq 0,$$

$$A_1^2 = \langle \partial_t \rangle, \quad g = \tilde{g}(x), \quad f = \tilde{f}(x,u), \quad \tilde{g}' \neq 0, \quad \tilde{f}_{uu} \neq 0,$$

$$A_1^3 = \langle \partial_x + tu\partial_u \rangle, \quad g = x + \tilde{g}(t), \quad f = e^{tx}\tilde{f}(t,\omega), \quad \omega = e^{-tx}u, \quad \tilde{f}_{\omega\omega} \neq 0.$$

We proceed now to analyzing Eqs. (2.9) admitting two-dimensional symmetry algebras.

Theorem 6: *There exist, at most, three inequivalent nonlinear equations (2.9) that admit two-dimensional symmetry algebras, all of them being $A_{2.2}$-invariant equations. The forms of functions f and g and the corresponding realizations of the Lie algebra $A_{2.2}$ read as*

$$A_{2.2}^1 = \langle t\partial_t + x\partial_x, t^2\partial_t + x^2\partial_x + mut\partial_u \rangle \quad (m \in \mathbb{R}),$$

$$g = [mt + (k-m)x]t^{-1}(t-x)^{-1}, \quad k \neq 0,$$

$$f = |t-x|^{m-2}|x|^{-m}\tilde{f}(\omega),$$

$$\omega = u|t-x|^{-m}|x|^{m}, \quad \tilde{f}_{\omega\omega} \neq 0,$$

$$A^2_{2.2} = \langle t\partial_t + x\partial_x, t^2\partial_t + mtu\partial_u \rangle \quad (m \in \mathbb{R}),$$

$$g = t^{-2}[kx + mt], \quad k \neq 0, \quad f = |t|^{m-2}|x|^{-m}\tilde{f}(\omega),$$

$$\omega = |t|^{-m}|x|^{m}u, \quad \tilde{f}_{\omega\omega} \neq 0,$$

$$A^3_{2.2} = \langle t\partial_t + x\partial_x, x^2\partial_x + tu\partial_u \rangle,$$

$$g = (tx)^{-1}(mx - t)(m \in \mathbb{R}), \quad f = x^{-2}\exp(-tx^{-1})\tilde{f}(\omega),$$

$$\omega = u\exp(tx^{-1}), \quad \tilde{f}_{\omega\omega} \neq 0.$$

Note that if the function $\tilde{f}$ is arbitrary, then the invariance algebras given in the statement of Theorem 6 are maximal.

It turns out that the above theorems provide complete group classification of the class of PDEs (2.9). Namely, the following assertion holds true.

Theorem 7: *A nonlinear equation (2.9) having nontrivial symmetry properties is equivalent to one of the equations listed in Theorems 5 and 6.*

V. GROUP CLASSIFICATION OF Eq. (2.10)

As earlier, we present the results of the first step of our group classification algorithm skipping derivation details.

Assertion 4: Invariance group of equation (2.10) is generated by infinitesimal operator

$$Q = \tau(t)\partial_t + \xi(x)\partial_x + (ku + r(t,x))\partial_u, \tag{5.1}$$

where k is a constant τ, ξ, r, f are functions satisfying the relation

$$r_{tx} + [k - \tau' - \xi']f = \tau f_t + \xi f_x + [ku + r]f_u. \tag{5.2}$$

Assertion 5: Equivalence group $\mathcal{E}$ of the class of equations (2.10) is formed by the following transformations:

$$\begin{aligned} &(1) \quad \bar{t} = T(t), \quad \bar{x} = X(x), \quad v = mu + Y(t,x), \\ &(2) \quad \bar{t} = T(x), \quad \bar{x} = X(t), \quad v = mu + Y(t,x), \quad T'X'm \neq 0. \end{aligned} \tag{5.3}$$

Note that given an arbitrary function f, it follows from (5.2) that $\tau=\xi=k=r=0$, i.e., the group admitted is trivial. To obtain equations with nontrivial symmetry we need to specify properly the function f. To this end we perform classification of equations under study admitting one-dimensional invariance algebras. The following assertions give exhaustive classification of those.

Lemma 3: There exist transformations from the group $\mathcal{E}$ (5.3) that reduce (5.1) to one of the four canonical forms,

$$Q = \partial_t + \partial_x + \epsilon u\partial_u \quad (\epsilon = 0,1),$$

TABLE I. Invariant equations (2.10).

Number	Function f	Symmetry operators	Invariance algebra type
1	$e^t\tilde{f}(\omega)$, $\omega=ue^{-t}$, $\tilde{f}_{\omega\omega}\neq 0$	$\partial_t+u\partial_u$, ∂_x	$A_{2.1}$
2	$e^{t+x}\tilde{f}(\omega)$, $\omega=ue^{-t-x}$, $\tilde{f}_{\omega\omega}\neq 0$	$\partial_t+u\partial_u$, $\partial_x+u\partial_u$	$A_{2.1}$
3	$(t-x)^{-3}\tilde{f}(\omega)$, $\omega=(t-x)u$, $\tilde{f}_{\omega\omega}\neq 0$	$-t\partial_t-x\partial_x+u\partial_u$, $\partial_t+\partial_x$	$A_{2.2}$
4	$x^{-1}\tilde{f}(\omega)$, $\omega=x^{-1}u$, $\tilde{f}_{\omega\omega}\neq 0$	$-t\partial_t-x\partial_x-u\partial_u$, ∂_t	$A_{2.2}$
5	$(t-x)^{-2}\tilde{f}(u)$, $\tilde{f}_{uu}\neq 0$	$\partial_t+\partial_x$, $t\partial_t+x\partial_x$, $t^2\partial_t+x^2\partial_x$	$\mathrm{sl}(2,R)$
6	$\exp(x^{-1}u)$	$-t\partial_t+x\partial_u$, ∂_t, $x\partial_x+u\partial_u$	$A_{2.2}\oplus A_1$
7	$\lambda\lvert x\rvert^{-m-2}\lvert u\rvert^{m+1}$, $\lambda\neq 0$, $m\neq 0$, $-$, $1-2$	∂_t, $t\partial_t-1/mu\partial_u$, $x\partial_x+m+1/mu\partial_u$	$A_{2.2}\oplus A_1$
8	$\tilde{f}(u)$, $\tilde{f}_{uu}\neq 0$	∂_t, ∂_x, $-t\partial_t-x\partial_x$	$A_{3.6}$
9	$\lambda\lvert u\rvert^{n+1}$, $\lambda\neq 0$, $n\neq 0$, -1	$t\partial_t-1/nu\partial_u$, $x\partial_x-1/nu\partial_u$, ∂_t, ∂_x	$A_{2.2}\oplus A_{2.2}$

$$Q=\partial_t+\epsilon u\partial_u \quad (\epsilon=0,1),$$

$$Q=u\partial_u, \quad Q=g(t,x)\partial_u \quad (g\neq 0).$$

Theorem 8: *There exist exactly two nonlinear equations of the form (2.10) admitting one-dimensional invariance algebras. The corresponding expressions for function f and invariance algebras are given below,*

$$A_1^1=\langle \partial_t+\partial_x+\epsilon u\partial_u\rangle \quad (\epsilon=0,1), \quad f=e^{\epsilon t}\tilde{f}(\theta,\omega), \quad \theta=t-x, \quad \omega=e^{-\epsilon t}u, \quad \tilde{f}_{\omega\omega}\neq 0,$$

$$A_1^2=\langle \partial_t+\epsilon u\partial_u\rangle \quad (\epsilon=0,1), \quad f=e^{\epsilon t}\tilde{f}(x,\omega), \quad \omega=e^{-\epsilon t}u, \quad \tilde{f}_{\omega\omega}\neq 0.$$

Our analysis of Eqs. (2.10) admitting higher dimensional invariance algebras yields the following assertion.

Theorem 9: *The Liouville equation $u_{tx}=\lambda e^u$, $\lambda\neq 0$, has the highest symmetry among equations (2.10). Its maximal invariance algebra is infinite-dimensional and is spanned by the following infinite set of basis operators:*

$$Q=h(t)\partial_t+g(x)\partial_x-(h'(t)+g'(x))\partial_u,$$

where h and g are arbitrary smooth functions. Next, there exist exactly nine inequivalent equations of the form (2.10), whose maximal invariance algebras have dimension higher that one. We give these equations and their invariance algebras in Table I.

Details of the proof can be found in Ref. 35.

VI. GROUP CLASSIFICATION OF Eq. (2.7)

The first step of the algorithm of group classification of (2.7),

$$u_{tt} = u_{xx} + F(t,x,u,u_x), \quad F_{u_x u_x} \neq 0,$$

has been partially performed in Sec. II. It follows from Theorem 1 that the invariance group of Eq. (2.7) is generated by infinitesimal operator (2.4). What is more, the real constants λ, λ_1, λ_2 and real-valued functions $h=h(x)$, $r=r(t,x)$, $F=F(t,x,u,u_x)$ obey the relation (2.5). The equivalence group of the class of equations (2.7) is formed by transformations (3.1).

With these facts in hand we can utilize results of group classification of Eq. (2.8) in order to classify Eq. (2.7). In particular, using Lemma 1 and Lemma 2 from Ref. 35 it is straightforward to verify that the following assertions hold true.

Theorem 10: *There are, at most, seven inequivalent classes of nonlinear equations (2.7) invariant under the one-dimensional Lie algebras.*

Below we give the full list of the invariant equations and the corresponding invariance algebras,

$$A_1^1 = \langle t\partial_t + x\partial_x \rangle, \quad F = t^{-2}G(\xi,u,\omega), \quad \xi = tx^{-1}, \quad \omega = xu_x,$$

$$A_1^2 = \langle \partial_t + k\partial_x \rangle \quad (k>0), \quad F = G(\eta,u,u_x), \quad \eta = x - kt,$$

$$A_1^3 = \langle \partial_x \rangle, \quad F = G(t,u,u_x),$$

$$A_1^4 = \langle \partial_t \rangle, \quad F = G(x,u,u_x),$$

$$A_1^5 = \langle \partial_t + f(x)u\partial_u \rangle \quad (f \neq 0),$$

$$F = -tf''u + t^2(f')^2u - 2tf'u_x + e^{tf}G(x,v,\omega),$$

$$v = e^{-tf}u, \quad \omega = u^{-1}u_x - f'f^{-1}\ln|u|,$$

$$A_1^6 = \langle f(x)u\partial_u \rangle \quad (f \neq 0), \quad F = -f^{-1}f''u\ln|u| - 2f^{-1}f'u_x\ln|u| + f^{-2}(f')^2u\ln^2|u| + uG(t,x,\omega),$$

$$\omega = u^{-1}u_x - f'f^{-1}\ln|u|,$$

$$A_1^7 = \langle f(t,x)\partial_u \rangle \quad (f \neq 0), \quad F = f^{-1}(f_{tt} - f_{xx})u + G(t,x,\omega),$$

$$\omega = u_x - f^{-1}f_x u.$$

Note that if the functions F and G are arbitrary, then the presented algebras are maximal (in Lie's sense) symmetry algebras of the respective equations.

Theorem 11: *An equation of the form (2.7) cannot admit Lie algebra which has a subalgebra having nontrivial Levi factor.*

With account of the above facts we conclude that nonlinear equations (2.7) admit a symmetry algebra of the dimension higher than one only if the latter is a solvable real Lie algebra. That is why, we turn to classifying equations (2.7) whose invariance algebras are two-dimensional solvable Lie algebras.

Below we present the list of invariant equations and the corresponding realizations of the two-dimensional invariance algebras.

(I) $A_{2.1}$-invariant equations,

$$A^1_{2.1} = \langle t\partial_t + x\partial_x, u\partial_u\rangle, \quad F = x^{-2}uG(\xi,\omega),$$

$$\xi = tx^{-1}, \quad \omega = u^{-1}xu_x,$$

$$A^2_{2.1} = \langle t\partial_t + x\partial_x, \sigma(\xi)\partial_u\rangle \quad (\sigma \neq 0, \xi = tx^{-1}),$$

$$F = x^{-2}[\sigma^{-1}((1-\xi^2)\sigma'' - 2\xi\sigma')u + G(\xi,\omega)],$$

$$\omega = \xi\sigma' u + \sigma x u_x,$$

$$A^3_{2.1} = \langle \partial_t + k\partial_x, u\partial_u\rangle \quad (k > 0), \quad F = uG(\eta,\omega),$$

$$\eta = x - kt, \quad \omega = u^{-1}u_x,$$

$$A^4_{2.1} = \langle \partial_t + k\partial_x, \varphi(\eta)\partial_u\rangle \quad (k > 0, \eta = x - kt, \varphi \neq 0),$$

$$F = (k^2-1)\varphi''\varphi^{-1}u + G(\eta,\omega), \quad \omega = \varphi u_x - \varphi' u,$$

$$A^5_{2.1} = \langle \partial_t + k\partial_x, \partial_x + u\partial_u\rangle \quad (k > 0),$$

$$F = e^{\eta}G(\omega,v), \quad \eta = x - kt, \quad \omega = ue^{-\eta}, \quad v = u^{-1}u_x,$$

$$A^6_{2.1} = \langle \partial_t, \partial_x\rangle, \quad F = G(u,u_x),$$

$$A^7_{2.1} = \langle \partial_x, u\partial_u\rangle, \quad F = uG(t,\omega), \quad \omega = u^{-1}u_x,$$

$$A^8_{2.1} = \langle \partial_x, \varphi(t)\partial_u\rangle \quad (\varphi \neq 0),$$

$$F = \varphi^{-1}\varphi'' u + G(t,u_x),$$

$$A^9_{2.1} = \langle \partial_t, \partial_u\rangle, \quad F = G(x,u_x),$$

$$A^{10}_{2.1} = \langle \partial_t, f(x)u\partial_u\rangle \quad (f \neq 0),$$

$$F = -u^{-1}u_x^2 + uG(x,\omega),$$

$$\omega = u^{-1}u_x - f' f^{-1}\ln|u|,$$

$$A^{11}_{2.1} = \langle \partial_t + f(x)u\partial_u, g(x)u\partial_u\rangle \quad (\delta = f^{-1}f' - g^{-1}g' \neq 0),$$

$$F = -g^{-1}g''u\ln|u| - 2g^{-1}g'u_x\ln|u| + g^{-2}(g')^2 u\ln^2|u| - 2f\delta t u_x + 2f\delta g' g^{-1}tu\ln|u| + f^2\delta^2 t^2 u + f(g^{-1}g'' - f^{-1}f'')tu + uG(x,\omega),$$

$$\omega = u^{-1}u_x - g'g^{-1}\ln|u| - tf\delta,$$

$$A^{12}_{2.1} = \langle \partial_t + f(x)u\partial_u, e^{tf}\partial_u\rangle \quad (f \neq 0),$$

$$F=[f^2-tf''+t^2(f')^2]u-2tf'u_x+e^{tf}G(x,\omega),$$

$$\omega=e^{-tf}(u_x-tf'u),$$

$$A_{2.1}^{13}=\langle f(x)u\partial_u,g(x)u\partial_u\rangle \quad (\delta=f'g-g'f\neq 0),$$

$$F=-u^{-1}u_x^2-\delta^{-1}\delta'u_x+\delta^{-1}[f''g'-g''f']u\ln|u|+uG(t,x),$$

$$A_{2.1}^{14}=\langle\varphi(t)\partial_u,\psi(t)\partial_u\rangle \quad (\varphi'\psi-\varphi\psi'\neq 0),$$

$$F=\varphi^{-1}\varphi''u+G(t,x,u_x), \quad \varphi''\psi-\varphi\psi''=0.$$

(II) $A_{2.2}$-invariant equations,

$$A_{2.2}^1=\langle t\partial_t+x\partial_x,xu\partial_u\rangle, \quad F=x^{-2}u\ln^2|u|-2x^{-1}u_x\ln|u|+t^{-2}uG(\xi,\omega), \quad \xi=tx^{-1},$$

$$\omega=xu^{-1}u_x-\ln|u|,$$

$$A_{2.2}^2=\langle t\partial_t+x\partial_x,t\varphi(\xi)\partial_u\rangle \quad (\varphi\neq 0,\xi=tx^{-1}),$$

$$F=t^{-2}(1-\xi^2)\varphi^{-1}\xi(2\varphi'+\xi\varphi'')u+t^{-2}G(\xi,\omega),$$

$$\omega=x\varphi u_x+\xi\varphi' u,$$

$$A_{2.2}^3=\langle\partial_t+k\partial_x,\exp(k^{-1}x)u\partial_u\rangle(k>0),$$

$$F=k^{-2}u\ln^2|u|-2k^{-1}u_x\ln|u|-k^{-2}u\ln|u|+uG(\eta,\omega), \quad \eta=x-kt, \quad \omega=u^{-1}u_x-k^{-1}\ln|u|,$$

$$A_{2.2}^4=\langle\partial_t+k\partial_x,e^t\varphi(\eta)\partial_u\rangle \quad (\eta=x-kt,k>0,\varphi\neq 0),$$

$$F=((k^2-1)\varphi''\varphi^{-1}-2k\varphi'\varphi^{-1}+1)u+G(\eta,\omega),$$

$$\omega=\varphi u_x-\varphi' u, \quad \varphi'=\frac{\mathrm{d}\varphi}{\mathrm{d}\eta},$$

$$A_{2.2}^5=\langle -t\partial_t-x\partial_x,\partial_t+k\partial_x\rangle \quad (k>0),$$

$$F=\eta^{-2}G(u,\omega), \quad \eta=x-kt, \quad \omega=u_x\eta,$$

$$A_{2.2}^6=\langle -t\partial_t-x\partial_x+mu\partial_u,\partial_t+k\partial_x\rangle \quad (k>0,m\neq 0),$$

$$F=|\eta|^{-2-m}G(v,\omega), \quad \eta=x-kt,$$

$$\omega=u|\eta|^m, \quad v=u_x|\eta|^{m+1},$$

$$A_{2.2}^7=\langle\partial_x,e^xu\partial_u\rangle, \quad F=u\ln^2|u|-u\ln|u|-2u_x\ln|u|+uG(t,\omega), \quad \omega=u^{-1}u_x-\ln|u|,$$

$$A^{8}_{2.2}=\langle\partial_x,e^x\varphi(t)\partial_u\rangle\quad(\varphi\neq 0),$$

$$F=(\varphi^{-1}\varphi''-1)u+G(t,\omega),\quad \omega=u_x-u,$$

$$A^{9}_{2.2}=\langle -t\partial_t-x\partial_x,\partial_x\rangle,\quad F=t^{-2}G(u,tu_x),$$

$$A^{10}_{2.2}=\langle -t\partial_t-x\partial_x+ku\partial_u,\partial_x\rangle\quad(k\neq 0),$$

$$F=|t|^{-2-k}G(v,\omega),\quad v=|t|^{k}u,\quad \omega=|t|^{k+1}u_x,$$

$$A^{11}_{2.2}=\langle\partial_t,e^t\partial_u\rangle,\quad F=u+G(x,u_x),$$

$$A^{12}_{2.2}=\langle -t\partial_t-x\partial_x,\partial_t\rangle,\quad F=x^{-2}G(u,\omega),\quad \omega=xu_x,$$

$$A^{13}_{2.2}=\langle\partial_t+f(x)u\partial_u,e^{(1+f)t}\partial_u\rangle\quad(f\neq 0),$$

$$F=-(tf''-t^2(f')^2-(1+f^2))u-2tf'u_x+e^{tf}G(x,\omega),\quad \omega=e^{-tf}(u_x-f'(t+f^{-1})u),$$

$$A^{14}_{2.2}=\langle -t\partial_t-x\partial_x,\partial_t+kx^{-1}u\partial_u\rangle\quad(k>0),$$

$$F=-2ktx^{-3}u+k^2t^2x^{-4}u+2ktx^{-2}u_x+x^{-2}\exp(ktx^{-1})G(v,\omega),\quad v=\exp(-kx^{-1}t)u,$$

$$\omega=xu^{-1}u_x+\ln|u|,$$

$$A^{15}_{2.2}=\langle k(t\partial_t+x\partial_x),|x|^{k^{-1}}u\partial_u\rangle\quad(k\neq 0,1),$$

$$F=-k^{-2}(1-k)x^{-2}u\ln|u|-2k^{-1}x^{-1}u_x\ln|u|+k^{-2}x^{-2}u\ln^2|u|+x^{-2}uG(v,\omega),$$

$$v=tx^{-1},\quad \omega=xu^{-1}u_x-k^{-1}\ln|u|,$$

$$A^{16}_{2.2}=\langle k(t\partial_t+x\partial_x),|t|^{k^{-1}}\varphi(\xi)\partial_u\rangle\quad(k\neq 0,1,\varphi\neq 0,\xi=tx^{-1}),\quad F=[k^{-1}(k^{-1}-1)+2\xi(k^{-1}-\xi^2)\varphi^{-1}\varphi'+\xi^2(1-\xi)^2\varphi^{-1}\varphi'']t^{-2}u+t^{-2}G(\xi,\omega),$$

$$\omega=x\varphi u_x+\xi\varphi' u.$$

In the above formulas G stands for an arbitrary smooth function. As customary, the prime denotes the derivative of a function of one variable.

A. Group classification of the equation $u_{tt}=u_{xx}-u^{-1}u_x^2+A(x)u_x+B(x)u\ln|u|+uD(t,x)$

Before analyzing Eqs. (2.7) admitting algebras of the dimension higher than two we perform group classification of the equation

$$u_{tt}=u_{xx}-u^{-1}u_x^2+A(x)u_x+B(x)u\ln|u|+uD(t,x).\tag{6.1}$$

Here $A(x),B(x),D(t,x)$ are arbitrary smooth functions. Note that the above class of PDEs contains $A^{13}_{2.1}$-invariant equation. Importantly, class (6.1) contains a major part of equations of the form (2.7), whose maximal symmetry algebras have dimension three or four. This fact is used to simplify group classification of Eqs. (2.7).

The complete account of symmetry properties of PDE (6.1) is given in the following assertions.

Lemma 4: If A, B, and D are arbitrary, then the maximal invariance algebra of PDE (6.1) is the two-dimensional Lie algebra equivalent to $A_{2.1}^{13}$ *and (6.1) reduces to* $A_{2.1}^{13}$*-invariant equation. Next, if the maximal symmetry algebra of an equation of the form (6.1) is three-dimensional (we denote it as* A_3*), then this equation is equivalent to one of the following ones*:

$$\text{(I) } A_3 \sim A_{3.1}, \quad A_3 = \langle \partial_t, f(x)u\partial_u, \varphi(x)u\partial_u \rangle,$$

$$A = -\sigma^{-1}\sigma', \quad B = \sigma^{-1}\rho, \quad D = 0, \quad \sigma = f'\varphi - f\varphi' \neq 0,$$

$$\rho = \varphi' f'' - \varphi'' f',$$

$$\text{(II) } A_3 \sim A_{3.1}, \quad A_3 = \langle f(x)u\partial_u, \varphi(x)u\partial_u, \partial_t + \psi(x)u\partial_u \rangle,$$

$$A = -\sigma^{-1}\sigma', \quad B = \sigma^{-1}\rho,$$

$$D = t\sigma^{-1}[\sigma'\psi' - \psi\rho - \sigma\psi'],$$

$$\sigma = f'\varphi - \varphi' f \neq 0, \quad \rho = f''\varphi' - \varphi'' f',$$

$$f'\psi - f\psi' \neq 0, \quad \varphi'\psi - \varphi\psi' \neq 0,$$

$$\text{(III) } D = x^{-2}G(\xi), \quad \xi = tx^{-1}, G \neq 0,$$

$$\text{(1) } A_3 \sim A_{3.2}, \; A_3 = \langle t\partial_t + x\partial_x, u\partial_u, |x|^{1-n}u\partial_u \rangle,$$

$$A = nx^{-1} \quad (n \neq 1), \quad B = 0,$$

$$\text{(2) } A_3 \sim A_{3.3}, \quad A_3 = \langle t\partial_t + x\partial_x, u\partial_u, u\ln|x|\partial_u \rangle,$$
$$A = x^{-1}, \quad B = 0,$$

$$\text{(3) } A_3 \sim A_{3.4}, \quad A_3 = \langle t\partial_t + x\partial_x, \sqrt{|x|}u\partial_u, \sqrt{|x|}\ln|x|u\partial_u \rangle,$$

$$A = 0, \quad B = \tfrac{1}{4}x^{-2},$$

$$\text{(4) } A_3 \sim A_{3.9}, \quad A_3 = \left\langle t\partial_t + x\partial_x, \sqrt{|x|}\cos\left(\tfrac{1}{2}\beta\ln|x|\right)u\partial_u, \sqrt{|x|}\sin\left(\tfrac{1}{2}\beta\ln|x|\right)u\partial_u \right\rangle,$$
$$A = 0, \quad B = mx^{-2},$$

$$m > \tfrac{1}{4}, \quad \beta = \sqrt{4m-1},$$

$$\text{(5) } A_3 \sim A_{3.7}, \quad A_3 = \langle t\partial_t + x\partial_x, (\sqrt{|x|})^{1+\beta}u\partial_u, (\sqrt{|x|})^{1-\beta}u\partial_u \rangle,$$

$$A = 0, \quad B = mx^{-2}, \quad m < \tfrac{1}{4}, \quad m \neq 0, \quad \beta = \sqrt{1-4m},$$

(6) $A_3 \sim A_{3.8}$, $A_3 = \langle t\partial_t + x\partial_x, \cos(\sqrt{m}\ln|x|)u\partial_u, \sin(\sqrt{m}\ln|x|)u\partial_u\rangle$,
$A = x^{-1}$, $B = mx^{-2}$, $m > 0$,

(7) $A_3 \sim A_{3.6}$, $A_3 = \langle t\partial_t + x\partial_x, |x|^{\sqrt{|m|}}u\partial_u, |x|^{-\sqrt{|m|}}u\partial_u\rangle$,

$A = x^{-1}$, $B = mx^{-2}$, $m < 0$,

(8) $A_3 \sim A_{3.4}$, $A_3 = \langle t\partial_t + x\partial_x, (\sqrt{|x|})^{1-n}u\partial_u, (\sqrt{|x|})^{1-n} \times \ln|x|u\partial_u\rangle$,
$A = nx^{-1}$ $(n \neq 0,1)$, $B = \frac{1}{4}(n-1)^2x^{-2}$,

(9) $A_3 \sim A_{3.9}$, $A_3 = \left\langle t\partial_t + x\partial_x, (\sqrt{|x|})^{1-n}\cos\left(\frac{1}{2}\beta\ln|x|\right)u\partial_u, (\sqrt{|x|})^{1-n}\sin\left(\frac{1}{2}\beta\ln|x|\right)u\partial_u\right\rangle$,
$A = nx^{-1}$ $(n \neq 0,1)$,

$B = mx^{-2}$ $\left(m > \frac{1}{4}(n-1)^2\right)$, $\beta = \sqrt{4m-(n-1)^2}$,

(10) $A_3 \sim A_{3.7}$, $A_3 = \langle t\partial_t + x\partial_x, (\sqrt{|x|})^{1-\beta-n}u\partial_u, (\sqrt{|x|})^{1-n+\beta} \times u\partial_u\rangle$,
$A = nx^{-1}$ $(n \neq 0,1)$, $B = mx^{-2}$

$\left(m < \frac{1}{4}(n-1)^2, m \neq 0\right)$, $\beta = \sqrt{(n-1)^2-4m}$.

(IV) $D = G(t)$,

(1) $A_3 \sim A_{3.3}$, $A_3 = \langle \partial_x, u\partial_u, xu\partial_u\rangle$,

$$(7)\ A_3\sim A_{3.9},\quad A_3=\left\langle \partial_t+k\partial_x, \exp\left(\tfrac{1}{2}x\right)\cos\left(\tfrac{1}{2}\beta x\right)u\partial_u, \exp\left(\tfrac{1}{2}x\right)\sin\left(\tfrac{1}{2}\beta x\right)u\partial_u\right\rangle,$$

$$A=-1,\quad B=m\quad \left(m>\tfrac{1}{4}\right),\quad \beta=\sqrt{4m-1}.$$

Theorem 12: *Equation* $u_{tt}=u_{xx}-u^{-1}u_x^2$ *has the widest symmetry group amongst equations of the form (6.1). Its maximal invariance algebra is the five-dimensional Lie algebra,*

$$A_5^1=\langle \partial_t, \partial_x, t\partial_t+x\partial_x, xu\partial_u, u\partial_u\rangle.$$

There are no equations of the form (6.1) which are inequivalent to the above equation and admit invariance algebra of the dimension higher than four. Inequivalent equations (6.1) admitting four-dimensional algebras are listed below together with their symmetry algebras.

$$(\mathrm{I})\ D=0,$$

$$(1)\ A_4 \sim A_{3.6} \oplus A_1, \quad A_4 = \langle \partial_t, \partial_x, u\,\mathrm{ch}(\beta x)\partial_u, u\,\sinh(\beta x)\partial_u \rangle,$$

Proof can be found in Ref. 35.

B. Nonlinear equations (2.7) invariant under three-dimensional Lie algebras

Equations of the form (2.7) cannot be invariant under the algebra which is isomorphic to a Lie algebra with a nontrivial Levi ideal.[35] That is why, to complete the second step of our classification algorithm it suffices to consider three-dimensional solvable real Lie algebras. We begin by considering two decomposable three-dimensional solvable Lie algebras.

Note that while classifying invariant equations (2.7) we skip those belonging to the class (6.1), since the latter has already been analyzed.

1. Invariance under decomposable Lie algebras

As $A_{3.1}=3A_1=A_{2.1}\oplus A_1$, $A_{3.2}=A_{2.2}\oplus A_1$, to construct all realizations of $A_{3.1}$ it suffices to compute all possible extensions of the (already known) realizations of the algebras $A_{2.1}=\langle e_1, e_2\rangle$ and $A_{2.2}=\langle e_1, e_2\rangle$. To this end we need to supplement the latter by a basis operator e_3 of the form (2.4) in order to satisfy the commutation relations

$$[e_1, e_3] = [e_2, e_3] = 0. \tag{6.2}$$

What is more, to simplify the form of e_3 we may use those transformations from $\mathcal{E}$ that do not alter the remaining basis operators of the corresponding two-dimensional Lie algebras.

We skip the full calculation details and give a couple of examples illustrating the main calculation steps needed to extend $A_{2.1}$ to a realization of $A_{3.1}$.

Consider the realization $A^1_{2.1}$. Upon checking commutation relations (6.2), where e_3 is of form (2.4), we get

$$\lambda_1 = \lambda_2 = r(t,x) = 0, \quad h = k = \text{const}.$$

Consequently, e_3 is the linear combination of e_1, e_2, namely, $e_3=\lambda e_1+ke_2$, which is impossible by the assumption that the algebra under study is three dimensional. Hence we conclude that the above realization of $A^1_{2.1}$ cannot be extended to a realization of the algebra $A_{3.1}$.

Turn now to the realization $A^2_{2.1}$. Checking commutation relations (6.2), where e_3 is of form (2.4) yields the following realization of $A_{3.1}$:

$$\langle t\partial_t + x\partial_x, \sigma(\xi)\partial_u, \gamma(\xi)\partial_u \rangle, \quad \xi = tx^{-1},$$

where $\gamma'\sigma - \gamma\sigma' \neq 0$ However, the corresponding invariant equation (2.7) is linear.

Finally, consider the realization $A^3_{2.1}$. Inserting its basis operators and the operator e_3 of the form (2.4) into (6.2) and solving the obtained equations gives the following realization of $A_{3.1}$:

$$\langle \partial_t, \partial_x, u\partial_u \rangle.$$

Inserting the obtained coefficients for e_3 into the classifying equation (2.5) we get invariant equation

$$u_{tt} = u_{xx} + uG(\omega), \quad \omega = u^{-1}u_x,$$

where (to ensure nonlinearity) we need to have $G_{\omega\omega} \neq 0$.

Similar analysis of the realizations $A^i_{2.1}$ $(i=4,5,\ldots,12,14)$ yields three new invariant equations. For two of thus obtained $A_{3.1}$-invariant equations the corresponding three-dimensional algebras are maximal. The other two may admit four-dimensional invariance algebras provided arbitrary elements are properly specified.

Handling in a similar way the extensions of $A_{2.2}$ up to realizations of $A_{3.2}$ gives 10 inequivalent nonlinear equations whose maximal invariance algebras are realizations of the three-dimensional algebra $A_{3.2}$ and four inequivalent equations (2.7) admitting four-dimensional symmetry algebras.

We perform analysis of equations admitting four-dimensional algebras in the next section. Here we present the complete list of nonlinear equations (2.7) whose maximal symmetry algebras are realizations of three-dimensional Lie algebras $A_{3.1}$ and $A_{3.2}$.

$A_{3.1}$-invariant equations,

$$A^1_{3.1}=\langle \partial_t, \partial_x, u\partial_u\rangle,$$

$$F=uG(\omega), \quad \omega=u^{-1}u_x,$$

$$A^2_{3.1}=\langle \partial_x, \varphi(t)\partial_u, \psi(t)\partial_u\rangle,$$

$$\sigma=\psi'\varphi-\psi\varphi'\neq 0, \quad \sigma'=0,$$

$$F=\varphi^{-1}\varphi'' u+G(t,u_x).$$

$A_{3.2}$-invariant equations,

$$A^1_{3.2}=\langle \partial_t, \partial_x, e^x u\partial_u\rangle,$$

$$F=-u^{-1}u_x^2-u\ln|u|+uG(\omega),$$

$$\omega=u^{-1}u_x-\ln|u|,$$

$$A^2_{3.2}=\langle -t\partial_t-x\partial_x, \partial_t+k\partial_x, u\partial_u\rangle \quad (k\geqslant 0),$$

$$F=u\eta^{-2}G(\omega), \quad \eta=x-kt,$$

$$\omega=\eta u^{-1}u_x,$$

$$A^3_{3.2}=\langle -t\partial_t-x\partial_x+mu\partial_u, \partial_t+k\partial_x, |\eta|^{-m}\partial_u\rangle$$

$$(\eta=x-kt,\ k=m=0 \text{ or } k>0,\ m\in\mathbb{R}),$$

$$F=m(k^2-1)(m+1)\eta^{-2}u+|\eta|^{-2-m}G(\omega),$$

$$\omega=|\eta|^m(mu+\eta u_x),$$

$$A^4_{3.2}=\langle \partial_x, e^x u\partial_u, \partial_t+mu\partial_u\rangle \quad (m>0),$$

$$F=-u^{-1}u_x^2-u_x+uG(\omega),$$

$$\omega = u^{-1}u_x - \ln|u| + mt,$$

$$A^5_{3.2} = \langle -t\partial_t - x\partial_x, \partial_x, u\partial_u \rangle,$$

$$F = ut^{-2}G(\omega), \quad \omega = tu^{-1}u_x,$$

$$A^6_{3.2} = \langle -t\partial_t - x\partial_x, \partial_t + kx^{-1}u\partial_u, u\partial_u \rangle \quad (k > 0),$$

$$F = 2ktx^{-2}u_x - 2ktx^{-3}u + k^2t^2x^{-4}u + x^{-2}uG(\omega),$$

$$\omega = xu^{-1}u_x + ktx^{-1},$$

$$A^7_{3.2} = \langle -t\partial_t - x\partial_x, \partial_t + kx^{-1}u\partial_u, \exp(ktx^{-1})\partial_u \rangle \quad (k > 0),$$

$$F = 2ktx^{-2}u_x + (k^2t^2x^{-4} - 2ktx^{-3} + k^2x^{-2})u + x^{-2}\exp(ktx^{-1})G(\omega), \quad \omega = \exp(-ktx^{-1})(xu_x + ktx^{-1}u),$$

$$A^8_{3.2} = \left\langle \frac{1}{2k}(\partial_t + k\partial_x), e^{x+kt}\partial_u, e^{\eta}\partial_u \right\rangle \quad (k > 0,\ \eta = x - kt),$$

$$F = (k^2 - 1)u + G(\eta, \omega), \quad \omega = u_x - u,$$

$$A^9_{3.2} = \langle \partial_t + f(x)u\partial_u, e^{(1+f(x))t}\partial_u, f(x)e^{f(x)t}\partial_u \rangle,$$

$$F = -(tf'' - t^2(f')^2 - (1 + f)^2)u - 2tf'u_x + e^{tf}G(x, \omega),$$

$$\omega = e^{-tf}(u_x - f'(t + f^{-1})u), \quad f'' + 2f^2 + f = 0, \quad f \neq 0,$$

$$A^{10}_{3.2} = \langle k(t\partial_t + x\partial_x), |t|^{k^{-1}}|\xi|^{(k-1)/2k}\partial_u, |\xi|^{(k-1)/2k}\partial_u \rangle \quad (k \neq 0; 1),$$

$$F = \left[\frac{1-k}{k}\xi^2 + \frac{1-k^2}{4k^2}(1 - \xi^2) \right] t^{-2}u + t^{-2}G(\xi, \omega),$$

$$\omega = |\xi|^{(k-1)/2k}\left[xu_x + \frac{k-1}{2k}u \right], \quad \xi = tx^{-1}.$$

2. Invariance under nondecomposable three-dimensional solvable Lie algebras

There exist seven nondecomposable three-dimensional solvable Lie algebras over the field of real numbers. All those algebras contain a subalgebra which is the two-dimensional Abelian ideal. Consequently, we can use the results of classification of $A_{2.1}$-invariant equations in order to describe equations admitting nondecomposable three-dimensional solvable real Lie algebras. We remind that equations of the form (6.1) has already been analyzed and therefore are not considered in the sequel.

Note that there are nonlinear PDEs of the considered form that admits four-dimensional invariance algebras. As four-dimensional algebras will be considered separately in the next section, we give below only those nonlinear invariant equations whose maximal symmetry algebras are three-dimensional nondecomposable solvable real Lie algebras.

$A_{3.3}$-invariant equations,

$$A^1_{3.3} = \langle u\partial_u, \partial_t + k\partial_x, m\partial_t + k^{-1}xu\partial_u \rangle \quad (k > 0, m \neq 0),$$

$$F = -u^{-1}u_x^2 + uG(\omega), \quad \omega = x - kt + mk^2u^{-1}u_x,$$

$$A^2_{3.3} = \langle u\partial_u, \partial_x, m\partial_t + xu\partial_u \rangle \quad (m > 0),$$

$$F = -u^{-1}u_x^2 + uG(\omega), \quad \omega = t - mu^{-1}u_x,$$

$$A^3_{3.3} = \left\langle |t|^{\frac{1}{2}}\partial_u, -|t|^{\frac{1}{2}} \ln|t|\partial_u, t\partial_t + x\partial_x + \tfrac{1}{2}u\partial_u \right\rangle,$$

$$F = -\tfrac{1}{4}t^{-2}u + u_x^3 G(\xi, \omega), \quad \xi = tx^{-1}, \quad \omega = xu_x^2,$$

$$A^4_{3.3} = \langle \partial_u, -t\partial_u, \partial_t + k\partial_x \rangle \quad (k \geqslant 0),$$

$$F = G(\eta, u_x), \quad \eta = x - kt.$$

$A_{3.4}$-invariant equations,

$$A^1_{3.4} = \langle |\eta|^{m-1}\partial_u, \partial_t + k\partial_x, t\partial_t + x\partial_x + (mu + t|\eta|^{m-1})\partial_u \rangle$$

$$(\eta = x - kt,\ k > 0,\ m \neq 1),$$

$$F = (k^2 - 1)(m - 1)(m - 2)\eta^{-2}u - 2k(m - 1)\eta^{m-2} \ln|\eta| + |\eta|^{m-2}G(\omega),$$
$$\omega = [\eta u_x - (m - 1)u]|\eta|^{-m},$$

$$A^2_{3.4} = \langle \partial_u, -t\partial_u, \partial_t + k\partial_x + u\partial_u \rangle \quad (k \geqslant 0),$$

$$F = e^t G(\eta, \omega), \quad \eta = x - kt, \quad \omega = e^{-t}u_x,$$

$$A^3_{3.4} = \left\langle |t|^{\frac{1}{2}}\partial_u, -|t|^{\frac{1}{2}} \ln|t|\partial_u, t\partial_t + x\partial_x + \tfrac{3}{2}u\partial_u \right\rangle,$$

$$F = -\tfrac{1}{4}t^{-2}u + u_x^{-1}G(\xi, \omega), \quad \xi = tx^{-1}, \quad \omega = x^{-1}u_x^2,$$

$$A^4_{3.4} = \langle kx^{-1}u\partial_u, \partial_t - kx^{-1} \ln|x|u\partial_u, t\partial_t + x\partial_x \rangle \quad (k > 0),$$

$$F = -3ktx^{-3}u - 2x^{-2}u \ln|u| - u^{-1}u_x^2 + x^{-2}uG(\omega),$$

$$\omega = xu^{-1}u_x + \ln|u| + ktx^{-1},$$

$$A^5_{3.4} = \langle \exp(ktx^{-1})\partial_u, \partial_t + kx^{-1}u\partial_u, t\partial_t + x\partial_x + (u + t\exp(ktx^{-1}))\partial_u \rangle \quad (k > 0),$$

$$F = k^2x^{-4}u(t^2 + x^2) + 2x^{-1}(ktx^{-1} + 1)u_x + 2k\exp(ktx^{-1})x^{-1} \ln|x| + x^{-1}\exp(ktx^{-1})G(\omega),$$

$$\omega = \exp(-ktx^{-1})(u_x + ktx^{-2}u).$$

$A_{3.5}$-invariant equations,

$$A^1_{3.5} = \langle |\eta|^{m-1}\partial_u, \partial_t + k\partial_x, t\partial_t + x\partial_x + mu\partial_u\rangle \quad (k > 0,\ m \neq 1),$$

$$F = (k^2 - 1)(m - 1)(m - 2)\,\eta^{-2}u + |\eta|^{m-2}G(\omega),$$

$$\omega = |\eta|^{-m}[\eta u_x - (m - 1)u], \quad \eta = x - kt,$$

$$A^2_{3.5} = \langle \partial_t, \partial_x, t\partial_t + x\partial_x\rangle,$$

$$F = u_x^2 G(u),$$

$$A^3_{3.5} = \langle \partial_t, \partial_x, t\partial_t + x\partial_x + mu\partial_u\rangle \quad (m \neq 0),$$

$$F = |u|^{1-(2/m)}G(\omega), \quad \omega = |u_x|^m |u|^{1-m},$$

$$A^4_{3.5} = \langle \partial_t, \partial_x, t\partial_t + x\partial_x + \partial_u\rangle,$$

$$F = e^{-2u}G(\omega), \quad \omega = e^u u_x,$$

$$A^5_{3.5} = \langle \partial_t, x^{-1}u\partial_u, t\partial_t + x\partial_x\rangle,$$

$$F = -u^{-1}u_x^2 - 2x^{-2}u\ln|u| + x^{-2}uG(\omega),$$

$$\omega = xu^{-1}u_x + \ln|u|,$$

$$A^6_{3.5} = \langle \partial_t + kx^{-1}u\partial_u, \exp(ktx^{-1})\partial_u, t\partial_t + x\partial_x + u\partial_u\rangle \quad (k > 0),$$

$$F = kx^{-4}u[kt^2 - 2tx + kx^2] + 2ktx^{-2}u_x + x^{-1}\exp(ktx^{-1})G(\omega),$$

$$\omega = \exp(-ktx^{-1})(u_x + ktx^{-2}u),$$

$$A^7_{3.5} = \langle \varphi(t)\partial_u, \psi(t)\partial_u, \partial_x + u\partial_u\rangle \quad (\varphi'\psi - \varphi\psi' \neq 0),$$

$$F = \varphi^{-1}\varphi'' u + u_x G(t, \omega),$$

$$\omega = e^{-x}u_x, \quad \varphi''\psi - \varphi\psi'' = 0.$$

$A_{3.6}$-invariant equations,

$$A^1_{3.6} = \langle \partial_t + k\partial_x, |\eta|^{m+1}\partial_u, t\partial_t + x\partial_x + mu\partial_u\rangle \quad (k > 0,\ m \neq -1),$$

$$F = m(k^2 - 1)(m + 1)\,\eta^{-2}u + |\eta|^{m-2}G(\omega),$$

$$\omega = |\eta|^{1-m}[u_x - \eta^{-1}(m + 1)u], \quad \eta = x - kt,$$

$$A^2_{3.6} = \langle \partial_t + mx^{-1}u\partial_u, xu\partial_u, t\partial_t + x\partial_x\rangle \quad (m \geqslant 0),$$

$$F = -u^{-1}u_x^2 - 2mtx^{-3}u + x^{-2}uG(\omega),$$

$$\omega = xu^{-1}u_x - \ln|u| + 2mtx^{-1},$$

$$A_{3.6}^3 = \langle \partial_t + kx^{-1}u\partial_u, \exp(ktx^{-1})\partial_u, t\partial_t + x\partial_x - u\partial_u \rangle \quad (k > 0),$$

$$F = x^{-4}[k^2x^2 - 2ktx + k^2t^2]u + 2ktx^{-2}u_x + x^{-3}\exp(ktx^{-1})G(\omega),$$

$$\omega = \exp(-ktx^{-1})(x^2u_x + ktu),$$

$$A_{3.6}^4 = \langle e^{-t}\partial_u, e^t\partial_u, \partial_t + k\partial_x \rangle \quad (k \geqslant 0),$$

$$F = u + G(\eta, u_x), \quad \eta = x - kt,$$

$$A_{3.6}^5 = \left\langle |t|^{-\frac{1}{2}}\partial_u, |t|^{\frac{3}{2}}\partial_u, t\partial_t + x\partial_x + \tfrac{1}{2}u\partial_u \right\rangle,$$

$$F = \tfrac{3}{4}t^{-2}u + |t|^{-3/2}G(\xi, \omega), \quad \xi = tx^{-1}, \quad \omega = x^{-1}u_x^2.$$

$A_{3.7}$-invariant equations,

$$A_{3.7}^1 = \langle \partial_t + k\partial_x, |\eta|^{m-q}\partial_u, t\partial_t + x\partial_x + mu\partial_u \rangle$$

$$(k > 0,\ m \neq q,\ 0 < |q| < 1),$$

$$F = (k^2 - 1)(m - q)(m - q - 1)\eta^{-2}u + |\eta|^{m-2}G(\omega),$$

$$\omega = |\eta|^{1-m}[u_x - (m - q)\eta^{-1}u], \quad \eta = x - kt,$$

$$A_{3.7}^2 = \langle \partial_t + kx^{-1}u\partial_u, \exp(ktx^{-1})\partial_u, t\partial_t + x\partial_x + qu\partial_u \rangle$$

$$(k > 0, 0 < |q| < 1),$$

$$F = [k^2x^{-2} + k^2x^{-4}t^2 - 2ktx^{-3}]u + 2ktx^{-2}u_x + |x|^{q-2}\exp(ktx^{-1})G(\omega),$$

$$\omega = |x|^{1-q}\exp(-ktx^{-1})(u_x + ktx^{-2}u),$$

$$A_{3.7}^3 = \left\langle |t|^{\frac{1}{2}q}\partial_u, |t|^{1-\frac{1}{2}q}\partial_u, t\partial_t + x\partial_x + \left(1 + \tfrac{1}{2}q\right)u\partial_u \right\rangle \quad (q \neq 0, \pm 1),$$

$$F = \tfrac{1}{4}q(q - 2)t^{-2}u + |t|^{\frac{1}{2}(q-2)}G(\xi, \omega),$$

$$\xi = tx^{-1}, \quad \omega = |t|^{-\frac{1}{2}q}u_x,$$

$$A_{3.7}^4 = \left\langle \exp\left(\tfrac{1}{2}(q - 1)t\right)\partial_u, \exp\left(\tfrac{1}{2}(1 - q)t\right)\partial_u, \partial_t + k\partial_x + \tfrac{1}{2}(1 + q)u\partial_u \right\rangle$$

$$(q \neq 0, \pm 1; k \geqslant 0),$$

$$F=\tfrac{1}{4}(q-1)^2u+\exp\left(\tfrac{1}{2}(1+q)t\right)G(\eta,\omega),$$

$$\eta=x-kt,\quad \omega=\exp\left(-\tfrac{1}{2}(1+q)t\right)u_x,$$

$$A^5_{3.7}=\langle\partial_t+kx^{-1}u\partial_u,|x|^{-q}u\partial_u,t\partial_t+x\partial_x\rangle\quad (k\geqslant 0,\ q\neq 0,\pm 1),$$

$$F=-u^{-1}u_x^2-q(q+1)x^{-2}u\ln|u|+k(q-1)(q+2)tx^{-3}u+ux^{-2}G(\omega),$$
$$\omega=xu^{-1}u_x+q\ln|u|+k(1-q)tx^{-1}.$$

$A_{3.8}$-invariant equations

$$A^1_{3.8}=\langle\cos t\partial_u,-\sin t\partial_u,\partial_t+k\partial_x\rangle\quad (k\geqslant 0),$$

$$F=-u+G(\eta,u_x),\quad \eta=x-kt,$$

$$A^2_{3.8}=\left\langle|t|^{\frac{1}{2}}\cos(\ln|t|)\partial_u,-|t|^{\frac{1}{2}}\sin(\ln|t|)\partial_u,t\partial_t+x\partial_x+\tfrac{1}{2}u\partial_u\right\rangle,$$

$$F=-\tfrac{5}{4}t^{-2}u+|t|^{-3/2}G(\xi,\omega),$$

$$\xi=tx^{-1},\quad \omega=|t|^{1/2}u_x.$$

$A_{3.9}$-invariant equations

$$A^1_{3.9}=\langle\sin t\partial_u,\cos t\partial_u,\partial_t+k\partial_x+qu\partial_u\rangle\quad (k\geqslant 0,\ q>0),$$

$$F=-u+e^{qt}G(\eta,\omega),\quad \eta=x-kt,\omega=e^{-qt}u_x,$$

$$A^2_{3.9}=\left\langle|t|^{\frac{1}{2}}\sin(\ln|t|)\partial_u,|t|^{\frac{1}{2}}\cos(\ln|t|)\partial_u,t\partial_t+x\partial_x+\left(\tfrac{1}{2}+q\right)u\partial_u\right\rangle$$

$$(q\neq 0),\quad F=-\tfrac{5}{4}t^{-2}u+|t|^{q-\frac{3}{2}}G(\xi,\omega),$$

$$\xi=tx^{-1},\quad \omega=|t|^{\frac{1}{2}-q}u_x.$$

C. Complete group classification of Eq. (2.7)

The aim of this section is finalizing group classification of (2.7). The majority of invariant equations obtained in the preceding section contain arbitrary functions of one variable. So that we can utilize the standard Lie–Ovsyannikov approach in order to complete their group classification.

1. Equations depending on an arbitrary function of one variable

Note that equations belonging to the already investigated class of (6.1) are not considered. As our computations show, new results could be obtained for the equations,

$$u_{tt}=u_{xx}+uG(\omega),\quad \omega=u^{-1}u_x, \tag{6.3}$$

$$u_{tt}=u_{xx}+G(u_x), \tag{6.4}$$

only. Below we give (without proof) the assertions describing their group properties.

Assertion 6: Equation (6.3) admits wider symmetry group iff it is equivalent to the following equation:

$$u_{tt} = u_{xx} + mu^{-1}u_x^2 \quad (m \neq 0, -1). \tag{6.5}$$

The maximal invariance algebra of (6.5) is the four-dimensional Lie algebra,

$$A_4 \sim A_{3.5} \oplus A_1, \quad A_4 = \langle \partial_t, \partial_x, t\partial_t + x\partial_x, u\partial_u \rangle.$$

Assertion 7: Equation (6.4) admits wider symmetry group iff it is equivalent to one of the following PDEs:

$$u_{tt} = u_{xx} + e^{u_x}, \tag{6.6}$$

$$u_{tt} = u_{xx} + m \ln|u_x|, \quad m > 0, \tag{6.7}$$

$$u_{tt} = u_{xx} + |u_x|^k, \quad k \neq 0, 1. \tag{6.8}$$

The maximal invariance algebras of the above equations are five-dimensional solvable Lie algebras listed below,

$$A_5^2 = \langle \partial_t, \partial_x, \partial_u, t\partial_u, t\partial_t + x\partial_x + (u - x)\partial_u \rangle,$$

$$A_5^3 = \left\langle \partial_t, \partial_x, \partial_u, t\partial_u, t\partial_t + x\partial_x + \left(2u + \tfrac{1}{2}mt^2\right)\partial_u \right\rangle,$$

$$A_5^4 = \left\langle \partial_t, \partial_x, \partial_u, t\partial_u, t\partial_t + x\partial_x + \frac{k-2}{k-1}u\partial_u \right\rangle.$$

Analyzing the remaining equations containing arbitrary functions of one variable we come to conclusion that one of them can admit wider invariance groups iff either

(1) it is equivalent to PDE of the form (6.1), or
(2) it is equivalent to PDE of the form (6.5).

To finalize the procedure of group classification of Eqs. (2.7) we need to consider invariant equations obtained in the preceding section that contain arbitrary functions of two variables.

2. Classification of equations with arbitrary functions of two variables

In the case under study the standard Lie–Ovsyannikov method is inefficient and we apply our classification algorithm. In order to do this we perform extension of three-dimensional solvable Lie algebras to all possible realizations of four-dimensional solvable Lie algebras. The next step will be to check which of the obtained realizations are symmetry algebras of nonlinear equations of the form (2.7). In what follows we use the results of Ref. 41, where all inequivalent (within the action of inner automorphism group) four-dimensional solvable abstract Lie algebras are given.

The computation details can be found in Ref. 35. Here we summarize the obtained results as follows:

(1) If the functions contained in the equations under study are arbitrary, then the corresponding realizations are their maximal invariance algebras, and
(2) Except for Eq. (6.4), all the equations in question do not allow for extension of their symmetry.

Below we give the complete list of PDEs (2.7) invariant under four-dimensional solvable Lie algebras that are obtained through group analysis of equations with arbitrary functions of two variables.

$A_{2.2} \oplus 2A_1$-invariant equations,

$$(1)\ \langle \partial_x, \partial_t + u\partial_u, e^t\partial_u, e^{-t}\partial_u \rangle, \quad F = u + e^t G(\omega), \quad \omega = u^{-t}u_x,$$

$$(2)\ \left\langle \frac{1}{2k}(\partial_t + k\partial_x), e^{x+kt}\partial_u, e^{\eta}\partial_u, \partial_x + u\partial_u \right\rangle \quad (k > 0, \eta = x - kt),$$

$$F = (k^2 - 1)u + e^{\eta}G(\omega), \quad \omega = e^{-\eta}(u_x - u).$$

$2A_{2.2}$-invariant equations,

$$(1)\ \langle \partial_t + \epsilon u\partial_u, \partial_x, e^{x+kt}\partial_u, e^{x-kt}\partial_u \rangle \quad (\epsilon = 0, 1; k > 0),$$

$$F = (k^2 - 1)u + e^{\epsilon t}G(\omega), \quad \omega = e^{-\epsilon t}(u_x - u),$$

$$(2)\ \langle \alpha\partial_x - u\partial_u, \partial_t + k\partial_x, e^{-t}\partial_u, e^t\partial_u \rangle \quad (k \geqslant 0, \alpha > 0),$$

$$F = u + \exp(-\alpha^{-1}\eta)G(\omega), \quad \eta = x - kt, \quad \omega = \exp(\alpha^{-1}\eta)u_x.$$

$A_{3.3} \oplus A_1$-invariant equations,

$$(1)\ \langle \partial_t, \partial_x, \partial_u, t\partial_u \rangle, \quad F = G(u_x).$$

$A_{3.4} \oplus A_1$-invariant equations

$$(1)\ \langle \partial_u, \partial_x, t\partial_t + x\partial_x + (u + x)\partial_u, t\partial_u \rangle,$$

$$F = t^{-1}G(\omega), \quad \omega = u_x - \ln|t|,$$

$$(2)\ \langle \partial_t + u\partial_u, \partial_x, t\partial_u, \partial_u \rangle, \quad F = e^t G(\omega), \omega = e^{-t}u_x,$$

$$(3)\ \langle x^{-1}\partial_u, \partial_x - x^{-1}(u + \ln|x|)\partial_u, t\partial_t + x\partial_x, tx^{-1}\partial_u \rangle,$$

$$F = 2x^{-1}u_x + x^{-2} + t^{-1}x^{-1}G(\omega), \quad \omega = xu_x + u - \ln|tx^{-1}|.$$

$A_{3.5} \oplus A_1$-invariant equations,

$$(1)\ \langle \partial_x, \partial_u, t\partial_t + x\partial_x + u\partial_u, t\partial_u \rangle, \quad F = t^{-1}G(u_x),$$

$$(2)\ \langle x^{-1}\partial_u, \partial_x - x^{-1}u\partial_u, t\partial_t + x\partial_x, tx^{-1}\partial_u \rangle,$$

$$F = -2x^{-2}u + 2t^{-1}(u_x + x^{-1}u)\ln|t(u_x + x^{-1}u)| + t^{-1}(u_x + x^{-1}u)G(\omega), \quad \omega = xu_x + u.$$

$A_{3.6} \oplus A_1$-invariant equations,

$$(1)\ \langle \partial_x, t\partial_u, t\partial_t + x\partial_x, \partial_u \rangle, \quad F = t^{-2}G(\omega), \quad \omega = t^{-1}u_x,$$

$$(2)\ \langle \partial_t, \partial_x, e^t\partial_u, e^{-t}\partial_u \rangle, \quad F = u + G(u_x).$$

$A_{3.7} \oplus A_1$-invariant equations,

$$(1)\ \left\langle \partial_x, |t|^{\frac{1}{2}}\partial_u, -|t|^{\frac{1}{2}}\ln|t|\partial_u, t\partial_t + x\partial_x + \tfrac{1}{2}u\partial_u \right\rangle,$$

$$F = -\tfrac{1}{4}t^{-2}u + |t|^{-\frac{3}{2}}G(\omega), \quad \omega = |t|^{\frac{1}{2}}u_x,$$

$$(2)\ \langle \partial_x, t\partial_u, \partial_u, t\partial_t + x\partial_x \rangle, \quad F = t^{-2}G(\omega), \omega = tu_x,$$

$$(3)\ \langle e^{kt}\partial_u, \partial_t + ku\partial_u, \beta\partial_x + te^{kt}\partial_u, e^{-kt}\partial_u \rangle \quad (k \neq 0, \beta > 0),$$

$$F = k^2u + 2k\beta^{-1}xe^{kt} + e^{kt}G(\omega), \quad \omega = e^{-kt}u_x,$$

$$(4)\ \langle e^{x+kt}\partial_u, e^{\eta}\partial_u, \alpha(\partial_x + u\partial_u) + 2kte^{\eta}\partial_u, -(1/2k)(\partial_t + k\partial_x) \rangle$$

$$(\alpha \neq 0,\ k > 0), \quad F = (k^2 - 1)u - 4k^2\alpha^{-1}\eta e^{\eta} + e^{\eta}G(\omega),$$

$$\omega = e^{-\eta}(u_x - u), \quad \eta = x - kt.$$

$A_{4.4}$-invariant equations,

$$(1)\ \left\langle |t|^{\frac{1}{2}}\partial_u, -|t|^{\frac{1}{2}}\ln|t|\partial_u, \partial_x, t\partial_t + x\partial_x + \left[\tfrac{3}{2}u - x|t|^{\frac{1}{2}}\ln|t|\right]\partial_u \right\rangle,$$

$$F = \tfrac{1}{4}t^{-2}u + |t|^{-\frac{1}{2}}G(\omega), \omega = |t|^{-\frac{1}{2}}u_x + \tfrac{1}{2}\ln^2|t|.$$

$A_{4.5}$-invariant equations,

$$(1)\ \langle \partial_x, |t|^{m-\alpha}\partial_u, |t|^{1-m+\alpha}\partial_u, t\partial_t + x\partial_x + mu\partial_u \rangle$$

$$\left(m \neq \tfrac{1}{2}(1+\alpha), \tfrac{1}{2} + \alpha; \alpha \neq 0\right),$$

$$F = (m - \alpha)(m - \alpha - 1)t^{-2}u + |t|^{m-2}G(\omega), \quad \omega = |t|^{1-m}u_x.$$

$A_{4.6}$-invariant equations,

$$(1)\ \left\langle \partial_x, |t|^{\frac{1}{2}}\sin(q^{-1}\ln|t|)\partial_u, |t|^{\frac{1}{2}}\cos(q^{-1}\ln|t|)\partial_u, qt\partial_t + qx\partial_x + \left(\tfrac{1}{2}q + p\right)u\partial_u \right\rangle \quad (q \neq 0, p \geqslant 0),$$

$$F = -\left(\tfrac{1}{4} + q^{-2}\right)t^{-2}u + |t|^{q^{-1}\left(p - \frac{3}{2}q\right)}G(\omega), \quad \omega = |t|^{q^{-1}\left(\frac{1}{2}q - p\right)}u_x.$$

$A_{4.7}$-invariant equations,

$$(1)\ \left\langle \partial_u, -t\partial_u, \partial_t + k\partial_x, t\partial_t + x\partial_x + \left(2u - \tfrac{1}{2}t^2\right)\partial_u \right\rangle \quad (k \geqslant 0),$$

$$F = -\ln|\eta| + G(\omega), \quad \omega = \eta^{-1}u_x, \quad \eta = x - kt.$$

$A_{4.8}$-invariant equations,

$$(1)\ \langle \partial_t + \epsilon u\partial_u, \partial_x, e^x\partial_u, te^x\partial_u \rangle \quad (\epsilon = 0; 1),$$

$$F = -u + e^{\epsilon t}G(\omega), \quad \omega = e^{-\epsilon t}(u_x - u),$$

$$(2)\ \langle |x|^{m-q}\partial_u, \partial_t, t|x|^{m-q}\partial_u, t\partial_t + x\partial_x + mu\partial_u \rangle \quad (q \neq 0,\ m \in \mathbb{R}),$$

$$F = -(m-q)(m-q-1)x^{-2}u + |x|^{m-2}G(\omega),$$

$$\omega = |x|^{1-m}[u_x - (m-q)x^{-1}u],$$

$$(3)\ \langle \partial_t + k\partial_x, \partial_u, t\partial_u, t\partial_t + x\partial_x + qu\partial_u \rangle \quad (k > 0,\ q \in \mathbb{R}),$$

$$F = |\eta|^{q-2}G(\omega), \quad \omega = |\eta|^{1-q}u_x, \quad \eta = x - kt,$$

$$(4)\ \langle x^{-1}\partial_u, \partial_t + \partial_x - x^{-1}u\partial_u, tx^{-1}\partial_u, t\partial_t + x\partial_x \rangle,$$

$$F = 2x^{-1}u_x + x^{-1}(t-x)^{-1}G(\omega), \quad \omega = xu_x + u,$$

$$(5)\ \langle \partial_u, -t\partial_u, \partial_t + k\partial_x + u\partial_u, \alpha\partial_x + u\partial_u \rangle \quad (\alpha \neq 0,\ k \geqslant 0),$$

$$F = \exp(\alpha^{-1}\eta + t)G(\omega), \quad \omega = \exp(-\alpha^{-1}\eta - t)u_x, \quad \eta = x - kt.$$

$A_{4.10}$-invariant equations,

$$(1)\ \langle \sin t\partial_u, \cos t\partial_u, \partial_x + u\partial_u, \partial_t + k\partial_x \rangle \quad (k \geqslant 0),$$

$$F = -u + e^{\eta}G(\omega), \quad \omega = e^{-\eta}u_x, \quad \eta = x - kt.$$

In the above formulas $G = G(\omega)$ is an arbitrary function satisfying the condition $F_{u_x u_x} \neq 0$.

CONCLUDING REMARKS

Let us briefly summarize the results obtained in this paper.

We prove that the problem of group classification of the general quasilinear hyperbolic type equation (1.1) reduces to classifying equations of more specific forms,

$$\text{(I)}\ u_{tt} = u_{xx} + F(t,x,u,u_x), \quad F_{u_x u_x} \neq 0,$$

$$\text{(II)}\ u_{tt} = u_{xx} + g(t,x,u)u_x + f(t,x,u), \quad g_u \neq 0,$$

$$\text{(III)}\ u_{tx} = g(t,x)u_x + f(t,x,u), \quad g_x \neq 0, \quad f_{uu} \neq 0,$$

$$\text{(IV)}\ u_{tx} = f(t,x,u), \quad f_{uu} \neq 0.$$

If we denote as $\mathcal{DE}$ the set of PDEs (II)–(III), then the results of application of our algorithm for group classification of equations (I)–(IV) can be summarized as follows.

(1) We perform complete group classification of the class $\mathcal{DE}$. We prove that the Liouville equation has the highest symmetry properties among equations from $\mathcal{DE}$. Next, we prove that the only equation belonging to this class and admitting the four-dimensional invariance algebra is the nonlinear d'Alembert equations. It is established that there are 12 inequivalent equations from $\mathcal{DE}$ invariant under three-dimensional Lie algebras. We give the lists of all inequivalent equations from $\mathcal{DE}$ that admit one- and two-dimensional symmetry algebras.

(2) We have studied the structure of invariance algebras admitted by nonlinear equations from the class (I). It is proved, in particular, that their invariance algebras are necessarily solvable.

(3) We perform complete group classification of nonlinear equations from the class of PDEs (I). We prove that the highest symmetry algebras admitted by those equations are five dimen-

sional and construct all inequivalent classes of equations invariant with respect to five-dimensional Lie algebras. We also construct all inequivalent equations of the form (I) admitting one-, two-, three-, and four-dimensional Lie algebras.

In one of our future papers we intend to exploit the obtained classification results to construct exact solutions of nonlinear wave equations (I)–(IV).

(Received 4 October 2004; accepted 23 February 2005; published online 14 April 2005)

We analyze the two- and four-point truncated function of a lattice system of unbounded continuous spin variables describing a large class of light-mass quantum anharmonic crystals and some stochastic Ginzburg–Landau-type models under intense noise. We develop a cluster expansion and use it to obtain the decay of the two-point truncated function (which gives information about the one-particle excitations), for the interactions with finite range or with polynomial decay. Moreover, using a Bethe–Salpeter equation, we investigate the four-point truncated in a perturbative approach (whose reliability is supported by the convergence of the cluster expansion), and establish a condition for the existence of a two-particle bound state in the low-lying spectrum of the system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1895845]

I. INTRODUCTION

In this paper we develop a cluster expansion and investigate the low-lying spectrum of some systems related to commonly used physical models, namely, to light-mass quantum crystals and to stochastic Ginzburg–Landau- (GL) type models submitted to intense noise.

The interest of such problems is well known. The study of the basic properties of the quantum crystals, for example, is an old problem in physics. For these crystal models we mean a system of unbounded continuous spin variables $\varphi_i \in \mathbb{R}$, in a lattice space with Hamiltonian given by

$$H = \sum_{i \in \mathbb{Z}^d} -\frac{1}{2m}\frac{\partial^2}{\partial \varphi_i^2} + \frac{1}{2}\sum_{i,j \in \mathbb{Z}^d} \varphi_i J_{ij} \varphi_j + \sum_{i \in \mathbb{Z}^d} V(\varphi_i), \tag{1}$$

where $J_{i,j}$ is usually taken as a positive operator (e.g., the lattice Laplacian; i.e., in some recent rigorous works the pair interaction is restricted to the ferromagnetic case), and V is given, e.g., by $V(\varphi_i) = a\varphi_i^2 + b\varphi_i^4$. In the present paper, we consider more general cases, we do not restrict the quadratic interaction to ferromagnetic cases and neither the anharmonic potential to a local interaction. We give details later. Recently, several works have been devoted to a rigorous analysis of the small mass behavior of such lattice models (light-mass means that the system is strongly quantum). For example, in Refs. 1 and 2 the fact that small mass implies uniqueness of Gibbs states of a quantum crystal is rigorously established (there, for the ferromagnetic case and with local anharmonicity), an important result about the influence of quantum effects on structural

[c]Electronic mail: aldo@mat.ufmg.br

phase transitions. See also Ref. 3 and references therein for more recent results. Effects of nonlocality in the anharmonicity on the spectral properties of quantum crystals (in the regime of large mass) are presented in Ref. 4. In the present paper, besides other results, such as the uniqueness of a phase given by the convergence of the cluster expansion, we will establish conditions for the existence of a two-particle bound state in the excitation spectrum of these light-mass quantum crystals, showing that the system, although in a single phase region, may have nontrivial spectral excitations.

The stochastic GL-type models are also extensively investigated in physics, in particular, in the study of dynamical critical phenomena. The spectrum of the generator of the dynamics gives information about, e.g., the relaxation rates of the correlation functions, and so, it is of direct physical interest. Recently, several works have been devoted to detailed investigations on the spectral properties of such systems. For the weakly coupled GL model, the existence of an isolated one-particle and two-particle bound states have been established perturbatively in Ref. 5, and rigorously in Ref. 6. Effects on the spectrum due to changes in the noise strength are presented in Refs. 7–9, for the small noise regime, and in Ref. 10 for intense noise. In Ref. 11, the one-particle state is rigorously established for a particular case of these GL-type models under intense noise.

In order to make clear the relation between the stochastic GL system and the anharmonic quantum crystal, we present below a brief technical description of the dynamics generator of the stochastic model.

Consider a system of unbounded continuous spin variables $\phi_{\vec{x},t} \in \mathbb{R}$, in a lattice space box $\vec{x} \in V \subset \mathbb{Z}^d$ (the thermodynamic limit is considered when $V \to \mathbb{Z}^d$), with time evolution (Langevin dynamics) given by

$$\frac{\partial}{\partial t}\phi_{\vec{x},t} = -\frac{1}{2}\nabla S(\phi_{\vec{x},t}) + \eta_{\vec{x},t}, \quad \phi_{\vec{x},t=0} = \psi_{\vec{x}}, \tag{2}$$

where $\nabla S = \delta S / \delta \phi$, and the GL (spatial) interaction is

$$S(\phi) = \frac{1}{2}\sum_{\vec{x},\vec{y}\in V} J_{\vec{x},\vec{y}}\phi_{\vec{x}}\phi_{\vec{y}} + \lambda \sum_{\vec{x}\in V} \mathcal{P}(\phi_{\vec{x}}), \tag{3}$$

$\lambda > 0$, $\mathcal{P}$ is a polynomial bounded from below; η is a family of Gaussian white-noise processes with expectations

$$E(\eta_{\vec{x},t}) = 0, \quad E(\eta_{\vec{x},t}\eta_{\vec{y},t'}) = \gamma\delta_{\vec{x},\vec{y}}\delta(t-t'), \tag{4}$$

$\vec{x} \in V$, $t \in [0,\infty)$ (in principle, we extend the time interaction to $-t$ and introduce a time regularizer that makes t discrete later); $\gamma > 0$ is the noise strength, we will treat the regime $\gamma \gg 1$. $J_{\vec{x},\vec{y}}$ is an arbitrary summable spatial interaction, i.e., we assume that $J_{\vec{x},\vec{y}}$ is symmetric, translational invariant with

$$\sup_{\vec{x}\in\mathbb{Z}^d} \sum_{\vec{y}\in\mathbb{Z}^d} |J_{\vec{x},\vec{y}}| < \infty. \tag{5}$$

Note that the pair potential $J(\vec{x},\vec{y})$ does not have to be positive.

The time evolution of functions f of the spin configuration ϕ for such systems is defined by

$$f_t(\psi) = E(f(\phi_t)),$$

where $\psi = \phi_{t=0}$ is some initial condition. From Itô calculus, it follows that

$$f_t(\psi) = e^{-t\mathcal{H}_V^0} f(\psi), \quad \mathcal{H}_V^0 f = \left\{ \sum_{\vec{x}\in V} -\frac{1}{2}\gamma \frac{\partial^2}{\partial \phi_{\vec{x}}^2} + \frac{1}{2}\frac{\partial S}{\partial \phi_{\vec{x}}}\frac{\partial}{\partial \phi_{\vec{x}}} \right\} f. \tag{6}$$

The generator $\mathcal{H}_V^0$ of the strongly continuous semigroup describing the Markov dynamics above is Hermitian and positive in the Hilbert space $L^2(\mathrm{d}\sigma_V^0)$, where $\mathrm{d}\sigma_V^0$ is the invariant measure given by the Gibbs probability distribution

$$\mathrm{d}\sigma_V^0 = e^{-S(\phi)/\gamma}\, \mathrm{d}\phi_V/\text{normalization}, \quad \text{where } \mathrm{d}\phi_V = \prod_{\vec{x}\in V} \mathrm{d}\phi_{\vec{x}}. \tag{7}$$

The ground state of $\mathcal{H}_V^0$ is the eigenfunction $f \equiv 1$ with eigenvalue zero. We note that $\mathcal{H}_V^0$ is unitarily equivalent to a Schrödinger operator with a potential going to infinity, defining the unitary operator U_V^0 from $L^2(\mathrm{d}\sigma_V^0) \to L^2(\mathrm{d}\phi_V)$ as

$$(U_V^0 f)(\phi) = Z_V^{-1/2} e^{-(1/2\gamma)S} f(\phi),$$

where Z_V is the normalization in $\mathrm{d}\sigma_V^0$, a straightforward calculation gives us

$$H_V^0 = U_V^0 \mathcal{H}_V^0 (U_V^0)^{-1} = \sum_{\vec{x}\in V} -\frac{1}{2}\gamma \frac{\partial^2}{\partial \phi_{\vec{x}}^2} + \frac{1}{4}\sum_{\vec{x}\in V}\left[\frac{1}{2\gamma}\left(\frac{\partial S}{\partial \phi_{\vec{x}}} \right)^2 - \frac{\partial^2 S}{\partial \phi_{\vec{x}}^2} \right]. \tag{8}$$

Performing the derivatives, we get

$$\begin{aligned} H_V^0 = &-\frac{1}{2}\gamma \sum_{\vec{x}\in V} \frac{\partial^2}{\partial \phi_{\vec{x}}^2} + \frac{1}{8\gamma}\sum_{\vec{x},\vec{y}\in V} [J * J]_{\vec{x},\vec{y}} \phi_{\vec{x}} \phi_{\vec{y}} + \frac{\lambda}{4\gamma}\sum_{\vec{x},\vec{y}\in V} J_{\vec{x},\vec{y}} \mathcal{P}'(\phi_{\vec{x}})\phi_{\vec{y}} \\ &+ \sum_{\vec{x}\in V}\left[\frac{\lambda^2}{8\gamma}\mathcal{P}'(\phi_{\vec{x}})^2 - \frac{\lambda}{4}\mathcal{P}''(\phi_{\vec{x}}) + c \right], \end{aligned} \tag{9}$$

where c is a constant (depending of J and d), and $[J*J]_{\vec{x},\vec{y}} = \Sigma_{\vec{z}\in V} J_{\vec{x},\vec{z}} J_{\vec{z},\vec{y}}$ is the spatial convolution.

The relation between the spectral properties of the generator of the stochastic dynamics and the study of the excitation spectrum of the quantum anharmonic crystals becomes evident from the expression for H_V^0 above, as we have recalled, note that the large noise intensity γ above represents the inverse of small mass m of the particles for the anharmonic oscillators in (1); note also that the stochastic "potential" is more intricate.

It is useful to construct a Feynman–Kac integral formalism associated to H_V^0 [or to H (1)]. It follows from standard procedures.[12] If $f_1, \ldots, f_n$ are functions of the spin configuration in V, $\Omega(\phi) = 1$ is the ground state of $\mathcal{H}_V^0$ and for $t_1 \leqslant t_2 \leqslant \cdots t_n \in \mathbb{R}$, now $t_i \in [-T, T]$, then we have

$$\begin{aligned} (\Omega, f_1 e^{-(t_2-t_1)\mathcal{H}_V^0} f_2 \cdots e^{-(t_n-t_{n-1})\mathcal{H}_V^0} f_n \Omega)_{L^2(\mathrm{d}\sigma_V^0)} &= (U_V^0\Omega, f_1 e^{-(t_2-t_1)H_V^0} f_2 \cdots e^{-(t_n-t_{n-1})H_V^0} f_n U_V^0 \Omega)_{L^2(\mathrm{d}\phi_V)} \\ &= \int f_1(\phi(t_1)) \cdots f_n(\phi(f_n)) \mathrm{d}\rho_V^0, \end{aligned} \tag{10}$$

where the path space measure $\mathrm{d}\rho_V^0$ is the weak limit $T \to \infty$ of

$$\mathrm{d}\rho_\Lambda^0 = \frac{e^{-W_\Lambda^0(\phi)}\, \mathrm{d}\omega_\Lambda^0}{\displaystyle\int e^{-W_\Lambda^0(\phi)}\, \mathrm{d}\omega_\Lambda^0}, \tag{11}$$

with $\Lambda \equiv ([-T, T], V)$ and

$$W_\Lambda^0(\phi) = \int_{-T}^{T} \mathrm{d}t \left\{ \frac{\lambda}{4\gamma}\sum_{\vec{x},\vec{y},\in V} J_{\vec{x},\vec{y}} \mathcal{P}'(\phi_{\vec{x}})\phi_{\vec{y}} + \sum_{\vec{x}\in V}\left[\frac{\lambda^2}{8\gamma}\mathcal{P}'(\phi_{\vec{x}})^2 - \frac{\lambda}{4}\mathcal{P}''(\phi_{\vec{x}}) \right] \right\}, \tag{12}$$

and $\mathrm{d}\omega_\Lambda^0$ is a Gaussian measure with mean zero and variance given by

$$\gamma C_\Lambda(t,\vec{x};t',\vec{y}) = \int \phi_{t,\vec{x}}\phi_{t',\vec{y}}\,\mathrm{d}\omega_\Lambda^0 = \frac{\gamma}{2\pi|V|}\int_{-\infty}^{\infty}\mathrm{d}p_0 \sum_{\vec{p}\in\tilde{V}} \frac{e^{ip_0(t-t')}e^{i\vec{p}\cdot(\vec{x}-\vec{y})}}{p_0^2+[\tilde{J}(\vec{p})]^2/4}, \tag{13}$$

where $\tilde{J}(\vec{p})$ is the Fourier transform of $J_{\vec{x},\vec{y}}$; $|V|$ is the number of points in V; $\tilde{V}$ is the Fourier dual lattice; $\vec{p}=(p_1,\ldots,p_d)\in\tilde{V}$ and $\vec{p}\cdot(\vec{x}-\vec{y})=\Sigma_{i=1}^d p_i(x_i-y_i)$.

The Feynman–Kac formula above and the spectral theorem for Hermitian operators give us the connection between the spectrum of the generator of the dynamics and the behavior of the correlation functions. For example, for the truncated two-point function $S_2(x;y)\equiv\langle\phi_x\phi_y\rangle-\langle\phi_x\rangle\times\langle\phi_y\rangle\equiv\int\phi_x\phi_y\,\mathrm{d}\rho_V^0-\int\phi_x\,\mathrm{d}\rho_V^0\int\phi_y\,\mathrm{d}\rho_V^0$, $x\equiv(x_0,\vec{x})$, $x_0\equiv t\in\mathbb{R}$, $\vec{x}\in\mathbb{Z}^d$ (let us assume the thermodynamic limit in this short comment), direct calculations lead to

$$\tilde{S}_2(p) = \int_0^\infty \int_{\mathbf{T}^d} \frac{2E}{E^2+(p_0)^2}(2\pi)^d\delta(\vec{q}-\vec{p})d(\Omega,\phi\mathcal{E}(E,\vec{q})\phi\Omega), \tag{14}$$

where $\tilde{S}_2$ is the Fourier transform of S_2, $\mathcal{E}(E,\vec{p})$ is the spectral projection associated with the operators $(H,\vec{P})$ (the momentum operator $\vec{P}$ is the space translation generator), the integral over E runs from 0 to ∞ and that over $\vec{q}$ runs in T^d. Hence, a singularity in $\tilde{S}_2$ for imaginary $p_0=ik_0$ gives a point in the spectrum (one-particle sector) of the generator of the dynamics, and, by the Paley–Wiener theorem, the singularity in $\tilde{S}_2$ is related to the decay of S_2. Similarly, the decay of the truncated four-point function gives us information about, e.g., the existence of two-particle bound states. More details and comments are presented in Ref. 6 and references therein.

The rest of the paper is organized as follows.

In Sec. II we introduce the model to be treated here, describe a formalism for the correlations (a Feynman–Kac-type integral formalism) and list the main results of the paper. In Sec. III we present the cluster expansion, whose convergence is proved in Sec. IV. Section V is devoted to the study of the decay of the two-point truncated correlation, and Sec. VI to the analysis of the four-point truncated function.

II. THE MODEL AND MAIN RESULTS

In the present paper we will analyze in detail the model of unbounded continuous scalar field variables with (say) Hamiltonian

$$H_V = \sum_{\vec{x}\in V} -\frac{1}{2}\gamma\frac{\partial^2}{\partial\phi_{\vec{x}}^2} + \frac{1}{2}\sum_{\vec{x},\vec{y}\in V}\phi_{\vec{x}}J_{\vec{x},\vec{y}}\phi_{\vec{y}} + \lambda\sum_{\vec{x}\in V}Q(\phi_{\vec{x}}), \tag{15}$$

where

$$Q(\phi_{\vec{x}}) = P(\phi_{\vec{x}}) + \sum_{i=1}^{c}\sum_{\vec{y}\in V}\phi_{\vec{x}}^{a_i}D_{\vec{x},\vec{y}}^{(i)}\phi_{\vec{y}}^{b_i}, \tag{16}$$

$\phi_{\vec{x}}\in\mathbb{R}$, $V\subset\mathbb{Z}^d$, $\gamma>0$, $\lambda>0$, P is a polynomial bounded from below of degree $2m$, $c>0$ is an integer, a_i,b_i with $i=1,2,\ldots,c$, are integers such that $1\leqslant a_i,\ b_i\leqslant m$. $J_{\vec{x},\vec{y}}$ and $D_{\vec{x},\vec{y}}^{(i)}$ are symmetric spatial interactions, translational invariant and such that, $\forall_i=1,2,\ldots,c$,

$$\sup_{\vec{x}\in\mathbb{Z}^d}\sum_{\vec{y}\in\mathbb{Z}^d}|J_{\vec{x},\vec{y}}| \equiv J_M<\infty, \quad \sup_{\vec{x}\in\mathbb{Z}^d}\sum_{\vec{y}\in\mathbb{Z}^d}|D_{\vec{x},\vec{y}}^{(i)}| \equiv D_M^{(i)}<\infty. \tag{17}$$

Analyzing these specific models, we will get properties of a large class of anharmonic quantum crystals as well as of some stochastic GL models.

The spectral results to be presented are supported by a cluster expansion which we develop here. To obtain these results, in a rough resume, we start from the dynamics generator (or Hamiltonian), establish a lattice Feynman–Kac integral formula for the correlation functions, relating the

initial problem to a spatially nonlocal imaginary time quantum field theory. Then, we study the decay of some truncated correlation functions using our "high temperature" cluster expansion for unbounded spin systems, which is related to that recently proposed in Ref. 13. Information on the two-particle spectrum (related to the four-point correlation functions) is obtained in a perturbative analysis only, we use the Bethe–Salpeter (BS) equation with the BS kernel in a ladder approximation (details ahead). The reliability of the perturbative result is supported (again) by the convergence of the cluster expansion.

The Feynman–Kac functional integral associated to H_V follows, as said, from standard procedures. If $f_1,\ldots,f_n$ are functions of the spin configuration in V, $t_1\leqslant t_2\leqslant\cdots t_n\in\mathbb{R}$, as described in the introduction, we have an integral representation for the correlations

$$\int f_1(\phi(t_1))\cdots f_n(\phi(t_n))\mathrm{d}\rho_V, \tag{18}$$

where, now, the path space measure $\mathrm{d}\rho_V$ is the weak limit $T\to\infty$ of

$$\mathrm{d}\rho_\Lambda=\frac{e^{-W_\Lambda(\phi)}\,\mathrm{d}\omega_\Lambda}{\displaystyle\int e^{-W_\Lambda(\phi)}\,\mathrm{d}\omega_\Lambda}, \tag{19}$$

with $\Lambda\equiv([-T,T],V)$ and

$$W_\Lambda(\phi)=\int_{-T}^{T}\mathrm{d}t\,\lambda\sum_{\vec{x}\in V}Q(\phi_{t,\vec{x}})=\int_{-T}^{T}\mathrm{d}t\,\lambda\left[\sum_{\vec{x}\in V}P(\phi_{t,\vec{x}})+\sum_{i=1}^{c}\sum_{\vec{x},\vec{y}\in V}\phi_{t,\vec{x}}^{a_i}D_{\vec{x},\vec{y}}^{(i)}\phi_{t,\vec{y}}^{b_i}\right], \tag{20}$$

and $\mathrm{d}\omega_\Lambda$ is a Gaussian measure with mean zero and variance given by

$$\gamma C_\Lambda(t,\vec{x};t',\vec{y})=\int\phi_{t,\vec{x}}\phi_{t',\vec{y}}\,\mathrm{d}\omega_\Lambda=\frac{\gamma}{2\pi|V|}\int_{-\infty}^{\infty}\mathrm{d}p_0\sum_{\vec{p}\in\tilde{V}}\frac{e^{ip_0(t-t')}e^{i\vec{p}\cdot(\vec{x}-\vec{y})}}{p_0^2+\gamma\tilde{J}(\vec{p})}, \tag{21}$$

where $\tilde{J}(\vec{p})$ is the Fourier transform of $J_{\vec{x},\vec{y}}$; $|V|$ is the number of points in V; $\tilde{V}$ is the Fourier dual lattice; $\vec{p}=(p_1,\ldots,p_d)\in\tilde{V}$ and $\vec{p}\cdot(\vec{x}-\vec{y})=\sum_{i=1}^{d}p_i(x_i-y_i)$.

For technical reasons, we will consider a time regularized version of the measure $\mathrm{d}\rho_\Lambda$. Precisely, from now on, we consider only the values of t in $\mathbb{Z}\cap[-T,T]$, so that our Feynman–Kac integral formula (18) becomes, say, the description of continuous spin system in a finite box $\Lambda\equiv(\mathbb{Z}\cap[-T,T],V)$ in $\mathbb{Z}^{d+1}$ (with periodic boundary conditions in space and free boundary conditions in time). Recall from field theory that such a (ultraviolet) cutoff shall not change the low-lying spectrum. We also will use the notation $x=(x_0,\vec{x})\in\mathbb{Z}^{d+1}$ with $x_0\in\mathbb{Z}\cap[-T,T]$ being the discrete time coordinate and $\vec{x}\in V$ the space coordinate. We define $\beta\equiv1/\gamma$, and so, intense noise regime $\gamma\gg1$ corresponds to the small β regime. Hence, from the path space measure $\mathrm{d}\rho_\Lambda$ with discrete time, we introduce the "Gibbs measure" for such system,

$$\begin{aligned}\mu_\Lambda(\cdot)&=\left[\int e^{-W_\Lambda(\phi)}\,\mathrm{d}\omega_\Lambda\right]^{-1}\int(\cdot)e^{-W_\Lambda(\phi)}\,\mathrm{d}\omega_\Lambda=\frac{1}{Z_\Lambda}\int(\cdot)\exp\left\{-\lambda\sum_{x\in\Lambda}Q(\phi_x)\right\}\\&\quad\times\exp\left\{-\frac{1}{2\gamma}\sum_{x,y\in\Lambda}\phi_xC_\Lambda^{-1}(x,y)\phi_y\right\}\prod_{x\in\Lambda}\mathrm{d}\phi_x,\end{aligned} \tag{22}$$

where

$$\sum_{x\in\Lambda} Q(\phi_x) = \sum_{x\in\Lambda} P(\phi_x) + \sum_{i=1}^{c}\sum_{x,y\in\Lambda} \phi_x^{a_i} D^{(i)}_{\vec{x},\vec{y}} \phi_y^{b_i} \delta_{x_0,y_0}[\delta_{\vec{x},\vec{y}} + (1-\delta_{\vec{x},\vec{y}})] = \sum_{x\in\Lambda}\left[P(\phi_x) + \sum_{i=1}^{c} D^{(i)}_{\vec{x},\vec{x}} \phi^{a_i+b_i}\right]$$
$$+ \sum_{i=1}^{c}\sum_{x,y\in\Lambda} \phi_x^{a_i} D^{(i)}_{\vec{x},\vec{y}} \phi_y^{b_i} \delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}}), \tag{23}$$

$$\sum_{x,y\in\Lambda} \phi_x C^{-1}_{\Lambda}(x,y)\phi_y = \sum_{x,y\in\Lambda} \phi_x(-\delta_{\vec{x},\vec{y}}\Delta_t + \gamma J_{\vec{x},\vec{y}}\delta_{x_0,y_0})\phi_y = \sum_{x,y\in\Lambda} \phi_x\{\delta_{\vec{x},\vec{y}}(2\delta_{x_0,y_0} - \delta_{|x_0-y_0|,1})$$
$$+ \gamma J_{\vec{x},\vec{y}}\delta_{x_0,y_0}[\delta_{\vec{x},\vec{y}} + (1-\delta_{\vec{x},\vec{y}})]\}\phi_y = \sum_{x\in\Lambda}[2\phi_x^2 + \gamma J_{\vec{x},\vec{x}}\phi_x^2]$$
$$+ \sum_{x,y\in\Lambda} \phi_x[-\delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1} + \gamma J_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})]\phi_y. \tag{24}$$

We used above that, due to the discrete time, $-\Delta_t = 2\delta_{x_0,y_0} - \delta_{|x_0-y_0|,1}$. In short, we have

$$\mu_\Lambda(\cdot) = \frac{1}{Z_\Lambda}\int \prod_{x\in\Lambda} \mathrm{d}\phi_x\, e^{-\beta U(\phi_x)} \prod_{\{x,y\}\subset\Lambda} e^{\beta G_{xy}(\phi_x,\phi_y)}(\cdot), \tag{25}$$

where $\mathrm{d}\phi_x$ is the Lebesgue measure in $\mathbb{R}$ and the partition function Z_Λ is defined by

$$Z_\Lambda \equiv \int \prod_{\{x,y\}\subset\Lambda} e^{\beta G_{xy}(\phi_x,\phi_y)} \prod_{x\in\Lambda} \mathrm{d}\phi_x\, e^{-\beta U(\phi_x)}. \tag{26}$$

Here, $U(\phi)$ is a local polynomial function (on site potential) bounded from below and given by

$$U(\phi) = \frac{\lambda}{\beta}P(\phi) + \frac{J(0)}{2\beta}\phi^2 + \phi^2 + \frac{\lambda}{\beta}\sum_{i=1}^{c}\phi^{a_i+b_i}D_i(0), \tag{27}$$

with $J(0)\equiv J(\vec{x},\vec{x})$ and $D_i(0)\equiv D^{(i)}(\vec{x},\vec{x})$; we assume that $J(\vec{x},\vec{y})$ and $D^{(i)}(\vec{x},\vec{y})$ are translational invariant and $J(\vec{x},\vec{y}) = J(|\vec{y}-\vec{x}|)$, $D^{(i)}(\vec{x},\vec{y}) = D^{(i)}(|\vec{y}-\vec{x}|)$. The coupling term is given by

$$G_{xy}(\phi_x,\phi_y) = -\left[\frac{1}{\beta}J_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}}) - \delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\right]\frac{\phi_x\phi_y}{2} - \frac{\lambda}{\beta}\sum_{i=1}^{c} D^{(i)}_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})\phi_x^{a_i}\phi_y^{b_i}$$
$$= A^{(1)}_{xy}\phi_x\phi_y + \sum_{i=1}^{c} A^{(i+1)}_{xy}\phi_x^{a_i}\phi_y^{b_i} = \sum_{s=1}^{c+1} A^{(s)}_{xy}\phi_x^{a_{s-1}^{(1-\delta_{s,1})}}\phi_y^{b_{s-1}^{(1-\delta_{s,1})}}, \tag{28}$$

where we define $a_0\equiv 1$, $b_0\equiv 1$, and for $s=2,3,\ldots,(c+1)$.

$$A^{(1)}_{xy} \equiv -\frac{1}{2}\left[\frac{1}{\beta}J_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}}) - \delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\right], \quad A^{(s)}_{xy} \equiv -\frac{\lambda}{\beta}D^{(s-1)}_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}}). \tag{29}$$

Note that our problem involves, say, an unusual high temperature spin system, we have a nonlocal anharmonic potential and the interaction decay depends on the direction (polynomial in space, and short range in "time").

The two-point truncated function is given by

$$S_2(x;y) = \mu_\Lambda(\phi_x\phi_y) - \mu_\Lambda(\phi_x)\mu_\Lambda(\phi_y). \tag{30}$$

In the next section we will develop a polymer expansion for such model, which will permit us to show that $S_2(x;y)$ is analytic in β and admits upper and lower bounds uniform in Λ.

Now, let us state our main results.

Theorem 1: *The two-point truncated function $S_2(x;y)$, written as series in β, converges*

absolutely, uniformly in the volume $|\Lambda|$, *for* β, J_M *and* λ *small enough. Moreover,* $S_2(x;y)$ *has the following bounds:*

$$|S_2(x;y)| \leq C' e^{-m|x_0-y_0|-m_s|\vec{x}-\vec{y}|},$$

if $J_{\vec{x},\vec{y}}$ *and* $D^{(i)}_{\vec{x},\vec{y}}$ *are finite range (i.e., if* $\exists\, r>0$ *such that* $J_{\vec{x},\vec{y}}=0$ *for* $|\vec{x}-\vec{y}|>r$, *and the same for* $D^{(i)}_{\vec{x},\vec{y}}$, *where* C' *is a constant uniform in* β, J_M *and* $\lambda D^{(i)}_M$; *or*

$$|S_2(x;y)| \leq C'' e^{-m'|x_0-y_0|}\left(\frac{1-\delta_{\vec{x},\vec{y}}}{|\vec{x}-\vec{y}|^p}+\delta_{\vec{x},\vec{y}}\right),$$

if $J_{\vec{x},\vec{y}}$ *and* $D^{(i)}_{\vec{x},\vec{y}}$ *have polynomial decay, i.e., for* $\vec{x}\neq\vec{y}$, $J_{\vec{x},\vec{y}}\leq J/|\vec{x}-\vec{y}|^p$ *and* $D^{(i)}_{\vec{x},\vec{y}}\leq D_i/|\vec{x}-\vec{y}|^p$; *where* C'' *is a constant uniform in* β, J_M *and* $\lambda D^{(i)}_M$.

Remarks:

(1) The upper bound described in Theorem 1 shall give, essentially, the asymptotic behavior of the two-point truncated correlation. Namely, assuming that we still have lower bounds for the interactions, e.g., $J'/|\vec{x}-\vec{y}|^p \leq |J_{\vec{x},\vec{y}}| \leq J/|\vec{x}-\vec{y}|^p$ and $D'_i/|\vec{x}-\vec{y}|^p \leq |D^{(i)}_{\vec{x},\vec{y}}| \leq D_i/|\vec{x}-\vec{y}|^p$, $\vec{x}\neq\vec{y}$, it follows that we shall also obtain a lower bound for $S_2(x;y)$ involving $C'''/|\vec{x}-\vec{y}|^p$ (see, e.g., Ref. 13).

(2) The one-particle mass M is directly related to the "time" decay of S_2, i.e., $m'<M<\tilde{m}$, where m' is the term in upper bound above, and $\tilde{m}$ the similar one in a possible lower bound. A more precise estimate of M is possible by adopting standard techniques of constructive field theory, developed to study analyticity properties of one-particle irreducible Green's functions,[12] taking as input the cluster expansion developed here. We do not carry out these calculations here, but we go further on the mass spectrum and investigate the existence of two-particle bound states. To get the results, we analyze the "time" decay of the truncated four-point function in terms of a BS equation, and carry out the computation considering the BS kernel up to dominant order in β only (ladder approximation). The convergence of the cluster expansion (leading, e.g., to a convergent series in β for S_2, as described in Theorem 1) supports such a perturbative analysis. We emphasize that in some related spectral problems (e.g., Refs. 6,14,15), where a complete study has been established, the rigorous results show that the spectral properties (e.g., one-particle and two-particle bound state masses) are given as small corrections of those obtained by similar perturbative approximations. For clearness, we summarize these results on the two-particle bound states in the proposition below.

Proposition 1: Concerning the low-lying energy-momentum spectrum of the model, for the case of the interactions restricted to even functions of the spin variable ϕ, *for* β, J_M, *and* λ *small enough, considering the ladder approximation for the Bethe–Salpeter kernel, there is an isolated two-particle bound state with mass* $M^*=2M+\log(1-\zeta)$, *if* $\zeta>0$, *where* M *is the one-particle mass and* $\zeta=[\langle\phi^4\rangle-3\langle\phi^2\rangle]/[\langle\phi^4\rangle-\langle\phi^2\rangle]$, $\langle\cdot\rangle$ *is the expectation with respect to the single spin distribution* $d\nu(\phi)$ *(31).*

III. THE POLYMER EXPANSION

We now rewrite the expression for the partition function in terms of a polymer expansion. First we define the single spin distribution (SSD),

$$d\nu(\phi)=\frac{e^{-\beta U(\phi)}}{C(\lambda,\beta)}d\phi, \quad C(\lambda,\beta)=\int e^{-\beta U(\phi)}\,d\phi, \tag{31}$$

$d\nu(\phi)$ is a probability measure and (as usual) the partition function (26) can be rewritten as

$$Z_\Lambda = C^{|\Lambda|} \prod_{x\in\Lambda} \int \mathrm{d}\nu(\phi_x) \prod_{\{x,y\}\subset\Lambda} (e^{\beta G_{xy}(\phi_x,\phi_y)} - 1 + 1) = C^{|\Lambda|}\Xi_\Lambda, \tag{32}$$

with

$$\Xi_\Lambda = 1 + \sum_{n\geqslant 1} \frac{1}{n!} \sum_{\substack{R_1,\dots,R_n\subset\Lambda \\ R_i\cap R_j=\emptyset, |R_i|\geqslant 2}} \rho(R_1)\cdots\rho(R_n), \tag{33}$$

where $R_1,\dots,R_n\subset\Lambda$ is a collection of subsets of Λ with cardinality greater than 1, with associated activities $\rho(R)$ given by

$$\rho(R) = \prod_{x\in R} \int \mathrm{d}\nu(\phi_x) \sum_{g\in G_R} \prod_{\{x,y\}\subset\Lambda} (e^{\beta G_{xy}(\phi_x,\phi_y)} - 1), \tag{34}$$

where $\Sigma_{g\in G_R}$ is the sum over the connected graphs on the set R. Given a finite set A, we define a graph g in A as a collection $\{\gamma_1,\dots,\gamma_m\}$ of distinct pairs of A, i.e., $\gamma_i=\{x_i,y_i\}\subset A$ with $x_i\neq y_i$. A graph $g=\{\gamma_1,\dots,\gamma_m\}$ in A is connected if for any B,C of subsets of A such that $B\cup C=A$ and $B\cap C=\emptyset$, there is a $\gamma_i\in g$ such that $\gamma_i\cap B\neq\emptyset$ and $\gamma_i\cap C\neq\emptyset$. The pairs γ_i are called links of the graph. We denote by $|g|$ the number of links in g.

By standard arguments one can expand $\log\Xi_\Lambda$ as

$$\log\Xi_\Lambda = \sum_{n\geqslant 1} \frac{1}{n!} \sum_{\substack{R_1,\dots,R_n\subset\Lambda \\ |R_i|\geqslant 2}} \phi^T(R_1,\dots,R_n)\rho(R_1)\cdots\rho(R_n), \tag{35}$$

with

$$\phi^T(R_1,\dots,R_n) = \begin{cases} 1, & \text{if } n=1, \\ \displaystyle\sum_{\substack{f\in G_n \\ f\subset g(R_1,\dots,R_n)}} (-1)^{|f|}, & \text{if } n\geqslant 2 \text{ and } g(R_1,\dots,R_n)\in G_n, \\ 0, & \text{if } g(R_1,\dots,R_n)\notin G_n, \end{cases} \tag{36}$$

where G_n above denotes the set of the connected graphs on $\{1,\dots,n\}$, and $g(R_1,\dots,R_n)$ denotes the graph in $\{1,2,\dots,n\}$ which has the link $\{i,j\}$ if and only if $R_i\cap R_j\neq\emptyset$. The series (35) is known to converge absolutely, uniformly in Λ, if the activity $\rho(R)$ is sufficiently small,[16] e.g., if

$$\sup_{x\in\Lambda} \sum_{R\ni x} |\rho(R)| e^{a|R|} < a, \tag{37}$$

for some $a>0$. The two-point truncated correlation (30) can now be rewritten as

$$S_2(x_1;x_2) = \left.\frac{\partial^2}{\partial\alpha_1\,\partial\,\alpha_2} \log\tilde{\Xi}_\Lambda(\alpha_1,\alpha_2)\right|_{\alpha=0}, \tag{38}$$

where

$$\tilde{\Xi}_\Lambda(\alpha_1,\alpha_2) = \prod_{x\in\Lambda} \int \mathrm{d}\nu(\phi_x) e^{\beta G_{xy}(\phi_x,\phi_y)} (1+\alpha_1\phi_{x_1})(1+\alpha_2\phi_{x_2}). \tag{39}$$

Note that $\tilde{\Xi}_\Lambda(\alpha_1=0,\alpha_2=0)=\Xi_\Lambda$. Let us expand $\tilde{\Xi}_\Lambda(\alpha_1,\alpha_2)$ in terms of polymers. For any $R\subset\Lambda$, let us denote by I_R the subset (possibly empty) of $\{1, 2\}$ such that $i\in I_R$ iff $x_i\in R$, where $i=1, 2$. We get

$$\Xi_\Lambda(\alpha_1,\alpha_2) = 1 + \sum_{n\geqslant 1} \frac{1}{n!} \sum_{\substack{R_1,\dots R_n\subset\Lambda \\ R_i\cap R_j=\emptyset \mid R_i\mid\geqslant 1}} \tilde{\rho}(R_1,\alpha)\cdots\tilde{\rho}(R_n,\alpha), \tag{40}$$

where

$$\tilde{\rho}(R,\alpha) = \begin{cases} \displaystyle\prod_{x\in R}\int \mathrm{d}\nu(\phi_x)\prod_{i\in I_R}(1+\alpha_i\phi_{x_i})\sum_{g\in G_R}\prod_{\{x,y\}\in g}(e^{\beta G_{xy}(\phi_x,\phi_y)}-1) & \text{for } |R|\geqslant 2, \\ \displaystyle\prod_{x\in R}\int \mathrm{d}\nu(\phi_x)\prod_{i\in I_R}\alpha_i\phi_{x_i} & \text{for } I_R\neq\emptyset, |R|=1, \\ 0 \quad \text{for } I_R=\emptyset, |R|=1. \end{cases} \tag{41}$$

Note that the one-body polymers $R=\{x\}$ can also contribute to the partition function (40), but only if $x=x_i$ for some $i\in\{1,2\}$.

Taking the log of (40) and noting, from (38), that only the terms proportional to $\alpha_1\alpha_2$ give a nonvanishing contribution to the two-point truncated correlation function, we get

$$S_2(x_1;x_2) = \sum_{n\geqslant 1}\frac{1}{n!}\sum_{i_1,i_2=1}^{n}\sum_{\substack{R_1,\dots,R_n\subset\Lambda,|R_j|\geqslant 2 \\ R_{i_1}\ni x_1 R_{i_2}\ni x_2}} \phi^T(R_1,\dots,R_n)\tilde{\rho}(R_1)\cdots\tilde{\rho}(R_n), \tag{42}$$

where

$$\tilde{\rho}(R_i) = \prod_{x\in R_i}\int \mathrm{d}\nu(\phi_x)(\phi_{x_1}^{\beta_i^1}+\beta_i^1 l)(\phi_{x_2}^{\beta_i^2}+\beta_i^2 l)\sum_{g\in G_R}\prod_{\{x,y\}\in g}(e^{\beta G_{xy}(\phi_x,\phi_y)}-1), \tag{43}$$

with $\beta_i^j=0$ if $i\neq i_j$, or 1 if $i=i_j$ and $l=\int \mathrm{d}\nu(\phi)\phi$.

Note that the one-body polymers are absorbed in the activity of the many-body polymers (in the terms proportional to l), due to the fact that $R_1,\dots,R_n$ must be connected, and so each one-body polymer (if any) is always contained in (at least) one many-body polymer.

IV. CONVERGENCE OF THE POLYMER EXPANSION

We will treat in detail here the case where the pair potential $J_{\vec{x},\vec{y}}$ and $D^{(i)}_{\vec{x},\vec{y}}$ decays polynomially (the more complicated one). That is, we will assume that, $\forall i=1,2,\dots,c$, $\vec{x}\neq\vec{y}$,

$$J_{\vec{x},\vec{y}} \leqslant \frac{J}{|\vec{x}-\vec{y}|^p}, \quad D^{(i)}_{\vec{x},\vec{y}} \leqslant \frac{D_i}{|\vec{x}-\vec{y}|^p}, \tag{44}$$

$J, D_i\in\mathbb{R}$ are constants. We will treat the cases where $p\geqslant d+\varepsilon$ with $\varepsilon>0$.

The cases of $J_{\vec{x},\vec{y}}$ and $D^{(i)}_{\vec{x},\vec{y}}$ with finite range or with exponential decay are easier and can be treated in a similar way.

In order to ensure the convergence condition (37) we will bound the factor

$$\varepsilon_n(z,z') = \sum_{\substack{R\subset\Lambda:|R|=n \\ z,z'\in R}} |\rho(R)|, \tag{45}$$

and show that $\varepsilon_n(z,z')\leqslant[f(\beta,J,\lambda D_1,\dots,\lambda D_c)]^n$, where $f(\beta,J,\lambda D_1,\dots,\lambda D_c)\to 0$ as $\beta,J,\lambda D_1,\dots,\lambda D_c\to 0$.

In order to get an efficient bound for the factor

$$\sum_{g\in G_R}\prod_{\{x,y\}\subset\Lambda}(e^{\beta G_{xy}(\phi_x,\phi_y)}-1) \tag{46}$$

that appears in $\rho(R)$, we use a standard cluster expansion result, namely, the Brydges–Battle–Federbush tree graph inequality, which can be resumed in the following lemma.

Lemma 1: Let R be a finite set with cardinality $|R|$ *and let* $\{V_{xy}:\{x,y\}\in\mathbb{R}\}$ *a set with* $|R|(|R|-1)/2$ *real numbers (with* $\{x,y\}$ *unordered pair in R). Suppose now that there exist* $|R|$ *positive numbers* V_x *(with* $x\in R$ *such that, for any subset* $S\subset R$,

$$\sum_{x\in S}V_x+\sum_{\{x,y\}\in S}V_{xy}\geqslant 0. \tag{47}$$

Then

$$\left|\sum_{g\in G_R}\prod_{\{x,y\}\in g}(e^{-V_{xy}}-1)\right|\leqslant e^{\sum_{x\in R}V_x}\sum_{\tau\in T_R}\prod_{\{x,y\}\in\tau}|V_{xy}|, \tag{48}$$

where T_R *denotes the set of the tree graphs on R.*

For the proof of this lemma see, e.g., Refs. 17,18.

For any $\varphi,\phi\in\mathbb{R}$, we have $2|\varphi\phi|\leqslant|\varphi|^2+|\phi|^2$ and $|\varphi|^a|\phi|^b\leqslant|\varphi|^{a+b}+|\phi|^{a+b}$. Then, for any $R\subset\Lambda$, it follows that

$$\begin{aligned}\sum_{\{x,y\}\subset R}|G_{xy}(\phi_x,\phi_y)|&\leqslant\sum_{\{x,y\}\subset R}\left|\frac{1}{\beta}J_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})+\delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\right|\frac{|\phi_x\phi_y|}{2}+\sum_{i=1}^{c}\left|\frac{\lambda}{\beta}D^{(i)}_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1\right.\\&\left.-\delta_{\vec{x},\vec{y}})\right||\phi_x^{a_i}\phi_y^{b_i}|\leqslant\sum_{\{x,y\}\subset R}\left|\frac{1}{\beta}J_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})+\delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\right|\frac{1}{4}(|\phi_x|^2+|\phi_y|^2)\\&+\sum_{i=1}^{c}\left|\frac{\lambda}{\beta}D^{(i)}_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})\right|(|\phi_x|^{a_i+b_i}+|\phi_y|^{a_i+b_i})\\&\leqslant\sum_{x\in R}\frac{|\phi_x|^2}{2}\sum_{y\in R}\left|\frac{1}{\beta}J_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})+\delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\right|\\&+\sum_{i=1}^{c}\sum_{x\in R}|\phi_x|^{a_i+b_i}\sum_{y\in R}\left|\frac{2\lambda}{\beta}D^{(i)}_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})\right|.\end{aligned}$$

Note that

$$\sum_{y\in R}\delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\leqslant\sum_{y_0\in\mathbb{Z}}\delta_{|x_0-y_0|,1}\leqslant 2,$$

$$\sum_{y\in R}|J_{\vec{x},\vec{y}}|\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})\leqslant\sup_{\vec{x}\in\mathbb{Z}^d}\sum_{\vec{y}\in\mathbb{Z}^d}|J_{\vec{x},\vec{y}}|\leqslant J_M,$$

$$\sum_{y\in R}|D^{(i)}_{\vec{x},\vec{y}}|\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})\leqslant\sup_{\vec{x}\in\mathbb{Z}^d}\sum_{\vec{y}\in\mathbb{Z}^d}|D^{(i)}_{\vec{x},\vec{y}}|\leqslant D^{(i)}_M.$$

Hence,

$$\sum_{\{x,y\}\subset R}|G_{xy}(\phi_x,\phi_y)|\leqslant\sum_{x\in R}\left[\left(\frac{J_M}{2\beta}+1\right)|\phi_x|^2+\sum_{i=1}^{c}\frac{2\lambda D^{(i)}_M}{\beta}|\phi_x|^{a_i+b_i}\right].$$

As $|\phi|^2\leqslant|\phi|^{a_i+b_i}\leqslant|\phi|^{a_i+b_i}+1$ if $|\phi|\geqslant 1$ and $|\phi|^2\leqslant 1\leqslant|\phi|^{a_i+b_i}+1$ if $|\phi|\leqslant 1$ and, defining $(a,b)\equiv(a_j,b_j)$ for j such that $a_j+b_j=\max\{a_1+b_1,\ldots,a_c+b_c\}$, it follows that

$$\sum_{\{x,y\}\subset R} |G_{xy}(\phi_x,\phi_y)| \leqslant \sum_{x\in R} (C_1\phi_x^{a+b} + C_2),$$

where

$$C_1 \equiv \frac{J_M}{2\beta} + 1 + \sum_{i=1}^{c} \frac{2\lambda D_M^{(i)}}{\beta}, \quad C_2 \equiv \frac{J_M}{2\beta} + 1. \tag{49}$$

Using Lemma 1 we get

$$\left| \sum_{g\in G_R} \prod_{\{x,y\}\in g} (e^{\beta G_{xy}(\phi_x,\phi_y)} - 1) \right| \leqslant \prod_{x\in R} e^{\beta(C_1\phi_x^{a+b}+C_2)} \sum_{\tau\in T_R} \prod_{\{x,y\}\in\tau} |\beta G_{xy}(\phi_x,\phi_y)|, \tag{50}$$

and so,

$$\sum_{\substack{R\subset\Lambda:|R|\geqslant 2\\ z,z'\in R}} |\rho(R)|e^{|R|} = \sum_{n\geqslant 2} e^n \sum_{\substack{R\subset\Lambda:|R|=n\\ z,z'\in R}} |\rho(R)| = \sum_{n\geqslant 2} \frac{e^n}{(n-2)!} \sum_{\substack{x_1,\ldots,x_n\in\Lambda:\\ x_1=z,x_2=z',x_1\neq x_j}} |\rho(R=\{x_1,\ldots,x_n\})|$$

$$\leqslant \sum_{n\geqslant 2} \frac{e^n}{(n-2)!} \sum_{\substack{x_1,\ldots,x_n\in\Lambda:\\ x_1=z,x_2=z',x_i\neq x_j}} \int \prod_{i=1}^{n} \mathrm{d}\nu(\phi_{x_i}) e^{\beta(C_1\phi_{x_i}^{a+b}+C_2)} \sum_{\tau\in T_n} \prod_{\{i,j\}\in\tau} |\beta G_{x_iy_j}(\phi_{x_i}\phi_{x_j})|.$$

Recall now (28) and (29), and that $|\tau| = n-1$. Hence, fixing $\tau\in T_n$, we have

$$\prod_{\{i,j\}\in\tau} |G_{x_iy_j}(\phi_{x_i}\phi_{x_j})| \leqslant \prod_{\{i,j\}\in\tau} \sum_{s=1}^{c+1} |A_{x_ix_j}^{(s)}| |\phi_{x_i}^{a_{s-1}^{(1-\delta_{s,1})}}| |\phi_{x_j}^{b_{s-1}^{(1-\delta_{s,1})}}| \leqslant \sum_{\{i,j\}\in\tau} \sum_{s_{ij}=1}^{c+1} \prod_{k=1}^{n} |\phi_{x_k}|^{n_k(s)} \prod_{\{i,j\}\in\tau} |A_{x_ix_j}^{(s_{ij})}|,$$

where $n_k(s)$ depends on $a_1,\ldots,a_c$, $b_1,\ldots,b_c$ and on the sequence $\{s_{ij}\}_{\{i,j\}\in\tau}$. In any case, we have $d_k \leqslant n_k(s) \leqslant d_k \cdot \max\{a_1,\ldots,a_c,b_1,\ldots,b_c\} \leqslant md_k$, where $2m$ is the degree of the polynomial $P(\phi)$, and $\{d_k\}_{k=1}^n$ are the incidence indices of the tree $\tau\in T_n$, with $1\leqslant d_k\leqslant n-1$ and $\Sigma_{k=1}^n d_k = 2n-2$. Then

$$\sum_{\substack{R\subset\Lambda:|R|\geqslant 2\\ z,z'\in R}} |\rho(R)|e^{|R|} \leqslant \sum_{n\geqslant 2} \frac{e^n e^{n\beta C_2}\beta^{n-1}}{(n-2)!} \sum_{\substack{x_1,\ldots,x_n\in\Lambda:\\ x_1=z,x_2=z',x_i\neq x_j}} \int \prod_{i=1}^{n} \mathrm{d}\nu(\phi_{x_i}) e^{\beta C_1\phi_{x_i}^{a+b}}$$

$$\times \sum_{\tau\in T_n} \sum_{\{i,j\}\in\tau} \sum_{s_{ij}=1}^{c+1} \prod_{k=1}^{n} |\phi_{x_k}|^{n_k(s)} \prod_{\{i,j\}\in\tau} |A_{x_ix_j}^{(s_{ij})}| \leqslant \sum_{n\geqslant 2} \frac{e^n e^{n\beta C_2}\beta^{n-1}}{(n-2)!} \sum_{\substack{x_1,\ldots,x_n\in\Lambda:\\ x_1=z,x_2=z',x_i\neq x_j}}$$

$$\times \sum_{\tau\in T_n} \sum_{\{i,j\}\in\tau} \sum_{s_{ij}=1}^{c+1} \prod_{k=1}^{n} \left(\int \mathrm{d}\nu(\phi_{x_k}) e^{\beta C_1\phi_{x_k}^{a+b}} |\phi_{x_k}|^{n_k(s)} \right) \prod_{\{i,j\}\in\tau} |A_{x_ix_j}^{(s_{ij})}|.$$

Lemma 2: If $a\leqslant m$ and $b\leqslant m$, then $\forall\alpha>0$, $\alpha\in\mathbb{R}$, we have

$$\int \mathrm{d}\nu(\phi) e^{\beta C_1\phi^{a+b}} |\phi|^{\alpha} \leqslant \frac{e^{C_4-C_6} C_3^{1/2m}}{C_5^{(\alpha+1)/2m}} \left[\Gamma\left(\frac{1}{2m}\right) \right]^{-1} \Gamma\left(\frac{\alpha+1}{2m}\right),$$

where C_3, C_4, C_5, and *C_6 are constants such that, $\forall\phi\in\mathbb{R}$,*

$$\beta U(\phi) \leqslant C_3\phi^{2m} + C_4, \quad \beta U(\phi) - \beta C_1\phi^{a+b} \geqslant C_5\phi^{2m} + C_6.$$

Proof: As $P(\phi)$ is a polynomial of degree $2m$ bounded from below, there exist contants A_1, A_2, A_3, and A_4 (with A_1 and $A_3>0$) such that

$$A_1\phi^{2m} + A_2 \leqslant P(\phi) \leqslant A_3\phi^{2m} + A_4.$$

Then, as $\phi^2 \leqslant \phi^{a+b}+1$ and $\phi^{a_i+b_i} \leqslant \phi^{a+b} \leqslant \phi^{2m}$ since $a_i+b_i \leqslant a+b \leqslant 2m$, we obtain

$$\beta U(\phi) = \lambda P(\phi) + \frac{J(0)}{2}\phi^2 + \beta\phi^2 + \lambda\sum_{i=1}^{c} \phi^{a_i+b_i} D_i(0) \leqslant \lambda(A_3\phi^{2m} + A_4) + \frac{J(0)}{2}(\phi^{m2}+1) + \beta(\phi^{2m}+1)$$
$$+ \lambda\phi^{2m}\sum_{i=1}^{c} D_i(0) \leqslant C_3\phi^{2m} + C_4,$$

where

$$C_3 \equiv \lambda A_3 + \frac{J(0)}{2} + \beta + \lambda\sum_{i=1}^{c} D_i(0), \quad C_4 \equiv \lambda A_4 + \frac{J(0)}{2} + \beta + \lambda\sum_{i=1}^{c} D_i(0).$$

We also have

$$\beta U(\phi) - \beta C_1\phi^{a+b} = \lambda P(\phi) + \frac{J(0)}{2}\phi^2 + \beta\phi^2 + \lambda\sum_{i=1}^{c} \phi^{a_i+b_i} D_i(0) - \beta C_1\phi^{a+b} \geqslant \lambda(A_1\phi^{2m} + A_2)$$
$$+ \lambda\sum_{i=1}^{c} \phi^{a_i+b_i} D_i(0) - \beta C_1\phi^{a+b}.$$

If $a+b=2m$, we have

$$\beta U(\phi) - \beta C_1\phi^{a+b} \geqslant \left[\lambda A_1 - \beta C_1 + \lambda \sum_{i:a_i+b_i=2m}^{c} D_i(0)\right]\phi^{2m} + \lambda A_2 \geqslant C_5\phi^{2m} + C_6.$$

If $a+b<2m$, then $\phi^{a+b} \leqslant \phi^{2m}+1$ and it follows that

$$\beta U(\phi) - \beta C_1\phi^{a+b} \geqslant (\lambda A_1 - \beta C_1)\phi^{2m} + \lambda A_2 - \beta C_1 \geqslant C_5\phi^{2m} + C_6.$$

Hence, $C_5=\lambda A_1-\beta C_1+\lambda\Sigma^{c}_{i:a_i+b_i=2m}D_i(0)$ if $a+b=2m$, or $C_5=\lambda A_1-\beta C_1$ if $a+b<2m$. $C_6=\lambda A_2$ if $a+b=2m$, or $C_6=\lambda A_2-\beta C_1$ if $a+b<2m$. From the definition of the SSD $\mathrm{d}\nu(\phi)$, we have

$$\int \mathrm{d}\nu(\phi) e^{\beta C_1\phi^{a+b}} |\phi|^{\alpha} = \frac{1}{C(\lambda,\beta)} \int e^{-\beta U(\phi)} e^{\beta C_1\phi^{a+b}} |\phi|^{\alpha}\, \mathrm{d}\phi.$$

Hence,

$$C(\lambda,\beta) = \int_{\mathbb{R}} e^{-\beta U(\phi)}\, \mathrm{d}\phi \geqslant e^{-C_4}\int_{\mathbb{R}} e^{-C_3\phi^{2m}}\, \mathrm{d}\phi \geqslant e^{-C_4}\frac{1}{mC_3^{1/2m}}\Gamma\left(\frac{1}{2m}\right),$$

$$\int e^{-\beta U(\phi)} e^{\beta C_1\phi^{a+b}} |\phi|^{\alpha}\, \mathrm{d}\phi \leqslant e^{-C_6}\int_{\mathbb{R}} e^{-C_5\phi^{2m}} |\phi|^{\alpha}\, \mathrm{d}\phi \leqslant e^{-C_6}\frac{1}{mC_5^{(\alpha+1)/2m}}\Gamma\left(\frac{\alpha+1}{2m}\right),$$

where we used that $C_5>0$ for β small enough. Lemma 2 follows from these two bounds. ■

Recalling that $1 \leqslant d_k \leqslant n_k(s) \leqslant md_k$, we get $[n_k(s)+1]/2m \leqslant 2n_k(s)/2m \leqslant d_k$, and so, using Lemma 2, we obtain

$$\sum_{\substack{R\subset\Lambda:|R|\geqslant 2\\ z,z'\in R}}|\rho(R)|e^{|R|}\leqslant\sum_{n\geqslant 2}\frac{e^n e^{n\beta C_2}\beta^{n-1}}{(n-2)!}\sum_{\substack{x_1,\ldots,x_n\in\Lambda:\\ x_1=z,x_2=z',x_{i\neq}x_j}}\sum_{\tau\in T_n}\sum_{\{i,j\}\in\tau}\sum_{s_{ij}=1}^{c+1}$$

$$\times\prod_{k=1}^{n}\left\{\frac{e^{C_4-C_6}C_3^{1/2m}}{C_5^{d_k}}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-1}\Gamma(d_k)\right\}\prod_{\{i,j\}\in\tau}|A_{x_i x_j}^{(s_{ij})}|$$

$$\leqslant\sum_{n\geqslant 2}\frac{e^n e^{n\beta C_2}\beta^{n-1}}{(n-2)!}\frac{(e^{C_4-C_6}C_3^{1/2m})^n}{C_5^{2(n-1)}}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-n}\sum_{\tau\in T_n}\sum_{\{i,j\}\in\tau}\sum_{s_{ij}=1}^{c+1}$$

$$\times\prod_{k=1}^{n}\Gamma(d_k)\sum_{\substack{x_1,\ldots,x_n\in\Lambda:\\ x_1=z,x_2=z',x_i\neq x_j}}\prod_{\{i,j\}\in\tau}|A_{x_i x_j}^{(s_{ij})}|, \tag{51}$$

where we use that $\Pi_{k=1}^{n}C_5^{d_k}=C_5^{(d_1+d_2+\cdots+d_n)}=C_5^{2(n-1)}$.

We note that for any $\tau\in T_n$, there is a unique path $\overline{\tau}$ in τ which joins vertex 1 to vertex 2. Fixing $\tau\in T_n$, let $\overline{\tau}\equiv\{1,i_1\},\{i_1,i_2\},\{i_2,i_3\},\ldots,\{i_{k-1},i_k\},\{i_k,2\}$ and $I_\tau\equiv\{1,i_1,i_2,\ldots,i_k,2\}$ the subset of $\{1,2,3,\ldots,n\}$ whose elements are the vertices of the path $\overline{\tau}$. Hence, $|\tau|=n-1$, $|\overline{\tau}|=k+1$, and $|\tau\backslash\overline{\tau}|=n-k-2$.

From the definitions (29) of $|A_{xy}^{(s)}|:s=1,\ldots,(c+1)$, we see that all the terms vanish if $|x_0-y_0|>1$. Hence, fixing $\tau\in T_n$, if $\exists\{i,j\}\in\tau$ such that $|(x_i)_0-(x_j)_0|>1$ we have $|A_{x_i x_j}^{(s)}|=0\,\forall\, s=1,\ldots,(c+1)$, and so, this tree τ does not contribute to the sum (51). Then, given $|(x_1)_0-(x_2)_0|$, as $|\overline{\tau}|=k+1$, if $|(x_1)_0-(x_2)_0|>k+1$ then $\exists\{i,j\}\in\overline{\tau}$ such that $|(x_i)_0-(x_j)_0|>1$, and so, τ do not contribute to (51). As $\overline{\tau}\subset\tau$ we have $n-1\geqslant k+1$. Therefore, any tree $\tau\in T_n$ such that $|(x_1)_0-(x_2)_0|>n-1\geqslant k+1$ do not contribute to (51), in other words, $\rho(R)$ vanishes if $|(x_1)_0-(x_2)_0|>|R|-1$, i.e., if $|R|<|(x_1)_0-(x_2)_0|+1$.

So, we define $N\equiv|z_0-z'_0|+1$, and we have

$$\sum_{\substack{R\subset\Lambda:|R|\geqslant 2\\ z,z'\in R}}|\rho(R)|e^{|R|}\leqslant\sum_{\substack{R\subset\Lambda:|R|\geqslant N\\ z,z'\in R}}|\rho(R)|e^{|R|}. \tag{52}$$

Now, we note that

$$\delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\leqslant\delta_{\vec{x},\vec{y}}e^{-|x_0-y_0|+1},\quad \delta_{x_0,y_0}\leqslant e^{-|x_0-y_0|}.$$

Then,

$$|A_{xy}^{(1)}|=\frac{1}{2}\left|\frac{1}{\beta}J_{\vec{x},\vec{y}}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})-\delta_{\vec{x},\vec{y}}\delta_{|x_0-y_0|,1}\right|\leqslant\frac{e^{-|x_0-y_0|}}{2}\left[\frac{1}{\beta}\frac{J}{|\vec{x}-\vec{y}|^p}(1-\delta_{\vec{x},\vec{y}})+e\,\delta_{\vec{x},\vec{y}}\right],$$

$$|A_{xy}^{(s)}|=\left|\frac{\lambda}{\beta}D_{\vec{x},\vec{y}}^{(s-1)}\delta_{x_0,y_0}(1-\delta_{\vec{x},\vec{y}})\right|\leqslant\frac{\lambda D_{s-1}}{\beta|\vec{x}-\vec{y}|^p}(1-\delta_{\vec{x},\vec{y}})e^{-|x_0-y_0|}.$$

Hence, $\forall s=1,\ldots,(c+1)$,

$$|A_{xy}^{(s)}|\leqslant Ke^{-|x_0-y_0|}\left[\frac{1}{|\vec{x}-\vec{y}|^p}(1-d_{\vec{x},\vec{y}})+\frac{e}{2}\delta_{\vec{x},\vec{y}}\right]\leqslant eKe^{-|x_0-y_0|}\left[\frac{(1-\delta_{\vec{x},\vec{y}})}{|\vec{x}-\vec{y}|^p}+\delta_{\vec{x},\vec{y}}\right]\leqslant eKF_{xy}^{(1)},$$

$$\sup_{x\in\Lambda}\sum_{y\in\Lambda}|A_{xy}^{(s)}|\leqslant e\mathcal{O}(1)K,$$

where, we define

$$K \equiv \frac{1}{\beta}\max\left\{\frac{J}{2}, \lambda D_1, \lambda D_2 \ldots, \lambda D_c\right\}, \tag{53}$$

and, for $w \in \mathbb{R}$, $w > 0$,

$$F_{xy}^{(w)} \equiv e^{-w|x_0 - y_0|}\left[\frac{(1 - \delta_{\vec{x},\vec{y}})}{|\vec{x} - \vec{y}|^p} + \delta_{\vec{x},\vec{y}}\right].$$

Then, fixing $\tau \in T_n$ and the sequence $\{s_{ij}\}$, we get

$$\begin{aligned}
\sum_{\substack{x_1,\ldots,x_n \in \Lambda: \\ x_1 = z, x_2 = z', x_i \neq x_j}} \prod_{\{i,j\} \in \tau} |A_{x_i x_j}^{(s_{ij})}| &= \sum_{\substack{x_1,\ldots,x_n \in \Lambda: \\ x_1 = z, x_2 = z', x_i \neq x_j}} \prod_{\{i,j\} \in \tau \setminus \overline{\tau}} |A_{x_i x_j}^{(s_{ij})}| \prod_{\{i,j\} \in \overline{\tau}} |A_{x_i x_j}^{(s_{ij})}| \\
&\leqslant [e\mathcal{O}(1)K]^{(n-k-2)} \sum_{\substack{x_{i_1},\ldots,x_{i_k} \in \Lambda: \\ x_{i_r} \neq x_{i_q}\ \forall r,q = 1,\ldots,k}} \prod_{\{i,j\} \in \overline{\tau}} |A_{x_i x_j}^{(s_{ij})}| \\
&\leqslant [e\mathcal{O}(1)K]^{(n-k-2)} \sum_{\substack{x_{i_1},\ldots,x_{i_k} \in \Lambda: \\ x_{i_r} \neq x_{i_q}\ \forall r,q = 1,\ldots,k}} eKF_{x_1 x_{i_1}}^{(1)}\, eKF_{x_{i_1} x_{i_2}}^{(1)} \cdots eKF_{x_{i_{k-1}} x_{i_k}}^{(1)}\, eKF_{x_{i_k} x_2}^{(1)}.
\end{aligned}$$

Applying iteratively the inequality (for $w_1 < w_2$)

$$\sum_{\substack{x_i \in \Lambda: \\ x_i \neq x, y}} F_{x x_i}^{(w_1)} F_{x_i y}^{(w_2)} \leqslant \mathcal{O}(1) F_{xy}^{(w_1)}, \tag{54}$$

which follows from

$$\sum_{\substack{\vec{x}_i \in \mathbb{Z}^d: \\ \vec{x}_i \neq \vec{x}, \vec{y}}} \frac{1}{|\vec{x} - \vec{x}_i|^p} \frac{1}{|\vec{x}_i - \vec{y}|^p} \leqslant \frac{\mathcal{O}(1)}{|\vec{x} - \vec{y}|^p}, \qquad \sum_{\substack{z_0 \in \mathbb{R}: \\ z_0 \neq x_0, y_0}} e^{-w_1|x_0 - z_0|} e^{-w_2|z_0 - y_0|} \leqslant \mathcal{O}(1) e^{-w_1|x_0 - y_0|}$$

(the formula is valid for any $w_1 < w_2$, specific for $w_1 = 2/3$ and $w_2 = 1$, which we will take here), we get

$$\sum_{\substack{x_1,\ldots,x_n \in \Lambda: \\ x_1 = z, x_2 = z', x_i \neq x_j}} \prod_{\{i,j\} \in \tau} |A_{x_i x_j}^{(s_{ij})}| \leqslant [e\mathcal{O}(1)K]^{(n-1)} F_{zz'}^{(2/3)}. \tag{55}$$

Recall that

$$\sum_{\tau \in T_n} 1 = \sum_{\substack{d_1 + \cdots + d_n = 2n+2 \\ d_i \geqslant 1}} \sum_{\substack{\tau \in T_n: \\ \tau \approx (d1,\ldots,d_n)}} 1, \tag{56}$$

where the notation $\tau \approx (d_1, \ldots, d_n)$ means that the last sum above runs over the trees $\tau \in T_n$ that have fixed incidence indices $(d_1, \ldots, d_n)$. From the Cayley formula

$$\sum_{\substack{\tau \in T_n: \\ \approx (d1,\ldots,d_n)}} 1 = \frac{(n-2)!}{\prod_{i=1}^{n} (d_i - 1)!},$$

and, fixing $\tau \in T_n$, we have

$$\sum_{\{i,j\}\in\tau}\sum_{s_{ij}=1}^{c+1}1=(c+1)^{(n-1)}.$$

Hence, using (52), we get

$$\sum_{\substack{R\subset\Lambda:|R|\geqslant 2\\ z,z'\in R}}|\rho(R)|e^{|R|}\leqslant\sum_{n\geqslant N}\frac{e^n e^{n\beta C_2}\beta^{n-1}}{(n-2)!}\frac{(e^{C_4-C_6}C_3^{1/2m})^n}{C_5^{2(n-1)}}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-n}\times\sum_{\tau\in T_n}\sum_{\{i,j\}\in\tau}\sum_{s_{ij}=1}^{c+1}\prod_{k=1}^{n}\Gamma(d_k)$$

$$\times[e\mathcal{O}(1)K]^{(n-1)}F_{zz'}^{(2/3)}$$

$$\leqslant\sum_{n\geqslant N}\frac{e^n e^{n\beta C_2}\beta^{n-1}}{(n-2)!}\frac{(e^{C_4-C_6}C_3^{1/2m})^n}{C_5^{2(n-1)}}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-n}[e\mathcal{O}(1)K]^{(n-1)}\times F_{zz'}^{(2/3)}(c+1)^{(n-1)}\sum_{\substack{d_1+\cdots+d_n=2n+2\\ d_i\geqslant 1}}\prod_{k=1}^{n}(d_k-1)!\,\frac{(n-2)!}{\prod_{i=1}^{n}(d_i-1)!}$$

$$\leqslant\sum_{n\geqslant N}e^n e^{n\beta C_2}\beta^{n-1}\frac{(e^{C_4-C_6}C_3^{1/2m})^n}{C_5^{2(n-1)}}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-n}[e\mathcal{O}(1)K]^{(n-1)}F_{zz'}^{(2/3)}(c+1)^{(n-1)}4^n,$$

where we used the inequality

$$\sum_{\substack{d_1+\cdots+d_n=2n+2\\ d_i\geqslant 1}}1\leqslant 4^n.$$

Hence,

$$\sum_{\substack{R\subset\Lambda:|R|\geqslant 2\\ z,z'\in R}}|\rho(R)|e^{|R|}\leqslant e^N e^{N\beta C_2}\beta^N\frac{(e^{C_4-C_6}C_3^{1/2m})^N}{C_5^{2N}}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-N}[e\mathcal{O}(1)K]^N F_{zz'}^{(2/3)}$$

$$\times(c+1)^N 4^N\sum_{n\geqslant 0}\left\{e^2e^{\beta C_2}\beta\frac{(e^{C_4-C_6}C_3^{1/2m})}{C_5^2}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-1}\mathcal{O}(1)4(c+1)K\right\}^n.$$

In short, we have proved the following result.

Lemma 3: If β and $\beta K=\max\{J/2,\lambda D_1,\ldots,\lambda D_c\}$ are sufficiently small such that

$$\varepsilon(\beta,K)\equiv e^2e^{\beta C_2}4(c+1)\beta K\frac{(e^{C_4-C_6}C_3^{1/2m})}{C_5^2}\left[\Gamma\left(\frac{1}{2m}\right)\right]^{-1}\mathcal{O}(1)<1,$$

then, $\varepsilon(\beta,K)$ is a positive function and, for any $z\in\Lambda$, $z'\in\Lambda$ with $z\neq z'$,

$$\sum_{\substack{R\subset\Lambda:|R|\geqslant 2\\ z,z'\in R}}|\rho(R)|e^{|R|}\leqslant[\varepsilon(\beta,K)]^N F_{zz'}^{(2/3)}=[\varepsilon(\beta,K)]^{|z_0-z'_0|+1}F_{zz'}^{(2/3)}. \tag{57}$$

From Lemma 3, we obtain the following.

Corollary 4:

$$\sup_{x\in\mathbb{Z}^{d+1}}\sum_{R:x\in R}|\rho(R)|e^{|R|}\leqslant\mathcal{O}(1)\varepsilon(\beta,K).$$

Proof: In fact, as $\rho(R)=0$ if $|R|=1$, we have

$$\sup_{x\in\mathbb{Z}^{d+1}}\sum_{R:x\in R}|\rho(R)|e^{|R|}=\sup_{x\in\mathbb{Z}^{d+1}}\sum_{\substack{R:x\in R\\|R|\geqslant 2}}|\rho(R)|e^{|R|}\leqslant\sup_{x\in\mathbb{Z}^{d+1}}\sum_{\substack{z\in\mathbb{Z}^{d+1}:\\ z\neq x}}\sum_{\substack{R:|R|\geqslant 2\\ x,z\in R}}|\rho(R)|e^{|R|}$$

$$\leqslant\sup_{x\in\mathbb{Z}^{d+1}}\sum_{z\in\mathbb{Z}^{d+1}:z\neq x}[\varepsilon(\beta,K)]^{|x_0-z_0|+1}F_{xz}^{(2/3)}\leqslant\mathcal{O}(1)\varepsilon(\beta,K),$$

since, for $w>0$,

$$\sum_{z\in\mathbb{Z}^{d+1}:z\neq x}e^{-w|x_0-z_0|}\left[\frac{(1-\delta_{\vec{x},\vec{z}})}{|\vec{x}-\vec{z}|^p}+\delta_{\vec{x},\vec{z}}\right]=\mathcal{O}(1),$$

and so $\Sigma_{z\in\mathbb{Z}^{d+1}:z\neq x}F_{xz}^{(2/3)}\leqslant\mathcal{O}(1)$. ■

The results above establish the convergence of the cluster expansion for $\varepsilon(\beta,K)$ small enough such that $\mathcal{O}(1)\varepsilon(\beta,K)<1$ [see condition (37)].

V. DECAY OF TWO-POINT TRUNCATED CORRELATION

As it is well known, the convergence of the cluster expansion assures the decay of the correlation functions and lead to direct estimates. We present the main technical details related to the behavior of the truncated two-point function below.

Turning to the expression (43) which defines $\tilde{\rho}(R_i)$, we note that the index i of the term β_i^j is the same of the polymer R_i, and so $i\in\{1,2,3,\ldots,n\}$ as $j\in\{1,2\}$.

Consider the expression (30) for $S_2(x_1;x_2)$, and recall that $i_1,i_2\in\{1,2,3,\ldots,n\}$. Then, we have two distinct cases, $i_1=i_2$ or $i_1\neq i_2$. If $i_1=i_2$, then $\{x_1,x_2\}\subset R_{i_1}$, $\{x_1,x_2\}\cap R_i=\emptyset\ \forall i\neq i_1$ and $\beta_{i_1}^1=\beta_{i_1}^1=\beta_{i_2}^2=\beta_{i_2}^2=1$. If $i_1\neq i_2$, then $x_1\in R_{i_1}$, $x_1\notin R_{i_2}$, $x_2\in R_{i_2}$, $x_2\notin R_{i_1}$, $\{x_1,x_2\}\cap R_i=\emptyset\ \forall i\notin\{i_1,i_2\}$, $\beta_{i_1}^1=\beta_{i_2}^2=1$, and $\beta_{i_1}^2=\beta_{i_2}^1=0$.

Hence, as $1=(1-\delta_{i_1,i_2})+\delta_{i_1,i_2}$ we rewrite

$$S_2(x_1;x_2)=A_1(x_1,x_2)+A_2(x_1,x_2),$$

where

$$A_1(x_1,x_2)\equiv\sum_{n\geqslant 1}\frac{1}{n!}\sum_{i_1,i_2=1}^{n}(1-\delta_{i_1,i_2})\sum_{\substack{R_1,\ldots,R_n\subset\Lambda,|R_j|\geqslant 2\\ R_{i_1}\ni x_1 R_{i_2}\ni x_2}}\phi^T(R_1,\ldots,R_n)\tilde{\rho}(R_1)\cdots\tilde{\rho}(R_n)$$

$$=\sum_{n\geqslant 2}\frac{1}{(n-2)!}\sum_{\substack{R_1,\ldots,R_n\subset\Lambda,|R_j|\geqslant 2\\ R_1\ni x_1 R_2\ni x_2}}\phi^T(R_1,\ldots,R_n)\tilde{\rho}(R_1)\cdots\tilde{\rho}(R_n),$$

$$A_2(x_1,x_2)\equiv\sum_{n\geqslant 1}\frac{1}{n!}\sum_{i_1,i_2=1}^{n}\delta_{i_1,i_2}\sum_{\substack{R_1,\ldots,R_n\subset\Lambda,|R_j|\geqslant 2\\ R_{i_1}\ni x_1 R_{i_2}\ni x_2}}\phi^T(R_1,\ldots,R_n)\tilde{\rho}(R_1)\cdots\tilde{\rho}(R_n)$$

$$=\sum_{n\geqslant 1}\frac{1}{(n-1)!}\sum_{\substack{R_1,\ldots,R_n\subset\Lambda,|R_j|\geqslant 2\\ R_1\supset\{x_1,x_2\}}}\phi^T(R_1,\ldots,R_n)\tilde{\rho}(R_1)\cdots\tilde{\rho}(R_n),$$

since, in $A_1(x_1,x_2)$ when $n=1$ we have $\Sigma_{i_1,i_2=1}^1(1-\delta_{i_1,i_2})=0$ and, for any $n>2$ the sum $\Sigma_{i_1,i_2=1}^n(1-\delta_{i_1,i_2})$ leads to $n(n-1)$ equal terms. And, in $A_2(x_1,x_2)$ the sum $\Sigma_{i_1,i_2=1}^n\delta_{i_1,i_2}$ gives n equal terms.

Thus,

$$|S_2(x_1;x_2)|\leqslant|A_1(x_1,x_2)|+|A_2(x_1,x_2)|.$$

Comparing (34) and (43), we note that if $R_i \cap \{x_1, x_2\} = \emptyset$ then $\tilde{\rho}(R_i) = \rho(R_i)$. If $R_i \cap \{x_1, x_2\} \neq \emptyset$, we can obtain the result (57) of Lemma 3 for $\tilde{\rho}(R_i)$ by changing $n_k(s)$ by $n_k(s)+1$. With such result, we change $\Gamma(d_k)$ by $\Gamma(d_k+1)$ in (51) and obtain an extra $\Pi_{k=1}^{n} d_k$, which is bounded by $e^{2(n-1)}$. We use Lemma 2 to bound the factor $l = \int \mathrm{d}\nu(\phi)\phi$ in (43). Hence, we can apply Lemma 3 and Corollary 4 to estimate $\tilde{\rho}(R_i)$ (changing some multiplicative constants).

Now, let us find an upper bound for the term $|A_1(x_1, x_2)|$. We have

$$|A_1(x_1,x_2)| \leqslant \sum_{n \geqslant 2} \frac{1}{(n-2)!} B_n(x_1,x_2),$$

where

$$B_n(x_1,x_2) = \sum_{\substack{R_1,\ldots,R_n \subset \Lambda \\ |R_i| \geqslant 2, x_1 \in R_1, x_2 \in R_2}} |\phi^T(R_1,R_2,\ldots,R_n)| \tilde{\rho}(R_1) \| \tilde{\rho}(R_2) \| \tilde{\rho}(R_3) \cdots \tilde{\rho}(R_n)|.$$

Note that in (36), for $n \geqslant 2$, $\phi^T(R_1,\ldots,R_n) > 0$ only if $g(R_1,\ldots,R_n) \in G_n$. Thus,

$$\sum_{\substack{R_1,\ldots,R_n \subset \Lambda \\ |R_i| \geqslant 2, x_1 \in R_1, x_2 \in R_2}} |\phi^T(R_1,R_2,\ldots,R_n)|[\cdot] = \sum_{g \in G_n} \left| \sum_{\substack{f \in G_n \\ \subset g}} (-1)^{|f|} \right| \sum_{\substack{R_1,\ldots,R_n \subset \Lambda : |R_i| \geqslant 2 \\ g(R_1,\ldots,R_n) = g, x_1 \in R_1, x_2 \in R_2}} [\cdot].$$

By the Rota formula,[19] we have

$$\left| \sum_{\substack{f \in G_n \\ f \subset g}} (-1)^{|f|} \right| \leqslant \sum_{\tau \in T_n : \tau \subset g} 1 \equiv N(g).$$

A proof of the Rota formula above can be found, e.g., in Refs. 19 and 20.

We recall now that

$$\sum_{g \in G_n} [\cdot] = \sum_{\tau \in T_n} \sum_{g : \tau \subset g} \frac{1}{N(g)} [\cdot],$$

since in the double sum $\Sigma_\tau \Sigma_{g \supset t}$ each g will be repeated exactly $N(g)$ times.

Thus,

$$B_n(x_1,x_2) \leqslant \sum_{\tau \in T_n} w_n(\tau, x_1, x_2),$$

where we have defined

$$w_n(\tau,x_1,x_2) \equiv \sum_{\substack{R_1,\ldots,R_n \subset \Lambda : |R_i| \geqslant 2 \\ g(R_1,R_2,\ldots,R_n) \supset \tau, x_1 \in R_1, x_2 \in R_2}} |\tilde{\rho}(R_1)\| \tilde{\rho}(R_2)\| \tilde{\rho}(R_3) \cdots \tilde{\rho}(R_n)|.$$

Using now the obvious bound

$$\sum_{R : R \cap R' \neq \emptyset} |\cdot| \leqslant |R'| \sup_{x \in R'} \sum_{R : x \in R} |\cdot|,$$

and denoting again as $\overline{\tau}$ the subtree of τ which is the unique path joining vertex 1 to vertex 2, and denoting as $I_\tau = \{1, i_1, \ldots, i_k, 2\}$ the ordered set of the vertices of $\overline{\tau}$, one can easily check that

$$w_n(\tau,x_1,x_2) \leqslant \prod_{i\notin I_\tau}\left[\sup_{x\in Z^d}\sum_{R_i:x\in R_i}|R_i|^{d_i-1}|\tilde{\rho}(R_i)|\right]$$
$$\times \sum_{\substack{R_1,R_{i_1},\dots,R_{i_k},R_2:x_1\in R_1,x_2\in R_2\\ R_1\cap R_{i_1}\neq\emptyset,\dots R_{i_k}\cap R_2\neq\emptyset}} |R_1|^{d_1-1}|\tilde{\rho}(R_1)||R_2|^{d_2-1}|\tilde{\rho}(R_2)|\prod_{\substack{i\in I_\tau\\ i\neq 1,2}}^{n}|R_i|^{d_i-2}|\tilde{\rho}(R_i)|$$
$$\leqslant \prod_{i\notin I_\tau}\left[\sup_{x\in Z^d}\sum_{R_i:x\in R_i}(d_i-1)!\,|\tilde{\rho}(R_i)|e^{|R_i|}\right](d_1-1)!\,(d_2-1)!$$
$$\times \sum_{\substack{R_1,R_{i_1},\dots,R_{i_k},R_2:x_1\in R_1,x_2\in R_2\\ R_1\cap R_{i_1}\neq\emptyset,\dots,R_{i_k}\cap R_2\neq\emptyset}} |\tilde{\rho}(R_1)|e^{|R_1|}|\tilde{\rho}(R_2)|e^{|R_2|}\prod_{\substack{i\in I_\tau\\ i\neq 1,2}}(d_i-2)!\,|\tilde{\rho}(R_i)|e^{|R_i|},$$

since $|R|^n\leqslant n!\,e^{|R|}$. Now, note that

$$\sum_{\substack{R_1,R_{i_1},\dots,R_{i_k},R_2:x_1\in R_1,x_2\in R_2\\ R_1\cap R_{i_1}\neq\emptyset,\dots,R_{i_k}\cap R_2\neq\emptyset}} \leqslant \sum_{x_{i_0}\in Z^d}\sum_{x_{i_1}\in Z^d}\cdots\sum_{x_{i_k}\in Z^d}\sum_{\substack{R_1\\ x_1,x_{i_0}\in R_1}}\sum_{\substack{R_{i_1}\\ x_{i_0},x_{i_1}\in R_{i_1}}}\cdots\sum_{\substack{R_{i_k}\\ x_{i_{k-1}},x_{i_k}\in R_{i_k}}}\sum_{\substack{R_2\\ x_{i_k},x_2\in R_2}}.$$

Hence, recalling (57) and applying iteratively the inequality (54) with $w_1=1/2$ and $w_2=2/3$,

$$\sum_{\substack{R_1,R_{i_1},\dots,R_{i_k},R_2:x_1\in R_1,x_2\in R_2\\ R_1\cap R_{i_1}\neq\emptyset,\dots,R_{i_k}\cap R_2\neq\emptyset}} |\tilde{\rho}(R_1)|e^{|R_1|}|\tilde{\rho}(R_2)|e^{|R_2|}\prod_{i\in I_\tau}|\tilde{\rho}(R_i)|e^{|R_i|}$$
$$\leqslant \sum_{x_{i_0}\in Z^d}\sum_{x_{i_1}\in Z^d}\cdots\sum_{x_{i_k}\in Z^d}[\varepsilon(\beta,K)]^{|(x_1)_0-(x_{i_0})_0|+1}F^{(2/3)}_{x_1x_{i_0}}\cdots[\varepsilon(\beta,K)]^{|(x_{i_k})_0-(x_2)_0|+1}F^{(2/3)}_{x_{i_k}x_2}$$
$$\leqslant [\mathcal{O}(1)]^{k+1}[\varepsilon(\beta,K)]^{|(x_1)_0-(x_2)_0|+(k+2)}F^{(1/2)}_{x_1x_2},$$

since $\varepsilon(\beta,K)<1$ and $|(x_1)_0-(x_2)_0|\leqslant|(x_1)_0-(x_{i_0})_0|+|(x_{i_0})_0-(x_{i_1})_0|+\cdots+|(x_{i_k})_0-(x_2)_0|$.

Thus, using Corollary 4 and noting that $|\{1,\dots,n\}\backslash I_\tau|=n-k-2$,

$$w_n(\tau,x_1,x_2)\leqslant(d_1-1)!\,(d_2-1)!\left[\prod_{i\notin I_\tau}^{n}\sup_{x\in Z^d}\sum_{R_i:x\in R_i}(d_i-1)!\,|\rho(R_i)|e^{|R_i|}\right]$$
$$\times\left[\prod_{\substack{i\in I_\tau\\ i\neq 1,2}}^{n}(d_i-2)!\right][\varepsilon(\beta,K)]^{|(x_1)_0-(x_2)_0|+(k+2)}[\mathcal{O}(1)]^{k+1}F^{(1/2)}_{x_1x_2}$$
$$\leqslant[\mathcal{O}(1)]^n[\varepsilon(\beta,K)]^{|(x_1)_0-(x_2)_0|+n}F^{(1/2)}_{x_1x_2}\prod_{i=1}^{n}(d_i-1)!\,.$$

Finally, carrying out the sum over τ (and using, once again, the Cayley formula) we obtain

$$B_n(x_1,x_2)\leqslant(n-2)!\,[4\mathcal{O}(1)]^n[\varepsilon(\beta,K)]^{|(x_1)_0-(x_2)_0|+n}F^{(1/2)}_{x_1x_2}.$$

Taking β,K small enough to make $4\mathcal{O}(1)\varepsilon(\beta,K)<1$, for the contribution of A_1 to the correlations, we get the following bound:

$$|A_1(x_1,x_2)|\leqslant\sum_{n\geqslant 2}[4\mathcal{O}(1)]^n[\varepsilon(\beta,K)]^{|(x_1)_0-(x_2)_0|+n}F^{(1/2)}_{x_1x_2}\leqslant\mathcal{O}(1)[\varepsilon(\beta,K)]^{|(x_1)_0-(x_2)_0|+2}F^{(1/2)}_{x_1x_2}.$$

In a similar and much easier way one can also prove a completely analogous bound for $|A_2(x_1,x_2)|$,

$$|A_2(x_1,x_2)| \leqslant \mathcal{O}(1)[\varepsilon(\beta,K)]^{|(x_1)_0-(x_2)_0|+1} F^{(1/2)}_{x_1x_2}.$$

Hence,

$$|S_2(x;y)| \leqslant \mathcal{O}(1)[\varepsilon(\beta,K)]^{|x_0-y_0|} F^{(1/2)}_{xy} \leqslant \mathcal{O}(1)[\varepsilon(\beta,K)]^{|x_0-y_0|} e^{-|x_0-y_0|/2}\left(\frac{1-\delta_{\vec{x},\vec{y}}}{|\vec{x}-\vec{y}|^p}+\delta_{\vec{x},\vec{y}}\right)$$

$$\leqslant \mathcal{O}(1) e^{-m'(\beta,K)|x_0-y_0|}\left(\frac{1-\delta_{\vec{x},\vec{y}}}{|\vec{x}-\vec{y}|^p}+\delta_{\vec{x},\vec{y}}\right),$$

where, since $\varepsilon(\beta,K)<1$, we write above

$$m'(\beta,K) \equiv -\log\{\varepsilon(\beta,K)\} + 1/2 > 0.$$

These results prove part 2 of Theorem 1 (the part 1 is a simpler case and may be proved in a similar way).

A lower bound can be obtained, as said, by analogous procedures (see, e.g., Ref. 13).

VI. FOUR-POINT TRUNCATED CORRELATION

Now we analyze the "time" decay of the partially truncated four-point function in order to determine the mass spectrum in the interval $(M,2M)$, where M is the one-particle mass. In this section, we restrict the interaction to even function of the spin variable ϕ.

We use the BS equation, and omit several technical details (related to those presented, e.g., in Ref. 6). The computation is carried out in a perturbative approach, we keep only the dominant term in a β expansion of the BS kernel.

Roughly, we show that, for the model considered here, in the intense noise regime $\beta \ll 1$, if the polynomial $U(\phi)$ is such that $\langle\phi^4\rangle > 3\langle\phi^2\rangle^2$, where $\langle\cdot\rangle$ is the expectation with respect to the single spin distribution $\mathrm{d}\nu(\phi)$ (31), there is an isolated two-particle bound state with mass $M^*=2M+\log(1-\zeta)+\mathcal{O}(\beta)$, where $\zeta=[\langle\phi^4\rangle-3\langle\phi^2\rangle]/[\langle\phi^4\rangle-\langle\phi^2\rangle]$.

Sketch of the proof: We use the BS equation which writes the truncated four-point function $D(x_1,x_2;x_3,x_4)=S_4(x_1,x_2,x_3,x_4)-S_2(x_1,x_2)S_2(x_3,x_4)$ as

$$D(x_1,x_2;x_3,x_4) = D_0(x_1,x_2;x_3,x_4) + \sum_{y_1,y_2,y_3,y_4} D(x_1,x_2;y_1,y_2)K(y_1,y_2;y_3;y_4)D_0(y_3,y_4;x_3,x_4),$$

where $D_0(x_1,x_2;x_3,x_4) \equiv S_2(x_1,x_3)S_2(x_2,x_4)+S_2(x_1,x_4)S_2(x_2,x_3)$.

Due to translation invariance, D depends only on difference variable, i.e., $D=D(\xi,\eta,\tau)$, where here we take $\xi=x_2-x_1$, $\eta=x_4-x_3$, and $\tau=x_3-x_2$. Using p,q, and k, the conjugate variable (the Fourier transform) of ξ,η,τ, the BS equation becomes

$$\tilde{D}(p,q,k) = \tilde{D}_0(p,q,k) + \frac{1}{(2\pi)^{2(d+1)}}\int_{T^{d+1}} \mathrm{d}^{d+1}p'\,\mathrm{d}^{d+1}q'\,\tilde{D}(p,p',k)\tilde{K}(p',q',k)\tilde{D}_0(q',q,k),$$

or using the notation $(\tilde{D}(k)f)(p) \equiv \int_{T^{d+1}} \mathrm{d}^{d+1}q\ \tilde{D}(p,q,k)f(q)$,

$$\tilde{D}(k) = \tilde{D}_0(k) + \frac{1}{(2\pi)^{2(d+1)}}\tilde{D}(k)\tilde{K}(k)\tilde{D}_0(k) = \tilde{D}_0(k)[1-(2\pi)^{-2(d+1)}\tilde{K}(k)\tilde{D}_0(k)]^{-1}.$$

We restrict the analysis to the mass spectrum, i.e., we take $k=(k_0,\vec{k}=\vec{0})$, and consider $f(p)$ depending only on $\vec{p}$. From the definition of D_0, we get

$$\tilde{D}_0(p,q,k) = (2\pi)^{d+1}[\tilde{S}_2(p)\tilde{S}_2(q)\,\delta(k-p-q) + \tilde{S}_2(p)\tilde{S}_2(k-p)\,\delta(q-p)]. \tag{58}$$

Hence, $(\tilde{D}_0(k_0)f)(p) = (2\pi)^{d+1}\tilde{S}_2(p)\tilde{S}_2(k-p)[f(\vec{p})+f(-\vec{p})]$. For $f(\vec{p})=f(-\vec{p})$, we obtain

$$(\tilde{f},\tilde{D}(k_0)\tilde{f}) = \int \tilde{f}(\vec{p})\left\{2(2\pi)^{d+1}\int \mathrm{d}p_0\, \tilde{S}_2(p)\tilde{S}_2(k_0-p_0,-\vec{p})\right\} \times \left(\left[1-\frac{1}{(2\pi)^{2(d+1)}}\tilde{K}(k_0)\tilde{D}_0(k_0)\right]^{-1}\tilde{f}\right) \times(\vec{p})\mathrm{d}^d p. \tag{59}$$

As $\{\cdots\}(k_0,\vec{p})$ above is analytic in $|\mathrm{Im}\, k_0|<2M$, the singularities in such region come from where the inverse of $1-(2\pi)^{-2(d+1)}\tilde{K}(k_0)\tilde{D}_0(k_0)$ does not exist.

Now we follow replacing $\tilde{K}$ by the leading term in the perturbation expansion (in terms of β), which is named ladder approximation. We remark (once more time), as a comment on the reliability of such procedure, that in Refs. 6,14 and 15 a rigorous analysis (in similar "field theory") shows that the spectral properties calculated in the ladder approximation are maintained.

Using $K=D_0^{-1}-D^{-1}$ we obtain

$$\tilde{K}(p,q,k)_{\mathcal{O}(\beta=0)} = \frac{\langle\phi^4\rangle-3\langle\phi^2\rangle^2}{2\langle\phi^2\rangle^2[\langle\phi^4\rangle-\langle\phi^2\rangle^2]} = R, \tag{60}$$

i.e., constant (not depending on β), local in space and time. Writing $[1-A]^{-1}=1+[1-A]^{-1}A$ we get

$$(\tilde{f},\tilde{D}_0(k_0)\tilde{f}) = \int \overline{\tilde{f}}(\vec{p})\tilde{D}_0(p,q,k_0)\tilde{f}(\vec{q})\mathrm{d}p\ \mathrm{d}q + \frac{R'}{1-R'I_D}\left(\int \overline{\tilde{f}}(\vec{p})\tilde{D}_0(p,q,k_0)\mathrm{d}p\ \mathrm{d}q\right) \times\left(\int \tilde{D}_0(p',q',k_0)\tilde{f}(\vec{q}')\mathrm{d}p'\ \mathrm{d}q\right), \tag{61}$$

where $\mathrm{d}p\equiv\mathrm{d}^{d+1}p$, etc., $R'=R/(2\pi)^{2(d+1)}$ and

$$I_D = \int \mathrm{d}q'\ \mathrm{d}q\ \tilde{D}_0(q',q,k_0) = 2(2\pi)^{d+1}\int \mathrm{d}p\ \tilde{S}_2(p)\tilde{S}_2(k_0-p_0,-\vec{p}).$$

Thus, the singularity, and so the bound state, comes for $R'I_D=1$. We follow the calculations separating in the expression for $\tilde{S}_2(p)$ the dominant one-particle contribution (as usual, we take the Lehmann spectral representation, see, e.g., Refs. 6 and 12),

$$\tilde{S}_2(p) = (2\pi)^d\tilde{c}_2(\vec{p})\frac{\sinh M(\vec{p})}{\cosh M(\vec{p})-\cos p_0} + \int_{3M-\varepsilon}^{\infty}\frac{\sinh E}{\cosh E-\cos p_0}\mathrm{d}\eta(E,\vec{p}),$$

where $\tilde{c}_2(\vec{p})=\partial\tilde{\Gamma}(p_0=i\xi,\vec{p})/\partial\xi|_{\xi=M(\vec{p})}$. We have, for the (first) dominant term, $\tilde{c}_2(\vec{p})=[\langle\phi^2\rangle/(2\pi)^d]+\mathcal{O}(\beta)$. Thus, for the computation of (the leading part of) I_D we use $\tilde{S}_2(p)=\langle\phi^2\rangle\times\{\sinh M(\vec{p})/[\cosh M(\vec{p})-\cos p_0]\}$. Hence,

$$I_D = 2(2\pi)^{d+1}\int \mathrm{d}p\langle\phi^2\rangle^2\frac{(e^{M(\vec{p})}-e^{-M(\vec{p})})^2}{(e^{M(\vec{p})}+e^{-M(\vec{p})}-e^{ip_0}-e^{-ip_0})(e^{M(\vec{p})}+e^{-M(\vec{p})}-e^{ik_0-ip_0}-e^{-ik_0+ip_0})}.$$

Writing $ik_0=2M-\varepsilon$, we get (taking the leading term $\beta=0$) $I_D=2(2\pi)^{2(d+1)}\langle\phi^2\rangle^2/(1-e^{-\varepsilon})$. And for the eigenvalue equation $R'I_D=1$ we obtain

$$1-e^{-\varepsilon} = \frac{\langle\phi^4\rangle-3\langle\phi^2\rangle^2}{\langle\phi^4\rangle-\langle\phi^2\rangle^2} \equiv \zeta, \tag{62}$$

which leads, if $\zeta>0$, to the bound state mass

$$M^* = 2M+\ln(1-\zeta). \tag{63}$$

■

We have the same bound state mass expression of Ref. 15, calculated there for a ferromagnetic system with continuous spin, nearest neighbor interaction, and even single spin distribution.

As a final comment, let us say that we expect to apply the techniques presented here in the analysis of the correlation functions of other stochastic dynamical systems, such as those described by an anharmonic chain of oscillators, with conservative dynamics and different stochastic reservoirs[21] (in our case, for the intense noise, i.e., "high temperature" regime).

We study the dynamics of a quantum particle moving in a plane under the influence of a constant magnetic field and driven by a slowly time-dependent singular flux tube through a puncture. The known standard adiabatic results do not cover directly these models as the Hamiltonian has time-dependent domain. We give a meaning to the propagator and prove an adiabatic theorem. To this end we introduce and develop the new notion of a propagator weakly associated to a time-dependent Hamiltonian. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1895865]

I. INTRODUCTION

The model under consideration originates from Laughlin's[12] and Halperin's[9] discussion of the integer quantum Hall effect. In the mathematical physics literature Bellissard *et al.*[5] and Avron *et al.*[3] used an adiabatic limit of the model (with additional randomness) to introduce indices. The indices explain the quantization of charge transport observed in the experiments.[14]

In this paper we discuss some mathematical aspects of the existence of the propagator and the validity of the adiabatic approximation and propose how to overcome the difficulties originating from the strong singularity of the external field.

Let us specify the model, summarize our results and introduce the notation. The configuration space is $\mathbb{R}^2\backslash\{(0,0)\}$ and the model is considered in polar coordinates (r,θ). The vector potential A is the sum of a part for the homogeneous magnetic field of strength $B>0$,

$$\frac{B}{2}(x_1\,\mathrm{d}x_2 - x_2\,\mathrm{d}x_1) = \frac{Br^2}{2}\mathrm{d}\theta,$$

plus a part describing the flux Φ which varies in time,

$$\frac{\Phi}{2\pi}\frac{1}{|\vec{x}|^2}(x_1\,\mathrm{d}x_2 - x_2\,\mathrm{d}x_1) = \frac{\Phi}{2\pi}\mathrm{d}\theta;$$

the real-valued function Φ is assumed to be monotonous and C^2. With the metric coefficients $g_{11}=1$, $g_{22}=r^2$, $g_{12}=0$, the differential expression of the Hamiltonian acting in $L^2(\mathbb{R}_+\times[0,2\pi[,r\,\mathrm{d}r\,\mathrm{d}\theta)$ is

$$\frac{1}{2m}\left(-i\hbar\partial_j - \frac{e}{c}A_j\right)\sqrt{g}g^{jk}\left(-i\hbar\partial_k - \frac{e}{c}A_k\right) = \frac{\hbar^2}{2m}\left(-\frac{1}{r}\partial_r r\partial_r + \frac{1}{r^2}\left(-i\partial_\theta - \frac{e}{\hbar c}\frac{Br^2}{2} - \frac{e}{hc}\Phi\right)^2\right).$$

Our purpose is to study the response of the system if flux quanta hc/e are added adiabatically, i.e., the flux function is of the form $t\mapsto\Phi(t/\tau)$ with the time t varying in $[0,\tau]$ for some $\tau\gg 1$.

In a first step we analyze the case when Φ is linear. Furthermore, we fix an angular momentum sector defined by $-i\partial_\theta e^{im\theta}=me^{im\theta}$ ($m\in\mathbb{Z}$), and use a slow time s, i.e., the substitution $s=-m+e/(hc)\Phi(t/\tau)$. Also we are not interested here in keeping track of the behavior in the physical parameters e, $\hbar$, c, $2m$, so we set them all equal to one. This is our motivation to consider the operator

$$H(s)=-\frac{1}{r}\partial_r r\partial_r+\frac{1}{r^2}\left(s+\frac{Br^2}{2}\right)^2 \quad \text{in } L^2(\mathbb{R}_+,r\,\mathrm{d}r). \tag{1}$$

In a second step we shall then show that our analysis generalizes to Hamiltonians of the form $H(\zeta(s))$ where $\zeta\in C^2$ is a monotone function.

$H(s)$ is essentially self-adjoint on $C_0^\infty(]0,\infty[)$ iff $s^2\geqslant 1$.[13] For $0<s^2<1$ we impose the regular boundary condition as $r\to 0+$ [i.e., a wave function belongs to the domain if it has no part proportional to the (square integrable) singularity $r^{-|s|}$]. This is in fact the most common choice, see Ref. 8 for a detailed discussion. The case $s=0$ is particular since the singularity in question is logarithmic but otherwise the situation is similar, see Ref. 1. The Hamiltonian $H(s)$ is unambiguously determined by specifying a complete set of eigenfunctions with corresponding eigenvalues, see below.

The dynamics of the model should be defined by

$$i\partial_s U_\tau(s,s_0)\psi=\tau H(s)U_\tau(s,s_0)\psi, \quad U_\tau(s_0,s_0)\psi=\psi, \tag{2}$$

where U_τ is unitary and ψ is an arbitrary initial condition from the domain of $H(s_0)$. The existence of a propagator in this sense is, however, uncertain. The problem arises from the fact that the domain of $H(s)$ is not constant in s, respectively, that $\dot{H}(s)$ is not relatively bounded with respect to $H(s)$. Thus the usual theorems which assure the existence of the propagator[13] and the validity of the adiabatic approximation[4,2] are not directly applicable.

A convenient way to see this is to consider the eigenfunctions. The operator $H(s)$ has a simple discrete spectrum; the eigenvalues are

$$\lambda_n(s)=B(s+|s|+2n+1), \quad n\in\{0,1,2,\ldots\}, \tag{3}$$

with the corresponding normalized eigenfunctions

$$\varphi_n(s;r)=c_n(s)r^{|s|}L_n^{(|s|)}\left(\frac{Br^2}{2}\right)\exp\left(-\frac{Br^2}{4}\right),$$

where

$$c_n(s)=\left(\frac{B}{2}\right)^{(|s|+1)/2}\left(\frac{2n!}{\Gamma(n+|s|+1)}\right)^{1/2}$$

are the normalization constants and $L_n^{(|s|)}$ are the generalized Laguerre polynomials (see, for example, Ref. 8).

The derivative of $H(s)$ equals

$$\dot{H}(s)=\frac{2s}{r^2}+B.$$

Notice that if $|s|\leqslant 1$ then $\varphi_n(s)$ cannot belong to the domain $\mathrm{Dom}\,\dot{H}(s)$ since $\dot{H}(s)\varphi_n(s)\sim r^{-2+|s|}$ for $r\to 0+$. This means that $\dot{H}(s)$ is not relatively bounded with respect to $H(s)$.

Remark that, on the other hand, the quadratic expression

$$\int_0^\infty \varphi_m(s;r)\dot{H}(s)\varphi_n(s;r)r\,\mathrm{d}r$$

makes good sense. In order to avoid a complicated notation we shall denote it by the symbol $\langle\varphi_m(s),\dot{H}(s)\varphi_n(s)\rangle$ even though the symbol cannot be taken literally and is therefore somewhat misleading. Furthermore, the derivative of the eigenfunction, $\dot{\varphi}_n(s)$, belongs to $L^2(\mathbb{R}_+,r\,\mathrm{d}r)$. Since the eigenfunctions are chosen to be real valued it holds true that

$$\langle\varphi_n(s),\dot{\varphi}_n(s)\rangle = 0.$$

Let us also note that, similarly, if $|s|\leqslant 1$ and $s^2\neq s'^2$ then the eigenfunction $\varphi_n(s)$ cannot belong to $\mathrm{Dom}\,H(s')$. It is so because (as formal expressions) $H(s')-H(s)=(s'^2-s^2)/r^2+B(s'-s)$ and $H(s')\varphi_n(s;r)$ has a nonintegrable singularity at $r=0$. Hence $\mathrm{Dom}\,H(s)$ depends on s.

It turns out that, following the strategy of Born and Fock,[6] the problems of existence and adiabatic approximation can both be handled.

Denote the eigenprojector onto $\mathbb{C}\varphi_n(s)$ by $P_n(s)$; it is differentiable as a bounded operator. The hard part of our work consists in showing that

$$i\sum_{k=0}^{\infty}\dot{P}_k(s)P_k(s)$$

is a bounded operator. This is stated in Lemma 6. It requires work because its matrix elements have bad off-diagonal decay, see Lemma 4 (which is formulated for the unitarily equivalent operator Q).

Now

$$H_{AD}(s):=H(s)+\frac{i}{\tau}\sum_{n=0}^{\infty}\dot{P}_n(s)P_n(s)$$

has a propagator which is well defined in the usual way, i.e.,

$$i\partial_s U_{AD}(s,s_0)\psi=\tau H_{AD}(s)U_{AD}(s,s_0)\psi,\quad U_{AD}(s_0,s_0)\psi=\psi, \tag{4}$$

for $\psi\in\mathrm{Dom}(H_{AD}(s_0))$. To see this notice that U_{AD} can be computed by its action on the eigenbasis,

$$U_{AD}(s,s_0)\varphi_n(s_0)=e^{-i\tau\int_{s_0}^{s}\lambda_n(u)\mathrm{d}u}\varphi_n(s).$$

Furthermore, $\lambda_n(s)-\lambda_n(0)$ is bounded in n and so

$$U_{AD}(s,s_0)\mathrm{Dom}\,H_{AD}(s_0)=\mathrm{Dom}\,H_{AD}(s).$$

Since $H(s)-H_{AD}(s)$ is bounded the domains of $H(s)$ and $H_{AD}(s)$ are identical. By time-dependent transformation a natural candidate for the propagator of $H(s)$ is

$$U_\tau(s,s_0):=U_{AD}(s,0)C(s,s_0)U_{AD}(0,s_0), \tag{5}$$

where $C(s,s_0)$ is defined by

$$i\partial_s C(s,s_0)=-Q_\tau(s)C(s,s_0),\quad C(s_0,s_0)=\mathbb{I}, \tag{6}$$

with

$$Q_\tau(s):=U_{AD}(0,s)\left(i\sum_{k=0}^{\infty}\dot{P}_k(s)P_k(s)\right)U_{AD}(s,0). \tag{7}$$

Since $\|Q_\tau(s)\|$ is locally bounded the propagator $C(s,s_0)$ is well defined by the Dyson formula.

The adiabatic approximation problem is settled in Proposition 11 where it is shown that

$$\|U_\tau(s,0) - U_{AD}(s,0)\| = O\left(\frac{1}{\tau}\right).$$

It remains unclear, however, whether $C(s,s_0)$ preserves the domain of $H(0)$ and therefore whether the propagator $U_\tau(s,s_0)$ is actually related to the Hamiltonian $H(s)$ in the usual sense. To handle this problem we develop the general concept of weak association of a propagator and a time-dependent Hamiltonian. We can show that U_τ is weakly associated to $H(s)$ and that the Schrödinger equation (2) is fulfilled in the sense of distributions.

We shall use the following notation. The symbol $V(s)$ stands for the unitary operator which sends all eigenstates at time 0 to the corresponding eigenstates at time s, i.e.,

$$V(s)\varphi_n(0) = \varphi_n(s) \quad \forall\, n \in \mathbb{Z}_+ \tag{8}$$

(here and everywhere in what follows $\mathbb{Z}_+$ stands for the set of non-negative integers). Further set

$$W(s) = V(s)^{-1}H(s)V(s) = \sum_{n=0}^{\infty} \lambda_n(s)P_n(0) \tag{9}$$

and

$$\Omega(s) = \sum_{n=0}^{\infty} \omega_n(s)P_n(0), \tag{10}$$

where

$$\omega_n(s) = \int_0^s \lambda_n(u)\mathrm{d}u.$$

Remark that the adiabatic propagator decomposes as

$$U_{AD}(s,s_0) = V(s)e^{-i\tau(\Omega(s)-\Omega(s_0))}V(s_0)^{-1}.$$

The paper is organized as follows. In Secs. II and III we do the analysis necessary to prove the boundedness result stated in Lemma 6. Section IV is devoted to the existence problem for the propagator. In Sec. V we prove the adiabatic theorem in Proposition 11. The result is then extended to a more general time dependence in Sec. VI.

A rather independent part of the paper is the Appendix where we propose the notion of a propagator weakly associated to a time-dependent Hamiltonian. We indicate cases where the weak association can be verified while the usual relationship between a propagator and a Hamiltonian is unclear or even is not valid. In particular, this concept was inspired by the situation we encountered in the present model. We believe, however, that this idea need not be restricted to this case only and that it might turn out to be useful in resolving this type of difficulties in other models as well.

II. AUXILIARY ESTIMATES OF MATRIX OPERATORS

Here we derive some auxiliary estimates that will be useful later when verifying assumptions of the adiabatic theorem.

Lemma 1: *Let $A(\sigma)$ be an operator in $l^2(\mathbb{N})$ depending on a parameter $\sigma \geqslant 0$ whose matrix entries in the standard basis equal*

$$A(\sigma)_{mn} = \begin{cases} 0 & \text{for } m = n, \\ -\frac{i}{n}\left(\frac{m}{n}\right)^{\sigma} & \text{for } m < n, \\ \frac{i}{m}\left(\frac{n}{m}\right)^{\sigma} & \text{for } m > n. \end{cases}$$

Then $A(\sigma)$ is bounded, uniformly in σ, and its norm satisfies the estimate

$$\|A(\sigma)\| \leqslant 24.$$

Proof: The proof will be done in several steps.

(i) Let $K(\sigma)$ be an integral operator acting in $L^2(\mathbb{R}_+, \mathrm{d}x)$ with the integral kernel

$$\mathcal{K}_{\sigma}(x,y) = \begin{cases} -\frac{i}{y}\left(\frac{x}{y}\right)^{\sigma} & \text{for } x < y, \\ \frac{i}{x}\left(\frac{y}{x}\right)^{\sigma} & \text{for } x > y. \end{cases}$$

Let us show that

$$\|K(\sigma)\| = \frac{2}{2\sigma + 1}.$$

First we apply the unitary transform

$$U{:}L^2(\mathbb{R}_+, \mathrm{d}x) \to L^2(\mathbb{R}, \mathrm{d}y), \quad U\psi(y) = e^{y/2}\psi(e^y). \tag{11}$$

The inverse transform reads $U^{-1}\hat{\psi}(x) = x^{-1/2}\hat{\psi}(\ln x)$. Set

$$\widetilde{K}(\sigma) = UK(\sigma)U^{-1}.$$

One finds that $\widetilde{K}(\sigma)$ is again an integral operator with the integral kernel

$$\widetilde{\mathcal{K}}_{\sigma}(y,z) = i\,\mathrm{sgn}(y - z)e^{-(\sigma+1/2)|y-z|}.$$

Hence $\widetilde{K}(\sigma)$ is a convolution operator and it is therefore diagonalizable with the aid of the Fourier transform $\mathcal{F}$ on $\mathbb{R}$. This means that

$$(\mathcal{F}\widetilde{K}(\sigma)\mathcal{F}^{-1}\psi)(z) = \hat{q}(z)\psi(z),$$

where

$$\hat{q}(z) = \int_{\mathbb{R}} e^{izy}\,\mathrm{sgn}(y)e^{-(\sigma+1/2)|y|}\,\mathrm{d}y = \frac{2iz}{\left(\sigma + \frac{1}{2}\right)^2 + z^2}.$$

It follows that

$$\|K(\sigma)\| = \|\mathcal{F}\widetilde{K}(\sigma)\mathcal{F}^{-1}\| = \|\hat{q}\|_{\infty} = \frac{1}{\sigma + \frac{1}{2}}. \tag{12}$$

(ii) Suppose that $\{\psi\}_{n=1}^{\infty}$ is an orthogonal system in $L^2(\mathbb{R}_+, \mathrm{d}x)$ such that

$$\forall m,n \in \mathbb{N}, \quad \langle \psi_m, K(\sigma)\psi_n \rangle = A(\sigma)_{mn}$$

and

$$\forall n \in \mathbb{N}, \quad \|\psi_n\|^2 = \kappa > 0.$$

Let P_+ be the orthogonal projector onto span $\{\psi_n\}_{n=1}^{\infty}$ in $L^2(\mathbb{R}_+, \mathrm{d}x)$. Then one can identify $P_+K(\sigma)P_+$ with $\kappa^{-1}A(\sigma)$. Hence

$$\|A(\sigma)\| = \kappa\|P_+K(\sigma)P_+\| \leqslant \kappa\|K(\sigma)\|. \tag{13}$$

(iii) We shall construct an orthogonal system $\{\psi_n\}_{n=1}^{\infty}$ described in the preceding point as follows. Consider the natural embedding $L^2([n,n+1],\mathrm{d}x)\subset L^2(\mathbb{R}_+,\mathrm{d}x)$, $n\in\mathbb{N}$. We seek $\psi_n\in L^2([n,n+1],\mathrm{d}x)$ in the form

$$\psi_n = \alpha_n u_n + \beta_n v_n + f_n,$$

where α_n, $\beta_n\in\mathbb{R}$, u_n, v_n, $f_n\in L^2([n,n+1],\mathrm{d}x)$,

$$u_n(x) = x^{\sigma}, \quad v_n(x) = x^{-\sigma-1} \quad \text{for } x\in[n,n+1],$$

and $f_n\perp u_n$, $f_n\perp v_n$. Suppose for definiteness that $m<n$. Then

$$\langle\psi_m,K(\sigma)\psi_n\rangle = \int_m^{m+1}\mathrm{d}x\int_n^{n+1}\mathrm{d}y\ \mathcal{K}_\sigma(x,y)\psi_m(x)\psi_n(y) = -i\langle u_m,\psi_m\rangle\langle v_n,\psi_n\rangle.$$

Furthermore,

$$\langle\psi_n,K(\sigma)\psi_n\rangle = \int_n^{n+1}\int_n^{n+1}\mathcal{K}_\sigma(x,y)\psi_n(x)\psi_n(y)\mathrm{d}x\,\mathrm{d}y = 0$$

since $\mathcal{K}_\sigma(x,y)$ is antisymmetric, $\mathcal{K}_\sigma(y,x)=-\mathcal{K}_\sigma(x,y)$. Consequently, it suffices to choose the real coefficients α_n, β_n so that

$$\forall n\in\mathbb{N},\langle u_n,\psi_n\rangle = n^{\sigma}, \quad \langle v_n,\psi_n\rangle = n^{-\sigma-1}.$$

This system has a unique solution (α_n,β_n). The function f_n can be arbitrary. Its only purpose is to adjust the norms of the functions ψ_n so that they are all equal. Set

$$N_n(\sigma) = \|\alpha_n u_n + \beta_n v_n\|^2 = \int_n^{n+1}(\alpha_n x^{\sigma} + \beta_n x^{-\sigma-1})^2\,\mathrm{d}x$$

and

$$\kappa(\sigma) = \sup_{n\in\mathbb{N}} N_n(\sigma).$$

One can choose the orthogonal system $\{\psi_n\}_{n=1}^{\infty}$ so that $\|\psi_n\|^2=\kappa(\sigma)$ for all n. According to (12) and (13) we have

$$\|A(\sigma)\| \leqslant \frac{2\kappa(\sigma)}{2\sigma+1}. \tag{14}$$

(iv) It remains to find an upper bound on $\kappa(\sigma)$. Set

$$\xi_n = n^{\sigma}, \quad \eta_n = n^{-\sigma-1}.$$

Simple algebraic manipulations yield

$$N_n(\sigma) = \frac{\langle v_n,v_n\rangle\xi_n^2 - 2\langle u_n,v_n\rangle\xi_n\eta_n + \langle u_n,u_n\rangle\eta_n^2}{\langle u_n,u_n\rangle\langle v_n,v_n\rangle - \langle u_n,v_n\rangle^2}.$$

Here

$$\langle u_n,v_n\rangle = \ln\left(1+\frac{1}{n}\right),$$

$$\langle u_n, u_n\rangle = \frac{1}{2\sigma+1}((n+1)^{2\sigma+1} - n^{2\sigma+1}),$$

$$\langle v_n, v_n\rangle = \frac{1}{2\sigma+1}(n^{-2\sigma-1} - (n+1)^{-2\sigma-1}).$$

Set

$$w = \left(\sigma + \frac{1}{2}\right)\ln\left(1 + \frac{1}{n}\right).$$

One can rewrite the expression for $N_n(\sigma)$ as follows:

$$N_n(\sigma) = \frac{2\sigma+1}{n}\frac{\sinh(w)\cosh(w) - w}{\sinh^2(w) - w^2}.$$

Using an elementary analysis one can show that

$$\frac{\sinh(w)\cosh(w) - w}{\sinh^2(w) - w^2} \leqslant \frac{\sinh(w)\cosh(w) - w}{\sinh(w)(\sinh(w) - w)} \leqslant 4\,\mathrm{cotgh}(w).$$

Hence

$$N_n(\sigma) \leqslant \frac{4(2\sigma+1)}{n}\frac{\left(1 + \frac{1}{n}\right)^{2\sigma+1} + 1}{\left(1 + \frac{1}{n}\right)^{2\sigma+1} - 1} \leqslant 12(2\sigma+1).$$

Consequently,

$$\kappa(\sigma) \leqslant 12(2\sigma+1). \tag{15}$$

From (14) and (15) it follows that $\|A(\sigma)\| \leqslant 24$. □

Lemma 2: *Let $A(\sigma)$ be an operator in $l^2(\mathbb{N})$ whose matrix entries in the standard basis equal*

$$A(\sigma)_{mn} = \begin{cases} 0 & \text{for } m = n, \\ -\frac{i}{n} f_\sigma\left(\frac{m}{n}\right) & \text{for } m < n, \\ \frac{i}{m} f_\sigma\left(\frac{n}{m}\right) & \text{for } m > n, \end{cases}$$

where

$$f_\sigma(u) = \frac{1 - u^\sigma}{1 - u}, \qquad u \in]0,1[,$$

and $\sigma \in [0,1]$ is a parameter. Then $A(\sigma)$ is bounded and its norm satisfies the estimate

$$\|A(\sigma)\| \leqslant \left(\frac{\sqrt{2}}{3} + 4\right)\pi^2\sigma.$$

Proof: The proof will be done in several steps.

(i) Let $K(\sigma)$ be an integral operator acting in $L^2(\mathbb{R}_+, \mathrm{d}x)$ with the integral kernel

$$\mathcal{K}_\sigma(x,y) = \begin{cases} -\frac{i}{y} f_\sigma\left(\frac{x}{y}\right) & \text{for } x < y, \\ \frac{i}{x} f_\sigma\left(\frac{y}{x}\right) & \text{for } x > y. \end{cases}$$

Let us show that

$$\|K(\sigma)\| \leqslant \pi^2\sigma. \tag{16}$$

This step is quite analogous to the proof of point (i) in Lemma 1. First we apply the unitary transform U defined in (11). Set

$$\widetilde{K}(\sigma) = UK(\sigma)U^{-1}.$$

One finds that $\widetilde{K}(\sigma)$ is again an integral operator with the integral kernel,

$$\widetilde{\mathcal{K}}_\sigma(y,z) = i\,\mathrm{sgn}(y-z) f_\sigma(e^{-|y-z|}) e^{-|y-z|/2}.$$

Thus $\widetilde{K}(\sigma)$ is a convolution operator which is diagonalizable with the aid of the Fourier transform $\mathcal{F}$ on $\mathbb{R}$. This means that $(\mathcal{F}\widetilde{K}(\sigma)\mathcal{F}^{-1}\psi)(z) = \hat{q}(z)\psi(z)$ where

$$\hat{q}(z) = \int_{\mathbb{R}} e^{izy}\,\mathrm{sgn}(y) f_\sigma(e^{-|y|}) e^{-|y|/2}\,\mathrm{d}y.$$

A standard estimate yields

$$|\hat{q}(z)| \leqslant 2\int_0^\infty \frac{1-e^{-\sigma y}}{1-e^{-y}} e^{-y/2}\,\mathrm{d}y \leqslant \sigma\int_0^\infty \frac{y}{\sinh(y/2)}\mathrm{d}y = \pi^2\sigma.$$

It follows that

$$\|K(\sigma)\| = \|\mathcal{F}\widetilde{K}(\sigma)\mathcal{F}^{-1}\| = \|\hat{q}\|_\infty \leqslant \pi^2\sigma.$$

(ii) Let $\chi_n(x)$ be the characteristic function of the interval $]n, n+1[$. The linear mapping

$$J: l^2(\mathbb{N}) \to L^2(\mathbb{R}_+, \mathrm{d}x): \{\xi_n\} \mapsto \sum_{n=1}^{\infty} \xi_n \chi_n$$

is an isometry. The adjoint mapping reads

$$J^*: L^2(\mathbb{R}_+, \mathrm{d}x) \to l^2(\mathbb{N}): \psi \mapsto \{\langle \chi_n, \psi\rangle\}_{n=1}^{\infty}.$$

Set

$$L(\sigma) = JA(\sigma)J^*.$$

$L(\sigma)$ is an integral operator with the kernel

$$\mathcal{L}_\sigma(x,y) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} A(\sigma)_{mn}\chi_m(x)\chi_n(y).$$

This can be rewritten as

$$\mathcal{L}_\sigma(x,y) = \begin{cases} -\frac{i}{[y]} f_\sigma\left(\frac{[x]}{[y]}\right) & \text{if } 0 < [x] < [y], \\ \frac{i}{[x]} f_\sigma\left(\frac{[y]}{[x]}\right) & \text{if } 0 < [y] < [x], \\ 0 & \text{otherwise.} \end{cases}$$

Here $[x]$ denotes the integer part of x. Notice that J^*J is the identity on $l^2(\mathbb{N})$ and so $L(\sigma)J = JA(\sigma)$. Consequently,

$$\|A(\sigma)\| = \|JA(\sigma)\| = \|L(\sigma)J\| \leqslant \|L(\sigma)\|. \tag{17}$$

(iii) Denote by $\widetilde{P}_n$, $n \in \mathbb{Z}_+$, the orthogonal projector onto $\mathbb{C}\chi_n$ in $L^2(\mathbb{R}_+, \mathrm{d}x)$. Set

$$K^{\mathrm{off}}(\sigma) = K(\sigma) - \widetilde{P}_0 K(\sigma) - K(\sigma)\widetilde{P}_0 + \widetilde{P}_0 K(\sigma)\widetilde{P}_0 - \sum_{n=1}^{\infty} \widetilde{P}_n K(\sigma)\widetilde{P}_n.$$

In other words, we subtract from $K(\sigma)$ the diagonal as well as the first row and the first column (i.e., with index 0) with respect to the orthogonal system $\{\chi_n\}_{n=0}^{\infty}$. We can say also that the integral kernel $\mathcal{K}_\sigma^{\mathrm{off}}(x,y)$ vanishes if $[x]=[y]$ or $[x]=0$ or $[y]=0$ and otherwise it coincides with $\mathcal{K}_\sigma(x,y)$. Since

$$\left\| \widetilde{P}_0 K(\sigma)\widetilde{P}_0 - \sum_{n=1}^{\infty} \widetilde{P}_n K(\sigma)\widetilde{P}_n \right\| = \sup_{n\in\mathbb{Z}_+} \|\widetilde{P}_n K(\sigma)\widetilde{P}_n\| \leqslant \|K(\sigma)\|,$$

we have

$$\|K^{\mathrm{off}}(\sigma)\| \leqslant 4\|K(\sigma)\|. \tag{18}$$

(iv) It remains to estimate the norm of the difference $L(\sigma) - K^{\mathrm{off}}(\sigma)$. This is a Hermitian integral operator whose kernel does not vanish only if $0<[x]<[y]$ or $0<[y]<[x]$. Suppose for definiteness that $0<[x]<[y]$. Then the kernel equals, up to the multiplier $-i$,

$$\frac{1}{[y]} f_\sigma\left(\frac{[x]}{[y]}\right) - \frac{1}{y} f_\sigma\left(\frac{x}{y}\right) = \left(\frac{1}{[y]^\sigma} - \frac{1}{y^\sigma}\right)\frac{[y]^\sigma - [x]^\sigma}{[y]-[x]} + \frac{1}{y^\sigma}\left(\frac{[y]^\sigma - [x]^\sigma}{[y]-[x]} - \frac{y^\sigma - x^\sigma}{y-x}\right).$$

Let us show that

$$0 \leqslant \frac{1}{[y]} f_\sigma\left(\frac{[x]}{[y]}\right) - \frac{1}{y} f_\sigma\left(\frac{x}{y}\right) \leqslant \frac{2\sigma}{[x]([y]-[x])}. \tag{19}$$

First notice that

$$0 \leqslant \frac{1}{[y]^\sigma} - \frac{1}{y^\sigma} = -\sigma \int_y^{[y]} z^{-\sigma-1}\, \mathrm{d}z \leqslant \frac{\sigma(y-[y])}{[y]^{\sigma+1}}$$

and so

$$0 \leqslant \left(\frac{1}{[y]^\sigma} - \frac{1}{y^\sigma}\right)\frac{[y]^\sigma - [x]^\sigma}{[y]-[x]} \leqslant \frac{\sigma}{[y]([y]-[x])}. \tag{20}$$

Further set temporarily

$$D = \frac{[y]^\sigma - [x]^\sigma}{[y]-[x]} - \frac{y^\sigma - x^\sigma}{y-x} = \sigma \int_0^1 (([x](1-t) + [y]t)^{\sigma-1} - (x(1-t)+yt)^{\sigma-1})\mathrm{d}t.$$

The integrand in the last integral equals

$$\sigma(1-\sigma)\xi_t^{\sigma-2}((x-[x])(1-t) + (y-[y])t),$$

where ξ_t is a real number lying between $[x](1-t)+[y]t$ and $x(1-t)+yt$. Notice that

$$0 \leqslant (x-[x])(1-t) + (y-[y])t \leqslant 1.$$

We assume that $0 \leqslant \sigma \leqslant 1$. Therefore

$$0 \leqslant D \leqslant \sigma(1-\sigma)\int_0^1 ([x](1-t)+[y]t)^{\sigma-2}\,\mathrm{d}t = -\sigma\frac{[y]^{\sigma-1} - [x]^{\sigma-1}}{[y]-[x]}$$

and so

$$0 \leqslant \frac{1}{y^\sigma} D \leqslant \frac{\sigma [x]^{\sigma-1}}{y^\sigma([y]-[x])} \leqslant \frac{\sigma}{[x]([y]-[x])}. \tag{21}$$

Inequalities (20) and (21) jointly imply (19).

(v) From estimate (19) one can deduce that $L(\sigma)-K^{\mathrm{off}}(\sigma)$ is a Hilbert–Schmidt operator and

$$\|L(\sigma)-K^{\mathrm{off}}(\sigma)\|_{\mathrm{HS}} \leqslant \frac{\sqrt{2}\pi^2}{3}\sigma. \tag{22}$$

Actually,

$$\|L(\sigma)-K^{\mathrm{off}}(\sigma)\|_{\mathrm{HS}}^2 = 2\int_1^\infty \mathrm{d}x \int_{[x]+1}^\infty \mathrm{d}y |\mathcal{L}_\sigma(x,y)-\mathcal{K}_\sigma^{\mathrm{off}}(x,y)|^2 \leqslant 8\sigma^2 \int_1^\infty \mathrm{d}x \frac{1}{[x]^2}\int_{[x]+1}^\infty \mathrm{d}y \frac{1}{([y]-[x])^2}$$
$$= 8\sigma^2\left(\sum_{k=1}^\infty \frac{1}{k^2}\right)^2.$$

(vi) Inequalities (17), (18), (16), and (22) imply that

$$\|A(\sigma)\| \leqslant \|L(\sigma)\| \leqslant \|K^{\mathrm{off}}(\sigma)\| + \|L(\sigma)-K^{\mathrm{off}}(\sigma)\| \leqslant 4\pi^2\sigma + \frac{\sqrt{2}\pi^2}{3}\sigma.$$

This shows the lemma. □

Lemma 3: *Let $A(\sigma)$ be an operator in $l^2(\mathbb{N})$ with the matrix entries in the standard basis*

$$A(\sigma)_{mn} = \begin{cases} 0 & \text{for } m=n, \\ \frac{i}{n-m}\min\left\{\left(\frac{m}{n}\right)^\sigma, \left(\frac{n}{m}\right)^\sigma\right\} & \text{for } m \neq n. \end{cases}$$

Then $A(\sigma)$ is bounded for all $0 \leqslant \sigma$ and its norm satisfies the estimate

$$\|A(\sigma)\| \leqslant \pi + \left(\frac{\sqrt{2}}{3}+4\right)\pi^2\sigma.$$

Proof: Let us first show that

$$\|A(0)\| \leqslant \pi.$$

For $\sigma=0$ we get

$$A(0)_{mn} = \frac{i}{n-m} \quad \text{if } m \neq n.$$

Considering the natural embedding $l^2(\mathbb{N}) \subset l^2(\mathbb{Z})$ let us denote by P_+ the orthogonal projector onto $l^2(\mathbb{N})$ in $l^2(\mathbb{Z})$. Let B be an operator in $l^2(\mathbb{Z})$ with the matrix

$$B_{mn} = q(n-m) \quad \text{where } q(n) = \begin{cases} 0 & \text{for } n=0, \\ \frac{i}{n} & \text{for } n \neq 0. \end{cases}$$

One can identify $A(0)$ with P_+BP_+. B is a convolution operator and therefore it is diagonalizable by the Fourier transform $\mathcal{F}: l^2(\mathbb{Z}) \to L^2([0,2\pi], \mathrm{d}\theta)$. In more detail,

$$(\mathcal{F}B\mathcal{F}^{-1}\psi)(\theta) = \hat{q}(\theta)\psi(\theta) \quad \text{where } \hat{q}(\theta) = \sum_{n\in\mathbb{Z}} q(n)e^{in\theta}.$$

One finds that $\hat{q}(\theta) = -\pi + \theta$. Consequently,

$$\|A(0)\| = \|P_+ B P_+\| \leqslant \|B\| = \|\mathcal{F} B \mathcal{F}^{-1}\| = \max_{0\in[0,2\pi]} |\hat{q}(\theta)| = \pi.$$

Suppose now that $0<m<n$. Notice that

$$(A(\sigma+1) - A(\sigma))_{mn} = -\frac{i}{n}\left(\frac{m}{n}\right)^{\sigma}$$

and

$$(A(\sigma) - A(0))_{mn} = -\frac{i}{n} f_{\sigma}\left(\frac{m}{n}\right).$$

Using Lemma 1 and Lemma 2 one can estimate

$$\begin{aligned}\|A(\sigma)\| &\leqslant \|A(0)\| + \|A(\sigma - [\sigma]) - A(0)\| + \|A(\sigma - [\sigma] + 1) - A(\sigma - [\sigma])\| + \cdots + \|A(\sigma) - A(\sigma - 1)\| \\ &\leqslant \pi + \left(\frac{\sqrt{2}}{3} + 4\right)\pi^2(\sigma - [\sigma]) + 24[\sigma] \leqslant \pi + \left(\frac{\sqrt{2}}{3} + 4\right)\pi^2\sigma.\end{aligned}$$

This proves the lemma. □

III. BOUNDEDNESS OF THE OPERATOR $i\Sigma_{k=0}^{\infty}\dot{P}_k(s)P_k(s)$

We consider $i\Sigma_{k=0}^{\infty}\dot{P}_k(s)P_k(s)$ in the time independent frame, i.e., the operator $Q(s)$ defined by

$$Q(s) = iV(s)^*\sum_{k=0}^{\infty}\dot{P}_k(s)P_k(s)V(s) = -i\dot{V}(s)^*V(s) = iV(s)^*\dot{V}(s). \tag{23}$$

The operator $V(s)$ is defined in (8). $Q(s)$ is symmetric and its matrix entries in the basis $\{\varphi_n(0)\}$ are

$$\langle\varphi_m(0), Q(s)\varphi_n(0)\rangle = i\langle\varphi_m(s), \dot{\varphi}_n(s)\rangle.$$

Since $\varphi_n(s)$ depends on s only through the absolute value it holds true that $Q(-s)=-Q(s)$ for $s\neq 0$. For $s=0$ the operator-valued function $Q(s)$ has a discontinuity. The goal of this section is to show that the operator $Q(s)$ is in fact bounded.

To compute the matrix entries one can use the identity

$$\langle\varphi_m(s), \dot{\varphi}_n(s)\rangle = \frac{\langle\varphi_m(s), \dot{H}(s)\varphi_n(s)\rangle}{\lambda_n(s) - \lambda_m(s)}. \tag{24}$$

Let us emphasize once more that the scalar product on the right-hand side should be interpreted as a quadratic form since, in general, $\varphi_n(s) \notin \mathrm{Dom}\,\dot{H}(s)$. The derivation goes through basically as usual even though one cannot use the scalar product directly. Differentiating the equation on eigenvalues one arrives at the equality

$$H(s)\dot{\varphi}_n(s;r) + \dot{H}(s)\varphi_n(s;r) = \dot{\lambda}_n(s)\varphi_n(s;r) + \lambda_n(s)\dot{\varphi}_n(s;r),$$

valid for any $r>0$, in which one should substitute for $H(s)$ and $\dot{H}(s)$ the corresponding formal differential operators. Next one multiplies the equality by $r\varphi_m(s;r)$ and integrates the both sides from ε to infinity for some $\varepsilon>0$. In the integral

$$-\int_{\varepsilon}^{\infty}\varphi_m(s;r)\partial_r r\partial_r\dot{\varphi}_n(s;r)\mathrm{d}r$$

occurring on the left-hand side one integrates twice by parts. Checking the asymptotic behavior of the eigenfunctions near the origin,

$$\varphi_n(s;r) \sim \left(\frac{B}{2}\right)^{(|s|+1)/2}\left(\frac{2n!}{\Gamma(n+|s|+1)}\right)^{1/2} r^{|s|}(1+O(r^2)) \quad \text{for } r \to 0+, \tag{25}$$

one finds that

$$\lim_{r\to 0+} r\varphi_m(s;r)\partial_r\dot{\varphi}_n(s;r) = \lim_{r\to 0+} r(\partial_r\varphi_m(s;r))\dot{\varphi}_n(s;r) = 0.$$

Hence sending ε to 0 actually leads to equality (24).

Lemma 4: *The matrix entries of the operator $Q(s)$ for $s \neq 0$ are given by the formulas*

$$\langle \varphi_m(0), Q(s)\varphi_n(0)\rangle = 0 \quad \text{for } m = n,$$

and

$$\langle \varphi_m(0), Q(s)\varphi_n(0)\rangle = \frac{i\,\mathrm{sgn}(s)}{2(n-m)}\min\left\{\frac{\gamma_m(s)}{\gamma_n(s)}, \frac{\gamma_n(s)}{\gamma_m(s)}\right\} \quad \text{for } m \neq n,$$

where

$$\gamma_n(s) = \left(\frac{\Gamma(n+|s|+1)}{n!}\right)^{1/2}. \tag{26}$$

Proof: Assume that $m<n$ and $s>0$. Using the explicit expression for the generalized Laguerre polynomials,

$$L_n^{(\alpha)}(x) = \sum_{k=0}^{n} (-1)^k \binom{n+\alpha}{n-k}\frac{1}{k!}x^k,$$

one finds that

$$\begin{aligned}\langle \varphi_m(s), \dot{H}(s)\varphi_n(s)\rangle &= 2sc_m(s)c_n(s)\int_0^\infty r^{2s-1}L_m^{(s)}\left(\frac{Br^2}{2}\right)L_n^{(s)}\left(\frac{Br^2}{2}\right)\exp\left(-\frac{Br^2}{2}\right)dr \\ &= sc_m(s)c_n(s)\left(\frac{2}{B}\right)^s S_{m,n},\end{aligned}$$

where

$$S_{m,n} = \sum_{k=0}^{m}\sum_{\ell=0}^{n}(-1)^{k+\ell}\frac{\Gamma(m+s+1)\Gamma(n+s+1)\Gamma(k+\ell+s)}{\Gamma(k+s+1)\Gamma(\ell+s+1)m!n!}\binom{m}{k}\binom{n}{\ell}.$$

In this expression only the summand with $k=0$ does not vanish since

$$\sum_{\ell=0}^{n}(-1)^\ell\binom{n}{\ell}\ell^j = 0 \quad \text{for } j = 0,1,\ldots,n-1.$$

Hence

$$\begin{aligned}S_{m,n} &= \frac{\Gamma(m+s+1)\Gamma(n+s+1)}{\Gamma(s+1)m!n!}\sum_{\ell=0}^{n}(-1)^\ell\frac{\Gamma(\ell+s)}{\Gamma(\ell+s+1)}\binom{n}{\ell} = \frac{\Gamma(m+s+1)\Gamma(n+s+1)}{\Gamma(s+1)m!n!}B(s,n+1) \\ &= \frac{\Gamma(m+s+1)}{sm!}.\end{aligned}$$

Furthermore, $\lambda_n(s)-\lambda_m(s)=2B(n-m)$ and so

$$\langle \varphi_m(0), Q(s)\varphi_n(0)\rangle = i\left(\frac{2}{B}\right)^s \frac{c_m(s)c_n(s)}{2B(n-m)} \frac{\Gamma(m+s+1)}{m!}.$$

Now it suffices to plug in the explicit expressions for the normalization constants $c_m(s)$ and $c_n(s)$. □

Using the Stirling formula one can check the asymptotic behavior of the matrix entries of the operator $Q(s)$ for m and n large. It turns out that the operator $Q(s)$ is in some sense close to a Hermitian operator $A(s)$ in $L^2(\mathbb{R}_+, r\,\mathrm{d}r)$ with the matrix entries

$$\langle \varphi_m(0), A(s)\varphi_n(0)\rangle = 0 \quad \text{for } m = n, \tag{27}$$

and

$$\langle \varphi_m(0), A(s)\varphi_n(0)\rangle = \frac{i\,\mathrm{sgn}(s)}{2(n-m)} \min\left\{\left(\frac{m+1}{n+1}\right)^{|s|/2}, \left(\frac{n+1}{m+1}\right)^{|s|/2}\right\} \text{for } m \neq n. \tag{28}$$

Note that $A(0+) = Q(0+)$. We shall also write $Q(s)_{mn}$ instead of $\langle \varphi_m(0), Q(s)\varphi_n(0)\rangle$, and similarly for $A(s)$.

Lemma 5: *Let $A(s)$ be the Hermitian operator in $L^2(\mathbb{R}_+, r\,\mathrm{d}r)$ defined by relations* (27) and (28). *Then $Q(s) - A(s)$ is a Hilbert–Schmidt operator and it holds true that*

$$\|Q(s) - A(s)\|_{\mathrm{HS}} \leqslant \tfrac{1}{2}|s|(1+|s|)^{(3+|s|)/2}.$$

Proof: Let us suppose for definiteness that $s > 0$ and $m < n$. For $x \geqslant 1$ set

$$g_s(x) = \frac{\Gamma(x+s)}{x^s \Gamma(x)}.$$

One can express

$$\begin{aligned} |Q(s)_{mn} - A(s)_{mn}| &= \frac{1}{2(n-m)} |g_s(m+1)^{1/2} - g_s(n+1)^{1/2}| \left(\frac{m+1}{n+1}\right)^{s/2} g_s(n+1)^{-1/2} \\ &\leqslant \frac{1}{4} g_s(n+1)^{-1/2} \int_0^1 g_s(m+1+(n-m)t)^{-1/2} |g_s'(m+1+(n-m)t)|\,\mathrm{d}t. \end{aligned}$$

Notice that

$$\frac{g_s'(x)}{g_s(x)} = \frac{\Gamma'(x+s)}{\Gamma(x+s)} - \frac{\Gamma'(x)}{\Gamma(x)} - \frac{s}{x}.$$

Using the well-known formula for the logarithmic derivative of the gamma function,

$$-\frac{\Gamma'(z)}{\Gamma(z)} = \frac{1}{z} + \gamma + \sum_{n=1}^{\infty} \left(\frac{1}{n+z} - \frac{1}{n}\right), \tag{29}$$

one finds that

$$\frac{g_s'(x)}{g_s(x)} = s\left(\sum_{n=0}^{\infty} \frac{1}{(n+x)(n+x+s)} - \frac{1}{x}\right) \leqslant s\left(\sum_{n=0}^{\infty} \frac{1}{(n+x)^2} - \frac{1}{x}\right) \leqslant s\left(\frac{1}{x^2} + \int_x^{\infty} \frac{\mathrm{d}y}{y^2} - \frac{1}{x}\right) = \frac{s}{x^2}.$$

Similarly,

$$\frac{g_s'(x)}{g_s(x)} \geqslant s\left(\int_x^{\infty} \frac{\mathrm{d}y}{y(y+s)} - \frac{1}{x}\right) = \ln\left(1+\frac{s}{x}\right) - \frac{s}{x} \geqslant -\frac{s^2}{2x^2}.$$

In particular,

$$|g_s'(x)| \leqslant \frac{s(s+1)}{x^2} g_s(x).$$

From here one derives the estimates, for $t \in [0,1]$,

$$\frac{g_s(m+1+(n-m)t)}{g_s(n+1)} = \exp\left(-\int_{m+1+(n-m)t}^{n+1} \frac{g_s'(y)}{g_s(y)}\mathrm{d}y\right) \leqslant \exp\left(\int_{m+1}^{n+1}\left(\frac{s}{y} - \ln\left(\frac{y+s}{y}\right)\right)\mathrm{d}y\right)$$
$$= \exp\left((m+1+s)\ln\left(1+\frac{s}{m+1}\right) - (n+1+s)\ln\left(1+\frac{s}{n+1}\right)\right) \leqslant (1+s)^{1+s}$$

and

$$|Q(s)_{mn} - A(s)_{mn}| \leqslant \frac{s(s+1)}{4g_s(n+1)^{1/2}} \int_0^1 \frac{g_s(m+1+(n-m)t)^{1/2}}{(m+1+(n-m)t)^2}\mathrm{d}t$$
$$\leqslant \frac{1}{4}s(1+s)^{(3+s)/2} \int_0^1 \frac{\mathrm{d}t}{(m+1+(n-m)t)^2}.$$

Let $F(t)$ be a Hermitian operator in $L^2(\mathbb{R}_+, r\,\mathrm{d}r)$ with the following matrix entries in the basis $\{\varphi_n(0)\}$:

$$F(t)_{mn} = 0 \quad \text{for } m = n$$

and

$$F(t)_{mn} = (m+1+(n-m)t)^{-2} \quad \text{for } m < n.$$

Then $F(t)$ is a Hilbert–Schmidt operator and

$$\|F(t)\|_{\mathrm{HS}}^2 = 2\sum_{m=0}^{\infty}\sum_{n=m+1}^{\infty}(m+1+(n-m)t)^{-4} \leqslant 2\sum_{m=0}^{\infty}\int_0^{\infty}\frac{\mathrm{d}y}{(m+1+ty)^4} = \frac{2}{3t}\sum_{m=0}^{\infty}\frac{1}{(m+1)^3} \leqslant \frac{1}{t}.$$

Hence

$$\|Q(s) - A(s)\|_{\mathrm{HS}} \leqslant \frac{1}{4}s(1+s)^{(3+s)/2}\int_0^1 \|F(t)\|_{\mathrm{HS}}\,\mathrm{d}t \leqslant \frac{1}{2}s(1+s)^{(3+s)/2}.$$

This proves the lemma. □

Combining Lemma 3 and Lemma 5 we deduce that the operator $Q(s)$ is actually bounded.

Lemma 6: *The operator $Q(s)$ is bounded and its norm satisfies the estimate*

$$\|Q(s)\| \leqslant \frac{\pi}{2} + 12|s| + \frac{1}{2}|s|(1+|s|)^{(3+|s|)/2}.$$

Proof: Let $A(s)$ be the Hermitian operator in $L^2(\mathbb{R}_+, r\,\mathrm{d}r)$ defined by relations (27) and (28). According to Lemma 3 it holds true that

$$\|A(s)\| \leqslant \frac{1}{2}\left(\pi + \left(\frac{\sqrt{2}}{3} + 4\right)\pi^2\frac{|s|}{2}\right).$$

Lemma 5 leads to the estimate

$$\|Q(s)\| \leqslant \|A(s)\| + \|Q(s) - A(s)\| \leqslant \frac{1}{2}\left(\pi + \left(\frac{1}{3\sqrt{2}} + 2\right)\pi^2|s| + |s|(1+|s|)^{(3+|s|)/2}\right).$$

Since $(1+1/(6\sqrt{2}))\pi^2 < 12$ the lemma follows. □

IV. THE MEANING OF THE PROPAGATOR $U_\tau(s,s_0)$

As already discussed in the Introduction the natural propagator $U_\tau(s,s_0)$ defined in (5) is not related in the standard way to the Hamiltonian $\tau H(s)$ defined in (1). In particular it is not clear if $U_\tau(s,s_0)$ maps the domain Dom $H(s_0)$ into Dom $H(s)$. This is why we propose in the Appendix the notion of a propagator weakly associated to a Hamiltonian, see Definition A.3. We should like to emphasize that this relationship is unique, i.e., at most one propagator can be weakly associated to a Hamiltonian.

In this section we show that U_τ is weakly associated to τH and that $(s,r)\mapsto U_\tau(s,s_0)\psi_0(r)$ satisfies the Schrödinger equation as a distribution for all $\psi_0\in L^2(\mathbb{R}_+, r\,\mathrm{d}r\,\mathrm{d}\varphi)$.

Proposition 7: *The propagator $U_\tau(s,s_0)$ is weakly associated to $\tau H(s)$.*

Proof: Relation (5) means that

$$U_\tau(s,s_0) = V(s)e^{-i\tau\Omega(s)}C(s,s_0)e^{i\tau\Omega(s_0)}V(s_0)^{-1}.$$

So starting from $C(s,s_0)$ one can reach $U_\tau(s,s_0)$ by two consecutive unitary transformations. The propagator $C(s,s_0)$ was defined in (6). It corresponds to the Hamiltonian $-Q_\tau(s)$ defined in (7). According to Lemma 6 the function $\|Q_\tau(s)\|=\|Q(s)\|$ is locally bounded and thus $C(s,s_0)$ is given by the Dyson formula, see relation (31) in Sec. V.

First we apply Proposition A.4 in which we set

$$A(t) = -Q_\tau(t),\ D = \mathrm{Dom}\,H(0),\ T(t) = \exp(-i\tau\Omega(t)),$$

and

$$X(t) = i(\partial_t e^{-i\tau\Omega(t)})e^{i\tau\Omega(t)} = \tau W(t).$$

We conclude that the propagator $e^{-i\tau\Omega(s)}C(s,s_0)e^{i\tau\Omega(s_0)}$ is weakly associated to

$$\tau W(s) - e^{-i\tau\Omega(s)}Q_\tau(s)e^{i\tau\Omega(s)} = \tau W(s) - Q(s).$$

Next we apply Proposition A.6 in which we set $\widetilde{H}(t)=\tau W(t)-Q(t)$ and $\widetilde{U}(t,s)=e^{-i\tau\Omega(t)}C(t,s)e^{i\tau\Omega(s)}$. Recall further that $V(t)$ was defined in Eq. (8). We conclude that $U_\tau(s,s_0)=V(s)\widetilde{U}(s,s_0)V(s_0)^{-1}$ is weakly associated to

$$\tau V(s)W(s)V(s)^{-1} - V(s)Q(s)V(s)^{-1} + i\dot{V}(s)V(s)^{-1} = \tau H(s).$$

The proposition is proven. □

In the studied model $\mathcal{H}=L^2(\mathbb{R}_+, r\,\mathrm{d}r)$ and so

$$\mathcal{K} = L^2(\mathbb{R},\mathcal{H},\mathrm{d}s) = L^2(\mathbb{R}\times\mathbb{R}_+, r\,\mathrm{d}s\,\mathrm{d}r).$$

Let $\mathfrak{H}=\int_{\mathbb{R}}^{\oplus}H(s)\mathrm{d}s$ be the direct integral of the family of self-adjoint operators $H(s)$ which is nothing but a multiplication operator in $\mathcal{K}$. Let K_τ be the quasienergy operator associated to the propagator $U_\tau(s,s_0)$ (see Appendix). According to Proposition 7 it holds true that

$$K_\tau = \overline{-i\partial_s + \tau\mathfrak{H}}. \tag{30}$$

To an initial condition $\psi_0\in\mathcal{H}$ we relate the function $\psi(s,r)=(U_\tau(s,0)\psi_0)(r)$ which is a locally square integrable function in the variables s and r. We now show that $\psi(s,r)$ fulfills the Schrödinger equation in the space of distributions $\mathcal{D}'(\mathbb{R}\times]0,\infty[)$. Let us note that for the proof it suffices to know that $-i\partial_s+\tau\mathfrak{H}\subset K_\tau$, the stronger property Eq. (30) is not necessary.

Proposition 8: *For every $\psi_0\in\mathcal{H}$, the function $\psi(s,r)=(U_\tau(s,0)\psi_0)(r)$ satisfies the Schrödinger equation in the sense of distributions.*

Proof: Let $\xi\in C_0^\infty(\mathbb{R}\times]0,+\infty[)$ be an arbitrary real-valued test function. Set $g(s,r)=\xi(s,r)/r$. Clearly, $g\in\mathrm{Dom}(-i\partial_s+\tau\mathfrak{H})\subset\mathrm{Dom}\,K_\tau$. Let $[a,b]\times[c,d]$ be a rectangle containing supp ξ and choose $\eta\in C_0^\infty(\mathbb{R})$ so that $\eta\equiv 1$ on a neighborhood of the interval $[a,b]$. From Proposition A.2 we know that $K_\tau(\eta(s)\psi(s,r))=-i\eta'(s)\psi(s,r)$. From the choice of η it follows that

$$0 = -i\langle g, \eta'\psi\rangle_{\mathcal{K}} = \langle g, K_\tau(\eta\psi)\rangle_{\mathcal{K}} = \langle(-i\partial_s + \tau\mathfrak{H})g, \eta\psi\rangle_{\mathcal{K}}.$$

The last term equals

$$\int_{\mathbb{R}\times\mathbb{R}_+}\left(i\partial_s\frac{1}{r}\xi(s,r) + \tau H(s)\frac{1}{r}\xi(s,r)\right)\eta(s)\psi(s,r)r\,\mathrm{d}s\,\mathrm{d}r$$
$$= \int_{\mathbb{R}\times\mathbb{R}_+}\left(i\partial_s\xi(s,r) + \tau\left(-\partial_r r\partial_r\frac{1}{r} + \frac{1}{r^2}\left(s + \frac{Br^2}{2}\right)^2\right)\xi(s,r)\right)\psi(s,r)\mathrm{d}s\,\mathrm{d}r.$$

This means that

$$-i\partial_s\psi(s,r) + \tau\left(-\frac{1}{r}\partial_r r\partial_r + \frac{1}{r^2}\left(s + \frac{Br^2}{2}\right)^2\right)\psi(s,r) = 0$$

in the domain $\mathbb{R}\times]0,+\infty[$ in the sense of distributions. □

V. PROOF OF THE ADIABATIC THEOREM

We follow the strategy explained in the Introduction. The adiabatic propagator U_{AD} [see (4)] and the propagator U_τ defined in (5) differ by C defined by (6). Since $Q_\tau(s) = e^{i\tau\Omega(s)}Q(s)e^{-i\tau\Omega(s)}$, defined in (7), is unitarily equivalent to $Q(s)$ it is bounded, uniformly in s on every bounded interval $[0,S]$. Hence $C(s,s_0)$ exists and is given by the Dyson formula

$$C(s,s_0) = \mathbb{I} + \sum_{n=1}^{\infty} i^n \int_{s_0}^{s}\mathrm{d}s_1\int_{s_0}^{s_1}\mathrm{d}s_2\cdots\int_{s_0}^{s_{n-1}}\mathrm{d}s_n\, Q_\tau(s_1)Q_\tau(s_2)\cdots Q_\tau(s_n). \tag{31}$$

The task is to estimate the norm of the integral of Q_τ. This will be done by the integration by parts technique developed in the following two lemmas.

The first step is to find a bounded differentiable solution $X(s)$ of the commutation equation

$$Q(s) = i[W(s), X(s)].$$

The operator $W(s)$ was defined in (9). The off-diagonal entries of the $X(s)$ are determined unambiguously,

$$\langle\varphi_m(0), X(s)\varphi_n(0)\rangle = -i\frac{\langle\varphi_m(0), Q(s)\varphi_n(0)\rangle}{\lambda_m(s) - \lambda_n(s)}$$
$$= -\frac{\mathrm{sgn}(s)}{4B(n-m)^2}\min\left\{\frac{\gamma_m(s)}{\gamma_n(s)}, \frac{\gamma_n(s)}{\gamma_m(s)}\right\} \quad \text{for } m \neq n, \tag{32}$$

with $\gamma_n(s)$ defined in (26). We set

$$\langle\varphi_m(0), X(s)\varphi_n(0)\rangle = 0 \quad \text{for } m = n, \tag{33}$$

and write again $X(s)_{mn}$ instead of $\langle\varphi_m(0), X(s)\varphi_n(0)\rangle$.

Lemma 9: *The operator $X(s)$ defined by relations (33) and (32) is bounded and its norm satisfies the estimate*

$$\|X(s)\| \leqslant \frac{\pi^2}{12B}.$$

The derivative $\dot{X}(s)$ exists in the operator norm and satisfies the estimate

$$\|\dot{X}(s)\| \leqslant \frac{(1+\sqrt{2})\pi^2}{48B}.$$

Proof: The operator norm of $X(s)$ is bounded from above by the Shur–Holmgren norm,

$$\|X(s)\| \leqslant \|X(s)\|_{\mathrm{SH}} = \sup_{m\in\mathbb{Z}_+} \sum_{n=0}^{\infty} |X(s)_{mn}| \leqslant \frac{1}{2B}\sum_{k=1}^{\infty}\frac{1}{k^2} = \frac{\pi^2}{12B}.$$

Suppose that $s>0$ and $m<n$. Let us estimate the derivative of $X(s)_{mn}$. Using (29) one finds that

$$\left(\frac{\gamma_m(s)}{\gamma_n(s)}\right)' = \frac{\gamma_m(s)}{2\gamma_n(s)}\left(\frac{\Gamma'(m+s+1)}{\Gamma(m+s+1)} - \frac{\Gamma'(n+s+1)}{\Gamma(n+s+1)}\right)$$

$$= \frac{\gamma_m(s)}{2\gamma_n(s)}\sum_{k=0}^{\infty}\frac{n-m}{(k+m+s+1)(k+n+s+1)}.$$

Hence

$$\left|\frac{\mathrm{d}}{\mathrm{d}s}X(s)_{mn}\right| \leqslant \frac{1}{8B(n-m)}\left(\frac{1}{(m+1)(n+1)} + \int_1^{\infty}\frac{\mathrm{d}y}{(y+m)(y+n)}\right) = \frac{1}{8B(n-m)}\left(\frac{1}{(m+1)(n+1)} + \frac{1}{n-m}\ln\left(\frac{n+1}{m+1}\right)\right).$$

Thus we get, for $m\neq n$,

$$\left|\frac{\mathrm{d}}{\mathrm{d}s}X(s)_{mn}\right| \leqslant \frac{1}{8B}\left(\frac{1}{(m+1)(n+1)} + \frac{1}{|n-m|\min\{m+1,n+1\}}\right). \tag{34}$$

Let $\dot{X}(s)$ be a Hermitian operator in $L^2(\mathbb{R}_+, r\,\mathrm{d}r)$ with the matrix entries $\mathrm{d}X(s)_{mn}/\mathrm{d}s$. From the estimate (34) we deduce that $\dot{X}(s)$ is a Hilbert–Schmidt operator and

$$\|\dot{X}(s)\|_{\mathrm{HS}} \leqslant \frac{1}{8B}\left(\sum_{m=0}^{\infty}\frac{1}{(m+1)^2}\sum_{n=0}^{\infty}\frac{1}{(n+1)^2}\right)^{1/2} + \frac{1}{8B}\left(2\sum_{m=0}^{\infty}\frac{1}{(m+1)^2}\sum_{n=m+1}^{\infty}\frac{1}{(n-m)^2}\right)^{1/2}$$

$$= \frac{(1+\sqrt{2})\pi^2}{48B}.$$

Furthermore, since estimate (34) is uniform in s one can apply the Lebesgue dominated convergence theorem to conclude that

$$\lim_{\varepsilon\to 0}\left\|\frac{1}{\varepsilon}(X(s+\varepsilon)-X(s)) - \dot{X}(s)\right\|_{\mathrm{HS}} = 0.$$

Hence the derivative of the operator-valued function $X(s)$ exists in the operator norm and equals $\dot{X}(s)$. □

The matrix entries of the operator $Q_\tau(s)$ defined in (7) equal

$$\langle\varphi_m(0), Q_\tau(s)\varphi_n(0)\rangle = ie^{i\tau(\omega_m(s)-\omega_n(s))}\langle\varphi_m(s), \dot{\varphi}_n(s)\rangle.$$

Notice that the both operators $\Omega(s)$ and $W(s)=\Omega'(s)$ are diagonal in the basis $\{\varphi_n(0)\}$ and therefore they commute.

Lemma 10: *It holds true that*

$$\left\| \int_0^s Q_\tau(u)\mathrm{d}u \right\| \leqslant \left(1 + \frac{1+\sqrt{2}}{8}|s|\right)\frac{\pi^2}{6B\tau}.$$

Proof: Suppose that $s>0$. The integral can be rewritten as follows:

$$\int_0^s Q_\tau(u)\mathrm{d}u = i\int_0^s e^{i\pi\Omega(u)}[W(u),X(u)]e^{-i\pi\Omega(u)}\,\mathrm{d}u$$

$$=\frac{1}{\tau}\int_0^s ((e^{i\pi\Omega(u)})'X(u)e^{-i\pi\Omega(u)} + e^{i\pi\Omega(u)}X(u)(e^{-i\pi\Omega(u)})')\mathrm{d}u$$

$$=\frac{1}{\tau}\int_0^s ((e^{i\pi\Omega(u)}X(u)e^{-i\pi\Omega(u)})' - e^{i\pi\Omega(u)}\dot{X}(u)e^{-i\pi\Omega(u)})\mathrm{d}u.$$

Consequently,

$$\int_0^s Q_\tau(u)\mathrm{d}u = \frac{1}{\tau}\left(e^{i\pi\Omega(s)}X(s)e^{-i\pi\Omega(s)} - X(0) - \int_0^s e^{i\pi\Omega(u)}\dot{X}(u)e^{-i\pi\Omega(u)}\,\mathrm{d}u\right).$$

More precisely, the derivation of this equality was rather formal but it becomes rigorous when sandwiching the both sides with the scalar product $\langle\varphi_m(0),\cdot\varphi_n(0)\rangle$. This is to say that the both sides have the same matrix entries in the basis $\{\varphi_n(0)\}$. But since the equality concerns bounded operators it holds true.

Using Lemma 9 one arrives at the estimate

$$\left\| \int_0^s Q_\tau(u)\mathrm{d}u \right\| \leqslant \frac{1}{\tau}\left(\|X(s)\| + \|X(0)\| + \int_0^s \|\dot{X}(u)\|\mathrm{d}u\right) \leqslant \frac{\pi^2}{B\tau}\left(\frac{1}{6} + \frac{1+\sqrt{2}}{48}s\right).$$

The lemma is proven. □

We can now show that the adiabatic propagator $U_{AD}(s,0)$ [see (4)] is close to the propagator $U_\tau(s,0)=U_{AD}(s,0)C(s,0)$ defined in (5) provided the adiabatic parameter τ is large.

Proposition 11: *It holds true that*

$$\|U_\tau(s,0) - U_{AD}(s,0)\| \leqslant M(s)e^{|s|M(s)}\frac{\pi}{3B\tau},$$

where

$$M(s) = \frac{\pi}{2} + 12|s| + \frac{1}{2}|s|(1+|s|)^{(3+|s|)/2}. \tag{35}$$

Proof: According to Lemma 6, $\|Q(s)\|\leqslant M(s)$, and from Lemma 10 one easily deduces that

$$\left\| \int_0^s Q_\tau(u)\mathrm{d}u \right\| \leqslant \frac{\pi}{3B\tau}M(s).$$

Using formula (5) one can estimate

$$\|U_\tau(s,0) - U_{AD}(s,0)\| = \|C(s,0) - \mathbb{I}\| \leqslant \sum_{n=1}^{\infty}\int_0^{|s|}\mathrm{d}s_1\cdots\int_0^{s_{n-2}}\mathrm{d}s_{n-1}\|Q_\tau(s_1)\|\cdots\|Q_\tau(s_{n-1})\|$$
$$\times\left\|\int_0^{s_{n-1}}\mathrm{d}s_n\,Q_\tau(s_n)\right\| \leqslant \frac{\pi}{3B\tau}\sum_{n=1}^{\infty}M(s)^n\int_0^{|s|}\mathrm{d}s_1\cdots\int_0^{s_{n-2}}\mathrm{d}s_{n-1}$$

$$= \frac{\pi}{3B\tau} \sum_{n=1}^{\infty} M(s)^n \frac{|s|^{n-1}}{(n-1)!}.$$

The proposition is proven. □

VI. THE GENERAL DEPENDENCE ON TIME

Here we show that the adiabatic theorem extends to Hamiltonians of the form

$$H^\zeta(s) = H(\zeta(s))$$

where $H(s)$ is defined in (1) and $\zeta \in C^2(\mathbb{R})$ is a real-valued function. In order to simplify the discussion and to avoid considering discontinuities [recall that $Q(s)$ is discontinuous at $s=0$] we shall further assume that $\zeta'(s) > 0$ and $\zeta(0) = 0$.

Set

$$V^\zeta(s) = V(\zeta(s)), \quad W^\zeta(s) = W(\zeta(s)), \quad \Omega^\zeta(s) = \int_0^s W^\zeta(u) \mathrm{d}u.$$

Let $C^\zeta(s, s_0)$ be the propagator related via the Dyson formula to the Hamiltonian $-Q_\tau^\zeta(s)$, where

$$Q_\tau^\zeta(s) = \exp(i\tau\Omega^\zeta(s)) Q^\zeta(s) \exp(-i\tau\Omega^\zeta(s)), \quad Q^\zeta(s) = \zeta'(s) Q(\zeta(s)).$$

Exactly in the same way as in the proof of Proposition 7 one can show that the propagator

$$U_\tau^\zeta(s, s_0) = V^\zeta(s) \exp(-i\tau\Omega^\zeta(s)) C^\zeta(s, s_0) \exp(i\tau\Omega^\zeta(s_0)) V^\zeta(s_0)^{-1}$$

is weakly associated to the Hamiltonian $H^\zeta(s)$. The adiabatic propagator now reads

$$U_{AD}^\zeta(s, s_0) = V^\zeta(s) \exp(-i\tau(\Omega^\zeta(s) - \Omega^\zeta(s_0))) V^\zeta(s_0)^{-1}.$$

Proposition 12: *Assume that* $\zeta \in C^2(\mathbb{R})$, $\zeta'(s) > 0$ *and* $\zeta(0) = 0$. *Then there exists a locally bounded function* $m^\zeta(s)$ *such that*

$$\forall s \in \mathbb{R}, \quad \| U_\tau^\zeta(s, 0) - U_{AD}^\zeta(s, 0) \| \leqslant \frac{m^\zeta(s)}{B\tau}.$$

Proof: Suppose for definiteness that $s > 0$. Recall that $\|Q(s)\| \leqslant M(s)$ where $M(s)$ was defined in (35). The operator-valued function

$$X^\zeta(s) = \zeta'(s) X(\zeta(s)),$$

with $X(s)$ being defined in (32) and (33), satisfies the commutation equation

$$Q^\zeta(s) = i[W^\zeta(s), X^\zeta(s)].$$

Quite analogously as in the proof of Lemma 10 one derives the estimate

$$\left\| \int_0^s Q_\tau^\zeta(u) \mathrm{d}u \right\| \leqslant \frac{1}{\tau} \left(\|X^\zeta(s)\| + \|X^\zeta(0)\| + \int_0^s \|\dot{X}^\zeta(u)\| \mathrm{d}u \right).$$

In virtue of Lemma 9 we have

$$\|X^\zeta(s)\| \leqslant \frac{\pi^2}{12B} \zeta'(s)$$

and

$$\int_0^s \|\dot{X}^\zeta(u)\|\mathrm{d}u \leqslant \frac{\pi^2}{12B}\int_0^s |\zeta''(u)|\mathrm{d}u + \frac{(1+\sqrt{2})\pi^2}{48B}\int_0^s \zeta'(u)^2\,\mathrm{d}u.$$

Hence

$$\left\| \int_0^s Q_\tau^\zeta(u)\mathrm{d}u \right\| \leqslant \frac{q^\zeta(s)}{B\tau},$$

where

$$q^\zeta(s) = \frac{\pi^2}{12}\left(\zeta'(0) + \sup_{0\leqslant u\leqslant s}\zeta'(u) + \int_0^s |\zeta''(u)|\mathrm{d}u + \frac{1+\sqrt{2}}{4}\int_0^s \zeta'(u)^2\,\mathrm{d}u\right).$$

Finally one can proceed similarly as in the proof of Proposition 11 to derive the estimate

$$\|U_\tau^\zeta(s,0) - U_{AD}^\zeta(s,0)\| = \|C^\zeta(s,0) - \mathbb{I}\| \leqslant \exp\left(\int_0^{\zeta(s)} M(v)\mathrm{d}v\right)\frac{q^\zeta(s)}{B\tau}.$$

This completes the proof.

APPENDIX: PROPAGATOR WEAKLY ASSOCIATED TO A HAMILTONIAN

By a propagator $U(t,s)$ we mean a family of unitary operators in a separable Hilbert space $\mathcal{H}$ depending on t, $s\in\mathbb{R}$ which satisfies the following conditions:

(i) $U(t,s)$ is strongly continuous jointly in t, s,
(ii) the Chapman–Kolmogorov equality is satisfied, i.e.,

$$\forall\, t,s,r \in \mathbb{R}, \quad U(t,r)U(r,s) = U(t,s).$$

Let $H(t)$, $t\in\mathbb{R}$, be a family of self-adjoint operators in $\mathcal{H}$. The domain may depend on t. The standard way how one relates a propagator $U(t,s)$ to $H(t)$ is based on the following two requirements:

(i) $\forall t,s\in\mathbb{R}, \quad U(t,s)(\mathrm{Dom}\,H(s)) = \mathrm{Dom}\,H(t)$,
(ii) $\forall \psi\in\mathrm{Dom}\,H(s), \quad \forall\, t\in\mathbb{R}, \quad i\partial_t U(t,s)\psi = H(t)U(t,s)\psi$.

Clearly, if a propagator exists then it is unique. In some situations, however, these requirements may turn out to be unnecessarily strong. In particular this is true for the model studied in the current paper. The heart of the problem is illustrated on the following example.

Let $A(t)$ be a family of bounded Hermitian operators in $\mathcal{H}$ which is uniformly bounded. Then the propagator exits and is given by the Dyson formula. Let us call it $C(t,s)$. Let $D\subset\mathcal{H}$ be a dense linear subspace, and let $T(t)$ be a strongly continuous family of unitary operators such that D is invariant with respect to $T(t)$ and for every $\psi\in D$ there exists the derivative $\partial_t T(t)\psi$. Furthermore, suppose that $X(t) = i\dot{T}(t)T(t)^{-1}$, with $\mathrm{Dom}\,X(t) = D$, is a self-adjoint operator for all t (the dot designates the derivative). A formal computation gives

$$T(t)(-i\partial_t + A(t))T(t)^{-1} = -i\partial_t + X(t) + T(t)A(t)T(t)^{-1}.$$

If $C(t,s)$ preserved the domain D then the propagator $T(t)C(t,s)T(s)^{-1}$ would solve the Schrödinger equation for $X(t)+T(t)A(t)T(t)^{-1}$ on D. Thus it is natural to associate it to this family of self-adjoint operators. The hypothesis on $C(t,s)$ need not be, however, satisfied since $A(t)$ is an arbitrary family of bounded operators and so $C(t,s)$ will in general not preserve this domain.

In this appendix we propose a way how to associate a propagator to a given time-dependent Hamiltonian in a weak sense. This association is more general than the standard one (which supposes a constant domain and solving the Schrödinger equation in the strong sense) and it is still unique (i.e., there is at most one propagator weakly associated to a given time-dependent Hamiltonian).

Here we develop this approach only to an extent which makes it possible to apply these ideas to the studied model with a time-dependent Aharonov–Bohm flux. In particular, the described example is covered by Proposition A.4 below.

Let $\mathcal{X}$ be a Banach space. We shall say that a vector-valued function $f:\mathbb{R}\to\mathcal{X}$ is absolutely continuous on $\mathbb{R}$ if it is absolutely continuous on every compact interval $I\subset\mathbb{R}$. By the symbol $\widetilde{AC}(\mathbb{R},\mathcal{X})$ (or just $\widetilde{AC}$ if there is no danger of misunderstanding) we shall denote the space of all absolutely continuous vector-valued functions $f(t)$ such that the derivative $f'(t)$ exists almost everywhere on $\mathbb{R}$. In such a case the function $\|f'(t)\|$ is locally integrable and $f(t)=f(0)+\int_0^t f'(s)\mathrm{d}s$ (Ref. 10 Theorem 3.8.6). If the Banach space $\mathcal{X}$ has the Radon–Nikodym property then the space $\widetilde{AC}(\mathbb{R},\mathcal{X})$ coincides with the space of absolutely continuous vector-valued functions $AC(\mathbb{R},\mathcal{X})$. Let us recall that $\mathcal{X}$ is said to have the Radon–Nikodym property if the fundamental theorem of calculus holds, i.e., if any absolutely continuous function is the antiderivative of a Bochner integrable function. For example, separable Hilbert spaces are known to have the Radon–Nikodym property.[7]

Clearly, if $f,g\in AC(\mathbb{R},\mathcal{H})$ then the function $\langle f(t),g(t)\rangle$ is absolutely continuous and

$$\partial_t\langle f(t),g(t)\rangle = \langle f'(t),g(t)\rangle + \langle f(t),g'(t)\rangle \text{ a.e.}$$

Similarly, if $A\in\widetilde{AC}(\mathbb{R},\mathcal{B}(\mathcal{H}))$ and $f\in AC(\mathbb{R},\mathcal{H})$ then $A(t)f(t)\in AC(\mathbb{R},\mathcal{H})$ and

$$\partial_t A(t)f(t) = \dot{A}(t)f(t) + A(t)f'(t) \text{ a.e.}$$

Let $\{e_k\}$ be an orthonormal basis in $\mathcal{H}$. A vector-valued function $f(t)=\Sigma\,\eta_k(t)e_k$ belongs to $AC(\mathbb{R},\mathcal{H})$ if and only if the following two conditions are satisfied:

(i) $\exists a\in\mathbb{R}$ such that $\Sigma_k|\eta_k(a)|^2<\infty$,
(ii) $\forall k$, $\eta_k\in AC$, and $(\Sigma_k|\eta_k'(t)|^2)^{1/2}\in L^1_{\mathrm{loc}}(\mathbb{R})$.

From here one easily derives the following criterion [alternatively, one can again consult (Ref. 10, Theorem 3.8.6)].

Lemma A.1: *A vector-valued function $f:\mathbb{R}\to\mathcal{H}$ belongs to $AC(\mathbb{R},\mathcal{H})$ if and only if the following two conditions are satisfied:*

(i) *there exists a total set $\mathcal{T}\subset\mathcal{H}$ such that for all $\psi\in\mathcal{T}$, $\langle\psi,f(t)\rangle$ is absolutely continuous,*
(ii) *the derivative $f'(t)$ exists almost everywhere and $\|f'(t)\|\in L^1_{\mathrm{loc}}(\mathbb{R})$.*

Set $\mathcal{K}=L^2(\mathbb{R},\mathcal{H},\mathrm{d}t)$. Let us recall that to every propagator $U(t,s)$ on $\mathcal{H}$ one can relate a unique self-adjoint operator K in $\mathcal{K}$ which is the generator of the one-parameter group of unitary operators $\exp(-i\sigma K)$, $\sigma\in\mathbb{R}$, defined by[11]

$$(e^{-i\sigma K}f)(t) = U(t,t-\sigma)f(t-\sigma).$$

K is called the quasienergy operator. Equivalently,

$$K = \mathfrak{U}(-i\partial_t)\mathfrak{U}^*, \quad \text{where } \mathfrak{U} = \int_{\mathbb{R}}^{\oplus} U(t,0)\mathrm{d}t. \tag{A1}$$

So $f \in \mathrm{Dom}\, K$ if and only if $U(t,0)^{-1}f(t) \in \mathrm{Dom}(-i\partial_t)$ which means that $f \in L^2$, $U(t,0)^{-1}f(t) \in AC$ and $(U(t,0)^{-1}f(t))' \in L^2$.

From (A1) one concludes that the spectrum of K is purely absolutely continuous and coincides with $\mathbb{R}$. So the kernel of K is always trivial. It seems to be natural, however, to introduce a generalized kernel of K, called $\mathrm{Ker}_0\, K$, as follows:

$$\mathrm{Ker}_0\, K = \{f \in L^2_{\mathrm{loc}}(\mathbb{R},\mathcal{H},\mathrm{d}t);\ \forall\ \eta \in C_0^\infty(\mathbb{R}), \quad \eta f \in \mathrm{Dom}\, K \text{ and } K(\eta f) = -i\eta' f\}.$$

Since K can be very roughly imagined as the formal operator $-i\partial_t + H(t)$ the elements of $\mathrm{Ker}_0\, K$ can be regarded as solutions of the Schrödinger equation in a weak sense.

Proposition A.2: *Let $U(t,s)$ be a propagator and let K be the quasienergy operator associated to it. Then it holds*

$$\mathrm{Ker}_0\, K = \{U(t,0)\psi; \psi \in \mathcal{H}\}.$$

Proof: If $f(t) = U(t,0)\psi$, with $\psi \in \mathcal{H}$, and $\eta \in C_0^\infty(\mathbb{R})$ then, in $\mathcal{K}$, there exists the derivative

$$i\frac{\mathrm{d}}{\mathrm{d}\sigma}(e^{-i\sigma K}\eta f)(t)\bigg|_{\sigma=0} = i\frac{\mathrm{d}}{\mathrm{d}\sigma}(\eta(t-\sigma)U(t,0)\psi)\bigg|_{\sigma=0} = -i\eta'(t)f(t).$$

Hence, by the Stone theorem, $\eta f \in \mathrm{Dom}\, K$ and $K(\eta f) = -i\eta' f$.

Conversely, suppose that $f \in \mathrm{Ker}_0\, K$ and set $g(t) = U(t,0)^{-1}f(t)$. Let η be a test function. From (A1) one deduces that $\eta g \in \mathrm{Dom}(-i\partial_t)$ and

$$\partial_t(\eta(t)g(t)) = \eta'(t)g(t) \text{ a.e.}$$

Since $\eta \in C_0^\infty(\mathbb{R})$ is arbitrary this implies that $g(t) \in AC(\mathbb{R},\mathcal{H})$ and $g'(t) = 0$a.e. Consequently, $g(t) = \psi \in \mathcal{H}$ is a constant vector-valued function and $f(t) = U(t,0)\psi$. □

It is known that the correspondence between the propagators and the quasienergy operators is one-to-one [Ref. 11, Remark (1) on p. 321]. On the one hand, by the very definition, K is unambiguously determined by $U(t,s)$. On the other hand, if $U(t,s)$ and $U_1(t,s)$ are two propagators with equal quasienergy operators, $K = K_1$, then $U(t,s) = U_1(t,s)$. This uniqueness result is also a straightforward corollary of Proposition A.2. Actually, Proposition A.2 implies that for every $\psi \in \mathcal{H}$ there exists $\psi_1 \in \mathcal{H}$ such that $U(t,0)\psi = U_1(t,0)\psi_1$ for all t (we use the strong continuity of the propagators). By setting $t = 0$ one finds that $\psi = \psi_1$. Hence $U(t,0)\psi = U_1(t,0)\psi$ for all $\psi \in \mathcal{H}$. Consequently,

$$U(t,s) = U(t,0)U(s,0)^{-1} = U_1(t,0)U_1(s,0)^{-1} = U_1(t,s).$$

For a family of self-adjoint operators $H(t)$, $t \in \mathbb{R}$, set $\mathfrak{H} = \int_{\mathbb{R}}^{\oplus} H(t)\mathrm{d}t$. This means that $f \in \mathcal{K}$ belongs to $\mathrm{Dom}\, \mathfrak{H}$ if and only if $f(t) \in \mathrm{Dom}\, H(t)$a.e. and $\|H(t)f(t)\| \in L^2(\mathbb{R},\mathrm{d}t)$. Then $\mathfrak{H}$ is a self-adjoint operator in $\mathcal{K}$. In what follows we shall always suppose that the intersection $\mathrm{Dom}(-i\partial_t) \cap \mathrm{Dom}\, \mathfrak{H}$ is dense in $\mathcal{K}$. For example, this is true in the case when the domain $\mathrm{Dom}\, H(t)$ is independent of t. Consequently, $-i\partial_t + \mathfrak{H}$ is a densely defined symmetric operator.

Definition A.3: *We shall say that a propagator $U(t,s)$ is* weakly associated to $H(t)$ *if*

$$K = \overline{-i\partial_t + \mathfrak{H}}. \tag{A2}$$

Notice that equality (A2) is equivalent to the following two conditions:

(i) $-i\partial_t + \mathfrak{H} \subset K$,
(ii) $-i\partial_t + \mathfrak{H}$ is essentially self-adjoint.

Furthermore, it is important to note that this definition still guarantees the uniqueness, i.e., to $H(t)$ one can weakly associate at most one propagator $U(t,s)$. Actually, if $U(t,s)$ and $U_1(t,s)$ are weakly associated to $H(t)$ then $K=K_1$ according to equality (A2). But due to the one-to-one correspondence between the propagators and the quasienergy operators we have $U(t,s)=U_1(t,s)$.

Now we are ready to formulate and prove two propositions which are directly applicable to the model studied in this paper.

Proposition A.4: *Let $A(t)$ be a family of bounded self-adjoint operators in $\mathcal{H}$ which is locally bounded. Let $C(t,s)$ be the propagator associated to $A(t)$ via the Dyson formula. Let $D\subset\mathcal{H}$ be a dense linear subspace and let $T(t)$ be a strongly continuous family of unitary operators in $\mathcal{H}$ obeying the following conditions:*

(i) $\forall t\in\mathbb{R}$, $T(t)D=D$,
(ii) $\forall\psi\in D$, $T(t)\psi$ *is continuously differentiable,*
(iii) $\forall t\in\mathbb{R}$, $X(t)=i\dot{T}(t)T(t)^{-1}$, *with* $\mathrm{Dom}\,X(t)=D$, *is a self-adjoint operator.*

Then the propagator $T(t)C(t,s)T(s)^{-1}$ is weakly associated to the family

$$X(t)+T(t)A(t)T(t)^{-1}.$$

Proof: Set

$$Y(t)=X(t)+T(t)A(t)T(t)^{-1},\quad \mathfrak{Y}=\int_{\mathbb{R}}^{\oplus}Y(t)\mathrm{d}t,\quad \mathfrak{T}=\int_{\mathbb{R}}^{\oplus}T(t)\mathrm{d}t.$$

Let K_Y be the quasienergy operator associated to the propagator $T(t)C(t,s)T(s)^{-1}$. Set

$$C(t)=C(t,0),\quad \mathfrak{C}=\int_{\mathbb{R}}^{\oplus}C(t)\mathrm{d}t.$$

$C(t)$ is a family of unitary operators which satisfies $C(t)\in\widetilde{AC}(\mathbb{R},\mathfrak{B}(\mathcal{H}))$ and $A(t)=i\dot{C}(t)C(t)^{-1}$.

(i) Let us verify that

$$-i\partial_t+\mathfrak{Y}\subset K_Y=\mathfrak{T}\mathfrak{C}(-i\partial_t)\mathfrak{C}^{-1}\mathfrak{T}^{-1}.$$

Suppose that a vector-valued function $f:\mathbb{R}\to\mathcal{H}$ belongs to $\mathrm{Dom}(-i\partial_t+\mathfrak{Y})$. This happens if and only if f obeys the following conditions: $f\in L^2$, $f\in AC$, $f'\in L^2$, $f(t)\in D$ a.e. and $Y(t)f(t)\in L^2$. In that case the function $T(t)^{-1}f(t)$ is differentiable almost everywhere and the derivative

$$(T(t)^{-1}f(t))'=T(t)^{-1}(f'(t)+iX(t)f(t))$$

is square integrable. Moreover, if $\psi\in D$ then the function $\langle\psi,T(t)^{-1}f(t)\rangle=\langle T(t)\psi,f(t)\rangle$ is absolutely continuous. According to Lemma A.1 this implies that $T(t)^{-1}f(t)\in AC(\mathbb{R},\mathcal{H})$ and consequently $C(t)^{-1}T(t)^{-1}f(t)\in AC$ as well. Furthermore, a straightforward computation yields

$$Y(t)f(t)=i(\dot{T}(t)T(t)^{-1}f(t)+T(t)\dot{C}(t)C(t)^{-1}T(t)^{-1}f(t))$$

$$=i(T(t)C(t))'C(t)^{-1}T(t)^{-1}f(t)$$

$$=if'(t)-iT(t)C(t)(C(t)^{-1}T(t)^{-1}f(t))'.$$

Hence $(C(t)^{-1}T(t)^{-1}f(t))'\in L^2$, $f\in\mathrm{Dom}\,K_Y$ and $-if'(t)+Y(t)f(t)=K_Yf(t)$.

(ii) Let us verify that $-i\partial_t+\mathfrak{Y}$ is essentially self-adjoint. Suppose that $g\in\mathrm{Dom}(-i\partial_t+\mathfrak{Y})^*$ satisfies $(-i\partial_t+\mathfrak{Y})^*g=zg$ with $\mathrm{Im}(z)\neq 0$. This means that

$$\forall f \in \mathrm{Dom}(-i\partial_t + \mathfrak{Y}), \quad \langle(-i\partial_t + \mathfrak{Y})f, g\rangle_{\mathcal{K}} = z\langle f, g\rangle_{\mathcal{K}}.$$

Choose $f(t) = \eta(t)T(t)\psi$ where $\psi \in D$ and $\eta \in C_0^\infty(\mathbb{R})$ is real valued. Then $f \in \mathrm{Dom}(-i\partial_t + \mathfrak{Y})$ and an easy computation shows that

$$(-i\partial_t + \mathfrak{Y})f(t) = -i\eta'(t)T(t)\psi + \eta(t)T(t)A(t)\psi.$$

Hence for all $\eta \in C_0^\infty(\mathbb{R})$ we have

$$\int_{\mathbb{R}} (i\eta'(t)\langle T(t)\psi, g(t)\rangle + \eta(t)\langle T(t)A(t)\psi, g(t)\rangle)\mathrm{d}t = z\int_{\mathbb{R}} \eta(t)\langle T(t)\psi, g(t)\rangle \mathrm{d}t.$$

Setting

$$F(t) = \langle T(t)\psi, g(t)\rangle, \quad G(t) = \langle T(t)A(t)\psi, g(t)\rangle,$$

we find that

$$-i\partial_t F(t) + G(t) = zF(t) \tag{A3}$$

in the sense of distributions. Since both $F(t)$ and $G(t)$ are locally integrable, a standard result from the theory of distributions tells us that $F(t)$ is absolutely continuous and equality (A3) holds true in the usual sense. Moreover, equality (A3) implies that

$$\partial_t(e^{2\,\mathrm{Im}(z)t}|F(t)|^2) = 2e^{2\,\mathrm{Im}(z)t}\,\mathrm{Im}(\overline{F(t)}G(t)).$$

Let us now choose an orthonormal basis $\{\psi_k\}$ whose elements all belong to the domain D. Let us write F_k instead of F and G_k instead of G when replacing ψ by ψ_k. We have derived the equality

$$|F_k(t)|^2 = e^{-2\,\mathrm{Im}(z)(t-a)}|F_k(a)|^2 + 2\int_a^t e^{-2\,\mathrm{Im}(z)(t-s)}\,\mathrm{Im}(\overline{F_k(s)}G_k(s))\mathrm{d}s \tag{A4}$$

which is valid for all k and all a, $t \in \mathbb{R}$. Observe that

$$\sum_k |F_k(t)|^2 = \|g(t)\|^2 \quad \text{a.e.},$$

$$\sum_k |F_k(s)||G_k(s)| \leqslant \|g(s)\|\|A(s)T(s)^{-1}g(s)\| \in L^1_{\mathrm{loc}}(\mathbb{R}, \mathrm{d}s) \quad \text{a.e.},$$

and

$$\sum_k \overline{F_k(s)}G_k(s) = \langle g(s), T(s)A(s)T(s)^{-1}g(s)\rangle \in \mathbb{R} \quad \text{a.e.}$$

Summing in k in equality (A4) we find that

$$\|g(t)\| = e^{-\mathrm{Im}(z)(t-a)}\|g(a)\|$$

for almost all a, $t \in \mathbb{R}$. Since $\|g(t)\|$ is square integrable this is possible only if $g(t) = 0$ a.e. □

Proposition A.4 has a corollary justifying the adverb "weakly" in Definition A.3.

Corollary A.5: *Assume that a propagator $U(t, t_0)$ is associated as a strong solution of the Schrödinger equation to a time-dependent Hamiltonian $H(t)$ which has, however, a time-independent domain (i.e., the relationship between the propagator and the Hamiltonian is the usual one). Then $U(t, t_0)$ is weakly associated to $H(t)$.*

Proof: In Proposition A.4 it suffices to set $D = \mathrm{Dom}\, H(0)$, $T(t) = U(t, 0)$ and $A(t) = 0$. Then $X(t) = H(t)$, $C(t, s) = \mathbb{I}$, and $T(t)C(t, s)T(s)^{-1} = U(t, s)$. □

Proposition A.6: *Suppose that $V(t)$, $t \in \mathbb{R}$, is a family of unitary operators which is continu-*

ously differentiable in the strong sense. Let $\tilde{H}(t)$, $t\in\mathbb{R}$, *be a family of self-adjoint operators such that* $\mathrm{Dom}\,\tilde{H}(t)=D$ *for all* $t\in\mathbb{R}$. *Set*

$$H(t) = V(t)\tilde{H}(t)V(t)^{-1} + i\dot{V}(t)V(t)^{-1}.$$

If the propagator $\tilde{U}(t,s)$ *is weakly associated to* $\tilde{H}(t)$ *then the propagator* $U(t,s)=V(t)\tilde{U}(t,s)V(s)^{-1}$ *is weakly associated to* $H(t)$.

Proof: Set

$$\tilde{U}(t) = \tilde{U}(t,0), \quad \tilde{\mathfrak{U}} = \int_{\mathbb{R}}^{\oplus} \tilde{U}(t)\mathrm{d}t, \quad \mathfrak{V} = \int_{\mathbb{R}}^{\oplus} V(t)\mathrm{d}t.$$

By the assumption, $\tilde{\mathfrak{U}}(-i\partial_t)\tilde{\mathfrak{U}}^{-1}=\overline{-i\partial_t+\tilde{\mathfrak{H}}}$. We must show that

$$\mathfrak{V}\tilde{\mathfrak{U}}(-i\partial_t)\tilde{\mathfrak{U}}^{-1}\mathfrak{V}^{-1} = \overline{-i\partial_t+\mathfrak{H}}.$$

Since

$$\mathfrak{V}\tilde{\mathfrak{U}}(-i\partial_t)\tilde{\mathfrak{U}}^{-1}\mathfrak{V}^{-1} = \mathfrak{V}\overline{(-i\partial_t+\tilde{\mathfrak{H}})}\mathfrak{V}^{-1} = \overline{\mathfrak{V}(-i\partial_t+\tilde{\mathfrak{H}})\mathfrak{V}^{-1}}$$

it is sufficient to verify that

$$\mathfrak{V}(-i\partial_t+\tilde{\mathfrak{H}})\mathfrak{V}^{-1} = -i\partial_t+\mathfrak{H}.$$

This would also imply that $\mathrm{Dom}(-i\partial_t)\cap\mathrm{Dom}(\mathfrak{H})$ is dense in $\mathcal{K}$.

A vector-valued function $f:\mathbb{R}\to\mathcal{H}$ belongs to $\mathrm{Dom}(\mathfrak{V}(-i\partial_t+\tilde{\mathfrak{H}})\mathfrak{V}^{-1})$ if and only if it satisfies the following conditions: $f\in L^2$, $V(t)^{-1}f(t)\in AC$, $(V(t)^{-1}f(t))'\in L^2$, $V(t)^{-1}f(t)\in D$ a.e. and $\tilde{H}(t)V(t)^{-1}f(t)\in L^2$. Let us note that from the continuous differentiability of $V(t)$ in the strong sense and from the uniform boundedness principle it follows that $\dot{V}(t)$, $t\in\mathbb{R}$, is a family of bounded operators which is locally bounded. Furthermore, $V(t)^*=V(t)^{-1}$ is continuously differentiable in the strong sense as well and $V(t)^{-1}\psi\in AC$ for all $\psi\in\mathcal{H}$. Suppose that $f\in L^2$. If $V(t)^{-1}f(t)\in AC$ then $f'(t)$ exists almost everywhere and $\|f'(t)\|$ is locally integrable, the function $\langle\psi,f(t)\rangle=\langle V(t)^{-1}\psi,V(t)^{-1}f(t)\rangle$ is absolutely continuous for all $\psi\in\mathcal{H}$ and therefore, by Lemma A.1, $f(t)\in AC$. Similarly, the converse is also true. If $f(t)\in AC$ then $V(t)^{-1}f(t)\in AC$.

Using these facts and the relation between $\tilde{H}(t)$ and $H(t)$ [including that $\mathrm{Dom}\,H(t)=V(t)D$] one easily finds that the domains of $\mathfrak{V}(-i\partial_t+\tilde{\mathfrak{H}})\mathfrak{V}^{-1}$ and $-i\partial_t+\mathfrak{H}$ coincide and that

$$V(t)(-i\partial_t+\tilde{H}(t))V(t)^{-1}f(t) = -if'(t)+H(t)f(t)$$

for every $f\in\mathrm{Dom}(-i\partial_t+\mathfrak{H})$. □

Remark: Proposition A.6 can be easily extended to the case when the family of unitary operators $V(t)$ is continuous and piecewise continuously differentiable in the strong sense and in each point of discontinuity there exist the limits of the derivative both from the left and from the right.

(Received 17 December 2004; accepted 1 March 2005; published online 25 April 2005)

Based on the spectral properties of Ruelle transfer operators, we establish conditions for the absence of phase transitions in the continuum. Our approach differs in several aspects from those which use Kirkwood–Salsburg and Kirkwood–Ruelle operators. In particular the results follow in a concise and relatively direct way. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897163]

I. INTRODUCTION

The analysis of the equilibrium behavior of systems can be done by studying thermodynamical properties. One main aspect is the coexistence of two or more pure phases for "physically acceptable" interactions. In order to investigate the uniqueness of phases it is important to analyze the variation of some macroscopic quantities when thermodynamical parameters, such as the temperature, are changed.

Numerical studies show that restrictions on the configuration space favor the disappearance of phase transitions. The well known fact, stated by van Hove theorem,[2,15] that when the dimension is reduced to one is more difficult to observe phase transitions, would confirm those claims. In this vein, instead of reducing the dimension we could consider as well the confinement of the system configurations to a compact set. This can be achieved by considering special potentials between pairs of particles or adequate external fields.

In this paper we shall give conditions for ensuring the absence of phase transition in more general system of particles, in the sense that they are not necessarily confined. The systems we are thinking of consist of N particles into a container $\Omega \subset \mathbf{R}^d$, $|\Omega| = \mathrm{mes}(\Omega) \leqslant \infty$, interacting *via* a potential map $V_N : \Omega^N \to \mathbf{R}$ of the form

$$V_N(x_0, x_1, \ldots, x_{N-1}) = \sum_{i<j} \varphi(x_i, x_j) + \sum_i \psi(x_i), \tag{1}$$

where $\varphi : \Omega \times \Omega \to \mathbf{R}$ and $\psi : \Omega \to \mathbf{R}$ are maps that represent the pair potential and an external field, respectively.

The problem of the absence of phase transitions has been frequently treated by using spectral properties of the Kirkwood–Salsburg (KS) and Kirkwood–Ruelle (KR) operators. Historically the first contribution in that direction is the article by Pastur.[10] For further contributions see for instance Refs. 3 and 4 and 17–19. The analysis began with the consideration of confined systems in a bounded set Λ and then taking the thermodynamic limit to reach an infinite volume set. Here we propose an alternative way. In the first place, as we mentioned above, we considered a not necessarily bounded container for the particles, and so we do not need to take the thermodynamic limit. On the other hand, we use the Grothendieck theory of nuclear operators instead of the KR

[a]Electronic mail: meson@iflysib.unlp.edu.ar
[b]Electronic mail: vericat@iflysib.unlp.edu.ar

and KS operators. This approach allows to get a relationship between the spectral radius of the operators and the free energy, for any value of the temperature. The conclusions follow in a relatively direct manner from Grothendieck results.

From the mathematical point of view the absence of phase transition is established by means of the uniqueness of the *Gibbs states*, which are special probability measures on Ω. The set $\mathcal{G}$ of the Gibbs states is convex[12] so, any element of it can be written as a convex combination (*mixture*) of the extremal points of $\mathcal{G}$. The extremal Gibbs states are interpreted as *pure homogenous phases* and any Gibbs state admits a unique integral decomposition in terms of pure phases.

Recently, Franzosi *et al.*[1] have given sufficient conditions for the existence of just one phase in systems interacting via a general class of confined potentials in any dimension. These conditions include the extra hypothesis that each equipotential surface is C^∞-diffeomorphic to the others. This hypothesis, together with Morse theory of critical points, leads to differentiability of the free energy.

In this paper, we study the behavior of the phases when the inverse temperature q is varied. We use a formalism in which a "free energy function" $T(q)$ is identified with the limit of the logarithm of a partition function over the total particle number. From the Ruelle thermodynamic formalism,[12] which we can adapt for the continuous case, it is known that the Gibbs states are functional tangents to $T(q)$ and hence a phase transition is detected when this function has a singularity. In order to demonstrate the uniqueness of Gibbs states, we shall introduce adequate *transfer operators* and we will prove that $\exp(T(q))$ is an isolated eigenvalue of these operators. This kind of analysis, for one dimensional lattices, was already done by Ruelle[11,12] and Sinai.[13] In Ref. 9 we extended Sinai–Ruelle approaches in some directions. Instead of a symbolic space (a one dimensional lattice in the statistical mechanics terminology), we have considered a compact submanifold $X \subset \mathbf{R}^d$. On the other hand, the dynamics were more generally given by continuous maps $f: X \to X$ and we introduced a free energy $T(q)$ adequate to that context. In that case the partition function is defined by summing over the set of microstates (the periodic points of f), which will be finite by the conditions imposed on the dynamics.

Under the conditions assumed here, the states belong to a continuum, so that partition functions must be defined by mean of integrals. Moreover we emphasize the statistical mechanical more than the dynamic character of the system under study. Also, in our previous paper[9] we have considered systems which can be "discretized" and, because of this, the transfer operators are defined as sums. Here, the discretization property is relaxed and the operators are integral ones.

The paper layout is as follows: in the next section we review the concept of Gibbs states, in any dimension and introduce the formalism to define the partition functions and free energy functions. In Sec. III we use the transfer operators and prove the absence of phase transition in the models considered.

II. THE FREE ENERGY FUNCTION AND GIBBS STATES

Let us denote by $\mathcal{G}(q)$ the space of the *Gibbs states* for a system at inverse temperature q and described by a total potential of the form of Eq. (1). It is constituted by the probability measures μ_q which are infinite volume limits as $N \to \infty$ of the finite volume ensembles,

$$\mu_{q,N}(x_0, x_1, \ldots, x_{N-1}) = \frac{\exp(-qV_N)}{Z_N(q)} \delta_{(x_0, x_1, \ldots, x_{N-1})}. \tag{2}$$

Here δ_x is the point mass measure in x and the configurational partition function for the system reads

$$Z_N(q) = \int_{\Omega^N} \exp(-qV_N) \mathrm{d}x_0 \, \mathrm{d}x_1 \cdots \mathrm{d}x_{N-1}. \tag{3}$$

Therefore the *free energy function per particle* is, provided the limit exists,

$$T(q) = \lim_{N\to\infty} \frac{1}{N} \log Z_N(q). \tag{4}$$

It may be interesting to notice how this formalism could read in the context of dynamical systems. Let us consider a pair (X,f) with X be a compact subset of $\mathbf{R}^d$ $(d>0)$ and $f:X\to X$, a continuous map. For a potential $\varphi \in C(X)$ we define the *statistical sum* by

$$S_N(x) = \sum_{i=0}^{N-1} \varphi(f^i(x)). \tag{5}$$

Let us assume that the dynamical map f be *expansive*, i.e., there is a constant $\delta>0$, such that $d(f^N(x), f^N(y)) < \delta$, for any integer N implies $x=y$. Under these conditions the set of periodic points, $P_N(f) := \{x: f^N x = x\}$, is (N,δ)-separated and, since X is compact, then it is finite (these are standard facts in topological dynamics, see Ref. 16 or Ref. 7). Now, as a set of "microstates," we can consider the whole set of periodic points. The configurations can be given by the orbits of the points $x \in X$, i.e., $x_i = f^i(x)$, $i=0,1,\ldots,N-1$, and so the "Hamiltonian of a dynamical system of N particles" can be defined as the statistical sum $V_N = S_N$. A construction of a Gibbs state in this context can be done by defining the ensembles supported on periodic points of f,[7,14]

$$\mu_{q,N} = \frac{\exp(-qV_N(x))\delta_x}{Z_N(q)}, \tag{6}$$

with the corresponding partition function given by

$$Z_N(q) = \sum_{x\in P_N(f)} \exp(-qV_N(x)). \tag{7}$$

III. ANALYSIS OF PHASE TRANSITIONS

By $\mathcal{A}_\infty(U)$, $U \subset \mathbf{C}^d$, we denote the space of functions holomorphic in U and bounded on the closure of U (with the supreme norm). We consider the Gibbs–Boltzmann factor,

$$G(x,y) = \exp[-\varphi(x,y)]\exp\left(-\tfrac{1}{2}[\psi(x)+\psi(y)]\right)$$

and impose the following condition.

There exists an open neighborhood W of Ω such that $G:\Omega\times\Omega\to\mathbf{R}$ has an analytic extension to a map $\hat{G}:U\times U\to\mathbf{C}$, where U is a complex open neighborhood of W in $\mathbf{C}^d$ and such that $\hat{G}$ belong to $\mathcal{A}_\infty(U\times U)$. This requirement is of course fulfilled if $\varphi:\Omega\times\Omega\to\mathbf{R}$ satisfies such analytic extension and $\psi:\Omega\to\mathbf{R}$ also does.

We introduce next the transfer operators, in the sense of Ruelle thermodynamic formalism. They will be defined on the space of functions $\mathcal{A}_\infty(U)$, for an adequate domain U.

For any value of the temperature parameter q, let us introduce the *transfers operators* $\mathcal{L}_q:\mathcal{A}_\infty(U)\to\mathcal{A}_\infty(U)$ according to

$$\mathcal{L}_q(\varkappa)(z) = \int_\Omega \exp[-q\varphi(z,w)]\exp\left(-\frac{q}{2}[\psi(z)+\psi(w)]\right)\chi(w)\mathrm{d}w. \tag{8}$$

Lemma 1: The spectral radius $\rho(\mathcal{L}_q)$ of operators $\mathcal{L}_q$ equals $\exp(T(q))$.

Proof: Let E_q be the maximal eigenvalue, in modulus, of $\mathcal{L}_q$, so we have for any function $\xi \in C(\Omega): \lim_{N\to\infty} E_q^{-N} \log \mathcal{L}_q^N = \upsilon_q(\xi)\psi_q$, where υ_q is some functional on $C(\Omega)$ and ψ_q is the eigenfunction corresponding to E_q. If there is a unique Gibbs state μ_q associate to $q\varphi$ then υ_q is precisely μ_q, seen in this case as a functional. This arises from an adaptation of the Ruelle–Perron–Frobenius theorem. Now taking $\xi \equiv 1$, we obtain

$$\log E_q = \lim_{N\to\infty}\frac{1}{N}\log \mathcal{L}_q^N(1)(x_0,x_1,\ldots,x_{N-1}) = \lim_{N\to\infty}\frac{1}{N}\log\int_{\Omega^N}\exp(-qV_N)\mathrm{d}x_0\,\mathrm{d}x_1\ldots\mathrm{d}x_{N-1}$$

$$= \lim_{N\to\infty}\frac{1}{N}\log Z_N(q) = T(q).$$

Therefore $\rho(\mathcal{L}_q)=\exp(T(q))$.

■

One main fact about these operators is that they are *nuclear.* Let us recall that a map $\mathcal{L}$ acting on a Banach space B is nuclear if there exist sequences $(x_n)\subset B$, $(f_n)\subset B^*$ (the dual space of B) with $\|x_n\|=1$, $\|f_n\|=1$ and numbers (ρ_n) with $\Sigma_{n=0}^{\infty}|\rho_n|<\infty$ such that $\mathcal{L}(x)=\Sigma_{n=0}^{\infty}\rho_n f_n(x)x_n$ for every $x\in B$. This notion can be generalized to maps from complete metric topological spaces (Frechet spaces) to Banach spaces. For more details see Refs. 5 and 8. There is a particular class $\mathcal{F}$ of Frechet spaces with the property that any bounded map $\mathcal{L}:\mathcal{F}\to B$, with B an arbitrary Banach space is nuclear. Such spaces are also called nuclear.

Proposition 2: The transfer operators $\mathcal{L}_q:\mathcal{A}_\infty(U)\to\mathcal{A}_\infty(U)$, for a domain $U\subset\mathbf{C}^d$, are nuclear for any q.

Proof: The demonstration is an application of the Grothendieck theory.[5,6] We analyze the kernel of these operators which are operators of the following type:

$$P_{\hat{G}}(\chi)(z) = \hat{G}(z)\chi(z).$$

We shall consider an adequate nuclear space $\mathcal{F}$ and we prove that $P_{\hat{G}}$ defined on $\mathcal{F}$ is bounded. This space will be $\mathcal{H}(U)$ equal to the space of holomorphic functions in a domain $U\subset\mathbf{C}^d$ equipped with the seminorm $\|f\|_K=\sup_{z\in K}|f(z)|$, K is a compact subset of $\mathbf{C}^d$. It is known that the space $\mathcal{H}(U)$ with the topology of the seminorms $\|\bullet\|_K$ is nuclear.[8] Now by proving that the operators $P_{\hat{G}}:\mathcal{H}(U)\to\mathcal{A}_\infty(U)$ are bounded in the space $\mathcal{H}(U)$ we ensure that they are nuclear.

Let K be a compact subset of U, such that $\hat{G}(\overline{U})\subset K\subset U$, and we set $B_M:=\{f\in\mathcal{H}(U):\|f\|_K<M\}$. Thus $\|P_{\hat{G}}(\chi)\|=\sup_{z\in\overline{U}}\{|\hat{G}(z)\chi(z)|\}\leqslant\|\hat{G}\|_K\|\chi\|_K<M^2$.

So that the set B_M is carried by $P_{\hat{G}}$ in a bounded set in $\mathcal{A}_\infty(U)$. To show that $P_{\hat{G}}$ is defined on $\mathcal{A}_\infty(U)$ we change the composition of $P_{\hat{G}}$ with the canonical injection $\iota:\mathcal{A}_\infty(U)\hookrightarrow\mathcal{H}(U)$. Thus $P_{\hat{G}}\circ\iota:\mathcal{A}_\infty(D)\to\mathcal{A}_\infty(D)$ is nuclear.

■

Let us recall that the *Fredholm determinant* of $\mathcal{L}_q$ is

$$\det(1-z\mathcal{L}_q) = \exp\left(-\sum_{N=1}^{\infty}\frac{z^N}{N}\operatorname{Tr}(\mathcal{L}_q^N)\right),\quad z\in\mathbf{C}.$$

From the fact that $\mathcal{L}_q$ is nuclear it follows that the function $\det(1-z\mathcal{L}_q)$ is entire in both two variables z, q. Besides the set of zeros z of the Fredholm determinant agree with the set of the nonzero eigenvalues of $\mathcal{L}_q$.

The following formula[8] is useful to obtain a development of $\operatorname{Tr}(\mathcal{L}_q^N)$,

$$\det(1-\mathcal{L}) = \sum_{\kappa=0}^{d}(-1)^\kappa\operatorname{Tr}(\wedge_\kappa\mathcal{L}),$$

here $\wedge_\kappa\mathcal{L}$ is the κ-fold exterior product. Then we can define operators $\mathcal{L}_q^{(k)}$, $\wedge_k\mathcal{F}(U)\to\wedge_k\mathcal{F}(U)$, where $\wedge_k\mathcal{F}(U)$ denotes the Banach space of differential k-forms holomorphic in U. Now the operators are defined as

$$\mathcal{L}_q^{(k)}(\omega_k)(z) = \int_\Omega\exp[-q\varphi(z,w)]\exp\left(-\frac{q}{2}[\psi(z)+\psi(w)]\right)\wedge_k D(\varphi(z,w)+\psi(z)+\psi(w))(\omega_k)\mathrm{d}w$$

Here $\wedge_k D\phi$ means the k-fold exterior product of the linear operator $D\phi$.

The Fredholm determinant is related with the *Ruelle zeta function*[12] which is defined as

$$\zeta(z,q) = \exp\left(\sum_{n=1}^{\infty} \frac{z^N}{N} Z_N(q)\right).$$

This series converges in $\{z:|z|<\exp(-T(q))\}$. The Fredholm determinant is used to show that the Ruelle zeta function may have a meromorphic extension to the whole complex plane. For instance if $k=1$ holds,[8]

$$\zeta(z,q) = \frac{\det(1 - z\mathcal{L}_q^{(1)})}{\det(1 - z\mathcal{L}_q^{(0)})}.$$

Therefore the z poles of $\zeta(z,q)$ are found among the z zeros of $\det(1-z\mathcal{L}_q^{(0)})$, i.e., the nonzero eigenvalues of $\mathcal{L}_q^{(0)} \equiv \mathcal{L}_q$. The zeta function has a pole localized in $\exp(T(q))$, i.e., in the leading eingenvalue of $\mathcal{L}_q$. Then since $\exp(T(q))$ is an isolated singularity of the map ζ the leading eigenvalue of $\mathcal{L}_q$ is isolated. As we pointed out in the introduction, in this way the nonexistence of phase transition is proved.

From the above results and considerations we can state the following.

Theorem 3: For systems of particles in $\mathbf{R}^d$ with a Gibbs–Boltzmann factor belonging to the class $\mathcal{A}_\infty(U\times U)$, for some domain $U\subset \mathbf{C}^d$, and with transfer operators acting on $\mathcal{A}_\infty(U)$ there is no phase transition.

(Received 15 December 2004; accepted 22 February 2005; published online 27 April 2005)

Following Fröhlich and Spencer, we study one dimensional Ising spin systems with ferromagnetic, long range interactions which decay as $|x-y|^{-2+\alpha}$, $0\leqslant\alpha\leqslant 1/2$. We introduce a geometric description of the spin configurations in terms of triangles which play the role of contours and for which we establish Peierls bounds. This in particular yields a direct proof of the well-known result by Dyson about phase transitions at low temperatures. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897644]

I. INTRODUCTION

A rigorous proof of liquid–vapor phase transitions is a long standing challenge for mathematical physicists. A clear understanding of the phenomenon goes back to van der Waals, but a mathematically consistent theory is still lacking. Lebowitz, Mazel, and Presutti,[14] have tried to capture van der Waals ideas by considering an Hamiltonian which has a term given by an attractive, two-body Kac potential. The effort was to study the model without taking the Kac scaling parameter $\gamma\to 0$, as in the original works of Kac, Uhlenbeck, and Hemmer,[13] and Lebowitz and Penrose.[15] Technically, the idea was to study the system as a perturbation of mean field, which corresponds to the limit case $\gamma=0$, and to adapt to such a context the Pirogov–Sinai theory of finite temperature perturbations of ground states. To carry through the program, one needs a good control of an approximate model where the Kac potential term in the Hamiltonian is replaced by a self-consistent, external one-body field, whose intensity depends on the true value of the order parameter (the particles density) at equilibrium. In the continuum, the Hamiltonian cannot consist of just the attractive Kac potential (as in Ising models with Kac potentials) and a repulsive force is needed to prevent a collapse of matter. The natural choice (as proposed originally by Kac *et al.* [13]) is then to add a hard-core interaction, but, at the required values of the particles density, the cluster expansion results for the system with only hard cores are not valid and the implementation of the Pirogov–Sinai methods collapses. In Ref. 14 the problem has been avoided by using repulsive forces which are also given by Kac potentials, in particular four-body positive interactions. The escamotage is physically not totally satisfactory, as the phase transition should arise from a competition between the short range repulsive and the much longer range attractive intermolecular forces. Several efforts to extend[14] to such a context and in particular to the model with hard core plus attractive two-body Kac potentials have failed.

There is however some margin left if we restrict to one dimensions, because the pure hard rods system is isomorphic to an ideal gas. Unfortunately, there is a price to pay, to have a phase transition in $d=1$, we need to consider long range forces (potentials which decay as $|x-y|^{-2+\alpha}$, $\alpha\in[0,1)$) which are not covered by the traditional Pirogov–Sinai theory. Prior to Ref. 14, the problem of phase transition in the continuum in $d=1$ with such long range interactions had already been considered by Johansson,[11,12] who studied the system in the canonical ensemble, proving phase transition for the thermodynamic potentials. The existence of distinct DLR measures at the proper values of chemical potential and temperature remains however open.

The Pirogov–Sinai theory seems the natural way to answer these questions, as it provides powerful tools for investigating phase transitions at low temperatures and at low effective temperatures as well, with a quite satisfactory description of systems in dimensions larger or equal to two. In view of the desired applications to continuum particle models, our mid-term program is to extend Pirogov–Sinai to one-dimensional spin systems with long range interactions. The content of this paper will be the definition of contours and the establishment of Peierls estimates, as a preliminary step in this direction. After the papers by Dyson,[6,7] on a model with hierarchical interactions (which, by ferromagnetic inequalities, prove phase transitions in Ising systems as well), we find in the literature the fundamental paper by Fröhlich and Spencer,[8] where the critical case $\alpha=0$ is studied by deriving Peierls estimates for suitably defined contours. A further step forward has then been done by Imbrie,[9] who proved the validity of the cluster expansion for this gas of contours. A different approach, based on inequalities, has instead been followed by Dümcke and Spohn,[5] and Spohn,[18] to prove phase transitions for systems of ±1 spins on $\mathbb{R}$ with long range interactions, $\alpha\in[0,1)$. The results were used in the analysis of ground states for some quantum systems.

In this paper we revisit Fröhlich and Spencer[8] and extend it to the case $\alpha\in(0,1/2]$. In particular we prove that the probability of occurrence of a droplet of the opposite phase is depressed at least by $c\exp\{-\beta\zeta L^{\alpha}\}$, c and ζ positive constants, L the length of the droplet. The analogy with $d>1$ where the bound goes as $c\exp\{-\beta\zeta L^{(d-1)/d}\}$, is evident (our proof applies essentially unchanged through $\alpha=0$, where it yields the bound $c\exp\{-\beta\zeta\ln L\}$, losing however the analogy with $d>1$). Comforted by these results and the analogy with $d>1$, we plan, in the future, to extend the analysis to Ising systems with Kac potentials and then, hopefully, to prove phase transitions for hard rods with attractive Kac potentials, at least for $\alpha>0$.

The bibliography on the subject should also include the papers,[1,2,16,10,17] which refer to $d=1$, long range percolation. In fact, using the Fortuin and Kasteleyn (FK) representation, the results can be transferred to Ising systems, but it is not clear whether the approach could extend to the continuum particle systems where ferromagnetic inequalities are absent.

The techniques which have been developed in Ref. 8 and in the successive papers mentioned above can be used to prove the occurrence of a phase transition at large β also in the model we consider here ($\alpha>0$). In Ref. 8 Fröhlich and Spencer consider the sets of local fluctuations with the same energy and estimate their entropy. The hard part of the proof is to get a suitable lower bound for the energy.

Our approach based on a graphical representation of the spin configurations, gives a geometrical picture of the local fluctuations and allows to derive in easy and transparent way, estimates for their contribution to the total energy.

This more detailed description, that we developed for future applications, implies longer and more complex estimates but makes explicit hierarchical structure of the model and its relation with the original analysis of Dyson.[6,7]

Thus, the model we consider here is an Ising ferromagnet on a one dimensional lattice, with total energy

$$h(\sigma)=\frac{1}{2}\sum_{x,y\in\mathbb{Z}}J(|x-y|)\mathbf{1}_{\sigma(x)\neq\sigma(y)}, \tag{1.1}$$

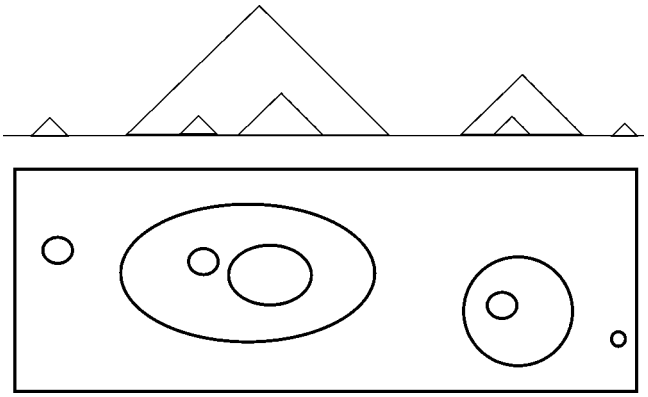

FIG. 1. External and internal interfaces in $d=1$ and $d=2$.

$$J(n) = \begin{cases} J(1) \gg 1 & \text{with } \alpha \in [0,1/2], \\ \dfrac{1}{n^{2-\alpha}} & \text{if } n > 1. \end{cases} \tag{1.2}$$

which will be studied at equilibrium with $\beta \gg 1$. In the sequel, for notational convenience, we restrict $\alpha \in (0,1/2]$, the analysis of the case $\alpha=0$ is analogous and treated in Appendixes A, E, and F.

In this paper we will show that the equilibrium configurations for the system associated to the Hamiltonian (1.1) can be described in terms of contours whose weights satisfy a Peierls bound. These contours (as in Pirogov–Sinai) are defined as regions which collect close-by deviations from the ground states. The Peierls bound follows from the fact that the excess energy of the associated interfaces is bounded from below proportionally to the size of the region to a positive power. To illustrate this point consider the simple case of three contiguous intervals B^-, A, and B^+. Let A be of size L and $B^\pm$ of size larger or equal to L and call $\mathcal{C}$ the set of configurations so that $\sigma=+1$ for all sites belonging to A and $\sigma=-1$ for all sites belonging to $B^\pm$. An explicit calculation, see Appendix A, shows that for all configurations in $\mathcal{C}$ the variation of energy obtained by flipping the spins inside A (thus getting all spins equal to $+1$ in $A \sqcup B^+ \sqcup B^-$) is bounded from below by $\zeta_\alpha L^\alpha$, with $\zeta_\alpha > 0$ for $\alpha \in (0,1/2]$ and if $J(1)$ is large enough.

In Sec. II we give a graphical description of a spin configuration in terms of a configuration of triangles, which allows to introduce the notion of internal and external interfaces (like in $d > 1$ dimensions), see Fig. 1 in Sec. II.

In Sec. III we introduce the notion of contours as clusters of nearby triangles and prove Peierls bounds for their energy. Our definition is very similar to that in Ref. 8, but our aim is to get a geometric representation of the contours more explicit and better suited for further generalizations.

In Sec. IV we prove that for β large enough the Peierls estimates on the energy of contours enable to control their entropy.

The approach we use can be generalized to a larger class of long range attractive forces where the assumption $J(1) \gg 1$ is dropped and $\alpha \in (0,1)$. We will discuss this point in a forthcoming paper together with a characterization of the typical configurations for slow decreasing ferromagnetic Kac potentials. As mentioned the ultimate goal is the extension to a one-dimensional system of hard-core particles interacting via such long range attractive forces, but at the moment we do not have concrete results in this direction.

II. SPIN AND TRIANGLE CONFIGURATIONS

We will consider in this paper homogeneous boundary conditions, i.e., the spins in the boundary conditions are either all $+1$ or all -1. By the spin–flip symmetry, we may and will restrict to the former, so that we will only study configurations $\sigma=\{\sigma_x, x \in \mathbb{Z}\} \in \mathcal{X}_+$, namely such that σ_x

$=1$ for all $|x|$ large enough. Our aim here is to recover a picture as in $d>1$, where the configurations are described by a collection of interfaces. In one dimensions, an interface at $(x,x+1)$ means $\sigma_x\sigma_{x+1}=-1$. The precise location of the interface in the interval is immaterial and we will use it to our advantage by choosing a point in each interval $(x+1/2)\pm\delta(\delta\in(0,1/4))$, $x\in\mathbb{Z}$, with the property that for any four distinct points r_i, $i=1,\ldots,4$, $|r_1-r_2|\neq|r_3-r_4|$. We suppose the choice done once for all, so that hereafter an interface point between x and $x+1$ is uniquely fixed. This will avoid ambiguities in the construction that follows.

Any interface point, by its definition, represents a change of phase so that after the first interface point (coming from the left), the second one corresponds to a reestablishing of the original phase, and so on. However, this is not the most convenient way to look at the spin configurations. Our construction is similar to that in Ref. 8 (where interface points were called spin–flip points) and it is based on suitably coupling together pairs of interface points. To this end we will use the criterion of minimal distance, which will be made geometrically intuitive by using a graphical representation where each spin configuration is mapped into a set of triangles. The endpoints of the triangles will be the pairs of coupled interface points.

Due to the above choice of the boundary conditions, any $\sigma\in\mathcal{X}_+$ has a finite, even number of interface points. We then let each interface point evolve into two trajectories represented in the (r,t) plane by the two lines $r\pm t$, $t\geqslant 0$. We have thus a bunch of growing v-lines each one emanating from an interface point. Once two v-lines meet, they are frozen and stop their growth, while the others are undisturbed and keep growing. Our choice of the location of the interface points ensure that collisions occur one at a time so that the above definition is unambiguous.

The collision of two points is represented graphically in the (r,t) plane by a triangle whose basis is the line joining the two interface points and whose sides are the two arms of the v-lines which enter into contact at the time of collision. Triangles will be usually denoted by T and we will write

$$|T| = \text{cardinality of } T\sqcap\mathbb{Z}, \quad \text{dist}(T,T') = \text{cardinality of } I\sqcap\mathbb{Z}, \tag{2.1}$$

where I is the interval between T and T' if T and T' are disjoint; if T and T' are one contained in the other (no other possibility may arise in the above construction) then I denotes the minimal interval between the two.

We have thus represented a configuration $\sigma\in\mathcal{X}_+$ as a collection $\underline{T}=(T_1,\ldots,T_n)$ of triangles in the (r,t) plane. The set of configurations of triangles obtained in this way are denoted by $\{\underline{T}\}$, and the above construction defines a one-to-one map from $\mathcal{X}_+$ onto $\{\underline{T}\}$. It is easy to see that a triangle configuration $\underline{T}$ belongs to $\{\underline{T}\}$ iff for any pair T and T' in $\underline{T}$,

$$\text{dist}(T,T')\geqslant\min\{|T|,|T'|\}. \tag{2.2}$$

The two endpoints of a triangle play the role which has the interface in higher dimensions and we thus have, also in $d=1$, a notion of external and internal interfaces (see Fig. 1).

Figure 1 is taken from a model for $d=1$ coarsening, see Derrida,[4] Carr and Pego,[3] and also some old, unpublished notes of two of the present authors (P.F. and E.P.). The general context is "spinodal decomposition," namely the phenomena which occur when an initial unstable state develops into a state where the stable state nucleate into droplets. Coarsening describes the evolution of these droplets where some of them grow to the expenses of the others. In $d=1$ this process is extremely slow and it is often a good approximation to say that in a given sequence of intervals of alternating phases, the shortest one disappears first, while all the others are unchanged. The dynamics is then described in terms of triangles by calling the first interval which disappears as the basis of the smallest triangle and then iterating the procedure. The interesting setup when studying coarsening is to have initially infinitely many phase changes and one of the aims is to understand if and which are the self-similar structures which emerge from the triangles picture. Here our task is simpler, we have finitely many phase changes and want to prove that each one of them has a small Gibbs weight.

Writing

$$H(\underline{T}) = h(\sigma), \quad \sigma \in \mathcal{X}_+ \Leftrightarrow \underline{T} \in \{\underline{T}\}, \tag{2.3}$$

and calling $\underline{T}=(T_1,\dots,T_n)$ with $|T_i| \leqslant |T_{i+1}|$, we have

$$H(\underline{T}) = H(T_1|\underline{T}\setminus T_1) + H(\underline{T}\setminus T_1), \quad H(\underline{S}|\underline{T}) := H(\underline{S}\sqcup\underline{T}) - H(\underline{T}). \tag{2.4}$$

In fact if $\underline{T}\in\{\underline{T}\}$, and $T\in\underline{T}$, then $\underline{T}\setminus T$ obviously satisfies (2.2) and therefore it is in $\{\underline{T}\}$. $\underline{T}\setminus T$ is obtained from the configuration σ corresponding to $\underline{T}$ by flipping all the spins inside the basis of T. By iteration,

$$H(\underline{T}) = \sum_{i=1}^{n} H(T_i|\underline{T}\setminus[T_1\sqcup\cdots\sqcup T_i]). \tag{2.5}$$

Lemma 2.1: *For any i,*

$$H(T_i|\underline{T}\setminus[T_1\sqcup\cdots\sqcup T_i]) \geqslant W(|T_i|), \tag{2.6}$$

where

$$W(L) = \sum_{x=1}^{L}\left(\sum_{\substack{y\in[L+1,2L]\\ y\in[-L+1,0]}} J(|x-y|) - \sum_{\substack{y\in[2L+1,\infty]\\ y\in[-\infty,-L]}} J(|x-y|)\right). \tag{2.7}$$

Proof: Call $I_i^{\pm}$ the two intervals in $\mathbb{Z}$ which are to the right and to the left of T_i, each one consisting of $|T_i|$ sites. There is no interface point inside T_i, and inside $I_i^{\pm}$ as well, because $|T_i|$ is the minimal length in $\underline{T}\setminus[T_1\sqcup\cdots\sqcup T_{i-1}]$ and all T_j, $j>i$, have distance from T_i which is $\geqslant|T_i|$. Then, if σ corresponds to $\underline{T}\setminus[T_1\sqcup\cdots\sqcup T_{i-1}]$, the spins in $T_i\sqcap\mathbb{Z}$ are all equal to each other and opposite to those in $I_i^{\pm}$. Instead, in the configuration σ' which corresponds to $\underline{T}\setminus[T_1\sqcup\cdots\sqcup T_i]$, the spins are all the same in $(T_i\sqcap\mathbb{Z})\sqcup I_i^{+}\sqcup I_i^{-}$. By (2.4), $H(T_i|\underline{T}\setminus[T_1\sqcup\cdots\sqcup T_i]) = h(\sigma)-h(\sigma')$, so that (2.6) and the lemma are proved. □

In Lemma A.1 it is proved that for $J(1)$ large enough, there is $\zeta>0$ so that

$$W(L) \geqslant \zeta h_\alpha(L) \quad \text{where } h_\alpha(L) := \begin{cases} L^\alpha, & \alpha\in(0,1/2],\\ \ln L + 4, & \alpha = 0 \end{cases} \tag{2.8}$$

in the sequel we fix our attention on the case $\alpha\in(0,1/2]$, and discuss the case $\alpha=0$ in Appendixes A, E, and F. Thus

$$H(\underline{T}) \geqslant \zeta\sum_{i=1}^{n} |T_i|^\alpha, \quad \underline{T} = (T_1,\dots,T_n). \tag{2.9}$$

The inequality must be seen as an analogue of the Peierls estimate in $d>1$ where the excess energy of a configuration of interfaces is bounded from below proportionally to the surface area of such interfaces. Since $|T_i|$ is the volume surrounded by the interface, α is identified to the ratio $(d-1)/d$, with d an "effective dimension" of the system.

This is however only an analogy. To really implement a Peierls bound in our setup, we need to "localize the estimates," being able to compute the weight of a given triangle in a generic configuration. The previous bound was easy, because we could estimate successively the weights of the triangles in the same order as their lengths. If we want to bound the energy of a generic triangle T in configuration $\underline{T}$, $|T|$ may not be the smallest length so that we are confronted with cases where there are other triangles in $T\sqcup I^+\sqcup I^-$ (see Lemma 2.1 for notation). Indeed, we could add to T smaller triangles T' in $T\sqcup I^+\sqcup I^-$ without violating (2.2). Our approach will be • to "connect" triangles if they are "dangerously close" to each other, • to define contours as "connected clusters" of triangles, and • to compute probabilities of contours rather than of single

triangles. To compute the probability of a contour, we first order increasingly the triangles in the contour, according to their lengths. Then the previous argument can be generalized, exploiting the fact that the triangles which are not in the contour are "sufficiently far away" (by the way contours are defined). In the next section we will see how triangles can be clustered into contours and then extend Lemma 2.1 to contours, thus concluding the analysis of the energy of contours; in Sec. IV we will prove entropy bounds (on the number of contours), which show that for β large enough, energy wins against entropy.

III. CONTOURS AND PEIERLS ESTIMATES

In Sec. III A we will define a function $\mathcal{R}$ which associates to any configuration $\underline{T}\in\{\underline{T}\}$ a configuration $\{\Gamma_j\}$ of contours, each Γ_j being a subset of triangles in $\underline{T}$. The crucial point in the definition is that the triangles in a contour are "close to each other," while all the other triangles are "far away;" using such a property we will be able to extend to contours the energy estimate of the preceding section, thus deriving the Peierls estimates of Sec. III B. In Sec. III C we will recall the classical argument for existence of a phase transition, using the Peierls bound proved in Sec. III B and the entropy estimates which will be proved in Sec. IV.

A. Contours

A contour Γ is a collection $\underline{T}$ of triangles ($\underline{T}$ in this section will always, and sometimes tacitly, denote an element in $\{\underline{T}\}$) joined together by a hierarchical network of connections, under which all the triangles of a contour become mutually connected. The structure has a self-similar property which we will exploit when counting the contours. The coarsest picture of a contour Γ is the pair $\{T(\Gamma),|\Gamma|\}$, $T(\Gamma)$ a triangle, $|\Gamma|$ its mass. $T(\Gamma)$ is the triangle whose basis is the smallest interval which contains all the triangles of the contour, the right and left endpoints of $T(\Gamma)\sqcap\mathbb{Z}$ are denoted by $x_{\pm}(\Gamma)|\Gamma|$, the mass of the contour, is the sum of the masses of all the triangles in Γ, the mass $|T_i|$ of a triangle being defined in (2.1).

Our aim is to define an algorithm $\mathcal{R}(\underline{T})$ on $\{\underline{T}\}$, which associates to any configuration $\underline{T}$ a configuration $\{\Gamma_j\}$ of contours with the following properties.

P.0. *Let* $\mathcal{R}(\underline{T})=(\Gamma_1,\cdots,\Gamma_n)$, $\Gamma_i=\{T_{j,i},1\leqslant j\leqslant k_i\}$, *then* $\underline{T}=\{T_{j,i},1\leqslant i\leqslant n,1\leqslant j\leqslant k_i\}$.

P.1. *Contours are well separated from each other.* Any pair $\Gamma\neq\Gamma'$ in $\mathcal{R}(\underline{T})$ verifies one of the following two alternatives: (i) $T(\Gamma)\sqcap T(\Gamma')=\emptyset$, in which case

$$\operatorname{dist}(\Gamma,\Gamma')>c\min\{|\Gamma|^3,|\Gamma'|^3\}, \tag{3.1}$$

where c is as in (3.15) below and $\operatorname{dist}(\cdot,\cdot)$ means distance as defined in (2.1) between the set of all the triangles in Γ from the corresponding set in Γ',

$$\operatorname{dist}(\Gamma,\Gamma'):=\min_{\substack{T\in\Gamma\\ T'\in\Gamma'}}\operatorname{dist}(T,T')$$

[which in the present case is equal to the distance between the two triangles $T(\Gamma)$ and $T(\Gamma')$].

(ii) $T(\Gamma)\sqcap T(\Gamma')\neq\emptyset$, then either $T(\Gamma)\sqsubset T(\Gamma')$ or $T(\Gamma')\sqsubset T(\Gamma)$; moreover, supposing for instance that the former case is verified (in which case we call Γ an inner contour), then for any triangle $T'_i\in\Gamma'$, either $T(\Gamma)\sqsubset T'_i$ or $T(\Gamma)\sqcap T'_i=\emptyset$; and

$$\operatorname{dist}(\Gamma,\Gamma')>c|\Gamma|^3,\quad \text{if } T(\Gamma)\sqsubset T(\Gamma'). \tag{3.2}$$

P.2. *Independence:* Let $\{\underline{T}^{(1)},\ldots,\underline{T}^{(k)}\}$, be $k>1$ configurations of triangles; $\mathcal{R}(\underline{T}^{(i)})=\{\Gamma_j^{(i)},j=1,\ldots,n_i\}$ the contours of the configuration $\underline{T}^{(i)}$. Then, if any distinct pair $\Gamma_j^{(i)}$ and $\Gamma_{j'}^{(i')}$ satisfies P.1,

$$\mathcal{R}(\underline{T}^{(1)}\ldots,\underline{T}^{(k)})=\{\Gamma_j^{(i)},j=1,\ldots,n_i;i=1,\ldots,k\}. \tag{3.3}$$

It is a nice fact of life that not only P.0, P.1, and P.2 can be actually implemented by some algorithm $\mathcal{R}$, but also that such an algorithm is unique. In Appendix B we will prove the following theorem.

Theorem 3.1: (Existence and uniqueness) *There is a unique algorithm $\mathcal{R}(\underline{T})$ which satisfies P.0, P.1, and P.2.*

B. Peierls estimates

The idea behind the proof of the Peierls estimates, Theorem 3.2 below, is that the property P.1 will ensure that the triangles which do not belong to a contour are so far away that, to leading order, they can be neglected and the bond (2.6) can be extended to contours.

Theorem 3.2: *Let the constant c in the definition of the contours (see P.1) be so large that* (3.15) *below holds. For any $\underline{T}\in\{\underline{T}\}$, let $\Gamma_0\in\mathcal{R}(\underline{T})$, $\underline{T}^{(0)}$ the triangles in Γ_0, $\zeta>0$ as in* (2.8). *Then*

$$H(\underline{T}^{(0)}|\underline{T}/\underline{T}^{(0)}) \leqslant \frac{\zeta}{2}\sum_{T\in\underline{T}^{(0)}}|T|^{\alpha} \tag{3.4}$$

[*for* $\alpha=0$, (3.4) *holds with* $|T|^{\alpha}$ *replaced by* $\log|T|+4$].

Proof: Calling $\underline{T}^{(0)}=(T_1,\dots,T_k)$, $|T_i|\leqslant|T_{i+1}|$, $i=1,\dots,k-1$,

$$H(\underline{T}^{(0)}|\underline{T}\setminus\underline{T}^{(0)}) = \sum_{i=1}^{k} H(T_i|\underline{T}\setminus\{T_1,\dots,T_i\}). \tag{3.5}$$

As a difference with Sec. II, here we may have triangles in $I_i^{\pm}$, but, by the argument after (2.4),

$$(I_i^{+}\sqcup I_i^{-})\sqcap T_j=\emptyset, \quad \text{for all } j>i T_j\not\perp T_i. \tag{3.6}$$

We also have, calling $\{\Gamma_j, j\geqslant 1\}$, the other contours of $\underline{T}$, different from Γ_0,

$$(I_i^{+}\sqcup I_i^{-})\sqcap T=\emptyset, \quad \text{for all } T\in\Gamma_j, \quad T\not\perp T_i, \quad j\geqslant 1 \text{ such that } |\Gamma_j|\geqslant|\Gamma_0| \tag{3.7}$$

because, by property P.1 of Sec. IV, $\operatorname{dist}(T_i,\Gamma_j)\geqslant \operatorname{dist}(\Gamma_0,\Gamma_j)\geqslant c|\Gamma_0|^3\geqslant|T_i|$.

Finally, using again P.1,

$$\operatorname{dist}(T_i,T)>c|\Gamma_j|^3, \quad \text{for all } T\in\Gamma_j, \quad j\geqslant 1 \text{ and such that } |\Gamma_j|<|\Gamma_0|. \tag{3.8}$$

With the notation introduced after (2.6), and with

$$A(T_i;\Gamma_j)=\bigsqcup_{T\in\Gamma_j, T_i\not\perp T} T\sqcap\mathbb{Z}, \quad |\Gamma|=\sum_{T\in\Gamma}|T| \tag{3.9}$$

we claim that

$$H(T_i|\underline{T}\setminus[T_1\sqcup\cdots\sqcup T_i])\geqslant W(|T_i|)-2\sum_{M}\sum_{j=1}^{n}\mathbf{1}_{|\Gamma_j|=M}\sum_{x\in T_i\sqcap\mathbb{Z}}\sum_{y\in I_i^{\pm}}J(|x-y|)(\mathbf{1}_{y\in A(T_i;\Gamma_j)}+\mathbf{1}_{x\in A(T_i;\Gamma_j)}). \tag{3.10}$$

To prove (3.10), we observe that the contribution of σ_x and σ_y [x and y as in (3.10)] is the same as in $W(|T_i|)$ whenever $\sigma_x\sigma_y=-1$; on the other hand, if $\sigma_x=\sigma_y$ then there must exist a triangle distinct from T_i which contains one site and not the other one. We thus automatically exclude the triangles which contain T_i, as, by (2.2), they will also contain $I_i^{\pm}$; by (3.6), $(T_{i+1},\dots,T_k)$ are also excluded. Then (3.10) follows after noticing that if $\sigma_x=\sigma_y$, the pair σ_x,σ_y contributes with the opposite sign to the energy as for $W(|T_i|)$, hence the factor 2 in the second term on the right-hand side (rhs) of (3.10). In (3.10) we have also split the sum over all contours setting together contours with the same mass, the mass of a contour Γ being defined in (3.9).

Call y_0 the rightmost point of $\mathbb{Z}$ in T_i, $y_1 \in I_i^+$ the point, if it exists, separated from y_0 by $[cM^3]$ sites, $[\cdot]$ the integer part of $\cdot$. By (3.7) and (3.8) the following holds: any Γ_j with $|\Gamma_j| = M$ is such that all its triangles which do not contain T_i and are to its right, have their left endpoint to the right of y_1. After changing labels, let Γ_1 be the contour of mass M with the closest triangle to y_1 (and to its right). The triangles in Γ_j, $j>1$, with mass M, cannot be closer than $y_2 \in I_i^+$, where y_2 (if it exists) is separated from y_1 by $[cM^3]$ sites. By iteration we define y_j, $j>2$, and have that the nth closest contour to T_i of mass M and to its right, is to the right of y_j. Calling y_n the last of such points in I_i^+, we have, for any $x \in T_i$,

$$\sum_{j=1}^{n} \mathbf{1}_{|\Gamma_j|=M} \sum_{y \in I_i^+} J(|x-y|) \mathbf{1}_{y \in A(T;\Gamma_j)} \leqslant M \sum_{k=1}^{n} J(|x-y_k|) \tag{3.11}$$

because $J(|x-y|) = J(y-x)$ is a decreasing function of y and the total number of sites in the triangles of a contour Γ is not larger than $|\Gamma|$ (not necessarily equal because a triangle might be contained in another one). Moreover, by monotonicity,

$$J(|x-y_k|) \leqslant \frac{1}{[cM^3]} \sum_{y \in (y_{k-1}, y_k)} J(|x-y|) \tag{3.12}$$

so that

$$\sum_{j=1}^{n} \mathbf{1}_{|\Gamma_j|=M} \sum_{y \in I_i^+} J(|x-y|) \mathbf{1}_{y \in A(T;\Gamma_j)} \leqslant \frac{M}{[cM^3]} \sum_{y \in I_i^+} J(|x-y|). \tag{3.13}$$

The sum is the same as in $W(|T_i|)$. Repeating the same procedure for T_i and I_i^- we finally get

$$H(T_i | \underline{T} \setminus [T_1 \sqcup \cdots \sqcup T_i]) \geqslant W(|T_i|) \left(1 - \sum_M \frac{4M}{[cM^3]} \right). \tag{3.14}$$

By choosing c so large that

$$\sum_M \frac{4M}{[cM^3]} \geqslant \frac{1}{2} \tag{3.15}$$

and recalling (2.8) we then prove the theorem. □

C. Phase transitions

To prove phase transitions we follow the well-known argument for $d>1$. Let Λ be an interval containing the origin, μ_Λ^+ the Gibbs measure in Λ with $+$ boundary conditions. Then

$$\mu_\Lambda^+(\sigma_0 = -1) \leqslant \mu_\Lambda^+(\{0 \in \Gamma\}), \tag{3.16}$$

where $\{0 \in \Gamma\}$ denotes the event that there is a contour Γ which has a triangle T which contains the origin. Then

$$\mu_\Lambda^+(\{0 \in \Gamma\}) = \frac{1}{Z_\Lambda^+} \sum_{\Gamma \ni 0} \sum_{\underline{T}: \Gamma \in \mathcal{R}(\underline{T})} e^{-\beta H(\underline{T})}.$$

Calling $\underline{T}^{(0)}$ the collection of triangles in Γ, $\mathcal{R}(\underline{T}^{(0)}) = \Gamma$, by Theorem 3.2,

$$e^{-\beta H(\underline{T})} \leqslant e^{-\beta H(\underline{T} \setminus \underline{T}^{(0)})} w_{\zeta\beta/2}(\Gamma), \tag{3.17}$$

where, for $b>0$,

$$w_b(\Gamma) := \prod_{T\in\Gamma} e^{-b|T|^\alpha}, \tag{3.18}$$

$w_b(\Gamma)$ is called the b-weight of the contour Γ. Then, using (3.17),

$$\mu_\Lambda^+(\{0\in\Gamma\}) \leqslant \sum_{\Gamma\ni 0} w_{\zeta\beta/2}(\Gamma) = \sum_m \sum_{\Gamma:|\Gamma|=m,0\in\Gamma} w_{\zeta\beta/2}(\Gamma) \tag{3.19}$$

and, by (4.1) below, valid for β large enough,

$$\mu_\Lambda^+(\{0\in\Gamma\}) \leqslant 2\sum_m m e^{-\zeta\beta m^\alpha/2}. \tag{3.20}$$

Since the sum starts from $m\geqslant 1$, the right-hand side (rhs) is $<1/2$ if β is large enough, hence the spin–flip symmetry is broken and there is a phase transition.

IV. ENTROPY OF CONTOURS

The main result in this section is Theorem 4.1 below, where we prove (3.20), and hence that, for β large, entropy is controlled by energy and a phase transition occurs.

Theorem 4.1: *For any b large enough and any* $m>0$,

$$\sum_{\Gamma:|\Gamma|=m,0\in\Gamma} w_b(\Gamma) \leqslant 2me^{-bm^\alpha}, \tag{4.1}$$

where $w_b(\Gamma)$ has been defined in (3.18).

The theorem is proved in Secs. IV C, by exploiting a self-similarity property of the contours which is the argument of the next two sections.

A. An auxiliary branching process

Contours can be described in terms of trees with a self-similar, hierarchical structure. We will first describe abstractly the trees and then relate them to the contours.

The nodes of the tree are "individuals" of two species, heavy triangles, h-triangles in short, and spheres; the h-triangles can be either black or white. Only black triangles can procreate and their offsprings contain at least two h-triangles. The offsprings in a branching are ordered, the h-triangles are drawn sequentially, the spheres, also drawn sequentially, can lie in each one of the intervals in between two consecutive h-triangles, but also "inside" the white triangles, the latter will be called "attached" to the white triangle in which they are contained.

Finally the tree has a root which consists either of a single black triangle or of a single white triangle with possibly spheres inside the white triangle. In the second alternative the tree consists of only its root, as white triangles and spheres cannot procreate. An example of tree is drawn in Fig. 2.

We will construct an algorithm which associates to any contour a tree with the above properties and later use such a correspondence to prove (4.1). We will in fact organize the sum over contours in (4.1) by summing over trees after having summed over all contours which produce the same tree. The identification of the nodes of the tree in terms of contours will allow for an inductive procedure which greatly reduces the complexity of the computation. We describe here the main features of the algorithm, which are those used in the proof of (4.1), while the existence of the algorithm itself will be proved in Sec. IV B, by exploiting a graphical representation of contours.

We will restrict in the sequel to configurations $\underline{T}$ such that $\mathcal{R}(\underline{T})$ is a singleton. As mentioned, the basic property of the algorithm which associates a tree to $\underline{T}$, is that each node of the tree is representative of a subset $\underline{T}'$ of $\underline{T}$ such that $\mathcal{R}(\underline{T}')$ is a singleton.

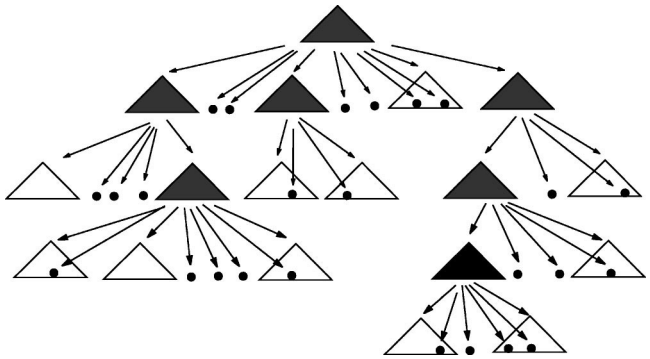

FIG. 2. Example of tree.

The root corresponds to the full $\underline{T}$. Moreover the collection of all the triangles associated to all the individuals of an offspring is the same as the set of triangles associated to the parent, so that a branching is nothing else than a partition of the triangles present in the branching node. In particular mass is conserved in a branching.

White triangles are associated to contours consisting of a single triangle, such triangle must be maximal, i.e., not contained in any other triangle of $\underline{T}$. Take notice, however, that the converse may not be true, as it may happen that a maximal triangle is one of the triangles associated to a black triangle or a sphere. If a maximal triangle T corresponds to a white triangle, then the spheres in the white triangle are associated to the contours of the configuration $\underline{T}'$ made of all the triangles of $\underline{T}$ which are contained in T.

The next properties we mention establish a quantitative relation between the ordering of the offsprings in the tree and the location of the corresponding triangles. If a black triangle generates $n \geqslant 2$ h-triangles labeled consecutively, call Γ_i, $1 \leqslant i \leqslant n$, the triangle associated to the ith h-triangle (by itself each Γ_i is a contour, hence the notation). Then the triangles $\{T(\Gamma_i)\}$ [recall that $T(\Gamma)$ is the minimal triangle which contains all the triangles forming Γ] are consecutive from left to right and

$$\operatorname{dist}(T(\Gamma_i), T(\Gamma_{i+1})) \leqslant c \min\{|\Gamma_i|^3, |\Gamma_{i+1}|^3\}, \quad i = 1, \ldots, n-1. \tag{4.2}$$

Moreover, if there are k_i spheres between the ith and $(i+1)$th h-triangle, call $\Gamma_j^{(i)}$, $j = 1, \ldots, k_i$, the contours associated to these spheres. Then all $T(\Gamma_j^{(i)})$ are in between $T(\Gamma_i)$ and $T(\Gamma_{i+1})$, $\{T(\Gamma_j^{(i)})\}$ is sequential and the following constraint on their mutual distances holds. Letting $x_\pm(\Gamma)$ as in the beginning of Sec. III A, the set of endpoints $\{x_\pm(\Gamma_j^{(i)}), a = x_+(\Gamma_i), b = x_-(\Gamma_{i+1})\}$ is such that there is p_i, $0 \leqslant p_i \leqslant k_i$ so that

$$0 \leqslant x_-(\Gamma_1^{(i)}) - a \leqslant c|\Gamma_1^{(i)}|^3 + 1,$$

$$0 \leqslant x_-(\Gamma_2^{(i)}) - x_+(\Gamma_1^{(i)}) \leqslant c|\Gamma_2^{(i)}|^3 + 1, \ldots, \ldots, x_-(\Gamma_{p_i}^{(i)}) - x_+(\Gamma_{p_i-1}^{(i)}) \leqslant c|\Gamma_{p_i}^{(i)}|^3 + 1,$$

$$0 \leqslant b - x_+(\Gamma_{k_i}^{(i)}) \leqslant c|\Gamma_{k_i}^{(i)}|^3 + 1,$$

$$0 \leqslant x_+(\Gamma_{k_i}^{(i)}) - x_-(\Gamma_{k_i-1}^{(i)}) \leqslant c|\Gamma_{k_i-1}^{(i)}|^3 + 1, \ldots, \ldots, x_+(\Gamma_{p_i+1}^{(i)}) - x_-(\Gamma_{p_i+2}^{(i)}) \leqslant c|\Gamma_{p_i+1}^{(i)}|^3 + 1. \tag{4.3}$$

Finally if Γ_j, $j = 1, \ldots, k$, are the sets of triangles associated to the spheres inside a white triangle, represented by T, then the triangles $T(\Gamma_j)$ satisfy the analogue of (4.3) with $a = x_-(T) + 1$ and $b = x_+(T) - 1$. These are the only properties on the structure of contours that we will use in the proof of (4.1) in Sec. IV C, the next section is only an existence proof of the algorithm for associating

a tree to a contour with the properties we have been describing so far, and, to a first reading, it may be skipped.

B. Graphical construction

We will construct here an algorithm which associates a tree (with the properties described in the preceding section) to any $\underline{T}$ such that $\mathcal{R}(\underline{T})$ is a single contour. The algorithm is obtained via a graphical representation of $\underline{T}$, where we draw at any integer time $t \in \{0,1,\ldots\}$ a configuration of mutually disjoint squares with a side in $\mathbb{R}$, called the basis of the square. Each square S is representative of a cluster $\{\underline{T}\}_S$ of triangles in $\underline{T}$, with the property that $\mathcal{R}(\{\underline{T}\}_S)$ is a singleton; the name "squares" is just to avoid confusion with the original triangles and the h-triangles of the tree. The mass of a square S equals the sum of the masses of the triangles in $\{\underline{T}\}_S$ (the mass of a triangle being the number of integers contained in its basis). The configurations of squares at the different times will be viewed as the successive applications of a renormalization group transformation.

1. The time $t=0$ configuration

This is obtained by associating to each "maximal" triangle of $\underline{T}$ a square with the same basis, $T \in \underline{T}$ is maximal if it is not contained in any other triangle of $\underline{T}$. By definition of maximality the set of maximal triangles, hence of squares, is sequential. The cluster of triangles $\{\underline{T}\}_S$ represented by the square S consists of a maximal triangle T and of all the triangles contained in T. The mass of S, according to the general rule, is then the sum of all the masses in $\{\underline{T}\}_S$. Statement (ii) in Lemma 4.2 below, proves that these squares verify the property that the sets $\{\underline{T}\}_S$ form a single contour, thus our definition of the square configuration at $t=0$ is well posed. In Appendix C we will prove the following.

Lemma 4.2: *Let S be a square corresponding to a maximal triangle T. Then (i) $\mathcal{R}(\{\underline{T}\}_S \setminus T) = \{\Gamma_j\}$ is sequential and the sequence $\{T(\Gamma_j)\}$ satisfies the analogue of* (4.3) *with $a = x_-(T)$ and $b = x_+(T)$; moreover, (ii) $\mathcal{R}(\{\underline{T}\}_S)$ consists of a single contour.*

By (i) the sequence $\{T(\Gamma_j)\}$ satisfies the same properties as the sequence of triangles obtained from the spheres attached to a white triangle, as described in the preceding section. Together with (ii), this shows that each one of the squares at time $t=0$ is a candidate for being a white triangle. Whether this will really happen, does depend in a complex way on the relative positions of the other triangles of $\underline{T}$, as we will see after completing the construction of the square process.

2. The next time-step configuration

The construction of the configuration of squares at time $t=n+1$ only depends on the configuration at time $t=n$, namely on the location of the squares in the configuration and on their masses. Like at time $t=0$, each square S is representative of a collection $\{\underline{T}\}_S$ of triangles in $\underline{T}$, more and more complex as time increases, but, as said, the construction of the configurations at the successive time will only depend on locations and masses of the squares, the latter being the sum of all the masses of the triangles represented. The rule for constructing the configuration at time $t=n+1$ given the one at time $t=n$, defines the action of the renormalization group transformation mentioned at the beginning of this section.

We start by drawing oriented arrows between pairs of squares, we set an arrow (S,S') from S to S' if $|S| \leqslant |S'|$, $|S|$ the mass of the square S (in case of equality if S is before S', going from left to right) and if the distance between S and S' is $\leqslant c|S|^3$. Arrows define a connection, which will be referred to as a-connection (a represents arrow), to distinguish it from the connection used in the definition of contours. Two squares are a-connected if they can be joined via a chain of pairs of squares, each pair linked by an arrow (independently of the direction of the arrow).

To each a-connected component we associate a protosquare, which is the minimal square which contains all the squares in that component, we call them protosquares because some of the protosquares will become a square in the configuration at time $t=n+1$. We will prove below that any two such protosquares are either disjoint or one contained in the other. We call maximal those which are not contained in any other one. *The maximal protosquares are the squares at time*

$t=n+1$. The set $\{\underline{T}\}_S$ represented by a maximal protosquare S, is the collection of all $\{\underline{T}\}_{S'}$, with S' running over all the squares at time $t=n$ which are contained in S. By maximality the new squares at time $t=n+1$ are sequential. In Lemma C.2, we will prove that $\mathcal{R}(\{\underline{T}\}_S)$ consists of a single contour, thus legitimating the present definition of the square configuration at time $t=n+1$.

We next state some features of the construction needed later for the identification of a tree structure. To this end it is convenient to erase some arrows, thus we will call "old arrows" the arrows defined so far and (old a)-connected squares connected by old arrows. Old arrows are erased with the following rule: if there are several arrows emanating from the same square, all in the same direction (i.e., right or left), we keep only the minimal one and erase all the others. This is done for all squares and all directions. The arrows which are left are the new arrows, and we will call (new a)-connected, squares connected by the new arrows. In Lemma D.1, it is proved that a set is (new a)-connected iff it is (old a)-connected. We will hereafter in this section call arrows the new arrows and a-connected, (new a)-connected sets.

The "*shadow*" of the arrow (S,S') is the interval between the two endpoints of S and S' which face each other. If two shadows have nonempty intersection, they must be one contained in the other, Lemma D.2; such a statement proves the above property about the fact that the protosquares are either disjoint or one contained in the other.

We then call *primary* an arrow with maximal shadow, i.e., which is not contained in any other shadow, and *primary* the two squares connected by a *primary* arrow. The set $\{\underline{T}'\}$ of all triangles in $\underline{T}$ whose basis are contained in the shadow (a,b) of a primary arrow (S_1,S_2) is such that we have the following.

Lemma 4.3: *With the above notation, (i)* $\mathcal{R}(\underline{T}')=\{\Gamma_j\}$ *and* $\{T(\Gamma_j)\}$ *is a sequence which satisfies the analogue of* (4.3) *with* $a=x_+(S_1)$ *and* $b=x_-(S_2)$ *supposing for instance that* S_1 *is before* S_2*; moreover, (ii)* $\mathcal{R}(\underline{T}'')$ *consists of a single contour,* $\underline{T}''$ *being the union of all triangles in* $\underline{T}'$ *and those associated to* S_1 *and* S_2.

Lemma 4.3 is proved in Appendix C. The primary squares may thus become h-triangles, as they form a sequence which satisfy (4.2), while all the squares in a shadow, called *secondary*, are eligible for being the spheres which lie between two h-triangles in the tree.

We finally observe that after a finite number of iterations the process stabilizes, the final configuration consisting of a single square S, $\{\underline{T}\}_S=\underline{T}$, its mass therefore being the sum of all $|T|$ over $\underline{T}$; the basis of S is $T(\Gamma)$, the triangle representative of the contour $\Gamma=\mathcal{R}(\underline{T})$. Any other final state would in fact contradict the assumption that $\mathcal{R}(\underline{T})$ consists of a single contour.

3. The tree structure

We have constructed so far, for any contour, a process, called the square process, evolving at integer times, whose state space is a square configuration, each square with its own mass. The evolution consists of a clustering mechanism, for which a cluster of squares at time t becomes a single square at time $t+1$. We have also distinguished in a forming cluster some squares which are primary, the others being called secondary. Our purpose now is to identify a tree structure from $\underline{T}$ via the realization of the square process. To this end, let t_f be the first time when the final configuration, consisting of a single square, is reached. This is identified to the root of the tree we are going to construct. If $t_f=0$ the root is a white triangle, otherwise it is black. In the former case, the configuration at time 0 has only one square, S, which, recalling the definition, means that there is a unique maximal triangle, T, in $\underline{T}$, and S has the same basis as T. The spheres attached to the white triangle root of the tree, are identified to the contours $\mathcal{R}(\underline{T}\backslash T)$, by Lemma 4.2 such an identification respects the requests of Sec. IV A. Notice that the identification of the spheres attached to a white triangle requires the knowledge of $\underline{T}$ and cannot be read only from the square process, which, as we will see, only identifies white and black triangles and spheres between h-triangles, all with their masses, but it does not give any information on the structure of the spheres inside the white triangles, except for their masses.

If $t_f>0$, the root is a black triangle and its offspring is the configuration at time t_f-1, identifying primary squares with h-triangles and secondary squares with spheres, consistently with the properties of such objects, by Lemma 4.3. Let S be one of the primary squares and $t_S<t_f$

-1 the time in the square process when there is a cluster of more than one square which at time t_S+1 becomes S; if such a time does not exist, then S was present also at time 0, and it is identified to a white triangle with the same procedure as above. Otherwise S is identified to a black triangle, whose offspring is determined by the configuration of squares at time t_S which merge into S at time t_S+1, with the same rules as those described for the branching of the root. By iterating the procedure we complete the identification of the tree.

C. Proof of Theorem 4.1

Since the number of translates of a contour with the property $0\in\Gamma$, is bounded by $|\Gamma|$, the proof of Theorem 4.1 reduces to proving that for any $b>0$ large enough and any $m>0$,

$$G_m := \sum_{\Gamma:|\Gamma|=m,x_-(\Gamma)=0} w_b(\Gamma) \leqslant 2e^{-bm^\alpha}. \tag{4.4}$$

The proof is by induction on the mass m of the contour, recall that the mass of a contour is necessarily an integer. We thus suppose (4.4) proved whenever $m\leqslant M-1$ and want to prove it for M. We have

$$G_M = G'_M + G''_M, \tag{4.5}$$

$$G'_M = \sum_{\substack{|\Gamma|=M,x_-(\Gamma)=0\\ \text{root of } \Gamma \text{ is white}}} w_b(\Gamma), \quad G''_M = \sum_{\substack{|\Gamma|=M,x_-(\Gamma)=0\\ \text{root of } \Gamma \text{ is black}}} w_b(\Gamma). \tag{4.6}$$

We start by bounding G'_M. We call $\ell=|T(\Gamma)|$, n the number of contours (spheres) attached to the white triangle; $m_1,\dots,m_n$ their masses. These variables are not independent, as, for instance, we must have $m_1+\cdots+m_n+\ell=M$. We organize the sum in (4.6) by fixing ℓ, n, $m_1,\dots,m_n$, then summing over all the contours compatible with such specifications and with (4.3) and finally summing over the specifications ℓ, n, $m_1,\dots,m_n$.

Let $\Gamma_1,\dots,\Gamma_n$ be n contours whose masses are $m_1,\dots,m_n$ and all with $x_-(\Gamma_i)=0$. We call $X_n(\ell,\Gamma_1,\dots,\Gamma_n)$ the set of all $(x_1,\dots,x_n)$ such that the collection $\{S_{x_i}(\Gamma_i)\}$, S_x denoting translation by x, fulfills (4.3) with $a=0$, $b=\ell$, and $k_i=n$. We then have

$$G'_M \leqslant \sum_{\ell>0} e^{-b\ell^\alpha} \sum_{n\geqslant 0} \sum_{\substack{m_1,\dots,m_n\\ m_1+m_2+\cdots+m_n+\ell=M}} \sum_{\substack{\Gamma_1,\dots,\Gamma_n\\ |\Gamma_i|=m_i,x_-(\Gamma_i)=0}} |X_n(\ell,\Gamma_1,\dots,\Gamma_n)| \prod_{i=1}^n w_b(\Gamma_i).$$

Writing $[a\wedge b] := \min\{a,b\}$, we have

$$|X_n(\ell,\Gamma_1,\dots,\Gamma_n)| \leqslant (n+1)\prod_{i=1}^n [cm_i^3 \wedge \ell\,],$$

where $n+1$ counts the number of values that p_i can take when $k_i=n$ in (4.3). Using the induction assumption we then get

$$G'_M \leqslant \sum_{\ell>0}\sum_{n\geqslant 0} \sum_{\substack{m_1,\dots,m_n\\ m_1+m_2+\cdots+m_n+\ell=M}} 2^n e^{-b(\ell^\alpha+m_1^\alpha+\cdots+m_n^\alpha)}(n+1)\prod_{i=1}^n [cm_i^3\wedge\ell].$$

To select the maximal among all masses, we rewrite the above as

$$G'_M \leqslant \sum_{\ell>0}\sum_{n\geqslant 0} 2^n(n+1) \sum_{\substack{m_1,\dots,m_n \\ m_1+m_2+\cdots+m_n+\ell=M}} e^{-b(\ell^\alpha+m_1^\alpha+\cdots+m_n^\alpha)}\prod_{i=1}^{n}[cm_i^3\wedge\ell]\times\Big[\mathbf{1}_{\{\ell\geqslant m_i\forall i\}}+\mathbf{1}\begin{Bmatrix} m_1\geqslant m_i\forall i\neq 1 \\ m_1\geqslant\ell\end{Bmatrix}$$
$$+\cdots+\mathbf{1}\begin{Bmatrix} m_n\geqslant m_i\forall i\neq n \\ m_n\geqslant\ell\end{Bmatrix}\Big]. \tag{4.7}$$

In the term where the maximum is m_i, we bound $[cm_i^3\wedge\ell]=\ell\leqslant c\ell^3$ and get

$$G'_M \leqslant \sum_{n\geqslant 0} 2^n(n+1)^2 \sum_{\substack{x_1+\cdots+x_n+y=M \\ 0\leqslant x_i\leqslant y}} e^{-by^\alpha}\prod_{i=1}^{n}[e^{-bx_i^\alpha}(cx_i^3)] \leqslant \sum_{n\geqslant 0}(n$$
$$+1)^2(2c)^n \sum_{\substack{x_1+\cdots+x_n+y=M \\ 0\leqslant x_i\leqslant y}} e^{-by^\alpha+\sum_i^n (b-a)x_i^\alpha}\prod_{i=1}^{n}[e^{-ax_i^\alpha}x_i^3]. \tag{4.8}$$

By Lemma E.1, if b/a is large enough,

$$\exp\left\{-by^\alpha+\sum_i^n (b-a)x_i^\alpha\right\} \leqslant \exp\{-b[y+x_1+\cdots+x_n]^\alpha\}, \tag{4.9}$$

so that

$$G'_M \leqslant e^{-bM^\alpha}\sum_{n>0}(n+1)^2(2c)^n\Big(\sum_x e^{-ax^\alpha}x^3\Big)^n.$$

Calling $\delta(a)$ the sum in the last parentheses and noticing that $\delta(a)\to 0$ as $a\to\infty$, for a large enough,

$$G'_M \leqslant e^{-bM^\alpha}\Big(1+\sum_{n\geqslant 1}(n+1)^2(2c)^n[\delta(a)]^n\Big) \leqslant \frac{3}{2}e^{-bM^\alpha}.$$

Bound on G''_M: We now call $n\geqslant 2$ the number of (black and white) triangles generated by the root, m_i their masses. We fix all the contours with such specifications and sum over the spheres between two consecutive triangles. Denote by $k_i\geqslant 0$ the number of spheres between the ith and $(i+1)$th triangles, m_j^i their masses. The space interval where such spheres can be located is determined by the position of the triangles i and $i+1$, by (4.2) its length is bounded by $cm_{i,i+1}^3$, where $m_{i,i+1}:=[m_i\wedge m_{i+1}]$. Then the sum over the spheres, once their number and masses are fixed, is bounded as in (4.7). We can also sum over all possible realizations of the n black and white triangles, given their number and masses using (4.2) and the induction assumption. We then get (with an extra 2^n factor counting the number of ways to color, either black or white, the n triangles)

$$G''_M \leqslant \sum_{n\geqslant 2} 2^n \sum_{\substack{m_1,\dots,m_n \\ m_i>0}} \Big\{\prod_{i=1}^{n-1} cm_{i,i+1}^3\Big\}\Big\{\prod_{i=1}^{n}[2e^{-bm_i^\alpha}]\Big\}\times\sum_{k_1\geqslant 0}\sum_{\substack{m_1^1\dots,m_{k_1}^1 \\ m_j^1>0}}\Big\{(k_1+1)\prod_{j=1}^{k_1} c[(m_j^1)^3\wedge m_{1,2}^3]\Big\}$$
$$\times\Big\{\prod_{j=1}^{k_1}[2e^{-b(m_j^1)^\alpha}]\Big\}\times\cdots\sum_{k_{n-1}\geqslant 0}\sum_{\substack{m_1^{n-1}\cdots m_{k_1}^{n-1} \\ m_j^{n-1}>0}}\Big\{(k_{n-1}+1)\prod_{j=1}^{k_{n-1}} c[(m_j^{n-1})^3\wedge m_{n-1,n}^3]\Big\}$$
$$\times\Big\{\prod_{j=1}^{k_{n-1}}[2e^{-b(m_j^{k_{n-1}})^\alpha}]\Big\}\mathbf{1}_{\{\sum_i m_i+\sum_{k,l} m_k^l=M\}}.$$

We fix $n,k_1,\dots,k_{n-1}$ and sum over all masses. As in (4.8) we split the sum by fixing which one of the masses is larger. This will give a factor $(n+k_1+\cdots+k_{n-1})$ equal to the number of masses which are present. Except for the largest mass we write the generic factor $e^{-bm^\alpha}=e^{-(b-a)m^\alpha}e^{-am^\alpha}$. In order to apply Lemma E.1 and get the analogue of (4.9), we must check that there is not a term with the maximal mass to the cube. If the maximal is one of the masses m_i, then it does not appear because we have products of $m^3_{i,i+1}$ which automatically select the smaller and avoid the larger. If the maximal mass is one of those relative to spheres, say m^i_j, we use the same trick as for G'_M and bound $[(m^i_j)^3\wedge m^3_{i,i+1}]\leqslant m^3_{i,i+1}$, so that the term $(m^i_j)^3$ does not appear. Notice that in this way there could be factors $m^6_{i,i+1}$. We then get

$$\leqslant e^{-bM^\alpha}\sum_{n\geqslant 2}2^n\sum_{k_1\geqslant 0,\dots,k_{n-1}\geqslant 0}(n+k_1+\cdots+k_{n-1})(k_1+1)\times\cdots(k_{n-1}+1)$$
$$\times\left(\sum_{x\geqslant 1}e^{-ax^\alpha}(2c)x^6\right)^{(n-1+k_1+\cdots+k_{n-1})},$$

calling $\delta=\Sigma_{x\geqslant 1}e^{-ax^\alpha}(2c)x^6$,

$$\leqslant e^{-bM^\alpha}\sum_{n\geqslant 2}2^n\delta^{n-1}\sum_{k_1\geqslant 0}\delta^{k_1}(k_1+1)\cdots\sum_{k_{n-1}\geqslant 0}\delta^{k_{n-1}}\times(k_{n-1}+1)(n+k_1+\cdots+k_{n-1}).$$

Since $(n+k_1+\cdots+k_{n-1})=[(k_1+1)+\cdots+(k_{n-1}+1)+1]\leqslant 2[(k_1+1)+\cdots+(k_{n-1}+1)]$,

$$\leqslant e^{-bM^\alpha}\sum_{n\geqslant 2}2^n\delta^{n-1}2n\left(\sum_{k\geqslant 0}\delta^k(k+1)^2\right)^n$$

$$\leqslant e^{-bM^\alpha}\sum_{n\geqslant 2}\delta^{n-1}2^{2n+1}n\leqslant\frac{e^{-bM^\alpha}}{2}$$

because for a large enough

$$\sum_{k\geqslant 0}\delta^k(k+1)^2\leqslant 2,\quad \sum_{n\geqslant 2}\delta^{n-1}2^{2n+1}n\leqslant 1/2.$$

We have thus proved that

$$G_M=G'_M+G''_M\leqslant\left(\tfrac{3}{2}+\tfrac{1}{2}\right)e^{-bM^\alpha},$$

hence (4.4) and Theorem 4.1 are proved.

ACKNOWLEDGMENTS

The authors are indebted to Vladas Sidoravicius, Herbert Spohn, and Milos Zahradnik for many helpful comments. APPENDIX A

In this appendix we will prove (2.8) identifying the value of the parameter ζ. We set

$$\zeta_\alpha:=1-2(2^\alpha-1)>0,\quad 0<\alpha<\alpha_+:=\frac{\ln 3}{\ln 2}-1 \tag{A1}$$

observing that $\alpha_+>1/2$. We call $W_\alpha(L)$ the rhs of (2.7), the subscript underlining the dependence on α.

Lemma A.1: *Given* $\alpha\in[0,\alpha_+)$, *for* $J(1)$ *large enough*

$$W_\alpha(L)\geqslant\begin{cases}\zeta_\alpha L^\alpha, & \text{if } \alpha>0,\\ 2\ln L+8, & \text{if } \alpha=0.\end{cases}\tag{A2}$$

Proof: We first consider the case $\alpha>0$ and call $W'_\alpha(L)=W_\alpha(L)-2(J(1)-1)$. Using (1.2) and (2.7) reads

$$W'_\alpha(L)=\sum_{x=1}^{L}\left(\sum_{\substack{y\in[L+1,2L]\\ y\in[-L+1,0]}}\frac{1}{|x-y|^{2-\alpha}}-\sum_{\substack{y\in[2L+1,\infty]\\ y\in[-\infty,-L]}}\frac{1}{|x-y|^{2-\alpha}}\right)=2\sum_{x=1}^{L}\left(\sum_{y=L+1}^{2L}\frac{1}{|x-y|^{2-\alpha}}\right.$$
$$\left.-\sum_{y=2L+1}^{\infty}\frac{1}{|x-y|^{2-\alpha}}\right)=2\sum_{x=1}^{L}\left(\sum_{y=L+1-x}^{2L-x}\frac{1}{y^{2-\alpha}}-\sum_{y=2L+1-x}^{\infty}\frac{1}{y^{2-\alpha}}\right)$$

and using monotonicity to replace sums by integrals,

$$\geqslant 2\sum_{x=1}^{L}\left[\int_{L+1-x}^{2L+1-x}\frac{dz}{z^{2-\alpha}}-\int_{2L-x}^{\infty}\frac{dz}{z^{2-\alpha}}\right]\geqslant 2\sum_{x=1}^{L}\frac{1}{\alpha-1}\{[(2L-x)^{\alpha-1}-(L+1-x)^{\alpha-1}]+(2L-x)^{\alpha-1}\}$$
$$\geqslant 2\sum_{x=1}^{L}\frac{1}{1-\alpha}\{[-2(2L-x)^{\alpha-1}+(L+1-x)^{\alpha-1}]\}\geqslant\frac{2}{1-\alpha}\left[-2\sum_{y=0}^{L-1}(L+y)^{\alpha-1}+\sum_{y=0}^{L-1}(y+1)^{\alpha-1}\right]$$
$$\geqslant\frac{2}{1-\alpha}\left[-2\int_{y=-1}^{L-1}(L+y)^{\alpha-1}+\int_{y=0}^{L}(y+1)^{\alpha-1}\right]\geqslant\frac{2}{\alpha(1-\alpha)}[-2[(2L-1)^\alpha-(L-1)^\alpha]$$
$$+(L+1)^\alpha-1]$$

hence, recalling that $W_\alpha(L)=W'_\alpha(L)+2(J(1)-1)$ and that $\alpha\in(0,\alpha_+)$, we get $W_\alpha(L)\geqslant\zeta_\alpha L^\alpha$ for L large enough, and for all L, if $J(1)$ is large enough.

In the case $\alpha=0$ we can repeat the same computations obtaining

$$W_0(L)\geqslant 2\ln(L+2)+[2J(1)-4\ln(3)-2]\geqslant 2\ln L+8$$

for $J(1)$ large enough. The lemma is proved. □

APPENDIX B

We start by a preliminary lemma.

Lemma B.1: *Let* $\mathcal{R}(\underline{T})$ *satisfy P.0, P.1, and P.2,* $\Gamma\in\mathcal{R}(\underline{T})$ *and* $\underline{T}'$ *the configuration of triangles in* Γ. *Then* $\mathcal{R}(\underline{T}')=\{\Gamma\}$.

Proof: Writing $\mathcal{R}(\underline{T})=\{\Gamma_i, i=1,\dots,n\}$, denote by $\underline{T}^{(i)}$ the triangles in Γ_i and write

$$\mathcal{R}(\underline{T}^{(i)})=\{\Gamma_1^{(i)},\dots,\Gamma_{n_i}^{(i)}\}.$$

Each pair (Γ_i,Γ_j), $i\neq j$, verifies P.1, we want to show that P.1 is also verified by each distinct pair $\Gamma_j^{(i)}$, $\Gamma_{j'}^{(i')}$. This is by definition if $i=i'$, let us then suppose $i\neq i'$. If $T(\Gamma_i)\sqcap T(\Gamma_{i'})=\emptyset$, then the same holds for $T(\Gamma_j^{(i)})$ and $T(\Gamma_{j'}^{(i')})$ and (3.1) holds. If instead $T(\Gamma_i)\sqsubset T(\Gamma_{i'})$ (or vice versa), if instead $T(\Gamma_i)\sqsubset T(\Gamma_{i'})$ (or vice versa) then $\operatorname{dist}(\Gamma_j^{(i)},\Gamma_{j'}^{(i')})\geqslant\operatorname{dist}(\Gamma_j^{(i)},\Gamma_{i'})\geqslant\operatorname{dist}(\Gamma_i,\Gamma_{i'})\geqslant c|\Gamma_i|^3$ $\geqslant c|\Gamma_j^{(i)}|^3\geqslant c\min\{|\Gamma_j^{(i)}|^3,|\Gamma_{j'}^{(i')}|^3\}$ so that $\Gamma_j^{(i)}$, $\Gamma_{j'}^{(i')}$ verifies P.1.

By applying P.2, $\mathcal{R}(\underline{T})=\{\Gamma_j^{(i)}\}$ which must therefore coincide with $\{\Gamma_i\}$. Hence the decomposition of each Γ_i into $\Gamma_j^{(i)}$ is trivial, i.e., $n_i=1$ and $\Gamma_1^{(i)}=\gamma_i$. The lemma is proved. □

Proof of Theorem 3.1: *Uniqueness:* Suppose there are two algorithms, $\mathcal{R}^{(i)}$, $i=1,2$ which both satisfy P.1 and P.2 and let $\mathcal{R}^{(i)}(\underline{T})=\{\Gamma_j^{(i)}, j=1,\dots,n_i\}$. Let

$$A_h^{(1)} = \Gamma_1^{(1)} \sqcap \Gamma_h^{(2)} \tag{B1}$$

be the collection of those triangles which are both in $\Gamma_1^{(1)}$ and $\Gamma_h^{(2)}$. Of course the union of $A_h^{(1)}$ over h is equal to $\Gamma_1^{(1)}$.

Call $\{K_{h,j}^{(1)}, j=1,\ldots,m_h\}=\mathcal{R}^{(1)}(A_h^{(1)})$. Each distinct pair $K_{h,j}^{(1)}$, $K_{h',j'}^{(1)}$ verifies P.1, by an argument similar to that used in the proof of Lemma B.1 and which is omitted. Then, by P.2, $\{K_{h,j}^{(1)}, h=1,\ldots,n_2, j=1,\ldots,m_h\}=\mathcal{R}^{(1)}(\underline{T}^{(1)})$, $\underline{T}^{(1)}$ the collection of all triangles in $\Gamma_1^{(1)}$. By Lemma B.1 the decomposition is then trivial, which means that $\Gamma_1^{(1)}=\Gamma_i^{(2)}$ for some i. By iteration we then conclude that the two systems of contours $\{\Gamma_j^{(1)}\}$ and $\{\Gamma_i^{(2)}\}$ are identical. Thus $\mathcal{R}^{(1)}=\mathcal{R}^{(2)}$.

Existence: Given a configuration $\underline{T}$ of triangles, we call $\mathcal{C}$ the collection of all partitions $\underline{C}=(C_1,\ldots,C_n)$ of $\underline{T}$ so that each pair (C_i,C_j), $i\neq j$, verifies P.1 and P.0 (relative to $\underline{T}$). $\mathcal{C}$ is nonempty as the trivial partition in a single atom verifies P.0 and P.1 (as in that case there is nothing to check). We order $\mathcal{C}$ by setting $\underline{C}\geqslant\underline{C}'$ if the partition $\underline{C}$ is finer than $\underline{C}'$. We claim that $\mathcal{C}$ has a unique maximal element, which will be called $\mathcal{M}(\underline{T})$; we will then prove that $\mathcal{M}(\cdot)$ satisfies P.1 and P.2 and conclude the proof of existence.

The claim will follow from showing that the partition

$$\underline{C}\vee\underline{C}'=\{C_i\sqcap C_j'\},\quad \underline{C}=(C_1,\ldots,C_n),\quad \underline{C}'=(C_1',\ldots,C_m')$$

is in $\mathcal{C}$, if also $\underline{C}$ and $\underline{C}'$ are in $\mathcal{C}$.

Without loss of generality we must thus prove that any distinct pair $(C_i\sqcap C_j', C_{i'}\sqcap C_{j'}')$ verifies the alternatives in P.1. By symmetry between the two clusters, we may suppose $i\neq i'$. If $T(C_i)\sqcap T(C_{i'})=\emptyset$, then also $T(C_i\sqcap C_j')\sqcap T(C_{i'}\sqcap C_{j'}')=\emptyset$ and (3.1) holds. Let us suppose (again without loss of generality) that $T(C_i)\sqsubset T(C_{i'})$, then for any $T_k\in C_{i'}$, either $T(C_i)\sqsubset T_k$ or $T(C_i)\sqcap T_k=\emptyset$. If $T_k\in C_{j'}'$, in correspondence with the previous alternative, either $T(C_i\sqcap C_j')\sqsubset T_k$ or $T(C_i\sqcap C_j')\sqcap T_k=\emptyset$. If instead $T_k\notin C_{j'}'$, then $T_k\notin C_{i'}\sqcap C_{j'}'$ and there is nothing to check. In conclusion the pair $(C_i\sqcap C_j', C_{i'}\sqcap C_{j'}')$ verifies the alternatives (i) and (ii) and in case the latter is verified, (3.2) holds.

To complete the proof we must show that $\mathcal{M}(\underline{T})$ satisfies P.2. Let $\underline{T}$ and $\underline{T}^{(i)}$: $\sqcup\underline{T}^{(i)}=\underline{T}$ be as in P.2 and suppose that the elements of $\{\mathcal{M}(\underline{T}^{(i)}), i=1,\ldots,k\}$ satisfy (3.1) and (3.2). Suppose by contradiction that $\mathcal{M}(\underline{T})$ is not equal to $\{\mathcal{M}(\underline{T}^{(i)}), i=1,\ldots,k\}$, since the latter is in $\mathcal{C}$ (relative to $\underline{T}$), $\mathcal{M}(\underline{T})$ must then be finer than $\{\mathcal{M}(\underline{T}^{(i)}), i=1,\ldots,k\}$. But then we would have a finer partition of $\underline{T}^{(i)}$, for some i, which still verifies P.1. We have thus reached a contradiction.

The theorem is proved. □

As a consequence of P.1 and P.2 we have the following obvious property, namely that by adding triangles it cannot happen that contours split; the new triangles can either form separate contours or join other preexistent ones and possibly cause them to merge.

Lemma B.2: *Monotonicity*.

Let $\underline{T}$, $\underline{T}'$ be two configurations of triangles, $\underline{T}\sqsubset\underline{T}'$, then for any $\Gamma\in\mathcal{R}(\underline{T})$, there is $\Gamma'\in\mathcal{R}(\underline{T}')$ so that $\Gamma\sqsubset\Gamma'$.

Proof: Let $\Gamma_0\in\mathcal{R}(\underline{T})$, $\mathcal{R}(\underline{T}')=\{\Gamma_j'\}$ and [recalling the notation in (B1)] $A_j:=\Gamma_0\sqcap\Gamma_j'$. We must prove that for any j, either $A_j=\emptyset$ or $A_j=\Gamma_0$. Suppose by contradiction that this is not the case. We then consider the new partition of $\underline{T}$:$\underline{C}:=[\mathcal{R}(\underline{T})\vee\{(\mathcal{R}(\underline{T})\setminus\Gamma_0), A_1,\ldots,A_m\}]$. $\underline{C}$ is then in $\mathcal{C}$ (relative to $\underline{T}$) and is finer than $\mathcal{R}(\underline{T})$, which contradicts the fact that $\mathcal{R}(\underline{T})$ is the unique, finest partition of $\underline{T}$ verifying P.0, P.1, and P.2. The lemma is proved. □

APPENDIX C

An interval $[a,b]$ is compatible with $\underline{T}$ if a is an endpoint of a triangle of $\underline{T}$, b is also an endpoint of a triangle of $\underline{T}$ and for all $T\in\underline{T}$, $T\sqcap(a,b)$ is either void or equal to (a,b).

Lemma C.1: *Let $\underline{T}''\sqsubset\underline{T}$, with $\mathcal{R}(\underline{T}'')$ a singleton; $[a,b]$ a $\underline{T}''$-compatible interval; $\underline{T}'$ the collection of all triangles of $\underline{T}$ with basis in (a,b). Then if $\mathcal{R}(\underline{T}',\underline{T}'')$ is not a singleton, also $\mathcal{R}(\underline{T})$ is not a singleton.*

Proof: Since $\mathcal{R}(\underline{T}'')$ is a singleton, by Lemma B.2 there is a contour Γ_0 in $\mathcal{R}(\underline{T}',\underline{T}'')$ which contains $\underline{T}''$. In order to prove the lemma we must consider the case

$$\mathcal{R}(\underline{T}',\underline{T}'')=\{\Gamma_0,\ldots,\Gamma_n\},\quad n\geqslant 1.$$

Since Γ_i, $i\geqslant 1$, is distinct from Γ_0, it is a subset of $\underline{T}'$ and therefore $T(\Gamma_i)$ is strictly contained in (a,b). Let

$$\mathcal{R}(\{\underline{T}\setminus\underline{T}'\}\sqcup\Gamma_0)=\{\Gamma_1'\cdots\Gamma_k'\}.$$

We claim that

$$\mathcal{R}(\underline{T})=\{\Gamma_1,\ldots,\Gamma_n,\Gamma_1'\cdots\Gamma_k'\} \tag{C1}$$

hence $\mathcal{R}(\underline{T})$ is not a singleton and the lemma is proved.

To prove (C1), it is enough to show that $\{\Gamma_1,\ldots,\Gamma_n,\Gamma_1'\cdots\Gamma_k'\}$ satisfy properties P.0 and P.1 in the definition of contours, see Sec. III, because (C1) would then follow from P.2.

P.0 is obviously satisfied. Pairs Γ_i, Γ_j and Γ_i', Γ_j' satisfy P.1 by definition, it thus remains to check P.1 for pairs Γ_i, Γ_j'. By Lemma B.2, Γ_0 is contained in one of the contours Γ_j', say Γ_1', and let us start from this case. Then $\mathrm{dist}(\Gamma_i,\Gamma_1')=\mathrm{dist}(\Gamma_i,\Gamma_0)$ [because the triangles in $\Gamma_1'\setminus\Gamma_0$ are outside $[a,b]$, while Γ_0 contains triangle(s) whose endpoints are a, b and Γ_i has support inside (a,b)]. Since the pair Γ_i, Γ_0 satisfies P.1 then also Γ_i, Γ_1' satisfies P.1. For the same reason as before, also for $j>1$, $\mathrm{dist}(\Gamma_i,\Gamma_j')\geqslant\mathrm{dist}(T(\Gamma_i),\{a,b\})=\mathrm{dist}(\Gamma_i,\Gamma_0)>c|\Gamma_i|^3$ [the latter inequality by (ii) of P.1]. Hence $\mathrm{dist}(\Gamma_i,\Gamma_j')>c\ \min\{|\Gamma_i|^3,|\Gamma_j'|^3\}$. We have thus completed the proof of P.1, (C1) and Lemma C.1 are thus proved. □

Proof of (ii) of Lemma 4.2: We apply Lemma C.1 with $\underline{T}''=T$ (the maximal triangle), a, b the endpoints of T. Since $\mathcal{R}(\underline{T}'')=T$, $\mathcal{R}(\underline{T}'')$ is a singleton; $\underline{T}'=\{\underline{T}\}_S\setminus T$. By assumption $\mathcal{R}(\underline{T})$ is a singleton, then, by Lemma C.1, also $\mathcal{R}(\underline{T}',\underline{T}'')$ is a singleton, hence (ii) of Lemma 4.2 because $\mathcal{R}(\underline{T}',\underline{T}'')=\mathcal{R}(\{\underline{T}\}_S)$. □

Proof of (ii) of Lemma 4.3: $\mathcal{R}(\{\underline{T}\}_{S_i})$, $i=1,2$, are singletons (by definition of squares); then $\mathcal{R}(\{\underline{T}\}_{S_1},\{\underline{T}\}_{S_2})$ is a singleton as well, because S_1 and S_2 are a-connected. We then apply Lemma C.1, identifying $T''=\{\{\underline{T}\}_{S_1},\{\underline{T}\}_{S_2}\}$ and a, b as the endpoints of the squares S_1, S_2 which face each other. The argument is hereafter the same as in the proof of (ii) of Lemma 4.2. □

Lemma C.2: *Let $\underline{S}$ be the square configuration at time $t=n$. Call $\underline{S}'$ the collection of squares in a maximal a-connected component of $\underline{S}$, $(\{\underline{T}\}_{\underline{S}'})$ the set of triangles represented by the squares in $\underline{S}'$. Then $\mathcal{R}(\{\underline{T}\}_{\underline{S}'})$ is a singleton and $\underline{S}'$ will be represented by a square in the square configuration at time $t=n+1$.*

Proof: Suppose $\underline{S}'$ is not a singleton (otherwise the statement of the lemma would trivially hold). If $S_1\in\underline{S}'$ there must be $S_2\in\underline{S}'$ with S_1 and S_2 endpoints of an arrow. Then either S_1 is an endpoint of a primary arrow, or it is in a shadow of a primary arrow. By the assumed maximality of $\underline{S}'$ it then follows that $\underline{S}'$ is made of a sequence of squares each one connected by a primary arrow to the successive one and all other squares contained in the shadow of these primary arrows.

By (ii) of Lemma 4.3, the collection of all the triangles in the shadow of a primary arrow and those in the two squares connected by the primary arrow form a single contour. The statement of the lemma then follows by monotonicity, Lemma B.2.

Proof of (i) of Lemma 4.2: We will first prove that $\Gamma_1,\ldots,\Gamma_n$ are sequential, where

$$\{\Gamma_1,\ldots,\Gamma_n\}=\mathcal{R}(\{\underline{T}\}_S\setminus T). \tag{C2}$$

Suppose by contradiction that $T(\Gamma_i)\sqsubset T(\Gamma_j)$, $i\neq j$. By property P.1 in the definition of contours, there is a minimal contour Γ_k distinct from Γ_i such that $T(\Gamma_i)\sqsubset T(\Gamma_k)$. Let $[a,b]$ be the smallest interval containing $T(\Gamma_i)$ and compatible with Γ_k. Let $\underline{T}'$ be the collection of triangles with basis in (a,b). Then $\mathcal{R}(\underline{T}',\Gamma_k)$ contains at least Γ_i and Γ_k (by Lemma B.2), so that, by Lemma C.1, $\mathcal{R}(\underline{T})$ is not a singleton, against the assumption. Therefore $\Gamma_1,\ldots,\Gamma_n$ are sequential.

We will next prove the analogue of (4.3), calling a^*, b^* the endpoints of T, shorthanding $\{\Gamma_i\}:=\{\Gamma_1,\dots,\Gamma_n\}$ and labelling the contours so that Γ_i is before Γ_j when $i<j$ (we have already proved that $\{\Gamma_i\}$ is sequential). There is Γ_j such that $\mathrm{dist}(\Gamma_j,\{a^*,b^*\})\equiv\mathrm{dist}(T(\Gamma_j),\{a^*,b^*\})\leqslant c|\Gamma_j|^3$, otherwise all Γ_i would be contours in $\mathcal{R}(\underline{T})$, by the argument already used several times above. Supposing for the sake of definiteness that $\mathrm{dist}(\Gamma_j,a^*)\leqslant c|\Gamma_j|^3$, we then claim that

$$\mathrm{dist}(\Gamma_1,a^*)\leqslant c|\Gamma_1|^3. \tag{C3}$$

Suppose by contradiction that there is $1<k\leqslant j$ so that for any $i<k$, $\mathrm{dist}(\Gamma_i,a^*)>c|\Gamma_i|^3$ while $\mathrm{dist}(\Gamma_k,a^*)\leqslant c|\Gamma_k|^3$. This would imply that, for any $i<k$, $c|\Gamma_i|^3<\mathrm{dist}(\Gamma_i,a^*)\leqslant\mathrm{dist}(\Gamma_k,a^*)\leqslant c|\Gamma_k|^3$. Thus $|\Gamma_i|\leqslant|\Gamma_k|$ for any $i\leqslant k$. Since $\{\Gamma_1,\dots,\Gamma_n\}$ are distinct contours, $\mathrm{dist}(\Gamma_i,\Gamma_k)>c\min\{|\Gamma_i|^3,|\Gamma_k|^3\}=c|\Gamma_i|^3$, for any $i<k$.

Call $\underline{T}'$ the collection of all triangles in $\{\Gamma_1,\dots,\Gamma_{k-1}\}$, $[a,b]=[a^*,x_-(\Gamma_k)]$, $\underline{T}''=\{T,\Gamma_k\}$. We can then apply Lemma C.1 because $\mathcal{R}(\underline{T}'')$ is a singleton, since $\mathrm{dist}(\Gamma_k,a^*)\leqslant c|\Gamma_k|^3$: then $\{\Gamma_1,\dots,\Gamma_{k-1}\}$ are contours for $\mathcal{R}(\underline{T})$ which contradicts the assumption that the latter is a singleton. Equation (C3) is proved.

By (C3), $\mathcal{R}(\{T\}_{\Gamma_1},T)$ is a singleton, so that the previous analysis applies again with T replaced by $\{\Gamma_1,T\}$ and a^* replaced by $a_1^*=x_+(\Gamma_1)$, showing that if $\mathrm{dist}(\Gamma_j,a^*)\leqslant c|\Gamma_j|^3$ with $j>2$, then $\mathrm{dist}(\Gamma_2,a_1^*)\leqslant c|\Gamma_2|^3$. By iterating the argument we then conclude the proof of (i) of Lemma 4.2.□

Proof of (i) of Lemma 4.3: Since $\mathcal{R}(\{S_1,S_2\})$ is a singleton [see the proof above of (ii) of Lemma 4.3] the previous applies unchanged with a^* and b^* the endpoints of S_1 and S_2 which face each other. □

APPENDIX D

Lemma D.1: *A squares configuration $\underline{S}$ is (new a)-connected iff it is (old a)-connected.*

Proof: If $\underline{S}$ is (new a)-connected, then it is also (old a)-connected, as the new arrows are also old arrows. We thus only need to prove the reverse implication, we suppose $\underline{S}$ (old a)-connected but not (new a)-connected and want to show that this leads to a contradiction.

We call "odd" a pair S and S' of squares when there is an old arrow between S and S' [denoted by $(S,S')_{\mathrm{old}}$] while S and S' are not (new a)-connected. We will first show that if $\underline{S}$ is (old a)-connected but not (new a)-connected then there exist odd pairs; we will then prove that odd pairs "can be shortened" in the sense that if S and S' is an odd pair, then there is another square S'' in between S and S' such that either S and S'' or S' and S'' is an odd pair. The endless iteration of the argument leads to a contradiction.

Existence of odd pairs: If $\underline{S}$ is not (new a)-connected, there are two squares S and S' which are not (new a)-connected; since S and S' are (old a)-connected, there is a sequence $\{S_{\ell_i},i=1,\dots,j\}$ such that each pair $S_{\ell_i},S_{\ell_{i+1}}$ is connected by an old arrow, and $S_{\ell_1}=S$ and $S_{\ell_j}=S'$. Then one of the pairs $S_{\ell_i},S_{\ell_{i+1}}$ must be odd, otherwise S and S' would be (new a)-connected.

Shortening odd pairs: Writing $S\prec S'$ if the square S is before S' (recall that a square configuration is sequential), we label $\underline{S}$ so that $S_1\prec S_2\prec\cdots\prec S_n$. Let S_k, S_m be an odd pair and suppose, without loss of generality, that $S_k\prec S_m$ and that the old arrow which connects them goes from S_k to S_m. The old arrow which connects S_k to S_m is not a new arrow, otherwise S_k and S_m would be (new a)-connected, therefore there exists $S_\ell: S_k\prec S_\ell\prec S_m$; $|S_\ell|\geqslant|S_k|$ such that there is a new arrow from S_k to S_ℓ. Consider separately the two possible cases (1) $|S_\ell|\leqslant|S_m|$ and (2) $|S_\ell|>|S_m|$.

(1) Since $c|S_\ell|^3\geqslant c|S_k|^3\geqslant\mathrm{dist}(S_k,S_m)>\mathrm{dist}(S_m,S_\ell)$, there is an old arrow connecting S_ℓ and S_m; on the other hand, by definition, S_ℓ and S_k are (new a)-connected, hence S_ℓ and S_m cannot be (new a)-connected, hence S_ℓ, S_m is an odd pair.

(2) As in (1), $c|S_m|^3>\mathrm{dist}(S_m,S_\ell)$, which implies that there is an old arrow from S_m to S_ℓ, as well as an old arrow from S_k to S_ℓ. There are two subcases, (a) S_m and S_ℓ are also connected by a new arrow or else (b) they are not. In subcase (a), S_ℓ is (new a)-connected to S_m, hence it cannot be (new a)-connected to S_k, thus S_k, S_ℓ is an odd pair. In subcase (b), there is $S_h: S_\ell\prec S_h$

$<S_m; |S_h| \geq |S_m|$, such that there is a new arrow from S_m to S_h. Again, as S_h is (new a)-connected to S_m, it is not (new a)-connected to S_k. On the other hand, $|S_h| \geq |S_m| \geq |S_k|$, hence there is an old arrow from S_k to S_h, thus S_k, S_h is an odd pair.

This concludes the analysis of case (2), and the proof of the shortening property of odd pairs. Thus the lemma is proved. □

Proposition D.2: *The shadows of two new arrows have either empty intersection or else, one is contained in the other.*

Proof: Suppose by contradiction that there are four squares $S_a < S_u < S_b < S_z$, with the crossing arrows $\vec{\xi}_{ab}$ (denoting a new arrow from a to b) and $\vec{\xi}_{uz}$. By definition of new arrow, this implies that there is no arrow $\vec{\xi}_{au}$ (there could be however an arrow in the opposite direction $\vec{\xi}_{ua}$) and that $\mathrm{dist}(S_a, S_b) \leq c|S_a|^3$. Recalling that $S_u < S_b$ the only compatible sizes with the new arrow $\vec{\xi}_{a,b}$ are $|S_u| < |S_a| < |S_b|$. On the other hand, $\mathrm{dist}(S_u, S_b) < \mathrm{dist}(S_u, S_z) \leq c|S_u|^3$ then, being $|S_b| > |S_u|$ there should be an arrow $\vec{\xi}_{u,b}: S_u \to S_b$ contradicting the fact $\vec{\xi}_{uz}$ is a new arrow (i.e., that S_z is the first square connected with S_u).

Consider now the case in which the crossing arrows are $\vec{\xi}_{b,a}$ and $\vec{\xi}_{u,z}$ (that implies that $|S_b| > |S_a|$ and $|S_z| > |S_u|$). The existence of these arrows implies that there are no arrows $\vec{\xi}_{b,u}$ and $\vec{\xi}_{u,b}$, and, since $\mathrm{dist}(S_b, S_u) < \mathrm{dist}(S_a, S_b) \leq c|S_b|^3$, this implies that $|S_u| \leq c|S_b|$. We get a contradiction by observing that, since $\mathrm{dist}(S_u, S_b) \leq \mathrm{dist}(S_u, S_z) \leq |S_u|^3$, there should be an arrow $\vec{\xi}_{u,b}$ that is incompatible with $\vec{\xi}_{u,z}$.

The other possible crossing cases are reduced to those above by reflection and the proposition is proved. □

APPENDIX E

Lemma E.1: *Let $\alpha \in [0, 1/2]$, a and b positive and b/a large enough. Then for any $n \geq 2$, any $x_1, \ldots, x_{n-1}$, y such that $1 \leq x_i \leq y$,*

$$bh_\alpha(y) + (b-a)\sum_{i=1}^{n-1} h_\alpha(x) \geq bh_\alpha\left(\sum_{i=1}^{n-1} x_i + y\right), \tag{E1}$$

where $h_\alpha(L)$ is defined in (2.8).

Proof: We will prove (E1) by induction on $n \geq 2$ showing that

$$f_n(x_1, \ldots, x_{n-1}, y) := \frac{b}{b-a} h_\alpha(y) + \sum_{i=1}^{n-1} h_\alpha(x) - \frac{b}{b-a} h_\alpha\left(y + \sum_{i=1}^{n-1} x_i\right)$$

is non-negative in the set $1 \leq x_i \leq y$.

We start the induction by supposing that for $n > 2$, for any $2 \leq m \leq n$, $f_m \geq 0$ and want to prove that $f_{n+1}(x_1, \ldots, x_n, y) \geq 0$. Since f_{n+1} is symmetric in the first n variables, we may suppose, without loss of generality, that $x_i \leq x_n \leq y \leq x_1 + \cdots + x_{n-1} + y =: L$. Then

$$f_{n+1}(x_1, \ldots, x_n, y) = f_n(x_1, \ldots, x_{n-1}, y) + h_\alpha(x_n) + \frac{b}{b-a} h_\alpha(L) - \frac{b}{b-a} h_\alpha(L + x_n) = f_n(x_1, \ldots, x_{n-1}, y)$$
$$+ f_2(x_n, L) \geq 0.$$

To complete the induction we need to prove that $f_2(x, y) \geq 0$.

The case $\alpha > 0$. We have $f_2(x, y) = y^\alpha g(x/y)$ where

$$g(x) := x^\alpha + \frac{b}{b-a} - \frac{b}{b-a}(x+1)^\alpha, \quad 0 \leq x \leq 1.$$

If b/a is large enough, $g'(x) > 0$ and $g(x) \geq g(0) = 0$ and the induction is proved. Thus (E1) is proved in the case $\alpha > 0$.

The case $\alpha=0$.
Let

$$p := \frac{b}{b-a}, \quad \text{choose } a \text{ so that } 1 < p < 2.$$

We have

$$f_2(x,y) = p(\ln y + 4) + (\ln x + 4) - p(\ln[x+y] - 4) = -p\ln(1+x/y) + \ln x + 4 \geqslant -2p + 4 + \ln x \geqslant 0$$

because $x \geqslant 1$ and $p < 2$. □

APPENDIX F

In this appendix we sketch the proof of the analogue of (4.1) in the case $\alpha=0$, namely that

$$\sum_{\Gamma:|\Gamma|=m,0\in\Gamma} w_b^0(\Gamma) \leqslant 2me^{-b(\ln m+4)}, \tag{F1}$$

where

$$w_b^0(\Gamma) := \prod_{T\in\Gamma} e^{-b(\ln(|T|+4))} = \prod_{T\in\Gamma} (|T|^{-b}e^{-4b}).$$

Equation (F1) yields the analogue of (3.20), i.e.,

$$\mu_\Lambda^+(\{0\in\Gamma\}) \leqslant 2\sum_{m\geqslant 1} me^{-\beta(\ln(m)+4)} = 2e^{-4\beta}\sum_{m\geqslant 1} m^{1-\beta}. \tag{F2}$$

The sum in (F1) is bounded using the same iterative procedure as when $\alpha\in(0,1/2]$, with the fundamental inequality (4.9) replaced by the "convexity" inequality

$$bh_0(y) + (b-a)\sum_{i=1}^{n-1} h_0(x) \geqslant bh_0\left(\sum_{i=1}^{n-1} x_i + y\right)$$

proved in Appendix D for $0<a<b/2$. The proof of (F1) then follows closely that of (4.1) for $\alpha>0$, and it is omitted. □

Multispecies extension of the solvable partially asymmetric reaction–diffusion processes

M. Alimohammadi[a] and Y. Naimi
Department of Physics, University of Tehran, North Karegar Ave., Tehran, Iran

(Received 7 November 2004; accepted 3 March 2005; published online 27 April 2005)

By considering the master equation of the partially asymmetric diffusion process on a one-dimensional lattice, the most general boundary condition (i.e., interactions) for the multispecies reaction–diffusion processes is considered. The resulting system has various interactions including diffusion to the left and right, two-particle interactions $A_\alpha A_\beta \rightarrow A_\gamma A_\delta$, and the extended n-particle drop–push interactions to the left and right. We obtain three distinct new models. The conditions on reaction rates to ensure the solvability of the resulting models are obtained. The two-particle conditional probabilities are calculated exactly. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897664]

I. INTRODUCTION

The understanding of nonequilibrium statistical physics is still much more incomplete than that of equilibrium theory, due to the absence of an analogue of the Boltzman–Gibbs approach and in spite of considerable recent progress.[1] Therefore nonequilibrium systems must be specified by some defining dynamical rules which are then analyzed. The topic has received a lot of attention and many reviews exist, e.g., Refs. 2–7.

One of the interesting and important examples of the nonequilibrium systems is the one-dimensional reaction–diffusion processes, which have application in various fields of physics like study of the shocks,[8] noisy Burgers equation,[9] polymers in random media,[10] traffic models,[11] and biopolymerization.[12] As these systems are interacting systems with N-particle, even simple models may pose a formidable problem if one wants to approach them analytically. See Refs. 13–16 for more recent references.

The simplest reaction–diffusion process is the totally asymmetric simple exclusion process (TASEP). In this model, each lattice site is occupied by at most one particle and all particles can only hop with equal rate to their right-neighboring sites, if these sites are not occupied. TASEP has been studied in Ref. 17 by introducing a master equation which describes the evolution equation of the particles when they are not in neighboring sites, and a so-called boundary condition, which specifies the situation in which the probabilities go outside the physical regions. This happens when some of the particles are in adjacent sites and the master equation cannot be applied to them. It has been shown that the model is integrable in the sense that the N-particle S-matrix is factorized into a product of two-particle S-matrices. The coordinate Bethe ansatz has been used in this proof.

The interesting observation is that if one chooses other boundary conditions, with the same master equation, one can in principle introduce other interactions (besides diffusion to right-neighboring sites), which may be integrable in the above-mentioned sense. This is what is first done in Ref. 18, in which the so-called drop–push model has been studied by this method. In this model the particle hops to the next right site, even if it is occupied. It can hop by pushing all the neighboring particles to their next right sites, with a rate depending on the number of these particles. Some other generalization of TASEP can be found in Refs. 19–21.

[a]Electronic mail: alimohmd@ut.ac.ir

The generalization of one-species reaction–diffusion processes to p-species is an important task. The main problem in this generalization, besides introducing a set of suitable boundary conditions to model an interacting system, arises from the above-mentioned factorization of N-particle scattering matrix. It was shown in Ref. 22 that in order that a more-than-one species system to be solvable, in the sense of the Bethe ansatz, certain relations should be satisfied between the rates. These relations can be written as some kind of a spectral Yang–Baxter (SYB) equation. By this method, all the solvable two-species reaction–diffusion models, without annihilation and creation reactions and with equal reaction rates, have been obtained in Ref. 22.

The multispecies generalization of the reactions considered in Ref. 22 has been studied in Ref. 23, and the drop–push reaction of Ref. 18 has been generalized to p-species in Ref. 24. The most general totally asymmetric reaction–diffusion processes have been recently studied in Ref. 25. These processes are

$$\begin{aligned} &A_\alpha \emptyset \to \emptyset A_\alpha \quad \text{with rate } D_R, \\ &A_\alpha A_\beta \to A_\gamma A_\delta \quad \text{with rate } c_{\gamma\delta}^{\alpha\beta}, \\ &A_\alpha A_\beta \emptyset \to \emptyset A_\gamma A_\delta \quad \text{with rate } b_{\gamma\delta}^{\alpha\beta}, \\ &\cdots, \end{aligned} \tag{1}$$

where the dots indicate the other drop–push reactions with n-adjacent particles, in which in the mean time the types of the particles can also be changed. These latter reactions are called the extended drop–push processes. It has been shown that the reaction rates of processes (1) must satisfy some specific constraints, in order that we have a set of consistent evolution equations. Also the corresponding two-particle S-matrices must satisfy the SYB equation. Some classes of the solutions of these equations have been discussed in Ref. 25.

In all of the above studies, only the totally asymmetric exclusion processes have been considered, i.e., the particles can only diffuse to their next right neighboring sites. If one wants to consider the left and right diffusions simultaneously, one must consider a more general master equation with suitable boundary conditions and then seek the situations in which the model is integrable. In Ref. 17, one-species model with only simple diffusion to left and right (i.e., partially asymmetric) has been considered, and in Ref. 26, the one-species partially asymmetric drop–push model has been studied. Finally a two-species model in which the particles, besides diffusion to the left and right, have exchange-reaction has been studied in Ref. 27.

In this paper we want to study the most general p-species integrable models with partially asymmetric reaction–diffusion processes, which all the previous studied models are the special cases of them. These general models may have some or all of the following reactions:

$$A_\alpha \emptyset \to \emptyset A_\alpha \quad \text{with rate } D_R, \tag{2}$$

$$\emptyset A_\alpha \to A_\alpha \emptyset \quad \text{with rate } D_L, \tag{3}$$

$$A_\alpha A_\beta \to A_\gamma A_\delta \quad \text{with rate } E_{\gamma\delta}^{\alpha\beta}, \tag{4}$$

$$A_\alpha A_\beta \emptyset \to \emptyset A_\gamma A_\delta \quad \text{with rate } R_{\gamma\delta}^{\alpha\beta}, \tag{5}$$

$$\cdots$$

and

$$\emptyset A_\alpha A_\beta \to A_\gamma A_\delta \emptyset \quad \text{with rate } L_{\gamma\delta}^{\alpha\beta}, \tag{6}$$

$$\cdots .$$

In the above equations $\alpha,\beta,\ldots=(1,\ldots,p),\emptyset$ stands for vacancy, and dots in Eqs. (5) and (6) indicate the drop–push of n-adjacent particles to the right and left sites, respectively, in which in the mean time the types of the particles can also be changed. We call interactions (5) and (6) as right-drop–pushing and left-drop–pushing, respectively. We show that there are three distinct models which are integrable and each of these models contains reactions (2) and (3) and one or two of the reactions (4)–(6).

The scheme of the paper is as follows. There are two kinds of boundary conditions that can be generalized to p-species cases. In Sec. II, we generalize the first kind of boundary condition, which was introduced in Ref. 26, to the most general p-species case. Using the law of conservation of the number of particles, it is shown that there exists five constraints that must be satisfied by reaction rates of Eqs. (2)–(6), in order to have a set of consistent evolution equations to express the interactions (2)–(6). But it is seen that there is no solution for these constraints. The situation does not change even if we relax one of the constraints by including the annihilation processes. Therefore one cannot explain all the reactions (2)–(6) by this method. But it will be shown that we can have two distinct models. In the first type model the reactions are Eqs. (2)–(5) and in the second type the reactions are Eqs. (2)–(4) and (6).

The second kind of boundary condition, which was used in Refs. 17 and 27, is generalized to the most general p-species case in Sec. III. We show that the resulting consistent boundary condition can explain the reactions (2)–(4). This is the type 3 model. It must be mentioned that the type 3 model is not a subclass of types 1 and 2 and is a new distinct one. In Sec. IV we investigate the Bethe ansatz solution for these models and discuss the solutions of the corresponding SYB equations. We see that the S-matrix of type 3 model is much more involved than two other ones and therefore only some special classes of solutions of its SYB equation can be obtained. Finally we study the conditional probabilities of these models and in special two-particle sector, we obtain the exact expressions.

II. FIRST KIND GENERALIZATION

Consider a p-species system with particles $A_1,A_2,\ldots,A_p$. The basic objects we are interested in are the probabilities $P_{\alpha_1\cdots\alpha_N}(x_1,\ldots,x_N;t)$ for finding at time t the particle of type α_1 at site x_1, particle of type α_2 at site x_2, etc. We take the physical region of coordinates as $x_1<x_2<\cdots<x_N$. The master equation for a partially asymmetric exclusion process is

$$\begin{aligned}\frac{\partial}{\partial t}P_{\alpha_1\cdots\alpha_N}(x_1,\ldots,x_N;t) &= D_R\sum_{i=1}^{N} P_{\alpha_1\cdots\alpha_N}(x_1,\ldots,x_{i-1},x_i-1,x_{i+1},\ldots,x_N;t)\\ &\quad + D_L\sum_{i=1}^{N} P_{\alpha_1\cdots\alpha_N}(x_1,\ldots,x_{i-1},x_i+1,x_{i+1},\ldots,x_N;t)\\ &\quad - NP_{\alpha_1\cdots\alpha_N}(x_1,\ldots,x_N;t). \qquad (7)\end{aligned}$$

This equation describes a collection of N particles, diffusing to the next-right sites by rate D_R and to the next-left sites by rate D_L. In Eq. (7) we have used a time scale so that

$$D_R+D_L\equiv 1. \qquad (8)$$

This master equation is only valid for $x_i<x_{i+1}-1$. For $x_i=x_{i+1}-1$, there will be some terms with $x_i=x_{i+1}$ in the right-hand side of Eq. (7) which are out of the physical region. But one can assume that (7) is valid for all the physical regions $x_i<x_{i+1}$ by imposing certain boundary conditions for $x_i=x_{i+1}$. Different boundary condition introduces different interactions for particles. Following the argument given in Ref. 25, it can be easily seen that the master equation (7) leads to the following relation for two-particle probabilities:

$$\frac{\partial}{\partial t}\sum_{x_2}\sum_{x_1<x_2} P_{\alpha_1\alpha_2}(x_1,x_2;t) = \sum_x [D_R P_{\alpha_1\alpha_2}(x,x;t) + D_L P_{\alpha_1\alpha_2}(x+1,x+1;t)] - \sum_x P_{\alpha_1\alpha_2}(x,x+1;t)$$
$$= \sum_x P_{\alpha_1\alpha_2}(x,x;t) - \sum_x P_{\alpha_1\alpha_2}(x,x+1;t). \tag{9}$$

This equation leads us to take $P_{\alpha_1\alpha_2}(x,x;t)$ as linear combination of $P_{\beta_1\beta_2}(x,x+1;t)$ and $P_{\beta_1\beta_2}(x-1,x;t)$'s as the only choice for having a consistent set of evolution equations in more-than-two-particle sectors.[25] Therefore the most general boundary condition is

$$P_{\alpha_1\alpha_2}(x,x) = \sum_\beta b^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x-1,x) + \sum_\beta c^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x,x+1). \tag{10}$$

β stands for $(\beta_1\beta_2)$ and b and c are $p^2\times p^2$ matrices which determine the interactions. In the probabilities of Eq. (10), we have suppressed all the other coordinates and the time t for simplicity. In fact $P_{\alpha_1\alpha_2}(x,x) \equiv P_{\gamma_1\cdots\gamma_i\alpha_1\alpha_2\gamma_{i+3}\cdots\gamma_N}(x_1,\ldots,x_i,x,x,x_{i+3},\ldots,x_N)$. In the first step, let us exclude the creation and annihilation processes (it can be shown that one cannot study the creation processes by this method, so in fact in this step, we exclude the annihilation processes). Since the number of particles is constant in time, summing over α_1 and α_2 makes the left-hand side of (9) zero and results in

$$-\sum_x\sum_\alpha P_{\alpha_1\alpha_2}(x,x+1) + \sum_x\sum_\beta\left(\sum_\alpha (b+c)^{\beta_1\beta_2}_{\alpha_1\alpha_2}\right) P_{\beta_1\beta_2}(x,x+1) = 0, \tag{11}$$

in which Eq. (10) has been used. Clearly Eq. (11) gives

$$\sum_\alpha (b+c)^{\beta_1\beta_2}_{\alpha_1\alpha_2} = 1 \quad \text{constraint (I)}. \tag{12}$$

Note that in $p=1$, the boundary condition (10) and constraint (12) reduce to those considered in Ref. 26. Also in the case of totally asymmetric processes in which $D_L=0$, our problem reduces to one considered in Ref. 25. Following the same steps as Ref. 25, we first consider $\dot{P}_{\alpha_1\alpha_2}(x,x+1)$. Using Eqs. (7) and (10), it is found

$$\dot{P}_{\alpha_1\alpha_2}(x,x+1) = D_R P_{\alpha_1\alpha_2}(x-1,x+1) + D_L P_{\alpha_1\alpha_2}(x,x+2) + D_R\sum_\beta b^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x-1,x)$$
$$+ D_L\sum_\beta c^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x+1,x+2) + \left(D_R\sum_\beta c^{\beta_1\beta_2}_{\alpha_1\alpha_2} + D_L\sum_\beta b^{\beta_1\beta_2}_{\alpha_1\alpha_2}\right) P_{\beta_1\beta_2}(x,x+1)$$
$$-2P_{\alpha_1\alpha_2}(x,x+1) = D_R P_{\alpha_1\alpha_2}(x-1,x+1) + D_L P_{\alpha_1\alpha_2}(x,x+2) + D_R\sum_\beta b^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}$$
$$(x-1,x) + D_L\sum_\beta c^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x+1,x+2) + \sum_{\beta\neq\alpha}(D_R c^{\beta_1\beta_2}_{\alpha_1\alpha_2} + D_L b^{\beta_1\beta_2}_{\alpha_1\alpha_2}) P_{\beta_1\beta_2}(x,x+1)$$
$$-\left[D_R + D_L + \sum_{\beta\neq\alpha}(D_R c^{\alpha_1\alpha_2}_{\beta_1\beta_2} + D_L b^{\alpha_1\alpha_2}_{\beta_1\beta_2}) + \sum_\beta (D_R b^{\alpha_1\alpha_2}_{\beta_1\beta_2} + D_L c^{\alpha_1\alpha_2}_{\beta_1\beta_2})\right] P_{\alpha_1\alpha_2}(x,x+1), \tag{13}$$

in which we use Eqs. (8) and (12). The latter can be written as

$$c^{\alpha_1\alpha_2}_{\alpha_1\alpha_2} = 1 - \sum_\beta b^{\alpha_1\alpha_2}_{\beta_1\beta_2} - \sum_{\beta\neq\alpha} c^{\alpha_1\alpha_2}_{\beta_1\beta_2} \tag{14}$$

or

$$b_{\alpha_1\alpha_2}^{\alpha_1\alpha_2} = 1 - \sum_{\beta\neq\alpha} b_{\beta_1\beta_2}^{\alpha_1\alpha_2} - \sum_{\beta} c_{\beta_1\beta_2}^{\alpha_1\alpha_2}. \tag{15}$$

It is seen that the evolution equation (13) describes the following two-particle interactions:

$$\begin{gathered} A_\alpha\emptyset \to \emptyset A_\alpha \quad \text{with rate } D_R, \\ \emptyset A_\alpha \to A_\alpha\emptyset \quad \text{with rate } D_L, \\ A_\alpha A_\beta \to A_\gamma A_\delta \quad \text{with rate } D_R c_{\gamma\delta}^{\alpha\beta} + D_L b_{\gamma\delta}^{\alpha\beta}, \\ A_\alpha A_\beta \emptyset \to \emptyset A_\gamma A_\delta \quad \text{with rate } D_R b_{\gamma\delta}^{\alpha\beta}, \\ \emptyset A_\alpha A_\beta \to A_\gamma A_\delta \emptyset \quad \text{with rate } D_L c_{\gamma\delta}^{\alpha\beta}. \end{gathered} \tag{16}$$

To study the consistency of our formalism and also deriving the more-than-two particle interactions, we consider $\dot{P}_{\alpha_1\cdots\alpha_n}(x,x+1,\ldots,x+n-1)$. In $n=3$, we encounter two boundary terms $P_{\alpha_1\alpha_2\alpha_3}(x,x+1,x+1)$ and $P_{\alpha_1\alpha_2\alpha_3}(x+1,x+1,x+2)$. Using (10), the first one becomes

$$\begin{aligned} P_{\alpha_1\alpha_2\alpha_3}(x,x+1,x+1) = &\sum_{\beta\gamma} b_{\alpha_2\alpha_3}^{\beta_2\beta_3}[b_{\alpha_1\beta_2}^{\gamma_1\gamma_2} P_{\gamma_1\gamma_2\beta_3}(x-1,x,x+1) + c_{\alpha_1\beta_2}^{\gamma_1\gamma_2} P_{\gamma_1\gamma_2\beta_3}(x,x+1,x+1)] \\ &+ \sum_{\beta} c_{\alpha_2\alpha_3}^{\beta_2\beta_3} P_{\alpha_1\beta_2\beta_3}(x,x+1,x+2) \end{aligned} \tag{17}$$

which describes the boundary term $P_{\alpha_1\alpha_2\alpha_3}(x,x+1,x+1)$ as a linear combination of other boundary terms, i.e., $P_{\gamma_1\gamma_2\beta_3}(x,x+1,x+1)$'s. As has been shown in Ref. 25, the only consistent solution to this problem is the vanishing of these terms on the right-hand side of Eq. (17), which results in

$$\sum_{\beta_2} c_{\alpha_1\beta_2}^{\gamma_1\gamma_2} b_{\alpha_2\alpha_3}^{\beta_2\beta_3} = 0 \quad \text{constraint (II)} \tag{18}$$

or

$$(1\otimes b)(c\otimes 1) = 0, \tag{19}$$

in which 1 stands for the $p\times p$ identity matrix. The second boundary term is

$$\begin{aligned} P_{\alpha_1\alpha_2\alpha_3}(x+1,x+1,x+2) = &\sum_{\beta} b_{\alpha_1\alpha_2}^{\beta_1\beta_2} P_{\beta_1\beta_2\alpha_3}(x,x+1,x+2) + \sum_{\beta\gamma} c_{\alpha_1\alpha_2}^{\beta_1\beta_2}[b_{\beta_2\alpha_3}^{\gamma_2\gamma_3} P_{\beta_1\gamma_2\gamma_3} \\ &(x+1,x+1,x+2) + c_{\beta_2\alpha_3}^{\gamma_2\gamma_3} P_{\beta_1\gamma_2\gamma_3}(x+1,x+2,x+3)], \end{aligned} \tag{20}$$

which again leads us to take

$$\sum_{\beta_2} c_{\alpha_1\alpha_2}^{\beta_1\beta_2} b_{\beta_2\alpha_3}^{\gamma_2\gamma_3} = 0 \quad \text{constraint (III)}, \tag{21}$$

or

$$(c\otimes 1)(1\otimes b) = 0. \tag{22}$$

Assuming constraints (18) and (21) and using Eqs. (7) and (10), $\dot{P}_{\vec{\alpha}}(x,x+1,x+2)$ is

$$\dot{P}_{\vec{\alpha}}(x,x+1,x+2) = D_R P_{\vec{\alpha}}(x-1,x+1,x+2) + D_L P_{\vec{\alpha}}(x,x+1,x+3) + D_R \sum_{\beta} b^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2\alpha_3}$$
$$(x-1,x,x+2) + D_L \sum_{\beta} c^{\beta_2\beta_3}_{\alpha_2\alpha_3} P_{\alpha_1\beta_2\beta_3}(x,x+2,x+3) + \sum_{\beta\neq\alpha} (D_R c^{\beta_1\beta_2}_{\alpha_1\alpha_2}$$
$$+ D_L b^{\beta_1\beta_2}_{\alpha_1\alpha_2}) P_{\beta_1\beta_2\alpha_3}$$
$$(x,x+1,x+2) + \sum_{\beta\neq\alpha} (D_R c^{\beta_2\beta_3}_{\alpha_2\alpha_3} + D_L b^{\beta_2\beta_3}_{\alpha_2\alpha_3}) P_{\alpha_1\beta_2\beta_3}(x,x+1,x+2) + D_R \sum_{\gamma} b^{\vec{\gamma}}_{\vec{\alpha}} P_{\vec{\gamma}}$$
$$(x-1,x,x+1) + D_L \sum_{\gamma} c^{\vec{\gamma}}_{\vec{\alpha}} P_{\vec{\gamma}}(x+1,x+2,x+3) - \Bigg[D_R + D_L + D_R \sum_{\beta} b^{\alpha_1\alpha_2}_{\beta_1\beta_2}$$
$$+ D_L \sum_{\beta} c^{\alpha_1\alpha_2}_{\beta_1\beta_2} + D_R \sum_{\beta} b^{\alpha_2\alpha_3}_{\beta_2\beta_3} + D_L \sum_{\beta} c^{\alpha_2\alpha_3}_{\beta_2\beta_3} + \sum_{\beta\neq\alpha} (D_R c^{\alpha_1\alpha_2}_{\beta_1\beta_2} + D_L b^{\alpha_1\alpha_2}_{\beta_1\beta_2})$$
$$+ \sum_{\beta\neq\alpha} (D_R c^{\alpha_2\alpha_3}_{\beta_2\beta_3} + D_L b^{\alpha_2\alpha_3}_{\beta_2\beta_3}) \Bigg] P_{\vec{\alpha}}(x,x+1,x+2), \tag{23}$$

in which we have used Eqs. (14) and (15) for diagonal elements of matrix $D_R c + D_L b$. $b^{\vec{\gamma}}_{\vec{\alpha}}$ and $c^{\vec{\gamma}}_{\vec{\alpha}}$ are defined as follows:

$$b^{\vec{\gamma}}_{\vec{\alpha}} = \sum_{\gamma} b^{\gamma_1\gamma_2}_{\alpha_1\beta} b^{\beta\gamma_3}_{\alpha_2\alpha_3}, \tag{24}$$

$$c^{\vec{\gamma}}_{\vec{\alpha}} = \sum_{\gamma} c^{\gamma_1\beta}_{\alpha_1\alpha_2} c^{\gamma_2\gamma_3}_{\beta\alpha_3}. \tag{25}$$

Looking at source terms of Eq. (23), it is obvious that they describe the reactions (16) and the following three-particle drop–push reactions:

$$A_{\gamma_1} A_{\gamma_2} A_{\gamma_3} \emptyset \to \emptyset A_{\alpha_1} A_{\alpha_2} A_{\alpha_3} \quad \text{with rate } D_R b^{\vec{\gamma}}_{\vec{\alpha}} \tag{26}$$

and

$$\emptyset A_{\gamma_1} A_{\gamma_2} A_{\gamma_3} \to A_{\alpha_1} A_{\alpha_2} A_{\alpha_3} \emptyset \quad \text{with rate } D_L c^{\vec{\gamma}}_{\vec{\alpha}}. \tag{27}$$

The sink terms are consistent with this description, provided

$$\sum_{\beta} b^{\vec{\alpha}}_{\vec{\beta}} = \sum_{\beta\gamma} b^{\alpha_1\alpha_2}_{\beta_1\gamma} b^{\gamma\alpha_3}_{\beta_2\beta_3} = \sum_{\beta} b^{\alpha_1\alpha_2}_{\beta_1\beta_2} \quad \text{constraint (IV)} \tag{28}$$

and

$$\sum_{\beta} c^{\vec{\alpha}}_{\vec{\beta}} = \sum_{\beta\gamma} c^{\alpha_1\gamma}_{\beta_1\beta_2} c^{\alpha_2\alpha_3}_{\gamma\beta_3} = \sum_{\beta} c^{\alpha_2\alpha_3}_{\beta_2\beta_3} \quad \text{constraint (V)}. \tag{29}$$

By calculating other $\dot{P}_{\vec{\alpha}}(x,x+1,\ldots,x+n-1)$'s it can be shown that we do not need any more constraints and therefore the master equation (7) with boundary condition (10) and five constraints (I)–(V) can consistently describe the following reactions:

$$A_\alpha \emptyset \to \emptyset A_\alpha \quad \text{with rate } D_R, \tag{30}$$

$$\emptyset A_\alpha \to A_\alpha \emptyset \quad \text{with rate } D_L, \tag{31}$$

$$A_\alpha A_\beta \to A_\gamma A_\delta \quad \text{with rate } D_R c^{\alpha\beta}_{\gamma\delta} + D_L b^{\alpha\beta}_{\gamma\delta}, \tag{32}$$

$$A_{\alpha_0}\cdots A_{\alpha_n}\emptyset \to \emptyset A_{\gamma_0}\cdots A_{\gamma_n} \quad \text{with rate } D_R(b_{n-1,n}\cdots b_{0,1})^{\alpha_0\cdots\alpha_n}_{\gamma_0\cdots\gamma_n}, \tag{33}$$

$$\emptyset A_{\alpha_0}\cdots A_{\alpha_n} \to A_{\gamma_0}\cdots A_{\gamma_n}\emptyset \quad \text{with rate } D_L(c_{0,1}\cdots c_{n-1,n})^{\alpha_0\cdots\alpha_n}_{\gamma_0\cdots\gamma_n}. \tag{34}$$

In the above equations we use the following definition for $b_{k,k+1}$ and $c_{k,k+1}$:

$$a_{k,k+1} = 1 \otimes \cdots \otimes 1 \otimes \underbrace{a}_{k,k+1} \otimes 1 \otimes \cdots \otimes 1. \tag{35}$$

Note that for $D_L=0$, the five classes of the above reactions reduce to three classes discussed in Ref. 25. In Ref. 25, the constraints between reaction rates are three relations (I), (II), and (IV). Note that at $D_L=0$, the constraints (III) and (V) do not appear since the multiplication factors of their corresponding terms in evolution equation is D_L, which is zero.

To find the set of solutions of five constraints (I)–(V), one can consider the solutions of equations (I), (II), and (IV), that is the solutions derived in Ref. 25, and then considers the subset of them satisfies (III) and (V). We must note that in our models, the diagonal elements of matrix c are the reaction rates of the last line of Eq. (16) and must be positive. This is in contrast to the case studied in Ref. 25 in which the diagonal elements of c can be negative.

We can also follow another approach. That is trying to find the solution of equations (II)–(IV) and then seek ones which satisfy relation (I). As these relations are rather complex, we cannot completely solve them for arbitrary p, but we try them as much as possible.

As all the matrix elements of matrices b and c are reaction rates, they cannot be negative, so the only solution of Eq. (18) is

$$c^{\gamma_1\gamma_2}_{\alpha_1\beta_2} b^{\beta_2\beta_3}_{\alpha_2\alpha_3} = 0 \quad (\text{without sum over } \beta_2). \tag{36}$$

This relation has the two following solutions (for each β_2):

$$c^{\gamma_1\gamma_2}_{\alpha_1\beta_2} = 0 \quad \text{and } b^{\beta_2\beta_3}_{\alpha_2\alpha_3} = 0. \tag{37}$$

So for each β_2 we have two solutions, and as β_2 runs from 1 to p, we have 2^p-2 set of solutions for constraint (II). We exclude two of the solutions in which all of the elements of c or b is zero, since we look for the situations in which $b\neq 0$ and $c\neq 0$. We will later study the cases $b=0$ or $c=0$ in which the number of independent classes of reactions (30)–(34) reduces to four. By the same argument, the solutions of Eq. (21) are (for each β_2)

$$c^{\beta_1\beta_2}_{\alpha_1\alpha_2} = 0 \quad \text{and } b^{\gamma_2\gamma_3}_{\beta_2\alpha_3} = 0, \tag{38}$$

and therefore we again have 2^p-2 set of solutions for constraint (III). Note that from 2^p-2 solutions of constraints (II) [and (III)] only $(p-1)$ of them are independent, that is, does not transform to each other under interchanging of the labels of the species of the particles. So the number of independent solutions of constraints (II) and (III) are $(p-1)(2^p-2)$. For example, in $p=2$, the independent solutions of (II) and (III) are

$$\begin{aligned} &\{c^{\gamma_1\gamma_2}_{\alpha_1 1} = 0, b^{2\beta_3}_{\alpha_2\alpha_3} = 0, c^{\beta_1 1}_{\alpha_1\alpha_2} = 0, b^{\gamma_2\gamma_3}_{2\alpha_3} = 0\}, \\ &\{c^{\gamma_1\gamma_2}_{\alpha_1 1} = 0, b^{2\beta_3}_{\alpha_2\alpha_3} = 0, c^{\beta_1 2}_{\alpha_1\alpha_2} = 0, b^{\gamma_2\gamma_3}_{1\alpha_3} = 0\}, \end{aligned} \tag{39}$$

which can be written as

$$b=\begin{pmatrix} b_{11} & b_{12} & 0 & 0 \\ b_{21} & b_{22} & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad c=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & c_{22} & 0 & c_{24} \\ 0 & 0 & 0 & 0 \\ 0 & c_{42} & 0 & c_{44} \end{pmatrix} \tag{40}$$

and

$$b=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ b_{31} & b_{32} & 0 & 0 \\ b_{41} & b_{42} & 0 & 0 \end{pmatrix}, \quad c=\begin{pmatrix} 0 & 0 & 0 & 0 \\ c_{21} & 0 & c_{23} & 0 \\ 0 & 0 & 0 & 0 \\ c_{41} & 0 & c_{43} & 0 \end{pmatrix}, \tag{41}$$

respectively. We label the states as $|1\rangle=(1,1)$, $|2\rangle=(1,2)$, $|3\rangle=(2,1)$ and $|4\rangle=(2,2)$. Setting Eqs. (40) and (41) into the constraints (IV) and (V) [Eqs. (28) and (29)] results in

$$b=\begin{pmatrix} 1 & 1 & 0 & 0 \\ b_{21} & b_{21} & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad c=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & c_{22} & 0 & c_{22} \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 \end{pmatrix} \tag{42}$$

and

$$b=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ b_{41} & b_{41} & 0 & 0 \end{pmatrix}, \quad c=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ c_{41} & 0 & c_{41} & 0 \end{pmatrix}, \tag{43}$$

respectively. Now Eq. (12) [constraint (I)] says that the sum of the elements of each column of matrix $(b+c)$ must be one, which unfortunately does not satisfy by (42) and (43). The sum of the elements of the second column of $(b+c)$ of Eq. (42) and the first column of Eq. (43) are greater than (or equal to) 2. So reactions (30)–(34) have not any representation in $p=2$, the situation which we expect to be true for other p's. For example, in $p=3$, constraints (II) and (III) have 12 independent solutions, which are in two categories, the number of constraints on ${b_i}^j$ and ${c_k}^l$'s are equal (three on ${b_i}^j$ and three on ${c_k}^l$), and one which these numbers differ, i.e., 4 and 2. As an example of the first category, we consider the case in which ${c_{\alpha 1}}^j=0$, ${c_{\alpha 2}}^j=0$, ${c_i}^{\beta 1}=0$, ${b_k}^{3\gamma}=0$, ${b_{1\alpha}}^k=0$, ${b_{3\alpha}}^k=0$. It means that in matrix c, the rows 1,2,4,5,7,8 and columns 2,5, and 8 are zero, so it has 18 nonzero elements, and b is a matrix in which the rows 1,2,3,7,8,9 and columns 7,8, and 9 are zero so it also has 18 nonzero elements. Setting these b and c matrices in constraints (IV) and (V) results in two of the following solutions for each b and c:

$$\begin{aligned} &c_1{:}\{c_{31}=c_{34}=c_{37}=1, c_{33} \text{ and } c_{36} \text{ arbitrary}\}, \\ &c_2{:}\{c_{93}=c_{96}=c_{99}=1, c_{91} \text{ and } c_{94} \text{ arbitrary}\}, \\ &b_1{:}\{b_{41}=b_{42}=b_{43}=1, b_{44} \text{ and } b_{45} \text{ arbitrary}\}, \\ &b_2{:}\{b_{54}=b_{55}=b_{56}=1, b_{51} \text{ and } b_{52} \text{ arbitrary}\}, \end{aligned} \tag{44}$$

in which we only write down the nonzero elements. It can be easily seen that none of the combinations b_1+c_1, b_1+c_2, b_2+c_1, b_2+c_2 are acceptable in the sense of constraint (I), as at least the sum of the elements of one of the columns of these matrices are greater than (or equal to) 2. We have checked that the same situation arises in other 11 solutions. So again in $p=3$, we have no

representation. We cannot generally prove this, but we believe that the set of constraints (I)–(V) have no solution for arbitrary p.

One may suppose that if we somehow change the constraint (I), then it may be possible to find some solution for our equations. So we add the annihilation processes to our previous interactions. Note that these interactions appear only in the sink terms of the evolution equation, as if we consider the initial state with n particles, no annihilation processes can lead to a n-particle state at any other time t. So if we change the constraint (I) to (as we do not have the conservation of particles)

$$\sum_{\alpha} (b+c)^{\beta_1\beta_2}_{\alpha_1\alpha_2} = 1 - \lambda_{\beta_1\beta_2}, \tag{45}$$

and using it in the calculation of $\dot{P}_{\alpha_1\alpha_2}(x,x+1)$, we find the same equation as (13), except an extra term $\lambda_{\alpha_1\alpha_2}\dot{P}_{\alpha_1\alpha_2}(x,x+1)$ which is added to sink terms. So $\lambda_{\alpha_1\alpha_2}$ is the sum of the rates of all annihilation processes with initial state $(\alpha_1\alpha_2)$ and therefore is a positive quantity. Therefore adding the annihilation processes to interactions (30)–(34) means that the sum of the elements of each column of $(b+c)$ can now be less than or equal to 1. But as we have shown in Eqs. (42)–(44), the sum of the elements of some of the columns of $(b+c)$ in these examples are at least 2, which differs from what is suggested by Eq. (45). In brief, including the annihilation processes cannot alter our result and the set of processes (30)–(34) have no representation, with or without adding the annihilation processes.

Now it is interesting to note that even if one of the matrices b or c is equal to zero, we have yet all four desired reactions, diffusion to left *and* right, two-particle reactions $A_\alpha A_\beta \to A_\gamma A_\delta$, and the extended drop–push reactions, which the latter occur only on one side (left *or* right). These are almost the general reactions that one can study in this framework. Let us check the constraints in these cases.

A. Type 1 model

Take $c=0$. Equation (12) becomes

$$\sum_{\alpha} b^{\beta_1\beta_2}_{\alpha_1\alpha_2} = 1. \tag{46}$$

Constraints (II), (III), and (V) are satisfied trivially and constraint (IV) is also satisfied: using Eq. (46), both sides of constraint (IV) become one. Therefore master equation (7) with boundary condition

$$P_{\alpha_1\alpha_2}(x,x) = \sum_{\beta} b^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x-1,x), \tag{47}$$

and constraint (46), describe consistently the following reactions:

$$\begin{gathered} A_\alpha \emptyset \to \emptyset A_\alpha \quad \text{with rate } D_R, \\ \emptyset A_\alpha \to A_\alpha \emptyset \quad \text{with rate } D_L, \\ A_\alpha A_\beta \to A_\gamma A_\delta \quad \text{with rate } D_L b^{\alpha\beta}_{\gamma\delta}, \\ A_{\alpha_0}\cdots A_{\alpha_n}\emptyset \to \emptyset A_{\gamma_0}\cdots A_{\gamma_n} \quad \text{with rate } D_R (b_{n-1,n}\cdots b_{0,1})^{\alpha_0\cdots\alpha_n}_{\gamma_0\cdots\gamma_n}. \end{gathered} \tag{48}$$

B. Type 2 model

In the same way, for $b=0$ it can be seen that the master equation (7) with boundary condition

$$P_{\alpha_1\alpha_2}(x,x) = \sum_{\beta} c^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x,x+1), \tag{49}$$

and constraint

$$\sum_{\alpha} c^{\beta_1\beta_2}_{\alpha_1\alpha_2} = 1, \tag{50}$$

describe successfully the reactions

$$\begin{aligned} A_\alpha \emptyset &\to \emptyset A_\alpha \quad \text{with rate } D_R, \\ \emptyset A_\alpha &\to A_\alpha \emptyset \quad \text{with rate } D_L, \\ A_\alpha A_\beta &\to A_\gamma A_\delta \quad \text{with rate } D_R c^{\alpha\beta}_{\gamma\delta}, \end{aligned} \tag{51}$$

$$\emptyset A_{\alpha_0} \cdots A_{\alpha_n} \to A_{\gamma_0} \cdots A_{\gamma_n} \emptyset \quad \text{with rate } D_L (c_{0,1} \cdots c_{n-1,n})^{\alpha_0 \cdots \alpha_n}_{\gamma_0 \cdots \gamma_n}.$$

The condition of solvability of these models will be discussed in the next sections.

III. SECOND KIND GENERALIZATION

By noting the first line of Eq. (9), it is seen that Eq. (10) is not the only possible p-species boundary condition. In fact, one can instead consider the following boundary condition:

$$D_R P_{\alpha_1\alpha_2}(x,x) + D_L P_{\alpha_1\alpha_2}(x+1,x+1) = \sum_{\beta} b^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x-1,x) + \sum_{\beta} c^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x,x+1). \tag{52}$$

This is the multispecies generalization of the boundary condition considered in Refs. 17 and 27.

To study the interactions introduced by (7) and (52), we must again consider $\dot{P}_{\alpha_1\cdots\alpha_n}(x,x+1,\ldots,x+n-1)$. In $n=3$, we encounter the boundary term $D_R P_{\alpha_1\alpha_2\alpha_3}(x,x+1,x+1) + D_L P_{\alpha_1\alpha_2\alpha_3}(x,x+2,x+2)$, where using (52) results in $\Sigma_\beta b^{\beta_2\beta_3}_{\alpha_2\alpha_3} P_{\alpha_1\beta_2\beta_3}(x,x,x+1) + \Sigma_\beta c^{\beta_2\beta_3}_{\alpha_2\alpha_3} P_{\alpha_1\beta_2\beta_3}(x,x+1,x+2)$. But the first term $P_{\alpha_1\beta_2\beta_3}(x,x,x+1)$ cannot be written in terms of physical probabilities, since in this case only the linear combination $D_R P_{\alpha_1\alpha_2\cdots}(x,x,\ldots) + D_L P_{\alpha_1\alpha_2\cdots}(x+1,x+1,\ldots)$ can be written in terms of physical function [Eq. (52)]. This is in contrast with the case studied in Sec. II. The only solution to this problem is taking

$$b = 0. \tag{53}$$

So our second kind p-species model is defined through the master equation (7) and the following boundary condition:

$$D_R P_{\alpha_1\alpha_2}(x,x) + D_L P_{\alpha_1\alpha_2}(x+1,x+1) = \sum_{\beta} c^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x,x+1). \tag{54}$$

Conservation of the number of particles gives

$$\sum_{\alpha} c^{\beta_1\beta_2}_{\alpha_1\alpha_2} = 1, \tag{55}$$

and calculating $\dot{P}_{\alpha_1\alpha_2}(x,x+1)$ results in

$$\dot{P}_{\alpha_1\alpha_2}(x,x+1) = D_R P_{\alpha_1\alpha_2}(x-1,x+1) + D_L P_{\alpha_1\alpha_2}(x,x+2) + \sum_{\beta\neq\alpha} c^{\beta_1\beta_2}_{\alpha_1\alpha_2} P_{\beta_1\beta_2}(x,x+1)$$
$$- \left(D_R + D_L + \sum_{\beta\neq\alpha} c^{\alpha_1\alpha_2}_{\beta_1\beta_2}\right) P_{\alpha_1\alpha_2}(x,x+1). \tag{56}$$

This equation describes the following reactions as source and sink terms:

$$A_\alpha\emptyset \to \emptyset A_\alpha \quad \text{with rate } D_R,$$
$$\emptyset A_\alpha \to A_\alpha\emptyset \quad \text{with rate } D_L, \tag{57}$$
$$A_\alpha A_\beta \to A_\gamma A_\delta \quad \text{with rate } c^{\alpha\beta}_{\gamma\delta}.$$

Calculating other $\dot{P}_{\alpha_1\cdots\alpha_n}(x,x+1,\ldots,x+n-1)$'s confirms these reactions without any further constraint. So the **type 3 model** is defined by the master equation (7), boundary condition (54), constraint (55), and reactions (57).

IV. BETHE ANSATZ SOLUTION

Until now, we have constructed a consistent formalism to study some reaction–diffusion processes. Now we want to solve the resulting evolution equations and check the solvability of these models. To solve the master equation (7), we consider the following Bethe ansatz:

$$P_{\alpha_1\cdots\alpha_N}(\mathbf{x};t) = e^{-E_N t}\psi_{\alpha_1\cdots\alpha_N}(\mathbf{x}), \tag{58}$$

with

$$\Psi(\mathbf{x}) = \sum_\sigma \mathbf{A}_\sigma e^{i\sigma(\mathbf{p})\cdot\mathbf{x}}. \tag{59}$$

Ψ is a tensor of rank N with components $\psi_{\alpha_1\cdots\alpha_N}(\mathbf{x})$ and the summation runs over the elements of the permutation group of N objects.[28,29] Inserting (58) in (7), results in

$$E_N = \sum_{k=1}^{N} (1 - D_R e^{-ip_k} - D_L e^{ip_k}). \tag{60}$$

Inserting (58) in boundary condition (47) gives

$$\Psi(\ldots,x_k = x, x_{k+1} = x, \ldots) = b_{k,k+1}\Psi(\ldots,x_k = x-1, x_{k+1} = x, \ldots), \tag{61}$$

which using (59) results

$$[1 - e^{-i\sigma(p_k)}b_{k,k+1}]\mathbf{A}_\sigma + [1 - e^{-i\sigma(p_{k+1})}b_{k,k+1}]\mathbf{A}_{\sigma\sigma_k} = 0. \tag{62}$$

σ_k is an element of permutation group which only interchanges p_k and p_{k+1},

$$\sigma_k:(p_1,\ldots,p_k,p_{k+1},\ldots,p_N) \to (p_1,\ldots,p_{k+1},p_k,\ldots,p_N). \tag{63}$$

Equation (62) gives $\mathbf{A}_{\sigma\sigma_k}$ in terms of $\mathbf{A}_\sigma$ as follows:

$$\mathbf{A}_{\sigma\sigma_k} = S^{(1)}_{k,k+1}(\sigma(p_k),\sigma(p_{k+1}))\mathbf{A}_\sigma, \tag{64}$$

where

$$S^{(1)}_{k,k+1}(z_1,z_2) = 1 \otimes \cdots \otimes 1 \otimes \underbrace{S^{(1)}(z_1,z_2)}_{k,k+1} \otimes 1 \otimes \cdots \otimes 1, \tag{65}$$

and $S^{(1)}(z_1,z_2)$ is the following $p^2 \times p^2$ matrix:

$$S^{(1)}(z_1,z_2) = -(1-z_2^{-1}b)^{-1}(1-z_1^{-1}b), \tag{66}$$

in which $z_k = e^{ip_k}$. The same procedure for boundary conditions (49) and (54), i.e., the type 2 and type 3 models, results in

$$S^{(2)}(z_1,z_2) = -(1-z_1c)^{-1}(1-z_2c) \tag{67}$$

and

$$S^{(3)}(z_1,z_2) = -(D_R + z_1z_2D_L - z_1c)^{-1}(D_R + z_1z_2D_L - z_2c), \tag{68}$$

respectively. Equation (64) allows one to compute all $\mathbf{A}_\sigma$'s in terms of $\mathbf{A}_1$ (which is set to unity).

As the generators of permutation group satisfy $\sigma_k\sigma_{k+1}\sigma_k = \sigma_{k+1}\sigma_k\sigma_{k+1}$, so one also needs

$$\mathbf{A}_{\sigma_k\sigma_{k+1}\sigma_k} = \mathbf{A}_{\sigma_{k+1}\sigma_k\sigma_{k+1}}. \tag{69}$$

This, in terms of S-matrices becomes

$$S_{12}(z_2,z_3)S_{23}(z_1,z_3)S_{12}(z_1,z_2) = S_{23}(z_1,z_2)S_{12}(z_1,z_3)S_{23}(z_2,z_3). \tag{70}$$

In the terms of R-matrix defined through

$$S_{k,k+1} =: \Pi_{k,k+1}R_{k,k+1}, \tag{71}$$

where Π is the permutation matrix, Eq. (70) is transformed to

$$R_{23}(z_2,z_3)R_{13}(z_1,z_3)R_{12}(z_1,z_2) = R_{12}(z_1,z_2)R_{13}(z_1,z_3)R_{23}(z_2,z_3). \tag{72}$$

This is the spectral Yang–Baxter equation.

The Bethe ansatz solution exists, if the scattering matrix satisfies (70). In other words, the matrix b in (66) and c in (67) and (68) is acceptable only if the resulting S-matrices satisfy (70). This is a very restricted condition and needed for having the solvability.

The S-matrices (66) and (67) are exactly the ones considered in Refs. 24 and 23, respectively. Using the fact that $S^{(1)}$ is a binomial of degree one with respect to $z_1^{-1} = e^{-ip_1}$ and $S^{(2)}$ is of degree one with respect to z_2, it can be shown that SYB equation (70) for $S^{(1)}$ and $S^{(2)}$ reduces to

$$b_{23}[b_{23},b_{12}] = [b_{23},b_{12}]b_{12} \tag{73}$$

and

$$c_{12}[c_{12},c_{23}] = [c_{12},c_{23}]c_{23}, \tag{74}$$

respectively.[23,24] Note that although the above equations are much simpler than Eq. (70), but they are very complicated yet. In p-species, each one is an equality between two $p^3\times p^3$ matrices which results a system of p^6 equations to be solved for p^4-p^2 elements of b (or c), which may or may not have solution [Eq. (46) and (50) reduce the number of independent elements of b and c to p^4-p^2]. The general properties of the solutions of Eq. (73) and Eq. (74) have been discussed in Refs. 24 and 23, respectively, which can be directly used here. In other words, for every solution of Eq. (74), there exists a corresponding solvable model which has been discussed in Ref. 23, i.e.,

$$\begin{aligned} A_\alpha\emptyset &\to \emptyset A_\alpha \quad \text{with rate 1},\\ A_\alpha A_\beta &\to A_\gamma A_\delta \quad \text{with rate } c_{\gamma\delta}^{\alpha\beta}. \end{aligned} \tag{75}$$

and a type 2 model with reactions written in Eq. (51) [note that the reactions (75) are a subset of (51) with $D_L=0$]. The same is true for solutions of (73). They can describe the following solvable model (discussed in Ref. 24):

$$A_\alpha\emptyset \to \emptyset A_\alpha \quad \text{with rate 1},$$

$$A_{\alpha_0}\cdots A_{\alpha_n}\emptyset \to \emptyset A_{\gamma_0}\cdots A_{\gamma_n} \quad \text{with rate } (b_{n-1,n}\cdots b_{0,1})^{\alpha_0\cdots\alpha_n}_{\gamma_0\cdots\gamma_n}, \tag{76}$$

and a type 1 model with reaction (48) [again at $D_L=0$, (48) reduces to (76)].

The reasoning which leads the SYB equations of $S^{(1)}$ and $S^{(2)}$ to (73) and (74) does not work for $S^{(3)}$ since it is not a binomial of degree one with respect to z_1 or z_2, in fact it contains all powers of z_1 and z_2. So obtaining the solutions of (70) for $S^{(3)}$ is more difficult than for $S^{(1)}$ and $S^{(2)}$, even in the simplest case $p=2$. In the $p=2$ case we encounter a system of 64 equations that must be solved for 12 nondiagonal elements of c [the diagonal elements are determined by Eq. (55)]. The solution must be momentum independent (independent of z_1, z_2, and z_3) and non-negative. We cannot solve this equation generally (taking all $c_{ij}\neq 0$) by standard mathematical softwares and therefore restrict ourselves to some specific cases. For example, taking

$$c=\begin{pmatrix} c_{11} & 0 & 0 & c_{14} \\ c_{21} & 1 & 0 & c_{24} \\ 1-c_{11}-c_{21} & 0 & 1 & 1-c_{14}-c_{24} \\ 0 & 0 & 0 & 0 \end{pmatrix}, \tag{77}$$

or

$$c=\begin{pmatrix} 0 & 0 & 0 & 0 \\ c_{21} & 1 & 0 & c_{24} \\ c_{31} & 0 & 1 & c_{34} \\ 1-c_{21}-c_{31} & 0 & 0 & 1-c_{24}-c_{34} \end{pmatrix}, \tag{78}$$

which are the four-parameters cases, one obtains two solutions

$$c=\begin{pmatrix} 0 & 0 & 0 & 0 \\ D_R & 1 & 0 & D_L \\ D_L & 0 & 1 & D_R \\ 0 & 0 & 0 & 0 \end{pmatrix}, \tag{79}$$

and one with $D_L \leftrightarrow D_R$. Taking

$$c=\begin{pmatrix} 1-c_{41} & 1-c_{42} & 1-c_{43} & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ c_{41} & c_{42} & c_{43} & 1 \end{pmatrix} \tag{80}$$

or

$$c=\begin{pmatrix} 1 & 1-c_{42} & 1-c_{43} & 1-c_{44} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & c_{42} & c_{43} & c_{44} \end{pmatrix}, \tag{81}$$

as some three-parameters cases, we find four solutions

$$c = \begin{pmatrix} 1 & 1-c_{42} & 1-c_{43} & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & c_{42} & c_{43} & 1 \end{pmatrix}, \tag{82}$$

where each of c_{42} and c_{43} are either D_R or D_L. Taking $A_1 \equiv A$ and $A_2 \equiv B$, the interactions introduced by (79), for instance, are

$$\begin{aligned} A\emptyset &\xrightarrow{D_R} \emptyset A, \\ B\emptyset &\xrightarrow{D_R} \emptyset B, \\ \emptyset A &\xrightarrow{D_L} A\emptyset, \\ \emptyset B &\xrightarrow{D_L} B\emptyset, \\ AA &\xrightarrow{D_R} AB, \\ BB &\xrightarrow{D_L} AB, \\ AA &\xrightarrow{D_L} BA, \\ BB &\xrightarrow{D_R} BA. \end{aligned} \tag{83}$$

The model built on the reactions (83) is integrable.

Assuming that the solvability condition (70) is satisfied, it is easy to see that the conditional probability (the propagator) is

$$U(\mathbf{x};t|\mathbf{y};0) = \int \frac{d^N p}{(2\pi)^N} e^{-E_N t} e^{-i\mathbf{p}.\mathbf{y}} \sum_{\sigma} \mathbf{A}_{\sigma} e^{i\sigma(\mathbf{p})\cdot\mathbf{x}}, \tag{84}$$

where the integration region for each p_i is $[0, 2\pi]$ and $A_1 = 1$. The singularity in A_σ is removed by setting $p_j \to p_j + i\varepsilon$, where one should consider the limit $\varepsilon \to 0^+$. Using this propagator, one can write the probability at the time t in terms of the initial value of probability,

$$|P(\mathbf{x};t)\rangle = \sum_{y} U(\mathbf{x};t|\mathbf{y};0)|P(\mathbf{y};0)\rangle. \tag{85}$$

Note that although $S^{(1)}$ and $S^{(2)}$ are similar to ones considered in Refs. 24 and 23, the propagators $U^{(1)}$ and $U^{(2)}$ are different since the energy spectrum of our models differs from those considered there. In $D_L = 0$, our results must coincide with those obtained in Refs. 23 and 24.

For the two-particle sector, there is only one matrix in the expression of $U^{(i)}$s (b in $U^{(1)}$ and c in $U^{(2)}$ and $U^{(3)}$). So it can be treated as a c-number. Using calculation similar to what has been done in Refs. 23–25, one arrives at

$$U^{(1)}(x_1,x_2;t|y_1,y_2;0) = e^{-2t}\sum_{n,m=0}^{\infty}\left\{\frac{D_L^n D_R^{x_1-y_1+n}t^{x_1-y_1+2n}}{n!(x_1-y_1+n)!}\frac{D_L^m D_R^{x_2-y_2+m}t^{x_2-y_2+2m}}{m!(x_2-y_2+m)!}\right.$$
$$+\sum_{l=0}^{\infty}\frac{D_L^n D_R^{x_2-y_1+n}t^{x_2-y_1+2n}}{n!(x_2-y_1+n)!}\frac{D_L^m D_R^{x_1-y_2-l+m}t^{x_1-y_2-l+2m}}{m!(x_1-y_2-l+m)!}$$
$$\left.\times b^l\left[-1+\frac{x_2-y_1+n}{D_R t}b\right]\right\}, \tag{86}$$

and

$$U^{(2)}(x_1,x_2;t|y_1,y_2;0) = e^{-2t}\sum_{n,m=0}^{\infty}\left\{\frac{D_L^n D_R^{x_1-y_1+n}t^{x_1-y_1+2n}}{n!(x_1-y_1+n)!}\frac{D_L^m D_R^{x_2-y_2+m}t^{x_2-y_2+2m}}{m!(x_2-y_2+m)!}\right.$$
$$+\sum_{l=0}^{\infty}\frac{D_L^n D_R^{x_2-y_1+l+n}t^{x_2-y_1+l+2n}}{n!(x_2-y_1+l+n)!}\frac{D_L^m D_R^{x_1-y_2+m}t^{x_1-y_2+2m}}{m!(x_1-y_2+m)!}$$
$$\left.\times c^l\left[-1+\frac{D_R t}{x_1-y_2+m+1}c\right]\right\}. \tag{87}$$

Similarly one can obtain a more lengthy expression for $U^{(3)}$. Note that at $D_L=0$, Eqs. (86) and (87) lead Eqs. (38) of Ref. 24 and (30) of Ref. 23, respectively.

To investigate the large-time behaviors of the probabilities $U^{(1)}$, $U^{(2)}$, and $U^{(3)}$, it is useful to decompose the vector spaces on which b (in type 1 model) and c (in types 2 and 3 models) act, in two subspaces invariant under the action of $b(c)$, the first subspace corresponding to eigenvalues with modulus one, and another invariant subspace. For types 1 and 2 models with conditions (46) and (50), as all the elements of matrix $b(c)$ are non-negative, the second subspace corresponds to eigenvalues with modulus less than 1. By focusing on type 1 model, this decomposition can be done by introducing two projectors Q and R, satisfying

$$Q+R=1,$$
$$QR=RQ=0, \tag{88}$$
$$[b,Q]=[b,R]=0.$$

Q projects on the first subspace and R projects on the second. Following Ref. 23, we multiply $U^{(1)}$ by $Q+R=1$:

$$U^{(1)}(\mathbf{x};t|\mathbf{y};0) = U^{(1)}Q + U^{(1)}R. \tag{89}$$

In the terms multiplied by R, one can treat b as a number with modulus different from 1. So the integrand in (84) is nonsingular at points $p_j=0$, which have the main contributions at large times. Setting $p_j=0$, we have $S^{(1)}\approx -1$ and $\mathbf{A}_\sigma \approx (-1)^{[\sigma]}$, and Eq. (84) results in

$$\text{the second term of } U^{(1)} = \frac{1}{2\pi t}\{e^{-\{[x_1-y_1-(D_R-D_L)t]^2+[x_2-y_2-(D_R-D_L)t]^2\}/(2t)}$$
$$-e^{-\{[x_1-y_2-(D_R-D_L)t]^2+[x_2-y_1-(D_R-D_L)t]^2\}/(2t)}\}R, \quad t\to\infty, \tag{90}$$

which is independent of b. So at large time, the second term of $U^{(1)}$ tends to zero faster than t^{-1} and the leading term in $U^{(1)}$, which is order t^{-1}, does not involve the second term.

If the only eigenvalue of b with modulus 1 is 1, then $bQ=Q$ and $U^{(1)}$ has a simple behavior at $t\to\infty$,

$$U^{(1)}(x_1,x_2;t|y_1,y_2;0) = e^{-2t}\sum_{n,m=0}^{\infty}\left\{\frac{D_L^n D_R^{x_1-y_1+n}t^{x_1-y_1+2n}}{n!(x_1-y_1+n)!}\frac{D_L^m D_R^{x_2-y_2+m}t^{x_2-y_2+2m}}{m!(x_2-y_2+m)!}\right.$$
$$+\sum_{l=0}^{\infty}\frac{D_L^n D_R^{x_2-y_1+n}t^{x_2-y_1+2n}}{n!(x_2-y_1+n)!}\frac{D_L^m D_R^{x_1-y_2-l+m}t^{x_1-y_2-l+2m}}{m!(x_1-y_2-l+m)!}$$
$$\left.\times\left[-1+\frac{x_2-y_1+n}{D_R t}\right]\right\}Q. \tag{91}$$

This is simply the propagator of a single-species model with diffusions to the right and left and drop–push to the right (i.e., the $\lambda=0$ case of the reactions studied in Refs. 26 and 30), multiplied by Q. In fact Eq. (91) is $\lambda=0$ case of Eq. (30) of Ref. 26, times Q.

For $U^{(2)}$, the same decomposition leads to Eq. (90) for its second term and in the case $cQ=Q$, $U^{(2)}$ tends to (87), with $c=1$, times Q, at $t\to\infty$. The resulting one-species model is the $\mu=0$ case of the reactions studied in Refs. 26 and 30. For $U^{(3)}$, we again find (90) and the one-species partially asymmetric simple exclusion process of Ref. 17.

(Received 6 December 2004; accepted 3 March 2005; published online 28 April 2005)

In this paper, we give a condition on the bicharacteristic which guarantees the global existence of the mild solution to the Boltzmann equation with an external force for the hard-sphere model and potentials with angular cutoff in infinite vacuum. This generalizes the previous results to the case when the force can have arbitrary strength. The constructive condition on the bicharacteristic is used to obtain the pointwise estimates on the collision operator so that the global existence comes from the contraction mapping theorem. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1899985]

I. INTRODUCTION

The purpose of this paper is to study the global existence of mild solutions to the initial value problem for the Boltzmann equation with an external force for the hard-sphere model and some angle cutoff potential. Let $f=f(t,x,v)$ be the density distribution function of the interacting gas particles at time $t\geqslant 0$ and position $x\in\mathbf{R}^3$ with velocity $v\in\mathbf{R}^3$ for rarefied gases. In the presence of external forces depending only on space and time variables, the evolution of f is described by the Boltzmann equation

$$f_t = v\cdot\nabla_x f + E(t,x)\cdot\nabla_v f = Q[f], \tag{1.1}$$

with initial data

$$f(0,x,v) = f_0(x,v), \tag{1.2}$$

where $E(t,x)\in\mathbf{R}^3$ is an external force and Q is a nonlinear collision operator capturing the binary collisions between particles whose specific form will be given below.

Let (v,v_*) and (v',v_*') be velocities before and after the collision, respectively. Under the assumption of elastic collision, the conservation of the momentum and energy:

$$v+v_* = v'+v_*',$$

$$|v|^2+|v_*|^2 = |v'|^2+|v_*'|^2,$$

yields

[a)]Author to whom correspondence should be addressed. Electronic mail: cjzhu@mail.ccnu.edu.cn

$$v' = v - [(v - v_*) \cdot \omega]\omega, \quad v'_* = v_* + [(v - v_*) \cdot \omega]\omega, \tag{1.3}$$

where $\omega \in S^2_+ = \{\omega \in S^2 : (v - v_*) \cdot \omega \geqslant 0\}$. Moreover, the collision term $Q[f]$ takes the form

$$Q[f](v) = \frac{1}{\varepsilon} \int_{\mathbf{R}^3 \times S^2_+} B(|v - v_*|, \theta)\{f(v')f(v'_*) - f(v)f(v_*)\} \mathrm{d}v_* \, \mathrm{d}\omega, \tag{1.4}$$

where ε is the Knudsen number proportional to the mean free path. For simplicity of notation, we sometimes use $f(v)$ to denote $f(t,x,v)$ without any ambiguity. In (1.4), the function $B(|v - v_*|, \theta)$ is the collision cross section with

$$\theta = \cos^{-1}\left(\frac{(v - v_*) \cdot \omega}{|v - v_*|} \right) \in \left[0, \frac{\pi}{2} \right] \tag{1.5}$$

being the scattering angle between $v - v_*$ and ω. The definition of B depends on the physics of collision. In fact, for the inverse power interaction potential, B takes the form of

$$B(|v - v_*|, \theta) = b_\gamma(\theta)|v - v_*|^\gamma, \quad -3 < \gamma < 1, \tag{1.6}$$

with $\gamma = 0$ corresponding to the Maxwellian molecules, $\gamma > 0$ corresponding to the hard interaction and $\gamma < 0$ corresponding to the soft interaction. Moreover, the hard-sphere model satisfies $B(|v - v_*|, \theta) = \sigma |v - v_*| \cos\theta$ with σ being the radius of the hard sphere.

For later use, as in Ref. 11 we denote $u = v - v_*$, $u_\parallel = (u \cdot \omega)\omega$ and $u_\perp = u - u_\parallel$ so that

$$v' = v - u_\parallel, \quad v'_* = v - u_\perp. \tag{1.7}$$

Then the collision term $Q[f]$ becomes

$$Q[f](v) = \frac{1}{\varepsilon} \int_{\mathbf{R}^3 \times S^2_+} B(|u|, \theta)\{f(v')f(v'_*) - f(v)f(v - u)\} \mathrm{d}u \, \mathrm{d}\omega, \tag{1.8}$$

where v' and v'_* are given by (1.7). Furthermore, let us denote the collision operator

$$Q(f,g) = Q^+(f,g) - Q^-(f,g) \tag{1.9}$$

with the gain term Q^+ and the loss term Q^- given by

$$Q^+(f,g)(t,x,v) = \frac{1}{\varepsilon} \int_{\mathbf{R}^3 \times S^2_+} B(|u|, \theta) f(t,x,v') g(t,x,v'_*) \mathrm{d}u \, \mathrm{d}\omega \tag{1.10}$$

and

$$Q^-(f,g)(t,x,v) = \frac{1}{\varepsilon} \int_{\mathbf{R}^3 \times S^2_+} B(|u|, \theta) f(t,x,v) g(t,x,v - u) \mathrm{d}u \, \mathrm{d}\omega. \tag{1.11}$$

Clearly,

$$Q[f] = Q(f,f). \tag{1.12}$$

For any fixed point (t,x,v) in $\mathbf{R}^+ \times \mathbf{R}^3 \times \mathbf{R}^3$, we now consider the bicharacteristic equations of (1.1) in $\mathbf{R}^3 \times \mathbf{R}^3$,

$$\frac{\mathrm{d}X}{\mathrm{d}s} = V, \quad \frac{\mathrm{d}V}{\mathrm{d}s} = E(s,X), \qquad (X,V)|_{s=t} = (x,v). \tag{1.13}$$

Suppose that the above ODE system have smooth solutions globally in time denoted by

$$[X(s;t,x,v),V(s;t,x,v)] \tag{1.14}$$

for any $(t,x,v)\in\mathbf{R}^+\times\mathbf{R}^3\times\mathbf{R}^3$. Then integrating (1.1) along the bicharacteristic, we obtain the representation of the mild solution to the Boltzmann equation,

$$f(t,x,v)=f_0(X(0;t,x,v),V(0;t,x,v))+\int_0^t Q(f,f)(s,X(s;t,x,v),V(s;t,x,v))\mathrm{d}s. \tag{1.15}$$

In fact, the mild solution can be defined as follows:

Definition 1.1: *A non-negative function* $f(t,x,v)\in C([0,T);L^1_+(\mathbf{R}^3\times\mathbf{R}^3))$ *is a mild solution to* (1.1) *with a non-negative initial data* f_0 *if and only if* f *satisfies the integral equation* (1.15) *for all* $t\in[0,T)$ *and a.e.* $(x,v)\in\mathbf{R}^3\times\mathbf{R}^3$.

The function spaces on $\mathbf{R}^+\times\mathbf{R}^3\times\mathbf{R}^3$ for the solutions constructed later can be defined in the following. For any $p>0,q>0$, let $S_{p,q}$ be the completion of the set consisting of the continuous functions of compact support with respect to the norm

$$|||f|||=\sup_{t,x,v}(1+|X(0;t,x,v)|^2)^p\exp\{q|V(0;t,x,v)|^2\}|f(t,x,v)|. \tag{1.16}$$

And for any fixed time t, define the norm

$$\|f(t)\|=\sup_{x,v}(1+|X(0;t,x,v)|^2)^p\exp\{q|V(0;t,x,v)|^2\}|f(t,x,v)|, \tag{1.17}$$

in particular,

$$\|f_0\|_{p,q}=\sup_{x,v}(1+|x|^2)^p e^{q|v|^2}|f_0(x,v)|. \tag{1.18}$$

Throughout this paper, the assumptions on p,q, the collision kernel and the external force can be summarized as follows:

(A1) $p>\frac{1}{2}$.

(A2) The cross section B is in the form of (1.6) with $-2<\gamma\leqslant 1$ satisfying

$$\int_0^{\pi/2} b_\gamma(\theta)(1+\tan\theta)\mathrm{d}\theta\leqslant b_0, \tag{1.19}$$

where b_0 is a positive constant.

(A3) The external force $E(t,x)$ is C^0 in (t,x). Furthermore, for any fixed point $(t,x,v)\in\mathbf{R}^+\times\mathbf{R}^3\times\mathbf{R}^3$, the first order ODE system (1.13) has global smooth solutions (1.14) satisfying the following constructive condition:

$$\begin{aligned} X(0;s,X(s;t,x,v),V(s;t,x,v)-\xi)&=X(0;t,x,v)+\alpha_1(s;t,x,v)\xi,\\ V(0;s,X(s;t,x,v),V(s;t,x,v)-\xi)&=V(0;t,x,v)-\alpha_2(s;t,x,v)\xi, \end{aligned} \tag{1.20}$$

for any $s\in\mathbf{R}^+$ and $\xi\in\mathbf{R}^3$, where $\alpha_1(s;t,x,v),\alpha_2(s;t,x,v)\in C^1(s)$ satisfy the following inequalities:

$$\alpha_i(s;t,x,v)>0,\quad i=1,2,$$

$$\alpha(s;t,x,v)\equiv\alpha_1'(s;t,x,v)\alpha_2(s;t,x,v)-\alpha_1(s;t,x,v)\alpha_2'(s;t,x,v)>0, \tag{1.21}$$

$$(\alpha_2(s;t,x,v))^{\gamma+1}\alpha(s;t,x,v)\geqslant\alpha_0>0,$$

where α_0 is a positive constant independent of s and (t,x,v). Here and in the sequel $\alpha_i'(s;t,x,v)$ represent the derivative with respect to s.

Now we can state the main result of this paper as follows:

Theorem 1.2: *Under the assumptions (A1)–(A3), there is a sufficiently small positive constant* $\delta_0>0$ *such that if* $0\leqslant f_0(x,v)$ *and* $\|f_0\|_{p,q}\leqslant\varepsilon\delta_0$, *then there exists a unique global in time mild solution* $f(t,x,v)$ *to the initial value problem* (1.1) and (1.2) *satisfying* $|||f|||\leqslant 2\varepsilon\delta_0$.

Remark 1.3: For the moment let us discuss the assumptions (A1)–(A3). First, (A1) means that initial data decays with algebraic rate in the space variable x, and decays with exponential rate in the velocity variable v. Then (A2) holds for the collision kernels satisfying the inverse power law with an angular cutoff assumption and the hard-sphere model. Finally, (A3) is a constructive assumption on the external forces which can be satisfied by forces without decay or smallness assumption on their strength. In the following, we will give two examples of external forces satisfying (A3). Even though in general the assumption (A3) is difficult to verify and is in some sense unsatisfactory, it can be viewed as the improvement of the previous results on the study on the Boltzmann equation with the external force.

Remark 1.4: Based on the estimates on the cross section from Refs. 2 and 22, similar argument in this paper holds for the polynomial decay norm in the velocity. That is, define

$$|||f|||' = \sup_{t,x,v,}(1+|X(0;t,x,v)|^2)^p(1+|V(0;t,x,v,)|^2)^q|f(t,x,v)|$$

and

$$\|f_0\|'_{p,q} = \sup_{x,v}(1+|x|^2)^p(1+|v|^2)^q|f_0(x,v)|.$$

Moreover, instead of the assumptions (A1) and (A2), we assume the following:

(A1)′ $p>\frac{1}{2}$ and $q>\frac{3}{2}$.

(A2)′ The cross section B is in the form of (1.6) with $-2<\gamma\leqslant 1$ and satisfying

$$\left|\frac{b_\gamma(\theta)}{\cos\theta}\right|\leqslant b_0',$$

where b_0' is some positive constant.

Then similar to Theorem 1.2, we also have that under the assumptions (A1)′, (A2)′, and (A3), there is a sufficiently small positive constant $\delta_0'>0$ such that if $0\leqslant f_0(x,v)$ and $\|f_0\|'_{p,q}\leqslant\varepsilon\delta_0'$, then there exists a unique global in time mild solution $f(t,x,v)$ to the initial value problem (1.1) and (1.2) satisfying $|||f|||'\leqslant 2\varepsilon\delta_0'$.

Now to understand the assumption (A3), we give the following two examples:

Example 1.4: Let $E(t,x)\equiv E(t)$. For any fixed (t,x,v), the bicharacteristic equations (1.13) have solutions

$$X(s;t,x,v) = x+v(s-t)+\int_t^s\int_t^\eta E(\tau)\mathrm{d}\tau\,\mathrm{d}\eta,$$

$$V(s;t,x,v) = v+\int_t^s E(\tau)\mathrm{d}\tau.$$

Hence,

$$X(0;t,x,v) = x-vt-\int_0^t\int_t^\eta E(\tau)\mathrm{d}\tau\,\mathrm{d}\eta,$$

$$V(0;t,x,v) = v-\int_0^t E(\tau)\mathrm{d}\tau.$$

Therefore, (A3) holds with

$$\alpha_1(s;t,x,v) = s \quad \text{and } \alpha_2(s;t,x,v) = 1,$$

when $0 < \alpha_0 \leqslant 1$ and $-2 < \gamma \leqslant 1$.

In fact, notice that for this case when external forces depend only on the time t, the Boltzmann equation with external forces can be rewritten to the Boltzmann equation without forces by the following transformation of independent variables, cf. Ref. 8:

$$\tilde{t} = t,$$

$$\tilde{x} = x - \int_0^t \int_0^\eta E(\tau)\mathrm{d}\tau\,\mathrm{d}\eta, \tag{1.22}$$

$$\tilde{v} = v - \int_0^t E(\tau)\mathrm{d}\tau.$$

Therefore, the existence of mild and classical solutions and L^1 stability around vacuum to the Boltzmann equation without forces, cf. Refs. 13, 25, and 12, can be applied to this case without any difficulty.

Example 1.5: Let $E(t,x) = a^2x + E_0(t)$, with $a > 0$ being a constant. For any fixed (t,x,v), the bicharacteristic equations (1.13) have solutions

$$X(s;t,x,v) = \frac{ax+v}{2a}e^{a(s-t)} + \frac{ax-v}{2a}e^{-a(s-t)} - \frac{E_2(t)}{2a}e^{a(s-t)} + \frac{E_3(t)}{2a}e^{-a(s-t)} + E_1(s),$$

$$V(s;t,x,v) = \frac{ax+v}{2}e^{a(s-t)} - \frac{ax-v}{2}e^{-a(s-t)} - \frac{E_2(t)}{2}e^{a(s-t)} - \frac{E_3(t)}{2}e^{-a(s-t)} + E_1'(s),$$

where $E_1(s)$ is some special solution to the second order linear ODE,

$$\frac{d^2E_1(s)}{\mathrm{d}s^2} = a^2E_1(s) + E_0(s),$$

and $(E_2(t), E_3(t))$ are defined by

$$E_2(t) = E_1'(t) + aE_1(t),$$

$$E_3(t) = E_1'(t) - aE_1(t).$$

Hence,

$$X(0;t,x,v) = \frac{ax+v}{2a}e^{-at} + \frac{ax-v}{2a}e^{at} - \frac{E_2(t)}{2a}e^{-at} + \frac{E_3(t)}{2a}e^{at} + E_1(0),$$

$$V(0;t,x,v) = \frac{ax+v}{2}e^{-at} - \frac{ax-v}{2}e^{at} - \frac{E_2(t)}{2}e^{-at} - \frac{E_3(t)}{2}e^{at} + E_1'(0).$$

Straightforward calculation shows that

$$\alpha_1(s;t,x,v) = \frac{1}{2a}(e^{as} - e^{-as}) \quad \text{and } \alpha_2(s;t,x,v,) = \frac{1}{2}(e^{as} + e^{-as}).$$

Thus,

$$\alpha(s;t,x,v) = \alpha_1'(s;t,x,v)\alpha_2(s;t,x,v) - \alpha_1(s;t,x,v)\alpha_2'(s;t,x,v) \equiv 1 > 0$$

and

$$\alpha_2(s;t,x,v) \geqslant 1.$$

If $0 < \alpha_0 \leqslant 1$ and $-1 \leqslant \gamma \leqslant 1$, then (A3) holds.

Notice that the positive coefficient in front of x in the force term of Example 1.5 implies that the bicharacteristic curves go to infinity in space as time tends to infinity. If the coefficient is negative, then the bicharacteristic is oscillating in the space of (X,V) and there is no known existence results on this interesting case for the nonlinear Boltzmann equation. However, for the linearized Boltzmann equation, the case when $E(t,x) = -x$ was studied by Tabata[20] using the semigroup approach. This result was later generalized in Ref. 21 to the case of linearized Boltzmann equation with an unbounded external force potential that is spherically symmetric and satisfies some differential inequalities.

Now we compare Theorems 1.2 with the previous related work. First, if $p > 3/2$, the bound on the initial data f_0 implies the total mass satisfies

$$\int_{\mathbf{R}^3 \times \mathbf{R}^3} |f_0(x,v)| \mathrm{d}x\, \mathrm{d}v \leqslant C\varepsilon\delta_0,$$

where C is a generic positive constant. This requires that the mean free path is sufficient large if total mass is finite because δ_0 is sufficiently small. This is exactly the requirement on the Boltzmann equation without forces in infinite vacuum considered by Illner and Shinbrot in Ref. 13. On the other hand, as in Ref. 2, if $1/2 < p \leqslant 3/2$, then the initial total mass can be infinite. For the method of proof, as in Refs. 11 and 25. Theorem 1.2 is obtained by using the contraction mapping theorem. Precisely, we obtain the following estimates:

$$\begin{aligned} |||\mathbf{T}f||| &\leqslant C\|f_0\|_{p,q} + C|||f|||^2, \\ |||\mathbf{T}f - \mathbf{T}g||| &\leqslant C(|||f||| + |||g|||)|||f - g|||, \end{aligned} \tag{1.23}$$

where $\mathbf{T}$ is a mapping from $S_{p,q}$ to $S_{p,q}$ defined by (3.18) in Sec. III. In order to prove (1.23), we need to control the time integration of the collision term $Q(f,g)$ along the bicharacteristic,

$$\int_0^t Q(f,g)(s, X(s;t,x,v), V(s;t,x,v))\mathrm{d}s.$$

The estimation on this integral is based on the constructive assumption (A3) and is given in Lemma 3.1 of Sec. III.

There have been extensive studies on the mathematical aspects on the Boltzmann equation, see Refs. 2, 4, and 5. For the Boltzmann equation in the absence of an external force in infinite vacuum, the global existence of mild solutions to (1.1) was first given by Illner–Shinbrot[13] following the work on local existence by Kaniel–Shinbrot in Ref. 14. For perturbation of a global Maxwellian, Ukai,[24] Nishida–Imai,[16] Shizuta–Asano,[19] and Uaki–Asano,[26] and others showed the global existence of solutions to the initial or initial boundary value problem of the Boltzmann equation in various situations. For other interesting issues, such as large data existence theory, stability and convergence to the Maxwellian, see Refs. 6, 15, 18, and 23, and references therein.

However, there are fewer works done for the Boltzmann equation with an external force. Glikson[9,10] obtained the unique local existence of solutions to the initial value problem for sufficiently small initial data. When the initial data was arbitrary large, the local existence of solutions to the initial and initial boundary value problem was obtained by Asano.[1] And a general framework on the global existence solutions in infinite vacuum is given in Ref. 3. Recently, Guo[11] proved the global existence of classical solutions with small amplitude to the initial value problem for the Boltzmann equation with an external force and a "soft" potential when the external force

decays in time (see also Ref. 7). Moreover, the global existence and stability of the stationary solutions to time independent potential force was obtained by Ukai–Yang–Zhao in Ref. 27 through the energy method. Our result is new in the sense that a constructive condition is given for the global existence of mild solutions in infinite vacuum when external force can be arbitrary large.

The rest of this paper is organized as follows. In Sec. II, we give some preliminary estimates for later use. In Sec. III, we study the integration of the collision term to obtain the global in time estimate. And then the existence of the mild solution to the initial value problem (1.1) and (1.2) follows from the contraction mapping theorem.

II. PRELIMINARIES

In this section, we give some preliminary lemmas which will be used in the proof of the global existence of solutions in the next section. First we borrow three lemmas from Refs. 12 and 17 for the completeness of the paper. Interested readers please refer to these two papers for their proofs.

Lemma 2.1: *For any* $z \in \mathbf{R}^3$, $\eta \in \mathbf{R}$ *and* $(u_\parallel, u_\perp) \in \mathbf{R}^3 \times \mathbf{R}^3$ *with* $u_\parallel \cdot u_\perp = 0$, *we have*

$$|z + \eta u_\parallel|^2 + |z + \eta u_\perp|^2 = |z|^2 + |z + \eta(u_\parallel + u_\perp)|^2. \tag{2.1}$$

Lemma 2.2: *For any* $p > \frac{1}{2}$ *and* $(z,u) \in \mathbf{R}^3 \times \mathbf{R}^3$ *with* $u \neq 0$, *we have*

$$\int_0^\infty (1 + |z + \eta u|^2)^{-p} \, \mathrm{d}\eta \leqslant \frac{4p}{|u|(2p-1)}. \tag{2.2}$$

Moreover, for any $q > 0, -2 < \gamma \leqslant 1$ *and* $z \in \mathbf{R}^3$, *we have*

$$\int_{\mathbf{R}^3} |u|^{\gamma - 1} \exp\{-q|z-u|^2\} \mathrm{d}u \leqslant I^1_{\gamma,q}, \tag{2.3}$$

where

$$I^1_{\gamma,q} = \frac{4\pi}{\gamma + 2} + \frac{\pi}{q^{3/2}}, \tag{2.4}$$

is a positive constant depending only on γ *and* q.

Lemma 2.3: *For any* $p > 0$, $z \in \mathbf{R}^3$, $s \in \mathbf{R}^+$ *and* $(u_\parallel, u_\perp) \in \mathbf{R}^3 \times \mathbf{R}^3$ *with* $u_\parallel \cdot u_\perp = 0$, *we have that*

$$\begin{aligned}(1 + |z + su_\parallel|^2)^{-p}(1 + |z + su_\perp|^2)^{-p} \leqslant (1 + |z|^2)^{-p}\{&(1 + |z + su_\parallel|^2)^{-p} \\ &+ (1 + |z + su_\perp|^2)^{-p} + (1 + |z + s(u_\parallel + u_\perp)|^2)^{-p}\}.\end{aligned} \tag{2.5}$$

In order to control the integration of the collision term $Q(f,g)$ along the bicharacteristic

$$\int_0^t \int_{\mathbf{R}^3 \times S^2_+} (\cdots)(s, X(s;t,x,v), V(s;t,x,v)) \mathrm{d}u \, \mathrm{d}\omega \, \mathrm{d}s,$$

we consider the following two integrals:

$$\begin{aligned}I^{2,1}(z_1, z_2, t, x, v) = \int_0^\infty \int_{\mathbf{R}^3 \times S^2_+} &b_\gamma(\theta)|u|^\gamma (1 + |z_1 + \alpha_1(s;t,x,v)u|^2)^{-p} \\ &\times \exp\{-q|z_2 - \alpha_2(s;t,x,v)u|^2\} \mathrm{d}u \, \mathrm{d}\omega \, \mathrm{d}s\end{aligned} \tag{2.6}$$

and

$$I^{2,2}(z_1,z_2,t,x,v)=\int_0^\infty\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|u|^\gamma\{(1+|z_1+\alpha_1(s;t,x,v)u_\parallel|^2)^{-p}+(1+|z_1+\alpha_1(s;t,x,v)u_\perp|^2)^{-p}\}$$
$$\times\exp\{-q|z_2-\alpha_2(s;t,x,v)u|^2\}\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s, \tag{2.7}$$

for any $(z_1,z_2)\in\mathbf{R}^3\times\mathbf{R}^3$ and $(t,x,v)\in\mathbf{R}^+\times\mathbf{R}^3\times\mathbf{R}^3$. Here $\alpha_1(s;t,x,v)$ and $\alpha_2(s;t,x,v)$ satisfy the assumption (A3). The estimates on (2.6) and (2.7) are given in the following lemma:

Lemma 2.4: *Under the assumptions (A1)–(A3), it holds that*

$$\sup I^{2,i}(z_1,z_2,t,x,v)\leqslant I^2_{\gamma,p,q},\ i=1,2, \tag{2.8}$$

where

$$I^2_{\gamma,p,q}=\frac{8\pi p b_0 I^1_{\gamma,q}}{\alpha_0(2p-1)}, \tag{2.9}$$

is a positive constant depending only on γ,p,q,α_0, *and* b_0.

Proof: For $i=1$, fix $(z_1,z_2)\in\mathbf{R}^3\times\mathbf{R}^3$ and $(t,x,v)\in\mathbf{R}^+\times\mathbf{R}^3\times\mathbf{R}^3$. Since $\alpha_2(s;t,x,v)>0$, we let

$$\alpha_2(s;t,x,v)u=\overline{u},$$

to obtain

$$I^{2,1}(z_1,z_2,t,x,v)=\int_0^\infty\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|\overline{u}|^\gamma(\alpha_2(s;t,x,v))^{-\gamma-3}\left(1+\left|z_1+\frac{\alpha_1(s;t,x,v)}{\alpha_2(s;t,x,v)}\overline{u}\right|^2\right)^{-p}$$
$$\times\exp\{-q|z_2-\overline{u}|^2\}\mathrm{d}\overline{u}\,\mathrm{d}\omega\,\mathrm{d}s. \tag{2.10}$$

Since

$$\frac{d}{\mathrm{d}s}\left(\frac{\alpha_1(s;t,x,v)}{\alpha_2(s;t,x,v)}\right)=\frac{\alpha_1'(s;t,x,v)\alpha_2(s;t,x,v)-\alpha_1(s;t,x,v)\alpha_2'(s;t,x,v)}{(\alpha_2(s;t,x,v))^2}=\frac{\alpha(s;t,x,v)}{(\alpha_2(s;t,x,v))^2}>0,$$

by the assumption (A3), we can let variable

$$\eta=\frac{\alpha_1(s;t,x,v)}{\alpha_2(s;t,x,v)},$$

to have

$$I^{2,1}(z_1,z_2,t,x,v)\leqslant\int_0^\infty\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|\overline{u}|^\gamma\frac{1}{(\alpha_2(s;t,x,v))^{\gamma+1}\alpha(s;t,x,v)}(1+|z_1+\eta\overline{u}|^2)^{-p}$$
$$\times\exp\{-q|z_2-\overline{u}|^2\}\mathrm{d}\overline{u}\,\mathrm{d}\omega\,\mathrm{d}\eta\leqslant\frac{1}{\alpha_0}\int_0^\infty\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|\overline{u}|^\gamma(1+|z_1+\eta\overline{u}|^2)^{-p}$$
$$\times\exp\{-q|z_2-\overline{u}|^2\}\mathrm{d}\overline{u}\,\mathrm{d}\omega\,\mathrm{d}\eta. \tag{2.11}$$

Then it follows from the Lemma 2.2 and the assumption (A2) that

$$I^{2,1}(z_1,z_2,t,x,v) \leqslant \frac{4p}{\alpha_0(2p-1)}\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|\overline{u}|^{\gamma-1}\exp\{-q|z_2-\overline{u}|^2\}\mathrm{d}\overline{u}\,\mathrm{d}\omega$$
$$= \frac{8\pi p}{\alpha_0(2p-1)}\int_0^{\frac{\pi}{2}} b_\gamma(\theta)\sin\theta\,\mathrm{d}\theta\int_{\mathbf{R}^3}|\overline{u}|^{\gamma-1}\exp\{-q|z_2-\overline{u}|^2\}\mathrm{d}\overline{u} \leqslant \frac{8\pi p b_0 I^1_{\gamma,q}}{\alpha_0(2p-1)}. \tag{2.12}$$

This completes the proof for $i=1$.

For the case of $i=2$, similar to (2.11) and (2.12), we have

$$I^{2,2}(z_1,z_2,t,x,v) \leqslant \frac{4p}{\alpha_0(2p-1)}\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|\overline{u}|^\gamma\left(\frac{1}{|\overline{u}_\parallel|}+\frac{1}{|\overline{u}_\perp|}\right)\exp\{-q|z_2-\overline{u}|^2\}\mathrm{d}\overline{u}\,\mathrm{d}\omega$$
$$= \frac{8\pi p}{\alpha_0(2p-1)}\int_{\mathbf{R}^3}\int_0^{\pi/2} b_\gamma(\theta)|\overline{u}|^\gamma\left(\frac{1}{|\overline{u}|\cos\theta}+\frac{1}{|\overline{u}|\sin\theta}\right)\exp\{-q|z_2-\overline{u}|^2\}\sin\theta\,\mathrm{d}\overline{u}\,\mathrm{d}\theta$$
$$= \frac{8\pi p}{\alpha_0(2p-1)}\int_0^{\pi/2} b_\gamma(\theta)(1+\tan\theta)\mathrm{d}\theta\int_{\mathbf{R}^3}|\overline{u}|^{\gamma-1}\exp\{-q|z_2-\overline{u}|^2\}\mathrm{d}\overline{u} \leqslant \frac{8\pi p b_0 I^1_{\gamma,q}}{\alpha_0(2p-1)}. \tag{2.13}$$

Hence, (2.12) and (2.13) yields the proof of Lemma 2.4.

III. EXISTENCE OF THE MILD SOLUTION

In this section, we give the crucial estimate for the global existence of the solution by the contraction mapping theorem.

First, similar to (1.9)–(1.11), denote

$$N(f,g) = N^+(f,g) - N^-(f,g), \tag{3.1}$$

by

$$N^+(f,g)(t,x,v) = \int_0^t Q^+(f,g)(s,X(s;t,x,v),V(s;t,x,v))\mathrm{d}s$$
$$= \frac{1}{\varepsilon}\int_0^t\int_{\mathbf{R}^3 S_+^2} b_\gamma(\theta)|u|^\gamma f(s,X(s;t,x,v),V(s;t,x,v)-u_\parallel)g(s,X(s;t,x,v),$$
$$\times V(s;t,x,v)-u_\perp)\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s \tag{3.2}$$

and

$$N^-(f,g)(t,x,v) = \int_0^t Q^-(f,g)(s,X(s;t,x,v),V(s;t,x,v))\mathrm{d}s$$
$$= \frac{1}{\varepsilon}\int_0^t\int_{\mathbf{R}^3 S_+^2} b_\gamma(\theta)|u|^\gamma f(s,X(s;t,x,v),V(s;t,x,v))g(s,X(s;t,x,v),$$
$$\times V(s;t,x,v)-u)\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s. \tag{3.3}$$

From (1.9), we have

$$N(f,g)(t,x,v) = \int_0^t Q(f,g)(s,X(s;t,x,v),V(s;t,x,v))\mathrm{d}s. \tag{3.4}$$

Lemma 3.1: *Under the assumptions (A1)–(A3), it holds that*

$$|||N(f,g)||| \leqslant \frac{1}{\varepsilon} I_{\gamma,p,q} |||f||| \times |||g|||, \tag{3.5}$$

where $I_{\gamma,p,q}$ is a positive constant.

Proof: We first estimate the loss term $N^-(f,g)$ in (3.1). Let (t,x,v) fixed. From the definition (1.17) of the norm $\|\cdot\|$ and the assumption (A3), we have for any s in $(0,t)$,

$$\begin{aligned}
&|f(s,X(s;t,x,v),V(s;t,x,v))| \\
&\qquad \leqslant \|f(s)\|(1+|X(0;s,X(s;t,x,v),V(s;t,x,v))|^2)^{-p} \\
&\qquad\quad \times \exp\{-q|V(0;s,X(s;t,x,v),V(s;t,x,v))|^2\} \\
&\qquad = \|f(s)\|(1+|X(0;t,x,v)|^2)^{-p} \exp\{-q|V(0;t,x,v)|^2\}
\end{aligned} \tag{3.6}$$

and

$$\begin{aligned}
&|g(s,X(s;t,x,v),V(s;t,x,v)-u)| \\
&\qquad \leqslant \|g(s)\|(1+|X(0;s,X(s;t,x,v),V(s;t,x,v)-u)|^2)^{-p} \\
&\qquad\quad \times \exp\{-q|V(0;s,X(s;t,x,v),V(s;t,x,v)-u)|^2\} \\
&\qquad = \|g(s)\|(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u|^2)^{-p} \times \exp\{-q|V(0;t,x,v) \\
&\qquad\quad -\alpha_2(s;t,x,v)u|^2\}.
\end{aligned} \tag{3.7}$$

Hence, from (3.3), we have

$$\begin{aligned}
|N^-(f,g)(t,x,v)| &\leqslant \frac{1}{\varepsilon}\int_0^t \int_{\mathbf{R}^3\times S^2_+} b_\gamma(\theta)|u|^\gamma \|f(s)\|\|g(s)\|(1+|X(0;t,x,v)|^2)^{-p}\exp\{-q|V(0;t,x,v)|^2\} \\
&\quad \times(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u|^2)^{-p}\exp\{-q|V(0;t,x,v) \\
&\quad -\alpha_2(s;t,x,v)u|^2\}\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s \leqslant \frac{1}{\varepsilon}(1+|X(0;t,x,v)|^2)^{-p}\exp\{-q|V(0;t,x,v)|^2\} \\
&\quad \times|||f|||||g|||\int_0^\infty \int_{\mathbf{R}^3\times S^2_+} b_\gamma(\theta)|u|^\gamma(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u|^2)^{-p} \\
&\quad \times \exp\{-q|V(0;t,x,v)-\alpha_2(s;t,x,v)u|^2\}\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s.
\end{aligned} \tag{3.8}$$

By Lemma 2.4, we have

$$|N^-(f,g)(t,x,v)| \leqslant \frac{1}{\varepsilon} I^2_{\gamma,p,q}(1+|X(0;t,x,v)|^2)^{-p}\exp\{-q|V(0;t,x,v)|^2\}|||f||| \times |||g|||. \tag{3.9}$$

Multiplying (3.9) by $(1+|X(0;t,x,v)|^2)^p \exp\{q|V(0;t,x,v)|^2\}$ and taking the supremum with respect to (t,x,v) in $\mathbf{R}^+\times\mathbf{R}^3\times\mathbf{R}^3$, we have by (1.16) that

$$|||N^-(f,g)||| \leqslant \frac{1}{\varepsilon} I^2_{\gamma,p,q}|||f||| \times |||g|||. \tag{3.10}$$

Next for the gain term $N^+(f,g)$, similar to (3.6) and (3.7), we have for any s in $(0,t)$,

$$
\begin{aligned}
&|f(s,X(s;t,x,v),V(s;t,x,v)-u_{\|})| \\
&\qquad \leqslant \|f(s)\|(1+|X(0;s,X(s;t,x,v),V(s;t,x,v)-u_{\|})|^2)^{-p}\times\exp\{ \\
&\qquad\quad -q|V(0;s,X(s;t,x,v),V(s;t,x,v)-u_{\|})|^2\} \\
&\qquad = \|f(s)\|(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\|}|^2)^{-p}\exp\{-q|V(0;t,x,v) \\
&\qquad\quad -\alpha_2(s;t,x,v)u_{\|}|^2\} \qquad (3.11)
\end{aligned}
$$

and

$$
\begin{aligned}
&|g(s,X(s;t,x,v),V(s;t,x,v)-u_{\perp})| \\
&\qquad \leqslant \|g(s)\|(1+|X(0;s,X(s;t,x,v),V(s;t,x,v)-u_{\perp})|^2)^{-p} \\
&\qquad\quad \times\exp\{-q|V(0;s,X(s;t,x,v),V(s;t,x,v)-u_{\perp})|^2\} \\
&\qquad = \|g(s)\|(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\perp}|^2)^{-p} \\
&\qquad\quad \times\exp\{-q|V(0;t,x,v)-\alpha_2(s;t,x,v)u_{\perp}|^2\}. \qquad (3.12)
\end{aligned}
$$

Setting (3.11) and (3.12) into (3.2), we have that

$$
\begin{aligned}
|N^+(f,g)(t,x,v)| &\leqslant \frac{1}{\varepsilon}\int_0^t\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|u|^\gamma\|f(s)\|\|g(s)\|(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\|}|^2)^{-p} \\
&\quad\times(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\perp}|^2)^{-p}\times\exp\{-q|V(0;t,x,v)-\alpha_2(s;t,x,v)u_{\|}|^2 \\
&\quad -q|V(0;t,x,v)-\alpha_2(s;t,x,v)u_{\perp}|^2\}\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s \leqslant \frac{1}{\varepsilon}|||f|||\times|||g|||\int_0^\infty\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta) \\
&\quad\times|u|^\gamma(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\|}|^2)^{-p}\times(1+|X(0;t,x,v) \\
&\quad +\alpha_1(s;t,x,v)u_{\perp}|^2)^{-p}\times\exp\{-q|V(0;t,x,v)-\alpha_2(s;t,x,v)u_{\|}|^2-q|V(0;t,x,v) \\
&\quad -\alpha_2(s;t,x,v)u_{\perp}|^2\}\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s. \qquad (3.13)
\end{aligned}
$$

By Lemmas 2.1 and 2.3, we have

$$
\begin{aligned}
|N^+(f,g)(t,x,v)| &\leqslant \frac{1}{\varepsilon}|||f|||\times|||g|||\int_0^\infty\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|u|^\gamma(1+|X(0;t,x,v)|^2)^{-p} \\
&\quad\times\{(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\|}|^2)^{-p}+(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\perp}|^2)^{-p} \\
&\quad +(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u|^2)^{-p}\}\times\exp\{-q|V(0;t,x,v)|^2-q|V(0;t,x,v) \\
&\quad -\alpha_2(s;t,x,v)u|^2\}\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s \leqslant \frac{1}{\varepsilon}(1+|X(0;t,x,v)|^2)^{-p}\exp\{-q|V(0;t,x,v)|^2\}|||f||| \\
&\quad\times|||g|||\times\int_0^\infty\int_{\mathbf{R}^3\times S_+^2} b_\gamma(\theta)|u|^\gamma\{(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\|}|^2)^{-p}+(1 \\
&\quad +|X(0;t,x,v)+\alpha_1(s;t,x,v)u_{\perp}|^2)^{-p}+(1+|X(0;t,x,v)+\alpha_1(s;t,x,v)u|^2)^{-p}\} \\
&\quad\times\exp\{-q|V(0;t,x,v)-\alpha_2(s;t,x,v)u|^2\}\mathrm{d}u\,\mathrm{d}\omega\,\mathrm{d}s. \qquad (3.14)
\end{aligned}
$$

Thus, it follows from Lemma 2.4 that

$$
|N^+(f,g)(t,x,v)| \leqslant \frac{2}{\varepsilon}I^2_{\gamma,p,q}(1+|X(0;t,x,v)|^2)^{-p}\exp\{-q|V(0;t,x,v)|^2\}|||f|||\times|||g|||,
$$

That is,

$$|||N^+(f,g)||| \leqslant \frac{2}{\varepsilon} I_{\gamma,p,q}^2 |||f||| \times |||g|||. \tag{3.15}$$

Combining (3.10) and (3.15), we have

$$|||N(f,g)||| \leqslant |||N^+(f,g)||| + |||N^-(f,g)||| \leqslant \frac{3}{\varepsilon} I_{\gamma,p,q}^2 |||f||| \times |||g|||. \tag{3.16}$$

Take $I_{\gamma,p,q}=3I_{\gamma,p,q}^2$ and then it follows from (2.4) and (2.9) that

$$I_{\gamma,p,q} = \frac{24\pi p b_0 I_{\gamma,q}^1}{\alpha_0(2p-1)} = \frac{24\pi p b_0}{\alpha_0(2p-1)}\left(\frac{4\pi}{\gamma+2} + \frac{\pi}{q^{3/2}}\right). \tag{3.17}$$

Therefore, (3.16) yields (3.5) and this completes the proof of Lemma 3.1.

Finally, we prove Theorem 1.2. For this purpose, we define the mapping $\mathbf{T}: S_{p,q} \to S_{p,q}$ by

$$\mathbf{T}f(t,x,v) = f_0(X(0;t,x,v), V(0;t,x,v)) + N(f,f)(t,x,v) \tag{3.18}$$

for any $f \in S_{p,q}$. For the mapping $\mathbf{T}$, we have the following lemma.

Lemma 3.2: *For any f, $g \in S_{p,q}$, it holds that*

$$\begin{aligned} |||\mathbf{T}f||| &\leqslant \|f_0\|_{p,q} + \frac{1}{\varepsilon} I_{\gamma,p,q} |||f|||^2, \\ |||\mathbf{T}f - \mathbf{T}g||| &\leqslant \frac{1}{\varepsilon} I_{\gamma,p,q} (|||f||| + |||g|||) |||f-g|||, \end{aligned} \tag{3.19}$$

where $I_{\gamma,p,q}$ is defined by (3.17).

Proof: Fix $f \in S_{p,q}$. Multiplying (3.18) by $(1+|X(0;t,x,v)|^2)^p \exp\{q|V(0;t,x,v)|^2\}$ and taking the supremum with respect to (t,x,v) over $\mathbf{R}^+ \times \mathbf{R}^3 \times \mathbf{R}^3$, by Lemma 3.1, we obtain the first estimate in (3.19). Then, notice that

$$\mathbf{T}f - \mathbf{T}g = N(f-g,f) + N(g,f-g). \tag{3.20}$$

The second estimate in (3.19) follows similarly.

Proof of Theorem 1.2: We only need to show that $\mathbf{T}$ has a fixed point by the contraction mapping theorem. In fact, let us denote the closed subset S_0 of $S_{p,q}$ by

$$S_0 = \{f \in S_{p,q} : |||f||| \leqslant 2\varepsilon\delta_0\}, \tag{3.21}$$

where δ_0 is a sufficiently small positive constant such that

$$\lambda_0 \equiv 4\delta_0 I_{\gamma,p,q} < 1. \tag{3.22}$$

Let $\|f_0\|_{p,q} \leqslant \varepsilon\delta_0$ and then we have from Lemma 3.2 that

$$\mathbf{T}f \in S_0 \quad \text{and } |||\mathbf{T}f - \mathbf{T}g||| \leqslant \lambda_0 |||f-g|||, \tag{3.23}$$

for any f, $g \in S_0$. Thus the mapping $\mathbf{T}: S_0 \to S_0$ is a contraction and hence has a fixed point f in $S_0 = \{f \in S_{p,q} : |||f||| \leqslant 2\varepsilon\delta_0\}$. This implies that the initial value problem (1.1) and (1.2) has a unique solution f such that $|||f||| \leqslant 2\varepsilon\delta_0$. It then follows from the same argument as the one in Ref. 25 that if $f_0(x,v) \geqslant 0$ then $f(t,x,v) \geqslant 0$. Hence, the proof of Theorem 1.2 is complete.

(Received 20 September 2004; accepted 8 November 2004; published online 6 April 2005)

We present a classification of the hyperbolic Kac–Moody (HKM) superalgebras. The HKM superalgebras of rank $r \geqslant 3$ are finite in number (213) and limited in rank (6). The Dynkin–Kac diagrams and the corresponding simple root systems are determined. We also discuss a class of singular sub(super)algebras obtained by a folding procedure. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1851605]

I. INTRODUCTION

Affine Kac–Moody are presently well established tools of theoretical physics. The indefinite Kac–Moody (KM) algebras[1] form a so general set of algebras that they defy any general classification. A subclass of these KM algebras, called hyperbolic, which are defined by the property that the diagrams (generally disconnected) obtained taking away a dot from their defining diagrams define a direct sum of finite and/or affine KM algebras have been classified in Refs. 2 and 3. It has been found that these algebras are finite in number (238 in which 142 have a symmetric or symmetrizable Cartan matrix) and bounded in rank (10). These algebras have in the last decade attracted the attention of physicists, as they appear in a variety of physical models in two-dimensional field theories (supergravity, string theory, cosmological billiards).[4–7] Therefore it seems natural to study the corresponding partners in the realm of Kac–Moody superalgebras.[8–10] From these motivations, the authors of Ref. 11 have recently classified hyperbolic Kac–Moody (HKM) superalgebras by a procedure quite close to that followed to classify the hyperbolic Kac–Moody ones, showing that they are limited in rank, now the maximum rank being 6, and that they are finite in number (for rank >2). However, as we remarked that many diagrams are missing, while some of the proposed Dynkin–Kac diagrams correspond in fact to diagrams of untwisted or twisted affine Lie superalgebras (sometimes in the not distinguished basis), we present here a, hopefully exhaustive, classification of HKM superalgebras, together with a corresponding simple roots basis and we discuss a class of singular subalgebras.

The paper is organized as follows: in Sec. II we recall the definition of a superalgebra, the relation between Dynkin–Kac diagrams and generalized Cartan matrices, the action of the (super)Weyl or generalized Weyl transformations on the simple roots systems and the structure of the supplementary or non-Serre relations. Although most of the material is not new, we believe it is worthwhile to report it in some details for several reasons: (i) the standard rules of translating matrices in diagrams must be slightly and suitably defined to include the case of indefinite, in particular hyperbolic, KM superalgebras; (ii) the deformation of the Dynkin–Kac diagrams must be carefully handled, otherwise one is lead to naively include diagrams for HKM superalgebras, which really correspond to more general indefinite KM superalgebras; (iii) the action of the generalized Weyl transformations, which provides also in the case of HKM superalgebras all the not equivalent simple roots systems, allows one not to be worried about the appearance of new non-Serre relations. In Sec. III and the related appendixes we present the diagrams corresponding to HKM superalgebras, together with their (not unique) system of simple roots and with their

maximal regular subalgebras; in Sec. IV we list the singular subalgebras, obtained by the procedure of folding.

II. KAC–MOODY SUPERALGEBRAS

A. Generalized Cartan matrices and Dynkin diagrams

Let A be a $r\times r$ matrix and $\{i_1,\ldots,i_p\}$ be a subset of indices of $I=\{1,\ldots,r\}$. The principal $\{i_1,\ldots,i_p\}$-submatrix of A, of order $r-p$, is a matrix obtained from A by deleting the rows and columns labelled by $i_1,\ldots,i_p$. A principal submatrix of order $r-1$ is called leading.

We start by defining the notion of the generalized Cartan matrix. In the case of $\mathbb{Z}_2$-graded algebras, it is convenient to deal with a recursive definition.

Definition 2.1: *A $r\times r$ matrix A with integral entries a_{ij} is called a* generalized Cartan matrix *if for each $i\in\{1,\ldots,r\}$, the leading principal $\{i\}$-submatrix of A is a generalized Cartan matrix (which may be of block diagonal form).*

The Cartan matrices of the simple Lie algebras—A_n, B_n, C_n, D_n, $E_{6,7,8}$, F_4, and G_2—and of the basic Lie superalgebras—$A(m,n)$, $B(m,n)$, $C(n+1)$, $D(m,n)$, $F(4)$, $G(3)$, and $D(2,1,\alpha)$—are generalized Cartan matrices.

The matrix A is called symmetrizable *if it exists an invertible diagonal matrix D such that DA is a symmetric matrix. The matrix A is called* indecomposable *if it cannot be reduced to a block diagonal form by reordering rows and columns.*

We will only consider generalized Cartan matrices which are indecomposable and symmetrizable. Moreover, we assume that the generalized Cartan matrices are properly normalized, i.e., $a_{ii}=2$ or $a_{ii}=0$ for each i. If one defines the matrix $D_{ij}=d_i\delta_{ij}$ where the rational coefficients d_i satisfy $d_ia_{ij}=d_ja_{ji}$, the symmetric Cartan matrix A' is given from the generalized Cartan matrix A by $A'=DA$. Note that, due to the fact that off-diagonal entries of a row of a Cartan matrix corresponding to $a_{ii}=0$ may have different signs, the diagonal entries of the symmetric Cartan matrices are not necessarily positive.

Remark 2.1: It follows from the definition that the Cartan matrices of the affine (untwisted or twisted) Kac–Moody algebras and superalgebras are generalized Cartan matrices.

Definition 2.2: *Let τ be a subset of $I=\{1,\ldots,r\}$. To a given generalized Cartan matrix A and subset τ, we associate a complex contragradient Lie superalgebra $\mathcal{G}(A,\tau)$—called Kac–Moody superalgebra—with $3r$ generators h_i, $e_i^{\pm}$ and $\mathbb{Z}_2$-gradation defined by* $\deg e_i^{\pm}=\bar{0}$ *if $i\notin\tau$,* $\deg e_i^{\pm}=\bar{1}$ *if $i\in\tau$ and* $\deg h_i=\bar{0}$ *for all i. The generators h_i and $e_i^{\pm}$ are subject to the following set of relations:*

$$[h_i,h_j]=0, \tag{2.1}$$

$$[h_i,e_j^{\pm}]=\pm a_{ij}e_j^{\pm}, \tag{2.2}$$

$$[\![e_i^{+},e_j^{-}]\!]=\delta_{ij}h_i, \tag{2.3}$$

$$[\![e_i^{\pm},e_i^{\pm}]\!]=0 \quad \text{if } a_{ii}=0 \tag{2.4}$$

and

$$(\mathrm{ad}\, e_i^{\pm})^{1-\tilde{a}_{ij}}e_j^{\pm}=0 \tag{2.5}$$

where the matrix $\tilde{A}=(\tilde{a}_{ij})$ is deduced from the Cartan matrix $A=(a_{ij})$ of $\mathcal{G}(A,\tau)$ by replacing all its positive off-diagonal entries by -1. Here ad *denotes the adjoint action*

$$(\mathrm{ad}\, X)Y=[\![X,Y]\!]=XY-(-1)^{\deg X\cdot\deg Y}YX. \tag{2.6}$$

We denote by $\mathcal{G}_{\bar{0}}$ and $\mathcal{G}_{\bar{1}}$ the even and odd parts of the Kac–Moody superalgebra $\mathcal{G}(A,\tau)$. Let $\mathcal{H}\subset\mathcal{G}_{\bar{0}}$ be the subalgebra of $\mathcal{G}$ generated by the h_i (Cartan subalgebra). The superalgebra $\mathcal{G}(A,\tau)$ can be decomposed as $\mathcal{G}=\oplus_\alpha\mathcal{G}_\alpha$ where $\mathcal{G}_\alpha=\{x\in\mathcal{G}\,|\,[h,x]=\alpha(h)x, h\in\mathcal{H}\}$. By definition, the root system of $\mathcal{G}$ is the set $\Delta=\{\alpha\in\mathcal{H}^*\,|\,\mathcal{G}_\alpha\neq 0\}$. A root α is called even (respectively, odd) if $\mathcal{G}_\alpha\cap\mathcal{G}_{\bar{0}}\neq\emptyset$ (respectively, $\mathcal{G}_\alpha\cap\mathcal{G}_{\bar{1}}\neq\emptyset$). The set of even (respectively, odd) roots is denoted by $\Delta_{\bar{0}}$

(respectively, $\Delta_{\bar{1}}$). Since $\mathcal{G}(A,\tau)$ clearly admits a Borel decomposition, one defines as usual the notion of simple root system.[8,12]

To each superalgebra $\mathcal{G}(A,\tau)$ can be associated a Dynkin diagram according to the following rules.[12] We will always assume that $i\in\tau$ if $a_{ii}=0$.

(1) Using the generalized Cartan matrix A,

(a) one associates to each i such that $a_{ii}=2$ and $i\notin\tau$ a white dot, to each i such that $a_{ii}=2$ and $i\in\tau$ a black dot, to each i such that $a_{ii}=0$ and $i\in\tau$ a grey dot,

white dot ○ black dot ● grey dot ⊗ .

(b) The ith and jth dots will be joined by η_{ij} lines where

$$\eta_{ij}=\max(|a_{ij}|,|a_{ji}|) \quad \text{if } a_{ii}\neq 0 \text{ or/and } a_{jj}\neq 0 \text{ and } |a_{ij}a_{ji}|\leqslant 4,$$

$$\eta_{ij}=|a_{ij}|=|a_{ij}| \quad \text{if } a_{ii}=a_{jj}=0 \text{ and } |a_{ij}|,|a_{ji}|\leqslant 4.$$

Otherwise, the ith and jth dots will be joined by a boldface line equipped with an ordered pair of integers $(|a_{ij}|,|a_{ji}|)$. Note that this latter case does not appear for finite or affine Kac–Moody superalgebras.

(c) We add an arrow on the lines connecting the ith and jth dots when $\eta_{ij}>1$ and $|a_{ij}|\neq|a_{ji}|$, pointing from j to i if $|a_{ij}|>1$.

(d) For $D(2,1;\alpha)$, $\eta_{ij}=1$ if $a_{ij}\neq 0$ and $\eta_{ij}=0$ if $a_{ij}=0$. No arrow is set on the Dynkin diagram.

(2) Using the symmetric Cartan matrix A',

(a) one associates to each i such that $a'_{ii}\neq 0$ and $i\notin\tau$ a white dot, to each i such that $a'_{ii}\neq 0$ and $i\in\tau$ a black dot, to each i such that $a'_{ii}=0$ and $i\in\tau$ a grey dot (see pictures above).

(b) The ith and jth dots will be joined by η_{ij} lines where

$$\eta_{ij}=\frac{2|a'_{ij}|}{\min(|a'_{ii}|,|a'_{jj}|)} \quad \text{if } a'_{ii}\cdot a'_{jj}\neq 0 \text{ and } a'^{2}_{ij}\leqslant|a'_{ii}\cdot a'_{jj}|,$$

$$\eta_{ij}=\frac{2|a'_{ij}|}{\min(|a'_{ii}|,2)} \quad \text{if } a'_{ii}\neq 0,\ a'_{jj}=0 \text{ and } \eta_{ij}\leqslant 4,$$

$$\eta_{ij}=|a'_{ij}| \quad \text{if } a'_{ii}=a'_{jj}=0 \text{ and } |a'_{ij}|\leqslant 4.$$

Otherwise, the ith and jth dots will be joined by a boldface line equipped with an ordered pair of integers $(|a_{ij}|,|a_{ji}|)$.

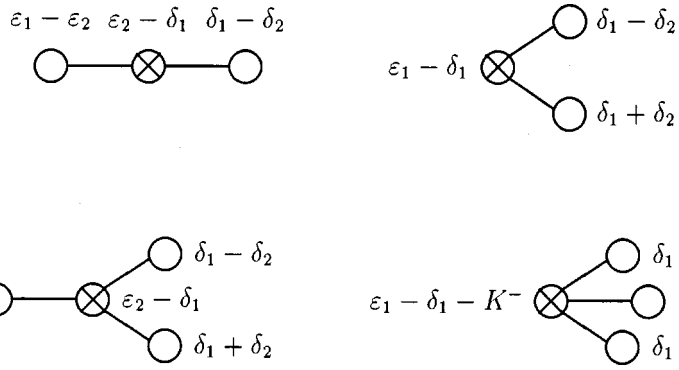
(c) We add an arrow on the lines connecting the ith and jth dots when $\eta_{ij}>1$, pointing from i to j if $a'_{ii}\cdot a'_{jj}\neq 0$ and $|a'_{ii}|>|a'_{jj}|$ or if $a'_{ii}=0$, $a'_{jj}\neq 0$, $|a'_{jj}|<2$, and pointing from j to i if $a'_{ii}=0$, $a'_{jj}\neq 0$, $|a'_{jj}|>2$.

(d) For $D(2,1;\alpha)$, $\eta_{ij}=1$ if $a'_{ij}\neq 0$ and $\eta_{ij}=0$ if $a'_{ij}=0$. No arrow is set on the Dynkin diagram. Although the rules seem more complicated when using the symmetric Cartan matrix A', the computation of the Cartan matrix A is often more involved than the symmetric Cartan matrix A'.

Remark 2.2: The entries of the symmetric Cartan matrices A' can be obtained as the scalar products of the simple roots, i.e., $a'_{ij}=(\alpha_i,\alpha_j)$ (up to a multiplication by a suitable factor in order to get integer entries).

Remark 2.3: The above rules imply that two white/black dots of square length L and scalar product S are connected by $|2S/L|$ lines. With this convention, the Dynkin diagram of the affine Kac–Moody algebra $A_1^{(1)}$ is simply given by two white dots connected by two lines without any arrow.

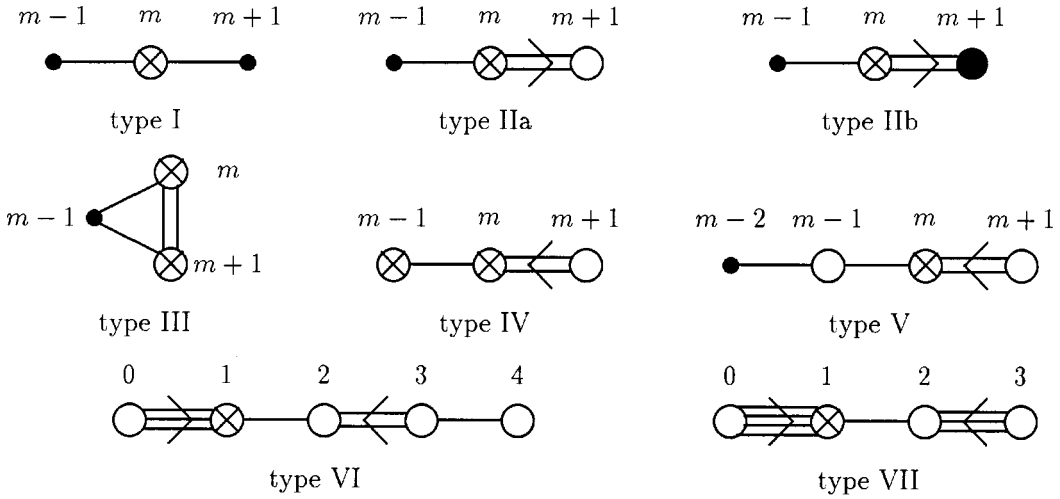
Note that for superalgebras Dynkin–Kac diagrams with the same "topology" may be different. For example the diagrams drawn below represent, respectively, the superalgebras sl(2|2), osp(4|2), osp(4|4) and a hyperbolic Kac–Moody superalgebra of rank four (see Definition 3.1). The root systems are described in terms of the orthogonal vectors ε_i, δ_i, and $K^{\pm}$ (see Appendix B for conventions),



B. Non-Serre-type relations and generalized Weyl transformations

In the case of finite and affine Kac–Moody superalgebras, it is known that the description given by the Serre relations (2.1) to (2.4) may lead to superalgebras with nontrivial ideals.[13,14] In order to obtain a simple superalgebra, it is necessary to write supplementary relations involving more than two generators, in order to quotient the bigger superalgebra. These supplementary non-Serre-type conditions appear when one deals with isotropic odd roots (that is $a_{ii}=0$).

The supplementary conditions depend on the different kinds of vertices which appear in the Dynkin diagrams. The vertices for finite and affine superalgebras can be of the following type:



where the small black dots represent either white dots associated to even roots or grey dots associated to isotropic odd roots. Hyperbolic superalgebras exhibit also more complicated vertices.

The supplementary conditions take the following form:[13–15]

$$\text{type I, IIa, and IIb vertices,} \quad [[e_m^{\pm},[[e_{m+1}^{\pm},[[e_m^{\pm},e_{m-1}^{\pm}]]]]]=0,$$

$$\text{type III vertex,} \quad [[e_m^{\pm},[[e_{m+1}^{\pm},e_{m-1}^{\pm}]]]-[[e_{m+1}^{\pm},[[e_m^{\pm},e_{m-1}^{\pm}]]]=0,$$

$$\text{type IV vertex,} \quad [[e_m^{\pm},[[[[e_{m+1}^{\pm},[[e_m^{\pm},e_{m-1}^{\pm}]]],[[e_m^{\pm},e_{m-1}^{\pm}]]]]=0,$$

$$\text{type V vertex,} \quad [[e_m^{\pm},[[e_{m-1}^{\pm},[[e_m^{\pm},[[e_{m+1}^{\pm},[[e_m^{\pm},[[e_{m-1}^{\pm},e_{m-2}^{\pm}]]]]]]]]]]]=0,$$

$$\text{type VI vertex,} \quad [[e_2^\pm,[[e_1^\pm,[[e_3^\pm,[[e_2^\pm,[[e_1^\pm,e_0^\pm]]]]]]]]] - 2[[e_1^\pm,[[e_2^\pm,[[e_3^\pm,[[e_2^\pm,[[e_1^\pm,e_0^\pm]]]]]]]]] = 0,$$

$$\text{type VII vertex,} \quad 2\,[[e_2^\pm,[[e_1^\pm,[[e_3^\pm,[[e_2^\pm,[[e_1^\pm,e_0^\pm]]]]]]]]] - 3[[e_1^\pm,[[e_2^\pm,[[e_3^\pm,[[e_2^\pm,[[e_1^\pm,e_0^\pm]]]]]]]]] = 0.$$

For Kac–Moody superalgebras, there are in general many inequivalent simple root systems (when they contain isotropic odd roots), up to a transformation of the Weyl group $W(\mathcal{G})$ of $\mathcal{G}$. Following Ref. 16, the Weyl group $W(\mathcal{G})$ is extended by adding the following transformations (called generalized Weyl transformations) associated to the isotropic odd roots of $\mathcal{G}$. For $\alpha \in \Delta_{\bar{1}}$, one defines

$$w_\alpha(\beta) = \beta - 2\frac{(\alpha,\beta)}{(\alpha,\alpha)}\alpha \quad \text{if } (\alpha,\alpha) \neq 0,$$

$$w_\alpha(\beta) = \beta + \alpha \quad \text{if } (\alpha,\alpha) = 0 \text{ and } (\alpha,\beta) \neq 0,$$

$$w_\alpha(\beta) = \beta \quad \text{if } (\alpha,\alpha) = 0 \text{ and } (\alpha,\beta) = 0,$$

$$w_\alpha(\alpha) = -\alpha. \tag{2.7}$$

The transformation associated to an isotropic odd root α cannot be lifted to an automorphism of the superalgebra since w_α transforms even roots into odd ones, and vice versa, and the $\mathbb{Z}_2$-gradation would not be respected.

Let Δ^0 be a simple root system of $\mathcal{G}$ and α an isotropic odd root. Then one has for any root $\gamma \neq n_\alpha \alpha$,

$$\gamma = \sum_{\substack{\beta \neq \alpha \in \Delta^0 \\ a_{\alpha\beta} \neq 0}} n_\beta \beta + \sum_{\substack{\beta \neq \alpha \in \Delta^0 \\ a_{\alpha\beta} = 0}} n_\beta \beta + n_\alpha \alpha = \sum_{\beta \neq \alpha \in \Delta^0} n_\beta w_\alpha(\beta) + s_\gamma w_\alpha(\alpha), \tag{2.8}$$

where the coefficients n_α, $n_\beta \in \mathbb{Z}_{\geqslant 0}$ and s_γ is given by

$$s_\gamma = \sum_{\substack{\beta \neq \alpha \in \Delta^0 \\ a_{\alpha\beta} \neq 0}} n_\beta - n_\alpha. \tag{2.9}$$

Then, by induction on the height of the root γ, one can prove that s_γ is a non-negative number, which shows that the transformed simple root system $w_\alpha(\Delta^0)$ is again a simple root system.[16] The generalization of the Weyl group gives a method for constructing all the simple root systems of $\mathcal{G}$ and hence all the inequivalent Dynkin diagrams. A simple root system Δ^0 being given, from any isotropic odd root $\alpha \in \Delta^0$, one constructs the simple root system $w_\alpha(\Delta^0)$ where w_α is the generalized Weyl reflection with respect to α and one repeats the procedure on the obtained system until no new basis arises.

Note that this procedure is in fact very general and apply for any Kac–Moody superalgebra whose simple root systems contain isotropic odd roots. However, for Kac–Moody superalgebras which are neither of finite type nor of affine one, one may obtain in certain cases simple root systems containing even or odd root(s) of very large negative length. We will comment this point in the next section in the peculiar case of hyperbolic KM superalgebras.

III. HYPERBOLIC KAC–MOODY SUPERALGEBRAS

A. Definition

Let $\mathcal{G}(A,\tau)$ be a Kac–Moody superalgebra with generalized Cartan matrix A and $\mathbb{Z}_2$-gradation τ. By convention, it will be called indefinite Kac–Moody superalgebra if it is neither of finite nor of affine type. Of course, when the $\mathbb{Z}_2$-gradation τ is trivial, one recovers the usual classification of the Kac–Moody algebras.

Definition 3.1: *Let $\mathcal{G}(A,\tau)$ be an indefinite Kac–Moody superalgebra with generalized Cartan*

matrix A and nontrivial $\mathbb{Z}_2$*-gradation* τ *corresponding to a connected Dynkin–Kac diagram.* $\mathcal{G}(A,\tau)$ *is called a* hyperbolic Kac–Moody (HKM) *superalgebra if every leading principal submatrix of A decomposes into constituents of finite or affine type, or equivalently, if deleting a vertex of the Dynkin diagram, one gets Dynkin diagrams of finite or affine type.*

The hyperbolic superalgebras are divided into the following classes:

(1) strictly hyperbolic if every leading principal submatrix of A decomposes into constituents of finite type,
(2) purely hyperbolic if every leading principal submatrix of A decomposes into constituents of affine type,
(3) hyperfinite if at least one leading principal submatrix of A decomposes into constituents of finite type,
(4) hyperaffine if at least one leading principal submatrix of A decomposes into constituents of affine type.

Theorem 3.2: *The hyperbolic Kac–Moody superalgebras of rank* $r \geqslant 3$ *are finite in number (213) and limited in rank (6). They are listed in Appendix A.*

Remark 3.1: As in the algebraic case, the HKM superalgebras are *not* of finite growth.[10,17] Let us remind the notion of growth: let $\mathcal{G}(A,\tau)$ be a Kac–Moody superalgebra and $\mathcal{I} \subset \mathcal{G}$ a finite subset of $\mathcal{G}$. The growth of $\mathcal{G}$ is by definition the number

$$r(\mathcal{G}) = \sup_{\mathcal{I}} \overline{\lim_{n\to\infty}} (\ln d(\mathcal{I},n)/\ln n), \tag{3.1}$$

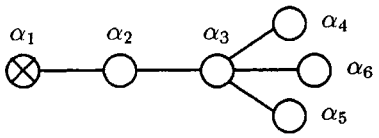
where $\mathcal{I}$ runs over all finite subsets of $\mathcal{G}$ and $d(\mathcal{I},n)$ is the dimension of the linear span of the commutators of length at most n of elements of $\mathcal{I}$. The superalgebra $\mathcal{G}$ is of finite growth if $r(\mathcal{G}) < \infty$.

By applying the Definition 3.1, one gets a Dynkin diagram for a given HKM superalgebra. The other Dynkin diagrams are obtained by means of generalized Weyl transformations. Generally, the transformed Dynkin diagrams do not satisfy the Definition 3.1 (see example below). We conjecture that it always exists only one Dynkin diagram with the minimal number of odd roots satisfying Definition 3.1. Such a Dynkin diagram will be called distinguished.

B. Example

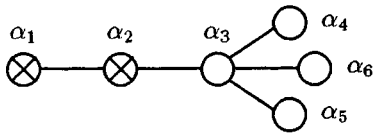
As an illustration of the generalized Weyl transformations procedure, we give below the different inequivalent simple root systems with the corresponding Dynkin diagrams and symmetric Cartan matrices of a HKM superalgebra of rank 6. Let $(\varepsilon_+ = K^+, \varepsilon_- = K^-, \varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5 = \delta)$ be a basis of $\mathbb{R}^{(5,2)}$ with metric $g_{ij} = (\varepsilon_i, \varepsilon_j)$ such that $g_{+-} = g_{-+} = g_{11} = g_{22} = g_{33} = g_{44} = -g_{55} = 1$ and all other values are zero.

(i) Simple root system $\Delta^0 = \{\alpha_1 = \delta - \varepsilon_1 - K^-, \alpha_2 = \varepsilon_1 - \varepsilon_2, \alpha_3 = \varepsilon_2 - \varepsilon_3, \alpha_4 = \varepsilon_3 - \varepsilon_4, \alpha_5 = \varepsilon_3 + \varepsilon_4, \alpha_6 = K^+ - \varepsilon_1 - \varepsilon_2\}$,



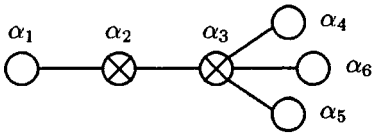
$$\begin{pmatrix} 0 & -1 & 0 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 & 0 \\ 0 & -1 & 2 & -1 & -1 & -1 \\ 0 & 0 & -1 & 2 & 0 & 0 \\ 0 & 0 & -1 & 0 & 2 & 0 \\ 0 & 0 & -1 & 0 & 0 & 2 \end{pmatrix}.$$

(ii) Simple root system $\Delta^0 = \{\alpha_1 = K^- - \delta + \varepsilon_1, \alpha_2 = \delta - \varepsilon_2 - K^-, \alpha_3 = \varepsilon_2 - \varepsilon_3, \alpha_4 = \varepsilon_3 - \varepsilon_4, \alpha_5 = \varepsilon_3 + \varepsilon_4, \alpha_6 = K^+ - \varepsilon_1 - \varepsilon_2\}$,



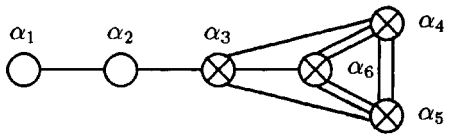
$$\begin{pmatrix} 0 & -1 & 0 & 0 & 0 & 0 \\ -1 & 0 & -1 & 0 & 0 & 0 \\ 0 & -1 & 2 & -1 & -1 & -1 \\ 0 & 0 & -1 & 2 & 0 & 0 \\ 0 & 0 & -1 & 0 & 2 & 0 \\ 0 & 0 & -1 & 0 & 0 & 2 \end{pmatrix}.$$

(iii) Simple root system $\Delta^0=\{\alpha_1=\varepsilon_1-\varepsilon_2, \alpha_2=K^- -\delta+\varepsilon_2, \alpha_3=\delta-\varepsilon_3-K^-, \alpha_4=\varepsilon_3-\varepsilon_4, \alpha_5=\varepsilon_3+\varepsilon_4, \alpha_6=K^+-\varepsilon_1-\varepsilon_2\}$,



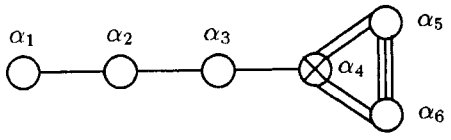
$$\begin{pmatrix} 2 & -1 & 0 & 0 & 0 & 0 \\ -1 & 0 & -1 & 0 & 0 & 0 \\ 0 & -1 & 2 & -1 & -1 & -1 \\ 0 & 0 & -1 & 2 & 0 & 0 \\ 0 & 0 & -1 & 0 & 2 & 0 \\ 0 & 0 & -1 & 0 & 0 & 2 \end{pmatrix}.$$

(iv) Simple root system $\Delta^0=\{\alpha_1=\varepsilon_1-\varepsilon_2, \alpha_2=\varepsilon_2-\varepsilon_3, \alpha_3=K^- -\delta+\varepsilon_3, \alpha_4=\delta-\varepsilon_4-K^-, \alpha_5=\delta+\varepsilon_4-K^-, \alpha_6=K^+-K^-+\delta-\varepsilon_1-\varepsilon_2-\varepsilon_3\}$,



$$\begin{pmatrix} 2 & -1 & 0 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 & -2 & -2 \\ 0 & 0 & 1 & -2 & 0 & -2 \\ 0 & 0 & 1 & -2 & -2 & 0 \end{pmatrix}.$$

(v) Simple root system $\Delta^0=\{\alpha_1=\varepsilon_1-\varepsilon_2, \alpha_2=\varepsilon_2-\varepsilon_3, \alpha_3=\varepsilon_3-\varepsilon_4, \alpha_4=K^- -\delta+\varepsilon_4, \alpha_5=2\delta-2K^-, \alpha_6=K^+-2K^-+2\delta-\varepsilon_1-\varepsilon_2-\varepsilon_3-\varepsilon_4\}$



$$\begin{pmatrix} 2 & -1 & 0 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 2 & 2 \\ 0 & 0 & 0 & 2 & -4 & -6 \\ 0 & 0 & 0 & 2 & -6 & -4 \end{pmatrix}.$$

The explicit form of the non-Serre-type supplementary relations for HKM superalgebras is not known yet, at least for the vertices which are not of finite nor of affine type. However, another alternative way of describing the HKM superalgebras is to consider *all* inequivalent Dynkin diagrams and write the usual Serre relations (2.1) and (2.2) (of course this leads to redundant information). Indeed, the non-Serre-type relations become Serre relations after a generalized Weyl reflection with respect to an appropriate isotropic odd root.[18]

Note nevertheless that in the case of HKM superalgebras, one may produce by generalized Weyl transformations some exotic simple root systems corresponding to Cartan matrices with noninteger (rational) entries associated to weird nonstandard Dynkin diagrams (this was *not* the

case in the above example). As in the usual case, one gets supplementary non-Serre-type relations, but now also associated to nonisotropic even simple roots.

C. Rank two HKM superalgebras

Clearly any rank 2 HKM superalgebra is described by a Dynkin–Kac diagram of the form

where the dot can be a white, black or grey dot. Both dots cannot be either white, as this diagram describes KM algebras, or grey, as this diagram is isomorphic to the diagram, in the nondistinguished basis, of sl(1/2). The Dynkin–Kac diagrams corresponding to rank 2 finite and affine KM superalgebras, up to generalized Weyl transformations, are listed below

$$\mathrm{osp}(1|4) \quad \begin{pmatrix} 2 & -1 \\ -2 & 2 \end{pmatrix},$$

$$\mathrm{sl}(1|3)^{(4)} \quad \begin{pmatrix} 2 & -2 \\ -2 & 2 \end{pmatrix},$$

$$\mathrm{sl}(1|2) \quad \begin{pmatrix} 0 & 1 \\ -1 & 2 \end{pmatrix},$$

$$\mathrm{osp}(1|2)^{(1)} \quad \begin{pmatrix} 2 & -1 \\ -4 & 2 \end{pmatrix},$$

$$\mathrm{osp}(2|2)^{(2)} \quad \begin{pmatrix} 2 & -2 \\ -2 & 2 \end{pmatrix},$$

$$\mathrm{osp}(3|2) \quad \begin{pmatrix} 0 & 1 \\ -2 & 2 \end{pmatrix},$$

In Refs. 17 and 10, it is proven that any superalgebra associated to a 2×2 matrix not appearing in the above list is of *infinite growth*. It follows.

Theorem 3.3: *The hyperbolic Kac–Moody superalgebras of rank two are infinite in number. Their generalized Cartan matrix and Dynkin diagram are, up to generalized Weyl transformations, reducible to one of the following list:*

(i) *with* $\mathbb{Z}_2$*-gradation* $\tau=\{1\}$,

$$\begin{pmatrix} 2 & -k \\ -k' & 2 \end{pmatrix} \quad \text{with } (k,k')=(1,k'), \quad k'\leqslant 4, \quad (k,k')=(3,1) \text{ or } k,k'\in\mathbb{Z}_{>0}, \quad kk'>4,$$

$$\begin{pmatrix} 0 & 1 \\ -k & 2 \end{pmatrix} \quad \text{with } k\in\mathbb{Z}_{>0}, \quad k>2,$$

(ii) *with* $\mathbb{Z}_2$*-gradation* $\tau=\{1,2\}$,

$$\begin{pmatrix} 2 & -k \\ -k' & 2 \end{pmatrix} \quad \text{with } (k,k')=(1,k'), \quad k'\leqslant 4 \text{ or } k,k'\in\mathbb{Z}_{>0}, \quad kk'>4,$$

$$\begin{pmatrix} 0 & 1 \\ -k & 2 \end{pmatrix} \quad \text{with } k\in\mathbb{Z}_{>0}, \quad k\neq 2.$$

We denote them as $BW(k,k')$, $GW(k)$, $BB(k,k')$, and $GB(k)$, with corresponding Dynkin diagrams,

Note that in order to write only one type of diagram, we have not strictly followed the rules given in Sec. II.

The simple root systems of the HKM superalgebras $BW(k,k')$ and $BB(k,k')$ are given by

$$\alpha = \sum_{i=1}^{n} k_i \varepsilon_i + k_\alpha K^+ \quad \text{and} \quad \alpha' = -\sum_{i=1}^{n'} k'_i \varepsilon_i - k'_\alpha K^-, \tag{3.2}$$

where k_i, k'_i, k_α, $k'_\alpha \in \mathbb{Z}_{\geqslant 0}$ satisfy $kk' = k_\alpha k'_\alpha + \Sigma_{i=1}^{\min(n,n')} k_i k'_i$, $k^2 = \Sigma_{i=1}^{n} k_i^2$, and $k'^2 = \Sigma_{i=1}^{n'} k_i'^2$, while for the HKM superalgebras $GW(k)$ and $GB(k)$ the simple roots are $\alpha = -kK^-$ and $\alpha' = \varepsilon_1 - \varepsilon_2 + K^+$.

IV. SUBALGEBRAS OF HYPERBOLIC KM SUPERALGEBRAS

Let $\mathcal{G}$ be a Kac–Moody superalgebra, and consider its canonical root decomposition

$$\mathcal{G} = \mathcal{H} \oplus \bigoplus_{\alpha \in \Delta} \mathcal{G}_\alpha,$$

where $\mathcal{H}$ is the Cartan subalgebra of $\mathcal{G}$ and Δ its corresponding root system. A sub(super)algebra $\mathcal{G}'$ of $\mathcal{G}$ is called regular if $\mathcal{G}'$ has the root decomposition

$$\mathcal{G}' = \mathcal{H}' \oplus \bigoplus_{\alpha' \in \Delta'} \mathcal{G}'_{\alpha'},$$

where $\mathcal{H}' \subset \mathcal{H}$ and $\Delta \subset \Delta'$.

Consider a HKM superalgebra $\mathcal{G}$. Deleting a dot in the distinguished Dynkin diagram of $\mathcal{G}$ leads to regular sub(super)algebras of $\mathcal{G}$ of finite or affine type by definition. In Appendix C, we list these regular sub(super)algebras corresponding to the Dynkin diagrams of Appendix A. Note that in several cases, the diagram of the subsuperalgebra is not the distinguished one.

A sub(super)algebra $\mathcal{G}'$ of $\mathcal{G}$ is called singular if it is not regular. The folding method allows one to obtain some singular sub(super)algebras of the HKM superalgebras. Let $\mathcal{G}$ be a HKM superalgebra with a distinguished Dynkin diagram exhibiting a $\mathbb{Z}_N$ symmetry. This $\mathbb{Z}_N$ symmetry is generated by an automorphism τ of order $N(\tau^N = 1)$ acting on the root system. The automorphism τ can be lifted at the algebra level by setting $\tau(e_\alpha) = e_{\tau(\alpha)}$ for a generator e_α associated to a simple root α. The symmetry of the Dynkin diagram induces a direct construction of the sub(super)algebra $\mathcal{G}'$ invariant under the $\mathcal{G}$ automorphism associated to τ. Indeed, if the simple root α is transformed into $\tau(\alpha)$, then $\alpha' = \alpha + \tau(\alpha) + \cdots + \tau^{N-1}(\alpha)$ is τ-invariant since $\tau^N = 1$, and appears as a simple root of $\mathcal{G}'$ associated to the generator $e_{\alpha'} = e_\alpha + e_{\tau(\alpha)} + \cdots + e_{\tau^{N-1}(\alpha)}$, where $e_{\tau^k(\alpha)}$ is the generator corresponding to the root $\tau^k(\alpha)$ $(k = 0, \ldots, N-1)$. A Dynkin diagram of $\mathcal{G}'$ will therefore be obtained by folding the $\mathbb{Z}_N$-symmetric Dynkin diagram of $\mathcal{G}$, that is by transforming each N-uple $(\alpha, \tau(\alpha), \ldots, \tau^{N-1}(\alpha))$ into the root $\alpha' = \alpha + \tau(\alpha) + \cdots + \tau^{N-1}(\alpha)$ of $\mathcal{G}'$. It is easy to convince oneself that for $\mathcal{G}'$ the defining relations (2.1)–(2.5) of a HKM superalgebra hold [be aware that, in particular for the Serre relations (2.5), the entries of the Cartan matrix are now those of $\mathcal{G}'$].

We present in Table I the list of HKM superalgebras $\mathcal{G}$ to which the folding procedure can be applied and the corresponding singular subsuperalgebras $\mathcal{G}'$. Note that in general the obtained singular subsuperalgebras are also HKM superalgebras. However, in the case of the HKM superalgebra #6 of rank 6, one obtains for $\mathcal{G}'$ the simple Lie superalgebra $F(4)$ [note that for affine Lie (super)algebras the folding procedure always leads to (super)algebras of affine type]. This is due to the fact that for HKM superalgebras the root system contains *two* isotropic roots whose scalar product is not trivial.

Remark 4.1: The folding procedure cannot be applied to the rank four HKM superalgebras labelled by the numbers #59 to #62, despite the apparent $\mathbb{Z}_2$-symmetry of the distinguished Dynkin diagram, as the $\mathbb{Z}_2$-grading of the invariant generators would not be respected.

APPENDIX B: SIMPLE ROOT SYSTEMS

We describe in this section the simple root systems corresponding to the Dynkin diagrams of Appendix A (as usual, the parametrization is not unique). We give below the conventions used to describe the simple root systems depending on the topology of the considered Dynkin diagrams. In any case, the simple roots are written in terms of orthogonal vectors ε_i, δ_i, K^+, and K^- such that $(\varepsilon_i,\varepsilon_j)=1$, $(\delta_i,\delta_j)=-1$, $(K^+,K^-)=1$ and all other scalar products are zero. It is also convenient to introduce $\tilde{\delta}=\delta_1+\delta_2+\delta_3$ which satisfies $(\tilde{\delta},\tilde{\delta})=-3$ and $(\tilde{\delta},\varepsilon_i)=(\tilde{\delta},K^+)=(\tilde{\delta},K^-)=0$.

Rank 3 hyperbolic superalgebras: Conventions for the simple root systems $\Delta^0=\{\alpha_1,\alpha_2,\alpha_3\}$,

$$\#1{:}\Delta^0 = \{2\varepsilon_1 - \varepsilon_2 - \varepsilon_3 - K^-, \varepsilon_2 - \varepsilon_1, 2K^+ + \varepsilon_1\},$$

$$\#2{:}\Delta^0 = \left\{\tfrac{1}{3}(2\varepsilon_1 - \varepsilon_2 - \varepsilon_3) - K^-, \varepsilon_2 - \varepsilon_1, \tfrac{2}{3}K^+ + \varepsilon_1\right\},$$

$$\#3{:}\Delta^0 = \left\{-\tfrac{1}{2}(\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4) - K^-, \varepsilon_1, -\varepsilon_1 + \tfrac{1}{2}K^+\right\},$$

$$\#4{:}\Delta^0 = \{-2\varepsilon_1 + 2\varepsilon_2 - K^-, \varepsilon_1 - \varepsilon_2, 2K^+ + \varepsilon_2\},$$

$$\#5{:}\Delta^0 = \left\{-\tfrac{1}{2}(\varepsilon_1 - \varepsilon_2) - K^-, \varepsilon_1 - \varepsilon_2, \tfrac{1}{2}K^+ + \varepsilon_2\right\},$$

$$\#6{:}\Delta^0 = \{-\varepsilon_1 - K^-, \varepsilon_1, -\varepsilon_1 + K^+\},$$

On unitary, irreducible representations of the proper, orthochronous Lorentz group

J. Kubieniec[a)]
Marian Smoluchowski Institute of Physics, Jagellonian University, Reymonta 4, 30-059 Kraków, Poland

(Received 12 July 2004; accepted 13 November 2004; published online 7 April 2005)

The theory of unitary, irreducible representations of the proper, orthochronous Lorentz group is presented by means of the usual tensor calculus in Minkowski space–time. This makes all steps manifestly Lorentz invariant. Explicit expressions for spherically symmetric eigenfunctions of the first Casimir operator C_1 of the proper, orthochronous Lorentz group are calculated and their completeness is proved. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1869537]

I. INTRODUCTION

Unitary, irreducible representations of the proper, orthochronous Lorentz group were discovered simultaneously and independently by Gelfand and Neumark,[1] Bargmann,[2] and Harish-Chandra.[3] They are described in several textbooks, both mathematical[4,5] and physical.[6,7] In all those textbooks the functions spanning the representation space depend on one complex variable. The connection with the Lorentz group arises from the well-known isomorphism between the group of proper, orthochronous Lorentz transformations of null directions and the group of homographic transformations of the complex plane. However, the existence of this isomorphism allows only to check the Lorentz invariance, which in the tensor calculus in Minkowski space–time is manifest.

In this paper we shall construct the representations of the proper, orthochronous Lorentz group by analogy with the representations of the rotation group SO(3). The spherical functions Y_{lm}, which span the unitary, irreducible representations of the rotation group SO(3), can be obtained as the solutions of the Laplace equation

$$\Delta f \equiv \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2} = 0, \tag{1}$$

which have a fixed degree of homogeneity d,

$$f(\lambda x, \lambda y, \lambda z) = \lambda^d f(x,y,z) \quad \text{for each } \lambda > 0. \tag{2}$$

Solving the Laplace equation we obtain

$$f(x,y,z) = r^l Y_{lm}(\theta, \varphi), \tag{3}$$

where r, θ, and φ are the usual spherical coordinates, $l=0,1,2,\ldots$ and $m=-l,\ldots,l$. Thus $d=l=0,1,2,\ldots$.

By analogy, we shall consider the solutions of the d'Alembert equation ($c=1$),

a)Electronic mail: jakub@th.if.uj.edu.pl

$$\Box f \equiv \frac{\partial^2 f}{\partial t^2} - \frac{\partial^2 f}{\partial x^2} - \frac{\partial^2 f}{\partial y^2} - \frac{\partial^2 f}{\partial z^2} = 0, \tag{4}$$

which have a fixed degree of homogeneity d,

$$f(\lambda t, \lambda x, \lambda y, \lambda z) = \lambda^d f(t,x,y,z) \quad \text{for each } \lambda > 0. \tag{5}$$

This approach allows to use the tensor calculus in Minkowski space–time, thus making the Lorentz invariance manifest at each step. Moreover, it reveals the spatiotemporal shape of solutions which is completely absent in the standard expositions mentioned above.

We use units in which $\hbar = 1 = c$. We use the metric tensor $g_{\mu\nu}$ such that $xx = g_{\mu\nu}x^\mu x^\nu \equiv (x^0)^2 - (x^1)^2 - (x^2)^2 - (x^3)^2$. Finally, we restrict our treatment to the spinless case $C_2 = 0$, where C_2 is the second Casimir operator of the proper, orthochronous Lorentz group. The reason is that $C_2 = 0$ for the so-called supplementary series, which is the hardest case from the point of view of the Lorentz invariance and quantum-mechanical significance.

II. THE INTERNAL GEOMETRY OF THE LIGHT CONE

We describe the internal geometry of the light cone, following Gelfand, Graev, and Vilenkin[4] (cf. p. 426), and Staruszkiewicz.[8]

The upper light cone (here in the momentum space) is a figure formed by positive frequency null vectors $kk = 0$, $k^0 > 0$. It consists of null directions. A null direction is a set of null vectors parallel to a given null vector. Null directions generate two Lorentz invariant measures on the upper light cone, the projective distance along the null directions,

$$\left.\frac{\mathrm{d}k^0}{k^0}\right| \; k^1 : k^2 : k^3 = \text{const} \tag{6}$$

and the volume of the set of null directions

$$\mathrm{d}^2 k = \frac{k^1\, \mathrm{d}k^2 \wedge \mathrm{d}k^3 + k^2\, \mathrm{d}k^3 \wedge \mathrm{d}k^1 + k^3\, \mathrm{d}k^1 \wedge \mathrm{d}k^2}{k^0}. \tag{7}$$

Here $\wedge$ denotes the outer product. The well-known Lorentz invariant volume of the upper light cone

$$\mathrm{d}k = \frac{\mathrm{d}k^1 \wedge \mathrm{d}k^2 \wedge \mathrm{d}k^3}{k^0} \tag{8}$$

can be written as the outer product of the projective distance along the null directions and the volume of the set of null directions,

$$\mathrm{d}k = \frac{\mathrm{d}k^0}{k^0} \wedge \mathrm{d}^2 k. \tag{9}$$

The Lorentz invariant measure $\mathrm{d}^2 k$ is applicable when one integrates a homogeneous of degree -2 function of k because then one obtains a manifestly Lorentz invariant integral. This allows, e.g., to calculate many difficult integrals in a simple way.[8]

Consider, for example, the simplest integral of this form

$$I(u) = \int \frac{\mathrm{d}^2 k}{(uk)^2}, \tag{10}$$

where u is a timelike vector $uu > 0$. In the spherical coordinates,

$$k^0 = \omega,$$

$$k^1 = \omega \sin\theta \cos\varphi,$$

$$k^2 = \omega \sin\theta \sin\varphi,$$

$$k^3 = \omega \cos\theta, \tag{11}$$

$\mathrm{d}^2k = \omega^2 \sin\theta\, \mathrm{d}\theta \wedge \mathrm{d}\varphi$. The integral $I(u)$ is manifestly Lorentz invariant and therefore can be calculated in the rest frame of u, in which it is equal to

$$I(u) = \int \frac{\omega^2 \sin\theta\, \mathrm{d}\theta\, \mathrm{d}\varphi}{(u^0)^2\omega^2} = \frac{4\pi}{(u^0)^2} = \frac{4\pi}{uu}. \tag{12}$$

Someone who does not know that the integral $I(u)$ is Lorentz invariant will use only its rotational invariance and will have to take an additional integral over θ. In this case the use of the Lorentz invariance is a matter of convenience but in more complicated cases it makes a difference between what can and what cannot be done.

III. SOLUTIONS OF THE D'ALEMBERT EQUATION WITH A FIXED DEGREE OF HOMOGENEITY

The generators of the proper, orthochronous Lorentz group for the spinless case in Minkowski space–time written in a manifestly Lorentz covariant form are

$$M_{\mu\nu} = x_\mu p_\nu - x_\nu p_\mu = i\left(x_\mu \frac{\partial}{\partial x^\nu} - x_\nu \frac{\partial}{\partial x^\mu}\right). \tag{13}$$

The Casimir operators of the proper, orthochronous Lorentz group for the spinless case in Minkowski space–time written in a manifestly Lorentz invariant form are

$$C_1 = -\tfrac{1}{2} M_{\mu\nu}M^{\mu\nu} = xx\Box - x^\mu \frac{\partial}{\partial x^\mu}\left(x^\nu \frac{\partial}{\partial x^\nu} + 2\right), \tag{14}$$

$$C_2 = \tfrac{1}{8}\epsilon^{\mu\nu\rho\sigma} M_{\mu\nu}M_{\rho\sigma} \equiv 0. \tag{15}$$

Here $\Box$ denotes the d'Alembert operator, $\epsilon^{\mu\nu\rho\sigma}$ denotes the Levi–Civita symbol, $\epsilon^{0123} = 1$.

Assume that f is a solution of the d'Alembert equation $\Box f = 0$ with a fixed degree of homogeneity d. The Euler theorem on homogeneous functions states that

$$x^\mu \frac{\partial}{\partial x^\mu} f = df. \tag{16}$$

Then

$$C_1 f = -d(d+2)f, \tag{17}$$

which shows that the degree of homogeneity d fixes the eigenvalue of the Casimir operator C_1. Hence irreducible representations can be classified according to the degree of homogeneity.

To have unitarity we need a positive definite scalar product. It is well known that such a scalar product is obtained when the standard sesquilinear, Hermitian form

$$(f,f) = i\int_{\mathrm{CS}} \mathrm{d}\Sigma^\mu \left(\bar{f}\frac{\partial f}{\partial x^\mu} - \frac{\partial \bar{f}}{\partial x^\mu} f\right), \tag{18}$$

where CS is an arbitrary Cauchy surface and $\mathrm{d}\Sigma^\mu$ is the volume element on this surface, is restricted to positive frequency solutions, i.e., to solutions whose Fourier transform has the support on the upper light cone in the momentum space.

This closes our construction for the so-called main series.

IV. THE MAIN SERIES

The Casimir operator C_1 for the main series has values[4] $C_1=1+\nu^2\geqslant 1$, which means that the degree of homogeneity $d=-1-i\nu$ with ν real. Positive frequency solutions of the d'Alembert equation, which are homogeneous of degree $-1-i\nu$ can be represented by the Fourier transform

$$f(x)=\int \mathrm{d}k\, e^{-ikx}f(k), \tag{19}$$

where the function $f(k)$, defined on the upper light cone in the momentum space, is homogeneous of degree $-1+i\nu$. Expressing the sesquilinear, Hermitian form (f,f) from the preceding section by the Fourier transform $f(k)$ we obtain

$$(f,f)=2(2\pi)^3\int_0^\infty \frac{\mathrm{d}k^0}{k^0}\cdot\int \mathrm{d}^2k\,\overline{f(k)}f(k). \tag{20}$$

Dropping the infinite constant $2(2\pi)^3\int_0^\infty \mathrm{d}k^0/k^0$ we have the local scalar product in the momentum space appropriate for the main series

$$\langle f|f\rangle=\int \mathrm{d}^2k\,\overline{f(k)}f(k), \tag{21}$$

which is manifestly Lorentz invariant and positive definite. In this manner we obtain a Hilbert space, in which irreducible representations of the proper, orthochronous Lorentz group are unitary. The functions belonging to this Hilbert space are square integrable.

It is clear that a spherically symmetric function $f(k)$ must be proportional to

$$(k^0)^{-1+i\nu}. \tag{22}$$

This gives spherically symmetric solutions $f(x)$ in Minkowski space–time proportional to (see Appendix A)

$$\frac{1}{r}\left\{\left[\cosh\left(\frac{\pi}{2}\nu\right)+\mathrm{sign}(t-r)\sinh\left(\frac{\pi}{2}\nu\right)\right]|t-r|^{-i\nu}-\left[\cosh\left(\frac{\pi}{2}\nu\right)+\mathrm{sign}(t+r)\sinh\left(\frac{\pi}{2}\nu\right)\right]|t+r|^{-i\nu}\right\}, \tag{23}$$

where $t=x^0$, $r=\sqrt{(x^1)^2+(x^2)^2+(x^3)^2}$, sign is the signum function.

The functions belonging to the main series form a complete set (see Appendix B). Thus someone who knows quantum mechanics would suspect that these are all representations. There exists, nevertheless, the supplementary series.

V. THE SUPPLEMENTARY SERIES

The existence of the supplementary series, undoubtedly surprising from the point of view of quantum mechanics, can be inferred as follows. Consider the hyperboloid $xx=-1$. This hyperboloid is a three-dimensional space–time analogous to the four-dimensional de Sitter space–time used sometimes in cosmology. The operator $-C_1=(1/2)M_{\mu\nu}M^{\mu\nu}$, given by Eq. (14), is the d'Alembert operator in this space–time. Therefore the eigenequation

$$C_1 f=-d(d+2)f \tag{24}$$

is the Klein–Gordon equation in the three-dimensional de Sitter space–time $xx=-1$. For the main series the square of the "mass" $-d(d+2)=1+\nu^2\geqslant 1$. Physically this is of course the square of the product of physical mass and radius; the condition $-d(d+2)=1+\nu^2\geqslant 1$ means simply that the square of this product is bigger than the critical value equal to 1. There is no reason, however, to

assume the condition $-d(d+2) \geqslant 1$. Space–time, in this case the three-dimensional de Sitter space–time $xx=-1$, is simply a container in which we should be able to place a quantum particle of arbitrary real and positive physical mass. Using this physically obvious principle we set[4]

$$\nu = i\sigma, \quad 0 < \sigma < 1, \tag{25}$$

which means that $0 < C_1 = -d(d+2) = 1-\sigma^2 < 1$ and $f(x)$ is now homogeneous of degree $-1+\sigma$ while $f(k)$ is homogeneous of degree $-1-\sigma$.

The de Sitter space–time $xx=-1$ has a compact Cauchy surface which means that the standard sesquilinear, Hermitian form

$$(f,f) = i\int_{\mathrm{CS}} \mathrm{d}\Sigma^k \left(\bar{f}\frac{\partial f}{\partial \xi^k} - \frac{\partial \bar{f}}{\partial \xi^k} f \right), \tag{26}$$

where ξ^1, ξ^2, ξ^3 are arbitrary internal coordinates in this space–time, is always perfectly well defined. We assume the definition of a positive frequency solution in the de Sitter space–time $xx=-1$ first given by Staruszkiewicz:[9] a solution of the Klein–Gordon equation with the square of the "mass" $-d(d+2)$ in the de Sitter space–time $xx=-1$ is a positive frequency one if it is a restriction to the hyperboloid $xx=-1$ of a homogeneous of degree d, positive frequency solution of the d'Alembert equation in Minkowski space–time. Thus we obtain a Lorentz invariant and positive definite scalar product, which we need to have a unitary representation.

Let us express the sesquilinear, Hermitian form (f,f) by the Fourier transform $f(k)$ which now is homogeneous of degree $-1-\sigma$. Since (f,f) is a Lorentz invariant scalar product, there is a function $K(\sigma)$ such that

$$(f,f) = \int \frac{\mathrm{d}^2k\, \mathrm{d}^2l}{(kl)^{1-\sigma}} \overline{f(k)} f(l) \cdot K(\sigma). \tag{27}$$

Dropping the irrelevant function $K(\sigma)$ we have the nonlocal scalar product in the momentum space appropriate for the supplementary series

$$\langle f|f\rangle_\sigma = \int \frac{\mathrm{d}^2k\, \mathrm{d}^2l}{(kl)^{1-\sigma}} \overline{f(k)} f(l), \tag{28}$$

which is manifestly Lorentz invariant. The reader is invited to compare this expression with the same scalar product given by Mukunda and Simon[10] in Eq. (5.4) of their paper to see the improvement brought about by the use of the Lorentz invariant measure d^2k. In this manner we obtain a Hilbert space, in which irreducible representations of the proper, orthochronous Lorentz group are unitary.

It is clear that a spherically symmetric function $f(k)$ must be proportional to

$$(k^0)^{-1-\sigma}. \tag{29}$$

This gives spherically symmetric solutions $f(x)$ in Minkowski space–time proportional to (see again Appendix A)

$$\frac{1}{r}\left\{ \left[\cos\left(\frac{\pi}{2}\sigma\right) + i\,\mathrm{sign}(t-r)\sin\left(\frac{\pi}{2}\sigma\right) \right] |t-r|^\sigma - \left[\cos\left(\frac{\pi}{2}\sigma\right) + i\,\mathrm{sign}(t+r)\sin\left(\frac{\pi}{2}\sigma\right) \right] |t+r|^\sigma \right\}. \tag{30}$$

ACKNOWLEDGMENT

I thank Professor A. Staruszkiewicz for several useful suggestions.

APPENDIX A: THE USEFUL INTEGRAL

Let us consider the integral analytic in the lower half-plane of complex time $\mathrm{Im}\, x^0 < 0$,

$$\int \mathrm{d}k\, e^{-ikx}(k^0)^{-1-C}, \tag{A1}$$

which is to be understood as the limit of the integral

$$\int \mathrm{d}k\, e^{-ik(x-i\varepsilon)}(k^0)^{-1-C}, \tag{A2}$$

where ε is an infinitesimal future oriented timelike vector $\varepsilon\varepsilon > 0$, $\varepsilon^0 > 0$. The last integral is convergent for $\mathrm{Re}\, C < 1$ and in the limit it equals[11]

$$\frac{2\pi\Gamma(-C)}{i}\frac{1}{r}\left\{\left[\cos\left(\frac{\pi}{2}C\right) + i\,\mathrm{sign}(t-r)\sin\left(\frac{\pi}{2}C\right)\right]|t-r|^C - \left[\cos\left(\frac{\pi}{2}C\right) + i\,\mathrm{sign}(t+r)\sin\left(\frac{\pi}{2}C\right)\right]|t+r|^C\right\}, \tag{A3}$$

where $t = x^0$, $r = \sqrt{(x^1)^2 + (x^2)^2 + (x^3)^2}$, Γ is the gamma function, sign is the signum function.

APPENDIX B: PROOF OF COMPLETENESS

All functions defined on the upper light cone in the momentum space with a given degree of homogeneity can be obtained from the spherically symmetric function by application of Lorentz "boosts." Thus, in order to prove that the functions belonging to the main series form a complete set, it is sufficient to show that spherically symmetric ones form a complete set in the subspace of spherically symmetric functions.

It is easy to calculate that

$$\int \mathrm{d}k\overline{(k^0)^{-1+i\mu}}(k^0)^{-1+i\nu} = 8\pi^2\delta(\mu-\nu). \tag{B1}$$

Using this result we get the decomposition of an arbitrary spherically symmetric function $\psi(k^0)$ defined on the upper light cone in the momentum space,

$$\begin{aligned}\psi(k^0) &= \int_{-\infty}^{+\infty}\mathrm{d}\nu(k^0)^{-1+i\nu}\psi(\nu),\\ \psi(\nu) &= \frac{1}{2\pi}\int_0^{\infty}\mathrm{d}k^0(k^0)^{-i\nu}\psi(k^0),\end{aligned} \tag{B2}$$

which boils down to the pair of Mellin transforms and gives all the results known for this pair. Thus we see that spherically symmetric functions from the main series form a complete set in the subspace of spherically symmetric functions.

(Received 11 June 2004; accepted 2 January 2005; published online 7 April 2005)

We prove existence of standing wave solutions for a nonlinear Schrödinger equation on $\mathbb{R}^3$ under the influence of an external magnetic field B. In particular we deal with the physically meaningful case of a constant magnetic field $B=(0,0,b)$ having source in the potential $A(x)=(b/2)(-x_2,x_1,0)$ corresponding to the Lorentz gauge. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1874333]

I. INTRODUCTION

In quantum mechanics the introduction of an external magnetic field $B:\mathbb{R}^3\to\mathbb{R}^3$ involves replacing the gradient operator ∇ with $\nabla+iA(x)$ where A is a vector (or magnetic) potential and satisfies curl $A(x)=B(x)$. The Schrödinger operator with a magnetic field having source in A and a scalar (electric) potential W has the following expression:

$$L^{\hbar}_{A,W}=\left(\frac{\hbar}{i}\nabla-A\right)^2+W(x)=-\hbar^2\Delta-\frac{2\hbar}{i}A\cdot\nabla+|A|^2-\frac{\hbar}{i}\operatorname{div}A+W(x), \tag{1}$$

where $i^2=-1$ and $\hbar$ is the Planck constant. We notice that if we replace the magnetic potential A by $\tilde{A}(x)=A(x)+\nabla\varphi(x)$ for some real-valued C^2 function φ then $\tilde{B}(x)=\operatorname{curl}\tilde{A}(x)=\operatorname{curl}A(x)=B(x)$ and

$$e^{-i\varphi}\left[\left(\frac{1}{i}\nabla-\tilde{A}(x)\right)^2+W(x)\right]e^{i\varphi}=\left(\frac{1}{i}\nabla-A(x)\right)^2+W(x),$$

so that the spectral properties of $L^{\hbar}_{A,W}$ and $L^{\hbar}_{\tilde{A},W}$ are the same. The above properties is called the *gauge invariance* of the magnetic Schrödinger operator and it is in accordance with the fact that the physically relevant quantity is the magnetic field B and not its vector potential A (cf. Ref. 6).

Motivated by the theory of superconductivity, a lot of papers are devoted to the analysis of the spectrum of $L^{\hbar}_{A,W}$ in a semiclassical regime, namely as, $\hbar\to 0$. We quote in particular the works by Bernoff-Stenberg,[7] Del Pino–Felmer–Stenberg,[16] Lu–Pan,[7,26] devoted to the analysis, in a semiclassical regime, of the lowest eigenvalue of the magnetic Schrödinger operator. Finally we mention a recent paper by Helffer and Morame,[20] concerning the localization of the ground state in the case of a constant magnetic field.

[b)]Supported by MIUR, national project Variational methods and Nonlinear differential equations. Electronic mail: secchi@mat.unimi.it

In the present work we study, in a semiclassical regime, a nonlinear Schrödinger equation with an additional cubic term, which arises in many fields of physics, in a particular condensed matter physics and nonlinear optics (see Ref. 33). More precisely, we are looking for stationary states to the evolution equation

$$i\hbar\frac{\partial\psi}{\partial t} = L^{\hbar}_{A,W}\psi - |\psi|^2\psi \quad \text{in } \mathbb{R}^+ \times \mathbb{R}^3, \tag{2}$$

as $\hbar \to 0$. The *ansatz* that the solution $\psi(x,t)$ to (2) is a standing wave of the form

$$\psi(t,x) = e^{-iE\hbar^{-1}t}u(x),$$

with $E \in \mathbb{R}$ and u: $\mathbb{R}^3 \to \mathbb{C}$, leads us to solve the semilinear elliptic equation

$$L^{\hbar}_{A,W}u = Eu + |u|^2u \quad \text{in } \mathbb{R}^3. \tag{3}$$

In the work we consider an electric potential $W(x)$ which is bounded from below on $\mathbb{R}^3$, and we choose E such that $V(x) = W(x) - E$ is strictly positive. Hence Eq. (3) becomes

$$L^{\hbar}_{A,V}u = |u|^2u \quad \text{in } \mathbb{R}^3, \tag{4}$$

where V is a strictly positive potential.

While there is an extensive literature dealing with (4) in the case $A=0$ (see Refs. 3, 4, 9, 10, 13, 15, 14, 19, 24, 27, and 29), there are few papers concerning the nonlinear Schrödinger equation with magnetic fields.

To our knowledge, the first paper, in which semilinear Schrödinger equation (4) with external magnetic field is considered, is by Esteban and Lions.[18] The authors proved the existence of standing wave solutions to (4), by a constrained minimization in the case $V(x)=1$ on $\mathbb{R}^3$ and $\hbar > 0$ is fixed. Concentration and compactness arguments are applied to solve such minimization problems for special classes of magnetic fields.

Afterward, in Ref. 21, Kurata has proved the existence of least energy solutions to (4) for any fixed $\hbar > 0$, under some assumptions linking the magnetic field B and the electric potential V (see also Ref. 32).

A first multiplicity result for standing wave solutions to (4), as $\hbar \to 0$, has been proved by Cingolani in Ref. 8, using topological arguments that allow to relate the number of standing wave solutions to (4) to the *topology* of the set of global minima of V. This result covers the case of magnetic potentials having polynomial growths, having special physical interest, but the used approach works only near global minima of V.

In a recent paper,[11] the more general case, in which the electric potential V has a manifold M of stationary points, not necessarily global minima, has been considered. For bounded electric and magnetic potentials, it has been proved a multiplicity result of semiclassical standing waves of (4), following the new perturbation approach contained in the paper[4] by Ambrosetti, Malchiodi, and Secchi (see also Refs. 2 and 3). Precisely, by means of a finite dimensional reduction, the complex-valued solutions to (4) are found near least energy solutions of the complex-valued limiting equation

$$\left(\frac{\nabla}{i} - A(\hbar\xi)\right)^2 u + u + V(\hbar\xi)u = |u|^2u \quad \text{in } \mathbb{R}^3, \tag{5}$$

where $\hbar\xi$ belongs to a neighborhood of M. We remark that in Ref. 11 the boundedness of the scalar and magnetic potentials on $\mathbb{R}^3$ is a crucial assumption to guarantee that the variational framework, in which problem (4) is set up, becomes *equivalent* to the space $H^1(\mathbb{R}^3,\mathbb{C})$, which is the variational setting of the limiting problem (5), independently of the vector potential A.

Concerning other papers on this topic, we mention a recent work[31] by Secchi and Squassina in which the authors have established necessary conditions for a sequence of standing wave solutions

to (4) to concentrate, in different senses, around a given point. Finally we quote the paper by Arioli and Szulkin[5] where existence of infinitely many solutions of (5) is proved assuming that V and B are periodic and $\hbar$ fixed.

In the present work we are concerned with the study of standing wave solutions to (4) in a semiclassical regime, in the presence of a magnetic field, having source in a vector potential A possibly unbounded on $\mathbb{R}^3$. This is a relevant case in physics, since constant magnetic fields B lead to vector potentials A, having polynomial growths on $\mathbb{R}^3$. For instance, if B is the constant magnetic field $(0,0,b)$, then a suitable vector field is given by $A(x)=(b/2)(-x_2,x_1,0)$. In physical literature the potential A corresponds to the so-called *Lorentz gauge* (see Ref. 18).

In Main Theorem, which is the main result, we prove that for each topologically nontrivial critical point x_0 of the scalar potential V, there exists a standing wave solution $\psi_\hbar$ of (2) whose modulus concentrates at x_0 for $\hbar$ small. The magnetic field only influences the phase factor of the standing wave as $\hbar$ is small.

The used approach is variational and is based on a penalization procedure, introduced by Del Pino and Felmer in Ref. 13 for studying nonlinear Schrödinger equations with $A(x)=0$ in the semiclassical limit.

We point out that in the presence of a magnetic field new difficulties arise in order to carry out a penalization procedure as in Ref. 13. First, the problem is complex valued (unless $A\equiv 0$) and the penalization acts only on the modulus of the functions. Moreover differently from Refs. 11 and 13, if A is an unbounded function on $\mathbb{R}^3$, there is no kind of relationship between the variational setting $H^\hbar_{A,V}$ associated to problem (4), and the limit space $H^1(\mathbb{R}^3,\mathbb{C})$ as $\hbar\to 0$ (see Remark 3.1). Kato's inequality for magnetic fields and delicate subsolution estimates will provide the tools to extend the results in Ref. 13 for nonlinear Schrödinger equations in presence of an external magnetic field.

We use the following notations:

(1) The complex conjugate of any number $z\in\mathbb{C}$ will be denoted by $\bar{z}$.
(2) The real part of a number $z\in\mathbb{C}$ will be denoted by $\mathrm{Re}\, z$.
(3) The ordinary inner product between two vectors $a,b\in\mathbb{R}^3$ will be denoted by $a\cdot b$.
(4) From time to time, when no confusion can arise, we omit the symbol dx in integrals over $\mathbb{R}^3$.
(5) The letter C denotes a generic positive constant, which may vary inside a chain of inequalities.
(6) We use the Landau symbols. For example, $O(\varepsilon)$ is a generic function such that $\limsup_{\varepsilon\to 0}[O(\varepsilon)/\varepsilon]<\infty$, and $o(\varepsilon)$ is a function such that $\lim_{\varepsilon\to 0}[o(\varepsilon)/\varepsilon]=0$.

II. STATEMENT OF THE MAIN RESULT

In the work we consider, more generally, with the semilinear elliptic equation

$$\left(\frac{\hbar}{i}\nabla - A(x)\right)^2 u + V(x)u = f(|u|^2)u \quad \text{in } \mathbb{R}^3, \tag{6}$$

where $\hbar$ is regarded as a small parameter and $f:[0,+\infty[\to\mathbb{R}$ satisfies the following assumptions.

(f1) f is of class C^1 increasing, $f(0)=0$ and

$$\lim_{s\to\infty}\frac{f(s)}{s^{\frac{p-1}{2}}}=0 \quad \text{and } 0<\vartheta F(s)\leqslant f(s)s$$

for some $p\in(1,5)$ and $\vartheta>2$, where $F(s)=\frac{1}{2}\int_0^s f(t)dt$, for $s\in\mathbb{R}^+$.

(f2) For each $a>0$, the limiting functional $I_a:H^1(\mathbb{R}^3,\mathbb{R})\to\mathbb{R}$, defined as

$$I_a(v) = \frac{1}{2}\int_{\mathbb{R}^3} [|\nabla v|^2 + a|v|^2] - \int_{\mathbb{R}^3} F(|v|^2), \tag{7}$$

possesses a unique critical point, whose critical value is denoted by b^a.

Throughout the paper we also make the following mild assumptions on the vector and scalar potentials.

(A1) A: $\mathbb{R}^3 \to \mathbb{R}^3$ is a C^1-vector field such that, for some positive constants C and γ,

$$|J_A(x)| \leqslant Ce^{\gamma|x|}, \tag{8}$$

where $J_A(x)$ denotes the Jacobian matrix of A at x.

(V1) $V: \mathbb{R}^3 \to \mathbb{R}$ is a positive C^1 function such that $\inf_{x\in\mathbb{R}^3} V(x) = V_0 > 0$ and for some positive constants C_1 and γ_1,

$$|\nabla V(x)| \leqslant C_1 e^{\gamma_1|x|}. \tag{9}$$

(V2) There is an open, bounded set $\Lambda \subset \mathbb{R}^3$ with smooth boundary and there exist closed subsets B, B_0 of Λ such that B is connected and $B_0 \subset B$. Let Γ be the family of all continuous functions ϕ: $B \to \Lambda$ with the property that $\phi(x) = x$ whenever $x \in B_0$. Define

$$c = \inf_{\phi\in\Gamma} \max_{x\in B} V(\phi(x)). \tag{10}$$

Moreover we assume that $\sup_{x\in B_0} V(x) < c$ and for all $\phi \in \Gamma$,

$$c \leqslant \inf_{x\in B} V(\phi(x)).$$

(V3) For all $x \in \partial\Lambda$ such that $V(x) = c$, there holds $\partial_\tau V(x) \neq 0$, where ∂_τ stands for the tangential derivative.

We notice that assumptions (V2) and (V3) express a local linking for V in Λ (see for instance Ref. 14) and guarantee the existence of a critical point for V inside Λ at level c. Particular cases of local linking of V in Λ are local maxima, local minima or saddle points for V inside Λ.

We can state the main result of this work, which is going to be proved in the last section.

Main Theorem: *Assume* (f1) and (f2), (A1), (V1)–(V3). *Then there is a number* $\hbar_0 > 0$ *such that for all* $0 < \hbar < \hbar_0$, *there exists a solution* $u_\hbar$ *to Eq.* (6) *such that*

$$\int_{\mathbb{R}^3} \left| \left(\frac{\hbar}{i}\nabla - A(x) \right) u_\hbar \right|^2 \mathrm{d}x + \int_{\mathbb{R}^3} V(x)|u_\hbar|^2 \,\mathrm{d}x < +\infty. \tag{11}$$

Furthermore $u_\hbar \in C^{2,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$, *with* $\alpha \in (0,1)$.

We remark that assumption (f1) is clearly satisfied if the nonlinear term in (6) is homogeneous, namely $f(t) = |t|^{(p-2)/2}$. In this case, assumption (f2) is also satisfied by the uniqueness results in Ref. 22. By Main Theorem, we deduce the following corollary.

Corollary 2.1: Assume (A1), (V1)–(V3). *Then there is a number* $\hbar_0 > 0$ *such that for all* $0 < \hbar < \hbar_0$, *there exists a solution* $u_\hbar$ *to Eq.* (4) *such that* (11) *holds. Furthermore* $u_\hbar \in C^{2,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$, *with* $\alpha \in (0,1)$.

We remark that in Main Theorem we deal with a nonlinear Schrödinger equation in $\mathbb{R}^3$ as this is the main relevant case in quantum mechanics. Actually, the result of Main Theorem also holds for nonlinear Schrödinger equations in $\mathbb{R}^N$, assuming the following.

(f2′) The nonlinearity f is of class C^1, increasing, $f(0) = 0$ and

$$\lim_{s\to\infty}\frac{f(s)}{s^{\frac{p-1}{2}}}=0 \quad \text{and } 0<\vartheta F(s)\leqslant f(s)s$$

for some $p>1$ if $N=1$, 2 and $p\in\left[1,(N+2)\big/(N-2)\right]$ if $N\geqslant 3$ and $\vartheta>2$, where $F(s)=\frac{1}{2}\int_0^s f(t)\mathrm{d}t$, for $s\in\mathbb{R}^+$.

III. MAGNETIC FIELDS: THE SPACE H_A

In this section we recall some classical results on Schrödinger operators with magnetic field, which are useful in the proof of Main Theorem.

We consider the space $H_A(\mathbb{R}^3,\mathbb{C})$ consisting of all the function $u\in L^2(\mathbb{R}^3,\mathbb{C})$ with $(\partial_j+iA_j)u\in L^2(\mathbb{R}^3,\mathbb{C})$ for any $j=1,2,3$ endowed with the norm

$$\|u\|_{H_A}^2=\int_{\mathbb{R}^3}|(\nabla+iA)u|^2\,\mathrm{d}x+\int_{\mathbb{R}^3}|u|^2\,\mathrm{d}x.$$

Remark 3.1: We do not assume that ∇u or Au are separately in $L^2(\mathbb{R}^3,\mathbb{C})$. Therefore, in general, there is no relationship between the spaces $H_A(\mathbb{R}^3,\mathbb{C})$ and $H^1(\mathbb{R}^3,\mathbb{C})$, namely $H_A(\mathbb{R}^3,\mathbb{C})\not\subset H^1(\mathbb{R}^3,\mathbb{C})$ or $H^1(\mathbb{R}^3,\mathbb{C})\not\subset H_A^{\hbar}(\mathbb{R}^3,\mathbb{C})$ (see Ref. 18).

Theorem 3.2: *Let A: $\mathbb{R}^3\to\mathbb{R}^3$ be in $L^2_{\mathrm{loc}}(\mathbb{R}^3)$ and let $u\in H_A^1(\mathbb{R}^3,\mathbb{C})$. Then $|u|\in H^1(\mathbb{R}^3,\mathbb{R})$ and the diamagnetic inequality*

$$|\nabla|u|(x)|\leqslant|(\nabla+iA)u(x)| \tag{12}$$

holds for almost every $x\in\mathbb{R}^3$.

By the diamagnetic inequality, the following result follows (see Ref. 18).

Theorem 3.3: *The space $C_0^\infty(\mathbb{R}^3,\mathbb{C})$ is dense in $H_A^1(\mathbb{R}^3,\mathbb{C})$.*

Furthermore we recall the following Kato's inequality (see Ref. 30).

Theorem 3.4: *Let $u\in L^1_{\mathrm{loc}}(\mathbb{R}^3,\mathbb{C})$ with $\nabla u\in L^1_{\mathrm{loc}}(\mathbb{R}^3,\mathbb{C})$. Define*

$$(\operatorname{sign} u)(x)=\begin{cases}\dfrac{\overline{u(x)}}{|u(x)|} & \text{if } u(x)\neq 0,\\ 0 & \text{if } u(x)=0,\end{cases} \tag{13}$$

we have that $\operatorname{sign} u\in L^\infty(\mathbb{R}^3)$ *and* $(\operatorname{sign} u)\nabla u(x)$ *is locally L^1 and hence a distribution. Moreover we have*

$$\Delta|u|\geqslant\operatorname{Re}[(\operatorname{sign} u)\Delta u].$$

We furthermore recall the application of Kato's inequality to the Schrödinger operator with magnetic field (see Ref. 30).

Theorem 3.5: *Let A: $\mathbb{R}^3\to\mathbb{R}^3$ be a C^1 real vector valued function. Let $D_k u=(1/i)(\partial u/\partial x_k)-A_k u$, for any $k=1,2,3$ and $D_A^2=\Sigma_{k=1}^3 D_k^2$. Then for any $u\in L^1_{\mathrm{loc}}(\mathbb{R}^3,\mathbb{C})$ and $D^2u\in L^2_{\mathrm{loc}}(\mathbb{R}^3,\mathbb{C})$ we have*

$$\Delta|u|\geqslant-\operatorname{Re}[(\operatorname{sign} u)D_A^2u].$$

Throughout the paper, we set $\hbar=\varepsilon$ and denote by D_ε and D^ε for each $\varepsilon>0$ the (formal) differential operators

$$D_\varepsilon=\frac{\varepsilon}{i}\nabla-A(x), \tag{14}$$

$$D^{\varepsilon} = \frac{\nabla}{i} - A(\varepsilon x). \tag{15}$$

As in Sec. II, we introduce the real Hilbert space $H^{\varepsilon}_{A,V}$ as the completion of $C_0^{\infty}(\mathbb{R}^3, \mathbb{C})$ with respect to the inner product

$$\langle u, v\rangle_{H^{\varepsilon}_{A,V}} = \mathrm{Re}\int_{\mathbb{R}^3} D_{\varepsilon}u \cdot \overline{D_{\varepsilon}v}\, \mathrm{d}x + \mathrm{Re}\int_{\mathbb{R}^3} V(x)u\overline{v}\, \mathrm{d}x. \tag{16}$$

As remarked above, this space has in general no relationship with $H^1(\mathbb{R}^3, \mathbb{C})$. Anyway, by Theorem 3.2, we have the following *diamagnetic inequality*:

$$\int_{\mathbb{R}^3} \varepsilon^2 |\nabla |u||^2\, \mathrm{d}x \leqslant \int_{\mathbb{R}^3} |D_{\varepsilon}u|^2\, \mathrm{d}x, \quad \text{for every } u \in H^{\varepsilon}_{A,V}. \tag{17}$$

It is easy to check that, under our assumptions, the functional

$$\mathcal{F}_{\varepsilon}(u) = \frac{1}{2}\int_{\mathbb{R}^3} |D_{\varepsilon}u|^2\, \mathrm{d}x + \int_{\mathbb{R}^3} V(x)|u|^2\, \mathrm{d}x - \int_{\mathbb{R}^3} F(|u|^2)\mathrm{d}x \tag{18}$$

is of class C^2, so that solutions to (6) correspond to critical points of $\mathcal{F}_{\varepsilon}$.

IV. A PENALIZATION ACTING ON THE MODULUS

In this section we perform a penalization of the Euler functional $\mathcal{F}_{\varepsilon}$, inspired by Refs. 13 and 14. To this order, we begin to assume, without loss of generality, that the infimum of V in $\overline{\Lambda}$ is very close to c. Let $\delta > 0$ be a small but fixed number, we can assume that $\Lambda = \{x \,|\, V(x) > c - \delta\}$ and

$$B \subset \{x \in \Lambda \,|\, V(x) \geqslant c(\varepsilon)\}, \quad B_0 \subset \{x \in \Lambda \,|\, V(x) = c(\varepsilon)\},$$

where $c - \delta < c(\varepsilon) < c$, $\lim_{\varepsilon \to 0} c(\varepsilon) = c - \delta$ and $\mathrm{dist}(B_0, \partial\Lambda) = \sqrt{\varepsilon}$. In fact as in Ref. 14, we can redefine $\Lambda_{\delta} = \Lambda \cap \{x \,|\, V(x) > c - \delta\}$ and

$$B^{\delta,\varepsilon} = B \cap \{x | V(x) \geqslant c(\varepsilon)\}, \tag{19}$$

$$B_0^{\delta,\varepsilon} = B_0 \cap \{x | V(x) = c(\varepsilon)\}, \tag{20}$$

where

$$c(\varepsilon) = \inf\{\xi | \mathrm{dist}(\{x \in \Lambda | V(x) = \xi\}, \Lambda_{\delta}) \geqslant \sqrt{\varepsilon}\}$$

without affecting condition (V3) in the definition of linking. We notice that the set $B_0^{\delta,\varepsilon}$ is not empty as B is connected. Then if ϕ: $B^{\delta,\varepsilon} \to \Lambda_{\delta}$ is a continuous map with $\phi(x) = x$ for every $x \in B_0^{\delta,\varepsilon}$, we can define its extension $\tilde{\phi}$ as the identity on $B \setminus B^{\delta,\varepsilon}$. Thus $\tilde{\phi}$: $B \to \Lambda$ and $\sup_{x \in B} V(\tilde{\phi}) = \sup_{x \in B^{\delta,\varepsilon}} V(\tilde{\phi}) \geqslant c$.

We consider a modification of the nonlinear term in (6), that will prevent concentration outside Λ. We remark that differently from Ref. 13, as our problem is complex valued, the penalization affects only the modulus of the functions.

Let ϑ be the number defined in (f1) and choose $k > 0$ such that $k > \vartheta/(\vartheta - 2)$. Since f is increasing, we can fix a number $a > 0$ with $f(a) = V_0/k$. Set

$$\tilde{f}(s) = \begin{cases} f(s) & \text{if } s \leqslant a, \\ V_0/k & \text{if } s > a, \end{cases} \tag{21}$$

we define g: $\mathbb{R}^3 \times \mathbb{R}^+ \to \mathbb{R}$ by

$$g(x,s) = \chi_\Lambda(x) f(s) + (1 - \chi_\Lambda(x))\tilde{f}(s), \tag{22}$$

where χ_Λ is the characteristic function of the set Λ and we consider the modified equation

$$\left(\frac{\varepsilon}{i}\nabla - A(x)\right)^2 u + V(x)u = g(x,|u|^2)u \quad \text{in } \mathbb{R}^3. \tag{23}$$

Weak solutions of Eq. (23) correspond to critical points of the C^1 functional J_ε: $H^\varepsilon_{A,V} \to \mathbb{R}$,

$$J_\varepsilon(u) = \frac{1}{2}\int_{\mathbb{R}^3} |D_\varepsilon u|^2 + V(x)|u|^2 - \int_{\mathbb{R}^3} G(x,|u|^2)\mathrm{d}x, \tag{24}$$

where $G(x,s) = \frac{1}{2}\int_0^s g(x,t)\mathrm{d}t$.

For the sake of convenience, we highlight some obvious properties of g, which follow directly from (f1) and (f2).

(g1) $\lim_{s\to 0^+} g(x,s) = 0$, uniformly with respect to $x \in \mathbb{R}^3$.

(g2) There exist a bounded subset K of $\mathbb{R}^3$ and a number $\vartheta > 2$ such that

$$0 < \vartheta G(x,s) \leqslant g(x,s)$$

for all $x \in K$.

(g3) For all $s \geqslant 0$, $x \notin K$,

$$0 \leqslant 2G(x,s) \leqslant g(x,s) \leqslant \frac{1}{k}V(x)$$

with a constant $k > \vartheta/(\vartheta - 2)$.

We begin to show that the penalized functional J_ε satisfies the Palais–Smale condition. This may not be true for the functional $\mathcal{F}_\varepsilon$.

Lemma 4.1: For any $\varepsilon > 0$ fixed, the penalized functional J_ε satisfies the Palais–Smale condition at all positive levels.

Proof: Let $\varepsilon > 0$ be fixed. Let $\{u_n\}$ be a sequence in $H^\varepsilon_{A,V}$ such that $\{J_\varepsilon(u_n)\}$ is bounded and $J'_\varepsilon(u_n) \to 0$. First we prove that $\{u_n\}$ is bounded. By (g3), it follows that

$$\frac{1}{2}\int_K g(x,|u_n|^2)|u_n|^2 + o(\|u_n\|) \leqslant \frac{1}{2}\int_{\mathbb{R}^3} |D_\varepsilon u_n|^2 + V|u_n|^2 \leqslant \int_K G(x,|u_n|^2) + \frac{1}{2k}\int_{\mathbb{R}^3\setminus K} V|u_n|^2 + O(1),$$

where $\|\cdot\|$ denotes the norm in $H^\varepsilon_{A,V}$ induced by the scalar product in (16). Thus the above inequality and (g2) imply

$$\left(\frac{\vartheta}{2} - 1\right)\int_{\mathbb{R}^3} |D_\varepsilon u_n|^2 + V|u_n|^2 \leqslant \frac{\vartheta}{2k}\int_{\mathbb{R}^3\setminus K} V|u_n|^2 + o(\|u_n\|) + O(1).$$

In particular, it follows that $\{u_n\}$ is bounded in $H^\varepsilon_{A,V}$. We choose a subsequence, still denoted by $\{u_n\}$ for simplicity, that converges weakly to some u in $H^\varepsilon_{A,V}$. we claim that $u_n \to u$ strongly in $H^\varepsilon_{A,V}$. To this aim, it suffices to show that for any given $\delta > 0$ there exists $R > 0$ such that

$$\limsup_{n\to\infty} \int_{|x|>R} (|D_\varepsilon u_n|^2 + V(x)|u_n|^2)\mathrm{d}x < \delta.$$

Without loss of generality, we can take R so large that $K \subset B_{R/2}$. Fix a smooth cutoff function η_R such that $\eta_R = 0$ on $B_{R/2}$, $\eta_R = 1$ outside $B_{R/2}$, $0 \leqslant \eta_R \leqslant 1$ and $|\nabla \eta_R| \leqslant c/R$ for some constant $c > 0$. Since $\{u_n\}$ is a bounded Palais–Smale sequence, we have

$$J'(u_n)[\eta_R u_n] = o(1),$$

so that

$$\int_{\mathbb{R}^3} (|D_\varepsilon u_n|^2 + V|u_n|^2)\,\eta_R + \mathrm{Re}\int_{\mathbb{R}^3} u_n D_\varepsilon u_n \cdot \overline{D_\varepsilon \eta_R} = \mathrm{Re}\int_{\mathbb{R}^3} g(x,|u_n|^2)\,\eta_R |u_n|^2 + o(1)$$

$$\leqslant \frac{1}{k}\int_{\mathbb{R}^3} V|u_n|^2\,\eta_R + o(1).$$

We conclude that

$$\int_{|x|>R} |D_\varepsilon u_n|^2 + V(x)|u_n|^2 \leqslant \frac{C}{R}\|u_n\|_{L^2}\|D_\varepsilon u_n\|_{L^2} + o(1),$$

which clearly proves the claim. □

V. THE MINIMAX SCHEME

By assumption (f2) the limiting functional I_a defined in (7) has a unique critical value, which we can characterize as

$$b^a = \inf_{v\in H^1(\mathbb{R}^3)\setminus\{0\}} \sup_{t>0} I_a(tv). \tag{25}$$

It can be shown that the map $a \mapsto b^a$, with $a>0$, is strictly increasing and continuous. Associated to the critical value b^a there exists a radially symmetric solution $\omega_a \in H^1(\mathbb{R}^3,\mathbb{R})$ of the scalar equation

$$\Delta\omega - a\omega + f(|\omega|^2)\omega = 0. \tag{26}$$

Fix a small number $\delta_0>0$. For each $y\in\mathbb{R}^3$ with $\mathrm{dist}(y,\partial\Lambda)>\delta_0$ we denote by w_ε^y the function in $H^\varepsilon_{A,V}$ given by

$$w_\varepsilon^y(x) = e^{iA(y)[(y-x)/\varepsilon]}\eta(|x-y|/\delta_0)\,\omega_{V(y)}\left(\frac{y-x}{\varepsilon}\right), \tag{27}$$

where η is a smooth cutoff function that equals 1 on (0, 1) and 0 on $(2,+\infty)$.

Define now the class Γ_ε of all continuous maps ϕ: $B^\varepsilon \to \mathcal{M}_\varepsilon$ such that

$$\phi(y) = t(\varepsilon,y)w_\varepsilon^y \quad \text{for all } y\in B_0^\varepsilon, \tag{28}$$

where

$$\mathcal{M}_\varepsilon = \left\{ u\in H^\varepsilon_{A,V}\setminus\{0\} \middle| \int_{\mathbb{R}^3} |D_\varepsilon u|^2 + V(x)|u|^2 = \int_{\mathbb{R}^3} g(x,|u|^2)|u|^2 \right\}$$

is the Nehari manifold associated to the polarized functional J_ε and $t(\varepsilon,y)$ is the unique positive number such that $t(\varepsilon,y)w_\varepsilon^y \in \mathcal{M}_\varepsilon$. We define a minimax value as follows:

$$\gamma_\varepsilon = \inf_{\phi\in\Gamma_\varepsilon} \sup_{y\in B^\varepsilon} J_\varepsilon(\phi(y)). \tag{29}$$

By slightly deforming w_ε^y and recalling the definitions of B^ε and B_0^ε, one can show that

$$b^c \geqslant \limsup_{\varepsilon\to 0} \varepsilon^{-3}\gamma_\varepsilon \geqslant \liminf_{\varepsilon\to 0} \varepsilon^{-3}\gamma_\varepsilon \geqslant b^{c-\delta}. \tag{30}$$

We show that the last inequality in (30) is strict. We begin to prove the following useful lemma, which generalizes Lemma 2.3 in Ref. 14 (see also Ref. 17) to the case of a complex valued equation.

Lemma 5.1: Let $v \in H^1(\mathbb{R}^3,\mathbb{C}) \cap C(\mathbb{R}^3)$ *be a weak solution of the equation*

$$\Delta v - V(\xi)v + \chi_{\{x_1<0\}} f(|v|^2)v + \chi_{\{x_1>0\}} \tilde{f}(|v|^2)v = 0, \tag{31}$$

where $\xi \in \mathbb{R}^3$. *Then* $|v| \leqslant \sqrt{a}$ *for any* $x_1 > 0$ *and* v *actually solves the equation*

$$\Delta v - V(\xi)v + f(|v|^2)v = 0.$$

Proof: We test Eq. (31) by $\overline{\partial v}/\partial x_1$ and we derive [x' stands for $=(x^2,x^3)$]

$$\int_{\mathbb{R}^2} dx' \int_{-\infty}^{\infty} \frac{\partial}{\partial x_1}[|\nabla v|^2 + V(\xi)|v|^2]dx_1 + \int_{\mathbb{R}^2} \left[F(|v(0,x')|^2) - \tilde{F}(|v(0,x')|^2)\right]dx' = 0. \tag{32}$$

We notice that $F(s) \geqslant \tilde{F}(s)$ with inequality if $s \leqslant a$. Thus $|v(0,x')| \leqslant \sqrt{a}$. Finally we show that $|v(x_1,x')|^2 \leqslant \sqrt{a}$ for any $x_1 > 0$.

By Kato's inequality we derive that

$$\Delta|v| \geqslant V(\xi)|v| - \chi_{\{x_1<0\}} f(|v|^2)|v| - \chi_{\{x_1>0\}} \tilde{f}(|v|^2)|v|. \tag{33}$$

Now we can test (33) by $\phi = \chi_{\{x_1>0\}}(|v| - \sqrt{a})_+ \in H^1(\mathbb{R}^3,\mathbb{R})$ and we derive

$$\int_{\mathbb{R}^3} \chi_{\{x_1>0\}} |\nabla(|v| - \sqrt{a})_+|^2 + q(x)\chi_{\{x_1>0\}}(|v| - \sqrt{a})_+^2 + \sqrt{aq}(x)\chi_{\{x_1>0\}}(|v| - \sqrt{a})_+ \leqslant 0, \tag{34}$$

where

$$q(x) = V(\xi) - \tilde{f}(|v|^2)\chi_{\{x_1>0\}}.$$

For $s \geqslant a$, $\tilde{f}(s) = (V_0/k) < V(\xi)$, so that $q(x) > 0$ and all the terms in (34) are necessarily zero, and $\phi = \chi_{\{x_1>0\}}(|v| - \sqrt{a})_+ = 0$. We conclude that

$$|v(x_1,x')| \leqslant \sqrt{a} \quad \forall\, x_1 > 0,\ \ x' \in \mathbb{R}^2.$$

□

Lemma 5.2: There results

$$\liminf_{\varepsilon \to 0} \varepsilon^{-3} \gamma_\varepsilon > b^{c-\delta}. \tag{35}$$

Proof: We argue by contradiction, following arguments strictly related to Ref. 14, Lemma 1.1. If (35) is not true, then there exists a sequence $\varepsilon_n \to 0$ such that

$$\varepsilon_n^{-3} \gamma_{\varepsilon_n} \leqslant b^{c-\delta} + o(1).$$

Fix some $\phi_n \in \Gamma_{\varepsilon_n}$ with the property that

$$\varepsilon_n^{-3} \sup_{y \in B^{\varepsilon_n}} J_{\varepsilon_n}(\phi_n(y)) \leqslant b^{c-\delta} + o(1). \tag{36}$$

For the reader's convenience, we split the proof in several steps.

Step I: Setting $\Lambda_n = \{x \in \mathbb{R}^3 | \operatorname{dist}(x,\Lambda) < \sqrt{\varepsilon_n}\}$, we claim that

$$\lim_{n\to\infty} \varepsilon_n^{-3} \sup_{y\in B^{\varepsilon_n}} \int_{\mathbb{R}^3\setminus\Lambda_n} |\phi_n(x)|^2 = 0. \tag{37}$$

To prove this claim, we fix $y_n \in B^{\varepsilon_n}$ and simplify notation by introducing $u_n = \phi_n(y_n)$.

Since $u_n \in \mathcal{M}_{\varepsilon_n}$, we have

$$J_{\varepsilon_n}(u_n) \geqslant J_{\varepsilon_n}(tu_n)$$

for any $t>0$. Let us set

$$E_n(v) = \frac{1}{2}\int_{\Lambda_n} |D_{\varepsilon_n} v|^2 + V(x)|v|^2 - \int_{\Lambda_n} G(x,|v|^2)\mathrm{d}x,$$

and choose numbers $t_n>0$ with the property that

$$E_n(t_n u_n) = \max_{t>0} E_n(tu_n).$$

Now, from the properties of the penalization g, it follows that

$$\frac{V(x)}{2} - G(x,s) \geqslant \gamma \quad \text{for all } x \in \mathbb{R}^3 \setminus \Lambda \text{ and } s>0.$$

This and Eq. (36) imply that

$$E_n(t_n u_n) + \gamma t_n^2 \int_{R^3\setminus\Lambda_n} |u_n|^2 \leqslant \varepsilon_n^3 (b^{c-\delta} + o(1))$$

with an error $o(1)$ uniform with respect to $\{y_n\}$. Furthermore, we claim that there exists $\sigma>0$ such that

$$\inf_{n\geqslant 1} t_n \geqslant \sigma. \tag{38}$$

First we notice that from the relation $J_{\varepsilon_n}(u_n) \leqslant C\varepsilon_n^3$, the diamagnetic inequality and again the properties of g, the existence of a constant C_0, independent of $\{y_n\}$, such that

$$\int_{\mathbb{R}^3} |D_{\varepsilon_n} u_n|^2 + |u_n|^2 \leqslant C_0 \varepsilon_n^3 \tag{39}$$

follows easily. Set now $v_n(x) = t_n u_n(\varepsilon_n x)$ and $\tilde{\Lambda}_n = \varepsilon_n^{-1}\Lambda_n$. The definition of t_n implies

$$\int_{\tilde{\Lambda}_n} |D^{\varepsilon_n} v_n|^2 + V(\varepsilon_n x)|v_n|^2 = \int_{\tilde{\Lambda}_n} g(\varepsilon_n x, |v_n|^2)|v_n|^2 \,\mathrm{d}x \leqslant \int_{\tilde{\Lambda}_n} C_0|v_n|^{p+1} + \rho|v_n|^2, \tag{40}$$

where $\rho>0$ can be fixed as small as we please. We can deduce from the Sobolev embedding theorem as stated in Ref. 1, Lemma 5.10 that there exists a constant $\overline{C}>0$, independent of n, such that

$$\int_{\tilde{\Lambda}_n} |v_n|^{p+1} \leqslant \overline{C}\left(\int_{\tilde{\Lambda}_n} |\nabla |v_n||^2 + |v_n|^2\right)^{(p+1)/2} \leqslant \overline{C}\left(\int_{\tilde{\Lambda}_n} |D^{\varepsilon_n} v_n|^2 + |v_n|^2\right)^{(p+1)/2}. \tag{41}$$

By combining (41) with Eq. (40), we see that

$$\int_{\tilde{\Lambda}_n} |v_n|^{p+1} \geqslant \sigma > 0,$$

and in particular $\int_{\tilde{\Lambda}_n} |D^{\varepsilon_n} v_n|^2 + |v_n|^2 \geqslant \sigma > 0$ for a suitable $\sigma > 0$ independent of n, and so

$$t_n^2 \int_{\Lambda_n} (|D_{\varepsilon_n} u_n|^2 + |u_n|^2) \geqslant \sigma \varepsilon_n^3.$$

This proves (38).

Observe now that, from the definition of t_n and from the diamagnetic inequality, we get

$$E_n(t_n u_n) \geqslant \inf_{u \in H^1(\Lambda_n)} \sup_{t>0} E_n(tu) \equiv b_n.$$

If we prove that

$$\lim_{n \to \infty} \varepsilon_n^{-3} b_n = b^{c-\delta}, \tag{42}$$

then Eq. (37) follows from our previous arguments.

Step II: We prove that identity (42) holds.

We follow Ref. 15, with minor changes. By a deformation argument, it is easy to see that

$$b_n \leqslant (b^{c-\delta} + o(1))\varepsilon_n^3. \tag{43}$$

We prove the opposite inequality. Since the functional E_n satisfies (PS), by standard Critical Point Theory, the number b_n is a critical value for E_n. Let $w_n \in H^1(\Lambda_n)$ be an associated critical point. As such, it satisfies the equation

$$\begin{cases} \left(\dfrac{\varepsilon_n}{i} \nabla - A \right)^2 w_n + V w_n = g(x, |w_n|^2) w_n \quad \text{in } \Lambda_n, \\ \dfrac{\partial w_n}{\partial \nu} = 0 \quad \text{on } \partial \Lambda_n. \end{cases}$$

In particular, by Kato's inequality, $|w_n|$ solves the differential inequality

$$\begin{cases} \varepsilon_n^2 \Delta |w_n| - V(x)|w_n| + g(x, |w_n|^2)|w_n|^2 \geqslant 0 \quad \text{in } \Lambda_n, \\ \dfrac{\partial w_n}{\partial \nu} = 0 \quad \text{on } \partial \Lambda_n. \end{cases} \tag{44}$$

By the maximum principle, $|w_n|$ cannot attain a local maximum inside $\overline{\Lambda_n} \setminus \Lambda$, thanks to the Neumann boundary condition in (44). If x_n is a maximum of $|w_n|$, then necessarily $x_n \in \overline{\Lambda}$. Moreover, $\inf_n \max_{\Lambda_n} |w_n| > 0$. Assume, without loss of generality, that $x_n \to x^* \in \overline{\Lambda}$. Scaling w_n to a map on $\Omega_n \equiv \varepsilon_n^{-1}(\Lambda_n - x_n)$ defined by $v_n(x) = w_n(x_n + \varepsilon_n x)$, we have that v_n satisfies the equation

$$\begin{aligned} &-\Delta v_n - \frac{2}{i} A(x_n + \varepsilon_n x) \cdot \nabla v_n + |A(x_n + \varepsilon_n x)|^2 v_n - \frac{\varepsilon_n}{i} \operatorname{div} A(x_n + \varepsilon_n x) v_n \\ &\quad + V(x_n + \varepsilon_n x) v_n = g(x_n + \varepsilon_n x, |v_n|^2) v_n \quad \text{in } \Omega_n \end{aligned} \tag{45}$$

with Neumann boundary condition, and, again by Kato's inequality,

$$\Delta |v_n| \geqslant V(x_n + \varepsilon_n x)|v_n| - g(x_n + \varepsilon_n x, |v_n|^2)|v_n| \quad \text{in } \Omega_n.$$

From (43) we deduce that

$$\sup_{n\geqslant 1}\int_{\Omega_n}[|D^{\varepsilon_n}v_n|^2\,\mathrm{d}x+V_n|v_n|^2]\mathrm{d}x<+\infty,$$

where $A_n(x)=A(x_n+\varepsilon_n x)$ and $V_n(x)=V(x_n+\varepsilon_n x)$. Take an arbitrary open set Ω, relatively compact in $\mathbb{R}^3$. Since we may assume that $\Omega\subset\Omega_n$ for all n sufficiently large, Eq. (43) and the diamagnetic inequality (12), entail that the sequence $\{|v_n|\}$ is bounded in $H^1(\Omega,\mathbb{R})$ and, up to subsequences, converges weakly in $H^1(\Omega,\mathbb{R})$ and strongly in $L^q(\Omega,\mathbb{R})$ with $q<5$ to some $v^*\in H^1(\Omega,\mathbb{R})$. Moreover $\{v_n\}$ is a bounded sequence in $H^1(\Omega,\mathbb{C})$. Since Ω is arbitrary, the limit v^* can be extended to a function defined on $\mathbb{R}^3$. Thus by applying the subsolution estimates (see Theorems 13.1, 14.1 in Ref. 23) we infer that the sequence $\{v_n\}$ is bounded in $L^\infty(\Omega)$. By Schauder estimates, the sequence $\{v_n\}$ is bounded in $C^{2,\alpha}(K)$ for some $\alpha\in(0,1)$ and thus, up to subsequences, v_n converges to v in $C^2_{\mathrm{loc}}(\mathbb{R}^3)$ and also weakly in $L^q(\mathbb{R}^3,\mathbb{R})$ with $q<5$. It follows that $|v|=v^*\in H^1(\mathbb{R}^3,\mathbb{R})$ and $v\neq 0$ as $\inf_n|v_n(0)|\geqslant b>0$. Therefore,

$$-\Delta v-\frac{2}{i}A(x^*)\cdot\nabla v+|A(x^*)|^2v+V(x^*)v=\bar{g}(x,|v|^2)v\quad\text{in }\mathbb{R}^3,\tag{46}$$

in the sense of distributions, where $\bar{g}(x,s)=\chi(x)f(s)+(1-\chi(x))\tilde{f}(s)$ and χ is the weak * limit of the sequence $\{\chi_\Lambda(x_n+\varepsilon_n)\}_{n\geqslant 1}$ in $L^\infty(\mathbb{R}^3)$. Since $|v|\in H^1(\mathbb{R}^3,\mathbb{R})$ and by definition of $\bar{g}$, we deduce that $\int_{\mathbb{R}^3}\bar{g}(x,|v|^2)|v|^2\,\mathrm{d}x$ is finite and by (46) we have $v\in H^1(\mathbb{R}^3,\mathbb{C})$ and thus v solves (46) in weak sense. By performing a rotation, Lemma 5.1 can be applied to prove that the function $v(x)=e^{-\mathrm{i}A(x^*)\cdot x}\tilde{v}(x)$ satisfies

$$\Delta v-V(x^*)v+f(|v|^2)v=0.$$

We must have

$$\liminf_{n\to\infty}\varepsilon_n^{-3}E_n(w_n)=\liminf_{n\to\infty}E_n(v_n)\geqslant I_{V(x^*)}(v).$$

Indeed, as v_n converges to v in $C^2_{\mathrm{loc}}(\mathbb{R}^3)$, we derive that

$$\lim_{n\to+\infty}\int_{B_R}\sigma_n=\frac{1}{2}\int_{B_R}\left|\left(\frac{\nabla}{i}-A(x^*)\right)v\right|^2+\frac{V(x^*)}{2}\int_{B_R}|v|^2-\int_{B_R}\bar{G}(x,|v|^2),\tag{47}$$

where

$$\sigma_n(x)=\frac{1}{2}\left[\left|\left(\frac{\nabla}{i}-A_n(x)\right)v_n\right|^2+V_n(x)|v_n|^2\right]-\bar{G}(x,|v_n|^2).$$

Since $v\in H^1(\mathbb{R}^N,\mathbb{C})$, we have that for each $\delta>0$ there exists $R>0$ so large that

$$\lim_{n\to+\infty}\int_{B_R}\sigma_n\geqslant I_{V(x^*)}(v)-\delta.$$

To complete the proof, we need to show that

$$\liminf_{n\to\infty}\int_{\varepsilon_n^{-1}(\Lambda_n-x_n)\setminus B_R}\sigma_n(x)\mathrm{d}x\geqslant-\delta\tag{48}$$

for R sufficiently large. Choose a smooth cutoff function η such that $\eta=0$ on B_{R-1}, $\eta=1$ on $\mathbb{R}^3\setminus B_R$, and $|\nabla\eta|\leqslant C$ where C is a positive constant, independent of R and n. Now test the identity $J_n'(v_n)=0$ against the function $\eta\bar{v}_n\in H^1_{A_n,V_n}$ to obtain

$$0 = J_n'(v_n)[\eta\overline{v_n}] = H_n + \int_{\varepsilon_n^{-1}(\Lambda_n - x_n)\setminus B_R} (2\sigma_n + g_n)$$

with $g_n(x) = 2G(x_n + \varepsilon_n x, |v_n|^2) - g(x_n + \varepsilon_n x, |v_n|^2)|v_n|^2$ and

$$H_n = \mathrm{Re}\int_{B_R\setminus B_{R-1}} \nabla v_n \cdot \overline{\nabla(\eta v_n)} + \int_{B_R\setminus B_{R-1}} |A(x_n + \varepsilon_n x)|^2 \eta |v_n|^2 - \mathrm{Re}\frac{2}{i}\int_{B_R\setminus B_{R-1}} A(x_n + \varepsilon_n x)\cdot \nabla v_n \eta\overline{v_n}$$
$$+ \int_{B_R\setminus B_{R-1}} V(x_n + \varepsilon_n x)\,\eta |v_n|^2 - \int_{B_R\setminus B_{R-1}} g(x_n + \varepsilon_n x, |v_n|^2)\,\eta |v_n|^2.$$

From the local C^1 convergence of $\{v_n\}$ to v and the fact that $v \in H^1(\mathbb{R}^N, \mathbb{C})$, we deduce that there exists $R > 0$ so large that $\lim_{n\to\infty} |H_n| \leqslant \delta$. Recalling that $g_n \leqslant 0$ because of the properties of g, one easily gets (48). But $V(x^*) \geqslant c - \delta$ so that $I_{V(x^*)}(v) \geqslant b^{c-\delta}$. We conclude that $b_n \geqslant (b^{c-\delta} + o(1))\varepsilon^3$. Equation (37) follows easily from (42) and (38).

Step III: We now introduce the well-known tool of the *center of mass* for an L^2 function, and apply it to our ϕ_n.

Let $u \in L^2(\mathbb{R}^3)$ be a given map. We define its center of mass $\beta(u) \in \mathbb{R}^3$ as

$$\beta(u) = \frac{\int_{\Lambda^+} x|u(x)|^2\,\mathrm{d}x}{\int_{R^2} |u(x)|^2\,\mathrm{d}x},$$

where Λ^+ is a fixed small neighborhood of $\overline{\Lambda}$. We may of course assume that $\delta_0 < \mathrm{dist}(\partial\Lambda^+, \overline{\Lambda})$ where δ_0 is fixed in (27). We claim that

$$\beta(\phi_n(y)) \in \Lambda^+ \cap \left\{ x \in \mathbb{R}^3 \,\middle|\, V(x) \leqslant c - \frac{\delta}{2} \right\} \quad \text{for all } y \in B^{\varepsilon_n}. \tag{49}$$

Again, the proof of this fact is by contradiction. If (49) is false, then, passing to some subsequence, the existence of $y_n \in B^{\varepsilon_n}$ is assured, such that

$$\beta(\phi_n(y_n)) \notin \Lambda^+ \cap \left\{ x \in \mathbb{R}^3 \,\middle|\, V(x) \leqslant c - \frac{\delta}{2} \right\} \tag{50}$$

for all $n \in N$. If we set $u_n = \phi_n(y_n)$ and $v_n(x) = u_n(\varepsilon_n x)$, we have

$$\sup_{t>0} I_{c-\delta}(t|v_n|) \leqslant b^{c-\delta} + o(1). \tag{51}$$

This inequality is proved as follows: it is already known from (36) and (17) that $\{|v_n|\}$ is bounded in $H^1(\mathbb{R}^3, \mathbb{R})$. Moreover, it follows from

$$\int_{\mathbb{R}^3} (|D^{\varepsilon_n} v_n|^2 + V(\varepsilon_n x)|v_n|^2)\mathrm{d}x = \int_{\mathbb{R}^3} g(\varepsilon_n x, |v_n|^2)|v_n|^2 \leqslant \int_{\mathbb{R}^3} f(|v_n|^2)|v_n|^2$$

that

$$\inf_n \int_{\mathbb{R}^3} |v_n|^{p+1} = \sigma > 0.$$

By virtue of Lions' vanishing lemma (Ref. 25, Lemma I.1) we may find a sequence $\{B_n\}$ of balls of fixed radius (say 1) with

$$\inf_n \int_{B_n} |v_n|^2 \geqslant \sigma > 0.$$

For each n, select a number $t_n > 0$ such that $I_{c-\delta}(t_n|v_n|) = \sup_{t>0} I_{c-\delta}(t|v_n|)$. From the boundedness of $\{|v_n|\}$ in $H^1(\mathbb{R}^3, \mathbb{R})$, we get

$$Ct_n^2 - \int_{R^3} F(|t_n v_n|^2) \geqslant I_{c-\delta}(t_n|v_n|) \geqslant b^{c-\delta}.$$

Recalling assumption (H2), we have

$$t_n^{\vartheta-2} \int_{R^3} |v_n|^{\vartheta} \leqslant C$$

with $2 < \vartheta < 5$. Thus $\{t_n\}$ is bounded, and from (37) we have

$$\lim_{n\to\infty} \int_{\mathbb{R}^3 \setminus (\varepsilon_n^{-1}\Lambda^+)} |t_n v_n|^2 = 0. \tag{52}$$

Finally, from (36) we have

$$b^{c-\delta} + o(1) \geqslant \varepsilon_n^{-3} J_{\varepsilon_n}(t_n u_n) \geqslant I_{c-\delta}(t_n|v_n|) - \frac{t_n^2}{2} \int_{\mathbb{R}^3 \setminus (\varepsilon_n^{-1}\Lambda^+)} (c - \delta + o(1))|v_n|^2,$$

and (51) follows from (52).

Set now $w_n = t_n|v_n|$, with the same t_n as before. The function w_n belongs to the Nehari manifold of $I_{c-\delta}$ and (51) implies that w_n is a minimizing sequence of $I_{c-\delta}$ constrained on the Nehari manifold. A standard application of Ekeland's variational principle yields a (PS) sequence $\{\tilde{w}_n\}$ for $I_{c-\delta}$ such that $|w_n| - \tilde{w}_n \to 0$ in $H^1(\mathbb{R}^3, \mathbb{R})$. By concentration-compactness arguments, there exists a sequence $\{z_n\}$ of points in $\mathbb{R}^3$ such that $w_n(\cdot - z_n)$ converges in H^1 to some w which solves

$$\Delta w - (c - \delta)w + f(|w|^2)w = 0 \quad \text{in } \mathbb{R}^3.$$

Denote $\bar{y}_n = \varepsilon_n z_n$. From (37), we can assume that, up to a subsequence, $\bar{y}_n \to \bar{y}$ in $\overline{\Lambda}$. Since

$$b^{c-\delta} \geqslant \lim_{n\to\infty} \varepsilon_n^{-3} J_{\varepsilon_n}(t_n u_n) \geqslant \lim_{n\to\infty} I(t_n|v_n|) = I_{V(\bar{y})}(\omega),$$

we have $b^{c-\delta} \geqslant b^{V(\bar{y})}$, so that $V(\bar{y}) \leqslant c - \delta$. But $\beta(u_n) \to \bar{y} \in \overline{\Lambda}$ and (50) implies $V(\bar{y}) > c - \delta/2$. This contradiction proves (49).

Step IV: We are going to find a contradiction that proves (35), which will complete the proof. Recall the validity of (49). Let $\varphi_n(y) = \pi(\beta(\phi_n(y)))$ where π: $\Lambda^+ \to \Lambda$ is a continuous mapping that equals the identity on Λ and Λ^+ is a fixed small neighborhood of Λ fixed in Step III. Now, $\phi_n(y) = w^w_{\varepsilon_n}$ for each $y \in B_0^{\varepsilon_n}$, and $w^y_{\varepsilon_n}$ is radially symmetric with respect to the point y. Therefore ϕ_n acts as the identity on $B_0^{\varepsilon_n}$. As such, map ϕ_n is admissible in the class of functions that defines the level c. Assumption (V2) implies now that $c \leqslant \sup_{y \in B_0^{\epsilon_n}} V(\varphi_n(y))$ for all $n \geqslant 1$. If n is large enough, this contradicts (49), and we have proved that (35) is true. □

Proposition 5.3: For each ε sufficiently small, the number γ_ε defined by (29) is a critical value for the functional J_ε. As a consequence, there exists a solution $u_\varepsilon \in H^\varepsilon_{A,V}$ to Eq. (23) such that $J_\varepsilon(u_\varepsilon) = \gamma_\varepsilon$. Furthermore $u_\varepsilon \in C^{2,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$, with $\alpha \in (0,1)$.

Proof: We already know from Lemma 4.1 that J_ε satisfies the (PS) condition, provided ε is small enough. Moreover, the last lemma implies that $\varepsilon^{-3}\gamma_\varepsilon \geqslant b^{c-\delta} + o(1)$ for all ε small. If $\phi \in \Gamma_\varepsilon$, then $\phi(y) = w^y_\varepsilon$ whenever $y \in B_0^\varepsilon$. This entails that

$$\sup_{y\in B_0^\varepsilon} \varepsilon^{-3} J_\varepsilon(\phi(y)) \leqslant b^{c-\delta} + o(1).$$

The proof is completed by a standard deformation argument. By standard regularity results, $u_\varepsilon \in C^{2,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$. □

VI. PROOF OF THE MAIN THEOREM

First we derive the following proposition in which the asymptotic behavior of $\max_{\partial\Lambda}|u_\varepsilon|$ is described.

Proposition 6.1: Let

$$m_\varepsilon = \max_{x\in\partial\Lambda} |u_\varepsilon(x)|,$$

then

$$\lim_{\varepsilon\to 0} m_\varepsilon = 0. \tag{53}$$

Proof: We split again the proof.

Step I: We begin to establish the following fact: if $\varepsilon_n \to 0$ and $x_n \in \overline{\Lambda}$ are such that $|u_{\varepsilon_n}(x_n)| \geqslant b > 0$, then

$$\limsup_{n\to\infty} V(x_n) \leqslant c.$$

By contradiction, we assume, up to a subsequence, that $x_n \to x^* \in \overline{\Lambda}$ and $V(x^*) > c$. Set $v_n(x) = u_{\epsilon_n}(x_n + \epsilon_n x)$, we have that v_n satisfies the equation

$$-\Delta v_n - \frac{2}{i} A(x_n + \varepsilon_n x)\cdot \nabla v_n + |A(x_n+\epsilon_n x)|^2 v_n - \frac{\varepsilon_n}{i}\operatorname{div} A(x_n+\varepsilon_n x) v_n + V(x_n+\varepsilon_n x) v_n = g(x_n+\varepsilon_n x, |v_n|^2) v_n \quad \text{in } \mathbb{R}^3 \tag{54}$$

By reasoning as in Step II of Lemma 2, $\{v_n\}$ converges in $C^2_{\mathrm{loc}}(\mathbb{R}^3)$ to some v. Let χ be the weak * limit in $L^\infty(\mathbb{R}^3)$ of the sequence $\{\chi_\Lambda(x_n+\varepsilon_n\cdot)\}$, $v \in C^2_{\mathrm{loc}}(\mathbb{R}^3)$ solves the equation in each compact set

$$-\Delta v - \frac{2}{i} A(x^*)\cdot \nabla v + |A(x^*)|^2 v + V(x^*) v = \bar{g}(x, |v|^2) v \quad \text{in } \mathbb{R}^3, \tag{55}$$

where $\bar{g}(x,s) = \chi(x) f(s) + (1-\chi(x))\tilde{f}(s)$ and $0 \leqslant \chi \leqslant 1$. Since $v \in H^1(\mathbb{R}^3, \mathbb{C})$, we infer v solves (46) in weak sense. Setting $\tilde{v}(x) = e^{-iA(x^*)\cdot x} v(x)$, we see that $\tilde{v}$ weakly solves

$$-\Delta \tilde{v} + V(x^*)\tilde{v} = \bar{g}(x, |\tilde{v}|^2)\tilde{v} \quad \text{in } \mathbb{R}^3 \tag{56}$$

Let $\bar{J}$: $H^1(\mathbb{R}, \mathbb{C}) \to R$ be the functional defined by

$$\bar{J}(u) = \frac{1}{2}\int_{\mathbb{R}^3} |\nabla u|^2 + V(x^*)|u|^2 - \int_{\mathbb{R}^3} \bar{G}(x, |u|^2),$$

where $\bar{G}(x,s) = \int_0^s \bar{g}(x,t)\mathrm{d}t$, we observe that $\tilde{v}$ is a critical point of $\bar{J}$. Following Step II of Lemma 5.2, one can prove that

$$\bar{J}(\tilde{v}) \leqslant \liminf_{n\to\infty} J_{\varepsilon_n}(v_n). \tag{57}$$

By (57) and taking into account (30) we deduce that $b^c \geqslant \bar{J}(\tilde{v})$. Since $h(s) \geqslant \tilde{h}(s)$ for all s we derive

$$b^c \geqslant \bar{J}(\tilde{v}) = \max_{\tau \geqslant 0} \bar{J}(\tau v) \geqslant \max_{\tau \geqslant 0} I_{V(x^*)}(tv) \geqslant b^{V(x^*)},$$

where

$$I_{V(x^*)}(u) = \frac{1}{2}\int_{\mathbb{R}^3} |\nabla u|^2 + V(x^*)|u|^2 - \int_{\mathbb{R}^3} F(|u|^2).$$

It follows that $V(x^*) \leqslant c$, which contradicts the fact that $V(x^*) > c$.

Step II: Now we pass to prove (53). By contradiction, we assume, up to a subsequence, that there exists a sequence $x_n \in \partial\Lambda$ such that $x_n \to \bar{x} \in \overline{\partial\Lambda}$ and

$$|u_{\varepsilon_n}(x_n)| \geqslant \gamma > 0. \tag{58}$$

It follows that $V(\bar{x}) \leqslant c$. We claim that $V(\bar{x}) > c - \delta$. By contradiction, we suppose that $V(\bar{x}) = c - \delta$.

Arguing as before, we can consider the scaled sequence $v_n(x) = u_{\varepsilon_n}(x_n + \varepsilon_n x)$, and we can deduce that v_n solves (45) and it converges to some $v \in H^1(\mathbb{R}^3, \mathbb{C})$ in $C^2_{\mathrm{loc}}(\mathbb{R}^3)$, up to subsequences and $v \neq 0$. Moreover v weakly solves the equation

$$-\Delta v - \frac{2}{i}A(\bar{x}) \cdot \nabla v + |A(\bar{x})|^2 v + V(\bar{x})v = \bar{g}(x, |v|^2)v \quad \text{in } \mathbb{R}^3, \tag{59}$$

where $\bar{g}(x,s) = \chi(x)f(s) + (1 - \chi(x))\tilde{f}(s)$.

Setting $\tilde{v}(x) = e^{-iA(\bar{x})\cdot x}v(x)$, we see that $\tilde{v}$ weakly solves

$$-\Delta \tilde{v} + V(\bar{x})\tilde{v} = \bar{g}(x, |\tilde{v}|^2)\tilde{v} \quad \text{in } \mathbb{R}^3 \tag{60}$$

and thus $\tilde{v}$ is a critical point of the functional $\bar{I}$: $H^1(\mathbb{R}^3, \mathbb{C}) \to \mathbb{R}$ defined by

$$\bar{I}(u) = \frac{1}{2}\int_{\mathbb{R}^3} |\nabla u|^2 + V(\bar{x})|u|^2 - \int_{\mathbb{R}^3} \bar{G}(x, |u|^2),$$

where $\bar{G}(x,s) = \int_0^s \bar{g}(x,t)\mathrm{d}t$.

Now for any $n \in N$ we consider the positive measure $\mu_n(\Omega) = \int_\Omega |\nabla |v_n||^2 + V(x_n + \varepsilon_n x)|v_n|$. We have that the sequence $\{\mu_n(\mathbb{R}^3)\}_n$ is bounded and, up to subsequences, μ_n tends to some $\tilde{c}$.

Therefore there exists a subsequence of $\{\mu_n\}_n$ (without relabelling) for which one of the three possibilities of Lions' concentration-compactness lemma (see Ref. 25) holds. First we notice that vanishing cannot occur, as $|v(0)| > 0$.

If we have tightness, we derive that there exists z_n with the following property: for any $\gamma > 0$ there exists $\rho > 0$ such that

$$\int_{B_\rho(z_n)} |\nabla |v_n||^2 + V(x_n + \varepsilon_n x)|v_n| \geqslant \tilde{c} - \gamma.$$

If $\varepsilon_n z_n$ tends to some point $y \in \mathbb{R}^3$, then we derive that $|v_n|$ tends to $|v|$ strongly in $H^1(\mathbb{R}^3, \mathbb{R})$ and thus $|v_n|$ tends to $|v|$ strongly in $L^q(\mathbb{R}^3, \mathbb{R})$ with $q < 5$.

Testing Eq. (45) we get that

$$\int_{\mathbb{R}^3} \left| \left(\frac{\nabla}{i} - A_n(x) \right) v_n \right|^2 + V_n(x)|v_n|^2 = \int_{\mathbb{R}^3} \bar{g}(x, |v_n|^2)|v_n|^2$$

and, since $\int \bar{g}(x, |v_n|^2)|v_n|^2 \to \int \bar{g}(x, |v|^2)|v|^2$ and v solves (60) we deduce

$$\int_{R^3}\left|\left(\frac{\nabla}{i}-A_n(x)\right)v_n\right|^2+V_n(x)|v_n|^2\to\int_{R^3}\left|\left(\frac{\nabla}{i}-A(\bar{x})\right)v\right|^2+V(\bar{x})|v|^2 \tag{61}$$

and so

$$b^c\geqslant\lim_n\varepsilon_n^{-3}J_{\varepsilon_n}(u_n)=\bar{I}(\tilde{v}).$$

After a rotation, by Lemma 5.1, $\tilde{v}$ solves

$$-\Delta\tilde{v}+V(\bar{x})\tilde{v}=f(|\tilde{v}|^2)\tilde{v}$$

and since we have assumed $V(\bar{x})=c-\delta$, we get $\bar{I}(\tilde{v})=b^{c-\delta}$. This is a contradiction to (35).

Conversely, if $|\varepsilon_n z_n|\to\infty$, we can conclude that

$$b^c\geqslant\lim_n\varepsilon_n^{-3}J_{\varepsilon_n}(u_n)=b^{c-\delta}+b^{V_0}$$

which, by the continuity of $a\mapsto b^a$, is not possible if δ is chosen sufficiently small. In a similar way we can infer that dichotomy cannot occur.

Therefore $V(\bar{x})>c-\delta$ and $|v_n|\to|v|$ strongly in $H^1(\mathbb{R}^3,\mathbb{R})$ as $n\to+\infty$.

Step III: Observe that we can assume that δ was fixed so that $\bar{x}$ lies in a region where $\partial\Lambda$ is smooth and $\partial_\tau V(\bar{x})\neq 0$.

Arguing as in Ref. 14 we can assume $\bar{x}=0$ and the domain Λ can be described as

$$\Lambda\cap B(0,2\rho)=\{(x,x')\in B(0,2\rho)|x'\in\mathbb{R}^2,\ x_3<\psi(x')\},$$

where ψ is a smooth function such that $\psi(0)=0$ and $\nabla\psi(0)=0$. So we have that in $B(0,\rho/\varepsilon_n)v_n$ satisfies

$$\begin{aligned}&-\Delta v_n-\frac{2}{i}A(x_n+\varepsilon_n x)\cdot\nabla v_n+|A(x_n+\varepsilon_n x)|^2v_n-\frac{\varepsilon_n}{i}\operatorname{div}A(x_n+\varepsilon_n x)v_n+V(x_n+\varepsilon_n x)v_n\\&=\chi_{\{z_3<\varepsilon^{-1}\psi(\varepsilon z')\}}f(|v_n|^2)v_n+\chi_{\{z_3>\varepsilon^{-1}\psi(\varepsilon z')\}}\tilde{f}(|v_n|^2)v_n.\end{aligned} \tag{62}$$

Since $|v_n|$ converges to $|v|$ strongly in $H^1(\mathbb{R}^3,\mathbb{R})$, arguing as in Ref. 21 or in Ref. 31 we derive that $|v_n(z)|\leqslant Ce^{-\beta|z|}$ for some constants C, β independent of n. Recalling that each v_n is complex valued, it is not so easy to prove a similar decaying behavior for the gradients ∇v_n, too. Hence we need to modify the proof in Ref. 14. The main tool is a kind of variational identity inspired to the celebrated Pucci–Serrin identity in Ref. 28 (see also Ref. 12). Since all the details for deriving this identity for complex-valued solutions to the Schrödinger equation with magnetic field can be found in Ref. 31, we will be rather sketchy. Fix the index $n\geqslant 1$, and choose a sequence $\{\psi_h\}_{h\in\mathbb{N}}$ of functions from $C_0^\infty(B(0,\rho/\varepsilon_n))$ such that their supports converge to $B(0,\rho/\varepsilon_n)$ as $h\to+\infty$. Now multiply equation (62) by $\psi_h(\partial v_n/\partial x_k)$ $(k=1,2)$ and integrate by parts. By reasoning as in Ref. 31 and exploiting (8) and (9), we can show that it is possible to take first the limit as $h\to\infty$ and then the limit $n\to\infty$, finally deducing that

$$\begin{aligned}&\int_{\mathbb{R}^3}\frac{\partial A}{\partial x_k}(0)\cdot A(0)|v|^2\,\mathrm{d}x-\mathrm{Re}\frac{1}{i}\int_{\mathbb{R}^3}\nabla v\cdot\frac{\partial A}{\partial x_k}(0)\bar{v}\,\mathrm{d}x+\frac{\partial V}{\partial x_k}(0)\int_{\mathbb{R}^3}\frac{|v|^2}{2}\mathrm{d}x\\&=\int_{\mathbb{R}^2}\left[F(|v|^2)-\tilde{F}(|v|^2)\right]z'\cdot\nabla\frac{\partial\psi}{\partial x_k}(0)\mathrm{d}z'.\end{aligned}$$

If we define U_0 by $v(x)=e^{iA(0)\cdot x}U_0(x)$, then $U_0\in H^1(\mathbb{R}^3,\mathbb{C})$ satisfies the identity

$$-\Delta U_0 + V(0)U_0 = \chi_{\{z_3<\psi(0)\}} f(|U_0|^2)U_0 + \chi_{\{z_3>\psi(0)\}} \tilde{f}(|U_0|^2)U_0.$$

Hence by Lemma 5.1 (after a suitable rotation) and an elementary calculation we conclude that

$$\frac{\partial A}{\partial x_k}(0) \cdot \int_{\mathbb{R}^3} \mathrm{Re}(i\overline{U}_0 \nabla U_0)\mathrm{d}x + \frac{\partial V}{\partial x_k}(0) \int_{\mathbb{R}^3} \frac{|U_0|^2}{2}\mathrm{d}x = 0.$$

But by the uniqueness of critical points for the functional I_a [see assumption (f2) and the arguments in Ref. 31], $\mathrm{Re}(i\overline{U}_0 \nabla U_0)=0$ a.e. in $\mathbb{R}^3$. This immediately implies that $(\partial V/\partial x_k)(0)=0$ for $k=1,2$ and so $\partial_\tau V(\bar{x})=0$. This contradiction complete the proof. □

Finally we prove the main result. For the reader's convenience, we repeat its statement below.

Main Theorem: *Under assumptions* (f1) and (f2), (A1), (V1–V3), *there is a number* $\varepsilon_0>0$ *such that for all* $\varepsilon<\varepsilon_0$, *there exists a solution* $u_\varepsilon \in H^\varepsilon_{A,V}$ *of* Eq. (6). *Furthermore* $u_\varepsilon \in C^{2,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$ *with* $\alpha \in (0,1)$.

Proof: By Proposition 6.1, for all ε small enough,

$$|u_\varepsilon(x)| < \sqrt{a} \quad \text{for all } x \in \partial\Lambda.$$

The function u_ε satisfies the equation

$$\left(\frac{\varepsilon}{i}\nabla - A\right)^2 u_\varepsilon + Vu_\varepsilon = g(x,|u_\varepsilon|^2)u_\varepsilon \quad \text{in } \mathbb{R}^3. \tag{63}$$

Therefore we can test (63) against $(|u_\varepsilon|-\sqrt{a})_+$, and recalling Kato's inequality we find

$$\int_{\mathbb{R}^3\setminus\Lambda} \varepsilon^2 |\nabla (|u_\varepsilon| - \sqrt{a})_+|^2 + c(x)(|u_\varepsilon| - \sqrt{a})_+^2 + c(x)\sqrt{a}(|u_\varepsilon| - \sqrt{a})_+ \leqslant 0, \tag{64}$$

where

$$c(x) = V(x) - g(x,|u_\varepsilon(x)|^2).$$

By definition of g, we have $c>0$ in $\mathbb{R}^3\setminus\Lambda$. Hence all terms in (64) are necessarily zero, and in particular

$$|u_\varepsilon(x)| \leqslant \sqrt{a} \quad \text{for all } x \in \mathbb{R}^3 \setminus \Lambda.$$

This, of course, implies that u_ε is a solution of (6). □

(Received 28 July 2004; accepted 10 February 2005; published online 8 April 2005)

It is well known that integrable models associated to rational R matrices give rise to certain non-Abelian symmetries known as Yangians. Analogously boundary symmetries arise when general but still integrable boundary conditions are implemented, as originally argued by Delius, Mackay, and Short from the field theory point of view, in the context of the principal chiral model on the half-line. In the present study we deal with a discrete quantum mechanical system with boundaries, that is the N site gl(n) open quantum spin chain. In particular, the open spin chain with two distinct types of boundary condition known as soliton preserving and soliton nonpreserving is considered. For both types of boundaries we present a unified framework for deriving the corresponding boundary nonlocal charges directly at the quantum level. The nonlocal charges are simply coproduct realizations of particular boundary quantum algebras called boundary or twisted Yangians, depending on the choice of boundary conditions. Finally, with the help of linear intertwining relations between the solutions of the reflection equation and the generators of the boundary or twisted Yangians we are able to exhibit the exact symmetry of the open spin chain, namely we show that a number of the boundary nonlocal charges are in fact conserved quantities. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1888029]

I. INTRODUCTION

Symmetry breaking mechanisms have been the subject of immense interest in modern physics. A well-known symmetry breaking process in the context of two dimensional integrable systems is the implementation of general boundaries that preserve however integrability.[1,2] The presence of general integrable boundaries usually reduces the original symmetry of the system giving rise to boundary algebraic structures known as boundary quantum groups (algebras) (see, e.g., Refs. 3–6). The boundary quantum groups are essentially subalgebras of the usual quantum groups,[7–10] and they provide the underlying algebraic structures in the reflection equation[1] exactly as quantum groups do in the Yang–Baxter equation.[11–13] As is well known the Yang–Baxter and reflection equations are collections of algebraic constraints ruling two dimensional integrable models with boundaries. The study of such boundary symmetries for a particular class of integrable systems will be the main objective of this investigation.

The present work may be seen as the continuation of the investigation undertaken in Ref. 6, where the boundary quantum group generators for the open XXZ spin chain, were constructed by studying the asymptotics of the open spin chain. Historically, boundary quantum group generators were obtained for the first time in the context of the sine-Gordon model in the free fermion point,[3] whereas in Ref. 14 realizations of such generators were constructed for models associated to higher rank algebras. In Ref. 4 the boundary quantum group was derived for the affine Toda field theories on the half-line, and solutions of the reflection equation associated to a certain type of boundary conditions were found. Also, boundary nonlocal charges were constructed classically, in

[a)]Electronic mail: doikou@lapp.in2p3.fr

the framework of the principal chiral model on the half-line,[5] for two distinct types of boundary conditions known as soliton preserving (SP) (Refs. 15–18) and soliton nonpreserving (SNP).[19–22]

In this paper we focus on the quantum mechanical system that is the N site gl(n) open quantum spin chain, and we consider two types of boundary conditions, i.e., SP and SNP. For both types of boundaries the corresponding nonlocal charges are constructed in a systematic way by studying the asymptotics of the gl(n) open spin chain. It turns out that the nonlocal charges are simply coproducts of certain boundary quantum algebras called boundary or twisted Yangians,[23–25] depending on the choice of boundary conditions. It is worth remarking that in Ref. 5 linear intertwining relations involving the boundary algebra generators were used as the starting point for deriving solutions of the reflection equation for both types of boundary conditions. In the present study on the other hand we start our analysis having at our disposal c-number solutions of the reflection equation, and we simply exploit the existence of the intertwining relations in order to derive the symmetry of the open spin chain (see also Ref. 6). In fact, we show explicitly that a set of the boundary nonlocal charges are conserved quantities, that is they commute with the transfer matrix of the open spin chain. It should be pointed out that our results rely on purely algebraic grounds, and therefore they are independent of the choice of representation.

II. THE UNDERLYING ALGEBRAS

In general, two types of spin chains exist known as closed (e.g., periodic boundary conditions) and open. To construct and study a periodic spin chain one must first introduce the basic building block, namely the $R(\mathcal{L})$ matrix satisfying the Yang–Baxter equation.[11–13] The construction of an open spin chain on the other hand requires the consideration of one more fundamental object called the $\mathcal{K}$ matrix, which satisfies another set of algebraic constraints known as the reflection equation.[1] The main objective of the two subsequent sections is to introduce the aforementioned fundamental objects, and also briefly describe the corresponding algebraic framework.

A. The Yang–Baxter equation

Let us first introduce the gl(n)R matrix, which is a solution of the Yang–Baxter equation,[11–13]

$$R_{12}(\lambda_1-\lambda_2)R_{13}(\lambda_1)R_{23}(\lambda_2)=R_{23}(\lambda_2)R_{13}(\lambda_1)R_{12}(\lambda_1-\lambda_2), \tag{2.1}$$

acting on $\mathbb{V}\otimes\mathbb{V}\otimes\mathbb{V}$, and as usual $R_{12}=R\otimes\mathbb{I}$, $R_{23}=\mathbb{I}\otimes R$, and so on. The R matrix may be written in the following compact form:

$$R(\lambda)=\mathbb{I}+\frac{i}{\lambda}\mathcal{P}, \tag{2.2}$$

where $\mathcal{P}$ is the permutation operator, acting on $(\mathbb{C}^n)^{\otimes 2}$ with

$$\mathcal{P}(a\otimes b)=b\otimes a \quad \text{and } \mathcal{P}^2=\mathbb{I}. \tag{2.3}$$

In addition, the R matrix satisfies the unitarity condition,

$$R(\lambda)\hat{R}(-\lambda)\propto\mathbb{I} \quad \text{where } \hat{R}(\lambda)=\mathcal{P}\,R(\lambda)\mathcal{P}. \tag{2.4}$$

Notice that $R(\lambda)\in\mathrm{End}(\mathbb{C}^n\otimes\mathbb{C}^n)$, however in general one may define the object $\mathcal{L}(\lambda)\in\mathrm{End}(\mathbb{C}^n)\otimes\mathcal{Y}[\lambda^{-1}]$, where the second space is not represented, but it is occupied by elements of the algebra $\mathcal{Y}$ called the gl(n) Yangian,[8,9] and defined by the following fundamental algebraic relation:

$$R_{12}(\lambda_1-\lambda_2)\mathcal{L}_{13}(\lambda_1)\mathcal{L}_{23}(\lambda_2)=\mathcal{L}_{23}(\lambda_2)\mathcal{L}_{13}(\lambda_1)R_{12}(\lambda_1-\lambda_2). \tag{2.5}$$

It is worth pointing out that the asymptotic expansion of $\mathcal{L}(\lambda)$ to powers of λ^{-1} yields the generators of the Yangian, which satisfy exchange relations dictated by (2.5). A more detailed analysis on the Yangian will be presented in Sec. III. A solution of the fundamental equation (2.5), which we shall use hereafter, may take the following simple form:

$$\mathcal{L}(\lambda) = \mathbb{I} + \frac{i}{\lambda}\mathbb{P}. \tag{2.6}$$

$\mathbb{P}$ is an $n \times n$ matrix with entries $\mathbb{P}_{ab} \in \mathrm{gl}(n)$.

The Yangian (2.5) is a Hopf algebra equipped with a coproduct $\Delta : \mathcal{Y} \to \mathcal{Y} \otimes \mathcal{Y}$,

$$(\mathrm{id} \otimes \Delta)\mathcal{L}(\lambda) = \mathcal{L}_{13}(\lambda)\mathcal{L}_{12}(\lambda), \tag{2.7}$$

and by treating $\mathcal{L}$ as an $n \times n$ matrix with entries $\mathcal{L}_{ab}$ being elements of $\mathcal{Y}$, we conclude that

$$\Delta(\mathcal{L}_{ab}(\lambda)) = \sum_{c=1}^{n} \mathcal{L}_{cb}(\lambda) \otimes \mathcal{L}_{ac}(\lambda), \quad a,b \in \{1,\ldots,n\}. \tag{2.8}$$

It will be helpful for the following to also introduce $\Delta' : \mathcal{Y} \to \mathcal{Y} \otimes \mathcal{Y}$ obtained from Δ by permutation. In particular, let Π be the shift operator $\Pi : \mathcal{O}_1 \otimes \mathcal{O}_2 \to \mathcal{O}_2 \otimes \mathcal{O}_1$ then one may write

$$\Delta'(x) = \Pi \circ \Delta(x), \quad x \in \mathcal{Y}. \tag{2.9}$$

Also, by iteration the l coproduct $\Delta^{(l)} : \mathcal{Y} \to \mathcal{Y}^{\otimes(l)}$ may be written as

$$\Delta^{(l)} = (\mathrm{id} \otimes \Delta^{(l-1)})\Delta. \tag{2.10}$$

By considering tensor products of $\mathcal{Y}$ one may construct the periodic spin chain. Let us first define the algebraic monodromy matrix T as tensor product of N $\mathcal{L}$ matrices, i.e.,

$$T_0(\lambda) = (\mathrm{id} \otimes \Delta^{(N)})\mathcal{L}(\lambda) = \mathcal{L}_{0N}(\lambda) \cdots \mathcal{L}_{01}(\lambda), \tag{2.11}$$

the monodromy matrix $T \in \mathrm{End}(\mathbb{C}^n) \otimes \mathcal{Y}^{\otimes N}$ is also a solution of (2.5). Traditionally the indices $i \in \{1,\ldots,N\}$ are associated to the quantum spaces and they are suppressed from the monodromy matrix (2.11), whereas the index 0 corresponds to the so-called auxiliary space. Finally, the transfer matrix of the periodic spin chain is derived by simply taking the trace over the auxiliary space,

$$t(\lambda) = Tr_0 T_0(\lambda), \tag{2.12}$$

and it is clear that $t(\lambda) \in \mathcal{Y}^{\otimes N}$. It follows immediately from (2.5) that the transfer matrix (2.12) provides a family of commuting operators,

$$[t(\lambda), t(\lambda')] = 0, \tag{2.13}$$

ensuring the integrability of the model. Each quantum space in (2.11) and (2.12) is associated to a copy of $\mathcal{Y}$, and the corresponding sequence of N copies of $\mathcal{Y}$ described by (2.11) and (2.12) is a purely algebraic construction. It acquires a physical meaning as a spin chain once the quantum spaces are mapped to finite or infinite dimensional spaces. Then the spectrum of the transfer matrix and the corresponding Bethe ansatz equations can be derived and the physically relevant quantities may be computed.[26]

B. The reflection equation

In the following two distinct types of boundary conditions SP, SNP are described using a unified framework, and the corresponding spin chains are constructed. As mentioned, in order to build the open spin chain an additional fundamental object needs to be considered, that is the $\mathcal{K}^*$ matrix, which is a solution of the reflection equation[1]

$$R_{12}(\lambda_1 - \lambda_2)\mathcal{K}_1^*(\lambda_1)R_{21}^*(\lambda_1 + \lambda_2)\mathcal{K}_2^*(\lambda_2) = \mathcal{K}_2^*(\lambda_2)R_{12}^*(\lambda_1 + \lambda_2)\mathcal{K}_1^*(\lambda_1)R_{21}(\lambda_1 - \lambda_2) \tag{2.14}$$

acting on $\mathbb{V} \otimes \mathbb{V}$, and as customary $\mathcal{K}_1^* = \mathcal{K}^* \otimes \mathbb{I}$, $\mathcal{K}_2^* = \mathbb{I} \otimes \mathcal{K}^*$. We also introduce the notation,

$$\mathcal{K}^*(\lambda) = \mathcal{K}(\lambda), \quad R^*(\lambda) = R(\lambda) \quad \text{for SP b . c . ,}$$

$$\mathcal{K}^*(\lambda) = \overline{\mathcal{K}}(\lambda), \quad R^*(\lambda) = \overline{R}(\lambda) \quad \text{for SNP bc . ,} \tag{2.15}$$

and we define

$$\overline{R}_{12}(\lambda) = f(\lambda)V_1 R_{12}^{t_2}(-\lambda - i\rho)V_1 = f(\lambda)V_2^{t_2}R_{12}^{t_1}(-\lambda - i\rho)V_2^{t_2},$$

$$\rho = \frac{n}{2}, \quad f(\lambda) = \frac{\lambda + i\rho}{\lambda}, \tag{2.16}$$

$\overline{R}_{21}(\lambda) = \overline{R}_{12}(\lambda)^{t_1 t_2}$, t_i denotes the transposition on the ith space. V is the charge conjugation being of the form

$$V = \text{antidiag}(1,1,\ldots,1,1), \quad n \quad \text{odd and even, or}$$

$$V = \text{antidiag}(i,-i,\ldots,i,-i), \quad n \quad \text{even only.} \tag{2.17}$$

The $\overline{R}$ matrix may be also written in a compact form as

$$\overline{R}(\lambda) = \frac{\lambda + i\rho}{\lambda}\mathbb{I} - \frac{i}{\lambda}K = \mathbb{I} + \frac{i}{\lambda}\check{\mathcal{P}}, \tag{2.18}$$

where K is a one-dimensional projector satisfying

$$K\,\mathcal{P} = \mathcal{P}, \quad K = \pm K, \quad K^2 = nK, \tag{2.19}$$

and consequently $\check{\mathcal{P}}^2 = \rho^2\mathbb{I}$. For the special case $n=2$, it is clear that $\check{\mathcal{P}} = \mathcal{P}$. Relation (2.14) defines the so-called reflection algebra (boundary Yangian)[2,27–30] or the twisted Yangian[23–25] depending on the action of $*$ (2.15). Let us denote the boundary or twisted Yangian as $\mathbb{B}^*$, more specifically

$$\mathbb{B}^* = \mathbb{B} \text{ boundary Yangian for SP b . c . , } \quad \mathbb{B}^* = \overline{\mathbb{B}} \text{ twisted Yangian for SNP b . c.} \tag{2.20}$$

It should be noted that from the physical point of view SP b.c. describe the reflection of a soliton to a soliton, while SNP b.c. describe the reflection of a soliton to an antisoliton.

The general form of the gl(n)c-number $\mathcal{K}^*$ matrix is given by[1]

$$\mathcal{K}^*(\lambda) = \lambda k^* + f^*, \tag{2.21}$$

where f^*, k^* are $n \times n$ λ independent matrices with $f^* = f$ or $\overline{f}$ and $k^* = k$ or $\overline{k}$ for SP and SNP bc., respectively. For SP b

c. in particular, $f = i\xi\mathbb{I}$ and k is a $n \times n$ λ independent matrix with nonzero entries given by[17]

$$k_{11}(\lambda) = -1, \quad k_{nn}(\lambda) = 1, \quad k_{1n}(\lambda) = k_{n1}(\lambda) = 2\kappa,$$

$$k_{jj}(\lambda) = 1 + 2c, \quad j = 2,\ldots,n-1, \tag{2.22}$$

with ξ arbitrary constant, and c, κ constants satisfying $\kappa^2 = c(c+1)$ (see also Ref. 17), so there are two arbitrary boundary parameters ξ and κ. Notice that the entries of the $\mathcal{K}$ matrix are simply c numbers and this is the reason why (2.22) is called a c-number solution of the reflection equation.

Although certain solutions $\overline{\mathcal{K}}$ (SNP) of (2.14) have been derived for the trigonometric[4,20] and rational case,[5,22] the situation is not completely clear yet for this type of boundary conditions. Nevertheless, assuming the general form (2.21) for the c-number $\overline{\mathcal{K}}$ matrix is sufficient for our analysis. It is evident that the gl(2) case is rather special, because $R_{12} - \overline{R}_{12}$ [by choosing the second V in (2.17)], and consequently $\mathcal{K} = \overline{\mathcal{K}}$.

Having at our disposal *c*-number solutions of (2.14) we may build the more general form of solution. To do so it is first necessary to define the following objects:

$$\hat{\mathcal{L}}_{12}(\lambda) = \mathcal{L}_{12}^{-1}(-\lambda), \quad \overline{\mathcal{L}'}(\lambda) = f(\lambda) V_1^{t_1} \mathcal{L}_{12}^{t_1}(-\lambda - i\rho) V_1^{t_1} \tag{2.23}$$

and

$$\mathcal{L}^*(\lambda) = \hat{\mathcal{L}}(\lambda), \quad \text{for SP b . c . }, \quad \mathcal{L}^*(\lambda) = \overline{\mathcal{L}'}(\lambda) \quad \text{for SNP b . c.} \tag{2.24}$$

It will be instructive for the following to present explicit expressions of the $\mathcal{L}^*$. Although the expressions for $\mathcal{L}^{-1}$ and consequently $\hat{\mathcal{L}}$ are quite intricate, fortunately for our purposes it is only necessary to consider the asymptotic behavior as $\lambda \to \infty$, keeping terms up to $1/\lambda^2$,

$$\hat{\mathcal{L}}_{12}(\lambda \to \infty) \propto \mathbb{I} + \frac{i}{\lambda}\mathbb{P}_{12} - \frac{1}{\lambda^2}\mathbb{P}_{12}^2 + \mathcal{O}\left(\frac{1}{\lambda^3}\right) \quad \text{and} \quad \overline{\mathcal{L}'}_{12}(\lambda) = \mathbb{I} + \frac{i}{\lambda}\check{\mathbb{P}}_{12}, \tag{2.25}$$

where

$$\check{\mathbb{P}}_{12} = \rho\mathbb{I} - V_1^{t_1}\mathbb{P}_{12}^{t_1}V_1^{t_1}. \tag{2.26}$$

And more specifically, $\hat{R}(\lambda)$ is provided by (2.4), and $\overline{R'}(\lambda) = \mathcal{P}\,\overline{R}(\lambda)\mathcal{P}$.

The more general solution of (2.14) is then given by[2]

$$\mathbb{K}^*(\lambda) = \mathcal{L}(\lambda - \Theta)(\mathcal{K}^*(\lambda) \otimes \mathbb{I})\mathcal{L}^*(\lambda + \Theta). \tag{2.27}$$

Θ some times is called inhomogeneity and henceforth for simplicity we shall consider it to be zero. The entries of $\mathbb{K}^*$ are elements of the $\mathbb{B}^*$ algebra defined by (2.14). It is clear that the general solution (2.27) allows the expansion in powers of λ^{-1} as we shall see in subsequent sections, providing the generators of the boundary Yangian (for SP) or the twisted Yangian (for SNP), which obey commutation relations dictated by the defining algebraic relations (2.14). The algebra $\mathbb{B}^*$ is also endowed with a coproduct inherited essentially from the Yangian. In particular, let us first derive the coproduct for $\mathcal{L}^*$, i.e.,

$$(\mathrm{id} \otimes \Delta)\mathcal{L}^*(\lambda) = \mathcal{L}_{12}^*(\lambda)\mathcal{L}_{13}^*(\lambda) \to \Delta(\mathcal{L}_{ab}^*(\lambda)) = \sum_{c=1}^{n} \mathcal{L}_{ac}^*(\lambda) \otimes \mathcal{L}_{cb}^*(\lambda), \quad a,b \in \{1,\ldots,n\}. \tag{2.28}$$

Then it is clear from (2.8) and (2.28) that the elements of $\mathbb{B}^*$ form coproducts $\Delta : \mathbb{B}^* \to \mathbb{B}^* \otimes \mathcal{Y}$, such that (see also Refs. 4 and 5)

$$\Delta(\mathbb{K}_{ab}^*(\lambda)) = \sum_{k,l=1}^{n} \mathbb{K}_{kl}^*(\lambda) \otimes \mathcal{L}_{ak}(\lambda)\mathcal{L}_{lb}^*(\lambda), \quad a,b \in \{1,\ldots,n\}. \tag{2.29}$$

Our final aim of course is to build the corresponding quantum system that is the open quantum spin chain. For this purpose we shall need tensor product realizations of the general solution (2.27). We define

$$T_0^*(\lambda) = (\mathrm{id} \otimes \Delta^{(N)})\mathcal{L}^*(\lambda) = \mathcal{L}_{01}^*(\lambda) \cdots \mathcal{L}_{0N}^*(\lambda) \tag{2.30}$$

then the general tensor type solution of the (2.14) takes the form

$$\mathcal{T}_0^*(\lambda) = T_0(\lambda)\mathcal{K}_0^*(\lambda)T_0^*(\lambda), \tag{2.31}$$

with entries being clearly coproducts of the $\mathbb{B}^*$ algebra, namely

$$\mathcal{T}^{*}_{ab}(\lambda) = \Delta^{(N)}(\mathbb{K}_{ab}(\lambda)) \tag{2.32}$$

recall that $\Delta^{(N)}$ is defined via (2.10), and $\Delta(\mathbb{K}_{ab})$ is given in (2.29). Finally, we introduce the transfer matrix of the open spin chain,[2] which may be written as

$$t^{*}(\lambda) = Tr_0 \mathcal{K}^{(+)*}_0(\lambda)\mathcal{T}^{*}_0(\lambda), \tag{2.33}$$

$\mathcal{K}^{(+)*}(\lambda) = \mathcal{K}^{(l)*}(-\lambda - i\rho)$, where $\mathcal{K}^{(l)*}(\lambda)$ is also a solution of (2.14), but here for simplicity is considered to be $\mathbb{I}$. The $*$ notation for the aforementioned objects is applied as follows:

$$T^{*}(\lambda) = \hat{T}(\lambda), \quad \mathcal{T}^{*}(\lambda) = \mathcal{T}(\lambda), \quad t^{*}(\lambda) = t(\lambda), \quad \text{for SP b . c . ,}$$

$$T^{*}(\lambda) = \overline{T}(\lambda), \quad \mathcal{T}^{*}(\lambda) = \overline{\mathcal{T}}(\lambda), \quad t^{*}(\lambda) = \overline{t}(\lambda), \quad \text{for SNP b . c.} \tag{2.34}$$

It can be shown,[2,21] using the fact that $\mathcal{T}^{*}$ is a solution of the reflection equation (2.14), that the transfer matrices (2.33) provide families of commuting operators, i.e.,

$$[t^{*}(\lambda), t^{*}(\lambda')] = 0. \tag{2.35}$$

The latter commutation relations (2.35) ensure the integrability of the relevant models.

III. MORE ON YANGIANS

It is instructive for what follows to recall in more detail the basic definitions associated to Yangians[8,31] (for a review on Yangians see, e.g., Ref. 32). The gl(n) Yangian $\mathcal{Y}$, is a non-Abelian algebra—a quantum group[9,10]—with generators $\mathcal{Q}^{(p)}_{ab}$ and defining relations given below

$$[\mathcal{Q}^{(0)}_{ab}, \mathcal{Q}^{(0)}_{cd}] = i\delta_{cb}\mathcal{Q}^{(0)}_{ad} - i\delta_{ad}\mathcal{Q}^{(0)}_{cb},$$

$$[\mathcal{Q}^{(0)}_{ab}, \mathcal{Q}^{(1)}_{cd}] = i\delta_{cb}\mathcal{Q}^{(1)}_{ad} - i\delta_{ad}\mathcal{Q}^{(1)}_{cb},$$

$$[\mathcal{Q}^{(1)}_{ab}, \mathcal{Q}^{(1)}_{cd}] = i\delta_{cb}\mathcal{Q}^{(2)}_{ad} - i\delta_{ad}\mathcal{Q}^{(2)}_{cb} + \frac{ih^2}{4}\mathcal{Q}^{(0)}_{ad}\left(\sum_e \mathcal{Q}^{(0)}_{ce}\mathcal{Q}^{(0)}_{eb}\right) - \frac{ih^2}{4}\left(\sum_e \mathcal{Q}^{(0)}_{ae}\mathcal{Q}^{(0)}_{ed}\right)\mathcal{Q}^{(0)}_{cb},$$

$$a, b \in \{1, \ldots, n\}, \tag{3.1}$$

and also relations

$$[\mathcal{Q}^{(0)}_{ab}, [\mathcal{Q}^{(1)}_{cd}, \mathcal{Q}^{(1)}_{ef}]] - [\mathcal{Q}^{(1)}_{ab}, [\mathcal{Q}^{(0)}_{cd}, \mathcal{Q}^{(1)}_{ef}]] = \frac{h^2}{4}\sum_{p,q}([\mathcal{Q}^{(0)}_{ab}, [\mathcal{Q}^{(0)}_{cp}\mathcal{Q}^{(0)}_{pd}, \mathcal{Q}^{(0)}_{eq}\mathcal{Q}^{(0)}_{qf}]] - [\mathcal{Q}^{(0)}_{ap}\mathcal{Q}^{(0)}_{pd}, [\mathcal{Q}^{(0)}_{cd}, \mathcal{Q}^{(0)}_{eq}\mathcal{Q}^{(0)}_{qf}]]). \tag{3.2}$$

As already mentioned (2.8) the Yangian is endowed with a coproduct $\Delta : \mathcal{Y} \to \mathcal{Y} \otimes \mathcal{Y}$. In particular, the coproducts of the generators $\mathcal{Q}^{(p)}_{ab}$ may be written as

$$\Delta(\mathcal{Q}^{(0)}_{ab}) = \mathcal{Q}^{(0)}_{ab} \otimes \mathbb{I} + \mathbb{I} \otimes \mathcal{Q}^{(0)}_{ab},$$

$$\Delta(\mathcal{Q}^{(1)}_{ab}) = \mathcal{Q}^{(1)}_{ab} \otimes \mathbb{I} + \mathbb{I} \otimes \mathcal{Q}^{(1)}_{ab} + \frac{h}{2}\sum_{d=1}^{n}(\mathcal{Q}^{(0)}_{ad} \otimes \mathcal{Q}^{(0)}_{db} - \mathcal{Q}^{(0)}_{db} \otimes \mathcal{Q}^{(0)}_{ad}), \tag{3.3}$$

also for Δ' similar expressions may be deduced. In fact the only difference between expressions Δ and Δ' is a minus sign in front of h in the coproduct of $\mathcal{Q}^{(1)}_{ab}$. Using (2.10) we can get explicit expression for the l coproducts,

$$\Delta^{(l)}(\mathcal{Q}_{ab}^{(0)}) = \sum_{i=1}^{l} (\mathcal{Q}_{ab}^{(0)})_i,$$

$$\Delta^{(l)}(\mathcal{Q}_{ab}^{(1)}) = \sum_{i=1}^{l} (\mathcal{Q}_{ab}^{(1)})_i + \frac{h}{2} \sum_{j>i=1}^{l} \sum_{d=1}^{n} ((\mathcal{Q}_{ad}^{(0)})_i \otimes (\mathcal{Q}_{db}^{(0)})_j - (\mathcal{Q}_{db}^{(0)})_i \otimes (\mathcal{Q}_{ad}^{(0)})_j), \tag{3.4}$$

where the indices i,j denote the site in the l coproduct sequence. We may also define $\Delta'^{(l)}: \mathcal{Y} \to \mathcal{Y}^{\otimes(l)}$ as

$$\Delta'^{(l)} = (\mathrm{id} \otimes \Delta^{(l-1)})\Delta'. \tag{3.5}$$

Note that there also exists the opposite coproduct $\Delta^{\mathrm{op}(l)} = (\mathrm{id} \otimes \Delta^{\mathrm{op}(l-1)})\Delta^{\mathrm{op}}$ with $\Delta^{\mathrm{op}} = \Delta'$. For generic values of l, $\Delta^{\mathrm{op}(l)} \neq \Delta'^{(l)}$ and they only coincide for $l=2$. Expressions similar to (3.4) may be derived for $\Delta'^{(l)}$, but we omit them here for brevity.

Realizations of Yangian generators: As is known the asymptotic behavior of the monodromy matrix T (2.11) as $\lambda \to \infty$ provides tensor product representations of $\mathcal{Y}$. Let us briefly review how this process works. Recall that the operators $\mathcal{L}$ and T are treated as $n \times n$ matrices with entries being elements of $\mathcal{Y}, \mathcal{Y}^{\otimes N}$, respectively. The monodromy matrix T as $\lambda \to \infty$ may be written as (for simplicity we suppress the auxiliary space index 0 from T in the following)

$$T(\lambda \to \infty) \propto \mathbb{I} + \sum_{m=0}^{\infty} \lambda^{-m-1} t^{(m)}. \tag{3.6}$$

Exchange relations among the charges $t_{ab}^{(m)}$ (the entries of $t^{(m)}$) may be derived by virtue of the fundamental algebraic relation (2.5), as $\lambda_i \to \infty$. To extract the Yangian generators we study the asymptotic expansion (3.6) keeping higher orders in the $1/\lambda$ expansion. Recalling the form of $\mathcal{L}$ (2.6) and T (2.11) we conclude that

$$T(\lambda \to \infty) \propto \mathbb{I} + \frac{i}{\lambda} \sum_{i=1}^{N} \mathbb{P}_{0i} - \frac{1}{\lambda^2} \sum_{i>j=1}^{N} \mathbb{P}_{0i}\mathbb{P}_{0j} + \mathcal{O}\left(\frac{1}{\lambda^3}\right). \tag{3.7}$$

Now consider the quantities below written as combinations of $t^{(p)}$, $p \in \{0,1\}$,

$$Q^{(0)} = t^{(0)}, \quad Q^{(1)} = t^{(1)} - \tfrac{1}{2} Q^{(0)} Q^{(0)}, \tag{3.8}$$

where the form of $t^{(p)}$ is defined by (3.6) and (3.7). Then $Q^{(p)}$ may be written as combinations of the operators $\mathbb{P}_{0i}$, each acting on $\mathbb{C}^n \otimes \mathcal{Y}$, namely [from now on we consider $h=-1$ in (3.3)]

$$Q^{(0)} = i \sum_{i=1}^{N} \mathbb{P}_{0i}, \quad Q^{(1)} = \frac{1}{2} \sum_{i=1}^{N} \mathbb{P}_{0i}^2 + \frac{1}{2} \sum_{j>i=1}^{N} (\mathbb{P}_{0i}\mathbb{P}_{0j} - \mathbb{P}_{0j}\mathbb{P}_{0i}). \tag{3.9}$$

Note that for simplicity both quantum and auxiliary indices in $Q^{(p)}$ (3.9) are omitted. The entries of the matrices $Q^{(p)}$ are the nonlocal charges $Q_{ab}^{(p)} \in \mathcal{Y}^{\otimes N}$ being coproduct realizations of the Yangian, i.e.,

$$Q_{ab}^{(p)} = \Delta^{(N)}(\mathcal{Q}_{ab}^{(p)}), \quad p \in \{0,1\}, \quad a,b \in \{1,\ldots,n\}. \tag{3.10}$$

The charges $Q_{ab}^{(0)}$ in particular, are coproducts of the generators of the gl(n) Lie algebra. It is also apparent from (3.10) that for $N=1$, $Q_{ab}^{(p)} \to \mathcal{Q}_{ab}^{(p)}$.

IV. BOUNDARY AND TWISTED YANGIAN GENERATORS

After the brief review on Yangians we are in the position to deal with realizations of boundary or twisted Yangians. As already mentioned two different types of boundary conditions, the SP and

the SNP[19–22,33] will be investigated using a unified framework. The SNP boundary conditions were studied for the first time in the context of integrable lattice models in Ref. 21, whereas a generalized description of these boundaries is presented in Ref. 33.

As we have seen in Sec. II B the entries of $\mathcal{T}^*$ are coproducts of the $\mathbb{B}^*$ algebra. The main objective now is to obtain, as in the case of Yangians, the exact form of tensor products of the generators of $\mathbb{B}^*$ via the asymptotic expansion of $\mathcal{T}^*$. Again $\mathcal{L}(\mathcal{L}^*)$, $T(T^*)$, and consequently $\mathcal{T}^*$ (2.33) are treated as $n\times n$ matrices with entries being elements of $\mathcal{Y},\mathcal{Y}^{\otimes N}$, respectively. Recall also that $\mathcal{K}^*$ (2.22) is a $n\times n$ matrix with c-number entries. The expansion of $\mathcal{T}^*$ (2.33) as $\lambda\to\infty$ reads (again for simplicity we suppress the auxiliary space index 0 from T,T^*, and $\mathcal{T}^*$ in the following)

$$\mathcal{T}^*(\lambda\to\infty)\propto\mathbb{I}+\sum_{m=0}^{\infty}\lambda^{-m-1}\tilde{t}^{(m)}, \tag{4.1}$$

while exchange relations among the charges $\tilde{t}_{ab}^{(m)}$ may be now found by virtue of the algebraic relations (2.14).

As in the bulk case to extract the boundary or twisted Yangian generators we shall keep higher order terms in the expansion (4.1). We need first the asymptotic behavior of the matrices T,T^* as well as $\mathcal{K}^*$. The expansion of T is given by (3.7), while T^* reads as $\lambda\to\infty$,

$$T^*(\lambda\to\infty)\propto\mathbb{I}+\frac{i}{\lambda}\sum_{i=1}^{N}\mathbb{P}_{0i}^*-\frac{1}{\lambda^2}\left(\sum_{i<j=1}^{N}\mathbb{P}_{0i}^*\mathbb{P}_{0j}^*+Y^*\right)+\mathcal{O}\left(\frac{1}{\lambda^3}\right), \tag{4.2}$$

where

$$\mathbb{P}^*=\mathbb{P}\quad\text{for SP b . c . ,}\quad \mathbb{P}^*=\check{\mathbb{P}}\quad\text{for SNP b . c,} \tag{4.3}$$

and

$$Y^*=\sum_{i=1}^{N}\mathbb{P}_{0i}^2\quad\text{for SP b . c . ,}\quad Y^*=0\quad\text{for SNP b . c.}$$

Before we continue with the asymptotics of $\mathcal{T}^*$ it is necessary for our purposes to derive the charges from the expansion of $\overline{T}$ as $\lambda\to\infty$ [the expansion of $\hat{T}$ yields the same charges as in (3.9)]. Note that $\overline{T}$ also satisfies the defining relation of the Yangian (2.5), therefore the corresponding charges are expected to be coproducts of the Yangian generators. In fact, the asymptotic expansion of $\overline{T}$ (up to $1/\lambda^2$) provides the following operators:

$$\check{Q}^{(0)}=i\sum_{i=1}^{N}\check{\mathbb{P}}_{0i},\quad \check{Q}^{(1)}=-\frac{1}{2}\sum_{i=1}^{N}\check{\mathbb{P}}_{0i}^2+\frac{1}{2}\sum_{j>i=1}^{N}(\check{\mathbb{P}}_{0i}\check{\mathbb{P}}_{0j}-\check{\mathbb{P}}_{0j}\check{\mathbb{P}}_{0i}). \tag{4.4}$$

The entries of the matrices (4.4) may be indeed written as coproducts of an alternative set of generators of the Yangian $\check{\mathcal{Q}}_{ab}^{(p)}$,

$$\check{Q}_{ab}^{(p)}=\Delta^{(N)}(\check{\mathcal{Q}}_{ab}^{(p)}),\quad p\in\{0,1\},\quad a,b\in\{1,\ldots,n\}, \tag{4.5}$$

where $\check{\mathcal{Q}}_{ab}^{(p)}$ are the entries of the matrices derived in (4.4) for $N=1$. The generators $\check{\mathcal{Q}}_{ab}^{(p)}$ are isomorphic to $\mathcal{Q}_{ab}^{(p)}$, and their exact correspondence may be found by exploiting the relation between $\mathbb{P}$ and $\check{\mathbb{P}}$ given by (2.26).

Recall also that the $\mathcal{K}^*$ matrix is given by the general form (2.21) for any solution of the reflection equation (2.14), associated to the gl(n)R matrix. Having derived the expansions of T, T^*, and $\mathcal{K}^*$ we may now come to the asymptotic behavior of $\mathcal{T}^*$ as $\lambda\to\infty$ (we keep here up to $1/\lambda^2$ terms), i.e.,

$$\mathcal{T}^*(\lambda\to\infty)\propto k^*+\frac{1}{\lambda}\left(f^*+ik^*\sum_{i=1}^{N}\mathbb{P}_{0i}^*+i\sum_{i=1}^{N}\mathbb{P}_{0i}k^*\right)+\frac{1}{\lambda^2}\left(-k^*\sum_{i<j=1}^{N}\mathbb{P}_{0i}^*\mathbb{P}_{0j}^*-\sum_{i>j=1}^{N}\mathbb{P}_{0i}\mathbb{P}_{0j}k^*\right.$$
$$\left.-\sum_{i,j=1}^{N}\mathbb{P}_{0i}k^*\mathbb{P}_{0j}^*+if^*\sum_{i=1}^{N}\mathbb{P}_{0i}^*+i\sum_{i=1}^{N}\mathbb{P}_{0i}f^*-k^*Y^*\right)+\mathcal{O}\left(\frac{1}{\lambda^3}\right), \tag{4.6}$$

which provides the form of $\tilde{t}^{(p)}$, $p\in\{0,1\}$ (4.1). Consider now the following combinations of $\tilde{t}^{(p)}$:

$$\tilde{Q}^{(0)}=\tilde{t}^{(0)}-f^*,\quad \tilde{Q}^{(1)}=\tilde{t}^{(1)}-\tfrac{1}{2}\tilde{Q}^{(0)}(k^*)^{-1}\tilde{Q}^{(0)}, \tag{4.7}$$

where for the general gl(n) solution (2.22) $k^{-1}=[1/(1+4\kappa^2)]k$, and $\overline{k}$ (SNP b.c.) is also invertible (see, e.g., Ref. 20). Let us also introduce the following objects:

$$\mathcal{D}=(\mathbb{P}k^*-k^*\mathbb{P}^*),\quad \mathcal{S}=(k^*\mathbb{P}^*+\mathbb{P}k^*), \tag{4.8}$$

$$Q^{*(p)}=Q^{(p)}\quad \text{for SP b.c.},\quad Q^{*(p)}=\check{Q}^{(p)}\ \text{for SNP b.c.} \tag{4.9}$$

Then according to (3.9), (4.4), (4.7), and (4.8) the matrices $\tilde{Q}^{(p)}$ may be written as

$$\tilde{Q}^{(0)}=i\sum_{i=1}^{N}\mathcal{S}_{0i},$$

$$\tilde{Q}^{(1)}=f^*Q^{*(0)}+Q^{(0)}f^*+\frac{1}{2}\sum_{i<j=1}^{N}(\mathcal{S}_{0i}(k^*)^{-1}\mathcal{D}_{0j}-\mathcal{D}_{0j}(k^*)^{-1}\mathcal{S}_{0i})-k^*Y^*+\frac{1}{2}k^*\sum_{i=1}^{N}\mathbb{P}_{0i}^{*2}+\frac{1}{2}\sum_{i=1}^{N}\mathbb{P}_{0i}^2k^*$$
$$+\frac{1}{2}\sum_{i=1}^{N}(k^*\mathbb{P}_{0i}^*(k^*)^{-1}\mathbb{P}_{0i}k^*-\mathbb{P}_{0i}k^*\mathbb{P}_{0i}^*). \tag{4.10}$$

The corresponding entries $\tilde{Q}_{ab}^{(p)}$ $a,b\in\{1,\ldots,n\}$ are the boundary nonlocal charges. Notice that the two last terms in (4.10) vanish for the special case of SP where $k=\mathbb{I}$. $\mathcal{K}^*=\mathbb{I}$ ($k^*=\mathbb{I}$, $f^*=0$) is a valid solution of (2.14) for both boundary conditions. We should point out that for $\mathcal{K}=\mathbb{I}$ (SP b.c.) $\tilde{Q}_{ab}^{(1)}=0$ (4.10), so the only charges that survive are the $\tilde{Q}_{ab}^{(0)}\propto Q_{ab}^{(0)}$. There exist of course higher nonlocal charges that may be obtained by keeping higher order terms in the asymptotic expansion (4.6). This is a significant investigation, which will be undertaken however in a forthcoming work.

The nonlocal charges $\tilde{Q}_{ab}^{(p)}$ (4.10) may be written as combinations of the Yangian coproducts $Q_{ab}^{(p)},\check{Q}_{ab}^{(p)}$ (3.9) and (4.4),

$$\tilde{Q}_{ab}^{(0)}=k_{ac}^*Q_{cb}^{*(0)}+Q_{ac}^{(0)}k_{cb}^*,$$

$$\tilde{Q}_{ab}^{(1)}=-k_{ac}^*Q_{cb}^{*(1)}+Q_{ac}^{(1)}k_{cb}^*+f_{ac}^*Q_{cb}^{*(0)}+Q_{ac}^{(0)}f_{cb}^*-\tfrac{1}{2}(k_{ac}^*Q_{cd}^{*(0)}(k^*)_{de}^{-1}Q_{ef}^{(0)}k_{fb}^*-Q_{ac}^{(0)}k_{cd}^*Q_{db}^{*(0)}),$$
$$a,b\in\{1,\ldots,n\}. \tag{4.11}$$

Note that the summation over repeated indices is omitted from now on. The quantities k_{ab}^*,f_{ab}^* are c numbers (the entries of the matrices k^*,f^*), $Q_{ab}^{(p)}$ are given by (3.9) and $Q_{ab}^{*(p)}$ by (4.9). The derivation of the boundary nonlocal charges (4.11) is one of the main results of this study. It is worth emphasizing that the nonlocal charges (4.11) were derived independently of the choice of representation.

V. THE SYMMETRY

Our ultimate goal is to study the symmetry of the open spin chain, namely to derive conserved quantities commuting with the open transfer matrix. This may be achieved by using linear intertwining relations between representations of the boundary Yangian generators and the solutions of the reflection equation.

In the preceding section we derived the boundary nonlocal charges (4.11) as coproducts of the boundary or twisted Yangian generators. It is evident that from the expressions (4.11) for $N=1$, one may write down the corresponding abstract generators of $\mathbb{B}^*$,

$$\tilde{\mathcal{Q}}^{(0)}_{ab} = k^*_{ac}\mathcal{Q}^{*(0)}_{cb} + \mathcal{Q}^{(0)}_{ac}k^*_{cb},$$

$$\tilde{\mathcal{Q}}^{(1)}_{ab} = -k^*_{ac}\mathcal{Q}^{*(1)}_{cb} + \mathcal{Q}^{(1)}_{ac}k^*_{cb} + f^*_{ac}\mathcal{Q}^{*(0)}_{cb} + \mathcal{Q}^{(0)}_{ac}f^*_{cb} - \tfrac{1}{2}(k^*_{ac}\mathcal{Q}^{*(0)}_{cd}(k^*)^{-1}_{de}\mathcal{Q}^{(0)}_{ef}k^*_{fb} - \mathcal{Q}^{(0)}_{ac}k^*_{cd}\mathcal{Q}^{*(0)}_{db}),$$
$$a,b \in \{1,\ldots,n\}. \tag{5.1}$$

The quantities $\tilde{\mathcal{Q}}^{(0)}_{ab}$ are simply linear combinations of the generators of the gl(n) Lie algebra. For SNP b.c. in particular the conjugate generators $\check{\mathcal{Q}}^{(0)}_{ab}$ are combined together with $\mathcal{Q}^{(0)}_{ab}$ in the expression (5.1) for $\tilde{\mathcal{Q}}^{(0)}_{ab}$, a fact that implies the folding of the gl(n) algebra for $k^*=\mathbb{I}$ (for more details on this subject see, e.g., Refs. 21 and 33).

As an immediate consequence of (3.10), (4.11), and (5.1) the boundary nonlocal charges may be written in a more compact form as

$$\tilde{Q}^{(p)}_{ab} = \Delta^{(N)}(\tilde{\mathcal{Q}}^{(p)}_{ab}), \quad p \in \{0,1\}. \tag{5.2}$$

The main advantage when deriving generators of $\mathbb{B}^*$ via the asymptotics of the spin chain is that one directly obtains the explicit form of the coproducts of $\mathbb{B}^*$ generators (3.10) and (4.11). Bearing in mind the coproducts of the Yangian generators (3.3) and also equations (3.10) and (4.11) for $N=2$ one may derive the following more convenient expressions for $\Delta:\mathbb{B}^*\to\mathbb{B}^*\otimes\mathcal{Y}$:

$$\Delta(\tilde{\mathcal{Q}}^{(0)}_{ab}) = \mathbb{I}\otimes\tilde{\mathcal{Q}}^{(0)}_{ab} + \tilde{\mathcal{Q}}^{(0)}_{ab}\otimes\mathbb{I},$$

$$\Delta(\tilde{\mathcal{Q}}^{(1)}_{ab}) = \mathbb{I}\otimes\tilde{\mathcal{Q}}^{(1)}_{ab} + \tilde{\mathcal{Q}}^{(1)}_{ab}\otimes\mathbb{I} - \frac{(k^*)^{-1}_{cd}}{2}(\tilde{\mathcal{Q}}^{(0)}_{ac}\otimes\tilde{\mathcal{Q}}^{(0)^-}_{db} - \tilde{\mathcal{Q}}^{(0)}_{db}\otimes\tilde{\mathcal{Q}}^{(0)^-}_{ac}), \tag{5.3}$$

where

$$\tilde{\mathcal{Q}}^{(0)^-}_{ab} = \mathcal{Q}^{(0)}_{ac}k^*_{cb} - k^*_{ac}\mathcal{Q}^{*(0)}_{cb}. \tag{5.4}$$

Similarly, with the help of (2.9) one obtains $\Delta':\mathbb{B}^*\to\mathcal{Y}\otimes\mathbb{B}^*$,

$$\Delta'(\tilde{\mathcal{Q}}^{(1)}_{ab}) = \mathbb{I}\otimes\tilde{\mathcal{Q}}^{(1)}_{ab} + \tilde{\mathcal{Q}}^{(1)}_{ab}\otimes\mathbb{I} + \frac{(k^*)^{-1}_{cd}}{2}(\tilde{\mathcal{Q}}^{(0)^-}_{ac}\otimes\tilde{\mathcal{Q}}^{(0)}_{db} - \tilde{\mathcal{Q}}^{(0)^-}_{db}\otimes\tilde{\mathcal{Q}}^{(0)}_{ac}), \tag{5.5}$$

and the l coproducts are deduced in a straightforward manner via (2.10) and (3.5). Note that expressions similar to (5.1), (5.3), and (5.5), but not exactly the same, were also derived in Ref. 5 from a field theoretical point of view.

Consider now the evaluation representation $\pi_\lambda:\mathcal{Y}\to\mathrm{End}(\mathbb{C}^n)$ such that

$$\pi_\lambda(\mathcal{Q}^{*(1)}_{ab}) = i\lambda\mathcal{P}^*_{ab}, \quad \pi_\lambda(\mathcal{Q}^{*(0)}_{ab}) = i\mathcal{P}^*_{ab}, \quad a,b \in \{1,\ldots,n\}. \tag{5.6}$$

$\mathcal{P}^*$ is an $n\times n$ matrix, with entries $\mathcal{P}^*_{ab}$ being operators which act on $\mathbb{C}^n$. The generators (5.1) are then expressed in terms of the operators $\mathcal{P}^*_{ab}$ as

$$\pi_\lambda(\tilde{\mathcal{Q}}^{(0)}_{ab}) = ik^*_{ac}\mathcal{P}^*_{cb} + i\mathcal{P}_{ac}k^*_{cb},$$

$$\pi_\lambda(\tilde{\mathcal{Q}}^{(1)}_{ab}) = -i\lambda k^*_{ac}\mathcal{P}^*_{cb} + i\lambda\mathcal{P}_{ac}k^*_{cb} + if^*_{ac}\mathcal{P}^*_{cb} + i\mathcal{P}_{ac}f^*_{cb} + \tfrac{1}{2}(k^*_{ac}\mathcal{P}^*_{cd}(k^*)^{-1}_{de}\mathcal{P}_{ef}\,k^*_{fb} - \mathcal{P}_{ac}k^*_{cd}\mathcal{P}^*_{db}). \tag{5.7}$$

We shall henceforth restrict our attention to SP boundary conditions only, and we shall derive certain intertwining relations between the charges (5.7) and the $\mathcal{K}$ matrix (2.22). More specifically, it may be directly deduced from the reflection equation (2.14) that all the elements of the algebra $\mathbb{B}$ commute with the $\mathcal{K}$ matrix (see also Refs. 4 and 5). Indeed, by acting with the evaluation representation on the second space of (2.27) we obtain

$$(\mathrm{id}\otimes\pi_{\pm\lambda})\mathbb{K}(\lambda') = R(\lambda'\mp\lambda)(\mathcal{K}(\lambda')\otimes\mathbb{I})\hat{R}(\lambda\pm\lambda'). \tag{5.8}$$

Now recalling the reflection equation (2.14) and because of the form of the above expressions it is straightforward to show that

$$(\mathrm{id}\otimes\pi_\lambda)\mathbb{K}(\lambda')(\mathbb{I}\otimes\mathcal{K}(\lambda)) = (\mathbb{I}\otimes\mathcal{K}(\lambda))(\mathrm{id}\otimes\pi_{-\lambda})\mathbb{K}(\lambda'). \tag{5.9}$$

As a consequence the entries of $\mathbb{K}$ in the evaluation representation commute with the *c*-number $\mathcal{K}$ matrix (2.22),

$$\pi_\lambda(\mathbb{K}_{ab}(\lambda'))\mathcal{K}(\lambda) = \mathcal{K}(\lambda)\pi_{-\lambda}(\mathbb{K}_{ab}(\lambda')), \quad a,b\in\{1,\ldots,n\}. \tag{5.10}$$

In addition, as we have seen from the analysis of the preceding section, the elements $\mathbb{K}_{ab}(\lambda'\to\infty)$ provide essentially the generators (5.1), and therefore we conclude that

$$\pi_\lambda(\tilde{\mathcal{Q}}^{(p)}_{ab})\mathcal{K}(\lambda) = \mathcal{K}(\lambda)\pi_{-\lambda}(\tilde{\mathcal{Q}}^{(p)}_{ab}). \tag{5.11}$$

Note that we also verified by inspection, taking into account the form of the $\mathrm{gl}(n)\mathcal{K}$ matrices (2.21), (2.22), and (5.7), that the latter relations (5.11) are indeed satisfied.

Equations (5.11) are the boundary analogues of the bulk intertwining relations for the $\mathcal{L}$ matrix, i.e.,

$$(\pi_\lambda\otimes\mathrm{id})\Delta'(\mathcal{Q}^{(p)}_{ab})\mathcal{L}(\lambda) = \mathcal{L}(\lambda)(\pi_\lambda\otimes\mathrm{id})\Delta(\mathcal{Q}^{(p)}_{ab}),$$

$$(\pi_{-\lambda}\otimes\mathrm{id})\Delta(\mathcal{Q}^{(p)}_{ab})\hat{\mathcal{L}}(\lambda) = \hat{\mathcal{L}}(\lambda)(\pi_{-\lambda}\otimes\mathrm{id})\Delta'(\mathcal{Q}^{(p)}_{ab}). \tag{5.12}$$

Relations of the form (5.11) should also hold for solutions $\overline{\mathcal{K}}$ of (2.14) for the general $\mathrm{gl}(n)$ case, which however merits further study and it will be the subject of a forthcoming work. It is worth remarking that in Refs. 4 and 5 intertwining relations such as in (5.11) were used as a starting point for deriving solutions of the reflection equation.

Expressions of the type (5.11) may be obtained for $\mathcal{T}$ (2.31) as well (see also Ref. 6). To derive the generalized intertwining relations for the $\mathcal{T}$ matrix we first need to show relations similar to (5.12) for the monodromy matrices T and $\hat{T}$. Indeed, it immediately follows by induction using (5.12) and the definitions (2.11) and (2.30) that

$$(\pi_\lambda\otimes\mathrm{id}^{\otimes N})\Delta'^{(N+1)}(\mathcal{Q}^{(p)}_{ab})T(\lambda) = T(\lambda)(\pi_\lambda\otimes\mathrm{id}^{\otimes N})\Delta^{(N+1)}(\mathcal{Q}^{(p)}_{ab}),$$

$$(\pi_{-\lambda}\otimes\mathrm{id}^{\otimes N})\Delta^{(N+1)}(\mathcal{Q}^{(p)}_{ab})\hat{T}(\lambda) = \hat{T}(\lambda)(\pi_{-\lambda}\otimes\mathrm{id}^{\otimes N})\Delta'^{(N+1)}(\mathcal{Q}^{(p)}_{ab}), \quad p\in\{0,1\}. \tag{5.13}$$

It should be stressed that the latter relations provide also an effective means for studying the symmetry of the periodic $\mathrm{gl}(n)$ spin chain. From (5.11) and because of the form of the coproducts (5.3) we conclude also that

$$(\pi_\lambda \otimes \mathrm{id}^{\otimes N})\Delta^{(N+1)}(\tilde{\mathcal{Q}}_{ab}^{(p)})\mathcal{K}(\lambda) = \mathcal{K}(\lambda)(\pi_{-\lambda} \otimes \mathrm{id}^{\otimes N})\Delta^{(N+1)}(\tilde{\mathcal{Q}}_{ab}^{(p)}). \tag{5.14}$$

Recalling that the generators of $\mathbb{B}$ (5.1) are written exclusively in terms of $\mathcal{Q}_{ab}^{(p)}$ we conclude that the intertwining relations (5.13) hold also for $\tilde{\mathcal{Q}}_{ab}^{(p)}$. Then taking into account relations (5.13) for $\tilde{\mathcal{Q}}_{ab}^{(p)}$, (5.14), and also (2.31), we may derive the following relations:

$$(\pi_\lambda \otimes \mathrm{id}^{\otimes N})\Delta'^{(N+1)}(\tilde{\mathcal{Q}}_{ab}^{(p)})\mathcal{T}(\lambda) = \mathcal{T}(\lambda)(\pi_{-\lambda} \otimes \mathrm{id}^{\otimes N})\Delta'^{(N+1)}(\tilde{\mathcal{Q}}_{ab}^{(p)}), \tag{5.15}$$

which hold for the general gl(n) case. The derivation of the representations (5.7) and the intertwining relations (5.11) and (5.15) are also among the main results of this paper. The latter relations (5.15) in particular are of great significance as we shall see below, because they facilitate the study of the exact symmetry of the open spin chain.

Before we continue with the investigation of the symmetry it will be instructive to write explicitly the following coproducts, which are valid for the gl(n) case [see also (2.10), (3.5), (5.2), (5.3), and (5.5)]:

$$(\pi_\lambda \otimes \mathrm{id}^{\otimes N})\Delta^{(N+1)}(\tilde{\mathcal{Q}}_{ab}^{(0)}) = \pi_\lambda(\tilde{\mathcal{Q}}_{ab}^{(0)}) \otimes \mathbb{I} + \mathbb{I} \otimes \tilde{Q}_{ab}^{(0)},$$

$$(\pi_\lambda \otimes \mathrm{id}^{\otimes N})\Delta^{(N+1)}(\tilde{\mathcal{Q}}_{ab}^{(1)}) = \pi_\lambda(\tilde{\mathcal{Q}}_{ab}^{(1)}) \otimes \mathbb{I} + \mathbb{I} \otimes \tilde{Q}_{ab}^{(1)} - \frac{(k^*)_{cd}^{-1}}{2}(\pi_\lambda(\tilde{\mathcal{Q}}_{ac}^{(0)}) \otimes \tilde{Q}_{db}^{(0)-} - \pi_\lambda(\tilde{\mathcal{Q}}_{db}^{(0)}) \otimes \tilde{Q}_{ac}^{(0)-}),$$

$$(\pi_\lambda \otimes \mathrm{id}^{\otimes N})\Delta'^{(N+1)}(\tilde{\mathcal{Q}}_{ab}^{(1)}) = \pi_\lambda(\tilde{\mathcal{Q}}_{ab}^{(1)}) \otimes \mathbb{I} + \mathbb{I} \otimes \tilde{Q}_{ab}^{(1)} + \frac{(k^*)_{cd}^{-1}}{2}(\pi_\lambda(\tilde{\mathcal{Q}}_{ac}^{(0)-}) \otimes \tilde{Q}_{db}^{(0)} - \pi_\lambda(\tilde{\mathcal{Q}}_{db}^{(0)-}) \otimes \tilde{Q}_{ac}^{(0)}), \tag{5.16}$$

where

$$\tilde{Q}_{ab}^{(0)-} = \Delta^{(N)}(\tilde{\mathcal{Q}}_{ab}^{(0)-}). \tag{5.17}$$

The crucial point is that Eqs. (5.15) bear algebraic relations between the entries of the operator $\mathcal{T}$ and the boundary nonlocal charges (4.11). For simplicity we use the XXX (gl(2)) model to exhibit the symmetry of the open transfer matrix (2.33), although the following procedure may be easily generalized for the gl(n) case. Note that the gl(2) case is quite special, because the twisted Yangian coincides essentially with the boundary Yangian, recall that $R_{12}(\lambda) = \overline{R}_{12}(\lambda)$ (and $\mathcal{P} = \check{\mathcal{P}}$), nevertheless it provides an illuminating paradigm. Let

$$\mathcal{T}_0(\lambda) = \begin{pmatrix} \mathcal{A}_1 & \mathcal{B} \\ \mathcal{C} & \mathcal{A}_2 \end{pmatrix} \quad \text{and } t(\lambda) = \mathcal{A}_1 + \mathcal{A}_2 \tag{5.18}$$

then from the commutation relations (5.15) and also (5.1), (5.6), and (5.16) we obtain

$$[\tilde{Q}_{aa}^{(0)}, \mathcal{A}_1] = 2i\kappa(\mathcal{B} - \mathcal{C}), \quad [\tilde{Q}_{aa}^{(0)}, \mathcal{A}_2] = -2i\kappa(\mathcal{B} - \mathcal{C}), \quad a \in \{1,2\},$$

$$[\tilde{Q}_{ab}^{(0)}, \mathcal{A}_1] = [\tilde{Q}_{ab}^{(0)}, \mathcal{A}_2] = [\tilde{Q}_{ab}^{(0)}, \mathcal{B}] = [\tilde{Q}_{ab}^{(0)}, \mathcal{C}] = 0, \quad a \neq b,$$

$$[\tilde{Q}_{aa}^{(0)}, \mathcal{B}] = 2i\kappa(\mathcal{A}_1 - \mathcal{A}_2) + 2i\mathcal{B}, \quad [\tilde{Q}_{aa}^{(0)}, \mathcal{C}] = -2i\kappa(\mathcal{A}_1 - \mathcal{A}_2) - 2i\mathcal{C}, \tag{5.19}$$

and it follows that

$$[t(\lambda), \tilde{Q}_{ab}^{(0)}] = 0, \quad a,b \in \{1,2\}. \tag{5.20}$$

From the intertwining relations (5.15) and with the help of (5.19) it also follows that

$$[t(\lambda),\tilde{Q}_{11}^{(1)}]=-[t(\lambda),\tilde{Q}_{22}^{(1)}]=[t(\lambda),\kappa(\tilde{Q}_{12}^{(1)}+\tilde{Q}_{21}^{(1)})]=4\kappa i(\lambda+i)(\mathcal{B}-\mathcal{C}), \tag{5.21}$$

and consequently

$$[t(\lambda),\tilde{Q}_{11}^{(1)}+\tilde{Q}_{22}^{(1)}]=[t(\lambda),\kappa(\tilde{Q}_{12}^{(1)}+\tilde{Q}_{21}^{(1)})+(-)^a\tilde{Q}_{aa}^{(1)}]=0. \tag{5.22}$$

It should be pointed out that the combinations of nonlocal charges appearing in (5.22) are expressed solely in terms of $\tilde{Q}_{ab}^{(0)}$'s, which means that the only conserved charges entailed so far are the $\tilde{Q}_{ab}^{(0)}$'s. In fact the first combination is trivial, because $\tilde{Q}_{11}^{(1)}+\tilde{Q}_{22}^{(1)}\propto\mathbb{I}$, and it is also expected from the commutation relation (2.35) as $\lambda'\to\infty$. The existence of higher nontrivial conserved charges is an intriguing question that will be examined in detail elsewhere. It is clear that generalized commutation relations between the generators $\tilde{Q}_{ab}^{(p)}, a,b\in\{1,\ldots,n\}$ and the entries of the $\mathrm{gl}(n)\mathcal{T}$ matrix may be now deduced in an analogous, although technically more complicated way.

It is finally worth emphasizing that the general intertwining relations (5.15) and the discovered symmetry (5.20) and (5.22) are independent of the choice of representation on the quantum spaces, and therefore they are universal results. In the special case where the quantum spaces are mapped via the evaluation representation (5.6), and $\mathcal{L}\to R$ the relations (5.15), (5.16), (5.20), and (5.22) are of course still valid, but with $\mathrm{id}^{\otimes N}\to\pi_0^{\otimes N}$.

VI. DISCUSSION

Let us briefly review the main results of this investigation. The main objective of this work was the study of the remaining symmetries of rational integrable spin chains ($\mathrm{gl}(n)$) once nondiagonal integrable boundaries are implemented. We considered two types of boundary conditions known as soliton preserving and soliton nonpreserving. For both types of boundaries nonlocal charges (4.11) were derived explicitly by means of the study of the asymptotic behavior of the coproduct type solution of the reflection equation $\mathcal{T}$. The nonlocal charges (4.11) were simply coproducts of generators of the boundary or twisted Yangian (5.1) depending on the choice of boundary conditions (2.14). Furthermore, by using the intertwining relations (5.11) and (5.15) we were able to derive the symmetry of the open spin chain (5.20). Relations of the form (5.11) provide also an alternative way of finding solutions of the reflection equation (2.14) (see, e.g., Refs. 4 and 5), although there exist other effective algebraic techniques allowing the solution of the reflection equation (see, e.g., Ref. 34).

It should be finally emphasized that R matrices associated to, e.g., $\mathrm{o}(n)$, $\mathrm{sp}(n)$ algebras enjoy crossing symmetry, i.e., $R_{12}(\lambda)=\overline{R}_{12}(\lambda)$ (2.16), and therefore in this case the boundary Yangian coincides with the twisted Yangian (see also Refs. 29 and 35).

A Weyl-covariant tensor calculus

Nicolas Boulanger[a)]
Université de Mons-Hainaut, Mécanique et Gravitation, 6, Avenue du Champ de Mars, 7000 Mons, Belgium

(Received 24 February 2005; accepted 25 February 2005; published online 15 April 2005)

On a (pseudo-) Riemannian manifold of dimension $n \geqslant 3$, the space of tensors which transform covariantly under Weyl rescalings of the metric is built. This construction is related to a Weyl-covariant operator $\mathcal{D}$ whose commutator $[\mathcal{D},\mathcal{D}]$ gives the conformally invariant Weyl tensor plus the Cotton tensor. So-called generalized connections and their transformation laws under diffeomorphisms and Weyl rescalings are also derived. These results are obtained by application of Becchi Rouet Stora Tyutin techniques. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1896381]

I. INTRODUCTION

Recently,[1] a purely algebraic method was used to solve the problem of constructing and classifying all the local scalar invariants of a conformal structure on a (pseudo-) Riemannian manifold of dimension $n=8$. The approach, however, is not confined to $n=8$, and one of the purposes of this paper is to explain the derivation of the so-called Weyl-covariant tensors, the building blocks of the local conformal invariants in arbitrary dimension $n \geqslant 3$.

In the context of local gauge field theory, the determination of quantities which are invariant under a given set of gauge transformations can be rephrased in terms of local Becchi Rouet Stora Tyutin (BRST) cohomology. Within the BRST framework, the gauge symmetry and its algebra are encoded in a single differential s.[2–5] Powerful techniques for the computation of BRST cohomologies are proposed in Ref. 6 (see also Ref. 7), that apply to a large class of gauge theories and relate the BRST cohomology to an underlying gauge covariant algebra. At the core of this analysis is a definition of tensor fields and connections on which an underlying gauge covariant algebra is realized. Such a characterization of tensor fields, connections and the corresponding transformation laws has the advantage that it is purely algebraic and does not invoke any concept in addition to the BRST cohomology itself.

In the present paper, we consider theories where the only classical field is the metric $g_{\mu\nu} = g_{\nu\mu}$ and the gauge symmetries are diffeomorphisms plus Weyl rescalings. Explicitly, the infinitesimal gauge transformations read

$$\delta g_{\mu\nu} = \mathcal{L}_\xi g_{\mu\nu} + \delta^W_\phi g_{\mu\nu} = \xi^\rho \partial_\rho g_{\mu\nu} + \partial_\mu \xi^\rho g_{\rho\nu} + \partial_\nu \xi^\rho g_{\mu\rho} + 2\phi g_{\mu\nu}. \tag{1}$$

Our aim is to construct the space $\mathcal{W}$ of tensors and generalized connections that transform covariantly with respect to diffeomorphisms and Weyl transformations. The latter property means that, under Weyl rescalings, the tensors belonging to $\mathcal{W}$ will make appear at most the first derivative $\partial_\mu \phi$ of the Weyl parameter ϕ, and no derivative $\partial_{\mu_1} \cdots \partial_{\mu_k} \phi$ with $k \geqslant 2$.

Knowing the space $\mathcal{W}$, we are able to define an operator $\mathcal{D}$ acting in $\mathcal{W}$ and such that $[\mathcal{D},\mathcal{D}] \sim C + \tilde{C}$, where C and $\tilde{C}$, respectively, denote the conformally invariant Weyl tensor and the Cotton tensor. The Weyl-covariant derivative $\mathcal{D}$ generates the whole space of tensor fields belonging to $\mathcal{W}$ by successive applications on C (and $\tilde{C}$ in $n=3$). The rule for the commutator $[\mathcal{D},\mathcal{D}]$ is

at the basis of the Weyl-covariant tensor calculus utilized in Ref. 1. Other useful relations are obtained which are nothing but the Jacobi identities for the underlying gauge covariant algebra alluded to before.

The generalized connections play no role in the construction of local Weyl invariants, but are of prime importance in many other issues, like for example in the determination of the counterterms, the consistent interactions and the conservation laws that a gauge theory admits. They are also relevant for the classification of the Weyl anomalies, the solutions of the Wess–Zumino consistency condition for a theory describing conformal massless matter fields in an external gravitational background.

II. BRST FORMULATION

A. Some definitions

As mentioned above, the derivation of the space $\mathcal{W}$ of Weyl-covariant tensors and generalized connections is purely algebraic and requires no dynamical information. As a consequence, all that we need is contained in Eq. (1) and the BRST differential s reduces to γ, the differential along the gauge orbits. We refer to Refs. 8 and 9 for more details on the BRST formalism as used throughout the present work. For an application of this formalism in the context of Weyl gravity, see Ref. 10.

A $\mathbb{Z}$-grading called *ghost number* is associated to the differential γ. The latter raises the ghost number by one unit and is decomposed according to the degree in the Weyl ghost (the fermionic field associated to the Weyl parameter), $\gamma=\gamma_0+\gamma_1$. The first part γ_0 contains the information about the diffeomorphisms. The second part, γ_1, corresponds to Weyl rescalings of the metric and increases the number of (possibly differentiated) Weyl ghosts by 1.

The action of γ on the fields Φ^A (including the ghosts) is given as follows:

$$\gamma_0 g_{\mu\nu}=\xi^\rho\partial_\rho g_{\mu\nu}+\partial_\mu\xi^\rho g_{\rho\nu}+\partial_\nu\xi^\rho g_{\mu\rho},\quad \gamma_1 g_{\mu\nu}=2\omega g_{\mu\nu}, \tag{2a}$$

$$\gamma_0\xi^\mu=\xi^\rho\partial_\rho\xi^\mu,\quad \gamma_0\omega=\xi^\rho\partial_\rho\omega,\quad \gamma_1\xi^\mu=0,\quad \gamma_1\omega=0. \tag{2b}$$

The field ω is the Weyl ghost, the anticommuting field associated to the Weyl parameter ϕ, while ξ^μ is the anticommuting diffeomorphisms ghost associated to the vector field ζ^μ of Eq. (1). By definition, the Grassmann-odd fields ω and ξ^μ have ghost number +1. The last equality of (2b) reflects the Abelian nature of the algebra of Weyl transformations. From the above equations and by using the fact that γ is an odd derivation, it is easy to check that γ is indeed a differential.

One unites the BRST differential γ and the total exterior derivative d into a single differential $\tilde{\gamma}=\gamma+d$. Then, the Wess–Zumino consistency condition and its descent are encapsulated in

$$\tilde{\gamma}\tilde{a}=0,\quad \tilde{a}\neq\tilde{\gamma}\tilde{b}+\text{constant} \tag{3}$$

for the local total forms $\tilde{a}$ and $\tilde{b}$ of total degrees $G=n+1$ and $G=n$.[6] Total local forms are by definition formal sums of local forms with different form degrees and ghost numbers, $\tilde{a}=\sum_{p=0}^{n}a_p^{G-p}$, where subscripts (respectively, superscripts) denote the form degree (respectively, the ghost number). A local p-form ω_p depends on the fields Φ^A and their derivatives up to some finite (but otherwise unspecified) order, which is denoted by $\omega_p=(1/p!)\mathrm{d}x^{\mu_1}\cdots\mathrm{d}x^{\mu_p}\,\omega_{\mu_1\cdots\mu_p}(x,[\Phi^A])$.

The relations (3) imply that $\tilde{a}$ is a nontrivial element of the cohomology group $H(\tilde{\gamma})$ in the algebra of total local forms. As shown in Ref. 6, the cohomology of γ in the space of local functionals (integrals of local n forms) is indeed locally isomorphic to the cohomology of $\tilde{\gamma}$ in the space of local total forms. In other words, the solutions a_n^g of the Wess–Zumino consistency condition

$$\gamma a_n^g+\mathrm{d}a_{n-1}^{g+1}=0,\quad a_n^g\neq\gamma b_n^{g-1}+\mathrm{d}b_{n-1}^g \tag{4}$$

correspond one-to-one (modulo trivial solutions) to the solutions $\tilde{a}$ of (3) at total degree $G=g+n$, $\mathrm{tot\,deg}(\tilde{a})=g+n$.

The solutions of (3) or (4) determine the general structure of the counterterms that an action admits, the possible gauge anomalies, the conserved currents, the consistent interactions, etc.[9] In the next sections and in the appendix, we determine the restricted space $\mathcal{W}$ of the space of total local forms in which these solutions naturally appear, for a gravity theory invariant under the transformations (1).

We close this section with some more definitions and conventions. The conformally invariant Weyl tensor $C^{\beta}{}_{\gamma\delta\varepsilon}$, the tensor $K_{\alpha\beta}$ and the Cotton tensor $\widetilde{C}_{\alpha\mu\nu}$ are given by

$$C^{\alpha}{}_{\beta\gamma\delta} := R^{\alpha}{}_{\beta\gamma\delta} - 2(\delta^{\alpha}_{[\gamma} K_{\delta]\beta} - g_{\beta[\gamma} K_{\delta]}{}^{\alpha}), \tag{5a}$$

$$K_{\alpha\beta} := \frac{1}{n-2}\left(R_{\alpha\beta} - \frac{1}{2(n-1)} g_{\alpha\beta} R\right), \tag{5b}$$

$$\widetilde{C}_{\alpha\mu\nu} := \tfrac{1}{2}\nabla_{[\nu} K_{\mu]\alpha}. \tag{5c}$$

The Ricci tensor is $R_{\beta\delta}=R^{\alpha}{}_{\beta\alpha\delta}$, where $R^{\alpha}{}_{\beta\gamma\delta}=(\partial_{\gamma}\Gamma_{\beta\delta}{}^{\alpha}+\Gamma_{\gamma\lambda}{}^{\alpha}\Gamma_{\beta\delta}{}^{\lambda})-(\gamma\leftrightarrow\delta)$ is the Riemann tensor. The Christoffel symbols are given by $\Gamma_{\alpha\beta}{}^{\gamma}=\frac{1}{2}g^{\gamma\lambda}(\partial_{\alpha}g_{\beta\lambda}+\partial_{\beta}g_{\alpha\lambda}-\partial_{\lambda}g_{\alpha\beta})$. Curved brackets denote strength-one complete symmetrization, whereas square brackets denote strength-one complete antisymmetrization. We have $\nabla_{\mu}g_{\alpha\beta}=0$, where the symbol ∇ denotes the usual torsion-free covariant derivative associated to $\Gamma_{\alpha\beta}{}^{\gamma}$. Finally, the derivative $\partial_{\alpha}\omega$ of the Weyl ghost will sometimes be noted $\omega_{\alpha}\equiv\partial_{\alpha}\omega$.

B. Contracting homotopy

A well-known technique in the study of cohomologies is the use of contracting homotopies. The idea is to construct contracting homotopy operators which allow to eliminate certain local jet coordinates, called *trivial pairs*, from the cohomological analysis. This reduces the cohomological problem to an analogous one involving only the remaining jet coordinates. For that purpose one needs to construct suitable sets of jets coordinates replacing the fields, the ghosts and all their derivatives and satisfying appropriate requirements.

The following lemma is at the basis of the contracting homotopy techniques. We use the notations of Ref. 6 to which we refer for more details.

Lemma 1. Suppose there is a set of local jet coordinates,

$$\mathcal{B}=\{\mathcal{U}^{\ell},\mathcal{V}^{\ell},\mathcal{W}^{\Lambda}\},$$

such that the change of coordinates from $\mathcal{J}=\{[\Phi^{A}],x^{\mu},\mathrm{d}x^{\mu}\}$ *to* $\mathcal{B}$ *is local and locally invertible and*

$$\tilde{\gamma}\mathcal{U}^{\ell}=\mathcal{V}^{\ell}\ \forall\ \ell, \tag{6a}$$

$$\tilde{\gamma}\mathcal{W}^{\Lambda}=\mathcal{R}^{\Lambda}(\mathcal{W})\ \forall\ \Lambda. \tag{6b}$$

Then, locally the $\mathcal{U}$*'s and* $\mathcal{V}$*'s can be eliminated from the* $\tilde{\gamma}$*-cohomology, i.e., the latter reduces locally to the* $\tilde{\gamma}$*-cohomology on total local forms depending only on the* $\mathcal{W}$*'s.*

Note that both (6a) and (6b) must hold in order to eliminate the $\mathcal{U}$'s and $\mathcal{V}$'s from the cohomology. It is important to stress that the existence of a pair of jet coordinates satisfying (6a) does in general *not* guarantee the existence of complementary $\mathcal{W}$'s satisfying (6b). Clearly, the aim is to construct a set of local jet coordinates containing as many trivial pairs as possible. The difficulty of this construction is in general *not* the finding of pairs satisfying (6a), but the construction of complementary $\mathcal{W}$'s satisfying (6b). There is no general rule to deal with the latter, nontrivial problem.

To our knowledge, the $\mathcal{U}$-$\mathcal{V}$-$\mathcal{W}$ decomposition had never been done in the context of Weyl gravity theories in arbitrary dimension $n \geqslant 3$. Here, we fill this gap and compactly summarize our main results in the following proposition.

Proposition 1: Let $\mathcal{J}$ be the jet space $\mathcal{J}=\{[g_{\mu\nu}],[\omega],[\xi^\mu],x^\mu,\mathrm{d}x^\mu\}$ and $\tilde{\gamma}=\gamma_0+\gamma_1+d$ the differential acting on $\mathcal{J}$ according to

$$\gamma_0 g_{\mu\nu} = \xi^\rho \partial_\rho g_{\mu\nu} + \partial_\mu \xi^\rho g_{\rho\nu} + \partial_\nu \xi^\rho g_{\mu\rho}, \quad \gamma_1 g_{\mu\nu} = 2\omega g_{\mu\nu},$$
$$\gamma_0 \xi^\mu = \xi^\rho \partial_\rho \xi^\mu, \quad \gamma_0 \omega = \xi^\rho \partial_\rho \omega, \quad \gamma_1 \xi^\mu = 0, \quad \gamma_1 \omega = 0. \tag{7}$$

Then, the $\{\mathcal{U},\mathcal{V},\mathcal{W}\}$-decomposition of $\mathcal{J}$ corresponding to $\tilde{\gamma}$ is

$$\{\mathcal{U}^\ell\} = \{x^\mu, \partial_{(\mu_1\cdots\mu_k} \Gamma^{\nu}{}_{\mu_{k+1}\mu_{k+2})}, \nabla_{(\mu_1\cdots\mu_k} K_{\mu_{k+1}\mu_{k+2})}, k \in \mathbb{N}\},$$

$$\{\mathcal{V}^\ell\} = \{\tilde{\gamma}\mathcal{U}^\ell\}, \quad \{\mathcal{W}^\Lambda\} = \{\mathcal{T}^i, \tilde{C}^N\},$$

$$\{\mathcal{T}^i\} = \{g_{\mu\nu}, \mathcal{D}_{(\mu_1} \cdots \mathcal{D}_{\mu_k} C^\beta{}_{\gamma\delta)\varepsilon}, k \in \mathbb{N}\}, \tag{8a}$$

$$\{\tilde{C}^N\} = \{2\omega, \tilde{\xi}^\nu, \tilde{C}_\nu{}^\rho, \tilde{\omega}_\alpha\}, \tag{8b}$$

$$\tilde{\xi}^\nu := \xi^\nu + \mathrm{d}x^\nu, \quad \tilde{C}_\nu{}^\rho := \partial_\nu \xi^\rho + \tilde{\xi}^\alpha \Gamma_{\alpha\nu}{}^\rho, \quad \tilde{\omega}_\alpha := \omega_\alpha - \tilde{\xi}^\beta K_{\alpha\beta}.$$

The rest of the paper contains the definition of the operator $\mathcal{D}$ together with the $\tilde{\gamma}$-transformation rules for the elements of $\mathcal{W}$. A remark will also be made for the case $n=3$. In order to derive the results of Proposition 1, we used the fact that every function of the Riemann tensor and its covariant derivatives can be written as a function of the Weyl tensor, its covariant derivatives and the completely symmetric tensors $\nabla_{(\lambda_1\lambda_2\cdots\lambda_k} K_{\alpha\beta)}$. A proof of the latter statement can be found in the appendix of Ref. 1. The same proof can be used to show that, in $n=3$, every function of the Ricci tensor and its covariant derivatives can be written as a function of the Cotton tensor, its covariant derivatives and the completely symmetric tensors $\nabla_{(\lambda_1\lambda_2\cdots\lambda_k} K_{\alpha\beta)}$.

It is understood that only the algebraically independent components of $g_{\mu\nu}$ and $C^\beta{}_{\gamma\delta\varepsilon}$ enter into (8a). [Together with the symmetrization of the indices in (8a), this guarantees the absence of algebraic identities between the generators $\mathcal{T}^i$, taking into account the second equation of (13c) and the Bianchi identity (14b).]

The tensor fields $\{\mathcal{T}^i\}$ have total degree zero whereas the generalized connections $\{\tilde{C}^N\}$ have total degree 1. They decompose into two parts, the first of ghost number 1 and form degree zero, the second of ghost number zero and form degree 1,

$$\mathrm{tot\,deg}(\mathcal{T}^i) = 0, \quad \mathrm{tot\,deg}(\tilde{C}^N) = 1, \quad \tilde{C}^N = \hat{C}^N + \mathcal{A}^N,$$

$$\mathrm{gh}(\hat{C}^N) = 1 = \mathrm{form\,deg}(\mathcal{A}^N), \quad \mathrm{gh}(\mathcal{A}^N) = 0 = \mathrm{form\,deg}(\hat{C}^N),$$

where, from (8b),

$$\{\hat{C}^N\} = \{2\omega, \xi^\nu, \hat{C}_\nu{}^\rho := \partial_\nu \xi^\rho + \xi^\alpha \Gamma_{\alpha\nu}{}^\rho, \hat{\omega}_\alpha := \omega_\alpha - \xi^\mu K_{\mu\alpha}\}, \tag{9a}$$

$$\{\mathcal{A}^N\} = \{0, \mathrm{d}x^\mu\, \delta_\mu^\nu, \mathrm{d}x^\mu\, \Gamma_{\mu\nu}{}^\rho, -\mathrm{d}x^\mu\, K_{\mu\alpha}\}. \tag{9b}$$

The $\mathcal{A}^N$'s and $\hat{C}^N$'s are called, respectively, connection 1-forms and covariant ghosts.[6] Since $\tilde{\gamma}$ raises the total degree by one unit, we have

$$\tilde{\gamma}\mathcal{T}^i = \tilde{C}^N \Delta_N \mathcal{T}^i \Leftrightarrow \begin{cases} \gamma\mathcal{T}^i = \hat{C}^N \Delta_N \mathcal{T}^i, \\ d\mathcal{T}^i = \mathcal{A}^N \Delta_N \mathcal{T}^i, \end{cases} \tag{10a}$$

$$\{\Delta_N\} = \{\Delta, \mathcal{D}_\nu, \Delta_\rho{}^\nu, \mathbf{\Gamma}^\alpha\}. \tag{10b}$$

C. BRST covariant algebra for Weyl gravity

The Weyl-covariant derivative $\mathcal{D}$ is given by

$$\mathcal{D}_\mu := \partial_\mu - \Gamma_{\mu\nu}{}^\rho \Delta_\rho{}^\nu + K_{\mu\alpha}\mathbf{\Gamma}^\alpha. \tag{11}$$

The aim of this section is to make precise the above definition by explicitly defining the three operators $\{\Delta, \Delta_\rho{}^\nu, \mathbf{\Gamma}^\alpha\}$ introduced in (10). An underlying gauge covariant algebra will be exhibited, which provides a compact formulation of the BRST algebra on tensor fields and generalized connections.

(1) The operator Δ corresponds to the dimension operator. It counts the number of metrics that explicitly appear in a given expression,

$$\Delta := g_{\mu\nu}\frac{\partial^{\text{expl}}}{\partial g_{\mu\nu}}.$$

For example, $\Delta(g^{\gamma\mu_2}g^{\lambda\mu_1}\mathcal{D}_{\mu_1}C^\beta{}_{\gamma\delta\varepsilon}) = -2(g^{\gamma\mu_2}g^{\lambda\mu_1}\mathcal{D}_{\mu_1}C^\beta{}_{\gamma\delta\varepsilon})$ and $\Delta(g_{\alpha\beta}g^{\gamma\delta}) = 0$. As a consequence of (10a), (10b), and (9a), we can write $\gamma_1\sqrt{|g|} = 2\omega\Delta\sqrt{|g|} = 2\omega[(n/2)\sqrt{|g|}] = n\omega\sqrt{|g|}$, where $|g|$ denotes the absolute value of the determinant of $g_{\mu\nu}$ (supposed invertible).

(2) The operator $\Delta_\mu{}^\rho$ generates GL(n)-transformations of world indices according to

$$\Delta_\mu{}^\nu T^\beta_\alpha = \delta^\nu_\alpha T^\beta_\mu - \delta^\beta_\mu T^\nu_\alpha,$$

where T^β_α is a (1,1)-type tensor under GL(n) transformations. The usual torsion-free covariant derivative can thus be written $\nabla_\mu = \partial_\mu - \Gamma_{\mu\nu}{}^\rho \Delta_\rho{}^\nu$. Note that this expression must be completed by $p\Gamma_{\mu\alpha}{}^\alpha$ if one takes the covariant derivative ∇_μ of a weight-p tensor density, so $\nabla = \mathrm{d}x^\mu \nabla_\mu = \mathrm{d}x^\mu \partial_\mu - \tilde{C}_\nu{}^\rho \Delta_\rho{}^\nu + p\tilde{C}_\mu{}^\mu$.

(3) In order to conveniently define the action of the generator $\mathbf{\Gamma}^\alpha$, we first define the so-called W-tensors carrying superindices Ω_k,

$$W_{\Omega_0} := C^\beta{}_{\gamma\delta\varepsilon}, \quad W_{\Omega_1} := \mathcal{D}_{\alpha_1} C^\beta{}_{\gamma\delta\varepsilon}, \ \dots,$$

$$W_{\Omega_k} := \mathcal{D}_{\alpha_k}\mathcal{D}_{\alpha_{k-1}} \cdots \mathcal{D}_{\alpha_2}\mathcal{D}_{\alpha_1} C^\beta{}_{\gamma\delta\varepsilon}.$$

Then, we can write $\{\mathcal{T}^i\} \subset \{g_{\mu\nu}, \{W_{\Omega_k}\} : k = 0, 1, \dots\}$ and the operator $\mathbf{\Gamma}^\alpha$ acts on space of the W-tensors according to

$$\mathbf{\Gamma}^\alpha W_{\Omega_j} = [T^\alpha]_{\Omega_j}{}^{\Omega_{j-1}} W_{\Omega_{j-1}}, \quad \mathbf{\Gamma}^\alpha := [T^\alpha]_{\Omega_i}{}^{\Omega_{i-1}} \Delta_{\Omega_{i-1}}{}^{\Omega_i}, \tag{12}$$

where $\Delta_{\Omega_j}{}^{\Omega_k} W_{\Omega_i} = \delta^{\Omega_k}_{\Omega_i} W_{\Omega_j}$ and where the symbol $\delta^{\Omega_k}_{\Omega_i}$ is such that $\delta^{\Omega_k}_{\Omega_i} W_{\Omega_k} = W_{\Omega_i}$. We use Einstein's summation conventions for the W-tensor superindices Ω_i. The matrices $[T^\alpha]_{\Omega_j}{}^{\Omega_{j-1}}$ are obtained by recursion in the appendix, with $[T^\alpha]_{\Omega_j}{}^{\Omega_{j-1}} = 0 \ \forall j \leqslant 0$. The action of $\mathbf{\Gamma}^\alpha$ gives zero on everything but the W tensors. In particular, $\mathbf{\Gamma}^\alpha g_{\mu\nu} = 0$.

The W-tensors transform under $\tilde{\gamma}$ according to (10) and (9). They are the building blocks for the construction of Weyl invariants.[1] Note that the Bach tensor is nothing but the following double trace of W_{Ω_2}:

$$B_{\mu\nu} \equiv \nabla^{\alpha}\tilde{C}_{\mu\nu\alpha} - K^{\lambda\rho}C_{\lambda\mu\nu} = \frac{1}{(3-n)}g^{\alpha\rho}\mathcal{D}_{\alpha}\mathcal{D}_{\beta}C^{\beta}{}_{\mu\nu\rho}.$$

For the action of $\tilde{\gamma}$ on the generalized connections, we find

$$\tilde{\gamma}\omega = \tilde{\xi}^{\mu}\tilde{\omega}_{\mu},$$

$$\tilde{\gamma}\tilde{\xi}^{\mu} = \tilde{\xi}^{\rho}\tilde{C}_{\rho}{}^{\mu},$$

$$\tilde{\gamma}\tilde{C}_{\mu}{}^{\nu} = \tilde{C}_{\mu}{}^{\alpha}\tilde{C}_{\alpha}{}^{\nu} + \tfrac{1}{2}\tilde{\xi}^{\rho}\tilde{\xi}^{\sigma}C^{\nu}{}_{\mu\rho\sigma} + \mathcal{P}^{\alpha\nu}_{\mu\beta}\tilde{\omega}_{\alpha}\tilde{\xi}^{\beta},$$

$$\tilde{\gamma}\tilde{\omega}_{\alpha} = \tfrac{1}{2}\tilde{\xi}^{\rho}\tilde{\xi}^{\sigma}\tilde{C}_{\alpha\rho\sigma} + \tilde{C}_{\alpha}{}^{\beta}\tilde{\omega}_{\beta},$$

where $\mathcal{P}^{\alpha\nu}_{\mu\beta} := (-g^{\alpha\nu}g_{\mu\beta} + \delta^{\alpha}_{\mu}\delta^{\nu}_{\beta} + \delta^{\alpha}_{\beta}\delta^{\nu}_{\mu})$. Note the relations $C^{\mu}{}_{\nu\alpha\beta} = R^{\mu}{}_{\nu\alpha\beta} - 2\mathcal{P}^{\mu\rho}_{\nu[\alpha}K_{\beta]\rho}$ and $\gamma_1\Gamma_{\mu\beta}{}^{\nu} = \mathcal{P}^{\alpha\nu}_{\mu\beta}\omega_{\alpha}$.

From $\tilde{\gamma}^2\mathcal{T}^i = 0$, we derive the gauge covariant algebra generated by $\{\Delta, \mathcal{D}_{\nu}, \Delta_{\rho}{}^{\nu}, \mathbf{\Gamma}^{\alpha}\}$,

$$[\Delta_{\nu}{}^{\rho}, \mathbf{\Gamma}^{\alpha}] = -\delta^{\alpha}_{\nu}\mathbf{\Gamma}^{\rho}, \quad [\mathbf{\Gamma}^{\alpha}, \mathbf{\Gamma}^{\beta}] = 0, \tag{13a}$$

$$[\Delta_{\nu}{}^{\rho}, \mathcal{D}_{\mu}] = \delta^{\rho}_{\mu}\mathcal{D}_{\nu}, \quad [\Delta_{\mu}{}^{\rho}, \Delta_{\nu}{}^{\sigma}] = \delta^{\rho}_{\nu}\Delta_{\mu}{}^{\sigma} - \delta^{\rho}_{\nu}\Delta_{\mu}{}^{\sigma}, \tag{13b}$$

$$[\mathbf{\Gamma}^{\alpha}, \mathcal{D}_{\beta}] = -\mathcal{P}^{\alpha\nu}_{\mu\beta}\Delta_{\nu}{}^{\mu}, \quad [\mathcal{D}_{\mu}, \mathcal{D}_{\nu}] = C_{\mu\nu\rho}{}^{\sigma}\Delta_{\sigma}{}^{\rho} - \tilde{C}_{\alpha\mu\nu}\mathbf{\Gamma}^{\alpha}, \tag{13c}$$

where the operator Δ commutes with everything. The second equality of (13a) reflects the Abelian nature of the Weyl transformations, while the second equality of (13c) displays the commutator of two Weyl-covariant derivatives in terms of the Weyl tensor and the Cotton tensor. Note that the commutator of two covariant derivatives reads $[\nabla_{\mu}, \nabla_{\nu}] = R_{\mu\nu\rho}{}^{\sigma}\Delta_{\sigma}{}^{\rho}$.

From $\tilde{\gamma}^2\tilde{C}^N = 0$, we find the following set of Bianchi identities:

$$\tilde{\gamma}^2\omega = 0 \Rightarrow \tilde{C}_{[\mu\rho\sigma]} = 0, \tag{14a}$$

$$\tilde{\gamma}^2\tilde{C}_{\mu}{}^{\nu} = 0 \Rightarrow \nabla_{[\gamma}C_{\delta\varepsilon]\alpha\beta} - \tilde{C}_{\alpha[\gamma\delta}g_{\varepsilon]\beta} + \tilde{C}_{\beta[\gamma\delta}g_{\varepsilon]\alpha} = 0, \tag{14b}$$

$$\tilde{\gamma}^2\tilde{\xi}^{\mu} = 0 \Rightarrow \begin{cases} \mathcal{P}^{\alpha\mu}_{[\rho\nu]} = 0, \\ C^{\mu}{}_{[\nu\rho\sigma]} = 0, \end{cases} \tag{14c}$$

$$\tilde{\gamma}^2\tilde{\omega}_{\alpha} = 0 \Rightarrow \begin{cases} \mathbf{\Gamma}^{\alpha}\tilde{C}_{\beta\rho\sigma} + C^{\alpha}{}_{\beta\rho\sigma} = 0, \\ \mathcal{D}_{[\beta}\tilde{C}_{\rho\sigma]\alpha} = 0 \end{cases} \tag{14d}$$

which are nothing but the Jacobi identities for the algebra (13).

Note that the case $n=3$ proceeds in exactly the same way, provided one sets $C^{\mu}{}_{\nu\rho\sigma}$ to zero and one defines $W^{(3)}_{\Omega_0} := \tilde{C}_{\alpha\rho\sigma}$. In other words, the relations (13) and (14) still hold, setting $C^{\mu}{}_{\nu\rho\sigma} = 0$. The representation matrices $\mathbf{\Gamma}^{\alpha}$ and the Weyl-covariant derivative (11) are unchanged as well. More explicitly, we have

$$n \geqslant 4, \quad \gamma_1\mathcal{D}_{\alpha_1}C^{\beta}{}_{\gamma\delta\varepsilon} = \omega_{\alpha}(-\mathcal{P}^{\alpha\nu}_{\mu\alpha_1}\Delta_{\nu}{}^{\mu})C^{\beta}{}_{\gamma\delta\varepsilon} \rightsquigarrow \gamma_1 W_{\Omega_1} = \omega_{\alpha}\mathbf{\Gamma}^{\alpha}W_{\Omega_1},$$

$$n=3, \quad \gamma_1 \mathcal{D}_{\alpha_1} \widetilde{C}_{\gamma\delta\varepsilon} = \omega_\alpha (-\mathcal{P}^{\alpha\nu}_{\mu\alpha_1} \Delta_\nu{}^\mu) \widetilde{C}_{\gamma\delta\varepsilon} \rightsquigarrow \gamma_1 W^{(3)}_{\Omega_1} = \omega_\alpha \mathbf{\Gamma}^\alpha_{(3)} W^{(3)}_{\Omega_1},$$

which shows that the representation matrices $\mathbf{\Gamma}^\alpha$ and $\mathbf{\Gamma}^\alpha_{(3)}$ are essentially the same. Indeed, the iterative procedure given in the appendix reproduces itself in exactly the same way when $n=3$, with the convention that $W^{(3)}_{\Omega_0} \equiv \widetilde{C}_{\alpha\rho\sigma}$.

This work was partly done at the DAMTP (Cambridge, UK), where the author was Wiener-Anspach postdoctoral fellow (Belgium).

APPENDIX: *W*-TENSORS AND THEIR TRANSFORMATIONS

The *W*-tensors are computed iteratively, together with their transformation laws under Weyl rescalings of the metric.

(A) First, we have $\gamma_1 W_{\Omega_0} = \omega_\alpha \mathbf{\Gamma}^\alpha W_{\Omega_0} = 0$. Then, we form $W_{\Omega_1} = \nabla_{\alpha_1} W_{\Omega_0}$. Taking the Weyl variation gives

$$\gamma_1 W_{\Omega_1} = \gamma_1 [(\partial_{\alpha_1} - \Gamma_{\alpha_1\mu}{}^\nu \Delta_\nu{}^\mu) W_{\Omega_0}] = -\omega_\lambda \mathcal{P}^{\lambda\nu}_{\mu\alpha_1} \Delta_\nu{}^\mu W_{\Omega_0} = \omega_\lambda [T^\lambda]_{\Omega_1}{}^{\Omega_0} W_{\Omega_0},$$

where the last equality serves as a definition for the tensor $[T^\lambda]_{\Omega_1}{}^{\Omega_0}$, which satisfies $\gamma_1 [T^\lambda]_{\Omega_1}{}^{\Omega_0} = 0 = \nabla_\mu [T^\lambda]_{\Omega_1}{}^{\Omega_0}$. We also use the notation $\gamma_1 W_{\Omega_1} = \omega_\alpha \mathbf{\Gamma}^\alpha W_{\Omega_0}$, cf. Eq. (12).

Continuing, we compute the Weyl variation of $\nabla_{\alpha_2} W_{\Omega_1}$,

$$\begin{aligned}\gamma_1 \nabla_{\alpha_2} W_{\Omega_1} &= \nabla_{\alpha_2} (\omega_\lambda [T^\lambda]_{\Omega_1}{}^{\Omega_0} W_{\Omega_0}) - \omega_\lambda \mathcal{P}^{\lambda\nu}_{\mu\alpha_2} \Delta_\nu{}^\mu W_{\Omega_1} \\ &= (-\gamma_1 K_{\lambda\alpha_2}) [T^\lambda]_{\Omega_1}{}^{\Omega_0} W_{\Omega_0} + \omega_\lambda [T^\lambda]_{\Omega_1}{}^{\Omega_0} \nabla_{\alpha_2} W_{\Omega_0} - \omega_\lambda \mathcal{P}^{\lambda\nu}_{\mu\alpha_2} \Delta_\nu{}^\mu W_{\Omega_1}.\end{aligned}$$

Using $\gamma_1([T^\lambda]_{\Omega_1}{}^{\Omega_0} W_{\Omega_0}) = 0$, we obtain

$$\gamma_1 (\nabla_{\alpha_2} W_{\Omega_1} + K_{\lambda\alpha_2} [T^\lambda]_{\Omega_1}{}^{\Omega_0} W_{\Omega_0}) = \omega_\lambda (\delta^{\Omega'}_{\alpha_2\Omega_0}{}^1 [T^\lambda]_{\Omega_1}{}^{\Omega_0} - \delta^{\Omega'}_{\Omega_1}{}^1 \mathcal{P}^{\lambda\nu}_{\mu\alpha_2} \Delta_\nu{}^\mu) W_{\Omega'_1}$$

which we rewrite

$$\gamma_1 W_{\Omega_2} = \omega_\lambda [T^\lambda]_{\Omega_2}{}^{\Omega_1} W_{\Omega_1} = \omega_\alpha \mathbf{\Gamma}^\alpha W_{\Omega_2},$$

where $W_{\Omega_2} \equiv \mathcal{D}_{\alpha_2} W_{\Omega_1} = \nabla_{\alpha_2} W_{\Omega_1} + K_{\lambda\alpha_2} [T^\lambda]_{\Omega_1}{}^{\Omega_0} W_{\Omega_0}$.

Calculating $\gamma_1 \gamma_1 W_{\Omega_2}$, we find $0 = \omega_\alpha \omega_\beta \mathbf{\Gamma}^\alpha \mathbf{\Gamma}^\beta W_{\Omega_2}$, or $[\mathbf{\Gamma}^\alpha, \mathbf{\Gamma}^\beta] = 0$, cf. second equation of (13a). Also, since

$$W_{\Omega_2} \equiv \mathcal{D}_{\alpha_2} W_{\Omega_1} \equiv \mathcal{D}_{\alpha_2} \mathcal{D}_{\alpha_1} W_{\Omega_0} = (\nabla_{\alpha_2} \nabla_{\alpha_1} + K_{\lambda\alpha_2} [T^\lambda]_{\Omega_1}{}^{\Omega_0}) W_{\Omega_0},$$

we find that

$$[\mathcal{D}_{\alpha_2}, \mathcal{D}_{\alpha_1}] W_{\Omega_0} = C_{\alpha_2\alpha_1\mu}{}^\nu \Delta_\nu{}^\mu W_{\Omega_0},$$

in agreement with the second equation of (13c) and $\mathbf{\Gamma}^\alpha W_{\Omega_0} = 0$ (equivalent to $\gamma_1 W_{\Omega_0} = 0$).

(B) Suppose that we have $W_{\Omega_k} \equiv \mathcal{D}_{\alpha_k} \cdots \mathcal{D}_{\alpha_2} \mathcal{D}_{\alpha_1} W_{\Omega_0}$, $k \geqslant 2$. In other words, we know that

$$W_{\Omega_k} = (\nabla_{\alpha_k} + K_{\lambda\alpha_k} \mathbf{\Gamma}^\lambda) W_{\Omega_{k-1}},$$

$$\gamma_1 W_{\Omega_k} = \omega_\alpha \mathbf{\Gamma}^\alpha W_{\Omega_k} = \omega_\alpha [T^\alpha]_{\Omega_k}{}^{\Omega_{k-1}} W_{\Omega_{k-1}},$$

and

$$\mathbf{\Gamma}^{[\alpha}\,\mathbf{\Gamma}^{\beta]} W_{\Omega_k} = 0.$$

We want to obtain the next tensor, $W_{\Omega_{k+1}} \equiv \mathcal{D}_{\alpha_{k+1}} W_{\Omega_k}$, and its transformation rule.

As before, we first compute the Weyl transformation of $\nabla_{\alpha_{k+1}} W_{\Omega_k}$,

$$\begin{aligned}\gamma_1 \nabla_{\alpha_{k+1}} W_{\Omega_k} &= \nabla_{\alpha_{k+1}} (\omega_\alpha \mathbf{\Gamma}^\alpha W_{\Omega_k}) - \omega_\alpha \mathcal{P}^{\alpha\mu}_{\nu\alpha_{k+1}} \Delta_\mu{}^\nu W_{\Omega_k} \\ &= (-\gamma_1 K_{\alpha\alpha_{k+1}}) \mathbf{\Gamma}^\alpha W_{\Omega_k} + \omega_\alpha [T^\alpha]_{\Omega_k}{}^{\Omega_{k-1}} \nabla_{\alpha_{k+1}} W_{\Omega_{k-1}} - \omega_\alpha \mathcal{P}^{\alpha\mu}_{\nu\alpha_{k+1}} \Delta_\mu{}^\nu W_{\Omega_k}.\end{aligned}$$

Hence, we get

$$\gamma_1 (\nabla_{\alpha_{k+1}} W_{\Omega_k} + K_{\alpha\alpha_{k+1}} \mathbf{\Gamma}^\alpha W_{\Omega_k}) = K_{\alpha\alpha_{k+1}} \omega_\beta \mathbf{\Gamma}^\alpha \mathbf{\Gamma}^\beta W_{\Omega_k} - \omega_\alpha \mathcal{P}^{\alpha\mu}_{\nu\alpha_{k+1}} \Delta_\mu{}^\nu W_{\Omega_k} + \omega_\alpha [T^\alpha]_{\Omega_k}{}^{\Omega_{k-1}} \nabla_{\alpha_{k+1}} W_{\Omega_{k-1}}.$$

Using

$$\nabla_{\alpha_{k+1}} W_{\Omega_{k-1}} = \mathcal{D}_{\alpha_{k+1}} W_{\Omega_{k-1}} - K_{\beta\alpha_{k+1}} \mathbf{\Gamma}^\beta W_{\Omega_{k-1}}$$

and posing

$$\mathcal{D}_{\alpha_{k+1}} W_{\Omega_k} = \nabla_{\alpha_{k+1}} W_{\Omega_k} + K_{\alpha_{k+1}\lambda} \mathbf{\Gamma}^\lambda W_{\Omega_k},$$

we find

$$\begin{aligned}\gamma_1 \mathcal{D}_{\alpha_{k+1}} W_{\Omega_k} &= K_{\alpha\alpha_{k+1}} \omega_\beta \mathbf{\Gamma}^\alpha \mathbf{\Gamma}^\beta W_{\Omega_k} - K_{\beta\alpha_{k+1}} \omega_\alpha \mathbf{\Gamma}^\alpha \mathbf{\Gamma}^\beta W_{\Omega_k} - \omega_\alpha \mathcal{P}^{\alpha\mu}_{\nu\alpha_{k+1}} \Delta_\mu{}^\nu W_{\Omega_k} \\ &\quad + \omega_\alpha \delta^{\Omega'_k}_{\alpha_{k+1}\Omega_{k-1}} [T^\alpha]^{\Omega_{k-1}}_{\Omega_k} W_{\Omega'_k} \\ &= \omega_\lambda (\delta^{\Omega'_k}_{\alpha_{k+1}\Omega_{k-1}} [T^\alpha]^{\Omega_{k-1}}_{\Omega_k} - \delta^{\Omega'_k}_{\Omega_k} \mathcal{P}^{\lambda\mu}_{\nu\alpha_{k+1}} \Delta_\mu{}^\nu) W_{\Omega'_k} = \omega_\lambda [T^\alpha]^{\Omega'_k}_{\alpha_{k+1}\Omega_k} W_{\Omega'_k},\end{aligned}$$

where we used $\mathbf{\Gamma}^{[\alpha}\,\mathbf{\Gamma}^{\beta]} W_{\Omega_k} = 0$. □

(Received 30 November 2004; accepted 2 March 2005; published online 21 April 2005)

This paper is the first in a series that lays the groundwork for a structure and classification theory of second-order superintegrable systems, both classical and quantum, in conformally flat spaces. Many examples of such systems are known, and lists of possible systems have been determined for constant curvature spaces in two and three dimensions, as well as few other spaces. Observed features of these systems are multiseparability, closure of the quadratic algebra of second-order symmetries at order 6, use of representation theory of the quadratic algebra to derive spectral properties of the quantum Schrödinger operator, and a close relationship with exactly solvable and quasi-exactly solvable systems. Our approach is, rather than focus on particular spaces and systems, to use a general theoretical method based on integrability conditions to derive structure common to all systems. In this first paper we consider classical superintegrable systems on a general two-dimensional Riemannian manifold and uncover their common structure. We show that for superintegrable systems with nondegenerate potentials there exists a standard structure based on the algebra of 2×2 symmetric matrices, that such systems are necessarily multiseparable and that the quadratic algebra closes at level 6. Superintegrable systems with degenerate potentials are also analyzed. This is all done without making use of lists of systems, so that generalization to higher dimensions, where relatively few examples are known, is much easier. [DOI: 10.1063/1.1897183]

I. INTRODUCTION AND EXAMPLES

The goal of this series of papers is a structure and classification theory of second-order superintegrable systems, both classical and quantum, in conformally flat spaces. A classical superintegrable system $\mathcal{H}=\Sigma_{ij}g^{ij}p_ip_j+V(\mathbf{x})$ on an n-dimensional local Riemannian manifold is one that admits $2n-1$ functionally independent symmetries (i.e., constants of the motion) $\mathcal{S}_k$, $k=1,\ldots,2n-1$ with $\mathcal{S}_1=\mathcal{H}$. That is, $\{\mathcal{H},\mathcal{S}_k\}=0$ where

$$\{f,g\}=\sum_{j=1}^{n}(\partial_{x_j}f\partial_{p_j}g-\partial_{p_j}f\partial_{x_j}g))$$

is the Poisson bracket for functions $f(\mathbf{x},\mathbf{p}),g(\mathbf{x},\mathbf{p})$ on phase space.[1–8] Note that $2n-1$ is the maximum possible number of functionally independent symmetries and, locally, such symmetries always exist. The main interest is in symmetries that are polynomials in the p_k and are globally

[a)]Electronic mail: j.kress@unsw.edu.au

defined, except for lower dimensional singularities such as poles and branch points. Many tools in the theory of Hamiltonian systems have been brought to bear on superintegrable systems, such as R-matrix theory, Lax pairs, exact solvability, quasi-exact solvability, and the Jacobi metric.[9–13] However, the most detailed and complete results are obtained from separation of variables methods in those cases where they are applicable. Standard orthogonal separation of variables techniques are associated with second-order symmetries, e.g., Refs. 14–20 and multiseparable Hamiltonian systems provide numerous examples of superintegrability. In these papers we shall concentrate on second-order superintegrable systems, that is, those in which the symmetries take the form $\mathcal{S}=\Sigma a^{ij}(\mathbf{x})p_ip_j+W(\mathbf{x})$, quadratic in the momenta.

There is an analogous definition for second-order quantum superintegrable systems with Schrödinger operator

$$H=\Delta+V(\mathbf{x}),\quad \Delta=\frac{1}{\sqrt{g}}\sum_{ij}\partial_{x_i}(\sqrt{g}g^{ij})\partial_{x_j},$$

where Δ is the Laplace–Beltrami operator on a Riemannian manifold, expressed in local coordinates x_j.[15] Here there are $2n-1$ second-order symmetry operators

$$S_k=\frac{1}{\sqrt{g}}\sum_{ij}\partial_{x_i}(\sqrt{g}a^{ij}_{(k)})\partial_{x_j},\quad k=1,\ldots,2n-1$$

with $S_1=H$ and $[H,S_k]\equiv HS_k-S_kH=0$. Again multiseparable systems yield many examples of superintegrability. However, as we shall show, not all multiseparable systems are superintegrable and not all second-order superintegrable systems are multiseparable. There is also a quantization problem in extending the results for classical systems to operator systems. This problem turns out to be very easily solved in two dimensions and not difficult in higher dimensions for nondegenerate systems.

Superintegrable systems can (1) be solved explicitly, and (2) they can be solved in multiple ways. It is the information gleaned from comparing the distinct solutions and expressing one solution set in terms of another that is a primary reason for their interest.

To illustrate some of the main features of superintegrable systems we give a simple example in real Euclidean space. (To make clearer the connection with quantum theory and Hilbert space methods we shall, for this example alone, adopt standard physical normalizations, such as using the factor $-\frac{1}{2}$ in front of the free Hamiltonian.) Consider the Schrödinger eigenvalue equation $H\Psi=E\Psi$ or

$$-\frac{1}{2}\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right)\Psi+\frac{1}{2}\left(\omega^2(x^2+y^2)+\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right)\Psi=E\Psi. \tag{1}$$

This equation separates in three systems: *Cartesian* coordinates (x,y); *polar* coordinates $x=r\cos\theta$, $y=r\sin\theta$, and *elliptical* coordinates

$$x^2=c^2\frac{(u_1-e_1)(u_2-e_1)}{(e_1-e_2)},\quad y^2=c^2\frac{(u_1-e_2)(u_2-e_2)}{(e_2-e_1)}.$$

The bound states are degenerate with energies given by $E_n=\omega(2n+2+k_1+k_2)$ for integer n. The corresponding wave functions are (1) *Cartesian:*

$$\Psi_{n_1,n_2}(x,y)=2\omega^{(1/2)(k_1+k_2+2)}\sqrt{\frac{n_1!n_2!}{\Gamma(n_1+k_1+1)\Gamma(n_2+k_2+1)}}x^{(k_1+1/2)}y^{(k_2+1/2)}e^{-(\omega/2)(x^2+y^2)}L_{n_1}^{k_1}(\omega x^2)$$
$$\times L_{n_2}^{k_2}(\omega y^2),\quad n=n_1+n_2, \tag{2}$$

and the $L_n^k(x)$ are Laguerre polynomials.[21] (2) *Polar:*

$$\Psi(r,\theta)=\Phi_q^{(k_1,k_2)}(\theta)\omega^{(1/2)(2q+k_1+k_2+1)}\sqrt{\frac{2m!}{\Gamma(m+2q+k_1+k_2+1)}}e^{(-\omega r^2/2)}r^{(2q+k_1+k_2+1)}L_m^{2q+k_1+k_2+1}(\omega r^2),$$
$$n=m+q, \tag{3}$$

$$\Phi_q^{(k_1,k_2)}(\theta)=\sqrt{2(2q+k_1+k_2+1)\frac{q!\Gamma(k_1+k_2+q+1)}{\Gamma(k_2+q+1)\Gamma(k_1+q+1)}}(\cos\theta)^{k_1+(1/2)}(\sin\theta)^{k_2+(1/2)}P_q^{(k_1,k_2)}\times(\cos 2\theta), \tag{4}$$

and the $P_q^{(k_1,k_2)}(\cos 2\theta)$ are Jacobi polynomials.[21] (3) *Elliptical:*

$$\Psi=e^{-\omega(x^2+y^2)}x^{k_1+1/2}y^{k_2+1/2}\prod_{m=1}^{n}\left(\frac{x^2}{\theta_m-e_1}+\frac{y^2}{\theta_m-e_2}-c^2\right)$$

where

$$\frac{x^2}{\theta-e_1}+\frac{y^2}{\theta-e_2}-c^2=-c^2\frac{(u_1-\theta)(u_2-\theta)}{(\theta-e_1)(\theta-e_2)} \tag{5}$$

are ellipsoidal wave functions.[22,23] A basis for the second-order symmetry operators is

$$L_1=\partial_x^2+\frac{\left(\frac{1}{4}-k_1^2\right)}{x^2}-\omega^2x^2,\quad L_2=\partial_y^2+\frac{\left(\frac{1}{4}-k_2^2\right)}{y^2}-\omega^2y^2,$$
$$L_3=(x\partial_y-y\partial_x)^2+\left(\frac{1}{4}-k_1^2\right)\frac{y^2}{x^2}+\left(\frac{1}{4}-k_2^2\right)\frac{x^2}{y^2}-\frac{1}{2}. \tag{6}$$

(Note that $-2H=L_1+L_2$.) The separable solutions are eigenfunctions of the symmetry operators L_1, L_3 and $L_3+e_2L_1+e_1L_2$ with eigenvalues

$$\lambda_c=-\omega(2n_1+k_1+1),\quad \lambda_p=(2q+k_1+k_2+1)^2+(1+k_1^2+k_2^2),$$

$$\lambda_e=2(1-k_1)(1-k_2)-2e_2\omega(k_1+1)-2e_1\omega(k_2+1)-\omega^2e_1e_2-4\sum_{m=1}^{q}\left[e_2\frac{k_1+1}{\theta_m-e_1}+e_1\frac{k_2+1}{\theta_m-e_2}\right],$$

respectively. The algebra constructed by repeated commutators is

$$[L_1,L_3]=[L_3,L_2]\equiv R,\quad [L_i,R]=-4\{L_i,L_j\}+16\omega^2L_3,\quad i\neq j,\quad i,j=1,2,$$

$$[L_3,R]=4\{L_1,L_3\}-4\{L_2,L_3\}+8(1-k_2^2)L_1-8(1-k_1^2)L_2,$$

$$R^2=\tfrac{8}{3}\{L_1,L_2,L_3\}+\tfrac{64}{3}\{L_1,L_2\}+16\omega^2L_3^2-16(1-k_2^2)L_1^2-16(1-k_1^2)L_2^2-\tfrac{128}{3}\omega^2L_3-64\omega^2(1-k_1^2)(1-k_2^2). \tag{7}$$

Note that these relations are quadratic. Here $\{A,B\}=AB+BA$, is a double symmetrizer and there is a corresponding definition for the triple symmetrizer. The important fact to observe about the algebra generated by L_1,L_2,L_3, R is that it is *closed under commutation*.[24,25] This is a remarkable fact, but typical of superintegrable systems with nondegenerate potentials, as we shall show. Indeed the closure is at level 6, since we have to express the square of the third-order operator R

in terms of the L_j basis of second-order operators. Note that the degeneracy of the energy eigenspace is broken by the alternate separated bases of eigenfunctions. The eigenfunctions of one separable system can be expanded in terms of the eigenfunctions of another, and this is the source of nontrivial special function expansion theorems.[26] The symmetry operators are in formal self-adjoint form and suitable for spectral analysis. Also, the quadratic algebra identities allow us to relate eigenbases and eigenvalues of one symmetry operator to those of another. Indeed the representation theory of the abstract quadratic algebra can be used to derive spectral properties of the generators L_j, in a manner analogous to the use of Lie algebra representation theory to derive spectral properties of quantum systems that admit Lie symmetry algebras.[26–29] (Note however that for superintegrable systems with nondegenerate potential, there is no first-order Lie symmetry.)

A common feature of quantum superintegrable systems, exhibited in the above-given example, is that after splitting off a multiplicative functional factor, $x^{(k_1+1/2)}y^{(k_2+1/2)}e^{-(\omega/2)(x^2+y^2)}$ in the example, the Schrödinger and symmetry operators are acting on a space of polynomials.[30] This is closely related to the theory of exactly and quasi-exactly solvable systems.[11,31,32] In the example the one-dimensional ordinary differential equations (ODEs) obtained by separation in the Cartesian and polar systems are exactly solvable, in terms of hypergeometric functions, i.e., there is an infinite set of nested invariant subspaces under the Cartesian or polar separated ODEs, and the energy eigenvalues are easily obtained. The elliptic system separated equations are quasi-exactly solvable, i.e., there is a single invariant finite dimensional subspace of a separated ODE and only for certain parameter choices, and polynomial solutions are obtained for only particular values of E. However, these values are just the energy eigenvalues obtained in the Cartesian and polar systems. This characterization of quasi-exactly solvable systems as embedded in PDE superintegrable systems provides insight into the nature of these phenomena.

The classical analog of the above-given example is obtained by the replacements $\partial_x \to p_x$, $\partial_y \to p_y$. Commutators go over to Poisson brackets. The operator symmetries become second-order constants of the motion. Symmetrized operators become products of functions. The quadratic algebra relations simplify: the highest order terms agree with the operator case but there are fewer nonzero lower order terms. Indeed, the classical algebra has basis

$$\mathcal{S}_1 = p_x^2 + \frac{\frac{1}{4} - k_1^2}{x^2} - \omega^2 x^2, \quad \mathcal{S}_2 = p_y^2 + \frac{\frac{1}{4} - k_2^2}{y^2} - \omega^2 y^2,$$
$$\mathcal{S}_3 = (xp_y - yp_x)^2 + \left(\frac{1}{4} - k_1^2\right)\frac{y^2}{x^2} + \left(\frac{1}{4} - k_2^2\right)\frac{x^2}{y^2}, \quad -2\mathcal{H} = \mathcal{S}_1 + \mathcal{S}_2. \tag{8}$$

The classical quadratic algebra relations are

$$\{\mathcal{S}_1, \mathcal{S}_3\} = \{\mathcal{S}_3, \mathcal{S}_2\} \equiv \mathcal{R}, \quad \{\mathcal{S}_i, \mathcal{R}\} = 8\mathcal{S}_i\mathcal{S}_j + 16\omega^2\mathcal{S}_3, \quad i \neq j, \quad i,j = 1,2,$$
$$\{\mathcal{S}_3, \mathcal{R}\} = 8\mathcal{S}_1\mathcal{S}_3 - 8\mathcal{S}_2\mathcal{S}_3 + (4 - 16k_2^2)\mathcal{S}_1 - (4 - 16k_1^2)\mathcal{S}_2, \tag{9}$$
$$\mathcal{R}^2 = 16\mathcal{S}_1\mathcal{S}_2\mathcal{S}_3 - 16\omega^2\mathcal{S}_3^2 + (4 - 16k_2^2)\mathcal{S}_1^2 - (4 - 16k_1^2)\mathcal{S}_2^2 + 4\omega^2(1 - 4k_1^2)(1 - 4k_2^2).$$

In the example the potential

$$V(x,y) = \frac{1}{2}\left(\omega^2(x^2 + y^2) + \frac{k_1^2 - \frac{1}{4}}{x^2} + \frac{k_2^2 - \frac{1}{4}}{y^2}\right)$$

is *nondegenerate* in the sense that at any point x_0, y_0 where the potential is defined and analytic and the $\mathcal{S}_k$ are functionally independent, we can prescribe the values of $V_1(x_0,y_0), V_2(x_0,y_0), V_{11}(x_0,y_0)$ arbitrarily by choosing appropriate values for the parameters

ω, k_1, k_2. Here, $V_1 = \partial V/\partial x$, $V_2 = \partial V/\partial y$, etc. [Another way to look at this is to say that

$$V_1(x_0,y_0), V_2(x_0,y_0), V_{11}(x_0,y_0)$$

are the parameters.] This is in addition to the trivial constant that we can always add to a potential. As we shall show, this requirement for a superintegrable system implies that the potential is any solution of a system of coupled PDEs of the form

$$V_{22} = V_{11} + A^{22}(x,y)V_1 + B^{22}(x,y)V_2, \quad V_{12} = A^{12}(x,y)V_1 + B^{12}(x,y)V_2,$$

where the functions A^{ij}, B^{ij} are subject to certain compatibility conditions, so that the solution space is of dimension four. In $n \geqslant 2$ dimensions the analogous nondegenerate potentials depend on $n+2$ parameters. Systems with nondegenerate potentials have the most beautiful properties but there are also superintegrable systems with degenerate potentials depending on $<n+2$ parameters. For $n=2$ we will show that all of these systems depending on two or three parameters are in a certain sense specializations of the nondegenerate systems. (For degenerate systems, first-order symmetries may exist.) However, superintegrable systems with one parameter (i.e., constant) potentials are in general not restrictions of systems with nondegenerate potentials. [Note that in the classical case the symmetries corresponding to a constant potential are just Killing tensors.[15]] Indeed superintegrable systems with constant potential do not necessarily have a closed quadratic algebra. See Ref. 44 for a counterexample.

Many examples of such systems are known, and lists of possible systems have been determined for constant curvature spaces in two and three dimensions, as well as a few other spaces.[33–38] Here, rather than focus on particular spaces and systems, we employ a theoretical method based on integrability conditions to derive structure common to all such systems. In this paper we consider classical superintegrable systems on a general two-dimensional (2D) Riemannian manifold, real or complex, and uncover their common structure. We show that for superintegrable systems with nondegenerate potentials there exists a standard structure based on the algebra of 2×2 symmetric matrices, that such systems are necessarily multiseparable, and that the quadratic algebra closes at level 6. Superintegrable systems with degenerate potentials are also analyzed. This is all done without making use of lists of such systems, so that generalization to higher dimensions, where relatively few examples are known,[38] is much easier.

In the next paper in this series we will study the Stäckel transform, or coupling constant metamorphosis,[39,40] for 2D classical superintegrable systems. This is a conformal transformation of a superintegrable system on one space to a superintegrable system on another space. We will prove that all nondegenerate 2D superintegrable systems are Stäckel transforms of constant curvature systems and give a complete classification of all 2D superintegrable systems. The following papers will extend these results to three-dimensional (3D) systems and the quantum analogs of 2D and 3D classical systems.

II. SECOND-ORDER KILLING TENSORS FOR 2D COMPLEX RIEMANNIAN MANIFOLDS

Before proceeding to the study of superintegrable systems with potential, we review some basic facts about second-order symmetries (without potential) of the underlying 2D complex Riemannian spaces, i.e., second-order Killing tensors.[15] These were worked out by Koenigs,[41] though here we make an alternate presentation suggested by Refs. 42, 43, and 17. It is always possible to find a local coordinate system $(x,y) \equiv (x_1,x_2)$ defined in a neighborhood of (0,0) on the manifold such that the metric is

$$ds^2 = \lambda(x,y)(dx^2 + dy^2) = \lambda\, dz\, d\overline{z}, \quad z = x + iy, \quad \overline{z} = x - iy,$$

and the Hamiltonian is $H_0 = (p_1^2 + p_2^2)/\lambda$. We can consider a second-order Killing tensor (symmetry) as a quadratic form $\mathcal{L} = \Sigma_{i,j=1}^2 a^{ij}(x,y)p_i p_j$, $a^{ij} = a^{ji}$, that is in involution with the free Hamiltonian H_0: $\{H_0, \mathcal{L}\} = 0$. The conditions are

$$a_i^{ii} = -\frac{\lambda_1}{\lambda}a^{i1} - \frac{\lambda_2}{\lambda}a^{i2}, \quad i = 1,2,$$
$$2a_i^{ij} + a_j^{ii} = -\frac{\lambda_1}{\lambda}a^{j1} - \frac{\lambda_2}{\lambda}a^{j2}, \quad i,j = 1,2, \quad i \neq j. \tag{10}$$

From these conditions we easily obtain the requirements

$$2a_1^{12} = -(a^{11} - a^{22})_2, \quad 2a_2^{12} = (a^{11} - a^{22})_1.$$

From the integrability conditions for these last equations we see that

$$\Delta a^{12} = 0, \quad \Delta(a^{11} - a^{22}) = 0, \quad \Delta = \partial_x^2 + \partial_y^2$$

and that there exist analytic functions $f(z)$, $g(\overline{z})$ such that

$$2a^{12} = f(z) + g(\overline{z}), \quad a^{11} - a^{22} = i(f(z) - g(\overline{z})).$$

Substituting these results in the remaining equations we find

$$(a^{11}\lambda)_1 = -\tfrac{1}{2}\lambda_2(f+g), \quad (a^{22}\lambda)_2 = -\tfrac{1}{2}\lambda_1(f+g).$$

The integrability condition for these last equations is

$$\partial_{12}((\lambda(f-g)) + \frac{i}{2}\partial_1((\lambda_1(f+g)) - \frac{i}{2}\partial_2((\lambda_2(f+g)) = 0$$

or

$$f'' + 3f'\frac{\lambda_z}{\lambda} + 2f\frac{\lambda_{zz}}{\lambda} = -g'' - 3g'\frac{\lambda_{\overline{z}}}{\lambda} - 2g\frac{\lambda_{\overline{zz}}}{\lambda}. \tag{11}$$

If the space admits at least one Killing tensor independent of the Hamiltonian, then we can always assume that it is of the form $(f,g)=(1,1)$, i.e., we can make the change of coordinates $Z = \int dz/\sqrt{f(z)}$, $\overline{Z} = \int d\overline{z}/\sqrt{g(\overline{z})}$ so that (11) implies

$$\lambda_{zz} = \lambda_{\overline{zz}}.$$

Prescribing the values of $g(0), g'(0), g''(0), f(0), f'(0)$, we can use (11) to compute $f''(0)$. Differentiating this equation successively with respect to z and $\overline{z}$ we can compute all derivatives of f and g. Thus any solution (f,g) of the integrability conditions is uniquely determined by the five prescribed values. Once f and g are given, the Killing tensor a^{ij} is determined to within addition of an arbitrary multiple of the Hamiltonian H_0. Thus the maximum dimension of the space of second-order Killing tensors is six. As is very well known, this maximum is actually achieved for flat space and spaces of nonzero constant curvature. Recall that a 2D manifold is of constant curvature if and only if $k = (\partial_{z\overline{z}}\ln\lambda)/\lambda$ is a constant. The space is flat if and only if $k \equiv 0$.

Note that the maximum dimension of six is achieved if and only if the integrability conditions for (11) are themselves satisfied identically. Applying the operator $\partial_{z\overline{z}}$ to both sides of this expression we find

$$3\partial_{\overline{z}}\left(\frac{\lambda_z}{\lambda}\right)f'' + \left(2\partial_{\overline{z}}\left(\frac{\lambda_{zz}}{\lambda}\right) + 3\partial_{z\overline{z}}\left(\frac{\lambda_z}{\lambda}\right)\right)f' + 2\partial_{z\overline{z}}\left(\frac{\lambda_{zz}}{\lambda}\right)f$$
$$= -3\partial_z\left(\frac{\lambda_{\overline{z}}}{\lambda}\right)g'' - \left(2\partial_z\left(\frac{\lambda_{\overline{zz}}}{\lambda}\right) + 3\partial_{z\overline{z}}\left(\frac{\lambda_{\overline{z}}}{\lambda}\right)\right)g' - 2\partial_{z\overline{z}}\left(\frac{\lambda_{\overline{zz}}}{\lambda}\right)g. \tag{12}$$

If dimension six is achieved then this last condition on f and g cannot be independent of (11). Hence, either the coefficients of f'',f',f,g'',g',g all vanish identically, in which case $\partial_{z\bar{z}}\ln\lambda \equiv 0$ and the space is flat, or $\partial_{z\bar{z}}\ln\lambda \neq 0$ and (12) is obtained from (11) through multiplication by $\partial_{z\bar{z}}\ln\lambda$. In the second case one can easily see that

$$\partial_z\left(\frac{\partial_{z\bar{z}}\ln\lambda}{\lambda}\right) = \partial_{\bar{z}}\left(\frac{\partial_{z\bar{z}}\ln\lambda}{\lambda}\right) = 0$$

so the space is of nonzero constant curvature.

If the dimension of the space of symmetries is less than six then (12) is independent of (11). In this case we can eliminate f'' and g'' between these two equations and obtain a condition relating only f',f,g',g:

$$\left[2\left(\frac{\lambda_{zz}}{\lambda}\right)_{\bar{z}} - 9k\lambda_z + 3\left(\frac{\lambda_z}{\lambda}\right)_{z\bar{z}}\right]f' + \left[2\left(\frac{\lambda_{zz}}{\lambda}\right)_{z\bar{z}} - 6k\lambda_{zz}\right]f$$
$$= -\left[2\left(\frac{\lambda_{zz}}{\lambda}\right)_{z} - 9k\lambda_z + 3\left(\frac{\lambda_z}{\lambda}\right)_{z\bar{z}}\right]g' - \left[2\left(\frac{\lambda_{\bar{z}\bar{z}}}{\lambda}\right)_{z\bar{z}} - 6k\lambda_{zz}\right]g. \tag{13}$$

Thus the remaining systems have spaces of symmetries of dimensions $\leqslant 4$. A straightforward computation shows that this last equation can be rewritten as

$$[5\lambda k_z]f + [2\lambda k_{zz} + 8\lambda_z k_z]f' = -[5\lambda k_{\bar{z}}]g' - [2\lambda k_{\bar{z}\bar{z}} + 8\lambda_{\bar{z}} k_{\bar{z}}]g \tag{14}$$

where $2\lambda k_{zz} + 8\lambda_z k_z = 2\lambda k_{\bar{z}\bar{z}} + 8\lambda_{\bar{z}} k_{\bar{z}}$. If the space of symmetries is of dimension four then the integrability conditions for this last equation are satisfied identically. The systems with dimension four (which we call the Darboux spaces) were classified by Koenigs and are four in number.[41] If the equations are not satisfied identically, then we can repeat this procedure and find integrability conditions for the spaces of symmetries of dimension three. These spaces were also classified by Koenigs. In the next paper in this series we will find an alternate, much simpler derivation of these spaces that shows that they all admit superintegrable systems with nondegenerate potentials.

Functional independence and functional linear independence of superintegrable systems. Suppose we have a Hamiltonian $H=H_0+V=\Sigma_{i,j=1}^2 g^{ij}p_ip_j+V(x,y)$ and constants of the motion $L_k = \mathcal{L}_k + W^{(k)} = \Sigma_{i,j=1}^2 a_{(k)}^{ij}p_ip_j + W^{(k)}(x,y)$, for $k=1,2$. We say that such a system is *superintegrable* provided the two functions L_h together with H are functionally independent in the four-dimensional phase space. (Here the possible V will always be assumed to form a vector space and we require functional independence for each such V and the associated $W^{(k)}$. This means that we require that the three quadratic forms $\mathcal{L}_k, H_0$ are functionally independent.)

In the work to follow it will be important that the functionally independent symmetries also be functionally linearly independent. It is clear that there are no constants α,β,γ not all 0 such that $\alpha\mathcal{L}_1+\beta\mathcal{L}_2+\gamma H_0 \equiv 0$. However such a relation is possible if α,β,γ are functions. Indeed we have the example

$$H_0 = p_zp_{\bar{z}} + V(\bar{z}), \quad \mathcal{L}_1 = p_z^2, \quad \mathcal{L}_2 = p_z(zp_z - \bar{z}p_{\bar{z}}),$$

$$W^{(1)} = 0, \quad W^{(2)} = W^{(2)}(\bar{z}), \tag{15}$$

where $-\bar{z}V_{\bar{z}} = W_{\bar{z}}^{(2)}$. Here $\mathcal{L}_2 = z\mathcal{L}_1 - \bar{z}H_0$. (This superintegrable system is in Lie form.[41] It is not multiseparable.) The following result shows that this example is unique.

Theorem 1: *The flat space system* (15) *is the only superintegrable system in a 2D complex Riemannian space such that the functionally independent symmetries are functionally linearly dependent*.

Proof: Suppose L_1,L_2,H are functionally independent symmetries that are functionally linearly dependent. Without loss of generality we can assume that

$$\mathcal{L}_2 = f(x,y)\mathcal{L}_1 + g(x,y)H, \quad df \neq 0, \quad dg \neq 0.$$

Since L_2 is a symmetry we have the condition $\{f,H_0\}\mathcal{L}_1+\{g,H_0\}H_0=0$ or

$$\begin{gathered} f_x a^{11} + g_x/\lambda = 0, \\ f_y a^{22} + g_y/\lambda = 0, \\ f_y a^{11} + 2f_x a^{12} + g_y/\lambda = 0, \\ f_x a^{22} + 2f_y a^{12} + g_x/\lambda = 0. \end{gathered} \tag{16}$$

Thus $g_x=-\lambda f_x a^{11}$, $g_y=-\lambda f_y a^{22}$ and the remaining conditions take the form

$$\begin{pmatrix} 2a^{12} & a^{11}-a^{22} \\ a^{22}-a^{11} & 2a^{12} \end{pmatrix}\begin{pmatrix} f_x \\ f_y \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

Since $df\neq 0$ the determinant of the 2×2 matrix must be zero:

$$4(a^{12})^2 + (a^{22}-a^{11})^2 = 0.$$

We consider the case $a^{22}-a^{11}=-2ia^{12}$. Then $f_x=-if_y$, so $f=f(z)$. From the Killing equations (10) we see that $a_2^{12}=ia_1^{12}$ so, $a^{12}=a^{12}(z)$. The symmetry conditions for $V,W^{(1)},W^2$ are $W_k^{(j)}=a^{k1}V_1+a^{k2}V_2$, $j,k=1,2$ and the integrability conditions for these equations are the Bertrand–Darboux (BD) conditions $(W_1^{(j)})_2=(W_2^{(j)})_1$, $j=1,2$, which in this case simplify to

$$V_{22}-V_{11}+2iV_{12} = -\left[3\frac{a_2^{12}}{a^{12}} + 2i\frac{\lambda_1}{\lambda} + 2\frac{\lambda_2}{\lambda}\right](V_2+iV_1),$$

$$V_{22}-V_{11}+2iV_{12} = -\left[3\frac{a_2^{12}}{a^{12}} + 2i\frac{\lambda_1}{\lambda} + 2\frac{\lambda_2}{\lambda}\right](V_2+iV_1) - 3\frac{f_2}{f}(V_2+iV_1).$$

Subtracting the second BD equation from the first, we find $V_1-iV_2=0$ or $V=V(\overline{z})$. The remaining Killing tensor equations are

$$(a^{11}\lambda)_1 = -\lambda_2 a^{12}, \quad (a^{11}\lambda)_2 = 2i(a^{12}\lambda)_2 - \lambda_1 a^{12},$$

with integrability condition

$$-(\lambda_2 a^{12})_2 = 2i(\lambda a^{12})_{12} - (\lambda_1 a^{12})_1.$$

At this point it is useful to write all equations in terms of the variables $z,\overline{z}$. Then the Killing tensor equations become

$$\lambda_{zz}=0, \quad \left(\lambda\left[a^{11}-\frac{i}{2}\right]\right)_z = 0 \tag{17}$$

and the previous integrability condition becomes

$$s'' + 3s'\frac{\lambda_{zz}}{\lambda} + 2\frac{\lambda_{zz}}{\lambda} = 0,$$

where

$$2a^{12} = s(z),\ a^{11} - a^{22} = is(z).$$

We can change to new variables $Z(z),\overline{Z(\overline{z})}=\overline{z}$ such that this last equation becomes $s(Z)\equiv 1$, $\lambda_{ZZ}=0$. From now on, we assume that the original coordinates $z,\overline{z}$ were chosen so that $\lambda_{zz}=0$, $2a^{12}=1$, $a^{11}-a^{22}=i$. In the new coordinates we have

$$H_0 = 2\frac{p_z p_{\overline{z}}}{\lambda},\quad \mathcal{L}_1 = 2ip_z^2 + 4\left(a^{11} - \frac{i}{2}\right)p_z p_{\overline{z}},\quad g_{\overline{z}} = -i\lambda f'(z),$$

$$g_z = -2\lambda\left(a^{11} - \frac{i}{2}\right)f'(z),$$

so the integrability equation for g is

$$-i\lambda_z f' - i\lambda f'' = -2\lambda_{\overline{z}} f\left(a^{11} - \frac{i}{2}\right)f' - 2\lambda a_z^{11} f',$$

which simplifies to $(\lambda f'(z))_z = 0$. From (17) we see that there are functions $M(\overline{z}),N(\overline{z})$ such that

$$\lambda = izM'(\overline{z}) + N(\overline{z}),\quad a^{11} - \frac{i}{2} = \frac{M(\overline{z})}{izM'(\overline{z}) + N(\overline{z})}.$$

If $M'(\overline{z})\neq 0$ then we can choose a new variable $\overline{Z(\overline{z})}$ such that $M'(\overline{Z})=-i$. Assume that we have made this choice for $\overline{z}$ from the beginning. Then the equation $(\lambda f'(z))_z=0$ implies $zf'(z) + N(\overline{z})f'(z) = Q(\overline{z})$, so $N'(\overline{z})f''(z)=0$. If $f''(z)=0$ then f is linear in z and this is impossible unless f is constant, a contradiction. Thus $L'=0$ and we can take $\lambda=z$, $f(z)=\ln(z)$, $a^{11}-i/2=-i\overline{z}/z$ which implies that the space is flat. Further we can introduce a new variable $Z(z)$ such that in the new variables $\lambda=1$. If on the other hand $M'(\overline{z})\equiv 0$, then again the space is flat and we can introduce a new variable $\overline{Z(\overline{z})}$ such that $\lambda=1$ with respect to the new variables. In the case that $a^{22}-a^{11} = +2ia^{12}$ the argument is the same, but with the roles of z and $\overline{z}$ interchanged. Q.E.D.

III. MAXIMUM DIMENSIONS OF THE SPACES OF POLYNOMIAL CONSTANTS IN 2D FOR TWO-PARAMETER POTENTIALS

In order to demonstrate the existence and structure of quadratic algebras for 2D superintegrable systems, it is important to compute the dimensions of the spaces of symmetries of these systems that are of orders 2, 3, 4, and 6. These symmetries are necessarily of a special type. The highest order terms in the momenta are independent of the parameters in the potential, while the terms of order 2 less in the momenta are linear in these parameters, those of order 4 less are quadratic, and those of order 6 less are cubic. We will obtain these dimensions exactly, but first we need to establish sharp upper bounds.

Consider a Hamiltonian in a general two-dimensional space of the form

$$H = \frac{p_1^2 + p_2^2}{\lambda} + \alpha_1 V^1 + \alpha_2 V^2. \tag{18}$$

Here, λ and the terms in the potential V^i depend on the coordinates x_i while the α_i are arbitrary parameters. We say that V is a *two-parameter potential* if the gradients of V^1 and V^2 are linearly independent, that is $V_1^1V_2^2 - V_2^1V_1^2 \neq 0$. We are free to redefine V^1 and V^2 by taking linear combinations and so we will also assume that $V_1^1\neq 0$ and $V_2^2\neq 0$.

A. Quadratic constants

We wish to determine how large the space of second-order constants of the motion can be when V is a two-parameter superintegrable potential, i.e., it admits three functionally independent constants of the motion. The general constant of second order in the momenta is

$$L = a^{11}p_1^2 + a^{22}p_2^2 + 2a^{12}p_1p_2 + \alpha_1 b^1 + \alpha_2 b^2 \tag{19}$$

with a^{ij} and b^i being functions of the coordinates alone.

Since $\{H,L\}$ is polynomial in p_1, p_2, α_1 and α_2, and the a^{ij}, b^i and V^i depend only on the coordinates x_1 and x_2, the vanishing of $\{H,L\}$ gives eight equations for the derivatives of a^{ij} and b^i. Introducing two new symbols, $c^1=a_1^{12}$ and $c^2=a_2^{12}$, we solve these equations to obtain

$$a_1^{11} = -\frac{\lambda_1}{\lambda}a^{11} - \frac{\lambda_2}{\lambda}a^{12}, \quad b_1^1 = V_1^1\lambda a^{11} + V_2^1\lambda a^{12},$$

$$a_2^{11} = -2c^1 - \frac{\lambda_2}{\lambda}a^{22} - \frac{\lambda_1}{\lambda}a^{12}, \quad b_2^1 = V_1^1\lambda a^{12} + V_2^1\lambda a^{22},$$

$$a_1^{22} = -2c^2 - \frac{\lambda_1}{\lambda}a^{11} - \frac{\lambda_2}{\lambda}a^{12}, \quad b_1^2 = V_1^2\lambda a^{11} + V_2^2\lambda a^{12},$$

$$a_2^{22} = -\frac{\lambda_2}{\lambda}a^{22} - \frac{\lambda_1}{\lambda}a^{12}, \quad b_2^2 = V_1^2\lambda a^{12} + V_2^2\lambda a^{22}. \tag{20}$$

Without expressions for the derivatives of c^1 and c^2 the system is not involutive. However, the integrability conditions for b^1 and b^2 give equations (the Bertrand–Darboux equations) that can be used to express c^1 and c^2 entirely in terms of the a^{ij}. Calculating each of b_{12}^1 and b_{12}^2 in two different ways and replacing derivatives of the form a_j^{ii} with the above-given expressions leads to two equations for c^1 and c^2,

$$\begin{aligned} -3V_1^1\lambda c^1 + 3V_2^1\lambda c^2 &= (V_1^1\lambda_2 + V_2^1\lambda_1 + \lambda V_{12}^1)(a^{22}-a^{11}) + (V_1^1\lambda_1 + V_{11}^1\lambda - V_2^1\lambda_2 - V_{22}^1\lambda)a^{12}, \\ -3V_1^2\lambda c^1 + 3V_2^2\lambda c^2 &= (V_1^2\lambda_2 + V_2^2\lambda_1 + \lambda V_{12}^2)(a^{22}-a^{11}) + (V_1^2\lambda_1 + V_{11}^2\lambda - V_2^2\lambda_2 - V_{22}^2\lambda)a^{12}. \end{aligned} \tag{21}$$

These can be solved for c^1 and c^2 since the gradients of V^1 and V^2 are linearly independent.

Since all of the derivatives of a^{11}, a^{22}, and a^{12} can be expressed in terms of the a^{ij}, at any regular point, the second-order part of L is determined by three numbers.

Theorem 2: *The space of second-order constants for a 2D superintegrable potential with two parameters is exactly three-dimensional.*

B. Cubic constants

Theorem 3: *The space of third-order constants for a 2D superintegrable potential with two parameters is at most one-dimensional.*

Proof: The general constant of third order in the momenta has the form

$$L = a^{111}p_1^3 + a^{222}p_2^3 + 3a^{112}p_1^2p_2 + 3a^{122}p_1p_2^2 + (\alpha_1 b^{11} + \alpha_2 b^{12})p_1 + (\alpha_1 b^{21} + \alpha_2 b^{22})p_2. \tag{22}$$

As for the second-order constants, we demand that the coefficients of p_1, p_2, α_1, and α_2 vanish. The terms of zeroth order in the momenta lead to

$$V_1^1 b^{11} + V_2^1 b^{21} = 0, \quad V_1^2 b^{12} + V_2^2 b^{22} = 0, \tag{23}$$

$$V_1^1 b^{12} + V_2^1 b^{22} + V_1^2 b^{11} + V_2^2 b^{21} = 0.$$

Since we have chosen V^1 and V^2 such that $V_2^2 \neq 0$, we can solve for b^{11}, b^{22}, and b^{21} in terms of b^{12}, and find

$$b^{11} = -\frac{V_2^1}{V_2^2} b^{12}, \quad b^{22} = \frac{V_2^1}{V_2^2} b^{12}, \quad b^{21} = -\frac{V_1^1}{V_2^2} b^{12}. \tag{24}$$

The coefficients in $\{H,L\}$ that are first order in the momenta give the six equations,

$$\begin{aligned}
3V_1^1 a^{111} + 3V_2^1 a^{112} &= \frac{2}{\lambda} b_1^{11} + \frac{\lambda_1}{\lambda^2} b^{11} + \frac{\lambda_2}{\lambda^2} b^{21}, \\
3V_1^2 a^{111} + 3V_2^2 a^{112} &= \frac{2}{\lambda} b_1^{12} + \frac{\lambda_1}{\lambda^2} b^{12} + \frac{\lambda_2}{\lambda^2} b^{22}, \\
3V_1^2 a^{122} + 3V_2^2 a^{222} &= \frac{2}{\lambda} b_2^{22} + \frac{\lambda_1}{\lambda^2} b^{12} + \frac{\lambda_2}{\lambda^2} b^{22}, \\
3V_1^1 a^{122} + 3V_2^1 a^{222} &= \frac{2}{\lambda} b_2^{21} + \frac{\lambda_1}{\lambda^2} b^{11} + \frac{\lambda_2}{\lambda^2} b^{21}, \\
3V_1^1 a^{112} + 3V_2^1 a^{122} &= \frac{2}{\lambda} b_1^{21} + \frac{2}{\lambda} b_2^{11}, \\
3V_1^2 a^{112} + 3V_2^2 a^{122} &= \frac{2}{\lambda} b_1^{22} + \frac{2}{\lambda} b^{12}.
\end{aligned} \tag{25}$$

The first four of these, together with (24), allow a^{111}, a^{222}, a^{112}, and a^{122} to be expressed in terms of b^{12} and its derivatives, provided that, as assumed, $V_1^1 V_2^2 - V_2^1 V_1^2 \neq 0$. Then, substituting these expressions and (24) into the last two equations we obtain two equations for b_1^{12} and b_2^{12} of the form

$$-V_1^1 b_1^{12} + V_2^1 b_2^{12} = \frac{f_1(\lambda, \lambda_i, V_k^j)}{\lambda (V_1^1 V_2^2 - V_2^1 V_1^2) V_2^2} b^{12}, \tag{26}$$

$$-V_1^2 b_1^{12} + V_2^2 b_2^{12} = \frac{f_2(\lambda, \lambda_i, V_k^j)}{\lambda (V_1^1 V_2^2 - V_2^1 V_1^2) V_2^2} b^{12}, \tag{27}$$

where the two functions $f_m(\lambda, \lambda_i, V_k^j)$ are polynomial in their arguments. So the derivatives of b^{12} are multiples of b^{12} provided $V_1^1 V_2^2 - V_2^1 V_1^2 \neq 0$ and $V_2^2 \neq 0$. Hence at any regular point, all of the a^{ijk} and b^{ij} are determined by one number and so the space of third-order constants is at most one-dimensional. Q.E.D.

C. Fourth- and sixth-order constants

Theorem 4: *The space of fourth-order constants for a 2D superintegrable potential with two parameters is at most six-dimensional.*

Proof: The general constant of fourth order has the form

$$L = \sum_{i,j,k,l=1,2} a^{ijkl} p_i p_j p_k p_l + \sum_{i,j,k=1,2} b^{ij,k} \alpha_k p_i p_j + \sum_{i,j=1,2} c^{,ij} \alpha_i \alpha_j. \tag{28}$$

The vanishing of the coefficients of p_i in $\{H,L\}$ allow all of the derivative of the $c^{,ij}$ to be expressed in terms of the $b^{ij,k}$,

$$\begin{aligned}
c_1^{,11} &= \lambda V_1^1 b^{11,1} + \lambda V_2^1 b^{12,1},\\
c_2^{,11} &= \lambda V_1^1 b^{12,1} + \lambda V_2^1 b^{22,1},\\
c_1^{,12} &= \lambda V_1^1 b^{11,2} + \lambda V_2^1 b^{12,2} + \lambda V_1^2 b^{11,1} + \lambda V_2^2 b^{12,1},\\
c_2^{,12} &= \lambda V_1^1 b^{12,2} + \lambda V_2^1 b^{12,2} + \lambda V_1^2 b^{11,1} + \lambda V_2^2 b^{12,1},\\
c_1^{,22} &= \lambda V_1^2 b^{11,2} + \lambda V_2^2 b^{12,2},\\
c_2^{,22} &= \lambda V_1^2 b^{12,2} + \lambda V_1^2 b^{22,2}.
\end{aligned} \tag{29}$$

The integrability conditions of these equations, that is, equations of the form $c_{12}^{,ij} = c_{21}^{,ij}$, along with terms from $\{H,L\}$ that are cubic in the momenta, provide eleven equations for the twelve derivatives of the $b^{ij,k}$. If we define $\mathbf{b} = (b_1^{11,1}, b_2^{11,1}, b_1^{11,2}, b_2^{11,2}, b_1^{12,1}, b_1^{12,2}, b_2^{12,2}, b_1^{22,1}, b_2^{22,1}, b_1^{22,2}, b_2^{22,2})$, i.e., all of the derivatives of the b's excluding $b_2^{12,1}$, then when these equations are written in matrix form as $\mathbf{Ab} = \mathbf{B}$, the coefficient matrix $\mathbf{A}$ has determinant that is a constant multiple of $\lambda^{-5} V_1^1 (V_1^1 V_2^2 - V_2^1 V_1^2)$. Hence all of the derivative of the b's except $b_2^{12,1}$ can be expressed in terms of the $b^{ij,k}$ and the a^{ijkl} provided that $V_1^1 \neq 0$ and $V_1^1 V_2^2 - V_2^1 V_1^2 \neq 0$. For the remaining derivative, we define $d^1 = b_2^{12,1}$.

Now, the integrability conditions for the $b^{ij,k}$ and the equations obtained from the terms of $\{H,L\}$ that are of fifth order in the momenta give twelve equations for the ten derivatives of $a^{ijkl,m}$ and the two derivatives d_1^1 and d_2^1. The coefficient matrix of these terms in the equations has determinant that is a constant multiple of $(V_1^1 V_2^2 - V_2^1 V_1^2)^3 (\lambda V_1^1)^{-2}$, hence these equations can be solved provided $V_1^1 V_2^2 - V_2^1 V_1^2 \neq 0$ and $V_1^1 \neq 0$.

So, the 5 a^{ijkl}, 6 $b^{ij,k}$, 3 $c^{,ij}$ and d^1 form an involutive system. Each of these symbols can be specified arbitrarily at a point. The three $c^{,ij}$ give rise to three zeroth-order constants, the six $b^{ij,k}$ give rise to six quadratic constants (three multiplied by α_1 and three multiplied by α_2), and so there are at most $5+1=6$ genuinely fourth-order constants. Q.E.D.

For the general sixth-order constant

$$\begin{aligned}
L = &\sum_{i,j,k,l,m,n=1,2} a^{ijklmn} p_i p_j p_k p_l p_m p_n + \sum_{i,j,k,l,m=1,2} b^{ijkl,m} \alpha_m p_i p_j p_k p_l + \sum_{i,j,k,l=1,2} c^{ij,kl} \alpha_k \alpha_l p_i p_j\\
&+ \sum_{i,j,k=1,2} d^{,ijk} \alpha_i \alpha_j \alpha_k
\end{aligned} \tag{30}$$

the argument proceeds similarly.

Theorem 5: *The space of sixth-order constants for a 2D superintegrable potential with two parameters is at most ten-dimensional.*

We will show that the space is exactly ten-dimensional.

IV. NONDEGENERATE SUPERINTEGRABLE SYSTEMS IN TWO DIMENSIONS

Now we take up our main topic: a nondegenerate superintegrable system on a two-dimensional manifold. In earlier work we have classified the possible superintegrable systems on

2D complex flat space, the two-sphere, and on Darboux spaces.[44,45,34–36]. The theory we present here applies to all 2D spaces and adds greater understanding of the structure of these systems. The Hamiltonian system is

$$H = \frac{p_1^2 + p_2^2}{\lambda(x,y)} + V(x,y) \tag{31}$$

in local orthogonal coordinates. We say that the system is *second-order superintegrable* with *nondegenerate potential* if it admits three functionally independent second-order symmetries and the potential is three-parameter (in addition to the usual additive parameter). That is, at each point where the potential is defined and analytic (a regular point), we can prescribe the value of V_1, V_2 and V_{11} for some unique choice of parameters. Using the two Bertrand–Darboux equations satisfied by the potential (coming from the two symmetries other than the Hamiltonian) we can solve for $V_{22}-V_{11}$ and V_{12} in terms of the first derivatives of V.

Thus a nondegenerate potential $V(x,y)$ obeys

$$\begin{aligned} V_{22} &= V_{11} + A^{22}V_1 + B^{22}V_2, \\ V_{12} &= A^{12}V_1 + B^{12}V_2. \end{aligned} \tag{32}$$

Here, V_1,V_2,V_{11} can be prescribed arbitrarily at a fixed regular point.

A seemingly weaker requirement for a superintegrable system is that, as usual, it admits three functionally independent constants of the motion, but only for a two-parameter family of potentials $V(x,y)=\alpha V^{(1)}(x,y)+\beta V^{(2)}(x,y)$, where the gradients of $V^{(1)},V^{(2)}$ are linearly independent.

Lemma 1: "Two implies three." If the system (31) admits three functionally independent constants of the motion and a two-parameter family of potentials, then it admits a three-parameter family (32).

Proof: The system admits a symmetry $\Sigma a^{ij}p_ip_j+W$ if and only if the Bertrand–Darboux equation is satisfied. This is $\partial_j W_i=\partial_i W_j$ or

$$(V_{22}-V_{11})a^{12} + V_{12}(a^{11}-a^{22}) = \left[\frac{(\lambda a^{12})_1 - (\lambda a^{11})_2}{\lambda}\right]V_1 + \left[\frac{(\lambda a^{22})_1 - (\lambda a^{12})_2}{\lambda}\right]V_2.$$

We can always find a symmetry such that a^{11},a^{12},a^{22} take on any prescribed values at a regular point $\mathbf{x}_0$. Thus we can solve the three Bertrand–Darboux equations for the potential to obtain the system

$$V_{22} = V_{11} + A^{22}V_1 + B^{22}V_2,$$

$$V_{12} = A^{12}V_1 + B^{12}V_2,$$

$$0 = A^3V_1 + B^3V_2.$$

Case 1. $A^3\equiv B^3\equiv 0$. Then the equations are (32) and the system admits a three-parameter family of potentials.

Case 2. $A^3\not\equiv 0$. Then $V_1=D^4V_2$ so we find $V_{11}=D^5V_2$, $V_{22}=D^6V_2$, $V_{12}=D^7V_2$. Thus V depends on only one parameter. Impossible!

Case 3. $B^3\not\equiv 0$. Then $V_2=E^4V_1$ so we find $V_{11}=E^5V_1$, $V_{22}=E^6V_1$, $V_{12}=E^7V_1$. Thus V depends on only one parameter. Impossible! Q.E.D.

[Note added in proof. There is a fourth case to consider. It could be that V satisfies (32) but that the integrability conditions are not satisfied indentically, and this yields a further condition $V_{11}=A^{11}V_1+B^{11}V_2$. The lemma still holds but the proof for this case requires the Stäckel transform and will be given later in this series.]

To obtain the integrability conditions for Eq. (32) we introduce the dependent variables $W^{(1)}=V_1$, $W^{(2)}=V_2$, $W^{(3)}=V_{11}$, the vector

$$\mathbf{w} = \begin{pmatrix} W^{(1)} \\ W^{(2)} \\ W^{(3)} \end{pmatrix}, \tag{33}$$

and the matrices

$$\mathbf{A}^{(1)} = \begin{pmatrix} 0 & 0 & 1 \\ A^{12} & B^{12} & 0 \\ A^{13} & B^{13} & B^{12} - A^{22} \end{pmatrix}, \tag{34}$$

$$\mathbf{A}^{(2)} = \begin{pmatrix} A^{12} & B^{12} & 0 \\ A^{22} & B^{22} & 1 \\ A^{23} & B^{23} & A^{12} \end{pmatrix}, \tag{35}$$

where

$$A^{13} = A_2^{12} - A_1^{22} + B^{12}A^{22} + A^{12}A^{12} - B^{22}A^{12},$$

$$B^{13} = B_2^{12} - B_1^{22} + A^{12}B^{12}, \tag{36}$$

$$A^{23} = A_1^{12} + B^{12}A^{12}, \quad B^{23} = B_1^{12} + B^{12}B^{12}. \tag{37}$$

Then the integrability conditions for the system

$$\partial_{x_j}\mathbf{w} = \mathbf{A}^{(j)}\mathbf{w}, \quad j = 1,2, \tag{38}$$

must hold. These conditions are

$$A_i^{(j)} - A_j^{(i)} = A^{(i)}A^{(j)} - A^{(j)}A^{(i)} \equiv [A^{(i)},A^{(j)}]. \tag{39}$$

If and only if these conditions hold, the system has a solution V depending on three parameters.

From the conditions that

$$L = \sum_{k,j=1}^{2} a^{kj}(x,y)p_k p_j + W(x,y), \quad a^{kj} = a^{jk},$$

be a symmetry of the Hamiltonian and relations (32) we can solve for all of the first partial derivatives $\partial_i(\lambda a^{jk})$ to obtain

$$\partial_1(\lambda a^{11}) = -\frac{\lambda_2}{\lambda}(\lambda a^{12}), \quad \partial_2(\lambda a^{22}) = -\frac{\lambda_1}{\lambda}(\lambda a^{12}),$$

$$3\partial_2(\lambda a^{12}) = (\lambda a^{11} - \lambda a^{22})\left(-B^{12} - \frac{\lambda_1}{\lambda}\right) + (\lambda a^{12})\left(-B^{22} + \frac{\lambda_2}{\lambda}\right),$$

$$3\partial_1(\lambda a^{22}) = (\lambda a^{11} - \lambda a^{22})\left(2B^{12} - \frac{\lambda_1}{\lambda}\right) + (\lambda a^{12})\left(2B^{22} + \frac{\lambda_2}{\lambda}\right), \tag{40}$$

$$3\partial_1(\lambda a^{12}) = (\lambda a^{11} - \lambda a^{22})\left(A^{12} + \frac{\lambda_2}{\lambda}\right) + (\lambda a^{12})\left(A^{22} + \frac{\lambda_1}{\lambda}\right),$$

$$3\partial_2(\lambda a^{11}) = (\lambda a^{11} - \lambda a^{22})\left(-2A^{12} + \frac{\lambda_2}{\lambda}\right) + (\lambda a^{12})\left(-2A^{22} + \frac{\lambda_1}{\lambda}\right).$$

This system closes, so the space of solutions is at most three dimensional. However, by the assumption of superintegrability there are at least three functionally independent symmetries. Hence the space of second-order symmetries is exactly three dimensional. A symmetry is uniquely determined by the 2×2 symmetric matrix $(A^{ij}(\mathbf{x}_0))$ of its values at a regular point $\mathbf{x}_0$, and any such matrix corresponds to a symmetry.

To determine the integrability conditions for system (40) we define the vector-valued function

$$\mathbf{h}(x,y,z) = \begin{pmatrix} a^{11} \\ a^{12} \\ a^{22} \end{pmatrix}$$

and directly compute the 3×3 matrix functions $\mathcal{A}(j)$ to get the first-order system

$$\partial_{x_j}\mathbf{h} = \mathcal{A}^{(j)}\mathbf{h}, \quad j = 1,2. \tag{41}$$

The integrability conditions for this system are

$$\mathcal{A}_1^{(2)} - \mathcal{A}_2^{(1)} = \mathcal{A}^{(1)}\mathcal{A}^{(2)} - \mathcal{A}^{(2)}\mathcal{A}^{(1)} \equiv [\mathcal{A}^{(1)}, \mathcal{A}^{(2)}]. \tag{42}$$

Now we investigate the space of third-order constants of the motion:

$$K = \sum_{k,j,i=1}^{2} a^{kji}(x_1,x_2)p_k p_j p_i + b^{\ell}(x_1,x_2)p_{\ell}, \tag{43}$$

which must satisfy $\{H,K\}=0$. Here a^{kji} is symmetric in the indices k,j,i.

The conditions are

$$2\frac{\partial a^{iii}}{\partial x_i} = -3\left(\frac{\partial \ln\lambda}{\partial_{x_i}}a^{iii} + \frac{\partial \ln\lambda}{\partial_{x_j}}a^{jii}\right), \quad i \neq j,$$

$$3\frac{\partial a^{jii}}{\partial x_i} + \frac{\partial a^{iii}}{\partial x_j} = 3\left(-\frac{\partial \ln\lambda}{\partial_{x_i}}a^{iij} - \frac{\partial \ln\lambda}{\partial_{x_j}}a^{ijj}\right), \quad i \neq j,$$

$$2\left(\frac{\partial a^{122}}{\partial x_1} + \frac{\partial a^{112}}{\partial x_2}\right) = -\frac{\partial \ln\lambda}{\partial_{x_1}}a^{122} - \frac{\partial \ln\lambda}{\partial_{x_1}}a^{111} - \frac{\partial \ln\lambda}{\partial_{x_2}}a^{222} - \frac{\partial \ln\lambda}{\partial_{x_2}}a^{112}, \tag{44}$$

$$\frac{\partial b^1}{\partial x_2}+\frac{\partial b^2}{\partial x_1}=3\sum_{s=1}^{2}\lambda a^{s21}\frac{\partial V}{\partial x_s},$$

$$\frac{\partial b^j}{\partial x_j}=\frac{3}{2}\sum_{s=1}^{2}a^{sjj}\frac{\partial V}{\partial x_s}-\frac{1}{2}\sum_{s=1}^{2}\frac{\partial \ln\lambda}{\partial x_s}b^s,\quad j=1,2, \tag{45}$$

and

$$\sum_{s=1}^{2}b^s\frac{\partial V}{\partial x_s}=0. \tag{46}$$

The general solution for the terms third order in the p_j is a sum of third-order monomials in the p_j and $J_3=x_1p_2-x_2p_1$. The a^{kji} is just a third-order Killing tensor. We require the potential V to be superintegrable and nondegenerate, and that the highest order terms, the a^{kji} in the constant of the motion, be independent of the three parameters in V. The b^ℓ must depend on these parameters linearly. We set

$$b^\ell(x_1,x_2)=\sum_{j=1}^{2}f^{\ell,j}(x_1,x_2)\frac{\partial V}{\partial x_j}(x_1,x_2).$$

(We are excluding the purely first order symmetries.) Substituting this expression into (46) we see that

$$f^{\ell,j}+f^{j,\ell}=0,\quad 1\leqslant \ell,j\leqslant 2.$$

Further

$$b_1^1=f_1^{1,2}V_2+f^{1,2}V_{12},\quad b_2^1=f_2^{1,2}V_2+f^{1,2}V_{22},$$

$$b_1^2=f_1^{2,1}V_1+f^{2,1}V_{11},\quad b_2^2=f_2^{2,1}V_1+f^{2,1}V_{12},$$

where the subscript j denotes the partial derivative with respect to x_j. Substituting these results and expressions (32) into the defining equations (45) and equating coefficients of V_1, V_2, V_{11}, respectively, we obtain the independent conditions:

$$\begin{gathered}\lambda a^{111}=\tfrac{1}{3}f^{1,2}(2A^{12}-(\ln\lambda)_2),\\ \lambda a^{222}=\tfrac{1}{3}f^{1,2}(-2B^{12}+(\ln\lambda)_1),\\ \lambda a^{112}=\tfrac{1}{9}f^{1,2}(2A^{22}+2B^{12}+(\ln\lambda)_1),\\ \lambda a^{122}=\tfrac{1}{9}f^{1,2}(-2A^{12}+2B^{22}-(\ln\lambda)_2),\end{gathered} \tag{47}$$

$$\begin{gathered}f_1^{1,2}=\tfrac{1}{3}f^{1,2}(A^{22}-2B^{12}-(\ln\lambda)_1),\\ f_2^{1,2}=\tfrac{1}{3}f^{1,2}(-2A^{12}-B^{22}+(\ln\lambda)_2),\end{gathered} \tag{48}$$

Note that (47) yields expressions for all a^{ijk} in terms of $f^{1,2}$ and the A^{ij},B^{ij}, functions. Similarly (48) yields expressions for $f_k^{1,2}$ in terms of $f^{1,2}$ and the $A^{k\ell}$,$B^{k\ell}$ functions. Thus we have an involutive system for $f^{1,2}$, possibly subject to additional conditions from (45). Thus any third-order

constant of the motion defined by $f^{1,2}(x,y)$ is uniquely determined by its value $f^{1,2}(x_0,y_0)$ at some regular point (x_0,y_0). This means that the space of third-order constants of the motion is at most one-dimensional.

There are two cases to consider.

Case 1: $2A^{12}=B^{22}=(\ln\lambda)_2$, $2B^{12}=-A^{22}=(\ln\lambda)_1$. Then it follows from (47) that all $a^{ijk}\equiv 0$. The integrability conditions require $(\ln\lambda)_{11}+(\ln\lambda)_{22}=0$, which is the condition for flat space, Thus by an appropriate orthogonal change of coordinates we can assume that $\lambda\equiv 1$. In these new coordinates we see that $A^{ij}=B^{ij}\equiv 0$ for all i,j. The general solution is

$$f^{1,2}=c_1,$$

where c_1, is a constant. This is the *homogeneous isotropic oscillator:*

$$V(x,y)=\alpha x+\beta y+\gamma(x^2+y^2). \tag{49}$$

Note that for this very special case a nonzero Poisson bracket of two second-order constants of the motion must be first order.

Case 2: The conditions for Case 1 do not hold for all A^{ij},B^{ij}. Now (47) yield expressions for all a^{ijk} in terms of f^{12} and the A^{ij},B^{ij} functions and not all a^{ijk} vanish. Similarly (48) yields expressions for all $f_i^{1,2}$ in terms of $f^{1,2}$ and the $A^{k\ell},B^{k\ell}$ functions. We will show that the space of symmetries is exactly one dimensional.

Theorem 6: *Let K be a third-order constant of the motion for a superintegrable system with nondegenerate potential V*:

$$K=\sum_{k,j,i=1}^{2} a^{kji}(x,y)p_kp_jp_i+\sum_{\ell=1}^{2} b^{\ell}(x,y)p_{\ell}.$$

Then

$$b^{\ell}(x,y)=\sum_{j=1}^{2} f^{\ell,j}(x,y)\frac{\partial V}{\partial x_j}(x,y) \tag{50}$$

with

$$f^{\ell,j}+f^{j,\ell}=0,\quad 1\leqslant \ell,j\leqslant 2,$$

and the a^{ijk}, b^{ℓ} are uniquely determined by the number $f^{1,2}(x_0,y_0)$ at some regular point (x_0,y_0) of V.

Let

$$L_1=\sum a^{kj}_{(1)}p_kp_j+W_{(1)},\quad L_2=\sum a^{kj}_{(2)}p_kp_j+W_{(2)}$$

be second-order constants of the the motion for a superintegrable system with nondegenerate potential and let $\mathcal{A}_{(i)}(x,y)=\{a^{kj}_{(i)}(x,y)\}$, $i=1,2$ be 2×2 matrix functions. Then the Poisson bracket of these symmetries is given by

$$\{L_1,L_2\}=\sum_{k,j,i=1}^{2} a^{kji}(x,y)p_kp_jp_i+b^{\ell}(x,y)p_{\ell} \tag{51}$$

where

$$f^{k,\ell}=2\lambda\sum_j (a^{kj}_{(2)}a^{j\ell}_{(1)}-a^{kj}_{(1)}a^{j\ell}_{(2)}). \tag{52}$$

Thus $\{L_1,L_2\}$ is uniquely determined by the skew-symmetric matrix

$$[\mathcal{A}_{(2)},\mathcal{A}_{(1)}] \equiv \mathcal{A}_{(2)}\mathcal{A}_{(1)} - \mathcal{A}_{(1)}\mathcal{A}_{(2)}, \tag{53}$$

hence by the constant matrix $[\mathcal{A}_{(2)}(x_0,y_0),\mathcal{A}_{(1)}(x_0,y_0)]$ evaluated at a regular point.

Corollary 1: Let V be a superintegrable nondegenerate potential. The space of third-order constants of the motion is one-dimensional and is spanned by Poisson brackets of the second-order constants of the motion.

Corollary 2: Let V be a superintegrable nondegenerate potential and L_1,L_2 *be second-order constants of the motion with matrices* $\mathcal{A}_{(1)},\mathcal{A}_{(2)}$*, respectively. Then*

$$\{L_1,L_2\} \equiv 0 \Leftrightarrow [\mathcal{A}_{(1)},\mathcal{A}_{(2)}] \equiv 0 \Leftrightarrow [\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)] = 0$$

at a regular point $\mathbf{x}_0$.

A. A standard form for 2D superintegrable systems

For superintegrable nondegenerate potentials there is a standard structure allowing the identification of the space of second-order constants of the motion with the space of 2×2 symmetric matrices, as well as identification of the space of third-order constants of the motion with the space of 2×2 skew-symmetric matrices. Indeed, if $\mathbf{x}_0$ is a regular point then there is a $1-1$ linear correspondence between second-order operators L and their associated symmetric matrices $\mathcal{A}(\mathbf{x}_0)$. Let $\{L_1,L_2\}' = \{L_2,L_1\}$ be the reversed Poisson bracket. Then the map

$$\{L_1,L_2\}' \Leftrightarrow [\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)]$$

is an algebraic isomorphism. Here, L_1,L_2 are in involution if and only if matrices $\mathcal{A}_{(1)}(\mathbf{x}_0)$, $\mathcal{A}_{(2)}\times(\mathbf{x}_0)$ commute. If $\{L_1,L_2\}\neq 0$ then it is a third-order symmetry and can be uniquely associated with the skew-symmetric matrix $[\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)]$. Since commutators of second-order constants of the motion span the space of third-order constants, we can identify these $1-1$ with 2×2 skew-symmetric matrices. Let $\mathcal{E}^{ij}$ be the 2×2 matrix with a 1 in row i, column j and 0 for every other matrix element. Then the symmetric matrices

$$\mathcal{A}^{(ij)} = \tfrac{1}{2}(\mathcal{E}^{ij} + \mathcal{E}^{ji}) = \mathcal{A}^{(ji)}, \quad i,j = 1,2 \tag{54}$$

form a basis for the three-dimensional space of symmetric matrices. Moreover,

$$[\mathcal{A}^{(ij)},\mathcal{A}^{(k\ell)}] = \tfrac{1}{2}(\delta_{jk}\mathcal{B}^{(i\ell)} + \delta_{j\ell}\mathcal{B}^{(ik)} + \delta_{ik}\mathcal{B}^{(j\ell)} + \delta_{i\ell}\mathcal{B}^{(jk)}) \tag{55}$$

where

$$\mathcal{B}^{(ij)} = \tfrac{1}{2}(\mathcal{E}^{ij} - \mathcal{E}^{ji}) = -\mathcal{B}^{(ji)}, \quad i,j = 1,2.$$

Here $\mathcal{B}^{(ii)}=0$ and $\mathcal{B}^{(12)}$ forms a basis for the space of skew-symmetric matrices. Thus (55) gives the commutation relations for the second-order symmetries. If V is the isotropic oscillator then there is no truly third-order symmetry. For any other nondegenerate potential, the space of symmetries is exactly one dimensional.

To gain a deeper understanding of this structure, it is useful to reformulate the problem of determining the second-order symmetries of (31). We set

$$W(x) = f^1V_1 + f^2V_2 + f^{11}V_{11}$$

and substitute this result into $W_i = \lambda\Sigma_{j=1}^2 a^{ij}V_j$. Additionally we must impose the Killing tensor conditions

$$a_i^{ii} = -(\ln\lambda)_1 a^{1i} - (\ln\lambda)_2 a^{2i}, \quad 2a_i^{ij} + a_j^{ii} = -(\ln\lambda)_1 a^{1j} - (\ln\lambda)_2 a^{2j}, \quad i\neq j.$$

From the expressions for W_i we obtain the equations for the a^{ij}:

$$\lambda a^{11} = f_1^1 + f^2 A^{12} + f^{11} A^{13},$$

$$\lambda a^{12} = f_2^1 + f^1 A^{12} + f^2 A^{22}, \tag{56}$$

$$\lambda a^{22} = f_2^2 + f^1 B^{12} + f^2 B^{22}$$

and the condition on the first derivatives of the f^i:

$$f_2^1 - f_1^2 = -f^1 A^{12} + f^2 (A^{22} - B^{12}) - f^{11} B^{13}. \tag{57}$$

Note the expressions for f_1^{11} and f_2^{11} in terms of f^1, f^2, f^{11}:

$$f_1^{11} + f^1 + f^{11}(B^{12} - A^{22}) = 0, \quad f_2^{11} + f^2 + f^{11} A^{12} = 0.$$

Differentiating (57) with respect to each of x_1 and x_2 and substituting (56) into the Killing equations we see that we can express each of the second derivatives of f^1, f^2 in terms of lower order derivatives of f^1, f^2, f^{11}. Thus the system is in involution at the second derivative level, but not at the first derivative level because we have only one condition for the six derivatives $f_1^1, f_2^1, f_1^2, f_2^2$. We can uniquely determine a symmetry at a regular point by choosing the six parameters $(f^1, f^2, f^{11}, f_1^1, f_2^1, f_2^2)$. The values of f^1, f^2, f^{11} at the regular point are analogous to the three parameters that we can add to the potentials in the three parameter family. For our standard basis, we fix $(f^1, f^2, f^{11})_{\mathbf{x}_0} = (0,0,0)$. Then from (56) and (57) we have

$$\begin{pmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{pmatrix} = \lambda \begin{pmatrix} a^{11} & a^{12} \\ a^{21} & a^{22} \end{pmatrix}.$$

Thus we can define a standard set of basis symmetries $\mathcal{S}^{(jk)} = \Sigma_{i,h} a^{ih}_{(jk)}(\mathbf{x}) p_i p_h + W^{(jk)}(\mathbf{x})$ corresponding to a regular point $\mathbf{x}_0$ by

$$\begin{pmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{pmatrix}_{\mathbf{x}_0} = \lambda(\mathbf{x}_0) \begin{pmatrix} a^{11} & a^{12} \\ a^{21} & a^{22} \end{pmatrix}_{\mathbf{x}_0} = \lambda(\mathbf{x}_0) \mathcal{A}^{(jk)}, \quad W^{(jk)}(\mathbf{x}_0) = 0.$$

The condition on $W^{(jk)}$ is actually three conditions since $W^{(jk)}$ depends on three parameters.

B. Multiseparability of 2D systems

From the general theory of variable separation for Hamilton–Jacobi equations[19,20] we know that a second-order symmetry L defines a separable system for

$$H = \frac{p_x^2 + p_y^2}{\lambda(x,y)} + V(x,y) = E$$

if and only if

1. The symmetries H, L form a linearly independent set as quadratic forms.
2. The two quadratic forms have a common eigenbasis of differential forms.

This last requirement means that, expressed in Cartesian coordinates, the matrix $\mathcal{A}(\mathbf{x})$ can be diagonalized by conjugacy transforms in a neighborhood of a regular point.

Corollary 3: Let V be a superintegrable nondegenerate potential and L be a second-order constant of the motion with matrix function $\mathcal{A}(\mathbf{x})$. If at some regular point $\mathbf{x}_0$ the matrix $\mathcal{A}(\mathbf{x}_0)$ has two distinct eigenvalues, then H,L characterize an orthogonal separable coordinate system.

Note: Since a generic 2×2 symmetric matrix has distinct roots, it follows that any superintegrable nondegenerate potential is multiseparable.

C. The quadratic algebra

Next we investigate the space of fourth-order constants of the motion for 2D systems in some detail. We already know that the dimension of this space is at most 6. Here a constant of the motion

$$F=\sum_{\ell,k,j,i=1}^{2} a^{\ell kji}(x,y,z)p_\ell p_k p_j p_i+\sum_{m,q=1}^{2} b^{mq}(x,y,z)p_m p_q+W(x,y,z), \tag{58}$$

must satisfy $\{H,F\}=0$. Again $a^{\ell kji}$, b^{mq} are symmetric in all indices.

The conditions are

$$\frac{\partial a^{iiii}}{\partial x_i}=-2\sum_{s=1}^{2} a^{siii}\frac{\partial \ln \lambda}{\partial x_s}, \tag{59}$$

$$4\frac{\partial a^{jiii}}{\partial x_i}+\frac{\partial a^{iiii}}{\partial x_j}=-6\sum_{s=1}^{2} a^{siij}\frac{\partial \ln \lambda}{\partial x_s}, \quad i\neq j, \tag{60}$$

$$3\frac{\partial a^{jjii}}{\partial x_i}+2\frac{\partial a^{iiij}}{\partial x_j}=-\sum_{s=1}^{2} a^{siii}\frac{\partial \ln \lambda}{\partial x_s}-3\sum_{s=1}^{2} a^{sijj}\frac{\partial \ln \lambda}{\partial x_s}, \quad i\neq j,$$

$$2\frac{\partial b^{ij}}{\partial x_i}+\frac{\partial b^{ii}}{\partial x_j}=6\lambda\sum_{s=1}^{3} a^{sjii}\frac{\partial V}{\partial x_s}-\sum_{s=1}^{2} b^{sj}\frac{\partial \ln \lambda}{\partial x_s}, \quad i\neq j,$$

$$\frac{\partial b^{ii}}{\partial x_i}=2\lambda\sum_{s=1}^{3} a^{siii}\frac{\partial V}{\partial x_s}-\sum_{s=1}^{2} b^{sj}\frac{\partial \ln \lambda}{\partial x_s}, \tag{61}$$

and

$$\lambda\sum_{s=1}^{3} b^{si}\frac{\partial V}{\partial x_s}=\frac{\partial W}{\partial x_i}. \tag{62}$$

Note that the $a^{\ell kji}$ is a fourth-order Killing tensor. We require the potential V to be superintegrable and nondegenerate and that the highest order terms, the $a^{\ell kji}$ in the constant of the motion, be independent of the three parameters in V. The b^{mq} must depend linearly and W quadratically on these parameters.

We set

$$b^{jk}=\sum_{\alpha=1}^{3} f^{jk,\alpha}W^{(\alpha)}, \quad f^{jk,\alpha}=f^{kj,\alpha},$$

where $W^{(\alpha)}$ is defined by

$$\begin{pmatrix} W^{(1)} \\ W^{(2)} \\ W^{(3)} \end{pmatrix}=\begin{pmatrix} V_1 \\ V_2 \\ V_{11} \end{pmatrix}.$$

Then conditions (61) become

$$\frac{\partial}{\partial_{x_h}}f^{jk,\alpha}+\frac{\partial}{\partial_{x_k}}f^{hj,\alpha}+\frac{\partial}{\partial_{x_j}}f^{kh,\alpha}-2\lambda a^{\alpha hjk}=-\sum_{\gamma=1}^{3}(f^{jk,\gamma}A^{(h)}_{\gamma\alpha}+f^{hj,\gamma}A^{(k)}_{\gamma\alpha}+f^{kh,\gamma}A^{(j)}_{\gamma\alpha})$$
$$-\sum_{s=1}^{2}(f^{sk,\alpha}\delta_{hk}+f^{sj,\alpha}\delta_{kh}+f^{sh,\alpha}\delta_{jk})\frac{\partial}{\partial_{x_s}}\ln\lambda, \qquad (63)$$

where $1\leqslant j,k,h\leqslant 2$ and we set $a^{3hjk}\equiv 0$. From the integrability conditions $(\partial/\partial_{x_j})(\partial W/\partial x_i)=(\partial/\partial_{x_i})(\partial W/\partial x_j)$, $i\neq j$ for Eq. (62) we obtain the conditions

$$\partial_{x_j}f^{\beta k,\alpha}+\partial_{x_j}f^{\alpha k,\beta}-\partial_{x_k}f^{\beta j,\alpha}-\partial_{x_k}f^{\alpha j,\beta}=\sum_{s=1}^{2}(A^{(k)}_{\beta s}f^{sj,\alpha}+A^{(k)}_{\alpha s}f^{sj,\beta}-A^{(j)}_{\beta s}f^{sk,\alpha}-A^{(j)}_{\alpha s}f^{sk,\beta})$$
$$+\sum_{\gamma=1}^{3}(f^{\beta j,\gamma}A^{(k)}_{\gamma\alpha}+f^{\alpha j,\gamma}A^{(k)}_{\gamma\beta}-f^{\beta k,\gamma}A^{(j)}_{\gamma\alpha}-f^{\alpha k,\gamma}A^{(j)}_{\gamma\beta})$$
$$-(f^{\beta k,\alpha}+f^{\alpha k,\beta})\frac{\partial}{\partial_{x_j}}\ln\lambda+(f^{\beta j,\alpha}+f^{\alpha j,\beta})\frac{\partial}{\partial_{x_k}}\ln\lambda, \qquad (64)$$

where $j\neq k$, $1\leqslant\alpha,\ \beta\leqslant 3$ and we set $f^{3j,\alpha}\equiv 0$.

There are eight independent equations (63) with $\alpha\neq 3$ and we use five of these to define the five components a^{ihjk} as linear combinations of $(\partial/\partial_{x_h})f^{jk,\alpha}$ and $f^{jk,\alpha}$. We can then eliminate the a^{ihjk} from the remaining three equations to obtain three conditions relating $(\partial/\partial_{x_h})f^{jk,\alpha}$ and $f^{jk,\alpha}$. There are six terms of the form $(\partial/\partial_{x_h})f^{jk,3}$. Equation (64) with $\alpha=\beta=3$ is satisfied identically. There are two equations (64) with $\beta=3$, $1\leqslant\alpha\leqslant 2$ and four equations (63) with $\alpha=3$. Thus all six terms of the form $(\partial/\partial_{x_h})f^{jk,3}$ can be expressed as linear combinations of $f^{jk,\alpha}$. There are a total of twelve distinct terms of the form $(\partial/\partial_{x_h})f^{jk,m}$, $1\leqslant h,j,k,m\leqslant 2$. We have seen that there are three conditions on these terms remaining from (63); there are an additional three such conditions from (64) with $\alpha,\beta\neq 3$. Thus there is a shortfall of six conditions on the first derivatives $(\partial/\partial_{x_h})f^{jk,m}$.

There are a total of eighteen distinct terms of the form $(\partial^2/\partial_{x_h}\partial_{x_\ell})f^{jk,m}$ with $1\leqslant h,j,k,\ell,m\leqslant 2$. Differentiating with respect to x_1,x_2 the three first-order conditions of (63), from which the a^{ihjk} have been eliminated, we obtain six independent conditions on these second derivatives. Differentiating each of our expressions for the a^{ihjk} and substituting into Eq. (59) we find six additional conditions on the second derivatives. Also, we can differentiate the three equations from (62) with $\alpha,\beta\neq 3$ to obtain six additional conditions on the second derivatives. This allows us to express each second-order derivative as a linear combination of lower order derivatives, Thus the system is in involution.

We conclude that any fourth-order symmetry is uniquely determined by the values $f^{jk,\alpha}(\mathbf{x}_0)$ and a subset of six of the values $(\partial/\partial_{x_h})f^{jk,m}(\mathbf{x}_0)$ at a regular point $\mathbf{x}_0$. Note that by adding an appropriate linear combination of purely second-order symmetries to the fourth-order symmetry we can achieve $f^{jk,\alpha}(\mathbf{x}_0)=0$ for all j,k,α, so the maximum possible dimension of the space of purely fourth-order symmetries is six. However any second-order polynomial in the second-order symmetries is a fourth-order symmetry, and the subspace of polynomial symmetries is at least five and at most six. We show that it is exactly six.

Theorem 7: *The six distinct monomials*

$$(\mathcal{S}^{(11)})^2,\quad (\mathcal{S}^{(22)})^2,\quad (\mathcal{S}^{(12)})^2,\quad \mathcal{S}^{(11)}\mathcal{S}^{(22)},\quad \mathcal{S}^{(11)}\mathcal{S}^{(12)},\quad \mathcal{S}^{(12)}\mathcal{S}^{(22)},$$

form a basis for the space of fourth order symmetries.

Proof: Since the three symmetries $\mathcal{S}^{(11)}$, $\mathcal{S}^{(22)}$, $\mathcal{S}^{(12)}$ are functionally independent, the six monomials listed above are linearly independent. Hence they form a basis. Q.E.D.

We can use this result to explicitly expand a general fourth-order symmetry

$$F = \sum_{\ell,k,j,i=1}^{2} a^{\ell kji}(x,y,z)p_\ell p_k p_j p_i + \sum_{m,q=1}^{2} b^{mq}(x,y,z)p_m p_q + W(x,y,z)$$

in terms of the standard basis. Without loss of generality we can assume that $(0,0)=\mathbf{0}$ is a regular point. Then F is uniquely determined by the data $a^{\ell kji}(\mathbf{0})$, $\partial_m a^{\ell kji}(\mathbf{0})$, $b^{mq}(\mathbf{0})$, $W(\mathbf{0})$. We can uniquely match the data $a^{\ell kji}(\mathbf{0})$ by taking a linear combination of the basis symmetries

$$(\mathcal{S}^{(11)})^2, \quad (\mathcal{S}^{(22)})^2, \quad (\mathcal{S}^{(12)})^2, \quad \mathcal{S}^{(11)}\mathcal{S}^{(12)}, \quad \mathcal{S}^{(12)}\mathcal{S}^{(22)}.$$

This leaves the symmetry $\mathcal{S}^{(11)}\mathcal{S}^{(22)}-(\mathcal{S}^{(12)})^2$, whose leading order terms vanish at the regular point. The expansion coefficient for this term is obtained uniquely from the derivative data $\partial_m a^{\ell kji}(\mathbf{0})$. Now we have matched all of the fourth order terms in F with an expansion of the form $\mathcal{F}=\Sigma\xi_{ijk\ell}\mathcal{S}^{(ij)}\mathcal{S}^{(k\ell)}$. The difference $F-\mathcal{F}$ is a second-order symmetry. It is uniquely determined by the data $b^{mq}(\mathbf{0}),W(\mathbf{0})$, which has not changed since $W^{(ij)}(\mathbf{0})=0$ for all terms in the standard basis, Thus $F-\mathcal{F}=\Sigma b^{mq}(\mathbf{0})\mathcal{S}^{(mq)}+W(\mathbf{0})$ and we have expanded the original symmetry in terms of second-order polynomials in the standard basis.

Similarly we see that the maximal dimension of ten sixth-order symmetries is achieved by monomials in the second order symmetries.

Theorem 8: *The ten distinct monomials*

$$(\mathcal{S}^{(ii)})^3, \quad (\mathcal{S}^{(ij)})^3, \quad (\mathcal{S}^{(ii)})^2\mathcal{S}^{(jj)}, \quad (\mathcal{S}^{(ii)})^2\mathcal{S}^{(ij)}, \quad (\mathcal{S}^{(ij)})^2\mathcal{S}^{(ii)}, \quad \mathcal{S}^{(11)}\mathcal{S}^{(12)}\mathcal{S}^{(22)},$$

for $i,j=1,2$, $i\neq j$ *form a basis for the space of sixth-order symmetries*.

Proof: Since the three symmetries $\mathcal{S}^{(11)}$, $\mathcal{S}^{(22)}$, $\mathcal{S}^{(12)}$ are functionally independent, the ten monomials listed above are linearly independent. Hence they form a basis. Q.E.D.

These theorems establish the closure of the quadratic algebra for 2D superintegrable potentials: All fourth-order and sixth-order symmetries can be expressed as polynomials in the second-order symmetries.

Again, we can use these results to explicitly expand a general sixth-order symmetry

$$G = \sum_{i,j,k,l,m,n=1,2} a^{ijklmn}p_i p_j p_k p_l p_m p_n + \sum_{i,j,k,l=1,2} b^{ijkl}p_i p_j p_k p_l + \sum_{i,j=1,2} c^{ij}p_i p_j + W \tag{65}$$

in terms of the standard basis. Without loss of generality we can assume that $(0,0)=\mathbf{0}$ is a regular point. Then G is uniquely determined by the data $a^{ijklmn}(\mathbf{0})$, $\partial_q a^{ijklmn}(\mathbf{0})$, $b^{ijkl}(\mathbf{0})$, $\partial_m b^{ijkl}(\mathbf{0})$, $W(\mathbf{0})$. We can uniquely match the data $a^{ijklmn}(\mathbf{0})$ by taking a linear combination of the seven symmetries

$$(\mathcal{S}^{(ii)})^3, \quad (\mathcal{S}^{(ij)})^3, \quad (\mathcal{S}^{(ii)})^2\mathcal{S}^{(jj)}, \quad (\mathcal{S}^{(ii)})^2\mathcal{S}^{(ij)},$$

for $i,j=1,2$, $i\neq j$. This leaves the three symmetries

$$\mathcal{S}^{(11)}(\mathcal{S}^{(11)}\mathcal{S}^{(22)}-(\mathcal{S}^{(12)})^2), \quad \mathcal{S}^{(12)}(\mathcal{S}^{(11)}\mathcal{S}^{(22)}-(\mathcal{S}^{(12)})^2), \quad \mathcal{S}^{(22)}(\mathcal{S}^{(11)}\mathcal{S}^{(22)}-(\mathcal{S}^{(12)})^2)$$

whose leading order terms vanish at the regular point. The expansion coefficients for these three terms are obtained uniquely from the derivative data $\partial_q a^{ijklmn}$. Now we have matched all of the sixth order terms in G with an expansion of the form $\mathcal{G}=\Sigma\xi_{ijklmn}\mathcal{S}^{(ij)}\mathcal{S}^{(kl)}\mathcal{S}^{(mn)}$. The difference $G-\mathcal{G}$ is a fourth-order symmetry. It is uniquely determined by the data $b^{ijkl}(\mathbf{0})$, $W(\mathbf{0})$ $b^{mq}(\mathbf{0})$, $W(\mathbf{0})$ [which has not changed since $W^{(ij)}(\mathbf{0})=0$ for all terms in the standard basis], and the data $\partial_m\tilde{b}^{ijkl}(\mathbf{0})$ which has changed. Now we can use the argument presented above to expand this fourth-order symmetry in terms of polynomials in the standard basis.

Example: We indicate, briefly, how the example that we started with, (1), fits into the present structure. In the example the potential is

$$V(x,y)=\frac{1}{2}\left(\omega^2(x^2+y^2)+\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right),$$

where ω, k_1 and k_2 are arbitrary parameters. It is easy to verify that, apart from an additve constant, this is the general solution of the system

$$V_{22}-V_{11}=\frac{3}{x}V_1-\frac{3}{y}V_2,\quad V_{12}=0.$$

Hence we have a nondegenerate potential with

$$A^{22}=\frac{3}{x},\quad B^{22}=-\frac{3}{y},\quad A^{12}=B^{12}=0.$$

A natural basis of functionally independent second-order symmetries is $\{\mathcal{S}_1,\mathcal{S}_2,\mathcal{S}_3\}$, (8). To apply the above results directly, we need to choose a standard basis at a regular point. We choose the regular point $\mathbf{x}_0=(1,1)$. Then the standard second-order symmetries $\mathcal{S}^{(11)}$, $\mathcal{S}^{(22)}$, $\mathcal{S}^{(12)}$ are the unique symmetries that restrict to p_x^2, p_y^2, p_xp_y, respectively, at $\mathbf{x}_0$. Thus

$$\mathcal{S}^{(11)}=p_x^2+\left(\frac{1}{4}-k_1^2\right)\left(\frac{1}{x^2}-1\right)+\omega^2(1-x^2),$$

$$\mathcal{S}^{(22)}=p_y^2+\left(\frac{1}{4}-k_2^2\right)\left(\frac{1}{y^2}-1\right)+\omega^2(1-y^2),$$

$$\mathcal{S}^{(12)}=\frac{1}{2}(p_x^2+p_y^2-(xp_y-yp_x)^2)+\frac{1}{2}\left(\left(\frac{1}{4}-k_1^2\right)\frac{1-y^2}{x^2}+\left(\frac{1}{4}-k_2^2\right)\left(\frac{1-x^2}{y^2}\right)\right)+\omega^2(2-x^2-y^2).$$

The bases are related by

$$\mathcal{S}_1=\mathcal{S}^{(11)}+\omega^2+k_1^2-\tfrac{1}{4},\quad \mathcal{S}_2=\mathcal{S}^{(22)}+\omega^2+k_2^2-\tfrac{1}{4},$$

$$\mathcal{S}_3=\mathcal{S}^{(11)}+\mathcal{S}^{(22)}-2\mathcal{S}^{(12)}+\tfrac{1}{2}-k_1^2-k_2^2.$$

Using these relations and our theory we can verify the quadratic algebra structure for (8).

V. FINE STRUCTURE FOR 2D SUPERINTEGRABLE SYSTEMS: A ONE-PARAMETER POTENTIAL

Here we consider a superintegrable system that admits three functionally independent constants of the motion, but only for a one-parameter family of potentials $V(x,y)=\alpha V^{(0)}(x,y)$, where the gradient of $V^{(0)}$ is nonzero. If the one-parameter family of potentials cannot be extended to a two-parameter family, then by the proof of Lemma 1 the system must admit a four-dimensional family of symmetries $\Sigma a_{(k)}^{ij}p_ip_j+W^{(k)}$, $k=1,\ldots,4$. The Bertrand–Darboux equations for the potential are equivalent to a single first-order equation that, without loss of generality, we can write as

$$V_1+DV_2=0. \tag{66}$$

We change variables to a new orthogonal coordinate system $\{u,v\}$ so that (66) transforms to $\partial_u V=0$. In these coordinates the Bertrand–Darboux equation for a symmetry becomes

$$-V_{vv}\lambda a^{12}=[(\lambda a^{12})_v-(\lambda a^{22})_u]V_v \tag{67}$$

where

$$-\lambda a^{12}A(v) = (\lambda a^{12})_v - (\lambda a^{22})_u$$

for all symmetries a^{ij}. Thus the equation for the potential $V(v)$ becomes $V_{vv}=A(v)V_v$.

The equations for a second-order symmetry are now

$$(\lambda a^{11})_u = -\lambda_v a^{12},$$

$$(\lambda a^{22})_u = \tfrac{2}{3}A(v)\lambda a^{12} + \tfrac{1}{3}\lambda_v a^{12} + \tfrac{1}{3}\lambda_u(a^{22} - a^{11}),$$

$$(\lambda a^{22})_v = -\lambda_u a^{12}, \tag{68}$$

$$(\lambda a^{12})_v = -\tfrac{1}{3}A(v)\lambda a^{12} + \tfrac{1}{3}\lambda_v a^{12} + \tfrac{1}{3}\lambda_u(a^{22} - a^{11}),$$

$$2(\lambda a^{12})_u + (\lambda a^{11})_v = \lambda_u a^{12} + \lambda_v(a^{11} - a^{22}).$$

From the integrability condition $\partial_u(\lambda a^{22})_v = \partial_v(\lambda a^{22})_u$ and (68) we can derive an equation of the form $\lambda_u a_v^{22}=\cdots$ where the right-hand side does not depend on the derivatives of the a^{ij}. If $\lambda_u \neq 0$ then we have an involutory system $a_u^{ij}=\cdots$, $a_v^{ij}=\cdots$ at the first derivative level. Hence the space of symmetries would be at most three-dimensional. This is a contradiction, so we must have $\lambda_u = 0$. This implies that the system admits the first-order symmetry $L=p_u$ as well as a second-order symmetry p_u^2.

Introducing these simplifications into (68) and setting $a_v^{11}=s$ we obtain the involutive system

$$a_u^{11} = -\frac{\lambda'}{\lambda}a^{12},$$

$$a_u^{22} = \frac{2}{3}A(v)a^{12} + \frac{1}{3}\frac{\lambda'}{\lambda}a^{12},$$

$$a_v^{22} = -\frac{\lambda'}{\lambda}a^{22},$$

$$a_v^{12} = -\left(\frac{1}{3}A(v) + \frac{2}{3}\frac{\lambda'}{\lambda}\right)a^{12}, \tag{69}$$

$$a_u^{12} = -\frac{1}{2}\left(\frac{\lambda'}{\lambda}a^{22} + s\right),$$

$$s_u = \left(-\left(\frac{\lambda'}{\lambda}\right)' + \frac{1}{3}\frac{\lambda'}{\lambda}\left(2\frac{\lambda'}{\lambda} + A(v)\right)\right)a^{12},$$

$$s_v = \frac{1}{3}\left(2\frac{\lambda'}{\lambda} + A(v)\right)\left(-\frac{\lambda'}{\lambda}a^{22} - s\right) + \left(\left(\frac{\lambda'}{\lambda}\right)^2 - \left(\frac{\lambda'}{\lambda}\right)'\right)a^{22},$$

where $\lambda=\lambda(v)$. This system can depend on at most four constants a^{11}, a^{12}, a^{22}, s at a regular point. Since the system is at least four-dimensional, we see that it is *exactly* four-dimensional and that the integrability conditions must be satisfied. (Thus the system corresponds to a Darboux space.[41,35,36]) The only nontrivial integrability condition is $\partial_u a_v^{22} = \partial_v a_u^{22}$ or

$$2A' - \frac{2}{3}A^2 + \frac{1}{3}A\frac{\lambda'}{\lambda} + \frac{1}{3}\left(\frac{\lambda'}{\lambda}\right)^2 + \left(\frac{\lambda'}{\lambda}\right)' = 0. \tag{70}$$

In terms of the potential function V, this condition can be expressed as

$$\frac{\lambda'}{\lambda} + 2\frac{V''}{V'} = \alpha\lambda^{-1/3}(V')^{1/3}$$

for α a constant.

Theorem 9: *Every system with a one-parameter potential and three functionally independent second-order symmetries is the restriction of some three-parameter potential to a single parameter, such that the restricted potential is annihilated by some first-order symmetry of the Darboux space*.

Proof: From the discussion above, we can pass to coordinates u,v such that the system takes the form

$$H = \frac{p_u^2 + p_v^2}{\lambda(v)} + \gamma V(v).$$

The Poisson bracket $\{p_u, S\}$ for any second-order symmetry $S=\Sigma a^{ij}p_ip_j+W$ of our system is also a second-order symmetry $\Sigma a_u^{ij}p_ip_j+W_u$. Thus the linear operation of differentiating with respect to u leaves the four-dimensional space of second-order symmetries invariant. We can get more detailed information about this space by choosing a basis in which ∂_u is in Jordan canonical form. A two-dimensional subspace of the symmetries is spanned by H and p_u^2, which are in the null space of ∂_u. Thus the possible Jordan forms for ∂_u are

$$(i):\begin{pmatrix} \xi_1 & 0 & 0 & 0 \\ 0 & \xi_2 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (ii):\begin{pmatrix} \xi & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$(iii):\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (iv):\begin{pmatrix} \xi & 1 & 0 & 0 \\ 0 & \xi & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$(v):\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

where ξ and ξ_1 are nonzero.

We will use these canonical forms to show that there always exists a three-dimensional subspace of the four parameter subspace of second-order symmetries and a nondegenerate potential $\tilde{V}$, containing, V as a special case, such that the subspace is spanned by $\tilde{H}=(p_u^2+p_v^2)/\lambda+\tilde{V}$, $p_u^2+\tilde{W}_1$, and $\Sigma a^{ij}p_ip_j+\tilde{W}_2$ where $\Sigma a^{ij}p_ip_j+W_k$ is one of the symmetries of the one-parameter system. First note from the Bertrand–Darboux equations and Eq. (69) that the defining equations for the nondegenerate potential associated to these three symmetries must be

$$\tilde{V}_{vv} = \tilde{V}_{uu} + 3(\ln a^{12})_u \tilde{V}_u + A(v)\tilde{V}_v,$$
$$\tilde{V}_{uv} = -\frac{\lambda'}{\lambda}\tilde{V}_u. \tag{71}$$

Here $(\ln a^{12})_{uv} = 0$ and $\Sigma a^{ij}p_i p_j + W_k$ is the third symmetry. The integrability conditions for Eq. (71) reduce to the single requirement

$$A\left(\frac{\lambda'}{\lambda}\right)' + A'\left(\frac{\lambda'}{\lambda}\right) + 2\left(\frac{\lambda'}{\lambda}\right)\left(\frac{\lambda'}{\lambda}\right)' - \left(\frac{\lambda'}{\lambda}\right)'' = 0. \tag{72}$$

Consider the case where ∂_u acting on the space of second-order symmetries has an eigenvector S with eigenvalue $\xi \neq 0$. Then this symmetry must have the form

$$a^{11} = b^{11}(v)e^{\xi u}, \quad a^{12} = b^{12}(v)e^{\xi u}, \quad a^{22} = b^{22}(v)e^{\xi u}.$$

Substituting these expressions into Eq. (69) we obtain the conditions

$$2\xi^2 - \left(\frac{\lambda'}{\lambda}\right)' + \left(\frac{\lambda'}{\lambda}\right)^2 + A\frac{\lambda'}{\lambda} = 0, \quad (\ln a^{12})_u = \xi \tag{73}$$

which, together with (70), implies (72). Further, the integrability conditions for the three symmetries $\tilde{H}$, $p_u^2 + \tilde{W}$, S to correspond to a nondegenerate potential are

$$18\xi^2 = 12\left(\frac{\lambda'}{\lambda}\right)' - 8\left(\frac{\lambda'}{\lambda}\right)^2 - 8A\frac{\lambda'}{\lambda} + 6A' - 2A^2, \quad 2\xi^2 = \left(\frac{\lambda'}{\lambda}\right)' - \left(\frac{\lambda'}{\lambda}\right)^2 - A\frac{\lambda'}{\lambda}, \tag{74}$$

and these are also implied by (73) and (70).

For the remaining systems there is a second-order symmetry whose quadratic terms are $S_2 = \Sigma a^{ij}p_i p_j$ such that the quadratic terms in $S_1 = \partial_u S_2$ also correspond to a symmetry, and $\partial_u S_1 \equiv 0$. Clearly, there are constants α,β with $|\alpha|^2 + |\beta|^2 > 0$ and

$$S_1 = \alpha\frac{p_u^2 + p_v^2}{\lambda} + \beta p_u^2, \quad S_2 = uS_1 + T_2(v),$$

where T_2 is a quadratic form in p_u, p_v that depends only on v. From conditions (69) it is straightforward to compute that

$$a^{12} = b^{12}(v), \quad a^{22} = \frac{\alpha u + \beta}{\lambda}, \quad a^{11} = -\frac{\lambda'}{\lambda}b^{12}(v)u + c^{12}(v),$$

and, finally, that

$$-\left(\frac{\lambda'}{\lambda}\right)' + \left(\frac{\lambda'}{\lambda}\right)^2 + A\frac{\lambda'}{\lambda} = 0, \quad (\ln a^{12})_u = \xi. \tag{75}$$

The integrability conditions for the three symmetries $\tilde{H}$, $p_u^2 + \tilde{W}$, $S_2 + \tilde{W}_2$ to correspond to a nondegenerate potential are

$$0 = 12\left(\frac{\lambda'}{\lambda}\right)' - 8\left(\frac{\lambda'}{\lambda}\right)^2 - 8A\frac{\lambda'}{\lambda} + 6A' - 2A^2, \quad 0 = \left(\frac{\lambda'}{\lambda}\right)' - \left(\frac{\lambda'}{\lambda}\right)^2 - A\frac{\lambda'}{\lambda}, \tag{76}$$

and these, as well as (72) are implied by (73) and (70). Q.E.D.

Remark: It is easy to show using conditions (69) that the Jordan form (iv) does not, in fact, occur.

VI. CONCLUSIONS AND FURTHER WORK

In this paper we have uncovered the structure of 2D classical superintegrable systems with nondegenerate potential and verified the existence of a quadratic algebra of symmetries for all such systems. We have shown how to compute the quadratic algebra relations in general. We have shown that superintegrable systems with degenerate one and two parameter potentials (in addition to the trivial added constant) can be considered as restrictions of nondegenerate systems. We have verified that, with one exception, all nondegenerate superintegrable 2D systems are multiseparable. In the next paper in this series we will develop the properties of the Stäckel transform between superintegrable systems and verify that all nondegenerate 2D systems are Stäckel transforms of 2D constant curvature systems (already classified[44,45]). This will lead to a simple classification of all 2D nondegenerate superintegrable systems. Koenigs[41] in a remarkable paper has already classified all 2D (zero potential) spaces that admit three second-order Killing tensors. Our classification, considerably simpler than Koenigs', will show that all of his spaces also admit nondegenerate potentials. The next papers will extend these results to the case $n=3$, a prelude to a treatment for general n. The case $n=2$ is very special and new techniques have to be developed for higher n. However the basic conclusions and structure theorems can be generalized. We will also show how to solve the quantization problem and carry over the structure theory to the operator case.

This paper is one of a series that lays the groundwork for a structure and classification theory of second order superintegrable systems, both classical and quantum, in conformally flat spaces. Here we study the Stäckel transform (or coupling constant metamorphosis) as an invertible mapping between classical superintegrable systems on different spaces. Through the use of this tool we derive and classify for the first time all two-dimensional (2D) superintegrable systems. The underlying spaces are exactly those derived by Koenigs in his remarkable paper giving all 2D manifolds (with zero potential) that admit at least three second order symmetries. Our derivation is very simple and quite distinct. We also show that every superintegrable system is the Stäckel transform of a superintegrable system on a constant curvature space. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1894985]

I. INTRODUCTION

This is a sequel to our first paper.[1] Our purpose is to lay the groundwork for a structure and classification theory of second order superintegrable systems, both classical and quantum, in complex conformally flat spaces. Real spaces are considered as restrictions of these to the various real forms. In Ref. 1 we have given examples, described the background as well as the interest and importance of these systems in mathematical physics and given many relevant references. Observed features of the systems are multiseparability, closure of the quadratic algebra of second order symmetries at order 6, use of representation theory of the quadratic algebra to derive spectral properties of the quantum Schrödinger operator, and a close relationship with exactly solvable and quasiexactly solvable problems.[2–9] Our approach is, rather than focus on particular spaces and systems, to use a general theoretical method based on integrability conditions to derive structure common to all systems.

In this paper we study the Stäckel transform, or coupling constant metamorphosis,[10,11] for two-dimensional(2D) classical superintegrable systems. Recall that for a classical 2D system on a Riemannian manifold we can always choose local coordinates x,y, not unique, such that the Hamiltonian takes the form

$$H=\frac{p_1^2+p_2^2}{\lambda(x,y)}+V(x,y).$$

a)Electronic mail: j.kress@unsw.edu.au

This system is *second order superintegrable* with *nondegenerate* potential $V=V(x,y,\alpha,\beta,\gamma)$ if it admits three functionally independent quadratic constants of the motion

$$S_k = \sum_{ij} a^{ij}_{(k)} p_i p_j + W_{(k)}(x,y,\alpha,\beta,\gamma).$$

(We also refer to these constants of the motion as symmetries because; each leads to a conserved quantity for the associated physical system; their Poisson brackets with the Hamiltonian vanish, so that they are generalized symmetries in the Lie sense; and their quantizations lead to second order partial differential operators that commute with the Schrödinger operator, so are again generalized symmetries in the Lie sense.) The potential V is nondegenerate in the sense that at any regular point x_0,y_0 where the potential is defined and analytic and the S_k are functionally independent, we can prescribe the values of $V_1(x_0,y_0),V_2(x_0,y_0),V_{11}(x_0,y_0)$ arbitrarily by choosing appropriate values for the parameters α,β,γ. Here, $V_1=\partial V/\partial x$, $V_2=\partial V/\partial y$, etc. [Another way to look at this is to say that $V_1(x_0,y_0),V_2(x_0,y_0),V_{11}(x_0,y_0)$ are the parameters.] This is in addition to the trivial constant that we can always add to a potential. This requirement implies that the potential satisfies a system of coupled PDEs of the form

$$V_{22} = V_{11} + A^{22}(x,y)V_1 + B^{22}(x,y)V_2, \quad V_{12} = A^{12}(x,y)V_1 + B^{12}(x,y)V_2.$$

The Stäckel transform is a conformal transformation of a superintegrable system on one space to a superintegrable system on another space. We prove that all nondegenerate 2D superintegrable systems are Stäckel transforms of constant curvature systems and give a complete and simple classification of all 2D superintegrable systems. The following papers will extend these results to three-dimensional (3D) systems and the quantum analogs of 2D and 3D classical systems.

II. THE STÄCKEL TRANSFORM FOR TWO-DIMENSIONAL SYSTEMS

The Stäckel transform[10] or coupling constant metamorphosis[11] plays a fundamental role in relating superintegrable systems on different manifolds. The basic idea behind this transform has long been observed in various important classical and quantum mechanical systems. One of the most familiar is the Hamilton–Jacobi equation for the classical Coulomb problem $H\equiv p_1^2+p_2^2+p_3^2+Z/r=E$ where r is the radial coordinate and Z is the charge. Division of the equation by the potential term r^{-1} converts it into the pseudo-Coulomb problem $H'\equiv r(p_1^2+p_2^3+p_3^2)-Er=-Z$, much easier to solve from a group theoretic point of view, where the space has changed and the energy and charge have switched roles. In Ref. 11 it was pointed out that if $H+ZV(\mathbf{x})=E$ is an integrable Hamiltonian system for some additive potential V and all values of the parameters Z,E, then the system $H/V-E/V=Z$ is also integrable, where the parameters E and Z have changed roles. This general transformation was called coupling constant metamorphosis. Independently in Ref. 10 it was observed that if the Hamilton–Jacobi equations $\Sigma g^{ij}p_1p_j+V(\mathbf{q})=E$, $\Sigma g^{ij}p_1p_j+U(\mathbf{q})=E$ each admit a complete integral via separation of variables in the orthogonal coordinates $\mathbf{q}$, where U is nonzero, then the system $U^{-1}\Sigma g^{ij}p_1p_j+U^{-1}V(\mathbf{q})=E'$ also admits a complete integral via separation in the same coordinates, but on a different manifold. The second order constants of the motion that describe the separation and the corresponding Stäckel matrices are mapped into one another by the transformation. We called this the Stäckel transform since it preserved the Stäckel form of the separable system. All of these observations have straightforward extensions to n dimensions and to the corresponding quantum mechanical operators.

Suppose we have a superintegrable system

$$H = \frac{p_1^2+p_2^2}{\lambda(x,y)} + V(x,y) \tag{1}$$

in local orthogonal coordinates, with nondegenerate potential $V(x,y)$,

$$V_{22} = V_{11} + A^{22}V_1 + B^{22}V_2,$$
$$V_{12} = A^{12}V_1 + B^{12}V_2 \tag{2}$$

and suppose $U(x,y)$ is a particular solution of equations (2), nonzero in an open set. Then the transformed system

$$\tilde{H} = \frac{p_1^2 + p_2^2}{\tilde{\lambda}(x,y)} + \tilde{V}(x,y) \tag{3}$$

with nondegenerate potential $\tilde{V}(x,y)$,

$$\tilde{V}_{22} = \tilde{V}_{11} + \tilde{A}^{22}\tilde{V}_1 + \tilde{B}^{22}\tilde{V}_2,$$
$$\tilde{V}_{12} = \tilde{A}^{12}\tilde{V}_1 + \tilde{B}^{12}\tilde{V}_2 \tag{4}$$

is also superintegrable, where

$$\tilde{\lambda} = \lambda U, \quad \tilde{V} = \frac{V}{U},$$

$$\tilde{A}^{12} = A^{12} - \frac{U_2}{U}, \quad \tilde{A}^{22} = A^{22} + 2\frac{U_1}{U}, \quad \tilde{B}^{12} = B^{12} - \frac{U_1}{U}, \quad \tilde{B}^{22} = B^{22} - 2\frac{U_2}{U}.$$

Let $S=\Sigma a^{ij}p_ip_j+W=S_0+W$ be a second order symmetry of H and $S_U=\Sigma a^{ij}p_ip_j+W_U=S_0+W_U$ be the special case of this that is in involution with $p_1^2+p_2^2/\lambda+U$. Then

$$\tilde{S} = S_0 - \frac{W_U}{U}H + \frac{1}{U}H$$

is the corresponding symmetry of $\tilde{H}$. Since one can always add a constant to a nondegenerate potential, it follows that $1/U$ defines an inverse Stäckel transform of $\tilde{H}$ to H. See Refs. 10 and 12 for many examples of this transform. We say that two superintegrable systems are Stäckel equivalent if one can be obtained from the other by a Stäckel transform.

A. A Stäckel transform approach to the classification of nondegenerate superintegrable systems

Through the use the Stäckel transform we can develop a method for classifying 2D nondegenerate superintegrable systems that is differential equations based. (In particular it is distinct from the Koenigs analytic function approach to finding spaces that admit at least three second order Killing tensors.) Let

$$ds^2 = \lambda(x,y)(dx^2 + dy^2)$$

be a metric for a nondegenerate superintegrable system. We recall from Sec. 2 of Ref. 1 that necessary and sufficient conditions for a^{ij} to be a second order Killing tensor for λ are that

$$\Delta a^{12} = 0, \quad \Delta(a^{11} - a^{22}) = 0, \quad \Delta = \partial_x^2 + \partial_y^2,$$

where

$$(a^{22} - a^{11})_2 = 2a_1^{12}, \quad (a^{22} - a^{11})_1 = -2a_2^{12},$$

and the a^{ij} satisfy the integrability condition

$$(\lambda_{22}-\lambda_{11})a^{12}-\lambda_{12}(a^{22}-a^{11})=3\lambda_1 a_1^{12}-3\lambda_2 a_2^{12}+(a_{11}^{12}-a_{22}^{12})\lambda. \tag{5}$$

Since λ is nondegenerate superintegrable we have three independent symmetries of the form $\mathcal{S}=\Sigma a^{ij}p_ip_j+W$ and a nondegenerate potential V satisfying the Bertrand–Darboux equations

$$(V_{22}-V_{11})a^{12}+V_{12}(a^{11}-a^{22})=\left[\frac{(\lambda a^{12})_1-(\lambda a^{11})_2}{\lambda}\right]V_1+\left[\frac{(\lambda a^{22})_1-(\lambda a^{12})_2}{\lambda}\right]V_2 \tag{6}$$

for all symmetries with quadratic terms a^{ij}.

For a superintegrable system we can always use the independent symmetries to solve equations (6) for $V_{22}-V_{11}, V_{12}$ in the form (2). If these two equations are the only conditions on the potential function V then it will depend on four parameters, the maximum number possible. Thus we can prescribe the derivatives V_1, V_2, V_{11} and the value of V at a fixed point. This is the case of a nondegenerate potential. If, however, the equations (6) put additional conditions on the potential then there will be a restriction on the first derivatives and the potential will depend on fewer parameters than four. In this case the potential is degenerate. In Ref. 1 we showed that superintegrable systems with three and two parameter potentials were, essentially, just restrictions of the four parameter nondegenerate potentials. One parameter potentials (i.e., constant potentials) are different. They in general are not restrictions of nondegenerate potentials and, indeed, the quadratic algebra structure may not hold. See Ref. 13 for a counterexample.

Returning to our nondegeneracy assumption, the system of equations (6) has a four parameter family of solutions V, counting the addition of a scalar to V as a parameter. Also, every Stäckel transform of this system to a system with metric μ must be of the form $\hat{V}=\mu/\lambda$ where $V=\hat{V}$ is some particular solution of the equations (6). Thus it is of interest to determine the equations that characterize μ.

To simplify the computations to follow, we recall that we can choose our orthogonal coordinates x,y such that one of our symmetries takes the form $a^{12}\equiv 0$, $a^{22}-a^{11}=1$. In this system the symmetry and (5) imply $\lambda_{12}=0$, and, as we will see, $\mu_{12}=0$. A second symmetry is defined by the Hamiltonian itself, $a^{11}=a^{22}=1/\lambda$, $a^{12}=0$, which clearly always satisfies equations (5) and (6). Due to nondegeneracy, for the third symmetry we must have $a^{12}\neq 0$ and it is on this third symmetry that we will focus our attention in the following. Now the fundamental integrability conditions can be rewritten as

$$\lambda_{12}=0, \quad \lambda_{22}-\lambda_{11}=3\lambda_1 A_1-3\lambda_2 A_2+(A_{11}+A_1^2-A_{22}-A_2^2)\lambda, \tag{7}$$

where $A=\ln a^{12}$ and the subscripts denote differentiation. Similarly, using this result and (6) we find that the equations characterizing μ are

$$\mu_{12}=0, \quad \mu_{22}-\mu_{11}=3\mu_1 A_1-3\mu_2 A_2+(A_{11}+A_1^2-A_{22}-A_2^2)\mu. \tag{8}$$

Note that these two equations appear identical. However they have different interpretations. The fixed metric λ satisfies (7) and is a special solution of (8). Here μ designates a four-parameter family of solutions, of which λ is a particular special case. It follows that A satisfies the integrability conditions for this system.

Let us apply ∂_{12} to both sides of (8). The result, using $\mu_{12}=0$ and $\Delta a^{12}=0$, is

$$0=3A_{12}(\mu_{11}-\mu_{22})+(3A_{112}+2[A_{11}+A_1^2]_2)\mu_1+(-3A_{122}+2[A_{11}+A_1^2]_1)\mu_2+2\mu(A_{11}+A_1^2)_{12}. \tag{9}$$

There are two possibilities here.

(1) *Case I:* $A_{12}=0$. Then every term in the preceding equation vanishes identically. We conclude that a^{12} factors as $a^{12}=X(x)Y(y)$, where $\Delta a^{12}=0$. Thus there is a constant α such that

$$X'' = \alpha^2 X, \quad Y'' = -\alpha^2 Y.$$

We have solutions

$$X(x) = \beta_1 e^{\alpha x} + \beta_2 e^{-\alpha_2 x}, \quad Y(y) = \gamma_1 e^{i\alpha y} + \gamma_1 e^{-i\alpha y}.$$

Variables separate in the equations for μ into two ODEs. Thus for every choice of a^{12} we can find all solutions μ explicitly.

(2) *Case II:* $A_{12} \neq 0$. Now the coefficients of μ_{11}, μ_{22} in (9) are nonvanishing. The equation can be rewritten as

$$\mu_{22} - \mu_{11} = \mu_1 \left[\frac{3A_{112} + 2(A_{11} + A_1^2)_2}{3A_{12}} \right] + \mu_2 \left[\frac{-3A_{122} + 2(A_{11} + A_1^2)_1}{3A_{12}} \right] + 2\mu(A_{11} + A_1^2)_{12}.$$

Since μ is a four-parameter solution, the coefficients of μ_1, μ_2, and μ can be equated. Thus we have three new identities, which together with $\Delta a^{12} = 0$ give

$$\begin{gathered} \text{(i) } 9A_1A_{12} = 3A_{112} + 2(A_{11} + A_1^2)_2, \quad \text{(ii) } 9A_2A_{12} = 3A_{122} + 2(A_{22} + A_2^2)_1, \\ \text{(iii) } 3(A_{11} + A_1^2)A_{12} = (A_{11} + A_1^2)_{12}, \quad \text{(iv) } A_{11} + A_1^2 + A_{22} + A_2^2 = 0. \end{gathered} \tag{10}$$

The first two identities imply $A_{12} = Ce^A$ for some nonzero constant C. This is the Liouville equation with general solution

$$a^{12} = e^A = \frac{2X'(x)Y'(y)}{C(X(x) + Y(y))^2},$$

where $X(x)$ and $Y(y)$ are functions such that $X'(x)Y'(y) \neq 0$. At this point it is convenient to use X, Y as new coordinates. Thus there are functions $F(X), G(Y)$ such that

$$(X')^2 = F(X), \quad X'' = \tfrac{1}{2}F'(X), \quad (Y')^2 = G(Y), \quad Y'' = \tfrac{1}{2}G'(Y).$$

Substituting these expressions into the identities (i)–(iv) we obtain a system of functional differential equations for F, G with the general solution

$$F(X) = \frac{\alpha}{24}X^4 + \frac{\gamma_1}{6}X^3 + \frac{\gamma_2}{2}X^2 + \gamma_3 X + \gamma_4,$$

$$G(Y) = -\frac{\alpha}{24}Y^4 + \frac{\gamma_1}{6}Y^3 - \frac{\gamma_2}{2}Y^2 + \gamma_3 Y - \gamma_4,$$

where α, γ_j are constants. Note that the equations for x, y in terms of X, Y take the form of elliptic integrals,

$$x = \int \frac{dX}{\sqrt{\frac{\alpha}{24}X^4 + \frac{\gamma_1}{6}X^3 + \frac{\gamma_2}{2}X^2 + \gamma_3 X + \gamma_4}},$$

$$y = \int \frac{dY}{\sqrt{\frac{-\alpha}{24}Y^4 + \frac{\gamma_1}{6}Y^3 - \frac{\gamma_2}{2}Y^2 + \gamma_3 Y - \gamma_4}}.$$

Again, variables separate into two ODEs in the equations for μ. Thus for every choice of a^{12} we can find all solutions μ explicitly.

Theorem 1: If $ds^2 = \lambda(dx^2 + dy^2)$ is the metric of a nondegenerate superintegrable system (expressed in coordinates x, y such that $\lambda_{12} = 0$) then $\lambda = \mu$ is a solution of the system

$$\mu_{12}=0, \quad \mu_{22}-\mu_{11}=3\mu_1(\ln a^{12})_1-3\mu_2(\ln a^{12})_2+\left(\frac{a_{11}^{12}-a_{22}^{12}}{a^{12}}\right)\mu, \tag{11}$$

where either

$$\text{(I) } a^{12}=X(x)Y(y), \quad X''=\alpha^2 X, \quad Y''=-\alpha^2 Y,$$

or

$$\text{(II) } a^{12}=\frac{2X'(x)Y'(y)}{C(X(x)+Y(y))^2},$$

$$(X')^2=F(X), \quad X''=\frac{1}{2}F'(X), \quad (Y')^2=G(Y), \quad Y''=\frac{1}{2}G'(Y),$$

where

$$F(X)=\frac{\alpha}{24}X^4+\frac{\gamma_1}{6}X^3+\frac{\gamma_2}{2}X^2+\gamma_3 X+\gamma_4,$$

$$G(Y)=-\frac{\alpha}{24}Y^4+\frac{\gamma_1}{6}Y^3-\frac{\gamma_2}{2}Y^2+\gamma_3 Y-\gamma_4.$$

Conversely, every solution λ of one of these systems defines a nondegenerate superintegrable system. If λ is a solution then the remaining solutions μ are exactly the nondegenerate superintegrable systems that are Stäckel equivalent to λ.

This result provides the basis for a simple classification of all nondegenerate superintegrable systems. In fact the spaces that arise correspond one-to-one with Koenigs' tables of 2D spaces that admit at least three second order symmetries. Indeed, from the fact that $F(X)$ and $G(Y)$ are fourth order polynomials we can determine which solutions of the functions $X(x)$ and $Y(y)$ yield the lists drawn up by Koenigs in his two tables. (We give the details of these tables in Sec. II B.)

To understand more clearly the significance of cases (I) and (II) in the preceding theorem, we make use of the symmetry of equations (8), first exploited by Koenigs. We write the system in the form

$$a_{11}^{12}+a_{22}^{12}=0, \quad \mu_{12}=0, \quad a^{12}(\mu_{11}-\mu_{22})+3\mu_1 a_1^{12}-3\mu_2 a_2^{12}+(a_{11}^{12}-a_{22}^{12})\mu=0, \tag{12}$$

Lemma 1: Suppose $\mu=\lambda(x,y)$, $a^{12}=a(x,y)$ satisfy (12). Then $\mu=\tilde{a}(x,y)$, $a^{12}=\tilde{\lambda}(x,y)$ also satisfy (12) where

$$\tilde{a}(x,y)=a(x+y,ix-iy), \quad \tilde{\lambda}(x,y)=\lambda(x-iy,y-ix).$$

This transformation is invertible.

Proof: It is straightforward to check that $\tilde{a}_{12}=0$, $\tilde{\lambda}_{11}+\tilde{\lambda}_{22}=0$. The symmetry of the third equation under this invertible transform is obvious. Q.E.D.

Theorem 2: System (12) characterizes a nondegenerate superintegrable system if and only if the metric $\tilde{a}^{12}(x,y)$ is of constant curvature. Equivalently, the system (12) characterizes a nondegenerate superintegrable system if and only if the symmetry a^{12} is the image $a^{12}=\tilde{\lambda}$ where the metric λ (with $\lambda_{12}=0$ is of constant curvature).

Proof: System (12) characterizes a nondegenerate superintegrable system if and only if the symmetry a^{12} satisfies the Liouville equation $(\ln a^{12})_{12}=Ca^{12}$ for some constant C. [If $C=0$ we have case (I), and if $C\neq 0$ we have case (II).] It is straightforward to check that this means that

$$\frac{\tilde{a}^{12}_{11}+\tilde{a}^{12}_{22}}{(\tilde{a}^{12})^2}-\frac{(\tilde{a}^{12}{}_1)^2+(\tilde{a}^{12}_2)^2}{(\tilde{a}^{12})^3}=4iC,$$

so the scalar curvature of metric $\tilde{a}^{12}(dx^2+dy^2)$ is constant. Similarly, if λ is of constant curvature then $\tilde{\lambda}$ satisfies Liouville's equation. Q.E.D.

Theorem 3: Every nondegenerate superintegrable 2D system is Stäckel equivalent to a nondegenerate superintegrable system on a constant curvature space.

Proof: Every nondegenerate superintegrable 2D system with metric $\lambda(dx^2+dy^2)$ corresponds to a function a^{12}_0 and a system of equations (12) (with $a^{12}=a^{12}_0$) where $\mu=\lambda$ is a solution and the integrabilty conditions are satisfied identically, so that the space of solutions μ is four dimensional. From Theorem 1 we see that a^{12}_0 must satisfy the Liouville equation, so by Theorem 2 the metric $\xi=\tilde{a}^{12}_0$ is of constant curvature. Recall that the space of second order symmetries of a constant curvature space is six dimensional. Consider the possible symmetries a^{12} such that standard equations

$$a^{12}_{11}+a^{12}_{22}=0,\quad a^{12}(\xi_{11}-\xi_{22})+3\xi_1 a^{12}_1-3\xi_2 a^{12}_2+(a^{12}_{11}-a^{12}_{22})\xi=0$$

are satisfied. One constant curvature space symmetry with $a^{12}=0$ determines the separable coordinates $\{x,y\}$ and one symmetry is the Hamiltonian $(p_1^2+p_2^2)/\lambda$. A basis for the remaining symmetries consists of four linearly independent symmetries with a^{12} harmonic and nonzero. It is clear that the Koenig duality mapping $\tilde{\mu}$ for μ a solution of system (12) maps the four-dimensional space of solutions μ (except $\mu=0$) one-to-one onto the constant curvature space symmetries with a^{12} harmonic and nonzero. For constant curvature spaces we know that there are symmetries a^{12} that define nondegenerate superintegrable systems (the systems on flat space and the 2-sphere.) Let $a^{12}=b^{12}$ be one such symmetry. By Theorem 1 b^{12} satisfies the Liouville equation. Since the Koenigs duality map is onto, there must exist a solution $\mu=\nu$ of system (12) such that $\tilde{\nu}=b^{12}$. By Theorem 2 ν is the metric of a constant curvature space. This means that the system with metric λ is Stäckel equivalent to the constant curvature system with metric ν. Q.E.D.

B. Examples and relationship with the Koenigs tables

In a tour de force, Koenigs[14] has classified all 2D manifolds that admit exactly three second order Killing tensors and listed them in two tables, Table VI and Table VII.

In each case Koenigs gave the terms that give rise to the leading coefficients of the additional quadratic constant of the motion not implicitly defined by the Liouville form of the metric. We have given these metrics in a symmetric orthogonal form.

We can now reproduce the tables via the duality between separable coordinate systems on spaces of constant curvature and the form of the Killing tensors admitted in these particular coordinate systems.

For example, taking $\alpha=1$ in case (I), a solution for a^{12} is

$$X(x)=\sin x,\quad Y(y)=\sinh y\Rightarrow a^{12}=\sin x\sinh y.$$

Now $\mu_{12}=0\Rightarrow\mu=f(x)+g(y)$ and so Eq. (11) for μ becomes

$$g''-f''=3f'\cot x-3g'\coth x-2(f+g)$$

which separates into a pair of ordinary differential equations,

$$g''+3\coth y g'+2g=K,\quad f''+\cot x f'-2f=K,$$

for some separation constant K. These equations have solutions

$$f(x)=\frac{c_1\cos x+c_2}{\sin^2 x}-\frac{1}{2}K,\quad g(y)=\frac{c_3\cosh y+c_4}{\sinh^2 y}+\frac{1}{2}K$$

and so

$$\mu = \frac{c_1 \cos x + c_2}{\sin^2 x} + \frac{c_3 \cosh y + c_4}{\sin^2 y}. \tag{13}$$

In the preceding, we have used coordinates in which the metric was a multiple of $dx^2 + dy^2$, while Koenigs used coordinates in which the metric was a multiple of $dx\, dy$. To bridge this gap, we make the change of coordinates $x \to a$, $y \to ib$ to obtain (with a trivial redefinition of the parameters c_i) the first metric in Table VI.

The remaining metrics in Table VI are obtained by similar calculations using the following particular solutions to the case (I) equations in Theorem 1:

(1) $X = \sin x, \quad Y = \sinh y,$

(2) $X = \sinh x, \quad Y = e^{iy},$

(3) $X = e^x, \quad Y = e^{iy},$

(4) $X = x, \quad Y = y,$

(5) $X = x, \quad Y = 1,$

(6) $X = Y = 1,$

The metrics in Table VII are obtained from particular solutions to the case (II) equations in Theorem 1 in the same way as described for Table VI.

(1) Both $F(X)$ and $G(Y)$ are general fourth order polynomials,

(2) $$\left.\begin{aligned} 4F(X) &= 1 - X^2 \\ 4G(Y) &= Y^2 - 1 \end{aligned}\right\} \Rightarrow \begin{cases} X = -2\cos 2x, \\ Y = \cosh 2y, \end{cases}$$

(3) $$\left.\begin{aligned} F(X) &= X^2(X-1)^2 \\ G(Y) &= -Y^2(Y+1)^2 \end{aligned}\right\} \Rightarrow \begin{cases} X = \dfrac{1}{1+e^x}, \\ Y = \dfrac{1}{-1+e^{iy}}, \end{cases}$$

(4) $$\left.\begin{aligned} F(X) &= X^3(X-1) \\ G(Y) &= -Y^3(Y+1) \end{aligned}\right\} \Rightarrow \begin{cases} X = \dfrac{1}{1-\frac{1}{4}x^2}, \\ Y = -\dfrac{1}{1+\frac{1}{4}y^2}, \end{cases}$$

$$(5)\qquad \left.\begin{aligned} F(X) &= 1 \\ G(Y) &= 1 \end{aligned}\right\} \Rightarrow \begin{cases} X = x, \\ Y = y, \end{cases}$$

There are clearly other choices possible for X and Y but they revert to various versions of the cases given in Koenigs' tables. Since a single space may have more than one nondegenerate potential, our classification may include a space more than once.

Next, we examine each of his spaces and show in detail what was proved in the last section: that every superintegrable system on the space can be obtained as the Stäckel transform of a constant curvature space with respect to Koenigs Table VI,

$$(1)\qquad ds^2 = \left[\frac{c_1\cos a + c_2}{\sin^2 a} + \frac{c_3\cos b + c_4}{\sin^2 b}\right](da^2 - db^2)$$

$$(2)\qquad ds^2 = \left[\frac{c_1\cosh a + c_2}{\sinh^2 a} + \frac{c_3 e^b + c_4}{e^{2b}}\right](da^2 - db^2)$$

$$(3)\qquad ds^2 = \left[\frac{c_1 e^a + c_2}{e^{2a}} + \frac{c_3 e^b + c_4}{e^{2b}}\right](da^2 - db^2)$$

$$(4)\qquad ds^2 = \left[c_1(a^2 - b^2) + \frac{c_2}{a^2} + \frac{c_3}{b^2} + c_4\right](da^2 - db^2)$$

$$(5)\qquad ds^2 = \left[c_1(a^2 - b^2) + \frac{c_2}{a^2} + c_3 b + c_4\right](da^2 - db^2)$$

$$(6)\qquad ds^2 = [c_1(a^2 - b^2) + c_2 a + c_3 b + c_4](da^2 - db^2)$$

and Koenigs Table VII,

$$(1)\qquad ds^2 = \left[c_1\left(\frac{1}{\mathrm{sn}^2(a,k)} - \frac{1}{\mathrm{sn}^2(b,k)}\right) + c_2\left(\frac{1}{\mathrm{cn}^2(a,k)} - \frac{1}{\mathrm{cn}^2(b,k)}\right) + c_3\left(\frac{1}{\mathrm{dn}^2(a,k)} - \frac{1}{\mathrm{dn}^2(b,k)}\right) + c_4(\mathrm{sn}^2(a,k) - \mathrm{sn}^2(b,k))\right](da^2 - db^2)$$

$$(2)\qquad ds^2 = \left[c_1\left(\frac{1}{\sin^2 a} - \frac{1}{\sin^2 b}\right) + c_2\left(\frac{1}{\cos^2 a} - \frac{1}{\cos^2 b}\right) + c_3(\cos 2a - \cos 2b) + c_4(\cos 4a - \cos 4b)\right](da^2 - db^2)$$

$$(3)\qquad ds^2 = [c_1(\sin 4a - \sin 4b) + c_2(\cos 4a - \cos 4b) + c_3(\sin 2a - \sin 2b) + c_4(\cos 2a - \cos 2b)](da^2 - db^2)$$

$$(4)\qquad ds^2 = \left[c_1\left(\frac{1}{a^2} - \frac{1}{b^2}\right) + c_2(a^2 - b^2) + c_3(a^4 - b^4) + c_4(a^6 - b^6)\right](da^2 - db^2)$$

$$(5)\qquad ds^2 = [c_1(a - b) + c_2(a^2 - b^2) + c_3(a^3 - b^3) + c_4(a^4 - b^4)](da^2 - db^2)$$

to a nondegenerate superintegrable potential. In Refs. 3–16 the authors have computed all the

nondegenerate (and degenerate) superintegrable potentials for complex 2D flat space, potentials [**E1**]–[**E20**], and nonzero constant curvature space, potentials [**S1**]–[**S9**], and we identify the relevant potentials on the list that is given in Ref. 16.

1. Table VI

(1) In this case the infinitesimal distance has the form

$$ds^2 = \left(\frac{c_1\cos a + c_2}{\sin^2 a} + \frac{c_3\cos b + c_4}{\sin^2 b}\right)(da^2 - db^2).$$

If we rewrite the Hamilton–Jacobi equation on the sphere,

$$H = p_1^2 + p_2^2 + p_3^2 + \hat{c}_1 + \frac{i\hat{c}_2 s_3}{\sqrt{s_1^2 + s_2^2}} + \frac{\hat{c}_3 s_2}{s_1^2\sqrt{s_1^2 + s_2^2}} + \frac{\hat{c}_4}{s_1^2} = E,$$

using a variant of spherical coordinates

$$s_1 = \frac{\sin b}{\sin a}, \quad s_2 = \frac{\cos b}{\sin a}, \quad s_3 = -i\frac{\cos a}{\sin a}$$

we obtain the form

$$p_b^2 - p_a^2 - \frac{E + \hat{c}_1}{\sin^2 a} - \frac{\hat{c}_2\cos a}{\sin^2 a} - \frac{\hat{c}_3\cos b}{\sin^2 b} - \frac{\hat{c}_4}{\sin^2 b} = 0.$$

Thus the potential from which this metric has been derived via Stäckel transform is [**S7**].

(2) In this case the metric is

$$ds^2 = \left(\frac{c_1\cosh a + c_2}{\sinh^2 a} + c_3 e^{-b} + c_4 e^{-2b}\right)(da^2 - db^2)$$

Choosing Euclidean space coordinates of the form

$$x = \exp\left(-\tfrac{1}{2}u\right)\cosh\left(\tfrac{1}{2}v\right), \quad y = i\exp\left(-\tfrac{1}{2}u\right)\sinh\left(\tfrac{1}{2}v\right)$$

and substituting into the Hamilton–Jacobi equation

$$H = p_x^2 + p_y^2 + \hat{c}_1(x^2 + y^2) + \frac{\hat{c}_2}{x^2} + \frac{\hat{c}_3}{y^2} + \hat{c}_4 = E$$

we obtain the form

$$p_u^2 - p_v^2 + \frac{1}{4}\hat{c}_1 e^{-2u} + \mathcal{C}_2\frac{\cosh v}{\sinh^2 v} + \mathcal{C}_3\frac{1}{\sinh^2 v} + \frac{1}{4}(\hat{c}_4 - E)e^{-u},$$

where $\mathcal{C}_2 = \frac{1}{2}(\hat{c}_2 + \hat{c}_3)$ and $\mathcal{C}_3 = \frac{1}{2}(\hat{c}_3 - \hat{c}_2)$. From this it follows that the potential from which this metric is derived via Stäckel transform is [**E1**].

(3) In this case the infinitesimal distance has the form

$$ds^2 = (c_1 e^{-a} + c_2 e^{-2a} + c_3 e^{-b} + c_4 e^{-2b})(da^2 - db^2).$$

In the variables

$$x = e^{-a}\cosh b, \quad y = -ie^{-a}\sinh b$$

this metric assumes the form

$$ds^2 = \left(\frac{c_1}{\sqrt{x^2 + y^2}} + c_2 + \frac{c_3}{\sqrt{x^2 + y^2}(x + iy)} + \frac{c_4}{(x + iy)^2}\right)(dx^2 - dy^2).$$

We recognize this as arising via Stäckel transform from [**E17**]. Indeed note that if we write out the equation $H=E$ in suitable coordinates we obtain

$$p_1^2 + p_2^2 + \frac{\hat{c}_1}{\sqrt{x^2+y^2}} + \frac{\hat{c}_2}{(x+iy)^2} + \frac{\hat{c}_3}{\sqrt{x^2+y^2}(x+iy)} - E = 0$$

from which we can clearly see the identification.

(4) In this case the infinitesimal distance is

$$ds^2 = \left(c_1(a^2-b^2) + \frac{c_2}{a^2} + \frac{c_3}{b^2} + c_4\right)(da^2 - db^2),$$

and by setting $a=x$, $b=iy$ this metric can be clearly related to a Stäckel transform from the potential [**E1**].

(5) Here

$$ds^2 = \left(c_1(a^2-b^2) + \frac{c_2}{a^2} + c_3 b + c_4\right)(da^2 - db^2).$$

It is clear that this metric is derived by Stäckel transform from the potential

$$V = \hat{c}_1(x^2+y^2) + \frac{\hat{c}_2}{x^2} + \hat{c}_3 y + \hat{c}_4,$$

where $a=x$, $b=iy$. As we do not distinguish the use of Cartesian coordinates in any way it is always possible to rotate and translate them. If we do this then for the various choices of $\hat{c}_i$ we have the following potentials from our complete list.

(i) $\hat{c}_1 \neq 0$: We can translate with respect to y and make $\hat{c}_3=0$ to obtain a special case of [**E1**]. If further $\hat{c}_2=0$ then we obtain [**E3**].

(ii) $\hat{c}_1=0$: We have a special case of [**E2**] if $\hat{c}_2, \hat{c}_3 \neq 0$. If $\hat{c}_3=0$ we obtain [**E6**], and if $\hat{c}_2=0$ we obtain [**E5**].

(6) Here

$$ds^2 = (c_1(a^2-b^2) + c_2 a + c_3 b + c_4)(da^2 - db^2)$$

and this is easily recognized to be in the form corresponding to the potential

$$V = \hat{c}_1(x^2+y^2) + \hat{c}_2 x + \hat{c}_3 y + \hat{c}_4.$$

This can easily be interpreted. If $\hat{c}_1 \neq 0$ then we can take $\hat{c}_2$ and $\hat{c}_3=0$ by suitable translations and relate our system to a Stäckel transform of [**E3**]. If $\hat{c}_1=0$ then V can take one of the two forms

(i) $V=\alpha(x+iy)+\beta$ corresponding to [**E4**] or

(ii) $V=\alpha x$ corresponding to [**E6**].

2. Table VII

(1) Here the metric has the form

$$ds^2 = c_1(P(a)-P(b)) + c_2(P(a+\omega_1)-P(b+\omega_1)) + c_3(P(a+\omega_2)-P(b+\omega_2)) + c_4(P(a+\omega_3)-P(b+\omega_3))(da^2-db^2),$$

where $P(a)$ is the Weierstrass function.[17] If we make the choice $e_1=1/k^2$, $e_2=1$, and $e_3=0$ in the standard formulas for these functions we can relate them directly to the Jacobi elliptic functions,[17] via the formulas

$$P(kz) = \frac{1}{k^2\,\mathrm{sn}^2(z,k)}, \quad P(kz+\omega_1) = \frac{1}{k^2} - \frac{k'^2\,\mathrm{sn}^2(z,k)}{k^2\,\mathrm{cn}^2(z,k)},$$

$$P(kz+\omega_2) = \mathrm{sn}^2(z,k), \quad P(kz+\omega_3) = 1 - k'^2\frac{\mathrm{sn}^2(z,k)}{\mathrm{cn}^2(z,k)}.$$

With these formulas the relationship to a constant curvature superintegrable system becomes clear. Indeed if we write the Hamilton–Jacobi equation

$$H = p_1^2 + p_2^2 + p_3^2 + \frac{\hat{c}_1}{s_1^2} + \frac{\hat{c}_2}{s_2^2} + \frac{\hat{c}_3}{s_3^2} + \hat{c}_4 = E$$

using conical coordinates in Jacobi elliptic function form,[17] viz.

$$s_1 = k\,\mathrm{sn}(\alpha,k)\mathrm{sn}(\beta,k), \quad s_2 = i\frac{k'}{k}\mathrm{cn}(\alpha,k)\mathrm{cn}(\beta,k),$$

$$s_3 = \frac{k'}{k}\mathrm{dn}(\alpha,k)\mathrm{dn}(\beta,k), \quad s_1^2 + s_2^2 + s_3^2 = 1,$$

then it becomes

$$p_\alpha^2 + p_\beta^2 + \frac{\hat{c}_1}{k^2}\left(\frac{1}{\mathrm{sn}^2(\alpha,k)} - \frac{1}{\mathrm{sn}^2(\beta,k)}\right) + \frac{\hat{c}_2 k'^2}{k^2}\left(\frac{1}{\mathrm{cn}^2(\alpha,k)} - \frac{1}{\mathrm{cn}^2(\beta,k)}\right)$$
$$+ \frac{\hat{c}_3 k'^2}{k^2}\left(\frac{1}{\mathrm{dn}^2(\alpha,k)} - \frac{1}{\mathrm{dn}^2(\beta,k)}\right) + (\hat{c}_4 - E)(\mathrm{sn}^2(\alpha,k) - \mathrm{sn}^2(\beta,k)) = 0$$

which has the form we expect. This system is therefore related to [**S9**] on the sphere, via a Stäckel transform.

(2) In this case

$$\mathrm{d}s^2 = \left(c_1\left(\frac{1}{\sin^2 a} - \frac{1}{\sin^2 b}\right) + c_2\left(\frac{1}{\cos^2 a} - \frac{1}{\cos^2 b}\right) + c_3(\cos 2a - \cos 2b)\right.$$
$$\left. + c_4(\cos 4a - \cos 4b)\right)(\mathrm{d}a^2 - \mathrm{d}b^2).$$

If we write out the Hamilton–Jacobi equation

$$H = p_1^2 + p_2^2 + \hat{c}_1(x^2 + y^2) + \frac{\hat{c}_2}{x^2} + \frac{\hat{c}_3}{y^2} + \hat{c}_4 = E$$

using coordinates $x = \cos a \cos b$, $y = i \sin a \sin b$ we obtain

$$p_a^2 - p_b^2 + \hat{c}_1(\cos^4 b - \cos^4 b) + \hat{c}_2\left(\frac{1}{\cos^2 a} - \frac{1}{\cos^2 b}\right) + \hat{c}_3\left(\frac{1}{\sin^2 a} - \frac{1}{\sin^2 b}\right)$$
$$+ (\hat{c}_4 - E)(\cos^2 b - \cos^2 a) = 0.$$

The potential for this case arises from [**E1**] via the choice of elliptic coordinates. This is clear from the usual multiplication formulas

$$\cos 2x = 2\cos^2 x - 1, \quad \cos 4x = 8\cos^4 x - 8\cos^2 x + 1.$$

(3) Here

$$ds^2 = (c_1(\sin 4a - \sin 4b) + c_2(\cos 4a - \cos 4b) + c_3(\sin 2a - \sin 2b) + c_4(\cos 2a - \cos 2b))(da^2 - db^2).$$

If we write the Hamilton–Jacobi equation

$$H = p_1^2 + p_2^2 + \hat{c}_1 + \frac{\hat{c}_2(x - iy)}{\sqrt{(x - iy)^2 + 4}} + \frac{\hat{c}_3(x + iy)}{((x - iy)^2 + 4)(x - iy + \sqrt{(x - iy)^2 + 4})^2} + \hat{c}_4(x^2 + y^2) = E,$$

using the coordinates $x = 2i \cos u \cos v$, $y = 2 \sin u \sin v$ we obtain

$$p_u^2 - p_v^2 + 2(\hat{c}_1 - 2E)(\cos 2u - \cos 2v) + \hat{c}_2(\sin 2u - \sin 2v) + \tfrac{1}{4}\hat{c}_3(\cos 4u + i \sin 4u - \cos 4v - i \sin 4v) + 2\hat{c}_4(\cos 4v - \cos 4u) = 0$$

which gives rise to a metric of this type. This corresponds to system [**E7**].

(4) Here

$$ds^2 = \left(c_1\left(\frac{1}{a^2} - \frac{1}{b^2}\right) + c_2(a^2 - b^2) + c_3(a^4 - b^4) + c_4(a^6 - b^6)\right)(da^2 - db^2).$$

In the coordinates $x = \frac{1}{2}(\xi^2 + \eta^2)$, $y = i\xi\eta$ the Hamilton–Jacobi equation

$$p_1^2 + p_2^2 + \hat{c}_1(4x^2 + y^2) + \hat{c}_2 x + \frac{\hat{c}_3}{y^2} + \hat{c}_4 = E$$

is equivalent to

$$p_\xi^2 - p_\eta^2 + (\hat{c}_4 - E)(\xi^2 - \eta^2) + \hat{c}_1(\xi^6 - \eta^6) + \frac{1}{2}\hat{c}_2(\xi^4 - \eta^4) + \hat{c}_3\left(\frac{1}{\xi^2} - \frac{1}{\eta^2}\right) = 0,$$

from which we see that this system is obtained from [**E2**].

(5) The infinitesimal distance has the form

$$ds^2 = (c_1(a^4 - b^4) + c_2(a^3 - b^3) + c_3(a^2 - b^2) + c_4(a - b))(da^2 - db^2).$$

Consider the Hamilton–Jacobi equation

$$H = p_z p_{\bar{z}} + \hat{c}_1 + \hat{c}_2 z + \hat{c}_3\left(\bar{z} - \frac{3}{8}iz^2\right) - \frac{i}{8}\hat{c}_4(z^3 + 8iz\bar{z}) = E,$$

where $z = x + iy$, $\bar{z} = x - iy$. In coordinates $z = 4i(u + w)$, $\bar{z} = 2i(u - w)^2$ this equation is equivalent to

$$p_u^2 - p_w^2 + 16(\hat{c}_1 - E)(u - w) + 64i\hat{c}_2(u^2 - w^2) + 128i\hat{c}_3(u^3 - w^3) - 256\hat{c}_4(u^4 - w^4) = 0$$

from which we see that this system is Stäckel equivalent to [**E10**] with some minor corrections.

In the last section we gave a simple derivation of all 2D superintegrable systems with nondegenerate potential. Such systems must admit at least three second order Killing tensors. Koenigs solved a different and more general problem. He found all spaces that admit at least three second order Killing tensors. It is a remarkable fact that the lists are the same. Thus from our point of view the Koenigs derivation is a proof of the following result.

Theorem 4: Every 2D Riemannian space with at least three linearly independent second order Killing tensors admits a superintegrable system with nondegenerate potential.

Corollary 1: Necessary and sufficient conditions for a superintegrable system with nondegenerate potential on a 2D Riemannian manifold are that there are local orthogonal coordinates x, y such that the system takes the form $H/U(x, y)$ where

$$H = \frac{p_x^2 + p_y^2}{\lambda(x,y)} + V(x,y)$$

is a superintegrable system on a constant curvature space with nondegenerate potential

$$V(x,y) = \alpha V^{(1)}(x,y) + \beta V^{(2)}(x,y) + \gamma V^{(3)}(x,y) + \delta$$

and

$$U(x,y) = \alpha_0 V^{(1)}(x,y) + \beta_0 V^{(2)}(x,y) + \gamma_0 V^{(3)}(x,y) + \delta_0.$$

Corollary 2: Necessary and sufficient conditions for a 2D Riemannian manifold to admit a three dimensional space of second order Killing tensors are that there are local orthogonal coordinates x,y such that the metric takes the form $ds^2 = \lambda(x,y)U(x,y)(dx^2 + dy^2)$ where $\lambda(x,y)(dx^2 + dy^2)$ is a metric on a constant curvature space with nondegenerate potential,

$$V(x,y) = \alpha V^{(1)}(x,y) + \beta V^{(2)}(x,y) + \gamma V^{(3)}(x,y) + \delta$$

and

$$U(x,y) = \alpha_0 V^{(1)}(x,y) + \beta_0 V^{(2)}(x,y) + \gamma_0 V^{(3)}(x,y) + \delta_0.$$

III. CONCLUSIONS AND FURTHER WORK

In this paper we have shown that every 2D nondegenerate superintegrable system is Stäckel equivalent (or equivalent via coupling constant metamorphosis) to a 2D nondegenerate superintegrable system on a constant curvature space. We found a simple derivation of all such spaces and potentials. We found that the list of spaces with nondegenerate potentials coincided with the Koenigs list of all 2D manifolds with three linearly independent second order Killing tensors. Thus any 2D space with three second order Killing tensors necessarily admits a nondegenerate potential.

In a forthcoming paper we will extend these results to 2D quantum systems, where the same spaces and potentials will occur. We will uncover the structure of the quantum quadratic algebra generated by the second order symmetry operators and show how to compute it in general.

Extension of our results to 3D systems is more challenging. Here the spaces we consider are conformally flat, since the Stäckel transform is conformal and the best known examples of superintegrable systems are in constant curvature spaces. Now for a superintegrable system we must have five functionally independent symmetries. Although several technical problems related to dimension must be overcome, we will be able to show that the structure theory for the quadratic algebras works in analogy to the 2D case. The extension to the quantum case is again more challenging, but the basic structure results for the quadratic algebra carry over for suitably modified potentials.

Exact solution for the hypergeometric Green's function describing spectral formation in x-ray pulsars

Peter A. Becker[a)]
Center for Earth Observing and Space Research, School of Computational Sciences, George Mason University, Fairfax, Virginia 22030-4444

(Received 11 December 2004; accepted 17 February 2005; published online 25 April 2005)

An eigenfunction expansion method involving hypergeometric functions is used to solve the partial differential equation governing the transport of radiation in an x-ray pulsar accretion column containing a radiative shock. The procedure yields the exact solution for the Green's function, which describes the scattering of monochromatic radiation injected into the column from a source located near the surface of the star. Collisions between the injected photons and the infalling electrons cause the radiation to gain energy as it diffuses through the gas and gradually escapes by passing through the walls of the column. The presence of the shock enhances the energization of the radiation and creates a power-law spectrum at high energies, which is typical for a Fermi process. The analytical solution for the Green's function provides important physical insight into the spectral formation process in x-ray pulsars, and it also has direct relevance for the interpretation of spectral data for these sources. Additional interesting mathematical aspects of the problem include the establishment of a closed-form expression for the quadratic normalization integrals of the orthogonal eigenfunctions, and the derivation of a new summation formula involving products of hypergeometric functions. By taking various limits of the general expressions, we also develop new linear and bilinear generating functions for the Jacobi polynomials. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1894965]

I. INTRODUCTION

In this paper, methods of classical analysis are employed to obtain the exact solution for the Green's function describing the spectrum of radiation emitted by an x-ray pulsar. Beyond the direct physical relevance of the Green's function, the method of solution also yields several additional results of mathematical interest, including a new summation formula involving products of two hypergeometric functions, as well as new linear and bilinear generating functions for the Jacobi polynomials. We also obtain an exact expression for the quadratic normalization integrals of the orthogonal hypergeometric eigenfunctions. Before proceeding with the main derivation, some physical background is called for. The radiation produced in bright x-ray pulsars is powered by the gravitational accretion (inflow) of ionized gas that is channeled onto the poles of a rotating neutron star by the strong magnetic field. In these sources, the radiation pressure greatly exceeds the gas pressure, and therefore the pressure of the photons governs the dynamical structure of the accretion flow. It follows that the gas must pass through a radiation-dominated shock on its way to the stellar surface, and the kinetic energy of the gas is carried away by the high-energy radiation that escapes from the column.[1] The strong gradient of the radiation pressure decelerates the material to rest at the surface of the star, and the compression of the infalling gas drives its temperatures up to a few million Kelvins. The gas therefore radiates x-rays, which appear to

[a)]Electronic mail: pbecker@gmu.edu

pulsate due to the star's spin. However, the observed x-ray spectrum is nonthermal, indicating that nonequilibrium processes are playing an important role in the formation of the radiation distribution.

The nonthermal shape of the spectrum is primarily due to the flow compression, which causes Fermi energization of the photons as they collide with infalling electrons in the column, until the radiation escapes from the column into space. Our primary goal in this paper is to obtain an exact solution for the Green's function describing the upscattering of soft, monoenergetic photons injected by a source located in the base of the accretion column, near the surface of the star. The Green's function contains a complete representation of the fundamental physics governing the propagation of the photons in the physical and energy spaces. Since the transport equation governing the radiation spectrum is linear, we can compute the solution associated with an arbitrary source distribution via convolution. Hence the Green's function provides the most direct means for exploring the relationship between the physics occurring in the accretion shock and the production of the observed nonthermal x radiation.

II. FUNDAMENTAL EQUATIONS

We assume that the accretion column is cylindrical, and we define x as the spatial coordinate measured along the column axis. The gas flows through the column onto the stellar surface with velocity v. We define the Green's function, $f_{\mathrm{G}}(x_0,x,\epsilon_0,\epsilon)$, as the radiation distribution at location x and energy ϵ resulting from the injection of $\dot{N}_0$ photons per second with energy ϵ_0 from a monochromatic source at location x_0 inside the column. In a steady-state situation, f_{G} satisfies the transport equation[2,3]

$$v\frac{\partial f_{\mathrm{G}}}{\partial x}=\frac{\mathrm{d}v}{\mathrm{d}x}\frac{\epsilon}{3}\frac{\partial f_{\mathrm{G}}}{\partial\epsilon}+\frac{\partial}{\partial x}\left(\frac{c}{3n_e\sigma_{\parallel}}\frac{\partial f_{\mathrm{G}}}{\partial x}\right)+\frac{\dot{N}_0\delta(\epsilon-\epsilon_0)\delta(x-x_0)}{\pi r_0^2\epsilon_0^2}-\frac{f_{\mathrm{G}}}{t_{\mathrm{esc}}}-\beta v_0\delta(x-x_0)f_{\mathrm{G}},\tag{1}$$

where n_e is the electron number density, $\sigma_{\parallel}$ is the electron scattering cross section for photons propagating parallel to the x axis, r_0 is the radius of the column, v_0 is the flow speed at the source location, c is the speed of light, and t_{esc} is the mean time photons spend in the column before escaping through the walls into space. The total radiation number and energy densities associated with the distribution function f_{G} are, respectively,

$$n_{\mathrm{G}}(x)\equiv\int_0^{\infty}\epsilon^2 f_{\mathrm{G}}\,\mathrm{d}\epsilon,\quad U_{\mathrm{G}}(x)\equiv\int_0^{\infty}\epsilon^3 f_{\mathrm{G}}\,\mathrm{d}\epsilon.\tag{2}$$

The terms in (1) represent, from left to right, the comoving (convective) time derivative, first-order Fermi energization ("bulk comptonization") of the radiation in the converging flow, spatial diffusion of the photons parallel to the column axis, the monochromatic photon source, escape of radiation from the column, and the possible absorption of radiation at the source location, respectively. In physical terms, the first-order Fermi energization corresponds to the $P\,\mathrm{d}V$ work done on the radiation by the compression of the background plasma as it accretes onto the stellar surface.[3] The dimensionless constant β expresses the strength of the absorption (if any) occurring at the source location, and the mean escape time is given by

$$t_{\mathrm{esc}}=\frac{r_0^2 n_e\sigma_{\perp}}{c},\tag{3}$$

where $\sigma_{\perp}$ is the electron scattering cross section for photons propagating perpendicular to the column axis. In general, $\sigma_{\parallel}\neq\sigma_{\perp}$ due to the influence of the strong magnetic field, which is directed parallel to the axis of the column. Absorption at the source location is expected if the photons are produced in a black-body "mound" of dense gas near the base of the accretion column,[1] because a perfect black body acts as both a source and a sink of radiation.[4]

The flux of electrons flowing down the column is denoted by $J \equiv n_e v$. In our cylindrical, steady-state problem, J maintains a constant value. Becker[5] demonstrated that in order for the inflowing matter to come to rest at the stellar surface as required, the parameters r_0, J, $\sigma_\parallel$, and $\sigma_\perp$ must satisfy the dynamical constraint

$$r_0^2 J^2 \sigma_\perp \sigma_\parallel = \tfrac{3}{4} c^2. \tag{4}$$

In general, radiation-dominated shocks are continuous velocity transitions, with an overall thickness of a few Thomson scattering lengths, unlike standard (discontinuous) gas-mediated shocks.[6] The exact solution for the inflow velocity v as a function of the spatial coordinate x is given by[5,7]

$$\frac{v(x)}{v_c} = \frac{7}{4}\left[1 - \left(\frac{7}{3}\right)^{-1+x/x_{\rm st}}\right], \tag{5}$$

where v_c is the flow velocity at the sonic point, which is related to the stellar mass M_*, the stellar radius R_*, and the gravitational constant G via[5]

$$v_c = \frac{4}{7}\left(\frac{2GM_*}{R_*}\right)^{1/2}. \tag{6}$$

The quantity $x_{\rm st}$ appearing in (5) is the distance between the sonic point and the stellar surface, which can be evaluated using Eq. (4.16) from Ref. 5 to obtain

$$x_{\rm st} = \frac{r_0}{2\sqrt{3}}\left(\frac{\sigma_\perp}{\sigma_\parallel}\right)^{1/2} \ln\left(\frac{7}{3}\right). \tag{7}$$

According to (5), the flow does come to rest at the surface of the star as required, since $v(x_{\rm st}) = 0$. Furthermore, the constancy of the electron flux J in our cylindrical, steady-state problem implies that the electron number density n_e is a function of x because v varies with the height inside the column [see Eq. (5)].

Further simplification is possible if we work in terms of the new spatial variable y, defined by

$$y(x) \equiv \left(\frac{7}{3}\right)^{-1+x/x_{\rm st}}. \tag{8}$$

Note that $y \to 0$ in the far upstream region ($x \to -\infty$), and $y \to 1$ at the surface of the star ($x \to x_{\rm st}$). Based on (5) and (8), we find that the variation of the velocity v as a function of the new variable y is given by the simple expression

$$\frac{v(y)}{v_c} = \frac{7}{4}(1-y). \tag{9}$$

By combining (3), (4), and (9) with the derivative relation

$$\frac{{\rm d}x}{{\rm d}y} = \frac{r_0}{2\sqrt{3}}\left(\frac{\sigma_\perp}{\sigma_\parallel}\right)^{1/2} y^{-1}, \tag{10}$$

we can transform the transport equation (1) for $f_{\rm G}$ from x to y to obtain

$$y(1-y)\frac{\partial^2 f_{\rm G}}{\partial y^2} + \left(\frac{1-5y}{4}\right)\frac{\partial f_{\rm G}}{\partial y} - \frac{\epsilon}{4}\frac{\partial f_{\rm G}}{\partial \epsilon} + \left(\frac{y-1}{4y}\right) f_{\rm G} = \frac{3\beta v_0 \delta(y-y_0) f_{\rm G}}{7 v_c} - \frac{3\dot{N}_0 \delta(\epsilon-\epsilon_0)\delta(y-y_0)}{7\pi r_0^2 \epsilon_0^2 v_c}, \tag{11}$$

where $y_0 \equiv y(x_0)$ denotes the value of y at the source location. According to (9), the flow velocity at the source, v_0, is related to v_c and y_0 by

$$\frac{v_0}{v_c} = \frac{7}{4}(1 - y_0). \tag{12}$$

Note that we can write the Green's function as either $f_G(x_0, x, \epsilon_0, \epsilon)$ or $f_G(y_0, y, \epsilon_0, \epsilon)$ since the parameters (x, x_0) and (y, y_0) are interchangeable via (8).

III. SOLUTION FOR THE GREEN'S FUNCTION

The physical model considered here includes Fermi energization, which tends to boost the energy of the injected photons as they collide with high-energy electrons streaming down through the accretion column towards the surface of the neutron star. Moreover, since no process that can lower the photon energy is included in the model, all of the photons injected from a source of monochromatic radiation with energy $\epsilon = \epsilon_0$ must at later times have energy $\epsilon > \epsilon_0$. It follows that $f_G = 0$ for $\epsilon < \epsilon_0$. When $\epsilon > \epsilon_0$, (11) is separable in energy and space using the functions

$$f_\lambda(\epsilon, y) = \epsilon^{-\lambda} g(\lambda, y), \tag{13}$$

where λ is the separation constant, and the spatial function g satisfies the differential equation

$$y(1 - y)\frac{d^2 g}{dy^2} + \left(\frac{1 - 5y}{4}\right)\frac{dg}{dy} + \left(\frac{\lambda y + y - 1}{4y}\right)g = \frac{3\beta v_0 \delta(y - y_0)}{7 v_c} g. \tag{14}$$

In order to avoid an infinite spatial diffusion flux at $y = y_0$, the function g must be continuous there, and consequently we obtain the condition

$$\Delta[g(\lambda, y)]\big|_{y=y_0} \equiv \lim_{\varepsilon \to 0} g(\lambda, y_0 + \varepsilon) - g(\lambda, y_0 - \varepsilon) = 0. \tag{15}$$

We can also derive a jump condition for the derivative dg/dy at the source location by integrating (14) with respect to y in a small region around $y = y_0$. The result obtained is

$$\Delta\left[\frac{dg}{dy}\right]\Bigg|_{y=y_0} = \frac{3\beta}{4y_0} g(\lambda, y_0), \tag{16}$$

where we have used (12) to substitute for v_0.

The homogeneous version of (14) obtained when $y \neq y_0$ has fundamental solutions given by

$$\varphi_1(\lambda, y) \equiv y F(a, b; c; y), \tag{17}$$

$$\varphi_1^*(\lambda, y) \equiv y^{-1/4} F(a - 5/4, b - 5/4; 2 - c; y), \tag{18}$$

where $F(a, b; c; z)$ denotes the hypergeometric function,[8] and the parameters a, b, and c are defined by

$$a \equiv \frac{9 - \sqrt{17 + 16\lambda}}{8}, \quad b \equiv \frac{9 + \sqrt{17 + 16\lambda}}{8}, \quad c \equiv \frac{9}{4}, \tag{19}$$

and therefore $a + b = c$.

A. Asymptotic analysis

The source photons injected into the flow are unable to diffuse very far upstream due to the high speed of the inflowing electrons. Most of the photons escape through the walls of the column within a few scattering lengths of the source, and therefore we conclude that the function g must *vanish* in the upstream limit, $y \to 0$. Asymptotic analysis indicates that the function $\varphi_1(\lambda, y) \to 0$ in the limit $y \to 0$ as required, but $\varphi_1^*(\lambda, y)$ diverges and therefore it cannot be utilized in the upstream region $(y \leqslant y_0)$. Hence g must be given by φ_1 for $y \leqslant y_0$. Conversely, in the downstream limit, the gas settles onto the surface of the star and therefore g should approach a constant as $y \to 1$. These

conditions are satisfied if λ is equal to one of the eigenvalues, λ_n, which are associated with the spatial eigenfunctions, $g_n(y)$, defined by

$$g_n(y) \equiv g(\lambda_n, y). \tag{20}$$

In order to obtain a complete understanding of the global behavior of the eigenfunctions, we must also consider the asymptotic behaviors of the two functions φ_1 and φ_1^* in the downstream region, which are discussed below.

The hypergeometric functions appearing in (17) and (18) can be evaluated at $y=1$ using Eq. (15.1.20) from Abramowitz and Stegun,[8] which gives for general values of a, b, and c,

$$F(a,b;c;1) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}. \tag{21}$$

However, for the values of a, b, and c in (17) and (18), we find that [see Eq. (19)]

$$c - a - b = 0, \tag{22}$$

and therefore the hypergeometric functions $F(a,b;c;y)$ and $F(a-5/4, b-5/4; 2-c; y)$ each *diverge* in the downstream limit $y \to 1$. Since the eigenfunction g_n should approach a constant as $y \to 1$ based on physical considerations, we conclude that in the downstream region ($y \geqslant y_0$), g_n must be represented by a suitable linear combination of φ_1 and φ_1^* that remains *finite* as $y \to 1$. In order to make further progress, we need to employ Eq. (15.3.10) from Abramowitz and Stegun,[8] which yields for general a, b, and y,

$$F(a,b;a+b;y) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(n!)^2} [2\Psi(n+1) - \Psi(a+n) - \Psi(b+n) - \ln(1-y)](1-y)^n, \tag{23}$$

where

$$\Psi(z) \equiv \frac{1}{\Gamma(z)} \frac{d\Gamma(z)}{dz}. \tag{24}$$

Asymptotic analysis of this expression reveals that in the limit $y \to 1$, the logarithmic divergences of the two functions φ_1 and φ_1^* can be balanced by creating the new function

$$\varphi_2(\lambda, y) \equiv \frac{\Gamma(b)}{\Gamma(c)\Gamma(1-b)} \varphi_1(\lambda, y) - \frac{\Gamma(1-a)}{\Gamma(2-c)\Gamma(a)} \varphi_1^*(\lambda, y), \tag{25}$$

which remains finite as $y \to 1$. Hence φ_2 represents the fundamental solution for g_n in the region downstream from the source. We can use the asymptotic behaviors of φ_1 and φ_1^* to show that

$$\lim_{y \to 1} \varphi_2(\lambda, y) = \frac{\pi[\cot(\pi a) + \cot(\pi b)]}{\Gamma(a)\Gamma(1-b)}. \tag{26}$$

Since the solutions φ_1 and φ_2 are applicable in the upstream and downstream regions, respectively, the global expression for the eigenfunction g_n is therefore given by

$$g_n(y) = \begin{cases} \varphi_1(\lambda_n, y), & y \leqslant y_0, \\ B_n \varphi_2(\lambda_n, y), & y \geqslant y_0, \end{cases} \tag{27}$$

where the constant B_n is evaluated using the continuity condition [Eq. (15)], which yields

$$B_n = \frac{\varphi_1(\lambda_n, y_0)}{\varphi_2(\lambda_n, y_0)}. \tag{28}$$

It follows from (26)–(28) that the downstream value of g_n is given by

$$\lim_{y\to 1} g_n(y) = \frac{\pi[\cot(\pi a) + \cot(\pi b)]}{\Gamma(a)\Gamma(1-b)} \frac{\varphi_1(\lambda_n, y_0)}{\varphi_2(\lambda_n, y_0)}. \tag{29}$$

Conversely, in the upstream region, $\varphi_1 \to y$, and therefore we have the asympototic behavior

$$\lim_{y\to 0} \frac{g_n(y)}{y} = 1. \tag{30}$$

B. Eigenvalue equation

We can combine (16), (27), and (28) to show that the eigenvalues λ_n satisfy the equation

$$W(\lambda_n, y_0) - \frac{3\beta\varphi_1(\lambda_n, y_0)\varphi_2(\lambda_n, y_0)}{4y_0} = 0, \tag{31}$$

where the Wronskian of the two functions φ_1 and φ_2 is defined for general values of λ and y by

$$W(\lambda, y) \equiv \varphi_1 \frac{d\varphi_2}{dy} - \varphi_2 \frac{d\varphi_1}{dy}. \tag{32}$$

Further progress can be made by deriving an analytical expression for the Wronskian. We begin by writing the differential equation (14) governing the two functions φ_1 and φ_2 in the self-adjoint form

$$\frac{d}{dy}\left[y^{1/4}(1-y)\frac{d\varphi}{dy} \right] + \frac{\lambda}{4y^{3/4}}\varphi - T\varphi = 0, \tag{33}$$

where

$$T \equiv \frac{1-y}{4y^{7/4}} + \frac{3\beta v_0 \delta(y-y_0)}{7v_c y^{3/4}}. \tag{34}$$

By applying (33) to the function φ_2 and multiplying the result by φ_1, and then subtracting from this the same expression with φ_1 and φ_2 interchanged, we obtain

$$\varphi_1 \frac{d}{dy}\left[y^{1/4}(1-y)\frac{d\varphi_2}{dy} \right] - \varphi_2 \frac{d}{dy}\left[y^{1/4}(1-y)\frac{d\varphi_1}{dy} \right] = 0, \tag{35}$$

which can be rewritten as

$$y^{1/4}(1-y)\frac{dW}{dy} + W\frac{d}{dy}[y^{1/4}(1-y)] = 0, \tag{36}$$

where we have made use of the result

$$\frac{dW}{dy} = \varphi_1 \frac{d^2\varphi_2}{dy^2} - \varphi_2 \frac{d^2\varphi_1}{dy^2}. \tag{37}$$

Equation (36) can be rearranged in the form

$$\frac{\mathrm{d}\ln W}{\mathrm{d}y} = -\frac{\mathrm{d}}{\mathrm{d}y}\ln[y^{1/4}(1-y)], \tag{38}$$

which can be integrated to obtain the exact solution

$$W(\lambda,y) = \frac{D(\lambda)}{y^{1/4}(1-y)}, \tag{39}$$

where $D(\lambda)$ is an integration constant that depends on λ but not on y. The exact dependence of D on λ can be derived by analyzing the behaviors of the functions φ_1 and φ_2 in the limit $y\to 0$. For small values of y, we have the asymptotic expressions[8]

$$\varphi_1 \to y, \quad y \to 0,$$

$$\varphi_2 \to -\frac{\Gamma(1-a)}{\Gamma(a)\Gamma(2-c)}y^{-1/4}, \quad y \to 0. \tag{40}$$

Combining (32) and (40), we find that asymptotically,

$$W \to \frac{5}{4}\frac{\Gamma(1-a)}{\Gamma(a)\Gamma(2-c)}y^{-1/4}, \quad y \to 0. \tag{41}$$

Comparing this result with (39), we conclude that

$$D(\lambda) = \frac{5}{4}\frac{\Gamma(1-a)}{\Gamma(a)\Gamma(2-c)}, \tag{42}$$

and therefore the exact solution for the Wronskian for general values of λ and y is given by

$$W(\lambda,y) = \frac{5}{4}\frac{\Gamma(1-a)}{\Gamma(a)\Gamma(2-c)}\frac{y^{-1/4}}{1-y}. \tag{43}$$

Substituting for W in (31) using (43), we can rewrite the eigenvalue equation in the equivalent form

$$\frac{5}{3}\frac{\Gamma(1-a)}{\Gamma(a)\Gamma(2-c)}\frac{y_0^{3/4}}{1-y_0} = \beta\varphi_1(\lambda_n,y_0)\varphi_2(\lambda_n,y_0), \tag{44}$$

where a and b are functions of λ_n by virtue of (19), and $c=9/4$. The roots of this expression are the eigenvalues λ_n, and the associated eigenfunctions are evaluated using (27). The first eigenvalue, λ_0, is especially important because it determines the power-law shape of the high-energy portion of the Green's function [see Eq. (13)].

In Fig. 1 we plot the first eigenvalue λ_0 as a function of the dimensionless parameters β and y_0. Note that λ_0 is a double-valued function of y_0 for fixed β, which is a consequence of the imposed velocity profile [Eq. (5)]. Physically, this behavior reflects the fact that it is always possible to achieve a desired amount of compression (first-order Fermi energization) by placing the source in a specific location in either the upstream or downstream regions of the flow. We also observe that if we increase the absorption parameter β while holding y_0 fixed, then λ_0 increases monotonically, and therefore the high-energy spectrum becomes progressively steeper. This behavior is expected physically because as the absorption parameter is increased, the injected photons spend less time on average being energized by collisions with electrons before either escaping from the column or being absorbed at the source location. The decreased amount of energization naturally leads to a steepening of the radiation spectrum. When $\beta=0$, no absorption occurs, and the index λ_0 achieves its minimum (limiting) value of 4. This limit is, however, unphysical since

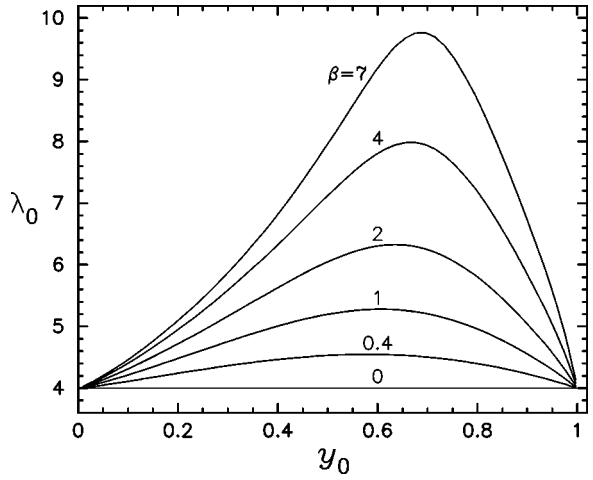

FIG. 1. First eigenvalue λ_0 of the Green's function expansion plotted as a function of the source location y_0 for the indicated values of the absorption parameter β. Note the steepening of the radiation spectrum that occurs when β is increased for a fixed value of y_0, which reflects the decreasing residence time for the photons in the plasma (see the discussion in the text).

it yields a divergent result for the total photon energy density U_G according to (2). Nonetheless, the case with $\beta=0$ is interesting from a mathematical viewpoint, and for that reason it is further discussed in Sec. V.

C. Orthogonality of the eigenfunctions

We shall next demonstrate that the eigenfunctions $g_n(y)$ form an orthogonal set, which is an extremely useful property. This is a standard Sturm–Liouville problem and therefore we follow the usual procedure. Let us suppose that $g_n(y)$ and $g_m(y)$ are two eigenfunctions corresponding to the distinct eigenvalues λ_n and λ_m, respectively. The functions g_n and g_m each satisfy the differential equation (14), and therefore we can utilize the self-adoint form to write [cf. Eq. (33)]

$$g_m\left\{\frac{\mathrm{d}}{\mathrm{d}y}\left[y^{1/4}(1-y)\frac{\mathrm{d}g_n}{\mathrm{d}y}\right]+\frac{\lambda_n}{4y^{3/4}}g_n-Tg_n\right\}=0 \tag{45}$$

and

$$g_n\left\{\frac{\mathrm{d}}{\mathrm{d}y}\left[y^{1/4}(1-y)\frac{\mathrm{d}g_m}{\mathrm{d}y}\right]+\frac{\lambda_m}{4y^{3/4}}g_m-Tg_m\right\}=0, \tag{46}$$

where T is given by (34). Subtracting the second equation from the first yields, after integrating by parts with respect to y from $y=0$ to $y=1$,

$$(\lambda_n-\lambda_m)\int_0^1 y^{-3/4}g_n(y)g_m(y)\mathrm{d}y=4y^{1/4}(1-y)\left[g_n\frac{\mathrm{d}g_m}{\mathrm{d}y}-g_m\frac{\mathrm{d}g_n}{\mathrm{d}y}\right]\Bigg|_0^1. \tag{47}$$

Based on the asymptotic behaviors of the eigenfunctions g_n and g_m given by (29) and (30), we find that the right-hand side of (47) vanishes exactly, and therefore we obtain

$$(\lambda_n-\lambda_m)\int_0^1 y^{-3/4}g_n(y)g_m(y)\mathrm{d}y=0, \tag{48}$$

which establishes the orthogonality of the eigenfunctions. The set of eigenfunctions is also complete according to the Sturm–Liouville theorem. Since the eigenfunctions are orthogonal, the Green's function can be expressed as the infinite series

$$f_G(y_0,y,\epsilon_0,\epsilon)=\sum_{n=0}^{\infty}A_n\left(\frac{\epsilon}{\epsilon_0}\right)^{-\lambda_n}g_n(y), \tag{49}$$

for $\epsilon \geqslant \epsilon_0$, where the expansion coefficients A_n are computed by employing the orthogonality of the eigenfunctions along with the condition

$$f_G(y_0,y,\epsilon_0,\epsilon)|_{\epsilon=\epsilon_0}=\frac{12\dot{N}_0}{7\pi r_0^2\epsilon_0^3 v_c}\delta(y-y_0), \tag{50}$$

which is obtained by integrating the transport equation (11) with respect to ϵ in a small range surrounding the injection energy ϵ_0. The result obtained for the nth expansion coefficient is

$$A_n=\frac{12\dot{N}_0 y_0^{-3/4}g_n(y_0)}{7\pi r_0^2\epsilon_0^3 v_c \mathfrak{C}_n}, \tag{51}$$

where the quadratic normalization integrals, $\mathfrak{C}_n$, are defined by

$$\mathfrak{C}_n \equiv \int_0^1 y^{-3/4}g_n^2(y)\mathrm{d}y. \tag{52}$$

As an alternative to numerical integration, in Sec. III D we derive a closed-form expression for evaluating the normalization integrals based directly on the associated differential equation.

D. Quadratic normalization integrals

The direct computation of the normalization integrals $\mathfrak{C}_n$ via numerical integration is costly and time consuming, and therefore it is desirable to have an alternative procedure available for their evaluation. In fact, it is possible to derive an analytical expression for the normalization integrals based on manipulation of the fundamental differential equation (14) governing the eigenfunctions $g_n(y)$.

Let us suppose that $g(\lambda,y)$ is a general solution to (14) for an arbitrary value of λ (i.e., not necessarily an eigenvalue) with the asymptotic (upstream) behavior

$$g(\lambda,y)\to y, \quad y\to 0, \tag{53}$$

which is the same as the upstream behavior of the eigenfunction $g_n(y)$ [see Eq. (30)]. We also stipulate that g must be continuous at $y=y_0$, and that it satisfies the derivative jump condition given by (16). After a bit of algebra, we find that the global solution for g consistent with these requirements can be expressed as

$$g(\lambda,y)=\begin{cases}\varphi_1(\lambda,y), & y\leqslant y_0,\\ (1+\hat{a})\varphi_1(\lambda,y)+\hat{b}\varphi_2(\lambda,y), & y\geqslant y_0,\end{cases} \tag{54}$$

where the coefficients $\hat{a}$ and $\hat{b}$ are are given by

$$\hat{a}=-\frac{3\beta\varphi_1(\lambda,y_0)\varphi_2(\lambda,y_0)}{4y_0W(\lambda,y_0)}, \quad \hat{b}=\frac{3\beta\varphi_1^2(\lambda,y_0)}{4y_0W(\lambda,y_0)}, \tag{55}$$

and the Wronskian W is evaluated using (43).

Comparing the general solution for $g(\lambda,y)$ with the solution for the eigenfunction $g_n(y)$ given by (27), we note that

$$\lim_{\lambda\to\lambda_n}\hat{a}=-1, \quad \lim_{\lambda\to\lambda_n}\hat{b}=B_n. \tag{56}$$

We can now use the self-adoint form of (14) to write [cf. Eqs. (45) and (46)]

$$g_n\left\{\frac{\partial}{\partial y}\left[y^{1/4}(1-y)\frac{\partial g}{\partial y}\right]+\frac{\lambda}{4y^{3/4}}g-Tg\right\}=0 \tag{57}$$

and

$$g\left\{\frac{\mathrm{d}}{\mathrm{d}y}\left[y^{1/4}(1-y)\frac{\mathrm{d}g_n}{\mathrm{d}y}\right]+\frac{\lambda_n}{4y^{3/4}}g_n-Tg_n\right\}=0, \tag{58}$$

where T is defined by (34). Subtracting the second equation from the first and integrating by parts from $y=0$ to $y=1$ yields

$$(\lambda-\lambda_n)\int_0^1 y^{-3/4}g(\lambda,y)g_n(y)\mathrm{d}y=4y^{1/4}(1-y)\left[g(\lambda,y)\frac{\mathrm{d}g_n}{\mathrm{d}y}-g_n(y)\frac{\partial g}{\partial y}\right]\Bigg|_0^1. \tag{59}$$

Since $g\to y$ and $g_n\to y$ as $y\to 0$, we conclude that the evaluation at the lower bound $y=0$ on the right-hand side yields zero, and consequently in the limit $\lambda\to\lambda_n$ we obtain for the quadratic normalization integral $\mathfrak{C}_n$ [see Eq. (52)],

$$\mathfrak{C}_n=\int_0^1 y^{-3/4}g_n^2(y)\mathrm{d}y=\lim_{\lambda\to\lambda_n}\frac{4y^{1/4}(1-y)[g(\lambda,y)(\mathrm{d}g_n/\mathrm{d}y)-g_n(y)(\partial g/\partial y)]}{\lambda-\lambda_n}\Bigg|_{y=1}. \tag{60}$$

The numerator and denominator on the right-hand side of (60) each vanish in the limit $\lambda\to\lambda_n$, and therefore we can employ L'Hôpital's rule to show that (e.g., Becker[9])

$$\mathfrak{C}_n=\lim_{\lambda\to\lambda_n}4y^{1/4}(1-y)\left[\frac{\partial g}{\partial y}\frac{\mathrm{d}g_n}{\mathrm{d}y}-g_n\frac{\partial^2 g}{\partial y\partial\lambda}\right]\Bigg|_{y=1}. \tag{61}$$

Substituting the analytical forms for $g_n(y)$ and $g(\lambda,y)$ given by (27) and (54), respectively, we find that (61) can be rewritten as

$$\mathfrak{C}_n=\lim_{y\to 1}4y^{1/4}(1-y)B_n\left[W(\lambda,y)\frac{\mathrm{d}\hat{a}}{\mathrm{d}\lambda}+B_n\frac{\partial\varphi_2}{\partial\lambda}\frac{\partial\varphi_2}{\partial y}-B_n\varphi_2(\lambda,y)\frac{\partial^2\varphi_2}{\partial y\partial\lambda}\right]\Bigg|_{\lambda=\lambda_n}, \tag{62}$$

where we have also utilized (32) and (56). Based on the asymptotic behavior of φ_2 [see (26)], we conclude that the final two terms on the right-hand side of (62) contribute nothing in the limit $y\to 1$, and therefore our expression for $\mathfrak{C}_n$ reduces to

$$\mathfrak{C}_n=\lim_{y\to 1}4y^{1/4}(1-y)B_nW(\lambda,y)\left.\frac{\mathrm{d}\hat{a}}{\mathrm{d}\lambda}\right|_{\lambda=\lambda_n}. \tag{63}$$

Since $y=1$ is a singular point of the differential equation (14), it is convenient to employ the relation [see Eq. (39)]

$$W(\lambda,y)y^{1/4}(1-y)=W(\lambda,y_0)y_0^{1/4}(1-y_0), \tag{64}$$

which allows us to transform the evaluation in (63) from $y=1$ to $y=y_0$ to obtain the equivalent result

$$\mathfrak{C}_n=4y_0^{1/4}(1-y_0)\hat{a}W(\lambda,y_0)\frac{\varphi_1(\lambda_n,y_0)}{\varphi_2(\lambda_n,y_0)}\left.\frac{\mathrm{d}\ln\hat{a}}{\mathrm{d}\lambda}\right|_{\lambda=\lambda_n}, \tag{65}$$

where we have also substituted for B_n using (28). The derivative on the right-hand side can be evaluated using (55), which yields

$$\frac{\mathrm{d}\ln \hat{a}}{\mathrm{d}\lambda} = \frac{\partial \ln \varphi_1}{\partial \lambda} + \frac{\partial \ln \varphi_2}{\partial \lambda} - \frac{\partial \ln W}{\partial \lambda}, \tag{66}$$

where the derivative of the Wronskian is given by [see Eqs. (19) and (43)]

$$\frac{\partial \ln W}{\partial \lambda} = \frac{\Psi(a) + \Psi(1-a)}{(17+16\lambda)^{1/2}} \tag{67}$$

and

$$\Psi(z) \equiv \frac{1}{\Gamma(z)} \frac{\mathrm{d}\Gamma(z)}{\mathrm{d}z}. \tag{68}$$

Combining (55) and (65)–(67), we find that the quadratic normalization integrals can be evaluated using the closed-form expression

$$\mathfrak{C}_n = K(\lambda_n, y_0), \tag{69}$$

where

$$K(\lambda,y) \equiv 3\beta y^{-3/4}(1-y)\varphi_1^2(\lambda,y)\left[\frac{\Psi(a)+\Psi(1-a)}{(17+16\lambda)^{1/2}} - \frac{\partial \ln \varphi_1}{\partial \lambda} - \frac{\partial \ln \varphi_2}{\partial \lambda}\right]. \tag{70}$$

This formula provides an extremely efficient alternative to numerical integration for the computation of $\mathfrak{C}_n$.

E. Numerical examples

In this section we illustrate the computational method by examining the dependence of the Green's function $f_{\mathrm{G}}(y_0, y, \epsilon_0, \epsilon)$ on the spatial location y and the energy ϵ. We remind the reader that the solution for the Green's function represents the photon spectrum inside the accretion column at the specified position and energy, resulting from the injection of monochromatic photons with energy ϵ_0 from a source located at y_0. Hence analysis of f_{G} allows us to explore the competing effects of Fermi energization and diffusion as photons travel through the column. The Green's function can be computed by combining (49), (51), and (69) once the eigenvalues λ_n have been determined using (44). The eigenfunction expansion for f_{G} converges fairly rapidly, and in general one obtains at least five decimal digits of accuracy if the series in (49) is terminated after the first 20 terms.

The Green's function $f_{\mathrm{G}}(y_0, y, \epsilon_0, \epsilon)$ is plotted as a function of the energy ratio ϵ/ϵ_0 and the location y in Fig. 2 for the parameter values $\beta = 0.4$ and $y_0 = 0.9$. In this case the first eigenvalue is given by $\lambda_0 = 4.231$ (see Fig. 1), which is equal to the high-energy slope of the Green's function in the log–log plots in Fig. 2. The selected value of y_0 corresponds to a source located near the bottom of the accretion column, just above the stellar surface. At the source location, $y = y_0 = 0.9$, the energy spectrum extends down to the injection energy, ϵ_0. However, at all other radii the spectrum displays a steep turnover above that energy because all of the photons have experienced Fermi energization due to collisions with the infalling electrons. The photons with energy $\epsilon = \epsilon_0$ at the source location have been injected so recently that they have not yet experienced significant energization. Note that in the far upstream region (i.e., for small values of y), the spectrum is greatly attenuated due to the inability of the photons to diffuse upstream through the rapidly infalling plasma. In this example, the average photon energy achieves its maximum value in the upstream region because these are the photons that have resided in the flow the longest and therefore experienced the most energy amplification. However, due to the attenuation mentioned above, there are not many of these photons.

In Fig. 3 we plot the Green's function f_{G} for the case with $\beta = 4$ and $y_0 = 0.4$, which yields for the first eigenvalue $\lambda_0 = 6.325$. The source is now located in the upstream region and the absorption is stronger, and consequently the behavior is somewhat different from that displayed in Fig. 2. In

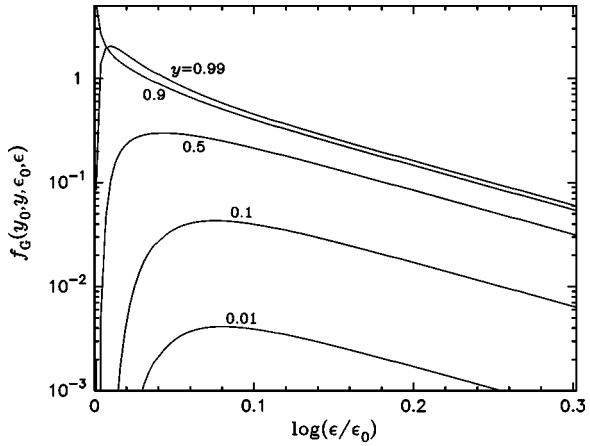

FIG. 2. Green's function $f_G(y_0,y,\epsilon_0,\epsilon)$ [Eq. (49)] plotted in units of $\dot{N}_0/(r_0^2\epsilon_0^3 v_c)$ as a function of the photon energy ratio ϵ/ϵ_0 for the indicated values of the spatial variable y. In this example we have set the absorption constant $\beta=0.4$ and the source location parameter $y_0=0.9$, so that the source is located near the base of the accretion column.

particular, the photons experience less overall compression in the flow and therefore the spectrum is steeper at high energies, as evidenced by the increase in the primary eigenvalue λ_0. This is mainly due to the larger value of β, which causes the photons to spend less time on average in the flow being energized by collisions with the electrons before they escape from the column or are "recycled" by absorption. We also note that in this case the average radiation energy displays its maximum value in the downstream region. This is the reverse of the behavior displayed in Fig. 2 because in the present situation, the source is located in the upstream region and therefore the photons that diffuse further upstream do not experience as much energization as those considered in Fig. 2. The radiation distribution in the far upstream region is greatly attenuated due to diffusion against the current of infalling electrons, as in Fig. 2. The analytical results for the Green's function obtained here provide the basis for the consideration of any source distribution since the fundamental differential equation (1) is linear. This is further discussed in Sec. IV.

IV. HYPERGEOMETRIC SUMMATION FORMULA

We can derive two interesting summation formulas for the hypergeometric eigenfunctions by using the transport equation (11) to study the behavior of the "energy moments," I_ℓ, defined by

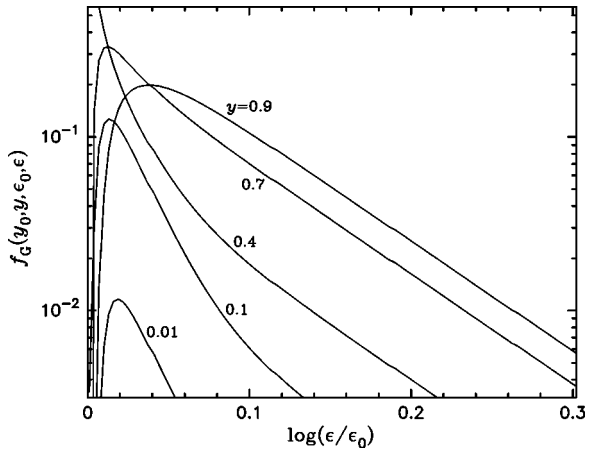

FIG. 3. Same as Fig. 2, except $\beta=4.0$ and $y_0=0.4$. In this case the source is located in the upstream region, and the average photon energy achieves its maximum value in the downstream region.

$$I_\ell(y) \equiv \int_{\epsilon_0}^{\infty} \epsilon^\ell f_G \mathrm{d}\epsilon. \tag{71}$$

The lower bound of ϵ_0 is chosen because $f_G=0$ for $\epsilon<\epsilon_0$ as explained in the discussion preceding (13). Note that according to (2), the number and energy densities are given by $n_G=I_2$ and $U_G=I_3$, respectively. The differential equation satisfied by I_ℓ is obtained by operating on (11) with $\int \epsilon^\ell \, d\epsilon$, which yields

$$y(1-y)\frac{\mathrm{d}^2 I_\ell}{\mathrm{d}y^2} + \left(\frac{1-5y}{4}\right)\frac{\mathrm{d}I_\ell}{\mathrm{d}y} + \left(\frac{\ell y + 2y - 1}{4y}\right) I_\ell = \frac{3\beta v_0 \delta(y-y_0) I_\ell}{7 v_c} - \frac{3\dot{N}_0 \epsilon_0^{\ell-2}\delta(y-y_0)}{7\pi r_0^2 v_c}. \tag{72}$$

The energy moment I_ℓ must be continuous at $y=y_0$ in order to avoid generating an infinite spatial diffusion flux there, and consequently we have

$$\Delta\,[I_\ell(y)]|_{y=y_0} = 0. \tag{73}$$

By integrating (72) in a small region around $y=y_0$, we can show that I_ℓ also satisfies the derivative jump condition

$$\Delta \left[\frac{\mathrm{d}I_\ell}{\mathrm{d}y}\right]\Bigg|_{y=y_0} = \frac{3\beta I_\ell(y_0)}{4y_0} - \frac{3\dot{N}_0 \epsilon_0^{\ell-2}}{7\pi r_0^2 v_c y_0 (1-y_0)}, \tag{74}$$

where we have also utilized (12).

The homogeneous version of (72) obtained when $y \neq y_0$ is equivalent to (14) for g if we replace λ with $\ell+1$. Since the energy moments I_ℓ must satisfy the same upstream and downstream boundary conditions that apply to the separation eigenfunctions g_n, we can therefore write the general solution for I_ℓ as

$$I_\ell(y) = \begin{cases} C_\ell \varphi_1(\ell+1, y), & y \leqslant y_0, \\ D_\ell \varphi_2(\ell+1, y), & y \geqslant y_0, \end{cases} \tag{75}$$

where the constants C_ℓ and D_ℓ are computed by satisfying the continuity and derivative jump conditions given by (73) and (74). Upon substitution, we obtain after some algebra

$$C_\ell = \frac{12\dot{N}_0 \epsilon_0^{\ell-2}}{7\pi v_c r_0^2} \frac{(1-y_0)^{-1}\varphi_2(\ell+1, y_0)}{3\beta\varphi_1(\ell+1, y_0)\varphi_2(\ell+1, y_0) - 4y_0 W(\ell+1, y_0)}, \tag{76}$$

$$D_\ell = \frac{12\dot{N}_0 \epsilon_0^{\ell-2}}{7\pi v_c r_0^2} \frac{(1-y_0)^{-1}\varphi_1(\ell+1, y_0)}{3\beta\varphi_1(\ell+1, y_0)\varphi_2(\ell+1, y_0) - 4y_0 W(\ell+1, y_0)}, \tag{77}$$

where $W(\ell+1, y_0)$ is computed using [cf. Eq. (43)]

$$W(\ell+1, y_0) = \frac{5}{4}\frac{\Gamma(1-a_\ell)}{\Gamma(a_\ell)\Gamma(-1/4)}\frac{y_0^{-1/4}}{1-y_0} \tag{78}$$

and

$$a_\ell \equiv \frac{9 - \sqrt{33+16\ell}}{8}. \tag{79}$$

The energy moments $I_\ell(y)$ can also be calculated by substituting for the Green's function in the fundamental integral (71) using (49). Reversing the order or summation and integration yields

$$I_\ell(y) = \epsilon_0^{\ell+1} \sum_{n=0}^{\infty} A_n (\lambda_n - \ell - 1)^{-1} g_n(y), \tag{80}$$

where $g_n(y)$ and A_n are given by (27) and (51), respectively. Note that the expression for $g_n(y)$ can be rewritten as

$$g_n(y) = \frac{\varphi_1(\lambda_n, y_{\min}) \varphi_2(\lambda_n, y_{\max})}{\varphi_2(\lambda_n, y_0)}, \tag{81}$$

where

$$y_{\min} \equiv \min(y, y_0), \quad y_{\max} \equiv \max(y, y_0). \tag{82}$$

Eliminating $I_\ell(y)$ between (75) and (80) and making use of (51), (76), (77), and (81), we find after some simplification that

$$\sum_{n=0}^{\infty} \frac{\varphi_1(\lambda_n, y_0)}{\varphi_2(\lambda_n, y_0)} \frac{\varphi_1(\lambda_n, y_{\min}) \varphi_2(\lambda_n, y_{\max})}{(\lambda_n - \ell - 1) \mathfrak{C}_n} = \frac{y_0^{3/4} (1 - y_0)^{-1} \varphi_1(\ell + 1, y_{\min}) \varphi_2(\ell + 1, y_{\max})}{3\beta \varphi_1(\ell + 1, y_0) \varphi_2(\ell + 1, y_0) - 4 y_0 W(\ell + 1, y_0)}, \tag{83}$$

where the eigenvalues λ_n are computed using (44). Equation (83) is a new hypergeometric summation formula that has not appeared previously in the literature. This relation holds for all real values of ℓ.

V. LINEAR AND BILINEAR GENERATING FUNCTIONS

The case with $\beta = 0$ is interesting from a mathematical point of view because in this limit, the hypergeometric eigenfunctions reduce to Jacobi polynomials. We can therefore combine various results from Secs. III and IV to obtain two new summation formulas (i.e., linear and bilinear generating functions) for the Jacobi polynomials that have not appeared previously in the literature. In the limit $\beta \to 0$, the eigenvalue equation (31) reduces to

$$W(\lambda_n, y_0) = \frac{5}{4} \frac{\Gamma(1 - a)}{\Gamma(a) \Gamma(-1/4)} \frac{y_0^{-1/4}}{1 - y_0} = 0, \tag{84}$$

where we have also made use of (43). Roots of this expression occur where $|\Gamma(a)| \to \infty$, which corresponds to

$$a = -n, \quad n = 0, 1, 2, \ldots . \tag{85}$$

In this situation, we can use (19) to demonstrate that the exact solution for the eigenvalues λ_n is given by

$$\lambda_n = 4n^2 + 9n + 4. \tag{86}$$

Next we note that $a + b = 9/4$ in general according to (19), and therefore we find that

$$b = \tfrac{9}{4} + n. \tag{87}$$

The corresponding expression for the fundamental upstream eigensolution, $\varphi_1(\lambda_n, y)$, is given in this case by the polynomial [see Eq. (17)]

$$\varphi_1(\lambda_n, y) = y F\left(-n, \tfrac{9}{4} + n; \tfrac{9}{4}; y\right), \tag{88}$$

and the fundamental eigensolution in the downstream region, $\varphi_2(\lambda_n, y)$, likewise reduces to [see Eq. (25)]

$$\varphi_2(\lambda_n,y) = \frac{\Gamma(n+9/4)}{\Gamma(9/4)\Gamma(-n-5/4)}\varphi_1(\lambda_n,y). \tag{89}$$

Hence the two eigensolutions $\varphi_1(\lambda_n,y)$ and $\varphi_2(\lambda_n,y)$ are *linearly dependent functions* in this case, which is expected since the Wronskian $W(\lambda_n,y_0)=0$ according to (84). This in turn reflects the fact that there is no derivative jump in the global separation eigenfunction $g_n(y)$ at $y=y_0$ when $\beta=0$ [see Eq. (16)].

Due to the linear dependence of $\varphi_1(\lambda_n,y)$ and $\varphi_2(\lambda_n,y)$, Eq. (81) for the global eigenfunction $g_n(y)$ now simplifies to

$$g_n(y) = \varphi_1(\lambda_n,y), \tag{90}$$

and therefore the summation formula presented in (83) can be rewritten in the $\beta=0$ case as

$$\sum_{n=0}^{\infty} \frac{\varphi_1(\lambda_n,y_0)\varphi_1(\lambda_n,y)}{(\lambda_n-\ell-1)\mathfrak{C}_n} = -\frac{\varphi_1(\ell+1,y_{\min})\varphi_2(\ell+1,y_{\max})}{4y_0^{1/4}(1-y_0)W(\ell+1,y_0)}, \tag{91}$$

where $y_{\min}$ and $y_{\max}$ are defined by (82) and $W(\ell+1,y_0)$ is computed using (78).

We are now in a position to derive an interesting summation formula for products of Jacobi polynomials. Using Eq. (15.4.6) from Abramowitz and Stegun,[8] our expression for the eigensolution $\varphi_1(\lambda_n,y)$ can be rewritten as

$$\varphi_1(\lambda_n,y) = \frac{n!}{(9/4)_n} y P_n^{(5/4,0)}(1-2y), \tag{92}$$

where

$$P_n^{(5/4,0)}(1-2y) = \frac{(9/4)_n}{n!} F\left(-n,\frac{9}{4}+n;\frac{9}{4};y\right) \tag{93}$$

represents the Jacobi polynomial, and $(a)_n$ denotes the Pochhammer symbol, defined by[8]

$$(a)_n \equiv \frac{\Gamma(a+n)}{\Gamma(a)}. \tag{94}$$

In the present application, with $\beta=0$, we can combine (52), (90), and (92) to express the quadratic normalization integrals, $\mathfrak{C}_n$, as

$$\mathfrak{C}_n = \left[\frac{n!}{(9/4)_n}\right]^2 \int_0^1 y^{5/4}[P_n^{(5/4,0)}(1-2y)]^2\,dy, \tag{95}$$

which can be evaluated using Eq. (7.391.1) from Gradshteyn and Ryzhik[10] to obtain

$$\mathfrak{C}_n = \left[\frac{n!}{(9/4)_n}\right]^2 \left(2n+\frac{9}{4}\right)^{-1}. \tag{96}$$

Equations (78), (86), (91), (92), and (96) can be combined to derive a new *bilinear generating function* for the Jacobi polynomials, which can be written as

$$\sum_{n=0}^{\infty} (9+8n)\frac{P_n^{(5/4,0)}(1-2y_0)P_n^{(5/4,0)}(1-2y)}{4n^2+9n+3-\ell} = \frac{16}{5}\frac{\Gamma(3/4)\Gamma(a_\ell)}{\Gamma(1-a_\ell)}\frac{\varphi_1(\ell+1,y_{\min})\varphi_2(\ell+1,y_{\max})}{yy_0}, \tag{97}$$

where a_ℓ is defined by (79). Note that the functions $\varphi_1(\ell+1,y_{\min})$ and $\varphi_2(\ell+1,y_{\max})$ appearing on the right-hand side of (97) are *not* eigenfunctions since in general the quantity $\ell+1$ is not equal to one of the eigenvalues λ_n.

An interesting special case occurs in the limit $y_0 \to 0$. Making use of the relation [see Eq. (93)]

$$P_n^{(5/4,0)}(1) = \frac{(9/4)_n}{n!}, \tag{98}$$

and the identity

$$\Gamma\left(\tfrac{3}{4}\right)\Gamma\left(\tfrac{9}{4}\right) = \tfrac{5}{16}\pi 2^{1/2}, \tag{99}$$

we now find that (97) reduces to the *linear generating function*

$$\sum_{n=0}^{\infty} \frac{(9+8n)\Gamma(n+9/4)}{(4n^2+9n+3-\ell)n!} P_n^{(5/4,0)}(1-2y) = \frac{\pi 2^{1/2}\Gamma(a_\ell)}{\Gamma(1-a_\ell)} \frac{\varphi_2(\ell+1,y)}{y}, \tag{100}$$

which is valid for all real values of ℓ. Equations (97) and (100) are new results that are useful for the evaluation of infinite sums containing either products of Jacobi polynomials or single Jacobi polynomials, respectively.

VI. CONCLUSION

In this paper we have employed methods of classical analysis to obtain the exact solution for the Green's function describing the Fermi energization of photons scattered by infalling electrons in a pulsar accretion column. This process is of central importance in the development of theoretical models for the production of the x-ray spectra observed from these objects, which are among the brightest sources in the Milky Way galaxy. As demonstrated in Fig. 1 and Eq. (49), the Green's function is characterized by a power-law shape at high photon energies, which is typical for a Fermi process. In this scenario, photons gain their energy by diffusing back and forth across the shock many times. The probability of multiple shock crossings decreases exponentially with the number of crossings, and the mean energy of the photons increases exponentially with the number of crossings. This combination of factors naturally gives rise to a power-law energy distribution.[11] Hence shock energization in the pulsar accretion column provides a simple explanation for the spectrum of the high-energy radiation produced by x-ray pulsars. Specific examples of the Green's function are plotted in Figs. 2 and 3.

Due to the linearity of the transport equation (1), we can employ the Green's function to calculate the radiation spectrum inside the accretion column resulting from an arbitrary source spectrum using the convolution[12]

$$f(y_0,y,\epsilon) = \int_0^{\infty} j(\epsilon_0) \frac{f_G(y_0,y,\epsilon_0,\epsilon)}{\dot{N}_0} \mathrm{d}\epsilon_0, \tag{101}$$

where $j(\epsilon_0)\mathrm{d}\epsilon_0$ represents the number of photons injected per unit time into the accretion column at location y_0 with energy between ϵ_0 and $\epsilon_0+\mathrm{d}\epsilon_0$. The source distribution of greatest astrophysical interest is the "thermal mound" source located near the base of the accretion column, where the gas has decelerated almost to rest and is therefore extremely dense. This hot plasma is in full thermodynamic equilibrium, and consequently it radiates a black-body spectrum.[1] The absorption parameter β has been included in the transport equation (1) in order to account for the fact that a black body acts as both a source and a sink of radiation.[4] The fundamental results for the Green's function obtained in the present paper will be used to study the reprocessing of the black-body radiation emitted from the thermal mound in a subsequent paper.

In addition to the analytical results for the Green's function, we have also obtained an interesting formula for the evaluation of an infinite series involving products of the orthogonal hypergeometric eigenfunctions [see Eq. (83)]. This derivation was based on the simultaneous calculation of the energy moments $I_\ell(y)$ using both an expression based on term-by-term integration of the Green's function expansion (49), and an independent solution developed via direct integration of the fundamental transport equation (1). In the special case $\beta \to 0$, which corresponds physically

to the neglect of absorption at the source location, our general formula for the hypergeometric summation reduces to a bilinear generating function for the Jacobi polynomials given by (97). This relation in turn simplifies to yield a linear generating function for the Jacobi polynomials in the limit $y_0 \to 0$, which corresponds physically to a source located in the far upstream region [see Eq. (100)].

The results derived in this paper for the linear and bilinear generating functions of Jacobi polynomials are related to various similar expressions obtained previously by Chen and Srivastava,[13,14] Srivastava,[15] Rangarajan,[16] and Pittaluga, Sacripante, and Srivastava.[17] However, our results are not identical to any of their formulas and therefore they represent an interesting new family of relations. Although the linear and bilinear generating functions developed here relate specifically to the properties of the polynomials $P_n^{(5/4,0)}(1-2y)$, we expect that some level of generalization may be possible. We plan to pursue this question in future work.

(Received 1 September 2003; accepted 29 January 2005; published online 26 April 2005)

We describe the behavior of the generalized theta function with respect to the Hecke transformations. Let E be a holomorphic vector bundle over rank r and degree $r(g-1)$ over a compact Riemann surface X of genus g. Let $P(E)$ [respectively, $\mathbb{P}(E)$] be the space of all lines (respectively, hyperplanes) in the fibers of E. Certain Zariski open subsets of $\mathbb{P}(E)\times\times P(E)$ and $\mathbb{P}(E)\times\mathbb{P}(E)\times P(E)\times P(E)$ parametrize holomorphic families of vector bundles over X of rank r and degree $r(g-1)$. We describe the generalized theta line bundle for these families. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1879082]

I. INTRODUCTION

In a well known paper, Hawley and Schiffer [5]generalized the notion of a Szegö kernel from a domain in the complex plane (with smooth boundary) to a compact connected Riemann surface X of arbitrary genus g. More recently, it was observed by physicists that the Szegö kernel could be identified as the "two-point function" of a model two-dimensional quantum field theory appearing in conformal field theory and string theory (see Ref. 10 for references). It was shown by Raina[10,11] that the physics could be in a natural way reformulated in the language of algebraic geometry. Given a line bundle α on X of degree $g-1$ lying outside the theta divisor, i.e., a holomorphic line bundle α with $H^0(X,\alpha)=0=H^1(X,\alpha)$, a "$2n$-point function" is interpreted as a meromorphic section with certain physically required zeros and poles of the line bundle over X^{2n} which is constructed using the (external) tensor product of n copies of α and n copies of its Serre dual $K_X\otimes\alpha^{-1}$. The line bundle K_X is the holomorphic cotangent bundle of X. A proof of the uniqueness of the $2n$-point functions and an application of a "Riemann lemma" enabled the explicit determination of these sections in terms of theta functions associated with the Riemann surface. In the case of the four-point function, this led to a proof of the trisecant identity for theta functions associated to a Jacobian.[10]

A subject of much speculation has been whether there is an interesting analog of these results when the line bundle α is replaced by a vector bundle E of rank r and degree $r(g-1)$. Indeed, it was remarked by Raina (see Ref. 10, Remark 5.7) that the proof of the uniqueness of the $2n$-point function remained valid if E has no holomorphic sections and is simple. However, the interesting question is to relate the sections to *generalized theta functions* and possibly to arrive at a corresponding generalization of the trisecant identity. We shall carry out the first part and give indications towards the second. In a recent paper,[2] David Ben-Zvi and one of us (I.B.) studied the corresponding Szegö kernel and its relationship with generalized theta functions. We remark that, while there have been other works thematically related to the present one, (see Refs. 3 and 8), the present work is quite different from these. While in Polishchuk[8], the approach to the higher rank

[a)]E-mail: indranil@math.tifr.res.in
[b)]E-mail: raina@tifr.res.in

generalization of the trisecant identity is through generalized determinants, and in Gómez and González[3], the natural embedding of $X\times X$ in the moduli space of vector bundles over X defined by $(x,y)\mapsto E\otimes\mathcal{O}_X(x-y)$ is investigated (just as done in the case of line bundles), the aim here is to investigate the relationship between the Hecke transformations and the Quillen determinant line bundle. The relationships between them established here turn out to suggest a possible approach to the higher rank generalization of the trisecant identity.

Remark 5.7 of Ref. 10 also provided motivation for the construction of a higher rank analog of the *bc*-system carried out by Schork.[12,13] The generalized theta functions on the parameter spaces considered here are related to the correlation functions of that system.

To describe the results proved here, let E be a holomorphic vector bundle of rank r and degree $r(g-1)$ over X, with $P(E)$ [respectively, $\mathbb{P}(E)$] being the space of all lines (respectively, hyperplanes) in the fibers of E. Given a line ℓ or a hyperplane H in the fiber E_x of E over $x\in X$, the Hecke transformation gives vector bundles defined by the exact sequences

$$0\to V\to E\to E_x/\ell\to 0$$

and

$$0\to W\to E\to E_x/H\to 0.$$

So V and W are canonically identified with E over $X\backslash\{x\}$.

Now, given a point of $P(E)$ and a point of $\mathbb{P}(E)$, a new vector bundle over X can be constructed by combining the above constructions. Therefore, we have a family of vector bundles over X parametrized by a Zariski open dense subset $\mathcal{U}\subset\mathbb{P}(E)\times P(E)$. This construction does not give a vector bundle if the hyperplane contains the line in the fiber of E; therefore, that family is actually parametrized by an open subset of $\mathbb{P}(E)\times P(E)$.

In Lemma 2.1 we identify the generalized theta line bundle (= determinant line bundle) for this family. Since the complement of $\mathcal{U}$ in $\mathbb{P}(E)\times P(E)$ is of codimension at least two, the generalized theta line bundle as well as its section given by the generalized theta function extend to $\mathbb{P}(E)\times P(E)$.

A family of vector bundles over X can similarly be constructed which is parametrized by a Zariski open dense subset

$$\mathcal{U}_2\subset\mathbb{P}(E)\times\mathbb{P}(E)\times P(E)\times P(E).$$

For any point $(y_1,y_2,z_1,z_2)\in\mathcal{U}_2$, the corresponding vector bundle over X is constructed by performing Hecke transformations using the lines z_1, z_2 as well as the hyperplanes y_1, y_2. In Lemma 2.3 we identify the determinant line bundle over $\mathcal{U}_2$ for this family. In Theorem 3.1 it is shown that this line bundle over $\mathcal{U}_2$ has the property that the space of its global holomorphic sections is one dimensional, provided $\dim H^0(X,E)=0=\dim H^0(X,\mathrm{End}(E))-1$.

For any vector bundle E satisfying the above cohomology conditions, let ϑ and ϑ_2 be the generalized theta functions on $\mathbb{P}(E)\times P(E)$ and $\mathbb{P}(E)\times\mathbb{P}(E)\times P(E)\times P(E)$, respectively, for the above families of vector bundles over X (the functions extend). Consider $q_{13}^*\vartheta\otimes q_{24}^*\vartheta-q_{14}^*\vartheta\otimes q_{23}^*\vartheta$, where q_{ij}, $1\leqslant i<j\leqslant 4$, is the projection of $\mathbb{P}(E)\times\mathbb{P}(E)\times P(E)\times P(E)$ to the product of the ith and jth factor, that is, $q_{ij}(a_1,a_2,a_3,a_4)=(a_i,a_j)$. If $r=1$, then $\mathbb{P}(E)\cong X\cong P(E)$, and hence this section vanishes over the two images of X^3 in X^4 defined by $(x,y,z)\mapsto(x,x,y,z)$ and $(x,y,z)\mapsto(x,y,z,z)$. This immediately implies that the above defined section coincides with ϑ_2. This equality of sections is the trisecant identity. However, if $r>1$, then we do not know if the section vanishes over the two images of X^3. If it does, then a similar identity for the generalized function would follow immediately.

II. THE DETERMINANT LINE BUNDLE

Let X be a compact connected Riemann surface, or equivalently, a connected smooth projective curve defined over $\mathbb{C}$. The genus of X will be denoted by g.

Fix a holomorphic vector bundle E over X of rank r and degree $r(g-1)$. Let $\mathbb{P}(E)$ [respectively, $P(E)$] be the projective bundle over X parametrizing all hyperplanes (respectively, lines) in the fibers of E. Let $\mathcal{O}_{\mathbb{P}(E)}(1)$ [respectively, $\mathcal{O}_{P(E)}(1)$] be the tautological line bundle over $\mathbb{P}(E)$ [respectively, $P(E)$] whose fiber over any point is the quotient by the hyperplane (respectively, dual of the line) represented by the point.

For notational simplicity, the variety $\mathbb{P}(E)$ [respectively, $P(E)$] will be denoted by Y (respectively, Z). For the same reason, the line bundle $\mathcal{O}_{\mathbb{P}(E)}(1)$ [respectively, $\mathcal{O}_{P(E)}(1)$] will be denoted by ζ (respectively, η).

Let $f_2\colon Z\to X$ be the natural projection. Note that we have a natural inclusion of $\mathcal{O}_{P(E)}(-1) := \eta^*$ in f_2^*E as a subbundle. Let Q be the vector bundle over $P(E)=Z$ of rank $r-1$ that fits in the following exact sequence of vector bundles

$$0 \to \mathcal{O}_{P(E)}(-1) = \eta^* \to f_2^*E \to Q \to 0 \tag{2.1}$$

over Z.

Let $f_1\colon Y\to X$ be the natural projection. Note that the vector bundle f_1^*E has a natural projection to the line bundle ζ. Let Q' (respectively, ζ') over $X\times Z$ (respectively, $X\times Y$) be the direct image of Q (respectively, ζ) by the embedding that sends any point $z\in Z$ (respectively, $y\in Y$) to $(f_2(z),z)\in X\times Z$ [respectively, $(f_1(y),y)\in X\times Y$]. So both Q' and ζ' are torsion sheaves.

Consider the Cartesian product $X\times Y\times Z$, which is a projective variety of dimension $2r+1$. Let

$$p_1\colon X\times Y\times Z\to X$$

be the projection to the first factor. So we have a homomorphism

$$\alpha=\alpha_1\oplus\alpha_2\colon p_1^*E\to p_{12}^*\zeta'\oplus p_{13}^*Q', \tag{2.2}$$

where p_{12} (respectively, p_{13}) is the projection $X\times Y\times Z$ to $X\times Y$ (respectively, $X\times Z$); the homomorphism α_2 is the pullback of the projection map in (2.1), and α_1 is the pullback of the projection $f_1^*E\to\zeta$. Let p_Y and p_Z be the projections of $Y\times Z$ to Y and Z, respectively.

We note that $p_{12}^*\zeta'$ (respectively, p_{13}^*Q') is identified with the direct image of $p_Y^*\zeta$ (respectively, p_Z^*Q) by the embedding of $Y\times Z$ in $X\times Y\times Z$ that sends any point (y,z) to $(f_1(y),y,z)$ [respectively, $(f_2(z),y,z)$].

Let

$$\mathcal{E}' := \text{kernel}(\alpha)\subset f^*E \tag{2.3}$$

be the kernel of the homomorphism α defined in (2.2) (see Ref. 7, Sec. 4 for this construction which is known as the Hecke transformation). The torsionfree coherent sheaf $\mathcal{E}'$ on $X\times Y\times Z$ is not locally free in general. The projection of $X\times Y\times Z$ to $Y\times Z$ will be denoted by p_{23}. Consider the closed subvariety $S\subset Y\times Z$ defined by all points of the form (y,z) satisfying the two conditions that $f_1(y)=f_2(z)$ and the hyperplane in the fiber $E_{f_1(y)}$ defined by y contains the line in $E_{f_2(z)}$ defined by z. Let

$$\mathcal{U} := (Y\times Z)\setminus S \tag{2.4}$$

be the complement. The coherent sheaf $\mathcal{E}'$ is locally free over $p_{23}^{-1}(\mathcal{U})\subset X\times Y\times Z$. Indeed, this follows from the fact that for any $(y,z)\in\mathcal{U}$, the two subspaces of $E_{f_1(y)}$, namely $\eta_{f_2(z)}$ and the kernel of the projection $E_{f_1(y)}\to\zeta_{f_1(y)}$, are transversal. Note that the codimension of S in $Y\times Z$ is two if $\text{rank}(E)\geqslant 2$, and if E is a line bundle, then S is the empty set. Although we do not need it, it may be mentioned that $\mathcal{E}'$ fails to be locally free exactly over the subvariety of $X\times Y\times Z$ defined by all points (x,y,z) satisfying the two conditions that $(y,z)\in S$ and $x=f_1(y)$.

Since $\mathcal{E}'$ is a vector bundle over $p_{23}^{-1}(\mathcal{U})$, we can—and we will—consider $\mathcal{E}'|_{p_{23}^{-1}(\mathcal{U})}$ as an algebraic family of vector bundles over X parametrized by $\mathcal{U}$. Note that for any point $(y,z)\in\mathcal{U}$

with $f_1(y)=f_2(z)$, the corresponding vector bundle over X for this family (that is, the restriction of $\mathcal{E}'$ to $X\times\{y\}\times\{z\}$) is canonically identified with the vector bundle $E\otimes\mathcal{O}_X(-f_1(y))$.

Let p_i, $i=1,2,3$, be the projection of $X\times Y\times Z$ to the ith factor (the projection p_1 was defined earlier). So then $p_{1j}=p_1\times p_j$, where $j=2,3$, and we also have $p_2=p_Y\circ p_{23}$ and $p_3=p_Z\circ p_{23}$.

Let $\Delta\subset X\times X$ be the (reduced) diagonal divisor defined by all points of the form (x,x), where $x\in X$. Let

$$L_\Delta := (p_1\times(f_2\circ p_3))^*\mathcal{O}_{X\times X}(\Delta) \tag{2.5}$$

be the line bundle over $X\times Y\times Z$.

Define the vector bundle

$$\mathcal{E} := \mathcal{E}'\otimes L_\Delta \tag{2.6}$$

over $p_{23}^{-1}(\mathcal{U})\cong X\times\mathcal{U}$, where $\mathcal{E}'$ is defined in (2.3) and L_Δ is defined in (2.5). We will consider $\mathcal{E}$ as an algebraic family of vector bundles over X parametrized by $\mathcal{U}$. For any point $t\in\mathcal{U}$, the vector bundle over X obtained by restricting $\mathcal{E}$ to $X\times\{t\}$ will be denoted by $\mathcal{E}_t$. Note that if $f_1\circ p_Y(t)=f_2\circ p_Z(t)\in X$, where $t\in\mathcal{U}$, then $\mathcal{E}_t$ is identified with E. Indeed, this follows from the earlier observation that $\mathcal{E}'|_{X\times\{y\}\times\{z\}}\cong E\otimes\mathcal{O}_X(-f_1(y))$.

Let

$$\mathcal{L} := d(\mathcal{E}) \tag{2.7}$$

be the determinant line bundle over $\mathcal{U}$ for the family of vector bundles over X defined by $\mathcal{E}$ (see Refs. 9 and 1 for the determinant line bundle). So, for any point $t\in\mathcal{U}$ the fiber $\mathcal{L}_t$ is canonically identified with the line $(\wedge^{\text{top}}H^0(X,\mathcal{E}_t)^*)\otimes(\wedge^{\text{top}}H^1(X,\mathcal{E}_t))$. These lines fit together in a natural fashion to define a holomorphic line bundle over the parameter space (namely, $\mathcal{U}$).

For a holomorphic vector bundle F over X, we will denote by $d(F)$ the complex line $(\wedge^{\text{top}}H^0(X,F)^*)\otimes(\wedge^{\text{top}}H^1(X,F))$.

Lemma 2.1: The determinant line bundle $\mathcal{L}$ over $\mathcal{U}$ is canonically isomorphic to the restriction to $\mathcal{U}\subset Y\times Z$ of $p_Y^*\zeta\otimes p_Z^*(\eta^*\otimes f_2^*K_X)\otimes(f_1\times f_2)^*\mathcal{O}_{X\times X}(\Delta)\otimes l$, where K_X is the holomorphic cotangent bundle of X and l is the trivial line bundle over $Y\times Z$ with fiber $d(E)$, where $d(E)$ is the line defined above.

Proof: The natural isomorphism between $p_Y^*\zeta\otimes p_Z^*(\eta^*\otimes f_2^*K_X)\otimes(f_1\times f_2)^*\mathcal{O}_{X\times X}(\Delta)\otimes l$ and $\mathcal{L}$ over $\mathcal{U}$ asserted in the lemma is produced by identifying the fibers of the two line bundles.

Take any point $t=(y,z)\in\mathcal{U}\subset Y\times Z$. Set $x_1=f_1(y)$ and $x_2=f_2(z)$. The vector bundle $\mathcal{E}_t$ is identified with the kernel of the subjective homomorphism

$$E\otimes_{\mathcal{O}_X}\mathcal{O}_X(x_2)\to(\zeta_y\otimes\mathcal{O}_X(x_2)_{x_1})\oplus(Q_z\otimes\mathcal{O}_X(x_2)_{x_2}), \tag{2.8}$$

where $\mathcal{O}_X(x_2)_x$ is the fiber of the line bundle $\mathcal{O}_X(x_2)$ over x. Note that this description of $\mathcal{E}_t$ implies that if $x_1=x_2$, then $\mathcal{E}_t$ is identified with E. Indeed, in that case the fiber $E_{x_2}\otimes\mathcal{O}_X(x_2)_{x_2}$ is mapped isomorphically to $(\zeta_y\otimes\mathcal{O}_X(x_2)_{x_1})\oplus(Q_z\otimes\mathcal{O}_X(x_2)_{x_2})$ by the homomorphism defined in (2.8). Consequently, the kernel of the homomorphism in (2.8) is identified with the image of E in $E\otimes_{\mathcal{O}_X}\mathcal{O}_X(x_2)$ by the inclusion map.

For an exact sequence of coherent sheaves

$$0\to A\to B\to C\to 0$$

over X, where A and B are locally free (vector bundles) and C is a torsion sheaf supported over a point with $\dim_{\mathbb{C}}C=n$, we have an isomorphism

$$d(A)\cong d(B)\otimes\wedge^n C \tag{2.9}$$

(recall that $d(F):=\wedge^{\text{top}}H^0(X,F)^*\otimes\wedge^{\text{top}}H^1(X,F)$). Consequently, setting $A=E$ and $B=E\otimes_{\mathcal{O}_X}\mathcal{O}_X(x_2)$ we obtain

$$d(E\otimes_{\mathcal{O}_X}\mathcal{O}_X(x_2))\cong d(E)\otimes\wedge^r(E_{x_2}\otimes T_{x_2}X)^*, \tag{2.10}$$

where $r=\mathrm{rank}(E)$.

Let V be the vector bundle over X defined by the exact sequence of coherent sheaves

$$0\to V\to E\otimes_{\mathcal{O}_X}\mathcal{O}_X(x_2)\to Q_z\otimes\mathcal{O}_X(x_2)_{x_2}\to 0,$$

where Q_z is the quotient of E_{x_2} defined by the point $z\in Z$. Using (2.9) and (2.10) it follows that

$$d(V)\cong d(E)\otimes K_{x_2}\otimes\eta_z, \tag{2.11}$$

where K_{x_2} is the fiber over x_2 of the holomorphic cotangent bundle K_X.

The vector bundle $\mathcal{E}_t$ over X (recall that $t=(y,z)$) fits in the exact sequence

$$0\to\mathcal{E}_t\to V\to\zeta_y\otimes\mathcal{O}_X(x_2)_{x_1}\to 0.$$

Therefore, using (2.9) and (2.11) we have

$$d(\mathcal{E}_t)\cong d(V)\otimes\zeta_y\otimes\mathcal{O}_X(x_2)_{x_1}\cong d(E)\otimes K_{x_2}\otimes\eta_z\otimes\zeta_y\otimes\mathcal{O}_{X\times X}(\Delta)_{(x_1,x_2)}$$

as $\mathcal{O}_X(x_2)_{x_1}$ is identified with the fiber over the point $(x_1,x_2)\subset X\times X$ of the line bundle $\mathcal{O}_{X\times X}(\Delta)$. This completes the proof of the lemma. □

Since we have $\chi(E)=0$, the determinant line bundle $d(\mathcal{E})$ in (2.7) has a canonical section, which is know as the *generalized theta function*[1,9]. This section vanishes at a point $u\in\mathcal{U}$ if and only if $H^0(X,\ \mathcal{E}|_{X\times\{u\}})\neq 0$. Let

$$\theta\in H^0(\mathcal{U},d(\mathcal{E})) \tag{2.12}$$

be the generalized theta function. We recall that θ vanishes at a point $t\in\mathcal{U}$ if and only if $H^0(X,\mathcal{E}_t)\neq 0$. In particular, if $\mathcal{E}_t$ is not semistable, then $\theta(t)=0$.

Let

$$\vartheta\in H^0(\mathcal{U},p_Y^*\zeta\otimes p_Z^*(\eta^*\otimes f_2^*K_X)\otimes(f_1\times f_2)^*\mathcal{O}_{X\times X}(\Delta)\otimes l) \tag{2.13}$$

be the section over $\mathcal{U}$ defined by θ [in (2.12)] using the isomorphism in Lemma 2.1. Note that the complement of $\mathcal{U}$ in $Y\times Z$ is of codimension at least two. Therefore, ϑ extends to $Y\times Z$; the extended section will also be denoted by ϑ.

We will now identify the determinant line bundle over $Y\times Y\times Z\times Z$ for a family of vector bundles constructed also using Hecke transformation.

Let $\Delta_Y\subset Y\times Y$ and $\Delta_Z\subset Z\times Z$ be the diagonals. Let q_{ij}, $1\leqslant i<j\leqslant 4$, be the projection $Y\times Y\times Z\times Z$ to the product of the ith and the jth factor. Therefore, q_{ij} sends any point (x_1,x_2,x_3,x_4) of $Y\times Y\times Z\times Z$ to (x_i,x_j). Set

$$S_2:=q_{12}^{-1}(\Delta_Y)\cup q_{34}^{-1}(\Delta_Z)\bigcup_{i=1,2;j=3,4}q_{ij}^{-1}(S)\subset Y\times Y\times Z\times Z, \tag{2.14}$$

where $S\subset Y\times Z$ is the subvariety in (2.4). Let

$$\mathcal{U}_2:=S_2^c=(Y\times Y\times Z\times Z)\setminus S_2\subset Y\times Y\times Z\times Z \tag{2.15}$$

be the complement of S_2 [defined in (2.14)], which is a Zariski open dense subset.

As before, there is a natural family of vector bundles over X parametrized by $\mathcal{U}_2$. We will describe this family.

Let ϕ_i, $1\leqslant i\leqslant 5$, be the projection of $X\times Y\times Y\times Z\times Z$ to the ith factor. The projection of $X\times Y\times Y\times Z\times Z$ to the product of the ith factor and the jth factor, where $1\leqslant i<j\leqslant 5$, will be denoted by ϕ_{ij}. So ϕ_i (respectively, ϕ_{ij}) sends any point (x_1,x_2,x_3,x_4,x_5) of $X\times Y\times Y\times Z\times Z$ to x_i [respectively, (x_i,x_j)].

Consider the homomorphism

$$\beta := (\beta_{11} \oplus \beta_{12}) \oplus (\beta_{21} \oplus \beta_{22}) : \phi_1^* E \to (\phi_1 \times \phi_{24})^* (p_{12}^* \zeta' \oplus p_{13}^* Q') \oplus (\phi_1 \times \phi_{35})^* (p_{12}^* \zeta' \oplus p_{13}^* Q') \tag{2.16}$$

over $X \times Y \times Y \times Z \times Z$, where β_{ij}, $i,j \in \{1,2\}$, is the pullback to $X \times Y \times Y \times Z \times Z$ of the homomorphism α_j in (2.2). Thus $\beta_{11} : \phi_1^* E \to (\phi_1 \times \phi_{24})^* p_{12}^* \zeta'$ and $\beta_{21} : \phi_1^* E \to (\phi_1 \times \phi_{35})^* p_{12}^* \zeta'$ are the pullbacks of α_1 [defined in (2.2)] using the projections $\phi_1 \times \phi_{24}$ and $\phi_1 \times \phi_{35}$, respectively. The homomorphisms β_{12} and β_{22} are constructed from α_2 in a similar fashion.

Proposition 2.2: The kernel of the homomorphism β constructed in (2.16) is locally free over $X \times \mathcal{U}_2$, where $\mathcal{U}_2$ is defined in (2.15).

Proof: Let Δ_1 (respectively, Δ_2) be the reduced divisor on $X \times Y \times Y \times Z \times Z$ defined by all points $(x_1, x_2, x_3, x_4, x_5)$ with $f_1(x_2) = x_1$ (respectively, $f_1(x_3) = x_1$), where, as before, f_1 is the projection of Y to X. On Δ_i, $i = 1,2$, we have a subbundle $V_i \subset (\phi_1^* E)|_{\Delta_i}$ of rank $r-1$ defined as the kernel of the natural projection of $(\phi_1^* E)|_{\Delta_i}$ to $(\phi_{i+1}|_{\Delta_i})^* \zeta$.

Similarly, define Δ_3 (respectively, Δ_4) to be the reduced divisor on $X \times Y \times Y \times Z \times Z$ defined by all points $(x_1, x_2, x_3, x_4, x_5)$ with $f_2(x_4) = x_1$ [respectively, $f_2(x_5) = x_1$], where f_2 is the projection of Z to X. Let $V_i = (\phi_{i+1}|_{\Delta_i})^* \eta^*$, $i = 3,4$, be the line subbundle of $(\phi_1^* E)|_{\Delta_i}$ defined using (2.1).

The union

$$\overline{\Delta} := \sum_{i=1}^{4} \Delta_i$$

constitutes a normal crossing divisor on $X \times Y \times Y \times Z \times Z$. Over any connected component of $\Delta_i \cap \Delta_j \cap (X \times \mathcal{U}_2)$, where $1 \leqslant i < j \leqslant 4$, the intersection of the two subbundles V_i and V_j is again a subbundle of $(\phi_1^* E)|_{\Delta_i \cap \Delta_j \cap (X \times \mathcal{U}_2)}$. In other words, the dimension of $(V_i)_y \cap (V_j)_y \subset (\phi_1^* E)_y$ is independent of y, where y runs over a connected component of $\Delta_i \cap \Delta_j \cap (X \times \mathcal{U}_2)$.

The same assertion holds for each connected component of each triple intersection $\Delta_i \cap \Delta_j \cap \Delta_l \cap (X \times \mathcal{U}_2)$, where $1 \leqslant i < j < k \leqslant 4$, that is, $\dim (V_i)_y \cap (V_j)_y \cap (V_k)_y$ does not change while y runs over a connected component. This also holds for the total intersection $\cap_{i=1}^4 \Delta_i$.

These observations immediately imply that the kernel of the homomorphism β is locally free over $X \times \mathcal{U}_2$, completing the proof of the proposition. □

Thus kernel(β) [as in (2.16)] defines a vector bundle over $X \times \mathcal{U}_2$; this vector bundle will be denoted by $\mathcal{E}_2'$.

Now, define the vector bundle

$$\mathcal{E}_2 := \mathcal{E}_2' \otimes (\phi_1 \times \phi_{24})^* L_\Delta \otimes (\phi_1 \times \phi_{35})^* L_\Delta \tag{2.17}$$

over $X \times \mathcal{U}_2$, where L_Δ is the line bundle over $X \times Y \times Z$ defined in (2.5). Note that both $(\phi_1 \times \phi_{24})^* L_\Delta$ and $(\phi_1 \times \phi_{35})^* L_\Delta$ are pullbacks to $X \times Y \times Y \times Z \times Z$ of line bundles over $X \times Y \times Z$.

Let

$$\mathcal{L}_2 := d(\mathcal{E}_2) \tag{2.18}$$

be the determinant line bundle over $\mathcal{U}_2$ for the algebraic family, defined by $\mathcal{E}_2$, of vector bundles over X parametrized by $\mathcal{U}_2$. We will identify the line bundle $d(\mathcal{E}_2)$ in the spirit of Lemma 2.1.

Let

$$\delta := p_Y^* \zeta \otimes p_Z^* (\eta^* \otimes f_2^* K_X) \otimes (f_1 \times f_2)^* \mathcal{O}_{X \times X}(\Delta) \tag{2.19}$$

be the line bundle over $Y \times Z$ (see Lemma 2.1). Let

$$L_Y := (f_1 \times f_1)^* \mathcal{O}_{X \times X}(\Delta)$$

be the line bundle over $Y \times Y$. Similarly, define the line bundle $L_Z := (f_2 \times f_2)^* \mathcal{O}_{X \times X}(\Delta)$ over $Z \times Z$. Let

$$L' := (f_1 \times f_2)^* \mathcal{O}_{X\times X}(\Delta) \tag{2.20}$$

be the line bundle over $Y \times Z$.

Lemma 2.3: The determinant line bundle $\mathcal{L}_2$ over $\mathcal{U}_2$ [defined in (2.18)] is canonically identified with the line bundle

$$l_2 \otimes q_{13}^* \delta \otimes q_{24}^* \delta \otimes (q_{12}^* L_Y \otimes q_{34}^* L_Z)^* \otimes q_{14}^* L' \otimes q_{23}^* L'$$

where l_2 is the trivial line bundle over $\mathcal{U}_2$ with fiber $d(E)$; the line bundles δ and L' are defined, respectively, in (2.19) and (2.20), and L_Y, L_Z are defined above.

Proof: The proof of this lemma is very similar to the proof of Lemma 2.1. However, for the sake of completeness, we give the details.

Take a point $t=(y_1,y_2,z_1,z_2) \in \mathcal{U}_2$. Set $x_i=f_2(z_i)$, $i=1,2$. Consider the vector bundle W over X defined by the exact sequence

$$0 \to E \to W \to A_1 \to 0$$

of coherent sheaves, where A_1 is a torsion sheaf of dimension one supported at the (reduced) point x_1, and the kernel of the homomorphism $E_{x_1} \to W_{x_1}$ is the line in E_{x_1} represented by z_1. Note that since $z_2 \neq z_1$, the line in the fiber E_{x_2} represented by z_2 defines a line in W_{x_2}. Let W' be the vector bundle over X defined by the exact sequence

$$0 \to W \to W' \to A_2 \to 0$$

of coherent sheaves, where A_2 is a torsion sheaf of dimension one supported at the (reduced) point x_2, and the kernel of the homomorphism $W_{x_2} \to W'_{x_2}$ is the line defined by z_2.

From the definition of W and W' it follows immediately that $A_1 \cong \eta_{z_1} \otimes T_{x_1}X$ and

$$A_2 \cong \eta_{z_2} \otimes T_{x_2}X \otimes \mathcal{O}_{X\times X}(\Delta)_{(x_1,x_2)}$$

as the fiber $\mathcal{O}_{X\times X}(\Delta)_{(x_1,x_2)}$ of the line bundle $\mathcal{O}_{X\times X}(\Delta)$ over the point (x_1,x_2) is identified with the fiber of $\mathcal{O}_X(x_1)$ over x_2. Now using the isomorphism in (2.9) we conclude that

$$d(W') \cong d(E) \otimes \eta_{z_1}^* \otimes K_{x_1} \otimes \eta_{z_2}^* \otimes K_{x_2} \otimes \mathcal{O}_{X\times X}(-\Delta)_{(x_1,x_2)}, \tag{2.21}$$

where K_x is the fiber over the point x of the holomorphic cotangent bundle of X.

Set $x_1^0=f_1(y_1) \in X$. Let V be the vector bundle over X defined by the exact sequence

$$0 \to V \to W' \to \zeta_{y_1} \otimes_{\mathbb{C}} \mathcal{O}_X(x_1+x_2) \to 0.$$

Note that $\zeta_{y_1} \otimes_{\mathbb{C}} \mathcal{O}_X(x_1+x_2)$ is a torsion sheaf of dimension one supported on the reduced point x_1^0. The projection of W' to $\zeta_{y_1} \otimes_{\mathbb{C}} \mathcal{O}_X(x_1+x_2)$ is defined by the natural projection $E_{x_1^0} \to \zeta_{y_1}$. The identity (2.9) for this exact sequence gives

$$d(V) \cong d(W') \otimes \zeta_{y_1} \otimes \mathcal{O}_{X\times X}(\Delta)_{(x_1^0,x_1)} \otimes \mathcal{O}_{X\times X}(\Delta)_{(x_1^0,x_2)}. \tag{2.22}$$

Similarly, set $x_2^0=f_1(y_2) \in X$. The vector bundle $\mathcal{E}_2|_t$ over X, obtained by restricting $\mathcal{E}_2$ to $X \times \{t\} \subset X \times Y \times Y \times Z \times Z$, fits in the following exact sequence

$$0 \to \mathcal{E}_2|_t \to V \to \zeta_{y_2} \otimes_{\mathbb{C}} \mathcal{O}_X(x_1+x_2-x_1^0) \to 0,$$

where $\zeta_{y_2} \otimes_{\mathbb{C}} \mathcal{O}_X(x_1+x_2-x_1^0)$ is the torsion sheaf of dimension one supported on x_2^0, and the projection of V to $\zeta_{y_2} \otimes_{\mathbb{C}} \mathcal{O}_X(x_1+x_2-x_1^0)$ is defined by the natural projection $E_{x_2^0} \to \zeta_{y_2}$. The identity (2.9) gives

$$d(\mathcal{E}_2|_t) \cong d(V) \otimes \zeta_{y_1} \otimes \mathcal{O}_{X\times X}(\Delta)_{(x_2^0,x_1)} \otimes \mathcal{O}_{X\times X}(\Delta)_{(x_2^0,x_2)} \otimes \mathcal{O}_{X\times X}(-\Delta)_{(x_2^0,x_1^0)}. \tag{2.23}$$

Finally, (2.21)–(2.23) together complete the proof of the lemma.

□

Let

$$\theta_2 \in H^0(\mathcal{U}_2, \mathcal{L}_2) \tag{2.24}$$

be the generalized theta function for the family of vector bundles over X defined by $\mathcal{E}_2$. Set

$$L_2 := l_2 \otimes q_{13}^*\delta \otimes q_{24}^*\delta \otimes (q_{12}^*L_Y \otimes q_{34}^*L_Z)^* \otimes q_{14}^*L' \otimes q_{23}^*L' \tag{2.25}$$

to be the line bundle over $Y\times Y\times Z\times Z$, where l_2 as before is the trivial line bundle with fiber $d(E)$ (see Lemma 2.3). Let

$$\vartheta_2 \in H^0(\mathcal{U}_2,\, L_2|_{\mathcal{U}_2}) \tag{2.26}$$

be the section defined by θ_2 using the isomorphism in Lemma 2.3.

Assume that $r=\mathrm{rank}(E)\geqslant 2$. Consequently, the codimension of the subvariety S_2 defined in (2.14) is at least two. (Note that if $r=1$, then both Δ_Y and Δ_Z coincide with the diagonal divisor in $X\times X$.) Therefore, ϑ_2 extends to a section of L_2 over $Y\times Y\times Z\times Z$. This extended section will also be denoted by ϑ_2.

If $r=1$, then $\mathcal{E}_2$ extends naturally to $X\times Y\times Y\times Z\times Z$ as a line bundle. So even in the case $r=1$, the section ϑ_2 is defined over $Y\times Y\times Z\times Z$ (see Ref. 6, Chap. 11, p. 357, Proposition 10.2).

In the next section we will describe ϑ_2 using the section ϑ over $Y\times Z$ constructed in (2.13).

III. SECTIONS OF THE PULLBACK BUNDLE

Assume that $H^0(X,E)=0$. Consequently, $H^1(X,E)=0$, as $\mathrm{degree}(E)=r(g-1)$. Note that the condition $H^0(X,E)=0$ implies that the vector bundle E is semistable. Let

$$\xi := L_2 \otimes l_2^* = q_{13}^*\delta \otimes q_{24}^*\delta \otimes (q_{12}^*L_Y \otimes q_{34}^*L_Z)^* \otimes q_{14}^*L' \otimes q_{23}^*L' \tag{3.1}$$

be the line bundle over $Y\times Y\times Z\times Z$, where L_2 is defined in (2.25).

Theorem 3.1: *Let E be a holomorphic vector bundle with $H^i(X,E)=0$, $i=0,1$, and $H^0(X,\mathrm{End}(E))\cong\mathbb{C}$. Then we have*

$$\dim H^0(Y\times Y\times Z\times Z,\xi)=1,$$

where ξ is the line bundle defined above.

Proof: Let

$$F: Y\times Y\times Z\times Z \to X^4$$

be the natural projection defined by

$$(y_1,y_2,z_1,z_2)\mapsto (f_1(y_1),f_1(y_2),f_2(z_1),f_2(z_2)).$$

The fibers of F are products of projective spaces. Note that for any point $x\in X^4$, we have $H^i(F^{-1}(x),\, \xi|_{F^{-1}(x)})=0$ for each $i\geqslant 1$. Indeed, this follows from the Künneth formula and the fact that ξ is relatively ample for the projection F.

Therefore, we have

$$H^0(Y\times Y\times Z\times Z,\xi)\cong H^0(X^4,F_*\xi). \tag{3.2}$$

Let $\psi_i: X^4\to X$, $1\leqslant i\leqslant 4$, be the projection to the ith factor. For $1\leqslant i<j\leqslant 4$, let $\psi_{ij}=\psi_i\times\psi_j$ be the projection of X^4 to X^2. The divisor $\psi_{ij}^{-1}(\Delta)\subset X^4$ will be denoted by Δ_{ij}.

Since $f_{1*}\zeta\cong E$ and $f_{2*}\eta\cong E^*$, we have

$$F_*\xi \cong \mathcal{W}_E := \psi_1^*(E) \otimes \psi_2^*(E) \otimes \psi_3^*(E^* \otimes K_X) \otimes \psi_4^*(E^* \otimes K_X) \otimes \mathcal{O}_{X^4}(\Delta_{13} + \Delta_{24} + \Delta_{14} + \Delta_{23} - \Delta_{12} - \Delta_{34})$$

over X^4.

Now, $\dim H^0(X^4, \mathcal{W}_E) = 1$ as $\dim H^0(X, \mathrm{End}(E)) = 1$ [see Ref. 10, p. 239, Remark 5.7]. As noted in Ref. 10, Remark 5.7, the proof of Theorem 5.5 in Ref. 10, p. 239 (which is for line bundles) goes through for vector bundles under that assumption that the vector bundle is simple. This completes the proof of the theorem. □

Note that X admits a stable vector bundle E of rank at least two with $H^0(X, \mathrm{End}(E)) \cong \mathbb{C}$ if and only if the genus of X is at least two.

For any vector bundle E with $H^0(X,E) = 0 = H^1(X,E)$, the line

$$d(E) := \wedge^{\mathrm{top}} H^0(X,E)^* \otimes \wedge^{\mathrm{top}} H^1(X,E)$$

is canonically identified with $\mathbb{C}$, as the condition $H^i(X,E) = 0$ gives a nonzero element in $d(E)$. Let

$$\vartheta \in H^0(Y \times Z, p_Y^*\zeta \otimes p_Z^*(\eta^* \otimes f_2^* K_X) \otimes (f_1 \times f_2)^* \mathcal{O}_{X \times X}(\Delta))$$

be the section constructed using this identification of $d(E)$ with $\mathbb{C}$ from the section defined in (2.13) (recall that the section in (2.13) extends to $Y \times Z$).

Note that both the tensor products $q_{13}^*\vartheta \otimes q_{24}^*\vartheta$ and $q_{14}^*\vartheta \otimes q_{23}^*\vartheta$ are sections of

$$q_{13}^*\delta \otimes q_{24}^*\delta \otimes q_{14}^*L' \otimes q_{23}^*L' \cong \xi \otimes q_{12}^*L_Y \otimes q_{34}^*L_Z$$

over $Y \times Y \times Z \times Z$, where ξ is defined in (3.1); the line bundles δ and L' are defined in (2.19) and (2.20), respectively, and the projections q_{ij} are as in (2.14). Hence

$$q_{13}^*\vartheta \otimes q_{24}^*\vartheta - q_{14}^*\vartheta \otimes q_{23}^*\vartheta \in H^0(Y \times Y \times Z \times Z, \xi \otimes q_{12}^*L_Y \otimes q_{34}^*L_Z). \tag{3.3}$$

Since the line bundle $q_{12}^*L_Y \otimes q_{34}^*L_Z$ is defined by the effective divisor $((f_1 \times f_1) \circ q_{12})^{-1}(\Delta) + ((f_2 \times f_2) \circ q_{34})^{-1}(\Delta)$, there is a natural inclusion of $H^0(Y \times Y \times Z \times Z, \xi)$ in $H^0(Y \times Y \times Z \times Z, \xi \otimes q_{12}^*L_Y \otimes q_{34}^*L_Z)$.

Assume that $\dim H^0(X, \mathrm{End}(E)) = 1$. If the section in (3.3) is contained in the image

$$H^0(Y \times Y \times Z \times Z, \xi) \hookrightarrow H^0(Y \times Y \times Z \times Z, \xi \otimes q_{12}^*L_Y \otimes q_{34}^*L_Z)$$

by the above inclusion map, then it is easy to check that the section in (3.3) coincides with the section ϑ_2 [constructed in (2.26)] after using the isomorphism of $d(E)$ with $\mathbb{C}$. Note that from Theorem 3.1 it follows that the section in (3.3) must be a constant scalar multiple of ϑ_2 [if the section in (3.3) comes from a section of ξ].

If $r = 1$, then clearly the section in (3.3) comes from a section of ξ. Therefore, it coincides with ϑ_2 (if $r = 1$). The equality of ϑ_2 with the section in (3.3) is the well known trisecant identity (for $r = 1$); see Ref. 6, Chap. 11, p. 357, Proposition 10.2, and Ref. 10 for the details.

(Received 6 March 2004; accepted 4 March 2005; published online 26 April 2005; publisher error corrected 29 June 2005)

Di Bartolo, Dolgert, and Dorsey [Phys. Rev. B **53**, 5650–5660 (1996)] have constructed asymptotic matched solutions at order 2 for the half-space Ginzburg–Landau model in the weak-κ limit. These authors deduced a formal expansion for the superheating field $h^{\mathrm{sh}}(\kappa)$ up to order 4, extending the de Gennes formula [Proceedings of the Eighth Latin American School of Physics, Caracas, 1966] and the two terms in Parr's formula [Z. Phys. B **25**, 359–361 (1976)]. On the other hand, the present author [Eur. J. Appl. Math **13**, 519–547 (2002)] obtained two terms in the lower bound for $h^{\mathrm{sh}}(\kappa)$. In this paper, we prove rigorously that the second term of the expansion of $h^{\mathrm{sh}}(\kappa)$ is of the order of $\mathcal{O}(\kappa^{1/2})$ and we get the Parr formula. We improve the upper bound obtained by Bolley and Helffer [Ann. Inst. Henri Poincaré, Anal. Non Linéaire **14**, 597–613 (1997)] and we get $\kappa(h^{\mathrm{sh}}(\kappa))^2 \leqslant 2^{-3/2} + \frac{15}{32}\kappa + \mathcal{O}(\kappa^{1+\rho})$, $\rho > 0$. The proof is based on new estimates for f', A, and A'. To achieve this, we are guided by the analysis of the properties of the approximate solution constructed previously in [Del Castillo, Math Modell. Numer. Anal. **36**, 971–973 (2002); J. Math. Phys. **44**, 2416–2450 (2003); Dolgert *et al.*, Phys. Rev. B **53**, 5650–5660 (1996)]. © *2005 American Institute of Physics.*

I. INTRODUCTION

The states of a superconducting material in an exterior magnetic field are described by the Ginzburg–Landau theory which introduces a functional depending in particular on a complex wave function and on the magnetic potential A. These states are characterized as global or local minima of this functional. When the sample is a film and the exterior magnetic field is parallel to the surface, the Ginzburg–Landau model reduces to a one-dimensional problem where the wave function is real (and denoted by f) and where the functional is the following:

$$\varepsilon_d(f,A;h) = \int_{-d/2}^{d/2} \left[\frac{1}{2}(1-f(x)^2)^2 - \frac{1}{2} + \kappa^{-2} f'(x)^2 + f(x)^2 A(x)^2 + (A'(x)-h)^2 \right] \mathrm{d}x,$$

with $(f,A) \in (H^1([-d/2,d/2]))^2$. Here, d is proportional to the thickness of the film, h is proportional to the exterior magnetic field, and κ is the Ginzburg–Landau (GL) parameter characterizing the properties of the material. The value of κ determines the type of superconductor according to the type of phase transition which takes place between the normal phase and the superconducting phase. κ small describes what is known as a type I superconductor and κ large as a type II. More precisely, for a type I superconductor, there is a critical magnetic field h_c such that $h < h_c$, the material is entirely superconducting, and the magnetic field is expelled from the sample apart from a boundary layer of size λ. This is called the Meissner effect. If $h > h_c$, superconductivity is

a)Electronic mail: pierre.delcastillo@u-picardie.fr

destroyed and the material is in the normal state, that is $f \equiv 0$ and $A' \equiv h$. For a type II superconductor, the phase transition is different and there are two critical field h_{c_1} and h_{c_2}. For $h < h_{c_1}$, the exterior magnetic field is expelled from the sample and there is a Meissner effect as for type I superconductors. When h increases above h_{c_1}, superconductivity is not destroyed straight away, since the superconducting and the normal phase coexist under the form of filaments or vortices. As h increases further, the vortices become more numerous until the critical value h_{c_2} is reached at which superconductivity is destroyed. For $h > h_{c_2}$, the material is in the normal state. The way superconductivity is nucleated is highly dependent on d and κ (see, for example, Ref. 25).

In the following, we restrict ourselves to the research of *symmetric solutions*. By symmetric solutions, we mean solutions (f,A) such that f is even and A is odd. Hence, we reduce the study of ε_d to the interval $]-d,0[$ and then to $]0,d[$ by a translation (the edge of the film is then at 0). A reduced GL functional is then defined by

$$\varepsilon_d(f,A;h) = \int_0^d \left[\frac{1}{2} f^4 - f^2 + \kappa^{-2}(f')^2 + f^2 A^2 + (A' - h)^2 \right] \mathrm{d}x, \tag{1}$$

for the pairs (f,A) of $H^1(]0,d[)^2$ such that $A(d)=0$.

When the width d of the film is large (in the sense that κd is large), a slightly different modelization is considered, which was first introduced by Ginzburg and which is usually called the superconducting half-space. To get formally the limiting problem on the interval $[0,+\infty[$, we put $d=+\infty$ in the definition of the GL functional (1) after a renormalization obtained by adding the term $(h^2-\frac{1}{2})d$. We then get

$$\varepsilon_\infty(f,A) = \int_0^{+\infty} \left[\frac{1}{2}(1 - f(x)^2)^2 + \kappa^{-2} f'(x)^2 + f(x)^2 A(x)^2 + A'(x)^2 \right] \mathrm{d}x + 2hA(0), \tag{2}$$

defined for $(f,A) \in E_\infty = \{(f,A); (1-f) \in H^1(]0,+\infty[), A \in H^1(]0,+\infty[)\}$. The corresponding Ginzburg–Landau equations expressing the necessary conditions for minima are then

$$(\mathrm{GL})_\infty \begin{cases} (a) & -\kappa^{-2} f'' - f + f^3 + fA^2 = 0 \quad \text{on } [0,+\infty[, \\ (b) & -A'' + Af^2 = 0 \quad \text{on } [0,+\infty[, \end{cases} \tag{3}$$

with the boundary conditions

$$f'(0) = 0, \quad A'(0) = h. \tag{4}$$

The problem $(\mathrm{GL})_\infty$ is called the half-space model and was studied in Refs. 18 and 19 where numerical solutions are given.

We consider the set $\mathcal{H}_\infty \subset \mathbb{R}^+$ of the h's such that there exist solutions of the (GL) system with $f > 0$. We know that $\mathcal{H}_\infty$ is a bounded interval $[0,h^+)$ (see Ref. 4, Proposition 2.1) and we then introduce the superheating field $h^{\mathrm{sh}}(\kappa)$, defined as the supremum of the interval $\mathcal{H}_\infty$. This critical field is very important for many applications. For instance, measuring the superheating field provides one of the few methods of experimentally determining the Ginzburg–Landau parameter κ in type-I superconductors (see Ref. 10 and also Ref. 1 for other properties and developments).

P. G. de Gennes[12] (see also Ref. 22) has proposed the formula

$$\lim_{\kappa \to 0} \kappa (h^{\mathrm{sh}}(\kappa))^2 = 2^{-3/2}. \tag{5}$$

In Refs. 4 and 6, Bolley and Helffer have rigorously proved (5). To get an upper bound for $A'(0)$, these authors have proved the following estimates, for any pairs (f,A) solutions of $(\mathrm{GL})_\infty$:

$$A'(0)^2 \leqslant \sqrt{2}[(1 - f(0)^2) f(0)^2 \kappa^{-1} - 5A(0) f(0)^{-1}], \tag{6}$$

$$\kappa A'(0)^2 \geqslant \sqrt{2}(1-f(0)^2)f(0)^2. \tag{7}$$

On the other hand, in Ref. 9 (see Proposition 3, p. 361), these authors have proved the following estimate:

Proposition 1.1: There exist κ_0 *and* C *such that, for all* $\kappa \leqslant \kappa_0$ *and any solution* (f,A) *of* $(GL)_\infty$, *we have*

$$A'(0)^2 = h^2 \leqslant \frac{1}{2} + C\frac{f(0)}{\kappa}. \tag{8}$$

From (6), taking the maximum of $(1-f(0)^2)f(0)^2$ on the interval $[0,1]$, and from (8), they have deduced the upperbound

$$\kappa h^2 \leqslant 2^{-3/2} + \mathcal{O}(\kappa^{1/2}), \tag{9}$$

for all $h \in \mathcal{H}_\infty$ and for κ small enough.

Parr[23] has proposed on the basis of some heuristic computations, the more general formula

$$\kappa(h^{\mathrm{sh}}(\kappa))^2 = 2^{-3/2} + \tfrac{15}{32}\kappa + o(\kappa). \tag{10}$$

In Ref. 17, using the method of matched asymptotic expansions,[21–26] Dorsey, Di Bartolo, and Dolgert have obtained a formal expansion in powers of $\kappa^{1/2}$ up to order 4 for the superheating field $h^{\mathrm{sh}}(\kappa)$, recovering in particular formula (10) at a formal level. On the other hand, in Ref. 8, Bolley and Helffer have shown that numerical computations fit very well with the Parr formula.

Constructing subsolutions and supersolutions of $(\mathrm{GL})_\infty$ based on the existence of formal solutions of the half-space Ginzburg–Landau model obtained in Ref. 17, we have proved in Ref. 14 the following theorem:

Theorem 1.2: *There exist* $\kappa_0 > 0$ *and* C *such that, for all* $\kappa \leqslant \kappa_0$, *we have*

$$\kappa(h^{\mathrm{sh}}(\kappa))^2 \geqslant 2^{-3/2} + \tfrac{15}{32}\kappa + C\kappa^2. \tag{11}$$

In this paper, to get a complete and rigorous proof of the Parr formula, we prove the following theorem:

Theorem 1.3: *There exist* κ_0 *and* $\rho > 0$, *such that, for all pairs* (f,A) *solution of* $(GL)_\infty$, *for all* $\kappa \leqslant \kappa_0$, *we have*

$$\kappa A'(0)^2 = \kappa h^2 \leqslant 2^{-3/2} + \tfrac{15}{32}\kappa + \mathcal{O}(\kappa^{1+\rho}). \tag{12}$$

The approach proposed by the physicists Dorsey, Di Bartolo, and Dolgert and the approach exposed here are distinct. The first uses the method of asymptotic matched expansions and leads in particular to a formal proof of the Parr formula. The second one is essentially based on the maximum principle and leads to a rigorous proof of this formula. Nevertheless, we are guided in our analysis by the structure of the formal construction.

The key of Theorem 1.3 is the improvement of estimates for f', A, and A' obtained in Refs. 4 and 5. Notably, we get an estimate for f' on $[0,\kappa^{-\rho}]$, $\rho > 0$ coinciding with the formal estimate given in Ref. 17.

The plan of this paper is the following. In Sec. II, we first recall some estimates for the functions f, A, f' and, A' obtained in Refs. 4 and 6. We get new estimates for A and A'. In Sec. III, we analyze the estimate for $A'(0)=h$ obtained by Bolley and Helffer in Ref. 6. We get the estimate for f'. In Sec. IV, we improve the upper bound for $A'(0)$ given in (6) and get Theorem 1.3. We deduce the Parr formula (10).

II. PROPERTIES OF SOLUTIONS OF $(GL)_\infty$

A. General properties of the Ginzburg–Landau equations

Let us recall some properties of the functions f, A, f', and A' obtained in Refs. 4 and 5.

Proposition 2.1: Let (f,A) be a solution of $(GL)_\infty$.

1. *f is increasing on $\mathbb{R}^+$ and we have*

$$0 < f(x) \leqslant \tanh\left(\frac{\kappa x}{\sqrt{2}} + x_0\right), \quad \tanh(x_0) = f(0). \tag{13}$$

2. *A is strictly increasing on $[0,+\infty[$ and we have*

$$0 \leqslant A'(x) \leqslant h, \quad \forall\, x \in [0,+\infty[. \tag{14}$$

3. *f' satisfies the inequalities*

$$0 \leqslant f'(x) \leqslant \frac{\kappa}{\sqrt{2}}, \quad \forall\, x \in [0,+\infty[. \tag{15}$$

4. *The pair (f,A) satisfies the following energy conservation:*

$$\kappa^{-2} f'(x)^2 + A'(x)^2 = A(x)^2 f(x)^2 + \frac{(1-f(x)^2)^2}{2}, \quad \forall\, x \in [0,+\infty[. \tag{16}$$

5. *The pair (f,A) satisfies the inequalities*

$$0 < -Af \leqslant A', \quad \forall\, x \in [0,+\infty[. \tag{17}$$

Remark 2.2: From Proposition 2.1 [see (13)], we deduce that in a region $[0,\kappa^{-\rho}]$, $\rho>0$, we have for some $c>0$,

$$f(0) \leqslant f(x) \leqslant f(0) + c\kappa^{1-\rho}. \tag{18}$$

B. New estimates for f', A, and A'

In the next sections, we use two useful versions of the maximum principle (cf. Refs. 6 and 3).

Lemma 2.3: Let $d \in \mathbb{R}^+ \cup \{+\infty\}$. Let C be a bounded function on $]0,d[$ such that

$$C(x) \geqslant 0, \quad \forall\, x \in\ ]0,d[,$$

and let $u \in C^2([0,d])$ be a function such that

$$\begin{gathered} -u(x)'' + C(x)u(x) \leqslant 0 \quad \text{on }]0,d[, \\ u'(0) \geqslant 0. \end{gathered} \tag{19}$$

If $d \in \mathbb{R}^+$, we assume that $u(d) \leqslant 0$, and if $d=+\infty$, $u'(x) \to 0$ when $x \to +\infty$.

Then, in these two cases,

$$u(x) \leqslant 0 \quad \text{on }]0,d[.$$

From Proposition 1.1, we deduce that Inequality (12) is true for any pairs (f,A) solutions of $(GL)_\infty$ such that $f(0) \leqslant 1/10C$. In all the following sections, we will restrict ourselves to the pairs (f,A) such that

$$f(0) \geqslant \frac{1}{10C}. \tag{20}$$

Some inequalities on the functions f', A, and A' are not optimal in $[0, \kappa^{-\rho}]$. In this section, we get a better control on A and A'. Let us recall that in Ref. 4, Bolley and Helffer have obtained the following control for A:

$$h \exp(-x) \leqslant -A \leqslant \frac{h}{f(0)} \exp(-f(0)x), \quad \forall x \in \mathbb{R}^+. \tag{21}$$

In Ref. 15 (see also Refs. 13 and 17), we have constructed an asymptotic matched solution $(f^{\mathrm{vd},(n)}, A^{\mathrm{vd},(n)})$ of $(\mathrm{GL})_\infty$. Let us recall that

$$f^{\mathrm{vd},(0)}(x) = \tanh\left(\frac{\kappa x}{\sqrt{2}} + x_0\right), \tag{22}$$

and

$$\kappa^{1/2} A^{\mathrm{vd},(0)}(x) = -2^{1/4}(1 - A_0^2)^{1/2} \exp(-A_0 x), \tag{23}$$

where $A_0 = \tanh(x_0)$, $x_0 \geqslant 0$.

The comparison with the behavior of the formal solution suggests that the lower bound for $-A$ is not optimal in the interval $[0, \kappa^{-\rho}]$. We get a better lower bound for $-A$ in the following proposition:

Proposition 2.4: Let $\rho \in]0, \frac{1}{2}[$. *There exist* $\kappa_0 > 0$ *and* $C > 0$ *such that, for all* $\kappa \leqslant \kappa_0$, *for all pairs* (f, A) *solutions of* $(\mathrm{GL})_\infty$ *satisfying (20), the function A satisfies the inequality*

$$\forall x \in [0, \kappa^{-\rho}], \quad -A \geqslant \frac{h}{f(0)}(1 - C\kappa^{1-2\rho}) \exp -(f(0)x). \tag{24}$$

Proof: We set

$$v_2(x) := \tanh\left(\frac{\kappa x}{\sqrt{2}} + x_0\right), \quad \tanh(x_0) = f(0). \tag{25}$$

From (13), we get

$$f \leqslant v_2. \tag{26}$$

Let us consider the unique solution in $H^2(]0, +\infty[)$ of the problem

$$\begin{aligned} -W'' + v_2^2 W &= 0, \\ W'(0) &= h. \end{aligned} \tag{27}$$

From (27), and applying Lemma 2.3 with $d = +\infty$, $C = v_2^2$, and $u = W$, we get $W \leqslant 0$ on $\mathbb{R}^+$. From $(3)_b$, (26) and (27), we get $-(A-W)'' + f^2(A-W) \leqslant 0$. Applying again Lemma 2.3 with $d = +\infty$, $C = f^2$, and $u = A - W$, we get

$$A \leqslant W. \tag{28}$$

We set

$$\phi(x) := \int_0^x (v_2 + c_1 \kappa) \mathrm{d}t, \tag{29}$$

where c_1 is a strictly positive parameter, which will be determined later. We consider

$$z(x) = z(0)\exp(-\phi(x)), \tag{30}$$

where $z(0)$ is determined by the condition $z'(0)=h$. We get $z'(0)=-(v_2(0)+c_1\kappa)z(0)=h$. Hence, from (25), it derives that

$$z(0) = -\frac{h}{f(0)+c_1\kappa}. \tag{31}$$

We have

$$-(W-z)''+v_2^2(W-z) = z(0)\exp(-\phi(x))\left(-\frac{\kappa}{\sqrt{2}}\frac{1}{\cosh^2((\kappa x/\sqrt{2})+x_0)}+2v_2c_1\kappa+c_1^2\kappa^2\right). \tag{32}$$

From the definition of the function v_2, we get

$$-\frac{1}{\sqrt{2}}\cosh^{-2}\left(\frac{\kappa x}{\sqrt{2}}+x_0\right)+2v_2c_1+c_1^2\kappa \geqslant 2c_1\tanh(x_0)-\frac{1}{\sqrt{2}}\cosh^{-2}(x_0). \tag{33}$$

We choose c_1 such that

$$c_1 > \frac{1}{2\sqrt{2}}(\sinh(x_0)\cosh(x_0))^{-1}. \tag{34}$$

From (31), as $z(0)<0$ and according to (32)–(34), we get $-(W-z)''+v_2^2(W-z)<0$. Applying Lemma 2.3 on $[0,+\infty[$ with $C=v_2^2$ and $u=W-z$, we deduce that $W-u\leqslant 0$. From (30) and (31), it results that

$$-W \geqslant -z = \frac{h}{f(0)+c_1\kappa}\exp(-\phi(x)). \tag{35}$$

From (29), we get

$$\phi(x) = \phi'(0)x + x^2\int_0^1 \phi''(\theta x)\mathrm{d}\theta.$$

According to (25) and (29) it derives that there exists $\rho>0$ such that

$$\forall x \in [0,\kappa^{-\rho}], \quad \phi(x) \leqslant (f(0)+c_1\kappa)x + \frac{\kappa^{1-2\rho}}{\sqrt{2}}. \tag{36}$$

Finally, from (28), (35), and (36), we get the inequality

$$-A \geqslant -W \geqslant \frac{h}{f(0)+c_1\kappa}\exp\left(-f(0)x-c_1\kappa x-\frac{\kappa^{1-2\rho}}{\sqrt{2}}\right).$$

From (20), we deduce that there exist $C>0$ and κ_0, such that, for all $\kappa \in]0,\kappa_0]$, for all $x \in [0,\kappa^{-\rho}]$, we have the inequality

$$-A \geqslant \frac{h}{f(0)}(1-C\kappa^{1-2\rho})\exp(-f(0)x).$$

The proof of Proposition 2.4 follows.

We also have to get a lower bound and an upper bound for A'. In Ref. 4, Bolley and Helffer get in Proposition 2.4 the following estimate for A':

$$h\exp(-x) \leqslant A'(x) \leqslant \frac{h}{f(0)}\exp(-f(0)x), \quad \forall\, x \in \mathbb{R}^+. \tag{37}$$

Equalities (22) and (23) suggest that these estimates are not optimal in $[0,\kappa^{-\rho}]$. We get a better control for A' in the following proposition:

Proposition 2.5: Let $\rho \in \left[0,\frac{1}{4}\right]$. *There exists* $\kappa_0 > 0$ *such that, for all* $\kappa \leqslant \kappa_0$ *and for all* (f,A) *solutions of* $(GL)_\infty$ *satisfying (20), we have the following estimate for* A':

$$A' = (h + \mathcal{O}(\kappa^{1/2-2\rho}))\exp(-f(0)x), \quad \forall\, x \in [0,\kappa^{-\rho}]. \tag{38}$$

Proof: From $(3)_b$, the function A' satisfies

$$-(A')'' + f^2A' = -2f'fA, \quad A''(0) = A(0)f(0)^2. \tag{39}$$

From (13), (15), and (21), we get the inequality

$$-2f'fA \leqslant \frac{2\kappa h}{\sqrt{2}f(0)}\exp(-f(0)x), \quad \forall\, x \in \mathbb{R}^+. \tag{40}$$

We can compare A' with the unique solution in $H^2(\mathbb{R}^+)$ of

$$\begin{aligned} -y'' + f(0)^2y &= \frac{\sqrt{2}\kappa h}{f(0)}\exp(-f(0)x), \\ y'(0) &= A(0)f(0)^2, \end{aligned} \tag{41}$$

given by

$$y(x) = \left(-A(0)f(0) + \frac{\sqrt{2}\kappa h(1+f(0)x)}{2f(0)^3}\right)\exp(-f(0)x). \tag{42}$$

According to (39)–(41), we get $-(A'-y)''+f^2A'-f(0)^2y \leqslant 0$. Applying the principle maximum (see Lemma 2.3) with $d=+\infty$, $C(x)=f(0)^2$, and $u=A'-y$, we get $A' \leqslant y$ on $\mathbb{R}^+$. From (17) at the point $x=0$, it results that $-A(0)f(0) \leqslant h$. From (9), we have $h=\mathcal{O}(\kappa^{-1/2})$. As $1/10C \leqslant f(0) \leqslant 1$, for $x \in [0,\kappa^{-\rho}]$, we deduce the estimate

$$\frac{\sqrt{2}\kappa h(1+f(0)x)}{2f(0)^3} = \mathcal{O}(\kappa^{1/2-\rho}).$$

As $A' \leqslant y$, and from (42), it results that

$$A' \leqslant (h + \mathcal{O}(\kappa^{1/2-\rho}))\exp(-f(0)x). \tag{43}$$

To get a lower bound for A', we proceed as in Proposition 2.4. We compare A' solution of (39) with the unique solution in $H^2(]0,+\infty[)$ of

$$\begin{aligned} -W'' + v_2^2W &= 0, \\ W'(0) &= A(0)f(0)^2, \end{aligned} \tag{44}$$

where v_2 is defined in (25). From Lemma 2.3 with $u=-W$ and $C=v_2^2$, let us remark that we have $W \geqslant 0$ on $\mathbb{R}^+$. Applying again this lemma with $d=+\infty$, $C=f^2$, and $u=W-A'$, we deduce $W \leqslant A'$. Now, we compare W with the function z defined in (30) and satisfying $z'(0)=A(0)f(0)^2$. The function $z-W$ satisfies (32) [replacing $z(0)$ with $-z(0)$] and taking c_1 as in (34), we get $-(z-W)''+v_2^2(z-W) < 0$. Applying Lemma 2.3 with $d=+\infty$, $u=z-W$, and $C=v_2^2$, we get

$$z(x) = -\frac{A(0)f(0)^2}{f(0)+c_1\kappa}\exp(-\phi(x)) \leqslant W(x).$$

Following Proposition 2.4, for $x \in [0, \kappa^{-\rho}]$, we get

$$-\frac{A(0)f(0)^2}{f(0)+c_1\kappa}\exp\left(-f(0)x - c_1\kappa - \frac{\kappa^{1-2\rho}}{\sqrt{2}}\right) \leqslant z(x).$$

It derives that

$$-A(0)f(0)(1-C\kappa^{1-2\rho})\exp(-f(0)x) \leqslant A'. \tag{45}$$

From (24) at the point $x=0$, we get

$$h(1-C\kappa^{1-2\rho}) \leqslant -A(0)f(0).$$

From (45), it results that

$$h(1-C\kappa^{1-2\rho})\exp(-f(0)x) \leqslant A'. \tag{46}$$

According to (43) and (46), the proof of Proposition 2.5 follows.

III. ESTIMATES FOR $A'(0)$

A. Preliminaries

First, we show that Inequality (12) is true for some pairs (f,A) such that

$$f(0) \in \left[0, \frac{1}{\sqrt{2}} - \alpha\kappa^{\gamma}\right] \cup \left[\frac{1}{\sqrt{2}} + \alpha\kappa^{\gamma}, 1\right], (\alpha,\gamma) \in (\mathbb{R}^+)^2.$$

Lemma 3.1: There exist $\alpha>0$ and κ_0, such that, for all $\kappa \leqslant \kappa_0$, for all pairs (f,A) solutions of $(GL)_\infty$ such that

$$f(0) \in \left[0, \frac{1}{\sqrt{2}} - \alpha\kappa^{1/4}\right] \cup \left[\frac{1}{\sqrt{2}} + \alpha\kappa^{1/4}, 1\right],$$

we have

$$\kappa(A'(0))^2 \leqslant 2^{-3/2}. \tag{47}$$

Proof: We set

$$\phi_0(y) = \sqrt{2}y^2(1-y^2). \tag{48}$$

This function achieves its unique maximum on $[0,1]$ at the point $y=1/\sqrt{2}$, and $\phi_0(1/\sqrt{2})=2^{-3/2}$. We have seen that Inequality (47) is satisfied for $f(0) \leqslant 1/10C$. If $f(0) \geqslant 1/10C$, then from (38), we have

$$\frac{A'(0)}{f(0)} = \mathcal{O}(\kappa^{-1/2}).$$

From (6), with the choice $f(0)=1/\sqrt{2}+\alpha\kappa^{1/4}$, we get for some $\widetilde{C}$,

$$\kappa(A'(0))^2 \leqslant 2^{-3/2} + \frac{1}{2}\phi_0''\left(\frac{1}{\sqrt{2}}\right)\alpha^2\kappa^{1/2} + \widetilde{C}\kappa^{1/2} + \mathcal{O}_\alpha(\kappa^{3/4}).$$

We choose first α such that $\frac{1}{2}\phi_0''(1/\sqrt{2})\alpha^2 + \widetilde{C} \leqslant -1$ and then $\kappa \leqslant \kappa_0$ for κ_0 small enough. The proof of Lemma 3.1 follows.

From now on, α is fixed according to Lemma 3.1 and we assume that

$$f(0) \in \left[\frac{1}{\sqrt{2}} - \alpha\kappa^{1/4}, \frac{1}{\sqrt{2}} + \alpha\kappa^{1/4} \right], \quad \alpha > 0. \tag{49}$$

From (7), for all pairs (f,A) solution of $(\mathrm{GL})_\infty$ satisfying (49), we have

$$\kappa h^2 \geqslant 2^{-3/2} + \mathcal{O}(\kappa^{1/4}). \tag{50}$$

From (9) and (50), we deduce that

$$\kappa h^2 = 2^{-3/2} + \mathcal{O}(\kappa^{1/4}), \tag{51}$$

for all pairs (f,A) solution of $(\mathrm{GL})_\infty$ satisfying (49). In order to get Inequality (12), let us analyze the proof by Bolley and Helffer of the De Gennes formula (Ref. 6, p. 604), and improve some of their estimates. For doing this, we are guided by the analysis of the properties of the approximate solution constructed in Ref. 15. To get an upper bound on $A'(0)$, Bolley and Helffer start by the identity

$$h^2 = -2\int_0^{+\infty} A'(t)A''(t)\mathrm{d}t.$$

Then, from $(3)_{(b)}$, they get

$$h^2 = 2\int_0^{+\infty} A'(t)(-A(t)f(t)^2)\mathrm{d}t. \tag{52}$$

Then, using Inequality (17), they obtain

$$h^2 \leqslant 2\int_0^{+\infty} f(t)A'(t)^2\mathrm{d}t. \tag{53}$$

We suspect that something has been lost when writing

$$-Af \leqslant A'.$$

Then, using $(3)_{(a)}$ and the energy conservation (16), they get

$$h^2 \leqslant 2\int_0^{+\infty} f(t)A'(t)^2\mathrm{d}t = \int_0^{+\infty} f(x)(1-f(x)^4)\mathrm{d}x - 6\kappa^{-2}\int_0^{+\infty} f(x)f'(x)^2\mathrm{d}x. \tag{54}$$

In order to get the control of the right-hand side of Inequality (54), in particular the two terms f' and $1-f^2$, they use the conservation law (16). If we rewrite the energy conservation in the form

$$(\kappa^{-1}f'(x) + A'(x))^2 = A(x)^2f(x)^2 + 2\kappa^{-1}f'(x)A'(x) + \tfrac{1}{2}(1-f(x)^2)^2,$$

we observe that these authors have neglected the positive term $A(x)^2f(x)^2+2\kappa^{-1}f'(x)A'(x)$ for getting the inequality

$$\kappa^{-1}f'(x) + A'(x) \geqslant \frac{1}{\sqrt{2}}(1-f(x)^2).$$

To improve Inequality (54), in the next sections, we get an upper bound and a lower bound for the difference $(A')^2-A^2f^2$. Moreover, we improve the control on f' given in (15). This is the object of the following subsection.

B. Estimate for f'

In order to get an estimate on f' on the interval $[0,\kappa^{-\rho}]$, we establish the following lemma:

Lemma 3.2: Let $\rho\in\left[0,\frac{1}{4}\right]$. *There exists* κ_0 *such that, for all* $\kappa\leqslant\kappa_0$, *for all pairs* (f,A) *solutions of* $(GL)_\infty$ *satisfying (49), we have the following estimate:*

$$A'f'=\frac{\kappa^2h^3}{2f(0)^2}\exp(-f(0)x)(1-\exp(-2f(0)x)+\mathcal{O}(\kappa^\rho)),\quad\forall\, x\in[0,\kappa^{-\rho}]. \tag{55}$$

Proof: Step 1: Estimate for $A'f'$ *at the point* $x=\kappa^{-\rho}$. Let $\rho\in\left[0,\frac{1}{4}\right]$. We set $Y=A'f'$. As $f'\geqslant 0$ and $A'\geqslant 0$, we have $Y\geqslant 0$. In order to use Lemma 2.3 with $d=\kappa^{-\rho}$, we estimate $A'f'$ at the point $x=\kappa^{-\rho}$. From (13) and (16) at the point $x=\kappa^{-\rho}$ and (17), we deduce that

$$f'(\kappa^{-\rho})\leqslant\frac{\kappa}{\sqrt{2}}(1-f(\kappa^{-\rho})^2)\leqslant\frac{\kappa}{\sqrt{2}}(1-\tanh(x_0)^2).$$

According to (38), and as $\tanh(x_0)=f(0)$ with

$$f(0)\in\left[\frac{1}{\sqrt{2}}-\alpha\kappa^{1/4},\frac{1}{\sqrt{2}}+\alpha\kappa^{1/4}\right],$$

we deduce that there exists $\hat{C}$ such that

$$(A'f')(\kappa^{-\rho})\leqslant\left(\frac{\kappa h}{2\sqrt{2}}+\hat{C}\kappa^{3/4}\right)\exp(-f(0)\kappa^{-\rho}). \tag{56}$$

To get a lower bound for $(A'f')(\kappa^{-\rho})$, let us remark that, from (21) and (37) at the point $x=\kappa^{-\rho}$, for κ small, we have $(A^2f^2-A'^2)(\kappa^{-\rho})=\mathcal{O}(\kappa^{-1})\exp(-f(0)\kappa^{-\rho})=\mathcal{O}(\kappa^2)$. From (16) at the point $x=\kappa^{-\rho}$, we deduce that

$$\kappa^{-2}f'(\kappa^{-\rho})^2=\frac{(1-f(\kappa^{-\rho})^2)^2}{2}+\mathcal{O}(\kappa^2)\geqslant\frac{1}{2}\left(1-\tanh^2\left(\frac{\kappa^{1-\rho}}{\sqrt{2}}+x_0\right)\right)^2+\mathcal{O}(\kappa^2).$$

Hence, from (49), we get

$$f'(\kappa^{-\rho})\geqslant\frac{\kappa}{2\sqrt{2}}(1+\mathcal{O}(\kappa^{3/4})).$$

According to (38), it results that there exists $\tilde{C}$ such that

$$\left(\frac{\kappa h}{2\sqrt{2}}+\tilde{C}\kappa^{3/4}\right)\exp(-f(0)\kappa^{-\rho})\leqslant(A'f')(\kappa^{-\rho}). \tag{57}$$

Step 2: Upper bound for Y. Using the Ginzburg–Landau equations (3), we get

$$Y'=Af^2f'+\kappa^2A'(-f+f^3+A^2f).$$

We observe that $Y'(0)=hf''(0)$. Differentiating once more and using (3), we deduce that the function Y is the unique solution in $H^2(\mathbb{R}^+)$ of the problem

$$Y''-f^2Y=2ff'^2A+2\kappa^2Af^2(-f+f^3+A^2f)+\kappa^2A'(-f'+3f'f^2)+2\kappa^2A'^2Af+2\kappa^2A'A^2f',$$

$$Y'(0)=hf''(0).$$

Hence, we get

$$-Y''+GY=-2ff'^2A-2\kappa^2Af^2(f^3-f)-2\kappa^2A^3f^3-2\kappa^2A'^2Af,$$

$$Y'(0) = hf''(0), \tag{58}$$

where

$$G := f^2 + \kappa^2(-1 + 3f^2 + A^2). \tag{59}$$

According to (18) and (21), for $x \in [0, \kappa^{-\rho}]$, we get

$$f(0)^2 \leqslant G(x) \leqslant f(0)^2 + \mathcal{O}(\kappa^{1-\rho}). \tag{60}$$

In order to get an upper bound for Y, we look for an upper bound of the right-hand side of (58). First, let us analyze the main term of (58) which is given by $-2\kappa^2 Af(A^2f^2+A'^2)$. According to (18) and (21), it derives that there exists C_2 such that, for $x \in [0, \kappa^{-\rho}]$, we get

$$-2\kappa^2 Af(A^2f^2 + A'^2) \leqslant (4\kappa^2h^3 + C_2\kappa^{1-\rho})\exp(-3f(0)x).$$

As $0 \leqslant f \leqslant 1$ and $A < 0$ on $\mathbb{R}^+$, we get

$$-2ff'^2A - 2\kappa^2Af^2(f^3 - f) \leqslant -2ff'^2A.$$

As $h = \mathcal{O}(\kappa^{-1/2})$ [see (9)], and from (15), (21), (38), and (49), there exists C_1 such that, for all $x \in [0, \kappa^{-\rho}]$, we get

$$-2ff'^2A \leqslant C_1\kappa^{3/2}\exp(-f(0)x).$$

Then, to get an upper bound for Y, we compare this function with the solution in $H^2([0, \kappa^{-\rho}])$ of

$$-y_1'' + f(0)^2y_1 = (4\kappa^2h^3 + C_2\kappa^{1-\rho})\exp(-3f(0)x) + C_1\kappa^{3/2}\exp(-f(0)x), \tag{61}$$

satisfying

$$y_1'(0) = Y'(0), \quad y_1(\kappa^{-\rho}) = \left(\frac{\kappa h}{2\sqrt{2}} + \hat{C}\kappa^{3/4}\right)\exp(-f(0)\kappa^{-\rho}). \tag{62}$$

From (60) and as $Y \geqslant 0$, we have

$$-(Y - y_1)'' + f(0)^2(Y - y_1) \leqslant -(Y - y_1)'' + GY - f(0)^2y_1 \leqslant 0.$$

From (56) and (62), we have $(Y-y_1)'(0) = 0$ and $(Y-y_1)(\kappa^{-\rho}) \leqslant 0$. Applying Lemma 2.3 with $d = \kappa^{-\rho}$, $C = f(0)^2$, and $u = Y - y_1$, for $x \in [0, \kappa^{-\rho}]$, we get $Y \leqslant y_1$ on $[0, \kappa^{-\rho}]$. The solution of (61) is given by

$$\begin{aligned} y_1(x) = {} & \widetilde{C}_1(\kappa)\exp(-f(0)x) + \widetilde{C}_2(\kappa)\exp(f(0)x) - \frac{1}{8f(0)^2}\exp(-3f(0)x)(4\kappa^2h^3 + C_2\kappa^{1-\rho}) \\ & + \exp(-f(0)x)\left(\frac{C_1}{4f(0)^2}\kappa^{3/2}(1 + 2f(0)x)\right). \end{aligned} \tag{63}$$

For $x \in [0, \kappa^{-\rho}]$, $\left(\rho \leqslant \frac{1}{4}\right)$, we have $\kappa^{3/2}(1+2f(0)x) = \mathcal{O}(\kappa)$. Hence, from (62) and (63), we get

$$y_1(\kappa^{-\rho}) = \widetilde{C}_2(\kappa)\exp(f(0)\kappa^{-\rho}) + (\widetilde{C}_1(\kappa) + \mathcal{O}(\kappa))\exp(-f(0)\kappa^{-\rho}) = \left(\frac{\kappa h}{2\sqrt{2}} + \hat{C}\kappa^{3/4}\right)\exp(-f(0)\kappa^{-\rho}). \tag{64}$$

As $\kappa h = \mathcal{O}(\kappa^{1/2})$, from (64), it results that

$$\widetilde{C}_2(\kappa) = (-\widetilde{C}_1(\kappa) + \mathcal{O}(\kappa^{1/2}))\exp(-2f(0)\kappa^{-\rho}). \tag{65}$$

From (63), we have

$$y_1'(0) = f(0)\widetilde{C}_2(\kappa) - f(0)\widetilde{C}_1(\kappa) + \frac{1}{8f(0)}(12\kappa^2h^3 - 2C_1\kappa^{3/2} + 3C_2\kappa^{1-\rho}).$$

From (65) and the condition $y_1'(0)=Y'(0)=hf''(0)$, we get for κ small

$$\widetilde{C}_1(\kappa) = -\frac{hf''(0)}{f(0)} + \frac{3}{2}\frac{\kappa^2h^3}{2(0)^2} + \mathcal{O}(\kappa^{1-\rho}).$$

From (3), (21), and (24), we get

$$f''(0) = \frac{\kappa^2h^2}{f(0)} + \mathcal{O}(\kappa^2). \tag{66}$$

Hence, we get

$$\widetilde{C}_1(\kappa) = \frac{\kappa^2h^3}{2f(0)^2} + \mathcal{O}(\kappa^{1-\rho}). \tag{67}$$

According to (63) and (65), for $x \in [0, \kappa^{-\rho}]$, we get

$$y_1(x) = -\frac{\kappa^2h^3}{2f(0)^2}\exp(-3f(0)x) + \exp(-f(0)x)[\widetilde{C}_1(\kappa) + (-\widetilde{C}_1(\kappa) + \mathcal{O}(\kappa^{1/2}))\exp(2f(0)(x-\kappa^{-\rho}))]. \tag{68}$$

From (67), we have $\widetilde{C}_1(\kappa)=\mathcal{O}(\kappa^{1/2})$. Let us remark that, for $x \in [0, \kappa^{-\rho}/2]$, for all $n \in \mathbb{N}$, we have

$$(-\widetilde{C}_1(\kappa) + \mathcal{O}(\kappa^{1/2}))\exp(2f(0)(x-\kappa^{-\rho})) = \mathcal{O}(\kappa^n).$$

From (67) and (68), for $x \in [0, \kappa^{-\rho}/2]$, it results that

$$Y \leqslant y_1(x) = -\frac{\kappa^2h^3}{2f(0)^2}\exp(-3f(0)x) + \left(\frac{\kappa^2h^3}{2f(0)^2} + \mathcal{O}(\kappa^{1-\rho})\right)\exp(-f(0)x). \tag{69}$$

If we make κ_0 smaller, we get (55) on $[0, \kappa^{-\rho}]$.

Step 3: Lower bound for Y. According to (13), (15), and (21), and as $A' \geqslant 0$ and $A < 0$, we deduce that there exists C_3 such that, for $x \in [0, \kappa^{-\rho}]$, we get

$$-2ff'^2A + 2\kappa^2Af^2(f-f^3) \geqslant 2\kappa^2Af^2(f-f^3) \geqslant C_3\kappa^{3/2}\exp(-f(0)x).$$

On the other hand, from (24) and (38), it results that there exists C_4 such that

$$-2\kappa^2Af(A^2f^2 + A'^2) \geqslant (4\kappa^2h^3 + C_4\kappa^{1-\rho})\exp(-3f(0)x), \quad \forall\, x \in [0, \kappa^{-\rho}].$$

From Remark 2.2, we can compare Y with the solution in $H^2([0, \kappa^{-\rho}])$ of

$$-y_2'' + (f(0)^2 + C_5\kappa^{1-\rho})y_2 = (4\kappa^2h^3 + C_4\kappa^{1-\rho})\exp(-3f(0)x) - C_3\kappa^{3/2}\exp(-f(0)x) \tag{70}$$

satisfying the conditions

$$y_2'(0) = Y'(0), \quad y_2(\kappa^{-\rho}) = \left(\frac{\kappa h}{2\sqrt{2}} + \widetilde{C}\kappa^{3/4}\right)\exp(-f(0)\kappa^{-\rho}). \tag{71}$$

According to (57), (70), and (71), Lemma 2.3 with $d=\kappa^{-\rho}$, $C(x)=f(0)^2+C_5\kappa^{1-\rho}$, and $u=y_2-Y$, we get $y_2 \leqslant Y$ on $[0, \kappa^{-\rho}]$. We set $\bar{C} := \sqrt{f(0)^2+C_5\kappa^{1-\rho}}$. The solution of (70) is given by

$$y_2(x) = \hat{C}_1(\kappa)\exp(-\bar{C}x) + \hat{C}_2(\kappa)\exp(\bar{C}x) + F(x)\exp(-f(0)x), \tag{72}$$

where

$$F(x) = -\frac{4\kappa^2 h^3 \exp(-2f(0)x) + 8\frac{C_3}{C_5}\kappa^{1/2+\rho} f(0)^2 - C_3\kappa^{3/2} + C_4\kappa^{1-\rho}\exp(-2f(0)x)}{8f(0)^2 - C_5\kappa^{1-\rho}} \exp(-f(0)x).$$

From (51), we have $\kappa^2 h^3 = \mathcal{O}(\kappa^{1/2})$, hence

$$F(\kappa^{-\rho}) = \mathcal{O}(\kappa^{1/2+\rho}).$$

From (70) and (72) at the point $x = \kappa^{-\rho}$, it results that

$$\hat{C}_2(\kappa) = -\hat{C}_1(\kappa)\exp(-2\bar{C}\kappa^{-\rho}) + \mathcal{O}(\kappa^{1/2})\exp(-(\bar{C} + f(0))\kappa^{-\rho}). \tag{73}$$

From (72), we get

$$y_2'(0) = -\frac{8\frac{C_3}{C_5}\kappa^{1/2+\rho} f(0)^3 + 12\kappa^2 h^3 f(0) + 3\kappa^{1-\rho} C_4 f(0) - f(0) C_3 \kappa^{3/2}}{(-8f(0)^2 + C_5\kappa^{1-\rho})} + \bar{C}(\hat{C}_2(\kappa) - \hat{C}_1(\kappa)).$$

The condition $y_2'(0) = hf''(0)$, (66) and (73) lead to

$$-\hat{C}_1(\kappa)\bar{C} + \frac{3\kappa^2 h^3}{2f(0)} + \mathcal{O}(\kappa^{1/2+\rho}) = hf''(0),$$

hence, as $\bar{C} = \sqrt{f(0)^2 + C_5\kappa^{1-\rho}}$,

$$\hat{C}_1(\kappa) = -\frac{hf''(0)}{f(0)} + \frac{3\kappa^2 h^3}{2f(0)^2} + \mathcal{O}(\kappa^{1/2+\rho}).$$

Following step 1, we restrict ourselves to $[0, \kappa^{-\rho}/2]$ and from (66), we get

$$Y(x) \geqslant \frac{\kappa^2 h^3}{2f(0)^2}\exp(-f(0)x)(1 - \exp(-2f(0)x) + \mathcal{O}(\kappa^{\rho})). \tag{74}$$

From (69) and (74), we deduce that there exists κ_0 such that, for all $\kappa \leqslant \kappa_0$, for all pairs (f, A) satisfying (49), Estimate (55) is true on $[0, \kappa^{-\rho}]$. The proof of Lemma 3.2 follows.

From Lemma 3.2, we deduce an estimate for f' in the following proposition:

Proposition 3.3: Let $\rho \in \left[0, \frac{1}{8}\right]$. *There exists* κ_0 *such that, for all* $\kappa \leqslant \kappa_0$, *for all pairs* (f, A) *solutions of* $(GL)_\infty$ *satisfying (49), we have the estimate*

$$f'(x) = \kappa^2 h^2 (1 - \exp(-\sqrt{2}x) + \mathcal{O}(\kappa^{\rho})), \quad \forall\, x \in [0, \kappa^{-\rho}]. \tag{75}$$

Proof: According to Proposition 2.5 and Lemma 3.2, we get

$$f'(x) = \frac{\kappa^2 h^3}{2f(0)^2}(1 - \exp(-2f(0)x) + \mathcal{O}(\kappa^{\rho})) \cdot \left(\frac{1}{h} + \mathcal{O}(\kappa^{3/2-2\rho})\right).$$

For

$$f(0) = \frac{1}{\sqrt{2}} + \mathcal{O}(\kappa^{1/4}),$$

and for $x \in [0, \kappa^{-\rho}]$, we have $\exp(-2f(0)x) = \exp(-\sqrt{2}x) + \mathcal{O}(\kappa^{1/4-\rho})$. As $\rho \in \left[0, \frac{1}{8}\right]$, Estimate (75) follows and this achieves the proof of Proposition 3.3.

Remark 3.4: For $n = 1$, *at the superheating field, we have shown in Ref. 15 (see also Ref. 17) that*

$$f^{\mathrm{vd},(1)}(x) = \tanh\left(\frac{\kappa x}{\sqrt{2}} + x_0\right) + \frac{\kappa}{4}\exp(-\sqrt{2}x), \tag{76}$$

where

$$\tanh(x_0) = \frac{1}{\sqrt{2}}.$$

From (76), it results that, for $x \in [0, \kappa^{-\rho}]$, *we have*

$$(f^{\mathrm{vd},(1)})'(x) = \frac{\sqrt{2}}{4}\kappa(1 - \exp(-\sqrt{2}x)) + \mathcal{O}(\kappa^{2-\rho}). \tag{77}$$

According to (7) and (8) with $f(0) = 1/\sqrt{2}$, *the main term of Estimate (75) is the one of Estimate (77). Therefore, we suspect that Estimate (75) is optimal.*

C. Estimate for $A' + Af$

To get an estimate for $A' + Af$, we use Lemma 2.3 and estimates for A', A, f', and f obtained in Propositions 2.4 and 2.5.

Lemma 3.5: Let $\rho \in \left[0, \frac{1}{8}\right]$. *There exists* κ_0 *such that, for all* $\kappa \leqslant \kappa_0$, *for all pairs* (f, A) *solutions of* $(GL)_\infty$ *satisfying (49), we have the following estimate:*

$$A' + Af = \frac{1}{2}\exp\left(-\frac{1}{\sqrt{2}}x\right)\left(-\kappa^2 h^3 \exp(-\sqrt{2}x) - \frac{1}{8h} + 3\kappa^2 h^3 + \mathcal{O}(\kappa^{1/2+\rho})\right), \quad \forall\, x \in [0, \kappa^{-\rho}]. \tag{78}$$

Proof: Step 1: Upper bound for $A' + Af$. We introduce the function $Z := A' + Af$. From (17), this function is positive. At the point $x = \kappa^{-\rho}$, from (21), (24), and (38), we deduce that there exist $\hat{C}$ and $\widetilde{C}$ such that

$$\hat{C}\kappa^{1/2-2\rho}\exp(-f(0)\kappa^{-\rho}) \leqslant Z(\kappa^{-\rho}) = (A' + Af)(\kappa^{-\rho}) \leqslant \widetilde{C}\kappa^{1/2-2\rho}\exp(-f(0)\kappa^{-\rho}). \tag{79}$$

From $(3)_{(b)}$, we have

$$Z' = Af^2 + A'f + Af'.$$

Differentiating more, and using the GL equations, we get

$$Z'' = A'f^2 + 2Af'f + Af^3 + 2A'f' + \kappa^2 A(-f + f^3 + A^2 f).$$

It results that the function Z satisfies

$$-Z'' + (f^2 + 2f')Z = -\kappa^2 A(-f + f^3 + A^2 f). \tag{80}$$

Let us estimate $Z'(0)$. As $f'(0) = 0$ and from (16) at the point $x = 0$, we get

$$Z'(0) = f(0)(h + A(0)f(0)) = \frac{f(0)(1 - f(0)^2)^2}{2(h - A(0)f(0))}.$$

From (17) and (24) at the point $x = 0$, we get $h(2 + \mathcal{O}(\kappa^{3/2-2\rho})) \leqslant h - A(0)f(0) \leqslant 2h$. It results that

$$\frac{f(0)(1 - f(0)^2)^2}{4h} \leqslant Z'(0) \leqslant \frac{f(0)(1 - f(0)^2)^2}{4h(1 + \mathcal{O}(\kappa^{3/2-2\rho}))}.$$

Hence, as

$$f(0) = \frac{1}{\sqrt{2}} + \mathcal{O}(\kappa^{1/4}),$$

we get

$$Z'(0) = \frac{1}{16\sqrt{2}h}(1 + \mathcal{O}(\kappa^{1/4})). \tag{81}$$

Now, we can estimate the term $-\kappa^2 A(-f+f^3+A^2 f)$. First, for $x \in \mathbb{R}^+$, as $A<0$ and $0 \leqslant f \leqslant 1$, we have $-\kappa^2 A(-f+f^3)<0$. According to (18) and (21) and using

$$f(0) = \frac{1}{\sqrt{2}} + \mathcal{O}(\kappa^{1/4}),$$

we deduce that there exists C_6 such that, for $x \in [0, \kappa^{-\rho}]$, we get the estimate

$$-\kappa^2 A^3 f \leqslant (2\kappa^2 h^3 + C_6 \kappa^{3/4}) \exp(-3f(0)x).$$

To get an upper bound for Z, as $f^2+2f' \geqslant f(0)^2$, we compare this function with the solution in $H^2([0, \kappa^{-\rho}])$ of

$$-V'' + f(0)^2 V = (2\kappa^2 h^3 + C_6 \kappa^{3/4}) \exp(-3f(0)x), \tag{82}$$

and satisfying

$$V'(0) = Z'(0), \quad V(\kappa^{-\rho}) = \widetilde{C} \kappa^{1/2-2\rho} \exp(-f(0)\kappa^{-\rho}). \tag{83}$$

According to (79), (80), (82), and (83) and as $Z \geqslant 0$, we can apply Lemma 2.3 with $d=\kappa^{-\rho}$, $C=f(0)^2$ and $u=Z-V$ and we get $Z \leqslant V$. For $x \in [0, \kappa^{-\rho}]$, the solution of (82) is given by

$$V(x) = \widetilde{C}_3(\kappa)\exp(-f(0)x) + \widetilde{C}_4(\kappa)\exp(f(0)x) - \left(\frac{\kappa^2 h^3}{4f(0)^2} + \frac{C_6}{8f(0)^2}\kappa^{3/4}\right)\exp(-3f(0)x). \tag{84}$$

From (83) and (84), we get

$$\widetilde{C}_4(\kappa) = (-\widetilde{C}_3(\kappa) + \mathcal{O}(\kappa^{1/2-2\rho}))\exp(-2f(0)\kappa^{-\rho}). \tag{85}$$

From (84), we deduce that

$$V'(0) = -f(0)\widetilde{C}_3(\kappa) + f(0)\widetilde{C}_4(\kappa) + \frac{3\kappa^2 h^3}{4f(0)} + \frac{3C_6}{8f(0)}\kappa^{3/4}.$$

From (85) and taking account the condition $V'(0)=Z'(0)$ (see (81)) and replacing $f(0)$ with

$$\frac{1}{\sqrt{2}} + \mathcal{O}(\kappa^{1/4}),$$

we get

$$\widetilde{C}_3(\kappa) = -\frac{1}{16h}(1 + \mathcal{O}(\kappa^{1/4})) + \frac{3\kappa^2 h^3}{2}. \tag{86}$$

We have

$$\exp(-f(0)) = \exp\left(-\frac{1}{\sqrt{2}}x\right)(1 + \mathcal{O}(\kappa^{1/4-\rho}))$$

on $[0, \kappa^{-\rho}]$. From (84)–(86), we get the estimate, for $x \in [0, \kappa^{-\rho}/2]$ and for κ small enough

$$Z \leqslant V(x) = \frac{1}{2}\exp\left(-\frac{1}{\sqrt{2}}x\right)\left(-\kappa^2 h^3 \exp(-\sqrt{2}x) - \frac{1}{8h} + 3\kappa^2 h^3 + \mathcal{O}(\kappa^{3/4-\rho})\right). \tag{87}$$

Step 2: Lower bound for $A'+Af$. First, from (24), we remark that there exists C_7 such that, for $x \in [0, \kappa^{-\rho}]$,

$$-\kappa^2 A(-f+f^3) \geqslant C_7 \kappa^{3/2}\exp(-f(0)x).$$

According to (15) and (18), we deduce that there exists C_8 such that $f^2+2f' \leqslant f(0)^2 + C_8\kappa^{1-\rho}$. To get a lower bound, we compare Z with the solution of

$$\begin{gathered} -W'' + (f(0)^2 + C_8\kappa^{1-\rho})W = (2\kappa^2 h^3 + C_6\kappa^{3/4})\exp(-3f(0)x) + C_7\kappa^{3/2}\exp(-f(0)x), \\ W'(0) = Z'(0), \quad W(\kappa^{-\rho}) = \hat{C}\kappa^{1/2-2\rho}\exp(-f(0)\kappa^{-\rho}). \end{gathered} \tag{88}$$

Following Step 1, we apply Lemma (2.3) with $d=\kappa^{-\rho}$, $C=(f(0)^2+C_8\kappa^{1-\rho})$, and $u=W-Z$, and we get $W \leqslant Z$ on $[0, \kappa^{-\rho}]$. Following Step 2, in the proof of Lemma 3.2, one can prove that

$$W(x) = \frac{1}{2}\exp\left(-\frac{1}{\sqrt{2}}x\right)\left(-\kappa^2 h^3 \exp(-\sqrt{2}x) - \frac{1}{8h} + 3\kappa^2 h^3 + \mathcal{O}(\kappa^{1/2+\rho})\right) \leqslant Z(x). \tag{89}$$

Taking into account (87) and (89), we deduce that there exists κ_0 such that, for all $\kappa \leqslant \kappa_0$, for all pairs (f,A) satisfying (49), we get Estimate (78) on $[0, \kappa^{-\rho}]$. The proof of Lemma 3.5 follows.

Then, from Lemma 3.5, we can improve Inequality (17) and get the following proposition:

Proposition 3.6: There exists κ_0 such that, for all $\kappa \leqslant \kappa_0$, for all pairs (f,A) solutions of $(GL)_\infty$ satisfying (49), we have the following estimate:

$$-Af = A' - B, \quad \forall\, x \in [0, \kappa^{-\rho}], \tag{90}$$

where B is defined by

$$B(x) := \frac{1}{2}\exp\left(-\frac{1}{\sqrt{2}}x\right)\left(-\kappa^2 h^3 \exp(-\sqrt{2}x) - \frac{1}{8h} + 3\kappa^2 h^3 + \mathcal{O}(\kappa^{1/2+\rho})\right). \tag{91}$$

D. Control of the function $S := \sqrt{(A')^2 - A^2 f^2}$

In all the following sections, we set

$$S^2 := (A')^2 - A^2 f^2. \tag{92}$$

From Proposition 3.5, we can state the following proposition:

Proposition 3.7: Let $\rho \in [0, \frac{1}{8}]$ and S^2 be the function defined in (92). There exists κ_0 such that, for all $\kappa \leqslant \kappa_0$, for all pairs (f,A) solutions of $(\mathrm{GL})_\infty$ satisfying (49), we have the following estimate:

$$S^2 = \tfrac{1}{8}(-8\kappa^2 h^4 \exp(-\sqrt{2}x) - 1 + 24\kappa^2 h^4 + \mathcal{O}(\kappa^\rho))\exp(-\sqrt{2}x), \quad \forall\, x \in [0, \kappa^{-\rho}]. \tag{93}$$

Proof: According to (21), (24), (37), and (38), for $x \in [0, \kappa^{-\rho}]$, we deduce the estimate

$$A' - Af = 2(h + \mathcal{O}(\kappa^{1/2-2\rho}))\exp(-f(0)x). \tag{94}$$

From (94) and Lemma 3.5 [see (78)], we can write

$$S^2 = (A' - Af)\,.\,(A' + Af) = \tfrac{1}{8}(-8\kappa^2 h^4 \exp(-\sqrt{2}x) - 1 + 24\kappa^2 h^4 + \mathcal{O}(\kappa^\rho))\exp(-\sqrt{2}x).$$

The proof of Proposition 3.7 follows.

IV. PROOF OF THE PARR FORMULA

In this section, first, using Propositions 3.3, 3.6, and 3.7, we get Inequality (12) for all pairs (f,A) solution of $(\mathrm{GL})_\infty$ such that

$$f(0) \in \left[\frac{1}{\sqrt{2}} - \alpha\kappa^{1/4}, \frac{1}{\sqrt{2}} + \alpha\kappa^{1/4} \right].$$

In the following, we use the elementary equality, for $a>0$ and $b>0$,

$$\sqrt{a^2+b^2} = a + b - \frac{2ab}{a+b+\sqrt{a^2+b^2}}. \tag{95}$$

Proof of Inequality (12): Step 1: New estimate for $A'(0)$. According to (52) and Proposition 3.6 [see (90)], we get the upper bound for $A'(0)^2$,

$$h^2 \leqslant 2\int_0^\infty f(t)A'(t)^2 \mathrm{d}t - 2\int_0^{\kappa^{-\rho}} A'(t)f(t)B(t)\mathrm{d}t,$$

where B is defined in (91). From (54), we get

$$h^2 \leqslant -2\int_0^{\kappa^{-\rho}} A'(t)f(t)B(t)\mathrm{d}t + \int_0^{+\infty} f(x)(1-f(x)^4)\mathrm{d}x - 6\kappa^{-2}\int_0^{+\infty} f(x)f'(x)^2\mathrm{d}x. \tag{96}$$

According to (16) and (95) with the choice $a=\kappa^{-1}f'$ and $b=S$, the following equality results:

$$\frac{1}{\sqrt{2}}(1-f^2) = \kappa^{-1}f' + S - T, \tag{97}$$

where T is defined on $\mathbb{R}^+$ by

$$T(x) := \frac{2\kappa^{-1}f'S}{S+\kappa^{-1}f'+\sqrt{S^2+\kappa^{-2}(f')^2}}. \tag{98}$$

From (97) and following Ref. 6 (see Proposition 3.1, p. 604), we get

$$\int_0^\infty (1-f^4(x))f(x)\mathrm{d}x = \frac{1}{2\sqrt{2}}\kappa^{-1}(1-f(0)^2)(3+f(0)^2) + \sqrt{2}\int_0^\infty f(x)(1+f(x)^2)\,.\,S(x)\mathrm{d}x$$
$$-\sqrt{2}\int_0^\infty f(x)(1+f(x)^2)T(x)\mathrm{d}x,$$

and

$$\int_0^\infty f(x)f'(x)^2\mathrm{d}x = \frac{\kappa}{4\sqrt{2}}(1-f(0)^2)^2 - \kappa\int_0^\infty f(x)f'(x)S(x)\mathrm{d}x + \kappa\int_0^\infty f(x)f'(x)T(x)\mathrm{d}x.$$

Hence, from (96) we get

$$h^2 \leqslant \kappa^{-1}\phi_0(f(0)) + I_1 + I_2 + I_3,$$

where ϕ_0 is defined in (48),

$$I_1 := -2\int_0^{\kappa^{-\rho}} A'(t)f(t)B(t)\mathrm{d}t, \tag{99}$$

$$I_2 := \sqrt{2}\int_0^\infty f(x)(1+f(x)^2)S(x)\mathrm{d}x + 6\kappa^{-1}\int_0^\infty f(x)f'(x)S(x)\mathrm{d}x, \tag{100}$$

$$I_3 := -\sqrt{2}\int_0^\infty f(x)(1+f(x)^2)T(x)\mathrm{d}x - 6\kappa^{-1}\int_0^\infty f(x)f'(x)T(x)\mathrm{d}x. \tag{101}$$

For all $f(0)\in\,]0,1]$, we have $\phi_0(f(0))\leqslant 2^{-3/2}$. Then, we get

$$h^2 \leqslant \kappa^{-1}2^{-3/2} + I_1 + I_2 + I_3. \tag{102}$$

For $\rho\in\,]0,\frac{1}{8}[$, we cut the integration interval in $[0,\kappa^{-\rho}]$ and $[\kappa^{-\rho},+\infty[$. As the functions f and f' are bounded and the function S admits for upper bound and lower bound an exponential polynomial in the form of $P(x)\exp(-\sqrt{2}x)$, the integrals in (100) and (101) on the interval $[\kappa^{-\rho},+\infty[$ are equal to $\mathcal{O}(\kappa^n)$ for all $n\in\mathbb{N}$. According to (18), (38), and (91), we get

$$-2\int_0^{\kappa^{-\rho}} A'(t)f(t)B(t)\mathrm{d}t \leqslant -f(0)\int_0^{\kappa^{-\rho}} \exp(-\sqrt{2}x)\left(\kappa^2h^4\exp(-\sqrt{2}x) - \frac{1}{8} + 3\kappa^2h^4 + \mathcal{O}(\kappa^\rho)\right)\mathrm{d}x.$$

From (51) and as $e^{-\sqrt{2}\kappa^{-\rho}}=\mathcal{O}(\kappa^n)$ for κ small, it results that

$$I_1 \leqslant -\tfrac{3}{32} + \mathcal{O}(\kappa^\rho). \tag{103}$$

Step 2: Estimate for I_2. On the other hand, using Proposition 3.7, and making the scaling $u=\exp(-\sqrt{2}x)$, we get

$$\begin{aligned}\int_0^{\kappa^{-\rho}} S(x)\mathrm{d}x &= \frac{1}{4}\int_{e^{-\sqrt{2}\kappa^{-\rho}}}^1 \frac{\sqrt{2u-u^2}}{u}\mathrm{d}u + \mathcal{O}(\kappa^\rho)\\ &= \left[\frac{1}{4}\sqrt{2u-u^2} + \frac{1}{4}\arcsin(u-1)\right]_{e^{-\sqrt{2}\kappa^{-\rho}}}^1 + \mathcal{O}(\kappa^\rho)\end{aligned}$$

hence, for κ small

$$\int_0^{\kappa^{-\rho}} S(x)\mathrm{d}x = \frac{\pi}{8} + \frac{1}{4} + \mathcal{O}(\kappa^\rho). \tag{104}$$

From (18) and (104) and Proposition 3.3 [see (75)], it results that

$$6\kappa^{-1}\int_0^{\kappa^{-\rho}} f(x)f'(x)S(x)\mathrm{d}x \leqslant 6\kappa^{-1}(f(0)+c\kappa^{1-\rho})\int_0^{\kappa^{-\rho}} \kappa^2h^2(1-\exp(-\sqrt{2}x))\,.\,S(x)\mathrm{d}x.$$

From (51) and making the scaling $u=\exp(-\sqrt{2}x)$, we get

$$\begin{aligned}\int_0^{\kappa^{-\rho}} (1-\exp(-\sqrt{2}x))\,.\,S(x)\mathrm{d}x &= \frac{1}{4}\int_{e^{-\sqrt{2}\kappa^{-\rho}}}^1 \frac{(1-u)}{u}\sqrt{2u-u^2}\mathrm{d}u + \mathcal{O}(\kappa^\rho)\\ &= \left[\left(\frac{3}{8}-\frac{u}{8}\right)\sqrt{2u-u^2} + \frac{1}{8}\arcsin(u-1)\right]_{e^{-\sqrt{2}\kappa^{-\rho}}}^1 + \mathcal{O}(\kappa^\rho),\end{aligned}$$

hence

$$\int_0^{\kappa^{-\rho}} (1-\exp(-\sqrt{2}x))\,.\,S(x)\mathrm{d}x = \frac{\pi}{16} + \frac{1}{4} + \mathcal{O}(\kappa^\rho).$$

From (49) and (51), we get

$$6\kappa^{-1}\int_0^{\kappa^{-\rho}} f(x)f'(x)S(x)\mathrm{d}x \leqslant \frac{3}{2}\left(\frac{\pi}{16}+\frac{1}{4}\right)+\mathcal{O}(\kappa^{\rho}). \tag{105}$$

According to (18) and (104), we deduce that

$$\sqrt{2}\int_0^{\kappa^{-\rho}} f(x)(1+f(x)^2)S(x)\mathrm{d}x \leqslant \sqrt{2}(f(0)+c\kappa^{1-\rho})(1+(f(0)+c\kappa^{1-\rho})^2)\int_0^{\kappa^{-\rho}} S(x)\mathrm{d}x.$$

From (104), we get

$$\sqrt{2}\int_0^{\kappa^{-\rho}} f(x)(1+f(x)^2)S(x)\mathrm{d}x \leqslant \frac{3}{2}\left(\frac{\pi}{8}+\frac{1}{4}\right)+\mathcal{O}(\kappa^{\rho}). \tag{106}$$

According to (100), (105), and (106), we get

$$I_2 \leqslant \frac{9\pi}{32}+\frac{3}{4}+\mathcal{O}(\kappa^{\rho}). \tag{107}$$

Step 3: Estimate for I_3. From Proposition 3.3 [see (75)] and (51), on the interval $[0,\kappa^{-\rho}]$, we have

$$T \geqslant U := \frac{B}{C}, \tag{108}$$

where

$$B(x) := \frac{\sqrt{2}}{2}(1-\exp(-\sqrt{2}x)+\mathcal{O}(\kappa^{\rho}))\,.\,S, \tag{109}$$

and

$$C(x) := S+\frac{\sqrt{2}}{4}(1-\exp(-\sqrt{2}x)+\mathcal{O}(\kappa^{\rho}))\,.\,S+\sqrt{S^2+\frac{1}{8}(1-\exp(-\sqrt{2}x)+\mathcal{O}(\kappa^{\rho}))^2}. \tag{110}$$

As the functions f' and S are positive on $\mathbb{R}^+$, from (98), we deduce that $T \geqslant 0$. Thus, from (18) and (108), we get

$$-\sqrt{2}\int_0^{\infty} f(x)(1+f(x)^2)T(x)\mathrm{d}x \leqslant -\frac{3}{2}\int_0^{\kappa^{-\rho}} U(x)\mathrm{d}x+\mathcal{O}(\kappa^{\rho}). \tag{111}$$

Moreover, we have

$$-6\kappa^{-1}\int_0^{\infty} f(x)f'(x)T(x)\mathrm{d}x \leqslant -\frac{3}{2}\int_0^{\kappa^{-\rho}} (1-\exp(-\sqrt{2}x))\,.\,U(x)\mathrm{d}x+\mathcal{O}(\kappa^{\rho}). \tag{112}$$

Making the scaling $u=\exp(-\sqrt{2}x)$, from (51) and (108)–(110), we get

$$\int_0^{\kappa^{-\rho}} U(x)\mathrm{d}x = \frac{1}{\sqrt{2}}\int_{e^{-\sqrt{2}\kappa^{-\rho}}}^1 \frac{1}{\sqrt{2}u}\frac{\sqrt{u(2-u)}(u-1)}{u-2-\sqrt{u(2-u)}}\mathrm{d}u+\mathcal{O}(\kappa^{\rho}), \tag{113}$$

and

$$\int_0^{\kappa^{-\rho}} (1-\exp(-\sqrt{2}x))\,.\,U(x)\mathrm{d}x = \frac{1}{\sqrt{2}}\int_{e^{-\sqrt{2}\kappa^{-\rho}}}^1 -\frac{1}{\sqrt{2}u}\frac{\sqrt{u(2-u)}(u-1)^2}{u-2-\sqrt{u(2-u)}}\mathrm{d}u+\mathcal{O}(\kappa^{\rho}). \tag{114}$$

For $u \in]0,2[$, we have

$$\int \frac{1}{\sqrt{2}u}\frac{\sqrt{u(2-u)}(u-1)}{u-2-\sqrt{u(2-u)}}\mathrm{d}u = \frac{\sqrt{2}}{4}(\arcsin(u-1)-u+\sqrt{2u-u^2}),$$

and

$$\int -\frac{1}{\sqrt{2}u}\frac{\sqrt{u(2-u)}(u-1)^2}{u-2-\sqrt{u(2-u)}}\mathrm{d}u = \frac{1}{8}\arcsin(u-1)+\frac{\sqrt{2}}{8}\sqrt{2u-u^2}(3-u)-\frac{\sqrt{2}}{4}u\left(1-\frac{u}{2}\right).$$

From (113), it results that

$$\int_0^{\kappa^{-\rho}} U(x)\mathrm{d}x = \frac{\pi}{8}+\mathcal{O}(\kappa^{\rho}). \tag{115}$$

Moreover, from (114), we get

$$\int_0^{\kappa^{-\rho}} (1-\exp(-\sqrt{2}x))\,.\,U(x)\mathrm{d}x = \frac{1}{8}\left(1+\frac{\pi}{2}\right)+\mathcal{O}(\kappa^{\rho}). \tag{116}$$

From (111), (112), (115), and (116), we get

$$I_3 \leqslant -\frac{9\pi}{32}-\frac{3}{16}+\mathcal{O}(\kappa^{\rho}). \tag{117}$$

Step 4: Upper bound for $A'(0)$. According to (102), (103), (107), and (117), we deduce that there exists κ_0, such that, for all $\kappa \leqslant \kappa_0$ and all pairs (f,A) solutions of $(\mathrm{GL})_\infty$ satisfying (49), we have

$$h^2 \leqslant \kappa^{-1}2^{-3/2}+\tfrac{15}{32}+\mathcal{O}(\kappa^{\rho}). \tag{118}$$

From Lemma 3.1 and (118), the proof of Theorem 1.3 follows.

According to (11) and Theorem 1.3, we deduce the Parr formula (10).

Theorem 4.1 *(Parr formula): There exists* κ_0 *such that, for all* $\kappa_0 \leqslant \kappa$, *we have*

$$\kappa(h^{\mathrm{sh}}(\kappa))^2 = 2^{-3/2}+\frac{15}{32}\kappa+o(\kappa).$$

Remark 4.2: In Ref. 2, Bolley and the authors have proved that the set $\{(f_0,h)\in\,]0,1]\times[0,+\infty[\ \text{s.t.}\ \exists(f,A)$ *solution of* $(GL)_\infty$ *with* $f(0)=f_0\}$ *is a graph of a map* σ *from* $]0,1]$ *into* $[0,+\infty[$. *From Theorem 1.3, we deduce an upper bound for the maximum of* σ *on* $]0,1]$.

V. CONCLUSION

In the weak-κ limit, we have rigorously proved that the second term in the expansion of $\kappa^{1/2}h^{\mathrm{sh}}(\kappa)$ is of order of $\mathcal{O}(\kappa)$ and we have recovered the constant of Parr. In Ref. 23, this author associated the initial condition

$$f_0 = \frac{1}{\sqrt{2}}-\frac{7}{32}\kappa$$

to the superheating field. An open problem is to prove that the second term in the expansion of f_0 is of the order of $\mathcal{O}(\kappa)$. Consequently, we will prove the following conjecture introduced in Ref. 15 (see also Ref. 24). At the superheating field, there exists κ_0 such that, for all $\kappa \leqslant \kappa_0$, we have the asymptotic expansion

$$-\frac{A_\kappa(0)}{A'_\kappa(0)} = \sqrt{2} + \frac{3}{16}\kappa + \mathcal{O}(\kappa^2). \tag{119}$$

More generally, in Ref. 15 (see also Ref. 17), as a consequence of the construction of an asymptotic matched solution, we have obtained a complete expansion for the superheating field, denoted by $h^{\mathrm{sh},f}(\kappa) = \kappa^{-1/2}\Sigma_{i=0}^{\infty} h_i \kappa^i$. In Ref. 16, we have rigorously proved that for all $n \in \mathbb{N}$, there exist κ_0 and C such that, for all $\kappa \leqslant \kappa_0$, we have

$$\kappa^{1/2} h^{\mathrm{sh}}(\kappa) \geqslant \sum_{i=0}^{n} h_i \kappa^i + C\kappa^{n+1}.$$

An open problem is to prove that for all $n \in \mathbb{N}$, we have

$$\kappa^{1/2} h^{\mathrm{sh}}(\kappa) = \sum_{i=0}^{n} h_i \kappa^i + o(\kappa^n). \tag{120}$$

It seems difficult to extend the approach presented here to obtain the coefficients of higher order terms. It is necessary to recover the asymptotic matched solution at all orders constructed in Ref. 15 to get these terms.

In the large-κ limit, using a method of matched asymptotic expansions, Chapman[11] (see also Refs. 7 and 20) has formally proved the formula

$$h^{\mathrm{sh}}(\kappa) = \frac{1}{\sqrt{2}} + C\kappa^{-4/3} + o(\kappa^{-4/3}) \tag{121}$$

for some $C \sim 0.3$. This suggests that the superheating field $h^{\mathrm{sh}}(\kappa)$ admits an expansion in powers of $\kappa^{-4/3}$ when κ is large. The rigorous proof of formula (121) is also an open problem.

Discrete and continuous cosine transform generalized to Lie groups SU(2)×SU(2) and O(5)

J. Patera[a] and A. Zaratsyan[b]
Centre de Recherches Mathématiques, Université de Montréal, C.P. 6128 SUCC. Centre-Ville, Montréal, Québec, Canada H3C 3J7

(Received 6 January 2005; accepted 21 February 2005; published online 26 April 2005)

We develop and describe continuous and discrete transforms of class functions on compact semisimple Lie group G as their expansions into series of uncommon special functions, called here C-functions in recognition of the fact that the functions generalize cosine to any dimension $n<\infty$. A uniform discretization of the problem on lattices of any density is described. Continuous and discrete orthogonality of C-functions is shown. Discrete transform is known in the case $n=1$ as the cosine transform. Continuous extension of the discrete transform is described. In general, C-functions are the contributions to irreducible characters from just one orbit of the Weyl group of G. Their products are fully decomposable to the sums of C-functions, so are the reductions to subgroups of the Lie group. They are eigenfunctions of Laplace operator, satisfying Neumann conditions at the boundary of the fundamental region of G, etc. A ready-to-use presentation is made of two of the four variants of the two-dimensional transforms. Both variants have in common exploitation of square lattices for the discrete version of the transforms. They are based on the compact Lie groups SU(2)×SU(2) and O(5), or, equivalently, Sp(4). Remaining two groups, SU(3) and G(2), involve triangular lattices. They are considered separately. Processing digital data, sampled on square lattices, is our motivating application.
[DOI: 10.1063/1.1897143]

I. INTRODUCTION

This is the first in the series of three papers[1,2] dealing with two families of special functions, called here C- and S-functions, whose many properties, very useful for applications, apparently went mostly unnoticed, although the functions have been known in Lie theory for decades. The C-functions were called "orbit functions" or "orbit sums" since Ref. 3, while the S-functions appear in Weyl's character formula under the name "characteristic functions."

The aim of the series is twofold, (i) to formulate, derive, and bring forward practically useful properties of these functions and their discretization in general, and (ii) to work out all the details of all the four variants in two dimensions.

In this paper we consider two of the four variants of C-functions, since both of them involve rectangular lattices. Two other cases, which involve triangular lattices, are given in Ref. 1. The S-functions for all four cases are described in Ref. 2.

The present approach can be viewed as originating from three sources. First it is the traditional theory of compact semisimple Lie groups and their finite dimensional representations. Indeed, from there we take the definition of C- and S-functions (though under different names and to be used for a very different purpose), second is the general discretization of the Fourier-like trans-

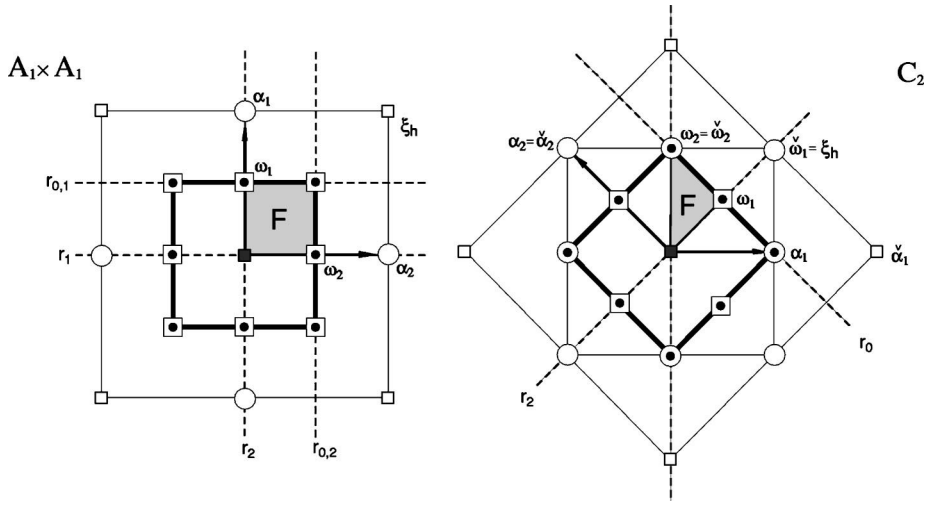

FIG. 1. The simple roots, the fundamental weights, along with their duals, and the fundamental region for the cases $A_1 \times A_1$ and C_2.

forms involving C-functions,[3] and finally it is the observation, made in Ref. 4, that the continuous extensions of discrete C-expansions interpolates smoothly between points where digital data are given.

Two and three dimensional digital data is often collected in physical experiments, the largest and, probably, the most costly of them being the elaborate batteries of particle counters in high-energy experimental astrophysics and particle physics. In the recent years digital images have also been generated in innumerable applications. Quite often processing such data involves Fourier analysis and discrete transforms.[5]

In this paper we describe a new versatile approach to the treatment of such data, which has been mostly unexplored so far. One of our objectives is to make the approach as ready to use as possible. Its one-dimensional (discrete) version was discovered some 30 years ago and is extensively used ever since under the name of the cosine transform.[6,7] Its straightforward generalization to two dimensions is, in our notation, the (discrete) case of $A_1 \times A_1$ [equivalently SU(2) $\times$ SU(2)]. Apparently, the first exploitation of the case A_2 [equivalently SU(3)] is quite recent,[4,8,9] although the problem of processing the digital data sampled on triangular lattices is not new.[10]

The important difference between the presented method and the traditional decomposition into Fourier series is not in that here we consider other compact semisimple Lie groups of rank 2 rather than the traditional SU(2) $\times$ SU(2). This is merely a technicality; the reason for the approach lies elsewhere. Traditionally, in any dimension $1 \leqslant n \leqslant \infty$, one uses the periodicity of the functions (the functions to be decomposed as well as the expansion functions). The underlying group in that case is the U(1) of our example (2.2), or a product of n of them. Thus, the involved group is the group of discrete translations. In our method a larger group is involved, the affine Weyl group, which contains the translations as its subgroup. It requires the use of more complicated functions (the C-functions or S-functions), but, in comparison, it involves lower harmonics in the expansions, which in turn results in much smoother interpolation between digital points during the continuous extension of the method,[4] etc.

As a quantitative measure of the difference between the two methods (the number of "harmonics," for example), we can take the comparison of the area of the fundamental region for the affine Weyl group and for its translation subgroup, assuming we have the grids of comparable densities. The fundamental regions F of the affine groups are shown in Fig. 1, the fundamental region of the translation subgroup is the Voronoi domain[11] (also called the proximty cell) of the corresponding root lattice. For A_1 the ratio is 1 : 2, for $A_1 \times A_1, A_2, C_2$, and G_2 the ratio is 1 : 4, 1 : 6, 1 : 8, and 1 : 12, respectively.

There are three compact simple Lie groups of rank 2, namely the following: SU(3), O(5) or Sp(4), and G(2). There is only one nonsimple but semisimple compact Lie group, SU(2) ×SU(2). In this paper, we use the notation more familiar in Lie algebra theory,

$$A_1 \leftrightarrow \mathrm{SU}(2),$$

and

$$\begin{gathered} A_1 \times A_1 \leftrightarrow \mathrm{SU}(2) \times \mathrm{SU}(2), \\ A_2 \leftrightarrow \mathrm{SU}(3), \\ C_2 \leftrightarrow \mathrm{O}(5) \text{or } \mathrm{Sp}(4), \\ G_2 \leftrightarrow \mathrm{G}(2). \end{gathered} \tag{1.1}$$

In principle, one could also consider the compact Lie groups of rank 2, U(1)×U(1) and U(1) ×SU(2), which are not semisimple. In view of (2.2), that would lead to the traditional Fourier decompositions. Here we disregard those cases.

In Sec. II, our general goals are compared with the traditional approach, namely, with the decomposition of a class function f into series irreducible characters. It is pointed out that our expansion functions are different, and that we are considering in parallel continuous f as well as f sampled on a discrete lattice of any density. Section III deals with the one-dimensional case, both continuous and discrete. It serves as a didactic illustration and an introduction to higher rank cases. General continuous case of any semisimple compact Lie group is presented in a uniform way in Sec. IV. Properties of C-functions are our main target. Sections V and VI contain, respectively, all the details for exploitation of the method for $A_1 \times A_1$ and C_2. Discretization of two-dimensional cases in general, as well as the specialization to $A_1 \times A_1$ and C_2 is the subject of Sec. VII. Examples are shown. Concluding remarks and related problems are brought forward in Sec. VIII.

Let us underline some notations used throughout the paper. The symbols $\mathbb{R}, \mathbb{Z}$, and $\mathbb{N}$ denote the real numbers, integers, and positive integers, respectively. The scalar product of $a, b \in \mathbb{R}^2$ in a real Euclidean space $\mathbb{R}^n$ of dimension n, is denoted by $\langle a|b\rangle$. The same notation is used for the Hermitian product of the class functions in the functional space spanned by irreducible characters (or C-functions).

II. GENERAL GOALS

The standard general problem of harmonic analysis on a compact Lie group G, is to consider the functions depending on conjugacy classes of elements of the group, i.e., such that

$$f(g') = f(g_0 g\, g_0^{-1}), \quad \text{for all } g, g_0 \in G,$$

and to find their expansions, along with their inversions

$$f(g) = \sum_{\lambda} \mathrm{d}_\lambda \chi_\lambda(g), \quad \mathrm{d}_\lambda = \int_F f(g)\overline{\chi_\lambda(g)}\mathrm{d}g, \tag{2.1}$$

in terms of irreducible characters χ_λ. The inversion is possible due to the orthogonality of the characters when integrated over the fundamental region F of the group.

The simplest example of (2.1) is the case when G is the 1-parametric compact Lie group U(1). In this case the irreducible characters are the exponential functions,

$$\chi_m(\theta) = e^{2\pi i m\theta}, \quad \text{where } m \in \mathbb{Z} \text{ and } \theta \in \mathbb{R}. \tag{2.2}$$

We take a similar problem, but it differs from (2.1) in two important ways.

(i) Our expansions are into series of C-functions (4.7), rather than irreducible characters of compact semisimple Lie groups. It offers a considerable practical advantage, since the C-functions, unlike the characters, do not get more complicated as λ increases. The second advantage has yet to be utilized, the C-functions are the eigenfunctions of the corresponding Laplace operator[12] and their eigenvalues are explicitly known.

(ii) We are interested in discrete expansions (7.7) besides the continuous ones. That is, expansions of functions given digitally by their values on a discrete grid of points F_M in F. Those functions are then expanded into a series in terms of C-functions given on the same grid. Inversion of such expansions is possible because of the discrete orthogonality of C-functions (7.4) established in Ref. 13 for any semisimple compact Lie group. Practically useful appears to be subsequent continuous extensions of discrete expansions (7.9).

Also it is difficult to overestimate the versatility of different choices of the grid F_M in F offered by our approach, which are equivalent to choosing, for each $M \in \mathbb{N}$, the finite Abelian subgroup of the maximal torus of the Lie group generated by all elements of order M.

III. DISCRETIZATION IN THE CASE OF A_1

Leaving aside the simplest case (2.2), there remains only one other compact Lie group of rank 1, namely A_1. One can recognize a familiar situation in this one-dimensional setup, without any group theory, once the C-functions $\Omega_m(\theta)$ are explicitly written below, in (3.1). In spite of that, it is useful to go through it using terms and notions that are indispensable in the case of higher ranks.

A. The continuous case

The Weyl group of A_1 has two elements $W=\{1,r\}$, where r is the reflection in the origin. The weight lattice $P(A_1)$ consists of all the points $x=\mathbb{Z}\omega$, where $\mathbb{Z}$ stands for any integer, while the root lattice $Q(A_1)$ consists of the even points of P. Symbolically, we write it as

$$Q(A_1) = \mathbb{Z}\alpha = 2\mathbb{Z}\omega,$$

$$P(A_1) = \mathbb{Z}\omega = Q(A_1) \cup (\omega + Q(A_1)).$$

Here α is called the simple root of A_1 and ω is the fundamental weight. Hence the relative lengths of the basis vectors of Q and P are fixed, $\alpha=2\omega$. We fix also their absolute length by choosing the value of the scalar product $\langle\alpha|\alpha\rangle=4\langle\omega|\omega\rangle=2$. The root system, $\Delta(A_1)=\{\pm\alpha\}$ has just two roots.

Given a point $\lambda=m\omega\in P$, its Weyl group orbit W_λ is the following:

$$W_\lambda \equiv W_m = \begin{cases} \{0\}, & \text{if } m = 0, \\ \{m\omega, -m\omega\}, & \text{if } 0 \neq m \in \mathbb{Z}. \end{cases}$$

The A_1 C-function $\Omega_\lambda(z)\equiv\Omega_m(\theta)$ is defined for $\theta\in\mathbb{R}$ as

$$\Omega_m(\theta) \overset{\text{def}}{=} \sum_{\mu\in W_\lambda} e^{2\pi i\langle\mu|z\rangle} = \begin{cases} 1, & \text{for } m = 0, \\ 2\cos\pi m\theta, & \text{for } m \in \mathbb{N}. \end{cases} \tag{3.1}$$

Here we have used $\langle\mu|z\rangle=\pm m\theta\langle\omega|\omega\rangle=\pm\frac{1}{2}m\theta$. Sometimes it is convenient to introduce a different normalization of the C-functions, namely the following one:

$$\Phi_m(\theta) = 2\cos\pi m\theta, \quad \text{for all } m \in \mathbb{Z}^{\geqslant 0}. \tag{3.2}$$

The fundamental region $F(A_1)$ is the closed segment with the end points 0 and ω. Its length is $|\omega|=1/\sqrt{2}$. Hence $0\leqslant\theta\leqslant 1$ within $F(A_1)$.

It is straightforward to verify the decomposition of the products,

$$\Phi_m(\theta)\Phi_{m'}(\theta) = \Phi_{m+m'}(\theta) + \Phi_{m-m'}(\theta), \quad \text{for } m,m' \in \mathbb{Z}^{\geqslant 0}.$$

Any two functions $\Omega_m(\theta), \Omega_{m'}(\theta)$, where $m \neq m'$, are orthogonal, i.e.,

$$\int_0^1 \Omega_m(\theta)\Omega_{m'}(\theta)\mathrm{d}\theta = \begin{cases} 0, & \text{if } m \neq m', \\ 1, & \text{if } m = m' = 0, \\ 2, & \text{if } m = m' > 0. \end{cases} \tag{3.3}$$

It is useful to notice the special case of (3.3) arising for $m>0$ and $m'=0$,

$$\int_0^1 \Omega_m(\theta)\mathrm{d}\theta = 0, \quad \text{for any } m \in \mathbb{N}.$$

The orthogonality can be used to invert the Fourier series (2.1) on $F(A_1)$ in the traditional way.

Every element of the group A_1 is conjugate to an element of its torus. Elements of the torus are parametrized by points of a circle. Every point of F stands for one conjugacy class of the elements of A_1.

B. Discretization of A_1

The objective of this section is the description of the A_1 version of the discrete orthogonality (7.4) of the C-functions.

Here we are interested in the elements $s\omega \in F$ with rational values of s. They are specified by two non-negative integers s_0 and s_1. It is convenient to set it up as follows:

$$F \ni s\omega = \frac{s_1}{M}\omega, \quad \text{where } s_0 + s_1 = M > 0, \quad s_0, s_1 \in \mathbb{Z}^{\geqslant 0}.$$

Fixing M determines an equidistant grid of $M+1$ points $s\omega \in F$. The set F_M of their coordinates is

$$F_M \overset{\text{def}}{=} \left\{ 0, \frac{1}{M}, \frac{2}{M}, \frac{3}{M}, \ldots, \frac{M-1}{M}, 1 \right\}.$$

C. Scalar product on the grid F_M

The points of F are in one-to-one correspondence with conjugacy classes of elements of A_1. They represent the conjugacy classes of elements of orders equal to M, as well as all the divisors of M.

In general, one introduces a scalar product in the space of functions defined digitally on F_M,

$$\langle f|h\rangle_M \overset{\text{def}}{=} \sum_{s \in T_M} f(s)h(s) = \sum_{s \in F_M} c_s f(s)h(s). \tag{3.4}$$

Here T_M stands for the Abelian subgroup of the maximal torus of A_1, which is generated by all the elements of order M. The coefficients c_s in the sum over F_M count the number of points in the torus that are conjugate to s. One has

$$c_0 = c_1 = 1, \quad \text{and } c_{1/M} = c_{2/M} = \cdots = c_{(M-1)/M} = 2. \tag{3.5}$$

The C-functions take the following values on the points of the grid:

$$\Omega_0(s) = 1, \quad \Omega_m(s) = 2\cos \pi m s, \quad \text{for } s \in F_M \text{ and } m \in \mathbb{N}. \tag{3.6}$$

In order to reduce the number of calculations, it is more convenient to utilize in the discretization the normalized form of the C-functions given in (3.2).

TABLE I. Values of several normalized C-functions of A_1 on the points of the grid F_M with $M=3$. Note that only the first four C-functions are pairwise orthogonal. The higher ones repeat the values of the lowest four. c_s are the coefficients from ((3.5)).

s	0	$\frac{1}{3}$	$\frac{2}{3}$	1
$\Phi_0(s)$	2	2	2	2
$\Phi_1(s)$	2	1	−1	−2
$\Phi_2(s)$	2	−1	−1	2
$\Phi_3(s)$	2	−2	2	−2
$\Phi_4(s)$	2	−1	−1	2
$\Phi_5(s)$	2	1	−1	−2
$\Phi_6(s)$	2	2	2	2
c_s	1	2	2	1

$$\Phi_m(s) = 2\cos \pi m s, \quad \text{for } s \in F_M \text{ and all } m \in \mathbb{Z}^{\geqslant 0}. \tag{3.7}$$

The crucial discrete orthogonality property of the normalized C-functions over F_M is the following:

$$\langle \Phi_m | \Phi_{m'} \rangle_M = \begin{cases} 8M, & \text{if } m = m' = 0 \mod M, \\ 4M, & \text{if } m = m' \neq 0 \mod M, \\ 0, & \text{if } m \neq m' \mod M. \end{cases} \tag{3.8}$$

Note that the orthogonality (3.8) is valid not only when m and m' are constrained to the range $\{0,1,\ldots,M\}$.

Examples of several A_1 normalized C-functions on the grid F_3 are given in the Table I.

Our aim in the development of the formalism so far is to use it for the expansion in terms of the C-functions of any function $f(s)$, given by its values on the grid F_M.

More precisely, a function $f(s)$, with known real values on F_M, can be decomposed as follows:

$$f(s) = \sum_{k=0}^{M} d_k \Phi_k(s), \quad s \in F_M. \tag{3.9}$$

Then we can compute the coefficients d_k from

$$\langle f | \Phi_k \rangle_M = \sum_{s \in F_M} c_s f(s) \Phi_k(s) = \begin{cases} 8M d_k, & \text{if } k = 0 \text{ or } k = M, \\ 4M d_k, & \text{if } k = 1,2,\ldots,M-1. \end{cases} \tag{3.10}$$

After the coefficients d_k have been calculated, one can replace s in (3.9) by the continuous variable θ,

$$f_{\text{cont}}(\theta) \overset{\text{def}}{=} \sum_{k=0}^{M} d_k \Phi_k(\theta), \quad \text{where } \theta \in \mathbb{R}. \tag{3.11}$$

At $\theta = s \in F_M$, the continuous function $f_{\text{cont}}(\theta)$ coincides with $f(s)$.

The all-important property that distinguishes (3.11) from the standard Fourier transform and that was apparently established only recently,[4] is the smoothness of the interpolation of f_{cont} between the points of the grid F_M.

IV. HIGHER RANK CASES IN GENERAL

The basic tools that we need, in order to develop the formalism of every case, can be introduced equally simply for all the cases at once and for any rank $n<\infty$. Thus, we do not always require that $n=2$. The rank of the Lie group is the dimension of the decomposition problem, i.e., the number of variables in a C-function.

A. The α and ω bases and their dual bases

The root system $\Delta \in \mathbb{R}^n$ contains k distinct vectors/roots. A suitable basis $\Pi = \{\alpha_1, \ldots, \alpha_n\} \subset \Delta$ consists of the simple roots (α basis). For any simple Lie algebra, its simple roots are of at most of two different lengths.

Relative lengths and angles between simple roots of the basis Π are concisely specified in terms of the elements of the Cartan matrix C,

$$C_{jk} = \frac{2\langle \alpha_j | \alpha_k \rangle}{\langle \alpha_k | \alpha_k \rangle} = \langle \alpha_j | \hat{\alpha}_k \rangle, \quad \text{for } j,k = 1, \ldots, n, \tag{4.1}$$

where $\hat{\alpha}_k$ is the simple root of the dual root system $\hat{\Delta}$. Adopting the standard convention for the lengths of the long root of Π, namely $\langle \alpha_l | \alpha_l \rangle = 2$, the elements of the Cartan matrix become the smallest possible integers. During the dualization,

$$\alpha \leftrightarrow \hat{\alpha} = \frac{2\alpha}{\langle \alpha | \alpha \rangle} \quad \text{of } \alpha \in \Delta,$$

the long roots do not change, while the short ones become long (see Fig. 1).

In addition to the α and $\hat{\alpha}$ bases, we introduce the basis of the fundamental weights and its dual basis, called ω and $\hat{\omega}$ basis, respectively. In the matrix form, using (4.1), we have

$$\alpha = C\omega, \quad \omega = C^{-1}\alpha, \quad \hat{\alpha} = C^T \hat{\omega}, \quad \hat{\omega} = C^{T-1}\hat{\alpha}. \tag{4.2}$$

Given a specific Cartan matrix, one can verify the following frequently used multiplication rules:

$$\langle \hat{\alpha}_j | \omega_k \rangle = \langle \alpha_j | \hat{\omega}_k \rangle = \frac{2\langle \alpha_j | \omega_k \rangle}{\langle \alpha_j | \alpha_j \rangle} = \delta_{jk}. \tag{4.3}$$

B. Reflections of the finite Weyl group

For each $\xi \in \Delta$ there are reflections r_ξ, which act in $\mathbb{R}^n$ according to

$$r_\xi x = x - \frac{2\langle x | \xi \rangle}{\langle \xi | \xi \rangle} \xi, \quad \text{where } \xi \in \Delta,\ x \in \mathbb{R}^n. \tag{4.4}$$

Those with $\xi \in \Pi$ generate the finite Weyl group W.

Observe that r_ξ does depend on the direction of ξ, but not on its length or orientation along that direction. In particular, it is easy to check that $r_\xi \xi = -\xi$ and also that

$$r_\xi r_\xi x = r_\xi \left(x - \frac{2\langle x | \xi \rangle}{\langle \xi | \xi \rangle} \xi \right) = r_\xi x - \frac{2\langle x | \xi \rangle}{\langle \xi | \xi \rangle} r_\xi \xi = x.$$

The application of W to the basis Π yields the root system, $W\Pi = \Delta$. Consequently, one has the W invariance, $\Delta = W\Delta$. Thus, a root is transformed into a root of the same system by any element of W. Each root appears exactly once in Δ. It is known that for simple Lie groups the root system is obtained by applying W to either one, or at most two roots of the basis Π.

C. The affine Weyl group

The group W contains the reflections r_ξ in mirrors, which are orthogonal to any $\xi \in \Delta$ and pass through the origin. The affine Weyl group W^{aff} contains all the reflections $R_{N\xi}$ in mirrors, which are orthogonal to ξ and displaced from the origin by any $N\xi$, where $N \in \mathbb{Z}$. Hence W^{aff} is of infinite order, and $W \subset W^{\text{aff}}$.

One has the affine reflections $R_{N\xi}$,

$$R_{N\xi}x \overset{\text{def}}{=} N\xi + r_\xi x, \quad \text{where } x \in \mathbb{R}^n,\ N \in \mathbb{Z} \text{ and } \xi \in \Delta. \tag{4.5}$$

Note that $R_{0\xi} = r_\xi$ and that $R_{N\xi} \neq R_{-N\xi}$. In particular, $R_{N\xi}0 = N\xi$ is the reflection of the origin in the midpoint $\frac{1}{2}N\xi$, and $R_{N\xi}(N\xi) = 0$. In general, one has

$$R_{N\xi}R_{N\xi}x = R_{N\xi}(N\xi + r_\xi x) = N\xi + r_\xi(N\xi + r_\xi x) = N(\xi + r_\xi\xi) + r_\xi r_\xi x = x.$$

It is useful to note the presence of a translation subgroup $T \subset W^{\text{aff}}$. It is an Abelian subgroup of W^{aff}, whose elements are all the translations $t_{N\xi}$, $N \in \mathbb{Z}$,

$$t_{N\xi}x \overset{\text{def}}{=} R_{N\xi}r_\xi x = r_\xi R_{-N\xi}x = (N\xi + r_\xi^2 x) = x + N\xi, \quad \text{where } N \in \mathbb{Z},\ \xi \in \Delta \text{ and } x \in \mathbb{R}^n. \tag{4.6}$$

As an example, one may verify that $t_{-N\xi}x = r_\xi R_{N\xi}x$.

In general, W^{aff} can be defined as the semidirect product $W \ltimes T$.

D. Root and weight lattice

The root lattice Q consists of all the elements that can be written symbolically as

$$\mathbb{Z}\alpha_1 + \cdots + \mathbb{Z}\alpha_n \in Q, \quad \text{where } \alpha_1, \ldots, \alpha_n \in \Pi,$$

in which $\mathbb{Z}$ stands for any integer chosen independently in each term of the sum. In particular, $\Delta \subset Q$.

We will mainly consider the weight lattice P and its positive chamber P^+,

$$\mathbb{Z}\omega_1 + \cdots + \mathbb{Z}\omega_n \in P, \quad \text{and } \mathbb{Z}^{\geqslant 0}\omega_1 + \cdots + \mathbb{Z}^{\geqslant 0}\omega_n \in P^+.$$

In all cases $Q \subseteq P$.

In addition to the root and weight lattices Q and P, we have also their dual latices, $\hat{Q}$ and $\hat{P}$, each along with its basis, namely the $\alpha, \omega, \hat{\alpha}, \hat{\omega}$ basis, respectively.

E. Weyl group orbits

Let $\lambda \in P \subset \mathbb{R}^n$. The Weyl group orbit W_λ of λ is the set of distinct elements of P obtained by all possible applications of W to λ. We write $W\lambda = W_\lambda$. In a similar way, one defines $W_\lambda^{\text{aff}} = W^{\text{aff}}\lambda$. The orbit W_λ is always finite, while W_λ^{aff} is infinite. The size $|W_\lambda|$ of W_λ is the number of distinct points which are generated from λ by W. The maximal value of $|W_\lambda|$ equals to the order $|W|$ of the Weyl group. Other possible values of $|W_\lambda|$ are some of the divisors of $|W|$.

In particular, we are interested in the following properties:

$$W0 = 0 \quad \text{and } W\Pi = \Delta.$$

In general, P is a union of several W^{aff} orbits.

Each $\lambda \in P$ is contained in precisely one W-orbit W_λ. Elements of W_λ are called weights. Each W orbit contains a unique element belonging to P^+, called the dominant weight of W_λ. The dominant weight is easy to recognize since its coordinates in ω basis are non-negative integers. It is then usually taken as the λ to be used in the symbol W_λ.

F. C-functions

The definition of a C-function $\Omega_\lambda(z)$ involves $\lambda \in P^+$ and $z \in \mathbb{R}^n$. It requires also the W-orbit W_λ of λ. The compact semisimple Lie group figures only through its Weyl group. One has

$$\Omega_\lambda(z) \overset{\text{def}}{=} \sum_{\mu \in W_\lambda} e^{2\pi i \langle \mu | z \rangle}, \quad \text{where } \lambda \in P^+ \text{ and } z \in \mathbb{R}^n. \tag{4.7}$$

The number of summands in (4.7) is the number $|W_\lambda|$ of weights in W_λ,

$$|W_\lambda| = \frac{|W|}{|\mathrm{Stab}_W(\lambda)|},$$

where $\mathrm{Stab}_W(\lambda)$ is the stabilizer of λ in W, the subgroup of W generated by reflections which do not move λ.

A different normalization of C-functions than (4.7) may occasionally be more convenient. We will use the following one:

$$\Phi_\lambda(z) \overset{\text{def}}{=} |\mathrm{Stab}_W(\lambda)| \Omega_\lambda(z). \tag{4.8}$$

All C-functions, renormalized in such way, take the same value at the origin,

$$\Phi_\lambda(0) = \Phi_{\lambda'}(0), \quad \text{for all } \lambda, \lambda' \in P^+.$$

In order to make explicit the dependencies of C-functions on λ and z, one needs to fix a particular semisimple Lie group, or, equivalently, a Weyl group, choose the weight λ, and provide more details on how to calculate the products $\langle \mu | z \rangle$. That is, in which bases one has z and λ. In the rest of this paper it is done explicitly for the cases of interest, where $n=2$. Most often λ is given relative to either ω or α basis, while z is taken relative to $\hat{\omega}$ basis.

G. Other properties of C-functions

Important symmetry properties of C-functions are the following:

$$\Omega_{(a,b)}(z) = \Omega_{(a,b)}(wz),$$

$$\Omega_{(a,b)}(z) = \Omega_{(a,b)}(R_{N\gamma} z) = \Omega_{(a,b)}(r_\gamma z + N\gamma) = \Omega_{(a,b)}(r_\gamma z), \tag{4.9}$$

$$\Omega_{(a,b)}(z) = \Omega_{(a,b)}(r_\gamma R_{N\gamma} z) = \Omega_{(a,b)}(R_{N\gamma} r_\gamma z) = \Omega_{(a,b)}(z \pm N\gamma),$$

where $w \in W$, $\gamma \in \hat{\Delta}$, and $N \in \mathbb{Z}^{>0}$.

In view of (4.3), $\langle \lambda | \gamma \rangle$ for all $\gamma \in \hat{Q}$, $\lambda \in P$ take integer values. Hence, they do not change the value of a C-function (4.7). The first property in (4.9) follows from $\langle \eta | z \rangle = \langle w\eta | wz \rangle$ for all $w \in W$ and $\eta \in W_\lambda$.

Another useful property of C-functions is the complete decomposability of their products into a linear combination of C-functions with positive integer coefficients,

$$\Omega_\lambda \Omega_{\lambda'} = \Omega_{\lambda+\lambda'} + \cdots . \tag{4.10}$$

The problem of finding the remaining terms of the sum and their multiplicities is a question of computation. Many examples are found in Refs. 14,15.

H. The fundamental region

The fundamental region F of a group, in general, is a finite region, where every conjugacy class of the elements of the group is represented precisely by one point. For a compact simple Lie

group of rank n, F is a simplex in $\mathbb{R}^n$. When $n=2$, it forms a triangle. For a nonsimple group, it is a Cartesian product of corresponding simplexes. Thus, for A_1, F is a segment, for $A_1 \times A_1$, a square.

The definition (4.7) of the C-function clearly allows one to consider z in the entire space $\mathbb{R}^n$. However, due to the symmetries (4.9), we are mainly interested in the C-functions with z in the fundamental region of the corresponding semisimple Lie group.

The fundamental region of a simple Lie group consists of the points x such that $0 \leqslant \langle x | \xi_h \rangle \leqslant 1$, where ξ_h is the highest root of Δ. Suppose,

$$\xi_h = q_1\alpha_1 + q_2\alpha_2 + \cdots + q_n\alpha_n, \tag{4.11}$$

where $q_1, \ldots, q_n$ are well-known positive integers for each root system. Then the vertices of the simplex F are the following:

$$F: \left\{ 0, \frac{1}{q_1}\hat{\omega}_1, \frac{1}{q_2}\hat{\omega}_2, \ldots, \frac{1}{q_n}\hat{\omega}_n \right\}. \tag{4.12}$$

I. C-functions and irreducible characters

The character χ_λ of a finite-dimensional irreducible representation of a group G is a linear combination of C-functions,

$$\chi_\lambda(z) = \sum_\mu m_{\lambda\mu}\Omega_\mu(z), \tag{4.13}$$

where the summation extends over the set of distinct dominant weights in the weight system V_λ of the representation labeled by λ. Coefficients $m_{\lambda\mu}$ are the multiplicities of the dominant weights in V_λ. It is a well-known computational problem in Lie theory to find the multiplicities $m_{\lambda\mu}$ for a given λ, see, for example, the tables[16] and references therein. The matrix $(m_{\lambda\mu})$ is nonsingular. A suitable ordering of the dominant weights makes it triangular. Hence, it can be inverted, so that one has

$$\Omega_\lambda(z) = \sum_\mu n_{\lambda\mu}\chi_\mu(z), \tag{4.14}$$

where $n_{\lambda\mu}$ are the (integer) matrix elements of the inverse matrix of dominant weight multiplicities. The summation in (4.14) ranges over the same finite set of dominant weights as in (4.13).

Consequently, C-functions form another basis in the space spanned by irreducible characters of G.

J. Orthogonality of C-functions

The orthogonality property of C-functions,
